Then, combined measurements of pH and visible absorption spectrophotometry were performed in order to get spectra in controlled experimental conditions, suitable for further high quality computer-assisted treatment. The visible absorption spectra, recorded as a function of pH on various solutions, are strongly dependent upon the metal-to-ligand molar ratio. The trend of these spectra (Figs. 1–3) strongly suggests the occupation of copper(II) axial positions when $Cu(bipy)_2$ and $Cu(bipy)_3$ are formed. Coupling the blend of experimental spectra and the chemical model (Table 1) we were able to calculate an absorption spectrum for each complex of the investigated binary system under the experimental conditions previously described. Fig. 4 shows the visible spectra calculated for single complexes of the Cu^{2+}–2,2′-bipyridine system; the results are collected in Table 1, also containing structural hypotheses under discussion below. Jorgensen [12] recorded some spectrophotometric data related to Cu^{2+}–2,2′-bipyridine and Cu^{2+}–*o*-phenantroline systems. If considering that: (i) pH values are not declared (and perhaps not stated), (ii) there are not thermodynamic data for solution speciation, (iii) 50% of ethanol is present in the solutions under measurement (which modify both species distribution and absorption features), and (iv) an attempt of deconvolution of experimental spectra was not made (the dimer is still present in excess of ligand), we have not considered the above report in the prosecution of our paper.

3.2. Complexes of L-aspartic acid

Copper(II) complex formation with L-aspartic was also investigated by coupled pH-metric and visible spectrophotometric techniques (25 °C and $I = 0.1$ M) to check the

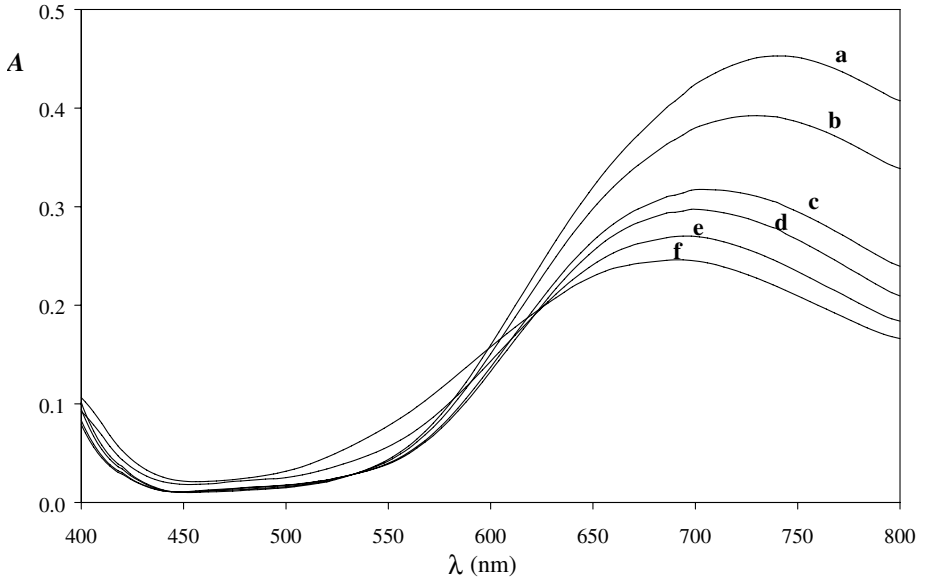

Fig. 3. Experimental visible absorption spectra Cu^{2+}–2,2′-bipyridine system. $C_{Cu} = 4.0$, $C_{bipy} = 12.0$ mM. a: pH 2.75; b: pH 3.37; c: pH 4.24; d: 5.02; e: pH 9.36; and f: pH 10.14.

eventual axial co-ordination. Stability constants (including protonation) was from Ref. [13]. In our current study, M:L molar ratio was forced towards the excess of ligand, to test the ability of the L-aspartic acid in acting as tridentate molecule, thus increasing the probability of an axial co-ordination. Solutions with M:L ratio from 1:1 to 1:5 were tested. Main complexes, as confirmed by the literature [11,13,14,16], are CuLH, CuL and CuL_2. The deconvolution of the wide blend of experimental spectra (recorded as a function of pH) allowed us to calculate a visible absorption spectrum for each complex species. We obtained: for CuLH $\lambda_{max} = 730$ nm and $\varepsilon_{730} = 34$ dm^3 mol^{-1} cm^{-1}, for CuL $\lambda_{max} = 685$ nm and $\varepsilon_{685} = 42$ dm^3 mol^{-1} cm^{-1} and for CuL_2 $\lambda_{max} = 630$ nm and $\varepsilon_{630} = 53$ dm^3 mol^{-1} cm^{-1} (with a ligand excess, solutions containing $Cu(asp)_2$ alone in the neutral-basic range of pH can be prepared).

4. Discussion

4.1. The model

The model to study the co-ordination chemistry of copper(II) ion in aqueous solution must unavoidably refer to two cases.

Table 1
Thermodynamic and visible spectrophotometric results (25 °C, $I = 0.1$ M) with structural hypotheses for copper(II) complexes with 2,2′-bipyridine in aqueous solution

Complex	*p q r*	Thermodynamic results	Spectrophotometric results		Structural hypotheses			
					Pure equatorial case		Mixed equatorial and axial case	
		$\log\beta_{pqr}$	λ_{max} [b]	ε_{max} [b]	Donor groups *per* copper(II) [c]	$\lambda_{max\ calc.}$ [d]	Planar donor groups *per* copper(II)	Axial donor groups *per* copper(II)
CuL	1 1 0	8.12	689	24	2pyn, 2wo	692		
$Cu_2L_2H_{-2}$	2 2 −2	5.59 ± 0.02 [a]	611	96	2pyn, 2ho	612		
CuL_2	1 2 0	13.63	750	138	3pyn, 1wo	634	2pyn	2pyn
CuL_3	1 3 0	17.0	670	54	4pyn	585	4pyn	2pyn

[a] Value optimized in this paper. Uncertainty expressed as ±SD.
[b] λ_{max} in nm; ε_{max} in $dm^3\ mol^{-1}\ cm^{-1}$.
[c] Pyridine nitrogen: pyn; hydroxide oxygen: ho; water oxygen: wo.
[d] Ref. [1].

For structural hypothesis of *pure equatorially co-ordinated* copper(II) complexes (the square planar case) the following equation [1] can be used:

$$\lambda_{max} = 10^3 / \sum_{i=1}^{4} n_i \bar{v}_i \quad (1)$$

where $\bar{v}_i$ represents the individual contribution of each donor group to the ligand field of the complex. The equation allows an estimation of the λ_{max} values of a copper(II) complex ($\lambda_{max\ calc.}$) by means of a simulation considering a planar hypothesis of co-ordination. It is noteworthy, for the meaning of this paper, that $\bar{v}_i$ values were optimized on the basis of experimental data of absorption spectra, thus the energies estimated for a planar co-ordination include intrinsically the contribution of the two water molecules along the *z*-axis of the copper(II) distorted octahedron. The donor groups considered, whit the related $\bar{v}_i$ values, are:

Amino nitrogen (an): 0.450; peptide nitrogen (pn): 0.495; imidazole nitrogen (in): 0.427; carboxylate oxygen (co): 0.353; alcoholate oxygen (ao): 0.39; hydroxide oxygen (ho): 0.39; water oxygen (wo): 0.296. The same $\bar{v}_i$ value was assumed in calculations for amide nitrogen (adn) with respect to that of peptide nitrogen and for pyridine nitrogen (pyn) with respect to that of imidazole nitrogen.

For structural hypothesis of *mixed equatorially and axially co-ordinated* copper(II) complexes – including both the square pyramid and the octahedron (or tetragonal bipyramid) cases – experience shows that d–d energies decrease if a position along the *z*-axis is occupied by a donor group substituting pre-existing water oxygen. The evaluation of the red shift (quantity defined in Section 1) must be carried out considering a reference complex showing the same planar co-ordination environment as that of the axially co-ordinated complex under study.

4.2. Complexes of 2,2′-bipyridine with molar ratios of 1:1

We found $\lambda_{max} = 689$ nm for CuL and $\lambda_{max} = 611$ nm for $Cu_2L_2H_{-2}$ (Table 1). If we assume for CuL a structure of bidentate complex with two nitrogen donors involved, we can estimate (Eq. (1) and [1]) $\lambda_{max} = 692$ nm. Moreover, if we hypothesise for $Cu_2L_2H_{-2}$ a structure corresponding to two CuL units connected by two bridged hydroxide groups – $Cu_2L_2(\mu\text{-}OH)_2$ – we obtain $\lambda_{max} =$ 612 nm [1], assuming two equivalent chromophores in the complex.

4.3. Complexes of 2,2′-bipyridine with molar ratios of 1:2 and 1:3

The situation is more complicated for CuL_2 and CuL_3. In fact, $\log\beta_{pqr}$ (Table 1) indicates an increase in stability, leading to the hypothesis of an increasing of

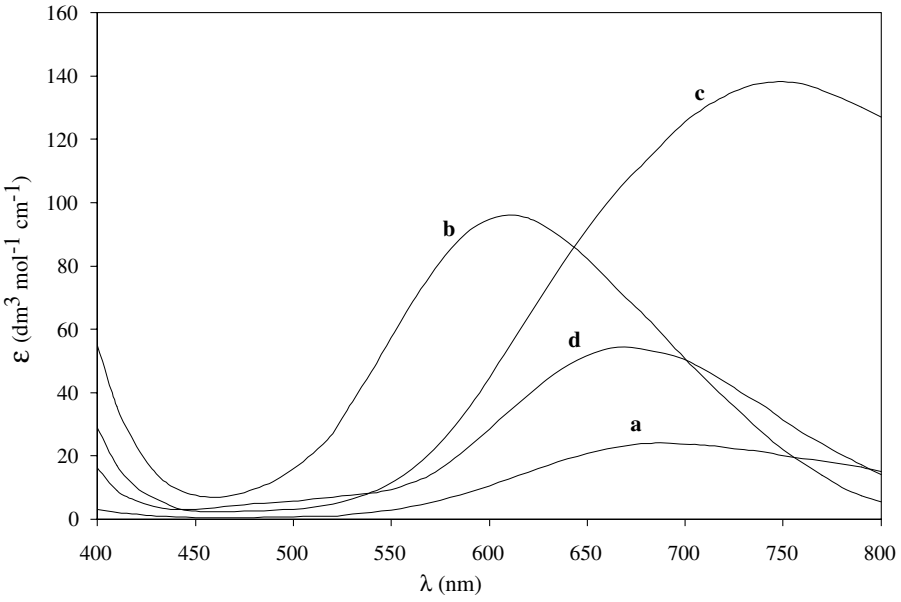

Fig. 4. Calculated visible absorption spectra for the individual complexes. a: Cu(bipy); b: $Cu_2(bipy)_2H_{-2}$; c: $Cu(bipy)_2$; and d: $Cu(bipy)_3$.

donor groups around copper(II) with respect to CuL. Moreover, also calorimetric data agree with a greater number of donor groups in CuL_2 and CuL_3 with respect to CuL. In fact, we have (25 °C, $I = 0.1$ M) $\Delta H = -46.0$, $\Delta H = -71.9$ and $\Delta H = -102$ kJ/mol for CuL, CuL_2 and CuL_3, respectively [11]. Nevertheless, a non-univocal trend of λ_{max} values, from CuL_2 and CuL_3, is clearly shown in Table 1 and in Fig. 4, inducing us to imagine a mixed equatorial and axial arrangement of the donors. Furthermore, calculation of λ_{max} [1] for CuL_2 and CuL_3, simply based on equatorial location of donors, fails (see Table 1, sixth column), although in accordance with stability and calorimetric findings. Then, axial hypotheses of donor arrangement must be formulated to fit our data with a coherent structure of these complexes in solution, accounting for the whole of the available indications. Particularly, for CuL_2 we can hypothesise each ligand disposed with a pyridine nitrogen in the equatorial plane and with the other one in an axial position. If only planar environment is considered, we have $\lambda_{max} = 689$ nm (as CuL), hence we can obtain the red shift *per* donor group as $(750 - 689)/2 = 31$ nm. Alternatively, even if considering only one nitrogen donor in axial position, we have $\lambda_{max} = 630$ nm [17] (calculated value with Eq. (1) is 634 nm) for a planar environment with three pyridine nitrogen and a water molecule; hence, the red shift should be $750 - 630 = 120$ nm, too big for one nitrogen atom along the *z*-axis, on the basis of current knowledge.

Moreover, for CuL_3 we can simply plan a fully occupied distorted octahedron of copper(II). Being the calculated λ_{max} for such a planar environment of 585 nm, we can obtain the red shift *per* donor group as $(670 - 585)/2 = 43$ nm. Fig. 5 shows the structures proposed for Cu(bipy), $Cu(bipy)_2$ and $Cu(bipy)_3$ (the ligand is schematised for sake of simplicity).

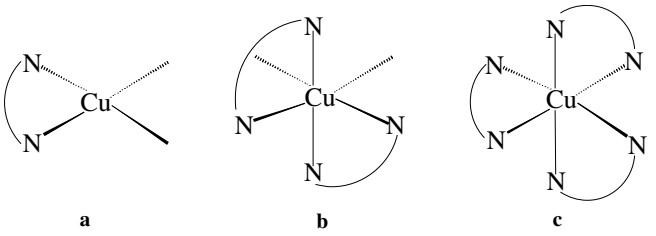

Fig. 5. Structure proposed for the complexes. a: Cu(bipy); b: $Cu(bipy)_2$; and c: $Cu(bipy)_3$. The ligand is schematised for sake of simplicity.

4.4. Complexes of L-aspartic acid

Some authors [13–15] have suggested a participation of the ω-carboxylate group of aspartate in co-ordination towards copper(II) ion, on the basis of thermodynamic data ($\log\beta_{110}$ and $\log\beta_{120}$ [10], ΔH and ΔS [14] values). Kinoshita et al. [15] underlined, via visible circular dichroism spectra, the important role played by the ω-carboxylate group of aspartate.

As for Cu(asp), our value of $\lambda_{max} = 685$ nm is fully compatible with a tridentate complex in the equatorial plane (two chelate rings of 5 and 6 terms are formed); a chromophore showing two carboxylate oxygen (α- and ω-carboxylate groups), one amino nitrogen and a water molecule allow us to calculate $\lambda_{max\ calc.} = 689$ nm with Eq. (1). The stability constants ($\log\beta_{110} = 8.83$ [13] or 8.89 [11] or 8.84 [16] at 25 °C and $I = 0.1$ M) is compatible with the hypothesis (for Cu(gly), $\log\beta_{110} = 8.14$ [13], gly = glycine). Claridge et al. [16] found for Cu(asp) $\lambda_{max} = 729$ nm. This value (declared ±5 nm by the authors) has been simply inferred by experimental spectra recorded on solution(s) containing Cu(asp) as major species; analogous treatment is forwarded for both Cu(asp)H ($\lambda_{max} = 733$ nm [16]) and $Cu(asp)_2$ ($\lambda_{max} = 621$ nm [16]) complexes (molar

absorptivity values are ignored by the authors). Unfortunately, it seems very hard to estimate the λ_{max} value for Cu(asp) from spectra at pH around 3.6 chosen by the authors. In fact, Cu(asp) and Cu(asp)H shows very similar molar concentration (M:L molar ratio 1:1 or 1:2), while the big amount of free copper(II) ion, with λ_{max} around 820 nm, shifts significantly the λ_{max} value of the solutions under measurement towards red. In this case, a Lambert–Beer-based deconvolution is inalienable.

The λ_{max} value we have obtained for Cu(asp)H is compatible with a glycine-like mode of co-ordination (calculated value with Eq. (1) is 717 nm). Visible absorption and ESR parameters reported in [16] indicate that the complexes Cu(asp)H have the α-amino carboxylate group co-ordinated to copper(II) ion.

The value of $\lambda_{max} = 630$ nm here determined for $Cu(asp)_2$ complex suggests a structure with two amino and two α-carboxylate groups in the equatorial plane together with a probable weak axial interaction from one ω-carboxylate (for amino acids without a co-ordinating side chain, the λ_{max} value of the $Cu(aminoacidate)_2$ complex is very close to 620 nm). An inspection of ΔS value reported for $Cu(asp)_2$ species confirms that the axial interaction from ω-carboxylate is weak. In fact, at 25 °C and $I = 0.1$ M, $\Delta S = 31.1$ cal/K mol for $Cu(asp)_2$ [11], while ΔS is 28.6 cal/K mol for $Cu(\text{L-alanine})_2$ [11], 58.5 cal/K mol [11] for Cu(EDTA). As a consequence of all the above considerations, the axial interaction, if any, from a ω-carboxylate group is weak and we have not considered this small red shift in the course of the paper.

4.5. Complexes of other ligands

A re-examination of a series of co-ordination hypothesis is analyzed in this paragraph.

As for multidentate ligands, such as the *N*-(phosphonomethyl)glycine (the widely used herbicide commercially known as *glyphosate*), various hypotheses for its CuL_2 complex ($\lambda_{max} = 715$ nm [18]) appear to be likely, although it is clear the involvement of both the nitrogen atoms of the ligand [18]. In Table 2 is proposed the structure involving an equatorial arrangement of the $Cu(aminoacidate)_2$ type, with a phosphonate donor group in axial position. Moreover, also for the CuL species ($\lambda_{max} = 730$ nm [18]) an axial co-ordination can be hypothesized (Table 2). The low value of λ_{max} can be suitably explained with an axial co-ordination, since $\log\beta_{110} = 11.80$ [18] is not compatible with a low co-ordination number. Hence, a red shift of apparently logic amplitude is estimated locating a phosphonate donor group in an axial position. The knowledge of the ligand field of the alcholate donor group, optimized in Ref. [1], strongly helped us in the actual structural definition.

Another multidentate ligand considered in the past, the oligopeptide hyppuryl-L-histidyl-L-leucine [24], is interesting for a structural re-discussion in the light of current findings. The equatorial arrangement of the donors in the species $CuLH_{-2}$ ($\lambda_{max} = 575$ nm) includes amide, N(3)-imidazole and deprotonated peptide nitrogens. As for the structure of the complex $CuLH_{-3}$ ($\lambda_{max} = 575$ nm), formed at more basic pH values, we can put forward a new hypothesis according to which in the deprotonation reaction to form $CuLH_{-3}$ there is a structural re-arrangement and in the equatorial plane we have one amido and two deprotonated peptide nitrogens with the carboxylate group, while N(3)-imidazole group occupies an axial position. For such a planar environment the calculations (Eq. (1)) leads to $\lambda_{max} = 544$ nm, hence the red shift results to be $575 - 544 = 31$ nm (Table 2).

In the paper of Bonomo et al. [25] the interaction of copper(II) with glycyl-L-histidyl-glycyl-L-histidine in aqueous solution is investigated. The structure of the complex $CuLH_{-2}$ ($\lambda_{max} = 575$ nm) can be explained assuming an equatorial plane fully occupied by one amino, two deprotonated peptide nitrogens and one imidazole nitrogen atoms (that of the C-terminal histidyl residue). Furthermore, one imidazole nitrogen atoms is located in an axial positions. The λ_{max} estimated for the planar co-ordination, considering the complex $CuLH_{-2}$ with glycyl-glycyl-L-histidyl-L-alanine, is 530 nm [26]. The red shift is $575 - 530 = 45$ nm, compatible with our current findings (Table 2).

The structure of the copper(II)–EDTA complex species is reported by Jorgensen [4], who indicates a pentadentate co-ordination as $Cu(EDTA)(H_2O)^{2-}$ ($\lambda_{max} = 734$ nm). Unfortunately, speciation is ignored while the author reports, for the mentioned complex, $\lambda_{max} = 734$ nm [4] and $\lambda_{max} = 730$ nm [12]. On the other side, structures of the copper(II)–EDTA complex(es) are investigated in the solid state. EDTA is considered as a pentadentate ligand with respect to copper(II) complex formation [27], owing to its capability to form only five-membered chelate rings. An EDTA-type ligand – 1,3-propanediamine-*N*,*N*′-diacetate-*N*,*N*′-di-3-propionate ion – able to form both five- and six-membred chelate rings, is reported [27] as exadentate towards copper(II) on the basis of X-ray data. As to EDTA, assuming a planar co-ordination as Cu(N,N,O,O), we should have a red shift of $734 - 620 = 114$ nm, enormous for a single donor (penta co-ordination), according to current knowledge on the topic. On the other hand, Billo [5] supposed a planar tridentate structure as $Cu(N,N,O)(H_2O)$, and two carboxylate groups in axial position: in such an arrangement we should have a red shift of $(734 - 646)/2 = 44$ nm, in agreement with the actual findings.

Jorgensen [12] considered CuL_3 complexes with ethylenediamine (en) or glycine (gly); he reported: $Cu(en)_3$, $\lambda_{max} = 610$ nm, $Cu(gly)_3$, $\lambda_{max} = 662$ nm, to be compared with the corresponding CuL_2 species, $\lambda_{max} = 549$ for $Cu(en)_2$ and $\lambda_{max} = 633$ for $Cu(gly)_2$. The mentioned data revealed a red shift from CuL_2 to CuL_3 species, in accordance with the theory here examined. Nevertheless, there are some aspects which make hard the interpretation of these data. In fact, the formation of the species $Cu(gly)_3$ is eventually possible only under extreme experimental conditions and the stability constant of this complex in not considered by the NIST database [11]. Hence, it is difficult

Table 2
Visible spectrophotometric λ_{max} values and structural hypotheses for single copper(II) complexes with probable axial co-ordination in aqueous solution

Structures, although reasonable, are not always univocally proven.

[a] Donor group(s) supposed along the *z*-axis. Symbols: Amino nitrogen: an; amide nitrogen: adn; imidazole nitrogen: in; peptide nitrogen: pn; pyridine nitrogen: pyn; carboxylate oxygen: co; alcoholate oxygen: ao; hydroxide oxygen: ho; water oxygen: wo.

[b] Indexes for the interaction among the metal ion and mixed ligands L and L′ (charges omitted) are referred to the reaction: $pCu + qL + rL' + sH \leftrightarrows Cu_pL_qL'_rH_s$.

[c] Red shift expressed as $\Delta\lambda_{max}$ (nm) for each donor group in axial position (see Section 1).

to hypothesize whether one or two donors are located along the *z*-axis. As to $Cu(en)_3$, Romano and Bjerrum [19] suggest that the participation of the third molecule of en involves only one of the two potential nitrogen donors. For these reasons we does not considered these species quantitatively but simply as a display of axial co-ordination (the link of the spectral data reported with the mentioned single complex molecules does not convince).

As to ammonia complexes, considering the paper of Bjerrum et al. [6] we have: $\lambda_{max} = 640$ nm for $Cu(NH_3)_5^{2+}$ and $\lambda_{max} = 590$ nm for $Cu(NH_3)_4^{2+}$ complex. A red shift of 50 nm results (Table 2). Furthermore, the species $Cu(NH_3)_6^{2+}$ with $\lambda_{max} = 640$ nm is also considered by Bjerrum et al. [6] with an anomalous spectral behaviour, since the sixth ammonia molecules in axial position does not cause further red shift. In addition to the explanations of Bjerrum et al., the species $Cu(NH_3)_6^{2+}$ cannot be used in this context, since it can be obtained only in liquid ammonia. In our previous paper on the relationship between λ_{max} and ε_{max} values [2], we attributed a $\lambda_{max} = 640$ nm to the $Cu(NH_3)_4^{2+}$ complex, which it is very probably due to $Cu(NH_3)_5^{2+}$.

5. Conclusive remarks

Unfortunately, literature is poor of well-characterised copper(II) complexes in aqueous solution, handled with

care for both stability and structural aspects. As well known, if speciation is neglected, structures cannot be surely referred to a single complex species and this can introduce dangerous noise when the structures in solution are discussed. Despite the mentioned severe limitations, an attempt to gain in the knowledge of this topic was pursued, providing an indicative criterion to support a hypothesis of axial co-ordination around the copper(II) ion in aqueous solution. Obviously, features of the ligand(s) involved, as steric hindrance of some donor group and number and dimension of the chelate ring(s), cannot be neglected in a correct structure assessment of a complex in solution.

Pyridine nitrogen and N(3) imidazole nitrogen donor groups, as summarised in Table 2, tend to exhibit values of red shift *per* axial donor group ranging between 31 and 45 nm (the value of 23 nm, found for CuL_2 with L-histidine or τ-methyl-L-histidine, is not considered in this discussion, since it has been obtained by mixed contributions, very probably due to both carboxylate oxygen and imidazole nitrogen).

A wide range of red shift values are observed for the axial displacement of a carboxylate donor group, ranging between 19 nm (L = nitrilotriacetic acid) and 44 nm (L = EDTA).

As for other donor groups listed in Table 2, namely hydroxide, amino (or ammonia) and alcoholate, we can estimate a red shift ranging between 41 nm (donor: amino group) and 58 nm (donor: hydroxide group) *per* axial donor group.

In spite of this attempt to rationalize the visible spectrophotometric results, it appears rather difficult to reach unambiguous identification of the red shift value for an individual donor group. In fact, effects attributable to the overall ligand structure (as those observed in [2]) cannot be excluded, so as the influence of the stability of the chemical bond on the red shift amplitude. Nevertheless, on the basis of all the red shifts handled in this paper, we calculated a mean value of 36 nm *per* axial donor group, while extreme values observed are 19 and 58 nm.

CuO_6 chromophore. It has focused on the analysis of a disorder, noticed in large thermal ellipsoids of the coordinated atoms [5]. An impact of this disorder was correlated to changes in the ground state of the complex.

2. Experimental

All starting compounds and solvents were used as purchased, without any further purification. The title compound, *cis*-[Cu($C_8H_7O_3$)$_2$(H_2O)$_2$], was synthesized as described previously [4].

Diffraction data were collected on a Nonius Kappa CCD diffractometer with graphite monochromated Mo Kα radiation. The data were processed using the DENZO program [11]. The structure was solved by direct methods using SIR97 [12]. We employed full-matrix least-squares refinements on F magnitudes with anisotropic displacement factors for all non-hydrogen atoms using XTAL3.6 [13]. The hydrogen atoms were located from the difference Fourier maps. Their positions together with their isotropic displacement factors were refined using restraints on O—H and C—H distances. Crystal data: $C_{16}H_{18}CuO_8$, M_r = 401.86, monoclinic, a = 7.7401(1) Å, b = 10.4922(2) Å, c = 21.2398(3) Å, β = 95.6277(7)°, V = 1716.58(5) Å^3, T = 115(2) K, space group $P2_1/c$ (No. 14), Z = 4, μ = 1.313 mm^{-1}, crystal size 0.30 × 0.25 × 0.10 mm^3 (plate), 19814 reflections measured (integrated), θ_{max} 27.48°, 3921 unique (R_{int} = 0.031), 3244 observed [$F^2 > 2\sigma(F^2)$], R = 0.031 ($R = \sum(||F_o| - |F_c||)/\sum|F_o|$), wR = 0.026 ($wR = \sum(w||F_o| - |F_c||)/\sum(w|F_o|)$), 298 refined parameters, 3676 reflections.

Spectra of the powdered samples were recorded by a Bruker ESP-300 spectrometer, operating at X-band (9.59 GHz) at variable temperatures.

3. Results and discussion

X-ray data of the title compound *cis*-diaqua-bis(4-formyl-2-methoxyphenolato-*O*:*O*′)copper(II) were collected at 115 K and an analysis reveals two bidentate vanillinate anions (4-formyl-2-methoxyphenolate) and two water molecules in a *cis* orientation around the central copper(II) ion (Fig. 1). The vanillinates are coordinated through methoxy (Cu—O1a 2.151(1), Cu—O1b 2.354(1) Å) and deprotonated hydroxy (Cu—O2a 1.919(1), Cu—O2b 1.914(1) Å) oxygen atoms, while water molecules complete the octahedral coordination sphere (Cu—O1w 2.163(1), Cu—O2w 2.020(1) Å). The methoxy oxygen atoms and the water molecules are in *trans* positions with respect to the copper ion, thus forming two non-symmetrical axes O1a—Cu—O2w and O1b—Cu—O1w. The hydroxy oxygen atoms describe the third axis O2a—Cu—O2b.

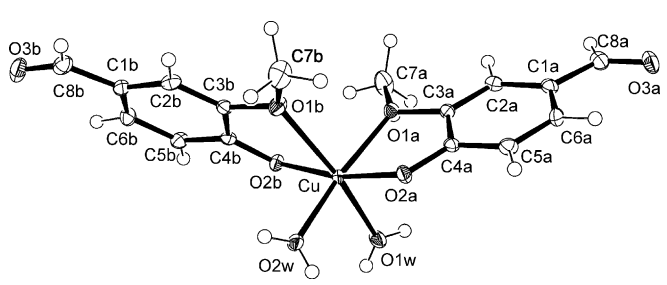

Fig. 1. An ORTEP molecular structure of *cis*-[Cu($C_8H_7O_3$)$_2$(H_2O)$_2$], 115 K [14,15]. Thermal ellipsoids are drawn at the 50% probability level.

The *cis* arrangement of the ligands is found also in the room temperature structure of the title compound. The whole conformation of the complex molecules is very similar in both structures, however at room temperature the complex posses a twofold symmetry axis, which is lost at 115 K (Table 1, Scheme 1) [5]. This is related with two O(methoxy)—Cu—O(water) coordination axes of the same length, and the third shorter O(hydroxy)—Cu—O(hydroxy) axis of the axial coordination sphere in the 293 K structure. Consequently, in spite of a similarity of the packing arrangement and the unit cell parameters, the symmetry of the space group $C2/c$ at room temperature is lowered to its sub-group $P2_1/n$ at 115 K. The unit cell parameters for the 293 and 115 K data, respectively, are: a = 22.0422(3), 23.3084(3) Å; b = 10.6891(2), 10.4922(2) Å; c = 7.6668(1), 7.7401(1) Å; β = 104.8463(8), 114.9252(7)°; V = 1746.08(5), 1716.58(5) Å^3 (The later set of parameters is transformed from that written in Section 2, using the 3 × 3 matrix (−1 0 1 0 1 0 1 0 0) and corresponds to the $P2_1/n$ space group, enabling a more adequate comparison of both structures. Initially, the $P2_1/c$ space group was chosen, since the corresponding β angle 95.6277(7)° is closer to 90° and thus favourable for computations reasons). The unit cell parameters show an anisotropic change, similarly as noticed for the coordination bond distances. It is interesting that the colour of the compound changes reversibly from orange at room temperature to yellow-green at 115 K.

Fig. 2 shows an ORTEP plot of the central coordination sphere of the title complex, determined from the 293 K dataset [5]. It can easily be seen that the thermal ellipsoids of the donor atoms mainly, as well as that of the central copper(II) atom, are large and significantly elongated. In the structure of the same complex measured at 115 K, an electron density distribution of these atoms is much more located (see Fig. 1). Since the thermal ellipsoids of the donor atoms are more perpendicular to the corresponding Cu—O bonds, a static distortion would in theory be suggested (for the dynamic disorder, the ellipsoids should be parallel to the Cu—O bond) [8,9]. However, such a disorder along a metal—ligand bond is not always evident in the visible shape of the thermal ellipsoids of the atoms concerned. Therefore, a more sensitive MSDA (mean-square displacement amplitude) analysis was applied [7,8,14,15]. Certain disordered bonds may show high $\langle d^2 \rangle$ values from the high temperature structure thermal motion data. If they are accompanied with significant reduction of $\langle d^2 \rangle$ for the low temperature data, it should be a proof for the dynamic disorder. Indeed, much higher $\langle d^2 \rangle$ values and their temperature dependence along

the Cu—O(methoxy) than for the other coordination bonds Cu—O(hydroxy) and Cu—O(water) were found (Scheme 1). A comparison with *cis*-diaqua-bis(methoxyacetato)zinc(II) of related geometry (295 K), does not show the same ellipsoid elongation effect of the related atoms [9]. This is in agreement with a Zn(II) d^{10} configuration, where the Jahn–Teller phenomenon is not expected. Altogether this indicates more towards a higher pseudo-Jahn–Teller fluxionality in the title Cu(II)-complex above 180 K, which is gradually frozen out by decreasing temperature (see Fig. 3). Thus, a librational dynamic disorder of the Jahn–Teller distorted axes leads to an equalisation of the determined bond lengths, imitating a higher symmetry in the structure at higher temperature. The herein described disorder may be induced with one type of a ligand (high $\langle d^2 \rangle$ only for Cu—O(methoxy)), but the consequences are certainly evident in both O(methoxy)—Cu—O(water) coordination axes, as a whole.

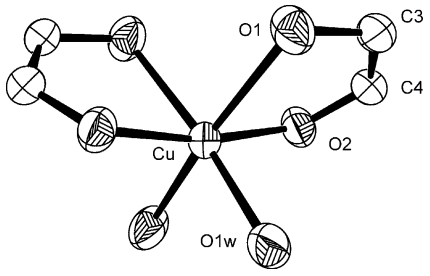

Fig. 2. An ORTEP-plot of the central coordination sphere of the title complex (293 K), showing 50% atomic displacement ellipsoids [5,14,15]. Other atoms are omitted for clarity.

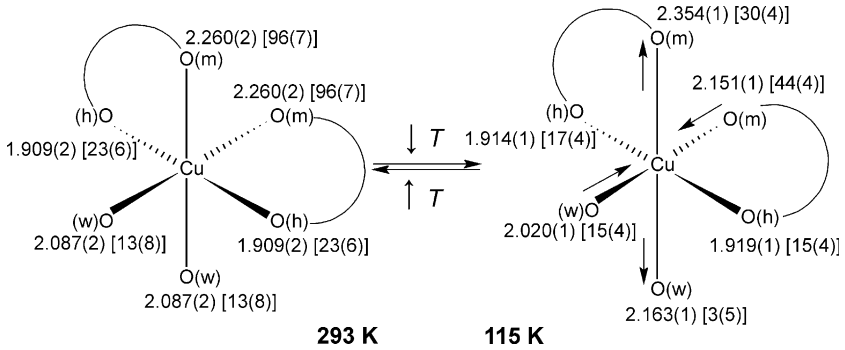
EPR spectra of the *cis*-vanillinate title complex were measured in the temperature range from 298 to 115 K (Fig. 3). The room temperature spectrum shows an inverse axial symmetry pattern with $g_\perp(g_1 \sim g_2) > g_\parallel(g_3) = 2.005(3)$, while the 115 K spectrum shows rhombic symmetry with



Scheme 1. A temperature induced reversible change of the Cu—O coordination bond distances (Å) in *cis*-[$Cu(C_8H_7O_3)_2(H_2O)_2$] (h – hydroxy, m – methoxy, w – water). Cu—O $\langle d^2 \rangle$ values ($\times 10^4$ Å^2) are in square brackets.

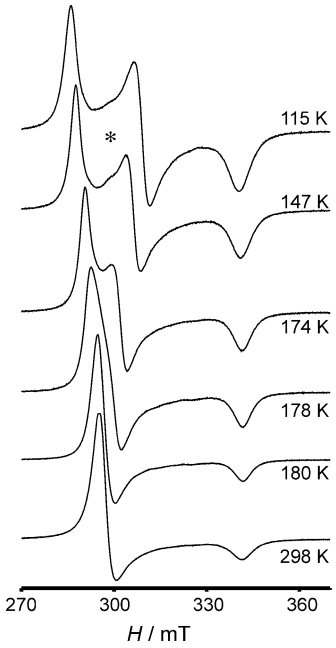


Fig. 3. Splitting of the $g_{1,2}$ signal to g_1 and g_2 in the EPR spectra of *cis*-$[Cu(C_8H_7O_3)_2(H_2O)_2]$, while cooling from 298 to 115 K. An asterisk marks a weak signal between dominant g_1 and g_2 noticed in the low temperature spectra.

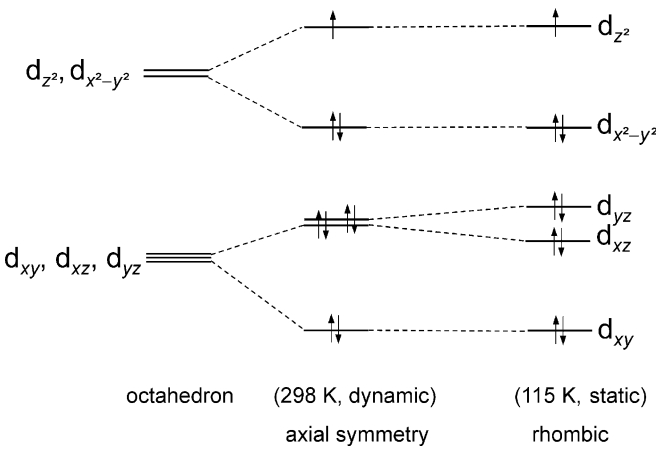
$g_1 > g_2 > g_3 = 2.010(3)$ [5]. The g_{12} ($g_\perp$) signal is unchanged in the temperature range from 298 to 180 K, and further decrease of temperature shows its gradual splitting to g_1 and g_2 that probably continues below 115 K. This change between the low and the high temperature spectra is reversible (Scheme 1).

For a more detailed discussion of the complex electronic situation, an assignment of the axes orientation is necessary. In our case, we would orient the coordination system as follows: *x*-axis O1w′—Cu—O1(m), O1w—Cu—O1b(m); *y*-axis O1w—Cu—O1′(m), O2w—Cu—O1a(m); *z*-axis O2(h)—Cu—O2′(h), O2a(h)—Cu—O2b(h) (m – methoxy, h – hydroxy) for the high and the low temperature situation, respectively. Therefore, we have for the two compressed octahedral cases, a tetragonal and a rhombic stereochemistry with short *z*-axis and more or less elongated *x*- and *y*-axes. The resulting orbital splitting diagrams are given in Scheme 2.

Due to the non-equivalence of the six donor sites in the complex, a rhombic distortion of the coordination sphere is expected and the d-energy levels would not posses any degeneracy. However, at room temperature, the dynamic librational disorder of the molecule is fast enough to simulate degeneracy along the *x* and *y*-axes (see Scheme 2). This librational dynamics is fast in the X-ray and EPR timescales showing averaged bond lengths along these axes, and an 'inverse' axial (tetragonal) symmetry found in the X-ray structure analysis and EPR spectra $g_{1,2}(g_\perp) > g_3(g_\parallel, g_Z) \sim g_e$ (pseudo Jahn–Teller distortion). Due to the orbital splitting (see Scheme 2), the high temperature EPR spectrum and the low g_3 value (2.005), a $\{d_{z^2}\}^1$-ground state can be assumed (see Table 2).



Scheme 2. An orbital splitting diagram of a Jahn–Teller compressed octahedron along the *z*-axis.

By decreasing temperature, the dynamic process will be frozen, thus adopting the true rhombic symmetry of the coordination sphere and splitting all degeneracy of the energy levels. As in the X-ray structure analysis (Scheme 1), this is also clearly observable in the EPR spectra, which are of rhombic symmetry below ~178 K, with $g_1(g_x) > g_2(g_y) > g_3(g_z)$ (see Fig. 3). The $g_3(g_z)$ value is more or less unchanged at different temperatures according to the relatively small changes of the bond distances along the *z*-axis, whereas $g_\perp$ splits into $g_1(g_x) > g_2(g_y)$, due to more static situation in the structure with the expected rhombic symmetry (D_{2h}). Therefore, a $\{d_{x^2-y^2}\}^1$ ground state of the title complex at low temperature might be suggested, but the unchanged signal for $g_3(g_z)$ indicates that the ground states at 293 and 115 K have a similar character. Furthermore, a mixing of the $d_{x^2-y^2}$ and the d_{z^2} orbital cannot be excluded for this symmetry. This can easily lead to miss-assignments of the ground state, especially if the structure is solved only from the room temperature data and no other complementary methods (EPR, UV–Vis, EXAFS, MSDA) with temperature variation are used [7]. Cu(II) complexes with a compressed octahedral symmetry and a $\{d_{z^2}\}^1$ ground state are therefore very rare [7,16–20].

Since the theory with a disorder in such cases is not fully clear-cut, an alternative explanation for related complexes was introduced. Namely, a switch of the ground state

Table 2
Temperature dependence of selected EPR parameters of the vanillinate complex with a CuO_6 chromophore

from a $\{d_{z^2}\}^1$ at 295 K to a $\{d_{x^2-y^2}\}^1$ at 5 K for [Cu(2,6-bis(hydrazonomethyl)pyridine)$_2$](ClO$_4$)$_2$ and [Cu(2,6-bis-(oximomethyl)pyridine)$_2$](ClO$_4$)$_2$ was reported [7,10]. It was suggested that a temperature-dependent switching between two different ground states would be possible, if the distal Cu—ligand bond is inductively weakened, possibly by an electron withdrawing substituent. Through this perspective, the rigid vanillinate ion in *cis*-[Cu(C$_8$H$_7$O$_3$)$_2$-(H$_2$O)$_2$], due to its strong hydroxy coordination that would not allow the methoxy group to coordinate closer, was expected to be interesting for a possible switch. A small signal between g_1 and g_2 (see the low temperature spectra in Fig. 3), observed also in the spectra of the above mentioned two $\{d_{z^2}\}^1$ species [7,10] that was tentatively assigned as a small fraction of fluctional $\{d_{x^2-y^2}\}^1$ Cu(II) spins, could be in favour of the last explanation.

Additionally, it should not be forgotten that the title compound was isolated in a pure form only under specific conditions by quick and careful melting of vanillin, followed by its immediate dissolution in hot acidified Cu^{2+}(aq), since otherwise another isomer (*trans*) predominates [4]. Therefore, a high temperature was crucial during the synthesis, possibly enabling a sterical advantage of the compressed *cis* isomer against the elongated *trans* isomer. Maybe the complex was already formed in the $\{d_{z^2}\}^1$ state, which requires a specific geometry around the Cu(II) ion, later preserved after cooling to room temperature, due to specific conditions with a fixed *cis* coordination enabled by the rigid bidentate ligand with a withdrawing group. The preservation of a very similar conformation and packing of the molecules with a temperature change is seen also in only minor differences in the coordination sphere angles and H-bonding network (Table 1, and as well from a great similarity of the powder diffraction patterns). This would agree with the ligand imposed distortion or packing in the crystal.

4. Concluding remarks

X-ray structure analysis of *cis*-[Cu(C$_8$H$_7$O$_3$)$_2$(H$_2$O)$_2$] at 115 K reveals a *cis* coordination of vanillinate ions and water molecules, with three rhombic coordination axes. The distances and the symmetry of the coordination sphere differ importantly from the room temperature molecular structure, where compressed axial axes were determined. The MSDA thermal ellipsoid analysis confirms the vibrational disorder in the structure at high temperature, and its gradual freezing by decreasing temperature. These results are fully in agreement with the EPR spectra, showing also the reversibility of this change. Based on the EPR data, a $\{d_{z^2}\}^1$ ground state is proposed, although the room temperature spectrum suggests a 'normal' $\{d_{x^2-y^2}\}^1$ ground state, but with a small g_3 value (close to g_e). A careful analysis of the data in such cases is recommended.

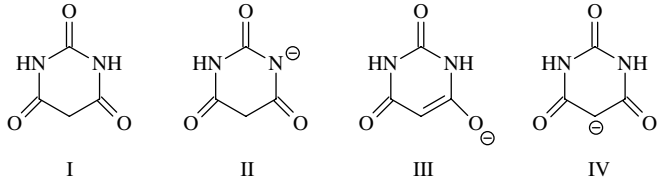
(py) and on the basis of IR spectral data, suggested that the barbiturate ligands are coordinated to copper(II) through an oxygen atom. However, X-ray structures of $[M^{II}(barb)_2(im)_2]$ (M^{II} = Co and Zn; im = imidazole) [6], $[Ni(isoamylbarb)_2(im)_2]$ [7], $[Cu(barb)_2(py)_2]$ [8], $[Cu(barb)_2(pic)_2]\cdot 2H_2O$ [9] and $[Zn(barb)_2(pic)_2]$ (pic = picoline) [10] showed that in all these complexes, the barbital moiety is deprotonated and the donor site of the barbiturate anion is the deprotonated N atom. On the other hand, it was recently reported that in $[Cu(C_4N_2H_3)_2(H_2O)_3]$ [11], the barbiturate ligands were found to be O-coordinated. Furthermore, in the case of platinum metals, 1,3-dimethybarbiturate (dmbarb) exhibited linkage isomerism. For example, in $[Pd(en)_2(dmbarb)_2]\cdot 5.5H_2O$ [12] and $[Pt(en)_2(dmbarb)_2]$ (en = ethylenediamine) [13], one barbiturate ligand coordinates at the deprotonated carbon atom and the other at a deprotonated enol oxygen, while both barbiturate ligands in $[Pt(en)_2(dmbarb)_2]\cdot 2H_2O$ [13] are C-bonded.

The presence of several potential donor atoms such as two amine nitrogen atoms and three carbonyl oxygen atoms makes barbiturates very interesting and polyfunctional ligands in coordination chemistry. They have often been used as building blocks in ordered organic supramolecular assemblies with specific and directional hydrogen bonds [14–18], and they also seem to be capable of bridging metal centres to form polymeric structures. However, a literature survey indicates that metal complexes of barbiturates are rare. Recently, we have reported the synthesis, thermal, spectral and structural characterization of two new copper and cadmium complexes of barb with en, namely *cis*-$[Cu(barb)_2(en)]$ [19] and $\{[Cd(barb)_2(\mu\text{-}en)]\cdot 2H_2O\}_n$ [19]. The barb ligand in both complexes acts as a bidentate chelating ligand via the negatively charged imino N atom and one of the carbonyl O atoms adjacent to the imino N atom. In the case of zinc, $[Zn(barb)_2(en)]$ and $[Zn(barb)_2(bpy)]\cdot H_2O$ (bpy = 2,2′-bipyridine) complexes were obtained [20], and both barb ligands in $[Zn(barb)_2(en)]$ are N-bonded. It was shown that the barbiturate coordination modes depend on the nature of the barbiturate anion (Scheme 1). This has prompted us to study the Ag^I-barb system to probe the coordination modes of barb with silver(I) in the solid state, and herein we report the syntheses, crystal structures, thermal behaviors and spectroscopic properties of three novel Ag^I-barb frameworks containing en and *trans*-1,2-bis-(4-pyridyl)ethylene (bpe), namely $Na_3[Ag_3(\mu\text{-}barb)_6]$ (**1**), $\{[Ag_2(\mu\text{-}barb)_2][Ag_2(\mu\text{-}en)_2]\cdot 5H_2O\}_n$ (**2**) and $[Ag(barb)(\mu\text{-}bpe)]_n$ (**3**). The structures of the complexes were determined by single-crystal X-ray diffraction and also supported by IR, ^1H NMR and thermal decomposition studies. The antimicrobial activity of the ligands and complexes was also studied.



Scheme 1. Barbiturate and its anions.

2. Experimental

2.1. Materials and measurements

All commercial reagents were used as supplied. Elemental analyses for C, H, and N were performed using a Carlo Erba 1106 microanalyser. IR spectra were recorded with a Jasco FTIR-430 spectrophotometer with samples as KBr pellets in the 4000–400 cm^{-1} range. ^1H NMR spectra were recorded at room temperature (298 K) with a Bruker AC200 spectrometer. Thermal analysis curves (TG and DTA) were obtained using a Rigaku TG8110 thermal analyzer in a static air atmosphere with a heating rate of 10 °C min^{-1} and a sample size of 5–10 mg.

2.2. Preparation of $Na_3[Ag_3(\mu\text{-}barb)_6]$ (1)

A solution of $AgNO_3$ (0.34 g, 2 mmol) in distilled water (10 mL) was mixed with a solution of Nabarb (5,5-diethylbarbituric acid sodium salt) (0.41 g, 2 mmol) in distilled water (10 mL) with continuous stirring at room temperature. The solution immediately became milky. The addition of *N*-(2-hydroxyethyl)ethylenediamine (0.21 mL) together with 10 mL of 2-propanol to the milky suspension resulted in a clear solution. The resulting solution was allowed to stand in darkness at room temperature and colorless prisms of **1** were obtained after 3 days. Yield 72%. *Anal.* Calc. for $C_{48}H_{66}N_{12}O_{18}Ag_3Na_3$: C, 38.65; H, 4.46; N, 11.27. Found: C, 38.53; H, 4.59; N, 11.39%. IR (solid KBr pellet): ν (cm^{-1}) 3184 sb, 3058 vw, 2970 vw, 1697 vs, 1666 vs, 1558 vs, 1464 s, 1411 s, 1376 s, 1311 vs, 1265 vs, 1043 m, 937 m, 841 vs, 793 m, 752 m, 652 m, 522 m, 476 m, 443 m. ^1H NMR (200 MHz, [D6]DMSO, 25 °C): $\delta = 0.69$ (t, 3H, CH_3), 1.75 (q, 2H, CH_2), 10.66 (s, H, NH) ppm.

2.3. Preparation of $\{[Ag_2(\mu\text{-}barb)_2][Ag_2(\mu\text{-}en)_2]\cdot 5H_2O\}_n$ (2)

The preparation method of **2** was the same as described for **1** with ethylenediamine (en) replacing *N*-(2-hydroxyethyl)ethylenediamine. The colorless crystals were obtained after 2 days. Yield 56%. *Anal.* Calc. for $C_{20}H_{46}N_8O_{11}Ag_4$: C, 23.87; H, 4.61; N, 11.13. Found: C, 23.73; H, 4.52; N, 11.25%. IR (solid KBr pellet): ν (cm^{-1}) 3197 sb, 3088 vw, 2973 w, 1676 sh, 1615 vs, 1431 vs, 1337 vs, 1258 s, 1013 s, 951 w, 829 m, 768 m, 543 m, 451 m, 420 w. ^1H NMR (200 MHz, [D6]DMSO, 25 °C): $\delta = 0.65$ (t, 3H, CH_3), 1.72 (q, 2H, CH_2), 2.80 (s, 2H, $\underline{CH_2}$–NH_2), 3.37 (s, H, NH_2) ppm.

2.4. Preparation of [Ag(barb)(μ-bpe)]$_n$ (3)

Compound **3** was synthesized in a similar manner to **2** except that *trans*-1,2-bis(4-pyridyl)ethylene (bpe) was used instead of en. Colorless crystals suitable for X-ray were formed by slow evaporation of the resulting solution in darkness at room temperature after a few days. Yield 87%. *Anal.* Calc. for $C_{20}H_{21}N_4O_3Ag$: C, 50.74; H, 4.47; N, 11.84. Found: C, 50.85; H, 4.57; N, 11.72%. IR (solid KBr pellet): ν (cm^{-1}) 3170 sb, 2979 w, 1677 vs, 1584 vs, 1414 vs, 1347 vs, 1275 sh, 987 s, 837 s, 760 m, 554 s, 452 m, 410 w. ^1H NMR (200 MHz, [D6]DMSO, 25 °C): $\delta = 0.69$ (t, 3H, CH_3), 1.75 (q, 2H, CH_2), 7.57 (s, H, CH=CH), 7.63 (dd, 2H, py ring), 8.62 (dd, 2H, py ring), 10.65 (s, H, NH) ppm.

2.5. Antimicrobial testing

For antimicrobial activities, the compounds were tested against standard strains of Gram-negative *Escherichia coli* MC4100 and *Pseudomonas aeruginosa* ATCC27853, Gram-positive *Bacillus subtilis* and *Staphylococcus aureus* ATCC 43300, and two yeasts *Candida albicans* ATCC 10231 and *C. parapsilosis* ATCC 22019. Antimicrobial activity tests were carried out using the broth dilution method. For the broth dilution method, cultures were started inoculating a single colony from a freshly grown culture on nutrient broth agar (Acumedia) and grown overnight in nutrient broth (Acumedia) at 37 °C for 18 h in an orbital shaker incubator (GLF, Germany) shaking at 200 rpm. These cultures were used as starter cultures. Approximately, 10^6 cells from starter cultures were inoculated in 5 ml nutrient broth media. For *Candida* strains cultures were initially grown on PDA plates (Merck) 37 °C for 48 h and used for inoculation in fresh nutrient broth medium. The inoculum amount was same as that of bacterial strains. All the test cultures were grown at 37 °C in the shaker incubator. The incubation period was 24 h for bacterial strains and 48 h for fungal strains. Nutrient broth containing test tubes first supplemented with various amounts of each compound, made serial dilutions in nutrient broth from 100 to 0.1 μg/ml. The compounds were first tested in 10-fold serial dilution; eventually the ranges were narrowed to define more exact values. The minimum inhibitor concentration, at which no growth was observed, was taken as the MIC value (μg/ml), and represents the mean of at least three determinations. Ampicillin (Applichem) was used as a reference inhibitor for bacterial strains and nystatin (BDH) for fungal strains. For comparison, $AgNO_3$ was tested for MIC values. All the ligands and the solvents used were also tested for antimicrobial activity.

2.6. X-ray crystallography

The intensity data of the complexes **1**–**3** were collected using a STOE IPDS 2 diffractometer with graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$). Complexes **1** and **2** were measured at 100 K, while complex **3** was measured at 293 K. The structures were solved by direct methods and refined on F^2 with the SHELXL-97 program [21]. All non-hydrogen atoms were found from the difference Fourier map and refined anisotropically. All hydrogen atoms

were included using a riding model. The details of data collection, refinement and crystallographic data are summarized in Table 1.

3. Results and discussion

3.1. Synthetic aspects

Silver complexes **1**–**3** were obtained by the direct reaction of sodium barbital with $AgNO_3$ in the presence of the co-ligands. Initially, we aimed to prepare mixed-ligand silver(I)-barb complexes with some diamine ligands such as *N*-(2-hydroxyethyl)ethylenediamine (heen), en and bpe. However, in the case of heen, the desired silver(I) complex could not be prepared since the coordination of the ligand seemed to be unsuccessful in the present conditions. Instead, a new anionic complex, $Na_3[Ag_3(\mu\text{-barb})_6]$ (**1**), was obtained. The direct synthesis of **1** from sodium barbital and $AgNO_3$ in the absence of heen was attempted, but the reaction resulted in the rapid precipitation of a polycrystalline powder, presumably $[Ag(barb)]_n$ which is barely soluble in known solvents.

Complexes **1**–**3** are air stable and do not exhibit a melting point, but decompose at 310, 36 and 232 °C, respectively. They were obtained in reasonably high yields (over 55%). The analytical data are consistent with the proposed formulation of the complexes. All three complexes are highly soluble in a 4:1 mixture of water and 2-propanol, and slightly soluble in pure water and common alcohols such as methanol, ethanol and 2-propanol.

3.2. IR and ^1H NMR spectra

The IR spectra (KBr disks) of complexes **1**–**3** were recorded in KBr in the 4000–400 cm^{-1} range. For comparative purposes the IR spectra of the free ligands were also obtained. The complexes display the characteristic bands of the ligands, somewhat modified by coordination. The strong and broad absorption bands at 3170–3197 cm^{-1} in the spectra of the complexes indicate the presence of the NH groups. The relatively weak bands in the 2970–3080 cm^{-1} range are attributed to the C–H stretching vibrations. The sharp absorption bands in the frequency range 1560–1700 cm^{-1} characterize vibrations of the carbonyl groups. The barb ligand exists in the triketo form and all carbonyl groups interact with sodium(I) in Na(barb) [3]. As will be discussed later, similar interactions of the carbonyl groups with the sodium(I) ion were observed in **1** and, therefore, the IR spectra of Na(barb) and **1** both possess two sharp bands at 1697 and 1666 cm^{-1}, in accord with the presence of two different carbonyl groups. Two types of strong absorption bands of the carbonyl group were also observed at 1676 and 1615 cm^{-1} for **2**, whereas only a single band was found at 1677 cm^{-1} in the spectrum of **3**. In **2** and **3**, carbonyl groups do not participate in coordination and the apparent red-shifts may be associated with strong hydrogen bonding. The strong bands at 1584 and 1558 cm^{-1} in the spectra of **1** and **3**, respectively, are due to N–H deformation vibrations of the barb ligand. The absence of this band in the spectrum of **2** clearly suggests the complete deprotonation of both amine groups. These conclusions are supported by the results of X-ray diffraction studies. The bands with strong intensity between 1464 and 1311 cm^{-1} correspond to the C–H deformation vibrations and the band centered around 1265 cm^{-1} is attributed to the C–N stretching vibrations [5]. The weak or medium intensity bands in the region 455–410 cm^{-1} can be assigned to the Ag–N stretching vibration.

The ^1H NMR spectra of complex **1** show all expected resonances of the barb moiety. The signal at 10.66 ppm was assigned to the NH proton of barb and was shifted to downfield by about 1 ppm, compared to Na(barb). The NH proton appears as a sharp band in DMSO and is absent in the spectra of complex **2**, confirming deprotonation of the barb monoanion to a dianion, also proposed above from its IR spectra. In the NMR spectra of **2**, signals at 2.80 and 3.37 ppm correspond to the CH_2–NH_2 and NH_2 groups, respectively, and are shifted upfield compared to those of free en; this is quite similar to findings reported for platinum complexes with en derivatives [22]. The protons of the water molecules appear as a broad band centered at 3.65 ppm. For complex **3**, the ^1H NMR spectra are similar to that of complex **1**, the only differences arising from the py rings of the bpe ligand. The spectra show that the chemical shifts of the protons of the py ring exhibit two sets of signal at 7.64 ppm, as a doublet, and 8.62 ppm, also as a doublet. Moreover, the protons of the ethylene moiety appear at 7.57 ppm as a singlet.

3.3. Thermal studies

To study the thermal decomposition behaviors and thermal stabilizes of complexes **1**–**3**, thermogravimetric (TG) and differential thermal analyses (DTA) of the compounds were performed in an atmosphere of air in the temperature range 20–900 °C. The final decomposition residues were identified by elemental analysis and also confirmed by mass loss calculations. Complex **1** shows a very high thermal stability and begins to decompose at 309 °C. Its thermal stability is comparable to $Na[Ag(sac)_2]$ (sac = saccharinate) [23]. The degradation of the barb moiety is completed in a single step with a continuous mass loss in the TG curve between 309 and 450 °C, and the DTA curve presents an endothermic peak at 330 °C and three highly exothermic peaks at 377, 398 and 439 °C, giving a final decomposition product containing silver, sodium and oxygen.

Complex **2** shows a two-step decomposition process and in the first step, it starts to lose water molecules between 36 and 198 °C with a mass loss of 8.57% (calc. 8.94%). The initial temperature of dehydration is relatively low and suggests that the water molecules are uncoordinated. In the second step, the anhydrous compound begins to decompose at 204 °C with a continuous mass loss and due to

overlapping decomposition processes of both en and barb ligands it is impossible to calculate mass loss values for the elimination of each ligand. However, the overall mass loss of the second step is 49.05% (calc. 48.11%). The end product at 398 °C was presumably silver oxide.

Complex **3** is thermally stable up to 232 °C, a significantly lower temperature than that of **1**. It shows a continuous decomposition in the temperature range 232–381 °C. The endothermic peak at 309 °C corresponds to the decomposition of the bpe ligands, while the violently exothermic peak at 356 °C characterizes the decomposition of the barb ligands. The total weight loss value of 74.46% is in agreement with the calculated value 75.52%. The end decomposition product was suggested to be silver oxide.

3.4. Description of the structures

3.4.1. $Na_3[Ag_3(\mu\text{-barb})_6]$ (1)

The asymmetric unit of **1** is shown in Fig. 1 and selected bond lengths and angles are listed in Table 2. Complex **1** is a coordination polymer, in which the barb anions simultaneously bridge the silver and sodium cations giving rise to a 3D network. The structure of **1** contains two different silver and Na atoms, as depicted in Fig. 1. Both silver(I) ions are linearly coordinated by the negatively charged N atoms of the two barbital ions. In contrast to atom Ag1, atom Ag2 is coordinated a barb ligand and its symmetry-equivalent partner. All Ag–N bond distances are almost identical, resulting in an average value of 2.075(4) Å. The barb anions act as a bridge between the sodium(I) cations through their carbonyl groups. The coordination mode of the three distinct barb ligands in **1** differs: ligands barb1 and barb2 with atoms N1, and N3, respectively, behave as tridentate ligands through a N and two carbonyl O atoms, while ligand barb3 with atom N5 acts as a bidentate bridging ligand via one of the carbonyl O and a N atom. To the best of our knowledge, the simultaneous presence of two coordination modes of the barb ligand has not been reported until now.

H-bonds	N···O (Å)	N–H···O (°)
N2–H2···O4^{v}	2.817(6)	155
N4–H4···O1^{i}	2.802(6)	164
N6–H6···O7^{ii}	2.778(6)	179

[a] Symmetry operations: (i) $1/2+x,1/2+y,z$; (ii) $1-x,1-y,1-z$; (iii) $3/2-x,1/2-y,1-z$; (iv) $1-x,y,1/2-z$; (v) $x-1/2,y-1/2,z$; (vi) $3/2-x,y-1/2,1/2-z$.

In contrast to the tetrahedrally coordinated sodium(I) ions in Nabarb [3], in **1** both sodium(I) ions are octahedrally coordinated by the carbonyl O atoms from six different barb ligands with Na–O bond distances ranging from 2.333(5) to 2.700(4) Å and *cis*-O–Na–O bond angles ranging between 71.81(15) and 112.30(15), as listed in Table 2. The Na–O bond distances were found to be

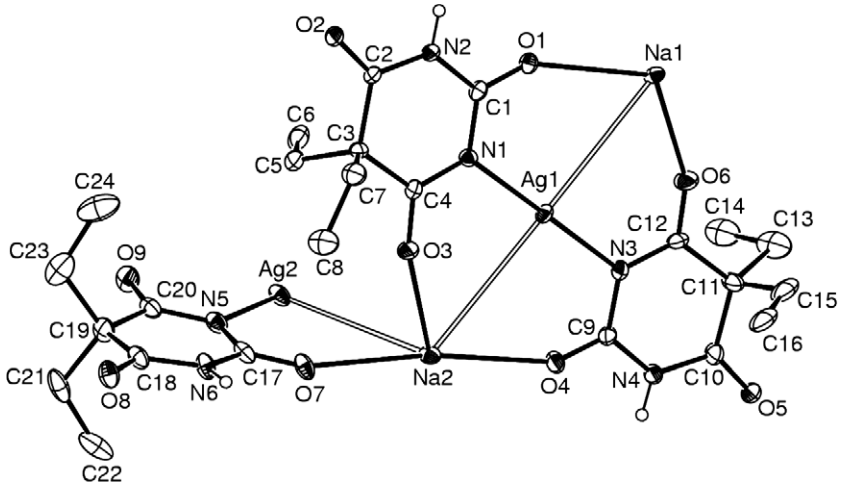

Fig. 1. View of the asymmetric unit of **1**, showing coordination environments of silver and sodium atoms (30% probability thermal ellipsoids; C–H hydrogen atoms were omitted for clarity).

significantly longer than those reported for Nabarb [3]. Since the total van der Waals radii of sodium and silver ($r_{Na} = 2.27$ Å and $r_{Ag} = 1.72$ Å) is 3.99 Å, the Ag···Na separations of 3.537(2), 3.651(2) and 3.638(2) Å may indicate a kind of 'metallophilic' interactions between silver(I) and sodium(I) ions. The minimum Ag···Ag and Na···Na distances are 5.733 and 7.188 Å, respectively.

The pyrimidine rings in the three barb ligands are essentially planar and the three carbonyl groups are not significantly displaced from the mean planes of their attached pyrimidine ring. The dihedral angle between the barb1 and barb2 mean planes is 5.90(18)°, indicating the co-planarity of these barb ligands. Conformation, bond lengths and angles of the barb ligands in **1** are similar to those of the barb ion [3,4]. The two ethyl groups in barb2 are disordered over two positions with approximately equal occupancy. Fig. 2 shows the packing of anionic $[Ag(barb)_2]$ units in the absence of sodium(I) ions. $[Ag(barb)_2]$ units are linked by N–H···O hydrogen bonds generating a 2D supramolecular framework and the sodium(I) cations further connect these layers to a 3D network (Fig. 2).

3.4.2. $\{[Ag_2(\mu\text{-}barb)_2][Ag_2(\mu\text{-}en)_2]\cdot 5H_2O\}_n$ (2)

The asymmetric unit of complex **2** is shown in Fig. 3, and Table 3 lists selected bond length and angles together with the hydrogen bonding geometry. The asymmetric unit contains four crystallographically unique Ag atoms, each having a significantly different environment. As shown in

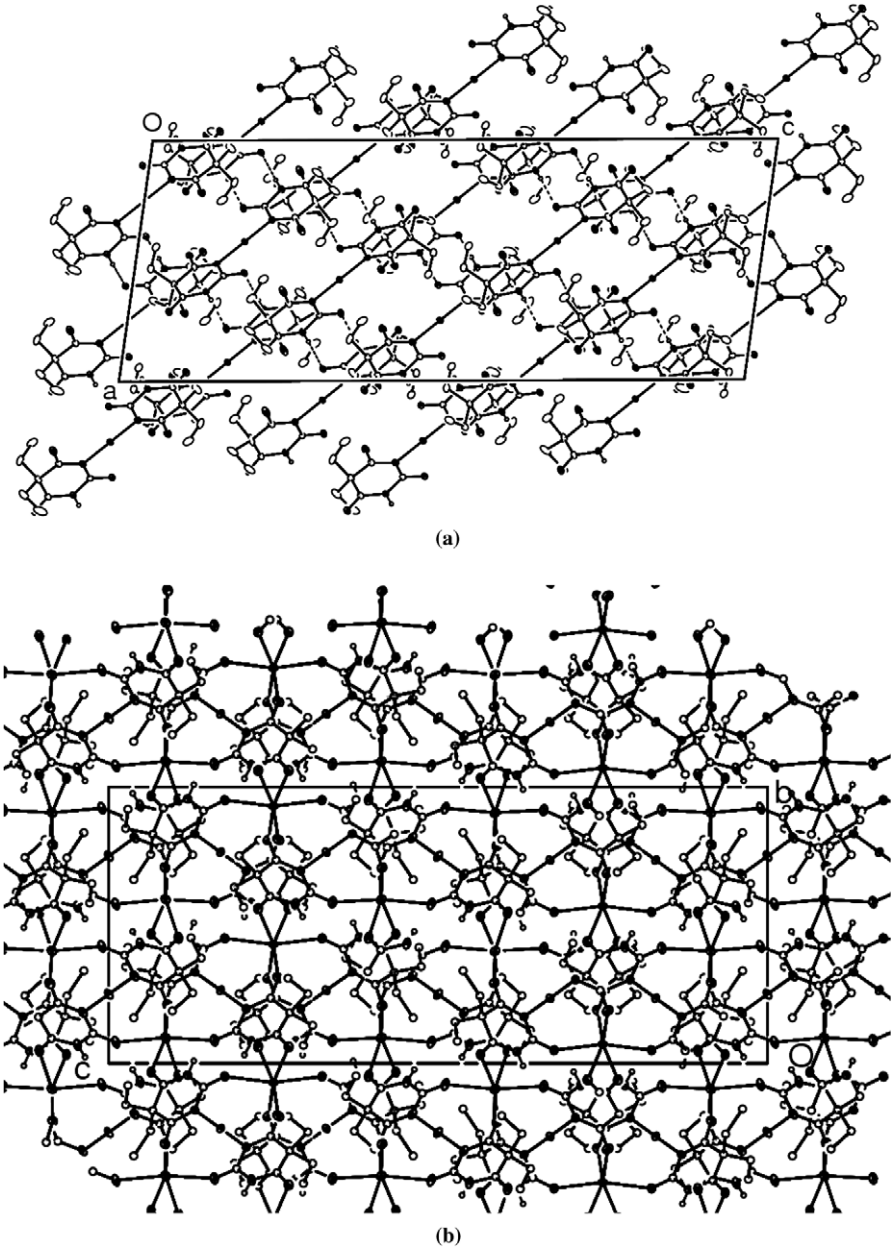

Fig. 2. (a) Interaction of $[Ag(barb)_2]$ units in **1** via hydrogen bonds (Na and C–H hydrogen atoms were omitted for clarity). (b) View of the crystal packing of **1**, viewed along the *a* axis.

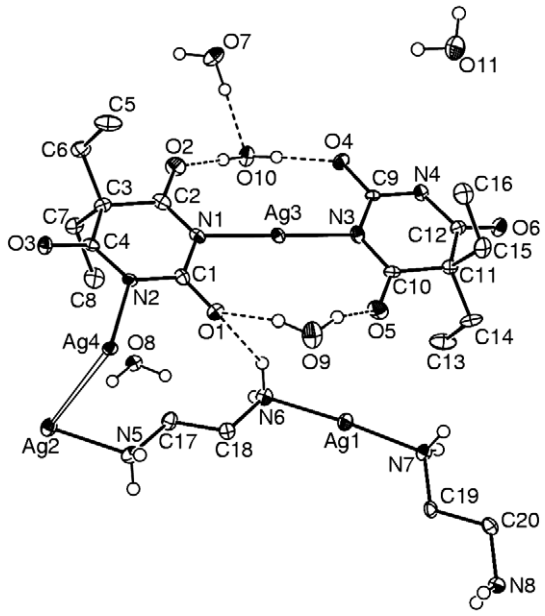

Fig. 3. View of the asymmetric unit of **2**, showing coordination environments of silver atoms (30% probability thermal ellipsoids; C–H hydrogen atoms were omitted for clarity).

Fig. 4, complex **2** consists of two different chains: an anionic 1D linear chain with [Ag(μ-barb)] units and a cationic 1D zig-zag chain containing [Ag(μ-en)] units. These anionic and cationic chains are interconnected by way of Ag···Ag interactions to form an unusual 2D framework, in which the chains interact each other leading to a rectangle-grid motif with dimensions of 17.04×34.55 Å^2 (Fig. 4). In complex **2**, the barb ligand is further deprotonated to form a dianion, which acts as a bidentate bridging ligand via both negatively charged N atoms. Again, to the best of our knowledge, this is the first example of a barb dianion coordinating to a metal ion, and the *N*,*N*′-bridging coordination mode of the ligand has also been observed for the first time in this work. As a result, Scheme 1 should be extended to include the new anionic form of barb.

In both anionic and cationic units, each Ag^I center has a slightly distorted linear $\{AgN_2\}$ coordination geometry. The average Ag–N_{en} bond distance of 2.13(5) Å is similar to that observed in $[Ag_2(sac)_2(en)(H_2O)]_n$ [24], but is noticeably longer than the Ag–N_{barb} bond distances in **2**. The silver atoms appear to be interacting based on the Ag–Ag distances of 3.236(1) and 3.404(1) Å, which are significantly shorter than twice the van der Waals radius of silver (3.44 Å) and clearly indicate a bonding interaction as observed in $[Ag_2(sac)_2(en)(H_2O)]_n$ [24]. The intra-chain Ag–Ag distances are 5.827(5) and 7.449(4) Å in the anionic and cationic chains. Ag···Ag interactions have been a subject of discussion: Jansen [25] suggested a upper limit value of 3.30 Å for an Ag···Ag contact in silver(I) coordination compounds, but Dance et al. [26] argued that since the linear geometry around silver(I) indicates the fulfillment of its coordination requirements, there is no bonding interaction between silver(I) centers as close to each other as 2.886 Å in $[Ag(SCMeEt)_2]_n$. However, although the closed d^{10} configuration of silver(I) appears to cancel any intermetallic bonding in silver(I) complexes, there are many examples of silver(I) complexes with definite Ag···Ag attractive forces known as 'argentophilic' interactions [27].

Both barb ligands are almost planar, but the C atoms bearing the two ethyl groups deviate from the mean plane by 0.2 Å. The barb rings are co-planar with a dihedral angle of 3.98(15)°. The torsion angle of 178.6(7)° suggests that the non-hydrogen atoms of en lie in the same plane. Complex **2** exhibits a number of intra- and intermolecular N–H···O and O–H···O hydrogen bonds as listed in Table 3. The amine hydrogen atoms of en participate in

weak hydrogen bonding with the O atoms of barb ligands and water molecules. The water O atoms do not participate in coordination with silver(I) and their hydrogen atoms form strong hydrogen bonds with the O atoms of barb ligands and water molecules. Thus, the 2D layers of **2** are linked by these hydrogen bonds into a 3D network with open channels (Fig. 5). Calculations with PLATON [28] show that in the absence of the water molecules, the structure of **2** has solvent accessible voids with a volume of 73.7 $Å^3$, which is approximately 9% of the total cell volume, indicating that the channels are filled with water molecules.

*3.4.3. [Ag(barb)(μ-bpe)]$_n$ (**3**)*

The X-ray crystal structure shows that complex **3** is an infinite 1D coordination polymer. The coordination environment around the silver(I) ion is shown in Fig. 6. The N–Ag–N bond angles in Table 4 suggest that the local AgN_3 geometry is between trigonal and T-shape. The basic building blocks in the extended structure are [Ag(barb)(bpe)], which are bridged by the two N atoms of the bpe ligand, generating a helical chain running along the *a* axis (Fig. 7). The barb ligands are *N*-coordinated through the negatively charged N atom. The Ag–N_{barb} bond distances are slightly longer than the Ag–N_{bpe} bond

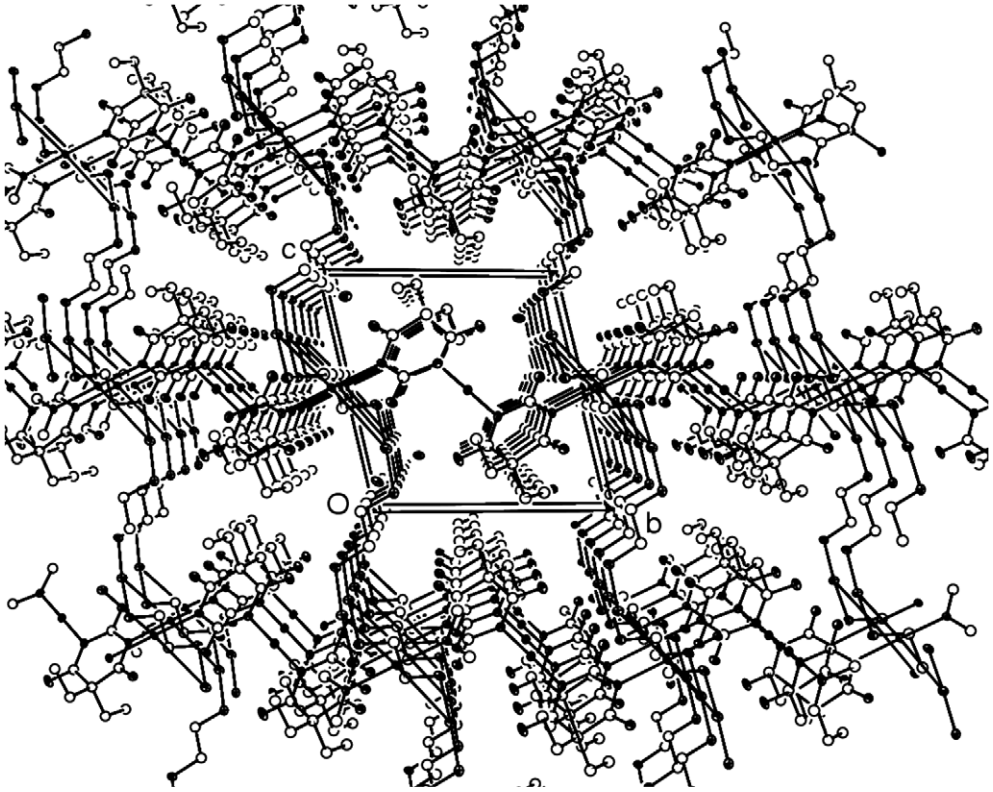

Fig. 5. View of the stacking sheets along the *a* axis of **2**.

bpe molecule is basically flat, the py rings within a bpe molecule are tilted by about 6.5°. Individual chains are connected by N–H···O hydrogen bonds between the barb ligands into 2D layers, which are further linked by aromatic π–π stacking interactions between the py rings of the bpe ligands [$C_g \cdots C_g^i = 3.543$ Å; i = $1 + x, y, z$ and $C_g \cdots C_g^{ii} = 3.558$ Å; (ii) $-1 + x, y, z$; C_g is the centroid on the benzene ring] to generate a 3D framework as shown in Fig. 7.

3.5. Antimicrobial activities

The metal-free ligands and their silver(I) complexes were tested for their in vitro antimicrobial activities against two Gram-positive bacteria, *B. subtilis* and *S. aureus*, two Gram-negative bacteria, *E. coli* and *P. aeruginosa*, and two fungi *C. albicans* and *C. parapsilosis*. The results are presented in Table 5 as minimum inhibitor concentration (MIC) values (μg/ml) which is the minimum concentration to inhibit the growth of bacteria or fungi.

The free ligands and solvents showed no antimicrobial activity against either bacterial or fungal strains tested at a concentration of 100 μg/ml, but the ligands in the form of silver complexes had significant levels of activity due to facts that in general silver(I) complexes are kinetically labile and a ligand exchange process is quite likely to occur. The antimicrobial activity of $AgNO_3$ was, almost without exception, superior to that of complexes **1**–**3** across all of

Table 5
Antimicrobial activity of compounds evaluated by minimum inhibitory concentration (MIC = μg/ml)

Compound	*P. aeruginosa*	*E. coli*	*B. subtilis*	*S. aureus*	*C. albicans*	*C. parapsilosis*
Na(barb)	>100	>100	>100	>100	>100	>100
en	>100	>100	>100	>100	>100	>100

1	12	23	27	25	25	15
2	13	15	47	15	35	35
3	42	42	43	43	38	47
Ampicillin	>100	50	55	10		
Nystatin					7	3

the bacterial and the fungal strains studied. Complex **1** had a higher activity on all the strains especially against *P. aeruginosa* and *C. parapsilosis*. The MICs for four strains, *E. coli*, *B. subtilis*, *S. aureus* and *C. albicans*, were ca. 25 μg/ml, while the growth of the other two strains, *P. aeruginosa* and *C. parapsilosis*, was inhibited more effectively at ca. 12 μg/ml. For complex **2**, the growth of the strains *P. aeruginosa*, *E. coli* and *S. aureus* was inhibited at a concentration of ca. 15 μg/ml of the complex, while the MICs were 47 μg/ml for *B. subtilis* and 35 μg/ml for both fungal strains. Complex **3** showed similar MIC values for all the strains. Compared to complexes **1** and **2**, the MICs of **3** were found to be noticeably higher and this may be consequence of the slow precipitation tendency of this complex in the growth medium. Among the three silver-barbital complexes, complex **2** seems to be more effective against all bacterial strains. Compared to ampicillin, all three complexes demonstrated a remarkable microbial activity on bacterial strains with exception of *S. aureus*. It is interesting to note that *P. aeruginosa* was significantly affected by complexes **1** and **2**. These facts are consistent with recently observed results for polymeric silver(I) complexes containing Ag–N and Ag–O bonds [29–32]

Nystatin and $AgNO_3$ inhibited the growth of the fungi at MIC values less than 10 μg/ml. Complexes **1**–**3** are remarkably active against both the *Candida* strains. Both strains were more susceptible to complex **1**, while similar MIC values were found for the other two complexes conclusively, having less activity than $AgNO_3$ and nystatin.

In the case of silver(I) complexes, two key factors were proposed for a wide range of antimicrobial activities: (i) the type of the coordinating ligands around silver(I), and (ii) the ease of their replacement with biological ligands such as proteins, enzymes, amino acids and nucleic acids [33–36]. As can be seen from Tables 1–3, the silver(I) ion has a AgN_3 core in complexes **1**–**3** and the Ag–N bond lengths increase in the order of **1**, **2** and **3**. Although complex **3** seems to have higher ligand exchange ability among the three complexes, its precipitation in the growth medium makes complex **2** a good inhibitory agent. On the other hand, there are contrasting effects regarding drug solubility. For example, a water-insoluble polymeric complex, sulfadiazinesilver(I) (commercially known as silvadene or flamazine), is used to treat burn wounds [37] and its antimicrobial activity is mainly attributed to the slow liberation of silver. In conclusion, the title complexes show effective antimicrobial inhibition and their low solubility in water promises some potential antibacterial and antifungal applications.

Supplementary material

Crystallographic data for the structures reported in this paper have been deposited at the CCDC as supplementary data, CCDC-290101 (**1**), -290102 (**2**) and -290103 (**3**). Copies of the data can be obtained on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK. E-mail: deposit@ccdc.cam.ac.uk.

2. Experimental

2.1. Materials

Solvents (benzene, alcohols, dichloromethane, *n*-hexane, acetone and diethyl ether, etc.) were dried and purified according to the literature methods [24]. Phosphorous pentasulfide (E. Merck) was used as received. Ethane-1,2-dithiol (E. Merck), antimony trichloride (S. D. Fine), glycols [butane-2,3-diol (E. Merck) and 2,3-dimethylbutane-2,3-diol (Aldrich)] were distilled before use. 2-Chloro-1,3-dithia-2-stibacyclopentane [25] and the alkylene-/diorganodithiophosphoric acids and their sodium/ammonium salts were synthesized by earlier reported methods [2,5].

2.2. Measurements

The elemental analysis (C and H) was performed on a Perkin–Elmer 2400 elemental analyzer. Sulfur was estimated gravimetrically as barium sulfate and antimony was estimated iodometrically titrating against standard sodium thiosulfate solution [6,7]. Molecular weights were determined cryoscopically in benzene. IR spectra were recorded in KBr discs on a Perkin–Elmer 557 spectrophotometer in the region 4000–200 cm^{-1}. The UV spectra were recorded in chloroform solution at room temperature on a Shimadzu UV-1601 UV–Vis spectrophotometer within the range 500–200 nm. ^{1}H, ^{13}C and ^{31}P spectra of all these newly synthesized complexes were recorded in $CDCl_3$ solution using TMS and 85% H_3PO_4 as standards, respectively. The ^{1}H and ^{13}C NMR spectra were operated at 300.13 and 75.49 MHz respectively, on a Bruker AC-300F NMR spectrophotometer at the Sophisticated Analytical Instrument (SAIF) Facility, Punjab University, Chandigarh and ^{31}P NMR spectra were operated at 121.50 MHz on a DRX-300 NMR spectrophotometer, SAIF, Central Drug Research Institute (CDRI), Lucknow.

The single crystal X-ray diffraction analysis was performed on a STOE IPDS (imaging plate system) diffractometer at 25 °C, using graphite monochromated Mo Kα X-ray radiation ($\lambda = 0.71073$ Å). A suitable crystal, grown from a toluene–isopropyl alcohol solution, was sealed in a glass capillary under dry nitrogen atmosphere and mounted on the goniometer head. The data collection was performed at room temperature using the ω–θ scan technique. The crystal structure was solved by direct methods and refined by full-matrix least squares on F^2 using the SHELXS software package for crystal structure solution and refinement. All non-hydrogen atoms were refined with anisotropic thermal parameters in the later cycles of refinement. The hydrogen atoms were placed in idealized positions and refined using the riding model with general isotropic temperature factors. The data collection was performed only up to 27.87°. Selected atomic parameters are collected in Tables 2 and 3, and the crystallographic numbering scheme is shown in Fig. 1.

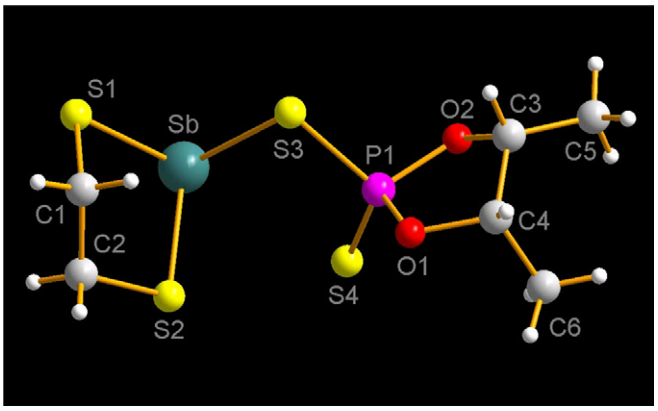

Fig. 1. X-ray single crystal structure of 1,3-dithia-2-stibacyclopentane 2,3-butylenedithiophosphate.

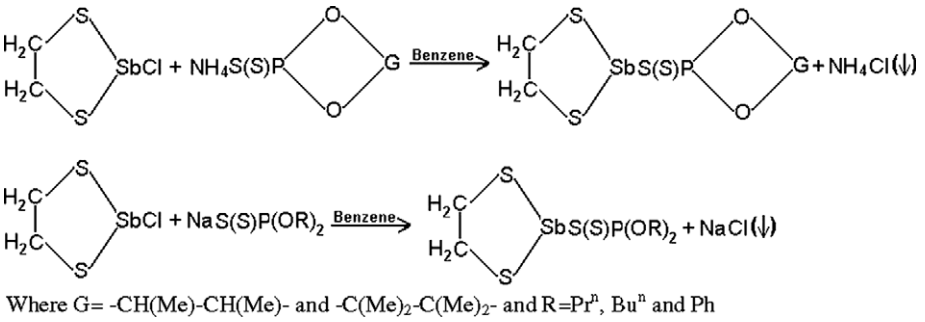
2.3. Antimicrobial studies

The following strains of bacteria and fungi were used: *Staphylococcus aureus* (ATCC 9144), *Bacillus subtilis* (ATCC 6051), *Escherichia coli* (ATCC 9637), *Pseudomonas aeruginosa* (ATCC 25619), *Aspergillus niger* (ATCC 9029) and *Penicillium chrysogenum* (ATCC 10106). Antimicrobial activities were evaluated by the disc diffusion method [27–29] for the tested compounds as follows.

A 0.5 mL (containing 10^6–10^7 microorganisms mL^{-1}) of each of the investigated organisms was added to a sterile agar medium just before solidification, then poured into sterile petri dishes (9 cm in diameter) and left to solidify.



Scheme 1. Reaction of 2-chloro-1,3-dithia-2-stibacyclopentane with sodium/ammonium dithiophosphates in an equimolar ratio.

Using a sterile cork borer (6 mm in diameter), three holes (wells) were made in each dish, then 0.1 ml of tested compounds dissolved in DMF (50, 100 and 200 μg mL^{-1}) were poured into these holes. Finally the dishes were incubated at 37 °C for 24 h (for bacteria) and at 30 °C for 72 h (for fungi), then inhibition zones were detected around each hole.

A quantity of 0.1 ml DMF alone was also tested under the same conditions for each organism and it was found that DMF had no effect on the organisms at the concentrations studied.

2.4. Synthesis of mixed 1,3-dithia-2-stibacyclopentane alkylene-/dialkyl-dithiophosphate derivatives

2.4.1. Synthesis of 1,3-dithia-2-stibacyclopentane 2,3-butylenedithiophosphate

A benzene solution (30 ml) of 2-chloro-1,3-dithia-2-stibacyclopentane (0.72 g, 2.88 mmol) was added to the ammonium salt of 2,3-butylenedithiophosphoric acid (0.58 g, 2.88 mmol) in an equimolar ratio (Scheme 1). The reaction mixture was refluxed with stirring for ~5 h followed by cooling to room temperature. The precipitated ammonium chloride (0.15 g) was removed by filtration. The removal of the solvent from the filtrate under reduced pressure afforded a yellow crystalline compound, which was recrystallised in dichloromethane (yield: 1.13 g, 98%).

The other complexes were synthesized by adopting a similar method. Pertinent analytical and physico-chemical data for these complexes are listed in Table 1.

3. Results and discussion

3.1. Synthesis of antimony(III) complexes

1,3-Dithia-2-stibacyclopentane derivatives with alkylene-/dialkyl-dithiophosphate have been synthesized by the reactions of 2-chloro-1,3-dithia-2-stibacyclopentane with the ammonium/sodium salts of alkylene-/dialkyl-dithiophosphoric acids in an equimolar (1:1) ratio in refluxing benzene ~5 h.

All these newly synthesized derivatives are either yellow crystalline solids or yellow sticky solids and are soluble in common organic solvents like benzene, chloroform, acetone, dichloromethane, DMF and DMSO, etc., but decompose in water.

3.2. Electronic spectra

In the electronic absorption spectra [12–15,26], all the 1,3-dithia-2-stibacyclopentane dithiophosphate derivatives absorb strongly in the region 230–235 nm, corresponding to a π–π^* transition. Another rather weak absorption occurs at 304–309 nm, which may be due to a n–π^* transition. These dithiophosphates also absorb in these regions.

3.3. Infra-red spectra

These newly synthesized complexes show medium to strong intensity bands in the regions 1000–1030 cm^{-1} and 830–860 cm^{-1} which are assigned due to ν\{(P)–O–C\} and ν\{P–O–(C)\}, respectively [5–8,17,18]. A broad band in the region 690–720 cm^{-1} (alkylenedithiophosphates) and 660–690 cm^{-1} (dialkyldithiophosphates) due to ν(P=S), present in the free phosphoric acids, is shifted towards lower frequencies in the spectra of all these complexes and is present in the regions 650–660 and 635–645 cm^{-1} respectively, this also overlaps with the ν(C–S) vibrations of dithiolate moieties in these complexes. A sharp band present in the region 925–930 cm^{-1} in the corresponding alkylenedithiophosphate may be assigned to the ring vibrations of the dioxaphospholane ring [30]. The bands of medium to weak intensity in the regions 530–540 and 310–320 cm^{-1} are assigned to ν(P–S) and ν(Sb–S), respectively [17].

3.4. NMR spectral data

3.4.1. ^{1}H NMR spectra

The chemical shifts corresponding to the protons of mixed 1,3-dithia-2-stibacyclopentane derivatives with alkylene-/dialkyl-dithiophosphate are listed in Table 4. In the ^{1}H NMR spectra of these compounds, a sharp singlet observed in the region δ 3.61–3.74 ppm is due to four CH_2S protons of the 1,3-dithia-2-stibacyclopentane ring [17,18], indicating that these protons are equivalent. In addition, these compounds also exhibit the characteristic proton resonances [5–18] for the corresponding protons of dithiophosphate moieties (Table 4). In a few of the alkylene-/dialkyl-dithiophosphate derivatives, OCH and OCH_2 protons couple with ^{31}P nuclei and appear as a multiplets and doublets of triplets.

3.4.2. ^{13}C NMR spectra

The ^{13}C NMR spectra of the ethane-1,2-dithiolate moiety show only one sharp singlet signal in the region δ 41.41–42.40 ppm due to SCH_2 carbons [17,18] indicating that these two carbon atoms are magnetically equivalent, thus supporting the results of the ^{1}H NMR spectra. In addition, these derivatives also exhibit the expected signals due to the carbons of dithiophosphate moieties [5–17]. The methylene carbons attached to P–O and P–O–C groups

give rise to a doublet for compound No. 4 due to the coupling with ^{31}P nuclei [9] (Table 4).

3.4.3. ^{31}P NMR spectra

The proton decoupled ^{31}P NMR spectra show only one sharp singlet between δ 103.7–108.1 ppm (in alkylenedithiophosphate derivatives). Chemical shift values appear to be downfield by about δ 10–13 ppm with respect to their parent alkylene dithiophosphoric acids (δ 93.07–95.49 ppm) indicating the bidentate behaviour of these dithiophosphate ligands. The corresponding complexes with dialkyldithiophosphate ligands show a ^{31}P signal in the region δ 88–91 ppm. Glidewell [31] concluded that diorganodithiophosphate complexes showing their ^{31}P NMR signals in the range δ 82–101 exhibit a bidentate mode of attachment of the ligands, thus indicating the bidentate mode of binding of diorganodithiophosphate ligands in these synthesized complexes. It is valid for many cases, however doubts have been made about the universality of the above generalization [32,33].

3.5. Crystal structure

The solid-state structure of the compound 1,3-dithia-2-stibacyclopentane 2,3-butylenedithiophosphate has been established by single crystal X-ray analysis, which revealed a monomeric unit. The molecular structure of 1,3-dithia-2-stibacyclopentane 2,3-butylenedithiophosphate is shown in

Fig. 1 and selected interatomic parameters are collected in Table 3. The antimony atom forms three close contacts, two to the ethane-1,2-dithiolato sulfur atoms, Sb(1)–S(2) (2.4485 Å) and Sb(1)–S(1) (2.4491 Å), and one to the dithiophosphato sulfur atom, Sb(1)–S(3) (2.5566 Å). If these three close contacts were considered to define the coordination geometry, the dithiophosphate ligand behaves in a monodentate fashion. Considering the observed Sb–S interactions, the environment about the antimony would be best described as trigonal pyramidal with the lone pair of electrons being stereochemically active, but with non-equivalent S–Sb–S bond angles [87.80(3)°, 92.17(4)° and 94.83(4)°] (Table 3) [34]. The phosphorus atom is tetrahedrally coordinated to two sulfur and two oxygen atoms, which are further attached with carbon atoms of the alkylene group (Fig. 1). The crystal structure shows that the heteroalkylene ring is markedly non-planar and that the configuration of the bonds about the antimony atom is nearly orthogonal.

The structure of this compound is unique as in this compound the 2,3-butylenedithiophosphate ligand is exhibiting monodentate behaviour. However, in most alkylenedithiophosphate derivatives of main group metals, bismuth(III) [20] and organotin(IV) [22,23], the bidentate behaviour of these alkylenedithiophosphate ligands has been reported. However, in (2,9-dimethyl-1,10-phenanthroline) *bis*(4,4,5,5-tetramethyl-1,3,2-dioxaphospholane-2-thione-2-thiolato)-nickel(II), one ligand is unidentate and the other one is bidentate [21]. It is also noticeable here that diorganodithiophosphate and dithiophosphinate ligands exhibited a bidentate as well as a bidentate triconnective chelating nature in their antimony(III) complexes [2,3].

3.6. Antimicrobial activity

The free ligands and their antimony(III) complexes were screened to evaluate their antimicrobial activity against *S. aureus*, *B. subtilis*, *E. coli*, *P. aeruginosa*, *A. niger* and *P. chrysogenum* at three different concentrations, and results are listed in Table 5. The antibacterial activities of some earlier reported antibiotics [29] were compared with the free ligands and their antimony(III) complexes.

The results showed that the antimony(III) complexes exhibit higher antibacterial and antifungal activity than the free diorganodithiophosphate ligands (dtp). It is noticeable here that *E. coli* and *P. aeruginosa* are resistant to the free dtp ligands. It may be concluded that the free ligands and antimony complexes inhibit the growth of bacteria to a greater extent as the concentration is increased. Nevertheless, it is difficult to make out an exact structure and activity relationship between microbial activity and the structure of these complexes.

A comparison of the antimicrobial activities of the free ligands and synthesized complexes with some previously investigated antibiotics [29] shows the following results:

(i) The free ligands (dtp) and their antimony(III) compounds show a greater effect towards *S. aureus* compared to amikacin, septrin, cefobid, ampicillin and traivid. However, the free ligands (dtp) and antimony(III) compounds show a lesser effect towards *S. aureus* compared to doxycllin, augmantin, sulperazon, unasyn, nitrofurantion and erythromycin.

Table 5
Antimicrobial activity[a] of the free dithiophosphate ligands and 1,3-dithia-2-stibacyclopentane alkylene-/dialkyl-dithiophosphate complexes

Chloroamphenicol	−	−	−	−	−	−	+	+	++	+	+	++	+	++	+++	+	++	+++
Terbinafin	+	++	++	+	++	++	−	−	−	−	−	−	−	−	−	−	−	−

[a] The test was done using the diffusion agar technique, well diameter = 6 mm, inhibition values beyond control are + = 1–5 mm, ++ = 6–10 mm, +++ = 11–15 mm, 0 = not active and − = not tested.

(ii) The antimony(III) compounds show a greater antibacterial effect towards *P. aeruginosa* than doxycillin, augmantin, unasyn, septrin, cefobid, nitrofurantion, traivid, erythromycin and free dtp ligands. However, the antimony(III) compounds show a lesser effect towards *P. aeruginosa* compared to amikacin, sulperazon and chloroamphenicol.
(iii) The antimony(III) complexes show a greater effect towards *E. coli* compared to unasyn, cefobid, ampicillin, erythromycin and dtp ligands (resistance to *E. coli*). However, the antimony(III) compounds show a lesser effect towards *E. coli* compared to amikacin, doxycllin, augmantin, sulperazon, nitrofurantion, traivid and chloroamphenicol.
(iv) Some of the antimony(III) compounds exhibit an equal antimicrobial effect as that of some antibiotics.

From all of the above results we can conclude that some of the free ligands and their antimony complexes show greater antibacterial effects to some of the investigated antibiotics.

4. Conclusions

Present study describes a series of 1,3-dithia-2-stibacyclopentane complexes with alkylene-/dialkyl-dithiophosphate. On the basis of physico-chemical and spectroscopic data we propose a monodentate behaviour of these ligands in these complexes, which is further confirmed by the X-ray crystal structure of 1,3-dithia-2-stibacyclopentane 2,3-butylenedithiophosphate.

Biological activity of the free ligands and their antimony(III) derivatives has been studied by the disc diffusion method on various microorganisms. All antimony(III) complexes exhibit greater antimicrobial activity compared to that of the free ligands. The free alkylene-/dialkyldithiophosphate and their mixed antimony compounds exhibited a higher antibacterial effect than the some of the previously investigated antibiotics.

5. Supplementary materials

Crystallographic data, tables of atomic coordinates, thermal parameters, bond lengths and bond angles of the structure have been deposited with the Cambridge Crystallographic Data Centre, with the deposition number: 604201. Copies of this are available free of charge from the Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44 1223 336 033; deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Acknowledgements

Elemental analyses as well as spectral studies were carried out at the SAIF of the CDRI, Lucknow and Punjab University, Chandigarh. The authors are also thankful to S. Srivastava, Holkar Science College, for providing facilities for antimicrobial studies and to Dr. D. Buddhi for UV–Vis spectra.

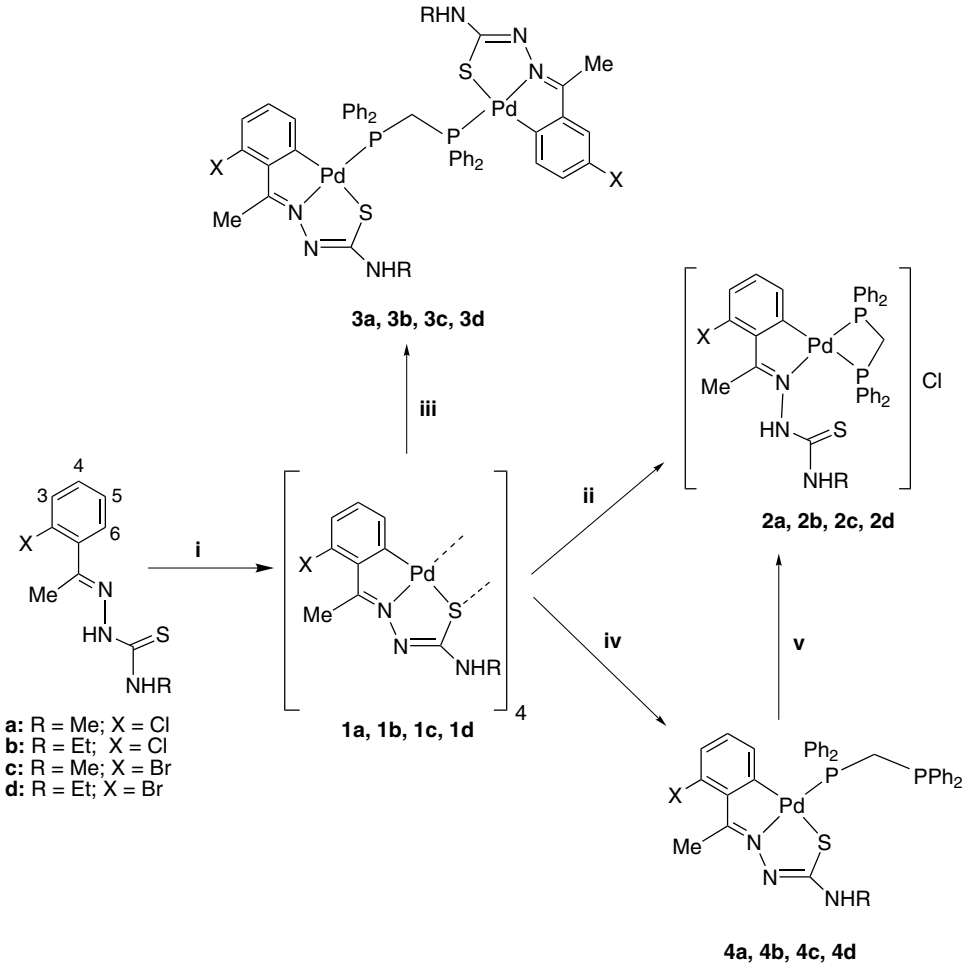
acid, however without cleavage of the Pd–$S_{chelating}$ bond. Therefore, in view of these findings and in our efforts to succeed in devising a route aimed at the preparation of cyclometallated thiosemicarbazone complexes with chelating diphosphines we reasoned that reaction of the tetranuclear palladacycles with a strong chelating diphosphine, plus concentrated hydrochloric acid, should suffice to yield the aforementioned species, and the results of this enterprise are presented herein.

2. Results and discussion

The ligands **a**–**d** were synthesized by reaction of 4-methyl or 4-ethyl-3-thiosemicarbazide with 2′-chloro- or 2′-bromoacetophenone as appropriate, in good yields, and were adequately characterized (see Section 6). The most prominent features were the characteristic ν(N–H) bands in the IR spectra ca. 3350 and 3200 cm^{-1}, assigned to the NHR and NH groups, respectively; distinctive ν(C=N) and ν(C=S) stretches appeared in the ranges 1620–1590 and 840–800 cm^{-1}, also, respectively. The NHR and NH proton resonances in the ^{1}H NMR appeared ca. δ 8.6 and 7.5 ppm, respectively. Reaction of the ligands by any one of the two alternative methods described, i.e., (a) lithium tetrachloropalladate and sodium acetate in methanol; or (b) palladium(II) acetate in glacial acetic acid, resulted in all cases in tetranuclear species, $[Pd\{2\text{-}XC_6H_3C(Me)=NN=C(S)NHR\}]_4$ (X/R: Cl/Me, **1a**; Cl/Et, **1b**; Br/Me, **1c**; Br/Et, **1d**) as air-stable solids, with the ligand in the *E*,*Z* configuration, which were fully characterized by microanalytical, mass spectra, IR and ^{1}H NMR determinations (see Section 6). The mass spectrum (FAB) showed peaks at *m*/*z* 1384 (**1a**), 1441 (**1b**), 1563 (**1c**) and 1620 (**1d**) for the molecular ion whose isotopic composition suggests a tetranuclear complex of the formula $C_{40}H_{40}Cl_4N_{12}Pd_4S_4$ (**1a**), $C_{44}H_{48}Cl_4N_{12}Pd_4S_4$ (**1b**), $C_{40}H_{40}Br_4N_{12}Pd_4S_4$ (**1c**) and $C_{44}H_{48}Br_4N_{12}Pd_4S_4$ (**1d**) (see Section 6).

The ν(C=N) band was shifted to lower wavenumbers ca. 30 cm^{-1} [24] indicating palladium coordination to the C=N moiety through the nitrogen lone pair [25,26]. The absence of the N*H* proton resonance in the ^{1}H NMR spectra was in agreement with deprotonation of the hydrazinic nitrogen atom [27,28]; accordingly, the C=S double bond character was minimized as confirmed by the non-existence of the ν(C=S) band [29]. Metallation of the ligands was



Scheme 1. (i) $Li_2[PdCl_4]$/NaAcO/MeOH; $Pd(AcO)_2$/AcOH; (ii) $Ph_2PCH_2PPh_2$/$HCl_{(aq)}$/acetone/1:4; (iii) $Ph_2PCH_2PPh_2$/acetone/1:2; (iv) $Ph_2PCH_2PPh_2$/acetone/1.4; (v) $HCl_{(aq)}$/acetone.

clear from the absence of the four proton ABCD spin system of the *ortho*-substituted phenyl ring; in the spectra of the complexes only three resonances were observed, which were unambiguously assigned to the H3, H4 and H5 protons (see Section 6).

3. Reactivity of the complexes

The reactions of **1a**–**1d** with $Ph_2PCH_2PPh_2$ in a 1:4 molar ratio and concentrated hydrochloric acid gave the hitherto unknown complexes [Pd{2-$XC_6H_3C(Me)$=NN(H)–C(=S)NHR}($Ph_2PCH_2PPh_2$-P,P)](Cl) **2a**–**2d** which were fully characterized (Section 6 and Scheme 1). Conductivity measurements in dry acetonitrile showed they were 1:1 electrolytes, with Λ_m values of ca. 130 ohm^{-1} cm^2 mol^{-1}. The most noticeable feature of these compounds was that protonation occurred at the hydrazinic nitrogen atom as shown by a broad resonance signal at ca. 8.80 ppm in the ^1H NMR spectra, and a band assignable to the ν(C=S) mode at ca. 8.35 cm^{-1} in the IR spectra. The ^{31}P–{^1H} NMR spectra showed two doublets for the two non-equivalent phosphorus nuclei. The resonance at lower frequency was assigned to the phosphorus nucleus *trans* to the phenyl carbon atom in accordance with the higher *trans* influence of the latter with respect to the C=N nitrogen atom [30]. The *H*C=N resonance was only coupled to the ^{31}P nucleus *trans* to nitrogen. This was confirmed by selective decoupling experiments on the ^{31}P atoms. Alternatively, compounds **2a**–**2d** could be prepared by stirring a mixture of **4a**–**4d** and concentrated hydrochloric acid at room temperature. Unfortunately, the yields were rather low in these cases, ca. 25%, and the final product contained unreacted starting material, and so far pure **2a**–**2d** could not be made by this additional route.

Treatment of the tetranuclear species with $Ph_2PCH_2PPh_2$ in the absence of acid gave dinuclear and mononuclear compounds with a bridging or monocoordinate phosphine ligand, respectively. Thus, reaction of **1a**–**1d** and the phosphine in a 1:2 molar ratio produced compounds [{Pd[2-$XC_6H_3C(Me)$=NN=C(S)NHR]}$_2$(μ-$Ph_2PCH_2PPh_2$)] (**3a**–**3d**) as pure air-stable solids, which were completely characterized (see Section 6). The symmetric nature of the complexes was evident from the ^1H NMR data, which showed only one set of signals; and consequently, only one singlet was observed in the ^{31}P–{^1H} spectra showing two equivalent phosphorus nuclei, with a δ value pointing

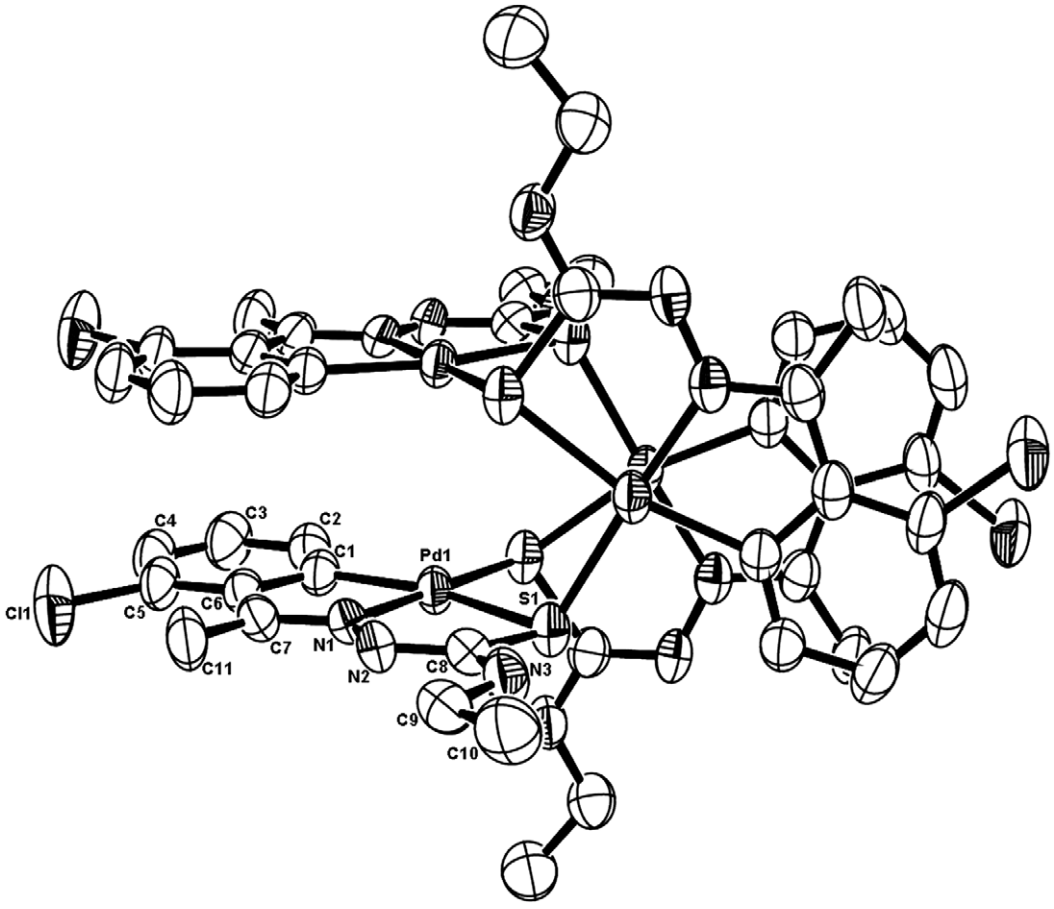


Fig. 1. An ORTEP drawing of the molecular structure for **1b** with the labelling scheme (50% probability). Hydrogen atoms have been omitted for clarity. Selected bond lengths (Å) and angles (°): Pd(1)–N(1) 1.989(4), Pd(1)–C(1) 2.007(5), Pd(1)–S(1)#1 2.3186(16), Pd(1)–S(1) 2.3551(16), S(1)–C(8) 1.792(6), N(1)–C(7) 1.316(6), N(1)–N(2) 1.385(6), N(2)–C(8) 1.308(6), C(6)–C(7) 1.469(8); N(1)–Pd(1)–C(1) 80.9(2), N(1)–Pd(1)–S(1)#1 177.11(13), C(1)–Pd(1)–S(1)#1 96.44(17), N(1)–Pd(1)–S(1) 84.10(13), C(1)–Pd(1)–S(1) 164.66(17), S(1)#1–Pd(1)–S(1) 98.52(4).

towards a phosphorus *trans* to nitrogen geometry [31,32]. The H5 resonance was low frequency shifted by ca. 1.5 ppm, showing coupling to the ^{31}P nucleus, also sustaining a P *trans* to N arrangement [33].

Reaction of **1a**–**1d** with $Ph_2PCH_2PPh_2$ in a 1:4 molar ratio gave the air-stable compounds [Pd{2-XC_6H_3C(Me)=NN=C(S)NHR}($Ph_2PCH_2PPh_2$-P)] (**4a**–**4d**). Characteristic microanalytical and spectroscopic data are given in Section 6. Even when excess diphosphine was used, only cleavage of the Pd–$S_{bridging}$ bonds was produced, therefore yielding species with coordination of the phosphine to the metal atom only through one phosphorus atom. The two doublets in the ^{31}P–{^1H} spectra were assigned to the two non-equivalent phosphorus nuclei with the signal for the phosphorus nucleus bonded to the metal center at higher frequency. The proton part of the *PCH_2P* ABXY spin system appeared as an apparent doublet at ca. 3.2 ppm.

4. Structural studies

4.1. Crystal structures of complexes *1b*, *1d*, *4c* and *4d*

Suitable crystals were grown by slowly evaporating chloroform/*n*-hexane solutions. The crystal structures are shown in Figs. 1–4. Crystal data are given in Table 1.

4.1.1. [Pd{2-XC_6H_3C(Me)=NN=C(S)NHEt}]$_4$ (X = Cl, *1b*; X = Br, *1d*)

The palladium(II) atoms in each structure are in slightly distorted square-planar environments (rms = 0.0132 **1b** and rms = 0.0132 **1d**), with small deviations from the coordination plane (±0.0412 **1b** and ±0.0437 **1d**), and are associated to two fused five-membered chelate rings: the C,N metallacycle and the N,S-chelate moiety, as a consequence of bonding to a terdentate C,N,S ligand. An eight-membered ring of palladium and sulfur atoms, with alternating Pd–$S_{bridging}$ and Pd–$S_{chelating}$ bonds compiles the central part of the molecule; the other two coordination positions at the metal are occupied by a phenyl carbon atom and the nitrogen atom of the C=N group (Figs. 1 and 2).

The angles between adjoining atoms in the coordination sphere are close to the theoretical value of 90°; with the most noteworthy strain in the C(1)–Pd(1)–N(1) values due to chelation of the ligand [22,23] [80.9(2)° **1b**; 81.4(3)° **1d**]. The Pd–C [2.007(5) Å **1b**, 1.990(7) Å **1d**] and Pd–N [1.989(4) Å **1b**, 1.988(6) Å **1d**] bond lengths are shorter than the expected values of 2.081 Å and 2.01 Å [34], respectively, probably induced by partial multiple-bond character [19,35]. The differing *trans* influence of the phenyl carbon and the azomethine nitrogen atoms is

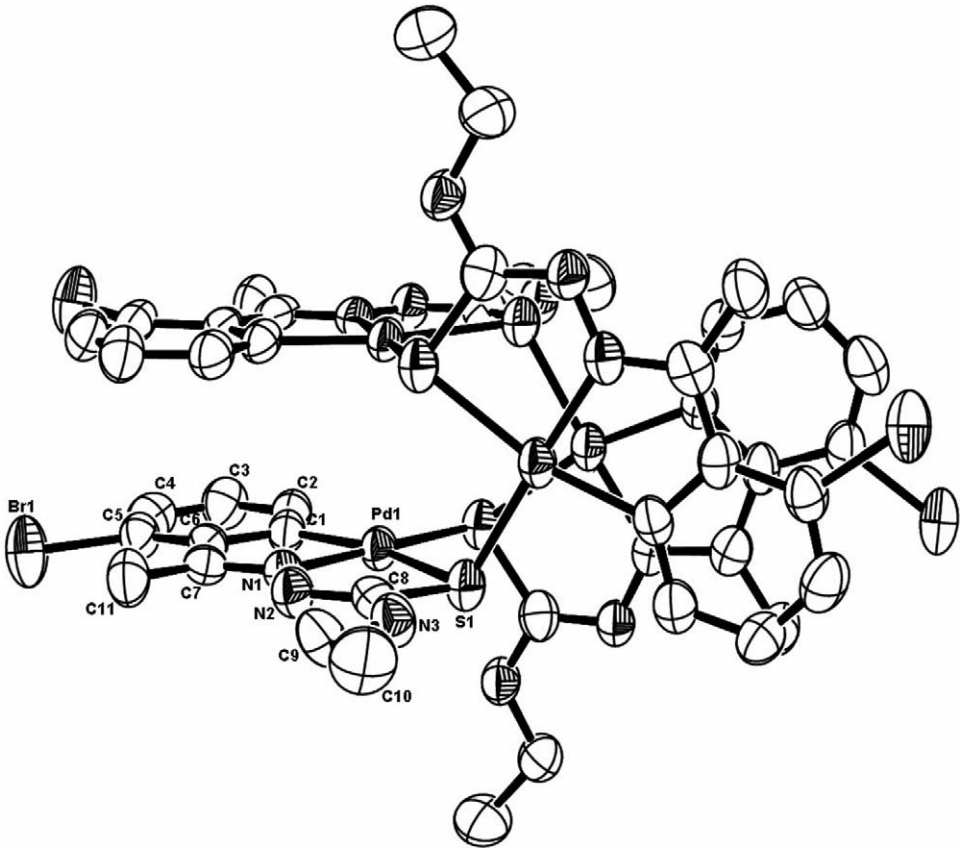

Fig. 2. An ORTEP drawing of the molecular structure for **1d** with the labelling scheme (50% probability). Hydrogen atoms have been omitted for clarity. Fig. 3. An ORTEP drawing of the molecular structure for **4c** with the labelling scheme (50% probability). Hydrogen atoms and solvent molecules have been omitted for clarity. Selected bond lengths (Å) and angles (°): Pd(1)–N(1) 2.018(2), Pd(1)–C(1) 2.026(3), Pd(1)–P(1) 2.2626(8), Pd(1)–S(1) 2.3192(9), P(1)–C(18) 1.823(3), P(1)–C(12) 1.828(3), P(1)–C(11) 1.838(3), S(1)–C(8) 1.754(3), N(1)–C(7) 1.303(4), N(1)–N(2) 1.388(3), N(2)–C(8) 1.307(4), C(6)–C(7) 1.472(4); N(1)–Pd(1)–C(1) 80.77(7), N(1)–Pd(1)–P(1) 177.29(8), C(1)–Pd(1)–P(1) 97.94(2), N(1)–Pd(1)–S(1) 83.23(7), C(1)–Pd(1)–S(1) 163.95(9), P(1)–Pd(1)–S(1) 97.99(3).

put forward in the distinct values of the Pd–$S_{bridging}$ and Pd–$S_{chelating}$ distances [Pd(1)–S(1) 2.3551(16) Å, Pd(1)–S(1)#1 2.3186(16) Å **1b**; Pd(1)–S(1) 2.355(2) Å, Pd(1)–S(1)#1 2.315(2) Å **1d**]. The S(1)–C(8) [1.792(6) Å **1b**; 1.794(7) Å **1d**] and N(2)–C(8) [1.308(6) Å **1b**; 1.304(8) Å **1d**] distances, are consistent with increased single- and double-bond character, respectively, in the deprotonated form. The Pd–Pd lengths of 3.3725(7) Å **1b**, and 3.3596(16) Å **1d**, preclude any Pd–Pd interactions.

*4.1.2. [Pd{2-BrC$_6$H$_3$C(Me)=NN=C(S)NHR}-(Ph$_2$PCH$_2$PPh$_2$-P)] (R: Me **4c**; Et **4d**)*

The crystals consist of discrete molecules and $CHCl_3$, separated by normal van der Waals distances. The palladium coordination sphere is defined by an assorted set of four atoms arising from a terdentate C,N,S thiosemicarbazone and a η^1-diphosphine: the aryl C(1) carbon, the imine N(1) nitrogen, the thioamide S(1) sulfur and the phosphorus P(1) atoms, in a slightly distorted square-planar coordination, [N(1), S(1), C(1), P(1), plane 1] (r.m.s. = 0.0064 Å) **4c**, (Fig. 3), [N(1), S(1), C(1), P(1), plane 1] (r.m.s. = 0.0153 Å) **4d**, (Fig. 4), from which the palladium atom deviates by ±0.0382 Å **4c** and ±0.0328 Å **4d**.

As for the bond distances and the angles at palladium, the data observed for both structures show analogous values that are in accordance with the known theoretical data, with the most noticeable difference being in the Pd–N bond, which displays a marked lengthening due to the *trans* influence of the phosphine ligand [Pd(1)–N(1), 2.018(2) Å **4c**, 2.015(3) Å, **4d**], and the somewhat diminished C(1)–Pd(1)–N(1) angle, 80.77(7)° **4c**, 80.54(14)° **4d** (vide supra). The palladium coordination plane [Pd(1), C(1), N(1), S(1)], and the P(1)C(11)P(2), **4c**, and P(1)C(12)P(2), **4d**, planes are at angles of 68.72° and 69.70°, respectively.

5. Conclusions

We have shown that thiosemicarbazone ligands may yield tetranuclear palladacycles with two distinct Pd–$S_{bridging}$ and Pd–$S_{chelating}$ bonds; the strength of the latter hinders opening of the coordination ring, PdNNCS, bearing the Pd–$S_{chelating}$ bond, and upon reaction with $Ph_2PCH_2PPh_2$, in the absence of acid, only dinuclear and mononuclear compounds were obtained with bridging or monodentate phosphine ligands, respectively, and with the thiosemicarbazone ligand as a terdentate ligand [C,N,S]. However, when concentrated hydrochloric acid

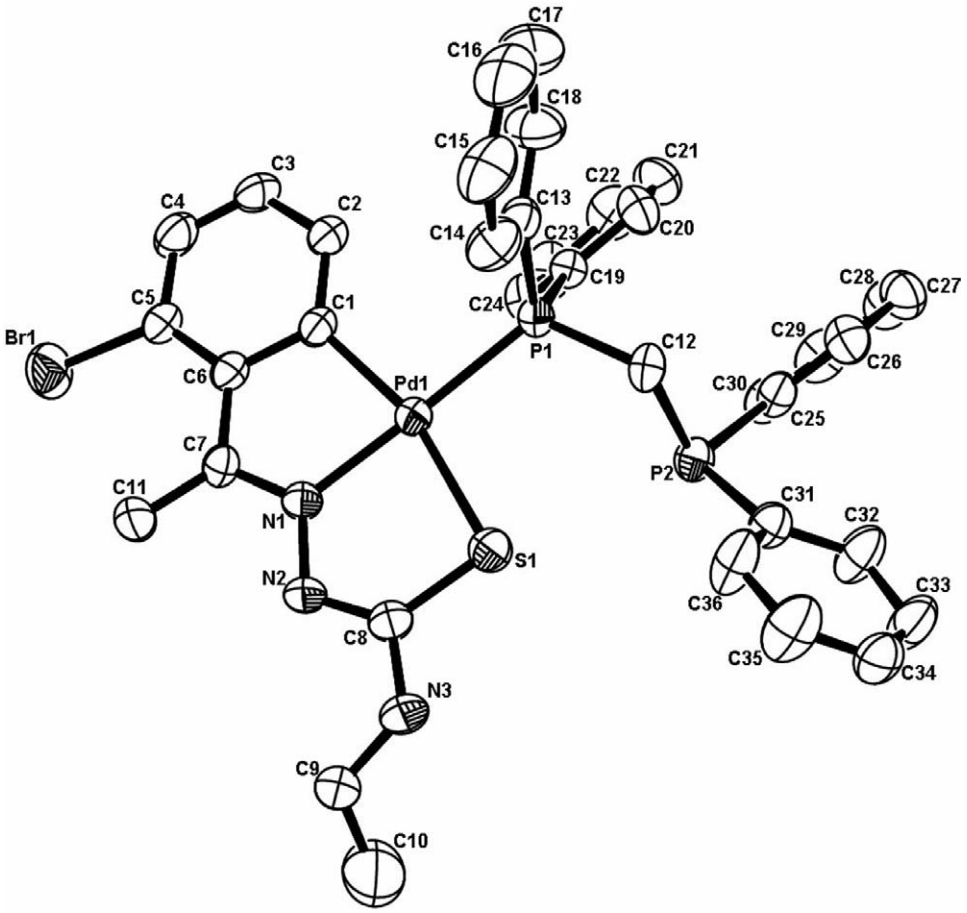

Fig. 4. An ORTEP drawing of the molecular structure for **4d** with the labelling scheme (50% probability). Hydrogen atoms and solvent molecules have been omitted for clarity. Selected bond lengths (Å) and angles (°): Pd(1)–N(1) 2.015(3), Pd(1)–C(1) 2.022(4), Pd(1)–P(1) 2.2659(10), Pd(1)–S(1) 2.3231(11), S(1)–C(8) 1.746(4), P(1)–C(13) 1.833(4), P(1)–C(19) 1.819(4), P(1)–C(12) 1.834(4), N(1)–C(7) 1.302(5), N(1)–N(2) 1.396(4), N(2)–C(8) 1.307(5), C(6)–C(7) 1.467(5); N(1)–Pd(1)–C(1) 80.54(14), N(1)–Pd(1)–P(1) 177.26(9), C(1)–Pd(1)–P(1) 98.33(12), N(1)–Pd(1)–S(1) 83.51(9), C(1)–Pd(1)–S(1) 164.05(12), P(1)–Pd(1)–S(1) 97.59(4).

was added to the reaction mixture, cleavage of the Pd–$S_{chelating}$ bond was produced, with protonation of the thiosemicarbazone and subsequent chelation of the diphosphine ligand, yielding the new thiosemicarbazone palladacycles as 1:1 electrolytes. These could also be made, although impure, by treatment of the compounds with η^1-diphosphine with hydrochloric acid.

6. Experimental

6.1. General procedures

Solvents were purified by standard methods [36]. Chemicals were reagent grade. Lithium tetrachloropalladate was prepared in situ by treatment of palladium(II) chloride with lithium chloride in methanol. Palladium(II) acetate and palladium(II) chloride were purchased from Alfa Products. The diphosphine $Ph_2PCH_2PPh_2$ (dppm) was purchased from Aldrich-Chemie. Microanalyses were carried out at the Servicio de Análisis Elemental at the Universidad of Santiago using a Carlo Erba Elemental Analyzer Model EA1108. IR spectra were recorded as Nujol mulls or KBr discs with Perkin–Elmer 1330, IR-FT Mattson Model Cygnus-100 and Bruker Model IFS-66V spectrophotometers. NMR spectra were obtained as $CDCl_3$ solutions and referenced to $SiMe_4$ (^1H) or H_3PO_4 (^{31}P–{^1H}) and were recorded with Bruker AMX 300, AMX 500 and WM250 spectrometers. All chemical shifts are reported downfield from standards. The FAB mass spectra were recorded with a Fisons Quatro mass spectrometer with a Cs ion gun; 3-nitrobenzyl alcohol was used as the matrix. Conductivity measurements were made on a CRISON GLP 32 conductivimeter using 10^{-3} mol dm^{-3} solutions in dry acetonitrile.

6.2. Syntheses

6.2.1. Preparation of thiosemicarbazone 2-$ClC_6H_4C(Me)$=$NN(H)C(=S)NHMe$ (**a**)

2′-Chloroacetophenone (147 mg, 9.51 mmol) and hydrochloric acid (35%, 0.65 cm^3) were added to a suspension of 4-methyl-3-thiosemicarbazide (100 mg, 9.51 mmol) in water (25 cm^3) to give a clear solution, which was stirred at room temperature for 4 h. The white solid that precipitated was

filtered off, washed with cold water and dried in air. Yield: 209 mg, 91%. *Anal.* $C_{10}H_{12}ClN_3S$ (241.7 g/mol) requires C, 49.7; H, 5.0; N, 17.4; S, 13.3. 6.2.16. [Pd{2-BrC$_6$H$_3$C(Me)=NN=C(S)NHEt}-(Ph$_2$PCH$_2$PPh$_2$-P)] (**4d**)

Yield: 149 mg, 86%. *Anal.* $C_{36}H_{34}BrN_3P_2PdS$ (789.0 g/mol) requires C, 54.8; H, 4.3; N, 5.3; S, 4.1. Found: C, 55.0; H, 4.5; N, 5.0; S, 3.9%. IR (cm^{-1}): ν(N–H) 3418m; ν(C=N) 1556m. ^{1}H NMR ($CDCl_3$, δ ppm, J Hz): 6.97 (m, 1H, H3), 6.21 (m, 1H, H4), 6.12 (m, 1H, H5), 4.81 (br, 1H, N*H*Et), 3.42 (m, 2H, NH*CH*$_2$CH$_3$), 3.24 (d, 2H, P*CH*$_2$P, ^2J(HP) = 9.7), 2.68 (s, 3H, *Me*C=N), 1.22 (t, 3H, NHCH$_2$*CH*$_3$, ^3J(HH) = 7.4 Hz). ^{31}P–{^{1}H} NMR ($CDCl_3$, δ ppm, J Hz): 23.6 (d, 1P, P_A, ^2J(PP) = 75.1), −26.7 (d, 1P, P_B, ^2J(PP) = 75.1).

7. Crystal structures

Crystals of complexes **1b**, **1d**, **4c** and **4d**, were mounted on a glass fibre and transferred to the diffractometer. Three dimensional, room temperature X-ray data were collected with CAD4 Enraf Nonius (**1b** and **1d**) and Siemens (**4c** and **4d**) diffractometers by the omega scan method, using monochromated Mo K_α radiation. All the measured reflections were corrected for Lorentz and polarization effects and for absorption by semi-empirical methods based on symmetry-equivalent and repeated reflections [T_{max}/T_{min} = 0.643/0.603 (**1b**), 0.309/0.200 (**1d**), 0.373/0.319 (**4c**) and 0.711/0.547 (**4d**)]. The structures were solved by direct methods and refined by full matrix least squares on F^2. Hydrogen atoms were included in calculated positions and refined using the riding mode. The structure of **4d** contains 1 symmetry related void of 297.00 Å^3 containing unresolvable solvent, this was treated using the squeeze method lowering the R_1 value by 5.76% [37]. Refinement converged at a final R = 0.0424 (**1b**), 0.0358 (**1d**), 0.0394 (**4c**) and 0.0506 (**4d**) (observed data, F), and wR_2 = 0.1026 (**1b**), 0.0926 (**1d**), 0.0982 (**4c**) and 0.1148 (**4d**) (all unique data, F^2), with allowance for thermal anisotropy of all non-hydrogen atoms. Minimum and maximum final electron densities: −0.790 and 0.543 (**1b**), −0.660 and 0.557 (**1d**), −0.642 and 0.757 (**4c**), −0.530 and 0.595 e Å^{-3} (**4d**). The structure solutions and refinements were carried out with the SHELX-97 [38] program package.

some bimetallic enzymes [22–24]. The catecholase activity of binuclear Cu(II) complexes was studied to identify functional as well as structural models for type III copper enzymes like tyrosinase and catechol oxidase [25–27]. Hydrolysis is found to be the key process in the active sites of a number of enzymes, namely urease, carbon monoxide dehydrogenase, superoxide dismutase, etc., mediated by nickel ions [28] and carboxy peptidase, alkaline phosphatase and β-lactanase mediated by zinc ions [29,30]. The hydrolysis of phosphate mono-, di- and tri-esters by metal complexes such as Cu(II), Zn(II), Cd(II), etc., are used in the development of artificial nucleases for use in molecular genetics and genetic engineering [31–33]. A variety of 'end-off' binuclear complexes containing an endogenous phenolato bridge with either one or two exogenous bridging units, such as acetato, hydroxo, azido and cyano groups, have already been reported [34–38].

Thus, in the present work, we have synthesized a new 'end-off' binucleating ligand (L) by the Mannich base reaction. The ligand contains a highly reactive aldehyde group, which may lead to the extension of its structure into a supramolecular moiety. Synthesis and electrochemical studies of such supramolecular moieties are also in progress. The structure of ligand (L) has been solved by the X-ray crystallographic method. The ligand has been used to prepare Cu(II), Ni(II) and Zn(II) mononuclear complexes and μ-phenoxo endogenous and bis-μ-acetato exogenous tribridged binuclear complexes. The spectral, electrochemical, magnetic and catalytic studies of these complexes are also discussed.

2. Experimental

2.1. Physical measurements

Elemental analysis of the complexes was obtained using a Haereus C, H, N rapid analyzer. ^{1}H NMR spectra were recorded using a JEOL GSX 400 MHz NMR spectrometer. Electronic spectral studies were carried out on a Hitachi 320 spectrophotometer in the range 200–800 nm. IR spectra were recorded on a Shimadzu FT-IR 8300 series spectrophotometer on KBr disks in the range 4000–400 cm^{-1}. Mass spectra were obtained on a JEOL DX-303 Mass spectrometer. Molar conductivity was measured by using an Elico digital conductivity bridge model CM-88 using a freshly prepared solution of the complex in dimethyl formamide. Cyclic voltammograms were obtained on CHI-600A electrochemical analyzer. The measurements were carried out under oxygen free conditions using a three-electrode cell in which a glassy carbon electrode was the working electrode, a saturated Ag/AgCl electrode was the reference electrode and a platinum wire was used as the auxiliary electrode. A ferrocene/ferrocenium (1+) couple was used as an internal standard and $E_{1/2}$ of the ferrocene/ferrocenium (Fc/Fc^+) couple under the experimental conditions is 470 mV. Tetra(*n*-butyl)ammonium perchlorate (TBAP) was used as the supporting electrolyte. The room temperature magnetic moment was measured on a PAR vibrating sample magnetometer Model-155. The variable-temperature magnetic moment was measured on an EG&G Princeton applied research VSM model 4500. X-band ESR spectra were recorded at 25 °C on a Varian EPR-E 112 spectrometer using diphenylpicrylhydrazine (DPPH) as the reference. The atomic absorption spectral data were recorded using a Varian spectra AA-200 model atomic absorption spectrophotometer. The catalytic oxidation of catechol to *o*-quinone by the copper complexes and the hydrolysis of 4-nitrophenylphosphate by the copper, nickel and zinc complexes were studied in a 10^{-3} M dimethylformamide solution. The reaction was followed spectrophotometrically by choosing the strongest absorbance of *o*-quinone at 390 nm and monitoring the increase in the absorbance, and the hydrolysis of *p*-nitrophenyl phosphate was monitored by following the UV absorbance change at 390 nm (assigned to the 4-nitrophenolate anion) as a function of time. A plot of $\log(A\alpha/A\alpha - A_t)$ versus time was made for each complex and the rate constant for the catalytic oxidation and the hydrolysis of 4-nitrophenyl phosphate was calculated.

The crystal data of ligand L were measured on a CAD4 diffractometer using the $\omega/2\theta$ scan mode. The stability of the crystal was checked by monitoring three standard reflections after every 200 reflections. Unit cell parameters were determined by least-squares refinement of 18 reflec-

Table 1
Summary of crystallographic data for ligand (L)

Empirical formula	$C_{19}H_{33}Cl_3N_4O_{17}$
Formula weight (g mol^{-1})	695.84
Temperature (K)	293(2)
Wavelength (Å)	0.71073
Crystal system	triclinic
Space group	$P\bar{1}$
Unit cell dimensions	
a (Å)	9.848(3)
b (Å)	10.679(5)
c (Å)	15.645(8)
α (°)	93.50(4)
β (°)	99.96(4)
γ (°)	104.55(3)
V (Å^3)	1559.1(12)
Z	2
D_{calc} (Mg m^{-3})	1.482
Absorption coefficient (mm^{-1})	0.373
$F(000)$	724
Crystal size (mm)	$0.60 \times 0.32 \times 0.25$
θ Range for data collection (°)	1.33–28.97
Index ranges	$-13 \leqslant h \leqslant 13$, $-14 \leqslant k \leqslant 14$, $0 \leqslant l \leqslant 21$
Reflections collected/unique (R_{int})	8758/8257 (0.075)
Refinement method	full-matrix least-squares on F^2
Data/restraints/parameters	8257/0/404
Goodness-of-fit on F^2	1.438
Final R indices [$I > 2\sigma(I)$]	$R_1 = 0.119$, $wR_2 = 0.345$
R indices (all data)	$R_1 = 0.162$, $wR_2 = 0.376$
Largest difference in peak and hole (e Å^{-3})	1.442 and −0.683

Table 2
Selected bond lengths (Å) and angles (°)

Atoms	Bond length (Å)	Atoms	Angle (°)
C1–O1	1.347(4)	O2–C7–C4	124.5(4)
C7–O2	1.219(6)	C12–N1–C9	109.4(3)

tions in the range 7.29–13.52°. The ranges of *h*, *k* and *l* are −13–13, −14–14 and 0–21, respectively.

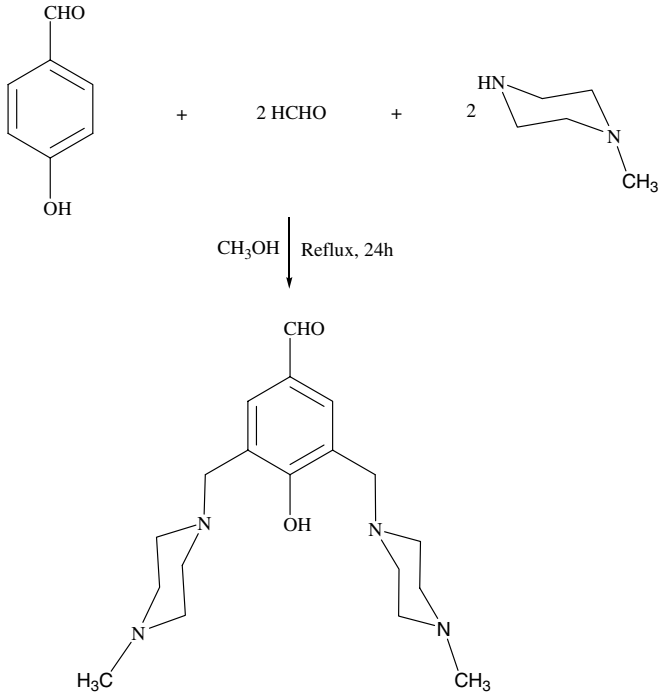
The structure was solved by direct methods using the program SHELXS-97 [39]. All non-hydrogen atoms were refined anisotropically [39] by full-matrix least-squares procedures with the weight $w = 1/[\sigma^2(F_o^2) + (0.2000P)^2]$, where $P = (F_o^2 + 2F_c^2)/3$. All hydrogen atoms were fixed geometrically and allowed to ride along with the corresponding non-hydrogen atoms during the refinement. The crystal data and structure refinement details for ligand L are given in Table 1, whereas selected bond lengths and angles are listed in Table 2.

2.2. Materials and safety note

Formaldehyde solution, *N*-methyl piperazine and *p*-hydroxybenzaldehyde were purchased from Qualigens and used as such. Methanol, acetonitrile and dimethyl formamide were purchased from Qualigens and distilled before usage. TBAP, used as the supporting electrolyte in electrochemical measurements, was purchased from Fluka and recrystallised from hot methanol. (*Caution!* TBAP is potentially explosive; hence care should be taken in handling the compound). All other chemicals and solvents were of analytical grade and were used as received without any further purification.

2.3. Synthesis of the ligand, 2,6-bis[(N-methyl piperazine-1-yl)methyl]-4-formyl phenol (L)

The ligand (L) was synthesized by taking *p*-hydroxybenzaldehyde (4.27 g, 0.035 mol) in methanol (100 ml) mixed with *N*-methyl piperazine (7.76 ml, 0.07 mol) and the solution was refluxed for 1 h. Then formaldehyde solution (37%) (5.28 ml, 0.07 mol) was added slowly with stirring and the resulting solution was kept at this temperature for 24 h. Two 5 ml portions of formaldehyde were added at approximately 8 h intervals. After that time, methanol was evaporated under vacuum and the resulting oil was extracted with chloroform and recrystallised with diethylether (Scheme 1). A colourless compound was obtained. Yield: 8.1 g (67%), m.p.: 96 °C. Mass (EI) *m*/*z*: 346.47. *Anal.* Calc. for $C_{19}H_{30}N_4O_2$: C, 65.87; H, 8.73; N, 16.17. Found: C, 65.97; H, 8.62; N, 16.29%. Selected IR data (KBr disc, ν/cm^{-1}): 1680 (C=O) s, 3398 (OH) br, 1456 (N–CH_3) br. ^1H NMR (δ ppm in $CDCl_3$) ~2.22 (s, 6H, N–CH_3), ~2.45 (broad S, 16H, methylene protons), ~3.64 (s, 4H, benzylic protons), ~7.3 (s, 2H, Ar–H), 9.8 (s, 1H, –CHO proton). UV–Vis [λ_{max} (nm) (ε, $M^{-1}\,cm^{-1}$)] in MeOH: 286 (21 900).



Scheme 1.

2.4. Synthesis of the mononuclear complexes

2.4.1. Synthesis of the [CuL(OAc)] · H_2O complex

To a 40 ml methanol solution of the ligand (L) (1.039 g, 0.003 mol) was added $Cu(OAc)_2 \cdot H_2O$ (0.598 g, 0.003 mol) dissolved in 20 ml of methanol, and the resulting solution was refluxed for 4 h. After the reaction was over, the solution was filtered when hot and allowed to stand at room temperature. After slow evaporation of the solvent at 25 °C, a dark green compound was obtained. The compound was recrystallised from acetonitrile. Yield: 1.32 g (75%). *Anal.* Calc. for $[C_{21}H_{32}N_4O_4Cu] \cdot H_2O$: C, 51.89; H, 7.05; N, 11.53; Cu, 13.07. Found: C, 51.81; H, 7.12; N, 11.47; Cu, 13.13%. Selected IR data (KBr disc, ν/cm^{-1}): 3449, 1680, 1450, 1103, 651. UV–Vis [λ_{max} (nm) (ε, $M^{-1}\,cm^{-1}$)] in MeOH: 590 (125), 352 (17 200), 288 (23 500), $g_{\|} = 2.21$, $g_{\perp} = 2.09$ and $A_{\|} = 180$. $\mu_{eff} = 1.72$ BM.

2.4.2. Synthesis of the [NiL(OAc)] · H_2O complex

The Ni(II) complex was prepared by following the above procedure using the ligand (L) (1.039 g, 0.003 mol)

and $Ni(OAc)_2 \cdot 4H_2O$ (0.746 g, 0.003 mol). A light green compound was obtained on recrystallisation from acetonitrile. Yield: 1.38 g (79%). *Anal.* Calc. for $[C_{21}H_{32}N_4O_4Ni] \cdot H_2O$: C, 52.41; H, 7.12; N, 11.64; Ni, 12.20, Found: C, 52.44; H, 7.06; N, 11.67; Ni, 12.16%. Selected IR data (KBr disc, ν/cm^{-1}): 3451, 1680, 1453, 1106, 653. UV–Vis [λ_{max} (nm) (ε, $M^{-1}\,cm^{-1}$)] in MeOH: 574 (143), 356 (16100), 289 (21700).

2.4.3. Synthesis of the $[ZnL(OAc)(H_2O)_2]$ complex

The Zn(II) complex was prepared by following the above procedure using the ligand (L) (1.039 g, 0.003 mol) and $Zn(OAc)_2 \cdot 2H_2O$ (0.658 g, 0.003 mol). A colourless compound was obtained on recrystallisation from acetonitrile. Yield: 1.25 g (71%). *Anal.* Calc. for $[C_{21}H_{32}N_4O_4Zn(H_2O)_2]$: C, 49.85; H, 7.17; N, 11.07; Zn, 12.92. Found: C, 49.81; H, 7.21; N, 11.15; Zn, 12.83%. Selected IR data (KBr disc, ν/cm^{-1}): 3451, 1680, 1455, 1108, 649. UV–Vis [λ_{max} (nm) (ε, $M^{-1}\,cm^{-1}$)] in MeOH: 286 (21600).

2.5. Synthesis of the binuclear complexes

2.5.1. Synthesis of the $[Cu_2L(OAc)_2](ClO_4) \cdot 2H_2O$ complex

A solution of the ligand (L) (0.693 g, 0.002 mol) in MeOH (40 ml) was added to $Cu(OAc)_2 \cdot H_2O$ (0.798 g, 0.004 mol) in MeOH (20 ml), and the resulting solution was refluxed for 7 h. The mixture was then reacted with one equivalent of $NaClO_4$ dissolved in 10 ml of methanol and refluxed for a further hour. A dark green precipitate was collected on evaporation of the resulting solution to half the volume and then cooling by standing at room temperature (25 °C). A dark green coloured compound was obtained on recrystallisation from acetonitrile. Yield: 1.13 g (78%). *Anal.* Calc. for $[C_{23}H_{35}N_4O_6Cu_2](ClO_4) \cdot 2H_2O$: C, 38.04; H, 5.41; N, 7.72; Cu, 17.50. Found: C, 38.09; H, 5.36; N, 7.62, Cu; 17.38%. Selected IR data (KBr disc, ν/cm^{-1}): 3447, 1680, 1485, 1105, 654. Conductance ($\Lambda_m/S\,cm^2\,mol^{-1}$) in DMF 84. UV–Vis [$\lambda_{max}$ (nm) (ε, $M^{-1}\,cm^{-1}$)] in MeOH: 662 (118), 358 (15800), 284 (24600). $g = 2.1$. $\mu_{eff} = 1.58$ BM.

2.5.2. Synthesis of the $[Ni_2L(OAc)_2(H_2O)_2]ClO_4$ complex

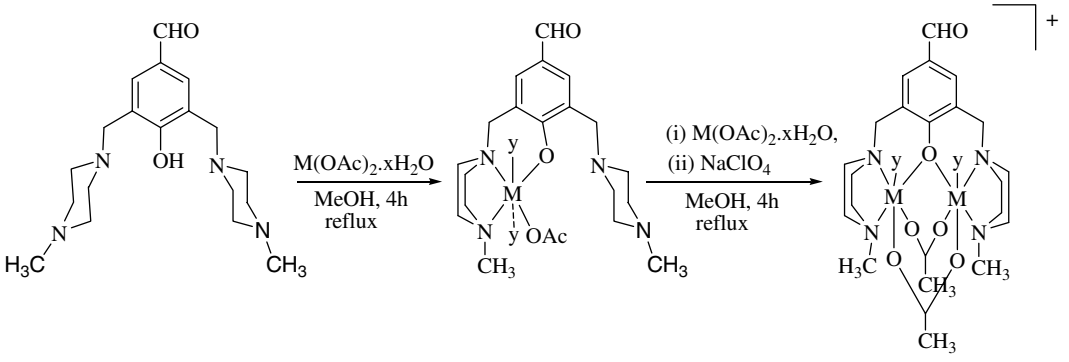
The Ni(II) complex was prepared by following the above procedure by using the ligand (L) (0.693 g, 0.002 mol) and $Ni(OAc)_2 \cdot 4H_2O$ (0.995 g, 0.004 mol). A light green compound was obtained on recrystallisation from acetonitrile. Yield: 1.04 g (73%). *Anal.* Calc. for $[C_{23}H_{35}N_4O_6Ni_2(H_2O)_2](ClO_4)$: C, 38.56; H, 5.49; N, 7.82; Ni, 16.38. Found: C, 38.43; H, 5.38; N, 7.97; Ni, 16.33%. Selected IR data (KBr disc, ν/cm^{-1}): 3449, 1680, 1467, 1104, 653. Conductance ($\Lambda_m/S\,cm^2\,mol^{-1}$) in DMF 89. UV–Vis [$\lambda_{max}$ (nm) (ε, $M^{-1}\,cm^{-1}$)] in MeOH: 800 (105), 618 (140), 561 (225), 363 (16700), 286 (23100).

2.5.3. Synthesis of the $[Zn_2L(OAc)_2(H_2O)_2]ClO_4$ complex

The Zn(II) complex was prepared by following the above procedure using the ligand (L) (0.693 g, 0.002 mol) and $Zn(OAc)_2 \cdot 2H_2O$ (0.878 g, 0.004 mol). A colourless compound was obtained on recrystallisation from acetonitrile. Yield: 1.02 g (70%). *Anal.* Calc. for $[C_{23}H_{35}N_4O_6Zn_2(H_2O)_2](ClO_4)$: C, 36.07; H, 5.66; N, 7.31; Zn, 17.08. Found: C, 36.18; H, 5.54; N, 7.42; Zn, 17.05%. Selected IR data (KBr disc, ν/cm^{-1}): 3451, 1680, 1475, 1108, 652. Conductance ($\Lambda_m/S\,cm^2\,mol^{-1}$) in DMF 81. UV–Vis [$\lambda_{max}$ (nm) (ε, $M^{-1}\,cm^{-1}$)] in MeOH: 286 (22500).

3. Results and discussion

A new end-off type ligand has been synthesized by the usual procedure of the Mannich reaction (Scheme 1) and characterized. Using this end-off ligand, mono and binuclear Cu(II), Ni(II) and Zn(II) complexes were prepared as shown in Scheme 2. The complexes were characterized by spectral studies. Their magnetic, electrochemical and catalytic behaviors are discussed.



Complexes	M	x	y
1	Cu	1	-
2	Ni	4	-
3	Zn	2	H_2O

Scheme 2.

3.1. The structure of ligand (L)

Crystals of the ligand L of X-ray quality were obtained from 1% perchloric acid in methanol by slow evaporation at room temperature. The ORTEP diagram of the ligand is shown in Fig. 1. The average C_{sp^2}–C_{sp^2} [1.395(2) Å] in the phenyl ring and C_{sp^3}–N [1.481(2) Å] bond distances are comparable with the corresponding values reported by Allen et al., in 1987 [40] [1.397(9) Å and 1.499(18) Å]. The piperazine rings adopt a chair conformation, which is confirmed by puckering parameters [41] and asymmetry parameters [42] [$Q_T = 0.579(8)$ and $\theta = 179.1(7)°$]. The mirror and twofold symmetry pass through N1 ($\Delta C_s = 0.006(4)$), C9 ($\Delta C_s = 0.002(4)$) and C10 ($\Delta C_s = 0.007(4)$) atoms and N1–C12 ($\Delta C_s = 0.006(3)$), C9–N1 ($\Delta C_2 = 0.004(3)$) and C10–C9 ($\Delta C_2 = 0.004(3)$) bonds, respectively. N–H···O, O–H···O and C–H···O hydrogen bonds stabilize the crystal packing. The O8 atom of the perchlorate is involved in C–H···O hydrogen bonds [H11A···$O8^i$ = 2.53 Å; C11···$O8^i$ = 3.380(1) Å and C11–H11A···$O8^i$ = 134°; i = −1 + *x*, *y*, *z*] and the O9 atom is involved in bifurcated hydrogen bonds C14–H14A···O9···H15B–C15 = 42.7(1)°. Neighboring molecules linked through N–H···O hydrogen bonds run along the '*ac*' plane, stabilizing the unit cell packing.

3.2. Spectral studies

The IR spectrum of the ligand shows a broad band at 3398 cm^{-1} due to the presence of the phenolic OH group. A sharp band at 1680 cm^{-1} shows the presence of an aromatic aldehyde in the ligand and the fact it remains unchanged in all the complexes indicates that the aromatic aldehyde group does not change on complexation. The absence of a peak around 3398 cm^{-1} in all the complexes indicates the absence of ν(OH) due to deprotonation followed by complexation [43a]. The strong $\nu(CO_2)$ bands at around 1450 cm^{-1} in the mononuclear complexes indicates the presence of an acetate linkage. The biacetato bridged binuclear complexes showed strong $\nu(CO_2)$ bands at 1460–1490 cm^{-1} [43b]. A broad band in the region around 3450 cm^{-1} indicates the presence of ν(OH) of water molecules for all the complexes. The presence of uncoordinated perchlorate anions in all complexes **1**–**6** are inferred from a single broad band around 1100 cm^{-1} (ν_3-antisymmetric stretching), which is not split, and a band around 650 cm^{-1} (ν_4-antisymmetric bending). The band around 930 cm^{-1} (ν_2-symmetric stretching) due to coordinated perchlorate is not observed and this vividly indicates that no perchlorate ions are coordinated in the complexes [44,45].

The electronic spectra of the mono and binuclear Cu(II) complexes and the mononuclear Ni(II) complex exhibit three main transitions. The moderately intense peak observed in the range 280–300 nm is probably due to an intra-ligand charge transfer transition [46]. A peak or shoulder in the range 350–365 nm is due to phenolato to copper(II) charge transfer transitions [47]. The mononuclear Cu(II) complex shows a λ_{max} at 590 nm due to a d–d transition, which is characteristic of a square planar geometry, and the d–d transition for the binuclear Cu(II) complex, observed at 662 nm, is indicative of a distorted square-pyramidal geometry [37,48]. The binuclear

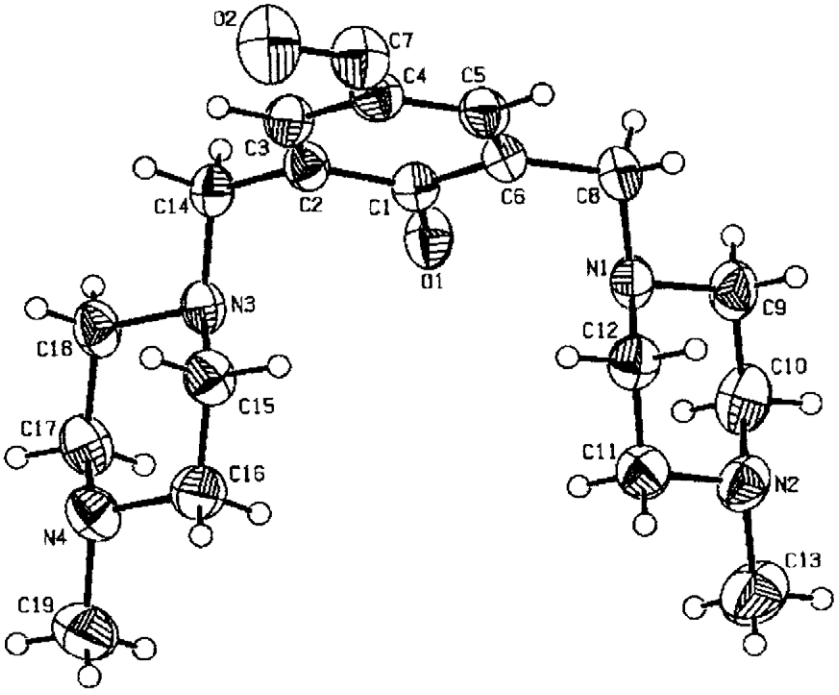

Fig. 1. ORTEP diagram of the ligand L with atom labels and numbering scheme (perchlorate and water molecules are omitted for clarity). The probability level for the ORTEP plot is 35%.

copper(II) complexes with exogenous diacetato bridges suggest that the endogenous bridging phenolate oxygen adopts the more strained pyramidal geometry. The bridging acetate groups in binuclear complexes present in a semi-bridging mode is primarily the result of the overall steric strain induced by the ligand, perhaps combined with the presence of two bridging acetate groups rather than one [37]. The mononuclear Ni(II) complex shows a single weak d–d band observed at 574 nm due to an $^1A_{1g} \rightarrow {}^1A_{2g}$ transition and this indicates that the complex has a square planar geometry [49,50]. The binuclear Ni(II) complex shows three d–d transitions at 800 nm, 618 nm and 561 nm assigned to $^3A_{2g} \rightarrow {}^3T_{2g}$, $^3A_{2g} \rightarrow {}^3T_{1g}$, $^3A_{2g} \rightarrow {}^3T_{1g}(P)$ spin allowed electronic transitions, which are characteristic of Ni^{2+} in an octahedral site [51,52]. The mono and binuclear Zn(II) complexes display only ligand centered charge transfer transitions in the UV region [53].

3.3. ESR spectra

The solid state ESR spectra of the copper(II) complexes were recorded at room temperature in the X-band region. The ESR spectra of the mononuclear complex $[CuL(OAc)]\cdot H_2O$ and the binuclear complex $[Cu_2L(OAc)_2]ClO_4\cdot 2H_2O$ are shown in Fig. 2. The ESR spectra of the mononuclear copper (II) complex shows four lines [54] with nuclear hyperfine spin 3/2 due to hyperfine splitting. The observed $g_{\|}$ value is 2.21, $g_{\perp} = 2.09$ and $A_{\|}$ is 180. A broad [55] spectrum with no hyperfine splitting was obtained for the dicopper complex with $g = 2.1$, indicating the presence of an anti-ferromagnetic interaction between the two copper ions. Owing to the favorable relative orientation of the magnetic orbitals and in spite of the Cu–Cu separation, an anti-ferromagnetic interaction is observed.

3.4. Magnetic studies

The magnetic moment values of the mono and binuclear complexes were calculated at room temperature. The magnetic moment value for the mononuclear copper(II) complex $[CuL(OAc)]\cdot H_2O$ is 1.72 BM, which is very close to that of the spin only value (1.73 BM) expected for complexes having one copper(II) ion [56] with a single unpaired electron sited in an essentially $d_{x^2-y^2}$ orbital. The value of the magnetic moment observed at room temperature for the binuclear copper (II) complex $[Cu_2L(OAc)_2]ClO_4\cdot 2H_2O$ is 1.58 BM. This confirms the presence of an anti-ferromagnetic interaction between the two copper(II) ions [57]. To evaluate the singlet–triplet energy separation ($-2J$), a variable-temperature magnetic study of the binuclear copper complex (Fig. 3) was carried out in the temperature range 77–300 K and the experimental magnetic susceptibility values were fitted to the modified Bleaney–Bowers equation [58]

$$\chi_m = (Ng^2\beta^2/3kT)[3 + \exp(-2J/kT)]^{-1}(1 - P) + (0.45P/T) + N_\alpha,$$

where χ_m is the paramagnetic susceptibility per metal atom after the correction for diamagnetism, N is Avogadro's number, β is the Boltzmann constant, g is the average gyromagnetic ratio and P is the fraction of monomeric copper(II) impurities. $-2J$ is the singlet–triplet energy separation, N_α is the temperature independent fraction, usually assumed to be 120×10^{-6} cgs units for copper (II) compounds. The value of the exchange integral $-2J$ for the binuclear copper complex is 134 cm^{-1}, indicative of weak antiferromagnetic coupling between the copper (II) ions. With few exceptions, magneto-structural correlations [59] for several phenoxo bridged dicopper complexes show that the major factor controlling the exchange interactions is the Cu–O–Cu bridge angle, however, other factors such as degree of distortion from planarity [60] and the dihedral angle [61] between the two copper planes also have an influence on the extent of the spin–spin interaction.

The position of the maximum in χ_{Cu} for the bis(μ-acetato) complex occurs at much lower temperatures because of weak exchange coupling. The acetate groups in the binuclear copper complex may connect the basal plane ($d_{x^2-y^2}$)

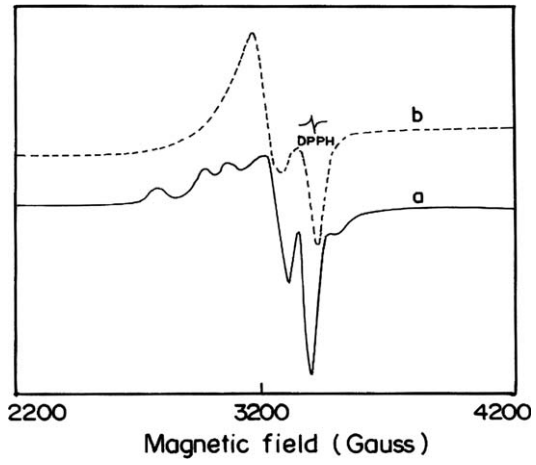

Fig. 2. ESR spectra of mononuclear: (a) $[CuL(OAc)]\cdot H_2O$ (**1**) and binuclear: (b) $[Cu_2L(OAc)_2]ClO_4\cdot 2H_2O$ (**4**) complexes.

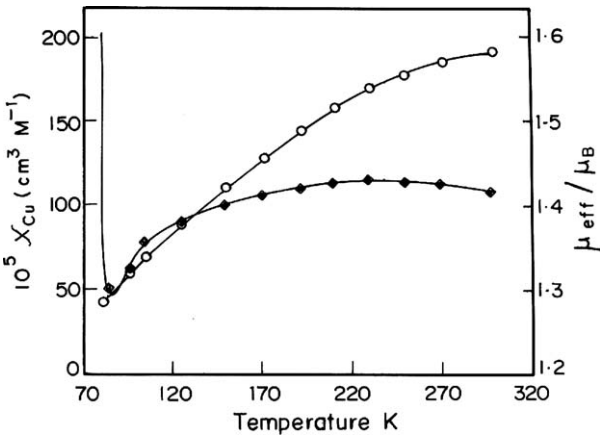

Fig. 3. Temperature-dependence magnetic properties for complex $[Cu_2L(OAc)_2]ClO_4\cdot 2H_2O$, where ○ is μ_{eff}/μ_B, ◆ is χ.

positions on one Cu with the apical (d_{z^2}) positions on the other, which will lead to a low overall J value, probably because of J_{ferro} contributions from these pathways [37]. Any contributions from the counter complementary effects of phenolate versus acetate bridging orbitals, proposed by Reed et al. [62] and Nishida and Kida [63], will be small in the complex because of the relative disposition of the Cu ($d_{x^2-y^2}$) orbitals. The mononuclear Ni(II) complex has a square planar geometry and is diamagnetic [56]. The binuclear Ni(II) complex has a magnetic moment value of 2.98 BM, characteristic of Ni^{2+} in an octahedral site [52,64].

3.5. Electrochemistry

3.5.1. Reduction process at negative potential

Conductivity measurements for the binuclear complexes were carried out in DMF, which showed conductance values in the range 80–90 (Λ_m/S cm^2 mol^{-1}), indicating that they are of 1:1 electrolyte type [65]. The electrochemical properties of the complexes were studied by cyclic voltammetry in the potential range 0 to −1.7 V in DMF, containing 0.1 M TBAP as the supporting electrolyte, and the data are summarized in Table 3. The electronegativity and hard nature of the phenoxide ligands influence the electrochemical properties of the complexes [66–68]. In general, this type of end-off complexes shows irreversible reduction waves in the cathodic potential region [37]. The cyclic voltammograms for mono and binuclear nickel(II) and zinc(II) complexes are depicted in Figs. 4 and 5, respectively. Cyclic voltammograms with different scan rates show no corresponding anodic peak in the cathodic direction, which indicates the electrode process is irreversible in nature. The mononuclear copper(II), nickel(II) and zinc(II) complexes **1**–**3** show an irreversible one-electron transfer reduction in the cathodic region. The binuclear copper(II), nickel(II) and zinc(II) complexes **4**–**6** show two-step irreversible one-electron transfer reductions. Controlled potential electrolysis was also carried out for the complexes at 100 mV s^{-1} more negative to the cathodic peak, consuming one electron per molecule ($n = 0.95$), which reports that each wave corresponds to a one-electron transfer process. So the two reduction processes are assigned generally as follows:

Table 3
Electrochemical data[a] for the complexes (reduction at cathodic potential)

Number	Complexes	E^1_{pc} (V)	E^2_{pc} (V)
1	$[CuL(OAc)]\cdot H_2O$	−0.74	
2	$[NiL(OAc)]\cdot H_2O$	−0.83	
3	$[ZnL(OAc)(H_2O)_2]$	−0.84	
4	$[Cu_2L(OAc)_2](ClO_4)\cdot 2H_2O$	−0.76	−1.21
5	$[Ni_2L(OAc)_2(H_2O)_2](ClO_4)$	−0.73	−1.35
6	$[Zn_2L(OAc)_2(H_2O)_2](ClO_4)$	−0.74	−1.61

[a] Measured by CV at 50 mV/s. E vs. Ag/AgCl conditions: GC working and Ag/AgCl reference electrodes; supporting electrolyte TBAP; concentration of complex 1×10^{-3} M, concentration of TBAP 1×10^{-1} M.

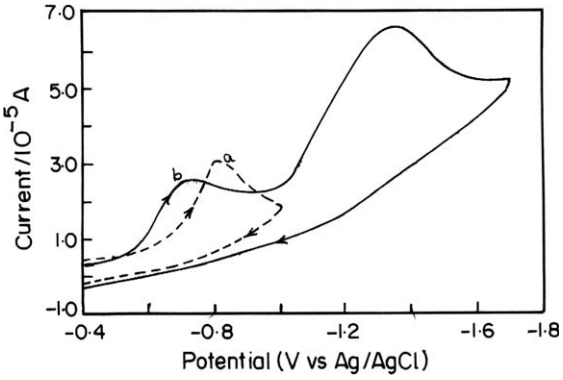

Fig. 4. Cyclic voltammograms of the mono and binuclear nickel(II) complexes: (a) $[NiL(OAc)]\cdot H_2O$ (**2**); (b) $[Ni_2L(OAc)_2(H_2O)_2]ClO_4$ (**5**) (reduction process).

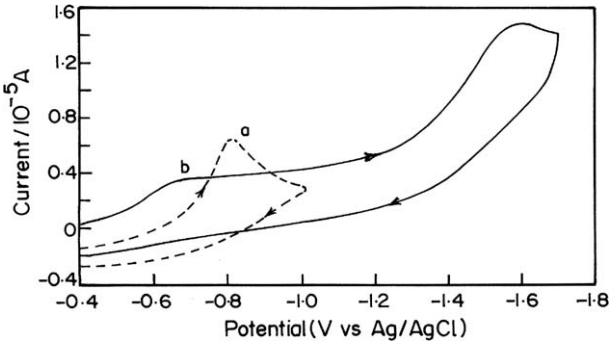

Fig. 5. Cyclic voltammograms of the mono and binuclear zinc(II) complexes: (a) $[ZnL(OAc)(H_2O)_2]$ (**3**); (b) $[Zn_2L(OAc)_2(H_2O)_2](ClO_4)$ (**6**) (reduction process).

$$M^{II}M^{II} \rightarrow M^{II}M^{I} \rightarrow M^{I}M^{I}.$$

3.5.2. Oxidation process at anodic potential

The cyclic voltammogram of the nickel(II) complexes **2** and **4** in the anodic potential region is given in Fig. 6. The mononuclear Ni(II) complex shows an irreversible oxidation wave in the positive potential at +0.76 V. The binuclear Ni(II) complex shows a two-step one-electron transfer processes in the potential range +0.82 V and +1.40 V and both are found to be irreversible in nature. The two oxidation processes are assigned generally as follows:

$$M^{II}M^{II} \rightarrow M^{III}M^{II} \rightarrow M^{III}M^{III}.$$

3.6. Kinetic studies

3.6.1. Oxidation of pyrocatechol (catecholase activity)

Measurement of the catecholase activity of both mono and binuclear copper(II) complexes synthesized in the present work was carried out using pyrocatechol as the convenient model substrate for the identification of functional models for the metalloenzymes [25,26]. For this purpose,

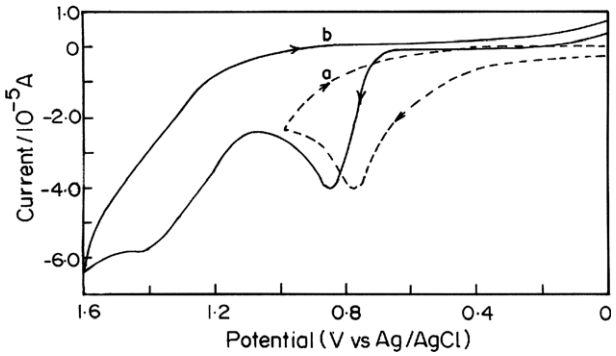

Fig. 6. Cyclic voltammograms of the mono and binuclear nickel(II) complexes: (a) $[NiL(OAc)]\cdot H_2O$ (**2**); (b) $[Ni_2L(OAc)_2(H_2O)_2](ClO_4)$ (**5**) (oxidation process).

10^{-3} mol dm^{-3} solutions of the complexes in dimethylformamide were treated with 100 equivalents of pyrocatechol in the presence of air. The course of the reaction was followed spectrophotometrically at 390 nm for nearly 45 min at regular time intervals of 5 min. The slope was determined by the method of initial rates by monitoring the growth of the 390 nm band of the product *o*-quinone. A linear relationship for initial rate and the complex concentration obtained for both the copper(II) complexes shows a first-order dependence on the complex concentration for the systems.

Plots of $\log(A_\infty/A_\alpha - A_t)$ versus time for catecholase activity of the mono and binuclear complexes are obtained and shown in Fig. 7. The observed initial rate constant value for the mononuclear and binuclear copper(II) complexes is given in Table 4. It is found that the binuclear copper(II) complex show higher reactivity than its mononuclear complex. This is due to the fact that the oxidation of pyrocatechol to *o*-quinone requires two metal ions in close proximity [27]; hence the rate constant for the binuclear copper complex is high.

Table 4
Hydrolysis of 4-nitrophenylphosphate[a] and catecholase activity[a]

Number	Complexes	Rate constant, k ($\times 10^{-3}$ min^{-1})	
		NPP	Catecholase
1	$[CuL(OAc)]\cdot H_2O$	4.60	6.40
2	$[NiL(OAc)]\cdot H_2O$	4.90	
3	$[ZnL(OAc)(H_2O)_2]$	4.30	
4	$[Cu_2L(OAc)_2](ClO_4)\cdot 2H_2O$	11.10	12.80
5	$[Ni_2L(OAc)_2(H_2O)_2](ClO_4)$	12.5	
6	$[Zn_2L(OAc)_2(H_2O)_2](ClO_4)$	9.60	

[a] Measured spectrophotometrically in DMF. Concentration of the complexes: 1×10^{-3} M; concentration of 4-nitrophenylphosphate: 1×10^{-1} M; concentration of pyrocatechol: 1×10^{-1} M.

3.6.2. Kinetic studies of hydrolysis of 4-nitrophenylphosphate

The catalytic activity of the mono and binuclear copper(II), nickel(II) and zinc(II) complexes on the hydrolysis of 4-nitrophenylphosphate was determined spectrophotometrically by monitoring the increase of the 4-nitrophenolate anion characteristic absorption at 420 nm over the time in DMF at 25 °C. For this purpose, 10^{-3} mol dm^{-3} solutions of the complexes in dimethylformamide and a 2.5×10^{-3} M solution of tetramethylammonium hydroxide were treated with 100 equivalents of nitrophenylphosphate in the presence of air.

The course of the reaction was followed at 420 nm for nearly 45 min at regular time intervals. The slope was determined by the method of initial rates by monitoring the growth of the 420 nm band of the product, the 4-nitrophenolate anion. A linear relationship for all the complexes shows a first-order dependence on the complex concentration for the systems. Plots of $\log(A_\infty/A_\alpha - A_t)$ versus time for the hydrolysis of 4-nitro phenyl phosphate activity of the complexes are obtained and shown in Fig. 8. The observed initial rate constant value for the mononuclear and binuclear copper(II) complexes is given in Table 4. It

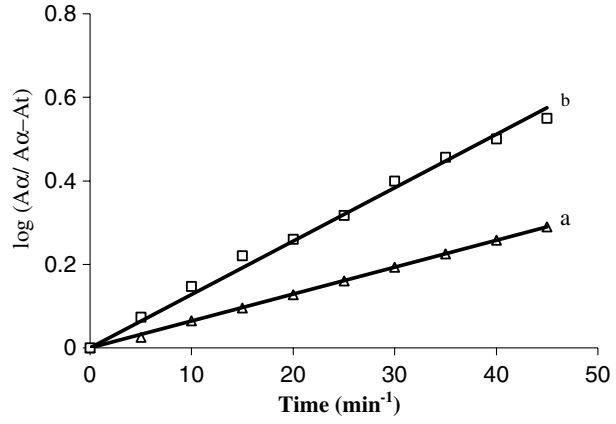

Fig. 7. Catecholase activity of the copper (II) complexes: (a) $[CuL(OAc)]\cdot H_2O$ (**1**); (b) $[Cu_2L(OAc)_2](ClO_4)\cdot 2H_2O$ (**4**).

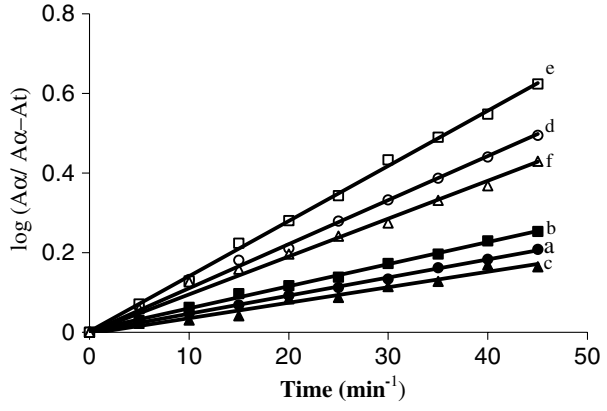

Fig. 8. Hydrolysis of 4-nitrophenylphosphate by copper(II), nickel(II) and zinc(II) complexes. (a) $[CuL(OAc)]\cdot H_2O$ (**1**); (b) $[NiL(OAc)]\cdot H_2O$ (**2**); (c) $[ZnL(OAc)(H_2O)_2]$ (**3**); (d) $[Cu_2L(OAc)_2](ClO_4)\cdot 2H_2O$ (**4**); (e) $[Ni_2L(OAc)_2(H_2O)_2](ClO_4)$ (**5**); and (f) $[Zn_2L(OAc)_2(H_2O)_2](ClO_4)$ (**6**).

is found that the binuclear complexes show higher reactivity than their corresponding mononuclear complexes due to the fact that this kind of mechanism requires two metal ions in close proximity. The mechanism of action has already been explained with the help of model complexes [69,70].

On the comparison of the hydrolysis of 4-nitrophenylphosphate by the copper(II), nickel(II) and zinc(II) complexes, the nickel(II) complexes have a higher rate constant value than the copper(II) and zinc(II) complexes. It is similar to the result of higher catalytic activity of the Ni(II)(tren) complex than the copper(II)(tren) and zinc(II)(tren) complexes reported by De Rosch and Trogler [32]. From the results, it is found that the catalytic activity of copper(II) complexes towards oxidation of pyrocatechol is more than that of the phosphate hydrolysis.

4. Supplementary material

Full crystal data and structure refinement details for ligand L have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 272757. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44 1223 336 033; e-mail: deposit@ccdc.cam.ac.uk or www.ccdc.cam.ac.uk).

energy transfer from the resulting ligand-based triplet state [2i,3]. This is the usual basis for achieving sensitized emission from Eu(III) and Tb(III) [2]. Recently there have been intense efforts directed at attaching chromophores with relatively long wavelength absorption maxima (in the visible region), e.g., suitably functionalized organic dyes that have particularly low-energy π–π transitions [4] or d-metal complexes that have very strong charge-transfer absorptions at a range of wavelengths that span the visible region [5], to near-IR-emissive Ln^{III} ions, such as Yb(III), Nd(III), Pr(III) and Er(III).

The chances of identifying new 4f-metal complexes with interesting photophysical properties will benefit from the development of new reaction systems with suitable organic ligands. With this in mind we have started a systematic study of the coordination properties of complexing agents capable of efficiently sensitizing Eu(III) and Tb(III) emission. Our ligand design will employ simple units, based on strong binding sites for Ln^{III} coordination and bulky aromatic groups, to play the dual role of antenna and solvent shield, and to thus form – if possible – a hydrophobic shell around the metal ion. It should be mentioned at this point that species containing high-energy oscillators, such as C–H and O–H bonds (typically found in the ligand, coordinated solvent and moisture), are able to quench the metal excited states non-radiatively, leading to decreased luminescence intensities and shorter excited-state lifetimes [6]. In the ligands we plan to use, the binding and antenna domains may be or may not be independent of each other; in the former case this will allow the sensitizing group to be energetically optimized for a particular Ln^{III} ion without changing the binding characteristics of the ligand [2a].

In this paper, we describe our initial studies in this area based on the ligand di-2-pyridyl ketone, $(py)_2CO$ (Fig. 1). Our groups [7,8] and others [9] have been exploring reaction systems involving Mn, Fe, Co, Ni, Cu and Zn ions, and either (i) the monoanion, $(py)_2C(OH)O^-$, or the dianion, $(py)_2CO_2^{2-}$, of the *gem*-diol form (derivative), $(py)_2C(OH)_2$, of di-2-pyridyl ketone, $(py)_2CO$, or (ii) the monoanion, $(py)_2C(OR)O^-$ (R = Me, Et, etc.) of the hemiacetal form (derivative), $(py)_2C(OR)(OH)$, of di-2-pyridyl ketone. The formulae of these ligands and their abbreviations are shown in Fig. 1. The general goal of these efforts is the isolation of polynuclear complexes with interesting magnetic and optical properties. There is a chemical characteristic of $(py)_2CO$ that makes this molecule special as ligand; this is its carbonyl group. Water and alcohols (ROH) have been shown to add to the carbonyl group *upon coordination of the carbonyl oxygen and/or the 2-pyridyl rings* forming the ligands $(py)_2C(OH)_2$ (the *gem*-diol form of $(py)_2CO$) and $(py)_2C(OR)(OH)$ (the hemiacetal form of $(py)_2CO$), respectively [7]. Interesting coordination modes are seen when the ligands $(py)_2C(OH)_2$ and $(py)_2C(OR)(OH)$ are deprotonated. The presence of deprotonated hydroxyl group(s) leads to a great coordinative flexibility, due to the well known ability of the negatively charged oxygen atom to bridge two or three (μ_3) metal ions, while the dianionic form can bridge as many as five metal sites (μ_5). The immense structural diversity displayed by the 3d-metal complexes reported stems in part from the ability of $(py)_2C(OH)O^-$, $(py)_2CO_2^{2-}$ and $(py)_2C(OR)O^-$ to exhibit no less than ten distinct bridging coordination modes [7].Employment of carboxylates, β-diketonates or inorganic anions (NO_3^-, SO_4^{2-}, N_3^-, $N(CN)_2^-$, etc.) as ancillary ligands in the reaction mixtures gives an extraordinary structural flexibility in the mixed-ligand systems, allowing the preparation of a variety of 3d-metal clusters with nuclearities ranging from 3 to 26 [7], and with interesting physical properties including single-molecule magnetism [8d].

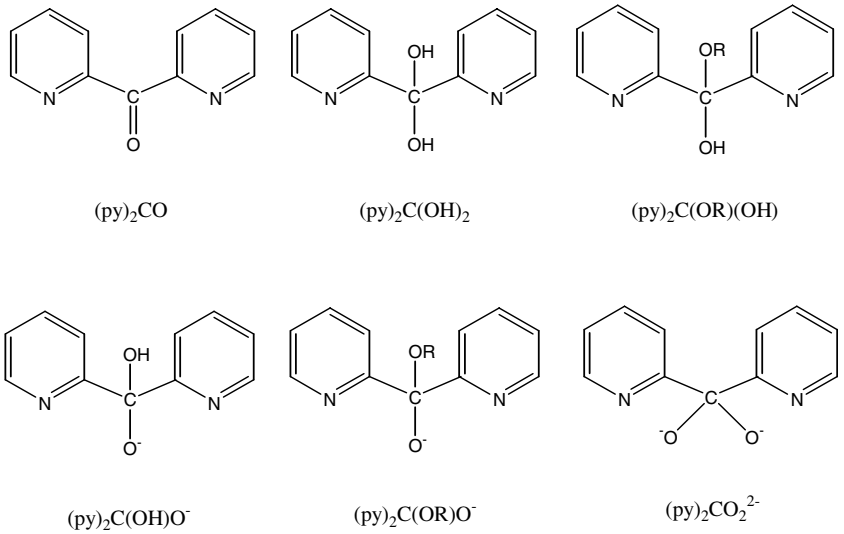

Fig. 1. The formulae of the ligands discussed in the text; note that $(py)_2C(OH)_2$, $(py)_2C(OR)(OH)$ and all four anions do not exist as free species but exist only in their respective metal complexes (R = Me, Et, etc.).

Surprisingly, however, $(py)_2CO$-based ligands have been practically ignored in 4f-metal chemistry. We have recently extended the reactions of $(py)_2CO$ in lanthanide(III) chemistry and investigated the $Er^{III}/SCN^-/(py)_2CO$ reaction mixtures in alcohols (MeOH, EtOH). Depending on the OH^- concentration in the reaction system, we were able to isolate and structurally characterize complexes $[Er(NCS)_3\{(py)_2C(OR)(OH)\}_3]$ and $[Er_2(NCS)_3\{(py)_2C(OMe)O\}_3(MeOH)]$ [10a]. We suspected that there might be a number of other Ln_x^{III} species accessible and have therefore been investigating the reactions of $(py)_2CO$ with lanthanide(III) nitrates under a variety of conditions; the products of these reactions are the subject of this report. It should be mentioned at this point that lanthanide(III) nitrate complexes of the somewhat similar ligand methyl-2-pyridyl ketone benzoyl hydrazone have been recently prepared [10b]; tentative structures for the complexes were proposed based on spectroscopic techniques.

2. Experimental

2.1. General and physical measurements

All manipulations were performed under aerobic conditions using materials (reagent grade) and solvents as received. Hydrated lanthanide(III) nitrates were purchased from Alfa Aesar.

Microanalyses (C, H, N) were performed by the University of Ioannina (Greece) Microanalytical Laboratory using an EA 1108 Carlo Erba analyzer. The metal content was determined volumetrically with ethylenediaminetetra-acetate using Xylenol Orange as indicator. IR spectra (4000–400 cm^{-1}) were recorded on a Perkin–Elmer 16 PC FT-spectrometer with samples prepared as KBr pellets; the spectra were also recorded as Nujol and hexachlorobutadiene mulls between CsI discs. Magnetic susceptibilities were measured at room temperature using the Faraday method with a Cahn-Ventron RM-2 balance standardized with $HgCo(NCS)_4$; diamagnetic corrections were estimated from Pascal's constants. Solid-state (diffuse reflectance, DRS) spectra in the 200–800 nm range were recorded on a Varian Cary 3 spectrometer equipped with an integration sphere under high-resolution detection conditions. Powders of the samples were used. Luminescence was recorded using an Ocean Optics S-2000 diode array spectrophotometer. The excitation source was a pulsed N_2 laser (336 nm). Luminescence was collected with an optical fiber. The excitation spectra were recorded using a Cary Eclipse fluorescence spectrophotometer.

2.2. Compound preparation

2.2.1. $[Pr_2(NO_3)_3\{(py)_2C(OMe)O\}_2\{(py)_2C(OH)O\}]$ (**1**)

Solids $(py)_2CO$ (0.037 g, 0.20 mmol) and $LiOH \cdot H_2O$ (0.0084 g, 0.20 mmol) were dissolved in MeOH (3 ml) resulting in a colourless solution. This was added to a pale green solution of $Pr(NO_3)_3 \cdot 6H_2O$ (0.086 g, 0.20 mmol) in EtOH (5 ml). The resulting new pale green solution was stirred for about 1 h during which time a precipitate formed. The solid was collected by filtration, washed with cold MeOH (2×2 ml) and Et_2O (2×5 ml), and dried in vacuo over silica gel. Yield: 21% (based on the ligand). *Anal.* Calc. for $C_{35}H_{31}Pr_2N_9O_{15}$: C, 38.23; H, 2.85; N, 11.47; Pr, 25.63. Found: C, 37.99; H, 2.90; N, 11.62; Pr, 26.13%. IR (KBr pellet, cm^{-1}): 3410 mb, 2975 w, 2912 w, 1599 m, 1569 w, 1476 s, 1464 s, 1438 s, 1384 s, 1304 m, 1284 m, 1233 w, 1224 w, 1154 w, 1112 sh, 1104 m, 1075 s, 1049 m, 1035 sh, 1012 m, 815 m, 766 m, 748 sh, 683 m, 661 w, 633 m, 541 w, 432 sh, 417 m. μ_{eff} (BM) per Pr^{III}: 3.44 (22 °C). DRS (nm): 268, 280, 340, 449, 474, 485, 599.

2.2.2. $[Eu_2(NO_3)_3\{(py)_2C(OMe)O\}_2\{(py)_2C(OH)O\}]$ (**2**)

Using $Eu(NO_3)_3 \cdot 6H_2O$, slightly different solvent volumes (MeOH: 7 ml, EtOH: 2 ml) and following exactly the same procedure as that described for the corresponding praseodymium(III) complex, a white microcrystalline material was isolated. Yield: 25% (based on the ligand). *Anal.* Calc. for $C_{35}H_{31}Eu_2N_9O_{15}$: C, 37.48; H, 2.79; N, 11.24; Eu, 27.10. Found: C, 37.62; H, 2.69; N, 11.38; Eu, 26.31%. IR (KBr pellet, cm^{-1}): 3399 mb, 2980 w, 2942 w, 1600 m, 1568 w, 1482 s, 1465 s, 1439 m, 1384 s, 1308 m, 1266 sh, 1232 w, 1222 w, 1154 w, 1111 sh, 1105 m, 1078 s, 1051 m, 1036 sh, 1015 m, 815 m, 767 m, 749 sh, 684 m, 662 w, 634 m, 542 w, 433 w, 417 m. μ_{eff} (BM) per Eu^{III}: 3.40 (20 °C). DRS (nm): 265, 281, 338, 363, 397.

2.2.3. $[Tb_2(NO_3)_3\{(py)_2C(OMe)O\}_2\{(py)_2C(OH)O\}]$ (**3**)

Solids $(py)_2CO$ (0.037 g, 0.20 mmol) and $LiOH \cdot H_2O$ (0.0084 g, 0.20 mmol) were dissolved in MeOH (6 ml) resulting in a colourless solution. This was added to a pale pink solution of $Tb(NO_3)_3 \cdot 6H_2O$ (0.087 g, 0.19 mmol) in a solvent mixture comprising MeOH (3 ml) and EtOH (3 ml). No noticeable colour change occurred. The resulting solution was stirred for about 1 h and layered with a mixture of Et_2O and *n*-hexane (20 ml, 1:1 v/v). Slow mixing gave a white microcrystalline solid, which was collected by filtration, washed with cold MeOH (2×3 ml) and Et_2O (2×5 ml), and dried in vacuo over silica gel. Yield: 19% (based on the ligand). *Anal.* Calc. for $C_{35}H_{31}Tb_2N_9O_{15}$: C, 37.02; H, 2.76; N, 11.10; Tb, 27.99. Found: C, 37.18; H, 2.80; N, 11.01; Tb, 28.63%. IR (KBr pellet, cm^{-1}): 3400 mb, 2985 w, 2930 w, 1601 m, 1568 w, 1480 s, 1467 s, 1439 m, 1384 s, 1309 m, 1285 m, 1267 sh, 1233 sh, 1224 w, 1155 w, 1112 sh, 1106 m, 1079 s, 1051 m, 815 m, 1035 sh, 1015 m, 815 m, 767 m, 750 sh, 684 m, 665 w, 634 m, 543 w, 437 w, 420 m. μ_{eff} (BM) per Tb^{III}: 9.59 (25 °C). DRS (nm): 266, 282, ~330, 373, 492.

2.2.4. $[Er_2(NO_3)_3\{(py)_2C(OMe)O\}_2\{(py)_2C(OH)O\}]\cdot 0.8EtOH\cdot 0.4MeOH$ ($\mathbf{4}\cdot 0.8EtOH\cdot 0.4MeOH$)

Solids $(py)_2CO$ (0.037 g, 0.20 mmol) and $LiOH\cdot H_2O$ (0.0084 g, 0.20 mmol) were dissolved in MeOH (5 ml) resulting in a colourless solution. This was added to a pale pink solution of $Er(NO_3)_3\cdot 5H_2O$ (0.090 g, 0.20 mmol) in a solvent mixture comprising MeOH (2 ml) and EtOH (3 ml). The resulting new pinkish solution was stirred for about 90 min and stored at 5 °C. After 8 days, pale pink (almost colourless), X-ray quality prisms formed; they were collected by filtration, washed with cold MeOH (2×2 ml) and Et_2O (2×5 ml) and dried in vacuo over silica gel. Yield: 39% (based on the ligand). A sample for crystallography was kept in contact with the mother liquor to prevent interstitial solvent loss. The dried sample analysed as solvent-free. *Anal.* Calc. for $C_{35}H_{31}Er_2N_9O_{15}$: C, 36.48; H, 2.72; N, 10.94; Er, 29.03. Found: C, 36.70, H, 2.65; N, 11.13; Er, 30.00%. IR (KBr pellet, cm^{-1}): 3380 mb, 2983 w, 2935 w, 1602 m, 1570 m, 1506 s, 1475 sh, 1438 m, 1384 m, 1298 m, 1284 m, 1260 sh, 1226 m, 1156 m, 1116 m, 1084 m, 1050 m, 1016 sh, 814 m, 786 sh, 762 m, 684 m, 666 w, 636 m, 532 w, 454 m, 425 m. μ_{eff} (BM) per Er^{III}: 9.54 (20 °C). DRS (nm): 262, 277, ~330, 370 sh, 380, 492, 520, 524, 530 sh, 542, 652, 657.

2.3. Single-crystal X-ray crystallography

A crystal of $\mathbf{4}\cdot 0.8EtOH\cdot 0.4MeOH$ was mounted in capillary. Diffraction measurements were made on a Crystal Logic Dual Goniometer diffractometer using graphite-monochromated Mo radiation. Complete crystal data and parameters for data collection and processing are reported in Table 1. Unit cell dimensions were determined and refined by using the angular settings of 25 automatically centered reflections in the range $11 < 2\theta < 23°$. Three standard reflections monitored every 97 reflections showed less than 3% variation and no decay. Lorentz, polarization and Ψ-scan absorption corrections were applied using Crystal Logic software.

The structure was solved by direct methods using SHELXS-86 [11a] and refined by full-matrix least-squares techniques on F^2 with SHELXL-97 [11b]. All hydrogen atoms were introduced at calculated positions as riding on bonded atoms and were refined isotropically. All non-hydrogen atoms were refined using anisotropic thermal parameters, except of the solvent molecules, which were refined isotropically.

Table 1
Crystallographic data for complex $\mathbf{4}\cdot 0.8EtOH\cdot 0.4MeOH$

Formula	$C_{37}H_{37.4}Er_2N_9O_{16.2}$
Formula weight	1201.88
Crystal colour, habit	colourless, prism
Crystal dimensions (mm)	$0.04\times 0.12\times 0.40$

[a] $R_1 = \sum(|F_o| - |F_c|)/\sum(|F_o|)$.

[b] $wR_2 = \{\sum[w(F_o^2 - F_c^2)^2]/\sum[w(F_o^2)^2]\}^{1/2}$.

3. Results and discussion

3.1. Synthetic comments

The 1:1:1 reactions between $Ln(NO_3)_3\cdot xH_2O$ (Ln = Pr, Eu, Tb, Er; $x = 5$ or 6), OH^- and $(py)_2CO$ in MeOH–EtOH gave the dinuclear complexes $[Ln_2(NO_3)_3\{(py)_2C(OMe)O\}_2\{(py)_2C(OH)O\}]$(**1**–**4**); the erbium(III) compound was crystallographically identified as $\mathbf{4}\cdot 0.8EtOH\cdot 0.4MeOH$. The formation of these lanthanide(III) complexes can be summarized in the general balanced Eq. (1).

$$2Ln(NO_3)_3\cdot xH_2O + 3(py)_2CO + 3LiOH\cdot H_2O + 2MeOH \xrightarrow{MeOH\text{–}EtOH} [Ln_2(NO_3)_3\{(py)_2C(\underset{\mathbf{1-4}}{OMe})O\}_2\{(py)_2C(OH)O\}] + 3LiNO_3 + (2x+5)H_2O \quad (1)$$

The Ln^{III}-mediated addition of solvent (MeOH, H_2O from the solvents and the starting materials) to $(py)_2CO$ to give the monoanion of the hemiacetal form of di-2-pyridyl ketone, $(py)_2C(OMe)O^-$ (Fig. 1), and the monoanion of the *gem*-diol form of this ligand, $(py)_2C(OH)O^-$ (Fig. 1), in **1**–**4** involves a nucleophilic attack of the MeOH and H_2O molecules on the carbonyl group [7]. The electrophilic character of the carbonyl group of $(py)_2CO$ is increased by coordination of the carbonyl oxygen to the metal ion (direct polarization) and/or coordination of the more remote 2-pyridyl sites (induced polarization) [7].

Several features of the general reaction represented by Eq. (1) deserve comments. First, the "wrong" reaction ratio employed for the preparation of **1**–**4** (see Section 2.2), compared to the stoichiometric ratio required by Eq. (1), obviously did not prove detrimental to the formation of the complexes. With the identities of **1**–**4** established, the "correct" stoichiometric ratio, i.e., Ln(III): OH^-:$(py)_2CO$ = 2:3:3, was employed and led to pure compounds in satisfactory yields. Second, use of bases other than $LiOH\cdot H_2O$ leads again to the same complexes. Thus,

the 2:3:3 $Ln(NO_3)_3 \cdot xH_2O/(py)_2CO/Et_3N$ reaction mixtures in MeOH–EtOH (the detailed procedures are not given in Section 2.2) lead to the isolation of **1**–**4** in yields higher than 30% according to Eq. (2). Third, the incorporation of the monoanions of *both* the hemiacetal and the *gem*-diol forms of $(py)_2CO$ as ligands in **1**–**4** was rather unexpected, given the fact that the complexes were isolated from alcohols. For example, the products isolated from the $Er^{III}/SCN^-/(py)_2CO$ reaction mixtures in MeOH contain *only* $(py)_2C(OMe)(OH)$ or $(py)_2C(OMe)O^-$ species as ligands [10a]. With hindsight this can be explained by the presence of H_2O (from the starting materials and from the moisture of the organic solvents) in the reaction mixtures. One possible reason for the presence of both $(py)_2C(OMe)O^-$ and $(py)_2C(OH)O^-$ is the satisfaction of the crystal lattice. It is likely that the reaction solution contains a complicated mixture of several species in equilibrium, with factors such as relative solubility, lattice energy and crystallization kinetics – amongst others – determining the identity of the isolated product. It should be mentioned at this point that the presence of both $(py)_2C(OH)O^-$ and $(py)_2C(OR)O^-$ in the same complex is rare in d-metal chemistry [9c,9f,12]. Forth, complexes **1**–**4** seem to be the only isolable products from the $Ln(NO_3)_3 \cdot xH_2O/OH^-/(py)_2CO$ reaction systems in MeOH of MeOH–EtOH. The Ln^{III} to ligand reaction ratio, the presence/absence of counter-cations or – anions (e.g., NBu^n_4 or ClO_4^-), and the precipitation/crystallization method have no influence on the identity of the products. With the identity of compounds **1**–**4** established we also tried similar reactions but employing a large excess of OH^- as a means of obtaining complexes containing the doubly deprotonated ligand $(py)_2CO_2^{2-}$ (Fig. 1) [7]. However, these yielded the same complexes $[Ln_2(NO_3)_3\{(py)_2C(OMe)O\}_2\{(py)_2C(OH)O\}]$ and/or amorphous hydroxo materials with poor analytical results. Fifth, the full synthetic investigation of the $Ln(NO_3)_3 \cdot xH_2O/LiOH \cdot H_2O$ or $Et_3N/(py)_2CO$ reaction systems in H_2O, MeCN or $MeCN/H_2O$ led to non-crystalline solids with non-reproducible analytical results. Sixth, the employment of EtOH as co-solvent is beneficial only for the isolation of crystalline solids in the case of **1**–**3** and single crystals of $\mathbf{4} \cdot 0.8EtOH \cdot 0.4MeOH$; in other words, its presence does not affect the identity of the product, but only its crystallization. The employment of EtOH might imply the presence of the monoanion $(py)_2C(OEt)O^-$ in the complexes. Although this is possible *in solution*, only the $(py)_2C(OMe)O^-$ and $(py)_2C(OH)O^-$ ligands are present in the *solid* complexes **1**–**4**. This result is difficult to be rationalized; suffice it to say that complexes **1**–**4** are the thermodynamically stable products from the $Ln(NO_3)_3 \cdot xH_2O/OH^-/(py)_2CO$ reaction system in a solvent mixture comprising non-absolute MeOH *and* EtOH. And seventh, despite our efforts, we could not isolate mononuclear complexes containing the neutral or anionic ligand, e.g., $Ln(NO_3)_3\{(py)_2C(OR)(OH)\}_x$ ($x = 1$ or 2) and $Ln(NO_3)_2\{(py)_2C(OR)O\}$. In the absence of external base, the $Er^{III}/SCN^-/(py)_2CO$ reaction mixture in alcohols (MeOH, EtOH) yielded [10a] the mononuclear complexes $[Er(NCS)_3\{(py)_2C(OR)(OH)\}_3]$ (R = Me, Et).

$$2Ln(NO_3)_3 \cdot xH_2O + 3(py)_2CO + 3Et_3N + 2MeOH \xrightarrow{MeOH–EtOH} [Ln_2(NO_3)_3\{(py)_2C(OMe)O\}_2\{(py)_2C(OH)O\}] + 3Et_3NHNO_3 + (2x-1)H_2O \quad (2)$$

3.2. Description of structure

A partially labelled plot of the dinuclear molecule present in complex $\mathbf{4} \cdot 0.8EtOH \cdot 0.4MeOH$ is shown in Fig. 2. A graphical representation of this complex appears in Fig. 3. The coordination polyhedra of the two Er^{III} atoms are shown in Fig. 5. Selected interatomic distances and angles are listed in Table 2.

The crystal structure of $\mathbf{4} \cdot 0.8EtOH \cdot 0.4MeOH$ consists of discrete dinuclear $[Er_2(NO_3)_3\{(py)_2C(OMe)O\}_2\{(py)_2C(OH)O\}]$ molecules and solvate molecules; the latter will not be further discussed. In the dinuclear molecule, the

monoanion of the *gem*-diol form of di-2-pyridyl ketone, $(py)_2C(OH)O^-$, and one monoanionic hemiacetal form of the organic ligand, $(py)_2C(OMe)O^-$, bridge the metal centers through their deprotonated hydroxyl groups. Thus, the two Er^{III} atoms are doubly bridged by the deprotonated hydroxyl oxygen atoms O(1) and O(11). The Er(1) atom is in a nine-coordinate ligand environment comprising the two just mentioned hydroxyl oxygen atoms, four oxygen atoms from two chelating nitrato ligands (O(31), O(32), O(41), O(42)), the two 2-pyridyl nitrogen atoms from the $(py)_2C(OH)O^-$ ligand (N(11), N(12)) and one 2-pyridyl nitrogen atom from the bridging $(py)_2C(OMe)O^-$ ligand (N(1)). Two oxygen atoms from the remaining chelating nitrato ligand (O(51), O(52)), the second nitrogen atom from the bridging $(py)_2C(OMe)O^-$ ligand (N(2)) and the N(21), N(22), O(21) triad of atoms from the tridentate chelating (i.e., terminal) $(py)_2C(OMe)O^-$ ligand complete eight-coordination at Er(2).

The coordination modes of the organic ligands of complex **4** · 0.8EtOH · 0.4MeOH are shown in Fig. 4. The $(py)_2C(OH)O^-$ anion behaves as an $\eta^1{:}\eta^2{:}\eta^1{:}\mu_2$ ligand or in a 2.201_11_1 mode (as described using Harris notation [13]). According to the latter, the binding mode of a ligand is referred to as $X.Y_1Y_2Y_3\cdots Y_n$, where X is the overall number of metals bound by the whole ligand and each value of Y refers to the metal ions attached to the different donor atoms. The ordering of Y is listed by the Cahn–Ingold–Prelog priority rules, hence here O before N. In the case of chelating/bridging ligands, to distinguish between several alternatives, a subscript number is included

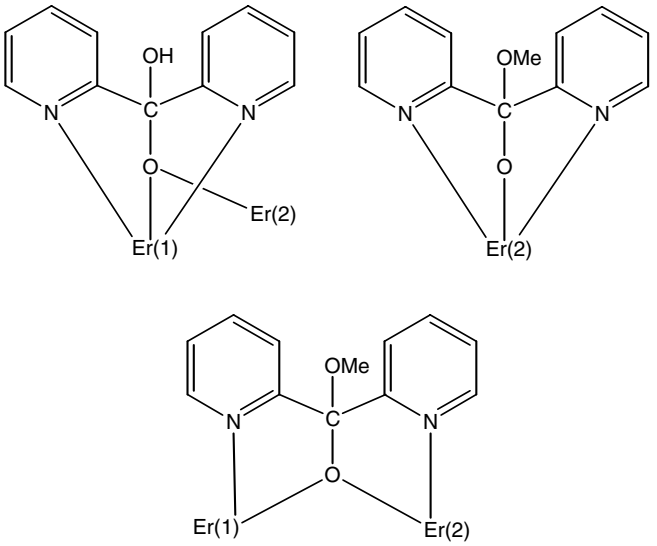

Fig. 4. The crystallographically established coordination modes of the organic ligands $(py)_2C(OH)O^-$ and $(py)_2C(OMe)O^-$ in complex **4** · 0.8EtOH · 0.4MeOH, and the Harris notation [13] that describes these modes.

to show to which metal ion the donor is attached. The bridging $(py)_2C(OMe)O^-$ anion behaves as an $\eta^1{:}\eta^2{:}\eta^1{:}\mu_2$ (or as 2.201_11_2 using Harris notation [13]) ligand, while the terminal $(py)_2C(OMe)O^-$ ligand is tridentate chelating ($\eta^1{:}\eta^1{:}\eta^1$ or 1.1011). The methoxy oxygen atom of both the $(py)_2C(OMe)O^-$ ligands and the hydroxyl oxygen atom of the $(py)_2C(OH)O^-$ ligand remain unbound to the metals. Ligands based on the *gem*-diol or the hemiacetal forms of di-2-pyridyl ketone have been observed in numerous ligation modes over the years [7]. The observed terminal and bridging ligation modes of $(py)_2C(OMe)O^-$ are common in the coordination chemistry of the hemiacetal forms of di-2-pyridyl ketone [7]. On the contrary, the observed 2.201_11_1 coordination mode of $(py)_2C(OH)O^-$ (Fig. 4) is extremely rare and has crystallographically been identified only in the dinuclear complex $[Bi_2(O_2CCF_3)_4\{(py)_2C(OH)O\}_2(THF)_2]$ [14].

The presence of two monoatomic bridges (O(1), O(11)) causes the Er(1)···Er(2) distance to be relatively short (3.681(2) Å). The Er–N distances are in the relatively narrow range 2.478(9)–2.572(9) Å; this range is typical for eight- and nine-coordinate Er(III) complexes [2f,2k,5c,13]. The Er–O bond lengths fall into two distinct categories; those involving the organic ligands (2.222(8)–2.330(7) Å) and those involving the nitrato ligands (2.380(9)–2.466(8) Å). The bridging Er–O distances involving O(1) and O(11) are asymmetric, e.g., Er(1)–O(11) = 2.330(7) Å and Er(2)–O(11) = 2.258(6) Å. The Er(2)–O bond distance for the bridging alkoxo-type oxygen atom of $(py)_2C(OMe)O^-$ (Er(2)–O(1) = 2.293(6) Å) is longer than the Er(2)–O distance exhibited by the terminal oxygen atom of $(py)_2C(OMe)O^-$ (Er(2)–O(21) = 2.222(8) Å). The Er(2)–O(alkoxo-type) distances have an average value of 2.258(8) Å, which is shorter than the corresponding value

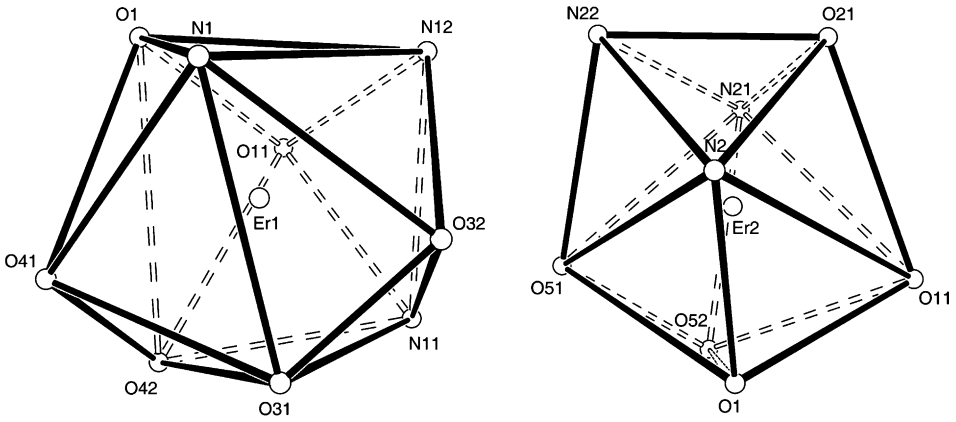

Fig. 5. Views of the inner coordination polyhedra of **4** · 0.8EtOH · 0.4MeOH showing the tricapped trigonal prismatic coordination of Er(1) and the dodecahedral stereochemistry about Er(2).

for the Er(1)–O (alkoxo-type) distances (2.292(7) Å); the decreased Er–O distances for Er(2) may be a consequence of the lower coordination number of this metal ion compared to that for Er(1) (eight versus nine). An analogous trend holds true for the Er–O(nitrato) bond distances; the average Er(1)–O(nitrato) and Er(2)–O(nitrato) distances are 2.447(8) and 2.416(9) Å, respectively. The nitrato ligands are planar, as indicated by the sum of O–N–O angles (359.7–360.0°), and almost symmetrically chelated. The Er–O(nitrato) bond lengths agree well with the values reported [15] for other eight- and nine-coordinate erbium(III) nitrate complexes.

The coordination polyhedron of Er(1) (Fig. 5) is best described as a distorted tricapped trigonal prism with the alkoxo-type oxygen atom, O(11), and the nitrate oxygen atoms O(32) and O(41) forming the three rectangular face caps. The angle sum subtended by the three capping atoms at Er(1) is 357.8°. It may be emphasized that in each nitrato ligand, the capping atom forms a slightly weaker bond to Er(1) than the non-capping atom, e.g., Er(1)–O(41) = 2.466(8) Å versus Er(1)–O(42) = 2.411(8) Å. The coordination polyhedron of the eight donor atoms about Er(2) (Fig. 5) is best described [10a] as a distorted dodecahedron. Atoms N(22), O(21), O(1), O(52) constitute a distorted tetrahedron that has been elongated along the fourfold inversion axis of the idealized polyhedron, whereas the set of atoms N(2), N(21), O(11), O(51) form a distorted tetrahedron that has been squashed along the same axis. An alternative way of viewing the dodecahedron about Er(2) is to consider it [16] as two interpenetrating planar trapezoids N(22)O(21)O(11)O(51) and N(2)N(21)O(1)O(52).

The distances O(12)···O(21) and O(ethanol)···O(42) ($-x+2$, $y+1/2$, $-z+3/2$) are only 2.557 and 2.985 Å, respectively, raising the possibility of the presence of hydrogen bonds. However, due to the fact that the hydrogen atoms of the structure were not located, the hydrogen bonds can not be considered in detail. The crystal structure is stabilized by four, crystallographically independent π–π stacking interactions (one intramolecular, three intermolecular). The intramolecular interaction involves the two 2-pyridyl rings that possess N(2) and N(12), the intercentroid distance (Cg···Cg*) and the dihedral angle being 3.740 Å and 10.1°, respectively. The corresponding perpendicular distances from Cg and Cg* to the best least-squares ring planes of the other stacking moieties are 3.490 and 3.549 Å. The first type of intermolecular interaction involves the two 2-pyridyl rings that possess N(11) and N(22) (the symmetry code is $x+1$, y, z), the intercentroid distance and the dihedral angle being 3.795° and 5.5°, respectively. The corresponding perpendicular distances from Cg and Cg* to the best least-squares ring planes of the other stacking moieties are 3.439 and 3.575 Å. The other intermolecular π–π stacking interactions involve the rings that possess N(2) and N(21) (x, $-y+1/2$, $z+1/2$), and the rings that possess N(1) and N(1) ($-x+2$, $-y+1$, $-z+1$).

The structural comparison of the dinuclear complexes $[Er_2(NO_3)_3\{(py)_2C(OMe)O\}_2\{(py)_2C(OH)O\}]$ (**4**) and $[Er_2(NCS)_3\{(py)_2C(OMe)O\}_3(MeOH)]$ [10a] reveals the following differences: (i) The former possesses two different types of monoanionic $(py)_2CO$-based ligands, whereas the latter only one; (ii) the organic ligands in **4** exhibit three *different* coordination modes (one terminal and two bridging), whereas the three $(py)_2C(OMe)O^-$ ligands in the isothiocyanate complex exhibit the same coordination mode; (iii) the two Er^{III} atoms are doubly bridged by deprotonated hydroxyl oxygens in **4** but triply bridged in the isothiocyanate compound [10a], and as a result the Er···Er distance is longer in the former (3.681(2) Å) than in the latter (3.380(2) Å), and (iv) the two Er^{III} atoms in the nitrate complex **4** have different coordination numbers (eight and nine) and hence two different coordination geometries (dodecahedral and tricapped trigonal prismatic), whereas the coordination number for both Er^{III} atoms in the isothiocyanate complex is the same (eight).

Complex **4** · 0.8EtOH · 0.4MeOH is the third structurally characterized lanthanide(III) complex with a $(py)_2CO$-based ligand (see Section 1) and joins only a handful of complexes of any metal that contain both $(py)_2C(OH)O^-$ and $(py)_2C(OR)O^-$ ions as ligands [9c,9f,12].

It also covers a gap in the erbium(III) literature in being the first crystallographically characterized dinuclear nitrate complex.

3.3. Magnetic moments, electronic and IR spectra

The experimental, room-temperature effective magnetic moment (μ_{eff}) values per Ln^{III} atom for complexes **1**–**4** (see Section 2.2) show very little deviation from the theoretical values (Pr^{III}, 3.62 BM; Eu^{III}, 3.5 BM; Tb, 9.7 BM; Er, 9.6 BM) predicted by Eq. (3), suggesting that the 4f electrons in the complexed Ln^{III} atoms are well-shielded by the outermost 5s and 5p electrons [16]

$$\mu_{eff} = g[J(J+1)]^{1/2} \quad (3)$$

The solid-state (diffuse reflectance) electronic spectra of the prepared complexes involve intraligand and f–f transitions. Detailed assignments (based on the literature data [17]) of the observed weak f–f bands are given in Table 3. The shape and the fine structure of the f–f band assigned to the "hypersensitive" transition $^4I_{15/2} \rightarrow {}^2H_{11/2}$ (Er-I) in the spectrum of **4** are sensitive to the coordination number [18]. By comparing the spectrum of **4** with the spectra of Er(III) complexes of known structures [10a,18,19] in the region of this transition (520–530 nm), it is confirmed that the metal ions are eight- or/and nine-coordinate.

The values of the bonding parameters $\bar{\beta}$ (nephelauxetic ratio), δ (Sinha's parameter) and $b^{1/2}$ (covalent factor) for complexes **1** and **4**, calculated from the solid-state f–f spectra by standard equations [10a,19,20] and listed in Table 4, indicate that the interaction between Pr^{III} and Er^{III} and the ligands is essentially electrostatic and that there is a minor participation of the 4f orbitals in bonding [20].

The IR spectra of vacuum-dried samples of **1**–**4** exhibit a medium intensity band at 3410–3380 cm^{-1}, assignable to the ν(OH) vibration of the $(py)_2C(OH)O^-$ ligand [8b]. The spectra of the four complexes do not exhibit bands in the region expected for the carbonyl stretching vibration (ν(C=O), at 1684 cm^{-1} for free $(py)_2CO$) with the nearest IR absorption at ~1600 cm^{-1} assigned as a 2-pyridyl stretching mode raised from 1582 cm^{-1}, as observed earlier on complex formation involving hydration or alcoholysis of $(py)_2CO$ [8b,21]. The bands at ~1050, ~765 and ~635 cm^{-1} can be assigned [22] to pyridyl ring breathing, pyridyl C–H out-of-plane bending and in-plane pyridyl ring deformation vibrations, respectively.

Diagnostic IR bands assigned to nitrate vibrations are listed in Table 5. The cited nitrate frequencies in Table 5 arise from spectra obtained as Nujol and hexachlorobutadiene mulls (whereas those cited in Section 2.2 arise from KBr pellets), since it is well known that pressing a pellet affects the nitrate coordination [23]; the organic ligands' frequencies are identical in both the KBr and mull spectra. The IR spectra of **1**–**4** in KBr are indicative of the presence of ionic nitrates (although the X-ray structure of **4** · 0.8EtOH · 0.4MeOH revealed no nitrate counterions); their existence in the KBr pellet is deduced from the appearance of the $\nu_3(E')(\nu_d(NO))$ mode of the D_{3h} ionic nitrate at 1384 cm^{-1} [24], suggesting [23] that a certain amount of nitrato ligands are replaced by bromides (thus generating ionic nitrates) in the KBr matrix. In the mull spectra of **1**–**4**, the bands at ~1475 and ~1285 cm^{-1} are assigned [24] to the $\nu_1(A_1)$ and $\nu_5(B_2)$ (under C_{2v} symmetry) stretching modes of the nitrato ligands, respectively. Their separation is large (~190 cm^{-1}) suggesting (**1**–**3**) or confirming (**4**) the bidentate character of the nitrato ligands [24]. The 1700–1800 cm^{-1} region is viewed as the key to

Table 3
Solid-state f–f bands for complexes **1**–**4**

4	0.996	+0.40	0.045

[a] Calculated from the solid-state f–f spectra taking into account the wavenumbers of the transitions mentioned in Table 3.

Table 5
Diagnostic IR bands (cm^{-1}) of the NO_3^- ligands present in complexes **1**–**4**[a,b]

Complex	$\nu_1(A_1') + \nu_4(E')$[c]	$\nu_1(A_1)$[d]	$\nu_5(B_2)$[e]
1	1754, 1725	1474 s	1284 m
2	1749, 1712	1480 s	1283 m
3	1753, 1715	1480 s	1287 m
4	1758, 1716	1473 m	1282 m

[a] The cited wavenumbers arise from spectra recorded as Nujol and hexachlorobutadiene mulls.
[b] The spectra of these complexes in KBr exhibit a medium to strong intensity band at 1384 cm^{-1} (see text in Section 3.3).
[c] These terms refer to the free NO_3^-; $\nu_1(A_1')$ and $\nu_4(E')$ are the ν_s(NO) and δ_d(ONO) vibrations, respectively.
[d] ν(N=O).
[e] $\nu_{as}(NO_2)$.

differentiate between bidentate and monodentate nitrate coordination [15d,23–25]. Lever et al. [25] proposed the combination band $\nu_1(A_1') + \nu_4(E')$ of free NO_3^-, which appears in the 1700–1800 cm^{-1} region, as a spectroscopic criterion for structural diagnosis. Upon coordination, ν_4 (E′, in-plane bending) near 700 cm^{-1} splits into two bands, and the magnitude of the splitting is expected to be larger for bidentate than for monodentate ligands. This is reflected in the separation of the two ($\nu_1 + \nu_4$) weak bands in the 1700–1800 cm^{-1} region. The separation of the combination bands is 29–42 cm^{-1} (see Table 5) in our complexes and these values indicate bidentate nitrato ligands [15d,23–25]. As it has been observed by Fukuda et al. [15d], the value of this splitting parameter increases with decreasing ionic size across the lanthanide series.

3.4. Photoluminescence properties of the Eu(III) and Tb(III) complexes

Excitation and luminescence spectra of complex **2** and the luminescence spectrum of complex **3**, recorded in the solid state at 295 K, are shown in Figs. 6 and 7, respectively. Excitation at 336 nm into the lowest energy ligand-centered absorption band results in the luminescence characteristic of the Ln^{3+} ion (Ln = Eu, Tb).

The strong red emission of **2** is assigned to the characteristic $^5D_0 \rightarrow {}^7F_j$ ($j = 0$–4) transitions or Eu^{3+}. Specific assignments [2a,2j,26] are as follows: $^5D_0 \rightarrow {}^7F_0$ (580 nm), $^5D_0 \rightarrow {}^7F_1$ (587 nm), $^5D_0 \rightarrow {}^7F_2$ (615 nm), $^5D_0 \rightarrow {}^7F_3$ (652 nm) and $^5D_0 \rightarrow {}^7F_4$ (688 nm). The appearance of a slight structure in the symmetry-forbidden emission $^5D_0 \rightarrow {}^7F_0$ may indicate that more than one coordination environments are present for Eu(III) [2j,26a,26b]. The Eu^{3+} ion is unique in that both the ground state $^7F_0$ and the excited emissive state $^5D_0$ are non-degenerate. Since the $^5D_0 \rightarrow {}^7F_0$ transition occurs between non-degenerate energy levels, neither of which can be split by a ligand field, a single environment gives rise to only a single transition; if more than one Eu^{III} environments are present, each will have its own characteristic transition energy [2j]. The dominant band in the emission spectrum is the hypersensitive $^5D_0 \rightarrow {}^7F_2$ transition, which shows signs of splitting. The higher intensity of this transition compared to that of the magnetic-dipole allowed $^5D_0 \rightarrow {}^7F_1$ transition indicates that this complex has a structure with no imposed symmetry [26a]. As a matter of fact, complexes with a centrosymmetric coordination sphere have $(^5D_0 \rightarrow {}^7F_2)/(^5D_0 \rightarrow {}^7F_1)$ intensity ratios lower than 0.7 [26a,26c].

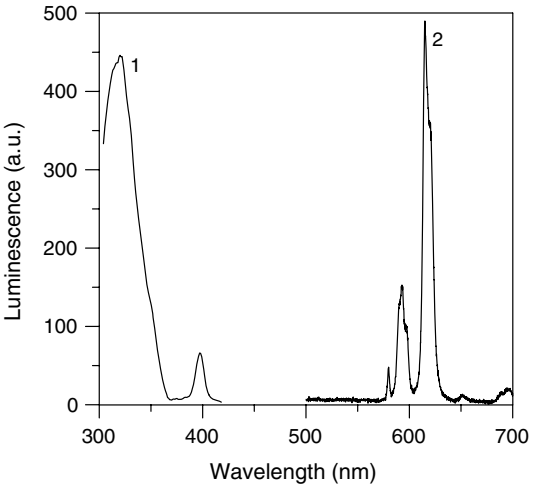

Fig. 6. Excitation (emission at 616 nm) (1) and emission (excitation at 336 nm) (2) spectra of **2** in the solid state at room temperature.

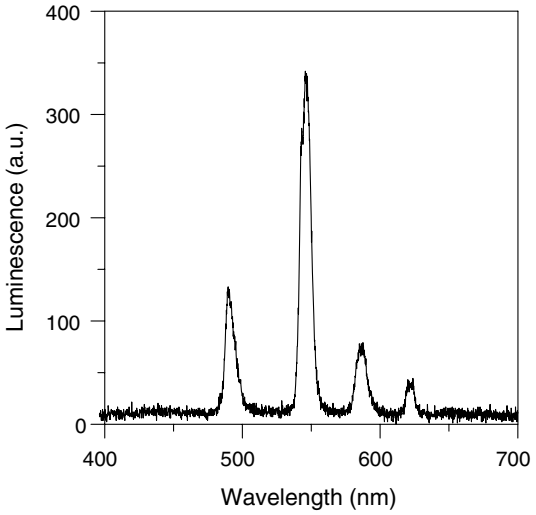

Fig. 7. The emission spectrum of **3** in the solid state at room temperature (excitation at 336 nm).

The Tb(III) complex **3** gives an entirely typical Tb^{3+} emission spectrum containing the expected sequence of $^5D_4 \rightarrow {}^7F_j$ transitions, with the $j = 3$–6 components being visible. Specific assignments [2a,26a,27] are as follows: $^5D_4 \rightarrow {}^7F_6$ (489 nm), $^5D_4 \rightarrow {}^7F_5$ (546 nm), $^5D_4 \rightarrow {}^7F_4$ (586 nm) and $^5D_4 \rightarrow {}^7F_3$ (622 nm). The spectrum is dominated by the $^5D_4 \rightarrow {}^7F_5$ transition, which gives an intense green luminescence output for the solid sample.

Generally, it is possible to obtain detectable luminescence for Eu(III) and Tb(III) only be direct excitation at their absorption peaks (at 396 and 370 nm, respectively) [28]. The fact that, for both **2** and **3**, strong luminescence was observed by excitation at 336 nm indicates that we have succeeded to increase the absorption cross-section of both lanthanides by excitation of the ligand(s) and energy transfer to the Ln^{III} ion, i.e., by an indirect process (antenna effect).

It is well known that the antenna-to-cation sensitization process, which seems to be general in Eu(III) and Tb(III) complexes, includes a sequence of steps [1j,2a,2e,2k]: (i) Light absorption to produce an excited singlet (S) from the ground singlet state in the organic ligand(s). (ii) Intersystem crossing (ISC) to populate the lowest-lying triplet (T) state by a radiationless process; competing with this are organic fluorescence and radiationless deactivation of the excited singlet as thermal energy. (iii) Radiationless

transfer of energy from the triplet state to one (or more) lanthanide-centered excited levels; the requirement for effective transfer is that the triplet state should be close in energy to or above the 4f levels concerned, and (iv) Emission of energy if one of the 4f levels excited by the transfer has an allowed transition to a lower 4f level.

4. Concluding comments and perspectives

The present work extends the body of results that emphasize the ability of the monoanionic ligands $(py)_2C(OH)O^-$ and $(py)_2C(OMe)O^-$ to form structurally interesting 4f-metal complexes. The use of the $(py)_2CO/NO_3^-$ "blend" in erbium(III) chemistry has provided access to the new complex $[Er_2(NO_3)_3\{(py)_2C(OMe)O\}_2\{(py)_2C(OH)O\}]$ (**4**) which has been structurally characterized; this complex has the $\{Er_2(\mu\text{-}OR)(\mu\text{-}OR')\}^{4+}$ core, where $R = (py)_2C(OH)-$ and $R' = (py)_2C(OMe)-$. Thus, complex **4** becomes the third structurally characterized lanthanide(III) complex with $(py)_2CO$-based ligands. Contrary to the previously characterized complexes $[Er(NCS)_3\{(py)_2C(OEt)(OH)\}_3]$ and $[Er_2(NCS)_3\{(py)_2C(OMe)O\}_3(MeOH)]$ [10], compound **4** possesses two different types of $(py)_2CO$-based ligands, i.e., $(py)_2C(OH)O^-$ and $(py)_2C(OMe)O^-$, that exhibit three distinct coordination modes. Thus, the principal objective of our studies, i.e., new structural types in $Ln(III)/(py)_2CO$ chemistry, has been realized. Based on analytical and spectroscopic studies, it seems that complexes **1**–**3** have a similar molecular structure with that of **4**. In this paper we have also demonstrated that the coordination of $(py)_2C(OH)O^-$ and $(py)_2C(OMe)O^-$ leads to complexes with efficient Ln(III) luminescence sensitization for Eu^{III} and Tb^{III} that emit in the visible region. This can be attributed to several factors such as the shielding of the metal ion from water and/or alcohol ligands, the lack of any strong ligand-to-metal charge-transfer bands that are usually responsible for the weak emission of the more readily reduced Eu(III), the lack of any energy back-transfer from the sensitizer triplet state, etc.

The nitrate terminal ligands present in **1**–**4** could have future utility as a means to access higher-nuclearity neutral or cationic clusters using bis(bidentate) bridging ligands, including aromatic heterocycles and dicarboxylates; such chemistry might alter the photophysical properties of the products. The ability of the *gem*-diol form of di-2-pyridyl ketone, "$(py)_2C(OH)_2$" (Fig. 1), to act as a dianionic ligand ($(py)_2CO_2^{2-}$, Fig. 1) and to bridge 3, 4 or 5 transition metal ions [7] gives also hopes for the isolation of high-nuclearity Ln(III) clusters if we find the right synthetic conditions for the formation of $(py)_2CO_2^{2-}$. A ligand "blend" that might prove successful for this synthetic purpose is $(py)_2CO/RCO_2^-$ [7]. Although only mononuclear and dinuclear complexes have been discovered from our work to date with lanthanide isothiocyanates and nitrates, clearly the $Ln^{III}/(py)_2CO$ chemistry warrants further study and also expansion to other inorganic anions with a higher charge and a higher bridging ability, e.g., SO_4^{2-}. Such synthetic efforts are in progress. In addition, we plan to try to design ligands in which the binding and antenna domains will be independent of each other; this will offer a wealth of possibilities for further derivatisation on the antenna part of the organic ligand, whilst maintaining binding properties, leading to improved photoluminescence properties of the resultant lanthanide(III) complexes.

5. Supplementary data

Full crystallographic details have been deposited with the Cambridge Crystallographic Data Centre. Copies of the data can be obtained free of charge on request from The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax : +44 1233 336033; e-mail: deposit@ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk) quoting the deposition number CCDC 295807 ($\mathbf{4} \cdot 0.8EtOH \cdot 0.4MeOH$).

(d_{001}) of about 18 Å and specific area of 200–300 m^2/g were reported by Pinnavaia [18] and Vaughan et al. [19]. These studies proposed that the intercalated species that give rise to this stable basal spacing is the so-called Keggin,s ion ($Al_{13}O_4(OH)_{24}(H_2O)_{12}^{7+}$), which has been characterized by angle X-ray scattering technique and by ^{27}Al nuclear magnetic resonance (^{27}Al NMR) data.

The chemical, surface, and structural properties of PILCs determine and can limit the potential applications which fall mainly into two categories: catalytic and adsorption processes. Presently, those materials can be used in a wide range of catalysis reactions, such as cracking, cycle hexane conversion, toluene with methanol alkylation, and propylene oligomerization. They are also commonly employed in the petroleum industry for long-chain hydrocarbons filtering and azeotropic cracking [20–30].

The aim of the present investigation is to study the structural and physical–chemical characteristics of two different types of smectites, such as natural and pillared clays, which were developed with $Al_{13}O_4(OH)_{24}(H_2O)_{12}^{7+}$ intercalation. This study investigated various parameters (chemical composition of the matrices, temperature of calcination, method of synthesis of the PILCs and effect of the acid activation) and their application into adsorption process with butylamine. Their adsorptive capacity was examined through adsorption isotherms, and the influence of the variation of parameters on PILCs texture was analyzed by different techniques.

2. Experimental

2.1. Raw material

Clay samples used in this investigation were obtained from the ''Serra do Maicuru'' area Para state, north of Brazil. Two different samples were used in this paper as starting materials and are named as A_1 and A_2. The particles that were lesser than 2 μm fraction of the sample were separated by sedimentation. The cation-exchange capacity (CEC) was ensured in order to evaluate the potential use of those clays for intercalation, following the ammonium acetate method by using a concentration of 2 mol dm^{-3} at pH 8. The results obtained were 9.2 mmol g^{-1} (A_1) and 10.5 mmol g^{-1} (A_2) on an air-dried basis and pointed for the continuation of the study. Mineralogical and chemical characterizations were carried out using the analytical techniques that will be described further.

2.2. Sample preparation and preliminary characterization

The samples were dried at 60 °C up to humidity between 12% and 15%. They were ground and passed in USS sieve No. 200 (74 mm) and examined through powder X-ray diffraction to confirm the presence of smectite clays by conventional sample preparation procedures, such as air-dried oriented mounts, ethylene glycol solvated and heated at 300 and 500 °C.

2.3. Synthesis of the pillaring solution and pillaring processes

Two distinct methods were used in the preparation of PILC materials:

(A) Method 1: The samples were saturated with Na_2CO_3 by adding the solution to dry materials at room temperature. This treatment was carried out using saturated solution of Na_2CO_3 (0.20 g cm^{-3}) in proportion of 1.00 mmol g^{-1} of sample. The mixture was homogenized and left standing for 12 h. The intercalating solution was obtained by slow addition of NaOH (0.2 mol dm^{-3}) in a $AlCl_3 \cdot 6H_2O$ (0.2 mol dm^{-3}) solution, with a basicity relationship OH/Al = 2. The sodium hydroxide solution was incorporated drop by drop in the aluminum chloride solution, which was maintained under vigorous stirring at 60 °C. The resultant solution was aged under reflux during 24 h. The polymeric solution was incorporated drop by drop in a suspension composed by 5% of Na-montmorillonite in a mixture of deionized water and ethanol. The amount of oligocation incorporated exhibited 20 mmol of Al per gram of natural clay. The resultant solution (polymeric solution and Na-montmorillonite) was filtrated and washed with deionized water. The sample was calcinated at 450 and 600 °C for 2 h. The resultant material was called Al-$PILC_1$.

(B) Method 2: The aluminum oligocation was prepared by using a solution of the following commercial product: Locron® $Al(NO_3)_3$ (0.2 mol dm^{-3}). The intercalating solution was obtained by slowly adding NaOH (0.2 mol dm^{-3}) into a $Al(NO_3)_3$ (0.2 mol dm^{-3}) solution, which was incorporated drop by drop into a suspension made with 50% of natural clay into a mixture of water, ethylene glycol and glycerin. The basicity ratio was 2 and quality of Al (0.2 M) was 20 mmol per gram of natural clay. The final solution containing clay, aluminum nitrate and sodium hydroxide was continuously stirred for 4 h and allowed to stand for 5 days. Finally, the material was washed with deionized water and calcinated at 450 and 600 °C. The resulting material was called Al-$PILC_1$ (450 °C) and Al-$PILC_1$ (600 °C), for sample A1 and Al-$PILC_2$ (450 °C) and Al-$PILC_2$ (600 °C), for sample A2.

2.4. Acid treatment

The pillared clays were activated with HCl in concentrations of 0.6 mol dm^{-3} by slowly adding the solutions to dry materials at room temperature, with continuous stirring for 2 h. The resultant solutions obtained (HCl and pillared clays) were filtrated and the resultant materials were washed with deionized water and dried at 60 °C. The resulting materials were called Al-PILC.

2.5. Adsorption process with butylamine

The adsorption process was carried out by suspending about 0.60 mg of the pillared clay in aqueous solution of each butylamine at room temperature. The isotherms of

concentration versus time were obtained through a batch method [31]. The number of moles adsorbed per gram (n_f) is calculated by the difference between the initial (n_i) and the supernatant (n_s) number of moles of amine divided by mass (m) of the compound used, $n_f = (n_i - n_s)/m$. The number of moles of butylamine adsorbed (n_f) increased with time (t) as a function of the concentration of the supernatant (C_s), until the plateau related total saturation of the acid center in the layered structure was obtained.

2.5.1. Adsorption isotherms

The most commonly used isotherms are the Langmuir isotherms, which have been originally derived for the adsorption of gases on plane surfaces such as glass, mica, and platinum; however, this adsorption process is applied to heavy metal ions adsorption in porous surfaces in the classical Langmuir form, where the quantity q_i of an adsorbate i adsorbed is related to the equilibrium solution concentration of the adsorbate c_i by the parameters K and b, the steepness of the isotherm is determined by K. It can be looked upon as a measure of the adsorbate for the surface. The value of b is the upper limit for q_i and represents the maximum adsorption of i determined by the number of reactive surface adsorption data by converting Eq. (1) into the linear form:

$$[C_s/N_f] = [1/(K \times b)] + [C_s/b] \quad (1)$$

Then the ratio $c_i/q_i = C_s/N_f$, the so-called distribution coefficient Kd, can be plotted against q_i. If the Langmuir equation can be applied, the measured data should fall on a straight line with slope of $-K$ and intercept of Kb, where $1/Kb$ is angular coefficient and $1/b$ is linear coefficient.

Another fitting for the adsorption process is established by Freundlich equation which has the form:

$$N_f = KfC^{1/n} \quad (2)$$

where Kf and n are adjustable positive valued parameters with n ranging only between 0 and 1. For $n = 1$ the linear C-type isotherms would be produced. The parameters are estimated by plotting $\log c_i$ with the resulting straight line having a y intercept of $\log a$ and a slope of n. The Temkin equation was also applied for solid/liquid interface:

$$N_f = A \ln C + B \quad (3)$$

where A and B are parameters of equation, estimating by plotting N_f against $\ln C$. The values are obtained for A and B, where B is the linear coefficient and A is the angular coefficient of the straight line. The coefficients obtained from these equations were used to adjust the theoretical model to the experimental data.

2.6. Analytical techniques

X-ray powder diffraction (XDR) patterns were recorded with a Philips PW 1050 diffractometer using Cu Kα (1.54060 Å) radiation in the region between 2° and 65° 2θ at a speed of 2° per minute and a step of 0.05°.

For the infrared spectroscopy, the samples were oven-dried at 120 °C to remove any adsorbed water. Each sample of about 0.200 g was finely ground for 1 min, combined with oven-dried spectroscopic grade KBr (0.0013 g) and pressed with 7 ton into a disc under vacuum. The spectrum of each sample was recorded in triplicate by accumulating 64 scans at 4 cm^{-1} resolution between 400 and 4000 cm^{-1}, using the Perkin–Elmer 1760X Fourier transform infrared spectrometer (FTIR).

The ^{27}Al MAS NMR spectra of the solid material were obtained on an AC 300/P Bruker spectrometer at room temperature at 75.5 MHz. A conical Andrew type rotor was used, and the spinning frequency was in the range of 4.5 kHz, with $Al(H_2O)_6^{3+}$ being used as an external standard.

Thermal analysis was carried out in a Stanton Redcroft 1000/1500 coupled to a DC ampler and temperature controller. Data from DTA-TG were obtained in all cases at a heating rate of 20 °C/min between 40 and 900 °C and under static air atmosphere.

BET surface areas and porosity measurements of the Al-PILC samples were determined using a Quantachome/Nova Surface Area Pore Volume Analyzer, Model 1200/5.01. The mesopore size distribution was obtained by applying the Barret–Joyner–Halenda (BJH) method to the adsorption branch of the isotherm.

The natural clays (A_1 and A_2), Al-$PILC_1$ and Al-$PILC_2$, were analyzed by induced coupled plasma-atomic emission spectrometry (ICP-AES), using an ARL 34000 instrument. The oven-dried powdered sample weighing exactly 0.231 g, 0.254 g, 0.241 g and 0.234 g, respectively, were placed separately on glass weighing dishes and transferred quantitatively to pre-cleaned nitric acid digestion bottles. The samples were then digested with 7 cm^3 of mixture of one part of nitric acid, three parts of hydrochloric acid and fifteen parts of hydrofluoric acid, and allowed to stand for five days. The samples were cooled in an ice-bath and 25 cm^3 of boric acid was added with stirring. Then, 50 cm^3 of deionized water was added and the solution was diluted to 100 cm^3. For each sample, a blank and a set of elemental standards were run to calibrate the instrument.

The samples for scanning electron microscopy (SEM) and micro-analysis (dispersive-energy system – EDS) were prepared in orientated blades at 25 °C and sputtered with gold. The used instrument was a model LEO-ZEISS, 430 Vp, in conditions of analysis using secondary images obtained to 20 KV, with distance of work of 11 mm.

3. Results and discussion

3.1. X-ray powder diffraction

Total mineralogical composition of the starting materials, A_1 and A_2 clays, was carried out in no oriented mounts

which exhibited mainly nontronite and goethite, besides the existence of kaolinite.

The results obtained for the d_{001} values are shown in Table 1. Figs. 1 and 2 show the X-ray powder diffractions for natural A_1 and A_2 clays and pillared/activated clays ($AlPILC_1$ and $AlPILC_2$) are given in a molar ratio of 2. It was observed that the pillared matrices obtained an increase in their interlayer distances after pillared process, with a *d* value of 18.97 Å for the sample $ALPILC_1$ and 18.86 Å for the sample $AlPILC_2$. It was also observed that the sample $ALPILC_1$ presented a slightly broader peak, in comparison with $ALPIC_2$, representing differences in the degree of crystallinity (calculated using the Biscaye's [13] equation, results shown in Table 1), related to interferences with the pillaring process. This fact can be explained based on the hypothesis of the existence of different species in the interlayer region that makes the entrance of the intercalation ion difficult, resulting in a structure distortion. Another possibility is the inadequate entrance of the ion in the interlayer region. When the matrix is submitted to a high temperature of calcination, it will exhibit a premature dehydroxylation of its pillars at a certain point of the interlayer region, resulting in a partial pillaring process of this matrix. In all cases, well-pillared samples showed approximately the same (d_{001}) basal spacing. The great influence of the number of pillars in interlayer spacing on the constitution and distribution of the pillars has been previously indicated in the literature [7–9].

3.2. Thermal analysis (DTA-TG)

The thermal curves are depicted in Figs. 3 and 4 in the 298–1273 °C range. The curves correspond to the starting natural clays, $AlPILC_1$ and $ALPIC_2$, after equilibrating in a desiccator, at room temperature and after a 2-h thermal treatment at 450 °C, temperature of calcination. The general feature of thermal curves clearly reveals two steps: (1) in the 25–300 °C and (2) in the 200–400 °C temperature ranges. The first step with natural clays A1 and A2 and pillared clays has been ascribed to physisorption of the hydrating water, whereas the second step is due to dehydroxylation of silicate structure. Sometimes, this step occurs dissociated into two,

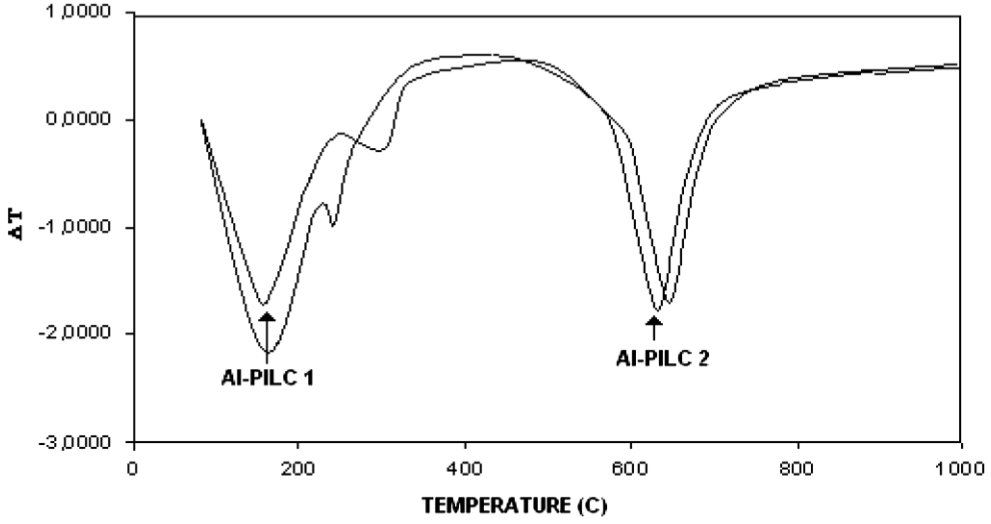

Fig. 4. DTG curves of the pillared/activated clays.

which is not well visible here but is clearly shown in the corresponding DTG and, more so, in the TGA curve (Fig. 4), denoting dehydroxylation of the silicate structure in two different environments. For Al and Mg, pillared materials, the net isomorphic substitution in the clay with different bonding strengths between the oligocations and the surrounding oxygen (or hydroxyl) ions can be observed. Dehydroxylation continues between 500 and 700 °C and is also detected to approximately 680 °C in an important step. This step is related with the stability of the pillars, since an important decrease in the basal spacing values occurs at this temperature, indicating the collapse of the clay structure. Therefore, the thermogravimetric analyses are in agreement with the aforementioned thermal stability of the synthesized pillared clay up to 600 °C.

3.3. Fourier-transformed infrared spectroscopy

Fig. 5 shows the infrared spectra of the $AlPILC_1$ and $AlPILC_2$ calcinated in a temperature of 450 °C. The low frequency regions of the infrared spectra of the $AlPILC_1$ and $AlPILC_2$ are very similar but the latter show a very small low intensity band around 667 cm^{-1} (Fig. 6). The lattice vibration at 667 cm^{-1} can be ascribed to the Al–O bond of tetrahedrally coordinated Al cations in the center of the Al_{13} pillars. The infrared spectra of natural clays presented bands in the region of 1787–1740 cm^{-1}, attributed to hydrating water. Similar results were reported by Kloprogge et al. [27], after using $Al(NO_3)_3$ as the aluminum source.

At high frequency regions of the infrared spectra (Fig. 7), the samples show a band at 3744 cm^{-1} related to the OH stretching of SiOH, corresponding to silanol groups, which adsorb at 3747 cm^{-1} on silica or on the external surfaces of zeolite [24,25]. Such hydroxyls are either located at corners and fractures of sheets or are formed by the processes of tetrahedral inversion. For Al-$PILC_1$-450 sample a new band is found at 3738 cm^{-1} (Fig. 6), which is probably produced by the change of position of the SiOH group in the structure of the smectite. The original position was altered by the entrance of the Al ion in the smectite structure, which is likely to be due to SiOH species perturbed by pillars, and

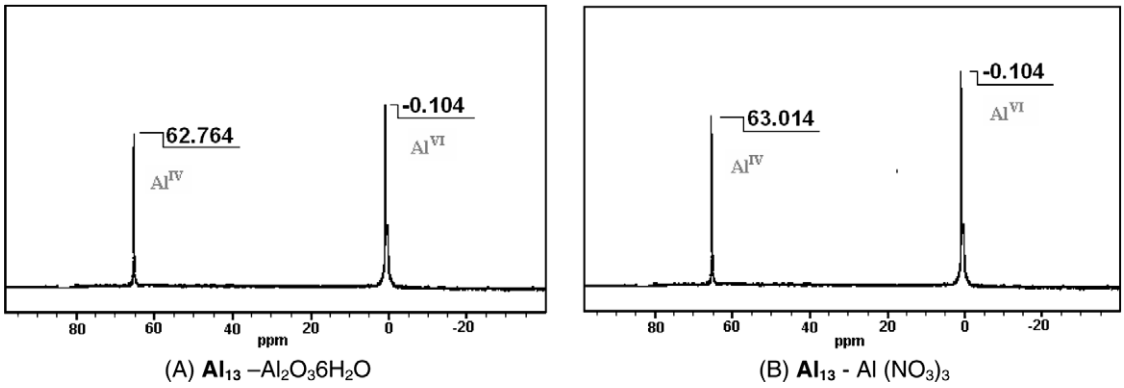

Fig. 7. ^{27}Al MAS NMR spectra of the aluminum polyhydroxypolymer solutions (Al_{13}).

designated as SiOH*, and similar results were previously reported by Bodoardo et al. [30].

A weak shoulder at 3715 cm^{-1} is observed in all clays, which is characteristic of isolated hydroxyl group on octahedral aluminum in Al_2O_3. A similar interpretation was proposed by Bodoardo et al. [30], but involving cations in the octahedral sheet and possibly in pillars in the case of Al-PILC$_1$-450 and Al-PILC$_1$-450 samples. Accordingly, the hydroxyl species were also denominated as $Al^{VI}OH$.

3.4. ^{27}Al and ^{29}Si MAS NMR

Fig. 7 shows the ^{27}Al MAS NMR spectra of the aluminum polyhydroxypolymer solutions. Most of the samples used Al_2O_3 as the aluminum source and the others were prepared with $Al(NO_3)_3$. These solutions exhibit two types of resonances corresponding to octahedral and tetrahedral-coordinated aluminum with a broad signal centered at 2.5 and 60 ppm, respectively.

Fig. 8 presents the ^{27}Al MAS NMR spectra. Signals were observed in the tetrahedral position ($\delta = 68$ ppm) and in Al in the octahedral position ($\delta = 0$ ppm) with percentages of 15% and 85%, respectively, which can indicate a possible charge deficiency in the tetrahedral layer. Also, a small signal was checked in the region of 58.7 ppm. This signal can be attributed to the tetrahedral aluminum that can be connected with the presence of the Keggin's ion (Al_{13}) in the interlayer region. After calcination, significant change was not observed in the spectra. In Fig. 9 are presented the of ^{29}Si MAS NMR spectra. Signals were observed in the −80 ppm attributed to the crystalline structure and signals in the 105 ppm attributed to the presence of quartz in the sample. After intercalation and pillaring processes, significant differences were not observed in the of ^{29}Si MAS NMR spectra.

3.5. Textural analysis

The nitrogen adsorption–desorption isotherms of pillared and activated clays are shown in Fig. 10. All isotherms are type IV of the BDDT classification and correspond to a microporous network formed in the interlayer spacing, with a well-defined H4 hysteresis loop, in accordance with Boer's classification that can be related to these micropores which

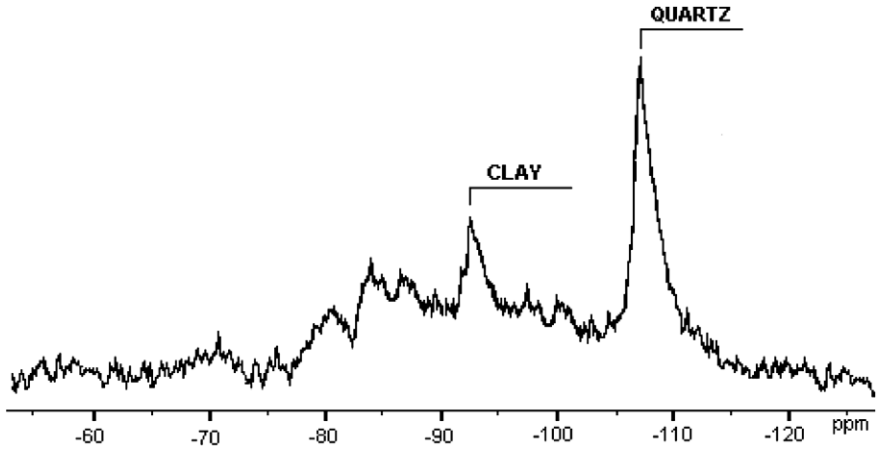

Fig. 9. ^{29}Si MAS NMR spectra of the pillared samples (Al-PILC$_2$) with Al_{13} and activated with HCl.

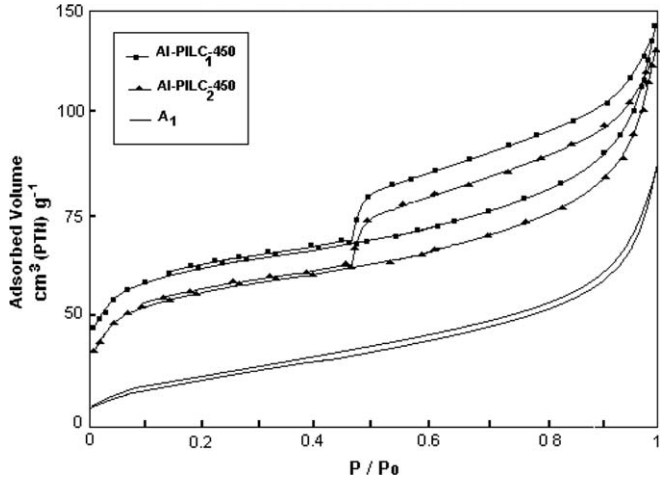

Fig. 10. N_2 adsorption–desorption isotherms of natural clay and pillared/activated samples.

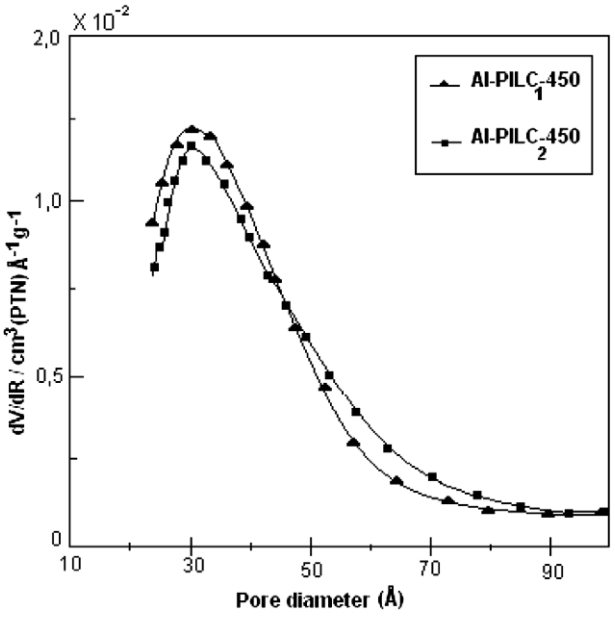

Fig. 11. Pore size distribution curve of pillared/activated samples.

are capillaries due to the interlayer space between parallel walls of aluminosilicate units [13].

Table 1 gathers the values for the surface area and micropore volume after BET equation and the BJH method along with the H–J standard curve. Also shown is $V_{0.98}$ where the total pore volume reached up to $p/p^0 = 0.98$.

Pore size distribution in Al series varies depending on the raw material source and particle size. Thus, AlPILC$_1$ and AlPILC$_2$ show unimodal distributions with pore sizes as listed in Table 1 and shown in Fig. 11.

3.6. Elemental analysis

The ICP-AES analyses of all samples are reported in Table 2. The results are consistent with nontronite being the major clay mineral containing significant amounts of iron and aluminum in its structure. The elemental analysis for AlPILC$_1$ and ALPILC$_2$ was obtained with major values for Al and significant variations of Ca, K and Ti of the present study. The results confirmed the entrance of the Al ion in the smectite structure.

Table 2
Elemental analyses (wt.%) of the clay samples and pillared clays

Samples	Al_2O_3	CaO	Na_2O	K_2O	TiO_2
A_1	17.89	4.78	1.20	1.80	4.90
A_2	12.01	5.03	1.70	1.91	5.21
Al-PILC$_1$	26.90	0.94	0.17	0.72	2.42
Al-PILC$_2$	25.95	1.08	0.19	0.75	3.14

3.7. Scanning electron microscopy with energy dispersive system

In the analysis of the results of the scanning electron microscopy (SEM) for the pillared matrix in a molar ratio of 2, it is possible to affirm that the pillaring process does not produce any change in the crystal form and crystalline size of the original smectites. It was observed that in all the experiments the smectite remained in the primitive crystal form, presenting itself in the foliated form with illite crys-

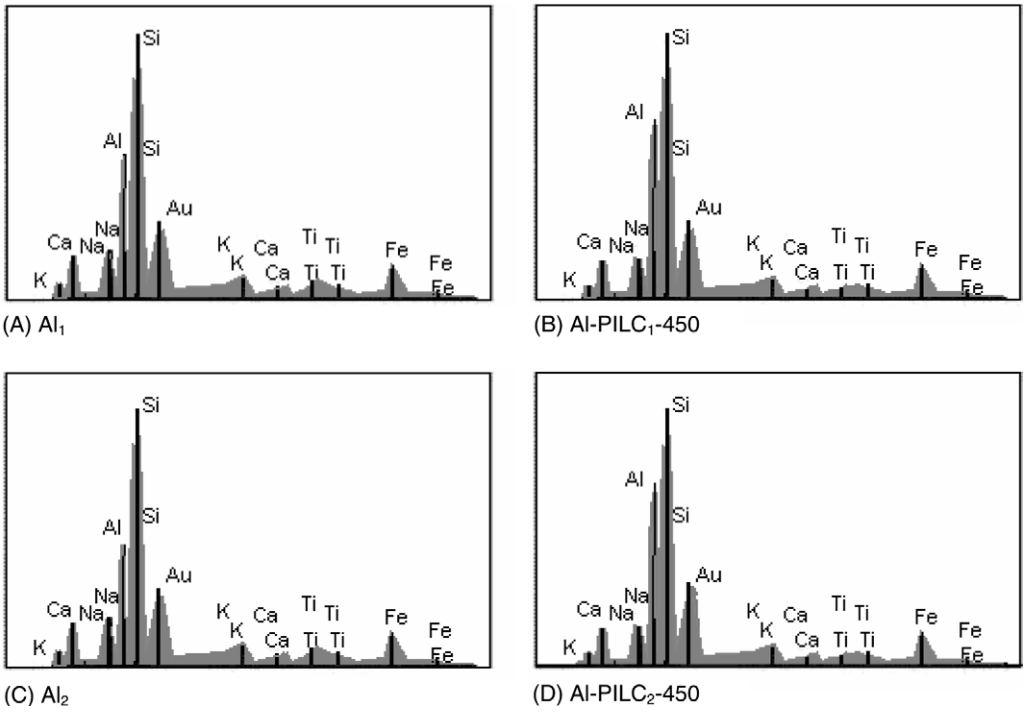

Fig. 12. EDS analysis of the natural clays and pillared samples.

tals in the extremities. Semi-quantitative analysis using EDS is shown in Fig. 12 exhibiting high aluminum concentration, related to the pillared matrix, which can be explained by the existence of pillars in the structure.

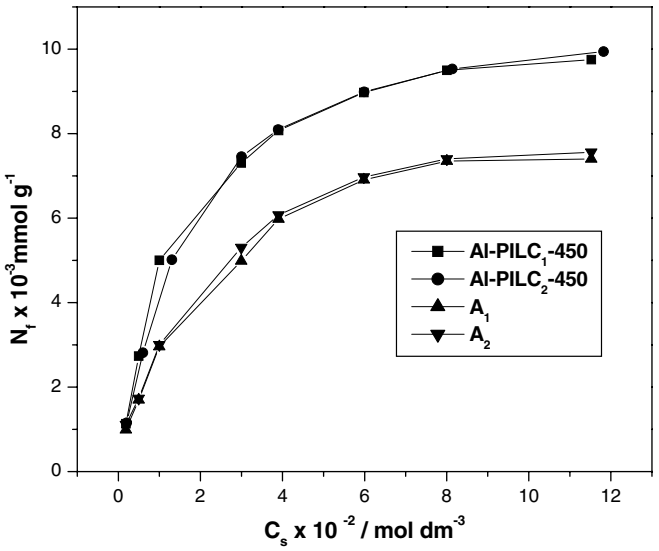

Fig. 13. Experimental values of butylamine adsorption.

3.8. Butylamine adsorption

In Fig. 13, the results of the experiments obtained of the butylamine adsorption are shown. The influence of acid activation was observed through adsorption values of saturation in matrices. In Table 3 and Figs. 14 and 15, the results of the linear correlation coefficients obtained from the Langmuir, Freundlich and Temkin equations are displayed. They indicate that three models of adsorption can be used to explain the significant capacity of the pillared matrix to quantify the adsorbed butylamine. The Langmuir model presents a significant advantage in comparison with the other models. It allows to quantify the adsorption's capacity of the present ions in the structure of the matrix and to evaluate the constant related to the bonding energy.

The complexation of metallic ions with bridgings immobilized external and internal surfaces of smectite structures, besides the external part of the pillars, is governed by the microenvironment around those bridgings, which are usually acidic centers. They are formed as accessories in the pillars and hydroxyls that still exist in the surfaces, mainly in the internal structure of hydration. Such hydroxyls act as bridgings for H^+ groups that result from the matrix acidi-

Table 3
Parameters of the Langmuir, Freundlich and Temkin equations used in the butylamine adsorption in Al_{13} pillared clay

Sample	Langmuir			Freundlich			Temkin		
	b	*K*	*r*	*kf*	*n*	*R*	*B*	*A*	*r*

fication. Water removal in such surfaces becomes difficult due to the octahedral and tetrahedral sheet positions and also by the remaining hydroxyl groups from the primitive clay structure. Finally, quimisorption process is controlled by the positioning and amount of hydroxyl groups in the outer regions, as in lamellae borders and central structure.

4. Conclusions

The results of this investigation show that the clay deposits from Amazon region, Brazil, mainly montmorillonite (nontronite) present variations in the amounts of quartz, kaolinite and goethite as impurities. The results obtained by means of XRD powder diffraction confirmed an expansion of the original smectites to a thermally stable d_{001} spacing of 18.97 Å (Al-PILC$_1$-450), which requires a rather well defined Al polymer, such as the so-called Al_{13} species. The permanence of the d_{001} peak proved the resistance of the pillared matrix to support high temperature of calcinations (600 °C).

FTIR analysis confirmed the formation of Al-pillars in the pillared samples by the two methods employed. A weak shoulder at 667 cm^{-1} is observed in pillared clays. This low intensity band is observed in the pillared samples also by means of the two synthetic methods used. The presence of a band in the 3738 cm^{-1} region also proves the entrance of the Keggin's ion in the matrix structures.

The analyses of ^{27}Al MAS NMR demonstrated the formation of Al in the tetrahedral and octahedral positions in the pillaring solutions. The pillared matrix is shown with a signal in the region of 58.7 ppm. This signal can be attributed to the tetrahedral aluminum that can be connected with the presence of the Keggin's ion in the interlayer region.

The textural analysis of the pillared samples evaluated from the obtained isotherms pointed to the production of material containing mesopores and micropores, according to the Boer classification. The specific area of the pillared samples obtained grows in the two adopted methods. This growth is attributed to several factors: the production of Keggin's ions, the entrance of these ions in the interlayer, density of the pillars and number of pillars.

The models used of the isotherms' evaluation exhibited constant values similar to those observed for the experimental isotherm. A greater variation was observed in the Freundlich model. The results obtained using linear equations are very close to those obtained from the literature that frequently use a non-linear computational method based on the "Enzefitte" system. With the adsorption results obtained, it is possible to establish a relationship between the number of adsorbed ions and the number of acid sites produced after pillaring process. In this work, the K and b values from the Langmuir and Freundlich equations exhibited small variations when a "flat" was observed. In other words, this fact implies a saturation of the acid centers in the new smectite system produced after pillaring process, which stabilizes the two mathematical variables that drive the process.

The linear regression method used in this work did not produce significant systematic deviation of the adjusted isotherms. Therefore, it certainly can be used to describe ionic exchange processes related to metallic ions removal present in industrial sludges and from the mineral extraction.

$(CdBr_2)] \cdot H_2O$, was prepared by mixing [DEA]Br (0.171 g, 1 mmol) and $CdBr_2$ (0.819 g, 3 mmol) in a solution of deionized water (10 mL) and methanol (3 mL). Short, clear, colorless needles formed after one week.

2.2. X-ray structure analysis

Crystals were removed from solution and immediately placed in hydrocarbon oil to prevent the crystalline material from possible deterioration due to solvent loss. A suitable crystal was selected, attached to a glass fiber, and placed immediately in the low-temperature nitrogen stream [7]. Data was collected at ca. 86(2) K using a Bruker/Siemens SMART APEX instrument (Mo Kα radiation, $\lambda = 0.71073$ Å) equipped with a Cryocool NeverIce low temperature device. Data were measured using omega scans of 0.3° per frame, and a full sphere of data was collected. The first 50 frames were recollected at the end of the data collection to monitor for decay. Cell parameters were retrieved using SMART [8] software and refined using SAINTPLUS [9] on all observed reflections. Data reduction and correction for Lp and decay was performed using the SAINTPLUS [9] software. Absorption corrections were applied using SADABS [10]. The structure was solved by direct methods and refined by the least squares method on F^2 using the SHELXTL program package [11]. No decomposition was observed during data collection. The pendant $CdBr_2$ group was disordered with occupancies of 95% for Cd5, Br9, and Br10 and 5% for Cd6, Br11, and Br12. The major moiety was refined anisotropically. It was not possible to resolve the disorder in the organic groups, so

Symmetry transformations used to generate equivalent atoms: #1 $-x, -y+2, -z+2$; #2 $-x-1, -y+2, -z+2$; #3 $x-1, y, z$; #4 $x+1, y, z$.

only the major components were included at 95% occupancies. Hydrogen atoms associated with water molecules were added geometrically to ensure optimal hydrogen bonding contacts. Data collection and refinement parameters are given in Table 1, atomic coordinates and equivalent isotropic thermal displacement parameters are given in Table 2 and pertinent bond distances and angles are given in Table 3.

3. Structure description

The unique structure of $[DEA]_2[Cd_3Br_8(CdBr_2)] \cdot H_2O$ is based on ribbons comprised of three infinite chains of edge-shared octahedra. These simple cadmium bromide ribbons can be envisioned as being cut from the original $CdBr_2$ parent hexagonal lattice by the $[DEA]^+$ cations. The edges of these ribbons have "fringed" edges consisting of $CdBr_4$ tetrahedra. These distinctive tetrahedral fringes, water molecules, and two crystallographically independent diethylammonium cations play an important role in linking these unique ribbons together.

The asymmetric unit is shown in Fig. 2. Differences in Cd–Br distances are observed throughout the body of the ribbon (Cd–Br range: 2.678(1)–2.840(1) Å) and in the octahedral angles (Br–Cd–Br range: 87.06(3)–98.34(4)°) due to the tetrahedral $CdBr_4$ fringe that caps the edges of each ribbon, as shown in Fig. 3. Significant angular distortion is also necessary within the tetrahedron in order to link two adjacent $CdBr_6$ octahedra. The Cd–Br bond distances in

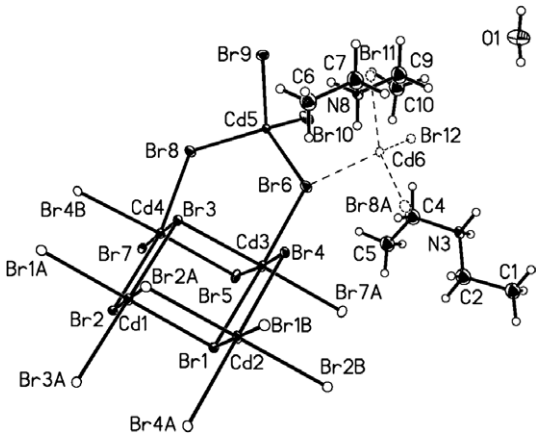

Fig. 2. Illustration of the asymmetric unit of the $[DEA]_2[Cd_3Br_8(CdBr_2)] \cdot H_2O$ structure. The disorder involving Cd5 and Cd6 is indicated by the dashed bonds surrounding Cd6. The octahedral coordination of each cadmium(II) atom has been completed with symmetry-related atoms (open ellipsoids). Thermal ellipsoids are shown at the 50% probability level.

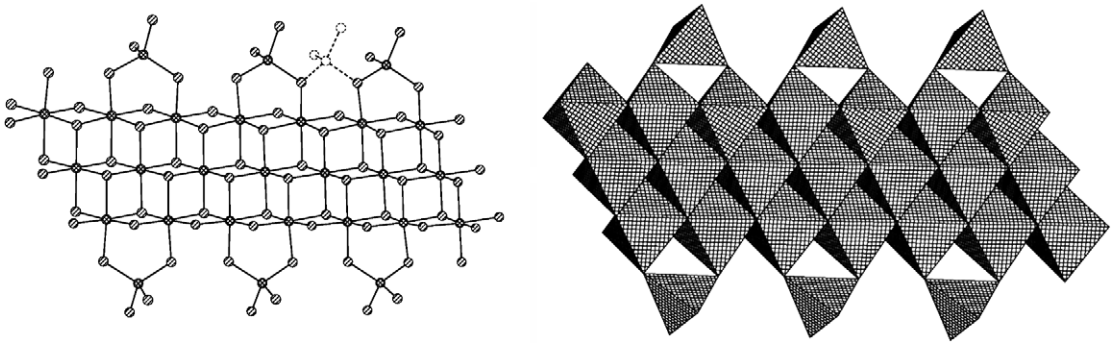

Fig. 3. Ball-and-stick (left) and polyhedral (right) illustrations showing the extended, fringed ribbon of the $[DEA]_2[Cd_3Br_8(CdBr_2)]\cdot H_2O$ structure which runs parallel to the *a*-axis. The ball-and-stick illustration also shows the location of a single disordered tetrahedral group (indicated by the dashed bonds).

the tetrahedra differ very little (av. 2.575 Å) while the Br–Cd–Br tetrahedral angles range from 105.7(2)° to 114.49(4)°. Additionally, disorder in the location of the tetrahedral fringe was observed, as discussed in Section 2. A small fraction (5%) bridge the other set of adjacent $CdBr_6$ octahedra as indicated by dashed lines in the asymmetric unit shown in Figs. 2 and 3.

Also present in this structure are lattice water molecules and two crystallographically independent $[DEA]^+$ cations. Cations lying almost perpendicular to the ribbon (thus virtually perpendicular to the *a* axis) have ethyl arms of *trans* conformations. Cations lying roughly parallel to the ribbons have one arm in the *gauche* conformation and the other in the *trans* conformation. These two different cations are illustrated in Fig. 4.

The isolated networks are linked together by a complex array of hydrogen bonding, involving the diethylammonium cations, water molecules and the bromide ions of the tetrahedral fringe, to stabilize the three dimensional structure (Fig. 5). Significant hydrogen bonding interactions are listed in Table 4 and a detailed diagram of the hydrogen bonding is shown in Fig. 6. Each cation lying perpendicular to the ribbons (labeled N8 in Fig. 6) hydrogen bonds to the $CdBr_4$ tetrahedra of a single ribbon, forming one normal (3.409(8) Å) and one bifurcated contact (with N–H···Br7 and N–H···Br5 bond distances of 3.447(8) and 3.533(8) Å, respectively). Thus, this type of

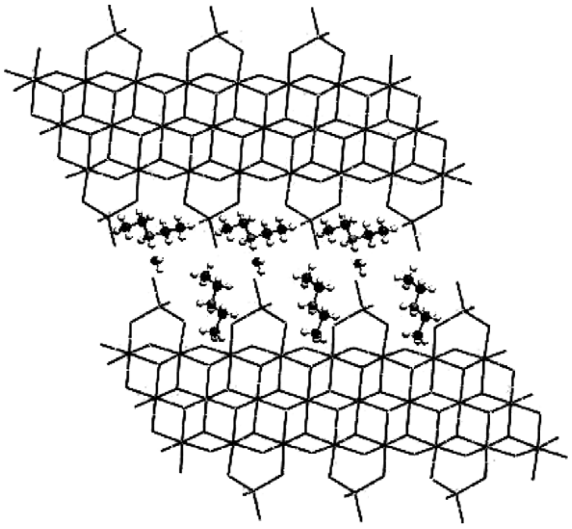

Fig. 5. Diagram of the $[DEA]_2[Cd_3Br_8(CdBr_2)]\cdot H_2O$ structure as viewed with the *a*-axis running horizontally to show the location of the $[DEA]^+$ cations and water molecules between the tetrahedral fringes. Only the cations and water molecules lying above the fringed gaps are shown.

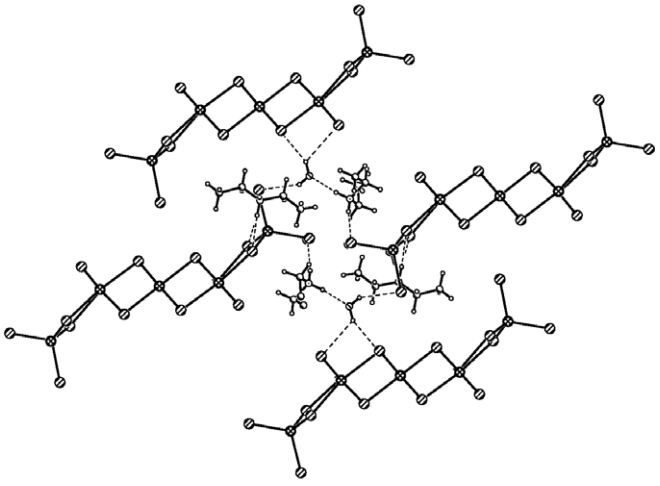

Fig. 4. Ball-and-stick packing diagram of the $[DEA]_2[Cd_3Br_8(CdBr_2)]\cdot H_2O$ structure as viewed along the *a*-axis to show the packing of the ribbons and the hydrogen bonding between water molecules and $[DEA]^+$ cations within the lattice.

Table 4
Hydrogen bonds for the structure of $[DEA]_2[Cd_3Br_8(CdBr_2)]\cdot H_2O$ (Å and °)

D–H···A	D–H (Å)	H···A (Å)	D···A (Å)	D–H···A (°)
N3–H1···O1	0.92	1.87	2.781(1)	171.5

O1–H2···Br2[a]	0.88	2.91	3.673(7)	146.8

[a] This hydrogen bond is not shown in Fig. 6.

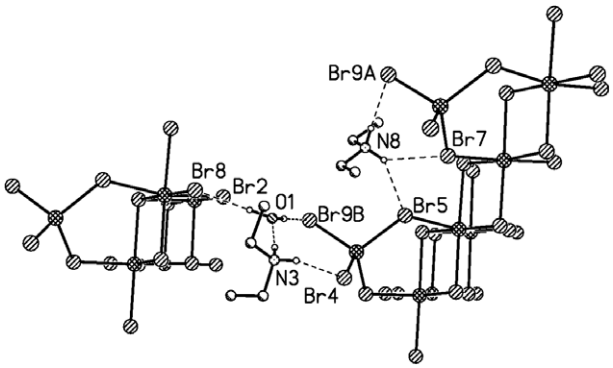

Fig. 6. Detailed diagram of the $[DEA]_2[Cd_3Br_8(CdBr_2)] \cdot H_2O$ structure to show the difference in hydrogen bonding between the two different types of cations. The hydrogen atoms on the $[DEA]^+$ cations have been removed and one of the bifurcated bonds (O1–H···Br2) is not shown for clarity.

cation is solely involved in providing partial charge balance for the ribbons. In contrast, cations containing N3 lie parallel to the ribbons and interact with water molecules to form a hydrogen bonding network which links the ribbons together. This type of cation forms a normal hydrogen bond to a terminal bromide ion on one ribbon via a N–H···Br4 (3.451(8) Å) contact and to a lattice water molecule via a N–H···O1 (2.781(1) Å) contact. The water molecule in turn forms a bifurcated hydrogen bond to two bridging bromide ions, labeled Br2 and Br8, on one ribbon and a normal hydrogen bond to a terminal bromide ion, Br9B, on an adjacent ribbon. In this manner, the three dimensional supramolecular structure is constructed.

4. Discussion

The decorated ribbon network found in this structure is a generalization of the decorated single chain network found in $(NH_3C_2H_4NH_3)[CdBr_4(CdBr_2)] \cdot 2H_2O$, illustrated in Fig. 7 [12]. In this structure, single chains of edge-shared CdX_6 octahedra are fringed by Cd ions in tetrahedral sites. These types of decorated ribbon structures can be considered as precursors to the perforated layer networks found in $Ca(H_2O)_8\{Cd_4Cl_{10}[Cd(H_2O)_2]\} \cdot 1.5H_2O$ [13] and $Ca(H_2O)_7\{Cd_4Cl_{10}[Cd_2Cl_2(H_2O)_2]\} \cdot H_2O$ [14], which are shown in polyhedral representations in Fig. 8. In these structures, ribbons composed of double chains of $CdCl_6$ octahedra are linked together via $CdCl_4(H_2O)_2$ octahedra and by pairs of $CdCl_5(H_2O)$ octahedra, respectively. The latter structure can be envisioned as arising from decorated $[Cd_2Cl_4(CdCl_2)]$ double chains via expansion of the coordination geometry of the $CdCl_4$ tetrahedra through fusion of the tetrahedra accompanied by the insertion of water molecules. In the former, expulsion of $CdCl_2$ fragments accompany the fusion process.

This process whereby the ribbons are augmented by the tetrahedral fringes can be understood on the basis of simple electrostatic arguments. A ribbon of $(Cd_nX_{2n+2})^{2n-}$ stoichiometry has an excess negative charge. This can be compensated in several ways: (a) strong, extensive

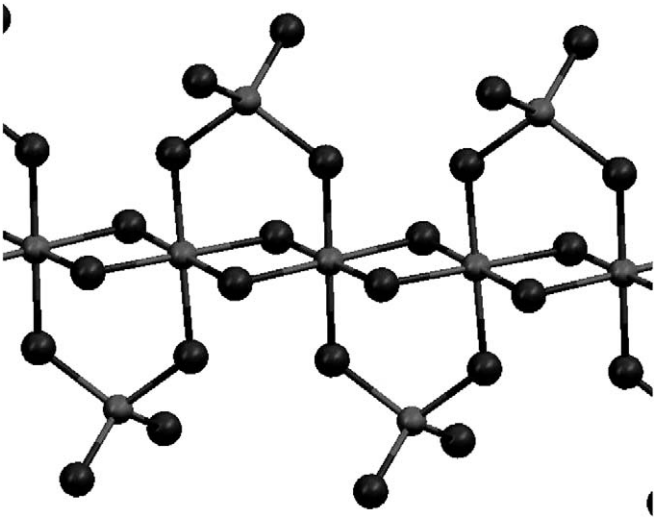

Fig. 7. Illustration of the fringed single network in $(NH_3C_2H_4NH_3)[CdBr_4(CdBr_2)] \cdot 2H_2O$.

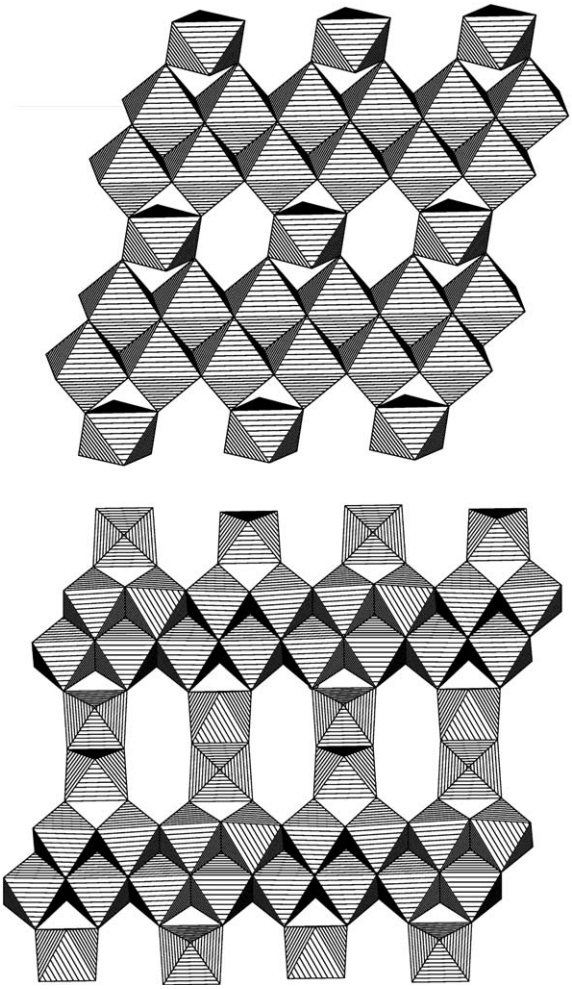

Fig. 8. Polyhedral representations of the perforated layer networks in (top) $Ca(H_2O)_8\{Cd_4Cl_{10}[Cd(H_2O)_2]\} \cdot 1.5H_2O$ and (bottom) $Ca(H_2O)_7\{Cd_4Cl_{10}[Cd_2Cl_2(H_2O)_2]\} \cdot H_2O$.

N–H···X and/or O–H···X hydrogen bonding, as in $(MEDA)_2Cd_4Cl_{12} \cdot 2H_2O$ [1]; (b) replacement of terminal halide ions by water or other solvent molecules, as in $(DEA)Cd_2Cl_5(H_2O) \cdot 2H_2O$ [6,15]; (c) addition of the CdX_2 decorations, as in the title structure. Here, the addition of the decorations reduces the X:Cd ration from 2.67 to 2.50, thus spreading the excess charge over more halide ions. In addition, the terminal halide ions are now part of tetrahedral species, rather than octahedral species, and thus are more accessible sterically for hydrogen bonding interactions.

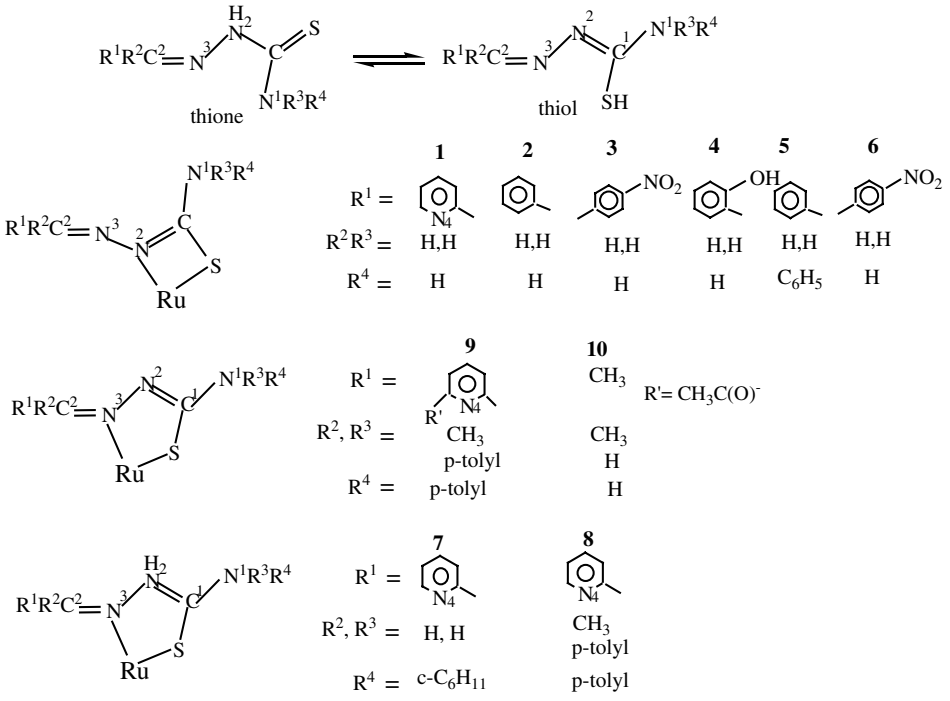

Chart 1.

coordination behaviour of these thiosemicarbazones is investigated under the influence of a potentially P,P-chelating diphosphine ligand $\{(C_6H_5)_2P–(CH_2)_4–P(C_6H_5)_2\}$ in compound **1**, and an unidenate PPh_3 ligand in compound **2**. To the best of our knowledge, compound **1** is the first example of a ruthenium(II)–thiosemicarbazone complex with a diphosphine ligand.

2. Experimental

2.1. Materials and techniques

The starting ruthenium(II) complexes, $RuCl_2(PPh_3)_3$ [12] and $Ru_2Cl_4(dppb)_3$ [13], were prepared by refluxing $RuCl_3 \cdot xH_2O$ and the suitable phosphine in dry ethanol for 5–6 h. Ligands benzaldehyde thiosemicarbazone and pyridine-2-carbaldehyde thiosemicarbazone were prepared by the reported methods [15]. Elemental analysis for C, H and N were carried out using a Thermoelectron FLASHEA1112 analyser. The melting points were determined with a Gallenkamp electrically heated apparatus. UV spectra were recorded using an UV-1601PC Shimadzu. IR spectra were recorded using KBr pellets on a Pye-Unicam SP3-300 spectrophotometer. ^{1}H NMR spectra were recorded on a JEOL AL300 FT spectrometer at 300 MHz in $CDCl_3$ with TMS as internal reference. ^{13}C NMR spectra were recorded at 75.45 MHz with TMS as internal reference. ^{31}P NMR spectra were recorded at 121.5 MHz with TMP $\{(CH_3O)_3P\}$ as external reference taken as zero position.

2.2. Synthesis of [Ru(pytsc)$_2$(dppb)] (1)

To a solution of Hpytsc (0.022 g; 0.12 mmol) in methanol (30 mL) was added solid $[Ru_2Cl_4(dppb)_3]$ (0.05 g; 0.03 mmol) followed by addition of NEt_3 (0.5 mL). The mixture was stirred for about 15 h. The red solid that formed was filtered, washed with methanol and dried. Crystals were grown from dichloromethane–acetonitrile–methanol. Yield: 51%, m.p. 172 °C. *Anal.* Calc. for $C_{42}H_{42}N_8P_2S_2Ru \cdot 2H_2O \cdot CH_3CN$: C, 54.6; H, 5.48; N, 13.02. Found: C, 54.0; H, 5.04; N, 13.25%. Main IR peaks (KBr, cm^{-1}): $\nu(NH_2) + \nu(OH_2)$ 3457m, 3360–3300m, 3150w; $\nu(C{=}N) + \delta NH_2 + \nu(C{=}C) + \delta(OH_2)$ 1585s, 1573sh, 1562sh; $\nu(C{=}S)$ 1047s; $\nu(P–C)$ 1093s; electronic spectra (CH_2Cl_2, $\lambda_{max/nm}$, ε/L mol^{-1} cm^{-1}) 391.50 (17600), 328.50 (24580), 245 (40000). ^{1}H NMR ($CDCl_3$): $\delta = 8.80$ (s, C^{2}H, 2H), 8.52 (d, C^{7}H, 2H), 7.10–7.66 (m, Ph–H + C^{4,5,6}H, 26H), 5.46 (s, NH_2, 4H), 1.26–2.89 (–CH_2–, 8 H) ppm; ^{13}C NMR ($CDCl_3$), $\delta = 182.0$ (C^1), 155.2 (C^3), 149.0 (C^7), 145.2 (C^2), 138.6–140.6 (*i*-C), 135.8 (C^5), 132.5 (*o*-C), 126.9–128.6 (*m*- and *p*-C), 122.4 (C^6), 120.7 (C^4), 30.1, 23.4 {–$(CH_2)_4$-carbons} ppm; ^{31}P NMR ($CDCl_3$), $\delta = -57.413$ ppm, $\Delta\delta(\delta_{complex} - \delta_{ligand}) = 66.48$ ppm.

2.3. Synthesis of [Ru(btsc)$_2$(Ph$_3$P)$_2$] (2)

This complex was prepared by the literature method [9]. To a solution of Hbtsc (0.0186 g; 0.1 mmol) in methanol (30 mL) was added solid $RuCl_2(Ph_3P)_3$ (0.05 g; 0.05 mmol) followed by NEt_3 base (0.5 mL). The mixture was stirred for 2 h and the yellow solid which separated was filtered,

washed with methanol and dried. The compound was recrystallized from dichloromethane–methanol solution. Yield: 60% m.p. 170 °C. Main IR peaks (KBr, cm^{-1}), $\nu(NH_2)$ 3483s, 3361s; $\nu(C{=}N) + \delta NH_2 + \nu(C{=}C)$ 1600s, 1577; $\nu(C{=}S)$ 1050s, 754 s; $\nu(P–C)$ 1087s. ^1H NMR ($CDCl_3$) $\delta = 8.88$ (s, C^2H, 2H), 5.03 (s, NH_2, 4H), 6.97–7.90 (m, $C^{2,4–6,8}H + 40H$, Ph). ^{13}C NMR ($CDCl_3$) 179.46 (C^1), 147.28 (C^2), 136.06 (C^3), 128.49 ($C^{4,8}$), 127.23 (C^5), 137.24 (*i*-C), 134.2 (t, *o*-C), 128.27 (d, *p*-C), 126.75 (t, *m*-C). ^{31}P NMR ($CDCl_3$), $\delta = -56.015$ ppm, $\Delta\delta(\delta_{complex} - \delta_{ligand}) = 57.13$ ppm.

2.3.1. Ligand NMR data

Hpytsc (dmso-d_6): ^1H NMR, $\delta = 11.57$ (s, N^2H, 1H), 8.47 (s, C^2H, 1H), 7.2–8.06 (6H, $C^{4,5,6,7} + Ph–H$) ppm. ^{13}C NMR 178.05 (C^1), 152.17 (C^3), 148.42 (C^2), 142.38 (C^7), 135.56 (C^5), 123.09 (C^6), 119.73 (C^4) ppm; Hbtsc [17] ^1H NMR $\delta = 7.27$, 6.60 (s, N^1H_2, 2H), 10.22 (s, N^2H, 1H), 9.26 (s, C_2H, 1H), 7.69 (m, $C^{4,8}H$, 2H), 7.43 (m, $C^{5,6,7}H$, 3H). ^{13}C NMR 178.86 (C^1), 143.94 (C^2), 133.99 (C^3), 130.87 (C^6), 128.96 ($C^{4,8}$), 127.54 ($C^{5,7}$); ^{31}P NMR of dppb: $\delta = -123.89$ ppm; ^{31}P NMR of PPh_3, $\delta = -113.15$ ppm.

2.4. X-ray crystallography

Suitable crystals of **1** and **2** were mounted on X-ray diffractomers (Bruker APEX II for **1**; CCD area detector for **2**), each equipped with graphite monochromators and a Mo Kα radiation source ($\lambda = 0.71073$ Å). The unit cell dimensions and intensity data were measured at 293 K. The structures were solved by direct methods and refined by full-matrix least-square methods based on F^2 with anisotropic thermal parameters for non-hydrogen atoms, using Bruker SMART (data collection and cell refinement), Bruker SHELXTL (data reduction and computing molecular graphics), SHELXS-97 (structure solution) and SHELXL-97 (structure refinement)] [16]. An empirical absorption correction was applied. Calculated positions for the H atoms were used in structure factor (SF) calculations. ω scans were to 56° (2θ). In compound **1**, one of the pyridine groups in each pytsc ligand was found to be disordered and these atoms were treated in an equal population model. One of the terminal pyridyl groups displayed disorder. During refinement the disorder in this group was resolved. Selected crystal data for compounds **1** and **2** are given in Table 1.

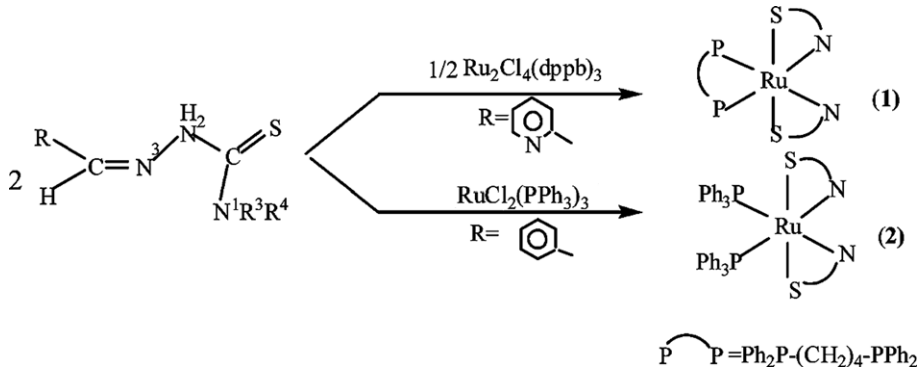
3. Results and discussion

3.1. Synthesis and IR spectroscopy

Scheme 1 shows the formation of complexes **1** and **2**. Reaction of $Ru_2Cl_4(dppb)_3$ {dppb = $Ph_2P–(CH_2)_4–PPh_2$} with pyridine-2-carbaldehyde thiosemicarbazone {$C_5H_4N–C(H){=}N^3–N^2H–C(=S)NH_2$, Hpytsc}, and that of $RuCl_2(PPh_3)_3$ with benzaldehyde thiosemicarbazone {$C_6H_5–C(H){=}N^3–N^2H–C(=S)–NH_2$, Hbtsc}, in the presence of Et_3N base led to loss of the $–N^2H–$ proton in each case, and yielded [Ru(pytsc)$_2$(dppb)] (**1**) and [Ru(btsc)$_2$(Ph_3P)$_2$] (**2**) [9], respectively. Both the complexes



Scheme 1.

are soluble in dichloromethane, chloroform, acetone or toluene, but partially soluble in acetonitrile. The compounds are stable in air in the solid state; however in solution phase the complexes turn green on standing for a long time.

Due to the presence of H_2O in complex **1**, the ν(N–H) region has broad signals at 3457m, 3360–3300m and 3150w, and these peaks are attributed to ν(N–H) + ν(O–H). However in complex **2**, the ν(N–H) region shows sharp peaks at 3483s and 3361s. The free ligands show very strong signals due to ν(N–H) of the hydrazinic –N^2H– group in the region 3140–3150 cm^{-1} [14,18]. Thus in complex **2**, it is unequivocally established that deprotonation of the N^2H proton occurs after complexation; and in complex **1** due to obscuring of the ν(N–H) region by water, deprotonation of the N^2H proton appears less apparent. It may be pointed out here that in a series of complexes of copper(I) with neutral thiosemicarbazones, ν(N–H) of the hydrazinic –N^2H– group was clearly visible though shifted from the free ligand position [19]. Other important IR peaks are listed in the Section 2. The thioamide bands ν(C=S) + ν(C–N) appear in the range 1050–803 cm^{-1} (cf. free ligands, 1060–817 cm^{-1}), and on complexation, these shift to either lower energy or higher energy, but the shifts are not significant. The appearance of characteristic ν(P–C_{Ph}) bands at around 1090 cm^{-1} indicates the presence of Ph_3P and dppb in the complexes.

3.2. Crystal structures

The atomic numbering schemes for **1** and **2** are given in Figs. 1 and 2 respectively, and selected bond angles and bond lengths are listed in Table 2. Compounds **1** and **2** crystallized in triclinic crystal systems with the space group $P\bar{1}$ in each case. In compound **1**, the thiosemicarbazone ligand in its deprotonated form (pytsc$^-$) is chelating via its N^2, S-donor atoms, thus forming four membered chelate rings with average Ru(II)–N and Ru(II)–S distances of 2.202 Å and 2.418 Å, respectively, and the pyridyl group is pendant. The diphosphine ligand (dppb) is also chelating via its P,P donor atoms with an average Ru–P distance of 2.264 Å (Tables 2 and 3). The donor atoms around the Ru(II) center occupy *cis*:*cis*:*trans* N,N:P,P:S,S positions. The angles around the Ru(II) center lie in the range, 65–163°, with a N^2–Ru–S bite angle of 65.85°, N–Ru–N angle of 83.07° and *trans* S(1)–Ru–S(2) angle of 163.30°. The diphosphine ligand dppb forms a seven membered chelate ring with a P–Ru–P angle of 94.54°. Similarly, compound **2** has average Ru(II)–N, Ru(II)–S and Ru–P distances of 2.145, 2.410 and 2.301 Å, respectively. The average bond angles for N^2–Ru–S, N–Ru–N, S–Ru–S, P–Ru–P are 65.80°, 78.80°, 162.54° and 105.37°, respectively. The geometry of both the complexes is distorted octahedral.

On comparing the bond parameters of **1** and **2**, the most striking difference is found in their Ru–N and Ru–P distances. Interestingly, the Ru–P distances of **1** are shorter and its Ru–N distances are longer as compared to those of **2**. This shows the chelating effect of the dppb ligand which forms stronger Ru(II)–P bonds as compared to Ru(II)–PPh_3 bonds, which in turn affect the Ru(II)–N bonds *trans* to Ru–P bonds. The Ru–P distance for **1** is the shortest among all the complexes listed in Table 3. The Ru–S bonds remain unaffected by this change as can be seen by comparing the bonds in both the compounds. The C–S distances in both the compounds are similar, in

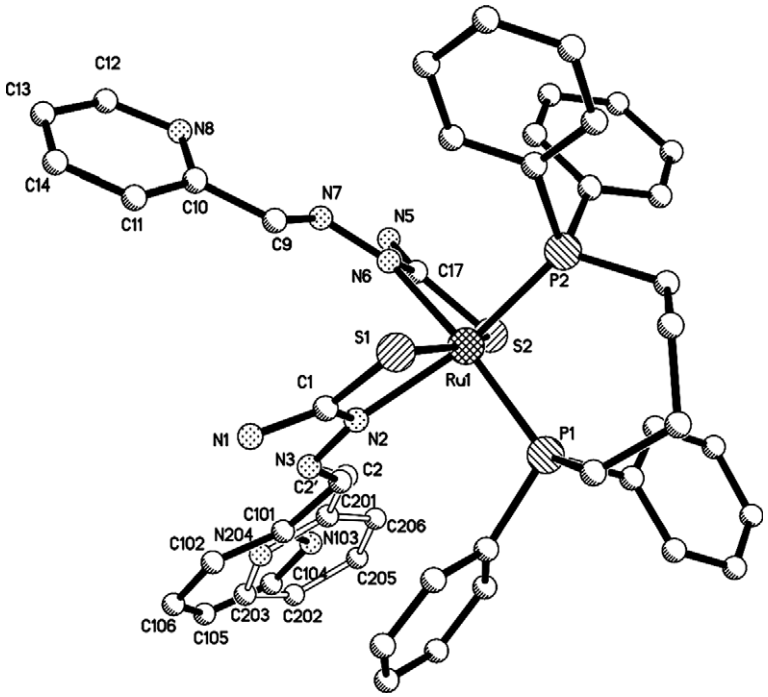


Fig. 1. The structure of [Ru(pytsc)$_2$(dppb)] (**1**) with the atomic numbering scheme.

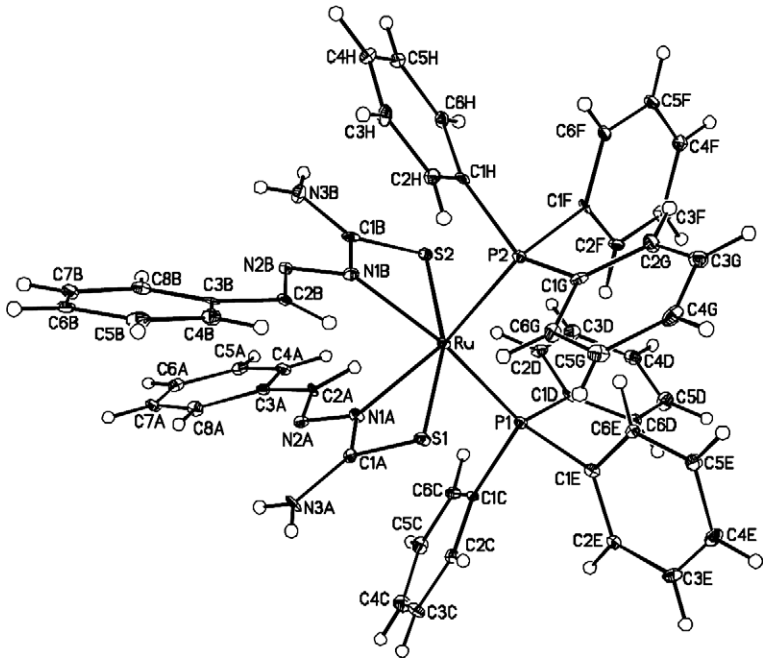

Fig. 2. The structure of $[Ru(btsc)_2(PPh_3)_2]$ (**2**) with the atomic numbering scheme.

N(1B)–Ru–P(2)	89.02(15)	N(1B)–Ru–S(2)	65.85(14)
P(1)–Ru–P(2)	105.37(7)	P(1)–Ru–S(2)	104.21(6)
N(1A)–Ru–S(1)	65.75(14)	P(2)–Ru–S(2)	85.43(6)
S(1)–Ru(1)–S(2)	162.54(6)		

the range 1.68–1.71 Å, which is shorter than a C–S single bond of 1.81 Å but longer than a C–S double bond of 1.62 Å, indicating a partial double bond character [20].

The second major difference lies in the P–Ru–P bond angle which is smaller for **1** as compared to that in **2**, and this is attributed to the presence of bulky PPh_3 ligands adjacent to each other which causes this angle to deviate towards the higher side. As a matter of fact, the P–Ru–P bond angle of **1** is the smallest among all the Ru(II) complexes of thiosemicarbazones reported to date. The N–Ru–N bond angle in **1** is bigger than that in **2**, and this variation is attributed to the scissoring effect of P–Ru–P angles. The S–Ru–S bond angles in both the complexes are comparable and are similar to other complexes reported in the literature (Table 3). From Table 3, it may be noted that parameters of **2** are very close to those of complexes **3**–**5**, but different from those of **1**. Complexes **1**–**5**, forming four-membered rings, have a bite angle of ca. 66°, which is small relative to the bite angles (ca. 81°) of complexes (**7**–**9**) which form five-membered rings.

Compounds **1**–**5** are analogous with four membered rings formed by the thiosemicarbazone, the steric bulk of the phosphines appears to favour N^2, S chelation irrespective of the substituents on the C^2 or N^1 atoms. Compound **7** has N^3, S chelation with five membered ring formation, despite the presence of bulky PPh_3 ligands in the *cis* position, and it is apparent that the presence of bulky groups at the N^1 atom appears to disfavour N^2, S chelation. In **8** and **9** the steric effect of PPh_3 is less demanding in view of the presence of one thiosemicarbazone ligand in each complex and this leads to a large P–Ru–P bond angle and also both have bulky R groups at N^1 and this leads to N^3, S chelation. As regards compound **6** and **10**, each have two bipyridine ligands and the only difference lies in the presence of substituents at the C^2 carbon while the substituents at $N^1$are identical (R^3, $R^4 = H$). This difference leads to N^2, S chelation in **6** and N^3, S chelation in **10**.

3.3. NMR spectroscopy

The signals due to N^2H protons in the free ligands (see Section 2) were absent in the complexes **1** and **2**, and it showed that the ligands are uninegative. The NH_2 protons appear as single peaks in both the complexes due to free rotation of the N^1H_2 group along the C^1–N^1 bond axis, instead of two broad peaks as observed in the free ligands, due to the restricted rotation of the N^1H_2 group along the C^1–N^1 bond axis at room temperature [18]. All other protons appear in the aromatic region as multiplets and overlapping signals. The ^{13}C NMR spectra of both the compounds showed bands due to tsc^- anions and phosphine ligands (cf. Section 2). The C^1 carbons of both ligands move downfield, and it shows coordination via the S-donor atom, and likewise C^2 and C^3 move downfield, but the shift is small. All other tsc^- carbons show much smaller shifts. Various signals due to *ipso*, *ortho*, *meta* and *para* carbons of the phosphine ligands are resolved in the complexes. Finally, the ^{31}P NMR spectra of **1** and **2** showed coordination shifts $\{\Delta\delta(\delta_{complex}-\delta_{ligand})\}$ of 66.48 and 57.13 ppm, respectively, revealing that both the phosphorus atoms are equivalent in each case, and that the dppb ligand binds more strongly than PPh_3, in conformity with the structural data.

4. Conclusion

Compound **1** represents the first example of a ruthenium(II) complex with a chelating diphosphine, forming a stable seven membered P,P-chelate ring in the presence of a potentially tridentate pyridine-2-carbaldehyde thiosemicarbazonate anion coordinating via N^2, S-donor atoms, which is stable in solid and solution states. For R = Ph and py at the C^2 carbon of the tsc^- ligands, the mode of coordination remains same, viz., N^2, S.

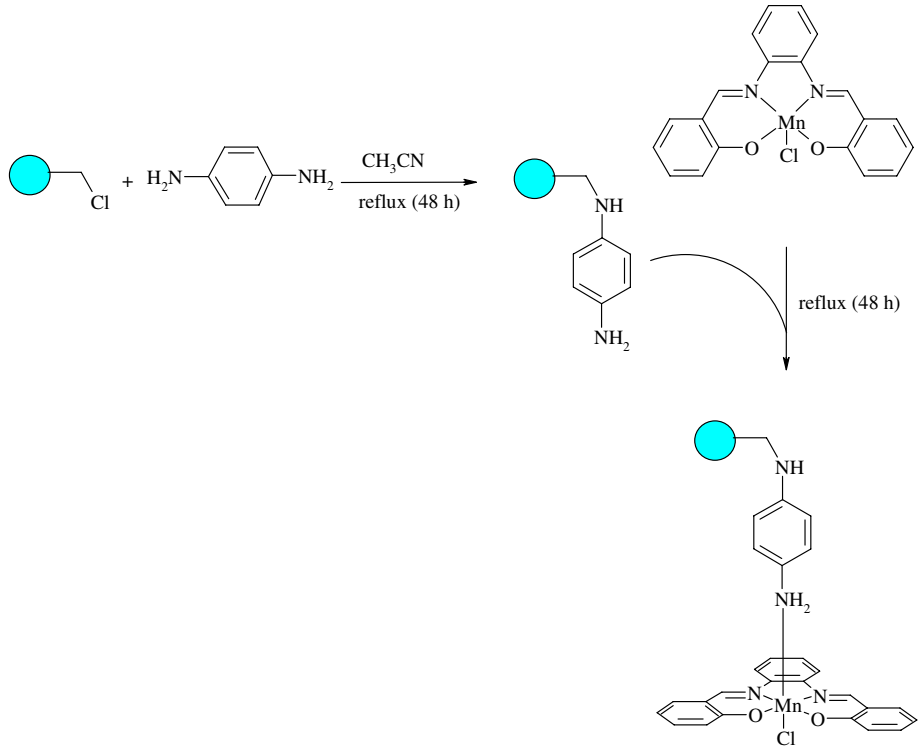

Scheme 1. Preparation of polymer supported catalyst, [Mn(salophen)Cl-PSP].

in many ways, namely: (a) non-covalent immobilization in zeolites, clay or siloxane membranes [22–25]; (b) covalent grafting onto inorganic supports such as silica or MCM-41 [26–30]; (c) co-polymerization of a functionalized salen monomer into an organic polymer [31]; and (d) attachment or build-up of a salen structure to a performed polymer [32–37]. Polymers, which are used as supports, have gained much attention being inert, non-toxic, non-volatile, insoluble and often recyclable. Imidazoles and pyridines were chosen since they ligate strongly to the axial positions of metallosalens in free solution [38,39], and furthermore, such a nitrogen base can increase the catalytic efficiency in the epoxidation with single oxygen atom donors.

This paper describes a catalytic system based on a chloromethylated polystyrene support modified with 1,4-phenylenediamine, which can act as an axial ligand for Mn(salophen) by covalent attachment (Scheme 1). The heterogeneous Mn(salophen) catalyst, [Mn(salophen)Cl-PSP], was characterized by FT-IR, UV–Vis and TG–DTG. Catalytic activity and reusability of this catalyst in the heterogeneous epoxidation of alkenes and hydroxylation of alkanes has also been demonstrated.

2. Results and discussion

2.1. Preparation of polymer-supported manganese salophen catalyst, [Mn(salophen)Cl-PSP]

Chloromethylated polystyrene (cross-linked with 2% divinylbenzene, 4–5% Cl content, 1.14–1.40 mmol/g Cl) was treated with an appropriate quantity of 1,4-phenylenediamine, using CH_3CN as solvent, and was refluxed for 48 h [40]. The supported [Mn(salophen)] was prepared by stirring a suspension of the support, (PSP), in a solution of Mn(salophen) in CH_3CN as solvent, because of better solvation and swelling of the polymer in it. The degree of incorporation of manganese salophen into the polymer was determined by neutron activation analysis (NAA). The covalent bonding of the polymer and the manganese salophen is so strong that Mn(III)-salophen is not eluted from the polymer with water and common organic solvents.

2.2. Characterization of catalyst

The prepared catalyst was characterized by IR, UV and TGA. [Mn(salophen)Cl-PSP] was characterized by elemental analysis. The amount of grafted Mn(salophen), which was calculated by neutron activation analysis (NAA), was 0.136 mmol/g base on Mn. The nitrogen content of this resin was 2.06%. According to this value, the degree of 1,4-phenylenediamine which was introduced into the polymer composition was 0.735 mmol/g of support. This shows that only 53–64% of the total chlorine was substituted by 1,4-phenylenediamine.

The diffuse reflectance spectra provide further evidence for the presence of the Mn(salophen) complex on the support. The absorption spectrum of [Mn(salophen)Cl-PSP] exhibits a broad peak near 450 nm which could be due to the d–d transition of Mn(III). Its homogeneous counterpart also shows a peak near 450 nm, which indicates the presence of the manganese catalyst on the polymer (Fig. 1).

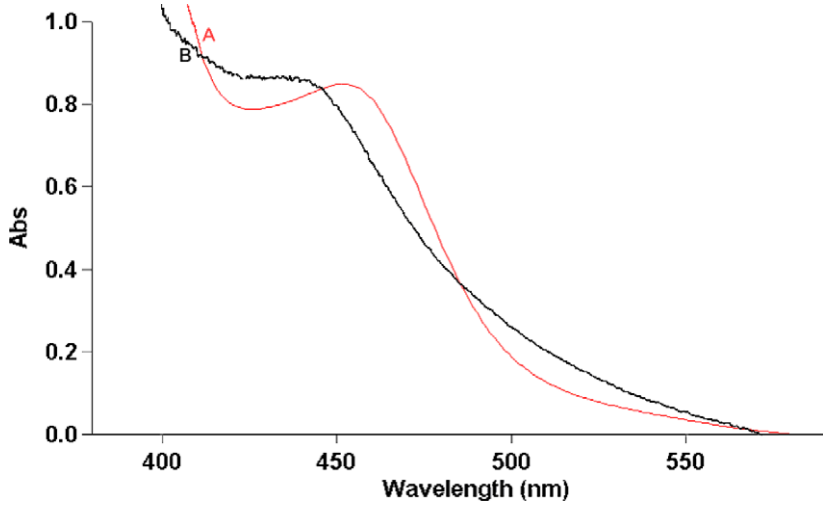

Fig. 1. UV–Vis spectra of: (a) Mn(salophen)Cl; (b) [Mn(salophen)Cl-PSP].

In order to ascertain the attachment of salophen on the polymer support, IR spectra were recorded in the (4000–400 cm^{-1}) regions. The sharp C–Cl peak (due to $–CH_2Cl$ groups) at 1264 cm^{-1} in the starting polymer (Fig. 2a) practically disappeared or was seen as a weak band after introduction of 1,4-phenylenediamine and manganese salophen on the polymer. The appearance of a band in the region of 1629–1550 cm^{-1}, assigned to $\nu_{C=N}$ (azomethine), and a medium intensity band due to stretching C–N at 1193 cm^{-1} clearly indicate the promotion of manganese salophen on the support (Fig. 2b and c).

Differential thermal analysis and thermogravimetric analysis have been used to characterize the immobilized of the metal complex. The decomposition behavior of the free complex and supported complex has been compared in order to understand the effect of the supporting (Fig. 3). The free complex shows a weight loss of 72% at a temperature 305 °C (Fig. 3a). However, for the corresponding supported complex, a 43% weight loss appears at the temperature 308 °C and a 54% weight loss appears at 418 °C (Fig. 3b). TG and DTA analysis for the free complex and supported complex indicated no change in thermal stability of the polymer after the complex is anchored, which may be due to the dissociation of covalently bound salophen ligand moieties or partial scission of the polymeric chain might be occurring at the same temperature [41]. These criteria indicate that the catalyst is thermally stable up to 200 °C.

2.3. The effect of terminal oxidants on the oxidations of cyclooctene catalyzed by Mn(salophen)Cl-PSP

In the catalytic epoxidation of alkenes the choice of oxygen donor and solvent is of crucial importance. In this study, we investigated the ability of different oxidants, such as NaOCl, $NaIO_4$, Bu_4NIO_4, H_2O_2, $KHSO_5$ and *tert*-butylhydroperoxide, urea–H_2O_2 (UHP), in the epoxidation of cyclooctene, catalyzed by the heterogeneous Mn(III) salophen. The results are summarized in Table 1. When NaOCl, H_2O_2, *tert*-butylhydroperoxide and urea–H_2O_2 (UHP) were used as the oxygen source, either in acetonitrile or dichloromethane, only small amounts of cyclooctene oxide was detected in the reaction mixture. The use of Oxone ($KHSO_5$) was not favored because of disadvantages such as needing a buffered media and the bleaching of the metal catalysts during the oxidation reactions.

The results show that in the presence of the Mn(salophen)Cl-PSP catalyst, $NaIO_4$ is the best oxygen source, because of good oxidation conversions, inertness in the absence of catalyst and high solubility in the CH_3CN/H_2O mixture.

2.4. The effect of solvent on the oxidation of cyclooctene catalyzed by [Mn(salophen)Cl-PSP]

The epoxidation of cyclooctene was studied in various solvents at room temperature (Table 2). Among the mixtures of methanol, ethanol, acetone, acetonitrile (single phase systems), chloroform, dichloromethane and carbontetrachloride (two phase systems with Bu_4NBr as a phase transfer catalyst) with water, the 2:1 mixture of acetonitrile/water mixture was chosen as the reaction medium, because a higher epoxidation yield was observed. The higher catalytic activity in aqueous acetonitrile is attributed to the polarity of the solvent, better swelling of the polymer and solubility of $NaIO_4$ in the solvent.

2.5. Catalytic alkene epoxidation with $NaIO_4$ catalyzed by Mn(salophen)Cl-PSP

It is well known that the catalytic ability of manganese Schiff bases is improved by the use of a nitrogen base as a co-catalyst [38,39]. In this study, the polystyrene-bound 1,4-phenylenediamine, was not only used as a support, but it also plays the axial ligand role in this catalytic system. Reactions were performed at room temperature

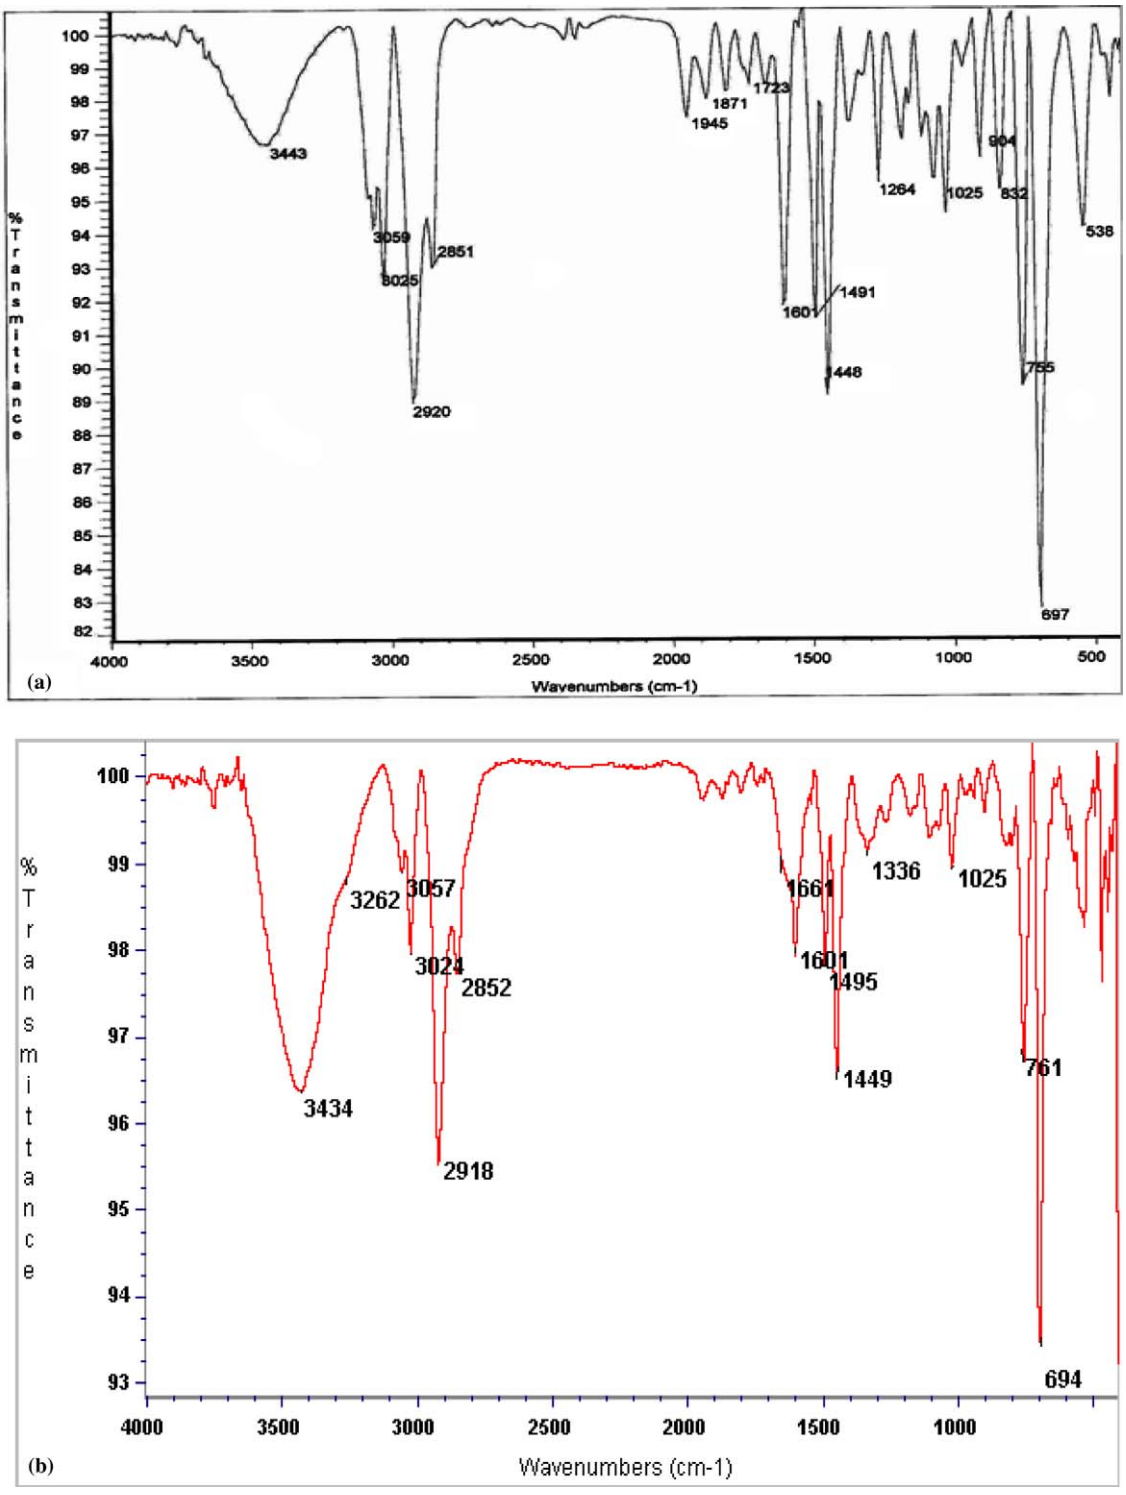

Fig. 2. (a) Chloromethylated polystyrene; (b) chloromethylated polystyrene modified with 1,4-phenylenediamine; (c) Mn(salophen)Cl-PSP; (d) recovered Mn(salophen)Cl-PSP.

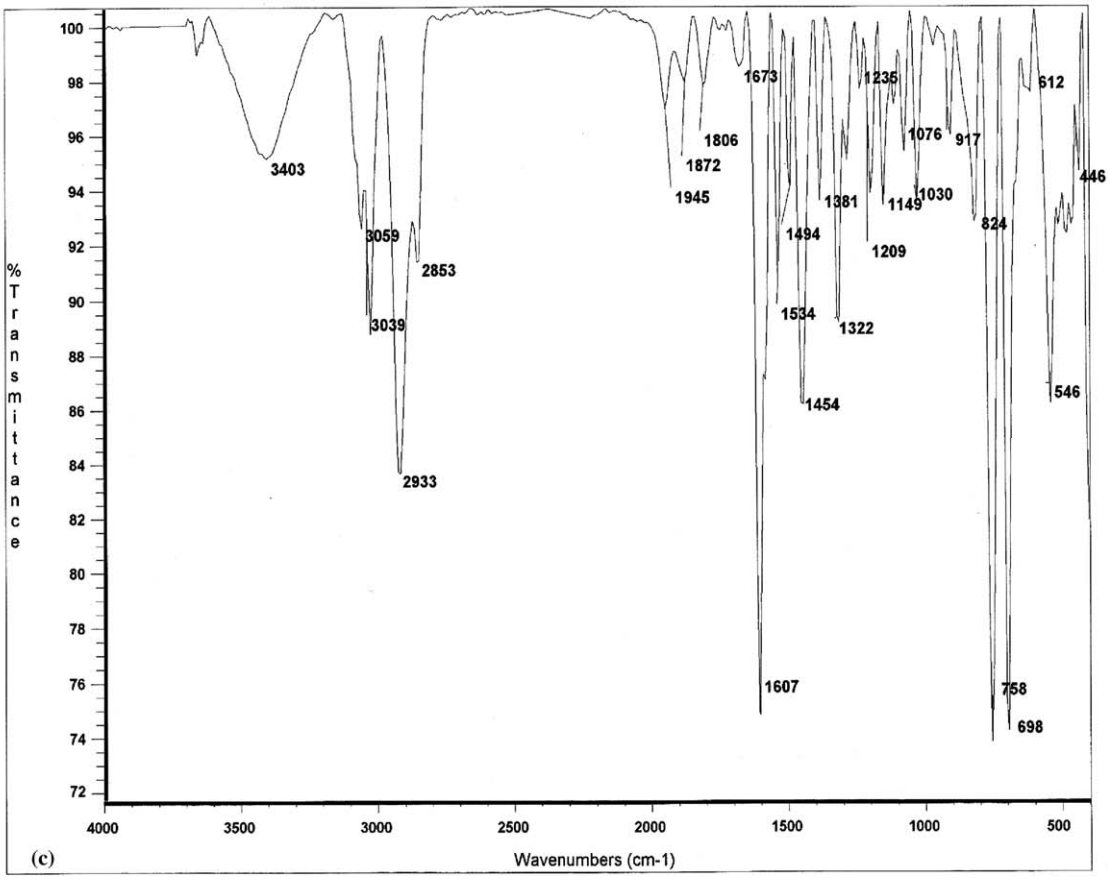
under air in CH_3CN/H_2O containing the alkene, oxidant and catalyst. This catalytic system led to the epoxidation of various alkenes (Table 3) with good to excellent yields (64–99%). Cyclooctene was oxidized in the presence of this catalyst in high yield. Styrene and α-methylstyrene were oxidized to styrene oxide and α-methylstyrene oxide in 96% and 99% yield, respectively (see Table 3, entries 3 and 4). Under the heterogeneous Mn-catalyzed conditions and only traces of undesirable benzaldehyde and acetophenone were detected. Similarly, oxidation of cyclohexene was achieved in a high conversion yield and only 8% of cyclohexenone was produced. Epoxidation of



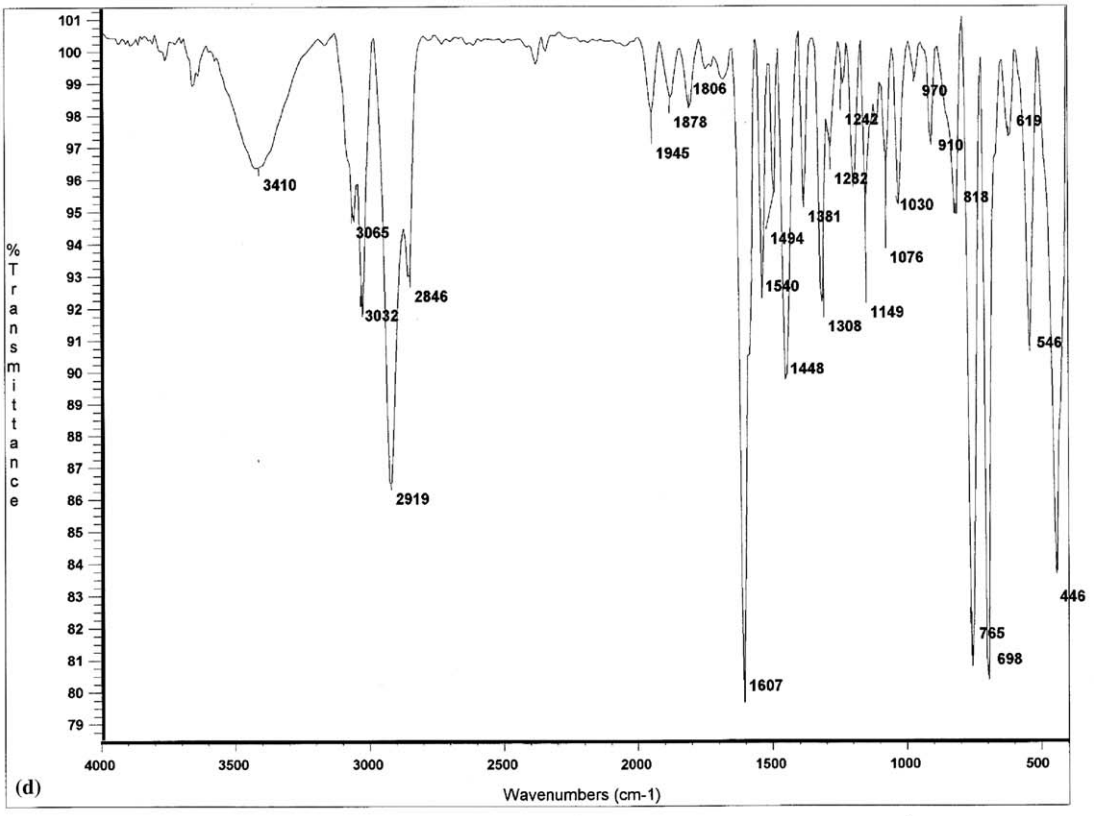


Fig. 2 (*continued*)

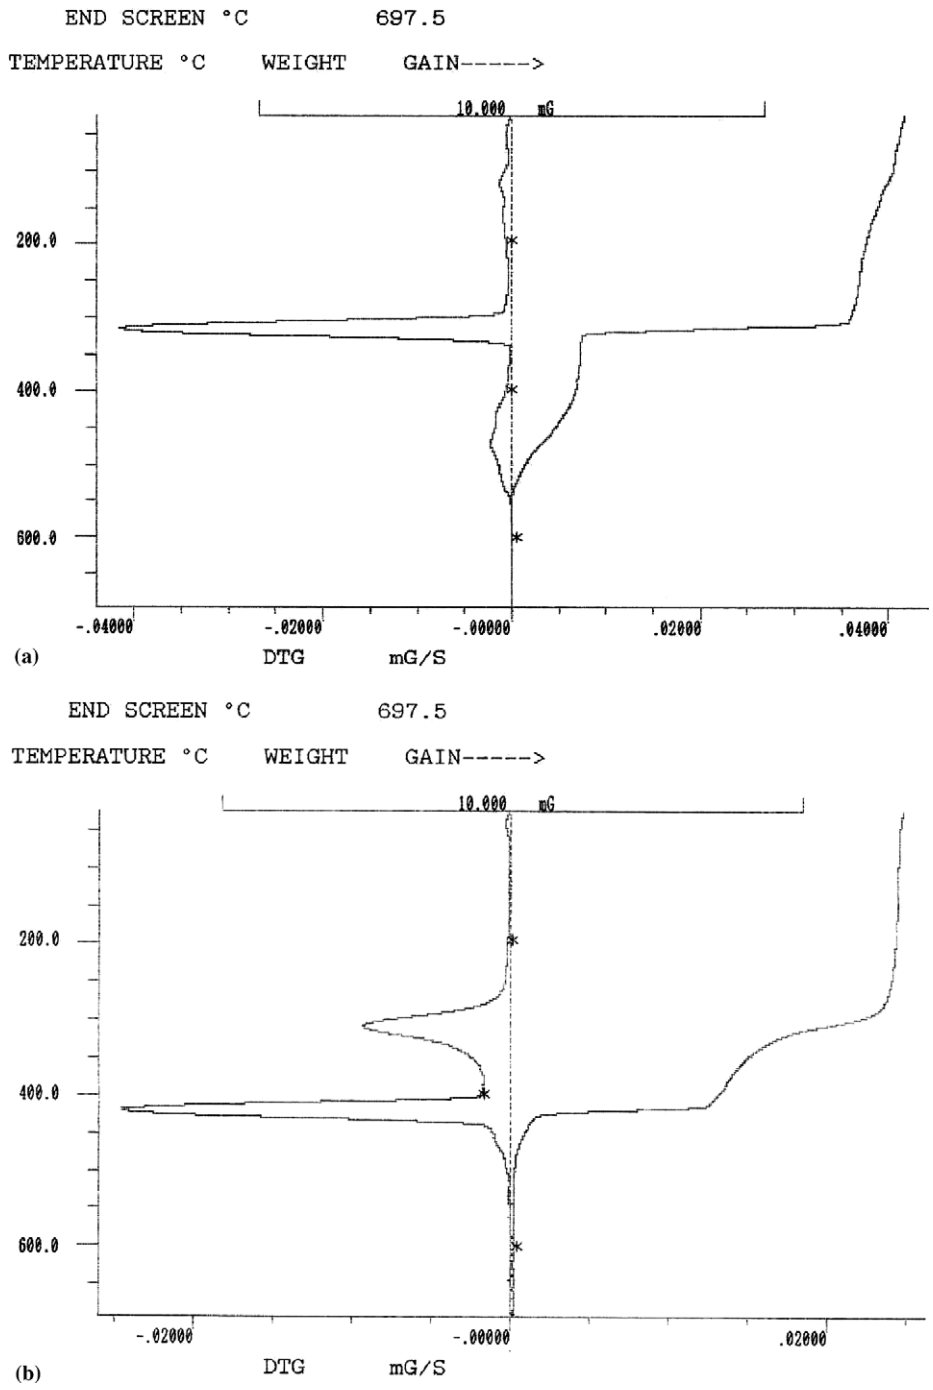

Fig. 3. TG–DTA curves of: (a) Mn(salophen)Cl; (b) Mn(salophen)Cl-PSP.

trans-stilbene proceed in a stereospecific manner with complete retention of configuration. In contrast, the epoxidation of *cis*-stilbene is associated with some loss of stereochemistry and affords 58% *cis*- and 23% *trans*-stilbene oxides, respectively. Apparently, formation of the thermodynamically more stable *trans*-stilbene oxide requires free rotation about the alkene C–C bond during some intermediate steps; such a rotation is expected to be more feasible using catalysts with less steric strain, as observed [42]. We used linear, cyclic and phenyl substituted olefins as substrates in this system. Electron-rich cyclic olefins are more active than the electron-poor terminal olefins. This reflects the electrophilic nature of oxygen transfer from the manganese-oxo intermediate to the olefinic double bond. This catalytic system shows a good activity in the epoxidation of linear alkenes such as 1-hexene and 1-dodecene. The Mn(salophen)Cl-PSP/$NaIO_4$ catalytic system exhibits good regioselectivity in the epoxidation of (*R*)-(+)-limonene. The ratio among 1,2- and 8,9-epoxide was found to be 2.4:1.

In the case of α-pinene, the major product is α-pinene oxide (93%), and allylic oxidation products, Verbenone

[c] The by-product is 4% benzaldehyde for the heterogeneous system and 15% for the homogeneous system.
[d] The by-product is acetophenone.
[e] Both ^{1}HNMR and GLC data approved the reported yields.
[f] The by-products are 7% verbenone and 3% verbenol for the heterogeneous system and 3% verbenone and 2% verbenol for the homogeneous system.

(which is used as a building block of taxol) and Verbenol, were produced as minor products (Scheme 2).

A blank experiment in the presence of oxidant and using the same experimental conditions in the absence of catalyst was also investigated in the epoxidation of cyclooctene. The obtained results showed that $NaIO_4$ has poor ability to oxidize the cyclooctene. Also, no cyclooctene oxide was detected in the absence of oxidant in the reaction mixture.

The ability of aqueous manganese(II) salts, which was previously reported in the alkene epoxidation with H_2O_2 [43], was also investigated in the epoxidation of cyclooctene. The results indicated that these salts were unable to catalyze the epoxidation of cyclooctene with sodium periodate.

The polystyrene-bound 1,4-phenylenediamine modified with $Mn(II)ClO_4$ was also tested for its activity in the epoxidation of cyclooctene with $NaIO_4$. The amount of cyclooctene oxide after 6 h was 13%.

2.6. Oxidation of alkanes with $NaIO_4$ catalyzed by Mn(salophen)Cl-PSP

Direct oxidation of hydrocarbons is also one of the typical reactions of cytochrome P-450 [3]. The catalytic oxidation of alkanes with oxygen sources under mild conditions is an especially rewarding goal, since direct functionalization of inactivated C–H bonds in saturated hydrocarbons usually requires drastic conditions such as high pressure and high temperature. As shown in Table 4, we have found that the supported Mn(salophen)Cl is an efficient catalyst for the biomimetic functionalization of saturated hydrocarbons. Over oxidation of the alkane, the hydroxylation product is highly dependent on the nature of the hydrocarbon itself. Cyclooctane, cyclohexane, 1,2,3,4-tetrahydronaphthalene and adamantane were converted in high yields to their corresponding alcohols and ketones. In

contrast, ethylbenzene, propylbenzene and fluorene only produced the corresponding ketones. In the case of adamantane, 1-adamantanol and 2-adamantanone were produced in the reaction mixture.

2.7. Catalyst reuse and stability

To assess the long-term stability and reusability of [Mn(salophen)Cl-PSP], cyclooctene was used as a model substrate, and recycling experiments were carried out with a single sample of the catalyst. After each experiment, the catalyst was separated from the reaction mixture by simple filtration, washed with the methanol and dried carefully before using it in the subsequent run. After the use of the catalyst four consecutive times, the epoxide yields were 94%. No manganese was detectable in the filtrates by atomic absorption spectrometry (Table 5).

The nature of the recovered catalyst has been followed by IR. The results indicated that after reusing the catalyst several times, it showed no change in its IR spectra (Fig. 2c).

2.8. Comparison of homogeneous Mn(salophen)Cl and heterogeneous Mn(salophen)Cl-PSI in alkene epoxidation and alkane hydroxylation with sodium periodate

In order to demonstrate the effect of supporting on the catalytic activity of manganese (III) salophen in the alkene epoxidation and alkane hydroxylation with sodium periodate, we repeated all reactions under the same reaction conditions and with the same amounts of catalyst, substrate, $NaIO_4$ and imidazole as axial ligand in a CH_3CN:H_2O mixture. The obtained results are summarized in Tables 3 and 4 for alkene epoxidation and alkane hydroxylation, respectively.

In the alkene epoxidation, the production of by-products in the heterogenized system decreased in comparison with the homogeneous system. In the case of *R*-(+)-limonene, the ratio among 1,2- and 8,9-epoxide increased from 1.96 to 2.4. While, *cis–trans* isomerization decreased in the case of *cis*-stilbene, in which the ratio of *cis*/*trans* stilbene oxide increased from 1.64 to 2.52. The Mn(salophen)-PSP/$NaIO_4$ catalytic system showed a higher catalytic activity in the oxidation of linear alkenes (Table 3, entries 9 and 10).

Table 5
The results of [Mn(salophen)Cl-PSP] catalyst recovery and the manganese leached in the epoxidation of cyclooctene with sodium periodate

2.9. Conclusion

We have demonstrated that the supported manganese(III) salophen complex catalyst is featured by: (i) easy preparation and handling of the tethered catalyst; (ii) no need of axial ligand in the catalytic system; (iii) facile and effective recovery and recycling; (iv) catalyst efficiency comparable to that observed in the homogeneous phase.

3. Experimental

All materials were commercial reagent grade. Chloromethylated polystyrene (4–5% Cl and 2% cross-linked with divinylbenzene) was a product of Merck. Alkene, alkane and alkylaromatic compounds were obtained from Merck or Fluka. All of these compounds were passed through a column containing active alumina to remove peroxidic impurities.

3.1. Preparation of the salicylaldehyde-o-phenylenediimine(salophen) ligand

The Schiff base ligand was prepared by the standard procedure of refluxing ethanolic solutions of the corresponding diamine and salicylaldehyde derivative in a 1:2 molar ratio [44].

A stoichiometric amount of salicylaldehyde (2.44 g) in ethanol (25 mL) was added drop by drop to an alcoholic solution of *ortho*-phenylenediamine (1.08 g in 25 mL ethanol). The mixture was refluxed for 3 h and a bright yellow precipitate was separated by filtration, washed and dried in vacuum. It was then recrystallized from ethanol to yield the salophen ligand (2.8 g).

3.2. Preparation of Mn(III) salophen

The salophen ligand (1.58 g) was dissolved in hot absolute ethanol. Solid hydrated manganese(II) acetate (2.45 g) was added and the solution was refluxed for 1 h. Approximately, three equivalents of lithium chloride was then added, and the mixture was heated to reflux for an additional 0.5 h. Cooling the mixture to 273 K afforded the Mn(III) complex as dark brown crystals. Elemental analysis confirmed the obtained complex; [Mn(salophen)Cl], [*N*,*N*′-bis(salicylidine)-*o*-phenylenediaminato]manganese(III) chloride: UV–Vis, λ_{max}/nm: 285, 296, 330, ~430 (sh); FT-IR, ν/cm^{-1}: 1609 (vs), 1572 (vs), 1535 (vs), 1481 (m), 1445 (m), 1381 (m), 1313 (m), 1206 (m), 1152 (m), 888 (w), 816 (m), 756 (s), 657 (m), 548 (m) and 440 (w).

3.3. Preparation of polymer-supported manganese salophen

To a solution of 0.4 g manganese(III) salophen in acetonitrile (100 mL) was added chloromethylated polystyrene-bound 1,4-phenylenediamine (3 g). The mixture was vigorously stirred at 80 °C for 24 h. After cooling to room temperature, the brown resin was collected by filtration, washed thoroughly with acetonitrile, methanol and diethyl

ether, successively, and dried in vacuum at room temperature for several hours. The content of mangenese(III) salophen on the polymer support, which was calculated from the manganese content of the heterogenized catalyst, was determined by NAA.

3.4. Physico-chemical measurements

Diffuse reflectance spectra were recorded on a Shimadzu UV-265 instrument using optical grade $BaSO_4$ as reference. Thermogravimetric analysis of the catalyst was carried out on a Mettler TA4000 instrument. FT-IR spectra were obtained as potassium bromide pellets in the range 400–4000 cm^{-1} with a Nicolet-Impact 400D instrument. Gas chromatography experiments (GC) were performed with a Shimadzu GC-16A instrument using a 2 m column peaked with silicon DC-200 or Carbowax 20 m. ^1H NMR spectra were recorded on a Bruker-Arance AQS 300 MHz spectrometer.

3.5. General procedure for catalytic oxidation reactions catalyzed by [Mn(salophen)Cl-PSP]

All of the reactions were carried out at room temperature under air in a 25 ml flask equipped with a magnetic stirrer bar. A solution of $NaIO_4$ (1 mmol) in H_2O (2.5 ml) was added to a mixture of alkene or alkane (0.5 mmol), and Mn(salophen)-PSP (0.054 mmol) in CH_3CN (5 ml). The progress of the reaction was monitored by GLC. The reaction mixture was diluted with CH_2Cl_2 (20 ml) and filtered. The resin was thoroughly washed with CH_2Cl_2 and combined washings and filtrates were purified on silica-gel plates or a silica-gel column. IR and ^1HNMR spectral data confirmed the identities of the products. Blank experiments with each oxidant and using the same experimental conditions but without the catalyst were also performed.

3.6. General procedure for catalytic epoxidation of alkenes and hydroxylation of alkanes with sodium periodate catalyzed by Mn(salophen)Cl

To a 25 ml round-bottom flask containing alkene or alkane (0.5 mmol), Mn(salophen)Cl (0.05 mmol) and imidazole (0.05 mmol) in CH_3CN (5 ml) were added a solution of $NaIO_4$ (1 mmol) in H_2O (2.5 ml). The reaction progress was monitored by GLC. At the end of the reaction, the reaction mixture was diluted with water (20 ml) and the products and substrate were extracted with CH_2Cl_2 (2×10 ml). The extracts were purified on silica-gel plates or a silica-gel column. IR and ^1HNMR spectral data confirmed the identities of the products.

result, as the biological chemistry of mercury is dominated by coordination to cysteine [13]. The preference of Hg for sulfur donor sites, due to its soft nature, is well known. In mercury thiolates, apart from the Hg–S bond, the possibility of a secondary mercury(II)–sulfur interaction has also been reported [14–16], which makes it difficult to anticipate the structures of such complexes.

2. Experimental

The C and H analyses were carried out with a Perkin–Elmer elemental analyzer 240 C. The ^{1}H and $^{13}C\{^{1}H\}$ NMR spectra were recorded on a Bruker Spectrospin DPX-300 NMR spectrometer at 300.13 and 75.47 MHz, respectively. $^{31}P\{^{1}H\}$ NMR spectra were recorded at 121.49 MHz using H_3PO_4 as an external indicator. IR spectra in the range 4000–250 cm^{-1} were recorded on a Nicolet Protége 460 FT-IR spectrometer as KBr pellets. The conductance measurements were made in acetonitrile (concentration ~1 mM) using an ORION conductivity meter model 162. The molecular weights (concentration ~5 mM) in chloroform were determined with a Knauer vapour pressure osmometer model A0280. The melting points determined in open capillary are reported as such. The Ph_2PCl and 2-chloroethyl ethyl sulfide were obtained from Aldrich (USA). $[RuCl_2(p\text{-cymene})]_2$ was synthesized by the reported method [17].

2.1. Synthesis of 1-(ethylthio)-2-(diphenylphosphino) ethane (*L*)

Chlorodiphenylphosphine solution (5.0 cm^3 of 1.0 M solution in THF) was added to lithium (0.63 g, 5.0 mmol) in dry THF (25 cm^3) at room temperature in a Schlenk flask. The mixture was stirred until the solution became dark red in colour, which indicated the formation of lithium diphenylphosphide. The PPh_2Li was then filtered and transferred to a Schlenk tube under nitrogen atmosphere and cooled to −78 °C. 2-Chloroethyl ethyl sulfide (0.62 g, 5.0 mmol) was added to it with constant stirring. The mixture was allowed to come to room temperature over ~12 h, after which all the THF was evaporated off from the mixture on a rotary evaporator and the residue was dissolved in deoxygenated dichloromethane (30 cm^3). The solution was again concentrated to ~10 cm^3on a rotary evaporator and mixed with hexane (30 cm^3). The resulting solid was then recrystallized with a dichloromethane–methanol mixture (1:1) to obtain **L** as a white crystalline solid. Yield ~85%; m.p. 45 °C. *Anal.* Calc.: C, 70.04, H, 6.98. Found: C, 70.01; H, 6.30%. ^{1}H NMR (δ vs TMS, $CDCl_3$, 25 °C): 1.17–1.22 (t, 3H, H_1), 2.30–2.35 (m, 2H, H_4), 2.49–2.62 (m, 4H, H_3 and H_2), 7.32–7.47 (m, 10H, Ar-H of PPh_2).

2.2. Synthesis of [CuBr(*L*)]$_2$ (*1*)

To a solution of **L** (0.13 g, 0.50 mmol) made in 10 cm^3 of chloroform was added Cu_2Br_2 (0.07 g, 0.50 mmol) dissolved in 10 cm^3 of nitromethane under nitrogen atmosphere. The resulting mixture was stirred under an inert nitrogen atmosphere for 2 h at room temperature. Thereafter, the solution was filtered through celite. The clear filtrate was concentrated to ~10 cm^3 on a rotary evaporator and mixed with hexane (20 cm^3). The resulting white solid was filtered, washed with hexane (3×20 cm^3) and dried in vacuo and stored under inert conditions. Complex **1** was recrystallized from chloroform–hexane mixture (1:1). Yield: 75%; m.p.: 78 °C (d). *Anal.* Calc.: C, 38.79, H, 3.81. Found: C, 38.72, H, 3.01%. Λ_m: 6.50 Ω^{-1} cm^2 mol^{-1}; ^{1}H NMR (δ vs TMS, $CDCl_3$, 25 °C) 1.21–1.26 (t, 3H, H_1), 2.58–2.60 (m, 2H, H_4), 2.69–2.76 (m, 2H, H_2), 2.83–2.88 (m, 2H, H_3), 7.30–7.47 (m, 10H, Ar-H of –PPh_2); $^{13}C\{^{1}H\}$ NMR (δ vs TMS, 25 °C), 13.5 (C_1), 26.5, 26.7 (C_4), 29.5, 29.7 (C_2), 30.1 (C_3), 128.7, 128.8, 130.8, 131.2, 132.5, 133.1, 133.3 (Ar-C of PPh_2).

2.3. Synthesis of [HgBr$_2$(*L*)] (*2*)

$HgBr_2$ (0.20 g, 0.55 mmol) was dissolved in acetone (20 cm^3) and mixed with a solution of **L** (0.15 g, 0.55 mmol) in chloroform (20 cm^3). The resulting mixture was stirred at room temperature until the ligand **L** was consumed (as monitored by TLC). The solvent was removed from the mixture on a rotary evaporator. The resulting residue was dissolved in 20 cm^3 of chloroform and filtered through celite. The filtrate was concentrated to 10 cm^3 on a rotary evaporator and mixed with 20 cm^3 of hexane. The white complex **2** was filtered, dried in vacuo and recrystallized from chloroform–hexane (1:1) mixture. Yield: 80%; m.p.: 135 °C. *Anal.* Calc.: C, 30.26, H, 2.29. Found: C, 30.04, H, 2.66%. Molecular weight; found: 659.0, calculated: 634.39; Λ_m: 4.60 Ω^{-1} cm^2 mol^{-1}; ^{1}H NMR (δ vs TMS, $CDCl_3$, 25 °C), 1.27–1.32 (t, 3H, H_1), 2.66–3.11 (m, 6H, H_4, H_3 and H_2), 7.59–7.80 (m, 10H, Ar-H of –PPh_2); $^{13}C\{^{1}H\}$ NMR (δ vs TMS, 25 °C), 13.8 (C_1), 26.3 (C_4), 27.4 (C_2), 30.1 (C_3), 129.9, 130.00, 132.9, 33.26, 134.00 (Ar-C of PPh_2).

2.4. Synthesis of [Ru(p-cymene)Cl$_2$(*L*)] (*3*)

$[RuCl_2(p\text{-cymene})]_2$ (0.61 g, 1.0 mmol) was taken in 20 cm^3 of dichloromethane and a solution of **L** (0.54 g, 2.0 mmol) in 10 cm^3 of dichloromethane was added to it. The mixture was stirred for 2 h at room temperature. The solvent was completely removed on a rotary evaporator under reduced pressure. The residue obtained was dissolved in dichloromethane (5 cm^3) and mixed with hexane (30 cm^3). The resulting red precipitate (**3**) was filtered, washed with hexane (3×20 cm^3) and dried in vacuo. It was recrystallized from dichloromethane–hexane (1:1) mixture. Yield: 80%; m.p.: 89 °C (d). *Anal.* Calc.: C, 53.78, H, 5.68. Found: C, 52.71, H, 5.25%. Molecular weight; found: 620.0, calculated: 580.07; Λ_m: 3.80 Ω^{-1} cm^2 mol^{-1}; ^{1}H NMR (δ vs TMS, $CDCl_3$, 25 °C), 1.22–1.33 (m, 9H, $H_1 + CH_3$ of *i*-Pr), 2.15 (s, 3H, CH_3 of *p*-cymene), 2.29

(m, 1H, CH of *p*-cymene), 2.81–3.06 (m, 6H, H_4, H_3 and H_2), 7.37–7.72 (m, 10H, Ar-H of $-PPh_2$); $^{13}C\{^1H\}$ NMR (δ vs TMS, 25 °C), 12.09 (C_1), 17.11 (CH_3 of *i*-Pr), 20.1 (C_4), 22.3 (CH_3 of *p*-cymene), 28.8 (C_2), 32.5 (CH of *p*-cymene), 33.1 (C_3), 87.9, 91.0 (Ar-C of *p*-cymene), 127.0, 128.3 129.9, 130.3, 132.2, 137.0 (Ar-C of PPh_2).

2.5. X-ray crystallography

The X-ray data for **2** were collected (at 120 K) on an Enraf Nonius Kappa CCD area detector diffractometer, with ϕ and ω scans chosen to give a complete asymmetric unit. Cell refinement [18,19] corresponds to an orthorhombic cell whose dimensions are given in Table 1, along with other experimental parameters. An absorption correction was applied [18,19]. The structure was solved by direct methods [20] and refined using the WinGX version [21] of SHELX-97 [22]. Hydrogen atoms were included in idealized positions with isotropic thermal parameters set at 1.2 times that of the carbon atom to which they were attached. Non-hydrogen atoms were treated anisotropically. The final cycle of full-matrix least-squares refinement for **2** was based on 4199 observed reflections (3243 for $F^2 > 4\sigma(F^2)$) and 191 variable parameters and converged (largest parameter shift was 0.001 times its esd). The molecular structure of **2** is displayed as an ORTEP diagram in Fig. 1. Its selected bond lengths and bond angles are given in Table 2.

Table 1
Crystal data and structure refinement for **2**

Empirical formula	$C_{16}H_{19}PSBr_2Hg$
Formula weight	634.75
Temperature (K)	120(2)
Wavelength (Å)	0.71073
Crystal system	orthorhombic
Space group	*Pbca*
a (Å)	13.567(1)
b (Å)	14.859(1)
c (Å)	18.095(1)
V (Å^3)	3647.6(6)
Z	8
D_{calc} (g/cm^3)	2.312
Absorption coefficient (mm^{-1})	13.014
F(000)	2368
Crystal size (mm^3)	$0.15 \times 0.08 \times 0.02$
θ Range for data collection (°)	3.30–27.53.
Index ranges	$-17 \leqslant h \leqslant 17$, $-19 \leqslant k \leqslant 19$, $-23 \leqslant l \leqslant 23$
Reflections collected	29610
Independent reflections (R_{int})	4199 (0.0602)
Maximum and minimum transmission	0.7808 and 0.2456
Refinement method	full-matrix least-squares on F^2
Data/restraints/parameters	4199/0/191
Goodness-of-fit on F^2	1.036
Final *R* indices [$F^2 > 4\sigma(F^2)$]	$R_1 = 0.0331$, $wR_2 = 0.0649$
R indices (all data)	$R_1 = 0.0526$, $wR_2 = 0.0711$
Largest difference in peak and hole (e Å^{-3})	1.001 and −1.162

3. Results and discussion

The ligand **L**, obtained as white crystalline solid, is unstable and is moisture and air sensitive. It can be stored at low temperature ~5 °C in dry nitrogen atmosphere without appreciable decomposition for 2–3 months easily. It is soluble in common organic solvents such as chloroform, dichloromethane and acetone, but is insoluble in hexane. The crystals of **2** are not air and moisture sensitive, but **1** and **3** require storing in a refrigerator to avoid their decay. The complexes are soluble in common organic solvents such as chloroform, dichloromethane and acetone, but are insoluble in hexane. The molar conductance values Λ_m of the complexes **1**–**3** in acetonitrile at ~1 mM

concentration have been found to be between 3.8 and 6.5 Ω^{-1} cm^2 mol^{-1}, which are much lower than the values expected for a 1:1 electrolyte. The molecular weights of complexes **2**–**3**, determined in chloroform by the vapour pressure osmometric method, were found to be very close to the values calculated from their molecular formulae. This indicates that there is no appreciable dissociation of these complexes in solution. In the IR spectrum of **1**, the band at 248 cm^{-1} suggests the presence of bridging Cu–Br unit. The IR spectrum of **3** has ν_{sym}(Ru–Cl) and ν_{asym}(Ru–Cl) at 326 and 294 cm^{-1}, respectively [23,24]. In the ^{1}H NMR spectrum of **L**, signals of H_2 and H_3 protons are merged together and appear as a multiplet, whereas the signal of H_4 appears shielded in comparison to those of H_2 and H_3. In the ^{1}H NMR spectrum of **1**, the signals corresponding to H_2 and H_3 get separated and deshielding of the order of 0.2–0.3 ppm is found with respect to the corresponding signals of ligand **L**. The signal of H_4 appears deshielded by ~0.25 ppm in comparison to the corresponding signal of **L**. Signals for aromatic protons remain unchanged on the formation of **1**. In the ^{1}H NMR spectrum of **2**, signals corresponding to all –CH_2 protons merge at 2.66–3.11 ppm, showing deshielding of ~0.35–0.45 ppm. In the proton NMR spectrum of **3** also, signals of all the CH_2 protons are merged and the average deshielding was found to be ~0.5 ppm. The CH_3 signal of the ligand (**L**) appears to be merged with the CH_3 signal of the isopropyl group of the *p*-cymene ring in the ^{1}H NMR spectrum of **3**. No significant shift occurs in the aromatic protons.

In the carbon-13 NMR spectrum of **1**, the C_4 signal is deshielded by ~0.8 ppm as compared to that of free **L**. The signals for C_2 and C_1 appear to be deshielded by 1.9 and 1.6 ppm, respectively, with respect to the corresponding signals of free **L**. In the carbon-13 NMR spectrum of **2**, the C_4 signal appears deshielded by 0.68 ppm and the C_3 signal by 1.68 ppm in comparison to those of free **L**, whereas in the spectrum of **3**, the deshielding of the C_2 signal is ~1.2 ppm and the other signals do not undergo any significant change in their chemical shifts. The ^{31}P {^{1}H} NMR spectra of **L**, **1**, **2** and **3** all have a single peak at −17.0, 31.3, 20.16 and 28.9 ppm, respectively. The signals in the spectra of the complexes are deshielded with respect to that of the ligand. All these NMR data indicate that the interaction of **L** with Cu(I), Hg(II) and Ru(II) is through both phosphorous and sulfur. With sulfur it may be weak (secondary type), as found out in the case of **2** when its single crystal structure was determined. However, in the case of **1** and **3**, which did not give crystals suitable for X-ray diffraction, it could not be ascertained unequivocally.

3.1. Crystal structure

The molecular structure of **2** is shown in Fig. 1 and selected bond lengths and angles are given in Table 2. The ligand **L** coordinates through phosphorus only, resulting in a coordination number of three for Hg. The three coordination number for mercury is already known [25–28] and such examples include Hg arsine complexes [25]. The chemistry of Hg–phosphine complexes has been extensively studied by Bell et al. [30], including three coordinate Hg species containing phosphine ligands. However, **2** is the first example of a Hg–(P, S) ligand complex where Hg is three coordinated. The Hg(1)–P(1) bond length of 2.415(1) Å is consistent with the earlier reported values of 2.513(2) and 2.408(2)–2.437(2) Å [29,30]. The Hg(1)···S(1) bond distance [3.063(1)] is shorter than the sum of the van der Waal's radii (3.35 Å). The Hg(1)–Br(1) and Hg(1)–Br(2) bond lengths are 2.5152(6) and 2.5952(6) Å and these are consistent with our earlier observations [31] of 2.505(2)–2.700(2) Å, and 2.528(3) and 2.637(3) Å reported by Bell et al. [30]. The bond angles around Hg are in the range of 78.78(4)–135.52(4)°, with a Br(1)–Hg(1)–Br(2) angle of 104.98(2)° and P(1)–Hg(1)–S(1) angle of 78.78(4)°. However, the sum of the bond angles P(1)–Hg(1)–Br(1), P(1)–Hg(1)–Br(2) and Br(1)–Hg(1)–Br(2) is ≈360°. Therefore, the Hg, two Br and P atoms are coplanar and the geometry around Hg can be best described as essentially trigonal planar. There is a Hg···S secondary interaction in **2** and the S atom is nearly perpendicular to the plane of the three coordinate Hg-complex. In **2**, the C–C bond lengths and bond angles of all the phosphine rings were found to be normal.

4. Conclusion

A relatively simple method is reported for the synthesis of the (P, S) ligand 1-(ethylthio)-2-(diphenylphosphino) ethane (**L**). Its complexation with Cu(I), Hg(II) and organometallic species of Ru(II) have been explored. The single crystal structure of the Hg(II) complex has been determined. It is found to be a three coordinate species. The sum of the bond angles at Hg, viz. P(1)–Hg(1)–Br(1), P(1)–Hg(1)–Br(2) and Br(1)–Hg(1)–Br(2), is ≈360°, and consequently the geometry of Hg can be best described as trigonal planar. There exists a weak secondary interaction between Hg and the S donor site of the ligand [Hg(1)···S(1) bond distance 3.063(1) Å; sum of van der Waal's radii 3.35 Å].

5. Supplementary data

The CCDC No. 602402 contains the supplementary crystallographic data for **2**. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (internat.) +44 1223 336 033; e-mail: deposit@ccdc.cam.ac.uk].

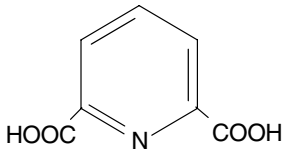

Fig. 1. Schematic structure of the dipicolinic acid (2,6-pyridinedicarboxilic acid).

this ligand and some derivatives form a variety of coordination compounds with vanadium in diverse oxidation states.

Dipicolinic acid shows various biological functions and is a suitable ligand for modeling potential pharmacological compounds because of its low toxicity and amphiphilic nature [12]. Recent results show that vanadium complexes of this compound have enhanced pharmacological activity as compared with the free ligand. Even though one of the desirable qualities of compounds for pharmaceutical use is its neutral charge, the insulin-like properties of the $[VO_2(dipic)]^-$ anion and its 4-hydroxydipicolinate derivative, $[VO_2(dipic)–OH]^-$, have been determined [12–14].

As part of our studies of the interaction of vanadium species with organic compounds displaying pharmacological activity, we have recently reported the synthesis, crystal structure and spectroscopic characterization of a new bis-oxo-bridge vanadium (V) compound of stoichiometry: $[CH_3NHC(NH_2)_2]_2[V_2O_4(dipic)_2]$. The two methyl guanidinium counterions stabilized the crystal structure by an extended H-bonds network [15]. The H-bond pattern gives rise to an eight-member ring, with irregular hexagonal geometry, similar to that described for the interaction between the guanidyl moiety of arginine and different oxoanion groups [16].

The aim of this work is the study of related compounds containing the monomeric anion $[VO_2(dipic)]^-$ with cations able to form intermolecular contacts mediated by H-bonding interactions. This kind of interlinkages is known to be relevant in biological systems involving metal containing moieties [4,17–19]. Herein, we report the synthesis and characterization of a new complex with the formula $C(NH_2)_3[VO_2(dipic)]\cdot 2H_2O$ and compare it with the corresponding ammonium salt. The later was selected as a reference compound due to its well-known therapeutic activity [12]. This complex has been previously prepared and characterized by different methods [12,14,20] and its crystal structure is reported here for the first time. Our structural data show a less symmetrical conformation that the one already reported for the cesium salt [21].

The guanidinium ion was chosen as counterion in $C(NH_2)_3[VO_2(dipic)]\cdot 2H_2O$, as it is present in a great number of naturally occurring and synthetic biologically and pharmacologically relevant systems. This highly resonance-stabilized ion remains protonated over a wide pH range including physiological pH (pK_a around 12.5). It is often used in molecular recognition in chemical and biological systems [22]. Its geometrical characteristics make it an efficient functional group in the binding of anionic species by means of strong non-covalent (H-bonding and charge-pairing) interactions. Specifically, the double hydrogen bond that forms the guanidinium group of arginine and the carboxylate moiety of aspartic acid is a determinant step in the interaction between the HIV virus and the cell primary receptor [23].

Finally, a geometry optimization and the corresponding vibrational analysis are carried out on the isolated vanadium (V) complex anion using tools based on the density functional theory. The optimized geometry is compared with the crystallographic data and the calculated vibrational frequencies are used to aid in the assignment of experimental vibrational modes. Some recent papers describe theoretical studies on vanadate complexes with biological activity. In particular, several works deal with the role of some complexes to model vanadium containing haloperoxidases. The B3LYP hybrid exchange-correlation functional was used to investigate structural and electronic properties of complexes that model the active site of the enzymes [24]. Peroxovanadate imidazole complexes, which can be thought of as models to investigate the oxidative chemistry of those systems, were also studied using the BP86 exchange-correlation within the density functional theory [25]. Furthermore, time-dependent density gradient-corrected density functional theory was used to calculate electronic excitations for vanadate species in different geometries and protonation states [26]. Other vanadium containing species with biological activity were also recently investigated. The study of the interaction of diperoxovanadate complexes with histidine-like ligands using the B3LYP method of the density functional theory has been recently reported [27]. The biological implications of several vanadium (V) peroxocomplexes with emphasis on several theoretical calculations that elucidate some of their properties have been also described [28]. However, in spite of those studies and to the best of our knowledge, there are no previous theoretical studies on the $[VO_2(dipic)]^-$ anion.

2. Experimental

2.1. Reagents and instrumentation

All chemicals were of analytical grade. V_2O_5 and NH_4VO_3 (Merck), dipicolinic acid and guanidine hydrochloride (Sigma), were used without further purification. IR spectra were recorded with a Bruker 113v FT-IR instrument, using the KBr pellet technique. Raman spectra were obtained with a Bruker IFS 66 FT-IR spectrophotometer, using the FRA 106 Raman accessory and the 1064 nm line of a Nd:YAG solid state laser for excitation. Elemental analysis (C, H, N) was performed using a Carlo Erba EA 1108 analyzer.

2.2. Synthesis of complexes

2.2.1. $C(NH_2)_3[VO_2(dipic)]\cdot 2H_2O$ (1)

1.5 g (8.2 mmol) of V_2O_5 and 2.76 g (16.5 mmol) of dipicolinic acid were dissolved in 65 ml of bidistilled water at 70 °C. To the resulting cooled (15 °C) and filtered solution, 1 drop of 100 vol. H_2O_2 was added to avoid V(V) reduction. A change to deep red color was immediately observed. Saturated guanidine hydrochloride aqueous solution was dropwise added until precipitation started. The system was then stored in the refrigerator during one week. The colorless obtained crystals (yield 18%) were filtered off and washed with cold water. In order to improve the yield of the reaction, the orange filtrate was concentrated by evaporation. The yellow solution obtained was afterwards cooled down to 0 °C. More guanidine hydrochloride saturated solution was added until opalescence appeared and the mixture was stored at room temperature. After several days, colorless prismatic crystals, suitable for X-ray structural analysis, were obtained.

Anal. Calc. for $C_8H_{13}N_4O_8V$: C, 27.9; H, 3.8; N, 16.3. Found: C, 27.2; H, 3.5; N, 15.8%.

2.2.2. $NH_4[VO_2(dipic)]$ (2)

The complex was prepared according to the reported procedure [20]. 2.9 g (24.8 mmol) of NH_4VO_3 and 4.17 g (24.9 mmol) of dipicolinic acid were dissolved in 25 ml of bidistilled water and heated at 80 °C until a yellow solution was obtained. After cooling it at 0 °C, a solid precipitates. It was separated by filtration and the filtrate was stored in the refrigerator. After one week, colorless plate shaped crystals of the complex were obtained, filtered off and washed with ethanol and ether (yield: 78%). *Anal.* Calc. for $C_7H_7N_2O_6V$: C, 31.6; H, 2.7; N, 10.5. Found: C, 31.2; H, 2.6; N, 10.1%. Both powder and crystals samples showed identical IR spectra.

2.3. X-ray diffraction data and crystal structure determination

Crystal data and refinement results for the two compounds are summarized in Table 1. Diffraction data of $C(NH_2)_3[VO_2(dipic)]\cdot 2H_2O$ were collected on an Enraf-Nonius Kappa CCD diffractometer with COLLECT [29] and reduced with DENZO and SCALEPACK [30] programs. The corresponding data for $NH_4[VO_2(dipic)]$ were collected on a Enraf-Nonius CAD4 diffractometer with EXPRESS [31] and reduced with XCAD4 [32]. Both data were corrected numerically for absorption with PLATON [33]. The structures were solved by direct and Fourier methods with SHELXS [34] program and its non-H atom refined by full-matrix least-squares with SHELXL [35] program. The hydrogen atoms of the organic molecules in both substances were positioned stereo-chemically and refined with the riding model. In $C(NH_2)_3[VO_2(dipic)]\cdot 2H_2O$, the dioxovanadium group showed rotational disorder with vanadium acting as pivotal atom. This gives rise to somewhat large atomic displacement parameters of the oxygen atoms and concomitant errors in the VO_2 bond distances and angle.

Table 1
Crystal data and structure solution methods and refinement results for $C(NH_2)_3[VO_2(dipic)]\cdot 2H_2O$ (**1**) and $NH_4[VO_2(dipic)]$ (**2**)

Compound	**1**	**2**

$wR_2(F_o^2)$[b]	0.0776	0.0941

[a] $R_1 = \sum\|F_o| - |F_c\|/\sum|F_o|$.
[b] $wR_2 = [\sum w(|F_o|^2 - |F_c|^2)^2 / \sum w(F_o^2)^2]^{1/2}$.

The H-atoms of one crystallization water molecule of $C(NH_2)_3[VO_2(dipic)]\cdot 2H_2O$ were found in a difference Fourier map and refined isotropically with Ow–H and H···H distances restrained to target values of 0.86(1) and 1.36(1) Å, respectively. The other water molecule showed positional disorder. This was modeled in terms of two sites for the oxygen atom, which was refined anisotropically while keeping the sum of the occupational factors equal to one. The ammonium H-atoms of $NH_4[VO_2(dipic)]$ were located in a difference Fourier map and refined employing independent isotropic displacement parameters.

2.4. Theoretical calculations

Becke's three parameters hybrid exchange-correlation functional [36] as implemented in the GAUSSIAN-98 package [37] was used for the calculations. The Lee, Yang, and Parr density gradient-corrected correlation functional [38] was utilized then leading to the well-known B3LYP method. A basis set of triple-zeta quality in the valence space including both polarization and diffuse functions available as 6-311++G** in the GAUSSIAN-98 package was used for hydrogen, carbon, nitrogen, and oxygen. A $(14,9,5)/[8,5,3]/\{62111111,33111,311\}$ basis set including an additional p function with small orbital exponent was used for vanadium [39]. No scale factor was used in the calculated frequencies.

3. Results and discussion

3.1. Theoretical calculations

The geometry of the isolated $[VO_2(dipic)]^-$ anion was optimized using the density functional theory [40]. No

countercations were taken into account in the calculations. It should be stressed, then, that the optimized geometry obtained in this way must be strictly compared with gas phase experimental geometries. Thus, the discrepancies arising when comparing with solid state experimental geometries could be attributed to lattice effects (see below).

A vibrational analysis was performed to confirm that the optimized geometry is a true minimum on the molecular potential energy surface. Moreover, the assignment of experimental frequencies to molecular normal modes was accomplished with the help of the calculated vibrational spectrum.

3.2. Structure of the complex

Selected bond distances and angles around the vanadium (V) ion obtained from X-ray data and density functional calculations are compared in Table 2. Complete experimental and calculated geometrical parameters are available in Table S1. The ORTEP [41] drawings of the molecules are shown in Figs. 2 and 3.

Vanadium (V) shows a similar penta-coordinated environment in the guanidinium and ammonium salts of $[VO_2(dipic)]^-$. In the anion, the VO_2^+ group is coordinated to a $dipic^{2-}$ acting as a tridentate ligand through its carboxylic oxygen atoms [V–O distances of 1.983(2) and 1.988(2) Å in **1** and 1.974(2) and 1.978(2) Å in **2**] and the nitrogen atom [V–N distances of 2.086(2) (**1**) and 2.091(2) (**2**) Å]. The $dipic^{2-}$ ligand is planar [rms deviation of atoms from the least-squares plane of 0.012 (**1**) and 0.051 (**2**) Å] with the metal ion lying onto this plane in **1** [at 0.001(7) Å] and slightly above in **2** [at 0.136(1) Å]. The ligand plane of **1** bisects the dioxovanadium V=O double bonds whose lengths are 1.614(7) and 1.626(7) Å. This agrees with the structural data reported for the $[(VO_2)(dipic)]^-$ complex in $Cs[(VO_2)(dipic)]\cdot H_2O$ where

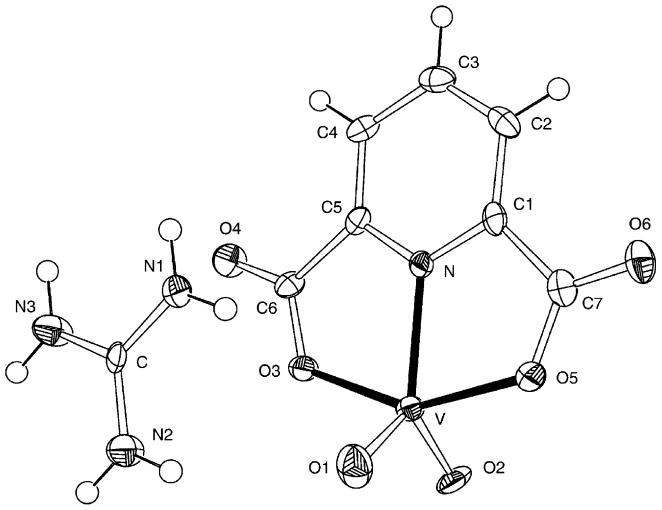

Fig. 2. Molecular plot of $C(NH_2)_3[VO_2(dipic)]\cdot 2H_2O$ showing the labeling of the non-H atoms and their displacement ellipsoids at the 50% probability level. Vanadium–ligand bonds are indicated by full lines. The crystallization water molecules are omitted for clarity.

the V=O double bond distances are 1.610(6) and 1.615(6) Å [18]. In contrast, the ligand plane of **2** structure departs appreciable from the O1=V=O2 bisector and the V–O1 bond distance is 0.012 Å (i.e. six times the rms error) longer than the V–O2 length [1.612(2) Å]. That difference in the VO distances is probably due to a pair of medium to strong N–H···O1 bonds with the NH_4^+ counter-ion (see below). We have recently reported an example of even more pronounced V=O bond asymmetry in the VO_2^+ group, namely in a bis oxo bridged binuclear vanadium (V) complex of stoichiometry $[CH_3NHC(NH_2)_2]_2[V_2O_4(dipic)_2]$ [15]. In this compound, the oxygen atom of the VO_2^+ moiety, laying near the coordination plane, bridges the two halves of a centro-symmetric dimer through a weak

Table 2
Selected experimental bond distances (Å) and angles (°) around vanadium (V) ion for $C(NH_2)_3[VO_2(dipic)]\cdot 2H_2O$ (**1**) and for $NH_4[VO_2(dipic)]$ (**2**)

	Experimental (**1**)	Experimental (**2**)	Calculated

O(3)–V–N	74.73(6)	74.72(7)	72.6

Calculated data for $[VO_2(dipic)]^-$ anion.

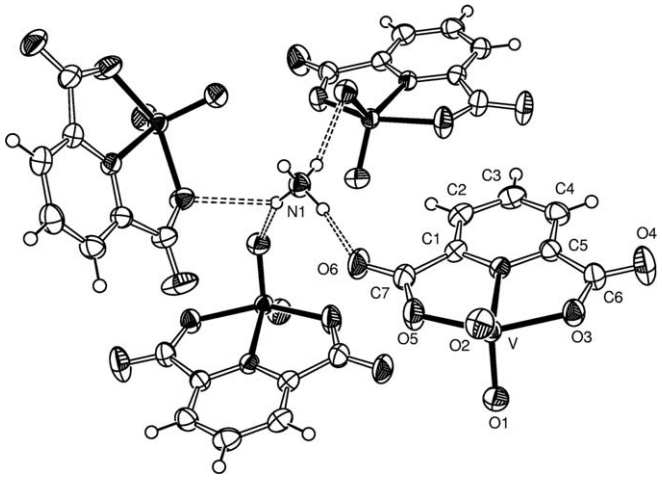

Fig. 3. Molecular diagram of $NH_4[VO_2(dipic)]$. The figure includes three additional, symmetry related, $[VO_2(dipic)]^-$ complexes to show the environment around the ammonium ion and the N–H···O bonding structure (in dashed lines).

axial V···O bond. As a consequence of this, the two V=O distances differ in 0.078(1) Å [d(V–O1) = 1.606(1) Å].

The carboxylic groups of the dipicolinate ligand of both complexes show, as expected, significant bond localization. In fact, the terminal C–O bond lengths are 0.07–0.10 Å shorter than the C–O distances corresponding to the oxygen atoms coordinated to the vanadium ion.

The optimized geometry of the $[VO_2(dipic)]^-$ anion shows a good general agreement with experimental data (Table S1). Nevertheless, it must be noted that several equivalent bond distances and bond angles are equal in the optimized geometry, in complete disagreement with experimental values as can be seen in Table 2. This result, however, is not surprising as the calculated geometry of the isolated anion corresponds to a low-pressure limit gas phase situation, with not allowance for lattice effects, whereas the anions interact with their counterions and, moreover, they are involved in hydrogen bonds when the complexes are formed in the solid state. Thus, the V=O distances are well reproduced within the experimental error for the $[VO_2(dipic)]^-$ anion in the guanidinium salt. On the other hand, for the ammonium salt, the present calculations are unable to reproduce the larger V–O1 distance, in agreement with the fact that the O1 atom is involved in an H-bonding interaction with neighboring NH_4^+ groups, as it was mentioned above. It can also be seen from Table 2 that the calculated O1–V–O2 bond angle overestimates the experimental value in the ammonium salt by ca. 4°. It is suggested that the larger V=O1 bond distance found in the solid **2** is the main responsible for the decreasing of the O1–V–O2 bond angle with respect to the calculated value.

The bond distances between the vanadium ion and the dipicolinate anion, namely V–N, V–O3, and V–O5, are overestimated by 0.06–0.08 Å. These discrepancies could be attributed both to deficiencies in the treatment of exchange and correlation effects within the B3LYP functional or to the fact that the basis sets used are not correlation consistent. More studies on related transition metal complexes are needed to shed light on this problem. The corresponding calculated bond angles are lower than experimental values by as much as 4°. This disagreement is consistent with the above mentioned differences found between calculated and experimental bond lengths.

The guanidinium cation shows three essentially equivalent C–N distances and C–N–C angles [average: 1.32 Å and 120°, respectively]. Its characteristic planar CN_3 skeleton, with a strong electronic delocalization, allows the cation to participate in an extended H-bonding network.

3.3. Hydrogen bonding interaction

3.3.1. $C(NH_2)_3[VO_2(dipic)]\cdot 2H_2O$

In this compound the planar guanidinium counterion lays parallel to the dipìc^{2-} ligand at a van der Waals contact distance of 3.1 Å. The $[VO_2(dipic)]^-$ and $[C(NH_2)_3]^+$ ions are arranged in the lattice along layers parallel to (0 1 0) crystallographic planes. These layers are stabilized by a network of medium to strong intra-layer N–H···O bonds involving the guanidinium NH_2 groups and carboxylic oxygen atoms of the dipic^{2-} ligand [N···O distances and N–H···O angles are found in the ranges 2.848–2.982 Å and 132.6–176.1°, respectively]. Two parallel N–H···O bonds are formed between the N2 and N3 atoms of the guanidinium ion and the carboxylate oxygens O3 and O4 of a neighboring anion. The interaction gives rise to an hexagonal pattern analogous to the observed in the bis-oxo-bridged V(V) complex [15] and similar to that found in a large number of H-bonded layered crystals and to that described for the interaction of phosphate, sulfonate, carboxylate and nitrate with this cation. In biological systems, this peculiar binding pattern is found in the interaction of the guanidinium group of L-arginine in some enzymes with the carboxylate group of aspartate or glutamate [16]. The N1 nitrogen atom of guanidinium interacts, through one of its hydrogen atoms, with the O6 oxygen from a carboxylate ion of another neighboring unit. The lattice is further stabilized by inter-layer H-bonds mediated by one crystallization water molecule held onto the layer by a N–H···Ow bond [the N···Ow distance and the N–H···Ow angle are 2.825 Å and 157.5°, respectively]. This molecule is acting as a donor in two Ow–H···O interactions with the dioxovanadium groups of neighboring layers [the corresponding Ow···O distances and Ow–H···O angles are 2.823 and 2.860 Å and 152.6° and 145.4°,

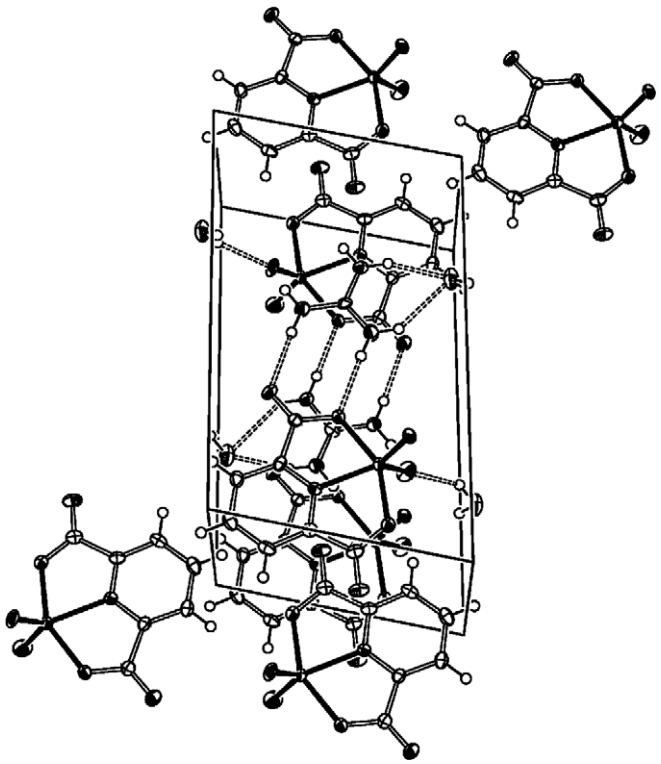

Fig. 4. Crystal packing of $C(NH_2)_3[VO_2(dipic)]\cdot 2H_2O$ showing the H-bonding interactions (dashed lines). The crystal unit cell a- and c-axis are along the horizontal and vertical directions, respectively.

respectively]. An ORTEP [41] drawing showing the crystal packing and the H-bonding network of compound **1** is presented in Fig. 4.

3.3.2. $NH_4[VO_2(dipic)]$

The crystal lattice of this compound is also stabilized by a network of N–H···O bonds. Each ammonium ion is linked to four $[VO_2(dipic)]^-$ units (see Fig. 3). To two of them with the VO_2^+ moiety through its O1 oxygen atom which, therefore, acts as a bifurcated H-bond acceptor [N···O1 distances and N–H···O1 angles are 2.873 and 2.984 Å and 155.6° and 159.7°, respectively]. To the other two units, through one of their carboxylate oxygens, namely O6 and O3 [N···O distances and N–H···O angles are 2.812 and 2.971 Å and 169.9° and 112.0°, respectively]. The NH_4^+ hydrogen atom bonded to the O3 atom on one unit forms a bifurcated H-bond as it is also linked to the O1 atom of another unit. Relevant hydrogen bonding interactions have been described also in other ammonium salts of dioxovanadium complexes, which were studied as structural models for the active site in vanadium-containing haloperoxidases [42,43]. The detailed H-bonding networks of compounds **1** and **2** are given in Tables S2 and S3.

3.4. Vibrational spectra

The solid-state properties of the compounds were examined by infrared (IR) and Raman spectroscopy. The spectra were compared with those of the free ligand and of guanidinium hydrochloride. In Table 3 we report the infrared and Raman frequencies of H_2dipic and the guanidinium and ammonium salts of $[VO_2(dipic)]^-$. Assignment of the more characteristic bands was performed with the help of the harmonic vibrational frequencies calculated in this work, which are also included in Table 3. Reported data of related compounds was also taken into account.

The IR spectrum of the free ligand shows a strong absorption in the 3100–2500 cm^{-1} range due to the O–H stretching mode of the COOH group, overlapped with the C–H stretching bands. The broad and irregular shape of this signal is indicative of a hydrogen-bonded dimer structure for the dipicolinic acid. The corresponding C–OH in-plane bending and out-of-plane OH···O deformation modes are located at 1417 and 927 cm^{-1}, respectively. The typical ν(C=O) stretch, due to the out-of-phase vibrations of the monomeric units in the dipicolinic acid dimer, appears as a broad and very strong IR band centered at 1705 cm^{-1}. The respective in-phase mode is situated at 1644 cm^{-1} in the Raman spectrum [44]. The ν(C–O) vibration is observed as two strong IR bands at 1332 and 1301 cm^{-1}, the corresponding Raman bands being at 1325 and 1296 cm^{-1}. Characteristic ring modes were also identified in the expected range [45].

The IR and Raman spectra of the complexes show very similar spectral pattern, except for the characteristic modes of the guanidinium and ammonium cations. This fact indicates similar coordination environments in both compounds as confirmed by crystal structural data. Compound **1** shows additional rather broad IR bands in the 3450–3100 cm^{-1} region that correspond to the O–H stretching vibrations of the crystallization water molecules and to N–H stretching modes of guanidinium. The position of these bands indicates that these groups are involved in H-bonds interactions. Characteristic bands of the guanidinium ion related to NH_2 in-plane and out-of-plane deformation are also present in the compound spectra. The strong Raman band at 1008 cm^{-1} corresponds to the symmetric stretching of the CN_3 skeleton of guanidinium [44,46]. The deformation mode of the water molecules are probably overlapped by the strong $\delta(NH_2)_{ip}$ IR band.

A weak band at 623 cm^{-1}, in the region of ring deformation modes, can be assigned to the water rocking motion. Compound **2** shows two IR bands of medium intensity at 3196 and 1401 cm^{-1}, attributed to the NH stretching and deformation of the NH_4^+ group, respectively.

In both compounds, $dipic^{2-}$ coordinates the VO_2^+ moiety as a tridentate ligand. The characteristic O–H bands of free carboxylate disappear, hence revealing the deprotonation of this group upon complex formation. This fact was also confirmed by the structural study.

The spectra exhibit strong IR absorption bands due to the symmetric and asymmetric stretching vibrations of the carboxylate anion. Each compound shows one strong IR band with a shoulder in the 1700–1650 cm^{-1} region, which can be assigned to the $\nu_{as}(COO^-)$ mode. The calculations clearly show that this splitting can be attributed to the in-phase (1733 cm^{-1}) and out-of-phase (1718 cm^{-1}) motions due to vibrational coupling between both terminal carboxylic groups. The symmetric stretch of carboxylate groups leads to a characteristic Raman line of medium intensity at 1337 cm^{-1} for compound **1** and at 1340 cm^{-1} for compound **2**. The corresponding IR bands are located at 1331 and 1337 cm^{-1}, respectively, whereas the calculated harmonic frequency is found at 1352 cm^{-1}, in excellent agreement with experimental values. The observed splitting in the IR bands (see Table 3) is consistent with the difference in the C–O distances of both coordinated carboxylate groups (see Table S1). This fact could be a consequence of different H-bond interactions with the counterion. The frequency difference between the asymmetric and symmetric vibrations for both complexes ($\Delta\nu > 300$ cm^{-1}) is in accordance with monodentate coordination of the carboxylate group [47]. As expected, the δ(COO) mode, which occurs in the free ligand as a strong band at 701 cm^{-1}, is shifted to higher frequency after coordination. Theoretical calculations show that it arises coupled with the in-plane ring deformation mode. Coordination through the heterocyclic nitrogen is evidenced by an intensity change and upward frequency shift of some skeletal vibration and in-plane and out-of-plane deformation ring modes (see below) [47].

The symmetric and asymmetric stretching vibrations of the VO_2^+ moiety are observed in the 960–940 cm^{-1} region for both compounds. Calculated harmonic vibrational frequencies for the asymmetric and symmetric modes of VO_2^+

are located at 1015 and 1014 cm^{-1}, respectively. The corresponding $\delta(VO_2^+)$ appears as a very weak band at 422 (**1**) and 428 cm^{-1} (**2**), whereas the calculated value is found at 432 cm^{-1}.

Upon complex formation, changes in intensity and position of some of the ligand bands were observed. The vibrational modes corresponding to ν(CH) and skeletal ring vibration appear in the ranges 3100–3050 and 1600–1470 cm^{-1}, respectively, whereas the corresponding calculated values are found at 3200–3160 and 1640–1620 cm^{-1}. Between 1200 and 1030 cm^{-1} it was possible to identify the $\delta(CH)_{ip}$ and δ(ring) modes, the calculated frequencies being located at 1086 and 1044 cm^{-1}, respectively (data not shown). Out-of-plane CH and ring deformations appear in the 850–770 cm^{-1} range, while the in-plane ring modes are found between 750 and 590 cm^{-1}. On the theoretical side, the out-of-plane CH and ring deformations are calculated at 855 and 776 cm^{-1}, the in-plane ring modes at 750 and 594 cm^{-1}.

Furthermore, new bands were found between 460 and 250 cm^{-1}, which can be assigned to the stretching modes of the metal-to-ligand bonds, ν(V–O) and ν(V–N), respectively [48]. Calculated frequencies in the range 449–217 cm^{-1} clearly indicate that these modes are strongly coupled either with several out-of-plane and in-plane ligand deformations or with bending modes involving the five-member ring (VOCCN) formed with vanadium upon coordination (see Table 3). It is interesting to note that

the calculated metal-to-ligand ν(V–N) and ν(V–O) frequencies are found to be lower than experimental values, with downwards wavenumbers shifts of about 75 cm^{-1}. This fact seems to be consistent with the larger V–N and V–O bond distances calculated at the present level of theory as previously mentioned.

effect), a co-ligand [10] or solvents [4,12] direct the course of the self-assembly processes. In search of the rational design of functional materials with extended architectures leading to supramolecular edifices, multicarboxylate ligands bearing differently oriented carboxylate groups with versatile coordination modes have been proved to be the most efficient ones [6,7,15–19] due to the considerably flexible steric orientation of the carboxylate groups enabling the carboxyl groups to connect metal ions in different directions, thus favoring the formation of helicate structures.

In view of the above-mentioned characteristics of multicarboxylate ligands, we thought it worthwhile to explore the possibility of ntp to generate supramolecular architectures, due to considerable flexibility and versatile coordination sites expected to exhibit both coordinate and non-covalent interactions. We report here the synthesis and characterization of coordination polymers of the type $[(H_2en)(ntpMCl_2)]_n$ and the single crystal structure and DNA binding studies of compound **1**. It seems to be the first report of its kind where en has dictated the formation of single stranded helical architectures. However, no interaction has been observed between MCl_2 and ntp in the absence of en, where ntp separates out leaving MCl_2 in solution.

2. Experimental

2.1. Physical measurements

The elemental analyses were obtained from the microanalytical laboratory of CDRI, Lucknow, India. The IR spectra (4000–200 cm^{-1}) of the compounds were recorded as nujol mulls on a Perkin–Elmer 2400 spectrophotometer using CsI optics. The ^1H NMR spectra of the compounds were recorded on a Jeol Eclipse 400 NMR spectrophotometer in D_2O. Metals and chlorides were determined volumetrically [20] and gravimetrically [21], respectively. The electrical conductivities of 10^{-3} M solutions in H_2O were obtained on a digital APX 185 conductivity bridge equilibrated at 25 ± 0.01 °C. Fluorescence measurements on the compound **1** were made on a Shimadzu RF-5301PC spectrofluorometer, equipped with a microcomputer. The fluorescence spectra were measured by three scans with a concentration of 50 μM with 1 cm cell path length. Excitation and emission slits were set at 5 nm each. The spectra were recorded in the 310–450 nm range and the excitation wavelength was set at 310 nm. All the stock solutions were filtered through 0.20 μm millipore filters prior to mixing, to minimize the inner filter effect [22].

2.2. Materials

The metal salts MCl_2 [M = Zn^{II} Cd^{II}, Hg^{II}], ethylenediamine, (All Aldrich) and 3,3′,3″-nitrilotripropionic acid, (TCI, Tokyo, Kasei) were commercially pure samples and used as received while MeOH (AR grade) was used without further purification. However, water was distilled before use.

2.3. Synthesis of the $[(H_2en)(ntpMCl_2)]_n$ polymers

An aqueous solution (20 ml) of ntp (6 mmol) was reacted with MCl_2 (3 mmol) [M = Zn^{II}, Cd^{II}, Hg^{II}] in MeOH (20 ml) followed by addition of en (6 mmol). The reaction contents were stirred at room temperature for about 18 h. The reaction mixture was allowed to stand at room temperature resulting in microcrystalline solids for Cd^{II} **2** and Hg^{II} **3**. However, good quality crystals appeared after a period of one week for Zn^{II} **1**.

2.4. Crystallographic data collection and refinement (*1*)

A colorless prismatic crystal of **1**, having approximate dimensions of $0.1 \times 0.25 \times 0.3$ mm, was mounted on a glass fibre. All measurements were made on a Rigaku AFC7R diffractometer with graphite monochromated radiation. Intensity data were corrected for Lorenz, polarization and absorption: the values for the mass attenuation coefficients are those of Creagh and Hubbel [23]. The structure was solved by heavy atom Patterson methods [24], expanded using Fourier techniques [25] and was refined on F by full-matrix least-squares. The non-hydrogen atoms were refined anisotropically. Hydrogen atoms were refined isotropically. Neutral atom scattering factors were taken from Cromer and Waber [26]. Anomalous dispersion effects were included in F_{cald} [27]; the values for $\Delta f'$ and $\Delta f''$ were those of Creagh and McAuley [28]. All calculations were performed using the TEXSAN [29] crystallographic software package of the molecular structure corporation. All crystallographic data are summarized in Table 1. Selected bond lengths and bond angles are given in Table 2.

2.5. Binding analysis (*1*)

The fluorescence intensity values at the emission maximum (325 nm) were used for calculating the relative fluorescence, considering the fluorescence intensity of the untreated control as 100. The least-square analysis of the initial linear points of relative fluorescence versus nucleotide to compound 1 molar ratio was used to determine the maximal quench, m (slope of the plot), from the following equation ($F = F_0 - mR$), where F is the fluorescence intensity at nucleotide to compound molar ratio (R) and F_0 is the fluorescence intensity of the nucleotide at zero compound concentration. Using the data points exhibiting deviations from the straight-line behavior, the fractional quench, Q, was determined at each nucleotide/compound molar ratio (R). This is obtained from the equation ($Q = F_0 - F/m$). The fractional quench Q is linearly related to the compound binding: (compound − nucleotide)/$(\text{compound})_T = Q$, where $(\text{compound})_T$ represents the total compound concentration. The binding affinity (K_a) and binding capacity (n) were determined from the slope and intercept on the X-axis of the straight line on the Scatchard plot Q versus $Q/(R - Q)$ $(\text{compound})_T$ [30].

Table 1
Crystal data, collection and refinement details for compound **1**

Empirical formula	$C_{11}H_{23}N_3Cl_2ZnO_6$
Formula weight	429.61
Crystal color, habit	colorless, prismatic
Crystal dimensions (mm)	$0.1 \times 0.25 \times 0.3$
Crystal system	monoclinic
Lattice type	primitive
Number of reflections used for unit cell	
Determination (2θ range, °)	25 (29.1–29.9)
Omega scan peak width at half-height (°)	0.38
Lattice parameters

3. Results and discussion

The compounds **1**–**3** were stable to atmosphere and were found to be soluble in distilled water. The molar conductance values (Table 3) recorded in distilled water correspond to a 1:1 electrolytic nature of the compounds [31] while the analytical data of the compounds (Table 3) agree well with the proposed composition.

3.1. Infrared spectra

The mode of bonding, including hydrogen-bonding interactions, found in the solid state by X-ray diffraction studies were correlated with the IR study. The IR spectra of the compounds **1**–**3** consist of characteristic IR bands for protonated amine cations and carboxylate groups (Table 4). The ν(NH) absorption of the protonated amine consists [14,32,33] of a strong band around 3216–3210 cm^{-1} and a broad band around 3061–3051 cm^{-1} suggesting that one of the NH_3^+ groups of en is free while the other is involved in some hydrogen bonding interaction (H16···O6) which typically causes a broadening and shift to lower frequency. The appearance of an absorption band in the region 2948–2915 cm^{-1} may be assigned to the (NH^+) vibration expected for the zwitterion whose position is consistent [33] with the hydrogen bonding interactions [(N1H1···O2) = 2.49(5), (N1H1···O6) = 2.17(5) Å]. The IR spectra of all the compounds exhibit characteristic bands in the region 1625–1618 and 1371–1364 cm^{-1} corresponding to antisymmetric stretching ν_{as}(COO) and symmetric stretching ν_s(COO) modes of vibration, with a frequency difference (Δ) of ca. 254 cm^{-1} suggesting [34] the unidentate coordination mode of the carboxyl group which is further corroborated by X-ray data. However, the appearance of an additional band ca. 1525–1500 cm^{-1} in the IR spectra

Table 3
Yield (%), analytical data and molar conductance for the compounds (**1**–**3**)

Compound	Yield (%)	Found (Calc.)%					Molar conductivity (ohm^{-1} cm^{-2} mol^{-1})
		M	Cl	C	H	N	
$[H_2en]^{+2}[ntpZnCl_2]^{-2}$ (**1**)	60	15.1 (15.2)	16.3 (16.5)	30.6 (30.7)	5.3 (5.3)	9.8 (9.7)	69
$[H_2en]^{+2}[ntpCdCl_2]^{-2}$ (**2**)	58	23.4 (23.5)	14.6 (14.8)	27.6 (27.7)	4.8 (4.8)	8.7 (8.8)	65
$[H_2en]^{+2}[ntpHgCl_2]^{-2}$ (**3**)	45	33.3 (33.5)	12.4 (12.5)	23.1 (23.3)	4.0 (4.1)	7.3 (7.4)	61

Table 4
IR vibrational frequencies (cm^{-1}) of the compounds (**1**–**3**)

Compound	$\nu(N–H)_{en}$	$\nu(N–H)_{ntp}$	$\nu_{as}(COO)$	$\nu_{s}(COO)$	$\nu(M–Cl)$	$\nu(M–O)$
$[H_2en]^{+2}[ntpZnCl_2]^{-2}$ (**1**)	3216, 3058	2948	1618, 1500	1371	298	460
$[H_2en]^{+2}[ntpCdCl_2]^{-2}$ (**2**)	3211, 3051	2938	1620, 1520	1369	290	445
$[H_2en]^{+2}[ntpHgCl_2]^{-2}$ (**3**)	3210, 3061	2915	1625, 1525	1364	295	440

of all the compounds may reasonably be assigned [32] to ν(COO) for a non-coordinated carboxyl group. The lowering in frequency as compared to the coordinated one may be due to hydrogen bonding with the protonated en N2H16$\cdots$O6 = 2.06(6) Å. The absence of characteristic band ca. 1750–1700 cm^{-1} in all the compounds attributed [6,33] to a carboxylic group (–COOH) indicates the complete deprotonation of the carboxylic groups in the zwitterion, $[NH^{+}(CH_2CH_2COOH)_2(CH_2CH_2COO)^{-}]$. Medium intensity bands in the 298–290 and 460–440 cm^{-1} regions may be assigned to M–Cl and M–O vibrations.

3.2. ^1H NMR spectra

Further confirmation regarding the structure of the compounds was obtained by the ^1H NMR spectra which show the absence of a peak around 10.9–8.38 ppm corresponding [17,33] to protons of –COOH groups of the ntp ligand, thus indicating the deprotonation of the carboxylic groups of the zwitterion $[NH^{+}(CH_2CH_2COOH)_2(CH_2CH_2COO)^{-}]$. Singlets at 3.1, 3.4 and 3.2 ppm correspond [35] to the resonance peak for CH_2 protons of protonated en (4H, $H_3N^{+}–CH_2–CH_2–NH_3^{+}$) for **1**, **2** and **3** respectively. Owing to the close proximity of resonance frequencies corresponding to CH_2 protons adjacent to the carboxyl group (6H, C–CH_2–COO) and CH_2 protons adjacent to the tertiary nitrogen (6H, N–CH_2–C) of ntp^{2-} in all three compounds it was not possible to resolve their individual frequencies, rather a broad resonance signal around [33] 3.5–3.7 ppm was observed. The proton resonance signals expected for the protonated ethylenediamine moiety and the protonated tertiary amine group of ntp^{2-} could not be observed due to deuterium exchange leading to a breakdown of the helicate structure by loss of hydrogen bonding interactions.

3.3. Crystal structure of compound *1*

The X-ray analysis performed on a single crystal of **1** revealed a single stranded helical structure sustained by both coordinate and hydrogen bonds. The structure of the compound (Figs. 1 and 2) consists of Zn(II) ions which are sequentially linked by two of the carboxylate units of the ditopic ntp^{2-} ligand formed in situ due to the deprotonation of the zwitterion, $[NH^{+}(CH_2CH_2COOH)_2$-$(CH_2CH_2COO)^{-}]$ by en. This ditopic ligand ntp^{2-} coordinates in an antimonodentate manner to generate a polymeric coordinative chain, evident [34] from Zn–O bond distances [Zn1–O1 = 1.987(3) Å, Zn1–O3* = 1.977(3) Å]. Thus it appears that en shows a template effect which

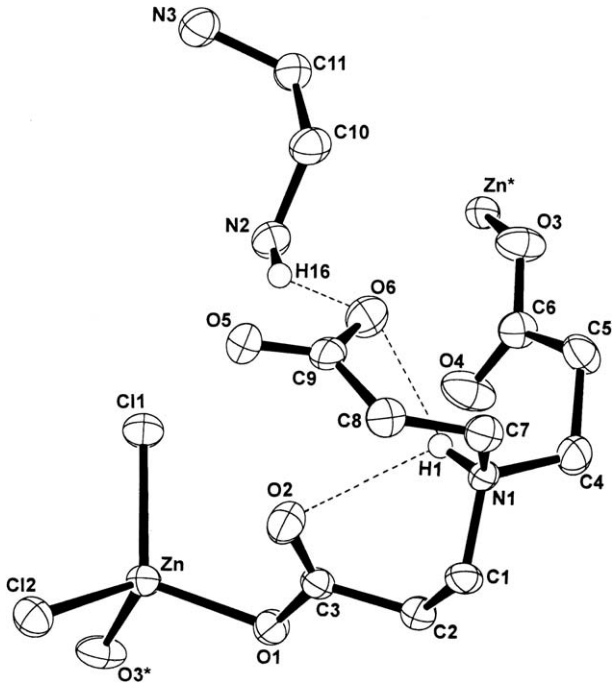

Fig. 1. Molecular structure of compound **1** showing the atom numbering scheme. H-atoms are drawn only for those that participate in hydrogen bonding. Broken lines denote hydrogen bonds. Displacement ellipsoids are drawn at 50% probability.

triggers formation of carboxylate bridged polynuclear compounds. This polymeric coordination compound is also sustained by hydrogen bonding interactions [H1$\cdots$O2 = 2.49(5), H1$\cdots$O6 = 2.17(5) Å]. Further, an intrastrand hydrogen bonding interaction between Cl1 and hydrogen atom H5 attached to the carbon atom C2 in the helical chain [H5$\cdots$Cl2 = 2.76(5) Å] plays an important role in stabilizing the resulted helical motif. As shown in Fig. 2, H_2en^{2+} molecules are incorporated into the groove of the helical chain by forming a hydrogen bond between the ammonium group N2 of en and the oxygen atom O6 of the metal-free carboxylate group of ntp [H16$\cdots$O6 = 2.06(6) Å].

In the crystal lattice, left-handed (M) and right-handed (L) helical chains co-exist with an equal molar ratio. The geometry around each zinc center is tetrahedral, defined by two oxygen donors from different ntp ligands and two chloride anions [Zn1–Cl1 = 2.230(1), Zn1–Cl2 = 2.277(1) Å]. Thus, the specific conformation of the ligand and therefore the compound itself is primarily governed by the interplay between possible versatile coordination modes and the flexibility of the ntp ligand and various hydrogen bonding interactions.

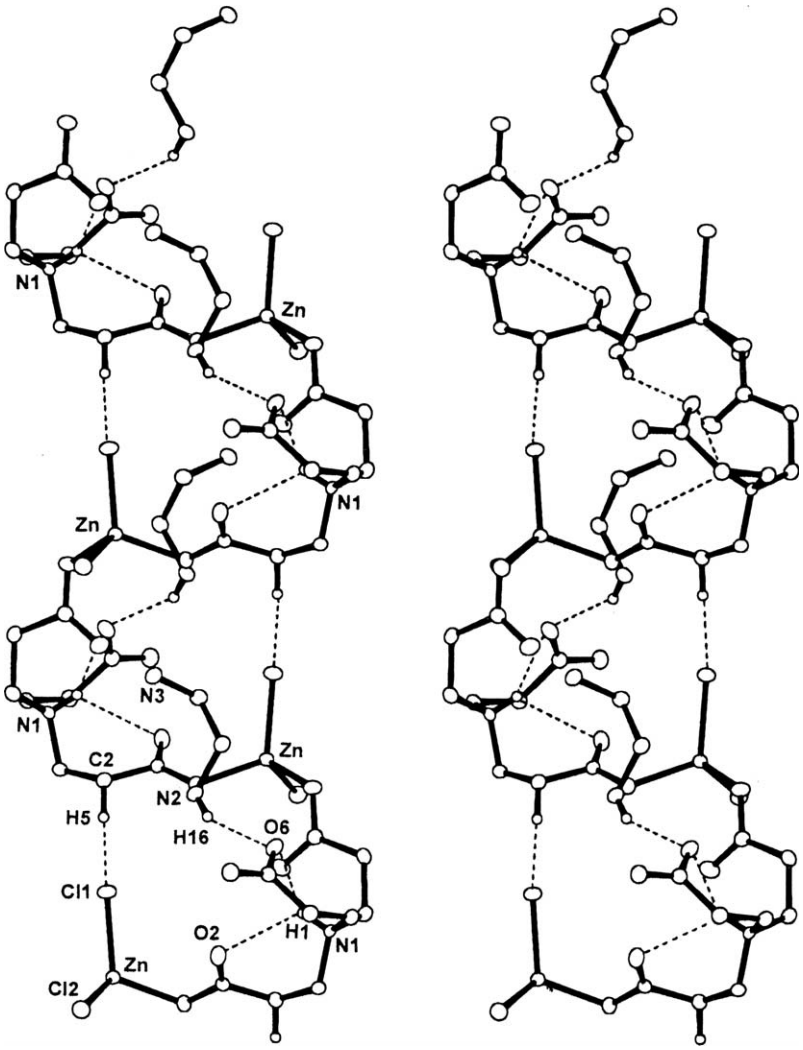

Fig. 2. Stereoview showing the formation of an infinite helical structure of compound **1** along a crystallographic twofold screw axis. H-atoms are drawn only for those that participate in hydrogen bonding. Broken lines denote hydrogen bonds. Note that H_2en^{2+} molecules are incorporated into the groove of the helical chain by forming the H16···O6 hydrogen bond.

3.4. Fluorescence measurements of the helical $[H_2en]^{+2}[ntpZnCl_2]^{-2}$ polymer

The interaction of compound **1** with calf thymus DNA was analyzed by measuring the changes in the intrinsic fluorescence of the compound at different nucleotide/compound molar ratios. A marked quenching effect was observed by the addition of DNA in the fluorescence emission spectra of the compound. The emission spectra observed was further interpreted as shown in Fig. 3. This showed a concentration dependent fluorescence quenching pattern of the compound. Fig. 4 shows the Scatchard [36] plot for the binding of the compound to calf thymus DNA. The slope and the intercept of the straight line obtained from Scatchard analysis gives the apparent association constant $(K_a) = 5.80 \times 10^3\ M^{-1}$ and the number of available binding sites per nucleotide phosphate $(n) = 0.19$, which is equivalent to ≈15 nucleotides per compound binding site.

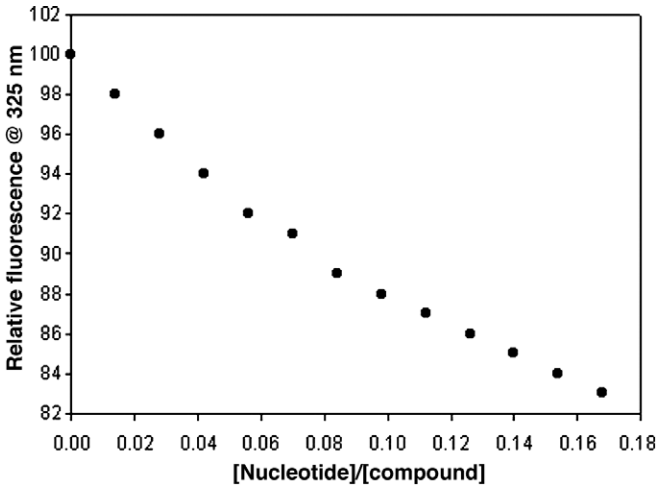

Fig. 3. Quenching effect of DNA at increasing concentration on the fluorescence of compound **1** (50 μM).

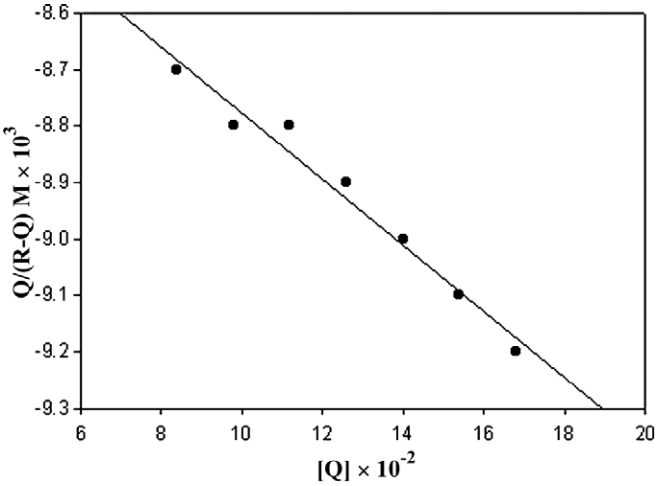

Fig. 4. Scatchard plot analysis for the binding of compound **1** with calf thymas DNA in 0.01 M in Tris–HCl buffer at 25 °C.

Our data suggests that the compound exhibits a good binding constant, which illustrates its binding ability to the DNA helix. This nature of the structure may also contribute to its better-fit position. This single stranded, helical structure of the compound with its tight binding to the DNA could be exploited to down regulate several undesirable expressed genes and so the technology might be analogous to antisense technology.

4. Supplementary data

Supplementary data are available from the CCDC, 12 Union Road, Cambridge CB2 IEZ, UK, quoting the Deposition number 272656.

$K_{0.2}Co_{1.4}Fe(CN)_6 \cdot 6.9H_2O$ structure resulted in the formation of paramagnetic Co^{II}–NC–Fe^{III} units [25,26]. Promising photochromic properties based on a spin transition was detected on a Co–Fe polycyanide $Na_{0.34}Co_{1.33}Fe(CN)_6 \cdot 4.5H_2O$ [27]. Reversible light induced metal-to-metal and metal-to-ligand charge transfers were observed in dinuclear complexes of the $Na[(L_5)Co–CN-Fe(CN)_5] \cdot nH_2O$ type (L_5 = tetradentate macrocyclic ligand with amine pendant arm) [28–31] while the temperature dependent charge transfer, causing the spin transition, was identified in the pentanuclear $\{[Co(tmphen)_2]_3[Fe(CN)_6]_2\} \cdot 9H_2O$ complex [32]. In 2–4 M NaCl solutions with $[Co(en)_3]^{3+}$ or $[Co(NH_3)_6]^{3+}$ and $[Fe(CN)_6]^{4-}$ ions, a photo-induced ionic pair charge transfer can occur [33,34].

Surprisingly, only a few Co–Fe heterobimetallic complexes based on hexacyanoferrate(II,III) anions and bearing amine-type ligands have been structurally characterized to date. The majority of them exhibit ionic structures [35–38], in some cases they contain dinuclear [28–31] or pentanuclear cores [32], but no polymeric structure has been determined yet.

Mössbauer spectroscopy has been used for the study of the dehydration processes in hexacyanoferrates(III); it was found that uncoordinated water molecules in the vicinity of $[Fe(CN)_6]^{3-}$ anions exhibited a strong effect on the quadrupole splitting parameter due to the changes in the electronic population of the t_{2g} level [39–42]. Usually, the dehydration process in coordination compounds leads to destruction of the single crystal character of the starting material. To our knowledge, the inverse situation, i.e. preservation of the single crystal character during dehydration, was observed in 3D-coordination polymers of the type $\{[Me(H_2O)_2(\mu\text{-}C_4O_4)(\mu\text{-}4,4'\text{-}bipy)]\}_n \cdot H_2O$ (Me = Co, Ni, Fe) [43].

In this work, as a part of our systematic study of hexacyanoferrates(II, III) [44,45], we report on the synthesis, crystal structure, thermal behaviour and dehydration process in single crystals of a new Co(III)–Fe(III) heterobimetallic compound, $[Co(en)_3][Fe(CN)_6] \cdot H_2O$. As a unique result of this study, the anhydrous and thermally more stable complex, $[Co(en)_3][Fe(CN)_6]$, was prepared by a solid-state single crystal dehydration of **1**, and its X-ray structure has been determined.

2. Experimental

2.1. Materials

$K_3[Fe(CN)_6]$ (Merck Co.) and dimethylformamide (Lachema Co.) were used as received. $[Co(en)_3]Cl_3 \cdot 3H_2O$ was prepared by a slightly modified procedure to that described in the literature [46].

2.2. Synthesis of $[Co(en)_3][Fe(CN)_6] \cdot H_2O$ (1)

A solution of $K_3[Fe(CN)_6]$ (0.33 g, 1 mmol) in 20 ml of water was added to 10 ml of an aqueous solution of $[Co(en)_3]Cl_3 \cdot 3H_2O$ (0.31 g, 1 mmol) with stirring at room temperature. The yellow precipitate which formed immediately in the solution, was filtered off and recrystallized from a hot aqueous solution. Upon cooling, orange needles, suitable for a single crystal X-ray data collection, were obtained. The crystals were filtered off, washed with a small amount of water and dried under an infrared lamp at 40 °C for 2 h. Yield: 65%.

2.3. Physical measurements

Elemental analyses (C, H, N) were performed on a Flash EA 1112 Elemental Analyser (ThermoFinnigan). The IR spectra (400–4000 cm^{-1}) as well as far-IR spectra (100–600 cm^{-1}) were obtained on a NEXUS 670 FT-IR spectrometer (ThermoNicolet) using KBr tablets and polyethylene discs, respectively. The transmission Mössbauer spectra of **1** and **2** were collected at 300 K using a Mössbauer spectrometer in constant acceleration mode with a ^{57}Co(Rh) source. The isomer shift values are calibrated with respect to metallic α-Fe.

TG and DSC (thermogravimetric and differential scanning calorimetry) measurements of complex **1** were made in air atmosphere using a THASS TG/DSC XP-10 thermal analyser (THASS GmbH) with a sample weight of 10 mg and thermal gradient of 5 °C per minute.

2.4. X-ray structure analysis

X-ray experiments were carried out on a four-circle κ-axis Xcalibur2 diffractometer equipped with a CCD detector Sapphire2 (Oxford Diffraction) at 100(2) K. The CrysAlis software package [47] was used for data collection and reduction. The structures were solved by the SIR97 program [48] incorporated in the WinGX program package [49]. All non-hydrogen atoms of $[Co(en)_3][Fe(CN)_6] \cdot H_2O$ (**1**) and $[Co(en)_3][Fe(CN)_6]$ (**2**) were refined anisotropically by the

full-matrix least-squares procedure [SHELXL-97] [50] on F^2 with weight: $w = 1/[\sigma^2(F_o)^2 + (0.036P)^2 + 0.745P]$ for **1** and $w = 1/[\sigma^2(F_o)^2 + (0.103P)^2]$ for **2**, where $P = (F_o^2 + 2F_c^2)/3$. Hydrogen atoms in both **1** and **2** were located from difference Fourier maps and refined using a 'riding' model, except for those belonging to the water molecule in **1** which were refined freely with fixed U_{eq} parameters. The molecular structures of **1** and **2** are depicted in Figs. 1, and 2, respectively, and were drawn using the Diamond software [51]. Crystal data and structure refinements for **1** and **2** are summarized in Table 1, while selected bond lengths and angles are given in Table 2.

3. Results and discussion

3.1. Synthesis and thermal behaviour study

Formerly, $[Co(en)_3]$ $[Fe(CN)_6]\cdot 2H_2O$ was prepared from an aqueous system containing $[Co(en)_3]Cl_3$ and $K_3[Fe(CN)_6]$, and moreover, the product was also structurally characterized [38]. In this study, the $[Co(en)_3][Fe(CN)_6]\cdot H_2O$ complex **1** used as the starting compound was synthesized by a similar manner as previously but hot water (80 °C) was used for recrystallization yielding the monohydrate upon slow cooling of the mother liquor.

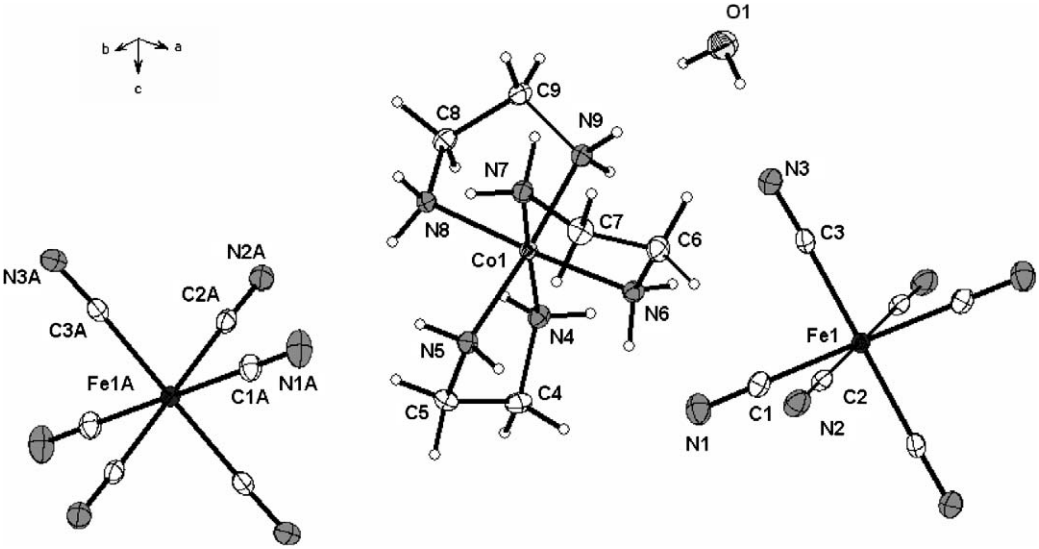

Fig. 1. The crystal structure of **1**. The thermal ellipsoids of non-hydrogen atoms are drawn at the 50% probability level. The H atoms are shown as small spheres of arbitrary radii.

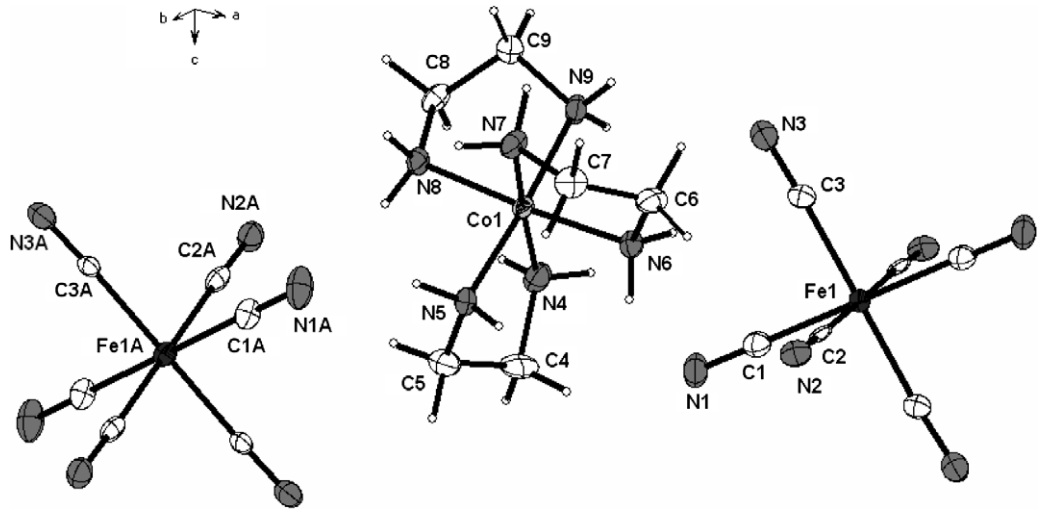

Fig. 2. The crystal structure of **2**. The thermal ellipsoids of non-hydrogen atoms are drawn at the 50% probability level. The H atoms are shown as small spheres of arbitrary radii.

It seems that a small change during the recrystallization process induced the formation of the monohydrated complex **1** instead of the dehydrated one. The existence of the monohydrated $[Co(en)_3][Fe(CN)_6] \cdot H_2O$ complex **1** follows not only from results of elemental analysis but mainly from single crystal X-ray analysis (see Section 3.2). The thermal stability interval of **1** lies between 25 and 70 °C (see Fig. 3). The complex starts to decompose and eliminate the water molecule at ca. 70 °C. This first step relating to one crystal water elimination is accompanied by a broad *endo*-effect observed on the DSC curve with the minimum at ca. 85 °C and it is finished at ca. 123 °C. Then, the anhydrous complex **2** remains thermally stable in the temperature interval of 125–215 °C (weight loss found/calcd.: 3.7/3.8%). Products of further thermal decomposition were not studied in detail. However, it is necessary to note that the thermal decomposition finishes at ca. 400 °C. The results following from this thermal study helped us to determine the thermal stability intervals both for **1** and **2**, and moreover, to suggest what solid-state synthetic route could be used for the preparation of single crystals of **2**.

Because the formation of an anhydrous complex by the dehydration of a hydrate is quite common, the formation and preservation of single crystals during the dehydration process was observed, to our knowledge, only in coordination polymers $\{[Me(H_2O)_2(\mu\text{-}C_4O_4)(\mu\text{-}4,4'\text{-}bipy)]\}_n \cdot H_2O$ (M = Co, Ni, Fe) [43]. Let us note that the anhydrous complex **2** is stable against secondary re-hydration when exposed to air humidity. This is not a common property

of heterometallic cyano-based complexes as reported e.g. for $\{[Zn(en)_2Ni(CN)_4Zn(en)][Ni(CN)_4]\cdot 3H_2O\}_n$ [52].

3.2. X-ray structure analysis

The crystal structures of both **1** and **2** exhibit ionic structures and the respective unit cells are built up of $[Co(en)_3]^{3+}$ complex cations (Co1) and two halves of crystallographically independent $[Fe(CN)_6]^{3-}$ complex anions with Fe1 and Fe1A iron(III) ions occupying special positions (a centre of inversion). Moreover, one crystallographically independent water molecule of crystallization is present in the structure of the hydrate **1** (Figs. 1 and 2). From the chemical and crystallographic point of views, the crystal structures of **1** and **2** are very similar to that as determined for the dihydrate $[Co(en)_3][Fe(CN)_6]\cdot 2H_2O$ [38]. As would be anticipated, the unit cell parameters of the anhydrous complex **2** are slightly shorter than those of the complex **1**, resulting in the unit cell volume of **2** being smaller in comparison with **1** (see Table 1).

The Co(III) ions in both the complexes **1** and **2** are coordinated in deformed octahedral arrangements by six nitrogen atoms from three *en* ligands. The Co–N distances vary from 1.958(2) to 1.972(2) Å for **1**, and 1.944(5) to 1.977(5) Å for **2** (Table 2). These values are comparable to those found for similar compounds, e.g. *Λ*-$[Co(en)_3]P_3O_9\cdot 2H_2O$ {1.953(4)–1.972(3) Å} [53], $[Co(en)_3]_3[FeCl_6]Cl_6\cdot H_2O$ {1.954(4)–1.979(4) Å} [54] and $[Co(en)_3]_2(pip)[(HPO_4)_2O_{15}Mo_5]\cdot 6H_2O$, where *pip* = piperazinium {1.958(3)–1.979(2) Å} [55]. The remaining geometric parameters within the *en* ligands are as expected.

In both structures, the $[Co(en)_3]^{3+}$ cations exhibit the $\Lambda\lambda\delta\delta$ (oblel$_2$) conformation. Due to the presence of the centre of inversion in both structures, there are also present antipodes with the $\Delta\delta\lambda\lambda$ (*elob*$_2$) conformation. The distinct situation was found in the case of $[Co(en)_3][Fe(CN)_6]\cdot 2H_2O$, where the $[Co(en)_3]^{3+}$ cations exhibit $\Lambda\delta\delta\delta$ and $\Delta\lambda\lambda\lambda$ conformations [38]. At this point, it is necessary to emphasize that most of the *Λ*-$[M(en)_3]^{n+}$ cations exhibit the $\Lambda\delta\delta\delta$ conformation, which is the most stable one as follows from the order of decreasing stability $\Lambda\delta\delta\delta(lel_3) > \Lambda\lambda\delta\delta(oblel_2) > \Lambda\lambda\lambda\delta(oblel_2) \cong \Delta\lambda\lambda\lambda(ob_3)$. The enthalpy increment is approximately 1.6 ± 0.9 kJ/mol for each δ to λ ring inversion [56]. The stabilization of the observed conformations is probably caused by the presence of the hydrogen bond system.

Each of the crystallographically independent Fe(III) ions in both structures are coordinated by six carbon-to-iron oriented terminal cyano ligands. In **2**, both $[Fe(CN)_6]^{3-}$ octahedrons are slightly compressed, with Fe1–C2 1.910(7) Å and Fe1A–C1A 1.917(7) Å bond lengths. On the other hand, the distance of Fe1–C1 1.956(2) Å is slightly elongated in **1** and contrarywise, the Fe1A–C1A distance {1.921(2) Å} is slightly compressed, similarly as in **2**. Generally, Fe–C distances vary from 1.935(7) to 1.956(2) Å (for **1**) and from 1.917(7) to 1.943(6) Å (for **2**) and all corresponding bond lengths are shorter in **2** as compared to **1**. For all that, the Fe–C distances are comparable with those found in other hexacyanoferrates(III), e.g. in $[Hbet]_3[Fe(CN)_6]\cdot 4H_2O$ (*bet* = betaine) {1.921(4)–1.942(3) Å} [57] or [tams][Fe(CN)$_6$]·$8H_2O$ (tams = 2,4,6-tris(1,4-diazabicyclo(2.2.2.)octane-*N*-methyl)mesitylene^{3+}) {1.934(3)–1.952(3) Å} [58]. The maximal deviation of 4.3° from the "ideal" right angle for the *cis* C–Fe–C angles was observed in the Fe1A octahedron (see Table 2). A similar conclusion can be made in the case of [tams][Fe(CN)$_6$]·$8H_2O$ [58], where the above-mentioned *cis* angles vary from 86.25(2)° to 93.03(2)°.

As follows from the results of the single crystal X-ray analysis of both structures, only the water molecule of crystallization has an influence on the re-arrangement of complex ions in the crystal structure during the dehydration process. In contrast, no significant changes were observed in interatomic parameters between both structures. The most marked changes are as follows: (I) a shortening of the Co1–N5 distance was observed upon dehydration {from 1.967(2) to 1.944(5) Å}; the remaining Co–N distances are essentially the same within the level of significance; (II) the FeC_6 octahedron is slightly elongated with the Fe1–C1 bond in **1** {1.956(2) Å}, as compared to **2**, being the longest one, while the FeC_6 octahedron is compressed with the shortest distance Fe1–C2 1.910(7) Å in the anhydrous compound **2** (see Table 2).

Symmetry codes: (a) $1-x$, $-y$, $1-z$; (b) $1-x$, $1-y$, $1-z$; (c) x, $1/2-y$, $-1/2+z$; (d) $1+x$, y, $-1+z$; (e) $1-x$, $1/2+y$, $3/2-z$; (f) $1-x$, $-1/2+y$, $3/2-z$; (g) x, $3/2-y$, $-1/2+z$; (h) x, $-1+y$, $-1+z$.

The crystal water molecule is situated in the space between both the complex ions in **1** and is involved in three hydrogen bonds. The oxygen atom of the water molecule acts as a donor in O–H···N hydrogen bonds and as an acceptor in N7–H7D···O1 ones (Table 3). The remaining hydrogen atoms from the amine group are involved in N–H···N(C) hydrogen bonds with N···N(C) distances in the range 2.848(3)–3.240(3) Å, and thus contribute to the stabilization of the crystal structure of **1**. In the anhydrous complex **2**, only N–H···N(C) hydrogen bonds are present with N···N(C) distances lying in the interval 2.890(8)–3.235(8) Å. A part of the crystal structure of **1** and **2** is depicted in Figs. 4a and 4b, respectively.

Additional structural information can be deduced from the comparison of hydrogen bond parameters in both compounds. As it can be seen from Table 3, almost all N–H···N(C) hydrogen bonds in compound **2** are shorter in comparison to **1**, indicating a somewhat higher contribution to the stabilization of the structure **2**, and moreover compensating the absence of the stabilization effect of the three medium hydrogen bonds in which the water molecules are involved in **1**. We assume that this ability to reinforce the hydrogen bond system after the loss of water molecules can be the reason for the fact that the crystal structure did not collapse during the heating process and the single crystal character was preserved. Moreover, the requirement to re-arrange the hydrogen bond system in **2** is most probably the reason for the above-mentioned changes in the coordination spheres of the Co1 and Fe1 central atoms.

3.3. Mössbauer study of *1* and *2*

The room temperature Mössbauer spectrum of $[Co(en)_3][Fe(CN)_6]\cdot H_2O$ (**1**) is depicted in Fig. 5. The room temperature Mössbauer spectra of both complex **1** and the dehydrated $[Co(en)_3][Fe(CN)_6]$ complex **2** reveal a doublet with almost the same isomer shift parameter

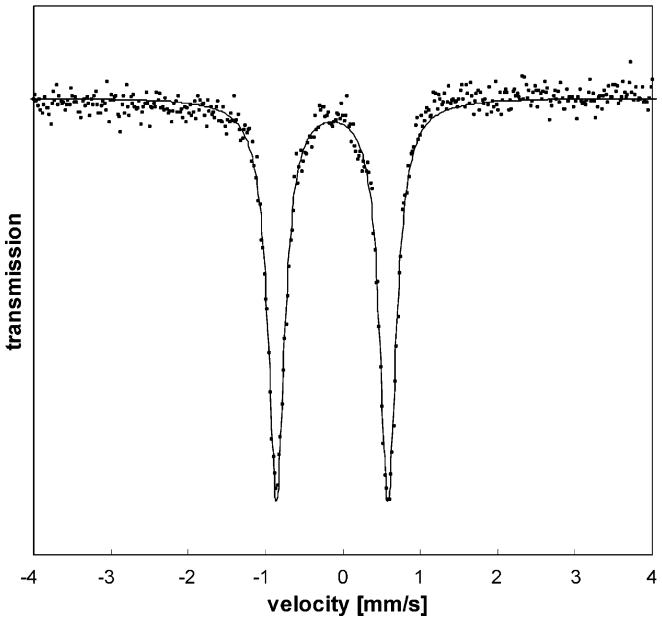

Fig. 5. The room temperature Mössbauer spectrum of **1**.

(−0.13 to −0.14 mm/s) characteristic for low-spin Fe^{3+} ions. Nevertheless, the dehydrated compound **2** exhibits significantly lower quadrupole splitting (0.99 mm/s) compared to the starting complex **1** (1.45 mm/s). This reflects an increase of the general symmetry of the iron environment due to the dehydration process. Such changes in quadrupole splitting parameters, depending on the number of water molecules and cation composition, were previously observed in Mössbauer spectra of various hexacyanoferrates(III) (see Table 4). The room temperature Mössbauer spectrum of the sample **1a** prepared by heating **1** up to 100 °C and occurring in an advanced dehydration stage (68%) is shown in Fig. 6. The fitting procedure gives clear evidence for the coexistence of both complexes **1** and **2**.

Table 4
Mössbauer parameters of **1** at room temperature and at ca. 100 °C (**1a**), and their comparison with the parameters of similar complexes involving $[Fe(CN)_6]^{3-}$ anions

Sample	δ (mm/s)	ΔE_Q (mm/s)	Γ (mm/s)	RA (%)	Assignment	Reference

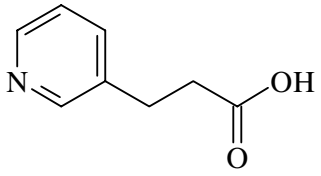
three complexes which show 1D and 2D polymeric structures, and found that weak interactions and hydrogen bonds, such as Ag···Ag, Ag···O, Cu···O, C–H···π and C–H···O, play important roles in linking the structures to form 3D supramolecular structures. The syntheses and crystal structures of $[Ag(PPIA)\cdot H_2O]_n$ (PPIA = 3-pyridinepropionic acid) (**1**), $[Cu(PPIA)_2\cdot 2H_2O]_n$ (**2**), and $[Zn(PPIA)_2(H_2O)_2]_n$ (**3**), form the subject of this report.



PPIA

2. Experimental

2.1. General procedures

The IR spectra were recorded on a Bio-Rad FTs-7 spectrometer. Elemental analyses were obtained from a PE 2400 series II CHNS/O analyzer, Perkin–Elmer CHN-2400 analyzer or HERAEUS VaruoEL analyzer.

2.2. Starting materials

The complexes $AgNO_3$, $Zn(NO_3)_2\cdot 6H_2O$ and $Cu(NO_3)_2\cdot 6H_2O$ were used as obtained from commercial sources without further purification. The reagent PPIA (PPIA = 3-pyridinepropionic acid) was purchased from Aldrich.

2.3. Preparation of $[Ag(PPIA)\cdot H_2O]_n$ (*1*)

$AgNO_3$ (0.17 g, 1.0 mmol) and PPIA (0.15 g, 1.0 mmol) were placed in a flask containing 15 mL CH_3OH. The mixture was stirred at room temperature for 20 h to yield a white precipitate. The solid was filtered out, washed with diethyl ether (2 × 10 ml) and dried under vacuum to give a white powder. Yield: 0.21 g, (76.1%). *Anal*. Calc. for $C_8H_{10}AgNO_3$ (MW = 276.04): C, 34.81; H, 3.65; N, 5.07. Found: C, 34.69; H, 3.46; N, 5.28%. IR (KBr disk, cm^{-1}): 3409(br), 3034(m), 2921(m), 2406(m), 1972(m), 1715(m), 1567(m), 1482(m), 1419(m), 1333(s), 1310(m), 1222(m), 1125(m), 1068(m), 1008(m), 909(m), 810(m), 699(m), 652(m), 634(m).

2.4. Preparation of $[Cu(PPIA)_2\cdot 2H_2O]_n$ (*2*)

$Cu(NO_3)_2\cdot 6H_2O$ (0.30 g, 1.0 mmol) was added to a MeOH solution (20 mL) containing PPIA (0.30 g, 2.0 mmol). The mixture was then refluxed for 20 h to afford

2.5. Preparation of $[Zn(PPIA)_2(H_2O)_2]_n$ (3)

$Zn(NO_3)_2 \cdot 6H_2O$ (0.297 g, 1.0 mmol) and PPIA (0.30 g, 2.0 mmol) were placed in a flask containing 15 mL CH_3OH. The mixture was stirred at room temperature for 20 h to yield a white precipitate. The solid was filtered out, washed with diethyl ether (2×10 ml) and dried under vacuum to give a white powder. Yield: 0.49 g (61.0%). *Anal*. Calc. for $C_{16}H_{20}ZnN_2O_6$ (MW = 401.71): C, 47.84; H, 5.02; N, 6.97. Found: C, 47.48; H, 4.96; N, 7.02%. IR (KBr disk, cm^{-1}): 3571(br), 3068(m), 2933(m), 2000(m), 1906(m), 1722(m), 1611(m), 1564(m), 1470(m), 1445(m), 1399(m), 1338(m), 1310(s), 1270(m), 1257(m), 1223(m), 1181(m), 1112(m), 1046(m), 981(m), 957(m), 836(m), 740(m), 676(m), 585(m). Colorless crystals suitable for X-ray crystallography were obtained by slow diffusion of diethyl ether into a MeOH solution of **3** over three days.

3. X-ray crystallography

The diffraction data of **1**–**3** were collected on a Siemens CCD diffractometer, which was equipped with graphite-monochromated Mo Kα (Kα = 0.71073 Å) radiation. Data reduction were carried by standard methods with the use of well-established computational procedures [10]. A colorless crystal of **1** was mounted on the top of a glass fiber with

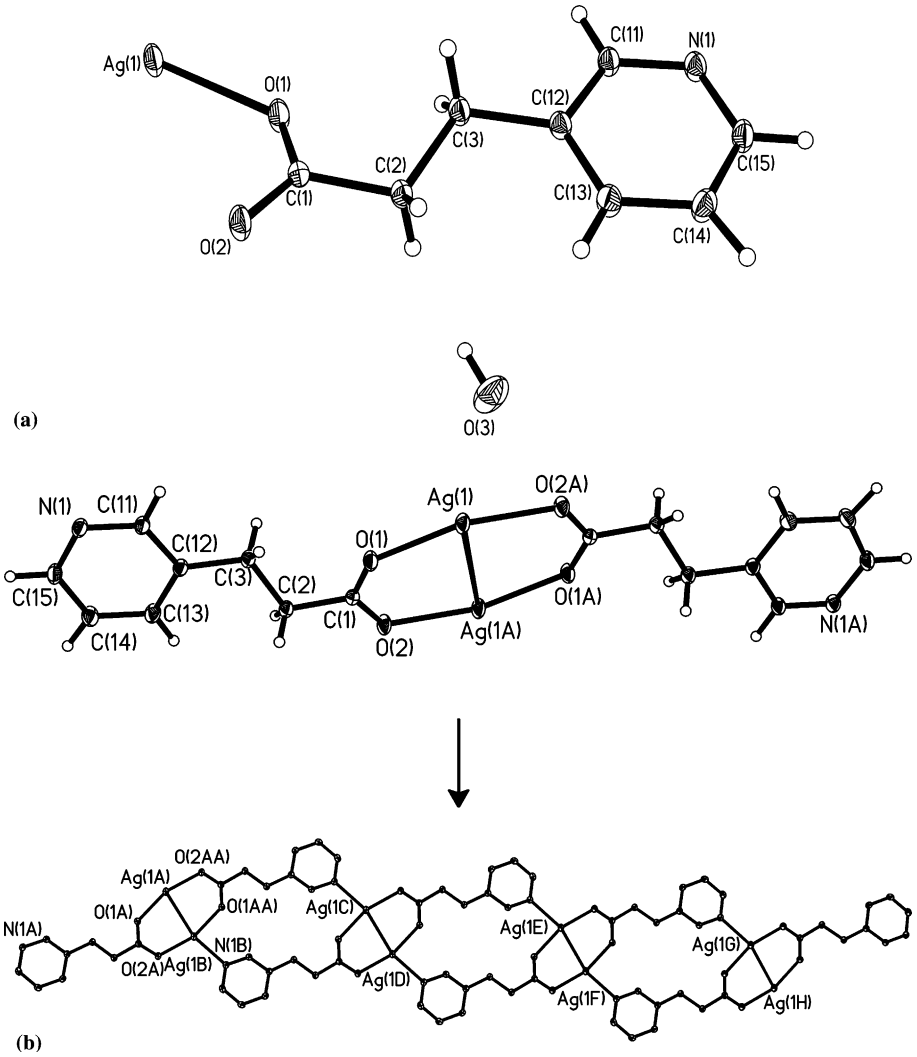

Fig. 1. (a) ORTEP drawing of the asymmetric unit of complex **1**. (b) An ORTEP drawing showing the coordination geometry of the silver metal center and the $Ag_2(PPIA)_2$ building blocks bound together by Ag–N bonds into a one-dimensional chain in **1**. Ellipsoids are scaled to enclose 20% of the electron density.

epoxy cement. The hemisphere data collection method were used to scan the data points at $5.28 < 2\theta < 50.02°$. The structure factors were obtained after Lorentz and polarization corrections. The positions of some of the heavier atoms, including the silver atom, were located by the direct method. The remaining atoms were found in a series of alternating difference Fourier maps and least-square refinements [11]. The final residuals of the final refinement were $R_1 = 0.0220$, $wR_2 = 0.0493$. The crystallographic procedures for **2** and **3** were similar to those for **1**. Basic information pertaining to crystal parameters and structure refinement is summarized in Table 1.

4. Results and discussion

4.1. Syntheses and spectroscopic studies

The reactions of 3-pyridinepropionic acid with $AgNO_3$, $Cu(NO_3)_2 \cdot 6H_2O$ and $Zn(NO_3)_2 \cdot 6H_2O$ in $MeOH/H_2O$ afforded complexes $[Ag(PPIA) \cdot H_2O]_n$ (PPIA = 3-pyridinepropionic acid) (**1**), $[Cu(PPIA)_2 \cdot 2H_2O]_n$ (**2**), and $[Zn(PPIA)_2(H_2O)_2]_n$ (**3**), respectively. For the complexes **1**–**3** and the PPIA ligand, the broad band centered at ca. 3400–3500 cm^{-1} indicates the O–H stretching of the carboxylic group or water molecules. The IR spectrum of the PPIA ligand suggests that the characteristic absorption bands of the COOH group occur at 1715 and 1482 cm^{-1}. For the complexes **1**–**3**, the peaks at 1567, 1609 and 1611 cm^{-1}, respectively, are attributed to the antisymmetric stretching vibrations, and 1419, 1399 and 1399 cm^{-1} to the symmetric vibrations of the carboxylic groups. Furthermore, the difference in values of the carboxylate group vibrations are 148, 210 and 212 cm^{-1} for **1**–**3**, respectively, agreeing with their solid state structural features [12].

4.2. Structure of $[Ag(PPIA) \cdot H_2O]_n$ (1)

Complex **1** crystallizes in the triclinic space group $P\bar{1}$. The asymmetric unit of **1**, Fig. 1(a), contains one Ag atom, one PPIA group and one included water molecule. The structure of complex **1**, emphasizing the environment around the silver, is shown in Fig. 1(b). Each Ag(I) center

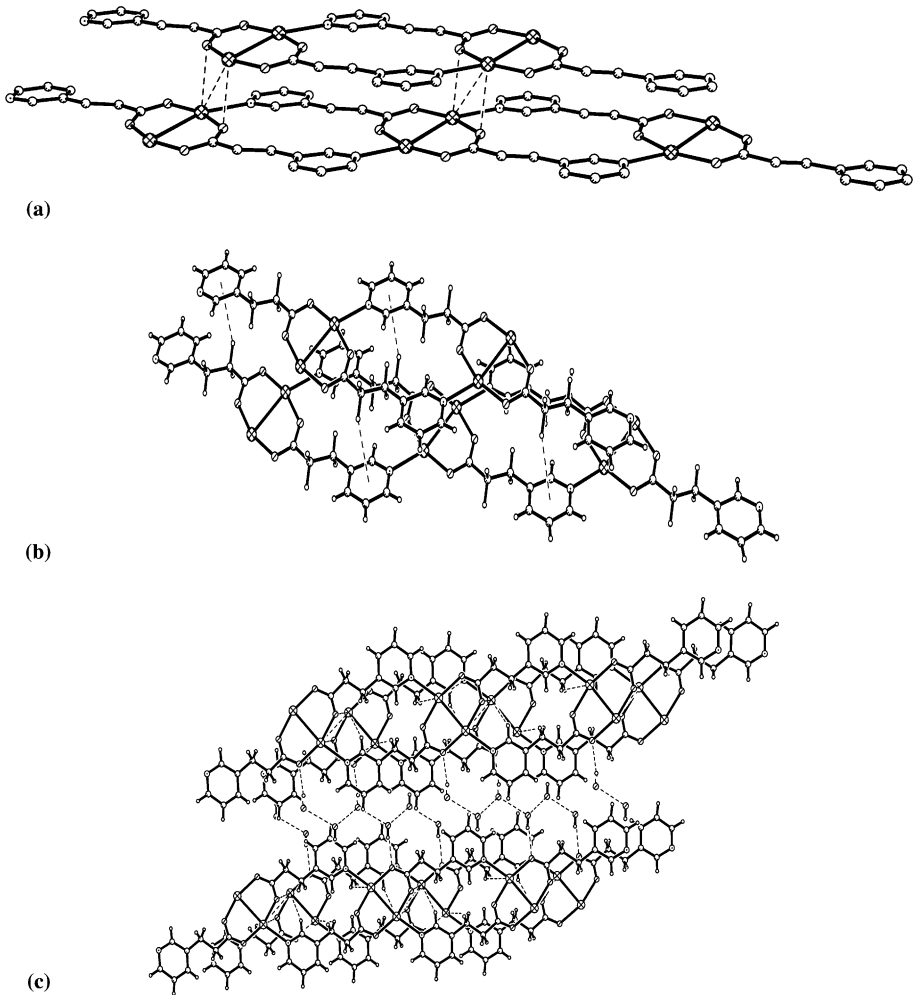

Fig. 2. (a) An ORTEP diagram showing the 1D chains penetrating into each other through Ag···Ag and Ag···O interactions in **1**. (b) An ORTEP diagram showing the set of one-dimensional chains stacking together through interchain C–H···π interactions in **1**. (c) An ORTEP diagram showing the 1D chains penetrating into each other through O–H···O interactions, forming a 3D supramolecular structure that is occupied by the water molecules in **1**.

lies in a distorted T-shaped coordination environment $\{AgNO_2\}$ consisting of one pyridyl nitrogen donor from one PPIA ligand (Ag(1)–N(1B) = 2.366(3) Å), and two oxygen atoms from different bridging carboxylate groups (Ag(1)–O(1) = 2.245(2) and Ag(1)–O(2A) = 2.216(2) Å). It is interesting that the tridentate PPIA ligand is coordinated to the silver center by the Ag–N bonds, linking $\{Ag_2(PPIA)_2\}$ building blocks into a one-dimensional polymeric chain (Fig. 1(b)). The Ag···Ag separation distance in the $\{Ag(PPIA)\}_2$ building block is 2.9203(7) Å, and the Ag···Ag separation distance in the 1D polymeric chain by the bridging PPIA ligand is 9.622 Å. The carboxylate groups of the PPIA ligand bridging silver centers form an eight-member ring $\{Ag_2O_4C_2\}$, while the 16-member ring $\{Ag_2O_2N_2C_{10}\}$ is formed by two silver atoms bonded to the pyridyl nitrogen donors and the carboxylate oxygen atoms of two bridging PPIA ligands in 1D chains.

The chains are further linked through extensive Ag···Ag and Ag···O weak interactions (Fig. 2(a)). The Ag···Ag distance is 3.539 Å, while the Ag···O distance is 2.977 Å, with the Ag(I) atom linking with the oxygen atom of a carboxylate group. The C–H···π type of interaction, from the methylene hydrogen atoms of the PPIA ligand to the center of the pyridyl ring of the other chain (H···π = 2.995 Å, ∠C–H···π = 145.8°), Fig. 2(b), were found in the structure. The hydrogen atoms of the water molecules also interact with the carboxylate oxygen atoms (H···O = 2.050 Å, ∠O–H···O = 168.7°) of the adjacent chains to form a 3D supramolecular structure. (Fig. 2(c)).

Complex **1** is in marked contrast to some Ag(I) complexes containing pyridine carboxylate ligands. The structure of $\{[Ag(Isonic)(HIsonic)]_{0.5}\cdot[Ag(Isonic)]\}_n$ (Isonic = the anion of isonicotinic acid) [13] consists two different of 1D chains; the hydrogen bonded assembly $[Ag(Isonic)(HIso)]_{0.5}$ and a wavy [Ag(Isonic)] polymeric chain. The complex $[Ag(nic)]_n$ (nic = the anion of nicotinic acid), [14] shows 1D zigzag chains of silver atoms, while each Ag atom is fivefold linked to two oxygen atoms of two different nicotinate ligands, to one nitrogen atom of a third nicotinate and to two other Ag atoms, having a dissymmetric

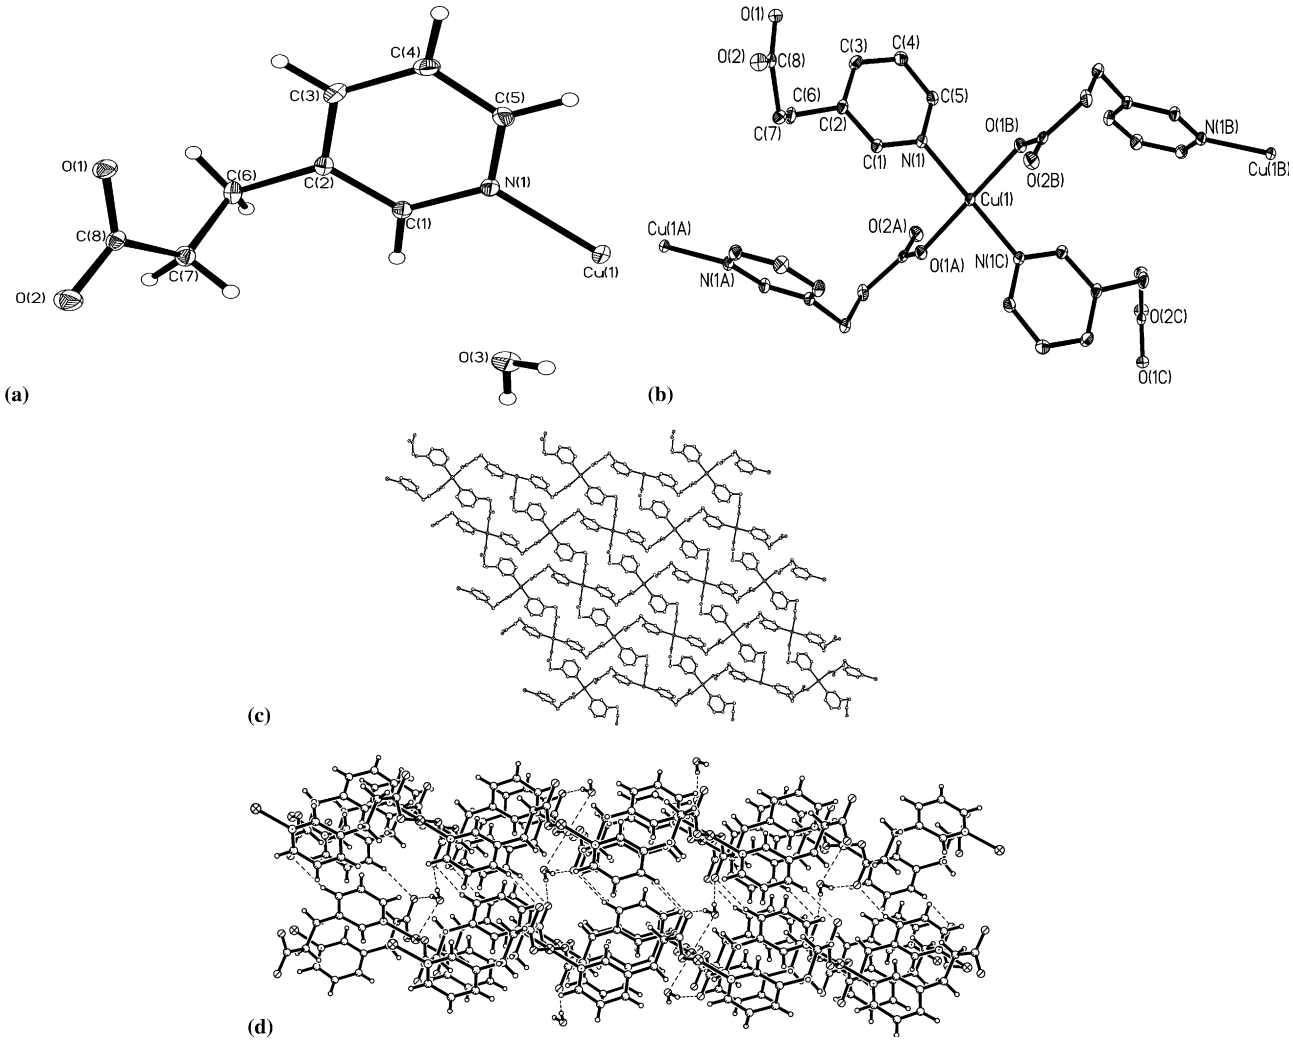

Fig. 3. (a) ORTEP drawing of the asymmetric unit of complex **2**. (b) An ORTEP drawing showing the coordination geometry of the copper metal center in **2**. trigonal bipyramid geometry. The reaction of $AgBF_4$ with isonicotinic acid led to the polymeric structure $\{[Ag_3(Isonic)_2]BF_4\}_n$ [15] consisting of Ag_3 triangles linked together by two isonicotinate ligands. The structure of polymeric $[Ag(nic)]_n$ is based on three-coordinate silver complex units which form the 1D helical chain, while $\{NH_4[Ag(nic)_2]\cdot H_2O\}_n$ shows 1D zigzag chains with the Ag(I) center adopting a distorted trigonal planar geometry. [16] The structure of $H[Ag(nic)_2]$ can be described as a 1D polymeric chain consisting of $[Ag(nic)_2]^-$ monomers linked via O···H···O hydrogen bondings [17].

4.3. Structure of $[Cu(PPIA)_2\cdot 2H_2O]_n$ (2)

Complex **2** was solved in the orthorhombic space group *Pbca*. The Cu(II) ion is at the center of symmetry. Thus, each asymmetric unit of **2** consists of one Cu(II) atom, a PPIA group and one free water molecule (Fig. 3(a)). The central Cu(II) ion is coordinated by two *trans* monodentate carboxylate groups from different PPIA ligands (Cu(1)–O(1A) = 1.9968(12) Å), and two *trans* pyridyl nitrogen atoms (Cu(1)–N(1) = 2.0254(14) Å) (Table 2). The overall coordination geometry about Cu(II) is slightly distorted square planar, as shown in Fig. 3(b). PPIA acts as a bridging ligand, through its pyridyl nitrogen atom and monodentate carboxylate group, linking different Cu(II) centers.

Four PPIA ligands ,with a head-to-tail aggregation, link Cu(II) into a $\{Cu(PPIA)\}_4$ 32-member ring. In the $\{Cu(PPIA)\}_4$ ring, the four Cu(II) ions and four PPIA ligands are not coplanar, which may be due to the different arrangement of PPIA and the coordination geometry of the metal ion. The $\{Cu(PPIA)\}_4$ rings are further extended into a 2D layer by sharing Cu(II) joints and PPIA edges, Fig. 3(c). The complex shows a void space with a Cu···Cu separation of 8.648 Å. The layers are further linked through extensive O–H···O (H···O = 1.921–2.133 Å; ∠O–H···O = 161.4–176.0°) and C–H···O (H···O = 2.027 Å; ∠C–H···O = 175.3°) hydrogen bondings and weak Cu···O interactions (Cu···O = 2.467 Å) among the layers Fig. 3(d).

The structure of complex **3** is in marked contrast to that found in the complex $Cu(PPIA)_2(H_2O)_2$, where the flexibility of the aliphatic part of the ligand allows the copper centers' coordinated water molecules to form into buckled layers. [18] The complex $[Cu_{1.5}(3\text{-}PYD)_3(H_2O)]\cdot 1.5H_2O$ is a twofold interpenetrating 3D framework based on $\{Cu(3\text{-}PYD)\}_6$ rings formed through head-to head and

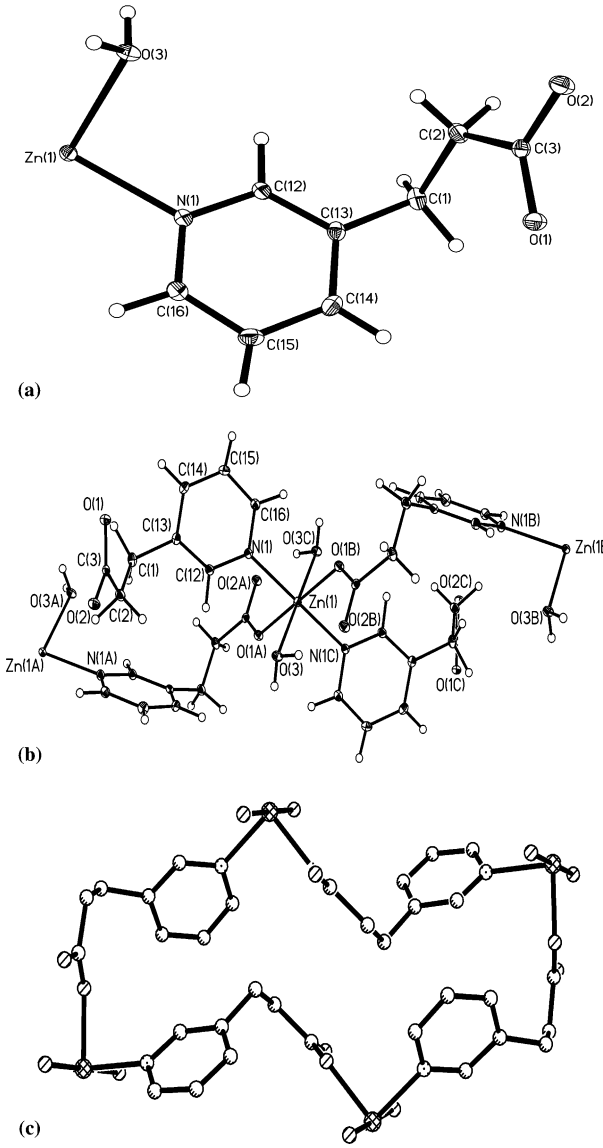

Fig. 4. (a) ORTEP drawing of the asymmetric unit of complex **3**. (b) An ORTEP drawing showing the coordination geometry of the zinc metal center in **3**. (c) $\{Zn(PPIA)\}_4$ rings from a head-to-tail arrangement of PPIA ligands. Ellipsoids are scaled to enclose 20% of the electron density.

head-to-tail mixed arrangements of 3-PYD [19]. The multidimensional Cu(II) coordination polymers $[Cu(Isonic)_2]\cdot EtOH$, $Cu(nic)_2$ [8f], $Cu(nic)_2$ [20], $\{[Cu_2(Isonic)_4\cdot 3H_2O]\cdot [Cu_2(Isonic)_4\cdot 2H_2O]\}\cdot 3H_2O$ [21] and $[Cu(Isonic)_2]\cdot 2H_2O$ [22] were synthesized by treating copper nitrate and copper chloride with isonicotinic acid and nicotinic acid under hydro(solvo)thermal conditions and they show rhombic open channels, pleated sheets, a perpendicular 24-member ring-like framework, mixed 2D and 3D open structures and chessboard tunnels, respectively.

4.4. Structure of $[Zn(PPIA)_2(H_2O)_2]_n$ (3)

Single-crystal X-ray diffraction analysis reveals that **3** is similar to **2**, showing a 2D supramolecular network consisting of $\{Zn(PPIA)\}_4$ rings derived from head-to-tail arranged PPIA ligands. Complex **3** was solved in the monoclinic space group $P2_1/n$. The asymmetric unit of **3**, Fig. 4(a), contains one Zn atom, one PPIA group and one bonded water molecule. Fig. 4(b) shows the coordination geometry about the Zn metal center. The zinc metal center adopts a distorted octahedral coordination geometry with the bond angles significantly deviated from 90° or 180° (Table 2). The Zn atom is bonded to two *trans* pyridyl nitrogen atoms (Zn(1)–N(1) = 2.164(2) Å) and two *trans* monodentate carboxylate groups (Zn(1)–O(1A) = 2.109(2) Å) in the equatorial plane. The Zn atom is also bonded to two H_2O ligands (Zn–O = 2.150(2) Å) in the axial positions to complete the distorted octahedral coordination geometry. Unlike complex **1**, the PPIA ligand bridges Zn(II) through the pyridyl nitrogen atoms and the oxygen atoms of the monodentate carboxylate groups, generating a head-to-tail aggregated $\{Zn(PPIA)\}_4$ 32-member ring, Fig. 4(c). In the $\{Zn(PPIA)\}_4$ ring, the four Zn(II) ions and four PPIA ligands are not coplanar, which may be due to the different arrangement of PPIA and the coordination geometry of the metal ion.

The $\{Zn(PPIA)\}_4$ rings are further extended into a 2D wave-like layer by sharing Zn(II) joints and PPIA edges, Fig. 5(a).The complex shows a void space with a Zn···Zn separation of 8.850 Å. The layers are further linked through extensive C–H···O (H···O = 2.369–2.441 Å; ∠C–H···O = 150.7–171.5°) and O–H···O (H···O = 2.027 Å; ∠O–H···O = 175.3°) hydrogen bondings, Fig. 5(b).

The nets in complex **3** are different from the chiral complex $Zn(nic)_2$ where the pyridine rings of the nicotinate groups intrude into the square cavities to result in interdigitation of the 2D square networks [23]. The noncentrosymmetric $[Zn(pecm)_2(H_2O)]_2\cdot CH_3CN\cdot 3H_2O$ (pecm = 4-[2-(4-pyridyl)ethenyl]cinnamate) adopts a caterpillar 1D chain structure [24] and the complex $[Zn(3\text{-}PYD)_2(H_2O)_2]$ (3-PYD = 3-(3-pyridyl)acrylic acid) shows a 3D supramolecular framework constructed by 1D {Zn(3-PYD)} chains through hydrogen-bonding interactions [19]. The complexes $Zn(nic)_2$ [25] and $Zn(Isonic)_2$ [26] were prepared by hydro(solvo)thermal reactions with 3-cyanopyridine or 4-cyanopyridine and $Zn(ClO_4)_2\cdot 6H_2O$, which exhibit complicated 2D grids with *exo*-tridentate nicotinate groups and 3D diamond-like networks.

5. Conclusion

Reactions of PPIA with different metal ions have afforded three coordination polymers based on $\{Ag(PPIA)\}_2$ and $\{M(PPIA)\}_4$ (M = Cu and Zn) rings or metal-carboxylate chains, respectively. Complex **1** forms 1D molecular chains through Ag···Ag, Ag···O interactions, C–H···π interactions and hydrogen bondings, to form 3D supramolecular structure. Complexes **2** and **3** form 2D layer structures which through hydrogen bondings form 3D

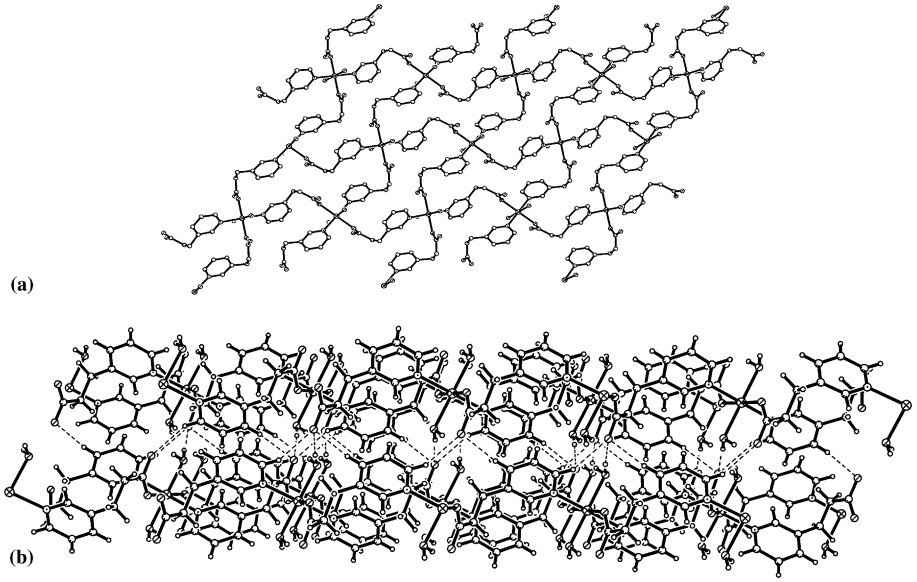

Fig. 5. (a) A 2D wave-like layer in **3** along the *c* axis. (b) Packing structure of **3** along the *b* axis showing the X–H···O (X = C or O) hydrogen bondings among the sheets.

supramolecular structures. Weak interactions like Ag···Ag, Ag···O interactions, C–H···π interactions and hydrogen bondings may play an important role in the self-assembly of such types of structures.

Teflon-lined stainless-steel autoclave and kept at 110 °C under autogenous pressure for 3 days. After cooling to room temperature, transparent prismatic crystals with suitable dimensions for crystallographic study were collected. The crystals were washed several times with distilled water and dried in the open air. They are stable for months under normal conditions of temperature and humidity. Schematically the reaction can be written as follows:

$$2.5ZnO + 3H_3PO_4 + C_6H_8N_2 + 5H_2O \rightarrow [Zn_{2.5}(HPO_4)_2(PO_4)][C_6N_2H_{10}] \cdot 5H_2O + 2.5H_2O$$

2.2. Investigation techniques

The title compound has been studied by various physico-chemical methods: X-ray diffraction, solid state NMR spectroscopy combined with ab initio calculations, infrared spectroscopy and thermal analysis.

2.2.1. X-ray diffraction

The intensity data collection was performed using a MACH3 Enraf Nonius diffractometer. The experimental conditions of data collection, the strategy followed for the structure determination and the final results are given in Table 1. The structure was solved by the SIR92 [16] program and refined by full matrix least-squares techniques based on F, using SHELXL97 [17]. Analytical empirical absorption corrections were made [18]. The structure factors were obtained after Lorentz polarization corrections. The positions of the heavier atoms, including the Zn atom, were located by the direct method. The remaining atoms were found in a series of alternating difference Fourier maps and least-square refinements. The positions of the hydrogen atoms of this hybrid compound were located directly from the difference Fourier maps. The drawings were made with DIAMOND [19].

2.2.2. NMR spectroscopy

All NMR spectra were recorded on a Bruker DSX-300 spectrometer operating at 75.49 MHz for ^{13}C and 121.51 MHz for ^{31}P with a classical 4 mm probehead allowing spinning rates up to 10 kHz. ^{13}C chemical shifts are given relative to tetramethylsilane and ^{31}P ones relative to 85% H_3PO_4 (external references, precision 0.5 ppm). The phosphorus spectrum was recorded under classical MAS conditions with high power proton decoupling while the carbon one was obtained by use of cross-polarization from protons (contact time 5 ms) and MAS. In all cases it was checked that there was a sufficient delay between the scans, allowing a full relaxation of the nuclei.

2.2.3. Ab initio calculations

DFT calculations (at the B3LYP/6-31+G* level) were made to allow the attribution of the ^{31}P and ^{13}C NMR signals to the various crystallographically unequivalent atoms. For phosphorus, the chemical shifts were determined by taking the coordinates of the PO_4 tetrahedra, found by X-ray diffraction, and calculating of the chemical shifts with the GIAO method. For carbon, the positions of the hydrogen atoms were first optimized at the same level of theory, the carbon and nitrogen atoms being frozen. All calculations were made with the GAUSSIAN 98 software.

Table 1
Crystal data and experimental parameters used for the intensity data collection

I. Crystal data	
Formula	$[Zn_{2.5}(HPO_4)_2(PO_4)][C_6N_2H_{10}] \cdot 5H_2O$
F_w	649.51
Crystal system	triclinic
Space group	$P\bar{1}$
a (Å)	9.841(4)
b (Å)	10.360(9)
c (Å)	12.852(4)
α (°)	111.07(5)
β (°)	90.72(3)
γ (°)	117.85(4)
V (Å^3)	1054.8(11)
Z	2
Refinement of unit-cell parameters with 25 reflection ($7° < \theta < 10°$)	
ρ_{calc} (g cm^{-3})	1.716
$F(000)$	556.00
Linear absorption factor: μ [Mo Kα] (cm^{-1})	2.471
Morphology	prism
Crystal size (mm)	$0.70 \times 0.35 \times 0.40$
Color	transparent
II. Intensity measurements	
Temperature (K)	293
Wavelength (Å) [Mo Kα]	0.7107
Diffractometer	Enraf-Nonius MACH 3
Scan mode	$\omega - 2\theta$
Monochromator	graphite plate
Theta range (°)	2.34–25.00
Measurement area	($\pm hkl$)
h_{max}; k_{max}; l_{max}	11; 12; 15
Number of scanned reflections (R_{int})	3679 (0.00)
Number of independent reflections	3516
Orientation and control reflections	2 −4 6 and 3 −5 4
III. Structure determination	
Lorentz and polarization corrections	
No absorption correction	
Program used	SHELX-97 [17]
Determination	direct methods
Hydrogen atoms located from difference Fourier maps and not refined	
Refined parameters	169
Absorption correction	analytical [18]
T_{min}, T_{max}	0.4167, 0.7088
Unique reflections included	(3516 ($I > 2\sigma$))
R; R_w	0.0449; 0.1333
Weighting scheme	σ
Goodness-of-fit on F^2	1.103
Residual Fourier density (Å^3)	$-1.77 < \rho < 2.66$
Largest shift/error	0.012
Drawings made with DIAMOND [19]	

Strategy and final results of the structure determination.

2.2.4. Thermal behavior

Thermal analysis was performed using the "multi-module 92 Setaram" analyzer operating from room temperature up to 500 °C at an average heating rate of 5 °C min^{-1} in a flowing drying argon atmosphere.

2.2.5. IR spectroscopy

Spectra were recorded in the range 4000–400 cm^{-1} with a "Perkin–Elmer FTIR" spectrophotometer 1000 using sample dispersed in a spectroscopically pure KBr pellet.

3. Results and discussion

3.1. Structure description

ZnP-2AMP exhibits a new type of layered structure. All non-hydrogen atoms occupy general positions in the unit cell, except the atom Zn(1) which is located in the special position 0, 1/2, 1/2 with half occupation. The three independent zinc atoms in ZnP-2AMP show distinct structural behaviour: Zn(2) and Zn(3) are tetrahedrally coordinated by O atoms with d_{av}[Zn(2)–O] = 1.940 Å and d_{av}[Zn(3)–O] = 1.939 Å. It is worth noting that Zn(1) with d_{av}[Zn(1)–O] = 2.092 Å is coordinated by two oxygen atoms, and four water molecules occupy the equatorial positions to form a slightly distorted octahedral coordination environment. The Zn(2) and Zn(3) atoms are both tetrahedrally coordinated and form Zn–O–P bonds via oxygen bridges, while Zn(1) forms only two Zn–O–P bonds. This environment yields rather larger displacement parameters for Zn(1) compared to Zn(2) and Zn(3). A similarly high coordination state of zinc atoms has been observed in other zinc phosphates [20,21]. The three independent P atoms represent three chemically distinct types of site; in each case the P atom is tetrahedrally coordinated to four oxygen atoms. The P(1) atom forms three P–O–Zn bonds via oxygen bridges and has one uncoordinated oxygen atom O(1) with a terminal –OH group (bond length d[P(1)–O(1)] = 1.580(5) Å). The P(2) atom makes the same linkages as P(1) (bond length d[P(2)–O(6)] = 1.591(5) Å). The P(3) atom makes linkages to three zinc atoms via bridging oxygen atoms and one terminal bond (bond length d[P(3)–O(11)] = 1.545(5) Å). There is one doubly protonated 2AMP molecule per asymmetric unit.

What is especially interesting about the framework structure of ZnP-2AMP is that it consists of one-dimensional tubes, linked together so as to form layers. The vertex linkage of ZnO_4, PO_4 and HPO_4 tetrahedra forms the building unit cage, which can been seen as building up of six 4-membered rings, two 8-membered rings and two 12-membered rings, as shown in Fig. 1, the octahedron pointing toward the interlayer space is the $ZnO_2(H_2O)_4$ group. It can also be considered as layers formed by two sheets, with 12-membered rings separated by about 4.1 Å. The linkage of the two sheets are made by P(2)–O(5)–Zn(2), P(3)–O(9)–Zn(3) and Zn(1)–O(4)–P(1) in a diagonal manner, as to form a regular sodalite cage built around the inversion center on which the octahedral $ZnO_2(H_2O)_4$ is located. The connection of the 12-membered cavity is similar to that of another zinc phosphate [22], and is shown in Fig. 1.

The inorganic sheets are anionic and the empirical formula of the layer is $[Zn_{2.5}(HPO_4)_2(PO_4)]_n^{2-}$, extended along the (a,b) plane. The neutrality is achieved by the incorporation of doubly protonated 2AMP. The inorganic–organic layers are shown in Fig. 2. The 2AMP and three water molecules [H_2O(3w), H_2O(4w), H_2O(5w)] occupy the interlayer spaces and are not bonded to each other. The 2AMP molecules serve as hydrogen bonding donors to the nearest oxygen framework atoms and balance the charge of anionic inorganic sheets. The interlayer hydrogen bonding between inorganic and organic layers

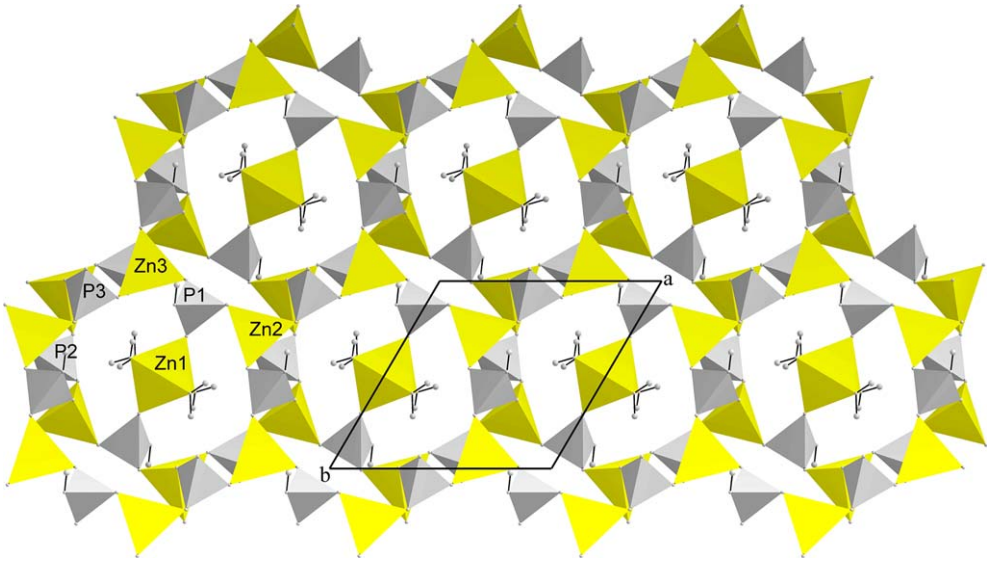

Fig. 1. Polyhedral representation of the framework $[Zn_{2.5}(HPO_4)_2(PO_4)][C_6N_2H_{10}] \cdot 5H_2O$, viewed down the c-direction.

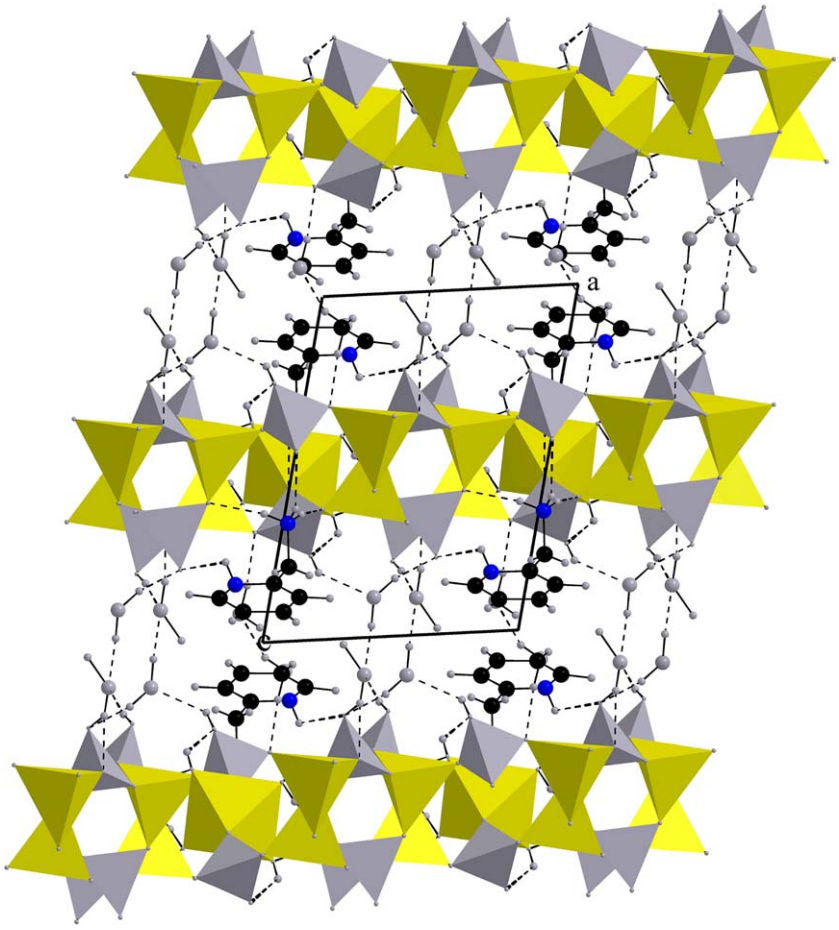

Fig. 2. Projection of $[Zn_{2.5}(HPO_4)_2(PO_4)][C_6N_2H_{10}]\cdot 5H_2O$ structure on the (a,c) plane.

and the intralayer hydrogen bonding between donor and acceptor in the same inorganic layer play an important role in stabilizing the ZnP-2AMP structure.

It can be pointed out that the structure of ZnP-2AMP is closely related to that of the metal phosphate $[Zn_{(2-x)}Co_x(HPO_4)_3]\cdot C_3N_2H_{12}$, $x = 0.05$ [23], in which the polyhedral connectivity of the MO_4 and HPO_4 centers leads to a layered structure with parallel 12-ring layers. The two dimensional sheets are built up from connecting infinite chains, through 4 rings, to form 12 rings; this type of chain contains triple edge-sharing 4-ring units. The latter have also been reported by Harrison et al. [22], and include edge sharing helixes of 4 rings in open-framework $NaZnPO_4\cdot H_2O$. The 12-ring layers presented in this paper are different from those reported by Harrison et al. [24,25]. First the linkage of 4-ring units that constitutes the 12-ring sheets is different and the orientation of the 12-ring sheets is distinct. Second, the 12 rings described here are linear and planar within a layer while those reported by Harrison et al. are split or "bifurcated".

3.2. NMR spectroscopy and ab initio calculations

Fig. 3 shows the proton-decoupled ^{31}P MAS NMR spectrum of crystalline monophosphate $[Zn_{2.5}(HPO_4)_2(PO_4)][C_6N_2H_{10}]\cdot 5H_2O$. This spectrum is in good agreement with the X-ray structure. Indeed, it exhibits three resonances at 0.5, 5.1 and 6.1 ppm, corresponding to three crystallographically independent phosphorus atoms. These chemical shift values agree well with those of monophosphates [26–31]. A tentative partial attribution of the NMR components to the phosphorus atoms P(1), P(2)

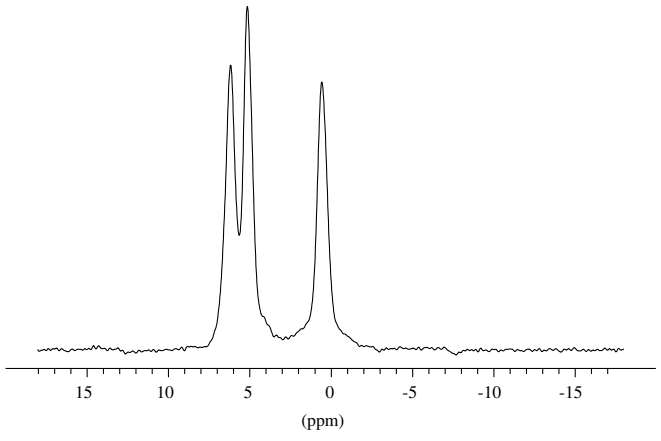

Fig. 3. ^{31}P MAS-NMR spectrum of crystalline $[Zn_{2.5}(HPO_4)_2(PO_4)][C_6N_2H_{10}]\cdot 5H_2O$.

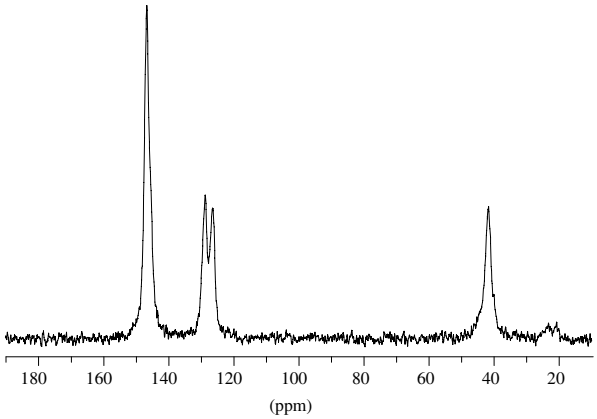

Fig. 4. ^{13}C CP-MAS-NMR spectrum of crystalline $[Zn_{2.5}(HPO_4)_2(PO_4)]\cdot[C_6N_2H_{10}]\cdot 5H_2O$.

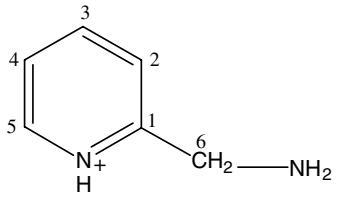
and P(3) was done by using ab initio calculations. For this purpose, the isotropic chemical shifts of the three phosphorus atoms P(1), P(2) and P(3) in the three PO4 tetrahedra were calculated. The calculated values were the same for P(1) and P(2) and slightly shifted to lower ppm (with reference to H_3PO_4) for P(3). However the shift (ca. 1 ppm) was smaller than the experimental value (ca. 4 ppm), probably due to the fact that our calculations did not take into account the presence of the atoms in the outer coordination sphere. However we can reasonably attribute the signal at 0.5 ppm to P(3) and the two other signals to P(1) and P(2).

Fig. 4 shows the ^{13}C CP-MAS NMR spectrum of the title compound. The carbon atoms of the organic moiety are labelled as depicted below:



The signal at 41.6 ppm corresponds to the aliphatic carbon atom C6 and proves the presence of only one organic entity in the asymmetric unit of the compound. This result is in good agreement with the X-ray data. The other signals at higher chemical shifts are related to the pyridinium ring carbon atoms (C1, C2, C3, C4 and C5). As for phosphorus, a tentative attribution can be made by using ab initio calculations. As the hydrogen atoms were not refined during the X-ray determination, these atoms were first optimized at the B3LYP/6-31+G* level before calculation of the carbon chemical shifts. The values were then corrected to the value of tetramethylsilane. The calculated values agree well with the experimental ones for C2 (125.2 for 126.4), C4 (127.3 for 128.7) and C6 (36.3 for 41.6) atoms, but are strongly shifted (at least for C5 which is shifted by ca. 10 ppm, C2 being shifted by ca. 5 ppm) for the carbon atoms ortho and para to the nitrogen. C1 is probably not seen experimentally as it is not linked to protons and C2 and C5 correspond probably to the NMR signal at 146.7 ppm. The difference between theory and experiment is probably related to the bad location of the pyridinium proton which also interacts with other molecules in the crystal.

3.3. Thermal analysis

The DTA curve shows that the zinc phosphate ZnP-2AMP undertakes, between 50 and 280 °C, four endothermic peaks:

- The first one corresponds to the removal of water molecules Ow(3), Ow(4), Ow(5) located in the interlayer spaces which evaporate almost simultaneously at the relatively low temperature of about 80 °C, (weight loss calculated 8.31%, experimental 8.22%).
- The second and the third peaks correspond to the removal of water molecules Ow(1) and Ow(2). They depart less easily from octahedral coordination, and we can consider probably that the removal of Ow(1) occurs before that of Ow(2), because its hydrogen bonds are weaker, (weight loss calculated 5.54%, experimental 5.61%).
- The fourth peak corresponds to the removal of one water molecule arising from the irreversible dehydroxylation reaction due to the presence of terminal P–OH groups and deprotonation of the amine cations, above 224 °C (weight loss calculated 2.77%, experimental 2.86%), according to the following reaction:

$$[Zn_{2.5}(HPO_4)_2(PO_4)][C_6N_2H_{10}]\cdot 5H_2O \rightarrow Zn_2P_2O_7 + 1/2Zn(PO_3)_2 + C_6N_2H_8 + 7H_2O$$

Finally the weight loss, between 274 and 500 °C, corresponds to the degradation of the template molecule (organic entities), giving $Zn_2P_2O_7$ and $Zn(PO_3)_2$ as the final decomposition products. The observed total weight loss of (32.89%) agrees well with the calculated value (33.38%) for the loss of ZnP-2AMP. A grey solid is obtained, probably containing a carbon residue. The latter can be eliminated by calcination of the sample at 850 °C in air.

3.4. IR spectroscopy

The infrared absorption spectrum of the title compound shows the band vibrations of the 2-aminomethylpyridinium cation and monophosphoric anions (HPO_4^{2-} and PO_4^{3-}). To assign the IR peaks to vibrational modes, we have examined the modes and frequencies in similar compounds [32]. The broad bands between 3500 and 2300 cm^{-1} correspond to the stretching of the organic and hydroxyl groups [ν(N–H), ν(C–H) and ν(O–H) of P–OH groups]. The vibrations between 1650 and 1200 cm^{-1} are assigned to bending and stretching modes (δNH^+), $\nu C(=C)$). The observed shoulder at 1260 cm^{-1} and the weak band at 830 cm^{-1} are

assigned to the δ (P–O–H) in plane bending and δ(P–O–H) out of plane bending modes [33]. Various valency and bending vibration bands between 1200 and 300 cm^{-1}, are characteristic of a PO_4 tetrahedron [32]. In this case, the stretching vibration bands originating from both symmetric $\nu_1(A_1)$ and asymmetric $\nu_3(F_2)$ modes are, respectively, observed in the range [1000–800] and [1200–1000] cm^{-1}. The PO_4 tetrahedra has also bending vibrations as symmetric $\nu_4(F_2)$ and asymmetric $\nu_2(E)$, respectively observed in the frequency range [650–500] and [500–300] cm^{-1}. Supplementary frequencies in the $\nu_s(PO_4)$ domain are attributed to bending modes $\delta(C_{aryl}–H)_{ip}$ [34].

polydentate 1,3,5-triazine-based N-donor ligands [25]. In the course of this study, it appeared that the architecture of these materials depends strongly on the reaction conditions, e.g. temperature and pressure [22,23]. This observation prompted us to study the influence of the reaction solvent on the topology of these complexes. In the present study, we selected *N*,*N*′-{2,4-di-[(di-pyridin-2-yl)amine]-1,3,5-triazine}ethylenediamine (L) as a flexible polydentate ligand and Zn(II) and Cd(II) metal centres, because only a few studies have been focused on late-transition metals so far. The ligand L reacts with Zn(II) and Cd(II) nitrate at 100 °C under autogenous pressure to afford either mononuclear complexes when the reaction is performed in methanol, or trinuclear species when the reaction is carried out in acetonitrile. The structures of these complexes are described in this report, as well as their spectroscopic characteristics.

2. Experimental

2.1. Syntheses

All commercially available reagents were used without further purification. The ligand L was prepared according to a reported method [26].

2.1.1. Preparation of coordination compounds *1* and *2*

Zinc(II) nitrate hexahydrate (20 mg, 0.066 mmol) or cadmium(II) nitrate tetrahydrate (20.8 mg, 0.067 mmol) was added to a suspension of L (15 mg, 0.016 mmol) in methanol (6 ml). The resulting colourless solutions were allowed to stand at 100 °C for 12 h under autogenous pressure in a sealed Pyrex tube to form in good yields **1**, or **2** as colourless single crystals.

*Analyses for **1**:* Yield 54% (10 mg). *Anal.* Calc.: C, 53.16; H, 3.50; N, 28.40. Found: C, 52.45; H, 3.54; N, 27.82%. Main IR absorption bands (cm^{-1}) 3300(w), 3085(w), 1604(w), 1583(s), 1557(s), 1538(w), 1367(s), 1303(s), 1020(m), 997(m), 808(s).

*Analyses for **2**:* Yield 48% (9 mg). *Anal.* Calc.: C, 50.95; H, 3.35; N, 27.22. Found: C, 49.84; H, 2.96; N, 26.53%. Main IR absorption bands (cm^{-1}) 3324(w), 3070(w), 1604(w), 1582(s), 1557(s), 1538(m), 1362(s), 1305(s), 1016(m), 997(m), 808(s).

2.1.2. Preparation of coordination compounds *3* and *4*

A similar procedure involving the same reactant quantities was followed but now using acetonitrile as solvent.

*Analyses for **3**:* Yield 41% (10.5 mg). *Anal.* Calc.: C, 39.92; H, 2.72; N, 25.12. Found: C, 40.04; H, 2.67; N, 25.19%. Main IR absorption bands (cm^{-1}) 3389(w), 3085(w), 1604(s), 1585(w), 1558(s), 1540(m), 1362(s), 1295(s), 1020(s), 809(s).

Analyses for ***4***: Yield 33% (9 mg). *Anal.* Calc.: C, 36.49; H, 2.49; N, 22.97. Found: C, 38.34; H, 2.61; N, 22.68%. Main IR absorption bands (cm^{-1}) 3382(w), 3085(w), 1600(s), 1581(w), 1558(s), 1540(m), 1367(s), 1300(s), 1017(s), 807(s).

2.2. Physical measurements

Elemental analyses for C, H and N were performed with a Perkin–Elmer 2400 analyser. FTIR spectra were recorded with a Perkin–Elmer Paragon 1000 FTIR spectrophoto-

2.3. Crystallographic analysis

2.3.1. Single crystal X-ray diffraction analysis for *1, 2 and 3*

The molecular structures of compounds **1**, **2** and **3** were determined by single-crystal X-ray diffraction methods. Crystallographic and experimental details for the different structures are summarized in Table 1. Intensity data and cell parameters were recorded at room temperature (293 K) on a Bruker AXS Smart 1000 single-crystal diffractometer (Mo Kα radiation) equipped with a CCD area detector. The data reductions were performed using the SAINT [27] and SADABS [28] programs. The structures were solved by direct methods using the SIR97 program [29] and refined on F_o^2 by full-matrix least-squares procedures, using the SHELXL-97 program [30]. The non-hydrogen atoms were refined with anisotropic atomic displacements, with the exception of the disordered acetonitrile molecule in compound **3**. The hydrogen atoms were included in the refinement at idealized geometries (C—H 0.95 Å) and refined "riding" on the corresponding parent atoms, with the exception of H1N in compounds **1** and **2** and H1N and H2N in compound **3**, which were located in the difference Fourier map. The weighting scheme used in the last cycle of refinement was $w = 1/[\sigma^2(F_o^2) + (0.1099P)^2]$ (**1**), $w = 1/[\sigma^2(F_o^2) + (0.0700P)^2]$ (**2**) and $w = 1/[\sigma^2(F_o^2) + (0.0747)^2]$ (**3**), where $P = (F_o^2 + 2F_c^2)/3$. Molecular geometry calculations were carried out using the PARST97 program [31]. All calculations were carried out on a DIGITAL Alpha Station 255 computer.

3. Results and discussion

3.1. General

The complexes **1**–**4** have been prepared by the reaction at 100 °C under autogenous pressure of the polydentate *N*,*N*′-{2,4-di-[(di-pyridin-2-yl)amine]-1,3,5-triazine}ethylenediamine ligand (L, Chart 1) with Zn(II) or Cd(II) nitrate. Interestingly, depending on the crystallisation solvent, mononuclear or trinuclear complexes have been obtained. **1** and **2** have been prepared in methanol and are formulated as $ZnL(NO_3)_2$ (**1**) and $CdL(NO_3)_2$ (**2**), according to X-ray single crystal analysis, while **3** and **4** have been isolated in acetonitrile. Complex **3** consists of a $Zn_3L(NO_3)_6 \cdot CH_3CN$ trinuclear species as elucidated by X-ray single crystal diffraction. Complex **4** crystallises as a poorly crystalline powder for which the X-ray powder diffraction pattern could not be interpreted. Elemental analyses of **4** are in agreement with a trinuclear stoichiometry and allow to state the formulation $Cd_3L(NO_3)_6 \cdot CH_3CN$ for this compound.

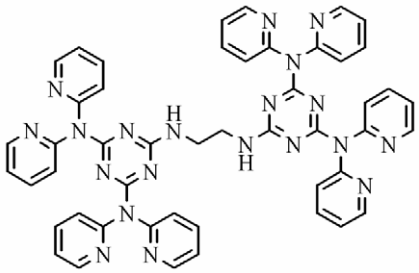

Chart 1. *N*,*N*′-{2,4-di-[(di-pyridin-2-yl)amine]-1,3,5-triazine}ethylene diamine (L).

3.2. Structures

3.2.1. Crystal structures of *1 and 2*

The complexes $ZnL(NO_3)_2$ (**1**) and $CdL(NO_3)_2$ (**2**) are isostructural and crystallise in the centric monoclinic *C*2/*c* space group, with the metal ions lying on the 2-fold rotation axis. Their ORTEP views are depicted in Figs. 1 and SI1, respectively. Selected bond distances and angles for both complexes are reported in Table 2. As can be seen in Fig. 1, only two of the four available dipyridylamine moieties of L are coordinated, and act as chelating ligands towards the same metal centre, resulting in the formation of a monometallic complex. The metal centre is in a distorted octahedral environment with a coordination sphere defined by four nitrogen atoms of two dipyridylamine units [Zn1—N6 = Zn1—N6′ = 2.127(3), Zn1—N7 = Zn1—N7′ = 2.148(3) Å for **1** and Cd1—N6 = Cd1—N6′ = 2.325(8), Cd1—N7 = Cd1—N7′ = 2.321(7) Å for **2**] and two oxygen atoms of the monodentate nitrate anions [Zn1—O1 = Zn1—O1′ = 2.146(5) Å for **1** and Cd1—O1 = Cd1—O1′ = 2.23(1) Å for **2**] (symmetry code ′: $1 - x$, y, $1/2 - z$ for **1** and $-x$, y, $1/2 - z$ for **2**).

The structures of **1** and **2** are additionally stabilised by π–π, C—H···O and C—H···N interactions (see Fig. 2 for compound **1**). The centroid-to-centroid distance between the triazine ring N1 C1 N2 C2 N3 C3 and the symmetry generated pyridine moiety N6′ C5′ C6′ C7′ C8′ C9′ is of 3.794(3) Å and the angle between the planes is of 28.74(3)°, indicating the presence of weak interactions

[32]. Also intermolecular hydrogen bonds are present, namely those involving the hydrogens H1N and H1N′ of the ethylene diamine fragment and the O2 and O2′ atoms of nitrate groups from neighbouring complexes [N4···O2 2.87(1), H1N···O2 2.17(5) Å, N4—H1N···O2 154(5)°]. An analogous situation with similar distances and angles is observed for compound **2**.

3.2.2. Crystal structure of *3*

The ORTEP view of complex $Zn_3L(NO_3)_6 \cdot CH_3CN$ (**3**) is shown in Fig. 3 together with the atomic labelling scheme; selected bond distances and angles are listed in Table 2. As in **1** and **2**, the ligand L chelates a metal centre (Zn2) through two dipyridylamine moieties, but here also the four remaining pyridine rings are coordinated to two Zn ions (Zn1 and Zn3), giving rise to a trinuclear complex.

Zn1 and Zn2 are both hexacoordinated but show different environments. Zn1 presents a highly distorted octahedral coordination involving one dipyridylamine group [Zn1—N6 = 2.065(4), Zn1—N7 = 2.032(4) Å] and two asymmetrically chelating nitrate ions [Zn1—O1 = 2.261(4), Zn1—O2 = 2.144(5), Zn1—O4 = 2.086(5), Zn1—O5 = 2.416(5) Å]. On the contrary Zn2 is surrounded by two dipyridylamine groups and one chelating nitrate ion. The equatorial positions are occupied by the two oxygens of the nitrate [Zn2—O7 = 2.230(3), Zn2—O8 = 2.191(3) Å] and by two nitrogens which belong to different dipyridylamine units [Zn2—N9A = 2.101(3), Zn2—N10 = 2.079(3) Å]. The two remaining nitrogen atoms complete the octahedral coordination in axial position [Zn2—N9 = 2.190(3), Zn2—N10A = 2.195(3) Å].

Zn3 is pentacoordinated with one dipyridylamine group and three monodentate nitrate ions forming a trigonal bipyramidal environment ($\tau = 0.81$ [33]). Two oxygen atoms from the nitrate ions [Zn3—O13 = 2.067(4), Zn3—O16 = 2.088(5) Å] and one nitrogen atom from the dipyridylamine moiety [Zn3—N6A = 2.116(4) Å] constitute the equatorial plane, while the remaining nitrate anion and pyridine fragment occupy the axial positions [Zn3—N7A = 2.155(4), Zn3—O10 = 2.088(3) Å].

Also in **3** intramolecular π–π interactions are present (Fig. 4). The triazine ring N1 C1 N2 C2 N3 C3 interacts with the pyridine ring N9A C19A C18A C17A C16A C15A with a centroid-to-centroid distance of 3.794(3) Å and a dihedral angle between the least-square planes passing through the aromatic rings of 18.2(1)°. This centroid-to-centroid distance is at the upper limit for aromatic stacking interactions [32]. It can be highlighted that the second triazine moiety in the trinuclear unit is not involved in such non-covalent forces. Moreover the complex exhibits also C—H···N interactions involving the ethylene diamine fragment, the pyridine rings and the nitrate ions (Fig. 4).

Additionally, each trinuclear unit is connected to neighbouring trinuclear units via intermolecular forces, which gives rise to the formation of a three-dimensional network.

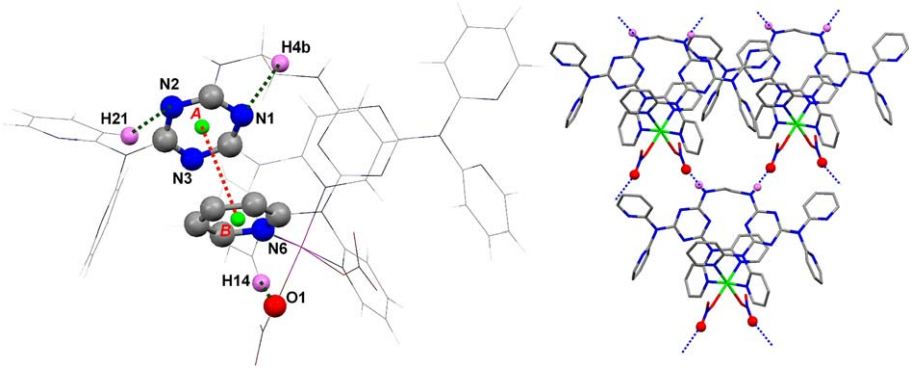

Fig. 2. Representation of the π–π, C—H···O, C—H···N interactions and intermolecular hydrogen bonds in **1**. *A*, centroid of the N1 C1 N2 C2 N3 C3 ring. *B*, centroid of the N6 C5 C6 C7 C8 C9 ring. Distance A···B = 3.794(3) Å. H4B···N1 2.395(4), H14···O1 2.481(5) and H21···N2 2.501(4) Å.

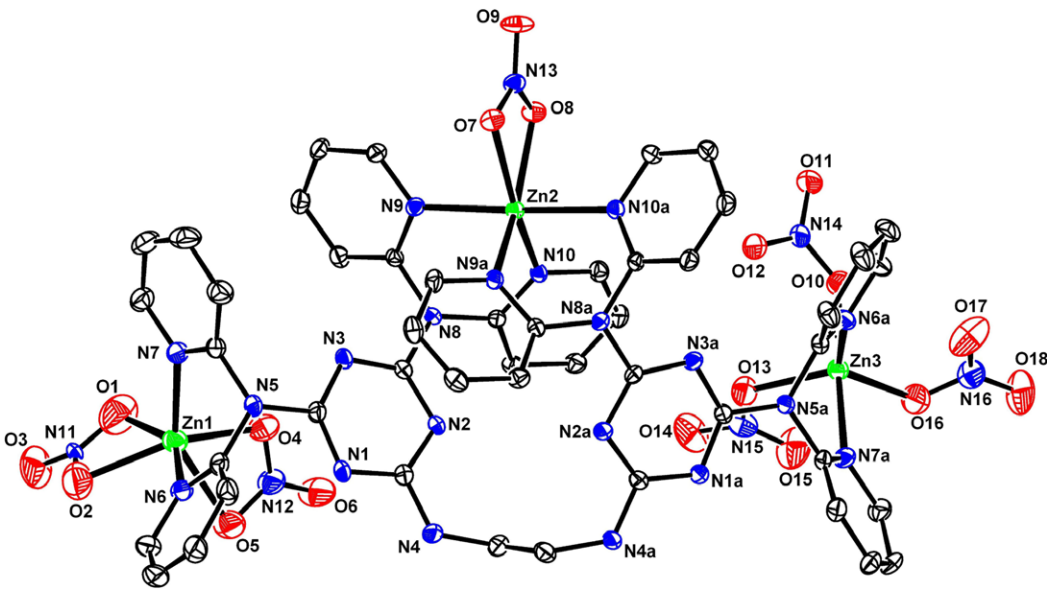

Fig. 3. ORTEP view of $Zn_3L(NO_3)_6 \cdot CH_3CN$ (**3**) (thermal ellipsoids drawn at 20% probability level, lattice solvent and hydrogen atoms are omitted for clarity).

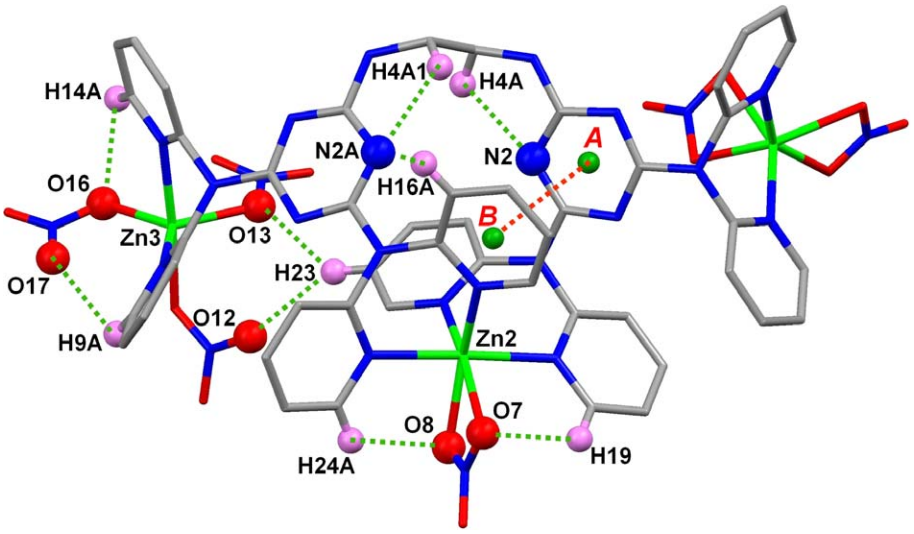

Fig. 4. Representation of the intramolecular non-covalent forces stabilising $Zn_3L(NO_3)_6 \cdot CH_3CN$ (**3**). π–π interactions: *A*, centroid of N1 C1 N2 C2 N3 C3 ring and *B*, centroid of N9A C15A C16A C17A C18A C19A ring. Distance A···B = 3.794(3) Å. C—H···N interactions: H4A1···N2A 2.412(3), H4A···N2 2.362(3), H16A···N2A 2.473(3) and H14a···O16 2.547(5) Å.

These forces are π–π stacking interactions and anion–π interactions (Fig. 5A and B, respectively). Through the π–π interactions a chain along the *c*-direction is formed; moreover the anion–π interactions involving the nitrate linked to Zn2 (N13 O7 O8 O9) favours the interchain interactions within the *ac*-plane, while the anion–π interactions involving the nitrate N15 O13 O14 O15 are responsible for the formation of an array along the *b*-direction.

3.3. Spectroscopy

First of all, it is important to highlight that only two distinct types of IR spectra were obtained for the four complexes. Indeed, the complexes **1** and **2** present similar spectra, and the compounds **3** and **4** exhibit also analogous spectra. For this reason, infrared spectroscopy appeared to be a powerful tool in the present study to discriminate between the mononuclear and trinuclear complexes. This is because some of the vibrations of the dipyridylamine pyridine ring are slightly, but clearly, affected upon coordination to a metal centre.

The vibration at 997 cm^{-1} observed in the free L ligand, associated with the pyridine ring breathing mode (ν_{CCN}), is known to shift to higher wave numbers when the pyridine is coordinated to a metal centre [23]. In our case, in the area 1050–950 cm^{-1}, the mononuclear complexes **1** and **2**

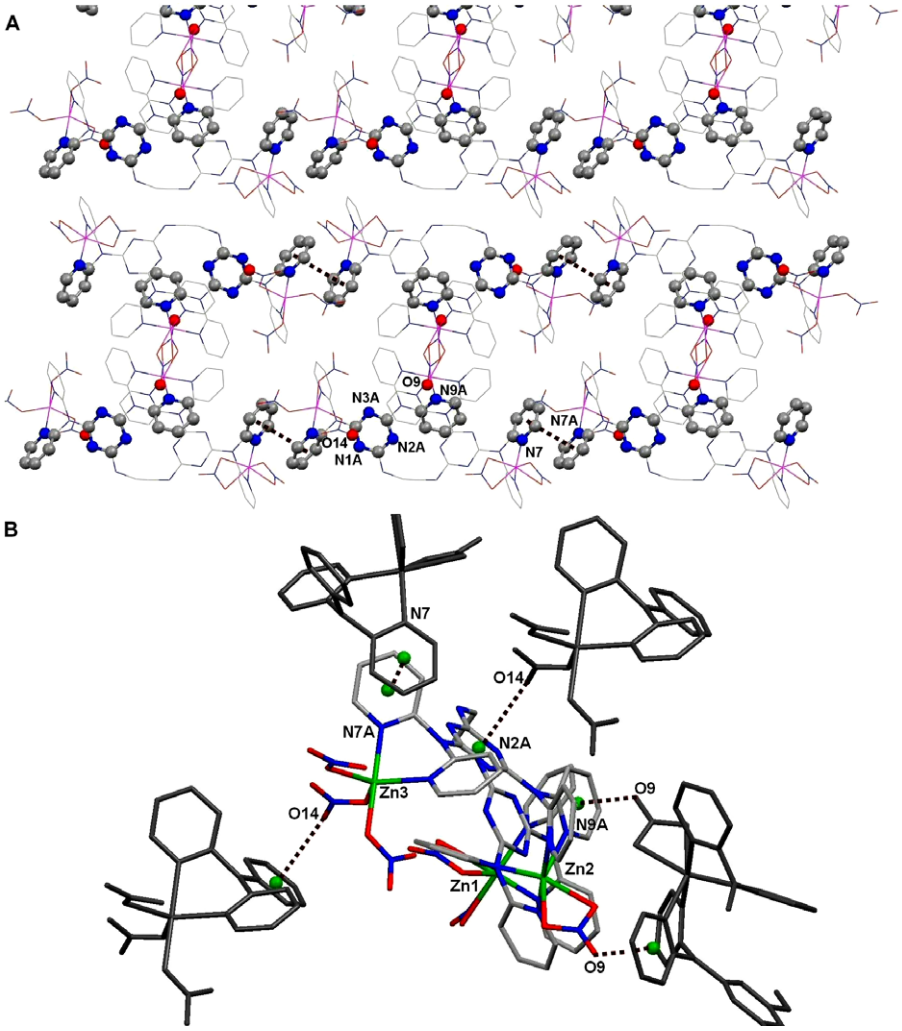

Fig. 5. (A) Schematic view of the packing of **3** along the *b*-direction, showing the intermolecular interactions between the pyridine rings (the atoms represented with balls are all involved in the interactions). (B) View of the asymmetric unit of **3** (represented in colour) involved in intermolecular interactions with fragments of four neighbouring complexes (represented in grey). π–π interactions between N7A C10A C11A C12A C13A C14A and N7i C10i C11i C12i C13i C14i. Centroid-to-centroid distance = 3.962(3) Å. Anion–π interactions (distance anion···ring centroid, Å): N13—O9...{N9A(ii) C15A(ii) C16A(ii) C17A(ii) C18A(ii) C19A(ii)} (3.067(4)); N15—O14...{N1A(iii) C1A(iii) N2A(iii) C2A(iii) N3A(iii) C3A(iii)} (3.28(6)). Symmetry codes: i: x, $1/2 - y$, $1/2 + z$; ii: $1 - x$, $1 - y$, $1 - z$; iii: x, $-1 + y$, z. (For interpretation of the references in colour in this figure legend, the reader is referred to the web version of this article.)

present two bands at ~1020 and 997 cm^{-1}, while the trinuclear complexes **3** and **4** show only one band at ~1020 cm^{-1} (Fig. 6). This clearly proves the partial coordination of L in **1**–**2** and its total coordination in **3**–**4**.

Important information is also provided by the bands present in the area 1610–1500 cm^{-1}. In this region, the pyridine ring stretching modes occur. For the free L ligand these $\nu_{C=C}$ modes are at 1579(s), 1550(s) and 1543(w) cm^{-1}. In **1**–**4** four bands are observed in this area at ~1605, ~1580, 1558 and 1540 cm^{-1}. The relative intensity of these bands allow to distinguish between mononuclear or trinuclear complexes: the mononuclear complexes show a very weak band at ~1600 cm^{-1} and an intense band at ~1580 cm^{-1}, while the trinuclear complexes present the inverse ratio (Fig. 6). The former band is assigned to the $\nu_{C=C-C=Csym}$ mode and the latter one to the $\nu_{C=C-C=Casym}$ mode [26].

At low frequency, below 800 cm^{-1}, the aromatic in-plane and out-of-plane deformation vibration modes (δ_{C-H}, γ_{C-H} and ρ_{C-H}) are found for the pyridine and triazine rings and the metal–nitrogen stretching vibrations (ν_{M-N}). Attempts to attribute these vibrations were unsuccessful due to the high numbers of bands in this area. The strong band observed at ~1370 cm^{-1} in all samples is assigned to the ring stretching of the triazine moiety. Characteristic aromatic stretching vibrations and N—H vibrations are found in the area 3300–3000 cm^{-1}.

Due to the large number of bands in the area characteristic for nitrate vibrations, it was rather difficult to assign the bands relative to nitrate anions. However, a band at ~1300 cm^{-1} could be clearly distinguished. In **1**–**2** this band appears at 1305 cm^{-1} and is assigned to the symmetric stretching vibration mode of monodentate nitrate anion. In **3** and **4** this band is observed at 1295 and

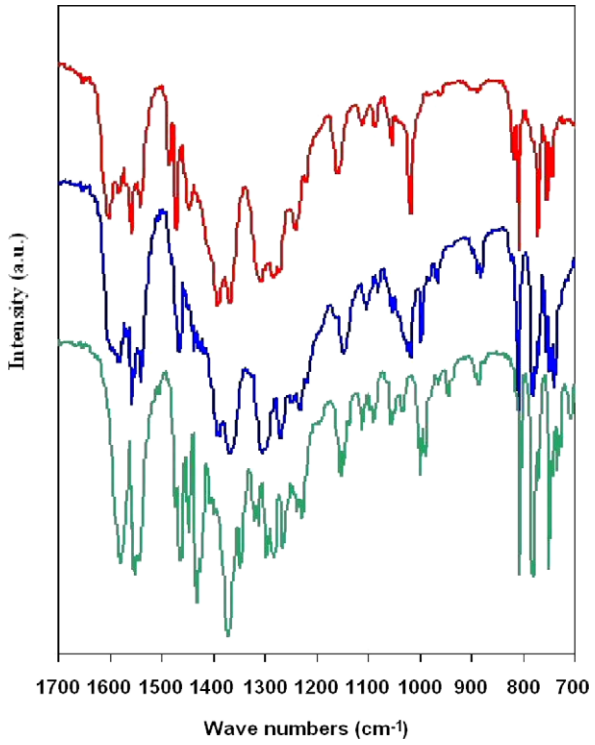

Fig. 6. IR spectra of the L ligand (red), the mononuclear $CdL(NO_3)_2$ (blue) and the trinuclear $Cd_3L(NO_3)_6 \cdot CH_3CN$ (green) complexes in the 1700–700 cm^{-1} area. (For interpretation of the references in colour in this figure legend, the reader is referred to the web version of this article.)

1300 cm^{-1}, respectively. It corresponds to the symmetric and asymmetric stretching vibration mode of monodentate and didentate nitrate anions.

From this analysis, it is clear that IR spectroscopy is a well suitable technique to distinguish between mononuclear and trinuclear complexes. As a consequence, this study gives an additional proof, if necessary, that the complex **4** can be stated as a trinuclear complex.

4. Conclusion

In conclusion, we have highlighted how the crystallisation solvent has a strong effect on the formation of three-dimensional supramolecular structures. Using the same synthetic procedure, i.e. self-assembly reaction at 100 °C under autogenous pressure, and changing only the nature of the solvent, we were able to tune the structure of Zn(II) and Cd(II) materials. In methanol, the mononuclear $ZnL(NO_3)_2$ (**1**) and $CdL(NO_3)_2$ (**2**) materials crystallised, whereas in acetonitrile, the trinuclear $Zn_3L(NO_3)_6 \cdot CH_3CN$ (**3**) and $Cd_3L(NO_3)_6 \cdot CH_3CN$ (**4**) compounds were obtained, as evidenced by single-crystal diffraction and infrared spectroscopy. The structures of these four materials are stabilised by an important network of non-coordinative forces: weak hydrogen bonding, aromatic stacking and anion–aromatic interactions.

It is worth mentioning that **1** and **2** represent the first examples of complexes where the L ligand is partially coordinated. As a perspective, these mononuclear species can be judiciously used as pre-constructed building blocks in further coordination reactions in order to prepare bimetallic supramolecular materials suitable for applications. Along this line, studies are in progress in the group to obtain heterometallic coordination compounds starting from **1** and **2**, which still have free coordination sites.

Pyrazine-derived ligands are important building-blocks in the design of extended structures because of the type and position of the donor atoms that allow linking metal ions together [17–37]. Particularly, 2-pyrazinecarboxylate has been demonstrated to be an extremely versatile ligand. It can act as a monodentate ligand through a carboxylate oxygen, as a bidentate chelating ligand through a pyrazine nitrogen and a carboxylate oxygen or as a tridentate bridging ligand [19,32–47]. Thus, its coordination versatility together with the nature of the central metal ion has led to a diversity of molecular architectures with different magnetic properties [19,32–47]. The coordination properties of 2-pyrazinecarboxylate can also be tuned by introducing various substituents into different positions of the pyrazine ring. The steric restrictions induced by these groups may allow for various molecular architectures and for the incorporation of interesting properties into the resulting coordination polymers. Our synthetic efforts are currently aimed towards synthesis of supramolecular architectures based on non-coordination intermolecular interactions and 5-methyl-2-pyrazinecarboxylate as ligand. Although 5-methyl-2-pyrazinecarboxylate has a great ability for the formation of coordinative bonds, as well as hydrogen-bonding and π–π stacking interactions, its coordination chemistry has hardly been explored [33,40,48–52]. In this paper, we report on the synthesis, spectroscopic and structural characterization, and magnetic properties of new complexes of 5-methyl-2-pyrazinecarboxylate (Hmpca) with cobalt(II), $[Co(mpca)_2(H_2O)_2]$ (**1**), nickel(II), $[Ni(mpca)_2(H_2O)_2]$ (**2**) and iron(III), $[Fe(mpca)_2(OH)]_2 \cdot 2H_2O$ (**3**). The use of the copper(II) ion leads to the mononuclear species $[Cu(mpca)_2(H_2O)] \cdot 3H_2O$ (**4**), which is in agreement with earlier reports [49,52]. However, we report herein the spectroscopic and magnetic properties of **4**, which had not been previously reported.

2. Experimental

2.1. General remarks

Starting materials were purchased from Aldrich and all manipulations were performed using materials as received.

2.2. Synthesis

2.2.1. $[Co(mpca)_2(H_2O)_2]$ (*1*)

A solution of $Co(ClO_4)_2 \cdot 6H_2O$ (0.5 mmol, 0.183 g) in 5 ml acetonitrile was slowly added to a solution of Hmpca (1 mmol, 0.138 g) in 5 ml water. Slow evaporation of the resulting orange solution led to orange crystals within two days. Yield: 68%. *Anal*. Calc. for $C_{12}H_{14}CoN_4O_6$: C, 39.04; H, 3.82; N, 15.18. Found: C, 38.54; H, 4.24; N, 15.46%. IR (ν_{max}/cm^{-1}): 3122 (br), 1652 (s), 1587 (m), 1540 (m), 1386 (s), 1328 (s) 1288 (s), 1186 (m), 1047 (s), 806 (s), 721 (m), 628 (m), 500 (m), 417 (s). UV/Vis/NIR (λ_{max}/nm): 379, 480, 1065, 1170.

2.2.2. $[Ni(mpca)_2(H_2O)_2]$ (*2*)

A solution of $Ni(ClO_4)_2 \cdot 6H_2O$ (0.5 mmol, 0.183 g) in 5 ml acetonitrile was slowly added to a solution of Hmpca (1 mmol, 0.138 g) in 5 ml water. Slow evaporation of the resulting blue solution led to blue crystals within two days. Yield: 56%. *Anal*. Calc. for $C_{12}H_{14}NiN_4O_6$: C, 39.06; H, 3.82; N, 15.18. Found: C, 38.50; H, 4.19; N, 15.35%. IR (ν_{max}/cm^{-1}): 3119 (br), 1652 (s), 1585 (m), 1543 (m), 1386 (s), 1331 (s) 1288 (s), 1187 (m), 1051 (s), 806 (s), 723 (m), 625 (m), 506 (m), 418 (s). UV/Vis/NIR (λ_{max}/nm): 390, 595, 920.

2.2.3. $[Fe(mpca)_2(OH)]_2 \cdot 2H_2O$ (*3*)

A solution of $Fe(ClO_4)_3 \cdot 10H_2O$ (2.5 mmol, 1.336 g) in 40 ml acetonitrile was slowly added to a solution of Hmpca (11.25 mmol, 1.554 g) and tetrabutyl ammonium hydroxide (11.25 mmol, 1 M solution in methanol) in 10 mL H_2O. After the mixture was stirred for 2 h the methanol was removed under reduced pressure. Orange cubic crystals of **3** were obtained by slow diffusion of diethyl ether into the acetonitrile–water solution. Yield: 48%. *Anal.* Calc. for $C_{24}H_{26}Fe_2N_8O_{12}$: C, 39.48; H, 3.59; N, 15.30. Found: C, 39.64; H, 3.08; N, 15.41%. IR (ν_{max}/cm^{-1}): 3066 (br), 1651 (s), 1588 (m), 1482 (m), 1373 (s), 1315 (s) 1281 (s), 1170 (m), 1010 (m), 874 (m), 800 (s), 720 (m), 671 (m), 631 (m), 500 (m), 416 (s). UV/Vis/NIR (λ_{max}/nm): 266, 350, 867.

2.2.4. $[Cu(mpca)_2(H_2O)] \cdot 3H_2O$ (*4*)

A solution of $Cu(ClO_4)_2 \cdot 6H_2O$ (0.5 mmol, 0.185 g) in 5 ml acetonitrile was slowly added to a solution of Hmpca (1 mmol, 0.138 g) in 5 ml water. Slow evaporation of the resulting blue solution led to blue crystals within one day. Yield: 72%. *Anal*. Calc. for $C_{12}H_{18}CuN_4O_8$: C, 35.17; H, 4.43; N, 13.67. Found: C, 35.50; H, 4.19; N, 13.35%. IR (ν_{max}/cm^{-1}): 3245 (br), 1636 (s), 1595 (m), 1560 (m), 1376 (s), 1329 (s) 11190 (s), 1168 (m), 1052 (s), 820 (m), 807 (s), 720 (m), 668 (m), 559 (m), 505 (m), 427 (s). UV/Vis/NIR (λ_{max}/nm): 365, 392, 623.

2.3. Physical measurements

C, H and N analyses were performed with a Perkin–Elmer 2400 series II analyzer. Infrared spectra (4000–300 cm^{-1}, resolution 4 cm^{-1}) were recorded on a Perkin–Elmer Paragon 1000 FTIR spectrometer equipped with a Golden Gate ATR device, using the reflectance technique. Diffuse reflectance spectra were obtained on a Perkin–Elmer Lambda 900 spectrophotometer with MgO as a reference. X-band powder EPR spectra were obtained on a Jeol RE2x electron spin resonance spectrometer using DPPH ($g = 2.0036$) as a standard. Magnetic susceptibility measurements (5–300 K) were carried out at 0.1 T using a Quantum Design MPMS-5 5T SQUID magnetometer. Data were corrected for the magnetization of the sample holder and for diamagnetic contributions, which were estimated from the Pascal constants.

Table 1
Crystal data and structure refinement for **1**–**3**

	1	**2**	**3**

2.4. X-ray crystallographic analysis and data collection

Intensity data for single crystals of **1**–**4** were collected using Mo Kα radiation ($\lambda = 0.71073$ Å) on a Nonius KappaCCD diffractometer. The intensity data were corrected for Lorentz and polarization effects and for absorption (SADABS multiscan correction [53]). The structures were solved by Patterson methods. The programs EVALCCD [54], DIRDIF96 [55] and SHELXL-97 [56] were used for data reduction, structure solution and structure refinement, respectively. Refinement of F^2 was done against all reflections. The weighted R factor, wR, and goodness of fit S are based on F^2. Conventional R factors are based on F, with F set to zero for negative F^2. All non-hydrogen atoms were refined with anisotropic displacement parameters. The hydrogens of water molecules were taken from difference Fourier maps and were independently refined. All other hydrogens were initially placed at calculated positions and were freely refined subsequently. Geometric calculations and molecular graphics were performed with the PLATON package [57]. Crystal data and details of the structure refinement for **1**–**3** are given in Table 1.

3. Results and discussion

3.1. Synthesis and spectroscopic characterization

The neutral molecular complexes **1**–**4** were obtained through solution assemblies of equimolar amounts of 5-methyl-2-pyrazinecarboxylate (Hmpca) and the corresponding metal ions. Crystals suitable for X-ray crystallography have been obtained by slow evaporation of a water–acetonitrile solution. All complexes are stable under ambient conditions with poor solubility in most of the common organic solvents, but better solubility is observed in hot water; these characteristics are in agreement with their polymeric structure. It is worth noting that for the complexes **1** and **2**, the metal to ligand ratio does not affect the yield of the reaction and it does not determine the product. The mononuclear compound **4** is always obtained irrespective of the nature of the copper(II) salt used and the reaction conditions [49,52].

The infrared spectra of complexes **1** and **2** are very similar in the terms of the position, intensity and shape of the bands over the whole frequency range. The broad band centered at 3222 cm^{-1} in **1** and at 3119 cm^{-1} in **2** is characteristic of the ν(O–H) stretching vibration of the aqua molecules. The significant difference in the position of the ν(O–H) stretching vibration for **1** and **2** is in agreement with the presence of the *cis* isomer for **1** and the *trans* isomer for **2**. In both compounds, the band of the asymmetric stretching vibration $\nu_a(COO^-)$ is located at 1652 cm^{-1}, while that assigned to the symmetric stretching vibration $\nu_s(COO^-)$ is positioned at 1386 cm^{-1}. The difference $\Delta\nu = \nu_a(COO^-) - \nu_s(COO^-)$ is 266 cm^{-1}, suggesting a monodentate binding of the carboxylate group to the central metal ion [58]. The absorption bands resulting from the skeletal vibrations of the pyrazine rings appear at ca. 800 and 720 cm^{-1}.

The ligand field spectrum of **1** shows two principal regions of absorption: a broad band with maximum at 1170 nm (8.5×10^{-3} cm^{-1}) and a band at 480 nm (20.8×10^{-3} cm^{-1}) that together are indicative of a pseudo-octahedral cobalt(II) ion [59]. These two bands correspond to the $^4T_{1g}(F) \rightarrow {}^4T_{2g}(F)$ and $^4T_{1g}(F) \rightarrow {}^4T_{1g}(P)$ transitions [59]. For **2**,

the ligand field spectrum is typical of pseudo-octahedral nickel(II) complexes exhibiting a broad band with maximum at 920 nm (10.9×10^{-3} cm^{-1}) that is assigned to the $^4A_{2g} \rightarrow {}^4T_{2g}(F)$ transition. An absorption maxima is observed at 595 nm (16.8×10^{-3} cm^{-1}) due to the $^4A_{2g} \rightarrow {}^4T_{1g}(F)$ transition and the shoulder located at 390 nm (25.6×10^{-3} cm^{-1}) is attributed to the $^4A_{2g} \rightarrow {}^4T_{1g}(P)$ transition. On the basis of the octahedral symmetry, the value of the ligand field strength (*10Dq*) and the parameter *B* are 10.9×10^{-3} and 868 cm^{-1}. These values are in the range of those observed for nickel(II) complexes with a NiN_2O_4 chromophore group [59].

The reaction of the ligand Hmpca with $Fe(ClO_4)_3 \cdot 10H_2O$ (4.5:1) in the presence of 4.5 equiv. of Bu_4NOH leads to the formation of the complex **3**. The complex **3** shows good solubility only in methanol and it is very stable in the solid state. The IR spectrum displays peaks of the carboxylate group at 1651 and 1373 cm^{-1}. The peaks in the range of 500–850 cm^{-1} can be assigned to the bis-(μ-hydroxido)-bridged diiron(III) core. The ligand field spectrum of a polycrystalline sample of **3** displays the features typical of bis(μ-hydroxido)-bridged iron(III) complexes: an intense absorption band at 350 nm (28.5×10^{-3} cm^{-1}) with a lower energy shoulder in the region of 400–550 nm. These bands have been assigned to have an oxido-to-iron charge transfer character (LMCT) [60–64]. The absorption band with maximum at 867 nm (11.5×10^{-3} cm^{-1}) is often attributed to the d–d transitions involving forbidden states of the octahedral high-spin iron(III) complexes [59].

In the case of the complex **4**, the infrared spectrum displays the characteristic asymmetric and symmetric stretching vibrations of the carboxylate groups at 1636 and 1376 cm^{-1}, with $\Delta\nu$ equal to 260 cm^{-1}. The ν(O–H) stretching of the both ligand and lattice water is located at 3245 cm^{-1}. The ligand field spectrum shows a broad asymmetric band at 623 nm (16.1×10^{-3} cm^{-1}), a Cu–O charge transfer at 392 nm (25.5×10^{-3} cm^{-1}) and a Cu–N charge transfer at 350 nm (28.6×10^{-3} cm^{-1}), features that are characteristic for copper(II) complexes with a square-pyramidal coordination environment [59]. The complex shows an axial $S = 1/2$ EPR spectrum with $g_\perp = 2.05(7)$ and $g_\parallel = 2.25(3)$, values that are characteristic for a copper(II) ion in a square-pyramidal geometry [65,66].

3.2. Description of the crystal structures

The crystal structures of complexes **1**, **2** and **3** have been determined by X-ray crystallography; selected bond lengths and angles of the three structures are listed in Table 2.

Complex **1** crystallizes in space group $P\bar{1}$. The asymmetric unit of **1** consists of one $[Co(mpca)_2(H_2O)_2]$ neutral molecule (Fig. 1). The cobalt(II) ion is octahedrally coordinated to two nitrogens and two oxygens from two $mpca^-$ ligands and two oxygens of two water molecules in *cis* arrangement. The octahedral geometry is distorted, as the Co–N bond lengths (average 2.147(5) Å) are longer than the Co–O bond lengths (average 2.066(5) Å). The largest deviation from the octahedral geometry of the CoN_2O_4 chromophore is defined by the angles O1–Co1–O21 = 166.93(9)° and O11–Co1–N12 = 78.30(8)°. A similar coordination geometry has been observed in the complex of cobalt(II) with 6-methyl-2-pyridinecarboxylate [67]. In the cobalt(II) complex of the parent 2-pyrazinecarboxylate, $[Co(pca)_2(H_2O)_2]$,

Table 2
Selected bond lengths (Å) and angles (°) for **1**, **2** and **3**

Bond lengths		Bond angles

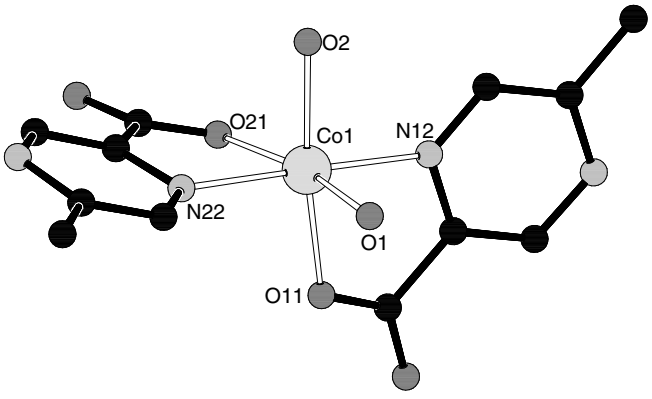

Fig. 1. Pluton projection of the molecular structure of *cis*-[Co(mpca)$_2$(H$_2$O)$_2$] (**1**). Hydrogens are omitted for clarity.

a *trans*-coordination of the two water molecules to cobalt(II) ion was observed [37].

The carbonyl oxygens and non-coordinated nitrogens of both mpca$^-$ ligands play an important role, as they are involved in an extended network of hydrogen bonds with the coordinated water molecules (Fig. 2 and Table 3). Through such hydrogen-bonding interactions, the cobalt(II) mononuclear units are linked together forming a two-dimensional architecture, with a Co···Co separation of 7.048 Å. The crystal lattice is further stabilized by face-to-face π–π stacking interactions involving the pyrazine rings. The shortest distance between the pyrazine planes is 3.59 Å, which is within the limit of common range for π–π interactions [68]. The pyrazine rings are nearly parallel with a deviation of 0.03°; the angle between the ring of the pyrazine and the centroid vector is 22.27°.

In the molecular structure of **2**, the nickel(II) ion is six-coordinated with a N_2O_4 donor set and a slightly distorted octahedral coordination geometry. In the equatorial plane, two mpca$^-$ ligands coordinate to nickel(II) ion in the bidentate N,O chelating manner, whilst the axial positions are occupied by two water molecules. A similar coordination geometry has been observed in the parent complex with 2-pyridinecarboxylate [69]. The complex **2** has an inversion center at the nickel(II) ion. The Ni–O bond lengths are slightly different (Ni–O1 = 2.0742(51) Å and Ni1–O11 = 2.0608(52) Å) and are somewhat shorter than the Ni–N bond lengths (Ni–N7 = 2.0488(48) Å). The largest distortion from the octahedral geometry is given by the angle O2–Ni1–N12 = 80.23(1)°. The pyrazine rings are coplanar with the equatorial chelate rings. This equatorial plane is stabilized by the weak C–H···O type intramolecular interactions (C16–H16···O1 = 3.310(2) Å). In **2**, the carbonyl oxygens of the mpca$^-$ ligands act as acceptors resulting in strong hydrogen bonds with the coordinated aqua molecules of adjacent mononuclear molecules (Table 3). Each $[Ni(mpca)_2(H_2O)_2]$ unit is hydrogen bonded to four neighboring molecules, thus forming a two-dimensional layer network (Fig. 3). The closest Ni···Ni separation is 6.339 Å.

The molecular structure of **3** consist of a centrosymmetric dinuclear bis(μ-hydroxido)iron(III) core that crystallizes

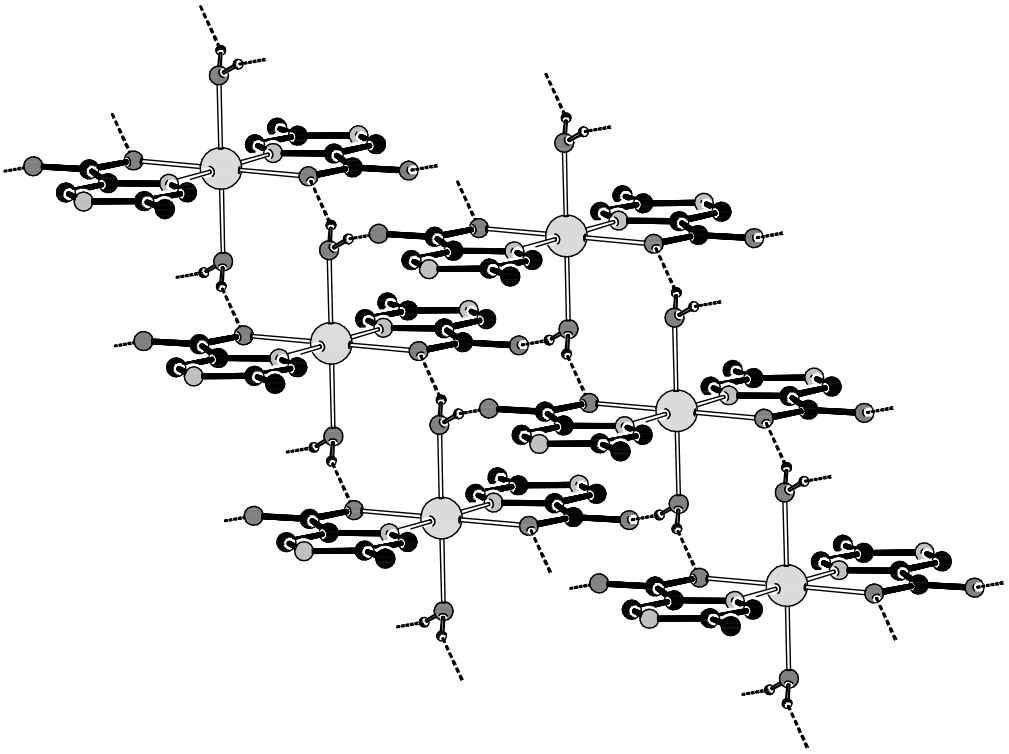

Fig. 3. View of the hydrogen-bonding and π–π stacking interactions in *trans*-[Ni(mpca)$_2$(H$_2$O)$_2$] (**2**).

with two water molecules in the lattice (Fig. 4). The two iron(III) ions of the dinuclear unit are equivalent and have pseudo-octahedral coordination geometry due to the bidentate chelating binding of two mpca$^-$ ions through one nitrogen atom of the pyrazine ring and one oxygen of the carboxylate group. The coordination geometry is completed by two bridging hydroxide ions coordinated *cis* to each other. The iron to nitrogen bond lengths are in the range 2.1684(16)–2.1728(16) Å, while the iron to oxygen bond lengths are in the range 1.9650(14)–1.9897(14) Å. The largest deviation from the octahedral geometry is indicated by the angle O1–Fe1–O11 = 164.22(6)°. The geometric features of the Fe$_2$(OH)$_2$ core, such as Fe···Fe = 3.008 Å and Fe1–O1–Fe1a = 99.71°, are in the range of those observed for other dinuclear bis(μ-hydroxido)iron(III) complexes [60–64].

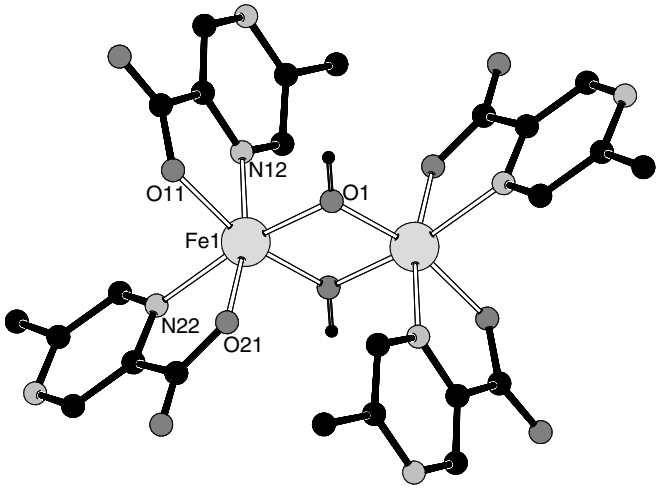

Fig. 4. Pluton projection of the molecular structure of [Fe(mpca)$_2$-(OH)]$_2$ · 2H$_2$O (**3**). Hydrogens are omitted for clarity.

In the crystal lattice of **3**, the dinuclear units Fe$_2$(OH)$_2$ are linked through π–π stacking and hydrogen-bonding interactions to form a three-dimensional network structure (Fig. 5). Each water molecule is involved in two O–H···O hydrogen bonding interactions with the hydroxido bridging groups of two neighboring Fe$_2$(OH)$_2$ cores and one O–H···N hydrogen bonding interaction with the pyrazine ring of a mpca$^-$ anion coordinated to a third Fe$_2$(OH)$_2$ unit (Table 3). The three-dimensional architecture is further stabilized by π–π stacking interactions between pyrazine rings of adjacent Fe$_2$(OH)$_2$ units, with a π–π stacking separation of 3.61 Å.

3.3. Magnetic properties

Temperature dependent magnetic susceptibility measurements for the complexes **1**–**4** were performed on polycrystalline samples in the range 5–300 K. In all cases the χ_M values have been corrected for diamagnetism.

The temperature dependence of $\chi_M T$ and χ_M for complex **1** is plotted in Fig. 6. The 2.582 cm^3 K mol^{-1} value of $\chi_M T$ observed in **1** at 300 K is significantly larger than the spin only value of 1.875 cm^3 K mol^{-1} expected for a total spin $S = 3/2$. Upon cooling, the $\chi_M T$ value decreases

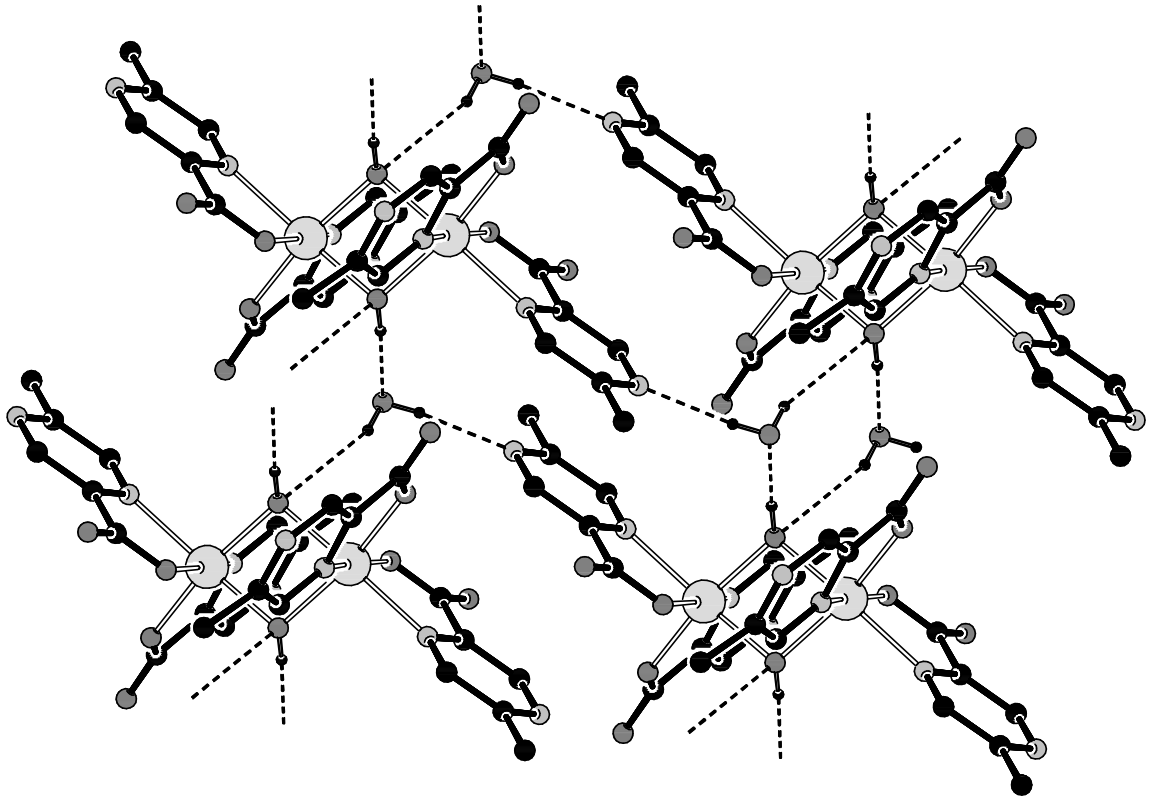

Fig. 5. View of the hydrogen-bonding and π–π stacking interactions in $[Fe(mpca)_2(OH)]_2 \cdot 2H_2O$ (**3**).

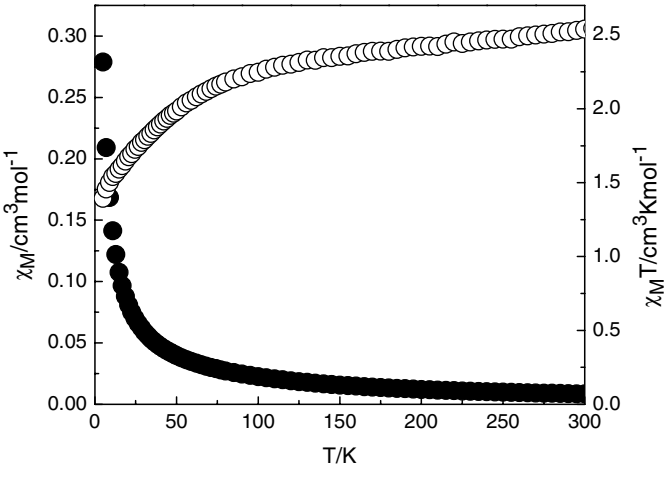

Fig. 6. Temperature dependence of $\chi_M T$ (○) and χ_M (●) at 0.1 T applied field for compound **1**.

to 1.394 cm^3 K mol^{-1} at 5 K. A plot of $1/\chi_M$ is linear between 40 and 300 K with a Curie constant of 2.698 cm^3 K mol^{-1} and a Weiss temperature of −20 K. From the fitted Curie constant, C, one can deduce the g value to be about 2.4. The high value of the Curie constant is a consequence of the spin–orbit coupling resulting from the $^4T_{2g}$ state of a cobalt(II) ion in an octahedral ligand field. Attempts to fit the magnetic data with the equation for the spin–orbital coupling [70] calculating the λ value (the spin–orbit coupling constant) and A parameter (A is a measure of the crystal field strength relative inter-electronic repulsions) have not been successful.

For **2**, the value of $\chi_M T$ observed at 300 K (1.215 cm^3 K mol^{-1}) is in the usual range for a non-interacting nickel(II) ion comprising a ^3A electronic state with $S = 1$. By lowering the temperature, the $\chi_M T$ value drops slightly to 1.092 cm^3 K mol^{-1} at 30 K, followed by a pronounced drop to 0.780 cm^3 K mol^{-1} at 5 K (Fig. 7). This behaviour is typical for a mononuclear nickel(II) complex with the low temperature drop associated to the zero-field splitting. The plot of $1/\chi_M$ is linear and obeys the Curie–Weiss law in the temperature range 30–300 K, giving a Curie constant of. 1.224 cm^3 K mol^{-1} and a Weiss temperature of −5.7 K. The calculated g value is found to be about 2.2, thus indicating the presence of magnetic anisotropy. The magnetic data were fitted to the model for isolated nickel(II) ions, in which the single-ion anisotropy was included [71]. With the consideration of a molecular field approximation (zJ'), the best fit was obtained with $g = 2.19$, $D = -2.5$ cm^{-1}, and $zJ' = -0.38$ ($R = 1.6 \times 10^{-4}$) in the temperature range 5–300 K. It is reasonable to assume that the intermolecular antiferromagnetic interactions occur via the hydrogen bonds [72]. The presence of magnetic anisotropy is also supported by the magnetization versus field measurements performed at different temperatures (results not shown).

The magnetic behaviour of **3** in the form $\chi_M T$ and χ_M versus T in the range 5–300 K at a 0.1 T applied field is

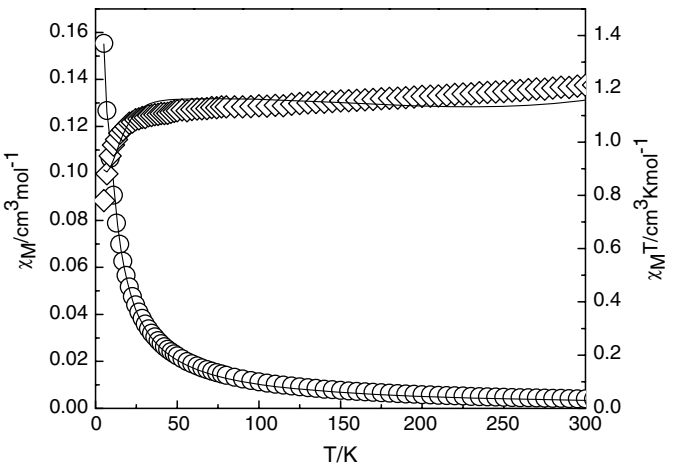

Fig. 7. Temperature dependence of $\chi_M T$ (◇) and χ_M (○) at 0.1 T applied field for compound **2**. Solid lines represents the calculated values for $g = 2.19$, $D = -2.5\ cm^{-1}$, and $zJ' = -0.38\ cm^{-1}$.

shown in Fig. 8. The value of the $\chi_M T$ product at room temperature ($8.68\ cm^3\ mol^{-1}\ K$) is close to the expected value for two non-interacting iron(III) ions with $S = 5/2$. The $\chi_M T$ product decreases gradually when lowering the temperature to 5 K, behaviour that suggests that antiferromagnetic interactions between the two iron(III) ions are operative in **3**. The magnetic experimental data were analyzed using the Van Vleck equation derived from the Heisenberg exchange Hamiltonian for two interacting spins $S_1 = S_2 = 5/2$ ($H = -JS_1S_2$) [73]. The temperature-independent paramagnetism ($TIP = 400 \times 10^{-6}\ cm^3\ K\ mol^{-1}$ for each iron ion) was taken into account. The best fit parameters were found to be $J = -21.2\ cm^{-1}$, $g = 2.01$ ($R = 2.5 \times 10^{-5}$). The exchange coupling parameter, J, is in the range of the values observed for other bis(μ-hydroxido)bridged iron(III) complexes, in which the low electron

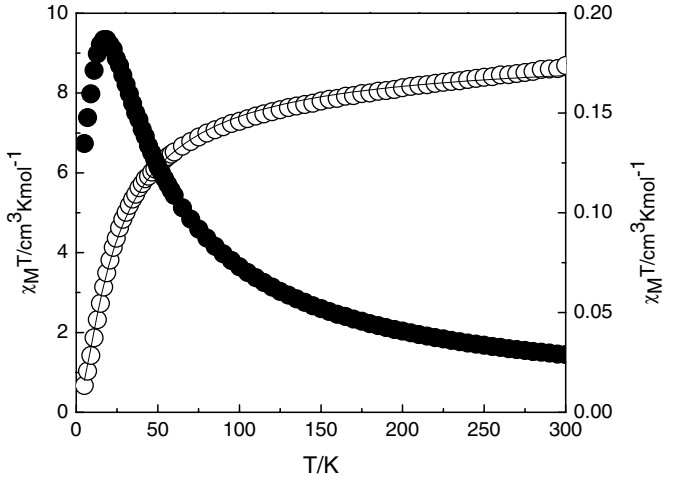

Fig. 8. Temperature dependence of $\chi_M T$ (○) and χ_M (●) at 0.1 T applied field for compound **3**. Solid line represents the calculated values for $J = -21.2\ cm^{-1}$ and $g = 2.01$.

density of the hydroxido-bridge is responsible for the observed weak antiferromagnetic coupling [60–64].

The $0.378\ cm^3\ K\ mol^{-1}$ value of $\chi_M T$ observed in **4** at 300 K corresponds to the expected value for non-interacting paramagnetic copper(II) ions ($S = 1/2$, $\chi_M T = 0.375\ cm^3\ K\ mol^{-1}$). The $\chi_M T$ value remains essentially constant as the temperature decreases to ca. 11 K, whereas below 11 K it decreases and at 5 K reaches the value of $0.316\ cm^3\ K\ mol^{-1}$. The magnetic data were fitted with the Curie–Weiss equation to give a Curie constant of $0.382\ cm^3\ K\ mol^{-1}$ and a Weiss temperature of −3 K.

4. Conclusions

Three new complexes of 5-methyl-2-pyrazinecarboxylate, i.e. *cis*-$[Co(mpca)_2(H_2O)_2]$ (**1**), *trans*-$[Ni(mpca)_2(H_2O)_2]$ (**2**) and $[Fe(mpca)_2(OH)]_2 \cdot 2H_2O$ (**3**), have been successfully synthesized and characterized. The mononuclear entities of **1** and **2** are linked through effective hydrogen-bonding and π–π stacking interactions to form extended network structures, in which the presence of antiferromagnetic interactions have been indicated by temperature dependent magnetic susceptibility measurements. The presence of the magnetic anisotropy in the complex $[Ni(mpca)_2(H_2O)_2]$ indicates that **2** might be a suitable building-block for the design of polynuclear complexes with single molecular magnet behaviour. The complex **3** has a bis(μ-hydroxido)diiron(III) core, in which the two iron(III) ions are antiferromagnetically coupled ($J = -21.2\ cm^{-1}$). In the crystal lattice, the adjacent dinuclear $Fe_2(OH)_2$ molecules are linked together via hydrogen-bonding and π–π stacking interactions to form a two-dimensional network.

5. Supplementary material

Crystallographic data (excluding structure factors) have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC 296380–296383. Copies of the data can be obtained free of charge on application to The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44 1223 366 033, e-mail: deposit@ccdc.ac.uk or on the web www: http://www.ccdc.cam.ac.uk).

2. Experimental

2.1. Materials

Reagent grade chemicals and doubly distilled water were used throughout this work. QDC was prepared by the reported method [2–4] and was characterised by IR spectra and m.p. −160 °C. The QDC solution was prepared by dissolving QDC in water and determining its concentration iodometrically [4]. The mercury(I) solution was obtained by dissolving mercury(I) nitrate (Fluka) in 1 mol dm^{-3} perchloric acid (70%) and the solution was standardised against potassium iodate solution [15a]. The palladium(II) solution was obtained by dissolving palladium chloride (Johnson Matthey) in 0.20 mol dm^{-3} hydrochloric acid (AR) and assaying for palladium(II) by complexometric titration with EDTA [15b]. For some kinetic runs, chloride had to be absent and hence the chloride in the palladium(II) stock solution was removed by precipitation with silver nitrate, followed by repeated centrifugation. The resulting clear solution contained less than 1.0×10^{-6} mol dm^{-3} chloride and silver ions. Such extremely low concentrations of Ag^{+} and Cl^{-} were found to have no significant effect on the reaction. The required chloride concentration was maintained with sodium chloride. The chromium(III) solution was prepared by dissolving chromium(III) potassium sulfate (BDH, AR), $Cr_2(SO_4)_3 \cdot K_2SO_4 \cdot 24H_2O$ in water. The mercury(II) solution was obtained by dissolving mercuric oxide, HgO (BDH) in 0.50 mol dm^{-3} sulfuric acid. The ionic strength was kept constant with sodium sulfate. Use of sodium perchlorate was precluded since precipitation occurred under the reaction conditions.

2.2. Kinetic procedure

Since the reaction was too fast to be monitored by the usual method, kinetic measurements were performed on a Hitachi 150-20 spectrophotometer (Tokyo, Japan) connected to a rapid kinetic accessory (HITECH SFA-12 unit). Kinetics were followed at 25 ± 0.1°C and I = 1.60 mol dm^{-3}. The reaction was initiated by mixing the pre-equilibrated reactant solutions, which also contained known concentrations of sulfuric acid and sodium sulfate to give the required acidity and ionic strength. The reaction was followed under second order conditions by measuring the absorbance of QDC in the form of the monomer in the reaction mixture at 440 nm. Application of Beer's law under the reaction conditions had been verified earlier between 1.0×10^{-4} and 2.0×10^{-3} mol dm^{-3} of QDC at 440 nm with molar absorptivity, ε resulting as 395 ± 10 dm^3 mol^{-1} cm^{-1}. The second order plots were non-linear due to the autocatalytic effect of the one of the products, chromium(III). Hence the choice of initial rates at 5% completion of the reaction was made. The initial rates of the reaction were obtained from the slopes of concentrations versus time curves at the initial stages (5%) of the reaction by the plane mirror method. The initial rates were reproducible within ±5%.

3. Results and discussion

3.1. Stoichiometry

Different sets of concentrations of reactants and catalyst, palladium(II), in 0.50 mol dm^{-3} sulfuric acid at constant ionic strength, 1.60 mol dm^{-3}, were kept for over 8 h at 25 °C in a closed container. When [QDC] > [mercury(I)], the remaining QDC was assayed by measuring the absorbance at 440 nm, whereas under the conditions [mercury(I)] > [QDC], when QDC had fully reacted, the remaining mercury(I) concentration was determined by titration with potassium iodate [15a]. One of the products, the chromium(III) concentration, was determined by measuring the absorbance at 584 nm. The results showed that QDC reacted with mercury(I) in a 1:3 mole ratio. The catalyst concentration was unchanged at the end of the reaction as found by estimating it spectrophotometrically as the palladium(II) azide complex [16].

$$\mathrm{QDC} + 3\mathrm{Hg(I)} \overset{\mathrm{Pd(II)}}{\rightarrow} \mathrm{Cr(III)} + 3\mathrm{Hg(II)} \quad (1)$$

3.2. Order of reaction

The reaction order was found from log–log plots of initial rates versus concentrations at constant ionic strength, I = 1.60 mol dm^{-3} and at constant sulfuric acid concentration (0.50 mol dm^{-3}). At constant palladium(II) concentration, 8.0×10^{-6} mol dm^{-3}, the order with respect to QDC in the concentration range 5.0×10^{-5}–5.0×10^{-4} mol dm^{-3} was found to be unity. The order with respect to mercury(I), between 5.0×10^{-5} and 6.0×10^{-4} mol dm^{-3} was less than unity, ca. 0.42 (Table 1). At constant reactant concentrations (3[QDC] = [Hg(I)] = 6.0×10^{-4} mol dm^{-3}), constant acidity and ionic strength ([H_2SO_4] = 0.50 mol dm^{-3} and I = 1.60 mol dm^{-3}), the palladium(II) concentration was varied between 1.0×10^{-6} and 1.0×10^{-5} mol dm^{-3} and the order was found to be unity (Table 1).

3.3. Effect of added products

The initially added products, chromium(III) and mercury(II), were studied in the 5.0×10^{-5}–5.0×10^{-4} and 1.0×10^{-4}–5.0×10^{-4} mol dm^{-3} concentration ranges, respectively, while keeping the reactant concentrations and all other conditions constant. It was observed that added chromium(III) enhances the reaction rate with an order of less than unity (0.73), whereas, the added mercury(II), does not change the rate appreciably (Table 2). This result indicates the autocatalytic nature of the product, chromium(III), which is also evident from the concentration of chromium(III) values versus t plot (Fig. 1) and a linear plot of (Initial rate) versus $(\mathrm{rate})_{\mathrm{calc}}$ for chromium(III) variations (Fig. 1, inset). However, in the case of the palladium(II)

catalysed chromium(VI) oxidation of mercury(I) reaction [14] such autocatalysis was not observed.

3.4. Effect of acid

At constant reactant concentrations and other constant conditions (Table 3) the sulfuric acid concentration was varied between 0.20 and 1.0 mol dm^{-3} and the rate was found to increase with an order of ca. 0.51 in $[H^+]$. The $[H^+]$ values calculated from the added sulfuric acid concentration and known equilibrium constant of the acid sulfate equilibrium [17] are shown in Table 3.

3.5. Effect of added chloride

For this purpose palladium(II) solutions, which did not contain chloride, were used. The initial rate increased with increase in $[Cl^-]$. This is ascribable to the formation of palladium(II) chloride complexes. The order in $[Cl^-]$ under the experimental conditions was close to unity (ca. 0.91). As with the dependence on mercury(I), the rate varies with

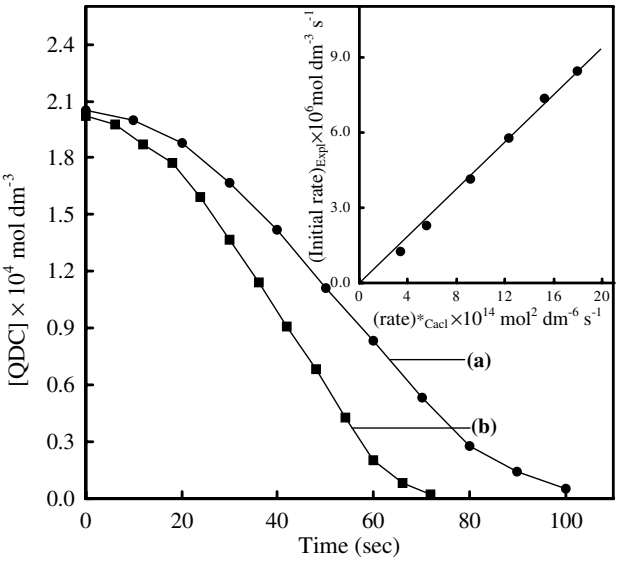

Fig. 1. Autocatalysis: [QDC] vs. t plots; $3[QDC] = [Hg(I)] = 6.0 \times 10^{-4}$, $[H_2SO_4] = 0.50$; $I = 1.60$ mol dm^{-3}. (a) $[Pd(II)] = 4.0 \times 10^{-6}$. (b) $[Pd(II)] = 8.0 \times 10^{-6}$ mol dm^{-3}. Inset: Plot of $(\text{Initial rate})_{\text{exptl}}$ vs. $(\text{rate})_{\text{calc}}$. $(\text{Rate})_{\text{calc}} = [QDC][Pd(II)][Hg(I)]^{0.42}[H^+]^{0.51}[Cr(III)]^{0.73}$ for variation of Cr(III) (Table 2).

Table 3
Effect of sulfuric acid concentration on Pd(II) catalysed oxidation of Hg(I) by QDC: $3[QDC] = [Hg(I)] = 6.0 \times 10^{-4}$; $[Pd(II)] = 8.0 \times 10^{-6}$; $I = 3.70$ mol dm^{-3}, 25 °C

1.0	0.911	6.45

$[Cl^-]$. Palladium(II) is known to form chloride complexes [18] of the formula $Pd(Cl)_n^{+2-n}$, n having values 1–4, the cumulative stability constants β_1 to β_4 being 1.0×10^4, 3.1×10^7, 5.4×10^9 and 1.3×10^{11}, respectively, as shown in the following equilibrium:

$$Pd^{2+} + Cl^- \rightleftharpoons PdCl^+ \qquad K_1 \tag{2}$$

$$PdCl^+ + Cl^- \rightleftharpoons PdCl_2 \qquad K_2 \tag{3}$$

$$PdCl_2 + Cl^- \rightleftharpoons PdCl_3^- \qquad K_3 \tag{4}$$

$$PdCl_3^- + Cl^- \rightleftharpoons PdCl_4^{2-} \qquad K_4 \tag{5}$$

The approximate concentrations of such species may be calculated based on the following equation:

$$[Pd(II)]_T = [Pd(II)]_f \left\{1 + \beta_1[Cl^-] + \beta_2[Cl^-]^2 + \beta_3[Cl^-]^3 + \beta_4[Cl^-]^4\right\} \tag{6}$$

from the concentrations of the dissolved palladium(II) and chloride, with their competing equilibria [19,20]. Variation in the concentrations of such species with increase in $[Cl^-]$ is shown in Table 4, along with the rates of the respective

[a] α_0, α_1, α_2, α_3 and α_4 are the fractions of total Pd(II) of the species Pd_f^{2+}, $PdCl^+$, $PdCl_2$, $PdCl_3^-$ and $PdCl_4^{2-}$, respectively. The stability constants of the different Pd(II) complexes are from Ref. [15].

catalysed reactions, and it is found that there is a parallelism only between rates and [$PdCl^+$] (Fig. 2).

Rates of reaction with 30 different sets of concentrations of QDC, mercury(I), palladium(II) and H^+ ion at constant ionic strength were found to obey the rate law (7) shown in Fig. 3.

$$\text{Rate} \propto [\text{QDC}][\text{Pd(II)}][\text{Hg(I)}]^{0.42}[\text{H}^+]^{0.51} \quad (7)$$

3.6. Effect of dielectric constant and ionic strength

When the acetic acid content (V/V) in the reaction medium was increased, keeping the reactant concentrations and other conditions constant, the reaction rate increases. Since the dielectric constants of aqueous acetic acid are not available in the literature, they were computed from the values for pure liquids [21]. No reaction of the solvent with the oxidant occurred under the experimental conditions employed. A plot of log(Initial rate) versus $1/D$ is linear with positive slope (Fig. 4, ($r \geqslant 0.999$, $\sigma \leqslant 0.015$)). Variation of ionic strength between 1.6 and 4.0 mol dm^{-3}, using sodium sulfate, caused a decrease in the rate of reaction. A plot of log(Initial rate) versus $I^{1/2}$ is linear with negative slope as shown in Fig. 4 ($r \geqslant 0.998$, $\sigma \leqslant 0.021$).

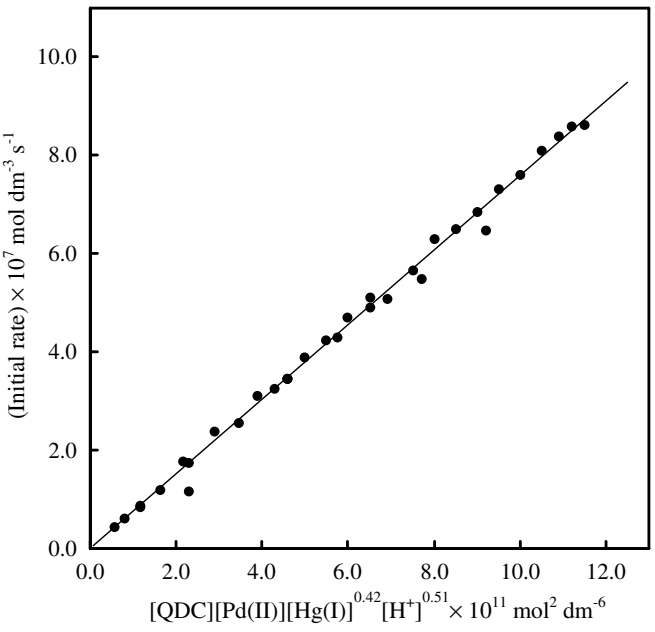

Fig. 3. Plot of the initial rate of the QDC–Hg(I) reaction vs. the product of reactant concentrations at 25 °C and I = 1.60 mol dm^{-3}.

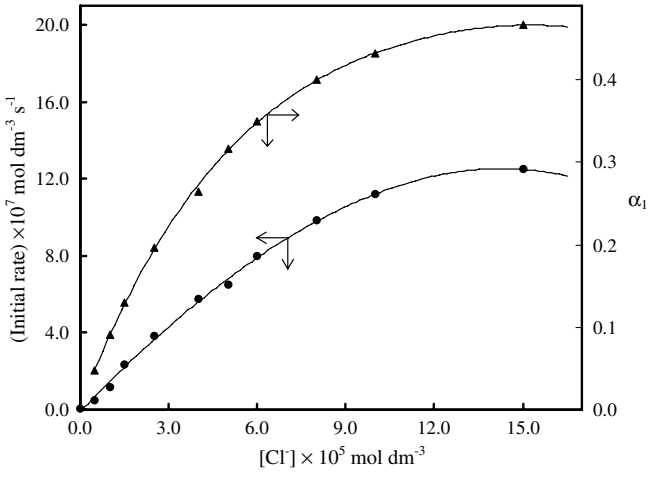

Fig. 2. Effect of chloride concentrations on different palladium(II) species and also on the rates of reaction (conditions as in Table 4).

3.7. Effect of added ions

In this case, the palladium(II) used contain chloride concentrations less than 1.0×10^{-6} mol dm^{-3} as stated in Section 2. When the reactant concentrations and other conditions were kept constant, ions such as Cu^{2+}, Na^+ and NO_3^- did not have any significant effect on the rate of the reaction, whereas added Mn^{2+} decreases the rate.

3.8. Effect of temperature

The rate constants (k_1) of the slow step of Scheme 1 were obtained from the intercepts of [QDC][Pd(II)]/(Initial rate) versus 1/[Hg(I)] plots at four different temperatures, by

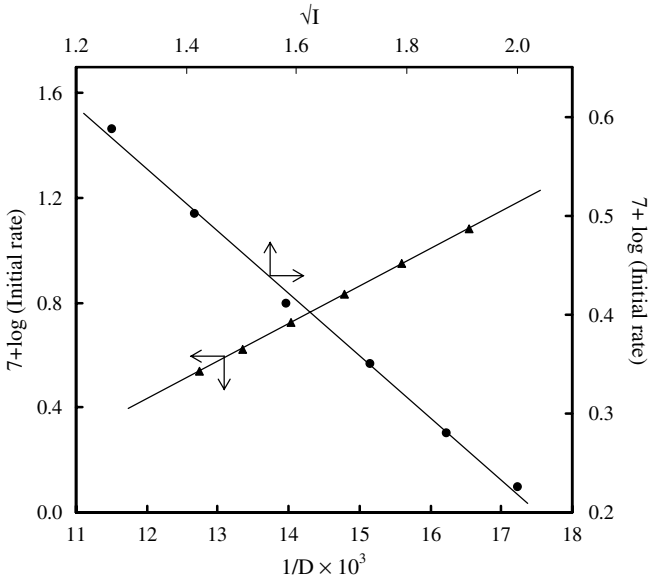

Fig. 4. Plot of log(Initial rate) vs. $I^{1/2}$ and log(Initial rate) vs. $1/D$.

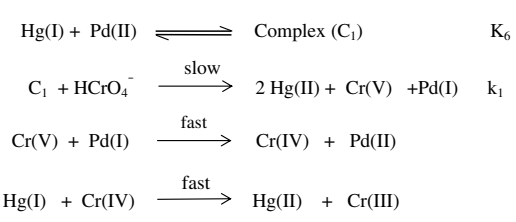
employing the values of K_5. The activation parameters for the rate determining step were obtained by the least-square method and from a plot of $\log k_1$ versus $1/T$ ($r \geqslant 0.987$, $\sigma \leqslant 0.019$). The values of $k_1 \times 10^2$ ($dm^3\,mol^{-1}\,s^{-1}$) are 3.88, 5.02, 6.94 and 9.42 at 298, 303, 308 and 313 K, respectively, which lead to the activation parameters $E_a = 23 \pm 1$ kJ mol^{-1}, $\Delta H^{\#} = 21 \pm 1$ kJ mol^{-1}, $\log A = 6.7 \pm 0.5$, $\Delta S^{\#} = -126 \pm 10$ J K^{-1} mol^{-1} and $\Delta G^{\#} = 58 \pm 5$ kJ mol^{-1}.

Thermodynamic quantities of first step of Scheme 1 are evaluated from the slope of the plot of [QDC][Pd(II)]/(Initial rate) versus $1/[H^+]$ at different temperatures. The values of K_5 at 298, 303, 308 and 313 K are 4.24, 4.65, 4.91 and 5.28 $dm^3\,mol^{-1}$, respectively. The Van't Hoff plot was drawn for the variation of K_5 with temperature ($\log K_5$ versus $1/T$; $r \geqslant 0.996$, $\sigma \leqslant 0.023$). The values of the thermodynamic quantities are $\Delta H = 11.0 \pm 0.5$ kJ mol^{-1}, $\Delta S = 49. \pm 3$ J K^{-1} mol^{-1} and $\Delta G = -4.0 \pm 0.2$ kJ mol^{-1}. A comparison of these values with those values obtained for the slow step shows that the reaction before the rate-determining step is fairly rapid [22].

The oxidation of mercury(I) by QDC is not observed in the absence of palladium(II) and, in the presence of latter, occurs with measurable speed only in aqueous sulfuric acid. Furthermore, since QDC does not oxidise palladium(II), even at the higher temperature (ca. 90 °C) of the aqueous acid, it is unlikely that any higher oxidation states, such as palladium(III) or palladium(IV), are involved in the reaction. In the presence of perchloric acid and nitric acid, the palladium(II) catalyst is inefficient, possibly due to active species of palladium as palladium chloride complexes, which are not possible in such media. Hence the study was undertaken in sulfuric acid and chloride medium.



Scheme 1.

The reaction between mercury(I) and QDC in sulfuric acid in the presence of palladium(II) has a stoichiometry of 1:3 with an apparent less than unit order in mercury(I) and H^+ and first order dependence on QDC, palladium(II) and Cl^-. It was observed that one of the products, chromium(III), increases the reaction rate, whereas another product, mercury(II), does not affect the rate of the reaction. However, in the palladium(II) catalysed chromium(VI) oxidation of mercury(I) an apparent less than unit order in mercury(I) and Cl^-, and first order dependence on Cr(VI), palladium(II) and H^+ concentrations were obtained. In this study, the initially added products have no effect on the rate of the reaction. The different behaviour in the palladium(II) catalysed oxidation of mercury(I) by chromium(VI) and QDC might be due to the presence of the quinolinium moiety. There are reports [23] that the reactivities of substituted pyridine, quinoline and isoquinoline complexes of chromium(VI) resemble one another. Such complexes show no dimerisation or polymerisation in solutions [24a]. In aqueous solution, QDC and chromium(VI) behave in different manners. Quinoline acts as an electron donor. Due to this, considerable quantities of QDC are reduced to chromium(III) [24b]. The thus formed chromium(III) immediately forms a weak complex with QDC, which is responsible for autocatalysis.

It is well known that in aqueous acid solution, QDC exists mainly in the form of the acid chromate ion [25,26], $HCrO_4^-$. The results suggest that mercury(I) reacts with palladium(II) to give a complex, which then reacts with $HCrO_4^-$ in a rate determining step to give the mercury(II) product, the intermediates chromium(V) and palladium(I) being generated. The intermediate chromium(V) reacts in further fast steps to give the products, palladium(II) being regenerated. The results can be accommodated by Scheme 1.

The evidence for complex formation was obtained from UV–Vis spectra of both palladium(II) and mercury(I)–palladium(II) mixtures, in which a hypsochromic shift of palladium(II) from 320 to 300 nm and hyperchromicity at 300 nm, occurred (Fig. 5). This was also evident from the Michaelis–Menten plot and such complex formation between substrate and catalyst has also been observed in other studies [27,28]. Since oxidation of mercury(I) by QDC is a non-complementary reaction, it may occur by the intervention of reactive chromium(V) and chromium(IV) species. The intervention of chromium(V) is evident from the induction experiment with iodide [25,26]. The induced oxidation of iodide yields two equivalent of iodine for each equivalent of the inductor oxidised. In any induced oxidation the inductor factor is defined as the ratio of the number of equivalents of reducing agent oxidised to

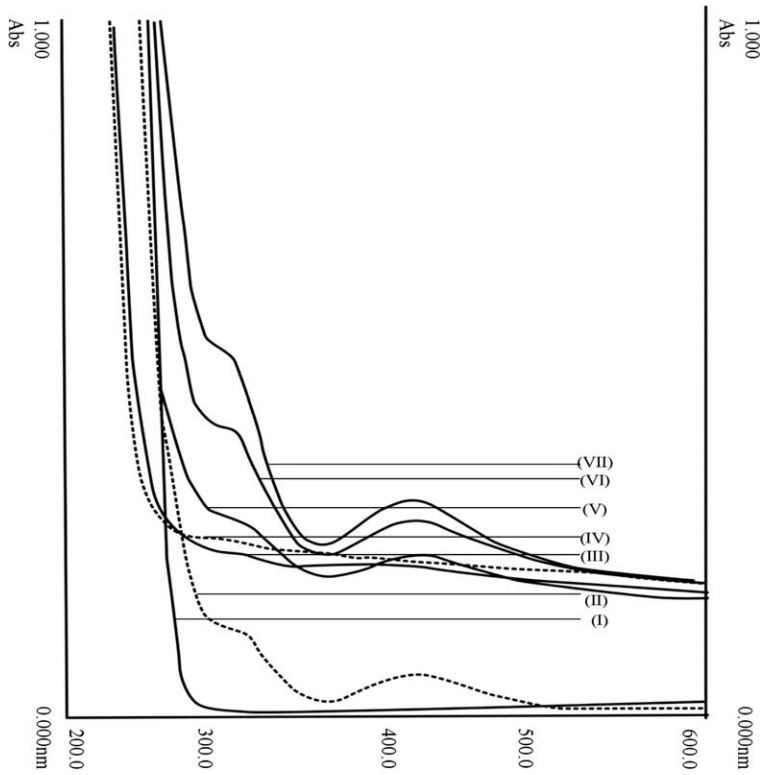


Fig. 5. UV–Vis spectra showing the formation of complex between Pd(II) and Hg(I) in the Pd(II) catalysed QDC oxidation of mercury(I) reaction in aqueous sulfuric acid at 25 °C. $[H_2SO_4] = 0.5$ mol dm^{-3} in all spectra. (I) Spectra of $[Hg(I)] = 2.0 \times 10^{-4}$ mol dm^{-3}. (II) Spectra of $[Pd(II)] = 2.0 \times 10^{-4}$ mol dm^{-3}. (III) Spectra of a mixture of $[Hg(I)] = 2.0 \times 10^{-4}$ and $[Pd(II)] = 0.5 \times 10^{-4}$/mol dm^{-3}. (IV) Spectra of a mixture of $[Hg(I)] = 2.0 \times 10^{-4}$ and $[Pd(II)] = 1.0 \times 10^{-4}$/mol dm^{-3}. (V) Spectra of a mixture of $[Hg(I)] = 2.0 \times 10^{-4}$ and $[Pd(II)] = 2.0 \times 10^{-4}$/mol dm^{-3}. (VI) Spectra of a mixture of $[Hg(I)] = 2.0 \times 10^{-4}$ and $[Pd(II)] = 3.0 \times 10^{-4}$/mol dm^{-3}. (VII) Spectra of a mixture of $[Hg(I)] = 2.0 \times 10^{-4}$ and $[Pd(II)] = 4.0 \times 10^{-4}$/mol dm^{-3}.

the number of equivalents of inductor oxidised. The induction factor for iodide oxidation is nearly two, which indicates that the active oxidising agent is pentavalent chromium. The intervention of chromium(IV) is evident from the progressive rate decrease in the presence of increasing amounts of added manganese(II), the decrease reaching a limit of about one half of the rate found in the absence of manganese(II). Such results have also been obtained for chromium(VI) oxidation of 2-propanol in aqueous acetic acid [29,30].

Scheme 1 leads to the rate law (8)

$$\text{Rate} = \frac{-\mathrm{d}[\text{QDC}]}{\mathrm{d}t} = \frac{k_1 K_5 K_6 [\text{QDC}][\text{Hg(I)}][\text{Pd(II)}][\text{H}^+]}{1 + K_5[\text{H}^+] + K_6[\text{Hg(I)}] + K_5 K_6 [\text{Hg(I)}][\text{H}^+]} \quad (8)$$

Rate law (8) accommodates all the experimental results except the autocatalytic effect of chromium(III). The rate law (8) may be rearranged to Eq. (9), which is suitable for verification.

$$\frac{[\text{QDC}][\text{Pd(II)}]}{\text{Rate}} = \frac{1}{k_1 K_5 [\text{H}^+]} + \frac{1}{k_1 K_6 [\text{Hg(I)}]} + \frac{1}{k_1 K_5 K_6 [\text{Hg(I)}][\text{H}^+]} + \frac{1}{k_1} \quad (9)$$

According to Eq. (9), a plot of the LHS versus $1/[\text{H}^+]$ and LHS versus $1/[\text{Hg(I)}]$ should be linear, and are found to be so (Fig. 6; $r \geqslant 0.999$, $\sigma \leqslant 0.018$ and $r \geqslant 0.998$, $\sigma \leqslant 0.018$). The slopes and the intercepts of such plots leads to values of k_1, K_5 and K_6 of $(3.88 \pm 0.15) \times 10^2$ dm^3 mol^{-1} s^{-1}, 4.24 ± 0.21 dm^3 mol^{-1} and $(8.23 \pm 0.38) \times 10^3$ dm^3 mol^{-1}, respectively. The modest activation energy and sizeable

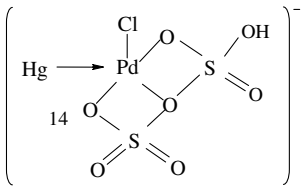
$$Hg^+ + Cr(IV) \xrightarrow{fast} Hg^{2+} + Cr(III)$$

Scheme 2.

entropy of activation supports a complex transition state in the reaction.

The active species involved in the mechanism can be understood as follows. In aqueous acid media, QDC is known to exist mainly as $HCrO_4^-$. Mercury(I) has been shown to exist [31] as the complex $[Hg_2(SO_4)HSO_4]^-$. Oxidation of mercury(I) is greatly facilitated in sulfuric acid solution and the reason may be that mercury(I) sulfate complexes are actively involved. The variation of rate with chloride ion was shown in Section 3. Except $PdCl^+$ species, the remaining species of palladium(II) do not parallel the rate (Table 4 and Fig. 2). Hence $PdCl^+$ is considered as the active species of palladium(II) in acid medium. In the same way, $PdCl^+$ is considered as the active species of palladium(II) in aqueous alkaline medium, since $PdCl^+$ species parallel the rate [32]. In both cases, the role of the medium is not very significant compared to the complexation of the ligand, chloride ion, with palladium. The mechanism of Scheme 1 will therefore involve the species shown in Scheme 2.

The probable structure of the complex (C_2) is as follows:



Therefore in terms of the active species, rate law (8) takes the following form:

$$Rate = \frac{k_1K_5K_6[HCrO_4^-][Hg_2(SO_4)HSO_4]^-[PdCl^+][H^+]}{1 + K_5[H^+] + K_6[Hg_2(SO_4)HSO_4]^- + K_5K_6[Hg_2(SO_4)HSO_4]^-[H^+]} \quad (10)$$

From the second equilibrium of Scheme 2

$$[Hg_2(SO_4)HSO_4]^- = K_7[Hg_2^{2+}][SO_4^{2-}][HSO_4^-] \quad (11)$$

But total [Hg(I)] is given by

$$[Hg(I)]_T = [Hg(I)]_f + [Hg_2(SO_4)HSO_4]^-$$
$$\therefore \quad [Hg(I)]_f = \frac{[Hg(I)]_T}{1 + K_7[SO_4^{2-}][HSO_4^-]} \quad (12)$$

Substituting Eq. (12) in Eq. (11), the following equation is obtained:

$$[Hg_2(SO_4)HSO_4]^- = \frac{K_7[Hg(I)]_T[SO_4^{2-}][HSO_4^-]}{1 + K_7[SO_4^{2-}][HSO_4^-]} \quad (13)$$

From the third step of Scheme 2

$$[PdCl^+] = K_1[Pd^{2+}][Cl^-] \quad (14)$$

Substituting Eq. (6) in Eq. (14)

$$\therefore \quad [PdCl^+] = \frac{K_1[Pd^{2+}]_T[Cl^-]}{1 + \beta_1[Cl^-] + \beta_2[Cl^-]^2 + \beta_3[Cl^-]^3 + \beta_4[Cl^-]^4} \quad (15)$$

Substituting Eqs. (13) and (15) in Eq. (10) and omitting subscripts, we obtain the following equation:

$$Rate = \left\{ \frac{k_1K_1K_5K_6K_7[Hg(I)][QDC][Pd(II)][Cl^-][SO_4^{2-}][HSO_4^-][H^+]}{(1 + K_7[SO_4^{2-}][HSO_4^-])\left(1 + \beta_1[Cl^-] + \beta_2[Cl^-]^2 + \beta_3[Cl^-]^3 + \beta_4[Cl^-]^4\right)} \right\} \times \left\{ 1 + K_5[H^+] + \frac{K_6K_7[Hg(I)][SO_4^{2-}][HSO_4^-]}{1 + K_7[SO_4^{2-}][HSO_4^-]} + \frac{K_5K_6K_7[Hg(I)][SO_4^{2-}][HSO_4^-][H^+]}{1 + K_7[SO_4^{2-}][HSO_4^-]} \right\}^{-1} \quad (16)$$

The reaction is accelerated in media of low polarity, which can be qualitatively explained by the involvement of oppositely charged ions, as in Scheme 1. However, the decrease in rate with increase in ionic strength is not easy to interpret. This might be due to the presence of various ionic reactions. The negative value of $\Delta S^{\#}$ (-126 ± 10 J K^{-1} mol^{-1}) suggests that the two ionic species combine in a rate determining step to give one intermediate complex which is more ordered than the reactants [33]. The negative value of $\Delta S^{\#}$ might be due to changes in vibrational frequencies and internal rotations of the reactants and complex [34]. The observed modest entropy of activation and higher rate constant of the slow step indicate that the oxidation presumably occurs by an inner-sphere mechanism. This conclusion is supported by the results of earlier work [35–37].

3.9. Autocatalysis

Autocatalysis by one of the products, chromium(III), is interesting. The apparent order of significantly less than

$$\text{QDC} + \text{Cr(III)} \rightleftharpoons \text{weak complex } (C_3) \quad K_8$$

$$C_3 + \text{Hg(I)} \xrightarrow{\text{slow}} \text{Products} \quad k_2$$

Scheme 3.

unity (0.73) in [Cr(III)], when [Cr(III)] is initially present, may be attributed to the weak complex formation between the product chromium(III) and oxidant, since chromium(III) is well known as a good complexing agent [38]. This is followed by the interaction of the weak complex with the reductant as in Scheme 3. The steps shown in Scheme 1 will form part of Scheme 1.

Evidence for the weak complex (C_3) was obtained by comparing UV–Vis spectra of chromium(III) with the mixture of QDC and chromium(III). There is a hypsochromic shift of chromium(III) from 584 to 580 nm, nearly 4 nm in the spectra of chromium(III) and the mixture of QDC and chromium(III). However, weak complex formation between chromium(III) and palladium(II) is disregarded due to our experimental rate law and lack of spectral evidence. Indeed such weak complex formation between QDC and chromium(III) has been observed in the literature [39–41].

Thus, when chromium(III) is initially present, a composite scheme involving all the steps of Schemes 1 and 3 operates and the rate law is given by the sum of the catalysed and autocatalysed rates.

$$\text{Rate}_{(\text{gross})} = \text{Rate}_{(\text{cat})} + \text{Rate}_{(\text{autocat})} \tag{17}$$

Thus, the rate law for the autocatalytic path can be obtained as:

$$\text{Rate}_{(\text{autocat})} = \text{Rate}_{(\text{gross})} - \text{Rate}_{(\text{cat})} = \frac{k_2 K_8 [\text{QDC}][\text{Hg(I)}][\text{Cr(III)}]}{1 + K_8[\text{Cr(III)}] + K_8[\text{QDC}] + K_8^2[\text{QDC}][\text{Cr(III)}]} \tag{18}$$

Eq. (18) can be rewritten as:

$$\frac{[\text{QDC}][\text{Hg(I)}]}{\text{Rate}_{(\text{autocat})}} = \frac{1 + K_8[\text{Cr(III)}] + K_8[\text{QDC}] + K_8^2[\text{QDC}][\text{Cr(III)}]}{k_2 K_8 [\text{Cr(III)}]} = \frac{1}{k_2 K_8 [\text{Cr(III)}]} + \frac{1}{k_2} + \frac{[\text{QDC}]}{k_2[\text{Cr(III)}]} + \frac{K_8[\text{QDC}]}{k_2} \tag{19}$$

Thus, Eq. (19) can be rearranged to the form (20) which is suitable for verification.

$$\frac{[\text{QDC}][\text{Hg(I)}]}{\text{Rate}_{(\text{autocat})}} = \frac{1}{k_2[\text{Cr(III)}]}\left\{\frac{1}{K_8} + [\text{QDC}]\right\} + \frac{1}{k_2}\{1 + K_8[\text{QDC}]\} \tag{20}$$

At constant concentrations of oxidant and reductant, a plot of LHS versus 1/[Cr(III)] of Eq. (20) should be linear and this was found to be so (Fig. 7; $r \geqslant 0.999$, $\sigma \leqslant 0.021$). Indeed it is to be noted that the plot shows an intercept which is in agreement with the complex formation, as in Scheme 3. The k_2 and K_8 values found from the intercepts and slope of such a plot were $(2.44 \pm 0.12) \times 10^2$ dm^3 mol^{-1} s^{-1} and $(1.10 \pm 0.04) \times 10^3$ dm^3 mol^{-1}, respectively. Using these values, the experimental rates for the added [Cr(III)] at constant concentrations of QDC and mercury(I) can be regenerated (Table 2).

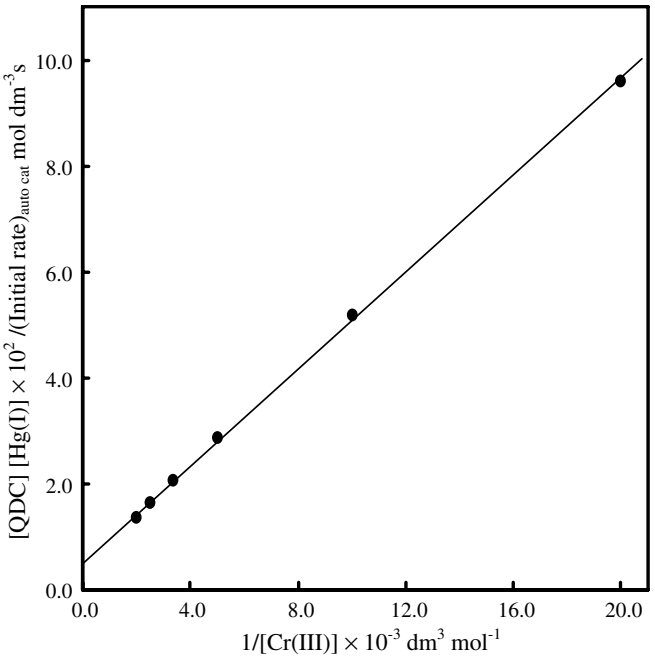


Fig. 7. Verification of rate law (19) in the form (20) (conditions as in Table 2).

4. Conclusion

The reaction between mercury(I) and QDC is very slow in sulfuric acid. Palladium(II) is known to catalyse the reaction with a measurable velocity at 10^{-6} mol dm^{-3}, especially in a sulfuric acid medium; which is not the case in perchloric acid and nitric acid media. The active species involved in the mechanism play an important role in the reaction. It is interesting to note that autocatalysis has taken place in the catalysed reaction, making a composite reaction scheme and rate law. The overall mechanistic sequence described here is consistent with the product, mechanistic and kinetic studies.

Scheme 1. Structures of the ligands: (a) vitamin B13; (b) 4(5)-methylimidazole tautomers.

2. Experimental

2.1. Preparation of the complexes

A solution of 4-Meim (0.82 g, 10 mmol) in methanol (10 ml) was added dropwise with stirring to a solution of $[Co(HOr)(H_2O)_4]\cdot H_2O$ [24] (0.76 g, 2.5 mmol) or $[Ni(HOr)(H_2O)_4]\cdot H_2O$ [20] (0.76 g, 2.5 mmol) in distilled water (30 ml). The solution was heated to 60 °C in a temperature-controlled bath and then stirred for 5 h at 60 °C. The reaction mixture was then cooled to room temperature. The red and blue crystals formed for the Co(II) and Ni(II) complexes, respectively, were filtered and washed with 10 ml of cold distilled water and methanol, and dried in air. *Anal*. Calc. for $C_{17}H_{22}N_8O_5Co$: C, 42.78; H, 4.65; N, 23.47. Found: C, 43.02; H, 4.52; N, 23.24%. *Anal*. Calc. for $C_{34}H_{54}N_{16}O_{15}Ni_2$: C, 39.11; H, 5.21; N, 21.46. Found: C, 39.12; H, 5.28; N, 21.74%.

2.2. Materials and measurements

All chemicals used were analytical reagent products. The elemental and mass spectroscopic analysis was carried out in TÜBİTAK Marmara Research Centre of Turkey. Mass spectroscopic analysis was performed on a Fisons MD 800 mass spectrometer coupled to a Fisons 8000 GC and FAB ionisation source. Magnetic susceptibility measurements at room temperature were performed using a Sherwood Scientific MXI model Gouy magnetic balance. The UV–Vis spectra were obtained for an aqueous solution of the complexes (10^{-3} M) with a Unicam UV2 spectrometer in the range 900–190 nm. The IR spectra were recorded in the 4000–400 cm^{-1} region with a Mattson 1000 FT-IR spectrometer using KBr pellets. A TG8110 thermal analyzer was used to record simultaneous TG, DTG and DTA curves in static air atmosphere at a heating rate of 10 K min^{-1} in the temperature range 20–1000 °C using platinum crucibles. Highly sintered α-Al_2O_3 was used as a reference and the DTG sensitivity was 0.05 mg s^{-1}.

2.3. Crystallographic analysis

Data collection was performed on a STOE IPDS II image plate detector using Mo Kα radiation ($\lambda = 0.71073$ Å). Intensity data were collected in the θ range 1.87–28.08° at 100 K. Data collections: Stoe X-AREA [40]. Cell refinement: Stoe X-AREA [40]. Data reduction: Stoe X-RED [40]. The structure was solved by direct-methods using SIR97 [41] and anisotropic displacement parameters were applied to non-hydrogen atoms in a full-matrix least-squares refinement based on F^2 using SHELXL-97 [42]. Molecular drawings were obtained using ORTEP-III [43] and DIAMOND [44]. All H atoms except for water hydrogens were treated as riding. Restrain was applied to water hydrogens to idealized geometry.

3. Results and discussion

3.1. UV–Vis spectra and magnetic susceptibility

The λ_{max} values of the two absorption bands in the UV–Vis spectra of **1** are 384 ($\varepsilon = 22$ L mol^{-1} cm^{-1}) and 522 nm ($\varepsilon = 34$ L mol^{-1} cm^{-1}). These values were assigned to the following d–d transitions, ν_3: $^4T_{1g} \rightarrow {}^4T_{1g}(P)$ and ν_2: $^4T_{1g} \rightarrow {}^4A_{2g}$, respectively. ν_1: $^4T_{1g} \rightarrow {}^4T_{2g}$ transition was not observed which is of low energy and shifts to the IR region and the Δ_0 values for **1** could not be calculated. The electronic spectrum of **2** in H_2O exhibits two absorption bands at 540 and 884 nm and the corresponding ε values are 21 and 18 L mol^{-1} cm^{-1}, respectively. These values were assigned to ν_2: $^3A_{2g} \rightarrow {}^3T_{1g}$ and ν_1: $^3A_{2g} \rightarrow {}^3T_{2g}$ d–d transitions. The Δ_0 value for **2** was calculated as 11300 cm^{-1} since $\Delta_0 = \nu_1$ for d^8 complexes [45].

The complexes **1** and **2** exhibit magnetic moment values of 4.27 and 2.41 BM which corresponds to three and two unpaired electrons, respectively, which are consistent with

Table 1
IR spectra of the complexes[a] (cm^{-1})

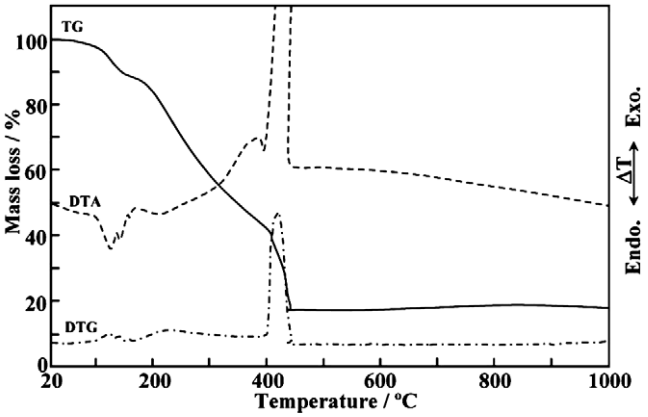

Fig. 2. TG, DTG and DTA curves of **2**.

a weak field octahedral geometry as expected. However, this magnetic moment value is lower than the spin only value for two unpaired electrons in the Ni(II) complex, indicative of some antiferromagnetic behavior [46].

3.2. IR spectra

The most significant frequencies in the IR spectra of both complexes are given in Table 1. The strong bands at 3544 and 3498 cm^{-1} are attributed to the ν(OH) vibration of water molecules in the IR spectra of **1** and **2**. The bands at 3255–3176 cm^{-1} are attributed to the NH stretching vibration in HOr and 4-Meim ligands. This data substantiates the suggestion that 4-Meim molecules coordinate to the central metal ion in their neutral form. The distinct weak bands in the 3012–2873 cm^{-1} region can be assigned to the CH stretching vibrations of the HOr and 4-Meim ligands in the complexes. The carbonyl groups appear as two main peaks at 1700 cm^{-1} [$\nu_{C=O(acid)} + \nu_{C(2)=O}$] and 1660 cm^{-1} [$\nu_{C(6)=O} + \nu_{C=C}$] in the free H_3Or [7]. These bands appear as strong bands at 1639 and 1620 cm^{-1} in the spectrum of the Co(II) complex, while the Ni(II) complex give a single and broad absorption band at 1614 cm^{-1}, probably due to overlapping of the two bands. The weak bands in the 450–500 and 500–600 cm^{-1} region are due to M–N and M–O stretching vibrations, respectively. In the Co(II) and Ni(II) complexes, the orotate ligand is coordinated as dianionic and bidentate through the carboxylic O and N(3) of the pyrimidine ring, while the 4-methylimidazole ligand is coordinated as neutral and monodentate through the N atom.

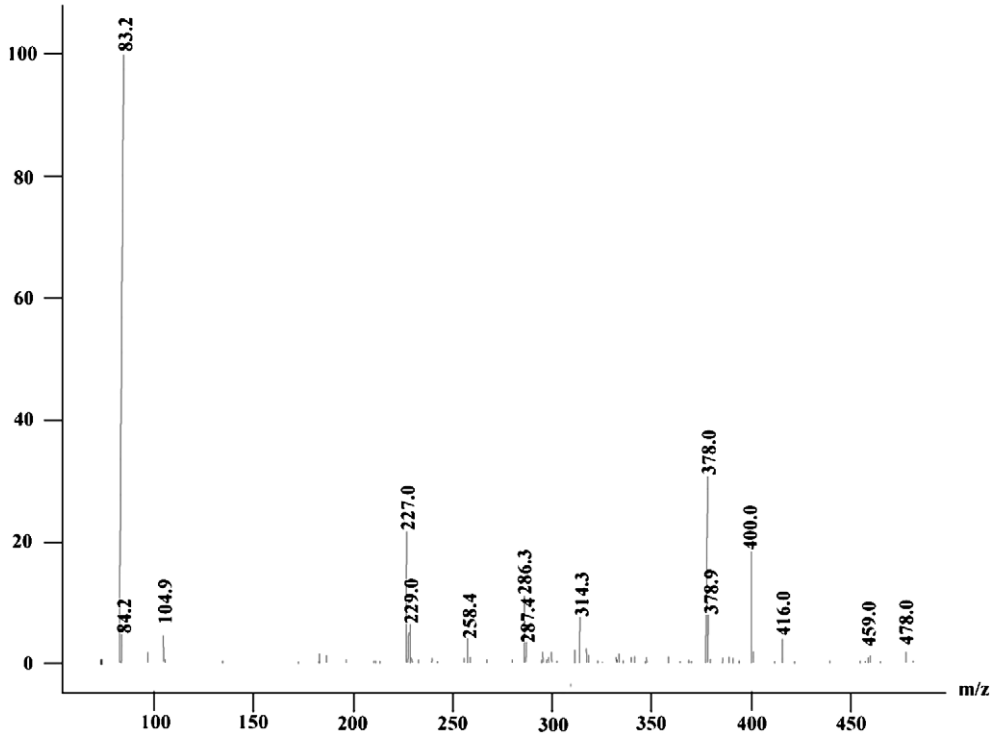

Fig. 3. The mass spectrum of **1**.

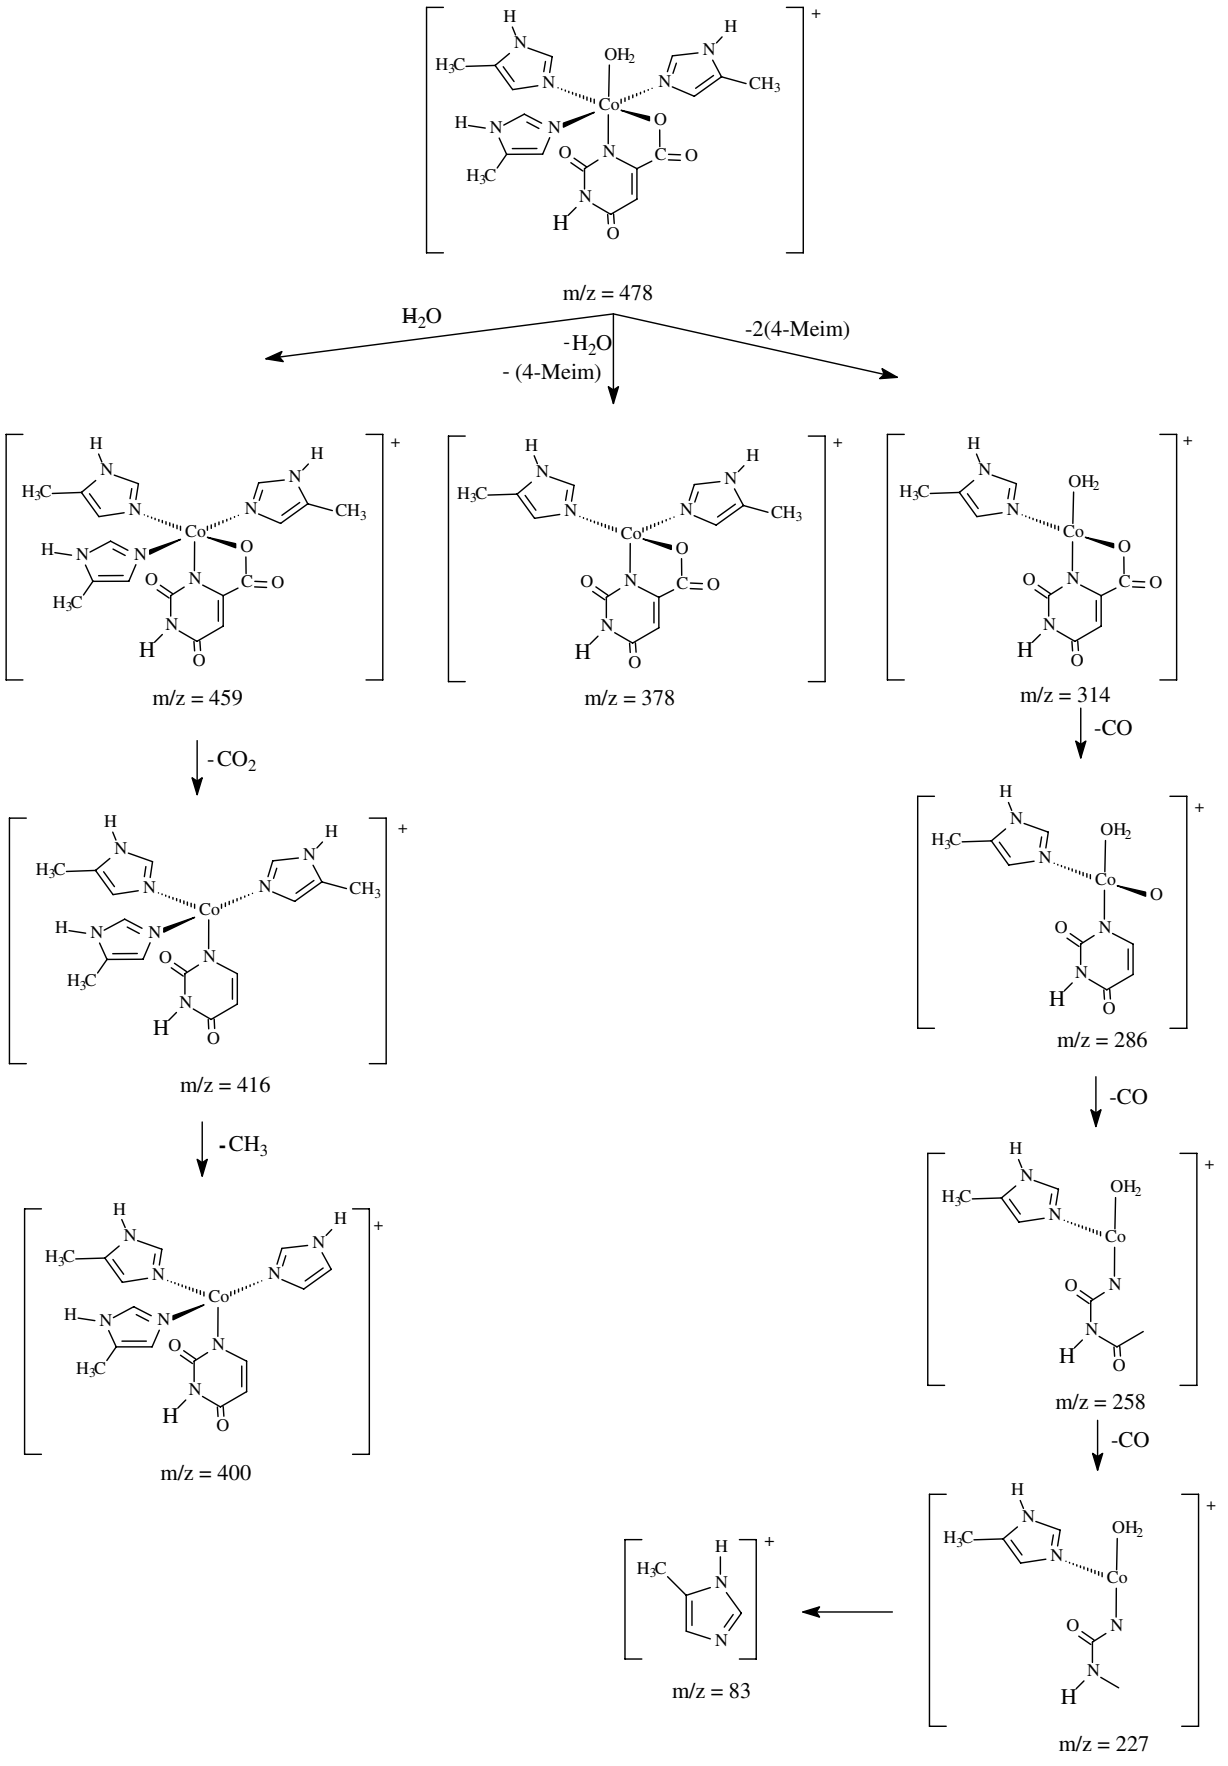

Fig. 4. Mass spectral fragmentation pattern of **1**.

3.3. Thermal analysis

3.3.1. [Co(HOr)(H$_2$O)(4-Meim)$_3$] (1)

Thermal decomposition of **1** proceeds in three stages (Fig. 1). The first stage, in the 122–190 °C temperature range, corresponds to the loss of one aqua ligand (found: 3.78; Calc. 4.35%), giving an endothermic effect (DTG_{max} = 161 °C). The originally red colour of the complex changes to blue-green on dehydration. The anhydrous complex reverts immediately to [Co(HOr)(H$_2$O)(4-Meim)$_3$] after cooling in the open atmosphere. The endothermic second stage of the Co(II) complex, observed as several consecutive steps, is related to the decomposition of the neutral 4-Meim ligans and decarboxylation of the orotato ligand, in the 191–380 °C temperature range (DTG_{max} = 241, 255, 276 and 300 °C). The mass spectrum of **1** also supports the decomposition of the orotate ligand with release of CO_2/CO (Fig. 3). In the last stage the strong exothermic peak of the DTA curve (DTG_{max} = 431 °C) is associated with the burning of the organic residue, leading finally to Co_3O_4. The endothermic peak at 889 °C (DTG_{max}) is related to the conversion of Co_3O_4 to CoO. The overall weight loss 82.19% (Calc. 84.30%) agrees with the propose structure well.

3.3.2. [Ni(HOr)(H$_2$O)(4-Meim)$_3$]$_2$ · 5H$_2$O (2)

The thermal decomposition of **2** (Fig. 2) is similar to **1**. In the first stage, dehydration of the complex occurs in the 49–173 °C range temperature, giving an endothermic effect. Initially 5 mol of crystal water are removed in the 49–138 °C range temperature (DTG_{max} = 128 °C, found: 8.51, Calc. 8.63%) and then two moles coordinated water molecules are released in the 139–173 °C range temperature (DTG_{max} = 147 and 163 °C, found: 3.33, Calc. 3.45%). The blue octahedral complex loses water molecules upon heating yielding a violet, probably square pyramidal dehydrated species. The second stage is related to the release of 4-Meim ligands and partial decomposition of the orotate ligand proceeds with release of CO_2/CO. In the following stage, the strong exothermic mass loss process occurs in a single step. During this stage, the remaining organic part is abruptly burnt (DTG_{max} = 431 °C). The final decomposition product, NiO, was identified by IR spectroscopy (found: 82.64, Calc. 85.70%).

3.4. Analysis of the mass spectrum

The volatile products observed in the thermal decomposition process were also observed in the mass spectrometer ionization process, except molecular peak, and it was concluded that the ionization and thermal decomposition pathway of the complex resemble each other.

The mass spectrum of **1** was recorded to establish a relation between the thermal and ionization process to predict a more appropriate thermal decomposition pathway. The mass spectrum recorded by the FAB technique is given in

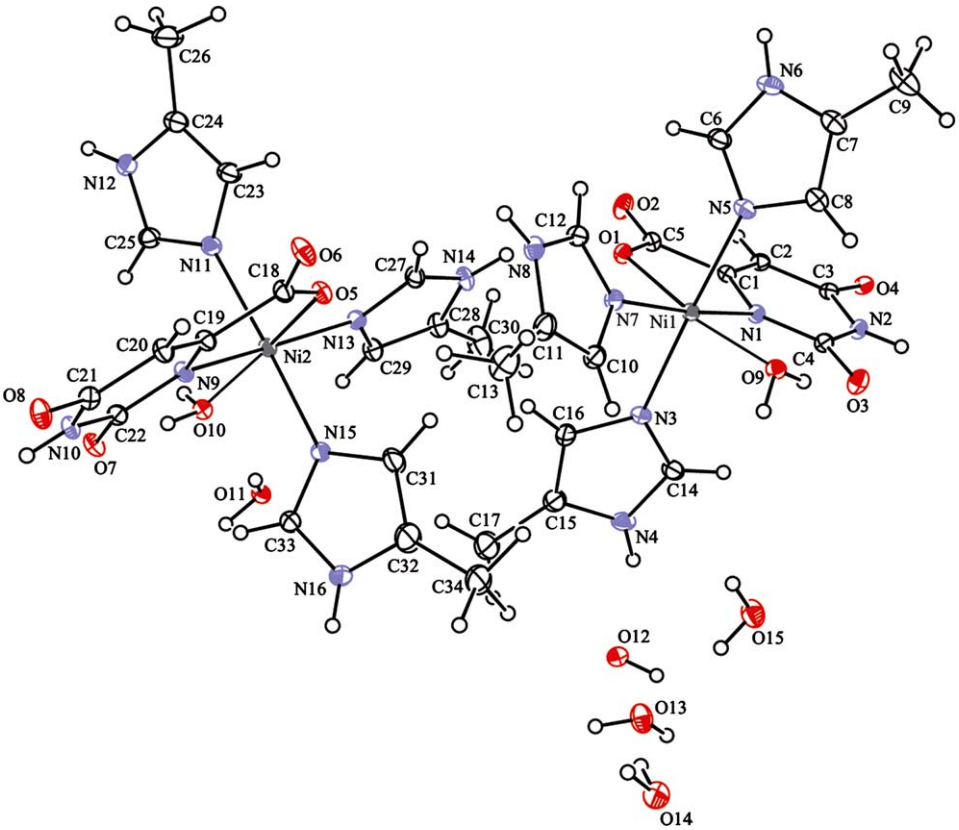

Fig. 5. ORTEP III view of **2** with the atom numbering scheme (30% probability ellipsoids).

Fig. 3. The mass spectrum of **1** is not very complicated and only the major peaks, which were produced in significant quantities, were apparent. In addition to this, the molecule ion peak (M^+) ($m/z = 478$) of **1** was visible in the mass spectrum. The peak observed at $m/z = 459$ possibly corresponds to the [Co(HOr)(4-Meim)$_3$] molecule produced by the loss of a water molecule from [Co(HOr)(H_2O)(4-Meim)$_3$] in the ionization process. The compound formed from [Co(HOr)(4-Meim)$_3$] by the release of CO_2 was observed in the mass spectrum at $m/z = 416$. In the literature, orotate and derivative complexes with similar structures are also reported to be decomposed by release of CO_2 [47–49]. The compound, [Co(uracil)(im)(4-Meim)$_2$], formed by the loss of the CH_3 ion was observed in the mass spectrum at $m/z = 400$. This type of ionization of the 4-Meim ligand in the [Zn(Han)$_2$(4-Meim)$_2$] (Han = *o*-aminobenzoate) complex has been reported earlier [50]. The peaks observed at $m/z = 378$ and $m/z = 314$ values may correspond to [Co(HOr)(4-Meim)$_2$] and [Co(HOr)(H_2O)(4-Meim)] complexes, respectively. Formation of these fragments in the thermal process may also be proved by the thermal analysis data. The possible decomposition products of the [Co(HOr)(H_2O)(4-Meim)$_3$] complex shows in the ionization process (Fig. 4).

3.5. Crystal structure of [Ni(HOr)(H_2O)-(4-Meim)$_3$]$_2$ · 5H_2O

The asymmetric unit of **2** is composed of two crystallographic independent [Ni(HOr)(H_2O)(4-Meim)$_3$]$_2$ molecules and five lattice water molecules, as shown in Fig. 5. The Ni(II) ion in [Ni(HOr)(H_2O)(4-Meim)$_3$]$_2$ is in a distorted octahedral configuration coordinated by a bidentate HOr ligand, a coordinated water molecule and three 4-Meim ligands (Fig. 6). The absolute configuration of the Ni(II) center is *Λ* and *Δ*, which is the highest energy conformation [51]. The distorted octahedral coordination geometry is comprised of a N atom and a carboxylate O atom from a doubly deprotonated bidentate orotate ligand, one aqua O atom and three N atoms from imidazole molecules. The N and O atoms of orotate are bonded to the metal to form a five-membered chelate ring [Ni(1)—N(1) = 2.0835(18) and Ni(1)—O(1) = 2.0783(15) Å in molecule A and Ni(2)—N(9) = 2.1184(18) and Ni(2)—O(5) = 2.0605(16) Å in molecule B]. All the N—Ni—N, N—Ni—O and O—Ni—O bond angles deviate significantly from 90° or 180°, which is presumably the result of the steric constraints arising from the shape of the ligands. The angles subtended at the Ni atom by the orotate ligand are 79.66(6)° in molecule A and 79.92(6)° in molecule B, which is in agreement with values previously reported for other orotate-containing Ni(II) complexes [20,52]. This 'bite' angle is far from the ideal value of 90° because of the constrained geometry of the orotate ligand.

The orotate ligand in **2** is essentially planar (r.m.s. deviations = 0.0600 and 0.0150 Å in molecules A and B, respectively), with a slight deviation from planarity arising from the non-zero torsion angle between the carboxylate group

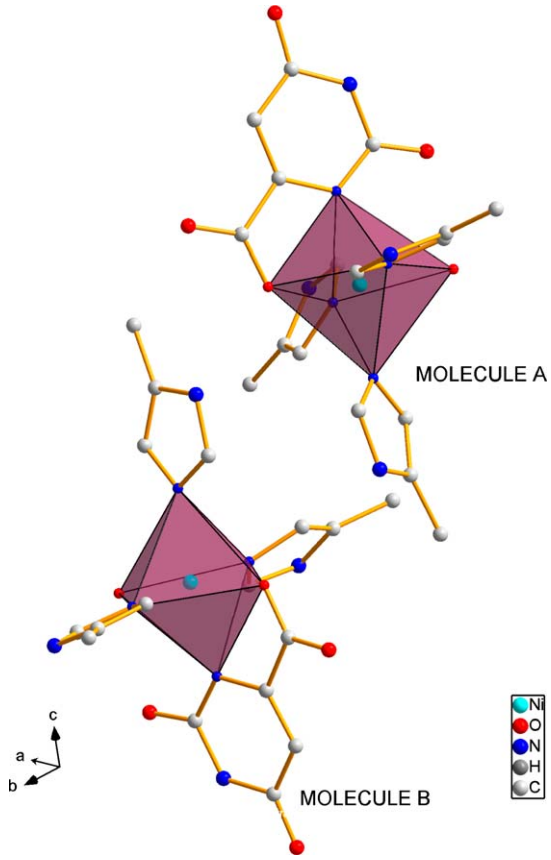

Fig. 6. Octahedral representation of **2**. Distorted octahedra are shaded dark. All H atoms and free water molecules have been omitted for clarity.

and the ring [N(1)—C(1)—C(5)—O(1) = 1.2(3)° and N(9)—C(19)—C(18)—O(5) = −7.5(3)°]. This torsion angle indicates distortion of the orotate ligand caused by coordination to the Ni(II) ion. While this torsion angle of molecule B is wider than the reported values in uncoordinated orotic acid ligands 5.9(4)° [37] and 5.0(2)° [38], the value for molecule A is even less. Of all the N—C bonds in the uracil ring of the orotate ligand, N(1)—C(1), N(1)—C(4), N(9)—C(19) and N(9)—C(12) are the shortest, with values in the range 1.340(2)–1.358(2) Å. This indicates a considerable π-electron delocalization within the C(2)—C(1)—N(1)—C(4) and C(20)—C(19)—N(9)—C(22) skeletons. The C=O bond lengths for exocyclic atoms are in the range 1.251(2)–1.260(2) Å. These values are slightly longer than those in typical orotate complexes and this can be attributed to the intermolecular hydrogen bonding (Table 2).

The orotate molecule seems to have a degree of elasticity with regard to its coordination to metal centers. In complexes of HOr with Ni(II) [37,52], Cu(II) [16] and Zn(II) [21], the C(4)—N(1)—C(1) and C(22)—N(9)—C(19) angles are smaller [119.16(16)° in molecule A and 118.12(16)° in molecule B, 118.25(15)°, 118.9(11)°, 117.9(2)° and 118.1(4)°, respectively] than that found in orotic acid 122.8(3)° [53], 123.07(14)° [38] and 122.8(3)° [37]. This shrinkage for this angle is due to the metal coordination at the N atom, which causes widening of the adjacent N—C—C and N—C—N angles (Table 2).

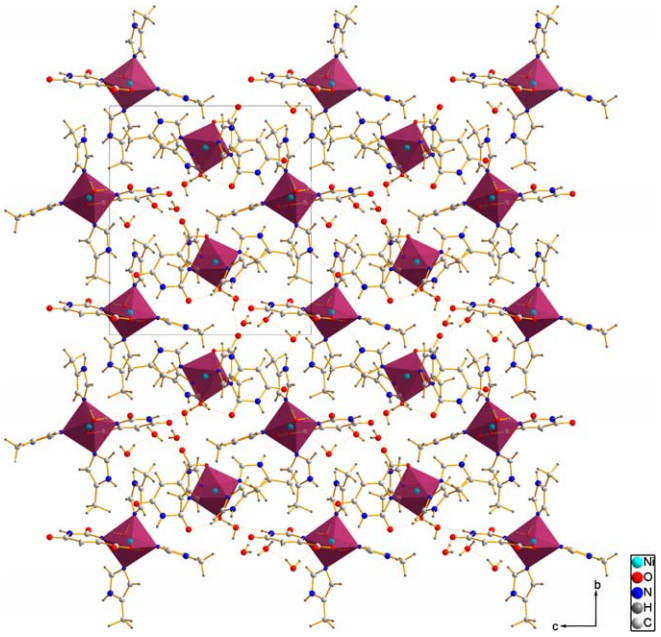

Fig. 7. Crystal packing and H bond interactions. Distorted octahedral are drawn as shaded dark.

The carboxylate C—O distances in the orotate anion also display some variability, depending on their environment. The C—O distances are practically equal in the uncoordinated HOr^{2-} anion and its Ni(II) and Li(I) complexes [54]. In **2**, the C—O bond lengths are in the range 1.244(2)–

1.268(2) Å, which is comparable with those in similar Ni(II) complexes [37,52].

The 4-Meim rings in **2** are individually planar, with r.m.s. deviations in the range of 0.0017–0.0084 Å. The dihedral angles between the apical positioned 4-Meim rings are 44.1(8)° and 39.7(7)°. The internal geometries are as expected, with the bond lengths N—C [in the range of 1.307(3)–1.318(3) Å] and C—C [in the range of 1.347(3)–1.364 (3) Å] corresponding exactly to typical double-bond lengths.

As a result of the existence of five free crystallization waters, the crystal is mainly stabilized by many strong intermolecular H bonds O(W)—H...O(W), O(W)—H...O, O(W)—H...N, N—H...O(W), etc. There are also intramolecular H bonds between coordinated water molecules O9, O10 and exocyclic O atoms of orotate and also imidazole C(8) and C(27) atoms and coordinated water molecules. From all of these intermolecular interactions, a three-dimensional hydrogen-bonded network results (Table 3, Fig. 7).

4. Supplementary material

Crystallographic data for the structure reported here have been deposited at the CCDC as supplementary data, CCDC No. 603935. Copies of the data can be obtained on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44 1223 336 033; e-mail: deposit@ccdc.cam.ac.uk or www.ccdc.cam.ac.uk).

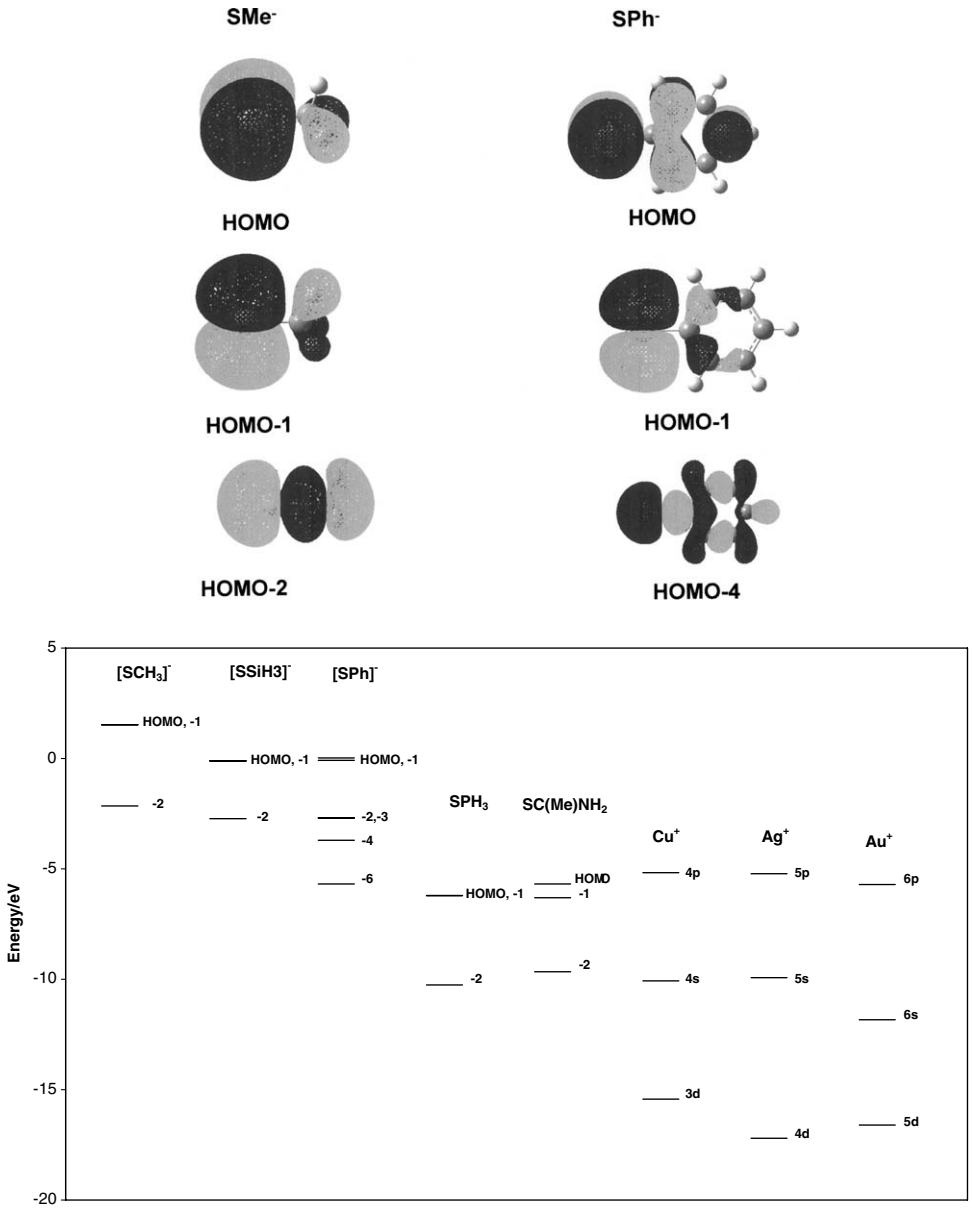

Fig. 1. Frontier molecular orbitals for 1–3 and energy level diagram for 1–5 and M^I.

3% and 10%, respectively [11]. Frequency calculations for energy minima showed no imaginary frequencies. Transition state structures exhibited one imaginary frequency. Calculated frequencies were scaled by a factor of 0.9613 [12]. Enthalpy values represent the sum of electronic and thermal enthalpies [13]. Molecular orbitals were generated using GaussView. All structures were minimised starting from a planar $M_n(SR)_n$ framework.

3. Results and discussion

3.1. $[SCH_3]^-$ as a model for $[SAr]^-$ and $[SSiR_3]^-$

For computational economy, all calculations have been performed using $[SCH_3]^-$ (**1**) as ligand. Most molecular $M_n(SR)_n$ complexes which have been structurally characterised in the solid state contain sterically demanding $[SAr]^-$ and $[SSiR_3]^-$ ligands to hinder aggregation. Using calculations on the free anions and on their CuSR complexes, an evaluation has been performed as to whether $[SCH_3]^-$ (**1**) serves as an adequate model electronically for $[SPh]^-$ (**2**) and $[SSiH_3]^-$ (**3**). All of **1**–**3** exhibit two filled orbitals perpendicular to the S–C axis and a third orbital at lower energy which is collinear with the S–C axis (Fig. 1) The HOMO/HOMO-1 pair of **2** are non-degenerate due to their differing interactions with the σ-framework of the ring. Also shown in Fig. 1 are the energies of the appropriate orbitals of SPH_3 (**4**) and thioacetamide **5**, sulfur ligands which are known to serve as neutral analogues of anionic thiolate (vide infra). The

donor orbitals for **1**–**3** are similar in energy, while those of the neutral sulfur donors **4** and **5** lie at slightly lower energy. No large differences are observed in the energies of the M^I valence orbitals.

The computed molecular structure of $CuSCH_3$ (**6a**) is non-linear with a Cu–S–C angle of 104°. Analysis of the molecular orbitals of **6a** (Fig. 2) shows that the HOMO-2 of $[SMe]^-$ (**1**) is used in formation of the HOMO-2/HOMO-7 pair whilst one of the degenerate HOMO/HOMO-1 pair is used to form the HOMO/HOMO-5 pair of π-symmetry. There is no net π-bond, and σ-bond formation provides the main stabilisation in the form of the bonding and weakly bonding HOMO-6/HOMO-1 pair. Two metal orbitals of δ-symmetry (HOMO-3/-4) remain non-bonding. The structures and energy level diagrams for $CuSSiH_3$ (**7**) and $MSCH_3$ (**6b**,**c**) (M = Ag, Au) are very similar. CuSPh (**8**) differs in that there is some mixing of one of the π-ring orbitals of **2** into the π-bonding molecular orbitals. The amount of stabilisation through delocalisation to the aryl ring is small, however, since the computed Cu–S bond rotational barriers in **6a** and **8** differ little (4.2 and 7.9 kJ mol^{-1}, respectively). It is therefore concluded that $[SMe]^-$ represents an adequate mimic in electronic terms for $[SAr]^-$ and $[SSiR_3]^-$ ligands.

Whilst no net π-bond exists in **6**–**8**, the HOMO in M(SMe) (M = Cu,Ag,Au) **6a**–**c** is a π-antibonding orbital. Removal of two electrons (either by oxidation or loss of a ligand) thus might be expected to turn on a net π-donor

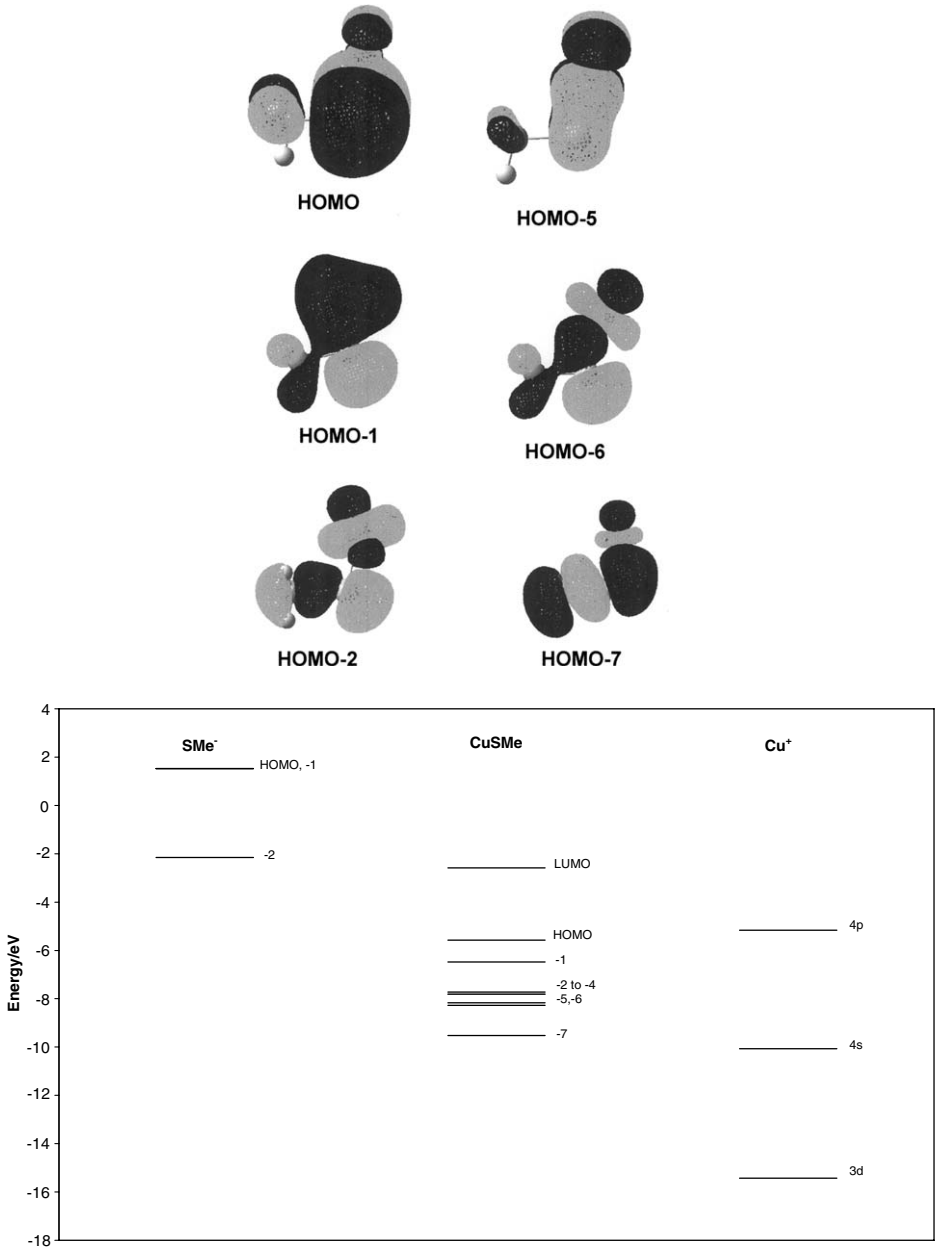

Fig. 2. Molecular orbitals and energy level diagram for CuSMe.

stabilisation. Hence, like Cl^-, thiolate may be viewed as a π-labilising ligand.

3.2. Ring formation in the $M_n(SMe)_n$ series ($n = 1$–6, M = Cu, Ag, Au)

The reader is referred to Table 1 for a full listing of experimental structures and their numbering.

Ring enlargement in this series corresponds to the formal reaction

$$M_n(SMe)_n + M(SMe) \rightarrow M_{n+1}(SMe)_{n+1}$$

A thermodynamic evaluation of the ring formation and enlargement process (Fig. 3) shows strongly exoenthalpic values for the $n = 2 \rightarrow 3$ and (to a lesser extent) the $n = 3 \rightarrow 4$ expansions, after which the enthalpy tends towards a more or less constant value. The energy value for $n = 1 \rightarrow 2$ corresponds to that for formation of the smallest possible $M_2(SMe)_2$ ring from M(SMe). No binary compounds containing only metal and thiolate exist for $n = 2$, though compounds supported by metal–ligand coordination are known. The driving force for ring expansion is an increase in the S–M–S angle towards the preferred linear coordination which is attained without substantial strain only for $n \geqslant 3$.

[a] This work.

[b] More substituted metal atom.

[c] Less substituted metal atom.

[d] θ is defined as the angle between the copper atoms and the midpoint of the S–S axis.

3.2.1. $M_2(SR)_2$ rings

A molecular orbital analysis for the four-membered ring of $Cu_2(SMe)_2$ (**9a**) exhibits some features which are common to **9b**,**c** (M = Ag, Au) and to the higher analogues. Structural minima for **9a** can be located for both *cis* and *trans* isomers, with the *trans* isomer being more stable by only 2 kJ mol^{-1}. There is no torsional strain in this model example; the Me-Me separation in the *cis* isomer (5.6 Å) is still substantially greater than the sum of the covalent radii. *cis* → *trans* Isomerisation occurs through a transition state **9a*** with a barrier of only 28 kJ mol^{-1}. Even in the calculated structures of *cis*/*trans*-$Cu_2(SMe)_2(PH_3)_4$ (**14a**,**d**), the *trans* isomer is more stable by only 3 kJ mol^{-1}, with a barrier for *cis* → *trans* isomerisation of 23 kJ mol^{-1}.

Neglecting S–C and C–H orbitals, the MO diagram of *trans*-$Cu_2(SMe)_2$ (**9a**) exhibits 16 occupied molecular orbitals (Fig. 4). The lowest energy σ molecular orbitals (such as HOMO-15) use mainly the HOMO-2 of $[SMe]^-$ while higher energy σ orbitals (such as HOMO-13) use one of the HOMO/HOMO-1 orbitals of $[SMe]^-$. HOMO-12 can be viewed as a π molecular orbital utilising the second of the HOMO/HOMO-1 pair of $[SMe]^-$. Whilst the non-bonding and antibonding partners of HOMO-12 are filled, there is a net σ-stabilisation of the ring since two antibonding partners of σ-symmetry remain unoccupied. A nest of four metal-centred orbitals [HOMO-4 to -6, -8] derived from the non-bonding δ orbitals of CuSMe is also evident. There is an increase in the number of occupied molecular orbitals by eight for each increase of ring size from n to $n + 1$. As each MSMe fragment may be viewed as contributing nine fragment orbitals [three from SMe^- and six from M (one p + five d)], there is a net increase in one bonding electron pair with each insertion of MSMe.

The calculated M–M distances in $M_2(SMe)_2$ (**9a**–**c**) (2.45 Å, 2.84 Å and 2.79 Å; Table 1) are longer than twice the covalent radii for two coordinate Cu^I, Ag^I and Au^I (2.26 Å, 2.66 Å and 2.50 Å, respectively) [14], though the Au–Au distance in **9c** is much less than the Au–Au distance seen in the solid state for LAu(SR) dimers held together by aurophilic interactions (3.13–3.16 Å) [15].

To our knowledge, no binary $M_2(SR)_2$ cluster is known. The simplest structurally characterised examples are ligand supported complexes of formulae $M_2(SR)_2L_n$ ($n = 2, 3, 4$; L = phosphine) and $M_2(SR)_2(o\text{-phen})_2$, all having a *trans* conformation of the SR^- ligands. A thermodynamic evaluation of complexation of *trans*-$Cu_2(SMe)_2$ (**9a**) by PH_3 (**15**) (Fig. 5) illustrates that complexation is strongly favoured for $n = 1, 2$; no complexes of formula

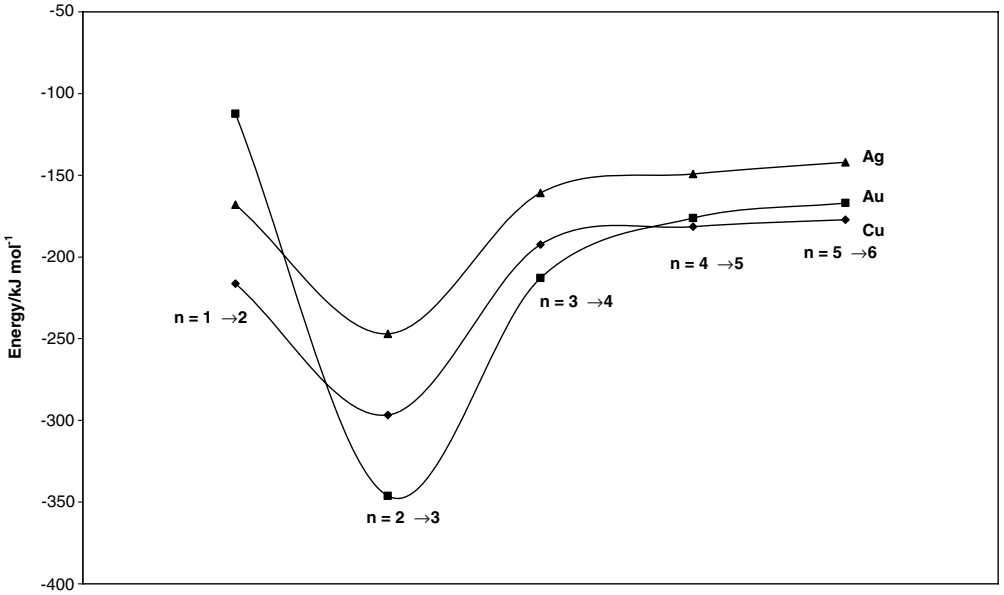

Fig. 3. Calculated enthalpy changes for the reaction $M_n(SMe)_n + M(SMe) \rightarrow M_{n+1}(SMe)_{n+1}$.

$M_2(SR)_2(PR_3)$ have been reported. The enthalpy of complexation for tri- and tetra-substitution by PH_3 is much less negative and relatively constant. For CuSMe (**6a**), the strong preference for a linear, two-coordinate structure can be seen in the very negative enthalpy for formation of $CuSMe(PH_3)$; additions of the second and third PH_3 ligands are much less exoenthalpic.

1,4-Diaza-1,3-butadiene (DAB) (**16**) has been used as a computationally less expensive analogue of 1,10-*o*-phenantholine [20]. The donor orbitals of PH_3 (**15**) and DAB (**16**) are incorporated mainly through mixing with the HOMO-2 of SMe^- to give low energy σ-bonding orbitals. The four molecular orbitals of π-symmetry observed for $Cu_2(SMe)_2$ (**9a**) remain essentially unperturbed and net non-contributory. Though decreasing symmetry means that mixing of the HOMO/-1/-2 orbitals of $[SMe]^-$ occurs in construction of the σ and π molecular orbitals for larger rings, $2n$ metal localised orbitals can be located for each $M_n(SMe)_n$ ring system. For planar ring systems ($n = 2,3$), the lowest energy ring-localised orbitals exhibit substantial M–M overlap, though there is no net M–M bond since the antibonding partner is also occupied. For non-planar rings ($n = 4$–6), direct M–M orbital overlap is substantially reduced or absent.

The calculated structures of $M_2(SMe)_2$ (**9a**–**c**) are planar with S–M–S and M–S–M angles expanded and contracted, respectively, from the ideal 90° internal angles (Table 1, Fig. 6). Calculated structures of $Cu_2(SMe)_2(PH_3)_3$ (**12a**)

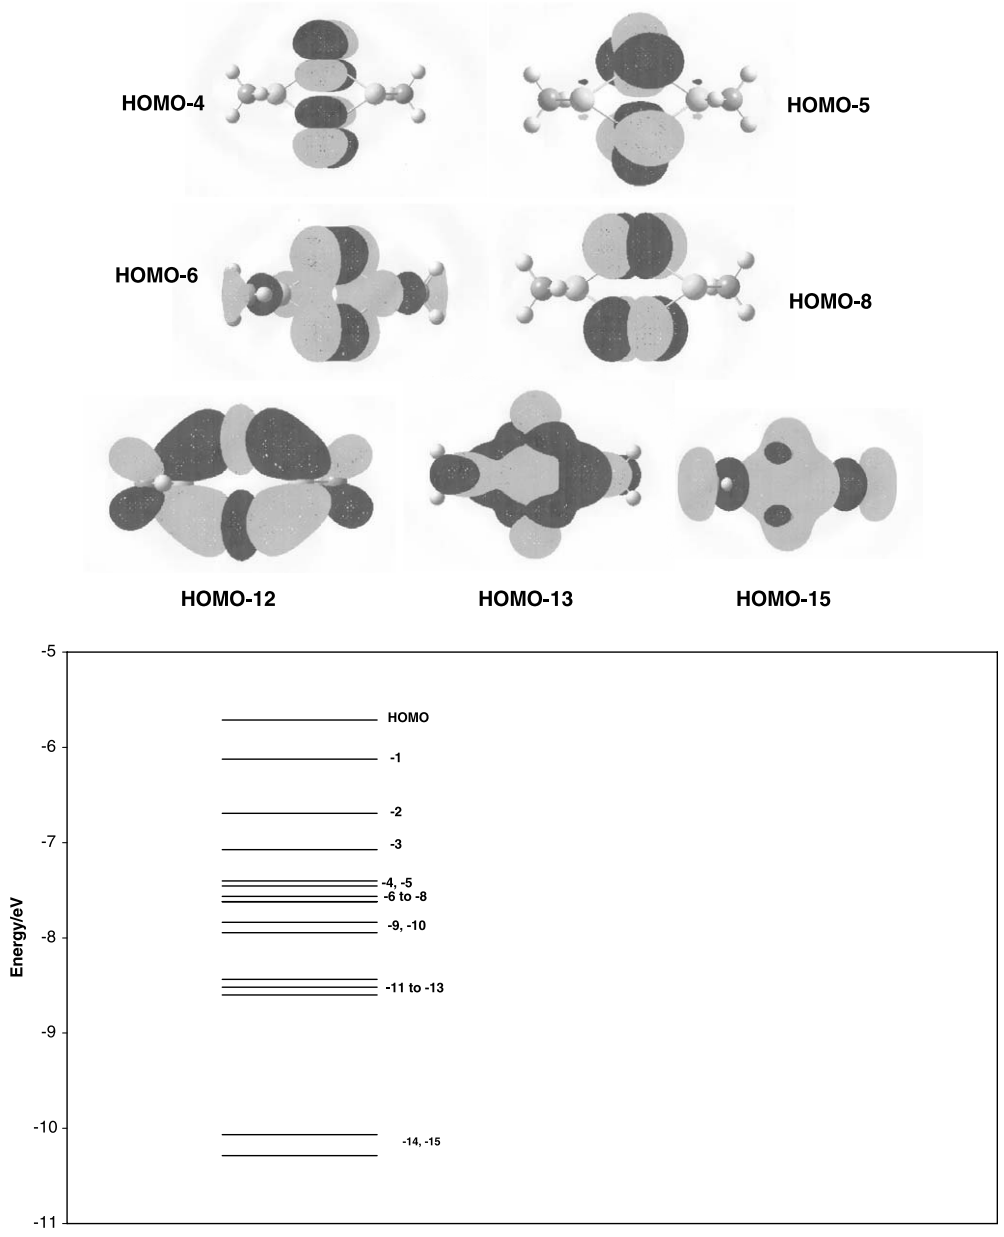

Fig. 4. Molecular orbitals and energy level diagram for *trans*-$Cu_2(SMe)_2$.

and $Cu_2(SMe)_2(DAB)_2$ (**14a**) show substantial deviations from ring planarity which are found experimentally in the $Cu_2(SR)_2(PR_3)_3$ complexes **12b–d** and the $Cu_2(SR)_2$-(*o*-phen) complex **14b**. Other things being equal, hinging along the S–S axis (as measured by the angle θ) results in a decrease in the S–M–S and M–S–M angles.[1] In **12b–d**, hinging may take place to accommodate a smaller S–M–S angle for the four-coordinate copper atom. In **14a**,**b** the bite angle of the DAB and *o*-phen ligands (about 80°) is much smaller than in the non-chelated $Cu_2(SR)_2(PR_3)_4$ derivative **13b** (118°), and hinging may take place to reduce an otherwise larger S–M–S angle. Nevertheless, these energy changes are subtle since the $Cu_2(SR)_2(PR_3)_3$ structure of **12e** and the $Cu_2(SR)_2$(*o*-phen) structure **14c** contain nearly planar rings.

It may be noted that no ligand-supported $L_yAu_n(SR)_n$ complexes have been reported. Computational attempts to minimise the structure of *trans*-$Au_2(SMe)_2(PH_3)_2$ result in decomposition to two molecules of $(PH_3)AuSMe$. In the case of $[Au_5(4\text{-}^tBuC_6H_4S)_5]_2$ (vide infra), reaction with PPh_3 is known to result in ring scission to give $(PPh_3)Au(4\text{-}^tBuC_6H_4S)$ [21].

3.2.2. $M_3(SR)_3$ rings

Unsupported rings are observed experimentally for the first time. The computed $M_3(SMe)_3$ structures **17a–c** and the experimental $M_3(SR)_3$ structures **17d**,**e** show only small deviations from planarity and compared to $M_2(SMe)_2$ (**9a–c**), the S–M–S angles (150–170°) are much

[1] The value of θ for cyclobutane is 166°.

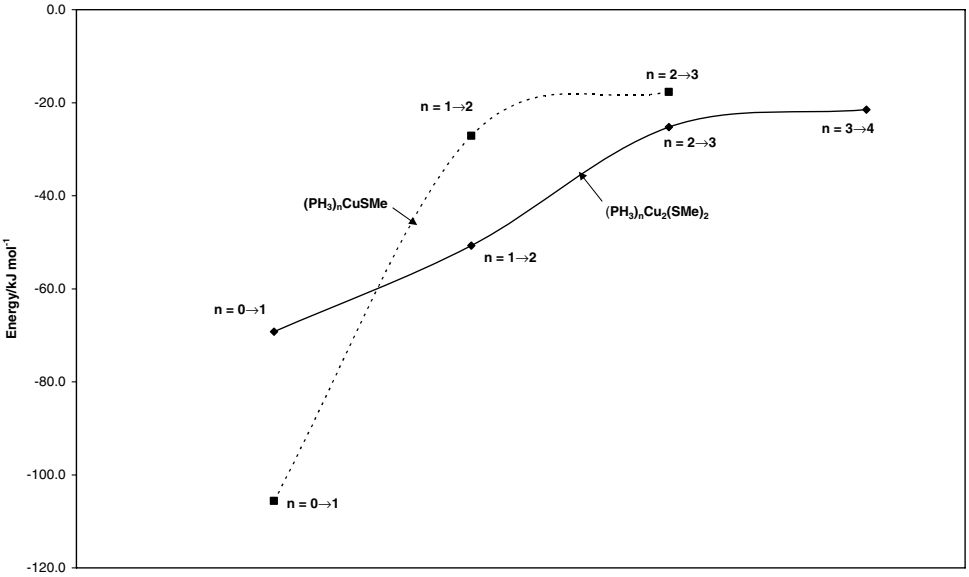

Fig. 5. Complexation enthalpies for reaction of CuSMe and *trans*-$Cu_2(SMe)_2$ with PH_3.

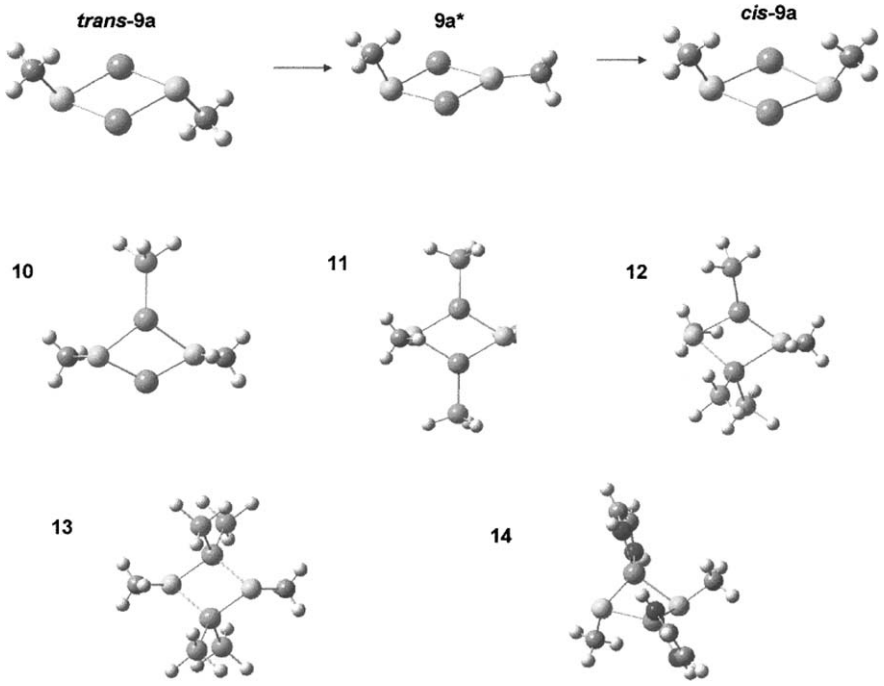

Fig. 6. Structures of $L_yM_2(SR)_2$ complexes.

expanded towards linearity (Table 1, Fig. 7). This is achieved by contraction of the M–S–M angle to about 75–85° from the natural angle of 120° for a planar six-membered ring. In relative terms, this is approximately the same degree of expansion/contraction of ideal ring angles observed in **9a**–**c**. The structures of three simple substituted derivatives $Cu_3(SR)_3(PR_3)_4$ (**18a**,**b**) and $Cu_2(SR)_2(o\text{-phen})_2$ (**19a**) have been reported. These complexes contain both trigonal planar and tetrahedral copper atoms; the calculated structures of $Cu_3(SMe)_3(PH_3)_4$ (**18c**) and $Cu_3(SMe)_4(DAB)_2$ (**19b**) are in good agreement and show that an approximate twist boat structure is the energy minimum and best satisfies a linear geometry for the single copper which remains uncoordinated by added ligand. For complexes where all metal atoms are ligand-substituted, the structures minimise to chair conformations. Complexes **20b** and **21b** contain *neutral* bridging sulfur ligands (thioacetamide and trimethylphosphine sulphide). Here, the trigonal planar coordination of the copper is completed by coordination of anionic Cl^-. The

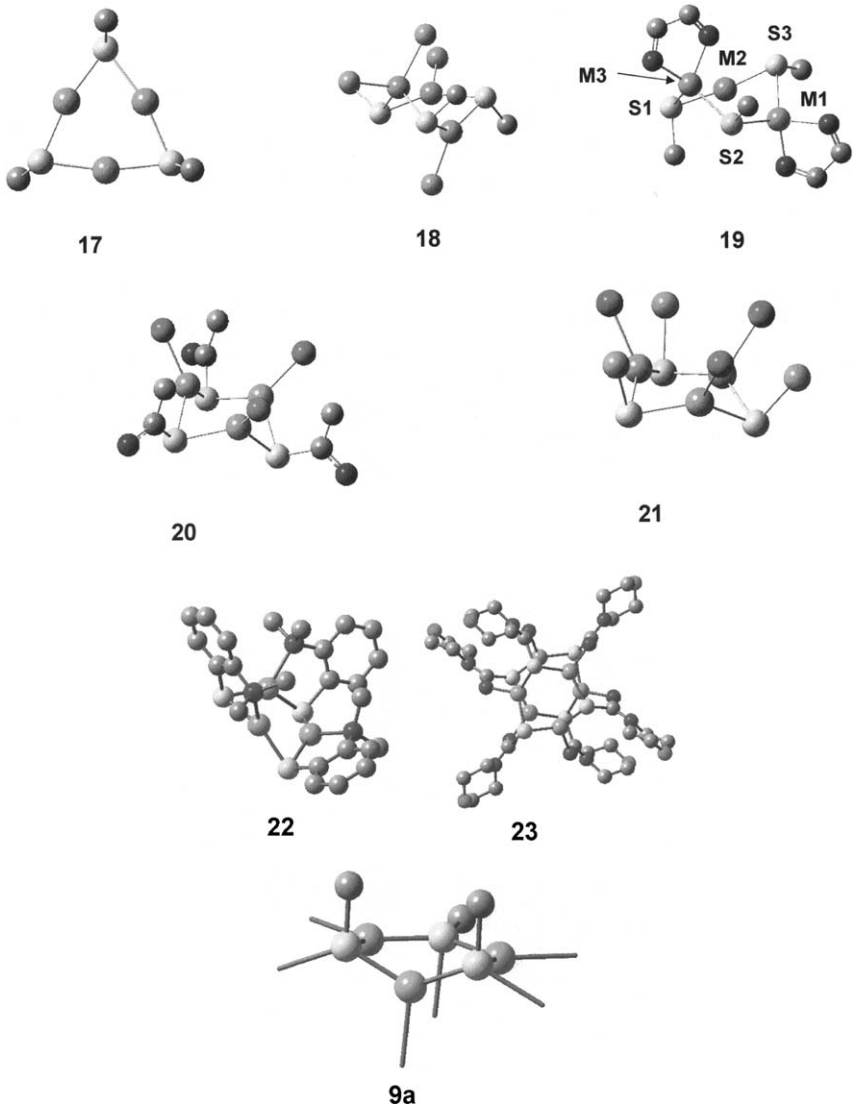

Fig. 7. Structures of $L_yM_3(SR)_3$ complexes.

calculated geometries of the model complexes **20a** and **21a** also show that a chair configuration best satisfies the requirements for trigonal planar coordination of copper.

Other related compounds containing trigonal planar copper and which also have a chair configuration include chelated derivatives such as **22** [26a–d] and **23** [27a–j]. A repeating chair motif is also seen in the structure of **9a** itself, determined by powder diffraction. Each copper atom is trigonally coordinated by three $[SMe]^-$ ligands and each thiolate bridges three copper atoms to form a distorted $MeSCu_3$ arrangement [28].

3.2.3. $M_4(SR)_4$ rings

For $M_n(SR)_n$ rings with $n \geqslant 4$, linearity of the S–M–S bonds can be achieved within a strain-free cycle, and the

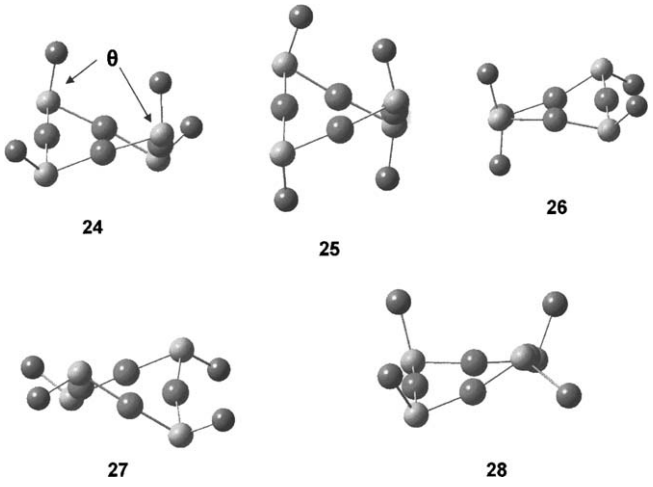

Fig. 8. Structures of $M_4(SR)_4$ complexes.

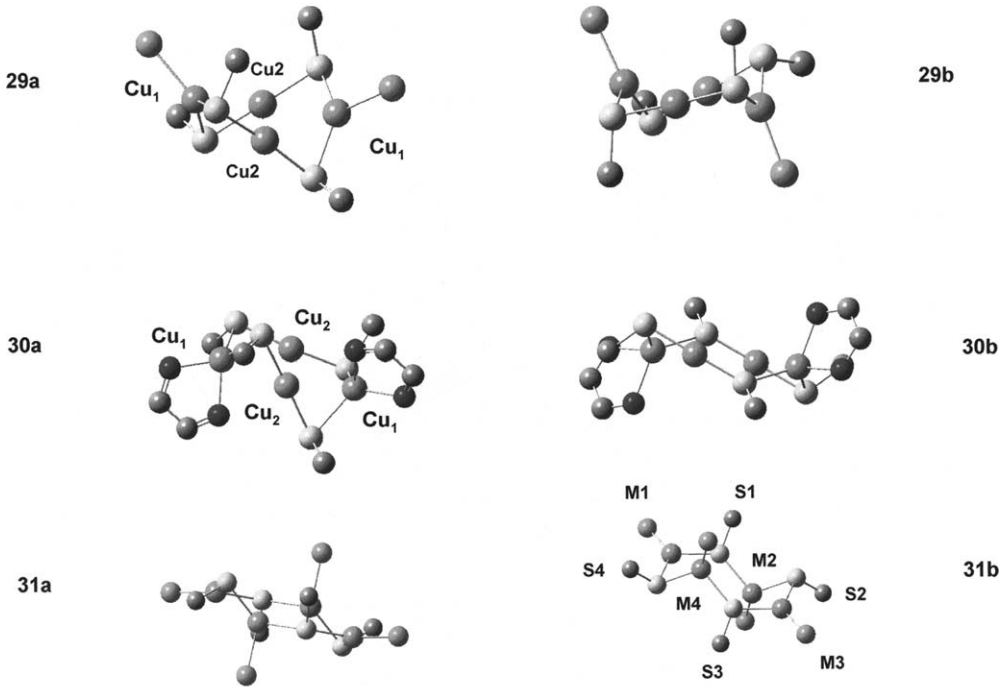

Fig. 9. Structures of $L_yM_4(SR)_4$ complexes.

structure is determined by the most efficient way of linking planar M_2S_3 units, with the sulfur atoms being placed at the vertices of the cycle.

The cyclobutane-like structures of several unsupported $M_4(SR)_4$ rings have been reported, and fall into one of four conformations **25** to **28** in terms of the arrangement of the sulfur substituents (Fig. 8). Energy minimisation of $M_4(SMe)_4$ (M = Cu, Ag, Au) from planar starting structures yields conformation **24** as the energy minimum. Geometrically, these structures differ mainly in the fold angle θ (Table 1). This angle is greatly dependent on the sulfur substituent; for example, the four compounds with conformation **27** have a θ range between 106° and 176°. The values of θ for the calculated $M_4(SMe)_4$ structures **24a–c** are thus reasonable.[1]

Supported complexes of formulae $M_4(SR)_4Ln$ ($n = 2$, $L = PPh_3$; $n = 4$, $L_2 = 2,2'$-bipyridine) exhibit non-planar M_2S_3 units, and are best regarded as six-membered cycles based on a $Cu_1S_4Cu_1$ framework with Cu_2 atoms inserted along the S–S edges (Fig. 9). The experimentally observed structures **29b** and **30b** exhibit a chair framework, whereas the model complexes **29a** and **30a** minimise to twist boat conformers. Where all the metal atoms are substituted, an eight-membered cyclooctane-type cycle is observed in **31a–c**.[2]

3.2.4. $M_5(SR)_5$ and $M_6(SR)_6$ rings

To our knowledge, the only compound reported which contains a $M_5(SR)_5$ ring is the catenated $Au_5(SR)_5$ compound **32** [21]. The configuration of the two rings is identical and has a cyclopentane-like structure containing an approximate M_3S_4 plane with the remaining planar M_2S fragment bent out of the plane (Fig. 10; Table 1).[3] The calculated geometry of the model complexes $M_5(SMe)_5$

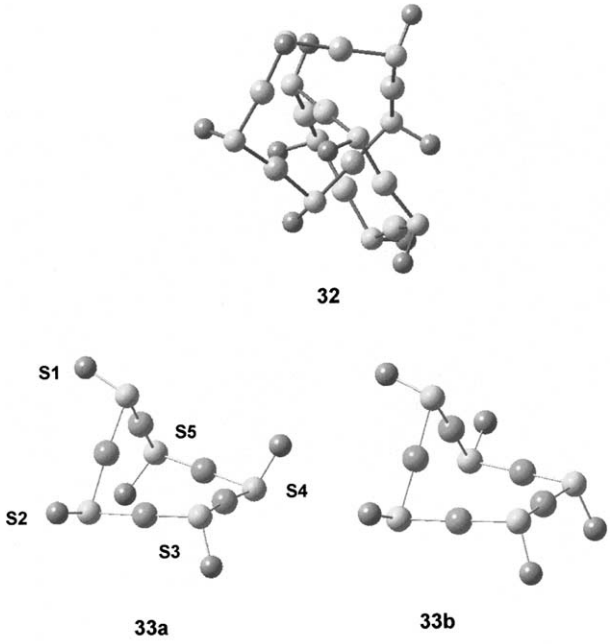

Fig. 10. Structures of $M_5(SR)_5$ complexes.

[2] The values of α, β and γ for cyclooctane are 0°, 122° and 38°.

[3] The values of α and β for cyclopentane are 10° and 141°.

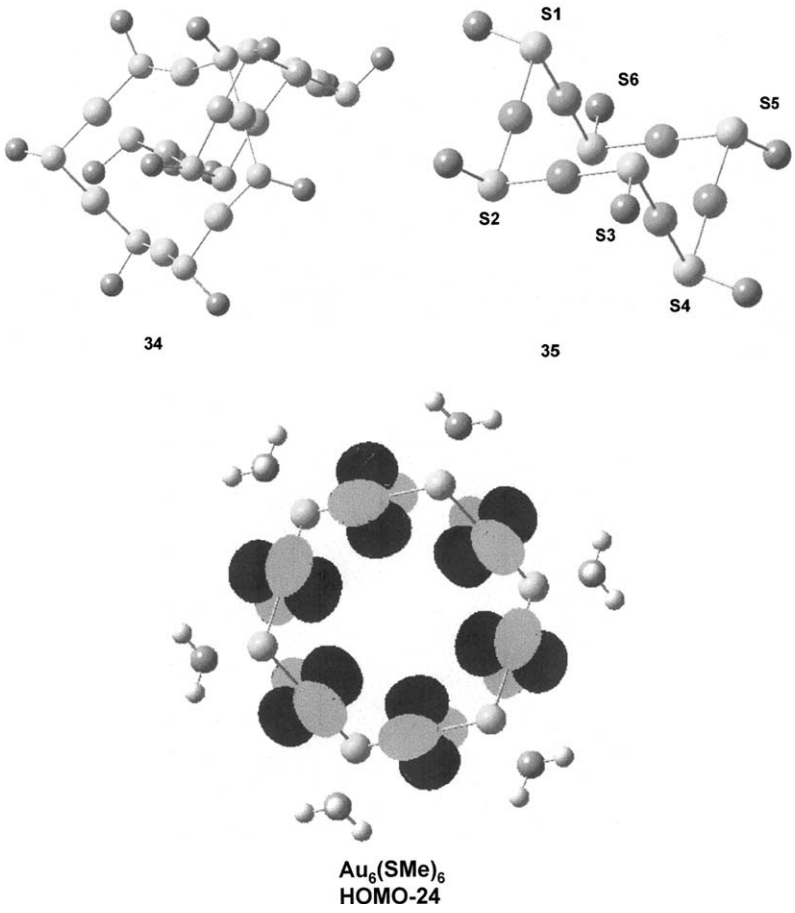

Fig. 11. Structures and non-bonding molecular orbital of $M_6(SR)_6$ complexes.

(**33a**–**c**) are similar. The degree of twist in the M_3S_4 plane is sensitive to the arrangement of the sulfur substituents, and in the case of copper, a structure **33b** having *cis* geometry about the S_3–S_4 axis lies only 3.1 kJ mol^{-1} higher in energy than the *trans* isomer **33a**, and has an almost perfectly planar M_3S_4 moiety.

Two $Au_6(SR)_6$ structures have been reported, one of which is the catenane **34**. The structure of **34**, and of the other calculated and observed $M_6(SR)_6$ complexes, may be described as a cyclohexane-like chair conformation defined by the sulfur atoms as ring vertices (Fig. 11; Table 1).[4] The catenated structures of **32** and **34** place mutual gold atoms at the centres of Au_5 and Au_6 pentagons and hexagons. This has been proposed to arise from delocalised aurophilic interactions [21], and Fig. 11 shows that the spatial extent of the Au_5 and Au_6 metal centred orbitals is sufficient to allow such overlap to occur.

Whilst monocyclic rings with $n > 6$ are known [37–39], we have not subjected them to computational examination. Nevertheless, their structures conform to the general principles of construction outlined above for rings with $n \leqslant 6$.

[4] The values of α and β for cyclohexane are 0° and 131° for a chair structure.

4. Conclusions

The bonding in cyclic $M_n(SR)_n$ complexes (M = Cu, Ag, Au) and their ligand substituted derivatives is primarily σ in nature. For each $M_n(SR)_n$ complex, there also exists a set of $2n$ metal-localised orbitals which in some cases have a spatial distribution suitable for M–M orbital overlap, though net M–M bonding is zero. The structures adopted are generally those which accommodate idealised linear, trigonal planar and tetrahedral metal coordination. In many case, the geometries resemble those of analogous cycloalkanes.

first row transition metals. Hmt, a spacer molecule which has been using to prepare different co-ordination polymers for decades can connect through two, three or all four of its tertiary nitrogen atoms to furnish a variety of polymers bearing interesting topologies [22]. Different co-ordination polymers are already reported in this area using it as a simple bidentate, tridentate or tetradentate spacer along with several bridging or non-bridging coligands as it seems to be quite efficient for the self-assembly of networks resulting in different topological motifs in the two or three-dimensional nets involving transition [12,23,24] and non-transition metal [25,26] centers. The self-assembly of these metallo-organic frameworks is vulnerable to many factors such as solvent system, template effect, pH of the solutions, steric parameters of the counter ions and above all the imposed reaction environment [24]. We have given our effort to study the combination effect of hmt, a polycyclic tertiary amine along with thiocyanate and azide as anionic ligands in two different cases with the same metal ion that ends in a construction of two new Co(II) metallo-organic clusters of high dimensionality containing hmt as a neutral organic spacer. In complex **1**, hexamine being attached terminally to the Co(II) center in one co-ordination group is acting as an efficient hydrogen bond carrier throughout the chain with its different donor sites. It helps to bind the adjacent metal centers to incorporate a high dimensionality inside the system by several inter-chain (O–H···N, O–H···S) and intra-chain (C–H···O, C–H···N, C–H···S) hydrogen bondings. In complex **2**, the same spacer ligand joins the adjacent Co(II) centers in a μ-*N*,*N*′ fashion by simple covalent bonds in a 1-D polymeric chain. Thiocyanate and azide are acting as terminal ligands in the respective complexes and efficiently involved in H-bondings with lattice water molecules to result in an infinite 2-D polymeric network finally.

We have reported herein the controlled hydrothermal synthesis of two extensively hydrogen bonded Co(II) L–M–L type polymeric co-ordination complexes. They have been systematically characterised by elemental analysis, FT-IR, UV–vis spectroscopy and thermal analyses. Structures have been established from X-ray single crystal diffraction data. Magneto-structural correlations have been drawn for both the complexes. Although there are plenty of interesting co-ordination complexes involving hmt as spacer, but their systematic characterisation, spectral and magneto-structural correlation studies especially for Co(II) is not a well explored field.

2. Experimental

2.1. Materials

All the chemicals and solvents used for this synthesis were of AR grade. Cobalt(II) chloride, hexahydrate; cobalt(II) acetate, tetrahydrate; potassium thiocyanate, sodium azide and hexamethylenetetramine were obtained from Aldrich Chemical Co. Inc. and used as received without further purification.

2.2. Physical measurements

The Fourier Transform infrared spectra (400–4000 cm^{-1}) of the complexes were recorded on a Perkin–Elmer Spectrum RX I FT-IR system with KBr disc. The electronic spectra were recorded on a Perkin–Elmer λ-40 UV/vis-spectrometer using HPLC grade methanol as solvent. C, H, N analyses were carried out using a Perkin–Elmer 2400 II elemental analyser. Thermal studies were done at a heating rate of 10 °C min^{-1} using a Schimadzu TGA-50 and DTA-50 thermal analyser system in a dynamic atmosphere of N_2 (flow rate 80 ml/min) in an alumina crucible.

Cryo-magnetic susceptibility measurements for the complexes were carried out at the Servei de Magnetoquímica of the Universitat de Barcelona, Spain with a Quantum Designed SQUID MPMS-XL susceptometer apparatus which works in the range 2–300 K under magnetic field of approximately 0.5 T. Diamagnetic corrections were estimated from Pascal's tables.

2.3. Synthesis of the complexes

2.3.1. $[\{Co(hmt)_2(NCS)_2(H_2O)_2\}\{Co(NCS)_2(H_2O)_4\}(2H_2O)]$ (**1**)

The complex was prepared under controlled hydrothermal condition. 0.299 g (1.03 mmol) $CoCl_2$, $6H_2O$, 0.217 g (2.237 mmol) KSCN, 0.067 g (0.484 mmol) hmt and 10 ml of water were loaded into a 23 cm^3 Teflon-lined stainless steel vessel, which was then sealed and placed in a computer programmable furnace. The resulting mixture was heated at the rate of 100 °C/h up to 160 °C, kept for 10 h, then cooled to 140 °C at the rate of 4 °C/h, held for 5 h, followed by further cooling at the same rate to room temperature to give an approximately 85.24% yield based on Co(II), as rosy pink colored prismatic single-crystals which were later collected by mechanical isolation and washed with water–ethanol (2:1 v/v) mixed solvent, then dried in an oven keeping them at 40 °C for 10 min.

Anal. Calc. for $[C_{16}H_{40}Co_2N_{12}O_8S_4]$: C, 24.80; H, 5.20; N, 21.70. Found: C, 24.79; H, 5.21; N, 21.69%.

2.3.2. $[Co(hmt)(N_3)_2(H_2O)_2]_n$ (**2**)

The complex was prepared following the same procedure as described above for the complex **1** except $Co(CH_3COO)_2 \cdot 4H_2O$, NaN_3 and hexamethylenetetramine were taken in the proportion of 0.262 g (1.05 mmol), 0.143 g (2.20 mmol) and 0.133 g (0.95 mmol), respectively. On slow cooling to ambient temperature purple prismatic single crystals were obtained with a yield of 80.04% based on Co(II). Suitable crystals were later collected by mechanical isolation and washed with water–ethanol (2:1 v/v) mixed solvent, dried in an oven keeping them at 40 °C for 10 min.

Anal. Calc. for $[C_6H_{16}CoN_{10}O_2]$: C, 22.57; H, 5.05; N, 43.87. Found: C, 22.56; H, 5.04; N, 43.85%.

2.4. Crystal structure determination

The X-ray diffraction experiment was carried out at 293 K on a rosy pink needle shaped single crystal block (0.09 mm × 0.08 mm × 0.07 mm) of complex **1** using graphite monochromatised Mo-K_α radiation ($\lambda = 0.71073$ Å). The data were collected on a CAD4 diffractometer with the ω-scan technique. Measuring standard reflections at fixed intervals during the data collection checked the stability of the crystal. However, no significant loss of intensity was noted for the crystals. The data were corrected for Lorentz and polarisation effects. The structures were solved by direct methods using the SHELXLTL-PLUS and SHELXS-97 system and refined to convergence by full-matrix least-squares techniques based on F^2 using SHELXL-97 [27]. The non-hydrogen atoms were refined with anisotropic thermal parameters in all the cases. The hydrogen atoms of the hexamethylenetetramine entity were positioned geometrically and allowed to ride on the parent C atoms; $U_{iso}(H) = 1.2U_{eq}(C)$.

The data for the complex **2** were collected at 293 K on a Rigaku AFC7R diffractometer using graphite monochromatised Mo-K_α radiation ($\lambda = 0.71073$ Å) and a rotating anode generator for a prismatic purple shaped single crystal block (0.50 mm × 0.20 mm × 0.10 mm). Cell constants and an orientation matrix for data collection were obtained from least-squares refinement using the setting angles of 12 carefully centered reflections in the range of $20° < 2\theta < 22°$. Structure was solved by direct methods with SHELXS-97 and refined to convergence on F^2 using SHELXL-97 [27]. Lorentz-polarisation corrections were applied. Hydrogen atoms attached to the oxygen atoms were located in the Fourier map and isotropically refined. All calculations were performed using SHELXS-97 and the structure was generated using TEXSAN crystallographic software package [27] from Molecular Structure Corporation. Other remaining measurement parameters are exactly the same as in the complex **1**. Selected crystallographic data, experimental conditions and some features of the structural refinements of both the complexes are summarised in Table 1.

Table 1
Crystal parameters of **1** and **2**

[b] $R_w = \{\sum[w(|F_o - F_c|)^2]/\sum[w|F_o|^2]\}^{1/2}$.

3. Results and discussion

Both the complexes have been synthesised under controlled hydrothermal condition by continuously varying the hmt concentration in different sets while keeping the concentration of other added reagents constant. Surprisingly, it was observed that the single crystal of the complex **1** was found as the sole product specifically in the concentration range of Co-salt:hmt:KSCN = 1:0.47:2.2, while single crystals were successfully obtained in case of complex **2** only when the relative concentrations were maintained at cobalt-salt:hmt:NaN_3 = 1:0.90:2.1.

3.1. FT-IR spectra

The solid state Fourier Transform infrared spectra of both the complexes, recorded on a FT-IR spectrophotometer for the range of 400–4000 cm^{-1} are fully consistent with their structures later confirmed from single crystal X-ray diffraction studies. The samples were studied as powder dispersed in KBr pellets. The spectral region for both the complexes are more or less similar due to their similar co-ordination modes except for the terminal ligands which is NCS^- in the first case and N_3^- in the later one. The whole spectrum region can be classified into three distinctive zones with the characteristic absorptions [28,29].

1. *Low energy range.* δ_{OH}: 1639 cm^{-1}; δ_{CH_2}: 1460 cm^{-1} and 1382 cm^{-1}. δ_{CN}: 1225 cm^{-1}, 1019 cm^{-1} and 1001 cm^{-1}; ν_{CS}: 1255 cm^{-1}.
2. *Mid energy range.* Shows characteristic absorption range for terminal NCS^- and N_3^- groups at 2110 cm^{-1} and 2117 cm^{-1}, respectively.
3. *High energy range.* ν_{CH_2}: at 2920 cm^{-1} reflects the frequency for methylene groups of hexamethylenetetramine molecules and ν_{OH_2}: >3400 cm^{-1} as a distinctive broad peak probably corresponding to different surroundings of methylene groups in hmt.

The peaks obtained in the different spectral regions correlate well with the observed values in the case of similar kind of systems found in the literature [25,26].

3.2. Electronic spectra

The UV–vis spectra of both the complexes were recorded in methanol HPLC grade solvent. They show a few strong and broad absorption bands at 8800, 12 000, 21 000 cm^{-1}, $\varepsilon = 6$ L mol^{-1} cm^{-1}, except ν_2 (very weak). Those absorption peaks can be tentatively assigned as typical d–d transitions of an octahedral Co(II) ion [30–32]. The speculated transitions may be due to the following: $^4T_{1g}(F) \rightarrow {}^4T_{2g} - \nu_1$, $^4T_{1g}(F) \rightarrow {}^4A_{2g} - \nu_2$, $^4T_{1g}(F) \rightarrow {}^4T_{1g}(P) - \nu_3$. The d–d transition energy levels for the octahedral Co(II) ion thus found experimentally are in well accordance with those found in the literature. The hydrogen bonding network structure in both the cases imparts apparently no effect on electronic absorption spectra.

3.3. Description of the crystal structures

3.3.1. $[\{Co(hmt)_2(NCS)_2(H_2O)_2\}\{Co(NCS)_2(H_2O)_4\}(2H_2O)]$ (1)

The X-ray structure of **1** reveals that it contains two independent neutral co-ordination groups: $[Co(hmt)_2(NCS)_2(H_2O)_2]$ and $[Co(NCS)_2(H_2O)_4]$ in the same asymmetric unit along with two lattice waters. In the first group Co(II) enjoys a perfectly octahedral environment with an equatorial base formed by two short distant Co(2)–N(2) bonds [2.043(4) Å] coming from NCS^- terminal ligands and two comparatively longer Co(2)–O(3W) bonds [2.095(3) Å] from co-ordinated water molecules while two hmt molecules occupying the apical positions with two Co(2)–N(3) bonds [2.325(3) Å]. An ORTEP drawing of the complex with atom labeling scheme has been provided in Fig. 1. Co(II) follows an ideal octahedral situation except a slight deviation in bond lengths between Co–N and Co–O, forming the equatorial base. Apical Co(2)–N(3) bonds are also a little bit longer by an amount of 0.265(3) Å than the average equatorial bonds. It may be due to the effect of slight distortion. The co-ordination group possesses an inversion center. The second co-ordination group contains one octahedral Co(II) center bearing a CoN_2O_4 chromophore where four oxygen atoms from four co-ordinated water molecules form an equatorial base while two terminal NCS^- groups occupy apical positions [Co(1)–O(1W) and Co(1)–O(2W): 2.065(3) Å and Co(1)–N(1): 2.096(4) Å, respectively]. The most interesting feature is that these independent co-ordination fragments are involved in extensive intra-chain hydrogen bondings [C(3)–H(3A)···O(3W), C(6)–H(6A)···N(2) and C(6)–H(6B)···O(3W)] among themselves or with lattice waters to shape it in an infinite 1-D polymeric chain that runs parallel to *bc*-plane. Such adjacent parallel 1-D chains lying on the same plane are further locked by several inter-chain hydrogen bonds [C(4)–H(4A)···S(2), C(9)–H(9A)···O(2W)] and many others involving the co-ordinated and lattice water molecules with the terminal NCS^- ligands to frame an infinite 2-D neutral polymeric sheet structure (Figs. 2 and 3) running along crystallographic *a*-axis. All the selected bond distances, bond angles and H-bonding parameters for complex **1** are listed in Tables 2 and 3, respectively.

3.3.2. $[Co(hmt)(N_3)_2(H_2O)_2]_n$ (2)

The X-ray analysis reveals that the complex **2** contains octahedral Co(II) center co-ordinated by two terminal N_3^- groups, two water molecules and two neutral hmt molecules (Fig. 4). The two nitrogen atoms N(1) and its

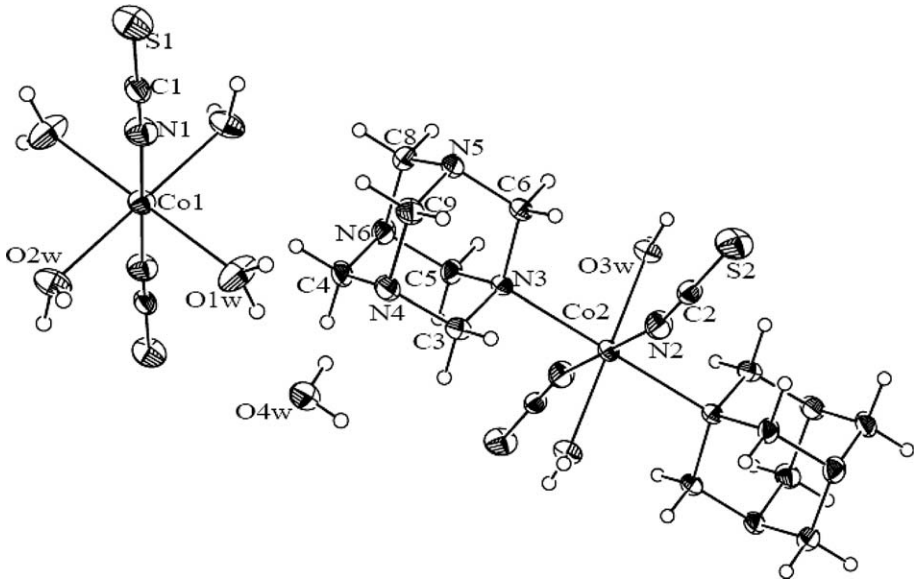

Fig. 1. ORTEP view of **1** with atom numbering scheme.

symmetry related counter part N(1**) of terminal azide groups [Co(1)−N(1) (azide): 2.044(3) Å] and the two oxygen atoms O(1) and O(1**) of coordinated water molecules [Co(1)–O(1)(H_2O): 2.099(2) Å], form the equatorial plane around each Co(II) and the *trans*-axial sites are occupied by the two nitrogen atoms N(4) and N(4**) from pendent bridging hmt molecules [Co(1)–N(4)(Hmt): 2.354(2) Å] to provide each Co(II) a $CoN_2(hmt)N_2(N_3^-)O_2(H_2O)$ chromophore (Fig. 4). The Co(II) atoms are bridged by neutral hmt molecule in a μ-*N*,*N*′ fashion with the occurrence of a

1-D infinite polymeric chain, further carrying into a 2-D net with the help of several weak inter-chain hydrogen bondings. ORTEP and PLATON [42] drawings of the chain with atom labeling scheme are shown in Figs. 5 and 6, respectively. The degrees of distortion from the ideal octahedral geometry are reflected in *cisoid* and *transoid* angles, all resembling the ideal values for an octahedral arrangement. The shortest Co–Co distance along the same chain is 6.313(3) Å. The N_3^- groups show almost linearity with N–N–N angle of 179.3(4)°. The azide ligand shows a slight deviation from linearity in connection with Co(II) [Co–N(1)–N(2): 165.6(3)°]. Each of the hmt molecule acts as a neutral organic bidentate spacer molecule joining the adjacent metal centers in μ-*N*,*N*′ fashion, while the Co(II) centers acting as a linear spacer to generate a 1-D zigzag polymeric chain. The hmt molecule bridges two consecutive metal centers using only two out of its four possible donor sites to link the adjacent units together. All the water molecules and uncoordinated N atoms are involved in intermolecular H-bondings (Fig. 5) making hmt a good tetrahedral template which is the ultimate requirement factor to establish an ordered supramolecular structure formed by self-assembly. Each of the infinite 1-D chains results in a 2-D polymeric network (Figs. 5 and 6) through pronounced inter-chain O–H···N hydrogen bonding between the co-ordinated water molecules to the Co(II) in one chain and N atom of the hmt in the other chain. Further inter-chain O–H···N hydrogen bonding is found between the co-ordinated water molecules of the Co(II) in one chain and the N atoms from terminal azide ligands present in an adjacent chain. Apart from this, there are also three different types of intra-chain hydrogen bonds present in the system (C–H···O, C–H···N, etc.). Another noteworthy point is that the water molecules co-ordinated to the alternative Co(II) centers along the same chain are not behaving identically in the hydrogen bonding mode to the acceptor sites present in the adjacent chain (Fig. 5). Such motif of H-bonding can be described in Etter's graph set notation as $R_2^2(12)$ [33]. As a result of these two types of hydrogen bonds the system has a high degree of thermal stability which is reflected through the thermal study. The co-ordinated water molecules are lost at a much higher temperature than what is

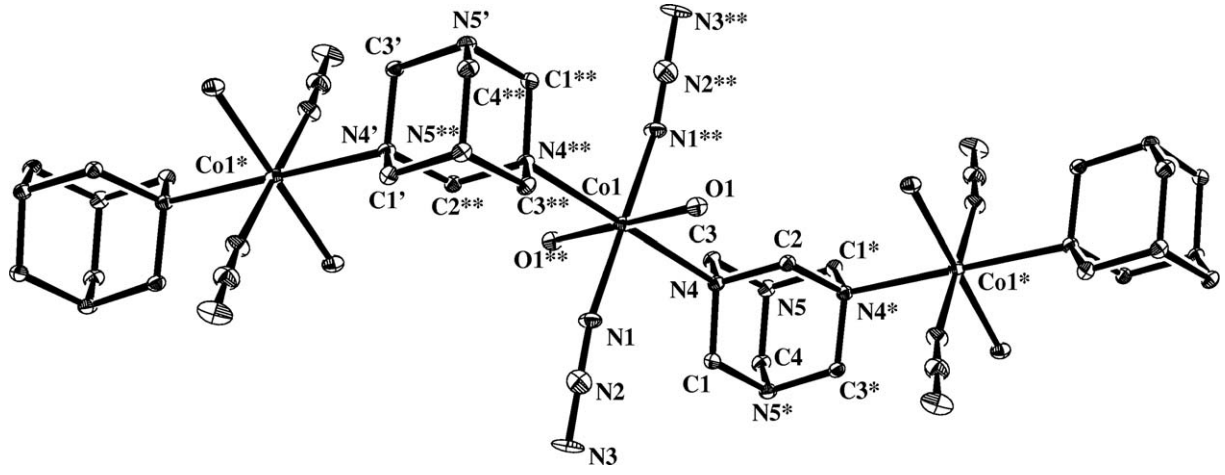

Fig. 4. ORTEP view of **2** with atom numbering scheme (symmetry code (′) = x, $-y$, $z+1/2$; (*) = $2-x$, y, $1/2-z$; (**) = $2-x$, $1-y$, $1-z$).

normally observed. All the selected bond distances, bond angles and H-bonding parameters for complex **2** are given in Tables 2 and 3, respectively.

3.4. Cryo-magnetic susceptibility studies

The magnetic properties of both the complexes are more or less same. So only a single plot of $\chi_M T$ versus T (χ_M is the molar magnetic susceptibility for one Co(II) ion), where T varies from 2 K to 300 K, has been provided for complex **2** (Fig. 7). An exactly similar curve corresponding to the first complex has been provided in Fig. 10 as Supplementary material. The value of $\chi_M T$ at 300 K is 2.685 cm^3 K mol^{-1}, which are larger than that expected for the spin-only case ($\chi_M T = 1.87$ cm^3 mol^{-1} K, $S = 3/2$) indicates that an important orbital contribution is involved. The $\chi_M T$ value continuously decreases from room temperature to 1.238 cm^3 K mol^{-1} at 1.99 K. The global feature is characteristic of weak antiferromagnetic interactions. The χ_M curve is less indicative at room temperature. It starts from 0.0089 cm^3 mol^{-1} and increases in a uniform way to 0.619 cm^3 mol^{-1} at 1.99 K. The absence of maxima in these χ_M curves may indicate that the possible antiferromagnetic coupling is very weak.

The analysis of magnetic data for cobalt complexes is usually complicated by the fact that single-ion effects, such as spin–orbit coupling, distortion from regular stereochemistry, electron delocalisation, crystal field mixing of excited states into the ground state, affect the magnetic properties in addition to possible magnetic exchange interactions [34a]. Considering the spin–orbit coupling due to the $^4T_{1g}$ ground state for octahedral Co(II) complexes [34b,34c,34d,34e,34f], exact calculations for deriving the J parameter from experimental data in all the temperature range is not possible unless for dinuclear complexes [35,36]. Other small polynuclear systems can also be fitted through sophisticated computer programs, based on full diagonalisation methods at low temperature region (where the effective spin $S' = 1/2$) [37]. One-dimensional systems of Co(II) are frequently associated with anisotropic Ising systems, and they can be fitted in the low temperature zone assuming again an effective spin $S' = 1/2$ [38]. More recently, Rueff et al. [38c,39] have proposed a phenomenological approach for some low-dimensional Co(II) systems that allows to gain an estimate of the strength of the antiferromagnetic exchange interactions. They postulate the phenomenological equation:

$$\chi_M T = A \exp(-E_1/kT) + B \exp(-E_2/kT) \quad (1)$$

in which, $A + B$ equals to the Curie constant (≈2.8–3.4 cm^3 mol^{-1} K for octahedral cobalt(II) ions), and E_1, E_2 represent the "activation energies" corresponding to the spin–orbit coupling and the antiferromagnetic exchange interaction, respectively. The E_1/k which is the effect of spin–orbit coupling and site distortion is of the

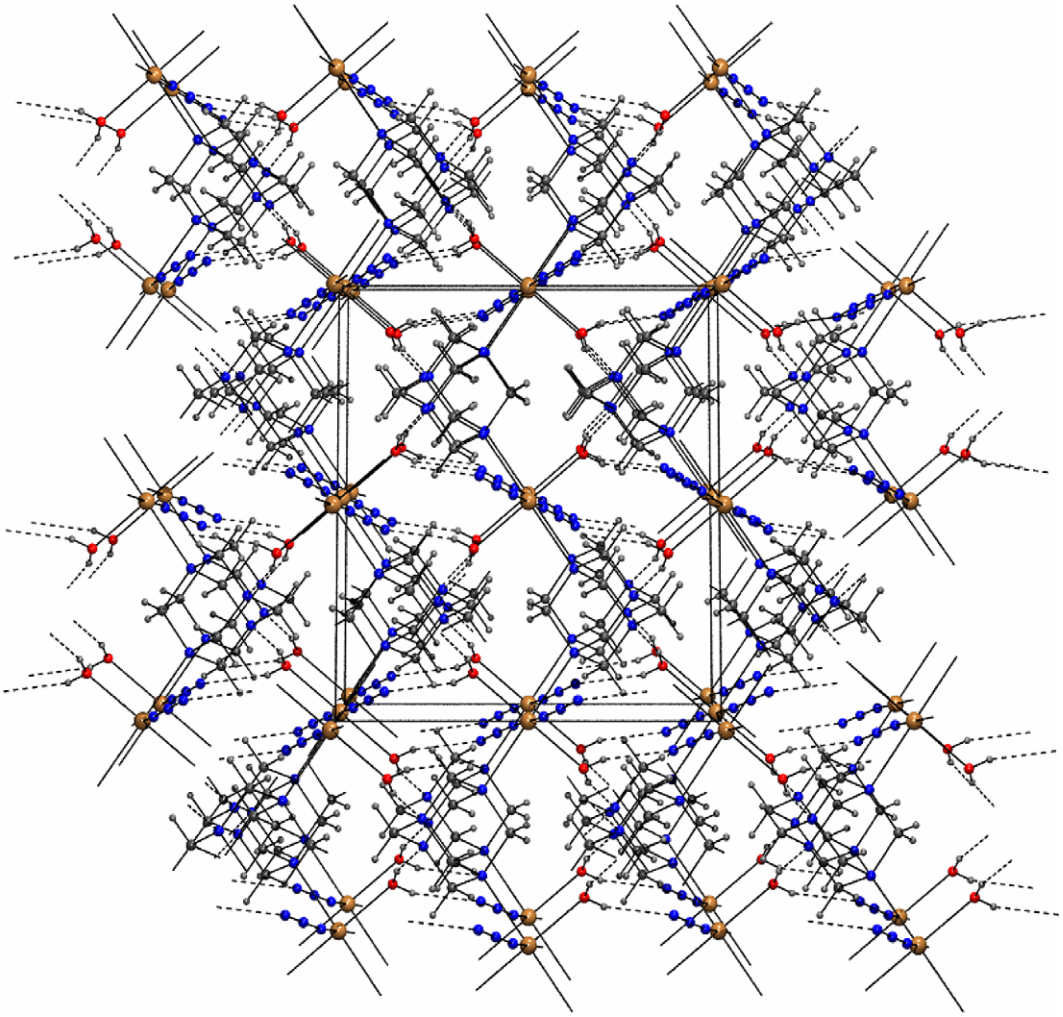

Fig. 6. Packing view along *a*-axis for **2**.

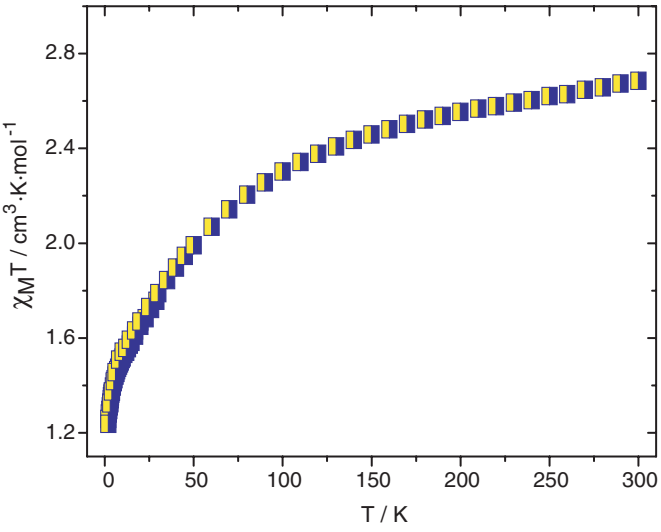

Fig. 7. Plot of $\chi_M T$ vs. T for **2**.

order of +100 K [38c–40]. Eq. (1) adequately describes the spin–orbit coupling, which results in a splitting between discrete levels, and the exponential low-temperature divergence of the susceptibility. Very good results have been reported in one- and two-dimensional Co(II) complexes [38c,39].

An important experimental feature obtained in these octahedral cobalt(II) complexes is that the $\chi_M T$ (or μ_{eff}) values at room temperature are greater than those expected for one isolated spin-only ion ($\chi_M T = 1.87\ cm^3\ mol^{-1}\ K$ for a $S = 3/2$ ion), indicating that an important orbital contribution is involved [34]. Typical values of $\chi_M T$ (or μ_{eff}) are 2.75–3.4 $cm^3\ mol^{-1}\ K$ (4.7–5.2 μ_β) [34,41]. Lower values at room temperature indicate perturbation from ideal octahedral geometry [41]. Based on Eq. (1), commented above, which is suitable for any temperature greater than the possible T_c [38c,39], an estimated J value for our complexes has been calculated. The fit values from this procedure are: $A + B = 2.87\ cm^3\ mol^{-1}\ K$, which perfectly agrees with those given in the literature for the Curie constant ($C \approx 2.8$–$3.4\ cm^3\ mol^{-1}\ K$), [38c,39] $E_1/k = 56.14\ K$ is of the same magnitude than those reported by Rueff et al. for several one- and two-dimensional cobalt(II) complexes [39]. As for the value found for the antiferromagnetic exchange interaction, it is very weak ($E_2/k = 0.55\ K$),

corresponding to $J = -1.1$ K ($=-0.77$ cm^{-1}), according to the Ising chain approximation, $\chi_M T \propto \exp(J/2kT)$.

These weak magnetic exchange couplings can be understood in both the cases considering the hexamethylenetetramine which is separating the Co(II) atoms with large distances (~6.313 Å) either through long distant covalent bondings or through weak hydrogen bondings, leading in this way to almost negligible coupling.

The attempts carried out to fit these complexes, assuming isolated Co(II) ions with perfect octahedral geometry [34] did not give good fit. Thus, we can conclude that these complexes are magnetically behaving as one-dimensional system, which are weakly coupled by hexamethylenetetramine in both the cases.

The reduced molar magnetisation ($M/N\beta$) per Co(II) attends to 1.88 (Fig. 8 for complex **2**, Fig. 11 corresponding to the first complex has been placed as Supplementary material). These values are less than that expected for an isolated Co(II) ion not coupled (2.5–3 $N\beta$). [39] This feature agrees to the weak antiferromagnetic coupling within the Co(II) ions reported in the literature [38c]. The shape of the curves at low fields (sigmoid shape) is also indicative that this antiferromagnetic coupling occurs in these complexes.

Experimental values of susceptibilities and other relevant magnetic parameters for the complexes **1** and **2** are listed in Tables 4 and 5.

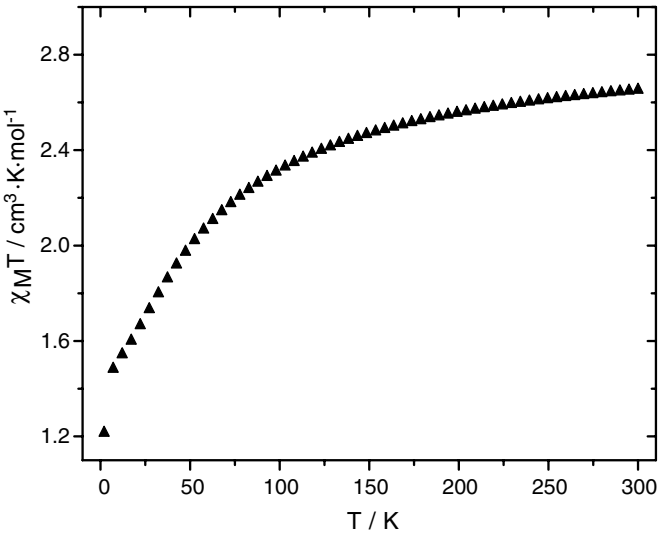

Fig. 10. Plot of $\chi_M T$ vs. T for **1**.

$\chi_M T = A\exp(-E_1/kT) + B\exp(-E_2/kT)$.

3.5. Thermal analyses

Thermal analysis was done only in the case of complex **1**. Complex **2** was avoided as it contains azide which may cause explosion under thermal treatment. The curve shown in Fig. 9 for thermal studies clearly depicts the decomposition of **1** in three consecutive steps. The weight losses are approximately 10.5% (205 °C); 15.0% (230 °C) and about 32% (234–345 °C) showing through three consecutive endothermal breaks. Weight loss at 205 °C is very close to the calculated water content for two co-ordinated H_2O molecules. So it can be regarded as an evidence of deaquation. This temperature is rather higher compared to the similar co-ordination polymers. It suggests the higher thermodynamic stability of the water molecules in the polymeric complex reported herein [43]. It may be due to the strong and extensive inter- and intra-chain hydrogen bonding network. The weight loss at 230 °C may be correlated to the decomposition of the SCN groups. The final step leads to the formation of a stable residue.

4. Conclusion

In this paper we have reported the controlled hydrothermal synthesis of two new hydrogen bonded metallo-organic co-ordination polymers $[\{Co(hmt)_2(NCS)_2(H_2O)_2\}\{Co(NCS)_2(H_2O)_4\}(2H_2O)]$ (**1**) and $[Co(hmt)(NNN)_2(H_2O)_2]_n$ (**2**) using hexamethylenetetramine as a neutral organic spacer or terminal ligand. Thiocyanate or azide is co-ordinated as terminal coligands in either case. Both the structures show an infinite robust 2-D network with several inter- and intra-chain hydrogen bondings which may be a probable cause for the stability of the system. The facts are well supported by several instrumental analyses and also firmly established from cryo-magnetic susceptibility studies.

of the complexes, we selected *p*-H_2CCA, *o*-H_2CCA, *p*-H_2BDC and *o*-H_2BDC, together with 1,2-bis(4-pyridyl)ethane (bpe) as linkers, to assemble coordination polymers. Under hydrothermal conditions, we obtained six coordination polymers, $[Co(o\text{-}CCA)(bpe)(H_2O)]_n \cdot 0.25nCH_3OH$ (**1**), $[Ni(o\text{-}CCA)(bpe)(H_2O)]_n \cdot 0.5nH_2O$ (**2**), $[M(p\text{-}CCA)(bpe)_{1.5}(H_2O)]_n \cdot nH_2O$ (M = Co, (**3**); Ni, (**4**)), $[Co(o\text{-}BDC)(bpe)(H_2O)]_n \cdot nH_2O$ (**5**) and $[Co(p\text{-}BDC)(bpe)]_n$ (**6**). Complex **6** is the same to that reported by Fu et al. [13], therefore, we report the syntheses and characterizations of five new complexes **1**–**5**.

2. Experimental

2.1. Materials and apparatus

All reagents were used as received without further purification. The C, H, N microanalyses were carried out with a Vario EL elemental analyzer. The IR spectra were recorded with a Nicolet Avatar 360 FT-IR spectrometer using the KBr pellet technique.

2.2. Synthesis

2.2.1. Synthesis of $[Co(o\text{-}CCA)(bpe)(H_2O)]_n \cdot 0.25nCH_3OH$ (*1*)

A mixture of *o*-H_2CCA (0.02 g, 0.1 mmol), $CoCl_2 \cdot 6H_2O$ (0.024 g, 0.1 mmol), bpe (0.018 g, 0.1 mmol), CH_3OH (5 mL) and deionized water (5 mL) was sealed in a Teflon-lined stainless vessel (25 mL), and heated at 140 °C for 72 h, then cooled slowly to room temperature. Yield: 0.037 g (80.4%). *Anal*. Calc. for $C_{22.25}H_{21}N_2O_{5.25}Co$: C, 58.13; H, 4.57; N, 6.10. Found: C, 58.31; H, 4.81; N, 6.14%. IR data (KBr pellet, cm^{-1}): 3442s, 3065m, 1637m, 1616s, 1571m, 1546s, 1419s, 1394s, 1285w, 1224w, 1071w, 1022w, 973w, 821w, 772m, 758m.

2.2.2. Synthesis of $[Ni(o\text{-}CCA)(bpe)(H_2O)]_n \cdot 0.5nH_2O$ (*2*)

A mixture of *o*-H_2CCA (0.02 g, 0.1 mmol), $NiCl_2 \cdot 6H_2O$ (0.024 g, 0.1 mmol), bpe (0.018 g, 0.1 mmol), NaOH aqueous solution (0.3 mL, 0.65 mol L^{-1}) and deionized water (5 mL) was sealed in a Teflon-lined stainless vessel (25 mL), and heated at 140 °C for 72 h, then cooled slowly to room temperature. Columnar crystals were obtained, washed with water and ethanol, and dried in air. Yield: 0.026 g (56.5%). *Anal*. Calc. for $C_{22}H_{21}N_2O_{5.5}Ni$: C, 57.38; H, 4.56; N, 6.09. Found: C, 57.52; H, 4.85; N, 5.94%. IR data (KBr pellet, cm^{-1}): 3454m, 3068m, 1637m, 1618s, 1571m, 1543s, 1411s, 1394s, 1285w, 1225w, 1071w, 973m, 821m, 772m, 759m.

2.2.3. Synthesis of $[Co(p\text{-}CCA)(bpe)_{1.5}(H_2O)]_n \cdot nH_2O$ (*3*)

The synthesis of complex **3** followed the similar procedure as for complex **2** except using *p*-H_2CCA instead of *o*-H_2CCA. Yield: 0.025 g (44.5%). *Anal*. Calc. for $C_{28}H_{28}N_3O_6Co$: C, 59.84; H, 4.99; N, 7.48. Found: C, 59.58; H, 5.17; N, 7.50%. 2.3. X-ray diffraction determination

Diffraction intensities for the six complexes were collected at 293 K on a Bruker SMART 1000 CCD diffractometer employing graphite monochromatized Mo Kα radiation ($\lambda = 0.71073$ Å). Semi-empirical absorption correction was applied using the SADABS program. The structures were solved by direct methods and refined by full-matrix least-squares on F^2 using SHELXTL 97 program [14]. Non-hydrogen atoms were refined anisotropically. All hydrogen atoms were initially located in a difference Fourier map. The O–H distances were then fixed at 0.85 Å and U_{iso}(H) of the hydrogen atoms of H_2O was 1.5 times of U_{eq}(O) in the next refinement. The crystallographic data for complexes **1**–**5** are listed in Table 1, and selected bond lengths (Å) and bond angles (°) in Tables 2 and 3.

3. Results and discussion

3.1. Description of the structures

Complexes **1** and **2**, **3** and **4** are two isomorphous pairs except that in complexes **1** and **2**, the clathrated guest molecules are different (CH_3OH for complex **1** and H_2O for complex **2**). And because of the different radii of the Co(II) and Ni(II) ions, there are corresponding differences in the distances of M–O and M–N (M = Ni or Co) in the two paired complexes, however only the structures of **1**, **3** and **5** will be described in detail.

3.1.1. $[Co(o\text{-}CCA)(bpe)(H_2O)]_n \cdot 0.25nCH_3OH$ (1)

The coordination environment of Co(II) ion in complex **1** is shown in Fig. 1. Each Co(II) ion is six-coordinated by three oxygen atoms (O(1), O(3A), O(4A)) of two *o*-CCA anions, one oxygen atom (O(5)) of water molecule and two nitrogen atoms (N(1), N(2)) of two bpe ligands,

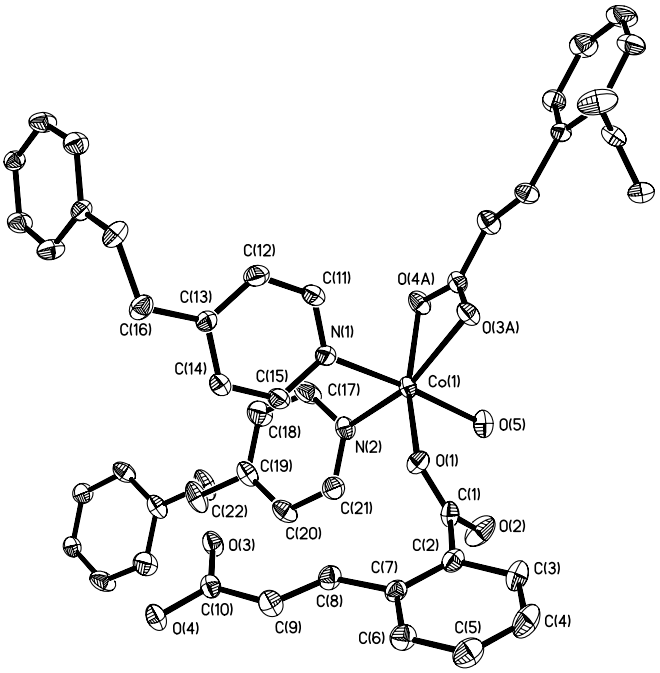

Fig. 1. Coordination environment of Co(II) ion in complex **1** with 30% thermal ellipsoids, all hydrogen atoms and crystal water molecules are omitted for clarity.

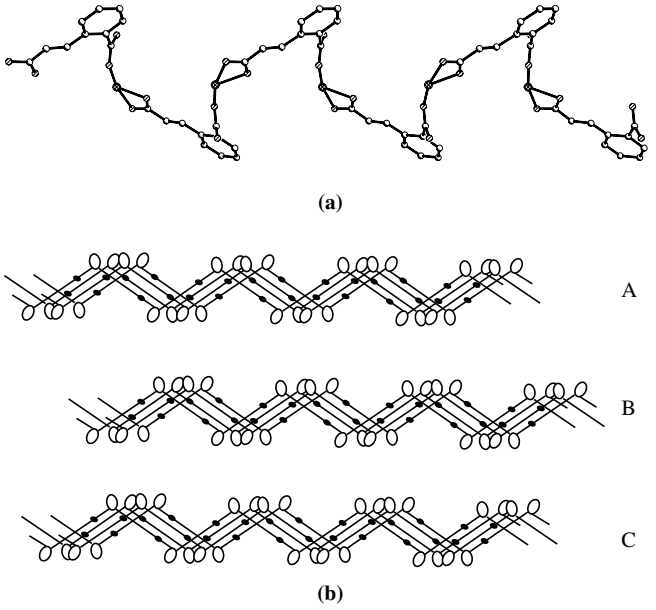

Fig. 2. (a) 1D zigzag chain constructed by *o*-CCA linking Co(II) ions and (b) the simplified representation of the 2D layers in complex **1** viewed along the *c* axis.

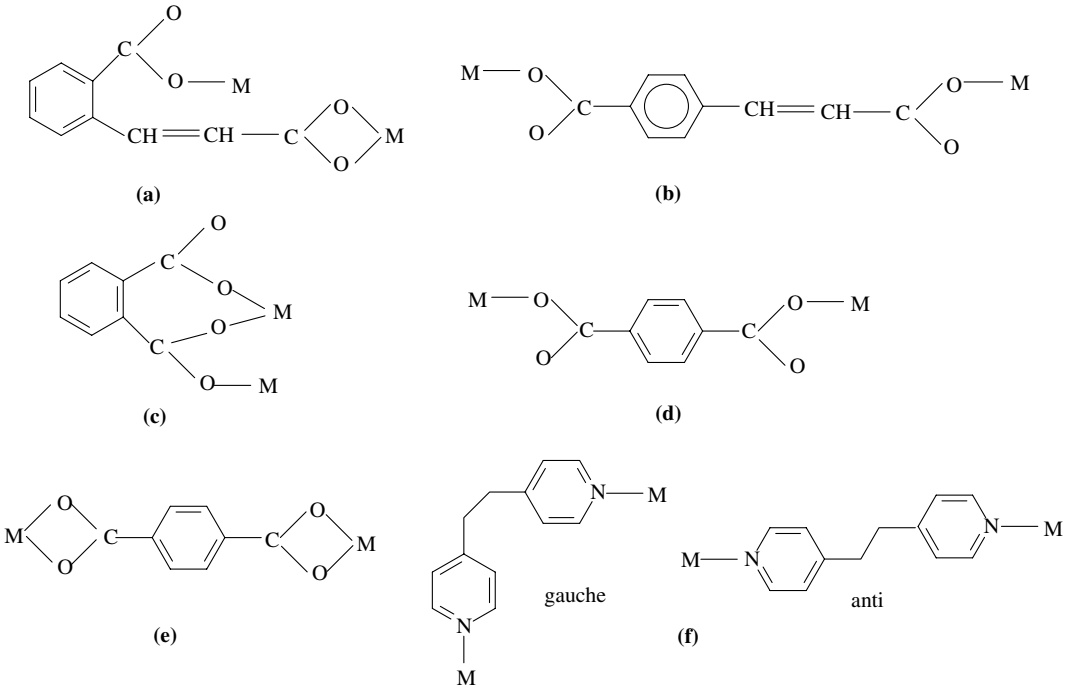
leading to a distorted octahedron. There is one kind of crystallographically independent *o*-CCA anion, acting as a tridentate ligand (see Scheme 1a). The formate group of the *o*-CCA anion adopts a monodentate mode, while the acrylate adopts a chelating-bidentate mode, and thus the *o*-CCA anion bridges two Co(II) ions, and the Co···Co distance is 7.181 Å (7.157 Å for Ni). All Co(II) ions are linked by *o*-CCA anions into 1D infinite zigzag chains, as shown in Fig. 2(a). Along the *c* axis, the chains are parallel to each other, forming 2D layers (see Fig. 2(b) A, B, C).

In complex **1**, bpe molecules adopt two conformations, anti and gauche forms (see Scheme 1f). They all act as bidentate ligands, bridging Co(II) ions into wave-like chains, as shown in Fig. 3. All these chains are parallel to



Scheme 1. The coordination modes of the ligands in complexes **1**–**6**.

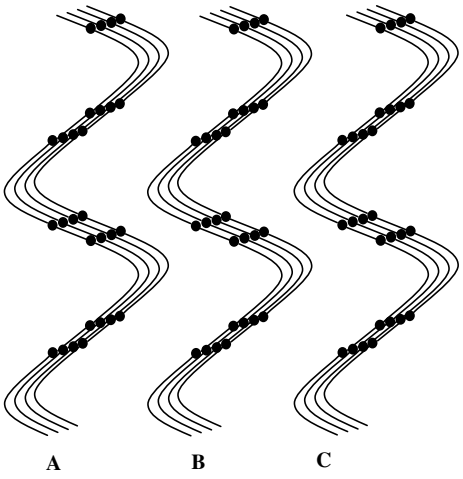


Fig. 3. The simplified representation of wave-like chains constructed by bpe linking Co(II) ions in complex **1** viewed along the *b* axis.

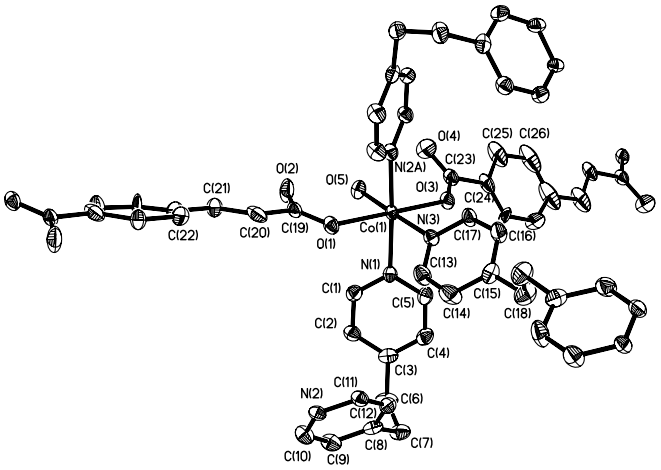

Fig. 5. Coordination environment of Co(II) ion in complex **3** with 30% thermal ellipsoids, all hydrogen atoms and crystal water molecule are omitted for clarity.

each other, forming 2D layers (see Fig. 3 A, B, C). The chains shown in Figs. 2 and 3 intersect at Co(II) ions and thus form a 3D metal-organic framework, in which free methanol molecules are clathrated (see Fig. 4, crystal water molecules in complex **2**). Hydrogen bonds are observed between the coordination water molecules and the uncoordinated carboxylate oxygen atoms (H···O = 1.831 Å, O···O = 2.662 Å, ∠OHO = 164.2°), and between the free methanol molecules and the uncoordinated carboxylate oxygen atoms (H···O = 1.895 Å, O···O = 2.738 Å, ∠OHO = 170.8°), which brings further stability for the structure.

3.1.2. $[Co(p\text{-}CCA)(bpe)_{1.5}(H_2O)]_n \cdot nH_2O$ (3)

Complex **3** possesses a 3D metal-organic framework with clathrated free water molecules. There is only one metal environment in complex **3**, as shown in Fig. 5. The coordination geometry around each Co(II) ion, comprising N_3O_3 from two *p*-CCA anions, one water molecule and three bpe molecules, can be described as a distorted octahedron. The oxygen atom (O5) of water molecule and the nitrogen atom (N3) of bpe ligand occupy the axial position. There is one kind of crystallographically independent *p*-CCA anion, acting as a bidentate ligand (see Scheme 1b). Both carboxylate groups of *p*-CCA anion adopt a monodentate mode, bridging two Co(II) ions, and the Co···Co distance is 7.657 Å (7.641 Å for Ni). In complex **3**, *p*-CCA anions are disordered and the occupancy is 0.5. All Co(II) ions are linked by *p*-CCA anions into 1D straight infinite chains, as shown in Fig. 6(a). The chains are parallel to each other, forming 2D layers, as shown in Fig. 6(b) A, B, C and D.

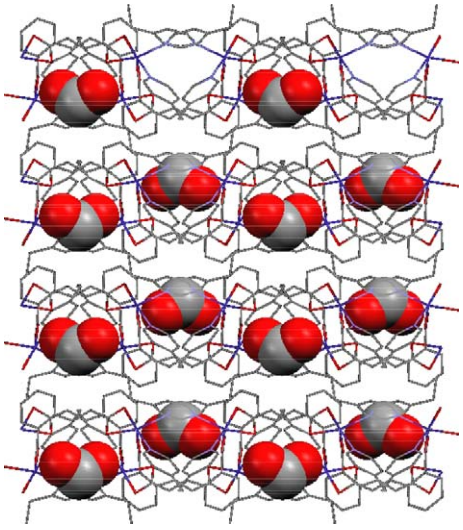

Fig. 4. The 3D network of complex **1** viewed along the *a* axis (the space filling diagram represents the clathrated methanol molecules).

In complex **3**, bpe ligands adopt two conformations, and act as bidentate ligands, too. All Co(II) ions are bridged by bpe ligands to form 2D brick-wall-like grids, as shown in Fig. 7. The chains shown in Fig. 6 and grids shown in Fig. 7 intersect at Co(II) ions, and thus form a 3D complicated metal-organic framework. And free water molecules are clathrated. There are hydrogen bonds between the coordinated/free water molecules and the uncoordinated carboxylate oxygen atoms (H···O = 1.887–2.767 Å, O···O = 2.583–2.892 Å, ∠OHO = 128.5°–138.0°), which stabilizes the structure.

3.1.3. $[Co(o\text{-}BDC)(bpe)(H_2O)]_n \cdot nH_2O$ (5)

There is only one kind of metal environment in complex **5** (see Fig. 8). Each Co(II) ion is coordinated by three oxygen atoms (O(1), O(3), O(4A)) of two *o*-BDC anions, one oxygen atom (O(5)) of coordinated water molecule and two nitrogen atoms (N(1), N(2A)) of two bpe ligands. The coordination geometry can be described as a distorted octahedron. In complex **5**, *o*-BDC anion adopts a tridentate mode, as shown in Scheme 1c. One carboxylate group adopts a bridging-bidentate mode, and the other adopts a monodentate mode, thus linking two Co(II) ions, in which the Co···Co distance is 5.290 Å. All bpe ligands are in

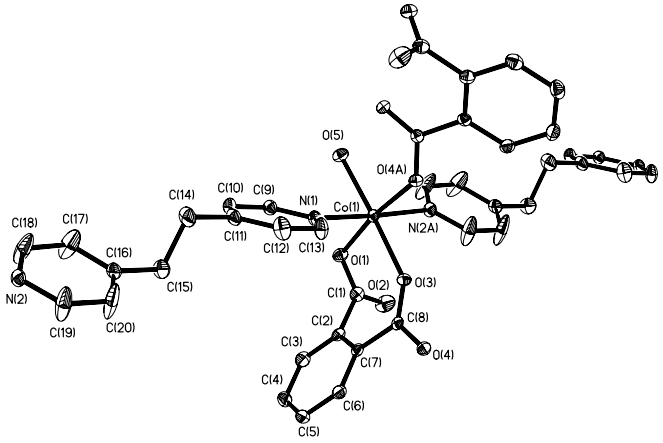

Fig. 8. The coordination environment of Co(II) ion in complex **5** with 30% thermal probability, all hydrogen atoms are omitted for clarity.

anti-form and act as bidentate ligands. Both *o*-BDC anions and bpe ligands link Co(II) ions into (4,4) 2D grid-like layers with cavity of 13.627×5.290 Å. These layers are stacked parallel along the *c* axis exhibiting the ABABAB sequence (see Fig. 9(a)). Crystal water molecules are located between the layers, as shown in Fig. 9(b). There are hydrogen bonds between the coordinated/crystal water molecules and carboxylate oxygen atoms (H···O = 2.110–2.311 Å, O···O = 2.880–2.972 Å, ∠OHO = 134.4°–163.2°), and between the coordinated water molecules and crystal water molecules (H···O = 2.121 Å, O···O = 2.924 Å, ∠OHO = 156.7°).

3.1.4. Comparison of the structures

From the above descriptions, it is obvious that the geometry of ligands has a significant effect on the formation and

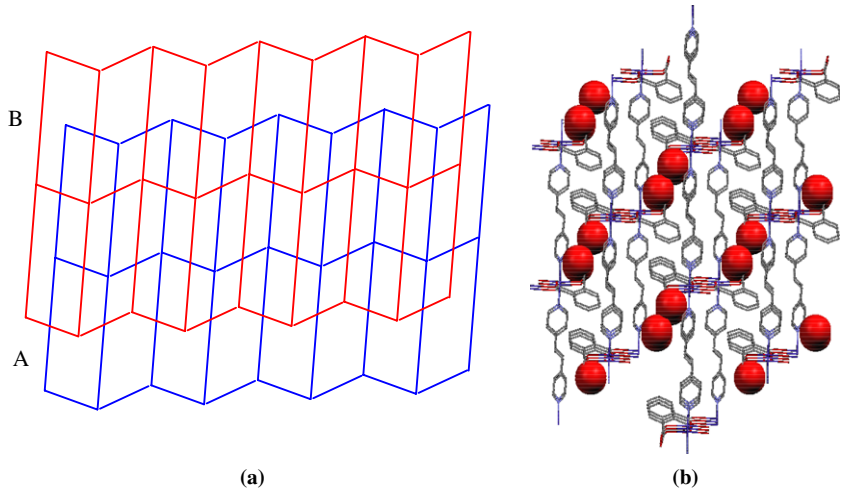

Fig. 9. (a) The simplified representation of 2D layers of complex **5** and (b) the 3D network of complex **5** viewed along the *b* axis (the red balls represent crystal water molecules). (For interpretation of the references to colour in this figure legend, the reader is referred to the Web version of this article.)

structure of the complexes. Complexes **1**–**4** all possess 3D metal-organic frameworks, while complexes **5** is of (4,4) 2D grid-like layers with cavities, and complex **6** is of 3D cuboidal box-like structure [13]. This may be attributed to flexible CCA ligands in complexes **1**–**4** and rigid BDC ligands in complexes **5** and **6**, respectively. The combination of mixed flexible ligands such as CCA and bpe in the construction of coordination polymers may result in complicated structure, while mixed rigid and flexible ligands such as BDC and bpe may result in regular geometry. Other examples can be found in literatures, such as 3,4-pyridinedicarboxylate and bpe [15], 5-nitro-1,3-benzenedicarboxylate and bpe [16], *o*-H_2CCA and 4,4′-bipyridine [11], nitrilotriacetic acid and 4,4′-bipyridine [17], 4,4′-oxybis(benzoic acid) and 4,4′-bipyridine [18]. In order to construct regular geometry for coordination polymers, it is feasible to use mixed rigid and flexible ligands, rather than mixed flexible ligands.

Comparing the structures of complexes **1** and **3**, it can be concluded that the position of functional groups takes an important role in formation and architecture of the complexes. In *o*-CCA anions, the two carboxylate groups are in the adjacent position and there is an angle of nearly 60° between the two carboxylate groups; while in *p*-CCA anions, the two carboxylate groups are in opposite position. So the two carboxylate groups in *o*-CCA anion are much nearer than those in *p*-CCA anion, which induces different steric effect. In complex **1**, there are two bpe and two *o*-CCA anions around each Co(II) ion, while in complex **3** there are three bpe and two *p*-CCA anions. In order to complete the six-coordination of the Co(II) ion, the acrylate group of *o*-CCA anion adopts a chelating-bidentate mode in complex **1** (see Scheme 1a). That is the reason why *p*-CCA and *o*-CCA anions adopt different coordination modes. Similar situation is observed in complexes **5** and **6**. In complex **5**, *o*-BDC anions act as tridentate ligands (see Scheme 1c), while in complex **6**, *p*-BDC anions adopt bis(monodentate) mode and bis(chelating-bidentate) mode (see Scheme 1d and e) [13], which induces distinctive structures for complexes **5** and **6.**

Table 4
Thermogravimetric analyses data of complexes **1**–**4**

	1	**2**	**3**	**4**

Further decomposition temperature [°C]	196–685	263–712	185–600	223–610
The residue	CoO	NiO	CoO	NiO

3.2. Thermal analyses

Thermogravimetric analyses of the complexes **1**–**4** were carried out to examine their thermal stabilities. The data of the thermogravimetric analyses for **1**–**4** are listed in Table 4. All guest molecules (methanol for **1** and water for **2**–**4**) and coordinating water molecules were lost at the first weight loss, indicating that the clathrated molecules are correlated with the formation and architecture of metal-organic frameworks in complexes **1**–**4**. Taking complex **1** as an example, the TG curve shows that the first weight loss of 5.9% from 91 °C to 161 °C corresponds to the loss of free methanol molecules and coordinating water molecules (calcd. 5.7%). Increasing temperature led to the further decomposition of complex **1** at 196 °C. The final pyrolysis was completed at 685 °C, giving the powder of CoO.

4. Conclusion

In summary, using hydrothermal reactions, we obtained five new coordination polymers $[Co(o\text{-CCA})(bpe)(H_2O)]_n$

$\cdot 0.25n$$CH_3OH$ (**1**), $[Ni(o\text{-}CCA)(bpe)(H_2O)]_n \cdot 0.5n$$H_2O$ (**2**), $[M(p\text{-}CCA)(bpe)_{1.5}(H_2O)]_n \cdot n$$H_2O$ (M = Co, (**3**); Ni, (**4**) and $[Co(o\text{-}BDC)(bpe)(H_2O)]_n \cdot n$$H_2O$ (**5**)). In complex **1**, bpe ligands link Co(II) ions into wave-like chains, while in complex **3**, Co(II) ions are bridged by bpe into brick-wall-like grids, which is mainly attributed to coordination characteristics of *o*-CCA anion and *p*-CCA anion, respectively. The position of functional dicarboxylate groups takes an important role in the architectures of metal-organic frameworks. Complexes **1**–**4** all possess 3D complicated and different metal-organic frameworks, while complex **5** is of (4,4) 2D grid-like layers with cavities. These results show that in order to construct regular geometry, it is feasible to use mixed rigid and flexible ligands rather than mixed flexible ligands.

5. Supplementary data

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 601065–601069 for **1**–**5**, respectively. Copies of this information may be obtained free of charge from the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44 1223 336 033; e-mail:deposit@ccdc.cam.ac.uk or www:http://www.ccdc.cam.ac.uk).

C–H···Cl hydrogen bonding both in the solid and solution states.

2. Experimental

2.1. Carboxymethyl(ethoxycarbonylmethyl)aminoacetic acid (6)

To a suspension of glycine ethyl ester hydrochloride (9.0 g, 64.5 mmol) and NaI (1.93 g) in CH_3CN (120 mL) was added diisopropylethylamine (35.9 mL, 206 mmol) at room temperature. The mixture was cooled to 0 °C and treated with benzyl bromoacetate (20.5 mL, 129 mmol) dropwise, after which it was warmed to room temperature and stirred for 24 h. The mixture was extracted with ethyl acetate and purified by flash chromatography (gradient elution: 10% EtOAc/hexane, and then 30% EtOAc/hexane) to afford dibenzyl ester **5** (23.3 g, 90%): δ_H (300 MHz; $CDCl_3$; Me_4Si) 7.3 (10H, m), 5.2 (4H, s), 4.2 (2H, q, $J = 7.1$ Hz), 3.8 (4H, s), 3.7 (2H, s), 1.3 (3H, t, $J = 7.1$ Hz); δ_C (75 MHz; $CDCl_3$; Me_4Si) 171.14, 171.05, 136.0, 129.0, 128.7, 66.9, 61.1, 55.6, 14.6; *m/z* 400 (M^+, 15), 326 (33), 308 (75), 264 (100); ν_{max}/cm^{-1} 3064, 2980, 2895, 1747, 1498, 1455, 1262, 1187, 1147. Hydrogenolysis of dibenzyl ester **5** (10% Pd/C, 5 wt%) at room temperature afforded diacid **6** in quantitative yield, after filtration through Celite and concentration in vacuo: m.p. 100–102 °C; δ_H (300 MHz; $CDCl_3$; Me_4Si) 12.4 (2H, br s), 4.1 (2H, q, $J = 7.1$ Hz), 3.6 (2H, s), 3.5 (4H, s), 1.2 (3H, t, $J = 7.1$ Hz); δ_C (75 MHz; $CDCl_3$; Me_4Si) 173.1, 171.5, 60.8, 55.3, 14.9; *m/z* 219 (M^+, 3), 174 (30), 146 (100), 102 (94); *Anal.* Calc. for $C_8H_{13}NO_6$: C, 43.84; H, 5.98; N, 6.39. Found: C, 43.87; H, 5.91; N, 6.00%.

2.2. (S,S)-(Bis[{(1-hydroxymethyl-2-methyl)-propylcarbamoyl}methyl]amino)acetic acid ethyl ester (7)

To a solution of diacid **6** (4.0 g, 18.2 mmol) in THF (150 mL) at −20 °C was added Et_3N (5.3 mL, 38 mmol), followed by $ClCO_2Et$ (1.76 mL, 18.2 mmol) dropwise. The mixture was stirred for 30 min at −20 °C, after which it was warmed to 0 °C and treated with L-valinol (882 mg, 18.2 mmol). The mixture was stirred 45 min at 0 °C, and then it was recooled to −20 °C and treated with $ClCO_2Et$ (1.76 mL, 18.2 mmol). The mixture was stirred for 45 min at −20 °C, and then it was rewarmed to 0 °C and treated with L-valinol (882 mg, 18.2 mmol). The mixture was stirred for 1 h at 0 °C, and then it was treated with water and extracted with ethyl acetate. The combined extracts were dried and evaporated under reduced pressure to leave an oil, which was purified by column chromatography on silica using 5% MeOH in ethyl acetate as eluent to give diamide **7** (5.3 g, 74%): $[\alpha]_D^{23}$ − 9.0 (*c* 0.8 in $CHCl_3$); δ_H (300 MHz; $CDCl_3$; Me_4Si) 7.6 (2H, d, $J = 9.2$ Hz, N*H*), 4.2 (3H, q, $J = 7.1$ Hz), 4.16 (1H, br s), 3.5–3.8 (4H, m), 3.4 (2H, s), 2.9 (1H, br s), 1.8–1.9 (2H, m), 1.3 (3H, t, $J = 7.1$ Hz), 0.94 (6H, d, $J = 7.3$ Hz), 0.92 (6H, d, $J = 7.3$ Hz); δ_C (75 MHz; $CDCl_3$; Me_4Si) 172.13, 172.06, 63.5, 61.7, 59.5, 57.6, 57.2, 29.9, 20.1, 19.6, 14.8; ν_{max}/cm^{-1} 3408, 2962, 1734, 1647, 1541, 1207, 1156, 1025.

2.3. (S,S)-[Bis{(4-isopropyl-4,5-dihydrooxazol-2-yl)-methyl}amino]acetic acid ethyl ester (11)

To a solution of diamide **7** (5.3 g, 13.5 mmol) in CH_2Cl_2 (45 mL) was added DMAP (160 mg, 1.3 mmol), followed by mesyl chloride (2.2 mL, 28 mmol). The mixture was cooled to 0 °C and treated with Et_3N (8.0 mL, 57 mmol), after which it was warmed to room temperature and further stirred for 20 h. The mixture was treated with aqueous NH_4Cl and extracted with CH_2Cl_2. The combined extracts were dried and evaporated under reduced pressure to leave an oil, which was purified by column chromatography on silica (gradient elution: EtOAc followed by 10% MeOH in EtOAc) to give bis(oxazoline) **11** (4.2 g, 88%): δ_H (300 MHz; $CDCl_3$; Me_4Si) 4.2–4.3 (2H, m), 4.16 (2H, m), 3.8–4.0 (4H, m), 3.7 (4H, s), 3.6 (2H, s), 1.6–1.8 (2H, m), 1.2 (3H, t, $J = 7.1$ Hz), 1.0 (6H, d, $J = 6.8$ Hz), 0.9 (6H, d, $J = 6.8$ Hz); δ_C (75 MHz; $CDCl_3$; Me_4Si) 171.1, 164.3, 72.5, 70.5, 60.9, 55.1, 51.1, 50.3, 32.9, 19.3, 18.6, 14.6; *m/z* 353 (M^+, 9), 227 (50), 181 (24), 153 (71), 127 (100); ν_{max}/cm^{-1} 2961, 1738, 1662, 1531, 1467, 1388, 1199, 1155, 1028.

2.4. (S,S)-[Bis{(4-isopropyl-4,5-dihydrooxazol-2-yl)-methyl}amino]acetic acid sodium salt (1)

A solution of bis(oxazoline) **11** (1.5 g, 4.2 mmol) in THF–water (3:1, 15 mL) at room temperature was treated with NaOH (210 mg) for 1 h, which resulted in the complete hydrolysis of the ester group. The mixture was concentrated under reduced pressure, after which it was redissolved in CH_2Cl_2 and filtered through a short pad of Celite to remove NaCl. The filtered solution was concentrated under reduced pressure to give sodium carboxylate **1** as an white powder in a quantitative yield, and it can be further purified by recrystallization from CH_2Cl_2/EtOAc/Et_2O: $[\alpha]_D^{28}$ − 56 (*c* 1.0 in $CHCl_3$); δ_H (300 MHz; $CDCl_3$; Me_4Si) 4.4 (2H, m, Ox-CH_2), 4.1 (2H, m, Ox–CH_2), 4.0 (2H, m, Ox–C*H*), 3.5 (4H, N–CH_2–Ox), 3.3 (2H, s, N–CH_2–CO_2Na), 1.7 (2H, m, ^{i}Pr–C*H*), 0.9 (12H, m); δ_C (75 MHz; $CDCl_3$; Me_4Si) 178.2, 166.2, 71.1, 71.0, 58.0, 50.7, 32.0, 17.93, 17.88; *m/z* 390 (M+Na^+, 100), 348 (M+H^+, 44); *Anal.* Calc. for $C_{16}H_{26}N_3O_4Na$: C, 55.32; H, 7.54; N, 12.10. Found: C, 55.16; H, 7.50; N, 11.94%.

2.5. Zn(II) complex 12

A solution of flamed-dried $ZnCl_2$ (40 mg, 0.29 mmol) in THF (1.0 mL) was added to a suspension of sodium carboxylate **1** (102 mg, 0.29 mmol) in THF (2.0 mL) through a cannula at room temperature. The mixture was stirred for 24 h, and then it was filtered through a short pad of

Celite to give a white solid. This solid was dissolved in CH_2Cl_2 and filtered through Celite again to remove NaCl, and the filtered solution was concentrated under reduced pressure to give **12** as a white solid in quantitative yield. The crude product can be purified by recrystallization from diethyl ether–chloroform: $[\alpha]_D^{20}$ +91 (*c* 0.9 in CH_2Cl_2); δ_H (300 MHz; $CDCl_3$; Me_4Si) 4.8 (1H, m), 4.3–4.6 (5H, m), 3.7–4.1 (4H, m), 3.3 (1H, d, $J = 17$ Hz), 3.1 (1H, d, $J = 17$ Hz), 2.5 (2H, m, ^{i}Pr–C*H*), 0.9 (6H, d, $J = 7.0$ Hz), 0.7–0.8 (6H, m); δ_C (75 MHz; $CDCl_3$; Me_4Si) 174.7, 173.9, 173.5, 73.7, 73.4, 67.7, 67.4, 61.9, 54.5, 54.3, 30.4, 19.2, 15.7.

2.6. Crystal structure determination of complex *12*

Single crystals suitable for X-ray diffraction study were grown by slow diffusion of diethyl ether into a solution of **12** in chloroform.

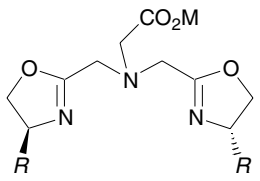
2.7. Crystal data

$C_{17}H_{27}C_{14}N_3O_4Zn$, $M = 544.59$, monoclinic, $a = 6.4791(2)$, $b = 18.1976(4)$, $c = 10.2735(3)$ Å, $T = 223(2)$ K, space group $P2_1$, $Z = 2$, μ (Mo Kα) = 1.509 mm^{-1}, 4829 reflections measured, 2640 unique ($R_{int} = 0.0371$). The final $wR(F_2)$ was 0.0942 (all data).

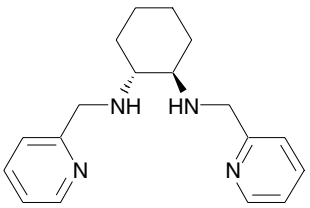
3. Results and discussion

3.1. Synthesis of the ligand *1*

As a part of our program toward the synthesis of several N_3O-type chelates and their metal complexes, we designed bis(oxazoline)-based, C_2 symmetric carboxylate **1** as a N_3O type chelate. The carboxylate group in **1** can act as O-ligand, and such an N_3O-chelate may be useful for the synthesis of novel metal complexes for further applications [7]. The symmetric nature of the ligand **1** together with the carboxylate donor may be useful for the synthesis of structurally simple, homochiral metal complexes, compared to a linear N_4 type of ligand **2** [5,6].



1 (M = Na; R = *i*-Pr)



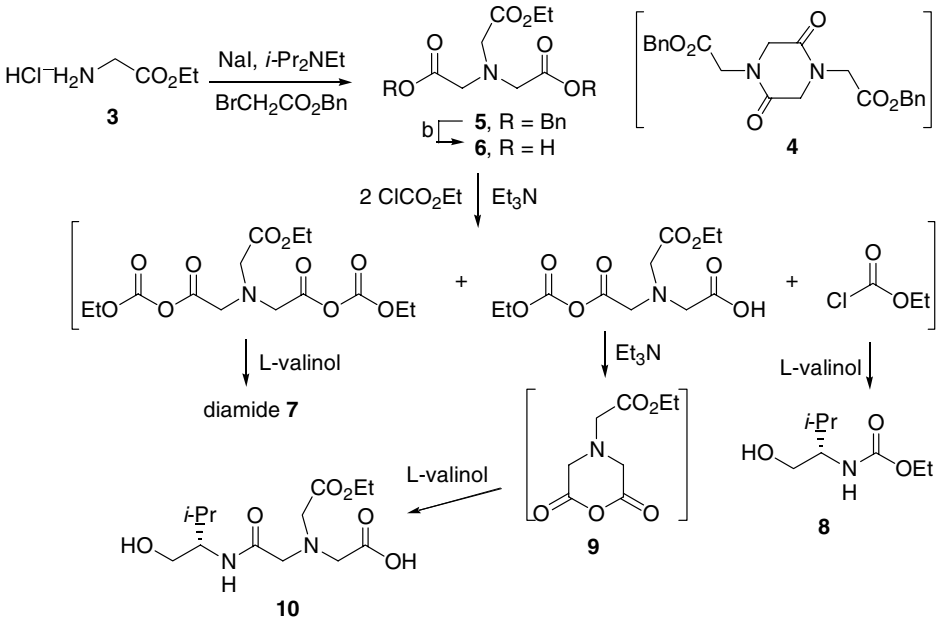
2

The synthesis of bis(oxazoline)-*N*-carboxylate **1** was started with glycine methyl ester (**3**). Our initial attempt at the di-alkylation of glycine methyl ester with benzyl bromoacetate in the presence of K_2CO_3 in DMF at room temperature, however, gave a cyclic compound **4** as the major product, through dimerization of a mono-substituted intermediate. However, by changing the base to triethylamine and the solvent to acetonitrile, we were able to get the desired product **5** in rather low yields (30–50%). Furthermore, by using a bulky base, diisopropylethylamine, we could dramatically increase the yield (90–95%). Then, hydrogenolysis of benzyl ester **5** provided diacid **6** in 97% yield. Next, an attempt to couple diacid **6** with L-valinol using DCC (*N*,*N*-dicyclohexylcarbodiimide) did not proceed at all. Therefore, the coupling method was changed to a mixed anhydride method, $ClCO_2Et$–Et_3N. Thus, treatment of diacid **6** with 2.0 molar equivalents of valinol under the mixed anhydride conditions (one-step coupling), however, gave diamide **7** in moderate yields (30–50%). There was little improvement in the coupling yield when *t*-butyl chloroformate was used instead of ethyl chloroformate. Also, this one-step coupling showed a problem in its reproducibility. We found that an ethyl carbamate of valinol (**8**) was a major side product along with monoamide **10**, which can be probably explained by the formation of anhydride **9** (Scheme 1).

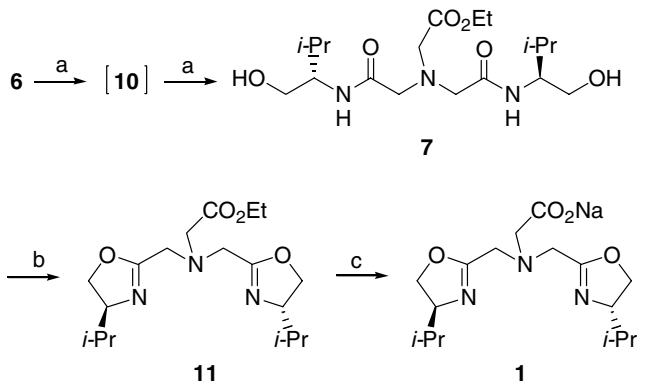
To overcome this problem, we carried out the amide formation in a stepwise manner. Thus, diacid **6** was treated with an equimolar amount of ethyl chloroformate in the presence of triethylamine at −20 °C, and then an equimolar amount of valinol was added at 0 °C to generate a mono-amide intermediate **10**. This mono-amide **10** was treated in situ again with an equimolar amount of ethyl chloroformate at −20 °C, and then an equimolar amount of valinol was added at 0 °C. This stepwise procedure greatly reduced the side product **8** and afforded diamide **7** in 74% yield. Finally, mesylation of the hydroxyl groups in **7**, and then a prolonged treatment of the resulting mesylate with triethylamine afforded bis(oxazoline)-ethyl ester **11** in 90% isolated yield. Hydrolysis of the ester with an aqueous NaOH in THF gave the desired N_3O chelate **1** in a quantitative yield (Scheme 2). Acidification of this sodium salt gave the corresponding acid, which is soluble in water and thus cannot be extracted with an organic solvent. Fortunately, the sodium salt **1**, obtained by condensation of water in vacuo, was soluble in CH_2Cl_2 and thus the remaining NaOH can be removed by simple filtration. An analytically pure sample could be obtained by recrystallization from CH_2Cl_2/EtOAc/Et_2O.

3.2. Zinc complex formation from the N_3O chelate *1*

The C_2 symmetric, carboxylate-containing N_3O ligand **1** may be potentially useful for the synthesis of various metal complexes. Among possible metal complexes, we synthesized the corresponding Zn(II) complex, keeping in mind that some oxazoline-based Zn(II) complexes are known [19]. Treatment of the N_3O chelate **1** with dry $ZnCl_2$ in THF at room temperature overnight afforded the corresponding Zn(II) complex **12** as a white solid, which was



Scheme 1. Plausible reaction pathways in the one-step coupling route.



Scheme 2. Synthesis of sodium bis(oxazoline)-N-carboxylate **1** through a stepwise route: (a) $ClCO_2Et$, Et_3N, THF; (b) MsCl, Et_3N, cat. DMAP, CH_2Cl_2; (c) NaOH, THF-H_2O (3:1).

purified by recrystallization from $CHCl_3/Et_2O$. The formation of the Zn(II) complex **12** was supported by ^1H NMR analysis in comparison with the sodium salt **1**. The sodium carboxylate **1** showed a splitting pattern expected for a symmetric structure, exhibiting total seven groups of proton peaks. Whereas, its Zn(II) complex **12** exhibited a more split pattern with significant downfield shifts for most of the protons (Fig. 2). These results indicate that, in the case of the Zn(II) complex, the two oxazolines bind to the metal but do not or very weakly bind in the case of the sodium salt. Also, the ^{13}C NMR spectrum of sodium salt **1** exhibited nine carbon peaks, including three peaks for the isopropyl groups, of which methyl groups appeared as narrowly separated, two peaks ($\Delta\delta = 0.5$ ppm). Whereas, its Zn(II) complex showed 13 carbon peaks, including three peaks for the isopropyl groups, of which methyl groups appeared as widely separated, two peaks ($\Delta\delta = 3.5$ ppm). Thus, the Zn(II) complex is no longer C_2- or pseudo-C_2-symmetric, being judged from the splitting pattern of its ^1H and ^{13}C NMR spectra. These NMR data suggest a chelated structure in the case of the Zn(II) complex, depicted as **12**. Of particular note is that the methine proton of the isopropyl group shows an unusual downfield shift ($\Delta\delta = 0.7$ ppm) and appears at 2.5 ppm, compared to the sodium carboxylate **1**. Such a large downfield shift of the CH protons is not likely due to an inductive effect from the rather remote Zn(II) metal coordinated to the oxazoline nitrogens. Also, steric congestion around the methine proton, without evoking C–H···Cl–Zn hydrogen bonding, cannot rationalize the large downfield shift, because an upfield shift should be observed in the case of steric congestion. Under such a hydrogen bonding, the isopropyl methyl groups would also appear as widely separated peaks due to the conformational restriction, as indeed observed. A CPK model of the Zn(II) complex suggested that both the isopropyl CH hydrogens have van der Waals contacts with the chloride atom bound to the Zn(II) (Fig. 1). Although C–H···Cl hydrogen bonding has been suggested from X-ray crystal structures of many complexes, its existence in solution has been known very recently. Recently, Rivas et al. reported a Zn(II) complex of a tripodal N_4 ligand, in which a downfield shift of a CH proton ($\Delta\delta = 0.11$ ppm) near Zn–Cl was observed due to similar C–H···Cl–Zn hydrogen bonding [18]. Together with this precedent, our Zn(II) complex provides an additional example of the C–H···Cl–M hydrogen bonding in solution.

3.3. Crystal structure of **12** · ($CHCl_3$)

Single crystals of the complex **12** was obtained as a colorless plate form by the diffusion of ethyl ether into a solution of Zn(II) complex **12** in chloroform. From X-ray crystallographic analysis, Zn(II) complex **12** was found to

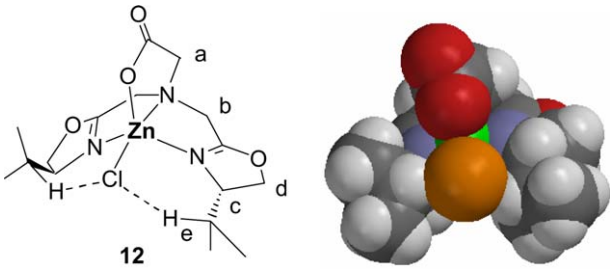


Fig. 1. A hydrogen bonded structure of Zn(II) complex **12** and its CPK model.

exist as a chiral monoclinic unit cell with space group $P2_1$ ($a = 6.480$, $b = 18.200$, $c = 10.274$ Å, $\beta = 100.943°$), wherein the bis(oxazoline)-*N*-carboxylate was chelated to the zinc atom in a tripodal fashion (see Fig. 3).

The zinc atom is trigonal bipyramidaly surrounded by two oxazoline nitrogen atoms (N2, N3) and one oxygen atom (O4) from the carboxylate in equatorial position, and central tertiary nitrogen (N1) and the chloride atom in the axial position. The triangle plane defined by N2, N3, O4, and central Zn atoms is slightly deviated from the flat plane, showing average in-plane bond angles of

Table 1
Selected bond lengths and angles around the Zn in **12**

Bond lengths		Bond angles	
Zn–Cl	2.3026(18)	Cl–Zn–N(1)	177.61(15)
Zn–N(1)	2.386(5)	Cl–Zn–N(2)	103.00(15)
Zn–N(2)	2.057(5)	Cl–Zn–N(3)	105.40(16)
Zn–N(3)	2.041(5)	Cl–Zn–O(4)	102.29(14)
Zn–O(4)	1.993(4)	Zn–N(1)–C(1)	107.6(4)
		Zn–N(1)–C(8)	105.1(4)
		Zn–N(1)–C(15)	102.2(4)

115° (Table 1). The coordination distances involving the zinc atom are also given in Table 1.

Three types of hydrogen bonding interactions were observed in the lattice structure involving the C–H···Cl–Zn hydrogen bonding. One type is between the chloride atom and a few protons of the bis(oxazoline)-*N*-carboxylate ligand; and another is between the chloride and the proton of solvent chloroform, which are strong and asymmetric with the shortest intra- and inter-molecular hydrogen distances: Cl···H(5a), 2.911 Å; Cl···H(12a), 2.850 Å; Cl···H(1b′), 2.560 Å; Cl···H(1s′), 2.489 Å (Fig. 3). The bond lengths and angles related to the C–H···Cl hydrogen bonding conform to the distance and angle criteria proposed by Aakeröy et al. [10]. The other type is the intermolecular hydrogen bonding interactions between oxygen atoms of the carboxylate and H(1b) and H(8a) with O···H distances of 2.2–3.0 Å (Table 2). This intermolecular hydrogen bonding interactions are mainly contributed to an evolution of unique framework. The unique binding mode ultimately yields microchannels in the *a*-axis direction, encapsulating a linear array of chloroform molecules (Fig. 4).

4. Conclusion

We have established an efficient route to a novel N_3O type chelate **1**. A key step of the synthesis involved a stepwise diamide formation, through which a detrimental side reaction was suppressed. A Zn(II) complex was formed from the N_3O ligand, which suggests C–H···Cl–Zn hydrogen bonding both in solid and solution states. This result provides a rare example of the C–H···Cl hydrogen bonding in solution. The X-ray crystal structure of the Zn(II) complex also shows unique microchannels, encapsulating a linear array of chloroform molecules.

with solid-state oxide gas-sensors. Typically solid-state oxide gas-sensors are made by screen-printing and tend to be very porous.

Here we report the first instance of an antimony oxide film being made using APCVD and the first investigation of the gas sensing properties of such a film. Indeed we show that thin film CVD prepared antimony oxide can be a useful gas sensing material for reducing gases such as ethanol.

2. Experimental

Nitrogen (99.99%) was obtained from the British Oxygen Company (BOC) and used as supplied. Coatings were obtained on SiO_2 coated float glass. APCVD experiments were conducted on 150 mm × 45 mm × 3 mm pieces of glass using a flat-bed cold-walled APCVD reactor. The glass was cleaned prior to use by washing with petroleum ether (60–80 °C) and isopropanol and then dried in air. A graphite block containing a Whatman cartridge heater was used to heat the glass substrate. The temperature of the substrate was monitored by a Pt–Rh thermocouple. Independent thermocouple measurements indicated that temperature gradients of up to 50 °C cm^{-1} were observable at 600 °C across the surface of the glass. The rig was designed so that four independent gas lines could be used. All gas handling lines, regulators and flow valves were made of stainless steel and were 6.5 mm internal diameter except for the inlet to the mixing chamber and the exhaust line from the apparatus that were 13 mm in diameter. In these experiments three gas lines were used. Gases came directly from a cylinder and were preheated by passing along 2 m lengths of stainless steel tubing, which were curled and inserted inside a tube furnace. The temperatures of all the gas inlet lines were monitored by Pt–Rh thermocouples and Eurotherm heat controllers.

Antimony (V) chloride (99.99%) was obtained from Aldrich and used without further purification and was placed into a stainless steel bubbler. The bubbler was heated to 120 °C by a heating jacket and $SbCl_5$ introduced into the gas streams by passing hot nitrogen gas through the liquid. Anhydrous methanol was purchased from Aldrich and used without further treatment. This was preferred over water as the later gives rise to powdery films. The two components of the system were mixed by the use of two concentric pipes of 6.5 and 13 mm diameter, respectively, the inner pipe being 3 cm shorter than the outer pipe. The concentric pipes were attached directly to the mixing chamber of the coater. Gas flows were adjusted using suitable regulators and flow controllers. The exhaust from the reactor was vented directly into the extraction system of a fume cupboard. All of the apparatus was baked out with nitrogen at 150 °C for 30 min before use. Deposition experiments were conducted by heating the horizontal-bed reactor and the bubblers to the desired temperatures before diverting the nitrogen line through the bubbler and hence to the reactor. Deposition experiments were timed by use of a stopwatch and were conducted typically for 1 min. The maximum possible deposition temperature with this equipment was 600 °C. At the end of the deposition only nitrogen was allowed to flow over the glass substrate until the substrate was sufficiently cool to handle (~60 °C). Samples were handled and stored in air. Additional runs were conducted using iron, copper and silicon wafer substrates and subjected to the same analysis. Deposition temperatures varied from 350 to 600 °C. Nitrogen flow rates were varied between 0.3 and 1.0 L min^{-1}.

X-ray photoelectron spectra were recorded with a VG ESCALAB 220I XL instrument using a focused (300 μm spot) monochromatic Al Kα radiation at a pass energy of 20 eV. Scans were acquired with steps of 50 meV. A flood gun was used to control charging and the binding energies were referenced to an adventitious C 1s peak at 284.6 eV. Depth profiling measurements were obtained by using argon beam sputtering. Electron microprobe analysis was obtained on a JEOL EMA and referenced against gallium and oxygen standards. EDXA was conducted using a JEOL 35-CF instrument. SEM images were acquired on a Hitachi S570 instrument. X-ray powder diffraction patterns were measured on a Siemens D5000 diffractometer using filtered (Cu Kα1, $\lambda = 1.5406$ Å) radiation in the reflection mode using glancing angle incidence (1.5°). Reflectance and transmission spectra were recorded between 300 and 1150 nm on a Zeiss miniature spectrometer. Measurements were standardised relative to a rhodium mirror (reflectance) and air (transmission). UV–Vis spectra were obtained using a Helios double beam instrument. Raman spectra were acquired on a Renishaw Raman system 1000 using a helium–neon laser of wavelength 632.8 nm. The Raman system was calibrated against the emission lines of neon. Electrical properties were determined by using a 4-probe device. Contact angle experiments were determined by measuring the spread of a 1 μl droplet of water on the film surface, and applying a simple trigonometric program.

For gas response, films were deposited onto commercially produced sensor substrates. The sensors consist of a gold track printed on the top of an alumina tile and a platinum heater track printed on the reverse side of the tile. Gold electrodes were formed by laser trimming to produce an interdigitised section with gap and finger widths of 50 μm. Contacts to the devices were formed by spot welding 50 μm diameter platinum wire to pads of the track material in the corner of the sensor chip. The sensor heater was kept at constant resistance and hence constant temperature by incorporating it into a Wheatstone bridge. Electrical experiments were formed on a locally constructed test rig [22]. Test gasses were diluted from cylinders of synthetic air (79% nitrogen, 21% oxygen) containing ethanol (100 ppm). The devices were investigated over a variety of temperatures between 400 and 600 °C.

3. Results

3.1. Synthesis and characterisation

Atmospheric pressure chemical vapour deposition reaction of antimony (III) chloride and ethyl acetate led to the creation of antimony (III) oxide thin films on glass and gas sensor substrates. The process was studied across a range of different substrate temperatures and flow conditions (Table 1).

Films would not grow at substrate temperatures lower than 550 °C and uniform films were obtained at 600 °C. In all cases films appeared transparent, unreflective and colourless. Some birefringence was observed at the edges of the films – this indicates a slight variation in thickness. The films all passed the Scotch tape test and were resistant to marking by a wet towel or a brass stylus, but could be marked by a steel scalpel. None of the films showed any change in their appearance on storage in air for six months.

Compositional analysis was determined by electron probe microanalysis (EPMA) and energy dispersive X-ray analysis (EDXA) and indicated that the films had single composition Sb_2O_3. With EDXA some breakthrough to the underlying glass substrate was seen. This was corrected for based on a sample of the pure substrate. The EDXA results showed that the films were free from contaminants such as chlorine and carbon. A film thickness of 500 nm (±100 nm) was estimated based on EDXA breakthrough to the underlying substrate for a sample prepared at 600 °C for 1 min giving a nominal growth rate of 500 nm min^{-1}. Samples prepared at lower deposition temperatures had film thickness in the region of 300–500 nm.

Scanning electron microscopy analysis of the films (Fig. 1) indicated, that in all cases, deposition occurred through an island growth mechanism. Antimony oxide consisted of grains of material forming a coherent coating across the surface of the substrate. There was no change or even variation of film morphology with differing substrate.

The films were investigated using Raman microscopy however, no Raman pattern was observed, it is thought antimony (III) oxide is a poor Raman scatterer, however this could be due to thickness effects. Raman microscopy did however; indicate the absence of impurities such as graphitic carbon.

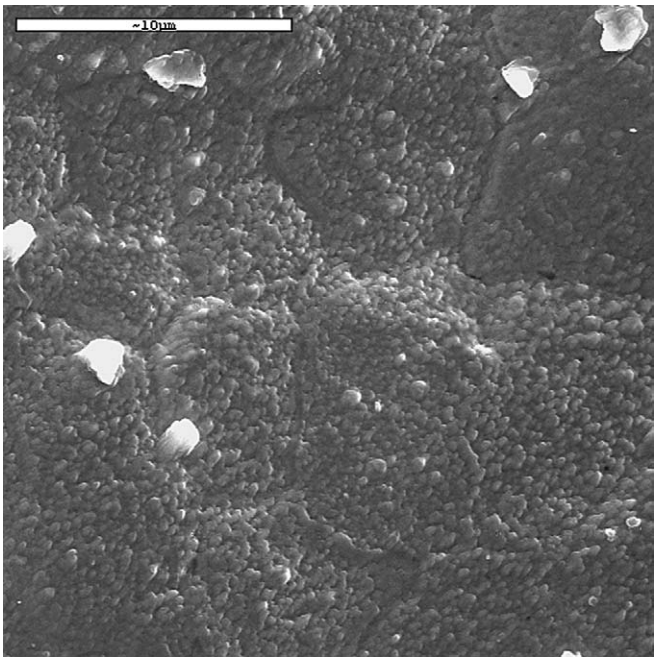

Fig. 1. A typical SEM picture for an antimony oxide sample produced by APCVD from antimony (V) chloride and ethyl acetate with a reactor temperature of 600 °C. Scale bar is 10 μm.

X-ray photoelectron spectroscopy of an Sb_2O_3 sample (Fig. 2) revealed binding energy shifts of 20.6 eV for O 2s and 35.4 eV for Sb 4d, respectively. The O 2s peak was investigated rather than the O 1s as this peak was obscured by the antimony Sb 3d5/2 peak. The XPS peak profiles are consistent with a single environment for antimony and oxygen. The binding energy shifts are in agreement with previous literature values [23].

The optical properties of the films were investigated using reflectance, transmission and UV–Vis measurements between 400 and 1100 nm. All samples showed a slight shift in the adsorption edge towards the visible relative to a plain glass substrate. The films displayed minimal reflectivity (5–15%) and high transmission (60–80%). All of the films were shown to have contact angles for water droplets in the

Table 1
Table of reaction conditions and micro-analytical results for the antimony oxide films formed from APCVD of $SbCl_5$ and ethylacetate

Substrate temperature (°C)	Nitrogen flow through SbX_5 bubbler l/min (bubbler set at 120 °C)	Nitrogen flow through ethyl acetate bubbler l/min (precursor) (bubbler set at 45 °C)	Nitrogen flow of make up gas l/min	EDAX and electron probe analysis of resultant film
550	0.5	0.5	1.0	Sb_2O_3

region of 65–85°, this is similar to that of plain glass 60–75°. Sheet resistance measurements using a four-point probe indicated that the antimony (III) oxide samples are insulators at room temperature.

3.2. Gas sensing properties

Gas response was measured as the ratio between R (the resistance when exposed to ethanol) and R_0 (the resistance at the point immediately preceding the introduction of ethanol). The resistance was measured between the two electrodes of an interdigitized gold electrode structure on an alumina tile. All samples were tested across a range of operation temperatures; from 400 to 600 °C, for their response to ethanol gas at concentrations ranging from 1 to 100 ppm. Additionally the sensors were evaluated for their response in dry air and humid air (50% humidity).

The antimony oxide sensors showed an n-type response to ethanol gas at a variety of operating temperatures. A typical example is indicated in Fig. 3.

In all cases response increased with ethanol concentration. The response is initially fast but tails off as a near plateau is reached after approximately 5 min. Once ethanol flow is stopped the response rapidly falls to near baseline levels then tails off more slowly. There is minimal baseline drift throughout the course of the experiment. The greatest response (R/R_0) was 1.47–100 ppm ethanol gas at an operating temperature of 400 °C (Table 2).

The gas response of the CVD produced antimony oxide sensor in the presence of 50% humidity was also evaluated (Fig. 4).

Addition of humidity into the chamber seems to have little effect on the resistance baseline, which is relatively flat. The magnitude of the resistance response is similar in dry and humid air.

4. Discussion

Reaction of antimony (V) chloride with ethyl acetate under APCVD conditions affords transparent films of

antimony (III) oxide on glass or gas sensor substrates. The films show good surface coverage, adhesion and uniformity. Oxide films of a single phase were obtained. These were colourless in appearance and were electrical insulators at room temperature.

Faster film growth rates were observed with an increase in substrate temperature, indicating that the reaction is surface reaction rate limited. The choice of substrate (glass or gas sensor) appeared not to affect the films in any way. The same composition, morphology and reaction onset temperature was seen irrespective of substrate. This indicates that deposition is not substrate specific.

The mechanism in these reactions was not investigated, though it appears likely that HCl is produced along with C_2H_5Cl and CH_3Cl [24] as exhaust gas tested with universal indicator paper during the reaction turned red. It is unlikely that an adduct reaction occurs as no material other than product was recovered from the reactor [25].

The surface of the APCVD films investigated here is relatively uneven and rough. There is evidence of some gas phase nucleation in that the surface consists mainly of interlinking islands, however, there is an absence of ''pin holing'' normally associated with gas phase nucleation and seen in other work where the deposited film had a similar morphology [26]. Pin holing is indicative of gas phase nucleation where particles grow in the gas phase but do not strongly bond to the substrate surface and may be blown off or fall off during handling. Additionally no solid material was recovered from the reactor exhaust, as is usually the case where gas phase nucleation is observed [27]. It is perhaps the case that nucleation can occur in the gas phase but due to either precursor species concentration or short gas phase residence time particle growth is primarily surface limited.

APCVD produced films are highly adherent to the substrate surface; this may prove to be an advantage over thick film technologies used in the production of sensor materials.

Previous work [12,13] on the production of antimony oxide thin films by CVD and thermal evaporation show some similarities with the antimony oxide films produced here. Films of antimony oxide produced by thermal evaporation of Sb_2O_3 powder were made up of small grains of antimony oxide; these were typically in the range of 50–150 nm across in size. The films were shown to be crystalline by XRD. A strictly island growth mechanism was seen with particles typically around 2 μm in diameter. Multiple phases were observed in these reaction systems, some Sb_6O_{13} were observed amongst the Sb_2O_3 on the substrate, these were found to increase if oxygen was added to the reactant gas flow. This is in contrast to what is reported here as no mixed phases were observed only Sb_2O_3 was found. The Sb_2O_3 films were X-ray amorphous and an island growth mechanism prevailed.

The current widely held view of gas sensors [20] states that the conductivity of semi-conducting oxides in air is determined by the trapping of electrons in surface states associated with surface absorbed oxygen. If interstitials or oxygen vacancies are immobile in the lattice, then the behaviour is described in terms of electron distribution between bulk and surface states. The surface conductivity is sensitive to small amounts of reactive gas as catalytic surface processes result in a change in the surface coverage of the oxygen surface trap states. If oxygen defects are mobile within the lattice then the conductivity is determined by the equilibrium between bulk lattice defects and oxygen in the gas phase, and sensitivity to trace reactive gases is lost. A further case for gas sensing can arise where there is a time dependence on the equilibration of lattice and surface states. Conductivity time dependence can also be observed as a result of lattice defect migration, which alters the potential and thus the charge carrier distribution near the surface. Due to a micro-structural effect part of the conductivity is gas sensitive due to modification in surface reactions whilst the conductivity contributed by the bulk is not gas sensitive [21]. If the films are especially thin (100s of nm) then dense films such as those produced by CVD methodology may produce high quality gas sensors. Semiconductor gas sensors are either n-type or p-type; this affects the type of gas response they provide. In an n-type semi-conducting oxide, such as tin oxide, oxygen adsorption decreases the charge carrier density at the surface; this is balanced by the charge carried on the ionised donors. A p-type semi-conducting oxide in contrast has an increased charge carrier density at the surface due to adsorption; this increase in charge is balanced by holes in the valence band. The change in electrical resistance on exposure to ppm levels of ethanol gas in the antimony oxide materials reported here is due to changes in oxygen trap sites in response to the catalytic oxidation of ethanol. This is not due to absorption, as we would expect to see a marked change in gas response on the introduction of humidity into the chamber. It is therefore likely that for these materials that surface absorbed water is not associated with the same surface state as the surface absorbed ethanol. Indeed this is a current problem in sensor technology that makes SnO_2 (the most widely used) devices unsuitable for a range of applications [28,29]. For these materials surface states are non-specific towards absorbed species. Much work has been conducted to improve the surface selectivity of SnO_2 devices [16] to lessen the effect of variable humidity.

The response peak shape for the antimony (III) oxide samples is quite ''square''; this indicates that some of the resistivity change is a result of contributions from the bulk of the material [30]. As dense films, such as those produced by CVD, have relatively fewer absorption sites than porous films, such as those produced by screen printing, they will saturate more quickly. This is likely to be a key factor to the square nature of the response. This will also affect the extent of the response. Sensors that give rise to a lower response are also subject to noise, which limits their usefulness in devices. Although in previous work [30] CVD prepared sensors had an advantage over other methodologies in terms of energy usage.

5. Conclusion

Reaction of antimony (V) chloride and ethyl acetate under APCVD conditions affords clear films of antimony (III) oxide on glass and gas sensor substrates. The films show good surface coverage, adhesion and uniformity. Single-phase films of antimony (III) oxide were obtained. These films were colourless in appearance and insulating at room temperature. The response to reducing gas (ethanol) by APCVD prepared antimony (III) oxide sensors was evaluated. It was found that there was a significant gas response to ethanol that was most pronounced at an operating temperature of 400 °C.

aminopyridine moieties in the complex [18]. Reference to a situation in which delocalization does not occur can be found in 2,6-(amidomethyl)pyridine complexes with a methylene group between the amido nitrogen and pyridine ring [19].

The pentagonal bipyramid represents one of the seven-coordination geometries. It is known that seven-coordinated complexes are prone to stereochemical nonrigidity. In the case of tantalum amidopyridines the coordination isomerism around tantalum probably originates from delocalization of nitrogens or loosely coordinated pyridine nitrogen. We have previously isolated amidopyridine complexes with amido groups *cis* to each other. Now, we tried to use bulky aminopyridine ligands to isolate and characterize the still unknown isomer of tantalum amidopyridine complexes with amido groups *trans* to each other (*vide infra*).

2. Experimental

For the synthesis of complexes **1** and **2** it was first necessary to synthesize the precursor aminopyridine. This was achieved using a typical method of aminopyridine synthesis involving a melt reaction described earlier [20]. The aminopyridine ligand for the complex **3** was purchased from Aldrich. The ligand precursor was then treated with $TaCl_5$ according to a previously known procedure [8]. Recrystallization from toluene produced crystals suitable for X-ray measurements. All reaction steps were carried out under an argon atmosphere using standard Schenk techniques. In all cases a portion of air-sensitive crystals was transferred to perfluoropolyether. The crystal selected for the X-ray measurements was mounted on glass fibre using the oil-drop method [21].

2.1. Structure determination and refinement

Structures were solved with the SHELXTL-5.1 program package using direct methods that showed the positions of the non-hydrogen atoms. Further refinement with full-matrix least-squares on F^2 was carried out with SHELXL-97 using all collected reflections. Non-hydrogen atoms were refined anisotropically. Hydrogen atoms were introduced into calculated positions.

3. Results and discussion

The coordination spheres of bis(amidopyridine) complexes presented in this work are pseudo-pentagonal bipyramids. In the polyhedron two chloro ligands occupy axial positions and the third together with four nitrogen atoms forms the pentagonal plane. The pentagonal bipyramidal coordination sphere seems to be quite typical of seven-coordinated niobium(V) and tantalum(V) complexes that contain two didentate ligands with a relatively small bite. Similar coordination polyhedra have been found for the amidinato [22], thioamidinato [23], thiocarbamato [24] and carboxylato [25] complexes.

Hence, amidopyridine ligands are unsymmetrical and three ligand arrangements with the described polyhedron can be found. In the two symmetric orientations either amido or pyridine nitrogen atoms are in *cis*-positions in the pentagonal plane. When one amido and one pyridine nitrogen atom are *cis* the complex adopts lower symmetry. If the axial ligands in the complex are different to each other two chiral isomers can exist. In the case of complexes presented here these isomers are equivalent because the pentagonal plane forms a mirror plane that gives C_s-symmetry to the complexes. All the complexes with 2-(benzyl-amido)pyridine ligands were found to crystallize in C_{2v}-symmetric orientations where amido groups are in *cis*-positions (Fig. 3B). In bis[2-(phenylamido)pyridine]

complexes of zirconium and tantalum the ligands adopt an orientation similar to that found in benzylamidopyridine complexes. Complex **3** was the only one that was found to crystallize in the C_s-symmetric configuration (Fig. 3C).

In order to obtain the other C_{2v}-symmetric orientation where the amido groups are in *trans*-positions, crowded 2,6-di(2-propyl)phenyl substituents were used at 2-amino-positions. Single crystal analysis of the trichlorobis{2-[2,6-di(2-propyl)phenylamido]-pyridine}tantalum(V) (Fig. 4) revealed that the third possible configuration (Fig. 3A) can be obtained when bulky ligands are used (vide supra). Furthermore, we assume that the other C_{2v}-symmetric orientation (Fig. 3B) is not possible because of steric reasons. It seems that configurational changes easily take place in seven-coordinated bis(amidopyridine) complexes (see Figs. 5 and 6).

Neglecting the ligand configuration, complex **1** is similar to our other studied tantalum complexes: it has very similar interatomic distances and angles (Table 1). The compound was found to crystallize with two complex molecules and three toluene solvate molecules in the asymmetric unit (see Tables 2 and 3).

Seven-coordinated bis(amidopyridine) complexes distort from ideal pentagonal bipyramids in various ways. Ideal *cis*-angles in pentagonal plane are 72° but the N–Ta–N

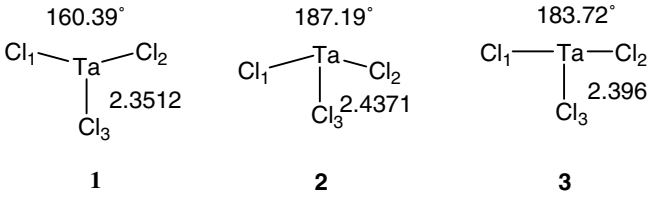

Fig. 7. The T-shape behavior of $TaCl_3$ of the complexes **1**–**3**; the Cl1–Ta–Cl2 angle decreases because of bulky isopropyl substituents occupy the space between the Cl1 and Cl3, and Cl2 and Cl3. Angle values for structures **2** and **3** are explementary values of tabulated values in order to be comparable with the structure **1**.

chelate angle is only about 60° due to the narrow bite of the rigid amidopyridine ligand. Regularity of the polyhedra can also be evaluated by how well the atoms fit to the pentagonal plane. This phenomenon was analyzed by calculating least-square mean planes through the M–N4–Cl equatorial-atoms. In all the bis[2-(phenylamido)pyridine] complexes, the plane forming atoms are located very close to the calculated planes, the average deviations are around 0.1 Å and all distances from the planes are less than 0.20 Å. In complex **1** deviations are smallest, even the maximum deviation is marginal, only 0.048(2) Å. Bis[2-(benzylamido)pyridine] complexes **7**–**10** seem to be more distorted in this sense, the average atom distances from the plane are typically around 0.2 Å. Maximum deviation, 0.418(5) Å, was found in complex **10**. All the maximal deviations were found for nitrogen atoms. In fact, distortion of the pentagonal plane can be seen as tilting of the chelate rings. One donor atom is located above the plane whereas the other nitrogen donor is tilted downwards. In most complexes the other ligand is tilted to the opposite direction (Table 4).

Axial chloro ligands fit quite well to their positions without significant distortions. In most bis(amidopyridine) complexes Cl–M–Cl *cis*-angles are typically between 85°

[a] Recalculated values differ from that given in Ref. [11].

and 90°. Tantalum complexes with bulky amidopyridine ligands show more distortion. In complex **1** the axial chloro ligands are bent away from the equatorial chloro ligands leading to Cl–Ta–Cl *cis*-angles between 99.52(5)° and 100.08(5)° (Fig. 7). In complex **11** the direction of bending is opposite, Cl–Ta–Cl angles are 81.86(8)° and 81.87(8)°.

Charge delocalization at donor nitrogens cannot be seen in the complexes **1**–**3**. The Ta–$N_{pyridine}$ bond lengths are approximately 0.1–0.2 Å longer than Ta–N_{amido} bond lengths. The bond lengths are in accordance with the literature data on amidopyridine complexes.

4. Conclusions

Tantalum(V) was found to form mononuclear bis(amidopyridine) complexes that have a pentagonal bipyramidal coordination sphere. This seven-coordination displays configurational isomerism that can be affected by substituents in the amidopyridine ligands. In contrast to our previous reports, we have successfully isolated the first C_{2v}-symmetric tantalum bis(amidopyridine) complex with the amido groups oriented in a *trans*-manner. This was caused by steric crowding of di-isopropyl substituents at the 2,6-positions of the phenyl part of the aminopyridine moiety. With the 3,4-dimethylaminopyridine ligand, the amido groups adopted a *cis*-orientation as they did in most of our earlier reported tantalum complexes. The tantalum bis[2-(phenylamido)pyridine] complex was found in two forms: one similar to its niobium congener and the other resembling the tantalum bis[3,4-dimethylamidopyridine] complex. All of the studied complexes indicate that the negative charge is localized on the amido nitrogen.

5. Supplementary data

Crystallographic data (excluding structure factors) for the structure reported in this paper have been deposited with the Cambridge Crystallographic Data Centre: CCDC 293089–CCDC 293091. Copies of the data can be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44 1223 336 033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

2. Experimental

2.1. Materials and methods

All materials were commercially available and used without further purification. Elemental analyses were conducted using the Vario EL elemental analyzer. PXRD (Powder X-ray diffraction) was performed on a Rigaku D/Max-IIIA diffractometer operated using a 0.02° step scan from 3° to 70° in 2θ and 0.2 s preset time. Infrared spectra were obtained as KBr pellets on a Bruker EQUINOX 55 FTIR spectrometer. Thermogravimetry was carried out with a Netzsch TG-209 analyzer under flowing nitrogen.

2.2. Syntheses of compounds I, *II* and *III*

$[Cu(1,5\text{-nds})(H_2O)_4]_n$ (**I**) and $[Cu(H_2O)_6](1,5\text{-nds})$ (**II**) were obtained according to the reported procedure [7]. $[Cd(p\text{-}NH_2C_6H_4SO_3)_2]$ (**III**) was prepared by heating $[Cd(p\text{-}NH_2C_6H_4SO_3)_2(H_2O)_2]$ [3] at 200 °C for 2 h. $C_{10}H_{14}CuO_{10}S_2$ (**I**): *Anal.* Calc. C, 28.47; H, 3.34. Found:

C, 28.31; H, 3.37%. $C_{12}H_{12}CdN_2O_6S_2$ (**III**): *Anal*. Calc. C, 31.55; N, 6.13; H 2.65. Found: C, 31.55; N, 6.15; H, 2.76%. $[Cu(H_2O)_6]$(1,5-nds) (**II**) was characterized by its PXRD which matched the simulated PXRD from its single crystal structure.

2.3. Solid–vapor reaction

Compounds **I**–**III** and the amine liquids were placed in two different but connected vessels and the reactions were carried out at room temperature. The reaction process was monitored via the net weight gain. It took a few days to 2 weeks for the reaction process to be complete. All reaction products were placed in an N_2 flow to remove the deposited amine and moisture on the crystalline surface before submission for characterization.

2.4. Characterization

The reaction products were characterized by EA, TGA, IR and PXRD. Since the final products formed by compounds **I** and **II** have the same PXRD patterns, only the results of **I** are presented. The EA and TGA results are showed in Tables 1 and 2. All complexes have similar IR patterns and only those obtained from **I** is shown in Fig. 1. The PXRD is shown in Fig. 2.

2.5. X-ray structure analysis

Diffraction data of $[Cd(n\text{-}C_3H_7NH_2)_4(H_2O)_2](p\text{-}H_2NC_6H_4SO_3)_2$ were collected on a Bruker Smart 1000 CCD area detector diffractometer with graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at room temperature.

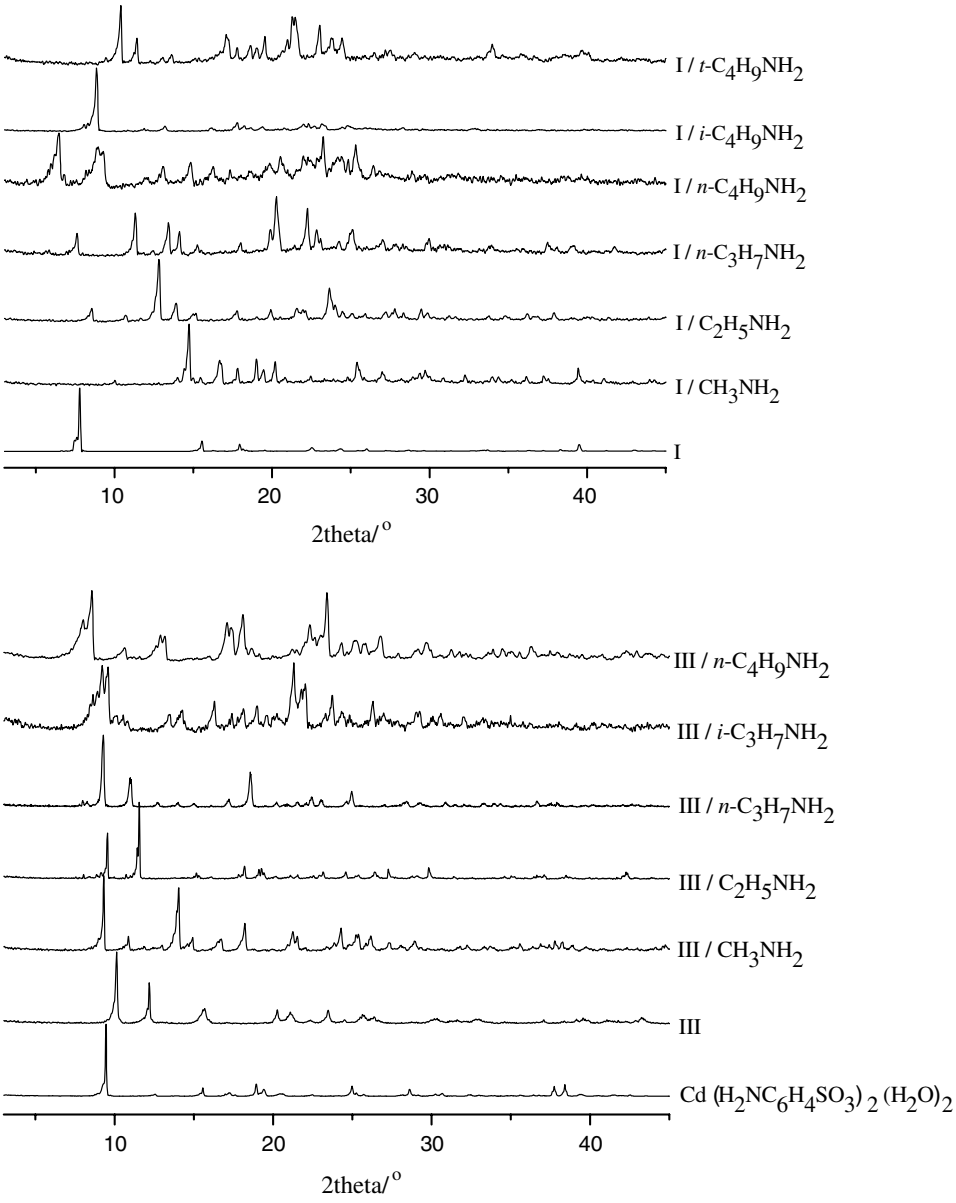

Fig. 2. PXRD of the amine complexes formed by $[Cu(1,5\text{-nds})(H_2O)_4]$ (**I**) and $[Cd(p\text{-}H_2NC_6H_4SO_3)_2]$ (**III**).

Goodness-of-fit on F^2	1.079
Final R indices [$I > 2\sigma(I)$]	$R_1 = 0.0222$, $wR_2 = 0.0591$
R indices (all data)	$R_1 = 0.0240$, $wR_2 = 0.0605$
Largest different peak and hole (e Å^{-3})	0.259 and −0.352

Absorption corrections were applied by SADABS [8]. The structure was solved by direct methods and refined using full-matrix least-squares/difference Fourier techniques by SHELXTL [9]. All non-hydrogen atoms were refined with anisotropic displacement parameters. After that, all hydrogen atoms of the ligands were placed in idealized positions and refined as riding atoms with the relative isotropic parameters. Crystal data are listed in Table 3.

3. Results and discussion

3.1. Syntheses and characterization

$[Cu(1,5\text{-nds})(H_2O)_4]_n$ (**I**) and $[Cu(H_2O)_6](1,5\text{-nds})$ (**II**) were obtained via the reaction between $CuCl_2$ and 1,5-naphthalenedisulfonate acid (1,5-nds) in aqueous media at different temperatures [7]. In **I**, Cu(II) is coordinated by the sulfonate group as well as by 4 water molecules, while one $-SO_3$ group coordinates as a $\eta^2\mu^2$ ligand to two different $[Cu(H_2O)_4]^+$ ions in *syn*/*anti* fashion, resulting in a one-dimensional structure, as shown in Fig. 3. In **II**, Cu(II) is coordinated by 6 water molecules and the sulfonate is the counter anion. They show different reactivity toward amine vapors, with **II** being more reactive than **I**. However, they produce the same final amine-coordinated complexes. Both complexes can quantitatively take up to 4 moles of CH_3NH_2, $C_2H_5NH_2$ and n-$C_3H_7NH_2$, 3 moles of i-$C_3H_7NH_2$, n-$C_4H_9NH_2$, i-$C_4H_9NH_2$ and t-$C_4H_9NH_2$, and form stable coordination compounds.

It is noted that the reaction process of $[Cu(1,5\text{-nds})(H_2O)_4]_n$ (**I**) with amine was accompanied by a color change, depending on the different amine molecules that the reactant was exposed to. With CH_3NH_2 and i-$C_3H_7NH_2$, the color changed from light blue to purple; with $C_2H_5NH_2$, n-$C_3H_7NH_2$, n-$C_4H_9NH_2$ and i-$C_4H_9NH_2$, the light blue deepened; with t-$C_4H_9NH_2$, the color became brown.

$[Cd(\mu_2\text{-N,O-}p\text{-}NH_2C_6H_4SO_3)_2(H_2O)_2]$ is a layered coordination compound with a 2D structure [3]. It can react with amine vapors and produce mono-amine coordinated complexes. $[Cd(p\text{-}NH_2C_6H_4SO_3)_2]$ (**III**) was obtained by dehydrating $[Cd(\mu_2\text{-N,O-}p\text{-}NH_2C_6H_4SO_3)_2(H_2O)_2]$ and is also a crystalline material. $[Cd(p\text{-}NH_2C_6H_4SO_3)_2]$ (**III**) can uptake 3 moles of CH_3NH_2, 4 moles of $C_2H_5NH_2$, n-$C_3H_7NH_2$ and n-$C_4H_9NH_2$, and 1 mole of i-$C_3H_7NH_2$. It is interesting to note that **III** has a much stronger amine-intercalation property for amines with a longer chain than that of $[Cd(\mu_2\text{-N,O-}p\text{-}NH_2C_6H_4SO_3)_2(H_2O)_2]$. $[Cd(p\text{-}NH_2\text{-}C_6H_4SO_3)_2]$ (**III**) can uptake 4 moles of n-$C_4H_9NH_2$, while its hydrated form can only uptake 1 mole of n-$C_4H_9NH_2$. This observation can be explained by the result that dehydration creates vacant reaction sites in Cd(II) that are more accessible for amines with longer carbon chains.

All complexes release amine molecules at temperatures higher than 50 °C, after the boiling points of the free amine molecules, indicating the coordinative nature of the amine ligands to the metal centers. Considering the compatible coordination strength of H_2O and $-SO_3$, whether the water molecules or the sulfonate groups occupy the spare coordination sites of the metal centers is not clear.

There are strong peaks around 3150–3350 cm^{-1} in the IR spectra of all the amine complexes, corresponding to the stretching bands of the coordinated N–H groups. There are alkyl C–H stretching bands observed around 2900–3000 cm^{-1} that are contributed by the alkyl amines, confirming the existence of the adducted amine molecules. The broad bands around 3500 cm^{-1} are contributed by the O–H stretching of the water molecules.

All the amine-coordinated complexes obtained via the solid–vapor reactions are crystalline materials, similar to that observed in the Cd(II) analogs [2,3]. The $C_2H_5NH_2$ and n-$C_3H_7NH_2$ products of $[Cd(p\text{-}NH_2C_6H_4SO_3)_2]$ (**III**) grow into single crystals in situ in the solid–vapor reaction, which makes direct structure characterization possible.

3.2. Reaction selectivity and preference

$[Cu(1,5\text{-nds})(H_2O)_4]$ (**I**) and $[Cu(H_2O)_6](1,5\text{-nds})$ (**II**) do not react with $(C_2H_5)_3N$ and $PhNH_2$. $[Cd(p\text{-}NH_2C_6H_4\text{-}SO_3)_2]$ (**III**) does not react with $NH_2CH_2CH_2NH_2$, $(C_2H_5)_2NH$ and $PhNH_2$.In order to reveal the reaction preferences toward different amines, the absorption exper-

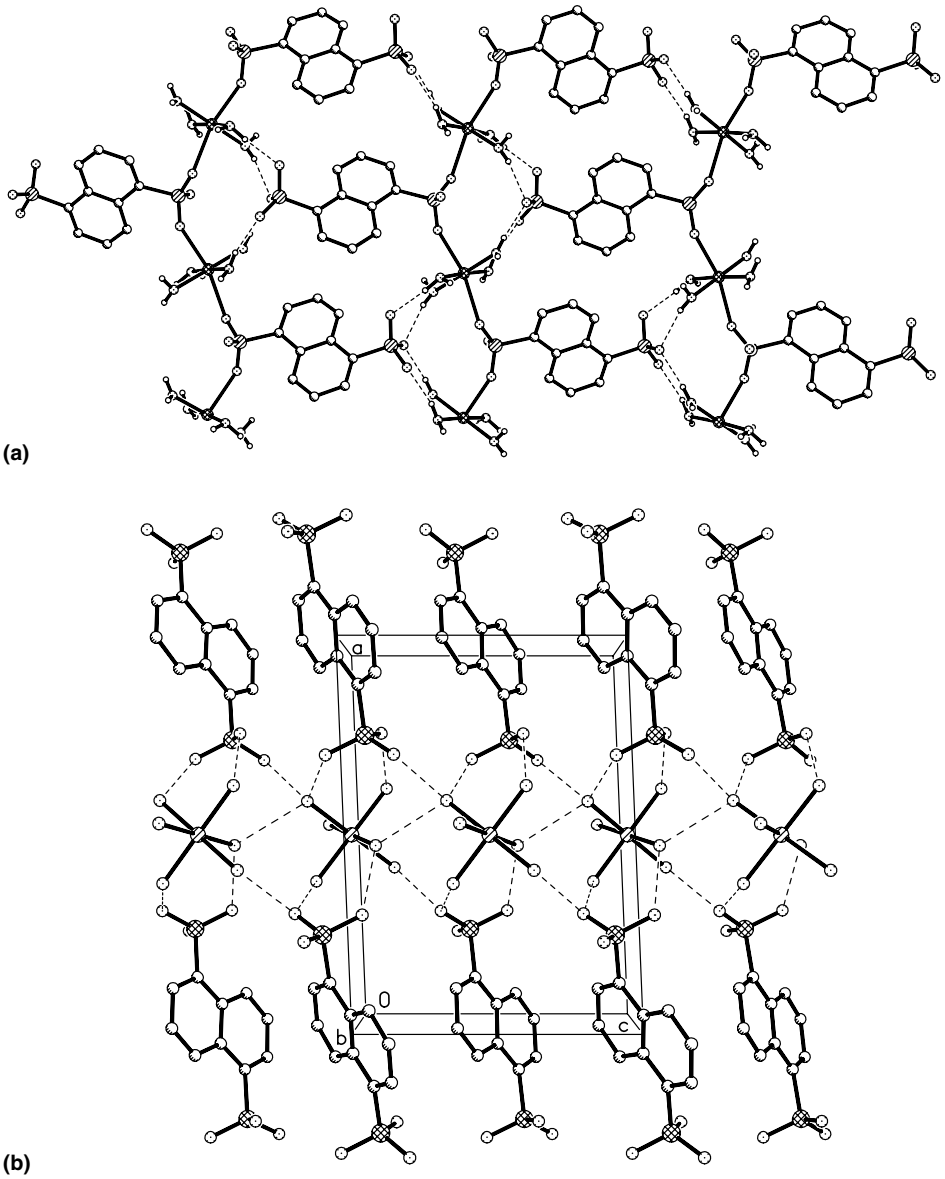

Fig. 3. Structures of $[Cu(1,5\text{-nds})(H_2O)_4]_n$ (**I**) (a) and $[Cu(H_2O)_6](1,5\text{-nds})$ (**II**) (b). The dashed lines represent the hydrogen bonds formed between the $-SO_3$ groups and H_2O.

iments of **I** and **II** with mixed amines $CH_3NH_2/C_2H_5NH_2$ and $C_2H_5NH_2/(C_2H_5)_2NH$ were conducted, and the results are shown in Fig. 4. The PXRD spectra of the resulting amine adduct is identical to that observed for Cu(1,5-nds)-$(H_2O)_2(C_2H_5NH_2)_4$, indicating that compound **I** has preferential reaction behavior, a similar observation made in its Cd(II) analogs [2,3].

3.3. Crystal structure of $[Cd(n\text{-}C_3H_7NH_2)_4(H_2O)_2](p\text{-}H_2NC_6H_4SO_3)_2$

When exposed to $C_2H_5NH_2$ and n-$C_3H_7NH_2$, the powder compound $[Cd(p\text{-}NH_2C_6H_4SO_3)_2]$ (**III**) became moisturized and single crystals were formed after 2–4 weeks which could be used directly for single crystal structure analysis, a phenomenon similar to that observed for $[Cd(\mu_2\text{-N,O-}p\text{-}NH_2\text{-}C_6H_4SO_3)_2(H_2O)_2]$ [3]. The crystal obtained in the case of $C_2H_5NH_2$ exposure has the cell parameters $a = 10.751(3)$, $b = 7.876(2)$, $c = 18.994(5)$ Å, $\alpha = 90$, $\beta = 100.432(5)$, $\gamma = 90°$, similar to that of $[Cd(C_2H_5NH_2)_4(H_2O)_2](p\text{-}H_2NC_6\text{-}H_4SO_3)_2$ [3], suggesting that water molecules were taken up from the $C_2H_5NH_2$ solution and the same complex as that from $[Cd(\mu_2\text{-N,O-}p\text{-}NH_2C_6H_4SO_3)_2(H_2O)_2]$ was formed.

It is noted that there are two forms of crystals produced in the case of n-$C_3H_7NH_2$ exposure. One of them has cell parameters $a = 8.016(2)$, $b = 15.422(4)$, $c = 15.680(4)$ Å, $\alpha = 89.097(3)$, $\beta = 88.123(3)$, $\gamma = 78.069(3)°$, similar to that recorded for $[Cd(n\text{-}C_3H_7NH_2)_4(p\text{-}H_2NC_6H_4SO_3)_2]\cdot C_3H_7\text{-}NH_2$ [3]. The other one is $[Cd(n\text{-}C_3H_7NH_2)_4(H_2O)_2]\text{-}(p\text{-}H_2NC_6H_4SO_3)_2$. The coordination structure of $[Cd\text{-}(n\text{-}C_3H_7NH_2)_4(H_2O)_2](p\text{-}H_2NC_6H_4SO_3)_2$, as well as that of $[Cd(n\text{-}C_3H_7NH_2)_4(p\text{-}H_2NC_6H_4SO_3)_2]\cdot C_3H_7NH_2$ [3] are

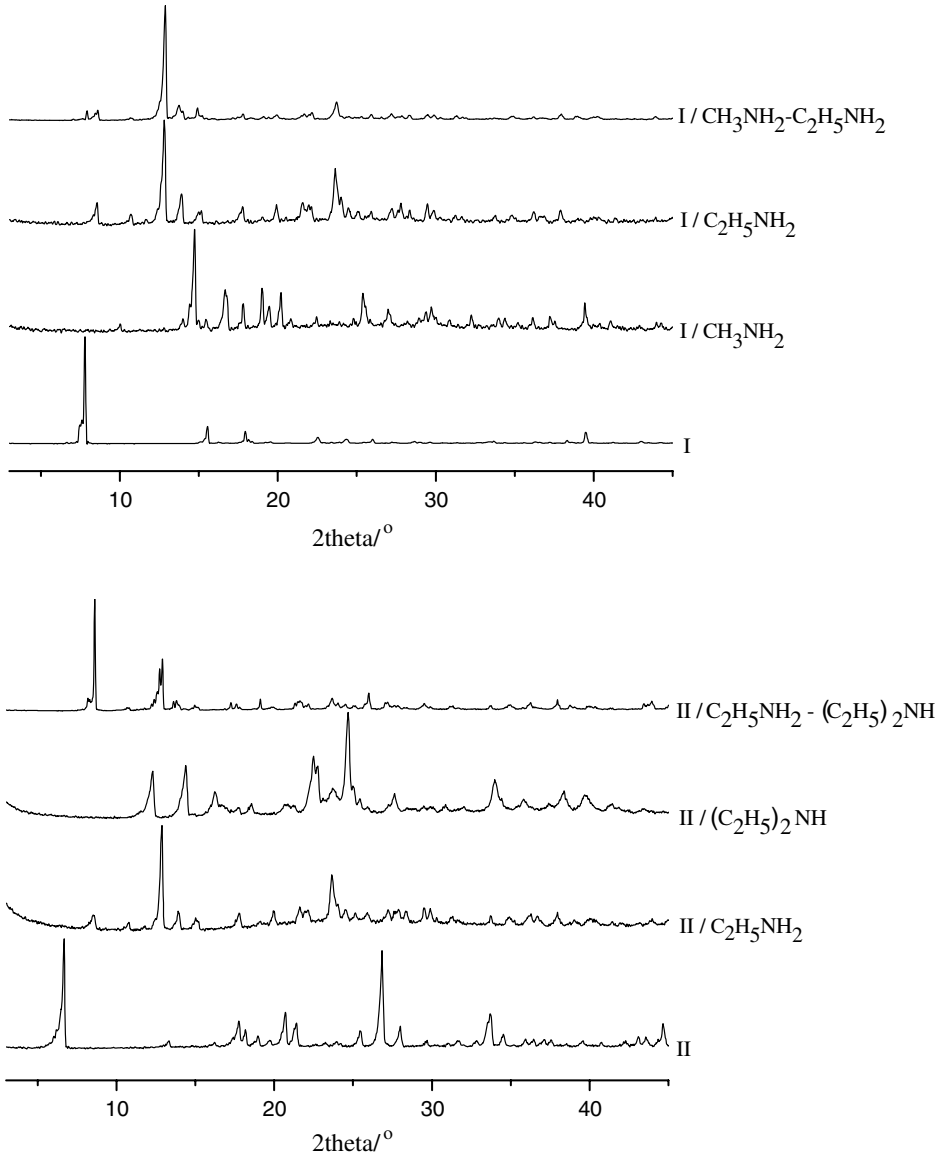

Fig. 4. PXRD of **I** and **II** with mixed amines.

shown in Fig. 5. In $[Cd(n\text{-}C_3H_7NH_2)_4(H_2O)_2](p\text{-}H_2NC_6H_4SO_3)_2$, four $C_3H_7NH_2$ molecules substitute the $p\text{-}H_2NC_6H_4SO_3^-$ ligands from the Cd(II) coordination sphere, and there are two water molecules coordinated to the metal center. The Cd–N distances are 2.3483(15) and 2.3231(16) Å, which are consistence with those observed in its analogs [3]. In $[Cd(n\text{-}C_3H_7NH_2)_4(p\text{-}H_2NC_6H_4SO_3)_2]\cdot C_3H_7NH_2$, four amines replace the two coordinated water molecules and $-NH_2$ groups of the two $p\text{-}H_2NC_6H_4SO_3^-$ ligands, and the two sulfonates remain coordinated to Cd(II).

The PXRD obtained for the final absorption powder is identical to that simulated for the single crystal structure of $[Cd(n\text{-}C_3H_7NH_2)_4(H_2O)_2](p\text{-}H_2NC_6H_4SO_3)_2$, as shown in Fig. 6, indicating that $[Cd(n\text{-}C_3H_7NH_2)_4(p\text{-}H_2NC_6H_4SO_3)_2]\cdot C_3H_7NH_2$ could be an intermediate product which is not stable and transforms into $[Cd(n\text{-}C_3H_7NH_2)_4(H_2O)_2](p\text{-}H_2NC_6H_4SO_3)_2$. This conclusion is also supported by the observation that $[Cd(n\text{-}C_3H_7NH_2)_4(p\text{-}H_2NC_6H_4SO_3)_2]\cdot C_3H_7NH_2$ crystals decayed and lost reflection power quickly when exposed to air [3], while $[Cd(n\text{-}C_3H_7NH_2)_4(H_2O)_2](p\text{-}H_2NC_6H_4SO_3)_2$ is much more stable.

The TGA behavior of the $n\text{-}C_4H_9NH_2$ complex of **III** is similar to that of $C_2H_5NH_2$ and $n\text{-}C_3H_7NH_2$, suggesting that the $n\text{-}C_4H_9NH_2$ complex could have a similar coordination structure as that of $[Cd(C_2H_5NH_2)_4(H_2O)_2](p\text{-}H_2NC_6H_4SO_3)_2$ and $[Cd(n\text{-}C_3H_7NH_2)_4(H_2O)_2](p\text{-}H_2NC_6H_4SO_3)_2$, with 4 $n\text{-}C_4H_9NH_2$ and 2 water molecules coordinated to Cd(II).

4. Summary

The solid–vapor reaction between metal sulfonates and amines has been extended from cadmium(II) to copper(II), and the properties of three transition metal compounds $[Cu(1,5\text{-nds})(H_2O)_4]_n$ (**I**), $[Cu(H_2O)_6](1,5\text{-nds})$ (**II**) and $[Cd(p\text{-}NH_2C_6H_4SO_3)_2]$ (**III**) with alkyl amines were

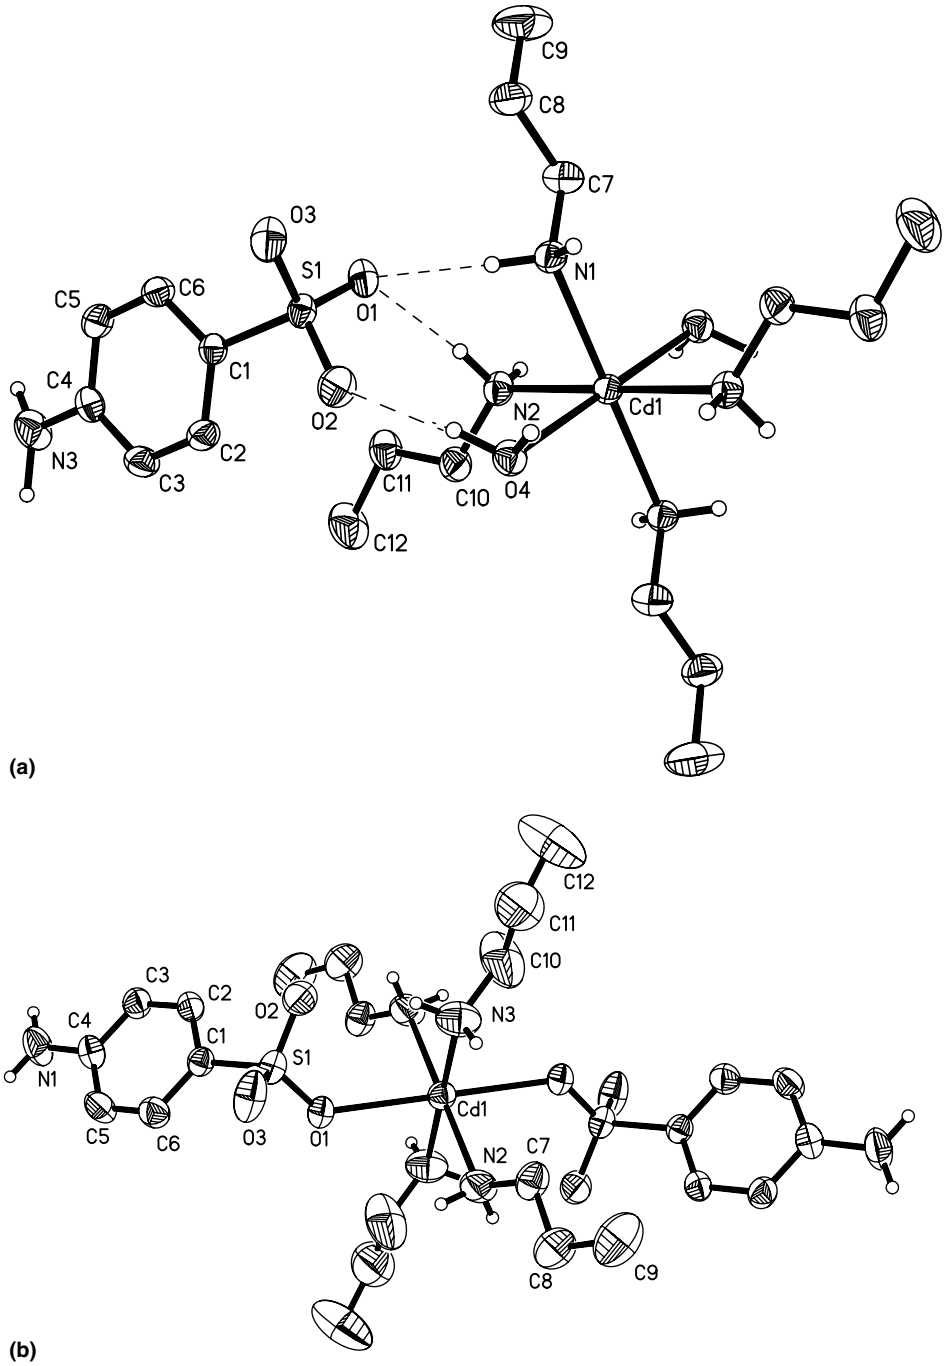

Fig. 5. The coordination structures of $[Cd(n\text{-}C_3H_7NH_2)_4(H_2O)_2](p\text{-}H_2NC_6H_4SO_3)_2$ (a) and $[Cd(n\text{-}C_3H_7NH_2)_4(p\text{-}H_2NC_6H_4SO_3)_2]\cdot C_3H_7NH_2$ (b). Hydrogen bonds are represented as dashed lines. Both Cd(II) centers locate on the symmetric centers and only the independent atoms are labelled. Hydrogen atoms bonded to carbon atoms are omitted for clarity.

investigated and the reaction products were characterized. The results show that the single phase monoamine-coordinated copper(II) and cadmium(II) complexes could be obtained without using any solvent or involving any purification process. The distinctive heterogeneous reaction can be employed as a solvent-free method to synthesize monoamine-coordinated Cu(II) and Cd(II) complexes. Furthermore, single crystals of the reaction products could be obtained in situ of the heterogeneous reaction process, which represents a unique method to obtain a single crystal via a green route [10].

5. Supplementary data

Crystallographic data for $[Cd(n\text{-}C_3H_7NH_2)_4(H_2O)_2](p\text{-}H_2NC_6H_4SO_3)_2$ has been deposited with the Cambridge Crystallographic Data Center as supplementary publication number CCDC 290252. Copies of the data can be

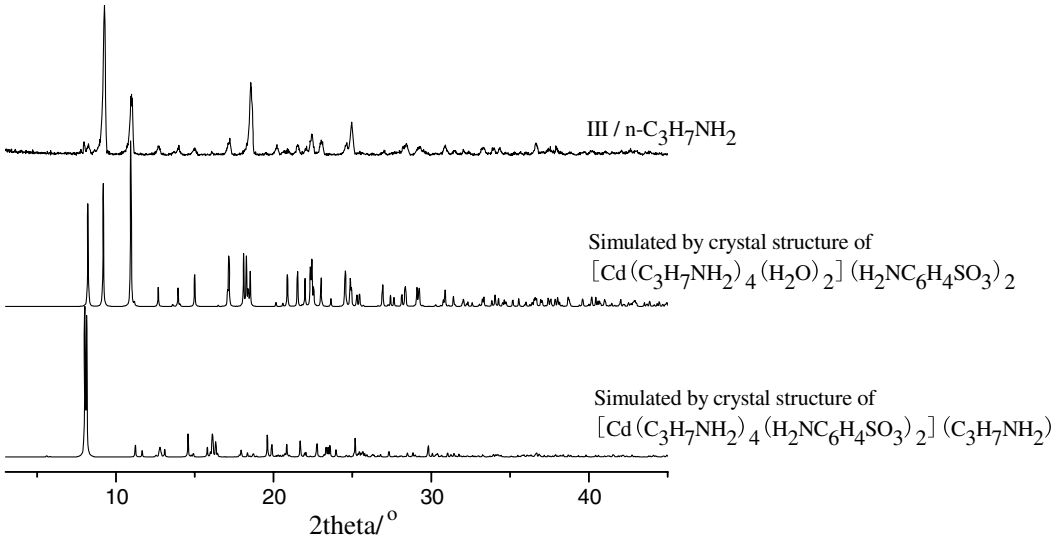

Fig. 6. PXRD of the n-$C_3H_7NH_2$ complex obtained from the reaction powder and the simulated PXRD from single crystal structures.

pyridyl)-2,3-diaza-1,3-butadiene (**2**) and 3,6-di-(2-thienyl)-1,2,4,5-tetrazine (**3**), in which the ligand bridges the diiron (Fe—Fe) unit through pyrrolyl, pyridyl and thienyl imine groups, imine nitrogen groups, imine σ and π, and N—N diaza groups. The original ligand undergoes nitrogen—nitrogen bond cleavage, *endo* cyclometallation or diaza coordination during the course of the reaction with $Fe_2(CO)_9$. The choice of this series of ligands stems from our interest in the synthesis and finding the reactivity of new diiron complexes, as well as their biological aspects. The (μ-η^1:η^2-pyrrolyl/thienyl; η^1:$\eta^1(N)$)hexacarbonyldiiron complexes, imine-bridged (μ-σ;π-η^1:η^2-(C,N); $\eta^1(N_{py})$)hexacarbonyldiiron complex and imine-bridged (μ-π-η^1:η^1-(C, N); $\eta^1(N_{py})$; $\eta^1(N'_{py})$)hexacarbonyldiiron complex show unique binding modes to the diiron (Fe—Fe) unit.

2. Results and discussion

2.1. Synthesis of ligands

The pyrrolyl, pyridyl and thienyl Schiff bases 1,4-di-(*N*-methyl-2-pyrrolyl)-2,3-diaza-1,3-butadiene (**1**), 1,4-di-(6-methyl-2-pyridyl)-2,3-diaza-1,3-butadiene (**2**) and 3,6-di-(2-thienyl)-1,2,4,5-tetrazine (**3**) were prepared by condensation of *N*-methyl-2-formylpyrrol, 6-methyl-2-formylpyridine and 2-thiophenecarbonitrile with hydrazine in anhydrous ethanol. These compounds were fully characterized spectrally. Each pyrrolyl, pyridyl or thienyl proton in each ligand can be easily assigned from the ^{1}H NMR spectra according to its specific chemical shift and the characteristic coupling constant(s). All the ligands show a characteristic C═N stretching absorption around 1600 cm^{-1} in their IR spectra. The mass spectra of the ligands all show their own specific molecular ion peak (M^+). The structures of the ligands **1** and **3** were further confirmed by single crystal X-ray analysis. Crystal and data collection parameters are shown in Table 1. Their crystal structures are shown in Figs. 1 and 2, respectively. Selected bond distances and bond angles are tabulated in Table 2. The geometries of both **1** and **3** are well planar and all the π electrons are delocalized through the whole molecule.

2.2. Complex formation and characterization

2.2.1. Complexes derived from ligand *1*

The pyrrolyl Schiff base **1** reacts with $Fe_2(CO)_9$ in refluxing toluene to give two complexes, which we formulated as **1a** and **1b**, respectively (Scheme 1). Product **1a** is a diiron hexacarbonyl complex with two new chemically identical independent ligands, *N*-methyl-2-pyrrolylmethylideneamido, which were derived from the N—N bond cleavage of the original ligand **1**, and that bridge two $Fe(CO)_3$ units through azomethine nitrogen atoms. Product **1b** is a cyclometallated diiron hexacarbonyl complex, in which the C—H bond of the β-carbon on one of the pyrrolyl groups has been activated.

The ^{1}H NMR spectrum of **1a** shows five sets of signals with the same pattern as that of ligand **1**, indicating that two pyrrolyl rings as well as two imines in the complex are in the same chemical environment. Although three sets of pyrrolyl protons show a little upfield shift, the signal corresponding to the imine proton downfield shifts from δ

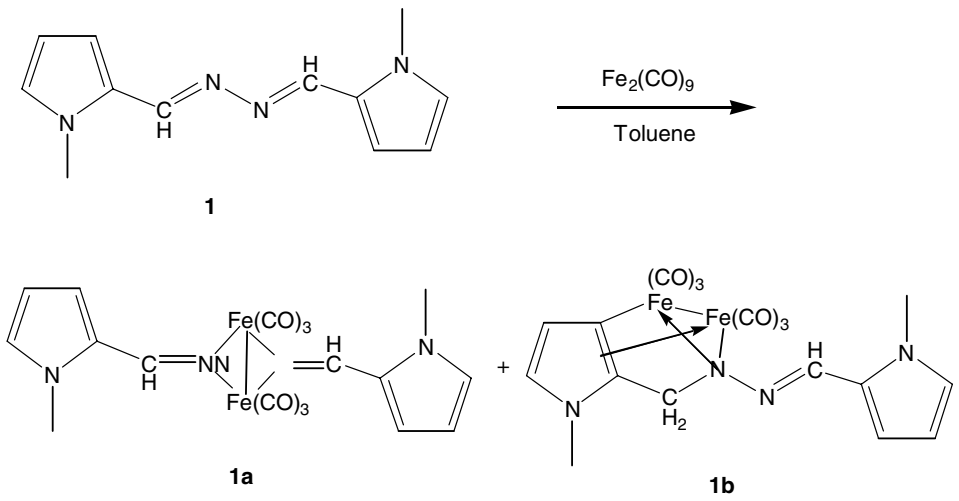
8.50 ppm (ligand **1**) to 9.00 ppm. In its IR spectrum, the C=N stretching shifts from 1625 cm^{-1} in **1** to 1638 cm^{-1}, and there are three sharp and intense C=O stretches appearing at 2061, 2021 and 1972 cm^{-1}. The fragmentation pattern of its mass spectrum shows no evidence of a peak with a m/z value of 214, corresponding to ligand **1**. However, peaks at m/z 107 and 108 were observed to accompany the presence of a molecular ion peak at m/z 495 and six peaks corresponding to sequential CO loss products, in accordance with the formulated structure.

The ^{1}H NMR spectrum of **1b** shows only one azomethine proton at δ 7.96 ppm, two methylene protons at δ 4.53 ppm, and six methyl protons at δ 3.84 ppm, in addition to the five sets of pyrrolyl protons in the range of δ 7.23–6.08 ppm. Among the five sets of pyrrolyl protons, three are doublets with a coupling constant $J_{H-H} = 2.7$ Hz, one is a doublet with a coupling constant $J_{H-H} = 3.6$ Hz, and another set

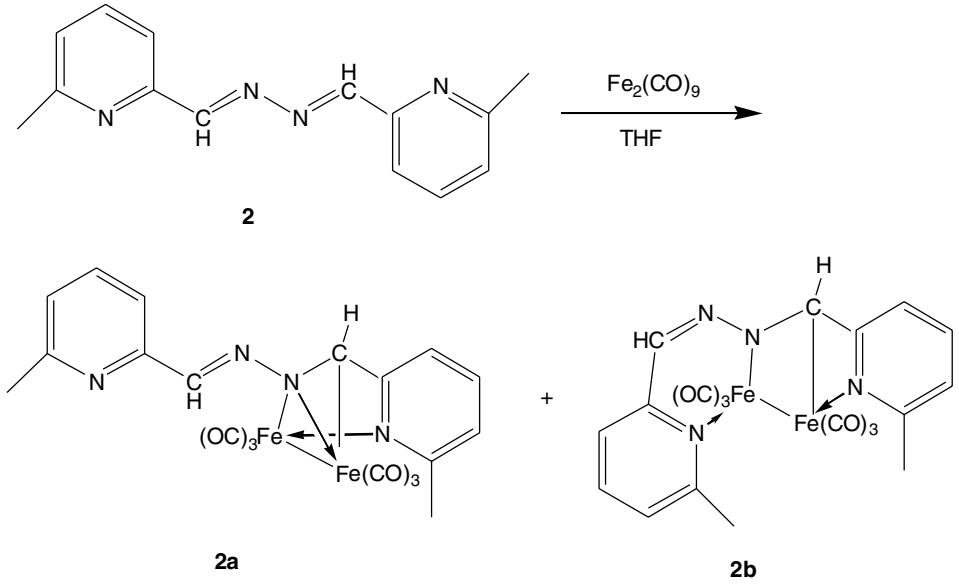


Scheme 1.

is a doublet of doublets with coupling constants $J_{H-H} = 3.6$ and 2.7 Hz, respectively. This result was interpreted as coordination of one of the azomethine nitrogens of the pyrrolyl azine ligand on one of the iron centers, C—H activation occurs at the β-carbon of the pyrrolyl ring, which is adjacent to the coordinated imine, to form a five-membered *endo* metallacycle, and the methine group becomes a methylene group by adopting the hydrogen originating from the β-carbon. This transformation follows the sequential route: coordination, *endo* cyclometallation and 1,3-hydrogen shift. The singlet signal of the methylene protons indicates that the two protons are equivalent. The lack of diastereotopicity of the methylene protons in the azametallacycle of the complex indicates that a fluxional process, the so-called 'windscreen-wiper type oscillation', of the ligand might occur in the complex [11]. The IR spectrum of the complex shows a characteristic C=N stretching at 1622 cm^{-1} and three sharp and intense C=O stretches at 2055, 2011 and 1963 cm^{-1}. The mass spectrum of **1b** shows the molecular ion peak and the complete loss of six CO ligands in a sequential manner, in accordance with the formulated structure.

2.2.2. Complexes derived from ligand 2

The pyridyl Schiff base **2** reacts with $Fe_2(CO)_9$ in refluxing THF to yield two hexacarbonyldiiron complexes **2a** and **2b** (Scheme 2) in moderate yield. Neither N—N bond cleavage of the molecule nor cyclometallation, as expected, was observed in this reaction. In both complexes, one of the imines of the original ligand is involved in coordination by using its π-electron system and bridges to two $Fe(CO)_3$ units. In complex **2a**, the azomethine nitrogen acts as the second bridging atom to the two $Fe(CO)_3$ units and one pyridyl nitrogen serves as a σ-donor atom to complete



Scheme 2.

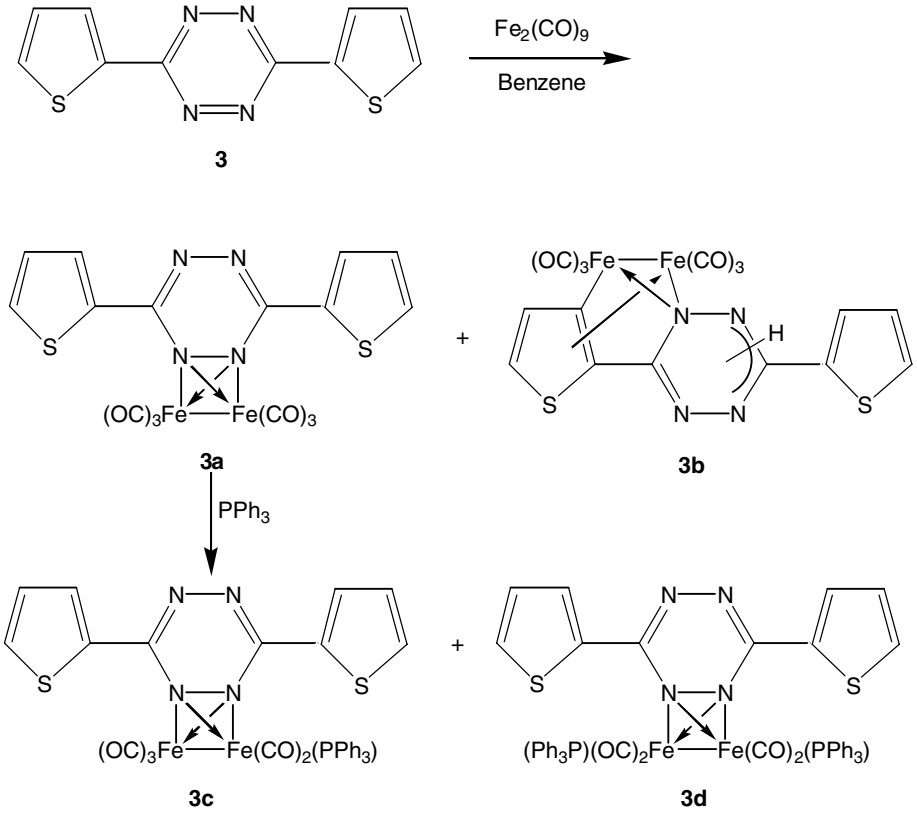
the 36-electron structure of the iron centers. In complex **2b**, in addition to the bridging imine, both pyridines are involved and coordinate to the two $Fe(CO)_3$ units, separately. When the reaction was conducted at room temperature, complex **2a** and a trace amount of **2b** were obtained. If the reaction was allowed to proceed under irradiation of UV light, a high yield of complex **2a** was obtained as the sole product.

The ^1H NMR spectrum of **2a** shows only one azomethine proton at δ 8.82 ppm, which is downfield shifted relative to that in the original ligand **2** (δ 8.58 ppm). There are six sets of signals in the aromatic region corresponding to two groups of three pyridyl protons indicating that the two pyridine rings are in different environments. One group of three pyridyl protons (δ 7.45(*t*), 7.21(*d*) and 6.79(*d*) ppm) are found to be substantially upfield shifted relative to that in the free ligand (δ 7.98(*d*), 7.81(*t*) and 7.37(*d*) ppm), due to the coordination of the pyridyl nitrogen, while another group of three pyridyl protons remain unchanged in their chemical shifts to that in the free ligand. There is a new singlet proton, appearing at δ 4.82 ppm, that is assigned to be the proton on the coordinated azomethine carbon, which has been turned from sp^2 into sp^3 hybridization causing a drastic upfield shift of the proton signal from δ 8.53 to 4.82 ppm. The IR spectrum of the complex shows a characteristic C=N stretching at 1583 cm^{-1} and three sharp and intense C=O stretches at 2054, 1083 and 1926 cm^{-1}. The mass spectrum of **2a** contains a signal for the molecular ion and six peaks corresponding to sequential CO loss products, in accordance with the formulated structure.

The ^1H NMR spectrum of **2b** is very similar in pattern to that of **2a**. Only one azomethine proton appears at δ 8.86 ppm. Six different pyridyl protons indicate that the two pyridine rings are in different chemical environments. However, different from that in complex **2a**, both two groups of pyridyl protons are found to be upfield shifted, indicating the coordination of both pyridine rings. The new singlet signal at δ 4.54 ppm is assigned to the proton on the coordinated azomethine carbon. The IR spectrum of the **2b** shows a characteristic C=N stretching at 1573 cm^{-1} and three sharp and intense C=O stretches at 2045, 1992 and 1967 cm^{-1}. The mass spectrum of **2b** shows the same result as that of **2a**.

2.2.3. Complexes derived from ligand 3

The thienyl ligand **3** reacts with $Fe_2(CO)_9$ in refluxing benzene to yield two hexacarbonyldiiron complexes **3a** and **3b** (Scheme 3). In complex **3a**, a diazo group acts as a 6-electron donor and bridges two $Fe(CO)_3$ units. Complex **3b** is a cyclometallated product, in which the C—H bond of the β-carbon on one of the thienyl groups has been activated. We attempted to prepare the doubly cyclometallated tetrairon complex and the N—N bond cleaved product under more vigorous reaction conditions in toluene, but in vain. In the presence of an excess



Scheme 3.

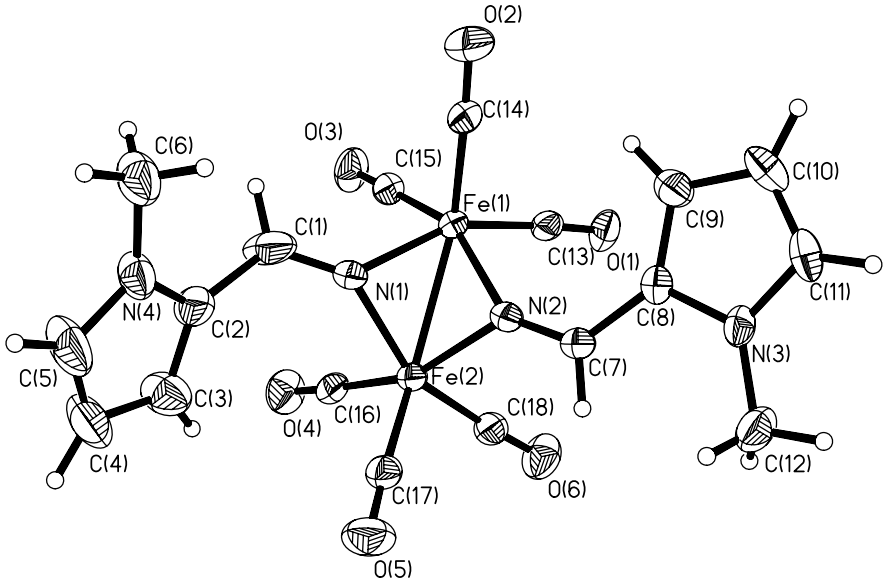


Fig. 3. ORTEP diagram of **1a** at the 30% probability level.

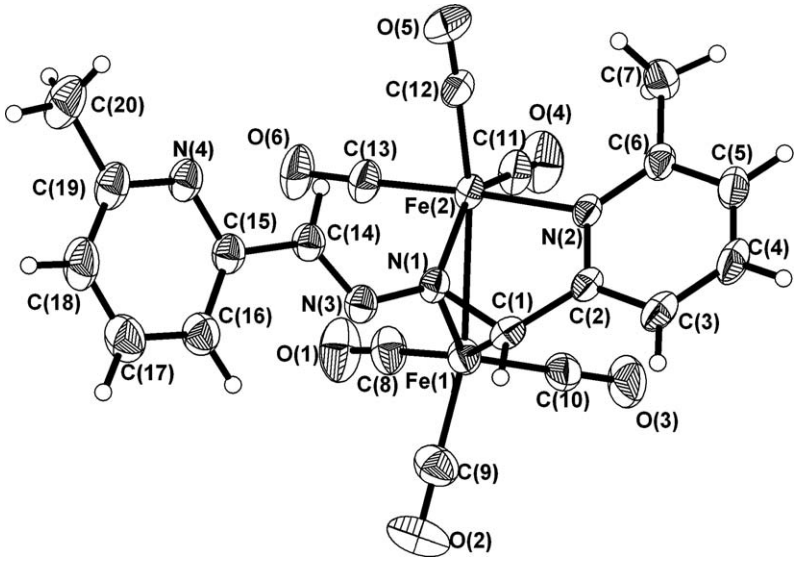

Fig. 4. ORTEP diagram of **2a** at the 30% probability level.

amount of triphenylphosphine, complex **3a** was converted into **3c** and **3d** in which one or two carbonyls were substituted by triphenylphosphine.

The ^{1}H NMR spectrum of **3a** shows three sets of thienyl proton signals similar to that of ligand **3**, indicating a symmetric geometry of the complex. In its IR spectrum, there is an imine stretching absorption at 1543 cm^{-1} and a number of terminal carbonyl stretches appearing in the range of 2076–1972 cm^{-1}. The mass spectrum of **3a** contains a signal for the molecular ion and six peaks corresponding to sequential CO loss products, in accordance with the formulated structure.

The ^{1}H NMR spectrum of **3b** shows five sets of signals with characteristic coupling constants ($J_{H-H} = 5.1$ and 3.6 Hz) corresponding to five specific thienyl protons, indicating an asymmetrical geometry of the complex, and a β-proton on one of the thienyl rings disappeared. There appears a new broad signal at δ 9.01 ppm, which is subjected to shift with different concentrations, and is assigned as an amine proton. In its IR spectrum, other than the imine (C═N) stretching absorptions at 1637 and 1573 cm^{-1} and terminal carbonyl (─CO) stretches at 2072–1952 cm^{-1}, there is a secondary amine N─H stretching absorption at 3352 cm^{-1} and a bending absorption at

1521 cm^{-1}. The mass spectrum of **3b** shows the same result as that of **3a**.

Complexes **3c** and **3d** are derived from **3a** through the substitution of carbonyl ligand(s) with triphenylphosphine. Their ^1H NMR spectra adopt the same pattern as that of **3a** except the additional signals of triphenylphosphine. However, the thienyl protons are upfield shifted from **3a** to **3c** to **3d** due to the inductive effect of the phosphine ligand. The inductive effect also drives the lower energy shift of the IR stretching frequencies of the terminal carbonyls in the same sequence. The mass spectra of **3c** and **3d** show their own specific molecular ion peak (M^+) at *m/z* 761 and 995, respectively, fragments corresponding to the sequential loss of CO ligands, phosphine and the ligand ion peak, in accordance with the formulated structures.

2.3. Molecular structure of complexes *1a, 2a, 3a* and *3c*

The molecular structures of **1a**, **2a**, **3a** and **3c**, as confirmed by the single crystal X-ray diffraction analysis, are shown in Figs. 3–6, respectively. Their crystal and data collection parameters are tabulated in Table 1 and selected bond distances and bond angles are summarized in Tables 3 and 4.

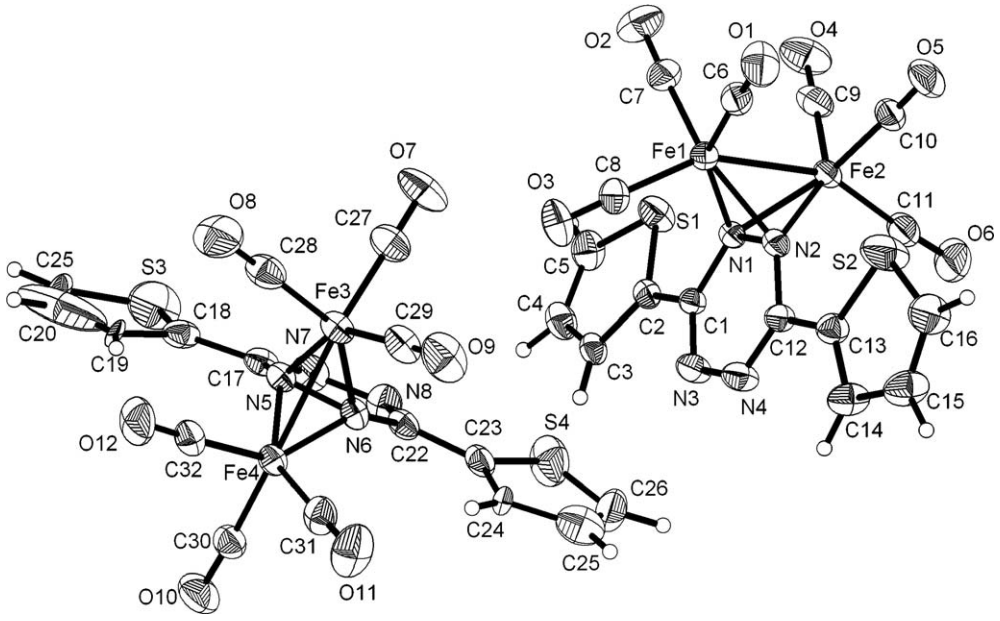

Fig. 5. ORTEP diagram of **3a** at the 30% probability level.

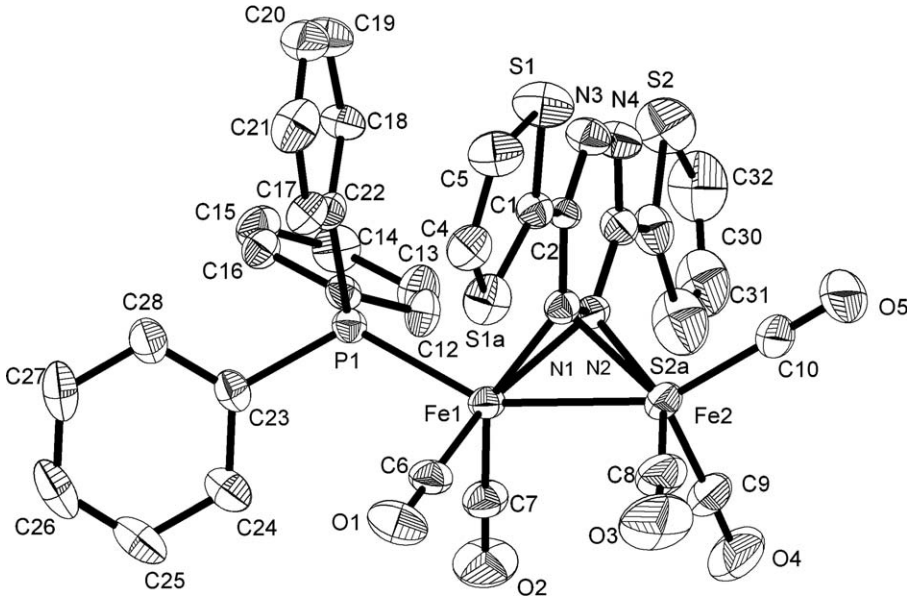

Fig. 6. ORTEP diagram of **3c** at the 30% probability level.

2.3.1. $[Fe(CO)_3(MeC_4H_3NCHN)]_2$ (**1a**)

The structure of **1a**, as shown in the Fig. 3, contains two 2-pyrrolylmethylideneamido moieties which bridge two $Fe(CO)_3$ units through amido nitrogen atoms. It is clear that the N—N bond in ligand **1** has been cleaved during the coordination reaction and the non-bonded N···N distance is 2.399 Å. The configuration of the individual molecule has idealized 2-fold symmetry. The tricarbonyl groups are eclipsed. The amido nitrogen and iron atoms form a tetrahedron. The central position of the molecule is thus similar in shape to that of $Co_2(CO)_8$. Plane calculations show that all pairs of atoms are equidistant from opposite sides to the C_2 axis, which is perpendicular to the mid-point of the Fe—Fe bond. Each iron center is coordinated by two nitrogen atoms and three carbonyls located at the corners of a distorted octahedron. The Fe—Fe distance is only 2.4084(7) Å, which is shorter than usual for diiron complexes (2.5–2.7 Å) [4f,4g,12], but can be compared with the value found in some nitrogen-bridged diiron complexes [4a,10g,13], and can be attributed to a distinct 'bent' iron—iron bond [14]. The bond distances between iron and bridging nitrogens are Fe(1)—N(1) 1.934(3) Å, Fe(1)—N(2) 1.922(3) Å, Fe(2)—N(1) 1.935(2) Å and Fe(2)—N(2) 1.922(2) Å, which are shorter than those in reported nitrogen bridged diiron complexes [4f,4g,10,12e,12f,13]. The significantly shorter averaged Fe—N bond distance of 1.928 Å in this complex can be ascribed to the structure possessing two three-coordinated trigonal-like bridging nitrogen atoms, instead of four-coordinated tetrahedral-like bridging nitrogen atoms, and the nitrogen atoms of the complex can be considered as sp^2 hybridized [15]. The bond distance between C(1) and N(1) (1.273(4) Å) is shorter than the C=N bond distance in ligand **1** (1.284(2) Å), and yet is still in the range of usual bond lengths of imine double bonds. In the central Fe_2N_2 system, the averaged Fe—N—Fe, N—Fe—Fe and N—Fe—N bond angles are 77.20°, 51.51° and 76.87°, respectively. The bond angles of Fe(1)—N(1)—C(1), Fe(2)—N(1)—C(1), Fe(1)—N(2)—C(7) and Fe(2)—N(2)—C(6) are 136.2(3)°, 140.7(3)°, 146.4(3)° and 134.1(3)°, respectively. These large angles are associated with the short Fe—Fe bond length and the sp^2 hybridization of the nitrogen atoms.

The cleavage of the N—N bond during the course of ligand coordination leads to a reduced degree of conjugation of the ligand and might increase the π-electron density on the imine group which explains why there is a 0.50 ppm downfield chemical shift of the azomethine protons in its ^{1}H NMR spectrum. On the other hand, relative to the highly conjugated ligand **1**, the bond order of the imine group in the complex might increase. The IR stretching absorption of the C=N group is higher energy shifted from 1625 cm^{-1} in ligand **1** to 1638 cm^{-1} in the iminato-bridged complex and is consistent with the shortening of the C=N bond length in **1a**.

2.3.2. $Fe_2(CO)_6(MeC_5H_3NCHNNCHC_5H_3NMe)$ (**2a**)

The molecular structure of compound **2a**, as shown in Fig. 4, shows that the iron atoms possess a distorted

octahedral coordination geometry. The Fe—Fe inter-metallic distance is 2.5689(5) Å (Table 3). The iron atoms are bridged by one of the imine fragments, C(1)=N(1), of the ligand in the η^2-C=N bonding mode. The azomethine N(1) atom and the pyridine N(2) atom, which is next to the coordinated azomethine, are σ-bonded to the Fe(1) and Fe(2) centers, respectively. Therefore, it can be inferred that the pyridyl azine is coordinated in the σ-N, μ^2-N′, η^2-C=N′ bonding mode to the iron atoms in which the ligand forms a 6e bridge between the two $Fe(CO)_3$ moieties. The Fe(1)—N(1) and Fe(2)—N(1) distances are 1.930(2) and 1.948(2) Å, respectively; the Fe(1)—C(1) distance is 2.025(3) Å, while the Fe(2)—N(2) distance is 2.030(2) Å. These are normal values for such bonds. The C(1)—N(1) distance of 1.401(3) Å is significantly elongated compared to the C(14)—N(3) bond distance (1.268(3) Å) in the uncoordinated C=N moiety, as expected for the η^2-bonding mode of this fragment [16]. The C(2)—N(2) distance of 1.353(3) Å in the σ-N-coordinated pyridine ring is comparable to the usual σ-N-coordinated azomethine group [17], which can be attributed to effective delocalization of electron density in the coordinated pyridine ring in the complex.

Around the central core, the N(1)—Fe(1)—Fe(2), N(1)—Fe(2)—Fe(1) and N(1)—Fe(1)—C(1) bond angles are 48.81(6)°, 48.20(6)° and 41.40(9)°, respectively, while the N(2)—Fe(2)—Fe(1) and N(2)—Fe(2)—N(1) angles are 86.64(6)° and 83.35(8)°. The Fe(1)—N(1)—Fe(2), Fe(1)—N(1)—C(1) and Fe(1)—C(1)—N(1) bond angles are 82.99°, 72.9(1)° and 65.7(1)°, respectively. The C(1)—N(1)—N(3) bond angle is squeezed to a value of 113.4(2)°. The Fe(2)—N(1)—C(1)—C(2)—N(2) atoms form a plane with a torsion angle of 21.44° between the C(1)—N(1) and C(2)—N(2) bonds. This implies that the planarity of the N=C—C=N system in the free ligand is not affected much by the σ-N, μ^2-N′, η^2-C=N′ type coordination [17b,18] and the dihedral angle defined by the mean plane of Fe(2)—N(1)—C(1)—C(2)—N(2) and the pyridine plane is 7.57°.

2.3.3. $Fe_2(CO)_6(C_4H_3SC_2N_4C_4H_3S)$ (**3a**)

The molecular structure of complex **3a**, as shown in Fig. 5, shows that the dithienyltetrazine ligand coordinates to the metal centers through one of its diazo moieties. The ligand has a σ-N, σ-N′, μ^2-η^2-N=N′ type of coordination mode in which the ligand forms a 6e bridge between the two $Fe(CO)_3$ units. The iron centers possess a distorted octahedral coordination geometry. The tricarbonyl groups are eclipsed. There are two geometries in the unit cell of **3a** with a difference in the orientation of the thienyl rings. The geometry of ligand **3**, as shown in Fig. 2, is planar with a C_{2h} symmetry. However, the two thienyl rings in complex **3a** are oriented in the same direction – with both of their thienyl S atoms pointing towards the iron centers in one geometry and backwards to the iron centers in the other geometry. In both cases the Fe—Fe bond is perpendicular to the N—N bond of the tertrazine ring. The dihedral angles between the central tetrazine ring and two thienyl rings, S(1)—C(2)—C(3)—C(4)—C(5) plane and S(2)—C(13)—C(14)—C(15)—C(16) plane, are 12.59° and 9.01°, respectively.

The Fe—Fe bond distance is 2.502(1) Å (Table 4). The bond distances Fe(1)—N(1), Fe(1)—N(2), Fe(2)—N(1) and Fe(2)—N(2) are 1.920(4), 1.918(4), 1.923(4) and 1.921(4) Å, respectively, which are shorter than usual nitrogen bridged diiron complexes. The Fe(1)—Fe(2)—N(1) and Fe(2)—Fe(1)—N(2) bond angles are 49.3(1)° and the Fe(2)—Fe(1)—N(1) and Fe(2)—Fe(1)—N(2) bond angles are 49.4(1)°. The bond angles of Fe(1)—N(1)—N(2), Fe(1)—N(2)—N(1), Fe(2)—N(1)—N(2) and Fe(2)—N(2)—N(1) are about the same and have an average value of 68.5(3)°. The N(1)—Fe(1)—N(2) and N(1)—Fe(2)—N(2) angles are also about the same (43.1(2)° versus 43.0(2)°), indicating that the Fe(1)Fe(2)N(2)N(1) core is quite symmetrical. The N(1)—N(2) bond of 1.410(6) Å is significantly elongated compared to the N(1)—N(2) bond distance (1.317(3) Å) in the highly conjugated ligand **3**, as expected for the σ-N and η^2-N=N bonding mode of this fragment. The elongation of N(3)=N(4), N(1)—C(1) and N(2)—C(12) bond distances (1.396(6), 1.395(6) and 1.410(6) Å) and the shortening of C(1)—N(3) and C(12)—N(4) distances (1.300(7) and 1.286(7) Å), relative to that in the uncoordinated ligand **3**, indicate that the aromaticity of the tetrazine ring has been destroyed and the ring has become the combination of a diaza (N—N) and a diimine (—C= N—N=C—).

2.3.4. $Fe_2(CO)_5PPh_3(C_4H_2SC_2N_4HC_4H_3S)$ (**3c**)

The molecular structure and bonding features of **3c**, as shown in Fig. 6 and Table 4, close resemble that of **3a** except one of carbonyl ligands on Fe(1) has been replaced by a triphenylphosphine ligand. The Fe(1)—P distance is 2.2542(2) Å. The P(1)—Fe(1)—N(1), P(1)—Fe(1)—N(2) and P(1)—Fe(1)—Fe(2) bond angles are 105.6(1)°, 104.5(1)° and 151.42(5)°, respectively. A disorder between S1 and S1a and between S2 and S2a on the two thiophene rings has been observed. The geometry of the molecule has ~70% with two thienyl sulfur atoms pointing toward the iron centers and ~30% with two sulfur atoms pointing backwards from the iron centers.

3. Conclusion

We have demonstrated that using different heterocyclic substituted azines **1**, **2** and **3** as ligands, hexacarbonyldiiron complexes with various coordination modes can be synthesized. In the reaction of iron carbonyls with azines, complexes with different coordination modes have been reported. In the reaction of $Fe_3(CO)_{12}$ with ketazines (R^1R^2C=N—N=C—R^1R^2, where $R^1 = R^2$ = Me; $R^1 = R^2 = p$-CH_3Ph; R^1 = Me, R^2 = Ph; R^1 = H, R^2 = thienyl), bis-(μ-ketoiminato)hexacarbonyldiiron complexes were produced, formed by cleavage of the N—N bond [10a,10f,19]. In contrast, in the similar benzaldazine system (R^1 = H, $R^2 = p$-substituted Ph), it led only to the *endo* cyclometallation of the phenyl ring [4a,20]. However, in

the reaction of *N*,*N*′-bis-(3-phenyl-allylidene)-hydrazine (RC=C–C=N–N=C–C=CR) with $Fe_2(CO)_9$, mono-, di- and tetrametallic iron carbonyl complexes were synthesized. In this case, no cleavage of the ligand was observed and only azomethine nitrogen atom(s) and allyl double bond(s) are bonded to the discrete $Fe(CO)_3$ center(s) [21]. Thus, the type of substituent on the azine system is critical for the way of complexation.

In this study, in the reaction with $Fe_2(CO)_9$, both N–N bond cleavage (η^2-N; η^2-N′ mode) and endo cyclometallation (μ-2,3-η^1:η^2-pyrrolyl; η^1:η^1(*N*) mode) are observed for ligand **1**, one pyridyl N and one imine-bridged (μ-σ;π-η^1:η^2-(*C*, *N*); η^1(N_{py}) mode), and two pyridyl N and one imine-bridged (μ-π-η^1:η^1-(*C*,*N*); η1(N_{py}); η^1(N'_{py}) mode) coordinations are found in the case of ligand **2**, whereas diaza-bridged (μ-η^2:η^2-(*N*,*N*′) mode) and endo cyclometallated (μ-2,3-η^1:η^2-thienyl; η^1:η^1(*N*) mode) coordinations are involved in the case of ligand **3**.

4. Experimental

4.1. General

Diiron nonacarbonyl was prepared through the photolysis of iron pentacarbonyl (Aldrich) in glacial acetic acid [22]. Solvents were dried (sodium/benzophenone, P_4O_{10}) and distilled under nitrogen prior to use. *N*-Methyl-2-pyrrolecarboxaldehyde (Acros) and 2-thiophenemethylamine (Aldrich) were distilled by a Kugelrohr distillation apparatus under reduced pressure (0.1 mmHg) prior to use. All other chemicals were reagent grade and used without further purification. The NMR spectra were recorded on a Bruker DX-300 NMR spectrometer (^{1}H, 299.95 MHz; ^{13}C, 75.43 MHz). Chemical shifts were referenced to TMS and deuterated acetone (Janssen) was used as a solvent and as a secondary reference. Mass spectra were obtained from a Micromass Platform II spectrometer. IR spectra were recorded employing a Mattson Genesis FTIR spectrophotometer. Elemental analyses were performed using a Perkin–Elmer 2400, 2400II elemental analyzer. Crystals for X-ray diffraction were obtained from ethyl acetate/dichloromethane (**1**), ethyl acetate/methanol (**1a**), ethyl acetate/ether (**2a**) and dichloromethane (**3**, **3a** and **3c**). A single crystal was mounted on a glass fiber and the X-ray diffraction intensity data were measured on a Bruker Smart 1000 CCD XRD (**1** and **1a**) or a Rigaku AFC7S diffractometer (**2a**, **3**, **3a**, and **3c**).

4.2. Synthesis of Schiff bases 1,4-di-(*N*-methyl-2′-pyrrolyl)-2,3-diaza-1,3-butadiene (*1*) and 1,4-di-(6-methyl-2′-pyridyl)-2,3-diaza-1,3-butadiene (*2*)

The synthesis of Schiff bases employed the usual approach of condensation in alcohol solution [23]. *N*-Methyl-2-formylpyrrol or 6-methyl-2-formylpyridine (40.0 mmol) and $N_2H_4 \cdot H_2O$ (Acros, 20.0 mmol) were heated at reflux in 95% ethanol (E. Merck, 100 mL) for 24 h. The solvent was removed by filtration. The precipitate was washed with several portions of ether and dried in vacuo to give pure yellow product **1** (18.8 mmol, 94% yield) or **2** (19.6 mmol, 98% yield).

*Compound **1**:* M.p. 114–115 °C. ^{1}H NMR: δ 8.50 (s, 2H), 6.93 (d, J_{H-H} = 2.6 Hz, 2H), 6.61 (d, J_{H-H} = 3.8 Hz, 2H), 6.15 (dd, J_{H-H} = 3.9, 2.7 Hz, 2H), 3.99 (s, 6H). ^{13}C NMR: δ 151.8, 128.8, 127.8, 117.0, 108.6, 36.1. IR (KBr film) $\nu_{C=N}$: 1625 cm^{-1}. MS (FAB): *m*/*z* 214 (M^+). *Anal.* Calc. for $C_{12}H_{14}N_4$: C, 67.28; H, 6.54; N, 26.16. Found: C, 67.01; H, 6.64; N, 26.30%.

*Compound **2**:* M.p. 175–176 °C. ^{1}H NMR (methanol-d_4): δ 8.58 (s, 2H), 7.98 (d, J_{H-H} = 7.8 Hz, 2H), 7.82 (t, J_{H-H} = 7.8 Hz, 2H), 7.37 (d, J_{H-H} = 7.8 Hz, 2H), 2.60 (s, 6H). ^{13}C NMR (methanol-d_4): δ 161.4, 158.8, 151.8, 137.4, 125.2, 119.4, 22.5. IR (KBr film) $\nu_{C=N}$: 1630 cm^{-1}. MS (FAB): *m*/*z* 239 (M^+). *Anal.* Calc. for $C_{14}H_{16}N_4$: C, 70.00; H, 5.87; N, 23.32. Found: C, 70.29; H, 5.79; N, 23.45%.

4.3. Synthesis of 3,6-bis(2′-thienyl)-1,2,4,5-tetrazine (*3*)

2-Thiophenecarbonitrile (4.36 g, 40.0 mmol) and hydrazine monohydrate (8.00 g, 160 mmol) were refluxed in ethanol (Merck, 50 ml) for 48 h. After the filtration, the filtrate was stirred at room temperature under air for 12 h. The red precipitate was collected and recrystallized using dichloromethane as a solvent to give pure product **3** (21.6 mmol, 54% yield). M.p. 191.5–192.5 °C. ^{1}H NMR: δ 8.28 (dd, *J* = 3.6, 1.2 Hz, 2H), 7.96 (dd, *J* = 3.6, 1.2 Hz, 2H), 7.38 (dd, *J* = 5.1, 3.6, 2H). ^{13}C NMR: δ 162.6, 137.3, 133.6, 131.6, 130.1. IR (KBr film) $\nu_{C=N}$: 1533 cm^{-1}. MS (FAB): *m*/*z* 247 (M^+). *Anal.* Calc. for $C_{10}H_6N_4S_2$: C, 48.78; H, 2.44; N, 22.76; S, 26.02. Found: C, 48.84; H, 2.56; N, 22.78; S, 26.62%.

4.4. Reaction of *1* with $Fe_2(CO)_9$ in refluxing toluene to yield complexes *1a* and *1b*

1.07 g (5.0 mmol) of compound **1** and 5.46 g (15.0 mmol) of $Fe_2(CO)_9$ were heated at reflux in 60 ml of toluene in the dark under nitrogen for 12 h. The reaction mixture was filtered through Celite 545 and the solvent was removed under reduced pressure. The residue was separated by a 3.5 cm diameter and 40 cm height column (230–400 mesh ASTM silica gel (Merck)) with ether/*n*-hexane (1:3) as eluent. The orange red band produced 0.97 g (2.0 mmol, 40% yield) of complex **1a**. The red band produced 0.69 g (1.4 mmol, 28% yield) of complex **1b**.

*Complex **1a**:* M.p. 148–149 °C. ^{1}H NMR: δ 9.00 (s, 2H), 6.93 (dd, J_{H-H} = 2.4, 2.1 Hz, 2H), 6.84 (dd, J_{H-H} = 3.6, 2.1 Hz, 2H), 6.20 (dd, J_{H-H} = 3.6, 2.7 Hz, 2H), 3.74 (s, 6H). ^{13}C NMR: δ 207.1, 155.7, 128.8, 126.1, 117.1, 108.6, 36.1. IR (CH_2Cl_2) $\nu_{C=N}$: 1638 cm^{-1}, $\nu_{C=O}$: 2061, 2021, 1972 cm^{-1}. MS (FAB): *m*/*z* 495 (M^+), 467 (M^+–CO), 439 (M^+–2CO), 411 (M^+–3CO), 383 (M^+–4CO), 355 (M^+–5CO), 327 (M^+–6CO), 271 (M^+–6CO–Fe). *Anal.*

Calc. for $C_{18}H_{14}Fe_2N_4O_6$: C, 43.76; H, 2.86; N, 11.34. Found: C, 43.65; H, 2.94; N, 11.24%.

Complex ***1b***: M.p. 129–130 °C. ^{1}H NMR: δ 7.96 (s, 1H), 7.23 (d, $J_{H-H} = 2.7$ Hz, 1H), 6.86 (d, $J_{H-H} = 2.7$, 1H), 6.55 (d, $J_{H-H} = 2.7$ Hz, 1H), 6.44 (dd, $J_{H-H} = 3.6$ Hz, 1H), 6.08 (dd, $J_{H-H} = 3.6$, 2.7 Hz, 1H), 4.53 (s, 2H), 4.21 (s, 6H). ^{13}C NMR: δ 211.9, 151.8, 144.7, 141.0, 131.9, 128.5, 126.7, 116.6, 117.6, 108.2, 61.8, 36.3, 34.7. IR (CH_2Cl_2) $\nu_{C\equiv N}$: 1638 cm^{-1}, $\nu_{C\equiv O}$: 2055, 2011, 1963 cm^{-1}. MS (FAB): *m/z* 495 (M^+), 466 (M^+-CO), 438 (M^+-2CO), 410 (M^+-3CO), 382 (M^+-4CO), 354 (M^+-5CO), 326 (M^+-6CO), 270 (M^+-6CO—Fe), 214 (L^+). *Anal.* Calc. for $C_{18}H_{14}Fe_2N_4O_6$: C, 43.76; H, 2.86; N, 11.34. Found: C, 43.85; H, 2.98; N, 11.17%.

4.5. Reaction of ***2*** *with $Fe_2(CO)_9$ in THF to yield complexes* ***2a*** *and* ***2b***

1.50 g (6.20 mmol) of compound **2** and 7.30 g (20.0 mmol) of $Fe_2(CO)_9$ were heated at reflux in 100 ml of anhydrous THF in the dark under nitrogen for 24 h. The reaction mixture was filtered through Celite 545 and the solvent was removed under reduced pressure. The residue was chromatographed on a silica gel column with ethyl acetate and then with ethanol as eluent to isolate dark red product **2a** (0.85 g, 1.6 mmol, 26% yield) and purple complex **2b** (1.30 g, 2.45 mmol, 40% yield), respectively.

If the reaction was carried on at room temperature, complex **2a** (3.3 mmol, 53% yield) and trace amount of complex **2b** were isolated. If the reaction was preceded under irradiation of UV light, only complex **2b** was produced in 94% yield.

Complex ***2a****:* M.p. 126–127 °C. ^{1}H NMR: δ 8.82 (s, 1H), 7.98 (d, $J_{H-H} = 7.8$ Hz, 1H), 7.81 (t $J_{H-H} = 7.8$ Hz, 1H), 7.45 (t, $J_{H-H} = 7.8$ Hz, 1H), 7.37 (d, $J_{H-H} = 7.8$ Hz, 1H), 7.21 (d, $J_{H-H} = 7.8$ Hz, 1H), 6.79 (d, $J_{H-H} = 7.5$ Hz, 1H), 4.82 (s, 1H), 2.64 (s, 3H), 2.62 (s, 3H). ^{13}C NMR: δ 212.8, 170.3, 160.7, 158.8, 155.7, 151.9, 137.8, 137.1, 124.3, 120.3, 118.6, 115.6, 67.9, 26.0, 23.4. 4.7. Reaction of complex ***3a*** *with triphenylphosphine in dichloromethane to give* ***3c*** *and* ***3d***

0.20 g (0.38 mmol) of complex **3a** in a 50 ml of anhydrous dichloromethane was stirred with 0.20 g (0.76 mmol) of PPh_3 at room temperature under N_2 atmosphere for 24 h. After the filtration, the solvent was removed under reduced pressure and the residue was separated by a 3.5 cm diameter and 40 cm height column (230–400 mesh) with ethyl acetate/*n*-hexane (1:5) as eluent to give 0.26 g (0.34 mmol, 89% yield) of complex **3c** and 40 mg (0.040 mmol, 10% yield) of complex **3d**.

Complex ***3c****:* M.p. 171.4–172.0 °C (decomp.). ^{1}H NMR: δ 7.89 (d, $J = 5.1$ Hz, 2H), 7.49 (d, $J = 3.6$ Hz, 1H), 7.32 (dd, $J = 5.1$, 3.6 Hz, 2H), 7.27 (m, 15 H). ^{13}C NMR: δ 211.4, 156.9, 135.3, 134.6, 134.0, 133.7, 133.5, 132.9, 131.5, 129.9, 129.6, 129.4, 129.3. Fig. 1. Schematic examples of trinuclear silver(I) alkyne clusters.

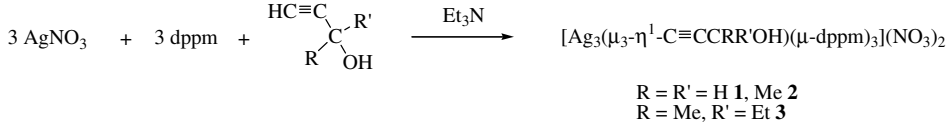
have been studying binuclear phosphane gold(I) acetylide complexes [12] as well as complexes containing the readily available propargyl alcohol ligands HC≡CCRR′OH (R = R′ = H, Me; R = Me, R′ = Et) [13]. Sigma-bonded *C*-coordinated propargyl alcohols readily undergo dehydration reactions (often spontaneous) to form vinylidene or allenylidene complexes, particularly in the presence of metals such as Os, Ru and Pt [14]. There are, however, very few examples of metal complexes containing σ-bonded *C*-coordinated propargyl alcohol ligands that do not undergo any dehydration reactions. We therefore wished to extend our studies of metal complexes of propargyl alcohols by preparing some silver(I) derivatives. The results of our investigation are presented here.

2. Results and discussion

Initially we attempted to react the propargyl alcohols 3-methyl-1-pentyn-3-ol, 2-methyl-3-butyn-2-ol and propargyl alcohol with the dinuclear silver(I) complex $[Ag_2(\mu\text{-dppm})_2](NO_3)_2$ in the presence of KOH. Somewhat surprisingly, we found that under these conditions no reaction took place; only starting materials were recovered. We then attempted to prepare silver(I) acetylides of the propargyl alcohols and planned to react those with dppm. However, during isolation of one of the propargyl silver(I) acetylides a violent explosion occurred! This prompted us to develop a new and safer method for the preparation of trinuclear silver(I) clusters. The strategy we employed was to prepare the polymeric silver(I) acetylides in situ and then to immediately react those with dppm. Thus, treatment of a MeCN solution of $AgNO_3$ with 0.33 equivalents of propargyl alcohol derivative and Et_3N resulted in instantaneous precipitation of the silver(I) acetylide complexes. Upon addition of dppm a pale yellow solution formed out of which the trinuclear silver(I) clusters $[Ag_3(\mu_3\text{-}\eta^1\text{-}C{\equiv}CCRR'OH)(\mu\text{-dppm})_3](NO_3)_2$ (R = R′ = H (**1**), Me (**2**); R = Me, R′ = Et (**3**)) could be isolated as air- and light-stable colourless solids in good yields after removal of $[Et_3NH]NO_3$ and recrystallisation (Scheme 1).

During the course of optimising reaction conditions, we found that the reaction time between the alkyne, Et_3N and $AgNO_3$ is critical to obtain a pure product. Even though the silver(I) acetylides precipitate instantaneously, shorter reaction times lead to isolation of a mixture of the desired Ag_3 clusters and the binuclear silver(I) dppm complex $[Ag_2(\mu\text{-dppm})_2](NO_3)_2$; in extreme cases a 50:50 mixture of these two complexes was obtained. The $^{31}P\{^1H\}$ NMR spectra (Fig. 2) of all three complexes consist of a pair of multiplet resonances, the major lines of which are separated by ca. 391 Hz. This coupling pattern is due to superposition of all four possible ^{31}P, ^{107}Ag and ^{109}Ag isotopomers ($^{107}Ag_3{}^{31}P$, $^{107}Ag_2{}^{109}Ag{}^{31}P$, $^{107}Ag{}^{109}Ag_2{}^{31}P$ and $^{109}Ag_3{}^{31}P$) further complicated by the fact that the two phosphorus atoms on each dppm unit are non-equivalent. At low temperatures (−80 °C) this spectral pattern did not change significantly, thus preventing us from obtaining data useable to attempt a simulation of this rather complex spin system.

The ^1H NMR spectra of the three compounds show very broad resonances for the dppm CH_2 protons, as well as the expected signals for the propargyl alcohol ligands. In the case of complex **1**, the hydroxyl proton can be observed as a triplet with small coupling (ca. 4 Hz) with the propargyl alcohol methylene protons. The IR spectra of complexes **1**–**3** show a weak signal due to the C≡C stretch at ca. 1965 cm^{-1}, typical for metal acetylide compounds. In the FAB+ mass spectra weak peaks of the mono-nitrato cationic clusters as well as peaks due to loss of dppm ligands are observed. The trinuclear structure of these compounds was confirmed by an X-ray crystallographic study of complex **3**. The unit cell contains a total of four molecules, two *R* and two *S* enantiomers due to the chiral centre



Scheme 1.

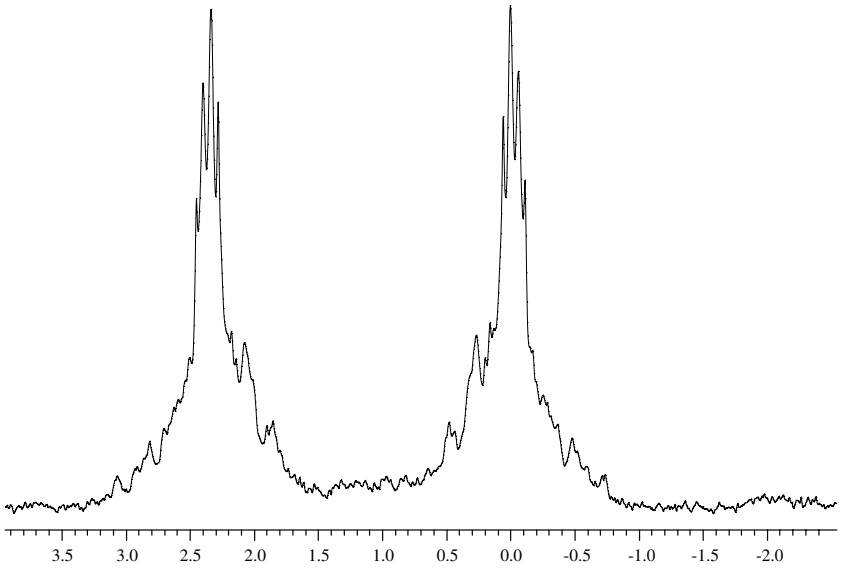


Fig. 2. Room temperature $^{31}P\{^{1}H\}$ NMR spectrum of complex **2**.

at C6. The molecular structure of one of these molecules is shown in Fig. 3. The complex consists of a planar triangle of silver atoms with Ag···Ag distances of 3.0046(7), 3.1876(7) and 3.3840(7) Å, bridged by three molecules of dppm. Although these distances represent only weak, if any, bonding interactions (van der Waals radius of silver 1.72 Å), they are examples of *argentophilicity*, i.e. weak closed-shell interactions between silver atoms [15,16]. The carbon atom of the alkynyl group, C(4), located above the centre of the Ag triangle, triply bridges the three silver atoms with the respective Ag–C distances being 2.265(5), 2.278(6) and 2.358(6) Å. On the other side of the Ag_3 triangle, a nitrato group acts as a weakly μ_3-bridging ligand via only two oxygen atoms so that the Ag(1)···O(2), Ag(2)···O(4) and Ag(3)···O(4) distances are 2.625(5), 2.700(5) and 2.783(5) Å, respectively. The other nitrate anion is located in the crystal space far away from the cluster but is associated via hydrogen bonding interactions to the O(1) atom of the acetylide group. In this case, and for the major component of the disordered acetylide, the O(1)–H atom lies between the O(5) and O(6) atoms and

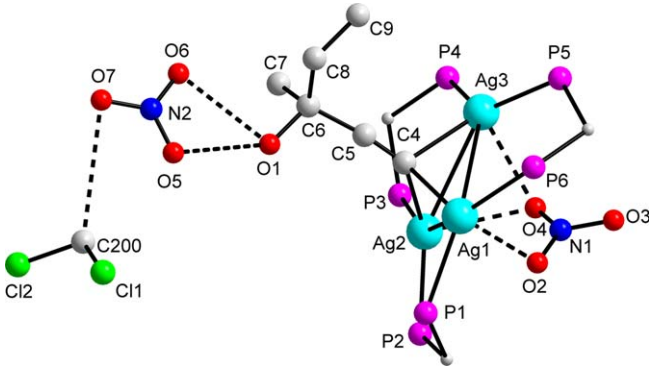

Fig. 3. Molecular structure of one of the enantiomers of *rac*-$[Ag_3\{\mu_3\text{-}\eta^1\text{-}C{\equiv}CC(Et)(Me)OH\}(\mu_2\text{-}O\text{-}NO_3)(\mu\text{-dppm})_3]NO_3 \cdot CH_2Cl_2$. Phenyl groups of the dppm ligands and hydrogen atoms have been omitted for clarity.

forms hydrogen bonds of O(1)–H···O(5) 2.28 Å [O(1)···O(5) = 2.940(12) Å] and an angle of 138°; the equivalent parameters for the O(1)–H···O(6) interaction are 2.10 Å, 2.859(12) Å and 154°. In turn, this nitrate anion is connected to the dichloromethane molecule of solvation with the most directional interaction involving the hitherto unused O(7) atom: C(200)–H···O(7) is 2.46 Å, C(200)···O(7) is 3.392(10) Å with an angle at H of 162°.

The three Ag···Ag distances in complex **3** are longer and more asymmetric than those in $[Ag_3(\mu_3\text{-}\eta^1\text{-}C{\equiv}CPh)_2(\mu\text{-dppm})_3]Cl$ [Ag···Ag = 2.983(1) and 2.866(2) Å] [6] but very similar to those in $[Ag_3(\mu_3\text{-}\eta^1\text{-}C{\equiv}CC_6H_4\text{-}4\text{-}NO_2)(\mu\text{-dppm})_3](BF_4)_2$ [Ag–Ag = 2.9850(6), 3.0877(6) and 3.4030(6) Å] [8]. It is worth noting the similarly in the asymmetry of the Ag···Ag distances: like in complex **3** two Ag–Ag distances are ca. 3 Å, while one is considerably longer with ca. 3.4 Å. Interestingly, in the ferrocenyl substituted alkyne cluster $[Ag_3(\mu_3\text{-}\eta^1\text{-}C{\equiv}CFc)(\mu\text{-dppm})_3](OTf)_2$ the Ag–Ag distances [Ag–Ag = 3.2416(6), 3.2451(6) and 3.2527(6) Å] are almost equal [9]. The angles within the Ag_3 triangle [54.32(1)°, 59.51(1)° and 66.18(2)°] as well as the Ag–C distances. are also very similar to those in $[Ag_3(\mu_3\text{-}\eta^1\text{-}C{\equiv}CC_6H_4\text{-}4\text{-}NO_2)(\mu\text{-dppm})_3](BF_4)_2$ [54.49°, 57.37° and 68.14° (no SUs given)] [Ag–C = 2.224(5), 2.269(5), 2.349(6) Å] [8]. All other bond distances and angles are unexceptional. Complexes **1**–**3** are luminescent in the solid state, both at room temperature and at 77 K. Photophysical data are shown in Table 1 and the emission spectrum (298 K) of complex **3** is shown in Fig. 4.

The emission maxima of complexes **1**–**3** are similar to those reported for other trinuclear silver(I) acetylide clusters [6,8]. At 298 K two maxima are observed for complexes **1** and **3**, whilst complex **2** displays a single broad band. Upon cooling to 77 K single, very broad bands are observed for all three complexes. The lowest energy transition is likely to be due to metal–metal $[d_{\sigma^*}(M\cdots M)]$ to ligand $[\pi^*(RC{\equiv}C^-)]$ charge transfer bands, consistent with

Table 1
Photophysical data of complexes **1**–**3**[a]

Complex	Emission λ_{max} (nm) at 298 K	Emission λ_{max} (nm) at 77 K
1	536, 565	550
2	540 (broad)	545
3	527, 545	530

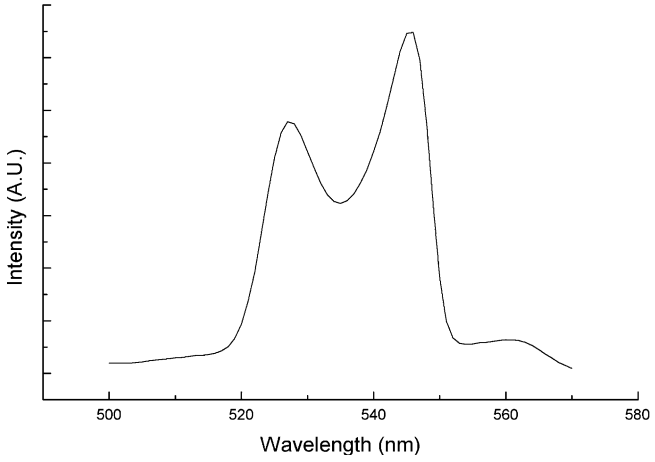

Fig. 4. The solid-state emission spectra of complex **3** at 298 K.

spectral and computational data reported by Che and co-workers [6].

We also attempted to prepare bicapped silver(I) clusters of the type $[Ag_3(\mu_3\text{-}\eta^1\text{-}C{\equiv}CR)_2(\mu\text{-dppm})_3]NO_3$, however, even with a large excess of alkyne only the monocapped cluster was formed. This result is in contrast to the work by Yam et al. who have successfully prepared and structurally characterised the bicapped cluster $[Ag_3(\mu_3\text{-}\eta^1\text{-}C{\equiv}CC_6H_4\text{-}4\text{-}NO_2)_2(\mu\text{-dppm})_3]OTf$ by simply increasing the ratio of alkyne:Ag [8]. A likely explanation for this behaviour in our case is the presence of the bridging nitro group. The Ag–O bonds may simply be too strong compared to the Ag–C bond so that addition of a second alkyne is disfavoured. We therefore attempted to prepare the bicapped cluster by using $AgBF_4$ as silver(I) precursor, however, during formation of the polymeric silver(I) acetylide significant decomposition to metallic Ag occurred and the only isolated product was the dinuclear $[Ag_2(\mu\text{-dppm})_2](OTf)_2$, as evident from the $^{31}P\{^1H\}$ NMR spectrum. Similarly, when AgOTf was used as precursor, we only obtained the monocapped clusters independent of the Ag:alkyne ratio. We also attempted to introduce the second alkyne by reacting the monocapped cluster **1** with a further equivalent of alkyne in the presence of Et_3N; however, after stirring for ca. 18 h only unreacted cluster **1** was isolated after work-up.

In conclusion, we present here a safe and simple one-pot self-assembly reaction that allows the high-yield synthesis of monocapped trinuclear silver(I) clusters with hydroxy-functionalised alkynes from simple, commercially available starting materials.

3. Experimental

3.1. General

^1H and $^{31}P\{^1H\}$ NMR spectra were recorded on a 400 MHz Bruker Avance spectrometer. Chemical shifts are quoted relative to external TMS (^1H) and 85% H_3PO_4 (^{31}P); coupling constants are reported in Hz. FAB mass spectra were measured on a VG Autospec spectrometer in positive ion mode using NBA as matrix. IR spectra were run as KBr pellets on a Perkin–Elmer Spectrum One instrument. Solid-state luminescence spectra were recorded at 275 and 77 K using a Fluorolog FL-11 spectrometer. All reagents and solvents were commercially available and used as received. All compounds gave satisfactory elemental analyses.

3.2. Preparation of $[Ag_3(\mu_3\text{-}\eta^1\text{-}C{\equiv}CRR'OH)(\mu\text{-dppm})_3](NO_3)_2$ complexes

To a solution of $AgNO_3$ (0.174 g, 1.02 mmol) in MeCN (10 mL) was added propargyl alcohol derivative (0.343 mmol) followed by Et_3N (0.4 mL, excess). After stirring the mixture protected from light for 3 h solid dppm (0.392 g, 1.02 mmol) was added. After a further 18 h of stirring the pale yellow solutions were passed through Celite and evaporated to dryness. The resulting solids were washed well with H_2O, Et_2O and dried. Recrystallisation from CH_2Cl_2/hexane afforded the complexes as colourless, crystalline solids.

Using this procedure the following compounds were prepared.

3.2.1. $[Ag_3(\mu_3\text{-}\eta^1\text{-}C{\equiv}CCH_2OH)(\mu\text{-dppm})_3](NO_3)_2$ (**1**)

Yield: 99% (no recrystallisation was necessary for this complex). ^1H NMR (400 MHz, $CDCl_3$, 25 °C): $\delta = 6.89$–7.20 (m, 60H, PPh_2), 6.25 (t, $J = 4.1$ Hz, 1H, O*H*), 4.66 (d, $J = 3.8$ Hz, 2H, CCH_2), 3.43 (br s, 6H, PCH_2P). $^{31}P\{^1H\}$ NMR (162 MHz, $CDCl_3$, 25 °C): $\delta = 1.16$ (centre of complex pattern; separation of main lines = 391 Hz). FAB MS *m*/*z* (%) = 1593 (5) $[M-NO_3]^+$, 1210 (25) $[M-NO_3-dppm]^+$. IR (KBr disk) 3289 cm^{-1} ν(OH), 1966 cm^{-1} ν(C≡C).

3.2.2. $[Ag_3(\mu_3\text{-}\eta^1\text{-}C{\equiv}CCMe_2OH)(\mu\text{-dppm})_3](NO_3)_2$ (**2**)

Yield: 57%. ^1H NMR (400 MHz, $CDCl_3$, 25 °C): $\delta = 6.90$–7.28 (m, 60H, PPh_2), 3.47 (br s, 6H, PCH_2P), 1.61 (s, 6H, Me). $^{31}P\{^1H\}$ NMR (162 MHz, $CDCl_3$, 25 °C): $\delta = 1.87$ (centre of complex pattern; separation of main lines = 390 Hz). FAB MS *m*/*z* (%) = 1621 (11) $[M-NO_3]^+$, 1236 (30) $[M-NO_3-dppm]^+$. IR (KBr disk) 3392 cm^{-1} ν(OH), 1965 cm^{-1} ν(C≡C).

3.2.3. rac-$[Ag_3\{\mu_3\text{-}\eta^1\text{-}C{\equiv}CC(Me)(Et)OH\}(\mu\text{-dppm})_3](NO_3)_2$ (**3**)

Yield: 80%. ^1H NMR (400 MHz, $CDCl_3$, 25 °C): $\delta =$ 6.89–7.28 (m, 60H, PPh_2), 3.47 (br s, 6H, PCH_2P), 1.85

FAB MS m/z (%): 1637 (10) $[M-NO_3]^+$, 1250 (35) $[M-NO_3-dppm]^+$. IR (KBr disk) 3296 cm^{-1} ν(OH), 1964 cm^{-1} ν(C≡C).

3.3. X-ray crystallography

Crystals of complex **3** suitable for X-ray diffraction were obtained by slow diffusion of hexane into a CH_2Cl_2 solution of the compound. A colourless needle with the dimensions $0.04 \times 0.09 \times 0.16$ mm^3 was mounted in oil on a glass fibre. Data were collected at 100 K using a Bruker Apex CCD. Data reduction and empirical absorption corrections were applied using SADABS [17]. The structure was solved using direct-methods and refined on F^2 using a full-matrix least-squares procedure [18]. Despite the data having been collected at 100 K, considerable disorder was noted in the structure. Two positions were discerned for the acetylide residue disposed approximately 120° to each other with respect to the C4–C6 axis. From refinement, the site occupancies were 0.676(10):0.324(10); the atoms comprising the disordered residue were refined with isotropic thermal parameters. Soft restraints were introduced (i.e. C–O = 1.35 Å and C–C = 1.52 Å) so as to allow for a chemically sensible model and, finally, the aromatic rings were refined as rigid hexagonal C_6H_5 groups. The remaining atoms were refined with anisotropic displacement parameters and all hydrogen atoms included in their calculated positions, including for the disordered residue. With the above model, convergence was readily achieved and the final shift/error (Δ/σ) was <0.001. Crystallographic and refinement details are collected in Table 2.

4. Supplementary data

Full crystallographic details for complex **3** (CIF file format) are available from the CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK by quoting the deposition code CCDC 600470.

2. Results and discussion

2.1. Synthesis of ligand *1*

The new bidentate ligand **1** was synthesized with anisole as starting material. Dry anisole was added at room temperature to *n*-BuLi in which *n*-hexane has been removed, and then the mixture was heated to 80 °C for 48 h to obtain the lithium salt of anisole. Reaction of the lithium salt with 2,3,4,5-tetramethyl-2-cyclopentenone in toluene at room temperature, followed by hydrolysis with saturated NH_4Cl (aq) and dehydration with concentrated HCl produced the ligand **1** (Scheme 1) in a moderate yield. The lithium salt of anisole could not be obtained when reactions were carried out in the presence of Et_2O or THF as solvent. The preparation of the lithium salt of anisole was reported in literature by reaction of 2-bromoanisole with *n*-BuLi [3a]. In comparison with the literature method, our method is simple and low cost. Ligand **1** was characterized by elemental analysis and NMR spectroscopy. ^{1}H NMR spectroscopic analysis indicates that freshly prepared sample of **1** is a mixture of three isomers, and the ratio of the isomers changes with time. When the sample was left at room temperature, one of the isomers was found to become the major product after several days. It has been reported by Marks et al. that a single isomer of the similar ligand for **I** was obtained after vacuum distillation [4]. Similar behavior has also been observed for the *N*,*N*-dimethylaminophenyl-tetramethylcyclopentadiene ligand system [10] and the substituted tetramethylcyclopentadienylphenol ligands [9].

2.2. Synthesis of (TCP)$TiCl_2$ (*2*)

Complex **2** was prepared by a convenient procedure (Scheme 2) from the reaction of $TiCl_4$ with the lithium salt of **1**. The ligand **1** was treated with one equivalent of *n*-BuLi, and then a solution of $TiCl_4$ in toluene was slowly added at −78 °C. The reaction mixture was allowed to warm to room temperature and then was heated to 65 °C overnight. After filtration and concentration of the reaction mixture, complex **2** was obtained as a yellowish crystalline solid in a moderate yield. The reaction was tried by One-Step Direct Synthesis strategy [11] while the yield of product was low. When the reaction was carried out at room temperature, some red oil was obtained. ^{1}H NMR analysis indicates that the red oil is a complicated mixture from which no pure compound could be isolated. Complex **2** should be formed by a CH_3Cl elimination reaction through a thermocyclization procedure (Scheme 3). It has been reported that the thermocyclization could take place between Ti–Cl and O–CH_3 in monocyclopentadienyltitanium trichloride complexes with a pendant methoxyphenyl group [3a,12]. The solid sample of complex **2** was found to be considerably stable to air and moisture and could be exposed to air for several days without obvious decomposition. Complex **2** also exhibits good thermostability and could be heated to 200 °C without decomposition.

2.3. Crystal structures of 2 and IVd

The molecular structures of complexes **2** and **IVd** were determined by X-ray crystal structure analyses. The ORTEP drawings of the molecule structures are shown in Figs. 1 and 2. The selected bond lengths and angles are summarized in Table 1. There are two independent molecules (**IVd** and **IVd′**) with minor structural differences in one unit cell for **IVd**. Selected bond lengths and angles for **IVd** will be used in subsequent discussion. The general structure features of **2** and **IVd** are comparable to those previously reported for **III**, **IV** and **I**. All molecules adopt C_s-symmetry with pseudo-tetrahedral geometry. The Cp(cent)–Ti–O angles for **2** and **IVd** are 107.4° and 107.0°, which are in line with those of complexes **IIIa**–**IIIb** (107.4°, 106.7°) [8], **IVa**–**IVc** (106.8°, 107.1°, 107.3°) [9], and that in **I** (107.7°) [4], indicating similar sterically open features for **2** to complexes **III**, **IV** and **I** as catalyst precursors. The Ti–C(ring) (av.) distances of 2.016 Å for **2** and 2.012 Å for **IVd** are similar to those in **IIIa**–**IIIb** (2.031 Å, 2.032 Å) [8]and **IVa**–**IVc** (2.014 Å, 2.005 Å, 2.011 Å) [9], and shorter than that in **I** (2.36(1) Å) [4]. The distances of Ti–C3 and Ti–C4 in **2** and **IVd** are obviously longer than those of the rest Ti–C(ring) bonds and the Ti–Cp(cent)–C1 angles of **2** (87.6°) and **IVd** (88.6°) are less than 90°, which is characteristic of constrained geometry metallocene catalyst [2–4]. The phenolate plane–Cp plane dihedral angle is 89.8° for **2** and 85.5° for **IVd** and the (phenolate)C–C(ring) vector is bent 11.2° in **2** and 12.0° in **IVd** from the Cp ring plane, which are similar to those for complexes **IIIa**–**IIIb** (89.7° and 9.4°, 86.5° and 9.4°) [8], **IVa**–**IVc** (89.3° and 9.9°, 87.6° and 10.8°, 85.3° and 11.3°) [9]. The corresponding data in **I** are 81(1)° and 15(1)°, reflecting less steric strain in **2**, **III** and **IV** than that in **I** in the solid state. The Ti–O bond lengths of 1.846(2) Å in **2** and 1.823(2) Å in **IVd** are shorter than that in **I** (1.851(7) Å) but longer than those in **IIIa** (1.813(4) Å) and **IIIb** (1.818(4) Å), while the Ti–O–C angles of 127.3(2)° in **2** and 127.7(2)° in **IVd** are larger than the one in **I** (126.6(6)°) and smaller than those in **IIIa**–**IIIb** (129.1(4)°, 129.8(4)°) [8], **IVa**–**IVb** (128.9(3)°, 128.8(4)°, 128.31(18)°) [9]. These results indicate that the Ti–O double-bond character [4,13] in **2** and **IVd** are intermediate compared with that in **III**, **IV** and **I**. It should be pointed out that the differences in solid state structures of **2**, **III**, **IV** and **I** probably result from packing force since there is no other reasonable explanation for them [8,9].

2.4. Ethylene polymerization studies

Complex **2** was studied briefly as ethylene polymerization catalyst together with other complexes **IVa–d** of this type and the results were summarized in Table 2. Upon alkylation and activation with Al^iBu_3 and $Ph_3C^+B(C_6F_5)_4^-$, complex **2** show moderate catalytic activity for ethylene polymerization, producing polyethylenes with moderate molecular weights and melting points, which are comparable to complexes **IVa–d**. The catalytic activity of complex **2** is slightly lower than those of complexes **IVc** and **IVd**, while obviously lower than those of **IVa** and **IVb**. These results further confirm the influence of the substituents on the phenolate on the catalytic property [9]. On the other hand, it was found that the M_η of the polyethylene produced by complex **2** is somewhat higher than those of polymers produced by **IVc** and **IVd** under similar conditions. It is possible that the O atom in **2** can coordinate to Al^iBu_3 due to the absence of a substituent at the *ortho* position of the phenolate, which should make the ligand bulkier and therefore affect the rates of chain propagation and termination reactions. Similar to complexes **IV**, the catalytic activity of **2** increases with the increase of Al/Ti ratio and reaches the highest catalytic activities with the Al/Ti ratio about 75. Further increase of the Al/Ti ratio results in a decrease in the catalytic activity. A possible explanation for this is that excessive Al^iBu_3 would consume so much $Ph_3C^+B(C_6F_5)_4^-$ that the catalyst could not be efficiently activated [14]. The catalytic activity of **2** was also found to increase with the B/Ti ratio increasing from 1.1 to 1.3. Further increase of the B/Ti ratio results in a decrease in the catalytic activity. It is understandable that excessive $Ph_3C^+B(C_6F_5)_4^-$ would further react with the already activated catalyst cation and deactivate the catalyst. The catalytic activity of complex **2** is also sensitive to temperature, which has been attributed to tight interaction between the catalyst cation and the cocatalyst anion in the constrained geometry catalyst systems [15]. The degree of ethyl branching is about 1 branch per 1000 C atoms for samples obtained with **2,** which is similar to the samples obtained with **IV**.

3. Experimental

3.1. General comments

Reactions with organometallic reagents were carried out under an argon atmosphere (ultra-high purity) using standard schlenk techniques [16]. Solvents were dried and distilled prior to use [17]. Polymerization grade ethylene was further purified by passage through columns of 10 A molecular sieves and MnO. $Al(^iBu)_3$, *n*-BuLi and $TiCl_4$ were purchased from Aldrich. 2,3,4,5-Tetramethyl-2-cyclopentenone [18], $Ph_3C^+B(C_6F_5)_4^-$ [19], and complex **IVd** [9] were prepared according to the literature procedures. NMR spectra were measured using a Varian Mercury-300 NMR spectrometer.

3.2. Preparation of 1-(2-methoxyphenyl)-2,3,4,5-tetramethyl cyclopentadiene (*1*)

8.3 mL of anisole (0.076 mol) was added dropwise to 76.0 mL (0.076 mol) of 1.0 M *n*-BuLi, in which the *n*-hexane has been evaporated, and then the mixture was heated to 80 °C for 48 h. The anisole lithium salt was washed with *n*-hexane and dissolved in toluene. At room temperature 11.5 mL (0.076 mol) of 2,3,4,5-tetramethyl-2-cyclopentenone was added. The reaction mixture was hydrolyzed with 20 mL of saturated NH_4Cl (aq) followed by dehydration with 20 mL of concentrated HCl. The organic layer was separated, dried over $MgSO_4$, filtered and concentrated by distillation under reduced pressure. Pure product (7.9 g, 45.6%) was obtained by column chromatography over silica (Hexanes/CH_2Cl_2, 3:2) as yellow oil. *Anal*. Calc. for $C_{16}H_{20}O$ (228.15): C, 84.16; H, 8.83. Found: C, 84.11; H, 8.80%. ^1H NMR ($CDCl_3$, 300 MHz, 298 K): δ 7.25 (m, 4H, Ph), 3.79 (s, 3H, OCH_3), 3.40 (q, 1H, CpH), 1.91

[d] Determined by DSC at a heating rate of 10 °C min^{-1}.

(s, 3H, C_5Me_4), 1.86 (s, 6H, C_5Me_4), 0.88 (d, 3H, C_5Me_4). ^{13}C NMR ($CDCl_3$, 75.4 MHz; 298 K): δ 157.26, 140.86, 140.31, 138.06, 134.54, 131.35, 127.35, 126.60, 120.17, 110.72, 55.39, 50.09, 14.29, 12.84, 12.01, 11.27.

3.3. Preparation of [η^5:η^1-(2,3,4,5-tetramethylcyclopentadienyl)-C_6H_4O]$TiCl_2$ (2)

A solution of *n*-BuLi (4.4 mmol) was added dropwise to a solution of 1-(2-methoxyphenyl)-2,3,4,5-tetramethylcyclopentadiene (1.0 g, 4.4 mmol) in Et_2O (100 mL) at −78 °C and the reaction mixture was warmed slowly to room temperature. After stirred overnight, the solvent was removed in vacuo and the residue was washed with hexane, and then dissolved in toluene (150 mL). A solution of $TiCl_4$ (4.4 mmol) in toluene (50 mL) was slowly added at −78 °C. The reaction mixture was allowed warm to room temperature and then was heated to 65 °C for 12 h. The precipitate was filtered off and the solvent was removed to leave a yellow residue. Recrystallization from CH_2Cl_2:hexane (1:4) gave pure **2** as yellow crystals (0.68 g, 46.7%). Calc. for $C_{15}H_{16}Cl_2OTi$ (331.06): C, 54.42; H, 4.87. Found: C, 54.32; H, 4.79%. ^1H NMR ($CDCl_3$, 300 MHz, 298 K): δ 7.30 (t, 1H, Ph), 7.27 (d, 1H, Ph), 7.16 (t, 1H, Ph), 6.65 (d, 1H, Ph), 2.44 (s, 6H, C_5Me_4), 2.08 (s, 6H, C_5Me_4). ^{13}C NMR ($CDCl_3$, 100.5 MHz, 298 K): δ 175.51, 146.34, 143.45, 131.09, 130.15, 129.04, 128.58, 123.86, 114.25, 13.75, 13.39.

3.4. X-ray structure determinations of 2 and IVd

Single crystals of **2** and **IVd** suitable for X-ray structural analysis were obtained from the mixture of CH_2Cl_2/hexane (V/V = 1/3). The data were collected at 293 K on the Bruker SMART-CCD diffractometer for **2** and **IVd** (graphite-monochromated Mo Kα-radiation: $\lambda = 0.71073$ Å). Details of the crystal data, data collections, and structure refinements are summarized in Table 3. All structures were solved by direct methods [20] and refined by full-matrix least-squares on F^2. All non-hydrogen atoms were refined anisotropically and the hydrogen atoms were included in idealized position. All calculations were performed using the SHELXTL [21] crystallographic software packages. CCDC-292295 (**2**), -292294 (**IVd**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: +44 1223 336 033; e-mail: deposit@ccdc.cam.ac.uk.

3.5. Ethylene polymerization

A dry 250 mL steel autoclave was charged with 60 mL of toluene, thermostated at desired temperature and saturated with ethylene (1.0 bar). The polymerization reaction was started by injection of a mixture of catalyst and $Al(^iBu)_3$ in toluene (5 mL) and a solution of $Ph_3C^+B(C_6F_5)_4^-$ in toluene (5 mL) at the same time. The vessel was repressurized to needed pressure with ethylene immediately and the pressure was kept by continuously feeding of ethylene. After 30 min, the polymerization was quenched by injecting acidified methanol [HCl (3 M)/methanol = 1:1]. The mixture was stirred overnight and the polymer was collected by filtration, washed with water, methanol, and dried at 60 °C in vacuo to a constant weight.

Table 3
Crystal data and structural refinement details for **2** and **IVd**

	2	**IVd**
Molecular formula	$C_{15}H_{16}Cl_2OTi$	$C_{16}H_{18}Cl_2OTi$
Molecular weight	331.08	345.10

confirmation has been carried out by single crystal X-ray diffraction studies in one case.

2. Experimental

2.1. Materials

$Co(OAc)_2 \cdot 4H_2O$ and NaN_3 were purchased from Loba Chemi, Bombay and 1-alkyl-2-(naphthyl-(α/β)-azo)imdazoles (α-/β-NaiR) were prepared following the literature procedures [9]. All other chemicals and solvents were of reagent grade. Solvents were used after drying.

2.2. Physical measurements

Microanalyses (C, H, N) were performed using a Perkin–Elmer 2400 CHNO/S elemental analyzer. Spectroscopic measurements were carried out using the following instruments: UV–Vis spectra, reflectance spectra, JASCO UV–Vis/NIR model V-570; IR spectra (KBr disk, 4000–200 cm^{-1}), JASCO FT-IR model 420. The room temperature magnetic moment was measured using a Vibrating sample 155 magnetometer at 298 K. Molar conductances (Λ_M) were measured in a Systronics conductivity meter 304 model using *ca.* 10^{-3} M solutions in MeOH. Electrochemical measurements were carried out with the use of computer controlled EG&G PARC VersaStat model 250 electrochemical instruments using a Pt-disk working electrode. The solution was IR compensated and the results were collected at 298 K. The reported results are referenced to SCE in acetonitrile and are uncorrected for junction potentials. Estimation of cobalt was carried out by the complexometric titration method [18].

CAUTION! Azide complexes of transition metal ions containing organic ligands are potentially explosive. Only a small amount of materials should be prepared, and it should be handled with care.

2.3. Preparation of bis-chelated azido complexes, $[Co(\alpha\text{-}NaiEt)_2(N_3)_2]$ (**3b**)

1-Ethyl-2-(naphthyl-α-azo)imidazole (α-NaiEt) (0.06 g, 0.50 mmol) in MeOH (10 ml) was added dropwise to a stirred solution of $Co(OAc)_2 \cdot 4H_2O$ (0.062 g, 0.25 mmol) in MeOH (10 ml) at 298 K. The brown solution was stirred for 15 min. Then NaN_3 (0.03 g, 0.50 mmol) in MeOH (10 ml) was added to the brown solution. The color changed from brown to deep brown. The solution was filtered and then left undisturbed for a week. Dark brown crystals were obtained, which were washed with water, methanol and ether. Finally, they was dried *in vacuo*. The yield was 0.12 g, (75%). The microanalytical data of the complexes are as follows: $[Co(\alpha\text{-}NaiMe)_2(N_3)_2]$ (**3a**): *Anal.* Calc. for $C_{28}H_{24}N_{14}Co$: C, 54.64; H, 3.90; N, 31.87; Co, 9.58. Found: C, 54.71; H, 4.01; N, 31.78; Co, 9.50%. $[Co(\alpha\text{-}NaiEt)_2(N_3)_2]$ (**3b**): *Anal.* Calc. for $C_{30}H_{28}N_{14}Co$: C, 55.99; H, 4.35; N, 30.48; Co, 9.16. Found: C, 55.71; H, 4.45; N, 30.28; Co, 9.12%. $[Co(\alpha\text{-}NaiBz)_2(N_3)_2]$ (**3c**): *Anal.* Calc. for $C_{36}H_{32}N_{14}Co$: C, 60.08; H, 4.45; N, 27.26; Co, 8.19. Found: C, 60.01; H, 4.40; N, 27.19; Co, 8.12%.

2.4. Preparation of $[Co(\beta\text{-}NaiEt)_2(N_3)_2]$ (**4b**)

1-Ethyl-2-(naphthyl-β-azo)imidazole (β-NaiEt) (0.06 g, 0.50 mmol) in MeOH (10 ml) was added dropwise to a stirred solution of $Co(OAc)_2 \cdot 4H_2O$ (0.062 g, 0.25 mmol) in MeOH (10 ml) at 298 K. The brown solution was stirred for 15 min. Then NaN_3 (0.03 g, 0.50 mmol) in MeOH (10 ml) was added to the brown solution. The color changed from brown to deep brown. The solution was filtered and then left undisturbed for a week. A dark brown crystal was obtained. It was washed with water, methanol and ether. Finally, it was dried *in vacuo*. Yield was 0.11 g, (70%). The microanalytical data of the complexes are as follows: $[Co(\beta\text{-}NaiMe)_2(N_3)_2]$ (**4a**): *Anal.* Calc. for $C_{28}H_{24}N_{14}Co$: C, 54.64; H, 3.90; N, 31.87; Co, 9.58. Found: C, 54.73; H, 4.06; N, 31.81; Co, 9.52%. $[Co(\beta\text{-}NaiEt)_2(N_3)_2]$ (**4b**): *Anal.* Calc. for $C_{30}H_{28}N_{14}Co$: C, 55.99; H, 4.35; N, 30.48; Co, 9.16. Found: C, 55.81; H, 4.41; N, 30.36; Co, 9.13%. $[Co(\beta\text{-}NaiBz)_2(N_3)_2]$ (**4c**): *Anal.* Calc. for $C_{36}H_{32}N_{14}Co$: C, 60.08; H, 4.45; N, 27.26; Co, 8.19. Found: C, 60.03; H, 4.41; N, 27.21; Co, 8.13%.

2.5. Preparation of tris-chelates, $[Co(\alpha\text{-}NaiMe)_3](ClO_4)_2 \cdot H_2O$ (**5a**)

To a degassed dry ethanol solution (15 ml) of $Co(ClO_4)_2 \cdot 6H_2O$ (0.25 g, 0.68 mmol), α-NaiMe (0.58 g, 2.46 mmol) in the same solvent (15 ml) was added under N_2 and stirred continuously. The solution colour turned to deep brown-violet. It was then refluxed for 8 h. Excess of $LiClO_4$ (5 mmol) in MeOH (5 ml) was added. Nitrogen gas was bubbled through this solution to reduce its volume to half of its original value and the flask was corked and kept at 10 °C for 18 h. Brown crystals deposited on the glass wall were collected by filtration, washed with ethanol and stored over $CaCl_2$. Yield: 0.25 g (37%). The purity of the compound was checked by microanalytical data. The compounds are sensitive to moisture and were kept under dry conditions. Microanalytical data of the complex is as follows: $[Co(\alpha\text{-}NaiMe)_3](ClO_4)_2 \cdot H_2O$ (**5a**) *Anal.* Calc. for $C_{42}H_{38}N_{12}Cl_2O_9Co$: C, 51.22; H, 3.66; N, 17.07. Found: C, 51.31; H, 3.71; N, 17.18%. All other complexes were prepared by the same procedure. The yield varied from 35% to 40% and microanalytical data of the complexes are as follows. $[Co(\alpha\text{-}NaiEt)_3](ClO_4)_2 \cdot H_2O$ (**5b**) *Anal.* Calc. for $C_{45}H_{44}N_{12}Cl_2O_9Co$: C, 52.64; H, 4.09; N, 16.38. Found: C, 52.59; H, 4.17; N, 16.29%. $[Co(\beta\text{-}NaiMe)_3](ClO_4)_2 \cdot H_2O$ (**6a**) *Anal.* Calc. for $C_{42}H_{38}N_{12}Cl_2O_9Co$: C, 51.22; H, 3.66; N, 17.07. Found: C, 51.30; H, 3.74; N, 17.16. $[Co(\alpha\text{-}NaiEt)_3](ClO_4)_2 \cdot H_2O$ (**6b**) *Anal.* Calc. for $C_{45}H_{44}N_{12}Cl_2O_9Co$: C, 52.64; H, 4.09; N, 16.38. Found: C, 52.58; H, 4.15; N, 16.27%.

2.6. X-ray crystal structure analysis of [Co(β-NaiEt)$_2$(N$_3$)$_2$] (**4b**)

The crystals were grown by slow evaporation of the reaction mixture over a week. Data were collected with a Bruker CCD area detector diffractometer [19] using fine-focus sealed graphite-monochromatized Mo Kα radiation ($\lambda = 0.71073$ Å) at 295(2) K for **4b**. Diffractions were recorded with 2θ in the range $3.84 \leqslant 2\theta \leqslant 56.62°$. A summary of the crystallographic data and structure refinement parameters are given in Table 1. Reflection data were recorded using the ψ and ω scan techniques. Data were corrected for Lp and an empirical absorption correction [20] in the hkl range: $-25 \leqslant h \leqslant 25$; $-17 \leqslant k \leqslant 18$; $-17 \leqslant l \leqslant 17$. Data reduction was carried out using the SAINT program [20]. In order to restrain the anisotropic displacements, we used several DELU and SIMU instructions in the refinement, so the number of restrained parameters is a little larger. The structure was solved by the direct method using SHELXS-97 [21] and successive difference Fourier syntheses. All non-hydrogen atoms were refined anisotropically. The hydrogen atoms were fixed geometrically and refined using the riding model. The molecular graphics were carried out using ORTEP-3 for Windows [21]. In the final difference Fourier map, the residual maxima and minima Δ_{max} (e Å^{-3}), 0.342 and Δ_{min} (e Å^{-3}), −0.264 for **4b** were carried out using SHELXL-97 [22], indicating that there is no solvent in the crystal.

3. Results and discussion

3.1. The complexes and their formulation

1-Alkyl-2-(naphthyl-(α/β)-azo)imidazoles, (α-/β-NaiR), are used in this work. The reaction of 1-alkyl-2-(naphthyl-(α/β)-azo)imidazoles (α/β-NaiR), $Co(OAc)_2 \cdot 4H_2O$ and NaN_3 in any mole ratio [1:1:2, 1:2:2; 1:1:excess (>4 mole)] in MeOH affords complexes of the formulae [Co(α/β-NaiR)$_2$(N$_3$)$_2$] (**3**, **4**).

$$Co(OAc)_2 + 2(\alpha/\beta) - NaiR + 2NaN_3 \xrightarrow[\text{Stir. 298 K}]{\text{MeOH}} \underset{\mathbf{3/4}}{[Co(N_3)_2(\alpha/\beta - NaiR)_2]} + 2NaOAc \quad (1)$$

The complexes are non-electrolytes in MeCN. The composition of the complexes was supported by microanalytical data. Room temperature (298 K) magnetic moment measurements show high spin data in the range 4.9–5.2 B.M.

3.2. Structure description of [Co(N$_3$)$_2$(β-NaiEt)$_2$] (**4b**)

The molecular structure of [Co(N$_3$)$_2$(β-NaiEt)$_2$] (**4b**) is shown in Fig. 1. The bond distances and angles are set out in Table 2. The structure is a severely distorted tetrahedron with C_{2v} symmetry. The cobalt(II) centre is surrounded by two N(imidazole) donor atoms from two β-NaiEt ligands and two azide-N atoms. β-NaiEt has two N-centres: N(imidazole) and N(azo). It could serve as a monodentate imidazole-N donor or N(azo), N(imidazole)

bidentate chelating agent. Forced chelation with the azoimine (—N=N—C=N—) function gives a very long Co—N(azo) distance (2.6844(1) Å) and low chelate angle (N(azo)—Co—N(imidazole), 66.22(5)°). The Co—N(imidazole) (2.0428(16) Å) distances are of reasonable length and are comparable with reported data [13,23]. The distortion may arise from the long Co···N(azo) distance. So, the structure may be considered as a tetrahedron with two additional weak interactions. In 1-alkyl-2-(arylazo)imidazole (RaaiR′) complexes of Co(II) we have isolated octahedral complexes when azide N_3^- is present as the counter ion [13]. In the presence of ClO_4^- as a counter ion we have isolated tetrahedral $[Co(RaaiR')_4]^{2+}$ where the ligands bind through N(imidazole) only, [19] which upon reaction with N_3^- or NCS^- have isolated octahedral complexes $Co(RaaiR')_2(X)_2$ ($X = N_3^-$ or NCS^-). That means azoimidazole may bind Co(II) as a monodentate imidazole-N or bidentate N(imidazole), N(azo) ligand [13,23]. There is a small difference in CFSE between octahedral and tetrahedral symmetry of high-spin Co(II) complexes and hence the steric reason is the determining factor in the geometrical preference of the complex. The naphthyl group is sterically more crowded than the pendant aryl group in azoimidazoles, which may lead to the generation of the distorted tetrahedral Co(II) geometry in the present case. The Co—N(azido) bond length is comparable with the reported data [13]. The N=N bond length is 1.252(2) Å in **4b.** Although data are not available for this ligand system, its isomeric analogue 1-ethyl-2-(naphthyl-α-azo)imidazolium hexafluorophosphate shows 1.267(3) Å for the N=N length [11]. The N—N—N bond parameters lie within the reported range [13,24]. An intermolecular hydrogen bonded unit is constituted by interaction between the imidazole C(2)—H(2) of one molecule with the azide—N(3) of a neighbouring molecule: (C(2)—H(2)···N(3): C(2)—H(2), 0.93 Å, H(2)—N(7), 2.54 Å, C(2)···N(3), 3.370(1) Å and ∠C(2)—H(2)···N(3), 149.22°). The existence of C—H···π (Cg) (Fig. 2) (C(13)—H(13)...Cg(1), 2.796(8) Å; C(15)—H(15B)···Cg(2), 3.390(5) Å) and π···π interactions (face-to-face type) (Cg(1)—Cg(2), 4.305(4) Å; Cg(1)—Cg(3), 4.039(7) Å; Cg(2)—Cg(2), 4.389(6) Å) increases the robustness of the structure (Cg(1): N(4)—C(1)—N(5)—C(2)—C(3);

Cg(2): C(4)—C(5)—C(6)—C(7)—C(12)—C(13); Cg(3): C(7)—C(8)—C(9)—C(10)—C(11)—C(12); symmetry, 1/2 − *x*, 1/2 − *y*, 1 − *z*).

3.3. Spectral studies

The IR bands were assigned by comparing with the free ligand data. The most significant observation is the appearance of a very strong sharp single band at 2035–2045 cm^{-1}. This corresponds to $\nu_{asym}(N_3)$. This supports the mononuclear monodentate N_3^- bonding in the complexes. The ligand α/β-NaiR shows characteristic vibrations at 1600–370 cm^{-1}. Moderately intense stretchings at 1570–1600 and 1435–1440 cm^{-1} are due to ν(C=N) and ν(N=N), respectively.

The solution electronic spectra of the complexes were recorded in acetonitrile solution in the UV/Vis region (250–900 nm). The data are listed in Table 3. In the visible region both types of complexes exhibit an intense band ⩽400 nm. These transitions are presumably due to intra-ligand π–π*/and n–π* transitions. The structural distortion undoubtedly effects the spectral transitions and intensity of the bands [25]. High-spin tetrahedral Co(II) complexes may exhibit two or three weak transitions at the visible to near-IR region. However, the intensity of these bands is very much dependent on the degree of distortion of the structures [26]. In the present example, the structural distortion from regular tetrahedron arises from weak Co···N(azo) (*vide supra*) interactions. There are three transitions in the range 415–640 nm for complexes **3**. The intensity patterns of the bands are different; the transitions 415–425 and 440–455 nm are highly intense ($\varepsilon \sim 10^4$ mol^{-1} cm^{-1}) and sharp, while the transition 630–640 nm is weak ($\varepsilon \sim 180$–450 mol^{-1} cm^{-1}) and very broad. Based on the low intensity and low energy, the band at 630–640 nm may be due to d–d transitions [26]. The high intense bands at 415–455 nm may be assigned to MLCT transitions. The complexes **4** also exhibit three transitions in the range 445–675 nm. The transition 440–445 nm is of high intensity ($\varepsilon \sim 10^4$ mol^{-1} cm^{-1}) and is sharp, while the other two transitions at 600–615 and 660–670 nm are weak and broad.

3.4. Cyclic voltammetry

Representative voltammograms are shown in Fig. 3 and data are collected in Table 4. The complexes display one oxidation couple at 1.3–1.5 V and I_{pa}/I_{pc} equals 0.9–1.0.

[a] Solvent, MeCN; working electrode, Pt-disk milli electrode, Pt-wire auxiliary, SCE reference; supporting electrolyte $[n\text{Bu}_4\text{N}][\text{ClO}_4]$; scan rate 0.05 V s^{-1}, potential $E_{1/2} = 0.5(E_{pa} + E_{pc})$, $\Delta E_p = |E_{pa} - E_{pc}|$, mV; E_{pa} = anodic peak potential, E_{pc} = cathodic peak potential.
[b] $E_{pc.}$

Although the peak heights are not equivalent for the various complexes, the areas under the peaks are comparable. The peak-to-peak separation is >120 mV. This supports the quasireversibility of the couple. The oxidation couple refers to the Co(III)/Co(II) response. Azo (—N=N—) is a good π-acidic function and can assist $d\pi \rightarrow \pi^*$(azo) charge transfer, which effectively stabilizes the lower oxidation state. The data in Table 4 suggest that Co(II) could be better stabilized in $Co(\alpha\text{-NaiR})_2(N_3)_2$ than in $Co(\beta\text{-NaiR})_2(N_3)_2$. There are three observable quasireversible to irreversible reduction couples appearing at −0.6 to −0.7 V, −1.3 to −1.4 V and <−1.6 V. Naphthylazoimidazole is an eligible reducing ligand. The azo (N=N) group is a potential electron receiving centre. Each ligand can accommodate two electrons corresponding to [—N=N—]/[—N⁻—N—]⁻ and [—N⁻—N]⁻/[—N⁻—N⁻—]²⁻ redox responses. In principle there will be four redox couples. However, we observed three reductive responses. α-NaiR is thermodynamically more stable than β-NaiR and this is supported by higher redox potential data of the respective cobalt complexes.

3.5. Tris-[{1-alkyl-2-(naphthyl-(α/β)-azo}imidazole]-cobalt(II) perchlorate monohydrate, $[Co(\alpha\text{-}/\beta\text{-})NaiR)_3](ClO_4)_2 \cdot H_2O$

The brown complexes of $[Co(NaiR)_3](ClO_4)_2 \cdot H_2O$ (**5**, **6**) have been prepared by stirring $Co(ClO_4)_2 \cdot 6H_2O$ and NaiR in the mole proportion 1:3.5 in dry ethanol under N_2 atmosphere and have been isolated as the monohydrate perchlorate salt by adding $NaClO_4$ under cold conditions. A very dry condition is absolutely necessary to get the pure product. On exposure to air the brown crystalline shining compound becomes moistened and results in an impure gummy compound. Because of its moisture sensitivity we could not crystallise this compound to get an X-ray quality crystal. In a dry inert atmosphere the compound is highly stable. In solution the complex is unstable and presumably dissociates to the solvato species $[Co(NaiR)_2(S)_2]^{2+}$. Upon addition of NaN_3 to an ethanolic solution of the complex, it immediately separates into $[Co(NaiR)_2(N_3)_2]$, which has been proved by spectral (IR, UV–Vis), magnetic, conductance data and on comparing with the previously prepared complex (*vide supra*). All our attempts to prepare $Co(NaiR)_2Cl_2$ using $CoCl_2$ and NaiR in different metal:ligand ratios, and even by addition of LiCl to an alcoholic solution of $Co(ClO_4)_2$ and NaiR, have failed.

$Co(NaiR)_3(ClO_4)_2$ is sufficiently stable in dry inert atmosphere. Solid state bulk magnetic moment measurements establish this conjecture. Initial measurement of the moment immediately after removal from a dessicator gives a magnetic moment corresponding to a low-spin electron configuration ($t_{2g}^6 e_g^1$, μ, ∼ 1.8B.M.). Exposure to air for a week in the same sample tube gives a moment much higher than the low-spin value, although it is lower than the spin-free ($t_{2g}^5 e_g^2$) value. This suggests the formation of a mixture of low-spin and high-spin complexes. The azido complexes, $Co(NaiEt)_2(N_3)_2$ are a high-spin system. Air oxidation of cobalt(II)-azoimine complexes has been ruled out from the literature report [13,23,26].

The complexes show a very strong and structured vibration at 1120–1110, 1100–1090 cm^{-1}, and a sharp, medium intense band at 630 cm^{-1}. This is assigned to the ClO_4^- vibration. The structured stretching may be due to reduction in Td symmetry of the ion by a hydrogen-bonding interaction with crystallized H_2O and/or C—H···O(ClO_3). A strong and sharp stretch at 1590–1600 cm^{-1} is due to ν(C=N) and ν(C=C) while another stretch at 1400–1390 cm^{-1} is referred to ν(N=N). The stretching vibration of the water of crystallization appears as a broad medium band centred at 3450 cm^{-1}.

Tris-chelates with unsymmetric *N*,*N*′ donor centre may, in principle, exist in two different isomeric forms: facial and meridional [27]. Additionally, tris-chelates undergo quick ligand dissociation to give bis-chelated solvento species. So we logically assume that the spectral transitions may be the combination of similar transitions from several isomers present in the solution. Similarly studies on the redox properties by solution electrochemistry of these complexes do not bring any definite conclusion. Thus, we are not interested in extending the solution studies of the tris-chelates.

4. Conclusion

This paper describes the mononuclear bis-azido Co(II) complexes of 1-alkyl-2-(naphthyl-(α/β)-azo)imidazoles. The complexes are characterized by different physicochemical

methods and single crystal X-ray structure determination in one case shows a distorted tetrahedral CoN_4 coordination arrangement. The complexes show high potential Co(III)/Co(II) redox couples along with azo reductions.

5. Supplementary material

Crystallographic data for the structure have been deposited with the Cambridge Crystallographic data center, CCDC No. 251235 for $[Co(\beta\text{-NaiEt})_2(N_3)_2]$ (**4b**). Copies of this information may be obtained free of charge from the Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (e-mail: deposit@ccdc.cam.ac.uk or www:http://www.ccdc.cam.ac.uk).

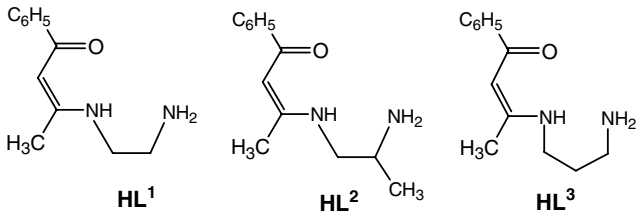
The carbonyl functional group is generally considered as non-bridging, but the group of N,N,O donor tridentate Schiff base ligands, derived from 1:1 condensation of acetylacetone and various diamines, can readily be involved in *basal–apical* type peripheral oxo-bridging to result in the formation of trinuclear Cu(II) complexes with a $[Cu_3OH]$ core by self-assembly [10]. The magneto structural correlation of such complexes reported so far suggest that the greatest coplanarity of the lowest distance of the O(H) above the Cu_3 plane and the greatest Cu–O–Cu′ angles provide the strongest antiferromagnetic coupling. However, new complexes need to be prepared with this kind of ligand to be able to draw clearer magneto-structural conclusions.

The mono-condensation product of salicylaldehyde and diamines, on the other hand, can yield either similar trinuclear [10c] or phenoxo-bridged dinuclear [11] compounds on reaction with Cu(II) perchlorate. We would like to replace the acetylacetone part of the Schiff base with 1- benzoylacetone to investigate whether the resulting complexes are dinuclear or trinuclear. If the complexes are trinuclear, one may expect wider Cu–O–Cu′ angles because of the steric effect of the phenyl group compared to their acetylacetone analogue. With this expectation, we synthesized three new tridentate ligands by mono condensation of 1-benzoylacetone with 1,2-ethanediamine (HL^1), 1,2-propanediamine (HL^2) and 1,3-propanediamine (HL^3), adopting a similar procedure as for acetylacetone analogue. On reaction with Cu(II), the ligands HL^1 and HL^2 produce trinuclear μ_3-hydroxo bridged complexes whereas HL^3 undergoes hydrolysis and affords an interesting mononuclear ternary complex in which two different chelating ligands, 1,3-propanediamine and 1-benzoylacetonate are coordinated to Cu(II). In this paper we report the synthesis, spectroscopic study and X-ray structures of these three complexes. The variable temperature magnetic behavior of the two trinuclear complexes has also been described and the results have been compared with those of similar complexes reported in the literature.

2. Experimental

The diamines and 1-benzoylacetone were purchased from Lancaster and were of reagent grade. They were used without further purification. Three new monocondensed ligands HL^1, HL^2 and HL^3 (Scheme 1) have been synthesized in our laboratory by the methods described below.



Scheme 1.

Caution! Although no problems were encountered in this work, perchlorate salts containing organic ligands are potentially explosive. They should be prepared in small quantities and handled with care.

2.1. Preparations

2.1.1. Preparation of HL^1 [6-amino-3-methyl-1-phenyl-4-azahex-2-en-1-one], HL^2 [6-amino-3,6-dimethyl-1-phenyl-4-azahex-2-en-1-one] and HL^3 [7-amino-3-methyl-1-phenyl-4-azahept-2-en-1-one]

The three ligands HL^1, HL^2 and HL^3 are the single condensation products of 1,2-ethanediamine, 1,2-propanediamine and 1,3-propanediamine, respectively, with 1-benzoylacetone. They were prepared by following a similar method to that adopted for the half condensation of 1,2-ethanediamine or 1,3-propanediamine with 2,4-pentanedione as reported earlier, i.e. by reacting the constituents in chloroform under high dilution [10,12–15].

A solution of 1-benzoylacetone (10 mmol, 1.62 g) in chloroform (50 cm^3) was added dropwise to a solution of 1,2-ethanediamine (10 mmol, 0.67 cm^3), 1,2-propanediamine (10 mmol, 0.85 cm^3) or 1,3-propanediamine (10 mmol, 0.83 cm^3) in chloroform (50 cm^3) at room temperature. After the addition, the solution was stirred for an additional 3 h and the chloroform was evaporated under reduced pressure. The resultant semi-solid product was collected as the ligand and dissolved in methanol (30 cm^3) for the synthesis of the respective complexes.

2.1.2. Synthesis of complexes $[(CuL^1)_3(\mu_3\text{-}OH)](ClO_4)_2$ (**1**), $\{[(CuL^2)_3(\mu_3\text{-}OH)]_2(ClO_4)_4\}_2 \cdot 0.75H_2O$ (**2**) and $[Cu(bn)(pn)ClO_4]$ (**3**) [bn = 1-benzoylacetonate and pn = 1,3-propanediamine]

A solution of $Cu(ClO_4)_2 \cdot 6H_2O$ (10 mmol, 3.7 g) in methanol (20 cm^3) was added to a stirred solution of each of the ligands, HL^1, HL^2 and HL^3 (10 mmol) in methanol (10 cm^3). Triethylamine (15 mmol, 2.1 cm^3) was then added dropwise to this solution with constant stirring. In the case of **1** and **2** an immediate separation of a small amount of green hydrolyzed product occurred during the addition of triethylamine, which was filtered off. The resulting green filtrate of **1** on keeping in a refrigerator for several days yielded single crystals as dark green hexagons, whereas the green microcrystalline product of **2** was obtained on keeping the filtrate overnight at room temperature. Single crystals of **2** suitable for X-ray diffraction analysis were obtained as green prisms by slow diffusion of *n*-hexane into a dichloromethane solution of the compound.

In the case of **3**, there was no immediate separation of a precipitate after addition of triethylamine. The resulting solution was set aside for several days at room temperature and deep blue single crystals of **3** suitable for X-ray analysis separated out.

Complex **3**: (Yield: 4.2 g; 69%). *Anal.* Calc. for $C_{13}H_{19}ClCuN_2O_6$ (398.3): C, 39.20; H, 4.81; N, 7.03. Found: C, 39.12; H, 4.98; N, 6.91%. λ_{max}/nm (ε_{max}/$dm^3\ mol^{-1}\ cm^{-1}$) (acetonitrile), 576 (68.41); IR: ν(C=N), 1522 cm^{-1}, ν(N—H), 3263 and 3312 cm^{-1}.

2.2. Physical measurements

Elemental analyses (carbon, hydrogen and nitrogen) were performed using a Perkin–Elmer 240C elemental analyzer. IR spectra in KBr (4500–500 cm^{-1}) were recorded using a Perkin–Elmer RXI FT-IR spectrophotometer. Electronic spectra in methanol (1200–350 nm) were recorded in a Hitachi U-3501 spectrophotometer. The magnetic measurements were carried out in the "Servei de Magnetoquimica (Universitat de Barcelona)" on polycrystalline samples (20 mg) with a Quantum Design SQUID MPMSXL magnetometer in the temperature range of 2–300 K and the magnetic field was 0.1 T. The diamagnetic corrections were evaluated from Pascal's constants. EPR spectra were recorded on powder samples at X-band frequency with a Bruker 300 E automatic spectrometer, varying the temperature between 4 and 300 K.

2.3. Crystallographic studies

The independent reflections for complexes **1**–**3** were measured with Mo Kα radiation using the MAR research Image Plate System at 293 K. Suitable single crystals of all three complexes were positioned at 70 mm from the Image Plate. A total of 100 frames were measured at 2° intervals with a counting time of 2 min. Data analyses were carried out with the XDS program [16]. The structures were solved using direct methods with the SHELX-97 program [17]. The non-hydrogen atoms were refined with anisotropic thermal parameters. The hydrogen atoms bonded to carbon and nitrogen were included in geometric positions and given thermal parameters equivalent to 1.2 times those of the atom to which they were attached. In **2** there are two independent cations and four independent perchlorate anions, all of which are disordered, and two sets of four oxygen atoms were refined. Solvent water molecules with 50% occupancy were located but the hydrogen atoms could not be located. Empirical absorption correction was applied using DIFABS [18], an empirical method amended to be suitable for the Image Plate. The structures were refined on F^2 using SHELXL [17]. The crystal structure illustrations were generated using ORTEP-3 [19]. Significant crystallographic data are summarized in Table 1.

3. Results and discussion

The two tridentate ligands HL^1 and HL^2 (Scheme 1) on treatment with the methanol solution of copper perchlorate hexahydrate and triethylamine in a 2:2:3 ratio yielded the trinuclear complexes **1** and **2**, respectively (Scheme 2). The ligand HL^3 (Scheme 1), on the other hand, undergoes hydrolysis under similar conditions and yielded the ternary complex **3**. There are several reports in the literature where the monocondensation of diamine and carbonyl compounds was done in presence of a metal ion [20]. In fact, it was the usual procedure for the synthesis of such ligands and their complexes before the discovery of the high dilution method [21]. Therefore, the formation of **3** is very interesting as one diamine and one 1-benzoylacetone molecule, that are the products of the hydrolysis of the Schiff base, are coordinated to each Cu(II) and to our knowledge this is the first such example in Cu(II) complexes. It is to be noted that HL^3 on hydrolysis produces 1,3-propanediamine and 1-benzoylacetone which on reaction with Cu(II) perchlorate would have yielded Cu-benzoylacetonate as well as Cu-diamine complexes along with **3**. But on repeating the procedure several times, we observed that **3** is always the exclusive product. A probable explanation may be given as follows: on the reaction of the tridentate Schiff base ligand, L^3 and Cu-perchlorate, probably a trinuclear complex like **1** or **2** is produced initially. The trinuclear complex is expected to be under high steric strain [10b] as there are two six-membered rings in each unit that facilitates the hydrolysis of the ligand in the complex. The ternary complex (**3**) thus produced separated immediately from the methanolic solution owing to its very low solubility, excluding the formation of other rearranged products.

3.1. IR and electronic spectra

Complex **1** shows a well defined band at 3535 cm^{-1} due to O–H stretching. Compound **2** contains a non-coordinating water molecule, which makes the assignment of the O–H stretching somewhat ambiguous. However, the well-defined bands at 3508 cm^{-1} appear within the typical range for O–H stretching vibrations in monohydroxo-bridged copper complexes [10,22]. Considering the ClO_4^- anions, the ν_3 mode at 1097 and 1107 cm^{-1} for **1** and **2**, respectively, is somewhat broadened, but the ν_4 band at 619, 622 cm^{-1}, respectively, is devoid of any splitting and is consistent with the IR normal modes for a T_d symmetry, suggesting that these anions are not coordinated to the copper atoms. However, both ν_3 (1163, 1102 and 1009 cm^{-1}) and ν_4 (665 and 623 cm^{-1}) for complex **3** are split, indicating the presence of coordinating perchlorate as substantiated by the crystal structure.

The electronic spectra of these compounds were recorded in acetonitrile solution and in the solid state.

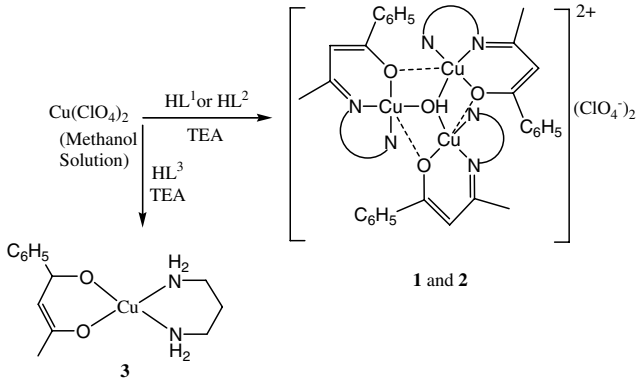

Scheme 2.

The observed ligand-field bands are in agreement with the fact that the trinuclear structures for **1** and **2** are retained in acetonitrile solution since similar visible absorption bands are observed in the solid state and in acetonitrile solution. The electronic spectra show a single absorption band at 596, 594 and 576 nm for **1**, **2** and **3**, respectively, in acetonitrile. The positions of these bands are consistent with the observed square based geometry around the copper center [10,23].

3.2. Description of the structures of complexes *1*, *2* and *3*

3.2.1. Complexes *1* and *2*

The structures of **1** and **2** are equivalent in essential detail and consist of a $[Cu_3L_3(OH)]^{2+}$ cationic fragment and two non-coordinated perchlorate anions per cation. In complex **2** there is lattice water molecule, which has partial occupancy. The molecular structure of **1** is shown in Fig. 1 together with the common atom-numbering scheme. There are two trimers (A and B) in the asymmetric unit of complex **2**, one of which is shown in Fig. S1. Selected bond distances and bond angles for the complexes are summarized in Table 2.

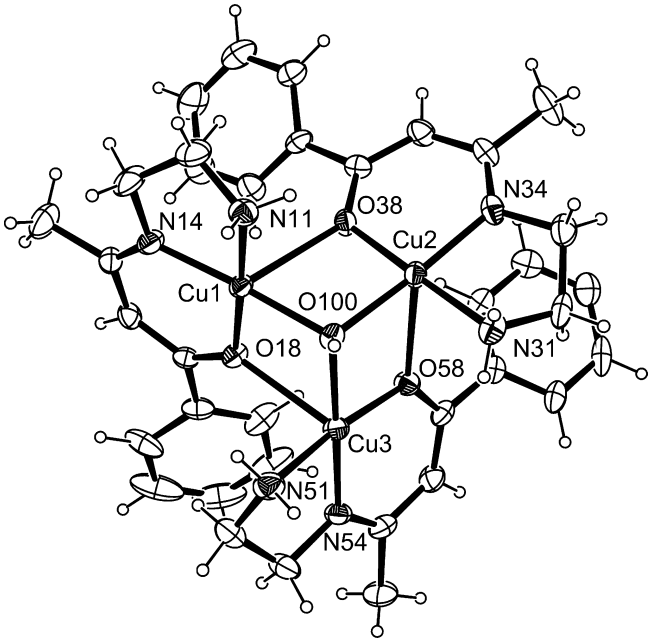

Fig. 1. The structure of **1** with ellipsoids at 25% probability.

In both complexes, each trinuclear cluster contains a triangular Cu_3 skeleton in which the copper atoms are held together by two bridging systems: (i) the oxygen atom (O100) of the central μ_3-hydroxo group and (ii) the three bridging carbonyl oxygen atoms, each of them from a different ligand molecule. The resulting trinuclear species do not contain any threefold symmetry axis. The three copper(II) ions and the bridging hydroxo group form a flattened trigonal pyramid with the copper atoms falling at

the corners of an approximate equilateral triangle. In the pyramidal [Cu_3OH] group, the averaged Cu–O–Cu′ angle is 107.85° in complex **1**, 107.75° in trimer A and 106.29° in trimer B of **2**. The oxygen atom (O100) of central μ_3-hydroxo group is situated above the plane defined by the three copper atoms at 0.727 Å in complex **1**, 0.724 Å in trimer A and 0.777 Å in trimer B of complex **2**.

As for the copper environment, in all the three structures (**1**, **2**A and **2**B), the three copper atoms of the trinuclear entity are five-coordinated with a (4 + 1) square-pyramidal (NNOO and O) geometry. The four coordinating atoms consisting the basal plane are the carbonyl oxygen, one imine nitrogen and one amino nitrogen from the tridentate Schiff base ligand (L) and the hydroxo (OH^-), while the apical site is occupied by one oxygen of another tridentate Schiff base ligand, which, in turn, is basal to a second copper atom. As expected, the axial Cu–O bond is much longer than the equatorial one. The lengths of the bonds between the copper atoms and the donor sites (O, N, N) of the tridentate ligand are within the range of values normally found for such bonds [10]. The Addison parameter τ [24] values are 0.018, 0.09 and 0.112 for Cu1, Cu2 and Cu3 of complex **1** and 0.003, 0.028 and 0.025 for Cu1, Cu2 and Cu3 of trimer A of complex **2** and 0.062, 0.008 and 0.168 for Cu4, Cu5 and Cu6 of trimer B of complex **2**, respectively. The τ values of other reported complexes [10] are also shown in Table 3 for comparison.

These trimeric structures can be compared with those observed previously with same type of N,N,O donor Schiff base ligands (acetylacetone analogues) [10]. There are two significant differences, first the axial oxygen atoms are much more weakly bound in the present trimers with an average of ca 2.51 Å compared to 2.25 Å in those previous structures and second the Cu–O–Cu angles are significantly greater compared to those found previously (Table 3). It seems likely that the presence of the phenyl ring in the present compounds compared to methyl groups in the previous compounds [10] has increased the non-bonded interactions leading to these significant changes.

The perchlorate anions in both complexes show some disorder. In **2** all the perchlorate ions are disordered such that the oxygen atoms are distributed over two sets of tetrahedral sites around the same chlorine atom while complex **1** shows the complete anion distribution over two separate sites.

In both complexes hydrogen-bonding interactions are observed among the isolated trimeric units with the perchlorate anions (Table 4). In complex **1** two centrosymmetrically related trinuclear units are linked via a N–H···O hydrogen bond involving hydrogen, H51a(N51) and oxygen, O13 of the centrosymmetrically related ($-x$, $1-y$, $-z$) perchlorate ion (Fig. S2, Table 4). The hydrogen atom H11b (N11) is also involved in another N–H···O contact with O12 of one of two perchlorate anions. H31a (N31) and H100 of the μ_3-hydroxy group form strong hydrogen bonds with same oxygen atom O13 of the same perchlorate ion. In the asymmetric unit of complex **2** two trimers are linked via a N–H···O hydrogen bond through the perchlorate ions. A view of hydrogen-bonded structure of complex **2** is shown in Fig. S3.

3.2.2. Complex 3

The ORTEP-3 view of complex **3** with the atom numbering scheme is shown in Fig. 2. This complex is ternary

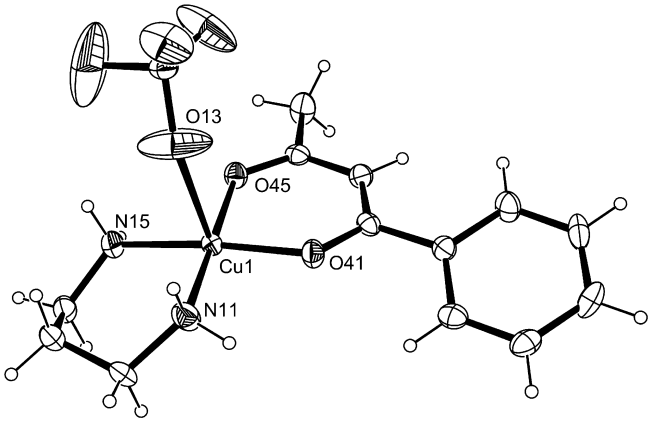

Fig. 2. The structure of **3** with ellipsoids at 25% probability.

in the sense that the copper atom is coordinated with two different ligands: a chelating diamine and a benzoylacetone moiety. This structure consists of a mononuclear cation together with a perchlorate anion.

The metal atom is in a five-coordinate square pyramidal environment with a disordered perchlorate oxygen atom O(13) weakly bound at 2.453(11) Å in an axial site. The four coordinating atoms consisting the equatorial plane are the two carbonyl oxygen atoms from the benzoylacetone moiety and two amine nitrogen atoms. The dimensions in the equatorial plane are as expected with Cu–O 1.919(7), 1.945(7) Å and Cu–N 2.009(8), 2.016(8) Å. The deviations of the coordinating atoms N11, N15, O45, O41 from the least square mean plane through them are 0.093(4), −0.093(4), 0.089(4), −0.088(4) Å. The deviations

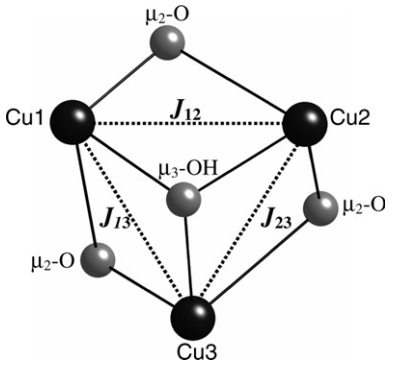
of copper(II) from the same plane towards the axially coordinated site is 0.034(4) Å. The Addison parameter for the copper atom is 0.06 [24].

The perchlorate ions play a significant role in the H-bonding network (Table 4). A view of the supramolecular hydrogen-bonded array of complex **3** is shown in Fig. 3. Of the two hydrogen atoms on N11, H11a is engaged in hydrogen bond formation with O13 of the perchlorate ion and H11b is involved in a strong hydrogen bond with the oxygen atom O41 of a benzoylacetone moiety of a neighboring centrosymmetrically related unit $(1-x, 2-y, 2-z)$ forming a H-bonded dimeric entity. These dimeric entities are interconnected via H15b of N15 by hydrogen bond formation with the perchlorate oxygen atom O14 from another crystallographically related unit $(1-x, 2-y, 1-z)$, providing an one-dimensional array.

3.3. Magnetic properties of *1* and *2*

In complexes **1** and **2** the three copper(II) ions, the μ_3-hydroxy ion and three μ_2-carbonyl oxygen atoms of the ligand molecules form an incomplete cube, with one apex lacking from the cube (Scheme 3).

Magnetic susceptibilities were determined for complexes **1** and **2** over the temperature range 2–300 K in an applied field of 0.1 T. The temperature dependence of $\chi_M T$ (χ_M being the magnetic susceptibility per $[Cu_3O_4]$ entity) for complexes **1** and **2** is shown in Figs. 4 and 5, respectively. At room temperature, the $\chi_M T$ values (1.31 and 1.22 $cm^3\,mol^{-1}\,K$ for **1** and **2**, respectively) are as expected for three uncoupled $S = 1/2$ spins (ca. 1.2 $cm^3\,mol^{-1}\,K$) and they decrease steadily with decreasing temperature. These curves clearly indicate that an intra-trimer antiferromagnetic coupling is operating. The typical plateau, at low temperatures, corresponding to the isolated trinuclear Cu^{II} species with antiferromagnetic coupling between the metal ions (spin doublet state, $\chi_M T = 0.375$, $g = 2.00$) do not appear due to the existence of a noticeable inter-trimer exchange interaction.



Scheme 3.

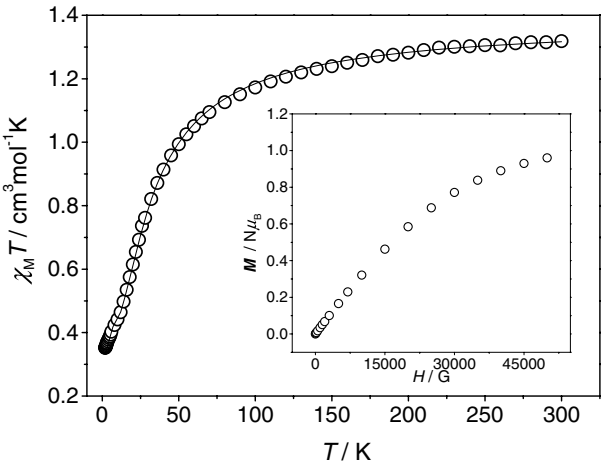


Fig. 4. Plot of the $\chi_M T$ vs. T in the range 2–300 K for **1**. Inset: magnetization vs. H at 2 K for **1**.

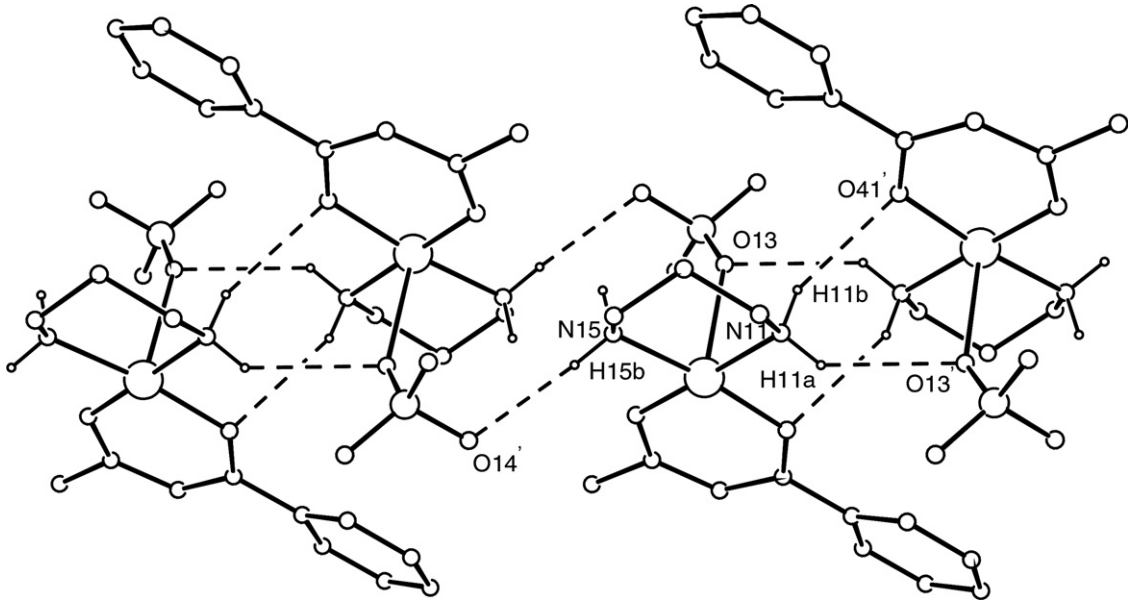

Fig. 3. Extended hydrogen-bonded network of complex **3**.

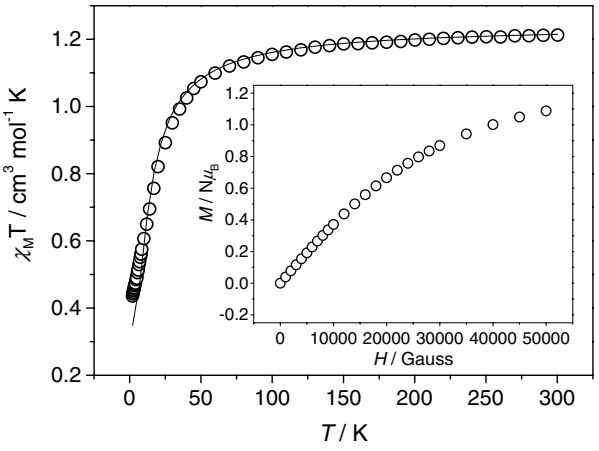

Fig. 5. Plot of the $\chi_M T$ vs. T in the range 2–300 K for **2**. Inset: magnetization vs. H at 2 K for **2**.

To determine the nature of the individual exchange interactions, we noted that the three copper(II) ions of the $[Cu_3O_4]$ system (complex **1** and trinuclear units A and B of complex **2**) occupy alternate partial cube corners. Thus there are three exchange interactions between the three magnetic ions in the molecule (Scheme 3). Each magnetic interaction involves the triple bridging hydroxo group and the bridging carbonyl oxygen atom of the ligand molecule. In order to investigate the magnetic behavior of these trinuclear complexes, an isotropic Heisenberg–Dirac–van Vleck (HDVV) Hamiltonian formalism (Eq. (1)) was used in the approach.

$$H = -J_{12}S_1S_2 - J_{13}S_1S_3 - J_{23}S_2S_3 \quad (1)$$

Since the three copper atoms of the $[Cu_3O_4]$ unit define a *quasi*-equilateral triangle, the three Cu^{II} ions can be considered equivalents and so $J_{12} = J_{13} = J_{23}$.

The magnetic susceptibility deduced from the Hamiltonian is given in Eq. (2), where N, g, β and k have their usual meanings [5e,25–27].

$$\chi_M = (N\beta^2 g^2/4kT)[1 + 5\exp(3J/2kT)]/[1 + \exp(3J/2kT)] \quad (2)$$

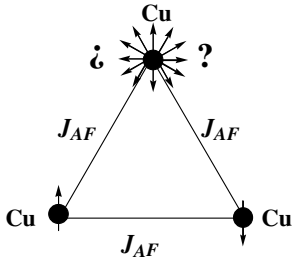
To take into account the interaction between the trinuclear entities, the susceptibility can be corrected by the molecular field approximation [28] (Eq. (3)) where zJ' denotes the intramolecular exchange parameter.

$$\chi'_M = \chi_M/[1 - 2zJ'\chi_M/Ng^2\beta^2] \quad (3)$$

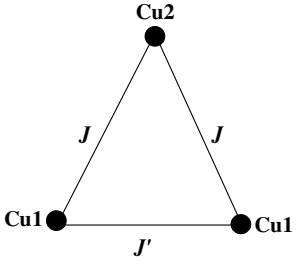
The experimental data for **1** and **2**, corrected for diamagnetic contributions and TIP (0.3×10^{-3} cm^3 mol^{-1}), were analyzed by Eqs. (2) and (3) on $\chi_M T$. The best-fitted curves are plotted in Figs. 4 and 5 along with the experimental data. The best-fit parameters obtained are $J = -25.6$ cm^{-1}, $g = 2.21$ and $zJ' = -2.0$ with $R = 9 \times 10^{-5}$ for **1** and $J = -11.2$ cm^{-1}, $g = 2.10$ and $zJ' = -1.0$ with $R = 2 \times 10^{-4}$ for **2** (where R is the agreement factor defined as $\sum_i[(\chi_M T)_i^{exp} - (\chi_M T)_i^{calc}]^2/\sum_i[(\chi_M T)_i^{exp}]^2$). The J' values are consistent with the presence of inter-trimer interactions through hydrogen bonds. The copper(II) ions are in a square pyramidal environment, as is described in the structural part. The axial bonds of each copper(II), which involve the oxygen atom of the carbonyl group of the ligand, are elongated (above 2.5 Å) due to a pseudo-Jahn–Teller distortion. Hence a very weak or null contribution to the magnetic exchange between each pair of copper(II) ions through this oxygen atom is expected and the J value is due to the interaction through the OH group of the $[Cu_3OH]$ core. The reduced molar magnetization of complexes **1** and **2**, at 2 K, tends to $1N\beta$ when the field reaches 5 T (Figs. 4 and 5 inset) indicating that the ground state at this temperature is $S = 1/2$.

It is well known that in triangular complexes when the arrangement of the magnetic centers corresponds to equilateral triangles and they show antiferromagnetic coupling giving rise to spin frustration effects [7c,29], it is impossible for all possible pairings of spins to be simultaneously antiferromagnetic (Scheme 4a). The spin frustration requires two conditions: (a) a highly symmetrical triangle and (b) a degenerate ground state. Complexes **1** and **2** are not fully equilateral, thus, spin frustration behavior might not be expected.

In the case of three $S = 1/2$ spins sitting in the corners of an isosceles triangle, the scheme of the magnetic interactions is shown in Scheme 4b. The magnetic interaction between the two Cu1 atoms is labelled J' and the magnetic interaction between the Cu2 atom and the two Cu1 atoms is labelled J. Using the CLUMAG program [30], the relative energy values of the different states of the trinuclear Cu_3



Scheme 4a.



Scheme 4b.

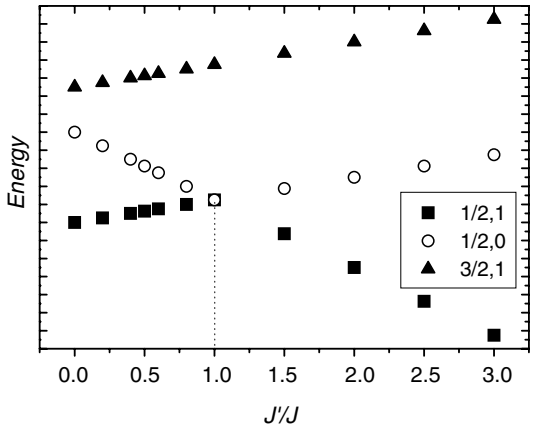


Fig. 6. Relative energies values for a trinuclear complex where the ions have a spin of 1/2 vs. J'/J (see text).

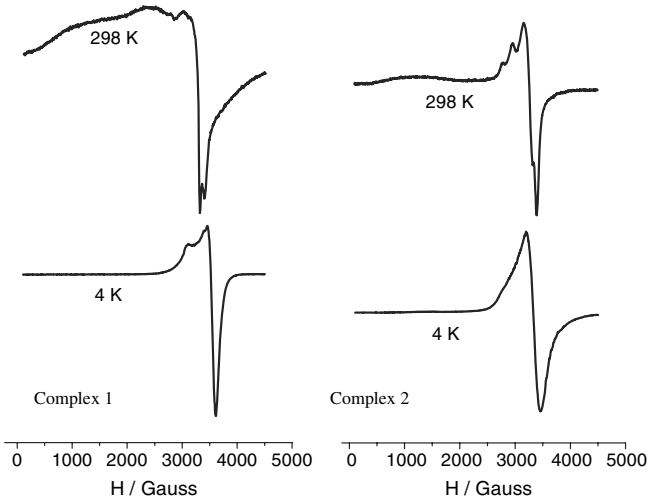

Fig. 7. Polycrystalline X-band EPR spectra for complexes **1** and **2** at room temperature and 4 K.

complex were calculated in the function of J'/J (Fig. 6). For the case of an equilateral triangle, $J'/J = 1$, the ground state is accidentally degenerated, ^2E ($|1/2, 0\rangle$, $|1/2, 1\rangle$) and the system is said to be frustrated. A small perturbation in the chemical surrounding of the metal ions may slightly change the J'/J ratio so that the degeneracy is lifted, leading to a well-defined ground state.

The necessity to introduce an antisymmetric exchange (G_{AB}) in the treatment of the magnetic data of highly symmetric spin clusters has long been known [25]. The presence of inter-trimeric exchange, due to the presence of hydrogen bonds, that is observable at low temperatures as the antisimetric exchange, preclude any calculation of the antisymmetric exchange term G_{AB}. From the literature data it seems more appropriate to study the possibility of the presence of spin frustration for this kind of complexes by means of EPR spectra at very low temperatures when only the degenerate $S = 1/2$ states are populated. One of the signatures of spin frustration is the appearance of g values lower than 2.00 [31,32].

3.4. EPR spectra

The X-band EPR spectra of complexes **1** and **2** were recorded on powder samples varying the temperature between 4 and 295 K (Fig. 7). The EPR spectra of trinuclear $S = 1/2$ compounds have been analyzed in terms of three active states (one quartet and two doublets), with a temperature dependent population [32–34]. In the light of the super-exchange parameter from the magnetic measurements, at low temperature only the doublets should be populated, whereas at room temperature signals due to the transitions inside the quartet may also be observed. This transition may show noticeable zero-field splitting (ZFS) ($S = 3/2$). Complex **2** shows a broad band at low fields at $g = 5.0$ due to the presence of ZFS of the $S = 3/2$ state, for complex **1** the spectra at low fields is not so clear (Fig. 7). At 4 K the spectra of complex **1** is anisotropic with $g_{\|} = 2.18$ and $g_{\perp} = 1.91$ and that corresponding to complex **2** shows a quasi-isotropic spectrum with a shoulder with $g = 2.23$, and a band centered at $g = 2.03$. The low value of $g_{\perp} = 1.91$, for complex **1**, could be indicative of a spin-frustrated system.

The EPR measurements in frozen methanol solution (Fig. S4) for complexes **1** and **2** clearly show the hyperfine splitting in $g_{\|}$ of approximately 190 G for the two complexes. In $g_{\perp}$ there is also a significant partial splitting.

3.5. Discussion

There are many examples in the literature of complexes with a cubane-like $[Cu_4O_4]$ core where the Cu^{II} ions and the oxygen atoms are located at alternating corners of a pseudo-cube [3d]. By contrast, complexes with a $[Cu_3O_4]$ core, with an incomplete cubane structure, are scarce [10]. From the magnetic point of view, complex **1** and **2** are trinuclear complexes in which the magnetic interaction takes place through the μ_3-OH group in the $[Cu_3OH]$ core. Previous work has established relationships for this kind of complexes between the magnetic coupling and structural features [27,35,36]. The electronic factors related to the nature of the ligands that afford the bridge are decisive in the magnetic behavior, so in Table 3 we correlate the magnitude of the magnetic coupling for trinuclear complexes of $[Cu_3O]$ core with analogous peripheral bridges. The general trends are: the shortest distance of the O(H) group above the plane formed by the three copper ions in the trinuclear Cu^{II} complexes and the greatest Cu–O–Cu′ angle provides the strong antiferromagnetic coupling.

In triangular arrangements of symmetric antiferromagnetically coupled metal ions, the magnetic properties at low temperatures can become complicated by the possible presence of spin frustration effects, because of the presence of the antisymmetric exchange interactions (ASE), described by the G_{AB} term [5e,25]. The experimental data for complex **1** indicate that this term is non-zero and the

phenomenon of spin frustration occurs. For complex **2** all data seem to indicate that there is no spin frustration.

4. Conclusion

The synthesis of the two new trinuclear complexes **1** and **2** suggests that the mono-condensation products of various diamines and benzoylacetone are also a group of tridentate ligands which can readily be involved in *basal–apical* type peripheral oxo-bridging to result in the formation of trinuclear Cu(II) complexes having a partial cubane structure with a $[Cu_3OH]$ core by self-assembly. However, replacing the acetyl acetone by benzoyl acetone make the ligands sterically more demanding. As a result, the Cu–O–Cu angles become significantly greater and the axial Cu–O bonds weaker. The effect is so much pronounced in the ligand derived from 1,3-propanediamine that the trinuclear complex does not exist and the ligand undergoes hydrolysis to produce the ternary complex **3**. Both complexes **1** and **2** show antiferromagnetic coupling, as was also found in other similar peripheral bridging complexes. The values of the coupling constants are in agreement with the hypothesis that the greatest coplanarity of the three principal ligand planes, the lowest distance of O(H) above the Cu_3 plane and the greatest Cu–O–Cu′ angles provide the strongest antiferromagnetic coupling.

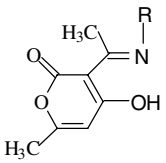
synthetic sequences incorporate an oxidation step in one form or another [8]. Oxidation of primary and secondary alcohols to aldehydes and ketones respectively, is a very fundamental accomplishment in organic synthesis. The transition metal-catalyzed oxidation of alcohols is of current interest, and various metal compounds and oxidant systems have been reported [9]. Among the second row transition metal ions, ruthenium mediated oxidations are finding application due to the unique properties of this extremely versatile transition metal, whose oxidation state can vary from −II to +VIII [10]. Of mechanistic relevance is the fact that different oxygen activated species formed in the presence of iodosylbenzene, sodium hypochlorite, hydrogen peroxide, *t*-BuOOH and *N*-methylmorpholine-*N*-oxide as oxygen sources operate in the oxygen transfer by these catalytic oxidation systems [11]. High valent ruthenium-oxo complexes have proven to be very suitable in the design of redox catalysts for a variety of reasons [12]. Sharpless et al. [13] carried out a yield oriented study of oxidation of cholesterol, geranial, etc., catalyzed by ruthenium complexes in the presence of *N*-methylmorpholine-*N*-oxide and *N*,*N*-dimethylaniline-*N*-oxide. Furthermore, the catalytic activities of ruthenium complexes containing tertiary phosphine or arsine ligands are well established [14] and these ligands modify the oxidation chemistry of ruthenium-oxo complexes due to their variety of steric and electronic properties [15]. In addition, new kind of chemotherapeutic Schiff bases are now attracting the attention of biochemists [16]. Earlier work reported that some drugs showed increased activity when administered as metal complexes rather than as organic compounds [17]. Chen et al. [18] have proposed that intercalation, hydrogen bonding and π–π interactions are some of the features implicated in the mode of action of ruthenium complexes as antitumour and antimetastatic agents and some compounds are in advance stages of preclinical studies. Although the mechanism of the action of antitumour-active ruthenium compounds is not fully understood yet, it is thought that, similar to platinum drugs [19], the chloride complexes can hydrolyze in vivo, allowing the Ru to bind to the nucleobases of the DNA [20].

In continuation of our research interest [21] to understand the role of these simple and inexpensive N,O-donor ligands towards ruthenium, the reaction of Schiff bases derived from DHA with ruthenium(III) precursors containing PPh_3/$AsPh_3$ has been carried out. Thus, the present paper describes the results of the synthesis, characterization and redox properties of hexacoordinated Ru(III) complexes exhibiting a N,O ligating core with their catalytic activity towards oxidation of alcohols in the presence of NMO. Further, the antibacterial activity of the Schiff bases and their ruthenium complexes were examined. The following Schiff bases, derived from condensation of dehydroacetic acid (DHA) with methylamine, cyclohexylamine and 2-aminopyridine (Scheme 1), were used to prepare the new ruthenium(III) complexes.



Where R = -CH_3; HL1 = DHA-met
= -C_6H_{11}; HL2 = DHA-chx

Scheme 1. Structure of Schiff bases.

2. Experimental

2.1. Reagents and materials

All the reagents used were chemically pure and were of analytical reagent grade. The solvents were dried and distilled before use following the standard procedures [22]. $RuCl_3 \cdot 3H_2O$ was purchased from Loba-Chemie Pvt. Ltd., and was used without further purification. The reagent *N*-methylmorpholine-*N*-oxide was obtained from Aldrich. Dehydroacetic acid (DHA) was purchased from SRL. The supporting electrolyte tetrabutyl ammonium perchlorate (TBAP) was dried in vacuum prior to use.

2.2. Physical measurements

The carbon, hydrogen and nitrogen microanalysis content of each sample was determined at STIC, Cochin University of Science and Technology, Cochin, India by analytic function testing VarioEL III CHNS elemental analyzer. Infrared spectra were collected using KBr pellets on a Jasco 400 Plus, FT-IR spectrophotometer in the range 4000–400 cm^{-1}. Electronic spectra of the complexes in chloroform were recorded on a Cary 300 Bio UV–Vis Varian spectrophotometer. Room temperature solid-state magnetic susceptibilities were measured using an EG and G model 155 vibrating sample magnetometer at IIT, Chennai. Diamagnetic corrections calculated from Pascal's constants [23] were used to obtain the molar paramagnetic susceptibilities. The X-band EPR spectra of the powdered samples were recorded on JEOL JES-FA200 EPR spectrometer at 278 K, the field being calibrated with diphenylpicryl hydrazyl (DPPH, $g = 2.0037$) at Pondicherry University, India. Electrochemical studies were performed using a Princeton EG and G-PARC model potentiostat in 0.001 M acetonitrile solutions of $[(n\text{-}C_4H_9)_4N]ClO_4$ (TBAP) as supporting electrolyte under a nitrogen atmosphere. A three-electrode cell was employed with a platinum working electrode, a platinum wire auxiliary electrode and an Ag/AgCl reference electrode. Melting points were recorded with a Boetius micro-heating table and are uncorrected. The precursor ruthenium(III) complexes $[RuCl_3(PPh_3)_3]$ [24], $[RuCl_3(AsPh_3)_3]$ [25], $[RuBr_3(AsPh_3)_3]$ [26] and $[RuBr_3(PPh_3)_2(CH_3OH)]$ [27] were prepared according to the literature procedures.

2.3. Preparation of Schiff base ligands

The monobasic bidentate Schiff base ligands were prepared by the condensation of dehydroacetic acid (0.21 g, 0.125 mmol) with the primary amines methylamine, cyclohexylamine and 2-aminopyridine (0.038–0.124 g, 0.125 mmol) in a 1:1 molar ratio in methanol (20 cm^3). The solution was heated under reflux for 3 h and then concentrated to 5 cm^3. Slow evaporation of the solvent led to the formation of the Schiff base ligands. The product was recrystallized from methanol and the purity was checked by TLC.

2.4. Synthesis of ruthenium(III) complexes

All the reactions were performed under strictly anhydrous conditions and the complexes were prepared by the following general procedure. To a benzene (20 cm^3) solution of $[RuX_3(EPh_3)_3]$ (0.124–0.157 g, 0.125 mmol) (X = Cl, E = P; X = Cl or Br, E = As) or $[RuBr_3(PPh_3)_2(CH_3OH)]$ (0.112 g, 0.125 mmol) was added the appropriate Schiff bases (0.022–0.031 g, 0.125 mmol) (HL1–HL3). The solution was allowed to heat under reflux for 7 h. The colour of the reaction mixture gradually deepened and the resulting solution was concentrated to ca. 3 cm^3 and cooled. Light petroleum ether (60–80 °C) (5 cm^3) was then added whereupon the complex separated out. Thus obtained solid product was recrystallized from a CH_2Cl_2/light petroleum ether mixture and dried in vacuo. The purity of the complexes were checked by TLC (yield:55–65%).

2.5. Catalytic oxidation

The catalytic activity of one of the synthesized complexes $[RuCl_2(AsPh_3)_2(DHA\text{-}ampy)]$ (**10**) for the oxidation of primary and secondary alcohols to their corresponding aldehydes or ketones was determined in the presence of NMO as co-oxidant. A typical reaction using the complex as a catalyst and various activated and non-activated alcohols as substrates in 1:100 molar ratio is described as follows. A solution of ruthenium complex **10** (0.01 mmol) in 20 cm^3 CH_2Cl_2 was added to the solution of the substrate (1 mmol) and NMO (3 mmol). The solution mixture was refluxed for an appropriate period of time, as mentioned, and the solvent was then evaporated from the mother liquor under reduced pressure. The solid residue was then extracted with petroleum ether (60–80 °C) (20 cm^3) and the products were analyzed and quantified by GC. In case of benzhydrol and benzoin, the products benzophenone and benzil were isolated and confirmed by melting point, IR and ^1H NMR.

2.6. Antibacterial activity

The in vitro antibacterial screening effects of the investigated compounds were tested against the bacteria *Staphylococcus aureus* (209p) and *Escherichia coli* ESS (2231) by the well diffusion method using agar nutrient as the medium at 37 °C for 18 h. The stock solutions of the Schiff bases and the complexes were prepared in 10% DMSO in methanol and were stored dry at room temperature. In a typical procedure [28] a well was made on the agar medium inoculated with microorganisms. The well was then filled with the test solution using a micropipette and the plates were incubated at 35 °C for 24 h for bacteria. During this period, the test solutions diffused and the growth of the inoculated microorganisms was affected. The inhibition zone developed on the plate was measured and the data is summarized in Table 6. Ampicillin was used as the control.

3. Results and discussions

The reactions of $[RuX_3(EPh_3)_3]$ (X = Cl, E = P; X = Cl or Br, E = As) or $[RuBr_3(PPh_3)_2(CH_3OH)]$ with Schiff base ligands (HL1–HL3) in a 1:1 molar ratio in dry benzene afforded new hexacoordinated low spin ruthenium(III) Schiff base complexes. The reaction proceeds as shown in Scheme 2. The proposed molecular formulae for all the complexes are in good agreement with the stoichiometries concluded from their analytical data (Table 1). In all these reactions, the Schiff bases behave as monobasic bidentate ligands replacing one triphenylphosphine or triphenylarsine molecule, one chloride or bromide and one methanol ligand from the precursors. All the complexes are air-stable, non-hygroscopic in nature, insoluble in water and highly soluble in common solvents such as dichloromethane, acetonitrile, chloroform and DMSO, producing intense dark color solutions.

3.1. Spectroscopic characterization

The IR bands for the metal complexes derived from Schiff bases of DHA, which are most useful in attempting to determine the mode of coordination, are listed in Table 2. The IR spectra of the free Schiff base ligands show a strong band in the region 1640–1659 cm^{-1} that is characteristic of the azomethine group. Coordination of the Schiff bases to the metal through the nitrogen atom is expected to reduce the electron density in the azomethine frequency. The band due to azomethine nitrogen $\nu_{(C=N)}$ shows a modest decrease in the stretching frequency for the complexes and is shifted to lower frequencies, appearing around 1631–1651 cm^{-1}, which indicates the coordination of the azomethine nitrogen [21a,29]. Also, there is an upward shift in the stretching frequency of phenolic oxygen in the complexes $\nu_{(C-O)} = 1273–1276\ cm^{-1}$ [30]. This fact is further supported by the disappearance of the $\nu_{(OH)}$ band in the range 3415–3434 cm^{-1} for all the complexes, indicating the subsequent deprotonation of the phenolic proton prior to coordination. Bands in the 510–550 and 450–475 cm^{-1} regions are ascribed to the formation of M–O and M–N bonds, respectively [31] which further supports the coordination of the azomethine nitrogen and the phenolic oxygen. The bands observed in the range 1719–1728 cm^{-1} of the ligands are due to the lactone carbonyl group, which remain unchanged after complexation indicating that they do not participate in bond formation with the metal ion. Further, the ruthenium(III) Schiff base complexes show strong vibrations near 520, 695, 740, 1445 and 1532 cm^{-1}, which are attributable to the triphenylphosphine or triphenylarsine fragments [32].

[a] $^2T_{2g} \rightarrow {}^2A_{2g}$.
[b] Charge transfer (LMCT).
[c] Where ν is in cm^{-1}, λ_{max} is in nm, ε is in $dm^3\ mol^{-1}\ cm^{-1}$.

The electronic spectra of the ruthenium(III) complexes were recorded in chloroform in the range 800–200 nm. Most of the complexes showed two to three bands in the region 812–241 nm, and are listed in Table 2. The ground state of ruthenium(III) in an octahedral environment is $^2T_{2g}$, arising from the t_{2g}^5 configuration, and the first excited doublet levels in the order of increasing energy are $^2A_{2g}$ and $^2T_{1g}$, arising from the $t_{2g}^4e_g^1$ configuration. Hence, two bands corresponding to $^2T_{2g} \rightarrow {}^2A_{2g}$ and $^2T_{2g} \rightarrow {}^2T_{1g}$ are possible. The absorption bands around 812–704 and 586–513 nm are assigned to d–d ($\varepsilon = 511–556\ dm^3/mol/cm$) and charge transfer (LMCT) ($\varepsilon = 1639–1696\ dm^3/mol/cm$) transitions respectively. In most ruthenium(III) Schiff base chelates, charge transfer bands of the type $L_{\pi y} \rightarrow T_{2g}$ are prominent in the low energy region, which obscures the weaker bands due to d–d transitions [21a]. It is therefore difficult to assign conclusively the bands of the ruthenium(III) complexes that appear in the visible region. However, the extinction coefficients for the bands 812–704 nm are found to be low compared to that of the charge transfer bands. Hence, the bands around 812–704 nm have been assigned to the $^2T_{2g} \rightarrow {}^2A_{2g}$ transition, which is in conformity with the assignment made for similar octahedral

ruthenium(III) complexes [33]. The spectral profiles below 400 nm are very similar and are ligand centered transitions. These bands have been designated as π–π^* and n–π^* transitions of non-bonding electrons present on the nitrogen of the azomethine group in the Schiff base complexes [21a]. The pattern of the electronic spectra of all the ruthenium(III) Schiff base complexes indicates the presence of an octahedral environment around the ruthenium(III) ion.

3.2. Magnetic moments and EPR spectra

The room temperature magnetic susceptibility measurements for the complexes lie in the range 1.79–1.92 BM, which indicates that these complexes are one electron paramagnetic, suggesting a low spin t_{2g}^5 ($S = 1/2$) configuration around the ruthenium(III) ion in an octahedral environment.

The room temperature solid-state EPR spectra of all the complexes were recorded at X-band frequencies. The 'g' values are given in Table 3 and a representative spectrum is shown in Fig. 1. The low spin d^5 configuration is a good probe of the molecular structure and bonding since the observed 'g' values are very sensitive to small changes in the structure and to metal–ligand covalency. The EPR spectra of all the complexes exhibit two different 'g' values ($g_x = g_y \neq g_z$) with $g_\perp = 2.03$–2.39 and $g_\parallel = 1.99$–1.89, characteristic of an axially symmetric system. The presence of two different 'g' values indicate a tetragonal distortion in the complexes [21a,34]. Overall the positions of lines and nature of the EPR spectra of the complexes are characteristic of low spin ruthenium(III) octahedral complexes.

3.3. Electrochemistry of the complexes

The redox properties of all the complexes were investigated in dichloromethane solution with tetrabutyl ammonium perchlorate (TBAP) as the supporting electrolyte by cyclic voltammetry and the redox potentials are expressed with reference to Ag/AgCl. A representative cyclic voltammogram of complex **11** is shown in Fig. 2 and voltammetric

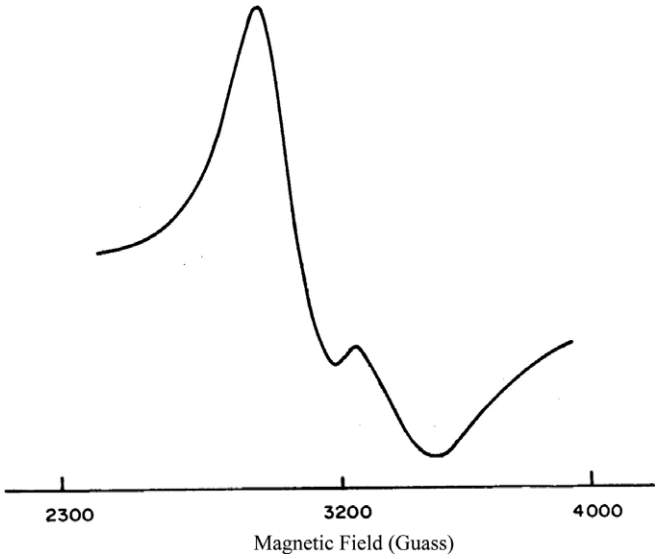

Fig. 1. EPR spectrum of $[RuCl_2(PPh_3)_2(DHA\text{-}met)]$.

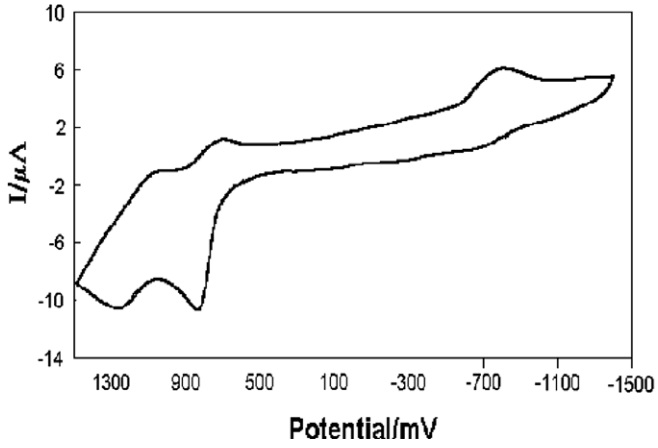

Fig. 2. Cyclic voltammogram of $[RuBr_2(AsPh_3)_2(DHA\text{-}ampy)]$.

data are presented in Table 4. All the complexes displayed two quasi-reversible oxidation couples Ru^{III}/Ru^{IV} at $E_{1/2} = 0.67$–0.82 V with a peak-to-peak separation $\Delta E_P =$ 100–150 mV and Ru^{IV}/Ru^{V} with $E_{1/2} = 1.00$–1.17 V with $\Delta E_P = 150$–210 mV, with respect to Ag/AgCl, which do not change with a change in scan rates, supporting reversibility [35]. The oxidations observed are quasi-reversible in nature, characterized by a rather large peak-to-peak separation (ΔE_p), and the cathodic peak current (i_{pc}) is less than the anodic peak current (i_{pa}). Further, all the complexes exhibit an irreversible reduction in the range -0.79 to -0.92 V. The reason for the irreversibility observed for the reductive response of all the complexes may be due to a short lived reduced state of the metal ion [36] or due to oxidative degradation of the ligands [37]. In these redox couples, electrons are gained or lost from the dπ levels orbital of the coordinated metal [38]. There is not much variation due to replacement of chlorides by bromides and triphenylphosphine by triphenylarsine. Hence, it is inferred

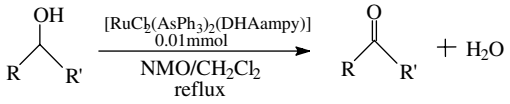
from the electrochemical data that the present ligand system is ideally suitable for stabilizing the higher oxidation state of ruthenium.

3.4. Catalytic activity of the complexes

Catalytic oxidation of primary and secondary alcohols by one of the synthesized ruthenium(III) Schiff base complexes was carried out in CH_2Cl_2 in the presence of NMO and the by-product water was removed using molecular sieves. The results are summarized in Table 5. The catalytic reaction was carried out under a set of conditions (see experimental for reaction conditions) and a series of blank or control experiments suggest that none of $RuCl_3 \cdot 3H_2O$, Ru(III) precursors or DHA-ampy, NMO alone or as a mixture causes these transformations under identical reaction conditions. This ascertained the necessity of the ruthenium(III) complex to observe the ensuing catalytic organic transformations. Complex **10** oxidizes primary alcohols to the corresponding aldehydes and secondary alcohols to ketones with high yield.



R, R' = alkyl (or) aryl

The aldehydes or ketones formed after reflux for the time mentioned was determined by GC with authentic samples. Results of the present investigation suggest that the complexes are able to react efficiently with NMO to yield a high valent ruthenium-oxo species [39,40], capable of oxygen transfer to alcohols. This was further supported by changes that occur on addition of NMO to a dichloromethane solution of the ruthenium(III) complexes. The appearance of the peak at 380 nm is attributed to the formation of $Ru^{V}{=}O$ species, which is in conformity with other ruthenium(V)-oxo complexes [40–42]. Further, support in favor of the formation of such species is identified from the IR spectrum of the solid mass (obtained by evaporation of the resultant solution to dryness), which shows a band at 860 cm^{-1}, characteristic of ruthenium(V)-oxo species [11d,40,41a] (see Scheme 3).

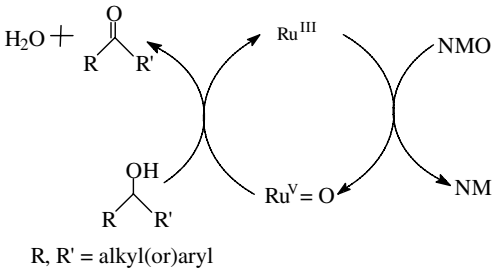

Scheme 3. Proposed catalytic cycle for the oxidation of alcohols by the Ru(III) Schiff base complex.

The oxidation of benzyl alcohol to benzaldehyde resulted in 89% conversion. An important characteristic of the ruthenium/NMO system results in the selective oxidation at the alcoholic group of unsaturated cinnamyl alcohol to cinnamaldehyde, tolerating the other reactive functional group (double bond). In case of benzoin and benzhydrol, the oxidized products, benzil and benzophenone respectively, were isolated and characterized by melting point, IR and ^{1}H NMR.

Allylic and benzylic alcohols are oxidized with maximum selectivity to aldehydes with, importantly, no further oxidation to the corresponding carboxylic acids. Unactivated secondary alcohols such as 2-butanol and 2-pentanol were also effectively oxidized into their corresponding ketones, ethyl methyl ketone and ethyl propyl ketone with 84% and 92% conversion respectively. Also, activated secondary alcohols such as 1-phenyl ethanol and 4-methoxy-1-phenyl ethanol undergo significant oxidation to give their corresponding ketones with high selectivities of 63% and 88% conversion respectively. The higher conversion in the case of 4-methoxy-1-phenyl ethanol, when compared to 1-phenyl ethanol, is due to the presence of the electron-withdrawing methoxy (OCH_3) group, which increases the reactivity by destabilizing the ruthenium-oxo intermediate making it a more reactive oxidant [8]. Interestingly, the complex efficiently catalyses the oxidation of five, six, seven and eight membered cyclic alcohols to the corresponding ketones with conversions >90% respectively.

It has been observed that these ruthenium(III) Schiff base complexes have better catalytic efficiency in the case of oxidation of benzyl alcohol, cinnamyl alcohol and cyclohexanol when compared to the earlier reports [11d,40–42], on similar ruthenium complexes as catalysts in the presence of NMO/*t*-BuOOH. Hence, it is relevant from the cyclic voltammetric data that the oxidation is likely to occur via higher ruthenium oxidation states, which are easily accessible through chemical oxidation with the co-oxidant NMO [39,42].

3.5. Antimicrobial studies

The Schiff base ligands and ruthenium(III) complexes were screened in vitro for their microbial activity against two human pathogenic bacterial species using the well diffusion method. These compounds were found to exhibit considerable activity against Gram +ve (*S. aureus* 209p) and Gram −ve (*E. coli* ESS 2231). The test solutions were prepared in dimethyl sulfoxide and the results are summarized in Table 6. Blank experiments with $RuCl_3 \cdot 3H_2O$ and the Ru(III) precursors were carried out under identical experimental conditions and show the inability of these complexes to inhibit the bacterial growth. The effectiveness of an antimicrobial agent in sensitivity is based on the zones of inhibition. The diameter of the zone is measured to the nearest millimeter (mm).

The obtained results indicate that the complexes (ruthenium chelates) are more toxic than the free ligands against same microbes under identical experimental conditions. This would suggest that the chelation could facilitate the ability of a complex to cross a cell membrane [43] and can be explained by Tweedy's chelation theory [44]. Chelation considerably reduces the polarity of the metal ion because of partial sharing of its positive charge with donor groups and possible π-electron delocalization over the whole chelate ring. Such a chelation could enhance the lipophilic character of the central metal atom, which subsequently favors its permeation through the lipid layers of the cell membrane [45] and blocking the metal binding sites on enzymes of microorganisms. The different compounds exhibit microbial activity with small variations against the bacterial species and this difference in activity could be attributed to the impermeability of the cell of the microbes which, in the case of Gram +ve is single layered and in the case of Gram −ve is a multilayered structure [46] or differences in the ribosomes of the microbial cells.

The observed results seem to conclude that the present ruthenium(III) chelates possess more cytotoxicity than the free Schiff base ligands. Further, it has been noted that these complexes show better antibacterial activity when compared to other metal complexes against the microbes *S. aureus* and *E. coli* [47]. Though complexes of this type

Table 6

– No inhibition; standard; solvent, DMSO (no inhibitory against the microorganisms).

were found to have potential antibacterial activity against the bacterial microbes, they could not reach the effectiveness of the conventional bacterial control Ampicillin.

4. Conclusion

In summary, we have synthesized and characterized a series of new ruthenium(III) Schiff base complexes incorporating triphenylphosphine/triphenylarsine and chloride/bromide ligands. One of the complexes has been tested as a new and efficient catalyst for the oxidation of both primary and secondary alcohols to the corresponding carbonyl compounds with excellent yields in the presence of *N*-methylmorpholine-*N*-oxide. Further, the possible explanations for the mode of action of these complexes against two different microbes are described.

Acknowledgement

We express our sincere thanks to Professor P. Sambasiva Rao, Department of Chemistry, Pondicherry University for providing the EPR facility.

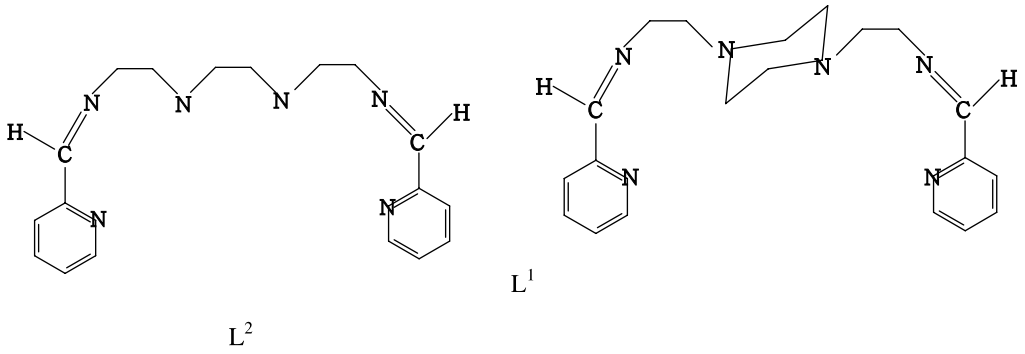

Scheme 1.

most important ones, which form various networks with different transition and non-transition metal ions in combination with organic spacers of varied denticities. In an effort to isolate and study new forms of such aggregates, we have been exploring the coordination behaviour of two different hexadentate Schiff base ligands (Scheme 1) towards zinc(II) in combination with pseudohalides. In this paper, we have reported the synthetic details, spectral characterization and different physicochemical properties of two series of zinc(II) pseudohalide complexes, along with the X-ray crystal structures of representative members, $[Zn_2(L^2)(N_3)_4]$ (**1c**) and $[Zn(L^1)][Zn(NCS)_4]$ (**2b**), where the azides and thiocyanates, established bridging ligands [16,17] in dimeric and polymeric systems, act as terminal ligands instead of adopting a bridging mode in the presence of a bis(tridentate) Schiff base.

2. Experimental

2.1. Materials and methods

High purity pyridine-2-carboxaldehyde (Lancaster, UK), triethylenetetramine (Lancaster, UK), 2-[4-(2-aminoethyl)-piperazin-1-yl]ethylamine (Aldrich, USA), sodium azide (Aldrich, USA), ammonium thiocyanate (Fluka, Germany) and zinc(II) nitrate tetrahydrate (E. Merck, India) were purchased from the respective concerns and used as received. Zinc(II) perchlorate hexahydrate was prepared by treatment of zinc carbonate (E. Merck, India) with perchloric acid (E. Merck, India) followed by slow evaporation on a steam-bath, then filtration through a fine glass-frit, and it was preserved in a desiccator containing concentrated sulfuric acid for subsequent use. All other chemicals and solvents were AR grade and were used as received.

Caution! Azido and perchlorate compounds of metal ions are potentially explosive especially in the presence of organic ligands. Only a small amount of the materials should be prepared and they should be handled with care.

2.2. Physical measurements

Elemental analyses (carbon, hydrogen and nitrogen) were performed on a Perkin–Elmer 2400 CHNS/O elemental analyzer. IR spectra (KBr discs, 4000–300 cm^{-1}) were recorded using a Perkin–Elmer FT-IR model RX1 spectrometer. Molar conductances were measured using a Systronics conductivity meter where the cell constant was calibrated with 0.01 M KCl solution and dry MeOH was used as the solvent. Ground state absorption and steady-state fluorescence measurements were made with a Jasco model V-530 UV–Vis spectrophotometer and Hitachi model F-4010 spectrofluorimeter, respectively. Time-resolved fluorescence measurements were carried out using a time-correlated single photon counting (TCSPC) spectrometer Edinburgh Instruments, model 199; a hydrogen filled coaxial flash lamp with a pulse width of 1.2 ns at FWHM and a Philips XP-2020Q Photopmultiplier tube were, respectively, used as the excitation source and the fluorescence detector.

2.3. Preparation of Schiff bases

The Schiff bases L^1 and L^2 were prepared following using reported method [15] with a little modification. Details are described below.

2.3.1. *N-(1-Pyridin-2-ylformylidene)-N′-[2-({2-[(1-pyridin-2-ylformylidene)amino]ethyl}amino)-ethyl]ethane-1,2-diamine (L^1)*

Pyridine-2-carboxaldehyde (0.214 g, 2 mmol) was refluxed with triethylenetetramine (0.146 g, 1 mmol) in dehydrated alcohol (15 cm^3). After 10 h the reaction solution was evaporated under reduced pressure to yield a gummy mass, which was dried and stored in vacuo over $CaCl_2$ for subsequent use. Yield: 0.212 g (80%). *Anal.* Calc. for $C_{18}H_{24}N_6$ (L^1): C, 66.63; H, 7.45; N, 25.91. Found: C, 66.58; H, 7.41; N, 25.86%. IR (KBr, cm^{-1}): 1590 ($\nu_{C=N}$). UV–Vis (λ_{max}, nm): 266, 280.

2.3.2. *N-(1-Pyridin-2-ylformylidene)-N′-[2-(4-{2-[(1-pyridin-2ylformylidene)amino]ethyl}-piperazin-1-yl)-ethyl]amine (L^2)*

L^2 was prepared similarly using 2-[4-(2-aminoethyl)-piperazin-1-yl]ethylamine [18] instead of triethylenetetramine. Yield: 0.212 g (80%). *Anal.* Calc. for $C_{20}H_{28}N_6$ (L^2): C, 68.14; H, 8.01; N, 23.84. Found: C, 68.09; H, 7.94; N, 23.79%. IR (KBr, cm^{-1}): 1592 ($\nu_{C=N}$). UV–Vis (λ_{max}, nm): 242, 290.

2.4. Preparation of the complexes

Complexes **1a**–**1d** were prepared from the perchlorate salt of zinc(II) using a 2:1:4 mole ratio of the metal, L^1/L^2 and azide/thiocyanate. Using a 1:1 mole ratio of metal–L^1/L^2 and a 1:4 mole ratio of metal-azide/thiocyanate **2a**–**2d** were isolated.

2.4.1. Synthesis of $[Zn_2(L^1)(N_3)_4]$ (**1a**) and $[Zn_2(L^1)(NCS)_4]$ (**1b**)

A methanolic solution (5 cm^3) of L^1 (0.32 g, 1 mmol) was added dropwise to a solution of $Zn(ClO_4)_2 \cdot 6H_2O$ (0.74 g, 2 mmol) in the same solvent (10 cm^3) then an aqueous solution (5 cm^3) of sodium azide (0.26 g, 4 mmol) was mixed slowly. The light yellow solution was filtered and the supernatant liquid was kept in air for slow evaporation. After a few days, the fine microcrystalline compound **1a** that separated out was washed with toluene and dried in vacuo over silica gel indicator. Compound **1b** was prepared by the same procedure using ammonium thiocyanate in place of sodium azide. Yield: 0.91 g (70%). *Anal.* Calc. for $C_{13}H_{24}N_{18}Zn_2$ (**1a**): C, 27.72; H, 4.29; N, 44.76. Found: C, 27.67; H, 4.23; N, 44.71%. IR (KBr, cm^{-1}): 1595 ($\nu_{C=N}$), 2042 (ν_{N_3}). UV–Vis (λ_{max}, nm): 330. Yield: 0.49 g (72%). *Anal.* Calc. for $C_{17}H_{24}N_{10}S_4Zn_2$ (**1b**): C, 32.55; H, 3.85; N, 22.33. Found: C, 32.48; H, 3.79; N, 22.281%. IR (KBr, cm^{-1}): 1595 ($\nu_{C=N}$), 2050, 2071 (ν_{NCS}). UV–Vis (λ_{max}, nm): 335.

2.4.2. $[Zn_2(L^2)(N_3)_4]$ (**1c**) and $[Zn_2(L^2)(NCS)_4]$ (**1d**)

To zinc(II) perchlorate tetrahydrate (0.74 g, 2 mmol) in methanol (10 cm^3), faint yellow L^2 (0.35 g, 1 mmol) was added dropwise. To this solution a methanolic solution of sodium azide (0.26 g, 4 mmol) was added with constant stirring. The final light brown solution was filtered and left for slow evaporation in air. After a few days fine whitish brown plate shaped single crystals of **1c**, suitable for X-ray measurements, separated out, and these were washed with toluene and dried in vacuo over silica gel indicator. The same route was followed to prepare **1d** only using ammonium thiocyanate instead of sodium azide. Yield: 0.91 g (70%). *Anal.* Calc. for $C_{20}H_{28}N_{18}Zn_2$ (**1c**): C, 36.88; H, 4.33; N, 38.71. Found: C, 36.80; H, 4.25; N, 38.67%. IR (KBr, cm^{-1}): 1595 ($\nu_{C=N}$), 2045 (ν_{N_3}). UV–Vis (λ_{max}, nm): 330. Yield: 0.50 g (70 %). *Anal.* Calc. for $C_{24}H_{28}N_{10}S_4Zn_2$ (**1d**): C, 40.29; H, 3.94; N, 19.58. Found: C, 40.20; H, 3.87; N, 19.51%. IR (KBr, cm^{-1}): 1595 ($\nu_{C=N}$), 2050, 2071 (ν_{NCS}). UV–Vis (λ_{max}, nm): 328.

2.4.3. Synthesis of $[Zn(L^1)][Zn(N_3)_4]$ (**2a**) and $[Zn(L^1)][Zn(NCS)_4]$ (**2b**)

2.4.3.1. Method A. An aqueous solution (5 cm^3) of NaN_3 (0.26 g, 4 mmol) was added to a solution of $Zn(NO_3)_2 \cdot 4H_2O$ (0.24 g, 1 mmol) in the same solvent (10 cm^3) with the formation of a colourless solution. In an another container $Zn(NO_3)_2 \cdot 4H_2O$ (0.24 g, 1 mmol) and L^1 (0.32 g, 1 mmol) were mixed together in MeOH (10 cm^3) producing a yellowish solution. This coloured solution was added dropwise to the above colourless solution. The final light brown mixture was filtered and left for slow evaporation in air. Light yellow compound **2a** separated out. X-ray quality cubic single crystals of **2b** were prepared by the same procedure using NH_4NCS in place of sodium azide. Yield: 0.51 g (75%). *Anal.* Calc. for $C_{13}H_{24}N_{18}Zn_2$ (**2a**): C, 27.72; H, 4.29; N, 44.76. Found: C, 27.67; H, 4.21; N, 44.71%. IR (KBr, cm^{-1}): 1601 ($\nu_{C=N}$), 2145 (ν_{N_3}). UV–Vis (λ_{max}, nm): 330. Yield: 0.49 g (72%). *Anal.* Calc. for $C_{17}H_{24}N_{10}S_4Zn_2$ (**2b**): C, 32.55; H, 3.85; N, 22.33. Found: C, 32.50; H, 3.84; N, 22.27%. IR (KBr, cm^{-1}): 1592 ($\nu_{C=N}$), 2065, 2071 (ν_{NCS}). UV–Vis (λ_{max}, nm): 330.

2.4.3.2. Method B. $Zn(NO_3)_2 \cdot 4H_2O$ (0.48 g, 2 mmol), L^1 (0.32 g, 1 mmol) and NaN_3 (0.26 g, 4 mmol) were mixed in a single container containing 20 cm^3 methanol, which resulted in a light brown solution. The mixture was filtered and kept for slow evaporation in air. Light yellow rectangular crystals of **2a** were formed after a week. NH_4NCS was used in place of NaN_3 to isolate **2b** by the same process. Yield: 0.51 g (75%). *Anal.* Calc. for $C_{13}H_{24}N_{18}Zn_2$ (**2a**): C, 27.72; H, 4.29; N, 44.76. Found: C, 27.67; H, 4.21; N, 44.71%. IR (KBr, cm^{-1}): 1595 ($\nu_{C=N}$), 2065, 2052 (ν_{N_3}). UV–Vis (λ_{max}, nm): 326. Yield: 0.49 g (72%). *Anal.* Calc. for $C_{17}H_{24}N_{10}S_4Zn_2$ (**2b**): C, 32.55; H, 3.85; N, 22.33. Found: C, 32.50; H, 3.84; N, 22.27%. IR (KBr, cm^{-1}): 1595 ($\nu_{C=N}$), 2065, 2071 (ν_{NCS}). UV–Vis (λ_{max}, nm): 330.

2.4.4. Synthesis of $[Zn(L^2)][Zn(N_3)_4]$ (**2c**) and $[Zn(L^2)][Zn(NCS)_4]$ (**2d**)

2.4.4.1. Method A. To a methanolic solution (10 cm^3) of L^2 (0.35, 1 mmol) a solution of $Zn(NO)_3 \cdot 4H_2O$ (0.24 g, 1 mmol) was added slowly in a glass beaker. In an another container, a solution of sodium azide (0.26 g, 4 mmol) was added to $Zn(NO)_3 \cdot 4H_2O$ (0.24 g, 1 mmol) in methanol (10 cm^3). The former yellow solution was transferred dropwise to the latter colourless solution yielding a whitish brown mixture. This was filtered and left for slow evaporation in air. Whitish brown rectangular crystals were found after a few days. A similar procedure was applied to yield **2d** except using NH_4NCS in place of NaN_3. Yield: 0.51 g (75%). *Anal.* Calc. for $C_{20}H_{28}N_{18}Zn_2$ (**2c**): C, 36.87; H, 4.33; N, 38.71. Found: C, 36.77; H, 4.28; N, 38.67%. IR (KBr, cm^{-1}): 1602 ($\nu_{C=N}$), 2040 (ν_{N_3}). UV–Vis (λ_{max}, nm): 328. Yield: 0.49 g (72%). *Anal.* Calc. for $C_{24}H_{28}N_{10}S_4Zn_2$ (**2d**): C, 40.29; H, 3.95; N, 19.58. Found: C, 40.21; H, 3.87; N, 19.50%. IR (KBr, cm^{-1}): 1595 ($\nu_{C=N}$), 2124, 2072 (ν_{NCS}). UV–Vis (λ_{max}, nm): 332.

2.4.4.2. Method B. $Zn(NO)_3 \cdot 4H_2O$ (0.48 g, 2 mmol), L^2 (0.35 g, 1 mmol) and sodium azide (0.26 g, 4 mmol) were mixed in a single pot giving a brownish solution which on slow evaporation in air yielded **2c**. When ammonium thiocyanate was used in place of sodium azide in the same reaction procedure, **2d** was separated out. Yield: 0.51 g (75%). *Anal.* Calc. for $C_{13}H_{24}N_{18}Zn_2$ (**2c**): C, 36.87; H, 4.33; N, 38.71. Found: C, 36.77; H, 4.28; N, 38.67%. IR

2.5. X-ray diffraction study

A plate-shaped single crystal ($0.10 \times 0.15 \times 0.20$ mm^3) of **1c** and a cube-shaped single crystal ($0.30 \times 0.30 \times 0.30$ mm^3) of **2b** were obtained by slow evaporation of MeOH solutions of the appropriate reaction mixtures. Colourless crystals, suitable for X-ray crystallographic analysis, were selected following examination under a microscope. Diffraction data at 297 K and 296 K for **1c** and **2b**, respectively, were collected on a Bruker-SMART CCD diffractometer using Mo Kα radiation ($\lambda = 0.71073$ Å). Systematically absent reflections led to the identification of space group $P2_1/n$ (No. 14) for **2b**. Of the 3159 and 6968 total reflections for the two respective complexes, 2349 and 4192 with $[I > 2\sigma(I)]$ were used for structure solutions. The structures were solved by direct methods, and the structure solution and refinement were based on $|F|^2$. All non-hydrogen atoms were refined with anisotropic displacement parameters whereas hydrogen atoms were placed in calculated positions when possible and given isotropic U values 1.2 times that of the atom to which they are bonded. At convergence the final residuals were $R_1 = 0.0360$; $wR_2 = 0.0884$ for **1c** and $R_1 = 0.0560$ and $wR_2 = 0.1070$ for **2b** with $[I > 2\sigma(I)]$, goodness-of-fit = 1.000 and 0.868 for **1c** and **2b**, respectively. The final differences Fourier map showed the minimum and maximum peak heights at −0.60 and 0.56 e $Å^{-3}$ for **1c** and −0.36 and 0.37 e $Å^{-3}$ for **2b** with no chemical significance. All calculations were carried out using SHELXL-97 [19] and ORTEP-32 [20]. The crystal data and data collection parameters are listed in Table 1.

Table 1

Largest peak and hole (e $Å^{-3}$)	−0.60 and 0.56	−0.36 and 0.37

Weighting scheme: Calculated $w = 1/[\sigma^2(F_o^2) + (0.0339P)^2 + 0.5866P]$ (**1c**); $w = 1/[\sigma^2(F_o^2) + (0.0520P)^2 + 2.2367P]$ (**2d**) where $P = (F_o^2 + 2F_c^2)/3$.

3. Results and discussion

3.1. Synthesis and formulation

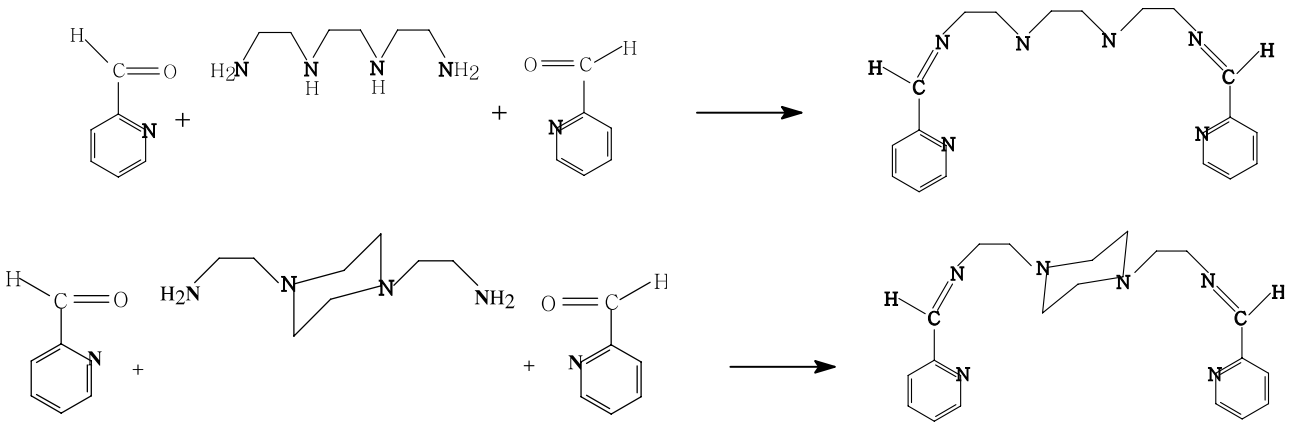
The ligands (L^1 and L^2) were synthesized by refluxing triethylenetetramine with pyridine-2-carboxaldehyde and 2-[4-(2-aminoethyl)-piperazin-1-yl]ethylamine, respectively, in a 1:2 mole ratio in boiling alcohol (Scheme 2).

Colourless powders of the pentacoordinated dinuclear complexes $[Zn_2(L^1/L^2)(X)_4]$ (**1a**–**1d**) (L^1:X = N_3^-, **1a** and X = NCS^-, **1b**; L^2:X = N_3^-, **1c** and X = NCS^-, **1d**) were produced in good yield through the reaction of a 2:1:4 molar ratio of the metal salts, organic blockers and pseudohalides. The process is summarized in the following equation:

$$Zn(ClO_4)_2 \cdot 6H_2O + L^1/L^2 + 4NaN_3/NH_4NCS \xrightarrow[298\ K]{MeOH} [Zn_2(L^1/L^2)(NCS/N_3)_4]\ (\mathbf{1}) + 4NaClO_4 + 6H_2O \quad (1)$$

The homobimetallic complexes $[Zn(L^1/L^2)][Zn(X)_4]$ (**2a**–**2d**) (L^1:X = N_3^-, **2a** and X = NCS^-, **2b**; L^2:X = N_3^-, **2c** and X = NCS^-, **2d**) were initially synthesized by the reaction of 2:1:4 molar ratios of the metal salts, organic blockers and pseudohalides at room temperature (298 K) with the aim to obtain homopolymers $[Zn_2(L^1/L^2)(NCS)_4]_n$. However, to our surprise ion pair complexes were obtained in low yields. The molecular ion, $[Zn(NCS)_4]^{2-}$, was generated in solution by addition of four moles of ammonium thiocyanate to one mole of zinc nitrate tetrahydrate in methanol. The complementary unit $[Zn(L^1/L^2)]^{2+}$ was prepared by dropwise addition of one mole of L^1/L^2 to one molar zinc nitrate tetrahydrate in methanol in a separate container. Compound **2** resulted in good yield through union of the $[Zn(L^1/L^2)]^{2+}$ and $[Zn(NCS)_4]^{2-}$ building blocks. The details of the sequential reactions are summarized in the following equations:

$$Zn(NO_3)_2 \cdot 4H_2O + L^1/L^2 \xrightarrow[298\ K]{MeOH} [Zn(L^1/L^2)](NO_3)_2 + 4H_2O \quad (2)$$



Scheme 2.

$$Zn(NO_3)_2 \cdot 4H_2O + 4NH_4NCS/NaN_3 \xrightarrow[298\ K]{MeOH} (NH_4)_2[Zn(NCS/N_3)_4] + 2NH_4NO_3 + 4H_2O \quad (3)$$

$$[Zn(L^1/L^2)](NO_3)_2 + (NH_4)_2[Zn(NCS/N_3)_4] \xrightarrow[298\ K]{MeOH} [Zn(L^1/L^2)][Zn(NCS/N_3)_4](\mathbf{2}) + NH_4NO_3 \quad (4)$$

The complexes were characterized using microanalytical, spectroscopic and physicochemical results. The air-stable moisture-insensitive complexes are soluble in common solvents like methanol, ethanol, acetonitrile, dimethylformamide and dimethylsulfoxide. In methanol solution complex **1** behaves as neutral and complex **2** shows a conductivity value of $\sim 140\ \Omega^{-1}\ cm^2\ mol^{-1}$ which reflects molecular association of the complex ions [21].

3.2. Spectral studies

In the IR spectra, the point of interest for **1a**, **1c**, **2a** and **2c** is the band due to the azide. The spectra exhibit a very strong and sharp absorption band at 2040–2060 cm^{-1} due to an asymmetric stretching vibration of the azide. Well resolved peaks attributed to ν(NCS) are observed for **1b**, **1d**, **2b** and **2d** at 2124, 2075, 2048 cm^{-1}. The presence of multiple bands in line with the different force constants of thiocyanates are observed. A band corresponding to the ν(CS) stretching frequency appears at 769 cm^{-1}. The bands belonging to the deformation frequency δ(NCS) are found as doublets at 468 and 472 cm^{-1}. The bimetallic assembly shows bands around 1590–1630 cm^{-1} due to the C=N stretching frequency of the Schiff base and weak bands in the range 2980–2900 cm^{-1} are assignable to the aliphatic C–H stretching frequency.

3.3. X-ray crystal structure

3.3.1. $[Zn_2(L^2)(N_3)_4]$ (**1c**)

In order to define the coordination sphere conspicuously, a single-crystal X-ray diffraction study was made. An ORTEP diagram with the atom numbering scheme of the dinuclear unit in **1c** is shown in Fig. 1. Selected bond distances and bond angles relevant to the Zn coordination sphere are given in Table 2. The crystal lattice of **1c** consists of neutral dinuclear $[Zn_2(L^2)(N_3)_4]$ units. The coordination polyhedron around zinc is best described as distorted trigonal bipyramidal, with a ZnN_5 chromophore. The distortion from ideal trigonal bipyramidal geometry is due to the asymmetric nature of the bound hexadentate Schiff base and the deviations of the angles formed at the metal center (Table 2). The metal ion is ligated by one pyridine nitrogen

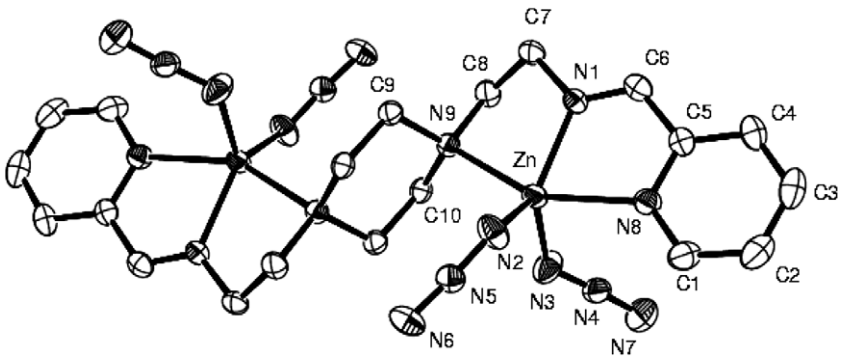


Fig. 1. ORTEP plot of $[Zn_2(L^2)(N_3)_4]$ (**1c**) with the atom numbering scheme and 20% probability ellipsoids for all non-hydrogen atoms.

Table 2
Selected bond distances (Å) and bond angles (°) for **1c**

Bond distances (Å)			
Zn–N(1)	2.0515(19)	N(2)–N(5)	1.191(3)
Zn–N(2)	1.960(3)	N(5)–N(6)	1.143(3)
Zn–N(3)	1.977(3)	N(3)–N(4)	1.175(4)
Zn–N(8)	2.289(2)	N(4)–N(7)	1.138(5)
Zn–N(9)	2.3645(18)		
Bond angles (°)			
N(1)–Zn–N(2)	127.60(10)	N(2)–Zn–N(8)	93.97(9)
N(1)–Zn–N(3)	118.76(12)	N(2)–Zn–N(9)	108.31(9)
N(1)–Zn–N(8)	74.68(8)	N(3)–Zn–N(8)	94.20(10)
N(1)–Zn–N(9)	78.57(8)	N(3)–Zn–N(9)	92.17(9)
N(2)–Zn–N(3)	112.90(13)	N(8)–Zn–N(9)	152.24(7)

(N8), one amine nitrogen (N9), one imine nitrogen (N1) and two terminal azide nitrogens (N2, N3). One imine nitrogen (N1) and two terminal azide nitrogens (N2, N3) occupy the equatorial positions of the distorted trigonal bipyramid, whereas the axial positions are occupied by the one pyridine nitrogen (N8) and the amine nitrogen (N9). Both the equatorial Zn–N distances [1.960(3)–2.3645(18) Å] and bond angles [112.90–127.60°] have some significant variation in that plane. The axial Zn–N distances are 2.289(2) and 2.3645 (18) Å. The axial bond angle N8–Zn–N9 [152.24(7)°] deviates from the ideal 180°. The sum (359.26°) of the equatorial angles N2–Zn1–N3 (112.90°), N1–Zn1–N3 (118.76°) and N1–Zn1–N2 (127.60°) are very close to 360.00°. So the atoms N1, N2, N3 and Zn1 are almost in a least-squares plane. In the terminal azide ligands, the N2–N5 [1.191(3) Å] and N3–N4 [1.175 (4) Å] distances are longer than N5–N6 [1.143(3) Å] and N4–N7 [1.138(5) Å], respectively, which indicates that the nitrogen atoms (N2 and N3) of the two terminal azides are coordinated to the zinc(II) centre.

In the crystal lattice the dinuclear units are packed with weak C–H···N hydrogen bonding. The nitrogen atoms (N3, N5, N6 and N7) from terminal azide ligands are hydrogen bond acceptors and C–H (H4, H6A, H7B, H10A and H10B) hydrogens of the organic ligand skeleton are donors (Table 3). An infinite 1D supramolecular chain (Fig. 2) results through C–H···N hydrogen bonding interactions [C(4)–H(4)···N(7), 2.5 Å, ∠C(4)–H(4)···N(7), 174°; ∠C(6)–H(6A)···N(6), 2.32 Å, 149°; ∠C(7)–H(7B)···N(7), 2.62 Å, 149°; C(10)–H(10A)···N(3), 2.58 Å, ∠C(10)–H(10A)···N(3), 116°; C(10)–H(10B)···N(5), 2.54 Å, ∠C(10)–H(10B)···N(5), 165°]. This chain is further stabilized by strong face-to-face π···π interactions from two terminal pyridine rings [ring(3)–ring(3): Cg(3)–Cg(3)^{i} separation: 4.5395(19) Å, vertical displacement of Cg: 3.471 Å; $^{i}1-x,\ 2-y,\ 1-z$. Ring3 = N(8)–C(1)–C(2)–C(3)–C(4)–C(5)] (Table 4).

3.3.2. $[Zn(L^1)][Zn(NCS)_4]$ (**2b**)

An ORTEP view with the atom numbering scheme of the ion-pair complex **2b** is shown in Fig. 3. Selected bond distances and bond angles relevant to the Zn coordination sphere are given in Table 5. In the solid state **2b** consists of $[Zn(L^1)]^{2+}$ cations and $[Zn(NCS)_4]^{2-}$ anions. The coordination polyhedron around zinc(II) is best described as a

distorted octahedron with a ZnN_6 chromophore for the cationic part and a distorted tetrahedron with a ZnN_4 chromophore for the anionic part. In the octahedral part, the metal ion is ligated by two pyridine nitrogens (N6, N8), two amine nitrogens (N5, N7) and two imine nitrogens (N9, N10). The two amine nitrogens (N5, N7) and two pyridine nitrogens (N6, N8) occupy the equatorial positions of the distorted octahedron, whereas the axial positions are occupied by the two imine nitrogens (N9, N10). The equatorial Zn–N distances lie within a close range [2.163(3)–2.219(3) Å] but there is a significant variation in the bond angles [80.55(11)–153.74(9)°] in that plane. The axial Zn–N distances [2.077(2) and 2.080 (3) Å] are found to be smaller than the equatorial ones. The N–C [1.136(6)–1.149(5) Å] and C–S [1.589(4)–1.614(4) Å] distances are as expected for N-coordination [17c]. Here tetragonal compression of the octahedral geometry may be raised from the π-acceptance of imine nitrogen atoms. Four hydrogen bonds, two of N–H···S type

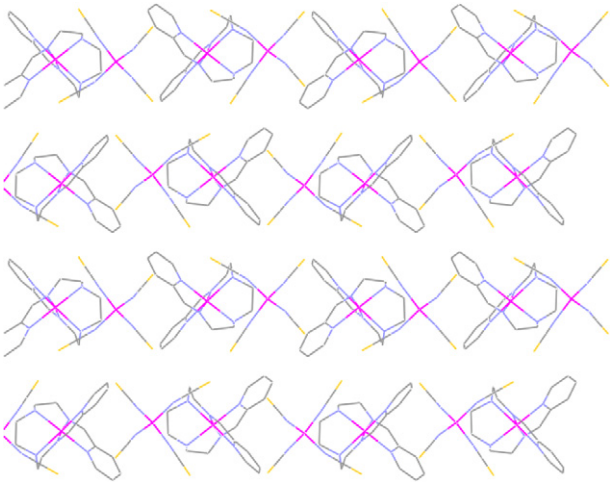

Fig. 4. Packing in **2b** viewed down the (100) plane.

Table 7
Photophysical data

Sample	Absorption (λ (nm))	Emission (λ (nm))		Life times (ns)
		Fluorescence	Phosphorescence	
1c	330	392	470	2.72
2b	330	390	482	2.43

[N(7)–H(7)···S(2), 2.81 Å; ∠N(7)–H(7)···S(2), 146°] and three of C–H···S type [C(13)–H(13B)···S(1), 2.61 Å, ∠C(13)–H(13B)···S(1), 144°; C(15)–H(15A)···S(3), 2.85 Å, ∠C(15)–H(15A)···S(3), 123°; C(15)–H(15B)···S(4), 2.63, ∠C(15)–H(15B)···S(4), 166°] link the components into an infinite line structure (Table 6, Fig. 4).

3.4. Luminescence properties

The spectroscopic data in methanol solutions and glasses of two representative compounds are listed in Table 7. Compound **1c** shows an emission spectrum at 392 nm while compound **2b** has a band at 390 nm at 298 K. These are assignable to intraligand $^1(\pi–\pi^*)$ fluorescence. Compound **2b** has very weak fluorescence; the lifetimes are 2.72 ns (**1c**) and 2.43 ns (**2b**), respectively. This higher lifetime in **1c** may be due to the presence of stronger π···π interactions, which are mainly responsible for fluorescence. In glassy solutions (77 K) a red shift is observable at ~470 nm which is presumably due to $^3(\pi–\pi^*)$ phosphorescence [22].

4. Conclusion

This work reports the synthesis, structure and photophysical behaviour of two different Zn(II) complexes with hexa- and pentacoordination environments of the metal centre. Tetracoordinated/pentacoordinated zinc(II) is well recognized [23] but hexacoordination of the metal ion is scarce. Under enforced conditions, the neutral N-donor hexacoordinated Schiff base directs such coordination of this 3d member of Group 12.

5. Supplementary data

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre Nos. 267534 for **1c** and 267535 for **2b**. Copies of this information can be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44 1223 336 033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

functional groups for subsequent introduction of ligands/chelating moieties which make them quite attractive. PEI is a cationic polymer exhibiting the highest positive charge density when fully protonated in aqueous solution [24–27]. These properties are useful for a variety of industrial applications, e.g., in the paper industry for flocculation of negatively charged fibers [28–30]. Meanwhile, new applications for PEI have emerged in biology and medicine. The branched form of PEI has yielded significantly greater success in terms of cell transfection and a possible alternative to viral and liposomal routes of gene delivery [31–34].

In this work, we present our results on the synthesis and studies on the interaction of DNA with a new polymer bound cobalt complex, which possesses both polyethyleneimine and bipyridyl ligands in the coordination sphere and some free amine groups of the polymer molecule. This polymer bound complex will provide a polymer with cationic metal complex moieties with high charges(+2) which will increase the electrostatic binding of the polymer to DNA. Thereby, our polymer-cobalt chelate may be a better candidate for viral and liposomal routes of gene delivery. The binding properties of this polymer-cobalt(III) complex to calf thymus DNA were studied using absorption and fluorescence spectroscopy. Electrophoresis experiments were also carried out using pBR322 DNA.

2. Experimental

2.1. Materials and methods

Cobaltous chloride hexahydrate and 2,2′-bipyridine were purchased from Merck, India. Calf thymus DNA and branched polyethyleneimine (BPEI) (M_w ca. 25000) were obtained from Sigma–Aldrich, Germany, and were used as such. The spectroscopic titration was carried out in the buffer (50 mM NaCl–5 mM Tris–HCl, pH 7.1) at room temperature. A solution of calf thymus DNA in the buffer gave a ratio of UV absorbance at 260 and 280 nm of ~1.8–1.9:1, indicating that the DNA was sufficiently free of protein [35]. Milli-Q water was used to prepare the solutions. The complex, *cis*-$[Co(bpy)_2Cl_2]Cl \cdot 3H_2O$, was prepared as reported earlier [36].

2.2. Synthesis of *cis*-$[Co(bpy)_2(BPEI)Cl]Cl_2 \cdot 4H_2O$

To 0.15 g of BPEI dissolved in 15 mL of ethanol was added a solution of 0.6 g of *cis*-$[Co(bpy)_2Cl_2]Cl \cdot 3H_2O$ in 15 mL of water. The mixture was heated to between 50 and 60 °C for 10 h in a water bath. The colour of the solution changed from violet to reddish brown. After being warmed, the mixture was filtered and the filtrate was dialyzed against cold water for several days. Afterwards the solvent was evaporated by a rotary evaporator under reduced pressure at room temperature. A dark reddish filmy substance was obtained. It was pulverized and dried. Yield: 0.2 g. *Anal.* Calc.: C, 36.99; H, 6.32; N, 16.08. Found: C, 36.99; H, 6.56; N, 16.73%.

2.3. Cobalt analysis

The cobalt content of the polymer-cobalt(III) complex was estimated by following Kitson's method [37]. A known weight of the complex was reduced with tin and concentrated hydrochloric acid. The reduced aqueous cobalt(II) ion was made up to 10 mL in a volumetric flask using 0.1 M perchloric acid. Two millilitres of this solution and 1 mL of 50% ammonium thiocyanate solution were pipetted into a 10 mL volumetric flask and made up to the 10 mL mark with acetone. The absorbance of this solution was measured at 625 nm against a blank reagent. From the absorbance, the concentration of the cobalt was calculated. Knowing the concentration of cobalt present in a given weight of the polymer-cobalt(III) complex, the ratio of the number of moles of amine groups coordinated to the cobalt chelate to the total number of moles of amine groups in the polymer chain was calculated. The percentage of cobalt thus obtained for our polymer-cobalt(III) complex, *cis*-$[Co(bpy)_2(BPEI)Cl]Cl_2 \cdot 4H_2O$, is 11.36%. *Anal.* Calc. 11.32%.

2.4. Determination of the degree of coordination

The structure of the polymer-cobalt complex is shown in Fig. 1. In this figure '*x*' represents the degree of coordination. The degree of coordination (x), means the number of moles of cobalt(III) chelate per mole of the repeating unit (amine group) of the polymeric ligand. If all the repeating units (amine groups) in the polymer are coordinated to cobalt, then the value of x is 1. The degree of coordination (x) of the cobalt chelate in the polymer-cobalt(III) complex could be calculated from the carbon content. Based on the x value thus calculated, the C, H and N contents were calculated [38]. The degree of coordination (x) thus obtained for our polymer-cobalt(III) complex, *cis*-$[Co(bpy)_2(BPEI)Cl]Cl_2 \cdot 4H_2O$, is 0.219.

2.5. Physical measurements

Absorption spectra were recorded on a UV–Vis–NIR Cary300 spectrophotomer using cuvettes of 1 cm path length, and emission spectra were recorded on a JASCO

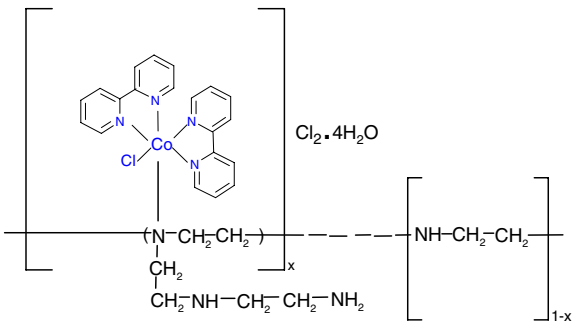

Fig. 1. Structure of *cis*-$[Co(bpy)_2(BPEI)Cl]Cl_2 \cdot 4H_2O$.

FP 770 spectrofluorimeter. FT-IR spectra were recorded on a FT-IR Perkin–Elmer spectrophotometer with samples prepared as KBr pellets. ^{1}H NMR spectra were recorded on a BRUKER 300 MHz spectrometer using D_2O as solvent.

2.6. DNA-binding experiments

The DNA concentration per nucleotide was determined by absorption spectroscopy using the known molar extinction coefficient value of 6600 M^{-1} cm^{-1} at 260 nm [39]. Absorption titrations were performed by using a fixed polymer-cobalt(III) complex concentration to which increments of the DNA stock solution were added. Polymer-cobalt(III) complex–DNA solutions were allowed to incubate for 10 min before the absorption spectra were recorded. Fluorescence quenching experiments were carried out with DNA pretreated with ethidium bromide (EB) for 30 min. To this pretreated DNA solution various amounts of polymer-cobalt complex were added and their effect on the emission intensity was measured. Samples were excited at 450 nm and the emission was observed between 500 and 700 nm.

For the gel electrophoresis experiments, supercoiled pBR322 DNA (0.1 μg) was treated with the polymer-coblat(III) complex in 50 mM Tris–HCl, 18 mM NaCl buffer, pH 7.2. The samples were electrophoresed for 3 h at 50 V on a 0.8% agarose gel in tris–acetic acid–EDTA buffer. The gel was stained with 0.5 μg/mL ethidium bromide and then photographed under UV light.

3. Results and discussion

3.1. Spectral characterization

3.1.1. IR spectrum

In the IR spectrum, there were some bands around 2853 cm^{-1} and 2924 cm^{-1} which might be assigned to C–C symmetric and asymmetric stretching vibrations of BPEI. The bands around 1018 cm^{-1} and 1629 cm^{-1} were due to the coordinated bipyridyl ligand, which were higher than the frequencies of free bipyridyl (990 cm^{-1} and 1670 cm^{-1}) [40–42]. This shift to higher frequency can be explained by the fact that the two nitrogen atoms of the bipyridyl ligands donate a pair of electrons each to the central metal forming a coordinate covalent bond.

3.1.2. UV–Visible spectrum

In the UV–Visible region, intense absorption bands appeared from 200 to 300 nm which are attributed to charge transfer transitions. Another band which appeared around 486 nm is assigned to ligand field transitions.

3.1.3. ^{1}H NMR spectrum

In the ^{1}H NMR spectrum, signals appeared between δ 2.3 and 3.6 ppm which correspond to N–CH_2–CH_2–N protons of BPEI [43]. The signals at δ 8.72, 8.42, 7.66 and 7.35 ppm might be assigned to bipyridyl protons [44].

3.2. DNA binding studies

3.2.1. Absorption spectral measurements

Electronic absorption spectra are initially employed to study the binding of the polymer-cobalt(III) complex with CT-DNA. Addition of increasing amounts of CT DNA results in the obvious tendency of hyperchromism and blue shift of the absorption bands (Fig. 2). An electrostatic interaction between the DNA and polymer-cobalt(III) complex can be predicted based on the hyperchromism exhibited and shift in absorbance of the polymer-cobalt complex. Since our complex contains the bipyridyl ligand, which is expected to be non-planar and possesses a smaller π system than phenanthroline, a classical intercalative interaction is precluded [45]. However, the high hyperchromism effects observed suggest that van der Waals contacts between the methylene groups of BPEI of the complex and the thymine methyl group (in DNA) are also very important. Also a coordination bond of DNA base with cobalt can occur through replacement of the chloride ligand in the complex, probably through aquation as has been observed with cisplatin [46]. It should be noted that a favorable hydrogen bond may be formed between NH in BPEI of the complex and N of adenine or O of thymine in the DNA. The intrinsic binding constant, K_b, was determined by using the following equation [47]:

$$[DNA]/(\varepsilon_a - \varepsilon_f) = [DNA]/(\varepsilon_o - \varepsilon_f) + 1/K_b(\varepsilon_o - \varepsilon_f)$$

where [DNA] is the concentration of DNA in base pairs, ε_a, ε_f and ε_o correspond to A_{obsd}/[Co], the extinction coefficient of the free cobalt complex and the extinction coefficient of the complex in the fully bound form, respectively, and K_b is the intrinsic binding constant. The ratio of the slope to intercept in the plot of [DNA]/($\varepsilon_a - \varepsilon_f$) versus [DNA] gives

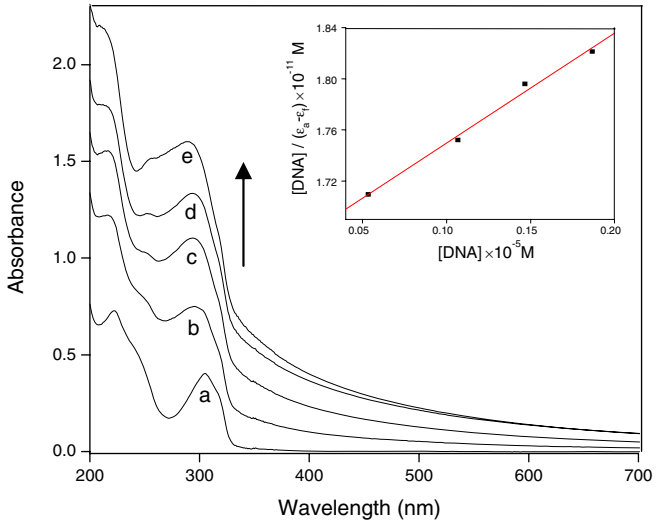

Fig. 2. Absorption spectra of *cis*-[Co(bpy)$_2$(BPEI)Cl]$Cl_2 \cdot 4H_2O$ in the absence (a) and in the presence of increasing amounts of DNA (b–e) [Complex] = 12 μM, [DNA] = 0.5–2 μM, Inset: plot of [DNA]/($\varepsilon_a - \varepsilon_f$) vs. [DNA]. Arrow shows the absorbance change upon increasing DNA concentrations.

the value of K_b and for our polymer-cobalt(III) complex it is 5.12×10^5 M^{-1}. Interestingly, this K_b value obtained for our polymer-cobalt(III) complex is very much higher than that for other ordinary complexes like $[Co(bpy)_3]^{3+}$ (K_b, 9.3×10^3 M^{-1}) [45], $[Co(bpy)_2(imp)]^{3+}$ (K_b, 1.1×10^4 M^{-1}) [48], $[Co(bpy)_3(BHBMe)]^{2+}$ (K_b, 1.23×10^4 M^{-1}), $[Co(bpy)_2(BHBNO_2)]^{2+}$ (K_b, 2.06×10^4 M^{-1}) [49]. This shows that our polymer-cobalt(III) complex binds very strongly with DNA compared to other ordinary cobalt(III)-bipyridyl complexes known in the literature [45,48,49].

3.2.2. Fluorescence studies

As the present polymer-cobalt(III) complex is non-emissive, ethidium bromide(EB) binding studies were undertaken to gain support for the extent of binding of the complex with DNA. Ethidium bromide (EB) was shown to emit intense fluorescence light in the presence of DNA, due to its strong intercalation between the adjacent DNA base pairs. It was previously reported that the fluorescent light could be quenched by the addition of a second molecule [50]. The quenching extent of the fluorescence of EB binding to DNA is used to determine the extent of binding between the second molecule and DNA. The addition of the complex to DNA pretreated with EB causes appreciable reduction in the emission intensity. This behaviour can be analysed through the Stern–Volmer equation [51], $I_o/I = 1 + K_{sv}r$, where I_o and I are the fluorescence intensities in the absence and the presence of complex, respectively. K_{sv} is a linear Stern–Volmer quenching constant, r is the ratio of the total concentration of complex to that of DNA. The quenching plot (Fig. 3) illustrates that the quenching of EB bound to DNA by the polymer-cobalt(III) complex is in good agreement with the linear Stern–Volmer equation, which also indicates that the complex binds to DNA. In the plot of I_o/I versus [Complex]/[DNA], K_{sv} is given by the ratio of the slope to intercept. The K_{sv} value for our polymer-cobalt(III) complex thus obtained is 0.2023, which is higher than that for ordinary transition metal terpyridine complexes [7]. This suggest that our polymer bound cobalt(III) complex binds strongly with DNA, which is also consistent with our absorption spectral results. It is generally agreed that strong fluorescence enhancement accompanies a strong interaction of the polymeric cobalt complex with calf thymus DNA. There is also evidence for additional non-intercalative fluorescence enhanced sites which are presumed to involve electrostatic binding [52].

3.2.3. Gel electrophoresis studies

Bronich et al. [53] and Tang and Szoka [54] have reported that DNA-polycation complexes are formed as a result of ionic interactions between cationic groups of the polycation and negatively charged phosphate groups of DNA. Branched polyethyleneimine is a cationic polymer exhibiting the highest positive charge density when fully protonated and it consists of primary, secondary and tertiary amines and about 25% of primary amines of PEI are reported to participate in forming complexes with

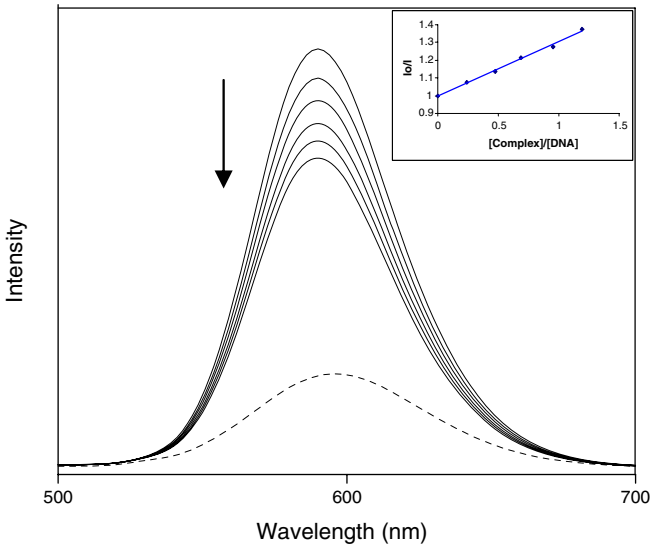

Fig. 3. Emission spectra of EB bound to DNA in the absence and in the presence of *cis*-$[Co(bpy)_2(BPEI)Cl]Cl_2 \cdot 4H_2O$ (—), [EB] = 4 μM, [DNA] = 4 μM, [Complex] = 0–6 μM. Inset: plot of I_o/I vs. [Complex]/[DNA]. Emission spectrum of EB alone (---).

DNA by an ionic interaction with the phosphate groups in the DNA [55,56]. Vinogradov et al. [57] also have reported that the binding between DNA and PEI is thought to occur mainly through electrostatic interactions among the participating species. That is the polymer-DNA complex is produced spontaneously resulting from the formation of ion pairs between ionized amino groups of PEI and the phosphate groups of DNA. In order to substantiate the binding of our polymer-cobalt complex to DNA, a gel retardation assay has been performed on pBR322 DNA (Fig. 4). Lane 1 is free polymer-cobalt(III) complex. Lane 2 is pure DNA not treated with any complex. Lanes 3–5 represent the DNA treated with the polymer-cobalt(III) complex. As reported by previous workers on the interaction of DNA–polyethyleneimine, in

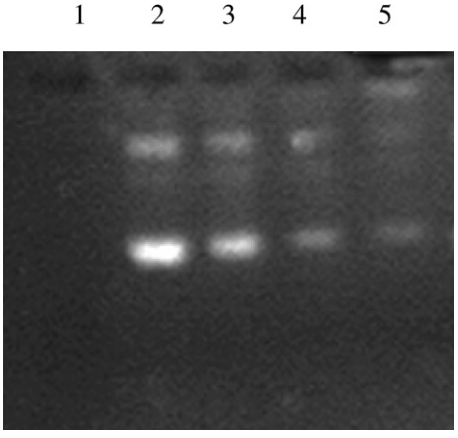

Fig. 4. Gel retardation assay of pBR322 DNA by *cis*-$[Co(bpy)_2(BPEI)Cl]Cl_2 \cdot 4H_2O$. Lane 1: polymer-cobalt complex alone, Lane 2: DNA (0.1 μg), Lanes 3–5: DNA + polymer-cobalt complex in the concentration of 20, 40, 60 μM.

our work the migration of the DNA band is also retarded as the amount of polymer-cobalt(III) complex is increased. This clearly demonstrates that the cationic segments of the polyethyleneimine are neutralizing the negative charges of DNA which could be facilitated further due to the increase of bpy groups of the cobalt(III) complex moieties [58].

4. Conclusion

The DNA binding of a polymer-cobalt complex containing the bipyridyl ligand has been examined by absorption spectroscopy, fluorescence spectroscopy and gel electrophoresis. The binding seems to be stronger than ordinary cobalt(III)-bipyridyl complexes. This may be due to the presence of multiple cobalt(III) complex molecular units and free amine groups in a single polymer molecule which between them cooperatively help in binding to DNA.

non-oxidative, hydrolytic pathway [5]. Recently, some lanthinide(III) complexes of amino acids have also been found to hydrolytically cleave bis(4-nitrophenyl)phosphate, a model DNA compound [6].

This report is part of a long term, systematic effort to investigate the factors affecting the nucleolytic efficiency of metal-chelated amino acids and peptides. Here, the potential nucleolytic property of different metal(II) complexes of *N*,*N*′-ethylenediaminediacetic acid (which is also called *N*,*N*′-ethylenediglycine, a *N*,*N*′-ethylene-bridged diaminoacid) seems interesting to us. *N*,*N*′-ethylene-bridged amino acids can act as tetradentate ligands, in contrast to bidentate simple amino acids such as glycine and L-alanine. The metal complexes of the former tetradentate ligands should also be more stable in aqueous solution than the latter bidentate ligands. In addition, the bridging excludes *cis–trans* isomerism as it fixes both the coordinated amino nitrogen atoms of these complexes into a *cis*-position, unlike the situation in the bis(aminoacidato)metal(II) complexes. Furthermore, copper(II) complexes of some *N*,*N*′-ethylene-bridged bidentate amino acids have been found to be SOD-mimetic, i.e. they have the ability to quench harmful superoxide anion radicals [7]. Another fascinating aspect of the M(edda) complexes is the position of the coordinated water molecules; the crystal structure of the octahedral Ni(edda) shows the two coordinated water molecules to be in a *cis*-position [8,9]. If the *cis*-coordinated water molecules of such a metal complex are labile and the Lewis acid strength of the metal is sufficiently strong, the complex is a potential phosphodiester hydrolytic agent [10].

Besides reporting the crystal structure of the Co(edda) complex, this paper details the solution properties of a series of metal complexes (M = Co, Ni, Cu, Zn) by UV–visible spectroscopy and electrospray ionization mass spectroscopy. For the reaction of the Cu(edda) complex with pBR322 in the presence of hydrogen peroxide, agarose gel electrophoresis has been used to study the effect of the concentration of the complex, pH, type of buffer and radical scavengers on the extent of DNA cleavage. An electrophoretic study has also been undertaken to compare the nucleolytic efficiency of Cu(edda) with (i) *cis*-aqua*bis*(glycinato)copper(II), *cis*-Cu(gly)$_2$; (ii) *trans*-aqua*bis*(*N*,*N*-dimethylglycinato)-copper(II) dihydrate, Cu(dmg)$_2$ and (iii) Fe(II)-EDTA. The reactions of Cu(edda), *cis*-Cu(gly)$_2$ and Cu(dmg)$_2$ with H_2O_2 have also been monitored with *p*-nitrosodimethyl-aniline (PNDA) which is one of two reagents used for determining the formation of hydroxyl radicals [11,12]. ROS scavengers have also been used to ascertain the reactive species responsible for DNA cleavage. In addition, electrospray ionization mass spectrometry and circular dichroism spectroscopy are used to investigate the binding and binding effect of Cu(edda) with a dodecanucleotide sequence d(CGCGAATTCGCG) which has been widely adopted as a general template for minor groove drugs [13].

2. Experimental

2.1. Reagents and materials

Most of the reagents were of analytical grade and were used as supplied. The pBR 322, gene ruler 1 kb DNA ladder, ethidium bromide, loading buffer, Tris and agarose were bought from BioSyn Tech (Fermentas). All solutions for DNA experiments were prepared with ultra-pure water from a Elga PURELAB ULTRA Bioscience water purification system with UV light accessory. The Tris–NaCl buffer (TN buffer) contains 0.1 M Tris and 0.15 M NaCl; TN buffer at lower pH was obtained by adding 1 M HCl acid. Phosphate buffer was prepared by adding 10 mM NaH_2PO_4 to 10 mM Na_2HPO_4 solution to adjust the pH to pH 7.5. TBE buffer (1×) contains Tris (0.09 M), boric acid (0.09 M) and Na_2H_2EDTA (0.002 M). The pH of the resulting TBE buffer was adjusted by adding 1 M HCl to pH 7.5. The Hepes buffer contain Hepes at 10 mM. All stock solutions of H_2O_2 in water and metal complexes in TN, TBE and Hepes buffers were freshly prepared daily.

2.2. Synthesis of the complexes

The Cu(dmg)$_2$, M(edda) and *cis*-Cu(gly)$_2$ complexes were synthesized by previously reported procedures [3,8,9,14].

Elemental analysis for Ni(edda): found C, 25.60; H, 5.52; N, 9.91% and calculated for $Ni(C_6H_{10}O_4N_2)\cdot 3H_2O$ C, 25.12; H, 5.62; N, 9.76. For Zn(edda): found C, 26.52; H, 4.94; N, 10.41% and calculated for $Zn(C_6H_{10}O_4N_2)\cdot 2H_2O$ C, 26.15; H, 5.12; N, 10.17%. For Cu(edda); found C, 30.13; H, 3.98; N, 11.57% and calculated for $Cu(C_6H_{10}O_4N_2)$ C, 30.32; H, 4.24; N, 11.79%. The FTIR of Cu(dmg)$_2$ and *cis*-Cu(gly)$_2$ were identical with those of aqua*bis*(*N*,*N*-dimethylglycinato)copper(II) [3] and *cis*-aqua*bis*(glycinato)copper(II) [14], respectively.

2.3. Synthesis of diaqua(*N*,*N*′-ethylenediaminediacetato)cobalt(II) monohydrate

NaOH solution was added to a mixture of $CoCl_2\cdot 6H_2O$ (4.07 g, 0.017 mol) and *N*,*N*-ethylenediaminediacetatic acid (3 g, 0.017 mol) until the pH value was 5.5. The deep wine red solution was filtered and the filtrate was heated in a water-bath at 45 °C for 2 days. The solution was allowed to cool at room temperature and slow evaporation of the solution yielded red crystals suitable for X-ray crystal structure analysis. Elemental analysis for Co(edda): found C, 25.46; H, 5.16; N, 9.32% and calculated for $Co(C_6H_{10}O_4N_2)\cdot 3H_2O$ C, 25.10; H, 5.62; N, 9.76%.

2.4. Physical measurements

The C, H and N microanalysis was carried out with a Perkin–Elmer 2400 CHN analyzer. Infrared spectra of all

compounds were recorded as KBr pellets using a Perkin–Elmer FT-IR spectrometer in the frequency range 4000–400 cm^{-1}. UV–visible spectroscopic measurement was carried out on a Perkin–Elmer Lambda 40 spectrophotometer; for studies on aqueous sample solutions, distilled water was filled into the reference cell while for those on buffered solutions, the corresponding buffer was the reference material. Positive ion electrospray ionization mass spectra of a 1:1 ultra pure water:methanol (v/v) solution of each M(edda) complex was obtained by using a MicroMass Quattro Micro LC-MS-MS triple quadrupole mass spectrometer. For a desolvation temperature (T_d) of 80 °C, the cone voltage (V_c) was 70 V, while for desolvation temperatures of 100 and 150 °C, the cone voltage was 60 V. A capillary voltage (V_s) of 4 kV was used for all measurements. Conformation studies of M(edda) complexes with the duplex oligonucleotide in phosphate buffer was carried out by the use of a Jasco J-810 spectropolarimeter.

2.5. X-ray crystallography

Room-temperature diffraction data were collected on a Bruker SMART APEX area-detector diffractometer (Mo Kα radiation, $\lambda = 0.71073$ Å) on a crystal of size $0.48 \times 0.28 \times 0.18$ mm over the range $2.0° < \theta < 26.0°$. The intensity data for Co(edda) was collected over the range $\theta = 2.0$–$26.0°$ for 4551 reflections. The structure was solved and refined by using the SHELX suite [15]. The final R ($I > 2\sigma(I)$) and R_w values were 0.025 and 0.075. All non-hydrogen atoms were refined anisotropically. The water and amino hydrogen atoms were located in a difference Fourier map and were refined. The perspective view of the molecule was obtained using ORTEP-3 for Windows [16]. Selected bond distances and angles together with hydrogen bonding data are listed in Table 1.

2.6. DNA cleavage experiments

Agarose gel electrophoresis experiments were carried out on supercoiled plasmid DNA pBR322 (4.4 kb) using a horizontal gel system. Each 20 μL sample consisted of the complex dissolved in buffer, DNA, the required volume of additional buffer and finally H_2O_2. All samples were incubated in the dark in a water-bath at a temperature of 37 °C for 2 h. For the hydrolytic cleavage studies, incubation of the samples was similarly carried out. The DNA cleavage profile was analyzed using 1% agarose gel in a horizontal gel set with a running time of 2.5 h, at a constant voltage of 78 V. Unless otherwise mentioned, each reaction mixture consisted of 0.0125 μg/μL DNA, 2 mM H_2O_2 and TN buffer, pH 7.5. The resultant DNA bands after the electrophoresis step for each set of experiments were stained with ethidium bromide before being photographed under UV light using a Syngene Bio Imaging system, and the digital image was viewed with Gene Flash software.

Besides comparing the nucleolytic property of the M(edda) complexes, the effect of various factors (concentration of complex, pH of the TN buffer and type of buffer used) on the cleavage of the DNA by Cu(edda) in presence of hydrogen peroxide was similarly investigated. The effect of radical scavengers DMSO and sodium azide on the oxidative cleavage of Cu(edda) was also carried out. In addition, a comparative study of DNA cleavage by Cu(edda), *cis*-$Cu(gly)_2$, $Cu(dmg)_2$ and $[Fe(EDTA)]^{2-}$ in TN buffer, pH 7.5, in the presence of hydrogen peroxide was undertaken. In the above investigations as well as other factors affecting the nucleolytic efficiency, the chosen fixed concentration of the complexes was sometimes varied to obtain a satisfactory visual comparison of the DNA banding patterns which resulted from varying the factor under consideration. The production of ·OH radicals from the reactions of the copper(II) amino acid complexes (0.1 mM) in TN buffer, pH 7.5, with 200 mM hydrogen peroxide was assayed by the use of *p*-nitrodimethylaniline (PNDA) indicator (56 μM) according to a previous procedure [12]. The % bleaching of PNDA after time t (in minutes) was calculated by using the formula $(A_0 - A_t)/A_t \times 100$ where A_0 and A_t are the absorbance of PNDA in the reaction mixture at the initial time and at time t. The initial absorbance reading was measured within 30 s. Additionally, a study to compare the DNA cleavage by the M(edda) complexes in the presence of hydrogen peroxide to that of the respective MCl_2 complexes was undertaken.

2.7. Interaction of the complex with ds(12-mer)

The self-complimentary 12-*mer* (5′-CGCGAATTCGCG-3′) was bought from Biosyn Tech and this was first annealed according to a previously reported procedure using a 0.1 M ammonium acetate solution to

give a 100 μM ds(12-*mer*) for ESI-MS studies [17,18]. The reaction mixture was prepared by mixing the pre-prepared ds(12-*mer*) with Cu(edda) stock solution. This was diluted using 0.1 M ammonium acetate prior to analysis by ESI-MS. Negative ion ESI mass spectra of ds(12-*mer*) and Cu(edda)-ds(12-*mer*) were obtained using the above mentioned MicroMass Quattro Micro LC-MS-MS.

For the CD studies of M(edda) with ds(12-*mer*), the annealing of the oligonucleotide was performed by using the supplied annealing buffer. Freshly prepared complex solutions, mixtures of M(edda) and ds(12-*mer*), and dilution were performed using phosphate buffer, pH 7.5. The concentration of each component in each M(edda)-ds(12-*mer*) mixture was set at 3.425 μM and the total volume of solution for each CD scan was 300 μL. The scan range for the CD spectra was 340–220 nm.

3. Results and discussion

3.1. Crystal structure of Co(edda) and analysis of the aqueous solution of M(edda)

The general formula of the solid state M(edda) complexes is $M(C_6H_{10}N_2O_4)\cdot xH_2O$ (where the M(II) and x values are: Co, 3; Ni, 3; Cu, 0; Zn, 2), where $(C_6H_{10}N_2O_4)^{2-}$ represents the dianionic edda ligand. These complexes are abbreviated as **1** (Co), **2** (Ni), **3** (Cu) and **4** (Zn). The synthesis of Cu(edda) needs treatment with ethanol, acetone and drying in an oven to recover a dry solid from the aqueous solution; otherwise, a gel or paste is recovered upon evaporation of the aqueous solution. The dried blue powder of Cu(edda) is completely dehydrated and can then be characterized by FTIR and elemental analysis.

Fig. 1 shows the molecular structure of diaqua(*N*,*N*′-ethylenediamine-diacetato)cobalt(II) monohydrate (**1**). The dianionic edda ligand is tetradentate and its coordinates to the cobalt atom such that the two amino nitrogen atoms occupy *cis*-positions while the two carboxylate oxygen atoms occupy *trans*-positions. Two coordinated water molecules, *cis* with respect each other, complete the octahedron about the cobalt(II) atom, resulting in a α-*cis* configuration of the ligating atoms. Therefore, the Co(edda) complex is isostructural with Ni(edda) [8,9]. Not surprisingly, both complexes have very similar FTIR spectra. Hydrogen bonding, both the direct intermolecular type and that through interlinking with the lattice water molecule, connects the $[Co(edda)(H_2O)_2]$ units into a vast three-dimensional network. The hydrogen bonding linkage involves the amino nitrogen, carbonyl and carboxylate oxygen, coordinated water and lattice water molecules. Selected bond distances and bond angles are summarized in Table 1.

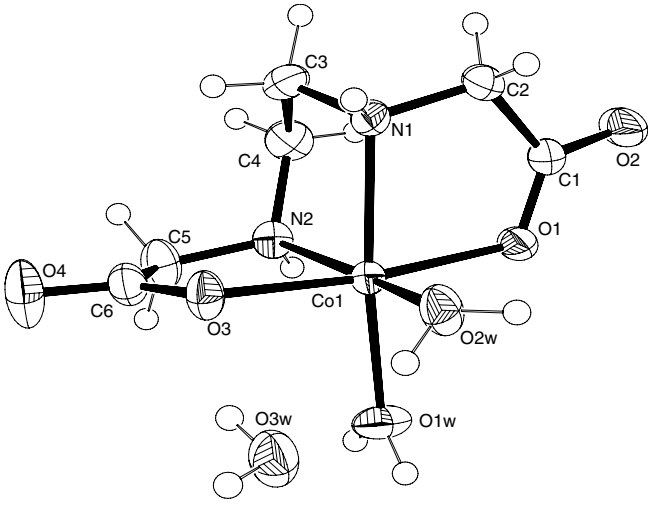

Fig. 1. 50% Probability ORTEP plot of the diaqua(*N*,*N*′-ethylenediglycinato)cobalt(II) molecule.

The electrospray ionization mass spectra (ESI-MS) of all the M(edda) complexes in 1:1 water-methanol solvent mixture (v/v) show the presence of molecule ion peaks ascribed to the various metal(II) complex species, each of which contains the $(C_6H_{10}N_2O_4)$ moiety ($C_6H_{10}N_2O_4$ = edda). This suggests that the edda ligand remains undissociated in aqueous solution (Table 2). Sufficiently high capillary

Table 2

		257.5	257.56	$[Zn(edda)(H_2O)]^+$	100

voltage (4 kV) and cone voltage (60–70 V) are needed to observe the above species. Depending on the desolvation temperature ($T_d = 80$, 100 and 150 °C), molecular ion peaks with T_d-dependent relative intensities corresponding to three metal(II) complex species, viz. $[M(edda)]^+$, $[M(edda)(H_2O)]^+$ and $[M(edda)(H_2O)_2]^+$, have been detected in the mass spectra. At $T_d = 80$ °C, the most abundant peaks (100%) in the ESI-MS for the M(edda) aqueous solutions are $[Co(edda)(H_2O)_2]^+$, $[Ni(edda)]^+$ (only this peak detected), $[Cu(edda)]^+$ and $[Zn(edda)(H_2O)]^+$. A very small amount (2–7%) of $[Ni(edda)(H_2O)_2]^+$ and $[Cu(edda)(H_2O)_2]^+$ can be observed at $T_d = 100$ °C while the most abundant species is $[M(edda)]^+$ (100%) for both metal complexes. With an increase of T_d to 150 °C, it is found that: (i) $[Co(edda)(H_2O)_2]^+$ still remains the most abundant of the three Co(II) complex species; (ii) $[Cu(edda)]^+$ and $[Ni(edda)]^+$ are most abundant among their respective species; and (iii) the relative abundance of $[Zn(edda)(H_2O)]^+$ is the highest among the Zn(II) species. It seems reasonable to assume that $[Co(edda)(H_2O)_2]$ is the octahedral diaqua(*N*,*N*′-ethylenediaminediacetato)-cobalt(II) complex and to conclude that it is the most stable and easily ionizable $[M(edda)(H_2O)_2]$ species.

The gaseous molecular ions $[Co(edda)(H_2O)_2]^+$, observed in the ESI-MS, suggest the structure of the solid octahedral complex **1** persists in aqueous solution. This is substantiated by the visible spectrum of **1** in water which has two bands at 503 nm (€, 11 M^{-1} cm^{-1}) and 1090 nm (€, 6 M^{-1} cm^{-1}) which are comparable with those of the aqueous solution of other octahedral complexes of 1-allylimidazole (495 nm) and of 4-methylimidazole-5-carbaldehyde (513 nm) [19,20]. The visible spectrum of an aqueous solution of **2** (Ni) shows two bands at 367 nm (€, 7 M^{-1} cm^{-1}) and 611 nm (€, 4 M^{-1} cm^{-1}) and this is consistent with a Ni(II) complex with an octahedral geometry [19]. The charge transfer band at 249 nm (€, 3847 M^{-1} cm^{-1}) and the visible d–d transition band centered at 672 nm (€, 100 M^{-1} cm^{-1}) for the aqueous solution of **3** (Cu) is consistent with a six-coordinate copper(II) complexes with octahedral geometry [19,21]. As for complex **4** (Zn), its ESI-MS at $T_d = 80$ °C shows an *m*/*z* molecular ion peak at 275.57 attributed to $[Zn(edda)(H_2O)_2]^+$ at 30% relative abundance. Thus, the M(edda) complexes (**1**–**4**) exist as octahedral species in aqueous solution.

3.2. Nucleolytic property. Electrophoresis study of M(edda) with pBR322 in the presence and absence of hydrogen peroxide

Agarose gel electrophoresis is a convenient method to assess the hydrolytic or oxidative cleavage of DNA by metal complexes, to assess the factors affecting the nucleolytic efficiency of a complex and to compare the nucleolytic property of different metal complexes. These have been done in the present study with the M(edda) complexes.

We have previously studied whether M(edda) complexes could hydrolytically cleave λDNA [22]. Incubation of the DNA with up to 6 mM of the complexes in Tris–NaCl buffer (abbreviated as TN buffer) at pH 7 overnight at 37 °C failed to induce any cleavage. Repetition of this experiment by incubating all the M(edda) complexes with pBR322 for 24 h in TN buffer at pH 7.5 also gave negative results. The M(edda) complexes are unable to effect hydrolytic cleavage due to some possible factors. The nucleolytic ability of lanthanide(III) complexes of α-amino acids (aa) has been attributed to the high Lewis acidity of the trivalent lanthanide ions and the active complex species have been identified as $[Ln(aa)_3(OH)]^{2+}$ and $[Ln(aa)_2(OH)_2]^+$ [6]. Various mononuclear metal-coordinated hydroxide containing species, such as $[(TACH)Cu(OH)(OH_2)_2]^+$, $[(cyclen)Co(OH)(OH_2)]^{2+}$ and $[(trpn)Co(OH)(OH_2)]^{2+}$, have been found to be capable of hydrolytic cleavage of DNA [23]. The insufficient Lewis acidity of the metal ion alone in $[M(edda)(H_2O)_2]$ or the absence of a overall positive charge may explain our negative results [23,24]. Thus, we have focused our studies on the cleavage of pBR322 by these complexes in the presence of hydrogen peroxide.

When 500 μM of the M(edda) complexes were incubated with pBR322 (0.0125 μg/μl) in TN buffer, pH 7.5, in the presence of 2 mM hydrogen peroxide, only **3** (Cu) showed appreciable cleavage of the DNA (Fig. 2; lanes **7**–**10**); there was complete conversion of supercoiled DNA to nicked and linear DNA. The complex **1** (Co) shows slight cleavage, nicking a small amount of the supercoiled pBR322. The complexes **2** (Ni) and **4** (Zn) are virtually inactive. A similar result has been obtained when 1 mM of these four complexes were incubated with λDNA (0.02 μg/μl) in TN buffer at pH 7 in the presence of 0.5 mM hydrogen peroxide [22].

The above shows that **3** (Cu(edda)) is more efficient than **1** (Co(edda)) as a nucleolytic agent. Both **2** and **4** are inactive. Similar results have been obtained when a comparison of the nucleolytic ability of different metal(II) complexes of *N*-(2-ethoxyethanol)-bis(2-picolyl)amine was made [25]. Due to its greater nucleolytic efficiency, the nucleolytic property of **3** in the presence of hydrogen peroxide has been more thoroughly investigated. This involves the use of radical scavengers to ascertain the type of radical species, the various factors affecting its nucleolytic efficiency and a comparison of its nucleolytic efficiency with

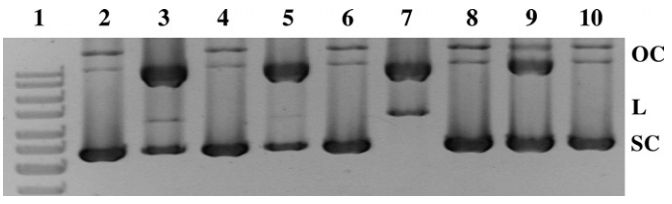

Fig. 2. Electrophoresis results of incubating different M(edda) complexes with pBR 322(0.0125 μg/μL) in the presence of 2 mM H_2O_2. Lane **1**, Gene Ruler 1 kb DNA ladder; lane **2**, DNA alone; lanes **3**–**6** refer to 100 μM of Cu(edda), Ni(edda), Co(edda) and Zn(edda), respectively; lanes **7**–**10** refer to 500 μM of Cu, Ni, Co and Zn complexes in the same sequence. DNA form: **SC**, supercoiled; **L**, linear; **OC**, open circular or nicked.

$[Fe(EDTA)]^{2-}$ and copper(II) complexes of glycine and *N*,*N*-dimethylglycine.

The effect of concentration of complex **3** (at various intervals, from 10 μM to 2 mM) is shown in Fig. 3. A low concentration of 10 μM can induce a single-strand break of the plasmid DNA in the presence of hydrogen peroxide as shown by the slightly more intense band of one of the nicked bands (Fig. 3, lane **6**). The extent of DNA cleavage is concentration dependent, and this is clearly shown in Fig. 3.

As the DNA in the presence of 2 mM hydrogen peroxide or the DNA in the presence of 2 mM of complex **3** shows no change in banding patterns compared to the control DNA alone, both **3** and hydrogen peroxide are needed for the DNA cleavage. This suggests oxidative cleavage. Both DMSO (a known $^{\cdot}OH$ radical scavenger) and sodium azide (a singlet oxygen scavenger) can inhibit DNA cleavage by **3**, suggesting involvement of both $^{\cdot}OH$ and $^1O_2$ (Fig. 4). The DNA cleavage can be totally quenched by 10 mM of EDTA (disodium salt; Fig. 4, lane **12**). Our investigation shows that quenching is due to displacement of edda from **3** by EDTA. Visible spectroscopic investigation of the titration of Cu(edda) with EDTA shows formation of $[Cu(EDTA)]^{2-}$ with a λ_{max} of 732 nm (**3** has λ_{max} of 672 nm); also, a white solid recovered from the reaction mixture is shown to be the edda ligand based on its FTIR spectrum. Complete quenching can thus be attributed to absence of the Cu(edda) species **3** and formation of the nucleolytically inactive $[Cu(EDTA)]^{2-}$. As such, the loading dye (6× loading dye solution containing 10 mM Tris–HCl (pH 7.6), 0.03% bromophenol blue, 0.03% xylene cyanol FF, 60% glycerol and 60 mM EDTA) used in our electrophoresis contains sufficient EDTA to quench the DNA reaction mixtures prior to the electrophoresis run on the horizontal gel set.

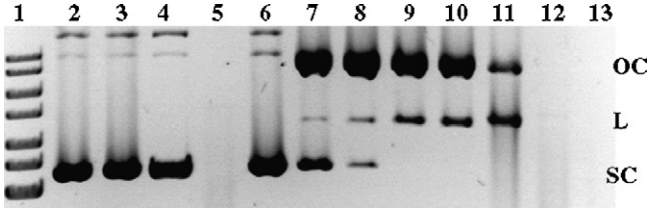

Fig. 3. Electrophoreis results of incubating pBR322 with varying concentration of Cu(edda) with 2 mM H_2O_2. Lane **1**, Gene Ruler 1 kb DNA ladder; lane **2**, DNA alone; lane **3**, DNA + 2 mM Cu(edda); lane **4**, DNA + 2 mM H_2O_2; lane **5**, DNA + 2 mM $CuCl_2$ + 2 mM H_2O_2. Lanes **6**–**13** involve DNA + H_2O_2 + different concentrations of Cu(edda): lane **6**, 10 μM; **7**, 50 μM; **8**, 100 μM; **9**, 200 μM; **10**, 250 μM; **11**, 500 μM; **12**, 1 mM; and lane **13**, 2 mM.

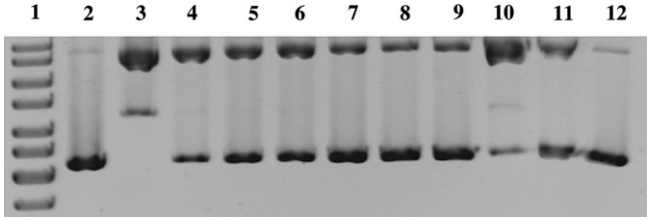

Fig. 4. Effect of radical scavengers on the reaction of DNA with 250 μM Cu(edda) and 2 mM H_2O_2. Lane **1**,Gene Ruler 1 kb DNA ladder; lane **2**, DNA alone; lane **3**, DNA + 250 μM Cu(edda) + 2 mM H_2O_2. Lanes **4**–**9** involve reaction mixtures with increasing concentrations of DMSO: lane **4**, 1 M; lane **5**, 2 M; lane **6**, 3 M; lane **7**, 4 M; lane **8**, 5 M; lane **8**, 7 M; lane **9**, 7 M DMSO. Lanes **10**–**11** involve reaction mixtures with different concentrations of NaN_3: lane **10**, 0.5 M; lane **11**, 2 M. Lane **12**: DNA + Cu(edda) + H_2O_2 + 10 mM EDTA.

The pH of the TN buffer was found to affect the extent of DNA cleavage by **3** in the presence of hydrogen peroxide (Fig. 5). Generally, more alkaline medium (pH 7.0–10.0) of the buffer brings about greater DNA cleavage compared to the acidic medium (pH 6.5). A recent study on the oxidation of quinaldine blue by copper(II)/amino acid/H_2O_2 system also obtained similar findings [12]. Here, the quinaldine blue indicator has been oxidized by hydroxyl radicals whose formation increases as the reaction medium becomes more alkaline.

Besides pH, we found that the type of buffer also affect the nucleolytic efficiency of complex **3**. At pH 7.5, a **3**/H_2O_2 mixture induces significantly more cleavage of DNA in Hepes and phosphate buffers than in TBE and TN buffers (Fig. 6). In a similar study on the interaction of Pd complexes with plasmid DNA in different buffer systems, it was found that the DNA binding efficiency capable of modifying the tertiary structure of pBR322 decreased from $NaClO_4$ to Hepes 2, Hepes 1 [Hepes = 4-(2-hydroxyethyl)-1-piperazineethanesulfonic acid] and Tris[tris(hydroxymethyl)aminomethane] buffers, in this order [26]. Cisplatin has also been found to cause more damage to DNA in Hepes buffer than in Tris buffer at the same concentration

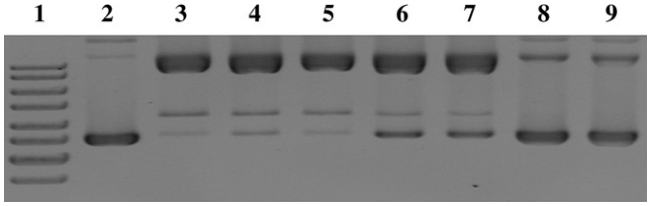

Fig. 5. Effect of pH on incubating pBR322 (0.0125 μg/μL) with 46 μM Cu(edda) and 2 mM H_2O_2 in TN buffers: lane **1**, Gene Ruler 1 kb DNA ladder; lane **2**, DNA alone; lanes **3**–**9** refers to pH 10.0, 9, 8.5, 8.0, 7.5, 7.0 and 6.5, respectively.

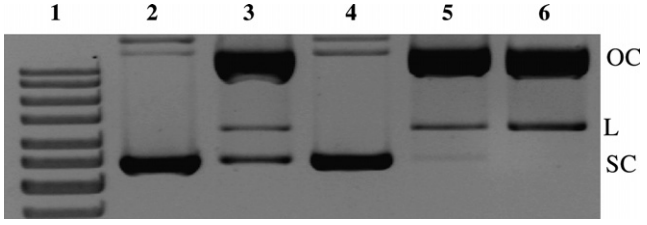

Fig. 6. Effect of type of buffer (at pH 7.5) on DNA cleavage by Cu(edda) (115 μM) in the presence of 2 mM H_2O_2: lane **1**, Gene Ruler 1 kb DNA ladder; lane 2, DNA alone (0.0125 μg/μL); for lanes **3**–**6**, the buffers are TN, 1× TBE, phosphate and Hepes, respectively.

[27]. The lower nucleolytic property of **3** in TBE and TN buffers may be due to the complexing agents in these buffers. TBE buffer contains EDTA, a well known strong chelating agent while both Hepes and TN buffers contains the hepes ligand and Tris, both of which can bind to the complex. The relative nucleolytic efficiency of **3** in TBE, TN and Hepes buffers may be due to the difference in the increasing potential of the buffer system components to bind transition metal complexes that compete with DNA for binding to the metal or hinders binding of the altered complex to the DNA. Nevertheless, the more bulky Hepes may not be able to bind to **3** as **3** has almost the same cleavage efficiency in both phosphate and Hepes buffers (Fig. 6).

In view of the above discussion, we have carried out further spectroscopic studies on complex **3** in TN buffer (which contain 0.1 M Tris component). In TN buffer in the pH range 5.0–7.5, λ_{max} remains quite stable (671–675 nm) and this suggests no change in the coordination sphere of **3**. At lower pH values, an increasing shift of λ_{max} to 728 nm suggests dissociation while at higher pH values, the significant decrease in λ_{max} suggests coordination of Tris (at pH 9, λ_{max} reaches 639 nm). Titration of an aqueous solution of **3** with increasing concentration of Tris (1 mM:0 mM to 1 mM:50 mM) shows initially an unchanged $\lambda_{max} \sim 672$ nm (up to 1:2 mole ratio of complex to Tris) and then a progressive decrease in λ_{max} to 629 nm. Thus, some complexation of Tris to Cu in complex **3** in our studies can occur in TN buffer above pH 7.5. Complex **3** is stable in TN buffer, pH 7.5, and there is no or minimal complexation of Tris. For the validity of the study on the dependence of the nucleolytic efficiency on the concentration of the complex, a plot of the absorbance at 672 nm against concentration (0.05–2 mM) in TN buffer, pH 7.5, gives a straight line with a good linearity factor of $R^2 = 0.9991$.

Additionally, we have compared the oxidative cleavage of DNA by **3** with two *bis*(aminoacidato)copper(II) complexes and $[Fe(EDTA)]^{2-}$ in TN buffer at pH 7.5 (Fig. 7). At complex concentrations of 100 and 500 μM, the *cis*-$Cu(gly)_2$ and $Cu(dmg)_2$ show distinctly superior nucleolytic ability than both **3** and $[Fe(EDTA)]^{2-}$. For example, 500 μM of the former two complexes totally degraded the DNA while the latter two at the same concentration merely converted the supercoiled DNA into nicked and linear DNA. In contrast to $[Cu(EDTA)]^{2-}$, $[Fe(EDTA)]^{2-}$ still can cleave DNA in the presence of hydrogen peroxide.

To elucidate the cause of the above differences in nucleolytic efficiency, a known hydroxyl radical assay has been used [12]. In *p*-nitrosodimethylaniline (PNDA) assay, it has been established that the production of ·OH radicals can be monitored by measuring the strong absorption peak of PNDA at 440 nm [12]. The percentage bleaching of PNDA corresponds to the formation of ·OH radicals as the molar ratio of PNDA: ·OH is 1:1. Our results show that the bleaching ability of both *cis*-$Cu(gly)_2$ and $Cu(dmg)_2$ is about twice that of **3**, and therefore their greater nucleolytic efficiency is the result of a higher production of ·OH (Fig. 8). As far as we know, this is the first instance whereby the oxidative-nucleolytic efficiency of such metal complexes has been correlated with the amount of hydroxyl radicals produced. An earlier study on the coordination-structural factors affecting similar oxidative damage of DNA by a series of copper(II) complexes does not show such a correlation as the trend of production of hydroxyl radical decreases in this order $Cu(HTCD)^{2+} \sim Cu(Im)_4Cl_2 > Cu(IDB)(NO_3)_2 > Cu(IDB)Cl_2 > Cu(IDBt)Cl_2$ while the order of decreasing DNA damage capacity is $Cu(Im)_4Cl_2 \sim Cu(IDB)(NO_3)_2 > Cu(HTCD)^{2+} > Cu(IDBt)Cl_2 > Cu(IDB)Cl_2$ [28].

Lastly, we have compared the nucleolytic property of the M(edda) complexes with their corresponding MCl_2 salts to elucidate the role of the edda anionic ligand. The results (Fig. 9) clearly show that edda upon complexation to the metal(II) ion inhibits DNA cleavage. How this inhibition comes about is now under investigation. Both the copper(II) ion and the Cu(edda) complex can cleave DNA better than the other metal(II) ions and their M(edda) complexes. The Cu(edda) complex may still undergo similar reactions as those proposed for the Cu(II) ion with hydrogen peroxide, as shown in the following equations, to yield the ROS responsible for the DNA cleavage [29,30].

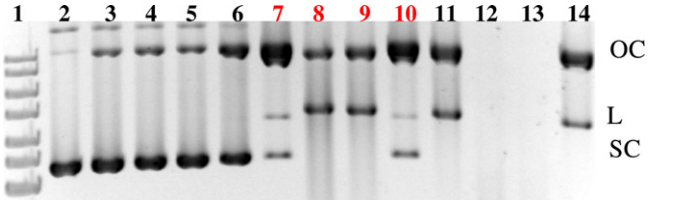

Fig. 7. Comparison of the nucleolytic properties of different copper(II) amino acid complexes and $[Fe(edta)]^{2-}$. Incubating pBR322 (0.0125 μg/μL) with the specified concentration of complexes with 2 mM H_2O_2: Lane **1**, Gene Ruler 1 kb DNA ladder; lane **2**, DNA alone; lanes **3**–**6** involve 10 μM of Cu(edda), *cis*-$Cu(gly)_2$, $Cu(dmg)_2$ and $[Fe(EDTA)]^{2-}$, respectively; lanes **7**–**10** involve 100 μM of Cu(edda), *cis*-$Cu(gly)_2$, $Cu(dmg)_2$ and $[Fe(EDTA)]^{2-}$, respectively; lanes **11**–**14** involve 500 μM of Cu(edda), *cis*-$Cu(gly)_2$, $Cu(dmg)_2$ and $[Fe(EDTA)]^{2-}$, respectively.

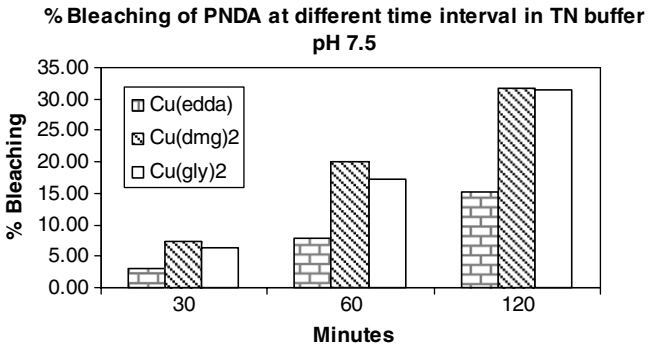

Fig. 8. The relative production of hydroxyl radicals by reaction of the copper(II) complexes with hydrogen peroxide in TN buffer at pH 7.5 as shown by the % bleaching of PNDA.

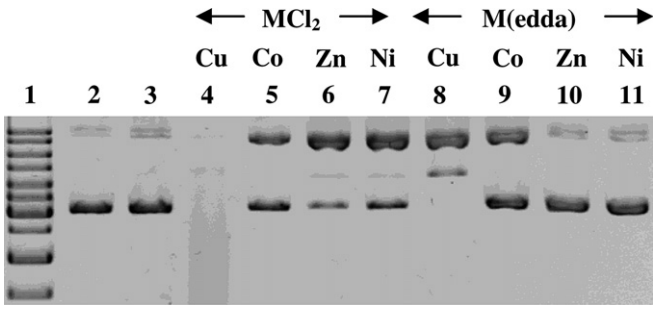

Fig. 9. Comparison of the nucleolytic properties of metal(II) ions with their corresponding M(edda) complexes. Incubating pBR322 with 500 μM of metal(II) salt or M(edda) complex with 2 mM H_2O_2. Lane **1**, Gene Ruler 1 kb DNA ladder; lane **2**, DNA alone; lane **3**, DNA + H_2O_2 alone; lanes **4**–**7** involve $CuCl_2$, $CoCl_2$, $ZnCl_2$ and $NiCl_2$; and lanes **8**–**11** involve Cu(edda), Co(edda), Zn(edda) and Ni(edda), respectively.

$$Cu^{II}(edda) + H_2O_2 \rightarrow [Cu^{I}(edda)]^- + O_2^{\cdot-} + 2H^+ \quad (1)$$

$$[Cu^{I}(edda)]^- + O_2 \rightarrow Cu^{II}(edda) + O_2^{\cdot-} \quad (2)$$

$$Cu^{II}(edda) + O_2^{\cdot-} \rightarrow [Cu^{I}(edda)]^- + O_2 \quad (3)$$

$$[Cu^{I}(edda)]^- + H_2O_2 \rightarrow Cu^{II}(edda) + {}^{\cdot}OH + OH^- \quad (4)$$

$$O_2^{\cdot-} + Cu^{II}(edda) \rightarrow {}^1O_2 + [Cu^{I}(edda)]^- \quad (5)$$

3.3. ESI-MS and CD studies on interaction of 3 with d(5′-CGCGAATTCGCG-3′)

Heating 200 μM of 12-*mer* oligonucleotide to 20 °C above its melting temperature and cooling it slowly to room temperature successfully converted it to ds(12-*mer*) which has a relative molecular mass, M_{ds}, of 3646.4. This is evidenced by a most intense negative ion ESI-MS peak of 1827.0 attributed to $[ds(DNA) + Na]^{4-}$ (calculated value, 1827.7). No *m*/*z* peak for the single strand 12-*mer* or its abducts with Na or K at negative charges of −1 to −11 can be found. An ESI-MS of a freshly prepared solution of 1:1 ratio of **3** and ds(12-*mer*) in 0.1 M ammonium acetate shows *m*/*z* peaks of 1828.3 (100%), 1887.8 (16%) and 1896.2 (33%) which are attributed to negative ions of $[ds(12\text{-}mer) + Na]^{4-}$ (calculated *m*/*z*, 1827.7), $[ds(12\text{-}mer) + Cu(edda) + Na]^{4-}$ (calculated *m*/*z*, 1887.1) and $[ds(12\text{-}mer) + [Cu(edda)(H_2O)_2] + Na]^{4-}$ (calculated *m*/*z* 1896.1), respectively.

The ds(12-*mer*) in phosphate buffer at pH 7.5 has B-form conformation, as shown by its CD spectrum which has a negative band at 247 nm and a positive band at 280 nm (Fig. 10). The CD spectrum of a freshly prepared mixture of 1:1 molar ratio of ds(12-*mer*) (3.425 μM) and Cu(edda) (3.425 μM) shows a decrease in the negative band of ds(12-*mer*) and an enhancement of the positive band of ds(12-*mer*). This change in the CD spectrum is similarly observed in the binding of antitumor trinuclear platinum complexes to B-DNA (Calf Thymus) at relatively low r_b values (<0.05) and it was ascribed to occurrence of short single-stranded segments containing unpaired bases (denatured regions) [31]. Thus, a similar non-denaturational conformational change may be induced by **3** on binding to ds(12-*mer*). Ni(edda), **2**, and Zn(edda), **4**, can induce a similar conformation change whereas Co(edda), **1**, has practically no effect on the CD of ds(12-*mer*).

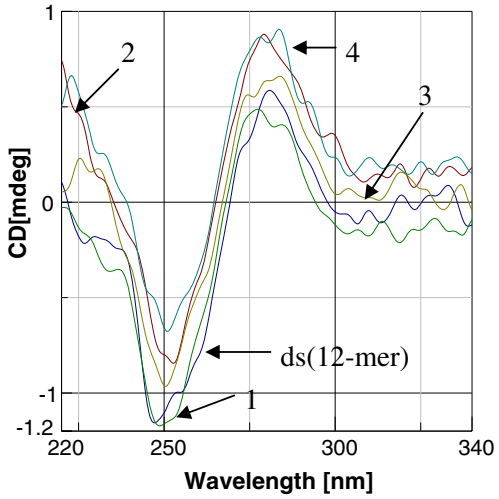

Fig. 10. CD spectra of ds(12-*mer*) alone and its modification by M(edda) complexes. The DNA and the complexes were dissolved in phosphate buffer at pH 7.5 (10 μM $Na_2HPO_4 \cdot 2H_2O$ and 10 μM $NaH_2PO_4 \cdot 2H_2O$). Ratio of DNA:complex is 1:1 with each species at a concentration of 3.425 μM. CD spectra of DNA modified by complexes: curve 1, Co(edda); curve 2, Ni(edda); curve 3, Cu(edda); curve 4, Zn(edda).

4. Conclusion

It seems that the copper(II) complex of *N*,*N*′-ethylene-bridged *bis*(amino acid), edda, is a poorer nucleolytic agent compared to the corresponding unbridged *bis*(aminoacidato)copper(II). This probably arises from the greater inhibitory effect of the tetradentate edda upon the nucleolytic property of the copper(II) ion compared to the unbridged bidentate amino acidate ligands. Comparison of nucleolytic efficiency of metal complexes should be made with care as various factors can affect it. For example, the component of the buffer system used can act as complexing agent and thus alter the property of the metal complex under investigation. The extent of DNA cleavage by the M(edda) and other metal(II) complexes in the presence of hydrogen peroxide can be predicted by or correlated with the total production of ·OH radicals produced. In this study, the binding of the some of the complexes to DNA seems to cause localized unwinding of the DNA at the binding sites.

5. Supplementary data

Detailed crystallographic data for the crystal structure analysis have been deposited with the Cambridge Crystallographic Data Center, CCDC 294380. Copies of this information can be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ,

UK (fax: +44 1223 336 033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Acknowledgments

This project is funded by a SAGA research grant from the Malaysian Academy of Science and the Ministry of Science, Technology and Inovation of Malaysia (C/4/02). We also like to acknowledge and thank the Chemistry Department of Malaysia in Kuala Lumpur for the use of the ESI-MS, and our respective universities.

We have determined the kinetic parameters and the reaction mechanism of the process to be:

$$[W_2S_4(\text{di-}i\text{-propyldtc})_2B_2]\ (\text{solid}) \rightarrow [W_2S_4((\text{di-}i\text{-propyldtc}))_2]\ (\text{solid}) + 2B\ (\text{gas})$$

and we have determined the activation energy and the pre-exponential Arrhenius factor for all the adducts synthesized, using a new non-isothermal kinetic method, reported previously by us.

The determination of kinetic parameters by non-isothermal methods offers interesting advantages over conventional isothermal studies [19–26]. Only a single sample and fewer data are required and the kinetics can be calculated over an entire temperature range in a continuous manner.

A disadvantage of the non-isothermal methods, when are compared with the isothermal techniques, is that the reaction mechanism cannot usually be determined, and hence the meaning of the kinetics parameters is uncertain. However, with the new proposed method, the reaction mechanism can be determined [27–29].

A comparison between activation energies (E_a), steric or inductive factors, infrared and electronic spectral data and pK_b values of the coordinated bases has also been explored.

2. Experimental

2.1. Synthesis

[W_2S_4(*di-i-propyldtc*)$_2$]: Prepared as previously reported [15].

[W_2S_4(*di-i-propyldtc*)$_2B_2$]: 0.01 mol of [W_2S_4(di-*i*-propyldtc)$_2$] was dissolved in 0.02 mol of the organic base (pyridine, 3-methyl, 4-methyl and 3,5-dimethylpyridine) or in an ethanolic solution of 0.02 mol of 3-amino and 4-aminopyridine and heated in a water bath for about 15 min. After cooling for 2 days, the adducts, obtained as brownish powders, were separated by filtration *in vacuo* and dried over P_4O_{10} in a nitrogen atmosphere.

3. Instrumentation

Elemental analyses were performed in a Perkin–Elmer 240 B elemental analyzer. Tungsten was determined by Atomic Absorption with a Perkin–Elmer 430 Atomic Absorption spectrophotometer, after decomposing the complexes with a 1:1 mixture of concentrated nitric and sulfuric acid. Magnetic susceptibility determinations were performed at room temperature on a Mettler H-51 AR balance and a type C Newport electromagnet. Reported magnetic moments are corrected for ligand diamagnetism. Infrared spectra were measured on a Perkin–Elmer 283 spectrophotometer. Visible–near UV spectra of the compounds were measured on a Beckman DU7 spectrophotometer, using complex solutions in DMSO. Thermogravimetric analysis and differential scanning calorimetry, were performed between 25 and 600 °C on a Mettler TA 3000 system fitted with a Mettler TG-50 thermobalance and a Mettler DSC-20 differential scanning calorimeter. The scanning rate used was 2 °C min^{-1} and samples of about 5 mg, as a very fine powder, were used, so as to render insignificant the temperature non-uniformity within the sample. An aluminium pan was used under a dynamic nitrogen atmosphere. The instrument calibration was checked periodically with standard samples of indium (99.99 % purity). Several runs were made.

3.1. Kinetic studies

The rate of a thermal decomposition reaction of a solid can be expressed by the Arrhenius equation:

$$d\alpha/dt = Ae^{-E_a/RT} f(\alpha) \quad (1)$$

In Eq. (1), α is the fraction of material which has reacted at time t, E_a is the activation energy, $f(\alpha)$ is a function which depends on the actual reaction mechanism and A is the pre-exponential Arrhenius factor.

We have collected in Table 1 the mathematical expressions of the functions $f(\alpha)$ corresponding to some of the thermal decomposition mechanisms found in the literature [19].

When the temperature of the sample is increased at a constant rate, we can write Eq. (2), where β is the heating rate, dT/dt:

$$d\alpha/dT = \alpha' = (A/\beta)e^{-E_a/RT} f(\alpha) \quad (2)$$

By differentiating the logarithmic form of Eq. (2) with respect to $d\ln(1-\alpha)$, we obtain the following equation:

$$\begin{aligned} d\ln\alpha'/d\ln(1-\alpha) &= -(E_a/R)[d(1/T)/d\ln(1-\alpha)] \\ &\quad + [d\ln f(\alpha)/d\ln(1-\alpha)] \quad \text{or} \\ \Delta\ln\alpha'/\Delta\ln(1-\alpha) &= -(E_a/R)[\Delta(1/T)/\Delta\ln(1-\alpha)] \\ &\quad + [\Delta\ln f(\alpha)/\Delta\ln(1-\alpha)] \quad \text{and} \\ [\Delta\ln\alpha' - \Delta\ln f(\alpha)]/\Delta\ln(1-\alpha) &= -(E_a/R)[\Delta(1/T)/\Delta\ln(1-\alpha)] \end{aligned} \quad (3)$$

Table 1
Kinetic equations

Mechanism (rate-controlling process)	$f(\alpha)$
D1 (one-dimensional diffusion)	$(1/2\alpha)$
D2 (two-dimensional diffusion)	$[-\ln(1-\alpha)]^{-1}$
D3 (three-dimensional diffusion: Jander equation)	$(3/2)(1-\alpha)^{2/3}[1-(1-\alpha)^{1/3}]^{-1}$
D4 (three-dimensional diffusion: Ginstling–Brounshtein equation)	$(3/2)[(1-\alpha)^{-1/3}-1]^{-1}$
F1 (random nucleation)	$(1-\alpha)$
R2 (phase-boundary reaction: cylindrical symmetry)	$2(1-\alpha)^{1/2}$
R3 (phase-boundary reaction: spherical symmetry)	$3(1-\alpha)^{2/3}$

Thus, the plots of $[\Delta\ln\alpha' - \Delta\ln f(\alpha)]/\Delta\ln(1-\alpha)$ versus $[\Delta(1/T)/\Delta\ln(1-\alpha)]$ should be a straight line with a slope $-E_a/R$, irrespective of the $f(\alpha)$ employed. However, we can select the $f(\alpha)$ that best fits the actual reaction mechanism studied, by means of the intercept value, which in an ideal agreement with Eq. (3) should be zero.

In order to test the validity of the above conclusions we have substituted the seven forms of $f(\alpha)$ into the Arrhenius equation in the logarithmic form (2), giving the following equation:

$$\ln\alpha' = \ln(A/\beta) - E_a/RT + \ln f(\alpha) \quad \text{or}$$
$$\ln\alpha' - \ln f(\alpha) = \ln(A/\beta) - E_a/RT \qquad (4)$$

The plot of $\ln\alpha' - \ln f(\alpha)$ versus $1/T$ should be a straight line with a slope $-E_a/R$ and intercept $\ln(A/\beta)$.

If the suggested mechanism is correct, the activation energy value should be the same as the value previously obtained.

4. Discussion

4.1. Magnetic susceptibility

All the complexes studied present very low values for the magnetic moments (0.10–0.00 B.M.), as occurs in similar W(V) complexes [12–18], which can be attributed to an interaction through the bridge atoms, or to the possible formation of a direct metal–metal bond, as has been proved for similar molybdenum(V) oxo-complexes [30–32].

4.2. Infrared spectra

The IR spectra show, in all cases, a band in the range 552–507 cm^{-1}, which we attribute to the vibration of the terminal W=S bond. If we compare the complex $[W_2S_4$(di-*i*-propyldtc$)_2]$ with the adducts $[W_2S_4$(di-*i*-propyldtc$)_2B_2]$, one observes that the adducts show the W=S band displaced to lower frequencies (539–507 cm^{-1}) than the complex (552–545 cm^{-1}). This displacement can be attributed to the different basicity of the pyridine or substituted pyridine employed [33,34]. The pK_b value reflects the basicity of the ligand towards the proton. It may be assumed that the pK_b of the ligand provides a measure of the ligand ability to form σ-bonds to metal ions. In general (see Table 2), the greater the basicity the lower the frequency of the W=S vibration.

The IR spectra of the adducts exhibit a band over 348–333 cm^{-1}, which is assigned to the stretching vibration of the W–N(base) bond [35–37]. The frequencies of this band listed in decreasing order are:

$[W_2S_4$(di-*i*-propyldtc$)_2$(4-AP$)_2]$
$> [W_2S_4$(di-*i*-propyldtc$)_2$(3-AP$)_2]$
$> [W_2S_4$(di-*i*-propyldtc$)_2$(3, 5-DMP$)_2]$
$> [W_2S_4$(di-*i*-propyldtc$)_2$(3-MP$)_2]$
$> [W_2S_4$(di-*i*-propyldtc$)_2$(4-MP$)_2]$
$> [W_2S_4$(di-*i*-propyldtc$)_2$Py$_2]$.

These differences can be attributed to the electronic donation of the pyridine or substituted pyridine to the tungsten (N → W) which increases the electron density on the metal d-orbitals and consequently the $p_\pi \rightarrow d_\pi$ donation from the sulfur atom to tungsten is expected to be reduced to an extent which depends of the base donor ability. As a result there will be a lowering of the W=S bond [hence ν(W=S)] and a greater frequency of the W–N bond.

We assign the bands corresponding to W–S–W bridge, which appear over 460 and 365 cm^{-1}, to the antisymmetric and symmetric stretching mode, respectively.

The IR spectra of these complexes show the C–N and C–S vibrations over 1515 and 1090 cm^{-1}. The displacement to greater frequencies for the C–N band and to lower frequencies for the C–S band, in comparison with the sodium dithiocarbamate, are indicative of bidentate ligands.

$[W_2S_4$(di-*i*-propyldtc$)_2$(4-AP$)_2]$	507	459	368	1512	1083	348

4.3. Visible and ultraviolet spectra

The electronic spectra of the compounds obtained is in accordance with the Ballhausen–Gray and Gray–Hare schemes [38,39] with a square pyramidal structure for the complex and a distorted octahedral structure for the adducts.

	35250	33364	$n \rightarrow \sigma^*$

The electronic spectra for all the complexes present a band in the 18500–16900 cm^{-1} region, which can be assigned to a $^2B_2 \rightarrow {}^2B_1$ transition. This band shows the greater or lesser bonding force from the tungsten to the ligand. Therefore the band is displaced to higher frequencies in the adducts, because the introduction of the base in the six-coordination position and the "*trans*" effect strengthen the ligand–tungsten σ-bond, as we have observed in the IR spectra (see Table 3).

In the visible zone we can detect three other bands over 20000, 22000 and 26500 cm^{-1} that we attribute to charge transfer transitions. The band which appears over 22000 cm^{-1} can be attributed to a $S^{2-} \rightarrow W(V)$ charge transfer, as has been observed in others transition metal complexes with a sulfur bridge [40,41].

In the ultraviolet zone, three transitions are detected over 30000, 32000 and 35000 cm^{-1}, attributable to intraligand transitions like $n \rightarrow n^*$, $\pi \rightarrow \pi^*$ and $n \rightarrow \sigma^*$, respectively.

4.4. DSC, TGA and kinetic studies

On the DSC curves of all the compounds, a first endothermic peak can be appreciated. The mass loss accompanying this transition corresponds on the TG curves to the loss of two moles of coordinated base to tungsten atoms, the residue being $[W_2S_4(di\text{-}i\text{-}propyldtc)_2]$ in all cases.

Compound	Mechanism	ΔH (kJ mol^{-1})	E_a (kJ mol^{-1})	A (s^{-1})	pK_b
[W_2S_4(di-*i*-propyldtc)$_2$(Py)$_2$]	R2	21.7 ± 0.3	137 ± 3	$(3.3 \pm 0.2) \times 10^{13}$	8.87
[W_2S_4(di-*i*-propyldtc)$_2$(3-MP)$_2$]	R2	26.5 ± 0.4	162 ± 2	$(3.4 \pm 0.1) \times 10^{20}$	8.32
[W_2S_4(di-*i*-propyldtc)$_2$(4-MP)$_2$]	R2	25.0 ± 0.3	154 ± 1	$(6.8 \pm 0.3) \times 10^{9}$	7.98
[W_2S_4(di-*i*-propyldtc)$_2$(3,5DMP)$_2$]	R2	34.6 ± 0.7	187 ± 2	$(1.2 \pm 0.1) \times 10^{27}$	7.85
[W_2S_4(di-*i*-propyldtc)$_2$(3-AP)$_2$]	R2	40.1 ± 0.3	203 ± 1	$(7.5 \pm 0.3) \times 10^{32}$	7.49
[W_2S_4(di-*i*-propyldtc)$_2$(4-AP)$_2$]	R2	31.3 ± 0.9	257 ± 3	$(2.5 \pm 0.2) \times 10^{27}$	4.88

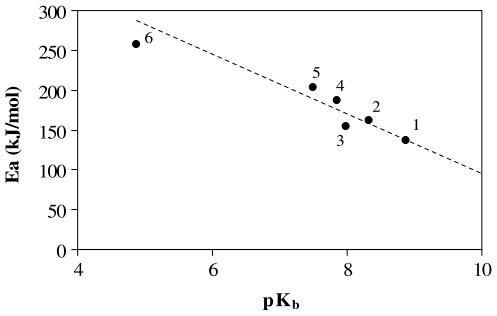

Fig. 1. Activation energy for decomposition of [W_2S_4(di-*i*-propyldtc)$_2B_2$] complexes vs. pK_b. Points 1–6 correspond to complexes with Py, 3-MP, 4-MP, 3,5-DMP, 3-AP and 4-AP, respectively.

Table 4 shows the data obtained from the DSC curve of the adduct [W_2S_4(di-*i*-propyldtc)$_2$Py$_2$], α being the reacted fraction at time t and $\alpha' = d\alpha/dT$.

We have plotted $[\Delta \ln \alpha' - \Delta \ln f(\alpha)]/\Delta \ln(1-\alpha)]$ versus $[\Delta(1/T)/\Delta \ln(1-\alpha)]$. From these representations, we can calculate the activation energy of the process. Table 5 shows the results for r (correlation coefficient), m (slope), i (intercept value) and E_a (activation energy) obtained for the seven mechanisms.

We can observe that in all cases the correlation coefficients (r) are very near to unity, consistent with the results of Criado [42]. Nevertheless, only when the analysis was performed with the mechanism R2 does the straight line present an intercept value (i) close to zero.

Therefore, according with our proposed method, we deduce that the thermal decomposition of the complex [W_2S_4(di-*i*-propyldtc)$_2$Py$_2$] and the loss of pyridine, is carry out by a R2 mechanism (Phase boundary reaction: cylindrical symmetry) with a function $f(\alpha) = 2(1-\alpha)^{1/2}$, an activation energy $E_a = 137 \pm 3$ kJ mol^{-1} and a pre-exponential Arrhenius factor $A = (3.3 \pm 0.2) \times 10^{13}$ s^{-1}.

The results obtained for the compounds studied, are listed in Table 6.

We can assume that the thermal decomposition and loss of coordinated base of the adducts with pyridine, 3-methylpyridine, 4-methylpyridine, 3,5-dimethylpyridine, 3-aminopyridine and 4-aminopyridine follows a R2 mechanism.

If we compare the results, in general, as can be seen from the data in Table 6, the greater the basicity of the base employed, the higher the activation energy and the pre-exponential Arrhenius factor for the process of the loss of the base. The outstanding exception is the 4-MP and 4-AP adducts, which can be attributed to the existence of resonance structures and a pronounced effect on the stability of the complex [29,33,34]. It can be seen that the steric impediment of 3,5-DMP, does not modify the kinetic parameters.

The plot of pK_b versus activation energy presented in Fig. 1, shows that, except for the 4-AP adduct, a very satisfactory correlation was obtained. It is obvious from this figure that the activation energy is linearly related to the basicity of the ligands.

also report, for the first time, the molecular structure of one of the products, tris(diphenyloxophosphino)ethylenediamine, elucidated by single crystal X-ray diffraction.

2. Experimental

2.1. General remarks

All reactions and manipulations were carried out under nitrogen unless otherwise stated and using nitrogen saturated solvents. Analytical grade and deuterated solvents were purchased from Merck (Darmstadt, Germany); ethylenediamine and diphenylchlorophosphine were purchased from Fluka (Buchs, Switzerland) and were used as received. Spectra were recorded on the following instruments: NMR, Bruker Avance DPX 400 (400.1 MHz for ^{1}H; and 100.6 MHz for ^{13}C); Elemental analyses, Fisons Model EA 1108; IR, Matson UNICAM-FTIR Model 1000 spectrophotometer; Melting points, Gallenkamp Model apparatus with open capilleries.

The reactions of diphenylchlorophosphine (PPh_2Cl) with ethylenediamine ($H_2NCH_2CH_2NH_2$) in different molar ratios 2:1, 3:1 and 4:1 were carried out for the synthesis of bis-, tris- and tetrakis(diphenyloxophosphino)ethylenediamine, respectively.

2.2. Bis(diphenyloxophosphino)ethylenediamine, $Ph_2P(O)NHCH_2CH_2NHP(O)Ph_2$

Diphenylchlorophosphine, Ph_2PCl (1.15 g, 5.2 mmol) was added slowly to a solution of ethylenediamine (0.16 g, 2.6 mmol) and Et_3N (0.53 g, 5.2 mmol) in dry diethyl ether (60 mL) at −10 °C under vigorous stirring. The resulting white suspension was stirred under argon at room temperature for 24 h. Solid triethylammonium chloride was removed by filtration under argon and the solvent removed in vacuo. The remaining solid was crystallised in ethylacetate in air. 0.80 g (67% yield): $C_{26}H_{26}O_2N_2P_2$; m.p.: 156–158 °C; *Anal.* Calc. for $C_{26}H_{26}O_2N_2P_2$: C, 67.88; H, 5.65. Found: C, 67.96; H, 5.52%. MS: *m*/*z* 460 (M^+). ^{1}H NMR (ppm rel. to TMS in $CDCl_3$): $\delta = 3.02$ (4H, N–CH_2–), 4.26 (2H, –NH–), 7.32 (m, 8H, *m*-hydrogens of phenyls), 7.38 (m, 4H, *p*-hydrogens of phenyls), and 7.76 (m, 8H, *o*-hydrogens of phenyls); ^{13}C NMR (ppm rel. to TMS in $CDCl_3$): $\delta = 43.26$ (N–CH_2–), 128.93 (d, $J(^{31}P\text{-}^{13}C) = 12$ Hz, *o*-carbons of phenyls), 132.18 (d, $J(^{31}P\text{-}^{13}C) = 2$ Hz, *p*-carbons of phenyls), 132.46 (d, $J(^{31}P\text{-}^{13}C) = 10$ Hz, *m*-carbons of phenyls), 132.79 (d, $J(^{31}P\text{-}^{13}C) = 122$ Hz, *i*-carbons of phenyls). ^{31}P NMR (ppm rel. to H_3PO_4 in $CDCl_3$): $\delta = 26.10$. Selected IR (KBr pellet, cm^{-1}): ν(P═O) = 1182, ν(N–H) = 3191.

2.3. Tris(diphenyloxophosphino)ethylenediamine, $(Ph_2P(O))_2NCH_2CH_2NHP(O)Ph_2$

Diphenylchlorophosphine, Ph_2PCl (9.80 g, 44.4 mmol) was added slowly to a solution of ethylenediamine (0.89 g, 14.8 mmol) and Et_3N (4.50 g, 44.5 mmol) in dry diethyl ether (80 mL) at −10 °C under vigorous stirring. The resulting white suspension was stirred under argon for 72 h at room temperature. Solid triethylammonium chloride was removed by filtration under argon and the solvent removed in vacuo. The remaining solid was crystallised in ethylacetate in air. 5.9 g (60% yield), $C_{38}H_{35}O_3N_2P_3$; m.p.: 178–180 °C. *Anal.* Calc. for $C_{38}H_{35}O_3N_2P_3$: C, 67.82; H, 5.62. Found: C, 67.94; H, 5.48%. MS: *m*/*z* 660 (M^+). ^{1}H NMR (ppm rel. to TMS in $CDCl_3$): $\delta = 2.86$ (m, 2H, N–CH_2–), 3.42 (m, 2H, N–CH_2–), 5.12 (broad, 1H, –NH–), 7.18, 7.32 and 7.72 (m, 30H, phenyl); ^{13}C NMR (ppm in $CDCl_3$): $\delta = 41.00$ (s, N–CH_2–), 48.50 (d, $J(^{31}P\text{-}^{13}C) = 8$ Hz, N–CH_2–), 128.54 (m, $J(^{31}P\text{-}^{13}C) = 10$ Hz, *o*-carbons of phenyls), 128.82 (d, $J(^{31}P\text{-}^{13}C) = 11$ Hz, *o*-carbons of phenyls), 130.87 (d, $J(^{31}P\text{-}^{13}C) = 126$ Hz, *i*-carbons of phenyls), 131.96 (s, *p*-carbons of phenyls), 132.22 (d, $J(^{31}P\text{-}^{13}C) = 10$ Hz, *m*-carbons of phenyls), 132.54 (s, *p*-carbons of phenyls), 132.87 (d, $J(^{31}P\text{-}^{13}C) = 185$ Hz, *i*-carbons of phenyls), 133.03 (m, $J(^{31}P\text{-}^{13}C) = 10$ Hz, *m*-carbons of phenyls); ^{31}P NMR (ppm rel. to H_3PO_4 in $CDCl_3$): $\delta = 24.82$, 32.92. Selected IR(KBr pellet, cm^{-1} ν(P–N–P) = 906, ν(P═O) = 1182, ν(N–H) = 3198.

2.4. Tetrakis(diphenylphosphino)ethylenediamine, $(Ph_2P)_2NCH_2CH_2N(PPh_2)_2$

Diphenylchlorophosphine, Ph_2PCl (2.62 g, 11.88 mmol) was added slowly to a solution of ethylenediamine (0.18 g, 2.99 mmol) and Et_3N (1.20 g, 11.86 mmol) in dry THF (75 mL) at −10 °C under vigorous stirring. The resulting white suspension was stirred under argon for 1 h. Solid triethylammonium chloride was removed by filtration under argon. The solution was evaporated to dryness. The residue was washed with diethylether and dried in vacuum. It was identified as $(Ph_2P)_2NCH_2CH_2N(PPh_2)_2$: 1.46 g (61% yield). m.p. 203–205 °C. *Anal.* Calc. for $C_{50}H_{44}N_2P_4$: C, 75.38; H, 5.53%. Found: C, 75.94; H, 5.80%, ^{1}H NMR (ppm in $CDCl_3$): $\delta = 3.10$ (s, 4H, N–CH_2–), 7.19–7. 31 (m, 40H, phenyls); ^{13}C NMR (ppm in $CDCl_3$): $\delta = 45.81$ (N–CH_2–), 128.00 (d, 6 Hz), 128.57, 132.71 (d, 21 Hz) 132.82, 139.23, 139.40; ^{31}P NMR (ppm rel. to H_3PO_4 in $CDCl_3$): $\delta = 61.29$. Selected IR (KBr, cm^{-1}): 889 ν(P–N–P).

2.5. Tetrakis(diphenyloxophosphino)ethylenediamine, $(Ph_2P(O))_2NCH_2CH_2N(P(O)Ph_2)_2$

H_2O_2 (0.28 mmol) was added slowly to a solution of $(Ph_2P)_2NCH_2CH_2N(PPh_2)_2$ (57 mg, 0.072 mmol) in 5 mL THF under stirring. The mixture was stirred for 2 h at room temperature. Then diethyl ether (5 mL) was added to the mixture and cooled to −10 °C. The white precipitate was separated from the supernatant solution and dried in vacuum. $(Ph_2P(O))_2NCH_2CH_2N(P(O)Ph_2)_2$ 42 mg (68% yield).; m.p.: 248–251 °C. *Anal.*, Calc. for $C_{50}H_{44}O_4N_2P_4$:

C, 69.76; H, 5.12. Found: C, 69.93; H, 5.28%, MS: *m*/*z* 860 (M^+). ^{1}H NMR (ppm rel. to TMS in $CDCl_3$): $\delta = 3.69$ (s, 4H, N–CH_2–), 7.18 (m, 16H, *m*-hydrogens of phenyls), 7.31 (m, 8H, *p*-hydrogens of phenyls), and 7.56 (m, 16H, *o*-hydrogens of phenyls);); ^{13}C NMR (ppm in $CDCl_3$): $\delta = 45.82$ (N–CH_2–), 127.90 (d, $J(^{31}P\text{-}^{13}C) = 14$ Hz, *o*-carbons of phenyls), 131.72 (s, *p*-carbons of phenyls), 131.38 (d, $J(^{31}P\text{-}^{13}C) = 124$ Hz, *i*-carbons of phenyls), 132.59 (d, $J(^{31}P\text{-}^{13}C) = 10$ Hz, *m*-C of phenyls), ^{31}P NMR (ppm rel. to H_3PO_4 in $CDCl_3$): $\delta = 31.53$).

Table 1
Crystal data and experimental details of the structural analysis of tris(diphenyloxophosphino)ethylenediamine

Empirical formula	$[PO(C_6H_5)_2]_3N_2H(CH_2)_2OH_2$
Formula weight	678.61
Crystal system	monoclinic
Crystal shape and color	Plate and colorless
Space group	$P2_1/n$

h, *k*, *l* Ranges	$-20 \rightarrow 0$, $0 \rightarrow 16$, $-20 \rightarrow 21$
Number of reflections collected/unique (R_{int})	7366–7113 (0.0326)
Number of reflections [$I > 2\sigma(I)$]	4184
Number of parameters/restrains	437/4
Goodness-of-fit on F^2	1.03
R indices [$I > 2\sigma(I)$]	$R_1 = 0.0497$, $wR_2 = 0.1161$
R indices [all data]	$R_1 = 0.01238$, $wR_2 = 0.1389$
$(\Delta/\sigma)_{max}$	0.000
Largest difference peak and hole (e/Å^3)	0.294 and −0.252

Additional material available from the Cambridge Crystallographic Data Center as deposition No: CCDC 296237 comprises H-atom coordinates, thermal parameters, and the remaining bond lengths and angles.

2.6. X-ray diffraction structure analysis

A colorless-plate crystal of $0.4 \times 0.4 \times 0.1$ mm was used for the X-ray diffraction study. X-ray diffraction data were collected on an Enraf-Nonius CAD4 (κ-geometry) diffractometer operating in $\omega/2\theta$ scan mode using graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at 20 ± 1 °C. The lattice parameters and their estimated standard deviations were determined from a least-squares refinement of 25 centered reflections in the range $9.90 \leqslant \theta \leqslant 18.01°$ by using CAD4 Express [12]. Three standard reflections were measured every 100 reflections and their intensities showed a good stability. A total of 7366 reflections were collected in the range $2.51 \leqslant \theta \leqslant 26.29°$, of which 7113 independent reflections were used for the structure determination. The intensity data were not corrected for absorption.

Data reduction was carried out using XCAD4 [13]. The structure was solved by direct methods and refined by full-matrix least-squares refinement on F^2 using the programs SHELXS97 and SHELXL97 [14], respectively, in the WinGX package [15]. Atomic scattering factors were taken from the International Tables for X-ray Crystallography [16]. Hydrogen atoms of the water molecule and the H atom on N1 were taken from a difference Fourier map, while the other hydrogen atoms were placed with

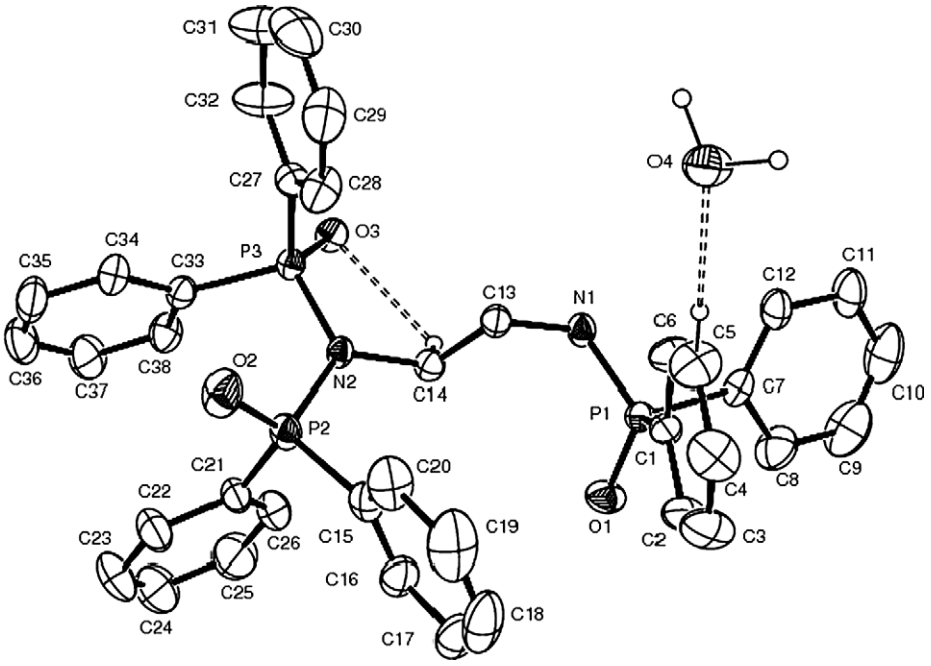

Fig. 1. ORTEP [17] drawing of the molecular structure of tris(diphenyloxophosphino)ethylenediamine with the atomic numbering scheme. Displacement ellipsoids are drawn at the 50% probability level and H atoms are shown as small circles of arbitrary radii.

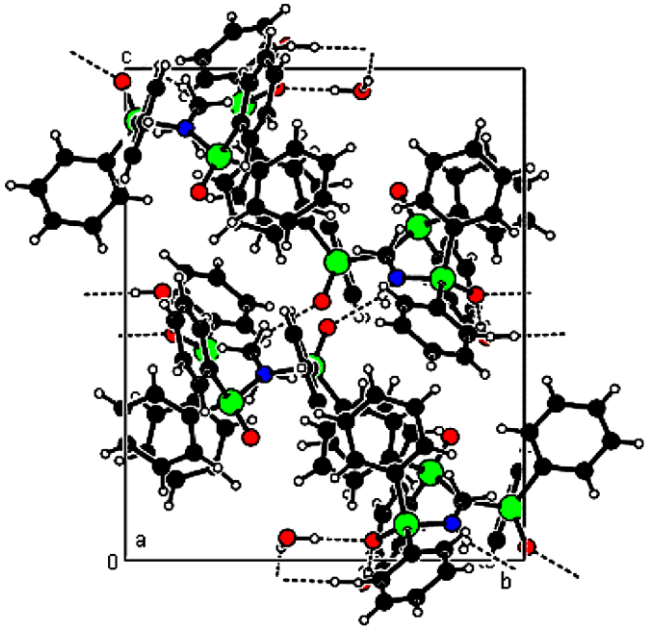

Fig. 2. Packing diagram of tris(diphenyloxophosphino)ethylenediamine.

$U_{iso}(H) = 1.2U_{eq}(C)$. For all non-hydrogen atoms anisotropic displacement parameters were refined. The data collection details, crystal data and refinement parameters are summarized in Table 1.

A perspective view of the molecule [17] is given in Fig. 1. Selected bond lengths and angles are given in Table 2. The hydrogen bonding and molecular packing geometry of the tris(diphenyloxophosphino)ethylenediamine molecule were calculated with PLATON [18] and the hydrogen bonding geometry is summarized in Table 3. There are two intra and four inter molecular hydrogen bonds occurring in the structure. Fig. 2 gives a perspective view of the crystal packing.

3. Results and discussion

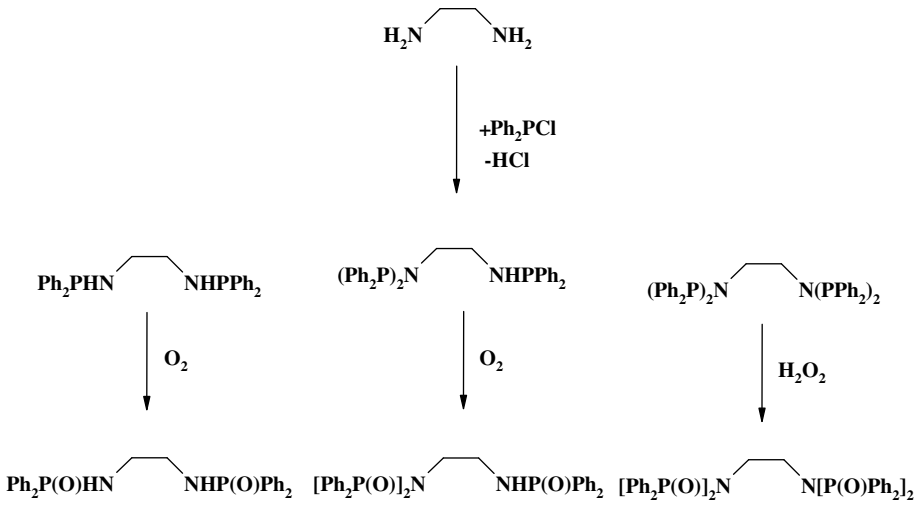
The reaction of ethylenediamine with diphenylchlorophosphine in various stoichiometric ratios gives the respective phosphine oxides through the intermediate $(Ph_2P)_nNCH_2CH_2N(PPh_2)_m$ $(n,m = 1,2)$ at room temperature (Scheme 1).

Bis(diphenylphosphino)ethylenediamine and tris(diphenylphosphino)ethylenediamine are formed as intermediates and can be oxidized to the respective phosphine oxides by oxygen dissolved in the reaction solution, while terakis(diphenylphosphino)ethylenediamine is less liable to oxidation and its oxidation requires a stronger oxidizing agent such as hydrogen peroxide. Consequently, only tetrakis(diphenylphosphino)ethylenediamine could be isolated from the reaction mixture and characterized.

All the three phosphine oxides could be isolated as analytically pure solid materials and fully characterized by elemental analysis, MS and NMR spectroscopies. In the case of tris(diphenylphosphino)ethylenediamine, single crystals could be obtained, so that its molecular structure could be elucidated by X-ray diffraction.

The molecular structure of tris(diphenyloxophosphino)ethylenediamine given in Fig. 1 shows the presence of one H_2O molecule, which is involved in hydrogen bonding through both of its hydrogen atoms with the host molecule. As shown in Fig. 2 and Table 3 there are two intermolecular hydrogen bonding sets involving the water molecule: ([O4–H1A···O1]^{i} and [O4–H1B···O1]^{ii} H-bonds with symmetry codes: (i) $x-1/2$, $y+1/2$, $z-1/2$ and (ii) $-x+1/2$, $y+1/2$, $-z+1/2$, respectively). The oxygen atom of the water molecule is also involved in relatively weak hydrogen bonding with the one of the phenyl hydrogens, [C5–H5···O4]). A strong intramolecular hydrogen bond is seen between N1 and O3, ([N1–H1N···O3] with symmetry code: $-x+1$, $-y+1$, $-z+1$). There are two more hydrogen bonding sets involving hydrogen atoms attached to the carbon, [C10–H10···O2] and [C14–H14A···O3]. The former one is intramolecular and the latter one is an intermolecular hydrogen bonding between two molecules of tris(diphenyloxophosphino)ethylenediamine within the unit cell.

Inspection of bond lengths and bond angles given in Table 2 for the tris(diphenyloxophosphino)ethylenedia-



Scheme 1. The reaction of ethylenediamine with diphenylchlorophosphine in the presence of triethylamine at room temperature.

mine reveals that the C–C, C–N, P–N and P–O bonds are of usual length as compared to similar compounds [4,10,19].

The ^{31}P NMR signal shows a remarkable shift on passing from the phosphino to oxophosphino compound, as illustrated in the case tetrakis(diphenylphosphino)etheylenediamine ($\delta = 61.29$ ppm) and its oxidized form ($\delta = 31.53$ ppm). This shift, due to the formation of an oxo group, is useful in the sense that the transformation of diphosphine to its oxo derivative can be followed by taking the ^{31}P NMR spectra during the reaction.

bond donor) ligands bound to palladium centres [10]. These compounds have been used as starting materials to achieve organic-organometallic hydrogen bonded networks by reaction with carboxylic acids. A study on a Pd_2N_4 core incorporating a diazo ligand is also known [11]. We report herein a new complex $[(3,5\text{-Hdmpz})_2Pd_2(\mu\text{-}3,5\text{-dmpz})_2(2,6\text{-dipic})]$ (**1**) that affords an unsymmetrical 1D chain, and the binuclear units assemble in a zigzag way propagated through 3,5-Hdmpz-carboxylate (2,6-dipic^{2-}) hydrogen bonds. The asymmetric unit of this compound shows a central Pd_2N_4 six-member heterocycle that adopts a distorted boat-like conformation.

We considered it of further interest to use another substituted pyrazole, 3-methyl-1-phenylpyrazole (3-me-1-phpz). An earlier report has been made that 3-me-1-phpz displaces acetonitrile from $[PdCl_2(CH_3CN)_2]$ to form *trans*-$[Pd(N_3)_2(3\text{-me-1-phpz})_2]$ via $[PdCl_2(3\text{-me-1-phpz})_2]$ [12]. In addition, the unsymmetrical N-substituted pyrazoles offer the possibility of formation of cyclometallated products [13]. With the aim to generate a pyrazole based product, we carried out the reaction of $PdCl_2(CH_3CN)_2$, 3-me-1-phpz and NaH2,6-dipic. The compound $[Na_2(H_2O)_4Pd(2,6\text{-dipic})_2]$ (**2**) is formed without incorporation of the 3-me-1-phpz ligand. A couple of precedents of Pd-2,6-dipic^{2-} complexes are known in the literature [14,15]. The single crystal X-ray analysis shows that **2** is stabilized through cationic Na^+–H_2O and anionic Pd-2,6-dipic^{2-} units to form an extended two-dimensional coordination polymer. A detailed study of the molecular and electronic structures coupled with experimental results obtained from IR, UV–Vis, ^{1}H NMR and mass spectral studies have been made. Data on the luminescence property and antimicrobial activity of **1** are also presented.

2. Experimental

2.1. Materials

Palladium chloride ($PdCl_2$) used in the complex was obtained from Arora-Matthey Limited (India). $PdCl_2(CH_3CN)_2$ was prepared according to the literature procedure [16]. 3,5-Dimethylpyrazole was purchased from Fluka. Pyridine-2,6-dicarboxylic acid and 3-methyl-1-phenylpyrazole were obtained from Lancaster. Sodium hydroxide was a Merck product. All solvents were dried and kept over molecular sieves prior to use. Double distilled water was used throughout.

2.2. Physical measurements

Elemental analysis was carried out in a 2400 Series-II CHN analyzer, Perkin–Elmer, USA. IR spectra were recorded on a Nicolate Magna IR 750 Series-II IR spectrophotometer. The ^{1}H NMR spectra were recorded on a 300 MHz Bruker Avance DPX 300 machine, Switzerland in $(CD_3)_2SO$ and D_2O solvent with TMS as the internal standard at room temperature. The mass spectra were recorded on a Qtof Micro YA263 mass spectrometer. Absorption and luminescence spectra were studied on a Shimadzu UV2100 UV–VIS recording spectrophotometer and a Perkin–Elmer LS 55 Luminescence spectrometer, respectively.

2.3. Computational details

A detailed quantum-chemical calculation on the Na-chain as retrieved from the crystal geometry of **2** was made at the DFT-level of B3LYP/6-31G$^+$(d,p) [17]. These sets of calculations have been performed using the GAUSSIAN 03 program suite [18].

2.4. Synthesis of the complexes

2.4.1. Synthesis of $[(3,5\text{-Hdmpz})_2Pd_2(\mu\text{-}3,5\text{-dmpz})_2(2,6\text{-dipic})]$ (**1**)

0.026 g (0.1 mmol) of $PdCl_2(CH_3CN)_2$ was dissolved in 10 cm^3 of methanol. To this deep orange solution was added a 10 cm^3 methanolic solution of 3,5-Hdmpz (0.020 g, 0.2 mmol). The resulting mixture was stirred for 10 min at room temperature and filtered off to remove any suspended material. To the filtrate, 15 cm^3 aqueous solution of NaH2,6-dipic (0.040 g, 0.2 mmol) was added and the solution was warmed at 50 °C for 30 min. The light yellow solution was cooled to room temperature. Deep yellow crystals suitable for X-ray diffraction were obtained after 7 days in a 71% yield based on Pd. *Anal*. Calc. for **1**: C, 42.60; H, 4.34; N, 16.57. Found: C, 42.26; H, 4.23; N, 16.43%. IR spectrum (KBr disk, ν/cm^{-1}): 3123 (w), 3090 (w), 1683 (s), 1673 (s), 1621 (s), 1573 (m), 1414 (m), 1375 (s). ^{1}H NMR spectrum (300 MHz, d_6-DMSO) δ: 2.43 (CH_3, s), 1.66 (CH_3, s), 6.08 (H, s), 2.43 (CH_3, s), 1.86 (CH_3, s), 5.93 (H, s); 2.11 (CH_3, s), 2.30 (CH_3, s), 5.44 (H, s), 12.96 (N–H,s), 2.20 (CH_3, s), 2.23 (CH_3, s), 5.61 (H, s), 17.21 (N–H, s); 7.90, 7,92 (H, d), 8.21, 8.24, 8.27 (H, t), 7.77, 7.79 (H, d). Mass spectrum (CH_3CN/H_2O): 762.28.

2.4.2. Synthesis of $[Na_2(H_2O)_4Pd(2,6\text{-dipic})_2]$ (**2**)

$PdCl_2(CH_3CN)_2$ (0.052 g, 0.2 mmol) was dissolved in 5 cm^3 of DMF. To the deep orange solution was added a solution of 3-me-1-phpz (0.063 g, 0.4 mmol) in 5 cm^3 of DMF under stirring. After 10 min, an aqueous solution of NaH2,6-dipic (0.080 g, 0.4 mmol) was added to the mixture and the solution stirred for 1 h. The resulting yellow solution was filtered off to remove any suspended material. Yellow crystals suitable for X-ray diffraction were obtained after 5 days in a 40% yield based on Pd. *Anal*. Calc. for **2**: C, 30.73; H, 1.10; N, 5.12. Found: C, 30.81; H 1.16; N, 5.14%. IR spectrum (KBr disk, ν/cm^{-1}): 3528 (s), 3426 (w), 1683 (s), 1633 (s), 1411 (m), 1376 (s). ^{1}H NMR spectrum (300 MHz, d_6-DMSO) δ: 7.90, 7.92 (H, d), 8.18, 8.20, 8.23 (H, t), 7.75, 7.72 (H, d). Mass spectrum (H_2O): 546.28.

2.5. Crystal structure determination and structural refinement of complexes *1* and *2*

Crystals of dimensions $0.19 \times 0.21 \times 0.49$ mm (**1**) and $0.19 \times 0.26 \times 0.55$ mm (**2**) were mounted on a Siemens P4 4-circle-diffractometer which was equipped with graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). Unit cell dimensions and intensity data were measured at 293 K for both **1** and **2**. All calculations for data reduction, structure solution and refinement were done by standard procedures (SHELXS-97) [19], (SHELXL-97) [20]. All non-hydrogen atoms were refined anisotropically by full-matrix least-squares techniques on F^2. All the hydrogen atoms of **1** and **2** were included at calculated positions and refined isotropically. Information concerning crystallographic data collection and refinement of the structures are summarized in Table 1.

3. Results and discussion

3.1. Synthesis and spectroscopic characterization of the complexes

The complexes reported here are formed by the process of slow crystallization. Sometimes it takes a long time to isolate the desired product. Moreover, the reported complexes are sparingly soluble in common organic solvents. We have tried to crystallize the products from an optimum dilution so that we could strike a balance between improved crystal quality and time of crystallization. Compound **1** [(3,5-Hdmpz)$_2$Pd$_2$(μ-3,5-dmpz)$_2$(2,6-dipic)] has been obtained as a deep-yellow crystalline solid by addition of 3,5-Hdmpz and NaH2,6-dipic to $PdCl_2(CH_3CN)_2$ in methanol at 50 °C without addition of the hydroxide ion or other bases. Compound **2** was obtained also as a well-formed deep-yellow crystalline solid by the addition of 3-me-1-phpz and an aqueous solution of NaH2,6-dipic to a DMF solution of $PdCl_2(CH_3CN)_2$. The formation of compound **2** instead of a substituted pyrazolate one is the result of a failed experiment. It clearly points out the relevance of the strength of the bidentate chelate (Hdipic$^-$) in determining the course of the reaction. In the absence of 3-me-1-phpz, no product is obtained. However, a similar compound, *trans*-$Na_2[Pd(2,6\text{-dipic})_2 \cdot 2H_2O$, was obtained earlier by the addition of K_2PdCl_4 to a warm aqueous solution of pyridine-2,6-dicarboxylic acid and maintaining the pH to 6 with 1 N NaOH solution. The yellow crystalline product was characterized by elemental analysis, ^{1}H NMR, IR and UV–Vis spectroscopy [14]. There is no report of the single crystal X-ray structural study of this compound. The IR spectrum of complex **1** displays all the characteristic bands of the coordinated 3,5-Hdmpz and 2,6-dipic^{2-} ions. These include a pair of strong bands at ca. 1683 and 1621 cm^{-1} corresponding to $\nu_{asym}(COO^-)$ vibrations of the bonded and free carboxylates, respectively, and another pair for $\nu_{sym}(COO^-)$ at 1414 and 1375 cm^{-1}, respectively for the bonded and free carboxylate groups. The ring-breathing mode for 3,5-Hdmpz is observed at 1573 cm^{-1}. The relatively low value of the ν(N–H) frequency at 3123 cm^{-1} indicates that the N–H $\cdots$ O hydrogen bonds observed in the X-ray structure of the compound must be quite strong. The IR spectrum of complex **2** is quite simple. The bands at 1683 and 1411 cm^{-1} correspond to the $\nu_{asym}(COO^-)$ and $\nu_{sym}(COO^-)$ vibrations, respectively, of the bonded carboxylates whilst that for the free carboxylates are observed at 1633 and 1376 cm^{-1}. A strong band at 3528 cm^{-1} is observed for the ν(O–H) frequency, which reveals the presence of the solvent water molecules. The ESIMS of compounds **1** and **2** corroborate well with their simulated spectra. The ^{1}H NMR spectrum of **1** at room temperature shows three sets of signals, one for the bridging 3,5-dmpz ($\delta = 2.43$ (CH_3, s), 1.66 (CH_3, s), 6.08 (H, s), 2.43 (CH_3, s), 1.86 (CH_3, s) 5.93 (H, s) ppm) and another one for the terminal 3,5-Hdmpz groups ($\delta = 2.11$ (CH_3, s), 2.30 (CH_3, s), 5.44 (H, s), 12.96 (N–H, s) 2.20 (CH_3, s), 2.23 (CH_3, s) 5.61 (H, s), 17.21 (N–H, s) ppm). The third set is for the 2,6-dipic^{2-} moiety ($\delta = 7.90$, 7.92 (H, d), 8.21, 8.24, 8.27 (H, t) and 7.77, 7.79 (H, d) ppm). The ^{1}H NMR spectrum of **2** at room temperature shows signals only for the 2,6-dipic^{2-} unit comparable to the signals observed in complex **1**.

3.2. Description of the crystal structures

As can be seen from the asymmetric unit (Fig. 1), **1** is a binuclear Pd(II) complex that contains two 3,5-Hdmpz,

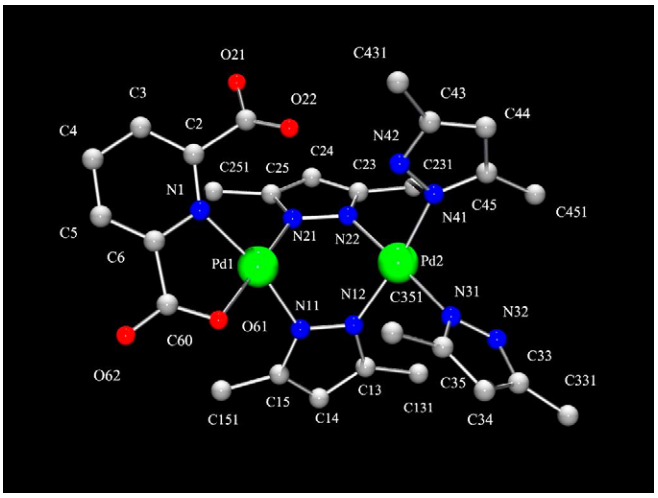

Fig. 1. Molecular structure of complex $[(3,5\text{-Hdmpz})_2Pd_2(\mu\text{-}3,5\text{-dmpz})_2(2,6\text{-dipic})]$ (**1**). All hydrogen atoms have been omitted for clarity.

two 3,5-dmpz and a 2,6-dipic unit. Pd2 contains two Hdmpz units as coordinating ligands whereas Pd1 contains only one 2,6-pyridinedicarboxylate unit. The two 3,5-dmpz units bridge the metal centres in a bidentate fashion. Table 2 lists selected bond distances and angles. Despite the presence of bridging 3,5-dmpz groups between the metal atoms, the intermetallic separation (3.397 Å) indicates no metal–metal bond. The intermetallic distance is comparable to $[\{Pd_2(\mu\text{-}3,5\text{-dmpz})(3,5\text{-dmpz})(3,5\text{-Hdmpz})\}_2]$ [9] (3.4020 Å) and $[Pd(\mu\text{-}3,5\text{-dmPz})(\eta^3\text{-}C_3H_4)]_2$ [21] (3.343 Å) but is longer than the corresponding distances in $[Pd_2Cl_2(\mu\text{-}3,5\text{-dmpz})_2(PMe_2Ph)_2]$ [22] (3.115(1) Å) and $[\{Pd_2(CH_2C_6H_4P\text{-}(o\text{-tolyl})_2\text{-}\kappa C,P)_2(\mu_3\text{-}3,5\text{-dmpz-}N,N',C^4)_2Ag(\mu\text{-}ClO_4)\}_2]$ [4] (3.2297(7) Å). Each palladium atom is in an almost square-planar coordination environment. The central six-member $[Pd(\mu\text{-}3,5\text{-dmpz})_2Pd]$ core is non-planar with Pd–$N_{3,5\text{-dmpz}}$ distances between 1.981(7) and 2.007(7) Å. These fall in the range found in other Pd and Pt complexes with this type of ligand [4,22–28]. The N–Pd–N angles are 87.8(3)° and 86.2(3)° between the 3,5-dimethylpyrazolate groups. The Pd_2N_4 six-member ring reveals a boat-like conformation; the dihedral angle formed by the best least-squares coordination planes of the metals being 89.7°. The metal atoms are positioned at the vertices of the boat and the angle between the planes containing the Pd–N–N–Pd fragments is 73.8° [29]. The boat folding of the Pd_2N_4 core has also been observed earlier for other pyrazolato bridged palladium complexes [9,30,31]. The mean deviation of the plane constructed by the four nitrogen atoms N11, N12, N21 and N22 is 0.0589 Å. The displacement of Pd1 towards N22 is 0.9391 Å while that for Pd2 towards N22 is 1.1145 Å. All of the 3,5-Hdmpz, 3,5-dmpz and 2,6-$dipic^{2-}$ ligands are planar, within experimental error. Comparable bond lengths within the 3,5-dimethylpyrazolate rings suggest substantial delocalization upon deprotonation. The bow angles between the planes N11–N12–N21–N22 and N12–Pd2–N22, N11–Pd1–N21 are 40.73°, 50.12°, respectively. This difference reflects the unsymmetrical environment around the metal centres. The dihedral angles between the monodentate 3,5-Hdmpz ligands N31–N32–C33–C34–C35 and N41–N42–C43–C44–C45, and bridging 3,5-dmpz ligands N11–N12–C13–C14–C15 and N21–N22–C23–C24–C25 are 91.1° and 90.3°, respectively. The ligand 2,6-$dipic^{2-}$ coordinates to Pd1 in a bidentate fashion through its pyridine nitrogen and one carboxylate oxygen atom while the other carboxylate remains free. To achieve internal charge balance, the non-coordinated oxygen atom O21 of the free carboxylate group must be deprotonated. The complex exhibits a zigzag chain configuration of the 1D network through intermolecular 3,5-Hdmpz-carboxylate hydrogen bonds. This arrangement results from the *trans* orientation of one protonated pyrazole and a free carboxylate group of 2,6-$dipic^{2-}$ moieties. This network is clearly affected by the intermolecular and intramolecular hydrogen bonding occurring between the atoms N32–H32 ··· O21 and N42–H42 ··· O22, respectively, which is responsible for the conformation and stability.

Table 2
Selected bond lengths (Å) and angles (°) in complex **1** with esds in parentheses

Bond lengths (Å)			
Pd1–O61	2.018(6)	Pd2–N41	2.053(6)

N32–H32–O21	2.740(10)	1.8800	173.00
N42–H42–O22	2.720(10)	2.0200	138.00

The X-ray structure and numbering scheme for complex **2** are shown in Fig. 2. Selected bond lengths and angles are listed in Table 3. The crystal is built up by centrosymmetric Pd-2, 6-$(dipic)_2^{2-}$ anions and Na^+ cations hexacoordinated by four water molecules and two carboxylate oxygens belonging to the $dipic^{2-}$ moiety. The 2,6-dipicolinate ion chelates in a bidentate fashion to the palladium atom and the resulting coordination around the palladium is square planar with Pd–N1 and Pd1–O1 bond distances of 2.028 and 2.004 Å, respectively. The arrangement of the oxygen atoms around the Na^+ ion is approximately octahedral

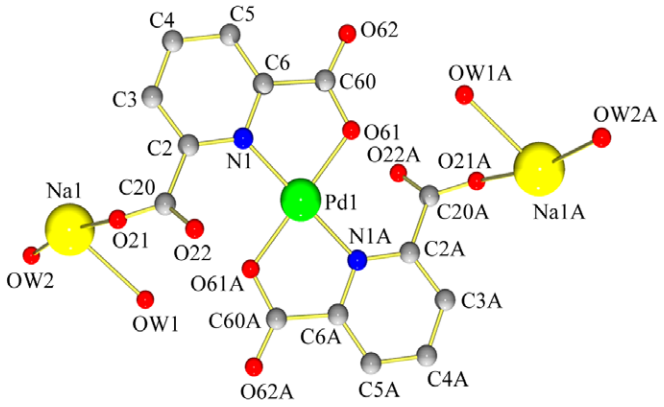

Fig. 2. Molecular structure of complex $[Na_2(H_2O)_4Pd(2,6\text{-dipic})_2]$ (**2**). All hydrogen atoms have been omitted for clarity.

OW1_b–Na1–OW2_d	89.85(16)	Na1–OW1–Na1_b	90.01(17)
Na1–OW2–Na1_d	95.99(15)		

[a] Symmetry transformations used to generate equivalent atoms: $a = -x, 1-y, 1-z$; $b = -x, 2-y, 2-z$; $c = 1-x, 1-y, 1-z$; $d = 1-x, 2-y, 2-z$.

as shown in Fig. 2. The cation coordination can be rationalized in terms of bond valence [32,33], which assumes that the total charge of the cations has to be saturated by the summation of the separated bond valence s_i of each coordinated atom or ion. The quantity s can be calculated by the expression $s = \exp[(r_0 - r)/B]$, where r is the actual Na–O distance, and r_0, B are parameters empirically determined ($r_0 = 1.803$ and $B = 0.37$) [34]. In the present structure, the value of 1.04 for $\sum s_i$ obtained for the sodium cation is in good agreement with the expected charge value of 1.00. The packing arrangement of **2** consists of cationic Na^+-water and anionic Pd-2,6-dipic^{2-} units to form a two-dimensional coordination-polymeric network as shown in Fig. 3. In the cationic part, solvent water molecules OW1 and OW2 link the Na atoms to form a –Na1–H_2O–Na– zigzag chain where there are two types of Na–Na distances, 3.656 and 3.550 Å. The chains line up in the *ab*-plane and are parallel to the Pd-2,6-dipic^{2-} sheet. Finally, every Pd-2,6-dipic^{2-} layer links two adjacent parallel Na-layers through the oxygen atoms (O2 and O21) to form the two dimensional network. No short contacts between Pd(II) atoms exist, the minimum Pd–Pd distance being 6.569 Å.

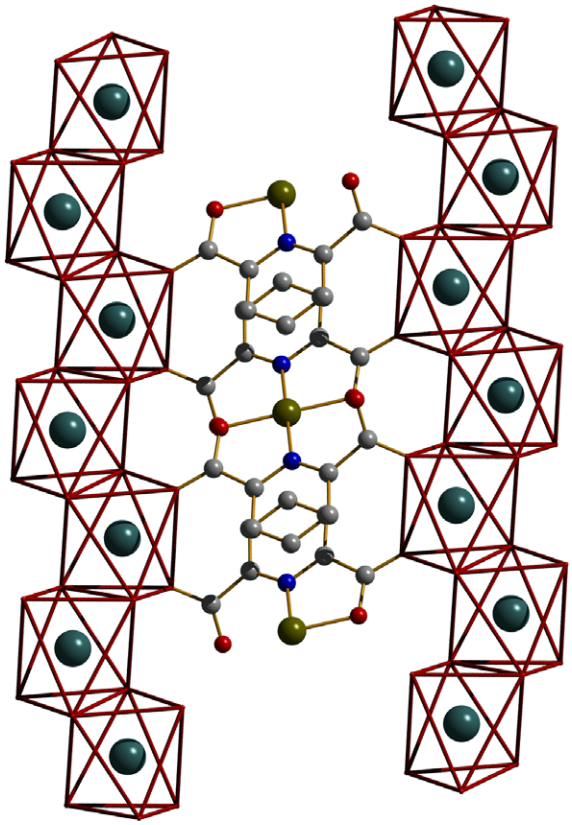

Fig. 3. The perspective view of the packing of $[Na_2(H_2O)_4Pd(2,6\text{-dipic})_2]$ (**2**) comprising of cationic Na^+–H_2O and anionic Pd-2,6-dipic^{2-} units.

A detailed analysis of the crystal geometries reveals an interesting phenomenon in compound **2**. The 1D Na-chain in the crystal shows a significant distortion with short and long alternating Na–Na distances [Na–Na (type 1) = 3.550 Å; Na–Na (type 2) = 3.655 Å]. Examples of Na–H_2O chains are known in the literature whereby alternating Na–Na distances in a particular system do not show any difference. The Na–Na distance in polyhedral $[Na_3(O)_4(H_2O)_{10}]^{3+}$ is 3.477(8) Å [35] and that in the cationic Na–H_2O-malonate chain is 3.786 Å [36]. A marginal difference in Na–Na distances (3.566(3) and 3.534(4) Å) has been reported in $[(L^3VO_2Na)_2(H_2O)_7]_\infty$ (L^3 = a schiff base ligand) [37]. Our observation is very similar to that known in the famous case of Peierls-distortion in *trans*-polyacetylene that leads formation of a gap near the Fermi-energy and leads to insulating behavior of polyacetylene [38,39]; for *trans*-polyacetylene, C=C (type 1) = 1.355 Å; C–C (type 2) = 1.54 Å. Thus, our system with a 1D Na-chain also exhibits a Peierls-distortion. To quantify the hypothesis, we performed a detailed quantum-chemical calculation on the Na-chain as retrieved from the crystal geometry at the DFT-level of B3LYP/6-31G$^+$(d,p). The calculations are performed on a finite sized

Fig. 4. Highest molecular orbital plot for the Na-chain: clearly seen electron localization over alternate Na–Na distances leading to alternate short and long distances supporting the Peierls-distortion in **2**.

(10 atoms) Na-atom chain. The Na atom, having one unpaired electron in the $3s^1$ orbital, shares a similarity to the polyacetylene chain which has one unpaired electron in the p_π orbital. The highest occupied molecular orbital (HOMO) indeed shows a localization of electrons on each alternating short bond and thereby supports the existence of alternating short and long Na–Na bonds with a Na–Na–Na angle of 127.11° (Fig. 4). It is true that the Na-chains do not have conventional bonding in terms of organic molecules. The Na–Na distance in the BCC Na-crystal is 3.72 Å. Of course, Na-crystal is bound through bonding interactions albeit weak in the solid state. One cannot argue that Na-atoms are packed with just hard-sphere packing with no Na–Na interactions. Anyway, in our system the Na–Na bonds are smaller than that in Na-crystal, rendering the possibility of weak interactions between the Na-atoms in the 1D-chains. Otherwise, one could see such localization on each atom and not on the bonds.

3.3. Absorption spectra and luminescence properties

Luminescent Pd(II) complexes are exceedingly rare if compared to the analogous Pt(II) luminophores [40]. With few notable exceptions [41,42], most systems emit only at low temperature and with low efficiency [43–46]. It has been also recognized that when incorporated in polynuclear complexes, Pd(II) centers may lead to partial quenching of luminescence. Nevertheless despite these unfavorable premises, several photoactive palladium(II) complexes recently have been the subject of accurate photophysical studies. The absorption spectrum of complex **1** in DMF solution is dominated by an intense band with the maxima at 267 nm in the ultraviolet region ($\varepsilon = 1.56 \times 10^4\ M^{-1}\ cm^{-1}$) which is assigned to a spin-allowed π–π^* transition. At longer wavelength in the range 320–400 nm, a shoulder is obtained which may be attributed to a metal-to-ligand charge transfer (MLCT) transition. Complex **2** also exhibits a strong band centered at 274 nm with a molar absorption coefficient of $7.19 \times 10^3\ M^{-1}\ cm^{-1}$. In addition, the lower energy band in the range 320–450 nm is assigned to the spin allowed MLCT transition. In the fluorescence emission spectrum of a solution of **1** in DMF (5.0×10^{-6} M) at room temperature, on excitation at 270 nm, the emission peaks are observed at 410 and 430 nm in the visible region and these are independent of the concentration of the solution. A value for quantum efficiency $\Phi_F = 0.04$ has been calculated using *p*-cresol in cyclohexane as a standard. The aqueous solution of compound **2** is very weakly emissive with a Φ_F value of 6.0×10^{-3} (measured against *p*-cresol in cyclohexane).

3.4. Antimicrobial activity

The antimicrobial activity of compound **1** was determined against *Bacillus subtilis*, *Escherichia coli* and *Aspergillus niger* in a medium of nutrient and Czapek-dox broth, respectively for bacteria and mold. 0.1 mL of cell suspension (5.0×10^5 cfu/mL) from 18 h cell culture of bacteria grown on nutrient agar at 37 °C was added per 5 ml of the medium. For *A. niger*, spore suspension was added instead of cell suspension. The compound was dissolved in a mixture of 1:1 DMF and absolute ethanol. The tubes were incubated at 37 °C for 24 h for the growth of the bacteria and at 30 °C for 48 h for mold. The lowest concentration of the compound that resulted in complete inhibition of the visible growth after incubation was recorded as the minimum inhibitory concentration (MIC). The MIC of the compound against *B. subtilis*, *E. coli* and *A. niger* has been found to be 100 μg/mL.

4. Conclusion

In conclusion, we have here shown two palladium derivatives, $[(3,5\text{-Hdmpz})_2Pd_2(\mu\text{-}3,5\text{-dmpz})_2(2,6\text{-dipic})]$ and $[Na_2(H_2O)_4Pd(2,6\text{-dipic})_2]$ which form hydrogen bonded 1D and 2D coordination networks, respectively. Compound **1** has been obtained as a homobimetallic complex bridged by two 3,5-dmpz units without addition of any external base. The central Pd_2N_4 core adopts a boat-like conformation. Compound **2** on the other hand, forms a 2D coordination polymeric network constructed of cationic Na^+–water and anionic Pd-2,6-dipic^{2-} units. Quantum-chemical calculation shows that alternate short and long Na–Na distances observed are due to Peierls-distortion in the Na-chains.

The binuclear compound **1** has been investigated as an inhibitory agent against microbial organisms and shows luminescence property with a Φ_F value of 0.04.

Acknowledgements

We thank Prof. A.K. Guha, Department of Biological Chemistry, IACS, Kolkata for his advice in the study of antimicrobial activity. We thank Mr. A. Datta of JNCASR, Bangalore for discussions on theoretical modelling.

Appendix A. Supplementary material

Full details of the crystal structure analyses of **1** and **2** have been deposited with the Cambridge Crystallographic Data Center, (CCDC Nos. 299284 and 299285). Copies may be obtained free of charge on application to the Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK, fax: +44 1223 336 033, e-mail: deposit@ccdc.cam.ac.uk or on the www.ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2006.05.030.

the metal–oxime interactions. The application of a previously developed theoretical model for $Ni(TRISOXH_3)Cl_2$ [7] to very similar complexes yields insight into the applicability and feasibility of using molecular modeling to explore the more complicated oxygen active complexes.

The series of complexes chosen for this study (Fig. 1) includes $Ni(TRISOXH_3)Cl_2$ (**1**), $Ni(TRISOXH_3)Br_2$ (**2**), $[Ni(TRISOXH_3)(CH_3OH)I]I$ (**3**), and $[Ni(TRISOXH_3)(H_2O)_2]F_2 \cdot 2H_2O$ (**4**). The complexes have been studied by a combined experimental and theoretical approach utilizing X-ray crystallography, vibrational spectroscopy and molecular modeling. X-ray crystallography has provided structural information for the series of complexes. Infrared and Raman spectroscopy reveal trends in the intraligand and metal ligand vibrations that result from the influences of the different halide or solvent ligands. As the molecules of interest are all relatively large transition metal complexes with two unpaired electrons, density functional theory is employed as the principal theoretical method; this approach has been successfully employed for studying electronic structure of transition metal systems [8–12].

We recently detailed the development of a theoretical model for $Ni(TRISOXH_3)Cl_2$ that compared the results of density functional theory (DFT) calculations with a variety of basis sets to structural and vibrational data [7]. This model, including theory level and basis set choice, has now been applied to the other complexes in the series. When using the functional B3LYP, the addition of polarization and diffuse functions to the metal center basis set has been shown to increase accuracy, notably in reproducing the metal–ligand bond lengths [7–12]. A theoretical model of the complex $Ni(TRISOXH_3)F_2$ (**5**), which has not yet been successfully isolated, is also presented and discussed. Electronic structure analysis is facilitated by performing a natural population analysis (npa) of the optimized theoretical models [13–15]. As a more useful alternative to the default Mulliken analysis, npa assists evaluation of the total and atomic spin densities as well as comparison of the natural charges of the metal, halide or solvent ligands, and the three oxime groups of the $TRISOXH_3$ ligand. This study highlights the utility of and caveats related to employing DFT theoretical models to a series of similar transition metal complexes notably in the pursuit of understanding the role of ligand variation in optimizing the unusual substrate oxidation chemistry of $Ni^{II}(TRISOX)$ derivatives. In addition, this work exploits an interesting wavenumber scaling approach to improve the correlation between experimental and theoretical vibrational modes previously developed and now applied to a series of similar complexes. The data suggest a single empirically derived linear scale function can be applied to other complexes, which are very similar in electronic structure to significantly improve the agreement between experimental and theoretical frequencies.

2. Experimental methods

2.1. Synthesis of complexes

All solvents and chemicals were obtained from Fisher/Acros or Sigma–Aldrich and were used as supplied, unless otherwise indicated. Syntheses of the ligand tris(1-propan-2-onyl oxime)-amine ($TRISOXH_3$) [5], $Ni(TRISOXH_3)Cl_2$ (**1**) [2], and $[Ni(TRISOXH_3)(NO_3)(H_2O)](NO_3)$ [1] have been previously reported.

2.1.1. $Ni(TRISOXH_3)Br_2$ (2)

0.46 mmol (0.21 g) of $[Ni(TRISOXH_3)(NO_3)(H_2O)](NO_3)$ was dissolved in 5 mL acetonitrile to form a purple solution; 1.02 mmol (0.33 g) of tetraethylammonium bromide was added and the mixture was stirred for approximately 5 min with gentle heating. The resulting blue-green solution was evaporated; the solid (75% yield) was dissolved in methanol and recrystallized by ethyl acetate vapor diffusion. Sapphire blue crystals were obtained. *Anal*. Calc. for $NiC_9N_4O_3H_{18}Br_2$: C, 24.09; H, 4.04; N, 12.48. Found: C, 24.35; H, 3.72; N, 12.52%.

2.1.2. $[Ni(TRISOXH_3)(CH_3OH)I]I$ (3)

After 30 mL methanol was purged with Ar for 30 min, 2.17 mmol (0.5 g) of $TRISOXH_3$ was combined with

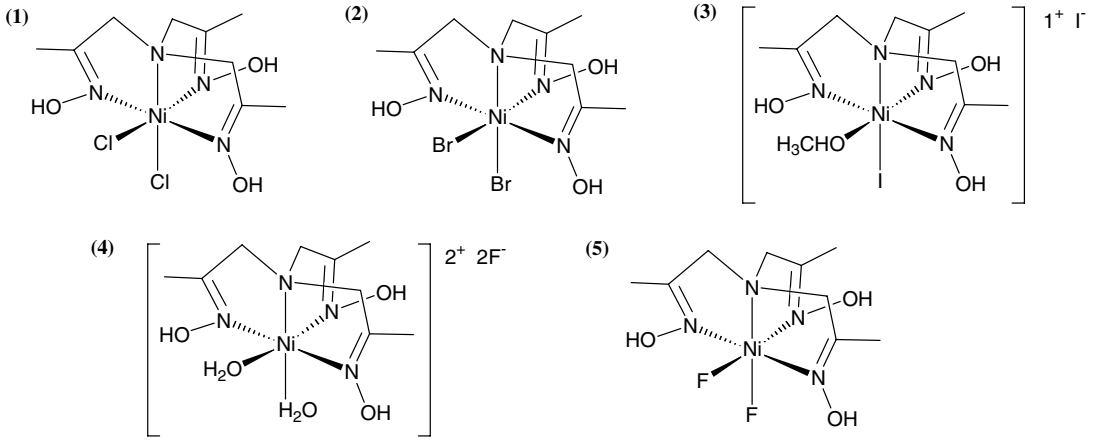

Fig. 1. Halide series of complexes $Ni(TRISOXH_3)Cl_2$ (**1**), $Ni(TRISOXH_3)Br_2$ (**2**), $[Ni(TRISOXH_3)(CH_3OH)I]I$ (**3**), $[Ni(TRISOXH_3)(H_2O)_2]F_2 \cdot 2H_2O$ (**4**), and $Ni(TRISOXH_3)F_2$ (**5**).

0.679 g nickel (II) iodide hydrate with stirring and low heat until dissolved, forming a green brown solution. The complex was crystallized by vapor diffusion of ethyl acetate into the reaction solution. Light blue-purple rods were obtained in a 40% yield. *Anal.* Calc. for $NiC_{10}N_4O_4H_{22}I_2$: C, 20.90; H, 3.86; N, 9.75. Found: C, 20.61; H, 3.46; N, 9.61%.

2.1.3. *[Ni(TRISOXH$_3$)(H$_2$O)$_2$]F$_2$ · 2H$_2$O (**4**)*

0.58 mmol (0.26 g) of [Ni(TRISOXH$_3$)(NO$_3$)(H$_2$O)](NO$_3$) was dissolved in 20 mL acetonitrile to form a purple solution; 1.2 mmol (0.40 g) of tetrabutylammonium fluoride trihydrate was added with gentle heating and stirring. After the salt dissolved, the solution turned green and a light purple powder precipitate formed. The purple powder (60% yield) was filtered, washed with acetonitrile, redissolved in methanol and recrystallized by ethyl acetate vapor diffusion. Lavender plates were obtained. *Anal.* Calc. for $NiC_9N_4O_7H_{26}F_2$: C, 27.28; H, 5.43; N, 13.88. Found: C, 27.09; H, 5.87; N, 14.04%.

3. X-ray crystallography: general procedures

Intensity data for **2** (150 K) and **4** (295 K) were collected on a Bruker SMART 1K CCD diffractometer while data for **3** (150 K) were collected on a Bruker SMART6000 CCD diffractometer. Both instruments used graphite-monochromated Mo Kα radiation, $\lambda = 0.71073$ Å, and a detector distance of 5 cm. A series of 10–30 s data frames measured at 0.3° increments of ω were collected to calculate a unit cell. For data collection, frames were measured for 10–25 s at 0.3° intervals of ω with a maximum θ value of 26° for **2** and 28° for **3** and **4**. All frames were processed using the program SAINT.[3] Absorption and beam corrections were applied using SADABS [16].

[3] SMART v5.622 & 5.628 and SAINT v6.02A & 6.28A programs were used for data collection and data processing, respectively.

All structures were solved by a combination of direct methods in SHELXTL [17] and the difference Fourier technique and refined by full-matrix least-squares on F^2. Non-hydrogen atoms were refined with anisotropic displacement parameters. For all complexes, the –OH hydrogens were located directly and the positions refined. All remaining hydrogen atoms were either located directly or calculated based on geometric criteria and treated with a riding model. The isotropic temperature factors for the hydrogen atoms were set as a^*U_{eq} of the adjacent atom ($a = 1.5$ for methyl and hydroxyl and 1.2 for all others). The refinements converged with crystallographic parameters as summarized in Table 1.

3.1. Vibrational spectroscopy

Raman spectra were collected using a SPEX 1404 0.85 m double spectrometer with a liquid N_2 cooled 13.6 mm back-thinned SPEX Spectrum-1 CCD chip detector. Raman scattering was excited by the 488.0 nm or 514.5 nm line of a Coherent 10 W Sabre Ar ion laser; the laser lines were chosen for intensity and the availability of holographic notch filters. The power used was typically 300 mW at the sample and no sample decomposition was observed. The scattered light was directed through a Kaiser Optical Systems holographic SuperNotch filter for each wavelength. Raman shifts were calibrated against the appropriate Raleigh line. Samples for Raman experiments were prepared by finely grinding the recrystallized complex with an agate mortar and pestle and filling a 1 mm i.d. melting point capillary tube. Samples were cooled to approximately −100 °C by a liquid nitrogen chilled stream of N_2 gas blown thru a quartz EPR-type cooling tube (Bruker Instruments). Resulting spectra were 4-point baseline corrected using GRAMS/32 (v5.22) and then multiple corrected spectra were averaged to improve the signal-to-noise ratios. Infrared spectra were collected using a Bio-Rad

Excalibur spectrometer and samples were dispersed in a KBr pellet.

3.2. Theoretical calculations

All calculations were performed with GAUSSIAN-98, Version A.11 [18] (G98) for **2**, **3**, and **5** and with GAUSSIAN-03, Revision B.05 [19] (G03) for **4** on a cluster of 16 Linux nodes, each with a 1.4 GHz processor. Modeling was performed on each molecule in its entirety, excluding solvents of crystallization and non-coordinated halides; gas-phase geometry optimizations and frequency calculations had neither symmetry constraints nor bond restrictions imposed. The theoretical models of **2** and **5** were neutral while **3** and **4** were given overall charges of 1^+ and 2^+, respectively. Spin unrestricted calculations on each triplet complex were first performed at Hartree–Fock levels with the 6-31G(d) basis set on all atoms; all further calculations used this UHF/6-31G(d) optimized geometry as a starting point. Density functional calculations facilitated the Becke three-parameter hybrid exchange functional [20] and the Lee, Yang, and Parr correlation functional [21], hereafter abbreviated B3LYP. Often, split basis sets were employed, via the *gen* keyword of G98, which applied a larger basis set such as 6-311+G(d) to the metal center and the smaller 6-31G(d) to

Table 2
Computational details for complexes **1**–**5**

Complex	Theory level	Basis set C, N, O, H	Basis set X	Basis set Ni
1	ub3lyp	6-31G(d)	6-311++G(d,p)	6-311++G(d,p)

5	ub3lyp	6-31G(d)	6-311++G(d,p)	6-311++G(d,p)

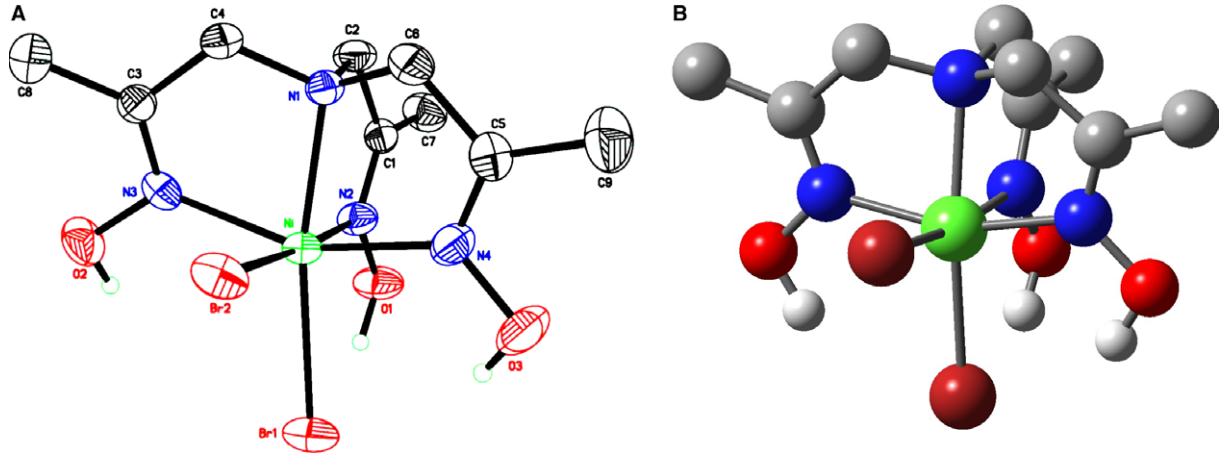

Fig. 2. Comparison of molecular geometries from X-ray crystallography (A, ORTEP view, 50% probability) and computationally optimized geometry (B) of $Ni(TRISOXH_3)Br_2$ (**5**), where the atoms correlate exactly to the arrangement shown in A. In both, methylene and methyl hydrogen atoms are omitted for clarity.

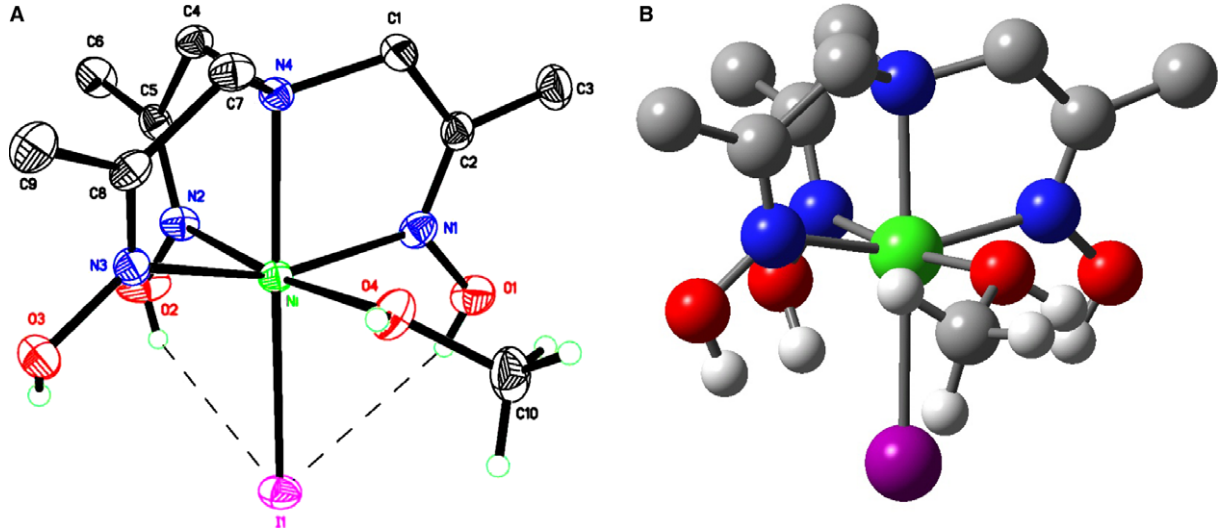

Fig. 3. Comparison of molecular geometries from X-ray crystallography (A, ORTEP view, 50% probability) and computationally optimized geometry (B) of $[Ni(TRISOXH_3)(CH_3OH)I]I$ (**3**), where the atoms correlate exactly to the arrangement shown in A. In both, methylene and methyl hydrogen atoms are omitted for clarity.

all other atoms. Except in the case of **3**, all-electron basis sets were chosen for accuracy. Due to the size of iodide, modeling complex **3** required additional considerations; the LANL2DZ basis set was applied to both the metal center and iodide in all calculations of **3**. Table 2 is a summary of the relevant theory and basis set details. Natural population analysis was preformed using the pop = npa keyword of Gaussian; GaussView was used to visualize molecular vibrations and spin density [22].

4. Results and analysis

Figs. 2–4 show the crystal structures and theoretically optimized geometry of **2**, **3**, and **4**, respectively; these data for **1** have been previously reported [7]. All complexes are characterized by a pseudo-octahedral geometry and intramolecular hydrogen bonding between the oxime protons and the axial halide. Intermolecular hydrogen bonds are also observed in the crystal structure; in **2**, the proton on O2 is intermolecularly H-bonded to Br2 of an adjacent molecule; in **3**, the proton on O3 is intermolecularly H-bonded to non-coordinated iodide in the crystal lattice; in **4**, the bound water molecules are intermolecularly H-bonded to non-coordinated fluoride ions in the crystal lattice. Selected bond distances are given in Tables 3–5 for the experimental crystal structures and best theoretical models.

Theoretical models for **2**, **3**, and **4** show good agreement with the experimental crystal structures, especially for important intraligand features, such as the carbon–nitrogen imine and nitrogen–oxygen oxime bonds, and the metal–ligand bonds. These data have similar average absolute deviations from experiment as observed for $Ni(TRISOXH_3)Cl_2$ (**1**): for the intraligand bonds noted, **1** (0.0141 Å), **2** (0.0196 Å), **3** (0.0175 Å), **4** (0.0128 Å); for the metal–ligand bonds, **1** (0.0320 Å), **2** (0.0495 Å), **3** (0.0452 Å), **4** (0.0476 Å). As an expected result of crystal-packing interactions, intermolecular hydrogen-bonds, and less accurate hydrogen atom determination based on X-ray rather than neutron data, bond angles and hydrogen-bonding distances in the crystal structures are not well reproduced in the theoretical models; these data are available in Tables 1S–4S. However, the observed deviations between the experiment and models for these features in **2**, **3**, and **4** are similar to those calculated for **1** [7].

Table 3
Geometry comparison of crystal structure and theoretical model for $Ni(TRISOXH_3)Br_2$ (**2**)

Feature	Crystal structure	ub3lyp/6-31G(d) and 6-311+G(d)

[a–d] See footnotes for Table 3.

One exception to the generally excellent correlation between the theoretical models and experimental data is observed in the Ni–amine bond lengths. The expected lengthening of the bond due to the *trans* influence of the axial halide is observed in the theoretical geometries [Ni–amine bond length for axial ligands I^- (2.1657 Å) > Br^- (2.1546 Å) > Cl^- (2.1471 Å)], however, it is not observed in the crystallographic data [I^- (2.096(2) Å), Br^- (2.112(3) Å), Cl^- (2.1131(13) Å)].

Vibrational spectra for **1**–**4** are shown in Figs. 5–9 along with theoretical line spectra for five regions, which include important metal–ligand and intraligand vibrations. By comparison to the mode assignments empirically derived

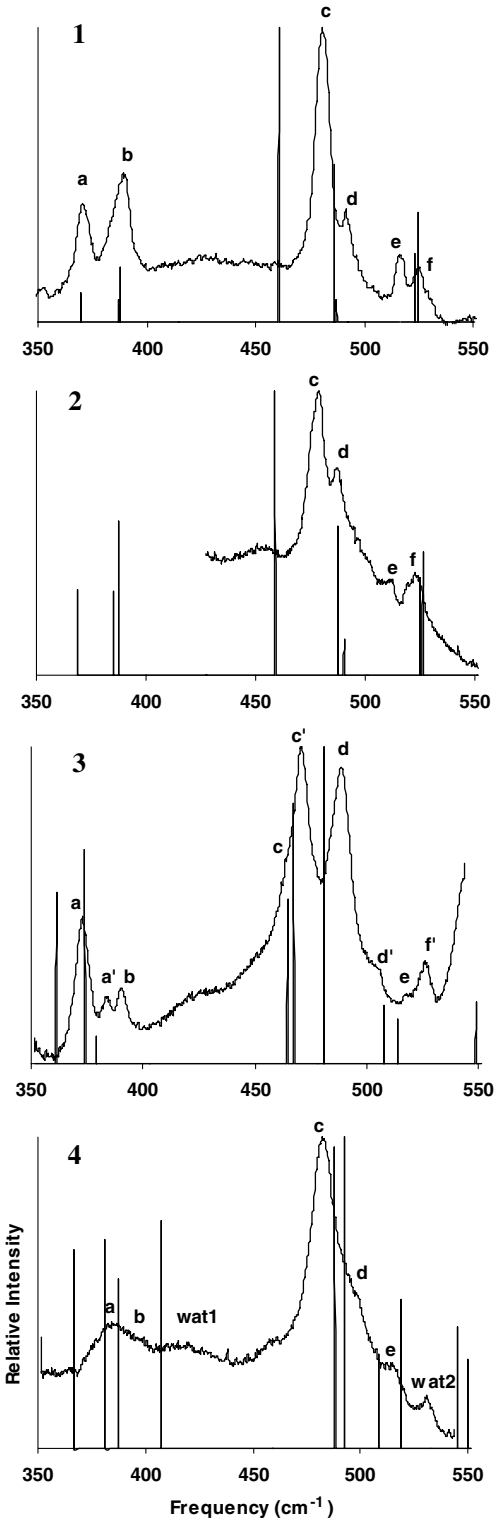

Fig. 5. Raman spectra and calculated vibrational positions and intensities for **1**–**4**, 350–550 cm^{-1}.

for **1**, via isotopic labeling [7], and the predicted theoretical modes, the vibrational modes for **2**, **3**, and **4** are assigned in Tables 6–8. Individual modes are assigned bold lower-case letters or phrases to aid in discussion. When the modes assigned for **2**, **3**, and **4** are very similar to those for **1**, the same lower case letter is used for each mode. Modes

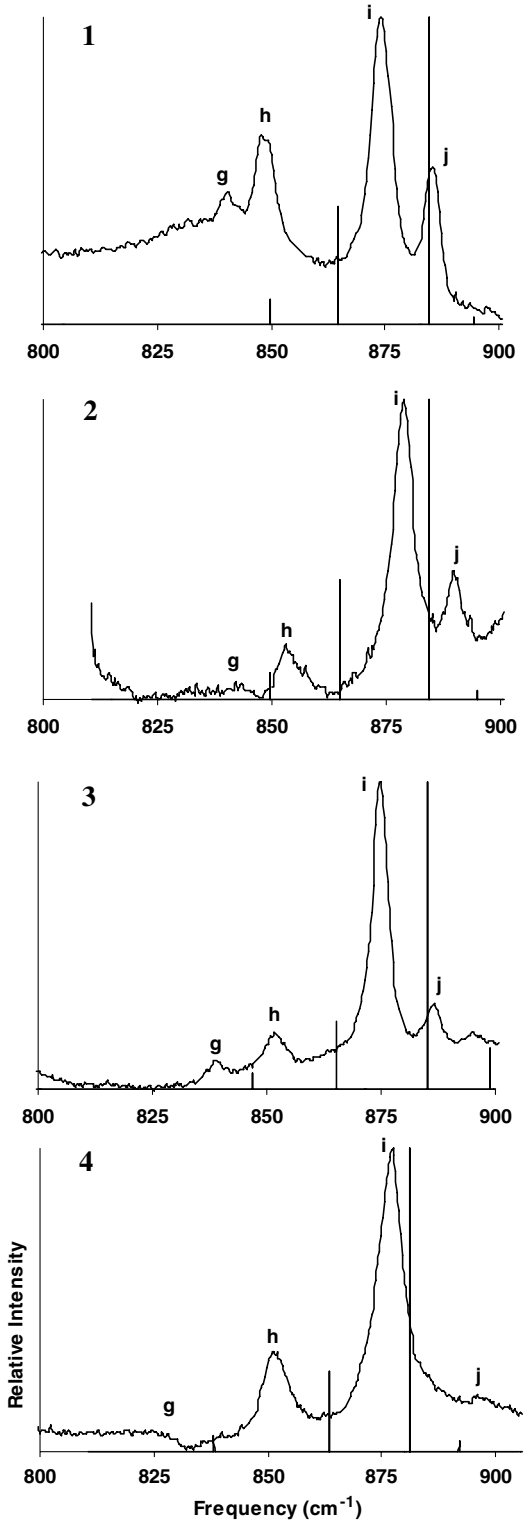

Fig. 6. Raman spectra and calculated vibrational positions and intensities for **1**–**4**, 800–900 cm^{-1}.

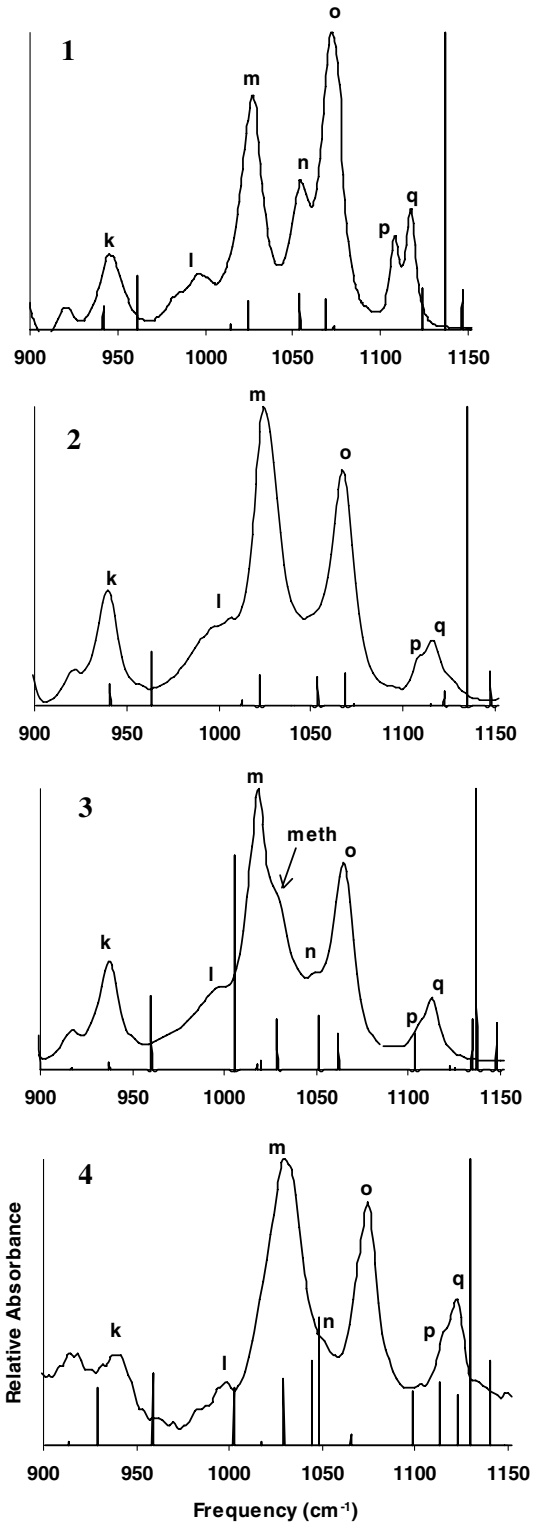

Fig. 7. Infrared spectra and calculated vibrational positions and intensities for **1**–**4**, 900–1150 cm^{-1}.

that are similar to those for **1**, but substantially influenced by the different X ligands of the halide series, are given the same descriptive letter as for **1** with a prime or double prime, for **3** and **4**, respectively. For example, upon substitution of methanol in the equatorial position in **3**, the symmetry is reduced to C_1 and two Ni–N(amine) stretching modes (labeled c and c′) are observed rather than the one mode observed (c) for **1**. Modes which exhibit bound solvent vibrations are given a phrase assignment, e.g. **meth** for the methanol centered vibration at 1030.0 cm^{-1} in **3**.

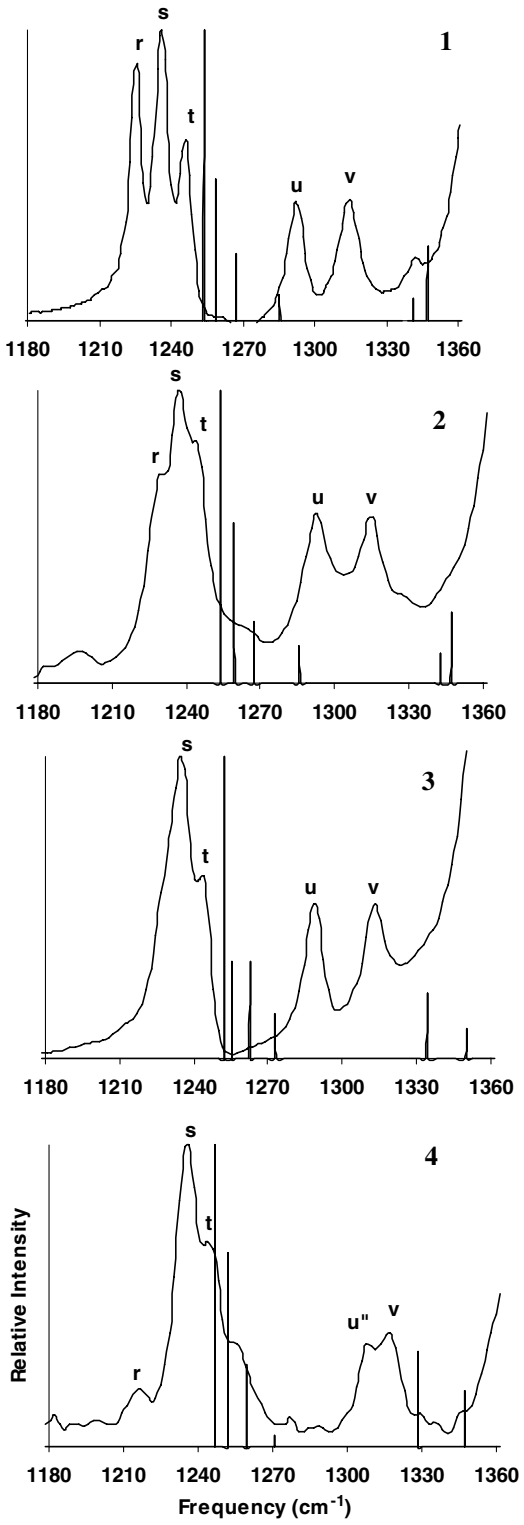

Fig. 8. Infrared spectra and calculated vibrational positions and intensities for **1**–**4**, 1180–1350 cm^{-1}.

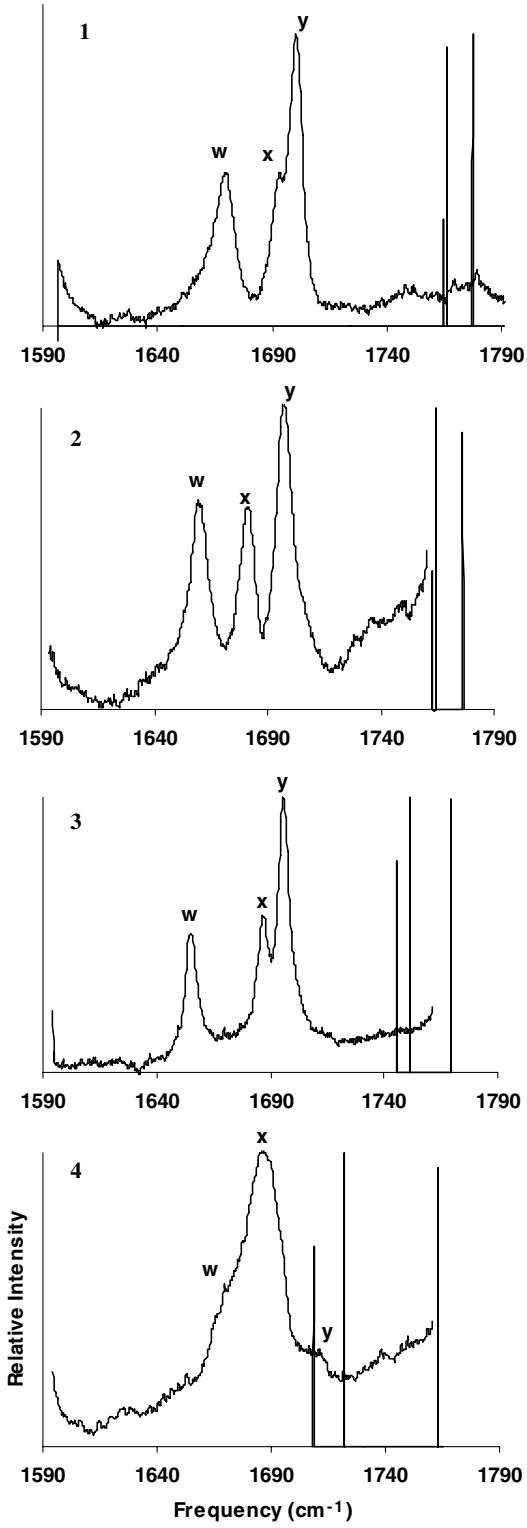

Fig. 9. Raman spectra and calculated vibrational positions and intensities for **1**–**4**, 1590–1790 cm^{-1}.

The complex closest to the benchmark $Ni(TRISOXH_3)Cl_2$ is **2** and very similar modes were observed experimentally and predicted theoretically. However, for complexes **3** and **4**, the loss of mirror symmetry leads to different mixing of the molecules' internal coordinates and thus different descriptions for the fundamental vibrational modes. For example, the two lowest energy imine stretches for **1** and **2** are clearly the asymmetric and symmetric combinations of the C=N(a) and C=N(c) stretches. However, for **3** and **4**, which do not have a mirror plane of symmetry, the two lowest energy imine stretches are dominated by either the C=N(a) or C=N(c) stretch. In addition,

[a] Natural abundance wavenumber data reported from both Raman and infrared experiments.
[b] Theoretical data assigned from calculation listed in Table 2.
[c] Assigned theoretical wavenumbers were scaled by applying Eq. (1).
[d] The optimized geometry for Ni(TRISOXH$_3$)Br$_2$ has C_s symmetry which places a mirror in the plane of arm b of the ligand and through each halide; mode symmetry was theoretically determined.
[e] Letter designations for atoms are the same as in Tables 3–5, utilizing a, b, and c to represent the three arms of the TRISOXH$_3$ ligand and atoms therein. Breathing modes for arms a, b, c involve all atoms. Twist and rock modes involve two or more atoms moving together, while wag modes are dominated by 1 atom motion. OOP indicates the modes are out-of-phase with respect to each other, and are not necessarily anti-symmetric with respect to the mirror plane.

complexes **3** and **4** exhibit modes specific to the bound solvents, methanol or water, respectively. In the regions studied, one methanol specific mode was observed for **3** and two water modes were observed for **4**.

The predicted theoretical frequencies for the halide series are generally higher than those observed experimentally; this is consistent with the literature precedent [23,24], including the trend observed for **1** [7]. A modified wavenumber-linear-scaling (WLS) approach [25,26] was employed after completing the vibrational mode assignment for **2**, **3**, and **4**; unique scale functions for each complex were derived by determining the best-fit linear function between the experimental and theoretical data. The resulting functions are very similar to the derived function for **1** and are shown in Eqs. (1)–(4), which correspond to complexes **1**–**4**. The scaled vibrational data were useful in clarifying previously ambiguous assignments of two vibrational modes in **4** and confirming assignments made principally by comparison to **1**.

$$(\mathbf{1})\ \nu_{\text{scaled}} = 0.919\nu_{\text{unscaled}} + 54.9\,\text{cm}^{-1}\ (R^2 = 0.999, 28\ \text{data}) \quad (1)$$

$$(\mathbf{2})\ \nu_{\text{scaled}} = 0.932\nu_{\text{unscaled}} + 44.5\,\text{cm}^{-1}\ (R^2 = 0.999, 22\ \text{data}) \quad (2)$$

$$(\mathbf{3})\ \nu_{\text{scaled}} = 0.939\nu_{\text{unscaled}} + 32.2\,\text{cm}^{-1}\ (R^2 = 0.999, 28\ \text{data}) \quad (3)$$

$$(\mathbf{4})\ \nu_{\text{scaled}} = 0.964\nu_{\text{unscaled}} + 19.6\,\text{cm}^{-1}\ (R^2 = 0.999, 27\ \text{data}) \quad (4)$$

As an alternative to Mulliken population analysis, the default charge distribution analysis protocol in Gaussian, natural population analysis offers more logical electron distributions for transition metal complexes [13–15]. The resulting natural charge data allow for a direct comparison of ligand influences on the metal center and the oximes and are summarized in Table 9.

For clarity, the equatorial plane is defined here as the plane that contains the oxime nitrogens, the nickel and the ligand X *cis* to the amine nitrogen; the axial positions are filled by the amine nitrogen and the ligand X *trans* to it. The natural charge on Ni predictably changes upon the ligand substitutions in the halide series; the value decreases (becomes less positive) along the series from 1.470 for the difluoride (**5**) to 1.194 for the methanol–iodide (**3**). The series trend in electron withdrawing strength follow the usual halide order, $F^- > Cl^- > Br^- > I^-$. The neutral aqua ligands result in a charge on nickel nearly as high as that of the fluoride complex. Throughout the halide series, oxime b, *trans* to the ligand X, generally shows larger (more negative) natural charge values than oxime a or c, which are *trans* to each other. The one exception to this trend is observed in **3**, where the charges on all three oximes are calculated to be essentially equal. In this complex,

[a] Mode label assigned based upon comparison to those frequencies assigned for **1**; similar modes between **3** and **1** are given the same letter, modes affected by the different X ligands in **3** are given the same letter with a prime symbol, the one observed methanol mode is assigned **meth**.
[b] Frequency (wavenumber) data reported from both Raman and infrared experiments.
[c] Theoretical data assigned from calculation listed in Table 2.
[d] Assigned theoretical wavenumbers were scaled by applying Eq. (2).
[e] The optimized geometry for Ni(TRISOXH$_3$)(CH$_3$OH)I has C1 symmetry; all vibrational frequencies have A symmetry. Letter designations for atoms are the same as in Tables 3–5, utilizing a, b, and c to represent the three arms of the TRISOXH$_3$ ligand and atoms therein. Breathing modes for arms a, b, c involve all atoms. Twist and rock modes involve two or more atoms moving together, while wag modes are dominated by one atom motion.

oxime b is *trans* to methanol rather than a negatively charged halide and all three oximes are *trans* to neutral atoms.

The localized spin density for each of 13 atoms (including Ni, nine oxime atoms (C, N, O for arms a, b, and c), the amine N, and the two X ligands) is defined as the difference between the α and β electron spin densities on each atom and is summarized in Table 10. The sum of these local spin densities is 2.00 ± 0.01 and accounts for the predicted two unpaired electrons in each complex. The unpaired electron density is mainly on the nickel, but significant portions are also delocalized onto the atoms directly bonded to the metal. Very similar unpaired electron densities are calculated for nickel in **1**, **2**, **4**, and **5** (all between 1.63 and 1.67). In **3**, the spin density is somewhat smaller (1.53) as a result of delocalization onto the axial iodide. There is very little unpaired electron density on the oxime C's and O's; however, including these values gives the expected total unpaired electron density.

5. Discussion

Notable trends in molecular geometries are observed in the series of complexes presented in this work, where two coordination positions are varied and the tetradentate TRISOXH$_3$ ligand remains intact. The Ni–amine bond, *trans* to the axial ligand X, should weaken upon substitution of a better σ-donating ligand, such as iodide, in the axial position due to the *trans* influence. This trend is observed in the theoretical geometries, in which the Ni–amine bond length is longest for **3**, with an axial iodide, and shortest for **1**, with an axial chloride. However, the trend is not observed in the crystallographic data, where the Ni–amine bond lengths in **1**, **2**, and **3** are very similar [2.096(2) Å, 2.112(3) Å, 2.1131(13) Å, respectively].

The inconsistency between the experimental and calculated nickel–amine bond lengths may result from inaccurate relative weighting of two effects in the calculation; the amount of covalency present in the bonds and the influence of the chelate ring strain on the bond length.

[a] Mode label assigned based upon comparison to those frequencies assigned for **1**; similar modes between **3** and **1** are given the same letter, modes affected by the different X ligands in **3** are given the same letter with a double-prime symbol, the modes dominated by water ligands are assigned **wat1** or **wat2**.
[b] Frequency (wavenumber) data reported from both Raman and infrared experiments.
[c] Theoretical data assigned from calculation listed in Table 2.
[d] Assigned theoretical wavenumbers were scaled by applying Eq. (3).
[e] The optimized geometry for $Ni(TRISOXH_3)(H_2O)_2$ has C1 symmetry; all vibrational frequencies have A symmetry. Letter designations for atoms are the same as in Tables 3–5, utilizing a, b, and c to represent the three arms of the $TRISOXH_3$ ligand and atoms therein. Breathing modes for arms a, b, c involve all atoms. Twist and rock modes involve two or more atoms moving together, while wag modes are dominated by one atom motion.

Table 9
Summary of calculated natural charge distribution

Natural charge[a]	**1**	**2**	**3**	**4**	**5**
Ni	1.374	1.328	1.194	1.457	1.470
Oxime a[b]	−0.035	−0.019	0.002	−0.029	−0.014
Oxime b	−0.054	−0.059	0.000	−0.011	−0.057
Oxime c	−0.035	−0.019	−0.005	−0.032	−0.014

[a] Natural charge is the sum of the charge in the α and β orbitals obtained from a natural population analysis.
[b] Oxime a, b, and c correspond to the C, N, O, and H atoms in arms a, b, and c, respectively, of the $TRISOXH_3$ ligand; the natural charge for each oxime in the sum of all the α and β orbitals of each atom in the oxime.

DFT calculations using the B3LYP functional have been shown to overestimate the covalency of transition metal bonds [27]. As a result, the observed *trans* influence trend may be exaggerated in the model systems. In the crystal structures, the three five-membered chelate rings of $TRISOXH_3$ may exert considerable strain on the nickel–amine bond length and render the predicted *trans* influence trend imperceptible. As an indicator of the influence of these two effects, we examine the methylene bond angles present in the chelate rings; if the covalency has been overestimated relative to the ring strain in the theoretical models, we expect to see greater deviations from ideal bond angles. Three intraligand bond angles, between the oxime carbons, methylene carbons, and amine nitrogen, in the calculated models are larger, averaging 113.3°, than those observed in the experimental structures, averaging 112.5°; these larger angles (Table 5S) are consistent with a relative underestimate of the ring strain compared to the covalency of the nickel–amine bond. In the crystallographically determined structures, the strain present in each five-membered chelate ring is more dominant and results in the lack of an experimentally observed trend.

The Ni–oxime nitrogen bonds (Ni–N(a), Ni–N(b), Ni–N(c)) also illustrate an interesting trend in theoretical molecular geometries. For the complexes (**1**, **2**, **3**, and **5**) which have at least one halide in the X positions, the theoretical models reveal longer bond lengths for Ni–N(b) than for Ni–N(a) and Ni–N(c), consistent with the *trans* equatorial ligand X being a better σ-donating ligand than an oxime nitrogen. However, no significant trend is found in

Table 10
Localized unpaired electron densities

Atom	1	2	3	4	5
Ni	1.64[a]	1.63	1.53	1.67	1.67

O(a)	0.00	0.00	0.00	0.00	0.00
O(b)	0.01	0.01	0.01	0.01	0.01
O(c)	0.00	0.00	0.00	0.01	0.00
Total[d]	2.00	2.00	1.99	1.99	2.00

[a] Unpaired electron density was determined by subtracting the total β spin density from the total α spin density for each atom.
[b] Atoms labels of a, b, or c are assigned to oxime arms a, b, or c, respectively.
[c] X(eq) is *trans* to N(b) and X(ax) is *trans* to the amine N.
[d] The sum unpaired electron density is the total of the densities on each of the 12 atoms listed; all other atoms in the molecule are neglected, due to very small unpaired electron densities.

the experimental bond lengths, where only very small or no differences in the collective Ni–N distances are observed. In the crystal structure of **1**, the longest Ni–oxime nitrogen bond is Ni–N(c), whereas for **2**, the longest Ni–oxime nitrogen bond is Ni–N(a). These longer experimental bond lengths are due to the intermolecular hydrogen-bonding observed in the crystal structure involving the hydrogen atoms of these oximes. In the crystal structures of **3** and **4**, all Ni–oxime nitrogen bonds are equivalent within the experimental range.

Vibrational spectroscopy serves as both a useful tool for considering the electronic differences between the complexes in the halide series and an evaluation of the theoretical models and derived scale functions. Due to their similarity and common $TRISOXH_3$ ligand, the complexes chosen in this study are not expected to have vastly different vibrational spectra. As described above, Ni($TRISOXH_3$)Cl_2 (**1**) and Ni($TRISOXH_3$)Br_2 (**2**) have very similar vibrational modes with no notable differences in the descriptions of the modes above 350 cm^{-1}; intensities and energies for the vibrations were different for some modes, specifically the symmetric imine stretching mode **x** which was 10 cm^{-1} lower in energy for **2** than **1**. The Ni–amine nitrogen stretch was very close in energy for both **2** (478.6 cm^{-1}) and **1** (481.1 cm^{-1}). In total, 22 normal modes were assigned for **2**.

The other two complexes in the series that were studied with vibrational spectroscopy, [Ni($TRISOXH_3$)(CH_3OH)I]I (**3**) and [Ni($TRISOXH_3$)(H_2O)$_2$]$F_2 \cdot 2H_2O$ (**4**), are expected to have somewhat different vibrational modes, due to the replacement of halides by solvent molecules and the C1 symmetry of their theoretical models (compared to C_s for **1** and **2**). The presence of a mirror plane in the optimized geometries of **1** and **2** simplifies the assignment and description of vibrational modes.[4] Without this symmetry element, the molecular vibrations become more complex and are more difficult to describe. For example, a Ni–amine stretch can be described by only one mode in both **1** and **2**, while two modes have significant Ni–amine character in **3** (**c′**, 464.5 and **c**, 471.6 cm^{-1}). The Ni–amine stretching frequencies consistently move to lower energy as the size of the X ligands is increased. In addition, vibrational modes for complexes **3** and **4** are influenced by the bound solvent molecules, methanol and water, respectively. Mode **f** was observed in **1** as being out-of-phase oxime H(a) and H(c) proton wagging; in **3**, this mode (denoted **f′**) also includes a proton wag from the metal-bound methanol molecule. In complex **4**, two modes (**wat1**, 423.6 cm^{-1} and **wat2**, 531.9 cm^{-1}) are observed in the lowest energy region studied, which can be solely attributed to the two bound water molecules.

The modified wavenumber-linear-scaling procedure is applied with success to partially correct for the anharmonicity of the true potential energy surfaces of the complexes [7,25,26]. Each unique empirically derived linear scale function has a very high correlation value. The resulting scaled theoretical wavenumbers (as listed in Tables 6–8) show a significant increase in agreement with experimental data, which is remarkably similar to the improvement in accuracy reported for **1**. For **2**, an average percent deviation of 2.59% (from 0.3 to 101.9 cm^{-1}, averaging 31.0 cm^{-1}) for the unscaled values is reduced to 1.13% (from 0.2 to 33.2 cm^{-1}, averaging 10.4 cm^{-1}) by applying the derived linear scale function (Eq. (2)). For **3**, an average percent deviation of 2.85% (from 0.1 to 90.8 cm^{-1}, averaging 29.7 cm^{-1}) for the unscaled values is reduced to 1.15% (from 0.2 to 38.8 cm^{-1}, averaging 10.7 cm^{-1}) by applying the derived linear scale function (Eq. (3)). Finally, for **4**, an average percent deviation of 2.30% (from 3.0 to 49.5 cm^{-1}, averaging 21.8 cm^{-1}) for the unscaled values is reduced to 1.29% (from 0.5 to 27.4 cm^{-1}, averaging 10.1 cm^{-1}) by applying the derived linear scale function (Eq. (4)). Application of the derived linear scale function for **4** aided assignment of two different modes associated with bound water (**wat1** and **wat2**). In summary, for **2** and **3**, the improvement in the agreement between experimental and theoretical absolute wavenumbers is 3-fold and for **4**, more than a 2-fold improvement is observed after scaling.

This series of complexes provides the opportunity to test the generality of the scale function derived from one complex for application to other similar complexes. The similarity between the unique scale functions (Eqs. (1)–(4)) for the halide series is striking. Might the function derived for **1** be applied to the series to yield improvement similar to the uniquely derived functions? The linear scale function derived for **1** yields close to a 3-fold improvement when

[4] Because of intermolecular hydrogen-bonding, the mirror plane predicted for **1**, **2**, and **5**, does not exist in the crystal structures; this symmetry element is used to facilitate mode assignment and identify the dominant vibrations associated with the experimentally observed peaks.

applied to the theoretical frequencies of **2** and **3**, the two other complexes which contain a metal-bound halide; the average deviation in **2** is improved from 31.0 to 12.2 cm^{-1} and in **3** from 29.6 to 13.1 cm^{-1}. However, applying the scale function derived for **1** to complex **4**, with two bound water molecules, yields no significant improvement; the average deviation changes from 21.8 to 20.1 cm^{-1}. The negligible improvement observed when applying the scale function derived for **1** to complex **4** indicates the interchange of the linear scale functions between complexes should be done with caution.

Evaluating the natural charge data facilitates a comparison of the ligand influences on the interactions between the metal center and oxime arms of $TRISOXH_3$. Through the series of theoretical model complexes, from $Ni(TRISOXH_3)F_2$ (**5**), $Ni(TRISOXH_3)Cl_2$ (**1**), $Ni(TRISOXH_3)Br_2$ (**2**), $[Ni(TRISOXH_3)(MeOH)I]^+$ (**3**), to $[Ni(TRISOXH_3)(H_2O)_2]^{2+}$ (**4**), we observe a decreasing (less positive) natural charge on Ni, consistent with the decreasing electronegativity of the ligands X. The complexes also show an interesting trend in the natural charge of the oxime arms; for **1**, **2**, and **5**, oxime b (*trans* to an equatorial Cl^-, Br^-, and F^-, respectively) has a more negative natural charge than oxime a or c (*trans* to each other), consistent with the halide ligands being better σ-donors than an oxime. For **4**, this trend is reversed, with oxime b having a smaller negative charge than either oxime a or c; intramolecular hydrogen-bonding and/or the neutrality of the aqua ligands in this complex may explain this observation. Despite the different *trans* ligand groups in **3**, there are very small differences between the three oxime arms (less than 0.005 Å), revealing a similarity in the σ-donation abilities of the equatorial methanol and oxime functional arms of $TRISOXH_3$.

For all of the complexes studied here, the unpaired electron density is not completely localized on the metal. The theoretical models of **1**–**5** show approximately 20% of the unpaired electron density is delocalized over ligand atoms. Recent EPR studies suggest that a ligand derived iminoxyl radical may be involved as an intermediate in the oxygen reaction with the Ni(TRISOX) complexes [6]. Thus, the computational evaluation of delocalization of the unpaired electron density will become more significant in future studies of the oxygen activating complexes.

This study of a series of nickel tris(oxime)amine complexes combines theoretical and experimental methods to evaluate trends in molecular geometry, vibrational spectra and electronic structure. The electronic structures of these complexes, which exhibit different natural charges on the metal center and delocalized unpaired electron density, are significantly influenced by the different halide and solvent ligands in the series. The subtle effect of changing the halide ligand, while maintaining the $TRISOXH_3$ ligand, yields small changes to the geometry and vibrational features; more significant differences are noted when solvent, such as water or methanol, replace one or both of the halide ligands. Experimentally observed trends are generally reproduced well in the computational models, however, the overestimation of bond covalency may exaggerate some electronic structure-based geometric features. In addition, the theoretical models of these complexes reveal inherent features and trends of the molecules that are masked in the solid state structure by intermolecular interactions. With this work as precedent, future research will apply these well developed molecular models to oxygen active complexes with different ligands from the bis(oxime)amine series [2]. By comparison to the detailed vibrational spectra for this series of complexes and facilitating the successful modified wavenumber-linear scaling procedure, spectra of the oxygen-active Ni(TRISOX) species will be elucidated in the pursuit of understanding their unique substrate oxidation chemistry.

Acknowledgments

The authors thank Professor Thomas Beck and Dr. Anping Liu of the University of Cincinnati for helpful discussions and computational support. The authors also thank Dr. James Hess and Douglas J. Fox from Gaussian, Inc. for software support. Data collection for **2** and **4** on the SMART 1K diffractometer was through the Ohio Crystallographic Consortium, funded by the Ohio Board of Regents 1995 Investment Fund (CAP-075) located at the University of Toledo, Instrumentation Center in A&S, Toledo, OH 43606. Funding for the SMART6000 diffractometer, which was used for **3**, was through NSF-MRI Grant CHE-0215950 located at the University of Cincinnati, Cincinnati, OH 45221-0172. Acknowledgment is made to the donors of the Petroleum Research Fund administered by the American Chemical Society (ACS-PRF 37653-AC3) and the Department of Chemistry at the University of Cincinnati who funded this research.

2. Experimental

2.1. Materials and methods

Palladium and platinum complexes, $MCl_2(P^{\frown}P)$ (M = Pd or Pt; $P^{\frown}P$ = dppm, dppe, dppp), *trans*-$MCl_2(P^nPr_3)_2$ [13,14] and $[M(SeCOC_6H_4Me\text{-}4)_2(P^{\frown}P)]$ [12] were prepared according to the literature methods. All reactions were carried out under an inert atmosphere (N_2 or Ar). Solvents were dried and distilled before use. All the newly reported complexes were crystallized from a CH_2Cl_2-hexane mixture. UV–Vis absorption spectra were recorded in CH_2Cl_2 on a Chemito Spectrascan UV double beam UV–Vis spectrophotometer. Microanalyses were carried out on a Carlo-Erba EA-1110 CHN-O instrument. ^1H, $^{31}P\{^1H\}$, $^{77}Se\{^1H\}$, $^{195}Pt\{^1H\}$ NMR spectra were recorded in CD_2Cl_2 on a Bruker DPX-300 NMR spectrometer operating at 300, 121.49, 57.24, 64.52 MHz, respectively and chemical shifts are relative to internal CH_2Cl_2 for ^1H, external 85% H_3PO_4 for $^{31}P\{^1H\}$, Me_2Se for ^{77}Se (secondary reference Ph_2Se_2 δ 463 ppm) and Na_2PtCl_6 in D_2O for $^{195}Pt\{^1H\}$.

2.2. Syntheses of complexes

2.2.1. Synthesis of $[Pd_3(\mu_3\text{-}Se)_2(dppm)_3][BPh_4]_2$ (**1a**)

A mixture of $[Pd(SeCOC_6H_4Me\text{-}4)_2(dppm)]$ (198 mg, 0.22 mmol) and $PdCl_2(dppm)$ (252 mg, 0.44 mmol) in dichloromethane (25 ml) containing few drops of methanol was stirred for 20 min. To the resulting orange solution, a methanolic solution (10 ml) of $NaBPh_4$ (307 mg, 0.90 mmol) was added and the reaction mixture was further stirred for 40 min. The solvents were removed *in vacuo* and the residue was extracted with dichloromethane. The extract was passed through a Florisil column (0.7 × 5 cm), concentrated and few drops of hexane were added which on cooling in a freezer gave orange microcrystals of the title compound (250 mg, 49%), m.p. 257–259 °C (decomp.) *Anal.* Calc. for $C_{123}H_{106}B_2P_6Pd_3Se_2$: C, 65.1; H, 4.7. Found: C, 64.7; H, 4.6%. UV–Vis(CH_2Cl_2): λ_{max}/nm (ε), 239 (1.3×10^5), 268 (sh, 6.5×10^4), 274 (sh, 6.0×10^4), 299 (5.6×10^4), 365 (3.7×10^4). $\delta_H(CD_2Cl_2)$: 4.29 (s, br, 6 H, PCH_2P); 6.85–7.63 (m, 100 H, Ph). $\delta_P(CD_2Cl_2)$: −46.6. $\delta_{Se}(CD_2Cl_2)$: −168.4.

2.2.2. Synthesis of $[Pd_3(\mu_3\text{-}Se)_2(dppe)_3][BPh_4]_2$ (**1b**)

Prepared analogously to **1a** from $[Pd(SeCOC_6H_4Me\text{-}4)_2(dppe)]$ (118 mg, 0.13 mmol), $PdCl_2(dppe)$ (152 mg, 0.26 mmol) and $NaBPh_4$ (184 mg, 0.54 mmol). Recrystallization from dichloromethane–hexane gave orange crystals of **1b** (192 mg, 63%), m.p. 292–295 °C (decomp.) *Anal.* Calc. for $C_{126}H_{112}B_2P_6Pd_3Se_2$: C, 65.5; H, 4.9. Found: C, 65.1; H, 4.6%. UV–Vis(CH_2Cl_2): λ_{max}/nm (ε), 239 (1.1×10^5), 266 (sh, 5.7×10^4), 275 (sh, 5.5×10^4), 302 (4.0×10^4), 357 (2.5×10^4). $\delta_H(CD_2Cl_2)$: 2.23 (d, 22 Hz, 12 H, PCH_2); 6.84–7.91 (m, 100 H, Ph). $\delta_P(CD_2Cl_2)$: 50.6. $\delta_{Se}(CD_2Cl_2)$: −131.7.

2.2.3. Synthesis of $[Pd_3(\mu_3\text{-}Se)_2(dppp)_3][BPh_4]_2$ (**1c**)

Prepared similar to **1a** by reacting $[Pd(SeCOC_6H_4Me\text{-}4)_2(dppp)]$ (132 mg, 0.14 mmol) with $PdCl_2(dppp)$ (170 mg, 0.29 mmol) and $NaBPh_4$ (228 mg, 0.67 mmol). Recrystallization from dichloromethane–hexane gave orange crystals of **1c** (260 mg, 76%), m.p. 277–280 °C (decomp.) *Anal.* Calc. for $C_{129}H_{118}B_2P_6Pd_3Se_2$: C, 65.8; H, 5.1. Found: C, 66.1; H, 5.2%. UV–Vis(CH_2Cl_2): λ_{max}/nm (ε), 239 (1.1×10^5), 266 (sh, 4.9×10^4), 273 (sh, 4.2×10^4), 291 (4.8×10^4), 356 (2.0×10^4). $\delta_H(CD_2Cl_2)$: 1.80 (br, 6H, CH_2); 2.41 (br, 12H, PCH_2); 6.86–7.44 (m, 100H, Ph). $\delta_P(CD_2Cl_2)$: −2.6. $\delta_{Se}(CD_2Cl_2)$ 48.8.

2.2.4. Synthesis of $[Pt_3(\mu_3\text{-}Se)_2(dppm)_3][BPh_4]_2$ (**2a**)

A dichloromethane solution (10 ml) of $[Pt(SeCOC_6H_4Me\text{-}4)_2(dppm)]$ (225 mg, 0.23 mmol) was added to a suspension (15 ml) of $PtCl_2(dppm)$ (285 mg, 0.45 mmol) in the same solvent containing few drops of methanol. Reaction mixture was stirred for 20 min and subsequent addition of methanolic solution (10 ml) of $NaBPh_4$ (308 mg, 0.90 mmol) gave orange solution. After further stirring for 1 h, solvent was removed under vacuum and contents were extracted with dichloromethane. The extract was passed through a Florisil column (0.7 × 5 cm) and concentrated to 2 ml. To this a few drops of hexane were added and the solution was cooled in freezer whereupon yellow microcrystals of **2a** were obtained (240 mg, 41%) m.p. 290–293 °C (decomp.) *Anal.* Calc. for $C_{123}H_{106}B_2P_6Pt_3Se_2$: C, 58.2; H, 4.2. Found: C, 57.7; H, 3.8%. UV–Vis(CH_2Cl_2): λ_{max}/nm(ε), 238 (1.1×10^5), 268 (sh, 7.7×10^4), 343 (3.9×10^3). $\delta_H(CD_2Cl_2)$: 4.60 (t, br, [$^2J_{P-H}$ = 10 Hz; $^3J_{Pt-H}$ = 63 Hz], 6H, PCH_2); 6.83–7.60 (m, 100H, Ph). $\delta_P(CD_2Cl_2)$: −57.1 [$^1J_{Pt-P}$ = 2817 Hz; $^2J_{Pt-Pt}$ = 795 Hz]. $\delta_{Se}(CD_2Cl_2)$: −292.7 [$^1J_{Pt-Se}$ = 482 Hz]. $\delta_{Pt}(CD_2Cl_2)$: −4242 [$^1J_{Pt-P}$ = 2820 Hz; $^2J_{Pt-Pt}$ = 796 Hz].

2.2.5. Synthesis of $[Pt_3(\mu_3\text{-}Se)_2(P^nPr_3)_6][BPh_4]_2$ (**2b**)

Prepared analogus to **2a** from $PtCl_2(P^nPr_3)_2$ (207 mg, 0.35 mmol), $[Pt(SeCOPh)_2(P^nPr_3)_2]$ (156 mg, 0.18 mmol) and $NaBPh_4$ (242 mg, 0.71 mmol). Recrystallization with dichloromethane–hexane gave orange microcrystals of title compound (163 mg, 51%) m.p. 271–273 °C (decomp.) *Anal.* Calc. for $C_{102}H_{166}B_2P_6Pt_3Se_2$: C, 52.3; H, 7.1. Found: C, 52.2; H, 7.2%. UV–Vis(CH_2Cl_2): λ_{max}/nm(ε), 240 (8.6×10^4), 309 (1.4×10^4). $\delta_H(CD_2Cl_2)$: 1.14 (t, 7 Hz, 18H, $PCH_2CH_2\mathbf{CH_3}$); 1.52 (br, 12H, PCH_2CH_2); 1.92 (br, 12H, PCH_2CH_2); 6.9 (t, 7 Hz); 7.06 (t, 7 Hz); 7.36 (br) (Ph). $\delta_P(CD_2Cl_2)$: −39.8, $^1J_{Pt-P}$ = 3122 Hz. $\delta_{Se}(CD_2Cl_2)$: −291.5 [$^1J_{Pt-Se}$ = 312 Hz]. $\delta_{Pt}(CD_2Cl_2)$: −4546, $^1J_{Pt-P}$ = 3122 Hz.

2.2.6. Synthesis of $[PdPt_2(\mu_3\text{-}Se)_2(dppm)_3][BPh_4]_2$ (**3**)

To a dichloromethane suspension (15 ml) of $PtCl_2(dppm)$ (289 mg, 0.44 mmol) a solution (10 ml) of $[Pd(SeCOC_6H_4Me\text{-}4)_2(dppm)]$ (197 mg, 0.22 mmol) in the same solvent was added with few drops of methanol and stirred for 20 min. To the resulting orange solution, a methanolic solution (10 ml) of $NaBPh_4$ (310 mg, 0.91 mmol) was

added and further stirred for 1 h. The solvents were removed *in vacuo* and the residue was extracted with dichloromethane which was passed through a Florisil column (0.7 × 5 cm) and concentrated (2 ml). To the concentrate few drops of hexane were added and cooled in freezer for one day to yield yellow microcrystals of the title compound (260 mg, 48%) m.p. 265 °C (decomp.). *Anal.* Calc. for $C_{123}H_{106}B_2P_6PdPt_2Se_2$: C, 60.4; H, 4.4. Found: C, 60.6; H, 4.4%. $\delta_H(CD_2Cl_2)$: 4.24 (m, CH_2, Pd bound dppm); 4.61 (m, Pt bound dppm, CH_2); 6.79–7.67 (m, 100H, Ph). $\delta_P(CD_2Cl_2)$: −55.4 (Pt bound dppm; $^1J_{Pt-P}$ = 2768 Hz); −49.1 (s, Pd bound dppm). $\delta_{Pt}(CD_2Cl_2)$: −4200 ($^1J_{Pt-P}$ = 2777 Hz).

2.2.7. Synthesis of $[Pd_2Pt(\mu_3\text{-}Se)_2(dppm)_3][BPh_4]_2$ (4)

Prepared from [Pt(SeCOC$_6$H$_4$Me-4)$_2$(dppm)] (260 mg, 0.27 mmol) and $PdCl_2$(dppm) (300 mg, 0.53 mmol) and $NaBPh_4$ (366 mg, 1.07 mmol). Recrystallization from dichloromethane–hexane yielded orange microcrystals of **4** (290 mg, 46%), m.p. 260 °C (decomp.). *Anal.* Calc. for $C_{123}H_{106}B_2P_6Pd_2PtSe_2$: C, 62.7; H, 4.5. Found: C, 61.3; H, 4.5%. $\delta_H(CD_2Cl_2)$: 4.24 (m, CH_2, Pd bound dppm); 4.62 (m, CH_2, Pt bound dppm); 6.79–7.67 (m, 100H, Ph). $\delta_P(CD_2Cl_2)$: −53.8 (Pt bound dppm, $^1J_{Pt-P}$ = 2745 Hz); −47.5 (s, Pd bound dppm). $\delta_{Pt}(CD_2Cl_2)$: −4160 ($^1J_{Pt-P}$ = 2774 Hz).

Index ranges	$-18 \leqslant h \leqslant 17$, $-20 \leqslant k \leqslant 19$, $-37 \leqslant l \leqslant 39$
Reflections collected	42916
Independent reflections [R_{int}]	26125 [0.0255]
Completeness to theta = 28.62°	91.1%
Absorption correction	semi-empirical from equivalents
Maximum and minimum transmission	1.000 and 0.736
Refinement method	full-matrix least-squares on F^2
Data/restraints/parameters	26125/0/1252
Goodness-of-fit on F^2	1.097
Final R indices [$I > 2\sigma(I)$]	$R_1 = 0.0384$, $wR_2 = 0.0797$
R indices (all data)	$R_1 = 0.0503$, $wR_2 = 0.0845$
Largest difference in Peak and hole (e Å^{-3})	0.851 and −1.202

2.3. Crystallography

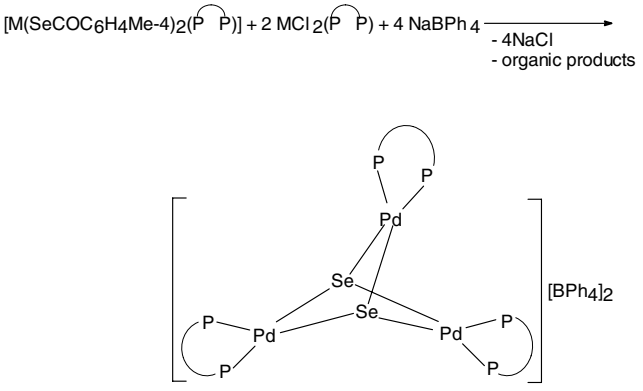
X-ray data of a yellow-orange crystal of $[Pd_3(\mu_3\text{-}Se)_2(dppe)_3][BPh_4]_2$ (**1b**) were collected on a Bruker Smart CCD diffractometer (at 93 (2) K) using graphite monochromated Mo Kα radiation (λ = 0.71073 Å). The intensity data were corrected for Lorentz, polarization and absorption effects [15]. The structure was solved by direct methods and refined by full matrix least square on F^2. All calculations were performed using SHELXL-97 program [16]. Selected crystallographic data are given in Table 1.

3. Results and discussion

3.1. Synthesis and spectroscopy

Treatment of [M(SeCOC$_6$H$_4$Me-4)$_2$(P⌒P)] with two equivalents of MCl$_2$(P⌒P) in dichloromethane/methanol mixture in the presence of $NaBPh_4$ gave the cationic tri-nuclear selenido-bridged complexes, $[M_3(\mu_3\text{-}Se)_2(P⌒P)_3][BPh_4]_2$ in fairly good yields (Eq. 1). These complexes were formed via unprecedented cleavage of the C–Se bond of monoselenocarboxylate.

The $^{31}P\{^1H\}$ NMR spectra of **1** showed single resonances suggesting that all the six P ligands are magnetically equivalent. The $^{31}P\{^1H\}$ NMR chemical shifts of **1b** (50.6 ppm) and **1c** (−2.6 ppm) can be compared with $[Pd_3(\mu_3\text{-}Se)_2(P⌒P)_3][PF_6]_2$ (P⌒P = dppe (50.6 ppm), dppp (−3.8 ppm)) [4]. The selenido ligands are also equivalent as only one ^{77}Se resonance is observed in the $^{77}Se\{^1H\}$ NMR spectra. The shielding of the ^{77}Se resonance depends on the chelate ring size of the phosphines and the signal appears at δ −168 (dppm), −132 (dppe) and 48.8 (dppp) ppm.



M	P⌒P	
Pd	dppm	**1a**
Pd	dppe	**1b**
Pd	dppp	**1c**
Pt	dppm	**2a**
Pt	$(P^nPr_3)_2$	**2b**

(1)

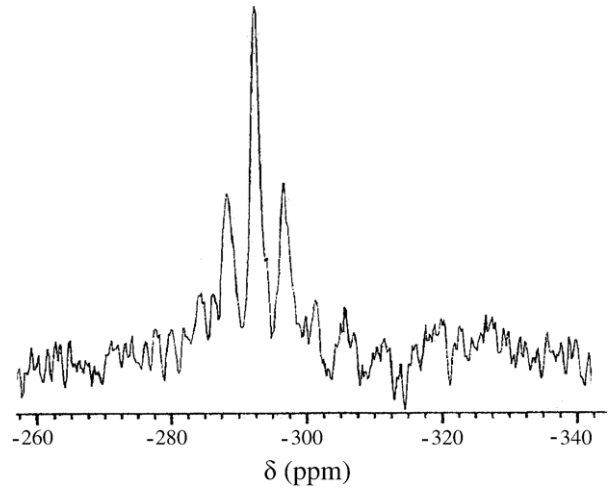


Fig. 1. $^{77}Se\{^{1}H\}$ NMR spectrum of $[Pt_3(\mu\text{-}Se)_2(dppm)_3][BPh_4]_2$ (**2a**) in CD_2Cl_2.

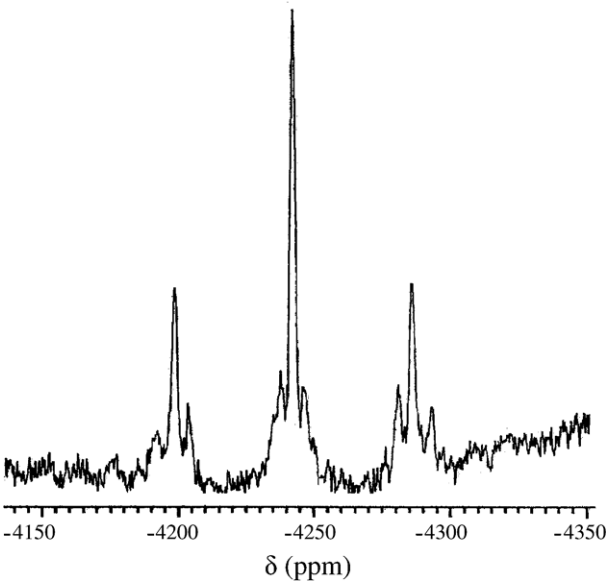

Fig. 2. $^{195}Pt\{^{1}H\}$ NMR spectrum of $[Pt_3(\mu\text{-}Se)_2(dppm)_3][BPh_4]_2$ in CD_2Cl_2.

The $^{31}P\{^{1}H\}$ NMR spectrum of **2a** showed a signal at δ −57.1 ppm with $^{1}J_{Pt-P}$ 2817 and $^{2}J_{Pt-Pt}$ 795 Hz. The magnitude of $^{1}J_{Pt-P}$ is in the range (∼3000 Hz) expected for phosphines *trans* to chalcogenido ligands [11,17,18]. However, for this complex $^{1}J_{Pt-P}$ of 4141 Hz has been reported earlier [4]. The $^{77}Se\{^{1}H\}$ NMR spectrum displayed a triplet at δ −292 ppm with $^{1}J_{Pt-Se}$ 482 Hz (Fig. 1). The ^{195}Pt NMR spectrum exhibited a triplet at −4242 ppm due to phosphorus coupling with $^{1}J_{Pt-P} = 2820$ Hz. Each peak of the triplet also showed $^{2}J_{Pt-Pt}$ of 796 Hz (Fig. 2). The ^{195}Pt resonance is progressively shielded by ∼40 ppm on replacing palladium by platinum atom in $[Pd_3(\mu_3\text{-}Se)_2(dppm)_3]^{2+}$ (Pd_2Pt (**4**) (−4160 ppm), $PdPt_2$ (**3**) (−4200 ppm) and Pt_3 (**2a**) (−4242 ppm)).

To assess whether the reaction **1** can be employed for the preparation of hetero-tri-nuclear Pd and Pt complexes, we carried out reactions of $[Pd(SeCOC_6H_4Me\text{-}4)_2(dppm)]$ with two equivalents of $PtCl_2(dppm)$ and $[Pt(SeCOC_6H_4Me\text{-}4)_2(dppm)]$ with two equivalents of $PdCl_2(dppm)$. These

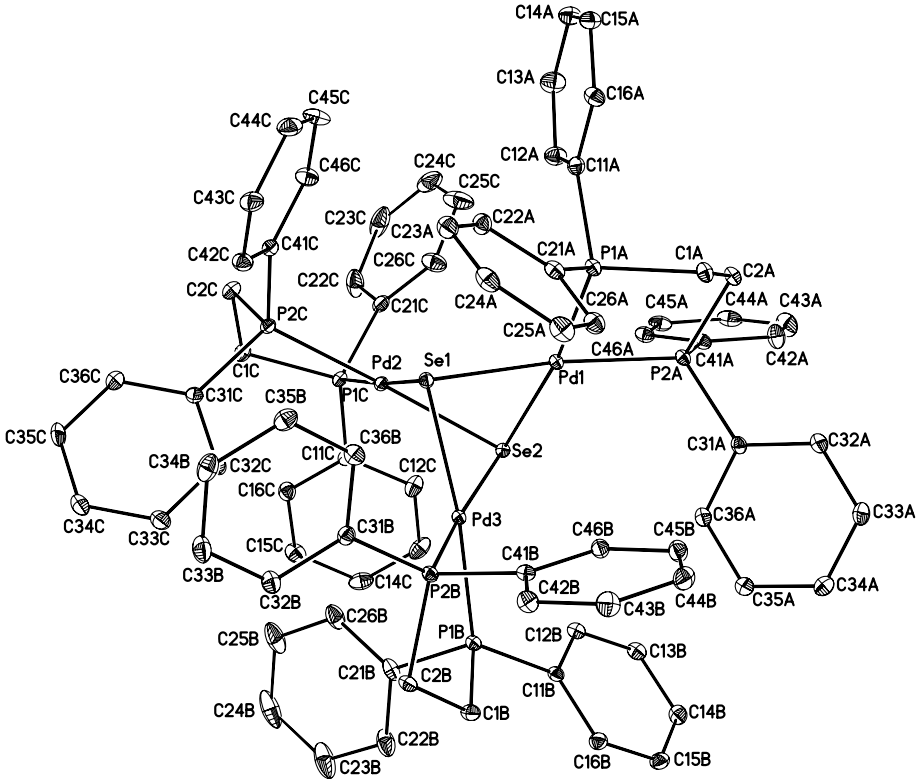

Fig. 3. ORTEP drawing of $[Pd_3(\mu\text{-}Se)_2(dppe)_3][BPh_4]_2$ (**1b**) with atomic number scheme (the two anion fragments, $[BPh_4]$, are omitted for clarity).

reactions gave $[PdPt_2(\mu_3\text{-}Se)_2(dppm)_3]^{2+}$ (**3**) and $[Pd_2Pt(\mu_3\text{-}Se)_2(dppm)_3]^{2+}$ (**4**), respectively, together with some redistribution products as established by ^{31}P NMR spectroscopy. The relative ratio of each species was calculated by integration of the ^{31}P NMR spectra. The former reaction gave a mixture of $[PdPt_2(\mu_3\text{-}Se)_2(dppm)_3]^{2+}$ (**3**) (65%); $[Pd_2Pt(\mu_3\text{-}Se)_2(dppm)_3]^{2+}$ (**4**) (20%); $[Pt_3(\mu_3\text{-}Se)_2(dppm)_3]^{2+}$ (**2a**) (13%) and $Pd_3(\mu_3\text{-}Se)_2(dppm)_3]^{2+}$ (**1a**) (2%) whereas from the latter reaction **4** (55%); **3** (36%) and **1a** (9%) were formed. These products seem to form during the course of the reaction. Attempts to separate individual tri-nuclear species by repeated crystallization were thwarted due to their similar solubility. No redistribution of the metal centers in the trinuclear species is observed when $CDCl_3$ solutions of **1a** and **2a** are mixed in 2:1 ratio. The $^{31}P\{^1H\}$ spectrum for this mixture showed signals for individual species even after a few days.

3.2. Structure of *1b*

The X-ray diffraction analysis of **1b** revealed the formation of a selenido-bridged tri-nuclear palladium complex (Fig. 3). The geometry around each palladium atom is approximately square planer with two P atoms of the chelating dppe and two Se atoms defining the coordination sphere. The two μ_3-Se ligands are shared by all the three palladium atoms.

Se(2)–Pd(2)–P(2C)	174.24(2)	Pd(2)–Se(2)–Pd(3)	78.552(13)

All six Pd–Se distances manifest the strong *trans* influence of the phosphine ligand. These distances are in good agreement with the values reported for the compounds, $[Pd_2Cl_3(\mu\text{-}SeC_5H_4N)(PPr_3)_2]$ (2.5077 (8) Å) [19] and $[Pd(SeCH_2CH_2CH_2NMe_2)]_6$ (~2.43 Å) [20], where selenium is trans to a strong *trans* influencing ligand. The Pd–Se distances in **1b** are, however, longer than those observed (2.32–2.40 Å) for $[Pd_3Cl_3(\mu\text{-}SeCH_2CH_2NMe_2)_3]$ [21], $[Pd_2Cl_2(\mu\text{-}SeCH_2CH_2NMe_2)_2]$ [22] and $[PdCl(SeCH_2CH_2NMe_2)(PMePh_2)]$ [23]. As is evident from Table 2, the Pd–Se(1) distances are marginally shorter than the Pd–Se(2) bond lengths. All the six Pd–P distances are essentially similar and are well in agreement with the reported values [24].

4. Conclusion

It has been demonstrated that monoselenocarboxylate complexes provide a useful route for the one pot synthesis of selenido-bridged tri-nuclear complexes in fairly good yields. This reaction can also be utilized for the preparation of hetero-tri-nuclear complexes.

certain biological systems and their potential to act as multielectron redox catalysts [11–14]. Some novel studies have been exploring a group of macrocyclic dioxime complexes of Co(III) in which the bridging protons of the bis-dioxime ligands have been replaced by BF_2^+ groups, an alteration that firms up the macrocyclic structure while removing acidic protons from the vicinity of the O_2 binding site [15–17].

In this work the synthesis and characterization of a (*E*,*E*)-dioxime containing bis(diazadioxa-12-crown-4 ethoxy) units and Ni(II), Cu(II) and Co(III) complexes of **H_2L** are reported. A cobalt(III) complex containing the BF_2^+ bridge macrocycle is synthesized as well. In addition, alkali and heavy metal extraction abilities of **1**, **3**, **6** and **10** are also examined.

2. Experimental

2.1. Materials

1,2-Bis(2-hydroxyethoxy)benzene [18], 1,2-bis(2-chloroethoxy)benzene [19], 1,2-bis(2-chloroethoxy)-4-nitrobenzene [20], 1,2-bis(2-iodoethoxy)-4-nitrobenzene [20], 6-[(4-methylphenyl)sulfonyl]-3,9-dioxa-6-aza-1,11-undecandiol-bis(methanesulfanate) [21], benzyl-4-[(4-methylphenyl)sulfonyl]-1,7-dioxa-4,10-diazacyclododecan [21], 4-[(4-methylphenyl)sulfonyl]-1,7-dioxa-4,10-diazacyclododecan [21] and cyanogen di-N-oxide [22] were prepared according to the literature procedures. Reagent grade chemicals were used as received. Solvents were purified according to standard methods [23] before use. Silica gel (70–230 mesh) was used for chromatographic separations.

2.2. Measurements

Melting points were determined using an electrothermal apparatus and were uncorrected. The ^{1}H and ^{13}C NMR spectra were recorded on a Varian XL-200 spectrometer and IR spectra were recorded on a Perkin–Elmer Spectrum One spectrometer with the samples in KBr pellets. The UV–Vis spectra were recorded on a model Schimadzu 1601 UV–Vis spectrometer using a 1 cm pathlength quartz UV-cell. Fast atom bombardment mass spectra were recorded on a Varian MAT 711 and VG Zap Spec spectrometers using *m*-nitrobenzyl alcohol as the matrix. The elemental analysis and the metal contents of the compounds were determined on a Hewlett-Packard 185 CHN analyzer and on a Unicam 929 AA spectrophotometer.

2.3. Synthesis

2.3.1. 4-[(4-Methlyphenyl)sulfonyl]-10-[2-((4-nitro-2-{2-[10-phenylsulfonyl)-1,7-dioxa-4,10-diazacyclododecan-4-yl]ethoxy}phenoxy)ethyl]-1,7-dioxa-4,10-diazacyclododecan (3)

Finely ground anhydrous Na_2CO_3 (4.0 g, 3.81 mmol), compound **1** (2.5 g, 7.62 mmol), anhydrous NaI (0.572 g, 3.81 mmol) and 70 mL dry acetonitrile were added to a three-necked flask fitted with a condenser which was evacuated, refilled three times with argon, and connected to a vacuum line. Under argon, the mixture was stirred at 45 °C for 30 min. Compound **2** (1.764 g, 3.81 mmol) was added to this mixture under argon and the reaction mixture was heated and stirred at 95 °C for 7 days. The reaction mixture was cooled to room temperature and filtered off and the precipitated salt was washed with 25 mL dichloromethane. The major liquor and washing solvents were combined and evaporated and a pale yellow solid-oily crude was obtained. The residue was purified in a silica gel column using chloroform:petroleum ether:methanol (7:2:1) as eluents. The second fraction was combined and evaporated, 10–15 mL methanol was added and the mixture was stirred at room temperature for 30 min. The precipitated pale yellow crystals were filtered off and dried in vacuo.

Compound ***3***: Yield: 2.92 g (89%); m.p. 190–192 °C. *Anal*. Calc. for $C_{40}H_{57}N_5O_{12}S_2$: C, 55.62; H, 6.60; N, 8.11. Found: C, 55.25; H, 6.47; N, 8.22%. IR (KBr): ν_{max} (cm^{-1}): 3087, 3027, 2919–2851, 1597, 1587–1338, 1514–1453, 1275–1229, 1160–1019. ^{1}H NMR ($CDCl_3$): δ 8.01 (d, 1H, Ar–H), 7.84 (s, 1H, Ar–H), 7.32 (d, 1H, Ar–H), 7.61 (d, 4H, Ar–H), 6.90 (d, 4H, Ar–H), 4.52–4.40 (m, 4H, Ar–O–CH_2), 4.13-3.95 (m, 4H, –CH_2N), 3.76–3.52 (m, 16H, $CH_2CH_2OCH_2CH_2$), 3.18–2.80 (m, 16H, CH_2N), 2.36 (s, 6H, Ar–CH_3). ^{13}C NMR ($CDCl_3$): δ 154.05 (ArCO), 148.12 (ArCS), 143.29 (ArCH), 141.25 (ArCN), 135.67, 129.68, 127.2, 117.93, 111.12, 107.72 (ArC), 70.25–69.75 (OCH_2), 56.08–55.06–60.63 (NCH_2), 21.5 (CH_3–Ar). MS (FAB positive): *m*/*z* 863 $[M]^+$.

2.3.2. 3,4-Bis(2-{10-[(4-methylphenyl)sulfonyl]-1,7-dioxa-4,10-diazacyclododecan-4-yl}ethoxy)aniline (4)

Compound **3** (2.92 g, 3.38 mmol) was dissolved in 120 mL *n*-butanol at 60 °C under an argon atmosphere and degassed in a vacuum line. 0.417 g Pd/C (10%) was added to the reaction mixture and heated at 125 °C. At reflux temperature, 5.96 mL hydrazinium hydrate (100%) was added to this mixture dropwise over 30 min. After 14 h, the reaction mixture was filtered off using Celite as the filtering agent and washed several times with *n*-butanol. The major liquor and washing solvents were combined and evaporated to dryness under reduced pressure. Diethyl ether was added to the residue under argon and the resulting solution was kept in darkness, otherwise the amino derivative can decompose. A little amount of the amino derivative **4** was kept to take its IR, ^{1}H NMR, ^{13}C NMR, elemental analysis and mass spectra. Compound **4** was used for the following reaction without any further purification.

Compound ***4***: Yield: 2.32 g (84%); m.p. 128–131 °C. *Anal*. Calc. for $C_{40}H_{59}N_5O_{10}S_2$: C, 57.62; H, 7.08; N, 8.40. Found: C, 57.40; H, 6.98; N, 8.57%. IR (KBr): ν_{max} (cm^{-1}): 3439–3362, 3060–3032, 2924–2856, 1621, 1597, 1511–1448, 1303–1225, 1159–1019. ^{1}H NMR ($CDCl_3$): δ

6.95 (d, 1H, Ar–CH–C–O), 6.72 (s, 1H, Ar–N–CH–C–O), 6.35 (d, 1H, Ar–NH_2–C–CH), 7.58 (d, 4H, Ar–SO_2–C–CH), 6.76 (d, 4H, H_3C–AR–CH), 4.57 (br, s, 2H, NH_2), 4.48–4.36 (m, 4H, Ar–O–CH_2), 4.01–3.87 (m, 16H, $CH_2CH_2OCH_2CH_2$), 3.72–3.46 (m, 4H, –CH_2N), 3.15–2.72 (m, 16H, CH_2N), 2.34 (s, 6H, Ar–CH_3). ^{13}C NMR ($CDCl_3$): δ 146.12 (ArCO), 143.36 (ArCS), 141.03 (ArCH), 138.11 (ArCN), 135.72, 129.65, 127.10, 108.22, 102.50 (ArC), 70.27–69.70–67.45 (OCH_2), 56.08–55.04–50.59 (NCH_2), 21.5. MS (FAB positive): m/z 833 $[M]^+$.

2.3.3. H_2L (6)

A cold solution, −10 °C, of cyanogen di-*N*-oxide (**5**) in 25 mL dichloromethane, which was prepared from (*E*,*E*)-dichloroglyoxime (0.785 g, 5 mmol), and 25 mL of an aqueous solution at −10 °C of 0.5 M Na_2CO_3 was added to a cold solution of 3,4-bis(2-{10-[(4-methylphenyl)sulfonyl]-1,7-dioxa-4,10-diazacyclododecan-4-yl}ethoxy)aniline **4** (2.36 g, 2.8 mmol) in 200 mL dichloromethane. The reaction was continued for 10–12 h at the same temperature and then evaporated to dryness. The crude product was crystallized from a dichloromethane:ethanol mixture (9:1) to yield champagne colored crystals.

Compound ***6***: Yield: 1.54 g (62%); mp 154–156 °C (dec). *Anal*. Calc. for $C_{82}H_{118}N_{12}O_{22}S_4$: C, 56.23; H, 6.74; N, 9.60. Found: C, 56.09; H, 6.52; N, 9.76%. IR (KBr): ν_{max} (cm^{-1}): 3350, 3230, 3082-3042, 2922-2868, 1640, 1611, 1596, 1514–1448, 1289–1228, 1160–1020, 942. ^1H NMR (DMSO-d_6): δ 10.20 (s, 2H, OH), 7.86 (s, 2H, NH), 7.60 (d, 8H, Ar–SO_2–C–CH), 6.78 (d, 8H, H_3C–Ar–CH), 6.92 (d, 2H, Ar–CH–C–O), 6.49 (s, 2H, Ar–N–CH–C–O), 6.25 (d, 2H, Ar–NH–C–CH), 4.45–4.34 (m, 8H, Ar–O–CH_2), 3.98-3.82 (m, 32H, $CH_2CH_2OCH_2CH_2$), 3.69–3.42 (m, 8H, –CH_2N), 3.14–2.71 (m, 32H, CH_2N), 2.35 (s, 12H, Ar–CH_3). ^{13}C NMR ($CDCl_3$): δ 154.09, 148.17, 145.02 (C=N–O–H), 143.25, 141.30, 135.69, 129.68, 127.15, 117.95, 111.12, 107.80, 70.29, 69.77, 67.53, 56.10, 55.04, 50.61, 21.5. MS (FAB positive): m/z 1750 $[M]^+$.

2.3.4. $[Ni(HL)_2]$ (7)

A solution of $NiCl_2 \cdot 6H_2O$ (12 mg, 0.05 mmol) in 5 mL ethanol was added to a solution of H_2L **6** (175 mg, 1 mmol) in 25 mL ethanol at 60 °C. A distinct change in color and a decrease in the pH of the solution (pH 2.42) was observed. While heating and stirring at the same temperature, an equivalent of ethanolic triethylamine (0.1 M) was added in order to increase the pH to 4.5–5.0. After heating the reaction mixture for 2 h in a water-bath, the precipitate was filtered off, washed several times with water, ethanol and diethyl ether and then dried in vacuo by P_2O_5.

Compound 7: Yield: 146 mg (82%); m.p. >300 °C. *Anal*. Calc. for $C_{164}H_{234}N_{24}O_{44}S_8Ni$: C, 55.34; H, 6.58; N, 9.45. Found: C, 55.13; H, 6.35; N, 9.54%. IR (KBr): ν_{max} (cm^{-1}): 3392, 3060–3018, 2923–2865, 1718, 1627, 1618, 1597, 1506–1449, 1286–1220, 1159–1020, 946. ^1H NMR (DMSO-d_6): δ 16.80 (s, 2H, O–H···O), 7.98 (br, s, 4H, NH), 7.58 (d, 16H, Ar–SO_2–C–CH), 6.73 (d, 16H, H_3C–Ar–CH), 6.88 (d, 4H, Ar–CH–C–O), 6.43 (s, 4H, Ar–N–CH–C–O), 6.21 (d, 4H, Ar–NH–C–CH), 4.40–4.32 (m,16H, Ar–O–CH_2), 3.92–3.78 (m, 64H, $CH_2CH_2OCH_2CH_2$), 3.67–3.39 (m, 16H, –CH_2N), 3.09–2.63 (m, 64H, CH_2N), 2.37 (s, 24H, Ar–CH_3). MS (FAB positive): m/z 3556 $[M+1]^+$.

2.3.5. $[Cu(HL)_2]$ (8)

A solution of $CuCl_2 \cdot 2H_2O$ (9 mg, 0.05 mmol) in 5 mL ethanol was added to a solution of H_2L **6** (175 mg, 1 mmol) in 25 mL ethanol at 60 °C. A distinct change in color and a decrease in the pH of the solution (pH 2.38) was observed. While heating and stirring at the same temperature, an equivalent of ethanolic triethylamine (0.1 M) was added in order to increase the pH to 5.0–6.0. After heating the reaction mixture for 2 h in a water-bath, the precipitate was filtered off, washed several times with water, ethanol and diethyl ether and then dried in vacuo by P_2O_5.

Compound ***8***: Yield: 136 mg (76%); m.p. >300 °C. *Anal*. Calc. for $C_{164}H_{234}N_{24}O_{44}S_8$: C, 55.26; H, 6.27; N, 9.43; Cu, 1.78. Found: C, 55.19; H, 6.13; N, 9.56; Cu, 1.63%. IR (KBr): ν_{max} (cm^{-1}): 3389, 3054–3021, 2920–2881, 1733, 1624, 1598, 1508–1446, 1303–1220, 1160–1020, 941. MS (FAB positive): m/z 3561 $[M+1]^+$.

2.3.6. $[Co(HL)_2L'Cl]$ (9)

A solution of $CoCl_2 \cdot 6H_2O$ (24 mg, 0.1 mmol) in 10 mL ethanol was added to a solution of H_2L **6** (350 mg, 2 mmol) in 75 mL ethanol at 60 °C whilst bubbling oxygen through the ligand solution. After 30 min, 0.01 mL pyridine (0.01 g, 0.1 mmol) in 5 mL ethanol was added to the mixture. The reaction mixture was heated and stirred for 4–5 h with oxygen passing through it. The total volume of the residue was decreased to 1/4 and then filtered off, washed several times with water, ethanol and diethyl ether and then dried in vacuo by P_2O_5.

Compound ***9***: Yield: 206 mg (56%); m.p. >300 °C. *Anal*. Calc. for $C_{169}H_{239}N_{25}O_{44}S_8CoClPy$: C, 55.24; H, 6.51; N, 9.53; Co, 1.59. Found: C, 55.17; H, 6.38; N, 9.47; Co, 1.50%. IR (KBr): ν_{max} (cm^{-1}): 3325, 3070, 3063–3025, 2924–2870, 1722, 1621, 1597, 1601, 1549–1510, 1286–1226, 1159–1020, 943. ^1H NMR (DMSO-d_6): δ 16.85 (s, 2H, O–H···O), 8.02 (br, s, 4H, NH), 7.71 (d, 2H, py-H), 7.50 (t, 2H, py-H), 6.84 (t, 1H, py-H), 7.60 (d, 16H, Ar–SO_2–C–CH), 6.79 (d, 16H, H_3C–Ar–CH), 6.84 (d, 4H, Ar–CH–C–O), 6.42 (s, 4H, Ar–N–CH–C–O), 6.21 (d, 4H, Ar–NH–C–CH), 4.42–4.31 (m, 16H, Ar–O–CH_2), 3.94–3.76 (m, 64H, $CH_2CH_2OCH_2CH_2$), 3.65–3.37 (m, 16H, –CH_2N), 3.11–2.65 (m, 64H, CH_2N), 2.35 (s, 24H, Ar–CH_3). MS (FAB positive): m/z 3671 $[M+1]^+$.

2.3.7. $[Co(LBF_2)_2L'Cl]$ (10)

A suspension of the diamagnetic cobalt (III) complex $[Co(HL)_2L'Cl]$ **9** (0.734 g, 0.2 mmol) in 100 mL of freshly distilled acetonitrile was brought to reflux temperature under an argon atmosphere. The equivalent amount of $BF_3 \cdot OEt_2$ (0.1 mL, 0.4 mmol) was added to the above

suspension and the reaction mixture became red immediately. The solution was boiled under reflux with stirring for 5 h and then allowed to cool to room temperature. The solvent was concentrated to 10 mL under reduced pressure; 20 mL of dry Et_2O was then added dropwise and the solution was allowed to stand at −18 °C overnight, whereupon the desired product precipitated. The claret red solid was collected by filtration, washed with cold acetonitrile and Et_2O and then dried in vacuo.

*Compound **10***: Yield: 512 mg (68%); m.p. >300 °C. *Anal.* Calc. for $C_{169}H_{237}N_{25}O_{44}S_8CoClB_2F_4$: C, 53.84; H, 6.29; N, 9.29; Co, 1.56. Found: C, 54.65; H, 6.78; N, 9.02, Co, 1.32%. IR (KBr): ν_{max} (cm^{-1}): 3336, 3068, 3060–3022, 2950–2863, 1649, 1590, 1605, 1545–1510, 1284–1223, 1156–1030, 948, 875–843. ^1H NMR (DMSO-d_6): δ 7.96 (br, s, 4H, NH), 7.68 (d, 2H, py-H), 7.47 (t, 2H, py-H), 6.80 (t, 1H, py-H), 7.59 (d, 16H, Ar–SO_2–C–CH), 6.75 (d, 16H, H_3C–Ar–CH), 6.81 (d, 4H, Ar–CH–C–O), 6.41 (s, 4H, Ar–N–CH–C–O), 6.19 (d, 4H, Ar–NH–C–CH), 4.39–4.27 (m, 16H, Ar–O–CH_2), 3.92–3.70 (m, 64H, $CH_2CH_2OCH_2CH_2$), 3.64–3.35 (m, 16H, –CH_2N), 3.13–2.64 (m, 64H, CH_2N), 2.38 (s, 24H, Ar–CH_3). MS (FAB positive): *m*/*z* 3768 $[M+1]^+$, 3785 $[M+H_2O]^+$ and 3686 $[M-pyr\text{-}2]^+$.

2.3.8. Measurement of alkali and heavy metal-binding properties of *1*, *3*, *6* and *10*

The extraction properties of **1**, **3**, **6** and **10** were investigated under liquid–liquid phase and neutral conditions using alkaline (Li^+, Na^+, K^+, Cs^+) and heavy metal picrates (Ag^+, Pb^{2+}, Cd^{2+}, Cu^{2+}, Zn^{2+}) as substrates and measuring by UV–Vis spectra the amounts of metal picrate in the aqueous phase before and after treatment with the compounds. Alkali metal picrates (3×10^{-5} M) were prepared from a mixture of the alkali metal hydroxides and picric acid in deionized water whereas the heavy metal picrates were prepared from a mixture of the metal nitrates and picric acid in deionized water. We also prepared 3×10^{-3} M solutions of the compounds (**1**, **3**, **6**, **10**) in 1,2-dichloroethane. Then equal volumes of both metal picrate solutions and compound solutions were added into plastic bottles and kept closed then shaken for 12 h by a shaker at 25 ± 1 °C. Finally we took the aqueous phase and measured the absorbance at maximum wavelength (~358 nm). For each combination of host and metal picrate, the picrate extraction was conducted on three different samples and the average value of percent picrate extracted, with a standard deviation, was calculated. The picrate extraction results are presented in Table 1. In the absence of host, a blank experiment, no metal ion picrate extraction was detected. The extractability was determined based on the absorbance of the picrate ion in the aqueous solutions. The extractability was calculated by using the equation below:

$$E(\%) = [(A_{before} - A_{after})/A_{before}] \times 100$$

where A_{before} is the absorbance in the absence of ligand. A_{after} denotes the absorbance in the aqueous solution phase after extraction.

3. Results and discussion

The synthesis of the nitro derivative **3** was performed by starting with 1,2-bis(2-iodoethoxy)-4-nitrobenzene (**2**) [20] and 4-[(4-methylphenyl)sulfonyl]-1,7-dioxa-4,10-diazacyclododecan (**1**) [21] in acetonitrile in the presence of anhydrous Na_2CO_3 and NaI for a period of 7 days, affording 4-[(4-methlyphenyl)sulfonyl]-10-[2-((4-nitro-2-{2-[10-phenylsulfonyl)-1,7-dioxa-4,10-diazacyclododecan-4-yl]ethoxy}phenoxy)ethyl]-1,7-dioxa-4,10-diazacyclododecan (**3**) (Scheme 1). The template effect of sodium cations accounts for the high yield obtained in the desired synthesis. Final purification of the nitro derivative **3** by chromatography [silica gel, chloroform:petroleum ether:methanol (7:2:1)] afforded **3** in 89% yield, for which elemental analysis and FAB mass spectral data were satisfactory: 863 $[M]^+$. In the ^1H NMR spectrum of **3**, the NH group of compound **1** disappeared as expected. It can also be observed in its IR spectrum, confirming the formation of compound **3**. The NO_2 functional group also can be seen at 1587–1338 cm^{-1} in the IR spectrum of compound **3**.

The transformation of the nitro derivative **3** into the amino derivative **4** was performed in the presence of *n*-butanol using hydrazinium hydrate (100%) and Pd/C (10%) for 14 h with a 84% yield. Since this method is more advantageous than the others, we preferred to use this one. No further purification was performed for compound **4** when it was obtained because of the characteristic property of so many amino derivatives that they decomposes very easily when exposed to light and heat. ^1H NMR spectrum of **4** showed a new signal due to NH_2 protons at $\delta = 4.52$, as expected. It is possible to see the NH_2 stretching vibra-

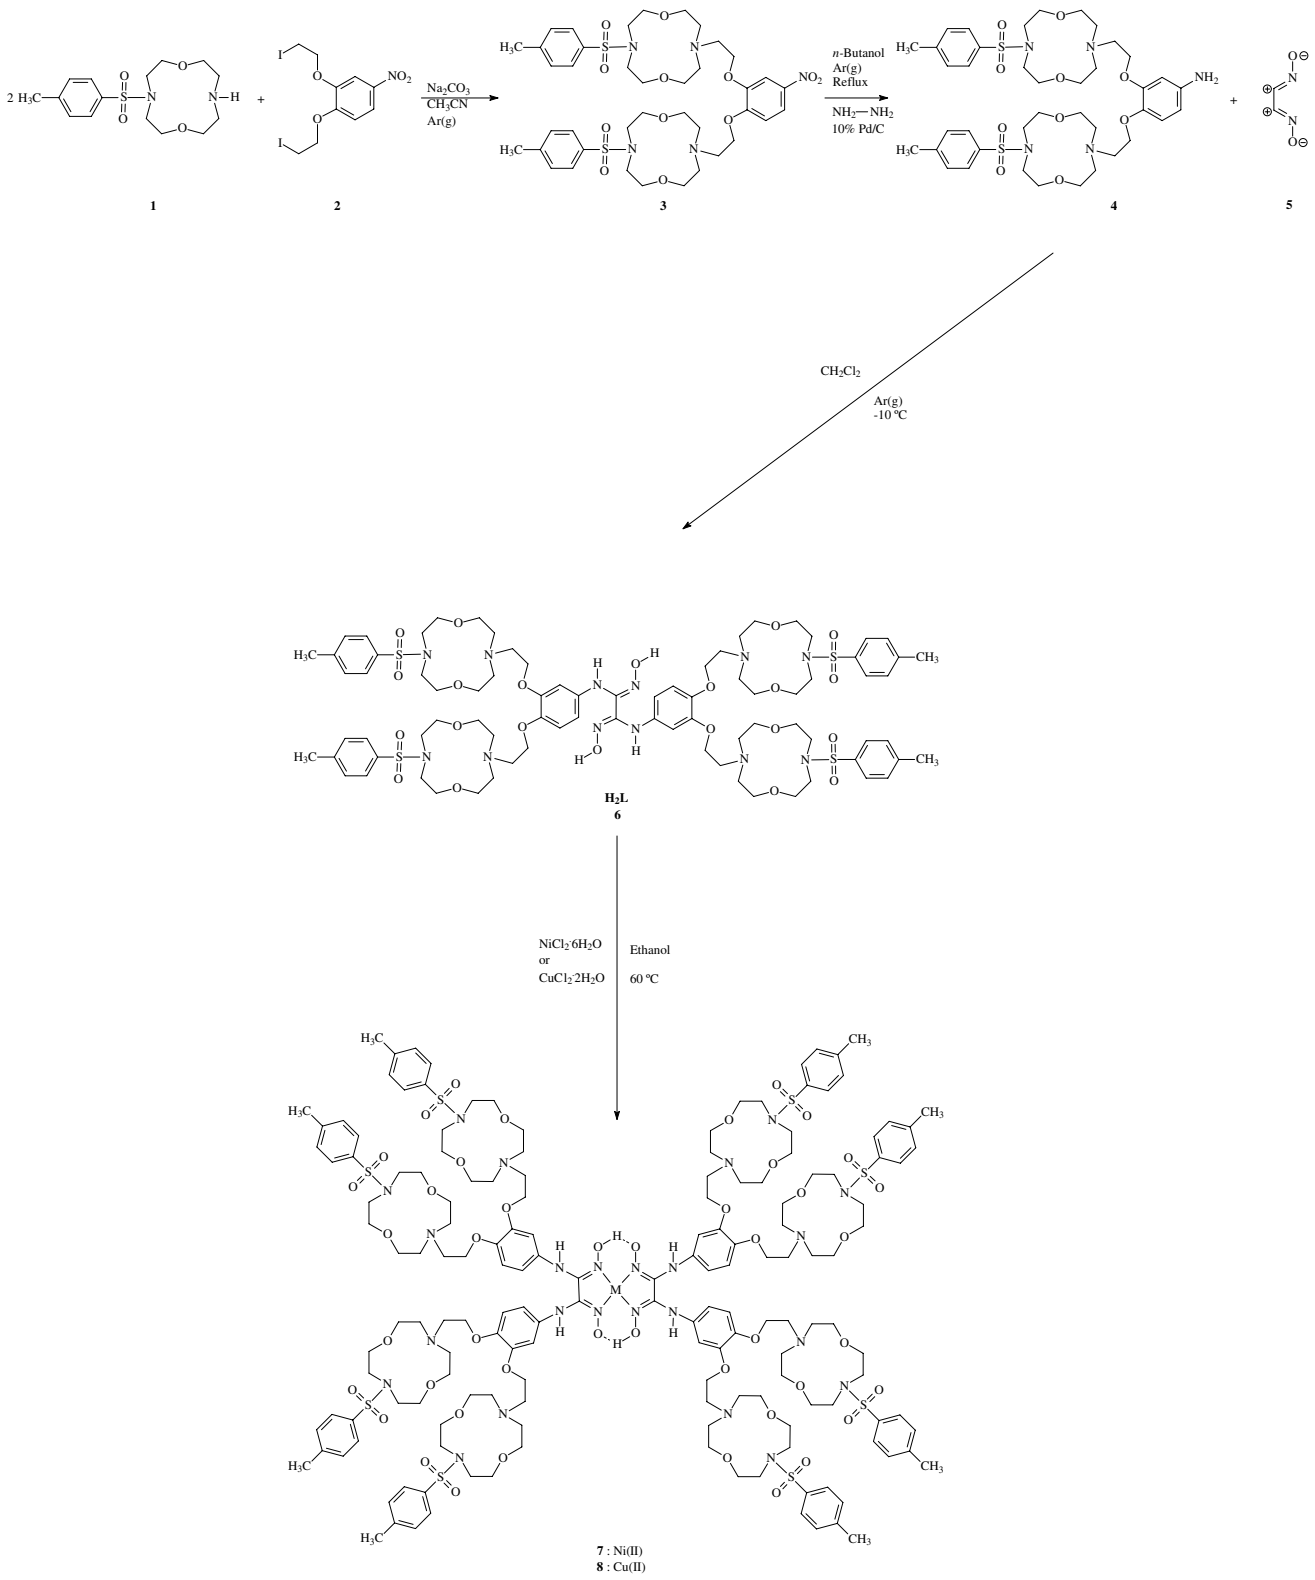


Scheme 1. Synthesis of $\mathbf{H_2L}$ and its complexes [Ni(II),Cu(II)].

tions at 3439 and 3362 cm^{-1} in the IR spectrum of compound **4**. In addition to this information, at 1621 cm^{-1} in the IR spectrum of compound **4** there is a peak belonging to NH_2 bending. Elemental analysis data was very satisfactory and FAB mass spectral data was: 833 $[M]^+$, as expected.

The novel *vic*-dioxime **6** was synthesized from the reaction of compound **4** and cyanogen di-*N*-oxide **5** at −10 °C

in dichloromethane in the presence of an aqueous solution of Na_2CO_3 (−10 °C) for a period of 10–12 h in 62% yield. In the ^1H NMR spectrum of **6** there are singlet signals at $\delta = 10.20$ and $\delta = 7.86$ due to the hydroxy imino groups and NH protons respectively which can be identified easily owing to deuterium-exchangeable characteristics of these protons. The singlet chemical shifts of the hydroxy imino groups indicate that the structure of this novel oxime derivative is (*E*,*E*). That the diamino glyoxime has the s-*trans* form was determined by ^1H NMR and X-ray structural analyses [24]. Therefore, the same structure can be proposed for this new oxime derivative **6**, too. A ^{13}C NMR spectrum is one of the most convenient ways to prove the true structure of *vic*-dioximes, and in the ^{13}C NMR spectrum of **6** a singlet peak at $\delta = 145.02$ belongs to hydroxy imino groups. That only one resonance is displayed relating to carbon atoms of oxime indicates that the structure of this novel oxime derivative **6** is of the (*E*,*E*)-dioxime formation [25]. In the IR spectrum of compound **6** there are NH, OH, C=N and NO stretching vibrations at 3350, 3230, 1640 and 942 cm^{-1}, respectively. Both C=N and OH stretching vibration data are harmonious with other oxime derivatives whose structures are of the s-formation [26]. Furthermore, FAB mass spectral data was 1750 $[M]^+$, proving that the structure is the same as the proposed structure. Elemental analysis data displays that the desired compound is synthesized as well.

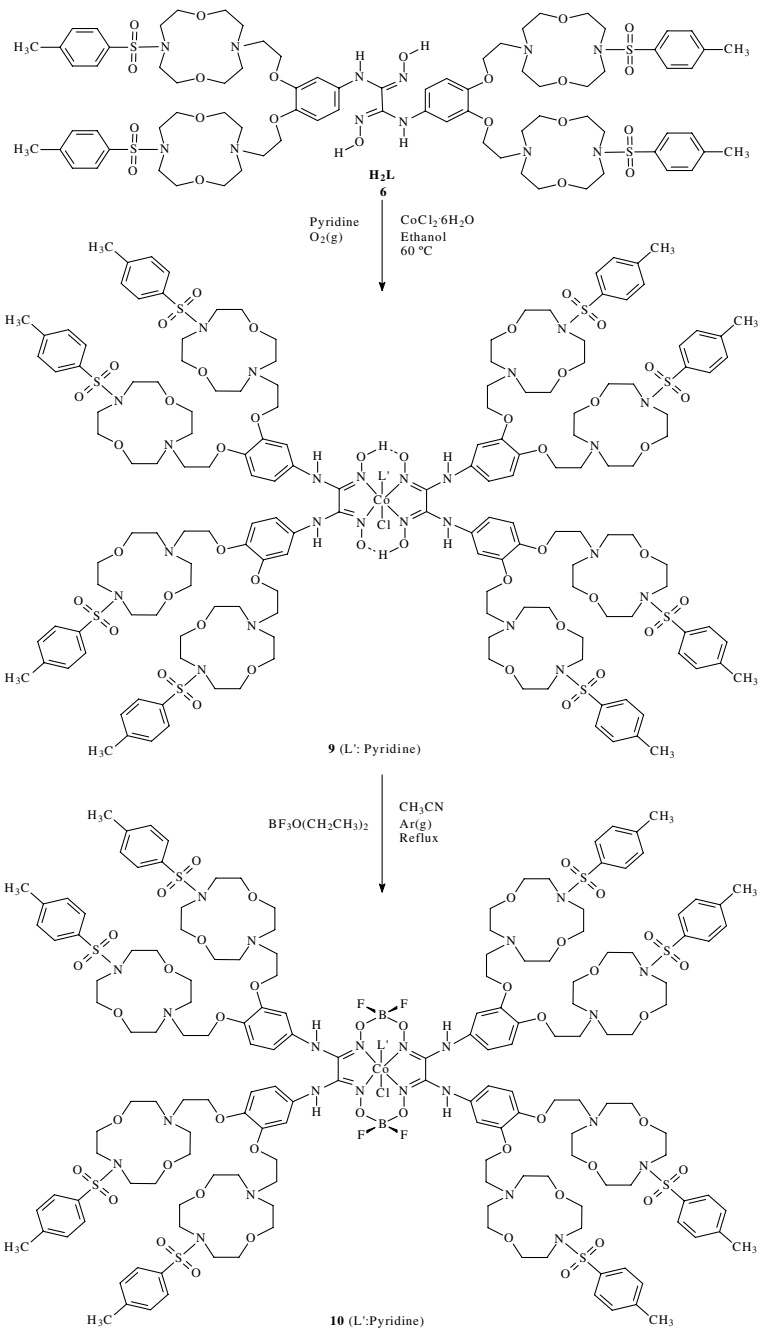
The mononuclear Ni(II) and Cu(II) complexes $[Ni(HL)_2]$ and $[Cu(HL)_2]$, **7** and **8**, were prepared from the oxime derivative **6** and with a stoichiometric amount of $NiCl_2 \cdot 6H_2O$ and $CuCl_2.2H_2O$ respectively, in the presence of ethanol (Scheme 1). FAB mass spectral data for the compounds **7** and **8** were 3556 $[M+1]^+$ and 3561 $[M+1]^+$ respectively. Both elemental analysis and FAB mass spectral data showed that the metal:ligand ratio is 1:2 for compounds **7** and **8**. In the IR spectra of compounds **7** and **8**, C=N stretching vibrations are at 1624 and 1627 cm^{-1}, respectively. That the C=N stretching vibrations of compounds **7** and **8** are lower than the stretching vibration of the oxime derivative **6** (1640 cm^{-1}) proved that the oxime ligand coordinates with the Ni(II) and Cu(II) cations in the *N*,*N*′ style. In addition, the disappearance of functional groups relating to δ OH and ν OH for compound **6**, at 1427 and 3230 cm^{-1}, indicates that intramolecular hydrogen bonds form with a peak at 1733 cm^{-1} for each complex. That there is a singlet peak at $\delta = 16.80$ in place of the OH functional group in the ^1H NMR spectrum of the square planar complex **7** indicates the existence of intramolecular hydrogen bonds (O–H···O) which can be easily observed by the deuterium-exchange method.

The mononuclear Co(III) complex, $[Co(HL)_2PyCl]$ **9**, was prepared from ligand **6**, pyridine and an equivalent amount of $CoCl_2 \cdot 6H_2O$ in the presence of ethanol (Scheme 2). Whilst the reaction proceeded, oxygen gas was passed through the reaction mixture in order to oxidize Co(II) to Co(III). The FAB mass spectral data for compound **9** was 3671 $[M+1]^+$. The metal:ligand ratio is 1:2 for this complex too, with the pyridine and chlorine ligands in axial positions of the octahedral complex, according to elemental analysis data. That there is a singlet peak at $\delta = 10.20$ in place of the OH functional group in the ^1H NMR spectrum of complex **9** indicates the existence of intramolecular hydrogen bonds (O–H···O) which can be easily observed by the deuterium-exchange method. The chemical shifts for pyridine at $\delta = 7.71$, 7.50 and 6.84 indicates the existence of an octahedral complex **9**. The stretching vibrations of the OH functional group at 3230 cm^{-1} for compound **6** disappeared and a new peak was observed at 1722 cm^{-1} which indicates of the existence of intramolecular hydrogen bonds. A broad C=N stretching vibration of compound **9** at 1621 cm^{-1} is lower than the stretching vibration of the oxime derivative **6** (1640 cm^{-1}) which proves that the oxime ligand coordinates with Co(III). All these data show that all the relevant groups participate in the formation of the complex.

The BF_2-bridged cobalt(III) complex **10** was obtained in high yield, 68%, at moderate dilution (0.2 mmol) from the hydrogen-bridged cobalt(III) complex and boron trifluoride etherate (0.4 mmol) linking reagent (Scheme 2). This reagent readily reacts with the O–H···O bridge in the precursor molecule, yielding an extremely stable compound containing two O–BF_2–O bridges, and the single mole of the axial ligand pyridine was retained, according to ^1H NMR and IR spectra and elemental analysis data of $[Co(LBF_2)_2L'Cl]$. In the IR spectrum of the BF_2^+-capped cobalt(III) complex, the C=N stretching region can be used to distinguish between the dihydrogen-bridged compound and the diboron-bridged compound. This BF_2-macrocycle exhibits upward shifts of ca. 35 cm^{-1} due to the strong electron-withdrawing influence of the BF_2 groups incorporated in the macrocycle. The weak and broad band at 1722 cm^{-1}, concerning O–H···O in-plane deformation of the short hydrogen bond, disappeared upon encapsulation of the H-bonded complex, with the concomitant appearance of peaks around 1156–1030 and 875–843 cm^{-1} for the B–O and B–F groups, respectively [27]. In the ^1H NMR spectrum of the BF_2^+-capped macrocycle, the deuterium exchangeable hydrogen-bridged protons belonging to the H-bonded pseudomacrocylic precursor cobalt(III) complex are no longer present after the formation of the BF_2 bridge [28]. This BF_2-bridged cobalt(III) complex is also confirmed by its fast atom bombardment mass spectrum, which gives a molecular ion peak at $m/z = 3768$ $[M+1]^+$.

3.1. Solvent extraction of alkali and heavy metal cations

The alkali and heavy metal ion binding properties of the compounds having diaza-12-crown-4 units was estimated by solvent extraction of alkali- and heavy metal picrates from the aqueous to an organic phase (Table 1). For comparison, the values obtained under the same conditions for *N*-tosyl-diazadioxa-12-crown-4 (**1**) are included in Table 1. In addition to compounds **3** and **6**, since the introduction of BF_2 groups to complex **9** leads



Scheme 2. Synthesis of complexes **9** and **10**.

to an increase in the solubility, in addition to the bulky diazacrown units just the BF_2-bridged cobalt(III) complex **10** among the other complexes was used as an extractant. In the case of all the host compounds, it might be expected that the capability of extraction of the lithium ion would be the highest among the alkali metal cations on comparing its size to the cavity size, as the diameter of the lithium ion is much more compatible with 12-membered macrocyclic units. Nevertheless the extraction was highest for the sodium ion due to the bis-crown effect. Therefore the sodium cation forms a sandwich type complex by binding between two diazacrown units with a metal:ligand ratio of 1:2. The capability of extraction for alkali metal cations increased with compounds **1**, **3**, **6** and **10**. However this increase was not so noteworthy as compared to the increase of the 12-membered macrocyclic units. This might be due to steric hindrance of the bulky diaza-12-crown-4 units.

We were not able to find extraction studies in the literature with heavy metal cations for compounds containing bis(diaza-12-crown-4) moieties. Therefore this work caused us to investigate and perform such a kind of study. However, there are some reports on the extracting properties of tricyclic compounds. According to these studies,

compounds having (diaza-12-crown-4) subunits can form dinuclear complexes with silver(I), zinc(II) and copper(II). They can also form mononuclear complexes with other cations such as mercury(II), lead(II) and cadmium(II) [29–31].

Aza-crown ethers form stable complexes with the Ag^+ cation by replacement of O atoms with N atoms in crown ether moieties [31]. As can be easily figured out from Table 1, Ag^+ has the highest extracting capability by forming M_2L type complexes since there are more diaza-12-crown-4 units which can coordinate with cations that have a small cation diameter. Also the compounds having diaza-12-crown-4 units form ML type complexes with cations having a bigger cation diameter. It means there are less diaza-12-crown-4 units per cation which is why their extracting capabilities are low. The other important fact obtained from the data in Table 1 is that the sodium and silver picrate capabilities of host molecules are closely parallel. It might be attributed the similarity of the cation diameters between Na^+ and Ag^+.

The cation binding properties of the ligands depend upon different factors such as macrocyclic effect, cavity size and the type and number of donor atoms. Also, it is known that *vic*-dioximes form stable complexes with transition metal cations. In the case of compound **6**, an increase concerning its extraction capability might be expected with the investigated metal cations having both oximes and macrocyclic groups for complexation. Since there is no noteworthy increase in its extraction capability, it is not remarkable in our work. This can be easily seen when it is compared to compound **3** or **10**. The number of macrocyclic groups from **3** to **6** increases. It is difficult to comment whether or not the increase in extraction capability is the result of oxime groups or the increase in the number of macrocyclic groups, but, according to these data, we can conclude that the macrocyclic effect and the number of donor atoms are much more effective than oxime groups.

4. Conclusions

In the course of this study, a new *vic*-dioxime ligand **H_2L** containing bis(diaza-12-crown-4) moieties and its complexes [Ni(II), Cu(II), Co(III) and BF_2-briged Co(III)] have been synthesized in good yields and characterized. Additionally, their cation-binding abilities were evaluated using a solvent extraction technique. Picrate was used as a counter anion for all compounds.

The results obtained by the extraction experiments of alkali and heavy metal picrates indicate that the extraction capability of **10** among the bis(diaza-12-crown-4) moieties studied has the highest value in all cases. The cation-binding abilities of **1**, **3**, **6** and **10** were found to be the highest for Na^+ among the alkali metals and Ag^+ among the heavy metals. The alkali and heavy metal ions extracting capabilities of bis(diaza-12-crown-4) moieties synthesized in this work follow the order **10** > **6** > **3** > **1**.

[13–18] and solution [19–21] clearly indicate that the bis(imidazol-2-yl)methyl moiety can form especially stable complexes with 3d transition metal ions, resulting in six membered chelate rings.

The coordination chemistry of bis(imidazol-2-yl)methyl ligands is more versatile when the chelating nitrogen donors are linked to other chelating ligands creating multi- and/or ambi-dentate ligands. In the last ten years we have studied copper(II), nickel(II) and zinc(II) complexes of numerous compounds, in which the bis(imidazol-2-yl) methyl group is connected to the C-terminal end of an amino acid or peptide molecule [22–27]. It can be concluded from the results of these studies that, because of the presence of two chelatable moieties, the coordination properties of the molecules are significantly different from both the simplest bis(imidazol-2-yl)methyl compounds and amino acids or peptides. In all cases, the bis(imidazol-2-yl)methyl residue is the main binding site in strongly acidic medium, but the amino group on the N-termini behaves as an anchor group promoting the deprotonation and coordination of the amide nitrogen. It results in the formation of dinuclear species with ligand bridging [22,24–27] and trinuclear complexes with a negatively charged imidazolato bridge [24,25,27]. The structure of the latter complexes for some amino acid and dipeptide derivatives is reminiscent of the active site of Cu,Zn-superoxide dismutase.

The structures of the copper(II) and zinc(II) complexes of all the studied amino acid and peptide derivatives, however, unambiguously show that at least one imidazole-N donor atom of bis-(imidazol-2-yl)methyl moiety takes part in the metal binding in the whole pH range, which, together with the coordination of the amino acid or peptide chain, lead to the formation of polynuclear species.

The recently synthesized and studied three ligands are tripeptide derivatives of the bis(imidazol-2-yl)methyl group: AlaPheGly-BIMA, GlyIleGly-BIMA and GlyGlyHis-BIMA (BIMA = bis(imidazol-2-yl)methylamine) (Scheme 1).

The difference between recently and earlier studied ligands is the length of the peptide chain, and the number of potential donor atoms. The nitrogen donor atoms of the peptide backbone could saturate the coordination sphere of the metal ion, excluding the binding of the imidazole nitrogens of the bis(imidazol-2-yl)methyl group. In the case of GlyGlyHis-BIMA, the formation of the outstandingly stable "GlyGlyHis"-like (NH_2,N^-,N^-,N(His)) coordination mode [28,29] could compete with the "bis(imidazol-2-yl)methyl"-like and "peptide"-like binding modes.

In this paper, we report the results of combined potentiometric and spectroscopic (EPR, UV–Vis, MS, NMR) studies on copper(II) and zinc(II) complexes of three tripeptide derivatives (AlaPheGly-BIMA, GlyIleGly-BIMA, GlyGlyHis-BIMA).

2. Experimental

2.1. Synthesis

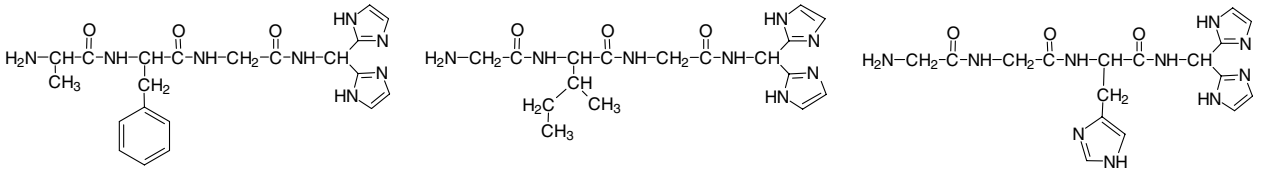
The synthetic procedure for the preparation of the free amino acids and dipeptides containing BIMA on their C-terminus has already been reported [22,30]. AlaPheGly-BIMA, GlyIleGly-BIMA and GlyGlyHis-BIMA were prepared accordingly. The purity of the above peptide derivatives was checked by thin layer chromatography (TLC) and high pressure liquid chromatography (HPLC) and their structures were proved by ^{1}H NMR.

2.2. Potentiometric measurements

The pH-potentiometric titrations in the pH range 2.0–11.0 were performed on 3–4 cm^3 samples in the concentration range 2×10^{-3}–8×10^{-3} mol dm^{-3} at metal ion to ligand ratios ranging between 1:3 and 2:1. Argon was bubbled through the samples to ensure the absence of oxygen and to stir the solutions. Measurements were carried out at 298 K and at a constant ionic strength of 0.2 mol dm^{-3} KCl with a MOLSPIN pH meter equipped with a 6.0234.100 combined glass electrode (Metrohm) and a MOL-ACS microburette controlled by computer.

The number of experimental points reached around 50–70 data (cm^3–pH) for each titration curve. The pH readings were converted into hydrogen ion concentration as described earlier [31].

Protonation constants of the ligands and the overall stability constants ($\log\beta_{pqr}$) of the systems were calculated by means of general computational programs, PSEQUAD [32] and SUPERQUAD [33] using:



AlaPheGly-BIMA **GlyIleGly-BIMA** **GlyGlyHis-BIMA**

Scheme 1.

$$pM + qH + rL \rightleftharpoons M_pH_qL_r \quad (1)$$

$$\beta_{pqr} = \frac{[M_pH_qL_r]}{[M]^p \cdot [H]^q \cdot [L]^r} \quad (2)$$

2.3. Spectroscopic measurements

UV–Vis spectra of the copper(II) complexes were recorded on a Hewlett Packard HP 8453, Perkin–Elmer Lambda 35 or JASCO UVIDEC-610 spectrophotometer in the same concentration range as used for the potentiometry.

Anisotropic X-band EPR spectra (9.15 GHz) of frozen solutions were recorded at 120 K, using a Varian E-9 and a Bruker EMX spectrometer after addition of 10% ethylene glycol to ensure good glass formation in frozen solutions. Copper(II) stock solutions for EPR measurements were prepared from $CuSO_4 \cdot 5H_2O$ enriched with ^{63}Cu to get better resolution for the EPR spectra. For this purpose metallic copper (99.3% ^{63}Cu and 0.7% ^{65}Cu) was purchased from JV Isoflex, Moscow, Russia and converted to the sulfate.

2.4. Electrospray ionization time-of-flight mass spectrometry (ESI-TOF MS)

ESI-MS analysis for the copper(II)-GlyGlyHis-BIMA system was performed on a Bruker BIOTOF II ESI-TOF instrument using 1×10^{-4} mol dm^{-3} GlyGlyHis-BIMA concentration and 1:1 and also 3:2 copper(II) to ligand ratios. The pH was set to 6.96 and 7.64, respectively, by addition of the required amount of 0.2 mol dm^{-3} KOH solution and measured with a Radiometer pHM 84 instrument equipped with a Metrohm combined electrode (type 6.0234.110).

The solutions were introduced directly into the ESI source by a syringe pump (Cole-Parmer Ins. Comp. type 74900) at a flow rate of 2 μL/min. The temperature of the drying gas (N_2) was maintained at 100 °C. The pressure of the nebulizating gas (N_2) was 30 psi. The voltages applied on the capillary entrance and the first and the second skimmers were 4500 V, 40 V and 30 V, respectively. The voltage applied on the capillary exit was varied between 50 V and 120 V to get the best resolution of the spectrum. The spectra were accumulated and recorded by a digitizer at a sampling rate of 2 GHz. The spectrometer was operated at unit mass resolution and was calibrated to the sodium salt of trifluoroacetic acid. The data acquisition was carried out with BioTOF v 2.2 software, the processing was done with XmassBioTOF v 6.0.0.

2.5. NMR

A pH-dependent series of ^1H NMR spectra for GlyGlyHis-BIMA and for the copper(II)- and zinc(II)-GlyGlyHis-BIMA system was recorded on a Bruker 360 MHz instrument at 25 °C. D_2O was used as the solvent. The pH measurements in the pH range 1.5–12.2 were performed in 2 cm^3 vessels, not in the NMR tubes, at a ligand concentration of 0.01 mol dm^{-3}. Different concentrations (1, 0.1 and 0.01 mol dm^{-3}) of NaOD and DCl solutions in D_2O were used to adjust the pH. The pH readings were converted into pD values by adding 0.4 to the pH values read. Chemical shifts were referenced to sodium 3-(trimethylsilyl)-1-propanesulfonate (DSS). Microscopic protonation processes of GlyGlyHis-BIMA were calculated using a method described earlier [34].

3. Results and discussion

3.1. Protonation equilibria of the ligands

The protonation constants of the tripeptide derivatives containing bis(imidazol-2-yl)methyl groups are collected in Table 1 together with some literature data for comparison.

It is clear from Table 1 that the highest pK values belong to the deprotonation process of protonated terminal amino groups. These values are in good agreement with those of simple tri- and tetrapeptides [35–37] and aliphatic amino acid- and dipeptide-derivatives of the bis(imidazol-2-yl)methyl group [22,25]. It can be concluded that the bis(imidazol-2-yl)methyl moiety does not affect the deprotonation of the protonated amino group on the N-termini and its pK value is practically independent of the length of the peptide chain. For GlyGlyHis-BIMA an additional imidazole ring is present in the molecule, but it is far away from the N-terminal end of the ligand and does not influence the protonation equilibrium of the amino group, similarly to GlyGlyHis [29] and Gly_4His [38].

The pK values of the bis(imidazol-2-yl)methyl moiety of AlaPheGly-BIMA and GlyIleGly-BIMA are similar and close to those of the amino acid- [22], dipeptide- [25] and N-protected tripeptide-derivatives [23] reflecting that the deprotonation processes of the bis(imidazol-2-yl) group do not depend on the length of the peptide chain connected to the bis(imidazol-2-yl) residue, namely the presence of the N-terminal amino group. The deprotonation of the imidazole rings of the bis(imidazol-2-yl) and histidine moieties of GlyGlyHis-BIMA, however, takes place at slightly lower pH than that of other tripeptide derivatives and GlyGlyHis or Gly_4His, respectively. As a consequence, the presence of an additional imidazole ring close to the bis(imidazol-2-yl) residue decreases the pK values of all imidazole nitrogens. Similar effects were observed for PheHis-BIMA [26] and BOC-ProLeuHis-BIMA [23].

The macroconstants of the proton complexes, however, do not give detailed information about the overlapping protonation equilibria of the three imidazole groups. The exact assignment of protonation sites requires the determination of microscopic protonation constants, which was done for GlyGlyHis-BIMA by the ^1H NMR technique [34]. The calculation results (Table 1, Fig. 1.) show that the lowest pk (and p$k^{1/2}$) values belong to the

Table 1
Protonation constants, pK values and microscopic protonation constants for 50% degree of protonation (p$k^{1/2}$) [34] of the ligands investigated and some other peptides and bis(imidazol-2-yl)methyl derivatives

first and second imidazole groups of the bis(imidazol-2-yl)methyl moiety. The actual values are in very good agreement with the bis(imidazol-2-yl)methyl pk and pK values of other derivatives. When the pH increases, histidine is the next group to be deprotonated. The p$k^{1/2}$ value for GlyGlyHis-BIMA is somewhat higher than that of His-BIMA or PheHis-BIMA, because both the protonated amino (in the case of His-BIMA) and the aromatic Phe (for PheHis-BIMA) group have electron-withdrawing effects. Furthermore, the amino p$k^{1/2}$ value is also higher for GlyGlyHis-BIMA than for the above mentioned other X-His-BIMA (X = H or Phe) derivatives, in agreement with several literature amino pK values measured for GlyGlyY (Y = His or GlyGlyHis) (see Table 1). Because of these effects, the overlap of four deprotonation steps (especially the pk values of the second imidazole of the bis(imidazol-2-yl)methyl moiety and the histidine imidazole) of GlyGlyHis-BIMA is much less than those found for His-BIMA and PheHis-BIMA.

3.2. Metal complexes of the ligands

It can be seen from the structures of the molecules (Scheme 1) that all three ligands have several different types of binding sites. In addition to the chelatable bis(imidazol-2-yl)methyl group, the tripeptide can coordinate to metal ions saturating its coordination sphere. In the case of histidine containing compounds, the very stable "GlyGlyHis"-like binding mode may form. These coordination modes alone and a mixture of them lead to very diverse complex formation processes. The stability constants of copper(II) and zinc(II) complexes and some selected equilibrium parameters are summarized in Table 2.

3.3. Copper(II) complexes of AlaPheGly-BIMA and GlyIleGly-BIMA

The bis(imidazol-2-yl)methyl residue is the main binding site in the acidic pH range. Protonated mono- and bis-

$\log(K_1/K_2)^{H} = 2\log\beta([MH_2L]^{4+}) - \log\beta([MH_4L_2]^{6+})$ or $2\log\beta([MHL]^{3+}) - \log\beta([MH_2L_2]^{4+})$.
$\log(K_1/K_2) = 2\log\beta([ML]^{2+}) - \log\beta([ML_2]^{2+})$.

ligand complexes are formed with the coordination of two or four imidazole nitrogens, while the non-coordinated amino nitrogens are protonated ($[CuHL]^{3+}$, $[CuH_2L_2]^{4+}$). The EPR and UV–Vis spectroscopic parameters (Table 3) are very similar to each others and those of BIM [39] ($[CuL]^{2+}$: $\lambda_{max} = 680$ nm, $g_{\parallel} = 2.307$, $A_{\parallel} = 181 \times 10^{-4}$ cm^{-1}, $[CuL_2]^{2+}$: $\lambda_{max} = 578$ nm, $g_{\parallel} = 2.237$, $A_{\parallel} = 199 \times 10^{-4}$ cm^{-1}), Gly-BIMA [22] ($[CuHL]^{3+}$: $\lambda_{max} = 681$ nm, $g_{\parallel} = 2.299$, $A_{\parallel} = 175 \times 10^{-4}$ cm^{-1}, $[CuH_2L_2]^{4+}$: $\lambda_{max} = 590$ nm, $g_{\parallel} = 2.236$, $A_{\parallel} = 201 \times 10^{-4}$ cm^{-1}) and BOC-His-LeuGly-BIMA [23] (Table 3).

The ratio of stepwise stability constants for protonated species ($\log(K_1/K_2)^{H}$) corresponds to that of BIM [20] ($\log(K_1/K_2) = 2.78$), Gly-BIMA [22] ($\log(K_1/K_2)^{H} = 2.58$), LeuGly-BIMA [25] ($\log(K_1/K_2)^{H} = 1.52$) and Ac-ProLeu-Gly-BIMA [23] ($\log(K_1/K_2) = 2.06$), which also indicate that the ligands are coordinated via the bis(imidazol-2-yl)methyl nitrogens in these complexes. The deprotonation of $[CuHL]^{3+}$ and $[CuH_2L_2]^{4+}$ can be assigned to the deprotonation of the N-terminal amino group and $[CuL]^{2+}$ and $[CuL_2]^{2+}$ species are present above pH 4 (Fig. 2).

The characteristic pK values (pK(MHL/ML), pK(MH_2L_2/MHL_2), pK(MHL_2/ML_2)) are, however, much lower than those of the amino group in the free ligands. As a consequence, the deprotonation of the terminal amino group occurs parallel with its binding to the copper(II)

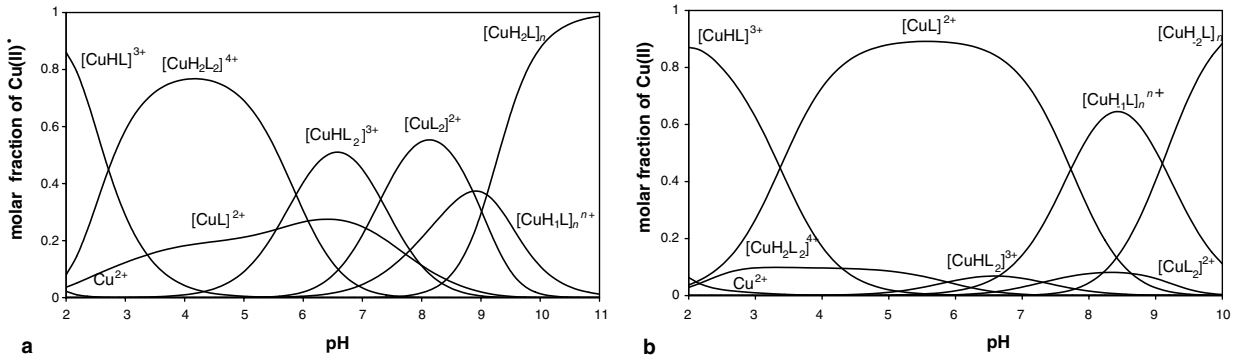

Fig. 2. Species distribution of the complexes formed in the copper(II)-GlyIleGly-BIMA system ($c_L = 4 \times 10^{-3}$ mol dm^{-3}, $c_M = 2 \times 10^{-3}$ mol dm^{-3} (a), $c_L = 5.5 \times 10^{-3}$ mol dm^{-3}, $c_M = 5 \times 10^{-3}$ mol dm^{-3} (b)).

ion. In contrast with dipeptide derivatives, it does not result in the formation of dimeric species, but mononuclear complexes are present in the physiological pH range, too. It means that both the bis(imidazol-2-yl)methyl residue and the terminal amino group are bound to the same metal ion forming macrochelated complexes. These structures are proved by EPR and UV–Vis spectra obtained in equimolar solution (Fig. 3) and with an excess of ligand. The deprotonation of $[CuHL]^{3+}$ and $[CuH_2L_2]^{4+}$ is accompanied by significant changes of EPR and UV–Vis parameters. The increase in $g_{\|}$ and decrease in $A_{\|}$ values indicate a strong axial interaction in the $[CuL_2]^{2+}$ complexes coordinated by four imidazole nitrogens in the equatorial plane. The strong axial binding of the amino group and the distorted octahedral structure of the complexes are also confirmed by the significant blue shift of the absorption maximum, accompanying the formation of $[CuL_2]^{2+}$. The spectral parameters of the $[CuL]^{2+}$ complexes are also different from those of the $[CuHL]^{3+}$ complexes of tripeptide derivatives and $[CuL]^{2+}$ of BIM, which suggests that a third nitrogen donor atom is bound in the coordination sphere of the metal ions. The length of the peptide chain makes the equatorial coordination of three nitrogen donor atoms possible, but the calculated absorption maximum for $(NH_2,CO) + (N(Im),N(Im))$ coordination is ~616 nm on the basis of an empirical formula [40]. So the equatorial–axial coordination of one end of the ligand is more probable in the $[CuL]^{2+}$ complex. Similar spectroscopic changes were observed in the case of $[CuL]^{2+}$ and $[CuL_2]^{2+}$ of BOC-HisLeuGly-BIMA[23] (Table 3), in which the axial coordination of histidine imidazole nitrogen was supposed.

Unfortunately, potentiometry is not an adequate method to distinguish between mononuclear and polynuclear complexes, which is why the stability constants for $[(CuH_{-1}L)]^{+}$ and $[(CuH_{-2}L)]$ species were calculated (Table 2). In the $[(CuH_{-1}L)_n]^{n+}$ and $[(CuH_{-2}L)_n]$ complexes, equatorial coordination of (NH_2,N^-) or (NH_2,N^-,N^-) donor sets can be supposed, respectively, while the one or two imidazole nitrogens of the other end of the ligand bind to another metal ion creating ligand bridged polynuclear structures. Above pH 10, it was not possible to observe the deprotonation of the third amide nitrogen because of the precipitation of the neutral polymeric species $[(CuH_{-2}L)_n]$.

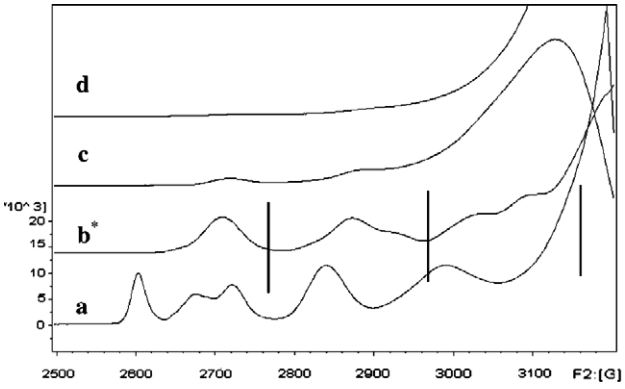

Fig. 3. EPR spectra obtained in the copper(II)-GlyIleGly-BIMA system at a 1:1.1 ratio at different pH values in frozen solution ($c_M = 5 \times 10^{-3}$ mol dm^{-3}) pH 2.17 (a), pH 5.66 (b), pH 8.48 (c), pH 10.37 (precipitation) (d). *At this pH in addition to $[CuL]^{2+}$ species bis chelated complexes with bis(imidazol-2-yl)methyl coordination are present (see Fig. 2b).

The two different coordination sites of the ligands make the binding of more than one copper(II) ion possible with a metal ion excess. The presence of $[Cu_3L_2H_{-4}]^{2+}$ complexes are proposed in slightly basic solution, in which two copper(II) ions are bound by an (NH_2,N^-,N^-) donor set, while the third metal ion is coordinated with four imidazole nitrogens. The EPR spectra measured at pH 8 in a solution at 3:2 copper(II) to ligand ratio is poorly resolved and this could be an indication of the formation of this trinuclear species.

3.4. Copper(II) complexes of GlyGlyHis-BIMA

The complex formation processes of GlyGlyHis-BIMA are very similar to the other two tripeptide derivatives in acidic medium. Mono- and bis-ligand complexes ($[CuH_4L_2]^{6+}$, $[CuH_2L]^{4+}$) are formed with the binding of four imidazole nitrogens; the amino and histidine residues

are protonated. The deprotonation of these groups results in the formation of $[CuHL]^{3+}$, $[CuL]^{2+}$ and $[CuH_nL_2]^{(2+n)+}$ ($n = 3$–0) species (Fig. 4).

The deprotonation steps of these complexes are cooperative and the averages of pK values are usually lower than those of the histidine imidazole and the amino groups of the free ligand. The ratio of characteristic stepwise stability constants are increased in comparison with that of fully protonated complexes. On the other hand, spectroscopic parameters assigned to the protonated and non-protonated species are different, and they are similar to those of $[CuL]^{2+}$ and $[CuL_2]^{2+}$ complexes of AlaPheGly-BIMA and GlyIleGly-BIMA, respectively. It can be concluded from these observations that the deprotonation of the amino and histidine imidazole nitrogen donor atoms occurs in parallel with their binding to the same metal ion forming macrochelates, similarly to the other two tripeptide derivatives. It means that the ligand is coordinated to the metal ion at least tridentately through the bis(imidazol-2-yl)methyl group and the amino or histidine imidazole nitrogens. This coordination mode could be supported by ^{1}H NMR measurements. The NMR spectra of the free ligand and the solution containing copper(II) and the ligand in a 1:10 ratio were detected at different pH values. A comparison of the spectra of the free ligand and the copper(II) containing system shows that the presence of copper(II) causes a broadening of the ^{1}H NMR signals of all three imidazole protons in the pH range 2–8, so it indicates that all three imidazole nitrogens take part in the coordination of copper(II) ion for $[CuH_nL_2]^{(n+2)+}$ ($n = 3$–0) complexes.

The deprotonation and coordination of amino and histidine imidazole groups are followed by extra base consuming processes, which correspond to the deprotonation and coordination of amide nitrogens. Both in equimolar solution and at ligand excess, $[CuH_{-2}L]$ complex predominates in basic solution (pH > 9). Its stoichiometry and spectroscopic parameters are in good agreement with that of $[CuH_{-2}L]^{2-}$ of GlyGlyHis [38] ($\lambda_{max} = 525$ nm, $g_{\|} = 2.178$, $A_{\|} = 209 \times 10^{-4}$ cm^{-1}), which indicates the ''GlyGlyHis''-like coordination mode. Although this binding mode is predominant above pH 5 for the Cu(II)-GlyGlyHis system [29], the coordination of the bis(imidazol-2-yl) residue of GlyGlyHis-BIMA suppresses the formation of (NH_2,N^-, N^-,N(His)) coordinated species. Fig. 5 is used to demonstrate the competition between the ''bis(imidazol-2-yl)methyl''- and ''GlyGlyHis''-like coordination modes. The theoretical distributions of the parent complexes formed in the Cu(II)-BIM(A)-GlyGlyHis(B) system are shown at 1:2:2 and 1:1:1 ratios (because of the high stability of both coordination modes, the formation of mixed complexes can be neglected).

It is clear from these figures that the ''bis(imidazol-2-yl)-methyl''-like coordination mode predominates in the pH range 4–8 at a 1:2:2 ratio, but above pH 9, the (NH_2,N^-,N^-,N(His)) coordinated species ($[CuH_{-2}B]^{2-}$) represents all the copper(II) in solution and, as a consequence, the binding of the bis(imidazol-2-yl)methyl group is replaced by the ''GlyGlyHis''-like coordination mode.

The coordination of the copper(II) ion to the peptide chain of the molecule, however, makes the binding of

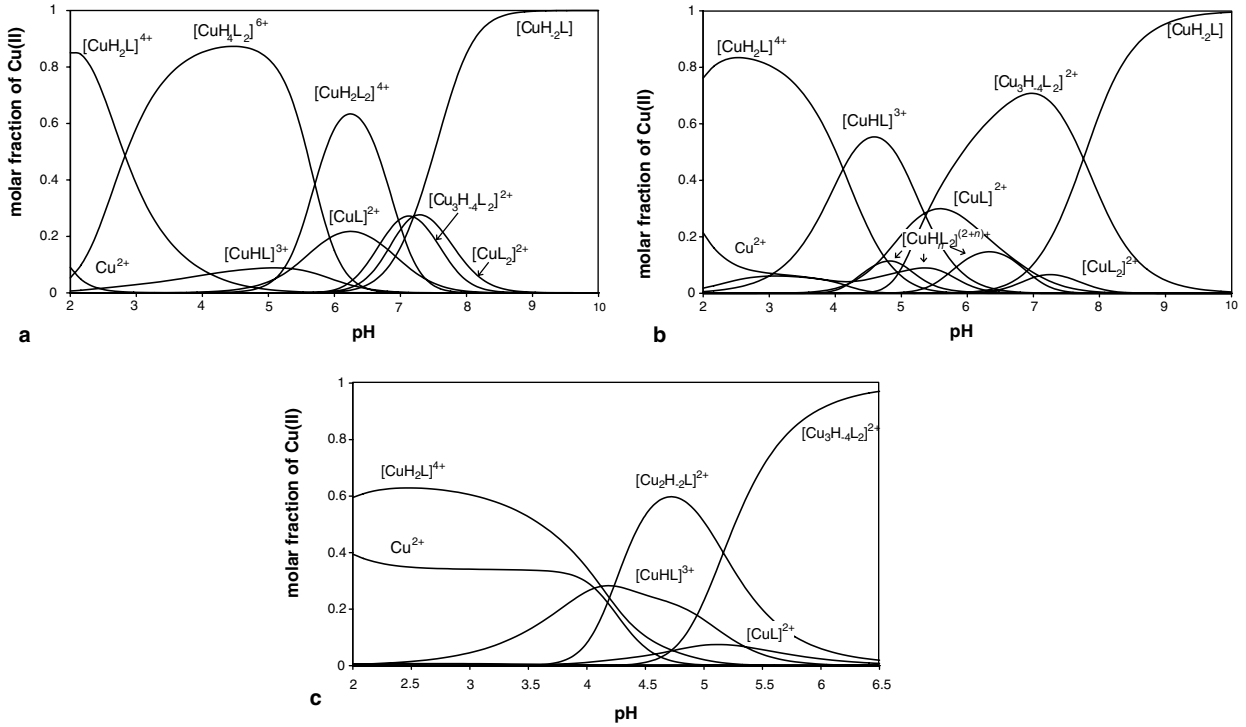

Fig. 4. Species distribution of the complexes formed in the copper(II)-GlyGlyHis-BIMA system ($c_L = 4 \times 10^{-3}$ mol dm^{-3}, $c_M = 2 \times 10^{-3}$ mol dm^{-3} (a), $c_L = 4 \times 10^{-3}$ mol dm^{-3}, $c_M = 4 \times 10^{-3}$ mol dm^{-3} (b), $c_L = 4 \times 10^{-3}$ mol dm^{-3}, $c_M = 6 \times 10^{-3}$ mol dm^{-3} (c)).

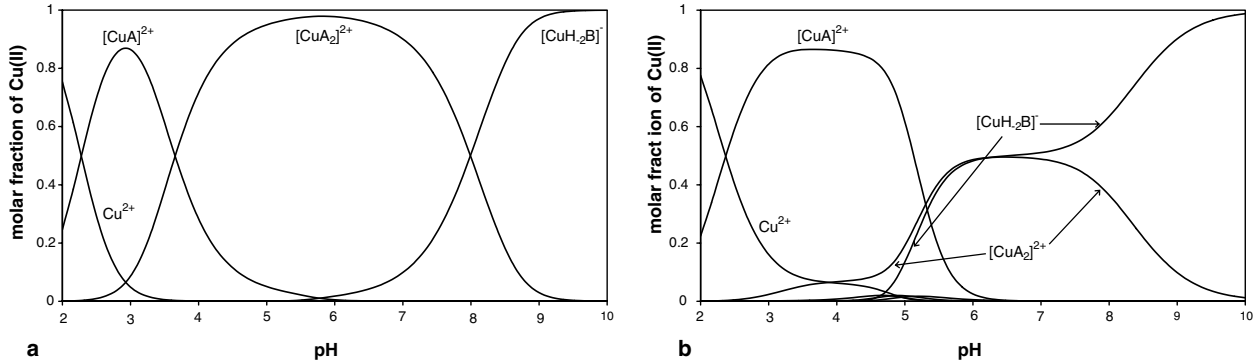

Fig. 5. Species distribution of the complexes formed in the copper(II)-BIM(*A*)-GlyGlyHis(*B*) system ($c_A = 4 \times 10^{-3}$ mol dm^{-3}, $c_B = 4 \times 10^{-3}$ mol dm^{-3}, $c_M = 2 \times 10^{-3}$ mol dm^{-3} (a), $c_A = 4 \times 10^{-3}$ mol dm^{-3}, $c_B = 4 \times 10^{-3}$ mol dm^{-3}, $c_M = 4 \times 10^{-3}$ mol dm^{-3} (b)).

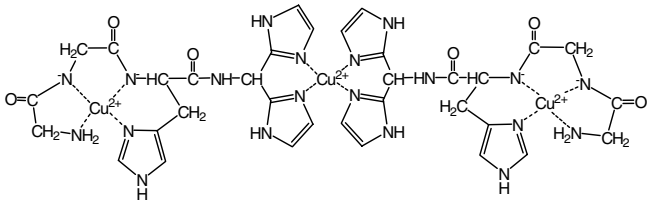

Scheme 2.

another metal ion to the ligand possible, resulting in the appearance of a trinuclear $[Cu_3H_{-4}L_2]^{2+}$ complex (Scheme 2).

This complex exists around pH 7 in an equimolar solution (Fig. 4b), whilst it is predominant above pH 6 with a metal ion excess (Fig. 4c). The speciation curves of the system Cu(II)-GlyGlyHis-BIM = 1:1:1 also support the distribution of the copper(II) ion between the bis(imidazol-2-yl)methyl group and the GlyGlyHis peptide chain. The existence of trinuclear species was proved by mass spectroscopic measurements carried out at 1:1 and 3:2 Cu(II)-GlyGlyHis-BIMA ratios at pH 7–8. Fig. 6 shows a small region of the spectra, and this region indicates the formation of a copper(II) complex with 3:2 stoichiometry both at 1:1 and 3:2 copper(II) to ligand ratios. The isotopic distribution patterns obtained for the complexes are in very good agreement with that calculated for the molecular ion $[Cu_3H_{-4}L_2]^{2+} = [Cu_3C_{34}H_{39}N_{30}O_6K]^{2+}$. (In the mass spectrum, one H of the ligand is replaced by K, which is present in the solution in relatively high concentration since KOH solution was used to adjust the pH.)

The two coordination sites of the ligand result in the formation of di- and trinuclear species in a solution of copper(II)–ligand with a ratio of 3:2 in almost the whole pH range, and both types of coordination mode (N(Im),N(Im) and NH_2,N^-,N^-,N(His)) are proposed in these complexes. The EPR spectra obtained at this ratio are poorly resolved, which also indicates the dipolar interaction between copper(II) ions (Fig. 7).

3.5. Zinc(II) complexes of GlyGlyHis-BIMA

The zinc(II) complexes of only GlyGlyHis-BIMA were studied and a comparison of data with those of BIM reveal that the presence of the GlyGlyHis residue does not influence the complex formation processes significantly. The stoichiometry and stability constants of complexes are collected in Table 2. In acidic medium, similarly to the copper(II) ion, protonated and non-protonated mono- and bis-ligand complexes are formed. The ratio of stepwise

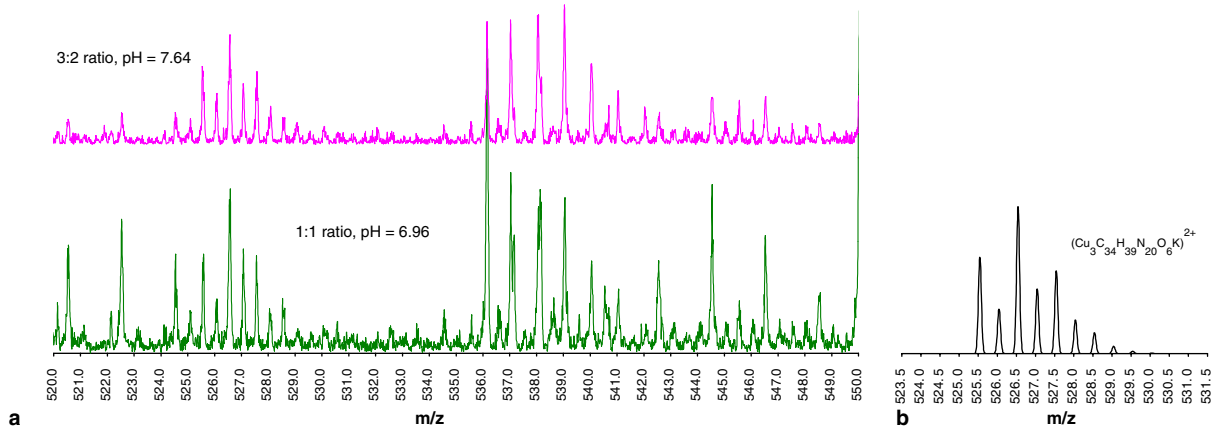

Fig. 6. ESI-MS spectra obtained in the copper(II)-GlyGlyHis-BIMA system at a 3:2 ratio and in equimolar solution (a) and the calculated isotopic distribution pattern for the molecule ion $[Cu_3H_{-4}L_2]K^{2+} = [Cu_3C_{34}H_{39}O_6N_{20}]K^{2+}$ (b).

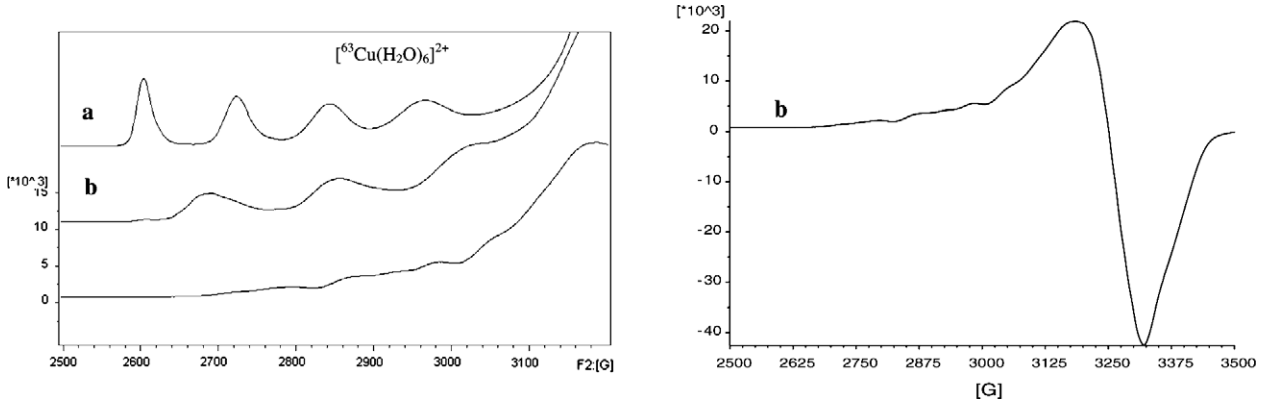

Fig. 7. EPR spectra obtained for the copper(II)-GlyGlyHis-BIMA system at a 3:2 ratio at different pH values in frozen solution ($c_M = 5 \times 10^{-3}$ mol dm^{-3}), pH 4.87 (a), pH 7.14 (b).

stability constants of protonated and non-protonated complexes, respectively, are higher than those of BOC-ProHis-Gly-BIMA [20] ($\log(K_1/K_2)^H = 0.56$, $\log(K_1/K_2) = 2.08$) and BIM [20] ($\log(K_1/K_2) = 0.84$), which indicates an additional weak interaction of one of the nitrogen donor atoms of the peptide chain. It is confirmed by the pK values characterizing the deprotonation processes of complexes too, which are slightly lower than those of the free ligand.

Fig. 8 shows the NMR spectra detected in a solution containing zinc(II) and ligand in 1:1 and 1:2 ratios, and also the difference of ^{1}H NMR shifts between the free ligand and the zinc(II) containing system ($\Delta\delta = \delta_{\text{zinc(II)–ligand system}} - \delta_{\text{free ligand}}$ at a given pH) together with the distribution of the complexes formed as a function of pH and at 1:2 zinc(II) to GlyGlyHis-BIMA ratio. It can be seen that the presence of the zinc(II) ion changes the signals of imidazole protons of the bis(imidazol-2-yl)methyl residue and the methylene protons of the N-terminal glycyl residue. On the basis of these data, it is probable that the terminal amino group takes part in the metal coordination forming macrochelates in addition to binding of the two imidazole rings of the bis(imidazol-2-yl)methyl residue. This coordination mode enhances the stability of $[ZnL]^{2+}$ and $[ZnL_2]^{2+}$ complexes and, in contrast to dipeptide derivatives [25], the hydrolysis of the complexes was not observed below pH 8. This coordination mode, however, is not able to promote the deprotonation of the amide nitrogen and precipitation occurs in basic solution both in equimolar solution and at ligand excess.

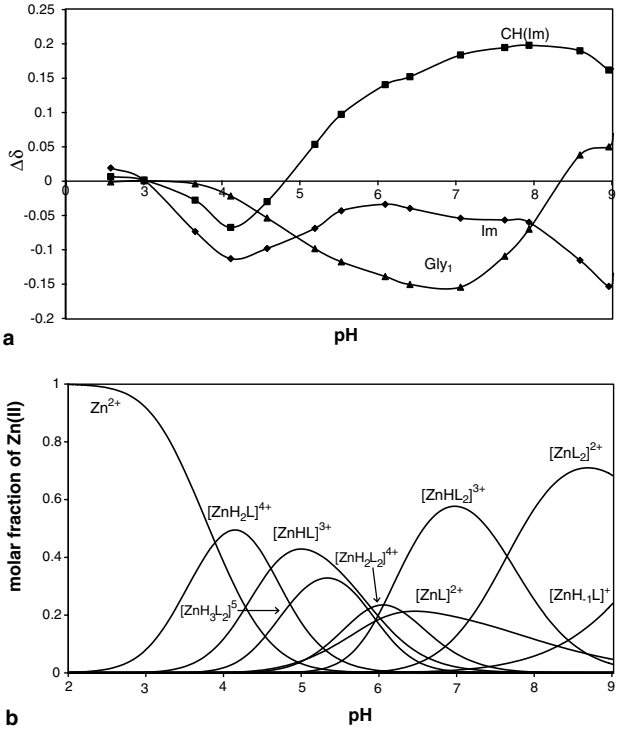

Fig. 8. Species distribution of the complexes formed in the zinc(II)-GlyGlyHis-BIMA system ($c_L = 4 \times 10^{-3}$ mol dm^{-3}, $c_M = 4 \times 10^{-3}$ mol dm^{-3}) (a) and the difference of ^{1}H NMR shifts between the free ligand and the zinc(II) containing system ($\Delta\delta = \delta_{\text{zinc(II)–ligand system}} - \delta_{\text{free ligand}}$) as a function of pH.

4. Conclusion

In our previous papers, copper(II) and zinc(II) complexes of a series of bis(imidazol-2-yl)methyl derivatives containing different amino acids and peptide chains were studied. We have continued our work with the studies on copper(II) and zinc(II) complexes of three tripeptide derivatives of the bis(imidazol-2-yl)methyl residue. The results of combined potentiometric, UV–Vis, EPR, ^{1}H NMR and mass spectroscopic measurements with these types of compounds provide further information about the coordination properties of this ligand family and allow the understanding of the effect of increased peptide chain connected to the bis(imidazol-2-yl)methyl moiety compared to amino acid and dipeptide derivatives.

The data reveal that the presence of two potential binding sites in the ligands makes their coordination chemistry versatile. Similarly to all the other studied ligands, the bis(imidazol-2-yl)methyl residue is the main binding site

in acidic medium in these cases. The presence of a terminal amino group modifies this coordination mode at higher pH. In contrast with amino acid and dipeptide derivatives, however, the coordination of the amino nitrogen donor atom does not lead to the formation of dimeric species in slightly acidic and neutral solution. Mononuclear complexes are present, in which the ligands are bound to the metal ions at least tridentately, resulting in macrochelates. This coordination mode increases the stability of $[ML]^{2+}$ and $[ML_2]^{2+}$ species resulting in a suppression of the deprotonation processes of the amide nitrogens for the copper(II) ion and the appearance of hydrolysis for the zinc(II) ion. In the case of copper(II) complexes, the deprotonation and coordination of the amide nitrogen take place at higher pH. For GlyIleGly-BIMA, polynuclear species exist in basic solution with participation of both binding sites of the molecules. The formation of a precipitate above pH 10, however, prevented the clarification whether the deprotonation and coordination of the third amide nitrogen or hydrolysis take place saturating the coordination sphere of the copper(II) ion. For GlyGlyHis-BIMA, the coordination of the (NH_2,N^-,N^-,N(His)) donor set was detected above pH 6 in equimolar solution together with the binding of the bis(imidazol-2-yl)methyl residue, leading to the formation of a trinuclear $[Cu_3H_{-4}L_2]^{2+}$ complex. Moreover, the ''GlyGlyHis''-like coordination was able to replace the bis(imidazol-2-yl)methyl residue in the coordination sphere of copper(II) ion at higher pH and the $[CuH_{-2}L]$ complex was predominant above pH 9 both with an excess of ligand and in equimolar solution.

To summarise, it can be stated that the presence of a longer peptide chain changes the coordination properties of the bis(imidazol-2-yl)methyl ligands compared to those of dipeptide or amino acid derivatives, because the long chain makes the formation of macrochelates sterically possible. The very effective binding ability of the bis(imidazol-2-yl)methyl group is reflected by the fact that the binding of at least one imidazole nitrogen of this group takes part in the metal ion coordination in all the cases in almost the whole pH range. Only the ''GlyGlyHis''-like coordination was detected, which is able to replace the binding of bis(imidazol-2-yl)methyl nitrogen donor atoms completely.

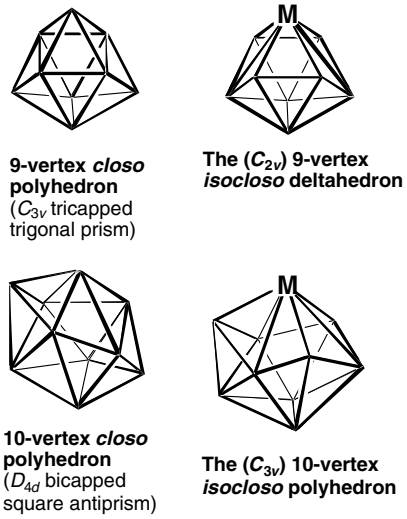

Fig. 1. A comparison between the *closo* and *isocloso* polyhedra with 9 and 10 vertices. The degree 6 vertices of the *isocloso* polyhedra occupied by transition metal atoms in the corresponding *isocloso* metallaboranes are indicated by **M**.

structures based on deltahedral topologically distinct from the deltahedra found in simple boranes and carboranes [5]. Of particular interest are the 9- and 10-vertex structures based on a deltahedron with a transition metal at a degree 6 vertex whereas the corresponding metal-free deltahedron has only degree 4 and 5 vertices (Fig. 1). What is even more interesting is the fact that such "anomalous" metallaborane structures are also "disobedient" in not having the expected $2v + 2$ skeletal electrons but only $2v$ skeletal electrons. Such disobedient deltahedral metallaborane skeletons with the anomalous $2v$ skeletal electrons have been called *isocloso* metallaboranes and this terminology will be used in this paper. These *isocloso* deltahedral metallaborane structures are derived from the corresponding *closo* deltahedron by diamond–square–diamond rearrangements, as has long been recognized [6]. A previous paper by one of us (RBK) [7] shows how removal of the transition metal vertex from an *isocloso* metallaborane having 9, 10, or 11 vertices and $2v$ skeletal electrons leads to a $B_nH_n^{2-}$ ligand or isoelectronic derivative thereof having one open hexagonal face for hexahapto bonding to the transition metal. This paper examines the roles of the formal oxidation state and valence electron count of the transition metal vertex in rationalizing the structures of metallaboranes.

2. Relationships between metal oxidation state, metal valence electron count, and metallaborane structure

The *closo*, *isocloso*, *nido*, and *isonido* structures for a metallaborane with v vertices have $2v + 2$, $2v$, $2v + 4$, and $2v + 2$ skeletal electrons, respectively. The relationships between the metal formal oxidation state (ω), the metal valence electron count (ε), and the structure type in such metallaboranes can be summarized as follows:

A. closo ($\omega = Y$, $\varepsilon = Z$) to isocloso ($\omega = Y + 2$, $\varepsilon = Z$)

This relationship arises from the following:

(a) The defining relationships for *closo* and *isocloso* metallaboranes can be summarized as follows:

$$\begin{aligned} &\textit{closo}\text{-M(borane)} \rightarrow [M^{x+} + \textit{nido}\text{-(borane)}^{x-}] \\ &\quad \leftrightarrow [M^{(x+2)+} + \textit{arachno}\text{-(borane)}^{(x+2)-}] \leftarrow \textit{isocloso}\text{-M(borane)} \end{aligned}$$

(b) Isolobal considerations relate to the equivalence of the metal fragment in an *isocloso* metallaborane to BH^{2+}, rather than BH in a *closo* metallaborane with the same number of vertices but two more skeletal electrons.

(c) Discrete oxidation reactions (Eqs. (1)–(3)) suggest a change in formal oxidation state (ω) without a change in the metal valence electron count (ε) [8]:

$$\begin{aligned} &\textit{closo}\text{-}(\eta^6\text{-}Me_6C_6)RuB_9H_9^{2-}\ (\mathbf{1}) \\ &\quad \rightarrow \textit{isocloso}\text{-}(\eta^6\text{-}Me_6C_6)RuB_9H_9\ (\mathbf{2}) + 2e^- \qquad (1) \\ &\textit{nido}\text{-}(CO)_3MnB_9H_{13}^-\ (\mathbf{3}) \\ &\quad \overset{UV}{\rightarrow} \textit{isocloso}\text{-}(CO)_3MnB_9H_9^-\ (\mathbf{4}) + 2H_2 \qquad (2) \\ &\textit{nido}\text{-}(\eta^6\text{-}Me_6C_6)CoB_9H_{13}\ (\mathbf{5}) + MeNC \\ &\quad \rightarrow \textit{isocloso}\text{-}(\eta^6\text{-}Me_6C_6)CoB_9H_9\ (\mathbf{6}) + Me_2NH \qquad (3) \end{aligned}$$

The diamond–square–diamond process converting a *closo* metallaborane to the corresponding *isocloso* metallaborane [7] with an increase of the degree of the metal vertex can be considered as an internal oxidative addition reaction at the metal atom.

(d) Experimental evidence for retention of the metal valence electron count ε arises from the observation that substitution of one PPh_3 ligand in *isocloso*-$(PPh_3)_2RuB_{10}H_8(OEt)_2$ (**7**) by the more strongly reducing PMe_3 gives *closo*-$(PMe_3)(PPh_3)RuB_{10}H_8(OEt)_2$ (**8**) with no apparent change in ε [9].

B. closo ($\omega = Y$, $\varepsilon = Z$) and isonido ($\omega = Y$, $\varepsilon = Z$)

This relationship arises from the following:

(a) The observed *closo–isonido* continua in 9-, 10- and 12-vertex structures indicate that *closo* and *isonido* cluster geometries are related by a smooth electronic continuum.

(b) The bonding topologies reported previously [7] suggest a close connection between *closo* and *isonido* structures.

C. closo ($\omega = Y$, $\varepsilon = Z$) and nido ($\omega = Y - 2$, $\varepsilon = Z$)

(a) Isolobal considerations relate to the equivalence of the metal vertex in the *nido* structure to BH^{2-} rather than BH.

(b) A unique pair of *closo* (Os(II)) and *nido* (Os(0)) isomers with $\varepsilon = 18$ exists as discussed below.

The two skeletal electrons added to a *closo* metallaborane deltahedron with $2v + 2$ skeletal electrons to open one of the (triangular) faces to give the corresponding *nido* metallaborane with $2v + 4$ skeletal electrons can be considered to reduce the metal formal oxidation state by two units.

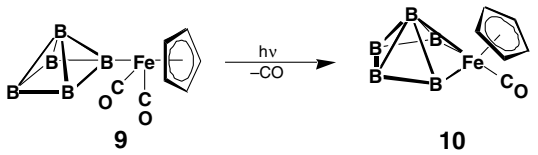
The relationship between *nido* ($\omega = Y - 2$, $\varepsilon = Z$) and *isonido* ($\omega = Y$, $\varepsilon = Z$) structures follows directly from the relationships indicated above and takes precisely the same form as that relating *closo* to *isocloso* structures so that all of the interrelationships are self-consistent. Furthermore, in metallaboranes the *closo* → *isocloso* or *nido* → *isonido* conversion is seen to increase the metal formal oxidation state by two units whereas the *closo* → *nido* conversion is seen to reduce the metal formal oxidation state by two units.

3. Nature of the borane ligands in metallaboranes: capping regime descriptors

The previous study [7] on the bonding topology in *isocloso* metallaboranes removed the transition metal vertex to give a free borane ligand. The electron donor properties of the resulting free borane ligand are influenced by the position on the open face of the nodal planes of the two highest occupied molecular orbitals (HOMOs). A *closo* metallaborane is generated by symmetrical "centroid" capping of the open face with the metal atom. A *nido* metallaborane is generated by skew-symmetrical or offset capping of the open face with the metal atom so that the metal atom is part of a remaining non-triangular face. The former can be considered to be symmetric borane ligands and the latter as asymmetric borane ligands. Each of these types of borane ligands has an associated capping regime.

Capping regime descriptors, typically of the form {**420**}, can be used to describe the capping regimes of the metallaborane ligands of interest. The first number in the capping regime descriptor refers to the number of electrons donated by the borane ligand to the metal center in the primary bonding mode of the capping process. In this connection, symmetric borane ligands donate 6 electrons. However, asymmetric borane ligands donate only 4 electrons since one borane-to-metal orbital overlap is spatially unfavorable, i.e., the relevant orbitals are effectively out of phase. The second two numbers in the capping regime descriptor refer to the number of electrons donated to the metal center in the secondary bonding mode, which can be applied more than once so that the descriptor can be extended further if required. Each application of the secondary bonding mode invokes an additional 2-electron donation from borane to metal. The role of this secondary mode is to generate the *iso*-classes (see below).

The postulate that asymmetric borane ligands function as donors of only four rather than six electrons is provided by some observations on iron derivatives of pentaborane (Fig. 2) [10]. Thus, photolysis of the *nido*-pentaborane



9 **10**

Fig. 2. Photolytic decarbonylation of 2-{(η^5-C_5H_5)Fe($CO)_2$}-*nido*-B_5H_8 (**9**) to give *nido*-2-(η^5-C_5H_5)Fe(CO)B_5H_8 (**10**). For clarity the hydrogen atoms and other monovalent groups are omitted from this and subsequent figures.

derivative 2-{(η^5-C_5H_5)$(OC)_2$Fe}-*nido*-B_5H_8 (**9**), with an iron atom external to the B_5 cluster, expels a single CO ligand to give directly a *nido*-FeB_5 cluster with an asymmetric borane ligand, namely *nido*-2-(η^5-C_5H_5)(OC)FeB_5H_8 (**10**). In this reaction, the metal formal oxidation state ($\omega = +2$) and metal valence electron count ($\varepsilon = 18$) are both preserved. If the asymmetric borane ligand in the metallaborane functioned as a 6-electron donor in (**10**), a second molecule of CO would need to be expelled in order to conserve the metal valence electron count.

The capacity of symmetric borane ligands to behave as 6-electron donor ligands becomes apparent upon comparison of the *nido*-ferrahexaborane (**10**) with other related ferraboranes (Fig. 3) including the 7-vertex *closo*-(η^6-arene)-$FeC_2B_4H_4R_2$ (**11**) [11] and even the less closely related 12-vertex *closo*-(η^6-C_6H_6)$FeC_2B_9H_{11}$ (**12**) [12]. Such comparisons indicate that when a symmetric borane ligand is present, there is no capacity for an additional two-electron donor ligand, such as CO, on the metal atom in the more symmetrical environment, in accord with a metal valence electron count of 18. Moreover, this cannot simply be attributed to steric hindrance as indicated by the 7-vertex *closo*-(η^5-C_5H_5)(H)$FeC_2B_4H_6$ (**13**) [10] closely related to **(11)**.

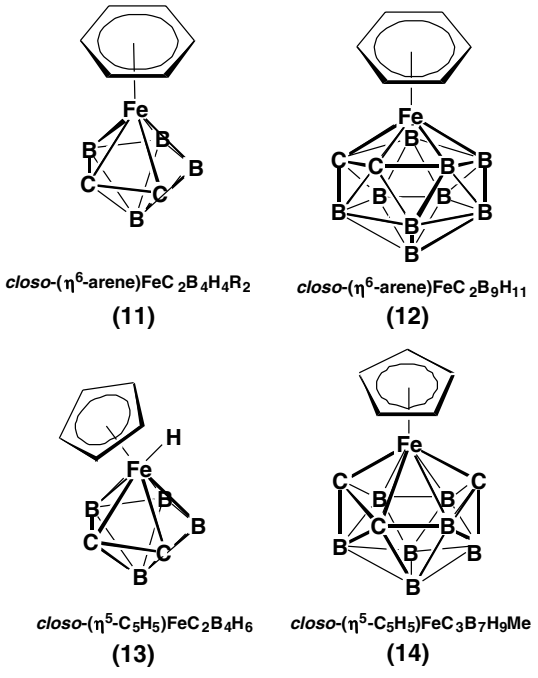


Fig. 3. Some ferracarborane derivatives.

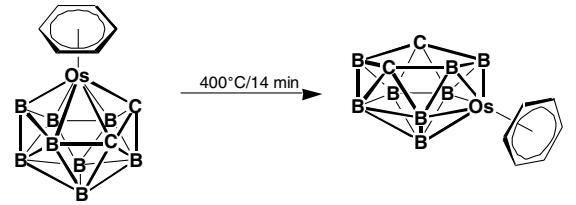

Fig. 4. A rearrangement in the 11-vertex osmacarborane series.

The fact that the "asymmetric" *arachno*-B_5H_8 ligand, acting as a 4-electron donor to the offset Fe center in (**10**), changes to a symmetric 6-electron donor in (**13**) is supported by comparing (**10**) with the 11-vertex Fe(II) species *closo*-(η^5-C_5H_5)$FeC_3B_7H_9Me$ (**14**) (Fig. 3) [13]. Here, the *nido*-$C_3B_7H_9Me$ ligand must be acting as a 6-electron donor by virtue of the loss of the CO ligand from the Fe center. The formulation of (**14**) as an authentic Fe(II) species, rather than an Fe(IV) species, is supported by the ease of oxidation of (**14**) to its Fe(III) analogue by Ag^+ ion.

A metallaborane obeying the Wade–Mingos rules [2] is not always the most stable possible isomer. For example, when *closo*-(η^6-Me_6C_6)$OsC_2B_8H_8Me_2$ (**15**), a cluster obeying the Wade–Mingos rules, is heated at 400 °C for 14 min, the *nido* isomer (**16**) is obtained in quantitative yield (Fig. 4) [14]. This product violates the Wade–Mingos rules and yet is clearly thermodynamically preferred. The abnormally long Os–B distances in (**16**) indicate that the osmium atom is in a lower formal oxidation state than is usually observed in osmaboranes, which are always assumed to contain Os(II) through isolobal considerations. The formal oxidation state in the *nido* isomer (**16**) is probably Os(0).

There are examples where an *isonido* structure is obtained when the *closo* isomer is predicted according to the Wade–Mingos rules [2]. Moreover, *nido*-2-(η^6-Me_6C_6)-RuB_9H_{13} (**17**) has been isolated with a hexagonal open face (Fig. 5) along with its *isoarachno*-1-(η^6-Me_6C_6)RuB_9H_{13} isomer (**18**) with a heptagonal open face [15]. In going from the *nido* isomer (**17**) to the corresponding *isoarachno* isomer

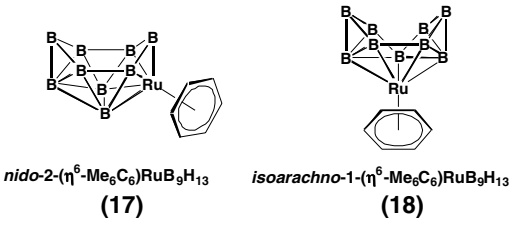

Fig. 5. Two isomers of (η^6-Me_6C_6)RuB_9H_{13}.

(**18**), one of the B–B edges is lengthened from ~2.00 Å in (**17**) to 2.50 Å in (**18**).

In some cases *closo* and *isonido* isomers have been found to lie on a structural continuum. Thus, metallaboranes with 9, 10 and 12 vertices have been isolated that exhibit structures intermediate between the two geometrical extremes [5c,16]. In addition, there is a case where a fluxional process has been observed to occur in solution, indicating that the two extreme geometries can possess very similar ground state energies, i.e., *trans*{*closo*-(η^6-$MeC_6H_4Pr^i$)$RuC_2B_9H_9Ph$}$_2$-(CH=CH) (**19**) versus an isomer in which one of the two (η^6-$MeC_6H_4Pr^i$)$RuC_2B_9H_9Ph$ units has changed from *closo* to *isonido* geometry by stretching the C···C distance in one of the RuC_2B_9 polyhedra from 1.77 to 2.36 Å [17]. The continuum can be explained in electronic terms by a smoothly progressive change in the capping regime from *closo* {**600**} to *isonido* {**420**} that, in turn, is permitted by the selection rules for rearrangement processes in polyhedra. Indeed, in support of this conjecture, an intrinsic mirror plane is retained throughout the "budding" open face in all of these cases. There are no known *closo–isonido* continua without this symmetry element being present.

The metallaboranes displaying structures between the *closo* and *isonido* isomers can be considered to be clusters in which the diamond–square component of a diamond–square–diamond (dsd) transformation [18] is "frozen". Although many examples of "frozen" dsd processes are known, no known metallaboranes exhibit structures lying along the square–diamond part of the dsd transformation. In terms of cluster geometry, this corresponds to the *isonido–isocloso* transformation. The lack of examples on this "discontinuum" is easily explicable from Table 1 by virtue of the fact that an *isonido–isocloso* transformation requires a discrete change in the metal formal oxidation state at the metal atom. This constitutes a "catastrophic flip" [19] so a continuum is not possible.

We can now use the capping regime to access previously unimagined cluster geometries. By ascribing to the *closo* form an arbitrary formal metal oxidation state, Y, and an arbitrary metal valence electron count, Z, the *closo/nido* electrostructural correlation table shown in Table 1 can be generated where Z remains constant, typically the favored 18-electron rare gas configuration for transition metals.

The "idealized" capping regimes specified in Table 1 depend upon the nodal plane-related symmetry characteristics of the borane ligand as well as the acceptor capability and the stereochemical preference of the metal center under consideration. The following aspects of the capping regimes indicated in Table 1 should be noted:

Table 1
The *closo/nido* electrostructural correlation table

Geometry (G)	*isoisocloso*	*isocloso*	*closo*	*isoisonido*	*isonido*	*nido*
Formal metal oxidation state (ω)	$Y+4$	$Y+2$	Y	$Y+2$	Y	$Y-2$
Capping regime	{622}	{620}	{600}	{422}	{420}	{400}
Metal valence electrons (ε)	Z	Z	Z	Z	Z	Z

Table 2
The *nido*/*arachno* electrostructural correlation table

G	*isoisonido*	*isonido*	*nido*	*isoisoarachno*	*isoarachno*	*arachno*
Formal metal oxidation state (ω)	$Y+2$	Y	$Y-2$	Y	$Y-2$	$Y-4$
Capping regime	{422}	{420}	{400}	{422}	{420}	{400}
Metal valence electrons (ε)	Z	Z	Z	$Z+2$	$Z+2$	$Z+2$

(1) A {**400**} capping regime would result in a complete, single capping of an open face that would normally be accorded a {**600**} capping regime, e.g., as in 11-vertex *closo*-PtC_2B_8 species derived from d^8 Pt(II) capping fragments ($\varepsilon = 12$), in "slipped *closo*" structures and also in *nido*-2,8,10-(η^6-Me_6C_6)-$OsC_2B_8H_8Me_2$ (**16**) with its unusual "canastide" type borane ligand (Fig. 4).

(2) A {**600**} capping regime, not {**400**}, is required to generate a *nido*, *arachno*, etc., structures with C_{nv} symmetry; as in the well-known C_{4v} *nido*-1-$CpCoB_4H_8$ (**20**) and its hypothetical homologue C_{5v} *nido*-1-$CpCoB_{10}H_{14}$ (**21**) (Fig. 6).

(3) A {**420**} capping regime, not {**620**}, results in an "unsymmetrical" *isocloso* structure.

(4) A {**422**} capping regime, not {**622**}, gives a less symmetrical *isoisocloso* structure, as in the putative Mo(IV) $[(\eta^3\text{-}C_3H_5)(OC)_2MoC_2B_9H_9Ph_2]^-$ ion (**22**) derived from an *arachno*-$C_2B_9H_9Ph_2^{4-}$ ligand and containing an irregular MoC_2B_9 icosahedron with two degree 6 vertices (the Mo vertex and a nearly antipodal B vertex), eight degree 5 vertices, and two degree 4 vertices (the two carbon vertices) (Fig. 7) [20].

An analogous *nido*/*arachno* electrostructural correlation table can be generated (Table 2).

The *isoiso* cluster geometries requiring more than one dsd transformation [18] from the most spherical deltahedron with the same number of vertices can be defined as "exotic". Such clusters exhibit highly oblate structures deviating considerably from a "spherical" geometry. Several examples of *isoiso* structures are known including not only the $[(\eta^3\text{-}C_3H_5)(OC)_2MoC_2B_9H_9Ph_2]^-$ ion discussed above (**22**: Fig. 7) but also the Re_2B_n ($n = 6$–9) and related W_2B_7 and W_3B_8 deltahedra [21] requiring two dsd transformations from the most spherical deltahedra (Fig. 8). A "supra-exotic" species, (η^5-Me_5C_5)$_2Re_2B_{10}H_{10}$ (**23**) [21c] (Fig. 8) is also known requiring four dsd transformations from the corresponding most spherical deltahedron. Since each "*iso*" dsd process requires an increase of two units in the formal metal oxidation state, such "exotic" metallaboranes are found with second and third row transition metals exhibiting relatively high oxidation states, notably molybdenum, tungsten, and rhenium. Furthermore, the two rhenium atoms in each of the oblate Re_2B_n deltahedra provide sites for the internal oxidative addition reactions required for the dsd processes to form the observed oblate deltahedra.

The "exotic" dirhenaboranes in Fig. 8 all have $2n - 4$ apparent skeletal electrons rather than the $2n + 2$ skeletal electrons required by the Wade–Mingos rules [2] for *closo*

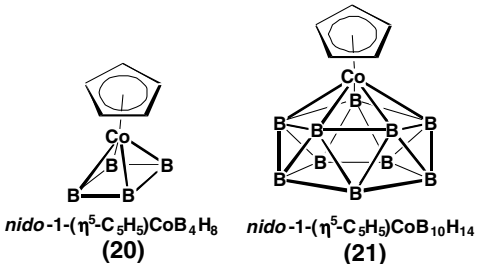

Fig. 6. Some *nido* cobaltaboranes with C_{nv} symmetry.

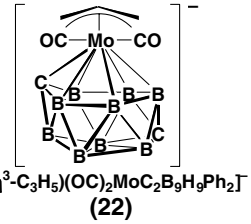

Fig. 7. An irregular icosahedral MoC_2B_9 molybdacarborane.

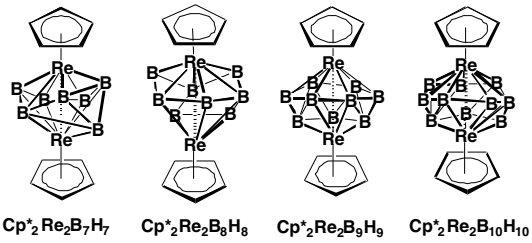

Fig. 8. Some "*isoisocloso*" and more "exotic" dirhenaboranes with oblate Re_2B_n deltahedra ($Cp^* = \eta^5$-Me_5C_5; methyl groups and hydrogen atoms omitted for clarity).

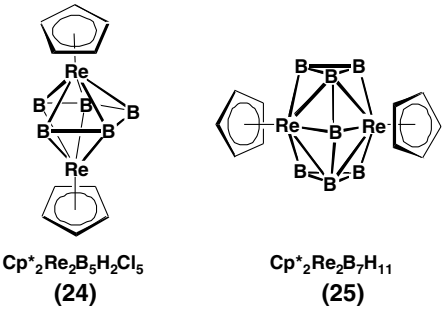

Fig. 9. The complexes $Cp^*_2Re_2B_5H_2Cl_5$ and $Cp^*_2Re_2B_7H_{11}$ ($Cp^* = \eta^5$-Me_5C_5; methyl groups, hydrogen atoms, and chlorine atoms omitted for clarity).

deltahedra assuming the Cp^*Re vertices and BH vertices to be donors of zero and two skeletal electrons, respectively. Related "exotic" *nido*- and *arachno*-type species (Fig. 9) are $Cp^*_2Re_2B_5H_2Cl_5$ (**24**) [21c] and $Cp^*_2Re_2B_7H_{11}$ (**25**) [22], respectively. Both of these species also have six fewer apparent skeletal electrons than required by the Wade–Mingos rules.

4. Summary

Relationships have been observed between the metal formal oxidation state and the metal valence electron counts in *closo*/*isocloso* and *nido*/*isonido* pairs of polyhedral metallaboranes. In general, the metal formal oxidation state increases by two units in a *closo* → *isocloso* or *nido* → *isonido* structural transformation, generally involving diamond–square–diamond processes. More exotic "*isoiso*" structures are found for metallaboranes containing metals exhibiting relatively high formal oxidation states such as molybdenum, tungsten, and rhenium.

The free borane ligand obtained by removal of the metal vertex from a metallaborane structure can be classified as symmetric or asymmetric depending upon the nature of the metal–ligand bond. In symmetric borane ligands found in *closo* metallaboranes, the metallaborane structure is generated by symmetrical "centroid" metal capping of the ligand open face. However, in asymmetric borane ligands found in *nido* metallaboranes, the metallaborane structure is generated by skew-symmetric or offset metal capping of the ligand open face. Capping regime descriptors are defined to describe these types of metal–borane bonding. In addition, electrostructural correlation tables are presented for *closo*/*nido* and *nido*/*arachno* pairs relating metal formal oxidation states, the numbers of metal valence electrons, and the capping regime descriptors.

Nomenclature

dppa	bis(diphenylphosphino)amine	dpp^{n}pr	bis(diphenylphosphino)*n*-propylamine
dppm	bis(diphenylphosphino)methane	OTf	trifluoromethane sulfonate anion
dppi-Pr	bis(diphenylphosphino)isopropylamine		

method adopted by us is outlined in (Scheme 1), in which silver triflate was used as the halide scavenger. To our surprise, this method did not yield the targeted ruthenium bipyridyl diphosphazane complexes; instead, silver(I) complexes of diphosphazanes were obtained, thus providing an unexpected entry into the silver(I) chemistry of diphosphazane ligands. Subsequently, the silver(I) complexes of the diphosphazanes, $Ph_2PN(Pr^i)PPh(OC_6H_3Me_2\text{-}2,6)$ ($\mathbf{L}^1$), $Ph_2PN(Pr^i)PPh_2$ ($\mathbf{L}^2$) and $Ph_2PN(H)PPh_2$ ($\mathbf{L}^3$) have been synthesized by the reactions of appropriate silver salts with these ligands. The silver(I) complexes have been characterized by ^1H, and $^{31}P\{^1H\}$ NMR spectroscopy, and the structures of some representative complexes determined by single crystal X-ray diffraction studies. The results of these studies are reported in this paper. While the silver(I) complexes of diphosphinoalkanes have been explored extensively [8,9], similar studies on "P–N–P" based ligands are limited mainly to the three ligands, $Ph_2PN(R)PPh_2$ (R = H, Me or *n*-Pr) [10–15].

2. Experimental

All reactions were carried out under an atmosphere of dry nitrogen by using standard Schlenk-line techniques. The ligands $Ph_2PN(Pr^i)PPh_2$ ($\mathbf{L}^2$) and $Ph_2PN(H)PPh_2$ ($\mathbf{L}^3$) were prepared using published procedures [16]. The syntheses of the silver complexes were carried out under dark conditions owing to the sensitivity of these compounds to light. Solvents were purified by standard procedures and freshly distilled prior to use. The ^1H and $^{31}P\{^1H\}$ NMR spectra were recorded in $CDCl_3$ using a Bruker Avance-400 spectrometer with Me_4Si as an internal standard for ^1H NMR measurements and 85% H_3PO_4 as an external standard for ^{31}P NMR measurements. The variable temperature $^{31}P\{^1H\}$ NMR experiments were carried out in CD_2Cl_2 from 183 to 303 K. Chemical shifts downfield from the standard were assigned positive values. Infrared spectra were recorded using a Perkin–Elmer Model 457 spectrometer. Elemental analyses were carried out using a Perkin–Elmer 2400 CHN analyzer.

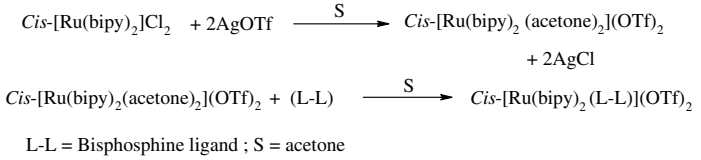
2.1. Synthesis of $Ph_2PN(Pr^i)PPh(OC_6H_3Me_2\text{-}2,6)$ (L^1)

A solution of PPh_2Cl (3.6 mL, 0.02 mol) in 20 mL benzene was added drop wise with stirring to a solution of isopropyl amine (5.12 mL, 0.06 mol) in 30 mL benzene at 0 °C. The reaction mixture was stirred at room temperature for 6 h and was filtered to remove the precipitated isopropyl amine hydrochloride. The filtrate was evaporated to dryness under vacuum to give the aminophosphane $Ph_2PNH(Pr^i)$ as a viscous oil. The oily residue was redissolved in benzene, and triethylamine (4.16 mL, 0.03 mol) added. The solution was cooled to 0 °C, and $PPhCl_2$ (2.71 mL, 0.02 mol) in benzene was added drop wise with stirring. The reaction mixture was stirred for 6 h at room temperature and filtered. The filtrate was evaporated to dryness and the residue dissolved in THF. This solution was added drop wise at room temperature to sodium 2,6-dimethylphenoxide, which was prepared by adding sodium hydride (60% dispersion in paraffin), (0.80 g, 0.016 mol) to a solution of 2,6-dimethylphenol (1.952 g, 0.016 mol) in dry THF. The reaction mixture was stirred at 30 °C for 5 h and evaporated to dryness. The residue was chromatographed on silica gel using benzene-petroleum ether (1:1 v/v) as the eluant. A concentrated solution of the ligand in $CHCl_3$ when cooled at 0 °C for 24 h gave colorless transparent crystals. Yield: 5.7 g, 60%. *Anal.* Calc. for $C_{29}H_{31}N_1O_1P_2$: C, 73.9; H, 6.6; N, 3.0. Found: C, 73.8; H, 6.6; N, 2.8%. ^1H NMR ($CDCl_3$, 293 K): δ 0.84, 1.38 (d, $CHMe_2$), 2.12 (s, $C_6H_3Me_2$), 3.99 (m, $CHMe_2$), 6.8–7.5 (m, aryl protons). $^{31}P\{^1H\}$ NMR ($CDCl_3$, 293 K): δ 36.5 (s), 121.8 (s). IR (KBr, cm^{-1}): 3443 w, 3202 w, 2960 s, 1600 s, 1260 s, 797 s, 695 s.

2.2. Synthesis of $[Ag_3(\mu\text{-}Cl)_2\{Ph_2PN(Pr^i)PPh_2\}_3]X$, ($X = NO_3$, PF_6) (**1a**, **1b**)

2.2.1. Method A

A solution of $Ru(bipy)_2Cl_2\cdot 2H_2O$ [7] (0.325 g, 6.25×10^{-4} mol) and $AgNO_3$ (0.138 g, 8.125×10^{-4} mol) in acetonitrile was stirred for 30 min after which Ph_2PN-



Scheme 1. Procedure adopted for the attempted synthesis of diphosphazane-bipyridyl complexes of ruthenium.

(Pr^i)PPh_2 (**L^2**) (0.267 g, 6.25×10^{-4} mol) was added. The reaction mixture was stirred for 3 h, and passed through a short plug (7 cm × 2 cm) of celite. The filtrate was concentrated under vacuum to ~5 mL. Colorless crystals of (**1a**) appeared over a period of 24 h. Yield: 0.85 g, 60%. *Anal.* Calc. for (**1a**): $C_{81}H_{81}Ag_3Cl_2N_4P_6O_3$: C, 55.8; H, 4.7; N, 3.2. Found: C, 55.7; H, 4.6; N, 3.2%. ^{1}H NMR ($CDCl_3$, 293 K): δ 0.32 (d, 18H, CHMe_2), 3.82 (s br, 3H, CHMe$_2$), 7–7.5 (m, 60H, C_6H_5). ^{31}P {^{1}H} NMR ($CDCl_3$, 293 K): δ 72.0 (s br). IR (Nujol, cm^{-1}): 3428 m, 3049 s, 2978 s, 1481 s, 1322 s, 1127 s, 1316 s, 967 s, 887 s, 855 s, 696 s, 424 m, 385 m, 342 m, 312 w.

The complex (**1b**) could be obtained from (**1a**) by a metathesis reaction, using a twofold excess of NH_4PF_6 in acetone. Yield (**1b**): 0.86 g, 58% (see below for characterization data).

2.2.2. Method B for (*1b*)

A solution of AgCl (0.117 g, 8.125×10^{-4} mol) and $Ph_2PN(Pr^i)PPh_2$ (0.521 g, 1.22×10^{-3} mol) in piperidine (20 mL) was stirred at room temperature for 12 h. Solvent was evaporated from the reaction mixture and freshly distilled acetone (20 mL) was added followed by the addition of a twofold excess of NH_4PF_6. The reaction mixture was stirred for a further period of 1 h; solvent was evaporated and the residue redissolved in the minimum quantity of dichloromethane (2 mL). The addition of diethyl ether gave a precipitate of the title complex (**1b**) in 40% yield (0.60 g). *Anal.* Calc. for (**1b**): $C_{81}H_{81}Ag_3Cl_2F_6N_3P_7$: C, 53.3; H, 4.4; N, 2.3. Found: C, 53.5; H, 4.5; N, 2.3%. ^{1}H NMR ($CDCl_3$, 293 K): δ 0.30 (d, 18H, CHMe_2), 3.76 (s br, 3H, CHMe$_2$), 7.0–7.7 (m, 60H, C_6H_5). ^{31}P{^{1}H} NMR ($CDCl_3$, 293 K): δ 73.5 (s, br). IR (Nujol, cm^{-1}): 3422 m, 3053 s, 2989 s, 1481 s,1127 s, 959 s, 887 s, 851 s, 695 s, 420 m, 382 m, 348 m, 322 w.

2.3. Synthesis of [$Ag_3(\mu$-$Cl)_2\{Ph_2PN(H)PPh_2\}_3$]X, (X = NO_3, PF_6) (*2a, 2b*)

Complexes (**2a**, **2b**) were prepared by the same procedures (method A for (**2a**), (**2b**); method B for (**2b**)) as described above for complexes (**1a**, **1b**) except that the ligand $Ph_2PN(H)PPh_2$ (**L^3**) was used instead of (**L^2**). Yield (**2a**): 0.56 g, 40% (method A). *Anal.* Calc. for (**2a**): $Ag_3C_{72}H_{63}N_4O_3P_6Cl_2$: C, 52.5; H, 3.9; N, 3.5. Found: C, 52.4; H, 4.0; N, 3.4%.

^{1}H NMR ($CDCl_3$, 293 K): δ 4.52 (s, 3H, NH), 6.9–7.4 (m, 60H, C_6H_5). ^{31}P {^{1}H} NMR ($CDCl_3$, 293 K): δ 53.0 (d, ^1J (^{31}P, Ag) = 452 Hz). IR (Nujol, cm^{-1}), (**2a**): 3289 s, 3160 s, 3058 m, 1574 m, 1312 s, 982 m, 897 m, 501 s, 432 s, 423 w, 385 w, 360 m, 330 m.

Yield (**2b**): 0.58 g, 40% (method A); 0.48 g, 33% (method B). *Anal.* Calc. for (**2b**) $C_{78}H_{75}Ag_3Cl_2F_6N_3O_2P_7$: C, 51.6; H, 4.1; N, 2.3. Found: C, 52.0; H, 4.0; N, 2.2%. ^{1}H NMR (**2b**) ($CDCl_3$, 293 K): δ 4.44 (s, 3H, NH), 7.0–7.6 (m, 60H, C_6H_5). ^{31}P {^{1}H} NMR (**2b**) ($CDCl_3$, 293 K): δ 52.5 (d, ^1J (^{31}P, Ag) = 450 Hz). IR (Nujol, cm^{-1}), (**2b**): 3286 s, 3168 s, 3050 m, 1584 m, 928 m, 900 m, 506 s, 437 s, 421 w, 380 w, 367 m, 319 m.

2.4. Synthesis of [$Ag(Ph_2PN(Pr^i)PPh_2)X]_2$ (X = NO_3, OTf) (*3a, 3b*)

The ligand $Ph_2PN(Pr^i)PPh_2$ (**L^2**) (0.267 g, 6.25×10^{-4} mol) was added to a solution of AgOTf (0.160 g, 6.25×10^{-4} mol) in acetonitrile at room temperature and the reaction mixture stirred for 4 h. Solvent was removed from the reaction mixture and the resulting colorless solid was redissolved in dichloromethane. The solution was passed through a short plug of celite (7 cm × 2 cm) and concentrated to ~5 mL. Colorless micro-crystals of (**3b**) appeared over a period of 24 h. Yield: 0.53 g, 62%. *Anal.* Calc. for (**3b**): $C_{56}H_{54}Ag_2F_6N_2O_6P_4S_2$: C, 49.0; H, 3.9; N, 2.0. Found: C, 49.2; H, 3.9; N, 2.2%. ^{1}H NMR ($CDCl_3$, 293 K): δ 0.59 (s br, 12H, CHMe_2), 3.94 (s br, 2H, CHMe$_2$), 7.2–7.6 (m, 40H, C_6H_5). ^{31}P{^{1}H}NMR ($CDCl_3$, 293 K): δ 81.8 (t, br). IR (Nujol, cm^{-1}), (**3b**): 3468 s, 3050 m, 2584 m, 1611 m, 1263 w, 1226 s, 1170 s, 968 m, 506 s, 421 w, 367 m, 305 m.

Complex (**3a)** was prepared by following the same procedure as above for (**3b)** using $AgNO_3$ in place of AgOTf. Yield (**3a**): 0.41 g, 55%. *Anal.* Calc. for (**3a**): $C_{54}H_{54}Ag_2N_4O_6P_4$: C, 54.2; H, 4.5; N, 4.7. Found: C, 54.0; H, 4.6; N, 4.7%. ^{1}H NMR ($CDCl_3$, 293 K): δ 0.61 (s br, 12H, CHMe_2), 3.90 (s br, 2H, CHMe$_2$), 7.1–7.6 (m, 40H, C_6H_5). ^{31}P{^{1}H}NMR ($CDCl_3$, 293 K): δ 82.0 (s, br). IR (Nujol, cm^{-1}), (**3a**): 3478 w, 3059 m, 2979 m, 1609 w, 1474 m, 1315 s, 1261 s, 964 m, 695 s, 570 s, 515 m, 411 s, 332 m, 307 w.

2.5. Synthesis of [$Ag\{Ph_2PN(Pr^i)PPh(OC_6H_3Me_2$-2,6)$\}_2$]-($PF_6$) (*4*)

The ligand $Ph_2PN(Pr^i)PPh(OC_6H_3Me_2$-2,6) (**$L^1$**) (0.589 g, 12.5×10^{-4} mol) was added to a solution of $AgNO_3$ (0.106 g, 6.25×10^{-4} mol) in acetonitrile at room temperature and the reaction mixture stirred for 24 h followed by the addition of a twofold excess of NH_4PF_6. The reaction mixture was stirred for a further period of 1 h; the colorless precipitate was filtered off using a Whatman No. 42 filter paper. The filtrate was concentrated to 5 mL, 5–6 drops of $CHCl_3$ were added, and the solution kept at 0 °C for 2 days to obtain colorless micro-crystals of the title compound. Yield: 0.52 g, 70%. *Anal.* Calc. for (**4**): $C_{58}H_{62}AgF_6N_2O_2P_5$: C, 58.2; H, 5.2; N, 2.3. Found: C, 58.4; H, 5.3; N, 2.2%. ^{1}H NMR ($CDCl_3$, 293 K): δ 1.41, (s br, 12H, CHMe_2), 2.19 (s, 12H, $C_6H_3Me_2$), 4.2 (m, 2H, CHMe$_2$), 7.5–6.8 (m, 36H, C_6H_5).

^{31}P {^{1}H} NMR ($CDCl_3$, 293 K): δP_A 136.0 ppm (s, br), δP_B 83.0 ppm (s, br). IR (Nujol, cm^{-1}): 3413 w, 3122 s, 2966 s, 1650 s, 1240 s, 798 s, 692 s, 615 m.

2.6. Synthesis of $[Ag\{Ph_2PN(Pr^i)PPh_2\}_2](PF_6)$ (**5**)

The ligand $Ph_2PN(Pr^i)PPh_2$ (L^2) (0.534 g, 12.5×10^{-4} mol) was added to a solution of $AgNO_3$ (0.160 g, 6.25×10^{-4} mol) in acetonitrile. The reaction mixture was stirred for 5 h at room temperature followed by the addition of a twofold excess of NH_4PF_6. The reaction mixture was stirred for a further period of 1 h; solvent was evaporated to dryness. The colorless solid residue was redissolved in CH_2Cl_2–$CHCl_3$ mixture (1:1 v/v), and the solution passed through a plug of celite and concentrated to ~15 mL. This solution was added drop wise to 30 mL of diethyl ether with rapid stirring. The colorless fluffy solid that precipitated was filtered, washed with diethyl ether (2×20 mL) and dried in air. Yield: 0.51 g, 73%. *Anal.* Calc. for $AgC_{54}H_{54}N_2P_5F_6$ (**5**): C, 58.5; H, 4.9; N, 2.5. Found: C, 58.1; H, 4.9; N, 2.6%. ^{1}H NMR ($CDCl_3$, 293 K): δ 0.60 (s br, 12H, CHMe_2), 3.78 (m, 2H, CHMe$_2$), 7.2–7.4 (m, 40H, C_6H_5). ^{31}P {^{1}H} NMR ($CDCl_3$, 293 K): δ 89.9 (s br). IR (Nujol, cm^{-1}): 3245 w, 3049 s, 2873 s, 1712 s, 1435 s, 965 s, 696 s, 516 s, 367 s, 319 s.

2.7. X-ray crystallography

Crystal data for the ligand (L^1) and the complexes (**1b**), (**2b**), (**3b**) and (**4**) were collected on a BRUKER SMART APEX CCD diffractometer with a D8 goniometer (graphite-monochromated Mo Kα radiation, $\lambda = 0.71073$ Å) using the SMART software [17a]. The data was integrated with SAINT [17b] and an empirical absorption correction was applied using SADABS [17c]. The structure was solved by SIR 92 [18a] or by Patterson method using SHELXS-97 [18b] and refined by full-matrix least-squares methods against F^2 (SHELXL-97) [18c]. All non-hydrogen atoms were refined with anisotropic displacement parameters and hydrogen atoms were placed in their calculated positions. Attempts to improve the data quality of (**2b**) were unsuccessful due to the poor stability of the compound when subjected to X-rays. The details of the structure solution and refinement are given in Table 1.

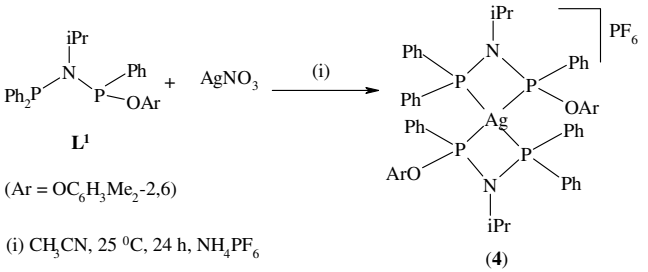
3. Results and discussion

3.1. Synthesis and NMR spectroscopic studies

When the reaction of $Ru(bipy)_2Cl_2 \cdot 2H_2O$ with the diphosphazane ligand $Ph_2PN(R)PPh_2$ ($R = Pr^i$, H) is carried out in the presence of a silver salt AgX ($X = NO_3$, OTf), a trinuclear silver species analogous to (**1a**) or (**2a**) is obtained in modest yield. The ruthenium precursor merely acts as a source of chloride ions in the formation of these trinuclear Ag(I) complexes, and no ruthenium bipyridyl complexes of diphosphazanes are formed.[2] Subsequently, the reactions of AgX salts with diphosphazane ligands (L^1–L^3) were carried out and the reaction conditions were optimized to obtain best yields of monuclear, binuclear and trinuclear silver complexes as outlined in Schemes 2–4 (see Section 2).

The reaction of the unsymmetrical ligand (L^1) with $AgNO_3$ in the presence of NH_4PF_6 gives the bischelate complex (**4**) in good yield (Scheme 2). The structure of (**4**) has been established by single crystal X-ray analysis

[2] A direct reaction of $[Ru(bipy)_2(MeCN)_2](PF_6)$ with the diphosphazane (L^2) in boiling MeCN was very sluggish and gave a P^{III} product with δ_P 79.0 (s) over a period of 48 h, along with a P^V species ($\delta_P \approx 30$); the two products could not be separated. Only a P^V species was formed if harsh conditions (DMSO, 120 °C) were employed.

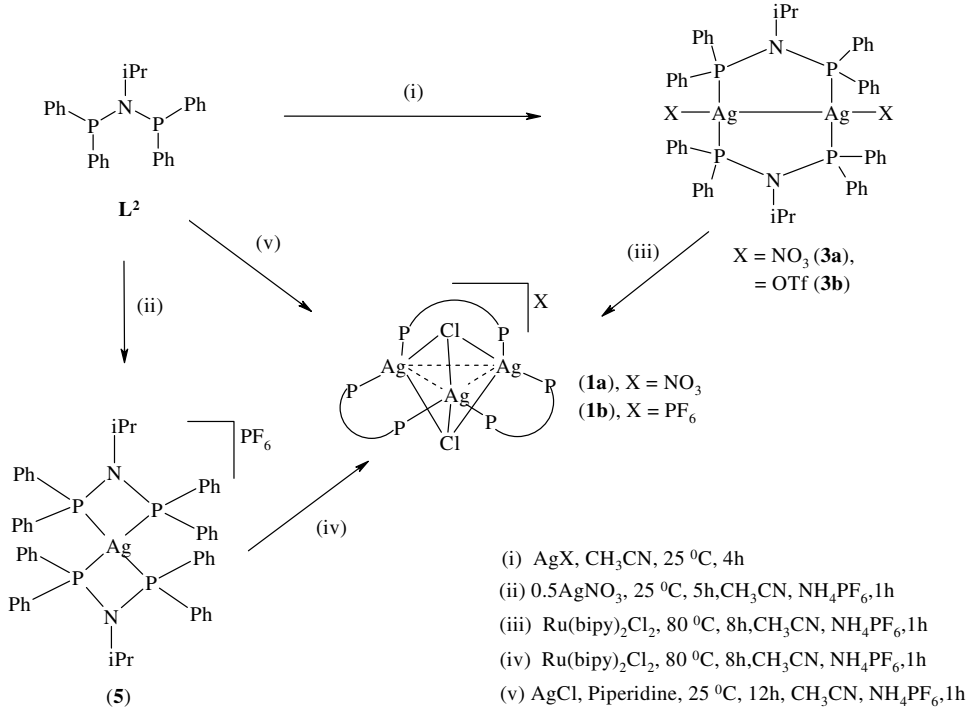


Scheme 2. Synthesis of mononuclear bischelate complex (**4**) using the unsymmetrical ligand ($\mathbf{L}^1$).

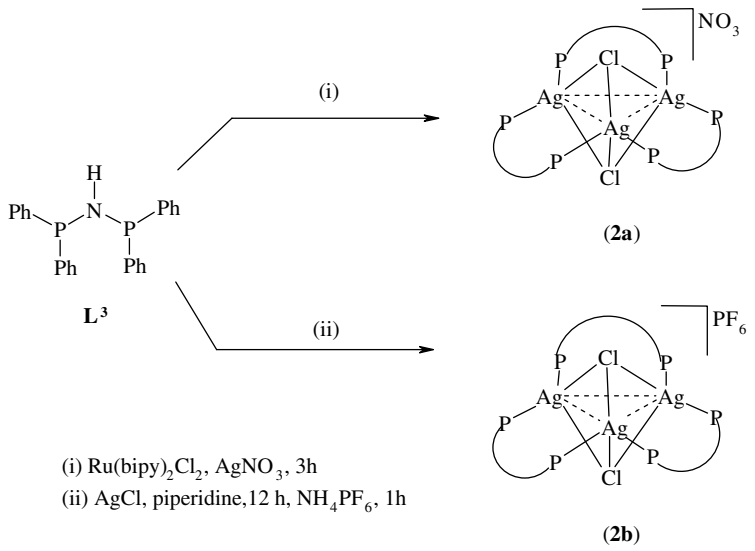
(see Section 3). The ^{31}P NMR spectrum of complex (**4**) at 293 K shows two broad peaks at 136.0 ppm and 83.0 ppm, which are assigned to the $-PPh_2(OAr)$ and the $-PPh_2$ phosphorus nuclei, respectively. These are shifted downfield compared to the ^{31}P chemical shifts for the free ligand. ($\delta_P = 121.8$ and 36.5 ppm, respectively). The ^{31}P NMR spectrum recorded at 183 K shows two symmetrical quartets, which constitute the AA′XX′ part of an AA′XX′M spin system. (A and X = P, M = Ag). Thus, complex (**4**) shows fluxional behavior in solution which is typical of the coordination chemistry of silver [8b,19]. The reaction of ligand ($\mathbf{L}^1$) with AgX (X = OTf, Cl) in a 1:1 or 1:2 molar ratio did not give products analogous to complex (**4**) when monitored by ^{31}P NMR spectroscopy, but instead formed a white intractable solid which could not be characterized any further.

The reaction of the symmetrical diphosphazane ($\mathbf{L}^2$) with $AgNO_3$ in a 1:1.3 ratio using $Ru(bipy)_2Cl_2 \cdot 2H_2O$ as the halide donor source gives the trinuclear complex (**1a**) (Scheme 3). Complex (**1b**) is prepared by the direct reaction of AgCl with ($\mathbf{L}^2$) in a 1:1.5 molar ratio in piperidine for 12 h, followed by counter ion metathesis using NH_4PF_6. The analogous complexes (**2a**, **2b**) of the ligand $Ph_2PNHPPh_2$ ($\mathbf{L}^3$) were obtained by following the same procedure (Scheme 4). Ellerman et al. have reported the synthesis of complex (**2b**) by the reaction of AgCl and ($\mathbf{L}^3$) in methanol [10a]. Structural assignment for this complex was based on analytical and spectroscopic data. The structures of (**1b**) and (**2b**) have been established by X-ray crystallography. The ^{31}P {^1H} NMR spectra of the trinuclear complexes $[Ag_3(\mu\text{-}Cl)_2\{Ph_2PN(Pr^i)PPh_2\}_3]X$ (X = NO_3, PF_6) (**1a**, **1b**) show a broad singlet (δ 72.0 ppm, br) at 293 K which is shifted downfield from the free ligand value ($\delta = 48.8$ ppm). The spectra of (**2a**) or (**2b**) show a doublet at 53.0 δ (δ free ligand = 43.1 ppm).

The silver salt AgX (X = NO_3, OTf) reacts with ($\mathbf{L}^2$) in a 1:1 molar ratio to form the binuclear complexes (**3a**) or (**3b**), respectively. The reaction of $AgNO_3$ with two molar equivalents of ($\mathbf{L}^2$) in acetonitrile in the presence of NH_4PF_6 gives the bischelate complex $[Ag\{Ph_2PN(Pr^i)\text{-}PPh_2\}_2](PF_6)$ (**5**) (Scheme 3). The molecular structure of (**3b**) has been established by X-ray crystallography (see Section 3). The ^{31}P NMR spectrum of $[Ag\{Ph_2PN(Pr^i)\text{-}PPh_2\}(NO_3)]_2$ (**3a**) shows a broad singlet at ~81.0 ppm, whereas that of $[Ag\{Ph_2PN(Pr^i)PPh_2\}(OTf)]_2$ (**3b**) displays a broad unresolved triplet at 81.8 ppm at 293 K with a $\Delta\delta$ value of ~33 ppm compared to the free ligand. This difference in the spectral pattern can be attributed to the effect of the counter ion on the Ag–P bond strength, which in turn would affect the Ag–P coupling constant [19b]. Complex (**3b**) contains a weakly coordinating anion such as triflate and probably exists essentially as an ionic species



Scheme 3. Synthesis of Ag(I) diphosphazane complexes of ligand ($\mathbf{L}^2$).



Scheme 4. Synthesis of trinuclear Ag(I) complexes (**2a**) and (**2b**) of the ligand ($\mathbf{L}^3$).

$[Ag_2(\mathbf{L}^2)_2]^{2+}[(OTf)_2]^{2-}$. By contrast, in complex (**3a**), the counter ion nitrate is strongly bound to the metal. The impact of the counter ion on the Ag–P bond has been well documented in the literature; larger ^1J (^{31}P, Ag) coupling constants are observed for silver(I) phosphine complexes containing the triflate ion [8d,19b]. The ^{31}P $\{^1$H$\}$ NMR spectrum of (**3b**) at 183 K appears as four distinct sets (1:1:1:1) centered at δ 98.4, 98.3, 71.7 and 68.1 ppm, respectively (Fig. 1). This result can be explained by assuming an exchange between two species (**3b**) and (**3b′**) at low temperature in CD_2Cl_2, as illustrated in (Scheme 5).

The isolation and X-ray crystallographic characterization of Ag(I) complexes $[Ag(CH_2Cl_2)(\eta^1\text{-}P_3N_3Cl_6)_2]X$ [20a] and $[Ag(CH_2Cl_2)_3]X$ [20b], in which dichloromethane is chelated to silver through its chlorine atoms lends credence to the above assumption. The ^{31}P $\{^1$H$\}$ NMR spectrum of (**5**) shows a broad resonance at 90.0 ppm at 293 K; the downfield shift compared to the free ligand value ($\Delta\delta = 41$ ppm) is maximum for this complex.

The reaction of AgOTf with ($\mathbf{L}^2$) in a 1:1 molar ratio was monitored by ^{31}P $\{^1$H$\}$ NMR spectroscopy (Fig. 2). The free-ligand resonance ($\delta = 48.8$ ppm, br) disappeared

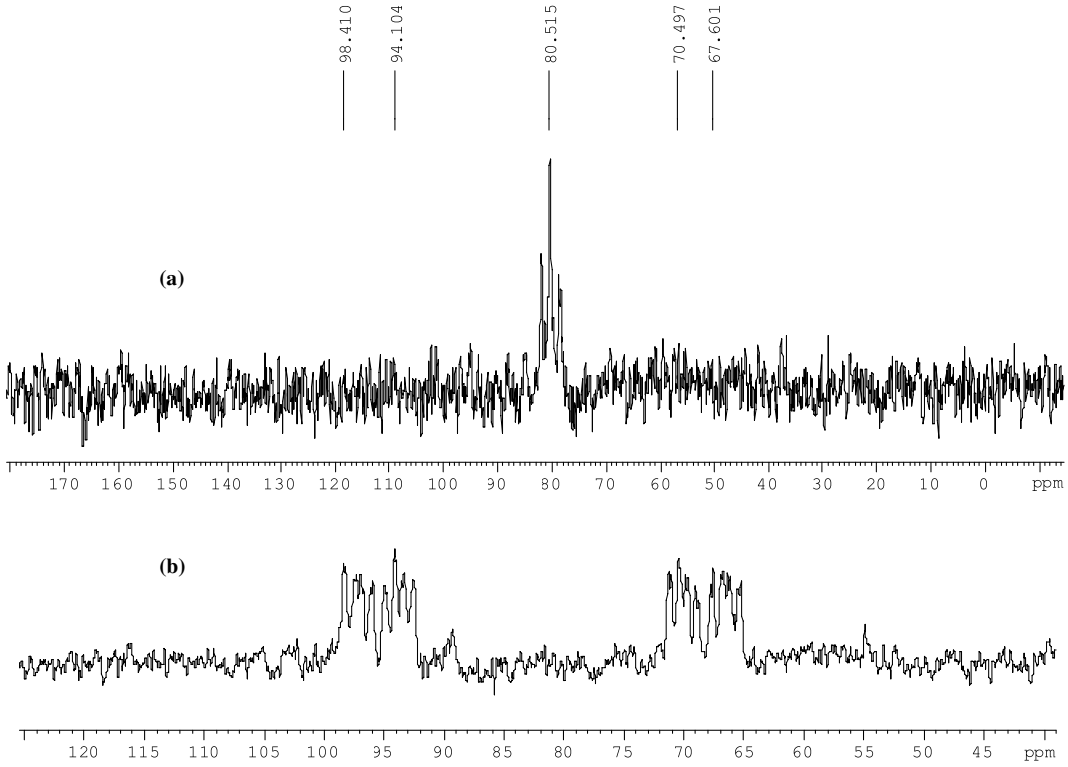


Fig. 1. The ^{31}P $\{^1$H$\}$ NMR spectrum of complex (**3b**) at 293 K (a) and 183 K (b) in CD_2Cl_2 solvent.

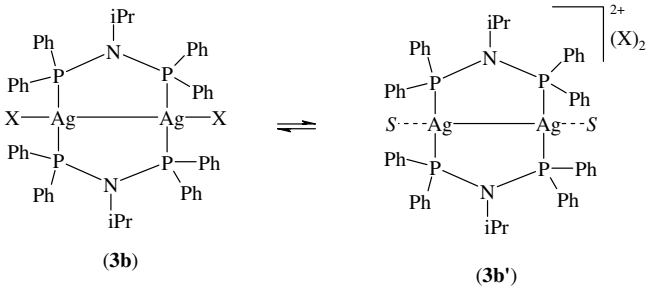

Scheme 5. Proposed structures for (**3b**) ⇋ (**3b**′) at 183 K.

completely within 15 min and two broad resonances at δ 52–55 ppm and 80 ppm appeared. The latter peak was assigned to complex (**3b**). The peak at δ 52–55 ppm which is attributed to an intermediate (**I**) disappeared over a period of 3 h at the expense of the resonance at 81 ppm (**3b**). When two more equivalents of the ligand $Ph_2PN(Pr^i)PPh_2$ ($\mathbf{L}^2$) were added to the reaction mixture of (**3b**) and (**I**) in the NMR tube, a single broad resonance at δ 90.0 ppm appeared immediately and the resonance at 80 ppm slowly disappeared. The resonance at δ 90.0 ppm was assigned to a mononuclear bischelate core as present in (**5**). Complex (**5**) could be isolated by adding NH_4PF_6 to the reaction mixture. Similarly, when an excess of ($\mathbf{L}^2$) was added to a mixture of the intermediate (**I**) (δ 52–55 ppm) and complex (**3b**), both the resonances disappeared completely and the resonances at δ 90 ppm due to (**5**) and the resonance at δ 48.8 ppm arising from unreacted ligand were observed (Fig. 2). This observation indicates that the intermediate species (**I**) is involved in the formation of both the complexes (**3b**) and (**5**). It is noteworthy that none of these complexes revert to the intermediate (**I**) under the given experimental conditions. It was further noted that, in the presence of a suitable chloride source in solution, the complexes (**3b**) and (**5**) transformed slowly to the trinuclear species at room temperature over a period of 20 h. The reaction occurred faster (within a period of 8 h) when the solution was heated under reflux. The ratio of free ligand to the silver salt appears to be the key factor that decides the nature of the complex formed, as noted previously [19,21]. The broad unresolved pattern at δ 52–55 ppm (293 K) attributed to intermediate species (**I**) splits into two doublets of equal intensity centered at δ 57.1 and 37.0 ppm at 183 K, with large Ag–P coupling constants of 812 Hz and 795 Hz (Fig. 3). The temperature dependence of the ^{31}P NMR spectra of the intermediate species (**I**) indicates that a dynamic chemical exchange process occurs in solution. We tentatively propose that the intermediate (**I**) consists of two species (**Ia**) and (**Ib**) in equilibrium (Scheme 6). Attempts to isolate and characterize the intermediate have been unsuccessful to date.

3.2. X-ray diffraction analyses

3.2.1. The crystal structure analysis of the ligand (L^1)

The solid-state structure of ligand ($\mathbf{L}^1$) has been determined by X-ray diffraction. A perspective view of the

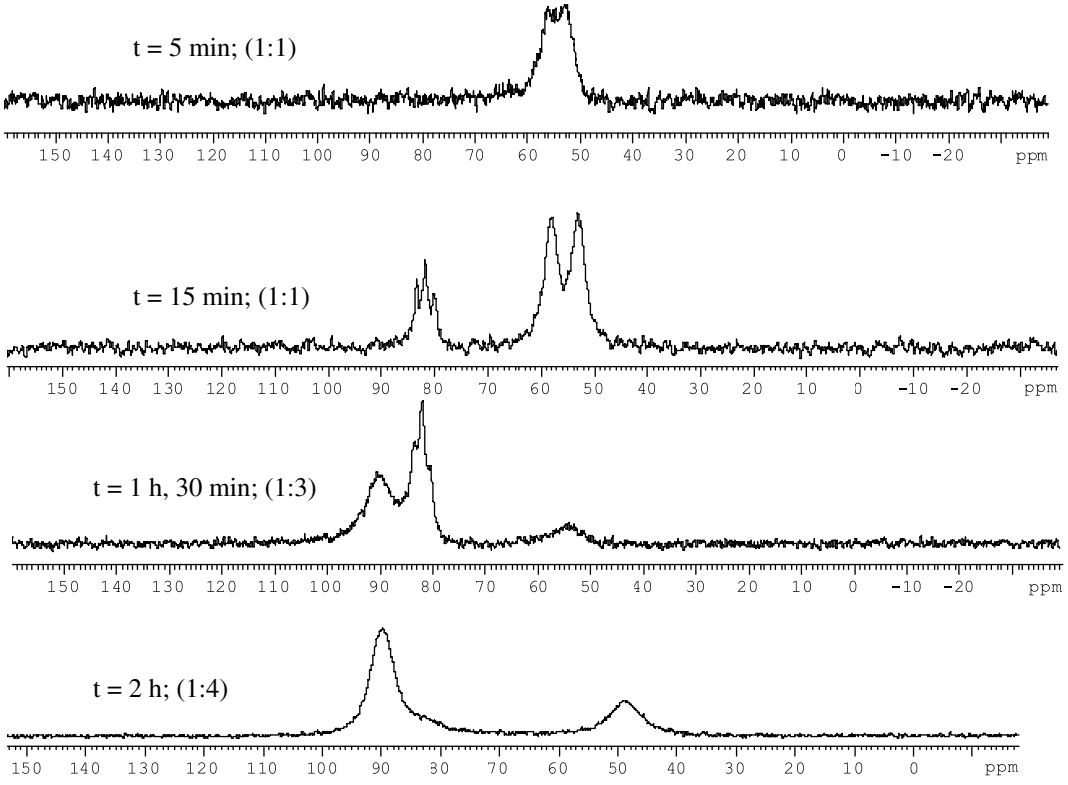

Fig. 2. ^{31}P NMR monitoring of the reaction of AgOTf with $Ph_2PN(Pr^i)PPh_2$ ($\mathbf{L}^2$) at 293 K in CD_2Cl_2 solvent. The ratios shown on each spectrum represents the relative proportions of AgOTf and ligand ($\mathbf{L}^2$).

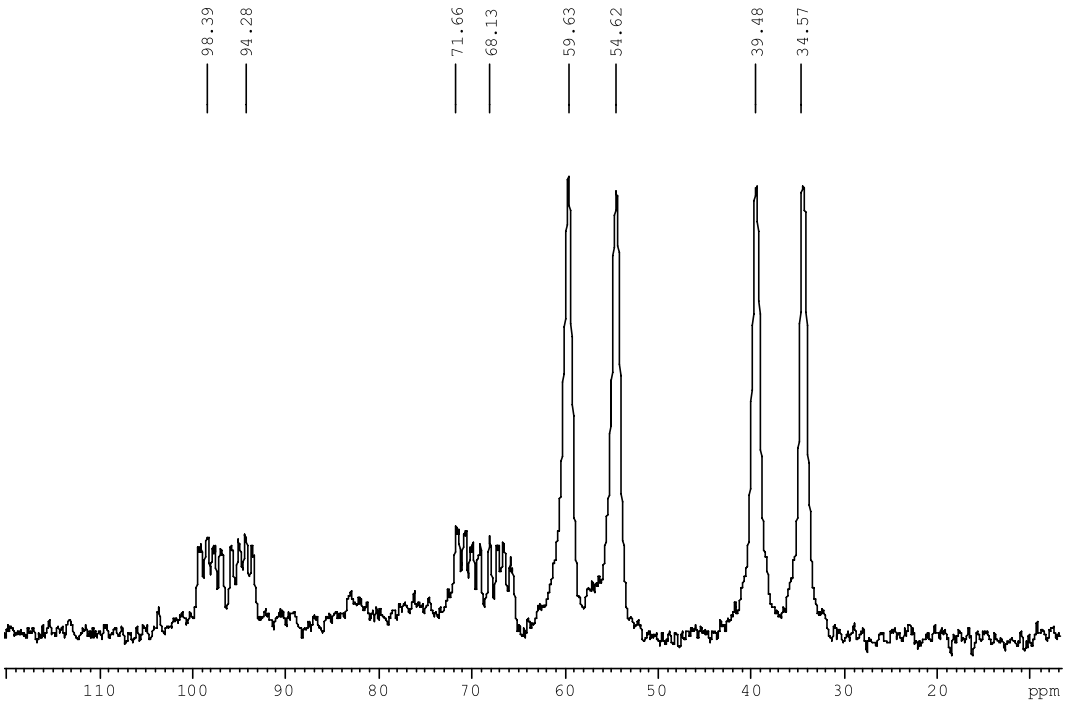

Fig. 3. The $^{31}P\{^{1}H\}$ NMR spectrum of complex (**3b**) and the intermediate (**I**) at 183 K in CD_2Cl_2 solvent.

molecule is shown in Fig. 4. Selected bond distances and bond angles are listed in Table 2. The geometry around the nitrogen atom is trigonal planar with a P–N–P angle of 122°. The ligand adopts a conformation wherein the lone pair on the PPh_2 phosphorus is oriented *trans* to the isopropyl group on the nitrogen atom whereas the lone pair on the PPh(OAr) fragment is *cis* to it. This is in contrast to the previous observation that the lone pair on the PPh_2 phosphorus in $Ph_2PN(Pr^i)P(O_2C_6H_4)$ [22a] and Ph_2PN-(CHMePh)PPh($N_2C_3HMe_2$-3,5) [22b] lies *cis* to the isopropyl group on nitrogen. The two phenyl rings subtend an angle of 101.5° at the PPh_2 phosphorus atom, but substituents on the PYY′ phosphorus subtend an angle of 94.7°. This could probably be due to the oxygen spacer, which relieves the steric strain arising from the 2,6- disubstituted aryl rings to some extent. Both the P–N bond lengths are nearly equal (1.71 Å) in the ligand ($\mathbf{L}^1$) and are close to the bond lengths observed for the diphosphazane ligands $Ph_2PN(Pr^i)PPh_2$ (1.71 Å) [23a] and $Ph_2PN((S)$-CHMePh)-PPh_2 (1.72 Å) [23b]. Two different P–N bond lengths are observed for the unsymmetrically substituted diphospha-

zanes, $Ph_2PN(Pr^i)P(O_2C_6H_4)$ [22a] and $Ph_2PN((S)$-CH-MePh)PPh($N_2C_3HMe_2$-3,5) [22b]; the P–N bond connected to the $P(O_2C_6H_4)$ or PPh($N_2C_3HMe_2$-3,5) (1.65 Å, 1.69 Å, respectively) is shorter than the other P–N bond connected to the PPh_2 center (1.74 Å, 1.73 Å, respectively). These differences are best explained in terms of the negative hyperconjugative interaction between the nitrogen lone pair and the adjacent P-X σ^* orbitals [24]. The near equality of the

two P–N bonds in ligand ($\mathbf{L}^1$) arises because the electron withdrawing effect of the oxygen spacer is compensated by the electron donating methyl substituents on the phenyl rings.

3.2.2. The crystal structure analyses of $[Ag_3(\mu\text{-}Cl)_2\{Ph_2PN(R)PPh_2\}_3]PF_6$ (R = Pr^i, (**1b**) and R = H (**2b**))

X-ray crystallographic studies reveal that the central core in both complexes (**1b**) and (**2b**) comprises a pair of halogen atoms, each of which is bonded to three Ag atoms which form an approximately equilateral triangular plane. The three metal atoms are bridged around the periphery of the triangle by three diphosphazane ligands in such a way that the coordination environments of the chlorine atoms are pyramidal three-coordinate $ClAg_3$, and the metal atoms are four coordinate $P_2Ag(\mu\text{-}Cl)_2$. The molecular structures of (**1b**) and (**2b**) are shown in Figs. 5 and 6, respectively. Selected bond lengths and bond angles for (**1b**) and (**2b**) are given in Table 2. The Ag–P distances of ~2.45 Å and Ag–Cl distances of ~2.72 Å in complexes (**1b**) and (**2b**) are comparable to those observed for $[Ag_3(\mu\text{-}Cl)_2(dppm)_3]$-X complexes reported recently in the literature [8b]. The Ag···Ag distances [2.97–3.10 Å in (**1b**) and 3.15–3.29 Å in (**2b**)] are shorter than that in the trinuclear Ag complex $[Ag_3(dppm)_3Cl_2]^+$(≈3.42 Å) [8b] and comparable to the bond distance in $[Ag_3(dppm)_3(\mu_3\text{-}\eta^1\text{-}C{\equiv}C\text{–}C_6H_4\text{-}NO_2\text{-}p)_2]^+$ (≈3.01 Å) [13b].

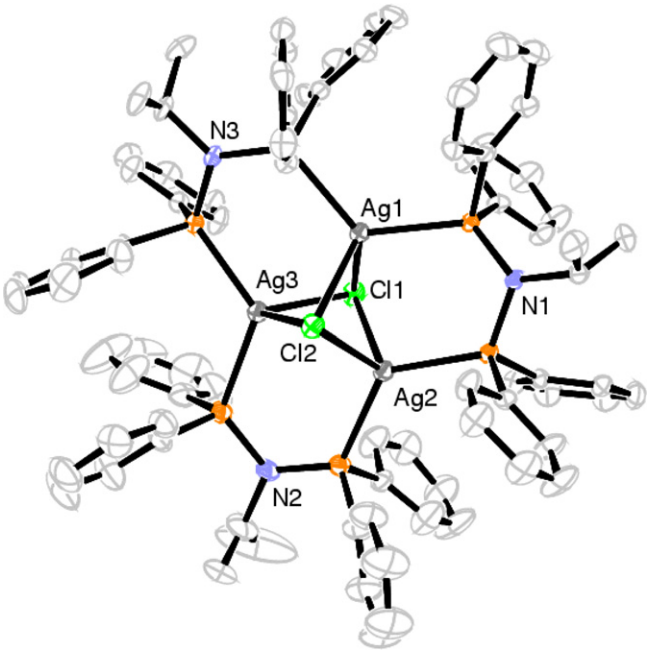

Fig. 5. ORTEP plot and atom labeling scheme for $[Ag_3(\mu\text{-}Cl)_2\{Ph_2PN(Pr^i)PPh_2\}_3](PF_6)$ (**1b**). (The hydrogen atoms and PF_6 ion have been omitted for clarity.)

3.2.3. The crystal structure analysis of $\{Ag(Ph_2PN(Pr^i)PPh_2)OTf\}_2$ (**3b**)

The molecular structure of $[Ag(\mathbf{L}^2)(OTf)]_2$ which has a crystallographic inversion symmetry is depicted in Fig. 7. The selected bond distances and angles are given in Table 2. The solid-state structure consists of a neutral dimeric molecular unit, in which the two silver atoms are bridged by a pair of diphosphazane ligands. In addition, each silver atom is bonded to a single triflate anion in a monodentate fashion. The Ag–P distances of 2.442 Å and 2.417 Å are in good agreement with those found for analogous dppm complexes reported earlier [25a]. The observed Ag–O distance of 2.398 Å is comparable to the bonding distance of 2.439 Å for the asymmetrically bound nitrate in $(PPh_3)AgNO_3$ [25b] and the reported value of 2.417 Å in case of the dppm analogue [25a]. The Ag–Ag distance (2.869 Å) is shorter than those observed in complexes (**1b**) and (**2b**), and also the corresponding dppa complex (2.961 Å) [14]. The P–Ag–P units are non-linear and eclipsed, resulting in a folding of the Ag_2P_4 core along the Ag–Ag axis to give rise to a staggered arrangement. The P (2)–Ag–P (1′) angle of 143.4° is significantly greater than the corresponding P (1)–Ag–P (2′) angle of 138.3 (1)° found in the related binuclear dppm complex with the formula $[Ag(dppm)(NO_3)]_2$ [25a] but less than that (148.4°) found for the dppa analogue [14].

3.2.4. The crystal structure analyses of complex (4)

The molecular structure of complex (**4**) as revealed by a single crystal X-ray study is shown in Fig. 8 and features a four coordinated tetrahedral silver ion. Selected bond lengths and bond angles are displayed in Table 2. The

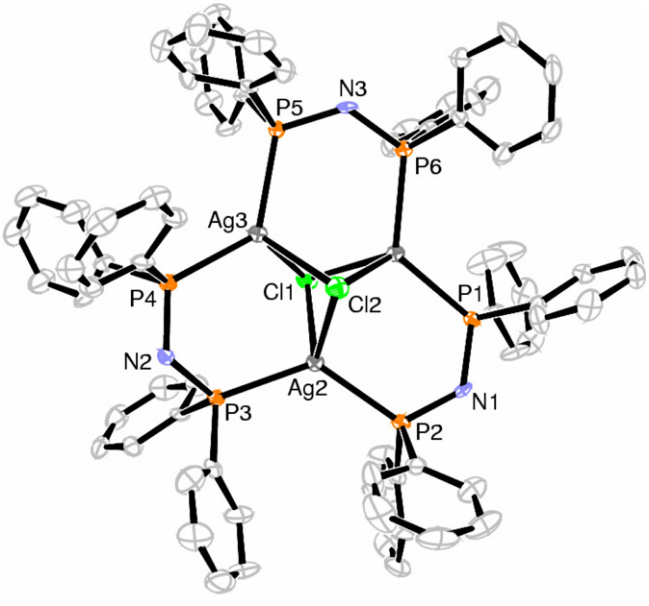

Fig. 6. ORTEP plot and atom labeling scheme for $[Ag_3(\mu\text{-}Cl)_2\{Ph_2PN(H)PPh_2\}_3](PF_6)$ (**2b**). (The hydrogen atoms and PF_6 ion have been omitted for clarity.)

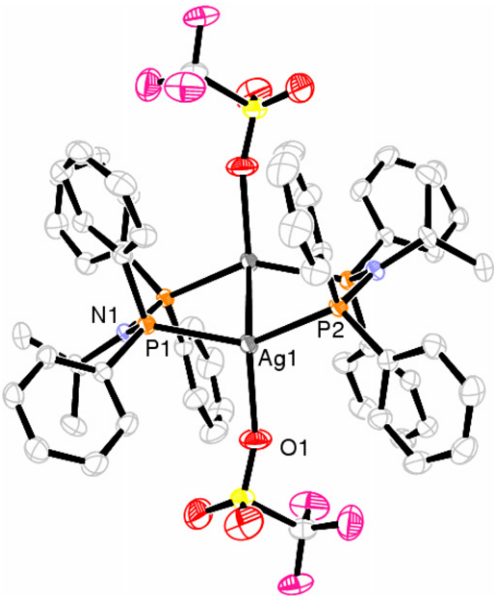

Fig. 7. ORTEP plot and atom labeling scheme for $[Ag\{Ph_2PN(Pr^i)PPh_2\}(OTf)]_2$ (**3b**). (The hydrogen atoms have been omitted for clarity.)

two "P–N–P" ligands are chelated to the metal center with a P–N–P angle of ~110° which is considerably less than that observed in case of the free ligand (122°). The bite angles of the two ligands are similar (~66.95°), while the interligand P–Ag–P angles vary approximately from 141.5° to 118.3° suggesting a highly distorted tetrahedral core. The Ag–P distances are in the range observed for the similar structures reported in the literature [21]. A comparison of the structural data for the complexes (**1b**), (**3b**) and (**4**) shows that the P–Ag–P angle subtended by the diphosphazane ligands on the metal center follows the

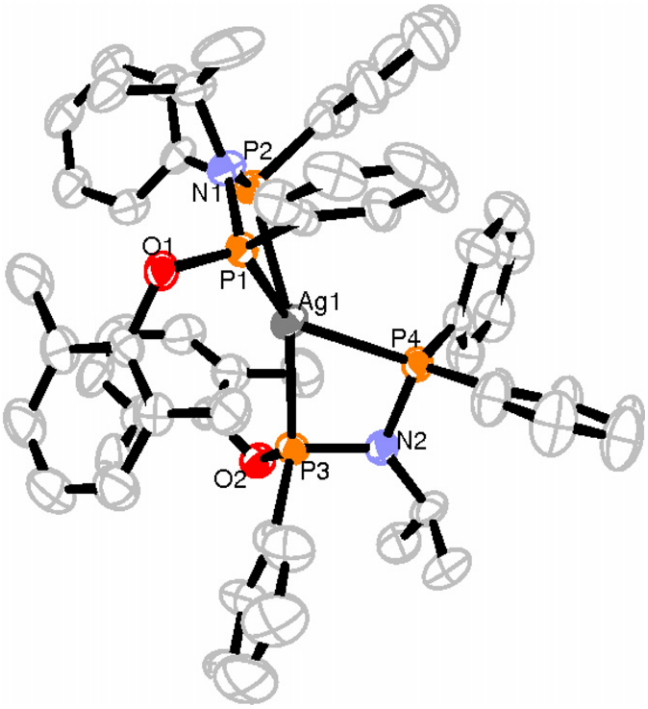

Fig. 8. ORTEP plot and atom labeling scheme for $[Ag\{Ph_2PN(Pr^i)PPh(OC_6H_3Me_2\text{-}2,6)\}_2](PF_6)$ (**4**). (The hydrogen atoms and PF_6 ion have been omitted for clarity.)

decreasing trend: (**3b**) > (**1b**) > (**4**). This observation is in accord with earlier findings that a change in the number of phosphine ligands around silver leads to difference in '*s*' contribution to the hybridization at the silver center, which in turn results in different P–Ag–P angles in the silver(I)-phosphine complexes [19].

4. Conclusions

Novel silver(I) complexes have been synthesized by the reaction of AgX (X = NO_3, OTf) with diphosphazane ligands $Ph_2PN(Pr^i)PPh(R)$ [R = Ph or $OC_6H_3Me_2$-2,6] by varying the stoichiometry and the reaction conditions. Symmetrically substituted diphosphazanes ($\mathbf{L}^2$ and $\mathbf{L}^3$) bearing a relatively weak π-acceptor phosphorus form stable Ag(I) complexes with different coordination numbers and geometries depending on the ratio of the reactants. On the other hand, the diphosphonite ligand, $(RO)_2PN(Me)P(OR)_2$ (R = C_6H_5) bearing a strong π-acceptor phosphorus does not form stable silver(I) complexes.[3] The unsymmetrical ligand ($\mathbf{L}^1$) which has similar π-acceptor ability as ligands ($\mathbf{L}^2$ and $\mathbf{L}^3$) forms only the mononuclear bischelate complex irrespective of the reaction stoichiometry, presumably due to steric reasons. It may also be noted that the sterically bulky [$(RO)_2PN(Me)P(OR)_2$, (R = OC_6-

[3] The diphosphonite ligands $(RO)_2PN(Me)P(OR)_2$ react with one equivalent of $AgNO_3$ in CH_3CN to give unstable Ag(I) complexes as shown by the ^{31}P NMR spectra of the reaction mixtures [δ_P 122.0 (d, br) and 126.0 (s, br) for R = C_6H_5; δ_P 126.0 (d, br) for R = C_6H_3 Me_2-2,6]; the complexes could not be isolated.

H_3Me_2-2,6] does not form stable silver(I) complexes.[3] NMR monitoring of the formation of silver(I) complexes of the diphosphazane ligand ($\mathbf{L}^2$) shows the involvement of an intermediate species in the transformation of bridged binuclear species to mononuclear bischelate species. In the presence of a chloride source, the mono and the binuclear species are converted into dichloro-bridged trinuclear complex. Further investigations are required to gain insights into the nature of the intermediate species and the mechanism of interconversions of Ag(I) complexes of varying nuclearity.

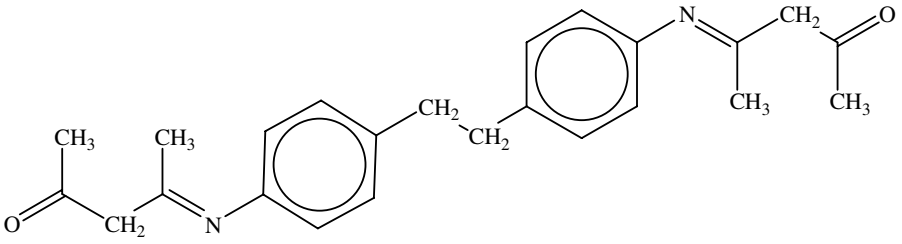

Fig. 1. Chemical structure of the ligand.

The keto-amine and enol-imine equilibrium of the Schiff base, 2-deoxy-2-(2-hydroxybenzaldimino)-D-glucopyranose was described in methanolic and dimethyl sulfoxide solutions. It reacts with nickel acetate to give a bidentate mononuclear Ni(II) complex [6].

Recently, Cerchiaro et al. reported some copper(II) complexes with isatin or imine ligands derived from isatin. In some derivatives, the metal ion is bound though the keto oxygen atom [7].

In our continuous work about symmetric Schiff bases built around 4,4′-diaminodiphenyl [8,9] we present here the crystal structure of a new symmetrical compound: 1,2-di[4-(2-imino 4-oxo pentane)phenyl]ethane (see Fig. 1) obtained by reacting 4,4′-diaminodiphenyl with acetylacetone. In addition, we discuss the structure and the electrochemical behaviour of its complexes with cobalt(II), nickel(II), copper(II) and cadmium(II).

2. Experimental

2.1. Reactants

All reactants and solvents were analytical grade. 4,4′-Diaminodiphenyl ethane and acetylacetone were purchased from Sigma–Aldrich, France. All the metals were used as hydrated chlorides and were used as received.

2.2. Preparation of the ligand

The ligand is obtained by reacting 4,4′-diaminodiphenyl ethane and acetylacetone in MeOH with a 1:2 ratio as previously described [10,11]. To a solution of diaminodiphenyl ethane (1 mmol, 0.21 g, 40 mL) was added a solution of acetylacetone (2 mmol, 0.2 g, 7 mL). The mixture was refluxed for 3 h and cooled. The yellow product was filtered, washed twice with EtOH (10 mL) and finally recrystallised from a mixture EtOH/$CHCl_3$ (30/70 v/v) and dried under vacuum. The single crystals for X-ray diffraction were obtained by slow evaporation from toluene.

2.3. Syntheses of the complexes

All the complexes were prepared by mixing in EtOH equimolar amounts of ligand (0.2 g, 4 mL) and hydrated chlorides (10 mL). After standing under reflux conditions for 8 h, the mixture was kept overnight at room temperature. After the addition of toluene (30 mL), the complex precipitated. It was removed by filtration, washed several times with hot EtOH, dried under vacuum.

Besides this operating mode we have obtained these complexes by template synthesis without isolating the ligand [12]. In a first step, we have mixed 4,4′-diaminodiphenyl ethane and acetylacetone as indicated above (see Section 2.2), after an 8-h reflux, the hydrated metal chloride (EtOH, 10 mL) in stoichiometric amount, was added. Finally, the complex species was obtained and purified, in the same way than previously described.

2.4. Measurements

All elemental analysis were carried out at the Service d'Analyse du C.N.R.S. de l'I.C.S.N., Gif sur Yvette (France). The melting points were determined with a Kofler bank and are uncorrected. The i.r. spectra were recorded with a Perkin–Elmer 1000 series FTIR spectrophotometer, using KBr disks. The UV–Vis spectra were obtained with a UNICAM UV300 spectrophotometer in DMF solutions. The ^1H NMR spectra were recorded on a Jeol GSX WB spectrometer at 270 MHz in $CDCl_3$ or DMSO-D_6, the chemical shifts are given in ppm, using TMS as internal reference. Electrochemical measurements were recorded on a Radiometer VOLTALAB 32 (DEA 332 type): the working electrode was a Pt rotating disk (2 mm diameter) and the auxiliary electrode a Pt wire. A saturated calomel electrode was used as the reference electrode and measurements were carried out at 25 ± 0.2 °C. DMF was used as solvent and the ionic strength was maintained at 0.1 mol L^{-1}, with Bu_4NPF_6 as supporting electrolyte. The concentration of all species was 2.5×10^{-3} mol L^{-1}.

2.5. Crystal data collection and processing

Crystals of H_2L are monoclinic with space group $P2_1/c$. The crystal and instrumental parameters used in the unit-cell determination and data collection are summarised in Table 1. X-ray single-crystal diffraction data were collected at 293 K on a STOE-IPDS diffractometer, equipped with a graphite monochromator utilising Mo Kα radiation ($\lambda = 0.71073$ Å) (CIMMA, UMR CNRS 6200, Angers). The structure was solved by direct methods using SIR92 [13] and the refinement was performed on F^2 by full matrix

least-squares techniques using SHELX-97 package [14]. All non-H atoms were refined anisotropically and the H atoms were included in the calculation without refinement. Absorption was corrected by Gaussian technique.

3. Results and discussion

3.1. Crystal structure of the ligand

The main crystal parameters are reported in Table 1. The bond distances and their angles are given in Table 2.

Table 2
Bond lengths (Å) and angles (°)

Bond lengths (Å)		Bond angles (°)	
C01—C′01	1.500(6)	C′01—C01—C02	114.3(3)
C01—C02	1.516(3)	C07—C02—C03	117.0(2)
C02—C07	1.374(4)	C07—C02—C01	120.9(3)

C11—O01	1.244(3)	C10—C08—C09	120.8(2)
C11—C12	1.507(3)	C08—C10—C11	124.4(2)
		O01—C11—C10	122.0(2)
		O01—C11—C12	119.3(2)
		C10—C11—C12	118.6(2)
		C08—N01—C05	127.9(2)

The molecule presents a symmetrical structure with two identical independent half-molecules. The structure, with the atoms numbering scheme, is given in Fig. 2. The angles and the distances around C11 are typical of a keto functional group. The bond distances between C05 and N01 correspond to a double bond length as already observed in similar compounds [15]. The C08—C10 (1.375 Å) and C08—N01 (1.346 Å) bond distances are close to that published by Nathan and Traina (1.368 Å and 1.365 Å, respectively) [15] but in our ligand, we note a shorter bond distance for C10—C11 (1.421 instead of 1.502 Å). These results are in good agreement with keto-imine or keto-amine tautomers.

All angles are close to 120°, showing sp^2 hybridisation of all atoms without taking into account the methyl groups. The azomethine moiety presents an E configuration around the carbon–nitrogen double bond.

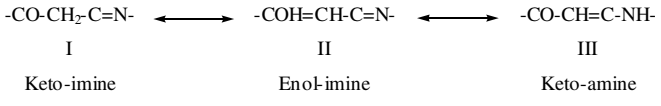
In a molecule, the two aromatic rings are in parallel planes and the two carbonyl oxygen atoms lie on the two sides of these planes. The packing along b-axis (Fig. 3) shows that the molecules lie in parallel planes. In a cell, there are four half-molecules giving two independent complete symmetrical ligands. The half-molecules lie in two planes with a 77° angle between them as presented in Fig. 4.

3.2. Complexes formulae

The analytical data are reported in Table 3. The purity of each species was verified using t.l.c. The complexes are formulated as $[CoL]\cdot(H_2O)_3$, $[(NiCl_2)_2(H_2L)]$, $[CuCl_2(H_2L)]$ and $[CdCl_2(H_2L)]$, respectively. The cobalt complex is the only complex obtained through the ionised hydroxyl enol-imino tautomer. The compounds **4** and **5** are slightly unstable as indicated by higher errors in elemental analysis. So, all spectroscopic and electrochemical determinations were performed using freshly prepared compounds.

3.3. Spectroscopic results

The main spectroscopic data are given in Table 4. We have to take into account the tautomeric equilibria giving three tautomers [15,16]:



As indicated by crystallographic data, a keto tautomer was observed in the solid state in the case of the ligand. The hydroxyl stretching vibration band appearing in the infrared spectra of the complex with cobalt is due to coordination water molecules [17]. In the case of the nickel(II) complex, the band centred at 3380 cm^{-1} is due to ν(N—H) from keto-amine tautomer [18]. The aromatic cycle vibrations at ca. 1270, 1030 and 825 cm^{-1} [19] and

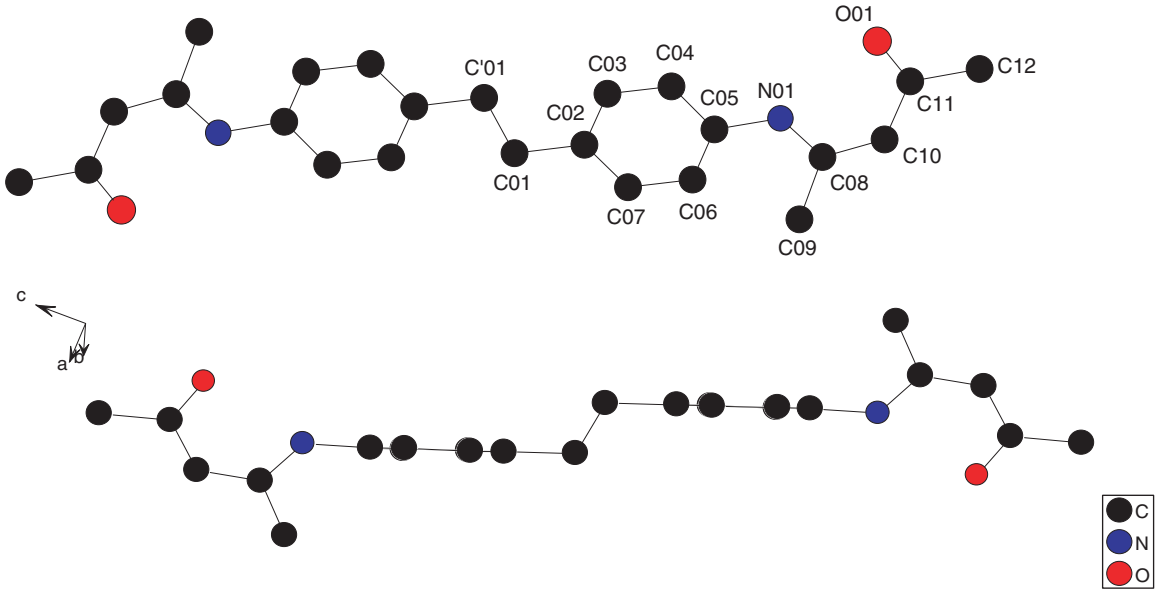


Fig. 2. Perspective view of the ligand with atom numbering (in the second identical part of the molecule, the atoms are noted C′, N′ and O′, respectively).

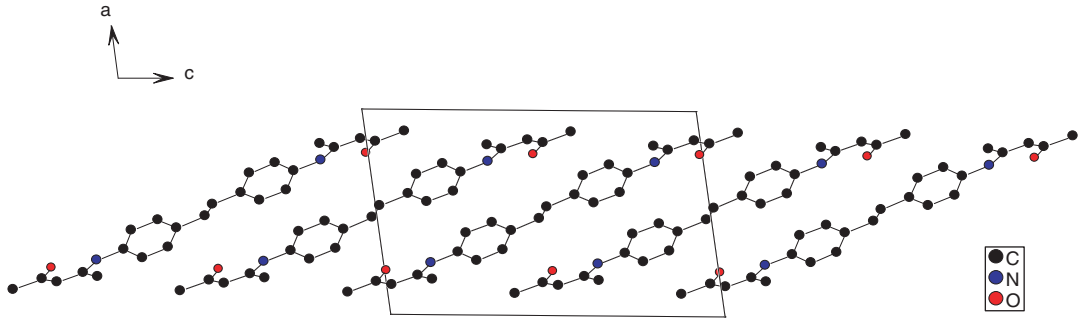

Fig. 3. Packing of the molecules along *b*-axis.

the CH_3 and CH_2 vibration band around 2925 cm^{-1} are not modified by coordination. The stretching vibration band ν(C=N) appearing at 1625 cm^{-1} is in good agreement with the values published for similar compounds [18]. In the complexes, this band is slightly shifted down as already observed by Losada et al. [20].

The electronic spectra in DMF solutions (see Table 4) show one absorption band at 332 nm in the case of the ligand. The Co^{II} compound absorbs at 315 nm and with a weak molar absorption coefficient. In Ni(II) complex, two bands are located at 305 and 270 nm while two shoulders are observed at 350 nm ($\varepsilon = 49\,000$ L mol^{-1} cm^{-1}) and 330 nm ($\varepsilon = 65\,000$ L mol^{-1} cm^{-1}). In the case of the cupric complex, a weak shoulder at 330 nm appears together with the absorption band at 300 nm. In the UV region three new bands are located at 265 ($\varepsilon = 14\,200$ L mol^{-1} cm^{-1}), 250 ($\varepsilon = 10\,600$ L mol^{-1} cm^{-1}) and 230 nm ($\varepsilon = 9000$ L mol^{-1} cm^{-1}). As expected, the spectra of the cadmium complex and of the free ligand are similar. These results agree with previous published results ([20–22] and references cited therein).

3.4. ^1H NMR

The ^1H NMR data for the ligand (in $CDCl_3$) and the cadmium complex (in DMSO–D_6) is given in Table 5. Though the ligand crystallises in keto-imine tautomer I, the solution NMR spectra of both compounds show signals corresponding to keto-amine tautomer III: the singlet at 12.3 ppm corresponds to the N—H proton [16] (the hydroxyl proton of the enol-imino tautomer leads to a singlet in the 8–9 ppm range [23]). This signal could be also observed in the spectrum of the cadmium complex with the same chemical shifts as it has been observed in similar compounds [24,25]. The signal of the aromatic protons, of the ethylene moiety and of the methyl groups are not modified by coordination. The only change is observed in the methyl groups signals: in the ligand, the terminal methyl groups give a singlet at 2.0 ppm and the methyl attached to C08 and C′08 a second signal at 2.1 ppm while the four methyl groups appear as a singlet corresponding to 12 hydrogen atoms in the cadmium complex.

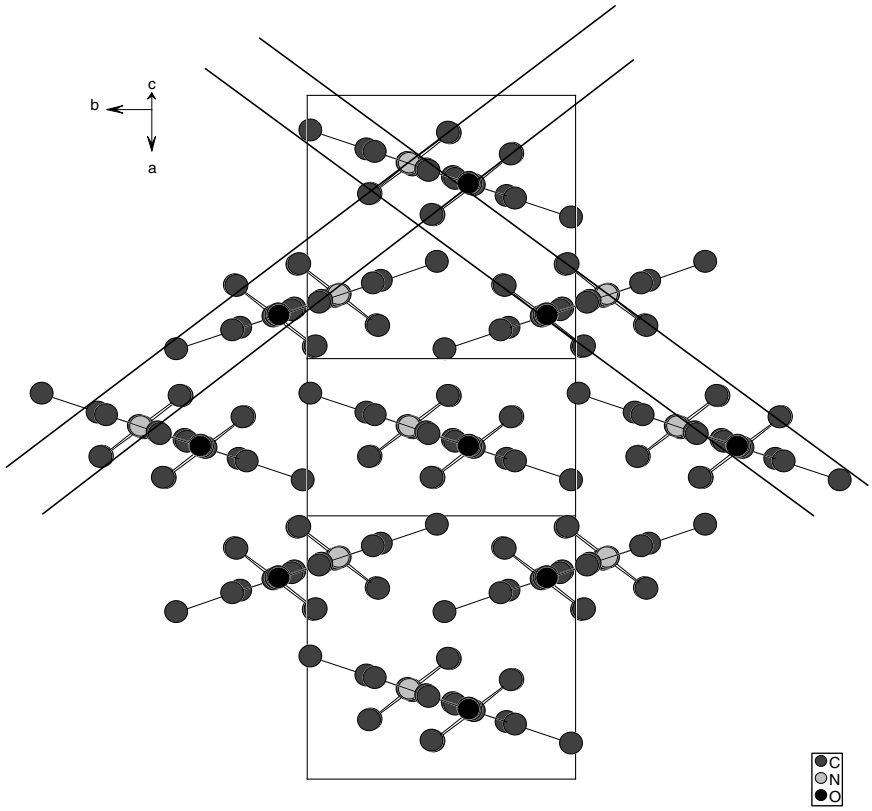

Fig. 4. Angles of 77° between the two types of aromatic planes.

Table 3
Analytical data

Compound	Color	Yield (%)	m.p. (°C)	Elemental analysis found (Calc.)		
				C (%)	H (%)	N (%)
Ligand H_2L (**1**)	yellow	65	152	76.0 (76.6)	7.4 (7.5)	7.4 (7.4)

3.5. Cyclic voltammetry

The main electrochemical data are given in Table 6 and some representative voltammograms are presented in Fig. 5.

For the ligand, a cyclic sweep in the −1.80 to +0.00 V range shows a cathodic peak at −1.05 V and an anodic peak at −1.15 V. The peak at −1.05 V is due to the reduction of the imino moiety of the molecule as suggested by Gilli et al. [26] and Andrieu and Savéant [27]:

$$R{-}CH{=}N{-}R' \overset{e^-}{\rightleftharpoons} [R{-}CH{=}N{-}R']^{-\cdot} \overset{H^+}{\rightarrow} [R{-}CH_2{-}N{-}R']^{\cdot}$$
$$\rightarrow \tfrac{1}{2}R{-}CH_2{-}N(R'){-}N(R'){-}CH_2{-}R$$

When the sweep is performed between 0.00 and +1.80 V, two anodic peaks are obtained at +0.91 and +1.37 V, respectively. The reoxidation of the last product in the above mechanism occurs at +1.37 V. In the range −1.80 to +1.80 V, a cathodic peak is located at −1.05 V together with a new anodic peak at −0.05 V. When performing a second sweep in the same range, a new cathodic peak is observed at −0.42 V and the peak at −1.05 V is shifted to higher potential values (−0.97 V).

In the case of the cobalt(II) complex, and in the −2.00 to +1.80 V, a cathodic peak appears at −0.98 V while three anodic peaks are observed at −0.17, +0.80 and +1.32 V, respectively. When the sweep is limited to the −1.00 to 0.00 V range, the peak at −0.17 V is lacking. This peak should be attributed to the reoxidation of the ligand previously reduced [26]. In addition, when performing a second sweep (−1.00 to 0.00 V), a new peak is observed at −0.36 V due to the reoxidation of cobalt reduced at −0.98 V [28]. The intensity of the anodic peak at +1.32 V is a linear function of the square root of sweep speed showing a slow electron transfer.

Table 4

Table 5
^{1}H NMR data, chemical shifts in ppm (TMS); ligand in $CDCl_3$, complex in DMSO-D_6

	Ligand (**1**)	Cd(II) complex (**5**)
H (C10)	5.2	5.2
CH_3 (C12)	2.1	2.0
CH_3 (C9)	2.0	2.0
CH_2—CH_2 (C01—C′01)	2.8	2.9
Aromatic	7.1	7.1
NH (keto amine)	12.3	12.4

The cyclic voltammogram of nickel(II) species shows one cathodic peak located at −1.31 V when sweeping from −1.80 to +1.80 V. During the reverse sweep, we observe three anodic peaks at +0.04 V, +0.83 V and +1.35 V. When performing successive sweeps in the same range, the peak at −1.35 V and its corresponding reoxidation peak disappear (Fig. 5c) while a new one appears at −1.10 V. The peak at +0.83 V has been reported by Pereira et al. [29] for nickel(II) complexes of asymmetric tetradentate Schiff bases.

A sweep from −1.80 to +1.80 V for copper(II) complex shows three cathodic peaks (−1.60 V, −0.78 V, +0.15 V) and the back sweep (+1.80 to −1.80 V) shows five anodic peaks at −0.16, +0.10, +0.63, +0.88 and +1.38 V, respectively. The peak at −0.88 V has already been observed by Losada et al. [20] in similar compounds. A second sweep shows that the peak at −1.60 V disappears, the peak at +1.38 V is slightly shifted to +1.36 V while its intensity diminishes. In the −2.00 to +0.30 V range, a peak is observed at +0.10 V. If the studied range is limited from −0.10 to +0.80 V, we observed the oxidation of Cu^{II} into Cu^{III} at +0.55 V while the reduction peak is located at +0.37 V [30]. The variation of the scan rate from 200 to 10 mV s^{-1} shows that the curve E_{pc} as a function of log v, for this reduction peak, is a straight line (Fig. 5g) and it does not depend upon the sweep speed.

Table 6
Voltamperometric results at 25 °C in DMF, ionic strength 0.1 mol L^{-1} (Bu_4NPF_6), results in V vs. SCE, sweep speed: 100 mV s^{-1}, E_a: anodic; E_c: cathodic

Compound	E range (V)	E_{pa1}	E_{pa2}	E_{pa3}	E_{pa4}	E_{pa5}	E_{pc1}	E_{pc2}	E_{pc3}
1	−1.8/0	−1.15					−1.05		
	0/1.8				+0.91	+1.37			
	−1.8/+1.8	−0.05					−1.05		
2	−2.0/+1.8	−0.17			+0.80	+1.32	−0.98		
	−1.0/0				+0.80	+1.32	−0.98		
3	−1.8/+1.8	+0.43			+0.83	+1.35		−1.31	
4	−1.8/+1.8	−0.17	+0.10	+0.63	+0.88	+1.38	+0.15	−0.78	−1.6
	−2.0/+0.3		+0.10						
	−0.1/+0.8			+0.54					
5	−1.8/+1.8					+1.45	−0.92	−1.18	

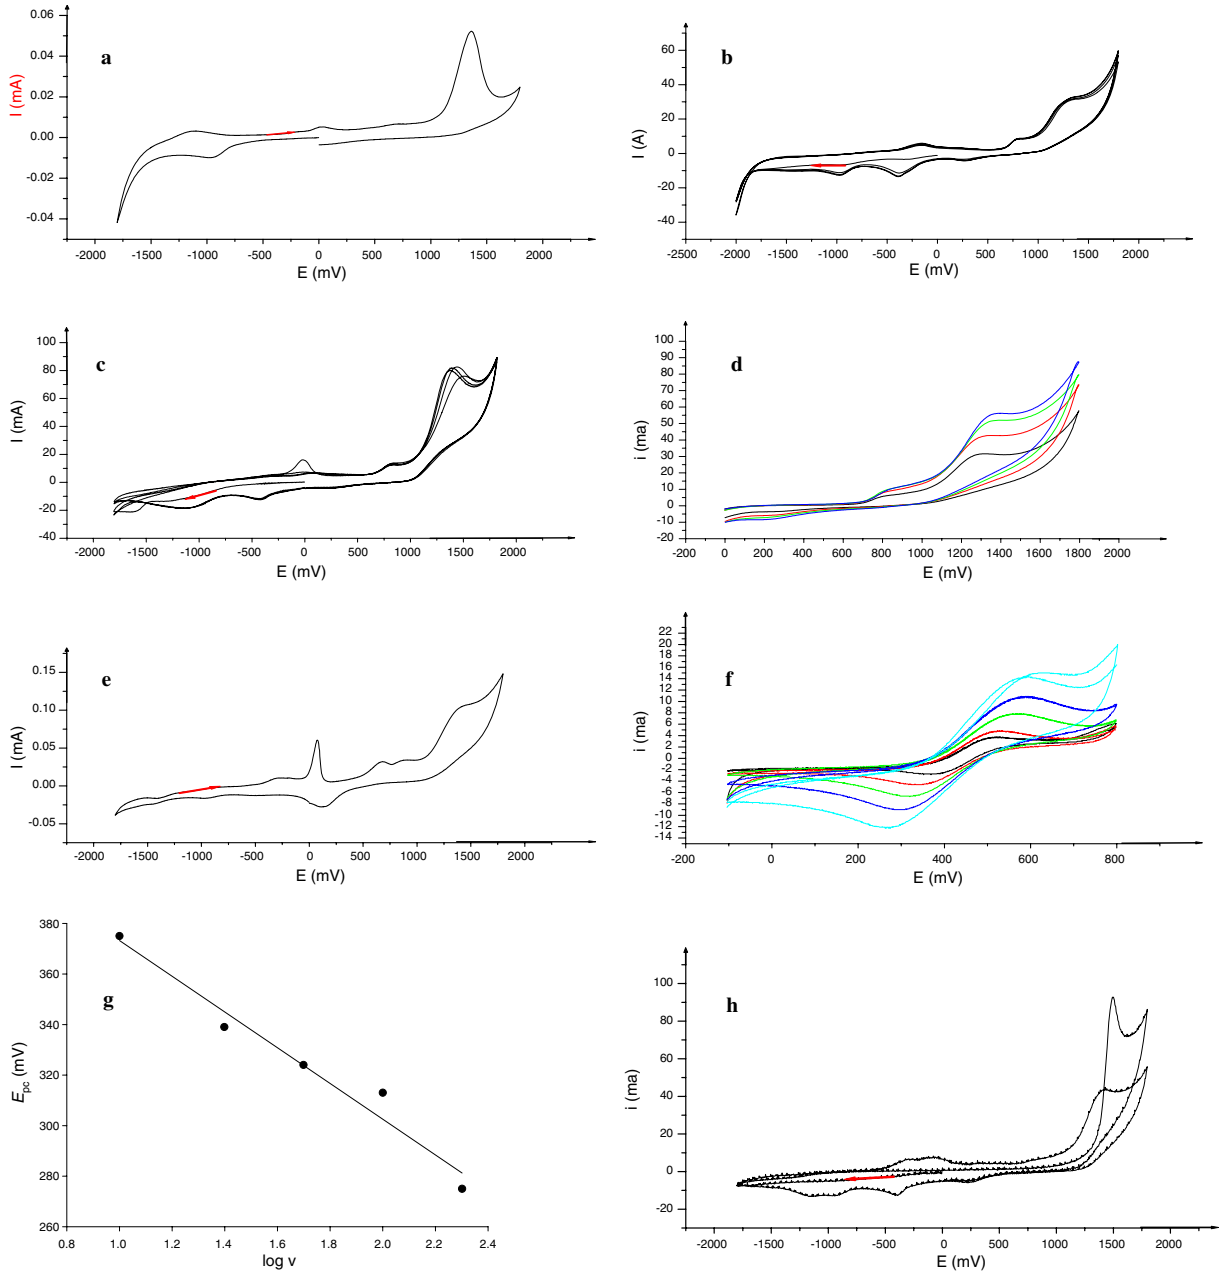

Fig. 5. Representative cyclic voltammograms in DMF (25 °C, ionic strength: 0.1 mol L^{-1}, Bu_4NPF_6, i in μA, $v = 100$ mV s^{-1}): (a) ligand; (b) Co(II) complex, successive sweeps; (c) Ni(II) complex, successive sweeps; (d) Co(II) with variable speed; (e) Cu(II) complex; (f) Cu(II) complex, variable speed; (g) Cu(II) complex $E_{pc} = f(\log v)$; (h) Cd(II) complex.

Finally, for the cadmium(II) compound, when sweeping from −180 to +1.80 V, two cathodic waves at −1.18 and −0.92 V and one anodic peak at +1.45 V are obtained (Fig. 5h). We note that, in this case, the reoxidation of the imino moiety occur at higher potential values in the other compounds (+1.45 V instead of +1.37 V). A second sweep leads to three oxidation peaks at −0.78 and −0.33 V together with two reduction ones located at −0.95 and −1.15 V.

3.6. Proposed structures for the complexes

The proposed structures for the complexes are given in Fig. 6. As indicated along the discussion, some differences have been noted between solid state and solution because of the tautomeric equilibria. The cobalt complex is obtained with ionised enol-imine tautomer. In this compound, two water molecules are bounded to Co(II). In addition this cation is linked to N (imino) and O^- (ionised

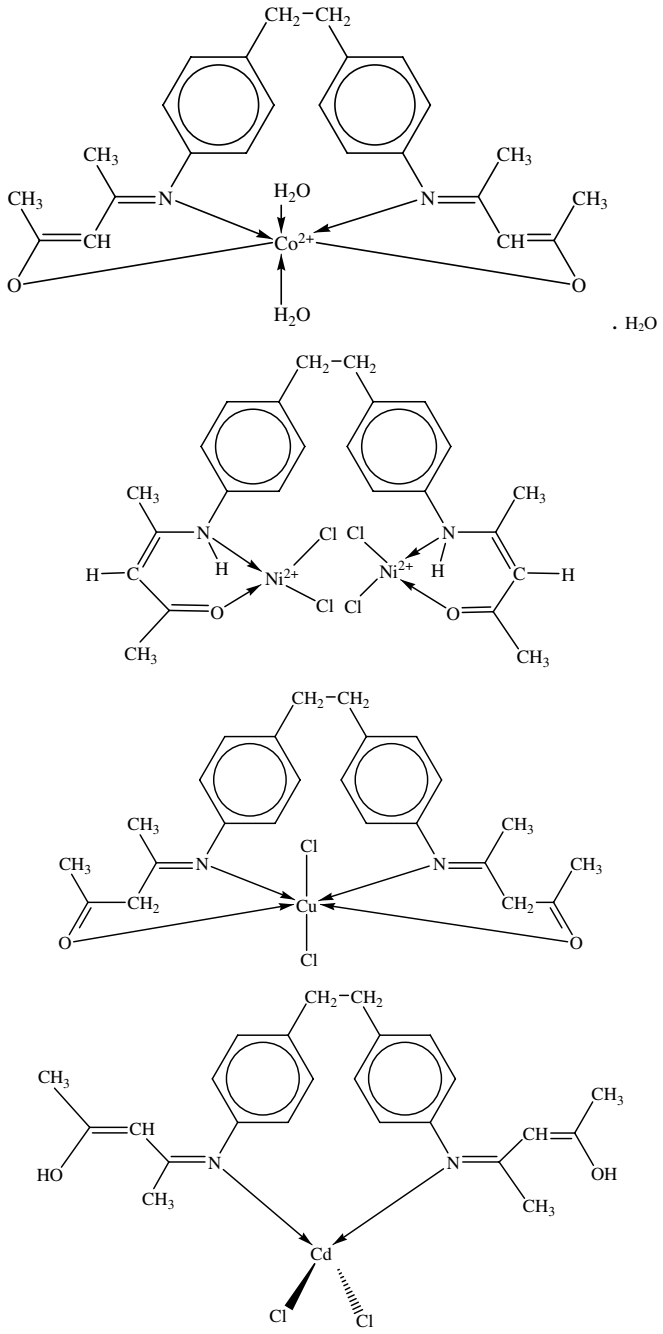

Fig. 6. Proposed structures for the complexes.

enol). So this metal ion shows an octahedral geometry. Finally, a third water molecule is in the outer coordination sphere.

The nickel(II) compound is a binuclear complex in which each nickel(II) ion presents a square planar arrangement and the Schiff base acts as a symmetrical tetradentate ligand through the keto-amine tautomer.

The copper(II) is the only compound obtained with the non-ionised keto-imine tautomer. The copper(II) ion shows a distorted octahedral geometry with O atoms (keto), N atoms (imine) in a plane and two chloride ions located on the orthogonal axis.

In the cadmium complex, the geometry around the metal cation is tetrahedral. It is linked to the keto-amine tautomer of the ligand through N (amine) atom.

4. Supplementary data

Crystallographic data have been deposited with the CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44 1223 336033; e-mail: deposit@ccdc.cam.ac.uk or at http://www.ccdc.cam.ac.uk), and are available on request quoting the deposition number CCDC 287415.

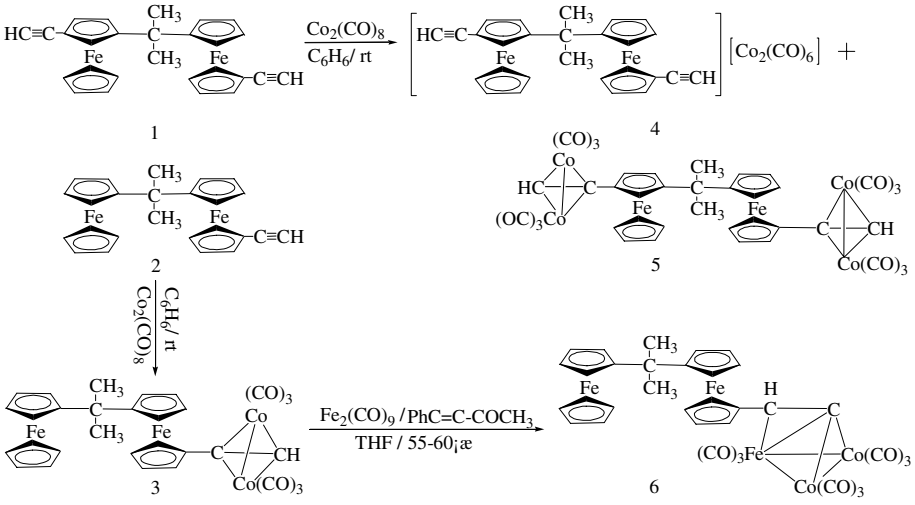
$CH_2CCl(C_5H_5FeC_5H_3)C(CH_3)_2Fc'CClCH_2$, prepared by the reaction of $POCl_3$ and $CH_3CO(C_5H_5FeC_5H_3)C(CH_3)_2Fc'COCH_3$ in DMF. The other reactions carried out in this work are summarized in Scheme 1. Because of the reactivity between the C≡C triple bonds of **1** and the Co–Co bond, complexes **4** and **5** can be prepared from ligand **1** and $Co_2(CO)_8$. Only stable complex **5** was obtained even if the mole ratio of $Co_2(CO)_8$ to ligand **1** was fixed at 1:1. Complex **4** slowly decomposed during the process of purification because of its thermal instability, and its IR spectrum (2090s, 2049vs, 2020vs) supports that there is a coordinated $Co_2(CO)_6$ species with an alternate C≡C triple bond of **1**. Complex **5** is a dark-green and air-stable crystalline compound which is soluble in both non-polar solvents such as hexane, petroleum ether, benzene and polar solvents such as acetonitrile and chloroform. The molecular structure of complex **5** was determined by X-ray crystallography and is shown in Fig. 1.

Complex **3** is regarded as the starting compound for synthesizing complex **6** by the nuclear expansion reaction between the C_2Co_2 core of complex **3** and $Fe_2(CO)_9$. If the reactivity could be extended, complex **6** may also be regarded as the starting compound for further synthesis of other polynuclear mix-metal clusters by a metal exchange reaction [6]. The IR spectrum of **6** indicates the characteristic absorption bands of terminal carbonyl ligands coordinated to Co and Fe in the region 2097–1961 cm^{-1}. ^1H and ^{13}C NMR spectra reflect that there are Fc, CH=C, $C(CH_3)_2$ and CO groups in complex **6**. The component of complex **6** is further proved by its element analysis data and MS. Complex **6** is a dark-red crys-



Scheme 1.

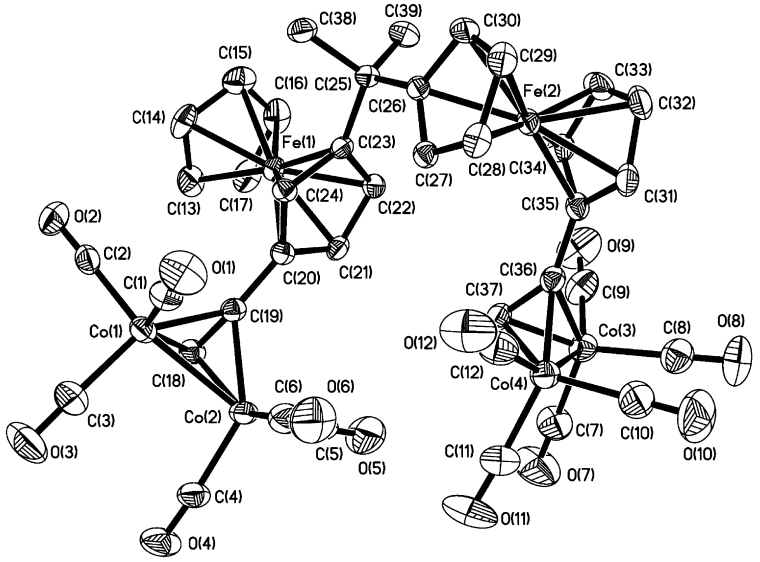


Fig. 1. Molecular structure of complex **5**.

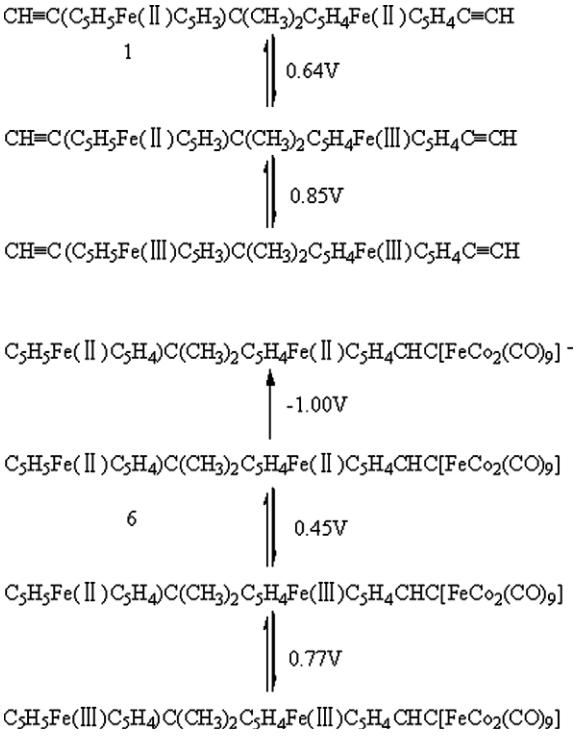
talline solid and is soluble in common polar solvents and slightly soluble in non-polar solvents.

2.2. Electrochemical properties of compounds *1*, *2*, *3*, *5* and *6*

The electrochemical properties of compounds **1**, **2**, **3**, **5** and **6** have been studied by cyclic voltammetry at 298 K in a standard three-electrode system with NEt_4ClO_4 in CH_3CN solution as the supporting electrolyte. The results are given in Table 1.

For compounds **1**, **2**, **3** and **6** the usual electrochemically quasi-reversible ferrocene (0, 0/0, 1+; 0, 1+/1+, 1+) peak couples were observed (Table 1), but these did not appear for complex **5**. The two ferrocenyl units in **2**, **3** and **6** are non-equivalent and show two resolved one-electron redox processes at $E_1^0 = 0.52,\ 0.45,\ 0.50$ V and $E_2^0 = 0.85,\ 0.75,\ 0.77$ V, respectively. ΔE^0 data of **2**, **3** and **6** indicate that there is significant electronic communication between the two ferrocenyl units, though the alkyl $C(CH_3)_2$ spacer is interpolated and the electronic communication decreases with weakening of the conjugation between the ferrocenyl unit and the alkyne group, which is induced by the coordination of the terminal acetylene with the Co_2 or $FeCo_2$ core. Noteworthy is the decrease in separation between the two ferrocenyl redox centres from 0.34 V, 0.30 V to 0.27 V within the series $FcC(CH_3)_2Fc'C{\equiv}CH$ (**2**), $[FcC(CH_3)_2Fc'C{\equiv}CH]Co_2(CO)_6$ (**3**) to $[FcC(CH_3)_2Fc'CH{=}C]FeCo_2(CO)_9$ (**6**), which demonstrates that the σ–π coordination of the $FeCo_2(CO)_9$ or $Co_2(CO)_6$ moieties decreases the communication between the two ferrocenyl redox centres because of the strengthening of interaction between the cluster core and the alkyne group [11]. In **1** two resolved one-electron redox processes are observed at $E_1^0 = 0.64$ V and $E_2^0 = 0.85$ V. The separation of the "two-electron" oxidation process for **1** into individual E_1^0 (0, 0/0, 1+) and E_2^0 (0, 1+/1+, 1+) couples is easily seen at ambient temperature. The change of the electrochemical data in **5** shows that the $Co_2(CO)_6$ moieties participate in the reducing process, which affects the two ferrocenyl redox centres. The irreversible reduction peak at $E_{pc} = -1.00$ V in **6** is regarded as the result of the arising reduction process on the $FeCo_2(CO)_9$ moieties [16]. The redox processes of compounds **1** and **6** are shown in Scheme 2.



Scheme 2.

2.3. Molecular structure of complex *5*

The molecular structure of complex **5** was determined by X-ray single crystal analysis. The selected bond lengths and angles are listed in Table 2.

The molecule of complex **5** contain two ferrocenyl units with approximately tetrahedral (μ-alkyne)dicobalt moieties bound to a cyclopentadiene ring (see Fig. 1). The CO ligands coordinated to the Co atoms are terminal and the average Co–Co bond distance (2.475 Å) is typical for the Co–Co bond lengths of classical alkyne dicobalt complexes. The alkyne bond adopts a typical μ_2–η^2 coordination fashion with the alkyne bond lying essentially perpendicular to the Co–Co bond in the C_2Co_2 units. The C–C bond lengths of the C_2Co_2 fragments are 1.320 Å and 1.341 Å, respectively, which reflect a bond dis-

tance of the coordinated C≡C bond in the scope of a C–C double bond. The Fe–C distances of the ferrocenyl moieties in complex **5** vary from 2.018 to 2.065 Å, comparable with those found in compounds with a ferrocenylalkynyl unit [9].

The bond distance figures of C(23)–C(25) (1.520 Å) and C(25)–C(26) (1.520 Å) indicate two ferrocenyl units in complex **5** are linked by two single bonds to the C atom in the $C(CH_3)_2$ group. The C atom of the $C(CH_3)_2$ group carries two ferrocenyl units orientated *trans* to each other and two C_2Co_2 units adopt a *cis*-bent configuration relative to the two cyclopentadiene rings. The molecular structure of complex **5** is asymmetric, which is similar to ligand **1**. One C_2Co_2 unit is linked to the unsubstituted cyclopentadiene ring of Fc′ by a short single bond (1.448 Å) between C(35) and C(36), and another C_2Co_2 unit is bonded to the substituted cyclopentadiene ring by a short single bond (1.437 Å) between C(19) and C(20), which suggests some degree of electron delocalization between the alkyne and the cyclopentadiene ring. The distortion of the quasi tetrahedral C_2Co_2 core is evidenced by the non-equivalence of the Co–C bond lengths and bond angles (see Table 2). The bond angle [C(18)–C(19)–C(20) 145.2° or C(35)–C(36)–C(37) 143.1°] is much smaller than 180° of sp-hybridized C(19) or C(36), which is attributed to the steric requirement between the (μ-alkyne)dicobalt and ferrocenyl moieties. The angle C(23)–C(25)–C(26), 109.9°, is nearly the angle of sp^3-hybridized C(25) and other angles around C(25) deviate from 109° as a result of steric influences.

The distances of the Fe atom to the plane of the cyclopentadiene rings [Fe(1) to the plane(1) C(13)C(14)C(15)C(16)C(17), 1.66 Å; Fe(1) to the plane(2) C(20)C(21)C(22)C(23)C(24), 1.64 Å; Fe(2) to the plane(3) C(26)C(27)C(28)C(29)C(30), 1.65 Å; Fe(2) to the plane(4) C(31)C(32)C(33)C(34)C(35), 1.65 Å] are nearly equal. The dihedral angle data between plane(1) and plane(2) (3.74°) and between plane(3) and plane(4) (4.86°) show that the two Cp planes in each ferrocenyl unit deviate from parallel because of the different substituted Cp rings. The dihedral angle between plane(2) and plane(3) is 74.07° as a result of the steric interaction between the $C_5H_5FeC_5H_3$ and $C(CH_3)_2Fc'$ groups.

3. Experimental

Published procedures or extensions thereof were used to synthesize initial intermediates $FcC(CH_3)_2Fc$, $CH_3CO(C_5H_5FeC_5H_3)C(CH_3)_2Fc'COCH_3$, ligand **2** $FcC(CH_3)_2Fc'$-C≡CH and complex **3** $[FcC(CH_3)_2Fc'C{\equiv}CH]Co_2(CO)_6$ [15,17,18]. Other chemicals were purchased and used as received.

Unless it is stated otherwise, all reactions and manipulations were carried out using standard Schlenk techniques under an atmosphere of pure nitrogen. Solvents were purified, dried and distilled under a nitrogen atmosphere prior to use. The reactions were monitored by TLC. Chromatographic separations and purification were performed on 200–300 mesh silica gel.

IR spectra were recorded on a Nicolet FT-IR spectrometer as KBr disks. Elemental analyses were carried out on an Elementar var III-type analyzer. $^1H(^{13}C)$ NMR spectra in $CDCl_3$ were recorded on an Inova 500FT-MHz spectrometer. Mass spectra were determined by using a Polaris Q MS and a Micromass Autospec ultima-TOF instrument. Electrochemical properties were determined by a BAS 100A-type analyzer. Melting points were determined using XT-4 melting point apparatus.

3.1. Synthesis of ligand $HC{\equiv}C(C_5H_5FeC_5H_3)C(CH_3)_2Fc'C{\equiv}CH$ (**1**)

$POCl_3$ (0.7 ml, 7.7 mmol) was dissolved in a 5 ml solution of *N*,*N*-dimethylformamide (DMF), which was dropped into a 6 ml DMF solution of $CH_3CO(C_5H_5FeC_5H_3)C(CH_3)_2Fc'COCH_3$ (0.2 g, 0.4 mmol) at 0 °C. The solution was stirred for 1.5 h at 0 °C and then 2 h at room temperature. The reaction mixture was transferred to a 30 ml solution of NaAc (20%) and stirred for 1.5 h. The resulting red mixture was extracted with CH_2Cl_2 and the organic phase was incorporated, and then dried using dehydrated $MgSO_4$ and filtered. The filtrate was concentrated and the residue was subjected to chromatographic separation on a neutral alumina column (1.5 × 30 cm). Elution with ether afforded a purplish red band. A red oil was obtained by concentrating the solution. The red oil was dissolved in 8 ml 1,4-dioxane, heated to reflux temperature, and then NaOH (4.5 ml, 0.5 M) was added. After refluxing for 15 min the reaction mixture was cooled to room temperature. The mixture was poured into 50 g water at 0 °C, and then the solution was neutralized to pH 6–8 using HCl (0.5 M). The mixture was extracted with ether and the ether layer was washed with water, dried over dehydrated $MgSO_4$, and the solvent was removed under reduced pres-

sure. The residue was purified by neutral alumina column chromatography using hexane–ether (4:1, v/v) as eluant. Ligand **1** was obtained as a yellow oil. Yield: 35%. *Anal.* Calc. for $C_{27}H_{24}Fe_2$: C, 70.47; H, 5.26. Found: C, 71.61; H, 6.04%. IR (KBr disk) *v* 823s, 1000w, 1107m, 2106s, 2868w, 2926w, 2970m, 3093w, 3289s cm^{-1}. ^1H NMR ($CDCl_3$, δ): 3.98–4.42 (m, 16H, Fc-H), 2.69 (s, 1H, C≡C–H), 2.72 (s, 1H, C≡C–H), 1.50–1.66 [m, 6H, $C(CH_3)_2$]. ^{13}C NMR ($CDCl_3$, δ): 30.28 (s, CH_3), 33.20 [s, $C(CH_3)_2$], 73.30–73.74 and 82.55–82.84 (m, C≡CH), 62.51–72.20 and 101.50–102.38 (m, Fc). MS (EI) 460 (M^+).

3.2. Syntheses of complexes $[HC{\equiv}C(C_5H_5FeC_5H_3)C(CH_3)_2Fc'C{\equiv}CH][Co_2(CO)_6]$ (4) and $[HC{\equiv}C(C_5H_5FeC_5H_3)C(CH_3)_2Fc'C{\equiv}CH][Co_2(CO)_6]_2$ (5)

A benzene solution of $Co_2(CO)_8$ (90 mg, 0.26 mmol) and ligand **1** (120 mg, 0.26 mmol) was stirred for 11 h at room temperature. The solvent of the resulting dark-green mixture was removed in vacuum. The residue was dissolved in a minimal amount of benzene and subjected to chromatographic separation on a silica gel column (1.5 × 30 cm). Elution with hexane–benzene (5:1 for **5**, 3:1 for **4**, v/v) afforded a first dark-green band (**5**) and then a second dark-green band (**4**). The pure product of complex **4** was too difficult to obtain because of its instability. A trace of complex **4** was only checked by IR (KBr disk, cm^{-1}) 3309 (w, $\nu_{\equiv C-H}$), 2109 (w, $\nu_{C\equiv C}$), 2925 (m, ν_{CH3}), 2966 (m, ν_{CH3}), 2090 (s, ν_{CO}), 2049 (s, ν_{CO}), 2020 (vs, ν_{CO}), 809 (s, δ_{Cp}), 1019 (s, γ_{Cp}), 1096 (s, γ_{Cp}). Crystals of complex **5** were obtained by recrystallizing solid **5** from hexane at −20 °C. Complex **5**: Yield: 74%. m.p., 123 °C (dec.). *Anal.* Calc. for $C_{39}H_{24}Co_4Fe_2O_{12}$: C, 45.39; H, 2.34. Found: C, 45.62; H, 2.37%. IR (KBr disk) *v*(CO) 2090s, 2044s, 2023vs cm^{-1}. ^1H NMR ($CDCl_3$, δ): 6.23 (s, 1H, C≡C–H), 6.27 (s, 1H, C≡C–H), 3.89–4.32 (m, 16H, Cp), 1.62, 1.63 [d, 6H, $C(CH_3)_2$]. ^{13}C NMR ($CDCl_3$, δ): 199.62 (CO), 83.17, 84.12, 101.90, 102.13 (–C≡CH), 67.8–73.87 (Cp), 33.46 [$C(CH_3)_2$], 30.15, 30.95 (CH_3). MS (FAB, relative abundance): 864 (M^+−6CO, 51%), 836 (M^+−7CO, 63%), 808 (M^+−8CO, 32%), 696 (M^+−12CO, 49%), 578 (M^+−12CO–2Co, 31%).

3.3. Synthesis of complex $[FcC(CH_3)_2Fc'CH{=}C][FeCo_2(CO)_9]$ (6)

A THF solution of complex **3** [$FcC(CH_3)_2Fc'C{\equiv}CH]Co_2(CO)_6$ (200 g, 0.28 mmol), $Fe_2(CO)_9$ (311 mg, 0.86 mmol) and $C_6H_5CH{=}CHCOCH_3$(83 mg, 0.57 mmol) was stirred for 39 h at 55–60 °C. The solvent of the resulting red mixture was removed in vacuum. The residue was dissolved in a minimal amount of benzene and subjected to chromatographic separation on a silica gel column (1.5 × 30 cm). Elution with hexane–benzene (7:1) afforded a red band (**6**). Crystals of **6** were obtained by recrystallizing the red solid **6** from hexane at −20 °C. Yield: 42%. m.p., 133 °C (dec.). *Anal.* Calc. for $C_{34}H_{24}Co_2Fe_3O_9$: C, 47.38; H, 2.81. Found: C, 47.59; H, 2.73%. IR(KBr disk) *v*(CO) 2097s, 2066s, 2034vs, 2004s, 1977s, 1961s cm^{-1}. ^1H NMR ($CDCl_3$, δ): 6.69 (s, 1H, HC), 3.87–4.48 (m, 17H, Cp), 1.50 [s, 6H, $C(CH_3)_2$]. ^{13}C NMR ($CDCl_3$, δ): 204.10 (CO), 103.12, 107.02 (CH=C), 66.19–69.95 (Cp), 30.63 (CH_3), 33.23 (C). MS (FAB, relative abundance): 862 (M^+, 24%), 750 (M^+−4CO, 75%), 694 (M^+−6CO, 96%), 610 (M^+−9CO, 18%), 227 ($C_5H_5FeC_5H_4C_3H_6^+$, 87%).

3.4. X-ray crystallography of complex 5

A dark-green crystal of **5** was mounted on a glass fiber. All measurements were made on a Bruker SMART APEX CCD diffractometer with graphite monochromated Mo Kα ($\lambda = 0.71073$ Å) radiation. All data were collected at 20 °C using the π and ω scan techniques. The structure was solved by direct methods and expanded using Fourier techniques [19]. An absorption correction based on SADABS was applied [20]. All non-hydrogen atoms were refined by full matrix least-squares on $F\langle 2\rangle$. Hydrogen atoms were located and refined geometrically. Data collection, data reduction and cell refinement were performed by Bruker SMART and SAINT software [21]. The structure solution and refinement were performed by SHELXL97 [22]. The crystal data and details of measurements are shown in Table 3.

Table 3
Crystal data and structure refinement of complex **5**

Empirical formula	$C_{39}H_{24}Co_4Fe_2O_{12}$
Formula weight	1032.00
Temperature (K)	293(2)
Wavelength (Å)	0.71073
Crystal system, space group	triclinic, $P\bar{1}$
Unit cell dimensions	
a (Å)	8.355(3)
b (Å)	11.048(4)
c (Å)	22.740(7)
α (°)	91.128(5)
β (°)	97.480(5)
γ (°)	107.381(5)
Volume (Å^3)	1982.5(11)
Z, calculated density (Mg/m^3)	2, 1.729
Absorption coefficient (mm^{-1})	2.408
F(000)	1028
Crystal size (mm)	0.25 × 0.10 × 0.10
θ Range for data collection (°)	0.90–26.01
Limiting indices	$-10 \leqslant h \leqslant 10$, $-12 \leqslant k \leqslant 13$, $-28 \leqslant l \leqslant 21$
Reflections collected/unique [R_{int}]	9177/7613 [0.0257]
Completeness to $\theta = 26.01$ (%)	97.6
Maximum and minimum transmission	0.7947 and 0.5843
Refinement method	full-matrix least-squares on F^2
Data/restraints/parameters	7613/0/516
Goodness-of-fit on F^2	0.999
Final *R* indices [$I > \sigma(I)$]	$R_1 = 0.0518$, $wR_2 = 0.0943$
R indices (all data)	$R_1 = 0.0876$, $wR_2 = 0.1095$
Largest difference in peak and hole (e Å^{-3})	0.510 and −0.396
Weighing scheme	$w = 1/[\sigma^2(F_o^2) + (0.0420P)^2 + 0.1703P]$ where $P = (F_o^2 + 2F_c^2)/3$

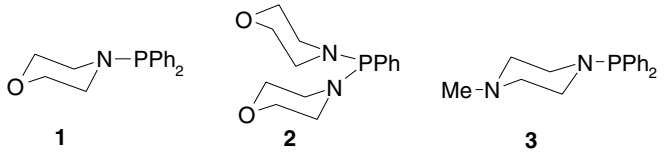
2. Results and discussion

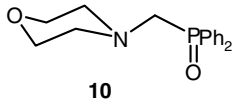
The reactions of two equivalents of morpholine or *N*-methylpiperazine with diphenylchlorophosphine in diethyl ether at room temperature afford the corresponding derivatives *N*-diphenylphosphinoamines $Ph_2PNC_4H_8O$ (**1**) and $Ph_2PNC_4H_8NMe$ (**2**) in good yield. Similarly, the reaction of four equivalents of morpholine with $PhPCl_2$ afforded bis(morpholino)phenylphosphine $PhP(NC_4H_8O)_2$ (**3**). Both the morpholine and *N*-methylpiperazine derivatives (**1**–**3**) react smoothly with elemental sulfur or selenium in toluene under reflux conditions to give the corresponding sulfide or selenide derivatives **4**–**9** as air stable solids. The preparation of some of these chalcogen derivatives have been reported previously but without all the details [12]

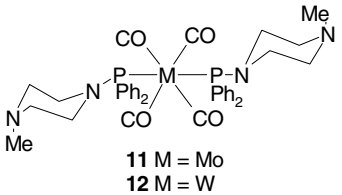


The $^{31}P\{^1H\}$ NMR spectra of compounds **1**–**3** show single resonances at 61.7, 63.3 and 95.8 ppm, respectively, whereas their chalcogenides **4**–**9** show single resonance in the range of 65–79 ppm. The mono-morpholine and *N*-methylpiperazine derivatives **7** and **8** show $^1J_{PSe}$ coupling around 760 Hz whereas the bis(morpholine) derivative **9** shows a $^1J_{PSe}$ coupling of 788 Hz. The ^1H NMR spectral data of **1**–**9** are consistent with the structures proposed. The structural composition of all compounds has been confirmed by elemental analysis.

The reaction of *N*-diphenylphosphinomorpholine **1** with paraformaldehyde in toluene under reflux conditions lead to methylene inserted product **10** in good yield. The methylene insertion reaction proceeds in accordance with our reports on similar aminophosphines [10e,13]. The ^{31}P NMR spectrum of **10** shows a singlet at 28.4 ppm. The ^1H NMR spectrum of compound **10** exhibits two types of resonances for the alkyl (NC_4H_8O and CH_2) protons apart from aryl protons. The NC_4H_8O protons appear at 3.80 ppm and CH_2 protons appear at 3.42 ppm. In the mass spectrum (MS), the most intense fragment ion appears at *m*/*e* 302 [$M^+ + 1$] which is the expected molecular ion.

The reactions of **2** with either $M(CO)_6$ or *cis*-$W(CO)_4(piperidine)_2$ under refluxing conditions produce the *trans*-tetracarbonyl complexes of the type *trans*-$[M(CO)_4(PPh_2NC_4H_8NMe)_2]$ (**11**, M = Mo; **12**, M = W). The ^{31}P NMR spectra of **11** and **12** exhibit single resonances at 106.2 and 80.8 ppm with tungsten complex showing tungsten satellites with a $^1J_{WP}$ coupling of 304.4 Hz which confirms the mutual *trans* dispositions of two phosphine ligands [10f]. Further confirmation for the *trans* geometry of complexes **11** and **12** comes from IR spectra which show single absorption for *ν*CO at 1888 and 1895 cm^{-1}, respectively, characteristic of complexes containing *trans*-$M(CO)_4$ moieties [14].





The ruthenium-arene dimer, $[(p\text{-cymene})RuCl_2]_2$ reacts with two equivalents of **2** in dichloromethane at room temperature to produce an orange-red complex $[(\eta^6\text{-}C_{10}H_{14})RuCl_2\{PPh_2NC_4H_8NMe\}]$ (**13**) in quantitative yield. The ^{31}P NMR spectrum of **13** shows a single resonance at 73.5 ppm with a coordination shift of 12 ppm. The mass spectrum of **13** exhibits parent ion peak (M + 1) at 591.3. The structure of complex **13** was further confirmed by single crystal X-ray diffraction study.

2.1. Structure of $[(\eta^6\text{-}C_{10}H_{14})RuCl_2\{PPh_2NC_4H_8NMe\}]$ (13)

Perspective view of the molecular structure of the compound **13** with the atomic numbering scheme is shown in Fig. 1 along with selected bond lengths and bond angles. The details of the structure determination are given in Table 1.

The coordination geometry around the ruthenium center in **13** can be best described as pseudo octahedral three-legged piano stool, typically of half-sandwich complexes. The P–N (1.680(2) Å) bond is shorter than the

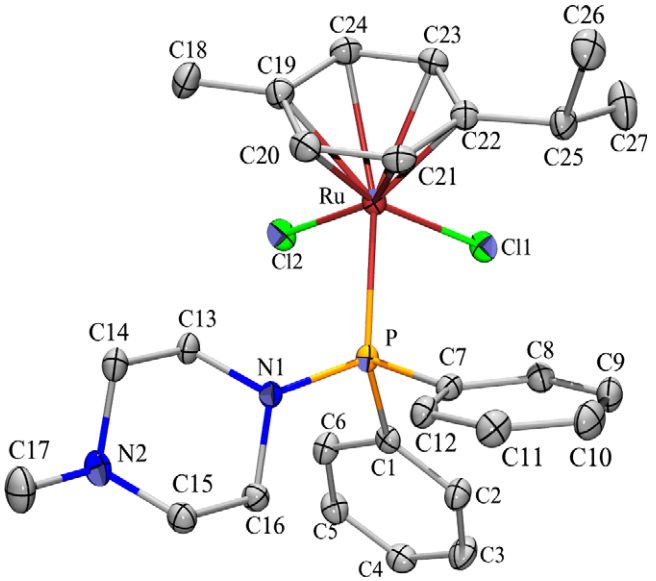


Fig. 1. Molecular structure of **13**. For clarity, solvent and all hydrogen atoms have been omitted. Thermal ellipsoids are drawn at 50% probability. Selected bond distances (Å): Ru–Cl(1), 2.4031(7); Ru–Cl(2), 2.4095(6); Ru–P, 2.3356(6); P–N(1), 1.680(2); N(1)–C(13), 1.471(3); N(2)–C(17), 1.448(3). Selected bond angles (°): Cl(1)–Ru–Cl(2), 86.83(2); Cl(1)–Ru–P, 84.78(2); Cl(1)–Ru–C(19), 150.28(6); Cl(2)–Ru–P, 87.25(2).

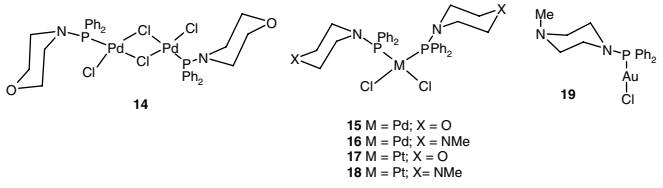
R	0.0373	0.0315
R'	0.0833	0.0747

normally accepted value for a single bond (1.77 Å), but it compares well with those found in a variety of phosphorus(III)–nitrogen compounds suggesting a degree of P–N multiple bonding. Similarly, the Ru–P bond distance is (2.336(1) Å) comparable with those observed in ruthenium complexes containing a variety of tertiary phosphines. The average Ru–Cl bond distance is 2.403(1) Å.

Treatment of $Pd(COD)Cl_2$ with one equivalent of ligand **1** in dichloromethane, afforded a chloro-bridged dinuclear complex, $[Pd_2Cl_2(\mu\text{-}Cl_2)\{Ph_2P(NC_4H_8O)\}_2]$ (**14**). The reaction of two equivalents of **1** with $Pd(COD)Cl_2$ in dichloromethane afforded mononuclear complex, *cis*-$[PdCl_2\{Ph_2PNC_4H_8O\}_2]$ (**15**) as a major product containing small quantities of dinuclear complex, **14** [15] which are separated by fractional crystallization. Surprisingly, $Pd(COD)Cl_2$ on treatment with **2** produced exclusively the *cis*-$[PdCl_2\{PPh_2NC_4H_8NMe\}_2]$ (**16**) as a major product irrespective of the stoichiometry of the reactants and the reaction conditions



In contrast, the reaction of either one or two equivalents of ligand **1** or **2** with $Pt(COD)Cl_2$ afforded only the mononuclear complexes, *cis*-$[PtCl_2\{Ph_2PNC_4H_8X\}_2]$ (**17**, X = O; **18**, X = NMe) in good yield. Further attempts to synthesize a dinuclear platinum complex analogues to the dipalladium complex **14** have been unsuccessful.

The $^{31}P\{^1H\}$ NMR spectra of **14** show a single resonance at 75.4 ppm. In the mass spectrum (MS) the expected molecular ion appears at m/e 862 [M − Cl]. The structure of **14** was confirmed by a single crystal X-ray diffraction study. The $^{31}P\{^1H\}$ NMR spectra of **15** and **16** exhibit single resonances at 67.3 and 68.5 ppm, respectively. The phosphorus-31 chemical shifts due to the corresponding platinum derivatives (**17** and **18**) are relatively shielded and appear at 50.7 and 50.2 ppm, respectively. Both the complexes show large $^1J_{PtP}$ coupling (**17**, 3968 Hz; **18**, 3965 Hz) which is characteristic of phosphines having mutually *cis*-dispositions [16].

The gold(I) complex, $[ClAu(PPh_2NC_4H_8NMe)]$ (**19**) was produced in the reaction between **2** and $AuCl(SMe_2)$ as colorless light sensitive solid soluble in most of the organic solvents. The ^{31}P NMR spectrum of **19** shows a single resonance at 77.9 ppm with a coordination shift of 16.5 ppm.

2.2. Structure of $[Pd_2Cl_2(\mu\text{-}Cl_2)\{Ph_2P(NC_4H_8O)\}_2]$ (**14**)

Perspective view of the molecular structure of the compound **14** with the atomic numbering scheme is shown in Fig. 2 along with selected bond lengths and bond angles. The Pd_2Cl_2 plane is perpendicular to morpholine rings. The Cl(1)–Pd–P angle is 93.35(3)° where as Cl(1_a)–Pd–Cl(2) angle is 89.61(3)° which clearly indicates some distortion at the metal center. The Cl(1)–Pd–P angle (93.35(3)°) appears to have increased from the squareplanar value of 90° to an extent limited by the development of phosphine–chloride interactions. The Pd–Cl(1) (2.32 Å) bond distance is slightly longer than Pd–Cl(2) (2.27 Å) bond distance. That there is only a single ^{31}P NMR resonance in solution suggests that the observed difference may result from packing (or) other solid state effects.

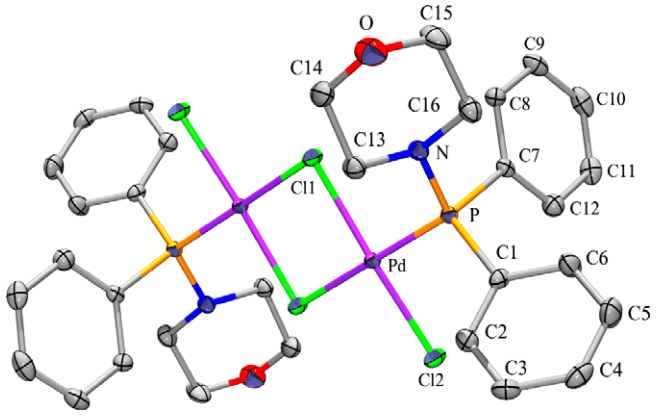


Fig. 2. Molecular structure of **14**. For clarity, solvent and all hydrogen atoms have been omitted. Thermal ellipsoids are drawn at 50% probability. Selected bond distances (Å): Pd–Cl(1), 2.325(8); Pd–Cl(2), 2.271(1); Pd–P, 2.215(1); Pd–Cl(1a), 2.437(1); P–N, 1.676(3); P–Cl, 1.808(3); P–C(7), 1.804(3). Selected bond angles (°): Cl(1)–Pd–Cl(2), 171.39(3); Cl(1)–Pd–P, 93.35(3); Cl(1)–Pd–C(11a), 86.80(3); Cl(2)–Pd–P, 89.73(5); Pd–P–N, 113.46(9).

3. Experimental

All experimental manipulations were carried out under an atmosphere of dry nitrogen or argon using Schlenk techniques. All the solvents were purified by conventional procedures and distilled prior to use. The metal precursors $[W(CO)_4(pip)_2]$ [17], $[(p\text{-cymene})RuCl_2]_2$ [18], $[AuCl(SMe_2)]$ [19], $[(COD)PdCl_2]$, $[(COD)PtCl_2]$ [20] are prepared according to the literature methods and $[Mo(CO)_6]$ was obtained from Aldrich chemicals.

The ^1H and ^{31}P NMR (δ in ppm) spectra were obtained on a VXR300S spectrometer operating at frequencies of 300 and 121 MHz, respectively. The spectra were recorded in $CDCl_3$ solutions with $CDCl_3$ as an internal lock; TMS and 85% H_3PO_4 were used as external standards for ^1H and $^{31}P\{^1H\}$ NMR, respectively. Positive shifts lie downfield of the standard in all cases. Melting points of all compounds were determined on Veego melting point apparatus and were uncorrected. Mass spectra were recorded on MASPEC (msco/9849) system. Microanalyses were carried out on a Carlo Erba model EA 1112 elemental analyzer.

3.1. Preparation of $Ph_2P(NC_4H_8O)$ (1)

A solution of HNC_4H_8O (1.73 g, 19.93 mmol) in dry diethyl ether (20 mL) was added drop wise to a chlorodiphenylphosphine (2 g, 9.06 mmol) also in diethyl ether (70 mL) at 0 °C with vigorous stirring. Then the solution was allowed to room temperature and stirring was continued for 24 h. The morpholine hydrochloride was removed by filtration. The solvent was removed under vacuum to give a white solid of the crude product, which was crystallized from dichloromethane/petroleum ether (b.p. 60–80 °C) (2:1). Yield: 89% (2.20 g); m.p. 84–85 °C. *Anal.* Calc. for $C_{16}H_{18}NOP$: C, 70.83; H, 6.68; N, 5.16. Found: C, 70.02; H, 6.32; N, 5.06%. ^1H NMR (300 MHz, $CDCl_3$): δ 7.23–7.59 (m, 10H, Ph), δ 3.71 (t, 4H, OC_2H_4), δ 3.07 (tt, 4H, NC_2H_4). $^{31}P\{^1H\}$ NMR (300 MHz, $CDCl_3$): δ 63.7 (s).

3.2. Preparation of $[Ph_2PNC_4H_8NMe]$ (2)

To an ice cooled solution of *N*-methylpiperazine (2.26 g, 22.5 mmol) in diethyl ether (50 mL), a solution of chlorodiphenylphosphine (2.48 g, 11.25 mmol) in diethyl ether (30 mL) was added dropwise over a period of 15 min with constant stirring. The reaction mixture was allowed to warm to room temperature and stirring was continued for 16 h. The piperazinehydrochloride was filtered off and the filtrate was dried under vacuum. The residue obtained was dissolved in 20 mL of acetonitrile and the solution was cooled to −25 °C for 10 h to give analytically pure product of **1** as colorless blocks. Yield: 70% (2.24 g); m.p. 58–60 °C. *Anal.* Calc. for $C_{17}H_{21}N_2P$: C, 71.81; H, 7.44; N, 9.85. Found: C, 71.31; H, 7.22; N, 9.91%. ^1H NMR (400 MHz, $CDCl_3$): δ 2.98 (s, 4H, CH_2), 2.38 (s, 4H, CH_2), 2.20 (s, 3H, *NMe*), 7.30–7.55 (m, 10H, *phenyl*). $^{31}P\{^1H\}$ NMR (400 MHz, $CDCl_3$): δ 61.3 (s).

3.3. Preparation of $PhP(NC_4H_8O)_2$ (3)

A solution of HNC_4H_8O (1.73 g, 19.93 mmol) in dry diethyl ether (20 mL) was added drop wise to chlorodiphenylphosphine (2 g, 9.06 mmol) also in diethyl ether (70 mL) at 0 °C with vigorous stirring. Then the solution was allowed to warm to room temperature and stirring was continued for 24 h. The morpholine hydrochloride was removed by filtration. The solvent was removed under vacuum to give a white solid of the crude product, which was crystallized from dichloromethane/petroleum ether (2:1). Yield: 91.0% (2.95 g); m.p. 98–100 °C. *Anal.* Calc. for $C_{14}H_{21}N_2O_2P$: C, 59.98; H, 7.51; N, 9.94. Found: C, 59.02; H, 7.24; N, 9.27%. $^{31}P\{^1H\}$ NMR (300 MHz, $CDCl_3$): δ 95.8 (s).

3.4. Preparation of $Ph_2P(S)(NC_4H_8O)$ (4)

A mixture of compound **1** (0.5 g, 1.8 mmol) and sulfur (0.06 g, 1.8 mmol) in toluene (10 mL) was heated under reflux for 12 h to give a clear solution. Solvent was removed under reduced pressure to give a white residue. The residue was dissolved in CH_2Cl_2 (5 mL), layered with 1 mL of petroleum ether and kept at room temperature to give colorless crystals of **3**. Yield: 90% (0.49 g); m.p. 116–118 °C (decomp.). *Anal.* Calc. for $C_{16}H_{18}NOPS$: C, 63.32; H, 5.98; N, 4.61; S, 10.57. Found: C, 63.61; H, 5.99; N, 4.92; S, 8.74%. $^{31}P\{^1H\}$ NMR (300 MHz, $CDCl_3$): δ 65.9 (s).

3.5. Synthesis of $[P(S)Ph_2NC_4H_8NMe]$ (5)

As for **4**, using $Ph_2PNC_4H_8NMe$ (0.19 mg, 67.5 mmol) and elemental sulfur (0.022 mg, 67.6 mmol). Yield: 95% (0.202 g); m.p. 106–108 °C. *Anal.* Calc. for $C_{17}H_{21}N_2PS$: C, 64.53; H, 6.69; N, 8.85; S, 10.13. Found: C, 63.92; H, 6.45; N, 8.31; S, 9.6%. ^1H NMR (400 MHz, $CDCl_3$): δ 2.98 (s, 4H, CH_2), 2.38 (s, 4H, CH_2), 2.2 (s, 3H, *NMe*), 8.1 (m, 5H, *phenyl*), 7.25 (m, 5H, *phenyl*). $^{31}P\{^1H\}$ NMR (400 MHz, $CDCl_3$): δ 65.8 (s).

3.6. Preparation of $PhP(S)(NC_4H_8O)_2$ (6)

As for **4**, using $PhP(NC_4H_8O)_2$ (1 g, 3.56 mmol) and selenium powder (0.15 g, 3.56 mmol). Yield: 92% (1 g); m.p. 120–122 °C. *Anal.* Calc. for $C_{14}H_{21}N_2O_2PS$: C, 53.83; H, 6.77; N, 8.99; S, 10.26. Found: C, 53.70; H, 6.68; N, 9.18; S, 8.85%. $^{31}P\{^1H\}$ NMR (300 MHz, $CDCl_3$): δ 74.8 (s).

3.7. Preparation of $Ph_2P(Se)(NC_4H_8O)$ (7)

A mixture of **1** (1 g, 3.68 mmol) and selenium powder (0.29 g, 3.68 mmol) in toluene (25 mL) was heated under reflux for 12 h. The solution was then cooled to 25 °C and filtered to remove any undissolved selenium. The solvent was removed under reduced pressure to give a sticky residue. The residue was dissolved in 3 mL of CH_2Cl_2, layered with 1 mL of petroleum ether and kept at room temperature to afford crystals of **5**. Yield: 92% (0.12 g); m.p.

120–122 °C. *Anal.* Calc. for $C_{16}H_{18}NOPSe$: C, 54.86; H, 5.17; N, 3.99. Found: C, 55.3; H, 5.2; N, 4.4%. ^{1}H NMR (300 MHz, $CDCl_3$): δ 8.12–7.2.1 (m, 21H, Ph), δ 3.77 (tt, 4H, OC_2H_4), δ 2.82 (tt, 4H, NC_2H_4). $^{31}P\{^1H\}$ NMR (300 MHz, $CDCl_3$): δ 66.9 (s), $^1J_{PSe} = 760$ Hz.

3.8. Preparation of *[P(Se)Ph$_2$NC$_4$H$_8$NMe] (**8**)*

As for **7** using $Ph_2PNC_4H_8NMe$ (0.230 g, 80.9 mmol) and grey selenium (0.064 g, 80.9 mmol). Yield: 90% (261 mg); m.p. 114–116 °C. *Anal.* Calc. for $C_{17}H_{21}N_2PSe$: C, 56.20; H, 5.83; N, 7.71. Found: C, 56.37; H, 5.46; N, 7.29%. ^{1}H NMR (400 MHz, $CDCl_3$): δ 2.9 (s, 4H, *CH*$_2$), 2.5 (s, 4H, *CH*$_2$), 2.3 (s, 3H, *NMe*), 8.2 (m, 5H, *phenyl*), 7.5 (m, 5H, *phenyl*). $^{31}P\{^1H\}$ NMR (400 MHz, $CDCl_3$): δ 66.28 (s), $^1J_{PSe} = 758.4$ Hz.

3.9. Preparation of *PhP(Se)(NC$_4$H$_8$O)$_2$ (**9**)*

As for **7** using $PhP(NC_4H_8O)_2$ (1 g, 3.68 mmol) and selenium powder (0.29 g, 3.68 mmol). Yield: 78% (1 g); m.p. 120–122 °C. *Anal.* Calc. for $C_{14}H_{21}N_2O_2PSe$: C, 46.86; H, 5.58; N, 7.79. Found: C, 46.8; H, 5.34; N, 8.04%. ^{1}H NMR (300 MHz, $CDCl_3$): δ 7.98–7.26 (m, 5H, Ph), δ 3.66 (tt, 4H, OC_2H_4), δ 3.07 (tt, 4H, NC_2H_4). $^{31}P\{^1H\}$ NMR (300 MHz, $CDCl_3$): δ 78.2 (s), $^1J_{PSe} = 788$ Hz.

3.10. Preparation of *Ph$_2$(O)PCH$_2$NC$_4$H$_8$O (**10**)*

A mixture of **1** (0.2 g, 0.73 mmol) and paraformaldehyde (0.02 g, 0.81 mmol) in toluene (6 mL) was heated at 100 °C with stirring for 12 h. The solution was then cooled to 25 °C and filtered to remove any undissolved impurities. The compound was crystallized from CH_2Cl_2–*n*-hexane (4:1). Yield: 81% (0.18 g); m.p. 136–138 °C. *Anal.* Calc. for $C_{17}H_{20}N0_2P$: C, 67.76; H, 6.69; N, 4.64. Found: C, 66.78; H, 6.79; N, 4.62%. ^{1}H NMR (300 MHz, $CDCl_3$): δ 7.85–7.26 (m, 10H, Ph), δ 3.72 (t, 4H, OC_2H_4), δ 3.42 (d, 2H, CH_2, $^2J_{PH} = 6$ Hz), δ 2.85 (s, 4H, NC_2H_4). $^{31}P\{^1H\}$ NMR (300 MHz, $CDCl_3$): δ 28.4 (s). MS (FAB): 302 ($M^+ + 1$).

3.11. Preparation of *trans-[Mo(CO)$_4${(Ph$_2$PNC$_4$H$_8$NMe)-κP}$_2$] (**11**)*

A mixture of **2** (0.044 g, 0.153 mmol) and $[Mo(CO)_6]$ (20.22 mg, 0.076 mmol) in toluene (15 mL) was heated at 90 °C for 10 h. The yellow solution obtained was cooled to room temperature and passed through a column containing celite and the solvent was removed under *vacuo*. The pale yellow micro crystalline residue obtained was washed twice with diethyl ether (3 mL) to afford analytically pure product of **11**. Yield: 70% (41 mg); m.p. 186–188 °C (dec). *Anal.* Calc. for $C_{38}H_{42}O_4N_4P_2Mo$: C, 58.77; H, 5.45; N, 7.21. Found: C, 57.69; H, 5.42; N, 6.38%. FT IR (KBr disc) cm^{-1}: ν_{CO} at 1888 s. ^{1}H NMR (400 MHz, $CDCl_3$): δ 3.2 (s, 4H, *CH*$_2$), 2.4 (s, 4H, *CH*$_2$), 2.2 (s, 3H, *NMe*), 7.4 (m, 5H, *phenyl*), 7.1 (m, 5H, *phenyl*). $^{31}P\{^1H\}$ NMR (400 MHz, $CDCl_3$): δ 106.2 (s).

3.12. Preparation of *trans-[W(CO)$_4${(Ph$_2$PNC$_4$H$_8$NMe)-κP}$_2$] (**12**)*

As for **11** using $[Ph_2PNC_4H_8NMe]$ (0.053 mg, 188 mmol) and $[W(CO)_4(pip)_2]$ (0.044 g, 94 μmol). Yield: 68% (0.055 g); m.p. 178–180 °C (dec). *Anal.* Calc. for $C_{38}H_{42}O_4N_4P_2W$: C, 52.79; H, 4.89; N, 6.48. Found: C, 53.23; H, 5.09; N, 6.65%. ^{1}H NMR (400 MHz, $CDCl_3$): δ 2.82 (s, 4H, *CH*$_2$), 2.43 (s, 4H, *CH*$_2$), 2.10 (s, 3H, *NMe*), 7.61–7.24 (m, 10H, *phenyl*). IR (KBr disc) cm^{-1}: ν_{CO} at 1890 s. $^{31}P\{^1H\}$ NMR (300 MHz, $CDCl_3$): δ 80.8 (s), $^1J_{PW} = 304.4$ Hz.

3.13. Preparation of *[Ru(η^6-C$_{10}$H$_{14}$)Cl$_2${(PPh$_2$NC$_4$H$_8$-NMe)-κP}] (**13**)*

A solution of [(*p*-cymene)$RuCl_2]_2$ (0.033 mg, 54.5 μmol) in dichloromethane (5 mL) was added dropwise to a solution of **2** (0.031 mg, 109 μmol) in the same solvent (5 mL) at room temperature. After the completion of the addition, the reaction mixture was stirred for 4 h and the solvent was removed under reduced pressure. The residue obtained was washed with diethyl ether to give analytically pure product of **13** as red micro crystalline solid. Yield: 85% (55 mg); m.p. 168–170 °C (dec). *Anal.* Calc. for $C_{27}H_{35}N_2PRuCl_2$: C, 54.91; H, 5.97; N, 4.74. Found: C, 54.63; H, 5.74; N, 4.07. ^{1}H NMR (400 MHz, $CDCl_3$): δ 7.70–7.43 (m, 10H, *phenyl*), 5.15 (d, $J_{HH} = 6.4$ Hz, 2H, *Cymene phenyl*), 4.95 (d, $J_{HH} = 6.4$ Hz, 2H, *Cymene phenyl*), 3.1 (s, 3H, *NMe*), 2.75 (septet, 1H, *CH*), 2.5 (s, 4H, *CH*$_2$) 2.4 (s, 4H, *CH*$_2$), 1.95 (s, 3H, *CH*$_3$). $^{31}P\{^1H\}$ NMR (300 MHz, $CDCl_3$): δ 73.5 (s).

3.14. Preparation of *[Pd$_2$(μ-Cl)$_2$Cl$_2${(Ph$_2$PNC$_4$H$_8$O)-κP}$_2$] (**14**)*

To a mixture of $Pd(COD)Cl_2$ (0.05 g, 0.17 mmol) and compound **1** (0.05 g, 0.17 mmol) a CH_2Cl_2 solution (8 mL) was added and the resultant reaction mixture was stirred at room temperature for 48 h. The solution was concentrated to 3 mL and 1 mL of petroleum ether was added. Cooling this solution to 0 °C gave **8** as red crystals. Yield: 77% (0.06 g); m.p. 160–162 °C. *Anal.* Calc. for $C_{32}H_{36}Cl_4N_2O_2P_2Pd_2$: C, 42.83; H, 4.04; N, 3.12. Found: C, 42.6; H, 3.7; N, 3.5%. ^{1}H NMR (300 MHz, $CDCl_3$): δ 7.26–8.05 (m, 10H, Ph), δ 3.68 (t, 4H, OC_2H_4), δ 3.13 (tt, 4H, NC_2H_4). $^{31}P\{^1H\}$ NMR (300 MHz, $CDCl_3$): δ 75.4 (s). MS (FAB): 862 (M − Cl).

3.15. Preparation of *cis-[PdCl$_2${(PPh$_2$NC$_4$H$_8$O)-κP}$_2$] (**15**)*

To a mixture of $Pd(COD)Cl_2$ (0.05 g, 0.17 mmol) and compound **1** (0.11 g, 0.35 mmol) a CH_2Cl_2 solution

(8 mL) was added and the resultant reaction mixture was stirred at room temperature for 48 h. The solution was concentrated to 3 mL and 1 mL of petroleum ether was added. Cooling this solution to 0 °C gave **9** as red crystalline material. Further cooling the remaining solution gave **9** as yellow crystals. Yield: 61% (0.08 g); m.p. 180–185 °C. *Anal.* Calc. for $C_{32}H_{36}Cl_2N_2O_2P_2Pd$: C, 53.38; H, 5.04; N, 3.91. Found: C, 52.82; H, 5.36; N, 3.72%. ^{1}H NMR (300 MHz, $CDCl_3$): δ 7.71–7.27 (m, 10H, Ph), δ 3.64 (t, 4H, OC_2H_4), δ 3.01 (tt, 4H, NC_2H_4). $^{31}P\{^1H\}$ NMR (300 MHz, $CDCl_3$): δ 67.3 (s).

3.16. Preparation of cis-[$PdCl_2\{(PPh_2NC_4H_8NMe)$-κP$\}_2$] (16)

As for **15**, using [Pd(COD)Cl_2] (25 mg, 88 μmol) and **2** (50 mg, 175 μmol). Yield: 95% (62 mg); m.p. 150–152 °C (dec). *Anal.* Calc. for $C_{34}H_{42}Cl_2N_4P_2Pd$: C, 54.74; H, 5.67; N, 7.51. Found: C, 53.68; H, 5.38; N, 7.32%. ^{1}H NMR (400 MHz, $CDCl_3$): δ 3.1 (s, 4H, CH_2), 2.5 (s, 4H, CH_2), 2.2 (s, 3H, CH_2), 7.71–7.42 (m, 10H, *phenyl*). $^{31}P\{^1H\}$ NMR (400 MHz, $CDCl_3$): δ 68.5 (s).

3.17. Preparation of cis-[$PtCl_2\{(Ph_2PNC_4H_8O)$-κP$\}_2$] (17)

To a solution of [Pt(COD)Cl_2] (0.03 g, 0.08 mmol) in CH_2Cl_2 (4 mL) was added a solution of **1** (0.04 g, 0.16 mmol) also in CH_2Cl_2 (5 mL) and the reaction mixture was stirred at room temperature for 48 h. The solution was concentrated to 2 mL and 1 mL of petroleum ether was added. Cooling this solution to 0 °C gave **10** as white crystalline material. Yield: 92% (0.06 g); m.p. 216–218 °C. *Anal.* Calc. for $C_{32}H_{36}Cl_2N_2O_2P_2Pt \cdot 0.5CH_2Cl_2$: C, 45.86; H, 4.38; N, 3.29. Found: C, 45.71; H, 4.30; N, 3.46%. ^{1}H NMR (300 MHz, $CDCl_3$): δ 7.89–6.91 (m, 10H, Ph), δ 3.53 (t, 4H, OC_2H_4), δ 3.22 (t, 4H, NC_2H_4). $^{31}P\{^1H\}$ NMR (300 MHz, $CDCl_3$): δ 50.7 (s), $^1J_{PPt} = 3968$ Hz. MS (FAB): 772 (M − Cl).

3.18. Preparation of cis-[$PtCl_2\{(Ph_2PNC_4H_8NMe)$-κP$\}_2$] (18)

As for **17**, using [Pt(COD)Cl_2] (0.02 g, 53 μmol) and **2** (0.03 g, 106 μmol). Yield: 95% (43 mg); m.p. 164–166 °C (dec). *Anal.* Calc. for $C_{34}H_{42}Cl_2N_4P_2Pt$: C, 48.93; H, 5.07; N, 6.71. Found: C, 48.26; H, 5.09; N, 6.17%. ^{1}H NMR (400 MHz, $CDCl_3$): δ 3.2 (s, 4H, CH_2), 2.4 (s, 4H, CH_2), 2.2 (s, 3H, CH_2), 7.43–7.16 (m, 10H, *phenyl*). $^{31}P\{^1H\}$ NMR (400 MHz, $CDCl_3$): δ 50.2 (s), $^1J_{PPt} = 3965$ Hz.

3.19. Preparation of [$AuCl\{(PPh_2NC_4H_8NMe)$-κP$\}$] (19)

A solution of [ClAu(SMe_2)] (0.026 g, 88.8 μmol) in dichloromethane (10 mL) was added dropwise to a solution of **2** (0.030 g, 88.8 μmol) also in dichloromethane (8 mL) at room temperature and the reaction mixture was stirred for 4 h. The solvent was removed under reduced pressure and the residue was washed with diethyl ether to give analytically pure product of **19** as white micro crystalline solid. Yield: 96% (41 mg); m.p. 150–152 °C (dec). *Anal.* Calc. for $C_{17}H_{21}N_2PAuCl$: C, 39.51; H, 4.09; N, 5.42. Found: C, 38.96; H, 3.85; N, 4.92%. ^{1}H NMR (400 MHz, $CDCl_3$): 3.24 (s, 4H, CH_2), 2.43 (s, 4H, CH_2), 2.21 (s, 3H, *NMe*), 7.71–7.50 (m, 10H, *phenyl*). $^{31}P\{^1H\}$ NMR (400 MHz, $CDCl_3$): δ 77.9 (s).

4. X-ray crystallography

Crystals of compounds **13** and **14** suitable for X-ray crystal analysis were mounted on Cryoloops™ with Paratone oil and placed in the cold nitrogen stream of the Bruker Kryoflex™ attachment of the Bruker APEX CCD diffractometer. Full spheres of data were collected using 606 scans in ω (0.3° per scan) at 0°, 120° and 240° and graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). The raw data were reduced to F^2 values at a resolution of 0.75 Å using the SAINT+ software (SAINT+, V. 6.35A, Bruker-AXS, Madison, WI, 2002) and global refinements of unit cell parameters using 5000–9000 reflections chosen from the full sets of data were performed. Multiple measurements of equivalent reflections provided the basis for empirical absorption corrections as well as corrections for any crystal deterioration during the data collection (SADABS, V. 2.05, Bruker-AXS, Madison, WI, 2000). The structures were solved by direct methods (SHELX-97) and refined by full-matrix least-squares based on F^2 using the SHELXTL-PLUS program package (SHELXTL-PLUS, V. 6.10, Bruker-AXS, Madison, WI, 2000). Hydrogen atoms were placed in calculated positions provided by a difference map. All were included as riding contributions (C–H = 0.95–0.98 Å) with isotropic displacement parameters 1.2–1.5 times those of the attached carbon atoms. Two orientations were deduced from difference maps and were constrained to be regular hexagons in the final refinement. Other details of the data collections and refinements specific to these compounds are summarized in Table 1.

Acknowledgements

We thank the Department of Science and Technology (DST), New Delhi, for financial support of the work done at the Indian Institution of Technology, Bombay. J.T.M. acknowledges the support of the Louisiana Board of Regents through the Louisiana Educational Quality Support Fund (Grant: LEQSF (2002-2003)-ENH-TR-67) for purchase of the Bruker APEX diffractometer and Tulane University, New Orleans, LA, USA for the support of the Crystallography Laboratory. We thank the regional Sophisticated Center (RSIC), IIT Bombay for recording NMR spectra.

Appendix A. Supplementary material

Full details of data collection and structure refinement for compounds **8** and **14** have been deposited with the Cambridge Crystallography Data Centre, CCDC Nos. 606036 and 265737. Copies of this information may be obtained free of charge from the Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44 1223 336033; e-mail: deposit@ccdc.cam.ac.uk or www://http.ccdc.cam.ac.uk). Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2006.05.041.

$Tp^{Th,Me}$. We have also synthesized the heteroscorpionate complexes of hydrogen bis(5-methyl-3-phenylpyrazol-1-yl)(3-methyl-5-phenylpyrazol-1-yl)borate ([HB(3-Me-5-Phpz)(5-Me-3-Phpz)$_2$]$^-$) with molybdenum and studied their fluxional behavior and reactivity along with the known hydrogen tris(3,5-dimethylpyrazol-1-yl)borate (Tp^*) analogues [4–6]. The oxidation of synthesized complexes of the type [Et_4N][Tp′Mo(CO)$_3$] and Tp′Mo(CO)$_2$(η^3-allyl) with iodine, *tert*-butylhydrogenperoxide, and dioxygen was studied here in order to detect high-valent molybdenum complexes with Tp′ ligands. We have isolated and structurally characterized the product of aerial oxidation of Tp^*Mo(CO)$_2$I.

2. Experimental

2.1. Syntheses

2.1.1. Syntheses of substituted pyrazoles and sodium hydrogen trispyrazolylborates (NaTp′)

3,5-Dimethylpyrazole and 3(5)-methyl-5(3)-phenylpyrazole were obtained by condensation of appropriate diketones with hydrazine as described by Trofimenko et al. [7]. 3(5)-Methyl-5(3)-(2-thienyl)pyrazole was obtained as follows.

In a three-necked round-bottomed flask 11.08 g of sodium was placed in a 250 cm^3 of dry toluene under nitrogen atmosphere, to which 200 cm^3 anhydrous methanol was added in portions until all sodium was converted into sodium methanolate. The excess of methanol was distilled off under reduced pressure. To the slurry of NaOMe 50 cm^3 of acetylthiophene was added (58.4 g, 0.463 mol). The color of the mixture changed to violet. To this mixture ethyl acetate (150 cm^3, 135 g, 1.53 mol) was added dropwise and the mixture was gradually heated up to reflux and kept as such for 1 h. The sodium diketonate precipitated upon cooling, which was filtered off, washed thoroughly with petroleum ether, dried and dissolved in 150 cm^3 methanol. Hydrazine monohydrate was added (30 cm^3, 0.506 mol), the mixture was heated under reflux for 1 h and then poured onto ice water (1 dm^3), neutralized with 36% aqueous HCl (ca. 25 cm^3), and left for 40 min for precipitation of 3(5)-methyl-5(3)-(2-thienyl)pyrazole. The crude product was dried on air, and three times dissolved in benzene, which was distilled off, then the dry product was boiled twice with petroleum ether and filtered off. Final yield: 8.89 g, 11.7%.

The sodium hydrogen tris(3-R^1-5-R^2-pyrazol-1-yl)-borates ($NaTp^{R1,R2}$) were obtained by condensation of sodium borohydride with three equivalents of substituted pyrazoles dispersed in high-boiling hydrocarbons. The progress of reaction was monitored by measuring the volume of hydrogen evolved. The heteroscorpionate Na[HB(3-Me-5-Phpz)(5-Me-3-Phpz)$_2$] [8] was obtained according to the optimized protocol [9]. In case of $NaTp^{Th,Me}$ the octadecane reflux (b.p. 317 °C) was used.

2.1.2. [Et_4N][$Tp^*Mo(CO)_3$] (**1**), $Tp^*Mo(CO)_2$(allyl) (**2**), and $Tp^*MoI(CO)_2$ (**3**)

Complex **1** was obtained from Mo(CO)$_6$ by heating with equimolar amount of $NaTp^*$ in refluxing acetonitrile for 2 h, followed by addition of excess aqueous [Et_4N]Cl into cold mixture and purified as described in [4]. **2** was synthesized according to published protocol [10]. From **1** the $Tp^*MoI(CO)_2$ (**3**) was prepared by oxidation with I_2 [11].

2.1.3. [Et_4N][HB(5-Me-3-Phpz)$_2$(3-Me-5-Phpz)Mo(CO)$_3$] (**4**)

Molybdenum hexacarbonyl (Mo(CO)$_6$ (0.496 g, 1.84 mmol) was dissolved in 15 cm^3 degassed acetonitrile and refluxed for 2 h under nitrogen atmosphere. Then 0.948 g of Na[HB(5-Me-3-Phpz)$_2$(3-Me-5-Phpz)] (1.87 mmol) was added in one portion and the mixture was stirred for 2 h at room temperature, later the volume of mixture was reduced twice and poured into 50 cm^3 of 1 M aqueous [Et_4N]Br. The yellow precipitate of crude **4** was filtered off and dried under reduced pressure. Yield: 1.213 g, 81.7%.

Elemental analysis: Calc. for $C_{41}H_{48}N_7O_3BMo$ (MW 793.63): C, 62.05; H, 6.10; N, 12.35. Found: C, 62.25; H, 6.16; N, 12.48%.

^{1}H NMR (chloroform-*d*, 298 K): 7.88–7.29 (15H, overlapping multiplets, aromatic (3,5-Ph)); 6.42 (1H, s, 4-H(3-Me-5-Phpz)); 6.33 (2H, s, (5-Me-3-Phpz)); 3.42 (8H, q, $CH_2(Et_4N^+)$; 2.20 (6H, s, 5-CH_3(5-Me-3-Phpz)); 2.11 (3H, s, CH_3(3-Ph-5-Mepz)); 1.34 (12H, t, $CH_3(Et_4N^+)$).

Electrochemical properties throughout the paper the potentials are quoted versus Fc^+/Fc): one-electron reversible oxidation at $E_{1/2} = -662$ mV ($\Delta E = 70$ mV, in MeCN) and one-electron irreversible oxidation wave (no corresponding reduction wave) at $E_a = 225$ mV.

2.1.4. [HB(5-Me-3-Phpz)$_2$(3-Me-5-Phpz)]Mo(CO)$_2$(allyl) (**5**)

Molybdenum hexacarbonyl (Mo(CO)$_6$ (0.797 g, 3.02 mmol) was dissolved in degassed acetonitrile (20 cm^3) and 15 cm^3 of allyl bromide was added. The mixture was refluxed under nitrogen for 2 h, Na[HB(5-Me-3-Phpz)$_2$(3-Me-5-Phpz)] (1.528 g, 3.02 mmol) was added in one portion into the cold mixture and stirred for 2 h. Then the solvent was removed on rotary evaporator, the residue was dissolved in benzene and the solution was passed through short bed of alumina. The benzene was distilled off under reduced pressure and solid yellow product was collected. Yield: 0.763 g, 37.3%.

Elemental analysis: Calc. for $C_{35}H_{33}N_6O_2BMo$ (MW 676.44): C, 62.15; H, 4.92; N, 12.42. Found: C, 62.59; H, 4.86; N, 12.24%.

IR (KBr): $\nu_{(BH)}$ 2475 (w); $\nu_{(CO)}$ 1918, 1834 (both s) cm^{-1}.

Electrochemical properties: two-electron oxidation at $E_{1/2} = 201$ mV (at 100 mV s^{-1} irreversible with no corresponding reduction wave, at higher scan rates becomes quasi-reversible, ΔE=110 mV, in THF).

2.1.5. $[Et_4N][Tp^{Th,Me}Mo(CO)_3]$ (6)

Complex **6** was synthesized according to the same protocol as **4** starting from 0.428 g $NaTp^{Th,Me}$ and 0.218 g $Mo(CO)_6$ (0.82 mmol scale). 0.390 g of yellow crystals of **6** (59.0% yield) was collected upon twice crystallization from acetonitrile.

Elemental analysis: Calc. for $C_{35}H_{42}N_7O_3S_3BMo$ (MW 811.69): C, 51.79; H, 5.22; N, 12.08. Found: C, 51.55; H, 5.16; N, 12.43%.

^{1}H NMR (DMSO-d_6, 298 K): 7.37–6.93 (9H, overlapping multiplets, thienyl (3-(2-thienyl)-5-Mepz)); 6.25 (3H, s, 4-H(pz)); 3.10 (8H, q, $CH_2(Et_4N^+)$; 2.18 (9H, s, 3-CH_3); 1.10 (12H, t, $CH_3(Et_4N^+)$).

IR (KBr): $\nu_{(BH)}$ 2556 (w); $\nu_{(CO)}$ 1994, 1937, 1886 (all s) cm^{-1}.

Electrochemical properties: one-electron irreversible oxidation at $E_a = -890$ mV (in MeCN) and a second irreversible oxidation wave at $E_a = 18$ mV.

2.1.6. $Tp^{Th,Me}Mo(CO)_2(allyl)$ (7)

Complex **7** was synthesized by the same procedure as **5** starting from 0.694 g $NaTp^{Th,Me}$ and 0.350 g $Mo(CO)_6$ (1.32 mmol scale) and isolated as yellow crystals upon twice crystallization from tetrahydrofuran. Yield: 0.630 g, 68.6%.

Elemental analysis: Calc. for $C_{29}H_{27}N_6O_2S_3BMo$ (MW 694.50): C, 50.15; H, 3.92; N, 12.10. Found: C, 50.55; H, 3.86; N, 12.40%.

^{1}H NMR (chloroform-*d*, 298 K): 7.74 (1H, dd ($J_{3'4'} = 3.6$ Hz, $J_{3'5'} = 1.1$ Hz), 3-H(3-(2-thienyl-pz_b)); 7.49 (1H, dd ($J_{4'5'} = 5.0$ Hz), 4-H(3-(2-thienyl-pz_b)); 7.34 (2H, dd ($J_{4'5'} = 5.1$ Hz, $J_{3'5'} = 1.1$ Hz), 5-H(3-(2-thienyl-pz_a)); 7.30 (2H, dd ($J_{3'4'} = 3.6$ Hz), 3-H(3-(2-thienyl-pz_a)); 7.22 (1H, dd, 4-H(3-(2-thienyl-pz_b)); 7.06 (2H, dd, 4-H(3-(2-thienyl-pz_a)); 6.18 (1H, s, 4-H(pz_b)); 6.05 (2H, s, 4-H(pz_a)); 2.71 (2H, d ($J_{1',3'\text{-}exo,2'} = 6.6$Hz, 1′,3′-$H_{exo}$(allyl)); 3.59 (1H, m, 2′-H(allyl)); 2.43 (6H, s, 5-CH_3(pz_a)); 2.32 (3H, s, 5-CH_3(pz_b)); 0.76 (2H, d ($J_{1'3'\text{-}endo,2'} = 10.4$ Hz, 1′,3′-H_{endo}(allyl)).

IR (KBr): $\nu_{(BH)}$ 2552 (w); $\nu_{(CO)}$ 1937, 1844 (both s) cm^{-1}.

Electrochemical properties: one-electron oxidation at $E_a = 216$ mV (at 100 mV s^{-1} irreversible with no corresponding reduction wave but at high scan rates (5 V s^{-1}) $\Delta E = 190$ mV, in THF) and a second irreversible oxidation process at $E_a = 746$ mV.

2.1.7. $[Tp^*Mo(O)(\mu\text{-}O)_2Mo(O)]_2(\mu\text{-}OH)_2$ (8)

50.0 mg of **3** was dissolved in 5 cm^3 acetonitrile and the solution was left on air for partial evaporation of the solvent. The red crystals of **8** suitable for X-ray analysis were collected after four days, yield 19.8 mg, 62.0%.

Elemental analysis: Calc. for $C_{46}H_{70}N_{20}O_{10}B_2Mo_4$ (MW 1468.60): C, 37.62; H, 4.80; N, 19.08. Found: C, 37.85; H, 4.91; N, 19.39%.

2.2. Methods

2.2.1. Spectroscopic and electrochemical measurements

The ^{1}H NMR spectra were recorded with Bruker AMX 300 spectrometer. Standard COSY and NOESY experiments were performed with repetition time 1.0 and mixing time 0.3 s (NOESY). IR spectra were recorded in KBr pellets on PARAGON 1000 FT-IR instrument (Perkin–Elmer). The cyclovoltametric (CV) measurements were performed with a BAS 100B/W instrument (Bioanalytical Systems, USA). CV runs were recorded using $[Bu_4N][BF_4]$ as the supporting electrolyte, platinum disc as the working and Ag/AgCl as the reference electrode at 100 mV s^{-1} standard sweep rate for 1 mM samples in MeCN and/or in THF. Throughout the paper, the potentials are quoted versus ferrocenium/ferrocene pair used as an internal standard (added to the solution for final measurements).

2.2.2. X-ray crystallography

Crystal data are given in Table 1, together with refinement details. All measurements of crystal were performed at low temperature using an Oxford Cryosystem device on a Kuma KM4CCD κ-axis diffractometer with graphite-monochromated Mo Kα radiation. The crystal was positioned 65 mm from the CCD camera. 612 frames were measured at 0.75° intervals with a counting time of 20 s. Accurate cell parameters were determined and refined by least-squares fit of 7200 of the strongest reflections. The data were corrected for Lorentz and polarization effects. No absorption correction was applied. Data reduction and analysis were carried out with the Oxford Diffraction (Poland) Sp. z o.o (formerly Kuma Diffraction Wrocław, Poland) programs. The structure was solved by direct methods (program SHELXS97 [12]) and refined by the full-matrix least-squares method on all F^2 data using the SHELXL97 [13] programs. Non-hydrogen atoms were refined with anisotropic displacement parameters; hydrogen atoms were included from geometry of molecules and $\Delta\rho$ maps. During refinement they were fixed.

3. Results and discussion

3.1. X-ray structures

The low-valence molybdenum complexes are suitable precursors for oxygen transfer catalyst [14]. Our systematic studies on transition metal ion complexes with polypyrazolylborates of low-symmetry prompted us to synthesize series of complexes of molybdenum(0) and (II) of the general formula $[Et_4N][Tp'Mo(CO)_3]$ and $Tp'Mo(CO)_2(\eta^3\text{-allyl})$ and attempted to oxidize them under spectroscopic

control. Thus, we have obtained a pair of compounds with relatively unexplored ligand $Tp^{Th,Me}$: the Mo(0) species **6** and Mo(II) derivative **7**. These complexes were characterized crystallographically. We have found that in both of them the Tp′ ligand was coordinated in η^3 mode via nitrogen donors only (Figs. 1 and 2). The averaged Mo–N(pz) bond length in **7** (2.305 Å) remain almost unchanged in comparison with that in **6** (2.313 Å). However upon increase of the coordination number from 6 to 8, i.e. the increase of steric crowding in **7** the $Tp^{Th,Me}$ is bound less tight than in **6** if consider the boron-centered angle α, which is considerably larger in **7** (92.3°) in comparison with 81.8° in **6**. This has been observed before for Tp^* ligand (compare entries 2 and/or 3 with 9 and 10) but obviously not for unhindered Tp ligand (compare entries 1 with 6 and 7 in Table 2). Within the Tp′Mo(CO)$_2$(allyl) series the growth of steric hindrance imposed by 3-substituents at pyrazolyl residues as measured by decreasing bite angle

(column 4 in Table 2) increases in the raw of ligands: $Tp \approx [HB(indazolyl)_3]^- < Tp^{Mes} < Tp^{CH_2Ph,Me} \approx Tp^* \approx Tp^{Br,Br,Br} < Tp^{Th,Me}$. Surprisingly the $Tp^{Th,Me}$ ligand has remarkably smallest bite while the averaged Mo–N(pz) distance is longer than in other $Tp'Mo(CO)^2$(allyl) complexes except Tp^{Mes}. At the limit of high steric hindrance there is the $[HB(2H\text{-benz(g)indazol-2yl})_3]^-$ ligand which coordinates in η^2 fashion to molybdenum(II) (entry 16 in Table 2).

During recrystallization of $Tp^*Mo(CO)_2I$ complex **3** from acetonitrile we have noticed the formation of another species, which crystallized well to give X-ray quality, red crystals of the tetranuclear Mo(V) complex **8** (Fig. 3). The Tp^* ligand was partially lost and two inner molybdenum(V)

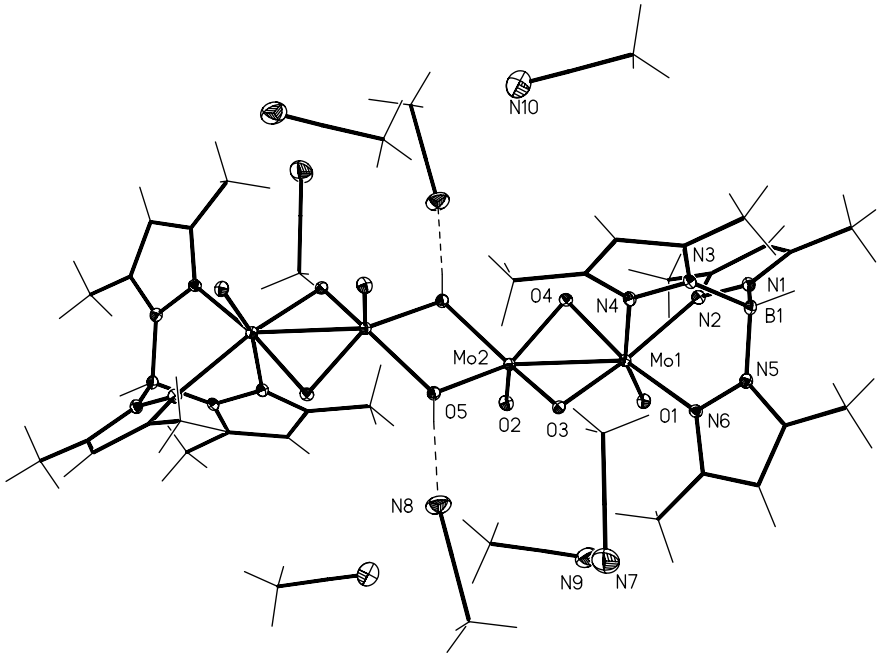

Fig. 3. View of molecule of **8**. Selected bond lengths (Å): Mo(1)–O(1), 1.6879(18); Mo(1)–O(3), 1.9634(18); Mo(1)–O(4), 1.9675(17); Mo(1)–N(2), 2.177(2); Mo(1)–N(6), 2.187(2); Mo(1)–N(4), 2.377(2); Mo(1)–Mo(2), 2.5588(3); Mo(2)–O(2), 1.6855(18); Mo(2)–O(3), 1.9046(17); Mo(2)–O(4), 1.9133(18); Mo(2)–O(5)′, 2.0587(18); Mo(2)–O(5), 2.0648(18).

centers of linear **8** are surrounded exclusively by oxygen donors. Generally, there are three tetranuclear complexes of Mo(V) with Tp-type ligands (Tp′) which were obtained from equimolar mixture of KTp and $MoCl_5$ [27] or by oxidation of $[Tp'Mo(CO)_3]^-$ salt with dimethyldioxirane [28] or **3** with dioxygen (**8**) in non-aqueous solvents (Table 3, Chart 1). In the former case the tetranuclear side-product **T**[9] was spontaneously formed, in which two terminal Mo(V) centers coordinated with Tp ligand and two inner Mo(V) centers were bound to oxygen donors. The cyclic tetramer **T**[10] is also composed of four Mo(V) centers, all bearing Tp anions coordinated in η^3 fashion. The structure of linear framework in **8** is similar to that in **T**[9]; the Mo(V)–Mo(V) distances between terminal and inner metal ion are 2.559 and 2.553 Å, respectively, while the distance between inner molybdenum(V) centers, connected together via two μ-(OR) are around 3.4 Å, considerably shorter than those between molybdenum centers in Tp′Mo–O–MoTp′ fragments in **T**[10] or in any dinuclear complex **D**[11]–**D**[16], where it was ca. 3.7 Å. The Tp′ ligands are bound slightly weaker in tetranuclear complexes than Tp* in dinuclear or mononuclear molybdenum(V) compounds if consider the mean Mo–N(pz) distance, which equals: 2.25, 2.23, and 2.22 Å, respectively. Thus the Mo–N(pz) bond length for tetranuclear complexes of molybdenum (V) is rather close to that for mononuclear oxomolybdenum(VI) complexes (ca. 2.26 Å). Throughout all the oxo-molybdenum complexes of Tp* or Tp ligands the Mo=O bond length is almost invariable (column 2 in Table 3) and equals 1.68 (±0.02) Å with two exceptions.

3.2. The ^{1}H NMR spectroscopy of 4–7

The symmetry of the ^{1}H NMR spectra of complexes **4** and **6** corresponded to the anionic ligand symmetry, i.e. two set of 4-H(pz) resonances of 1:2 integral intensity ratio were observed for **4**, while only one 4-H(pz) resonance was found in case of **6**.

The ^{1}H NMR spectrum of **5** taken at ambient temperature consists of one set of broad resonances both from Tp′ and allyl ligands. Mutual rotation of those ligands becomes slow in the ^{1}H NMR timescale at lower temperatures (Fig. 4). Thus, two 4-H(pz) resonances of 1:2 intensity ratio are observed at 298 K, which split into two sets due to the presence of two rotational isomers ***I*** (of effective C_S symmetry) and ***II*** (Fig. 5). The spectral assignments for ***I*** and ***II*** were done on the basis of COSY and NOESY measurements. Series of EXSY peaks were observed within the 3-CH_3 and 5-CH_3 resonances between ***I*** and ***II***, which enabled to assign 3-CH_3 resonance at 2.10 ppm to isomer ***II***. Additionally, the NOE peak between 1′,3′-H_{endo} and 3-CH_3(3-Me-5-Phpz) in isomer ***I*** was observed.

Surprisingly, the ^{1}H NMR spectrum of **7** indicates that in this molecule mutual rotation of Tp′ and allyl ligands is already slow on a timescale of the method at 298 K in $CDCl_3$ solvent. Accordingly, two sets of pyrazolyl, 3-(2-thienyl) and 3-CH_3 resonances of 1:2 intensity ratio are observed.

3.3. The infrared spectroscopy of 4–7

The infrared spectra were obtained for solid complexes **4**–**7** in KBr pellets. The single ν(B–H) stretching vibration was observed in all cases confirming the one kind of complex molecules were present in solid state. While two ν(C–O) stretching vibrations attributed to carbonyl ligands were observed for **1** in acetonitrile [4,5] in case of **4** and **6** complexes three ν(C–O) bands were observed. This was attributed to low symmetry of complexes in solid state (cf. structural data, previous section). For allyl complexes **5** and **7** only two ν(C–O) bands were found, similarly to simple analogue **2** as could be anticipated.

3.4. Oxidation of molybdenum complexes

Electrochemical studies demonstrated that the first one-electron oxidation of $[Tp^*Mo(CO)_3]^-$ (**1**) in MeCN at −587 mV is reversible, while in THF it is shifted cathodically to −808 mV and only partially reversible, which suggests the involvement of the solvent molecule as a ligand in

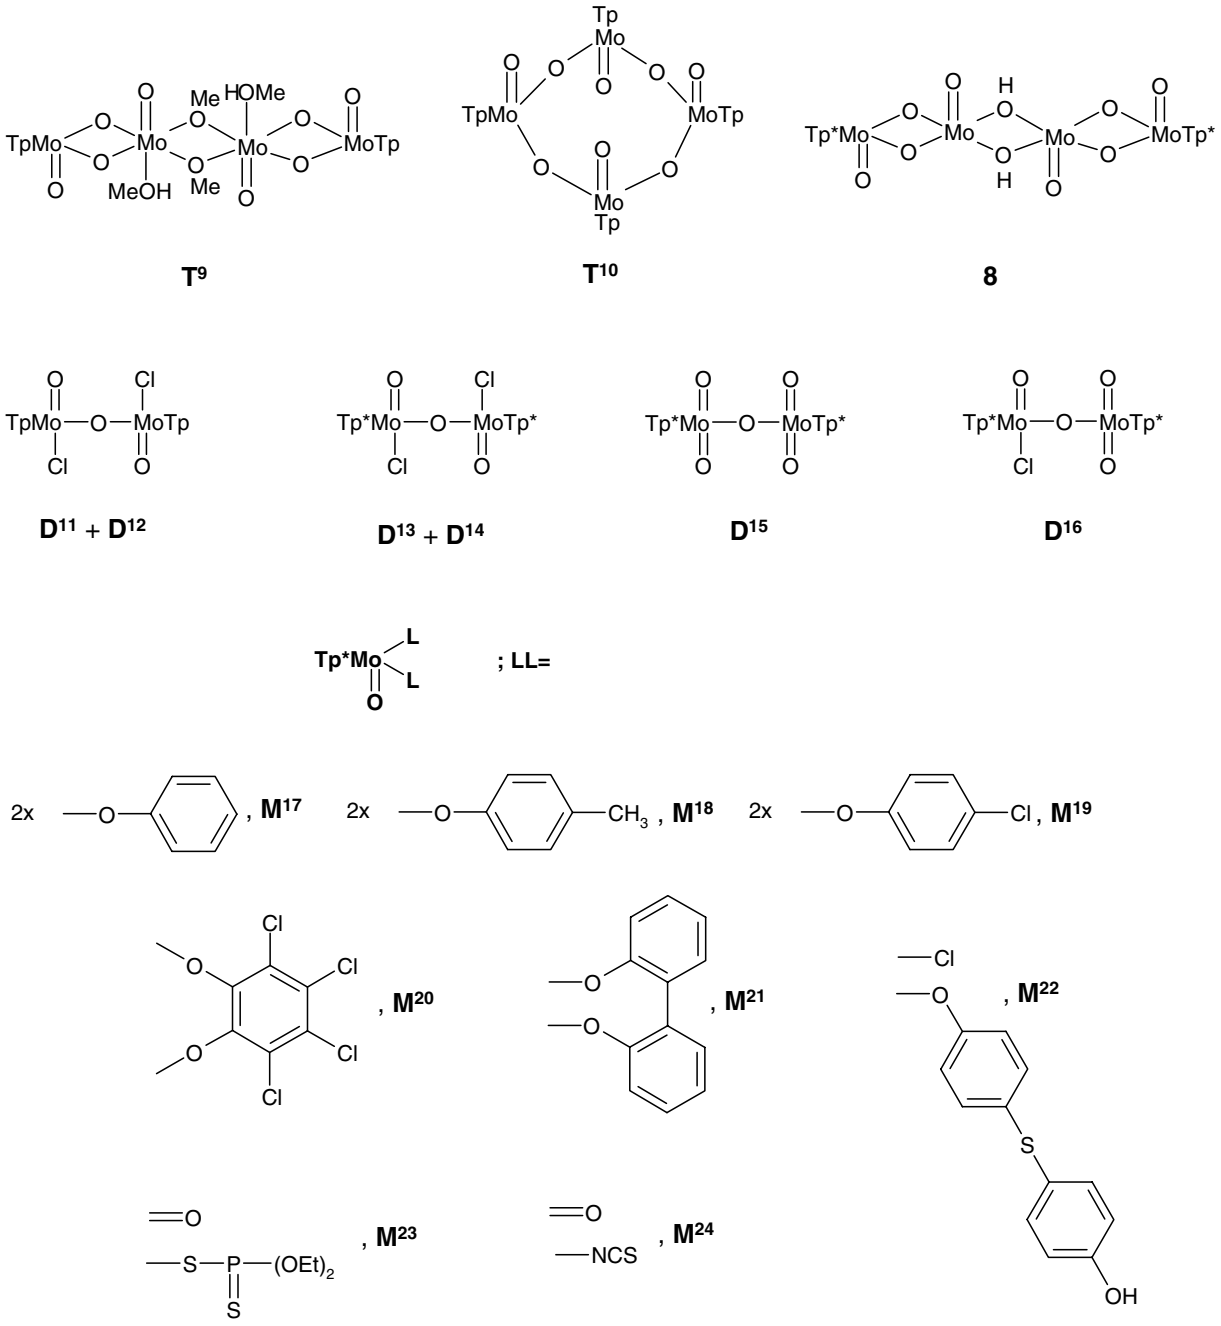

Chart 1. Schematic formulae of oxo-molybdenum complexes with Tp and Tp* ligands.

the process. The second oxidation is irreversible with no corresponding reduction wave, probably due to the loss of CO ligand from the two-electron oxidized species, which is characteristic of various $LMo(CO)_3$ type complexes. Surprisingly, the first oxidation of **4** occurs at a lower potential (−662 mV in MeCN) than that for **1** (−587 mV), which is counter to the expected electron-withdrawing effect of the phenyl substituents on pyrazolyl arms in **4**. This kind of such a reverse relationship has been previously observed for $Tp^{p\text{-}MeOPh}Mo(Cl)_2(NO)$ [41] and rationalized in terms of a weaker interaction between the $Tp^{p\text{-}MeOPh}$ ligand and Mo than that between Tp* and Mo in these compounds. The Mo–N(pz) bond distances in the former complex are longer. And indeed, in the case of our compounds, the Mo–N(pz) distances in **4** are longer than in **1** (cf. Table 2).

Within the $Tp'Mo(CO)_2(\eta^3\text{-allyl})$ complexes (**2**, **5**, and **7**) the oxidation of the molybdenum(II) complex was a two-electron process for **2** and **5**. It was virtually irreversible in the case of **5**, the corresponding reduction wave could be seen only at high scan rates. For **7**, however, two sluggish one-electron irreversible oxidation processes were observed with no corresponding reduction waves.

Chemical oxidation of reference complex **1** with iodine in $CDCl_3$ led to **3** as described in [11]. The complex **3** has characteristic spectrum, in which 3- and 5-methyl proton resonances are doubled due to effective C_S symmetry of

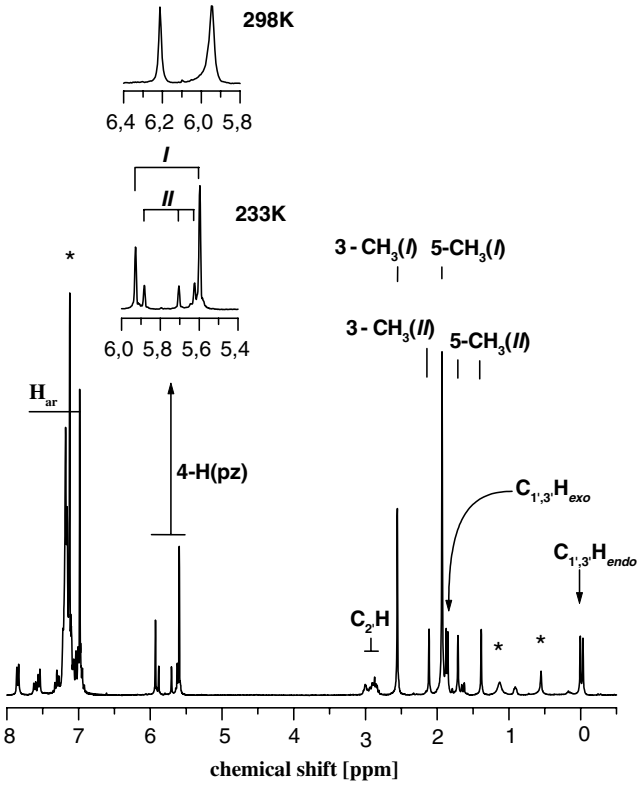

Fig. 4. The ^{1}H NMR spectrum of **5** in $CDCl_3$. The spectrum taken at 233 K (full spectrum presented) is composed of two set of resonances from isomers ***I*** and ***II***. Upper inset presents only the region of 4-H(pz) resonances at 298 K, which split into two sets at 233 K as presented in lower inset. The residual solvent and impurity resonances are labeled with asterisks.

$Tp^*Mo(CO)_2I$ complex and are observed at: 87.3 (3H); 70.1 (3H); 46.9 (6H); 34.7 (6H) ppm in $CDCl_3$ at 298 K. However, before this spectrum is produced, another species at early stage of titration of **1** with I_2 was observed; three low-intensity resonances at 18.7, 34.7, and 35.8 ppm are visible outside the diamagnetic region. That species is unstable and converts into the $Tp^*Mo(CO)_2Cl$ complex (**3′**) [11] identified on the basis of comparison with original sample (the 3- and 5-methyl proton resonances for the latter are observed at: 96.7 (3H); 71.4 (3H); 41.8 (6H); 31.7 (6H) ppm in $CDCl_3$ at 298 K). Upon addition of I_2, **3′** was further converted into **3**. Thus, the initial spectrum in undertitrated solution originate from $Tp^*Mo(CO)_3I$ or from other active form, like for instance $[Tp^*Mo(CO)_3]I$ or $Tp^*Mo(CO)_3I_2$, which is able to abstract the chloride anion from chloroform. This and the final conversion of **3′** into **3** mechanisms were unexplored. Oxidation of **2** with one equivalent I_2 or TBHP led cleanly to **3′** in $CDCl_3$ but not in acetone-d_6. Further addition of I_2 caused almost quantitative conversion of **3′** into the green species of the C_3 effective symmetry, for which only two methyl resonances were observed at 50.4 and 55.0 ppm.

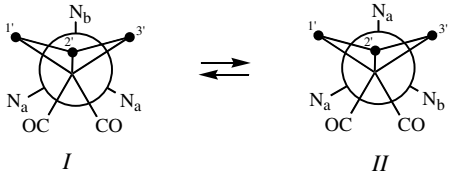

Fig. 5. Schematic presentation of two rotational isomers ***I*** and ***II*** of 5. N_a and N_b represent nitrogen donors from 3-Ph-5-Mepz and 3-Me-5-Phpz residues, respectively, the allyl carbon atoms (1′, 2′, and 3′) are depicted by dark circles.

A pair of molybdenum(0) and (II) complexes with $[HB(5\text{-Me-3-Phpz})_2(3\text{-Me-5-Phpz})]^-$ heteroscorpionate ligand, i.e. **4** and **5** were oxidized with I_2 under spectral control. Already at the very early stage of titration of **4** with I_2 the formation of many paramagnetic species was observed, among them the $[HB(5\text{-Me-3-Phpz})_2(3\text{-Me-5-Phpz})]Mo(CO)_2X$ (X = I or Cl) with characteristic methyl resonances at about 85 and 70 ppm. However, the major species was different. The attempts to isolate it were unsuccessful. The oxidation of **5** was monitored by the ^{1}H NMR spectroscopy. No paramagnetic spectra of intermediates were found in that experiment. Eventually, upon addition of two equivalents of I_2 two 4-H(pz) resonances of the 2:1 intensity ratio were found at about 6 ppm of the spectrum of diamagnetic product, which were tentatively assigned to $[Tp'MoO_3]^-$ species.

Generally, the molybdenum(II) complexes, either those obtained upon two-electron oxidation of $[Tp'Mo(CO)_3]^-$ or $Tp'Mo(CO)_2$(allyl) were easily oxidizable and no intermediates could be isolated or detected by the ^{1}H NMR method before final oxidation to Mo(V) or Mo(VI). Even simple and relatively stable ligand Tp^* was partially decomposed upon aerial oxidation of $Tp^*Mo(CO)_2I$ in mild conditions to produce complex **8**.

4. Supplementary data

Crystallographic data for the structures reported in this paper (excluding structure factors) have been deposited with the Cambridge Crystallographic Data Centre, CCDC no. 605472 (compound **6**), no. 605473 (compound **7**), and no. 605474 (compound **8**). Copies of this information may be obtained free of charge from the Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44 1223 336 033; e-mail: deposit@ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk).

cost ink-jet printing techniques [22,23]. However, because of the complicated and multi-step synthetic strategy for the preparation of polymer-supported AlQ_3, commercialization by this route is doubtful. Alternatively, reactive AlQ_3 derivatives such as $Al(Et)_2Q$ [24], $Al(Et)Q_2$ [25] and $Al(Q)_2(OH)$ [26] can be incorporated into polymers containing OH side groups by condensation reactions. High reactivity of the former and low solubility of the latter mentioned compounds can be overcome by replacing the ethyl or hydroxide group with long alkoxy groups. Furthermore, it has recently been proposed that the aluminium–nitrogen bond strength can be used as a parameter for tuning the complex emission wavelength [27], alternatively it may be possible to alter the emission wavelength to some extent using various alkoxy groups. As a contribution to the latest development of this interesting field, we would like to report the synthesis and characterization of the first examples of two highly soluble and stable alkoxy derivatives of AlQ_3, $[Al(Q_2)(OCH_2CH_2OR)]_2$ [R = CH_3 (**1**) and C_2H_5 (**2**)]. In addition, their photoluminescence behaviour was investigated and the molecular structure of complex **2** was determined by X-ray analysis.

2. Experimental

All manipulations were carried out under nitrogen, using standard Schlenk techniques. All chemicals were purchased from Merck and were used as received, except solvents which were dried and distilled under nitrogen prior to use. Both $Al(OCH_2CH_2OCH_3)_3$ and $Al(OCH_2CH_2OCH_2CH_3)_3$ were prepared by the alcohol exchange method from $Al(OCH(CH_3)CH_2CH_3)$ according to a previous report [28].

Infrared spectra were recorded on a Shimadzu 470 instrument, using KBr pellets. ^1H and ^{13}CNMR spectra were recorded in C_6D_6 on a Bruker AVANCE 300-MHz instrument using TMS as an internal reference. ^{27}Al NMR spectra were obtained on a Bruker AVANCE 500-MHz spectrophotometer in C_6D_6 using aluminium nitrate as an external reference in aqueous solution. The mass spectroscopy was performed on a Varian Matt 44 instrument (electron impact, 20 eV). Absorption spectra of solutions (10^{-6} M) were obtained in CH_2Cl_2 on a Shimadzu 2100 UV–Vis spectrophotometer. Emission spectra were recorded at room temperature on a Perkin–Elmer MPF-43A spectrofluorimeter from 440 to 550 nm by excitation with UV light using 30 μM solutions of **1** and **2** in dichloromethane.

2.1. Synthesis of *1*

Compound **1** was prepared by the reaction of 8-hydroxyquinoline (0.73 g, 5 mmol) with $Al(OCH_2CH_2OCH_3)_3$ (1.26 g, 5 mmol) in benzene (30 ml). The mixture was refluxed for 3 h and the solvent was removed under reduced pressure to leave a yellow solid. The solid was crystallized from dichloromethane–hexane; single crystals of the complex were isolated from the solution after several days at −5° C, m.p. decomposes at 280 °C. *Anal*. Calc. for $C_{21}H_{19}N_2O_4Al$: C, 64.62; H, 4.87; N, 7.18. Found: C, 64.22; H, 4.80; N, 6.62%. UV (CH_2Cl_2, nm): 318 (MLCT), 335 (π–π*) and 382 (n–π*). IR (cm^{-1}): 3035 (C–H, aromatic), 2968 (C–H, aliphatic), 1605 (C═N), 1575 (C═C), 1078 (C–O), 639 (Al–O), 752 (Al–O–Al). ^1H NMR (C_6D_6, ppm): 2.5 (3H, s, –OC*H*$_3$), 2.9–3.8 (4H, m, AlOC*H*$_2$C*H*$_2$–). C_9H_6NO ligand protons: 6.4 (1H, q), 6.9 (1H, d), 7.0 (1H, d), 7.1 (1H, d), 7.3 (2H, m), 7.4 (1H, t), 7.5 (1H, d) 7.6 (1H, t), 7.9 (1H, d), 8.6 (1H, d), 9.5 (1H, d). ^{13}C NMR (ppm): 57.15, 61.11, 73.63, 110.48, 110.79, 111.59, 120.67, 121.04, 129.25, 129.68, 130.44, 130.77, 138.33, 138.42, 140.31, 140.49, 144.21, 144.85, 147.25, 160.72, 160.87. ^{27}Al NMR (ppm): 26.8, 71.4. Mass spectral data, aluminium-bearing fragments (*m*/*e*): 390 $[Al(OCH_2CH_2OCH_3)(C_9H_6NO)_2]^{+\cdot}$, 315 $[Al(C_9H_6NO)_2]^+$, 246 $[Al(OCH_2CH_2OCH_3)(C_9H_6NO)]^{+\cdot}$, 201 $[Al(OCH_2)(C_9H_6NO)]^+$, 188 $[Al(C_9H_6NO)(OH)]^{+\cdot}$, 171 $[Al(C_9H_6NO)]^+$. Mass numbers are based upon ^1H, ^{12}C, ^{14}N, ^{16}O and ^{27}Al.

2.2. Synthesis of *2*

Compound **2** was prepared by the reaction of 8-hydroxyquinoline (0.73 g, 5 mmol) with $Al(OCH_2CH_2OCH_2CH_3)_3$ (1.47 g, 5 mmol) in benzene (30 ml). The mixture was refluxed for 3 h and the solvent was removed under reduced pressure to leave a yellow solid. The solid was crystallized from dichloromethane–hexane at −5 °C, m.p., decomposes at 240 °C. *Anal*. Calc. for $C_{22}H_{21}N_2O_4Al$: C, 65.34; H, 5.20; N, 6.93. Found: C, 64.75; H, 5.12; N, 7.1%. Refinement method	full-matrix least-squares on F^2
Data/restraints/parameters	7401/4/631
Goodness-of-fit on F^2	0.987
Final R indices for 2978 reflections with $[I > 2\sigma(I)]$	$R_1 = 0.0761$, $wR_2 = 0.1379$
R indices (all data)	$R_1 = 0.2157$, $wR_2 = 0.1521$
Larger difference in peak and hole (e A^{-3})	0.814 and −0.414

Table 1. Unit cell parameters were determined using Siemens P3/PC software [29]. The structure was solved by a direct method and refined with full matrix least-squares on F^2 to a final R value of 0.0761, $wR_2 = 0.1379$ with the SHELXL program [30]. The hydrogen atoms of CH_2Cl_2 and water molecules were found in difference Fourier synthesis; the H(C) atom positions were calculated. All hydrogen atoms were refined in isotropic approximation using the riding model with the U_{iso}(H) parameters equal to 1.2 U_{eq}(Ci), for methyl groups equal to 1.5 U_{eq}(Cii), where U(Ci) and U(Cii) are the equivalent thermal parameters of the atoms to which the corresponding H atoms are bonded.

4. Results and discussion

4.1. Preparation

Bis[μ-2-methoxy-ethanalato-di-(8-quinolinato)aluminium(III)] and bis[μ-2-ethoxy-ethanalato-di-(8-quinolinato)aluminium(III)] were obtained by the reaction of $Al(OCH_2CH_2OCH_3)_3$ and $Al(OCH_2CH_2OCH_2CH_3)_3$ with 8-hydroxyquinoline in a 1:1 ratio in refluxing benzene. These reactions are fast and their progress was followed by the appearance of a very intense yellow fluorescence colour. Due to the lability of metalloorganic and organometallic compounds, their reactions with 8-hydroxyquinoline and imine is facile and quantitative [31]. Both compounds are yellow solids and are soluble in common organic solvents and were purified by recrystallization from a mixture of dichloromethane and *n*-hexane. In contrast to the parent aluminium alkoxides, the 8-hydroxyquinoline derivatives are not sensitive to air and moisture, but they lose crystallinity when exposed to air. Our early attempt for the preparation of isopropoxide and ethoxide derivatives resulted in the formation of AlQ_3 in spite of using extra aluminium alkoxides. Apparently the long chain alkoxy ligands, 2-methoxyethoxide and 2-ethoxyethoxide, have a significant role in the stabilization of compounds **1** and **2**. Interestingly, the recent DFT optimization of the model pentacoordinated species $AlQ_2(OCH_3)$ shows that one of the pyridyl units of 8-hydroxyquinoline dissociates from aluminium [32].

4.2. Spectroscopic studies

The ready formation of compounds was established by the observation of $[Al(C_9H_6ON)_2(OCH_2CH_2OR)]^+$ and $[Al(C_9H_6ON)_2]^+$ (R = –CH_3 and –C_2H_5) fragments in the mass spectra. However, parent ions or dimeric species were not observed in the electron impact mass spectra. Furthermore, coordination of oxygen and nitrogen atoms of quinoline to aluminium was pursued by IR spectra by means of comparing the spectra with that of the free ligand. Absence of a band at 3300 cm^{-1} due to υ(OH) of free 8-hydroxyquinoline in the IR spectra of the complexes, and the appearance of new bands at 645 and 590 cm^{-1}, assigned to υ(Al–O) and υ(Al–N), respectively [33], confirmed coordination of the ligand to aluminium through oxygen and nitrogen. As previously noticed, by coordination of the 8-hydroxyquinoline nitrogen to various ions, υ(C=N) reduces in comparison with the free ligand value [34]. The absorption frequency of the phenolic C–O in the free ligand shifts from 1260 cm^{-1} to 1280 cm^{-1} on coordination to aluminium. The Al–O–Al vibrations appear at 755 cm^{-1} [31]. The ^{1}H NMR spectra of **1** and **2** exhibit the expected aromatic and aliphatic protons. However, there is

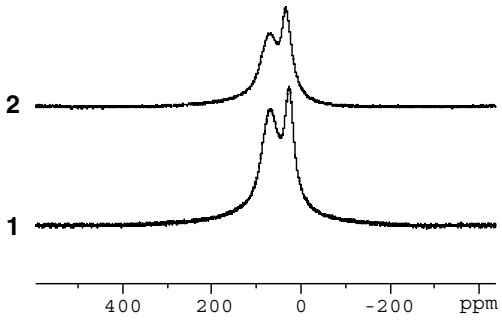

Fig. 1. ^{27}Al NMR spectra of **1** and **2**.

considerable deshielding of the proton bonded to the carbon atom adjacent to the nitrogen and shielding of the proton bonded to the carbon atom adjacent to the oxygen (phenolic ring) in comparison to the free ligand. Such a shift has been observed in the 8-quinolinolate vanadium complex [35]. The ^{27}Al NMR spectra of **1** and **2** (Fig. 1) with two signals at 26.9, 69.5 ppm (half width $w_{1/2}$, 2820 and 4812 Hz) and 26.6, 70.1 ppm (half width $w_{1/2}$, 2825 and 4832 Hz) indicate that the 6- and 4-coordinated aluminium atoms, respectively, exist in solution [36,37].

4.3. Crystal of **2** as the trihydrated bis(dichloromethane) solvate

Selected bond lengths and angles for **2** are given in Table 2. Compound **2**, as shown in Fig. 2, is an unsymmetrical dimer. Two 8-quinolinolato anions are chelated to Al and the coordination number is raised to six as the 2-ethoxymethoxy group is bridging, despite of the steric bulk of alkoxy ligand. The two bridging Al–O distances, Al(1)–O(5), 1.899(4) Å; Al(1)–O(7), 1.886(4) Å, are nearly identical and are somewhat longer than the other two Al–O distances, but they are somewhat shorter than those found in the six coordinated aluminium moiety in $\{C_6H_4O[CH{=}N(C_6H_5)]\}_2Al(\mu\text{-}OPr^i)_2Al(OPr^i)_2$ [37] and longer than those of in the centrosymmetric dimer $[Cp_2Al\text{-}\mu\text{-}OR]_2$ [38]. Interestingly, in the absence of an alkoxy group in a complex such as the centrosymmetric compound $[Al(Et)_2(Q)]_2$, for the formation of a dimeric complex, the quinoline oxygen atoms are bridged [24]. As noticed by several authors, oxygen bridging is more favourable in aluminium complexes with bidentate Schiff base ligands [31].

Table 2
Selected bond angles (°) and bond lengths (Å) for **2**

Bond distances			
Al(1)–O(3)	1.875(5)	Al(2)–O(4)	1.859(5)
Al(1)–O(2)	1.883(4)	Al(2)–O(1)	1.876(5)
Al(1)–O(7)	1.886(4)	Al(2)–O(7)	1.881(4)
Al(1)–O(5)	1.899(4)	Al(2)–O(5)	1.881(4)
Al(1)–N(2)	2.003(6)	Al(2)–N(1)	2.046(6)
Al(1)–N(3)	2.029(6)	Al(2)–N(4)	2.062(6)
Bond angles			
O(3)–Al(1)–O(2)	95.20(19)	O(4)–Al(2)–O(1)	167.7(2)
O(3)–Al(1)–O(7)	170.09(19)	O(4)–Al(2)–O(7)	90.1(2)
O(2)–Al(1)–O(7)	93.34(19)	O(1)–Al(2)–O(7)	98.8(2)
O(3)–Al(1)–O(5)	94.18(19)	O(4)–Al(2)–O(5)	99.2(2)
O(2)–Al(1)–O(5)	169.4(2)	O(1)–Al(2)–O(5)	90.9(2)
O(7)–Al(1)–O(5)	77.78(18)	O(7)–Al(2)–O(5)	78.34(18)
O(3)–Al(1)–N(2)	87.9(2)	O(4)–Al(2)–N(1)	88.7(2)
O(2)–Al(1)–N(2)	82.9(2)	O(1)–Al(2)–N(1)	81.9(2)
O(7)–Al(1)–N(2)	98.1(2)	O(7)–Al(2)–N(1)	97.1(2)
O(5)–Al(1)–N(2)	92.7(2)	O(5)–Al(2)–N(1)	170.8(3)
O(3)–Al(1)–N(3)	82.2(2)	O(4)–Al(2)–N(4)	82.2(2)

O(7)–Al(1)–N(3)	92.9(2)	O(7)–Al(2)–N(4)	169.5(2)
O(5)–Al(1)–N(3)	96.7(2)	O(5)–Al(2)–N(4)	95.8(2)
N(2)–Al(1)–N(3)	166.9(2)	N(1)–Al(2)–N(4)	89.9(2)

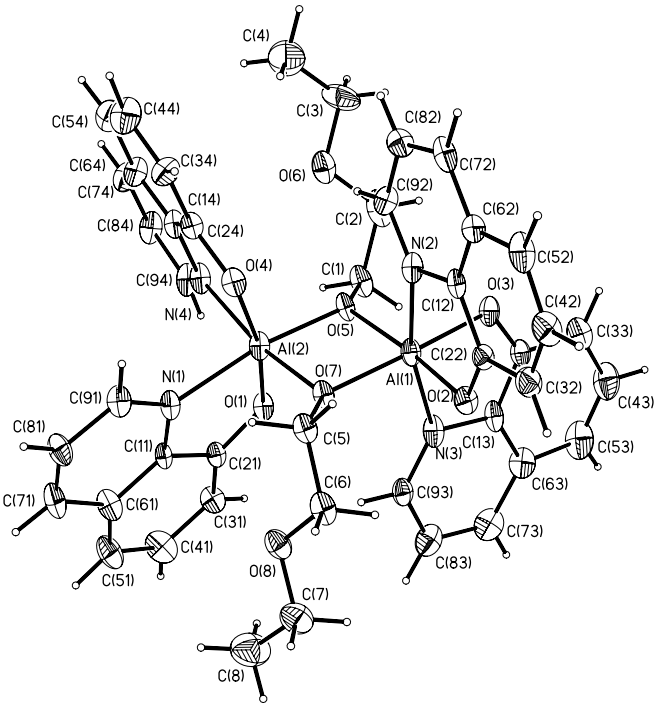

Fig. 2. ORTEP plot of **2**, with displacement ellipsoids at the 50% probability level. H atoms are drawn as spheres of arbitrary radii and solvent molecules are omitted for clarity.

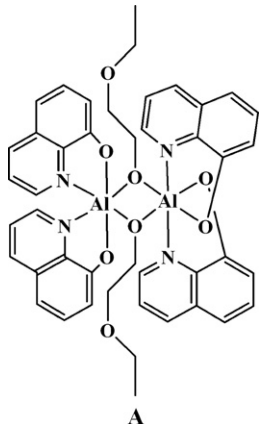
Probably the most interesting feature of this structure is the geometries around the aluminium atoms. Al(1) and Al(2) are six-coordinated in distorted octahedral geometries by two phenolate oxygen, two nitrogen and two bridging 2-ethoxyethoxy group oxygen atoms; and their bond angles range from 77.78(18)° to 99.2(2)°. Two nitrogen atoms on Al(1), with bond distances of 2.003(6) and 2.029(6) Å, are *trans* to each other. The N(2)–Al(1)–N(3), O(2)–Al(1)–O(5) and O(3)–Al(1)–O(7) angles of 166.9(2)°, 169.4(2)° and 170.09(19)°, respectively, are severely bent. The quinolines bite angles of 82.9(2)° and 82.2(2)° on Al(1) are almost identical and are comparable with those in AlQ_3 [39]. Interestingly, the coordination geometry of Al(2) differs from Al(1), the two nitrogen atoms on Al(2), with bond distances of 2.046(6), 2.062(6) Å and a N(1)–Al(2)–N(4) angle of 89.9(2)°, are *cis* to each other. The discrete unsymmetrical dimer contains *cis* and *trans* isomers and they are linked to each other by two bridging alkoxy groups. To illustrate the difference in coordination geometries more clearly, we have drawn the structure in Scheme 1. To our knowledge, dinuclear aluminium alkoxides or dinuclear organoaluminium derivatives where two aluminium atoms have different geometries in same ligand environment is very rare. In principle, for compound **2**, which has C_2 symmetry, a large number of stereoisomers are possible, therefore a number of pairs of enantiomers is expected. Notably, there is no disorder in the structure, which indicates only one isomer is present in the crystal.

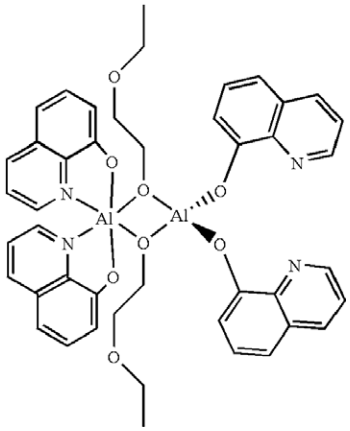


A

Scheme 1.

4.4. Solution behaviour of compounds *1* and *2*

Although the single crystal structure determination of compound **2** shows that the aluminium atoms are six coordinate, solution studies reveal that in solution six and four coordinated species are present. By taking into consideration that the molecule is severely distorted in the solid state, and also the steric hindrance caused by the two quinolines moieties around the aluminium atoms, it is not surprising to see that the solid structure is not retained in solution. Apparently, both nitrogen atoms around the aluminium atom dissociated and resulted in the formation of four-coordinated aluminium (Scheme 2). Dissociation of Al–N bonds and formation of a four-coordinate aluminium atom has also been observed for an unsymmetrical dimer of $[(CH_3COCHCOCH_3)Al(\mu\text{-}OPr^i)(C_9H_6NO)]_2$ [34]. Indeed, conversion of *fac*/*mer* isomers of AlQ_3 *via* dissociation of Al–N is well established [16]. Furthermore, 11 well resolved peaks in the ^1H and 18 in the ^{13}C NMR spectra of both compounds show that the C_2 symmetry after dissociation of the Al–N bond (Scheme 2) remains intact. We have not seen any evidence supporting the existence of other isomers.



Scheme 2.

Interestingly, compound **2** shows a specific rotation of $[\alpha]^{25} = 1.87°$ in dichloromethane, which indicates that an excess of enantiomer (**ee**) exists in solution. However, in accordance with the ^{27}Al NMR data, the solid state structure is not retained in solution, therefore one can conclude that a C_2 symmetry or lower also is the case for compound **2** in solution. The excess of enantiomer may be attributed to the highly crowded environments of the aluminium atoms and a preference for one enantiomer.

Despite several attempts to determine the molecular structure of compound **1** by X-ray diffraction for a comparison with the structure of **2**, due to crystal twining, we have not succeeded. However, a somewhat similar behaviour has been found for compound **1**. In fact the ^{27}Al NMR spectrum of compound **1** almost is identical to that of compound **2**. Furthermore, a specific rotation of $[\alpha]^{25} = -2.97°$ indicates that there is no inversion centre, neither mirror plane nor improper rotation axis (S_n) for **1**. Therefore, it may be concluded that for compound **1** a C_2 symmetry or lower also is the case in solution. Consistently, the ^{13}C NMR spectrum of **1** contains 18 peaks for the carbons of the quinoline ligands, which corresponds to two non-equivalent quinoline ligands. However, there is a difference in the specific rotation of **1** in comparison to **2**, which can be attributed to the difference in concentration of **ee** that may exist in solution. The difference in **ee** can be explained by taking into consideration the steric hindrance that may be imposed by the 2-ethoxyethoxide ligands which alters the amount of **ee**.

4.5. Luminescence measurements

In order to demonstrate that the luminescence properties of the new derivatives of AlQ_3 are preserved, we have measured emission spectra of both compounds in dichloromethane from 400 to 700 nm upon excitation by UV light. The UV–Vis absorption spectra of **1** and **2** in dichloromethane show peaks at 320, 338 and 382 nm, and 317, 334 and 382 nm, respectively. Two absorptions are comparable with the 312 and 389 nm peaks of AlQ_3 [39]. The origin of the new peaks, 334 and 338 nm, which appeared in spectra of **1** and **2**, respectively, is not understood at this time, however, it could be associated with the involvement of the 2-methoxyethoxide/2-ethoxyethoxide groups and a $n \rightarrow \pi^*$ transition.

As shown in Fig. 3, both complexes have identical emission spectra and are fluorescence at a wavelength of 502 nm, which is lower than AlQ_3 (526 nm). Similar to azaindole complexes of aluminium, luminescence can be attributed to the π–π transition of the deprotonated 8-hydroxyquinoline which is stabilized by coordination to the aluminium ion [40]. The blue shift of **1** and **2** with respect to AlQ_3 can be attributed to the presence of electron withdrawing alkoxy groups. This conclusion is consistent with the recent study on AlQ_3 complexes which show electron withdrawing substituents on the quinoline results in a shift of emission to a lower wavelength [27,39], and

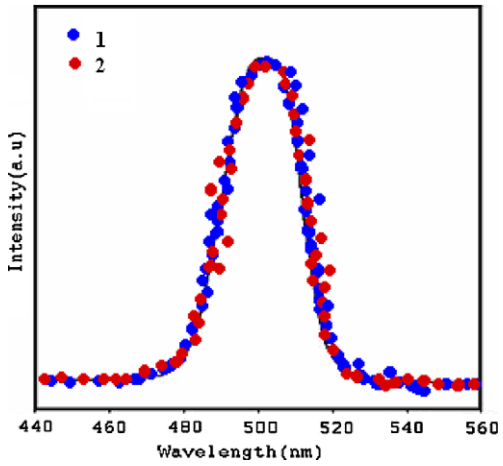


Fig. 3. Emission spectra of **1** and **2** in CH_2Cl_2.

also is consistent with the emission of AlQ_2OH at 485 nm [26]. Extensive studies on the photoluminescence properties of AlQ_3 show that the *fac*-AlQ_3 and *mer*-AlQ_3 spectral emission differ and each one has a distinctive fingerprint [16]. Therefore, a mixture of two isomers is expected to show a broad emission. Interestingly, a half width ($w_{1/2}$) of 60 nm has been observed for the emission spectrum of AlQ_3 [21,39], in comparison with a half width of 40 nm for the emission spectra of **1** and **2**. The smaller half width ($w_{1/2}$) may be attributed to the **ee** of compounds **1** and **2**, however additional work is required for new and deeper understanding.

In conclusion, we have prepared and characterized two derivatives of AlQ_3 containing long chain alkoxy groups. The derivatives have high solubility and suitable thermal stability and most importantly they have similar absorption and emission properties to AlQ_3. Further studies are underway to elucidate the correlation of the solution-state structure to electroluminescence performance.

Acknowledgments

The authors thank the Vice-President's Office for Research Affairs of Shahid Beheshti University for supporting this work and Professor Alexander Yanovsky and Dr. Zoya Starikov of the Russia Academy of Science for the crystallographic measurements.

2. Experimental

$Na_2MoO_4 \cdot 2H_2O$, dimethylsulfoxide and 1,10-phenanthroline were used as purchased from E. Merck. All solvents (methanol, ethanol, isopropanol, dichloromethane, and benzene) were dried by standard methods before use. Stringent precautions were taken to exclude moisture during experimental manipulations. Literature methods were used for the preparation of sodium or potassium salts of *N*,*N*-dialkyl dithiocarbamate [18] and *O*-alkyl dithiocarbonate [19].

2.1. Synthesis of $MoO_2Br(S_2CNEt_2)(OSMe_2)$ (1), $MoO_2Br(S_2CNPr^n_2)(OSMe_2)$ (2), $MoO_2Br(S_2CNPr^i_2)(OSMe_2)$ (3)

Typically, a suspension of NaS_2CNEt_2 in dichloromethane was added to a solution of $MoO_2Br_2(OSMe_2)_2$ (0.51 g, 1.14 mmol) in dichloromethane in equimolar ratio with constant stirring. The pale yellow solution immediately turned bright yellow. After stirring for 3 h, the precipitated NaBr was filtered and washed with CH_2Cl_2. Excess solvent was removed, then the product was dried in vacuo and purified by repeated washing with dried benzene to give $MoO_2Br(S_2CNEt_2)(OSMe_2)$ (**1**). Yellow powdery solid. Yield: 0.39 g, 80%; m.p. 92 °C. *Anal*. Calc. for $C_7H_{16}NO_3S_3BrMo$: Mo, 22.09; S, 22.15; Br, 18.40. Found: Mo, 22.56; S, 22.43; Br, 18.25%.

Method as above gave $MoO_2Br(S_2CNPr^n_2)(OSMe_2)$ (**2**). Pale yellow powdery solid. Yield: 84%; m.p. 82 °C. *Anal*. Calc. for $C_9H_{20}N_1O_3S_3BrMo$: Mo, 20.73; S, 20.81; Br, 17.28. Found: Mo, 20.73; S, 20.71; Br, 17.30%. *Anal*. Calc. for $C_9H_{20}N_1O_3S_3BrMo$: Mo, 20.73; S, 20.81; Br, 17.28%. Method as above gave $MoO_2Br(S_2CNPr^i_2)(OSMe_2)$ (**3**). Pale yellow powdery solid. Yield: 86%; m.p. 84 °C. *Anal*. Calc. for $C_9H_{20}N_1O_3S_3BrMo$: Mo, 20.73; S, 20.81; Br, 17.28. Found: Mo, 20.78; S, 20.71; Br, 17.29%.

2.2. Synthesis of $MoO_2Br(S_2COEt)(OSMe_2)$ (4), $MoO_2Br(S_2COPr^n)(OSMe_2)$ (5), $MoO_2Br(S_2COPr^i)(OSMe_2)$ (6)

A suspension of NaS_2COEt (0.15 g, 1.08 mmol) in dichloromethane was added to a solution of $MoO_2Br_2(OSMe_2)_2$ (0.48 g, 1.08 mmol) in dichloromethane, in equimolar ratio with constant stirring. The pale yellow solution immediately turned bright yellow. After stirring for 3 h, the precipitated NaBr was filtered and washed with dichloromethane. Excess solvent was removed and the product was dried in vacuo, and then purified by repeated washing with dried benzene to give $MoO_2Br(S_2COEt)(OSMe_2)$ (**4**). Yellow solid. Yield: 0.39 g, 89%; m.p. 96 °C. *Anal*. Calc. for $C_5H_{11}O_4S_3BrMo$: Mo, 23.56; S, 23.63; Br, 19.62. Found: Mo, 23.55; S, 23.51; Br 19.64%.

Method as above gave $MoO_2Br(S_2COPr^n)(OSMe_2)$ (**5**). Pale yellow solid. Yield: 81%; m.p. 89 °C. *Anal*. Calc. for $C_6H_{13}O_4S_3BrMo$: Mo, 22.78; S, 22.84; Br, 18.97. Found: Mo, 22.83; S, 22.80; Br, 18.97%. Method as above gave $MoO_2Br(S_2COPr^i)(OSMe_2)$ (**6**). Pale yellow solid. Yield: 85%; m.p. 91 °C. *Anal*. Calc. for $C_6H_{13}O_4S_3BrMo$: Mo, 22.78; S, 22.84; Br 18.97. Found: Mo, 22.79; S, 22.71; Br, 19.11%.

2.3. Synthesis of $MoO_2Br_2(OSMe_2)_2$ (7)

A solution of $Na_2MoO_4 \cdot 2H_2O$ (4.84 g, 20 mmol) in concentrated HBr (25 ml) was extracted with three 50 ml portions of diethyl ether. The combined extracts were concentrated under vacuum to approx. 25 ml and an ether solution of dimethylsulfoxide (3.11 g, 40 mmol) was added dropwise. A yellow precipitate was observed and the mixture was stirred for 30 min before the precipitate was filtered, washed with ether and dried over $P_2O_5 \cdot MoO_2Br_2(OSMe_2)_2$ (**7**). Yellow solid. Yield: 71%; m.p. 45 °C. *Anal*. Calc. for $C_4H_{12}O_4S_2Br_2Mo$: Mo, 21.61; S, 14.44; Br, 35.99. Found: Mo, 22.03; S, 14.58; Br, 36.57%.

2.4. Synthesis of $MoO_2Br_2(C_{12}H_8N_2)$ (8)

Concentrated HBr (5 ml) was added to a solution of $Na_2MoO_4 \cdot 2H_2O$ (0.51 g, 2.11 mmol) in distilled water (5 ml). A pale yellow solution along with a significant amount of crystallized NaBr was formed on stirring the mixture for 25–30 min. Diethyl ether (10 ml) was added, the solution was shaken vigorously, and the upper layer was collected. The extraction process was repeated twice more. The combined ether extract was stirred with anhydrous magnesium sulfate for 2 h and then filtered and washed with ether. A white precipitate was immediately observed when an ethanolic solution of $C_{12}H_8N_2$ (0.38 g, 2.11 mmol) was added dropwise to a stirred solution of the ether extract. The mixture was stirred for 30 min and filtered, washed with ether and dried under vacuum to give $MoO_2Br_2(C_{12}H_8N_2)$ (**8**). White solid. Yield: 86%; m.p. 88 °C. *Anal*. Calc. for $C_{12}H_8O_2N_2Br_2Mo$: Mo, 20.50; Br, 34.15%. Found: Mo, 20.13; Br, 34.72%.

2.5. Physical measurements

Molybdenum was estimated by precipitation as molybdenum oxinate, $MoO_2(C_9H_6ON)_2$. Sulfur was estimated gravimetrically as barium sulfate [Messenger's method] and bromide volumetrically by Volhard's method. IR spectra were recorded in the range 4000–400 cm^{-1} on a Shimadzu 8201 PC spectrophotometer as KBr pellets. Electronic spectra in the range 200–800 mm were recorded on a Systronic 2201 double beam UV–Vis spectrophotometer in CH_2Cl_2. ^1H NMR spectra were recorded on a Bruker DRX-300 spectrometer in $CDCl_3$ using TMS as an internal standard.

2.6. X-ray diffraction analysis

A green block crystal of $MoO_2Br_2(OSMe_2)_2$ and a colourless slab crystal of $MoO_2Br_2(C_{12}H_8N_2) \cdot CH_2Cl_2$ were

Table 1

mounted on a glass fibre. Data were collected on an Enraf Nonius KappaCCD area detector diffractometer, with ϕ and ω scans chosen to give a complete asymmetric unit. Data collection and cell refinement [20] gave cell constants corresponding to a monoclinic cell for both crystals, whose dimensions are given in Table 1 along with other experimental parameters. An absorption correction was applied [21,22].

The structures were solved by direct methods [23] and were refined using the WINGX version [24] of SHELX-97 [25]. All of the non-hydrogen atoms were treated anisotropically. Hydrogen atoms were included in idealized positions with isotropic thermal parameters set at 1.2 times that of the carbon atom to which they were attached. The final cycle of full-matrix least-squares refinement was based on 2917 (for **7**) and 3759 (for **8**), observed reflections (2506 (for **7**) and 3117 (for **8**) for $F^2>4s(F^2)$) and 122 (for **7**) and 199 (for **8**) variable parameters and converged (largest parameter shift was 0.001 times its esd).

Distances and bond angles are given in Tables 2 and 3 for molecules **7** and **8**, respectively and ORTEP diagrams are displayed in Figs. 1 and 2.

3. Results and discussion

Reactions of dibromodioxobis(dimethylsulfoxide)-molybdenum(VI) complexes with sodium/potassium salts of *N*,*N*′-dialkyl dithiocarbamates or *O*-alkyl dithiocarbonates in a 1:1 molar ratio in dichloromethane yield dioxomolybdenum(VI) complexes of the type, $MoO_2Br(S_2CNR_2)$-$(OSMe_2)$ or $MoO_2Br(S_2COR)(OSMe_2)$, respectively (see Fig. 3)

$$MoO_2Br_2(OSMe_2)_2 + NaS_2CNR_2 \rightarrow MoO_2Br(S_2CNR_2)(OSMe_2) + OSMe_2\ (\text{Free}) + NaBr$$

where R = Et, Pr^n, Pr^i

$$MoO_2Br_2(OSMe_2)_2 + NaS_2COR \rightarrow MoO_2Br(S_2COR)(OSMe_2) + OSMe_2\ (\text{Free}) + NaBr$$

where R = Et, Pr^n, Pr^i.

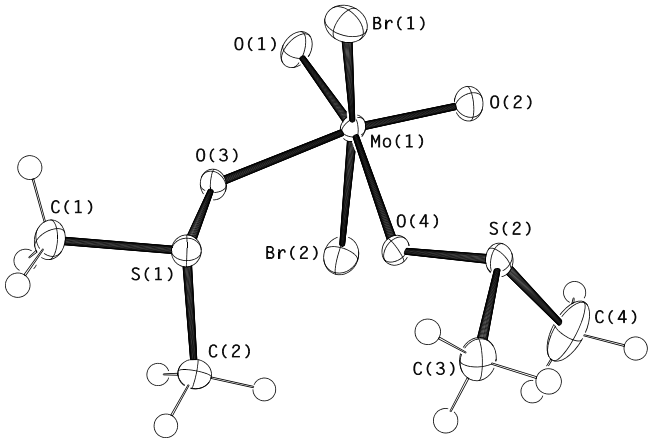

Fig. 1. ORTEP plot of the molecule $MoO_2Br_2(OSMe_2)_2$. The non-hydrogen atoms are drawn with 50% probability ellipsoids.

All of these molybdenum(VI) complexes are yellow powdery solids that are soluble in chloroform and dichloromethane and are characterized by elemental analysis and IR, UV–Vis and ^1H NMR spectroscopy.

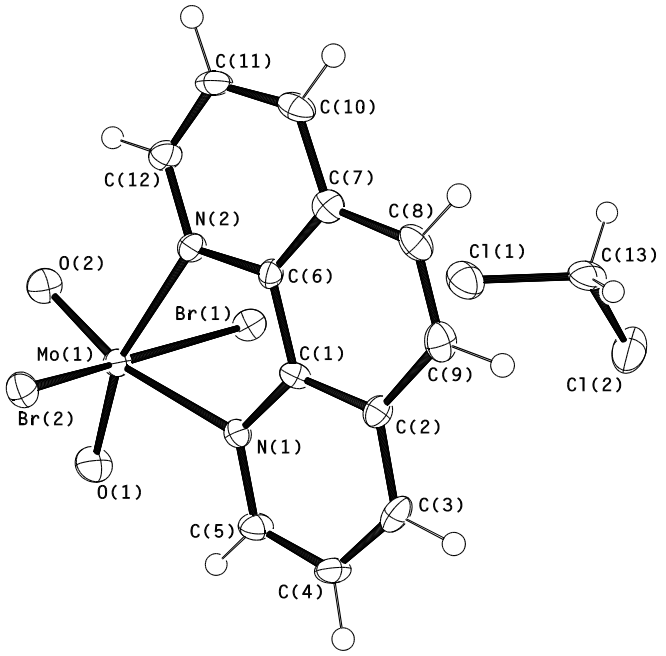

Fig. 2. ORTEP plot of the molecule MoO_2Br_2(1,10-phenanthroline) $\cdot CH_2Cl_2$. The non-hydrogen atoms are drawn with 50% probability ellipsoids.

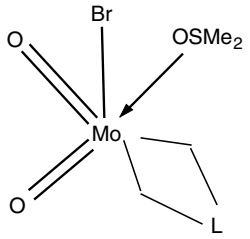

Fig. 3. Proposed structure of $MoO_2Br(L)(OSMe_2)$ [$L = S_2CNEt_2$, $S_2CNPr^n_2$, $S_2CNPr^i_2$, S_2COEt, S_2COPr^n, S_2COPr^i].

3.1. IR spectra

The assignments of the IR bands for bromodioxodimethylsulfoxide (*N*,*N*′-dialkyl dithiocarbamates)molybdenum(VI) and bromodioxodimethylsulfoxide(*O*-alkyl dithiocarbonate)molybdenum(VI) complexes (Table 4) were made by comparison with the spectra of the precursors, the complexes, dibromodioxobis(dimethyl sulfoxide)molybdenum(VI) and the sodium/potassium salts of *N*,*N*′-dialkyldithiocarbamates [18] and *O*-alkyl dithiocarbonates [19]. The bands arising from the C–N stretching mode in the dithiocarbamate derivatives are seen in the range 1520–1540 cm^{-1}, typical of analogous complexes [26]. Similarly, the presence of a band around 1250–1261 cm^{-1} in the xanthate derivatives can be attributed to ν(C–O–C) [26,27]. Complexes with both dithio ligand systems show CS_2^- group stretching vibration bands in the range 996–1100 cm^{-1} suggesting that the dithio ligands act as bidentate ligands [28].

Table 4
Some relevant IR spectral data (cm^{-1}) of the complexes[a]

S. no.	Compound	ν(C=N) or (C–O–C)	ν (C=S)	ν (S=O)	ν (Mo=O)
1	$MoO_2Br(S_2CNEt_2)(Me_2SO)$	1520(s)	1005(s)	1041(s)	910(s) 960(m)
2	$MoO_2Br(S_2CNPr^n_2)(Me_2SO)$	1530(s)	996(s)	1032(s)	924(s) 954(s)
3	$MoO_2Br(S_2CNPr^i_2)(Me_2SO)$	1540(s)	1020(w)	1043(s)	910(m) 978(s)
4	$MoO_2Br(S_2COEt)(Me_2SO)$	1261(s)	1100(s)	1043(s)	930(s) 969(s)
5	$MoO_2Br(S_2COPr^n)(Me_2SO)$	1250(br)	1050(s)	1045(s)	904(sbr)
6	$MoO_2Br(S_2COPr^i_2)(Me_2SO)$	1260(br)	1032(m)	1032(s)	906(sbr)

[a] *Key*. s, strong; m, medium; w, weak; br, broad.

A strong band due to ν(S=O) in the complexes is observed in the range 1033–1045 cm^{-1}, at slightly lower wave number than in the free ligands (1050 cm^{-1}), which is indicative of coordination through the oxygen atom [29]. Two characteristic strong bands in the range of 904–978 cm^{-1} can be assigned to the (Mo=O) symmetric and antisymmetric stretching modes in dioxomolybednum(VI) complexes [26].

3.2. Electronic absorption spectra

The electronic spectra of the dioxomolybdenum(VI) complexes recorded in CH_2Cl_2, are listed in Table 5. The bands in the region 329–332 and 203–212 nm may be ascribed to intra-ligand transitions of $n \rightarrow \pi^*$ and $\pi \rightarrow \pi^*$, respectively. The bands at 287–308 nm can be assigned to $O_T \rightarrow$ Mo(VI) charge transfer transitions. The intense bands at 347–369 nm can be attributed to S → Mo(VI) charge transfer [29].

3.3. ^1H NMR spectra

The chemical shifts and integrated intensity ratios of the protons in the dioxomolybdenum(VI) complexes are given in Table 6. These spectra were recorded in $CDCl_3$ solutions at room temperature. The ^1H NMR data of dioxomolybdenum(VI) complexes are remarkably similar to those of the salts of dithiocarbamates and dithiocarbonates [51], proba-

^1H NMR spectral data of the complexes[a,b,c]

S. no.	Compound	$NCH_2/OCH_2/NCH/OCH$	$NCCH_3/OCCH_3$	SCH_3
1	$MoO_2Br[S_2CN(CH_2CH_3)_2](Me_2SO)$	3.40 (4H, q, $J = 7$ Hz)	1.15 (6H, t, $J = 7$ Hz)	2.17 (6H, s)
2	$MoO_2Br[S_2CN(CH_2CH_2CH_3)_2](Me_2SO)$	3.73 (4H, m, $J = 7$ Hz)	1.57 (4H, m, $J = 6$ Hz)	2.17 (6H, s)
3	$MoO_2Br[S_2CN\{CH(CH_3)_2\}(Me_2SO)$	3.50 (2H, m, $J = 7$ Hz)	0.85 (12H, d, $J = 7$ Hz)	2.18 (6H, s)
4	$MoO_2Br[S_2COCH_2CH_3](Me_2SO)$	3.63 (4H, q, $J = 7$ Hz)	1.19 (6H, t, $J = 7$ Hz)	2.17 (6H, s)
5	$MoO_2Br[S_2COCH_2CH_2CH_3](Me_2SO)$	3.73 (4H, m, $J = 7$ Hz)	1.56 (4H, m, $J = 6$ Hz)	2.18 (6H, s)
6	$MoO_2Br[S_2COCH(CH_3)_2](Me_2SO)$	3.63 (4H, m, $J = 7$ Hz)	1.21 (12H, d, $J = 7$ Hz)	2.17 (6H, s)

[a] The spectra were recorded in $CDCl_3$ and reported in δ ppm from MeSi.
[b] Number of protons and multiplicities are in parentheses (s, singlet; d, doublet; t, triplet; m, multiplet).
[c] Coupling constants in Hz indicated by J(HH).

bly due to the large separation between the molybdenum and protons. The methyl protons of $OSMe_2$ show a downfield shift compared to the singlet observed in the precursor $MoO_2Br_2(OSMe_2)_2$ (δ 2.95 ppm) consistent with the coordination mode of these dithio ligands [15].

3.4. Molecular structures of trans-dibromodioxbis-(dimethylsulfoxide)molybdenum(VI), $MoO_2Br_2(OSMe_2)_2$ (7) and $MoO_2Br_2(C_{12}H_8N_2)\cdot CH_2Cl_2$ (8)

$MoO_2Br_2(OSMe_2)_2$ (**7**) and $MoO_2Br_2(C_{12}H_8N_2)\cdot CH_2Cl_2$ (**8**) both crystallize as monoclinic in the space groups $P2_1/n$ and $P2_1/c$, respectively. The asymmetric units of **7** and **8** are displayed as ORTEP diagrams in Figs. 1 and 2, respectively. The distorted octahedral environment around molybdenum in both molecules consists of *cis* terminal oxygen atoms (O_T) and *trans* bromine atoms with *cis* dimethylsulfoxide moieties in **7** and bidentate 1,10-phenanthroline in **8**. Comparable crystal structures of the complexes $MoO_2X_2L_2$ (X = Cl, Br and L = $OPPh_3$) [14] and $MoO_2Cl_2(OSMe_2)_2$ [15,16], have been reported. The average Mo–O_T bond distance of 1.691(4) Å in **7** and **8** is typical of a molybdenum–oxygen terminal double bond and is similar to those observed in the structurally similar complexes containing triphenylphosphine oxide {$MoO_2Cl_2(OPPh_3)_2$ (1.68(2) Å, ave.) and $MoO_2Br_2(OPPh_2)_2$ (1.71 (1) Å, ave.)} [14] as well as in several other dioxomolybdenum(VI) complexes such as $MoO_2Cl_2(OSMe_2)_2$ [15,16], $MoO_2(S_2CNEt_2)_2$ [30], $MoO_2(S_2CNPr^n_2)_2$ [31] and $MoO_2[S_2P(OEt)_2]\{HB(Me_2Pz)_3\}$ [32]. The Mo–O(dimethylsulfoxide) bond distances of 2.180(2) and 2.204(2) Å in **7** are in the range expected for unidentate oxygen donors and are comparable to the average length of 2.199(1) Å in $MoO_2Cl_2(OSMe_2)_2$ [15,16] and 2.214(9) Å in MoO_4 (Φ–O)$(OSMe_2)_2(SCN)_2$ [33]. These Mo–O_L bonds appear to be significantly stronger than the coordinated Mo–O(dimethylsulfoxide) bonds in $Mo_2O_2(\Phi\text{–}S_2)[S_2P(OEt)_2](OSMe_2)$ (2.462(2) Å) [34] and $Mo_2O_2(\phi\text{–}S_2)[S_2P(OPr^i)]_2(OSMe_2)$ (2.467(3) Å) [34]. The Mo–N bond distances of 2.317(4) and 2.322(4) Å in **8** are between the two Mo–N values (2.449(19) and 2.259(18) Å) obtained for MoO_2Br_2(2,2′-bipyridyl) [35]. The Mo–Br bond distances are slightly shorter, 2.5432(5) and 2.5148(5) Å in **7** and 2.522(1) and 2.5075(9) Å in **8** than those observed in $MoO_2Br_2(OPPh_3)_2$ (2.556(3) and 2.540(3) Å) [36], suggesting strong Mo–Br bonds in both **7** and **8**. There is no evidence of intermolecular interactions involving bromine or the ligands.

The four oxygen atoms and molybdenum in **7** are essentially coplanar, with bromine atoms "bent away" from the terminal oxygen atoms so that the Br–Mo–O_T angles range from 93.59(9)° to 96.66(9)° compared with 82.20(7)–83.31(7)° for those of Br–Mo–O_L. Similarly, two terminal oxygen, two nitrogen and the Mo atom are coplanar in **8**, with two bromine atoms also bent away from the terminal oxygen atoms and also from two nitrogen atoms. The Br–Mo–O_T angles range from 95.8(1)° to 97.2(1)° and those of Br–Mo–N_L from 80.1(1)° to 81.4(1)°. The Br–Mo–Br angles are 161.90(2)° and 158.02(3)° in **7** and **8**, respectively emphasizing that the distortion from octahedral is not limited to the presence of Mo–O/Mo–N bonding. As in the triphenylphosphine oxide analogues, the angle involving the terminal Mo=O double bonds [O_T–Mo–O_T, 103.9(1)° in **7** and 106.9(2)° in **8**] is considerably wider than 90°. The correspondingly compressed O_L–Mo–O_L angle of 76.49(9)° in **7** is as seen in $MoO_2Cl_2(OSMe_2)_2$ (77.68(5)°) [15], and also is unaltered when dimethylsulfoxide is replaced by triphenylphosphine oxide [$MoO_2Cl_2(OPPh_3)_2$ (77.81(5)°) and $MoO_2Br_2(OPPh_3)_2$ (77.0(4)°)] [14]. However, the N–Mo–N angle of 70.4(1)° in **8** is slightly larger than that found in MoO_2Br_2(2,2′-bipyridyl) (66.90(6)°) [35]. Therefore, the environment about the Mo atom is relatively unchanged whether unidentate dimethylsulfoxide, triphenylphosphine oxide or bidentated 1,10-phenanthroline is coordinated. Finally the bond lengths and angles within Me_2SO and 1,10-phenanthroline are similar to those obtained in other molybdenum complexes of these ligands [34,37].

4. Concluding comments

We have successfully prepared and characterized the following bromodioxodimethylsulfoxide(*N*,*N*′-dialkyldithiocarbamate/*O*-alkyldithiocarbonate)molybdenum(VI) complexes, $MoO_2Br(S_2CNR_2)(OSMe_2)$ (R = Et, Pr^n, Pr^i) and $MoO_2Br(S_2COR)(OSMe_2)$ (R = Et, Pr^n, Pr^i). The IR, UV–Vis and ^1H NMR spectra of all of these dioxomolybdenum(VI) complexes are consistent with the proposal of the following tentative structure.

The molecular structures of $MoO_2Br_2(OSMe_2)_2$ and $MoO_2Br_2(C_{12}H_8N_2)\cdot CH_2Cl_2$ have been determined. They have distorted octahedral environments around molybdenum which are similar to the structure reported for the complex $MoO_2Cl_2(OSMe_2)_2$ with *cis* terminal oxygen atoms, *cis* ligands and *trans* bromine atoms.

and characterization of new copper(II) and nickel(II) complexes of Hqaldsme, together with the X-ray crystallographic structures of two five-coordinate copper(II) and a six-coordinate nickel(II) complexes of this ligand.

2. Experimental

2.1. Materials and instrumentation

2-Quinoline carboxaldehyde and other chemicals employed in the present work were purchased from Aldrich Chemical Company and used as received. The solvents used were of analytical reagent grade. *S*-methyldithiocarbazate was prepared by following a published method [10]. The electronic spectra were recorded both in the solid state (as Nujol mull) on a Shimadzu UV-3100 spectrophotometer. The IR spectra were recorded as KBr discs on either a Perkin–Elmer 1600 FT IR spectrometer or a Perkin–Elmer 2000 spectrometer. Conductance measurements were made by means of a CMD 400 conductivity meter. Magnetic susceptibilities were measured with a Sherwood Scientific magnetic susceptibility balance calibrated with $HgCo(NCS)_4$. Diamagnetic corrections were applied using Pascal's constants.

2.2. Preparation of the Schiff base

The synthesis and characterization of the Schiff base has been reported previously [24].

2.3. General method of preparation of the complexes

A solution of hydrated metal(II) nitrate salt (0.001 mol) in hot methanol (20 ml) was added to a boiling solution of the Schiff base (0.001 mol for the copper complexes and 0.002 mol for the nickel complex) in methanol (100 ml). The mixture was gently heated on a water bath for 2 min and then left to stand overnight. The complexes that crystallized out of the reaction mixture were filtered off, washed with methanol and dried in a desiccator over anhydrous silica gel. The thiocyanato (**1**) and iodo (**3**) complexes of copper(II) were prepared by adding a solution of LiNCS or LiI (0.004 mol) to a boiling mixture containing copper(II) nitrate (0.001 mol) and ligand (0.001 mol) in methanol and letting the reaction mixture to stand overnight. Crystals of the copper(II)-nitrato complex (**1**) suitable for X-ray analysis were obtained during the preparation of the complex whereas those of the thiocyanato-copper complex (**2**) and nickel(II) complex (**4**) were obtained by recrystallizing the crude complexes from acetonitrile.

2.4. Crystallography

Cell constants were determined by a least-squares fit to the setting parameters of 25 independent reflections, measured on an Enraf-Nonius CAD4 four-circle diffractometer using graphite monochromated Mo Kα radiation (0.71073 Å) and operating in the ω–2θ mode within the range $3° < 2\theta < 50°$. Empirical absorption correction (ψ scans) [25] and data reduction [26] were performed within the WINGX [27] suite of programmes. The structures were solved by direct methods with SHELX86 [28] and refined by full-matrix least-squares analysis with SHELXL97 [29]. Non-hydrogen atoms were refined with anisotropic thermal parameters whereas H-atoms were included at estimated positions. Drawings of the molecules were produced with ORTEP3 [30] and PLUTON [31]. A summary of the crystal data, structure solution and refinement parameters are given in Table 1.

3. Results and discussion

Compounds containing the thioamide functional group, –NH–C(S), are capable of exhibiting thione–thiol tautomerism. However, we have previously shown that, in the solid state as well as in solution, the Schiff base, Hqaldsme exists only as the thione (**1a**) tautomer [24] (see Fig. 1).

In addition to the possibility of thione and thiol tautomers, the Schiff base is also capable of existing as *E* and *Z* isomeric forms (Fig. 2) or as a mixture of *E* and *Z* isomers since it also contains the –C=N– moiety.

Although, both in the solid state as well as in solution, the Schiff base remains in its thioketo tautomeric form, in ethanol and in the presence of copper(II) salts, it rapidly

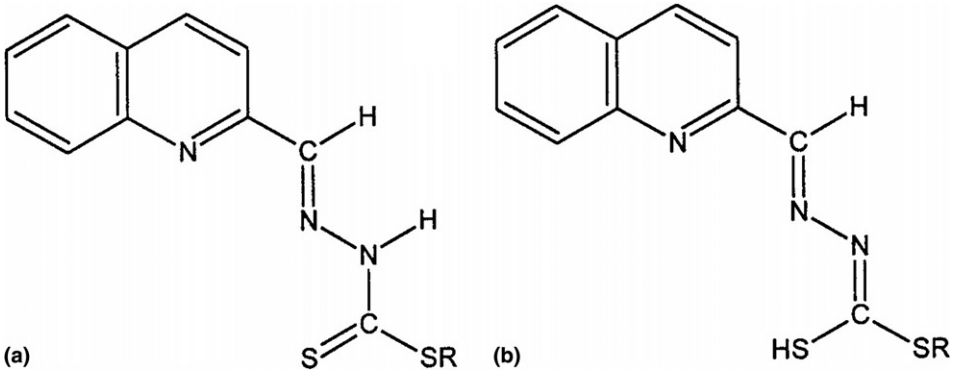

Fig. 1. The thione (**a**) and thiol (**b**) tautomeric forms of the Schiff bases.

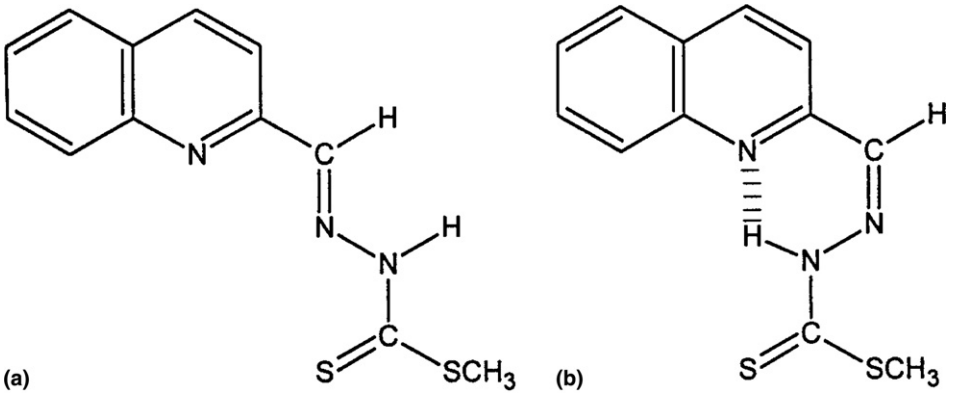

Fig. 2. The *E* and *Z* isomeric forms of the Schiff bases (**a**; the *E* form) (**b**; the *Z* form).

changes its configuration from the thione to the thiol form with the concomitant formation of complexes of empirical formula, $Cu(qaldsme)X(CH_3OH)_n$ (qaldsme = deprotonated form of the Schiff base; X = NCS, I, NO_3; $n = 0$, 1). The related tridentate NNS thiosemicarbazones derived from α-*N*-heterocyclic carboxaldehydes have been shown to coordinate to metal ions in both the protonated thione [32–37] and deprotonated thiolate [34] forms. In some metal–thiosemicarbazone complexes, the protonated thione and deprotonated thiolate forms of a thiosemicarbazone ligand have also been found to be present in the same complex [35–37]. In contrast with thiosemicarbazones, Schiff bases derived from *S*-alkyldithiocarbazates, however, almost always deprotonate upon coordination to give complexes of the ligands in their thiolate form. Our attempts to prepare copper(II) complexes of the protonated form of Hqaldsme have also not been successful.

The complexes are stable at room temperature and they do not show any sign of decomposition if kept in a desiccator over a long period of time. They are moderately soluble in organic solvents such as chloroform, dichloromethane, methyl cyanide, etc., but dissolve readily in donor solvents like DMSO, DMF, etc.

The molar conductances of the copper complexes in $(CH_3)_2SO$ fall in the 17.7–32.1 $ohm^{-1}\,cm^2\,mol^{-1}$ which are much lower than that expected for 1:1 electrolytes (50–70 $ohm^{-1}\,cm^2\,mol^{-1}$) in this solvent [38]. The conductivity of the nickel(II) complex is 2.0 $ohm^{-1}\,cm^2\,mol^{-1}$ indicating that it is essentially a non-electrolyte in this solvent. The conductivity data, therefore, indicate that the Schiff base is coordinated to the metal ions in its deprotonated thiolate form and that the anions in the copper complexes are also coordinated to the copper(II) ion. The IR spectrum of $[Cu(qaldsme)(NCS)]_2$ exhibits a strong band at 2095 cm^{-1} with a shoulder at ca. 2000 cm^{-1} indicating the presence of a monodentate N-bonded thiocyanate group [39] and that of $[Cu(qaldsme)(NO_3)(CH_3OH)]$ shows the ν_{sym} and ν_{asym} modes of the nitrate ligand at 1477 and 1298 cm^{-1}, respectively, indicating that the nitrate ion is coordinated to the copper(II) ion as monodentate ligand [40]. The IR spectra of the complexes also do not contain the *ν*NH band of the free ligand lending further support to the conductance evidence that the proton on the imine nitrogen atom of the ligand is lost during coordination with the copper(II) ion.

The IR spectral data containing relevant vibrational bands of the ligand and its nickel(II) and copper(II) complexes are given in Table 2. The data support coordination of the ligand via the quinoline nitrogen atom, azomethine nitrogen atom via the sulfur atom [41]. A similar tridentate NNS mode of coordination has already been established for the tin(IV) complex of this ligand [24].

The electronic spectral data of the complexes (Table 2), in addition to showing the intra-ligand bands in the 374–350 nm and 341–338 nm ranges corresponding to the $n \Rightarrow \pi^*$ and $\pi \Rightarrow \pi^*$ transitions, respectively, exhibit a d–d band in the 603–730 nm range for the copper complexes and two d–d bands at 815 and 515 nm for the nickel(II) complex. A strong $S \Rightarrow M$ charge-transfer band in the 406–448 nm range is also observed. The presence of a $S \Rightarrow M^{II}$ (LMCT) band in the electronic spectra of these complexes further supports bonding of the ligands to the metal ion via one of the sulfur atoms. The occurrence of a $S \Rightarrow M$ LMCT band is quite common in metal complexes of both thiosemicarbazones [42,43] and dithiocarbazates [23,44]. The appearance of a single d–d band at 645 nm for **1** and 724 nm for **2** is consistent with a square-pyramidal geometry similar to that found for the related $[Cu(bpsbz)NO_3]$ complex (bpsbz = anionic form of the tridentate dithiocarbazate ligand, 2-benzoylpyridine Schiff base of *S*-benzyldithiocarbazate), whose distorted square-pyramidal N_2SO_2 geometry has been established by X-ray diffraction [23].

The room temperature magnetic moments of the copper(II) complexes fall in the 1.75–2.1 B.M. range indicating that these complexes are magnetically dilute in nature. The room-temperature magnetic moment of the bis-ligand nickel(II) complex (2.83 B.M.) is consistent with a six-coordinate distorted octahedral nickel(II) complex. Six-coordinate nickel(II) complexes are expected to exhibit three bands in their electronic spectra corresponding to the $^3A_{2g} \rightarrow {}^3T_{2g}$, $^3A_{2g} \rightarrow {}^3T_{1g}(F)$ and $^3A_{2g} \rightarrow {}^3T_{1g}(P)$ transitions. In the electronic spectrum of the present nickel(II) complex, two d–d bands at 815 and 510 nm corresponding to the $^3A_{2g} \rightarrow {}^3T_{2g}(F)$ and $^3A_{2g} \rightarrow {}^3T_{1g}(F)$ transitions, respectively, are observed consistent with its six-coordinate octahedral geometry. The third band corresponding to the transition $^3A_{2g} \rightarrow {}^3T_{1g}(P)$ could not be observed because of the intrusion of the tail of the strong $S \rightarrow Ni^{II}$ charge transfer band in the visible region of the spectrum.

[a] qaldsme = anionic form of Hqaldsme.
[b] Data taken from Ref. [24].

3.1. The crystal structure of [Cu(qaldsme)(NO_3)(CH_3OH)]

The structure of the nitrato complex is depicted in Fig. 3 and important bond lengths and angles are compiled in Table 3. The structure shows that the complex is a monomer in which the copper atom adopts a five-coordinate geometry with the Schiff base being coordinated to it as a uninegatively charged tridentate chelating agent via the quinoline nitrogen atom, the azomethine nitrogen atom and the thiolate sulfur atom. An oxygen atom of the monodentate nitrate ligand is coordinated to the copper atom at the equatorial coordination position whereas an oxygen atom of the methanol molecule occupies the axial site. While coordinating with the copper(II) ion, deprotonation of the ligand generates a negative charge on the thiolate sulfur atom which is delocalized over the N(1)–C(1)–S(1) group [N(1)–C(1) 1.28(1) Å and C(1)–S(1) 1.72(1) Å]. The corresponding C(1)–S(1) and N(1)–C(1) bonds of the free ligand Hqaldsme are 1.643(4) and 1.346(8) Å, respectively [24]. It is notable that the N(1)–N(2) and C(3)–N(2) bond lengths (genuine single and double bonds, respectively) do not differ significantly going from the protonated free ligand to the deprotonated coordinated anion [24].

The two five-membered chelate rings S(1)–C(1)–N(1)–N(2)–Cu and N(3)–C(3)–C(4)–N(2)–Cu are virtually coplanar, with all atoms comprising the two rings lying within 0.06 Å of their least-squares plane. The conformation of the ligand also changes upon coordination, e.g., in the free state the ligand remains in an *E*,*E*, conformation but upon coordination, it adopts an *E*,*Z* configuration.

A comparison of the metal–donor atom distances in [Cu(qaldsme)(NO_3)(H_2O)] (Table 3) with those in the analogous five-coordinate copper(II) complex of an analogous dithiocarbazate ligand, [Cu(bpysbz)(NO_3)] (bpysbz = anionic form of the 2-benzoylpyridine Schiff base of *S*-benzyldithiocarbazate) which also has a similar N_2SO_2 coordination kernel [23] indicates that the Cu–S [2.291(4) Å], Cu–$N_{azomethine}$ [1.95(1) Å] and Cu–$N_{heterocyclic\ ring}$ [2.107(9) Å] bond lengths agree well with each other except that the Cu–S bond in the present complex is weaker than that in the Cu-bpysbz complex. As is usually the case, the Cu–$N_{heterocycle}$ distance in the present nitrato complex is longer than the Cu–$N_{azomethine}$ distance. The Cu–$O_{nitrate}$ and Cu–$O_{methanol}$ distances are 1.963(8) Å and 2.275(8) Å,

Symmetry operation: #1 $-x$, $-y$, $-z+2$.

respectively, which compare well with those found in other five-coordinate copper(II) complexes of dithiocarbazate ligands [2,44].

The coordination geometry of copper(II) ion in $[Cu(qaldsme)(NO_3)(CH_3OH)]$ is close to square-pyramidal. Addison et al. [45] have used an angular structural parameter τ (index of trigonality) for distinguishing between a trigonal-bipyramidal (TBPY) and square-pyramidal (SPY) geometry in five-coordinate complexes, $\tau = \beta - \alpha/60°$ where α and β are the two largest angles. $\tau = 0$ for an ideal square-pyramid (α and $\beta = 180°$) and $\tau = 1$ for an ideal trigonal-bipyramid ($\alpha = 120°$ and $\beta = 180°$). Using this criterion, the τ value is found to be 0.08 indicating that the complex has a near square-pyramidal geometry

3.2. The crystal structure of $[Cu(qaldsme)(NCS)]_2$

In contrast to the monomeric square-pyramidal complex defined in the nitrate salt $[Cu(qaldsme)(NO_3)(CH_3OH)]$, the thiocyanate analogue crystallized as a dimer. A view of the asymmetric (monomeric) unit of the structure is shown in Fig. 4, while the centrosymmetric dimer is depicted in Fig. 5. The two monomeric units are linked by a four-membered ring that includes both symmetry related Cu atoms and coordinated S-donors. The local coordination environment of each copper atom comprises a square-pyramidal N_3S_2 essential part. As expected, the deprotonated Schiff base again binds the copper atom via the quinoline nitrogen atom, the azomethine nitrogen atom and the thiolate sulfur atom. The quinoline nitrogen, the azomethine nitrogen atom and the thiolate sulfur atom of the Schiff base together with the nitrogen atom of the monodentate thiocyanate ligand comprise the basal plane whereas the apical position is occupied by a bridging sulfur atom, formally replacing the methanol ligand seen in $[Cu(qaldsme)(NO_3)(CH_3OH)]$.

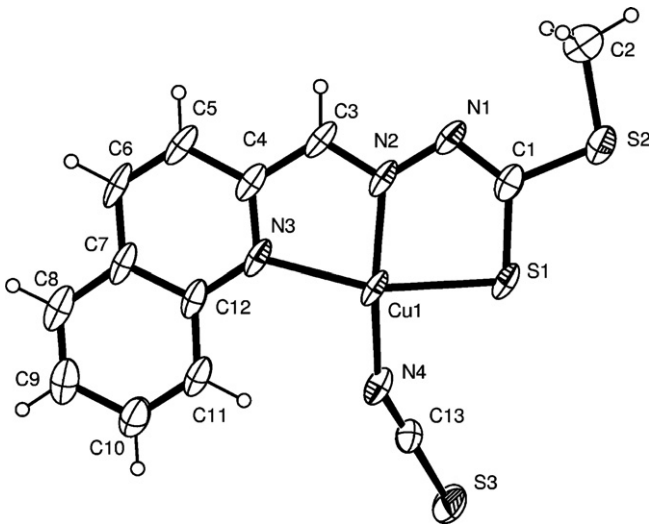

Fig. 4. ORTEP of the monomeric unit of $[Cu(qaldsme)(NCS)]_2$ (30% ellipsoids).

There are several structurally characterized dimeric copper(II) bearing a similar four-membered metallocyclic thiolate-bridging motif [46–51]. Most of these are 2-pyridine carboxaldehyde thiosemicarbazone complexes of Cu(II). For example $[Cu(fptsc)X]_2$ ($X = Cl^-$, Br^-, $HCOO^-$ and NO_3^-) (fptsc = anionic form of the 2-pyridinecarboxaldehyde thiosemicarbazone) whose structures have been confirmed by X-ray diffraction [46,49]. The Cu(1)–S(1), Cu(1)–N(2) and Cu(1)–N(4) bond distances, 2.314(2) Å, 1.945(6) Å and 1.897(6) Å, respectively, in $[Cu(qaldsme)(NCS)]_2$ compare favourably with those in $[Cu(fptsc)X]_2$. The coordination geometry around each copper(II) ion can be considered as approximately square-pyramidal since the geometrical parameter, τ, i.e., $\tau = (\beta - \alpha)/60°$ where α and β are N(4)–Cu(1)–N(3) and N(3)–Cu(1)–S(1) angles, respectively, has a value of 0.03.

The bond distances in the dithiocarbazate chain are the same within experimental uncertainty to those found in the monomeric analogue above. An examination of the bond angle data in Table 3 indicates that the complex does not have a perfect square-pyramidal geometry. The coordinate angles deviate significantly from 90° or 180° due to restraint imposed by the five-membered chelate rings; N(3)–Cu(1)–S(1) [162.2(2) versus 180°], N(4)–Cu(1)–N(2) [163.9(2) versus 180°], N(4)–Cu(1)–N(3) [104.9(2) versus 90°] and N(2)–Cu(1)–N(3) [80.3(2) versus 90°].

3.3. The crystal structure of $[Ni(qaldsme)_2] \cdot 0.5CH_3CN$

The structure of the complex with the atom numbering is depicted in Fig. 6. The bond lengths and bond angles are shown in Table 4. The nickel(II) ion in the complex, $[Ni(qaldsme)_2]$ is in a six-coordinate environment with both deprotonated ligands coordinated to the nickel(II) ion as NNS tridentates in an identical fashion to that seen in the Cu complexes above.

Although one would anticipate a shortening of the N(1)–C(1) and C(1)–S(1) bond lengths going from the free ligand to the coordinated anion (as seen in the Cu(II) complexes), the precision of the structure does not resolve these differences in the present case. The Schiff bases are coordinated to the nickel(II) ion in their meridional configurations the

quinoline nitrogen and thiolate sulfur atoms *cis* to each other and the two azomethine nitrogen atoms *trans*. Similar meridional configurations of tridentate NNS ligands around nickel(II) have also been observed in other bis-chelated nickel(II) complexes of NNS thiosemicarbazones [52,53] and dithiocarbazates [53]. The Ni–S [2.412(3) and 2.415(3) Å], Ni–N_{imine} [2.014(9) and 2.006(8) Å] and Ni–$N_{heterocycle}$ [2.213(8) and 2.210(8) Å] bond lengths are similar to those of other six-coordinate distorted octahedral nickel(II) complexes of tridentate sulfur–nitrogen chelating agents. The two Ni–$N_{quinoline}$ bond distances are close but they are significantly different from the Ni–N_{imine} bond distances. Similar differences between the Ni–N_{imine} and Ni–$N_{pyridine}$ bonds have also been observed in other related six-coordinated nickel(II) complexes [21,54,55]. For the purpose of comparison, nickel-donor atom distances in some six-coordinated nickel(II) complexes of closely related ligands, whose structures have been determined by X-ray diffraction, are shown in Table 5. The data show that the Ni–N_{imine} and Ni–$N_{heterocyclic}$, distances are always different the former being consistently shorter than the latter. The coordination sphere of the present nickel(II) complex is a distorted octahedron. Except for the angles, N(3A)–NI(1)–S(1B) [90.4(2)°] and N(3B)–NI(1)–S(1A) [89.2(2)°], all other angles deviate, some of them substantially, from that of an ideal octahedral geometry. The distortion is due to the restricted bite angles imposed by planar tridenate qaldsme ligands.

Table 5

of these structures with salts, alcohols, proteins and other compounds [18]. Surface active materials are major building blocks of many physical, chemical and biological systems. They have been introduced into several commercial products such as antiseptic agents in cosmetics and as germicides [5], and also have found a wide range of applications because of their unique solution properties such as detergency, solubilization and surface wetting capabilities, in diverse areas such as mining, petroleum and pharmaceutical industries. It has been observed that several redox reactions in micellar media were influenced by the hydrophobic and electrostatic forces and for a given set of reactions the observed rate depends on the extent of association between the reactants and micellar aggregates [19–23]. A growing number of applications have been developed to study metallosurfactants in this content. They are a good enzymatic model for the catalytic hydrolysis of carboxylic acid esters, since they mimic not only the active center of the metalloenzyme but also the microenvironment of the metalloenzyme. In the course of studies on the effects of metallosurfactants on chemical reactions, catalytic effects were observed above a critical micelle concentration (CMC). Such systems offered the possibility to investigate the effects of the local reactant concentrations in the micellar subphase, as well as the local microenvironment on the reactivity [24–28].

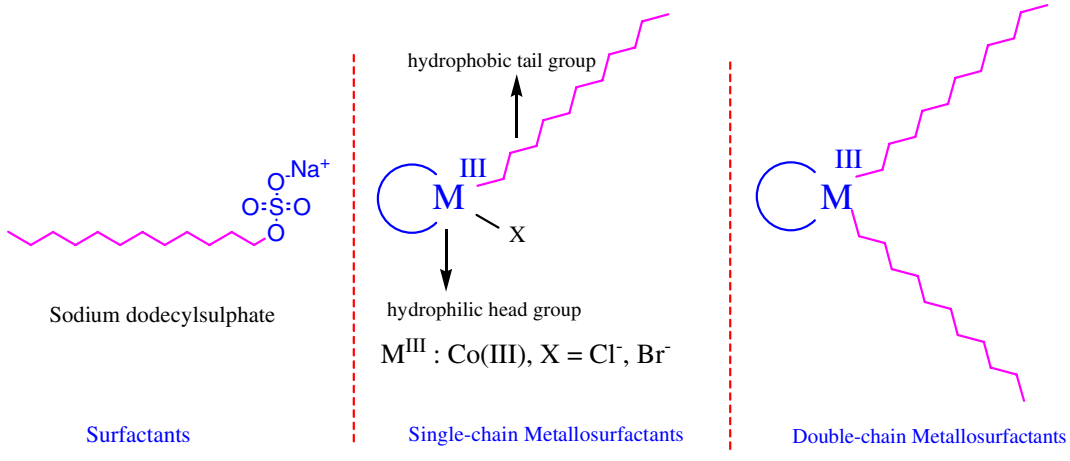
Cobalt(III) complexes, by virtue of their abundance and diversity, have played a fundamental role in our understanding of the structural, spectroscopic and electrochemical properties of coordination compounds. We have been interested in the synthesis and micelle forming properties of Co^{III} complexes containing lipophilic ligands for a long time [29–31]. As in biology, such compounds may exhibit novel physical and chemical properties with interesting and useful associated applications. Studies on the chemistry of Co^{III} metallosurfactants have received a sustained high level of attention due to their relevance in various redox processes in biological systems and act as promising agents for antitumor [32], anthelmintic [33], antiparasitic [34], antibiotics [35] and antimicrobial activities [17], and a boost of interest because of their multiple applications in fields such as medicine [36], magnetic resonance imaging [37] and drug delivery [38].

A characteristic feature of transition metals is their ability to form complexes with a variety of neutral molecules such as bpy and phen. These are widely used as a classical *N*,*N*′-bidentate ligand to prepare mixed-ligand complexes in coordination chemistry. A common feature of these ligands is the presence of a vacant π orbital that can accept electron density from the metal ion to form a type of π bonding that supplements the σ bonding arising from the donation of a lone pair of electrons. Most of the metal complexes containing bpy and phen chelators can act as potential anti-tumor agents. Intensive investigations of the coordination chemistry of metallosurfactants with chelating ligands continue to be stimulated by interest for metallobiomolecules, the search for appropriate systems for binding and activating simple molecules, catalysis, and magnetic interactions [39,40]. In spite of the greatest effort and success in the study of metallosurfactants of cobalt(III) complexes, such complexes still attract much attention due to their interesting properties and the relative simplicity of their synthesis (Scheme 1). Recently, there has been increasing interest in the use of these organized media to study the fundamental photochemical reactions of metal complexes in relevance to the conversion of solar energy into other useful forms of energy through photochemical reactions [41,42]. As a part of our studies on transition metal-based surfactants [29–31] in this paper we report the synthesis, characterization and determination of critical micelle concentration values of some more novel Co^{III} metallosurfactants.

2. Experimental

2.1. Materials

All the reagents were of analytical grade (Aldrich and Merck). Ultra pure water, obtained by deionising distilled water (conductivity $<10^{-6}$ S m^{-1}) using a Milli-Q Reagent



Scheme 1.

Grade water system, was used for preparative work and to make up solutions for all physical measurements.

2.2. Physical measurements and methods

^{1}H NMR spectra were recorded in appropriate deuteriated solvents using a Bruker AC 300F (300 MHz) spectrometer with TMS as internal reference. Infrared (IR) spectra were recorded on a Jasco 460 plus spectrometer using the potassium bromide discs method. Electronic absorption spectra were taken in 10^{-3} M perchloric acid medium recorded in a Varian Cary 500 Scan UV–Vis–NIR spectrophotometer. C, H and N were estimated using a Perkin–Elmer 2400 CHN instrument. Conductance measurements were carried out in aqueous solutions of the complexes with a Metrohm 712 conductivity meter and a dip-type cell with a cell constant of 1.0.

2.3. Synthesis of single chain metallosurfactants of cobalt(III) complexes

2.3.1. *cis*-$[Co(bpy)_2(C_{12}H_{25}NH_2)Cl](ClO_4)_2 \cdot 2H_2O$ and *cis*-$[Co(bpy)_2(C_{16}H_{33}NH_2)Cl](ClO_4)_2 \cdot 2H_2O$

Cis-$[Co(bpy)_2Cl_2]Cl \cdot 2H_2O$ [43] (3 g) was dissolved in water (10 mL). To this solution dodecylamine (1 mL), where the amine used was not sufficiently miscible with (soluble in) water, was first mixed with ethanol (2 mL) and then added drop by drop over a period of 30 min. The dark violet colour solution gradually became brown during the reaction. The mixture was set aside at 313 K for 2 days until no further change was observed. Afterwards a saturated solution of sodium perchlorate in very dilute perchloric acid was added. Slowly a pasty solid mass separated out and it was filtered off, washed with small amounts of alcohol followed by acetone, and then it was dried over air. The semi-dried solid was further dried in a drying pistol over fused calcium chloride and stored in a vacuum desiccator. For the complex *cis*-$[Co(bpy)_2(C_{16}H_{33}NH_2)Cl](ClO_4)_2 \cdot 2H_2O$, cetylamine was used in the place of dodecylamine.

2.3.2. *cis*-$[Co(bpy)_2(C_{12}H_{25}NH_2)Br](ClO_4)_2 \cdot 2H_2O$ and *cis*-$[Co(bpy)_2(C_{16}H_{33}NH_2)Br](ClO_4)_2 \cdot 2H_2O$

This complex was synthesized by adopting the same method as described for the synthesis of the complex *cis*-$[Co(bpy)_2(C_{12}H_{25}NH_2)Cl](ClO_4)_2 \cdot 2H_2O$ except that in place of *cis*-$[Co(bpy)_2Cl_2]Cl$, *cis*-$[Co(bpy)_2Br_2]Br$ [43] was used.

2.3.3. *cis*-$[Co(phen)_2(C_{12}H_{25}NH_2)Cl](ClO_4)_2 \cdot 2H_2O$, *cis*-$[Co(phen)_2(C_{16}H_{33}NH_2)Cl](ClO_4)_2 \cdot 2H_2O$, *cis*-$[Co(phen)_2(C_{12}H_{25}NH_2)Br](ClO_4)_2 \cdot 2H_2O$ and *cis*-$[Co(phen)_2(C_{16}H_{33}NH_2)Br](ClO_4)_2 \cdot 2H_2O$

The procedure for synthesizing these complexes is similar to that described above, but in the place of bipyridyl complexes, phenanthroline complexes *cis*-$[Co(phen)_2Cl_2]Cl$ and *cis*-$[Co(phen)_2Br_2]Br$ were used [44].

2.4. Synthesis of double-chain metallosurfactants of cobalt(III) complexes

2.4.1. *cis*-$[Co(en)_2(C_{12}H_{25}NH_2)_2](ClO_4)_3 \cdot 2H_2O$ and *cis*-$[Co(en)_2(C_{16}H_{33}NH_2)_2](ClO_4)_3 \cdot 2H_2O$

Trans-$[Co(en)_2Cl_2]Cl$ [45] (3.0 g) was dissolved in water (20 mL). To this solution a slightly more than the calculated amount of dodecylamine (4.3 mL) in ethanol (3 mL) was added drop by drop over a period of 30 min. The green solution gradually became red during the reaction and the mixture was set aside for 2 days at 313 K. Afterwards a saturated solution of sodium perchlorate in very dilute perchloric acid was added. The solid that formed filtered off and washed with alcohol followed by acetone and dried.

The complexes *cis*-$[Co(en)_2(C_{16}H_{33}NH_2)_2](ClO_4)_3 \cdot 2H_2O$, *cis*-α-$[Co(trien)(C_{12}H_{25}NH_2)_2](ClO_4)_3 \cdot 2H_2O$, *cis*-α-$[Co(trien)(C_{16}H_{33}NH_2)_2](ClO_4)_3 \cdot 2H_2O$, *cis*-$[Co(bpy)_2(C_{12}H_{25}NH_2)_2](ClO_4)_3 \cdot 2H_2O$, *cis*-$[Co(bpy)_2(C_{16}H_{33}NH_2)_2](ClO_4)_3 \cdot 2H_2O$, *cis*-$[Co(phen)_2(C_{12}H_{25}NH_2)_2](ClO_4)_3 \cdot 2H_2O$ and *cis*-$[Co(phen)_2(C_{16}H_{33}NH_2)_2](ClO_4)_3 \cdot 2H_2O$ were prepared by the ligand substitution method, replacing the chloride ion with dodecylamine/cetylamine from their corresponding parent complexes [29,43–45].

Safety note. Caution: Perchlorate salts of Co^{III} complexes containing organic ligands are potentially explosive! Although we have experienced no problems with the compounds reported in this work, they should only be handled in small quantities and never scraped from sintered glass frits nor heated in the solid state.

2.5. Determination of CMC

CMC values of the complexes were calculated using electrical conductance data measured using a digital conductivity meter (Metrohm 712). The conductivity cell (dip-type with a cell constant of 1.0) was calibrated with KCl solutions in the appropriate concentration range. The cell constant was calculated using molar conductivity data for KCl published by Barthel et al. [46]. Various concentrations of Co^{III}–surfactant complexes were prepared in the range 10^{-6}–10^{-2} mol dm^{-3}. All measurements were performed in a double-walled glass container, which was maintained at the desired temperature (±0.1 °C) using a circulating water bath. The conductivity of these solutions was measured at 303–313 K. The conductance was measured after thorough mixing and temperature equilibrating at each dilution. The measurement was started with a dilute solution and the subsequent concentrated solutions were prepared by adding a previously prepared stock solution. The establishment of equilibrium was checked by taking a series of reading after 15-min intervals until no significant change occurred.

3. Results and discussion

The cobalt(III)–surfactant complexes synthesized in the present study were characterized by UV–visible, IR and

NMR spectra and checked by comparing the spectra with those for the corresponding ordinary complexes where one of the ligands is butylamine instead of dodecylamine/cetylamine, which have been reported earlier [29]. The purity of the complexes was checked by cobalt [47], elemental, halide analyses, which were found to be in good agreement with that of calculated values (Table 1).

3.1. Spectroscopic characterization

3.1.1. Infrared spectra

For the assignment of a geometrical configuration to these complexes, infrared spectroscopy was used. Several attempts have been made to relate differences in infrared spectra to geometrical configuration of complexes. Various workers have employed [48–50] the NH_2 deformation mode in the 1700–1500 cm^{-1} region, CH_2 rocking mode in the 900–850 cm^{-1} and Co–N stretching mode in the 610–500 cm^{-1} region to distinguish between the *cis* and *trans* isomers of cobalt(III)–ethylenediamine complexes. Baldwin [48] suggested that the most consistent variations between the spectra of *cis*- and *trans*-isomers were found in the CH_2 rocking region (900–850 cm^{-1}). The *cis*-isomers always show two peaks, whereas the *trans*-isomers usually have only one. Hughes and Mcwhinnie [49] studied the infrared absorption spectra of several bis(ethylenediamine)cobalt(III) complexes and obtained a satisfactory correlation in the 610–500 cm^{-1} region, where Co–N stretching modes of the chelate ring occur. Here, no *trans*-isomers had more than three strong bands, while all *cis*-isomers had at least four, sometimes occurring as shoulders. The bands for the *trans* isomers were generally evenly distributed, while those for *cis*-complexes occurred in two groups with a wide separation between them. Because of the lower symmetry in the present study (Fig. 1), the *cis* isomers show two bands for the NH_2 deformation, two bands for the NH_2 wagging modes, two bands for CH_2 rocking mode and four bands occurring as groups of two with a

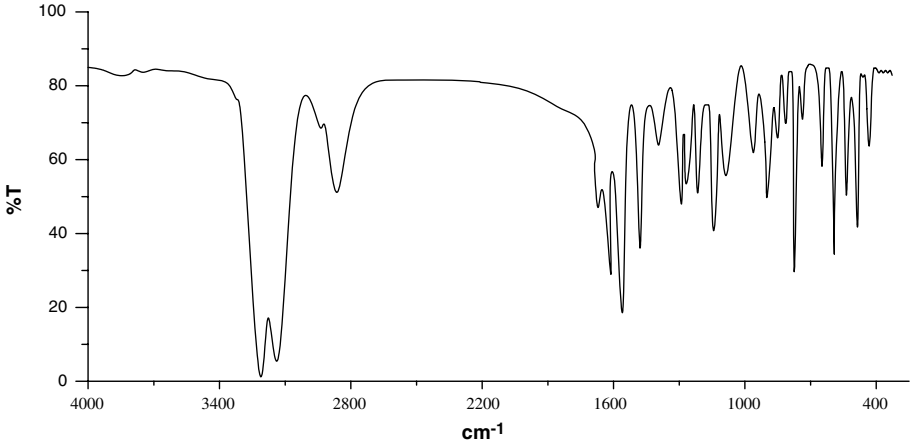

Fig. 1. Infrared spectra of *cis*-α-$[Co(trien)(C_{16}H_{33}NH_2)_2](ClO_4)_2$.

wide separation for the Co–N stretching mode. Complexes of the type *cis*-α-$[Co(trien)X_2]^{n+}$ in the present study show two bands for the NH_2 deformation in the region 1630–1580 cm^{-1}, two bands for the CH_2 or NH_2 twist mode in the region 1150–980 cm^{-1}, and the CH_2 rock mode in the region 940–860 cm^{-1} appearing as two bands [50]. Strukl and Walter [51] and Schilt and Taylor [52] studied the infrared spectra of several bipyridyl and phenanthroline complexes. They observed that the spectral shape of the bpy and phen complexes were quite similar, taking into account the similarity of both ligands. In the spectra of the phenanthroline complexes, strong bands were observed in three frequency regions namely between 700 and 900 cm^{-1}, between 1100 and 1250 cm^{-1} and between 1400 and 1650 cm^{-1}. Strong bands in the 700–900 cm^{-1} region were attributed to the aromatic hydrocarbons of the phenanthroline ring. The band near 720 cm^{-1} was assigned to the out of the plane motion of hydrogen atoms on the heterocyclic rings and the band near 840 cm^{-1} to the hydrogens on the centre ring. The multiple splitting which these bands exhibit in most of the spectra probably arise from out-of-plane hydrogen motion other than the one in which all atoms move in phase, and also possibly from overtones of low lying fundamentals in resonance. In the bipyridyl spectra, only one strong band was observed in this region as expected for two identical groups of four hydrogen atoms each. Not much can be said about the bands in the 1100–1250 cm^{-1} region expect that they may arise from in-plane hydrogen deformation motions or possibly ring vibrations. The spectra of the bpy complexes in general are less complicated than those of the phen complexes. Only three strong bands are present, one near 750 ascribed to out of plane bending of ring hydrogens, and one near 1450 cm^{-1} which is probably a ring frequency, and a ring frequency near 1600 cm^{-1}. Numerous weak bands were observed between 900 and 1350 cm^{-1}. The C=C and C=N stretching vibrations of the heterocyclic ring stem exhibit in the region at 1410, 1450, 1545 and 1570 cm^{-1}. Perchlorate bonds at ca. 1100, 925, 620 and 450 cm^{-1} belong to an ionic species; this means that this counter-ion is not involved in the cobalt-ligand coordination [53]. The IR spectroscopic data therefore clearly indicate a *cis* configuration for the cobalt(III) surfactant complexes.

3.1.2. ^1H NMR spectra

The ^1H NMR spectra offer a conclusive proof of the configuration of the isomers in solution. The *cis* and *trans* isomers of $[Co(en)_2X_2]^+$ ions have different symmetry properties, and this factor appears to govern the difference in their NMR spectra. The *cis* isomers possess C_2-symmetry with the twofold axis in the plane of cobalt and the two X groups and this makes $–CH_2CH_2–$ groups equivalent provided that the cobalt–ethylenediamine rings have the same conformation. In the present study (Fig. 2), for the *cis* complexes, due to the lower symmetry, the methylene protons of ethylenediamine show a more complex absorption around 2.5–2.8 ppm. The methylene protons of the long chain moieties (dodecylamine/cetylamine) give rise to a multiplet usually at 1.2–1.8 ppm, whereas the terminal methyl group of the hydrocarbon chain substituent gives a triplet at 0.84 ppm. The ^1H NMR spectral data for the cobalt(III)–triethylenetetramine complexes exhibit signals in the region 2.6–3.0 ppm attributable to the $–CH_2$ group of the triethylenetetramine chelate ring, thus confirming the *cis* structure of the complex. It is well established that bis-type cobalt(III) complexes of 2,2′-bipyridine or 1,10-phenanthroline take only the *cis*-configuration because of the repulsion between the ligands. The *cis* configuration of all the present complexes was confirmed by the ^1H NMR. The spectra of the 1,10 phenanthroline complexes exhibit patterns similar to those of the bipyridine complexes. The assignment of the 1,10 phenanthroline and bipyridine complexes were made in a manner similar to the case of their respective parent complexes [54,55].

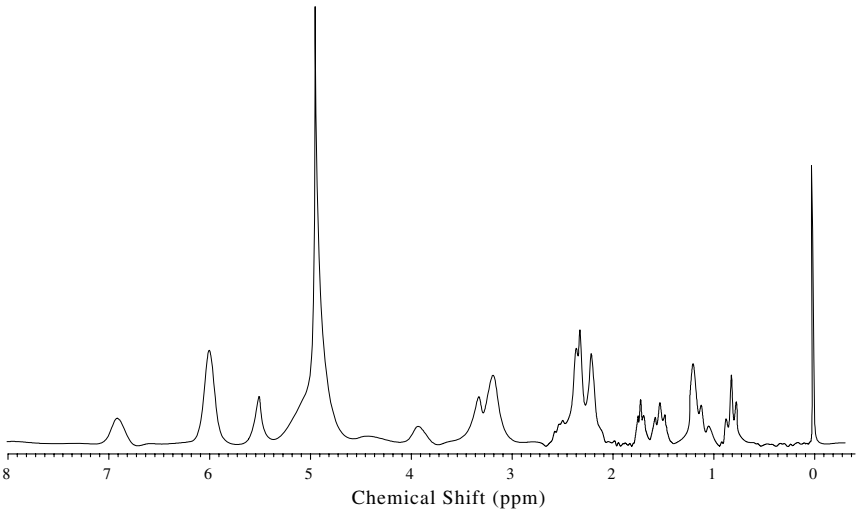

Fig. 2. ^1H NMR spectrum of *cis*-α-$[Co(trien)(C_{16}H_{33}NH_2)_2](ClO_4)_2$.

3.1.3. Electronic absorption spectra

The wavelength of the first absorption maximum in aqueous perchlorate medium for each complex is given in Table 1. It has been observed that the absorption spectra [56,57] of the *cis* and *trans* forms of $[Co(en)_2(NH_3)Y]^{n+}$ cations (Y = Cl or H_2O) showed some differences in the longest wavelength absorption band (d–d transition). The *trans* form showed a lower intensity ($\varepsilon < 50\ M^{-1}\ cm^{-1}$) whereas the *cis* form showed a higher intensity ($\varepsilon > 70\ M^{-1}\ cm^{-1}$). This observation can be used to determine the geometrical configuration of the present cations, whose longest wavelength absorption maxima are shown in Table 1. Similarly, the position of λ_{max} suggests that the strength of the bidentate ligands follows the order bpy < phen. The lower λ_{max} values for the complexes containing the phen ligand indicate that in these complexes the basal planes are comparatively more distorted than in the bpy containing complexes. By comparing the spectra of the corresponding butylamine complexes it reveals that both the ordinary and the surfactant complexes have the same structure and the replacement of lower aliphatic amine ligands by long chain aliphatic amine ligands does not affect the symmetry of the surfactant complexes. Consequently, it does not seem that micellization greatly influences the structure of the polar head.

3.2. Critical micelle concentration values (CMC)

The CMC values were computed from the slope of [Co(III)] versus specific conductance data. The complex concentration at which the micellization starts was evident from the change in the slope of the plot and that particular concentration is the CMC under the experimental conditions. The CMC values were determined at three different temperatures (303, 308 and 313 K). At all temperatures a break in the conductance versus concentration plots, characteristic of micelle formation, was observed. The CMC values were determined by fitting the data points above and below the break to two equation of the form $y = mx + c$ and solving the two equations simultaneously to obtain the point of intersection. Least-squares analysis was employed and correlation coefficients were greater than 0.98 in all the cases. The conductivity measurements at three different temperatures were repeated three times and the accuracy of the CMC values (Table 2) was found to be within ±3% error. Fig. 3 illustrates the plot for the complex *cis*-$[Co(en)_2(C_{12}H_{25}NH_2)_2](ClO_4)_2$; similar plots (not shown) were obtained for all the remaining complexes. It is observed that by changing the ion from Cl^- to Br^-, the CMC decreases. It may be due to the increase in the size of the ion in the coordination sphere, which makes it more weakly hydrated. Weakly hydrated ions can be adsorbed more readily in the micellar surface and that decreases the charge repulsion between the polar groups and thus facilitates the micellization. Further with the increase in the alkyl chain on polar head group, the CMC again shows a decrease. This may be due to an increase in hydrophobic character of the molecule in the coordination sphere with that of dodecyl/cetylamine.

3.3. Thermodynamics of micellization

The study of CMC versus temperature is often undertaken to obtain information on hydrophobic and head group interactions. This involves deriving various thermodynamic parameters of micelle formation. Two models are generally used, the mass-action or equilibrium model and the phase separation or pseudo-phase model. The mass-action model assumes that an equilibrium exists between the monomeric surfactant and the micelles. The phase separation model assumes that the aggregates have their counterions in the surrounding atmosphere in a separate phase [58–60]. According to these models, the standard Gibbs

Table 2

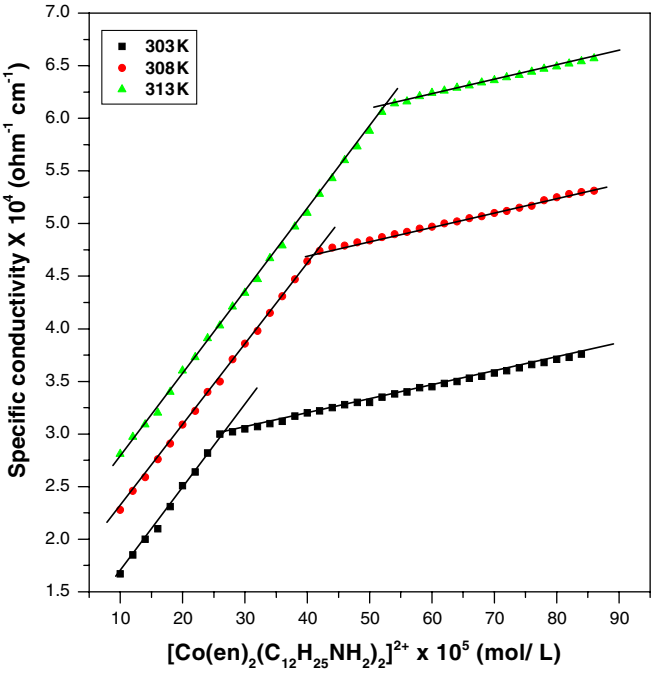

Fig. 3. Electrical conductivity vs. [Co(III)] in aqueous solution.

free energy of micelle formation per mole of monomer, ΔG^0_m, is given by

$$\Delta G^0_m = RT(2-\alpha_{ave})\ln \mathrm{CMC}, \quad (1)$$

where R, T and α_{ave} are gas constant, absolute temperature and average degree of micellar ionization, respectively.

The enthalpy of micelle formation can be obtained by applying the Gibbs–Helmholtz equation to Eq. (1)

$$\Delta H^0_m = -RT^2(2-\alpha_{ave})\mathrm{d}\ln \mathrm{CMC}/\mathrm{d}T. \quad (2)$$

Once the Gibbs free energy and the enthalpy of micelle formation are obtained, obviously the entropy of micelle formation can be determined by

$$\Delta S^0_m = (\Delta H^0_m - \Delta G^0_m)/T. \quad (3)$$

The thermodynamic parameters of micellization for the cationic surfactant are compiled in Table 2. The observed more negative Gibbs free energy of micellization indicates more favored micellization for the system under study when compared to hexadecyltrimethylammonium bromide ($\mathrm{CMC} = 9.0\times10^{-4}\,\mathrm{mol\,dm^{-3}}$). Moreover, since the changes of CMC with temperature are small, the value of ΔH^0_m and ΔS^0_m must be rather inaccurate and should be considered as only approximate. Nusselder and Engberts [61] have suggested that for negative ΔH^0_m values, London-dispersion forces play a major role in the micelle formation. Positive values of ΔS^0_m clearly indicate that the micellization of the studied surfactants in aqueous solution is governed mainly by hydrophobic interactions between the surfactant cations, resulting in the breakdown of the structured water surrounding the hydrophobic groups, and indicates that the cationic surfactant formation is an entropy driven process. The observed increase in the entropy values indicates that increasing head group polarity favors the micellization process. As mentioned in our previous reports [29–31], the CMC values for Co^{III} metallosurfactants in the present study are also very low compared to that of simple organic surfactants. Thus it is suggested that these metal surfactant complexes have more capacity to associate themselves forming aggregates compared to those of ordinary synthetic organic surfactants. Moreover, introduction of a metal complex to the hydrophilic part of the amphiphile can remarkably enhance the ability of aggregation.

eventually g_y), and zero-field splitting parameters D and E. This set can be enriched by the temperature-independent paramagnetism χ_{TIP}. The above parameters are frequently understood as internal characteristics of the complex under study (molecular constants). However, all of them originate in the electronic structure of the complex and they can be reconstructed with the help of the more principal electronic-structure parameters: the Racah parameters B and C (electron repulsion), the crystal-field strengths Dq, Ds, $\cdots$ (or more exactly the crystal-field poles for each ligand $F_2(L)$ and $F_4(L)$), the spin–orbit coupling constant ξ and the orbital reduction factors κ (which could be anisotropic, κ_z, κ_x) [9]. Such a target is far from being only of an academic interest, since just the sign and magnitude of the zero-field splitting parameter influence the key properties of the single-molecule magnets [10–12]. The tuning of the single-molecule magnets is, nowadays, an ultimate requirement for their possible technical exploitation.

Nickel(II) complexes are good candidates for studying the sign and magnitude of the zero-field splitting parameter D for several reasons. First, the ground-state of the octahedral and quasi-octahedral hexacoordinate complexes is $^3A_{2g}$ and $^3B_{1g}$, respectively so that the D-values can be studied over a wide range of geometries of the chromophore. Second, the D-values are enhanced by the spin–orbit splitting parameter $\lambda = -\xi/2S$ which adopts the highest value over the first-transition metal series. Moreover, the spin-Hamiltonian formalism offers a simple formula for the magnetic parameters in the form

$$D = \lambda^2[4\kappa_x^2/\Delta_{xy}(^3B_{1g} \rightarrow {}^3E_g) - 4\kappa_z^2/\Delta_z(^3B_{1g} \rightarrow {}^3B_{2g})], \quad (1)$$

$$g_z = g_e - 2\lambda[4\kappa_z^2/\Delta_z(^3B_{1g} \rightarrow {}^3B_{2g})] > g_e, \quad (2)$$

$$g_x = g_e - 2\lambda[4\kappa_x^2/\Delta_{xy}(^3B_{1g} \rightarrow {}^3E_g)] > g_e, \quad (3)$$

$$\chi_{TIP} = N_A\mu_0\mu_B^2(2/3)[2\cdot 4\kappa_x^2/\Delta_{xy}(^3B_{1g} \rightarrow {}^3E_g) + 4\kappa_z^2/\Delta_z(^3B_{1g} \rightarrow {}^3B_{2g})], \quad (4)$$

where the first excitation energy (split due to the tetragonality) occurs. Therefore, it is a natural demand to understand the impact of the quality of the ligands involved in the coordination sphere to the set of magnetic parameters.

In our preceding publications we correlated the zero-field splitting parameter D with analogous structural characteristics D_{str} that characterizes the degree of the tetragonality. Both these quantities measure the anisotropy (magnetic and/or structural). These parameters clearly show a mutual dependence (approximately along a straight line) [13,14]. However, the complexes involved in such a correlation were either homoleptic (imidazole and its derivative) or N-donor only of the $[Ni(base)_4(NCS)_2]$ type. In the present communication, we want to extend such a correlation to heteroleptic complexes possessing the $\{NiO_2O'_2N_2\}$ chromophore. Therefore, a series of complexes of the type $[Ni(base)_2(carboxylate)_2(H_2O)_2]$ have been prepared, structurally characterized and subjected to magnetochemical studies.

2. Experimental

2.1. Reagents

2-Methylimidazole, 1,2-dimethylimidazole, *iso*-quinoline, formic acid, $NiCl_2\cdot 6H_2O$ and CH_3COOK were purchased from commercial sources and used as received. Synthesis of the furo[3,2-*c*]pyridine has been conducted in accordance with published recipes [15–17].

Nickel(II) formate, as a hydrate, was synthesized by slowly adding a stoichiometric amount of nickel(II) carbonate to an aqueous-ethanol solution of formic acid in excess. Nickel(II) acetate was synthesized by adding potassium acetate to nickel(II) chloride ethanol solution. Elemental analysis (C, H, N) was performed on elemental analyzer Eager 300 (Carlo Erba). The nickel content was determined chelatometrically using murexide as an indicator.

2.2. Synthesis

The complexes $[Ni(2\text{-}Meiz)_2(HCOO)_2(H_2O)_2]$ (**1**) and $[Ni(1,2\text{-}Me_2iz)_2(HCOO)_2(H_2O)_2]$ (**2**) were prepared in warm dried ethanol over several hours under reflux. After several months green crystals were collected. The other two complexes $[Ni(iqu)_2(ac)_2(H_2O)_2]$ (**3**) and $[Ni(fupy)_2(ac)_2(H_2O)_2]$ (**4**) were prepared from nickel acetate: into a solution of nickel acetate a stoichiometric amount of ligand was added and stirred for half an hour. After two days the solid complexes were collected. Single crystals of **4** were grown from the ethanol solution. *Anal.* Calc. for (**1**) $C_{10}H_{18}N_4NiO_6$: C, 34.4; H, 5.21; N, 16.1; Ni, 15.9. Found: C, 35.0; H, 5.48; N, 15.9; Ni, 16.8%. Calc. for (**2**) $C_{12}H_{22}N_4NiO_6$: C, 38.2; H, 5.88; N, 14.9; Ni, 15.6. Found: C, 38.9; H, 6.01; N, 15.1; Ni, 15.6%. Calc. for (**3**) $C_{22}H_{24}N_2NiO_6$: C, 56.1; H, 5.13; N, 5.95; Ni, 12.5. Found: C, 56.1; H, 5.13; N, 5.95; Ni, 12.5%. Calc. for (**4**) $C_{18}H_{20}N_2NiO_8$: C, 47.9; H, 4.02; N, 6.21; Ni, 13.0. Found: C, 47.9; H, 4.47; N, 6.21; Ni, 13.0%.

2.3. Physical measurements

IR spectra were measured on Magna FTIR 750 spectrometer (Nicolet) in KBr pellets in the 4000–400 cm^{-1} region and in PE pellets in 400–200 cm^{-1} region.

Electronic spectra were measured using the DRIFT method on a Magna FTIR 750 spectrometer (Nicolet) in the region 5000–11 000 cm^{-1} and in Nujol mull on a Specord 200 (Analytical Jena) in the range 50 000–10 000 cm^{-1}.

Magnetic susceptibility and magnetization measurements were done using a SQUID magnetometer (Quantum Design) from 2 K at $B = 0.1$ T. The magnetization data were taken at $T = 2.0$ and 4.6 K, respectively. Raw susceptibility data were corrected for underlying diamagnetism using a set of Pascal constants. The effective magnetic moment has been calculated as usual: $\mu_{eff}/\mu_B = 798(\chi' T)^{1/2}$ where SI units are employed.

Single-crystal X-ray diffraction experiments for all complexes have been performed using Xcalibur CCD apparatus (Oxford Diffraction). Data reduction and empirical absorption correction were performed by SHELXS-97.

3. Results and discussion

3.1. Molecular and crystal structure

Crystal data for compounds **1**–**4** are collected in Table 1. The molecular structures are viewed in Fig. 1.

The structure of complex **1** consists of $[Ni(2\text{-}Meiz)_2(HCOO)_2(H_2O)_2]$ monomeric units in which the central Ni(II) atom has a distorted octahedral configuration. The coordination around Ni(II) atom is defined by two aqua ligands (w), two formato ligands (f) and two neutral 2-methylimidazole ligands (b). The distances Ni–O(f) are 2.081 Å, the distances Ni–O(w) are 2.075 and 2.136 Å and the distances Ni–N(b) are 2.082 Å (see Table 2). Two oxygen atoms from water molecules and two oxygen atoms from formato groups form the equatorial plane and two nitrogen atoms from 2–methylimidazole rings are situated in axial sites. The angle between the oxygen atoms from the formato groups is 169.61° and that feature points at deformation of the structure.

The registered intermolecular contacts for **1** are O–H···O [H···O = 1.94 and 1.97 Å, O···O = 2.714(5) and 2.827(5) Å, O–H···O = 172 and 167°] and N–H···O hydrogen bonds [H···O = 2.02 Å, N···O = 2.853(3) Å, N–H···O = 163°]. They are formed: (i) by aqua-ligand OH groups to the uncoordinated O atom from formato ligands in the equatorial plane; and (ii) through the secondary 2-methylimidazole N-atom to the coordinated formato O atom from another molecule of a neighboring layer. Thus, these hydrogen bonds form a three dimensional network. The N–H···O hydrogen bonds, present in **1**, are absent in the remaining complexes **2**, **3** and **4** (Fig. 2). The hydrogen-bond contacts are contained in the Supplementary material.

The molecular structure of complex **2** consists of discrete $[Ni(1,2\text{-}Me_2iz)_2(HCOO)_2(H_2O)_2]$ monomeric units with the Ni(II) atom in a distorted octahedral configuration defined by two formato ligands, two aqua ligands and two neutral 1,2-dimethylimidazole ligands. The distances Ni–O(f) are 2.071(2) Å, the distances Ni–O(w) are 2.11(2) Å and the distances Ni–N(1,2-dimethylimidazole) are 2.118(3) Å.

The intermolecular O–H···O hydrogen bonds for **2** [H···O = 1.898 and 1.939 Å, O···O = 2.737(3) and 2.776(4) Å and O–H···O = 168 and 165°] are formed from the aqua-ligand OH groups to the uncoordinated formato ligand O atoms from a neighboring molecule, and they are situated in the equatorial plane. In the crystal structure of this complex, the secondary N-atoms are not involved in the hydrogen bonds; consequently only a two-dimensional network is formed.

The $[Ni(iqu)_2(ac)_2(H_2O)_2]$ monomeric units represent the structure of compound **3**. The central Ni(II) atom possesses a distorted octahedral configuration formed by two acetato ligands (abbr. ac), two aqua ligands and two neutral *iso*-quinoline ligands (iqu). The distances inside the chromophore are Ni–O(w) 2.089 Å, Ni–O(ac) 2.061 Å and Ni–N(iqu) 2.115 Å. The deformation of the coordination polyhedron is caused by intramolecular and intermolecular hydrogen bonds. The intramolecular O–H···O hydrogen bonds [H···O = 1.828 Å, O···O = 2.657(2) Å, O–H···O = 166°] are in the equatorial plane between the oxygen atom from an aqua-ligand and an uncoordinated O atom from the acetato-ligand. Intermolecular O–H···O hydrogen bonds [H···O = 1.929 Å, O···O = 2.765 Å,

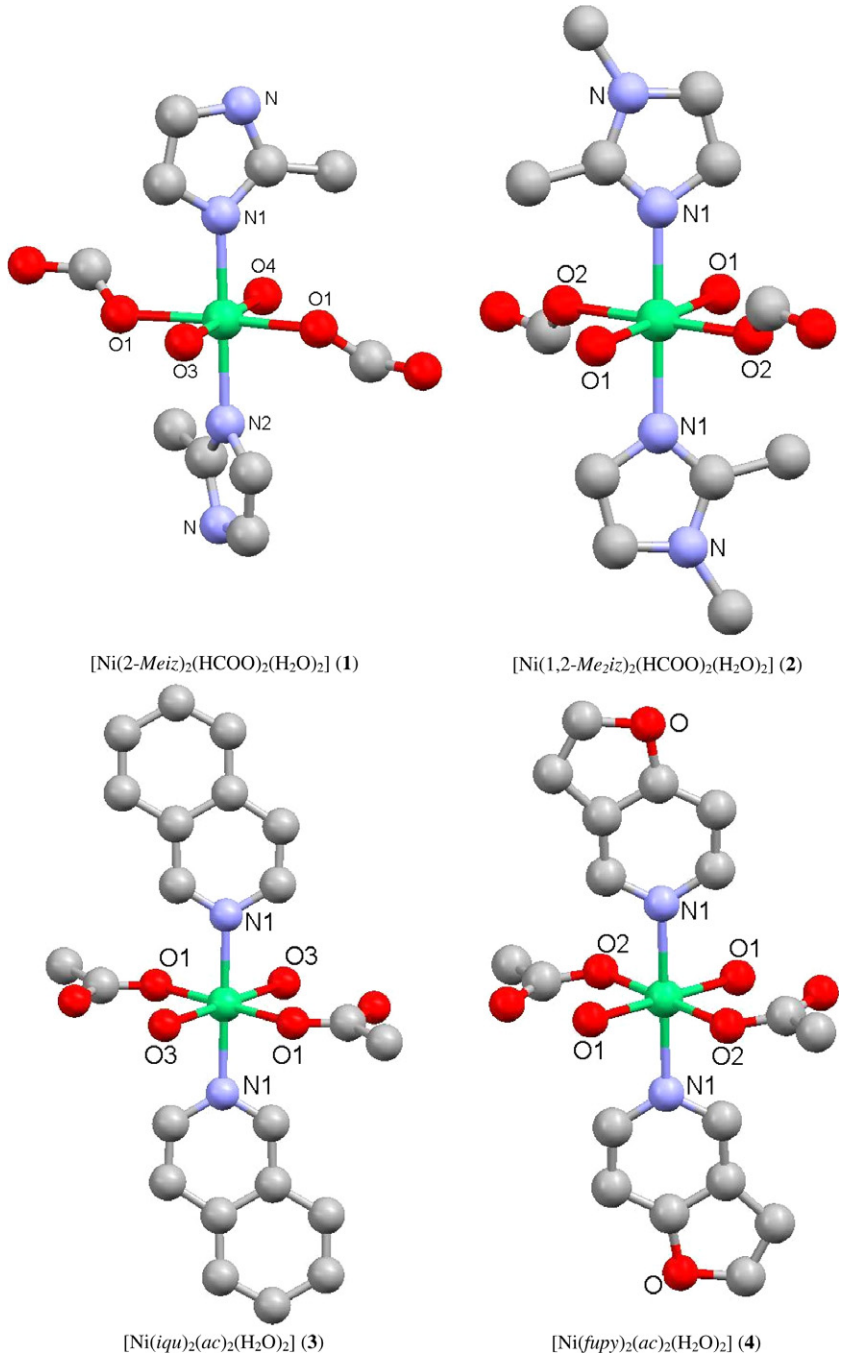

Fig. 1. Molecular structures of complexes **1**–**4** (hydrogen atoms are omitted for clarity).

O–H···O = 171°] from the aqua O atom to the uncoordinated acetato O atom join the molecules together to form a two-dimensional network.

The structure of **4** is formed by $[Ni(fupy)_2(ac)_2(H_2O)_2]$ monomeric units with a distorted octahedral configuration of the central Ni(II) atom. The distances inside the chromophore are Ni–O(w) 2.073 Å, Ni–O(ac) 2.052 Å and Ni–N(fupy) 2.130 Å. The intramolecular O–H···O hydrogen bonds [H···O = 1.849 Å, O···O = 2.652(3) Å, O–H..O = 160°] are formed in the equatorial plane between the oxygen atom from an aqua-ligand and an uncoordinated O atom from the acetato-ligand. The intermolecular O–H···O hydrogen bonds [H···O = 1.919 Å, O···O = 2.744 Å, O–H···O = 167°] are formed from the uncoordinated oxygen atom of the acetato-ligand to an aqua-ligand of a neighboring molecule, and the two-dimensional network is thus formed.

3.2. Infrared and electron spectra

The infrared spectra of the studied complexes show absorption bands of antisymmetric and symmetric vibrations of COO^- groups in the region 1548–1594 and 1353–1420 cm^{-1}. The bands assigned to the symmetric

[a] w – the aqua ligand.

stretching vibration are split into two sub-bands in all the complexes under study. The band assigned to the antisymmetric stretching vibration in compounds **3** and **4** is split into two sub-bands, too. The separation between antisymmetric and symmetric vibrations, $\Delta(COO^-)$, brings information about the carboxylate coordination mode. In the spectra of all four compounds the band of bending vibration of water spans the region 1630–1675 cm^{-1} and this value gives the information that the water molecule is coordinated to the central atom.

The electron spectra of the studied complexes show three principal d–d bands ($^3T_{2g} \leftarrow {}^3A_{2g}$, $^3T_{1g}(F) \leftarrow {}^3A_{2g}$ and $^3T_{1g}(P) \leftarrow {}^3A_{2g}$, characteristic for the octahedral geometry) in the region 9400–10 893, 15 300–16 207 and 26 000–26 870 cm^{-1}, which are split due to the symmetry lowering of the crystal field (Table 3, Fig. 3). The splitting is evidenced as an arm and is well visible for the second principal transition; this refers to the transition $^3B_{2g} \leftarrow {}^3B_{1g}$ within the point-group D_{4h}.

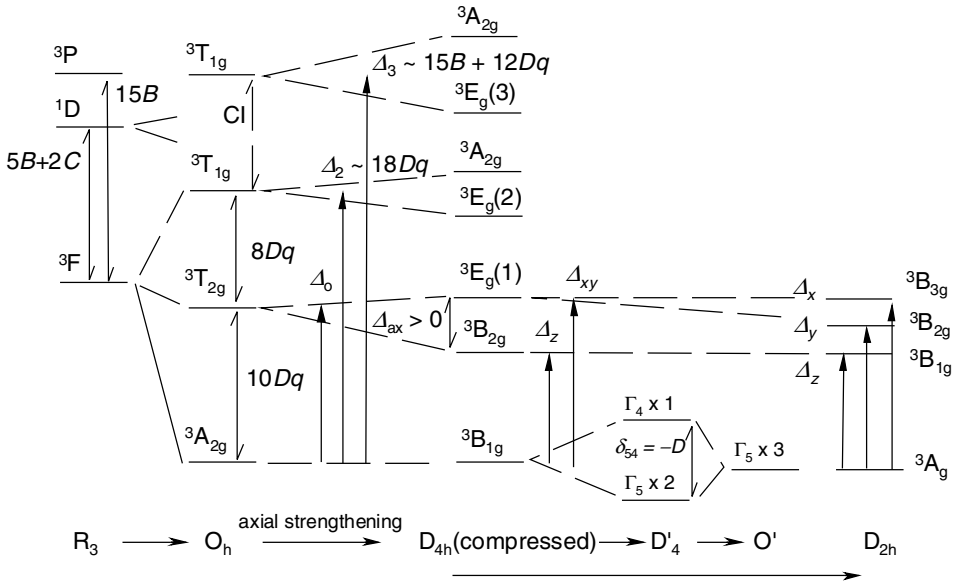

Fig. 3. Energy level diagram for tetragonally distorted octahedral d^8 complexes.

3.3. Magnetic data

The temperature dependence of the effective magnetic moment for complexes **1**–**4** is shown in Fig. 4. It can be seen that on cooling from room temperature μ_{eff} is almost constant down to low temperature (ca. 10 K); then it drops in value. These features are typical for zero-field splitting systems. It can be estimated that the axial zero-field splitting parameter will adopt moderate values of about $|D/hc| \sim 5\ cm^{-1}$.

The "susceptibility data-set" (in fact, M versus T at $B = 0.1$ T) and the magnetization data-set (M versus B at $T = 2.0$ and 4.6 K) have been treated simultaneously. They were used in constructing a common functional to be optimized by the same set of magnetic parameters: g_x, g_y, g_z and α_{TIP}. (The last quantity compensates uncertainties in determining the underlying diamagnetism and it accounts for the temperature-independent paramagnetism.) The zero-field splitting parameters entering the spin-Hamiltonian were calculated from the constraints $D = (\lambda/2)[g_z - (g_x + g_y)/2]$ and $E = (\lambda/4)(g_x - g_y)$, where $\lambda/hc = -315\ cm^{-1}$ is the spin–orbit splitting parameter for the Ni(II) ion [8,9]. The calculated data-points are also contained in Fig. 4 and the final set of magnetic parameters is presented in Table 4. Since the powder-sample data could bring an ambiguity in determining the sign of the D-parameter, both alternatives have been tested. In all cases the negative D-value results in a lower discrepancy R-factor (calculated from the susceptibility data). The magnetization data have been calculated as a correct powder average using a random spherical distribution of the magnetic-field vector [18,19].

The fitting procedure results in moderate and negative values of the axial zero-field splitting parameter D. They were used in a correlation with the structural D-values subtracted from the X-ray structure data. The latter, in the case of homoleptic complexes, has been defined using the bond-lengths within the chromophore as follows:

$$D_{str} = d_z - (d_x + d_y)/2, \quad (5)$$

$$E_{str} = (d_x - d_y)/2. \quad (6)$$

In the case of heteroleptic complexes this needs a modification

$$D_{str} = \Delta_z - (\Delta_y + \Delta_x)/2, \quad (7)$$

where $\Delta_a = (d_i - \bar{d}_i)$ for $a = x, y, z$ is a shift relative to the mean distance $\bar{d}_i$ for a given bond ($i = N, O$). For the N- and O-donor ligands these values have been taken from

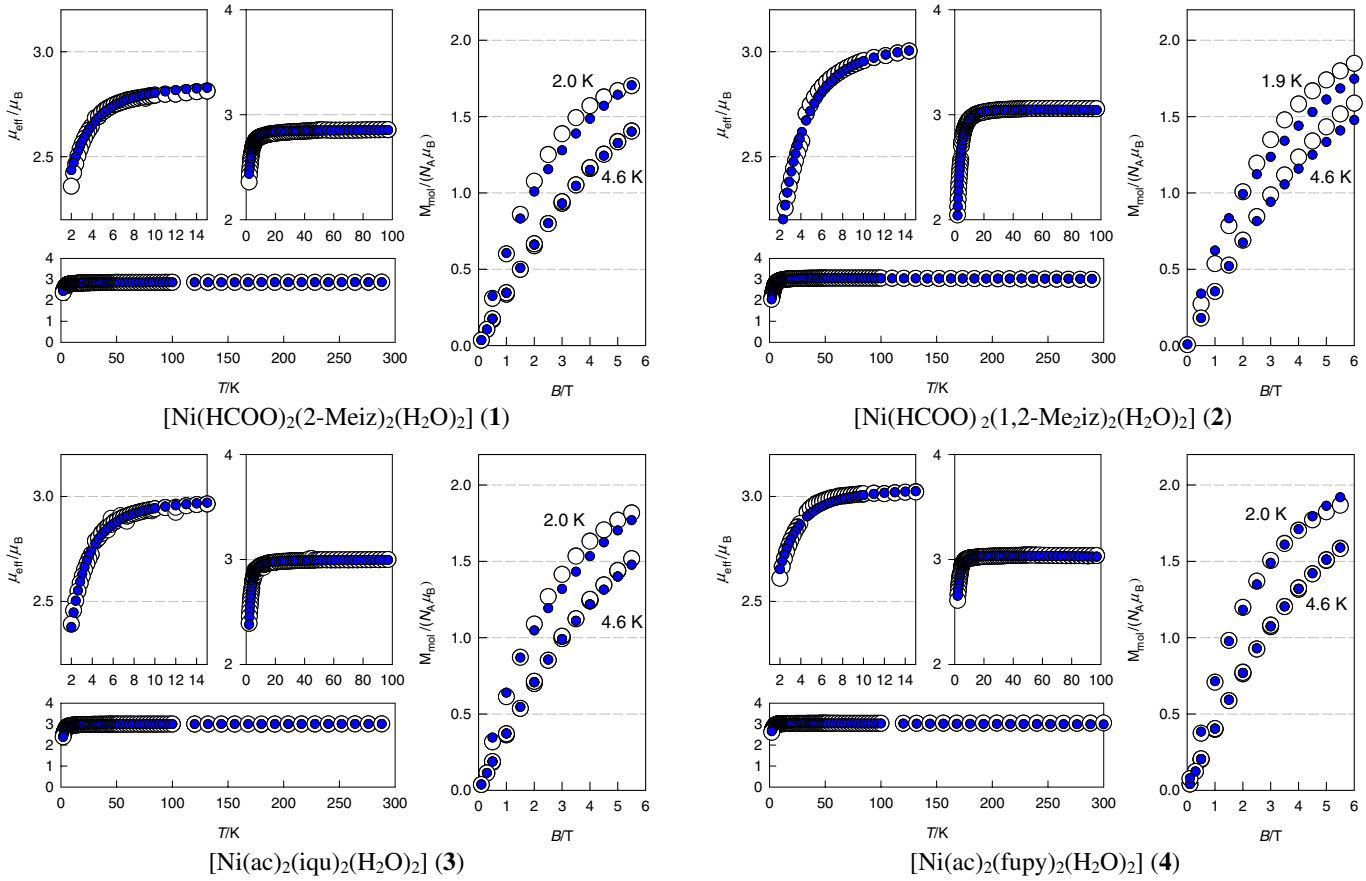

Fig. 4. Temperature dependence of the effective magnetic moment and field dependence of the magnetization (right panel) for **1**–**4**. Filled circles – fitted data assuming negative D.

Table 4
Fitted magnetic data with negative D-values

Compound[a]	g_x	g_y	g_z	D/hc (cm^{-1})	E/hc (cm^{-1})	α_{TIP} (10^9 m^3 mol^{-1})	R (%)	D_{str} (pm)	E_{str} (pm)
1	2.000	2.000	2.038	−6.0	0.7	+0.49	2.4	−9.9	1.1
2	2.140	2.139	2.190	−7.7	2.0	−1.12	1.8	−6.2	1.9
3	2.094	2.104	2.139	−5.3	1.2	+0.61	0.7	−5.0	1.4
4	2.147	2.149	2.179	−5.0	0.5	−2.25	0.5	−2.2	1.0

Estimated errors: 0.01 for g-factors, 0.1 for ZFS parameters.
[a] Compounds: **1** = $[Ni(2\text{-}Meiz)_2(HCOO)_2(H_2O)_2]$; **2** = $[Ni(1,2\text{-}Me_2iz)_2(HCOO)_2(H_2O)_2]$; **3** = $[Ni(iqu)_2(ac)_2(H_2O)_2]$; **4** = $[Ni(fupy)_2(ac)_2(H_2O)_2]$.

complexes containing the $[Ni(NH_3)_6]^{2+}$ and $[Ni(H_2O)_6]^{2+}$ units, respectively; $\bar{d}(Ni\text{–}N) = 2.145$ Å and $\bar{d}(Ni\text{–}O) = 2.055$ Å [20]. As seen from Fig. 5, the correlation of the magnetic D_{mag} values versus the structural distortion parameters D_{str} is fairly good. However, two notes need be added: (i) the magnetic as well as structural data bring evidence also for the rhombic anisotropy, which has not been accounted for in the correlation; (ii) the correlation curve cannot be linear, since the compressed bipyramid cannot be extrapolated to zero metal–ligand distances. Returning to Eq. (1) it needs to be pointed out that also the covalency (orbital reduction factor) enters the magnetic D-values and this is capable of altering its sign.

It is recapitulated that in free homoleptic Ni(II) complexes, like octahedral $[Ni(H_2O)_6]^{2+}$ in solution, the magnetic anisotropy vanishes [19]. In the solid state, however, the crystal packing along with the system of hydrogen bonds causes a symmetry-lowering of the chromophore and consequently the magnetic anisotropy appears: D/hc adopts values between −3.5 and +2.0 cm^{-1} for $[Ni(iz)_6](car)_2$ type complexes [14] (car – carboxylate). In heteroleptic complexes of the $[Ni(N\text{-}base)_4(NCS)_2]\cdot nH_2O$ type the registered magnetic anisotropy is not enhanced significantly: $D/hc = -3$ to -1.5 cm^{-1} [13]. This is due to analogous crystal-field strength of the N-donor heterocycle and thiocyanate groups, supported by an octahedral pattern of the electron spectra (no visible tetragonal splitting). This paper confirms the theoretical expectations that on passing to heteroleptic complexes of the $[Ni(N\text{-}base)_2(H_2O)_2(car)_2]$ type the magnetic anisotropy is enhanced: $D/hc = -8$ to -5 cm^{-1}. Such an enhancement could be in both negative and positive directions [21]; it originates in the electronic

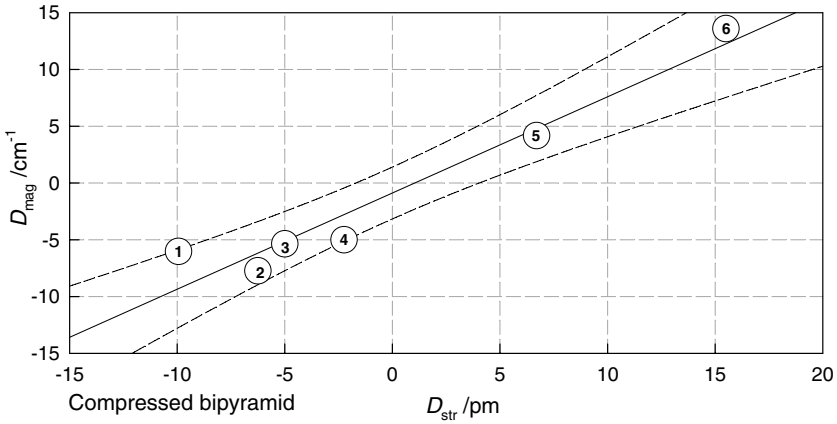

Fig. 5. Correlation of the magnetic vs. structural *D*-parameters. (Two compounds with the $\{NiN_4O_2\}$ chromophore, **5** = $[Ni(pz)_4(ac)_2]$ and **6** = $[Ni(chelate)_2(H_2O)_2]$, possessing positive *D*-values have been included into the correlation [21]; [**5**: +4.18 vs. +6.70, **6**: +13.60 vs. +15.50].) Broken lines – confidence intervals.

structure of the complex and it is supported by the splitting of the d–d bands in the electronic spectra. The crystal-packing effects, the hydrogen-bond networks and possible antiferromagnetic coupling among Ni(II) entities at low temperature, however, superimpose the electronic-structure driven magnetic anisotropy.

4. Supplementary material

Crystallographic data (excluding structure factors) for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 297162, 297165, 297164 and 297163 for **1**, **2**, **3** and **4**. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44 1223 336 033; e-mail: deposit @ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk). Hydrogen-bond contacts (Table S1) and calculated magnetic data for two sets of magnetic parameters with an opposite sign of the *D*-parameter (Table S2, Fig. S1) are deposited.

choice of cation. The WS_4 tetrahedron is flexible and can exist in a variety of structural environments as evidenced by the structural characterization of several $[WS_4]^{2-}$ complexes with different counter ions [10–18]. In many of these compounds, the WS_4 tetrahedron is slightly distorted with one or two of the W–S bonds elongated, which has been attributed to S···H interactions between $[WS_4]^{2-}$ and the organic ammonium cation. Our work with $[WS_4]^{2-}$ has shown that organic amines can be used as cationic handles to distort the WS_4 tetrahedron [17]. In order to understand the importance of H-bonding interactions in the structural chemistry of tetrathiotungstates, we are investigating the reactions of $[WS_4]^{2-}$ with several amines, which differ in terms of their steric bulk and the number of potential donor H atoms. In the present work, we wish to describe the spectroscopic and structural characterization of three new tetrathiotungstates obtained by the reaction of $(NH_4)_2[WS_4]$ with the cyclic diamine (±)*trans*-1,2-diaminocyclohexane (*trans*-1,2-cn) and the acyclic triamines bis-(2-aminoethyl)amine (dien) and bis(3-aminopropyl)amine (dipn). The title compounds constitute three additions to the growing list of structurally characterized tetrathiotungstates. The availability of structural information for several tetrathiotungstates permits us to make a comparative study of the structural features, the details of which are described in this paper.

2. Experimental

2.1. Materials and methods

The organic amines *trans*-1,2-cn, dien, dipn and the solvents were used as obtained from commercial sources with analytical purity. $(NH_4)_2[WS_4]$ was prepared by a literature method [19]. The details of the instrumentation used for the elemental analysis, IR, Raman and UV–Vis spectroscopy are the same as described in our previous reports [16,17].

2.2. Synthesis of organic ammonium tetrathiotungstates *1*–*3*

$(NH_4)_2[WS_4]$ (348 mg, 1 mmol) was dissolved in 15 mL of distilled water containing a few drops of aqueous ammonia, and filtered. To the clear yellow filtrate *trans*-1,2-cn (0.3 mL) was added in drops at room temperature and the reaction mixture was kept for crystallization. After a day, yellow blocks of compound **1** slowly crystallized. The crystals were isolated by filtration, washed well with ice-cold water (5 ml), isopropanol (10 mL) and ether (10 mL) and dried under vacuum. The yield of the product was 400 mg. The use of dipn and dien instead of (*trans*-1,2-cn) in the above procedure afforded complexes **2** and **3** in 60% yield. All the complexes are quite stable in air.

2.3. Crystal structure determination

Intensity data were collected on a STOE Imaging Plate Diffraction System for compound **1** and on an AED-II four-circle diffractometer for compounds **2** and **3**, using graphite monochromated Mo Kα radiation (λ = 0.7107 Å). The raw intensities were corrected for Lorentz, polarization effects. All structures were solved with direct methods using SHELXS-97 [20] and refinement was done against F^2 using SHELXL-97 [21]. All non-hydrogen atoms were refined using anisotropic displacement parameters. The hydrogen atoms were located in the difference map but were positioned with idealized geometry and refined isotropically using a riding model. In compound **2** the N atom of dien is disordered due to symmetry. The structure can also be solved and refined in the non-centrosymmetric space group $Pmn2_1$. In this case no disorder is present but the absolute structure cannot be determined (Flack *x*-parameter 0.5) and strong correlation of the atomic coordinates of the symmetry related atoms occur. When the structure was checked for higher symmetry using Platon, the space group *Pmmn* was selected. Therefore this space group was chosen. Intensity data were additionally collected at low temperature (170 K) using a different crystal to check whether the disorder is dynamic or static in nature. However the disorder persists even at low temperature and no indications were found for a symmetry change. In the present contribution we describe only the room temperature data because the quality of the structure model was much better than that of the low temperature data set. The technical details of data acquisition and some selected refinement results are summarized in Table 1.

3. Results and discussion

3.1. Synthesis and reactivity studies

The title compounds **1**–**3** were synthesized by a base promoted cation exchange method wherein the stronger organic bases *trans*-1,2-cn and the acyclic triamines dien and dipn replace the weak ammonia from the ammonium cation of $(NH_4)_2[WS_4]$. The complexes analyzed satisfactorily for the proposed formula containing the well-known $[WS_4]^{2-}$ anion in association with the monoprotonated cation of *trans*-1,2-cn in **1** and the diprotonated cations of dien and dipn in **2** and **3**. In an earlier report we have shown that the use of the polyamine tren (tren is tris(2-aminoethylamine)) results in the formation of $(trenH_2)^{2+}[WS_4]^{2-}$ [16]. In the present work, it is interesting to note that the terminal primary amine groups are protonated in **2** unlike in the related triamine dipropylenetriamine (dipn) in **3** where the protonation of the central secondary amine functionality and one of the terminal N atoms is observed. It has been reported that WO_3 dissolves in aqueous dien leading to the formation of the hexacoordinated neutral complex $[WO_3(dien)]$ where dien functions as a neutral tridentate ligand [22]. The neutral compound is highly water soluble and forms $(dienH_2)[WO_4]$ in solution. While $(dienH_2)[WO_4]$ exists only in solution, the corresponding tetrathio analogue **2** can be crystallized as a stable solid indicating the difference in the chemistry of oxo- and thiotungstates. The formation of **2** can be attributed to the weak H-bonding interactions (see the structure description) between the organic cation and $[WS_4]^{2-}$. Our efforts to prepare the neutral trithio complex $[WS_3(dien)]$ by the reaction of WS_3 with dien were not successful as WS_3 does not dissolve in aqueous dien unlike WO_3. Furthermore, our attempts to obtain a 1:1 $[WS_4]^{2-}$ complex containing the diprotonated cation of *trans*-1,2-cn or a 2:3 $[WS_4]^{2-}$ complex of the fully protonated dipn and dien by changing the reaction stoichiometries were not successful. It is well documented that $[WS_4]^{2-}$ can function as a bidentate ligand and bis(tetrathiotungstato) complexes of the type $[Ni(WS_4)_2]^{2-}$ are well known [3]. The availability of $[WS_4]^{2-}$ together with a N-donor ligand like dien suggested that the title complexes can be used to form S-bridged mixed ligand heterobimetallic complexes. Accordingly the reaction of the title complexes with $[Ni(H_2O)_6]Cl_2$ in aqueous ammonia were investigated. The use of ammonia was to facilitate the deprotonation of the organic cations. These reactions did not afford any mixed ligand complexes. However the reaction of the title complexes **1**–**3** under identical conditions with $[Ni(en)_3]^{2+}$ resulted in the formation of the highly insoluble complex $[Ni(en)_3][WS_4]$ in high yields. The complex $[Ni(en)_3][WS_4]$ has earlier been isolated under solvothermal conditions [12] and its facile formation indicates that $[WS_4]^{2-}$ is a weaker ligand as compared to en.

3.2. Description of crystal structures

Compound **1** crystallizes in the monoclinic space group $C2/c$ and is isostructural with the corresponding Mo analogue [23]. The substitution of Mo by W in **1** yields slightly larger unit cell parameters, which can be explained by the larger size of W. The asymmetric unit of **1** consists of the monoprotonated cation of *trans*-1,2-cn, which adopts a chair confirmation, and the $[WS_4]^{2-}$ anion (Fig. 1). The organic cation is located in a general position while the anion is situated on a twofold axis. The WS_4 tetrahedron is moderately distorted (S–W–S angles: 108.04(6)–110.89(5)°; average: 109.47°). The W–S bond lengths (2.1874(11)–2.1978(10) Å) have a mean value of 2.1926 Å (Table 2). The geometric parameters of **1** are in good agreement with those reported for other materials like $(enH_2)[WS_4]$ (en = ethylenediamine) [13] and $(1,3\text{-}pnH_2)[WS_4]$ (1,3-pn = 1,3-propanediamine) [14]. Two of the bond lengths are shorter while the other two are longer than the average W–S bond length of 2.1926 Å. As a result of the H-bonding interactions, the cations and anions in **1** are organized in a rod-like manner along [1 0 0] with the ammonium groups of *trans*-1,2-cn always pointing towards the S atoms of the anion. Hence, the sequence along this direction is $\cdots[WS_4]^{2-}$-*trans*-1,2-cnH-*trans*-1,2-cnH-$[WS_4]^{2-}\cdots$. The special arrangement of the constituents may be viewed as layers within the (0 0 1) plane. Along [0 1 0] and [0 0 1] the anions and cations each form individual stacks. Each anion is surrounded by six cations and five short S···H contacts ranging from 2.675 to 2.969 Å (Table 3) are observed, which are shorter than the sum of the van der Waals radii of S and H [24]. The shortest S···H contact of 2.675 Å and another at 2.769 Å observed for S1 can probably explain the elongation of the W–S1 bond. Although three S···H contacts are observed for S2, the W–S2 bond is slightly shorter at 2.1874(11) Å, which may be due to the longer S···H distances as well as the smaller values of the N–H···S angles. In addition, a very short N–H···N contact at 2.029 Å is observed which joins the cations to form pairs. The crystal packing diagram of the resulting hydrogen bonding network in **1** is shown in Fig. 2. The difference between the longest and shortest W–S bond Δ in **1** is 0.0104 Å and is indicative of little distortion. This value is much less compared to the Δ value of 0.0385 Å observed earlier for $(pipH_2)[WS_4]$ (pip is piperazine) [16].

Compound **2** crystallizes in the orthorhombic space group *Pmmn* and its structure consists of the $[WS_4]^{2-}$ anion and the $(dienH_2)^{2+}$ cation, both of which are located in special positions (Fig. 3). Four of the S–W–S angles are 109.4(1)°, the other two being 109.2(1)° and 110.1(1)°, indicating very little distortion. The W–S bond lengths vary from 2.172(1) to 2.189(1) Å (mean W–S bond length: 2.1805 Å) (Table 4). The geometric parameters are in good agreement with those for other organic ammonium tetrathiotungstates like **1** or $(enH_2)[WS_4]$. The W–S bonds show a pattern with two short (2.172(1) Å) and two longer (2.189(1) Å) values. In all, three short S···H contacts ranging from 2.531 to 2.968 Å are observed (Table 5). Interestingly the central secondary N atom is not involved in H-bonding. The single short contact of 2.765 Å is accompanied by a N–H···S angle of 140.76°, which may account for the shorter W–S2 bond, while the shortest contact of 2.531 Å accompanied by the largest N–H···S bond angle can explain the elongation of the W–S1 bond. The S···H interactions join adjacent WS_4 tetrahedra into layers extending in the (0 0 1) plane (Fig. 4). The difference between the longest and the shortest W–S bond Δ is 0.0170 Å and is slightly larger than that observed for **1**

but is quite less compared to the Δ value of 0.0385 Å observed earlier for $(pipH_2)[WS_4]$ [16].

Compound **3** crystallizes in the orthorhombic non-centrosymmetric space group $Pca2_1$ and its structure consists of discrete diprotonated dipn cations $(dipnH_2)^{2+}$ and $[WS_4]^{2-}$ anions (Fig. 5), with all atoms being located in general positions. One of the primary N atoms and the central secondary N atom are protonated, unlike in **2**. Again, the WS_4 tetrahedron is slightly distorted (S–W–S angles: 108.90(6)–110.23(5)°; average: 109.47°) with W–S bond lengths from 2.188(2) to 2.2053(12) Å (mean value: 2.195 Å) (Table 6). The geometric parameters are in close agreement with those for other organic ammonium tetrathiotungstates like **2** or $(tmenH_2)[WS_4]$ (tmen = *N*,*N*,*N*′,*N*′-tetramethylethylenediamine) [14]. Extended H-bonding interactions produce a three-dimensional network (Fig. 6). The cations and $[WS_4]^{2-}$ anions are stacked in rods along [0 0 1] to form a pseudo-hexagonal array. Along [1 0 0] and [0 1 0] cations and anions alternate. In the (0 1 0) plane a layer like arrangement is found with the anions being located in the pockets formed by three neighboring cations. A very short N3–H···N1 contact of 1.896 Å links the cations into a chain running along the *c* axis. Every anion is surrounded by four different cations and eight short S···H distances ranging from 2.532 to 2.958 Å (Table 7) indicate weak S···H bonding, with all H atoms attached to the N atoms being involved in H-bonding unlike in **2**. The difference between the longest and shortest W–S bond Δ is 0.0173 Å and is quite small compared to the Δ value (0.0385) observed earlier for $(pipH_2)[WS_4]$. In general the W–S bond lengths tend to be longer when the S···H contacts are shorter and the N–H···S angles are less acute [14–17]. In the present compound the shortest S···H

contact of 2.532 Å is accompanied by the shortest W–S3 bond. The reason for this is not clear. It is to be noted that no structurally characterized $[WS_4]^{2-}$ compound containing a protonated primary amine (N3), a protonated secondary amine (N2) and a free primary amine (N1) has so far been reported. Hence a possible explanation may be the type of N–H···S interactions are probably different in view of the differing nature of the amine groups. In addition, the very strong N3–H···N1 interaction may weaken the S···H interaction. For a better understanding more examples with the above-mentioned situation are needed and synthesis and characterization of such tetrathiotungstates are under way in our laboratories.

3.3. Spectral studies

A combination of UV–Vis, infrared and Raman spectroscopic techniques has been employed to characterize the compounds. The electronic spectra recorded in water exhibit bands at around 393, 280 and 220 nm. These peak positions are almost identical within experimental error to the corresponding ammonium or organic ammonium salts [3,16] and can be assigned to the charge transfer transitions of the $[WS_4]^{2-}$ moiety [3]. The mid IR up to 500 cm^{-1} exhibit several signals which can be attributed to the absorptions of the organic cations. Unlike the IR spectra of the previously reported compounds $(pipH_2)[WS_4]$, $(enH_2)[WS_4]$ etc., which exhibit a broad signal at around 3000 cm^{-1} for the N–H vibrations, more signals are observed in the N–H region (3300–3000 cm^{-1}) in **1**–**3**. This can be attributed to the presence of both free and protonated amine functionalities. For **1** the ν_{N-H} absorptions occur at around 3309 (s), 3239 (s) and 3054 (br) cm^{-1}. Similarly the bands at 3243 (s) and 3054 (br) cm^{-1} in **2** and the signals at 3309 (s), 3239 (s) and 3094 (br) cm^{-1} in **3** can be assigned to the N–H vibrations. The free tetrahedral $[WS_4]^{2-}$ anion is expected to show four normal modes of vibrations viz. $\nu_1(A_1)$, $\nu_2(E)$, $\nu_3(F_2)$ and $\nu_4(F_2)$ [25]. All four vibrations are Raman active while only ν_3 and ν_4 are infrared active. The usefulness of IR spectra for the characterization of the tetrathiotungstates is well documented in the literature as the metal–sulfur vibrations appear as characteristic signals below 500 cm^{-1} [26]. When the T_d symmetry of WS_4 is lowered to C_{2v}, as in $[Ni(WS_4)_2]^{2-}$ where $[WS_4]^{2-}$ functions as a bidentate ligand, it has been shown that this leads to a splitting of the triply degenerate $\nu_3(F_2)$ vibration of the W–S bond [25,26]. In $[Ni(WS_4)_2]^{2-}$ the W–S bond to the bridging S atom is long (W–S–Ni) and the W–S bond to terminal S atom is short (2.151 Å). In our compounds the longer W–S distances are always observed when strong S···H bonding interactions are present, and the W–S bond length distribution indicates a slight distortion of the tetrahedra. A splitting of the W–S vibration (Fig. 7) was observed in $(pipH_2)[WS_4]$ [16] which shows a difference of $\Delta = 0.0385$ Å between the longest and the shortest W–S bonds. However for **1**–**3** no such splitting is observed in the IR spectra. The symmetric stretching vibration ν_1 is observed as a shoulder along with the strong absorption due to the asymmetric mode of ν_3. In the Raman spectra of all the three compounds an intense signal is observed around 480 cm^{-1} indicating that the weak signal around the same frequency in the IR spectra should be due to the symmetric stretching mode. The asymmetric stretching vibration ν_3 in **1**–**3** occurs as a sharp signal at around 460 cm^{-1} along with a very weak band at about 480 cm^{-1} and these spectra do not show the characteristic splitting pattern observed in $(pipH_2)[WS_4]$ whose Δ value is more than twice that of the title complexes. The

signals due to the degenerate v_2 and v_4 vibrations occur at around 190 cm^{-1} in **1**–**3**.

3.4. Comparative study of the structural features of tetrathiotungstates

Tetrathiotungstates containing different cations like the fully inorganic $(NH_4)^+$, Rb^+, cationic metal complexes like $[Ni(tren)_2]^{2+}$, $[Ni(en)_3]^{2+}$ and $[Mn(en)_3]^{2+}$ and a variety of organic ammonium cations like $(enH_2)^{2+}$, $(dienH_2)^{2+}$ are known. The isolation and structural characterization of $[WS_4]^{2-}$ with these different cations indicates the flexibility of the tetrathiotungstate ion to exist in different structural environments. It is to be noted that of the 20 tetrathiotungstates listed in Table 8 only the $[WS_4]^{2-}$ complexes derived from $[Ni(en)_3]^{2+}$, en, N-Me-en and dipn crystallize in non-centrosymmetric space groups. In addition to $Rb_2[WS_4]$, where the mean Rb···S distance has been reported to be 3.5466 Å, the compounds $[(Et)_4N]_2[WS_4]$ and $[(Pr)_4N]_2[WS_4]$, which contain the fully alkylated organic ammonium cations, do not show any H-bonding interactions between the anion and cation [27]. All the other complexes exhibit weak H-bonding interactions between the cation and $[WS_4]^{2-}$. A comparative study of the structural parameters of 20 different tetrathiotungstates is presented here to explain the importance of the S···H bonding interactions in the structural chemistry of tetrathiotungstates. In all compounds the average S–W–S angles are very close to the ideal tetrahedral value. The average value of the W–S distance ranges from 2.1788 Å in $[Mn(en)_3][WS_4]$ to 2.195 Å in **3**. It is also noted that the difference Δ between the longest and the shortest W–S bond ranges from 0.0092 Å in $(enH_2)[WS_4]$ to 0.0542 in $[Ni(tren)_2][WS_4]$. The compound $[Ni(tren)_2][WS_4]$ is different compared with the organic ammonium tetrathiotungstates because it shows the shortest W–S distance of 2.1580 Å and also the maximum $\Delta = 0.0542$, even though the shortest S···H contact is observed for this complex at a distance of 2.73 Å. We note that in $[Ni(tren)_2][WS_4]$ the N atom of tren is not protonated, unlike in the organic ammonium compounds, but is linked to Ni(II). This indicates that the nature of the N–H···S contacts in $[Ni(tren)_2][WS_4]$ are probably different from those in the organic ammonium tetrathiotungstates. The same argument is applicable for the N–H···S contacts in the other two cationic complexes, namely $[Ni(en)_3][WS_4]$ and $[Mn(en)_3][WS_4]$.

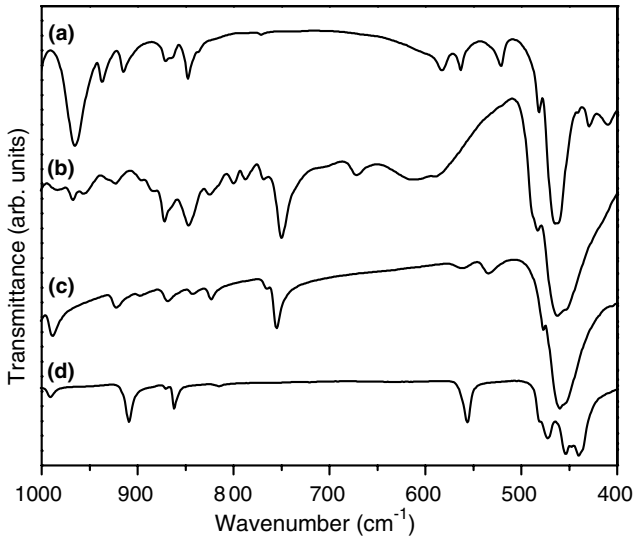

Fig. 7. Infrared spectra of (a) (*trans*-1,2-cnH)$_2$[WS$_4$], (b) (dienH$_2$)[WS$_4$], (c) (dipnH$_2$)[WS$_4$] and (d) (pipH$_2$)[WS$_4$].

In the organic ammonium $[WS_4]^{2-}$ complexes, including the fully protonated $(NH_4)_2[WS_4]$, the longest W–S bonds range from 2.2147 in (pipH$_2$)[WS$_4$] to 2.189 Å in (dienH$_2$)[WS$_4$] **2**. Furthermore, the shortest S···H contacts in all organic ammonium tetrathiotungstates are in a very narrow range of 2.31 Å for (N-Me-enH$_2$)[WS$_4$] (N-Me-en is *N*-methylethylenediamine) to 2.68 Å in **1** and **3**. The difference between the longest and shortest W–S bonds can probably be taken as a measure of the distortion of the $[WS_4]^{2-}$ tetrahedron. In an earlier report [17] we have shown that when the Δ value is larger than 0.033 Å a splitting of the W–S vibration is seen in the IR spectra. From the analysis of the structural features certain trends emerge. The substitution of one H by a methyl group in en to N-Me-en results in the increase of Δ, indicating the role of methyl groups in enhancing distortion. The same effect is also observed for the pair of cations 1,3-pn and (*N*,*N*′-dm-1,3-pn). It is of interest that when all H atoms in en are replaced by methyl groups, as in tmen, the experimental value for Δ is larger than that for en but smaller than that for N-Me-en by 0.01 Å. In all compounds listed in Table 8 (pipH$_2$)[WS$_4$] is unique as the cation is derived from a cyclic amine in which the N atoms are part of the ring. In the present work, the Δ value for compound **1** is 0.0104 Å and the cation in **1** is derived from the amine *trans*-1,2-cn where the –NH$_2$ functional groups are attached to a six membered ring.

The Δ values of the two organic ammonium tetrathiotungstates $[(Et)_4N]_2[WS_4]$ (Et is ethyl) and $[(Pr)_4N]_2[WS_4]$ (Pr is propyl) without N–H···S bonds are nearly identical (0.0184 and 0.0175 Å, respectively) [27] and the average is about 0.0180 Å. The usefulness of this value is that the observed difference Δ in the W–S bond lengths in these compounds is due to effects other than H-bonding interactions, i.e., they are probably of electrostatic nature. Interestingly, in the title compounds the values for Δ are 0.0104, 0.0170 and 0.0173 Å for **1**, **2** and **3**, respectively, and these values are smaller than or equal to that found for the fully alkylated organic ammonium tetrathiotungstates indicating that the H-bonding interactions do not show a pronounced influence in the title compounds to cause distortion in terms of the observed W–S bond

Table 8

distances. The infrared spectral observations are also indicative of a similar behavior. Hence the cation–anion interactions in the title compounds can be classified as weak interactions.

4. Conclusions

The reaction of $(NH_4)_2[WS_4]$ with the cyclic diamine *trans*-1,2-cn and the acyclic triamines bis(2-aminoethyl)amine (dien), bis(3-aminopropyl)amine (dipn) results in the formation of organic ammonium tetrathiotungstates **1**–**3**. The title complexes react with $[Ni(en)_3]^{2+}$ to form the highly insoluble complex $[Ni(en)_3][WS_4]$. The structures of **1**–**3** consist of tetrahedral $[WS_4]^{2-}$ anions which are linked to partially protonated organic ammonium cations with the aid of weak N–H···S interactions. The importance of these weak interactions can be evidenced especially in the case of compound **2** as the corresponding oxo analogue has been reported to exist only in solution [22]. Unlike WO_3, which dissolves in aqueous dien, WS_3 does not dissolve in dien indicating the differing nature of oxo and thio analogues of W. The complexes exhibit distinct W–S bond lengths and the observed Δ values are comparable to those observed in tetralkylammonium tetrathiotungstates. A comparative study of the structural features of 20 tetrathiotungstates indicates that tetrathiotungstates are less prone to pack in non-centrosymmetric space groups.

5. Supplementary material

Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as Supplementary Publication No. CCDC 601986 (**1**), CCDC 601987 (**2**) and CCDC 601988 (**3**). Copies of the data can be obtained, free of charge, on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK, fax: +44 122 3336 033 or email: deposit@ccdc.cam.ac.uk.

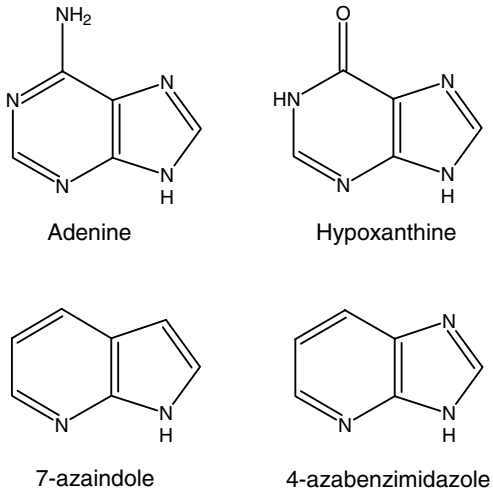

Scheme 1.

0.23 cm^{-1}. More recently the same structural type of compounds with the same structural, EPR and magnetically features as the above-mentioned compounds has been reported for some other ligands. In fact these ligands differ only slightly as they contain only one six-membered ring [14–16] in stead of two condensed rings, and they display a weaker antiferromagnetic interaction between the Cu(II) ions. An interesting application of $[Cu_2(7\text{-azaindole})_4(dmso)_2]$ has been reported to use this compound as a catalyst in the catalytic oxidation of aliphatic ethers and of some amines [29].

We have now extended the research on this type of compounds by using the ligand 4-azabenzimidazole (abbreviated as azab, see Scheme 1). Already in 1971 Cu(II) chloride and bromide compounds with azab have been synthesized [17], but X-ray structure analysis and magnetic susceptibility investigations lacked so far. A search in the CSD shows that only two X-ray structures with the ligand azab have been published before, i.e. with Fe(II) and Co(II) as metal ions [18].

We now report two related compounds with the general formula $[Cu_2(azab)_4X_2]X_2(S)$ (in which X = Cl (**1**), Br (**2**) and S = lattice solvent), together with their spectroscopic and magnetic properties and discuss them together with some related compounds. Also from both compounds $[Cu_2(azab)_4Cl_2]Cl_2(CH_3OH)_3$ (**1**) and $[Cu_2(azab)_4Br_2]Br_2(H_2O)_{1/2}$ (**2**), the X-ray structural analysis is presented in this study; they comprise the first 3D structures of dinuclear compounds with azab as a bridge.

2. Experimental

2.1. General

C, H, N determinations were performed on a Perkin–Elmer 2400 Series II analyzer. Ligand field spectra were obtained on a Perkin–Elmer Lambda900 spectrophotometer using the diffuse reflectance technique, with MgO as a reference. X-band powder EPR spectra were obtained on a Jeol RE2x electron spin resonance spectrometer using DPPH ($g = 2.0036$) as a standard. FT-IR spectra were obtained on a Perkin–Elmer Paragon 1000 FT-IR spectrophotometer equipped with a Golden Gate ATR device, using the reflectance technique (4000–300 cm^{-1}, res. 4 cm^{-1}). Magnetic susceptibility measurement (5–300 K) were carried out (at 0.1 T) using a Quantum Design MPMS-5S SQUID magnetometer. Data were corrected for the magnetization of the sample holder and for diamagnetic contributions, which were estimated from Pascal constants.

2.2. Synthesis

2.2.1. General synthesis of the compounds

The ligand azab and the metal salt were commercially available and used without purification. 0.2 mmol $CuCl_2$, or $CuBr_2$ and 0.4 mmol azab were each dissolved in methanol and put carefully together. The solution was filtered to remove any solid particles and was left to evaporate at room temperature. Within a few days blue crystals separated and were collected by filtration.

Yield about 75%. Elemental *Anal.* Calc. for $C_{27}H_{32}Cl_4Cu_2N_{12}O_3$ (**1**): C, 38.5; H, 3.8; N, 20.0. Found: C, 38.1; H, 3.8; N, 20.3%. IR: 3379 cm^{-1} (br, OH); strongest peaks: 1623, 1490, 1405, 1312, 1280, 1034, 971, 916, 801, 774, 736, 476 cm^{-1}.

2.3. X-ray crystallography

A crystal was selected and mounted to the glass fiber using the oil-drop method; data were collected on a Nonius KappaCCD diffractometer (graphite-monochromated Mo Kα radiation). The intensity data were corrected for Lorentz and polarization effects, for absorption and extinction. The structures were solved by direct methods. The programs COLLECT [19], SHELXS-97 [20], SHELXL-97 [21] were used for data reduction, structure solution and structure refinement, respectively. Refinement of F^2 was done against all reflections. In compound **1**, one methanol molecule was found to be disordered and this molecule was refined isotropically at 3 positions with population parameters 0.5, 0.25 and 0.25.

In compound **2**, the lattice water molecule was found to be disordered and was refined at 2 positions with population parameter 0.5. The water hydrogen atoms could neither be located, nor introduced at calculated positions. All other non-hydrogen atoms were refined anisotropically. The H atoms (except from the water molecule in **2**) were introduced in calculated positions and refined with fixed geometry with respect to their carrier atoms. Crystallographic data are presented in Table 1.

3. Results and discussion

3.1. Description of the crystal structures

3.1.1. Crystal structure of $[Cu_2(azab)_4Cl_2]Cl_2(CH_3OH)_3$ (*1*)

A plot of the projection of the structure of compound **1** is depicted in Fig. 1, with relevant bond length and bond angle information given in Table 2. The unit cell contains two chemically identical, but crystallographically independent dinuclear $[Cu_2(azab)_4Cl_2]$ units, four uncoordinating chloride anions and six molecules of methanol of which two are disordered over three positions. The basal plane of each Cu(II) ion is surrounded by four nitrogen atoms

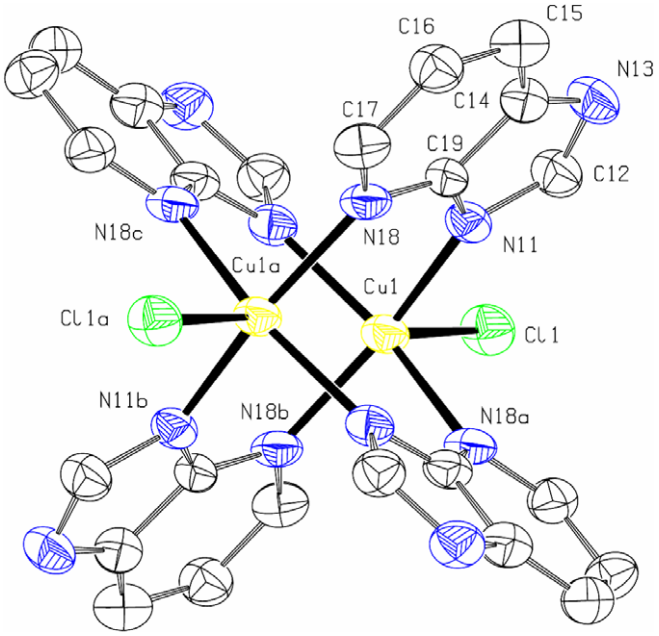

Fig. 1. Atomic displacement plot (50% probability level) of the molecular structure of one of the two crystallographic independent $[Cu_2(azab)_4Cl_2]Cl_2(CH_3OH)_3$ units. The uncoordinating chloride atoms and the uncoordinating methanol molecules are omitted for clarity.

of four bischelating azab molecules with Cu–N distances which vary from 2.033(5) to 2.056(5) Å in a paddlewheel-like fashion. The apical position is occupied by a chloride anion with Cu–Cl distances of 2.457(2) and 2.414(2) Å, while the Cu–Cu distances are 3.0611(14) and 3.0498(18) Å. The N–Cu–N angles in both dinuclear units are 162.38(18)° and 162.68(18)°.

The crystal lattice appears to be further stabilized by commonly found hydrogen bonding between the uncoordinating N atom and the uncoordinating Cl anion with N···Cl distances of 3.118(5)–3.257(5) Å and between the oxygen atom of a methanol molecule to an uncoordinating Cl atom with a distance of 3.135(6) Å.

3.1.2. Crystal structure of $[Cu_2(azab)_4Br_2]Br_2(H_2O)_{1/2}$ (*2*)

A plot of the projection of the structure of compound **2** is depicted in Fig. 2, with relevant bond length and bond angle

Symmetry codes: (A) $x, y, -z$; (B) $-x+1, -y, -z$; (C) $-x+1, -y, z$; (D) $-x, -y+1, -z$; (E) $-x, -y+1, z$.

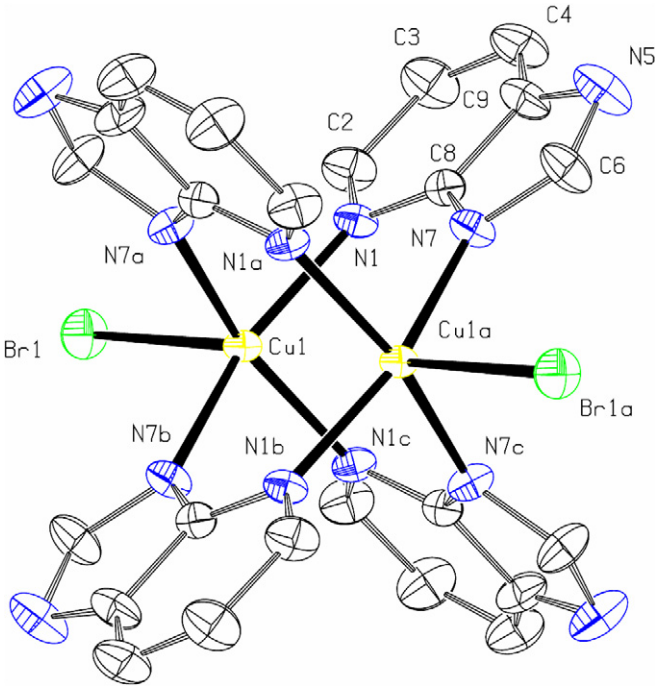

Fig. 2. Atomic displacement plot (50% probability level) of the molecular structure of $[Cu_2(azab)_4Br_2]Br_2(H_2O)_{1/2}$ unit. The uncoordinating bromide atoms and the uncoordinating water molecule are omitted for clarity.

information given in Table 3. Unlike the chloro compound **1**, this compound contains one dinuclear $[Cu_2(azab)_4Br_2]$ unit in the lattice unit, two uncoordinating bromide anions and one disordered water molecule per two dinuclear units. The basal plane of each Cu(II) ion is surrounded by four nitrogen atoms of four bischelating azab molecules with Cu–N distances of 2.036(5) and 2.039(5) Å in a paddle-wheel-like fashion. The apical position is occupied by a bromide anion with Cu–Br distance of 2.5922(14) Å, while the Cu–Cu distance is 3.038(2) Å. The N–Cu–N angles is 162.4(2)° and as the structure is very similar to the chlorido compound **1**, the Cu(II) ions have also a square-pyramidal geometry.

Table 3
Selected bond lengths (Å) and angles (°) for $[Cu_2(azab)_4Br_2]Br_2(H_2O)_{1/2}$ (**2**)

Cu(1)–N(1)	2.036(5)	Cu(1)–N(7)A	2.039(5)
Cu(1)–Br(1)	2.5922(14)	Cu(1)–Cu(1)A	3.038(2)
N(1)–Cu(1)–N(1)C	86.1(3)	N(1)A–Cu(1)–N(7)B	162.4(2)
N(1)–Cu(1)–N(7)A	89.1(2)	N(7)A–Cu(1)–N(7)B	90.3(3)
N(1)–Cu(1)–Br(1)	100.19(15)	N(7)B–Cu(1)–Br(1)	97.36(15)

Symmetry codes: (A) $x, -y-1, z$; (B) $-x, y, -z+1$; (C) $-x, -y-1, -z+1$.

The crystal lattice appears to be further stabilized by commonly found hydrogen bonding between the uncoordinating N atom and the uncoordinating Br anion with N···Br distance of 3.257(5) Å. As the water molecule is disordered over two positions its hydrogen bonds could not be located. Due to the difference in solvent the crystal lattice packing differs in both compounds (see Fig. 3).

3.2. Ligand field spectroscopy and EPR

The ligand-field transitions measured as a solid with the diffuse reflectance technique are observed as a very broad band with a maximum at $15.6\times10^3\ cm^{-1}$ and a shoulder at about $9.8\times10^3\ cm^{-1}$ for compound **1** and at $15.5\times10^3\ cm^{-1}$ with a broad shoulder at about $10.1\times10^3\ cm^{-1}$ for compound **2**. These are normal ligand-field transitions for (distorted) square pyramidal geometries [23].

The EPR spectra of compounds **1** and **2** were recorded as a polycrystalline powder at RT and 77 K from 0 to 800 mT at X-band frequency ($h\nu = 0.325\ cm^{-1}$).

For two antiferromagnetically coupled Cu(II) ions with a singlet ground state and an excited triplet state (with x, y and z as the principal axes) and in the case of an axial symmetry (axial zero-field splitting parameter $D < h\nu$ and rhombic zero-field splitting parameter $E = 0$) four $\Delta M_s = \pm1$ transitions along with a half-field ($\Delta M_s = \pm2$) transition are allowed [25]. The observed EPR spectrum of compound **1** measured at 77 K, which is almost identical as for compound **2**, is shown in Fig. 4. Transitions are

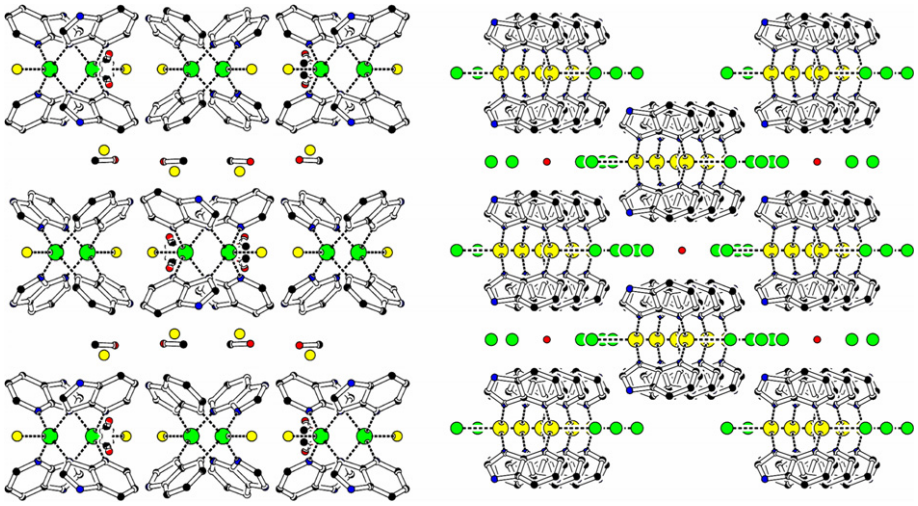

Fig. 3. Packing of both structures along the x-axis; left: compound **1**, right: compound **2**.

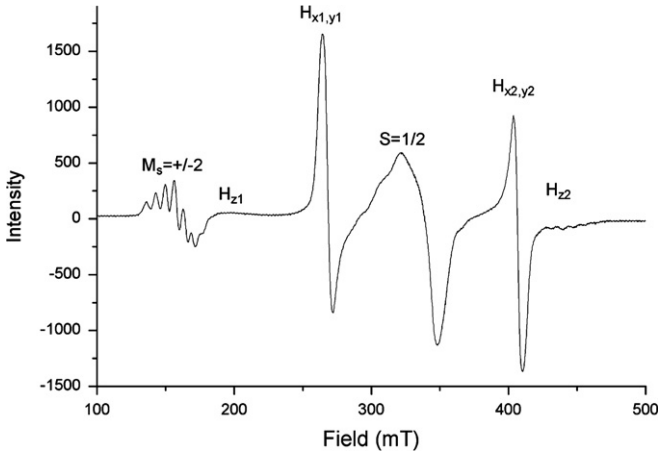

Fig. 4. EPR spectrum of compound **1** at 77 K.

observed at 190 (very weak), 260, 400 and 430 mT, which are assigned to the resonance fields H_{z1}, H_{x1y1}, H_{x2y2} and H_{z2}. The forbidden half-field signal ($\Delta M_s = \pm 2$) is observed at 155 mT and a typical copper hyperfine structure of seven lines is observed at 77 K, while at RT this splitting is not resolved. A copper hyperfine splitting is even observed at the (weak) resonances of the H_z components of $\Delta M_s = \pm 1$. The band at 320 mT is the $S = 1/2$ resonance from a mononuclear impurity, which in many cases is present in dinuclear compounds.

The observed spectra with the same features are in accordance with the earlier observed spectra with azab and a calculated D of 0.124 cm^{-1} [17]. In the related compounds, which are shown in Table 4, the EPR spectra, when published, are almost all similar to each other and the zero-field splitting parameter D was for these compounds calculated as being 0.11 cm^{-1} [10], 0.125 cm^{-1} [6], 0.11 cm^{-1} [24], 0.16 cm^{-1} [14] and 0.23 cm^{-1} [15,16]. The same type of EPR spectra were obtained from related Cu(7-methylazabenzimidazole) compounds (although no X-ray structures from these compounds were obtained) with a D of 0.135–0.140 cm^{-1} [22].

Table 4
Relevant $[Cu_2L_4]$ paddlewheel-like compounds, with X-ray structure and magnetism

Compound[a]	Geometry/chromophore	Cu–Cu distance (Å)	N–Cu–N angle (°)	J (cm^{-1})[d]	Reference[c]

[a] *Abbreviations:* sq.pyr., square pyramidal; sq.pl. (dist), square planar (distorted); adH, adenine (6-aminopurine); hpH, 6-hydroxypurine (Hypoxanthine); Hazaind, 7-azaindole; 5tpO, 4,5-dihydro-5-oxo[1,2,4]triazolo[1,5-α]pyrimidine; tz-tol, *N*-(thiazol-2-yl)toluenesulfonamide; tz-naf, *N*-(thiazol-2yl)naphthalenesulfonamide; azab, 4-azabenzimidazole; Hstz, sulfathiazole.

[b] The structure contains two crystallographic independent dinuclear units.

[c] (S), structure solved; (M), magnetic susceptibility measured.

[d] J is the exchange coupling parameter, which is also sometimes defined as $-2J$ (cm^{-1}) or $-J/k$ (K).

[e] Structure of the same compound with different lattice water, $[Cu_2(ad)_4(H_2O)_2](H_2O)_5$ was also solved [28]. Magnetic susceptibility was also measured of compounds with different lattice water, i.e. $[Cu_2(ad)_4(H_2O)_2](H_2O)$ with $J = -108$ cm^{-1} [8], $J = -210$ cm^{-1} [6] and $[Cu_2(ad)_4(H_2O)_2](H_2O)_6$ with $J = -179$ cm^{-1} [11].

[f] Magnetic susceptibility was also measured of a compound with different lattice water, i.e. $[Cu_2(adH)_4Cl_2]Cl_2(H_2O)$ with $J = -143$ cm^{-1} [8] and from the bromide adduct $[Cu_2(adH)_4Br_2]Br_2(H_2O)_4$ with $J = -145$ cm^{-1} [8].

[g] Magnetic susceptibility was measured from a sample with formula, $[Cu_2(hpH)_4Cl_2]Cl_2(H_2O)_2$, also the magnetism of the bromide adduct was measured, i.e. $[Cu_2(hpH)_4Br_2]Br_2(H_2O)$ with $J = -143$ cm^{-1} [8].

[h] Magnetic susceptibility was also measured from a DMSO adduct, $[Cu_2(azaind)_4(DMSO)_2]$ with $J = -389$ cm^{-1}.

3.3. Magnetic properties

The magnetic susceptibility of powdered samples were measured from 5 to 300 K. The magnetic behaviour of compounds **1** and **2** are depicted in Figs. 5 and 6 in the form of μ_{eff} versus T for two Cu(II) ions. At 300 K the μ_{eff} has a value of about 1.90 μ_B for both compounds (much below the spin only value for two Cu ions of 2.83 μ_B) and the μ_{eff} gradually decreases at 50 K to about 0.10 μ_B and stays then constant till 5 K. This behaviour agrees with a strong antiferromagnetic interaction. In compound **2** the value decreases somewhat more, due to the fact that some more paramagnetic impurity is present (vide infra).

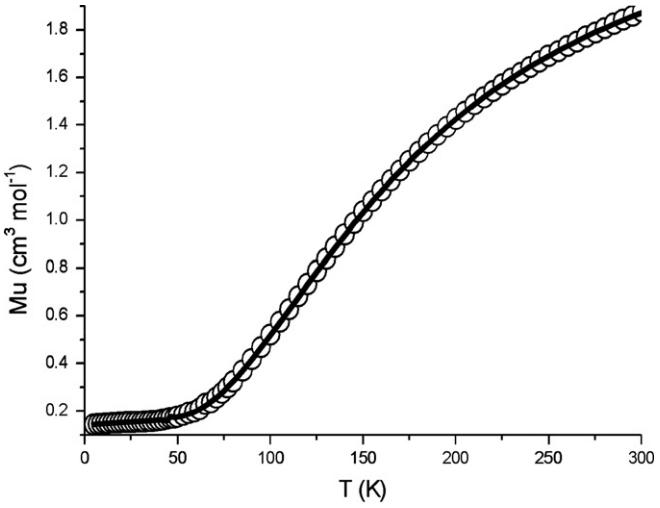

Fig. 5. A plot of the temperature dependence of μ vs. T for $[Cu_2(azab)_4Cl_2]Cl_2(CH_3OH)_3$ (**1**). The solid line represents the calculated curve for the parameters $J = -329\ cm^{-1}$, $g = 2.12$, $zJ' = 0.02.\ cm^{-1}$ (see text).

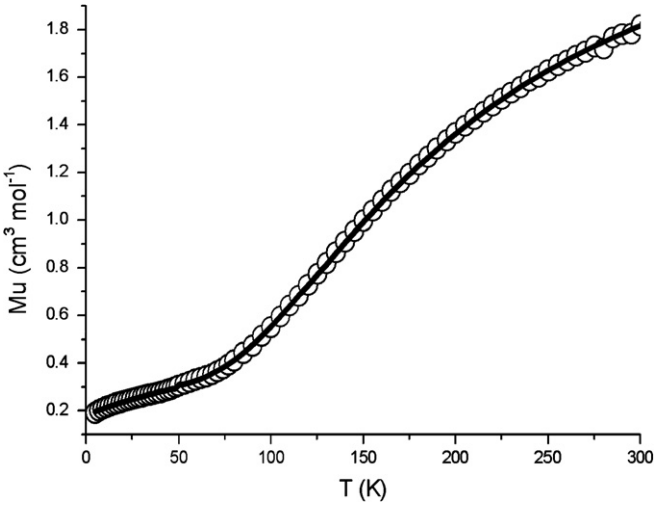

Fig. 6. A plot of the temperature dependence of μ vs. T for $[Cu_2(azab)_4Br_2]Br_2(H_2O)_{1/2}$ (**2**). The solid line represents the calculated curve for the parameters $J = -349\ cm^{-1}$, $g = 2.02$, $zJ' = -0.03\ cm^{-1}$ (see text).

The theoretical expression for the magnetic susceptibility for two interacting $S = 1/2$ centres, which is based on the general Hamiltonian [3] is: $H_{ex} = -JS_1S_2$, in which the exchange parameter J, is negative for antiferromagnetic and positive for ferromagnetic interaction. The magnetic data were fitted to the equation given in the literature [3] for dinuclear copper compounds:

$$\chi_m = (2Ng^2\beta^2)[kT - (2zJ'/(3 + \exp(-J/kT)))]^{-1} \times [3 + \exp(-J/kT)]^{-1}(1 - p) + \chi_p p,$$

in which N, g, β, k and T have their usual meanings [3]. The parameter p denotes the fraction of paramagnetic impurity in the sample and zJ' the interaction between neighbouring dinuclear identities. The fit was accomplished by minimization of $R = (\chi_m \cdot T_{calc} - \chi_m \cdot T_{obs})^2/(\chi_m \cdot T_{obs})^2$ by a least-squares procedure. The best fit for compound **1**, depicted in Fig. 5 as a solid line, was obtained for $J = -329\ cm^{-1}$, $g = 2.12$, $zJ' = 0.02\ cm^{-1}$, $p = 0.003$, with a final R of 3.5×10^{-3}. The best fit for compound **2**, depicted in Fig. 6 as a solid line, was obtained for $J = -349\ cm^{-1}$, $g = 2.02$, $zJ' = 0.03\ cm^{-1}$, $p = 0.005$, with a final R of 1.6×10^{-3}.

4. Concluding remarks

In this paper two novel dinuclear compounds with the chromophore $[Cu_2(azab)_4X_2]^{2+}$ (with X = Cl, Br) has been synthesized, characterized by infrared spectroscopy, EPR and also the X-ray structure of both compounds and the magnetic susceptibility have been investigated. As can be seen in Table 4, where related compounds are tabulated of which the X-ray structure has been performed as well as the magnetic susceptibility measured, the J values vary from -104 to $-361\ cm^{-1}$, while the Cu–Cu distances are between 2.7224(13) and 3.066 Å. All these compounds are structurally related with four ligands in a paddlewheel-like fashion and with (distorted) square pyramidal or square planar geometry and with the unpaired spin of the Cu(II) ion in the $d_{x^2-y^2}$ orbital.

The compounds investigated in this study have a very strong antiferromagnetic interaction (-328 and $-348\ cm^{-1}$). Only the Cu(II) compounds with 7-azaindole ($J = -361\ cm^{-1}$) and with the methylated 7-azaindole compounds, $[Cu(7\text{-methylazaindole})_4(H_2O)_2]^{4+}$, [20] ($J$ about $-350\ cm^{-1}$) have a related strong interaction, although from these last compounds no X-ray structure has been reported. The magnetic exchange interaction is due to the overlap of the unpaired Cu(II) electron in the $d_{x^2-y^2}$ orbital to the electrons of the N–C–N group. Some small geometric differences can influence the strength of the interaction. As can be seen from Table 4 the Cu–Cu distances or bond angles also vary and a correlation between such parameters could not be established so far. Casanova et al. [16] and Gutiérrez et al. [26] provided molecular orbital calculations to understand the differences between $[Cu_2(stz)_4]$ compounds (with one single ring) and

$[Cu_2(adenine)_4]$ compounds (with two condensed rings). They also calculated the influence of the axial atoms and observed indeed energy differences between the two types of compounds. However, they observed also still a great difference between the calculated (J_{calc}) and the experimental (J_{obs}) exchange coupling for the adenine compounds [26], so no pertinent conclusions can be drawn. Our further efforts are to obtain variations of this type of compounds with other ligands.

Acknowledgments

The work described in this paper was supported by the Leiden University Study group WFMO (Werkgroep Fundamenteel MaterialenOnderzoek). Part of the research was supported financially by the Graduate Research School Combination NRSC "Catalysis". Financial support and coordination by the FP6 Network of Excellence "Magmanet" (contract number 515767) is kindly acknowledged. Mr. Sharmarke Nur is thanked for his assistance in preparing some of the complexes.

Appendix A. Supplementary material

An ORTEP of the two units of compound **1** and the EPR spectra of compound **1** at RT and of compound **2** at RT and 77 K are given as Supplementary material.

Crystallographic data (excluding structure factors) for the structure reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication numbers CCDC-607116 and -607117 for compounds **1** and **2**, respectively. Copies of available material can be obtained, free of charge, on application to the Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44 1223 336 033 or e-mail: deposit@ccdc.cam.ac.uk). Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2006.06.009.

the amino acid histidine of living systems. Therefore, these scorpionate ligands were selected as a second group to construct an N_2S_2 or NS_2 coordination around copper atoms.

As has been pointed in our previous publications, this type of cluster can exhibit nonlinear optical activity. Here we report the NLO properties and crystal structure of $(NEt_4)_2[MoS_4(CuBp)_4]$; the synthesis of the complex has been reported previously [21].

2. X-ray crystallography experimental

Suitable crystals for X-ray crystallography were obtained by diffusing Et_2O into a saturated acetone solution of the title complex and leaving it for 3 days in a refrigerator. Diffraction studies of the title complex were performed on a Nonius KappaCCD diffractometer. Mo Kα radiation ($\lambda = 0.71073$ Å) was employed for data collection at 150 K. Crystal data: $(C_8H_{20}N^+)_2$-$[C_{28}H_{32}Cu_4MoN_{16}S_4]^{2-}$, $M = 1331.5$, tetragonal, space group $I4_1/a$, $a = 13.341(2)$ Å, $c = 32.490(7)$ Å, $V = 5782.6(17)$ Å^3, $Z = 4$, $\mu = 1.85$ mm^{-1}, crystal size $0.24 \times 0.20 \times 0.18$ mm^3; 51 790 reflections measured ($2\theta < 27.5°$), 3311 unique ($R_{int} = 0.0521$); R [$F^2 > 2\sigma(F^2)$] = 0.0277, R_w (all F^2 values) = 0.0649, goodness of fit 1.067, final difference map extremes +0.34 and −0.62 e Å^{-3}. Absorption corrections were semi-empirical from symmetry-equivalent and repeated reflections. The structure was solved by direct methods and refined by full-matrix least-squares on all unique F^2. Non-hydrogen atoms were refined with anisotropic displacement parameters. Hydrogen atoms were included in calculated positions and refined with isotropic displacement parameters riding on those of the parent atoms. Programs were standard Bruker AXS control and integration software, and SHELXTL [28].

3. Description of crystal structure of $(NEt_4)_2[MoS_4(CuBp)_4]$ (1)

The Mo atom lies on a special position of S_4 symmetry, and the cation lies on a C_2 axis. The anion is constructed of one MoS_4 and four symmetry-equivalent CuBp fragments linked through the bridging sulfur atoms, completely comparable to the analogous and isostructural tungsten complex [21] (unlike the tungsten complex, no twinning was detected in the molybdenum complex **1**). There is no significant interaction between the dianion $[MS_4(CuBp)_4]^{2-}$ and the two Et_4N^+ counter-cations other than normal coulombic and van der Waals forces. A projection of the dianion of complex **1**, with the atomic labelling scheme, is shown in Fig. 1 and selected bonding parameters are presented in Table 1. As in the precursor compounds $[MS_4(CuX)_4]^{2-}$ (M = Mo, W; X = Cl, Br) [29,30], the MoS_4 core has retained its tetrahedral symmetry. Apparently, the symmetrical coordination of four CuL groups does not lower the symmetry of the MoS_4 core significantly and the two unique S–Mo–S angles are very similar [108.65(2)° and 111.13(3)°]. All of the

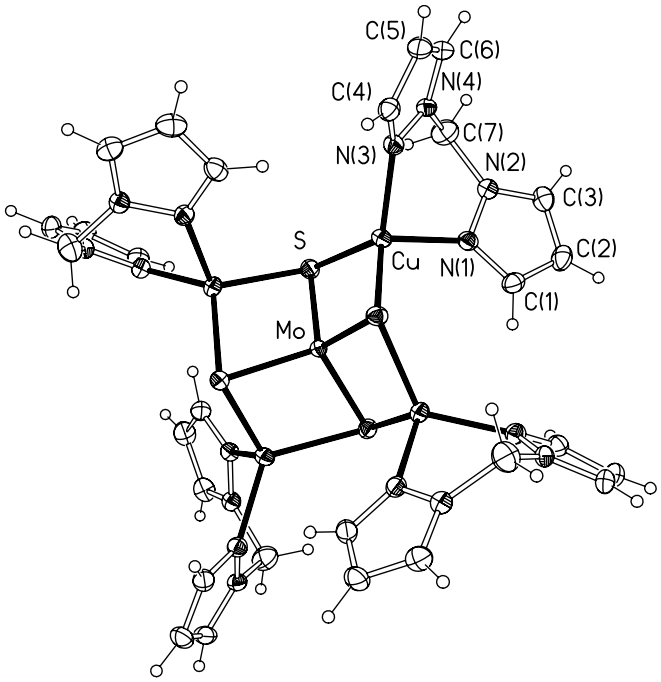

Fig. 1. Structure of the $[MoS_4(CuBp)_4]^{2-}$ anion, showing the numbering scheme for the asymmetric unit. The view is inclined to the S_4 axis.

Table 1
Selected bond lengths (Å) and bond angles (°) for $(NEt_4)_2[MoS_4(CuBp)_4]$

Mo–S	2.2472(6)	Cu–S	2.3097(7)
Cu–S(c)	2.2824(7)	Mo···Cu	2.6801(5)
Cu–N(1)	2.110(2)	Cu(1)–N(3)	2.020(2)
S–Mo–S(a)	108.65(2)	S–Mo–S(b)	111.13(3)
S–Cu–S(c)	105.31(3)	S–Cu–N(1)	105.27(6)
S–Cu–N(3)	122.09(6)	S(c)–Cu–N(1)	111.13(6)
S(c)–Cu–N(3)	119.11(6)	N(1)–Cu–N(3)	92.02(8)
Mo–S–Cu	72.04(2)	Mo–S–Cu(a)	72.55(2)
Cu–S–Cu(a)	111.97(3)		

Symmetry operations for equivalent atoms: (a) $-y + 5/4$, $x + 1/4$, $-z + 1/4$; (b) $-x + 1$, $-y + 3/2$, z; (c) $y - 1/4$, $-x + 5/4$, $-z + 1/4$.

Mo–S distances are 2.2472(6) Å, slightly longer than those of the similar bis-coordinated $(NEt_4)_2[MoS_4(CuBp')_2]$ (2.2103 Å) [$Bp' = H_2B(Pz^{Me2})_2$] [20] and rather longer than in the uncomplexed $[MoS_4]^{2-}$ anion (2.178 Å in the ammonium salt) [31]. This elongation of Mo–S and reduction of its double bond character as a result of coordination is in agreement with the decrease of the ν(Mo–S) stretching frequency in the IR spectrum. The very acute angles at the sulfur atoms bridging Cu and Mo [72.04(2)° and 72.55(2)°], together with the short Mo···Cu distances (2.680 Å) are suggestive of direct molybdenum–copper bonding interactions within the $Cu(S_b)_2Mo$ rings [Cu(I) (d^{10})–Mo(VI) (d^0) charge delocalization]. Although no definitive statement can be made about the existence of a metal–metal bond, the observed distances are consistent with a strong attractive interaction between Cu and Mo

atoms, as expected when placing two metals with greatly different formal oxidation states in close proximity, as they are in this pentanuclear cluster.

The coordination environment of all of the copper atoms is highly distorted tetrahedral, with angles ranging from 92.02(8)° (the bite angle of the chelating Bp ligand) to 122.09(6)°, and each Cu atom is coordinated by two sulfur atoms from MoS_4 and two nitrogen atoms of a Bp ligand. The bond distances in the CuS_2N_2 coordination are 2.3097(7) and 2.2824(7) Å for Cu–S, and 2.020(2) and 2.110(2) Å for Cu–N. These values are in agreement with reported ones for previous compounds of this type [21,32] or for similar compounds {e.g. 2.290(5) Å for Cu–S and 2.02(1) Å for Cu–N in $[WS_4Cu_3Cl(bpy)_2]$ [33]}.

In addition to the similarity between pyrazole (as N-donor in **1** and **2**) and imidazole in histidine, the arrangement and coordination environment of the Cu atoms in **1** are comparable to those found in active sites of some copper proteins such as poplar plastocyanin, cuperedoxin, cytochrome *c* oxides, etc. [22,34,35], indicating that the synthesized complex **1** can serve as a model for some copper proteins.

4. Nonlinear optical properties

Early investigations of planar-skeleton clusters revealed that the optical nonlinearity performance can be definitively attributed to the reverse saturable absorption under nanosecond pulsed radiation [36,37]. The *Z*-scan technique was applied to investigate the nonlinear optical refraction of $(NEt_4)_2[MoS_4(CuBp)_4]$. The output laser characteristics were as follows: pulse duration 8 ns; wavelength 532 nm; $E = 0.1$ mJ; 2 Hz repetition rate. The *Z*-scan scheme of complex **1** was calibrated using carbon disulfide (CS_2), which is often used as a standard reference nonlinear material. The nonlinear refractive index of CS_2 was measured as 2.5×10^{-10} esu (13.9×10^{-13} cm^2 W^{-1}) at 532 nm, which is in good agreement with previously reported data measured in the nanosecond range [18,38]. In Fig. 2, the normalized transmittance dependence of the sample of **1** is presented for the closed-aperture *Z*-scan scheme; it shows that the cluster possesses strong reverse saturable absorption, and it could be considered as a promising candidate for optical limiting. The closed-aperture scheme allowed us to determine the sign and magnitude of $n2$ and Re X(3). The normalized transmittance has a pair of sharp peaks and a valley. The peak-valley configuration is characteristic of self-defocusing and indicates that the sample possesses negative nonlinear refraction. Both the width and amplitude of the valley are smaller than those of the peak. The asymmetry of the peak and valley is caused by the strong reverse saturable absorption. From the measured value of the difference of normalized transmittance at the peak and valley positions, $\Delta T = 0.18$, the nonlinear optical refractive index $n2$ and Re X(3) were calculated to be -4.2×10^{-11} esu and -1.069×10^{-12} esu, respectively. The two-photon absorption coefficient β is 2.2×10^{-10} m W^{-1}. These results are comparable with those for ZnO and suitable for optical limiting applications.

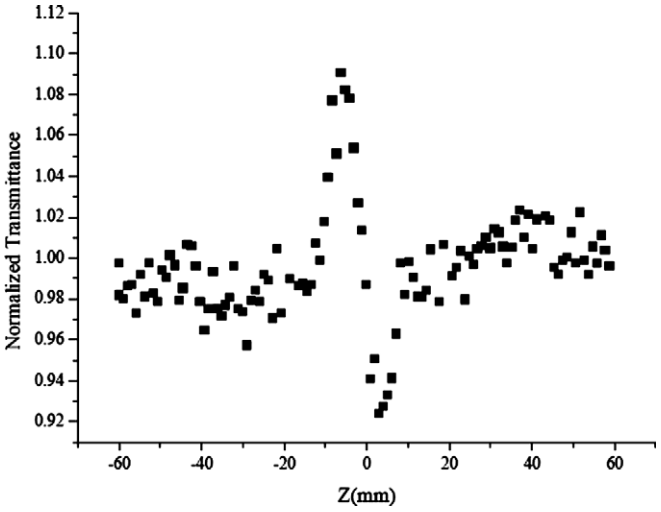

Fig. 2. The normalized transmittance dependence of $(NEt_4)_2[MoS_4(CuBp)_4]$ in the case of the closed-aperture scheme.

groups. In this paper, we introduce a series of new monoiminopyridyl ligands and their transition metal complexes. This monoiminopyridyl-transition metal catalyst system should be an interesting contrast to the previous system of iron and cobalt catalysts containing the 2,6-bis(imino)pyridine ligand [8–15]. We have explored the ethylene polymerization and oligomerization activity of these monoiminopyridyl-transition metal complexes in the presence of the cocatalyst methylaluminoxane (MAO) to clarify the reasons for this difference. We have also studied the influences of the metal center, the ligand architecture and the reaction conditions on the catalyst activity.

2. Results and discussion

2.1. Synthesis aspects

2.1.1. Synthesis of the precursor *4*

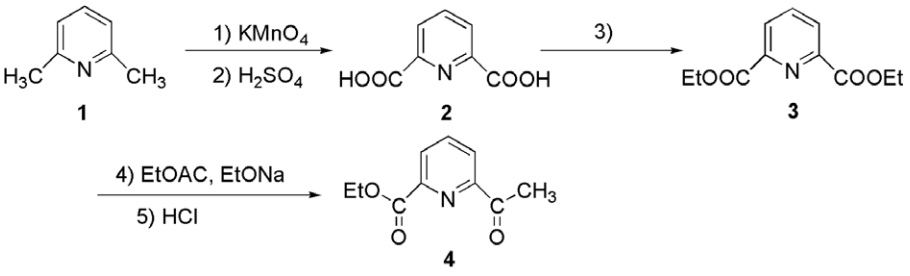
2-Carbethoxy-6-acetylpyridine (**4**) was prepared from 2,6-dimethylpyridine (**1**) (Scheme 1). Initially 2,6-dimethylpyridine (**1**) was converted to pyridine-2,6-dicarboxylic acid (**2**) according to the method reported in the literature [28,29]. Esterification of **2** was done by a modified procedure with a better yield (83%) than that of the reported method [30], resulting in 2,6-dicarbethoxypyridine (**3**), which was purified by a simplified method. **3** was dissolved in freshly distilled EtOAc, then treated with dry EtONa powder and an excess of concentrated HCl to afford compound 2-acetyl-6-carbethoxypyridine (**4**). The structure of the new compound **4** was proven by element analysis, ^{1}H NMR, IR and MS.

2.1.2. Synthesis of the ligands *5–7*

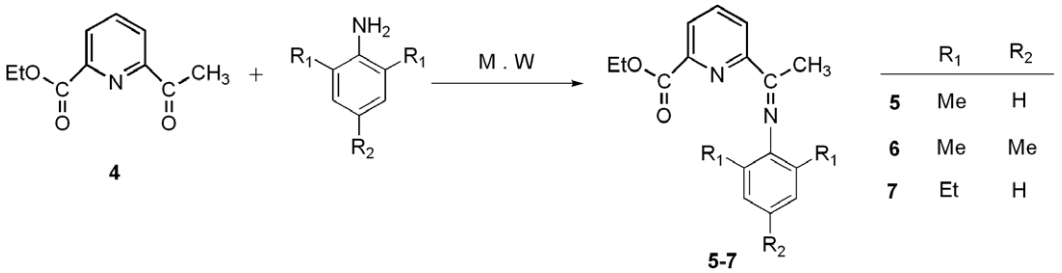
2-Carbethoxy-6-{1-[(2,6-dimethylphenyl)imino]ethyl}-pyridine (**5**), 2-carbethoxy-6-{1-[(2,4,6-trimethylphenyl)-imino]ethyl}pyridine (**6**), 2-carbethoxy-6-{1-[(2,6-diethylphenyl)-imino]ethyl}pyridine (**7**) were synthesized by condensation of 2-carbethoxy-6-acetylpyridine (**4**) and an excess of the corresponding substituted anilines using microwave irradiation (Scheme 2). After purification by column chromatography, the highly pure products were obtained in moderate yields (17.0–62.5%). Attempts to prepare **5–7** by catalytic condensation of **4** with the corresponding aryl aniline in refluxing ethanol and in the presence of acetic acid [31] were unsuccessful. We also found that the use of toluene as solvent, *p*-toluenesulfonic acid as catalyst and a Dean–Stark apparatus to remove the water formed in the reaction [32] afforded **5–7** in very low yields (about 10–15%), even after a long refluxing period (up to 3 days), and led to many byproducts. Compared with the two pathways mentioned above, microwave-assisted condensation seems to be much better in terms of improved reaction rate, simple work-up procedure and formation of cleaner products in preparing **5–7**, and moreover, it is a green method for chemical synthesis. The ligands **5–7** were characterized by element analysis, ^{1}H NMR and IR.

2.1.3. Synthesis of the complexes *8–19*

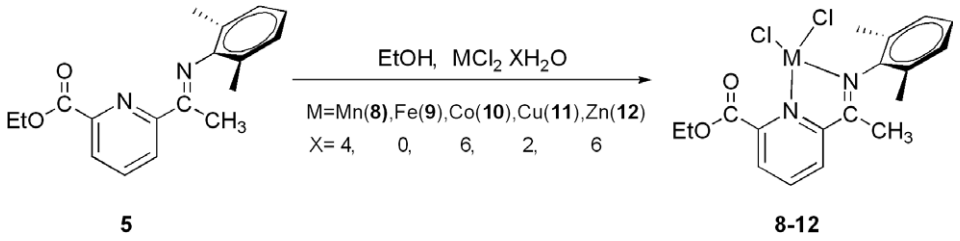
The transition metal complexes **8–13** (Schemes 3 and 4) were prepared by the reactions of ligand **5** with stoichiometric amounts of Mn(II), Fe(II), Co(II), Cu(II), Zn(II) and Ni(II) chlorides in ethanol at room temperature. The



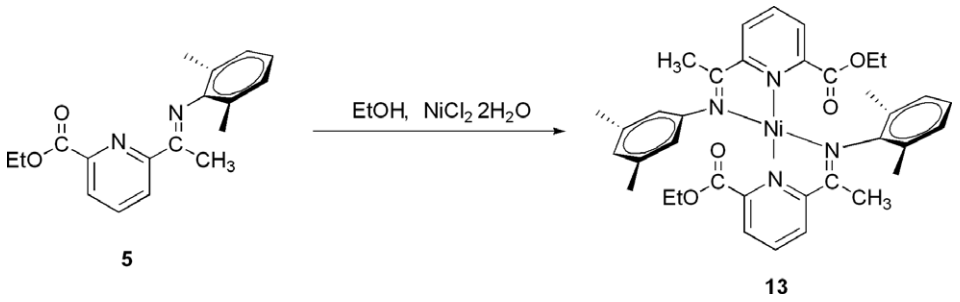
Scheme 1.



Scheme 2.



Scheme 3.

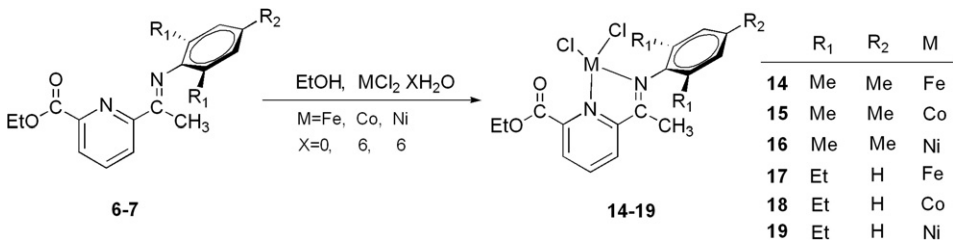


Scheme 4.

complexes **14**–**19** (Scheme 5) were synthesized by the selected metal Fe(II), Co(II), Ni(II) chlorides and the corresponding ligands **6** and **7** under the same experimental conditions as above. All the complexes were isolated as air-stable solids in high purity and in different yields. They were characterized by elemental analysis and IR spectroscopy. The elemental analysis results suggested that the components of complexes **8**–**12** and **14**–**19** were consistent with the formula $MLCl_2$, and complex **13** with the formula $ML_2Cl_2 \cdot H_2O$. The IR spectra of the free ligands **5**, **6** and **7** showed that the C=N stretching frequencies appeared at 1644, 1643 and 1640 cm^{-1}, respectively, and C=O vibrations at 1741, 1716 and 1742 cm^{-1}, respectively. In complexes **8**–**19**, the C=N stretching vibrations shifted toward lower frequencies ranging from 1621 to 1636 cm^{-1}, and were greatly reduced in intensity, which indicated coordination between the imino nitrogen atom and the metal ion. The C=O stretching vibrations also shifted toward lower frequencies ranging from 1665 to 1725 cm^{-1}, and were reduced in intensity, which suggested weak coordination between the carbonyl oxygen of the ester group and the metal ions.

2.2. The molecular structures of complexes *12* and *18*

Complexes **12** and **18** were further characterized by X-ray crystallography. Yellow crystals of **12** suitable for X-ray diffraction analysis were grown from a THF solution at room temperature, while green single crystals of complex **18** were obtained from a solution of $CoCl_2 \cdot 6H_2O$ in EtOH top layered with a solution of ligand **7** in Et_2O. The crystal structures of **12** and **18** are shown in Figs. 1 and 2, respectively, whereas selected bond lengths and angles are listed in Table 1. Fig. 1 indicates that in complex **12** the center Zn atom is coordinated in a distorted-tetrahedral environment by the pyridyl nitrogen atom, imino nitrogen atom and two chlorine atoms. The dimethyl-substituted phenyl ring is oriented nearly perpendicular to the coordination plane, and the dihedral angle is 89.50°. One THF molecule is observed in the crystal lattice of **12**. It should be pointed out that the oxygen atom in the carbonyl group is orientated toward the Zn center in **12**, and the distance between oxygen and Zn is 2.581 Å, which is longer than the normal Zn–O coordination bond length. The imino linkage N(1)–C(10) and linkage O(1)–C(16) have distinctive double-bond



Scheme 5.

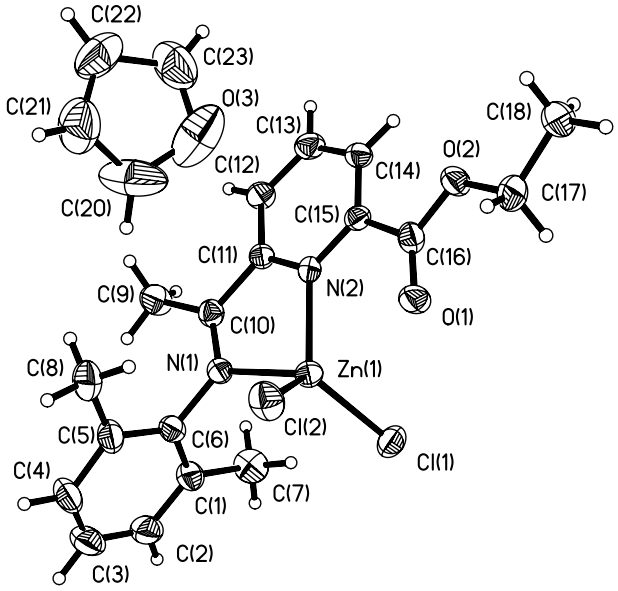


Fig. 1. Molecular diagram of {2-carbethoxy-6-[1-[(2,6-dimethylphenyl)-imino]ethyl]pyridine}-$ZnCl_2 \cdot THF$ (**12**).

character, with C–N and C–O distances of 1.275(7) and 1.206(7) Å, respectively. A perusal of the bond angles around the metal center of **12** shows that its coordination geometry is greatly distorted from an idealized tetrahedron, which may be attributed to the effect of the carbonyl oxygen atom on the coordination environment.

Fig. 2 shows that the carbonyl oxygen atom in **18** coordinates with Co(II). The coordination geometry around the central cobalt can be best described as distorted trigonal bipyramid, with the pyridyl nitrogen atom and the two chlorine atoms forming the equatorial plane. The deviation of the cobalt atom from the equatorial plane is 0.173 Å. The phenyl ring is oriented essentially orthogonal (88.11°) to the coordination plane containing the ligand backbone and the cobalt atom. It is noticeable that the Co–O(1) bond length (2.374(2) Å) is shorter than reported Co–O distances (2.460, 2.610 Å) [33], which indicates a strong coordination between the cobalt and carbonyl oxygen atom in **18**. As previously observed [12,13], the Co–N(pyridyl) bond (2.036(3) Å) is shorter than the Co–N(imino) bond (2.156(3) Å) in **18**.

2.3. Application of complexes 8–19 in the polymerization/oligomerization of ethylene

To probe the catalytic nature of these complexes for the ethylene polymerization/oligomerization, we carried out series of experiments over a range of active metal centers, ligand modifications, as well as a variety of polymerization/oligomerization reaction conditions in which the reaction temperature, time and Al/Metal ratio were systematically altered. The results are indicated in Table 2, Figs. 3–6, respectively.

2.3.1. Effect of the active metal center on the polymerization and oligomerization of ethylene

The nature of the center metal greatly influences the catalyst activity. The activities of the transition metal Mn(II), Fe(II), Co(II), Cu(II), Zn(II), Ni(II) complexes **8**–**13** bearing the same ligand **5** were tested at 1.0 atm of ethylene at 15.0–23.5 °C for 1 h, employing 1000 equiv. of MAO as cocatalyst (Table 2). Fe complex **9** shows considerable activity for the ethylene polymerization and moderate activity for ethylene oligomerization (Run 2), which implies that in this system the rate of chain propagation is in excess of the rate of chain transfer. While the ethylene oligomerization activities indicated by Co complex **10** and Ni complex **13** (Runs 3, 6) imply the reverse rate order, mainly producing butenes and hexenes and small amounts of higher oligomers. From Table 2, it can be concluded that the Mn, Cu, Zn complexes **8**, **11**, **12** are inactive for the ethylene polymerization/oligomerization (Runs 1, 4, 5), which is in agreement with the results observed from the bis(imino)pyridine-based transition metal analogues. The above results show that the different inherent electronic properties of the transition metals play a significant role in the catalyst activity, possibly leading to differences in the catalytic activity and product distribution.

2.3.2. Aryl ring ligand modification

A variety of substituted aryl-ring-containing ligands, including those with steric bulk and *ortho*- and *para*-substituted position modifications in the aryl ring, were employed to study their influence on the catalytic activity and product distribution of ethyl polymerization and oligomerization. The effect of these modifications on the oligomer distribution is not as remarkable as the effect on the catalytic activity, and no precise conclusion can be reached. Herein we mainly give the results on the catalytic activity. In Fig. 3, the curve 1 (■) was obtained from the activity of Fe, Co, Ni-based catalysts bearing ligand **5**, the curve 2 (◆)

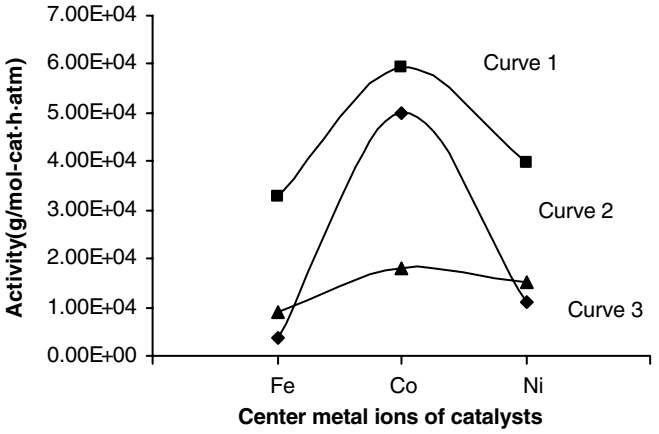

Fig. 3. Dependence of the activity on ligands **5** (curve 1 ■), **6** (curve 2 ◆), **7** (curve 3 ▲) for the Fe, Co, Ni-based catalysts.

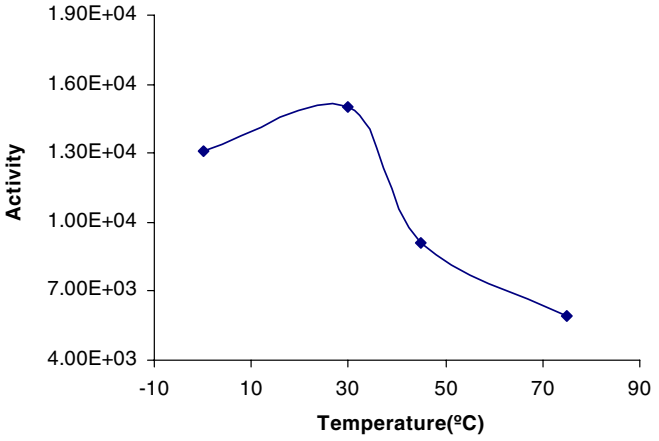

Fig. 4. Dependence of the activity on the reaction temperature for the catalyst **10**.

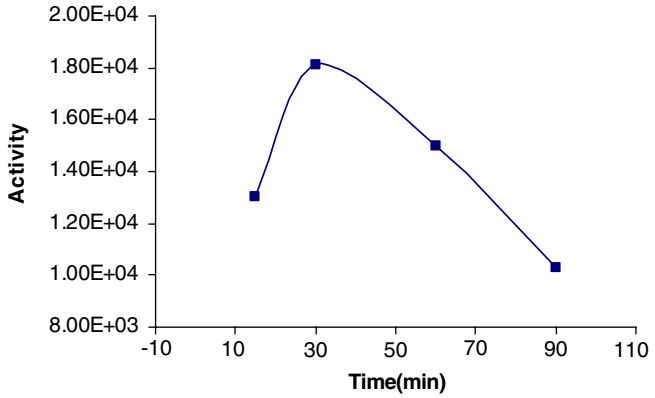

Fig. 5. Dependence of the activity on the reaction time for the catalyst **10**.

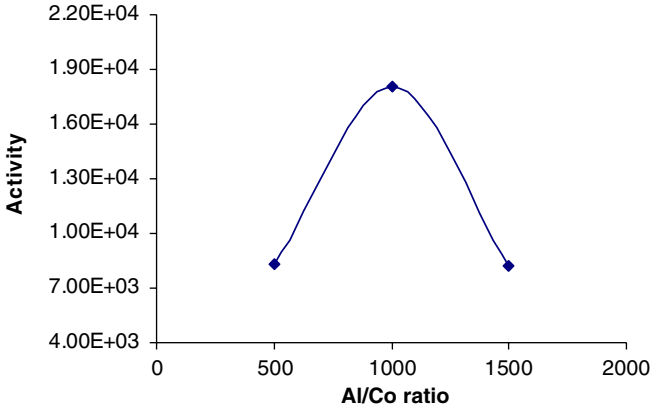

Fig. 6. Dependence of the activity on Al/Co ratio for the catalyst **10**.

and 3 (▲) were obtained from the activity of Fe, Co, Ni-based catalysts bearing ligands **6** and **7**, respectively. As shown in this figure, curve 1 is above both curve 2 and curve 3, which indicates that the activity of Fe, Co, Ni-based catalysts with a methyl group in the 2- and 6-position of the aryl ring are generally higher than those with a methyl group in the 2, 4, 6-position and those with an ethyl group in the 2- and 6-position. It suggests that replacing the *para*-aryl proton with a methyl group may result in a decrease in rate of propagation or β-H transfer (the major chain-transfer process), thus leading to a lower productivity in polymer or oligomer production (compare curve 1 with curve 2). On the other hand, bulky *ortho*-substituted aryl groups attached to the imine nitrogen also render less active catalysts (compare curve 1 with curve 3).

The influence of the metal center on catalytic activity also can be seen from Fig. 3. Comparison of the Fe, Co, Ni catalysts bearing different ligands indicates the same trend in activity changes. In general, Co catalysts are more active than the corresponding Ni catalysts, and Fe catalysts show the lowest activity in every set of Fe, Co, Ni catalysts. This result is slightly different from the trend observed for the bis(imino)pyridine ligand analogues [8,9]. The reason probably relates to the difference of the structure and electronic properties between the two types of ligands.

A study reported by Bianchini and co-workers [34,35] suggested that steric groups directly linked to the 2-position of pyridine were considered irrelevant in accounting for the superior activity of thiophenyl-substituted catalysts, but the chain length of the oligomers had been found to increase with the size of the sulfur-containing group in the catalyst 2-imino-6-(organyl)pyridine Co(II) dichloride. Compared with the other heteroatoms, the sulfur atom was suggested to have a great role in increasing both the activity and the Schulz–Flory parameter α (mol C_{n+2}/mol C_n). So the lesser activity indicated by the carbonyl group substituted in the 2-position of the pyridine ligand based Co(II) catalyst can be mainly attributed to the oxygen atom, but the great difference between the carbonyl group and the thiophenyl ring is also a reason for the catalytic performance. As yet no conclusion can be forwarded in the absence of further studies.

2.3.3. Effect of reaction conditions

To study the influence of the catalytic reaction conditions on the productivity of the catalyst system employed, we performed a series of experiments by employing Co catalyst **10** under different reaction temperatures, reaction times, as well as the ratio of Al/Metal. The results are shown in Figs. 4–6.

2.3.3.1. Effect of temperature on catalyst performance. To examine the role of the temperature variation on catalyst performance, four experiments were carried out at different temperatures (0, 30, 45 and 75 °C, respectively) for 60 min with an Al/Co ratio of 1000. As shown in Fig. 4, the activity increases slightly when the temperature rises from 0 to 30 °C (from 1.312×10^4 g/mol-Co h atm at 0 °C to 1.50×10^4 g/mol-Co h atm at 30 °C), and then it decreases as the temperature is increased continually up to 75 °C (0.593×10^4 g/mol-Co h atm at 75 °C). The lower temperature is unfavorable probably because it hinders the formation of the active species, but too high a temperature may also lead to a decrease of the activity due to a decrease of ethylene solubility [36,37] in toluene, and the deactivation of the catalyst.

2.3.3.2. Effect of reaction time. The reaction time can have a great effect on productivity as exemplified for catalyst **10**. At 30 °C and when Al/Co ratio was 1000, four ethylene polymerization experiments were performed for 15, 30, 60 and 90 min. From Fig. 5 we can see that as the reaction time increases from 15 to 30 min, the activity increases from 1.30×10^4 to 1.81×10^4 g/mol-Co h atm. Typically, 30 min later the activity slows down gradually and when the reaction has been performed for 90 min the activity reduces to 1.30×10^4 g/mol-Co h atm. These observations imply that a deactivation of the catalyst occurred about 30 min after initiating. The employed catalyst system has a relatively longer lifetime compared to other catalyst systems [38].

2.3.3.3. Effect of cocatalyst MAO. The cocatalyst is also a significant factor for the oligomerization of ethylene. To study this effect, three tests were performed for 30 min at 30 °C, in which the ratios of [MAO]/[Co] were systematically varied from 500 to 1500. As indicated in Fig. 6, the activity shows a maximum (1.81×10^4 g/mol-Co h atm) around a [MAO]/[Co] ratio of 1000. The possible reason is that an optimal amount of MAO as cocatalyst is needed to effectively activate the catalyst, while an excess amount of MAO will create too many trialkylaluminum impurities and may cause the degradation of the catalyst system.

3. Conclusion

A new compound 2-carbethoxy-6-acetylpyridine (**4**) was synthesized, from which a series of aryl substituted 2-carbethoxy-6-iminopyridine ligands (**5**, **6** and **7**) were prepared by microwave irradiation. Reactions of these ligands **5**, **6** and **7** with group 4B translation metal salts in ethanol provided the corresponding transition metal complexes (**8**–**19**). When MAO was employed as a cocatalyst, the Fe, Co, Ni complexes exhibited moderate catalytic activity and the Mn, Cu, Zn complexes were inactive for ethylene polymerization and oligomerization, which parallel the results observed for catalysts containing the 2,6-bis(imino)pyridine ligand. For the complexes of Fe, Co, Ni, the catalytic activities depend greatly on the structure and electronic properties of the ligand. In contrast to the bis(imino)pyridine analogue, the complexes bearing mono(imino)pyridine with two substituents in the *ortho*-position of the parent aniline are more active than those with substituents in both *ortho*- and *para*-positions as well as those with larger steric hindrance in the *ortho*-positions. Research on the influence of the carbethoxy group on catalytic activity is underway. The catalytic activity of the complexes is also influenced by the amount of cocatalyst employed and other factors such as reaction temperature and time. The optimum conditions have been chosen through a series of experiments to exhibit high activity. Comparing the activity of the catalyst bearing the asymmetrical mono(imino)-pyridine ligand **5** with the analogous catalyst [8,11] bearing the symmetrical bis(imino)pyridine ligand, we assume at this stage that the lesser activity of the former is due to the influence of the carbethoxy group in the ligand.

4. Experimental

4.1. General procedure

All experiments of air- and/or moisture-sensitive compounds were carried out under a nitrogen atmosphere using standard Schlenk techniques. Solvents were refluxed over an appropriate drying agent and distilled prior to use. C, H and N analyses were performed on a HP-MOD 1106 microanalyzer. IR spectra were measured with a Perkin–Elemer FTIR 2000 spectrometer. ^{1}H NMR spectra were recorded on a Bruker spectrometer DMX-300. Mass spectral analyses were performed with a Kratos AEI MS-50 instrument using the electron impact (EI) method. The microwave-assisted reactions were carried out in a domestic oven Midea PJ 21B-A 800w (21 L). The oligomerization products obtained were analyzed on a BF 3400 GC instrument which was equipped with a SE-54 capillary column (25 m × 0.32 mm) using a temperature program from 40 to 280 °C. 2,6-Dimethylpyridine, 2,6-dimethylaniline, 2,4,6-trimethylaniline and 2,6-diethylaniline were purchased from Acros and used as received. MAO in toluene (14 wt%) was from the Albemarle Co. (USA). Polymerization grade ethylene monomer, produced by Beijing Yanshan Petrochemical Co., was used without further purification.

4.2. Synthesis of complexes

4.2.1. 2-Carbethoxy-6-acetylpyridine (*4*)

Sodium (2.10 g, 91 mmol) was dissolved in 60 mL of pure, dry ethanol, then the excess ethanol was removed and the obtained white powder was dried in vacuum for 6 h. 11.17 g (50 mmol) of 2,6-dicarbethoxypyridine (**3**) in 40 mL of freshly distilled EtOAc was added dropwise to the dry EtONa powder with stirring to afford a yellow mixture, which was refluxed for 12 h, then allowed to stand overnight. An excess (33 mL) of concentrated HCl was added dropwise with stirring to the resulting mixture and refluxed for a period of 7–8 h to complete the reaction. After water was added to dissolve the NaCl formed in the reaction, the mixture turned into an orange solution (100 mL). The aqueous phase was shaken with $CHCl_3$ (4×25 mL). The combined extracts were washed with 5% aqueous Na_2CO_3 and the aqueous phase was extracted with $CHCl_3$ (3×10 mL) again. The combined organic phase was dried over anhydrous Na_2SO_4, filtered and the solvent was evaporated under reduced pressure. The obtained mixture was separated by column chromatography (silica-gel, petroleum ether:EtOAc = 4:1). First 2,6-diacetylpyridine was eluted, followed by 2-acetyl-6-carbethoxypyridine (yield: 2.71 g, 28.0%). M.p. 50.0–51.5 °C. ^{1}H NMR (400 MHz, $CDCl_3$): δ 8.27 (d, 1H, Py-Hm), 8.20 (d, 1H, Py-Hm), 7.99 (t, 1H, Py-Hp), 4.49 (m, 2H, CH_2), 2.81 (s, 3H, O–C(CH_3)), 1.47 (t, 3H, CH_2(CH_3)). IR (KBr): ν_{C-O} 1726, 1706, ν_{C-O-C} 1156 cm^{-1}. MS (EI): *m*/*z* 193 (M^+). *Anal.* Calc. for $C_{10}H_{11}NO_3$: C, 62.17; H, 5.74; N, 7.25. Found: C, 62.51; H, 5.76; N, 7.30%.

4.2.2. 2-Carbethoxy-6-{1-[(2,6-dimethylphenyl)imino]-ethyl}pyridine (*5*)

2-Carbethoxy-6-acetylpyridine (**4**) (0.580 g, 3.0 mmol) and an excess of 2,6-dimethylaniline (0.7272 g, 6.0 mmol) were mixed together in an opened Erlenmeyer flask (25 mL). The mixture was subjected to microwave for 30 min on the ''High'' setting (800 W). The crude product was purified by column chromatography (60 × 2.5 cm silica-gel, petroleum ether:EtOAc = 3:2). Ligand **5** was obtained as a highly pure yellow solid in 62.5% yield. M.p. 58.0–59.5 °C. ^{1}H NMR (400 MHz, $CDCl_3$): δ 8.57

(d, 1H, Py-Hm), 8.19 (d, 1H, Py-Hm), 7.94 (t, 1H, Py-Hp), 7.06 (d, 2H, Ar-Hm), 6.95 (t, 1H, Ar-Hp), 4.50 (m, 2H, CH_2), 2.26 (s, 3H, N-C(Me)), 2.02 (s, 6H, Ar-Me), 1.46 (t, 3H, $CH_2(CH_3)$). IR (KBr): ν_{C-O} 1741, ν_{C-N} 1644, ν_{C-O-C} 1141 cm^{-1}. *Anal.* Calc. for $C_{18}H_{20}N_2O_2$: C, 72.95; H, 6.80; N, 9.45. Found: C, 73.04; H, 6.81; N, 9.26%.

4.2.3. 2-Carbethoxy-6-{1-[(2,4,6-trimethylphenyl)imino]-ethyl}pyridine (6)

2,4,6-Trimethylaniline (1.08 g, 8.0 mmol) was mixed with **4** (0.772 g, 4.0 mmol) in a 25 mL Erlenmeyer flask. The mixture was subjected to microwave for 20 min on the "High" setting (800 W). The crude product was purified by column chromatography (60 × 2.5 cm silica-gel, petroleum ether:EtOAc = 2:1). Ligand **6** was obtained as yellow solid in 74.1% yield. M.p. 75.0–76.0 °C. ^1H NMR (400 MHz, $CDCl_3$): δ 8.56 (d, 1H, Py-Hm), 8.19 (d, 1H, Py-Hm), 7.94 (t, 1H, Py-Hp), 6.90 (s, 2H, Ar-Hm), 4.88 (m, 2H, CH_2), 2.26 (d, 3H, N-C(Me)), 2.06 (s, 6H, Ar-Me), 1.47 (t, 3H, $CH_2(CH_3)$). IR (KBr): ν_{C-O} 1715, ν_{C-N} 1643, ν_{C-O-C} 1137 cm^{-1}. *Anal.* Calc. for $C_{19}H_{22}N_2O_2$: C, 73.52; H, 7.14; N, 9.03. Found: C, 73.31; H, 7.12; N, 8.94%.

4.2.4. 2-Carbethoxy-6-{1-[(2,6-diethylphenyl)imino]-ethyl}pyridine (7)

2,6-Diethylaniline (1.07 g, 7.2 mmol) was mixed with **4** (0.67 g, 3.5 mmol) in a 25 mL Erlenmeyer flask. The mixture was subjected to microwave for 35 min on the "High" setting (800 W). The crude product was purified by column chromatography (30 × 1.5 cm silica-gel, *n*-hexane:dichloromethane = 1:2, 40 × 1.5 cm silica-gel, diethyl ether:petroleum ether = 2:3). Ligand **7** was obtained as yellow solid in 17.6% yield. M.p. 84.0–86.0 °C. ^1H NMR (400 MHz, $CDCl_3$): δ 8.48 (d, 1H, Py-Hm), 8.11 (d, 1H, Py-Hm), 7.87 (t, 1H, Py-Hp), 7.30 (d, 2H, Ar-Hm), 6.99 (t, 1H, Ar-Hp), 4.43 (m, 2H, $COOCH_2$), 2.28 (m, 4H, $(CH_2)CH_3$), 2.20 (s, 3H, N-C(Me)), 1.39 (t, 3H, $COOCH_2(CH_3)$), 1.05 (t, 6H, $CH_2(CH_3)$). IR (KBr): ν_{C-O} 1742, ν_{C-N} 1640, ν_{C-O-C} 1166 cm^{-1}. *Anal.* Calc. for $C_{20}H_{24}N_2O_2$: C, 74.04; H, 7.46; N, 8.64. Found: C, 74.18; H, 7.70; N, 8.17%.

4.2.5. {2-Carbethoxy-6-[1-[(2,6-dimethylphenyl)imino]-ethyl]pyridine}$MnCl_2$ (8)

A solution of $MnCl_2 \cdot 4H_2O$ (29.7 mg, 0.15 mmol) and **5** (44.4 mg, 0.15 mmol) in ethanol (8 mL) was stirred at room temperature for 6 h. During this period a yellow solid was obtained, which was washed repeatedly with diethyl ether and dried in vacuo. Yield: 26.3 mg (41.5%). M.p. >300 °C. IR (KBr): ν_{C-O} 1697, ν_{C-N} 1627 cm^{-1}. *Anal.* Calc. for $C_{18}H_{20}Cl_2MnN_2O_2$: C, 51.21; H, 4.77; N, 6.63. Found: C, 51.33; H, 4.80; N, 6.45%.

4.2.6. {2-Carbethoxy-6-[1-[(2,6-dimethylphenyl)imino]-ethyl]pyridine}$FeCl_2$ (9)

Using an analogous procedure as above, under a nitrogen atmosphere, **9** was obtained as a blue solid in 30.0% yield. M.p. >300 °C. IR (KBr): ν_{C-O} 1712, ν_{C-N} 1624 cm^{-1}. *Anal.* Calc. for $C_{18}H_{20}Cl_2FeN_2O_2$: C, 51.10; H, 4.76; N, 6.62. Found: C, 51.10; H, 4.83; N, 6.53%.

4.2.7. {2-Carbethoxy-6-[1-[(2,6-dimethylphenyl)imino]-ethyl]pyridine}$CoCl_2$ (10)

Using an analogous procedure as above, **10** was obtained as a green solid in 70.7% yield. M.p. >300 °C. IR (KBr): ν_{C-O} 1714, ν_{C-N} 1625 cm^{-1}. *Anal.* Calc. for $C_{18}H_{20}Cl_2CoN_2O_2$: C, 50.73; H, 4.73; N, 6.57. Found: C, 50.38; H, 4.85; N, 6.27%.

4.2.8. {2-Carbethoxy-6-[1-[(2,6-dimethylphenyl)imino]-ethyl]pyridine}$CuCl_2$ (11)

Using an analogous procedure as above, **11** was obtained as a yellow solid in 88.6% yield. M.p. >300 °C. IR (KBr): ν_{C-O} 1725, ν_{C-N} 1628 cm^{-1}. *Anal.* Calc. for $C_{18}H_{20}Cl_2CuN_2O_2$: C, 50.18; H, 4.68; N, 6.50. Found: C, 50.26; H, 4.77; N, 6.35%.

4.2.9. {2-Carbethoxy-6-[1-[(2,6-dimethylphenyl)imino]-ethyl]pyridine}$ZnCl_2$ (12)

Using an analogous procedure as above, **12** was obtained as a yellow solid in 88.3% yield. M.p. >300 °C. IR (KBr): ν_{C-O} 1723, ν_{C-N} 1636 cm^{-1}. *Anal.* Calc. for $C_{18}H_{20}Cl_2N_2O_2Zn$: C, 49.97; H, 4.66; N, 6.47. Found: C, 49.68; H, 4.68; N, 6.21%.

4.2.10. {2-Carbethoxy-6-[1-[(2,6-dimethylphenyl)imino]-ethyl]pyridine}$_2NiCl_2$ (13)

Using an analogous procedure as above, **13** was obtained as a red solid in 42.1% yield. M.p. >300 °C. IR (KBr): ν_{C-N} 1624 cm^{-1}. *Anal.* Calc. for $C_{36}H_{42}Cl_2N_4NiO_5$: C, 58.40; H, 5.72; N, 7.57. Found: C, 58.72; H, 5.46; N, 7.89%.

4.2.11. {2-Carbethoxy-6-[1-[(2,4,6-trimethylphenyl)-imino]ethyl]pyridine}$FeCl_2$ (14)

Using an analogous procedure as above, under a nitrogen atmosphere, **14** was obtained as a blue solid in 40.1% yield. M.p. >300 °C. IR (KBr): ν_{C-O} 1719, ν_{C-N} 1589 cm^{-1}. *Anal.* Calc. for $C_{19}H_{22}Cl_2FeN_2O_2$: C, 52.20; H, 5.07; N, 6.41. Found: C, 52.17; H, 5.01; N, 6.34%.

4.2.12. {2-Carbethoxy-6-[1-[(2,4,6-trimethylphenyl)-imino]ethyl]pyridine}$CoCl_2$ (15)

Using an analogous procedure as above, **15** was obtained as a green solid in 48.5% yield. M.p. > 300 °C. IR (KBr): ν_{C-O} 1717, ν_{C-N} 1592 cm^{-1}. *Anal.* Calc. for $C_{19}H_{22}Cl_2CoN_2O_2$: C, 51.84; H, 5.04; N, 6.36. Found: C, 51.88; H, 5.07; N, 6.20%.

4.2.13. {2-Carbethoxy-6-[1-[(2,4,6-trimethylphenyl)-imino]ethyl]pyridine}$NiCl_2$ (16)

Using an analogous procedure as above, **16** was obtained as a yellow solid in 50.7% yield. M.p. >300 °C. IR (KBr): ν_{C-O} 1720, ν_{C-N} 1592 cm^{-1}. *Anal.* Calc. for $C_{19}H_{22}Cl_2N_2NiO_2$: C, 51.87; H, 5.04; N, 6.37. Found: C, 52.09; H, 5.22; N, 6.11%.

4.2.14. {2-Carbethoxy-6-[1-[(2,6-diethylphenyl)imino]-ethyl]pyridine}$FeCl_2$ (**17**)

Using an analogous procedure as above, under a nitrogen atmosphere, **17** was obtained as a blue solid in 23.3% yield. M.p. >300 °C. IR (KBr): ν_{C-O} 1665, ν_{C-N} 1620 cm^{-1}. *Anal.* Calc. for $C_{20}H_{24}Cl_2FeN_2O_2 \cdot 0.5H_2O$: C, 52.20; H, 5.48; N, 6.09. Found: C, 52.39; H, 5.22; N, 5.99%.

4.2.15. {2-Carbethoxy-6-[1-[(2,6-diethylphenyl)imino]-ethyl]pyridine}$CoCl_2$ (**18**)

Using an analogous procedure as above, **18** was obtained as a green solid in 64.8% yield. M.p. >300 °C. IR (KBr): ν_{C-O} 1701, ν_{C-N} 1625 cm^{-1}. *Anal.* Calc. for $C_{20}H_{24}Cl_2CoN_2O_2$: C, 52.88; H, 5.33; N, 6.17. Found: C, 53.31; H, 5.38; N, 6.11%.

4.2.16. {2-Carbethoxy-6-[1-[(2,6-diethylphenyl)imino]-ethyl]pyridine}$NiCl_2$ (**19**)

Using an analogous procedure as above, **19** was obtained as a pale red solid in 61.0% yield. M.p. >300 °C. IR (KBr): ν_{C-O} 1691, ν_{C-N} 1623 cm^{-1}. *Anal.* Calc. for $C_{20}H_{26}Cl_2N_2NiO_3$: C, 50.89; H, 5.55; N, 5.93. Found: C, 50.71; H, 5.21; N, 5.78%.

4.3. General procedure for polymerization and oligomerization of ethylene

10 μmol of the transition metal complex was charged into a Schlenk tube. Air was eliminated from the Schlenk tube by three vacuum/nitrogen steps. Then the desired volume of MAO/toluene solution (14%) was added. Immediately the color of the solution changed. The solution was then stirred at 600 rpm for the time set and the active catalytic species in toluene solution was available.

The polymerization and oligomerization reactions were carried out in a 100 mL three-neck flask. After evacuation and flushing with nitrogen three times, then with ethylene two times, the flask was charged with 50 mL of toluene and magnetically stirred under ambient ethylene atmosphere. When the desired reaction temperature was established, the solution of the catalyst species was injected into the reactor. Stirring was carried out at 1200 rpm. After the times set for the experiment, the reaction solution was quickly cooled down to −20 °C and the reaction quenched with acidic ethanol solution. The precipitated polymer was collected and washed for several times with ethanol and then dried under vacuum at 50 °C for 24 h. The oligomer solution was dried over anhydrous Na_2SO_4, an aliquot of this solution was analyzed by GC (Gas Chromatograph).

4.4. X-ray analysis of **12** and **18**

Data collection for complexes **12** and **18** was performed at 293(2) and 296(2) K, respectively, on a Bruker SMART 1000 diffractometer with graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). The Smart program package was used to determine the unit-cell parameters. A SADABS absorption correction was applied. The structure was solved by direct methods and refined by full-matrix least-squares techniques with anisotropic thermal parameters for non-hydrogen atoms. Hydrogen atoms were placed at calculation positions and were included in the structure calculation without further refinement of the parameters. All calculations were performed using the SHELXS-97 program. Crystal data and structure refinement for complexes **12** and **18** are summarized in Table 3.

Table 3
Crystal data, data collection and structure refinement for complexes **12** · THF and **18**

Complex	**12**	**18**
Empirical formula	$C_{22}H_{24}Cl_2N_2O_3Zn$	$C_{20}H_{24}Cl_2CoN_2O_2$
Formula weight	500.70	454.24

Here we report the synthesis of two new complexes of tin tetrachloride with the ligands $R_2NP(O)F_2$ (R = Me or Et) in which two fluorine atoms have substituted two dialkylamino groups in the ligand $(R_2N)_3P(O)$. The new compounds were characterised by elemental analysis, IR and multinuclear (^{119}Sn, ^{31}P, ^{19}F and ^{1}H) NMR spectroscopy. On the basis of NMR data, we show that these ligands, once freed from the inductive and π-bonding (and/or steric) effects of the two dialkylamino groups, are unique in that they form almost exclusively the cis complex with $SnCl_4$ in solution. We have also carried out DFT/B3LYP calculations on the *cis* and *trans* isomers of complex **1** and its ligand in order to support and help the analysis of NMR data.

2. Experimental

2.1. General experimental procedures

All preparations were carried out under a nitrogen atmosphere in solvents dried by standard techniques [13] and stored over molecular sieves. NMR spectra were recorded on a Bruker AC-300 instrument in CD_2Cl_2 as solvent; ^{31}P at 121 MHz (85% H_3PO_4), ^{19}F at 282 MHz ($CFCl_3$), ^{1}H at 300 MHz (TMS) and ^{119}Sn at 111.8 MHz ($SnCl_4$). IR spectra: Perkin Elmer Paragon 1000 PC.

Tin tetrachloride was distilled under vacuum before use. The ligands $R_2NP(O)F_2$ were prepared according to methods described in literature (R = Me [14]; R = Et [15]).

2.2. Preparation of complexes

In a typical reaction $R_2NP(O)F_2$ (8 mmol) in dry $CHCl_3$ (10 cm^3) was slowly added to $SnCl_4$ (1.04 g, 4 mmol) in $CHCl_3$ (20 cm^3) over a 30 min period. The resulting solution, on continual stirring, began to precipitate the white solid complex $SnCl_4 \cdot 2(O)PF_2NR_2$. The precipitation was complete when the product was left 24 h at −15 °C. This was collected, washed with *n*-hexane/CCl_4 and obtained as a white powder (Yields: R = Me: 1.24 g, 60%; R = Et: 1.21 g, 53%). *Anal.* Calc. for $C_4H_{12}N_2O_2P_2F_4SnCl_4$: C, 9.26; H, 2.33; N, 5.40. Found: C, 9.00; H, 2.62; N, 5.68%. *Anal.* Calcd. for $C_8H_{20}N_2O_2P_2F_4SnCl_4$: C, 16.72; H, 3.51; N, 4.87. Found: C, 16.66; H, 3.52; N, 5.04%. IR (KBr): $\nu_{P=O}$ (1280–1310 cm^{-1}); ν_{Sn-O} (560–570 cm^{-1}).

2.3. Computational details

Density functional theory (DFT) calculations were carried out on the *cis* and *trans* isomers of complex **1** and its ligand using the suite of programs Gaussian 98W [16], with the non-local hybrid functional denoted as B3LYP [17]. Basis sets used were 6-31G* [18] for C, H, N, F, P, O and Cl and Steven, Bach and Krauss (SBK) [19] with ECP with polarisation for Sn. The geometries of both the *cis* and *trans* isomers of complex **1** and its ligand were optimised using analytical gradient. The harmonic vibrational frequencies of the different stationary points of the PES have been calculated at the same level of theory in order to identify the local minima as well as to estimate the corresponding zero-point vibrational energy (ZPE).

3. Results and discussion

3.1. Synthesis

Treatment of $SnCl_4$ in a chloroform solution with $R_2NP(O)F_2$ (R = Me or Et) gives white solids with the composition $SnCl_4 \cdot 2L$ ($L = R_2NP(O)F_2$). These complexes are soluble in dichloromethane and chloroform. They were characterised by elemental analysis and particularly by their NMR data and comparison with the corresponding data for the free ligands (see Table 1).

3.2. Spectroscopic studies

The infrared spectra show strong bands within the range 1285–1310 cm^{-1} attributed to $\nu_{P=O}$. The P=O stretching vibration is shifted towards lower wave numbers on coordination to the tin atom compared with its value for the free ligands. The coordination shift is about 35 cm^{-1} and is consistent with phosphoryl coordination to the tin atom. This shift is 30 cm^{-1} for $Me_2NP(O)F_2$ against 138 cm^{-1} for HMPA [5], explaining the difference in the basicity strength between these two ligands which is most probably due to the substitution of two dimethylamino groups by two fluorine atoms. The absorption band at 560–570 cm^{-1} corresponds to a stretching vibration of the Sn–O group.

The NMR spectra of the two complexes prepared are quite similar and the data obtained from these spectra are summarised in Table 1.

The ^{31}P NMR resonances of the bound ligands are shifted to lower frequency compared with those of the free ligand, whereas the ^{19}F and ^{1}H NMR resonances show a higher frequency shift on complexation. The difference in the ^{31}P chemical shift between free and bound ligands is more important than that observed in ^{19}F and ^{1}H NMR spectra, confirming coordination of the fluorophosphoramide ligand through the oxygen atom. The coupling constant $^{1}J_{P-F}$ is larger for the complexed ligand than for the free one (Table 1).

The ^{31}P NMR spectra of each of the complexes prepared showed a triplet pattern (the triplet being due to phosphorus–fluorine coupling) with splitting due to ^{31}P–Sn

Table 1
NMR data (δ/ppm and J/Hz) for the complexes $SnCl_4 \cdot 2L$ and the ligands $R_2NP(O)F_2$ in CD_2Cl_2 at −75 °C

Compound	$\delta_{^{31}P}$	$\delta_{^{19}F}$	$\delta_{^{1}H}$	$\delta_{^{119}Sn}$	$^{1}J_{P-F}$	$^{2}J_{P-Sn}$
$Me_2NP(O)F_2$	−2.50	81.50	2.78	–	997	–
$Et_2NP(O)F_2$	−5.00	83.50	–	–	1003	–
$SnCl_4 \cdot 2(O)PF_2NMe_2$ (**1**)	−7.63	83.16	2.93	−507	1015	145
$SnCl_4 \cdot 2(O)PF_2NEt_2$ (**2**)	−10.40	84.87	–	−510	1023	150

coupling. The latter splitting can be clearly seen only at low temperature (Fig. 1).

In addition, the spectra also contain a triplet of low intensity indicating the existence of a small amount of another species. This minor triplet also showed ^{31}P–Sn splitting at low temperature.

The ^{119}Sn NMR spectrum of each complex displayed at room temperature one broad signal in the region of hexacoordinated species [20]. This broad signal was converted at low temperature into the expected triplet. At −75 °C, the spectrum showed a triplet due to ^{119}Sn–^{31}P coupling. Clearly one species was present at this temperature and in which the tin atom is coupled to two phosphorus atoms, showing a stoichiometry of $SnCl_4 \cdot 2L$ (Fig. 2). This is in agreement with the ^{31}P NMR spectra where a triplet displaying Sn satellites with the corresponding coupling constants was present (Fig. 1).

At lower temperatures, the ^{119}Sn spectrum (Fig. 3) showed, in addition to the major triplet, two doublets in the region of pentacoordinated tin [20]. This indicates that these different tin species are presumably in rapid equilibrium with each other and with the free ligand, consistent with ^{31}P and ^{19}F NMR spectra where ligand exchange reactions are fast at room temperature. The rates of these reactions were decreased by lowering the temperature and separate signals corresponding to the free and bound ligands present in solution were observed. Cooling to −85 °C revealed the presence in the ^{31}P NMR spectrum (and also in the ^{19}F NMR spectrum) of a new signal at −9.41 ppm (Fig. 1), in addition to $SnCl_4 \cdot 2L$ and to the

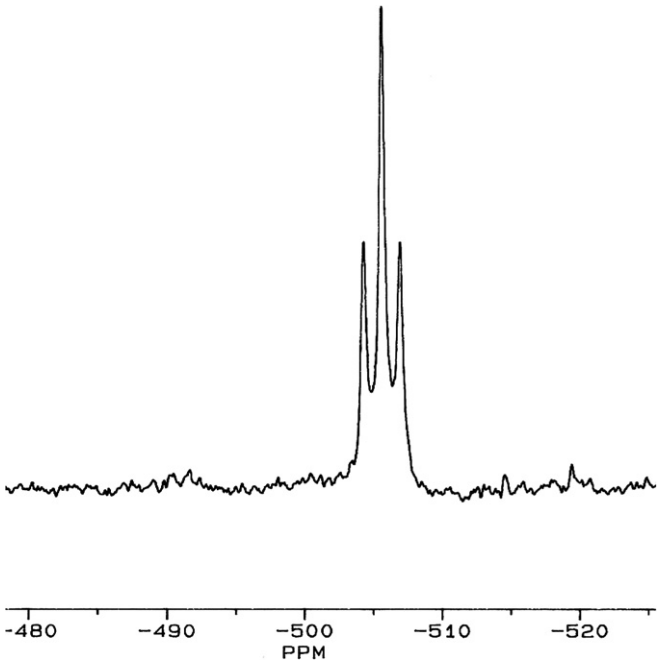

Fig. 2. ^{119}Sn NMR spectrum of the complex $SnCl_4 \cdot 2(O)PF_2NMe_2$ in CD_2Cl_2 at −75 °C.

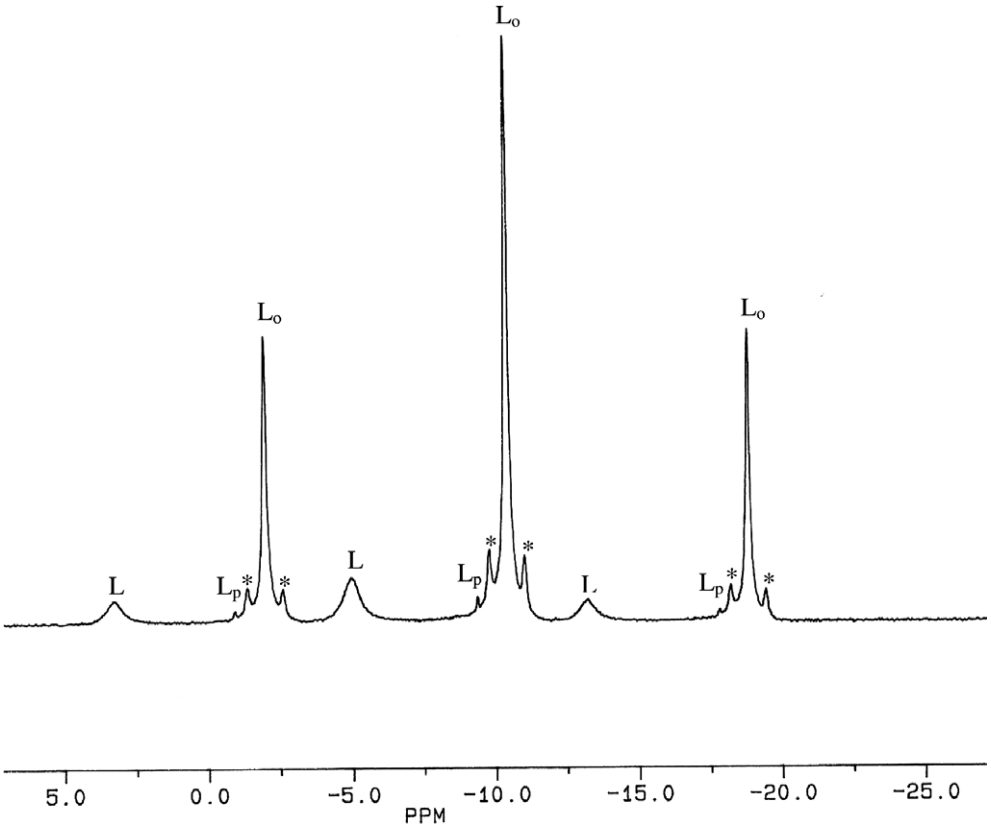

Fig. 1. ^{31}P-{^{1}H} NMR spectrum of the complex $SnCl_4 \cdot 2(O)PF_2NEt_2$ in CD_2Cl_2 at −85 °C (*: Sn satellites, L_o: octahedral tin complex, L_p: pentacoordinated tin complex, L: free ligand).

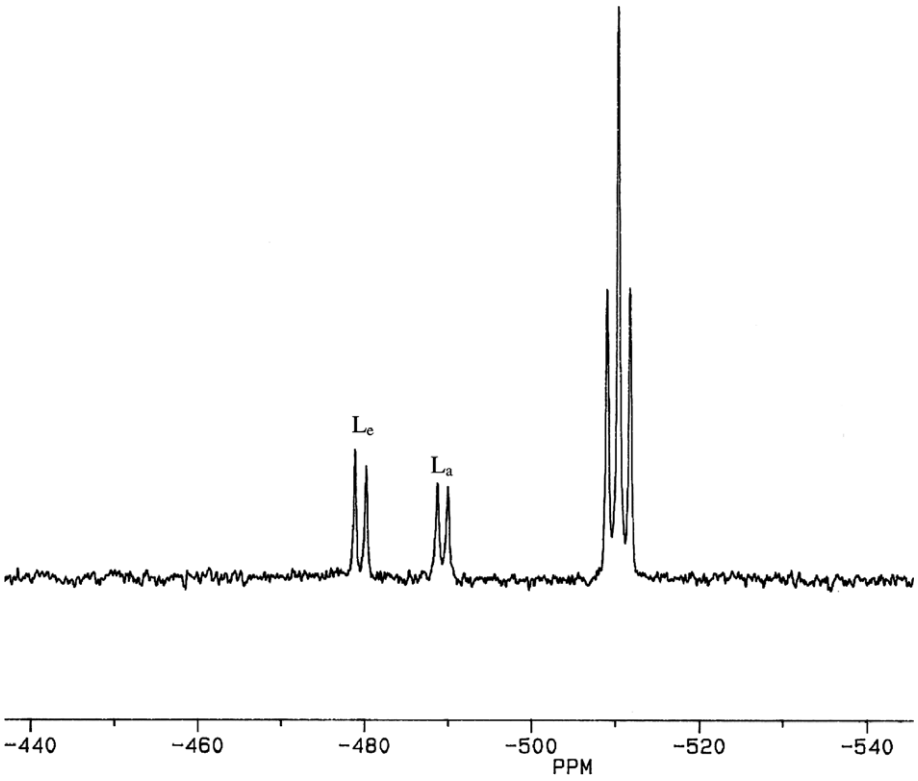

Fig. 3. ^{119}Sn NMR spectrum of the complex $SnCl_4 \cdot 2(O)PF_2NEt_2$in CD_2Cl_2 at −85 °C (L_a and L_e: ligands in axial and equatorial positions respectively).

free ligand, which we assign to $SnCl_4 \cdot L$. This assignment is supported by the presence of a doublet pattern in the ^{119}Sn NMR spectrum (10% relative intensity) (see Fig. 3).

This result suggests that the 1:1 complex is in equilibrium with the 1:2 complex and is detectable at −85 °C in significant concentration. Such an equilibrium was observed by Denmark et al. [21], sometimes referred to as partial dissociation of the type:

$$SnCl_4 \cdot 2L \rightleftharpoons SnCl_4 \cdot L + L$$

In solution, complexes of the general formula $SnCl_4 \cdot 2L$ exist as a mixture of both *cis* and *trans* isomers [22]. By correlating the IR and Raman data of the complex $SnCl_4 \cdot 2(HMPA)$ with ^{1}H and ^{31}P NMR studies, Ruzicka and Merbach [8] have shown that the coupling constants $^2J_{31P-119Sn}$ were different for *cis* and *trans* isomers in the complexes of $SnCl_4$ with $(MeO)_3PO$ (TMPA) and $Me_2N(MeO)_2PO$. At 203 K, the cis isomers of the two complexes had $^2J(^{31}P-^{119}Sn)$ of 146 and 141 Hz respectively, and those for the *trans* isomers were 195 and 194 Hz respectively, whereas coupling constants of 102 and 168 Hz at 183 K were observed for the *cis* and *trans* complexes of $SnCl_4 \cdot 2HMPA$ [9], respectively. These results are in agreement with the coupling constants of 126 and 192 Hz observed for $SnCl_4 \cdot 2(O)PF(NMe_2)_2$ at 268 K in our previous work [12] (see Table 2).

By comparing the coupling constants, the isomers of the complexes in Table 2 could be assigned by analogy, i.e., all of the complexes which have smaller $^2J(^{31}P-^{119}Sn)$ coupling constants could be assigned to the *cis* isomers and those with larger $^2J(^{31}P-^{119}Sn)$ coupling constants could be assigned to the *trans* ones. It is therefore possible to assign the only triplet observed in the ^{119}Sn NMR spectra of the complexes $SnCl_4 \cdot 2(O)PF_2NR_2$ at 198 K to the *cis* isomer ($^2J(^{31}P-^{119}Sn) = 145$ Hz for R = Me and 150 Hz for R = Et).

Table 2
^{119}Sn NMR data[a] of the complexes $SnCl_4 \cdot 2L$ in dichloromethane

Ligand (L)	$\delta_{^{119}Sn}$		$^2J_{P-Sn}$		% *Cis*[e]
	Cis	*Trans*	*Cis*	*Trans*	
$(Me_2N)_3P(O)$[b]	−569	−580	120	191	50
$(Me_2N)_2P(O)F$[c]	−548	−567	126	192	80
$Me_2NP(O)F_2$[d]	−507	–	145	–	100

[a] Measured at slow exchange where triplets are observed.
[b] At 25 °C.
[c] −5 °C.
[d] −75 °C.
[e] The approximate percentage of the cis isomer measured from ^{119}Sn NMR signals.

The two doublets observed in the five coordinate adduct region of the ^{119}Sn NMR spectrum at −85 °C (Fig. 3) presumably correspond to the two possible trigonal bipyramidal isomers. The chemical shifts and the magnitude of the couplings suggest that the downfield doublet at −479 ppm ($^2J(^{31}P-^{119}Sn) = 148$ Hz) is due to the equatorial isomer while the upfield doublet at −489 ppm ($^2J(^{31}P-^{119}Sn) = 140$ Hz) is due to axial phosphorus [23,24].

3.3. Theoretical calculations

Due to difficulties in obtaining crystals suitable for X-ray analysis, the geometries of the *cis* and *trans* isomers of **1** were optimised by means of the DFT/B3LYP method in order to confirm the NMR data obtained for the two complexes prepared. The optimised structure of the *cis* isomer is shown in Fig. 4. The *cis* and *trans* isomers of complex **1** and its ligand have been identified as local minima on the singlet potential energy surfaces (PES). Optimised values of selected geometrical parameters are listed in Table 3. The potential energy difference between the two isomers of **1** was 2 kcal mol^{-1}. This difference indicates that the Boltzmann population of the *cis* adduct corresponds to practically 100%. This is in good agreement with the experimental NMR data.

The value of the Sn–O distance, 2.228 Å, as well as the other bond distances and angles are in good agreement with the values reported for similar molecules using X-ray diffraction [7,9,25]. Interestingly, the P–O distance of 1.491 Å is identical to that of 1.49 obtained by the crystal structure for the HMPA complex [7].

In complex **1**, the coordination mode is confirmed by a lengthening of the P=O bond compared to that of the free ligand (1.467 Å) calculated at the same level of theory. This lengthening is consistent with the low stretching frequency observed in the IR spectra and may also explain the differences observed in the ^{31}P NMR chemical shifts between the free and bound ligands in solution. On forming complex **1** the ligand also shows a shortening of both the P–F and P–N bond distances by about 0.02 Å. This is accompanied by an increase in the bond angles at the phosphorus atom, i.e., the F–P–F and F–P–N angles are increased by 1.3° and 2.6° respectively compared to those of the free ligand (see Table 3).

The changes in bond distances are supported, in solution, by an observed increase in the $^{1}J_{P-F}$ coupling constant

Table 3
Selected B3LYP-optimized geometrical parameters[a] for complex **1** and its ligand

	Ligand	*Cis*	*Trans*

[a] See Fig. 4 for labelling of the atoms. Distances are in Å and angles in °.

value found in the complex compared with that in the free ligand. Comparable changes in geometry, i.e., shortened bonds and increased angles at the phosphorus atom, have been observed in related complexes [26,27].

It is worth noting that the longer Sn–O distance (2.25 versus 2.13 Å in the HMPA complex) and sharper Sn–O–P bond angles (139 versus 165° in the HMPA complex) in complex **1** probably reflect the effect of the substitution of two dimethylamino groups in HMPA by two fluorine atoms. The substantially longer Sn–O distance in complex **1** strongly suggests a weaker coordination of $Me_2NP(O)F_2$

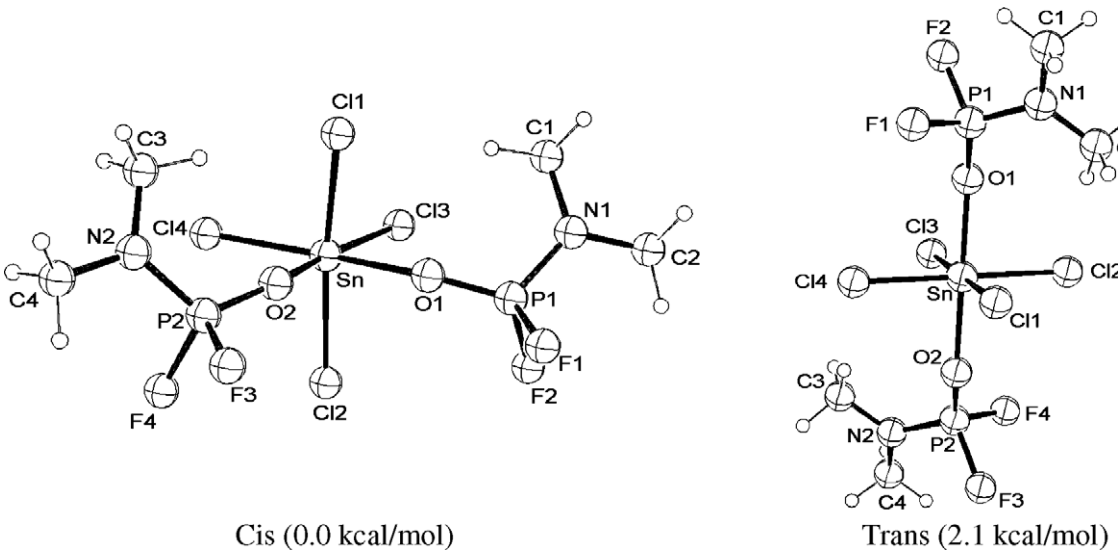

Fig. 4. DFT/B3LYP optimised structures and relative energies of *cis* and *trans* isomers of complex **1**.

compared to HMPA with $SnCl_4$, consistent with the experimental NMR data (see Table 2).

4. Conclusion

On the basis of the above results, the NMR data suggest the presence of only the *cis* geometry for the complexes $SnCl_4 \cdot 2(O)PF_2NR_2$ in dichloromethane solution within the temperature range studied. This could be explained in terms of a decrease both in the Lewis base character of the P=O group of the ligand $(O)PF_2NR_2$ and in its bulkiness compared with HMPA as a result of the substitution of two dialkylamino groups in the ligand $(R_2N)_3P(O)$ by two fluorine atoms. Our results are in good agreement with those reported by Smith and Wilkins [28] and Drago [29] who showed that in $SnX_4 \cdot 2L$ octahedral adducts the overlap of tin(IV) 5s, 5p and 5d orbitals depends on the positive charge on tin(IV). In our case, the presence of two fluorine atoms in the ligands renders the electronegativity of the donor atom of the ligand comparable to that of each of the four chlorine atoms on tin. This leads to a possible sp^3d^2 hybridisation and the molecule adopts the configuration which minimises the splitting between the $d_{x^2-y^2}$ and d_{z^2} orbitals, namely the *cis* one. The results further confirm the fact that the less bulky the ligand the more important the ratio of the *cis* isomer [30] (see Table 2). The NMR data also indicate that steric effects and/or the Lewis basicity of the ligand contribute to the equilibrium between hexacoordinate and pentacoordinate complexes. We have also shown that DFT calculations are a useful supporting tool for such a study since a combination of empirical and theoretical studies can, in favourable cases, overcome the limitations of each.

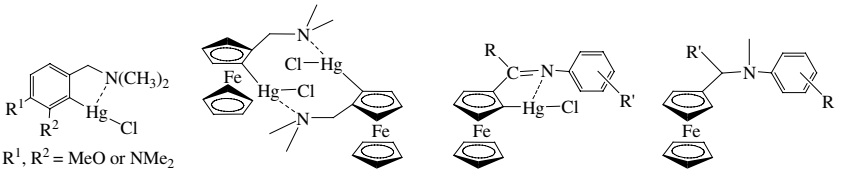
molecules. Very recently, we described the synthesis of *tertiary* aromatic ferrocenylamines **4** by methylation of ferrocenylimines [9a] or secondary ferrocenylamines [9b]. In this paper, we wish to report the synthesis and characterization of their *ortho*-mercurated complexes ($R' = H$). In addition, their transpalladation and the influence of the structural factors of substrates on the product distributions and aggregations will also be discussed. As far as we know it is the first reported example of *ortho*-mercurated aromatic ferrocenylamines.



2. Results and discussion

2.1. Ortho-mercuration of ferrocenylamines *4*

The reactions of ferrocenylamines **4** ($R' = H$) and an equivalent amount of mercury (II) acetate were carried out in methanol at room temperature (Scheme 1) and the reactions progress were monitored by TLC. After the reactions were completed, 1.5 equivalent of lithium chloride was added and the mixtures were stirred for 30 min. Removal of solvent yielded residues which were purified by column chromatography (silica gel, ethyl acetate/hexane = 1:1, v/v) to afford *ortho*-mercurated ferrocenylamines **6** and the 1,1′-disubstituted ferrocene derivative **7**. Complexes **6** and **7** are stable in air, and are soluble in most of organic solvents, but poorly soluble in hexane.

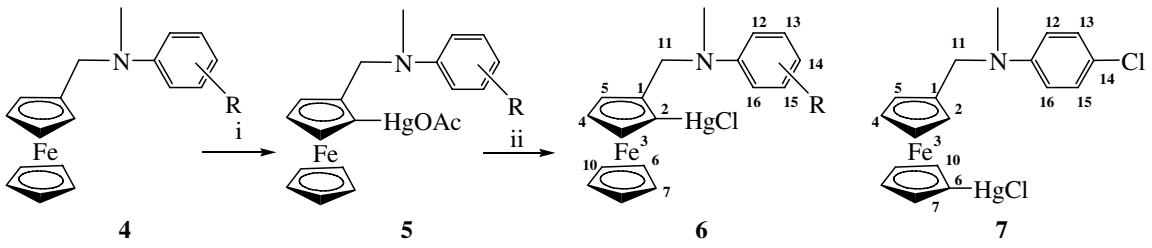
Experimental results show that the character of the substituents on the phenyl ring will play an important role in governing product distributions. For example, mercuration of ferrocenylamines bearing electron-donating groups (**4a**, **b**) normally give **6a** (**b**) in higher yields ($\geqslant$62%), whereas for mercuration of ferrocenylamines bearing electron-withdrawing groups (**4d**, **f**), the yields of **6d** (**f**) are lower ($\leqslant$ 58%). When ([*N*-methyl-*N*-4-nitrophenylamino]methyl)ferrocene is treated with mercury (II) acetate, the expected *ortho*-mercurated product is not isolated.

2.2. Spectra characterization of *6a–f, 7*

Complexes **6** and **7** were characterized by elemental analysis, IR and ^{1}H NMR. Elemental analyses for **6** and **7** are in good agreement with the proposed formula. In the IR spectra of **6**, the presence of two medium absorption bands, ν 1100 and 1000 cm^{-1}, confirms that they all have an unsubstituted cyclopentadienyl (Cp) ring [10]. On the contrary, such absorptions in **7** are absent. In the ^{1}H NMR spectra of **6**, a singlet appearing at δ 4.20 ppm corresponds to the unsubstituted Cp ring, two doublets approximately at δ 4.10 ppm are assigned to H3 and H5, respectively, and a multiplet appearing at δ 4.40 ppm is attributed to H4. In all cases the chemical shifts of H11 are overlapped with those of H4. In addition, the protons in the phenyl rings also give their corresponding splitting patterns.

2.3. N–Hg intermolecular vs intramolecular coordination

The crystal structure of **6a** (Fig. 1) demonstrates that the crystal consists of two unsymmetric molecular units. The distance Hg1–N2 2.927(1) Å is shorter than the sum of their van der Waals radii (3.00–3.23 Å) [11a], indicating that an intermolecular N–Hg coordination is present in this molecule. However, such coordination between Hg2 and N1 is absent. In the crystal structure of **6e** (Fig. 2), although the crystal consists of a monomer, the intermolecular N–Hg coordination (N1B–Hg1A 3.863(1) Å) is still present (Fig. 3). In addition, in these two crystals, a 10 membered ring, like in **2**, is not formed. All these results are partially consistence with Jacob's observation [1f]. The intermolecular N–Hg distance in **6a** is slightly longer than that in **6e**, but the intramolecular N–Hg distances in **6a**, **e** (4.125(1) Å, 4.100(1) Å, respectively) are nearly same and they all are significantly longer than the sum of their



Scheme 1. (i) $Hg(CH_3CO_2)_2$, methanol and (ii) LiCl, methanol. R = 4-MeO (a), 4-Me (b), H (c), 4-Cl (d), 3-Cl (e), and 3-NO_2 (f).

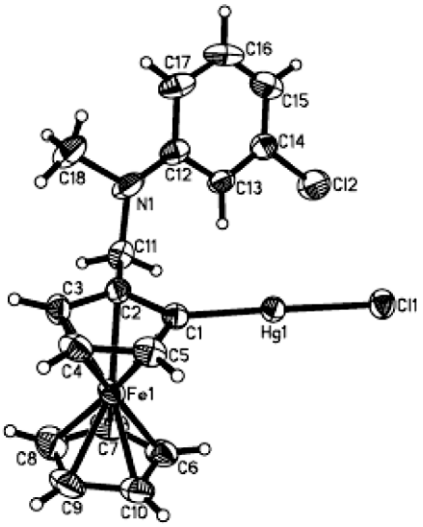

Fig. 2. Molecular structure of **6e** with the numbering scheme.

van der Waals radii [11a], suggesting that an N–Hg intramolecular coordination pattern is absent in these crystals. Therefore, we believe that the character of the substituents

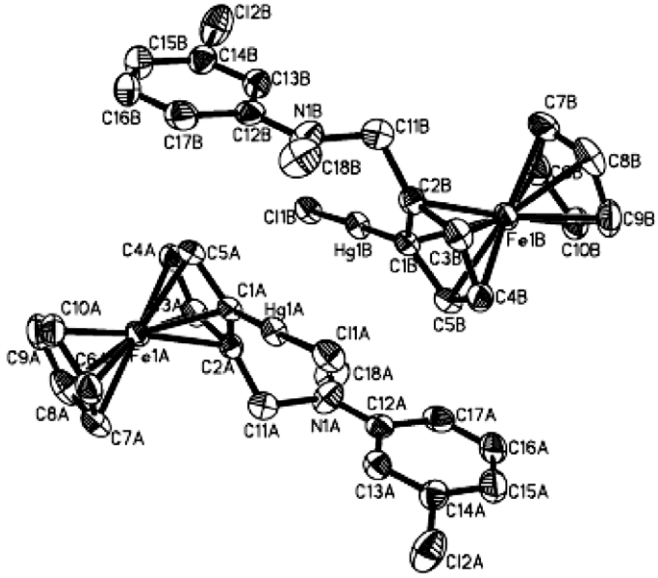

Fig. 3. Intermolecular N(1B)···Hg(1A) interaction pattern for compound **6e** (H atoms are omitted for clarity).

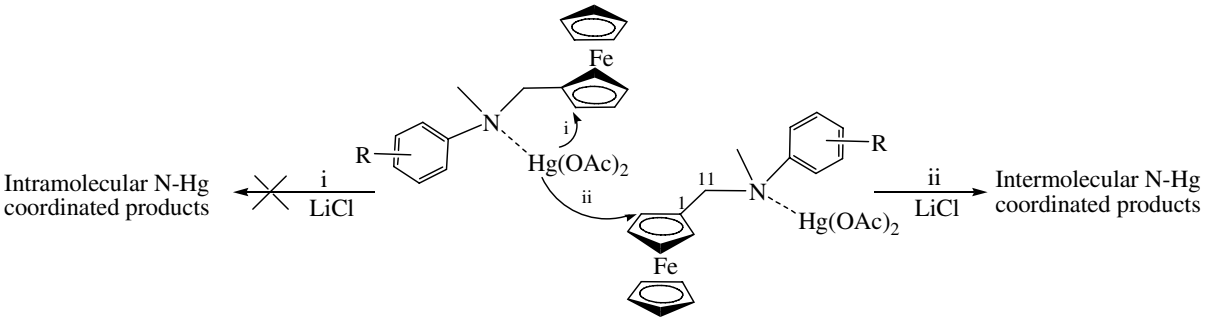
on the phenyl rings only increases or reduces the coordination ability of the N atom with Hg, but does not alter the type of N–Hg coordination (intermolecular *vs* intramolecular). Structurally, **4a**–**f** are more like FcN than ferrocenylimines, therefore, the possible mechanism for the formation of **6** is depicted as in Scheme 2.

According to the principle of *ortho*-metallation, initial coordination of the metal with the hetero atom is necessary, and then following is activation of its adjacent C–H bonds. As shown in Scheme 2, the coordinated N–Hg moiety can activate C–H bonds not only through path i (N–Hg intramolecular coordination) but also through path ii (N–Hg intermolecular coordination). However, the preference of intermolecular over intramolecular N–Hg coordination in our case is always observed. This is probably because (1) the N–Hg coordination is a non-covalent weak interaction, which is not sufficient to keep the rigid five member ring (path i) more stable than the corresponding palladocycles [12], and this weak coordination is supported by the molecular structure of **7** (Fig. 4), which is formed by the attack of free mercury (*i.e.*, without coordination with an N atom) on the unsubstituted Cp ring; (2) unlike the ferrocenylimines, their



Scheme 2. Possible mechanism for the formation of **6**, path i, intramolecular activation; path ii, intermolecular activation.

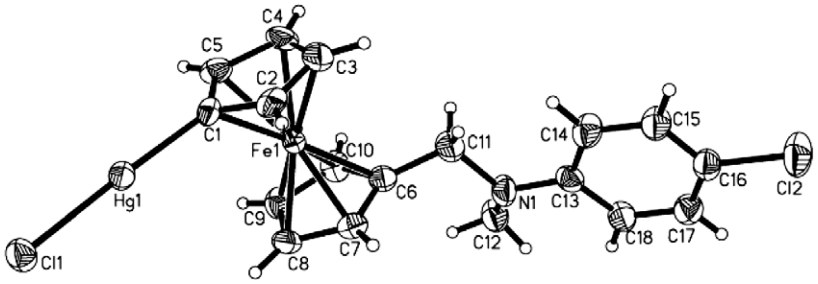


Fig. 4. Molecular structure of **7** with the numbering scheme.

imino groups are coplanar with the substituted Cp rings [8], the (*N*-methyl-*N*-phenyl)amino groups in **4** lie above the substituted Cp rings [9], thus the N–Hg coordinated intermediates adapting a similar conformation will disfavor the activation of the intramolecular C–H bond (path i). However, this conformation will enable the intermediates (Scheme 2) to activate the intermolecular C–H bonds with a minimum energy and hence produce a flexible zigzag link (path ii). This hypothesis is supported by the fact that both **6** and **4** keep a similar conformation (the torsion angle C2–C21–N1–C23 (69.5(5)°) in **6a** is the same as that in **4a** (70.0(3)°) [9b]. In addition, dimer complexes with a 10 membered ring are also excluded because their formation needs the N–Hg moiety in one intermediate to rotate around the axis of the C1–C11 bond and subsequently activate the intermolecular *ortho* C–H bond in another intermediate, and this rotation is probably retarded due to steric hindrance between the phenyl and the hydrogen in the Cp ring [12].

2.4. Crystal structures of *6a, e, and 7*

The molecular structures of **6a**, **e**, and **7** were determined by X-ray single crystal diffraction (Figs. 1, 2, and 4). The intermolecular N–Hg coordination pattern in **6e** is presented in Fig. 3. Crystal parameters and data collection for **6a**, **e** and **7** are summarized in Table 1. Their selected bond lengths and angles are listed in Tables 2 and 3, respectively.

Figs. 1 and 2 demonstrate that chloromercurio units in **6a** and **e** are connected directly to the *ortho* position of the amino group, whereas in **7** it is connected to the second Cp ring (Fig. 4). The Hg1–Cl bond lengths in **6a**, **e**, and **7** (2.043(4), 2.044(2), and 2.045(4) Å, respectively) are nearly the same and are in the normal range. The distance Fe–Hg 3.607(1) Å in **7** is nearly equal to the sum of the constituent van der Waals radii (3.55 Å) [11a], indicating that a weak Fe–Hg interaction is present. However, such an interaction in **6a** and **e** is absent. The Cl1–Hg1–C1 bond angles in **6a**, **e**, and **7** (176.2(2), 177.9(2), and 178.0(3)°, respectively) are closer to the ideal value of 180° in organic derivatives of mercury. The dihedral angle Cl1–Hg1–C1–C2 (−180(6)°) in **6e** means that the chloromercurio unit is coplanar with the substituted Cp ring. However, the Cl1 atom in **7** is pocketed between two paralleled Cp rings. The angle between the chloromercurio unit and the substituted Cp ring is 75.9(1)°, implying that they are nearly perpendicular to each other. In Fig. 1, the dihedral angle between the substituted Cp ring and the intramolecular phenyl

ring is 56.8(1)°, the dihedral angle between the intermolecular two phenyl rings is 72.0(1)°. In addition, the two pentagonal rings of the ferrocenyl moiety in **6a**, **e**, and **7** are planar and nearly parallel (interplanar angles 1.1, 2.2, and 0.9°, respectively). In addition, the Cp rings are also nearly eclipsed.

*2.5. Transpalladation via **6** and disodium tetrachloropalladate (II)*

In order to assess the properties of **6a**–**f**, their transpalladation reactions *via* disodium tetrachloropalladate (II) were carried out in methanol at room temperature. However, most of the palladium (II) was reduced to palladium (0) black by **6a**–**f**, and the yields of the isolated cyclopalladated complexes **8** were much lower (⩽20%) than that of the cyclopalladated ({*N*-methyl-*N*-benzylamino}methyl)ferrocenes. Direct cyclopalladation of **4a**–**f** gave similar results [12]. It is believe that intermolecular N–Hg coordination may account for such low yields of the cyclopalladated complexes see Scheme 3.

3. Experimental

3.1. Materials and instruments

Ferrocenylamines were prepared according to the literature procedure [9b], disodium tetrachloropalladate (II) was prepared in our laboratory. Mercury (II) acetate, lithium chloride and triphenylphosphine were obtained commercially and used without further purification. All of the solvents were purified with standard methods prior to use. Melting points were obtained from Yanaco micro melting point apparatus and were uncorrected. Elemental analyses were measured on a Carlo Erba 1106 Elemental analyzer. ^{1}H NMR spectra were obtained with a Bruker AV-400 spectrometer using $CDCl_3$ as the solvent and TMS as internal standard. IR spectra were taken on a BIO-RAD 3000 spectrophotometer.

Scheme 3. (i) Na_2PdCl_4, methanol, room temperature and (ii) PPh_3, methanol. R = 4-MeO (a), 4-Me (b), H (c), 4-Cl (d), 3-Cl (e), and 3-NO_2 (f).

*3.2. Preparation of [(η^5-C_5H_5)Fe(η^5-C_5H_3(HgCl)CH_2N-(CH_3)C_6H_4-R)] (**6**) and [(η^5-C_5H_4HgCl)Fe-(η^5-$C_5H_4CH_2N(CH_3)$-C_6H_4–Cl-4)] (**7**)*

General procedure. To a stirred solution of the ferrocenylamines (**4**) (5 mmol) in methanol (20 ml) and dichloromethane (5 ml), was added dropwise a solution of mercury (II) acetate (5 mmol) in sufficient methanol. The reactions were monitored by TLC until they were complete. A solution of lithium chloride (7.5 mmol) in methanol was then added and the mixtures were stirred for 30 min. The solvent was removed and the residues were extracted with dichloromethane (3 × 30 ml), the organic layer was dried over anhydrous sodium sulfate and evaporated under reduce pressure to give the crude products which were purified by chromatography (silica gel, ethyl acetate/hexane = 1:1, v/v), the second band eluted was collected, the solvent was removed *in vacuo* to give **6** as yellow powders.

IR (KBr): 3091, 2933, 2890, 1594, 1495, 1251, 1188, 1102, 987, 820, 795, 483 cm^{-1}. ^1H NMR: δ 2.90 (s, 3H, N-CH_3), 4.07 (d, 1H, H3), 4.11 (d, 1H, H5), 4.25 (s, 5H, η-C_5H_5), 4.40 (m, 3H, H4, H11), 6.78 (m, 3H, H12, H13, H14), 7.18 (t, 1H, H16) ppm.

*3.2.6. [(η^5-C_5H_5)Fe(η^5-C_5H_3(HgCl)CH_2N(CH_3)C_6H_4–NO_2-3)] (**6f**)*

Yellow solid. Yield 58%; m.p. 176 °C (dec.). *Anal.* Calc. for $C_{18}H_{17}ClFeHgN_2O_2$: C, 36.94; H, 2.93; N, 4.79. Found: C, 36.70, H, 3.02, N, 4.70%. IR (KBr): 3087, 2922, 1524, 1454, 1343, 1252, 1103, 734, 483 cm^{-1}. ^1H NMR: δ 2.92 (s, 3H, N-CH_3), 4.10 (d, 1H, H3), 4.12 (d, 1H, H5), 4.24 (s, 5H, η-C_5H_5), 4.41 (m, 3H, H4, 11), 6.97–7.57 (m, 4H, H12, H13, H14, H16) ppm.

*3.2.7. [(η^5-C_5H_4HgCl)Fe(η^5-$C_5H_4CH_2N(CH_3)$-C_6H_4–Cl-4)] (**7**)*

In the reaction of **4d** with mercury (II) acetate, the third band eluted was also collected and **7** was isolated as yellow powder. Yield 15%; m.p. 146 °C (dec.). *Anal.* Calc. for $C_{18}H_{17}Cl_2FeHgN$: C, 37.62; H, 2.98; N, 2.44. Found: C, 37.50; H, 2.84; N, 2.42%. IR (KBr): 3087, 2937, 1595, 1496, 1245, 809, 730, 486 cm^{-1}. ^1H NMR: ^1H–NMR: δ 2.70 (s, 3H, *N*-CH_3), 3.92 (d, 2H, H7, H10), 4.04 (m, 4H, H2, H5, H8, H9), 4.16 (d, 2H, H3, H4), 4.23 (s, 2H, H11), 6.58–7.00 (q, 4H, H12, H13, H15, H16) ppm.

3.3. Transpalladation of **6a–f** via disodium tetrachloropalladate (II)

To stirred solutions of **6** (2 mmol) in methanol (20 ml), was added dropwise a methanol solution (30 ml) of disodium tetrachloropalladate (II) (2 mmol) at room temperature over 1 h. The reactions progress were monitored by TLC until they were complete, then triphenylphosphine was added. The mixtures were filtered and the solvent was removed *in vacuo*. The residues were purified by column chromatography (silica gel, ethyl acetate/hexane = 3:1, v/v) to give **8** as red–purple solids. The yields of **8a–f** were 20%, 20%, 17%, 14%, 18%, and 10%, respectively. Their IR and NMR spectra were the same as the authentic samples [12].

3.4. Crystal structure determination for **6a, e, and 7**

Prismatic single crystals of **6a**, **e**, and **7** suitable for X-ray analysis were obtained by slow evaporation of a mixture of ethyl acetate and hexane at room temperature over a period of one week. The single crystals of **6a**, **e**, and **7** were mounted on a Bruker SMART CCD diffractometer equipped with graphite monochromated Mo Kα (λ = 0.71073 Å) radiation at ambient temperature (T = 294 K) using the ω-2θ multi-scans technique with the ranges $1.76° \leqslant \theta \leqslant 26.03°$ (**6a**), $1.83° \leqslant \theta \leqslant 26.32°$ (**6e**), and $1.00° \leqslant \theta \leqslant 26.59°$ (**7**) for data collection. Semi-empirical absorption corrections were applied using the SABABS program [13]. The structures were solved by direct methods and refined by full-matrix least-squares procedures on F^2 using the SHELX suite of programs [14]. The values of R_1 were given based on F_o with a typical threshold of $F^2 \geqslant 2\sigma(F^2)$. The weighted R-factors wR were based on F^2 with $w = 1/[\sigma^2(F_o^2) + (0.0265P)^2 + 0.0000P]$ where $P = (F_o^2 + 2F_c^2)/3$ for **6a**, $w = 1/[\sigma^2(F_o^2) + (0.0265P)^2 + 0.0000P]$ where $P = (F_o^2 + 2F_c^2)/3$ for **7**. Crystallographic data for **6a**, **e**, and **7** are summarized in Table 1. Selected bond lengths and angles for **6e**, **7** are presented in Tables 2 and 3, respectively.

4. Supplementary materials

Crystallographic data (excluding structure factors) for the structures of **6a**, **e**, and **7** in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication numbers CCDC 290135, 275037, and 275036. Copies of the data can be obtained, free of charge, on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44 1223 336033 or e-mail: deposit@ccdc.cam.ac.uk).

Acknowledgements

We are grateful to the Natural Scientific Foundation of Tianjin Metropolitan, People's Republic of China for their generous support for this project (Project No. 033609011), the Opening Fund from The State Key Laboratory of Elemento-organic Chemistry, Nankai University, People's Republic of China is also acknowledged.

containing a tridentate Schiff base (SAA) and a monodentate ligand (ImH)/bidentate ligands (bipy, phen). The single crystal X-ray analysis of complex **1** has revealed the presence of a distorted square planar geometry and complex **2** has a distorted square pyramidal geometry.

2. Experimental

2.1. Materials and methods

$CuCl_2 \cdot 2H_2O$, $CuSO_4 \cdot 5H_2O$, KOH, 1,10-phenanthroline, 2,2′-bipyridine, imidazole, MeOH, MeCN (S.D. Fine Chemicals) were used as purchased. The Schiff base was synthesized by reacting salicylaldehyde and anthranilic acid in an equimolar ratio at room temperature in methanol. Elemental analyses were performed on an elemental analyzer. FAB mass spectra were recorded on JEOL SX 102/DA 6000 mass spectrometer using xenon (6 kV, 10 mA) as the FAB gas. The magnetic susceptibility data were recorded on a Gouy balance at room temperature using mercury(II) tetrathiocyanato cobaltate(II) ($\chi_g = 16.44 \times 10^{-6}$ cgs unit) as the calibrant. The e.p.r. spectra were recorded at RT and also at LNT (77 K) on a Varian E-line Century Series EPR spectrometer operating at 9.4 GHz with TCNE as a calibrant. The e.p.r. parameters were measured using a reported method [21]. UV–Vis spectra were recorded on a Shimadzu UV–Vis 160 spectrophotometer in quartz cells. A BAS-100 Epsilon electrochemical analyzer was used for cyclic voltammetric experiments in a DMSO solution of the complex containing tetrabutylammonium perchlorate (TBAP) as the supporting electrolyte. The three electrode measurement was carried out at 298 K under a nitrogen atmosphere with a platinum working electrode, a platinum wire auxiliary electrode and a silver/silver chloride reference electrode (Ag/AgCl). The SOD activities were evaluated using alkaline DMSO as a source of superoxide radicals (O_2^-) and nitrobluetetrazolium chloride (NBT) as scavenger [18].

2.2. Synthesis of the complexes

2.2.1. Synthesis of [Cu(SAA)(ImH)] (1), [Cu(SAA)(bipy)]CH_3CN (2) and [Cu(SAA)(phen)] (3)

All the present complexes were synthesized following the same general procedure. To a MeOH solution (10 ml) of $CuCl_2 \cdot 2H_2O$ (1.0 mmol, 0.170 g) a solution of the potassium salt of the Schiff base (1 mmol, 0.240 g) was added and the reaction mixture was stirred for 30 min at 25 °C. To the above reaction mixture, a MeOH solution (10 ml) of ImH (1 mmol, 0.078 g) was added and the stirring was continued for 30 min more. The precipitate was separated by filtration and was dissolved in MeOH:MeCN (1:2 V/V) for recrystallization. After 2–3 days of slow evaporation of the reaction mixture, dark green prismatic crystals were

2.3. Crystal structure determination

Crystals suitable for single crystal X-ray analysis for complexes [Cu(SAA)(ImH)] (**1**) and [Cu(SAA)(bipy)]-CH_3CN (**2**) were grown by slow evaporation of the reaction mixture at room temperature. Single crystals suitable for single crystal X-ray of **1** and **2** were mounted on a glass fiber and used for data collection (Table 1). Crystal data were collected on an Enraf-Nonius $MACH_3$ diffractometer using graphite monochromatized Mo Kα radiation ($\lambda = 0.71073$Å). The crystal orientation, cell refinement and intensity measurements were made using the program CAD-4PC performing psi-scan measurements. The structure was solved by the direct method using the program SHELXS-97 [22] and refined by full-matrix least-squares techniques against F^2 using SHELXL-97 [23]. All non-hydrogen atoms were refined anisotropically. All the hydrogen atoms were geometrically fixed and allowed to refine using a riding model.

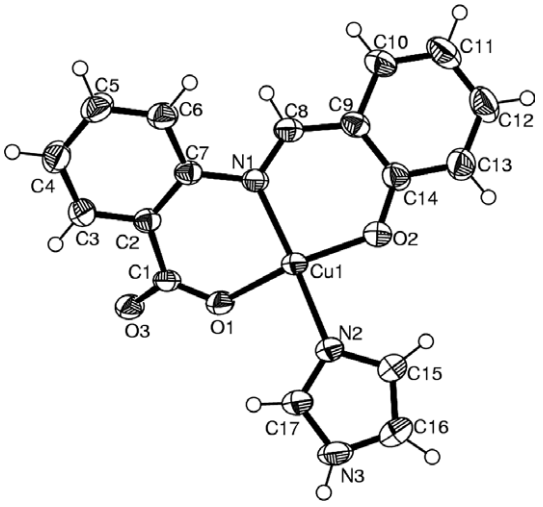

Fig. 1. ORTEP diagram of the complex [Cu(SAA)(ImH)] (**1**).

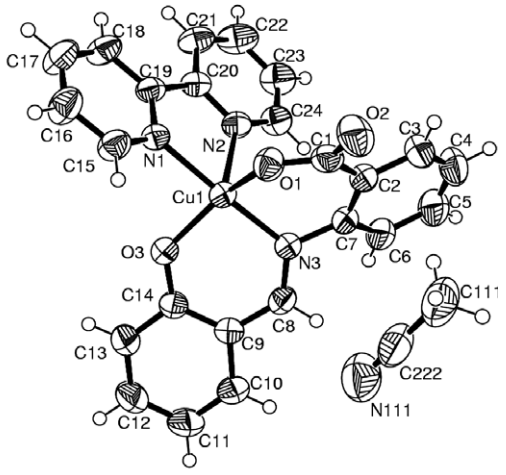

Fig. 2. ORTEP diagram of the complex [Cu(SAA)(bipy)]CH_3CN (**2**).

3. Results and discussion

All the reported complexes were synthesized by the following sequential routes:

$$L' + [Cu(H_2O)_6]^{2+} \xrightarrow{\text{Basic medium}} [Cu(L')H_2O] \quad (1)$$

$$[Cu(L')H_2O] + L'' \rightarrow [Cu(L')(L'')] + H_2O \quad (2)$$

where $L' = SAA$, $L'' = ImH/bipy/phen$.

The synthesized complexes were characterized by using different physio-chemical techniques.

3.1. Crystal structure

Complexes **1** and **2** have been characterized by the single crystal X-ray diffraction technique. The ORTEP views of the complexes are shown in Figs. 1 and 2. Crystallographic data, selected bond angles and distances are given in Tables 1–3. The crystal structures of the complexes reveals the presence of ternary copper(II) structures consisting of a tridentate ONO- donor Schiff base, a monodentate ligand (N-donor) or a bidentate ligand (NN-donor) and a copper (II) center in the discrete monomeric species. Complex **1** crystallizes in the orthorhombic system. The structure of complex **1** was solved in $Pna2_1$ space group, whereas **2** crystallizes in the triclinic $P\bar{1}$ space group. Complex **1** has a distorted square-planar geometry. The coordination geometry is distorted from square planar, as ascertained by the observed τ value of 0.13 (the structure index is defined as $\tau = (\beta - \alpha)/60$, where α and β are the largest coordination angles), such a square planar geometry was observed in a similar copper(II) complexes [24,25]. In these complexes the values of τ lie in the range 0.05–0.17. Complex **2** has a distorted square pyramidal (4 + 1) geometry, the distortion ($\tau = 0.59$) from square-pyramidal geometry was again ascertained by τ values; for a perfect square pyramidal geometry the τ value should be 0 [26]. The largest distortions from the square pyramidal geometry are indicated by the O(3)–Cu(1)–O(1) = 142.59(6)° and C(1)–O(1)–Cu(1) = 127.18(12)° angles. Similar copper(II) complexes, having distorted square planar geometries, have also been reported by Reddy et al. [2]. In both structures

the Schiff base ligand occupies the basal plane. The ONO donor Schiff base forms a three membered chelate ring and it occupies the basal plane with a bond length of ~1.9 Å which is close to ~1.9 Å [2]. In complex **2**, the NN-donor atoms of bipy display an axial-equatorial binding mode with bond distances Cu(1)–N(2) = 2.2259(16), Cu(1)–N(1) = 2.0162(14) Å which is again close to ~2 Å [2].

3.2. Magnetic measurements

The magnetic susceptibility measurements in the solid state show that the present complexes are paramagnetic at ambient temperature. The observed magnetic moment values (1.79 ± 0.01 BM) are quite close to the values expected for copper(II) complexes and is in fair agreement with the spin system $S = 1/2$. The magnetic moment (μ_{eff}) lies within the range normally found for other copper(II) complexes [27,28].

3.3. E.p.r. investigation

X-band e.p.r. spectra of the complexes were recorded in the polycrystalline state and also in 100% DMSO solution.

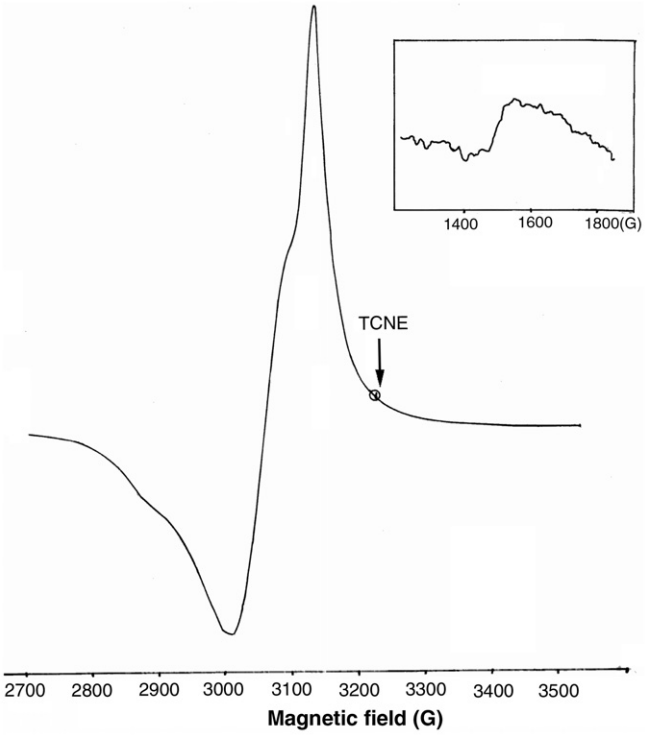

Fig. 3. Polycrystalline e.p.r. spectrum (room temperature) of [Cu(SAA)(phen)] (**3**).

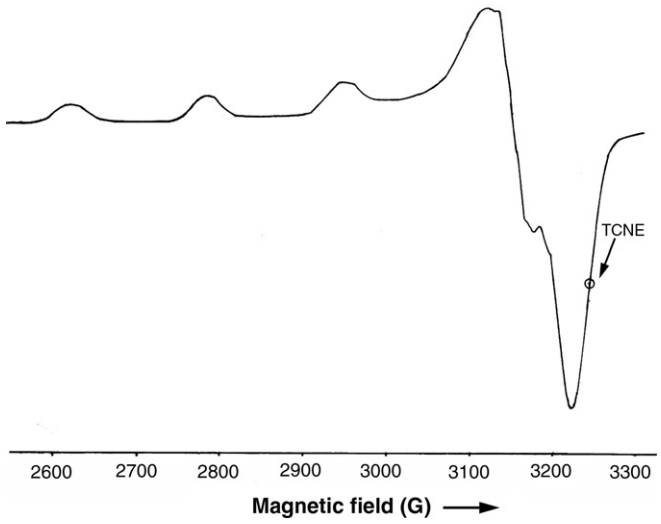

Fig. 4. E.p.r. spectrum (liquid nitrogen temperature) in 100% DMSO of [Cu(SAA)(ImH)] (**1**).

Some representative figures are shown in Figs. 3 and 4. The e.p.r. spectral parameters derived from their respective spectra are presented in Tables 4 and 5.

3.3.1. Solid state e.p.r. spectra

The e.p.r. spectra of polycrystalline samples show similar features at room temperature (RT) and at liquid nitrogen temperature (LNT). Basic spectral features at both

Table 4
E.p.r. parameters of polycrystalline samples (RT)

Complex	g_1	g_2	g_3	g_{av}
[Cu(SAA)(ImH)] (**1**)	2.049	2.110	2.237	2.132
[Cu(SAA)(bipy)] CH_3CN (**2**)	2.059	2.116	2.250	2.141
[Cu(SAA)(phen)] (**3**)	2.063	2.111	2.246	2.140

Table 5
E.p.r. parameters of frozen solution (77 K)

Complex	$g_\parallel$	$g_\perp$	$A_\parallel$ (G)	g_{av}
[Cu(SAA)(ImH)] (**1**)	2.224	2.057	165	2.140
[Cu(SAA)(bipy)] CH_3CN (**2**)	2.224	2.060	171	2.142
[Cu(SAA)(phen)] (**3**)	2.231	2.074	185	2.152

temperatures are the same with slightly better resolution at LNT. The e.p.r. spectra of the present complexes are indicative of a $S = 1/2$ system. $\Delta M_s = \pm 2$ signal (half-field signal) is observed in the e.p.r. spectra of the polycrystalline samples. The half field signal is due to interactions between the complexes in the pure solid. However, the nature of the interaction is intermolecular, which is confirmed by e.p.r. observations in solutions where the interaction is lost. The spectra of the present complexes at room temperature in the polycrystalline state show rhombic features with three g-tensor values viz. g_1, g_2 and g_3 where $g_3 > g_2 > g_1$. It is observed that the g_3 values for complexes are higher than 2.3 and assign covalent character to the M–L bonds [29].

In the spectra with $g_3 > g_2 > g_1$, the rhombic spectral values $R = (g_2 - g_1)/(g_3 - g_2)$ may be significant, if $R > 1$, a predominant d_{z^2} ground state is present. If $R < 1$, a predominant $d_{x^2-y^2}$ ground state is present and when $R = 1$, then the ground state is approximately an equal mixture of d_{z^2} and $d_{x^2-y^2}$, and the structure is intermediate between square planar and trigonal bipyramidal geometries. All the present complexes have values $R < 1$ (0.484 for **1**, 0.423 for **2** and 0.351 for **3**) suggesting a distorted square planar or square based pyramidal geometry with a $d_{x^2-y^2}$ ground state. These observations are consistent with the g values viz. g_1, g_2 and g_3 of the corresponding complexes in the polycrystalline state at room temperature and further supports the geometries, as observed by X-ray diffraction, around the copper(II) ion in these complexes.

3.3.2. Solution e.p.r. spectra

The g-tensor values of the copper(II) complexes can be used to derive the ground state. The one electron paramagnetic mononuclear copper(II) complexes display X-band e.p.r. spectra in 100% DMSO at 77 K giving $g_\parallel > g_\perp > 2.0023$, indicating a $d_{x^2-y^2}$ ground state, and spectral features are characteristic of axial symmetry [30–32]. Similar spectra have been observed by many workers for copper(II) mononuclear complexes [10,33]. α^2 (0.712–777), evaluated using the expression $\alpha^2 = A_\parallel/0.036 + (g_\parallel - 2.0023) + 3/7(g_\perp - 2.0023) + 0.04$ [34], indicate that there is substantial in-plane σ-bonding in these complexes. It has been observed [35] that the contribution of the 4s orbital to σ-bonding between the metal and the ligand donor atom orbitals is predominant in those complexes with α^2 values greater than 0.70. The values of the exchange-coupling parameters G of 3.18–4.03, estimated from low temperature e.p.r. spectra of the complexes, were ≈4.0, suggesting the presence of exchange interactions in these complexes in solution at LNT [36]. All complexes with $g_\parallel > g_\perp > 2.0023$, and G values falling within the range 2–4 are consistent with a $d_{x^2-y^2}$ ground state in a square planar or square pyramidal geometry. The same geometries have already been proved by single crystal X-ray analysis.

3.4. UV–Vis spectroscopy

The electronic spectra for complexes **1**–**3** show a prominent broad band (Fig. 5) in the range 680–700 nm, ascribed to the *d-d* transition ($d_{xz}, d_{yz} \rightarrow d_{x^2-y^2}$). These results are typical of square-planar and square pyramidal geometries [37], which in general exhibit a single band between 588–750 nm ($d_{xz}, d_{yz} \rightarrow d_{x^2-y^2}$). These geometries were further confirmed by e.p.r. and single crystal X-ray data.

3.5. Cyclic voltammetry

Cyclic voltammograms of the present complexes were recorded in DMSO with tetra butyl ammonium perchlorate (TBAP) as the supporting electrolyte in the potential range + 0.8 to −1.3 ± 1 V versus SCE. A typical voltammogram is displayed in Fig. 6. [Cu(SAA)(ImH)] (**1**) shows an irreversible redox wave ($E_{pc} = -0.767$ V, $E_{pa1} = -0.495$ V) with an additional oxidation wave ($E_{pa2} = 0.495$ V). We tentatively attribute the reduction wave as being the two electron reduction ($Cu^{2+} \rightarrow Cu^0$) $E_{pc} = -0.767$ V and two oxidation waves as being two step oxidation ($Cu^0 \rightarrow Cu^+$,

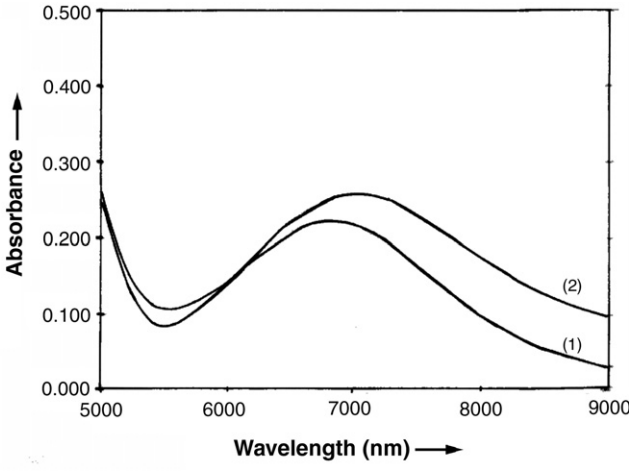

Fig. 5. The UV–Vis spectra (0.003 mol^{-1} dm^{-3}) of complexes: [Cu(SAA)(ImH)] (**1**) and [Cu(SAA)(bipy)]CH_3CN (**2**).

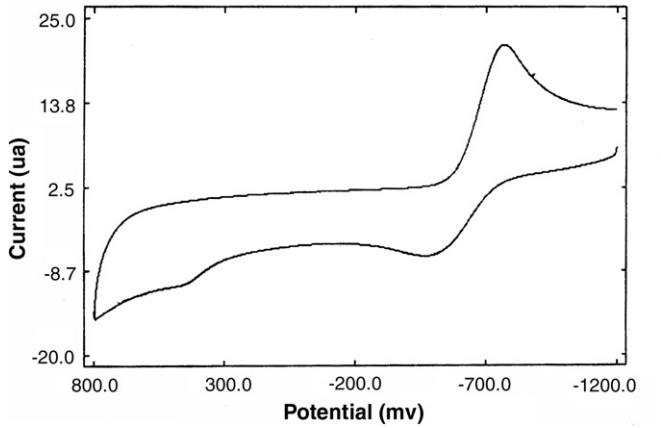

Fig. 6. Cyclic voltammogram of [Cu(SAA)(ImH)] (**1**) in 0.1 M TBAP [scan rate: 500 (mV/s)].

$Cu^{+} \rightarrow Cu^{2+}$) $E_{pa1} = -0.495$ V and $E_{pa2} = 0.495$ V. The electrochemical behaviour of the remaining two complexes are different to that observed for **1**. These two complexes exhibit two step reduction waves (peaks) ($Cu^{2+} \rightarrow Cu^{+}$ $E_{pc1} = -0.541$ V, $Cu^{+} \rightarrow Cu^{0}$ $E_{pc2} = -0.987$ V) and two oxidation waves ($E_{pa1} = -0.486$ for $Cu^{0} \rightarrow Cu^{+}$, $E_{pa2} =$ 0.113 V for $Cu^{+} \rightarrow Cu^{2+}$, for **2**). Similar observations were made by Kasumov et. al. [38] for copper(II) mononuclear complexes containing substituted salicylaldimines.

3.6. Superoxide dismutase activity

The superoxide dismutase activity of the present complexes were assayed by the use of alkaline dimethyl sulfoxide as a superoxide anion generating system in association with nitrobluetetrazolium chloride as a scavenger of superoxide [39]. Alkaline DMSO as a O_2^- generating system has the advantage that there is a marked decrease in the spontaneous dismutation rate of O_2^- due to the use of a relatively high pH combined with the low temperature and that a large amount of O_2^- is generated in solution as compared to SOD concentration. The SOD activity is related to the equatorial field experienced by the copper(II) complexes [40]. A strong equatorial field opposes the interaction of the complexed copper with superoxide radical, disfavouring the probable formation of the intermediate copper superoxide adduct [41]. Moreover, a strong field is a factor which disfavors the reduction process from copper(II) to copper(I). Another important factor in the catalytic process is the ability of the ligand to accommodate the reduced copper(I) in a tetrahedral-like or linear environment [42].

The complexes in the present study exhibit catalytic activity towards the dismutation of superoxide anions. The SOD activity data for complexes have been compiled in Table 6 along with the SOD activity values of some other ternary copper(II) complexes [10,19,43]. A representative plot of inhibition with increasing concentration of the complex **1** is given in Fig. 7 Complexes **1**–**3** are 750, 1400 and 1250 times less active than the native enzyme

Table 6
Superoxide dismutase activity of some copper(II) complexes

S. no.	Complex	IC_{50} (μmol dm^{-3})	Reference
1	$[Cu(PMDT)(bipy)](ClO_4)_2$	105	[10]
2	$[Cu(PMDT)(phen)](ClO_4)_2$	111	[10]
3	$[Cu(dien)(bipy)](BF_4)_2$	95	[19]
4	$[Cu(dien)(phen)](ClO_4)_2$	97	[19]
5	$[Cu(glygly)] \cdot 3H_2O$	132	[43]
6	$[Cu(glygly)(bipy)] \cdot 3H_2O$	22	[43]

8	[Cu(SAA)(ImH)]	30	present work
9	$[Cu(SAA)(bipy)]CH_3CN$	56	present work
10	[Cu(SAA)(phen)]	50	present work

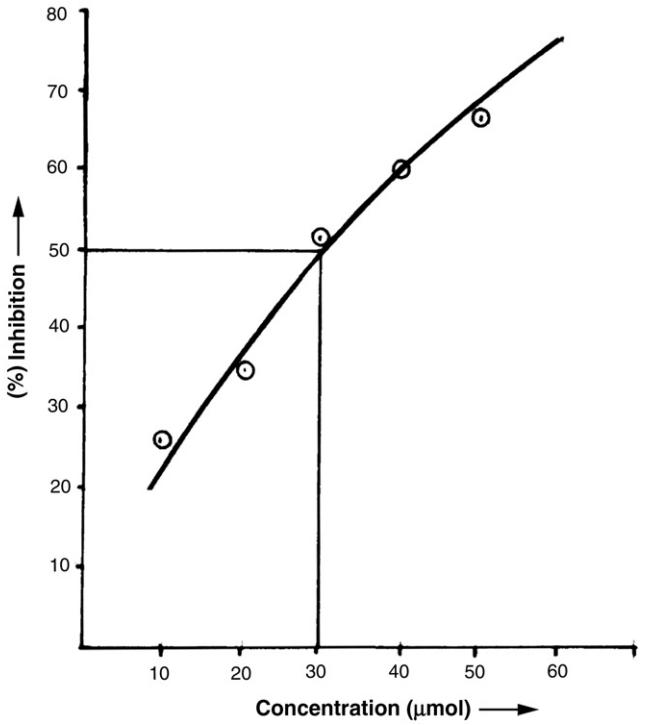

Fig. 7. Superoxide dismutase activity of [Cu(SAA)(ImH)] (**1**).

($IC_{50} = 0.04$ μmol dm^{-3}) on a molar base. This reduced activity may be due to the strong ligand field created by the SAA which opposes the interaction of the complexed copper with superoxide radical. In **1**, copper(II) is coordinated with two nitrogen atoms and two oxygen atoms to give a distorted square planar geometry whereas in complexes **2** and **3**, copper(II) is coordinated with three nitrogen atoms and two oxygen atoms to give a distorted square pyramidal geometry. The distortion of these complexes may favour the geometrical change, which is essential for the catalysis as the geometry of copper in the SOD enzyme also changes from distorted square pyramidal [44,45].

4. Conclusions

Copper(II) complexes of the general composition [Cu(SAA)(ImH)] (**1**) $[Cu(SAA)(bipy)]CH_3CN$ (**2**) and

[Cu(SAA)(phen)] (**3**) have been synthesized and characterized by using different physiochemical techniques. Molecular structures for complexes **1** and **2** have been revealed by single crystal X-ray analysis. The copper(II) complexes of **1**–**3** with Schiff base and mono/bidentate ligands are all neutral and found to have a distorted square planar geometry for (**1**) and distorted square pyramidal geometries for **2** and **3**. All complexes show $g_{\|} > g_{\perp} > 2.0023$, and G values falling within the range 2–4 are consistent with a $d_{x^2-y^2}$ ground state in a square planar geometry N_2O_2 **1** or a distorted square pyramidal geometry **2** and **3**. The complexes also exhibit catalytic activity towards the dismutation of superoxide anions. These complexes found to be less active than the native enzyme (SOD).

5. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 298983 for complex [Cu(SAA)(ImH)] (**1**) and CCDC No. 298982 for complex [Cu(SAA)(bipy)]-CH_3CN (**2**). Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK, fax: +44 1223 336 033, e-mail: deposit@ccdc-cam.ac.uk or http://www.ccdc.cam. ac.uk).

Acknowledgements

Our grateful thanks are due to National Diffraction Facility, X-ray Division and RSIC (SAIF), IIT Mumbai for single crystal data collection and e.p.r. measurements respectively. The Head RSIC, Central Drug Research Institute, Lucknow is also thankfully acknowledged for providing analytical and spectral facilities. Financial assistance from UGC [Scheme No. F.30-76/2004(SR)] New Delhi is also thankfully acknowledged.

the knowledge of the 'ionicity', i.e. degree of the partial oxidation. Resonance Raman and ^{129}I Mössbauer spectroscopies as well as diffuse X-ray scattering techniques are simple means of characterising the anionic polyiodine species and determine the 'ionicity' [19–23]. On the other hand, EPR spectroscopy is useful for characterising the materials, if both parts of the complex, i.e. the central metal (for example Mn, Fe, Co) and the π-electron macrocyclic ligand, are redox active since both oxidized forms $M^{2+}(Pc^{(1-)})I$ and $M^{3+}(Pc^{(2-)})I$ exhibit different EPR spectra. Additionally, EPR spectroscopy provides clear evidence for exchange coupling between the localised unpaired electron on the central metal ion and the π-carriers of the macrocycle within the stacks, as observed for CoPcI [24] and CuPcI [25], both linear-chain metal-spine conductors.

Although a few partially oxidized metallodiphthalocyaninato complexes are known [26], the correlation between the structure, π-orbital overlap and conductivity has not been systematically examined for such a system. In the course of our studies on metallodiphthalocyaninato complexes, the partially oxidized sandwich-type metallodiphthalocyanines are divided into two categories: (1) undoped metal(III) diphthalocyanines [27–32] and (2) iodine-doped partially oxidized metal(III) and metal(IV) diphthalocyanines [33–39]. In the first category M(III)Pc_2, exhibiting semiconducting properties, the central metal M(III) is sandwiched between the Pc^{2-} and one-electron oxidized $Pc^{-\cdot}$ radical ligand, however, the X-ray single crystal analysis shows that both halves of these sandwich complexes are equivalent structurally, thus a non-integral oxidation state should be assigned to both of them ($\rho = -1.5$). In the second category, iodine-doped metal(III) and metal(IV) diphthalocyanines, the conductivity depends strongly on the amount of iodine-doped atoms, which is closely correlated with the formal oxidation state of Pc macrocyclic ring.

Similar to iodine-doped metallomonophthalocyanines, the iodine-doped metallodiphthalocyaninato complexes also crystallise in the tetragonal system, in which the central metal ion is disordered over two symmetrically equivalent positions [33–39]. Quite recently we have stated that iodine-doped zirconium diphthalocyanine, depending on the crystallisation process and the amount of the iodine, can crystallise also in the monoclinic system [39]. Using a slightly modified method [40] we have obtained a new partially oxidized zirconium diphthalocyanine $[ZrPc_2]IBr_2$. Although, this complex contains the trihalide ions IBr_2^-, similar to the tetragonal iodine doped zirconium diphthalocyanine $[ZrPc_2](I_3)_{2/3}$ that contains the I_3^- ion [38], the complexes are not isostructural. Therefore for understanding the charge transport properties of $[ZrPc_2]IBr_2$ complex a knowledge of its crystal structure is needed. Additionally, the correlation between the crystal structures and charge transport properties of the two iodine-doped different zirconium diphthalocyaninato complexes $[ZrPc_2](I_3)_{2/3}$, $[ZrPc_2]I_3 \cdot I_2$, described earlier [38,39], with the third complex $[ZrPc_2]IBr_2$, described here, are reported. The crystal structures and properties of the partially oxidized zirconium diphthalocyanine complexes are discussed and compared with the undoped $ZrPc_2$ complex [41].

2. Experimental

2.1. Synthesis

All reagents were of the highest grade commercially available and were used as received. The crystals of $[ZrPc_2]IBr_2$ were obtained directly by the reaction of pure powdered zirconium and phthalonitrile under a stream of IBr. The powdered zirconium (0.182 g), phthalonitrile (2.050 g) and IBr (0.450 g) in a molar proportion of 1:8:2, with about 5% excess of IBr, were mixed together and pressed into pellets. The pellets were inserted into an evacuated glass ampoule (ca. 25 cm long) and sealed. The part of ampoule with the pellets was heated at about 220 °C for one day. At this temperature the liquid phthalonitrile undergoes catalytic tetramerization forming the phthalocyaninato rings, which accepts the electron from the zirconium and forms sandwich $ZrPc_2$ molecules. Simultaneously IBr partially oxidized the $ZrPc_2$ molecules and transforms into IBr_2^- ions and neutral diiodine molecules, yielding good quality single crystals with the composition $[ZrPc_2]IBr_2$. The major part of the iodine formed during formation of the $[ZrPc_2]IBr_2$ crystals resublimed at the cooler part of the ampoule. After opening the ampoule, the iodine that formed from IBr during the preparation procedure as an impurity is easily lost after expose to air at room temperature (3–4 days) or by slowly heating to about 40–45 °C. The elemental analysis has been performed on an energy dispersive spectrometer. Calc. for $C_{64}H_{32}N_{16}ZrIBr_2$: Zr, 6.50; I, 9.04; Br, 11.38; C, 54.78; N, 15.96; H, 2.34. Found: Zr, 6.45; I, 9.15; Br, 11.33; C, 54.84; N, 15.98; H, 2.29%.

2.2. X-ray diffraction study of $[ZrPc_2]IBr_2$

The X-ray single crystal data were collected on a KUMA KM-4 diffractometer equipped with a two-dimensional area CCD detector from a single crystal (black-violet) with dimensions of $0.22 \times 0.18 \times 0.14$ mm. The graphite-monochromatized Mo Kα radiation ($\lambda = 0.71073$ Å) and ω-scan technique with $\Delta\omega = 0.75°$ for one image were used. 960 images for six different runs covering over 95% of the Ewald sphere were performed. The exposure times were 20 s/image. Accurate cell parameters were refined by least-squares methods on the basis of 2577 of the strongest reflections. One image was monitored as a standard after every 40 images for a control of the stability of the crystal. Integration of the intensities, corrections for Lorentz and polarisation effects were carried out using KUMA KM-4 CCD software [42]. Face-indexed analytical absorption was calculated using the SHELXTL program [43]. The minimum and maximum transmission factors are 0.641 and 0.744, respectively. A total of 25 532 (6899 independent, $R_{int} = 0.0306$) reflections were integrated and used for the crystal

structure determination. The structure was solved by the Patterson heavy atom method and refined by full-matrix least-squares method using the SHELXL97 program [44] with anisotropic thermal parameters for all non-hydrogen atoms. The hydrogen atoms of the benzene rings were introduced in their geometrical positions (HFIX 43) with isotropic thermal parameters $U_{iso}(H) = 1.2U_{iso}(C)$, i.e. 20% higher than the thermal parameters of the carbon atom directly bonded to the H atom. The final difference Fourier maps showed no peaks of chemically significance (+0.335 e Å^{-3} and −0.926 e Å^{-3}). More details of data collection and final refinement parameters are listed in Table 1 and in the Supporting Information. Selected geometrical parameters are collected in Table 2.

2.3. Raman spectroscopy

The resonance Raman spectrum was recorded at room temperature on a Jobin-Yvon Ramanor U-1000 spectrometer equipped with a photomultiplier-type detector and phonon-counting hardware. 90° geometry was used. An argon-ion laser line at 514.5 nm at 100 mW power was used as the exciting radiation. The resolution was set at 3 cm^{-1}.

2.4. UV–Vis spectroscopy

Measurements of the electronic spectra of $[ZrPc_2]IBr_2$ and $ZrPc_2$ were carried out at room temperature using a Cary-Varian 2300 spectrometer. The UV–Vis spectra were recorded on a thin solid film between quartz glass prepared from a nujol mull, since a thin solid film of the $[ZrPc_2]IBr_2$ complex could not be obtained by sublimation in vacuum due to decomposition to $ZrPc_2$ and I_2 and Br_2.

2.5. Magnetic susceptibility measurement

Magnetic susceptibility measurement of $[ZrPc_2]IBr_2$ was carried out on a solid sample of 100 mg in the temperature range 300–2 K with a Quantum Design SQUID magnetometer (San Diego, CA). The susceptometer was calibrated with $(NH_4)_2Mn(SO_4)_2 \cdot 12H_2O$. Data were recorded at a magnetic field of 0.5 T.

2.6. Electron paramagnetic resonance measurements

EPR measurements were made on SE-Radiopan and ESR 300 E – Bruker X-band spectrometers at room temperature and variable temperature (300–90 K) using cold N_2 gas. The studies were carried out on solid samples of 4–10 mg. The concentrations of the free radicals in the samples of $[ZrPc_2]IBr_2$ were calculated using standard integration of the derivative signal and comparing the area with the area determined with the free radical standards. DPPH, TEMPO and TEMPOL were used as standards.

2.7. Single-crystal electrical conductivity measurements

Single crystals of $[ZrPc_2]IBr_2$ were mounted on silvered graphite fibers and electrical contacts were made with a palladium paste. Conductivity measurements were carried out along the a and c crystallographic axis (see Fig. 3a and b), i.e. along the stacks of one-electron oxidized $[ZrPc_2]^+$ units and perpendicular to the stacks using a standard four-point probe technique [45] with a sampling current of 20 μA. Variation of the temperature was archived by placing the samples in a cold-gas stream of N_2 or He. The conductivity of the material was calculated from the relationship $\sigma = L/RA$, where σ is the conductivity (in Ω^{-1} cm^{-1}), R is the measured resistance (in Ω) of the material between two inner contacts (in cm) and A is the cross-sectional area of the sample (in cm^2). For the conductivity measurement a crystal was selected with the greatest dimension of 0.834 mm (along the a axis), 0.456 mm (along the c axis) and 0.246 mm (along the b axis). The estimated uncertainty in these measurements is about 0.001 mm. The area A was estimated from the cross-sectional distance as

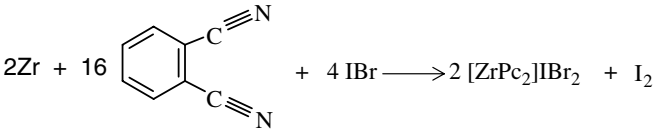
observed with a microscope. An empirical analysis of the measurement errors indicates that the area is uncertain by $\delta A/A \approx \pm 0.1$, leading to an uncertainty $\Delta\sigma/\sigma \approx 0.2$. The measurements were repeated on four single crystals with different dimensions (0.504–0.834, 0.322–0.456 and 0.186–0224 mm along the *a*, *c* and *b* axes, respectively). The differences in the measured conductivities on these single crystals are less than 5%. The conductivity measured on a single crystal perpendicular to the stacks of $[ZrPc_2]^+$ units (i.e. along the *c* axis) is smaller by a factor of $\sim 10^3$ than the conductivity along the stacks (*a* axis).

3. Results and discussion

3.1. Synthesis

Our preparation method leads directly to good-quality single crystals. The oxidation of the phthalocyaninato ring Pc(2−) → Pc(1−) by iodine is well known [46] and has been widely used to obtain partially oxidized metallophthalocyaninato and diphthalocyaninato complexes. IBr is a stronger oxidant than I_2 [47]. The synthesis of $[ZrPc_2]IBr_2$ from phthalonitrile and pure powdered zirconium under a stream of IBr requires the formation of the heterotrihalide IBr_2^- ions, i.e. electron-rich three center bonding mixed trihalide ions [48]. The formation of the IBr_2^- ion by the reaction of I^- with Br_2 is well known [49]. However, under the used reaction conditions the IBr_2^- ion is the result of heterolitic thermal dissociation of IBr: $3IBr \leftrightarrow I_2Br^+ + IBr_2^-$ or by the series of reactions: $2IBr + 2e \rightarrow I_2 + 2Br^-$ and $IBr + Br^- \rightarrow IBr_2^-$. Thus the formation of the $[ZrPc_2]IBr_2$ complex can be write as shown in Scheme 1, where $Pc = C_{32}H_{16}N_8$. During synthesis the $[ZrPc_2]IBr_2$, crystals grew in the hot part (∼220 °C) of the ampoule, and the I_2 resublimed in the cooler part. The crystals of $[ZrPc_2]IBr_2$ are air and light stable. Iodine as an impurity is easily lost by cooling up to ∼45 °C (10–15 min) or by exposure to air at room temperature (3–4 days).

The obtained $[ZrPc_2]IBr_2$ crystals are insoluble in water, ethanol and methanol and are slightly soluble in pyridine, DMF, DMSO, chloronaphthalene and other high boiling aromatic solvents. However, after several days a black powder material from the solution was obtained. Elemental analysis of this powder material is consistent with a $ZrPc_2$ complex that has been characterised earlier [41,50]. Thus it was found that a decomposition process takes place in solution. This process depends strongly on the temperature and is several times quicker in hot solvents. Contact of $[ZrPc_2]IBr_2$ with dilute inorganic acids (H_2SO_4, HNO_3 and their mixture or mixture with concentrated HCl) leads to demetallation, yielding the α-form of metal-free phthalocyanine (α-H_2Pc) [51] and the appropriate salts.



Scheme 1. Formation of the $[ZrPc_2]IBr_2$ complex; $Pc = C_{32}H_{16}N_8$.

3.2. Raman spectroscopy

In order to relate the charge transport properties the 'ionicity', i.e. the degree of oxidation of the $[ZrPc_2]$ unit, must be determined. Resonance Raman spectroscopy is useful for identification of the anionic part of the complex. The resonance Raman spectrum measured on a polycrystalline sample at room temperature (Fig. 1) exhibits only one strong fundamental band at 169 cm^{-1} (the expected value for IBr_2^- is 168 cm^{-1} [52]). The absence of a band at ∼110 cm^{-1} eliminates I_3^- ions and the absence of a peak at ∼160 cm^{-1} eliminates Br_3^- ions [19,20]. Free Br_2 ($\nu \approx 306$ cm^{-1}) [53,54] and free I_2 ($\nu \approx 210$ cm^{-1}) [55] are not present in detectable quantities in the crystals.

3.3. Description of the structure

The crystals of $[ZrPc_2]IBr_2$ are built up from one-electron oxidized $[ZrPc_2]^+$ sandwich units and mixed trihalide IBr_2^- counter ions. The $[ZrPc_2]^+$ unit is located on a special position and has crystallographic *m* symmetry, while the I atom of the IBr_2^- ion occupies the inversion center, so the IBr_2^- ion is linear and symmetrical. The central closed shell Zr^{4+} cation (d^0 configuration) is eight coordinated by two saucer shaped phthalocyaninato units (Fig. 2): Pc^{2-} and one-electron oxidized $Pc^{-\bullet}$ π-radical ligands (identified by EPR spectroscopy). This may be the reason for the slightly asymmetric location of the Zr^{4+} cation between the phthalocyaninato rings. The average Zr–N distance to one Pc ring is equal to 2.283 Å and is slightly longer (2.344 Å) than to the other Pc ring. On the other hand the slightly asymmetric location of the Zr^{4+} cation between the phthalocyaninato rings (1.233(3) Å from the N_4 plane of one Pc ring and 1.244(3) Å from the N_4 plane of the second ring) is due to the different interaction of the phthalocyaninato rings with the IBr_2^- ion that is located closely to the one of them. In conclusion, most probably the Zr^{4+} cation is sandwiched between the two phthalocyaninato macrocyclic rings with a non-integral formal oxidation state of −1.5.

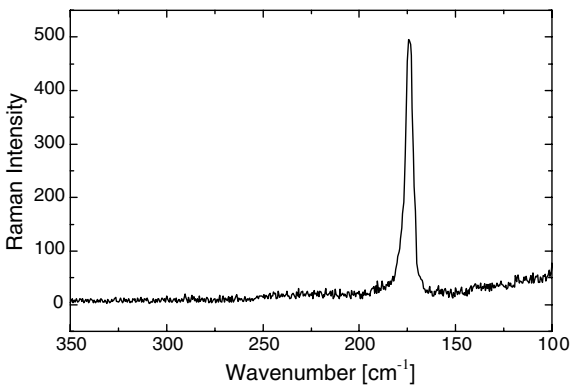


Fig. 1. Resonance Raman spectrum of $[ZrPc_2]IBr_2$ at room temperature.

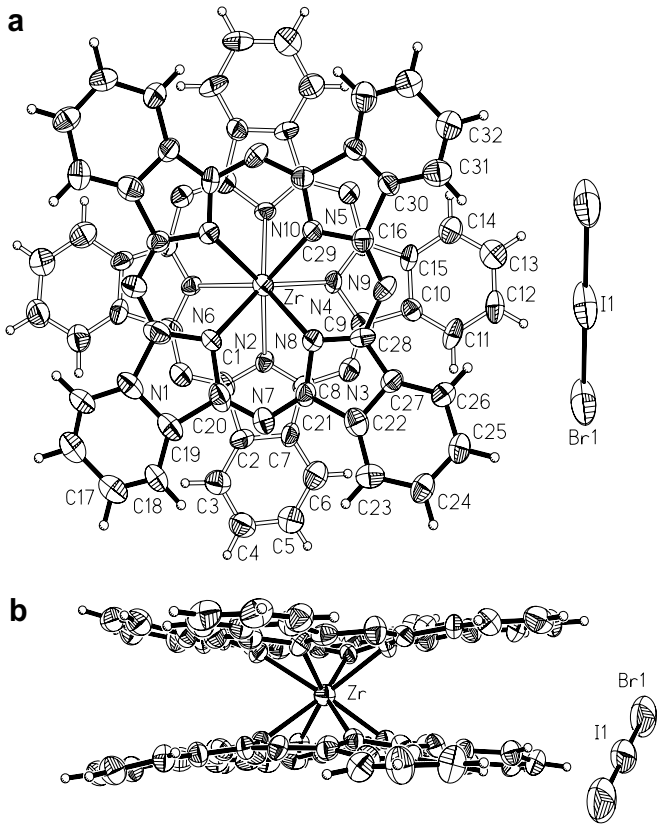

Fig. 2. Molecular structure of $[ZrPc_2]IBr_2$, top view (a) and side view (b). Displacement ellipsoids are shown at the 50% probability level.

Similarly a non-integral oxidation state of the Pc ring is observed in the class of partially oxidized $MPc(I_3)_{2/3}$, $[MPc_2](I_3)_{2/3}$ or $[MPc_2](I_3)_{5/9}$ complexes, in which the formal oxidation state of Pc ring equals −1.667 or −1.772 [35,37]. Both phthalocyaninato macrocyclic rings of the $[ZrPc_2]^+$ unit are significantly deviated from the weighted least-squares plane defined by four N-isoindole atoms. The largest deviations from the N_4-isoindole planes are observed for C5 (1.109 Å) for one Pc ring and C24 (0.762 Å) for the second Pc ring. The distortion of the phthalocyaninato rings from planarity is comparable to that found in the crystal of $[ZrPc_2](I_3 \cdot I_2)$ [39], but is smaller than that in the crystal of unoxidized $ZrPc_2$, in which the greatest deviation equals 1.47 Å [41]. The distortion of the phthalocyaninato macrocyclic rings of the zirconium diphthalocyaninato complexes, that can be estimated by the bending of the isoindole units with respect to the N_4-core and by the "twisting" of the peripheral carbon atoms of benzene rings, is collected in Table 3. The displacements of the carbon atoms of the benzene rings for some metallodiphthalocyaninato structures [55–61] are listed in Table 4, for a comparison. As can be seen from Tables 3 and 4, both one-electron oxidized zirconium diphthalocyanines, $[ZrPc_2]IBr_2$ and $[ZrPc_2]I_3 \cdot I_2$, and unoxidized $ZrPc_2$ contain the most deviated phthalocyaninato rings. The Zr–N distances in $[ZrPc_2]IBr_2$ range from 2.280(5) to 2.377(4) Å, and are compared with the distances in the $[ZrPc_2]I_3 \cdot I_2$ complex [39], but they are slightly shorter than those observed in the crystal structure of the unoxidized $ZrPc_2$ complex [41]. This is likely due to the weaker repulsive interaction between Pc^{2-} and the one-electron oxidized $Pc^{-\cdot}$ π-radical ligand in relation to the unoxidized $ZrPc_2$, in which the Pc···Pc interaction is undoubtedly greater, since both Pc rings are 2−. The M–N distances in zirconium diphthalocyaninato complexes are shorter than those of the other sandwich-type metallodiphthalocyaninato structures due to the relatively small radius of the Zr^{4+} cation [62]. The effect of the small radius of Zr^{4+} and its great formal oxidation state are the reasons for the more closely located phthalocyaninato macrocyclic rings around the Zr^{4+} cation, and the distance between the N_4-isoindole planes is the shortest within the sandwich-type metallodiphthalocyanines (see Table 5). The Pc rings in $[ZrPc_2]IBr_2$, similarly to $[ZrPc_2]I_3 \cdot I_2$, are staggered at an angle of 45.0(3)° and this is an additional reason for the closer location of the Pc rings in relation to the unoxidized $ZrPc_2$ complex in which the rotation angle of the Pc rings is equal to 42° [41]. The close proximity of the N_4-planes of the Pc rings indicates the strong interaction of the π-clouds and adds to the distortion of the rest of Pc rings from the N_4-planes. The π–π interaction is a common feature in the field of phthalocyanine chemistry, and it leads phthalocyanine and its metal complexes to form supramolecular aggregates [63–66]. The staggered orientation of the Pc rings give the square antiprismatic coordination of the central Zr^{4+} cation and, as can be seen from the Fig. 2a, indicates that the outermost carbon atoms of the benzene rings are apart, as for non-interpenetrating π-clouds. In the third crystal of

[b] 'Stapled' by two C–C σ bonds.

partially oxidized zirconium diphthalocyanine, $[ZrPc_2](I_3)_{2/3}$, the relatively long N_4–N_4 interplanar distance is due to the symmetry of the crystal (tetragonal system), and the space group of *P*4/*mcc* requires the location of the Pc rings on the special position in the crystal (the Pc rings are located on the crystallographic *m* plane) [38]. As can be seen from Tables 4 and 5, the greatest distortion of the Pc rings from planarity and the shortest N_4–N_4 interplanar distances are observed for $[NbPc_2]IBr_2 \cdot I_2$ and $[NbPc_2]IBr_2$ [60], as well as for $TiPc_2$ [59]. However, these three complexes belong to the new family of sandwiched metallodiphthalocyaninato complexes in which the close proximity of the Pc rings is due to two interligand C–C σ-bonds that have stapled both phthalocyaninato rings [59,60]. In this family of sandwiched MPc_2 complexes the delocalisation of the π-electrons in the inner 16-membered rings breaks down due to two C atoms with sp^3 hybridisation and the formation of the interligand σ-bonds. Additionally, it should be added that oxidation of the stapled $TiPc_2$ complex by iodine leads to the breaking of the interligand C–C σ-bonds [33].

The one-electron oxidized $[ZrPc_2]^+$ units of $[ZrPc_2]IBr_2$ in the crystal, similarly as in $[ZrPc_2]I_3 \cdot I_2$, form pseudo-mono-dimensional columnar stacks that are aligned along the *a* axis of the crystal (see Fig. 3a), and the mean planes of the phthalocyaninato rings are parallel to the *bc* plane (Fig. 3b). However, the anionic parts of these complexes are different (IBr_2^- in one and $I_3^- \cdot I_2$ in the second) and also are located differently in relation to the stacking columns of the $[ZrPc_2]^+$ units. In the crystal of $[ZrPc_2]I_3 \cdot I_2$ the slight bending of I_3^- ions due to the interaction with neutral I_2 molecules are parallel to the *b* crystallographic axis and together with I_2 neutral molecules form zigzag chains that are perpendicular to the columnar stacks of the $[ZrPc_2]^+$ units [39]. In this $[ZrPc_2]IBr_2$ crystal structure, the symmetrical mixed trihalide IBr_2^- that is located in the inversion center forms angles of 104.7(3)°, 47.3(3)° and 129.4(3)° with the *a*, *b* and *c* axes of the crystal, respectively. This structure ($[ZrPc_2]IBr_2$) is also different from the third zirconium diphthalocyaninato complex $[ZrPc_2](I_3)_{2/3}$ [38] in several aspects. The Pc rings of $[ZrPc_2](I_3)_{2/3}$ are crystallographically constrained to lie in the (0 0 1) plane of its tetragonal unit cell, so they are planar and strictly perpendicular to the stacking axis that is also the unique axis. Two Pc rings of $[ZrPc_2](I_3)_{2/3}$ are rotated by 42°, and are separated by a distance of 3.244(3) Å, which is significantly longer than the N_4–N_4 interplanar distance in the $[ZrPc_2]IBr_2$ crystal. The anionic part of the $[ZrPc_2](I_3)_{2/3}$ complex, i.e. the iodine doped atoms, form linear and symmetrical triiodide ions that in the crystal are disordered and located in the channels between the columnar stacks of $[ZrPc_2]^{2/3+}$ units, thus both mono-dimensional aggregates are parallel [38]. In the crystal of $[ZrPc_2]IBr_2$, the mono-dimensional columns of $[ZrPc_2]^+$ units are not parallel to the linear IBr_2^- ions. Additionally, due to the crystal symmetry and the space group of *P*4/*mcc*, the central

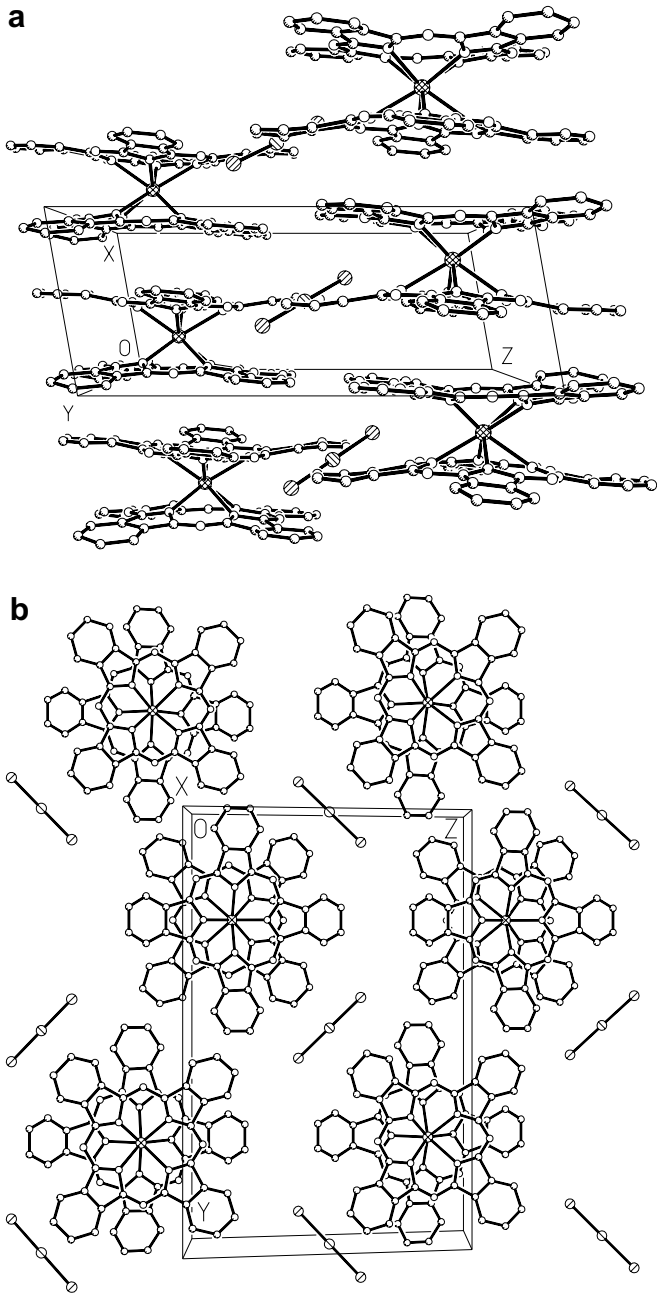

Fig. 3. View of the crystal structure of $[ZrPc_2]IBr_2$ perpendicular to the stacks of $[ZrPc_2]^+$ units (a) and along the stacks (b).

Zr^{4+} cation in the crystal of $[ZrPc_2](I_3)_{2/3}$ is statistically distributed over two symmetrically equivalent positions, in the $[ZrPc_2]IBr_2$ crystal the Zr^{4+} cation is ordered. One more difference between the $[ZrPc_2]IBr_2$ and $[ZrPc_2](I_3)_{2/3}$ complexes should be noted, the difference in the formal oxidation state of the cationic sandwich $[ZrPc_2]$ unit, +1 and +2/3 in $[ZrPc_2]IBr_2$ and $[ZrPc_2](I_3)_{2/3}$, respectively. The formal oxidation state of the $[ZrPc_2]$ units correlate with the holes of the electrons on the Pc rings that are strictly connected with the charge transport properties. The intermolecular back-to-back Pc ⋯ Pc distances in the crystal of $[ZrPc_2]IBr_2$, with an average value of ~3.35 Å between two neighbouring $[ZrPc_2]^+$ units, indicates a π–π interaction between the Pc rings within the columns, since this value is slightly shorter than the van der Waals distance of 3.4 Å for aromatic carbon atoms [67]. This π–π intermolecular interaction plays an important role in the charge transport.

The I–Br distances in the symmetrical IBr_2^- [(Br–I–Br)$^-$] ion are equal to 2.694(1) Å. This value is compared to those found in the other metallophthalocyaninato complexes containing the IBr_2^- ion [60,68]. The I–Br distances in the I_2Br^- ion [(I–Br–I)$^-$] are significantly longer as molecular orbital calculations show (the I–Br distance in the (I–Br–I)$^-$ ion is equal to ~2.91 Å) [48] and compared with those obtained by X-ray experimental results [69,70].

3.4. UV–Vis spectroscopy

The solid-state electronic absorption spectra recorded at room temperature on a thin-film made from nujol mulls between quartz plates of one-electron oxidized $[ZrPc_2]IBr_2$ and unoxidized $ZrPc_2$ are very similar (see Fig. 4). This indicates that the interaction between the $[ZrPc_2]^+$ and IBr_2^- units is insignificant in the positions of the phthalocyanine's HOMO and LUMO levels. The Q band arises from the excitation from HOMO (a_{1u}) to LUMO (e_g), while the B-Soret band is mostly an $a_{2u} \rightarrow e_g$ transition and the N band (at ~297 nm in both complexes) resulting mainly from a transition $b_{2u}(\pi) \rightarrow e_g(\pi^*)$. The Q band in the spectra of both complexes splits into two (Q_1 and Q_2) bands: 696 and 635 nm in unoxidized $ZrPc_2$ and 694 and 628 nm in one-electron oxidized $[ZrPc_2]IBr_2$. The splitting values of 61 nm in $ZrPc_2$ and 66 nm in $[ZrPc_2]IBr_2$ result from the vibronic coupling in the excited state [71–73]. Several authors reported that the splitting value of the Q band depends on the interplanar Pc–Pc distance, and decreases as the interplanar Pc–Pc distance increases [74,75]. Additionally, Takahashi et al. [74,76]. reported that if the interplanar Pc–Pc distance increases the intensity of the Q_1 band increases and the Q_2 band decreases. The inversion

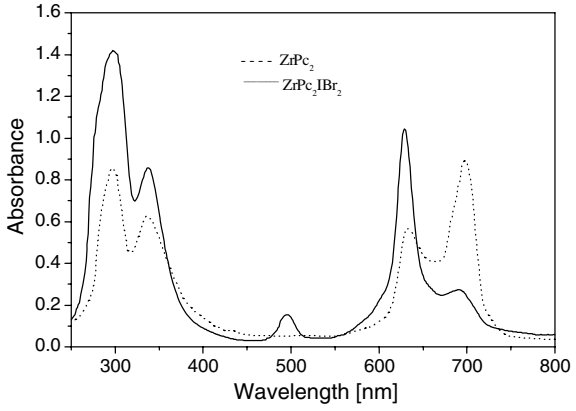

Fig. 4. Electronic absorption spectra of the one-electron oxidized $[ZrPc_2]IBr_2$ (solid line) and the non-oxidized $ZrPc_2$ complexes (dashed line).

of the intensities of the Q_1 and Q_2 bands and the splitting values in the spectra of $ZrPc_2$ and $[ZrPc_2]IBr_2$ are fully consistent with the X-ray single crystal analysis (the interplanar Pc–Pc distance of 2.434(3) Å in one-electron oxidized $[ZrPc_2]IBr_2$ is shorter than in $ZrPc_2$ (2.52 Å) [41]).

In the spectrum of $[ZrPc_2]IBr_2$, besides the characteristic bands (N, B and Q) also observed in the spectrum of unoxidized $ZrPc_2$, one additional band at ~496 nm is observed. Several authors that studied iodine-doped metallophthalocyaninato complexes containing the triiodide I_3^- ions suggested that the optical transition at ~500 nm may arise from a transition in the I_3^- ions, probably $\sigma_g \rightarrow \sigma_u^*$ split by spin–orbit coupling [54]. Gabes and Stufkens [77] studied the electronic absorption spectra of symmetrical and asymmetrical trihalide ions (I_3^-, IBr_2^-, ICl_2^-, Br_3^- and $BrCl_2^-$) observed in the spectrum of IBr_2^- ($CsIBr_2$) three bands at 248, 313 and 407 nm with decreasing intensities and one shoulder at about 493 nm. The intensity of the band at 493 nm in relation to the bands at 248, 313 and 407 nm is much lower [77] as well as lower than the intensities of the bands assigned to the transitions in the phthalocyaninato complexes. Therefore, the band observed at 496 nm in the spectrum of $[ZrPc_2]IBr_2$ complex is assigned to the electronic transition from a deeper level to the half-occupied HOMO level and is an evidence for the existence of the one-electron oxidized phthalocyaninato(1−) π-radical ligand . This assignment is supported by the fact that a similar band at ~500 nm has been observed in the spectra of other one-electron oxidized metallodiphthalocyaninato complexes such as $Ln^{(III)}Pc_2$ and $In^{(III)}Pc_2$ that not contain the trihalide ions [78,79].

3.5. Magnetic properties

The magnetic susceptibility of the $[ZrPc_2]IBr_2$ complex was measured between 300 and 1.8 K. The paramagnetic susceptibility was obtained by subtracting the temperature-independent diamagnetic contribution of the phthalocyaninato rings and the diamagnetic contribution of the closed shell (d^0) Zr^{4+} cation. Both contributions were obtained by the measurement of the diamagnetic susceptibility of the unoxidized $ZrPc_2$ complex, which is equal to -5.76×10^{-4} emu mol^{-1}. The value of the diamagnetic contribution of the mixed trihalide IBr_2^- ion was calculated from Pascal's constants as a sum of twice that for Br (42.4×10^{-6} emu mol^{-1}) and that for I^- (-50.6×10^{-6} emu mol^{-1}) [80–82]. The corrected paramagnetic susceptibility of one-electron oxidized $[ZrPc_2]IBr_2$ at 300 K is $\approx 1.162 \times 10^{-3}$ emu mol^{-1}. This value corresponds to ~0.96 spins per molecule ($S = 1/2$, $g \cong 2$). The temperature dependence of the corrected magnetic susceptibility of $[ZrPc_2]IBr_2$ can be fit approximately by the Curie–Weiss law, $\chi_M = C/(T - \Theta)$ with a Weiss constant Θ (K) of ≈−3.7 (see Fig. 5). The negative Weiss constant represents the antiferromagnetic coupling among unpaired electrons. The effective temperature-independent magnetic moment, calculated from the relationship $\mu_{eff} = 2.828(\chi_M T)^{1/2}$, is

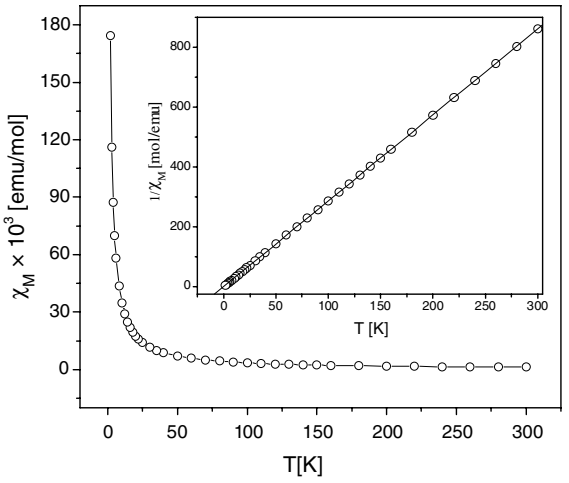

Fig. 5. Plots of the magnetic susceptibility (χ_M) of the $[ZrPc_2]IBr_2$ solid sample vs. temperature. Inset: $1/\chi_M$ vs. temperature.

equal to ≈1.67 μ_B. This value is slightly lower than the spin-only magnetic moment ($\mu_{spin\text{-}only} = 1.73\ \mu_B$).

The EPR spectrum, measured on a solid polycrystalline sample of $[ZrPc_2]IBr_2$ at room temperature (295 °C), exhibits one narrow signal in the proximity of the free electron g value. The g value of 2.0025 and a line width $\Gamma =$ 6.5 G indicate the formation of a ligand-centered π-radical. Integration of this signal results in 3.98×10^{20} spins/g, i.e. 0.927 spins per $[ZrPc_2]IBr_2$ molecule. The spin concentration obtained from the EPR measurements is in good agreement with that from magnetic susceptibility measurements. The EPR parameters, g, Γ and spins concentration per molecule obtained for the $[ZrPc_2]IBr_2$ complex are quite similar to that observed for one-electron oxidized $[ZrPc_2]I_3 \cdot I_2$ [39]. Although the g and Γ parameters observed in the spectrum of the third partially oxidized zirconium diphthalocyaninato complex $[ZrPc_2](I_3)_{2/3}$ are comparable, the spin concentration is significantly lower [38]. The difference in the spin concentrations between $[ZrPc_2]IBr_2$ and $[ZrPc_2]\ I_3 \cdot I_2$ – both one-electron oxidized and monoclinic and $[ZrPc_2](I_3)_{2/3}$ (tetragonal) results from the difference in their crystal structures. In the tetragonal crystal of $[ZrPc_2](I_3)_{2/3}$ the Pc ligands are closely planar and the interactions between $Pc^{-\cdot}$ radicals are more effective and decreases the spins concentration in relation to both monoclinic $[ZrPc_2]IBr_2$ and $[ZrPc_2]\ I_3 \cdot I_2$ crystals in which, due to the saucer shaped Pc rings, the interactions are less effective.

For $[ZrPc_2]IBr_2$ the g value remains constant with decreasing temperature, but the line width decreases only slightly to a value of 5.4 G at 80 K, the lowest measurement temperature. The narrow line width of the EPR signal within the temperature range is typical for one-dimensional conductors because the direction of spin–lattice relaxation is restricted and slower [83]. The decrease of the line width can be explained in term of enhanced motional narrowing from a reduction in carrier mobility with decreasing temperature.

3.6. Single-crystal electrical conductivity of $[ZrPc_2]IBr_2$

The single-crystal electrical conductivity along the stacking axis of one-electron oxidized $[ZrPc_2]^+$ units (*a* axis, see Fig. 3a) at room temperature is equal to $4.6\,\Omega^{-1}\,cm^{-1}$, while the conductivity measured along the *c* and *b* axes of the crystal is in the range $3.2–3.7\times10^{-3}\,\Omega^{-1}\,cm^{-1}$. The electrical conductivity of $[ZrPc_2]IBr_2$ is comparable to the conductivity of the second one-electron oxidized zirconium diphthalocyaninato complex $[ZrPc_2]I_3\cdot I_2$ [39]. The conductivity data of the third known, partially oxidized by iodine, zirconium diphthalocyanine $[ZrPc_2](I_3)_{2/3}$ are available only for the polycrystalline compacted sample [38]. Therefore, the electrical conductivity of this $[ZrPc_2]IBr_2$ complex was also performed on a polycrystalline sample, for comparison. The conductivity measured on the polycrystalline sample of $[ZrPc_2]IBr_2$ pressed into pellets ($\sim10^5$ kPa) is equal to $6.5–7.2\times10^{-2}\,\Omega^{-1}\,cm^{-1}$, and is slightly greater than for the complex of $[ZrPc_2](I_3)_{2/3}$ (see Table 6) [38]. The electrical conductivity measured on a polycrystalline sample of unoxidized $ZrPc_2$ at room temperature shows typical values for isolators ($\sigma_{RT}<10^{-9}\,\Omega^{-1}\,cm^{-1}$).

The single-crystal conductivity of $[ZrPc_2]IBr_2$ along the stacks of $[ZrPc_2]^+$ units decreases with decreasing temperature (Fig. 6), thus the crystal exhibits non-metallic character in conductivity ($d\sigma/dT>0$). Generally, non-metallic molecular conductors exhibit exponential temperature dependence of $\sigma_{(T)}$, because of the carrier density or mobility or both are activated. The temperature dependence of conductivity may be fitted to the expression $\sigma_{(T)}=\sigma_0\exp(-E_a/kT)$, where E_a is the activation energy and k is the Boltzman's constant. A least-squares fit to the data shows linear character of $\ln(\sigma_{(T)}/\sigma_{(RT)})$ versus $1/T$ (Fig. 6) and yields an activation energy of 0.025(2) eV. The relatively high room temperature conductivity of $[ZrPc_2]IBr_2$ along the stacking axis, but significantly lower in comparison to the conductivity of the best molecular conductor, i.e. iodine-doped nickel phthalocyanine $NiPcI_x$ ($\sigma_{(RT)}\approx600\,\Omega^{-1}\,cm^{-1}$)[3], can be explained by a significant overlap of the π-orbitals resulting from the staggered orientation of the Pc rings (rotation angle of the Pc rings equals 45.0(3)°) in the sandwich as well as between the sandwich within the stacks. This rotation of Pc rings makes eight short inter-ring contacts between the pyrrole α-carbon atoms (the inter-ring C_α–C_α contacts

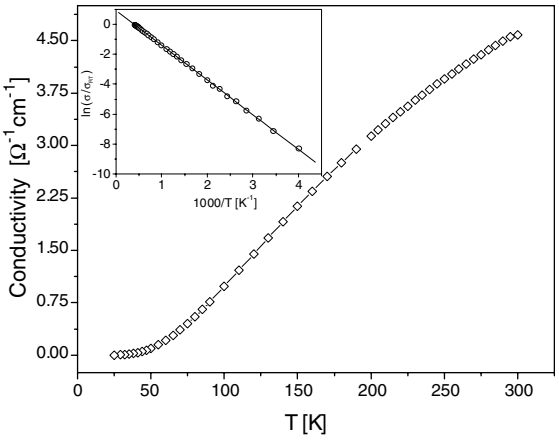

Fig. 6. Temperature dependence of the conductivity of $[ZrPc_2]IBr_2$ (single crystal) measured along the stacks of $[ZrPc_2]^+$ units. Inset: plot of $\ln(\sigma/\sigma_{RT})$ vs. $1000/T$.

range from 2.858(3) (C9–C28) to 3.017(3) Å (C8–C21)). The theoretical calculation shows that these carbon atoms make appreciable contributions to the partially occupied HOMO π-molecular orbital of the phthalocyaninato macrocycle and due to the relatively short contacts provide the greatest overlap of the HOMO π-molecular orbital of Pc that forms the conduction band of the partially oxidized molecular crystals [84,85]. These data clearly show that charge propagation mainly proceeds along the one-dimensional stacks of $[ZrPc_2]^+$ moieties. Each $[ZrPc_2]^+$ unit with the closed shell (d^0) Zr^{4+} cation contains the Pc^{2-} and one-electron oxidized $Pc^{-\cdot}$ π-radical ligands. During the charge transport there is no need for a change of the population distribution among the sites because the jumping of the electron from one side to another with the pre-formed hole takes place between isoenergetic configurations (see Scheme 2a). This is consistent with the relatively small activation energy of 0.025(2) eV, obtained by a fit of the conductivity data, compared with the activation energy of other one-dimensional iodine-doped molecular conductors [54]. The charge transport in the non-oxidized $ZrPc_2$ sample requires a large activation energy for carrier creation, since this involves high energy of states creating and separating the positive and negative (oxidized and reduced) $[ZrPc_2]^+$ and $[ZrPc_2]^-$ ions along the chains (see Scheme 2b). Thus the activation energy is compared to the sum of the energies

that are related to the one-electron oxidation and the one-electron reduction of the $ZrPc_2$ complex, i.e. the formation of $[ZrPc_2]^+$ and $[ZrPc_2]^-$ ions. The first oxidation and first reduction peaks obtained by cyclic voltammetry for $ZrPc_2$ are observed at +1.2 V and −1.4 V, respectively [50]. The charge transport in the tetragonal complex $[ZrPc_2](I_3)_{2/3}$, in which the formal oxidation state of the $[ZrPc_2]$ units is equal to +2/3, is less effective, since statistically one $[ZrPc_2]$ unit per three contains two Pc^{2-} ligands ($[ZrPc^{2-}Pc^{2-}]$-$[ZrPc^{2-}Pc^{-\cdot}][ZrPc^{2-}Pc^{-\cdot}](I_3)_2$), so the charge transport, i.e. the jumping of the electron with a pre-formed hole, is broken.

4. Conclusions

The investigation of doped metallodiphthalocyaninato complexes was undertaken with the dual goals of developing new controls over the structures of mono-dimensional electrically conductive molecular materials as well as investigating the dependence of the conductivity on the formal partial oxidation state of the phthalocyaninato rings in the sandwich MPc_2 system and on the nature of the anionic part of the sandwich complexes $[MPc_2]X$, where $X = I_3^-$, IBr_2^- or $(I_3^- \cdot I_2)$. The present study of $[ZrPc_2]IBr_2$ and our earlier results related to two other iodine-doped zirconium diphthalocyaninato complexes, partially oxidized $[ZrPc_2](I_3)_{2/3}$ and one-electron oxidized $[ZrPc_2]I_3 \cdot I_2$, shed new light on the properties of both types of doped materials. Upon one electron oxidation the $ZrPc_2$ complex is converted to an architecture with staggered rings (rotation angle of 45° in both one-electron oxidized complexes: $[ZrPc_2]IBr_2$ and $[ZrPc_2]I_3 \cdot I_2$), regardless of the interplanar Pc–Pc spacing. The driving force for this conformation change are the net "bonding" overlaps between the π-electron macrocyclic rings. Concerning the relationship between the interplanar spacing in the one-electron oxidized $[ZrPc_2]^+$ units and charge transfer properties, the following can be concluded: decreasing interplanar separation results in increasing charge transfer. Although the electrical conductivities in the stacking direction of the third complex of $[ZrPc_2](I_3)_{2/3}$ with a non-integral oxidation state of sandwiched $[ZrPc_2]^{2/3+}$ units are not available, established empirical correlation between single crystal and pressed powder data (Table 6) afford a reasonable estimation of the value and allow a qualitative comparison with both one-electron oxidized zirconium diphthalocyaninato complexes.

The EPR measurement shows significantly lower 'unpaired' spins in the tetragonal partially oxidized complex of $[ZrPc_2](I_3)_{2/3}$, in which both Pc rings are closely planar, resulting in increased π-orbital overlap. In both one-electron oxidized zirconium diphthalocyaninato complexes the concentration of the 'unpaired' spins are comparable, however, on looking at these results it can be told that in $[ZrPc_2]IBr_2$ the 'unpaired' electrons as well as the conductivity are slightly greater than for $[ZrPc_2]I_3 \cdot I_2$ (see Table 6), which correlate well with the interplanar Pc–Pc distance (2.434(3) Å in $[ZrPc_2]IBr_2$ and 2.493(3) Å in $[ZrPc_2]\ I_3 \cdot I_2$). The decreasing of the EPR line width (Γ) in $[ZrPc_2]IBr_2$ was interpreted in the terms of reduction in carrier mobility with decreasing temperature which correlates well with the temperature dependence of single-crystal conductivity.

A B

Scheme 1.

the X-enolic form (A) (Scheme 1) with the negative charge delocalization in *N*-thioacylamidophosphate-anions [6] pulls them together with ligands **1**.

On the other hand, the presence in coordination sphere of the central ion "hard" donor atom of oxygen of the phosphoric group makes it coordinatively unsaturated. Because of this, it can lead to complex formation, in which the central ion has a coordination number of 6. A similar coordination environment for *N*-thioacylamidophosphates **3** has been shown by us previously as an example of phosphorylated thiobenzamide PhC(S)NHP(O)(OPr*i*)$_2$ (HQ) complexes with Co(II) [14], Ni(II) [15] and Cd(II) [16] cations. The X-ray data confirms that they have the M(HQ)$_2$Q$_2$ type structure. Central atoms having a tetragonal-bipyramidal environment $(O^{ax})_2(O^{eq})_2(S^{eq})_2$ is obtained in these compounds. Axial positions are occupied by two neutral molecules HQ. They are coordinated through the oxygen atoms of P=O-groups. Thus, *N*-thioacylamidophosphates **3** can undergo significant changes of coordination properties both in comparison with oxygen-containing **2** and with dithioanalogues **1**.

In the present study, new data about the structure and properties of *N*-thioacylamidophosphate chelate complexes **3** with the Co(II) cation are reported.

2. Experimental

2.1. Synthesis of [RC(S)NHP(O)(OPr*i*)$_2$] (3a–j)

N-Diisopropoxyphosphorylthiobenzamide (**3a**) (R = Ph) and *N*-phosphorylated thioureas (**3b**–**j**) (R = PhNH, *p*-MeOPhNH, *p*-BrPhNH, *i*PrNH, *t*BuNH, Et$_2$N, *c*-C$_5$H$_{10}$N, *c*-OC$_4$H$_8$N, *c*-C$_6$H$_{11}$NH), were prepared according to the previously described techniques [17] and [18].

2.2. Synthesis of [CoL$_2$] (4a–j and 5a)

A suspension of **3a**–**j** (5 mmol) in aqueous ethanol (20 ml) was mixed with an ethanol solution of potassium hydroxide (6 mmol). To the resulting potassium salt, a water (20 ml) solution of Co(NO$_3$)$_2$ · 6H$_2$O (2.8 mmol) was added dropwise whilst stirring. The mixture was stirred at room temperature for a further 3 h and left overnight. The resulting complexes **4a**–**j** were extracted with methylene chloride, washed with water and dried over anhydrous MgSO$_4$. The solvent was then removed under vacuum. Dark blue precipitates were obtained from a methylene chloride–*n*-hexane mixture, 1:5 v/v.

2.2.1. Co[PhC(S)NP(O)(OPri)$_2$]$_2$ (4a)

This complex was prepared according to the previously described technique [14]. UV–Vis spectra (CH_2Cl_2) [λ_{max}, nm (ε, 1 mol^{-1} cm^{-1})]: 569 (394), 614 (386), 666 (173).

2.2.2. Co[PhNHC(S)NP(O)(OPri)$_2$]$_2$ (4b)

This complex was prepared according to the previously described technique [19]. UV–Vis spectra (CH_2Cl_2) [λ_{max}, nm (ε, 1 mol^{-1} cm^{-1})]: 560 (342), 610 (360), 657 (187). EIMS, *m*/*z* (rel. int. %): 690 (0.1) [M]$^+$, 316 (32) [HL]$^+$.

2.2.3. Co[p-MeOPhNHC(S)NP(O)(OPri)$_2$]$_2$ (4c)

Yield: ~68%, m.p. 156 °C. *Anal.* Calc. for $C_{28}H_{44}CoN_4O_8P_2S_2$: C, 44.86; H, 5.92; N, 7.47; S, 8.55. Found: C, 44.96; H, 6.01; N, 7.39; S, 8.58%. IR (cm^{-1}): 1508(s) (SCN), 1008(b, vs) (POC), 1128(s) (P=O), 3296(b) (NH). UV–Vis spectra (CH_2Cl_2) [λ_{max}, nm (ε, 1 mol^{-1} cm^{-1})]: 560 (326), 611 (340), 662 (173). EIMS, *m*/*z* (rel. int. %): 750 (0.1) [M]$^+$, 346 (19) [HL]$^+$.

2.2.4. Co[p-BrPhNHC(S)NP(O)(OPri)$_2$]$_2$ (4d)

Yield: ~79%, m.p. 170 °C. *Anal.* Calc. for $C_{26}H_{38}Br_2CoN_4O_6P_2S_2$: C, 36.85; H, 4.52; Br, 18.86; N, 6.61; S, 7.57. Found: C, 36.81; H, 4.57; Br, 18.94; N, 6.63; S, 7.62%. IR (cm^{-1}): 1512(s) (SCN), 1008(b, vs) (POC), 1116(s) (P=O), 3288(b) (NH). UV–Vis spectra (CH_2Cl_2) [λ_{max}, nm (ε, 1 mol^{-1} cm^{-1})]: 559 (332), 610 (340), 662 (166). EIMS, *m*/*z* (rel. int. %): 848 (0.2) [M]$^+$, 395 (5) [HL]$^+$.

2.2.5. Co[iPrNHC(S)NP(O)(OPri)$_2$]$_2$ (4e)

Yield: ~48%, m.p. 166 °C. *Anal.* Calc. for $C_{20}H_{44}CoN_4O_6P_2S_2$: C, 38.64; H, 7.13; N, 9.01; S, 10.32. Found: C, 38.93; H, 7.11; N, 9.09; S, 10.34%. IR (cm^{-1}): 1512(s) (SCN), 1000(b, vs) (POC), 1128(s) (P=O), 3312(b) (NH). UV–Vis spectra (CH_2Cl_2), [λ_{max}, nm (ε, 1 mol^{-1} cm^{-1})]: 561 (251), 611 (289), 660 (161). EIMS, *m*/*z* (rel. int. %): 622 (74) [M]$^+$, 282 (89) [HL]$^+$.

2.2.6. Co[tBuNHC(S)NP(O)(OPri)$_2$]$_2$ (4f)

Yield: ~74%, m.p. 164 °C. *Anal.* Calc. for $C_{22}H_{48}CoN_4O_6P_2S_2$: C, 40.67; H, 7.45; N, 8.62; S, 9.87. Found: C, 40.63; H, 7.42; N, 8.74; S, 9.91%. IR (cm^{-1}): 1522(s) (SCN), 1000(b, vs) (POC), 1120(s) (P=O), 3320(b) (NH). UV–Vis spectra (CH_2Cl_2), [λ_{max}, nm (ε, 1 mol^{-1} cm^{-1})]: 561 (246), 611 (279), 661 (154). EIMS, *m*/*z* (rel. int. %): 650 (4) [M]$^+$, 296 (10) [HL]$^+$.

2.2.7. Co[Et$_2$NC(S)NP(O)(OPri)$_2$]$_2$ (4g)

Yield: ~80%, m.p. 64 °C. *Anal.* Calc. for $C_{22}H_{48}CoN_4O_6P_2S_2$: C, 40.67; H, 7.45; N, 8.62; S, 9.87. Found: C, 39.93; H, 7.51; N, 8.94; S, 9.77%. IR (cm^{-1}): 1512(s) (SCN), 1000(b, vs) (POC), 1135(s) (P=O). UV–Vis spectra (CH_2Cl_2) [λ_{max}, nm (ε, 1 mol^{-1} cm^{-1})]: 558 (275), 610 (302), 663 (169). EIMS, *m*/*z* (rel. int. %): 650 (51) [M]$^+$, 296 (5) [HL]$^+$.

*2.2.8. Co[$C_5H_{10}NC(S)NP(O)(OPri)_2]_2$ (**4h**)*

Yield: ~71%, m.p. 62 °C. *Anal.* Calc. for $C_{24}H_{48}CoN_4O_6P_2S_2$: C, 42.79; H, 7.18; N, 8.32; S, 9.52. Found: C, 42.66; H, 7.23; N, 8.54; S, 9.61%. IR (cm^{-1}): 1510(s) (SCN), 1010(b, vs) (POC), 1140(s) (P=O). UV–Vis spectra (CH_2Cl_2) [λ_{max}, nm (ε, 1 mol^{-1} cm^{-1})]: 559 (263), 610 (281), 662 (167). EIMS, *m/z* (rel. int. %): 674 (15) $[M]^+$, 308 (3) $[HL]^+$.

*2.2.9. Co[$OC_4H_8NC(S)NP(O)(OPri)_2]_2$ (**4i**)*

Yield: ~67%, m.p. 58 °C. *Anal.* Calc. for $C_{22}H_{44}CoN_4O_8P_2S_2$: C, 38.99; H, 6.54; N, 8.27; S, 9.46. Found: C, 39.05; H, 6.49; N, 8.22; S, 9.50%. IR (cm^{-1}): 1504(s) (SCN), 1010(b, vs) (POC), 1120(s) (P=O). UV–Vis spectra (CH_2Cl_2) [λ_{max}, nm (ε, 1 mol^{-1} cm^{-1})]: 560 (257), 612 (287), 659 (163). EIMS, *m/z* (rel. int. %): 678 (12) $[M]^+$, 310 (9) $[HL]^+$.

*2.2.10. Co[$C_6H_{11}NHC(S)NP(O)(OPri)_2]_2$ (**4j**)*

Yield: ~77%, m.p. 144 °C. *Anal.* Calc. for $C_{26}H_{52}CoN_4O_6P_2S_2$: C, 44.50; H, 7.47; N, 7.98; S, 9.34. Found: C, 44.26; H, 7.34; N, 7.63; S, 8.97%. EIMS, *m/z* (rel. int. %): 702 (1) $[M]^+$, 322 (35) $[HL]^+$.

*2.2.11. Co[$PhC(S)NP(S)(OPri)_2]_2$ (**5a**)*

This complex was prepared according to the previously described technique [20].

*2.3. Synthesis of [Co(B)L_2] (**6a–d**)*

A solution of complexes **4a** or **4b** (0.45 mmol) in benzene (10 ml) was added dropwise whilst stirring to a solution of 2,2′-bipyridine (bpy) or 1,10-phenanthroline (phen) in benzene (10 ml). After complete addition, the solution was stirred for an hour. The solvent was then removed under vacuum. The residue was recrystallized from a methylene chloride–*n*-hexane mixture and the complexes **6a–d** have been isolated as red powders.

*2.3.1. Co[$PhC(S)NP(O)(OPri)_2]_2$(bpy) (**6a**)*

Yield: ~86%, m.p. 133 °C. *Anal.* Calc. for $C_{36}H_{46}CoN_4O_6P_2S_2$: C, 53.00; H, 5.68; N, 6.87; S, 7.86. Found: C, 52.96; H, 5.74; N, 7.17; S, 7.62%. IR (cm^{-1}): 1488(s) (SCN), 1016(b, vs) (POC), 1172(s) (P=O). UV–Vis spectra (CH_2Cl_2) [λ_{max}, nm (ε, 1 mol^{-1} cm^{-1})]: 546 (62). EIMS, *m/z* (rel. int. %): 659 (100) $[M]^+$, 301 (49) $[HL]^+$, 156 (18) $[bpy]^+$.

*2.3.2. Co[$PhC(S)NP(O)(OPri)_2]_2$(phen) (**6b**)*

Yield: ~94%, m.p. 148 °C. *Anal.* Calc. for $C_{38}H_{46}CoN_4O_6P_2S_2$: C, 54.35; H, 5.52; N, 6.67; S, 7.64. Found: C, 54.29; H, 5.57; N, 6.72; S, 7.68%. IR (cm^{-1}): 1490(s) (SCN), 996(b, vs) (POC), 1172(s) (P=O). UV–Vis spectra (CH_2Cl_2) [λ_{max}, nm (ε, 1 mol^{-1} cm^{-1})]: 549 (58). EIMS, *m/z* (rel. int. %): 659 (94) $[M]^+$, 301 (54) $[HL]^+$, 180 (20) $[phen]^+$.

*2.3.3. Co[$PhNHC(S)NP(O)(OPri)_2]_2$(bpy) (**6c**)*

Yield: ~91%, m.p. 142 °C. *Anal.* Calc. for $C_{36}H_{48}CoN_6O_6P_2S_2$: C, 51.12; H, 5.72; N, 9.94; S, 7.58. Found: C, 51.16; H, 5.69; N, 9.98; S, 7.53%. IR (cm^{-1}): 1522(s) (SCN), 1000(b, vs) (POC), 1172(s) (P=O), 3272(b) (NH). UV–Vis spectra (CH_2Cl_2), [λ_{max}, nm (ε, 1 mol^{-1} cm^{-1})]: 551 (56). EIMS, *m/z* (rel. int. %): 690 (0.8) $[M]^+$, 316 (27) $[HL]^+$, 156 (15) $[bpy]^+$.

*2.3.4. Co[$PhNhC(S)NP(O)(OPri)_2]_2$(phen) (**6d**)*

EIMS, *m/z* (rel. int. %): 690 (0.5) $[M]^+$, 316 (22) $[HL]^+$, 180 (23) $[phen]^+$.

2.4. Physical measurements

Infrared spectra (Nujol) were recorded on a Specord M-80 spectrometer in the range 400–3600 cm^{-1}. Electron ionization mass-spectra were measured on the TRACE MS Finnigan MAT instrument. Ionization energy was 70 eV. The substance was injected directly into the ion source at 150 °C. Heating was carried out in a programmed mode from 35 to 200 °C at a rate of 35 °C/min. Electronic spectra of absorption in 0.001 M solution of CH_2Cl_2 were measured on a Lambda-35 spectrometer in the range 200–1000 nm.

2.5. Crystal structure determination and refinement

The crystals of **5a** were obtained from the mixture of dichloromethane and *n*-hexane by the method of slow evaporation. The X-ray diffraction data for the crystal of **5a** were collected on a CAD4 Enraf-Nonius automatic diffractometer using graphite monochromated Cu Kα (1.54158 Å) radiation. The molecule of **5a** in the crystals occur in a special position. The details of the crystal data, data collection and the refinement are given in Table 1. The stability of the crystal and experimental conditions were checked every 2 h using three control reflections, while the orientation was monitored every 200 reflections by centralising two standards. The decay of three control reflections was not observed. An empirical absorption correction based on ψ-scans was applied. Cell parameters, data collection and data reduction were performed on an Alpha Station 200 computer using the MOLEN [21] program. The structures were solved by direct methods using the SIR 92 [22] program, and refined using the SHELXL-97 program [23]. The positions of the hydrogen atoms were idealised. All figures were made using the program PLATON [24].

3. Results and discussion

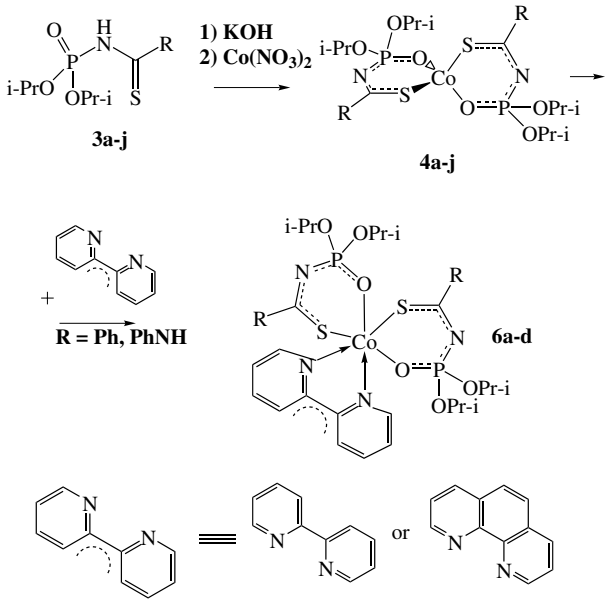
3.1. Synthesis

The ligand **3a** was prepared by reaction of thiobenzamide $PhC(S)NH_2$ with diisopropoxychlorphosphate $(iPrO)_2P(O)Cl$. Ligands **3b**–**j** were prepared by reaction of the corresponding amine with $(iPrO)_2P(O)NCS$.

Complexes of **3a**–**j** with Co(II) **4a**–**j** were prepared by the following procedure: the ligand was converted to the potassium salt, followed by interaction with $Co(NO_3)_2 \cdot 6H_2O$. The compounds obtained are crystalline solids soluble in most polar solvents.

Unsaturation of the CoO_2S_2 coordination environment opens up possibilities of a wide number of heteroligand complex syntheses. This can be obtained by interaction of such complexes with various donor agents [25]. As donors, both monodentate ligands and chelating agents might be used. A variety of donor structures opens up prospects for supramolecular units within the realm of advanced synthesis. We used bpy and phen in our work as donor ligands (Scheme 2).

Complexes **6a**–**d** were prepared by the following procedure: a benzene solution of bpy or phen was added dropwise to a benzene solution of the complex **4a** or **4b**. The compounds obtained **6a**–**d** are crystalline solids which are soluble in most polar solvents.



Scheme 2.

The research has shown that all listed complexes **4a**–**j** have the same coordination environment at the Co(II) atom. The UV–Vis spectroscopic data confirm that in a CH_2Cl_2 solution only ML_2 chelates with a tetrahedral MO_2S_2 core exist. In the case of complexes **6a**–**d** the coordination environment of the central atom differs from complexes **4a**–**j**. According to UV–Vis spectroscopy data obtained in a CH_2Cl_2 solution, complexes **6a**–**d** have an octahedral $MO_2S_2N_2$ core.

3.2. IR and UV–Vis spectroscopy

According to the IR spectroscopy, the absorption bands of the P═O group of anionic forms **3a**–**j** in complexes **4a**–**j** are shifted by approximately 76–116 cm^{-1} at low frequencies with respect to the parent ligand bands. It confirms their participation in chelate formation. In the spectra of the suspension of complexes **4a**–**j** in Nujol, there are intense absorption bands at 1504–1524 cm^{-1}, these are assigned to vibrations of the SCN fragment in the *N*-thioacylamidophosphate-anion [7]. The signal of the NH proton is absent in the IR spectra of the complexes **4a**,**g**–**i** and in the spectra of **4b**–**f** and **sj**, there is only a signal in the 3288–3320 cm^{-1} interval, corresponding to the NH-group vibrations of the R substituent.

The comparative analysis of IR spectra of **3a** and **3b** thioureas, their complexes with Co(II) cation formulas **4a** and **4b**, and adducts **6a**–**d** confirms the preservation of the CoL_2 core in compounds **6a**–**d**. The absorption band of the P═O group in complexes **6a**–**d** is shifted by approximately 72–80 cm^{-1} at low frequencies with respect to the free ligand bands **3a** and **3b**, and there is also an intense absorption band of the SCN fragment. All this confirms 1,5-S,O-coordination of the ligand anions. However, the shift of the P═O groups absorption bands in adducts **6a**–**d** is less than

32–36 cm^{-1}, compared to the initial Co(II) complexes **4a** and **4b**.

The structure of the chelate unit in Co(II) complexes in the CH_2Cl_2 solution is established by UV-spectroscopy. In complexes **4a–j** there is an absorption band with peaks in the ranges 558–562, 610–614 and 657–666 nm and with molar extinction coefficient (ε) 246–394, 279–386 and 154–187, respectively. Values of ε for complexes **4a–d**, containing arylamine substituents at thiocarbonic groups, are greater than 80–119 nm, compared to complexes **4e–j**. Absorption is observed in the red region of the spectrum, which explains the dark blue color of the complexes of Co(II) **4a–j**. The specified absorption band corresponds to a transition from the basic state $^4A_2$ to a $^4T_1(P)$ state. The thin structure is caused by spin–orbital interaction as a result of which, first, there is a splitting of the state $^4T_1(P)$ and, secondly, there are resolved transitions in the next doublet states with the same intensity. Other possible transitions: $^4A_2 \rightarrow {}^4T_2$ and $^4A_2 \rightarrow {}^4T_1(F)$ – are outside of the visible area. Data of UV-spectroscopy unequivocally confirm the tetrahedral environment of the Co(II) cation in complexes **4a–j**.

In the UV-spectra of complexes **6a–d** there is a shoulder with a peak of absorption in the region of 546–560 nm. Values of ε for **6a–d** are less, compered to the initial complexes **4a** and **4b**, which are in the 56–62 nm range. It is important to note that the absorption is weak enough and shifted to the violet part of a spectrum that causes the red color of complexes **6a–d**. The observable absorption band is caused by a $^4T_{1g}(F) \rightarrow {}^4T_{1g}(P)$ transition. It is easy to establish that the $^4T_{1g}(F) \rightarrow {}^4T_{2g}$ transition should correspond to the value of energy which is slightly lower in comparison with the energy of the $^4T_{1g}(F) \rightarrow {}^4T_{1g}(P)$ transition. But as the state $^4A_{2g}$ arises from a configuration $t_{2g}^3e_g^4$ and a state $^4T_{1g}(F)$ mainly from $t_{2g}^5e_g^2$, transition $^4T_{1g}(F) \rightarrow {}^4A_{2g}$ is in essence a two-electron transfer, and for this reason the band should be less intense (approximately by two orders), than the bands of other transitions. The specified two circumstances for $^4T_{1g}(F) \rightarrow {}^4A_{2g}$ transition: small intensity and affinity to the band $^4T_{1g}(F) \rightarrow {}^4T_{1g}(P)$ lead to fact that this transition is not observed in a spectrum. Data from UV-spectroscopy confirm a change of a Co(II) cation geometrical environment in compounds **4a** and **4b** after reaction with bpy and phen with the formation of adducts **6a–d**.

3.3. EI mass spectrometry

The electron impact (EIMS) mass spectra of **4b–j** contains the $[CoL_2]^+$ structure molecular ion peaks. The isotope bearing peaks of a molecular ion cluster correspond to the data calculated on the basis of gross-formulas of the CoL_2 structure. Stability of $[M]^+$ falls at complexes **4b** and **4c**, containing arylamine substituents at the carbon atom of the thiocarbonic groups. So, the peak of a molecular ion in the mass-spectrum of the complex **4b** has a very

small intensity equal to 0.1%, and in mass-spectrum of the complex **4c** – 0.2%. In EI mass-spectra of the **6a–d** adducts there are no peaks of molecular ions. Molecular ions of complexes **6a–d** are unstable under the conditions of measurement, and the heaviest molecular ion, observed in the spectra of **6a–d**, corresponds to the neutral CoL_2 complex core. In the EI-spectra there are also peaks of ligands **3a**, **3b**, bpy and phen, respectively.

3.4. The comparative analysis of molecular structure of CoL_2 complexes

The structure of complexes **4a** [14] and **4b** [19] have been investigated earlier by X-ray studies. It is of interest to compare their structure with the dithioanalogue **5a**.

According to the X-ray data complexes **4a**, **4b** and **5a** are spirocycling chelates in the crystal with a distorted-tetrahedral CoO_2S_2 core for **4a** and **4b** or CoS_4 for **5a**. The selected bond lengths and torsion angles are given in Table 2.

Distribution of bond lengths in a fragment S–C–N–P–Y for all compounds considered confirms the existence of two tautomeric forms: S-enolic (A) and Y-enolic (B) (Scheme 1). Bond lengths C–N and P–N in complexes of phosphorylated (Y = O) and thiophosphorylated (Y = S) derivatives differ slightly (Table 2). In order to make sense of this, one sees that the character of the negative charge delocalization in the coordinated *N*-thioacylamido(thio)phosphate-anion and the resonant forms (A) and (B) (Scheme 1) practically does not change at the transition from thiophosphoric derivatives to phosphoric derivatives.

In *N*-thioacylamidophospate complexes **1** the six-membered M–S1–P–N–C–S2 cycle, usually, has the conformation of a distorted boat. So, for example, in the complex **5a**, the cycles conformation is an asymmetrical boat with a planar PNCS fragment and with a deviation of metal and thiophosphoryl sulfur atoms (the fragment S2A–C1A–N1A–P1A is flat within the limits of 0.003(4) Å, a deviation of atoms S1A and Co1 −1.527(1) and −0.8364(7), respectively; similarly, the fragment S2B–C1B–N1B–P1B is flat within the limits of 0.029(4) Å, with a deviation of atoms Co1 and S1B of 1.1306(7) and 1.473(1) Å, respectively (Fig. 1)). Six-membered chelate cycles in molecules **4a** and **4b**, on the contrary, are appreciably flattened (Table 2).

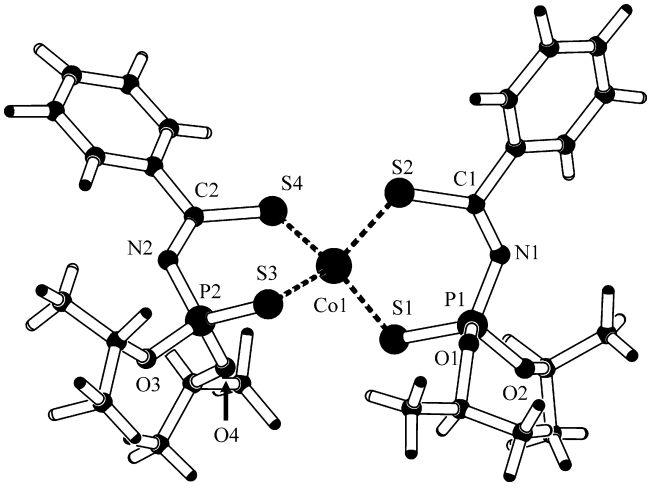

Fig. 1. Molecular structure of complex **5a**.

4. Conclusion

This research has shown that the structure and properties of *N*-thioacylamidophosphate complexes with the CoO_2S_2 core essentially differ from that investigated by us previously with the same cation. The Co(II) cation in such complexes shows coordination unsaturation. A consequence of this is the ability to increase the coordination number of the central atom with neutral donor ligands, with the formation of $Cd(B)L_2$ adducts. Ligands like the *N*-thioacylamidophosphate, as has been shown by us earlier [12], and also molecules of bpy and phen can act in this manner. Thus, complexes with CoO_2S_2 core can be used as electrophilic binding centers in organometallic receptor molecules, e.g. in polynuclear macrocyclic chelates of bifunctional *N*-thioacylamidophosphates [3].

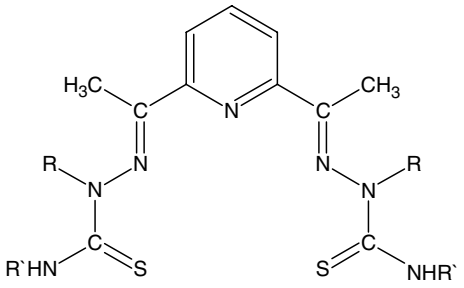

Fig. 1. 2,6-Diacetylpyridine bis(thiosemicarbazones).

characterized [14–18]. The related, 2,6-diacetylpyridine bis(^{4}N-methylthiosemicarbazone) (Fig. 1; R = H, R′ = CH_3) has also demonstrated its ability to act as a versatile chelating agent yielding a seven-coordinate manganese(II) complex [19], a five-coordinate lead(II) complex [20], a helical dimeric zinc(II) complex [20] and a seven-coordinate tin(II) complex [21].

Although pentagonal-bipyramidal complexes of zinc(II) [12], indium(III) [22], tin(IV) [14–18], tin(II) [21], iron(II) [22], bismuth(III) [23] of pentadentate N_3S_2 thiosemicarbazones have been well characterized, there does not seem to be a single report on seven-coordinate cadmium(II) complexes of a pentadentate thiosemicarbazone ligand. The only seven-coordinate cadmium(II) complex of a thiosemicarbazone that has been structurally characterized is $[Cd(HL^2)(Cl)_2(H_2O)_2]$ in which the HL^2 ligand is the 1:1 condensation product of 2,6-diacetylpyridine with thiosemicarbazide which behaves as an NNS tridentate chelating agent [24].

In view of limited structural and spectroscopic data available on seven-coordinate cadmium(II) complexes of pentadentate thiosemicarbazones and as part of our ongoing work on metal complexes of multidentate thiosemicarbazones, we report here the synthesis and characterization of new zinc(II) and cadmium(II) complexes of a neutral petadentate N_3S_2 thiosemicarbazone ligand, together with the X-ray crystal and molecular structures of the free ligand and its seven-coordinate cadmium(II) complex.

2. Experimental

2.1. Materials and instrumentation

All chemicals were of analytical reagent grades and used without any further purification. ^{2}N-Methylthiosemicarbazide was purchased from the Aldrich Chemical Company. The electronic spectra were recorded in solution on a Shimadzu UV-3100 spectrophotometer. The IR spectra were recorded as KBr discs on either a Perkin–Elmer 1600 FT IR spectrometer or a Perkin–Elmer 2000 spectrometer. Conductance measurements were made by means of a CMD 400 conductivity meter. The ^{1}H and ^{13}C NMR spectra were run in DMSO-d_6 on a Bruker Avance DPX 300 K FT NMR spectrometer using TMS as an internal standard.

2.2. Preparation of dap-^{2}NMetsc

2,6-Diacetylpyridine (1.63 g; 0.01 mol) was dissolved in boiling methanol (130 ml). Two drops of glacial acetic acid were added to the solution followed by the addition of a solution of ^{2}N-methylthiosemicarbazide (2.10 g; 0.02 mol) in methanol (100 ml). The reaction mixture was refluxed for three hours and then left to stand overnight. The yellow product that formed was filtered off, washed with cold methanol and dried in air. The crude compound was recrystallized from acetonitrile to afford crystals suitable for X-ray work. Yield: 2.30 g; 70%. *Anal.* Calc. for $C_{13}H_{19}N_7S_2$: C, 46.27; H, 5.67; N, 29.06. Found: C, 46.3; H, 5.66; N, 29.44%. NMR: δ_H(DMSO-d_6) 2.45 (6H, s, C–CH_3), 3.50 (6H, s, N–CH_3); 7.40 (s, br, NH_2); 8.34 (2H, d, pyH); 7.97 (1H, t, pyH), δ_C: (DMSO-d_6): 180.9 (C=S), 169.4 (pyC), 154.5 (pyC), 148.6 (C=N), 137.4 (pyC), 121.3 (pyC), 11.7 (CH_3), 41.9 (N–CH_3).

2.3. General method of preparation of $[M(dap\text{-}^2NMetsc)](NO_3)_2$ ($M = Zn^{2+}$, Cd^{2+})

The hydrated metal(II) nitrate salt (1 mmol) dissolved in boiling methanol (30 ml) was mixed with a boiling solution of the ligand (1 mmol) in a mixture of methanol (150 ml) and dichloromethane (20 ml). The reaction mixture was heated under reflux for 1 h and then left to stand overnight. The complexes generally crystallized out of the reaction mixture as diffraction quality crystals. Yield: 70–80%. *Anal.* Calc. for $[Zn(dap\text{-}^2NMetsc)(NO_3)_2]$ $C_{13}H_{19}N_9O_6S_2Zn$: C, 29.63; H, 3.63; N, 23.93. Found: C, 29.25; H, 3.73; N, 23.63%. δ_H(DMSO-d_6) 2.45 (6H, s, C–CH_3), 3.49 (6H, s, N–CH_3); 7.40 (s, br, NH_2); 8.30 (2H, d, pyH); 8.00 (1H, t, pyH), δ_C: (DMSO-d_6): 180.9 (C=S), 153.3 (C=N), 169.5, 168.3 (PyC), 126.4, 124.3, 123.5 (pyC); 138.9, 137.2 (pyC), 16.9, 16.8 (–CH_3), 41.9 (N–CH_3); Λ ($ohm^{-1}\,cm^2\,mol^{-1}$) in DMF: 90.7.

Anal. Calc. for $[Cd(dap\text{-}^2NMetsc)(NO_3)_2]$ ($C_{13}H_{19}N_9O_6Cd$): C, 27.20; H, 3.34; N, 21.96. Found: C, 27.11; H, 3.76; N, 21.39%. δ_H(DMSO-d_6): 2.63 (6H, s, C–CH_3), 8.60 (s, br, NH_2), 3.43 (6H, N–CH_3); 8.37 (2H, d, pyH);8.47 (1H, t, pyH); δ_C: (DMSO-d_6): 180.9 (C=S), 163.3 (pyC), 148.9 (C=N), 127.9 (pyC), 143.1 (pyC), 18.7 (CH_3); 43.77 (N–CH_3); Λ ($ohm^{-1}\,cm^2\,mol^{-1}$) in DMF: 47.7.

2.4. Crystallography

Cell constants were determined by a least-squares fit to the setting parameters of 25 independent reflections, measured on an Enraf-Nonius CAD 4 four-circle diffractometer using graphite monochromated Mo Kα radiation (0.71073 Å) and operating in the ω–2θ mode within the range $2° < 2\theta < 50°$. An empirical absorption correction (ψ scans) [25] and data reduction [26] were performed within the WINGX [27] suite programmes. The structures were solved by direct methods with SHELX86 [28] and

refined by full-matrix least-squares analysis with SHELXL97 [29]. Non-hydrogen atoms were refined with anisotropic thermal parameters whereas H-atoms were included at estimated positions. Drawings of the molecules were produced with ORTEP3 [30]. A summary of the crystal data, structure solution and refinement parameters are given in Table 1.

3. Results and discussion

Reaction of dap-^{2}NMetsc with zinc(II) and cadmium(II) nitrate in a boiling mixture of methanol and dichloromethane afforded crystalline complexes of empirical formula, [M(dap-^{2}NMetsc)$(NO_3)_2$] ($M = Zn^{II}$, Cd^{II}). These compounds are quite stable in air and could be kept in a desiccator for a long period of time without any sign of decomposition. The molar conductivities of the zinc and cadmium complexes in DMF are 90.7 and 47.7 ohm^{-1} cm^2 mol^{-1}, respectively indicating that the former behaves as a 1:1 electrolyte in DMF and the latter is extensively dissociated in this solvent. However, the IR spectrum of the zinc(II) complex exhibits the νN–O bands of the nitrato ligands at 1498 and 1308 cm^{-1} whereas that of the cadmium(II) complex shows the NO stretching bands at 1493 and 1298 cm^{-1} indicating that the nitrate anions are coordinated to the metal ions as monodentate ligands [31,32].

Reaction of dap-^{2}NMetsc with nickel(II) nitrate did not lead to the formation of a nickel(II) complex of dap-^{2}NMetsc but a green crystalline nickel(II) complex of formula, $[Ni(^2N\text{-Metsc})_2](NO_3)_2$ (^{2}N-Metsc = ^{2}N-methylthiosemicarbazide) was obtained due to complete hydrolysis of the bis(thiosemicarbazone) ligand to the precursors ^{2}N-methylthiosemicarbazide and 2,6-diacetylpyridine. The crystal structure of $[Ni(^2N\text{-Metsc})_2](NO_3)_2$ has previously been reported by Valdez-Martinez et al. [33]. The reluctance of the nickel(II) ion to form a seven-coordinate pentagonal bipyramidal nickel(II) complex with a planar pentadentate ligand is probably the driving force for the hydrolysis of the thiosemicarbazone ligand to its constituent thiosemicarbazide. Unlike Zn(II) and Cd(II) (both with d^{10} electronic configurations) there is an electronic (ligand field stabilization) driving force that favours for octahedral or square planar Ni(II) geometries of this d^8 ion. The planar pentadentate array of donor atoms offered by dap-^{2}NMetsc is thus incommensurate with the geometric preferences of the metal.

The IR spectrum of the ligand exhibits bands at 1646, 1072 and 894 cm^{-1} which can be assigned mainly to the νC=N, νN–N and νC=S vibrations, respectively. The νC=N and the νC=S bands of the free ligand are lowered in the spectra of the complexes consistent with coordination of the ligand to the metal ions *via* the azomethine and thione sulfur atoms.

The electronic spectrum of the free ligand shows a band at 340 nm attributable to the $n \rightarrow \pi^*$ transition of the azomethine group. In addition to this intra-ligand band, a new band at ca. 450 nm is observed in the spectra of the zinc and cadmium complexes. This band can safely be assigned to a $S \rightarrow M$ charge-transfer band. The appearance of an $S \rightarrow M$ charge transfer band in the electronic spectra of the zinc(II) and cadmium(II) complexes is strong evidence that the thione sulfur atoms of the ligand are coordinated to the zinc(II) and cadmium(II) ions (see Table 2).

The ^{1}H NMR spectrum of the free ligand when compared with those of the metal complexes indicates that the signals due to the protons on the C4, C11, N1, N7, C6 and C8 atoms are unaffected by complexation but the protons on C2, C12 and C7 are deshielded. The ^{13}C NMR spectra of the ligand and its complexes are more

Table 2
IR and electronic spectral data for dap-^{2}NMetsc and its zinc(II) and cadmium(II) complexes

Compound	ν(NH)	ν(CN)	ν(NN)	ν(CS)	State	λ_{max} (nm)

or less similar. A similar observation was also made with seven-coordinate cadmium(II) complex of the mono-condensed thiosemicarbazone of 2,6-diacetylpyridine [24].

3.1. The crystal structure of dap-^{2}NMetsc

The structure of the free ligand, dap-^{2}Metsc, together with the atom labelling scheme adopted, is shown in Fig. 2. The bond lengths and bond angles are given in Table 3. The ligand adopts an *E* configuration about the C3–N3 and C10–N5 bonds with both the azomethine nitrogen atoms and the pyridine nitrogen atom *trans* to the thione sulfur atoms. The conformation of the ligand as observed in the solid state, therefore, is ill-suited for it to act as a pentadentate N_3S_2 chelating agent. In order to coordinate through all of its donor atoms, 180° rotations about the C3–C5, C9–C10, C1–N2 and C13–N6 bonds must occur. The C1–S1 [1.688(2) Å], C1–N2 [1.368(3) Å], N2–N3 [1.419(2) Å], N3–C3 [1.283(2) Å] and C3–C5 [1.491(3) Å] bond lengths are comparable with those of the related ligands, 2,6-diacetylpyridine bis(3-hexamethyleneiminylthiosemicarbazone) monohydrate [16] and 2,6-diacetylpyridine bis(^{4}N-ethylthiosemicarbazone) [34]. The above bond lengths also indicate that there is some electron delocalization in the thiosemicarbazide side chain. The acetylpyridine moiety retains its expected planarity but the two terminal thiosemicarbazide residues are twisted about their N—N bonds well away from the plane of the pyridyl ring [C1–N2–N3–C3 150.1(2)° and C10–N5–N6–C13 148.7(2)°]. This twisting avoids 1,3-methyl-methyl interactions on each 'arm' of the ligand.

The thiosemicarbazide moieties are also distinctly non-planar [S1–C1–N2–C2 22.5(3)° and S2–C13–N6–C12 14.4(3)°]. The distortion from planarity relieves $-CH_3\cdots S$ non-bonded repulsions. In the absence of this methyl group the S1–C1–N2–N3 residue would be ideally planar.

3.2. The crystal structure of Cd(dap-^{2}NMetsc)$(NO_3)_2$

The structure of the complex, Cd(dap-^{2}NMetsc)$(NO_3)_2$ is shown in Fig. 3 and selected bond lengths and bond angles are given in Table 3. The coordination environment of the cadmium atom may be considered as a distorted pentagonal bipyramid with the thiosemicarbazone ligand coordinated to the cadmium(II) ion as a pentadentate N_3S_2 chelate *via* the pyridine nitrogen atom, the two azomethine nitrogen atoms and the two thione sulfur atoms. The two axially coordinated monodentate nitrato ligands complete the seven-coordinate geometry.

The structure resembles that of the seven-coordinate pentagonal bipyramidal zinc(II) complex, [Zn(dap-tsc)$(H_2O)_2$]$(NO_3)_2\cdot H_2O$ [dap-tsc = the 2,6-diacetylpyridine-bis(thiosemicarbazone)] in which the two apical positions are occupied by aqua ligands [12]. The Cd–S bond distances [2.589(1) and 2.587(2) Å] are close to each other as are the two Cd–N_{imine} distances [2.496(3) and 2.482(5) Å]. These bond distances compare well with those of the seven-coordinate cadmium(II) complex $[Cd(HL^2)Cl_2(H_2O)]\cdot H_2O$ (HL^2 = the mono-condensed 2,6-diacetylpyridine thiosemicarbazone) whose structure has been reported by Casas et al. [24]. Although the azomethine nitrogen atoms are typically stronger donors than pyridine, the two Cd–N_{imine} bond distances in the present complex are longer than the Cd–N_{py} distance [2.300(4) Å]. While M–N_{imine} bond distances in complexes of tridentate NNS thiosemicarbazone derived from heterocyclic aldehydes and ketones are invariably shorter than the M–$N_{pyridine}$ distances, the reverse appears to be true for metal complexes of pentadentate thiosemicarbazone ligands. This is probably due to the geometric requirements of the pentadentate N_3S_2 ligand and the fact that the pyridine N-donor occupies the central position of the pentadentate ligand and is forced into a shorter than normal interaction with the metal due to the restraints of the two chelating arms either side of the coordinating atom. The two Cd–O distances [2.394(5) and 2.545(3) Å] in the [Cd(dap-^{2}NMetsc)$(NO_3)_2$] complex differ substantially, one being short and the other long. The Cd–O1b bond length is much longer that that observed in other seven-coordinate cadmium(II) complexes.

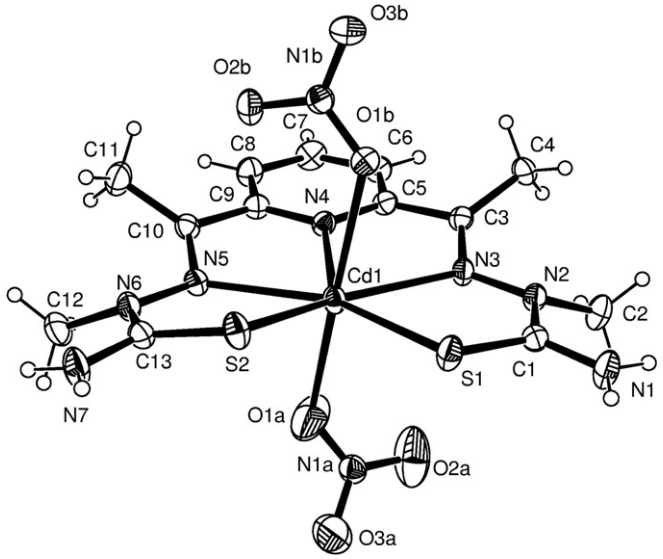

Fig. 3. ORTEP3 view of Cd(dap-^{2}NMetsc)$(NO_3)_2$ (30% ellipsoids).

As foreshadowed, the conformation of the coordinated ligand is very different to that seen in the metal free structure. However, similar steric influences are at work in the Cd complex that result in distortions from the normal planar conformation of a coordinated thiosemicarbazone. The ligand is still distinctly non-planar and a similar twisting distortion about both N–N bonds [C1–N2–N3–C3 159.1(4)° and C10–N5–N6–C13 –145.2(4)°] is seen in the complex in order to avoid methyl$\cdots$methyl non-bonded repulsions. Similarly the terminal thiosemicarbazide moieties are twisted about their C–N bonds by a similar degree as seen in the structure of the free ligand [N1–C1–N2–C2 19.5(7)° and N7–C13–N6–C12 –16.4(7)°]. Overall the ligand adopts a 'saddle' conformation with the methyl and terminal NH_2 groups alternating in their orientation above or below the approximate pentagonal coordination plane.

In most thiosemicarbazones, deprotonation of the N-atom at position 2 accompanies coordination and leads to significant alteration of electron density within the ligand backbone. In dap-^{2}NMetsc methylation of this N-atom blocks deprotonation and the intraligand bond lengths are basically unchanged upon coordination. The C–S bond length still has an intermediate value between a single bond (1.82 Å) and for a C=S double bond [1.56 Å]. The C1–N2 [1.368(6) Å], C13–N6 [1.354(6) Å], C–N1 [1.315(6) Å] and C13–N7 [1.320(6) Å] bond distances indicate that these bonds also have partial double bond characters. This is an indication that there is some electron delocalization in the hydrazine chain, but that it is independent of coordination.

For an ideal pentagonal bi-pyramidal complex, each of the five angles subtended at the equatorial plane should be 72°. Most of the coordinate angles within the equatorial plane are within 4° of this value; the S1–Cd–S1 angle (unrestrained by a chelate ring) shows the greatest deviation from the ideal value. It should be pointed out that for an ideal pentagonal array of donor atoms, a cyclic ligand with identical donor atoms and bond lengths is required.

4. Conclusions

The 2,6-diacetylpyridine bis(^{2}N-methylthiosemicarbazone) obtained by condensation of ^{2}N-methylthiosemicarbazide with 2,6-diacetylpyridine readily yields a

pentadentate N_3S_2 chelating agent forming pentagonal-bipyramidal zinc(II) and cadmium(II) complexes. Methylation at N2 blocks deprotonation of the ligand at each arm and the ligand binds as a neutral molecule in contrast to most other thiosemicarbazones which typically coordinate as anions. Notwithstanding the variations of bond lengths around the chelate rings within the coordinated ligand, the N_3S_2 donor set approaches that of an ideal pentagonal array and this ligand may be useful in enforcing this unusual geometry on other metal ions.

5. Supplementary material

Crystallographic data in CIF format (CCDC Deposition Nos. 604849 (dap-^{2}NMe) and 604850 (Cd(dap-^{2}NMe)$(NO_3)_2$)) have been deposited at the Cambridge Crystallographic Data Centre and are available on request from the Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44 1223 336 033; e-mail: deposit@ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk).

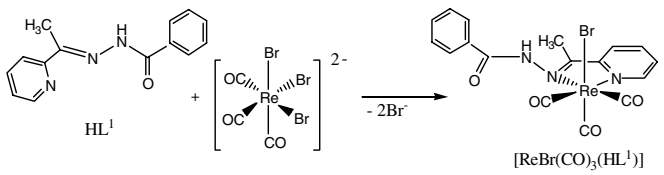


Scheme 1.

hydrazide, which was previously synthesized by Lu et al. [6], as well as the isolation and characterization of the rhenium(I) complex. The substitution of the acetylpyridine fragment of HL^1 by ferrocenyl carbaldehyde must give rise to a different coordination mode of the ligand. Furthermore, the incorporation of the ferrocenyl group into the complex will enable the exploration of potentially improved bioinorganic (antitumor and antivirus activities [7]) and catalytic applications. The latter possibility results from the modulation of the binding affinity of the ligand for the rhenium fragment by the redox state of the ferrocenyl group [8].

2. Results and discussion

2.1. Synthesis and spectroscopic characterization

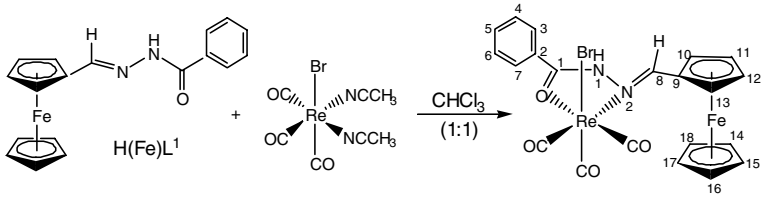
Ligand $H(Fe)L^1$ was obtained by treatment of ferrocenylcarbaldehyde with benzoylhydrazine in dry methanol. Single crystals of this compound were obtained from the mother liquor. The compound is air stable and soluble in common organic solvents (see Scheme 2).

Reaction of the ligand with the adduct *fac*-$[ReBr(CO)_3(NCCH_3)_2]$ afforded a red solid that is stable in air, moderately soluble in chloroform and highly soluble in acetone. Elemental analysis and mass spectrometry confirmed the stoichiometry $[ReBr(CO)_3\{H(Fe)L^1\}]\cdot\frac{1}{2}CHCl_3$ the mass spectrum contains a signal corresponding to the molecular ion, although the peak due to the species $[M-Br]^+$ is slightly more intense, as observed in the thiosemicarbazone derivatives described in Ref. [9]. Facial geometry around the rhenium atom is suggested by the three strong ν(C≡O) IR bands in the range 2027–1891 cm^{-1}. Furthermore, the band corresponding to the ν(C=O) mode is shifted from 1646 cm^{-1} in $H(Fe)L^1$ to 1594 cm^{-1} in the rhenium complex. This effect is contrary to that observed in the complex $[ReBr(CO)_3(HL^1)]$ (1677 cm^{-1}) in comparison to HL^1 (1657 cm^{-1}) [5], suggesting a different coordination mode in which the amide C=O group is, as one would expect, directly involved in the coordination. Both of these aspects – configuration around the metal atom and coordination mode of the ligand – were confirmed by an X-ray diffraction study (vide infra).

The ^1H NMR spectra of both compounds display signals corresponding to the ferrocenyl group (with clear differences between the linked and free cyclopentadienyl groups), the phenyl group and N–H protons. In general, all proton signals in the complex are shifted at low field respect to the free ligand, as in $[ReBr(CO)_3(HL^1)]$. However, the hydrazinic proton singlet at 10.70 ppm in $H(Fe)L^1$ is strongly shifted (12.80 ppm) in the spectrum of the rhenium complex. This effect of rhenium coordination has also been observed in other hydrazine-based ligands such as thiosemicarbazones [9,10] when the N–H group is a member of the chelate ring. In cases where the coordination mode of the ligand excludes the N–H group of the chelate ring, the singlet is only shifted by around 1 ppm (see for instance Refs. [11,5] for thiosemicarbazone and hydrazone systems, respectively). Both title compounds show signals corresponding to the ferrocenyl group and these are distributed in two sets: a singlet at 4.20 and 4.40 ppm, respectively, due to the free cyclopentadienyl ring and two doublets between 4.40 and 5.30 corresponding to the ring linked to the hydrazone moiety.

The UV–Vis solution spectra of the ligand and complex were also recorded (Fig. 1) and the main data are included in Table 1. The data for HL^1 and $[ReBr(CO)_3(HL^1)]$ [5] are also included for the sake of comparison. The spectra of the title compounds are strongly dominated by the ferrocene bands, which have been discussed by John et al. [12]. The spectra of the compounds were obtained in two solvents of different polarities, such as MeOH and chloroform, and suggest a slight positive hyperchromic effect in the $H(Fe)L^1$ derivatives but a hypsochromic shift with polarity in the HL^1 derivatives.

The absorptions in the range 320–360 nm and the bands centered at 265 nm in the ferrocene derivatives are due to π–π^* transitions, the latter probably those of the cyclopentadienyl rings [6]. The band centered at 295 nm, which is present in all uncoordinated ligands included in Table 1, is attributed to the IL π–π^* transitions arising probably from the aroylhydrazone moiety [6]. The shoulder between 430–495 nm is attributed to MLCT from Fe to either the non-bonding or the antibonding orbitals of the cyclopentadienyl rings.



Scheme 2.

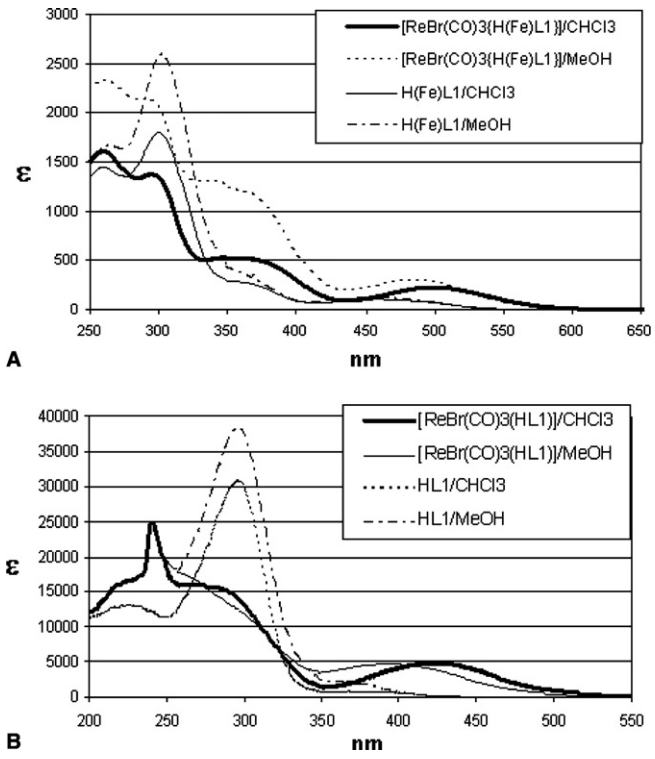


Fig. 1. UV–Vis spectra of $H(Fe)L^1$ (A) and HL^1 (B) and their rhenium(I) complexes.

The absorption patterns in the spectra of the complexes *fac*-[$ReBr(CO)_3(HL^1)$] and *fac*-[$ReBr(CO)_3\{H(Fe)L^1\}$] are quite similar to each other. The broad bands in the range 400–530 nm could be assigned to MLCT d –> π^* transitions, which are very similar to analogous absorptions in other rheniumtricarbonyl complexes [13]. The intense absorption at 294 nm is due to a ligand centered π–π^* transition, while the other IL transitions would be expected to appear in the range 200–210 nm. Surprisingly, the band due to the hydrazone group, in both kinds of complex, is strongly shifted when compared with that in the uncoordinated ligands – in spite of the very different chelation mode of the ligand with the rhenium centre observed in the solid state.

2.2. The molecular structures of the compounds

The molecular structures of the ligand $H(Fe)L^1$ and the rhenium(I) derivative are shown in Fig. 2 along with the atomic numbering scheme used. Selected bond lengths and angles are listed in Table 2.

Single crystals of the ligand were obtained from the mother liquor (methanol). Its structure is a rare example of the presence of four crystallographically independent molecules per asymmetric unit, together two methanol solvent molecules. All searches for missing symmetry were unsuccessful [14]. The differences between distances and angles in the $H(Fe)L^1$ molecules are statistically insignificant and, consequently, mean values are included in Table 2.

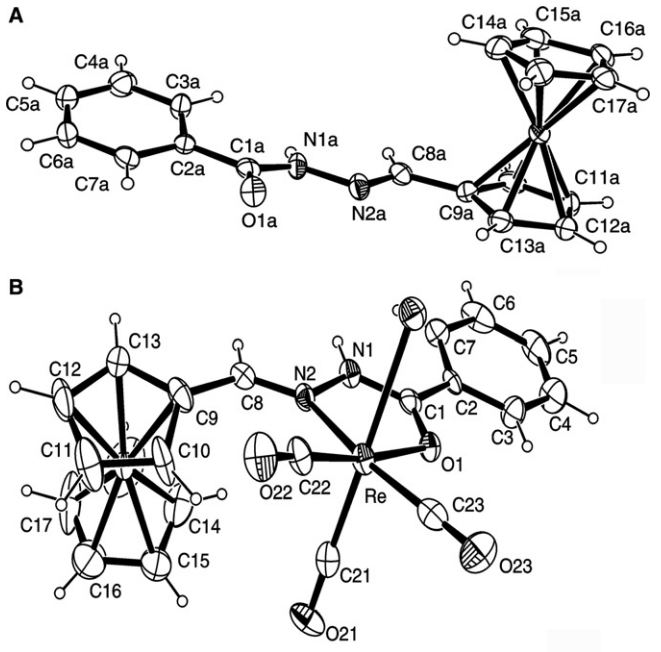

Fig. 2. Molecular structures of $H(Fe)L^1$ (A) and [$ReBr(CO)_3\{H(Fe)L^1\}$] (B) (the thermal ellipsoids represent 30% occupancy).

[a] Average values and standard deviations are estimated with the expressions: $x = (\sum x_j/\sigma_j^2)/\sum 1/\sigma_j^2$; $\sigma^2(x) = 1/\sum 1/\sigma_j^2$.

In the molecule of $H(Fe)L^1$, the hydrazone group and the cyclopentadienyl ring are almost coplanar, although the phenyl group deviates slightly from the idealized plane. The C–N and N–N bond distances suggest mainly a double-bond character for the C8–N2 link although some π delocalization around the hydrazone chain occurs is also possible. As in ferrocenylcarbaldehyde isonicotinylhydrazone [15], the configurations of the bonds in the fragment C1–N1–N2–C8 is, in all cases, *Z*,*E*,*E*, respectively.

Single crystals of the complex $[ReBr(CO)_3\{H(Fe)L^1\}]$ containing half chloroform molecule per asymmetric unit were obtained by slow evaporation of chloroform solutions. Since we were unable to find a statistical model for the disorder of the solvent molecule, the program SQUEEZE [16] was used to correct its diffuse scattering data. The rhenium atom is coordinated by the N2 and O1 hydrazone atoms, forming a five-membered chelate ring, as well as three carbonyl carbon atoms and bromine atoms. The resulting coordination polyhedron can be described as a distorted octahedron [the main distortion being C(22)–Re–N(2) and O(1)–Re–N(2)]. This coordination mode does not cause changes in the configuration of the hydrazone chain with respect to that observed in $H(Fe)L^1$. The C1–O1 distance is clearly longer than that in the free ligand as a consequence of Re–O1 coordination. However, this change does not appear to have any consequence on the hydrazone chain (only a slight shortening of the C1–C8 distance is observed).

2.3. Supramolecular structures

The supramolecular structure of $H(Fe)L^1\cdot\frac{1}{2}(CH_3OH)$ is shown in Figs. 3A and B and the main interactions are listed in Table 3. The association of the molecules in the crystal is strongly dominated by hydrogen bonding, either between

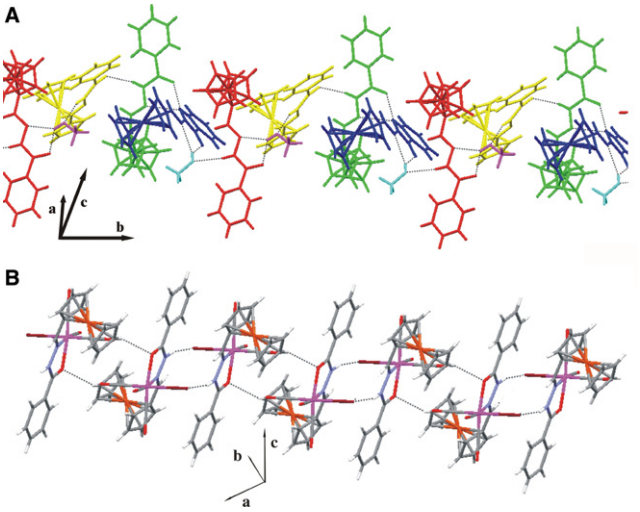

Fig. 3. Mercury [22] plots showing the hydrogen bonds in crystals of $[H(Fe)L^1]\cdot\frac{1}{2}CH_3OH$ (A) and $[ReBr(CO)_3\{H(Fe)L^1\}]\cdot\frac{1}{2}CHCl_3$ (B).

ligand molecules or involving the methanol molecules. These aspects are depicted in Fig. 3A, in which the asymmetric unit is represented. Three molecules of $H(Fe)L^1$ are associated by interactions between N1–H groups and N2 or O1 atoms of crystallographically independent neighbouring molecules. This virtual trimer is associated with another crystallographically independent molecule of $H(Fe)L^1$ by a methanol molecule. The resulting unit is associated through a second methanol molecule of other units to form chains running along the *b* axis (Fig. 3B).

The coordination of the tricarbonylrhenium(I) fragment hinders the hydrogen-bonding interactions involving the O1 atom and, consequently, the association of the complex $[ReBr(CO)_3\{H(Fe)L^1\}]$. Indeed, these complex molecules are associated in dimers by weak hydrogen-bonding interactions between the N1–H and the Br atom of a neighbouring molecule. Similar dimeric structures based on rhenium(I) thiosemicarbazones have been observed previously [9] and, in the present case, form chains oriented by weak C(Fc)H···O interactions [17] along the *a* axis.

3. Experimental

3.1. Materials and methods

All operations performed in the synthesis and isolation of the compounds were carried out under an atmosphere of dry argon. All solvents were dried over appropriate drying agents, degassed using a vacuum line and distilled under an Ar atmosphere [18a]. $[ReX(CO)_5]$ [18b], $[ReX(CO)_3(CH_3CN)_2]$ [18c], HL^1 and $[ReBr(CO)_3(HL^1)]$ [5] were synthesized by published methods.

Elemental analyses were carried out on a Fisons EA-1108. Melting points (m.p.) were determined on a Gallenkamp MFB-595 and are uncorrected. Mass spectra were recorded on a VG Autospec Micromass spectrometer operating under FAB conditions (nitrobenzyl alcohol matrix). Infrared spectra were recorded from KBr pellets on a Bruker Vector 22FT. UV–Vis spectra were performed on a CARY 100 (Varian) spectrophotometer from $CHCl_3$ or acetone solutions. ^1H NMR spectra were obtained on a Bruker AMX 400 spectrometer from acetone-d_6 solutions.

3.2. Synthesis of the ligand $H(Fe)L^1$

Ferrocenyl carbaldehyde (1003.0 mg, 4.69 mmol) and benzoylhydrazine (638.0 mg, 4.69 mmol) were dissolved in methanol (13 mL) and the mixture was refluxed for 2 h. The reaction mixture was allowed to cool down to r.t. and methanol (15 mL) was added. The resulting brown solid was filtered off and dried under vacuum over KOH. Single crystals were obtained from slow evaporation of the mother liquor.

3.3. Synthesis of the complex $[ReBr(CO)_3\{H(Fe)L^1\}]\cdot CHCl_3$

H(Fe)L^1 (39.6 mg, 0.12 mmol) and *fac*-bis(acetonitrile)bromotricarbonylrhenium(I) (53.1 mg, 0.12 mmol) were dissolved in freshly distilled chloroform (10 mL) and the mixture was heated under reflux for 2 h. The resulting red solid was filtered off and dried under vacuum. Single crystals were obtained by slow evaporation of a chloroform solution.

Yield: 36.7 mg (45%). M.p.: 200–202 °C. *Anal*. Calc. for $C_{22}H_{17}N_2O_4Cl_3BrFeRe$ requires: C, 33.0; H, 2.1; N, 3.5. Found: C, 32.9; H, 1.9; N, 3.7%. Mass spectrum [*m*/*z* (%)]: 682(3.3) $[M]^+$, 603(3.7) $[M-Br]^+$, 332(57.1) $[H(Fe)L^1]^+$. 3.4. X-ray data collection, structure determination and refinement

Crystallographic data collection and refinement parameters are listed in Table 4. All crystallographic measurements were performed on a Bruker Smart CCD apparatus at CACTI (Universidade de Vigo). The data were corrected for absorption effects using the program SADABS [19]. Structure analyses were carried out by direct methods [20]. Least-squares full-matrix refinements on F^2 were performed using the program SHELXL 97. Atomic scattering factors and anomalous dispersion corrections for all atoms were taken from International Tables for Crystallography [21]. For $[ReBr(CO)_3\{H(Fe)L^1\}]\cdot\frac{1}{2}CHCl_3$ contributions from disordered solvent molecule were removed by the SQUEEZE [16] routine of PLATON [14], and the number of chloroform molecules was estimated from the number of electrons so excluded per unit cell. All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were refined as riders except N2–H, which was refined isotropically at a position previously identified in the corresponding Fourier map. Graphics were produced with PLATON [14] and MERCURY [22].

(*R*,*R*)-Duxantphos

Chart 1.

catalysis. Indeed, wide bite-angle bidentate diphospholane chiral ligands such as Duxantphos (Chart 1) are very efficient and selective in palladium-catalyzed asymmetric allylic alkylation, even with small allylic substrates [4,5]. Given their success, we planned to expand the family of chelate, chiral, xanthene-based ligands towards air-stable and easy-to-synthesize P,N or N,N chelate ligands.

We report hereafter the synthesis and analysis of chiral ligands with a rigid xanthene scaffold bearing air-stable imine functions, and their applications in coordination chemistry of palladium, silver and rhodium, and in homogeneous catalysis. We used cheap (1*R*)-camphor and (1*S*)-fenchone as chiral sources, in analogy with reported diimine [6] and iminophosphine [7] ligands. Some of the ligand syntheses have been described in a preliminary communication [8].

2. Experimental

2.1. General details

Experiments were carried out under a nitrogen or argon atmosphere, using a vacuum line or Vacuum Atmospheres glovebox equipped with Dri-Train HE-493 inert gas purifier, except the syntheses of **3**, **4**, **7**, **8**, **12** and **13** which were not air-sensitive. Diethyl ether, THF and pentane were distilled over sodium and benzophenone, toluene over sodium, dichloromethane and acetonitrile over calcium hydride under nitrogen immediately before use. Column chromatography was carried out on Merck silica gel 60, 70-230 mesh ASTM, and thin layer chromatography on Macherey–Nagel 0.25 mm Polygram® Sil G/UV_{254} precoated silica gel plates. The following commercial reagents were used as received; Aldrich: 9,9-dimethyl-9*H*-xanthene (**1**), 2,7-di-*tert*butyl-4,5-dibromo-9,9-dimethyl-9*H*-xanthene (**10**), *n*-BuLi solution in hexanes (1.6 M), PhLi solution in cyclohexane–Et_2O (1.7 M), diphenylphosphoryl azide (DPPA), (1*R*)-(−)-fenchone, dimethyl malonate, allyltriethoxysilane, diphenylsilane; Sigma: (1*R*)-(+)-camphor; Lancaster: (1*S*)-(+)-fenchone; Fluka: benzyl alcohol, triethylamine; Acros: acetophenone; Prolabo: KOH; Strem: $TiCl_4$, $AgBF_4$, AgOTf, AgF; Johnson Matthey: $RhCl_3 \cdot 3H_2O$. The concentration of organolithium reagents was checked before use following a reported method [9]. Diphenylchlorophosphine (95% min., Strem) was distilled at 170 °C under reduced pressure and stored under argon. NaH (60% in mineral oil, Fluka) was washed three times with pentane, dried in vacuo and stored in the glovebox. Benzaldehyde (Aldrich) was purified by filtration through silica gel. Gaseous CO_2 (obtained by sublimation of dry ice) was dried by bubbling in H_2SO_4. The compounds listed hereafter were synthesized following reported procedures: (*rac*)-(*E*)-1-acetoxy-1,3-diphenylprop-2-ene (**16a**) [10], (*rac*)-(*E*)-2-acetoxypent-3-ene (**16b**) [11], (*rac*)-1-acetoxycyclohex-2-ene (**16c**) [12], bis[(η^3-allyl)chloropalladium] [13], tris(acetonitrile)trichlororhodium [14], bis[(η^4-1,5-cyclooctadiene)chlororhodium] [15]. The NMR spectra were obtained at room temperature (unless otherwise indicated) on Bruker spectrometers. ^{1}H NMR spectra were recorded at 200.13 MHz (AC-200 instrument), 300.16 MHz (AC-300) or 500.13 MHz (ARX-500) and referenced to $SiMe_4$. $^{13}C\{^1H\}$ NMR spectra (broadband decoupled) were recorded at 50.32 MHz (AC-200), 75.48 MHz (AC-300), 100.62 MHz (AM-400) or 125.76 MHz (ARX-500) and referenced to $SiMe_4$. $^{31}P\{^1H\}$ NMR spectra (broadband decoupled) were recorded at 121.51 MHz (AC-300) or 202.46 MHz (ARX-500) and referenced to 85% aqueous H_3PO_4. For variable-temperature spectra, the probe temperature was controlled (±1 K) by a B-VT 2000 unit calibrated with a methanol NMR tube. The NMR signals were assigned in agreement with Refs. [6,16]; the assignments were supported by COSY, NOESY or ROESY spectra or irradiations for ^{1}H NMR, and DEPT-135° and/or HSQC spectra for $^{13}C\{^1H\}$ NMR. FT-IR spectra were recorded on a Perkin–Elmer 1600 Series spectrometer on KBr pellets; the IR signals of silver complexes were assigned in agreement with published data [17]. ES-MS spectra and elemental analyses were carried out by the corresponding facilities at the Institut de Chimie, Université Louis Pasteur, Strasbourg. Melting points were determined with a Reichert WME Kofler block and are uncorrected. Optical rotations ($[\alpha]_D^{20}$) were measured on a Perkin–Elmer Otopol III polarimeter ($\lambda = 589$ nm); specific rotations are reported in degrees per decimeter at 20 °C, and the concentration (*c*) is given in grams per 100 mL. GC analyses were performed on a Hewlett Packard 5890 series II apparatus equipped with a capillary column (Pd- and Ag-catalyzed reactions: 30 m × 0.25 mm Restek Rt-βDEXse™; Rh-catalyzed hydrosilylation: 50 m × 0.25 mm Chiraldex β-PM™). HPLC analyses were done on a Hewlett Packard series 1100 apparatus equipped with 250 mm × 4.6 mm Daicel Chiralpak™ AD analytical columns, flow rate 1 mL min^{-1}, eluant *n*-hexane–*i*PrOH (95:5).

2.2. Syntheses

2.2.1. 9,9-Dimethyl-9H-xanthene-4,5-dicarboxylic acid (2) [18]

To a yellow solution of 9,9-dimethyl-9*H*-xanthene (3.00 g, 14.28 mmol) in 60 mL Et_2O was added *n*-BuLi (22.5 mL solution, 36 mmol) at 0 °C. The solution rapidly turns brown. The reaction mixture was brought to RT

and appeared as a beige suspension after 16 h stirring. CO_2 was bubbled until the mixture was converted to a pale green solution. 70 mL of an aqueous HCl solution (2 M) was added. The organic phase was extracted and the product isolated (2.04 g, 6.83 mmol, 49% yield) as reported in Ref. [18]. *Anal.* Calc. for $C_{17}H_{14}O_5$: C, 68.45; H, 4.73. Found: C, 68.31; H, 5.00%.

2.2.2. *N,N′-bis(benzyloxycarbonyl)-9,9-dimethyl-9H-xanthene-4,5-diamine (**3**)*

A mixture of **2** (1.76 g, 5.90 mmol), DPPA (3.25 g, 11.82 mmol), benzylic alcohol (1.27 g, 11.76 mmol) and triethylamine (1.21 g, 11.83 mmol) dissolved in 50 mL toluene was heated at 100 °C for 18 h. The yellow solution was allowed to cool to room temperature and treated with 20 mL aqueous HCl (0.5 M). The organic phase was neutralized with saturated aqueous $NaHCO_3$ and dried over $MgSO_4$. After evaporation of the solvent under reduced pressure, the resulting pale yellow oil was purified by column chromatography over silica gel eluting with CH_2Cl_2 (TLC: $R_f = 0.40$). Crystallization of the colorless oil in a CH_2Cl_2–pentane mixture led to **3** as colorless crystals (1.89 g, 3.71 mmol, 64% yield). Mp 135–137 °C. *Anal.* Calc. for $C_{31}H_{28}N_2O_5$: C, 73.21; H, 5.55; N, 5.51. Found: C, 73.38; H, 5.51; N, 5.45%. IR (KBr): ν (cm^{-1}) 1732 (C═O), 3299 (N–H). ^1H NMR (300 MHz, $CDCl_3$): δ 1.62 (s, 6H, CH_3), 5.15 (s, 4H, CH_2), 7.09 (t, 2H, $^3J_{HH} = 7.8$ Hz, $H_{ar\ xanthene}$), 7.17 (dd, 2H, $^3J_{HH} = 7.8$ Hz, $^4J_{HH} = 1.5$ Hz, $H_{ar\ xanthene}$), 7.20–7.35 (m, 10H, 10 H_{phenyl}), 7.46 (broad s, 2H, NH), 7.75 (broad d, 2H, $^3J_{HH} = 6.3$ Hz, $H_{ar\ xanthene}$). $^{13}C\{^1H\}$ NMR (50 MHz, $CDCl_3$): δ 31.7 (s, CH_3), 34.4 (s, $C(CH_3)_2$), 67.2 (s, CH_2), 119.4 (s, CH_{ar}), 120.7 (s, CH_{ar}), 123.3 (CH_{ar}), 125.6 (s, C_{ar}), 128.1 (s, CH_{ar}), 128.4 (s, CH_{ar}), 129.7 (s, CH_{ar}), 130.6 (s, C_{ar}), 136.0 (s, C_{ar}), 140.5 (s, C_{ar}), 154.0 (s, C═O).

2.2.3. *9,9-Dimethyl-9H-xanthene-4,5-diamine (**4**)*

A solution of **3** (1.88 g, 3.70 mmol) in 100 mL KOH-saturated ethanol was refluxed for 20 h. The brown solution was allowed to cool to room temperature. 100 mL water was added and the product extracted with 3×150 mL CH_2Cl_2. The organic phase was washed with water until the pH of the water phase was 7 and dried with $MgSO_4$. After evaporation of the solvent under reduced pressure, the crude product was purified by column chromatography over silica gel eluting with Et_2O (TLC: $R_f = 0.23$) and the pure product recovered as a beige powder (0.470 g, 1.96 mmol, 53% yield). Mp 150–152 °C. *Anal.* Calc. for $C_{15}H_{16}N_2O$: C, 74.97; H, 6.71; N, 11.66. Found: C, 75.14; H, 6.95; N, 11.93%. IR (KBr): ν (cm^{-1}) 3386, 3450 (N–H). ^1H NMR (200 MHz, $CDCl_3$): δ 1.60 (s, 6H, CH_3), 3.87 (broad s, 4H, NH_2), 6.66 (dd, 2H, $^3J_{HH} = 7.2$ Hz, $^4J_{HH} = 2.0$ Hz, H_{ar}), 6.84 (dd, 2H, $^3J_{HH} = 7.9$ Hz, $^4J_{HH} = 2.0$ Hz, H_{ar}), 6.91 (t, 2H, $^3J_{HH} = 7.8$ Hz, H_{ar}). $^{13}C\{^1H\}$ NMR (50 MHz, $CDCl_3$): δ 31.9 (s, CH_3), 34.3 (s, $C(CH_3)_2$), 113.6 (s, CH_{ar}), 115.7 (s, CH_{ar}), 123.1 (s, CH_{ar}), 130.6 (s, C_{ar}), 134.5 (s, C_{ar}), 138.6 (s, C_{ar}).

2.2.4. *(1′R)-N,N′-bis(1′,7′,7′-trimethylbicyclo[2.2.1]hept-2-ylidene)-9,9-dimethyl-9H-xanthene-4,5-diamine (**5**)*

To a solution of **4** (0.6 g, 2.48 mmol) and (1*R*)-camphor (1.14 g, 7.49 mmol) in 50 mL toluene was added triethylamine (6.94 mL, 49.8 mmol) at room temperature. The solution was cooled to 0 °C and a solution of $TiCl_4$(2.37 g, 12.5 mmol) in 5 mL toluene was added. The resulting brown suspension was refluxed for 16 h, then the mixture was cooled to room temperature and filtered. The pasty solid remaining on the frit was extracted with 4×50 mL Et_2O. After evaporation of the solvent under reduced pressure, the crude product was purified by column chromatography over silica gel eluting with pentane–Et_2O (9:1) (TLC: $R_f = 0.25$). The resulting white powder was recrystallized in an ethanol–water mixture and dried under high vacuum (10^{-9} bar) for 24 h (0.54 g, 1.06 mmol, 43% yield). Mp 210–212 °C. $[\alpha]_D^{20}$ −305° ($c = 1$, EtOH). *Anal.* Calc. for $C_{35}H_{44}N_2O$: C, 82.63; H, 8.72; N, 5.51. Found: C, 82.65; H, 8.97; N, 5.30%. IR (KBr): ν (cm^{-1}) 1690 (C═N). ^1H NMR (500 MHz, CD_2Cl_2): δ 0.85 (s, 6H, H_9), 0.96 (s, 6H, H_{10}), 1.11 (s, 6H, H_8), 1.26 (ddd, 2H, $^2J_{HH} = 12.1$ Hz, $^3J_{HH} = 8.3$ Hz, $^3J_{HH} = 2.6$ Hz, H_{5endo}), 1.49 (d, 2H, $^2J_{HH} = 17.6$ Hz, H_{3endo}), 1.61 (s, 6H, $CH_{3xanthene}$), 1.73–1.96 (m, 8H, H_4+ H_{5exo} + H_6), 2.14 (ddd, 2H, $^2J_{HH} = 17.5$ Hz, $^3J_{HH} = 5$ Hz, $^4J_{HH} = 3$ Hz, H_{3exo}), 6.49 (dd, 2H, $^3J_{HH} = 7.6$ Hz, $^4J_{HH} = 1.5$ Hz, H_{11}), 6.97 (t, 2H, $^3J_{HH} = 7.6$ Hz, H_{12}), 7.11 (dd, 2H, $^3J_{HH} = 7.8$ Hz, $^4J_{HH} = 1.6$ Hz, H_{13}). $^{13}C\{^1H\}$ NMR (50 MHz, $CDCl_3$): δ 11.3 (s, C_8), 19.1 (s, C_9/C_{10}), 19.6 (s, C_{10}/C_9), 27.4 (s, C_5), 32.1 (s, C_6), 32.2 (s, $CH_{3xanthene}$), 34.2 (s, $C(CH_3)_{2xanthene}$), 36.9 (s, C_3), 43.6 (s, C_4), 47.8 (s, C_7), 54.0 (s, C_1), 118.5 (s, CH_{ar}), 120.2 (s, CH_{ar}), 122.6 (s, CH_{ar}), 131.0 (s, C_{ar}), 140.7 (s, C_{ar}), 141.3 (s, C_{ar}), 186.8 (s, C_2).

2.2.5. *9,9-Dimethyl-9H-xanthene-4-carboxylic acid (**6**)*

To a solution of 9,9-dimethyl-9*H*-xanthene (1.14 g, 5.42 mmol) in 35 mL THF was slowly added PhLi (8.0 mL solution, 13.6 mmol) at −78 °C. The solution rapidly turned brown. The reaction mixture was brought to RT and stirred for 18 h. The temperature was lowered to −78 °C and CO_2 was bubbled into the mixture for 15 min while raising the temperature again to RT. 20 mL of an aqueous HCl solution (2 M) was added and the product extracted with 4×60 mL Et_2O. The organic phase was dried with $MgSO_4$ and evaporated to dryness. The green crude product was heated at 70 °C under vacuum in order to eliminate the by-product benzoic acid by sublimation, and the residual solid was purified by column chromatography over silica gel eluting with CH_2Cl_2–MeOH (98:2) (TLC: $R_f = 0.20$). The pure product was recovered as a white powder (0.617 g, 2.44 mmol, 47% yield). Mp 192–194 °C. *Anal.* Calc. for $C_{16}H_{14}O_3$: C, 75.58; H, 5.55. Found: C, 75.43; H, 5.65%. IR (KBr): ν (cm^{-1}) 1695 (C═O). ^1H NMR (200 MHz, DMSO-d_6): δ 1.59 (s, 6H, CH_3), 7.02 (dd, 1H, $^3J_{HH} = 7.8$ Hz, $^4J_{HH} = 1.4$ Hz, H_{ar}), 7.15 (td, 1H, $^3J_{HH} = 7.4$ Hz, $^4J_{HH} = 1.4$ Hz, H_{ar}), 7.17 (t, 1H, $^3J_{HH} = 7.7$ Hz, H_{ar}), 7.26 (td, 1H, $^3J_{HH} = 7.6$ Hz,

$^4J_{HH} = 1.7$ Hz, H_{ar}), 7.57 (2dd, 2H, $^3J_{HH} = 7.6$ Hz, $^4J_{HH} = 1.7$ Hz, H_{ar}), 7.73 (dd, 1H, $^3J_{HH} = 7.8$ Hz, $^4J_{HH} = 1.7$ Hz, H_{ar}), 12.91 (broad s, 1H, OH). $^{13}C\{^1H\}$ NMR (50 MHz, $CDCl_3$): δ 31.9 (s, CH_3), 33.7 (s, $C(CH_3)_2$), 116.1 (s, CH_{ar}), 122.0 (s, C_{ar}), 122.5 (s, CH_{ar}), 123.6 (s, CH_{ar}), 126.2 (s, CH_{ar}), 127.5 (s, CH_{ar}), 128.3 (s, CH_{ar}), 129.1 (s, CH_{ar}), 129.6 (s, C_{ar}), 130.9 (s, C_{ar}), 148.0 (s, C_{ar}), 149.3 (s, C_{ar}), 167.5 (s, C=O).

2.2.6. N-benzyloxycarbonyl-9,9-dimethyl-9H-xanthen-4-amine (7)

A mixture of **6** (0.590 g, 2.32 mmol), DPPA (0.642 g, 2.33 mmol), benzylic alcohol (0.251 g, 2.33 mmol) and triethylamine (0.240 g, 2.35 mmol) dissolved in 25 mL toluene was heated at 100 °C for 18 h. The orange solution was allowed to cool to RT, treated with 20 mL aqueous HCl (0.5 M) and extracted with 3×80 mL CH_2Cl_2. The organic phase was neutralized with saturated aqueous $NaHCO_3$ and dried over $MgSO_4$. After evaporation of the solvent under reduced pressure, the resulting yellow oil was purified by column chromatography over silica gel eluting with CH_2Cl_2–pentane (1:1) (TLC: $R_f = 0.25$), leading to a colorless oil (0.726 g, 2.02 mmol, 86% yield). IR (KBr): ν (cm^{-1}) 1737 (C=O), 3433 (N–H). ^1H NMR (200 MHz, $CDCl_3$): δ 1.62 (s, 6H, CH_3), 5.26 (s, 2H, OCH_2), 7.0–7.25 (m, 5H, H_{ar}), 7.35–7.5 (m, 7H, H_{ar} + NH), 8.04 (broad dd, 1H, $^3J_{HH} = 6.4$ Hz, $^4J_{HH} = 2.8$ Hz, H_{ar}). $^{13}C\{^1H\}$ NMR (50 MHz, $CDCl_3$): δ 32.1 (s, CH_3), 34.1 (s, $C(CH_3)_2$), 67.1 (s, CH_2), 116.2 (s, CH_{ar}), 116.6 (s, CH_{ar}), 119.7 (s, CH_{ar}), 123.0 (s, CH_{ar}), 123.6 (s, CH_{ar}), 126.0 (s, C_{ar}), 126.2 (s, CH_{ar}), 127.4 (s, CH_{ar}), 128.4 (s, $2CH_{ar}$), 128.6 (s, CH_{ar}), 129.8 (s, C_{ar}), 130.0 (s, C_{ar}), 136.1 (s, C_{ar}), 138.9 (s, C_{ar}), 149.6 (s, C_{ar}), 153.3 (s, C=O).

2.2.7. 9,9-Dimethyl-9H-xanthen-4-amine (8)

A solution of **7** (0.652 g, 1.81 mmol) in 150 mL KOH-saturated ethanol was refluxed for 18 h. The brown solution was allowed to cool to RT. 150 mL water was added and the product extracted with 3×100 mL CH_2Cl_2. The organic phase was washed with water until the pH of the water phase was 7 and dried with $MgSO_4$. After evaporation of the solvent under reduced pressure, the resulting brown oil was purified by column chromatography over silica gel eluting with CH_2Cl_2 (TLC: $R_f = 0.42$). Product **8** was recovered as an orange powder after recrystallization in toluene–pentane (0.352 g, 1.56 mmol, 86% yield). *Anal.* Calc. for $C_{15}H_{15}NO$: C, 79.97; H, 6.71; N, 6.22. Found: C, 79.07; H, 6.73; N, 6.34%. IR (KBr): ν (cm^{-1}) 3382, 3472 (N–H). ^1H NMR (200 MHz, $CDCl_3$): δ 1.53 (s, 6H, CH_3), 5.04 (broad s, 2H, NH_2), 6.59 (dd, 1H, $^3J_{HH} = 7.6$ Hz, $^4J_{HH} = 1.7$ Hz, H_{ar}), 6.68 (dd, 1H, $^3J_{HH} = 7.8$ Hz, $^4J_{HH} = 1.6$ Hz, H_{ar}), 6.81 (t, 1H, $^3J_{HH} = 7.7$ Hz, H_{ar}), 7.06–7.17 (m, 2H, H_{ar}), 7.23 (ddd, 1H, $^3J_{HH} = 6.9$ Hz, $^3J_{HH} = 8.3$ Hz, $^4J_{HH} = 1.6$ Hz, H_{ar}), 7.50 (dd, 1H, $^3J_{HH} = 7.7$ Hz, $^4J_{HH} = 1.5$ Hz, H_{ar}). $^{13}C\{^1H\}$ NMR (50 MHz, $CDCl_3$): δ 31.8 (s, CH_3), 33.5 (s, $C(CH_3)_2$), 112.1 (s, CH_{ar}), 112.7 (s, CH_{ar}), 116.0 (s, CH_{ar}), 122.9 (s, $2CH_{ar}$), 126.2 (s, CH_{ar}), 127.1 (s, CH_{ar}), 129.3 (s, C_{ar}), 129.9 (s, C_{ar}), 136.1 (s, C_{ar}), 136.8 (s, C_{ar}), 149.7 (s, C_{ar}).

2.2.8. (1′R)-N-(1′,7′,7′-trimethylbicyclo[2.2.1]hept-2-ylidene)-9,9-dimethyl-9H-xanthen-4-amine (9)

To a solution of **8** (0.415 g, 1.85 mmol) and (1*R*)-camphor (0.420 g, 2.78 mmol) in 40 mL toluene was added triethylamine (2.58 mL, 18.5 mmol) at RT. The solution was cooled to 0 °C and a solution of $TiCl_4$ (0.880 g, 4.62 mmol) in 8 mL toluene was added dropwise. The resulting brown mixture was refluxed for 18 h, then the mixture was cooled to room temperature and filtered. The pasty solid remaining on the frit was extracted with 4×50 mL Et_2O. After evaporation of the solvent under reduced pressure, the crude product was purified by column chromatography over silica gel eluting with pentane–Et_2O (9:1) (TLC: $R_f = 0.22$). The resulting pale yellow powder was recrystallized in an ethanol–water mixture and dried under high vacuum (10^{-9} bar) for 24 h (0.44 g, 1.22 mmol, 66% yield). Mp 88–90 °C. *Anal.* Calc. for $C_{25}H_{29}NO$: C, 83.52; H, 8.13; N, 3.90. Found: C, 83.49; H, 8.18; N, 3.84%.
