Although all complexes studied display expected similarities, there is a feature which is worth noting. Despite the close resemblance among the series of phosphines bearing 4-, 3- and 2-$OCH_3C_6H_4$ and 4-, 3- and 2-$CH_3C_6H_4$ substituents, only [RhCl(η^4-COD)(P(2-$CH_3C_6H_4$)$_3$)$_2$] (**11**) seems unable to remain as stable mononuclear complex in solution and rearranges to the starting materials [{Rh(μ-Cl)(η^4-COD)}$_2$] and P(2-$CH_3C_6H_4$)$_3$. The difference between both *ortho*-substituted phosphines with 2-$CH_3C_6H_4$ and 2-$OCH_3C_6H_4$, seems the larger flexibility of the methoxy group compared with the methyl moiety. Molecular models indicate a considerable steric hindrance with 2-$CH_3C_6H_4$ which is released when the methyl group is free to rotate around the oxygen atom. A previous work has proved the difference in reactivity between iridium complexes when two of these phosphines are bounded to the metal centre [16].

3.2. ^{31}P NMR spectroscopic analysis

Correlations between experimental $^1J_{Rh-P}$ or ^{31}P chemical shifts from the coordination compounds and electronic properties of the phosphine ligands could be useful to analyse the metallic environment of these complexes. Chemical shifts of free phosphines P(4-XC_6H_4)$_3$ (X = OCH_3, CH_3, H, F, Cl and CF_3) show a tendency almost parallel to the corresponding ^{31}P δ in their rhodium compounds, suggesting that electronic shielding is affected similarly in all compounds upon complexation.

As shown in Fig. 1, isosteric phosphines, according to their cone angle ($\theta = 145°$), show an inverse relation between their electronic properties, as accounted by Giering's electronic parameter χ, and the experimental magnetic coupling constant $^1J_{P-Rh}$. This is a similar behaviour to the previously reported for Pt(II)–P [9], and Pt(0)–P complexes [10], and it can be rationalized in terms of a reduction on the phosphorus covalent radius upon the addition of electron-withdrawing groups on the phenyl rings, considering these triarylphosphines as exclusively σ-donors [6a].

3.3. Crystal structure

Relevant bond distances and angles for complex **11** are displayed in Table 4. The asymmetric unit contains one molecule with all atoms on general positions (Fig. 2). Considering the COD molecule as a bidentate ligand, the metallic center displays a slightly distorted square planar coordination geometry found in numerous 16-electrons Rh(I) complexes. The COD ligand approximates a tub

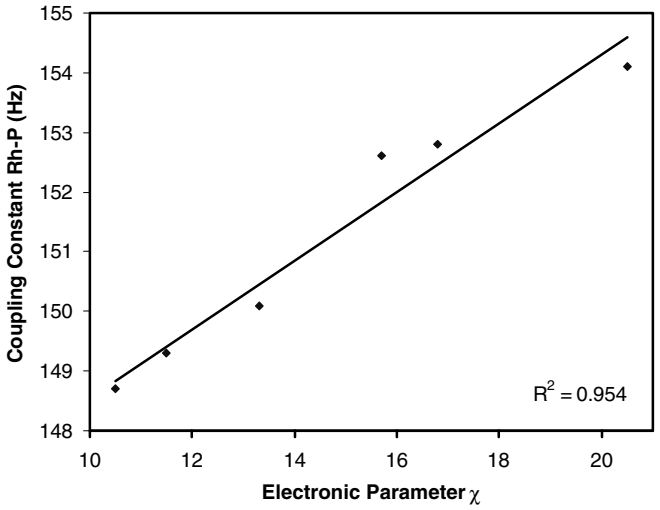

Fig. 1. Graph of the electronic parameter χ for the isosteric phosphines $P(4\text{-}XC_6H_4)_3$ ($X = OCH_3$, CH_3, H, F, Cl, and CF_3) and $^1J_{P-Rh}$ of $[RhCl(\eta^4\text{-}COD)(P(4\text{-}XC_6H_4)_3)]$ (**1**–**6**).

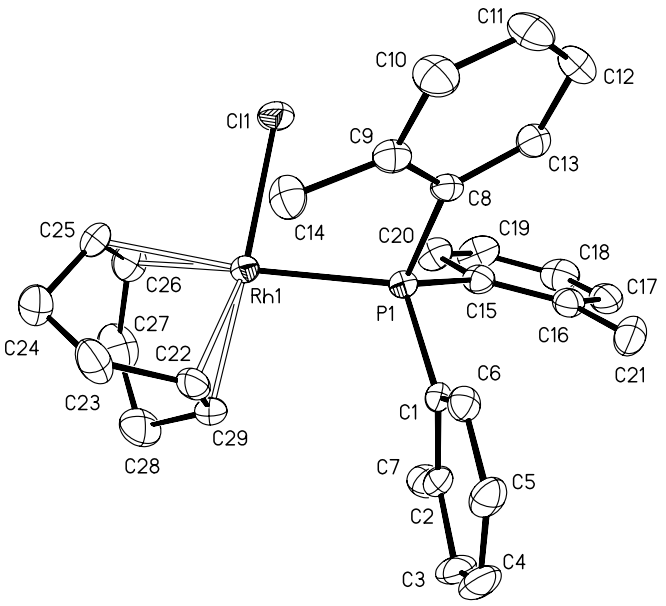

Fig. 2. X-ray structure of **11**, showing displacement ellipsoids at the 30% probability level. H atoms have been omitted for clarity.

Table 4
Selected bond lengths (Å) and angles (°) for $[RhCl(\eta^4\text{-}COD)(P(2\text{-}CH_3C_6H_4)_3)]$ (**11**)

P1–Rh1–Cl1	88.15(5)		

conformation (D_{2d} local symmetry) also found in the vast majority of COD-containing complexes. The geometry for the tri-*o*-tolylphosphine is unaffected by coordination and remains very close to that of the free ligand [17]. The main structural feature for the solid state structure of **11** is the significant *trans* influence of the phosphine: Rh–C bond lengths *trans* to the P atom are lengthened by ca. 0.06 Å by comparison of Rh–C bond lengths *trans* to the Cl atom (see Table 4). This effect also induces non-equivalent double bonds in the COD moiety, the shortest bond length, C25–C26 = 1.362(8) Å, being *trans* to the phosphine, while the C22–C29 bond, 1.384(8), which is located *trans* to the chloride. However, both double bonds are still shorter than in free COD [18].

A similar behaviour was previously observed in two directly related structures, namely those containing triphenylphosphine, complex **3** [19], and tri(*p*-fluorophenyl)phosphine, complex **4** [20]. In the former case, the *trans* influence induced by the triphenylphosphine is characterized by a lengthening of coordination of ca. 0.10 Å for Rh–C *trans* to the phosphine, and for the latter, the calculated effect is of ca. 0.11 Å. These strong *trans* influences yield, as in the previous case, unbalanced double bond lengths for the COD moiety, for example 1.363 and 1.440 Å in **4**.

The bulkiness of the phophine is evident from the Rh–P distance, significantly larger in the case of **11** [2.3607(14) Å] compared to **3** and **4** [2.308 and 2.297 Å, respectively]. It is obvious that **3** and **4** present similar Tolman's cone angles, $\theta \approx 145°$, while **11**, for which includes an *ortho* substituent, should have a significantly larger cone angle ($\theta \approx 178°$). Assuming, from purely steric considerations, that a smaller cone angle should result in a better ligand, a stronger phosphine coordination is expected for **3** and **4** compared to **11**, as actually observed in Rh–P bond distances. This also explains the lability of complex **11** in solution, which rapidly reorganizes to the dinuclear complex and the free phosphine.

4. Conclusions

The addition of two equivalents of twelve different triarylphosphines to solutions of the dinuclear complex $[\{Rh(\mu\text{-}Cl)(\eta^4\text{-}COD)\}_2]$ affords the mononuclear species $[RhCl(\eta^4\text{-}COD)(PR_3)]$. However, no mononuclear species could be detected in solution when electron-poor phosphines, like $P(C_6H_5)(C_6F_5)_2$ and $P(C_6F_5)_3$, or bulky phosphines, such as $P(2\text{-}CH_3C_6H_4)_3$, were employed. The solid state structure for the complex $[RhCl(\eta^4\text{-}COD)(P(2\text{-}CH_3C_6H_4)_3)]$ (**11**) displays a long Rh–P bond distance, compared to $[RhCl(\eta^4\text{-}COD)\{P(C_6H_5)_3\}]$ (**3**) and

[RhCl(η^4-COD){P(4-FC_6H_4)$_3$}] (**4**), which accounts for the lability of this complex in solution. Solution ^{31}P NMR data for complexes with isosteric phosphines **1**–**6**, reveals that electron-withdrawing groups on the phenyl rings increases the $^1J_{P-Rh}$, in a similar fashion to that observed for Pt compounds indicating comparable bonding characteristics.

5. Supplementary data

Crystallographic data for compound **11** has been deposited with the Cambridge Crystallographic Data Centre; CCDC 273550. Copy of this information can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

silanethiols. We have undertaken a structural study of ammonium tri-*tert*-butoxysilanethiolates, derivatives of various amines. It is known that primary ammonium tri-*tert*-butoxysilanethiolates form adducts with a cubane-like core [7]. In this paper, we describe syntheses and structures of selected secondary ammonium salts of tri-*tert*-butoxysilanethiol.

2. Experimental

General remarks: All synthetic procedures were carried out under argon, using standard Schlenk techniques. Tri-*tert*-butoxysilanethiol [13] was prepared according to the literature. The solvents and amines were dried by standard methods, and distilled under argon prior to use. Elemental analyses were performed on Elemental Analyser Ea 1108 (Carlo Erba Instruments). Melting points were determined on SMP3 apparatus (Stuart Scientific, UK) and are uncorrected.

*[(Bu^{t}O)$_3$SiS$^{(-)(+)}$NH$_2$(C$_2$H$_5$)$_2$]$_2$ (**1**):* Diethylamine (0.2 mL, 2 mmol) was added to a solution of (Bu^{t}O)$_3$SiSH (0.56 g, 2 mmol) in benzene (5 mL). Small, transparent crystals separated after one day at room temperature. They were collected and recrystallised from cold hexane giving small, good quality crystals with a sharp m.p. 92–94 °C. Calc. for $C_{16}H_{39}NO_3SSi$: C, 54.3; H, 11.1; N, 4.0; S, 8.9. Found: C, 54.2; H, 11.3; N, 3.7; S, 8.9%.

*[(Bu^{t}O)$_3$SiS$^{(-)(+)}$NH$_2$(C$_2$H$_4$)$_2$O]$_2$ (**2**):* (Bu^{t}O)$_3$SiSH (0.84 g, 3 mmol) was dissolved in benzene (10 mL). To the solution of tri-*tert*-butoxysilanethiol a portion of morpholine (0.26 mL, 3 mmol) was added. After standing for one week at room temperature, crystals of **2** formed and were suitable for X-ray analysis; m.p. 93–95 °C. Calc. for $C_{16}H_{37}NO_4SSi$: C, 52.3; H, 10.1; N, 3.8; S, 8.7. Found: C, 53.0; H, 10.5; N, 3.8; S, 8.5%.

*[(Bu^{t}O)$_3$SiS$^{(-)(+)}$NH$_2$(C$_6$H$_{11}$)$_2$]$_2$ (**3**):* To a solution of (Bu^{t}O)$_3$SiSH (0.56 g, 2 mmol) in acetonitrile (5 mL) dicyclohexylamine (0.4 mL, 2 mmol) was added. The crystals used for X-ray measurements were prepared by recrystallisation of the crude product from hot acetonitrile; m.p. 89–90 °C. Calc. for $C_{24}H_{51}NO_3SSi$: C, 62.4; H, 11.2; N, 3.0; S, 6.9. Found: C, 62.1; H, 11.2; N, 3.0; S, 6.9%.

*[(Bu^{t}O)$_3$SiS$^{(-)(+)}$NH$_2$C$_5$H$_6$Me$_4$]$_2$ (**4**):* 2,2,6,6-tetramethylpiperidine (0.3 mL, 2 mmol) was added to a solution of (Bu^{t}O)$_3$SiSH (0.56 g, 2 mmol) in propanol-2 (8 mL). Crystals (m.p. 104–106 °C) separated from the solution after 2 weeks at 0–5 °C. Calc. for $C_{21}H_{47}NO_3SSi$: C, 59.8; H, 11.2; N, 3.3; S, 7.6. Found: C, 59.6; H, 11.5; N, 3.3; S, 7.4%.

2.1. X-ray crystallographic study

Diffraction data were recorded on a KUMA KM4 diffractometer with graphite-monochromated Mo Kα radiation

using Sapphire-2 CCD detector. The apparatus was equipped with an open flow thermostat (Oxford Cryosystems) which enabled experiments at 200 K. The stream of nitrogen also prevented the specimen from contact with moist and oxygen. The structures were solved with direct methods and refined with the SHELX-97 program package [14] with the full-matrix least-squares refinement based on F^2. No absorption corrections were applied. All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were refined in geometrically idealised position with isotropic temperature factors 1.2 times the equivalent isotropic temperature factors U_{eq} of their attached atoms (1.5 for CH_3 groups). Hydrogen atoms of ammonium groups were found in the electron density Fourier map and refined without constraints. Disordered Bu^t groups: C12–C14 in **1** (s.o.f. 0.693(10)/0.307(10)); C31–C34 in **2** (s.o.f. 0.547(16)/0.453(16)); C22–C24 in **3** (s.o.f. 0.507(9)/0.493(9)). Basic crystal data, description of the diffraction experiment, and details of the structure refinement are given in Table 1.

3. Results and discussion

Tri-*tert*-butoxysilanethiol reacts readily with secondary amines. All the ammonium salts, described below, were obtained according to the general reaction scheme:

$$(Bu^tO)_3SiSH + R_2NH = (Bu^tO)_3SiS^{(-)}H_2N^{(+)}R_2$$

We decided to use diethylamine, morpholine, dicyclohexylamine and 2,2,4,4-tetramethylpiperidine to study the influence of an additional acceptor oxygen atom and steric hindrance in the vicinity of amine group on the pattern of the hydrogen bond network.

The reaction of tri-*tert*-butoxysilanethiol with the amines yields transparent crystals of: diethylammonium tri-*tert*-butoxysilanethiolate (**1**), morpholinium tri-*tert*-butoxysilanethiolate (**2**), dicyclohexylammonium tri-*tert*-butoxysilanethiolate (**3**) and 2,2,4,4-tetramethylpiperidinium tri-*tert*-butoxysilanethiolate (**4**). The products are hygroscopic and slowly oxidise in the air. Salt **1** was crystallised from hexane, **2** from benzene, **3** from acetonitrile and **4** from propanol-2. It is worthy to note, that none of the last two "hydrogen bond-active" solvents has been found in the solid state.

Molecular structures of the four salts, determined by X-ray diffraction analyses, are shown in Figs. 1–4.

X-ray structural analysis of the four ammonium tri-*tert*-butoxysilanethiolates **1**–**4** points to unexpected similarity of the compounds. It is apparent that the donor O atom of morpholinium salt **2** does not participate in bonding and does not change the hydrogen bonds pattern. The increase of steric hindrance around of the nitrogen atom in compounds **3** and **4** also has no impact on the type of hydrogen bonding.

Hydrogen bond parameters for compounds **1**–**4** are given in Table 2.

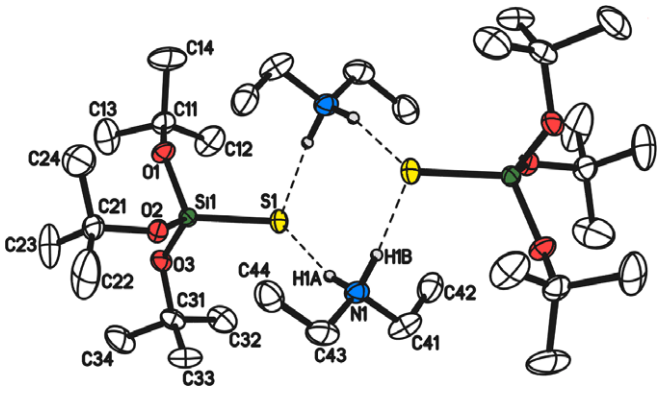

Fig. 1. The structure of $[(Bu^tO)_3SiS^{(-)}H_2N^{(+)}Et_2]_2$ (**1**). Thermal ellipsoids 30%, C–H hydrogen atoms omitted.

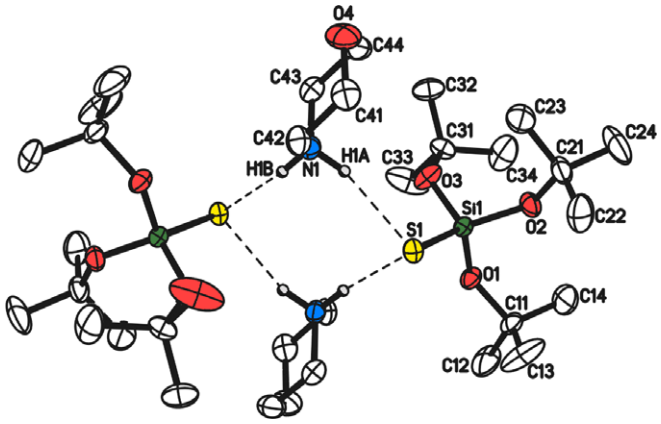

Fig. 2. Structure of $[(Bu^tO)_3SiS^{(-)}H_2N^{(+)}(C_2H_4)_2O]_2$ (**2**). Thermal ellipsoids 30%, C–H hydrogen atoms omitted.

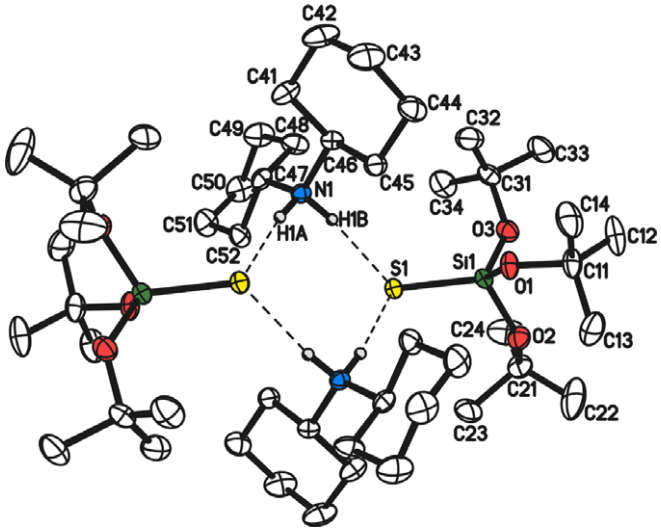

Fig. 3. Structure of $[(Bu^tO)_3SiS^{(-)}H_2N^{(+)}(C_6H_{11})_2]_2$ (**3**). Thermal ellipsoids 30%, C–H hydrogen atoms omitted.

The N···S distances of 3.16–3.34 Å are within the range typical for $N^{(+)}$–H···$^{(-)}$S hydrogen bond type observed in ammonium dithiocarbamates [2,3], aromatic thiolates [4,5,28] or silanethiolates [6,7].

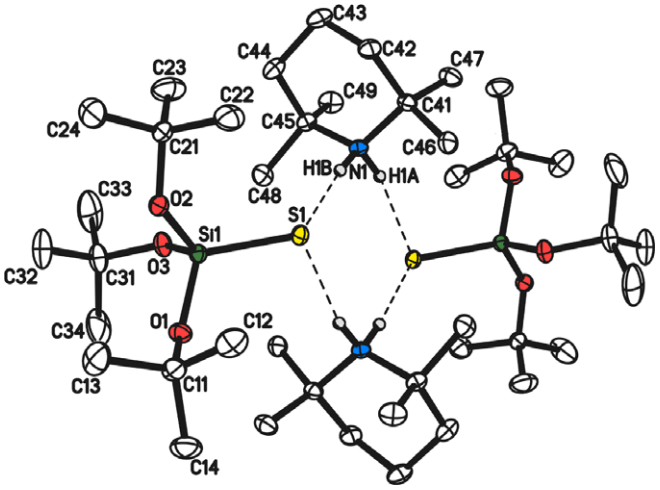

Fig. 4. Structure of $[(Bu^tO)_3SiS^{(-)}H_2N^{(+)}C_5H_6Me_4]_2$ (**4**). Thermal ellipsoids 30%, C–H hydrogen atoms omitted.

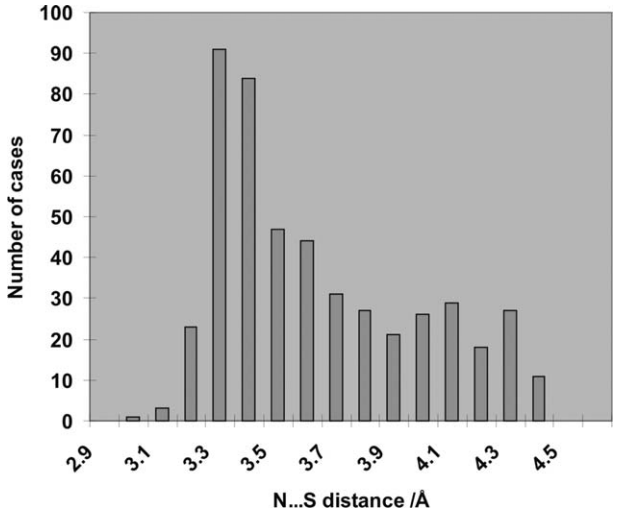

Fig. 5. Histogram of N···S distances reported in the CCDC database.

For comparison purposes, we performed a CCDC search, looking for compounds with N···S distances of hydrogen bonds shorter than 4.5 Å. Results of the search are shown in the form of histogram in Fig. 5. Maximum population lies between 3.3 and 3.5 Å and corresponds mainly to charge-assisted hydrogen bonds. Compounds with aliphatic mercapto groups, forming weak S–H···N hydrogen bonds, can be found in the 3.60–4.00 Å range of distances [5].

We assume that hydrogen bonding in the studied compounds **1**–**4** is relatively strong as acceptor–donor distances are short compared to the whole set of considered structures. The high strength of the bonding can be justified by complete proton transfer from silanethiol to the amine. There are several evidences of such a process. First, ammonium hydrogen atoms have been found in the electron density map close to the nitrogen atom. Second argument is based on positions of heavy atoms. In all cases Si–S bond length is short, which is typical for ionic silanethiolates. Covalent silanethiolates have Si–S bond lengths usually ca. 0.05 Å longer (see Table 3). Similar proton transfer is also assumed for 4-aminothiophenol [5], perhaps better described as "zwitterion" or internal ammonium thiophenolate.

All of the studied ammonium silanethiolates comprise a dimer $[(Bu^tO)_3SiS^{(-)}H_2N^{(+)}R_2]_2$, in which four charge-assisted $N^{(+)}$–H···$^{(-)}$S hydrogen bonds form a stable, repeatable core. This pattern of eight-membered ring with four donors and two acceptors is known as R4,2(8) in the graph theory [25,26] (see Fig. 6).

Dimeric unit [thiol-amine]$_2$ is a characteristic feature for all studied ammonium salts. The dimers are packed in crystal as separate units with no hydrogen bonds between them (only van der Waals forces). Exemplary packing diagram of **2** is presented in Fig. 7.

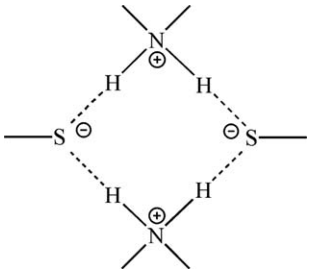

Fig. 6. Schematic drawing of R4,2(8) motif.

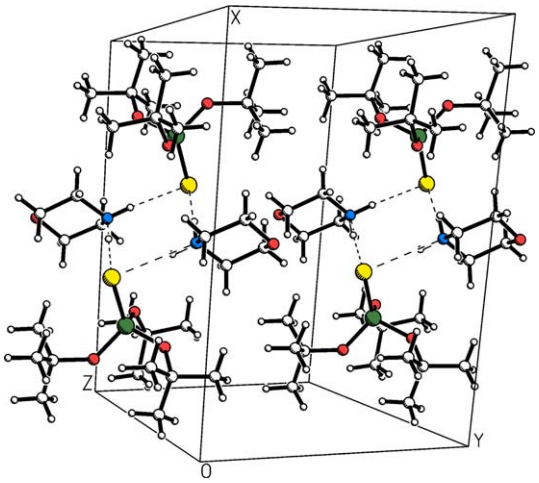

Fig. 7. Packing diagram for $(Bu^tO)_3SiS^{(-)}H_2N^{(+)}(C_2H_4)_2O$ (**2**).

Pattern R4,2(8), although rare, has already been found in ammonium dithiocarbamate [2] and amine-ketone dimers [27]. In the first case only the anionic sulfur atom from $–CS_2^-$ group (with the longer C–S bond) takes part in hydrogen bonding and the doubly bonded S atom is passive. Another example of this motif is present in study by Carmalt et al. [28], where anionic sulfur is donated by $C_6F_5S^{(-)}$ anion.

Some preliminary results [29] on salts of tri-*tert*-butoxysilanethiol with amines bearing hydroxyl groups also point to the robustness of the dimeric synthon.

Our earlier studies on salts of **primary** amines with silanethiols [7] have shown that cubane-like structures are formed. The cubanes can be regarded as combined dimers of two motifs R4,2(8) (see Fig. 8). The connection between

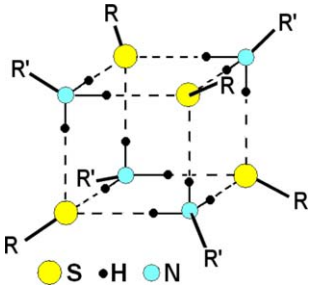

Fig. 8. Structure of primary ammonium silanethiolates.

dimers is also built from charge-assisted $N^{(+)}–H\cdots S^{(-)}$ hydrogen bonds. In other words, every face of the cube is formed by the ring R4,2(8). Final cubic structure is just the result of fact, that $–NH_3^{(+)}$ cation and $–S^{(-)}$ anion are perfect vertexes for the cube, being a triple donor and a triple acceptor, respectively.

When a less demanding thiophenolate anion is combined with dicyclohexylammonium cation an infinite chain structure of hydrogen bonds can be alternatively formed [4].

Crystal engineering scientists make wide use of supramolecular hydrogen bond motif R2,2(8) (eight-membered ring containing two donors and two acceptors) often observed in dimers of carboxylic acids. Although less abundant than R2,2(8), motif R4,2(8) shows also some universality and can be realised by several chemically different atomic arrangements (Fig. 9):

(a) $N^{(+)}–H\cdots O$ for antimony [30] or nickel [31] compounds, containing protonated amine as counter-cation,
(b) $N^{(+)}–H\cdots S^{(-)}$ for several classes of compounds, mainly metallothiolates [32–36,28,37]. All known ammonium silanethiolates belong to this class,
(c) $N^{(+)}–H\cdots O^{(-)}$ for some ammonium monothiooxalates [38,39]
(d) $O–H\cdots S^{(-)}$ for structures with water molecule as a donor [40,41].

The pattern can be seen, in some cases, only when less rigorous criteria for maximum hydrogen- acceptor distance, e.g., sum of van der Waals radii plus 0.1 A, are applied.

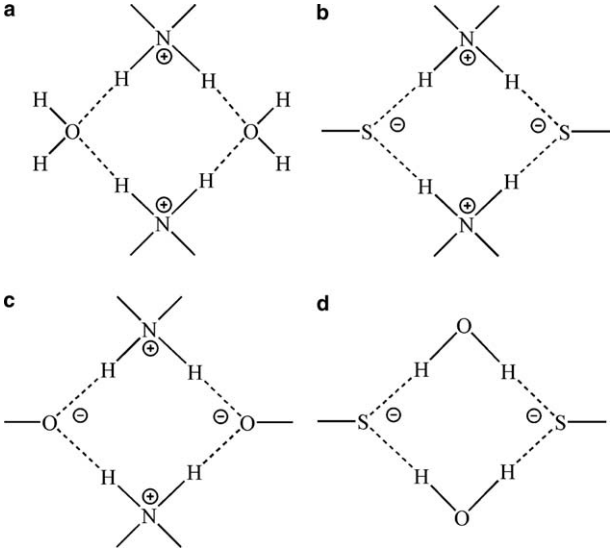

Fig. 9. Isographic functional groups of the R4,2(8) motif, (a) protonated amine–water, (b) protonated amine–anionic sulfur, (c) protonated amine–anionic oxygen, (d) anionic sulfur–water.

4. Conclusion

Eight-membered ring with four donors and two acceptors, R4,2(8), is characteristic for adducts of all studied amines with tri-*tert*-butoxysilanothiol. Oxygen atom of morpholinium salt **2** and the steric hindrance around of the nitrogen atom in compounds **3** and **4** have no impact on the hydrogen bond pattern.

5. Supplementary data

CCDC Nos. 237890–237893 (for compounds **1**, **2**, **3** and **4**, respectively) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge on request, quoting the deposition number, at www.ccdc.cam.ac.uk/conts/retrieving.html (or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (international) +44 1223 336 033; e-mail: deposit@ccdc.cam.ac.uk).

structure where 3-pyridylmethanol is terminal ligand coordinated through nitrogen atom of pyridine rings. The complexes $[CuX_2(\mu\text{-}3PM)_2]_n$ (where X = salicylate [13] (sal), flufenamate [14] (fluf) or clofibriate [15] (clof)) are two-dimensional coordination polymers, where Cu atoms are linked by bridged 3-pyridylmethanol ligand. On the other hand, the complex $[CuX_2(\mu\text{-}3PM)_2]_n$ (X = trichloroacetate [16], dichloroacetate [16], 3-nitrobenzoate [17], 3,5-dinitrobenzoate [11] and niflumate (nif) [18]) is one-dimensional coordination polymer, where Cu atoms are linked by bridged 3-pyridylmethanol ligand. The crystal structure of zinc(II) complex $[Zn(benzoate)_2(\mu\text{-}3PM)_2]_n$ consists also of one-dimensional coordination polymers, where Zn atoms are linked by bridged 3-pyridylmethanol ligand [19].

In this report, we describe the synthesis and spectral properties as well as X-ray structure analysis of coordination polymers with formulas: $[Cu(2\text{-}MeSnic)_2(\mu\text{-}3PM)_2]_n$ (**1**), where 2-MeSnic = 2-methyltionicotinate; $[Cu(2\text{-}Clbz)_2(\mu\text{-}3PM)_2]_n$ (**2**), where 2-Clbz = 2-chlorobenzoate and $[Cu_3(2\text{-}Clnic)_6(\mu\text{-}3PM)_4(3PM)_2]_n$ (**3**), where 2-Clnic = 2-chloronicotinate.

2. Results and discussion

2.1. Structure of complex *1*

The molecule of **1** lies about an inversion centre and the molecular structure of **1** is shown in Fig. 1. Selected bond lengths and bond angles are summarized in Table 1. Coordination environment of the copper(II) atom is tetragonal bipyramidal. The tetragonal plane is built up by a pair of unidentate 2-methylnicotinate anions using carboxylate oxygen atoms [Cu–O1 = 1.956(2) Å] and a pair of neutral 3-pyridylmethanol molecules using nitrogen atoms of pyridine ring [Cu–N2 = 2.010(2) Å] in *trans* positions. The axial positions are occupied by two hydroxyl oxygen atoms

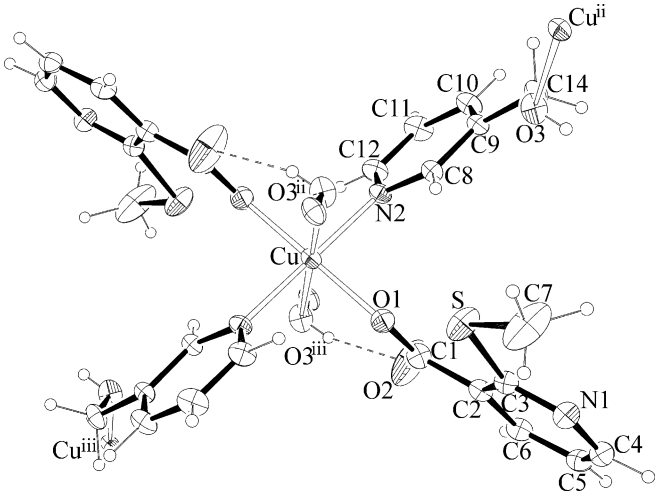

Fig. 1. Perspective view of complex $[Cu(2\text{-}MeSnic)_2(\mu\text{-}3\text{-}PM)_2]_n$ (**1**), with the atom numbering scheme. Thermal ellipsoids are drawn at the 50% probability level.

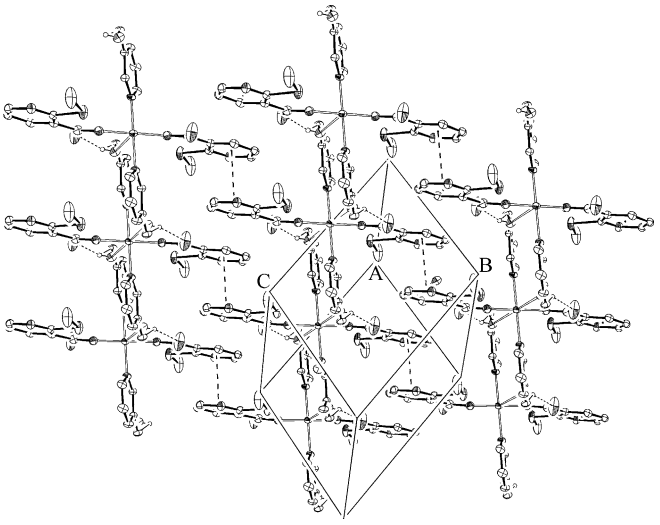

Fig. 2. View of the packing of $[Cu(2\text{-}MeSnic)_2(\mu\text{-}3\text{-}PM)_2]_n$ (**1**) in the crystal structure; hydrogen atoms are omitted for clarity.

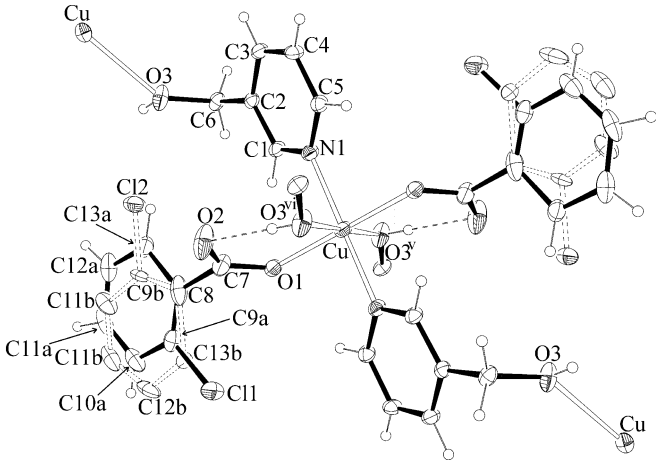

Fig. 3. Perspective view of complex $[Cu(2\text{-}Clbz)_2(\mu\text{-}3\text{-}PM)_2]_n$ (**2**), with the atom numbering scheme. Thermal ellipsoids are drawn at the 50% probability level.

pyridine rings of 2-methyltionicotinate anions ($-x-1$, $-y-1$, $-z+2$) of complex **1** and a weak hydrogen bond interaction. The plane–plane and centroid–centroid distances of $\pi\cdots\pi$ stacking interactions are 3.34 and 3.47 Å, respectively.

2.2. Structure of complex 2

The molecule of **2** lies about an inversion centre and the molecular structure of **2** is shown in Fig. 3. Selected bond lengths and bond angles are summarized in Table 1. The coordination environment of the copper(II) atom is tetragonal bipyramidal. The tetragonal plane is built up by a pair of unidentate 2-chlorobenzooate anions using carboxylate oxygen atoms [Cu–O1 = 1.964(1) Å] and a pair of neutral 3-pyridylmethanol molecules using nitrogen atoms of the pyridine ring [Cu–N1 = 2.017(1) Å] in *trans* positions. The axial positions are occupied by two hydroxyl oxygen atoms [$Cu\text{–}O3^{v} = Cu\text{–}O3^{vi}$ = 2.4668(9) Å] from adjacent two molecules of 3-pyridylmethanol ($-x$, $y+1/2$, $-z-1/2$ and x, $-y-1/2$, $z+1/2$). The intramolecular hydrogen bonds O3–H7···O2 (Table 2) create six membered metalocyclus and stabilize the molecular structure.

The crystal structure of **2** consists of 2-D sheets (Fig. 4). The layers are situated in *bc* plane and consist of two zigzag chains crossing at the Cu(II) atom as shown in Fig. 4.

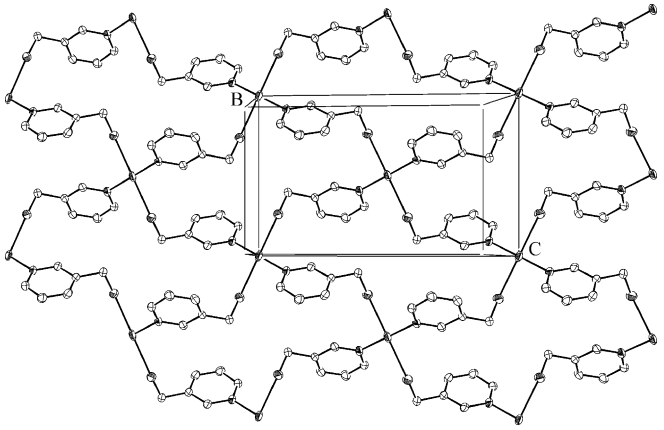

Fig. 4. View of the packing of $[Cu(2\text{-}Clbz)_2(\mu\text{-}3\text{-}PM)_2]_n$ (**2**) in the crystal structure; hydrogen atoms and 2-chlorbenzoate groups are omitted for clarity.

2.3. Structure of complex 3

The crystal structure of **3** consists of 1-D coordination polymers. The 1-D chains consist of two chemical by different copper(II) centers bridged by 3-pyridylmethanol ligands. The molecular structure of **3** is shown in Fig. 5 Selected bond lengths and bond angles are summarized in Table 1. The copper(II) atom Cu1 lies at the inversion centre [0, 0.5, 0.5]. The coordination environment of the Cu1 atom is tetragonal bipyramidal (Fig. 5). The tetragonal plane is built up by a pair of unidentate 2-chloronicotinate anions using carboxylate oxygen atoms [Cu1–O1 = 1.982(4) Å] and a pair of neutral bridging 3-pyridylmethanol molecules using nitrogen atoms of pyridine ring [Cu1–N2 = 2.025(4) Å] in *trans* positions. The axial positions are occupied by two hydroxyl oxygen atoms from adjusted bridging two molecules of 3-pyridylmethanol [$Cu1\text{–}O8^{viii} = Cu1\text{–}O8^{vii}$ = 2.418(4) Å ($-x+1$, $-y+1$, $-z+1$ and $x-1$, y, z)]. Atoms Cu2 lie in general crystallographic position. The coordination environment of the Cu2 atoms is tetragonal pyramidal (Fig. 5). The tetragonal plane is built up by a pair of unidentate 2-chloronicotinate anions using carboxylate oxygen atoms [Cu2–O4 = 1.958(4) and Cu2–O6 = 1.964(4) Å], one bridging and one terminal neutral 3-pyridylmethanol molecules using nitrogen atoms of the pyridine ring [Cu2–N5 = 2.019(5) and Cu2–N6 = 2.025(5) Å, respectively]. The axial position is occupied by the hydroxyl oxygen atom

of adjacent bridging molecule of 3-pyridylmethanol [Cu2–O3 = 2.338(4) Å]. The Cu2 atom is 0.092(3) Å above the equatorial plane O4–N5–O6–N6 toward water oxygen atom O3. For such five coordinated structures, the parameter τ ($\tau = \alpha - \beta/60$, where α and β are the longest angles) was introduced [21]. Value τ is 0 for perfectly tetragonal geometry and 1 for perfectly trigonal-bipyramidal geometry. In this case $\tau = 0.027$.

The crystal structure of **3** consists of 1-D "accordion" chains, which lie in *ac* plane (Fig. 6). As can be seen, the strong intramolecular O–H···O hydrogen bonds [O3–H10···O7; O8–H23···O2 ($x+1$, y, z)] (Table 2) create six membered metalocycles and stabilize with intermolecular O–H···O hydrogen bonds [O9–H30···O5 ($x-1$, y, z)] the 1-D "accordion" chains. In Fig. 6 a view of the packing of **3** perpendicular to *bc* plane is shown. The "accordion" chains are only connected by various weak hydrogen bond interactions C–H···O [C28–H19···O9 ($-x+1$, $-y+1$, $-z+2$); C35–H27···O4 ($x+1$, y, z)] and C–H···N [C33–H25···N4 (x, $y-1$, z)] (Table 2).

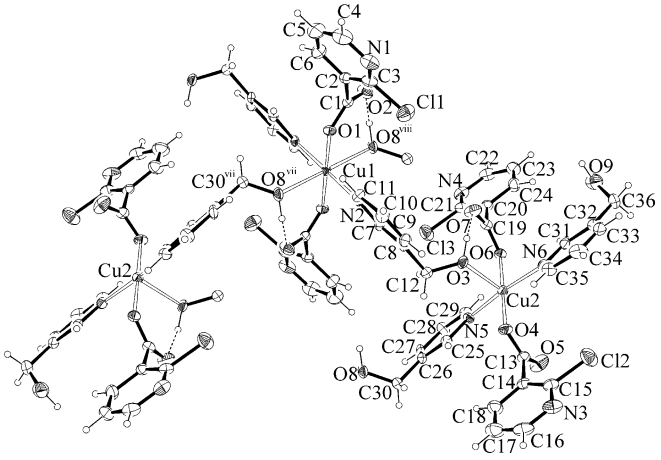

Fig. 5. Perspective view of complex $[Cu_3(2\text{-Clnic})_6(\mu\text{-3-PM})_4(3\text{-PM})_2]_n$ (**3**), with the atom numbering scheme. Thermal ellipsoids are drawn at the 30% probability level.

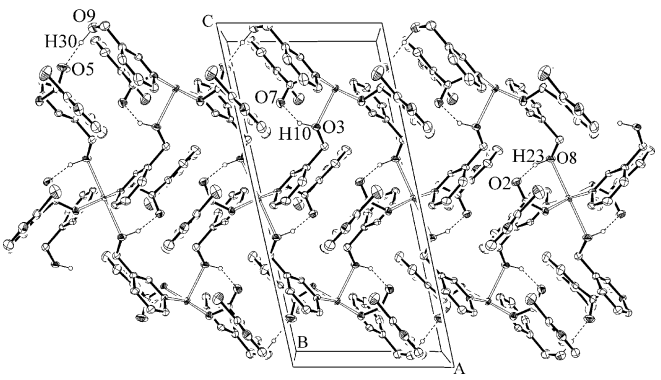

Fig. 6. View of the packing of $[Cu_3(2\text{-Clnic})_6(\mu\text{-3-PM})_4(3\text{-PM})_2]_n$ (**3**) in the crystal structure; hydrogen atoms are omitted for clarity.

2.4. EPR spectra

The EPR spectra of all complexes under study were measured in powder state at room temperature and were interpreted by computer simulation using spin Hamiltonian

$$\hat{H} = B \cdot \bar{g} \cdot \hat{S} + \hat{S} \cdot \bar{A} \cdot \hat{I}, \quad (1)$$

where the symbols have their usual meaning [22]. All three EPR spectra exhibit axial monomeric type of signal with values of the *g* factors (see Table 3) typical for compounds with tetragonal distorsion around the Cu(II) atom [23]. The order of $g_\perp < g_\parallel$ indicates $d_{x^2-y^2}$ ground state. In addition, the EPR spectrum of **2** also exhibits features of hyperfine splitting in parallel part of signal ($I^{Cu} = 3/2$) with a value of $A_\parallel = 174$ Gauss (see Fig. 7).

3. Experimental

3.1. Preparation of the complexes

3.1.1. *[Cu(2-MeSnic)$_2$(μ-3PM)$_2$]$_n$ (**1**)*

The complex **1** was prepared by adding 3PM (5 cm^3) in excess to methanol solutions (20 cm^3) of appropriate Cu(2-Mesnic)$_2 \cdot H_2O$ (1.25 mmol). The fine blue microcrystals produced on standing were separated, washed and dried in vacuo, yield 85%. *Anal*. Calc. for **1**: C, 50.52; H, 4.24; N, 9.06; S, 10.37; Cu, 10.28. Found: C, 50.4; H, 4.4; N, 9.1; S, 10.5; Cu, 10.15%. IR (KBr) cm^{-1}: 1607 $\nu_{as}(COO^-)$;

Table 3
EPR spin Hamiltonian parameters for studied complexes[a]

	$g_\perp$	$g_\parallel$	$A_\parallel$/Gauss
1	2.068	2.241	174
2	2.053	2.275	
3	2.088	2.288

1377 $\nu_s(COO^-)$; 1072 ν(C–O). IR (PE) cm^{-1}: 435 γ(py); 421 γ(py); 402 γ(py). VIS cm^{-1}: 16900, 13500.

3.1.2. [Cu(2-Clbz)$_2$(3PM)$_2$]$_n$ (2)

The complex **2** was prepared by adding 3PM (5 cm^3) in excess to methanol–acetone solutions (4 cm^3 methanol + 1 cm^3 acetone) of Cu(2-Clbz)$_2 \cdot H_2O$ (1.25 mmol). The fine blue microcrystals produced on standing were separated, washed and dried in vacuo. Well-shaped single crystals of [Cu(2-Clbz)$_2$(μ-3PM)$_2$]$_n$ **2** suitable for structure determination were obtained by recrystallizing in a mixture methanol–acetone (4 + 1), yield 80%. *Anal*. Calc. for **2**: C, 42.16; H, 2.95; N, 8.19; Cu, 9.29. Found: C, 42.2; H, 2.8, N, 8.2, Cu, 9.35%. IR (KBr) cm^{-1}: 1602 $\nu_{as}(COO^-)$; 1386 $\nu_s(COO^-)$; 1029 ν(C–O). IR (PE) cm^{-1}: 462 γ(py); 424 γ(py); 384 γ(py). VIS cm^{-1}: 16140.

3.1.3. [Cu$_3$(2-Clnic)$_6$(μ-3PM)$_4$(3PM)$_2$]$_n$ (3)

The complex **3** was prepared by adding 3PM (5 cm^3) in excess to methanol solutions (20 cm^3) of appropriate Cu(2-Clnic)$_2 \cdot H_2O$ (1.25 mmol). The fine blue microcrystals produced on standing were separated, washed and dried in vacuo. Well-shaped single crystals of [Cu$_3$(2-Clnic)$_6$(μ-3PM)$_4$(3PM)$_2$]$_n$ suitable for structure determination were obtained by recrystallizing in methanol, yield 80%. *Anal*. Calc. for **3**: C, 48.46; H, 3.39; N, 9.42; Cu, 10.68. Found. C, 48.2; H, 3.4; N, 9.4; Cu, 10.57%. IR (KBr) cm^{-1}: 1629 $\nu_{as}(COO^-)$; 1605 $\nu_{as}(COO^-)$; 1382 $\nu_s(COO^-)$; 1065 ν(C–O). IR (PE) cm^{-1}: 462 γ(py); 424 γ(py); 385 γ(py). VIS cm^{-1}: 15750.

3.2. Chemical reagents, analysis and spectral studies

All the chemicals used were of analytical grade (Aldrich or Sigma) and were used without further purification.

Copper was determined by electrolysis after mineralization of the complexes; carbon, hydrogen, nitrogen and sulfur were determined by microanalytical methods (Carlo Erba Instruments EA 1108). Besides the elemental analysis, the water content in hydrates was determined from thermogravimetrical curves.

Electronic spectra of the powdered samples in Nujol mulls were recorded at room temperature on a Specord M40 and Specord 200, respectively. IR spectra were recorded on a Nicolet Magna 750 spectrophotometer at room temperature. Spectra of solid samples were obtained in nujol mulls, KBr and polyethylene pellets at a resolution of 1 cm^{-1}. EPR spectra of powder samples were measured on a Bruker 200D SRC X-band (9.4 GHz) at room temperature. The simulations of the EPR spectra were performed using the commercially available program SIMFONIA (Bruker) [24].

3.3. Structure determination

Data collection and cell refinement were carried out using a κ-axis diffractometer Kuma KM-4 CCD with graphite monochromated Mo Kα radiation, using CRYSALIS software package [25]. The diffraction intensities were corrected for Lorentz and polarization factors. The structures were solved by direct methods using SHELXS-97 [26] or SIR-97 [27]. The numerical absorption correction

was made by using CRYSALIS. Geometrical analysis was performed using SHELXL-97 [28]. The structure of the complexes **1**, **2** and **3** was drawn by ORTEP-3 for Windows [29]. The Single Crystal Suite WINGX was used as an interface system for all the crystallographic programs and as software for preparing material for publication [30]. Crystal data and conditions of data collection and refinement are reported in Table 4.

The 2-chlorophenyl group of compound **2** is disordered occupying two statistical positions, represented by atoms C9a, C10a, C11a, C12a, C13a, Cl1 and atoms C9b, C10b, C11b, C12b, C13b, Cl2 with site occupancy factors of 0.647 and 0.353, respectively.

4. Conclusion

Three novel coordination polymers formed by copper(II) carboxylate with 3-pyridylmethanol have been prepared and characterized. The crystal structure of **1** consists of 1-D chains, which are linked by face-to-face $\pi\cdots\pi$ stacking interactions. The crystal structure of **2** consists of 2-D sheets. The crystal structure of **3** is a new type of coordination polymer and consists of 1-D "accordion" chains. Analysis of the packing of coordination polymers in the crystal structure shows that strong O–H$\cdots$O hydrogen bonds play a role in stabilization of polymeric chains.

5. Supplementary material

Crystallographic data (excluding structure factors) for the structure reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication nos. CCDC-282782 (**1**), CCDC-282783 (**2**) and CCDC-282784 (**3**). Copies of the data can be obtained free of charge on application to the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [fax: (internat.) +44 1223/336033; e-mail:deposit@ccdc.cam.ac.uk].

of 0.5 g (0.27 mmol) $H_3PMo_{12}O_{40}$. The yellow solution was allowed to stand for several days and the yellow crystals were collected. Yield: 35%. *Anal*. Calc. for $H_3PMo_{12}O_{40}$: C, 8.00; H, 1.73; N, 1.86. Found: C, 8.30; H, 1.60; N, 1.79%.

2.3. X-ray crystallography

Experimental parameters pertaining to single-crystal X-ray analysis of **I** are given in Table 1. Data were collected on a Siemens SMART 1000 CCD platform diffractometer with graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). The final unit cell was determined from 999 reflections in the range of $2.3° < \theta < 23.3°$. The data were integrated using the SAINT suite of software and corrected for the effects of absorption using SADABS. The structure was solved by direct methods and refined iteratively via full-matrix least-squares on F_o^2 and difference Fourier analysis using the SHELX-97 [17] suite of software, with the assistance of X-Seed [18]. All non-hydrogen atoms were refined with anisotropic displacement parameters. The hydrogen atoms of the proline moieties were placed in idealized positions and refined with a riding model whereas those of included water molecules were not modeled. There is some evidence of minor positional disorder of one of the proline moieties and two of the included water molecules which could not be successfully modeled.

3. Result and discussion

3.1. IR spectrum

Comparing the IR spectrum of **I**, with that of $H_3PMo_{12}O_{40}$, we can see that the vibrational bands of the $P–O_{a(\text{the central oxygens bonded to P})}$ and the $Mo–O_{d(\text{terminal or skin oxygen atoms})}$ have red-shifted from 1063.1 and 962.4 cm^{-1} to 1061.2 and 959.7 cm^{-1}, respectively. The vibrational bands of the $Mo–O_{b(\text{corner-shared oxygens})}$ and the $Mo–O_{c(\text{edge-shared oxygens})}$ have blue-shifted from 875.1 and 786.8 cm^{-1} to 880.5 and 789.2 cm^{-1}, respectively. The results indicate that the $P–O_a$ and $Mo–O_d$ bonds were weakened and $Mo–O_b$ and $Mo–O_c$ were strengthened in the title compound **I**. These observations suggest some interactions between the proline nitrogen atom and the oxygen atoms of the $[PMo_{12}O_{40}]^{3-}$ anion [19]. The peaks at 1391–1734 cm^{-1} and the peaks at 2950–2919 cm^{-1} are characteristic of $C_5H_{10}NO_2{}^{1+}$, the 1453.1 cm^{-1} feature is characteristic of the N–H vibration, and the features at 1615.4 and 1643.8 cm^{-1} are associated with N–H and C=O symmetric stretching vibration, respectively. The other bands at 2919 and 2950 cm^{-1} are attributed CH_2 group of the proline.

3.2. ^{13}C NMR spectrum

According to the ^{13}C NMR spectrum the lines at 170.980 ppm; 59.367 ppm; 46.026 ppm; 28.311 ppm; 23.602 ppm are assigned to C1, C2, C5, C3 and C4 of proline, respectively. These patterns are, generally, what one expects of protonated proline and there does not seem to be any striking clue that would require further analysis.

3.3. ^1H NMR spectrum

^1H NMR (ppm): 4.269 (T, 1H, C2H); 3.190 (T, 2H, C5H); 2.1–2.4 (Q, 2H, C3H); 1.7–2.1 (M, 2H, C4H). These shifts and patterns are consistent with the seven hydrogen atoms that are covalently bonded to the carbon atoms of the proline.

3.4. X-ray crystallography

The crystal structure of $[C_5H_{10}NO_2]_3[PMo_{12}O_{40}]\cdot 4.5H_2O$ (Fig. 1) consists of $[PMo_{12}O_{40}]^{3-}$ units linked together by $[C_5H_{10}NO_2]^{1+}$ ions through electrostatic interactions. The ratio of anion to proline is 1–3 and the prolines in the structure, having been protonated by the acidic hydrogens of $H_3PMo_{12}O_{40}$, function as cations and balance the charge.

In the Keggin-type $[PMo_{12}O_{40}]^{3-}$ polyoxoanion, the Mo centers exhibit a distorted $[MoO_6]$ octahedral environment, with all the Mo–O distances being within the 1.664(10)–2.453(7) Å. The MoO_6 octahedra are somewhat distorted and the Mo–O distances can be divided into several

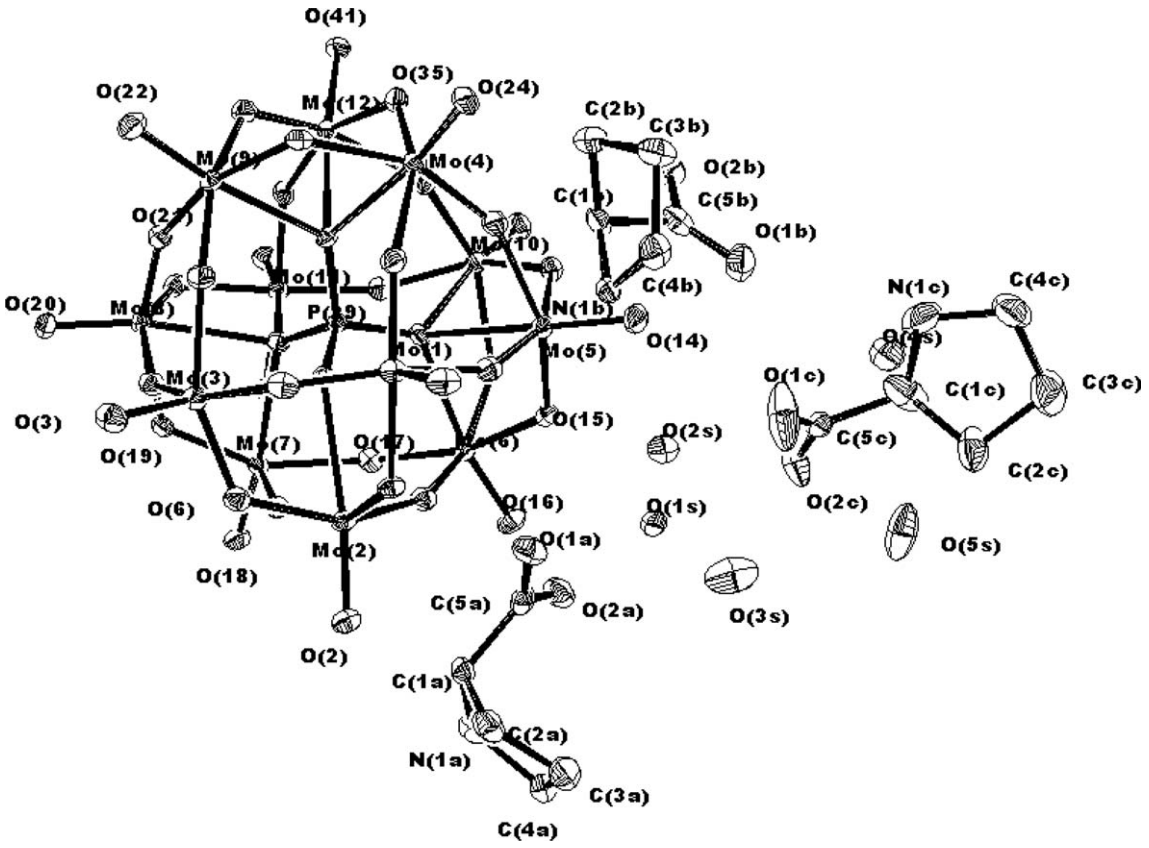

Fig. 1. Molecular structure unit with atom labeling of the title compound and ellipsoids are at 30% probability. The hydrogen atoms are omitted for clarity.

different groups according to the type of oxygen atoms, O_d, O_a, O_b and O_c, where O_d represents the terminal oxygen atoms, O_a represents those coordinated to P and to Mo atoms, O_b represents those coordinated to the Mo atoms whose MoO_6 octahedra are corner-shared and O_c represents those coordinated to the Mo atoms whose octahedra are edge-shared. As observed in many other polyoxomolybdates [20,21], the Mo–$O_{b/c}$ bonds fall into two well-resolved categories: the long pairs of Mo–O bonds and the short pairs of Mo–O bonds with the two bonds in a pair being in the *cis* positions. These are summarized in Table 2 with those of $H_3[PMo_{12}O_{40}]\cdot(29–31)H_2O$ for comparison [22]. This kind of distortion generates an interesting result. The Mo–$O_{b/c}$ bond lengths are alternately short and long, so that the distances of Mo–O–Mo are alternately short and long in the four rings around the structure (Fig. 2). The mean distance of Mo–Mo in four groups of edge-shared octahedra Mo_3O_{13} is 3.423 Å, 3.406 Å, 3.410 Å and 3.410 Å as compared with the analogue structure, i.e, $H_3[PMo_{12}O_{40}]\cdot(29–31)H_2O$, that is 3.42 Å with no significant alternating long/short bond lengths. The repulsion of Mo–Mo [23] may have brought about the alternative bond lengths in the prolinium 12-molybdophosphate but other major factors are effective to this evidence.

The proline structures bond distances and angles have standard values, thus there is no need to report them. In addition to intermolecular interactions between them, there

Table 2
Comparision of bond distances (Å and °) ([ ], average; ( ), difference)

	$H_3[PMo_{12}O_{40}]\cdot(29–31)H_2O$	$[C_5H_{10}NO_2]_3[PMo_{12}O_{40}]\cdot 4.5H_2O$

Mo–O_b	1.910(4)–1.914(4) [1.912] (0.004)	1.808(4)–2.028(4) [1.917] (0.220)
Mo–O_c	1.922(2)–1.924(4) [1.923] (0.002)	1.815(4)–2.038(4) [1.926] (0.223)
Mo–O_a	2.434(5)–2.436(3) [2.435] (0.002)	2.406(3)–2.453(3) [2.430] (0.047)

are intramolecular interactions that force the carboxylate group of one proline in the opposite direction (with respect to the pentagonal ring to which they are attached) of the carboxylate groupe of the neighboring proline. This spatial orientation is indicated by the torsion angle: O(5B)–C(1B)–N(1B)–C(4B) = 87.56°, C(5A)–C(1A)–N(1A)–C(4A) = 85.30° and C(5C)–C(1C)–N(1C)–C(4C) = 149.78°.

Another interesting feature of the crystal structure is evident from the view along the *z*-axis. POMs and prolines construct a network not dissimilar to the DNA strands. In the zig-zag arrangement of the polyoxometalate-proline

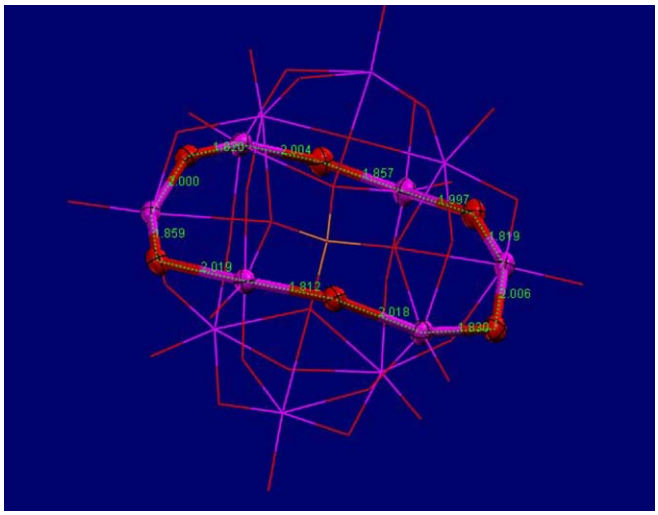

Fig. 2. Rings of alternative bonds in $[PMo_{12}O_{40}]^{-3}$ (show two rings and prolines omitted for clarity).

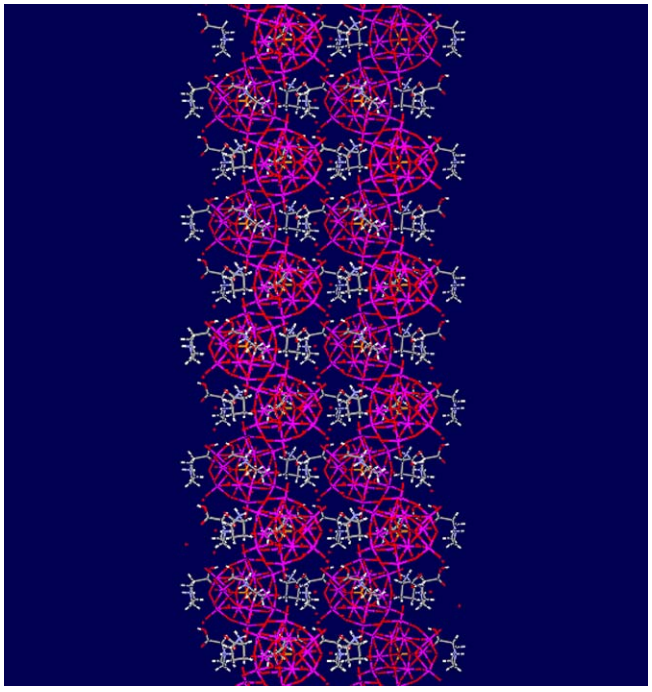

Fig. 3. View of the $[C_5H_{10}NO_2]_3[PMo_{12}O_{40}] \cdot 4.5H_2O$ along the *z*-axis.

chains, a directional orientationis is maintained that is, likely, caused by the noncovalent interactions among the constituents of the lattice (Fig. 3).

4. Conclusion

The synthesis and characterization of this new organic–inorganic salt, $(C_5H_{10}NO_2)_3PMo_{12}O_{40} \cdot 4.5H_2O$, is an important continuous step to incorporate organic molecules of biological significance into the network of inorganic cluster-compounds.

A combination of electrostatic forces and hydrogen bonding keeps this "adduct" stable in the solid state. The fact that in the solution phase the compound is also stable makes it a viable candidate for applications as homogeneous catalysis [24]. There may be potential pharmaceutical benefits that are yet to be explored.

5. Supplementary data

Crystallographic data for the structure reported in this paper have been deposited with the Cambridge Crystallographic Data Center as supplementary publication no. CCDC-280411. Copies of the data can be obtained free of charge an application to the CDCC, 12 Union Road, Cambridge CB2 1EZ, UK (e-mail: deposit@ccdc.cam.ac.uk).

data were obtained using the following instruments: UV–Vis spectra, JASCO UV–Vis–NIR model V 570; IR spectra (KBr disk, 4000–200 cm^{-1}), FTIR JASCO model 420; ^1H NMR spectra, Bruker (AC) 300 MHz FTNMR spectrometer. Electrochemical measurements were performed using computer-controlled PAR model 270 VERSASTAT electrochemical instruments with Pt-disk electrodes. All measurements were carried out under a nitrogen environment at 298 K with reference to saturated calomel electrode (SCE) in acetonitrile using $[n\mathrm{Bu_4N}][\mathrm{ClO_4}]$ as supporting electrolyte. The reported potentials are uncorrected for junction potential.

2.2. Materials

2-(Arylazo)pyrimidines were prepared by the reported procedure [10]. $H_2PtCl_6 \cdot xH_2O$ was purchased from Arrora Matthey, Kolkata, India. K_2PtCl_4 was prepared from the reported method [8]. Aniline, *o*-toluidine, *m*-toluidine, *p*-toluidine, *p*-chloroaniline were received from Sisco Research Lab (SRL). The purification of acetonitrile and preparation of *n*-tetra butylammonium perchlorate $[n\mathrm{Bu_4N}][\mathrm{ClO_4}]$ for electrochemical work were done as before [10]. Dinitrogen was purified by bubbling through an alkaline pyrogallol solution. All other chemicals and solvents were of reagent grade and were used without further purification. Commercially available SRL silica gel (60–120 mesh) was used for column chromatography.

2.3. Preparation of complexes

2.3.1. Dichloro[2-(phenylazo)pyrimidine]platinum(II), Pt(papm)Cl_2 (**4a**)

2-(Phenylazo)pyrimidine (papm) (0.2 g, 1.09 mmol) in MeCN–H_2O (15 ml) was added to an MeCN–H_2O (1:1, v/v, 40 ml) solution of K_2PtCl_4 (0.4 g, 0.96 mmol) and the mixture was refluxed for 24 h. On slow evaporation, a brown precipitate gradually appeared; it was filtered and washed with cold MeCN–H_2O (1:1, v/v, 3 × 5 ml). The dried mass was dissolved in a minimum volume of CH_2Cl_2 and chromatographed over a silica gel column. The desired compound was eluted by C_7H_9–MeCN (2:1, v/v) as an orange-red band; yield, 0.3 g (50%). Other complexes were prepared under identical conditions and yield varied in the range 45–50%. Calc. for $C_{10}H_8N_4Cl_2Pt$ (**4a**): C, 26.66; H, 1.77; N, 12.44. Found: C, 26.55; H, 1.69; N, 12.35%. Calc. for $C_{11}H_{10}N_4Cl_2Pt$ (**4b**): C, 28.44; H, 2.15; N, 12.07. Found: C, 28.55; H, 2.08; N, 11.99%. Calc. for $C_{10}H_7N_4Cl_2Pt$ (**4c**): C, 24.76; H, 1.44; N, 11.56. Found: C, 24.62; H, 1.37; N, 11.42%.

2.3.2. Chloro[(2-(8-imidophenyl)phenylazo)pyrimidine-N,N′,N″]platinum(II), Pt(papm-N–C_6H_5)Cl, (**5a**)

To an acetonitrile solution (15 ml) of Pt(papm)Cl_2 (90.3 mg, 0.67 mmol) was added slowly aniline (0.1 g, 1.08 mmol) in the same solvent (10 ml). The reaction mixture was stirred and refluxed continuously for 4 h. The colour of the solution changed gradually from orange-red to brown. The solution was evaporated in air, and the residue was washed thoroughly first with water (2 × 5 ml) and then with 50% aqueous-ethanol (3 × 5 ml). The residue was dissolved in dichloromethane (10 ml) and the solution was chromatographed over silica gel column (60–120 mesh). An orange-brown band was eluted by C_7H_9–MeCN (9:1) mixture. The eluted solution on evaporation in vacuo gave pure compound. Orange-brown compound was isolated in 45% yield.

The greenish-brown product is the coupled product, Pt(papm-N-C_6H_5)Cl. All other complexes were prepared similarly; yield, 40–55%. Calc. for $C_{16}H_{12}N_5ClPt$ (**5a**): C, 38.05; H, 2.38; N, 13.87. Found: C, 38.12; H, 2.31; N, 13.73%. Calc. for $C_{17}H_{14}N_5ClPt$ (**6a**): C, 39.34; H, 2.70; N, 13.50. 2.4. X-ray structure determination

The X-ray quality single crystal of Pt(papm-N–C_6H_4–Me-*m*)Cl (**7a**) was grown by slow diffusion of hexane into dichloromethane solution of the complex at 298 K. The crystal size was $0.25 \times 0.11 \times 0.08\ mm^3$. X-ray diffraction data were collected at 293(2) K with the Siemens SMART CCD using graphite-monochromatized Mo Kα radiation ($\lambda = 0.71073$ Å). Unit cell parameters were determined from least-squares refinement of setting angles with 2θ in the range 4–57°. A summary of the crystallographic data and structure refinement parameters are given in Table 1.

Table 1
Crystallographic data of Pt(papm-N–C_6H_4–Me-*m*)Cl (**7a**)

Chemical formula	$C_{17}H_{14}ClN_5Pt$
Formula weight	517.88
Crystal size (mm^3)	$0.25 \times 0.11 \times 0.08$

Space group	$P2_1/n$
a (Å)	7.459(1)
b (Å)	16.899(2)
c (Å)	13.117(18)
β (°)	92.497(3)
V ($Å^3$)	1652.0(4)
Z	4
T (K)	295(2)
λ (Å)	0.71073
2θ Range (°)	4–57
Reflection collected	9981
Unique reflections [a]	2522
hkl Range	$-9 \leqslant h \leqslant 9$, $-21 \leqslant k \leqslant 20$, $20 \leqslant l \leqslant -15$
ρ_{calc} (g cm^{-3})	2.082
μ (Mo Kα) (mm^{-1})	8.662
R[b]	0.0303
wR[c]	0.0569
Goodness-of-fit[d]	0.904

[a] $I > 2\sigma(I)$%.
[b] $R = \sum|F_o - F_c|/\sum F_o$.
[c] $wR = \left[\sum(F_o^2 - F_c^2)^2/\sum w(F_o^4)\right]^{1/2}$, $w = 1/[\sigma^2(F_o)^2 + (0.0283P)^2]$, where $P = (F_o + 2F_c^2)/3$.
[d] Goodness-of-fit is defined as $[w|F_o - F_c|/(n_o - n_v)]^{1/2}$, where n_o and n_v denotes the numbers of data and variables, respectively.

Of 9981 collected reflections 2522 unique reflections were recorded using ω-scan technique. Data were corrected for L_p effects and for linear decay. Semi-empirical absorption corrections based on ψ-scans were applied. The structure was solved by direct method using SHELX-97 and successive difference Fourier syntheses [11]. All non-hydrogen atoms were refined anisotropically. The hydrogen atoms were fixed geometrically and refined using riding model. In the final difference Fourier maps the residual maximum and minimum were 1.312 and -0.627 e $Å^{-3}$. All calculations were carried out using the SHELX-97.

2.5. Molecular orbital calculations

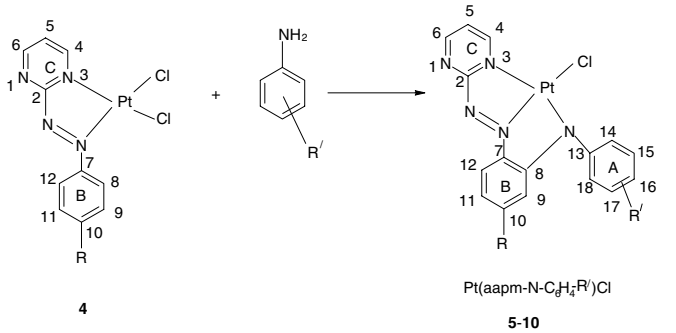
Extended Huckel molecular orbital calculation [12,13] was performed using the ICON software package originally developed by Hoffmann. The atomic parameters were taken from the crystallographic data (Table 1). For drawing figures and graphic package 'cacao' was used.

3. Results and discussion

3.1. Synthesis and formulation

2-(Arylazo)pyrimidines (aapm, **3**) are *N*,*N*′-chelators. The reaction of aapm with K_2PtCl_4 in MeCN–H_2O (1:1, v/v) has yielded orange-red crystalline product, Pt(aapm)Cl_2 (**4**), in the yield of 45–50%.

The reaction between Pt(aapm)Cl_2 and $ArNH_2$ in 1:1 ratio in MeCN suspension under refluxing condition has yielded greenish brown product (Eq. (1)). This has been identified as amine coupled product abbreviated Pt(aapm-N–C_6H_4-R′Cl) [where, R′ = H (**5**), *o*-Me (**6**) *m*-Me (**7**), *p*-Me (**8**), *p*-OMe (**9**), *p*-Cl (**10**)].



4 **5-10**

(1)

The arylamination takes place at the *ortho* position (at the C(8)–H bond) to azo function in the pendant aryl ring (B-ring) of aapm and forms platinum(II) complex of tridentate *N*,*N*′,*N*″-chelating ligand (*N*,*N*′,*N*″ refer to *N*(pyrimidine), *N*(azo) and *N*(arylamine), respectively). Microanalytical data support the composition of the complexes (see Section 2).

3.2. Molecular structure of Pt(papm-N–C_6H_4–Me-*m*)Cl (*7a*)

A molecular view of Pt(papm-N–C_6H_4–Me-*m*)Cl is shown in Fig. 1 and the selected bond parameters are listed in Table 2. The crystallographic asymmetry unit contains 24 non-hydrogen atoms of which 17 lie in a plane nearly perpendicular to crystallographic *c*-axis. These atoms comprise the two chelate rings, the aromatic groups fused to them and the Pt and Cl-atoms. The atomic groups Pt, N(1), C(4), N(3), N(4), and Pt, N(4), C(5), C(10), N(5) constitute two chelate planes (mean deviation <0.04 Å) and they are nearly planar (dihedral angle 1.8°). The chelate bite angles are N(1)–Pt–N(4), N(4)–Pt–N(5), 79.3°(4) and 81.8°(8). The Pt atom lies within the square plane defined by N_3Cl donor centers (deviation, <0.01). The pendant *m*-tolyl ring is inclined at an angles of 64.35° with the principal plane of 17 atoms. There are three types of Pt–N bonds: Pt–N(pyrimidine) [Pt–N(1)], 2.013(3) Å; Pt–N(azo) [Pt–N(4)], 1.919(9) Å and longest Pt–N(arylamine) [Pt–N(5)], 2.014(9) Å. The shortest Pt–N bond length is Pt–N(1) and longest Pt–N distance is Pt–N(5). The N=N bond length is 1.312(1) Å. The free ligand value of N=N bond is not available but the literature data available in some free arylazoheterocycles suggest that it is nearly 1.25(1) Å [14]. The elongation of N=N azo distance is consistent with electron delocalization from metal to ligand fragment [5,6]. A significant back-bone conjugation is also observed in the coordinated anionic ligand. This is viewed from the difference in N(azo)–C(phenyl-B/pyrimidine-C), distances. The N(azo)–C(pyrimidine-C) (N(3)–C(4)), 1.381(4) Å;

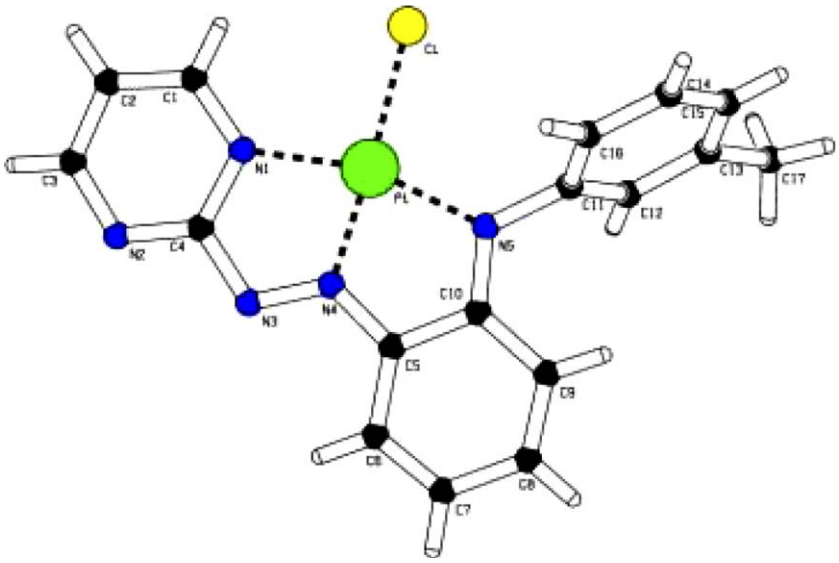


Fig. 1. Molecular structure of [Pt(papm-N–C_6H_4–Me-*o*)Cl] (**7a**).

Table 2
Selected bond lengths (Å) and angles (°) of Pt(papm-N–C_6H_4–Me-*m*)Cl (**7a**)

Bonds	Distances (Å)	Angles	Value (°)
Pt–N(1)	2.013(3)	N(1)–Pt–N(4)	79.3(4)
Pt–N(4)	1.919(9)	N(4)–Pt–N(5)	81.8(8)
Pt–N(5)	2.014(9)	N(1)–Pt–Cl(1)	97.0(4)
N(3)–N(4)	1.381(6)	N(5)–Pt–Cl(1)	101.7(4)
C(4)–N(1)	1.381(6)	N(1)–Pt–N(5)	161.1(8)
C(4)–N(3)	1.381(6)	N(4)–Pt–Cl(1)	176.3(8)
Pt–Cl(1)	2.291(2)	Pt–N(1)–C(4)	110.2(6)
C(5)–N(4)	1.346(6)	Pt–N(5)–C(10)	111.3(50)
C(10)–N(5)	1.332(8)	Pt–N(4)–C(5)	116.4(1)
C(11)–N(5)	1.441(1)		
N(1)–C(1)	1.332(8)		
N(2)–C(4)	1.322(1)		
N(2)–C(3)	1.333(3)		
C(2)–C(3)	1.361(9)		
C(1)–C(2)	1.353(8)		
C(5)–C(6)	1.411(7)		
C(6)–C(7)	1.350(8)		
C(7)–C(8)	1.419(9)		
C(8)–C(9)	1.367(6)		
C(9)–C(10)	1.435(1)		

N(azo)–C(phenyl-B) (N(4)–C(5)), 1.346(6) Å are noticeably shorter than that of N(imino)–C(phenyl-A) (N(5)–C(11)), 1.441(1) Å. More interesting feature is the ring C–C distance in B-ring C(5)–C(10); they have been elongated by 0.02–0.1 Å from that of ring-A and ring-C parameters. This leads us to conclude that the ring-B is more efficiently involve in back bone conjugation than that of other rings (A and C) with the coordinated Pt(II). This is also supported by the shortening of Pt–N(4) distance (1.919(9) Å) with reference to Pt–N(1), 2.013(3) and Pt–N(5), 2.014(9) Å. The bond parameters and backbone conjugation are also comparable with the literature data [5,6].

A hydrogen bonded cyclic dimmer is observed through C(12)–H(12)···N(3) C(12)–H, 0.93 Å; H(12)···N(3), 2.598(7) Å; C(12)···N(3), 2.598(7) Å and ∠C(12)–H(12)–N(3), 165.53°. Dimers are then arranged compactly to provide a platform for π–π interaction between pyrimidine (acceptor) of one unit with azophenyl ring (donor) of adjacent unit (distance between Cg(4) of pyrimidine···Cg(3) of azophenyl equals to 3.735(5) Å) and a supramolecular ladder is formed (Fig. 2).

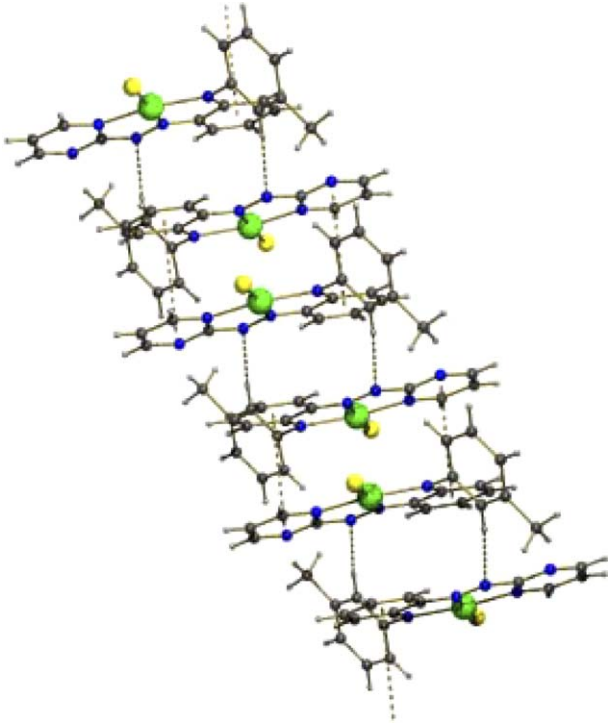

Fig. 2. Supramolecular ladder constituted via π···π interaction between pyrimidine and azoaryl in hydrogen-bonded cyclic dimers.

3.3. Spectra and bonding

The presence of two ν(Pt–Cl) stretches at 340 and 300 cm^{-1} in Pt(aapm)Cl_2 is in agreement with *cis*-$PtCl_2$ configuration [15] while a single transmission at 300–320 cm^{-1} is observed in the amine coupled products (**5**–**10**). The sharp single band at 1400–1415 cm^{-1} in free ligand is referred to ν(N=N) [5]. This has been shifted to lower frequency, 1360–1375 cm^{-1} in Pt(aapm)Cl_2 and supports the coordination of azo-N to Pt(II). In Pt(aapm-N–Ar)Cl (**5**–**10**) the ν(N=N) appears at 1260–1290 cm^{-1}; this significant reduction in azo frequency may be due to charge delocalization from N–Ar fragment (ring A) to the azo function intramolecularly (vide infra).

In chloroform solution of Pt(aapm)Cl_2 the absorption bands are observed at 250–550 nm. On comparison with free ligand data we may conclude that the transitions <400 nm are intraligand charge transfer transitions [10]. The spectral pattern have changed abruptly in Pt(aapm-N–Ar)Cl (**5**–**10**) and exhibit multiple transitions in the visible to NIR region (500–1250 nm). The spectral data are collected in Table 3 and a representative figure is shown in Fig. 3. The low energy spectral band in Pt(aapm-N–Ar)Cl, is associated with HOMO → LUMO (62a → 63a) charge transfer [5,6]. The MOs are calculated by EHMO approximation using X-ray crystallographic parameter of Pt(papm-N–C_6H_4–Me-*m*)Cl (**7a**). The HOMO (62a) receives 68% azoaryl group and 26% metal orbitals and

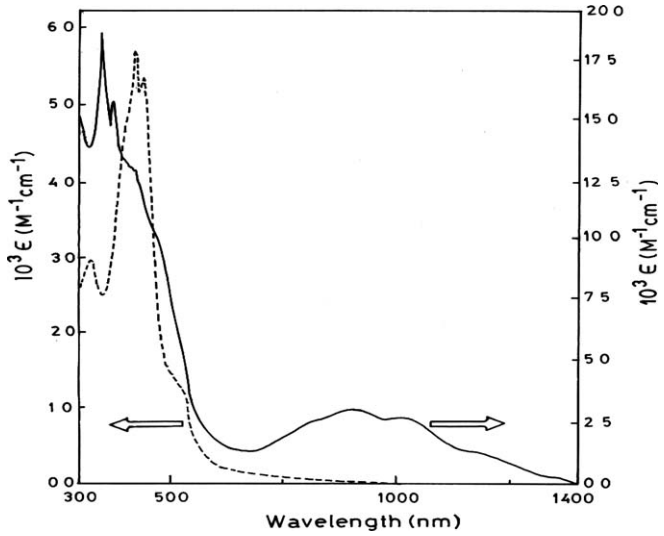

Fig. 3. Electronic spectra of Pt(*p*-tapm)Cl_2 (**4b**) (.....) and Pt(*p*-tapm–N–C_6H_4–Me-*m*) (**7b**) (—) in $CHCl_3$.

the LUMO (63a) shares 33% azo and 31% azoaryl character. Other transitions may be characterized to HOMO − 1 (61a) → LUMO (63a), HOMO − 2 (60a) → LUMO (63a), HOMO (62a) → LUMO + 1 (64a) etc. The effect of substituent R (at B-ring of arylazopyrimidine) and R′ (at A-ring of N–Ar) are also observed. Both steric and electronic effects of X influence the energy of HOMOs. The electron donating substituents destabilize the MOs and thus energy of HOMO is increased. The *o*-Me provides greater steric effect compared to other and influences the HOMO. The substituent R (at B-ring) influences more prominently to the LUMOs and the band maxima (λ_{max}) follow the sequence *p*-Clpapm < papm < *p*-tapm. This is expected in view of the electronic property of *p*-Me and *p*-Cl groups.

In the ^{1}H NMR spectra the signals were assigned on the basis of chemical shifts, spin–spin interaction and their effect on substitution and on comparison with the spectra of Pd(aapm)Cl_2 [5]. The spectral data are given in Table 4. The downfield portion of the spectra corresponds to pyrimidine-H (4-H–6-H, C-ring) [10] and upperfield portion refers to azo–aryl-protons, 8-H–12-H (B-ring). The binding of aapm with Pt(II) is supported by the appearance of spin–spin coupling [16] of ^{1}H (4-H) and ^{195}Pt (33.1%) and the coupling constant is $^3J_{Pt-H}$ is 20–24 Hz.

The NMR spectra of **5**–**10** resemble those of their Pd-containing analogues, Pd(aapm-N–Ar)Cl, [5] and are consistent with their proposed structures. A strong ^{195}Pt–^{1}H (J = 21–27 Hz) was observed to the pyrimidine 4H resonance (Fig. 4). The effect of substituents R′ (R′-C_6H_4–N–) on the signal movement is in accordance with the electronic effect of the group [16,17]. A significant observation is that azo–aryl protons (B-ring) (9-H–12-H) in Pt(aapm-N–C_6H_4-R′Cl) are up field shifted by 0.5–1.2 ppm relative to Pt(aapm)Cl_2 while pyrimidine protons (C-ring protons, 4-H–6-H) are shifted to up field side by 0.2–0.5 ppm compared to the parent complex, Pt(aapm)Cl_2. Azopyrimidine function is electron deficient while *N*-aryl ring (ring A) is σ-donor and may support intramolecular charge transfer transition. This may be reason for up field shifting of arylazopyrimidine protons (4-H–12-H) in the fused compound.

3.4. Electrochemistry

The electrochemical properties of Pt(aapm)Cl_2 (**4**) and Pt(aapm-N–Ar)Cl (**5**–**10**) have been investigated by cyclic voltammetry. The results are given in Table 3 and a representative voltammogram is shown in Fig. 5. Pt(aapm)Cl_2 exhibit two quasireversible ($\Delta E_p > 100$ mV) reduction couples at negative to SCE and have assigned to reduction of azo group [13,18,19]. Pt(aapm-N–Ar)Cl show four successive redox couples. One redox couple appears at positive side to SCE in the potential range 0.8–1.1 V and oxidative in nature. This redox response is quasireversible in nature which is supported from $\Delta E_p \geqslant 80$ mV ($\Delta E_p = [E_{pa} - E_{pc}]$, peak-to-peak separation). One electron nature of the redox couple is supported from i_{pa}/i_{pc} ($\approx$1.0) and differential pulse voltammetry (DPV). Platinum(II) unlike palladium

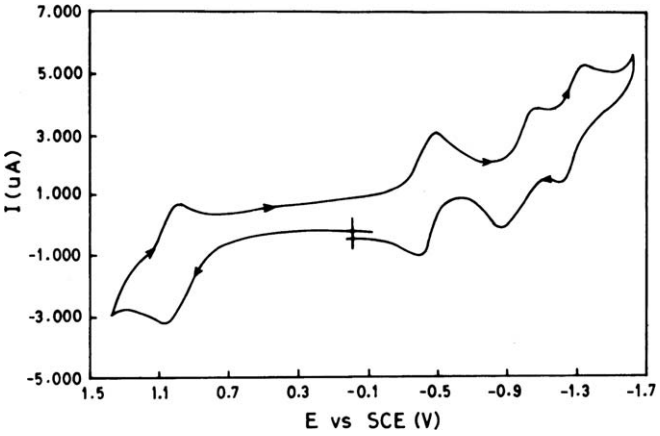

Fig. 5. Cyclic voltammogram of Pt(*p*-tapm–N–C_6H_4–Me-*m*)Cl (**7b**) in MeCN.

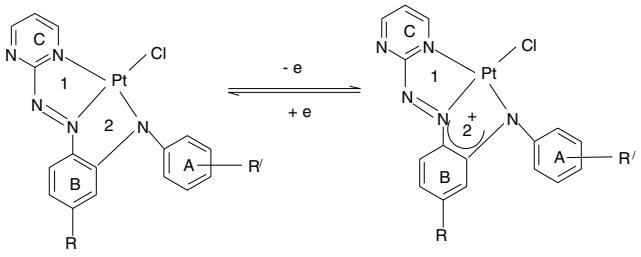
is irreversibly oxidized to platinum(IV) by 2e stoichiometry [6,18]. The redox responses at positive potential to SCE may be corresponding to electron extraction from HOMO (62a), which has major share from N–Ar group (68%). Thus Eq. (2) is justified.

Three redox responses at negative to SCE are reductive in nature. The reductions correspond to sequential electron feeding at LUMOs. There are four successive redox accessible levels in –N=N–C=N– group (Eqs. (3)–(6)). The LUMO (63a) shares 33% azo (–N=N–) contribution and thus electron may be localized at azo center. So the reductions may be ascribed by Eqs. (3)–(6).



(2)

$$[\text{–N=N–C=N–}] \overset{+e}{\rightleftharpoons} [\text{–N=N–C}^{\cdot-}\text{–N–}]^{-} \quad (3)$$

$$[\text{–N=N–C}^{\cdot-}\text{–N–}]^{-} \overset{+e}{\rightleftharpoons} [\text{–N}^{\cdot-}\text{–N–C}^{\cdot-}\text{–N–}]^{2-} \quad (4)$$

$$[\text{–N}^{\cdot-}\text{–N–C}^{\cdot-}\text{–N–}]^{2-} \overset{+e}{\rightleftharpoons} [\text{–N–N–C}^{\cdot-}\text{–N–}]^{3-} \quad (5)$$

$$[\text{–N–N–C}^{\cdot-}\text{–N–}]^{3-}\,1 \overset{+e}{\rightleftharpoons} [\text{–N–N–C–N–}]^{4-} \quad (6)$$

4. Conclusion

Pt(arylazopyrimidinie)Cl_2 have been reacted with arylamine ($ArNH_2$). The coupled products have been characterized by spectroscopic and electrochemical studies. In one case the structural confirmation has been carried out by X-ray diffraction study. Crystallographic parameters have been used to EHMO calculation. The spectral and electrochemical results have been correlated with MO calculation and compared with the results of palladium complexes.

5. Supplementary materials

Crystallographic data for the structure Pt(papm-N–C_6H_4–Me-*m*)Cl (**7a**) have been deposited with the Cambridge Crystallographic Data center, CCDC No. 184679. Copies of this information may be obtained free of charge from the Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK, e-mail: deposit@ccdc.cam.ac.uk or www: htpp://www.ccdc.cam.ac.uk.

with propane-1,3-diamine compounds of nickel(II) and copper(II) yield $[M(cis\text{-}Me_6[15]diene)]^{2+}$ compounds [13] and the structure of *N-rac*-$[Cu(cis\text{-}Me_6[15]diene)]Cl(ClO_4)_3$ {*cis*-Me_6[15]diene = 6,8,8,13,13,15-hexamethyl-1,5,9,12-tetraazacyclotpentadeca-5,15(1)-diene} has been reported [16]. Analogous reactions with butane-1,4-diamine complexes yield homologous *cis*-Me_6[16]diene complexes [17], which have not been structurally characterized. Reaction of tris(propane-1,3-diamine)nickel(II) perchlorate with acetone yields $[Ni(trans\text{-}Me_6[16]diene)](ClO_4)_2$ [18] for which the structures of cyclic amine reduction products have been reported [19]. Reaction of bis(propane-1,3-diamine)-copper(II) perchlorate with acetone yields both *cis* and *trans* isomers of $[Cu(Me_6[16]diene)]^{2+}$; the structures of *N-rac*-$[Cu(cis\text{-}Me_6[16]diene)][ZnCl_4]$ and of co-crystallised *N-rac*-$[Cu(trans\text{-}Me_6[16]diene)]$ *N-meso*-$[Cu(cis\text{-}Me_6[16]\text{-}diene)](ClO_4)_4$ have been determined [20]. Reaction of hexane-1,6-diamine hydroperchlorate with acetone yields $[H_2(trans\text{-}Me_6[22]diene)](ClO_4)_2$, from which copper(II) and nickel(II) compounds were prepared. The compound $[Cu_2(trans\text{-}Me_6[22]diene)(OMe)_2](ClO_4)_2$ has a dinuclear structure with each copper(II) ion coordinated by one amine and one imine group of the macrocycle and two bridging methoxy groups [21,22].

The structure of *N-rac*-$[Cu(cis\text{-}Me_6[14]diene)](ClO_4)_2$ is now reported, permitting comparison of the structures of the series of copper(II) *cis*-hexamethyl-tetraaza-cyclo-diene macrocycle compounds with fourteen to eighteen ring-members (see the Scheme 1).

Cations related to $[Cu(cis\text{-}Me_6[14]diene)]^{2+}$ often form very water-insoluble precipitates with tetracyanonickelate(II), but for $[Cu(cis\text{-}Me_6[14]diene)]^{2+}$ the product was sufficiently water-soluble to permit growth of crystals suitable for a structural study.

A number of compounds with amine cations and cyanometallate anions have been structurally characterized [23]. These frequently have bridging cyano groups with a variety of multi-nuclear groupings. For (tetraamine)copper(II) cations chain-polymeric structures are usual, as for the bis(ethane-1,2-diamine)copper(II) compound $[-(en)_2Cu\text{–}NC\text{–}Ni(CN)_2\text{–}CN\text{-}]_n$ [24,25] (and analogous compounds of other tetraaminecopper(II) cations), with *trans* axially-coordinated tetracyanonickelate anions. Related structures are present for *C-meso*-(5,5,7,12,12,14-hexamethyl-1,4,8,11-tetraazacyclotetradecane)copper(II) compounds with $[Fe(CN)_6]^{3-}$ [26] and $[Cr(CN)_6]^{3-}$ [27]. For the (13-ethyl-5,7,7-trimethyl-13-nitro-1,4,8,11-tetraazacyclotetradec-4-ene)copper(II) cation, $[Cu(L)]^{2+}$, a trinuclear tetracyanonickelate-bridged compound with cations $[(L)Cu\text{–}NC\text{–}Ni(CN)_2\text{–}CN\text{–}Cu(L)]^{2+}$ and independent $[Ni(CN)_4]^{2-}$ anions is formed [28]. The structure of a tetracyanonickelate(II) compound of $[Cu(cis\text{-}Me_6[14]diene)]^{2+}$ is now reported.

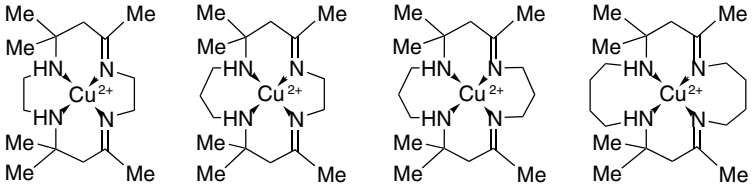
2. Results

2.1. N-rac-(5,7,7,12,12,14-hexamethyl-1,4,8,11-tetraazacyclotetradeca-4,14(1)-diene)copper(II) perchlorate

The structure of *N-rac*-$[Cu(cis[14]diene)](ClO_4)_2$ was determined by X-ray diffractometry, see Section 4 for details.

The compound is isostructural with the Ni(II) analogue [4]. The asymmetric unit consists of half the $[Cu(cis[14]\text{-}diene)]^{2+}$ cation and one perchlorate ion, see Fig. 1. The cation lies on a twofold axis, through Cu and the mid-points of bonds C2–C3, C9–C10, establishing the *N-rac*-configuration, with one NH group and one axially oriented methyl substituent on each side of the CuN_4 plane. The copper(II) ion is in slightly tetrahedrally twisted planar coordination by the four N-atoms (*trans* N–Cu–N angles = 176.67(5)°), see below and Table 1 for other significant dimensions. The Cu–N bond is, as is usual, slightly shorter for the imine nitrogen than for the secondary amine nitrogen. The N4–C5 distance of 1.284(2) Å and the bond angles about these atoms confirm the location of the imine function. The five-membered chelate rings have symmetrical, but different, gauche conformations, and the six-membered chelate ring has a twist conformation [angle N–Cu–N and displacements of atoms from relevant CuN_2 planes/°, Å: Cu,N4,$N4^i$ (diimine chelate): 85.62(7), C3, 0.339(1); Cu,N8,$N8^i$ (diamine chelate): 86.60(7), C9, −0.385(1); Cu,N4,N8 (amine–imine chelate): 93.98(5), C5, 0.070(1), C51, 0.433(3), C6, −0.170(3), C7, −0.841(2), C71, −0.873(3); C72, −2.258(1)].

A well-ordered perchlorate ion lies on each side of the planar cation, with the closest oxygen atom O1 {and $O1^i$} lying off the tetragonal axis, with O1–Cu–$O1^i$ = 174.3°, with Cl1 "above" $N4^i$, with Cu–O1 = 3.017(1) Å, indicating very weak interactions. Hydrogen bonds N8–H8···$O4^i$ [H···O, N–O, N–H···O/Å, °: 2.50, 3.211(2), 136] and N8–H8···$O1^{ii}$ [2.53, 3.168(2),



Scheme 1. The formulae of *cis*-(diamine–diimine) azamacrocycle copper(II) cations which have been structurally characterised.

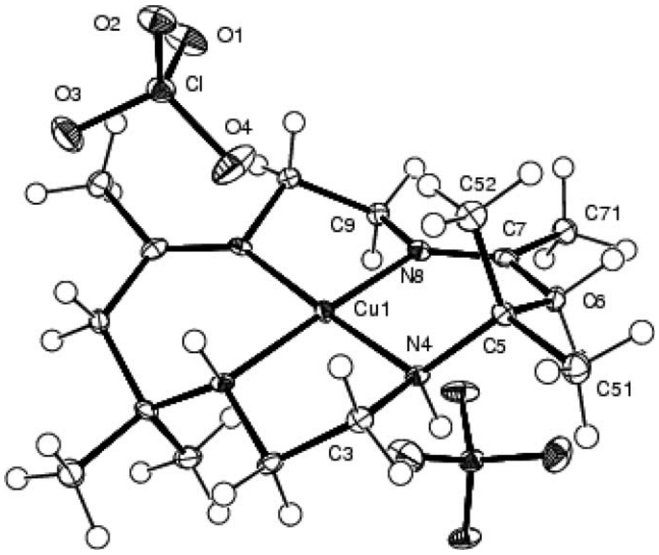


Fig. 1. *N-rac*-(5,7,7,12,12,14-hexamethyl-1,4,8,11-tetraazacyclotetradeca-4,14(1)-diene)copper(II) perchlorate, drawn [29] with displacement ellipsoids at the 50% confidence level, with hydrogen atoms shown as circles of arbitrary radius.

127] link the cation and perchlorate ions; symmetry operations i = $-x$, y, $-z + 1/2$; ii = $x + 1/2$, $y + 1/2$, $-z + 1/2$.

2.2. Di-μ-cyano-1:2κ^2 C:N;1:3κ^2 C:N-dicyano-1κ^2 C-bis(*N-rac*-5,7,7,12,12,14-hexamethyl-1,4,8,11-tetraazacyclotetradeca-4,14(1)-diene)copper(II)–nickel(II) tetra(cyano-κ^1C) nickelate(II)

The structure of [{*N-rac*-Cu(*cis*[14]diene)}$_2${Ni(CN)$_4$}]·[Ni(CN)$_4$] was determined by X-ray diffractometry, see Section 4.2 for details.

The crystal has an asymmetric unit including the (tetraazamacrocycle)copper(II) cation and halves of two independent centrosymmetrical tetracyanonickelate(II) ions [Ni2(N21–C21)(N22–C22)] and [Ni3(N30–C30)(N31–C31)], see Fig. 2. The tetracyanonickelate(II) ion including Ni3 links two (tetraazamacrocycle)copper(II) units to form symmetrical trinuclear cations, see Fig. 3. The bridging tetracyanonickelate ion is coordinated axially with Cu–N30 = 2.298(2), Cu···Cu = 9.918(2) Å, see Fig. 3. The second tetracyanonickelate(II) ion, including Ni2, which is inclined to the first at 8.3(1)°, does not interact with the copper(II) cation, other than by the hydrogen bond N11–H11···N33^{i} {N11–N33^{i} = 3.000(3), H11···N33^{i} = 2.26 Å, N11–H11···N33^{i} = 136°, symmetry operation i = $-x$, $-y$, $-z$.

The (5,7,7,12,14,14-hexamethyl-1,4,8,11-tetraazacyclotetradeca-4,11-diene)copper(II) cation is present in the *N-rac* configuration, with dimensions (see Table 1) similar to those of the perchlorate salt, except that the CuN$_4$ group is bent along the N1–Cu–N8 axis {N1–Cu–N8 = 178.25(7)°, N4–Cu–N11 = 160.30(7)°} with the Cu displaced towards the axially interacting cyano nitrogen atom N30 (see Fig. 4) {displacements of atoms from best N$_4$ plane: N1 −0.163(1), N4 0.159(1), N8 −0.156(1), N11

Table 1

[c] Co-crystallised.
[d] Isostructural with the Cu analogue.

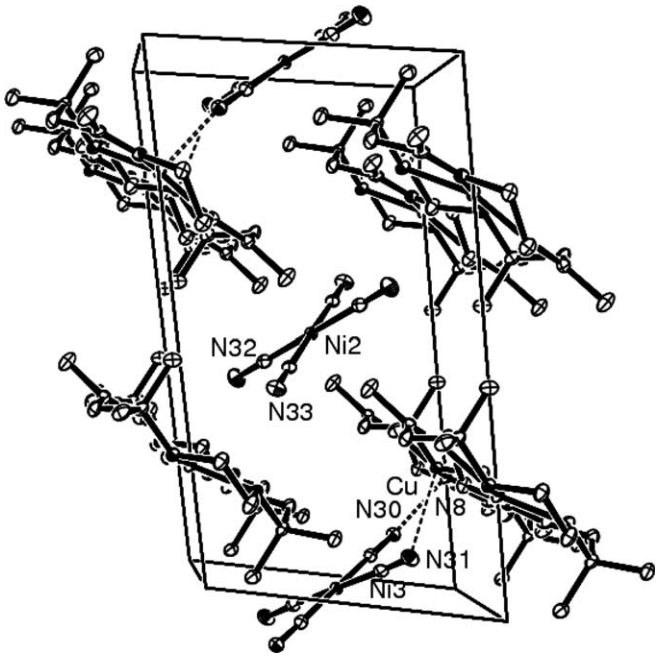

Fig. 2. The unit cell of $[\{N\text{-}rac\text{-}Cu(cis[14]diene)\}_2\{Ni(CN)_4\}]\cdot[Ni(CN)_4]$, viewed normal to (0 1 0), drawn as for Fig. 1, with hydrogen atoms omitted for clarity.

0.161(1) Cu −0.181(1) Å}. The Cu–N distances {Cu–N1 = 1.964(2), Cu–N4 = 1.987(2), Cu–N8 = 2.016(2), Cu–N11 = 2.002(2) Å} are slightly longer than the values for the perchlorate salt, again with Cu–N distances slightly shorter for imine than for amine nitrogen. These increased Cu–N distances with increased coordination number, together with the appreciable folding of the macrocycle in response to the axial coordination of the tetracyanonickelate group indicate the flexibility of these azamacrocycles.

The cyano nitrogen atom N30 is near the tetragonal axis of the tetraaza cation {angles N–Cu–N30 range from 85.0(1)° to 109.2(1)° with Cu–N30≡C30 = 142.1(2)°}. The plane of the $[Ni3(CN)_4]^{2-}$ ion is inclined to the best N_4 plane of the cation at 72.98(4)°, angled away from the axially oriented methyl group C121 and oriented such that the closest approach is N31 to N8, with a hydrogen bond N8–H8···N31 {N8···N31 = 3.328(3), H8···N31 = 2.53 Å. N8–H8···N31 = 145°}.

Both tetracyanonickelate ions are slightly distorted from D_{4h} symmetry, the bridging ion including Ni3 more so than the independent ion including Ni2, with the largest affects associated with the coordinated N30 atom. The bond C30≡N30 = 1.849(2) Å is slightly shorter than the other C≡N distances {all 1.861(2) Å}, and the coordinated cyano group Ni3–C30≡N30 more bent {bond angle = 174.6(2)°} than the others {Ni3–C31≡N31 = 176.2(2)°, Ni2–C32≡N32 179.2(2)° and Ni2–C33≡N33 = 178.7(2)°}.

3. Discussion

3.1. The perchlorate salt

Fourteen membered 1,4,8,11-tetraazacyclotetradecane macrocycles have the optimal (minimal strain energy) configurations for coordination to copper(II) ions, shown for $[Cu(cis[14]diene)](ClO_4)_2$ by the optimal Cu–N distances, near coplanarity of the CuN_4 group and near optimal ring bond and torsion angles. Like its nickel(II) analogue, $[Cu(cis[14]diene)](ClO_4)_2$ is most stable in the *N-rac* configuration.

Increasing the ring size for homologous metal-free tetraazamacrocycles leads to increasing "hole-size" and tetrahedral twisting of the N_4 group. However, the copper(II) cations of the *cis*-diene tetrazamacrocycles from 14 to 18 ring-members show little increase in Cu–N distance with increasing ring-size; the increasing strain being accommodated by a combination of increasing puckering of the ring and by increasing tetrahedral twisting of the CuN_4 group. The $[Cu(cis\text{-}Me_6[16]diene)]^{2+}$ cation has the CuN_4 group near co-planar for the perchlorate salt (with *N-meso* configuration) and appreciably twisted for the tetrachlorozincate

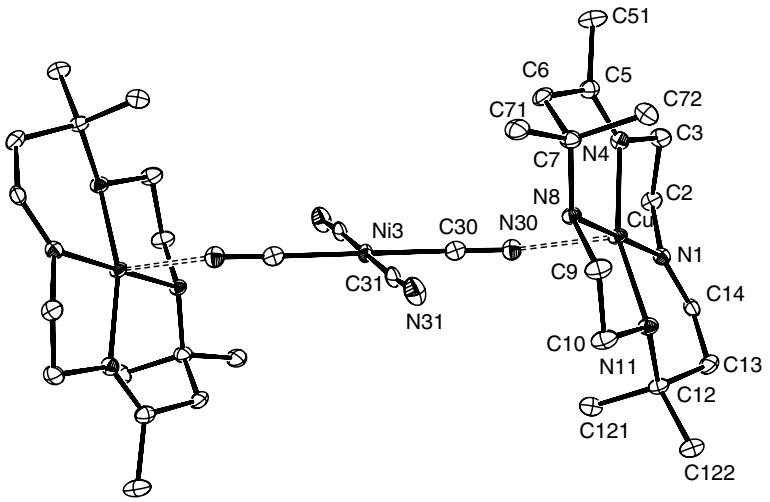

Fig. 3. The $[\{N\text{-}rac\text{-}Cu(cis[14]diene)\}_2\{Ni(CN)_4\}]^{2+}$ trinuclear cation, drawn as for Fig. 1.

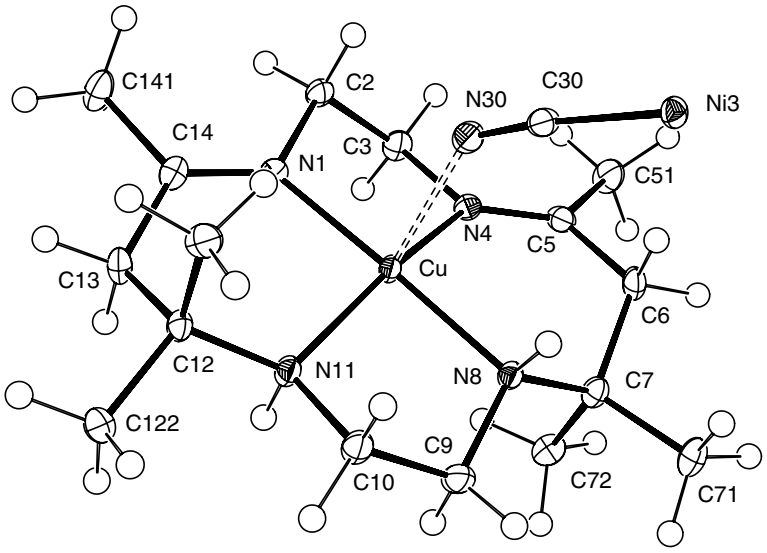

Fig. 4. The $[\{N\text{-}rac\text{-}Cu(cis[14]diene)\}_2\{Ni(CN)_4\}]^{2+}$ cation, showing the axial interaction with the bridging cyano group, drawn as for Fig. 1.

salt (with *N-rac* configuration), showing the influence of configuration on geometry [20]. For the perchlorate salts the *N-meso*-$[Cu(cis\text{-}Me_6[18]diene)]^{2+}$ cation has marginally shorter Cu–N distances and little (±0.007 Å) tetrahedral twisting of the N_4 group, but has a highly puckered ring, while the *N-rac*-$[Cu(trans\text{-}Me_6[18]diene)]^{2+}$ cation has a very twisted macrocycle, with ±0.13(1) Å displacements of the N_4 group.

3.2. The tetracyanonickelate(II) compound

The cation $[Cu(cis\text{-}Me_6[14]diene)]^{2+}$, like many similar cations, forms a compound with tetracyanonickelate(II) which is sparingly water-soluble (an analogous compound formed by $[Cu(trans\text{-}Me_6[14]diene)]^{2+}$ is much less soluble). A number of such compounds with metal–amine cations and cyanometallate anions have been structurally characterized [23]. These frequently have bridging cyano groups with a variety of multi-nuclear groupings, commonly chain-polymeric, which generally show some degree of antiferromagnetic spin coupling. A structurally similar compound, formed by (13-ethyl-5,7,7-trimethyl-13-nitro-1,4,8,11-tetraazacyclotetradec-4-ene)copper(II), has one trinuclear cation similar to that here described {Cu–N_{cyano} = 2.226(3) Å, Cu–N≡C = 168.2(3)°} and another with a water molecule coordinated *trans* to the bridging cyano group {Cu–N_{cyano} = 2.677(4), Cu–O = 2.396(3) Å and Cu–N≡C = 137.7(3)°}, and also has independent $[Ni(CN)_4]^{2-}$ ions [28].

The nickel(II) analogue of the compound now reported occurs as the singlet ground state salt with non-interacting ions $[Ni(cis\text{-}Me_6[14]diene)][Ni(CN)_4]\cdot H_2O$, while the *trans* isomeric cation occurs as both a singlet ground state salt *N-rac*-$[Ni(trans\text{-}Me_6[14]diene)][Ni(CN)_4]\cdot 3H_2O$ and as a triplet ground state linear polymer *N-meso*-$[\text{-}Ni(trans\text{-}Me_6[14]diene)NC\text{–}Ni(CN)_2\text{–}CN\text{–}]_\infty$, with Ni–$C_{cyano}$ = 2.207(1) Å [30].

4. Experimental

4.1. Preparation of compounds

4.1.1. N-rac-5,7,7,12,12,14-Hexamethyl-1,4,8,11-tetraazacyclotetradeca-4,1(14)-diene)copper(II) Perchlorate

Orange *N-rac*-$[Cu(cis[14]diene)](ClO_4)_2$ was prepared by reaction of tris(ethane-1,2-diamine)copper(II) perchlorate with acetone, separating the *cis*- and *trans* isomeric products by fractional crystallisation from water, as reported in [1]. The crystal used for the structural study was obtained by allowing a hot saturated solution in water to cool slowly.

4.1.2. Di-μ-cyano-1:2κ^2 C:N;1:3κ^2 C:N-dicyano-1κ^2 C-bis-(N-rac-5,7,7,12,12,14-hexamethyl-1,4,8,11-tetraazacyclo- tetra deca-4,1(14)-diene)copper(II)-nickel(II) tetra(cyano-κ^1C)nickelate(II)

A solution of $Na_2[Ni(CN)_4]\cdot 3H_2O$ in hot water was added to a solution of *N-rac*-$[Cu(cis[14]diene)](ClO_4)_2$ (equimolar amounts) in hot water. The sparingly soluble dark blue product was filtered from the cold solution, washed with cold water and air-dried. A crystal for the structural study was obtained by slow cooling of a hot aqueous solution. *Anal.* Calc. for $C_{20}H_{32}N_8CuNi$: C, 47.4; H, 6.4; N, 22.1. Found: C, 47.2; H, 6.2; N, 22.1%. IR spectrum: sharp bands were assignable to ν(NH) 3232 and ν(C=N) 1667 cm^{-1} of the $[Cu(cis[14]diene]^{2+}$ cation and a single sharp band at 2113 cm^{-1} to ν(C≡N) of the $Ni(CN)_4]^{2-}$ anions (although there are four structurally distinct cyanide ions in the structure.

4.1.3. Magnetic susceptibility

The magnetic susceptibility of $[\{Cu(cis\text{-}Me_6[14]diene)\}_2\{Ni(CN)_4\}][Ni(CN_4)]$, measured by the Gouy method at 293 K, was 1.32×10^{-8} m^3 (mol of Cu)$^{-1}$ which after correction for diamagnetism using Pascal's constants gives

an effective magnetic moment of 1.75 μ_B, indicating that little, if any, spin coupling is present.

4.2. Structural study for N-rac-(5,7,7,12,12,14-hexamethyl-1,4,8,11-tetraazacyclotetradeca-4,14(1)-diene)copper(II) perchlorate

4.2.1. Crystal data

$C_{16}H_{32}Cl_2CuN_4O_8$, $M_r = 542.91$, orange block grown from water, $0.36 \times 0.11 \times 0.10$ mm, orthorhombic, space group *P bcn*, $a = 10.483(1)$, $b = 10.934(1)$, $c = 19.195(3)$, $Z = 4$, $T = 273(2)$ K, cell from 7963 reflections, θ_{min} 2.69°, θ_{max} 32.85°.

Bruker SMART 1K CCD area detector diffractometer, φ and ω scans, Mo Kα radiation ($\lambda = 0.71073$ Å), $T =$ 88(2) K, multi-scan absorption correction (based on symmetry-related measurements, Bruker SADABS 2004/1) [31], $T_{min} = 0.695$, $T_{max} = 0.879$, 20617 measured reflections (average $R_{eqiv.}$ 0.0371), $h - 15 \rightarrow 12$, $k - 12 \rightarrow 16$, $l - 29 \rightarrow 8$, θ_{min} 2.12, θ_{max} 32.82°, 3763 independent reflections, 2956 reflections with $I > 2\sigma(I)$.

4.2.2. Solution and refinement [32]

Refinement on F^2, all H-atoms are in calculated positions and riding, 144 parameters. $R_1 = 0.0303$, $wR =$ 0.0708 $\{I > 2\sigma(I)\}$, R_1 0.0478, $wR = 0.0783$ {all reflections}, $\{w = 1/[\sigma^2(F_o^2) + (0.0375P)^2 + 1.2441P]$ where $P = (F_o^2 + 2F_c^2)/3)\}$.

4.3. Structural study for di-μ-cyano-1:2κ^2 C:N;1:3κ^2 C:N-dicyano-1κ^2 C-bis(N-rac-5,7,7,12,12,14-hexamethyl-1,4,8,11-tetraazacyclotetradeca-4,14(1)-diene)copper(II)-nickel(II) tetra(cyano-κ^1 C)nickelate(II)

4.3.1. Crystal data

$C_{40}H_{64}Cu_2N_{16}Ni_2$, $M_r = 1013.58$, violet block grown from water, $0.34 \times 0.16 \times 0.05$ mm, triclinic, space group $P\bar{1}$, $a = 8.5092(9)$, $b = 9.675(1)$, $c = 15.227(2)$ Å, $\alpha =$ 104.705(2)°, $\beta = 94.856(2)$°, $\gamma = 113.002(2)$°, Z 1, $T =$ 93(2) K, cell from 4208 refl., θ_{min} 2.90, $2\theta_{max}$ 25.65°.

4.3.2. Data collection

As for previous compound; $T = 88(2)$ K, $T_{min} = 0.8334$, $T_{max} = 1.000$ (as for the first compound), 6442 measured reflections (average $R_{eqiv.}$ 0.0205), $h - 10 \rightarrow 10$, $k - 10 \rightarrow 12$, $l - 19 \rightarrow 16$, θ_{min} 2.38°, θ_{max} 26.38°, 4792 independent reflections, 3713 reflections with $I > 2\sigma(I)$.

4.3.3. Refinement [32]

Refinement on F^2, all H-atoms are in calculated positions and riding, 282 parameters. $R_1 = 0.028$, $wR_2 =$ 0.069 $\{I > 2\sigma(I)\}$, $R_1 = 0.035$, $wR_2 = 0.072$ {all reflections} $\{w = 1/[\sigma^2(F_o^2) + ((0.0428P))^2]$ where $P = (F_o^2 + 2F_c^2)/3)\}$.

Appendix A. Supplementary data

Crystallographic data has been deposited with the Cambridge Crystallographic Data Centre; perchlorate salt CCDC 277925 and tetracyanonickelate compound CCDC 277926. Copies of this information may be obtained free of charge on application to The Director, CCDC, 12 Union Road, Cambridge CB2 2EZ, UK (fax: +44 1223 336033; e-mail: deposit@ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk). Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2005.10.025.

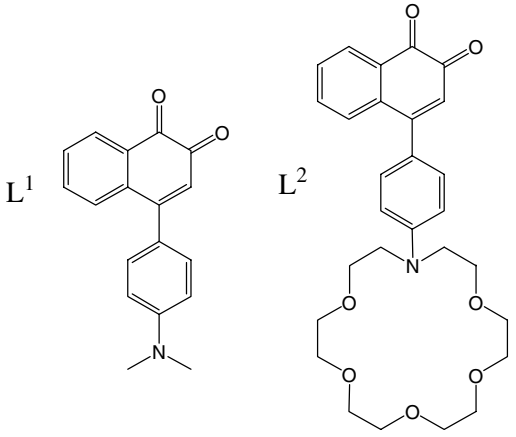
and excited state [43]. These bands emerge as consequence of the presence of donor and acceptor groups that could also act as binding centres. Transduction of the coordination events are based on selective guest interaction with either the donor or acceptor groups in the signalling framework. Those systems are of interest from either a photophysical point of view and as suitable scaffoldings for building up selective chromogenic chemosensors. Carbonyl groups are good acceptors in charge transfer bands. As donor groups nitrogen atoms are especially common due to their ability to delocalise their lone pair in the molecule. In fact there are a number of chemosensors based on charge transfer transitions containing amines as donor and carbonyls as acceptor groups, which have been employed as cations and anion sensors [44–47].

As part of our interest in the development of chromogenic chemosensors, we report here a study on the use of naphthoquinone derivatives as receptors for the chromogenic sensing of metal cations and anions in acetonitrile.

2. Results and discussion

Products L^1 and L^2 (see Scheme 1) have been synthesised following the process described by Yoshida et al. [48] by condensation reaction of the corresponding aniline derivate with the sodium salt of 1,2-naphthoquinone-4 sulphonate in acetic acid at 30 °C using nickel acetate as reaction promoter. The reaction proceeds via nickel coordination to the carbonyl groups increasing the sulphonate capacity as leaving group favouring the reaction. The products were purified by column chromatographic. The ^{1}H MNR spectrum of L^2 shows a broad unresolved signal centred at 3.7 ppm attributed to protons from the macrocycle, whereas L^1 shows a singlet at 3.07 ppm due to CH_3 groups. Both L^1 and L^2 compounds show a singlet at 6.4 ppm, and signals in the 7.4–8.2 range from the naphthoquinone framework and two doublets at 6.7 and 7.4 from the 1,4-disubstituted anilinium ring. ^{13}C NMR displayed the expected signals in the aliphatic region and signals in aromatic zone in the 111–157 ppm range. Resonances at 180.10 and 180.26 ppm were attributed to two nonequivalent carbonyl groups. The visible spectrum of these compounds shows a broad band centred at 534 ($\log\varepsilon = 3.80$) and 532 nm ($\log\varepsilon = 3.86$), for L^1 and L^2, respectively, attributed to an intra-ligand charge transfer band (ICT) form the amine to the carbonyl groups.



Scheme 1. Chemical structures of L^1 and L^2.

3. Cation sensing properties of L^1 and L^2

As stated above, the electronic transition of lower energy for both L^1 and L^2, is a broad band at ca. 532 nm attributed to an internal charge transfer transition. Changes observed in this band by the presence of alkaline (Li^+, Na^+, and K^+), alkaline earth (Mg^{2+}, Ca^{2+}, and Ba^{2+}) and transition metal cations (Fe^{3+}, Hg^{2+}, Cu^{2+}, Pb^{2+}, Zn^{2+}, Co^{2+}, Cd^{2+}, Ni^{2+}, and Ag^+) have been studied.

In a first experiment with these cations in acetonitrile it was evident that whereas the colour of acetonitrile solutions of L^2 were affected by the presence of Fe^{3+}, Hg^{2+}, Cu^{2+}, Pb^{2+} and Ba^{2+}, only the cations Fe^{3+}, Hg^{2+} and Cu^{2+}, induced a colour change for L^1. In the presence of the remaining metal cations, both L^1 and L^2 remained silent. The different behaviour observed for L^1 and L^2 in the presence of Pb^{2+} and Ba^{2+} should clearly be attributed to the presence of the 18-crown-6 macrocycle coordination unit in L^2 [49].

In a more detailed study with L^2, it was observed, however, that the behaviour found for Ba^{2+} was somewhat different to that found for Pb^{2+} (see Fig. 1). Thus, while the presence of Pb^{2+} resulted in a complete deactivation of the charge transfer band, the Ba^{2+} is only able to produce a partial decrease of the intensity of the band at 532 nm. This might be attributed to a stronger covalent Pb^{2+}–N interaction that could result in a more efficient capture the electron pair of the nitrogen [50]. On the contrary, the interaction of Ba^{2+} with L^2 is expected to have a stronger electrostatic character and, at least partially, the interaction with the nitrogen atoms is due to the charge of the cation that would additionally be coordinating the oxygen atoms from the macrocycle. This stronger preference of L^2 for Pb^{2+} over Ba^{2+} can also be observed when compared the stability constants obtained for the L^2–Pb^{2+} and L^2–Ba^{2+} systems which resulted to be near two order of magnitude larger for the former (see Table 1). In fact, visible titration experiments of acetonitrile solutions of L^2 with the metal cations Ba^{2+} or Pb^{2+} were indicative of the formation of 1:1 metal-to-ligand species in agreement with the coordination of the metal cations in the aza-oxa macrocycle. The $\log K$ for the formation of the corresponding $[M(L^2)]^{2+}$ ($M = Ba^{2+}$, Pb^{2+}) complexes were determined from nonlinear least-squares treatment of the titration profiles [51]. The results are shown in Table 1. Fig. 2 shows the titration curve of the system L^2–Ba^{2+}. From similar titration experiments, the stability constants for the formation of complexes of the ligands L^1 and L^2 with the metal cations Fe^{3+}, Hg^{2+}, Ba^{2+} and Pb^{2+} were also obtained and are shown in Table 1. As stated above, Ba^{2+} and Pb^{2+}

Table 1
Logarithm of the stability constants for the formation of complexes with receptors L^1 and L^2

	L^1	L^2
$Fe^{3+} + 2L \leftrightarrow [L_2Fe]^{3+}$	10.20(4)	9.67(7)
$Hg^{2+} + 2L \leftrightarrow [L_2Hg]^{2+}$	13.12(8)	14.71(7)
$Pb^{2+} + L \leftrightarrow [LPb]^{2+}$		7.99(3)
$Ba^{2+} + L \leftrightarrow [LBa]^{2+}$		4.58(5)

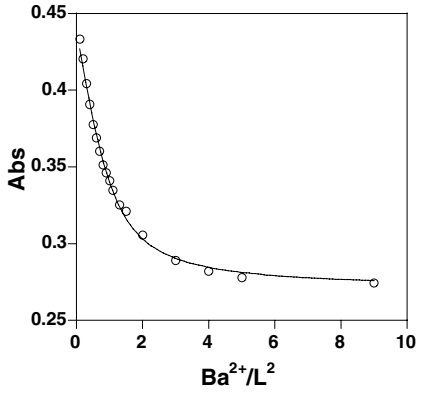

Fig. 2. Titration curve of the system L^2–Ba^{2+}.

are the only metal cations that produce optical changes with receptor L^2 but not with L^1, suggesting that they are coordinated through the aza-oxa macrocyclic unit. The coordination mode of Ba^{2+} and Pb^{2+} with L^2, was also followed by ^{1}H NMR. These studies were in agreement with cation coordination through the macrocycle. Thus, for instance, addition of Ba^{2+} to CD_3CN solutions of L^2 induced two significant variations in the resonances of the uncoordinated ligand, (i) a shift of the multiplet of the aliphatic zone from 3.5–3.8 to 3.6–4 ppm and (ii) a shift of the doublets of the aryl ring of the aniline subunit from 6.90 and 7.45 to 7.44 and 7.64 ppm, respectively, while the other aromatic signals showed unremarkable shifts in the presence of this cation.

The changes observed upon addition of increasing amount of Cu^{2+}, Hg^{2+} and Fe^{3+} to acetonitrile solutions of L^1 are shown in Figs. 3 and 4. In this case, a very similar behaviour was also found for ligand L^2 in the presence of these metal cations (not shown). As it can be seen in the Fig. 3, the Cu^{2+} cation induced the appearance of a new band at 420 nm, which resulted in a colour change of the solution form purple to yellow. Fe^{3+} and Hg^{2+} showed a somewhat different behaviour to that for Cu^{2+}. They both produce the bleaching of the solution upon addition of 0.5 equiv. but, in this case, the band at 420 nm does not appear and the solution remains colourless (see Fig. 4). This behaviour is somewhat similar to that found for Pb^{2+} with L^2, with the difference that 1 equiv. of Pb^{2+} is necessary to produce the complete bleaching. In fact, titration experiments strongly suggested that the Hg^{2+} and

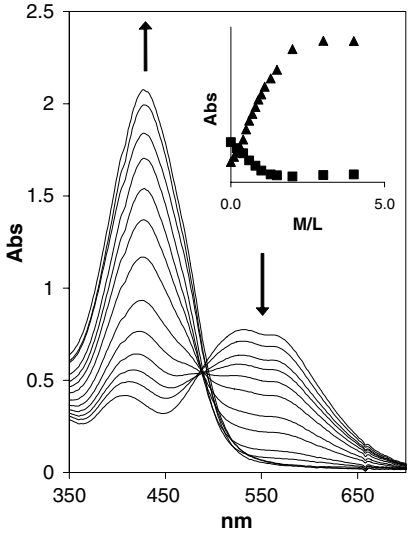

Fig. 3. UV–Vis titrations of compound L^1 (1.2×10^{-4} mol dm^{-3}) in acetonitrile with different concentrations of Cu^{2+}. The inset shows the titration curves at 534 and 420 nm.

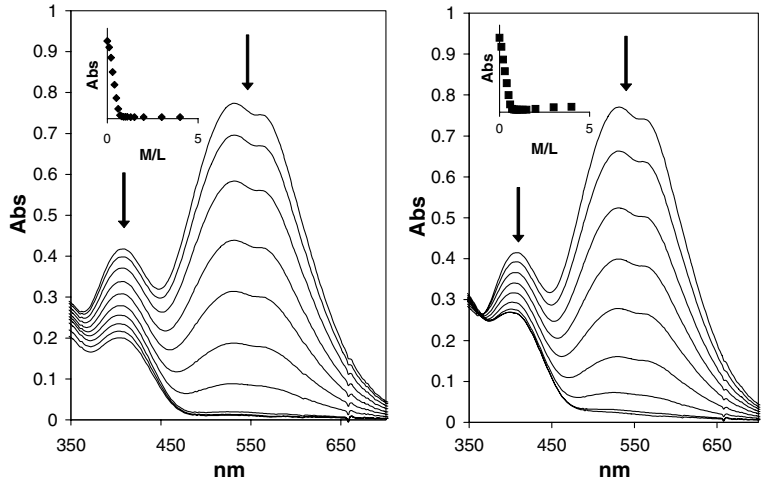

Fig. 4. UV–Vis titrations of compound L^1 (1.2×10^{-4} mol dm^{-3}) in acetonitrile with different concentrations of metals. Left: Hg^{2+}, right: Fe^{3+}. The inset shows the corresponding titration curve at 534 nm.

Fe^{3+} cations form 2:1 ligand-to-metal complexes with both L^1 and L^2. Additionally, the binding constants, obtained from titration profiles with Hg^{2+} or Fe^{3+}, are approximately the same for both L^1 and L^2 ligands (see Table 1) suggesting that the presence of the macrocycle in L^2 has no significant influence in the coordination process with these metals. This low influence of the macrocycle in the coordination and the partial positive charge in the nitrogen in the excited state might suggest a coordination mode through the carbonyls groups. However, all the remaining experimental results point towards coordination through the nitrogen. Thus, the interaction of the cations with the acceptor groups of molecules such L^1 and L^2 would result in a bathochromic shift of the absorbance as it has been reported for similar compounds in EtOH solutions in the presence of large amounts of the metal cations Cu^{2+} or Ni^{2+} [52]. However, we have not observed such a bathochromic shift in acetonitrile with L^1 or L^2 with any of the metal cations studied even in the presence of an excess of cation. This is indicative that the coordination through the nitrogen atom is relatively weaker in solvents with ability to form hydrogen bonds such as EtOH. In fact, in the presence of water no changes are observed in the absorbance spectra of L^1 and L^2 upon addition of metal cations. In contrast, in our case, we observed changes in the absorbance spectra of the systems L^2–Hg^{2+} and L^2–Fe^{3+} similar to those found for L^2–Pb^{2+}. This suggests that there is a similar coordination mode in the three cases and that this coordination occurs via the nitrogen atom as indicated the inhibition of the charge transfer band. Finally, we have performed ^{1}H NMR studies of L^1 in CD_3CN in the presence of Hg^{2+}. Fig. 6 (for H numbering scheme see Fig. 5) shows the evolution of the aromatic signals upon addition of Hg^{2+}. The most significant shifts are observed for Ha and Hb protons. Ha shifts from 6.9 to 7.8 and Hb from 7.45 to 7.8 ppm, indicating a decrease of the electronic density due to the coordination of the metal to the nitrogen. A

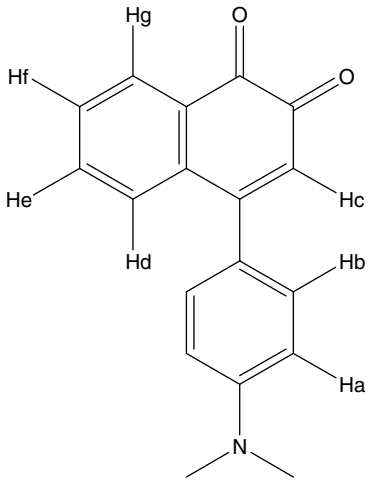

Fig. 5. Numbering scheme for protons of L^1.

similar behaviour was found for NMR titrations for the L^2–Hg^{2+} system. These shifts happen in the same direction than in the case of Ba^{2+}. Additionally, we can correlate the changes in the absorption spectra with the ^{1}H NMR shifts and the bonding strength. Thus, while Hg^{2+} induced $\Delta\delta$ of the Ha and Hb protons of 0.9 and 0.35, the cation Ba^{2+} gave $\Delta\delta$ of 0.65 and 0.15 ppm for the same protons, indicating that in the later the coordination to the nitrogen is less effective than with the Hg^{2+} metal cation. This is also in agreement with the observed optical behaviour; whereas, Hg^{2+} induced a complete elimination of the charge transfer band of L^2, the Ba^{2+} cation bring on only a decrease of the band intensity.

Due to its somewhat different behaviour, Cu^{2+} is discussed separately. Addition of increasing amounts of Cu^{2+} to either L^1 or L^2 induced the disappearance of the charge transfer band and the apparition of a new transition at 420 nm that turns yellow the solution. The decrease of the band at 534 nm and the increase of the band at

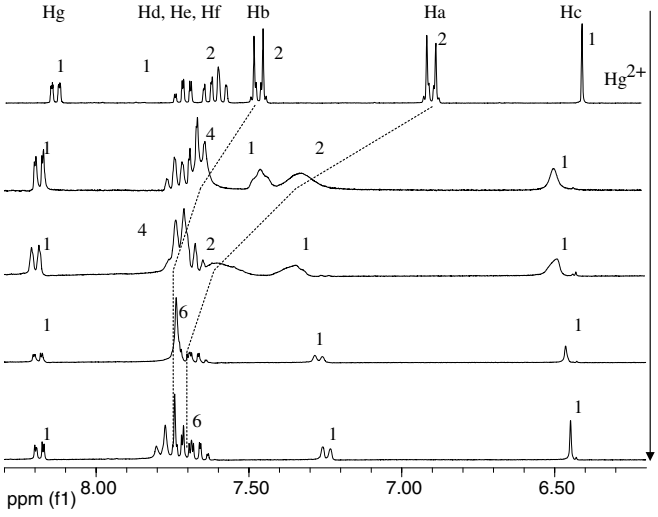

Fig. 6. ^{1}H NMR of L^1, aromatic protons, from up to down absence of Hg^{2+}, and 0.4, 1, 3 and 5 equiv. Numbers next to the signals indicate the amount of hydrogen atoms deduced from the integration.

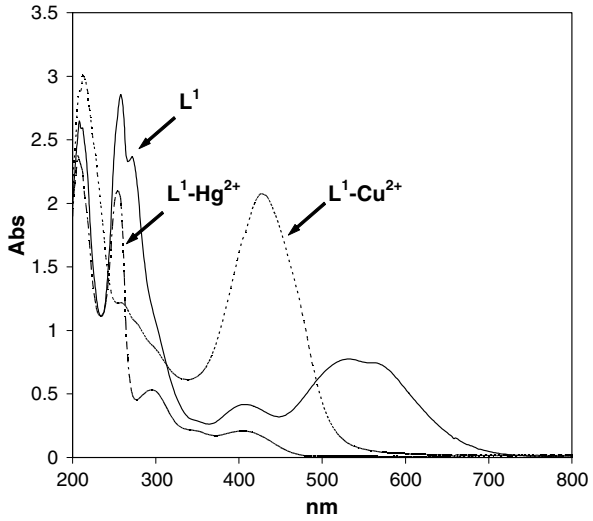

Fig. 7. Changes in the UV–Vis spectra of L^1 (1.2×10^{-4} mol dm^{-3}) upon addition of equimolar amounts of Hg^{2+} and Cu^{2+} in acetonitrile.

420 nm in the titration experiments with Cu^{2+}, did not evolve together. The apparition of the band at 420 nm needs a higher amount of Cu^{2+} and continues growing when the 534 nm band has disappeared. That suggested that there are more than two spices at the same time in solution, and more than a complex is statistically formed at the same time. In order to obtain more information of the system, we carried out some studies using as models both parts of the L^1–L^2 molecules, the *N*,*N*-dimethylaniline and the 1,2-naphthoquinone frameworks. The dimethylaniline group shows an absorption band at 253 nm ($\log\varepsilon = 4.18$) and the naphthoquinone at 250 nm ($\log\varepsilon = 4.37$). L^1 and L^2 showed a band at approximately at 260 nm with a shoulder at longer wavelength which can tentatively be assigned to a mixture of the two original bands of the *N*,*N*-dimethylaniline and the 1,2-naphthoquinone groups. Fig. 7 shows the UV–Vis spectrum of L^1 and the changes observed upon addition of 2 equiv. of the corresponding metal cation. The cations Fe^{3+}, Hg^{2+}, Pb^{2+} and Ba^{2+}, induced the disappearance of the shoulder but the band at shorter wavelength remain unaltered. This suggested a change in the electronic structure of the aniline whereas the naphthoquinone moiety remains basically unaffected in agreement with coordination through the nitrogen of the aniline. On the contrary, Cu^{2+} shows a special behaviour and not only the shoulder, but also the band assigned to the naphthoquinone group disappeared (see Fig. 7). This might indicate a double coordination of the Cu^{2+} cation through the amine and the carbonyl groups.

4. Interaction with anions

Addition of the tetrabutylammonium salts of the anions F^-, Cl^-, Br^-, NO_3^-, I^-, $H_2PO_4^-$ or HSO_4^- to acetonitrile solutions of L^1 or L^2 did not induce any change in the optical properties of the receptors, even in the presence of large amounts of anions (10 equiv.). This is a quite expected behaviour because receptors L^1 and L^2 do not have anion coordination sites. However, it has been known that metallic complexes of chromoionophores can also act as anion chemosensors as they could be very sensible to electronic changes induced by anions [53–59]. Therefore, we carried additional studies on the optical variation observed by addition of the anions F^-, Cl^-, Br^-, I^-, NO_3^-, HSO_4^- or $H_2PO_4^-$ to metal complexes of L^1 and L^2 and different behaviours were observed. In general there was found a partial recovery of the absorption bands of the original dye. This is, specially the case in the presence of the anions F^-, Cl^-, Br^-, I^- and NO_3^- that induced the recovery of the dye band in some extents for the L–M^{2+} systems when $M^{2+} = Pb^{2+}$, Hg^{2+}, Fe^{3+} and Ba^{2+}. This general behaviour is attributed to a debilitation of the M–N bond induced by coordination of the anions to the metal cation that induced a partial retrieving of the original charge transfer band of the dye. In some cases, the retrieving on the band intensity at 530 nm is complete suggesting that the metal cation is completely displaced. Additionally, the anions HSO_4^- or $H_2PO_4^-$ showed a different behaviour in their interaction with certain metal complexes. Thus, for instance, the addition of HSO_4^- to acetonitrile solutions of the L^2–Ba^{2+} complex resulted in a bleaching of the solution. On the other hand, the addition of HSO_4^- or $H_2PO_4^-$ to acetonitrile solutions of L^2 with of Pb^{2+}, Hg^{2+} or Fe^{3+} did not result in any remarkable optical variation. Fig. 8 shows the observed colour changes upon addition of 1 equiv. of the corresponding anion to acetonitrile solution of the Ba–L^2 system. As it can be observed there is a complete elimination of the band at 534 nm in the case of HSO_4^- and a partial bleaching in the presence of $H_2PO_4^-$.

The interaction of Ba^{2+} with the sulphate is widely known and, for example, it has been employed as a suitable method for the sulphate determination in aqueous

Fig. 8. L^2 in acetonitrile ($[L^1] = 1.06 \times 10^{-4}$ M) in presence of 1 equiv. of Ba^{2+} and 1 equiv. of the corresponding anion, from left to right, NO_3^-, HSO_4^-, $H_2PO_4^-$, F^-, Cl^-, Br^-, I^- and no anion.

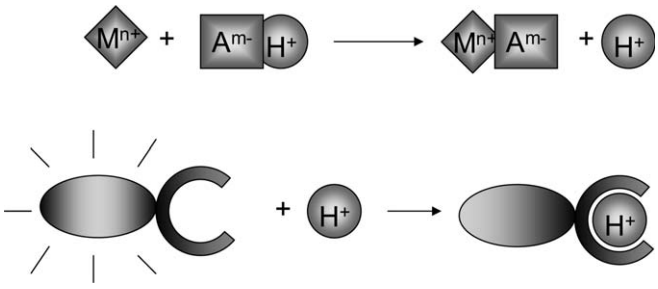

Fig. 9. Scheme of the coupled reactions.

environments, due to the formation of an insoluble precipitate. Although in our case, there was not evidence of precipitate formation, the interaction between Ba^{2+} and HSO_4^- is probably the origin of this significant variation. Most likely, the absorption changes can be due to the coordination of HSO_4^- with Ba^{2+} to form a short of ion pair. Additionally, the coordination increases the acidity of the sulphate that is then acid enough to protonate L^1 or L^2 inducing bleaching of the solution. In this case the anion, through the interaction with the metal, is "transformed" into a cation (H^+) which is the responsible of induce the change in the spectroscopic properties of the chromophore (see Fig. 9). The anion is then recognised via an indirect way, by a combination of metal coordination and dye protonation. This was confirmed by the effects observed upon addition of different acids (such as $HClO_4$, H_2SO_4 and *p*-toluensulphonic acid) to acetonitrile solutions of L^1 or L^2; a complete bleaching was observed upon addition of 1 equiv. of H^+.

5. Conclusions

We have reported here a study of the behaviour of naphthoquinone derivatives as receptors for the chromogenic sensing of metal cations and anions in acetonitrile. Both L^1 and L^2 showed a charge transfer band at ca. 530 nm that is hypochromically shifted upon addition of the metal cations Cu^{2+}, Fe^{3+} and Hg^{2+}. Additionally, the metal cations Pb^{2+} and Ba^{2+} also induced bleaching of acetonitrile solutions of L^2. In all cases, the results obtained suggested that the interaction with the receptor occurs via coordination with the nitrogen atom from the anilinium group. Studies in the presence of anions were also carried out. A chromogenic sensing of the anion HSO_4^- in acetonitrile was observed using the metal complex $[Ba(L^2)]^{2+}$.

6. Experimental

6.1. General remarks

All commercially available reagents were used without further purification. Air/water-sensitive reactions were performed in flame dried glassware under argon. Acetonitrile and CH_2Cl_2 were dried with CaH_2 and distilled prior to use. 16-Phenyl-16-aza-1,4,7,10,13-pentaoxacycloheptadecane, was prepared following known procedures.

6.2. Physical measurements

The NMR spectra were recorded with a Varian Gemini 300 spectrometer. Chemical shifts are reported in ppm downfield from the TMS signal. Spectra taken in $CDCl_3$ were referred to the residual $CHCl_3$.

6.3. Preparation of 4-(4-dimethylamino-phenyl)-[1,2]naphthoquinone (L^1)

The synthetic process was firstly reported by Yoshida et al. [48]. To 30 mL of glacial acetic acid containing 260 mg (1 mmol) of 1,2-naphthoquinone-4-sulfonate sodium salt and 249 mg (1 mmol) of nickel acetate, 10 mL of acetic acid containing 127 μL (1 mmol) of *N*,*N*-dimethylaniline were added. The reaction mixture was stirred at 30 °C for 5 h, mixed with 25 mL of water and extracted with CH_2Cl_2. The organic phase was washed several times with an aqueous solution of sodium carbonate until neutrality. Then the organic phase was dried and the solvent removed to dryness. The blue solid was purified by silica gel column chromatography with CH_2Cl_2:EtOH mixtures as eluent, obtaining 90.3 mg (32.3%) ^{1}H NMR: ($CDCl_3$) $\delta = 3.04$ (s, 6H, NCH_3), 6.37 (s, 1H, C=C*H*), 6.74 (d, 2H, Ar*H*), 7.35 (d, 2H, Ar*H*), 7.4–7.6 (m, 3H, Ar*H*), 8.13 (d, 1H, Ar*H*). ^{13}C NMR: ($CDCl_3$)$\delta = 40.11$, 111.63, 123.35, 125.66, 129.78, 129.87, 130.19, 130.39, 131.86, 134.69, 135.24, 151.57, 157.36, 180.10, 180.26. High resolution EI$^+$ mass spectra: Calc. for $C_{18}H_{15}NO_2$: 277.1102. Found: *m*/*z* 277.1078%.

6.4. Preparation of 4-[4-(1,4,7,10,13-pentaoxa-16-aza-cyclooctadec-16-il)-phenyl]-[1,2]naphthoquinone (L^2)

To 40 mL of glacial acetic acid containing 345 mg (1.3 mmol) of 1,2-naphthoquinone-4-sulfonate sodium salt and 330 mg (1.3 mmol) of nickel acetate, 15 mL of acetic acid containing 450 mg (1.3 mmol) of 16-phenyl-16-aza-1,4,7,10,13-pentaoxacycloheptadecane were added. The reaction mixture was stirred at 30 °C for 24 h, and then mixed with 40 mL of water and extracted with CH_2Cl_2. The organic phase was washed several times with an aqueous solution of sodium carbonate until neutrality. Then the

organic phase was dried and the solvent removed to dryness. The blue solid was purified by silica gel column chromatography with CH_2Cl_2:EtOH mixtures as eluent, obtaining 52.8 mg (8.2%) ^1H NMR: ($CDCl_3$)$\delta = 3.5$–3.9 (m, 24H, CH_2), 6.42 (s, 1H, C=C*H*), 6.81 (d, 2H, Ar*H*), 7.32 (d, 2H, Ar*H*), 7.4–7.6 (m, 3H, Ar*H*), 8.18 (d, 1H, Ar*H*). High resolution FAB^+ mass spectra: Calc. for $C_{28}H_{33}NO_7$: 495.2257. Found: *m*/*z* 495.2188%.

that its κ^2-N,N-chelated isomer is more stable than the η^1-N,η^3-arene ligated form by 37.9 kJ/mol. In this paper we detail further attempts to form complexes of the type, [:M{κ^2-*N*,*N*-*N*(R)C(R′)N(R)}]. Although unsuccessful, these have led to the formation of a number of novel group 13-amidinate and amidine complexes.

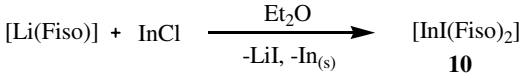
2. Results and discussion

2.1. Syntheses

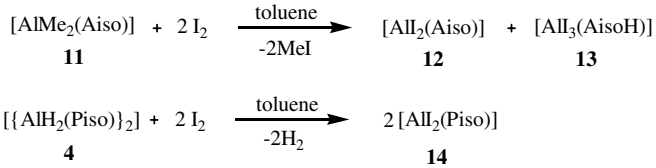
The synthesis of group 13 metal(I)-amidinate complexes using metal halides as precursors could potentially be achieved via two main routes, viz. metathesis reactions between an amidinate salt and a low oxidation state metal halide, or the reduction of a amidinato-metal(III) halide complex. In the first instance, the treatment of 'GaI' [7] with an in situ prepared solution of the lithium formamidinate, [Li(Fiso)], was carried at low temperature. Although the a Ga(I)-amidinate complex did not result, colourless crystals of an approximately 50:50 mixture of the gallium(II) and (III) complexes, [{GaI(Fiso)}$_2$] (**7**) and [GaI(Fiso)$_2$] (**8**), were obtained (Scheme 1). The mechanism of this reaction presumably involves a series of disproportionation reactions, as evidenced by the deposition of gallium metal. An intentional, moderately yielding synthesis of the Ga(II) complex, **7**, was devised whereby [Li(Fiso)] was treated at low temperature in Et_2O/toluene with the Ga(II) halide complex, [{$GaI_2(NHCy_2)$}$_2$] (Cy=cyclohexyl) [8]. The related reaction of [{$GaI_2(NHCy_2)$}$_2$] with the bulkier pivamidinate salt, [Li(Piso)], afforded the analogous dimeric complex, [{GaI(Piso)}$_2$] (**9**), though only in a trace yield. The only other products of the reaction that were identifiable were gallium metal, LiI, $NHCy_2$ and PisoH. It is noteworthy that when the potassium salt of the formamidinate, [K(Fiso)], was treated with [{$GaI_2(NHCy_2)$}$_2$] under similar conditions to the preparation of **7**, only the gallium(III) complex, **8**, was isolated in moderate yield (Scheme 1).

In an attempt to form an indium(I)-amidinate complex, [Li(Fiso)] was reacted with InCl in diethyl ether. This, however, led to indium metal deposition and the isolation of [InCl(Fiso)$_2$] (**10**) in moderate yield via a disproportionation process (Scheme 2). It is worthy of note that similar disproportionation reactions, but giving indium(II) complexes, have been observed in the reactions of bulky lithium β-diketiminates with InCl [9].

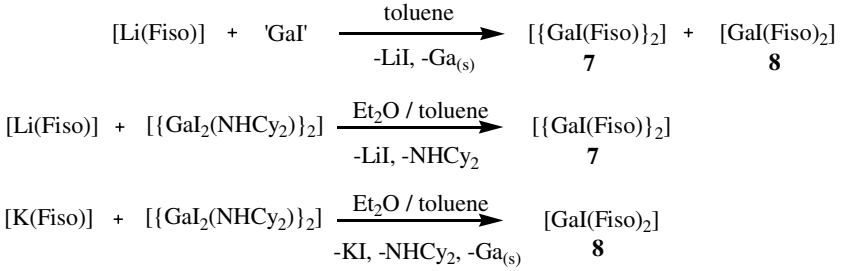
In the case of aluminium there is no known stable aluminium(I) halide that can be used as a precursor for metathesis reactions. To circumvent this problem we decided to synthesise suitable amidinato-aluminium(III) iodide complexes and attempt their reduction to four-membered aluminium(I) heterocycles. This seemed appropriate as six-membered aluminium(I) heterocycles have previously been prepared by this methodology [4a]. Therefore, we treated the known aluminium alkyl and hydride complexes, [$AlMe_2$(Aiso)] (**11**) [2c] and [{AlH_2(Piso)}$_2$] (**4**) [3], with iodine in toluene (Scheme 3). In both cases the expected complexes, **12** and **14**, resulted, but the AlI_3 adduct, **13**, was also formed in the former reaction. Reaction of [$AlMe_2$(Piso)] (**15**) [2c] with I_2 also yields **14**, however the hydride route allows a faster reaction, a higher yield and a cleaner product. Moreover, both iodine atoms of the I_2 reactant can be transferred to the Al centre because the in situ formed HI subsequently reacts with



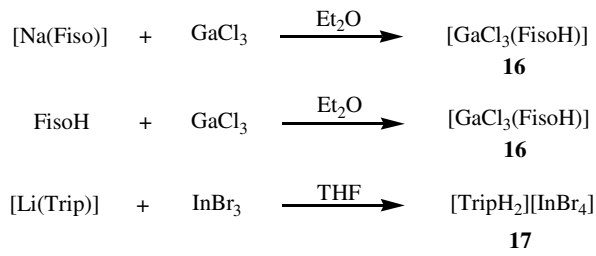
Scheme 2.



Scheme 3.



Scheme 1.



Scheme 4.

another hydride ligand, while the initially formed MeI in the alkyl route is less reactive and needs to be separated from the reaction mixture. Unfortunately, all attempts to reduce **12** or **14** to the corresponding aluminium(I) heterocycles using potassium metal, KC_8 or sodium have so far met with failure.

A number of attempts were made to prepare amidinatogallium(III) and indium(III) halide complexes as it was thought their reduction to metal(I) complexes would be more facile than for their aluminium counterparts. Little success has been had here as, for example, the only identifiable product from the reaction of [Na(Fiso)] with $GaCl_3$ was the adduct, **16**, formed in low yield (Scheme 4). Although not useful for reduction reactions, compound **16** was intentionally prepared in moderate to good yield by treating FisoH with $GaCl_3$ (Scheme 4). Similarly, when the very bulky lithium amidinate, [Li(Trip)] [10], was treated with $InBr_3$ and the reaction mixture recrystallised from chloroform, the only crystalline product obtained was the amidinium salt, **17** (Scheme 4). The protons of the cation presumably originate from either residual moisture in the reagents ($InBr_3$ or reaction solvents), or hydrogen abstraction from chloroform. The latter seems more likely as **17** was formed when the reaction and work-up was repeated under rigorous exclusion of moisture. Attempts to recrystallise the reaction product from THF instead of chloroform did not lead to a crystalline product.

2.2. Crystal structures

The crystal structure of **7** contains one full dimeric molecule in the asymmetric unit which is depicted in Fig. 2. Each of its gallium centres form essentially planar four-membered rings with the chelating amidinate unit (Ga–N: 2.012 Å average), and each is further coordinated by an iodine atom (Ga–I: 2.542 Å average). The distorted tetrahedral environments of the gallium centres are completed by a Ga–Ga bond with a length of 2.4304(10) Å, which is in the normal range for Ga–Ga bonds in compounds of the type [{LGaI}$_2$] [11].[1] The two N_2CGa planes are approximately parallel to each other and almost perpendicular to the nearly planar Ga_2I_2 fragment. The structure of compound **9** (Fig. 3) is similar to that of **7** but the molecule

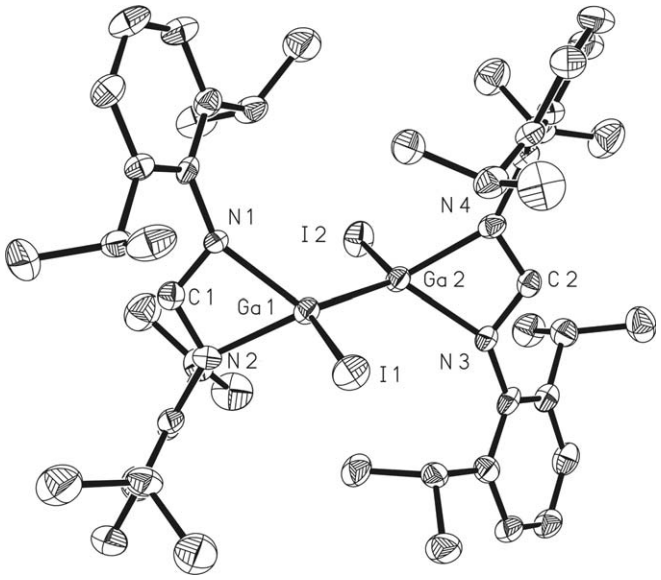


Fig. 2. Molecular structure of **7** (ORTEP, 50% thermal ellipsoids). Hydrogen atoms have been omitted for clarity. Selected bond lengths (Å) and angles (°): Ga1–Ga2 2.4304(10), Ga1–I1 2.5437(9), Ga2–I2 2.5396(9), Ga1–N1 2.009(4), Ga1–N2 2.019(4), Ga2–N3 2.011(4), Ga2–N4 2.008(4), C1–N1 1.313(6), C1–N2 1.316(6), C2–N3 1.331(6), C2–N4 1.322(6); N1–Ga1–N2 66.36(15), N3–Ga2–N4 66.75(16), Ga2–Ga1–I1 119.48(3), Ga1-Ga2-I2 121.19(3), N1–C1–N2 114.0(4), N3–C2–N4 112.9(4).

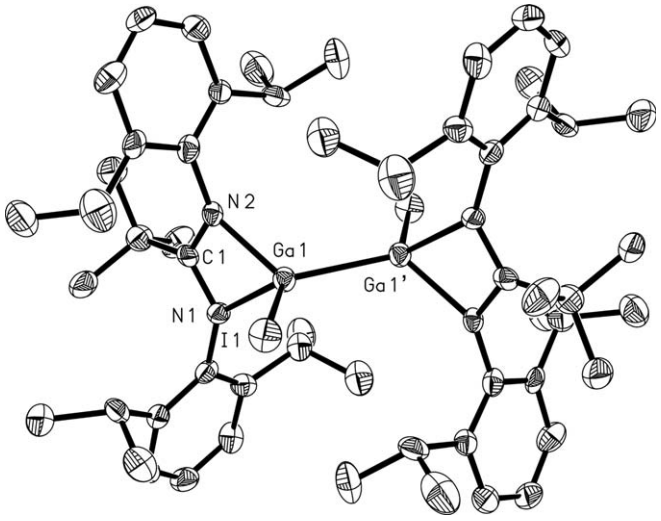

Fig. 3. Molecular structure of **9** (ORTEP, 50% thermal ellipsoids). Hydrogen atoms have been omitted for clarity. Selected bond lengths (Å) and angles (°): Ga1–Ga1′ 2.4521(15), Ga1–I1 2.5537(10), Ga1–N1 2.006(5), Ga1–N2 1.996(5), C1–N1 1.337(8), C1–N2 1.342(8); N1–Ga1–N2 66.2(2), Ga1'–Ga1–I1 115.56(5), N1–C1–N2 109.3(6). Symmetry operation ′: $-x+2, -y, -z+1$.

sits on an inversion centre and thus only half a molecule occupies the asymmetric unit. The bulkier substituent in the backbone of the amidinate unit in **9** leads to a slightly more acute NCN angle [109.3(6)°] compared with those of **7** [112.9(4)° and 114.0(4)°]. In both compounds, the C–N bond lengths within their four-membered rings are indicative of considerable delocalisation over the NCN

[1] As determined from a survey of the Cambridge Crystallographic Database, September, 2005.

fragments. It is noteworthy that compounds **7** and **9** represent the first examples of gallium(II) complexes bearing an amidinate group, though Uhl et al. [12] have reported a related gallium(II) complex bearing a 1,3-diphenyltriazenido group which is isoelectronic to formamidinates.

Compounds **8** and **10** are isomorphous with the group 13 hydride complexes $[MH(Fiso)_2]$ **1**–**3** [3], and display similar structural features to each other, though the quality of the data for **8** is too poor to allow comment on its structure here. The indium centre of **10** (Fig. 4) is five coordinate with two chelating amidinate units and one Cl atom [In–Cl: 2.3574(10) Å] giving it a heavily distorted trigonal bipyramidal coordination geometry with N(3) and N(1) in apical positions. As a result, these N-centres are significantly more distant from In(1) than equatorial N(2) and N(4). In addition, there appears to be a lesser degree of delocalisation over the amidinate backbones of **10** compared with those of **7** and **9**, as evidenced by the significantly different N–C distances within each NCN fragment of the former. The structural parameters of **10** compare well with those of the only other structurally characterised bis(amidinato) indium halide complex, $[InCl\{[N(Cy)]_2CBu^t\}_2]$ [13].

Both compounds **13** and **16** (Figs. 5 and 6, respectively) are adducts of a neutral amidine with a group 13 trihalide. The main difference between their structures is the configuration at the C(1)–N(1) bond which is *Z* for **13** and *E* for **16**. This difference most likely results from the greater steric influence of the methyl group on C(1) in **13** compared to the hydrogen at C(1) in **16**. The NCNM fragments of both **13** and **16** are essentially planar and the M–N bond lengths [**13** 1.935(6) Å, **16** 1.941(3) Å] are in the normal range, as are the metal–halide distances.[1] Surprisingly, an examination of the C–N distances within the NCN fragment of **16** suggests significant delocalisation over that fragment,

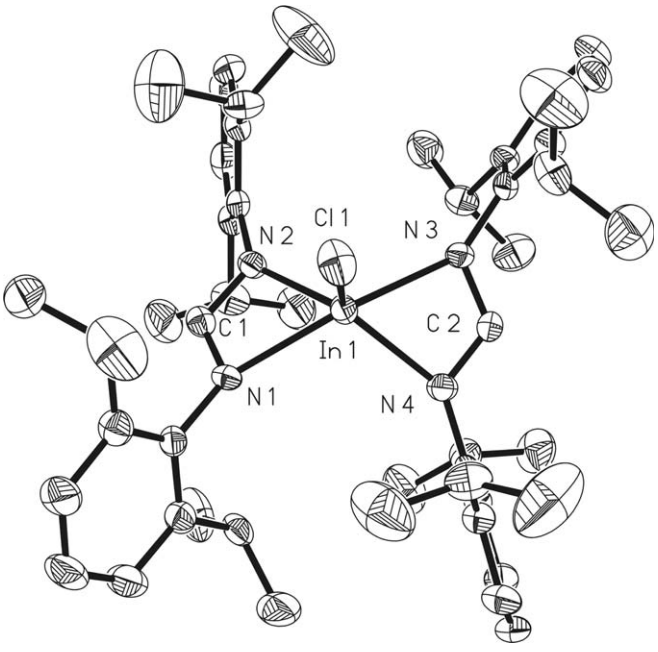

Fig. 4. Molecular structure of **10** (ORTEP, 50% thermal ellipsoids). Hydrogen atoms have been omitted for clarity. Selected bond lengths (Å) and angles (°): In1–Cl1 2.3574(11), In1–N1 2.244(3), In1–N2 2.181(3), In1–N3 2.270(3), In1–N4 2.168(3), C1–N1 1.309(5), C1–N2 1.327(5), C2–N3 1.304(5), C2–N4 1.326(5); N1–In1–N2 60.30(11), N3–In1–N4 60.35(11), N2–In1–N3 105.72(11), N1–In1–N4 109.18(11), N1–In1–Cl1 101.45(8), N1–C1–N2 115.0(4), N3–C2–N4 116.1(3).

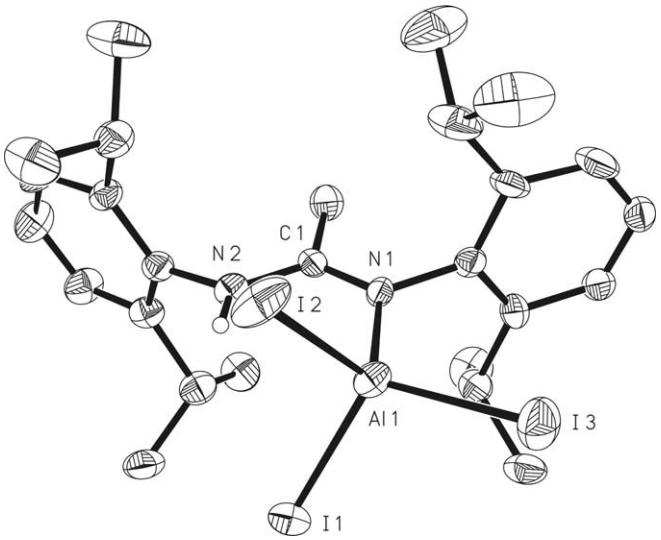

Fig. 5. Molecular structure of **13** (ORTEP, 50% thermal ellipsoids). Hydrogen atoms have been omitted for clarity. Selected bond lengths (Å) and angles (°): Al1–I1 2.530(2), Al1–I2 2.531(2), Al1–I3 2.473(2), Al1–N1 1.935(6), C1–N1 1.327(9), C1–N2 1.306(9); I1–Al1–I3 111.41(9), I1–Al1–I2 107.27(18), I2–Al1–I3 112.18(8), C1–N1–Al1 126.2(5), N1–C1–N2 120.0(6).

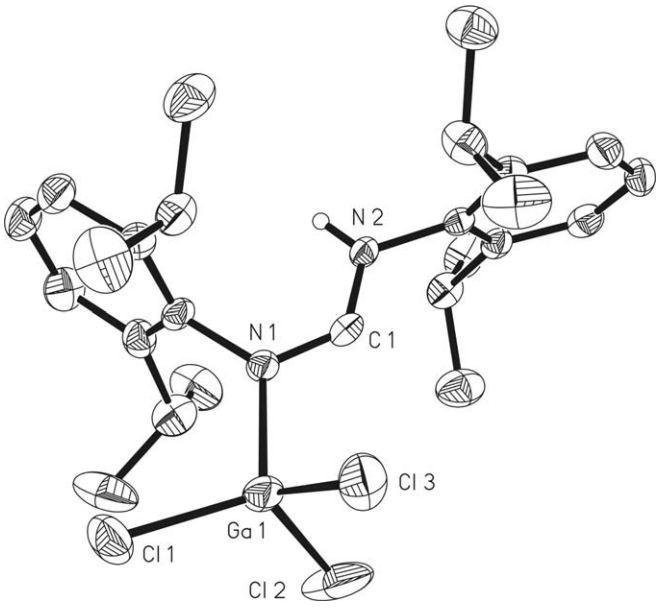

Fig. 6. Molecular structure of **16** (ORTEP, 50% thermal ellipsoids). Hydrogen atoms, except on N(2), have been omitted for clarity. Selected bond lengths (Å) and angles (°): Ga1–N1 1.941(3), Ga1–Cl1 2.1397(11), Ga1–Cl2 2.1683(14), Ga1–Cl3 2.1676(13), C1–N1 1.306(4), C1–N2 1.309(4); Cl1–Ga1–Cl2 114.75(5), Cl1–Ga1–Cl3 114.57(4), Cl2–Ga1–Cl3 107.29(6), C1–N1–Ga1 116.1(2), N1–C1–N2 128.6(3).

whereas the same fragment in **13** appears to be more localised, though both its amidine N–C bond lengths lie between those expected for single and double bonded distances.[1]

The molecular structure of **14** is depicted in Fig. 7 and is comparable with that of the corresponding methyl derivative [$AlMe_2$(Piso)] (**15**) [2c] in that its metal centre is chelated by the Piso ligand and has a distorted tetrahedral geometry. Its Al–N (1.886 Å average) and Al–I (2.460 Å average) distances lie in the expected regions[1]. The structure of the amidinium salt, **17**, (Fig. 8) shows the compound to consist of separate ions which have no significant contacts. The tetrahedral $[InBr_4]^-$ anion has been structurally characterised in salts on previous occasions [14]. The geometry of the amidinium cation closely resembles that of the neutral amidine [10], though the amidine exhibits largely localised backbone NC bonds, whereas those in **17** appear to be delocalised. In addition, the amidinium cation has a slightly more acute NCN angle [127.0(4)°] relative to that of the amidine, TripH [129.91(18)°].

2.3. Spectroscopic properties

The NMR spectra for the majority of the compounds reported here are consistent with their solid-state structures and will be only briefly discussed. For example, the ^{1}H NMR spectrum of [{GaI(Fiso)}$_2$] (**7**) displays two methyl doublet resonances and a virtual septet for the methine protons. The ^{1}H NMR spectra for the compounds [$MX(Fiso)_2$] (**8**: M = Ga, X = I; **10**: M = In, X = Cl) are less symmetrical and exhibit overlapping multiplet resonances for the protons of the methyl groups. Compounds [AlI_2(Aiso)] (**12**) and [AlI_3(AisoH)] (**13**) can be easily distinguished by their ^{1}H NMR spectra. As expected, the spectrum of the higher symmetry compound, **12**, shows two isopropyl methyl doublet signals and one methine virtual septet resonance, while the spectrum of **13** displays four isopropyl methyl doublets and two methine septets. Contrastingly, both the ^{1}H and ^{13}C NMR spectra of [$GaCl_3$-(FisoH)] (**16**) are indicative of a more symmetrical molecule than the solid-state structure suggests. This observation implies a fluxional exchange of the $GaCl_3$ fragment and amidine proton between N-centres, which is rapid on the NMR timescale. Cooling solutions of **16** did not lead to a resolution of the spectra. The N*H* proton of **13** resonates at δ 8.98 ppm (IR: N–H stretch 3295 cm^{-1}) and that for **16** appears at δ 8.67 ppm (IR: N–H stretch 3313 cm^{-1}), cf. **17** ^{1}H NMR: δ 5.42 ppm (NH); IR: 3358 cm^{-1} (N–H str.).

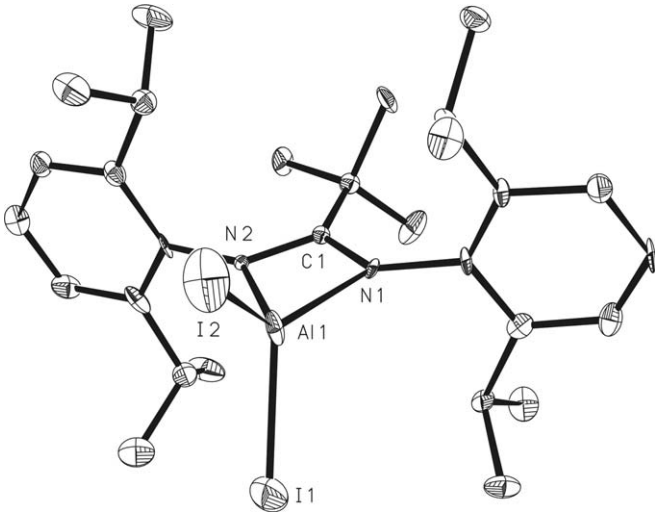

Fig. 7. Molecular structure of **14** (ORTEP, 50% thermal ellipsoids). Hydrogen atoms have been omitted for clarity. Selected bond lengths (Å) and angles (°): Al1–N1 1.884(7), Al1–N2 1.889(8), Al1–I1 2.481(3), Al1–I2 2.438(3), C1–N1 1.363(12), C1–N2 1.350(11); I1–Al1–I2 107.21(11), N1–Al1–N2 70.3(3), N1–C1–N2 106.4(7).

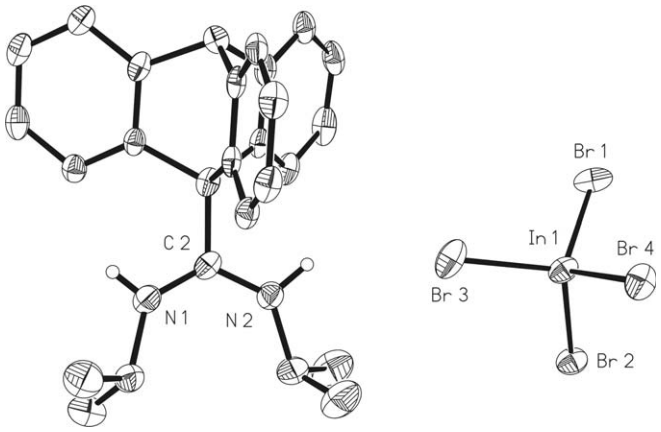

Fig. 8. Molecular structure of **17** (ORTEP, 50% thermal ellipsoids). Hydrogen atoms, except on nitrogen atoms, have been omitted for clarity. Selected bond lengths (Å) and angles (°): In1–Br1 2.5043(7), In1–Br2 2.5096(6), In1–Br3 2.4945(7), In1–Br4 2.4934(6), C2–N1 1.316(6), C2–N2 1.322(6); Br1–In1–Br2 105.20(2), Br3–In1–Br1 111.73(2), N1–C2–N2 127.0(4).

3. Conclusions

Attempts have been made to synthesise amidinato-group 13 metal(I) complexes, either by methathesis reactions between amidinate salts and metal(I) halides, or by reduction of amidinato-metal(III) halide complexes. Although no metal(I) complexes have been formed, the former route has led to a range of amidinato-metal(II) and (III) complexes via disproportionation processes. These include the first examples of gallium(II) amidinate complexes. Metathesis reactions between amidinate salts and metal(III) halides have afforded a series of amidinato-metal(III) halide complexes, amidine-metal(III) halide adducts and one amidinium salt. In general, and like our previous findings with amidinato-group 13 hydride complexes [3b], syntheses employing the Fiso ligand normally lead to complexes bearing two amidinate ligands (except the Ga(II) compound **7**), whereas only one Piso group could be transferred to a metal atom. This is probably because the bulky Bu^t group on the backbone of Piso, compared to the

hydrogen backbone atom of Fiso, gives a more rigid and sterically demanding amidinate unit. Further investigations using bulky amidinate and related ligands to stabilise low oxidation state group 13 complexes by metathesis or reduction pathways are underway in our laboratory.

4. Experimental

4.1. General

All manipulations were carried out using standard Schlenk line and glove box techniques under an inert atmosphere (argon or nitrogen). Hexane, toluene, THF and D_6-benzene were distilled over potassium, whilst diethyl ether was distilled over Na/K alloy. Infrared spectra were obtained as Nujol mulls using a Perkin–Elmer 1600 Series FTIR spectrometer with NaCl plates. NMR spectroscopy was carried out using either Jeol Eclipse 300, Bruker WM 250 or Bruker DPX 400 spectrometers, and were referenced to the residual ^{1}H or ^{13}C resonances of the solvent used. Mass spectra were recorded using a VG Fisons Platform II instrument operating under APCI conditions, or were obtained from the EPSRC Mass Spectrometry Service, Swansea. Melting points were obtained under argon in sealed capillaries and are not corrected. The compounds FisoH [15], PisoH [16], 'GaI' [17] and [AlMe$_2$(Aiso)] [2c] were synthesised by literature procedures. [K(Piso)][2] was obtained by treating PisoH with 1.05 eq. of K[N(SiMe$_3$)$_2$] in toluene (reflux, 2 h), then removing all volatiles in vacuo and drying the residue at 50 °C under vacuum for several hours. [AlMe$_2$(Piso)] was synthesised by treatment of PisoH with 1.05 eq of AlMe$_3$ in toluene (−78 °C to room temperature), removing all volatiles and drying the product under vacuum. The product was obtained almost quantitatively as a colourless crystalline material and the spectroscopic data were compared with the literature values [2c].

4.2. [{GaI(Fiso)}$_2$] (7)

Bu^{n}Li (0.743 ml of a 1.6 M solution in hexanes, 1.19 mmol) was added to solution of FisoH (0.433 g, 1.19 mmol) in diethyl ether (30 mL) at −20 °C. The resultant solution was warmed to room temperature and stirred overnight. It was then cooled to −50 °C and a solution of [{GaI$_2$(NHCy$_2$)}$_2$] (0.60 g, 0.59 mmol) in toluene (30 mL) added over 5 min. The resultant solution was stirred for 2 h and slowly warmed to room temperature overnight. Volatiles were then removed in vacuo and the residue was extracted into hexane (50 mL) and filtered. The filtrate was concentrated to ca. 30 mL and placed at −30 °C overnight giving colourless crystals of **7**. Yield: 0.30 g, 42%; m.p. >300 °C; ^{1}H NMR (250 MHz, C$_6$D$_6$, 298 K): δ 1.20 (d, $^3J_{HH} = 6.8$ Hz, 24 H, CH(CH_3)), 1.48 (d, $^3J_{HH} = 6.8$ Hz, 24 H, CH(CH_3)), 3.92 (v. sept, $^3J_{HH} = 6.8$ Hz, 8 H, CH(CH$_3$)), 7.10–7.30 (m, 12 H, Ar–H), 7.55 (s, 2H, NC(H)N); ^{13}C NMR (100.6 MHz, C$_6$D$_6$, 298 K): δ 25.0 (CH(*C*H$_3$)), 26.0 (CH(*C*H$_3$)), 29.2 (*C*H(CH$_3$)), 124.4 (*m*-Ar*C*), 127.4 (*p*-Ar*C*), 138.0 (*ipso*-Ar*C*), 145.4 (*o*-Ar*C*), 166.6 (N*C*N); MS/EI, *m*/*z* (%): 365.3 (FisoH$^+$, 12), 176.0 (ArNH$^+$, 100); IR ν/cm^{-1} (Nujol): 1668 m, 1636 m, 1585 m, 1260 s, 1097 m, 1055 m, 933 m, 799 m, 753 m. N.B. [{GaI(Piso)}$_2$] (**9**) was prepared by an equivalent procedure but was only obtained in trace amounts. As a result, no spectroscopic data were obtained for this compound.

4.3. [GaI(Fiso)$_2$] (8)

A solution of [{GaI$_2$(NHCy$_2$)}$_2$] (0.88 g, 0.87 mmol) in toluene (20 mL) and Et$_2$O (10 mL) was added at −80 °C to a slurry of [K(Fiso)] (0.77 g, 1.91 mmol) in toluene (20 mL) and Et$_2$O (10 mL). The mixture was warmed to room temperature overnight, filtered, concentrated to ca. 30 mL and placed at −30 °C overnight to yield colourless crystals of **8**. Yield: 0.33 g, 41%; m.p. 275–277 °C; ^{1}H NMR (400 MHz, C$_6$D$_6$, 298 K): δ 1.10–1.35 (m, 48 H, CH(CH_3)$_2$), 3.54 (br. v. sept, $^3J_{HH}$ = ca. 6.7 Hz, 8 H, CH(CH$_3$)$_2$), 6.97–7.30 (m, 12 H, Ar–H), 7.63 (s, 2 H, NCHN); ^{13}C NMR (100.6 MHz, C$_6$D$_6$, 298 K): δ 23.8 (CH(*C*H$_3$)), 24.5 (CH(*C*H$_3$)), 25.1 (CH(*C*H$_3$)), 25.5 (CH(*C*H$_3$)), 28.5 (*C*H(CH$_3$)), 28.6 (*C*H(CH$_3$)), 123.4 (*m*-Ar*C*), 125.6 (*p*-Ar*C*), 141.2 (*ipso*-Ar*C*), 144.0 (*o*-Ar*C*), 160.2 (N*C*N); MS/APCI *m*/*z* (%): 365 (FisoH$_2^+$, 100); IR ν/cm^{-1} (Nujol): 1668 m, 1560 m, 1260 s, 1200 m, 1176 m, 799 m, 751 m.

4.4. [InCl(Fiso)$_2$] (10)

Bu^{n}Li (2.50 ml of a 1.6 M solution in hexanes, 4.00 mmol) was added at room temperature to a solution of FisoH (1.39 g, 3.80 mmol) in Et$_2$O (70 mL) and the mixture stirred for 3 h. The resultant solution was added dropwise at to a slurry of InCl (1.20 g, 7.99 mmol) in Et$_2$O (20 mL) at −80 °C. The reaction mixture was slowly warmed to room temperature overnight in the absence of light. It was then filtered, volatiles removed from the filtrate in vacuo and the residue was extracted into hexane (40 mL). Placement of the extract at −30 °C overnight gave colourless crystals of **10**. Yield 0.42 g, 25%; m.p. 200–205 °C (dec.); ^{1}H NMR (400 MHz, C$_6$D$_6$, 298 K): δ 1.00–1.80 (m, 48 H, CH(CH_3)$_2$), 3.71–4.00 (m, 8 H, CH(CH$_3$)$_2$), 6.90–7.28 (m, 12 H, Ar–H), 7.47 (s, 2 H, NC(H)N); ^{13}C NMR (100.6 MHz, C$_6$D$_6$, 298 K): δ 24.0 (CH(*C*H$_3$)), 24.5 (CH(*C*H$_3$)), 25.3 (CH(*C*H$_3$)), 25.5 (CH(*C*H$_3$)), 28.3 (*C*H(CH$_3$)), 28.6 (*C*H(CH$_3$)), 123.5 (*m*-Ar*C*), 126.3 (*p*-Ar*C*), 139.3 (*ipso*-Ar*C*), 143.6, (*o*-Ar*C*), 158.1 (N*C*N); MS/APCI, *m*/*z* (%): 365 (FisoH$_2^+$, 100); IR ν/cm^{-1} (Nujol): 1668 m, 1636, 1585 m, 1260 s, 1097 m, 1055 m, 933 m, 799 m.

[2] THF adducts of [K(Piso)] have been previously obtained, see [15].

4.5. [AlI_2(Aiso)] (**12**) and [AlI_3(AisoH)] (**13**)

A solution of I_2 (3.85 g, 15.2 mmol) in toluene was added to a cooled solution (−80 °C) of [$AlMe_2$(Aiso)] (3.00 g, 6.90 mmol, 1.0 eq) in toluene (35 mL). The mixture was then warmed to room temperature and stirred for 2 d. Volatiles were removed in vacuo, the residue extracted with hexane (40 mL) and the extract placed at −30 °C overnight to give yellow crystals of **13**. Volatiles were removed from the mother liquor and the residue dissolved in toluene/hexane (2:1, 60 mL) and placed at −30°C overnight to give crystals of **13** in a first crop and a mixture of **12** and **13** in a second crop. The crystals were manually separated.

12: Yield 0.74 g, 16%; m.p. 186–187 °C; ^{1}H NMR (400 MHz, C_6D_6, 298 K): δ 1.02 (d, $^3J_{HH} = 6.8$ Hz, 12 H, CH(CH_3)), 1.17 (s, 3 H, CCH_3), 1.19 (d, $^3J_{HH} = 6.8$ Hz, 12 H, CH(CH_3)), 3.50 (v. sept, $^3J_{HH} = 6.8$ Hz, 4 H, CH(CH_3)), 6.82–7.08 (m, 6 H, Ar–H); ^{13}C NMR (100.6 MHz, C_6D_6, 298 K): δ 14.5 (H_3CC), 24.3 (CH(CH_3)), 25.8 (CH(CH_3)), 28.9 (CH(CH_3)), 124.6 (*m*-Ar*C*), 129.2 (*p*-Ar*C*), 135.1 (*ipso*-Ar*C*), 145.4 (*o*-Ar*C*), 172.0 (N*C*N); MS/EI *m*/*z* (%): 378.3 (AisoH$^+$, 22), 335.3 (AisoH$^+$ − Pr^i, 26), 202.2 (AisoH$^+$ − ArNH, 100), 177.2 ($ArNH_2^+$, 24); IR ν/cm^{-1} (Nujol): 1636 m, 1596 m, 1260 s, 1097 m, 934 m, 864 m, 799 m, 746 m.

13: Yield 1.20 g, 22%; m.p. 220–222 °C (dec.); ^{1}H NMR (400 MHz, C_6D_6, 298 K): δ 1.10 (d, $^3J_{HH} = 6.8$ Hz, 6 H, CH(CH_3)), 1.13 (d, $^3J_{HH} = 6.8$ Hz, 6 H, CH(CH_3)), 1.22 (d, $^3J_{HH} = 6.8$ Hz, 6 H, CH(CH_3)), 1.34 (s, 3 H, CCH_3), 1.60 (d, $^3J_{HH} = 6.8$ Hz, 6 H, CH(CH_3)), 3.54 (v. sept, $^3J_{HH} = 6.8$ Hz, 2 H, CH(CH_3)), 3.63 (v. sept, $^3J_{HH} = 6.8$ Hz, 2 H, CH(CH_3)), 7.00–7.24 (m, 6 H, Ar–H), 8.98 (s, 1 H, NH); ^{13}C NMR (100.6 MHz, C_6D_6, 298 K): δ 14.5 (H_3CC), 24.6 (CH(CH_3)), 24.8 (CH(CH_3)), 24.9 (CH(CH_3)), 25.1 (CH(CH_3)), 29.0 (CH(CH_3)), 29.1 (CH(CH_3)), 125.3 (*m*-Ar*C*), 129.3 (*p*-Ar*C*), 139.0 (*ipso*-Ar*C*), 144.8 (*o*-Ar*C*), 186.0 (N*C*N); MS/EI *m*/*z* (%): 785.7 (M$^+$, <5), 742.7 (M$^+$ − Pr^i, <5), 659.0 (M$^+$ − I, 100), 379.3 ($AisoH_2^+$, 19), 335.2 (AisoH$^+$ − Pr^i, 26), 202.2 (AisoH$^+$ − ArNH, 100); IR ν/cm^{-1} (Nujol): 3295 (NH), 1641 m, 1570 m, 1321 m, 1260 s, 1170 m, 1096 m, 934 m, 870 m; Acc. mass. EI for M$^+$ − I: found: 659.0926; calculated: 659.0934.

4.6. [AlI_2(Piso)] (**14**)

A solution of I_2 (0.54 g, 2.13 mmol) in toluene (30 mL) was added dropwise to a slurry of [{AlH_2(Piso)}$_2$] (0.91 g, 1.02 mmol) in toluene (15 mL) at −20 °C until gas evolution had ceased. The solution was then warmed to room temperature and stirred for 30 min. Volatiles were removed in vacuo and the residue dissolved in toluene (30 mL), filtered and concentrated under reduced pressure to give **14** as a light yellow crystalline solid after placement at −30°C overnight. Yield 1.25 g, 88%; m.p. 238–240 °C (no dec. until >300 °C); ^{1}H NMR (400 MHz, C_6D_6, 298 K): δ 0.94 (s, 9 H, C(CH_3)$_3$), 1.39 (d, $^3J_{HH} = 6.8$ Hz, 12 H, CH_3), 1.48 (d, $^3J_{HH} = 6.8$ Hz, 12 H, CH_3), 3.83 (v. sept, $^3J_{HH} = 6.8$ Hz, 4 H, CH), 7.06–7.26 (m, 6 H, Ar–H), ^{13}C NMR (100.6 MHz, C_6D_6, 298 K): δ 21.8 (CH(CH_3)), 28.0 (CH(CH_3)), 28.3 (CH(CH_3)), 28.7 (C(CH_3)$_3$), 41.2 (C(CH_3)$_3$), 123.2 (*m*-Ar*C*), 129.2 (*p*-ArC), 135.0 (*ipso*-Ar*C*), 144.1 (*o*-Ar*C*), 185.9 (N*C*N); MS/APCI *m*/*z* (%): 421 (PisoH$^+$, 100), 244 (PisoH$^+$ − ArNH, 71); IR ν/cm^{-1} (Nujol): 1641 m, 1590 m, 1542 m, 1323 m, 1257 s, 1200 m, 1178 m, 1098 m, 803 m, 756 m.

4.7. [$GaCl_3$(FisoH)] (**16**)

A solution of FisoH (0.50 g, 1.37 mmol) in Et_2O (20 mL) was added to a solution of $GaCl_3$ (0.25 g, 1.37 mmol) in Et_2O (10 mL) at −80 °C. The mixture was slowly warmed to room temperature, filtered and the solvent removed in vacuo. The residue was extracted into toluene (8 mL) and the extract cooled to −30 °C to give colourless crystals of **16**. Yield 0.48 g, 65%; m.p. 158–160 °C; ^{1}H NMR (300 MHz, C_6D_6, 298 K): δ 1.13 (br. d, $^3J_{HH} = 6.8$ Hz, 24 H, CH(CH_3)), 3.27 (br. sept, $^3J_{HH} = 6.8$ Hz, 4 H, CH(CH_3)), 7.02–7.09 (m, 6 H, Ar–H), 7.83 (s, 1 H, HCN_2), 8.67 (s, 1 H, NH); ^{13}C NMR (100.6 MHz, C_6D_6, 298 K): δ 22.5 (CH(CH_3)), 27.3 (CH(CH_3)), 122.6 (*m*-Ar*C*), 122.9 (*p*-Ar*C*), 124.9 (*ipso*-Ar*C*), 127.5 (*o*-Ar*C*), 146.6 (N*C*N); MS (APCI), *m*/*z* (%): 365 ($FisoH_2^+$, 100); IR ν/cm^{-1} (Nujol): 3313 (NH), 1586 m, 1327 m, 1175 m, 1058 m, 806 m.

4.8. [$TripH_2$][$InBr_4$] (**17**)

A solution of [Li(Trip)] (0.25 g, 65 mmol) in THF (15 mL) was added over 5 min to a solution of $InBr_3$ (0.23 g, 0.65 mmol) in THF (10 mL) at −50°C. The mixture was slowly warmed to room temperature and stirred for 2 d. Volatiles were removed in vacuo and the residue washed with hexane (20 mL) and Et_2O (15 mL). The residue was then recrystallised from chloroform at −30 °C giving colourless crystals of **17** overnight. Yield 0.09 g, 15%; m.p. 233–235 °C; ^{1}H NMR (300 MHz, $CDCl_3$, 298 K): δ 1.37 (d, $^3J_{HH} = 6.8$ Hz, 6 H, CH(CH_3)$_2$), 1.65 (d, $^3J_{HH} = 6.8$ Hz, 6 H, CH(CH_3)$_2$), 3.42 (v. sept, $^3J_{HH} = 6.8$ Hz, 2 H, CH(CH_3)$_2$), 3.55 (s, 1 H, CH), 5.42 (s, 2 H, NH), 6.97–7.18 (m, 3 H, ArH), 7.22–7.29 (m, 3 H, ArH), 7.33–7.43 (m, 3 H, ArH), 7.52–7.68 (m, 3 H, ArH); ^{13}C NMR (100.6 MHz, C_6D_6, 298 K): δ 22.1 (CH(CH_3)), 23.4 (CH(CH_3)), 24.7 (CH(CH_3)), 50.6 (CAr_3), 121.3 (*ArC*), 125.7 (*ArC*), 125.9 (*ArC*), 126.6 (*ArC*), 127.8 (*ArC*), 140.2 (*ArC*), 146.0 (N*C*N); MS/APCI *m*/*z* (%): 381 ($TripH_2^+$, 100); IR ν/cm^{-1} (Nujol): 3358 (NH), 1640 m, 1457 m, 1376 m, 1260 s, 1093 m, 911 m, 801 m, 750 m.

4.9. Crystallographic studies

Crystals of **7**, **9**, **10**, **13**, **14**, **16** and **17** suitable for X-ray crystal structure determination were mounted in

silicone oil. Crystallographic measurements were made using a Nonius Kappa CCD diffractometer. The structures were solved by direct methods and refined on F^2 by full matrix least squares (SHELX-97) [18] using all unique data. Data were corrected for absorption using a SORTAV multi-scan absorption correction [19]. The R_{int} values for several of the compounds were high due to poor crystal quality, though this has not led to any ambiguity regarding the molecular connectivity of these compounds. The Flack parameter of −0.05(5) for **14** confirms that it has been refined as its correct absolute configuration. Crystal data, details of data collections and refinement are given in Table 1.

5. Supplementary material

Crystallographic data (excluding structure factors) have been deposited with the Cambridge Crystallographic Data Centre. CCDC-283677 (**7**), CCDC-283672 (**9**), CCDC-283678 (**10**), CCDC-283673 (**13**), CCDC-283674 (**14**), CCDC-283675 (**16**) and CCDC-283676 (**17**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge via www.ccdc.cam.ac.uk/conts/reteiving.html (or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge, CB2 1EZ, UK; fax: +44 1223 336033; e-mail: deposit@ccdc. cam.ac.uk).

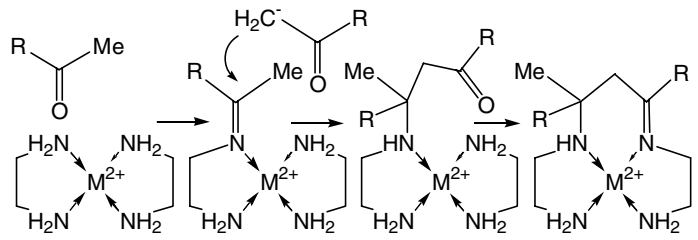
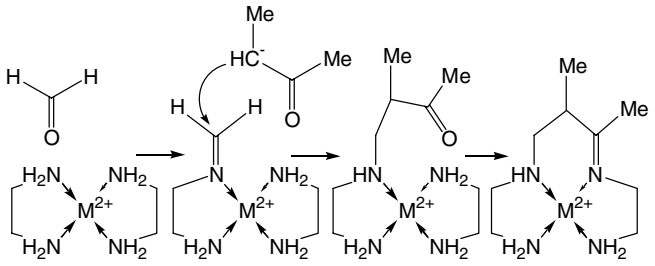


Scheme 1.



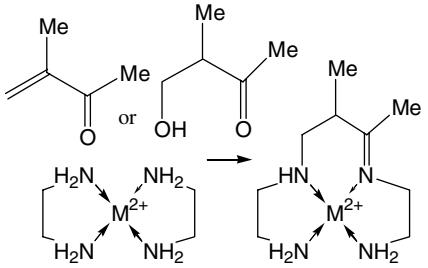
Scheme 2.

ligand (see Scheme 2). It was suggested that the methanal was formed by aerial oxidation of methanol, catalysed by other ingredients present in the reaction mixture.

If this reaction occurred as proposed, it seemed likely that the same product could be more easily formed by a conventional reaction of ethane-1,2-diamine complexes, butanone and methanal, in the presence of zinc chloride to provide the tetrachlorozincate anion which facilitates crystallisation of many related cations. This communication reports such reactions for nickel(II) and copper(II), and structural studies of the products formed by reactions of ethane-1,2-diamine complexes of nickel(II) with butanone, and with butanone plus methanal.

Alternative preparations of [Ni(enmekf)][$ZnCl_4$] by reactions of [$Ni(en)_3$][$ZnCl_4$] with preformed 3-methyl-4-hydroxybutan-2-one or 3-methylbut-3-ene-2-one have been reported, see Scheme 3 [6]. The formation of azamacrocycle compounds incorporating ethane-1,2-diamine and butanone has been reported [7] and structures of copper(II) and nickel(II) compounds of 5,7,12,14-tetraethyl-7,14-dimethyl-1,4,8,11-tetraazacyclotetradeca-4,11-diene have been reported [8–10].

The formation of compounds of 5,7,7-trimethyl-3,7-diazanon-3-ene-1,9-diamine (enac) by reaction of ethane-1,2-diamine compounds of nickel(II) or copper(II) with



Scheme 3.

acetone have been reported [1,3,11,12], and the structures of [Cu(enac)][$ZnCl_4$] [13] and [Ni(enac)(NO_2)]ClO_4 [12], have been reported.

Shevenko et al. have reported reactions of elemental metals, ethane-1,2-diamine dihydrochloride {or its *N*-(2-hydroxyethyl) derivative} and acetone to form [Cu(enac)][$MnCl_4$], [Ni(enac)][$MnCl_4$], [Cu(L)][$MnCl_4$] and [Ni(L)][$MnCl_4$], L = 1,15-dihydroxy-7,9,9-trimethyl-3,6,10,13-tetraazapentadeca-6-ene [14]. Structures were reported for [Ni(enac)][$MnCl_4$] and [Cu(L)][$MnCl_4$].

2. Results

Tris(ethane-1,2-diamine)nickel(II) and bis(ethane-1,2-diamine)copper(II) tetrachlorozincates react over a period of days in refluxing methanol/butanone to form the (4,6-diethyl-6-methyl-3,7-diazadecan-3-ene-1,9-diamine)-nickel(II) or -copper(II) tetrachlorozincate salts, [M(enmek)][$ZnCl_4$]. The structure of [Ni(enmek)][$ZnCl_4$] is reported below.

When the reactions were repeated in the presence of methanal (formaldehyde, as paraformaldehyde) more rapid reactions occurred, with products [M(enmekf)][$ZnCl_4$] formed, for which analysis indicated formulae [Ni($C_9H_{22}N_4$)][$ZnCl_4$] and [Cu($C_9H_{22}N_4$)][$ZnCl_4$]·H_2O, in agreement with a tetradentate ligand formed by combination of two ethane-1,2-diamine, one butanone and one methanal residue, with elimination of 2 mol of water. The structure of [Ni(enmekf)][$ZnCl_4$], reported below, shows the presence of the tetradentate ligand 4,5-dimethyl-3,7-diazanon-3-ene-1,9-diamine, the same as for the copper(II) compound described by Shevchenko et al. [5].

2.1. Structural studies

The structures of (4,6-diethyl-6-methyl-3,7-diazanon-3-ene-1,9-diamine)nickel(II) tetrachlorozincate and (4,5-dimethyl-3,7-diazanon-3-ene-1,9-diamine)nickel(II) tetrachlorozincate were determined by X-ray diffractometry, see Section 3.2 and Table 1 for crystallographic details.

2.1.1. 6SR,7RS-(4,6-diethyl-6-methyl-3,7-diazanon-3-ene-1,9-diamine)nickel(II) tetrachlorozincate, [Ni(enmek)][$ZnCl_4$]

The asymmetric unit contains discrete square planar (4,6-diethyl-6-methyl-3,7-diazadecan-3-ene-1,9-diamine)-nickel(II) cations and tetrachlorozincate anions, see Fig. 1,

Table 2 for selected dimensions, Table 3 for displacements of atoms from selected planes and Table 4 for hydrogen bonding interactions.

The N_4 group is slightly tetrahedrally twisted (displacements of N atoms from the N_4 plane ±0.014(1) Å), with the Ni displaced by 0.018(1) Å from the plane. Chloride ions of tetrachlorozincate ions are located in approximately axial positions. The C62 methyl substituent is axially oriented, on the opposite side of the N_4 plane as the N7–H group (configuration C6, *S*; N7, *R*). The C41 and C61 methylene groups are equatorially oriented, with the C42 and C63 methyl groups displaced on opposite sides of the N4 plane, with C42 on the same side as C62.

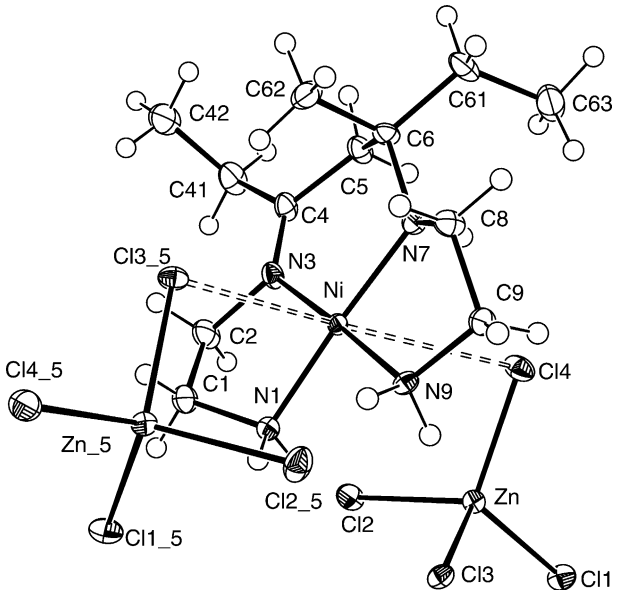

Fig. 1. [Ni(mek)][$ZnCl_4$] drawn [15] with displacement ellipsoids at the 50% confidence level, with hydrogen atoms shown as circles of arbitrary radius. The symmetry operation 5 = $-x + 1/2$, $y + 1/2$, $-z + 1/4$.

2.1.2. 5SR,7RS-(4,5-dimethyl-3,7-diazanon-3-ene-1,9-diamine)nickel(II) tetrachlorozincate, [Ni(enmekf)][$ZnCl_4$]

The asymmetric unit contains discrete square planar (4,6-dimethyl-3,7-diazanon-3-ene-1,9-diamine)nickel(II) cations and tetrachlorozincate anions, see Fig. 2, Table 2 for selected dimensions, Table 3 for displacements of atoms from selected planes and Table 5 for hydrogen bonding interactions.

The N_4 group has slight tetrahedral twisting (displacements of N atoms from N_4 plane ±0.006(1) Å), with the Ni displaced by 0.004(1) Å from the plane. Chloride ions of tetrachlorozincate ions are located in approximately axial positions. The C51 methyl substituent is axially oriented, on the same side of the N_4 plane as the N7–H group (configuration C5, *S*; N7, *R*).

2.1.3. Comparison of structures of (3-azanon-3-ene-1,9-diamine)metal(II) tetrachlorometalate salts

The structures of [Ni(enmekf)][$ZnCl_4$] and [Cu(enmekf)][$ZnCl_4$] are very similar, though they are not isostructural, with similar conformations of the ligands. In particular, both have the C5 methyl substituent axially oriented (see Table 3 for displacements of atoms from chelate (MN_2) planes). The M–N bond lengths are ca. 0.1 Å shorter for the singlet ground state nickel(II) compounds [Ni(enmek)][$ZnCl_4$], [Ni(enmekf)][$ZnCl_4$] and [Ni(enac)][$MnCl_4$] than for the copper(II) compounds [Cu(enmekf)][$ZnCl_4$] and [Cu(enac)][$ZnCl_4$], with the bond to the imine nitrogen only marginally shorter than the bonds to primary and secondary amine nitrogen atoms. The compounds have similar ligand conformations, though [Cu(enac)][$ZnCl_4$] has the CuN_4 group appreciably folded, whereas for the other cations it is near coplanar. The five-membered chelate rings all have asymmetric gauche conformations, with the pair having approximate C_2 symmetry. The six-membered chelate rings have C6 most displaced from the MN_2 plane, on the same side as the axial substituent for the enmekf compounds, on the opposite side for the other compounds.

For [Ni(enmek)][$ZnCl_4$], [Ni(enmekf)][$ZnCl_4$], [Ni(enac)][$MnCl_4$] and [Cu(enmek)][$ZnCl_4$] the cations are linked into chains by tetrachlorozincate ions, with chloride ions near both tetragonal axes, with unequal M–Cl distances (see Table 1). These M–Cl distances increase in the order $[Cu(enmek)]^{2+} < [Ni(enmekf)]^{2+} < [Ni(enmek)]^{2+}$, $[Ni(enac)]^{2+}$, though for the nickel(II) compounds, only Ni–Cl1 for [Ni(enmekf)][$ZnCl_4$] is significantly less than

[a] Positive displacements are in the direction of the axial substituents.
[b] Atom labels adjusted for comparability.

the sum of the van der Waals radii. In contrast [Cu(enac)][$ZnCl_4$] has a "molecular" structure with a close interaction of the cation with a single tetrachlorozincate ion, with one, much shorter, Cu–Cl interaction.

For all these compounds there is a network of N–H···Cl hydrogen bonds (see Tables 4 and 5).

3. Experimental

3.1. Synthesis of compounds

Preparations of Ni(enmek)][$ZnCl_4$] [2,4,6] and [Cu(enmekf)][$ZnCl_4$] [5] have been reported.

Table 4
Hydrogen bonding for [Ni(enmek)][$ZnCl_4$]

Atoms	H···Cl (Å)	N–H···Cl (°)	N···Cl (Å)
N1–H1C···Cl2	2.56	152.7	3.387
N1–H1C···Cl3	2.87	121.8	3.425
N1–H1D···Cl1^{i}	2.72	136.8	3.431
N7–H7···Cl4	2.64	138.1	3.372
N9–H9C···Cl2^{i}	2.40	164.3	3.274
N9–H9D···Cl3	2.44	160.4	3.305

Symmetry operation i = $-x - 1/2$, $y - 1/2$, $-z + 1/4$.

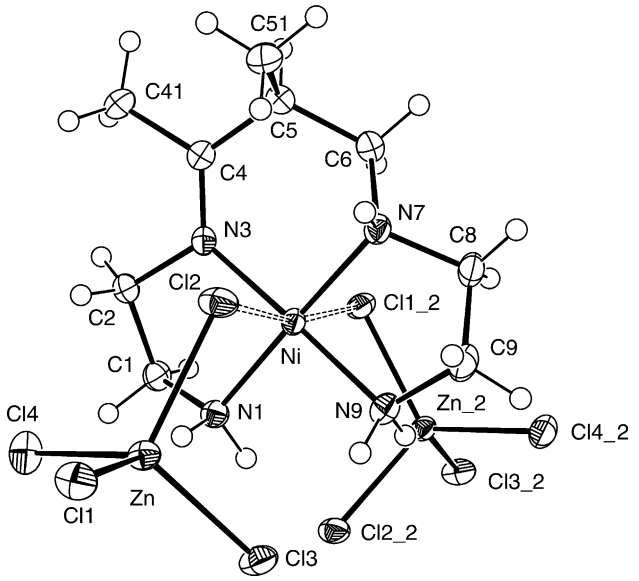

Fig. 2. [Ni(mekf)][$ZnCl_4$], drawn as for Fig. 1. The symmetry operation 2 = $-x$, $-y$, $z + 1/2$.

Table 5
Hydrogen bonding for [Ni(enmekf)][$ZnCl_4$]

Atoms	H···Cl (Å)	N–H···Cl (°)	N···Cl (Å)
N1–H1C···Cl2^{i}	2.39	159.6	3.251
N1–H1D···Cl4	2.63	153.7	3.457
N7–H7···Cl2	2.83	123.9	3.417
N9–H9C···Cl3	2.42	167.9	3.303
N9–H9D···Cl4^{i}	2.77	140.6	3.509
N9–H9D···Cl2^{i}	2.94	137.9	3.661

Symmetry operation i = $-x + 1$, $-y$, $z + 1/2$.

[Ni(enmekf)][$ZnCl_4$] and [Cu(enmekf)][$ZnCl_4$]·H_2O have now been prepared by refluxing [$Ni(en)_3$][$ZnCl_4$] or [$Cu(en)_2$][$ZnCl_4$] in 2:1 methanol:butanone plus 2 mol proportion of paraformaldehyde until the starting material had all reacted (ca. 6 h). This was obvious for the nickel compound as the sparingly soluble mauve coloured starting material was slowly converted to the sparingly soluble orange product. Reaction in the absence of the paraformaldehyde was much slower, taking several days under reflux to form [M(enmek)][$ZnCl_4$].

The compounds were recrystallised from hot 1:1 methanol:water by addition of propan-2-ol until turbid. The initial products were contaminated by small amounts of [M(enmek)][$ZnCl_4$], which was lost on recrystallisation. The copper(II) compound crystallised as a mono-hydrate, while the unhydrated compound for which the structure was reported [5] was crystallised from methanol.

[Ni(enmekf)][$ZnCl_4$]. Anal. Calc. for $C_9H_{22}Cl_4N_4NiZn$: C, 23.9; H, 4.9; N, 12.4. Found: C, 24.2; H, 4.9; N, 12.3%. IR (cm^{-1}): ν(NH) 3251, 3204, 3121w; ν(C=N) 1643; δ(NH2) 1583, 1572.

[Cu(enmekf)][$ZnCl_4$]·H_2O. Anal. Calc. for $C_9H_{24}Cl_4CuN_4OZn$: C, 22.8; H, 5.0; N, 12.0. Found: C, 22.8; H, 4.8; N, 12.3%. IR (cm^{-1}): ν(OH) 3480br; ν(NH) 3889, 3236, 3133w; ν(C=N) 1652; δ(NH2) 1584.

3.2. Structural determinations

The structures of [Ni(enmek)][$ZnCl_4$] and [Ni(enmekf)][$ZnCl_4$] were determined by X-ray diffractometry, by using a Bruker SMART 1K CCD area detector diffractometer, Mo Kα radiation (fine focus, sealed tube with graphite monochromator, $\lambda = 0.71073$ Å) with ϕ and ω scans [17] (see Table 1 for data). The data were corrected for absorption by multi-scans using SADABS v2.03 [18].

The structures were solved and refined on F^2 by using SHELXS97 and SHELXL97 [19], with hydrogen atoms in calculated positions and riding.

Appendix A. Supplementary data

Crystallographic data have been deposited with the Cambridge Crystallographic Data Centre; [Ni(enmek)][$ZnCl_4$] CCDC 283179 and [Ni(enmekf)][$ZnCl_4$] CCDC 283178. Copies may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CBZ 1EZ, UK (fax: +44 1223 336 033; e-mail: deposit @ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk). Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2005.10.030.

detail by cyclic voltammetry (CV) [29,30]. Consistent with previous reports, the electroreduction of **2** in the absence of MesBr occurs in two successive, reversible electron-transfer steps (Eqs. (1) and (2), Fig. 1(a)).

$$[\underset{\mathbf{2}}{NiBr_2(bpy)}] + 2e^- \rightleftharpoons [Ni(bpy)] + 2Br^- \quad E_p^{C_1} \tag{1}$$

$$[Ni(bpy)] + e^- \rightleftharpoons [Ni(bpy)]^{\bullet -} \quad E_p^{C_2} \tag{2}$$

MesBr is electrochemically inactive in the range of potentials corresponding to the reduction of nickel(II) complexes. Indeed, the electrochemical reduction of MesBr on the glassy carbon electrode, which involves the transfer of two electrons, takes place at more negative potentials than −2.5 V, in the region of the supporting electrolyte discharge.

In agreement with previously reported data [4,22,23], the anodic component of the first cathodic wave (C_1) of **2** disappeared in the presence of MesBr, and two new reduction waves (C_3 and C_4), showing anodic components, appeared at more negative potentials (Fig. 1(b); Table 1).

Waves C_3 and C_4 are due to the reduction of organo-nickel(II) products formed upon oxidative addition of MesBr to a nickel(0) species [4,22,23]. Indeed, wave C_3 corresponds to the reduction of the σ complex **1** formed by oxidative addition of MesBr to [Ni(bpy)] generated at potential C_1, while wave C_4 corresponds to the reduction of another intermediate, probably the bis-mesityl complex $[Ni(Mes)_2(bpy)]$ (**3**) formed by reaction of MesBr with the reduced form of **1**, generated at C_3, as previously reported (Eq. (3)) [4–6].

$$[\underset{\mathbf{1}}{NiBr(Mes)(bpy)}] + 2e^- + MesBr \xrightarrow{C_3} [\underset{\mathbf{3}}{Ni(Mes)_2(bpy)}] + 2Br^- \tag{3}$$

Unfortunately, we were unable to isolate compound **1** as a pure product as it was invariably contaminated by traces of solvent and of the supporting electrolyte salt. Analytically pure **1** was, however, obtained by extraction with toluene after electrolysis, which also allowed the recovery of the electrolyte. The electrochemically synthesized nickel complex **1** was authenticated by various methods, including a single-crystal X-ray analysis that showed the nickel center to be coordinated in a distorted square-planar environment by a chelating bpy ligand and a mesityl and a bromo ligand in a *cis* arrangement (Fig. 2). The mesityl ring is perpendicular to the N,N,Ni plane, apparently due to steric interaction of the methyl groups with the *cis* bromo ligand and the *ortho* hydrogen atom of bpy. The molecular structure is very similar to that previously reported for the same complex obtained by recrystallization from THF [17,21]. However, the two X-ray analyses differ crystallographically; the crystals of **1** obtained here exhibit a triclinic cell with two molecules of **1** and one toluene molecule in the unit cell, whereas the previously reported compound crystallized in the orthorhombic system with eight molecules of **1** and eight THF molecules in the unit cell (two independent molecules of each in the asymmetric unit) [21].

Table 1
Peak potentials and currents from the CV curves of the investigated nickel complexes[a]

Complex	Waves	E_p (V)	I_p (μA)	Number of electrons
$[NiBr_2(bpy)]$	C_1	−1.55	64	2
	A_1	−1.38	41	2
	C_2	−2.28	26	1
	A_2	−2.16	19	1
$[NiBr_2(bpy)]$ + MesBr	C_1	−1.55	63	2
	C_3	−1.80	18	
	A_3	−1.77	16	
	C_4	−2.01	17	
	A_4	−1.90	12	
[NiBr(Mes)(bpy)]	C_3	−1.78	29	1
	A_3	−1.71	19	1

[a] C – cathodic wave (reduction), A – anodic wave (oxidation).

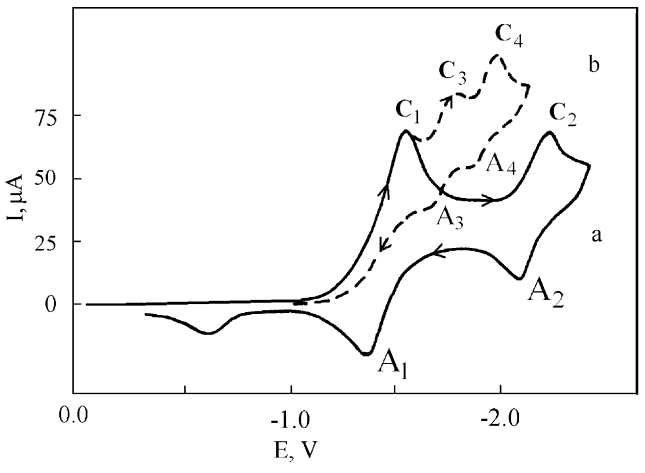

Fig. 1. Cyclic voltammograms in DMF of $[NiBr_2(bpy)]$ (10^{-2} M) in the absence (a) and in the presence (b) of MesBr (2×10^{-2} M) (CV curves were recorded at the first scan: curve a – from 0.00 to −2.40 V and back to 0.00 V; curve b – from 0.00 to −2.15 V and back to 0.00 V).

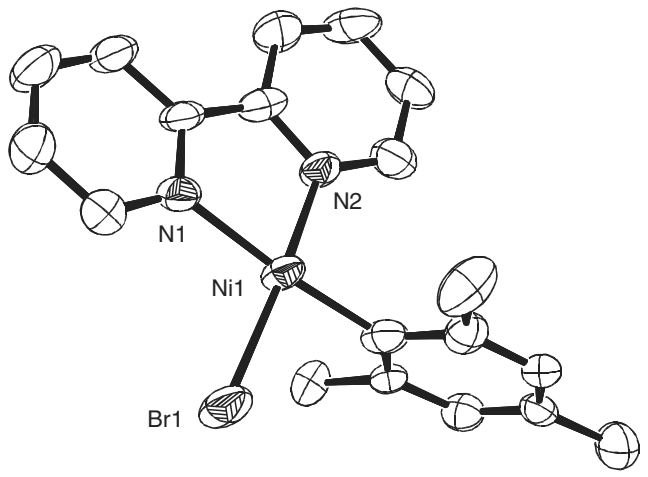

Fig. 2. ORTEP view of the electrochemically synthesized nickel complex **1** (hydrogen atoms are omitted for clarity).

The use of traditional reducing agents to prepare **1** from **2** and MesBr is not feasible, as other products, for example, **3** (Eq. (4)) and the homocoupling product Mes-Mes (Eq. (5)), are invariably formed.

$$[\underset{\mathbf{1}}{\mathrm{NiBr(Mes)(bpy)}}] + [\mathrm{Ni(bpy)}] + \mathrm{MesBr} \longrightarrow [\underset{\mathbf{2}}{\mathrm{NiBr_2(bpy)}}] + [\underset{\mathbf{3}}{\mathrm{Ni(Mes)_2(bpy)}}] \quad (4)$$

$$[\underset{\mathbf{3}}{\mathrm{Ni(Mes)_2(bpy)}}] \longrightarrow [\mathrm{Ni(bpy)}] + \mathrm{Mes\text{-}Mes} \quad (5)$$

Electrolysis of **2** in the presence of an equivalent amount of MesBr at the potential of the working electrode E_p^{Cl} (−1.48 to −1.55 V) is therefore the cleanest and most efficient method of preparing **1** (Eq. (6)).

$$[\underset{\mathbf{2}}{\mathrm{NiBr_2(bpy)}}] + 2e^- \xrightarrow[-2Br^-]{E_p^{Cl}} [\mathrm{Ni(bpy)}] \xrightarrow{\mathrm{MesBr}} [\underset{\mathbf{1}}{\mathrm{NiBr(Mes)(bpy)}}] \quad (6)$$

The σ-aryl complex **1** was also successfully prepared by treating [Ni(bpy)(COD)] [31], prepared in situ from [Ni(COD)$_2$] and bpy, with MesBr in toluene (Eqs. (7) and (8)):

$$[\mathrm{Ni(COD)_2}] + \mathrm{bpy} \longrightarrow [\mathrm{Ni(COD)(bpy)}] + \mathrm{COD} \quad (7)$$

$$[\mathrm{Ni(COD)(bpy)}] + \mathrm{MesBr} \longrightarrow [\mathrm{NiBr(Mes)(bpy)}] + \mathrm{COD} \quad (8)$$

The preparation of Ni^{II} σ-aryl complexes by oxidative addition of aromatic halides to nickel(0) complexes has been studied in detail by Tsou and Kochi [32]. In particular, several σ-organyl Ni^{II} complexes have been synthesized by oxidative addition of organic halides to [Ni(COD)$_2$] in the presence of various ligands, generally phosphines [33], while complexes with bpy, which are generally synthesized from the corresponding Ni^{II} phosphine complexes by ligand-exchange reactions, are less common [34,35].

Complex **1** was examined as catalyst precursor for the oligomerization of ethylene after activation with MAO in toluene at low ethylene pressure (5 bar) at an initial temperature of 25 °C. Under these conditions, **1** generated an active catalyst for the oligomerization of ethylene to even-numbered olefins in the C_4–C_{26} range with a Schulz–Flory distribution [36]. No solid material was obtained. Selected data (average values over three identical runs) are given in Table 2.

Excellent turnover frequencies, close to 10^5 moles of C_2H_4 converted (mol of Ni × h)$^{-1}$, were obtained, whereas no catalytic activity was observed in the absence of MAO. The selectivity for α-olefins was rather modest due to the occurrence of a fast isomerization process, which is typical for Ni^{II} oligomerization catalysts [37]. Increasing the ethylene pressure resulted in an appreciable increase of the selectivity for α-olefins, whereas the α value remained constant (entries 1–3). In a control experiment (entry 4), the oligomerization reaction was carried out in the presence of *n*-undecene, and the oligomeric mixture showed only a small amount of C_{11} internal olefins (<5%), which suggests that chain transfer occurs mainly from an internal olefin hydride nickel species rather than from an α-olefin hydride complex. In a second independent experiment (entry 5), the precatalyst concentration was reduced to one tenth while leaving the MAO concentration unchanged. As a result, an appreciable decrease in the catalytic activity was observed, probably due to a smaller increase in the temperature, and the α value increased slightly. Finally, **1** was replaced by **2** (entry 6). Under comparable experimental conditions, the dibromide precursor was significantly less active (also evidenced by a much less exothermic reaction), but showed a similar selectivity for α-olefins and a slightly higher α value.

The oligomerization of ethylene by **2**/MAO has been previously investigated by Brookhart and coworkers [7]. Scheme 1 shows the mechanisms of oligomerization, propagation, chain transfer and olefin isomerization proposed for a variety of Ni^{II} catalysts containing chelating nitrogen ligands [37]. The results obtained by using **1** as catalyst precursor nicely fit the overall mechanism illustrated in Scheme 1.

Indeed, after MAO has created a free coordination site at nickel, the first ethylene insertion(s) into the Ni-mesityl bond, followed by β-H elimination, would give a [(bpy)-NiH] moiety. The fact that both the activity and the α factor do not change on increasing the ethylene pressure is actually

Table 2

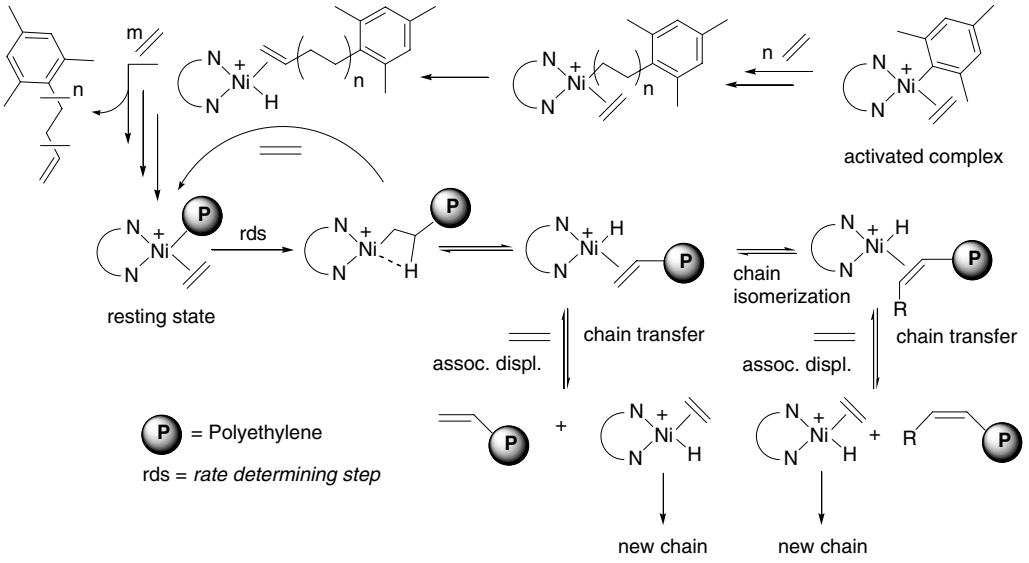

Scheme 1.

consistent with a Ni alkyl resting state, while the increase in α-olefin selectivity with monomer pressure can be explained by chain transfer occurring via an associative displacement. Finally, the absence of isomerization of added *n*-undecene (entry 4) indicates that chain transfer from an internal olefin hydride nickel complex is faster than chain transfer from an α-olefin hydride species [7].

Assuming that **1** and **2** exhibit the same mechanism of ethylene oligomerization, the lower activity of the dibromide complex **2** may be rationalized in terms of the different solubility of the two precursors in toluene. The dibromide complex **2** is much less soluble than the monobromide derivative **1**, and its reaction with MAO is initially heterogeneous. A shorter induction period for **1**, evidenced by a rapid exotherm, may also be caused by the presence of a metal–carbon bond in this precursor, which would favor the insertion of the monomer.

3. Conclusions

We have shown that preparative electrochemistry can be an effective, high-yield, and selective method for the generation of σ-organyl metal complexes. Using the synthetic protocol described in this paper a variety of (N-N)Ni σ-aryl complexes could be prepared and successfully employed in catalytic processes, where they show improved activity as compared to traditional precursors [4–7].

4. Experimental

4.1. General procedures

All manipulations and reactions were carried out under an atmosphere of dry nitrogen. All solvents were purified and dried prior to use. DMF was dried with calcium hydride and purified by distillation. [$NiBr_2$(bpy)] [38], [Ni(COD)$_2$] [39] and [Ni(COD)(bpy)] [31] were synthesized according to the literature procedures; $(NBu_4)BF_4$, bpy, MesBr and a 10% solution of methylalumoxane in toluene were commercial products. The electrolyte $(NBu_4)BF_4$ was dried by melting in vacuum and stored under nitrogen. Cyclic voltammograms were recorded at a glassy carbon electrode (working surface 3.14 mm^2) in a thermostatically controlled (20 °C) three-electrode electrochemical cell under N_2 in the presence of $(NBu_4)BF_4$ (0.1 M). A silver electrode $Ag/AgNO_3$ (0.01 mol L^{-1} solution in CH_3CN) was used as a reference electrode and a platinum wire served as an auxiliary electrode. Curves were recorded at a constant potential scan rate of 50 mV s^{-1}. The preparative electrolyses were carried out at room temperature in galvanostatic regime [potential of the working electrode −1.48 to −1.55 V, ref. $Ag/AgNO_3$ (0.01 mol · L^{-1} solution in CH_3CN)], using an EG&G Princeton Applied Research potentiostat/galvanostat model 273A in an electrochemical cell (three-electrode cell, 40 mL) with separation of anodic and cathodic compartments. Glassy carbon electrode with a surface area of 60 cm^2 was used as a cathode. Nitrogen was bubbled through the stirred electrolyte during the electrolysis. A solution of $(NBu_4)BF_4$ (0.1 M) in DMF was used as electrolyte. The NMR spectra were recorded on Bruker 400 spectrometers. Melting points were measured on Electrothermal IA9000 SERIES Digital Melting Point Apparatus in capillary tubes. The nickel content was determined by atomic absorption spectrometry using a Carl Zeiss AAS1 spectrometer. GC analyses were performed on a Shimadzu GC-17A equipped with a flame ionization detector and a 30 m (0.25 mm i.d., 0.25 mm film thickness) SPB-1 Supelco fused silica capillary column. GC/MS analyses were performed on a Shimadzu QP 5000 apparatus equipped with a column identical with that used for GC analysis. Infrared spectra were recorded on a Perkin–Elmer FT-IR Spectrum BX instrument.

4.2. Electrochemical synthesis of [NiBr(Mes)(bpy)]

A solution for electrolysis was prepared by mixing [$NiBr_2$(bpy)] (0.188 g, 0.5 mmol), MesBr (0.075 mL, 0.5 mmol), and $(NBu_4)BF_4$ (0.987 g, 3.0 mmol) in DMF (30 mL). A constant current of 26.8 mA was passed through the solution for 1 hour. After the electrolysis was completed, the solution was transferred to a flask, the solvent was evaporated in vacuum and the residue was extracted with toluene (three times). Toluene was partly evaporated and decanted to remove residual supporting electrolyte salt. The product was recrystallized from hot toluene; cooling to −20 °C gave 0.18 g (87%) of bright red crystals of **1**; m.p. 148 °C (decomp 186 °C). The compound **1** was dried in vacuum at room temperature prior to the NMR studies. ^{1}H NMR (400 MHz, [D_6]acetone, 25 °C): $\delta = 9.47$ (dd, $^3J(H^6–H^5) = 5.7$ Hz, $^4J(H^6–H^4) = 1.2$ Hz, 1H, H_{bpy}-6), 8.41 (d, $^3J(H^3–H^4) = 7.8$ Hz, 1H, H_{bpy}-3), 8.37 (d, $^3J(H^{3'}–H^{4'}) = 8.1$ Hz, 1H, H_{bpy}-3′), 8.24 (ddd, $^3J(H^4–H^5) = 7.5$ Hz, $^3J(H^4–H^3) = 7.8$ Hz, $^4J(H^4–H^6) = 1.2$ Hz, 1H, H_{bpy}-4), 8.21 (ddd, $^3J(H^{4'}–H^{5'}) = 7.5$ Hz, $^3J(H^{4'}–H^{3'}) = 8.1$ Hz, $^4J(H^{4'}–H^{6'}) = 1.2$ Hz, 1H, H_{bpy}-4′), 7.76 (ddd, $^3J(H^5–H^6) = 5.7$ Hz, $^3J(H^5–H^4) = 7.5$ Hz, $^4J(H^5–H^3) = 1.2$ Hz, 1H, H_{bpy}-5), 7.40 (ddd, $^3J(H^{5'}–H^{6'}) = 5.7$ Hz, $^3J(H^{5'}–H^{4'}) = 7.5$ Hz, $^4J(H^{5'}–H^{3'}) = 1.2$ Hz, 1H, H_{bpy}-5′), 7.26 (dd, 1H, $^3J(H^{6'}–H^{5'}) = 5.7$ Hz, $^3J(H^{6'}–H^{4'}) = 1.2$ Hz, 1H, H_{bpy}-6′), 6.51 (s, 2H, *m*-H in Mes), 3.10 (s, 6H, *o*-CH_3), 2.24 (s, 3H, *p*-CH_3) ppm. ^{13}C NMR (100 MHz, [D_6]acetone, 25 °C): $\delta = 157.6$ (C_{bpy}-2), 154.4 (C_{bpy}-2′), 152.0 (C_{bpy}-6), 151.3 (C_{bpy}-6′), 145.0 (C_{Mes}-1), 142.9 (C_{Mes}-2), 140.8 (C_{bpy}-4), 140.0 (C_{bpy}-4′), 133.0 (C_{Mes}-4), 128.4 (C_{bpy}-3), 127.9 (C_{bpy}-3′), 127.0 (C_{Mes}-3), 123.5 (C_{bpy}-5), 122.8 (C_{bpy}-5′), 26.6 (*o*-CH_3), 21.3 (*p*-CH_3) ppm. IR (KBr): 3103 (w), 3027 (w), 2907 (br, s), 1603 (s), 1515 (s), 1443 (br, s), 1312 (w), 1261 (w), 1241 (w), 1156 (w), 1062 (w), 1029 (s), 877 (w), 846 (s), 800 (w), 767 (s), 650 (w), 637 (w), 563 (w), 418 (w) cm^{-1}. $C_{19}H_{19}BrN_2Ni$ ($M = 413.98$ g mol^{-1}): Calc.: C, 55.12; H, 4.63; N, 6.77. Found: C, 55.37; H, 4.8; N, 6.76.

4.3. Synthesis of [NiBr(Mes)(bpy)] from [Ni(COD)$_2$]

A solution of bpy (0.390 g, 2.5 mmol) in toluene (5 mL) was added to a cooled (−30 °C) suspension of [Ni(COD)$_2$] (0.690 g, 2.5 mmol) in toluene (20 mL). Then, MesBr (3.8 mL, 25.4 mmol) was added to this mixture at −30 °C. The reaction mixture was slowly warmed to room temperature (over 3 h) and stirred at r.t. for 6 h. The resulting solution was filtered, the solvent evaporated in vacuum, and the product extracted from the residue with diethyl ether. Evaporation of diethyl ether gave **1** as a dark red powder (0.76 g, 73%); m.p. 144–146 °C. The NMR data (^{1}H and ^{13}C) were in agreement with those given above.

4.4. Crystal data for 1

Space group $P\bar{1}$, $Z = 2$, $a = 8.689(4)$ Å, $b = 9.292(4)$ Å, $c = 13.053(5)$ Å, $\alpha = 89.000(8)°$, $\beta = 77.600(8)°$, $\gamma = 84.730(8)°$. Data were collected with a Siemens CCD (SMART) diffractometer (ω-scans). Data reduction with SAINT, including SADABS, a program for empirical absorption correction. The structure was solved by direct methods and non-hydrogen atoms were refined anisotropically (SHELX97) with exception of toluene (solvent), which was located disordered on a special position and refined only isotropically. All H atoms were calculated on idealized positions. Pictures were generated with ORTEP for Windows [40]. Due to the small size of the crystal ($0.1 \times 0.06 \times 0.04$ mm^3) the structure parameters are of inferior quality.

4.5. Ethylene oligomerization reactions

A 500 mL stainless steel reactor was heated at 60 °C under vacuum overnight and then cooled to room temperature under a nitrogen atmosphere

Procedure A. The solid precatalyst (12 μmol) was charged into the reactor, which was sealed and placed under vacuum. An oxygen-free toluene solution of MAO (3600 μmol), prepared by adding 100 mL of a solution of MAO (2.37 mL) in toluene (97.63 mL), was then introduced into the reactor by suction. The reaction mixture was stirred at room temperature for a few seconds. The reactor was then pressurized with ethylene to 5 bar and stirred at 1500 rpm.

Procedure B. Oxygen-free toluene (97.63 mL) and a solution of MAO (2.37 mL) were introduced into the reactor. The system was then pressurized with ethylene (5 bar final pressure) and stirred at 1500 rpm for 5 min. In a separate Schlenk flask, the solid precatalyst (12 μmol) was dissolved in oxygen-free toluene (50 mL). The autoclave was slowly depressurized to 1 bar and the precatalyst solution (5 mL) was added by syringe. The system was repressurized to the appropriate pressure and stirred at 1500 rpm.

Irrespective of the procedure, ethylene was continuously fed to maintain the ethylene pressure at the desired value. After 15 min, the reactions were quenched by cooling the system to 10 °C, depressurizing, and then introducing acidic MeOH (2 mL, 5% HCl); a certain amount of pentadecane (C_{15} internal standard) was also injected into the reactor. The reaction mixtures were stirred at 1500 rpm for 10 min. The solutions were analyzed by GC and GC–MS. The mass and the α-olefin content of the C_{12}, C_{14}, and C_{16} fractions were determined by GC using calibration curves with standard solutions. The Schulz–Flory constant α was determined by the molar ratio of the C_{12}, C_{14}, and C_{16} fractions.

5. Supplementary material

CCDC No. 264389 (**1**) contains the supplementary crystallographic data for this paper. These data can be obtained free of charge via www.ccdc.cam.ac.uk/conts/retrieving.html (or from the Cambridge Crystallographic

Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: +44 1223 336 033; or deposit@ccdc.cam.uk).

[6]. In such hybrid systems, it has been found that the crystal packing pattern and charge state of the organic cations greatly depend on the combination of the organic cation and complex anions, resulting in a remarkable influence on the magnetic interaction between the anionic transition metal complexes via the organic cations [7,8]. Consequently, it is still a challenge for chemists to construct dual-property materials, seeking to establish for instance a coupling between the conduction electrons and the magnetic spin moments.

Therefore, intense investigations are devoted to the chemical modification of the donor atoms (S) of tetrathiafulvalene (TTF) series [9,10] or the attachment of functional groups to the core of the donor framework [11–18] for an enhancement of the intermolecular interactions among electron donors and acceptors (or counter anions) which is essential to stabilize the conducting and superconducting states (suppressing the Peierls distortions) at low temperature. Moreover, it is well known that cyano groups are able to engage in weak intermolecular interactions such as hydrogen bonding and halogen bonding with halogenated anions. In this context, a new organic donor tetracyanodibenzotetrathiafulvalene (TCN-DBTTF) has now been synthesized via triethyl phosphite mediated coupling reaction of 5,6-dicyanobenzene-1,3-dithiole-2-one; the synthesis of the latter has been published in Ref. [19].

In this paper, we describe the synthesis of the donor molecule TCN-DBTTF and also the crystal structure, electrical and magnetic properties of its charge transfer salt (TCN-DBTTF)[Fe(H_2O)$_6$][$FeBr_4$]$_3$ (**1**).

2. Experimental

2.1. Materials and equipments

Unless stated otherwise, all chemicals were purchased from commercial sources and used as received. Infrared spectra were obtained on a Perkin–Elmer SYSTEM 2000 FT-IR spectrometer. ^{1}H NMR (300 MHz) spectra were recorded on a Bruker AC-300 NMR spectrometer using TMS as an internal standard. Mass spectra were measured on an AutoSpec Q MS spectrometer. Elemental analyses were performed on a Carlo-Erba-1106 instrument. Tetraethylammonium iron(III) tetrabromide (TEA · $FeBr_4$) was prepared as described in the literature [6].

2.2. Synthesis of TCN-DBTTF

The compound 5,6-dicyanobenzene-1,3-dithiole-2-one (1 g, 4.6 mmol) was suspended in the mixture of triethyl phosphite (10 ml) and toluene (10 ml). The mixture was heated up to 120 °C under argon atmosphere and stirred for 3 h. During the reaction, a red precipitate was formed. After cooling to room temperature, 20 ml of methanol was added to the reaction mixture to complete precipitation. The product was isolated by filtration as a red powder and washed with methanol (0.74 g, 80%): m.p. >250 °C; EI-MS: 404(M^+); ^{1}H NMR (300 MHz, DMSO-d_6): $\delta = 8.33$ (s, 2H); IR (KBr, cm^{-1}): $\nu = 2232$ (s), 1566 (w), 1354 (s), 1218 (m), 891 (w). *Anal.* Calc. for $C_{18}H_4N_4S_4$: C, 53.40; H, 1.00; N, 13.80. Found: C, 53.10; H, 0.80; N, 13.60%.

2.3. Synthesis of (TCN-DBTTF)[Fe(H_2O)$_6$][$FeBr_4$]$_3$ (1)

In a two-compartment H-shaped cell, single crystals of **1** were grown by electrochemical oxidation in CH_2Cl_2 in the presence of TCN-DBTTF and TEA · $FeBr_4$ under a constant current of 1.5 μA with Pt electrodes. The anodic and cathodic chambers are separated by a porous frit. Brown block-shaped crystals were observed on the bottom of the anodic chamber after 20 days. The crystals were collected and washed with CH_2Cl_2. IR (KBr cm^{-1}): 2244 (m), 1616 (m), 1359 (w), 1222 (w), 892 (m). *Anal.* Calc. for $C_{18}H_{16}Br_{12}Fe_4N_4O_6S_4$: C, 12.80; H, 0.95; N, 3.30. Found: C, 13.07; H, 0.97; N, 3.16%.

2.4. Crystallography

A brown crystal of **1** was mounted on a Stoe Mark II-Imaging Plate Diffractometer System (Stoe & Cie, 2002) equipped with a graphite-monochromator. Data collection was performed at −120 °C using Mo Kα radiation ($\lambda = 0.71073$ Å). One hundred and ninety-seven exposures (3 min per exposure) were obtained at an image plate distance of 100 mm, 180 frames with $\varphi = 0°$ and $0 < \omega < 180°$, and 17 frames with $\varphi = 90°$ and $0 < \omega < 17°$, with the crystal oscillating through 1.5° in ω. The resolution was D_{min}–D_{max}: 17.78–0.72 Å. The structure was solved

by direct methods using the program SHELXS-97 [20] and refined by full matrix least squares on F^2 with SHELXL97 [21]. The hydrogen atoms were included in calculated positions and treated as riding atoms using SHELXL-97 default parameters. All non-hydrogen atoms were refined anisotropically. Four of the six water molecules in the $[Fe(H_2O)_6]^{2+}$ cation were disordered over two positions and refined with half occupations; no H-atoms were found for the water molecules in reasonable positions. A semi-empirical absorption correction was applied using MULABS (PLATON03 [22], $T_{min} = 0.146$, $T_{max} = 0.266$).

Crystallographic data of **1** are collected in Table 1. Selected bond lengths and angles are given in Table 2.

2.5. Physical measurements

Magnetic susceptibility data of a crystalline sample of **1** were collected on a MPMS Quantum Design SQUID magnetometer (XL-5) in the temperature range of 300–1.8 K at a field of 1000 G. The sample was wrapped in a saran bag and put into a straw, which served as sample holder. The molar magnetic susceptibility has been corrected for the diamagnetic contributions of the sample holder and of the sample, the latter is calculated from Pascal's constants.

3. Results and discussion

3.1. Structure of (TCN-DBTTF)[Fe(H$_2$O)$_6$][FeBr$_4$]$_3$ (1)

The compound crystallizes in a monoclinic space group ($C2/c$) and an ORTEP plot of the molecular structure with the atomic numbering scheme is shown in Fig. 1. The unit cell contains four oxidized TCN-DBTTF molecules, four $[Fe(H_2O)_6]^{2+}$ cations and 12 $[FeBr_4]^-$ anions.

In the crystal structure, the donor molecule shows approximate D_{2h} symmetry, whereby only a center of inversion at the midpoint of the C(1)=C(1b) bond is imposed by the exact space group symmetry. The TCN-DBTTF molecule is nearly planar (the dihedral angle between the benzene ring and the central TTF plane is 1.5°), and the four peripheral cyano groups lie also in the plane of the dibenzotetrathiafulvalene skeleton, which is quite similar to other dibenzotetrathiafulvalene derivatives [23]. One $[FeBr_4]^-$ anion (Fe(1)) is located on a site with a twofold rotation axis and one $[FeBr_4]^-$ anion (Fe(2)) lies on a general position. The Fe–Br bond lengths of the $[FeBr_4]^-$ anions, 2.3283(11)–2.3340(12) Å for Fe(1) and 2.3082(14)–2.3648(14) Å for Fe(2), are similar to other $[FeBr_4]^-$ salts [24]. The Fe(3) center of the $[Fe(H_2O)_6]^{2+}$ cation lies on an inversion center. Four of the six water molecules of the $[Fe(H_2O)_6]^{2+}$ cations are disordered over two positions and refined with half occupations and the Fe–O bond lengths of $[Fe(H_2O)_6]^{2+}$ are in the range of range of 2.089–2.14 Å.

Importantly, the bond lengths of the central C=C bond, the C–S bonds near the molecular center and the outer C=C bonds within the TTF molecule are related to the degree of ionicity of the donor molecule. The central C=C bond length of TCN-DBTTF moiety of **1** is 1.381(15) Å. Thus, it can be inferred that the TCN-DBTTF moiety in **1** is essentially fully oxidized according to the correlation between the oxidation states of TTF derivatives and bond lengths of central C=C bonds [25], which is fully in accordance with the stoichiometry of **1**.

In the crystal lattice of **1** (Fig. 2), the donor molecules are arranged in layers parallel to the *bc* plane. Along the *c*-axis, the direction of the molecular planes of two adjacent TCN-DBTTF molecules alternate with a dihedral angle of 77.4°. They are separated from each other by tetrahedral $[FeBr_4]^-$ anions; no specific CN···Br short contacts can be identified. However, weak intermolecular interactions of S···Br [3.566–3.741 Å], Br···C [3.487–3.533 Å] and Br···Br [3.651–3.871 Å] as well as hydrogen bonds C–H···Br [C···Br 3.742 Å; C–H···Br 178°] are observed. Along the *b*-direction, the donor molecules are parallel and coplanar to each other forming a columnar arrangement with S···S distances of 10 Å. In addition, $[Fe(H_2O)_6]^{2+}$ cations are located in-between the donor

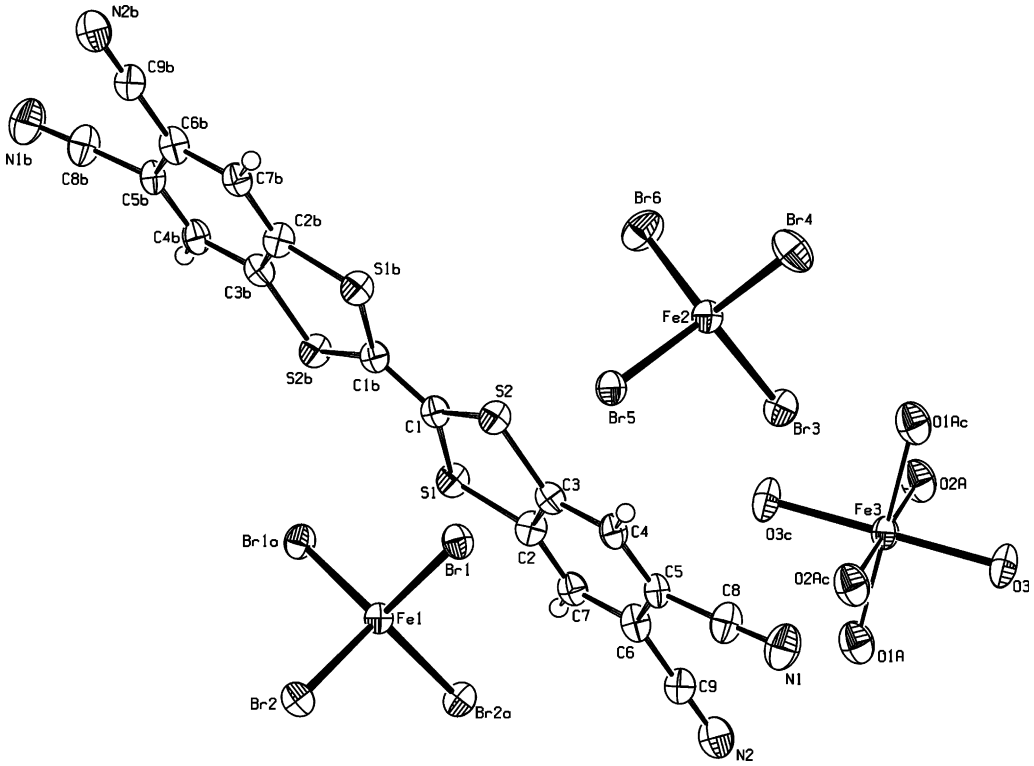

Fig. 1. ORTEP plot (50% probability ellipsoids) of **1**.

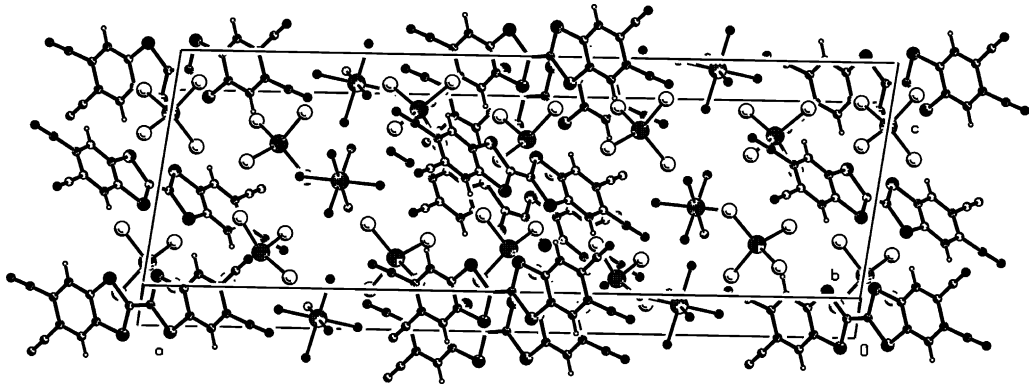

Fig. 2. Projection of the crystal structure of **1**. Hydrogen atoms are omitted for clarity.

molecule assemblies and there are CN···O [2.881–3.025 Å] and O···Br [3.316 Å] short contacts.

3.2. Electrical conductivity

The compound **1** shows a low electrical conductivity with a room temperature value $\sigma = 4.3 \times 10^{-7}$ S cm^{-1}. This observation corresponds to its structural feature of the crystal packing which does not show any specifically close stacking arrangements of the donor and acceptor units.

3.3. Magnetic properties

The compound **1** is composed of three types of paramagnetic spin carriers: oxidized TCN-DBTTF radicals ($S = 1/2$), $[Fe(H_2O)_6]^{2+}$ cations ($S = 2$) and $[FeBr_4]^-$ anions ($S = 5/2$), the latter ones are located on two crystallographically different sites. The thermal dependence of the magnetic susceptibility of **1** is shown in form of a $\chi_M T$ versus T plot (Fig. 3). The calculated $\chi_M T$ value is 17.9 emu K/mol per stoichiometric formula unit, with g (rad) = 2; g (Fe^{2+}) = 2.2 which is typical for HS Fe^{2+}; g (Fe^{3+}) = 2.06 [16]. This $\chi_M T$ value compares fairly well with the experimental $\chi_M T$ value at room temperature of 16.9 emu K/mol. With decreasing temperature, the $\chi_M T$ values decrease continuously, indicating overall antiferromagnetic interactions among these different paramagnetic centers. Clearly, the whole crystal structure is rather complex so that many different magnetic exchange pathways, extended in all three directions, are present. This situation

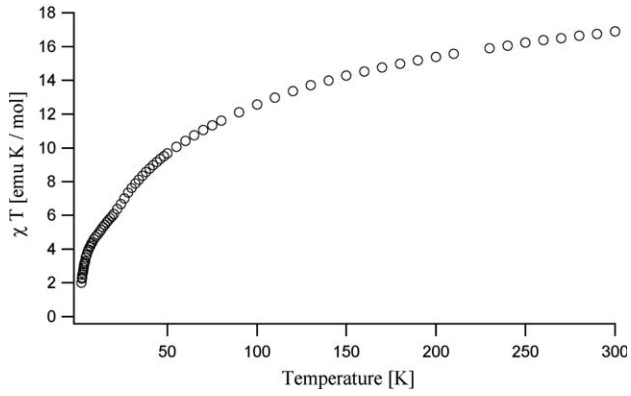

Fig. 3. Temperature dependence of $\chi_M T$ for compound **1**.

renders a meaningful analysis with the assignment of specific exchange coupling parameters as impossible. Additionally, there is no signature of a magnetically ordered phase down to 1.8 K.

4. Conclusions

A charge transfer salt (TCN-DBTTF)$[Fe(H_2O)_6][FeBr_4]_3$ (**1**) based on the new donor TCN-DBTTF was synthesized by electrocrystallization. In the crystal lattice, intermolecular CN···O interactions are observed rather than otherwise favorable CN···Br interactions. As a result of the specific crystal packing, the compound shows a low electrical conductivity in the order of 10^{-7} S cm^{-1} and the magnetic measurements exhibit overall antiferromagnetic exchange interactions among the three different spin carriers.

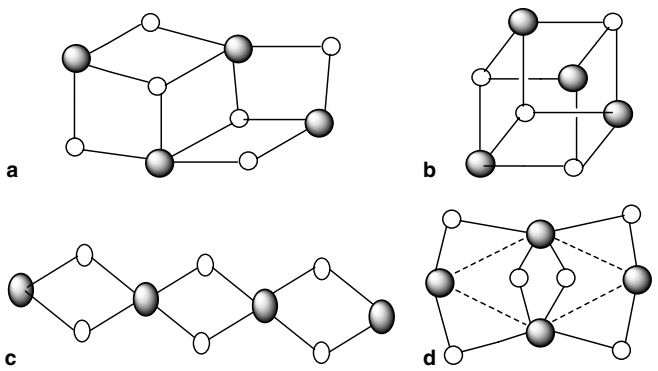

Scheme 1. (a) Dicubane-like; (b) cubane-like; (c) string; (d) rhomb-like.

of our knowledge, only one case doubly acetato-bridged dicubane Cu(II) complex with dpd-H has ever been documented, which is octanuclear [12].

2. Experimental

Caution: Perchlorate complexes of metal ions are potentially explosive. Only a small amount of material should be prepared and it should be handled with caution.

2.1. Synthesis

All chemicals were used as purchased with reagent grade. Infrared spectra were recorded on a Nicolet magna 750 FT-IR spectrophotometer using KBr pellets in the range of 400–4000 cm^{-1}. Elemental analyses were performed by the elemental analysis laboratories in our institute. UV–Vis spectra measurements were made at room temperature range from 330 to 1100 nm with Perkin–Elmer Lambda-35 UV/VIS spectrophotometer. Magnetic measurements for **1** were carried out on a PPMS60000 magnetometer.

2.1.1. [{Cu_4(dpd-H)$_4$(ClO_4)$_2$(H_2O)$_2$}(ClO_4)$_2$ · $2H_2O$] (*1*)

A 20 ml MeOH/H_2O solution (1:1, v/v) of $Cu(ClO_4)_2 \cdot 6H_2O$ (0.74 g, 2 mmol), di-2-pyridylketone (0.1843 g, 1 mmol) and 3-amino-1,2-propanediol (0.0936 g, 1 mmol) was refluxed for 1 h with stirred. The blue solution was left at ambient temperature for several days to obtain blue crystals. Yield: 34.2% (0.52 g) (based on dpk) (*Anal.* Calc. for $C_{44}H_{44}Cl_4Cu_4N_8O_{28}$: C, 34.57; H, 2.90; N 7.33. Found: C, 34.20; H, 3.07; N 7.25%). IR (KBr pellet, cm^{-1}): ν(OH) 3435, ν(C–O) 1607,ν(C=N, C=C) 1476, 1446, 1385, $\nu(ClO_4^-)$ 1084, 623.

2.1.2. [{Ni_4(dpd-H)$_4$(H_2O)$_4$}(ClO_4)$_4$ · $4H_2O$] (*2*)

Green crystals of **2** were obtained with the similar procedure to that of **1** except for the replacement of $Cu(ClO_4)_2 \cdot 6H_2O$ with $Ni(ClO_4)_2 \cdot 6H_2O$. Yield: 39.0% (0.61 g) (based on dpk) (*Anal.* Calc. for $C_{44}H_{52}Cl_4N_8Ni_4O_{32}$: C, 33.42; H, 3.31; N, 7.09. Found: C, 33.76; H, 3.32; N, 7.01%). IR (KBr pellet, cm^{-1}): ν(OH) 3434, ν(C–O) 1608, ν(C=N, C=C) 1475, 1443, 1384, $\nu(ClO_4^-)$ 1087, 626.

2.1.3. [{Ni_4(dpd-H)$_4$(OAc)$_2$(H_2O)$_2$}(ClO_4)$_2$] (*3*)

A 20 ml methanol solution of $Ni(OAc)_2 \cdot 4H_2O$ (0.4980 g, 2 mmol) and di-2-pyridylketone (0.1846 g, 1 mmol) was refluxed for 1 h with stirred. After cooled, $NaClO_4 \cdot H_2O$ (0.42 g, 3 mmol) was added. And the green solution was left at ambient temperature for several days to obtain green block crystals. Yield: 46.9% (0.65 g) (based on dpk) (*Anal.* Calc. for $C_{48}H_{46}Cl_2N_8Ni_4O_{22}$: C,41.40; H, 3.33; N, 8.05. Found: C, 41.03; H, 3.34; N, 7.92%) IR (KBr pellet, cm^{-1}): ν(OH) 3436, ν(C–O) 1605, $\nu(COO^-)$ 1573, 1337, ν(C=N, C=C) 1473, 1442, 1385, $\nu(ClO_4^-)$ 1089, 624.

2.2. X-ray crystallography

X-ray single crystal data were collected at 130.15 K (for **1**) and 293(2) K (for **3**) on a MERCURY-CCD area-detector diffractometer, and at 293(2) K on a Simens SMART-CCD area-detector diffractometer (for **2**) with Mo Kα radiation ($\lambda = 0.71073$ Å). Data reductions and absorption corrections of **1** and**3** were made with Multi-scan type, while those of **2** were performed with SMART and SADABS software. These structures were solved by direct methods and were refined by full matrix least-squares methods using SHELXL-97 [13]. Anisotropic displacement parameters were refined for all non-hydrogen atoms. And hydrogen atoms were added in the riding model and not refined. The crystal data and refinement details for the three complexes are listed in Table 1. Selected bond distances and bond angles are listed in Tables S1–3 (supplementary).

3. Results and discussion

3.1. Synthesis

Our previous attempt to prepare **1** and **2** without the use of 3-amino-1,2-propandiol was unsuccessful, and mononuclear Cu(II) and Ni(II) complexes [14,15] were obtained. Hence we infer that 3-amino-1,2-propandiol may act as a buffer in the course of the present reaction.

3.2. Description of the crystal structure of the complex *1*

The complex **1** is made up of the cation $[Cu_4(dpd\text{-}H)_4(ClO_4)_2(H_2O)_2]^{2+}$ (Fig. 1), two isolated ClO_4^- and two free H_2O. Within each $[Cu_4(dpd\text{-}H)_4(ClO_4)_2(H_2O)_2]^{2+}$, the cubane-like Cu_4O_4 core is dominated, constructed by four copper atoms and four oxygen atoms from four dpd-H ligands each at alternating corners. Four Cu(II) atoms are not crystallographically equivalent but all in distorted $[CuN_2O_4]$ octahedral geometries. Each Cu(II) atom is surrounded by two nitrogen donors and two oxygen atoms from dpd-H with the Cu–N and Cu–O bond lengths

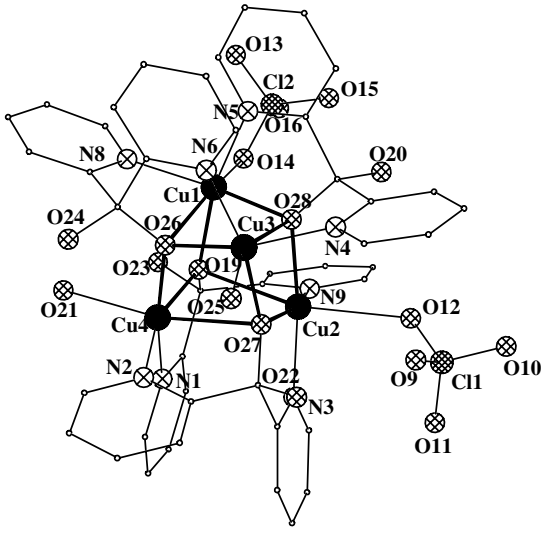

Fig. 1. View of the cation $[Cu_4(dpd\text{-}H)_4(ClO_4)_2(H_2O)_2]^{2+}$ in **1**. Hydrogen atoms are omitted for clarity.

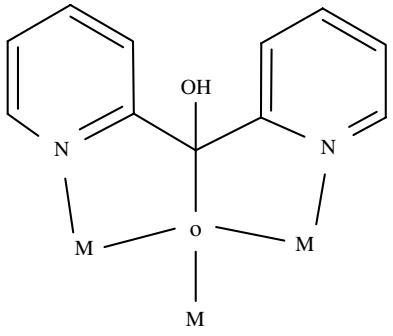
in the range of 1.970(3)–2.030(3) and 1.934(2)–2.010(2) Å. In addition, Cu(1) and Cu(2) atoms are weakly bonded to the other two oxygen atoms from dpd-H and ClO_4^- (Cu–O = 2.405(3)–2.503(3) Å) while Cu(3) and Cu(4) atoms are weakly coordinated by the other two oxygen atoms from dpd-H and H_2O (Cu–O = 2.246(3)–2.582(3) Å). Obviously, the axial bond lengths are longer than the corresponding equatorial bond distances, which may be ascribed to Jahn–Teller distortion. As is shown in Scheme 2, all dpd-H ligands adopt the same coordination way (μ_3:η_1:η_3:η_1), which are also observed in other compounds [7,16]. Each ligand uses one deprotonated alkoxo oxygen atom to bridge three metal atoms and another alkoxo oxygen atom remains protonated and unbound to metal ions. Furthermore, each ligand also uses two nitrogen atoms of the pyridine rings to coordinate to two Cu(II)



Scheme 2.

ions, respectively. The Cu···Cu separations are about 3.129–3.307 Å. In addition, there is a complex hydrogen-bonding network among H_2O molecules, the ClO_4^- counterion and hydroxyl group of dpd-H, with the distances in the range of about 2.684–3.056 Å.

To the best of our knowledge, only two compounds containing tetranuclear Cu(II) and dpd-H which show zigzag chain and rhombic coplanar structures have been reported [17]. In addition, one octanuclear complex $[Cu_8(dpk \cdot OH)_8(O_2CMe)_4](ClO_4)_4 \cdot 9H_2O$ have been reported, which presents the configuration two tetranuclear cubane cores connected by acetate [12].

3.3. Description of the crystal structure of the complexes 2 and 3

The structures of **2** and **3** are almost similar (Figs. 2 and 3), a little difference being that complex **2** contain lattice water molecules besides containing isolated perchlorate anions. Both of them contain the cubane-type $Ni_4(dpd\text{-}H)_4$ species. Each Ni_4O_4 cubane core is constructed by four nickel atoms and four oxygen atoms from four dpd-H ligands at alternating corners. All Ni(II) atoms are in distorted octahedral geometries. Ni1 and Ni1A atoms in **2** (A: $-x+1,\ y,\ -z+1/2$) or **3** (A: $-x+1,\ y,\ -z+3/2$) are coordinated by three nitrogen donors and three oxygen atoms from different dpd-H ligands, while the Ni2 and Ni2A centers are enclosed by one nitrogen donor from one dpd-H ligand and five oxygen atoms. Besides three μ_3-alkoxo oxygen atoms from three different dpd-H ligands and one oxygen atom from one H_2O molecule, the fifth oxygen atom is from one H_2O molecule and one monodentate CH_3COO^- group for **2** and **3**, respectively. Similar to those in **1**, another oxygen atom of each dpd-H ligand remains protonated and unbound to metal ions, and each dpd-H ligand adopts μ_3:η_1:η_3:η_1 coordination way. The Ni–N bond lengths are about 2.029–2.089 Å, while Ni–O bond distances are about 2.002–2.131 Å, of which Ni–O(CH_3COO^-) distances are shorter than Ni–O(H_2O) and Ni–O(dpd-H). The Ni···Ni separations are about 3.031–3.271 Å. Compound **2** exhibits a complex hydrogen-bonding network among the water molecules, ClO_4^- counterion and hydroxyl group of dpd-H (O···O 2.634–3.044 Å). And in compound **3**, there is also a complex hydrogen-bonding network among the water molecules, ClO_4^- counterion, hydroxyl group of dpd-H and CH_3COO^- group (O···O 2.637–3.040 Å). Thus, the present cubane-type $Ni_4(dpd\text{-}H)_4$ skeleton resembles that found in $[\{Ni_4(dpd\text{-}H)_4(OAc)_3(H_2O)\}(ClO_4) \cdot 8.25H_2O]$ and $[Ni_4(OAc)_2\{N(CN)_2\}_2(dpd\text{-}H)_4] \cdot 10H_2O$ [7a,7b,7c].

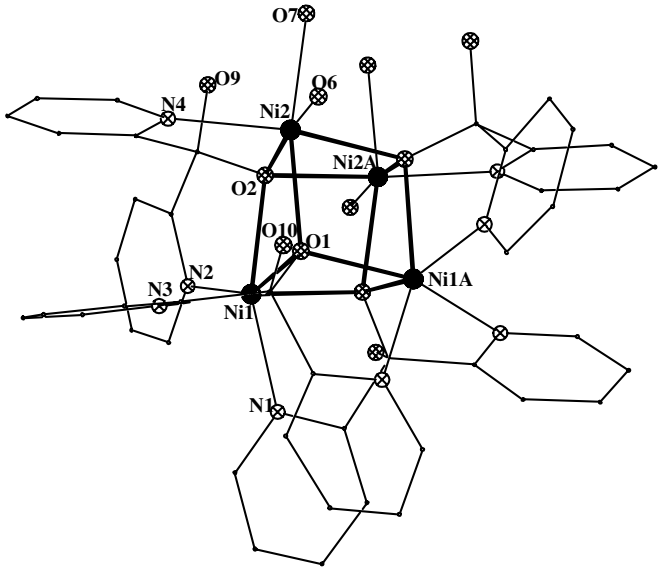


Fig. 2. View of the cation $[Ni_4(dpd\text{-}H)_4(H_2O)_4]^{2+}$ in **2**. (Symmetry codes: (A): $-x+1,\ y,\ -z+1/2$). Hydrogen atoms are omitted for clarity.

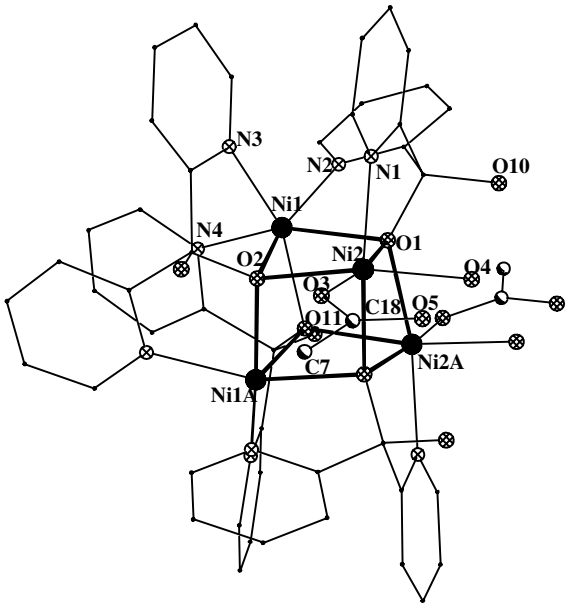

Fig. 3. View of the cation $[Ni_4(dpd\text{-}H)_4(OAc)_2(H_2O)_2]^{2+}$ in **3** (Symmetry codes: (A): $-x+1,\ y,\ -z+3/2$). Hydrogen atoms are omitted for clarity.

3.4. IR and UV/Vis spectroscopy

IR spectra of **1**, **2** and **3** are similar for their structural similarity. We analyze them with **3** as an example. The peak at about 1605 cm^{-1} is corresponding to single C–O bond from the ligand dpd-H. Additionally, the peaks at about 1473, 1442, 1385 cm^{-1} are attributed to the pyridyl ring stretching, 683 cm^{-1} for the pyridyl ring C–H in-plane vibration and 755, 770, 804 cm^{-1} for the pyridyl ring C–H out-of-plane vibration. In contrast with **1** and **2**, **3** have a CH_3COO^- group. Because two C–O bonds occur resonance, the typical strong C=O stretching vibration disappear. So the two spectral bands at about 1573 and 1337 cm^{-1} are, respectively, from asymmetrical and symmetrical vibrations of the COO^- group.

The UV/Vis spectroscopies of **1**, **2** and **3** are also similar. The $\pi \rightarrow \pi^*$ transition of **1**, **2** and **3** occur at 209, 210 and 216 nm, respectively, while the $n \rightarrow \pi^*$ transition of them appear at 264, 264 and 261 nm, respectively.

3.5. Magnetic property of *1*

Temperature dependent magnetic susceptibility of **1** was measured in the range of 2–300 K at 10 kG and shown in Fig. 4. At room temperature, the $\chi_m T$ values per Cu_4 unit is 1.66 $cm^3\,mol^{-1}\,K$, compared with the expected values (1.5 $cm^3\,mol^{-1}\,K$) for four spin only Cu^{II} ions ($S = 1/2$, $g = 2$). Upon cooling, **1** shows a continuous decreasing of $\chi_m T$, suggesting an overall antiferromagnetic coupling, as confirmed by the negative Weiss constant (−20.8 K).

Taking into account the compound topology, we group into two exchange parameters J and J' ($J = J_{13} = J_{24}$, $J' = J_{12} = J_{14} = J_{23} = J_{34}$). The corresponding network of exchange pathways is shown in Scheme 3. The magnetic behavior of such cubane-like cluster can be described by the Hamiltonian given in Eq. (1):

$$H = -J(S_1S_3 + S_2S_4) - J'(S_1S_2 + S_1S_4 + S_2S_3 + S_3S_4). \quad (1)$$

Which leads to Eq. (2):

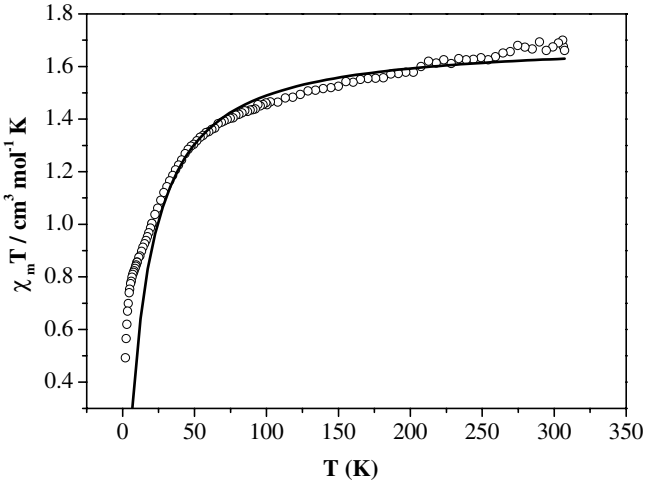

Fig. 4. Plot of $\chi_m T$ vs. T for **1**. Solid line, fit of Eq. (2); ∘, experimental data.

The best fit was obtain with $J_1 = -6.4\ cm^{-1}$, $J_2 = -10.9\ cm^{-1}$, $g = 2.119$, $\theta = 1.4$ K and $R = 4 \times 10^{-5}$. The above two results demonstrate antiferromagnetic coupling of **1**.

Strong dependence of the exchange integral magnitude versus the Cu–O–Cu angle is well documented in dimeric dibridged complexes. The exchange interaction is ferromagnetic for the Cu–O–Cu angles less than 97° and antiferromagnetic for larger angles [18]. However, the interaction within our tetranuclear Cu(II) complex is

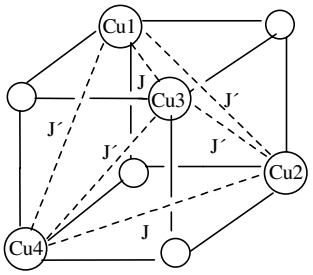
$$\chi = \frac{2Ng^2\beta^2}{kT} \frac{2\exp(J/kT) + \exp[(2J - J')/kT] + 5\exp[(2J + J')/kT]}{1 + 6\exp(J/kT) + \exp[(2J - 2J')/kT] + 3\exp[(2J - J')/kT] + 5\exp[(2J + J')/kT]}. \quad (2)$$

The fit was reached with the parameters $J = J' = -12.1\ cm^{-1}$, $g = 2.13$ and $R = 9.2 \times 10^{-4}$. In fact, adopting one exchange parameter J can obtain the similar results.

In addition, we also adopt another model to fit the curve. (Fig. 5) Without regard to the weaker Cu–O (Cu(4)–O(27), Cu(2)–O(19), Cu(3)–O(28)) interaction, we take on the compound exchange pathways as butterfly topology, and simplify them to two exchange parameters J_1 and J_2 ($J_1 = J_{12} = J_{23} = J_{34} = J_{14}$, $J_2 = J_{13}$), as is shown in Scheme 4. The exchange interaction can be described by the reduced Hamiltonian

$$H = -J_1(S_1S_2 + S_2S_3 + S_3S_4 + S_1S_4) - J_2(S_1S_3). \quad (3)$$

Hence, the 2–300 K experimental data were fitted next, by using the following resulting theoretical expression for the magnetic susceptibility:



Scheme 3.

$$\chi = \frac{Ng^2\beta^2}{3k(T-\theta)} \times \frac{30[\exp(2J_1 + 0.5J_2)/kT] + 6[\exp(-2J_1 + 0.5J_2)/kT] + 6\exp(0.5J_2/kT) + 6\exp(-1.5J_2/kT)}{5\exp[(2J_1 + 0.5J_2)/kT] + 3\exp[(-2J_1 + 0.5J_2)/kT] + \exp[(-4J_1 + 0.5J_2)/kT] + 3\exp(0.5J_2/kT) + 4\exp(-1.5J_2/kT)}. \quad (4)$$

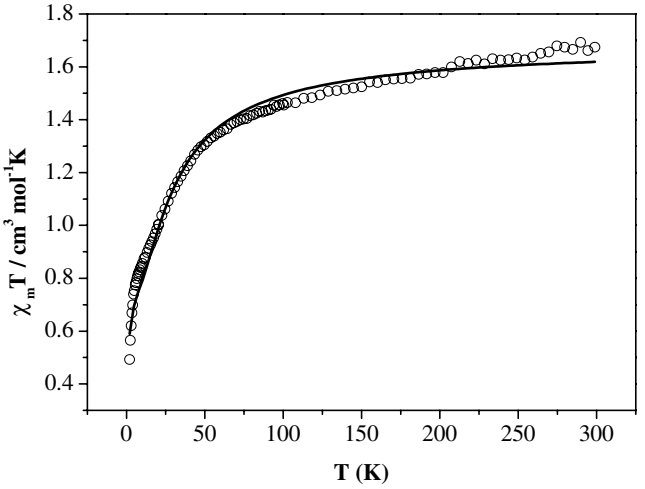


Fig. 5. Plot of $\chi_m T$ vs. T for **1**. Solid line, fit of Eq. (4); ○, experimental data.

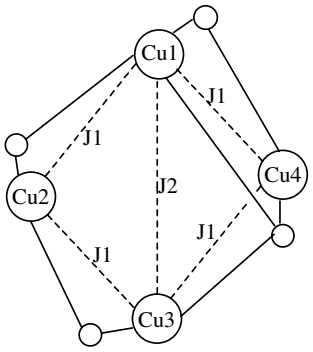

Scheme 4.

antiferromagnetic with the Cu–O–Cu angles in the range of 86.2–112.1°. It is reported in the literature that the ferromagnetic interaction occurs in the tetranuclear copper system with the Cu–O–Cu angles of 139.2–140.5° [19] while the antiferromagnetic interaction presents with Cu–O–Cu angles of 95.7–103.4° [20]. Apparently, the structure–exchange-interactions are complicated in the tetranuclear copper system and different from those in the dimeric copper complexes.

4. Conclusion

In summary, we have prepared three new tetranuclear cubane-like complexes constructed from multidentate ligand dpd-H. These compounds were characterized with X-ray single crystal diffraction as well as elemental analysis, IR and UV/Vis spectroscopy. The magnetic property of **1** was also studied.

5. Supplementary material

CCDC numbers 277929, 277930 and 277931 are for compounds **1–3**, respectively. behaviour of alkali metal amides derived from three commonly used chiral secondary amines; *S*-(α-methylbenzyl)benzylamine, *R*,*R*-bis-α-methylbenzylamine, and *S*-*N*-(α-methylbenzyl)allylamine, shown in Fig. 1 [21,22]. The lithium complexes are known to be extremely useful in enantioselective deprotonation reactions with prochiral ketones and epoxides, and in Michael addition reactions to α,β-unsaturated esters, producing high ee values [23–40]. Since both reactivity and structure are inextricably linked with selectivity then it is of interest to exam the structures of the chiral amine adducts of Me_3M, the aluminium amides formed from thermal elimination of MeH from these complexes and ultimately the complexes formed on reaction with unsaturated substrates. This is key to the future rational design of highly effective and selective reagents.

As the first part of this study we now report the synthesis and solid state characterisation of (*S*,*R*)-[$Me_3Al \cdot HN(CHMePh)(CH_2Ph)$] (**1**), [(*S*,*R*)-$Me_3Ga \cdot HN(CHMePh)(CH_2Ph)$] (**2**), $Me_3Al \cdot HN(CHMePh)_2$ (**3**), $Me_3Ga \cdot HN(CHMePh)_2$ (**4**), (*S*,*S*)-]$Me_3Al \cdot HN(CHMePh)(CH_2CH{=}CH_2)$] (**5**) and (*S*,*S*)-[$Me_3Ga \cdot HN(CHMePh)(CH_2CH{=}CH_2)$] (**6**), as well as the unusual solution behaviour observed for **1** in comparison with its gallium analogue **2**, and with the other complexes.

2. Results and discussion

2.1. Synthesis

Under inert conditions, each amine was added slowly to a hexane solution of Me_3M (M = Al, Ga) at −78 °C and allowed to warm slowly to room temperature. Following reduction of the solvent in vacuo, colourless crystals suitable for X-ray diffraction were readily obtained at −20 °C over 48 h. The crystals were all isolated and washed with cold hexane prior to further analysis. Whilst compounds **1**–**6** are stable at room temperature under inert atmosphere, crystals of the Me_3Ga adduct incorporating (*S*)-*N*-(α-methylbenzyl)allylamine (**6**) are highly soluble in trace amounts of solvent and have a melting point below room temperature. Due to the unusual NMR data obtained for complex **1** it was synthesised four times under differing conditions: (i) addition of amine to Me_3Al at −78 °C; (ii) addition of amine to Me_3Al at room temperature; (iii) addition of Me_3Al to amine at −78 °C, and, (iv) addition of Me_3Al to amine at room temperature. Irrespective of the mode of synthesis of the colourless crystals, similar NMR spectra and crystal structures were obtained.

2.2. NMR analysis

NMR data were collected on all six compounds in C_6D_6 at room temperature. While compounds **2**–**6** produced ^1H spectra with expected chemical shift patterns compound **1** gave an interesting spectrum of very broad signals which seemed to indicate the presence of two complexes in a ratio of approximately 2:1. The benzylic CH_2 protons in **1** are also diastereotopic appearing at δ3.80 and δ3.44, which is in contrast to that of the Ga analogue, **2**, for which there is only one signal attributable to these protons. Also, all the signals in the spectrum of **2** are significantly sharper, as are those of all the other complexes **3**–**6**. Indeed this was observed for four sets of crystals of **1**, all synthesised under different conditions as described above. We fully expected the two possible diastereomers for all complexes to be present in a 1:1 ratio expecting little discrimination over the way the N–Al dative bond formed and little restriction to rotation around the C–N bonds, and therefore, our first assumption was that the spectrum represented the possibility that there was an equilibrium between four and five coordinate Al species, [$Me_3Al \cdot L$] and [$Me_3Al \cdot L_2$], and free $AlMe_3$. However, there was no evidence in either the ^1H or ^{13}C spectra of differing AlMe signals. The ^{13}C NMR though also revealed two possible isomers. The second possibility was that there had been hydrolysis and that we were seeing both free and bound amine. However, this was ruled out by successive NMR measurements which showed a similar pattern for **1** but no sign of this occurring for all the other complexes. To examine this phenomenon more closely, variable temperature spectra were obtained in d_8-toluene on all complexes. While the others are unremarkable the spectra of **1** resolved into two species as the temperature was lowered and a comparison of **1** and **2** are shown in Figs. 2 and 3, respectively. That two distinct AlMe signals are now apparent at −60 °C suggests it could be possible that what is being observed is an equilibrium between the four coordinate monomeric species, [$Me_3Al \cdot L$], and the Me bridged dimer, [$Me_3Al \cdot L]_2$; an equilibrium which is not common for Ga given its lower Lewis acidity and reluctance to form five coordinate complexes. Such an equilibrium would give four and five coordinate Al centres, however, ^{27}Al NMR seemed to indicate that by far the only complex present in any substantial amount contains four coordinate Al, though the signal is quite broad (at −60 °C, δ 71.7, half-height line width 3448 Hz). Also, there was almost no change in the chemical shift value over the temperature range 30 to −60 °C, suggesting that the system is far from dynamic

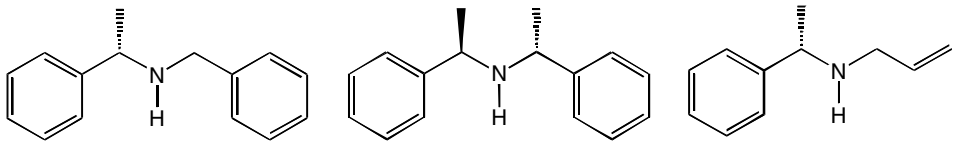

Fig. 1. Three common chiral secondary amines used in this study: *S*-(α-methylbenzyl)benzylamine, *R*,*R*-bis-α-methylbenzylamine, and *S*-*N*-(α-methylbenzyl)allylamine.

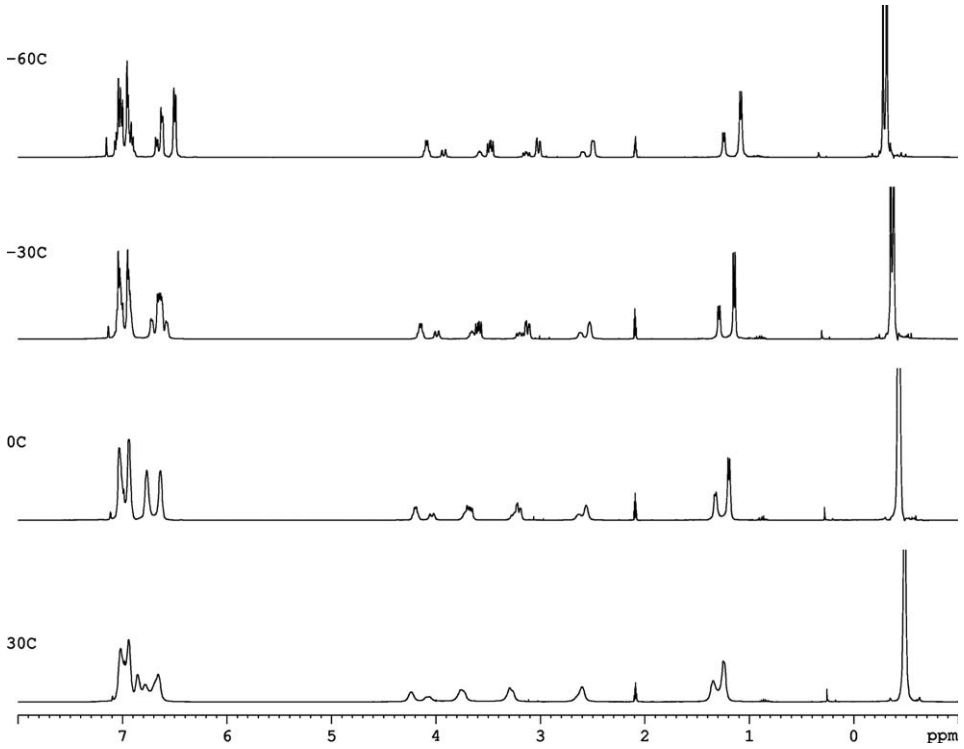

Fig. 2. Variable temperature ^{1}H NMR spectra in d_8-toluene of $Me_3Al \cdot HN(CHMePh)(CH_2Ph)$ (**1**).

[41]. The other alternative is, of course, that the two diastereomers (*S*,*S* and *S*,*R*) are quite distinct and form in relative amounts of 2:1. Why this should be the case for **1** and not for the other complexes, which seems to negate an argument involving the relative coordination abilities of Al over Ga, we have, as yet, no explanation. Some exploratory ab initio calculations on the two diastereomers revealed the *S*,*R* conformation to be more stable than the *S*,*S* but by only 11 kcal mol^{-1} and it would be difficult to see this energy difference as significant. In assuming an

equilibrium situation sample **1** was also heated to 80 °C to induce possible rearrangement of the two species through inversion at the N centre before being allowed to cool again to 30 °C. However, no difference in the respective amounts of the two species was observable.

Despite this a comparison of the NMR data for this series of chiral amine adducts dissolved in d_6-benzene is useful as it gives insight into the influence of factors such as increasing steric demands by the amino group and the nature of the metal on the chemical shift values. This data is listed in Table 1. Information obtained on compounds **1**–**6** is compared with that already reported for the $AlMe_3$ and $GaMe_3$ adducts of the dibenzylamine ligand, **7** and **8**, respectively [16,17].

With the exception of **4**, all ^1H and ^{13}C chemical shift values for the methyl groups attached to the metal centre are upfield from TMS and appear dependant on both the amine moiety and the metal. It is clear that the Ga adducts display higher chemical shift values than each of the corresponding Al compounds. Moreover, each of the chiral adducts experiences greater deshielding than that shown by dibenzylamine in **7** and **8** resulting in a slight downfield shift in both the ^1H and ^{13}C methyl peaks. This pattern is consistent in both the Al and Ga adduct series and suggests that increasing steric bulk around the nitrogen centre affects the chemical shift positioning. Such an analysis concords with previous studies [16,17] which hypothesise that such shift changes may be due to the increasing *p* character of the M–C bond as the C–M–C bond angles decrease to accommodate larger amine ligands. In particular, ^{13}C shifts are known to be very sensitive to steric effects. This is evidenced by the consistent increase in chemical shift from the less hindered **7** and **8** (δ −8.06 ppm, δ −5.10 ppm) to the more bulky structures of **1** and **2** (δ −6.18 ppm, δ −3.57 ppm) and **3** and **4** (δ −5.51 ppm, δ 0.46 ppm). Notably, the replacement of one methyl-benzyl group with a less bulky allyl component in **5** and **6** appears to reduce the steric effects thereby lowering the chemical shift (δ −6.82 ppm, δ −3.84 ppm).

2.3. Structural analysis

Each of the crystal structures obtained for **1**–**6** were found to be monomeric and crystallise under an orthorhombic crystal system in the $P2_12_12_1$ space group. Data on complex **1** was collected four times on each occasion producing the (*S*,*R*) diastereomer. Consequentially, a direct structural comparison of these adducts is likely to produce meaningful results. The molecular structures of **1**, **4** and **5** are shown in Figs. 4–6. Table 2 contains a summary of the crystallographic data for **1**–**6** whilst Table 3 provides

Table 1
Me_3M ^1H and ^{13}C data for the Me_3-M-amine adducts of **1**–**8** (M = Al, Ga)

a listing of selected bond lengths and angles for **1**–**6** with comparison to **7** and **8**.

All six structures are comparable with those of the dibenzylamine adducts previously reported for Me_3Al, **7**, and Me_3Ga, **8**. The structural solutions show the nitrogen on each amine to be bound to the *tris*-alkylated metal centre giving each metal a highly distorted tetrahedral geometry. The bond lengths between the metal and N donors (av. 2.064 Å, Al adducts; 2.160 Å, Ga adducts) are typical of these adduct complexes (ca. ~2.0 Å) [16,17] containing datively bonded nitrogen and metal atoms. As expected, the M–N bond distances of each amine adduct increase by approximately 0.1 Å with the heavier metal. The greater charge to radius ratio about the Ga nucleus and therefore weaker polarisability when compared to Al explains this trend. This hypothesis also serves to support the greater ^{13}C and ^{1}H NMR chemical shifts downfield of the free amine in the Me_3Ga adducts over the Me_3Al congeners.

The C–M–C angles for the Al adducts are more acute than those found for the analogous Ga structure which can be attributed to the greater size of the Ga(III) metal centre. The greater ionic radius provides an improved ability to reduce any geometric distortion caused by the proximity of the amine.

Increased steric hindrance created by the addition of α-methyl groups about the N centre causes a slight elongation of the M–N bond, as would be expected, though once established there is only a minimal effect on the bond distance whether there is one or two methyl groups or whether there is one or two benzyl groups. Thus, the N–Al bond distances for **1**, **3** and **5** (2.065(1), 2.068(1) and 2.066(2) Å, respectively) are longer than that observed in **7** (2.058(2) Å), though are strikingly similar to each other. The same pattern is observed for the N–Ga bond distances in **2**, **4** and **8** (2.162(1), 2.168(2) and 2.151(8) Å, respectively). So, even in **5** where one bulky benzyl group is replaced by a more flexible and less sterically demanding allyl tail there is no significant difference in bond length. Interestingly, there were no intra- or intermolecular electrostatic contacts between the allyl groups and the Al metal centres.

It would be expected that as methyl groups are added to the benzylic carbons on dibenzylamine there would be an increase in the relevant M–N–C bond angles. There would be firstly an observable decrease in symmetry when one is added (as in **1**, **2** and in **5**, **6** by analogy) and a re-establishment of higher symmetry on addition of two (as in **3** and **4**).

Table 4
Non-bonding methyl–metal distances (Å) for **1**–**6**

M = Al, Ga	1	2	3	4	5	6
C11–M	3.518	3.565	3.326	3.384	3.250	3.305
C21–M			3.732	3.790		

However, this is not the case. Within **7** and **8** the two M–N–C internal angles are different though they show an identical pattern to each other (cf. 114.7(2)°, 111.4(2)° in **7** and 114.3(2)° and 111.3(2)° in **8**). The marginal effect evident here on changing the metal is true for all the compounds under examination. In **1** and **2**, despite the introduction of the methyl group, the bond angles actually become closer (115.6(1)°, 113.6(1)° in **1** and 114.9°, 113.4(1)° in **2**), which contrasts with **5** in which a more substantial asymmetry in observed (117.9(1)°, 112.2(1)°) These values are closer to the angles observed in **3** and **4** which rather than being more symmetrical around the N–M bond are dramatically different (121.9(1)°, 112.4(1)° in **3** and 121.9(1)°, 112.1(1)° in **4**). The same pattern is also observed in the methyl–metal distances (Table 4).

One further point of interest in the structures of **3** and **4** is the staggered orientation of the benzylmethyl groups. These are arranged such that both methyl groups are located on the same side of the molecule though there is by necessity a positional interchange of Ph and H on one moiety. The Me groups in Me_3M are then positioned in the most sterically favourable orientation between the benzylic methyls. However, this is not completely symmetrical and the closest Me···Me interactions, as defined by the dihedral angles for C21(11)–C20(10)–M–C2, are 18° and 35.7° in **3** and 15° and 35.6° in **4**. This gives some indication of why there are significant differences in the C–N–M angles described above. This staggered orientation of the benzylmethyl groups is not unique and has been observed in other crystallographically characterised compounds which contain the bis-(α-methylbenzyl)amido moiety [42–46].

3. Conclusion

We have synthesised and structurally characterised, by NMR and X-ray diffraction, six chiral amine complexes of Me_3Al and Me_3Ga and demonstrated that in solid state they are all monomeric and found in the same space group, $P2_12_12_1$. The Me_3Al complex of (PhMeCH)($PhCH_2$)NH appears to form two distinct isomers in solution which is in contrast to the analogous Ga complex or other Al complexes studied. Whether this is the formation of two different distereoisomers has not been definitively answered but does not appear to result from varying coordination environments at the Al centre or hydrolysis. In general, increased steric effects caused by the presence of Me groups on the benzylic carbons of the amine causes a downfield shift in observed ^1H and ^{13}C chemical shift values of the Me groups in the alkylmetal moiety. The C_2 symmetrical amine $(PhMeCH)_2NH$ produces a structure which has both methyl groups on the amine located on the same side of the molecule but actually shows a reduced symmetry, with regards to the bond angles at the M–N bond, in comparison with the complexes derived from the less symmetrical amines, (PhMeCH)($PhCH_2$)NH and (PhMeCH)($CH_2CH{=}CH_2$)NH.

4. Experimental

4.1. General procedures

Owing to the highly air and moisture sensitive nature of the compounds investigated, syntheses and manipulation of all adducts were performed under Argon (CIG, high purity) through the use of standard Schlenk, vacuum line and dry box techniques. Amine reagents were dried and stored over molecular sieves whilst all solvents were dried over a NaK alloy, distilled under an atmosphere of nitrogen and stored over molecular sieves. Me_3Al and Me_3Ga, as neat liquids, were purchased from Strem Chemicals Inc. and used without further purification. C, H and N

elemental analyses were obtained for all new compounds from Chemical and Micro Analytical Services Pty Ltd., Belmont, Australia. NMR spectra were obtained on Brucker DRX-300 spectrometer with chemical shifts referenced to deuterated benzene. Melting points were determined in sealed capillaries using a Thomas Hoover melting point apparatus and were not corrected.

4.2. Structure determinations

Crystallographic data were collected on an Enraf Nonius KappaCCD with graphite monochromated MoKα ($\lambda_0 = 0.71073$ Å) radiation. Single crystals of compounds **1**–**6** of suitable quality for X-ray analysis were mounted on a glass fibre under oil. Data were collected at 123 K and processed using Nonius Software. Structures were solved refined by full matrix least-squares on F^2 and expanded using direct methods with all calculations performed by the SHELXS 97 software [47] and XSEED interface [48]. All H atoms were placed in calculated positions (C–H 0.95 Å) and included in the final least-squares refinement. All other atoms were located and refined anisotropically.

4.3. General synthesis of $Me_3Al \cdot$ amine adducts

In a typical synthesis, 12.5 mmol of the respective amine was added dropwise to a solution of $AlMe_3$ (12.5 mmol, 0.9 g) in hexane (15 ml) at −78 °C. The colourless solution was allowed to stir and warm to room temperature before filtration and reduction of the solvent under vacuum. Large colourless crystals which were suitable for crystallographic determination formed at −20 °C within 48 h. The crystals were washed with cold hexane, dried in vacuo and stored in a dry box.

4.4. General synthesis of $Me_3Ga \cdot$ amine adducts

In a typical synthesis, 17.4 mmol of the respective amine was added drop-wise to a solution of $GaMe_3$ (2 ml) in hexane (20 ml) at −78 °C. The colourless solution was allowed to stir and warm to room temperature before filtration and reduction of 70% of the solvent under vacuum. Large colourless crystals formed at −20 °C over 48 h which were suitable for crystallographic determination. The crystals were washed with cold hexane, dried in vacuo and stored in a dry box. In the case of adduct **6**, the crystals are highly sensitive to traces of solvent and have a melting point close to room temperature. If the crystals are subjected to any reduction in pressure they immediately melt.

development of new complexes having the ability to target specific tissues and physiological states [4,5,16,17]. Some chelating agents have been developed for metal intoxication, e.g., water soluble phosphine chelating agents are designed for chelating metals such as technetium, rhenium, platinum and gold [18–20]. Many organic compounds used in medicine do not have a purely organic mode of action; some are activated or biotransformed by metal ions including metalloenzyme, others have a direct or indirect effect on metal ion metabolism [4].

The pharmacological activities of these metal compounds depend on the metal ion, its ligands and the structure of the compounds. These factors are responsible for reaching them at the proper target site in the body [21]. Biologically relevant metal complexes have several requirements in terms of their synthetic design. First, a biologically active metal complex should have a sufficiently high thermodynamic stability to deliver the metal to the active site. The metal-ligand binding should be hydrolytically stable. The kinetics with which the metal ion undergoes ligation or deligation reactions is of great importance. The molecular weight of the metal complex is also critical. The compounds of low molecular weight with neutral charge and some water solubility are soluble in almost any medium and may slip through biological membranes by passive diffusion [22].

This article focuses on the chemistry and some recent developments on metal complexes relating to gold antiarthritic, silver antimicrobial, vanadium antidiabetic and bismuth antiulcer, drugs.

2. Gold antiarthritic and antitumor agents

Gold(I) drugs, such as gold(I) thiomalate [myocrisin $(Autm)_n$], gold(I) thioglucose [solganol $(Autg)_n$] and auranofin [2,3,4,6-tetra-*o*-acetyl-1-thio-β-D-glucopyranosato-(S)-triethylphosphine gold(I)] have been successfully used over many years for the treatment of rheumatoid arthritis [11,12,23]. Besides treating arthritis, a large number of phosphine gold(I) complexes especially, auranofin and $[Au(dppe)_2]Cl$ (dppe = 1,2-bis(diphenylphosphino) ethane) are also known to exhibit promising antitumor properties [24–28]. $[Au(CN)_2]^-$ and gold(I) thiocyanate complexes have also been investigated as chemotherapeutic agents, including mainly studies of the antitumor and anti-HIV activity, and cytotoxicity of several tertiary phosphine complexes of AuSCN [27,29,30]. Structures of some important gold drugs with their trade names are shown in Fig. 1.

The crystal structure of auranofin shows that gold is linearly coordinated by the sulfur atom of thioglucose and phosphorus of Et_3P to give a discrete monomeric molecular species [31]. Gold thiolates are polymeric in nature [32–34] (by sulfur bridging) with a gold–gold interaction (Fig. 2).

Since gold(I) is extremely labile, these gold(I) complexes after their administration, undergo several ligand exchange reactions in the body with biofluids, cells and proteins [32,35–38]. In the body gold(I) binds to the SH and S–S

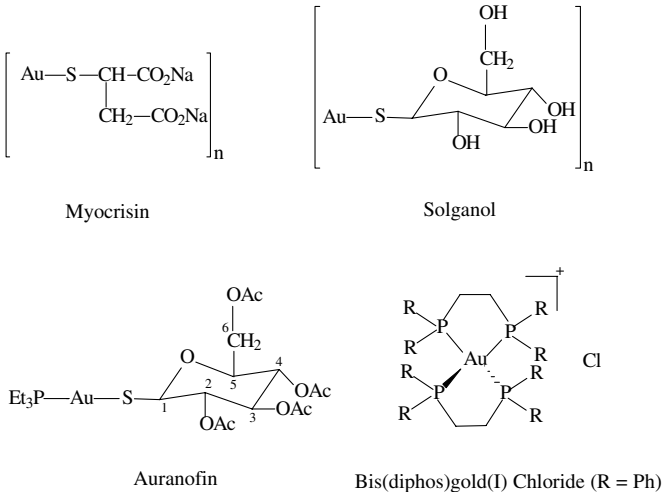

Fig. 1. Structures of some important gold drugs.

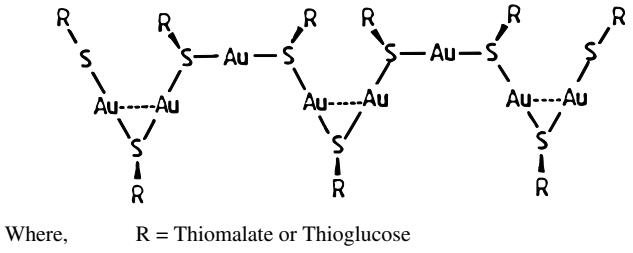

Fig. 2. Polymeric structure of gold(I) thiolates.

units of proteins such as blood serum albumin, which transport gold compounds throughout the body [39]. Gold(I) thiolates, (Gold(I), thiomalate and thioglucose) being polymers cannot enter red blood cells (RBCs) [40,41], while auranofin being monomeric does enter into RBCs immediately after its absorption and binds to glutathione (GSH) and hemoglobin (Hb) [42,43]. The RBCs, which contain thiol and thione ligands, e.g., GSH, Hb and ergothionine (ErS), can form stable complexes with gold drugs [44–46]. Gold has no known biological function in the body and hence there are no natural mechanisms for gold in the body. Therefore toxic effects may arise by the use of gold drugs [32].

Gold(I) thiolates because of their chain structure can undergo rapid ligand exchange reactions with the incoming ligands [11,12]. When excess thiols (RSH) such as cysteine and glutathione are added to $(Autm)_n$ polymers, they usually eject thiomalate by forming $[Au(thiolate)_2]^-$ species [47–49]. The kinetic analysis of these reactions shows that they proceed through associative mechanism. ^{13}C NMR studies suggest that thiols with the lowest pK_a values bind most strongly to gold(I) [47]. Thus binding of gold drugs with cysteine ($pK_a = 8.5$) will be thermodynamically more favored over glutathione ($pK_a = 8.9$). The phosphine gold(I) thiolate complexes undergo oxidation resulting in disulfide and tetragold clusters with bridging thiolate ligands [50].

$$2R_3PAuSR + Cp_2Fe^+ \rightarrow Cp_2Fe + 0.5(SR)_2 + 0.5[(R_3PAu)_2(\mu\text{-}SR)]_2^{2+} \quad (1)$$

The reaction of thiones such as ergothionine [46], Imt (imidazolidine-2-thione) [51], Diaz (1,3-diazinane-2-thione) [52] and mercaptopurines [53] with $(Autm)_n$ solution, usually results in the formation of a ternary complex of the type [>C=S–Au-tm], without ejecting thiomalate. Recently, it has been proposed that $(Autg)_n$ upon interaction with thiones does not form [>C=S–Au-tg], which suggests that the Au–S bond in $(Autg)_n$ is stronger compared to that in $(Autm)_n$ [54].

In auranofin ($Et_3PAuSATg$) both triethylphosphine and thioglucose ligands are strongly bound to gold(I), therefore, the ligand exchange reactions of auranofin are comparatively slower [32,42,44]. Several studies have shown that during the exchange reactions of auranofin ($Et_3PAuSATg$) with various biological sulfur containing ligands, e.g., bovine serum albumin and red blood cells, the $SATg^-$ ligand of auranofin is readily displaced while the gold bound phosphine is displaced slowly [36–38,44]. The presence of Et_3P bound to Au(I) appears to enhance the thiol exchange rates because of the high trans influence of phosphines [32].

Serum albumin is the most abundant plasma protein and principal extracellular source of sulfhydryl groups in the circulatory system [56]. Auranofin ($Et_3PAuSATg$) reacts rapidly with mercaptalbumin (AlbSH) via a ligand exchange reaction to form AlbS–Au–PEt_3 with gold binding to Cys-34 [36,57]

$$AlbSH + Et_3PAuSATg \rightleftarrows\rightleftarrows\rightleftarrows AlbS\text{–}Au\text{–}PEt_3 + HSATg \quad (2)$$

The albumin–gold complex, AlbS–Au–PEt_3 has been characterized by ^{31}P NMR [32,36,58], ^1H NMR [59,60] and chromatography [56,61]. The methyl and isopropyl analogues of auranofin ($R_3PAuSATg$; R = Me/*i*Pr) undergo similar reactions as (2) [62,63]. The AlbS–Au–PEt_3 complex further reacts with thiols leading to the oxidation of the phosphine moiety to Et_3PO [55]. The principal oxidants are albumin disulfide bonds and water is the major source of oxygen for the formation of Et_3PO [64].

$$AlbS\text{–}Au\text{–}PEt_3 + RSH \rightleftarrows\rightleftarrows\rightleftarrows AlbSH\text{–}Au\text{–}SR + Et_3PO + H^+ \quad (3)$$

The rate of phosphine oxidation increases as the affinity of thiol for gold increases, for example the ability of various thiols to cause Et_3PO formation from AlbS–Au–PEt_3 is; ATgSH > TgSH > GSH, as expected from their basicity [55]. The rate of formation of R_3PO decreases as the affinity of phosphine towards gold(I) in $R_3PAuSATg$ increases. For example, Me_3P is displaced to form the corresponding Me_3PO more readily than is Et_3P from auranofin, while *i*-Pr_3PO is formed only in small quantities from *i*-$Pr_3PAuSATg$ [62,63].

In addition to binding with mercaptalbumin, auranofin can also bind with disulfide sites of albumin as described by

$$AlbSSR + Et_3PAuSATg \rightleftarrows\rightleftarrows\rightleftarrows AlbSSR\text{–}Et_3PAuSATg \quad (4)$$

The AlbSSR–$Et_3PAuSATg$ complex is weakly bound and readily dissociates during separation by conventional gel chromatography [56]. Hemoglobin (Hb) and glutathione (GSH) in RBCs does not compete effectively with serum albumin for gold(I). The high affinity of albumin compared to Hb and GSH towards gold suggests that the accumulation/transfer of gold metabolites of auranofin in RBCs is thermodynamically not favored [43].

The kinetic analysis of the reaction between auranofin and serum albumin shows that the reaction is first order in albumin and zero order with respect to auranofin, with a rate constant, $k_1 = 3.4 \pm 0.3 \times 10^{-2}\ s^{-1}$ for Eq. (2). However, under physiological conditions, where auranofin concentration is low, 10–25 μM ([albumin] = ~400 μM) the reaction is suggested to follow the second order kinetics with a rate constant of $8 \pm 2 \times 10^2\ M^{-1}\ s^{-1}$ [56]. This high value of rate constant corresponding to a rapid ligand exchange reaction of auranofin with albumin explains the very strong affinity of Cys-34 for gold(I). A multistep mechanism was suggested [56] which can be explained as follow:

$$AlbSH \underset{k_{-1}}{\overset{k_1}{\rightleftharpoons}} {}^*AlbSH \quad (5)$$

$${}^*AlbSH + R_3PAuSATg \underset{k_{-2}}{\overset{k_2}{\rightleftharpoons}} {}^*AlbSAuPR_3 + AtgSH \quad (6)$$

$${}^*AlbSAuPR_3 \underset{k_{-3}}{\overset{k_3}{\rightleftharpoons}} AlbSAuPR_3 \quad (7)$$

where $^*AlbSH$ and $^*AlbSAuPR_3$ are conformationally altered albumin molecules in which cys-34 is accessible to other solute molecules. The rate law corresponding to this mechanism is:

$$\frac{d[AlbSAuPR_3]}{dt} = \frac{k_1k_2[R_3PAuSATg][AlbSH]}{k_{-1} + k_2[R_3PAuSATg]} = k_{obs}[AlbSH] \quad (8)$$

where

$$k_{obs} = \frac{k_1k_2[R_3PAuSATg]}{k_{-1} + k_2[R_3PAuSATg]}$$

In the interaction of auranofin with thiones such as thiourea and ergothionine, a simultaneous replacement of both Et_3P and $SATg^-$ ligands was observed, forming [>C=S–Au–SATg] and [Et_3P–Au–S=C<] type complexes [65,66]. These ligands are consequently oxidized to Et_3PO and $(SATg)_2$, respectively. Some of the liberated E_3P also reacts with thiones forming Et_3P–S=C< species. The Et_3PO resonance in ^{31}P NMR and $(SATg)_2$ resonances in ^{13}C NMR appeared after several (4–19) days showing that the exchange reactions are very slow. With thiols, the Et_3PO resonance was observed in the ^{31}P NMR after 24–72 h. A comparison of the rate of formation of Et_3PO from auranofin with various thiones demonstrates that their order of reactivity is Tu > Diaz > ErS > Imt [66].

The dicyanoaurate(I) anion, $[Au(CN)_2]^-$ has been identified as a common metabolite of the gold drugs in the blood and urine of chrysotherapy patients [67,68]. Model studies show that $[Au(CN)_2]^-$ is formed in vitro when CN^- reacts with the gold drugs or with the gold–protein metabolites such as the albumin–gold–triethylphosphine complex, AlbS–Au–PEt_3 [44,69]. As a result of this interaction, the intermediates $[RS–Au–CN]^-$ and $[Et_3P–Au–CN]$ are formed, which undergo disproportionation generating $[Au(CN)_2]^-$ that is readily taken up by red blood cells (RBCs) [44,69–73]. Several studies describe the formation of $[Au(CN)_2]^-$ by disproportionation of L–Au–CN complexes in solution [23,74–78] according to the following equilibrium;

$$2\,[L–Au–CN] \rightleftarrows\rightleftarrows\rightleftarrows [AuL_2]^+ + [Au(CN)_2]^- \quad (9)$$

Although the concentration of cyanide in RBCs is very low (0.3–1 μM) [79], the very large formation constant of $[Au(CN)_2]^-$ ($\log\beta = 36$) [80] favors its formation. Cyanide is produced in the body by oxidation of SCN^- by the enzyme myeloperoxidase in polymorphonuclear leukocytes [70,71]. The formation of aurocyanide is dependent on thiocyanate and occurs both by the myeloperoxidase dependent oxidation of thiocyanate and by a secondary reaction of hypochlorous acid with thiocyanate [71]. The aurocyanide formed inhibits the oxidative burst of polymorphonuclear leukocytes and inhibition of the oxidative burst of PMN may decrease the progression of the arthritis disease [71,81]. The level of $[Au(CN)_2]^-$ is higher for smokers than for nonsmokers because of inhalation of HCN from tobacco smoke [82,83]. Thus cyanide acts as a shuttle to carry gold into red blood cells, because of inhalation of HCN from tobacco smoke [84]. The most convincing mechanism by which $[Au(CN)_2]^-$ is transported through the cell membrane is the one, in which $[Au(CN)_2]^-$ undergoes ligand exchange reactions to bind to sulfhydryl groups immobilized on or in the membrane [79]. A series of such exchange reactions then passes the gold across the membrane and into the cells, where it may react with molecules containing sulfhydryl groups such as glutathione [79]. The displacement of CN^- from $[Au(CN)_2]^-$ by thiols in the model systems have already been studied [44], where the reaction may be written as:

$$[Au(CN)_2]^- + RSH \rightarrow [RSAuCN]^- + HCN \quad (10)$$

The replacement of cyanide from $[Au(CN)_2]^-$ depends on the strength of incoming ligand and stability of the resulting complex [23].

Gold compounds have been shown to possess antitumor and antibacterial activity, analogous to that of cisplatin [85]. In the light of close chemical similarity between the compounds of Pt and Au, there is a possibility that both may use DNA as a target site. Au(I) and Au(III) complexes can bind to DNA in vitro and can cleave DNA in cell culture [86]. Both gold(I) and gold(III) coordination compounds exhibit cytotoxic properties towards several tumor lines and both types of complexes are also effective on cells resistant to cisplatin [87–90]. In addition to a direct action on DNA, these complexes might also interact with other cellular sites and mitochondria appear as likely candidates [89]. Auranofin is cytotoxic to p388 leukaemia cells and inhibits DNA polymerases. Triethylphosphine gold(I) chloride reacts with DNA and inhibits oxidative phosphorylation [89]. $[Au(CN)_2]^-$ and Et_3PAuCN are also known to possess antitumor activity [27,33]. The tetrahedral chelate complex, $[Au(dppe)_2]Cl$ is active against certain types of cancer cells [91] and combination of $[Au(dppe)_2]Cl$ with cisplatin provided greater activity compared with either agent given alone [92]. Gold(I) complexes of bidentate pyridyl phosphines, $[Au(dpype)_2]Cl$ have shown promising in vitro and in vivo antitumor properties against B16 melanomia and p388 leukemia cells [93]. Another gold complex containing a monophosphine and a diphosphine instead of having both chelating phosphines, has been reported as potential antitumor agent [94]. Being structurally different, the linear two coordinate and tetrahedral gold(I) phosphine complexes may follow different mechanisms. Reactions with sulfhydryl groups are likely to be involved for auranofin and Et_3PAuCl, whereas lipophilic cationic properties of $[Au(dppe)_2]Cl$ and $[Au(dpype)_2]Cl$ may be important [89].

Auranofin and other gold complexes inhibited DNA replication but only at high concentrations compared with those that inhibited colony formation [95]. Et_3PAuCl appeared to interact with DNA under certain conditions (pH 9.5, borate buffer) but this compound did not produce DNA interstrand crosslinks and DNA breakage. The DNA reactivity of Et_3PAuCl was significantly less than that of cisplatin [96]. The high concentrations required for the cytotoxic effect suggested that DNA polymerases might not be a critical factor for the cytotoxic and antitumor actions of auranofin. Inhibition of DNA replication may have occurred via an interaction between auranofin and sulfhydryl groups on DNA polymerases [95]. Cisplatin-resistant cell lines with altered mitochondria were hypersensitive to auranofin and $[Au(dppe)_2]Cl$ along with a number of other antimitochondrial agents [87]. The results of various studies suggest that mitochondria are the primary intracellular targets for cytotoxic effects of auranofin and Et_3PAuCl [87,95–98].

The cationic tetrahedral complexes as $[Au(dppe)_2]^+$ are more stable with respect to ligand exchange reactions rather than the linear complexes and an important difference is that $[Au(dppe)_2]Cl$ is much less reactive towards thiols [99]. Lipophilicity of tetrahedral complexes plays a key role in determining their cellular uptake, cytotoxicity, host toxicity and in vivo antitumor activity [100]. In contrast to auranofin, inhibition of tumor colony formation by $[Au(dppe)_2]Cl$ was associated with preferential inhibition of protein synthesis compared to DNA and RNA synthesis and the production of DNA protein crosslinks [92]. Mitochondria were also suggested as potential targets involved in the antitumor and cytotoxic activity of $[Au(dppe)_2]Cl$.

$[Au(dppe)_2]Cl$ induced a rapid dissipation of the inner mitochondrial membrane potential, increased mitochondrial respiration, mitochondrial swelling and increased permeability of the inner membrane to cations and protons in isolated mitochondria [87,89,101].

In mitochondria, thioredoxin reductase appears as very specific target and both gold(I) and gold(III) complexes are highly specific inhibitors of mitochondrial thioredoxin reductase [90]. Thioredoxin reductase is a selenium enzyme with a selenol group present in the active site at the carboxy terminus of the enzyme [102]. Gold compounds preferentially interact with this site since selenol displays a greater affinity towards heavy metals [103]. Glutathione reductase, a protein, structurally and functionally closed to thioredoxin reductase but lacking selenol at the catalytic site requires concentrations of auranofin and other gold compounds orders of magnitude greater to be inhibited [104]. Both gold(I) and gold(III) markedly inhibit the activity of thioredoxin reductase, mitochondrial respiration to alter mmembrane potential and finally to induce swelling [90].

Gold(III) complexes, $(C_2H_5)_3P$-$AuBr_3$ [105], $[Au(PPh_3)L]$ (L = imidazole) [106], $[AuCl_2(dmamp)]$, (dmamp = 2-(dimethylaminomethyl) phenyl) [85], RAu(III)L (L = thiosalicylate) [107] and a number of amine–gold(III) complexes [108] are known to exhibit antibacterial and antitumor activity. Gold(III) complexes of aminoquinolines were also found to possess DNA binding properties and cytotoxicity against melanoma and lung tumor cells [109]. Gold(III) tetraaryl porphyrins are known to exert high potency than cisplatin in killing human cancer cells including drug resistant variants [110]. The cytotoxicity of gold(III) complexes is associated with the presence of gold(III) center, e.g., $[Au(en)_2]Cl_3$ and $[Au(dien)Cl]Cl_2$ are more cytotoxic than the corresponding platinum complexes [108]. Gold(III) compounds appear less effective than auranofin in stimulating mitochondrial swelling and this might depend on the different permeability characteristics of these compounds [90]. The development of gold(III) complexes as potential antitumor agent has been hampered by their poor stability under physiological conditions. The stability of gold(III) center may be enhanced by coordination to multidentate ligand. However, the excessive stabilization results into the loss of biological activity [108].

Although gold drugs have been in clinical use for over 70 years, their exact mechanisms of action are still unknown. This is because the specific cellular targets for gold are unclear. Gold(I) has a high affinity for thiolate sulfur, hence proteins containing cysteine thiolate groups (albumin, glutathione) are possible target sites for gold(I). Several metabolites of these drugs have been characterized; $[Au(CN)_2]^-$ has been identified as a common metabolite of all gold drugs. The antitumor properties of posphine–gold complexes are probably due to their antimitochondrial activity. Optimization of their hydrophilic–lipophilic balance may be a key to improving their selectivity for tumor mitochondria.

3. Silver antimicrobial agents

Silver and its compounds have long been used as antimicrobial agents in medicine. Silver is active at low concentrations and has a low toxicity. Silver sulfadiazine is a widely used broad-spectrum antibiotic ointment, effective against a broad range of bacteria and some yeasts. It is used to prevent and treat skin infections on the areas of burnt skin [4].

Silver complexes of oxygen donor ligands such as, $[Ag(hino)]_2$ (where hino = 4-isopropyltopolone) [111] and water-soluble silver(I) complexes of (*R*)-(+)- and (*S*)-(−)-2-pyrollidone-2-carboxylic acid [112] displayed wide ranging and effective activities against some bacteria, yeasts and moulds. It has been found that the silver–oxygen bonding properties rather than the chiral helical or achiral polymer structure play a role in exhibiting antimicrobial activities. The antimicrobial activities of the silver(I)–oxygen bonding complexes are independent of whether the ligand itself possesses antimicrobial activities. Examples of such complexes are; $\{[Ag(L\text{-}Hasp)]_2\}$ and $\{[Ag(L\text{-}Hasp)]_2\}_n$, where the ligand showed no activity [113]. Similarly, salicylic acid (salH) did not prevent the growth of a fungal pathogen, while the silver complexes, $[Ag(salH)]_2$ and $[Ag(NH_3)(salH)]_2$ greatly inhibited cell reproduction. These complexes also produced a cytotoxic response against human cancer cells [114].

The biological action of the silver(I) oxygen complexes comes from a weaker bonding property of the Ag–O bond. In the biological system, the ease of ligand replacement of the silver(I) complexes would result in further replacement with biological ligands [113,115–117]. The Ag–O bonding complexes can readily undergo ligand replacement with O-, N- or S-donor atoms. The antimicrobial activities by silver(I)–oxygen bonding complexes are due to the silver(I) ion itself, i.e., due to a direct interaction between the silver(I) ion and biological ligands such as protein, enzymes and membrane. The coordinating ligands of the silver(I) complexes play the role of carrier for the silver(I) ion to the biological system [111]. The magnitude of antimicrobial properties of silver complexes is related to the ease with which they participate in ligand exchange reactions [118]. For example, it has been speculated that the weak Ag–O [113] and Ag–N [115] bond strengths might play an important role in exhibiting wider spectrum of antimicrobial and antifungal activities and that the potential target sites for inhibition of bacterial and yeast growth by silver complexes might be the sulfur containing residues of proteins [119]. Generally, Ag–S complexes have been shown to have a narrower spectrum of antibacterial activity than Ag–N complexes but no antifungal activity [120]. In contrast, the compounds with Ag–P bonds have shown no activity against bacteria, yeast or molds [115,121].

A sulfur coordinated, water soluble silver(I) complex of thiomalic acid showed remarkable antimicrobial activity against some bacteria, yeast and moulds. Although aqueous silver nitrate itself has similar activities for bacteria, the complexation of silver(I) with thiomalate leads to

appreciably high activities for some moulds [122,123]. Antimicrobial activities have been observed for sulfur bonded silver complexes of 2-mercaptonicotinic acid, $[Ag(Hmna)]_6 \cdot 4H_2O$ [119] and 2-mercaptobenzoic acid, $[Ag(Hmba)]_n$ and $[Na\{Ag(Hmba)\} \cdot H_2O]_n$ [121]. The spectra of antimicrobial activities observed in Ag–S bonded compounds have so far been narrower than those in the Ag–N bonded compounds such as $[Ag(im)]_n$ (im = imidazole) and $[Ag(triaz)]_n$ (triaz = 1,2,4-triazole) [120,124]. The key factor determining the spectra of antimicrobial activity is the nature of atom coordinated to the silver(I) atom and its bonding properties, (i.e., the ease of ligand replacement), rather than the solid state structure, solubility, charge and degree of polymerization of the complexes [118,120].

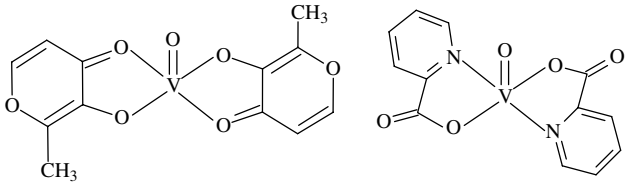
4. Vanadium antidiabetic agents

The discovery of vanadium's insulin behavior (stimulate glucose uptake and oxidation as well as glycogen synthesis) during 1975–1980 has stimulated the renewed interest in vanadium coordination chemistry [125,126]. Vanadium compounds mimic most of the metabolic effects of insulin on different cellular types [127–129]. Vanadium compounds modify glucose and lipid metabolism in adipose tissue, muscle, liver and several cultured cell lines, which may contribute to the glucose-regulating effects of vanadium [127,129]. The antidiabetic action of vanadium may be attributed to the inhibition of several enzymes involved in the carbohydrate and fat metabolism, such as phosphodiesterase and tyrosine phosphatases [127,129,130]. During the years 1980–90, the insulin like actions of vanadium salts were examined in a large variety of insulin responsive cells and tissues. Vanadium salts activate hexose transport in adipose and muscle tissues [127]. Vanadium activates glycogenesis and inhibits glycogenolysis in liver and diaphragm [131]. It inhibits several key metabolic enzyme systems in liver, muscle and adipose tissues, all of which act collectively towards utilizing or storing cell entered glucose as well as blocking the actions of hormones that oppose insulin actions [132]. It also serves as an electron acceptor, which could stimulate enzymatic and nonenzymatic oxidation of NAD and NADPH into their oxidized forms NAD^+ and $NADP^+$ [133,134]. Besides the antidiabetic effects for which it is now so well known, vanadium also exhibits a number of other therapeutic effects including anti-tumor and anti-inflammatory activities [135,136].

Vanadium possesses various oxidation states, e.g., +3, +4 and +5, all of which can interact with biomolecules containing negatively charged oxygen donors such as carboxylate, phenolate, phosphate, phosphonate and hydroxamate groups [137]. Under physiological conditions vanadium exists predominantly in the anionic form as vanadate, VO_4^{3-} (oxidation state +5) and in the + 4 oxidation state as vanadyl cation (VO^{2+}) [127]. In experimental diabetic animals, both vanadyl and vanadate ions have been found to have an insulin mimetic effects on glucose metabolism. However, vanadyl is less toxic than the vanadate ion [138]. Vanadium complexes with organic ligands are often less toxic and can have improved aqueous solubility and lipophilicity [4]. The chelated vanadium complexes have the property of increasing permeation into tissues by passive diffusion and corresponding increased insulin mimetic efficacy. The most effective ligands are those having nearly the same binding affinity for the vanadyl (+4) cation and the vanadate (+5) anion at physiological pH values [127,139].

In recent decades, some vanadyl complexes with several types of organic ligands such as maltol have been proposed for clinical use in humans [135,140–143]. Maltol (3-hydroxy-2-methyl-4-pyrone) and its derivatives like kojic acid (3-hydroxy-2-hydroxymethyl-4-pyrone) possess moderate intrinsic bioactivity and low toxicity profile. They can act as anionic and chelating *O*,*O*′ ligands forming neutral oxovanadium complexes [135,144–146]. Coordination complexes of oxovanadium(IV) with maltol and ethylmaltol (which are under clinical trials) have proven especially suitable for enhancing vanadium's insulin mimetic activity in experimental diabetic animals in recent years [144,147]. The orally active complex bis(maltolato)oxovanadium(IV) {BMOV} is three times more effective in vivo as insulin mimetic agent than $VOSO_4$ [148–150]. The insulin-enhancing properties of BMOV has been investigated thoroughly [140,143,144,150,151]. Several analogues of BMOV have been synthesized and tested for bioactivity as potential insulin enhancing agents [144,152]. Substitution of nitrogen for oxygen in the maltolato heterocycle lowers the solubility of complex rendering it unfit for therapeutic utility [144]. Vanadium complexes with thio derivatives of maltol also did not lower the blood glucose levels, possibly because of the rapid dissociation and excretion [153].

BMOV possesses several advantages over inorganic vanadium compounds in terms of its oral administration, low toxicity and enhanced tissue uptake [154]. The complex BMOV has a five coordinate square pyramidal geometry with the oxo ligand in the axial position and trans maltolato ligands (Fig. 3) [4]. In aqueous solutions or in alcohol, BMOV, V(IV) undergoes reversible oxidation to form the V(V) maltol complexes, $[VO_2(ma)_2]^-$ or $[VO(OR)(ma)_2]$, respectively. The oxidation kinetics being second order; substitution reactions of BMOV showed that oxygen must bind for the oxidation to $[VO_2(ma)_2]^-$ to take place [154]. The reaction in water is pH dependent and it has been



BMOV $VO(pic)_2$

Fig. 3. Structures of insulin mimetic vanadium complexes.

shown that both $[VO(H_2O)(ma)_2]$ and $[VO(OH)(ma)_2]^-$ can be oxidized by molecular oxygen [154]. A recent study shows that V(V)-dipicolinato complex is the more effective insulin enhancing agent compared to BMOV, which is so far considered as the most effective. The compound's acid stability or its redox chemistry may be key to the ability of the V(V) complex to lower the elevated glucose levels in the diabetic wistar rat during oral treatment [155].

β-Diketonato complexes such as $VO(acac)_2$ have been considered as potential insulin mimetic agents [156,157]. Recently, a new orally active complex, bis(α-furancarboxylato) oxovanadium(IV) has shown the glucose lowering ability comparable to BMOV, and possesses high water solubility and less toxicity when orally administered in diabetic rats [158]. Vanadium complexes of pyridine carboxylic acids are particularly interesting molecular model systems because they are potential agents for treating insulin dependent diabetes mellitus in rats by injection or oral administration [159]. Several oxovanadium complexes with substituted picolinic acid have been reported [137,160–165]. The picolinato complexes, for example bis(pyridine-2-carboxylato) oxovanadium(IV), $VO(pic)_2$ (Fig. 3) exerted a higher insulin mimetic activity than that of $VOSO_4$ [166]. For the oxovanadium complexes of 3-hydroxypyridine-2-carboxylic acid, mono as well as tetranuclear species are formed. The mononuclear complex exhibits relatively higher insulin mimetic activity than $VOSO_4$, while the tetranuclear complex shows significantly lower activity [167]. Some vanadyl complexes of anti-inflammatory drugs containing carboxylate ligands have been reported [168]. The oxovanadium picolinato system possesses satisfactory hydrolytic stability as well as disfavors interconversion between the oxovanadium(IV) and dioxovanadium(V) complexes, a property desired in insulin-mimetic drug.

Peptide bound complexes with one tetradentate ligand in place of two bidentate ligands may increase the stability constants of resulting complexes via the chelate effect. Hydrated oxovanadium complexes of *N*-alkylated derivatives of various amino acids, $[VO(XeX)(H_2O)]$ where XeX = *N*,*N*′-ethylene bis-α-amino acid have been synthesized and were observed to possess insulin mimetic effect [169–171]. Recently, some vanadyl complexes with amino acid derivatives containing an imidazole group have been reported [172].

A few V(V) complexes [155,173,174] and V(III)-hydroxypyrone and -pyridinone complexes [175] have been reported as having glucose lowering effects. V(III) complexes have been shown to lower diabetic hyperglycemia after acute treatment, but they are not usually considered as potential therapeutic agents because they readily oxidize to V(IV) and V(V) compounds under physiological conditions [175].

Several factors such as the electronic properties of the substituent, its position on the ligand and the hydrophobic nature of the complex alter the biological activity of the complex. The introduction of electron donating substituents in the pyridine ring of picolinato ligand alters the activity of the resulting complex. The picolinato complexes possessing iodo group $[VO(ipa)_2]^-$ and methyl groups $[VO(3\text{-}mpa)_2]$ and $[VO(6\text{-}mpa)_2]$ provided higher activities than $[VO(pa)_2]$ [159]. The complexes having electron withdrawing Cl^- groups $[VO(4\text{-}Clpa)_2]$ exhibits lower in vivo activity than $[VO(pa)_2]$ [176]. Moreover, the in vitro activity of $[VO(3\text{-}mpa)_2]$ is higher than that of $[VO(6\text{-}mpa)_2]$ [159]. The hydrophobicity of a complex also affects its biological activity. The insulin mimetic activity of $[VO(6mpa)_2]$ with the higher partition coefficient than $[VO(pa)_2]$ in the *n*-octanol/saline system was higher [177].

An important property of synthetic vanadium containing insulin-mimetic compounds is their varying patterns of tissue uptake. Vanadyl species were distributed in peripheral tissues and gradually eliminated from the circulating blood, depending on their chemical structures [159]. The slower elimination of vanadyl species from the circulating blood of rats given vanadyl–picolinato complexes was closely related with their interaction with the blood components such as serum proteins or erythrocytes [177]. The organ distribution of $VO(pic)_2 \cdot H_2O$ indicates a preferential accumulation in bone vs kidney, which is twice than that seen with BMOV. The ratio of vanadium in kidney vs liver was also far greater for BMOV (7.4: 1.0 compared to 1.4:1.0), which may be less suitable for an insulin mimetic [163,178]. Distribution studies indicated that vanadium distribution in the body was not homogeneous [178,179]. Vanadium was detected in almost all body tissues after drug administration with the following order of magnitude: bone > kidney ⩾ liver ⩾ spleen > heart > testes > lung > pancreas > blood ∼ muscle > brain. Residence time was short for blood, longer for kidney, testes and liver, and very long for bone. Vanadium concentration in bone, kidney and liver 24 h after oral administration of BMOV were two to three times higher than those of $VOSO_4$, which is consistent with the increased glucose lowering potency of BMOV compared with $VOSO_4$ [178,179].

Vanadium compounds show the insulin mimetic effect through an inhibition of protein tyrosine phosphatases (PTPases) [129,180–182]. Because PTPases are considered to be negative regulators of the insulin-signalling pathway, it was suggested that vanadium can enhance insulin signaling and action by virtue of its capacity to inhibit PTPase activity and increase tyrosine phosphorylation of substrate proteins [129,183–187]. The PTPase inhibition by vanadium prevents dephosphorylation of tyrosine phosphorylated insulin receptor substrate (IRS) and increases the tyrosine phosphorylation level [129]. Recent findings demonstrate that BMOV inhibited intracellular PTP1B activity and enhanced the autophosphorylation of the insulin receptor in vivo, supporting that PTP inhibition as the mechanism of insulin sensitization [180,181]. NMR and X-ray studies of the interaction of BMOV with two phosphatases, HCPTA (human low molecular wt cytoplasmic protein tyrosine phosphatase) and PTP1B (protein tyrosine phosphatase 1B) demonstrated that uncomplexed

vanadium (VO_4) is the active component of BMOV. The crystal structure of PTP1B soaked with BMOV reveals that VO_4 is coordinated to serine 215 through a complex network of hydrogen bonds. The chelating maltol ligands were not observed in the structure, suggesting that ligand dissociation and oxidation to VO_4 may be required for efficient phosphatase inhibition. The presence of uncomplexed VO_4 at the active site further suggests that the organic ligand plays no role at the enzyme except perhaps as a delivery vehicle for vanadium [180]. In addition, based on kinetics of ligand substitution, it has been proposed that maltol would be readily replaced by stronger ligands in biological fluids [188].

Another target of vanadium could be the lipid phosphatase, phosphatase and tensin homologue (PTEN), which can dephosphorylate PIP_3 (phosphatidylinositol 3,4,5-triphosphate) [129,189]. The PETN inhibition prevents dephosphorylation of PIP_3, which is important for the activation of phospholipid-dependent kinase (PDK) and related serine/threonine protein kinases responsible for phosphorylation and stimulation of several downstream signaling protein kinases, such as protein kinase B (PKB) [190,191]. Activation of these protein serine/threonine kinases has been implicated in many of the physiological responses of insulin at the level of glucose transport, glycogen and protein synthesis [192].

Despite their impressive antidiabetic properties, vanadium compounds have been associated with several toxic effects. The most common are diarrhea, decreased fluid and food uptake, dehydration and reduced body weight gain, which could be corrected by decreasing the dose level [129,193,194]. Organic vanadium compounds are much safer as antidiabetic agents than inorganic vanadium salts. Administration of the chelator iron was also found to minimize vanadate toxicity without altering its antidiabetic actions [195]. In addition to gastrointestinal discomfort, other toxic effects of vanadium salts include hepatotoxicity, nephrotoxicity and tetratogenicity as well as reproductive toxicity [194]. Further detailed investigations are needed to evaluate the toxicity of various vanadium compounds before undertaking long-term clinical trials in humans.

5. Bismuth antiulcer agents

Bismuth compounds are most commonly used for treating gastrointestinal disorders [196]. The effectiveness of bismuth has been attributed to its bactericidal action against the gram-negative bacterium *Helicobacter pylori* (the bacterium associated with the mucus layer of ulcers) [197]. The roles of colloidal bismuth citrate (CBS) and bismuth subsalicylate (BSS) in gastric and duodenal ulcer therapy and the eradication of Helicobacter pylori have been studied extensively [198–202]. Among the bismuth containing pharmaceuticals, bismuth subsalicylate (Pepto-Bismol), colloidal bismuth citrate (De-Nol) and ranitidine bismuth citrate (Pylorid) are the most widely used for the treatment of diarrhea, dyspepsia and peptic ulcers [196,203–205]. Recently, a bismuth single–triple capsule containing CBS, metroindazole and tetracycline has been approved for the eradication of *H. pylori* [206,207]. Several other bismuth salts such as $Bi(NO_3)_2 \cdot 5H_2O$, $BiCl_3$ and BiOCl are also employed in medicine. Elemental bismuth has also been found in natural medicinal plants. The diversity of bismuth compounds in medicine extends to the treatment of syphilis and tumors, in radioisotope therapies, in the reduction of renal toxicity of cisplatin and pharmacy [196]. Citrate (3-carboxy-3-hydroxypentane-1,5-dioic acid) salts of bismuth represent the most extensively studied series of bismuth compounds by virtue of their widespread medicinal use. Bismuth citrate is essentially insoluble in water, but a dramatic increase in solubility with increasing pH has been exploited as a bioready source of soluble bismuth, a material referred to as "Colloidal Bismuth Subcitrate" (CBS) [196]. Ranitidine bismuth citrate is a new water soluble therapy for peptic ulcer disease, which is obtained from the reaction of ranitidine hydrochloride (*N*,*N*-dimethyl-5-(3-nitromethylene-7-thia-2,4-diaaoctyl)furan-2-methamine) with bismuth citrate [153]. [^{1}H, ^{13}C] HSQC NMR has shown that a wide range of types of bound citrate in aqueous solutions of Ranitidine bismuth citrate at pH 7.4. The identification of cluster species in solution is particularly important since they may be taken up by cells by a different mechanism compared to low molecular mass complexes [208].

The coordination chemistry of Bi(III) with carboxylates and amino carboxylates is dominated by intermolecular interactions, which leads to polymeric structures [207]. The X-ray structures of Bi(III) citrate complexes are complicated and contain chains and sheets of dimeric $[Bi_2(Cit)_2]^{2-}$ units. The $[Bi_2(Cit)_2]^{2-}$ dimer contains strong Bi(III)-alkoxide bonds and a double carboxylate bridge (Fig. 4) [4,209]. ^{1}H and ^{13}C NMR studies indicate rapid exchange of citrate moieties at low concentration and the existence oligomeric and polymeric units at higher concentration [208,210–212]. Recently, the structure of colloidal bismuth subcitrate was determined under acidic conditions. X-ray crystallography revealed the presence of three types of Bi-citrate dinuclear unit $[Bi(cit)_2Bi]^{2-}$, which function as building blocks, assembling into a three dimensional polymer. CBS may rearrange from colloidal particles such as $[Bi_6O_4(cit)_4]^{6-}$ and $[Bi_{12}O_8(cit)_8]^{12-}$ at neutral pH value, to sheets and 3D polymers under acidic conditions (e.g., in stomach) due to rapid ligand exchange. Because the complex has significant resistance to acid (HCl), it can be regarded as the potential active species of the antiulcer

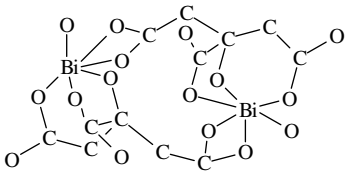


Fig. 4. Bismuth citrate dimer.

drug CBS in stomach and is thus a possible candidate for the tiny crystals found on the ulcer craters [213].

Despite its popular use, bismuth exhibits only modest antibacterial activity. Bismuth therapy provides short-term effects requiring administration of relatively large, frequent doses, which increase the chances of toxicity. The limited antibacterial effect of bismuth is attributed to the poor solubility of bismuth in water [214]. Chelation of bismuth with certain thiol compounds significantly enhanced its solubility and lipophilicity, thereby enhancing its potency and versatilely as an antimicrobial agent. The lipid aspect of bismuth-thiols facilitates transport into and through lipid membranes in bacteria [215]. Certain chemical features on thiols are necessary for the biological activity of Bi–S compounds. It has been observed that the addition of one or more carbon atoms to the chelate ring abolished the biological activity, whereas, the addition of a sulfur atom to the ring but not the addition of oxygen restored the biological activity [216]. Alcohols, amines and especially, acid group substitutions on thiols diminished activity, likely through their influence on lipophilicity. Dithiols are generally more active than monothiols, as they are better chelators [215]. Bismuth is likely the antibacterial moiety, since it is known to exchange with thiols and inactivate membrane-bound enzymes involved in respiration, such as the F_1-ATPase of *H. pylori* [217]. When bismuth is replaced with arsenic and antimony, the compound's antibacterial activities are reduced [215], which confirms that antibacterial activities are attributed to the bismuth contents.

The biological effects of Bi(III) are due to binding to proteins and enzymes [203]. Sulfur-based biomolecules represent the primary targets for Bi pharmaceuticals, such as CBS and BSS [218,219]. Bismuth compounds of such ligands have been characterized by ^{13}C NMR [197,220–222], mass spectrometry [218,219,223,224] and X-ray crystallography [223–225]. Bi(III) binds strongly to both oxygen and sulfur ligands. Cysteine and glutathione may play a role in the transport of Bi(III) in cells and biofluids. Bi(III)-thiolate adducts are kinetically labile, which allows rapid translocation of Bi(III) inside cells [203]. Animal studies have shown that simultaneous oral administration of bismuth salts and thiols produces a significant rise in bismuth concentration in blood plasma. The sulfur-based ligands are speculated to achieve *tris*-substitution in Bi(methionine)$_3$ and Bi(cysteine)$_3 \cdot 5H_2O$. The glutathione complex, [Bi(SG)$_3$] is very stable over a wide range of pH (2–10), with binding through sulfur atom only. The binding of bismuth with proteins of exposed ulcer tissue and the formation of a protective coating is proposed as a mode of action for the antiulcer behavior of some bismuth compounds [220]. A recent study shows that BSS reacts not only with thiol containing substrates but also with some common foods to produce soluble bismuth products and these products have excellent against the bacterium *Clostridium difficile* [226].

The antimicrobial activity of bismuth complexes towards gram-negative bacteria has been reported to be dependent on the iron uptake system, as iron is essential for the growth of *H. pylori*. Efficient iron acquisition is thought to be an important virulence factor for this bacterium [222]. Bismuth is primarily present in red blood cells, possibly binding to glutathione with the remainder in serum or plasma [227–229]. Previous investigations showed that albumin may be the major target for Bi(III) in plasma especially since albumin has a free thiolate group at cys-34 [227]. But recently, it has been demonstrated that binding of Bi(III) to transferrin (hTF) is much stronger than human albumin (HAS) in blood plasma [230]. Most of the Bi^{3+} was associated with transferrin in the presence of a large excess of albumin. Moreover, the binding constant for Bi^{3+} to HAS, log$K$ was calculated to be 11.2, which is much lower than that for Bi^{3+} to hTF ($\log K_1 = 19.9$ and $\log K_2$ 18.6) [230]. This suggests that transferrin is the major target for bismuth in blood plasma. Lactroferrin (hLF) is another major iron-binding protein in the transferrin family. Lactoferrin is present in significant amounts in the stomach secretions of patients with gastritis. Bi(III) binds to human lactoferrin into the two specific iron sites in the presence of either carbonate or oxalate. The presence of ATP facilitates the release of Bi(III) from the lactoferrin complex. The Bi_2-hLF complex blocked the iron uptake to intestinal cells. Bi(III) may be released inside the cells and inhibit target enzymes, in the case of bacteria, including enzymes essential for their survivals [222].

Bi(III) ions inhibits the biological activity of glycine-extended gastrin-17, a gastrointestinal hormone. The biological activity of gastrin-17 is associated with its binding to high affinity Fe(III) ions. Bi(III) ions inhibit the action of gastrin by blocking its effects on cell proliferation and cell migration in the gastrointestinal tract [231].

Bi(III) binds strongly to metallothionein (MT) with a stoichiometry Bi_7MT and can readily replace Zn^{2+} and Cd^{2+} ions. NMR studies suggest that Zn^{2+} is displaced faster than Cd^{2+}. Bi–S bonds in metallothionein are remarkably stable even down to pH values near 1.0, in contrast to Zn^{2+} and Cd^{2+}, which are 50% dissociated at pH 4.6 and 3.05, respectively. The high stability of Bi-MT suggests that it could play an important role in the pharmacological activity of bismuth antiulcer drugs [232]. Metallothionein may also play a role in cellular resistance to Pt anticancer drugs [232,233]. Bismuth is known to induce the synthesis of renal metallothionein [234]. Administration of bismuth can induce the synthesis of metallothionein in kidney but not in tumor tissue. This reduces the renal toxicity of cisplatin without compromising its antitumor activity [235,236]. The protection probably involves platinum binding to Bi-induced metallothionein. Therefore it has been suggested bismuth compounds are ideal for clinical application has adjuncts in chemotherapy with cisplatin [232]. Bismuth compounds themselves are known to possess antitumor activity and DNA-binding property [237].

Bismuth therapy is associated with several side effects. The most common consequence of overdose is neurological

dysfunction [238]. Neurotoxicity of bismuth drugs is generally diagnosed by the detection of bismuth in blood, plasma or serum [239]. In experimental animals bismuth overdose results in lowered serum testosterone levels suggesting that reproductive dysfunction may be an additional component of bismuth toxicity [238]. Bismuth toxicity is reversible over several week or months, when bismuth intake is stopped [240].

6. Conclusions

In this review, various structural and mechanistic aspects of some metallodrugs have been explained. Although the exact mechanism of these drugs is not completely understood, there have been many developments in understanding of the factors that control metal binding to possible biological target such as thiols. Further studies are required to explore their actual mechanism of action. For gold complexes, which exhibit promising antitumor properties, there is a need to study the interactions between gold complexes and mitochondrial enzymes and other cellular targets that could lead to cell death. The kinetics of metal–ligand interactions are crucial to all properties related to biological activity, therefore metallokinetics of these drugs should be investigated. For vanadium complexes however, several systematic kinetic studies have been reported. Understanding the nature of interactions of metallodrugs with cell membrane and the biological targets like DNA and proteins is also important. Such informations are useful in development of new compounds that comprise the efficient transport properties and possess minimum side effects.

important characteristics of the Schiff-base ligands is that even a small modification of the ligand structure can significantly change key properties of the corresponding iron complex. For instance, after introducing several electron-withdrawing nitro groups to iron complexes with H_2salen type of ligands, effective catalysts for hydrocarbon oxidations with dioxygen as the oxidant were obtained [18–20]. In a similar manner, concerning both the iron(II) and iron(III) coordination chemistry with Schiff-base ligands, much emphasis has been focused on the understanding of the factors which control the spin state of the metal ion, as well as the intermolecular solid-state effects that induce or influence the spin-crossover phenomenon [9,10,21]. It has been reported that the replacement of a methoxo group with an ethoxo group in a hexadentate N_4O_2 Schiff-base ligand results in dramatic changes of the magnetic properties of the corresponding iron(II) complexes, due to small alterations in the intermolecular interactions and crystal packing [21]. In addition, a small number of iron(III) complexes with Schiff-base ligands can exhibit both high-spin and low-spin electronic configuration and a thermal low-spin ⇆ high-spin transition has been observed for these spin-crossover complexes [12,15,22–27].

In this contribution we report on the synthesis, structural, spectroscopic and magnetic characterization of new examples of iron(III) complexes with dianionic N_4O_2 Schiff-base ligands (Chart 1): $[Fe(L_1)](ClO_4)$ (**1**), $[Fe(L_1)](BF_4)$ (**2**), $[Fe(L_2)](ClO_4)$ (**3**) and $[Fe(L_2)](BF_4)$ (**4**). Although the synthesis of the ligands H_2L_1 and H_2L_2 has been reported earlier [28], only one iron(III) complex of the ligand H_2L_1 has been reported so far [26].

2. Experimental

2.1. Synthesis

All chemicals and reagents used for the preparation of ligands and complexes were commercial products (Merck) and were used without purification. All reactions were carried out in air, unless stated otherwise.

Caution. Perchlorate salts are highly explosive, and should be handled with care and in small amounts.

2.1.1. General synthesis of the ligands dihydrogen [N,N′,N″,N‴-1,5,8,12-tetraazadodecane-bis(salicylaldiminato)] [H_2L_1] and dihydrogen [N,N′,N″,N‴-1,5,8,12-tetraazadodecane-bis(3-methoxysalicylaldiminato)] [H_2L_2]

1,5,8,12-Tetraazadodecane (0.01 mol) was dissolved in ethanol (10 ml) and then added to a stirred ethanol solution of the corresponding aldehyde (0.02 mol). The reaction mixture was heated to reflux over night. After cooling to room temperature, the solvent was removed under reduced pressure. The final viscous residue was kept under vacuum for 5 days and the ligands have been purified by repeated crystallizations in methanol.

H_2L_1. Nature: yellow solid. Yield: (2.678 g, 81%); m.p.: (28–30 °C). $C_{22}H_{30}N_4O_2$ (382.51); Calc.: C, 69.08; H, 7.90; N, 14.65. Found: C, 65.96; H, 7.80; N, 13.69%. IR: 1630 cm^{-1} (C=N). ^1H NMR (in CD_3OD): 8.18 (s, 2H, imine-H), 7.16 (m, 2H), 6.92 (m, 2H), 6.72 (m, 2H), 6.55 (m, 2H), 4.85 (s, 2H, b, N-H), 3.53 (t, 4H), 2.49 (m, 4H), 1.78 (m, 4H), 1.27 (m, 4H). ESI-MS, *m/z*: 383.

H_2L_2. Nature: yellow liquid. Yield: (3.5 g, 79%). $C_{24}H_{34}N_4O_4$ (442.56); Calc.: C, 65.14; H, 7.74; N, 14.46%. IR: 1629 cm^{-1} (C=N). ^1H NMR (in CD_3OD); 8.28 (s, 2H, imine-H), 6.83 (m, 2H), 6.78 (m, 2H), 6.52 (m, 2H), 4.79 (s, 2H, b, N-H), 3.70 (s, 6H OCH_3), 3.49 (m, 4H), 2.57 (m, 4H), 1.75 (m, 4H), 1.08 (m, 4H). ESI-MS, *m/z*: 443.

2.1.2. General synthesis of [$Fe^{III}L$]X ($X = ClO_4^-$ and BF_4^-) complexes

A methanol solution of $Fe(ClO_4)_2 \cdot 6H_2O$ or $Fe(BF_4)_2 \cdot 6H_2O$ (0.001 mol, 5 ml) was added dropwise to a stirred solution of the Schiff-base ligand (H_2L_1 and H_2L_2) (0.001 mol, 30 ml). The resulting solution was stirred for 3 h and then it was filtrated. The slow evaporation at room temperature of the resulting filtrates allows obtaining the solid compounds **1**–**4**. All four compounds were recrystallized from hot methanol. X-ray quality light green crystals for (**1**) and purple crystals for (**3** and **4**) were obtained by vapor diffusion of diethyl ether into CH_3OH: $CHCl_3$ mixture over 15 days. Numerous attempts to obtain crystals of **2** failed.

*[$Fe(L_1)$]ClO_4 (**1**)*. Yield: (0.256 g, 58%), $C_{22}H_{28}N_4O_6ClFe$ (535.78): Calc. C, 49.31; H, 5.26; N, 10.45. Found:

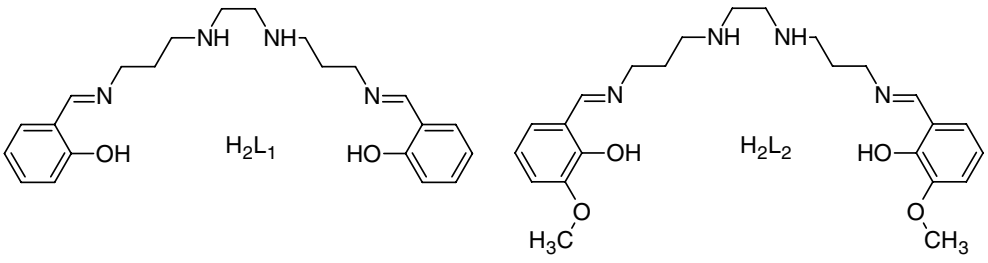

Chart 1.

*[Fe(L$_2$)](ClO$_4$) (**3**)*. Yield: (0.413 g, 83%). $C_{24}H_{32}N_4O_8ClFe$ (597.83): Calc.: C, 48.54; H, 5.41; N, 9.40. Found: C, 47.66; H, 5.51; N, 9.32%. IR (ν/cm^{-1}): 3236 (N-H), 1631 (C=N) and 1070, 621 ClO_4^-. UV/Vis/NIR, λ_{max}/nm: 602, 373.

*[Fe(L$_2$)](BF$_4$) (**4**)*. Yield: (0.264 g, 53%). $C_{24}H_{32}N_4O_4F_4BFe$ (583.20): Calc.: C, 49.42; H, 5.33; N, 9.60. Found: C, 49.95; H, 5.55; N, 8.72%. IR (ν/cm^{-1}): 3252 (N-H), 1651 (C=N) and 1068, 636 BF_4^-. UV/Vis/NIR, λ_{max}/nm: 605, 369.

2.2. Physical measurements

C, H and N analyses were performed with a Perkin–Elmer 2400 series II analyzer. Infrared spectra (4000–300 cm^{-1}) were recorded on a Perkin–Elmer Paragon 1000 FTIR spectrometer equipped with a Golden Gate ATR device, using the reflectance technique. ^{1}H NMR spectra were recorded on a Bruker 300 DPX MHz spectrometer in $CDCl_3$ solution, using TMS as the internal standard. Diffuse reflectance spectra were obtained on a Perkin–Elmer Lambda 900 spectrophotometer using MgO as a reference. The solution UV/Vis spectra of the compounds were recorded in the range of 200–800 nm with a Cary 50 Varian UV/Vis/NIR spectrometer. Electrospray mass spectra (ESI–MS) in CH_3CN were recorded on a Thermo finnigan AQA apparatus. The cyclic voltammetry measurements were performed with an Autolab PGstat10 potentiostat controlled by GPES4 software. A three-electrode system was used, consisting of a glassy carbon (GC) working electrode, a platinum (Pt) auxiliary electrode and an Ag/AgCl reference electrode. All potentials are given versus Ag/AgCl. The experiments were carried out in acetonitrile at room temperature under argon with tetrabutylammonium hexafluorophosphate as the electrolyte. The phenoxy ligands showed no redox activity between +2.00 and −2.00 V. Magnetic susceptibility measurements (5–300 K) were carried out at 0.1 T using a Quantum Design MPMS-5 5T SQUID magnetometer. Data were corrected for magnetization of the sample holder and for diamagnetic contributions, which were calculated from the Pascal constants. X-band electron paramagnetic resonance (EPR) measurements were performed at room temperature and at 77 K for polycrystalline samples, as well as at 77 K for frozen CH_3CN solutions on a JEOL RE2X electron spin resonance spectrometer, using DDPH ($g = 2.0036$) as a standard.

2.3. X-ray crystallography and data collection

Crystals suitable for structure determination were mounted on Lindemann-glass capillaries and transferred into the cold nitrogen stream of a Nonius KappaCCD diffractometer on a rotating anode (Mo Kα radiation, graphite monochromator, $\lambda = 0.71073$). The intensity data were corrected for Lorentz and polarization effects and for absorption. The structure was solved by direct methods. The programs COLLECT [29] SHELXS-97 [30] SHELXL-97 [31] were used for data reduction, structure solution and structure refinement, respectively. The plots were obtained using

Table 1
Crystal data and details of the structure determination for **1**, **3** and **4**

	1	**3**	**4**

the PLATON package [32]. All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were placed at idealized positions and allowed to ride on the connecting atom. Crystallographic data of the compounds are listed in Table 1.

3. Results and discussions

3.1. Synthesis and spectroscopic characterization

The Schiff-base ligands H_2L_1 and H_2L_2 were synthesized by small modification of the original procedure [28] and serve as hexadentate ligands in all four complexes (**1**–**4**) reported in this account. As shown in Chart 1, the ligands employ two secondary amine nitrogens, two imine nitrogens and two phenoxo oxygens to bind iron(III) in these complexes. The ether oxygen in H_2L_2 is unlikely to bind to metals. The complexes **1**–**4** were synthesized in good yield by the reaction of $Fe(ClO_4)_2 \cdot 6H_2O$ or $Fe(BF_4)_2 \cdot 6H_2O$ with H_2L_1 or H_2L_2 in a molar ratio 1:1, using methanol as solvent and at room temperature. Analytically pure compounds were obtained in all cases as indicated by elemental and mass analysis. Crystals suitable for single-crystal X-ray diffraction studies were obtained by slow diffusion of diethyl ether into methanol–chloroform solutions of complexes **1**, **3** and **4**. Attempts to similarly obtain single crystals of the complex **2** have remained unsuccessful, despite the large variety of solvents used.

The infrared spectra of the complexes **1**–**4** are dominated by the characteristic bands of the ligands L_1^{2-} and L_2^{2-}. In all cases, the absence of the ν_{O-H} stretching vibration in the range 3300–3600 cm^{-1} indicates that the phenolic group is dehydronated by the coordination to iron(III) ion. A sharp peak centered at 3230–3260 cm^{-1} is most likely due to the N–H stretching vibration of the secondary amine groups. The phenolic ν_{C-O} stretching vibration in the free Schiff bases is observed in the range of 1240–1270 cm^{-1} [33], which is shifted to 1297 cm^{-1} thus indicating coordination of the phenolic oxygen. The $\nu_{C=N}$ stretching vibration appears near 1630 cm^{-1} in the free Schiff base ligands [34]. In the present complexes, one strong band with a resolved doublet ($\Delta\nu_{C=N} < 50\ cm^{-1}$) is present around 1607–1615 cm^{-1} and it has been attributed to the $\nu_{C=N}$, shifted to lower energies by coordination to iron(III) ion. The multiplicity observed for the $\nu_{C=N}$ stretching vibration appears to be due to the crystal packing effects involving the counter anions ClO_4^- and BF_4^-, as also indicated by the X-ray crystal structures discussed below [35]. The presence of the perchlorate counter ion is indicated by the bands at 1072, 620 cm^{-1} (**1**) and 1070, 621 cm^{-1} (**3**). Apparently, a doublet was observed for the tetrafluoroborates at 1068, 997 cm^{-1} (**2**) and 1066, 994 cm^{-1} (**4**) for the analogues containing tetrafluoroborate counter ion. In fact, we observed subtle differences in the IR spectrum of repeated preparations of the complex **2**; this behaviour may perhaps be due to different wrapping environment of donor atoms (nitrogen and oxygen) to an iron(III) center.

In the solid state, the ligand field spectra of **1**–**4** display a single low-energy band with a maximum in the range of 593–649 nm, which is ascribed to the charge-transfer transition from the p_π orbitals of the phenolic oxygens to the d^*_π orbitals of the iron(III) ions. A second charge-transfer band occurs in the range 350–400 nm and it has been assigned to a $p_\pi \rightarrow d^*_\sigma$ type transition [33]. The absence of any other bands in the visible region suggests that the spin allowed d–d transitions are obscured by the tail of the charge-transfer band.

3.2. Description of crystal structures

Fig. 1 shows the molecular structures of the complex **1** along with the atomic numbering scheme used for all non-carbon and non-hydrogen atoms. Selected bond distances and angles are listed in Table 2. The lattice of **1** is made up of $[Fe(L_1)]^+$ cations and uncoordinated perchlorate anions. In the cationic complex, the coordination environment around the iron(III) center is a distorted octahedron built from two phenoxo oxygens, two imine nitrogens, and two secondary-amine nitrogens. The molecular entity shown in Fig. 1 exemplifies how the dianionic hexadentate ligand L_1^{2-} enfolds the iron(III) center in a *trans* coordination mode for the phenolic groups. The iron(III) ion lies within the plane defined by the four nitrogen atoms of the ligand L_1^{2-} and it is 0.006(1) Å out of this plane. The largest deviation from the octahedral geometry of the FeN_4O_2 chromophore is defined by the angle N(18)–Fe(1)–N(212) = 174.04(10)°. The iron to phenoxo oxygen bonds are *trans* to each other with O(10)–Fe(1)–O(20) = 174.43(9)°. The average Fe–N(imine) bond lengths is shorter than the Fe–N(amine) bond lengths (1.954(2) and 1.961(2) Å against 2.023(2) and 2.032(2) Å) and both are consistent with the reported bond lengths for similar

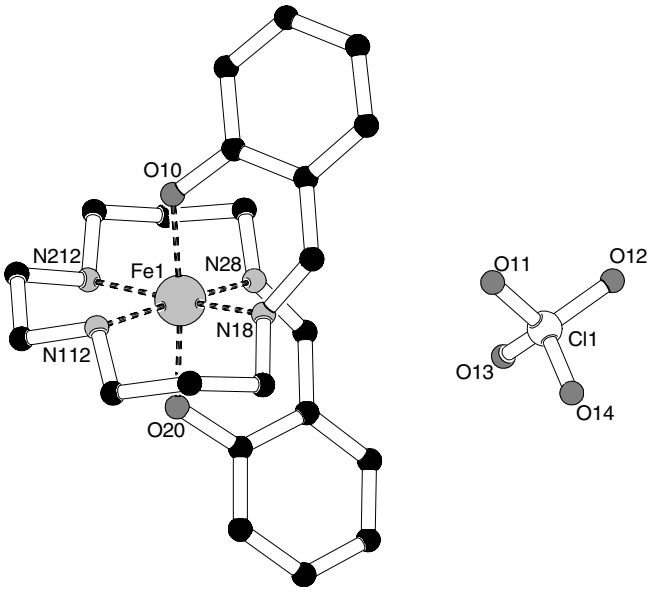

Fig. 1. Pluton projection of the molecular structure of **1**. Hydrogen atoms are omitted for clarity.

iron(III) low-spin complexes with Schiff-base ligands [15,16]. The average Fe–O bond length is known to be insensitive to the spin state of the iron(III) [9,10,12,24–27,36]. In the case of **1**, the iron to oxygen bond lengths are almost constant with Fe(1)–O(10) = 1.874(2) Å and Fe(1)–O(20) = 1.879(3) Å.

In the crystal lattice, the mononuclear entities of **1** are organized into infinite 1D chains due to the hydrogen-bonding interactions involving the secondary amine functions and one oxygen atom of a perchlorate anion (Fig. 2 and Table 3). The establishment of hydrogen bonds seems to be aiding crystallization, since their strength and directionality play a decisive role in the intermolecular interaction. Each molecule is chiral and both enantiomers occur in the crystal lattice.

The molecular structure of **3** consists of $[Fe(L_2)]^+$ cations and well separated perchlorate anions (Fig. 3). The coordination geometry around the iron(III) ion is distorted octahedral, and the coordination mode of L_2^{2-} is similar to that observed for the ligand L_1^{2-} in the complex **1**. Introduction of the methoxo groups in the ligand L_2^{2-} coordinated to the iron(III) ion induces only little changes in the metric parameters of **3** compared to **1** (Table 2). As a result, the Fe–O and Fe–N bond lengths are again consistent with the presence of an iron(III) low-spin complex (Table 2). The largest distortion from the octahedral geometry is determined by the angle N(114)–Fe(1)–N(210) = 173.43(15)°. As compared with the complex **1**, the iron to phenoxo-oxygen bonds are slightly longer and the angle O(10)–Fe(1)–O(20) = 176.13(13)° is less deviating from linearity. The hydrogen-bonding network that connects the cation complex $[Fe(L_2)]^+$ and the perchlorate ions is an important feature of **3** (Table 3). Although the individual molecules are connected into one-dimensional infinite chains via hydrogen-bonding interactions in a similar manner to that observed for **1**, the hydrogen contacts with the facial amine are weaker in **2** as compared with **1**.

The cation complex **4** is isostructural with that in complex **3**, as also seen in the almost identical infrared spectra; the structure again consisting of $[Fe(L_2)]^+$ cations and uncoordinated tetrafluoroborate anions. Necessarily, the geometric features of the complex are substantially similar to those of the complex **3** as can be seen from Table 2. In the crystal lattice, hydrogen bonds interactions are established between the $[Fe(L_2)]^+$ cations and tetrafluoroborate anions (Table 3).

Both compounds **3** and **4** are chiral in the solid and spontaneously crystallize as pure enantiomers; the absolute structure based on Flack's parameter has been determined, which was possible due to the presence of a heavy element. The fact that **3** and **4** have different lattice structures compared to **1** and **2** is ascribed to their different hydrogen bond patterns.

3.3. Solution chemistry and redox behaviour

Ligand field spectra of the complexes **1**–**4** have also been recorded in acetonitrile solution and all show spectroscopic

features that are similar to that in the solid state consisting of two absorption bands with maxima in the range 565–605 and 365–402 nm. Notably, the maximum of the LMCT band due to the $p_\pi \rightarrow d_\pi^*$ is shifted from ~560 nm in the compounds **1** and **2** to ~600 nm in **3** and **4**. This behaviour reflects changes in the Lewis acidity of the iron(III) center due to the presence of the OCH_3 donating group in the ligand L_2^{2-} (complexes **3** and **4**) which decreases the degree of any iron to ligand π bonding. The features discussed above suggest that geometry of the iron(III) core is similar in both solid and solution states. This property is further supported by the positive ESI-MS spectra of all complexes that exhibit a major peak at $m/z = 436.3$ for **1** and **2** or $m/z = 496.3$ for **3** and **4**.

Cyclic voltammograms of all four complexes were recorded in acetonitrile in the potential range −1.6 to +0.6 V versus Ag/AgCl reference electrode. In all cases, the cyclic voltammogram presents a quasi-reversible one-electron wave with the half-wave potential value, $E_{1/2}$, of 500 mV versus Ag/AgCl for the reduction of iron(III) to iron(II). Fig. 4 presents the cyclic voltammogram of the complex **3**. The phenoxy ligands showed no redox activity between +2.0 and −1.8 V. As a result, the electrochemical behaviour indicates that all four complexes are stable in acetonitrile solution and the coordination environment of iron(III) ion is similar.

3.4. EPR and Magnetic Susceptibility measurements

Temperature dependent magnetic susceptibility measurements for **1**–**4** were performed on polycrystalline samples in the range 5–300 K using SQUID magnetometer. In all cases the χ_M values have been corrected for diamagnetism [37]. At room temperature, the product of molar susceptibility times temperature ($\chi_M T$) of the $[Fe(L_1)](ClO_4)$ (**1**), $[Fe(L_1)](BF_4)$ (**2**), $[Fe(L_2)](ClO_4)$ (**3**), and $[Fe(L_2)](BF_4)$ (**4**) complexes is 0.453, 0.459, 0.456, and 0.454 $cm^3\ K\ mol^{-1}$, respectively. The observed $\chi_M T$ values are slightly higher than the spin-only value of 0.375 $cm^3\ K\ mol^{-1}$ expected for one unpaired electron

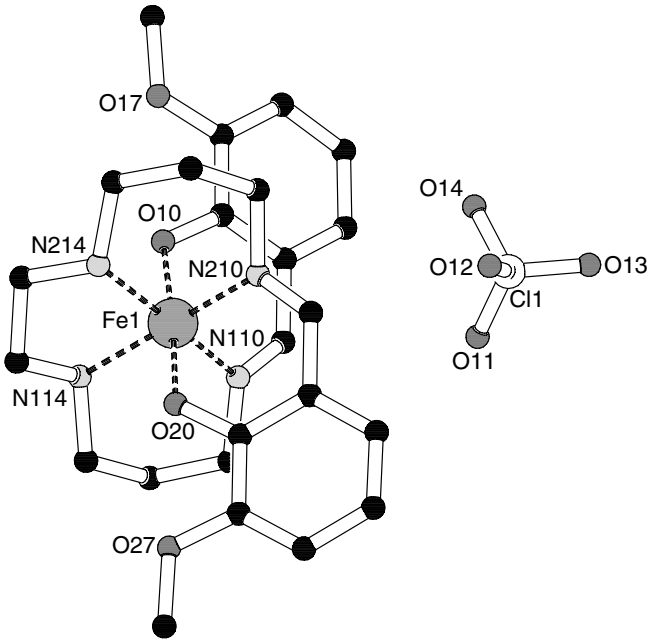

Fig. 3. Pluton projection of the molecular structure of **3**. Hydrogen atoms are omitted for clarity.

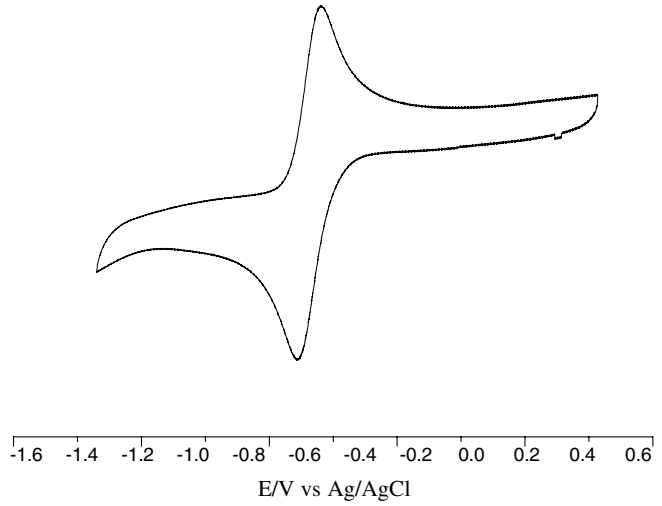

Fig. 4. Cyclic voltammogram of 1 mM $[Fe(L_2)](ClO_4)$ (**3**) in CH_3CN at room temperature and recorded at 100 mV/s scan rate.

($S = 1/2$) and this characteristic is due to the orbital contribution. The electronic ground state of the octahedral iron(III) complexes is orbitally degenerate ($^2T_{2g}$) and little to moderate orbital contribution to the $\chi_M T$ values is often observed for low-spin iron(III) complexes with Schiff-base ligands [26,37,38]. The $\chi_M T$ versus T curves follow a Curie law, in agreement with the presence of independent coordination sites.

The low-spin electronic configuration ($S = 1/2$) of the iron(III) centers in the complexes **1**–**4** is further confirmed by the EPR spectra at room temperature for solid-state samples and at 77 K for acetonitrile frozen solutions (Table 4). The EPR spectra of the complex **3** are displayed in Figs. 5 and 6. The results presented in Table 4 demonstrate that the iron(III) ions remains low-spin ($S = 1/2$) at both temperatures. Other six-coordinate iron(III) Schiff-base complexes with N_XO_Y donor sets like $[Fe(N_4O_2)]^+$, $[Fe(N_2O_2)L_2]^+$, $[Fe(N_3O_2)L]^+$ and $[Fe(N_4O_2)]^+$ are either high-spin ($S = 5/2$) or exhibit spin equilibrium [39,40]. Even closely related hexadentate Schiff-base ligands with N_4O_2 donor set do not afford low-spin ($S = 1/2$) iron(III) complexes [21]. Only in very few complexes the coordination of hexadentate ligands to iron(III) ion leads to low-spin electronic configuration [38]. Conversely, all four complexes are low-spin iron(III) compounds from room temperature down to 5 K. From Table 4, all the g matrix values are closely comparable to each other, this indicating that all four complexes are strict in their geometry with subtle distortion around iron(III) center.

The complexes **1**–**4** all have an N_4O_2 donor atom set forming a distorted octahedral coordination geometry around the iron(III) ion, with the oxygen donor atoms occupying *trans*-positions. In all four complexes, the crystallographic, spectroscopic and magnetic studies agree with the presence of a low-spin electronic configuration for the iron(III) ion. The previous studies on hexacoordinated iron(III) complexes with a N_4O_2 donor set have revealed that the *cis* positions of the oxygen donor atoms can provoke drastic changes on the spin state of the iron(III) complexes and high-spin or spin-crossover behaviors were observed, depending on the relative orientation of the additional ligands [15,25]. In addition, the intermolecular hydrogen-bonding interactions involving the amines bound to the iron(III) increase the donor strength of the ligand and favor the low-spin electronic configuration of the metal ion [21].

4. Conclusions

The synthesis and characterization of four new iron(III) complexes with hexadentate Schiff-base ligands with N_4O_2 donor sets is reported. The crystal structures of the

complexes **1**, **3** and **4** indicate the presence of $[Fe(L_1)]^+$ or $[Fe(L_2)]^+$ cations and well-separated perchlorate or tetrafluoroborate anions. The coordination geometry around iron(III) center is pseudo-octahedral with the two phenolic oxygen atoms in *trans* configurations. The crystal lattices are stabilized through extended hydrogen-bonding interactions. The structural, spectroscopic and magnetic studies indicate that the *trans* configuration and the hydrogen-bonding interactions play important role in the stabilization of the low-spin electronic state of the iron(III). The ligand field spectra, electrochemistry and ESI-MS studies suggest that the mononuclear $[Fe(L_1)]^+$ or $[Fe(L_2)]^+$ entities are retained in solution. The temperature dependent magnetic susceptibility studies as well as electron paramagnetic resonance indicate that all four iron(III) complexes remain in low-spin electronic configuration at room temperature as well as 77 K.

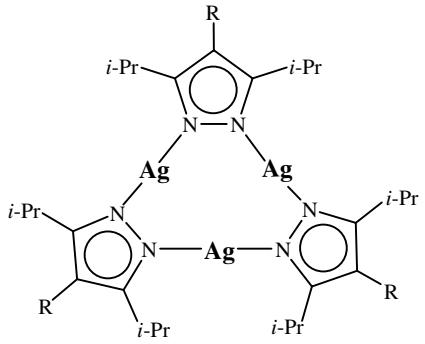
particular, we report the synthesis of {[3,5-(i-Pr)$_2$Pz]Ag}$_3$, {[3,5-(i-Pr)$_2$,4-(Br)Pz]Ag}$_3$, and {[3,5-(i-Pr)$_2$,4-(NO_2)Pz]-Ag}$_3$ via a very convenient route using silver(I) oxide and the corresponding pyrazoles, and their spectroscopic and solid-state structural data.



{[3,5-(i-Pr)$_2$,4-(R)Pz]Ag}$_3$

R = H, Br, NO_2

2. Experimental

2.1. General procedures

All manipulations were carried out under an atmosphere of purified nitrogen using standard Schlenk techniques. Solvents were purchased from commercial sources, distilled from conventional drying agents and degassed by the freeze–pump–thaw method twice prior to use. The glassware was oven-dried at 150 °C overnight. NMR spectra were recorded at 25 °C on a JEOL Eclipse 500 spectrometer (^{1}H, 500.16 MHz, ^{13}C, 125.78 MHz). Proton and carbon chemical shifts are reported in ppm versus Me_4Si. Infrared spectra were recorded on a JASCO FT-IR 410 spectrometer. Melting points were obtained on a Mel-Temp II apparatus and were not corrected. Elemental analyses were performed using a Perkin–Elmer Model 2400 CHN analyzer. Ag_2O and [3,5-(i-Pr)$_2$Pz]H were purchased from commercial sources. [3,5-(i-Pr)$_2$,4-(Br)Pz]H and [3,5-(i-Pr)$_2$,4-(NO_2)-Pz]H were prepared by published methods [35,36].

2.2. {[3,5-(i-Pr)$_2$Pz]Ag}$_3$

Ag_2O (0.42 g, 1.82 mmol) and [3,5-(i-Pr)$_2$Pz]H (0.50 g, 3.30 mmol) were mixed in benzene (20.0 mL). The resulting mixture was protected from light using aluminum foil and refluxed overnight. After cooling, the solution was filtered through a bed of celite to remove some insoluble black material. The filtrate was collected and the solvent was removed under reduced pressure to obtain crude {[3,5-(i-Pr)$_2$Pz]Ag}$_3$ as a colorless solid. X-ray quality crystals were grown from hexane at room temperature. Yield: 95% M.p.: 220 °C (dec.) ^{1}H NMR ($CDCl_3$): δ 1.33 (d, 36H, $J = 7.0$ Hz, CH_3), 2.96 (septet, 6H, $J = 7.0$ Hz, CH), 5.98 (s, 3H, Pz-H$_4$); ^{13}C{^{1}H} NMR ($CDCl_3$): δ 23.6 (CH_3), 28.8 (CH), 95.6 (Pz–CH), 160.6 (Pz–C$_{3,5}$). IR (Nujol): 3853, 2920, 1734, 1541, 1518, 1364, 1297, 1173, 1132, 1103, 1045, 918, 893, 721, 674. *Anal.* Calc. for $C_{27}H_{45}Ag_3N_3$: C, 41.72; H, 5.84; N, 10.81. Found: C, 41.51; H, 5.90; N, 10.80%.

2.3. {[3,5-(i-Pr)$_2$,4-(Br)Pz]Ag}$_3$

A mixture of Ag_2O (0.21 g, 0.91 mmol) and [3,5-(i-Pr)$_2$,4-(Br)Pz]H (0.38 g, 1.65 mmol) in benzene (15.0 mL) was protected from light using aluminum foil, and refluxed overnight. After cooling, the solution was filtered through a bed of celite and the filtrate was collected. The solvent was removed under reduced pressure to obtain crude {[3,5-(i-Pr)$_2$,4-(Br)Pz]Ag}$_3$ as a colorless solid. X-ray quality crystals were grown from hexane at 5 °C. Yield: 92% m.p.: 196–198 °C. ^{1}H NMR ($CDCl_3$): δ 1.40 (d, 36H, $J = 7.5$ Hz, CH_3), 3.14 (septet, 6H, $J = 7.5$ Hz CH); ^{13}C{^{1}H} NMR ($CDCl_3$): δ 22.0 (CH_3), 28.4 (CH), 89.0 (C–Br), 156.6 (Pz–C$_{3,5}$). IR (Nujol): 2920, 1653, 1276, 1168, 1141, 1103, 1088, 1037, 893, 665. *Anal.* Calc. for $C_{27}H_{42}Ag_3Br_3N_3$: C, 31.98; H, 4.17; N, 8.29. Found: C, 31.90; H, 4.00; N, 8.31%.

2.4. {[3,5-(i-Pr)$_2$,4-(NO_2)Pz]Ag}$_3$

Ag_2O (0.21 g, 0.91 mmol) and [3,5-(i-Pr)$_2$,4-(NO_2)Pz]H (0.32 g, 1.65 mmol) were mixed in benzene (15.0 mL). The resulting mixture was protected from light using aluminum foil and refluxed overnight. After cooling, the solution was filtered through a bed of celite to remove some insoluble black material. The filtrate was collected and the solvent was removed under reduced pressure to obtain crude {[3,5-(i-Pr)$_2$,4-(NO_2)Pz]Ag}$_3$ as a yellowish-white solid. X-ray quality crystals were grown from dichloromethane/hexane at 5 °C. Yield: 88% m.p.: >265 °C. ^{1}H NMR ($CDCl_3$): δ 1.47 (d, 36H, $J = 7.0$ Hz, CH_3), 3.67 (septet, 6H, $J = 7.0$ Hz, CH); ^{13}C{^{1}H} NMR ($CDCl_3$): δ 21.4 (CH_3), 28.6 (CH), 129.0 (C–NO_2), 158.5 (Pz–C$_{3,5}$). IR (Nujol): 2924, 2361, 1653, 1558, 1521, 1342, 1187, 1173, 1108, 1083, 1052, 1034, 833, 775, 665. *Anal.* Calc. for $C_{27}H_{42}Ag_3N_9O_6$: C, 35.55; H, 4.64; N, 13.82. Found: C, 35.40; H, 4.42; N, 13.73%.

2.5. X-ray structure determination

X-ray quality crystals of {[3,5-(i-Pr)$_2$Pz]Ag}$_3$ and {[3,5-(i-Pr)$_2$,4-(Br)Pz]Ag}$_3$ were obtained from hexane at room temperature and at 5 °C, respectively. A mixture of hexane and dichloromethane was used to obtain crystals of {[3,5-(i-Pr)$_2$,4-(NO_2)Pz]Ag}$_3$ at 5 °C. The X-ray intensity data were measured on a Bruker SMART APEX CCD area detector system equipped with a Low Temperature device, a graphite monochromator, and a Mo Kα fine-focus sealed tube ($\lambda = 0.71073$ Å). The data frames were integrated with the Bruker SAINT-PLUS software package. Data were corrected for absorption effects using the multi-scan technique (SADABS). All the structures were solved and refined using

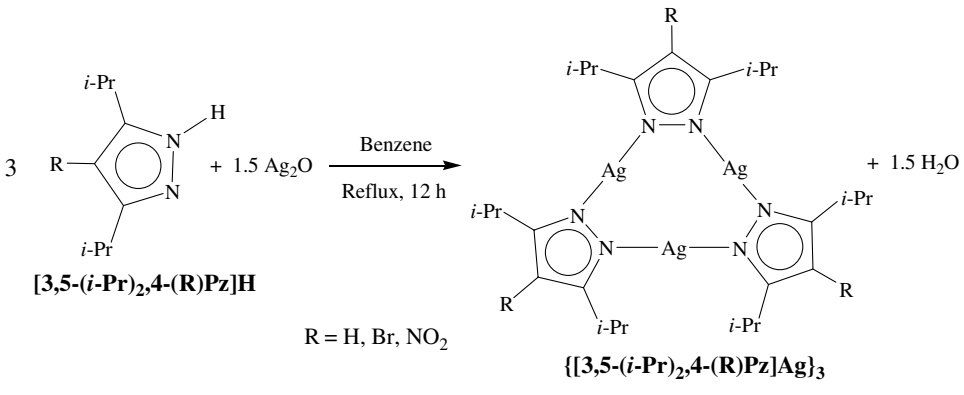
the Bruker SHELXTL software package. Table 1 shows the unit cell dimensions and important structural parameters for the compounds $\{[3,5\text{-}(i\text{-}Pr)_2Pz]Ag\}_3$, $\{[3,5\text{-}(i\text{-}Pr)_2,4\text{-}(Br)Pz]Ag\}_3$, and $\{[3,5\text{-}(i\text{-}Pr)_2,4\text{-}(NO_2)Pz]Ag\}_3$. The asymmetric unit of each of these compounds contains two trimer units. The $\{[3,5\text{-}(i\text{-}Pr)_2,4\text{-}(NO_2)Pz]Ag\}_3$ also crystallizes with 1.6 molecules of CH_2Cl_2 in the asymmetric unit. Crystallographic data (cif files) for these compounds have been deposited with the Cambridge Crystallographic Data Center, CCDS Nos. 281063–281065.

3. Results and discussion

Trimeric, silver(I) pyrazolates could be obtained using several methods. Fackler and co-workers reported the synthesis of $\{[3,5\text{-}(Ph)_2Pz]Ag\}_3$ from CuCl and $[3,5\text{-}(Ph)_2Pz]Na$ in the presence of $AgNO_3$ [16,23] or using $[3,5\text{-}(Ph)_2Pz]Na$ and $Ag(THT)NO_3$ [24]. Syntheses of several other trimeric silver(I) pyrazolates were reported during past two decades following closely related synthetic procedures [22,26]. Masciocchi et al. reported the synthesis of trimeric $\{[Pz]Ag\}_3$ by removing PPh_3 from dimeric silver(I) pyrazolate, $\{(PPh_3)Ag[Pz]\}_2$ [21]. Synthesis of the trimeric Ag(I) complex, $\{[3,5\text{-}(CF_3)_2Pz]Ag\}_3$ using a mixture of silver(I) oxide and 3,5-bis(trifluoromethyl) pyrazole was reported by our group in 2000 [15]. A very similar method was followed by Chi et al. to obtain $\{[3\text{-}(t\text{-}Bu),5\text{-}(CF_3)Pz]Ag\}_3$ and $\{[3,5\text{-}(t\text{-}Bu)_2Pz]Ag\}_3$ [27]. Trimeric $\{[Pz(IN)]Ag\}_3$ was synthesized by Ishida et al. by a reaction of [Pz(IN)]H (3-pyrazolyl imino nitroxide), $AgClO_4$, and 1,8-diazabicyclo[5.4.0]-7-undecene in acetonitrile [25].

The synthetic route established for $\{[3,5\text{-}(CF_3)_2Pz]Ag\}_3$ was utilized for the preparation of trimeric silver(I) complexes described in this paper. In particular, $\{[3,5\text{-}(i\text{-}Pr)_2Pz]Ag\}_3$, $\{[3,5\text{-}(i\text{-}Pr)_2,4\text{-}(Br)Pz]Ag\}_3$, and $\{[3,5\text{-}(i\text{-}Pr)_2,4\text{-}(NO_2)Pz]Ag\}_3$ were synthesized by reacting silver(I) oxide with $[3,5\text{-}(i\text{-}Pr)_2Pz]H$, $[3,5\text{-}(i\text{-}Pr)_2,4\text{-}(Br)Pz]H$, and $[3,5\text{-}(i\text{-}Pr)_2,4\text{-}(NO_2)Pz]H$, respectively. All these complexes are colorless, crystalline, and air stable solids. They are readily soluble in most of the common organic solvents such as hexane, methylene chloride, tetrahydrofuran, diethyl ether, and toluene. $\{[3,5\text{-}(i\text{-}Pr)_2Pz]Ag\}_3$, $\{[3,5\text{-}(i\text{-}Pr)_2,4\text{-}(Br)Pz]Ag\}_3$, and $\{[3,5\text{-}(i\text{-}Pr)_2,4\text{-}(NO_2)Pz]Ag\}_3$ were characterized by X-ray diffraction, IR and NMR spectroscopy data.



^{1}H and ^{13}C NMR spectral data of compounds $\{[3,5\text{-}(i\text{-}Pr)_2Pz]Ag\}_3$, $\{[3,5\text{-}(i\text{-}Pr)_2,4\text{-}(Br)Pz]Ag\}_3$, and $\{[3,5\text{-}(i\text{-}Pr)_2,4\text{-}(NO_2)Pz]Ag\}_3$ are fairly straightforward. In all three compounds, the ^{1}H and ^{13}C NMR chemical shift values are very close to those observed for their corresponding free ligands. However, as expected, the proton NMR spectra of the three silver adducts lack the broad peak corresponding to the N–H proton of the free pyrazole ligands.

X-ray crystallographic data show that the three complexes feature nine-membered Ag_3N_6 metallacycles. They show the presence of a trinuclear cyclic array of three linearly coordinated silver ions (N–Ag–N bond angles range from 168.61(16)° to 178.20(18)°) and three bridging pyrazolates, similar to the triangular framework found in several pyrazolate complexes of the coinage metal ions such as $\{[3,5\text{-}(Ph)_2Pz]Au\}_3$ [23], $\{[3,5\text{-}(CF_3)_2Pz]Ag\}_3$ [15], and $\{[3,5\text{-}(CH_3)_2Pz]Cu\}_3$ [12]. The Ag–N bond lengths are not unusual (range from 2.048(3) to 2.128(5) Å) (see Table 2).

The compound $\{[3,5\text{-}(i\text{-}Pr)_2Pz]Ag\}_3$ crystallizes in the $P2(1)/c$ space group with two chemically similar but crystallographically different trimer units in the asymmetric unit. The most notable feature of $\{[3,5\text{-}(i\text{-}Pr)_2Pz]Ag\}_3$ is that these trimers exist in pairs resulting in Ag–Ag bonded dimers of trimers as illustrated in Fig. 1. Each of these

Table 2
Bond distances (Å) and bond angles (°) for $\{[3,5\text{-}(i\text{-}Pr)_2Pz]Ag\}_3$, $\{[3,5\text{-}(i\text{-}Pr)_2,4\text{-}(Br)Pz]Ag\}_3$, and $\{[3,5\text{-}(i\text{-}Pr)_2,4\text{-}(NO_2)Pz]Ag\}_3$

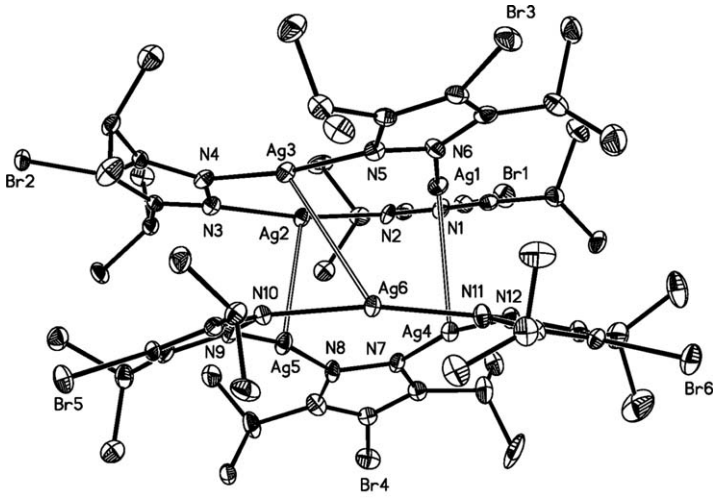
Table 3
Closest inter-trimer Ag–Ag distances (Å) for selected trimeric silver(I) pyrazolates

Compound	Closest inter-trimer Ag···Ag separation	Ref.
$\{[3,5\text{-}(Ph)_2Pz]Ag\}_3$ (from CH_2Cl_2)	2.971(1)	[24]
$\{[3,5\text{-}(i\text{-}PrSCH_2)_2Pz]Ag\}_3$	3.041(1)	[18]
$\{[Pz(IN)]Ag\}_3$	3.179(8)	[25]
$\{[2\text{-}(3(5)\text{-}Pz)Py]Ag\}_3$	3.227(2)	[20]
$\{[3,5\text{-}(Me)_2Pz]Ag\}_3$	3.230(13)	[22]
$\{[3,5\text{-}(CF_3)_2Pz]Ag\}_3$ (from CH_2Cl_2)	3.2037(4)	[2]
$\{[3,5\text{-}(CF_3)_2Pz]Ag\}_3$ (from hexane)	3.307(13)	[15]
$\{[Pz]Ag\}_3$	3.431(4)	[21]

dimer of trimers sits on a center of inversion. The Ag_6 units adopt a chair conformation. The third silver atom of each trimer unit does not show close inter-trimer Ag–Ag contacts. The Ag–Ag distances (of the two crystallographically different dimer of trimers) are 2.9869(4) and 2.9953(5) Å. These distances are significantly smaller than the sum of the van der Waals radii (3.40 Å) of silver. To our knowledge, $\{[3,5\text{-}(i\text{-}Pr)_2Pz]Ag\}_3$ has the second shortest Ag–Ag intermolecular distance (2.9869(4) Å) reported for a trimeric silver(I) pyrazolate. $\{[3,5\text{-}(Ph)_2Pz]Ag\}_3$ crystals obtained from CH_2Cl_2, which exist as dimer of trimers, has a slightly shorter Ag–Ag contact at 2.971(1) Å [24].



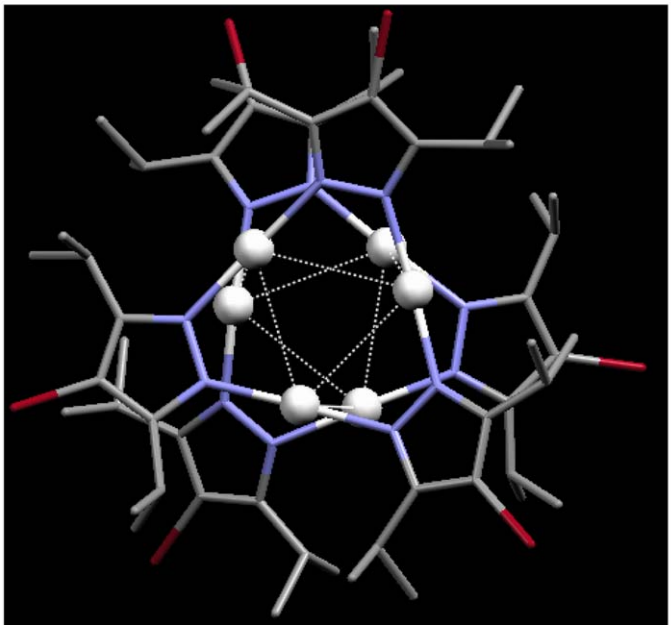


Fig. 2. Two views of the molecular structure of $\{[3,5\text{-}(i\text{-}Pr)_2,4\text{-}(Br)Pz]Ag\}_3$. Hydrogen atoms have been omitted for clarity. Selected bond lengths (Å) and bond angles (°): Ag(1)–N(6) 2.053(4), Ag(1)–N(1) 2.062(4), Ag(2)–N(3) 2.080(4), Ag(2)–N(2) 2.080(4), Ag(3)–N(4) 2.093(4), Ag(3)–N(5) 2.094(4), Ag(4)–N(12) 2.072(4), Ag(4)–N(7) 2.080(4), Ag(5)–N(8) 2.068(4), Ag(1)–Ag(4) 3.0438(5), Ag(2)–Ag(5) 3.2460(5), N(1)–N(2) 1.366(5), N(3)–N(4) 1.373(5), N(5)–N(6) 1.380(6), Br(1)–C(2) 1.899(5), Br(2)–C(11) 1.881(5), Br(3)–C(20) 1.884(5), N(1)–C(3) 1.351(7), N(2)–C(1) 1.350(6), N(4)–C(10) 1.348(6), N(6)–Ag(1)–N(1) 172.89(16), N(3)–Ag(2)–N(2) 171.02(16), N(4)–Ag(3)–N(5) 171.89(15), N(12)–Ag(4)–N(7) 171.89(15), N(8)–Ag(5)–N(9) 169.02(16), N(10)–Ag(6)–N(11) 169.98(16).

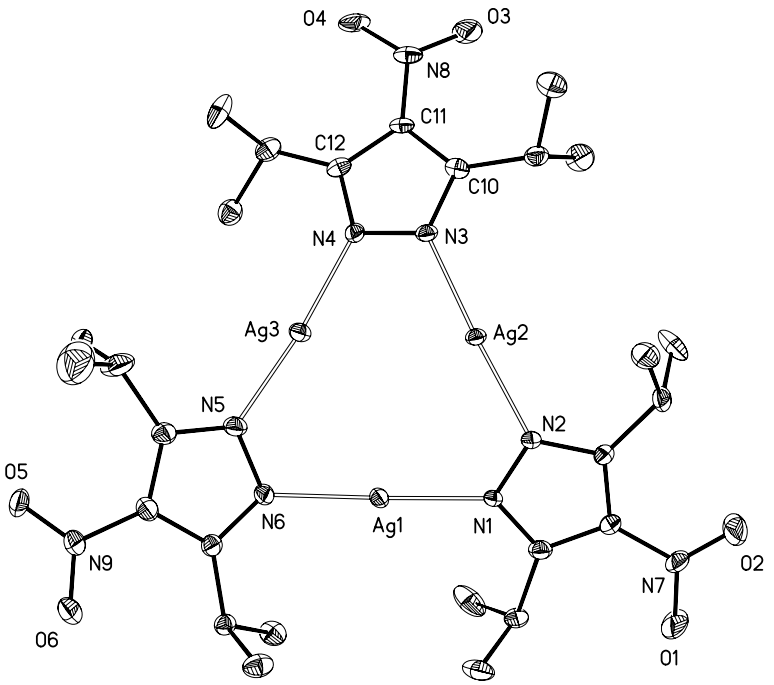

Fig. 3. Molecular structure of and $\{[3,5\text{-}(i\text{-}Pr)_2,4\text{-}(NO_2)Pz]Ag\}_3$. Only one of the trimers present in the asymmetric unit is shown. Hydrogen atoms and the dichloromethane molecules have been omitted for clarity. Selected bond lengths (Å) and bond angles (°): Ag(1)–N(1) 2.104(4), Ag(1)–N(6) 2.128(5), Ag(2)–N(3) 2.120(5), Ag(3)–N(4) 2.098(5), Ag(3)–N(5) 2.109(5), Ag(4)–N(15) 2.119(5), Ag(4)–N(10) 2.123(5), Ag(5)–N(12) 2.072(5), Ag(2)–Ag(3) 3.2962(6), Ag(4)–Ag(5) 3.3409(6), N(1)–C(1A) 1.343(8), N(2)–C(3) 1.344(7), N(3)–C(10) 1.334(7), N(4)–C(12) 1.344(7), N(5)–C(19) 1.323(8), N(1)–Ag(1)–N(6) 178.20(18), N(3)–Ag(2)–N(2) 171.28(19), N(4)–Ag(3)–N(5) 170.52(19), N(15)–Ag(4)–N(10) 173.8(2), N(15)–Ag(4)–N(10) 173.8(2).

We note however that $\{[3,5\text{-}(Ph)_2Pz]Ag\}_3$ has one short inter-trimer Ag–Ag contact whereas $\{[3,5\text{-}(i\text{-}Pr)_2Pz]Ag\}_3$ dimerizes with the formation of two Ag–Ag links. Solvents used in the crystallization could also affect the structures. For example, work by Fackler et al. showed that $\{[3,5\text{-}(Ph)_2Pz]Ag\}_3$ crystallizes from THF/Et_2O as well separated trimers with no close Ag–Ag contacts [23]. We have observed similar solvent effects on $\{[3,5\text{-}(CF_3)_2Pz]Ag\}_3$. In addition to $\{[3,5\text{-}(i\text{-}Pr)_2Pz]Ag\}_3$, $\{[3,5\text{-}(Ph)_2Pz]Ag\}_3$, and $\{[3,5\text{-}(CF_3)_2Pz]Ag\}_3$, silver(I) complexes such as $\{[3,5\text{-}(i\text{-}PrSCH_2)_2Pz]Ag\}_3$, $\{[2\text{-}(3(5)\text{-}Pz)Py]Ag\}_3$, and $\{[Pz(IN)]Ag\}_3$, reported by Meyer et al. [18], Stavropoulos et al. [20], and Ishida et al. [25], respectively, also display dimer of trimer structures with inter-trimer Ag–Ag distances in the range of the sum of the van der Waals radii of silver (Table 3). The copper(I) analog $\{[3,5\text{-}(i\text{-}Pr)_2Pz]Cu\}_3$ is known [19], and it also shows isolated dimer of trimers like the silver adduct $\{[3,5\text{-}(i\text{-}Pr)_2Pz]Ag\}_3$.

The trimer moieties in $\{[3,5\text{-}(i\text{-}Pr)_2,4\text{-}(Br)Pz]Ag\}_3$ form dimers leading to a pseudo octahedral Ag_6 unit (Fig. 2). All three silver atoms of the $\{[3,5\text{-}(i\text{-}Pr)_2,4\text{-}(Br)Pz]Ag\}_3$ moiety show close inter-trimer Ag–Ag interactions, which are less than or very close (from 3.044(5) to 3.408(5) Å) to the sum of the van der Waals radii of silver. The trimer units deviate from planarity and adopt bowl shaped structures facilitating these Ag–Ag contacts. The packing diagram of $\{[3,5\text{-}(i\text{-}Pr)_2,4\text{-}(Br)Pz]Ag\}_3$ shows that there are several inter-trimer Ag–Br links (at about 3.5 Å range) as well. Interestingly, the copper(I) analog of $\{[3,5\text{-}(i\text{-}Pr)_2,4\text{-}(Br)Pz]Ag\}_3$ adopts a tetrameric structure in the solid state forming $\{[3,5\text{-}(i\text{-}Pr)_2,4\text{-}(Br)Pz]Cu\}_4$ [37].

Unlike $\{[3,5\text{-}(i\text{-}Pr)_2Pz]Ag\}_3$ or $\{[3,5\text{-}(i\text{-}Pr)_2,4\text{-}(Br)Pz]Ag\}_3$, the 4-nitro analog $\{[3,5\text{-}(i\text{-}Pr)_2,4\text{-}(NO_2)Pz]Ag\}_3$ does not form dimer of trimers with Ag–Ag contacts. The asymmetric unit contains two trimer units and 1.6 molecules of dichloromethane. The $\{[3,5\text{-}(i\text{-}Pr)_2,4\text{-}(NO_2)Pz]Ag\}_3$ units exists as isolated trimers (Fig. 3). However, there are close inter-trimer Ag–O contacts (closest at 2.732 Å) between the silver atoms and the oxygen atoms of the nitro groups. This may be a reason for the non-existence of even weak inter-trimer Ag–Ag interactions. The H-atoms of the dichloromethane molecules present in the crystals also show close contacts with some of the oxygen atoms of the nitro groups.

Overall, we describe the synthesis and characterization of three new silver pyrazolates containing 3,5-isopropyl groups, and different substituents on the pyrazolyl ring 4-positions. They can be synthesized using silver(I) oxide as the Ag(I) source. They show different packing patterns with notable differences in inter-trimer Ag–Ag distances. We are currently carrying out studies on photochemical and physical properties of these silver adducts.

4. Supplementary material

Crystallographic data for $\{[3,5\text{-}(i\text{-}Pr)_2Pz]Ag\}_3$, $\{[3,5\text{-}(i\text{-}Pr)_2,4\text{-}(Br)Pz]Ag\}_3$, and $\{[3,5\text{-}(i\text{-}Pr)_2,4\text{-}(NO_2)Pz]Ag\}_3$ have been deposited with the Cambridge Crystallographic Data

Center, CCDS Nos. 281063–281065. Copies of this information may be obtained free of charge from the Director, Cambridge Crystallographic Data Centre (CCDC), 12 Union Road, Cambridge, CB2 1EZ (fax: +44 1223 336033; e-mail: deposit@ccdc.cam.ac.uk; or http://www.ccdc.cam.ac.uk).

Based on the strong coordinative behavior of the 2-aminobenzothiazole which is a molecular model for complex biological molecules, we decided to add supplementary coordination sites rich in lone pairs by substituting the NH protons by PPh_2 and $P(OEt)_2$ and their oxides (O, S and Se) and to study their structure, preferred conformations, intra- and intermolecular sulfur donor and acceptor interactions and cooperative hydrogen bonds.

The aim of our research was also to study the preferred conformers and the tautomeric preference of the N–H and the geometric isomers of N–P bonds, in order to understand the influence of hydrogen bonds and acid/base contacts and to know if groups like PY_2 (Y = Ph and OEt) or $Y_2P{=}E$ (E = O, S, Se) could favor the homodimerization through multiple hydrogen bonds. Labile N–H bonds favor intermolecular cooperative hydrogen bonds with electronic lone pairs (N, O, S and Cl) or aromatic π electrons. Hydrogen bond is a fundamental element for catenation of organic, inorganic or mixed molecular units to give a variety of complex structures [18,19]. N–H coordination networks are biologically important due to the molecular recognition of hydrogen bonds [20].

Our research has been focused on the exploration of supramolecular assemblies formed by double, triple and quadruple hydrogen bonds, these supramolecular units with multiple hydrogen bonds are scarcely reported and they have been only observed in organic systems as cianuric acid–melamina complex, dimers of diaminotriazines, diaminopirimidines, ureidopirimidone and dicarboxylic acids [21].

Another interest of our research is the study of weak donor acceptor interactions at sulfur and selenium atoms which determines preferred conformers and conglomerates. It is recognized that sulfur presents coordinating contacts at distances lesser than 3.70 Å, sulfur (Lewis base) is donor in the axis perpendicular to the plane depicted by the bonds X–S–Z or acceptor (Lewis acid) following the directions of S–X or Z–S bonds [8,9,22–29].

2. Experimental

2.1. Materials

All synthetic work and the handling of samples were carried out under inert atmosphere (N_2), using carefully dried glassware and dry solvents. $P(C_6H_5)_2Cl$, 2-aminobenzothiazole, NEt_3, Se and S powders were commercially available. Bis(trimethylsilyl)peroxide was prepared at the laboratory [30]. NEt_3 was dried according to established procedures, and freshly distilled before use. 2-Aminobenzothiazole was sublimated at low pressure before use.

2.2. Synthesis of the compounds **2**–**11**. General procedure

2.2.1. 2-Aminobenzothiazole-diphenylphosphane (**2**)

To a stirred solution of 2-aminobenzothiazole (2.0 g; 13.3 mmol) and NEt_3 (2.7 g; 26.7 mmol) in THF (125 mL) at −78 °C was added dropwise a solution of $P(C_6H_5)_2Cl$ (2.94 g; 13.3 mmol) in THF (20 mL) under nitrogen atmosphere. The mixture was warmed to r.t. and kept stirring for 2 h. Then, insoluble material was filtered off and the solvent removed at 0.1 torr. Compound **2** was obtained as a white powder, dried at 0.05 torr during 8 h and recrystallized from hot toluene or benzene. Colorless crystals were suitable for diffraction analysis. Yield: 4.27 g, 96%, m.p. 132–136 °C. *Anal.* Calc. for $C_{19}H_{15}N_2SP$: C, 68.26; H, 4.49; N, 8.38; S, 9.58. Found: C, 68.57; H, 4.81; N, 8.82; S, 8.99%. MS, *m/z* (%): 334(100) M^+, 257(23), 183(54), 150(8). FAB+ [335]. IR (ν cm^{-1}): NH 3448, C=N 1540, P–C 1445 and 1096, C–S 1391 and 639, P–N 1067 and 926. ^1H NMR (400 MHz; THF-d_8), δ (ppm): 7.30 [d, H4, $^3J(^1H{-}^1H)$ 8.0], 7.18 [dd, H5, $^3J(^1H{-}^1H)$ 8.0, 7.7], 7.06 [dd, H6, $^3J(^1H{-}^1H)$ 8.0, 7.7], 7.64 [d, H7, $^3J(^1H{-}^1H)$ 8.0], 7.55 [m, H_o], 7.35 [m, H_m, H_p].

2.2.2. 2-Aminobenzothiazole-diethylphosphite (**3**)

It was synthesized following the same procedure as for **2** using 1.0 g (6.7 mmol) of **1**, 1.35 g (13.3 mmol) of NEt_3 and 1.0 g (6.7 mmol) of $PCl(EtO)_2$ in 150 mL of THF. Compound **3** is a white solid. Yield: 1.67 g, 93%, m.p. 70–72 °C. *Anal.* Calc. for $C_{11}H_{15}N_2SO_2P$: C, 48.89; H, 5.55; N, 10.37; S, 11.85. Found: C, 49.33; H, 5.75; N, 10.86; S, 11.58%. MS, *m/z* (%): 270(68) M^+, 242(6), 226(19), 197(24), 180(18), 150(46), 121(91), 93 (100), 65(82). IR (ν cm^{-1}): NH (3323, 3235), C=N (1618, 1599), P–C (1450), C–S (1391, 618), P–N (1102, 922), P–O (1043, 1026), PO–C (1160). ^1H NMR (400 MHz; THF-d_8), δ (ppm): 7.54 [d, H4, $^3J(^1H{-}^1H)$ 7.8], 7.25 [dd, H5, $^3J(^1H{-}^1H)$ 7.8, 7.5], 7.08 [dd, H6, $^3J(^1H{-}^1H)$ 7.8, 7.5], 7.62 [d, H7, $^3J(^1H{-}^1H)$ 7.8], 3.94 [7.8] [dq, CH_2, $^3J(^1H{-}^1H)$ 7.0], 1.24 [t, CH_3, $^3J(^1H{-}^1H)$ 7.0].

2.2.3. 2-Aminobenzothiazole-diphenylphosphane oxide (**4**)

Bis(trimethylsilyl)peroxide (0.53 g, 3 mmol) was added dropwise at r.t. to a stirred suspension of **2** (1.0 g; 3 mmol) in 100 mL of toluene under nitrogen atmosphere. After stirring for 24 h, a white precipitate was filtered and dried at low pressure (0.05 Torr) during 8 h. Compound **4** is a white solid. Yield 0.89 g, 85%, m.p. 240–242 °C. *Anal.* Calc. for $C_{19}H_{15}N_2SPO$: C, 65.13; H, 4.32; N, 8.00; S, 8.15. Found: C, 65.25; H, 4.33; N, 8.01; S, 8.79%. MS, *m/z* (%): 350(100), 273(33), 226(21), 201(34). IR (ν cm^{-1}): NH 3578, 1266, C=N 1581, P–C 1435, 1125, C–S 1411, 626, P–N 1062, 954, P=O 1168. ^1H NMR (400 MHz; THF-d_8), δ (ppm): 7.20 [d, H4, $^3J(^1H{-}^1H)$ 7.7], 7.19 [dd, H5, $^3J(^1H{-}^1H)$ 7.7, 7.5], 7.04 [dd, H6, $^3J(^1H{-}^1H)$ 7.7, 7.5], 7.37 [d, H7, $^3J(^1H{-}^1H)$ 7.7], 7.84 [m, H_o], 7.37 [m, H_m, H_p].

2.3. General Method for compounds **5**–**8**

2.3.1. 2-Aminobenzothiazole-diphenylphosphane sulfide (**5**)

Compound **5** was obtained as a white solid prepared with the same procedure as described for compound **4**

using 1.0 g (3 mmol) of **2** and 0.96 g (3 mmol) of S powder. Yield: 0.89 g, 81%, dec. at 268–270 °C. *Anal.* Calc. for $C_{19}H_{15}N_2S_2P$: C, 62.28; H, 4.13; N, 7.64; S, 17.50. Found: C, 62.13; H, 4.26; N, 7.39; S, 17.43%. MS, *m*/*z* (%): 366(74) M^+, 289(7), 257(100), 217(38), 179(21), 139(33). IR (*v*, cm^{-1}): NH 3554, 1251, C=N 1583, P–C 1432, 1181, C–S 1400, P–N 1024, 952, P=S 673. ^1H NMR (400 MHz; THF-d_8), δ (ppm): 7.13 [d, H4, $^3J(^1H–^1H)$ 8.0], 7.19 [dd, H5, $^3J(^1H–^1H)$ 8.0, 7.5], 7.04 [dd, H6, $^3J(^1H–^1H)$ 8.0, 7.5], 7.44 [d, H7, $^3J(^1H–^1H)$ 8.0], 7.94 [m, H_o], 7.33 [m, H_m, H_p].

2.3.2. 2-Aminobenzothiazole-diphenylphosphane selenide (*6*)

Compound **6** was prepared with the same procedure as described for compound **4** using 1.0 g (3 mmol) of **2** and 0.24 g (3 mmol) of Se powder. The reaction mixture was kept stirring for 48 h at r.t., and then was heated at 115 °C for 6 h. Compound **6** is a white solid. Yield 0.90 g, 73%, dec. at 270–274 °C. *Anal.* Calc. for $C_{19}H_{15}N_2SPSe$: C, 55.21; H, 3.66; N, 6.58; S, 7.49. Found: C, 55.53; H, 3.64; N, 6.81; S, 7.25%. MS, *m*/*z* (%): 414(73) M^+, 334(23), 257(100), 179(29). IR (*v* cm^{-1}): NH 3468, 1250, C=N 1587, P–C 1431, 1098, C–S 1398, P–N 1023, 951, P=Se 438, 418. ^1H NMR (400 MHz; THF-d_8), δ (ppm): 7.17 [d, H4, $^3J(^1H–^1H)$ 8.0], 7.22 [dd, H5, $^3J(^1H–^1H)$ 8.0, 7.5], 7.07 [dd, H6, $^3J(^1H–^1H)$ 8.0, 7.5], 7.48 [d, H7, $^3J(^1H–^1H)$ 8.0], 7.96 [m, H_o], 7.34 [m, H_m, H_p].

2.3.3. 2-Aminobenzothiazole-diethylphosphate sulfide (*7*)

It was synthesized following the same procedure as described for compound **4** using 1.0 g (3 mmol) of **3** and 0.95 g (3.7 mmol) of S powder. Compound **7** gave colorless monocrystals from benzene suitable for diffraction analysis. Yield: 0.9 g, 79%, m.p. 159–162 °C. *Anal.* Calc. for $C_{11}H_{15}N_2S_2O_2P$: C, 43.70; H, 5.00; N, 9.27; S, 21.21. Found: C, 44.22; H, 4.89; N, 9.51; S, 21.39%. MS, *m*/*z* (%): 302(51) M+, 257(21), 225(24), 197(21), 150(100). IR (υ cm^{-1}): NH 3449, C=N 1599, 1580, P–C 1411, C–S 1389, P–N 978, 955, P–O 1052, 1028, POC 1158, P=S 659. ^1H NMR (400 MHz; THF-d_8), δ (ppm): 7.28 [d, H4, $^3J(^1H–^1H)$ 7.7], 7.27 [dd, H5, $^3J(^1H–^1H)$ 7.7, 7.5], 7.13 [dd, H6, $^3J(^1H–^1H)$ 7.7, 7.5], 7.54 [d, H7, $^3J(^1H–^1H)$ 7.7], 4.06 [$J(^1H–^{31}P)$ 9.5] [dq, CH_2, $^3J(^1H–^1H)$ 7.1], 1.26 [t, CH_3, $^3J(^1H–^1H)$ 7.1].

2.3.4. 2-Aminobenzothiazole-diethylphosphate selenide (*8*)

It was synthesized following the previous procedure using 1.0 g (3 mmol) of **3** and 0.29 g (3.7 mmol) of selenium. Compound **8** is a white solid. Yield: 1.06 g, 82%, m.p. 152–155 °C. *Anal.* Calc. for $C_{11}H_{15}N_2SO_2PSe \cdot 1/15C_7H_8$: C, 38.75; H, 4.41; N, 7.88; S, 9.02. Found: C, 38.74; H, 4.40; N, 8.32; S, 8.83%. MS, *m*/*z* (%): 350 (26) M^+, 241(32), 213(69), 197(31), 162(26), 150(100). IR (*v* cm^{-1}): NH 3418, C=N 1573, P–C 1449, C–S 1390, P–N 950, P–O 1047, 1020, POC (1159), P=Se 429. ^1H NMR (400 MHz; THF-d_8), δ (ppm): 7.23 [d, H4, $^3J(^1H–^1H)$ 8.0], 7.23 [dd, H5, $^3J(^1H–^1H)$ 8.0, 7.7], 7.11 [dd, H6, $^3J(^1H–^1H)$ 8.0, 7.7], 7.54 [d, H7, $^3J(^1H–^1H)$ 8.0], 4.04 [$J(^1H–^{31}P)$ 9.8] [dq, CH_2, $^3J(^1H–^1H)$ 7.0], 1.24 [t, CH_3, $3J(^1H–^1H)$ 7.0].

2.3.5. Lithium 2-aminobenzothiazolide-diphenylphosphane (*9*)

A solution of **2** (0.25 g; 0.75 mmol) and 1, 4, 7, 10, 13, 16-hexaoxaciclooctadecane (0.24 g; 0.89 mmol) in THF (80 mL) was cooled at −50 °C and under nitrogen atmosphere was added slowly *n*-BuLi [0.75 mmol; 1.5 M]. The mixture was warmed at r.t. and the solvent was eliminated at 0.05 Torr. Compound **9** is a pale yellow solid. Yield: quantitative. *Anal.* Calc. for $C_{27}H_{30}LiN_2O_2PS$: C, 66.93; H, 6.24; N, 5.78; S, 6.62. Found: C, 66.30; H, 6.52; N, 5.35; S, 6.90%. FAB(+): 485 ($C_7H_5SN_2P(C_6H_5)_2Li \cdot 2THF$), 341 ($C_7H_5SN_2P(C_6H_5)_2$-Li). IR (KBr) *v* ($cm^{-1}$): 1646, 1444, 1122, 1125, 627, 1021. ^1H RMN (400 MHz; THF-d_8), δ (ppm): 7.11 [d, H4, $^3J(^1H–^1H)$ 7.9], 7.04 [dd, H5, $^3J(^1H–^1H)$ 7.9, 7.5], 6.78 [dd, H6, $^3J(^1H–^1H)$ 7.9, 7.5], 7.36 [d, H7, $^3J(^1H–^1H)$ 7.9], 7.60 [m, H_o], 7.19 [m, H_m, H_p]. ^7Li NMR (155.4 MHz; THF-d_8), δ: +1.3.

2.3.6. Lithium 2-aminobenzothiazolide-diphenylphosphane oxide (*10*)

Compound **10** was obtained as colorless single crystals from a solution of **9** 200 mg (0.33 mmol) in THF (1.0 mL) and hexane (5.0 mL) and let aside for two months. Yield: 16 mg, 8%, m.p. 145 °C. X-ray diffraction analysis was performed.

2.3.7. Bis-(2-aminothiazolium) tetrachloro-diphenyl plumbate (*11*)

Compound **11** was obtained as colorless crystals from the equimolar mixture of compounds **2** and $Pb(NO_3)_2$, in THF and in the presence of $NHEt_3Cl$. No reaction was detected by NMR in the following hours and even after a few days at room temperature. The solution in an NMR tube was let aside for three months, few crystals were formed in THF-d_8 that were analyzed by X-ray diffraction.

2.4. Physical measurements

NMR spectra were recorded in DMSO-d_6 and THF-d_8 dried with sodium spheres, on a Jeol GSX-270, Jeol Eclipse 400 and Bruker 300 Avance spectrometers. Chemical shifts are given in ppm and referred to Me_4Si or H_3PO_4 (aq., 85 %) [$\delta^{31}P = 0$ with $\Xi(^{31}P) = 40.480747$ MHz, neat Me_2Se [$\delta^{77}Se = 0$ with $\Xi(^{77}Se) = 19.071513$ MHz] and $MeNO_2$ neat $\Xi(^{15}N) = 10.136767$ MHz. Assignment of ^1H and ^{13}C NMR data were supported by 2D $^1H/^{13}C$ HETCOR and $^1H/^{13}C$ HMBC experiments. NMR data are given in Tables 1 and 2. Electron impact (EI) mass spectra at 20 eV were performed in a Hewlett–Packard HP 5989A spectrometer with direct inlet. Melting points (uncorrected) were measured using a MeITemp II equipment in a closed capillar tube. Elemental Analyses were carried out in a Flash 1112 Thermo Finnigan analyzer. IR spectra were

2.5. X-ray crystallographic study

Suitable single crystals of compounds **2**, **7**, **10** and **11** were submerged in perfluoro ether oil and mounted in a capillary tube (0.5 mm). Crystal data and information about the data collection and structure refinement details are given in Tables 3–6. X-ray diffraction studies were performed with Siemens SMART Area-detector, CAD4, Kappa-CCD diffractometer using Mo radiation ($\lambda = 0.71073$ Å) at 293 K. The WINGX software was used. The crystal structures were determined and refined with the SHELXTL-97 $[x, y]$ system. Hydrogen atoms were found by Fourier difference in **2** and **10**.

3. Results and discussion

Phosphoramides **2** and **3** were prepared by the condensation of 2-aminobenzothiazole and the corresponding phosphorus halides in the presence of NEt_3. Their oxidation afforded compounds **4–8** P=E (E = O, S, Se), Scheme 1. Even though, that the synthesis of **2** and **4** was previously reported by Henning [31], where the characterization of **4** was only based on the melting point and IR spectrum.

Compounds **2–8** were prepared in good yield, they are white solids very reactive to moisture and oxygen, partially soluble in DMSO and THF, and insoluble in $CHCl_3$, CH_2Cl_2, acetone and hydrocarbons. They were characterized by NMR, IR, mass spectrometry, elemental analyses and X-ray diffraction (**2** and **7**). The reaction of **2** with *n*-BuLi in THF, at −78 °C and in the presence of 1,4,7,10,13,16-hexa-oxacyclooctadecane, was performed in order to obtain the lithium amide **9**, which was characterized in solution. After two months, suitable monocrystals were obtained from a solution of **9** in THF:hexane (1:5). X-ray diffraction study showed that a new compound **10** was formed in solution, which was the lithium coordination compound of the oxidized 2-aminobenzothiazole-diphenylphosphane.

The equimolar reaction of **2** with $Pb(NO_3)_2$ in THF, at room temperature and in presence of $NHEt_3Cl$ did not show the transformation of **2**. Nevertheless, after three months of storage at room temperature the solution contained some crystals which, after X-ray diffraction analysis, showed that they correspond to the tetrachlorodiphenylplumbate (IV) dianion bearing two molecules of protonated 2-aminobenzothiazole as counterions, compound **11**, Scheme 1. We can attribute the formation of **11** to the migration of phenyl groups from the phosphorus to the lead atom, the presence of NEt_3HCl (by-product in the synthesis of **1**) allowed the substitution of nitrate by chloride ions. There are no reports of similar transfer for lead, however a comparable phenyl migration in the reaction of $SbBr_2(C_6H_5)_2$ with $PtCl_2$ and *cis*-$[PtCl_2(P(C_6H_5)_3)_2]$ is proposed in order to explain the formation of *cis*-$[PtBr_2(Sb(C_6H_5)_3)_2]$, *trans*-$[PtBr(C_6H_5)(Sb(C_6H_5)_3)_2]$, *cis*-$[PtBr_2(P(C_6H_5)_3)(Sb(C_6H_5)_3)]$ and $[PtBr_3(Sb(C_6H_5)_3)]^-$ [32]. Reported anions such as $Cl_4(C_6H_5)_2Sn$(IV) and $Cl_4(C_6H_5)_2Sb$(IV) with one or two molecules of a protonated amine are isostructural with the new *bis*-phenyl plumbate. Jun et al. [33] reported the molecular structure of the complex $(C_6H_5)_2SbCl_4 \cdot 2,2'$-bipyridine having an hexacoordinated antimony atom with two phenyl groups in *anti* position, and explaining its formation from the hydrolysis of $(C_6H_5)_2SbCl_3 \cdot 2,2'$-bipyridine. Finally, Holmes et al. [34] found out that the hydrolysis of $(C_6H_5)_2SnCl_2 \cdot L$ (L = quinuclidine) produces the complex $[(C_6H_5)_2SnCl_4]^{-2}\ [LH]^{+1}{}_2$ through the formation of estanoxanes.

The reactions of the phosphates **7** and **8** with tin and germanium derivatives were attempted, but unfortunately no coordination compounds were observed.

3.1. NMR spectroscopy

Although ^1H, ^{13}C, ^{31}P and ^{77}Se NMR spectra clearly showed the phosphorus amides formation **2**–**8**, identification of the preferred tautomers and conformers remained to be carefully answered. The ^{15}N NMR data of compound **2** is shown in Scheme 2 and is compared with similar reported compounds. The value of the coupling constant

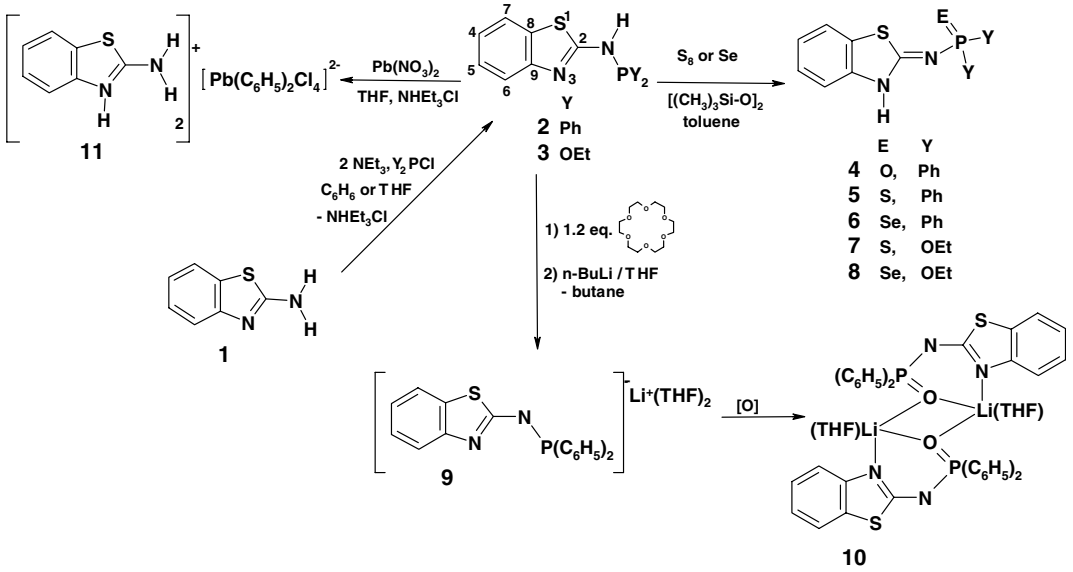
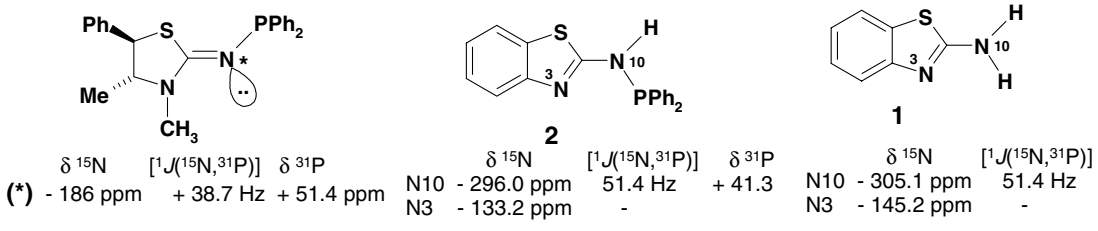
$^{1}J(^{15}N–^{31}P)$ is characteristic of phosphoramides [35–37]. Comparison of these data with those of the starting 2-aminobenzimidazole **1** shows that the endocyclic nitrogen and C2 contribute with electronic density to the exocyclic nitrogen, in order to compensate the phosphorus electron withdrawing effect. An important difference in the values of ^{15}N of compound **2** with those of the diphenylphosphoramide derived from 2-imino-1,3-thiazolidine [38] was found, which indicates that the two molecules present different tautomers and conformers. The ^{77}Se data for compounds **6** and **8** confirmed the phosphorus oxidation. Data for compound **6** is similar with those of a $Ph_2P{=}Se$ amide derived from 2-imino-1,3-thiazolidine [38] depicted in Scheme 3. A different trend was found when the dimethyl amide derived from 2-imino-1,3-thiazolidine [3] is compared with compound **8**, the variation of their ^{77}Se chemical shifts is due to the different effect of P–N versus P–O bonds, Scheme 3.

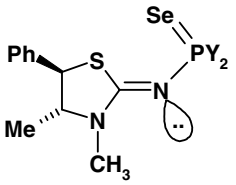
Regarding the identification of the preferred tautomers in solution, the ^{13}C NMR analysis could give evidence by closely looking at C9 chemical shift for all the compounds, in solution compounds **1**–**3** and **9** presented for C9 a chemical shift (151.6–153.3) which is characteristic of a carbon atom vicinal to an sp^2 nitrogen bearing a lone pair, as is shown in tautomers depicted in Scheme 1 [39]. In contrast, compounds **7** and **8** show a typical C9 bound to an N–H group ($\delta = 137.2$–138.8) which indicates the preference of



Scheme 1. Synthesis of compounds **2**–**10**.



Scheme 2. ^{31}P and ^{15}N NMR data for **1**, **2** are compared with those of analogous compound [38].



Y	δ ^{77}Se	[^{1}J(^{77}Se,^{31}P)]	δ ^{31}P

6 C_6H_5	- 203.0 ppm	689 Hz	+ 38.6 ppm
8 OEt_2	- 302.0 ppm	876 Hz	+ 68.5 ppm

Scheme 3. ^{31}P and ^{77}Se NMR data for **6** and **8** are compared with those of analogous compound [3].

the tautomer having protonated the endocyclic nitrogen. For compounds **4**–**6**, the chemical shift of C9 ($\delta = 144.0$–147.2) indicates a tautomeric equilibrium in solution, in fact it also agrees with the observation of NH protons signals at higher frequencies in ^{1}H NMR.

The configuration of the geometric isomers around the *exo* C=N bond [phosphorus atom in *cis* or *trans* position with respect to the endocyclic C–N (or C–S) bonds] was determined by the observation of *W* coupling constants $^{4}J(^{13}C–^{31}P)$ at C8 base of the sulfur, which indicate that P is on the same side of endocyclic nitrogen atom for compounds **2**, **3** and **9**. In contrast there is no visible phosphorus coupling with C8 for compounds **4**–**8** and therefore, it is proposed that these molecules present the conformation described in Scheme 1. However, an X-ray analysis of compound **2** showed the opposite conformation in solid state compared to the one found in solution.

NMR data gives evidence that the oxidation of the phosphorus atom changes the preferred tautomer of the molecule and therefore the electronic distribution in compounds **4**–**8**, Tables 1 and 2. It is quite interesting to observe some shielding effect at C8 resulting from the phosphorus oxidation which could be the consequence of O···S, S···S and Se···S electron donor acceptor interactions, Table 1. Oxidation also increases the coupling constants values ^{1}J and $^{2}J(^{13}C–^{31}P)$ of the $P(C_6H_5)_2$ groups; although a decreasing tendency in the order O < S < Se can be noticed for the coupling value $^{1}J(^{13}C_i–^{31}P)$ in **4**–**8**. The ^{1}H spectra of compounds **4**–**6** showed that the *ortho* protons of the phenyl group were shifted to higher frequencies with respect to **2**, indicating a proton interaction with the P-chalcogen, $\Delta\delta$ 0.29 (**4**); 0.39 (**5**), and 0.41 ppm (**6**).

^{7}Li NMR data of compound **9** indicates its ionic character and that the lithium atom is coordinated by THF molecules (δ ^{7}Li [+1.3; $\Delta\nu_{1/2} = 2.5$ Hz]). In addition, ^{13}C NMR confirmed the anionic character of the *exo*-nitrogen atom based on the shift at higher frequencies of the C2 signal.

The variation of N–H chemical shifts with the temperature ($\Delta\delta/\Delta T$) in a proton accepting solvent (THF-d_8) evidences the strength of intramolecular, intermolecular or with solvent N–H interactions. Values higher than 4×10^{-3} ppm/K usually correspond to solvated N–H and indicate weak intermolecular bonds, Table 2 [40]. Therefore, in compounds **2**, **4**–**8**, the values between 6.8 and 10×10^{-3} ppm/K indicating that they have weak hydrogen bonds in exchange with the solvent.

3.2. Crystal structures

Aminophosphine **2** crystallized from dried benzene at room temperature to give colorless crystals. The unit cell contains two molecules forming a dimer. The X-ray diffraction analysis showed that the diphenylphosphine group is on the same side of the sulfur atom, Fig. 1 and Table 3. The interatomic distance P···S 3.10 Å shorter than the sum of the van der Walls radii [$\sum r_{vdw}$ (P, S) = 3.65 Å] indicates a stabilizing contact. The phosphorus atom is almost in the molecular plane [torsional angles: S–C2–N_{exo}–P = 9.01°, N3–C2–N_{exo}–P = 171.13°]. The bond length N_{endo}–C2 [1.287(3) Å] indicates a localized double bond whereas the bond length C2–N_{exo} [1.347(3) Å] correspond to a delocalized bond, Table 4. The bond angles around N_{exo} (average 120.9(2)°) correspond to an sp^2 hybridization. The bond angles at phosphorus [N–P–C 101.1(1)°, C1–P–C2 103.6(1)°, N–P–C2 104.4(1)6°] denote 46% of sp^3 character and the P–N_{exo} bond length 1.689(2) Å is attributed to a delocalized P–N bond. The conformation of **2** favors six cooperative intermolecular hydrogen bonds, NH···N 2.14 and 2.22 Å and CH···C$^-$ 2.86, 2.84, 2.89 and 2.87 Å, Fig. 1. To our knowledge, this

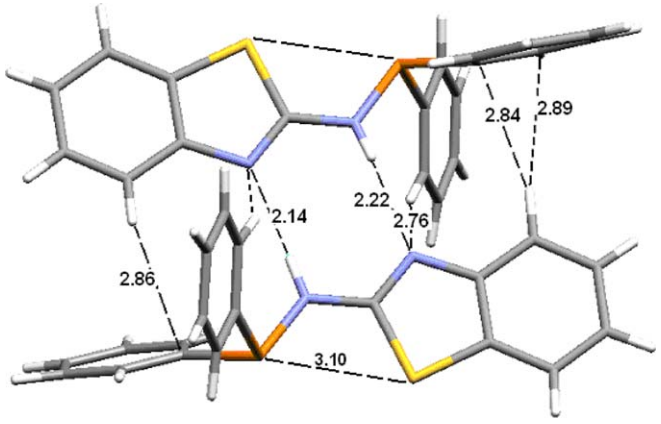

Fig. 1. Molecular structure of **2** showing six cooperative intermolecular hydrogen bonds.

is the first example of six hydrogen multiple bonds [41]. The crystalline cell of **2** shows a zig-zag polymeric arrangement.

Compound **7** crystallized from benzene, the X-ray analysis of the colorless monoclinic crystals shows the tautomer with the NH proton at the endocyclic nitrogen and the conjugate system C2═N–P═S, with endocyclic and exocyclic sulfur atoms almost coplanar and close to each other (3.13 Å); it is deduced that an S···S interaction occurs ($\sum r_{vdw}$ 3.60 Å), Fig. 2 and Table 4. The torsional angle S1–C2–N–P (1.31°) indicates that the phosphorus is in the molecular plane. The P–N bond length [1.633(3) Å], which falls between a P–N single bond (1.77 Å) and a P═N double bond (1.56 Å) indicates some delocalization, that is extended to bond C2–N3 [1.344(4) Å] and C2–N10 [1.312(4) Å]. Angles around phosphorus [S–P–N10 119.0(1)°, S–P–O16 113.9(1)°, S–P–O13 115.7(1)°, N–P–O16 103.8(1)°, O–P–O 99.8(1)°, N–P–O13 102.1(1)°] are characteristic of a distorted tetrahedral geometry.

The homodimerization of **7** can be seen in the unit cell through quadruple hydrogen bonds with an arrangement AADD–DDAA (A, acceptor site; D, donor site). This bonding situation generates three eight membered cycles

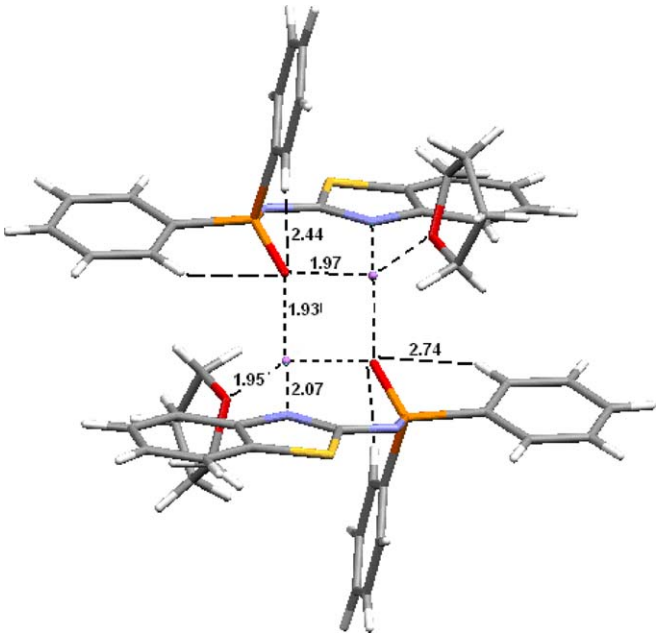

Fig. 4. X-ray structure of compound **10**.

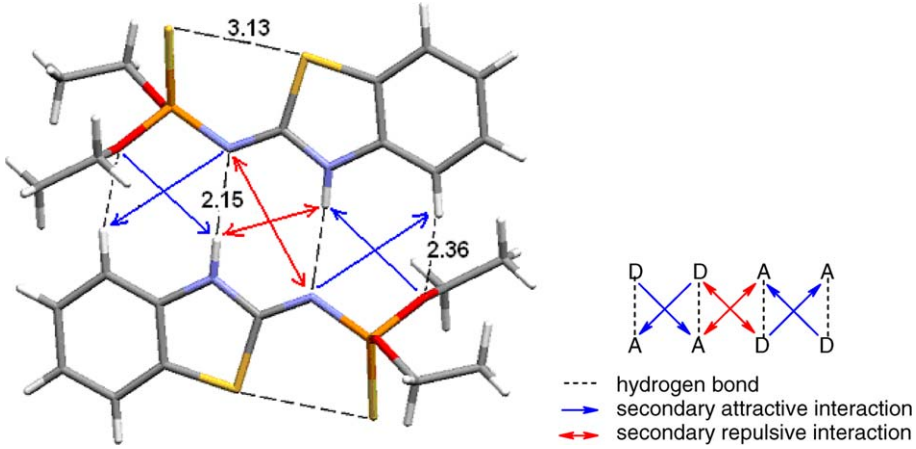

Fig. 2. Molecular structure of **7** showing quadruple hydrogen bonds, secondary repulsive and attractive interactions in AADD–DDAA arrangements.

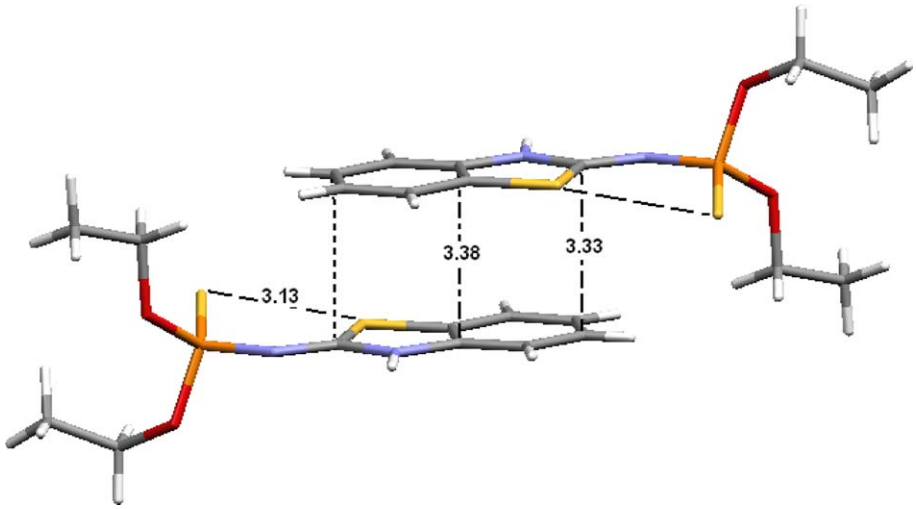

Fig. 3. Solid state structure of compound **7** showing π–π (3.33 and 3.38 Å) and S···S (3.13 Å) interactions.

by contacts NH···N$^-$ (2.152 Å) and H4···OP (2.36 Å), both shorter than the corresponding sum of the van der Waals radii ($\sum r_{vdw}(N, H) = 3.00$Å; $\sum r_{vdw}(O, H) = 2.95$ Å), Fig. 2. A π–π face to face interaction between the aromatic planes was observed (3.33 and 3.38 Å), Fig. 3.

As seen in Fig. 4 and Table 5, the crystal structure of **10** determined by X-ray diffraction shows a dimer containing an inversion center with O_{THF}–Li–Li–O_{THF} and N–Li–Li–N rotational angles of 180°. Each lithium atom is bound to three oxygen atoms and to the endocyclic nitrogen atom of one 2-aminobenzothiazole molecule. It is interesting to observe that in comparison to compound **4** where the preferred conformation in solution presents the P=O bond oriented *cis* to the S atom, in **10** the P=O group is *cis* to the endocyclic N. The bond lengths C2–N_{exo} [1.331(3) Å], C2–N_{endo} [1.326(3) Å], P–N_{exo} [1.613(2) Å] and P=O [1.511(2) Å] indicate an electronic delocalized system N–C2–N–P–O, Table 5. Torsional angles N–C2–N–P (10.8°), S–C2–N–P (169.2°) and C2–N–P–O (51.7°) showed that the P–O bond is out of the benzothiazole plane. The lengths N_{endo}–Li [2.08(5) Å] and Li···O [in average of 1.95 Å] are characteristic for covalent bonds. The Li–N–C2–N angle of 18.5° indicates that the lithium atom is slightly out of the benzothiazole plane. The

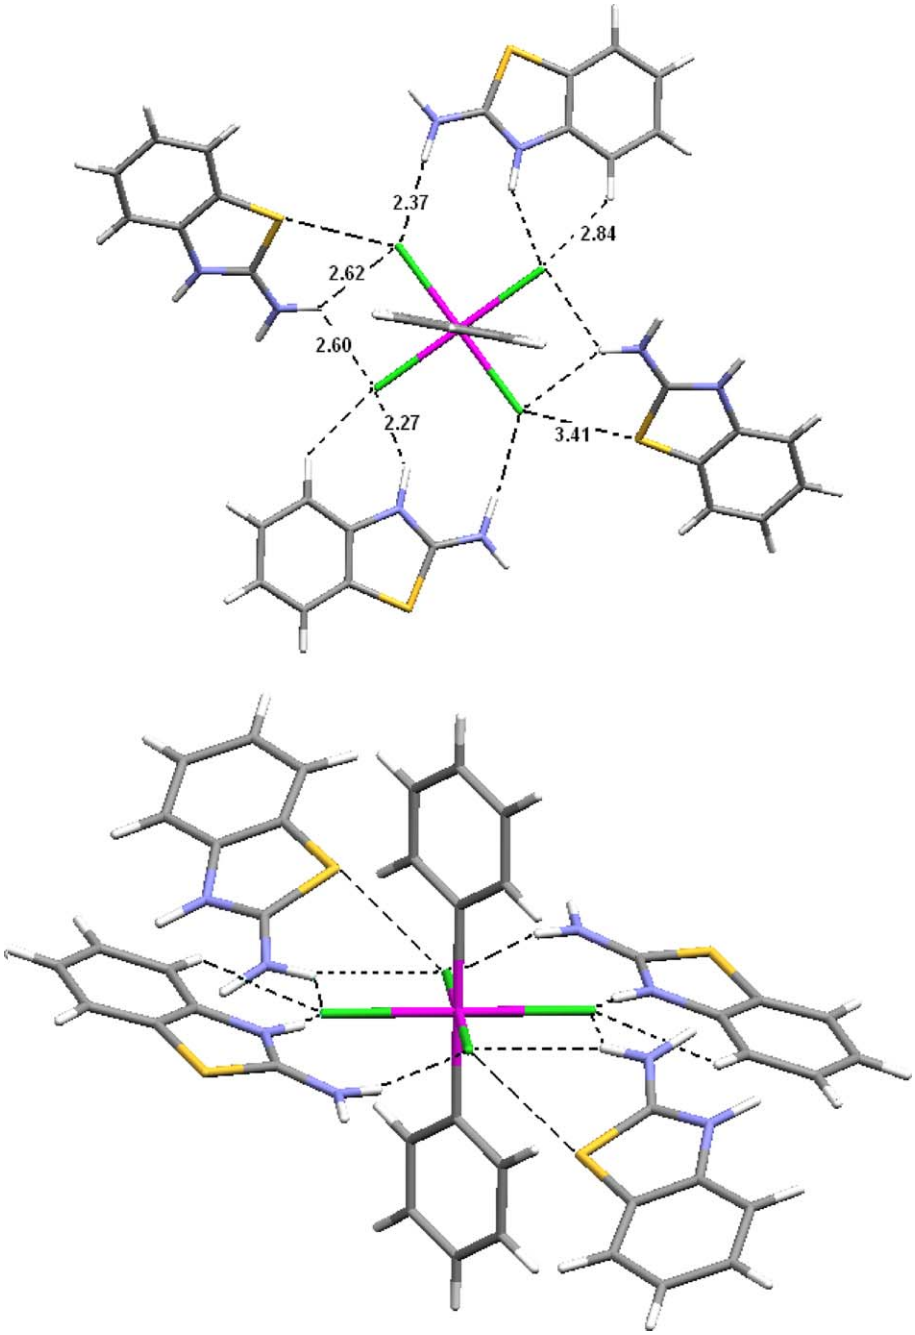

Fig. 5. Two views of the X-ray structure of compound **11**.

distance between the two lithium atoms is 2.69 and between the two P=O oxygen atoms is 2.82 Å. Each P=O oxygen atom has two short contacts with one *ortho* C–H of the P-phenyl group (2.74 and 2.44 Å), Fig. 4.

In compound **11** (Fig. 5 and Table 6), the metal atom is bound to two phenyl groups in *anti* position [Pb–C_{Ar} 2.138(7) Å; C_{Ar}–Pb–C_{Ar} 179.99(4)°] and to four coplanar chlorine atoms [Pb–Cl(1) 2.606(1) Å; Pb–Cl(2) 2.579(1) Å] [Cl(1)–Pb–Cl(1) = Cl(2)–Pb–Cl(2) = 180.0°], Table 6 and Fig. 5. In the cell four benzothiazolium cations interact by hydrogen bonds with the plumbate chlorine atoms, the distances of these multiple contacts are N2–H···Cl (2.37 Å), N3–H···Cl (2.27 Å) and S···Cl (3.41 Å) which are shorter than the corresponding sum of the van der Waals radii [$\sum r_{vdw}(H, Cl) = 2.90$–$3.35$ Å; $\sum r_{vdw}(S, Cl) = 3.70$ Å]. Two cations present three cooperative hydrogen bonds with two *cis* chlorine atoms (2.37, 2.27 and 2.84 Å) whereas the other two cations present only a bifurcate hydrogen bond with two *cis* chlorine atoms (2.6 Å). In addition, for each plumbate anion there are two chlorine–sulfur contacts of 3.41 Å, Fig. 5.

4. Summary

The 2-aminobenzothiazole phosphoramides are interesting polyfunctional and very reactive compounds, where preferred tautomers and conformers and hydrogen bonds were carefully established by multinuclear NMR.

We have found that phosphoramides are preferentially formed at the exocyclic nitrogen atom of the 2-aminobenzothiazole. In solution, compounds **2** and **3** have a preferred conformation with the P atom on the same side of the endocyclic nitrogen, and a preferred tautomer with the proton on the exocyclic nitrogen atom. Phosphorus oxidation changes the preferred tautomer and conformer to the one with a protonated endocyclic nitrogen.

In the solid state compound **2** presents a different conformer resulting from the extensive hydrogen bonds network which gives stabilized dimers through the cooperation of unusual six intermolecular hydrogen bonds and also forms the stabilizing S···P short contact of 3.11 Å, (sum of van der Walls radii 3.65 Å) where the P atom is in the plane of the heterocycle.

Compound **7** forms dimers through quadruple cooperative bonds two NH···N^- and two H4···O–P. The molecule presents a S···S interaction indicated by the geometry and the S···S distance (3.13 Å) which is smaller than the van der Waals radii (3.60 Å).

A lithiation of **2** furnishes **9** together with the dimeric lithium complex **10** as by product. The solid state structure of **10** presents a new conformation with the endocyclic nitrogen on the same side of the P=S bond. The reaction of **2** with $Pb(NO_3)_2$ did not afford the expected lead coordination compound but the diphenyl tetrachloro lead anion **11** resulting from phenyl and chloro migration to lead in very low yield. Compound **11** is remarkable regarding the structure of the hexacoordinated lead dianion unit and also by the protonated 2-aminobenzothiazole which establishes an interesting weak interactions network.

are possible [1–6]. These are the nitro (Cu–NO_2) and (nitrito-*O*) via either nitrogen or oxygen binding, respectively [1–6]. As a bidentate ligand, NO_2^- can chelate or bridge via the two oxygens (nitrito-*O*,*O*′) [7–10], via one nitrogen and one oxygen or via a single oxygen atom [6,11]. The tridentate behavior of the nitrite ligand was also found in a few cases where the coordination mode is accomplished in two ways. In the first case, the NO_2^- is chelated to one metal through its two oxygen atoms and bridged to a second metal ion via the nitrogen atom [12]. In the second case, the two metal ions are bridged via one oxygen while the second oxygen binds to one of the two metal ions [13,14]. On the other hand, besides the ambi-monodentate nature of the NCS^- ion, the ligand was extensively used to synthesize bridged polynuclear copper(II) complexes with different dimensionality [15–20]. In bridged copper(II)–thiocyanato systems, two principal modes of coordination are exhibited namely end-to-end ($\mu_{N,S}$-NCS), and end-on binding modes via $\mu_{N,N}$-NCS and $\mu_{S,S}$-NCS. A few examples were reported in the bridging coordination modes $\gtrdot$NCS ($\mu_{N,N}$-NCS) [19] and $\gtrdot$SCN ($\mu_{S,S}$-NCS) [20]. The interaction of the thiocyanate group with Cu^{2+} in the end-to-end ($\mu_{N,S}$-NCS) coordination mode led to a variety of 1D singly and doubly bridged NCS-polynuclear species [15–18].

The stereochemistry adapted by the nitrito- and thiocyanato-copper complexes ranges between square pyramidal (SP) and trigonal bipyramidal (TBP); most of the complexes are known to adapt geometries that are intermediate between the two extremes [1,2,5,8,18]. However, tetragonally distorted octahedron geometry was also observed in a relatively large number of nitrito and thiocyanato copper (II) complexes such as in $[Cu(dpyam)_2(ONO)]^+$ [4],[1] $[Cu(TIMM)(NO_2)_2]$ [9],[1] $[Cu(NO_2)_2CuL]_n$ where L = *N*, *N*′-bis(2-methyl-2-aminopropyl)oxamide [11], and $[Cu_2(L)_2(\mu_{N,S}\text{-}NCS)_2(OClO_3)_2]$ (L = dien and dpt) [17].[1]

In this paper, we report the synthesis, properties and molecular structure of the monomeric nitrito-Cu(II) and the dinuclear doubly bridged thiocyanato-Cu(II) complexes derived from 3,3′-diamino-*N*-methyldipropylamine (Medpt) and diethylenetriamine (dien). Also, the study provides more structural data concerning the bridged thiocyanato-Cu(II) complexes in an attempt to shed the light on the structural factors that might affect the formation of a certain bonding coordination mode over the other.

2. Experimental

2.1. Materials and physical measurements

3,3′-Diamino-*N*-methyldipropylamine (Medpt) and diethylenetriamine (dien) were purchased from Aldrich Chemical Company and copper(II) perchlorate hexahydrate from Strem Chemical Company, USA. All other materials were reagent grade quality. Infrared spectra were recorded on JASCO FT/IR-480 plus spectrometer as KBr pellets. Electronic spectra were recorded using Agillent 8453 HP diode UV–Vis spectrophotometer. Elemental analyses were carried out by the Atlantic Microlaboratory, Norcross, GA, USA. The magnetic measurements were carried out in the "Servei de Magnetoquímica (Universitat de Barcelona)" on polycrystalline sample (40 mg) with a Quantum Design SQUID MPMSXL susceptometer in the temperature range 2–300 K and the magnetic field was 1 T.

Caution: Salts of perchlorate and their metal complexes are potentially explosive and should be handled with great care and in small quantities.

2.2. Synthesis of the complexes

2.2.1. [Cu(Medpt)(ONO)(H2O)]ClO4 (1)

Copper(II) perchlorate hexahydrate (0.93 g, 2.5 mmol) dissolved in 20 ml of methanol was added to 3,3′-diamino-*N*-methyldipropylamine (0.37 g, 2.5 mmol) in methanol (10 ml). To this solution, $NaNO_2$ (0.35 g, 5 mmol) dissolved in 50 ml of hot MeOH was added dropwise. The resulting blue solution was heated for 10 min on a steam bath, filtered while hot and then allowed to crystallize at room temperature. Upon standing at room temperature, the navy-blue crystals which separated out were collected by filtration, washed with ether, and air dried (overall yield: 0.70 g, 97%). Crystals suitable for X-ray analysis were obtained from dilute methanolic solution by slow crystallization. Characterization: *Anal*. Calc. for $C_7H_{21}ClCuN_4O_7$: C, 22.58; H, 5.69; N, 15.05. Found: C, 22.71; H, 5.65; N, 15.00%. Selected IR bands (KBr, cm^{-1}): ν(O–H) (H_2O) stretching, 3449 (mb); ν(O–N)(NO_2^-) 1439 (s), 1268 (s); ν(Cl–O)(ClO_4^-) centered at 1092 (vs).

2.2.2. [Cu(dien)(ONO)]ClO4 (2)

A similar procedure as that described above for **1** was followed, and the complex was separated as blue crystals (overall yield: 77%). Crystals suitable for X-ray analysis were obtained from the second batch upon crystallization at ambient temperature. Characterization: *Anal*. Calc. for $C_4H_{13}ClCuN_4O_6$: C, 15.39; H, 4.20; N, 17.95. Found: C, 15.28; H, 4.13; N, 18.01%. Selected IR bands (KBr, cm^{-1}): ν(O–N)(NO_2^-) 1472 (m), 1271 (s); ν(Cl–O)(ClO_4^-) at 1144 (vs), 1116 (vs), 1085 (vs).

2.2.3. [Cu2(Medpt)2(μN,S-NCS)2](ClO4)2 (3)

To a solution containing $Cu(ClO_4)_2 \cdot 6H_2O$ (0.375 g, 1.0 mmol) and 3,3′-diamino-*N*-methyldipropylamine (0.145 g, 1.0 mmol) in methanol (40 ml), NH_4NCS (0.085 g, 1 mmol) dissolved in MeOH (10 ml) was added drop by drop. The resulting blue solution was heated on a steam-bath for 5 min, filtered while hot and allowed to crystallize at room temperature. After a few minutes, small blue crystals were

[1] Ligand abbreviations: Medpt, 3,3′-diamino-*N*-methyldipropylmine; dpt, dipropylenetriamine; dien, diethylenetriamine; Et_2dien, *N*,*N*-diethyldiethylenetriamine; TPA, tris(2-pyridyl methyl)amine, dpyam, 2,2′-dipyridylamine; and TIMM, tris[2-(1-methyl)imidazolyl]methane.

obtained. These were collected by filtration, washed with ether and air dried (yield: 0.35 g, 96%). Crystals of X-ray quality were obtained from the first batch. Characterization: *Anal*. Calc. for $C_8H_{19}ClCuN_4O_4S$: C, 26.32; H, 5.23; N, 15.29. Found: C, 26.51; H, 5.35; N, 15.36%. Selected IR bands (KBr, cm^{-1}): ν(NCS), 2116 (vs); ν(Cl–O)-(ClO_4^-), 1092 (vs).

2.3. X-ray data collection and refinement for complexes 1–3

The X-ray single-crystal data were collected on a modified STOE four-circle diffractometer. Graphite-monochromatized Mo Kα radiation ($\lambda = 0.71069$ Å) with the ω-scan technique were used to collect the data sets. The accurate unit-cell parameters were determined from automatic centering of 36 reflections ($7.4° < \theta < 14.7°$) for **1**, 38 reflections ($10.3° < \theta < 15.5°$) for **2**, and 60 reflections ($12.1° < \theta < 16.4°$) for **3**, and refined by least-squares methods. The intensities were corrected for Lorentz-polarization effects, intensity decay (intensity drop of 4%, 6% and 7% for **1**–**3**, respectively) and for absorption using the DIFABS [21] computer program. The structures were solved by direct methods and refined by full-matrix least-squares methods on F^2, using the SHELXTL/PC V 5.03 [22] program package. All non-hydrogen atoms were refined anisotropically. In case of **1**, split occupancy of disordered oxygen atoms of ClO_4 counter ion: 0.687(10) and 0.313(10) were applied. The hydrogen atoms were assigned with isotropic displacement factors and included in the final refinement cycles on calculated positions, except for **1**, where nine distance restraints (2 O–H, 4 N–H, 3 H–H) were applied to fix the internal geometry of the water molecule and $–NH_2–$ groups of the Medpt ligand. Residual extremes in the final difference Fourier syntheses were observed in vicinity of metal atoms. Table 1 lists the crystallographic data for the three complexes. Selected bond parameters are given in Tables 2–4 for **1**–**3**, respectively.

3. Results and discussion

3.1. Crystal structure of the complexes

3.1.1. [Cu(Medpt)(ONO)(H_2O)]ClO_4 (1)

A perspective view together with the atom labeling scheme is given in Fig. 1 and selected bond parameters are given in Table 2. The structure consists of isolated $[Cu(Medpt)(ONO)(H_2O)]^+$ cations and perchlorate counter anions. The copper centers are pentacoordinated by the three N atoms of the Medpt, oxygen atom O(1) of nitrito group and oxygen atom O(3) of a water molecule. The

coordination polyhedron may be described as an axially elongated square pyramid. The Cu(1)–O(1), Cu(1)–N(2), Cu(1)–N(3), Cu(1)–N(4) distances are 2.069(3), 1.975(3), 2.052(3) and 1.996(3) Å, respectively. The Cu(1)–O(3) distance is 2.297(3) Å and the Cu(1)···O(2) separation to non-coordinated oxygen atom of nitrito anion is 2.575(4) Å. The Cu···Cu separation is 5.468(2) Å. Hydrogen bonds of the types N–H···O and O–H···O (Table 5) form a 3D supramolecular network. In this case, the N(1)–O(1) distance [1.261(5) Å] of the nitrito group involving the stronger Cu(1)–O(1) interaction [2.069(3) Å] is longer than the N(1)–O(2) distance [1.213(5) Å] involving the very weak Cu(1)···O(2) [2.575(4) Å] interaction. Also, the Cu(1)–O(1)–N(1) angle [108.8(2)°] was found to be in the range reported for monodentate nitrite (pure monodentate nitrite angle Cu–O–NO is around 119.5°) [23], whereas the O(1)–N(1)–O(2) angle [114.2(3)°] is slightly smaller than 115.4° for the free nitrite ion [24].

3.1.2. *[Cu(dien)(ONO)]ClO$_4$ (**2**)*

A perspective view together with the atom labeling scheme is given in Fig. 2 and selected bond parameters are given in Table 3. The structure consists of [Cu(dien)(ONO)]$^+$ cations and perchlorate counter anions. Each copper atom forms bonds to the three N atoms of the dien ligand [Cu–N bonds from 1.958(4) to 2.000(4) Å], a short bond to oxygen atom O(1) [2.224(6) Å] and a longer bond [2.430(8) Å] to second oxygen atom O(2) of the nitrito group. The nitrito groups [N(4)–O(1) = 1.148(11) Å, N(4)–O(2) = 1.218(11) Å, O(1)–N(4)–O(2) = 120.2(8)°] act as μ-OO′ bridging ligands. Centrosymmetrically related pairs of [Cu(dien)(ONO)]$^+$ cations (Fig. 2) have Cu(1)···Cu(1B) and Cu(1)–O(1B) separations of 4.1265(17) and 2.670(6) Å, respectively, whereas the shortest inter-dimeric Cu···Cu separation is 6.0481(17) Å. Hydrogen bonds of type N–H···O are listed in Table 5. The O(1)–N(4)–O(2) angle is 120.2(8)° is larger than that found for the free nitrite ion [24], and the Cu(1)–O(1)–N(4) angle is 100.0(5)° which is in the range found for pure bidentate nitrite [93–100°] [25]. The O(1)–Cu(1)–O(2) bond angle of 52.1° agrees well with the values previously reported for the bite angle of the coordinated nitrite group reported in [Cu(dpyam)$_2$(ONO)]Y complexes (Y = ClO_4^-, NO_3^-, NO_2^-) [4a,23a]. Also, it is interesting to note that the bidentate nature of the nitrito group was established in the mononuclear analog diethylenetriamine-*N*,*N*′,*N*″-nitrito-O,O′nitrocopper(II) [10].

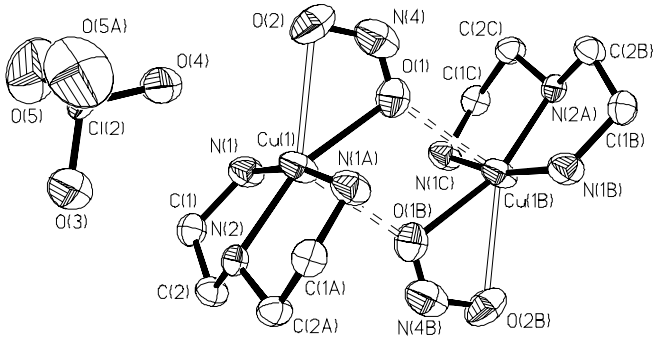

Fig. 2. ORTEP view (30% ellipsoids) with atom labeling scheme of **2**.

3.1.3. *[Cu$_2$(Medpt)$_2$($\mu_{N,S}$-NCS)$_2$](ClO$_4$)$_2$ (**3**)*

A perspective view together with the atom labeling scheme is given in Fig. 3(a)–(c) and selected bond parameters are given in Table 4. Each copper center is penta-coordinated by the three N atoms of the Medpt [Cu–N$_{(Medpt)}$ from 1.976(6) to 2.0786(6) Å], one N atom of NCS^- group in basal positions [Cu–N$_{(NCS)}$ bonds from 2.011(6) to 2.019(6) Å], and a sulfur atom from NCS^- ion in the apical position [Cu–S bonds from 2.698(2) to 2.735(2) Å]. The coordination polyhedra may be described as axially elongated square pyramids. The dinuclear subunits are established via the NCS groups which act as μ-NS bridging ligands. The structure consists of perchlorate counter anions and three crystallographically independent dinuclear [Cu$_2$(Medpt)$_2$(NCS)$_2$]$^{2+}$ cations. Two of the dinuclear units are located on inversion centers, one on a general position. The intradimeric Cu···Cu distances in these dinuclear units are 5.5132(15), 5.5157(16) and 5.4289(15) Å, and the shortest interdimeric Cu···Cu seperation is 6.1738(17) Å. The Cu$_2$(NCS)$_2$ rings are almost planar with mean "chair" angles of 8.4(3)°, 10.4(3)° and 15.4(4)°. The "chair" angle is defined as acute angle between plane formed by the two (NCS) bridges with (N–Cu–S) plane within a Cu$_2$(NCS)$_2$ ring. The deviations of the copper centers from their basal N$_4$ planes are 0.215(2), 0.216(2),

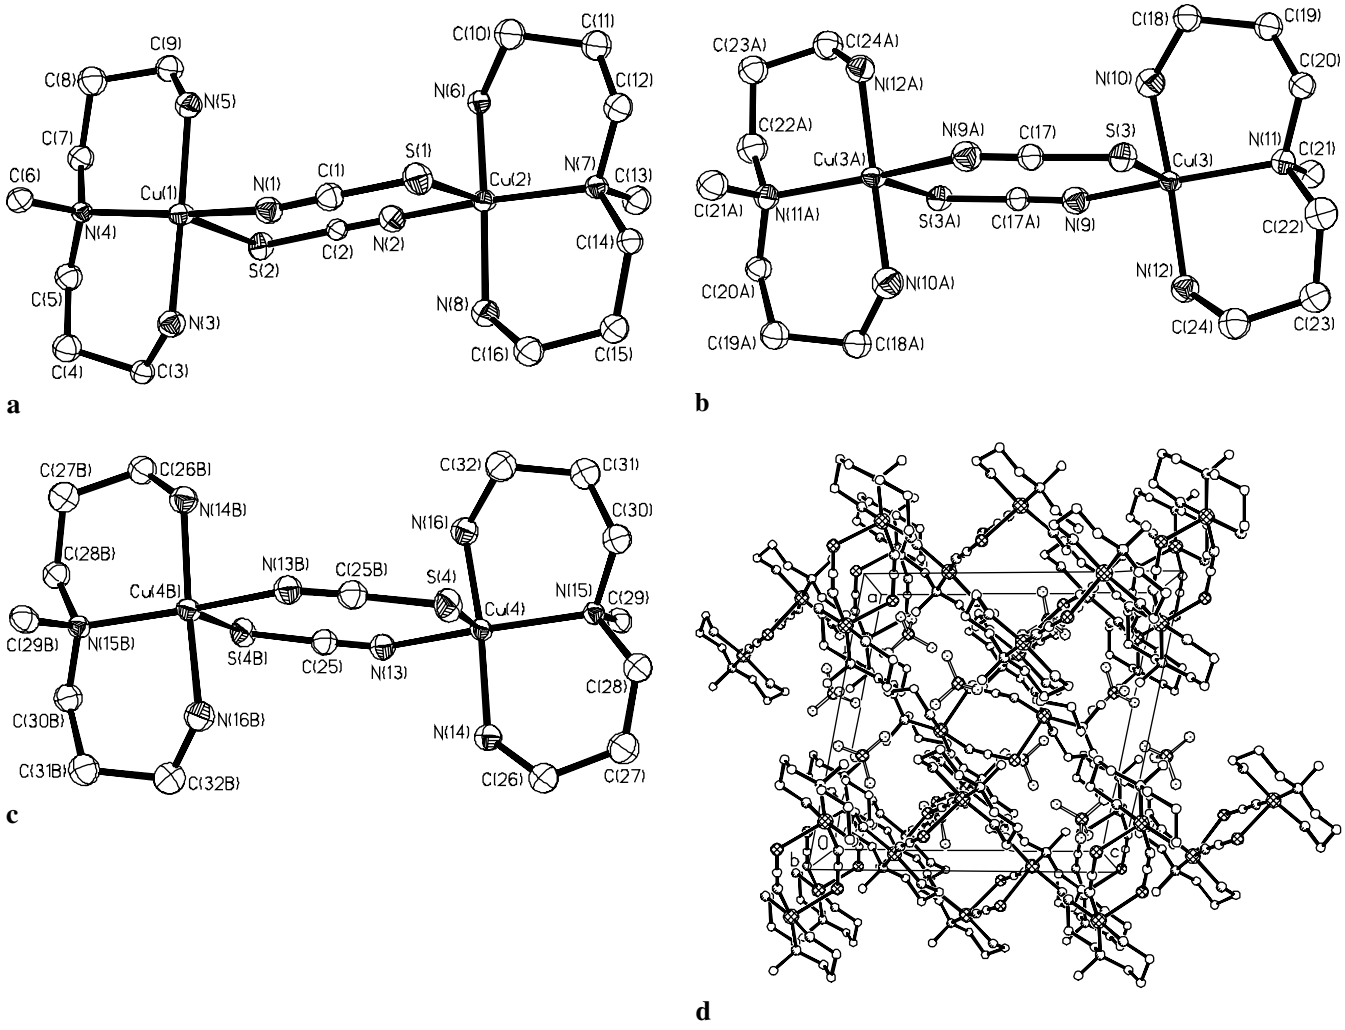

Fig. 3. (a)–(c) Molecular geometry with atom labeling scheme of the dinuclear $[Cu_2(Medpt)_2(\mu\text{-}NCS)_2]^{2+}$ subunits of **3**. (d) Packing view of **3**.

0.218(2) and 0.243(2) Å, respectively. Hydrogen bonds of type N–H···O (Table 5) form a 3D supramolecular network.

The same end-to-end bond fashion observed here in the doubly bridged thiocyanato-Cu(II)–Medpt complex **3** was observed with other Cu(II) complexes derived from linear tridentate amines such as dien, Et_2dien, and dpt [15].[1] The same type of bonding was also found in the azido complexes derived from Medpt and Et_2dien [15,26][1] but with dpt an end-on coordination mode was produced [27].

In the five-coordinate complexes, an intermediate structure may be found between the regular SP and the TBP geometries. The geometrical factor, τ which represents the degree of TBP distortion from ideal SP geometry ($\tau = 0$ for ideal SP and 1 for ideal TBP) [28] is used to obtain a quantitative picture for the degree of distortion in the complexes under investigation. The ratio between the two basal angles that would form the basal plane in the SP structure defines $\tau = (\theta - \phi)/60$. For the nitrito complexes **1** and **2** (see Figs. 1 and 2 for labeling) $\tau \approx 0.03$ and 0.13, respectively, whereas in **3** (Fig. 3 for labeling), the corresponding τ values are about 0.02, 0.01, 0.05 and 0.02 for Cu(1)–Cu(4), respectively. Aside from the relative strong distortion observed here in $[Cu(dien)(ONO)]^{2+}$ (**2**), these values still reveal the exclusive existence of the SP geometries in the three complexes.

3.2. Infrared spectra

The infrared spectrum of the nitrito complex **1** exhibits strong absorption bands at 1439 and 1268 cm^{-1} whereas **2** shows bands of medium intensities at 1472 and 1271 cm^{-1}, attributable to the stretching frequencies ν_{as}(O–N) and ν_s(O–N), respectively. The splitting between the two bands, $\Delta\nu(NO_2)$ (ν_{as}(O–N) − ν_s(O–N)) was used to distinguish between the various bridging modes of the coordinated NO_2^- group [29]. However, the observed $\Delta\nu(NO_2)$ values in these complexes (171 cm^{-1} for **1** and 201 cm^{-1} for **2**) did not provide a satisfactory conclusion concerning the coordination mode of the NO_2^- ligand [1,4,8,30]. This may result from the anisodentate nature of the NO_2^- group. The stretching frequency ν(Cl–O) of the perchlorate in complex **2** which occurs at 1116 cm^{-1} is split into three peaks indicating that the symmetry of

D, donor; A, acceptor.

the perchlorate ion is lowered from T_d to C_{3v} which most likely may result from its location along the O(1B)–Cu(1)–O(4) axis [29].

The infrared spectrum of the doubly bridged end-to-end thiocyanato complex **3** shows a very strong absorption band at 2116 cm^{-1} attributable to the stretching frequency of $\nu(NCS^-)$. This band is located at a relatively higher position compared to that found in $[Cu_2(Et_2dien)_2(\mu_{N,S}\text{-}NCS)_2](ClO_4)_2$ [15] or in 1D polymeric bridged end-to-end thiocyanato complexes derived from *N*,*N*-dimethylaminoethanol and glycine ($\nu(NCS^-) = 2100\ cm^{-1}$) [31]. In 1D singly bridged thiocyanato complex derived from 1,4-diazacycloheptan, two bands were reported (2140 and 2088 cm^{-1}) [18a]. Also two strong bands were observed in the mono-coordinated thiocyanato complex $[Cu(TPA)(NCS)]ClO_4$ at 2092 and 2050 cm^{-1} [1]. Bridging thiocyanato groups are expected to exhibit two absorption bands above and below the 2100 cm^{-1} region due to the stretching frequency of S- and N-bonded thiocyanate group, respectively. Interestingly, we synthesized the doubly bridged thiocyanato complex $[Cu_2(dpt)_2(\mu_{N,S}\text{-}NCS)_2(ClO_4)_2]$ in which the coordination polyhedron around the Cu(II) ion is strongly elongated octahedral.[1] The IR of this complex exhibited two strong absorbed resolved bands at 2118 and 2076 cm^{-1}. The appearance of a single unresolved $\nu(NCS^-)$ IR band is not unusual but it has been observed in a number of $\mu_{N,S}$-NCS complexes [18c,32b]. Thus, it is obvious that stretching frequency of the thiocyanate group cannot be used to predict the bonding coordination mode in the thiocyanato-Cu(II) complexes. Most probably, this is, in part, due to the broadness of the stretching frequency band of the coordinated NCS^- group which may result in overlap of two or more vibrational modes and also to the ligand structural environment around the Cu(II) centers.

3.3. Visible spectra

The visible spectra of the nitrito and thiocyanato complexes were recorded in different solvents and the data are collected in Table 6. The solution spectra of $[Cu(Medpt)(ONO)(H_2O)]^+$, $[Cu(dien)_2(ONO)]^{2+}$ and $[Cu_2(Medpt)_2(\mu_{N,S}\text{-}NCS)_2]^{2+}$ display a single broad band between 580 and 640 nm range. These spectral features are consistent

Table 6
Visible spectral data {λ_{max}/nm (ε_{max}/$M^{-1}cm^{-1}$)} for [Cu(Medpt)(ONO)-(H_2O)]ClO_4 (**1**), [Cu(dien)(ONO)]ClO_4 (**2**) and [Cu_2(Medpt)$_2$($\mu_{N,S}$-NCS)$_2$](ClO_4)$_2$ (**3**) in different solvents

with the five-coordinate geometry where the Cu(II) ion is adapting a distorted SP geometry. In general complexes with TBP geometry usually show a maximum at $\lambda >$ 800 nm with a higher energy shoulder [1,2,32]. This indicates that the solution spectrum of each complex ion is adequately explained by a d-d transition in Cu(II) ion in a distorted SP geometry with C_{4v} symmetry where the absorption maximum band observed in the visible region results from $^2B_1 \leftarrow {}^2E$ transition.

The spectra of the complexes and the position of λ_{max} show strong dependence on the nature of the solvent used with no sign to the appearance of a new band around 800 nm. This finding clearly rules out any stereochemical change around the central Cu(II) ion upon dissolution. The dissolution of the complexes was associated with color change which was also found to be temperature dependent. The absorption maxima of the complexes **1**–**3** were blue shifted by ca. 30–50 nm on going from H_2O or DMSO to CH_3CN or CH_3NO_2 without showing any specific trend (Table 6). These results could be explained by considering solvolysis of the complexes via the displacement of one of the coordinated ligands [15,33] and the presence of an equilibrium mixture between the dissolved complex and the solvolysis product at a given temperature. Most likely this process is taking place through water displacement in **1** [33], by replacement one of the coordinated oxygens of the nitrito group in **2** to form the mono-coordinated-nitrito species $[Cu(dien)(ONO)(solvent)]^+$ [10] or by displacement of one of the bridged thiocyanato ligands in **3** to form the bis(solvent) singly bridged species [Cu_2(Medpt)$_2$($\mu_{N,S}$-NCS)(solvent)$_2$]$^{3+}$ [15]. However, it is difficult to propose with certainty any nuclearity for the species in solution without measuring the electrical conductivity.

3.4. Magnetic measurements for [Cu_2(Medpt)$_2$($\mu_{N,S}$-NCS)$_2$](ClO_4)$_2$ (3)

The variable-temperature magnetic properties $\chi_M T$ (χ_M is the molar susceptibility for the two Cu^{2+} ions) versus T for **3** is illustrated in Fig. 4. In this complex, the $\chi_M T$ at 300 K is 0.87 cm^3 K mol^{-1}. This value which is similar to that expected for two uncoupled $S = 1/2$ spins ($g >$ 2.0), remains nearly constant upon cooling and decreases sharply in the low-temperature region, attaining a value of 0.55 cm^3 K mol^{-1} at 2 K. No maximum is observed in the plot of χ_M versus T. These features are characteristic

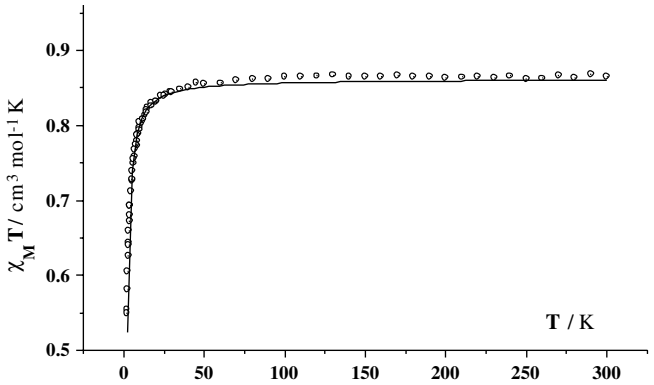

Fig. 4. Plot of $\chi_M T$ vs. T for [Cu_2(Medpt)$_2$(μ-NCS)$_2$](ClO_4)$_2$. The solid line has been generated from the best fit magnetic parameters (see text).

of week antiferromagnetic coupling between copper(II) ions. The experimental magnetic data have been fitted using the Bleaney–Bowers expression derived through the isotropic Hamiltonian $H = -JS_A \cdot S_B$, where J is the exchange coupling parameter and $S_A = S_B = 1/2$. Least-squares fitting of all experimental data leads to the following parameters: $J = -1.8(1)$ cm^{-1}, $g = 2.14(1)$ and $R = 7.5 \times 10^{-5}$ (R is the agreement coefficient and is defined as: $R = \sum[(\chi_M T)_{exp} - (\chi_M T)_{calcd}]^2 / \sum(\chi_M T)^2_{exp}$). The magnetic behavior of the complex under investigation was found to be very similar to that recently reported for the thiocyanato-bridged dimeric Cu(II) complex, [Cu_2(L)$_2$-($\mu_{N,S}$-NCS)$_2$] where L = *N*(3-aminopropyl)-salicylaldimine [34].

In conclusion, the results of X-ray structure determination for the complex [Cu_2(Medpt)$_2$($\mu_{N,S}$-NCS)$_2$](ClO_4)$_2$ are consistent with the dinuclear doubly-bridged thiocyanato groups. The copper centers in the complexes **1**–**3** are penta-coordinated with almost no significant (complexes **1** and **3**) to small distortion (complex **2**) from SP geometry. The same geometry was also confirmed in solution. The IR stretching frequencies $\nu(NO_2^-)$ or $\nu(NCS^-)$ reveal that we cannot always trust this technique to diagnose the bonding coordination mode in the nitrito or thiocyanato complexes.

Table 1
List of complexes

Complex	R
1 $[Mn_2(bipy)_2(\mu\text{-}O)(\mu\text{-}OOCR)_2(NO_3)(H_2O)](ClO_4)\cdot MeCN$	Ph
2 $[Mn_2(bipy)_2(\mu\text{-}O)(\mu\text{-}OOCR)_2(NO_3)(H_2O)](ClO_4)$	CH_2Cl
3 $[Mn_2(phen)_2(\mu\text{-}O)(\mu\text{-}OOCR)_2(NO_3)(H_2O)](ClO_4)$	CH_2Cl
4 $[Mn_2(bipy)_2(\mu\text{-}O)(\mu\text{-}OOCR)_2(H_2O)_2](ClO_4)_2$	CH_2NH_2
5 $[Mn_2(phen)_2(\mu\text{-}O)(\mu\text{-}OOCR)_2(H_2O)_2](ClO_4)_2$	CH_2NH_2
6 $[Mn_2(bipy)_2(\mu\text{-}O)(\mu\text{-}OOCR)_2(NO_3)(H_2O)](ClO_4)\cdot H_2O$	*p*-ClPh
7 $[Mn_2(phen)_2(\mu\text{-}O)(\mu\text{-}OOCR)_2(NO_3)(H_2O)](ClO_4)\cdot H_2O$	*p*-ClPh

Besides biological relevance, the study of magnetic exchange interactions through extended carboxylate bridging ligands is of major interest in the field of molecular magnetism [5,9]. In this context, sometimes the strong magnetic interactions between paramagnetic manganese centers and the search for the limiting distance for interaction between manganese centers has led magnetochemists to focus on binuclear and polynuclear manganese-complexes bridged by various carboxylate ligands (see Table 1).

2. Experimental

2.1. Materials

All chemicals and solvents were commercially available A.R. grade and were used without further purification.

2.2. Synthesis (*1*–*7*)

All complexes were prepared similarly by mixing and stirring an acetonitrile (10 mL) solution of benzoic or chloroacetic or *p*-chlorobenzoic acid or glycine (1.5 mmol), triethylamine (0.21 mL; 1.5 mmol) and 2,2′-bipyridyl or 1,10-phenanthroline (1.5 mmol) with an acetonitrile solution (10 mL) of $Mn(ClO_4)_2.6\,H_2O$ (0.547 g; 1.5 mmol). After a few minutes, an acetonitrile solution (25 mL) of ceric ammonium nitrate (1.1 g; 2.0 mmol) was added dropwise and the solution was stirred for 2 h at room temperature. The initial yellow color of the solution rapidly changed to brown. Some solids appeared during stirring which were separated by filtration and discarded. Solid $NaClO_4\cdot H_2O$ (0.56 g; 4.0 mmol) was added to the filtrate and the solution stirred briefly. The product separated as a black crystalline substance during slow evaporation of the solvent at room temperature. The solid was collected by filtration and washed with 1:1 ethanol–diethyl ether. Attempts to recrystallize this substance led only to decomposition upon dissolving in any solvent. Yields range from 70% to 80%.

Caution! Perchlorate salts are potentially explosive and should be used in small quantities with much care.

2.3. Physical measurements

Elemental analyses were performed using a Perkin–Elmer 2400II elemental analyzer. Electronic spectra were obtained using a JASCO 7850 spectrophotometer. For electrochemical and spectral measurements HPLC grade solvents were used. IR spectra were recorded on a JASCO FT/IR-460 spectrometer with samples prepared as KBr pellets. Electrochemical experiments were carried out using 'Echem' software supplied by PARC to control an EG&G PARC VersaStat II potentiostat with a three-electrode configuration consisting of a PARC glassy carbon working electrode, a Pt wire auxiliary electrode and a Ag/AgCl reference electrode. The supporting electrolyte was 0.1 mol dm^{-3} $[Et_4N][ClO_4]$ in acetonitrile or dimethylformamide solution. Data were collected under an atmosphere of dry nitrogen at room temperature. All electrochemical potentials are calibrated against a ferrocene/ferrocenium couple of 0.44 V under the same experimental conditions at the same temperature. The magnetic susceptibilities of complexes **1** and **2** were measured in the temperature range 2–300 K with a Quantum Design MPMS5S SQUID Magnetometer at a field strength of 1000 Oe. Diamagnetic corrections were estimated from Pascal Tables.

2.4. Crystallographic data collection and refinements for complex *2*

A black prismatic single crystal of $[Mn_2(bipy)_2(\mu\text{-}O)(\mu\text{-}OOCCH_2Cl)_2(NO_3)(H_2O)]$ (ClO_4) **2**, obtained by slow evaporation of a CH_3CN solution was used for the structure determination. The X-ray data were collected using a Bruker P4/CCD system with graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) and a sealed tube generator at −80 °C and are summarized in Table 2. A total of 21 385 reflections were measured of which 6193

Table 2
Summary of the X-ray crystal data for complex **2**

Empirical formula	$Mn_2C_{24}H_{22}N_5O_{13}Cl_3$

Z value	4
μ(Mo Kα) (mm^{-1})	0.117
T_{max}, T_{min}	0.922, 0.525
F_{000}	1624.00
Index ranges	$-13\leqslant h\leqslant 13$, $-19\leqslant k\leqslant 19$, $-23\leqslant l\leqslant 23$
Data/restraints/parameters	6193/0/490
R_1; wR_2	0.033; 0.087
Maximum and minimum peak in difference map (e Å^{-3})	0.59; −0.41
Goodness-of-fit on F^2	1.03

$R_1 = \sum||F_o| - |F_c||/\sum|F_o|$, $wR_2 = [\sum(w(F_o^2 - F_c^2)^2)/\sum w(F_o^2)^2]^{1/2}$.
$w = 1/[\sigma^2(F_o^2) + (0.0449P)^2 + 1.7963P]$, $P = (\mathrm{Max}(F_o^2, 0) + 2F_c^2)/3$.

[$R_{int} = 0.032$] were independent. The structure was solved by direct methods [6] and expanded using Fourier techniques [7]. The non-hydrogen atoms were refined anisotropically. Hydrogen atoms were included in calculated positions but not refined. The structure was solved using SHELXL-97 [8] and was refined by full-matrix least-squares methods on F^2. The weighting scheme employed was $w = 1/\sigma^2(F_o^2) + (0.0449P)^2 + 1.7963P]$, $P = (\mathrm{Max}(F_o^2, 0) + 2F_c^2)/3$. The refinement converged with the residuals summarized in Table 2. Selected bond distances and angles are given in Table 4.

3. Results and discussion

3.1. Synthesis

The synthetic route involved in the formation of the binuclear complexes (**1**–**7**) is given in the Scheme 1. All the complexes have been isolated in good yield and their micro-analytical data (Table 3) confirm the composition given. The synthetic route used to synthesize the binuclear manganese(III) complexes involves direct oxidation of Mn(II) by ceric ammonium nitrate in the presence of bipy or phen and different carboxylate anions in the ratio of (bipy/phen):Mn(II):Ce(IV) = 1:1:1. Other research groups [9] have synthesized binuclear or polynuclear manganese complexes with the metal in various oxidation states using $KMnO_4$ as both oxidant as well as source of manganese ion. We, however, have synthesized all the complexes by oxidation of Mn(II) with ceric ammonium nitrate. The molar conductivities Λ_M for all the complexes except **4** and **5** are 120–160 Ω^{-1} cm^3 mol^{-1} [10] in acetonitrile and 65 and 90 Ω^{-1} cm^3 mol^{-1} [10] in dimethylformamide are consistent with the behavior of 1:1 electrolytes. Molar conductivities Λ_M for **4** and **5** are consistent with 1:2 electrolytes.

3.2. Description of the crystal structure of 2

The ORTEP diagram and atom numbering scheme of the unsymmetrical binuclear manganese(III) complex **2** is

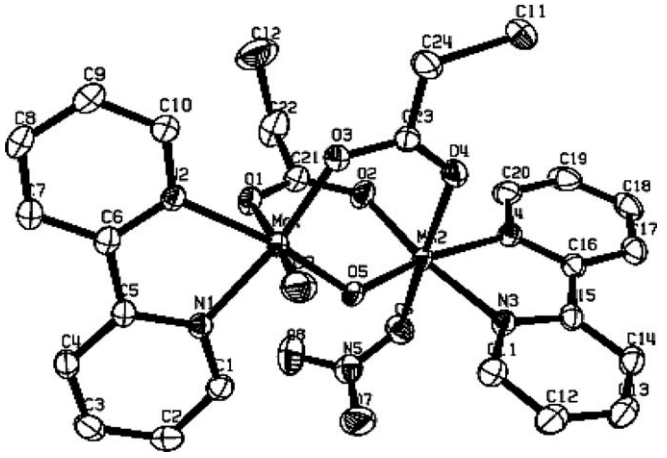

Fig. 1. ORTEP diagram for complex **2** [$Mn_2(bipy)_2(\mu\text{-}O)(\mu\text{-}OOCCH_2Cl)_2(NO_3)(H_2O)][ClO_4$] showing the atom labeling scheme and 50% probability ellipsoids for the non-hydrogen atoms. Hydrogen atoms and perchlorate ions have been excluded for clarity.

depicted in Fig. 1. The figure shows distorted manganese(III) atoms with the Mn–O_{oxo} bonds in the μ-*O* bridge being very little shorter (average 1.78 Å) than those of the μ-acetato bridges (average1.80 Å) of $[L_2Mn_2^{III}(\mu\text{-}O)(\mu\text{-}CH_3COO)_2](ClO_4)_2$ and $[L'_2Mn_2^{III}(\mu\text{-}O)(\mu\text{-}CH_3COO)_2](ClO_4)_2 \cdot H_2O$, where L and L′ are 1,4,7-triazacyclononane and *N*,*N*′,*N*″-trimethyl-1,4,7-triazacyclononane [12a]. On the other hand, that bond distance is much shorter than other μ-acetato bridges (average 2.05 Å) [14c]. The molecular cation consists of two hexacoordinated manganese(III) atoms bridged by a μ-oxide ion and two μ-chlorocarboxylate units. Each manganese atom is additionally ligated to the two N-atoms coming from a chelating bipyridyl. The sixth coordination position is occupied by NO_3^- ion in one case and by a water molecule in another. The manganese ions show a Jahn-Teller distortion as expected for high-spin d^4 manganese(III) ions in near octahedral geometry.

The Mn–O distances to each carboxylate oxygen are different. There are two types of Mn–O (carboxylate) distances, 1.9580/1.9682 Å and 2.2012/2.1907 Å, respectively, which was also found for other Mn_2(III) complexes such as $[Mn_2O(mpdp)(bipy)_2(H_2O)(MeCN)](ClO_4)_2$ (mpdp = *m*-phenylenedipropionate) [11]. The first two distances correspond to the bonds to oxygen atoms *trans* to the bipy ligand and the second pair of distances correspond to the bonds *trans* to the water molecule and nitrate ion, respectively. The average Mn–N (bipy) bond length (2.059 Å) is also very close to the average Mn–N (bipy) (2.069 Å) distance in the example above. The longer bonds, due to Jahn-Teller distortion along O_1–Mn_1–O_9 and O_4–Mn_2–O_6 (average 2.21 Å) are at the pseudo-axial positions and the shorter bonds are in pseudo-equatorial positions. The intramolecular Mn–Mn distance in the binuclear cation (3.155 Å) agrees well with those in the range 3.15–3.16 Å for known doubly carboxylato-bridged manganese(III) complexes [12,13]. The Mn–Mn distance in **2** is intermediate in length being longer than that of some similar types of compounds [14] and shorter than that in some other related compounds [15]. The bridging angle Mn–O–Mn is 124.45(9)° which is very close to those in some similar di-μ-carboxylato mono-μ-oxo Mn_2(III) complexes [12,13] and a little larger than that in the similar complex $[L_2Mn_4(III)(\mu\text{-}O)_2(\mu\text{-}CH_3COO)_4](ClO_4)_4 \cdot 3MeNO_2$ (L = α,α′-bis(bis(2-pyridylmethyl)-amino)-*m*-xylene) (118.5°) [15c]. A particularly noteworthy aspect of complex **2** is that the NO_3^- anion binds only to one manganese(III) atom while there is H_2O in the corresponding site on the other manganese atom. Comparative data for Mn–O–Mn angles and Mn–Mn distances are given in the Table 5 for similar types of compounds. The Mn(2) atom is 0.0178 Å below the basal plane defined by the four atoms O(2), O(5), N(3) and N(4) however, the Mn(1) atom is 0.0873 Å below the plane of O(1), O(5), O(9) and N(2). The dihedral angle between these two planes is 35.88°. The complex forms an infinite arrangement (Fig. 2) through two types of weak interaction. The O(6) and O(8) of the coordinated nitrate ion show close contact to H(22) of the coordinated H_2O. The other contact involves O(13) of ClO_4^- ion and H(21) of H_2O (Table 6) [16].

3.3. Infrared spectrum

All the complexes show two strong bands between 1630 and 1490 cm^{-1} in their infrared spectra attributable to carboxylate ν_a(CO) and ν_s(CO) vibrations, respectively. The difference between the asymmetric and symmetric stretching modes of the carboxylates of ca. 100 cm^{-1} can be attributed to the presence of bidentate bridging carboxylate ligands while the bands at ca. 615 and 620 cm^{-1} are due to δ(OCO) [17]. Two characteristic bands were observed at ca.

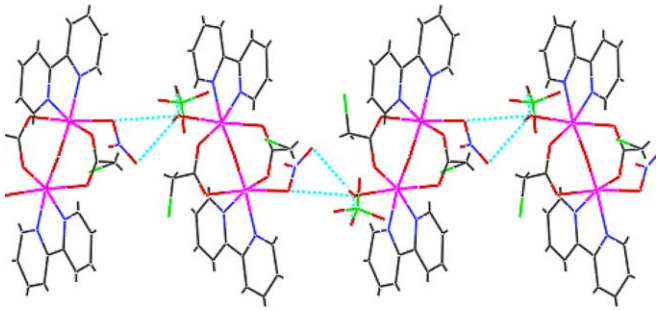

Fig. 2. Packing diagram for the complex $[Mn_2(bipy)_2(\mu\text{-}O)(\mu\text{-}OOCCH_2Cl)_2(NO_3)(H_2O)][ClO_4)$.

[a,b] Symmetry equivalent: [a]$1/2 - x, -1/2 + y, 1/2 - z$, [b]$1 - x, 1 - y, -z$.

1440 and 1305 cm^{-1} for all the complexes except **4** and **5**. These are attributable by comparison to the IR data of similar compounds [18] to unidentate, coordinated nitrate ion. In addition, the broad bands of uncoordinated perchlorates are noted near 1100 cm^{-1}. A broad peak centered at ca. 3450 cm^{-1} is observed for most of the complexes and is consistent with the presence of water. A strong band appearing at ca. 700 cm^{-1} is assigned to the Mn–O–Mn vibration by comparison to the spectra of some related compounds [18].

3.4. Electronic spectrum

The electronic spectra at 25 °C of all the μ-oxo and μ-carboxylato dimanganese(III) complexes (**1**–**7**) in acetonitrile except **2** have mostly similar features consisting of a band at ~625 nm, two bands of moderate intensity at ca. 510 and 470 nm and two more intense bands at 275–340 nm (Table 7). Similar types of electronic spectra have also been found for the dimanganese(III) complex $[Mn_2O(O_2CCH_3)_2(TACN)_2]^{+2}$ which displays at least four transitions at 495 nm ($\varepsilon = 324\ M^{-1}\ cm^{-1}$), 520 nm (250), 665 nm (95) and 910 nm (40) [19]. The low energy bands at ~625 nm could be assigned to d-d transitions by comparison with the spectrum of the related complex $[Mn_2O(O_2CCH_3)_2(bipy)_2]^{+2}$ [9d]. It is interesting to note that the two high intensity bands at ~510 and ~470 nm are also observed in spectra of complexes consisting of the $[Fe_2^{III}(\mu\text{-}O)(\mu\text{-}O_2CMe)_2]^{2+}$ core [20e] suggesting the presence of a similar core structure $[Mn_2^{III}(\mu\text{-}O)\ (\mu\text{-}O_2CR)_2]^{2+}$ in our complexes [20]. This is supported by the presence of bidentate bridging carboxylate bands at ~1630 and 1490 cm^{-1} and by a band at 730 cm^{-1} in the IR spectrum attributable to Mn–O–Mn vibration. The intense bands at ~280 and ~350 nm correspond to intra ligand transitions.

[a] In dimethylformamide solution.

3.5. Electrochemistry

The electron transfer properties of the mixed ligand complexes (**1**–**7**) were studied by the cyclic voltammetry and the differential pulse voltammetry (DPV) at a glassy carbon electrode. The electrochemical data are given in Table 8. All experiments were carried out at room temperature in acetonitrile or dimethylformamide solution using 0.1 mol dm^{-3} $[Et_4N][ClO_4]$ as a supporting electrolyte. The ligands, 2,2′-bipyridine(bipy) and 1,10-phenanthroline (phen), are electrochemically inactive from +1.5 to ~−1.4 V, but below −1.4 V all the complexes undergo two quasi-reversible reduction processes around −1.5 to −1.9 V versus Ag–AgCl at a glassy carbon electrode which are due to the reduction of the two ligands. On the other hand, at a Pt electrode, the reductive waves have been found to occur irreversibly. The reduction of bipy and phen in all the complexes can be represented according to Eqs. (1) and (2).

$$[Mn_2O(OOCR)_2(NO_3)(H_2O)(bipy)_2]^{1+} + e \rightleftharpoons [Mn_2O(OOCR)_2(NO_3)(H_2O)(bipy)(bipy^-)] \quad (1)$$

$$[Mn_2O(OOCR)_2(NO_3)(H_2O)(bipy)(bipy^-)] + e \rightleftharpoons [Mn_2O(OOCR)_2(NO_3)(H_2O)(bipy^-)_2]^- \quad (2)$$

Since each bipy or phen can accept two electrons in its lowest unoccupied molecular orbitals, one should expect to observe four such reduction steps in the series [21]. The observation of only two couples up to −2.0 V was the result

Table 8
Electrochemical data for acetonitrile solution

Complex	$E_{1/2}(Mn^{III}Mn^{IV}/Mn_2^{IV})$ [ΔE] (V) (all DPV)	$E_{1/2}(Mn_2^{III}/Mn^{III}Mn^{IV})$ [ΔE] (V)	$E_{1/2}(Mn_2^{III}/Mn^{III}Mn^{II})$ [ΔE] (V) (all irr)	$E_{1/2}(Mn^{III}Mn^{II}/Mn_2^{II})$ [ΔE] (V) (all DPV)
1[a]	1.09	0.43(0.09)[b]	−0.95	−1.29
2[a]		0.50(0.24)[b]	−0.81	
3	1.35	0.51(DPV)	−0.94	−1.36
4	1.01	0.38(DPV)	−0.81	−1.36
5	1.36	0.44(DPV)	−0.94	−1.40
6	1.07	0.44(0.07)[b]	−0.80	−1.34
7	1.25	0.45[c]	−0.87	−1.36

[*] $E_{1/2} = (E_{pa} + E_{pc})/2$ V, $\Delta E_p = E_{pa} - E_{pc}$ V, where E_{pa} and E_{pc} are anodic and cathodic peak potentials, respectively.
[a] In dimethylformamide solution.
[b] Quasi-reversible.
[c] Irreversible.

of limitations imposed by the cut-off potential of the supporting electrolyte in acetonitrile. The redox properties of all the complexes in a potential range +1.5 to −1.4 V consist of four single electron waves. The four different steps are probably due to two metal-centered one electron oxidative steps, $Mn_2^{III} \rightarrow Mn^{IV}Mn^{III} \rightarrow Mn_2^{IV}$, and two one electron reductive steps, $Mn_2^{III} \rightarrow Mn^{II}Mn^{III} \rightarrow Mn_2^{II}$ according to the Eqs. (3) and (4). These redox reactions are very similar to those reported for other (μ-oxo)(μ-carboxylato)Mn_2(III/III) complexes [12c,22].

$$[Mn_2^{III}O\ldots]^{+} \overset{E_1}{\underset{+e}{\overset{-e}{\rightleftharpoons}}} [Mn^{IV}Mn^{III}O\ldots]^{2+} \overset{E_2}{\underset{+e}{\overset{-e}{\rightleftharpoons}}} [Mn_2^{IV}O\ldots]^{3+} \tag{3}$$

$$[Mn_2^{III}O\ldots]^{+} \overset{E_3}{\underset{-e}{\overset{+e}{\rightleftharpoons}}} [Mn^{II}Mn^{III}O\ldots]^{0} \overset{E_4}{\underset{-e}{\overset{+e}{\rightleftharpoons}}} [Mn^{II}Mn^{II}O\ldots]^{-} \tag{4}$$

The single electron transfers proposed for the above couples have been confirmed by comparison of current height with the redox couple of a known complex $[Fe(bipy)_3]^{2+}$ under similar conditions. The cyclic voltammogram of **1** (Fig. 3) shows a quasi-reversible oxidation at $E^1_{1/2} = 0.43$ V ($\Delta E =$ 90 mV), probably due to $Mn_2^{III} \leftrightarrow Mn^{III}Mn^{IV}$. In addition, complex **1** shows a further three redox waves through DPV at +1.09, −0.95 and −1.29 V probably due to oxidation of $Mn^{IV}Mn^{III} \rightarrow Mn_2^{IV}$ and reductions of $Mn_2^{III} \rightarrow Mn^{II}Mn^{III} \rightarrow Mn_2^{II}$, respectively. By comparing the potential data of **6** ($E^2_{pa} = +1.07$ V, $E^1_{pa} = +0.44$ V, $E^3_{pc} = -0.80$ V and $E^4_{pc} = -1.34$ V) containing *p*-chloro benzoate as bridging ligand with the data for complex **1** having benzoate as bridging ligand, the electron-withdrawing group Cl can be seen to have little influence on oxidation potentials. However, there is a slightly more noticeable effect on reduction potentials by the Cl-group. Complex **7** involving *p*-chloro benzoate and phen as ligands also show four steps one electron transfer reactions. The voltammetric behaviour of complex **2** shows only two-electron transfer steps at potentials between +0.504 and −0.81 V that are assigned tentatively according to Eq. (5) by comparison to similar compounds mentioned in the literature [12a]. Surprisingly, the phen derivative of **2**, i.e., **3** exhibits four electron transfer processes according to Eqs. (3) and (4).

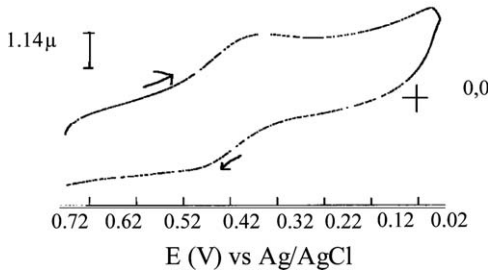

Fig. 3. Cyclic voltammogram of **1** in acetonitrile with 0.1 mol dm^{-1} $[Et_4N][ClO_4]$ as supporting electrolyte (working electrode; glassy-carbon; reference electrode; Ag/AgCl; scan rate 100 mV s^{-1}). (Only $Mn_2^{III}/Mn^{III}Mn^{IV}$ oxidation is shown.)

$$[Mn^{IV}Mn^{III}]^{+1} \overset{+e}{\underset{-e}{\rightleftharpoons}} Mn_2^{III} \overset{+e}{\underset{-e}{\rightleftharpoons}} [Mn^{II}Mn^{III}]^{-1} \tag{5}$$

Complexes **4** and **5**, the glycine-bridged complexes of bipy and phen, also show four electron transfer processes around the same potentials.

3.6. Magnetic properties

The room temperature magnetic moments of all the complexes lie within the range 2.1–2.8 BM and are lower than expected for uncoupled $S = 2$ ions. This suggests antiferromagnetic coupling [23] in the dimers as confirmed by the variable temperature susceptibility study. The results are similar to those reported for $[L_2Mn_4(III)(\mu\text{-}O)_2(\mu\text{-}CH_3COO)_4](ClO_4)_4.3MeNO_2$ (L = α,α′-bis(bis(2-pyridylmethyl)-amino)-*m*-xylene) [15c]. The cryomagnetic behavior of complex **1** is shown in Fig. 4 where the $\chi_M T$ value of 4.65 cm^3 mol^{-1} K at 300 K for this complex can be seen to be much lower than the calculated value of 5.99 cm^3 mol^{-1} K for two uncoupled spins ($S_1 = 2$, $S_2 = 2$) with $g = 2$. This value indicates that the local spin state of both the manganese centers is a quintet. With a decrease of temperature, $\chi_M T$ increases slowly to 4.95 cm^3 mol^{-1} K at 18 K and then decreases rapidly to 3.72 cm^3 mol^{-1} K at 2 K. The slight increase in $\chi_M T$ as the temperature decreases could arise from weak ferromagnetic interactions between the metal centers in **1**. The rapid decrease of $\chi_M T$ at low temperatures may be due to antiferromagnetic interdimer interactions. The susceptibility data were simulated with Eq. (6), which considers both the intramolecular and intermolecular interactions. Least-squares fittings of the susceptibility data with Eq. (6) converge with $J = 0.43$ cm^{-1}, $g = 1.75$, $zJ' = -0.12$ cm^{-1}, and $R = 2.15 \times 10^{-2}$

$$\chi_M = \frac{\chi_{M^D}}{1 - 2zJ'\chi_{1-D}/N\beta^2 g^2}, \tag{6}$$

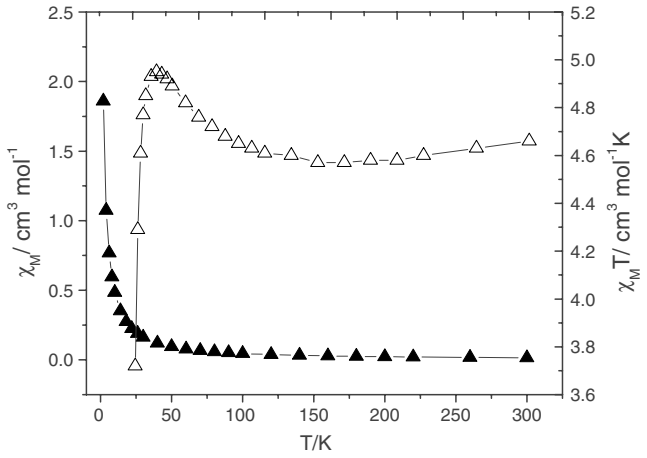

Fig. 4. Molar paramagnetic susceptibility (χ_M) and product of molar paramagnetic susceptibility and temperature ($\chi_M T$) vs. temperature curves for **1**.

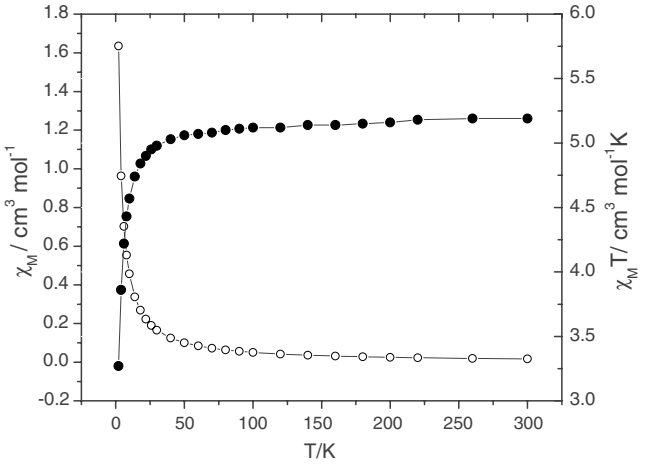

Fig. 5. Molar paramagnetic susceptibility (χ_M) and product of molar paramagnetic susceptibility and temperature ($\chi_M T$) vs. temperature curves for **2**.

where

$$\chi_{M^D} = \frac{N\beta^2 g^2}{kT}\frac{A}{B}$$

with $A = 2\exp(2x) + 10\exp(6x) + 28\exp(12x) + 60\exp(20x)$; $B = 1 + 3\exp(2x) + 5\exp(6x) + 7\exp(12x) + 9\exp(20x)$ and $x = 2J/kT$.

The variable-temperature (2–300 K) magnetic behavior of **2** is shown in Fig. 5, in χ_M versus T and $\chi_M T$ versus T plots. The $\chi_M T$ value of 5.19 $cm^3\ mol^{-1}$ K at 300 K for this complex is lower than the calculated value of 5.99 $cm^3\ mol^{-1}$ K for two uncoupled spins ($S_1 = 2$, $S_2 = 2$) with $g = 2$. With a decrease of temperatures, the $\chi_M T$ value decreases very slowly to 4.92 $cm^3\ mol^{-1}$ K at 22 K. On further lowering of temperatures, $\chi_M T$ decreases sharply to 3.26 $cm^3\ mol^{-1}$ K at 2 K. The trend of magnetic behavior indicates the existence of a weak antiferromagnetic interaction between the metal centers in **2**.

The susceptibility data were simulated with the theoretical expression [Eq. (7)] derived from the Heisenberg–Dirac–Van Vleck Hamiltonian ($\mathbf{H} = -2J\mathbf{S}_1 \cdot \mathbf{S}_2$) [23]. The global minimization takes place with $J = -0.15\ cm^{-1}$, $g = 1.85$; the agreement factor R defined as $[\sum\{(\chi_M T)_{obs} - (\chi_M T)_{calc}\}^2 / \sum(\chi_M T)^2_{obs}]$ being 1.68×10^{-2}

$$\chi_M = \frac{N\beta^2 g^2}{kT}\frac{A}{B}, \qquad (7)$$

where $A = 2\exp(2x) + 10\exp(6x) + 28\exp(12x) + 60\exp(20x)$; $B = 1 + 3\exp(2x) + 5\exp(6x) + 7\exp(12x) + 9\exp(20x)$ and $x = 2J/kT$.

So, for complexes **1** and **2**, the intradimer interactions are weak; ferromagnetic for **1** and antiferromagnetic for **2**. Similar trends in magnetic behavior for other complexes of $[Mn^{III}_2O(O_2CR_2)_2]^{2+}$ cores are reported [13b,24]. Christou et al. [11] have discussed the reason for variation between antiferromagnetic and ferromagnetic behavior as a result of changing the substituents in a series of $[Mn^{III}_2O(OAc)_2(bipy)_2X_2]$ [13a]. They observed a ferromagnetic interaction for X = azide but for chloride or water, the interaction is antiferromagnetic. They concluded that the substituent X influences the energy of the $d_{x^2-y^2}$ orbital. For a strong field ligand, the energy separation is high between the $d_{x^2-y^2}$ orbital and the orbitals of the carboxylate bridge and therefore, ferromagnetic interaction should be preferred. Experimentally, they found $J = +8.8\ cm^{-1}$ for N_3^- ion and $J = -4.1$ and $-3.4\ cm^{-1}$ for Cl^- and H_2O, respectively. In our case, we have observed $J = +0.43\ cm^{-1}$ for complex **1** and $J = -0.15\ cm^{-1}$ for complex **2** where both the terminal groups are H_2O and NO_3^-. The magneto-structural correlations here are compared with those of other Mn_2(III) systems in Table 5.

Acknowledgements

This study is supported by the UGC, CSIR and AICTE, India. We express our gratitude to Dr. Bob McDonald of the Department of Chemistry, University of Alberta, Canada, David O. Miller of the Department of Chemistry, Memorial University of Newfoundland, Canada for their assistance with the X-ray crystal structure and to Dr. Sasankashekhar Mohanta, Department of Chemistry, University of Calcutta for assistance with the magnetic measurements. We are also thankful to the DST-FIST program for providing FTIR and UV–vis Spectrophotometers.

Appendix A. Supplementary data

Crystallographic data for the structure have been deposited with the Cambridge Crystallographic Data, CCDC no. 277841. A copy of the data can be obtained free of charge on application to the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44 1223 336033 or e-mail: deposit@ccdc.cam.ac.uk) or from the authors upon request. complexes of VO_2^+ have been obtained using the N,N,O-donor monoanionic deprotonated *N*-(aroyl)-*N*′-(picolinylidene)hydrazines [8–10].

Hphsal (R = H)
HphsalOMe (R = OCH_3)
HphsalCl (R = Cl)
HphsalBr (R = Br)
HphsalNO_2 (R = NO_2)

In this work, we have explored the synthetic chemistry using [VO(acac)$_2$] and a similar Schiff base system *N*-(2-pyridyl)-*N*′-(5-R-salicylidene)hydrazines (HphsalR) which in the deprotonated state (phsalR^-) can coordinate a metal ion via the pyridine-N, the imine-N and the phenolate-O atoms. However, under aerobic and non-protic reaction conditions ternary complexes of oxovanadium(IV) have been isolated instead of dioxovanadium(V) complexes as observed before [8–10]. In the following account, we have described the syntheses and the physical properties of these ternary complexes having the general formula [VO(phsalR)(acac)]. The solid state molecular structures and self-assembly patterns of two representative complexes have been investigated by X-ray crystallography.

2. Experimental

2.1. Materials

The Schiff bases were prepared in 70–80% yield by condensation reactions of 2-hydrazinopyridine with the corresponding 5-substituted salicylaldehyde in methanolic media. Bis(acetylacetonato)oxovanadium(IV) was prepared by following a reported procedure [11]. All other chemicals and solvents used in this work were of analytical grade available commercially and were used without further purification.

2.2. Physical measurements

Microanalytical (C, H, N) data were obtained with a Thermo Finnigon Flash EA1112 series elemental analyzer. Infrared spectra were collected by using KBr pellets on a Jasco-5300 FT-IR spectrophotometer. A Shimadzu 3101-PC UV/vis/NIR spectrophotometer was used to record the electronic spectra. EPR spectra were recorded on a Jeol JES-FA200 spectrometer. Solution electrical conductivities were measured with a Digisun DI-909 conductivity meter. A Sherwood Scientific balance was used for magnetic susceptibility measurements. Diamagnetic corrections calculated from Pascal's constants [12] were used to obtain the molar paramagnetic susceptibilities.

2.3. Synthesis of [VO(phsal)(acac)] (1)

An acetonitrile solution (10 ml) of Hphsal (81 mg, 0.38 mmol) was added to an acetonitrile solution (25 ml) of [VO(acac)$_2$] (100 mg, 0.38 mmol). The mixture was heated on a water bath for 15–20 min. The resulting dark brown solution was kept in air at room temperature. Dark brown crystalline material separated in about 1–2 h was collected by filtration, washed with acetonitrile and finally dried in air. Yield, 65 mg (45%).

The other four complexes [VO(phsalOMe)(acac)] (**2**), [VO(phsalCl)(acac)] (**3**), [VO(phsalBr)(acac)] (**4**) and [VO(phsalNO_2)(acac)] (**5**) reported in this work were synthesized from acetonitrile media using one mole equivalent each of [VO(acac)$_2$] and the corresponding Schiff base in 30–48% yields by following similar procedures as described above.

2.4. X-ray crystallography

Single crystals of both [VO(phsal)(acac)] (**1**) and [VO(phsalCl)(acac)] (**3**) were collected directly from the products precipitated in the synthetic reaction mixtures. In each case, unit cell parameters and the intensity data were obtained on a Bruker–Nonius SMART APEX CCD single crystal diffractometer, equipped with a graphite monochromator and a Mo Kα fine-focus sealed tube ($\lambda = 0.71073$ Å) operated at 2.0 kW. The detector was placed at a distance of 6.0 cm from the crystal. Data were collected at 298 K with a scan width of 0.3° in ω and an exposure time of 15 s/frame. The SMART software was used for data acquisition and the SAINT-PLUS software was used for data extraction [13]. The absorption corrections were performed with the help of SADABS program [14]. The struc-

tures were solved by direct methods and refined on F^2 by full-matrix least-squares procedures. Both complexes crystallize in the space groups $P2_1/c$. All non-hydrogen atoms were refined using anisotropic thermal parameters. The hydrogen atoms were included in the structure factor calculations at idealized positions by using a riding model but not refined. The SHELX-97 programs [15] were used for structure solution and refinement. The ORTEX6a [16] and PLATON [17] packages were used for molecular graphics. Selected crystallographic data for both **1** and **3** are listed in Table 1.

3. Results and discussion

3.1. Synthesis and some properties

All the complexes were synthesized from acetonitrile media by reacting $[VO(acac)_2]$ and HphsalR in 1:1 mole ratio. The elemental analysis data are consistent with the general molecular formula [VO(phsalR)(acac)] (Table 2). Unlike our previous observations [8–10] there is no oxidation of the metal ion in the present reactions. Only one acetylacetonate of $[VO(acac)_2]$ has been replaced by $phsalR^-$ and the ternary complexes are formed. The complexes are insoluble in common organic solvents except dimethylsulphoxide and dimethylformamide. In solutions, they are electrically non-conducting. The room temperature (298 K) magnetic moments of the complexes in the solid state are in the range 1.68–1.92 μ_B (Table 2). These values are consistent with an $S = 1/2$ ground state expected for the metal ion in mononuclear oxovanadium(IV) species.

3.2. Spectroscopic properties

Infrared spectra of the complexes display a strong band in the range 1622–1634 cm^{-1}. The origin of this band is most probably the C=N stretch of the tridentate Schiff base ligand [4–8]. A broad band centred at ~3400 cm^{-1} is attributed to the N–H stretch of the hydrazine fragment of the ligand. Two medium to strong bands observed in the ranges 1512–1553 and 1582–1601 cm^{-1} are most likely due to the coupled C---C and C---O stretches of the acetylacetonate moiety [18]. In all the spectra, the V=O stretch appears as a strong band within 928–949 cm^{-1} (Table 2). These values are consistent with the V=O stretching frequencies reported for distorted octahedral oxovanadium(IV) species [19,20].

The dimethylsulfoxide solutions of the complexes have been used to record the electronic spectra. The main features of all the spectra are quite similar. A representative spectrum is shown in Fig. 1 and the spectral data are given in Table 3. There are two major absorptions within the ranges 510–420 and 383–340 nm in the visible region. These are attributed to the ligand-to-metal charge transfer transitions (LMCT). The high energy absorption (275–262 nm) is most likely due to a transition involving ligand orbitals only. The complexes **1**–**3** show an additional weak absorption in the range 643–720 nm due to d–d transition [19–21]. For complexes **4** and **5** this absorption is probably obscured by the tail of the following LMCT band.

The EPR spectra of the complexes have been collected using powdered samples as well as dimethylsulfoxide solutions. At room temperature (298 K) the powdered samples

[c] Shoulder.

of **1** and **5** display an isotropic signal at $g = 1.98$ and 2.0, respectively. Interestingly the powdered samples of complexes **2**–**4** at 298 K display well resolved axial spectra with ^{51}V ($I = 7/2$) hyperfine structure having $g_{\parallel} \sim 1.94$ ($A_{\parallel} \sim 178$ G) and $g_{\perp} \sim 1.98$ ($A_{\perp} \sim 60$ G). Lowering of temperature to 123 K makes the signals more sharp for **2**–**4**. In the case of **1**, a similar well resolved axial spectrum is observed at 123 K instead of the isotropic signal observed at room temperature. On the other hand, for **5** the hyperfine structure due to the metal centre is reasonably resolved for the $g_{\parallel}$ component and partially resolved for the $g_{\perp}$ component at 123 K. The observation of the isotropic signal for **1** and **5** at room temperature could be due to several factors such as spin–spin interaction, exchange interactions, spin–lattice relaxation and dynamic Jahn–Teller effect. Considering that the metal ion is coordinatively saturated in all the complex molecules (**1**–**5**) which differ only by the substituent on the tridentate ligand and the observation of the resolved spectrum at low temperature, it appears that one of the last two factors or both are responsible for the different behavior of **1** and **5**. The spectra of the complexes in frozen (123 K) dimethylsulfoxide solutions are grossly identical and very similar with the powder phase spectra observed at 298 and 123 K for **2**–**4** and at 123 K for **1**. The frozen solution spectral parameters are listed in Table 3 and a representative spectrum is shown in Fig. 2. The $g_{\parallel} < g_{\perp}$ and $A_{\parallel} > A_{\perp}$ relationships for all the complexes are consistent with an axially compressed octahedral geometry around the vanadium(IV) centre with the unpaired electron in the d_{xy} orbital [22,23].

3.3. Molecular structures of [VO(phsal)(acac)] (1) and [VO(phsalCl)(acac)] (3)

The molecular structures of **1** and **3** are depicted in Figs. 3 and 4, respectively. Bond parameters associated with the metal ions in both complexes are listed in Table 4. In each complex molecule, the metal centre is in a distorted octahedral N_2O_4 coordination sphere assembled by the pyridine-N, the imine-N and the phenolate-O donor phsalR^- (R = H or Cl), the O,O-donor acetylacetonate ($acac^-$) and the oxo group. The meridionally spaning tridentate ligand and one of the two O-atoms of $acac^-$ form a N_2O_2 square plane around the metal centre. The remaining two axial sites are occupied by the oxo group and the second O-atom of $acac^-$. The chelate bite angles are unexceptional and comparable in **1** and **3**. The V–N(pyridine), the V–N(imine) and the V=O bond lengths are very similar in both structures. However, the V–O(phenolate) bond length

N(3)–V–O(4)	96.30(10)	95.20(9)
O(1)–V–O(2)	93.70(8)	93.82(8)
O(1)–V–O(3)	84.57(8)	83.67(8)
O(1)–V–O(4)	101.44(10)	101.09(10)
O(2)–V–O(3)	82.94(8)	83.22(7)
O(2)–V–O(4)	94.03(9)	94.67(9)
O(3)–V–O(4)	173.47(10)	174.94(9)

is slightly longer in **3** than that in **1**. This difference is possibly due to the electron withdrawing effect of the Cl-atom at the *para* position of the phenolate-O in **3**. Not surprisingly the two V–O bond lengths associated with the $acac^-$ ligand are different in both complexes. The V–O bond which is *trans* to the oxo group is significantly longer than the V–O bond which is *cis* to the oxo group (Table 4). The *cis* and *trans* V–O bond lengths observed in **1** and **3** are comparable with those reported for oxovanadium(IV) species containing $acac^-$ as ligand in the same orientation [19,24]. In general, all the metal to coordinating atom bond lengths in both **1** and **3** are within the ranges reported for octahedral vanadium(IV) species containing the same coordinating atoms [19,20,22–24].

3.4. Intermolecular hydrogen bonding and self-assembly

The type of complex molecules described in this work contain two major functionalities which can participate in intermolecular hydrogen bond interactions. These are the N–H group of the hydrazine fragment of the tridentate ligand and the metal coordinated oxo group. It may be noted that the acidity of the N–H proton increases significantly in aroyl- or arylhydrazine based Schiff bases when the adjacent imine-N is coordinated to a metal ion [25]. A similar situation is expected in the present series of complexes also. The vanadium(IV/V) bound oxo group is fairly strong basic centre and is known to participate in intermolecular weak C–H···O interactions [10,24]. Thus, it is anticipated that the self-assembly of the molecules of both **1** and **3** in the crystal lattice will be guided by reasonably strong intermolecular N–H···O=V hydrogen bond interactions. Indeed this interaction is observed in both the structures. The N2···O4 distance and the N2–H···O4 angle are 2.909(3) Å and 177.4° for **1** and 2.980(3) Å and 175.6° for **3**. In each case, self-assembly of the complex molecules via these intermolecular N–H···O=V hydrogen bond interactions leads to one-dimensional supramolecular structure in the crystal lattice (Fig. 5). There are no significant short contacts and hence no additional non-covalent

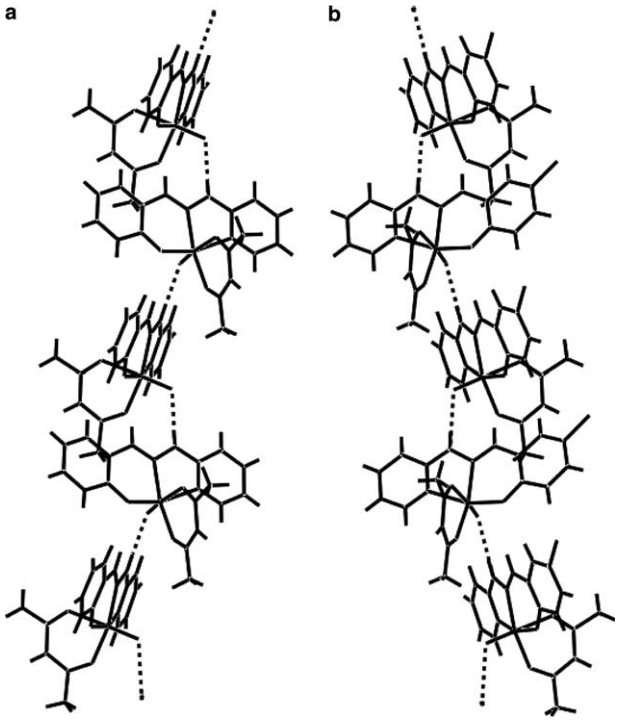

Fig. 5. One-dimensional ordering of (a) [VO(phsal)(acac)] (**1**) and (b) [VO(phsalCl)(acac)] (**3**) in the crystal lattice.

interactions between the parallel one-dimensional structures.

4. Conclusion

The synthesis and physical properties of a new series of oxovanadium(IV) ternary complexes are described. The general formula of these complexes is [VO(phsalR)(acac)] where Hacac and HphsalR represent the bidentate acetylacetone and the tridentate Schiff base *N*-(2-pyridyl)-*N*′-(5-R-salicylidene)hydrazine, respectively. The identities of the complexes have been established by microanalytical, magnetic, spectroscopic and X-ray crystallographic methods. The complexes display ligand-field and ligand-to-metal charge transfer bands in the electronic spectra. The EPR spectra of the complexes are characteristic of an axially compressed d^1_{xy} configuration. The crystal structures show that the meridional pyridine-N, imine-N and phenolate-O donor phsalR$^-$, the O,O-donor acac$^-$ and the oxo group form a distorted N_2O_4 octahedron around the metal centre. In the crystal lattice, the complex molecules are self-organized to one-dimensional supramolecular structure via intermolecular N–H···O=V hydrogen bond interaction.

5. Supplementary material

Crystallographic data for [VO(phsal)(acac)] (**1**) and [VO(phsalCl)(acac)] (**3**) have been deposited with the Cambridge Crystallographic Data Centre (deposition numbers are CCDC 286182 and 286183 for **1** and **3**, respectively). Copies of this information may be obtained from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK, fax: +44 1233 336 033; email: deposit@ccdc.cam.ac.uk; or the web: http://www.ccdc.cam.ac.uk.

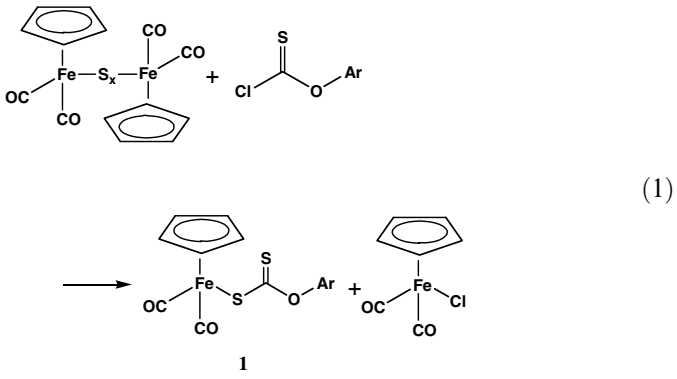
In the framework of synthetic studies of cyclopentadienyl iron sulfur complexes, we have studied the reactions of the iron sulfides $(\mu\text{-}S_x)[CpFe(CO)_2]_2$ with a variety of nucleophiles such as acid chlorides, sulfonyl chlorides and chloroformates. These reactions give the sulfur containing complexes, thiocarboxylates ($CpFe(CO)_2SCOR$) [22–24], thiosulfonates ($CpFe(CO)_2SSO_2R$) [25] and thiocarbonates ($CpFe(CO)_2SCO_2R$) [26]. We hereby report the synthesis of dithiocarbonate complexes of iron by the reaction of the iron sulfides, $(\mu\text{-}S_x)[CpFe(CO)_2]_2$, with aryl chlorothionoformates.

2. Results and discussion

2.1. Synthesis and characterization

The reaction of $(\mu\text{-}S_x)[CpFe(CO)_2]_2$ with various aryl chlorothionoformates proceeds smoothly to give the corresponding dithiocarbonate complexes $CpFe(CO)_2SC(S)OAr$ (**1**) as shown in Eq. (1). The iron chloride, $CpFe(CO)_2Cl$ is obtained as a by-product of this reaction and can be separated from the products **1** by column chromatography.



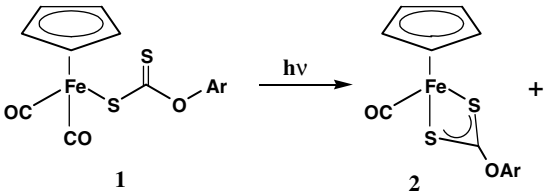
(1)

1

Ar = Ph (**a**), 4-C_6H_4Cl (**b**), 4-C_6H_4F (**c**), C_6F_5 (**d**), 4-$C_6H_4CH_3$ (**e**)

The new organoiron S-bonded dithiocarbonates (**1**) are stable solids and are also stable in solution. Structural features of **1** were identified on the basis of IR and ^1H NMR spectroscopy as well as by elemental analysis. The IR spectra of **1** in the carbonyl stretching region show two bands due to the terminal carbonyl groups in the ranges 2044–2049 and 1998–2006 cm^{-1}. These bands are higher than those reported for the corresponding thiocarboxylates $CpFe(CO)_2SCOR$ (2027–2060, 1984–1998 cm^{-1}) [22–24] and are similar to those of thiocarbonate complexes $CpFe(CO)_2SCO_2R$ (2044–2045 and 1997–1999 cm^{-1}) [26], suggesting that the mono- and di-thiocarbonate ligands have similar basicity. In the ^1H NMR spectra of **1**, the peak for the Cp-protons is found in the range 5.05–5.10 ppm. This chemical shift range is similar to that observed for the thiocarboxylate (4.98–5.13 ppm) [22–24] and thiocarbonate (4.98–5.12 ppm) analogues [26]. These results suggest a similar electron density around the iron center in all of these complexes.

When a THF solution containing $CpFe(CO)_2SCSOAr$ (**1**) was irradiated by UV-light for short time (ca. 30 min), the chelate complexes $CpFe(CO)(\kappa^2S,S\text{-}S_2COAr)$ (**2**) were obtained in high yields (Eq. (2)).



1 **2** (2)

Compounds **2** were characterized by IR, ^1H NMR spectroscopy and elemental analysis. The IR spectrum of each of complexes **2** in the carbonyl stretching region exhibits a singlet band in the range 1953–1961 cm^{-1} for the terminal carbonyl group coordinated to the iron center. This range is comparable to those found for iron complexes containing one CO-group such as $CpFe(CO)(EPh_3)SCOR$ (1950–1970 cm^{-1}). ^1H NMR spectra of **2** in $CDCl_3$ show singlet peak in the range 4.63–4.69 ppm for the cyclopentadienyl protons. This peak has lower chemical shift compared to the corresponding peak of the starting dicarbonyl complexes **1**. This shift may attributed to the higher electron-density around the Fe-atom in **2** compared to that in **1**. Comparing this peak to that of $CpFe(CO)(EPh_3)SCOR$, it is obvious that these values are comparable to each other.

2.2. Crystal structure

The structure of $CpFe(CO)_2SC(S)O\text{-}4\text{-}C_6H_4Cl$ (**1b**) was determined by single-crystal X-ray analysis and is shown in Fig. 1. Selected bond lengths and angles are shown in Table 1. The relevant bond parameters are listed in Table 2. As expected, the analysis proved that the dithiocarbonate ligand is bonded to the iron in a monodentate fashion through one sulfur atom with an Fe–S bond distance of 2.2765(5) Å. This distance is longer than the corresponding Fe–S distance in $CpFe(CO)_2SCO_2Et$ (2.2675(10) Å) and in $CpFe(CO)_2SCO\text{-}2\text{-}C_6H_4NO_2$ (2.266(1) Å) The Cp ligand is bound to the metal in an η^5-fashion with Fe–C bond distances comparable to those observed for Cp–iron complexes. The Fe–C (of carbonyl ligands) bond distances of 1.7745(19) and 1.7810(17) Å are in the normal range for $CpFe(CO)_2X$ complexes [24,26–28]. The Fe–S1–C8 angle is 113.50°.

3. Experimental

3.1. General

All reactions were carried out under an inert atmosphere of nitrogen using standard Schlenk line techniques. Solvents were dried by standard methods and were distilled under nitrogen prior to use. The complexes $(\mu\text{-}S_x)[CpFe(CO)_2]_2$ ($x = 2$, 3) were prepared by published method [29]. The reagents: aryl-chlorothionoformates,

Table 2
Selected crystal data and refinement parameters for $CpFe(CO)_2SC(S)O\text{-}4\text{-}C_6H_4Cl$ (**1b**)

Empirical formula	$C_{14}H_9ClFeO_3S_2$
Formula weight	380.63
Crystal size (mm)	$0.13 \times 0.10 \times 0.08$
Crystal system	monoclinic
Space group	$P2_1/c$
Unit cell dimensions	
a (Å)	11.4680 (10)
b (Å)	9.7400 (10)
c (Å)	13.678 (10)
α (°)	90.00
β (°)	103.21(5)
γ (°)	90.00
V (Å^3)	1487.4 (2)
Z	4
Index ranges	$-16 \leqslant h \leqslant 9$, $0 \leqslant k \leqslant 13$, $0 \leqslant l \leqslant 19$
Number of total reflections	4334
Number of unique reflections ($>2\sigma(I)$)	3711
D_{calc} (Mg m^{-3})	1.855
Radiation type	Mo Kα
μ (mm^{-1})	1.478
λ (Å)	0.71069
θ Range (°)	1.82–30.05
$R[F^2 > 2\sigma(F^2)]$	0.0280
$\omega R(F^2)$[a]	0.0765

[a] $\omega = 1/[\sigma^2(F_o^2) + (0.0426P)^2]$, where $P = (F_o^2 + 2F_c^2)/3$.

$[CpFe(CO)_2]_2$, and sulfur were obtained from Acros and were used as received.

Nuclear magnetic resonance (NMR) spectra were recorded on a Bruker 200 MHz spectrometer. Chemical shifts are in ppm relative to TMS at 0 ppm. Infrared (IR) spectra were recorded on a Nicolat Nexus FT-IR spectrometer using NaCl solvent cells. Elemental analyses were done in Laboratoire d'Analyse Elémentaire, Université de Montréal, Montréal, Que., Canada. Melting points were reported on an electrothermal melting point apparatus and are uncorrected. The photolytic reactions were carried out in a medium pressure mercury lamp (150 W) with a quartz immersion cell.

3.2. General procedure for the preparation of $CpFe(CO)_2SC(S)OAr$ (*1*)

To a solution of $(\mu\text{-}S_x)[CpFe(CO)_2]_2$ (0.50 mmol) in diethylether (100 mL), aryl chlorothionoformate (0.55 mmol) was added and the resulting mixture was stirred overnight at room temperature. The volatiles were removed under reduced pressure and the resulting solid was redissolved in a minimum amount of CH_2Cl_2 and transferred to a silica gel column made up in hexane. The column was first eluted with hexane to remove any unreacted aryl chlorothionoformates. Then, it was eluted with hexane/dichloromethane solution (1:1 v:v ratio) to give a red-orange band which was collected and identified as $CpFe(CO)_2SC(S)OAr$, followed by a red band which was also collected and identified as $CpFe(CO)_2Cl$. The $CpFe(CO)_2SC(S)OAr$ (**1**) were recrystallized from dichloromethane/hexane.

3.2.1. $CpFe(CO)_2SC(S)OC_6H_5$ (*1a*)

Yield, 79%; m.p. 132–133 °C. *Anal.* Required for $C_{14}H_{10}FeO_3S_2$: C, 48.57; H, 2.91; S, 18.53. Found: C, 47.78; H, 2.65; S, 18.03%. IR (CH_2Cl_2, cm^{-1}): 2045s,

1998s ν(C≡O). ^{1}H NMR ($CDCl_3$, δ, ppm): 5.05 (s, 5H, C_5H_5), 7.07 (m, 3H, C_6H_5), 7.31 (m, 2H, C_6H_5).

*3.2.2. $CpFe(CO)_2SC(S)O$-4-C_6H_4Cl (**1b**)*

Yield, 87%; m.p. 134–136 °C. *Anal.* Required for $C_{14}H_9ClFeO_3S_2$: C, 44.18; H, 2.38; S, 16.58. Found: C, 44.10; H, 2.23; S, 15.98%. IR (CH_2Cl_2, cm^{-1}): 2046s, 1999s ν(C≡O). ^{1}H NMR ($CDCl_3$, δ, ppm): 5.05 (s, 5H, C_5H_5), 6.95 (d, 2H, C_6H_4), 7.32 (d, 2H, C_6H_4).

*3.2.3. $CpFe(CO)_2SC(S)O$-4-C_6H_4F (**1c**)*

Yield, 86%; m.p. 128–129 °C. *Anal.* Required for $C_{14}H_9FFeO_3S_2$: C, 46.17; H, 2.49; S, 17.61. Found: C, 45.88; H, 2.28; S, 17.01%. IR (CH_2Cl_2, cm^{-1}): 2046s, 2000s ν(C≡O). ^{1}H NMR ($CDCl_3$, δ, ppm): 5.09 (s, 5H, C_5H_5), 7.00 (d, 2H, C_6H_4), 7.40 (d, 2H, C_6H_4).

*3.2.4. $CpFe(CO)_2SC(S)OC_6F_5$ (**1d**)*

Yield, 90%; m.p. 115–116 °C. *Anal.* Required for $C_{14}H_5F_5FeO_3S_2$: C, 38.55; H, 1.16; S, 14.70. Found: C, 38.22; H, 0.99; S, 14.13%. IR (CH_2Cl_2, cm^{-1}): 2049s, 2006s ν(C≡O). ^{1}H NMR ($CDCl_3$, δ, ppm): 5.10 (s, H's, C_5H_5).

*3.2.5. $CpFe(CO)_2SC(S)O$-4-C_6H_4Me (**1e**)*

Yield, 85%; m.p. 138–140 °C. *Anal.* Required for $C_{15}H_{12}FeO_3S_2$: C, 50.01; H, 3.24; S, 17.58. Found: C, 49.79; H, 3.36; S, 17.58%. IR (CH_2Cl_2, cm^{-1}): 2044s, 2000s ν(C≡O). ^{1}H NMR ($CDCl_3$, δ, ppm): 2.31 (s, 3H, CH_3), 5.05 (s, 5H, C_5H_5), 6.91 (d, 2H, C_6H_4), 7.22 (d, 2H, C_6H_4).

*3.3. General procedure for the preparation of $CpFe(CO)(\kappa^2S,S$-$SC(S)OAr)$ (**2**)*

A THF solution (30 mL) of $CpFe(CO)_2SC(S)OAr$ (0.25 mmol) was irradiated under a stream of N_2 for 30 min. The products were separated by column chromatography. The column was eluted with (2:1 v:v ratio) CH_2Cl_2/hexane to separate the products which were recrystallized from dichloromethane/hexane.

*3.3.1. $CpFe(CO)(\kappa^2S,S$-$SC(S)OC_6H_5)$ (**2a**)*

Yield, 80%; m.p. 89–91 °C. *Anal.* Required for $C_{13}H_{10}FeO_2S_2$: C, 49.07; H, 3.17; S, 20.16. Found: C, 48.51; H, 3.11; S, 19.77%. IR (CH_2Cl_2, cm^{-1}): 1954s ν(C≡O). ^{1}H NMR ($CDCl_3$, δ, ppm): 4.65 (s, 5H, C_5H_5), 7.41 (m, 5H, C_6H_5).

*3.3.2. $CpFe(CO)(\kappa^2S,S$-$SC(S)O$-4-$C_6H_4Cl)$ (**2b**)*

Yield, 82%; m.p. 102–103 °C. *Anal.* Required for $C_{13}H_9ClFeO_2S_2$: C, 44.28; H, 2.57; S, 18.19. Found: C, 44.01; H, 2.54; S, 17.50%. IR (CH_2Cl_2, cm^{-1}): 1956s ν(C≡O). ^{1}H NMR ($CDCl_3$, δ, ppm): 4.66 (s, 5H, C_5H_5), 7.09 (d, 2H, C_6H_4), 7.37 (d, 2H, C_6H_4).

*3.3.3. $CpFe(CO)(\kappa^2S,S$-$SC(S)O$-4-$C_6H_4F)$ (**2c**)*

Yield, 68%; m.p. 92–93 °C. *Anal.* Required for $C_{13}H_9FFeO_2S_2$: C, 46.44; H, 2.70; S, 19.08. Found: C, 46.12; H, 2.29; S, 18.56%. IR (CH_2Cl_2, cm^{-1}): 1956s ν(C≡O). ^{1}H NMR ($CDCl_3$, δ, ppm): 4.67 (s, 5H, C_5H_5), 7.19 (d, 2H, C_6H_4), 7.40 (d, 2H, C_6H_4).

*3.3.4. $CpFe(CO)(\kappa^2S,S$-$SC(S)OC_6F_5)$ (**2d**)*

Yield, 87%; m.p. 78–79 °C. *Anal.* Calc. for $C_{13}H_5F_5FeO_2S_2$: C, 38.25; H, 1.23; S, 15.71. Found: C, 37.90; H, 1.11; S, 15.07%. IR (CH_2Cl_2, cm^{-1}): 1961s ν(C≡O). ^{1}H NMR ($CDCl_3$, δ, ppm): 4.69 (s, H's, C_5H_5).

*3.3.5. $CpFe(CO)(\kappa^2S,S$-$SC(S)O$-4-$C_6H_4Me)$ (**2e**)*

Yield, 75%; m.p. 95–96 °C. *Anal.* Required for $C_{14}H_{12}FeO_2S_2$: C, 50.61; H, 3.64; S, 19.30. Found: C, 50.31; H, 3.78; S, 19.50%. IR (CH_2Cl_2, cm^{-1}): 1953s ν(C≡O). ^{1}H NMR ($CDCl_3$, δ, ppm): 2.33 (s, 3H, CH_3), 4.63 (s, 5H, C_5H_5); 6.97 (d, 2H, C_6H_4), 7.17 (d, 2H, C_6H_4).

3.4. X-ray structure analysis

Crystals suitable for X-ray diffraction of **1b** were obtained from CH_2Cl_2/hexane mixture. The data were collected on a KappaCCD diffractometer with graphite monochromated Mo Kα radiation at 175 K. The crystallographic data are shown in Table 2. The cell parameters were determined from 4335 reflections collected in the range $1.82 \leqslant \theta \leqslant 30.05°$. There were 4334 independent reflections with 3711 observed reflections ($>2\sigma(I)$). The structure was solved by direct method using SHELXS-97 [30] and DIFMAP synthesis using SHELXTL-96 [31].

4. Supplementary data

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 277850 for compound **1b**. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44 1233 336 033; e-mail: deposit@ccdc.cam.ac.uk or www:http://www.ccdc.cam.ac.uk).

Acknowledgments

The financial support (Grant No. 31/2002) from the Deanship of Scientific Research, Jordan University of Science and Technology is greatfully acknowledged. We thank Prof. Richard Welter (University of Strasburg, France) for determining the X-ray structure.

Despite these considerations, recent results have shown that oxygen ligands such as tri-*n*-octyl phosphine oxide prefer to bind to actinides rather than to lanthanides in suitable anionic extraction media [9]. In addition, diamides such as malonamides [10] and their derivatives [11], and ligands containing both phosphine oxide and amide functionalities such as CMPO molecules (CMPO = carbamoyl methyl phosphine oxide molecules of formula R^1R^2PO–CH_2–CO–NR^3R^4) [12] are henceforth targeted for carrying out both the co-extraction of the trivalent f-elements from the aqueous wastes and their subsequent separation. In this context, it is of interest to isolate and compare the structural parameters of analogous complexes of trivalent actinide and lanthanide ions with O=P and O=C donor ligands, with the aim to get further insight into the nature of the metal–oxygen bonds. Following previous work on the complexation of MI_3 (M = La, Ce, Nd) and $[UI_3(py)_4]$ with triphenylphosphine oxide [13], we focused our attention on the coordination of the simplest neutral *N*,*N*-dialkylamide, e.g. dimethylformamide (dmf), to these metal iodides. While dmf complexes of trivalent lanthanides [14–19] and uranium in high oxidation states are well documented [2,3], no uranium(III) compound with carbonyl-containing ligands has been reported so far. Here, we present the syntheses and crystal structures of dimethylformamide adducts of uranium(III) and lanthanide(III) iodides.

2. Results and discussion

2.1. Synthesis of the complexes

Evaporation of a dmf solution of LnI_3 (Ln = La, Ce, Nd) and trituration of the residue with diethyl ether or pentane afforded a pale yellow or white powder of the neodymium or cerium compounds, respectively, and a sticky white lanthanum product. Difficulties were encountered for isolating the complexes with a well-defined number of coordinated dmf molecules. Despite prolonged drying under vacuum, elemental analyses of the $[LnI_3(dmf)_n]$ complexes gave values of *n* close to 4 and 5 for Ln = Nd or Ce, respectively, and varying from 3 to 6 for Ln = La.

Dissolving $[UI_3(py)_4]$ in dmf gave a clear solution, the dark red colour of which was characteristic of an uranium(III) species. The latter was stable for days at room temperature but oxidation occurred upon heating at 110 °C, as shown by the rapid colour change from red to yellow and the formation of pale green crystals of $[U(dmf)_9]I_4$ [3a] after slow diffusion of diethyl ether into the dmf solution. The formation of $[U(dmf)_9]I_4$ may result from a disproportionation reaction of the thermally instable $[U(dmf)_9]I_3$ with concomitant formation of reactive low-valent species immediately oxidized by the solvent into unidentified species. Attempts to isolate the uranium(III) complex $[UI_3(dmf)_n]$ at room temperature gave an untractable dark red oil which was characterized only by its IR and ^{1}H NMR spectra.

The ^{1}H NMR spectra of the $[MI_3(dmf)_n]$ complexes (M = Ce, Nd, U) in acetonitrile-d_3 exhibit paramagnetic dmf signals with chemical shifts depending on the value of *n*. The strong absorptions in the 1644–1652 cm^{-1} region of the IR spectra are assigned to the stretching ν(C–O) frequencies (1675 cm^{-1} for the free ligand). In particular, the ν(C–O) band of the uranium complex (1644 cm^{-1}) is very close to that reported for the uranium(IV) derivative $[UI_4(dmf)_6]$ (1643 cm^{-1}) [3a].

2.2. Crystal structures of the complexes

Dark red crystals of $[U(dmf)_9]I_3$ suitable for X-ray diffraction analysis were obtained upon slow diffusion of diethyl ether into a dmf solution of $[UI_3(py)_4]$. In parallel, and although some $[Ln(dmf)_n]X_3$ complexes have already been crystallographically characterized [14–19], those with X = I have been prepared in order to compare the structures of analogous cationic compounds of closely sized 4f and 5f-elements with the same counterion. While crystallization of the $[Ln(dmf)_n]X_3$ complexes with weakly coordinating X anions was reported to be difficult [16], large colourless (La, Ce) and light pink (Nd) crystals were deposited in a few days from solutions of LnI_3 in a mixture of dmf and diethyl ether.

The two complexes $[Ln(dmf)_8]I_3$ (Ln = Ce (**1**), Nd (**2**)) are isomorphous; a view of the cation of **1** is represented in Fig. 1 and selected bond lengths and angles are given in Table 1. The metal centre, located on a binary axis, is eight-coordinate, surrounded by the oxygen atoms of eight monodentate dmf molecules, in a distorted square antiprismatic configuration. The two square faces of the antiprism, defined by the O(1), O(2), O(3′), O(4′) and O(1′), O(2′), O(3), O(4) atoms, are planar with the same maximum

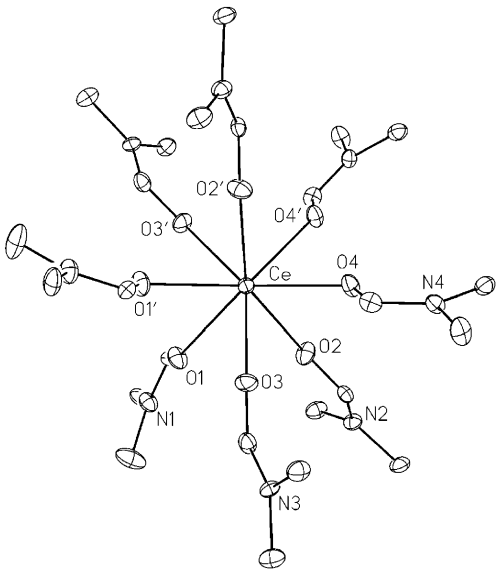

Fig. 1. View of the cation $[Ce(dmf)_8]^{3+}$ with displacement ellipsoids drawn at the 30% probability level. Hydrogen atoms are omitted for clarity. Symmetry code: $' = -x, y, 0.5 - z$.

deviation (due to the imposed symmetry) of 0.113(3) and 0.124(1) Å for **1** and **2**, respectively; these two bases are almost parallel with dihedral angles of 0.19(6)° (**1**) and 0.51(2)° (**2**). The geometry of the $[Ln(dmf)_8]^{3+}$ cation is quite identical to that found in the compounds $[Ce(dmf)_8]_2[WS_4]_3 \cdot H_2O$ [15], $\{[Ln(dmf)_8][Cu_6(CN)_9] \cdot 2dmf\}_\infty$ (Ln = Eu, Gd, Er) [14], $[Me_2NH_2][Gd(dmf)_8]_2[ClO_4]_4$ [16], $\{[Nd(dmf)_8][W_4Ag_5S_{16}]\}_\infty$ [18] and $[Ln(dmf)_8[ClO_4]_3$ (Ln = Gd, Tb) [16]. The average Ce–O and Nd–O bond lengths of 2.47(2) and 2.44(2) Å are similar to those measured in the aforementioned cerium and neodymium complexes [2.471 and 2.43 Å], and in the compound $\{[Nd(def)_8]_2[W_8Ag_{10}S_{32}]\}_\infty$ (def = diethylformamide) [2.42 (3) Å] [18,19].

Crystals of $[Ce(dmf)_9]I_3$ (**4**) were obtained in similar conditions from another batch of crystallization and were found to be isomorphous with those of the lanthanum and uranium analogues, **3** and **5**. Complex **5** provides, after $[U(MeCN)_9]I_3$ [20] and some compounds resulting from coordination of MX_3 (X = I, OSO_2CF_3) with polydentate nitrogen ligands [21], a new example of a uranium(III) trication. To the best of our knowledge, **5** is the first uranium(III) compound with coordinated O=C groups to have been isolated and crystallographically characterized. Aliphatic and aromatic ketones were found to be reductively coupled by U(III) species [22]. A view of one of the two independent and quite identical cations of **5** is shown in Fig. 2 and selected bond distances and angles are listed in Table 1, together with those of the lanthanum and cerium counterparts.

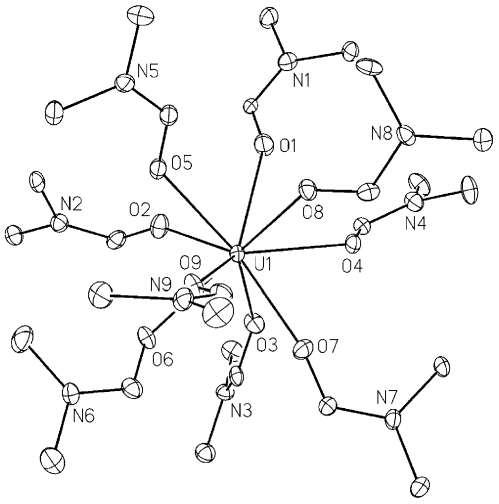

Fig. 2. View of one of the two independent cations $[U(dmf)_9]^{3+}$ with displacement ellipsoids drawn at the 20% probability level. Hydrogen atoms are omitted for clarity.

The metal atoms of **3**–**5** accommodate nine monodentate dmf ligands which form a slightly distorted monocapped square antiprism of oxygen atoms. The square faces are defined by the O(1,2,3,4) and O(5,6,7,8) atoms in the first cation and O(10,11,12,13) and O(14,15,16,17) atoms in the second, with atoms O(9) and O(18), respectively, in capping position of these second planes. The four atoms in each face are coplanar with a maximum deviation of 0.111(3) Å in **3**, 0.079(4) Å in **4** and 0.087(5) Å in **5**; the two mean planes in the two cations are almost parallel with dihedral angles of 2.8(3)° and 3.32(11)° in **3**, 2.5(5)° and 3.5(2)° in **4**, and 2.1(5)° and 3.8(2)° in **5**. The M(1)–O(9) and M(2)–O(18) axes are nearly perpendicular to the square faces, the angles with the normal to the proximal plane being 3.4° and 2.7° in **3**, 3.0° and 2.8° in **4**, and 3.4° and 2° in **5**. In the first independent cation of **3**–**5**, with the exception of the M(1)–O(4) distance of 2.597(5) Å in **3**, 2.579(7) Å in **4**, and 2.575(8) Å in **5**, the distances between M(1) and the capping O(9) atom of 2.575(5) Å in **3**, 2.560(8) Å in **4**, and 2.562(9) Å in **5** are longer than the distances between M(1) and the oxygen atoms of the square antiprism, which average 2.52(4), 2.50(4), and 2.52(3) Å for M = La, Ce and U, respectively. In the second independent cation, the M(2)–O(18) distances corresponding to the dmf ligand in capping position are the longest with values of 2.623(6) Å in **3**, 2.616(10) Å in **4**, and 2.628 (11) Å in **5**. The geometrical parameters of the $[La(dmf)_9]^{3+}$ cation are very similar to those found in $\{[La(dmf)_9]_2[Cu_{12}(CN)_{18}] \cdot 2dmf\}_\infty$ [14]. The trication $[U(dmf)_9]^{3+}$ adopts the same monocapped square antiprismatic configuration as the tetracation $[U(dmf)_9]^{4+}$ [3a]; the average distance between the uranium and oxygen atoms defining the square antiprism and that corresponding to the dmf ligands in capping position are longer in the uranium(III) complex, by ca. 0.13 and 0.14 Å, respectively. This difference reflects the variation in the radii of

the U^{3+} and U^{4+} ions and the distinct electronic charge of the complexes.

It is interesting to note that among the 4f series only the larger La^{3+} and Ce^{3+} ions can accommodate nine dmf ligands, whereas the other smaller lanthanide ions (Nd^{3+}, Eu^{3+}, Gd^{3+}, Tb^{3+}, Er^{3+}) give invariably the eight-coordinate solvate $[Ln(dmf)_8]^{3+}$. The U^{3+} ion, with an ionic radius intermediate between those of La^{3+} and Ce^{3+} [23], is also found in nine-coordination. The crystal structures of **3–5** confirm, after EXAFS studies of lanthanide perchlorates in dmf solution, that the nine-coordinate $[Ln(dmf)_9]^{3+}$ can exist in this solvent, particularly for Ln = La and Ce, while the eight-coordinate solvates were found to be present as the main species in dmf throughout the Ln(III) series [24]. These results would indicate that for the larger metals (La, U), $[M(dmf)_9]I_3$ predominates as the most easily crystallized complex, masking the isolation of the $[M(dmf)_8]I_3$ derivative.

Evidence for the more covalent character of the actinide–ligand versus lanthanide–ligand bonding was searched in the variations of bond distances in analogous An(III) and Ln(III) compounds [21,25,26]. A plot of the average M–O distances against the ionic radii of the metals in the eight- and nine-coordinate $[Ln(dmf)_n]^{3+}$ species (Ln = Yb, Gd, Nd, Ce and $n = 8$; M = La, Ce, U and $n = 9$) and also the nine-coordinate cation $[U(dmf)_9]^{4+}$ (Fig. 3) shows a quite perfect linear relationship, revealing that the M–dmf interactions in both trivalent and tetravalent 4f and 5f species are rather similar in nature. A similar observation was made with the complexes $[MX_2(OPPh_3)_4]X$ (M = Ce, U and $X = OSO_2CF_3$; M = Nd, Ce, La, U and X = I) where the variation of the M–O bond lengths of both the anionic and neutral ligands only reflected the differences between the radii of the M^{3+} ions [13]. This trend in the M–O distances whereas the U–N bond lengths of mono- and polyaromatic nitrogen ligands are systematically smaller than the corresponding Ln–N distances in analogous complexes demonstrates the presence of a larger contribution of covalency in the An–N bond.

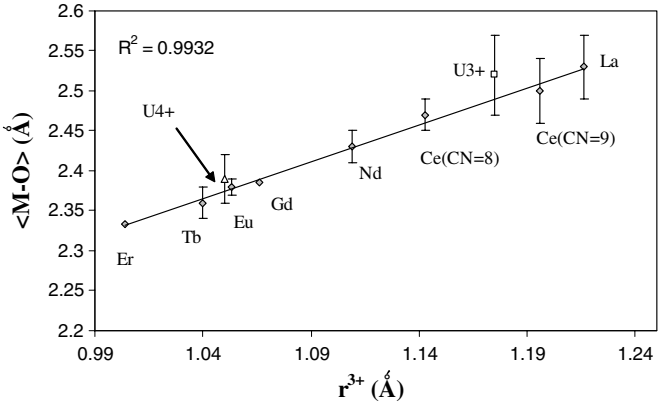

Fig. 3. Mean M–O distances as a function of the metal ionic radii in the $[Ln(dmf)_8]^{3+}$ (Ln = Er, Tb, Eu, Gd, Nd, Ce), $[M(dmf)_9]^{3+}$ (M = La, Ce, U) and $[U(dmf)_9]^{4+}$ cations. Standard deviations are indicated as vertical bars. The R^2 value corresponds to the line drawn for the sole Ln^{3+} ions.

3. Conclusion

Isolation of $[U(dmf)_9]I_3$, the first uranium(III) compound with carbonyl-containing ligands, demonstrates that uranium(III) species are stable at room temperature in dmf solution. The crystal structures of $[M(dmf)_9]I_3$ (M = La, Ce, U) confirm that the larger 4f and 5f trivalent ions can exist as nine-coordinate solvates in dmf solution. Comparison of the crystal structures of the $[M(dmf)_n]I_3$ compounds (M = Ce, Nd and $n = 8$; M = La, Ce, U and $n = 9$) and $[U(dmf)_9]I_4$ shows the difference between the average M–O distances to reflect the variation in the ionic radii of the metals, denoting that the nature of the M–O bonding is similar in these series of 4f and 5f compounds.

4. Experimental

4.1. General

All reactions were carried out under argon (<5 ppm oxygen or water) using standard Schlenk-vessel and vacuum-line techniques or in a glove box. Solvents (diethyl ether and acetonitrile) were dried over NaH and distilled immediately before use. Dimethylformamide (Aldrich) was stored over 3 Å molecular sieves and distilled immediately before use. Deuterated acetonitrile (Eurisotop) was dried over KH. $[UI_3(py)_4]$ was prepared as previously reported [27] and LnI_3 (Ln = La, Ce, Nd) (Aldrich) were used as received. ^{1}H NMR spectra were recorded on a Bruker DPX 200 instrument and referenced internally using the residual protio solvent resonances relative to tetramethylsilane (δ 0). IR spectra were recorded under nitrogen flush on a Perkin–Elmer FT-IR 1725X spectrometer, using nujol mulls of samples between KBr windows. The ultra-sound bath is a Branson 1510 apparatus (80 W, 40 kHz). Elemental analyses were performed by Analytische Laboratorien at Lindlar (Germany).

4.2. Syntheses

4.2.1. $[CeI_3(dmf)_5]$

A flask was charged with CeI_3 (79.5 mg, 0.15 mmol) and freshly distilled dmf (5 mL). The mixture was stirred for a few minutes until the solution was clear and the solvent was evaporated off. After drying under vacuum for 12 h at 25 °C, the white pasty powder was triturated in pentane (15 mL) and, after filtration, further dried for 15 h at room temperature, affording a white powder of $[CeI_3(dmf)_5]$ (135.3 mg, 80%).

^{1}H NMR (acetonitrile-d_3, 23 °C): 15.92 (1H, s, $w_{1/2}$ = 35 Hz, CH), 4.73 (3H, s, CH_3), 4.54 (3H, s, CH_3). IR ν/cm^{-1} 1645vs (CO). *Anal.* Calc. for $C_{15}H_{35}CeI_3N_5O_5$: C, 20.69; H, 4.04; N, 8.10. Found: C, 20.33; H, 3.98; N, 7.90%.

4.2.2. $[NdI_3(dmf)_n]$ (n = 4 and 4.5)

(a) A flask was charged with NdI_3 (136 mg, 0.259 mmol) and freshly distilled dmf (5 mL). The mixture was stirred at room temperature until a clear yellow-orange solution was obtained. Concentration to ca. 3 mL and addition of diethyl ether (ca. 10 mL) induced precipitation of a pale pink powder which was then washed with diethyl ether (2 × 5 mL). Drying under vacuum for 1 h at ca. 55 °C induce melting of the powder. The sticky residue was powdered by trituration in pentane (10 mL) and dried for 12 h at room temperature. The elemental analyses were in agreement with the formula $[NdI_3(dmf)_4]$ (169.4 mg, 80%).

^{1}H NMR (acetonitrile-d_3, 23 °C): 19.22 (1H, s, $w_{1/2}$ = 45 Hz, CH), 6.04 (3H, s, CH_3), 5.94 (3H, s, CH_3). IR ν/cm^{-1} 1650vs (CO). *Anal.* Calc. for $C_{12}H_{28}I_3N_4NdO_4$: C, 17.63; H, 3.45; N, 6.85. Found: C, 17.45; H, 3.31; N, 6.74%.

(b) A second experiment was carried out with NdI_3 (235 mg, 0.259 mmol) and freshly distilled dmf (5 mL). After complete dissolving, the solution was evaporated to dryness. The yellow residue melted when heated to ca. 50 °C, and was triturated and washed with pentane (10 mL). The yellow powder was dried under vacuum for 1 h at 65 °C (melting) and kept under dynamic vacuum for 15 h at room temperature. The elemental analyses were in agreement with the formula $[NdI_3(dmf)_{4.5}]$ (355 mg, 93%).

^{1}H NMR (acetonitrile-d_3, 23 °C): 17.09 (1H, s, $w_{1/2}$ = 30 Hz, CH), 5.35 (3H, s, CH_3), 5.20 (3H, s, CH_3). IR ν/cm^{-1} 1652vs (CO). *Anal.* Calc. for $C_{13.5}H_{31.5}I_3N_{4.5}NdO_{4.5}$: C, 18.42; H, 3.74; N, 7.43. Found: C, 18.77; H, 3.75; N, 7.44%.

4.2.3. $[LaI_3(dmf)_n]$ (n = 3 or 6)

(a) A flask was charged with LaI_3 (199 mg, 0.38 mmol) and freshly distilled dmf (5 mL). After heating at 70 °C for 1 h, the solution was evaporated to dryness and the residue dried under vacuum for 15 h, affording a white sticky residue. After addition of pentane (10 mL), the flask was immersed in the ultrasound bath for 30 min. Filtration and drying under vacuum for 2 h at room temperature afforded a white paste of $[LaI_3(dmf)_3]$ (276 mg, 97%).

^{1}H NMR (acetonitrile-d_3, 23 °C): 8.13 (1H, s, CH), 3.15 (3H, s, CH_3), 2.98 (3H, s, CH_3). IR ν/cm^{-1} 1644vs (CO). *Anal.* Calc. for $C_9H_{21}I_3LaN_3O_3$: C, 14.63; H, 2.86; N, 5.69. Found: C, 14.53; H, 2.96; N, 5.72%.

(b) An NMR tube was charged with LaI_3 (30 mg, 0.057 mmol) and freshly distilled dmf (1.5 mL). After heating at 110 °C for 3 h, diethyl ether (2 mL) was condensed under vacuum onto the colourless solution, inducing precipitation of a white powder. Filtration and drying under vacuum for 1 h at 60 °C then 12 h at room temperature afforded $[LaI_3(dmf)_6]$ as a white sticky powder (54 mg, 98%).

^{1}H NMR (acetonitrile-d_3, 23 °C): 8.14 (1H, s, CH), 3.13 (3H, s, CH_3), 2.94 (3H, s, CH_3). *Anal.* Calc. for $C_{18}H_{42}I_3LaN_6O_6$: C, 22.56; H, 4.42; N, 8.77. Found: C, 22.50; H, 4.35; N, 8.79%.

4.2.4. $[UI_3(dmf)_n]$

Dissolving $[UI_3(py)_4]$ in dmf led to a dark red solution. Evaporation of the solvent or attempts to precipitate the compound by concentration of the solution and addition of pentane or diethyl ether afforded a dark-red oil which was dried under vacuum for 12 h at room temperature.

^{1}H NMR (acetonitrile-d_3, 23 °C): 14.89 (1H, s, $w_{1/2}$ = 85 Hz, CH), 1.98 (3H, s, overlapped with solvent signal, CH_3), 1.86 (3H, s, CH_3). IR ν/cm^{-1} 1644vs (CO). The dark-red solution turned yellow by heating at 110 °C for 30 min; slow diffusion of diethyl ether into the solution induced the deposit of pale green crystals of $[U(dmf)_9]I_4$ in a few days.

4.3. Crystallography

Large well-shaped blocks, light pink (Nd), colourless (La, Ce) or dark red (U), were obtained in a few days at room temperature, by slow diffusion of diethyl ether into a dmf solution of LnI_3 or $[UI_3(py)_4]$. The data were collected at 100(2) K on a Nonius Kappa-CCD area detector diffractometer[1] using graphite-monochromated Mo Kα radiation (λ = 0.71073 Å). The crystals were introduced in glass capillaries with a protecting "Paratone-N" oil (Hampton Research) coating and quickly cooled in the nitrogen flow since all the crystals were found to melt in the oil within a few minutes. The data were processed with DENZO-SMN [28]. The structures were solved by direct methods with SHELXS-97 and subsequent Fourier-difference synthesis and refined by full-matrix least-squares on F^2 with SHELXL-97 [29]. Absorption effects were corrected empirically with the program DELABS from PLATON [30]. All non-hydrogen atoms were refined with anisotropic displacement parameters, with restraints for some unstable atoms in compounds **3**–**5**. Hydrogen atoms were introduced at calculated positions and were treated as riding atoms with a displacement parameter equal to 1.2 (CH) or 1.5 (CH_3) times that of the parent atom. Crystal data and refinement details are given in Table 2. The molecular plots were drawn with SHELXTL [31].

5. Supplementary material

Crystallographic data for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Center, CCDC 287215–287219 for **1**–**5**, respectively. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK on request (fax: +44 1223 336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Corrigendum

Corrigendum to "Tris(imidazolyl) cadmium and zinc complexes: structural and spectroscopic characterization of M–OH_2 motifs" [Polyhedron 23 (2004) 405–412]

Janis K. Voo, Christopher D. Incarvito, Glenn P.A. Yap, Arnold L. Rheingold, Charles G. Riordan *

Department of Chemistry and Biochemistry, University of Delaware, Newark, DE 19716, USA

Available online 27 January 2006

During the refinement of the crystallographic data of **5**, the nitrogen of the N–CH_3 was inadvertently labeled as a carbon atom. This error has been corrected and the data subsequently refined. The conclusions drawn have not changed. The corrected CIF file has been deposited in the Cambridge Crystallographic Database. Additional changes resulting from the corrected refinement are as follows:

p. 408: Zn–OH_2 distance of **5** is 2.030(2) Å.
p. 409: O1···O2 distance is 2.808(3) Å in **5**.

Fig. 1. Correctly labeled structure of **5**.

Our synthetic approach starts by focusing on the construction of new topological frameworks using flexible ligands by adjusting the lengths and flexibility, such as 1,2-bis(1,2,4-triazol-1-yl)ethane [9], 1,2-bis(benzotriazol-1-yl)ethane [10] and 1,4-bis(1,2,4-triazol-1-ylmethyl)-benzene [2e,11] due to their different conformations [12]. In order to investigate the influence of the flexibility of the ligand molecule, the counter anion and solvent system on the architecture of coordination polymers, we report in this paper the self-assembly reactions of the flexible ligand 1,2-bis(1,2,4-triazol-1-yl)ethane (bte) and cobalt(II) salts with different anions NO_3^-, NCO^- and NCS^-, and the structural characterization of five cobalt(II) coordination polymers, $\{[Co(bte)_2(H_2O)_2](NO_3)_2\}_n$ (**1**), $\{[Co(bte)(H_2O)_2(NCO)_2](H_2O)_2\}_n$ (**2**), $\{[Co(bte)_2(NCO)_2](H_2O)\}_n$ (**3**), $[Co(bte)_2(NCS)_2]_n$ (**4**) and $\{[Co(bte)(H_2O)_2(NCS)_2][Co(bte)_2(NCS)_2]\}_n$ (**5**). A conformational analysis of the ligand molecules in these complexes is also presented.

2. Experimental

2.1. General procedures

The flexible ligand 1,2-bis(1,2,4-triazol-1-yl)ethane was synthesized according to the literature method [12a]. All other reagents and solvents employed were commercially available and used as received without further purification. The C, H, N microanalyses were carried out with a Perkin–Elmer 240C analyser. IR spectra were obtained for KBr pellets on a Nicolet 170SX FT-IR spectrophotometer in the 4000–400 cm^{-1} region. Thermogravimetric data were collected on a Thermal Analyst 2100 TA Instrument and a SDT 2960 Simutaneous TGA-DTA Instrument in flowing dinitrogen at a heating rate 10 °C/min.

2.2. Preparation of the complexes

2.2.1. $\{[Co(bte)_2(H_2O)_2](NO_3)_2\}_n$ (**1**)

A methanolic solution (20 ml) of bte (0.164 g, 1.0 mmol) was added to an aqueous solution (20 ml) of $Co(NO_3)_2 \cdot 6H_2O$ (0.291 g, 1.0 mmol) with stirring. The pink single crystals 1 were obtained after the mixture was allowed to stand at room temperature for a month. Yield: 82%. *Anal*. Calc. for $C_{12}H_{20}CoN_{14}O_8$: C, 26.33; H, 3.68; N, 35.83. Found: C, 26.21; H, 3.52; N, 35.71%. IR data (cm^{-1}): 3372m, 3117m, 3040w, 1640w, 1531m, 1385vs, 1331 vs, 1285m, 1219w, 1138m, 1026m, 992w, 880w, 830w, 656s.

2.2.2. $\{[Co(bte)(H_2O)_2(NCO)_2](H_2O)_2\}_n$ (**2**)

A 20 ml DMF/H_2O (1:1, v/v) solution of $Co(NO_3)_2 \cdot 6H_2O$ (0.291 g, 1.0 mmol) and KNCO (0.162 g, 2.0 mmol) was added to one side of a "H-shape" tube, and 20 ml DMF/H_2O solution (1:1, v/v) of bte (0.164 g, 1.0 mmol) was added to the another side of the "H-shape" tube. After about two months, pale red crystals of **2** suitable for X-ray analysis were

obtained. Yield: 46%. *Anal*. Calc. for $C_8H_{16}CoN_8O_6$: C, 25.33; H, 4.25; N, 29.56. Found: C, 25.24; H, 4.31; N, 29.48%. IR data (cm^{-1}): 3484m, 3133m, 2924m, 2855w, 2184vs, 1524s, 1439w, 1385m, 1319w, 1285m, 1211w, 1134s, 1015m, 988m, 891w, 675m, 644m, 625w, 509w.

2.2.3. $\{[Co(bte)_2(NCO)_2](H_2O)_2\}_n$ (3)

A DMF solution (10 ml) of bte (0.164 g, 1.0 mmol) was added to a DMF solution (10 ml) of $Co(NO_3)_2 \cdot 6H_2O$ (0.146 g, 0.5 mmol) and KNCO (0.081 g, 1.0 mmol) with stirring. Red crystals of **3** suitable for X-ray analysis were obtained after the mixture was allowed to stand for several days. Yield: 78%. *Anal*. Calc. for $C_{14}H_{18}CoN_{14}O_3$: C, 34.36; H, 3.71; N, 40.08. Found: C, 33.43; H, 3.75; N, 38.92%. IR data (cm^{-1}): 3482m, 3132m, 2170vs, 1525s, 1440m, 1384w, 1286m, 1209w, 1133s, 1014m, 987m, 893w, 676m, 645m, 626w, 510w.

2.2.4. $[Co(bte)_2(NCS)_2]_n$ (4)

The synthetic procedure was similar to the synthesis of **3**, except that KNCS was used instead of KNCO. Yield: 75%. *Anal*. Calc. for $C_{14}H_{16}CoN_{14}S_2$: C, 33.40; H, 3.20; N, 38.96. Found: C, 33.24; H, 3.14; N, 38.81%. IR data (cm^{-1}): 3476w, 3117w, 2076vs, 1524s, 1439m, 1385w, 1350w, 1285m, 1211w, 1130s, 1069w, 1011m, 992m, 895w, 791w, 677m, 660w, 529w.

2.2.5. $\{[Co(bte)(H_2O)_2(NCS)_2]\ [Co(bte)_2(NCS)_2]\}_n$ (5)

A 20 ml DMF/H_2O (1:1, v/v) solution of $Co(NO_3)_2 \cdot 6H_2O$ (0.291 g, 1.0 mmol) and KSCN (0.194 g, 2.0 mmol) was added to one side of a "H-shape" tube, and 20 ml DMF/H_2O solution (1:1, v/v) of bte (0.328 g, 2.0 mmol) was added to the another side of the "H-shape" tube. Pink crystals of **5** suitable for X-ray analysis were obtained after one month. Yield: 45%. *Anal*. Calc. for $C_{22}H_{28}Co_2N_{22}O_2S_4$: C, 30.07; H, 3.21; N, 35.07. Found: C, 30.11; H, 3.15; N, 34.92%. IR data (cm^{-1}): 3360m, 3125m, 2963w, 2074vs, 2064vs, 1524s, 1447w, 1435w, 1385m, 1350w, 1289s, 1211m, 1134s, 1069w, 1022m, 992m, 903m, 864w, 791w, 675s, 644m, 517w.

2.3. X-ray crystallography

All data collections were performed at a temperature of 193 K on a Rigaku Mercury CCD diffractometer with the ω-scan technique. The structures were solved by direct methods and refined with the full-matrix least-squares technique using the SHELXS-97 and SHELXL-97 programs [13]. Anisotropic thermal parameters were assigned to all non-hydrogen atoms. The hydrogen atoms of bte ligands were generated geometrically. The hydrogen atoms of water molecules except the hydrogen atoms of disordered water molecules of **3** were located from difference maps. The crystallographic data and experimental details for the structural analyses are listed in Table 1. The selected bond lengths and angles are listed in Table 2.

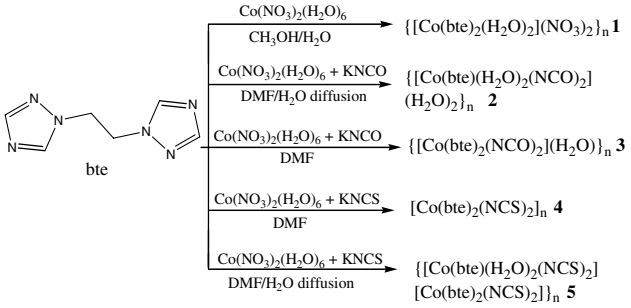
3. Results and discussion

3.1. Preparation of the complexes, IR and thermogravimetric analyses

During the preparation of the Co/bte complexes, the direct reaction of bte with cobalt nitrate in MeOH/H_2O solution produced **1**. As NCO^- and NCS^- not only can act as counter anions to sustain charge neutral but also have various coordination modes, they can provide the suitable "building block" for assembling novel coordination polymers. We want to introduce these anionic ligands into the $Co(NO_3)_2 \cdot 6H_2O$/bte reaction mixture as co-ligands in order to prepare some novel bte/Co complexes.



We found that the solvent systems and reaction methods (the direct reaction and the slow diffusion method) play a key role in the assembly of novel coordination polymers. Direct mixing of $Co(NO_3)_2 \cdot 6H_2O$, NCO^- or NCS^- and bte in MeOH/H_2O solution resulted in poor crystalline solids. The direct reaction of $Co(NO_3)_2 \cdot 6H_2O$, bte and NCO^- or NCS^- with different Co/bte stoichiometry (Co/bte = 1:2, 1:1.5, 1:1) in different solvent systems (DMF, DMF/H_2O) produces the similar double-stranded chain complexes **3** and **4**. When $Co(NO_3)_2 \cdot 6H_2O$, NCO^- or NCS^- react with bte in 1:2:1, 1:2:2 or 1:2:1.5 ratios in DMF/H_2O solution through the slow diffusion method the single chain complex **2** with $Co:NCO^-:bte = 1:2:1$ and the both single chain and double-stranded chain complex **5** with $Co:NCS^-:bte = 1:2:1.5$ are produced.

The very strong absorption at 1385 cm^{-1} in **1** is attributed to free nitrate anion. The very strong absorption bands at 2184 cm^{-1} in **2** and 2170 cm^{-1} in **3** are attributed to N-bonded NCO^- anions. The very strong absorption band in **4** at 2076 cm^{-1} is assigned to the N-bonded NCS^- anion. The very strong C≡N stretching vibrations of NCS^- ions at 2074 and 2064 cm^{-1} in **5** show two different coordination environment N-bonded NCS^- anions, which is confirmed by the crystal structure of **5** that contains both single- and double-stranded chains. The IR spectra determination show that the triazole ring breathing vibrations in complexes **1**, **2**, **3**, **4** and **5** are 1531, 1524, 1525, 1524 and 1524 cm^{-1}, respectively. The strong absorption bands at 1273 cm^{-1} assigned to the triazole ring stretching vibration for the free bte ligand are also present in the spectra of the complexes, these absorption band being shifted to 1285, 1285, 1286, 1285 and 1289 cm^{-1} in complexes **1**, **2**, **3**, **4** and **5**, respectively.

To study the stability of the five polymers, thermogravimetric analyses were performed (see supporting material). Thermal analysis of **1** shows that the coordinated water molecules were lost in a continuous fashion (obsd., 6.3%; calcd., 6.6%) from 120 to 190 °C, the next weight loss is about 58.6% from 190 to 303 °C, which is tentatively assigned to the loss of two bte molecules (obsd., 58.6%; calcd., 60.0%). Thermal analysis of **2** shows that the water molecules were lost from 30 to 120 °C (obsd., 18.2%; calcd., 19.0%). The weight of **2** rapidly decreased from 174 to 235 °C by 39.1%, and then the weight slowly decreased from 235 to 307 °C by 13.9%. Thermal analysis of **3** shows that lattice water molecules (obsd., 2.9%; calcd., 3.7%) were lost from 50 to 110 °C. Polymer **4** is stable up to 182 °C. The 31.6% weight loss of **3** and 33.5% weight loss of **4** occurred rapidly from 180 to 250 °C for **3** and from 182 to 262 °C for **4**, which can tentatively be assigned to one bte ligand (Calcd. 33.5% for **3** and 32.6% for **4**). Then 12.8% of the weight of **3** and 38.9% of the weight of **4** were lost from 250 to 303 °C for **3** and from 300 to 370 °C for **4**, respectively. Above this point, the weight of the samples slowly decreased. The coordinated water molecules of **5** were lost (obsd., 4.1%; calcd., 4.1%) from 150 to 193 °C. The 17.5% weight loss of **5**, occurring from 193 to 270 °C, is tentatively assigned to one bte ligand (calcd., 18.7%). Then the 42.1% weight loss from 310 to 370 °C may be assigned to two bte molecules (calcd., 37.4%) and part of NCS^-.

3.2. Crystal structures

The structure of **1** is isomorphous with those of the Cd and Zn derivatives $\{[Cd(bte)_2(H_2O)_2](NO_3)_2\}_n$ [9a] and $\{[Zn(bte)_2(H_2O)_2](NO_3)_2\}_n$ [9f]. The known bte complexes are presented in Table 3 for understanding the similarity/differences among them. As shown in Fig. 1(a), the cobalt(II) atom in **1** is in a distorted octahedral arrangement with two water molecules in *trans* positions (Co(1)–O(1) 2.078(3) Å) and four triazole nitrogen atoms in a basal plane (Co(1)–N(3) 2.165(3) Å, Co(1)–N(6)^i 2.136(3) Å) (Table 2). Each bte ligand connects two cobalt(II) atoms to form a two-dimensional (4,4) network containing square $Co_4(bte)_4$ units (Fig. 1(b)). The two-dimensional network structure consists of puckered rhombus grids with dimensions of 8.0 × 8.0 Å. The basic grid of the two-dimensional network is puckered [14,9a,9f] (Fig. 1(c)), which is different from that observed in previous grid-like

Table 3
The structures and space groups of the known bte complexes

$[Cu(en)_2(bte)](ClO_4)_2$	$P1$	1D chain	[9e]

structures where the basic grids are usually coplanar or quasi-coplanar [15]. The puckered shape of the basic grid in **1** is understandable because the bte ligands exhibit the *gauche* conformation in **1**. There are hydrogen bond interactions between hydrogen atoms of coordinated water molecules and oxygen atoms of nitrate anions [O(1)···O(3) $(-x+1,-y,-z+1)$ 2.735(4) Å, O(1)···O(2) $(-x+1,y-1/2,-z+1/2)$ 2.990(4) Å, O(1)···O(4) $(-x+1,y-1/2,-z+1/2)$ 2.910(4) Å].

The crystal structure of **2** consists of single chains. The cobalt(II) atom in **2** is in a distorted octahedral arrangement with two water molecules in *trans* positions (Co(1)–O(2) 2.136(2) Å), and two triazole nitrogen atoms (Co(1)–N(3) 2.170(2) Å) and two cyanate nitrogen atoms (Co(1)–N(4) 2.084(2) Å) (Table 2) in a basal plane (Fig. 2(a)). The bte ligand exhibits the *anti* conformation in **2**. Each bridging bte ligand links two Co(II) atoms to form a single chain. The Co···Co separation across the bridging bte is 12.138 Å. The coordinated water molecules act as a hydrogen bond donor, forming hydrogen bonds with the lattice water molecules [O(2)···O(3) $(-x,-y+1,-z+1)$ 2.739 Å, O(2)···O(3) $(x,y-1,z)$ 2.790 Å]. The lattice water molecules also act as a hydrogen bond donor, forming hydrogen bonds with the oxygen atom of the cyanate and the uncoordinated nitrogen atom in the 2-positions of the triazole rings in the neighboring one-dimensional chain [O(3)···O(1) $(x+1,y+1,z)$ 2.727 Å, O(3)···N(2) $(-x,-y+1,-z)$ 2.845 Å]. The three-dimensional network forms via these hydrogen bond interactions (Fig. 2(b)).

The structure of **3** is completely different from the structure of **2** although **2** and **3** are both constructed by cobalt(II), bte ligand and NCO^- anion. **3** forms a double-stranded chain structure whilst **2** exhibits a single chain structure. The key factor governing the structural topologies of these polymers is the Co/bte molar ratio (Co/bte = 1:1 in **2** and Co/bte = 1:2 in **3**).

3 and **4** have similar double-stranded chain structures and will be discussed together. The difference between **3** and **4** is that the lattice water is located at the voids for **3** but not for **4**. The cobalt(II) atom is in a distorted octahedral arrangement with two nitrogen atoms from two NCO^- anions in **3** (Fig. 3) and two NCS^- anions in **4** (Fig. 4) in *trans* positions and four triazole nitrogen atoms in a basal plane, which is similar to the coordination geometry of the cobalt(II) atoms in **1**, except two coordination water molecules in **1** are replaced by two coordination NCO^- anions or NCS^- anions in **3** and **4**, respectively. The four Co–$N_{triazole}$ bond lengths are all 2.170(2) Å in **3** and the two pairs of Co–$N_{triazole}$ bond lengths in **4** are 2.124(3) and 2.172(3) Å (Table 2). The two Co–$N_{cyanate}$ bond lengths in **3** are both 2.110(2) Å and the two Co–$N_{thiocyanate}$ bond lengths in **4** are 2.144(4) and 2.161(4) Å. **3**, **4** and **1** have the same Co/bte molar ratio (Co/bte = 1/2). The different structures in **1**, **3** and **4** show that the supramolecular topologies are highly influenced by the counter anions.

The bte ligands exhibit the *gauche* conformation in **3** and **4**. Two strands of bte ligands are wrapped around each other and are held together by Co(II) atoms, forming a double-stranded chain. Many double-stranded chain complexes have been reported recently [3a,7b,9a,9b,9c,14,16]. This structure is similar to other double-stranded chain structures containing the bte ligand, such as $\{[Cd(bte)_2(H_2O)_2](H_2O)_2(ClO_4)_2\}_n$ (**9a**), $[Mn(bte)_2(dca)_2]_n$ (dca = dicyanamide, **9b**) and $[Cd(bte)_2(dca)_2]_n$ (**9c**), which were reported by us recently. Each chain consists of 18-membered rings and a rhombic network with a size of 6.5×5.6 Å in **3** and **4** is formed. The

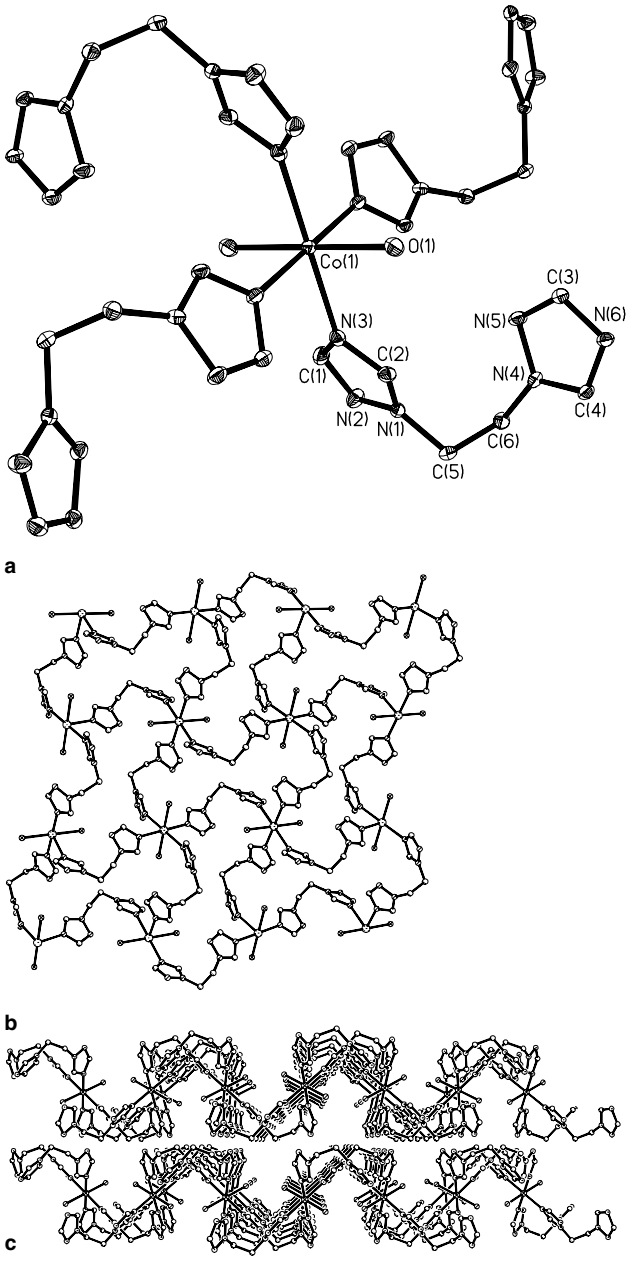

Fig. 1. (a) ORTEP drawing of the coordination environment of the cobalt(II) atom in **1**. (b) Viewing the 2D (4,4) network in **1** along the *a* direction. (c) Viewing the tightly packed structure in **1** along the *c* direction, only two layers are shown for clarity.

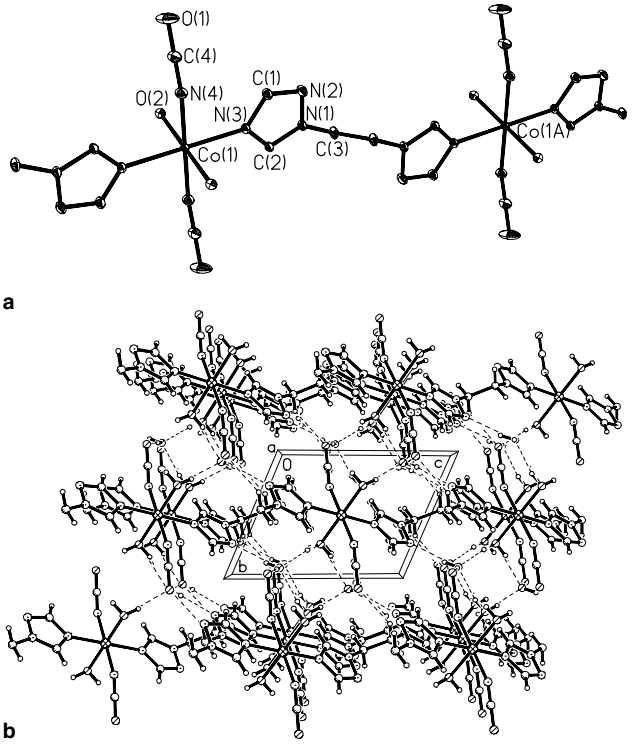

Fig. 2. (a) The coordination environment around the cobalt(II) center with 30% thermal ellipsoids in **2**. (b) The cell packing of **2** viewed along the *a* direction.

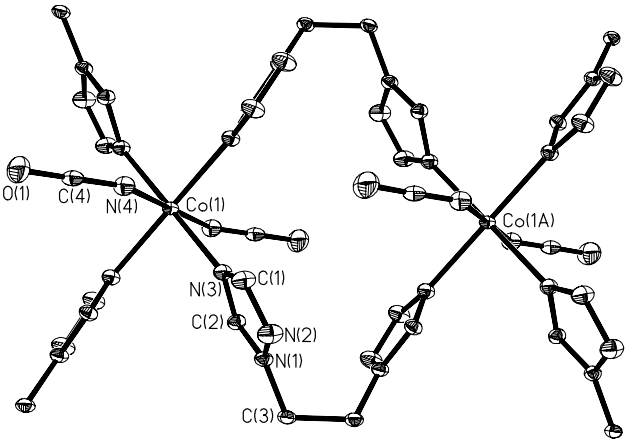

Fig. 3. The coordination environment around the cobalt(II) center with 30% thermal ellipsoids in **3**.

Co···Co separations across the bridging bte ligand are 7.425 and 7.942 Å in **3** and **4**, respectively.

The structure of **5** and $\{[Mn(bte)(H_2O)_2(NCS)_2]\text{-}[Mn(bte)_2(NCS)_2]\}_n$ (**9b**) are isomorphous, which is very interesting and can be regarded as a combination of two motifs (single chain + double-stranded chain). It is interesting to note that bte ligands adopt both the *gauche* and *anti* conformations in one compound.

As shown in Fig. 5(a), the single chain in **5** is very similar to that of **2**. The coordination environment of the cobalt (II) atom in **5** (Co(1)–N(3) 2.182(1) Å, Co(1)–N(4) 2.102(2) Å, Co(1)–O(1) 2.100(1) Å) (Table 2) is also similar to that of the cobalt(II) atom in **2**. The difference is only two NCS^- anions in **5** and two NCO^- anions in **2**. The bridging bte ligand links two cobalt(II) atoms forming the single chain. The Co···Co separation across the bridging bte in the single chain (12.320 Å) is similar to that in **2** (12.138 Å).

As depicted in Fig. 5(b), the double-stranded chain in **5** is very similar to that of **4** and **3**. The coordination environment of the cobalt (II) atom in **5** (Co(2)–N(7)

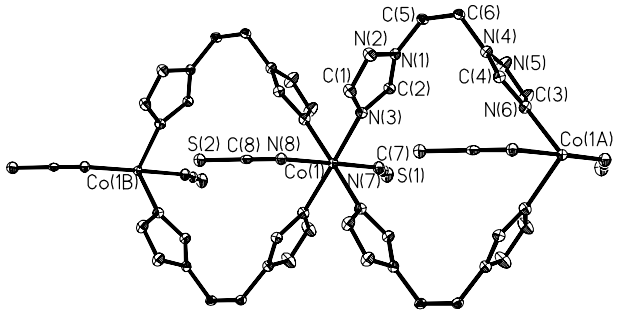

Fig. 4. The coordination environment around the cobalt(II) center with 30% thermal ellipsoids in **4**.

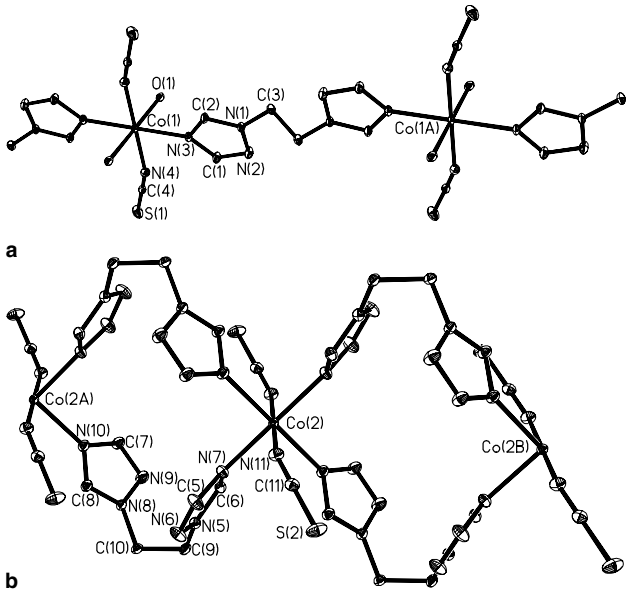

Fig. 5. The coordination environment around the cobalt(II) center with 30% thermal ellipsoids in **5**. (a) The single chain. (b) The double-stranded chain.

2.137(2) Å, Co(2)–N(10) 2.130(2) Å, Co(2)–N(11) 2.120(2) Å) (Table 2) is the same as that of the cobalt(II) atom in **4**. The Co···Co separation across the bridging bte ligand is equal to the *a* axis translation, 7.786 Å.

The most interesting structural feature of **5** is that there are two different structural motifs in one compound. Coordination polymers that have different topologies and/or chemical composition are relatively few at present [2,4a,4c,9b,17]. There are uncoordinated nitrogen atoms at the 2-position of the triazole rings of both the *gauche* and *anti* conformation bte molecules. A two-dimensional hydrogen bond network is formed by the hydrogen bond interactions between the oxygen atoms O(1) of coordinated water and the uncoordinated N(2) atoms at the 2-position of trazole rings of the *anti* conformation bte ligand of the neighboring 1D chains [O(1)···N(2)($-x, -y, -z+1$), 2.882 Å] (Fig. 6(a)). Hydrogen bond interactions also occur between the oxygen atoms O(1) of the single chains and uncoordinated nitrogen atoms N(6) at the 2-position of triazole rings of the *gauche* conformation bte ligand of the neighboring double-strand chains [O(1)···N(6) ($-x+1, -y, -z$), 2.791 Å]. The single chains and double-stranded chains in **5** stack alternately along the *c* axis via the hydrogen bond interactions and form the three-dimensional hydrogen bonding network (Fig. 6(b)).

3.3. Conformational analysis

In order to understand the influence of the flexibility of the bte ligand on the topologies of the motifs, the conformation of bte, N···N distance between two donor atoms of bte, Co···Co separation through bte, the torsion angles (°) $N_{triazole}$–$(C–C)_{ethane}$–$N_{triazole}$, $(N–N)_{triazole}$–$(C–C)_{ethane}$ and $(C–N)_{triazole}$–$(C–C)_{ethane}$ in free bte and the five cobalt(II) complexes are listed in Table 4. There are three motifs (2D (4,4) network, single chain and double-stranded chain) in the five complexes: 2D (4,4) network (**1**), single chain (**2**), double-stranded chain (**3** and **4**), and a combination of two motifs (single chain + double-stranded chain) (**5**). The bte ligands act in the *anti* conformation in **2**, part of **5** and free bte molecules, and act in the *gauche* conformation in **1**, **3**, **4** and part of **5**.

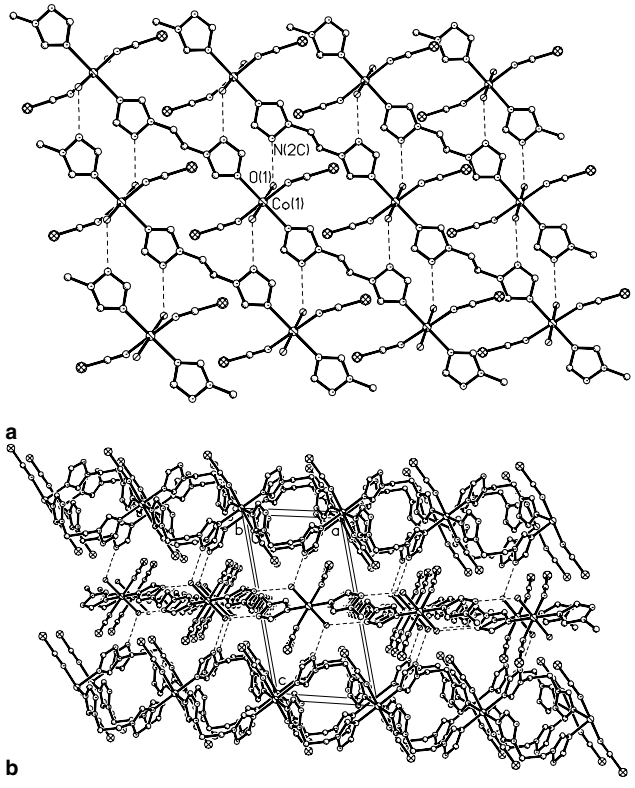

Fig. 6. (a) View of the hydrogen-bonding interaction between single chains in **5**. (b) The cell packing of **5** viewed along the *b* direction.

Table 4
The conformation of bte, N···N distance between two donor atoms of bte (Å), Co···Co separation through bte (Å), the torsion angles (°) $N_{triazole}$–$(C–C)_{ethane}$–$N_{triazole}$, $(N–N)_{triazole}$–$(C–C)_{ethane}$ and $(C–N)_{triazole}$–$(C–C)_{ethane}$ in bte and the five cobalt(II) complexes

	bte Conformation	N···N distance	Co···Co separation	Dihedral angle of two triazole rings	Torsion angle		
					$N_{triazole}$–$(C–C)_{ethane}$–$N_{triazole}$	$(N–N)_{triazole}$–$(C–C)_{ethane}$	$(C–N)_{triazole}$–$(C–C)_{ethane}$
Bte	*anti*	7.890		0.0	180.0	77.61(16)	−100.74(16)
1	*gauche*	5.619	8.003	32.7(2)	68.3(4)	88.7(4), −89.1(4)	−86.4(4), 91.3(4)
2	*anti*	7.969	12.138	0.0	180.0	65.7(2)	−116.5(2)
3	*gauche*	4.884	7.425	56.69(7)	48.8(3)	−61.5(4)	116.9(3)
4	*gauche*	5.314	7.942	66.29(9)	62.1(3)	67.3(4), 56.0(4)	−112.9(3), −126.0(3)
5							
A	*anti*	8.080	12.320	0.0	180.0	−49.3(3)	139.2(2)
B	*gauche*	5.204	7.786	65.35(6)	57.5(2)	63.2(2), −50.9(2)	−117.7(2), 127.75(19)

The transition from double-stranded chain (**3**, **4**, part of **5**), 2D (4,4) network (**1**), to single chain (**2** and part of **5**) corresponds to the change of the character of the bte molecules from angular (the *gauche* conformation in **3**, **4**, part of **5** and **1**) to more linear (the *anti* conformation in **2**, part of **5** and free bte). In consequence, the Co···Co separations through the *gauche* conformation bte molecules (7.425 Å in **3**, 7.942 Å in **4**, 7.786 Å in part of **5** and 8.003 Å in **1**) are about 4.1–4.9 Å shorter than the Co···Co separations through the *anti* conformation bte molecules (12.138 Å in **2** and 12.320 Å in part of **5**). The N···N distances between two donor atoms of the *gauche* conformation bte molecules (4.884 Å in **3**, 5.314 Å in **4**, 5.204 Å in part of **5** and 5.619 Å in **1**) are about 2.3–3.2 Å shorter than the corresponding N···N distances of the *anti* conformation bte molecules (7.969 Å in **2**, 8.080 Å in part of **5**, 7.890 Å in free bte).

The torsion angles $N_{triazole}$–$(C–C)_{ethane}$–$N_{triazole}$ and dihedral angles show great differences between the *gauche* and *anti* conformations of bte. The torsion angles and dihedral angles of the *anti* conformation bte are 180.0° and 0.0°, respectively, in **2**, part of **5** and free bte. The torsion angles of the *gauche* conformation bte show slight differences, which range from 48.8(3)° in **3** to 68.3(4)° in part of **5** in the four complexes, but the dihedral angles of the *gauche* conformation bte show large differences, which range from 32.7(2)° in **1**, to 56.69(7)° in **3**, 65.35(6)° in part of **5** and 66.29(9)° in **4**. There are also great differences of the torsion angles $(N–N)_{triazole}$–$(C–C)_{ethane}$ and $(C–N)_{triazole}$–$(C–C)_{ethane}$ between the *gauche* conformation bte molecules (in **1**, **3**, **4** and part of **5**) and in the *anti* conformation bte molecules (in **2**, part of **5** and free bte molecule) (Table 3). All these data indicate that the change of the spacer conformations and the relative orientations of the triazole rings are responsible for the N···N distances and Co···Co distances. The rotational freedom of the triazole rings and the conformational flexibility of the spacers (bte) result in the variety of topologies of the five cobalt complexes.

4. Conclusion

In spite of the similarity of the building blocks used, the products display a variety of topologies. There are three motifs (2D (4,4) network, single chain and double-stranded chain) in the five complexes: 2D (4,4) network (**1**), single chain (**2**), double-stranded chain (**3** and **4**), and a combination of two motifs (single chain + double-stranded chain) (**5**). The variety of the observed structural motifs confirms that rationalization of the resulting topologies is still difficult. Many factors play a role in the formation of the final product: (i) the effects of counter anions (NO_3^- in **1**, NCO^- in **2** and **3**, NCS^- in **4** and **5**); (ii) the conformation of the bte ligand (the *gauche* conformation in **1**, **3**, **4**, the *anti* conformation in **2**, both the *gauche* and *anti* conformations in **5**); (iii) the Co/bte molar ratio (1:2 in **1**, **3**, **4**; 1:1 in **2** and 1:1.5 in **5**); (iv) solvent system (**2** and **5** in DMF/H_2O, **3** and **4** in DMF). This work demonstrates the feasibility of achieving various polymeric frameworks by self-assembly of the flexible bis(triazole) ligand and metal salts and may provide useful information for crystal engineering.

with the phosphorus functional groups exhibit higher selectivity in complexation and sufficient thermodynamic stability [18,19].

The ligand 1,4,8,11-tetraazacyclotetradecane-1,8-bis-(methylphosphonic acid) (H_4dipon, H_4L), belongs to a group of cyclam (cyclam = 1,4,8,11-tetraazacyclotetradecane) derivatives, which forms stable complexes with a wide range of metal ions [20–23]. Copper(II) forms H_4dipon with two isomeric [Cu(H_2L)] complexes (Fig. 1) [23]. In the pentacoordinated *pc*-[Cu(H_2L)] complex (complex **A**), five donor atoms of the ligand (four macrocycle nitrogen atoms and one oxygen atom of a phosphonate moiety) coordinate the copper(II) ion, while all six donor atoms (four nitrogen atoms and one oxygen atom of each phosphonate group) bind the copper(II) ion in the hexacoordinated *trans-O,O*-[Cu(H_2L)] complex (*hx*-[Cu(H_2L)]; complex **B**) forming axially elongated octahedral structure. The *pc*-[Cu(H_2L)] complex is prepared by mixing aqueous solutions of H_4dipon and copper(II) ion, with rapid complex formation, while the *hx*-[Cu(H_2L)] complex is formed by refluxing an aqueous solution of the *pc*-[Cu(H_2L)] complex for several hours [23]. The isomerization reaction can be accelerated by the presence of ammonia [23].

Nowadays separation methods, mainly high-performance liquid chromatography (HPLC) and capillary electrophoresis (CE), are often used for separation and determination of inorganic complex species and isomers [24]. Diogenes et al. have monitored the synthesis of the ruthenium(III) cyclam complex by reversed-phase HPLC [25,26] to control the progress of its synthesis with identification of the *cis* and *trans* ruthenium(III) cyclam isomers formed during the reaction. Similarly, the characterization and kinetic studies of *cis* and *trans* ruthenium(III) cyclen (1,4,7,10-tetraazacyclododecane) complexes in aqueous solution were performed using cyclic voltammetry [27].

On the contrary, electromigration, mainly using CE methods, was successfully applied to the study of the kinetic and thermodynamic behaviour of metal complexes. The kinetic behaviour of complexes of four lanthanide ions, Sm^{3+}, Dy^{3+}, Yb^{3+} and Lu^{3+}, with the tetraazamacrocyclic chelating ligand 1,4,7,10-tetraazacyclododecane-1,4,7,10-tetraacetic acid (H_4dota) was investigated by means of CE and stability constants and second-order rate formation constants of the complexes formed were determined [28]. Stability constants of H_4dota complexes with Y^{3+} and Ho^{3+} were determined using isotachophoresis [29]. It was also demonstrated that the CE method is a powerful probe of the stereochemical changes accompanying photoinitiated racemization and ligand substitution of optically active chromium(III) complexes with diimines (2,2′-bipyridine or 1,10-phenanthroline) in aqueous solution [30–32]. CE was proposed as an exceptional tool for the separation of enantiomers of metal complexes. Harris et al. have shown the possibility to apply various buffer additives that may help to separate chiral complexes of transition metal ions by means of CE [32]. The CE method was also employed in speciation studies. Gaspar and Buglyo applied CE for the separation and determination of chromium(III) complex species [33]. One of us studied iridium(IV) [34] and rhodium(III) [35] speciation in hydrochloric acid by CE and UV/Vis spectrophotometry. Aleksenko et al. demonstrated the feasibility of CE to distinguish the rhodium(III) complex species which occur in solutions of different acidity [36]. Recently, it was demonstrated that CE is suitable for reaction kinetic study of the oxidation of the thiocyanate anion by hydrogen peroxide and the reaction mechanism was proposed from such experimental data [37].

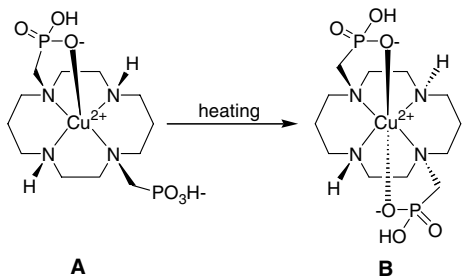

Fig. 1. Reaction scheme of isomerization of *pc*-$[Cu(L)]^{2-}$ (A) to *hx*-$[Cu(L)]^{2-}$ (B) (adapted from [23]).

This paper demonstrates the possibility of CE for separation of copper(II) complexes of 1,4,8,11-tetraazacyclotetradecane-1,8-bis(methylphosphonic acid) which would enable the reaction extent between copper(II) and the ligand to be followed. The CE procedure could be applied for kinetic study of the mechanism of the isomerization reaction of *pc*-[Cu(H_2L)] (A) into *hx*-[Cu(H_2L)] (B) (Fig. 1).

2. Experimental

All solutions were prepared in three times distilled water obtained from a quartz distillation apparatus (Heraeus, Germany). Stock copper(II) solution was prepared from $CuCl_2 \cdot 2H_2O$ (Pliva-Lachema, Czech Republic) and standardized by chelatometric titration. The ligand H_4dipon was synthesized according to the published procedure [20] and its stock solution was prepared from a weighed amount of $H_4L \cdot 4H_2O$. Disodium tetraborate decahydrate, boric acid, sodium phosphate dodecahydrate (Pliva-Lachema, Czech Republic) and *N*-tris(hydroxymethyl)methyl-2-aminoethanesulfonic acid (TAPS, Aldrich, USA) used in the electrophoretic study as the background electrolyte salts were of analytical grade purity. Other commonly used chemicals (Pliva-Lachema, Czech Republic) were of analytical grade purity.

CE experiments were carried out on the Agilent CE instrument (Agilent, USA) equipped with LC 3D Systems software running on ChemStation of the same company. The fused silica capillary column (Watrex, Czech Republic) was 47.5 cm long (the effective length to detector was 39 cm) with 75 μm inner diameter. UV/Vis detection was performed on-column for each compound separately at

three different wavelengths selective for the separated species: 220 nm (H_4dipon), 280 nm (*hx*-[Cu(H_2L)]) and 319 nm (*pc*-[Cu(H_2L)]). A new capillary column was rinsed by 0.1 M NaOH solution for 10 min at 40 °C, then 5 min flushed by deionized water and 10 min by the appropriate buffer solution prior to use. All solutions used in the CE system were filtered through 0.45 μm Spartan®-3 filters (Schleicher & Schull, Germany) prior to use and degassed in an ultrasonic bath (Branson, USA) for 10 min. The separation capillary was washed daily for 5 min with deionized water prior to and after use. Between each analysis, the capillary was washed for 2 min by the background electrolyte solution. Working conditions were: 50 mbar cathodic pressure injection for 5 s, capillary temperature 25 °C, applied voltage 15 kV (separation of isomers and ligand) and 20 kV (kinetic isomerization study). Mesityloxide (0.1% v/v solution) utilized as a marker of the electroosmotic flow was supplied by Fluka (Switzerland). The other conditions are specified in Section 4.

The isomerization reaction *pc*-[Cu(H_2L)] into *hx*-[Cu(H_2L)] (Fig. 1) was performed at two temperatures 80 ± 0.5 and 90 ± 0.5 °C. A stock solution of 0.3 mM *pc*-[Cu(H_2L)] (made from the solid sample of *pc*-[Cu(H_2L)]·5H_2O [23]; pH 4.56) was divided into set of sealed glass ampoules. This set was heated in a drying oven at constant temperature. The ampoules were sampled from the drying oven in a certain time interval and the reaction was stopped by cooling the ampoules to the laboratory temperature; the isomerization reaction does not proceed at ambient temperature [23]. Then the content of ampoules was analyzed by means of CE.

3. Theory

In general, the isomerization reactions proceed as one-step reaction (Reaction A) or multiple-step reaction (Reaction B). In the first case, the rate of the reaction can be expressed by Eq. (1):

$$[^{pc}\mathrm{CuL}] \xrightarrow{k} [^{hx}\mathrm{CuL}] \tag{A}$$

$$-\frac{\mathrm{d}[^{pc}\mathrm{CuL}]}{\mathrm{d}t} = \frac{\mathrm{d}[^{hx}\mathrm{CuL}]}{\mathrm{d}t} = k \times [^{pc}\mathrm{CuL}] \tag{1}$$

where $[^{pc}\mathrm{CuL}]$ and $[^{hx}\mathrm{CuL}]$ are concentrations of the pentacoordinated and hexacoordinated complexes, respectively, at time t and k represents a rate constant of the isomerization reaction. Using mass balance law (Eq. (2), c_{CuL} is the analytical – total concentration of copper(II) complexes)

$$c_{\mathrm{CuL}} = [^{pc}\mathrm{CuL}] + [^{hx}\mathrm{CuL}] \tag{2}$$

Eq. (1) can be written in an integral form as Eqs. (3) and (4):

$$[^{pc}\mathrm{CuL}] = [^{pc}\mathrm{CuL}]_0 \mathrm{e}^{-k\times t} \tag{3}$$

$$[^{hx}\mathrm{CuL}] = [^{hx}\mathrm{CuL}]_0 + [^{pc}\mathrm{CuL}]_0(1 - \mathrm{e}^{-k\times t}) \tag{4}$$

where $[^{pc}\mathrm{CuL}]_0$ is initial concentration of the pentacoordinated complex and $[^{hx}\mathrm{CuL}]_0$ is initial concentration of the hexacoordinated complex at the beginning of reaction ($t = 0$).

A general linear calibration function of concentration for analytical signal response (represented mostly by corrected and uncorrected peak area and/or a height of symmetric Gaussian peak) is defined by

$$S = a \times c_{\mathrm{CuL}} \tag{5}$$

where the parameter is the slope of the calibration straight line.

For copper(II) isomeric species the following expressions are valid:

$$S_{\mathrm{pc}} = a_{\mathrm{pc}}[^{pc}\mathrm{CuL}] \tag{6a}$$

$$S_{\mathrm{hx}} = a_{\mathrm{hx}}[^{hx}\mathrm{CuL}] \tag{6b}$$

where S_{pc} and S_{hx} are values of the analytical signal belonging to *pc*-$[\mathrm{Cu(L)}]^{2-}$ and *hx*-$[\mathrm{Cu(L)}]^{2-}$ species, respectively. Analogously the concentrations can be expressed by:

$$[^{pc}\mathrm{CuL}] = \frac{S_{\mathrm{pc}}}{a_{\mathrm{pc}}} \tag{7a}$$

$$[^{pc}\mathrm{CuL}]_0 = \frac{S^0_{\mathrm{pc}}}{a_{\mathrm{pc}}} \tag{7b}$$

$$[^{hx}\mathrm{CuL}] = \frac{S_{\mathrm{hx}}}{a_{\mathrm{hx}}} \tag{8a}$$

$$[^{hx}\mathrm{CuL}]_0 = \frac{S^0_{\mathrm{hx}}}{a_{\mathrm{hx}}} \tag{8b}$$

Considering a non-zero concentration of the product of the isomerization reaction at the beginning of the reaction, the substitution in Eqs. (3) and (4) by Eqs. (7) and (8) gives Eqs. (9) and (10):

$$S_{\mathrm{pc}} = S^0_{\mathrm{pc}} \times \mathrm{e}^{-k\times t} \tag{9}$$

$$S_{\mathrm{hx}} = S^0_{\mathrm{hx}} + S^0_{\mathrm{pc}} \times \frac{a_{\mathrm{hx}}}{a_{\mathrm{pc}}}(1 - \mathrm{e}^{-k\times t}) \tag{10}$$

Eq. (9) can be transformed into a logarithmic form

$$\ln(S_{\mathrm{pc}}) = \ln(S^0_{\mathrm{pc}}) - k \times t \tag{11}$$

From the assumption of a simple one-step reaction (Reaction A) it is clear, that the rate constants k evaluated from the experimental data using Eqs. (9) and (10) should be the same in both cases.

In contradiction, if a two-step mechanism is supposed (Reaction B)

$$[^{pc}\mathrm{CuL}] \xrightarrow{k_1} \quad \text{Intermediate} \xrightarrow{k_2} [^{hx}\mathrm{CuL}] \tag{B}$$

the reaction rates are defined by Eqs. (12)–(14) (k_1 and k_2 are the corresponding rate constants):

$$-\frac{\mathrm{d}[^{pc}\mathrm{CuL}]}{\mathrm{d}t} = k_1 \times [^{pc}\mathrm{CuL}] \tag{12}$$

$$-\frac{\mathrm{d}[\mathrm{Intermediate}]}{\mathrm{d}t} = k_2 \times [\mathrm{Intermediate}] - k_1 \times [^{pc}\mathrm{CuL}] \tag{13}$$

$$\frac{d[^{hx}CuL]}{dt} = k_2 \times [\text{Intermediate}] \quad (14)$$

After integration, one obtains Eqs. (15)–(17):

$$[^{pc}CuL] = [^{pc}CuL]_0 e^{-k_1 \times t} \quad (15)$$

$$[\text{Intermediate}] = [^{pc}CuL]_0 \times \frac{k_1}{k_2 - k_1}(e^{-k_1 \times t} - e^{-k_2 \times t}) \quad (16)$$

$$[^{hx}CuL] = [^{hx}CuL]_0 + [^{pc}CuL]_0 \times \left\{1 + \frac{1}{k_1 - k_2}(k_2 \times e^{-k_1 \times t} - k_1 \times e^{-k_2 \times t})\right\} \quad (17)$$

Using Eqs. (7) and (8), Eqs. (15) and (17) can be transformed to Eqs. (18) and (19):

$$S_{pc} = S^0_{pc} \times e^{-k_1 \times t} \quad (18)$$

$$S_{hx} = S^0_{hx} + S^0_{pc} \times \frac{a_{hx}}{a_{pc}} \times \left\{1 + \frac{1}{k_1 - k_2}(k_2 \times e^{-k_1 \times t} - k_1 \times e^{-k_2 \times t})\right\} \quad (19)$$

The time when the concentration of the **Intermediate** is maximal is given by

$$t_{max} = \frac{\ln\left(\frac{k_1}{k_2}\right)}{k_1 - k_2} \quad (20)$$

and after substitution into Eq. (16) and simplification, one obtains

$$\frac{[\text{Intermediate}]}{[^{pc}CuL]_0} = \left(\frac{k_2}{k_1}\right)^{\frac{k_2}{k_1 - k_2}} \quad (21)$$

Analyzing Eq. (21), two limiting cases can occur. If the rate-determining step (rds) of the reaction is the first step (i.e., $k_2 \gg k_1$), the concentration of the **Intermediate** will be negligible and the **Intermediate** will not be detectable. In the opposite case, when both steps proceed with a comparable rate ($k_2 \approx k_1$) and/or the rds is the second step ($k_2 \ll k_1$), the **Intermediate** may be detected in solution. It can be noted that Eqs. (3) and (15) are formally the same in both reaction mechanisms and, therefore, the determination of the rate constant of the starting complex decay is independent on an assumption of the reaction mechanism.

The magnitude of activation energy E_a can be calculated from the temperature dependence of the rate constant as

$$\ln(k) = \ln(A) - \frac{E_a}{RT} \quad (22)$$

where the activation parameters (activation enthalpy $\Delta H^{\neq}$ and entropy $\Delta S^{\neq}$) are calculated according to Eyring's theory [38–40]

$$\ln\left(\frac{k}{T}\right) = \ln\left(\frac{k_B}{h}\right) + \frac{\Delta S^{\neq}}{R} - \frac{\Delta H^{\neq}}{RT} \quad (23)$$

where R is the universal gas constant, T is the thermodynamic temperature, k_B is Boltzman's constant and h is Planck's constant.

4. Results and discussion

4.1. Development of the CE method for a separation of the isomeric complexes and the free ligand

The spectra of *pc*-[Cu(H_2L)], *hx*-[Cu(H_2L)] and H_4L species in aqueous solutions were recorded in order to select optimal wavelengths for spectrophotometric detection. Both isomers have different absorption maxima (319 and 280 nm) as described in the literature [23] and, therefore, three wavelengths (220, 280 and 319 nm) were selected for their simultaneous detection during the separation process in order to have the highest sensitivity of analysis. The species behave as acids and, therefore, the distribution diagrams showing all protonated forms for all three species were calculated (the protonation constants for H_4dipon and stability constants for its complexes were taken from the literature [20,23]) in order to find optimal pH values for the separation. The results are given in Fig. 2.

The pH of the background electrolyte solution was then selected to keep the charge of the species to be separated as high as possible in order to shorten the time of analysis (see distribution diagrams in Fig. 2) and this is possible at pH higher than 8. The optimal separation of a mixture of *pc*-$[Cu(L)]^{2-}$, *hx*-$[Cu(L)]^{2-}$ and $(H_2L)^{2-}$ was reached in 75 mM disodium tetraborate aqueous solution (pH 9.5) and it is presented in Fig. 3.

According to the basic theory of electromigration process [41], it can be supposed that both *pc*-$[Cu(L)]^{2-}$ and *hx*-$[Cu(L)]^{2-}$ species having the same charge and molecular weight should have the same molar mobility and/or conductivity. As was demonstrated in a real experiment (Fig. 3), the separation of a mixture of both isomers and the ligand is possible, however, the resolution of a *hx*-$[Cu(L])^{2-}$ and $(H_2L)^{2-}$ species is lower than that of *pc*-$[Cu(L)]^{2-}$ and *hx*-$[Cu(L)]^{2-}$ species (see Table 1). This can be explained either by a different solvation of the analysed complex species or by their interaction with borate/boric acid. Taking into account the knowledge of the structure of the species in the solid state and that the structures remain unchanged in aqueous solution [20,23], it can be expected that *hx*-$[Cu(L)]^{2-}$ and $(H_2L)^{2-}$ species have structure close to a sphere in aqueous solution. Therefore, their hydrodynamic radii are also of the same magnitude but the compounds have different molecular weights. In contrast, the *pc*-$[Cu(L)]^{2-}$ complex species having one non-bonding phosphonate group has a different shape in comparison with the former species. It probably would lead to a higher hydrodynamic radius due to a higher molecular volume and, certainly, to a different solvation of the complex. Further, it was observed that higher concentration of tetraborate in solution improved the resolution of the separation of *pc*-$[Cu(L)]^{2-}$ and *hx*-$[Cu(L)]^{2-}$ species. It means that borate/boric acid interacts differently with each of the isomeric species. This effect cannot be explained by an increase of the ionic strength of the solution because it was not observed in the presence of other compounds

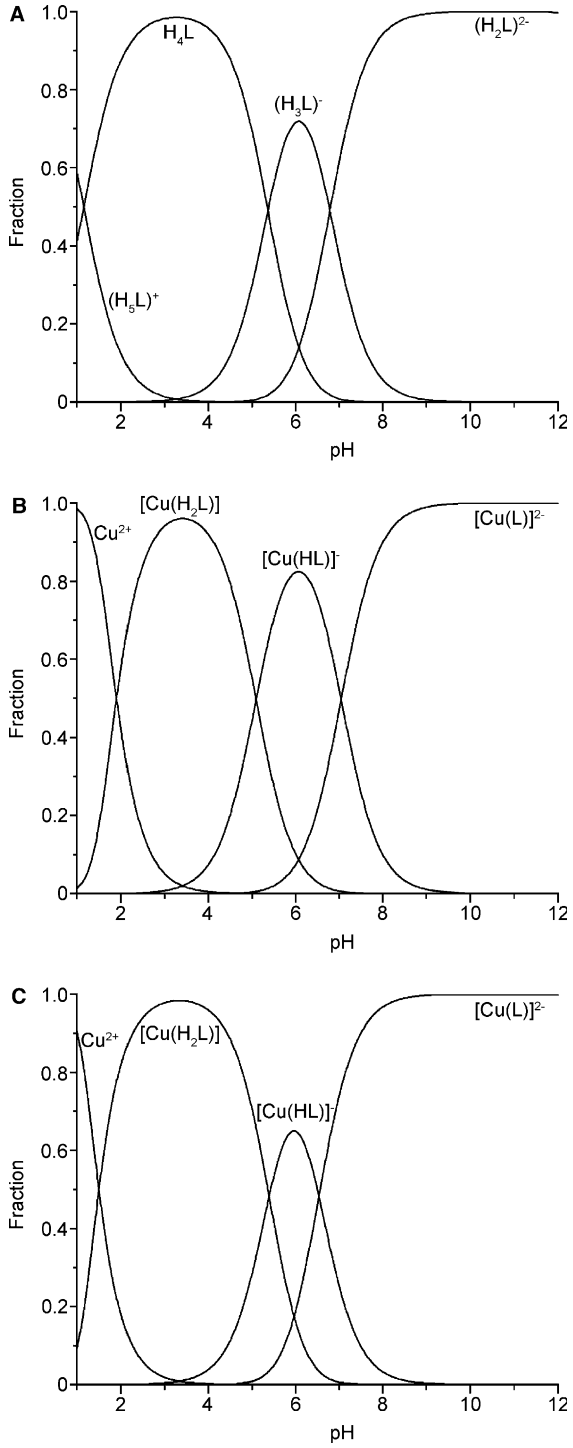

Fig. 2. Distribution diagrams for the $H^+ - H_4L$ (A), $H^+ - Cu^{2+} - H_4L$ (formation of *pc*-$[Cu(L)]^{2-}$ complex) (B) and $H^+ - Cu^{2+} - H_4L$ (formation of *hx*-$[Cu(L)]^{2-}$ complex) (C) systems in aqueous solutions ($c_L = c_{Cu} = 0.1$ mM).

(e.g., TAPS) used as a background electrolyte. A similar phenomenon has been also observed in case of CE separation of organophosphonates [42] and/or α- and β-naphthols [43] in tetraborate background electrolyte solution with the assumption that the complex/ester is formed. Another explanation can be the formation of hydrogen bonds between boric acid/borate and free phosphonate

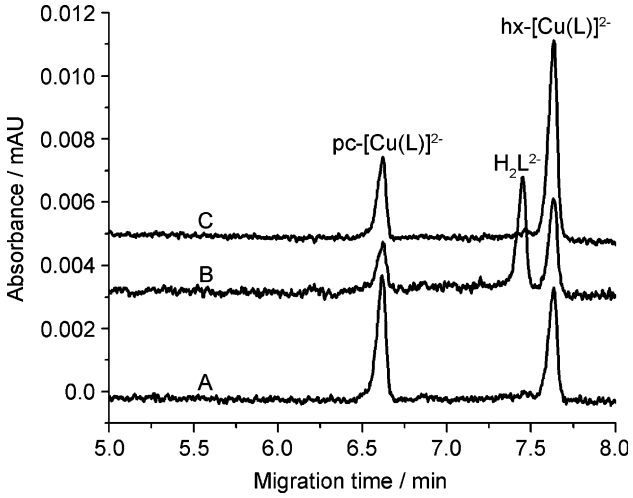

Fig. 3. CE separation of species under optimal experimental conditions (see text) for the aqueous solution mixture containing 98.7 μM *pc*-$[Cu(L)]^{2-}$, 145.5 μM *hx*-$[Cu(L)]^{2-}$ and 300.3 μM $(H_2L)^{2-}$. Detection wavelengths: (A) 319 nm, (B) 220 nm and (C) 280 nm.

Table 1
Effective mobilities, limit of detection (LOD) and quantification (LOQ) of analyzed species in aqueous solutions under optimal experimental conditions (75 mM sodium borate buffer, pH 9.5)

Parameter	*pc*-$[Cu(L)]^{2-}$	*hx*-$[Cu(L)]^{2-}$	$(H_2L)^{2-}$
$\log\beta$	25.40[a]	26.50[a]	26.41[b]
Effective mobility μ_{eff} ($cm^2\,kV^{-1}\,min^{-1}$)	-17.57 ± 0.09	-19.18 ± 0.08	-19.3 ± 0.3
LOD (μM)	6.4	6.1	19.6
LOQ (μM)	28	26	56

[a] For equilibria $Cu^{2+} + L^{4-} = [Cu(L)]^{2-}$, taken from Ref. [23].
[b] $\log\beta_2$ for equilibrium $2H^+ + L^{4-} = (H_2L)^{2-}$, taken from Ref. [20].

groups which is more pronounced for *pc*-$[Cu(L)]^{2-}$ than for *hx*-$[Cu(L)]^{2-}$ species. The separation of $(H_2L)^{2-}$ and *hx*-$[Cu(L)]^{2-}$ species is improved under more extreme experimental conditions (higher pH and tetraborate concentration of the background electrolyte solution) but such conditions could not be applied because of a worse reproducibility of the parameters used for quantification due to overheating of the capillary compared to that used under the working conditions specified in Section 2.

The reproducibility of experimental results such as peak height and area (analytical signal) was tested for a set of model samples of each species in the concentration range 0.05–0.4 mM and for detection wavelengths 220, 280 and 319 nm. These data were used for the construction of a calibration curve plot (figures are not shown). The squared correlation coefficients (R^2) of the calibration plots were typically about 0.999. If fluctuations of migration time of analyte, t_M, occur (this effect is reflected in a variation of the electroosmotic flow, EOF, between two consequent runs), then the correction of the peak area (peak area over the migration time, S_{pc}/t_M) leads to more precise results. Limits of detection (LOD) and quantification (LOQ) were estimated as the signal corresponding to three and ten times of the SD of the noise. The values of LOD's and

LOQ's are summarized in Table 1 and they are comparable with those estimated for spectrophotometric [44] and kinetic [45] copper(II) determination.

4.2. CE study of the isomerization reaction of *pc*-[Cu(H$_2$L)] → *hx*-[Cu(H$_2$L)]

CE analysis was applied in order to follow the extent of the isomerization reaction taking place in the aqueous solution at high temperature (Fig. 4). Since we would like to shorten analysis in batch analysis of aqueous solution where only two isomeric species are present, the formerly proposed method was modified (pH 9.0, separation voltage 20 kV). As can be seen from Figs. 3 and 4, the time of analysis was shortened from 8 to 6 min. The peak area divided by migration time was selected as a quantitative parameter in order to eliminate the fluctuation of migration times of the separated complex species. This new dependent variable is proportional to the concentration of the species and, therefore, can be used for a calculation of the abundance of the complex species as a function of time. An example of a time course of the isomerization reaction is shown in Fig. 5.

The rate constant of the first reaction step is independent of the knowledge of the correct chemical model as shown in Section 3 and, therefore, the time dependence of reactant concentration can be used for calculation of this rate constant. Fig. 6 presents the dependence according to Eq. (11) from which the rate constant can be estimated. Very close values of rate constants $k = (2.45 \pm 0.06) \times 10^{-3}$ and $(2.42 \pm 0.06) \times 10^{-3}$ min^{-1} were obtained from the dependence of the corrected and uncorrected peak areas versus time, respectively, for the temperature 90 °C (Table 2). The rate constant $k = (2.5 \pm 0.3) \times 10^{-3}$ min^{-1} and the ratio $a_{hx}/a_{pc} = 0.89 \pm 0.04$ with SD of the fit $\sigma_Y = 3.26$ were obtained by general least-squares fitting according to Eq. (10) through experimental data in order to verify the consistency of both methods. A good agreement between obtained values of rate constants and the ratio a_{hx}/a_{pc} compared to value 0.877 obtained independently from slopes of calibration curves was achieved. Analogously,

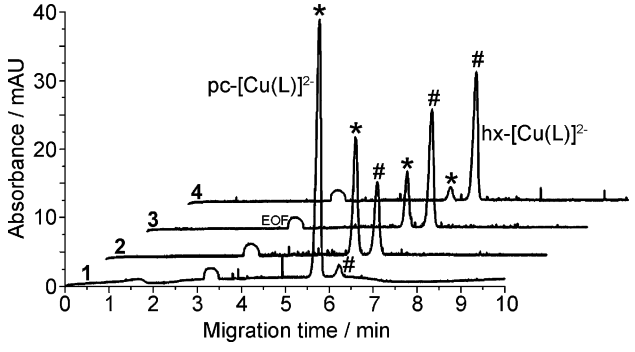

Fig. 4. Course of isomerization of *pc*-[Cu(L)]$^{2-}$ (*) to *hx*-[Cu(L)]$^{2-}$ (#) taking place in aqueous solution (pH 4.56) and at temperature 80 °C monitored by CE (detection wavelength 220 nm): (1) 35 min, (2) 310 min (5 h 10 min), (3) 606 min (10 h 6 min) and (4) 1261 min (21 h 1 min).

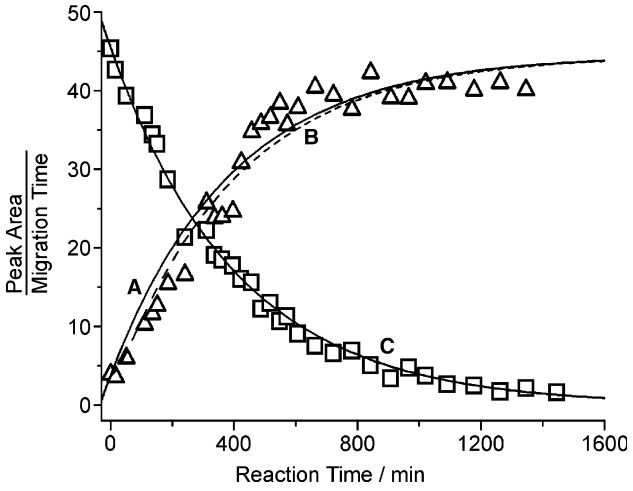

Fig. 5. Distribution of copper(II) complex species in aqueous solution as a function of time at temperature 90 °C: *pc*-[Cu(L)]$^{2-}$ (□) and *hx*-[Cu(L)]$^{2-}$ (Δ). (A) Curve simulated for the one-step reaction according to Eq. (10); (B) curve simulated for the two-step reaction according to Eq. (19); (C) decay of reactant (*pc*-[Cu(L)]$^{2-}$) with time; the curve was simulated accordingly to Eq. (9) (or Eq. (18), respectively).

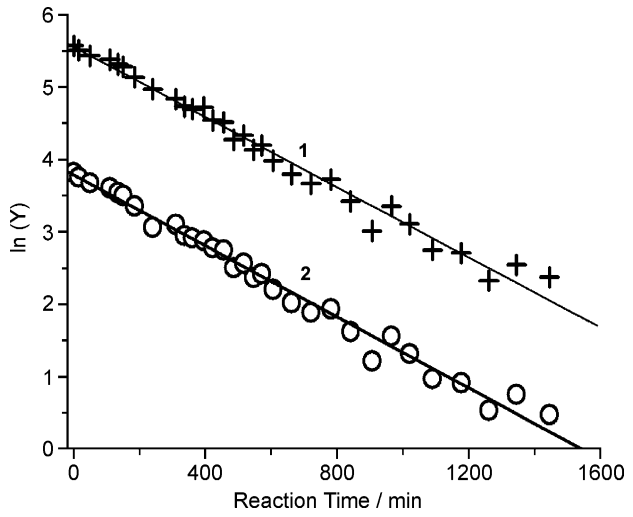

Fig. 6. Transformed time dependence of isomerization for the *pc*-[Cu(L)]$^{2-}$ complex accordingly to Eq. (11). Other experimental conditions are the same as in Fig. 5. Functions used: (1) $Y =$ (peak area) and (2) $Y =$ (peak area/migration time).

Table 2
The rate constants and activation parameters of the isomerization reaction *pc*-[Cu(L)]$^{2-}$ → *hx*-[Cu(L)]$^{2-}$

Parameters	Values
k_1 (80 °C)	$(1.37 \pm 0.07) \times 10^{-3}$ min^{-1}[a] $(1.23 \pm 0.09) \times 10^{-3}$ min^{-1}[b]
k_1 (90 °C)	$(2.42 \pm 0.06) \times 10^{-3}$ min^{-1}[a] $(2.45 \pm 0.06) \times 10^{-3}$ min^{-1}[b]
E_a	72 ± 8 kJ mol^{-1}[b]
$\Delta H^{\neq}$	69 ± 8 kJ mol^{-1}[b]
$\Delta S^{\neq}$	-106 ± 23 J K^{-1} mol^{-1}[b]

[a] Value from uncorrected values of ln(S_{pc}).
[b] Value from corrected values of ln(S_{pc}/t_M).

the corresponding rate constants k were estimated for the temperature 80 °C (Table 2). The activation parameters can be calculated according to Eqs. (22) and (23) and the estimated values are given in Table 2. The estimates of the error of activation parameters were calculated according to relationships published elsewhere [40].

The other question is the number of steps in the isomerization reaction (compare Reactions A and B). If there is only the one-step reaction, Eqs. (9) and (10) should give the same rate constants from the experimental data as discussed in the previous section. In the other case, the isomerization reaction is a multistep process. This can be resolved if the time traces of *hx*-$[Cu(L)]^{2-}$ concentration is simulated using the rate constant k (or k_1, respectively) evaluated from decay of *pc*-$[Cu(L)]^{2-}$. Below, we will consider that the reaction proceeds in two steps. As the other intermediate species were not detected, we can deduce that the rate of the first step is slower than the rate of the second step ($k_1 \ll k_2$). This means that the first step is the rds. Eq. (21) can be written in the logarithmic form as

$$\log\left(\frac{[\text{Intermediate}]}{[^{pc}\text{CuL}]_0}\right) = \frac{k_2}{k_1 - k_2} \times \log\left(\frac{k_2}{k_1}\right) \tag{24}$$

In the case $k_2 \gg k_1$, it can be simplified as

$$\log\left(\frac{[\text{Intermediate}]}{[^{pc}\text{CuL}]_0}\right) = \frac{k_2}{k_1 - k_2} \times \log\left(\frac{k_2}{k_1}\right) \approx -\log\left(\frac{k_2}{k_1}\right) \tag{25}$$

We consider a limit of quantification for **Intermediate** equal to 0.03 mM analogously to the other copper(II) complex species (Table 1) and the initial reactant concentration 0.3 mM. Then, after substitution into Eq. (24), one obtains $k_2 \geqslant 10k_1$ under the given experimental conditions. We used this initial estimate for the general least-squares fitting with Eq. (19) through experimental data and the following parameters $k_1 = (2.5 \pm 0.5) \times 10^{-3}\ \text{min}^{-1}$, $k_2 = (40 \pm 50) \times 10^{-3}\ \text{min}^{-1}$ and the ratio $a_{hx}/a_{pc} = 0.89 \pm 0.04$ with $\sigma_Y = 3.13$ were obtained. As it can be seen in Fig. 5, the difference between both models is not so dramatic. As it was pointed out elsewhere [46,47], the ability to distinguish among different chemical models is possible if some special mathematical procedure, e.g., Laplace transformation [46,47], can be applied. In our case using Ockham's razor theorem, the most probable mechanism will be the simpler mechanism (A).

In our previous work [23], the following mechanism (Reaction C):

$$\begin{aligned} &^{pc}\text{CuL}^{2-} + \text{NH}_3 \overset{K_{\text{NH}_3}}{\rightleftarrows} \text{CuL}(\text{NH}_3)^{2-}(\text{Intermediate}) \\ &\text{CuL}(\text{NH}_3)^{2-}(\text{Intermediate}) \overset{k_{\text{NH}_3}}{\rightarrow} {}^{hx}\text{CuL}^{2-} + \text{NH}_3 \end{aligned} \tag{C}$$

for the isomerization reaction taking place in the presence of ammonia was proposed and the corresponding relationship for kinetic law was derived

$$k_{obs} = \frac{k_{\text{NH}_3} K_{\text{NH}_3}[\text{NH}_3]}{1 + K_{\text{NH}_3}[\text{NH}_3]} \tag{26}$$

If $K_{\text{NH}_3}[\text{NH}_3] \ll 1$, then Eq. (26) can be simplified as

$$k_{obs} \approx k_{\text{NH}_3} K_{\text{NH}_3}[\text{NH}_3] = k^{is}_{\text{NH}_3}[\text{NH}_3] \tag{27}$$

Analogously we can propose the mechanism of the isomerization reaction:

$$\begin{aligned} &^{pc}\text{Cu}(\text{H}_2\text{L}) + \text{H}_2\text{O} \overset{K_{\text{H}_2\text{O}}}{\rightleftarrows} \text{Cu}(\text{H}_2\text{L})(\text{H}_2\text{O})(\text{Intermediate}) \\ &\text{Cu}(\text{H}_2\text{L})(\text{H}_2\text{O})(\text{Intermediate}) \overset{k_{\text{H}_2\text{O}}}{\rightarrow} {}^{hx}\text{Cu}(\text{H}_2\text{L}) + \text{H}_2\text{O} \end{aligned} \tag{D}$$

and the relationship is defined as

$$k_{obs} = \frac{k_{\text{H}_2\text{O}} K_{\text{H}_2\text{O}}[\text{H}_2\text{O}]}{1 + K_{\text{H}_2\text{O}}[\text{H}_2\text{O}]} \tag{28}$$

Again considering $[\text{H}_2\text{O}] \approx$ constant during the experiment and $K_{\text{H}_2\text{O}}[\text{H}_2\text{O}] \ll 1$, then Eq. (28) is simplified as

$$k_{obs} \approx k_{\text{H}_2\text{O}} K_{\text{H}_2\text{O}}[\text{H}_2\text{O}] = k^{is}_{\text{H}_2\text{O}}[\text{H}_2\text{O}] \tag{29}$$

and $k^{is}(\text{H}_2\text{O})$ can be calculated if we know the water concentration. Comparing the rate constants $k^{is}(\text{H}_2\text{O}) = 3.80 \times 10^{-7}\ \text{M}^{-1}\ \text{s}^{-1}$, $k^{is}(\text{NH}_3) = 7.61 \times 10^{-5}\ \text{M}^{-1}\ \text{s}^{-1}$ and $k^{is}(\text{H}_2\text{O}) = 7.67 \times 10^{-7}\ \text{M}^{-1}\ \text{s}^{-1}$, $k^{is}(\text{NH}_3) = 18.8 \times 10^{-5}\ \text{M}^{-1}\ \text{s}^{-1}$ for temperatures 80 and 90 °C, respectively, it can be seen that the values are two orders of magnitude different (the ratio $k^{is}(\text{NH}_3)/k^{is}(\text{H}_2\text{O})$ is equal to 200 and 246 for both the temperatures, respectively). This high difference of the rate of the isomerization reaction in both media favours the reaction pathway in ammonia more than in water and the results are in a good agreement with those published elsewhere [23]. In addition, this phenomena can be ascribed to various experimental conditions, mainly pH (H_2O: 4.56 versus NH_3: alkaline) while the species of different composition are present in solution ($[\text{Cu}(\text{H}_2\text{L})]$ versus $[\text{Cu}(\text{L})]^{2-}$). The values of activation parameters for the reaction in pure water ($E_a = 72 \pm 8\ \text{kJ mol}^{-1}$, $\Delta H^{\#} = 69 \pm 8\ \text{kJ mol}^{-1}$, $\Delta S^{\#} = -106 \pm 23\ \text{J K}^{-1}\ \text{mol}^{-1}$) can be compared with corresponding values found for isomerization of *pc*-$[Cu(L)]^{2-}$ complex species catalyzed by ammonia [23] ($E_a = 97 \pm 3\ \text{kJ mol}^{-1}$, $\Delta H^{\#} = 94 \pm 3\ \text{kJ mol}^{-1}$, $\Delta S^{\#} = 52 \pm 9\ \text{J K}^{-1}\ \text{mol}^{-1}$) [23]. The negative value of $\Delta S^{\neq}$ demonstrates that the overall reaction (Reaction D) has very probably a bimolecular character. Water molecule(s) as a weaker ligand stabilizes a transition state of the complex species less effectively than ammonia (two Cu–N bonds must be splitted during the isomerization process). In addition, ammonia is a good solvent as well and, therefore, the mechanism in the presence of ammonia is different because of solvent effects (e.g., orientation of solvent molecules around charged atom(s) and/or atoms with a developing charge, hydrogen bonds, etc.) [23,38–40]. The solvent effects can change the value of $\Delta S^{\neq}$ even if the molecularity of the reaction is the same (e.g., Reactions C and D) [38,39]. So, the fully deprotonated complex *pc*-$[Cu(L)]^{2-}$ is highly second-sphere solvated in ammonia

solution. Such solvation changes dramatically the reactivity of the copper(II) complex and it is reflected in the positive sign of the entropy of activation $\Delta S^{\neq}$ in Reaction C [23]. A less effective solvation is supposed in water with the diprotonated species.

5. Conclusions

The electrophoretic behaviour of copper(II) complexes with a recently synthesized macrocyclic ligand H_4dipon was studied as a function of pH and composition of background electrolyte solution. The optimum experimental conditions (composition, concentration and pH of background electrolyte, applied voltage, etc.) were used for the separation and determination of two isomeric complex species. The values of effective mobilities of the free ligand $(H_2L)^{2-}$ species and both copper(II) complexes, *pc*-$[Cu(L)]^{2-}$ and *hx*-$[Cu(L)]^{2-}$, in aqueous solution were estimated and explanation of a principle responsible for their separation was proposed. The knowledge of the electrophoretic behaviour of H_4dipon and its copper(II) complexes can be used to check the extent of the reaction between radioactive copper(II) and bifunctional chelating ligands and purity of prepared bifunctional chelates [12,48–55]. Introduction of chromophore or fluorophore into the structure of the ligand molecule would increase the sensitivity of the method and then the procedure can be applied for the determination of the content of labile copper in biological fluids as a consequence of copper metabolism diseases (e.g., Wilson disease [56]) or copper intoxication. The strategy is in progress in our laboratories.

The CE method was successfully applied to study the mechanism of the isomerization of the pentacoordinated copper(II) complex in aqueous solution. It was proved that the *pc*-$[Cu(L)]^{2-}$ complex species isomerizes into the *hx*-$[Cu(L)]^{2-}$ complex via a simple reaction process (Reaction A or D). The first reaction step is the rate-determining step while rate constant(s) of other reaction step(s) is/are at least 10 times faster coming from the fact that no intermediate was detected.

2. Experimental

2.1. Materials

All of used chemicals were reagent grade. Salicylaldehyde and aniline were used after distillation under reduced pressure. Ethylenediamine and cyclohexylamine were distilled before use. The other reagents were used without further purification. 5-Phenylazo salicylaldehyde was synthesized as described in the literature [20].

2.2. Physical measurements and methods

Infrared (FT-IR) spectra were recorded using KBr discs on a Bruker Tensor 27 instrument. ^{1}H NMR spectra were taken on a Bruker Spectrospin Avance 400 MHz ultrashield spectrometer. The electronic spectra in the 200–600 nm range were obtained on a Shimadzu UV-265 FW spectrophotometer and quartz cells of light pass length 1.00 cm, using solutions with the concentration of 1×10^{-5} in DMF. CHN elemental analyses were performed using a Heraeus CHN-O RAPID elemental analyzer. Melting points were taken using an electrothermal IA 9100 apparatus in open capillary tubes. Cyclic voltammograms were recorded using an AMEL instrument Model 2053 as potentiostat connected with AMEL Model 568 as function generator. All solutions were deoxygenated by passing a stream of argon into the solution for at least 10 min before recording the voltammogram. All potentials reported herein were measured at room temperature and referenced to the saturated Ag/AgCl electrode with ferrocene as an internal standard. A glassy carbon disc with a diameter of 3 mm was used as the working electrode and a platinum wire was used as counter electrode. Before each experiment the working electrode was polished with alumina and rinsed thoroughly with distilled water and acetone. The electrolytic medium consisted of 0.1 M $LiClO_4$ in DMF. Under these conditions the ferrocenium–ferrocene couple shows a peak separation of 89 mV. A Pentium IV computer with a 1200 MHz processor, 256 MB of RAM and the HYPERCHEM package version 7 [21] were used for quantum chemical calculations.

2.3. Synthesis of Schiff-base ligands

Schiff-base ligands were prepared in a similar manner according to the literature [22] as the following procedure: To a stirring solution of 2 mmol of appropriate aldehyde in ethanol was added a solution of 1 mmol diamine in ethanol dropwise and then refluxed for 2 h. The precipitated Schiff-base was filtered and recrystallized from hot ethanol giving *N*,*N*′-bis(5-X-salicylidene)-1,2-ethylenediamine, where X is H and N_2ph (diazophenyl) that will abbreviated here as H_2L^1 and H_2L^2, respectively. Some analytical and physical data of the ligands are summarized as follows.

2.3.1. Salen ($C_{16}H_{16}N_2O_2$) (H_2L^1)

Yellow crystals, yield 78% (0.4186 g); m.p.: 168 °C. ^{1}H NMR ($CDCl_3$): δ 13.22 (br s, 2H, OH), 8.35 (s, 2H, H_e), 8.29 (m, 2H, H_b), 7.22 (dd, 2H, H_d), 6.94 (d, 2H, H_a), 6.85 (m, 2H, H_c), 3.94 (s, 4H, $H_{f,g}$). FT-IR(KBr, cm^{-1}): 3300–3400 (m, OH), 2900 (aliphatic CH), 1645 (s, imine C═N), 1200 (phenolic CO).

2.3.2. Bis(5-phenyl azo)salen ($C_{28}H_{24}N_6O_2$) (H_2L^2)

Orange crystals, yield 92% (0.8768 g); m.p.: 229 °C. ^{1}H NMR ($CDCl_3$): δ 13.79 (br s, 2H, OH), 8.52 (s, 2H, H_e), 7.97 (dd, 2H, H_b), 7.92 (d, 2H, H_d), 7.84–7.87 (m, 4H, $H_{i,m}$), 7.42–7.52 (m, 6H, $H_{j,k,l}$), 7.07 (d, 2H, H_a), 4.04 (s, 4H, $H_{f,g}$). FT-IR(KBr, cm^{-1}): 3300–3400 (m, OH), 1635 (s, imine C═N), 1185 (phenolic CO).

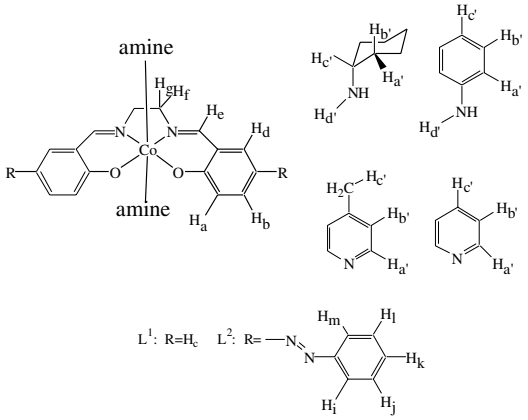
2.4. Synthesis of the complexes

The complexes shown in Scheme 1 were synthesized as follows.

1 mmol of Co (II) acetate tetrahydrate, 1 mmol of the appropriate Schiff-base ligand, 2 mmol of axial amine and 4 mmol of $LiClO_4$ were added to 100 ml of ethanol. The obtained solution turned red rapidly upon the formation of $Co^{(II)}$(salen) complex. Then air was bubbled through the reaction mixture for oxidizing the $Co^{(II)}$(salen) and the mixture stirred and refluxed for 2 h. Then air bubbling and stirring was continued for 24 h. After which the obtained brown material was washed and recrystallized from appropriate solvent systems.

2.4.1. Preparation of [CoL^1(cyclohexylamine)$_2$]ClO_4

The complex was recrystallized from hot ethanol, yielding brown crystals. Yield 96.5% (0.6012 g). *Anal*. Calc. for $CoC_{28}H_{40}N_4O_6Cl$: C, 54.0; H, 6.5; N, 9.0. Found: C, 53.3; H, 6.4; N, 8.8%; m.p.: 199.2 °C. ^{1}H NMR (CD_3CN): δ 8.17



H_2L^1 (salen) complexes: amine= pyridine, picoline, aniline, cyclohexylamine

H_2L^2 (bis(5-phenylazo)salen) complex: amine= pyridine

Scheme 1. A schematic representation of the studied complexes.

(s, 2H, H_e), 7.34 (dd, 2H, H_d), 7.24 (m, 2H, H_b), 7.10 (d, 2H, H_a), 6.53 (q, 2H, H_c), 3.39 (s, 4H, $H_{f,g}$), 2.82 (br d, 4H, $H_{d'}$), 2.21 (br m, 2H, $H_{c'}$), {1.37 (m, 10H) and 0.85 (m, 10H): $H_{a'}$ and $H_{b'}$}. FT-IR(KBr, cm^{-1}): 3295.69 and 3245.86 (m, NH), 1629 (s, C=N), 1090 (br s, ClO_4^-).

2.4.2. Preparation of $[CoL^1(aniline)_2]ClO_4$

The complex was recrystallized from acetonitrile/ethanol (1:2 v/v) yielding brown crystals. Yield 98.2% (0.5999 g). *Anal.* Calc. for $CoC_{28}H_{28}N_4O_6Cl$: C, 55.1; H, 4.6; N, 9.2. Found: C, 54.3; H, 4.8; N, 8.9%; m.p.: 228.6 °C. ^1H NMR (CD_3CN): δ 7.92 (s, 2H, H_e), 7.32 (m, 2H, H_d), 7.16 (dd, 4H, $H_{a'}$), 7.06 (m, 2H, H_b), 6.90–6.94 (m, 4H, $H_{a,c'}$), 6.54–6.61 (m, 6H, $H_{c,b'}$), 4.52 (br s, 4H, $H_{d'}$), 3.80 (s, 4H, $H_{f,g}$). FT-IR(KBr, cm^{-1}): 3234 and 3145 (m, NH), 1631 (s, C=N), 1208 (phenolic CO), 1099 (br s, ClO_4^-).

2.4.3. Preparation of $[CoL^1(4\text{-picoline})_2]ClO_4$

The complex was recrystallized from acetonitrile/ethanol (1:2 v/v) yielding brown crystals. Yield 93.2% (0.5694 g). *Anal.* Calc. for $CoC_{28}H_{28}N_4O_6Cl$: C, 55.1; H, 4.6; N, 9.17. Found: C, 54.1; H, 4.7; N, 9.0%; m.p.: 249.1 °C. ^1H NMR(CD_3CN): δ 8.39 (s, 2H, H_e), 7.89 (d, 4H, $H_{a'}$), 7.21–7.34 (m, 8H, $H_{b,d,b'}$), 7.10 (d, 2H, H_a), 6.52 (m, 2H, H_c), 4.12 (s, 4H, $H_{f,g}$), 2.27 (s, 6H, $H_{c'}$). FT-IR(KBr, cm^{-1}): 1626 (s, C=N), 1210 (phenolic CO), 1097 (br s, ClO_4^-).

2.4.4. Preparation of $[CoL^1(pyridine)_2]ClO_4$

The complex was recrystallized from acetonitrile/ethanol (1:2 v/v) yielding brown crystals. Yield 94.0% (0.5479 g). *Anal.* Calc. for $CoC_{26}H_{24}N_4O_6Cl$: C, 53.6; H, 4.2; N, 9.6. Found: C, 53.4; H, 4.2; N, 9.5%; m.p.: 282.5 °C. ^1H NMR (CD_3CN): δ 8.42 (s, 2H, H_e), 7.89 (d, 4H, $H_{a'}$), 7.86 (m, 2H, H_b), 7.22–7.42 (m, 8H, $H_{d,b',c'}$), 7.12 (d, 2H, H_a), 6.52 (m, 2H, H_c), 4.14 (s, 4H, $H_{f,g}$). FT-IR(KBr, cm^{-1}): 1626 (s, C=N), 1210 (phenolic CO), 1093 (br s, ClO_4^-).

2.4.5. Preparation of $[CoL^2(pyridine)_2]ClO_4$

The complex was recrystallized from acetonitrile/ethanol (1:2 v/v) yielding brown crystals. Yield 90.0% (0.7120 g). *Anal.* Calc. for $CoC_{38}H_{32}N_8O_6Cl$: C, 57.7; H, 4.1; N, 14.2. Found: C, 57.0; H, 4.4; N, 13.8%; m.p.: 265.1 °C. ^1H NMR (CD_3CN): δ 8.66 (s, 2H, H_e), 8.14 (dd, 4H, $H_{a'}$), 8.06 (d, 2H, H_d), 7.87–7.94 (m, 4H, $H_{b,c'}$), 7.75–7.78 (m, 4H, $H_{i,m}$), 7.55 (m, 4H, $H_{b'}$), 7.44–7.5 (m, 6H, $H_{j,k,l}$), 7.32 (d, 2H, H_a), 4.25 (s, 4H, $H_{f,g}$). FT-IR(KBr, cm^{-1}): 1628 (s, C=N), 1117 (br s, ClO_4^-).

2.5. X-ray crystallography

The red plate like single crystals of the complex $[CoL^1(aniline)_2]ClO_4$ obtained by slow evaporation of solvent from acetonitrile/ethanol (1:1 v/v) solution of the complex at room temperature.

All the measurements were performed using graphite monochromatized Mo Kα radiation (0.71069 Å) at 95 K: $C_{28}H_{28}ClCoN_4O_6$, M_r 610.92, monoclinic, space group $P2_1/c$, $a = 11.422(3)$ Å, $b = 16.219(5)$ Å, $c = 14.216(4)$ Å, $\beta = 101.77(2)°$, $V = 2578.2(13)$ Å^3, $Z = 4$, $D_{calc} = 1.574$ g/cm^3, absorption coefficient $\mu = 0.822\ mm^{-1}$. Due to the large organic ligand, the linear absorption coefficient (μ) is only $0.822\ mm^{-1}$ and the crystal used was small (max diameter $r = 0.28$ mm), so the product of $\mu \times r$ is only 0.23 and the absorption correction was not carried out. The other crystal data and structure refinement information are as follows: crystal size: $0.28 \times 0.18 \times 0.12$(mm), $F(000)$: 1264, diffractometer: Stoe, radiation source: fine-focus sealed tube, scan type: ω scans, standard reflections: 3 for every 100 reflections, intensity decay: 1.4%, θ range for data collection: 2.51–26.00 (°), index ranges: $-14 \leqslant h \leqslant 13$, $-1 \leqslant k \leqslant 20$, $-1 \leqslant l \leqslant 17$, reflections collected/unique: 6080/5061, significant unique reflections: 4047 with $I > 2\sigma(I)$, R(int)/R(sigma): 0.0319/0.0635, completeness to $\Theta = 26.0°$: 99.8%, refinement method: full-matrix least-squares on F^2, data/parameters/restraints: 5061/371/2, goodness-of-fit on F^2: 1.063, final R indices [$I > 2(I)$]: $R_1 = 0.0452$, $wR_2 = 0.0925$, R indices (all data): $R_1 = 0.0647$, $wR_2 = 0.1029$, extinction expression: none, weighting scheme: $w = 1/[\sigma^2(F_o^2) + (aP)^2 + bP]$, where $P = (F_o^2 + 2F_c^2)/3$, weighting scheme parameters a, b: 0.0242, 2.0103, largest Δ/σ in last cycle: 0.001, largest difference peak and hole (e/Å^3): 0.401 and −0.318, structure solution program: SHELXS-97 (Sheldrick, 1990), structure refinement program: SHELXL-97 (Sheldrick, 1997).

3. Results and discussion

3.1. Crystal structure

The molecular and crystal structure of the $[Co(salen)(aniline)_2]ClO_4$ are shown in Figs. 1 and 2, respectively. Some selected bond angles and lengths are listed in Table 1. The complex is composed of the $[Co(salen)(aniline)_2]^+$ cation complex and the anion ClO_4^-. Cobalt (III) center is coordinated by two phenolate oxygens, two imine nitrogens of the salen ligand and by the two nitrogen atoms of aniline groups, which occupy the axial positions of a distorted octahedral coordination geometry. The two axial ligands are approximately normal to the salen plane. The axial bond angle N(3)–Co–N(4) is 175.92(10)° which is comparable with those of corresponding angles in similar Co(III) complexes [14,15,19]. The salen ligand has a planar coordination geometry and the Co atom lies in the best plane through the atoms O(1), O(2), N(1) and N(2) (max dev. 0.006 (11) Å). The Co–O (1.894(2), 1.911(2) Å) and Co–N_{imine} (1.895(3), 1.892(2) Å) bond lengths are in good agreement with those of similar complexes [14,15,19]. Every N(4) of ion complex is hydrogen bonded to two phenolate oxygen atoms of other symmetrically related ion complex (Table 2 and

Fig. 2), so that two ion complexes are linked to each other by four hydrogen bonds to form a dimerized ion complex. Every N(3), also, connects to two perchlorate ions by hydrogen bonds. One of the perchlorate oxygens is hydrogen bonded to one of the N(3) of the other dimerized ion complex, so that, the dimerized ion complexes are linked together via ClO_4^- bridging group and form a ribbon along the *c*-axis. The ribbons in *bc*-plane have short contacts by the distances of less than the max sum of atomic van der walls radii.

3.2. Spectral characterization of the ligands and complexes

The IR and ^1H NMR are in accord with the proposed structures. The FT-IR spectra of all complexes, compared with those of the corresponding ligands, indicate that the ν(C=N) band at 1631–1626 cm^{-1} is shifted to lower energy by 14–19 cm^{-1} for salen complexes, but 7 cm^{-1} in the case of azosalen complex, indicating that the ligands are coordinated to the metal ions through the nitrogen atoms of the azomethine groups. On the other hand, the OH proton signals in ^1H NMR spectra of free ligands (13.2 and 13.79 ppm for H_2salen and H_2azosalen, respectively) disappears in the case of complexes indicating that the OH group has been deporotonated and bonded to metal ions as oxygen anion, therefore, the presence of one perchlorate counter ion for each ion-complex of Co(III) can be expected. The appearance of a broad strong band in the IR spectra of the complexes in 1090–1118 cm^{-1} is assigned to perchlorate stretching vibrations, which are typical of non-coordinating perchlorate [24].

Comparing the ^1H NMR spectra of the free ligands and complexes, the imine proton resonances of the ligands (8.35 and 8.52 ppm for H_2L^1 and H_2L^2, respectively) are shifted to lower fields (8.39, 8.42 and 8.66 ppm) in the case of $[CoL^1(4\text{-picoline})_2]ClO_4$, $[CoL^1(pyridine)_2]ClO_4$ and $[CoL^2(pyridine)_2]ClO_4$, respectively, and are shifted to high-field (7.92 and 8.14 ppm) in the case of $[CoL^1(aniline)_2]ClO_4$ and $[CoL^1(cyclohexylamine)_2]ClO_4$, respectively.

Table 3 shows the electronic absorption data for ligands and complexes. The electronic absorption spectrum (>280 nm) of free salen ligand consists of an intense band centered at 316.6 nm attributable to $\pi \rightarrow \pi^*$ transitions associated with azomethine chromophore [25]. Since such a band is seen for reduced imines too, it seems that the charge transfer from phenolate oxygens to phenyl rings

Table 3
Electronic absorption data for ligands and complexes in DMF solution

Compound	λ (nm)				
H_2L^1	273.8			316.6	
H_2L^2	268.6			367.2	428 (sh)
$[CoL^1(cyclohexylamine)_2]ClO_4$	268.2	300 (sh)		390.6	420 (sh)
$[CoL^1(aniline)_2]ClO_4$	267.6	300 (sh)	328 (sh)	392.2	420 (sh)
$[CoL^1(4\text{-picoline})_2]ClO_4$	268.2	300 (sh)	330 (sh)	392.6	420 (sh)
$[CoL^1(pyridine)_2]ClO_4$	268.0	300 (sh)		390.0	420 (sh)
$[CoL^2(pyridine)_2]ClO_4$	267.4	300 (sh)		398.2	440 (sh)

are may be involved in this band appearance too [26]. The similar azomethine $\pi \rightarrow \pi^*$ transitions take place at 367 nm in the case of azosalen ligand. A new band, as a shoulder, with a maximum at 428 nm appears in the UV–Vis spectrum of azosalen in contrast to salen, which is attributable to azophenyl substitute. There is some other intense band in high-energy region (about 270 nm) of the spectra of the free ligands which are related to $\pi \rightarrow \pi^*$ transitions of phenyl rings [19].

The Co(III) complexes of these ligands exhibit absorption bands that are red shifted approximately. Complexation of this ligands with Co(III) with different axial ligands does not affect the energy of the phenyl rings $\pi \rightarrow \pi^*$ transitions, whereas the azomethine $\pi \rightarrow \pi^*$ transitions in complexes show red shift about 70 nm in salen complexes and 30 nm in azosalen complex. These $\pi \rightarrow \pi^*$ azomethine transition bands, show a shoulder at 420 nm in salen complexes and at 440 nm in azosalen complex. Fig. 3 compares the electronic spectra for complexes and free ligands.

These shoulders in salen complexes spectra are attributable to metal–ligand charge transfer transitions (MLCT) ($d \rightarrow \pi^*$) transitions [14,19], while in azosalen complexes the shoulder can be attributed to $\pi \rightarrow \pi^*$ intraligand charge transfer with a small contribution of MLCT. These assignments of shoulders are supported by electronic structure calculation employing Zindo/S semiempirical Hamiltonian with π–π overlap weighting factor of 0.585 for structures optimized by Zindo/1 method [27–34]. The selected main atomic orbitals contributions to HOMO and LUMO of the complexes are shown in Table 4.

Azosalen spectrum bands show red shift in comparison to salen spectra due to the extended conjugated system in azosalen complexes. Different axially coordinated ligands have no effect on the energies of the electronic transitions.

3.3. Electrochemical studies

By scanning in the negative direction initiated at 0.0 mV, the first and second reduction waves correspond to Co(III) → Co(II) and Co(II) → Co(I) processes appear in the range of (−586)–(−247) and (−1107)–(−1037) mV, respectively (Table 5). The peak separation between the related cathodic and anodic waves indicate a quasireversible and reversible redox reactions for Co(III)/Co(II) (min $\Delta E_p = 302$ mV) and Co(II)/Co(I) (max $\Delta E_p = 86$ mV) systems, respectively. The quasireversible redox reaction can be due to the structural changes say by elongation of axial bond lengths or losing of axial amine ligands because of the addition of one electron to $(d_{z^2})^*$ orbital [19]. The redox peak heights increase by increasing of scan rate. Multiple scans result in nearly superposable cyclic voltammograms, i.e., the three oxidation states of cobalt involved are markedly stable.

For the cathodic process of the Co(III) → Co(II), the observed peak potentials are strongly depend on donor strength of the appropriate axial ligands, since the electron affinity of the Co(III) complexes, decreases by

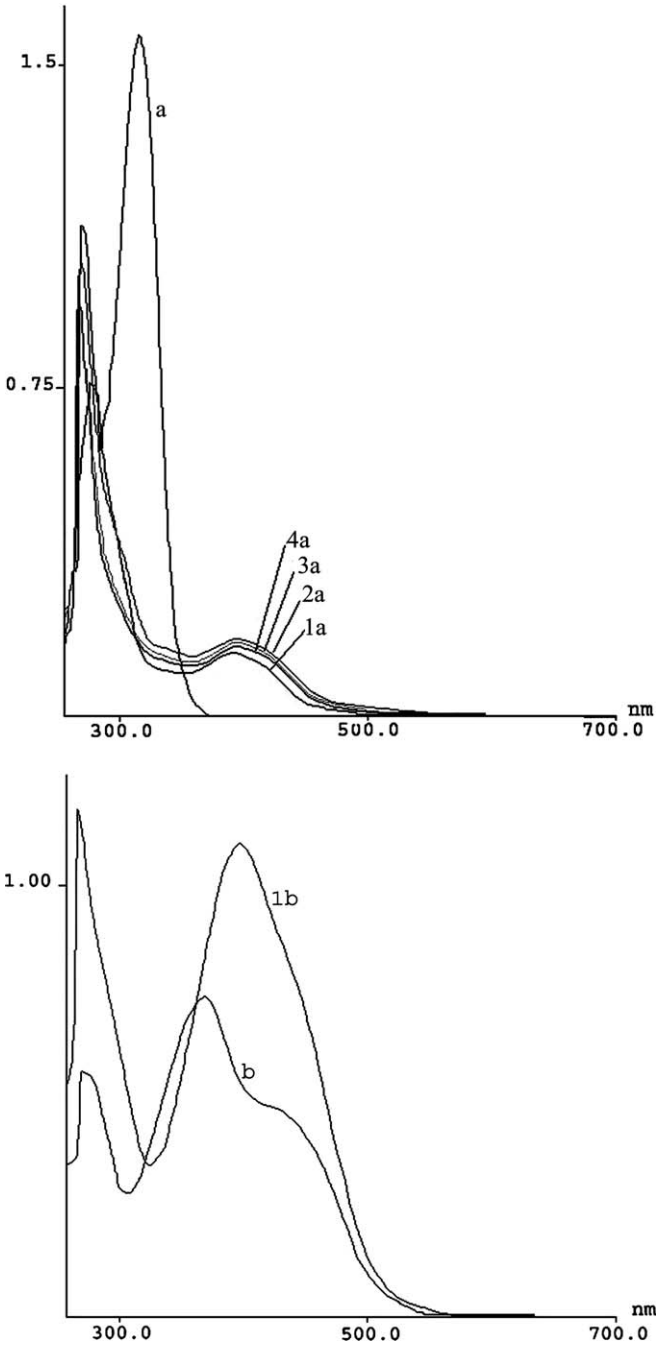

Fig. 3. The UV/Vis spectra of the ligands and complexes: H_2L^1 (a), $[CoL^1(cyclohexylamine)_2]ClO_4$ (1a), $[CoL^1(aniline)_2]ClO_4$ (2a), $[CoL^1(4\text{-picoline})_2]ClO_4$ (3a), $[CoL^1(pyridine)_2]ClO_4$ (4a), H_2L^2 (b) and $[CoL^2(pyridine)_2]ClO_4$ (1b).

increasing pK_a of the axial lewis base. The more negative cathodic potentials for Co(III) → Co(II) process are seen in the order of cyclohexylamine > 4-picoline > pyridine > aniline, that correlates with the pK_a values order (Table 5). Fig. 4 shows the cyclic voltamogram of $[CoL^1(cyclohexylamine)_2]ClO_4$.

Existing of a 5-phenylazo substitution on equatorial salen Schiff-base ligand, which acts as a good electron withdrawing group, causes a more electron affinity on cobalt

$B_{16}H_{20}$ or the intractable $\{B_8H_{10}\}_x$ species observed by Schaeffer [5].

2. Results and discussion

2.1. The reaction between $[B_9H_{14}]^-$ and BCl_3

In the earlier studies [1,2] of the reaction between $[NMe_4][B_9H_{14}]$ and BCl_3, the reaction was represented as follows:

$$2[Me_4N][B_9H_{14}] + 2BCl_3 \rightarrow B_{10}H_{14} + 1/n(B_8H_{10})_n + 2[Me_4N][BCl_3H] + H_2 \quad (1)$$

Although the previous studies give no details of the unidentified product, it is possible that the relative complexity of the ^{11}B NMR spectrum of this material led to the initial postulation of a polymeric structure. This suggestion was reminiscent of a study of the thermal decomposition of B_8H_{12} that gave $B_{16}H_{20}$, and an intractable orange material, formulated as polymeric $\{B_8H_{10}\}_x$ [5]. It turns out, however, that this material is very different in nature to the proposed $1/n(B_8H_{10})_n$ material produced in this work, which is soluble in common polar solvents.

In view of the results described herein, we believe that the overall reaction is better represented by the following equation:

$$2[Me_4N][B_9H_{14}] + 2BCl_3 \rightarrow B_{10}H_{14} + [Me_4N][B_9H_{11}Cl_3] + [Me_4N][BCl_3H] + H_2 \quad (2)$$

This reaction is undoubtedly initiated by the removal of H^- from $[B_9H_{14}]^-$ to form $[HBCl_3]^-$ and the reactive, unsaturated intermediate B_9H_{13}. In order for $B_{10}H_{14}$ to be formed, effectively a $\{BH\}$ unit has to be added to B_9H_{13}. We believe that this could be accomplished through the initial combination of two $\{B_9H_{13}\}$ units to give $(B_9H_{13})_2$, most likely through hydrogen bridges in a manner analogous to two $\{BH_3\}$ units forming B_2H_6. In this case, however, the proposed $(B_9H_{13})_2$ dimer is unstable and dissociates to give $B_{10}H_{14}$, H_2, and B_8H_{10}. Insertion of $[HBCl_3]^-$ into B_8H_{10} would produce $[B_9H_{11}Cl_3]^-$.

The reaction of $[Me_4N][B_9H_{14}]$ with BCl_3 in the absence of solvent was carried out as previously reported [2]. After removal of the volatile products ($B_{10}H_{14}$ and H_2), the non-volatile residue is partially soluble in polar solvents such as THF, Glyme, MeCN, or 1,2-dichloroethane. In the current study, the non-volatile residue was extracted with THF, leaving behind $[Me_4N][HBCl_3]$ formed in the reaction.

Single crystals of the extract were obtained by solvent diffusion of hexane into a THF solution at −30 °C. This method affords two distinct crystal habits: small colorless blocks, **1A**, and large colorless needles, **1B**. Crystals **1B**, extremely prevalent and highly sensitive to solvent loss, have THF incorporated into their lattice, while less common crystals **1A** contain no solvent molecules. Molecular structures were obtained from X-ray diffraction analyses of both crystals and crystallographic data for both structures are given in Table 1.

The structures of all of the chlorinated anions presented here are numbered according to the system shown in Chart 1, and are presented in the same orientation, so as to facilitate comparison with each other, and with the structure of the parent $[B_9H_{14}]^-$ anion [6–8]. This arrangement corresponds to the ground state of the $[B_9H_{14}]^-$ anion, as recently calculated by Hofmann and Schleyer [9]. In each case B(4) is shown as the distinct "prow" atom associated with two geminal bridging H atoms, $\{BH(\mu\text{-}H)_2\}$. The ground state is calculated to possess a $\{3\times\ \mu\text{-H}, 2\times\ endo\}$ arrangement of its five "inner sphere" hydrogen atoms [10].

Single crystal analysis of **1A** reveals that it exists primarily as $[Me_4N][arachno\text{-}B_9H_{11}\text{-}6,7,8\text{-}Cl_3]$[1]. The molecular structure of the anion is shown in Fig. 1(a). Selected bond lengths and interbond angles for the $[arachno\text{-}B_9H_{11}\text{-}6,7,8\text{-}Cl_3]^-$ anion are given in Table 2.

Only a very small number of other examples of halogen-substituted analogues of *arachno*-nonaborate anions have been reported previously. The preparation and structure of $[Me_4N][arachno\text{-}B_9H_{12}\text{-}4,8,Br_2]$ was included as part of a large analysis of known *arachno*-nonaborane structures [8], and a conference report of sequential bromination and iodination of *arachno*-$[B_9H_{14}]^-$ exists in which the production a number of substituted isomers was mentioned [11].

Because the structure and substitution pattern in structures **1A** and **1B** of both systems is similar, only the structure of $[arachno\text{-}B_9H_{11}\text{-}6,7,8\text{-}Cl_3]^-$ derived from crystalline **1A** is discussed in detail here, since it is much less afflicted by problems of disorder. The occupancies of chlorine atoms Cl(1), Cl(2), and Cl(3) at the B(6), B(7), and B(8) positions were allowed to vary during refinement. The final occupancies obtained were: Cl(1) 0.95, Cl(2) 0.80, and Cl(3) 0.97. The remaining fractional occupancy at each of the B(6), B(7), and B(8) vertices was assigned as *exo*-hydrogen atoms, so as to retain an overall total stoichiometry value of 14 substituent atoms per cluster, as in the parent $[B_9H_{14}]^-$.

The anion derived from crystal **1A** is the chlorinated analog of the $[B_9H_{14}]^-$. Its basic structure is very similar to the structure of the $[B_9H_{14}]^-$ anion [6–8]. The structure of $[B_9H_{14}]^-$ has been obtained at room temperature [6] and at low temperature [7,8]. They are in good agreement with each other with the exception that the low temperature structures have a bridging hydrogen between boron atoms B(7) and B(8), while the room temperature structure has an *endo*-terminal hydrogen on B(7). In the present case

[1] Following conventional IUPAC numbering whereby the positions of the Cl substituents are accorded the lowest possible number affords the following: The anions in structures **1A** and **1B** would be represented as $[arachno\text{-}B_9H_{11}\text{-}4,5,6,\text{-}Cl_3]^-$, and anion **2** would be numbered $[arachno\text{-}B_9H_{13}\text{-}4\text{-}Cl]^-$.

of **1A** the hydrogen in question appears closer to the (less commonly observed) terminal type located on B(7), although it does appear to have some semi-bridging character between B(7) and B(8). Relevant distances: B(7)–H(7) = 1.09(4) Å, and B(8)–H(7) = 1.63(4) Å. Distances between B(6)–Cl(1) and B(8)–Cl(3) are 1.835(3) Å and 1.837(2) Å, respectively, while the B(7)–Cl(2) separation appears anomalously short, at 1.792(3) Å. This may be explained by the disorder in the crystal, resulting in an approximately 20% contribution of *exo*-polyhedral bonding at B(7) to hydrogen.

Single crystal X-ray diffraction analyses of **1B** revealed an empirical composition of approximately $[(CH_3)_4N][B_9H_{12.5}Cl_{1.5}]\cdot$ THF. The disorder present may be better described as co-crystallization of a number of chlorononaborate anions in crystalline **1B**. The crystals were extremely solvent-sensitive, and rapidly lost solvent when removed from an atmosphere of THF vapor. This problem was circumvented by doubly coating the crystals in epoxy

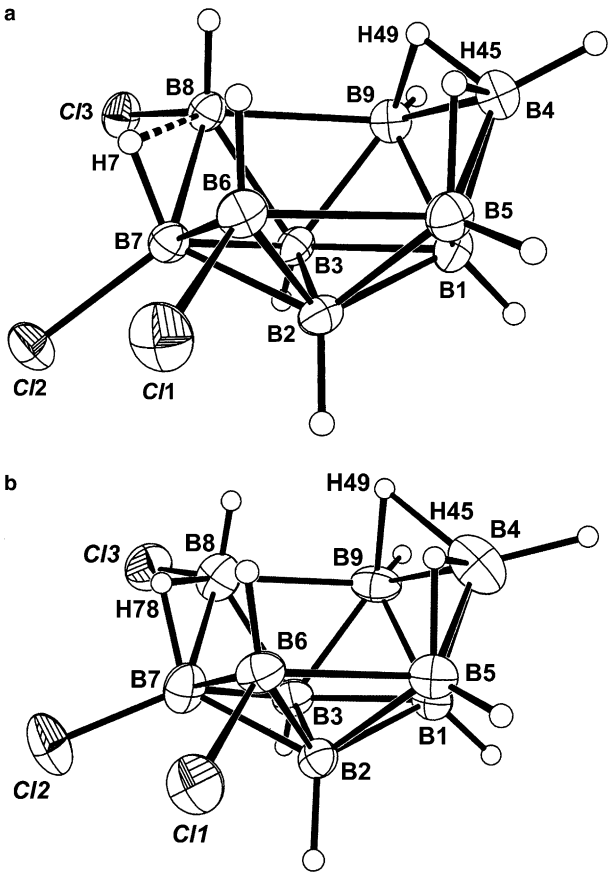

Fig. 1. (a) Plot of the [*arachno*-6,7,8-$B_9H_{11}Cl_3$]$^-$ anion derived from crystalline **1A**. Non-hydrogen atoms are shown as ellipsoids at the 25% probability level. resin. There are two independent B_9 frameworks in the asymmetric unit and there is a wide variation in the occupancies of the chlorine atom positions. One of the anions is shown in Fig. 1(b). The anion shows the typical {3× μ-H, 2× *endo*} arrangement of inner sphere hydrogens observed in the majority of anions of this type [8]. Chlorine and *exo*-hydrogen occupancies were allowed to vary at the B(6), B(7) , and B(8) vertices, such that the anion retained an overall stoichiometry of 14 hydrogen and chlorine atoms per cluster. One vertex in each B_9 framework was assumed to be occupied by 100% chlorine, but the occupancy over the three positions, B(6), B(7) and B(8) varied widely. Specifically, final Cl occupancy values obtained from the refinement at the other positions were Cl(1) 0.305(7) and Cl(2) 0.326(6), with the other independent anion giving the following values Cl(2A) 0.069(6) and Cl(3A) 0.256(7). The average empirical formula of both anions in the structure was $[B_9H_{12.52}Cl_{1.48}]^-$. From difference maps and thermal parameters there is no evidence for chlorine occupying positions on other boron atoms. Information regarding the results of the X-ray study of crystalline **1B** is provided in the Supporting Information.

The $^{11}B\{^1H\}$ spectrum obtained from a single large crystal of **1B** is shown in Fig. 2. This spectrum is essentially

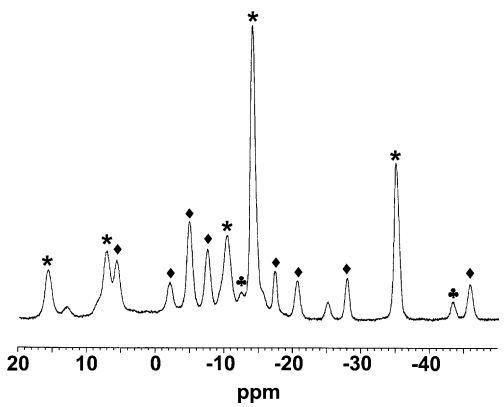

Fig. 2. $^{11}B\{^1H\}$ spectrum of a single large crystal of **1B**.

identical to that obtained from the extracted product prior to crystallization. Attempts to further purify the material by crystallization or thin layer chromatography also invariably yielded material that gave a spectrum with this essential complex appearance.

$^{11}B\{^1H\}$–$^{11}B\{^1H\}$ COSY spectroscopy was used to identify three distinct sets of resonances in the 2-dimensional spectrum. The $^{11}B\{^1H\}$–$^{11}B\{^1H\}$ COSY spectrum is available as Supporting Information. These sets of related resonances are identified by different labels (∗, ♦, and ♣) in Fig. 2.

Relative peak intensities indicate that the species corresponding to those peaks labeled ∗ is the most abundant species in the co-crystallized mixture. Further studies have been performed that show this species to be the *arachno*-monochlorononaborate $[Me_4N][B_9H_{13}Cl]$. Detailed NMR and structural information for this species is presented below. The second most prevalent species in the mixture is associated with the peaks labeled ♦. Although only 8 distinct resonances are observed for this species, it is likely that a ninth signal associated with it is coincident with another peak in the spectrum. For an *arachno*-nonaborate anion to display 9 resonances, it must have no effective symmetry in solution, so it appears reasonable to assign these resonances to a di-substituted species in solution in which the chlorine atoms are not related by an effective mirror plane. This suggests a species such as [*arachno*-B_9H_{12}-6,7-Cl_2]$^-$. Given that the NMR spectra of the initially-extracted mixture and of the very prevalent disordered crystals **1B** are essentially identical and the extreme difficulty in isolating appreciable quantities of crystals **1A** from the mixture, it then seems reasonable to suggest that the peaks of low relative intensity labeled ♣ may be attributable to the trisubstituted cluster [*arachno*-$B_9H_{11}Cl_3$]$^-$. We were fortunate enough to isolate crystals **1A** for X-ray study, but unfortunately they could not be isolated in sufficient quantity for further analyses. Furthermore, crystals **1A** also suffered from disorder, albeit much less so than **1B**.

Despite attempts to completely separate the individual anions in the co-crystallizing mixture by chromatographic methods, this has not proven possible. Given the propensity of the anions to co-exist in the solid state, with differently-substituted anions adopting equivalent positions in the crystal lattice, it is perhaps not surprising that they might also have extremely similar polarities and behavior in solution.

While we were unable to completely separate the co-crystallizing nonaborates, electrospray mass spectrometry was performed in negative ion mode on a sample of the co-crystallized species. Envelopes centered at *m*/*z* 214.076 ($[B_9H_{11}Cl_3]^-$, calculated: 214.745 amu); 180.122 $[B_9H_{12}Cl_2]^-$, calculated: 180.300 amu); and 146.2 ($[B_9H_{13}Cl]^-$, calculated: 145.855 amu) were observed, consistent with the presence of all three species in the crystalline material.

The production of a number of chloro-species in this reaction suggests that the actual process of cluster

expansion may be rather more complex than the simple representation in Eq. (2). Interestingly, BCl_3 (and the subsequently-produced intermediate $[HBCl_3]^-$) each initially have 3 chlorine atoms associated with a single boron atom. There is no evidence for more than one chlorine atom at any vertex in any of the products, suggesting that B–Cl cleavage and formation are central to the cluster formation processes. It is presumably as result of this chlorine-scrambling process that some significant fraction of the Cl atoms are lost from the clusters, possibly in the form of HCl or some chloroboranes such as BH_2Cl or $BHCl_2$, which could easily form a relatively stable adduct with a basic solvent such as THF. The ^{11}B NMR spectrum of the product mixture does not appear to change over prolonged periods of time, indicating that, once formed, the products are stable to positional rearrangement of their chlorine substituents.

2.2. Preparation and characterization of $[Me_4N][B_9H_{13}Cl]$

Due to the relative complexity of the above reaction, and the problems of disorder and co-crystallization suffered by the multiply-chlorinated products, an alternate, cleaner route to these types of species was investigated. In so doing, we were able to obtain a pure compound and alleviate the difficulties encountered above. Rather than starting from the *arachno*-$[B_9H_{14}]^-$ cluster, it was decided to begin with the known species *nido*-$[B_9H_{12}]^-$, (in the form of $[Me_4N][B_9H_{12}]$) which can be prepared by relatively simple literature methods [12]. In this case, rather than hydride abstraction by Lewis acid species, anhydrous HCl was used, which cleanly adds to the *nido*-cluster according to:

$$\textit{nido}\text{-}[B_9H_{12}]^- + HCl \rightarrow \textit{arachno}\text{-}[B_9H_{13}Cl]^- \quad (3)$$

The reaction is carried out in the absence of solvent, and produces only a single product, $[Me_4N][B_9H_{13}Cl]$. This salt has been characterized by ^{11}B, $^{11}B\{^1H\}$, and $^1H\{^{11}B\}$ NMR spectroscopy as well as by a single crystal X-ray study. X-ray data for **2** are contained in Table 1. The structure of the [*arachno*-B_9H_{13}-8-Cl]$^-$ anion is shown in Fig. 3. The structure is numbered according to the scheme shown in Chart 1[1]. Table 3 contains selected bond distances and angles within the anion. The anion is again isostructural with [*arachno*-$B_9H_{14}]^-$, with effective substitution of the *exo*-H atom on B(8) for Cl. The five inner-sphere H atoms are again disposed in a {3× μ-H, 2× *endo*} arrangement about the open face, with H atoms bridging the B(4)–B(5), B(4)–B(9), and B(6)–B(7) connectivities. The B(8)–Cl distance is typical, at 1.873(2) Å.

The $^{11}B\{^1H\}$ and ^{11}B NMR spectra of $[Me_4N][B_9H_{13}Cl]$ are shown in Fig. 4(a) and (b), respectively.

The $^{11}B\{^1H\}$ spectrum features 5 signals of relative intensities 1:1:1:4:2. These peaks clearly correspond to the peaks labeled ∗ in the $^{11}B\{^1H\}$ spectrum of the co-crystallized species (Fig. 2), above. That these 5 peaks are common to the co-crystallized material and the pure

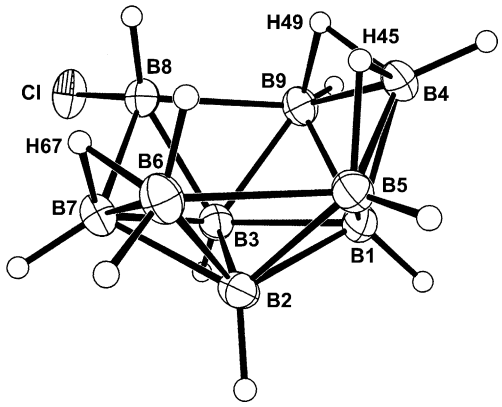

Fig. 3. Plot of the [*arachno*-8-$B_9H_{13}Cl]^-$ anion. Non-hydrogen atoms are shown as ellipsoids at the 25% probability level. H atoms are shown with arbitrary radius.

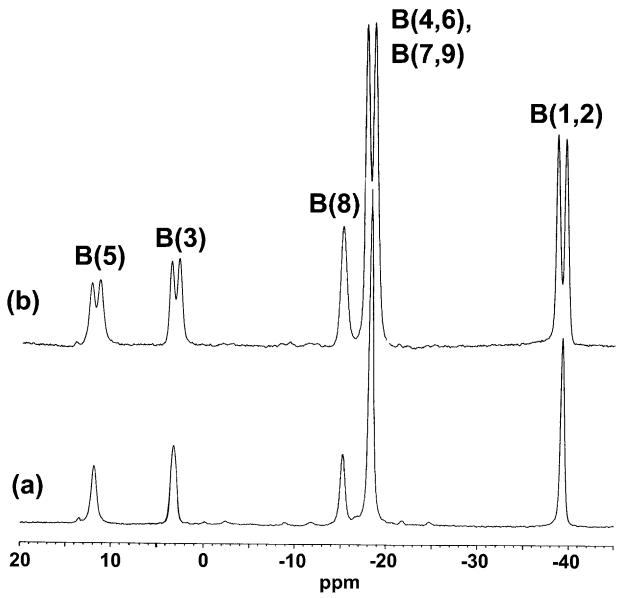

Fig. 4. (a) $^{11}B\{^1H\}$ spectrum; and (b) ^{11}B spectrum of $[Me_4N][arachno\text{-}8\text{-}B_9H_{13}Cl]$.

mono-chloro species is further clear evidence for co-crystallization of different chlorine-substituted analogs, rather than for any type of dynamic rearrangement process in solution after the clusters have been formed. The peak at −15.22 ppm is the only singlet in the ^{11}B spectrum, and so is assigned to the chlorine-bearing atom B(8). A 2-dimensional $^{11}B\{^1H\}$–$^{11}B\{^1H\}$ COSY experiment was also carried out for this compound, and afforded the assignment of all resonances in the spectrum. The $^{11}B\{^1H\}$–$^{11}B\{^1H\}$ COSY spectrum is available as Supporting Information. The peak of relative intensity 4 at −18.34 ppm in the $^{11}B\{^1H\}$ spectrum results from an accidental overlap of the B(4,6) and B(7,9) resonances. In addition to a signal for the tetramethylammonium ion, the $^1H\{^{11}B\}$ spectrum displays 6 signals of relative intensities 1:1:2:2:2:5, consistent with the effective C_s symmetry resulting from the fluxionality of the five inner sphere H atoms on the NMR timescale at ambient temperature.

Since the earliest structural studies on *arachno*-$\{B_9\}$ clusters [6], there has been some debate as to the exact nature and arrangement of the inner sphere hydrogen atoms associated with these clusters [10]. The earliest reported structure of the $[B_9H_{14}]^-$ anion was derived from a room temperature study of $Cs[B_9H_{14}]$, and showed a {2× μ-H, 3× *endo*} arrangement of its five inner-sphere H atoms [6]. This arrangement was accepted for many years as representing the most stable arrangement of bridging and *endo*-hydrogens in $[B_9H_{14}]^-$. More recently, the structure of $Cs[B_9H_{14}]$ was redetermined at low temperature [7], and an X-ray study of $K[B_9H_{14}]$ at 143 K has also been reported in recent years [8]. These two structures both indicate a {3× μ-H, 2× *endo*} arrangement of the inner sphere hydrogens. A detailed analysis of all known *arachno*-$\{B_9\}$ structures would appear to support the assertion that the {3× μ-H, 2× *endo*} arrangement represents the ground state of this structural type [8]. Of the three structures presented here, **1B** and **2** clearly display a {3× μ-H, 2× *endo*} arrangement, while the anion in structure **1A** has a structure closer to the {2× μ-H, 3× *endo*} type. However, the inner sphere hydrogen associated with B(7) in this structure is not symmetrically disposed above the open face of the cluster. It is closer to B(8) than to B(6), thus displaying at least some degree of bridging character. The original structure of $Cs[B_9H_{14}]$ was carried out at ambient temperature [6], and its {2× μ-H, 3× *endo*} structure is calculated to lie only 2.3 kcal/mol higher than the ground state [9].

3. Conclusion

The previously unidentified product of the reaction with BCl_3 and *arachno*-$[B_9H_{14}]^-$ was shown to consist of a mixture of multiply-chlorinated *arachno*-B_9 structures that crystallized in disordered fashions. This product had previously been thought to be polymeric in nature, perhaps as a result of the complex appearance of its ^{11}B NMR spectrum. Adoption of an alternate synthetic route that yielded the pure compound $[Me_4N][B_9H_{13}Cl]$ (**2**) in quantitative yield from $[Me_4N][B_9H_{12}]$ helped solve this problem. In addition to an X-ray structural analysis, a full spectral characterization of the monochloro compound was performed, which afforded understanding of the complicated spectral data of the mixture. This illustrates the need to explore alternative synthetic methodologies and their ability to help solve otherwise intractable problems of characterization.

Additionally, the central finding of this work that the initially-suspected polymeric species is actually a mixture of salts is very interesting, as it raises questions as to the nature of many boron hydride species previously proposed to have polymeric structures [3]. With the advent of more modern and improved methods of characterization, it is possible that at least some of these suspected polymeric species may indeed yet be found to possess discrete monomeric structures.

4. Experimental

4.1. General information

All materials were handled by standard vacuum line and inert atmosphere techniques [13]. $K[B_9H_{14}]$ was prepared from $B_{10}H_{14}$ by a published procedure [14]. $[Me_4N][B_9H_{12}]$ was prepared from $B_{10}H_{14}$ via $[(C_2H_5)_2S]_2B_{10}H_{12}$ using the literature procedure [12]. $B_{10}H_{14}$ was triply sublimed under vacuum prior to use. BCl_3 (Matheson) was fractionated through a −95 °C trap prior to use. HCl was purified by passing it through a trap held at −112 °C. Tetramethylammonium chloride was thoroughly dried under vacuum before use. All solvents were dried and distilled into vacuum storage bulbs prior to use.

4.2. NMR spectroscopy

^{11}B and ^{1}H NMR spectra were recorded on either a Brüker AM-250 or DRX-500 spectrometer operating at 80.2 and 250.1 MHz, or 160.4 and 500.0 MHz, respectively.

4.3. Mass spectrometry

All experiments were performed on a Micromass ESI-Tof™ II (Micromass, Wythenshawe, UK) mass spectrometer equipped with an orthogonal electrospray source (Z-spray) operated in negative ion mode. Sodium iodide was used for mass calibration for a calibration range of m/z 100–2000. Samples were prepared in a solution containing acidified methanol and infused into the electrospray source at a rate of 5–10 μL min^{-1}. Optimal ESI conditions were: capillary voltage 3000 V, source temperature 110 °C, and a cone voltage of 55 V. The ESI gas was nitrogen. Data were acquired in continuum mode until acceptable averaged data were obtained.

4.4. Preparation of $[Me_4N][B_9H_{14}]$

$K[B_9H_{14}]$ (0.395 g 2.62 mmol) and $[Me_4N]Cl$ (0.287 g, 2.62 mmol) were placed in a 100 mL flask fitted with a Solv-Seal adapter. The flask was evacuated and glyme (25 mL) was condensed into the system. The mixture was warmed to room temperature and stirred for one hour during which time a white precipitate formed. Filtration followed by removal of the solvent under vacuum afforded an approximately quantitative yield of $[Me_4N][B_9H_{14}]$.

4.5. Reaction of $[Me_4N][B_9H_{14}]$ with BCl_3

To $[Me_4N][B_9H_{14}]$ (2.62 mmol) was added BCl_3 by condensation of vapor, 2.62 mmol (measured manometrically) at −196 °C. The mixture was allowed to return to room temperature and was stirred vigorously for 3 h. The color of the mixture changed from pale yellow to orange-yellow, and small crystals of $B_{10}H_{14}$ were observed on the walls of the flask. The flask was cooled to −196 °C and H_2 gas (0.9 mmol) was removed. The $B_{10}H_{14}$ product was removed by vacuum sublimation (alternatively, it can be removed by extraction with Et_2O). Extraction of the remaining solid using polar solvents such as THF, glyme, or CH_3CN separates the chlorinated nonaborate salts (0.34 g, 45% yield if pure $[Me_4N][B_9H_{11}Cl_3]$) from the insoluble $[Me_4N][BCl_3H]$. The product was recrystallized by solvent diffusion of hexanes into a THF solution at −30 °C.

NMR data (THF-d_8). All peaks apparent doublets, except where noted. δ ppm (J_{BH}, Hz) 17.54 (146), 14.5 (140), 8.99 (146), 7.46 (146), −0.26 (148), −3.6 (d, 140), −5.76 (141), −8.61 (s), −12.46 (141), −15.53 (139), −18.80 (131), −23.16 (153), −26.13 (137), −33.35 (144), −41.73 (145), −44.10 (145).

IR (KBr pellet, cm^{-1}): 3048 (m), 2972 (w), 2937 (w), 2529 (vs), 1483 (s), 1225 (m, sh), 1197 (m), 1157 (w), 1075 (m), 1011 (w), 948 (s), 795 (m), 712 (m).

4.6. Preparation of $[Me_4N][B_9H_{13}Cl]$

$[Me_4N][B_9H_{12}]$ (0.1687 g, 0.919 mmol) was placed in a Solv-Seal flask fitted to a vacuum extractor, and the apparatus evacuated. HCl (0.921 mmol) was condensed into the reaction flask at −196 °C, and allowed to warm to −78 °C. Stirring was continued until the bath warmed to room temperature, then the volatiles were pumped away. The solid residue was washed with toluene (20 mL). A fresh receiver flask was fitted to the extractor and CH_2Cl_2 (25 mL) was condensed in at −196 °C, the mixture allowed to come to room temperature, and then filtered, and the colorless residue washed with CH_2Cl_2. The very pale yellow extract was reduced to dryness in vacuo to afford an off-white microcrystalline solid, $[Me_4N][B_9H_{13}Cl]$, in essentially quantitative yield.

NMR data (CD_3CN). ^{11}B: δ ppm (J_{BH}, Hz) 11.90 (1B, d, 146 Hz), 3.22 (1B, d, 134 Hz), −15.22 (1B, s, B(8)), −18.34, (4B, d, 139 Hz), −39.28 (2B, d, 143 Hz).

^{1}H: δ ppm 3.28, (12B, $(CH_3)_4N^+$), −1.13 (5H, μ- and *endo*-H).

$^{1}H\{^{11}B\}$: (CD_2Cl_2) δ ppm 3.74 (1H), 3.28 (12H, $(CH_3)_4N^+$), 3.01 (1H), 1.99 (2H), 1.53 (2H), 0.27 (2H), −1.13 (5H, μ- and *endo*-H).

IR (KBr pellet, cm^{-1}): 3033 (m), 2937 (w), 2910 (w), 2522 (vs), 1484 (s), 1417 (m), 1194 (m), 1154 (w), 1075 (m), 1055 (m, sh), 1011 (m), 975 (m), 948 (s), 769 (w), 726(w), 652 (m).

Colorless needle crystals of diffraction-quality were grown by solvent diffusion of hexane into a CH_2Cl_2 solution at −30 °C.

4.7. X-ray crystal structure determinations

Crystals were mounted on glass fibers using epoxy resin. Solvent-containing crystals were doubly coated with epoxy resin to prevent solvent loss. The crystallographic data for all structures were collected at −60 °C on an Enraf-Nonius CAD4 diffractometer with graphite-monochromated Mo Kα radiation. Unit cell parameters were obtained by a least squares refinement of the angular settings from 25 reflections, well distributed in reciprocal space and lying in a 2θ range of 24–30°. Intensity data were collected in the ω–2θ scan mode. All reflection data were corrected for Lorentz and polarization effects.

The structures were solved by direct methods and refined using SHELXTL (difference electron density calculations, full least-squares refinements) [15]. Additional calculations were performed using WINGX [16] and PLATON [17]. The partial Cl/H occupancies in structure **1B** were calculated using the SHELXL option "PART", with the fol-

lowing results for fractions of Cl: Cl(1) 0.305(7); Cl(2) 0.326(6); Cl(2A) 0.069(6); Cl(3A) 0.256(7). Chlorine occupancies of 0.8 or greater could not be treated this way. All non-hydrogen atoms were refined anisotropically. Hydrogen atoms in the anions were refined isotropically. Hydrogen atoms in the Me_4N^+ cations and THF molecules were calculated and their thermal and positional parameters were fixed during refinement. Crystallographic data for structures **1A**, **1B**, and **2** are provided in Table 1. Structure **1B** contains 1 THF solvent molecule per formula, and 2 crystallographically independent formulae per asymmetric unit, so the unit cell contains a total of 8 formulae.

Acknowledgments

We thank Professor S.G. Shore for generous access to analytical resources.

Appendix A. Supporting information available

Further details of the crystal structure determinations **1A**, **1B**, and **2** can be obtained from the Fachinformationszentrum Karlsruhe, 76344 Eggenstein-Leopoldshafen, Germany (fax: +49 7247 808 666; e-mail: crysdata @fiz.karslruhe.de) on quoting the depository numbers CSD-391332, CSD-391333, and CSD-391334, respectively. $^{11}B\{^1H\}$–$^{11}B\{^1H\}$(COSY) spectra are also available for each of the compounds discussed. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2005.12.002.

(20 mmol). The solution was stirred in a water bath at 90 °C for 8 h. The mixture (pH 3.5) was filtered and evaporated to about 20 ml. The colorless crystals obtained after standing for two days were collected and washed with 50% ethanol and 95% ethanol. Yield: 4.7 g (58%). *Anal.* Calc. for $C_{24}H_{50}Mo_4N_4Na_6O_{46}$: C, 17.4; H, 3.1; N, 3.4. Found: C, 17.4; H, 2.8; N, 3.3%. IR (KBr): ν(COOH) 1735_w; ν_{as}(C=O) 1652_{vs}; ν_s(C=O) 1446_m, 1383_{vs}, 1340_s; ν(Mo=O) 920_{vs}, 885_b; ν_{as}(MoO_bMo) 779_{vs}; ν_s(MoO_bMo) 685_m. ^{1}H NMR δ_H (500 MHz, D_2O, ppm): 4.137 (s). ^{13}C NMR δ_C (D_2O, ppm): 180.2, 179.0 and 177.8 $(CO_2)_\beta$, 65.5 (CH_2).

2.2. Preparation of $(NH_4)_{3n}[Mo_2O_5H(nta)_2]_n \cdot 4nH_2O$ (2)

Ammonium heptamolybdate (5 mmol) and nitrilotriacetic acid (35 mmol) were added to dilute ammonia (5 M, 40 ml). The solution (pH 4.0) was stirred until the color changed into light green and then it was evaporated to 20 ml. The colorless crystals obtained after standing overnight were collected and washed by 50% ethanol and 95% ethanol. Yield: 8.4 g (62%). *Anal.* Calc. for $C_{12}H_{33}Mo_2N_5O_{21}$: C, 18.6; H, 4.3; N, 9.0. Found: C, 18.2; H, 4.0; N, 8.0%. IR (KBr): ν(COOH) 1719_w; ν_{as}(C=O) 1639_{vs}; ν_s(C=O) 1448_s, 1399_{vs}, 1312_w; ν(Mo=O) 929_{vs}, 914_{vs}; ν_{as}(MoO_bMo) 883_s; ν_s(MoO_bMo) 690_m. ^{1}H NMR δ_H (500 MHz, D_2O, ppm): 3.976 (s). ^{13}C NMR δ_C (D_2O, ppm): 179.0 $(CO_2)_\beta$, 65.7 (CH_2).

Crystals of suitable quality for the subsequent X-ray diffraction studies were obtained as transparent prisms or rhombohedral blocks by slow evaporation of the related solution for one week at room temperature. The resulting crystals were sealed in a capillary to prevent loss of water molecules.

2.3. Transformation of 1–3 and 4

To the solution of $Na_{6n}\{[Mo_2O_5(ntaH)_2][(nta)_2Mo_2O_5]\}_n \cdot 12nH_2O$ (**1**) (pH 3.5), an appropriate amount of hydrochloric acid was added and the pH was adjusted to 2.5. The solution was then filtered and evaporated slowly. The crystals formed were collected and washed. The structural analysis shows the product as $Na_2[Mo_2O_5(Hnta)_2]$ (**3**). *Anal.* Calc. for $C_{12}H_{14}Mo_2N_2Na_2O_{17}$: C, 20.7; H, 2.0; N, 4.0. Found: C, 20.0; H, 2.4; N, 3.8%. IR (KBr): ν(COOH) 1750_s, ν_{as}(C=O) 1673_{vs}, 1600_v; ν_s(C=O) 1428_m, 1401_s, 1339_s, 1318_s; ν(Mo=O) 982_m, 947_s, 912_{vs}, 883_s; ν_{as}(MoO_bMo) 785_{vs}; ν_s(MoO_bMo) 695_m. ^{1}H NMR δ_H (500 MHz, D_2O, ppm): 4.119 (s). ^{13}C NMR δ_C (D_2O, ppm): 174.8 $(CO_2)_\beta$, 62.5 (CH_2).

In another experiment, sodium hydroxide was added and the pH was adjusted to 7.0. The solution was evaporated slowly. The crystals formed were collected and washed. The structural analysis shows the product as $Na_3[MoO_3(nta)] \cdot 4H_2O$ (**4**). *Anal.* Calc. for $C_6H_{14}MoNNa_3O_{13}$: C, 15.2; H, 3.0; N, 3.0. Found: C, 15.1; H, 2.8; N, 2.9%. IR (KBr): ν_{as}(C=O) 1644_s, 1602_{vs}; ν_s(C=O) 1439_m, 1409_s; ν(Mo=O) 939_{ms}, 897_s, 857_{vs}. ^{1}H NMR δ_H (500 MHz, D_2O, ppm): 3.982 (s). ^{13}C NMR δ_C (D_2O, ppm): 178.1 $(CO_2)_\beta$, 64.6 (CH_2).

2.4. Physical measurements

Infrared spectra were recorded as Nujol mulls between KBr plates using a Nicolet 360 FT-IR spectrometer. Elemental analyses were performed using EA 1110 elemental analyzers. ^{1}H NMR and ^{13}C NMR spectra were recorded on a Varian UNITY 500 NMR spectrometer with D_2O using DSS (sodium 2,2-dimethyl-2-silapentane-5-sulfonate) as internal reference.

2.5. X-ray data collection, structure solution and refinement

Crystallographic data for the nitrilotriacetato molybdates of **1**–**4** are summarized in Table 1. Diffraction data were collected on Bruker Smart CCD diffractometer with graphite monochromated Mo Kα ($\lambda = 0.71073$ Å) radiation at 296 K. Empirical absorption corrections were applied using the SADABS program [20]. The structures were primarily solved by the WINGX program [21] and refined by full-matrix least-squares procedures with anisotropic thermal parameters for all of the non-hydrogen atoms with SHELXL-97 [22]. Hydrogen atoms were located from the difference Fourier map and refined isotropically.

3. Results and discussion

3.1. Synthesis

Nitrilotriacetic acid is able to provide tetradentate chelation and different protonated forms, which might be expected to produce various types of anion complexes with molybdenum(VI). Previous potentiometric, spectrophotometric and enthalpimetric titrations in the molybdate (VI)–nitrilotriacetate system have been proceeded in the pH range 1.0–9.0 in solution [15]. The formation of the products may be represented by the general equation

$$p[MoO_4]^{2-} + q\text{nta}^{3-} + r\text{H}^+ \rightleftharpoons [\text{complex}]^{(2p+3q-r)-}$$

The major species are proposed to have Mo:nta:H ratios of 1:1:2, 1:1:3, 1:1:4, 2:2:7, 2:2:8, 2:1:5 and 2:1:6 in solution, depending mainly on the pH [15]. In our experiment, only the 1:1:2, 2:2:6, 2:2:7 and 2:2:8 species of nitrilotriacetato molybdates are separated in the acidic, weak acidic and neutral aqueous media. The transformation and the isolation of nitrilotriacetate complexes in different protonated forms have proven that 1:1 and 2:2 ratios (Mo:nta) of nitrilotriacetato molybdates are the major species. The 2:1 species is unfavorable due to the competitive formation of homopolyacid.

In an acidic solutions of pH 2.0–3.0, nitrilotriacetic acid can react with a Mo(VI) complex to form the protonated anion $[Mo_2O_5(Hnta)]^{2-}$, while in neutral solutions of pH 5.0–7.0, mononuclear $[MoO_3(nta)]^{3-}$ is formed. The adduct of protonated and deprotonated species

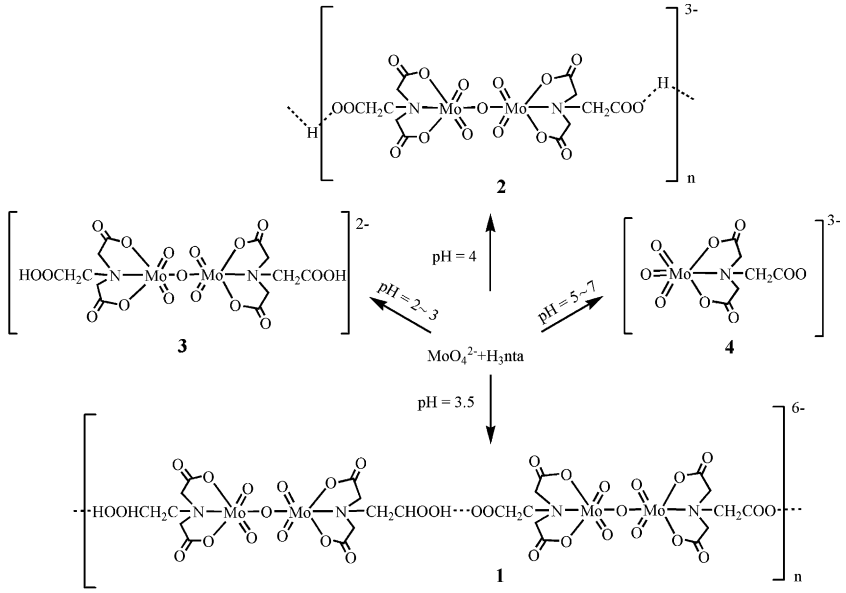
$Na_{6n}\{[Mo_2O_5(ntaH)_2][(nta)_2Mo_2O_5]\}_n \cdot 12nH_2O$ (**1**) and hydrogen nitrilotriacetato molybdate $(NH_4)_{3n}[Mo_2O_5H(nta)_2]_n \cdot 4nH_2O$ (**2**) were isolated in weak acidic solutions of pH 3.5–4.0. The later represents an intermediate between protonated $[Mo_2O_5(Hnta)_2]^{2-}$ and deprotonated $[Mo_2O_5(nta)_2]^{4-}$ molybdenum (VI)–nitrilotriacetate complexes. In compound **1**, the two uncoordinated β-carboxyl groups of nitrilotriacetate in one dimer are protonated, while those in the other are deprotonated. This is supported by a downshift of the *v*(COOH) vibration from 1750 in **3** to 1735 cm^{-1} in **1**. Transformations between **1**, **3** and **4** can be accomplished by adjusting the pH. The pH values in the reactions are controlled easily by hydrochloric acid or sodium hydroxide as shown in Scheme 1. The transformations of monomeric and dimeric nitrilotriacetato molybdate (VI) are different from that described previously, in which only the monomeric species is considered in the precursor of a NiMo/SiO_2 hydrotreating catalyst [23].



Scheme 1. Synthesis and transformation of nitrilotriacetato molybdates (VI).

3.2. Structure descriptions of complexes **1** and **2**

Complex **1** consists of a molybdenum–nitrilotriacetate adduct in a 2:2 stoichiometric ratio. The perspective view of the anion is presented in Fig. 1. Each molybdenum atom is octahedrally surrounded by two terminal oxygen atoms, one bridging oxygen atom and a tridentate nitrilotriacetate ligand, which binds through two β-carboxyl oxygen atoms and one nitrogen atom. The non-coordinated β-carboxyl oxygen O15 is protonated. This is supported by the relatively long C16–O15 bond, 1.307(9) Å, as compared with C16–O16, 1.214(9) Å. However, the non-coordinated carboxyl groups of the other do not show a distinct difference. The two neighboring carboxylate oxygen atoms are linked by a strong hydrogen bond [O5···H–O15 2.481(3) Å], generating a one-dimensional coordination polymer through the aggregation of fully protonated species $[Mo_2O_5(Hnta)_2]^{2-}$ and deprotonated units $[Mo_2O_5(nta)_2]^{4-}$.

Fig. 2 shows a perspective view of the anion in complex **2**. The crystal structure comprises ammonium cations, hydrogen oxo-μ-bis[*trans*-nitrilotriacetato-*cis*-dioxomolybdate] anions and lattice water molecules. The dimeric anion consists of MoO_2(Hnta) and MoO_2(nta) units bridged by an oxygen linkage [Mo–O–Mo = 180.00(3)°]. The two oxo atoms are *cis* to each other in the coordination octahedron. The two *cis*-dioxo groups are in a *trans*-configuration, which is the same as that found in tripotassium oxo-μ-bis[*trans*-nitrilotriacetato-*cis*-dioxotungstate] $K_3[W_2O_5H(nta)_2]\cdot 2H_2O$ [W–O–W = 161.9(7)°] [24]. The other three sites are occupied by the nta entity. Adjacent $Mo_2O_5H(nta)_2$ units are linked into an infinite zigzag chain through the acidic hydrogen [O6···H···O6b = 2.486(3) Å]. The space between the chains is occupied by the ammonium cations and the lattice water molecules.

The anion structures of compounds **3** and **4** are similar to the previous reported structures [11–14]. Evidently, the uncoordinated β-carboxyl groups in complex **3** are fully protonated, this is not only showed by the visibility of hydrogen atoms in difference maps, but also by the difference between the C–O distances of the terminal carboxylates, as well as from the consideration of charge balance. The conclusion of full deprotonation of the monomer **4** can be drawn from the observed carbon–oxygen bond distances of carboxyl groups that are equivalent [1.259(5), 1.251(5) Å] (see Figs. 3 and 4).

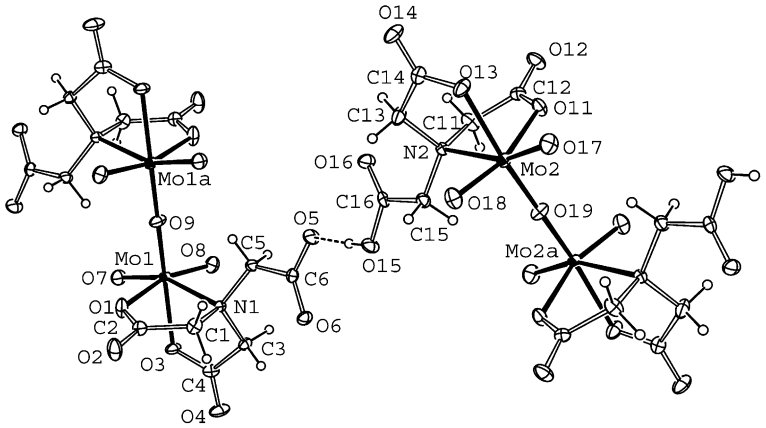


Fig. 1. ORTEP plot of the anion in $Na_{6n}\{[Mo_2O_5(ntaH)_2][(nta)_2Mo_2O_5]\}_n\cdot 12nH_2O$ (**1**) at the 30% probability level.

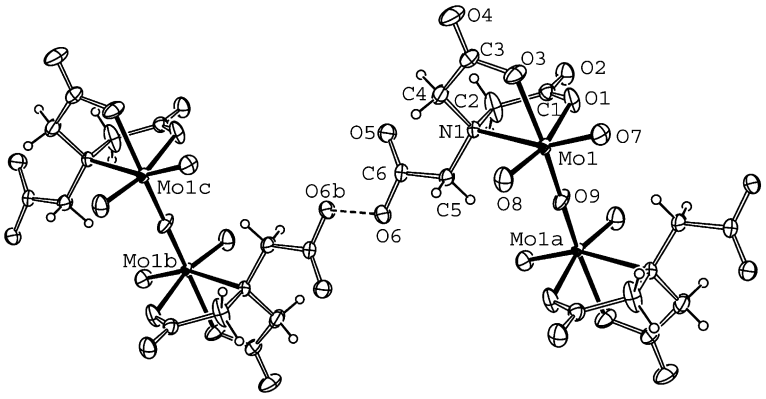

Fig. 2. ORTEP plot of the anion in $(NH_4)_{3n}[Mo_2O_5H(nta)_2]_n\cdot 4nH_2O$ (**2**) at the 30% probability level.

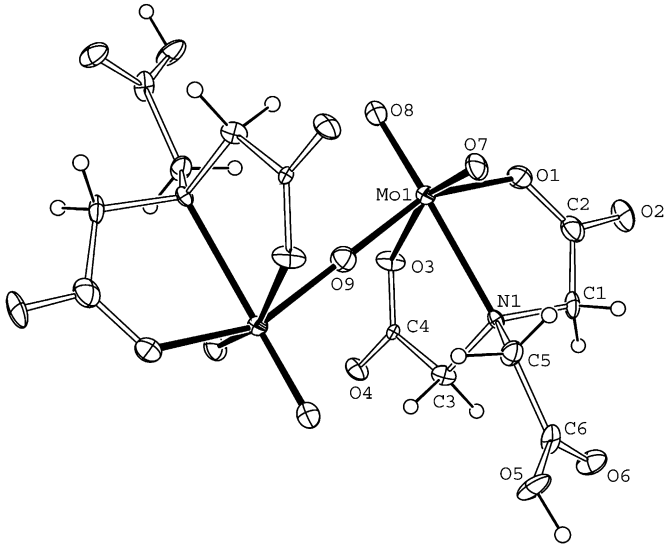

Fig. 3. ORTEP plot of the anion in $Na_2[Mo_2O_5(Hnta)_2]$ (**3**) at the 30% probability level.

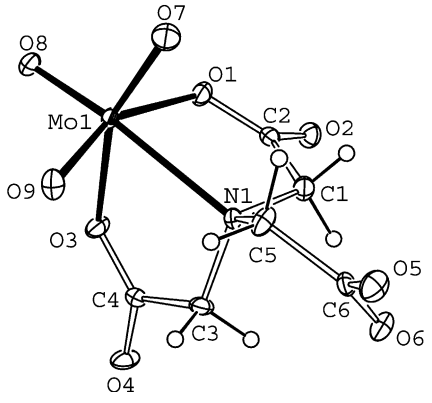

Fig. 4. ORTEP plot of the anion in $Na_3[MoO_3(nta)]\cdot 4H_2O$ (**4**) at the 30% probability level.

As shown in Table 2, the Mo–O distances in nitrilotriacetato molybdates vary systematically. The Mo=O bond lengths lie in the range 1.694–1.737 Å, indicating that they are double bonds. The observed O=Mo=O angles of 106.6(3), 106.1(3), 106.4(2), 105.8(2), 106.7(2), 104.9(2) and 105.8(1)° in compounds **1**–**4** are consistent with the large repulsion between oxo groups with short bonds to the metal atom. The bridging distances Mo–O_b–Mo are 1.8846(6), 1.8774(7), 1.8714(7) and 1.8724(3) Å. The Mo–N bonds are similar in all four structures, being in the range 2.37–2.46 Å.

3.3. IR spectroscopy

The infrared spectra of complexes **1**–**4** show strong and sharp absorption bands for the carboxylate groups of the coordinated nitrilotriacetate. Asymmetric stretching vibrations $\nu_{as}(COO^-)$ appear between 1673 and 1600 cm^{-1}. The corresponding symmetric stretches $\nu_s(COO^-)$ appear between 1448 and 1318 cm^{-1}. Compound **3** gives a typical band of a non-bonded and undissociated carboxylic acid group at 1750 cm^{-1}. The weak absorption bands at 1735 and 1719 cm^{-1} for compounds **1** and **2** indicate strong H-bonds between the free carboxylic acid and carboxyl groups. All of the carboxyl absorptions are shifted to lower frequencies with respect to those of the free nitrilotriacetic acid due to the influence of hydrogen bonds and counterions. These observations are in accord with the formation of a chelate ring and the bridging mode of the nitrilotriacetate ligand. Loss of the proton in compounds **1** and **2** and the absence of a oxo-bridge group in compound **4** reduce the number of bands and displace them to lower frequencies. In the region between 982 and 857 cm^{-1}, these complexes show several bands that result from the presence of *cis*-dioxo cores in two different environments. The low frequency symmetric MoO_2 stretching may be explained by intramolecular hydrogen bonding and the coordination of a sodium or ammonium cation. The strong IR band only observed for the dimers around 700 cm^{-1} may be attributed to the Mo–O_b–Mo bridges. The absence of IR bands between 1740–1700 cm^{-1} and 790–775 cm^{-1} indicate full deprotonation of β-carboxyl group in compound **4** [25].

3.4. Solution NMR spectroscopy

The solution ^{13}C NMR spectra of complexes **1**–**4** were measured in D_2O. The ^{13}C NMR spectra of **1** and **2** in Fig. 5 show two sets of resonances, which can be attributed to the nitrilotriacetate ligands in the molybdenum

Table 2
Comparisons of the Mo–O and Mo–N distances (Å) in the complexes of nitrilotriacetato molybdates (VI)

Compound	Mo–O_t	Mo–O_b	Mo–O_{c1}	Mo–O_{c2}	Mo–N	Ref.
$K_3[MoO_3(nta)]\cdot H_2O$	1.737(5)		2.176(4)	2.245(3)	2.388(5)	[11]
$Na_2[Mo_2O_5(Hnta)_2]\cdot 8H_2O$	1.695(6)	1.880(1)	2.069(5)	2.134(5)	2.410(6)	[12]
$(pyH)_2[Mo_2O_5(Hnta)_2]$	1.695(3)	1.870(3)	2.071(3)	2.145(3)	2.413(3)	[13]
$[(n\text{-}C_4H_9)N]_2[Mo_2O_5(Hnta)_2]\cdot H_2O$	1.702(7)	1.854(7)	2.077(7)	2.144(6)	2.457(7)	[14]
$Na_2[Mo_2O_5(Hnta)_2]$	1.703(5)	1.8846(6)	2.029(5)	2.187(5)	2.394(6)	
$Na_{6n}\{[Mo_2O_5(ntaH)_2][(nta)_2Mo_2O_5]\}_n\cdot 12nH_2O$	1.697(6)	1.8774(7)	2.083(5)	2.110(5)	2.436(6)	
	1.698(5)	1.8714(7)	2.074(5)	2.115(5)	2.377(6)	this work
$(NH_4)_{3n}[Mo_2O_5H(nta)_2]_n\cdot 4nH_2O$	1.695(3)	1.8724(3)	2.059(3)	2.162(3)	2.405(3)	
$Na_3[MoO_3(nta)]\cdot 4H_2O$	1.728(3)		2.186(3)	2.214(3)	2.395(3)	
Average (Å)	1.706	1.873	2.092	2.162	2.408	

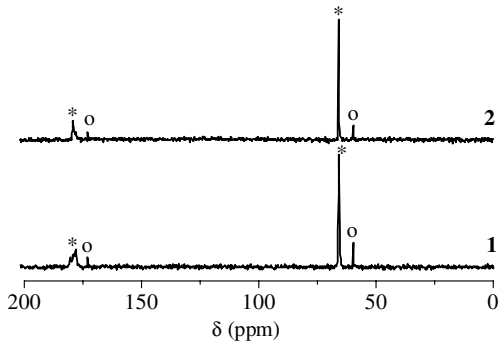

Fig. 5. ^{13}C NMR spectra of the complexes: (bottom) $Na_{6n}\{[Mo_2O_5(ntaH)_2][(nta)_2Mo_2O_5]\}_n \cdot 12nH_2O$ (**1**); (top) $(NH_4)_{3n}[Mo_2O_5H(nta)_2]_n \cdot 4nH_2O$ (**2**). The symbol '∗' indicates resonance signals of the coordinated ligand, '○' of the free ligand.

complexes and the decomposed free nitrilotriacetate [Na_2Hnta: ^{13}C NMR δ_C (D_2O) 171.3 $(CO_2)_\beta$, 58.1 (CH_2)]. Complex **1** shows one resonance in the high-field region (65.5 ppm) for the methylene groups of the nitrilotriacetate ligands. The resonances at 180.2, 179.0 and 177.8 ppm in the lower-field region can be assigned to the β-carboxylate carbons coordinated to the Mo(VI) central ion. The ^{13}C NMR spectra of **2**–**4** resemble one another. Large downfield shifts of the β-carboxylate ($\Delta\delta$ 7.7, 4.4, 6.8) and methylene ($\Delta\delta$ 7.6, 3.5, 6.5) carbons compared with the free nitrilotriacetate are observed for **2**–**4**, respectively. The downfield shifts of the β-carboxylate and CH_2 groups are in agreement with those in earlier studies [16,26]. The ^1H NMR spectra of all four complexes show one wide peak for the methylene protons, which may arise from the similar magnetic environment in solution. The similarities of the NMR spectra of the isolated Mo(VI) complexes suggest that the coordination mode of the nitrilotriacetate ligand is similar not only in the solid state but also in solution. The very strong hydrogen bonds in **1** and **2** may be related to the downshift of the β-carboxyl group from 177.8 to 179.0 ppm.

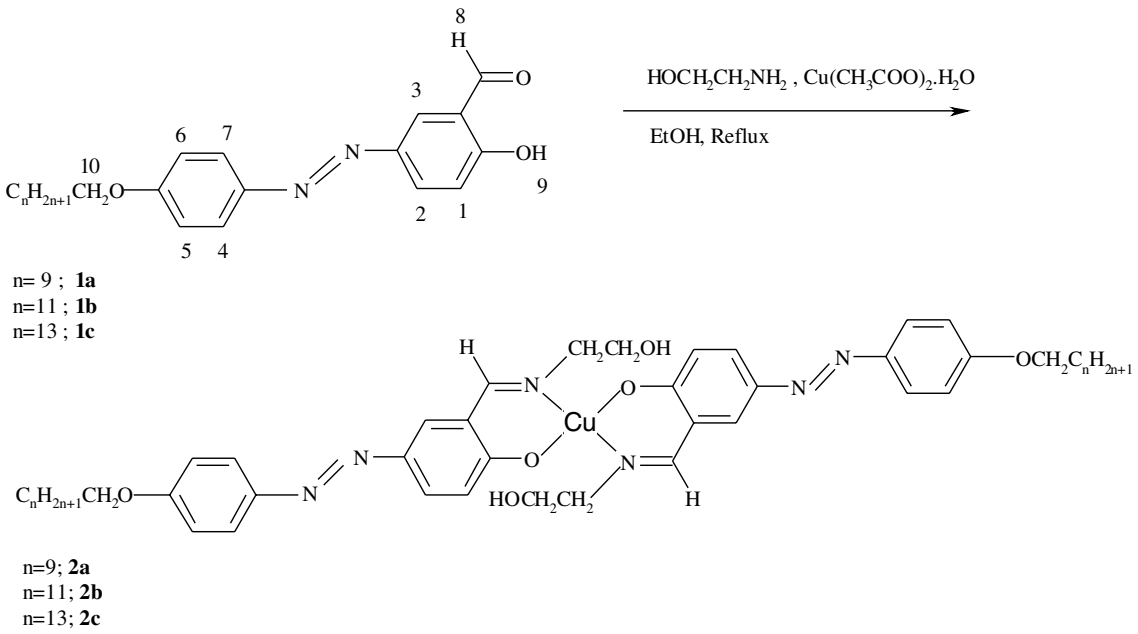

Scheme 1. Synthetic route to the copper complexes.

2.2. Physical measurements

Elemental (C, H and N) analyses were carried out on a Perkin–Elmer automatic equipment model 240B. Electron impact (70 eV) mass spectra were recorded on a Finnegan-mat GC–MS–DS spectrometer model 8430. Infrared spectra were taken with a FT-IR Bruker, vector 22 spectrometer using KBr pellets in the 400–4000 cm^{-1} range. The DSC thermograms of the compounds were obtained on a Mettler–Toledo DSC 822e module, which was calibrated with indium metal ($T = 156.6 \pm 0.3$, $\Delta H = 28.45 \pm 0.6$ J g^{-1}). Samples of 2–5 mg in the solid form were placed in aluminum pans (40 μl) with a pierced lid, and heated or cooled at a scan rate of 10 °C min^{-1} under a nitrogen flow. TGA was carried out on a Mettler–Toledo TGA 851e at a heating rate of 10 °C min^{-1} under a nitrogen atmosphere. The optical observations were made with a Zeiss polarizing microscope equipped with a Linkam THMSG 600 heating and cooling stage and a Linkam THMS 93 programmable temperature-controller. ^{1}H NMR spectra were obtained on a Bruker FT-NMR AC-400 (400 MHz) spectrometer with deutrated chloroform as the solvent. All chemical shifts are reported in δ(ppm) relative to tetramethylsilane as an internal standard.

2.3. Materials

All homologue materials were prepared similarly.

2.3.1. 5-(4-Decyloxyphenylazo) salicylaldehyde (*1a*)

This compound was prepared as described in the literature [20]. Yellow, yield 80%, m.p. 126 °C. MS *m/z* (relative intensity): 355.4 (M+1, 15), 354.3 (M, 40), 241.2 (M−$C_{10}H_{21}$, 25), 121.0 (M−$C_{10}H_{21}OC_6H_4N_2$, 100). *Anal.* Calc. for $C_{23}H_{30}N_2O_3$: C, 71.16; H, 7.39; N, 7.90. Found: C, 70.71; H, 7.12; N, 7.54%. ^{1}H NMR (400 MHz, $CDCl_3$) δ 11.27 (s, H-8), 10.02 (s, H-9), 8.18 (d, *J* 3.2 Hz, H-3), 8.14 (dd, *J* 3.1, 8.4 Hz, H-2), 7.91 (dd, *J* 3.1, 8.2 Hz, H-4, H-7), 7.10 (d, *J* 8.7, H-1), 7.01 (dd, *J* 3.6, 8.3 Hz, H-5,H-6), 4.05 (t, *J* 7.1 Hz, H-10), 1.81–1.00 (15H, alkyl chain).

2.3.2. 5-(4-Dodecyloxyphenylazo) salicylaldehyde (*1b*)

Yellow, yield 80%, m.p. 123 °C. MS *m/z* (relative intensity): 411.6 (M+1, 15), 410.6 (M, 45), 242.5 (M−$C_{12}H_{25}$, 25), 121.6 (M−$C_{12}H_{25}OC_6H_4N_2$, 100). *Anal.* Calc. for $C_{25}H_{34}N_2O_3$: C, 73.15; H, 8.35; N, 6.83. Found: C, 72.73; H, 8.14; N, 6.47%. ^{1}H NMR (400 MHz, $CDCl_3$) δ 11.26 (s, H-9), 10.02 (s, H-8), 8.15 (d, *J* 2.8 Hz, H-3), 8.13 (dd, *J* 2.9, 8.2 Hz, H-2), 7.89 (dd, *J* 3.0, 7.9 Hz, H-4, H-7), 7.11 (d, *J* 8.1 Hz, H-1), 7.01 (dd, *J* 3.2, 7.9 Hz, H-5, H-6), 4.04 (t, *J* 6.7 Hz, H-10), 1.84–0.87 (23H, alkyl chain).

2.3.3. 5-(4-Tetradecyloxyphenylazo) salicylaldehyde (*1c*)

Yellow, yield 80%, m.p. 123 °C. MS *m/z* (relative intensity): 411.6 (M+1, 15), 410.6 (M, 45), 242.5 (M−$C_{14}H_{29}$, 25), 121.6 (M−$C_{12}H_{25}OC_6H_4N_2$, 100). *Anal.* Calc. for $C_{27}H_{38}N_2O_3$: C, 73.15; H, 8.35; N, 6.83. Found: C, 72.73; H, 8.14; N, 6.47. ^{1}H NMR (400 MHz, $CDCl_3$) δ 11.26 (s, H-9), 10.02 (s, H-8), 8.15 (d, *J* 2.8 Hz, H-3), 8.13 (dd, *J* 2.9, 8.2 Hz, H-2), 7.89 (dd, *J* 3.0, 7.9 Hz, H-4, H-7), 7.11 (d, *J* 8.1 Hz, H-1), 7.01 (dd, *J* 3.2, 7.9 Hz, H-5, H-6), 4.04 (t, *J* 6.7 Hz, H-10), 1.84–0.87 (23H, alkyl chain).

2.3.4. Syntheses of the copper complexes

The copper complexes were prepared in similar manners using a method described elsewhere [21]. Thus, an alcoholic solution containing 10 mmol of ethanolamine was added to a solution of 5-alkoxyphenylazo salicylaldehyde (10 mmol)

in 50 ml of boiling absolute ethanol. Then 10 mmol sodium acetate in 10 ml water was added to the above reaction system. Finally 50 ml boiling ethanol solution containing 10 mmol $Cu(CH_3COO)_2 \cdot H_2O$ was added. The reaction mixture was kept boiling for 25 min. Crystals precipitated from the solution and recrystallization was performed from ethanol/chloroform (1:1 v/v) solution. The copper complexes were obtained as brown micro crystals. The micro crystals were filtered off, washed with absolute ethanol and then recrystallized from ethanol–chloroform (1:3 v/v).

Complex ***2a****:* Brown, yield 80%. *Anal.* Calc. for $C_{50}H_{68}N_6O_6Cu$: C, 65.83; H, 7.46; N, 9.22. Found: C, 65.4; H, 7.2; N, 9.2%.

Complex ***2b****:* Brown, yield 85%. *Anal.* Calc. for $C_{54}H_{76}N_6O_6Cu$: C, 66.98; H, 7.86; N, 8.68. Found: C, 66.6; H, 7.4; N, 8.2%.

Complex ***2c****:* Brown, yield 75%. *Anal.* Calc. for $C_{58}H_{84}N_6O_6Cu$: C, 68.00; H, 8.21; N, 8.21. Found: C, 67.6; H, 7.9; N, 8.0%.

3. Results and discussion

3.1. Synthesis

5-(4-Alkoxyphenylazo) salicylaldehyde homologues (**1a**–**c**; see Scheme 1) were synthesized in a three-step process, in which the hydroxy group in 4-nitrophenol is first replaced by an alkoxy chain followed by reduction of the nitro group to an amine. In the third step, salicylaldehyde was coupled with the diazonium chloride obtained from the 4-alkoxyaniline. **1a**–**c** were purified by repeated crystallization from ethanol to give a single spot on thin layer chromatography, and characterized by IR, ^{1}H NMR, mass spectroscopy and elemental analyses. The copper complexes were obtained in good yield and purity, and were characterized by C, H, N elemental analyses and IR spectroscopy. These copper compounds are all paramagnetic and their ^{1}H NMR spectra display only broad alkoxy signals. All other proton signals close to the paramagnetic copper centers are unobserved. The elemental analyses and spectroscopic data for the new compounds gave satisfactory results. Some physical and characterization data for 5-(4-alkoxyphenylazo) salicylaldehyde homologues and the copper complexes are given in the experimental section and selected IR data are tabulated in Table 1. The IR spectral frequencies of the synthesized compounds were obtained using KBr pellets as described in the experimental section. In the compounds **1a**–**c**, the hydroxyl group was observed at 3190 cm^{-1} because the intramolecular hydrogen bonding between OH and the formyl group in compound **1** leads to a decrease of the stretching frequency of OH, and the carbonyl group was observed at 1666 cm^{-1}. In the IR spectra of the copper complexes (**2a**–**c**), the phenolic OH group disappeared and a free lateral OH group was observed as a broad peak centered at 3320 cm^{-1} [21]. In addition, the C=N group was observed at 1620 cm^{-1}. It is well recognized that the C=N stretching frequency in bidentate salicylidenic schiff base ligands with N-alkyl structures appears in the 1635–1640 cm^{-1} region [14–17,22], so the appearance of C=N at 1622 cm^{-1} (at a lower wavenumber than the free schiff base ligands) in the copper complexes demonstrates that C=N has been formed by a [1 + 1] condensation reaction and that it is coordinated to the copper center. On the other hand, the lack of a phenolic OH group in the copper complexes indicates that the OH group has been deprotonated and is coordinated to the metal ion as $-O^-$. Reduction of the double bond character of the C=N bond, which is caused by the coordination of nitrogen into the metal center, is in agreement with results obtained from other similar complexes, described previously [14–17,22]. Based on these observations and the elemental analyses results we conclude that the Schiff-base ligands are coordinated to metal atoms as bidentate (N–O) ligands in a 2:1 ratio.

On the basis of the literature data for copper complexes with a similar coordination environment, the OH group is free of coordination [21] and is not bonded to the metal center. This fact may be related to the strong John–Teller effect in d^9 Cu^{+2}, which avoids the coordination of OH to the metal center. Therefore, it is suggested that the Cu(II) centres have square planar or nearly square planar coordination according to the common stereochemistry of this kind of compound [8,23].

3.2. Mesomorphism

The mesomorphic properties of 5-(4-^{n}alkoxyphenylazo) salicylaldehyde homologues (**1a**–**c**) and the Cu(II) complexes have been studied by polarizing optical microscopy observations using a heating–cooling stage and the phase transition temperature and enthalpy were obtained by differential scanning calorimetry (DSC). Phase transition temperatures along with the corresponding enthalpy values for the copper complexes are summarized in Table 2. The aldehyde homologues (**1a**–**c**) did not show any liquid crystalline character. These compounds clearly melted and transformed

Table 1
Selected IR data for the Schiff base ligands and metal complexes

Compound	ν (cm^{-1})					
	O–H	C–H (aromatic)	C–H (aliphatic)	C=N	C–O (etheric)	C=O
1(**a**–**c**)	3185–90(br, m)	3069–71(m)	2950–2850(s)		1241	1665–6(s)
2(**a**–**c**)	3220–40(br, m)	3050–60(m)	2955, 2860(s)	1621–3(s)	1255–86(s)	

s, strong; m, medium; br, broad.

Table 2
Transition temperatures and enthalpy changes of the copper(II) complexes

Compound	Transition[a]	T[b] (°C)	ΔH[b] (kJ mol^{-1})
2a	Cr_1–Cr_2	56.1	1.61
	Cr_2–Cr_3	167.0	1.59
	Cr_3–SmC	204.3	53.43
	SmC–I(dec)[c]	240.3	5.27

[c] dec: decomposition occurred immediately at clearing point.

into isotropic liquids and no mesophase was observed on the heating or cooling cycle from optical observations. The melting points of the ligands decrease with increasing n value (alkyl chain length, see Scheme 1).

All the copper complexes reported in this work exhibit liquid crystalline behavior. Fig. 1(**2a**–**2c**) shows the DSC curves of the copper complexes. The thermal behaviors of the complexes were similar as it is apparent from the DSC curves; therefore we describe here the behavior of compound **2a** as a representative example. The first heating cycle exhibits four endothermic transitions at 56.1, 167.0, 204.3 and 240.3 °C with ΔH values of 1.61, 1.59, 532.43 and 5.27 kJ mol^{-1}, respectively. The first two transitions correspond to the transition of a crystal phase to another crystal phase and cannot be observed optically. The third peak corresponds to the transition of a crystal phase to a mesophase. The mesophase was examined by optical observation. A highly viscous mesophase with a typical Schlieren texture [24] was observed for all copper complexes under POM. The fourth peak, having a relatively small ΔH value, corresponds to the transition of the mesophase to an isotropic liquid. This process can also be observed optically. A relatively larger clearing enthalpy for the mesophase-to-isotropic transition was observed at higher temperatures (203–240 °C) indicating that the mesophases were highly ordered. Results from DSC and POM therefore suggest the presence of a SmC mesophase. A microscopic picture from the SmC mesophase for complex **2a** is illustrated in Fig. 2.

Continued heating after the clearing point causes a considerable amount of decomposition immediately after isotropization, which has been detected by exothermic peaks in the DSC trace and optical observations. The subsequent cooling and heating processes do not give reproducible

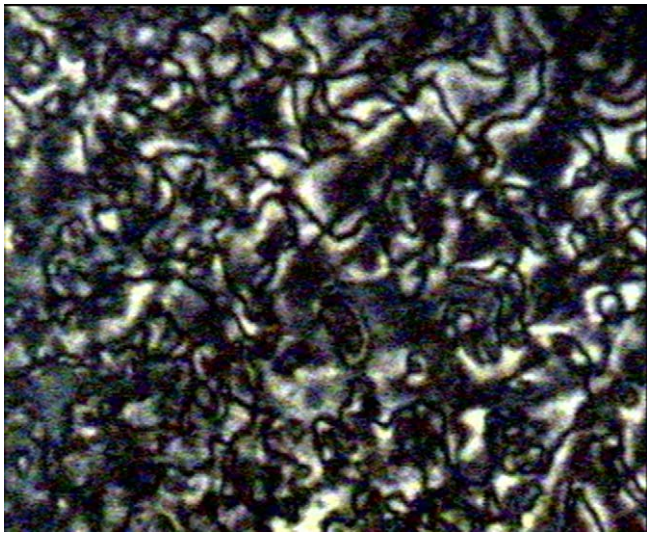

Fig. 2. Optical texture observed for **2a** through crossed polarizers at 210 °C.

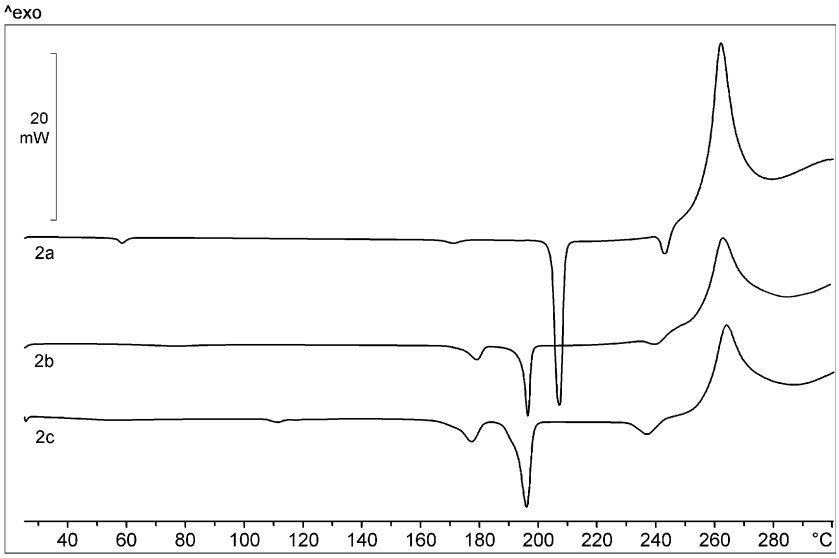

Fig. 1. DSC thermograms of the copper complexes.

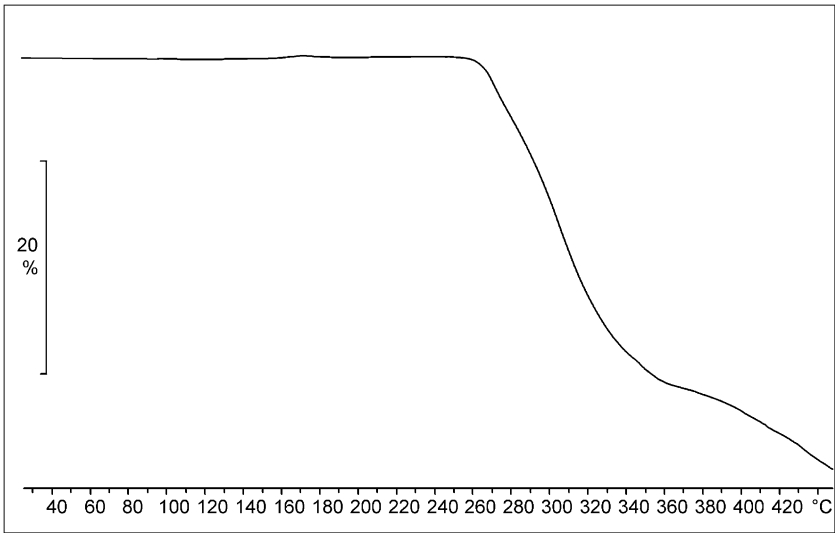

Fig. 3. TGA curve of **2a**.

results because thermal decomposition occurs during the first heating cycle. All the other members of this series of compounds also exhibit thermal decomposition behavior. Therefore, in Table 1, phase transition temperatures of the copper complexes are reported from the first heating cycle of the DSC thermogram. In general, melting temperatures of these copper compounds decrease slightly by increasing the alkyl chain length. The variation of clearing temperatures with increasing chain length has similar trends. In the first heating scan if the temperature increase is within the clearing point, in the first cooling stage the transition of isotropic liquid to mesophase is observed at 241 °C and the mesophase starts to crystallize at 224 °C, as detected by DSC and confirmed by POM, but after the clearing point the sample is decomposed and in the first cooling cycle no transitions was observed.

To understand the thermal decomposition process, the copper compounds were examined by thermogravimetric analysis (TGA). The TGA thermogram of the copper compounds at a heating rate of 10 °C/min shows that decomposition begins at 260 °C, which is near the temperature of clearing to the isotropic liquid. All the copper compounds have similar TGA thermograms. Fig. 3 shows the TGA thermogram of **2a** as a representative example.

The copper complexes reported in this work are the first example of metallomesogens based on two ring salicylidenic schiff base ligand system with an azo moiety and a polar OH on the ligands (N–CH_2CH_2OH). Recently some mesogenic copper complexes which have a similar structure to that of the title complex of this work have been reported. We have recently reported the investigation of liquid crystalline properties of bis[5-((4-^{n}alkoxyphenyl)azo)-*N*-(^{n}alkyl)-salicylaldiminato]copper(II) complex homologues [15]; metallomesogens based on two ring salicylidenic schiff base ligand with an azo moiety and an alkyl group on the ligands (N-alkyl). These complexes exhibited monotropic nematic (thermodynamically unstable) liquid crystalline character. Furthermore, Hoshino [25], Cruso [26], Marcos [27] and Barbera [28] have reported the nematic liquid crystalline properties of bis[4-((4-alkoxy)benzoyloxy)-salicylaldimine-*N*-alkyl]copper(II) complexes, but the complexes with an OH lateral group reported in this work exhibit a high order enantiotropic (thermodynamically stable) SmC phase. The comparison of mesogenic behavior of N-alkyl complexes with N–CH_2CH_2OH complexes demonstrates the role of the OH group on the mesogenic character. We can conclude that the presence of the OH group on the ligands considerably improves the liquid crystalline behavior from monotropic nematic to enantiotropic SmC phase in this type of metallomesogenic systems. This fact may be related to the attractive intermolecular interactions between HO···Cu and /or HO···HO.

4. Conclusion

In this work we have prepared copper complexes derived from 5-((4-^{n}alkoxyphenyl)azo)-*N*-(ethanol)-salicylaldimine homologues as the first example of azo-containing metallomesogens with a lateral OH group. In summary, the study outlined above has shown that all complexes exhibit an enantiotropic smectic C mesophase. Melting and clearing temperatures of the complexes slightly decrease with increasing alkoxy chain length. The mesomorphism can be greatly improved by introducing the lateral OH group close to the central core in this type of copper-containing metallomesogenic system.

with respect to 2 M Na_2WO_4 for ^{183}W and 85% H_3AsO_4 for ^{75}As. Crystals of **1** were dissolved in 0.2 M NaCl for ^{183}W and ^{75}As NMR. In order to obtain sufficient concentration for ^{183}W NMR, compound of **3** was converted to the lithium salt by treatment with a Li^+-form cation-exchange resin.

2.2. Preparation of compounds

2.2.1. $Na_{12}[Na_2As_2W_{18}U_2O_{72}]\cdot 35H_2O$ (1)

Glacial acetic acid (3.5 mL) was added to a solution of $Na_2WO_4\cdot 2H_2O$ (14.85 g, 45 mmol) and $Na_2HAsO_4\cdot 7H_2O$ (1.1.58 g, 55 mmol) in 50 mL H_2O, and then the resulting solution was added in small portions to a solution of $UO_2(OAc)_2\cdot 2H_2O$ (2.25 g, 5.30 mmol) in 50 mL H_2O and refluxed for 2 h. Addition of solid NaCl (15 g) to the filtrate led to a yellow crystalline powder, which was recrystallized in 0.2 M NaCl solution. Yellow crystals were obtained at 5 °C after 10 days. Yield 11.2 g (74.2%) Elemental analysis for $Na_{12}[Na_2As_2W_{18}U_2O_{72}]\cdot 35H_2O$: Na, 5.33; As, 2.48; W, 54.79; U, 7.88; H_2O, 10.43. Found: Na, 5.20; As, 2.24; W, 54.45; U, 7.50; H_2O, 10.00%.

2.2.2. $(NH_4)_{13}[NH_4As_2W_{18}U_2O_{72}]\cdot 17H_2O$ (2)

Complex **1** was prepared in solution as described above, and then ammonium chloride (20 g) instead of sodium chloride was added to the solution with stirring. A yellow-green solid formed immediately which was filtered off, redissolved in the least amount of hot water and twice precipitated by ammonium chloride (10 g). The resulting yellow-green solid was recrystallized in warm water. Crystals suitable for structure determination were obtained overnight. Yield 11.0 g (78%).

Elemental analysis for $(NH_4)_{13}[NH_4As_2W_{18}U_2O_{72}]\cdot 17H_2O$: As, 2.65; W, 58.61; U, 8.43; NH_3+H_2O, 9.88. Found: As, 2.18; W, 57.55; U, 7.95; NH_3+H_2O, 9.45%.

2.2.3. $K_{13}[KAs_2W_{18}U_2O_{72}]\cdot 10H_2O$ (3)

$K_{13}[KAs_2W_{18}U_2O_{72}]\cdot 10H_2O$ (**3**) was prepared according to a procedure similar to that for **2**. Instead of ammonium chloride, potassium chloride (20 and 10 g) was added. Yield 12.5 g (86%).

Elemental analysis for $K_{13}[KAs_2W_{18}U_2O_{72}]\cdot 10H_2O$: K, 9.39; As, 2.57; W, 56.75; U, 8.14; H_2O, 3.40. Found: K, 8.65; As, 2.28; W, 56.00; U, 7.72; H_2O, 3.20%.

2.3. Single crystal X-ray diffraction analysis

A pale yellow plate of $(NH_4)_{13}[NH_4As_2W_{18}U_2O_{72}]\cdot 17H_2O$ with dimensions $0.40\times 0.35\times 0.1$ mm^3 which crystallizes in the monoclinic space group $P2_1/m$ with $a=12.488(2)$ Å, $b=20.248(4)$ Å, $c=17.579(5)$ Å, $\beta=101.43°$, $V=4364.5(13)$ Å^3 and $Z=2$ was used for crystallographic analysis. The data were collected at 120(2) K on a Brucker SMART 1000 CCD single crystal diffractometer with graphite-monochoromated Mo Kα radiation ($\lambda=0.71073$ Å). A total of 12760 independent reflections ($2\theta_{max}=60.14°$ and $R_{int}=0.1046$) were recorded, of which 6881 reflections were considered [$I>2\sigma(I)$]. The final cycle of refinement converged at $R=0.0639$ and $R_w=0.1396$ [$I>2\sigma(I)$].

Crystallographic data and structure refinement parameters are listed in Table 1. Routine Lorentz and polarization corrections were applied and an absorption correction was performed using the SADABS program [10]. The structure was refined with SHELXL-97 [11] by full-matrix least squares on F^2. Selected bond lengths and bonds angles of **2** are given in Table 2.

3. Results and discussion

3.1. Syntheses and stabilities

When the pH of the WO_4^{2-} and $HAsO_4^{2-}$ solution is adjusted to 7–7.5 by glacial acetic acid, it seems that A-$AsW_9O_{34}^{9-}$ is formed [12]. This solution reacts with Cd^{2+}, Co^{2+}, Mn^{2+}, Zn^{2+} to form $[As_2W_{18}M_4(H_2O)_2O_{68}]^{10-}$ in high yield with a 1–2 h reflux [13]. But due to size and space restrictions, the solution reacts with the trans dioxouranium(VI) ion (UO_2^{2+}) to form $[Na_2As_2W_{18}U_2O_{72}]^{12-}$ (**1**). The anion **1** is formed in solution in the presence of excess Na^+, with addition of the ammonium or potassium ion a yellow-green solid is immediately formed. With addition of the ammonium or potassium ion, **1** is converted to **2** or **3**, and with elimination of the potassium ion and addition of sodium ion (addition of $NaClO_4$), **3** is convert to **1**. The sodium salt in the presence of excess Na^+, and the ammonium and potassium salts are stable in aqueous solution pH 5.5–7. These complexes are unstable in acidic media, we observed that when a solution of **1**, **2** or **3** (1.0 g in 10 mL H_2O) is passed through a strongly acidic ion exchange (Dowex-50W-X8) column, the main product is the Dawson anion, $[As_2W_{18}O_{68}]^{6-}$, which is isolated as $H_6[As_2W_{18}O_{68}]$. The IR spectrum of this compound (972(s), 912(s), 868(s), 745(vs)) is the same as A-α-$H_6[As_2W_{18}O_{68}]$ [14]. This observation confirms that the $AsW_9O_{34}^{9-}$ units in the complexes are the A-isomer (see below).

3.2. IR and Raman spectroscopy

The infrared spectra of **2** and **3** are similar, but that of **1** is slightly different those of **2** and **3** (Fig. 1). IR and Raman spectra of **1** (Fig. 2) are not similar, therefore it confirms that **1** has a centrosymmetric structure.

3.3. NMR spectroscopy

The ^{75}As NMR spectrum of **1** shows one peak at 690.20 ppm and the ^{183}W NMR of **1** shows five peaks with an intensity ratio of 2:2:2:1:2 at −91.18, −115.34, −146.15, −177.27, −199.45, respectively (Fig. 3). These are consistent with the C_i structure. The results of the elemental analysis, the single-line ^{75}As and ^{31}P NMR and five-line ^{183}W NMR pattern of both of compounds show that**1** and $[Na_2P_2W_{18}U_2O_{72}]^{12-}$ are isostructural [8a]. Therefore, the structure of **1** consists of two A-α-$AsW_9O_{34}^{9-}$ that sandwich two uranyl and two sodium ions, leading to a structure of C_i symmetry. In the filling of the sandwich, the UO_2^{2+} and Na^+ ions occupy opposite corners of a rectangular array. In order to obtain a solution of **3** that was concentrated enough for ^{183}W NMR spectroscopy it was necessary to convert the potassium salt by the use of a lithium form of cation exchange resin. The ^{183}W NMR spectrum of the lithium salt of **3** shows eight peaks with an approximate intensity ratio of (2 + 1):2:2:(2 + 2):2:1:2:2

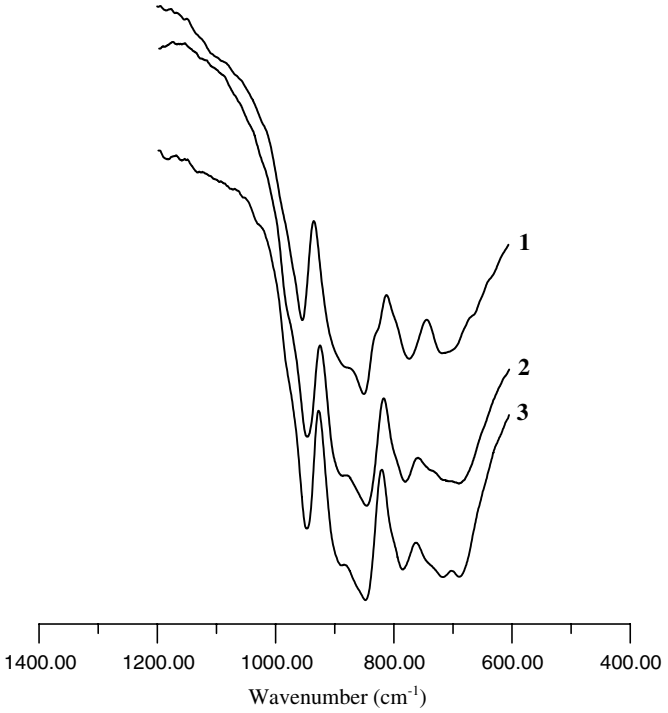

Fig. 1. IR spectra of **1**–**3**.

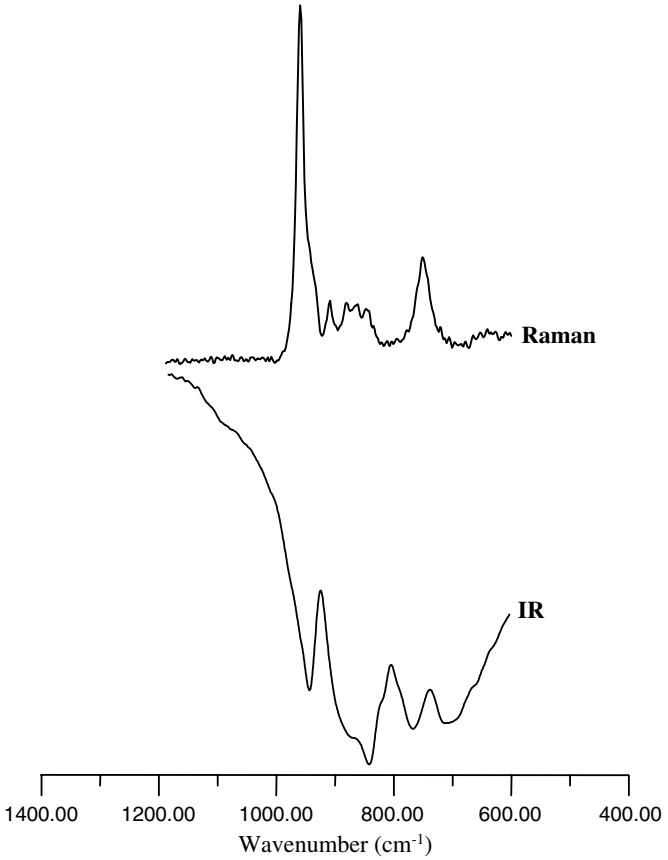

Fig. 2. IR and Raman spectra of **1**.

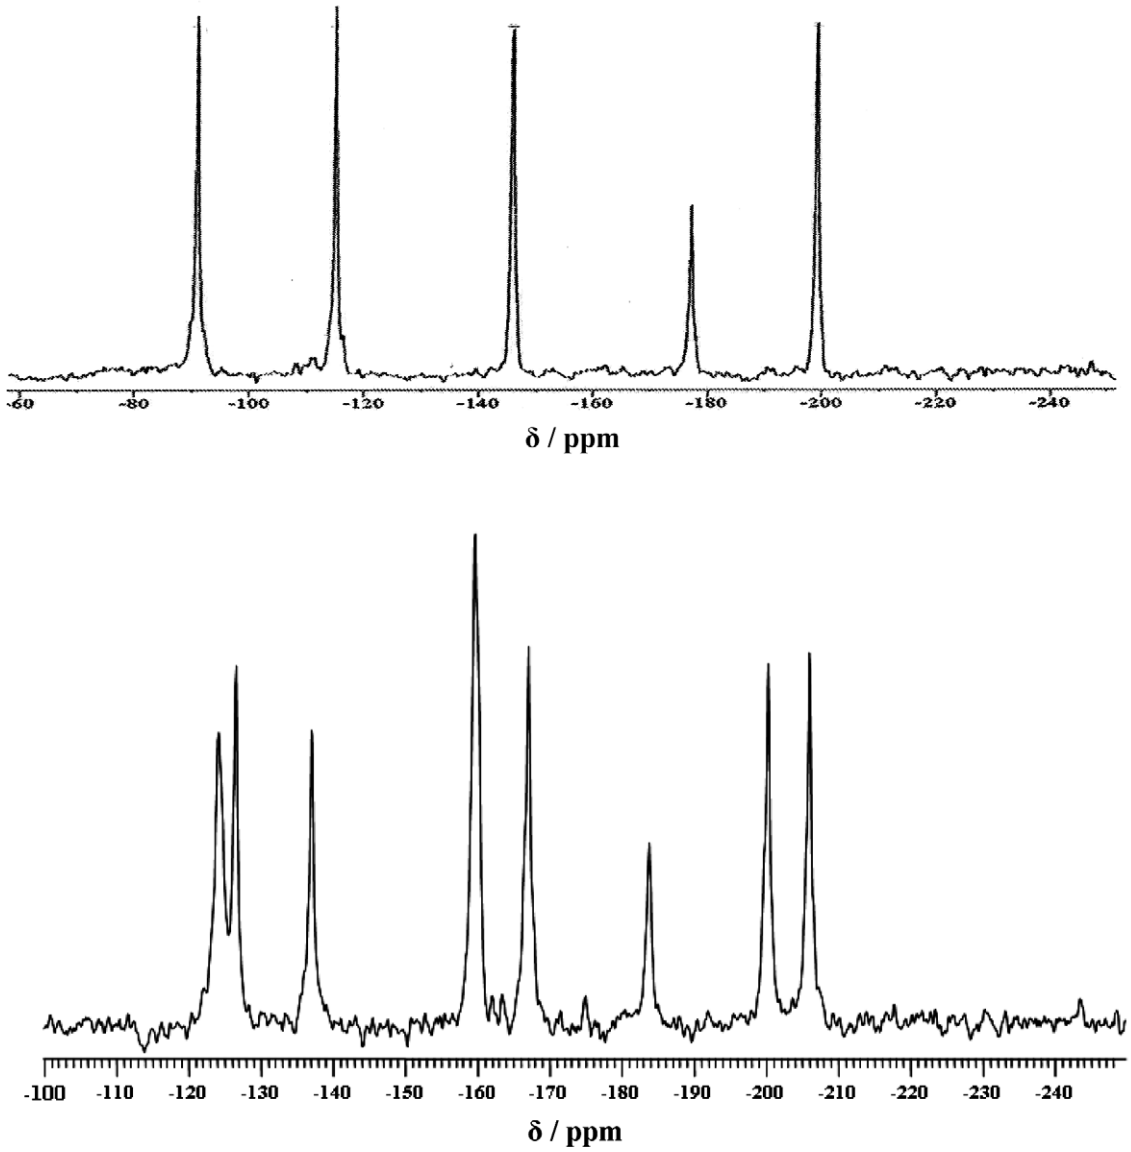

Fig. 3. ^{183}W NMR spectrum of **1** (top) and ^{183}W NMR spectrum of the lithium salt of **3** (bottom).

at −121, −127, −137, −160, −167, −184, −200, −206, respectively, (Fig. 3). The ^{183}W NMR pattern of the lithium salt shows that the anion has an approximate C_s structure. The anion structure in solution (lithium salt) and crystal (ammonium and potassium salt) is the same (see below). Therefore, due to their size, lithium ions cannot replace potassium ions in the anion hole.

3.4. X-ray single crystal structure analysis

Single crystal analysis has been carried out on **2**, which is isostructural with **3**. Since it is not possible on the basis of electron density to discriminate between water molecules and ammonium cations in the structures, the identity of the species occupying the equatorial lacunary site in the structure of anion **2** is not completely certain. Similar features were observed in the structures of the ammonium and potassium salts of the tungstophosphate complex and in the last case the atom could be modelled as a potassium ion [8a]. It therefore seems probable that the sandwiched "atom" is an ammonium ion in both phosphate and arsenate structures. The structure of **2** (Fig. 4) consist of two A-α-$AsW_9O_{34}^{9-}$ anions that sandwich unsymmetrically two uranyl and one ammonium ion. This arrangement leads to a structure with idealized C_s symmetry. The quasi-pentagonal-bipyramidal coordination demands of the uranium atoms means that the two $AsW_9O_{34}^{9-}$ groups are not equivalent; each uranium forms three U–O bonds to one $AsW_9O_{34}^{9-}$ moiety but only two such bonds to the other. Each uranium atom forms two equatorial bonds to the terminal oxygens (O_d) of an edge-shared pair of WO_6 octahedra of one

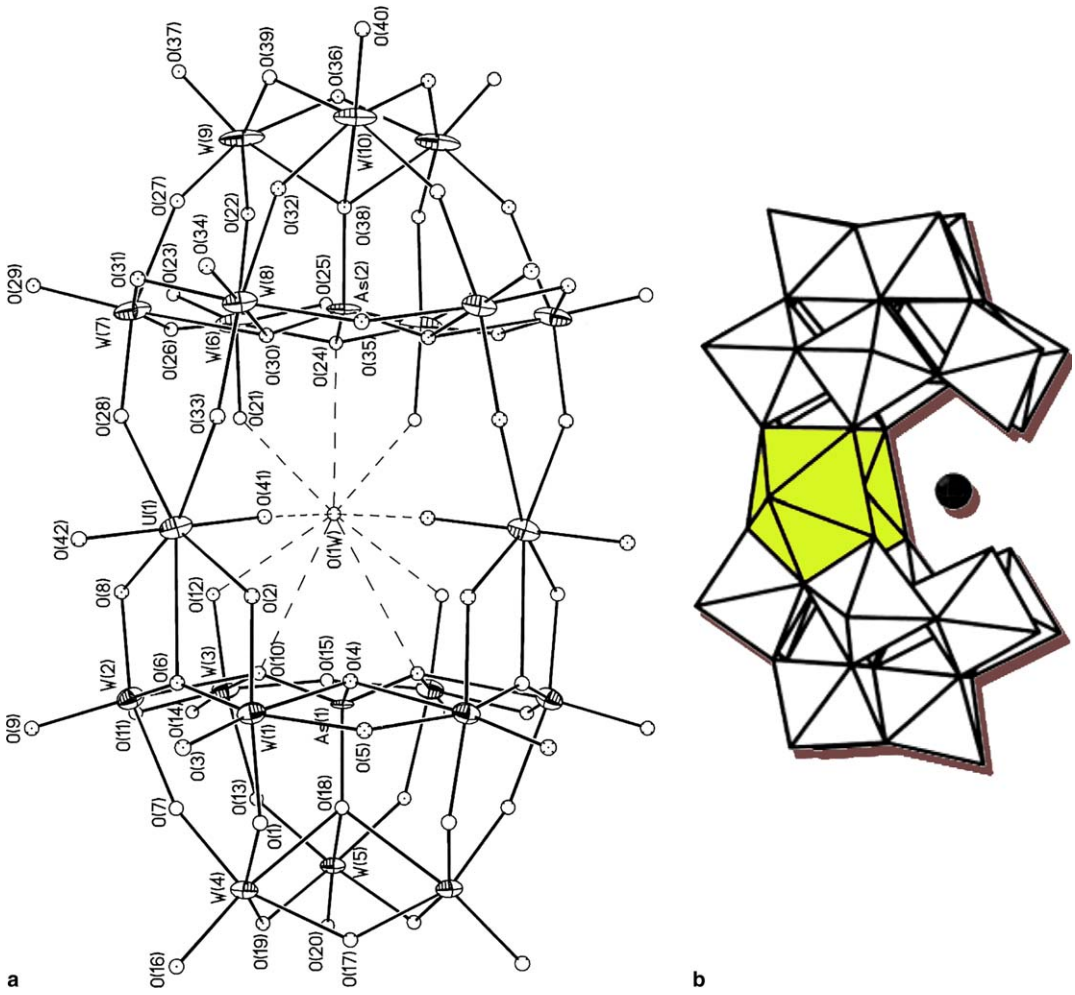

Fig. 4. (a) Thermal ellipsoid plot of **2**. (b) Polyhedral representations of **2**. The presumed ammonium cation (see text) is indicated by the black sphere.

$AsW_9O_{34}^{9-}$ and three bonds to terminal and bridging oxygen (O_c) of a corner-shared pair of octahedra of the other $AsW_9O_{34}^{9-}$ (Table 2). Oxo oxygens of the uranyl ion form the axial bonds of each pentagonal-bipyramid of the uranium atoms. The ammonium ion, Fig. 3, is surrounded by seven oxygens each within hydrogen bonding distances; two axial uranyl oxygens, four uncoordinated oxygens of $AsW_9O_{34}^{9-}$ units and one AsO_4 oxygen (see above).

4. Conclusion

The first examples of sandwich type polytungstate complexes incorporating As^V as a heteroatom and a seven-coordinate (pentagonal-bipyramidal) uranium atom have been synthesized by the facile "self-assembly" reaction of arsenate, tungstate and uranyl ions in a stoichiometric ratio. The anions' structures are controlled by the size of the counteractions, a C_i structure anion with a sodium ion and a C_s structure anion with ammonium or potassium ions are isolated. The anions are unstable in strongly acidic media and are converted to a $H_6As_2W_{18}O_{62}$ Dawson type polyoxometalate.

Acknowledgment

We thank Dr. Nebebech Belai, Department of Chemistry, Georgetown University, for critical recording of ^{183}W NMR spectra.

Appendix A. Supplementary data

Crystallographic data (CIF file) for the structural analysis has been deposited with the Fachinformationszentium Karlsruhe (FIZ), CSD-number 415521. E-mail: crysdata @FIZ-Karsruhe.de. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2005.12.019.

Table 1
T_c as a function of solvent, S, for $V[TCNE]_x \cdot ySy$ prepared from $V(C_6H_6)_2$ and $V(CO)_6$

V-source	Solvent (S)	T_{on} (K)	Ref.
$V(C_6H_6)_2$	CH_2Cl_2	~350	[b]
$V(C_6H_6)_2$	THF	215	[16a]
$V(C_6H_6)_2$	MeCN	138	[16b][a]
$V(CO)_6$	None (CVD)	370	[12a]
$V(CO)_6$	CH_2Cl_2	387	this work
$V(CO)_6$	PhMe	390	this work
$V(CO)_6$	$PhCF_3$	396	this work
$V(CO)_6$	hexane, C_6H_{14}	388	this work

[a] 5 K.
[b] Extrapolated from 150 Oe data presented in Ref. [11b].

The interpretation of T_c is problematic, as it is determined from low-field magnetization, $M(T)$, measurements taken on warming a sample toward the expected magnetic transition temperature. An abrupt drop of $M(T)$ was observed above ~350 K [12]; however, its value did not recover upon cooling, suggesting an irreversible structural transformation (which rapidly degrades the magnetic properties) occurs at almost the same temperature as the magnetic transition (vide infra). Therefore, to evaluate the T_c of the materials, the temperature dependence of the saturated magnetization, $M_s(T)$, was fit to the Bloch $T^{3/2}$ law [12], and T_cs were ~400 K.

Due to the lack of data on the influence other non-coordinating solvents have on T_c of the $V[TCNE]_x$ magnets, alternative solvents were studied with the objective of extending the ferrimagnetic behavior to higher temperatures, which is important for a practical applications. It is possible that different solvent molecules trapped in the $V[TCNE]_x$ structure may strengthen (or weaken) the $V[TCNE]_x$ network (for instance, via short contacts) stabilizing it against thermal degradation. Alternative solvents might also reduce the occlusion of impurities arising from the decomposition of $V(CO)_6$ in CH_2Cl_2. Hence, the effect of several non-coordinating solvents including toluene (PhMe), trifluoromethylbenzene ($PhCF_3$), and hexane, were studied. $PhCF_3$ was particularly intriguing as it has a dielectric constant (9.2) comparable to CH_2Cl_2 (8.9) [17]. Herein, we report the solvent dependence of the magnetic properties of $V[TCNE]_x \cdot ySy$ in the vicinity of magneto-structural transition temperature (see Table 1).

2. Experimental

All manipulations were performed under an inert nitrogen atmosphere (<1 ppm O_2 and <1 ppm H_2O) using standard Schlenk techniques and Vacuum Atmospheres DriLab gloveboxes. Methylene chloride (CH_2Cl_2), PhMe, and hexanes were sparged with nitrogen and passed over two columns of activated alumina prior to use to remove traces of oxygen and water [18]. Trifluoromethylbenzene ($PhCF_3$) was purified by distillation from phosphorous pentoxide under a nitrogen atmosphere. Hexacarbonylvanadium(0), $V(CO)_6$, was prepared by oxidizing tetraethylammonium hexacarbonylvanadium(−1) with phosphoric acid and purified by vacuum sublimation (25 °C, 0.1 Torr) [19]. Tetracyanoethylene (TCNE) was purchased from Acros and purified by vacuum sublimation from activated carbon (80 °C, 0.1 Torr).

2.1. $V[TCNE]_x \cdot ySy$ ($x \sim 2$, $y \sim 0.5$)

All materials were prepared with the desired solvent using a nominally identical procedure exemplified by the following reaction performed in $PhCF_3$. A yellow solution of $V(CO)_6$ (44.7 mg, 0.204 mmol) dissolved in ~5 mL of $PhCF_3$ was added dropwise to a stirred suspension of 2 equiv. TCNE (52.3 mg, 0.408 mmol) in ~10 mL $PhCF_3$. The mixture immediately became black and CO evolved. The mixture was allowed to stir for 12 h. (As the reaction is rapid, the amount of time reaction is stirred does not have a significant impact on the yield or magnetic properties of the product, and was variable between samples.) The black precipitate was collected by suction filtration and dried under vacuum. Yield: 68.5 mg (88%) of $V(TCNE)_2 \cdot 0.5PhCF_3$. IR (KBr, cm^{-1}): 2190, 2151, 2089 (1324, only observed in samples prepared from $PhCF_3$). Elemental *Anal.* Calc. C, 48.97; H, 0.66; N, 29.47. Found: C, 48.59; H, 0.73; N, 29.22%. Thermogravimetric analysis shows broad nearly featureless decomposition above 50 °C.

2.2. Properties characterization

The thermal properties were studied on a TA Instruments Model 2050 thermogravimetric analyzer (TGA) equipped with a TA-MS Fison triple filter quadrupole mass spectrometer, to identify gaseous products with masses less than 300 amu. This instrument was located in a Vacuum Atmospheres DriLab under nitrogen to protect air and moisture sensitive samples. Samples were placed in an aluminum pan and heated at 20 °C/min under a continuous 10-mL/min nitrogen flow. A TA Instruments Model 2910 differential scanning calorimeter was used to carry out DSC experiments. Samples were loaded into an aluminum pan with a lid and hermetically sealed with a special press inside the box. The samples were loaded into the instrument and DSC experiments were performed under nitrogen gas flow.

The 5–300 K magnetic susceptibility was determined on a Quantum Design MPMS-5XL 5 T SQUID (sensitivity $= 10^{-8}$ emu or 10^{-12} emu/Oe at 1 T) as previously described [20]. In addition to correcting for the diamagnetic contribution from the sample holder, core diamagnetic corrections based on summing Pascal's constants were used. Infrared spectra (400–4000 cm^{-1}; with 1 cm^{-1} resolution) were obtained on a Bruker Tensor 37 FT IR-40 spectrophotometer as KBr pellets. Elemental analyses were performed by Complete Analysis Laboratories Inc. of Parsippany, NJ.

3. Results and discussion

Solutions of $V(CO)_6$ in CH_2Cl_2 were observed to gradually decompose over time. The initially bright yellow solutions became green or brown in color after about 15–30 min, and after 24 h a fine black precipitate formed leaving a nearly colorless supernatant. The IR spectrum of the precipitate was featureless between 400 and 4000 cm^{-1} indicating the loss of all CO, and that the material does not contain vanadium oxides or hydroxides (from perhaps reaction with trace amounts of O_2 or H_2O). The material may be a chloride, possibly formed via a chlorine radical intermediate. This decomposition is not unprecedented, as $V(CO)_5PPh_3$ was reported to be unstable in the presence of CH_2Cl_2 or toluene [21]. The identity of the decomposition product or the mechanisms of its formation have not been fully investigated, to our knowledge. No solutions showing visible signs of decomposition were used to prepare the magnetic materials in this study.

Due to the small sample-to-sample variations observed in the physical properties of the materials, a survey of the effects that altering various synthetic protocols have on these properties was undertaken in order to determine if the variations were caused by inadvertent slight variation in the synthetic methods. It was generally found that the volume of solvent used for the reaction should be as small as is practical. It is surprising to note that incomplete dissolution of the TCNE is not detrimental to the reaction. As a result of this observation, all of the materials were prepared from TCNE slurries, as TCNE is only moderately soluble in CH_2Cl_2 and PhMe, slightly soluble in $PhCF_3$, and essentially insoluble in hexane. The use of large volumes of CH_2Cl_2 to completely dissolve the TCNE typically resulted in slightly reduced magnetic ordering temperature. The order of combination of the reagents is, however, critical, and the $V(CO)_6$ solutions must be added dropwise to the TCNE solutions or slurries (although the rate of addition is not important). The amount of time that the reaction mixture is allowed to stand after combination of the reagents (1 min to 48 h) had no affect on the magnetic properties of the materials although several hours were generally allowed to ensure that all of the TCNE had dissolved and reacted in order to prevent the inclusion of unreacted TCNE into the products collected, which was monitored by IR spectroscopy.

The zero-field cooled (ZFC) magnetization of $V[TCNE]_x \cdot ySS$ synthesized from PhMe, $PhCF_3$, hexanes, and CH_2Cl_2 is nearly temperature independent below 300 K, showing a ~10% decrease from 300 to 5 K. In this region, the $M(T)$ is reproducible and the variation between samples is not solvent dependent. Above 300 K the $M(T)$ gradually decreases with different rates for different solvents (Fig. 1) suggesting a magnetic transition. We define the onset temperature, T_{on}, as a temperature at which the magnetization is an order of magnitude greater than its paramagnetic limit of 0.05 emuOe/mol {at 400 K and 5 Oe external field {assuming only paramagnetic contribution from $S = 3/2$ V^{II} and two $S = 1/2$ $[TCNE]^{\bullet -}$}. Using this criterion, T_{on} was determined to be 387, 388, 390, and 396 K for $V[TCNE]_x \cdot ySS$ synthesized in CH_2Cl_2, hexanes, PhMe, and $PhCF_3$, respectively. The T_{on} for the materials prepared from CH_2Cl_2, hexanes, and PhMe are not significantly different given that the observed T_{on} values for $V[TCNE]_x \cdot ySS$ vary slightly between samples (due to extreme air sensitivity), and the similarity of $M(T)$ curve shapes when approaching the transition. This suggests that solvent has a minimal effect on T_{on}. In addition, there is no correlation between the stability of $V(CO)_6$ in a solvent and the ordering temperature of the material prepared from that solvent.

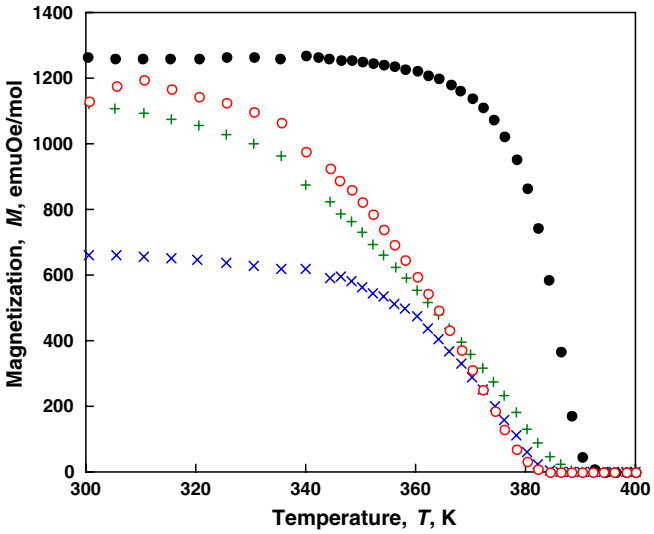

Fig. 1. $M(T)$ for $V[TCNE]_x \cdot ySS$ [S = CH_2Cl_2 (○) $PhCF_3$ (●), hexane (×), and PhMe (+)] in an applied field of 5 Oe.

We believe that the sample-to-sample variations are primarily a result of the extreme air sensitivity of $V[TCNE]_x$ and that slight amounts of oxidation occasionally contaminate the materials as they are being loaded into instruments for analysis, in spite of rigorous precautions taken to prevent as much oxidation as possible.

The reaction of $V(CO)_6$ and TCNE in CH_2Cl_2, hexanes, PhMe, and $PhCF_3$ form an immediate black precipitate, with IR spectra characteristic of $[TCNE]^{\bullet -}$ bonded to V^{II} (Fig. 2), i.e., ν_{CN} absorptions at 2150 and 2188 cm^{-1}, as well as two poorly resolved shoulders at ~2000 and ~2210 cm^{-1}. The position and peak intensity (with respect to the 2150 cm^{-1} band) of a broad feature at ~2090 ± 10 cm^{-1} is solvent dependent. However, no distinct correlation between its position and T_{on} was identified. We also observed similar variations in the ν_{CN} absorptions of $V[TCNE]_x \cdot ySS$ from different batches synthesized using the CH_2Cl_2 solvent with similar T_{on}'s. Earlier we tentatively assigned the 2150 and broad 2100 cm^{-1} bands to ν_{CN} of *trans*-μ-$[TCNE]^{\bullet -}$ and μ_4-$[TCNE]^{\bullet -}$ bonded to V, respectively [12a]. The relative insensitivity of the high frequency bands positions to solvent substitution most probably implies that the non-coordinating solvents do not change the effective electron

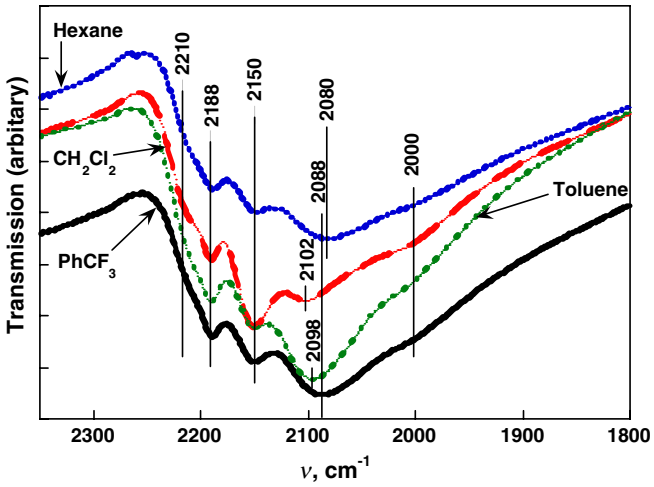

Fig. 2. ν_{CN} region of the IR spectra for $V[TCNE]_x \cdot ySS$ [S = CH_2Cl_2 (- - -) $PhCF_3$ (−), hexane (●●●), and PhMe (---)].

transfer between $[TCNE]^-$ and V, and therefore, do not affect T_{on}. The slight variations in numbers and structure of the μ_4-$[TCNE]^{\bullet -}$ are assumed to be related to the quantitatively non-reproducible intrinsic disorder in these amorphous materials regardless of the solvent from which the material was prepared. The degree of disorder is more sensitive to synthetic conditions, but much less (if any) to the solvent substitution.

However, the T_{on} for the $PhCF_3$-prepared sample is significantly higher. The drop in $M(T)$ with increasing temperature is very abrupt suggesting that the material preserves its structure to higher temperatures (Fig. 3). The DSC traces for $V[TCNE]_x \cdot ySS$ synthesized from CH_2Cl_2 and $PhCF_3$ reveals that the irreversible exothermic process associated with structural rearrangement and/or degradation in the prepared material prepared from CH_2Cl_2 starts ~13 K prior to that in the material prepared from $PhCF_3$ (Fig. 3). The enthalpy change, ΔH, of 129 kJ/mol for the $PhCF_3$-made

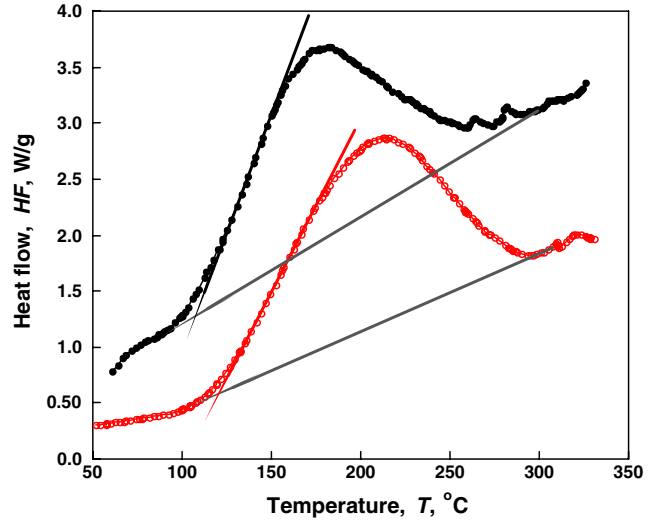

Fig. 3. DSC traces in the $50 \leqslant T \leqslant 325$ K region for $V[TCNE]_x \cdot ySS$ synthesized from CH_2Cl_2 (●), and $PhCF_3$ (○). Analysis was performed assuming a linear background between 100 and 300 K.

material is more than twice the 56 kJ/mol for the material made in CH_2Cl_2, This suggests that it is more robust against thermal degradation. The reason(s) of this effect are not entirely clear, but is under investigation. Hence, a new solvent has been identified that enables the preparation of a more thermally stable organic-based magnet.

Acknowledgments

The continued partial support by the Department of Energy Division of Materials Science (Grant No. DE-FG03-93ER45504) and Army Research Office (Grant No. DAAD19-01-1-0562) is appreciated.

2.1. Syntheses of complexes

2.1.1. Synthesis of $[Cu_2L_2Cl_2]$ (1), $[Cu_2L_2Br_2]$ (2), $[Cu_2L_2(NO_3)_2]$ (3) and $[Cu_4L_4(SO_4)_2]\cdot 3H_2O$ (7)

The ligand HL (1 mmol) was dissolved in 20 ml of hot ethanol and the appropriate copper(II) salt (1 mmol) in the same solvent was added to it. The solution was heated under reflux for 2 h and then evaporated to a small volume. After cooling at room temperature, the dark blue crystals formed were isolated and dried under vacuum.

2.1.2. Synthesis of $[Cu_2L_2(N_3)_2]$ (4) and $[Cu_2L_2(SCN)_2]$ (5)

To a 20 ml hot ethanolic solution of the ligand HL (1 mmol) was added copper(II) acetate (1 mmol) in hot methanol. The solution was heated under reflux. To the refluxing solution, sodium azide or potassium thiocyanate were added in portions in the same molar ratio and further refluxed for 2 h. After cooling at room temperature, the dark blue crystals formed were isolated and dried under vacuum.

2.1.3. Synthesis of $[Cu_2LCl_3]$ (6)

The ligand HL (1 mmol) was dissolved in 20 ml of hot ethanol and $CuCl_2\cdot 2H_2O$ (2 mmol) in the same solvent was added to it. The solution was heated under reflux for 2 h and then evaporated to a small volume. After cooling at room temperature, the dark blue crystals formed were isolated and dried under vacuum.

2.2. X-ray crystallography

Single crystals of compound **7** suitable for X-ray diffraction studies were grown from its solution in a mixture of methanol and chloroform (1:1) by slow evaporation at room temperature in air. A single crystal of dimension $0.40\times 0.35\times 0.30$ mm with $P\bar{1}$ symmetry was selected and mounted on a Bruker SMART APEX CCD diffractometer, equipped with a fine focus sealed tube X-ray source. The unit cell dimensions and intensity data were measured at 293 K. SMART software was used for data acquisition and SAINT software for data extraction [15]. Corrections for absorption were carried out by the SADABS method [16]. The whole structure was refined with SHELXL 97 [17] by the full-matrix least squares technique and the graphics tool was DIAMOND [18]. All non-hydrogen atoms were refined anisotropically, while the hydrogen atoms were treated with a mixture of independent and constrained refinements.

2.3. Physical methods

Elemental analyses were carried out using a Heraeus Elemental Analyzer at the Regional Sophisticated Instrumentation Center, CDRI, Lucknow, India. Molar conductance measurements of the complexes were carried out in DMF solvent on a Century CC-601 digital conductivity meter with a dip type cell and platinum electrode. Approximately 10^{-3} M solutions were used. Magnetic moment measurements were carried out in the polycrystalline state on a Vibrating Sample Magnetometer at 5 kOe field strength. Infrared spectra were recorded on a Shimadzu DR 8001 series FTIR instrument as KBr pellets for spectra run from 4000 to 400 cm^{-1}, and using polyethylene for the range 500–100 cm^{-1} in a Nicolet Magna 550 FTIR instrument. Solid-state reflectance spectra were recorded on Ocean Optics SD 2000 Fibre Optic Spectrometer.

3. Results and discussion

Di-2-pyridyl ketone *N*(4),*N*(4)-(butane-1,4-diyl) thiosemicarbazone (HL) interacts with copper(II) ions in the presence of anions, in the molar ratio 1:1:1 yielding complexes with the empirical formula [CuLX] where X = Cl, Br, NO_3, N_3, SCN. Analogously, the complexes $[Cu_2LCl_3]$ (**6**) and $[Cu_4L_4(SO_4)_2]$ (**7**) were obtained when the metal–ligand ratios were 2:1 and 1:1, respectively. Upon evaporation of the solvent, the complexes are precipitated as dark blue solids. These complexes are sparingly soluble in most non-polar solvents but soluble in DMF and DMSO giving non-conducting solutions [19]. Single crystals of the complex **7** suitable for X-ray diffraction were obtained by slow evaporation of its solution in a 1:1 mixture of methanol and chloroform in air at room temperature. The elemental analyses, molar conductance and magnetic susceptibility values are presented in Table 1. The magnetic susceptibility

[a] Molar conductivity, 10^{-3} M DMF at 298 K.
[b] Magnetic susceptibility per copper atom.

values per copper atom are found to be less than the spin only value, indicating an exchange interaction between the copper centres. All complexes are reported to be paramagnetic at room temperature.

3.1. Molecular and crystal structures of the complex $[Cu_4L_4(SO_4)_2]\cdot 3H_2O$

The structure of the tetranuclear complex $[Cu_4L_4(SO_4)_2]\cdot 3H_2O$ is illustrated in Fig. 1 and the structural refinement parameters are given in Table 2. Selected bond lengths and bond angles are given in Tables 3 and 4. The structure contains four units comprising of two identical Cu(1)L outer units and two identical Cu(2)L inner units. In other words, it can be regarded as a dimeric structure of binuclear $[Cu_2L_2SO_4]$ units. The atom numbering scheme of the bimetallic unit is given in Fig. 1. Each copper atom in the outer unit is coordinated by a pyridyl nitrogen, azomethine nitrogen and thiolate sulfur of the thiosemicarbazone moiety and an oxygen of the bridging sulfato group. In addition to these, there is an additional Cu1–S3 bridging interaction at an apical distance of 2.942 Å, which renders a distorted (4 + 1) square pyramidal geometry around the Cu1 atoms. The Cu–$N_{pyridyl}$ bonds are 0.0781 Å farther away than Cu–N_{imine} bonds, denoting the strength of the azomethine nitrogen coordination. The C(6)–N(3) bond length is slightly shorter than the corresponding bond distance of 1.308(4) Å in the free ligand, [13] indicating that there is no clear decrease in the double bond character on chelation. This can be attributed to the stabilization of the C–$N_{azomethine}$ bond in the copper(II) complexes due to the presence of an important metal-

to-ligand π-back donation. The lengthening of the S(1)–C(12) bond from the corresponding bond distance in the free ligand of 1.671(4) Å can be attributed to the delocalization of the negative charge on the N(3)–N(4)–C(12) system which is generated as a result of N(4)H deprotonation on complexation. The bond angles also are in conformity with a distorted square pyramidal structure around the copper centres.

Each copper atom in the inner subunit is also pentacoordinate with the bonds Cu(2)–S(3), Cu(2)–O(11), Cu(2)–N(1A), Cu(2)–N(3A) and Cu(2)–N(2A) adapting a distorted square pyramidal geometry with N(2A) of the third ligand moiety at the apical site. The pyridyl nitrogen N(1A), the imino nitrogen N(3A), and the thiolate sulfur S(3) atom, together with O(11) of the sulfato group, constitute the basal plane. The bond lengths in the basal plane agree with those found in copper(II) complexes containing thiosemicarbazones which act as uninegative tridentate ligands [20]. The bond lengths and bond angles reveal a distorted square pyramidal geometry around Cu(2).

The unit cell-packing diagram of the complex viewed down the *a*-axis is given in Fig. 2. It can be observed that the molecules are packed in a two-dimensional manner parallel to the *bc*-plane. The adjacent tetrameric units are interconnected through hydrogen bonding interactions involving the oxygen atoms of the water molecules and the sulfato group. The assemblage of molecules in the respective manner in the unit cell is also assisted by the diverse π–π stacking, CH–π and ring–metal interactions as shown in Tables 5 and 6. The hydrogen bonding interactions are observed with donor–acceptor distances in the range 2.8048–3.5360 Å. The π–π interactions are rather weak, with 3.3457 Å being the minimum distance between the centroids. The π–π, CH–π, ring–metal and hydrogen bonding interactions stabilize the unit cell and point out the possibility for metalloaromaticity – a classic concept reviewed by Masui [21].

3.2. Electronic spectra

The electronic spectral data of the copper(II) complexes are given in Table 7. The UV–Vis spectra give much insight into the coordination geometry around the copper(II) ion. The broad band around 36 000 cm^{-1} can be attributed to the $\pi \rightarrow \pi^*$ transition (pyridyl ring and the imine function) of thiosemicarbazone moiety. The shift of the $\pi \rightarrow \pi^*$ bands to the longer wavelength region in the complexes is the result of the C=S bond being weakened and the conjugation system being enhanced on complexation [22]. The pyridyl and imine function $n \rightarrow \pi^*$ band, centered around 29 100 cm^{-1}, overlaps and undergoes a small blue shift to ca. 31 500 cm^{-1} on complexation indicating coordination via the pyridyl nitrogen with a reduction in intensity [23]. The ligand → metal CT bands are found at ~23 000–26 000 cm^{-1}. The band near 26 000 cm^{-1} in the complexes corresponds to S → Cu(II) ligand to metal charge transfer bands. This band is in accordance with previous studies of copper(II) complexes with a similar type of ligand [24,25]. The pyridyl nitrogen N → Cu(II) LMCT transitions are observed at ~23 000 cm^{-1}. The spectra of the complexes exhibit weak $d \rightarrow d$ bands centered around 16 000 cm^{-1} for compounds **5** and **7**. Such a feature is expected for square planar complexes [26]. For square planar complexes

with a $d_{x^2-y^2}$ ground state [27], three transitions are possible $d_{z^2} \leftarrow d_{x^2-y^2}$, $d_{xy} \leftarrow d_{x^2-y^2}$ and $d_{xz}, d_{yz} \leftarrow d_{x^2-y^2}$ ($^2A_{1g} \leftarrow {}^2B_{1g}$, $^2B_{2g} \leftarrow {}^2B_{1g}$ and $^2B_{2g} \leftarrow {}^2B_{1g}$). Since the four d orbitals lie very close together, each transition cannot be distinguished by their energy and hence it is very difficult to resolve the three bands into separate components.

3.3. Infrared spectra

A square pyramidal geometry can be assigned for **1**–**5** consisting of one of the pyridyl nitrogens, azomethine nitrogen, thiolate sulfur and the anion forming the basal plane, while the pyridyl nitrogen of the second ligand unit occupies the apical positions (Fig. 3) as reported by us before [25]. For compound **6** (Fig. 4), the terminal nature of the chlorine atoms indicates its structure to be similar to the copper(II) complex of a di-2-pyridyl ketone thiosemicarbazone prepared by Swearingen et al. [28]. Selected vibration bands of HL and its metal complexes are listed in Table 8. Since the compound contains a thioamide function, HL can exhibit thione–thiol tautomerism. The *ν*(S–H) band at ~2600 cm^{-1} is absent in the spectrum of the ligand, indicating that it exists as the thione tautomer in the solid state. This is further supported by a medium band at 3049 cm^{-1}, indicative of the *ν*(N–H) vibration. The absence of *ν*(NH) in the spectrum of the complexes provides strong evidence for the ligand coordination around Cu(II) ion in its deprotonated form. The vibrations *ν*(C=N) and *δ* (C=S) contribute substantially to the bands at 1582 and 808 cm^{-1}, respectively, in the ligand. The band corresponding to azomethine nitrogen, *ν*(C=N), shifts to higher energy on coordination due to the combination of *ν*(C=N) with the newly formed *ν*(N=C) bond which results

[a] X represents the anion Cl, Br, etc.

from the loss of the thioamide hydrogen from the thiosemicarbazone moiety [29–33]. The band at 808 cm^{-1} shifts to lower wavenumbers in all complexes and this can be assigned to the δ(C=S) vibration suggesting the change of bond order and strong electron-delocalization upon chelation [34]. Coordination of the pyridine nitrogen causes the out-of-the plane bending vibrational bands to shift from 600 cm^{-1} to higher frequencies by 12–20 cm^{-1} [20].

Compounds **1** and **6** showed sharp bands at 320 and 310 cm^{-1}, respectively, indicating terminally bonded rather than bridging chlorine ligands. A sharp band at 250 cm^{-1} due to ν(Cu–Br) vibrations is suggestive of terminally bonded bromine in **2**. The ratio of ν(Cu–Br)/ν(Cu–Cl) is 0.77, which is consistent with the usual values obtained for the first row transition metals. For the nitrato complex (**3**), medium bands are observed at 1384, 1285 and 1013 cm^{-1} corresponding to ν_4, ν_2 and ν_1, respectively, with a separation of 102 cm^{-1}, suggestive of terminally bonded monodentate nitrato groups [35]. The bands due to ν_3, ν_5 and ν_6 could not be assigned due to the richness of the spectrum. The ν(Cu–N) of the complex is found at 445 cm^{-1}. The spectrum of complex **4** showed a strong band at 2042 cm^{-1} due to the asymmetric $\nu(N_3)$ mode. The band associated with the symmetric $\nu(N_3)$ mode is located at 1369 cm^{-1}. The band at 312 cm^{-1} is assigned to the ν(Cu–N_{azide}) mode. We have obtained three bands for compound **5**, a strong sharp band at 2081 cm^{-1}, medium band at 787 cm^{-1} and a weak band at 480 cm^{-1} corresponding to ν(CN), ν(CS) and δ(NCS), respectively. The intensity and band position indicates the unidentate coordination of the thiocyanate through the nitrogen atom. The sulfato complex **7** exhibits four fundamental vibrations: 970 cm^{-1} due to ν_1, a medium band at 459 cm^{-1} due to ν_2, medium and weak bands at 1243, 1181 and 1112 cm^{-1} corresponding to ν_3, and medium and weak bands at 650, 615 and 575 cm^{-1} due to ν_4, which are assigned to the bidentately coordinated sulfato group [35].

3.4. EPR spectral investigations

EPR parameters found for the complexes in the polycrystalline state (293 K) and in DMF at 293 and 77 K are presented in Table 9. The spectra in the polycrystalline state gave much information about the coordination geometry around the copper(II) ion. The complexes **1** and **3** revealed rhombic features. The compounds **2**, **4**, **5** and **7**

Table 9
EPR spectral assignments of the copper(II) complexes

Compound	State	Temperature (K)	$g_\parallel$	g_1	$g_\perp$	g_2	g_3	g_{iso}
[CuLCl] (**1**)	polycrystalline	298		2.006		2.060	2.145

	DMF	298						2.080
	DMF	77	2.180		2.051			

showed an axial spectrum with well defined $g_{\|}$ and $g_{\perp}$ features. The variation in the g values indicates that the geometry of the compound is affected by the nature of the coordinating anions. The solution state EPR measurements in DMF at 298 K give isotropic spectra with well resolved hyperfine lines. The isotropic nature of the spectra is due to the tumbling motion of the molecules in DMF. The spectra of complexes showed clearly four well resolved hyperfine lines, which are due to the interaction of the electron spin with the copper nuclear spin (^{65}Cu, $I = 3/2$). The A_0 and g_0 values show variations indicating dissimilar bonding character of the complexes. The EPR spectra of compounds **1**, **3** and **6** in DMF at 77 K showed rhombic features with three g values g_1, g_2 and g_3. However the azido complex (**4**) shows an axial spectrum. The g values for complexes in the solid state at 298 K and in DMF at 77 K are close to each other, which perceives that the geometry around the copper(II) ion is unaffected on cooling the solution to liquid nitrogen temperature.

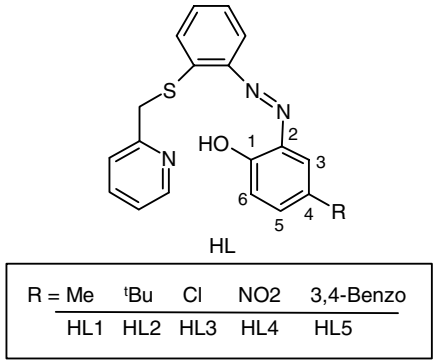

Scheme 1. The structures of the pyridylthioazophenols used as chelators.

this paper, we present an account of the *cis* and *trans* isomers of ruthenium (III) complexes of a series of tetradentate pyridylthioazophenolates (Scheme 1), and the role of the polarity of solvents in controlling the ratio of *cis* and *trans* isomers of the ruthenium (III) complexes. One of the complexes, *trans*-$[Ru(L1)Cl_2]$, has been subjected to single-crystal X-ray analysis to confirm the detailed structure, and the complex is found to be monomeric with the metal in an octahedral environment having the chlorines in mutually *trans* sites. It has been observed in our reactivity study that the two chlorines of the *cis*-isomers, but not of the *trans*-isomers, can be substituted successfully by bipyridine in the presence of $AgNO_3$. The resulting cationic ruthenium (III) complexes of the type $[Ru(L)(bipy)](PF_6)_2$ (bipy = 2,2′-bipyridine), bearing three heterocyclic N-donors in the coordination sphere of ruthenium (III) and obtained from the reaction of bipyridine with the *cis*-isomers using the $AgNO_3$ procedure, were characterized by elemental analyses, IR spectra, electrical conductivities and magnetic moment measurements.

2. Experimental

2.1. Materials

$RuCl_3 \cdot nH_2O$ was obtained from Arrora Matthey, Calcutta and was digested with concentrated HCl before use. The ligands were synthesized by the reported procedure [12]. Commercially available silica gel (60–120 mesh) from SRL was used for chromatographic separation. Purification of solvents for electrochemical and spectral work were carried out using appropriate drying agents [16]. Tetra-*n*-butylammonium perchlorate was prepared by the addition of sodium perchlorate to a hot solution of tetra-*n*-butylammoniumbromide (Aldrich). The products were recrystallised from aqueous ethanol and tested for the absence of bromide. All the reagents were obtained from commercial sources and used without further purification.

2.2. Physical measurements

IR spectra were measured on a JASCO FT-IR model 420 using KBr disks and UV–Vis spectra on a JASCO UV–Vis/NIR model V-570. Microanalyses were performed using a Perkin–Elmer 2400 CHN elemental analyzer. Molar conductances (Λ_M) were measured in a systronics conductivity meter 306 model using $\sim 10^{-3}$ M solutions in MeOH. Magnetic moments (μ, BM) were obtained from a vibrating sample magnetometer PAR 155 model. X-band EPR spectra were taken on a Brucker spectrometer with a variable temperature liquid nitrogen cryostat at NTHU, Hsinchu, Taiwan. The *g* values were measured at 77 K. Electrochemical measurements were made with a computer controlled EG&G PAR model 270 VERSTAT electrochemical instrument using platinum as the working electrode. All measurements were made at 298 K in dry DMF with $[Bu_4N]ClO_4$ as the supporting electrolyte with 50 mV S^{-1} scan rate. The experimental solutions were deoxygenated by bubbling with research grade dinitrogen. The reported potentials, referenced to the standard calomel electrode (SCE), were uncorrected for junction potential.

2.3. Synthesis of the Ru(III) complexes of the ligands (HL)

The preparation of the Ru(III) complexes follows a common procedure. To a methanolic/ethanolic solution (15 mL) of **1a** (0.335 g, 1.0 mmol), a ruthenium trichloride (1.0 mmol) solution in MeOH/EtOH was added dropwise and the resulting solution stirred for a period of 0.5 h at room temperature. The reddish brown solution was then evaporated in air and dissolved in a minimum volume of dichloromethane and chromatographed over a silica gel column prepared in CH_2Cl_2. Two brown colored bands were eluted by CH_2Cl_2–MeOH (95–5%) and CH_2Cl_2–MeOH (70–30%) successively to get the *trans* and *cis* isomers, respectively. The solvent of the eluents was removed using a rotary evaporator. The recrystallized products were obtained from MeCN–MeOH medium. They were then dried in vacuum. Total yield: 85–87%.

Other complexes were prepared under identical conditions; the yields varied in the range 55–70%. Here, the *cis*:*trans* ratio was ~3:1; but when CH_2Cl_2 was used as the solvent for preparation, the *cis*:*trans* ratio was the reverse to the above at ~1:3.

2.4. X-ray crystal structure analysis

Single crystals, suitable for X-ray work, of *trans*-$[Ru(L1)Cl_2]$ (**2a**) were grown by slow evaporation of a solution of the complex in methanol:toluene (1:2) at an ambient temperature of 293 K. Data were measured with Mo Kα radiation using the MARresearch Image Plate System. The crystal was positioned at 70 mm from the Image Plate. One hundred frames were measured at 2° intervals with a counting time of 2 min. Data analysis was carried out with the XDS program [17a] to provide 3450 independent reflections. The structure was solved using direct methods with the SHELX86 program [17b]. The hydrogen atoms bonded to carbon were included in geometric positions and given thermal parameters equivalent to 1.2 times those of the

atom to which they were attached. The structure was refined on F^2 using SHELXL [17c] to $R_1 = 0.0418$, $wR_2 = 0.0840$ for 2994 reflections with $I > 2\sigma(I)$.

3. Results and discussion

3.1. Syntheses

The ligands, having NSNO donor centres, act as tetradentate monobasic chelators on complexation with ruthenium (III). The mixture of ruthenium complexes (**1** and **2**) were obtained by their reaction with equimolar amounts of the chloro salts of the metals in MeOH/EtOH/CH_2Cl_2. On chromatographic separation, *trans*-dichloro and *cis*-dichloro ruthenium (III) complexes of pyridylthiazophenolates were eluted using 19:1 and 7:3 (v/v) DCM–MeOH mixtures, respectively. The reaction of the corresponding ligand and trichloro-ruthenium salts in methanol/ethanol at room temperature gave a *cis*:*trans* ratio of ~3:1, but in CH_2Cl_2 under the same conditions, the *cis*:*trans* ratio is reverse to the above and indeed it is almost ca. 1:3. On heating for 1 h in MeOH, the *trans* product is almost quantitatively converted to the *cis* isomer. It has been already observed under similar conditions, only *cis*-dichloro-iron (III) complexes have been obtained and not the isomeric mixtures having *cis* and *trans*-dichloro-iron (III) complexes of these ligands [12b]. Microanalytical data (Table 1) confirms the composition of the complexes. The conductivity measurement of the complexes **1** (*cis*) and **2** (*trans*) in methanolic solution suggest that both series of ruthenium (III) complexes exist as non-electrolytes. The magnetic moment studies exhibit that the complexes of both series (**1** and **2**) are one electron equivalent paramagnetic in nature and the magnetic moment values are in the range of 1.71–1.79 BM.

3.2. X-ray structure of trans-dichloro-2-(2-pyridylmethylthio)-phenylazo-(4-methyl)-phenolato-ruthenium (III) {[Ru^{III}(L1)Cl_2]} (**2a**)

The ORTEP view of **2a** is illustrated in Fig. 1 together with the numbering scheme. The crystallographic data, and the selected bond distances and angles are listed in Tables 2 and 3. In this monomeric complex, the metal ion centre is in a distorted octahedral environment, being bonded to four atoms of the ligand N(18), O(11), N(33) and S(26) in a equatorial plane together with two mutually *trans* chlorine atoms in axial positions. The two chlorine atoms are at same distance (2.362(3) and 2.369(3) Å) from the metal center, subtending an angle of 179.96(4)°. The

azo-N and pyridinic-N are mutually *trans* to each other (172.3(1)°), as are the phenolate-O and thioether-S atoms (175.9(1)°). The atoms in the equatorial plane are approximately coplanar with O(11) −0.11, N(18) 0.10, S(26) −0.10, N(33) 0.10 Å from the mean plane of these four donor atoms. The Ru atom is 0.03 Å from this plane. The thioether-S donor center behaves like a pyramidal μ_3-S type in that the angles subtended at this sulfur are 104.5(1)°, 96.3(1)° and 108.2(2)°. The six-membered ring forms a distorted envelope conformation with the metal 0.57 Å out of the plane formed by N(18), N(19), C(20), C(25) and S(26). The Ru–S(thioether) distance of 2.289 (2) Å is comparable with the average Ru–(μ_3-S) distance in the literature [18] and is very close to the values found in ruthenium (III) complexes of the type X[*trans*-$RuCl_4$(dmso–S)(imidazol)] (X = imidazol or Na for NAMI (2.296(1) Å) or NAMI-A (2.293(1) Å), respectively) which have interesting pharmacological properties in periclinical trials [19], but is longer than the Ru(II)–S distances, 2.353(3) Å [20] and Ru(III)–S (thiol) [21]. The N=N azo bond distance (1.288(5) Å) is longer than those found in the equivalent octahedral iron (III) (1.258 Å) and square planar copper (II) complexes (1.267 Å) of this ligand system but is comparable with the distance in the square pyramidal copper (II) complex (1.283 Å) of this ligand system[12]. The Ru(III)–pyridinic–N bond distance (1.980(4)) is longer that the bond length Ru(III–azo–N) (2.115(4)), as is usually found. There are no unusual intermolecular close contacts between molecules.

3.3. Spectral properties

3.3.1. IR spectra

In the IR spectra of the complexes, the characteristic IR bands at ~3300 cm^{-1} for O–H of H bonded phenolic–OH [22] of the ligand systems are not observed. This indicates coordination of oxygen to the metal centre [23]. The $\nu_{N=N}$ mode of the *trans*-complexes is somewhat low in comparison to that found in the *cis*-Ru(III), Cu(II) and Fe(II) complexes. This band in the free ligand is 1495–1505 cm^{-1} and it is shifted to lower to wave numbers ($\Delta \sim 25$–35 cm^{-1}) in the complexes, suggesting coordination of the metal ions to the azo function [24]. The $\nu_{N=N}$ band is observed at 1460–1472 cm^{-1} for all the *trans*-complexes, but for the *cis*-isomers it is somewhat higher 1467–1480 cm^{-1}. In addition to this, ν_{C-S} (790 cm^{-1}) for the ligands shifts to ~750 cm^{-1} for the *trans* complexes and is about 760 cm^{-1} for the *cis* isomers. Deep brown colored [Ru(L)(bpy)]$(PF_6)_2$ derivatives of the *cis*-isomers show sharp absorption bands around 840 and 540 cm^{-1} assignable to $\nu_{(PF_6)}$, which are absent for *cis*-[Ru(L)Cl_2], and the conductivity studies in

MeOH are consistent with the presence of 1:2 electrolytes. Magnetic susceptibility data (Table 1) reveal spin-only values for all the complexes as the values are very close to one electron equivalent low spin complexes.

3.3.2. Electronic spectra

The electronic absorption spectra of all the complexes were recorded at room temperature in Table 4 using MeOH as the solvent. The spectra of the complexes exhibit a transition at lower than 400 nm corresponding to intramolecular $\pi \rightarrow \pi^*$ and $n \rightarrow \pi^*$ transitions [25]. The transitions in the range 400–500 nm are due to intra-ligand charge transfer transitions. The transition in the range of 630–672 nm which is absent in the free ligands, can be assigned to a $d(Ru) \rightarrow \pi^*$ transition (MLCT) where the π^* level has large azo character [26]. In general *cis*-dichlororuthenium (III) complexes (**1**) exhibit absorption in the lower energy region compared to the *trans* analogs **2**. Here, the $d(Ru) \rightarrow \pi^*$ transitions in **1** appear at lower energy compared to those in **2**, though the π-acceptor–donor pyridinic-N is *trans* to azo-N in **2** in the same plane and the azo-N in **1** *trans* to chlorine (comparing with the Fe(III) complexes where the chlorine atoms are in *cis* positions), and the *trans* isomers **2** possess more symmetry in comparison to the *cis* analogs **1**. The phenomenon is the opposite to that found with the ruthenium (II) system. The absorption due to the $d(Ru) \rightarrow \pi^*$ transition in the complexes **3**, where bipyridyl is present as a bidentate ligand in place of two chlorines in the coordination sphere of ruthenium (III), is in a slightly higher energy region than that of **1**. From this observation it may be mentioned that ruthenium (III), being a d^5 system, is not as good a π-donor as ruthenium (II) (d^6 system).

3.3.3. EPR spectra

EPR spectra of the *cis*-dichloro-$[Ru(L)Cl_2]$ complexes (**1**) have been recorded in DMF at 298 and 77 K. The data are tabulated in Table 4 and a representative spectra of **1a** is reported in Fig. 2. In the high field region, the complexes display one isotropic EPR signal at room temperature (298 K) and an anisotropic pattern EPR signal having three different g values ($g_x \neq g_y \neq g_z$) at liquid nitrogen temperature (77 K). The EPR spectra at low temperature (77 K) show three strong signals and some weak resonances due to the hyperfine interaction with the nuclei of ^{101}Ru ($I = 5/2$, natural abundance 16.8%) and ^{99}Ru ($I = 5/2$, natural abundance 12.81%). Of these three major resonances, two are lower and one is higher than the field (~3200 G). As a result, two g-values are higher and one g-value is lower than 2. From the spectra it is revealed that

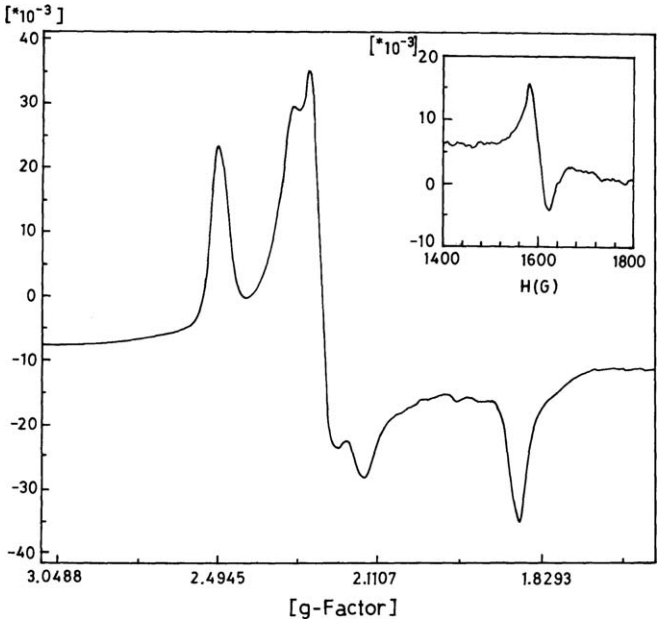

Fig. 2. EPR spectra of *cis*-dichloro $[Ru^{III}(L1)Cl_2]$ in DMF at 77 K ($g_1 = 2.481$, $g_2 = 2.184$ and $g_3 = 1.882$ at high field); in inset, display of one isotropic signal at low field.

3a	658 (660), 512 (2792), 480 (3114), 422 (3428)	267.5 (115) [325, 210]			
3b	652 (652), 506 (2751), 484 (3089), 420 (3398)	304.5 (127) [368, 241]			
3c	661 (677), 509 (2811), 480 (3142), 419 (3401)	275 (122) [336, 214]			
3d	653 (630), 510 (2769), 480 (3085), 424 (3379)	251 (102) [302, 200]			
3e	665 (672), 514 (2725), 480 (3170), 427 (3453)	299 (132) [365, 233]			

the t_g^5 configuration of the complexes **1** is a positive hole in the t_{2g} subshell as $g_\perp > g_\parallel$.

One weak isotropic band transition (Fig. 2, inset) corresponding to $\Delta M_s = 2$ at 77 K has been observed and it is centred around 1600 G, which is about half the field of the allowed $\Delta M_s = \pm 1$ transitions at around 3200 G. The spectra in this region show no splitting as here zero-field splitting is not possible. The results exhibit that the complexes are low-spin octahedral with one unpaired electron (low spin d^5 Ru^{III}, $S = 1/2$) [27–29].

3.4. Electrochemistry

The redox properties of the complexes were examined by cyclic voltammetry using a Pt-disk working electrode and a Pt-wire auxiliary electrode in dry DMF and in the presence of [*n*-Bu_4N]ClO_4 as supporting electrolyte. The potentials (Table 4 and Fig. 3) are expressed with reference to Ag|AgCl electrodes and all the complexes displayed a quasi-reversible voltammogram having $i_{pc}/i_{pa} \approx 1$. The influence of the geometrical isomerism of the complexes on the redox potential values is quite significant. The redox potential values for the *cis*-isomers are low in comparison to the corresponding trans-isomers. The ΔE_p is high in the *trans*-isomers compared to the *cis*-isomers, and it may be due to the greater stability of corresponding *trans*-dichloro-ruthenium (II) species over the *cis*-isomers. The ΔE_p values for the bipyridyl derivatives are comparable with those of the *cis* analogs. The influence of the substituents in the ligands is apparent from the data.

3.5. Reaction of [Ru(L)Cl_2] with bipyridyl to form [Ru(L)(bpy)$_2$](PF_6)$_2$

The *cis*-dichloro ruthenium (III) complexes **1** have been converted into a new series of ternary ruthenium (III) complexes **3**, having the general formula of [Ru(L)-$(bpy)_2$]$(PF_6)_2$, by the reaction with bipyridyl in the presence of $AgNO_3$. The conductivity measurements in MeOH support complexes **3** being 1:2 electrolytic.

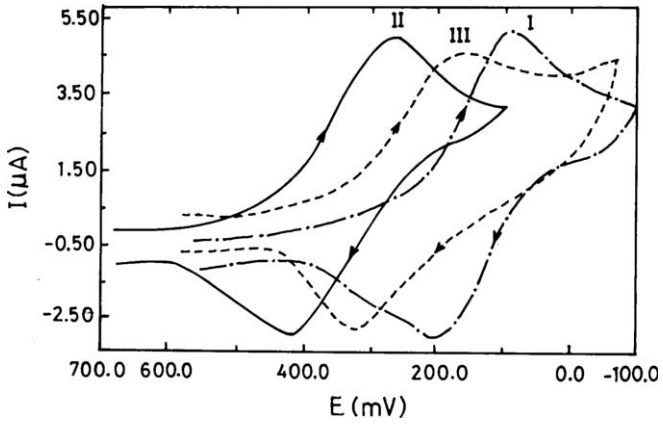

Fig. 3. Cyclic voltammogram of *cis*-[Ru(L1)Cl_2] (I), *trans*-[Ru(L1)Cl_2] (II) and [Ru(L1)(bipy)]$(PF_6)_2$ (III) in dry DMF, scan rate 50 mV S^{-1}.

The stretching band for $\nu_{(PF_6)}$ (around 840 cm^{-1} and 540 cm^{-1}) in the IR spectra confirms the presence of PF_6^- as the counter anion in the complexes **3**. All the complexes are one electron equivalent paramagnetic in nature which has been concluded from the magnetic moment measurement at room temperature. The electrochemical behavior of the *trans*-isomers is the same as that found for the *cis*-isomers with a difference only in the potential values.

4. Conclusion

The formation of *cis* and *trans* isomers of Ru(II) complexes of this series of ligands are dependent on the solvent used and the temperature. In relatively high polar solvents, formation of *cis* isomers is more favored whilst the yield of the *trans* isomers is greater than that of the *cis* analogs in less polar solvents. The X-ray crystal structure determination confirms the *trans*-dichloro type isomers. The structural data for the *cis*-dichloro type isomers could not be obtained, but the structure is likely to be similar to that found in recently published *cis*-dichloro-iron (III) complexes of this series of ligands and this is supported by spectroscopic data. In the case of the *cis* isomers, the donor atoms of the ligand are not in one plane, rather the pyridinic-N donor centre is located in an axial position, as is observed in the *cis*-dichloro-iron (III) complexes. However in the present work, in the *trans* isomers of the ruthenium (III) complexes, the donor sets of the pyridylthioazophenolate ligands are approximately planar, an arrangement which has not been observed in either the copper (II) or iron (III) complexes [12]. The redox potential values for the *cis*-isomers are low in comparison to the corresponding trans-isomers. The *cis* type isomers are reactive towards the bidentate bipyridyl ligand in the presence of $AgNO_3$ while, as might be expected, this is not true of the *trans* isomers.

ancillary chelate ligands. Such vanadyl species were found to be extremely active for the polymerisation of ethylene, when combined with dimethylaluminium chloride (DMAC) [9b]. Related niobium pro-catalysts were much less active under similar conditions [9c]. In an attempt to more fully understand the coordinating characteristics of these chelating aryloxides, we have extended our investigations to high valent tungsten, which is known to exhibit rich aryloxide chemistry [10]. Here, new tungsten(IV and VI) complexes incorporating linked aryloxide ligands derived from the triphenols **A** and **B**, and the trisphenols **C**, **D** and **E** are reported – see Schemes 1 and 2.

2. Results and discussion

2.1. Diphenolates

The starting material [WCl_6] has been used previously for the synthesis of aryloxides of tungsten(VI) [10a,10b]. The reaction of [WCl_6] and the biphenol ligands 2,2′-CHR[4,6-(Bu^t)$_2$C$_6$H$_2$OH]$_2$ (R = H (**A**), Me (**B**)) in either refluxing CCl_4 or toluene readily gives multi-gram quantities of [WCl_4{2,2′-CHR[4,6-(Bu^t)$_2$C$_6$H$_2$O]$_2$}] R = H (**1**), Me (**2**) as dark purple/black solids. Both **1** and **2** can be recrystallized from CH_2Cl_2 as dark purple needles and the structure of **1** was determined by a single crystal X-ray analysis. The tungsten centre (Fig. 1) is pseudo octahedral and resembles those found in the *cis*-aryloxide complexes [WCl_4(OC_6H_3-2,6-R_2)$_2$] (R = Ph, ^{i}Pr) [10a,10e]. The W–O bond lengths [1.848(3)–1.8621(4) Å] are typical [10], and the chelate bite angle is 92.52(15)°, with the 8-membered metallocyclic ring adopting the boat conformation. Selected bond lengths and angles are given in Table 1 and crystallographic data is presented in Table 3.

The reduction of **1** or **2** with sodium amalgam in toluene in the presence of PMe_3 gives red/brown prisms of the *cis*, *trans*-tungsten(IV) complexes [$WCl_2(PMe_3)_2${2,2′-CHR[4,6-(Bu^t)$_2$C$_6$H$_2$O]$_2$}] R = H (**3**), Me (**4**), respectively. For **4**, the ^{31}P NMR spectrum consists of a singlet at δ −8.8 ppm; ^{183}W satellites are present [J(P–W) = 222 Hz].

P(1)–W(1)–P(2)		176.36(5)	

The molecular structure of **3** is shown in Fig. 2; selected bond lengths and angles are given in Table 1. The molecule has approximate octahedral geometry with *trans*-phosphines, but *cis*-chlorines that are coplanar with the dioxometallacycle. This arrangement contrasts with the *trans*, *trans*, *trans*-$WCl_2O_2P_2$ core observed for the related aryloxide complex $[WCl_2(OC_6H_3\text{-}2,6\text{-}Ph_2)_2(PMe_2Ph)_2]$ [10c], and reflects the geometrical constraints imposed by the chelating ligand. In **3**, there is evidence of a *trans*-phosphine influence: the mutually *trans*, formally chemically equivalent phosphines quite unexpectedly differ in bond lengths [2.535(1) and 2.556(1) Å], a phenomenon ascribed to competitive π-back bonding. The diphenolate binds symmetrically with equal W–O–C angles [133.7(2)°], a bite angle of 99.8(1)° and adopts the flattened boat conformation seen previously.

The reaction of an ethereal solution of $[WOCl_4]$ with the biphenols **A** and **B** forms $[WOCl_2\{2,2'\text{-}CHR[4,6\text{-}(Bu^t)_2\text{-}C_6H_2O]_2\}]$ R = H (**5**), Me (**6**) in good yields (55–60%). Crystals of **5** suitable for a single crystal X-ray determination were grown from a saturated hexane solution at 0 °C. The molecular structure is shown in Fig. 3; the geometrical parameters – see Table 1 (and spectroscopic data), are very similar to those reported by Takashima et al. for the same product obtained in refluxing THF and crystallised form hexane/toluene [5].

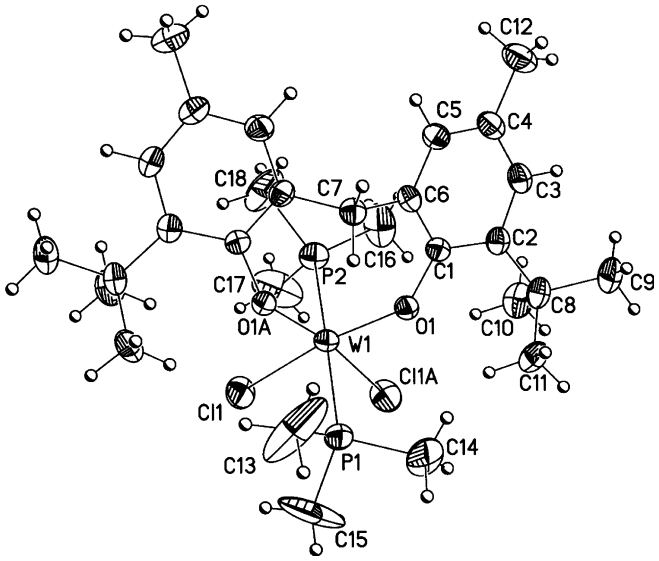

Fig. 2. ORTEP diagram of $[WCl_2(PMe_3)_2\{2,2'\text{-}CH_2[4,6\text{-}(Bu^t)_2C_6H_2O]_2\}]$ (**3**). Ellipsoids are shown at 50% probability levels.

A similar reaction of $[W(NPh)Cl_4(Et_2O)]$ with the biphenol $2,2'\text{-}CH_3CH[4,6\text{-}(Bu^t)_2C_6H_2OH]_2$ in diethyl ether at −78 °C leads to $[W(NPh)Cl_3\{(1,1'\text{-}O,OH)(2,2'\text{-}CH_3CH)\text{-}[4,6\text{-}(Bu^t)_2C_6H_2]_2\}]$ (**7**) in which the diphenol coordinates in a bidentate monoanionic form. Conformation of the monoanionic bonding is provided by IR spectra, where a band at 3492 cm^{-1} can be assigned as the stretch of the OH group. It is noteworthy that reaction of catechol with $[WOCl_4]$ has also been found to give a complex $[W(O)Cl(O_2C_6H_4)(O,OHC_6H_4)\cdot OEt_2]$ (see **F** below) containing a chelating monoanionic ligand [11].

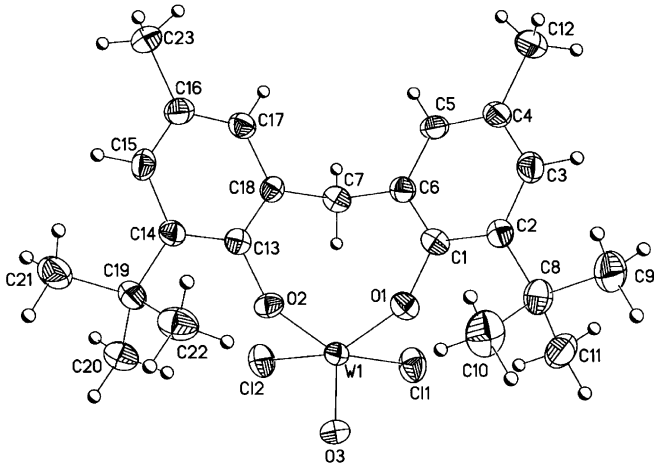

Fig. 3. ORTEP diagram of $[WOCl_2\{2,2'\text{-}CH_2[4,6\text{-}(Bu^t)_2C_6H_2O]_2\}]$ (**5**). Ellipsoids are shown at 50% probability levels.

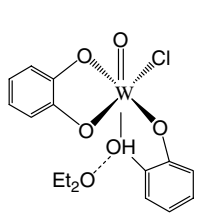
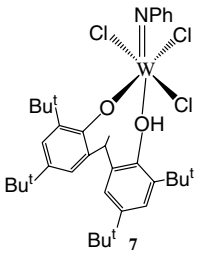


F



7

For 2,2′-methylenebis(6-*tert*-butyl-4-methylphenol), 2,2′-CH_2[4-Me,6-(Bu^t)$C_6H_2OH]_2$, it has previously been noted that the ^1H NMR resonances for the methylene bridge protons are sensitive to the changes in the metal coordination sphere [3a]. A similar situation is found in this work for both diphenols 2,2′-CHR[4,6-(Bu^t)$_2$-$C_6H_2OH]_2$) (R = H, Me), where dramatic changes in shifts are noted particularly for the CH proton of the bridge. For example, CH resonances for **1** and **5** (all recorded in $CDCl_3$) occur at δ 5.80, 3.99 and 4.11, 3.72, respectively.

2.2. Triphenolates

The interaction of $[WOCl_4]$ with the linear triphenol ligand $HOArCH_2Ar^1(OH)CH_2ArOH$ (Ar = 4,6-di-*t*-butylphenol; Ar^1 = 4-methylphenyl) **C**, in refluxing toluene yielded, on work-up, the complex $\{WOCl[OArCH_2Ar^1(O)CH_2ArO]\}_2$ (**8**), in good yield (ca. 55%). Crystals of **8**, suitable for a single crystal X-ray diffraction study, were obtained from a saturated acetonitrile solution on prolonged standing at ambient temperature. The molecular structure is shown in Fig. 4, with selected bond lengths and angles given in Table 2. The two pseudo octahedral tungsten centres are linked via asymmetric aryloxide bridges [W–O 2.053(5) and 2.207(5) Å], the bridges each derived from one of the *facially* bound triphenolate ligands, which adopts a *U* conformation. The W=O bond length [1.689(5) Å] is typical. The two halves of the molecule in **8** (space group *C*2/*c*, *Z* = 4) are related by an inversion site located at the centre of the W_2O_2 square. The core of the structure is reminiscent of that observed in a number of other tungsten(VI) oxo alkoxides – edge-shared bioctahedral structures featuring asymmetric alkoxide bridges, which are coplanar with terminal oxo ligands [10c].

Similar reaction of $[W(NPh)Cl_4(Et_2O)]$ with triphenol **D** 2,6-(3-*t*-butyl-5-methyl-2-hydroxybenzyl)-4-*t*-butylphenol, $HOAr^2CH_2Ar^3(OH)CH_2Ar^2OH$ (Ar^2 = 4-methyl-6-*t*-butylphenol; Ar^3 = 4-*t*-butylphenyl) afforded, on work-up, brown blocks of the hydrolysis product $\{WOCl[OAr^2CH_2Ar^3(O)CH_2Ar^2O]\}$ (**9**). Complex **9** can also be prepared directly from the reaction of $[WOCl_4]$ and **D**. The molecular

[a] Conventional $R = \sum||F_o| - |F_c||/\sum|F_o|$ for 'observed' reflections having $F^2 > 2\sigma(F^2)$.
[b] $R_w = [\sum w(F_o^2 - F_c^2)^2/\sum w(F_o^2)^2]^{1/2}$ for all data.
[c] $S = [\sum w(F_o^2 - F_c^2)^2/(\text{no. of unique reflections} - \text{no. of parameters})]^{1/2}$.

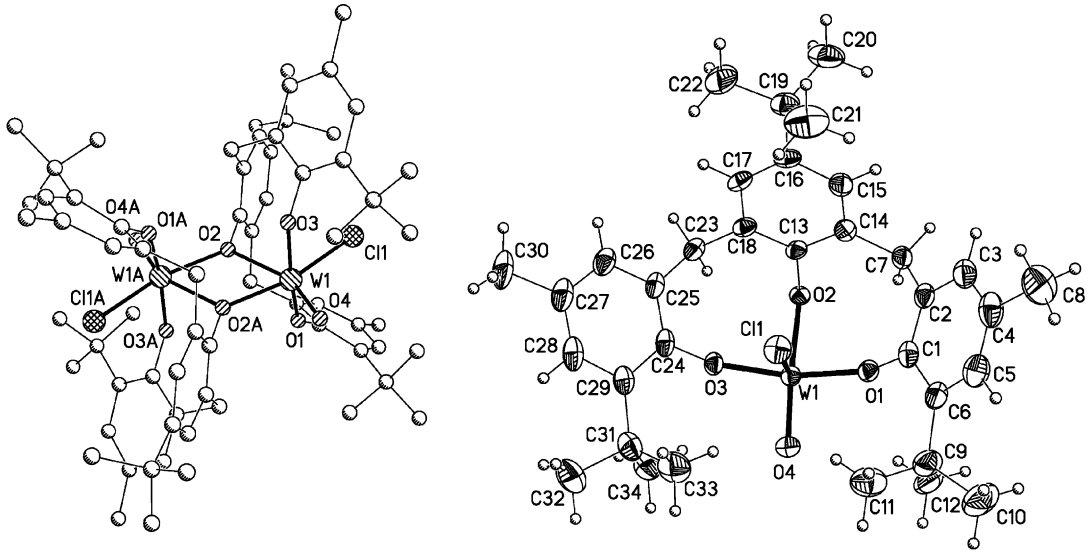

Fig. 5. ORTEP diagram of {WOCl[OAr^{2}CH$_2$Ar^3(O)CH$_2$Ar^{2}O]} (**9**). Ellipsoids are shown at 50% probability levels. Only half the molecule is shown for clarity.

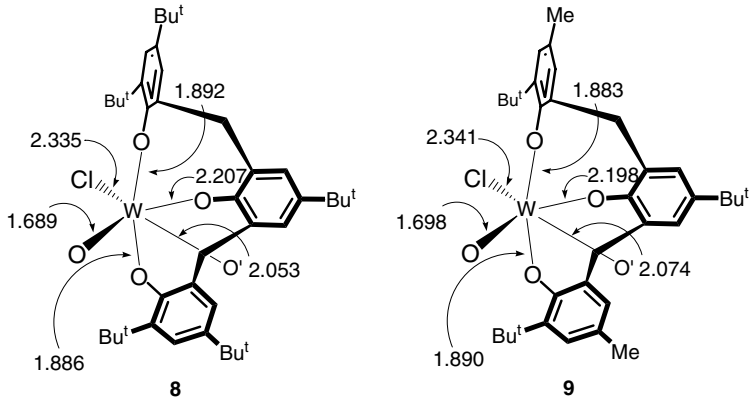

Fig. 6. Selected geometrical parameters associated with **8** and **9**.

ybenzyl)-4-*t*-butylphenol, $HOAr^4CH_2Ar^3(OH)CH_2Ar^4OH$ ($Ar^4 = 4,6$-di-methylphenol) in refluxing toluene afforded the orange complex $[W(eg)_2(OAr^4CH_2Ar^3(O)CH_2Ar^4OH)]$ (**10**) in good yield. Crystals suitable for an X-ray determination were grown from a saturated solution of acetonitrile at room temperature. The molecular structure is shown in Fig. 7. The tungsten centre is pseudo octahedral with coordination sites occupied by two chelating 1,2-ethanediolato ligands and a bidentate chelate ligand [bite angle = 85.65(8)°] derived from the triphenol **E** for which one of the phenolic groups remains unbound (pendant). The 8-membered metallocyclic ring adopting the boat conformation similar to that observed in the diphenolate complexes **1**, **3** and **5**, whilst the core geometry at tungsten resembles that reported for the diphenolate complexes $[W(eg)_2L]$ (L = 2,2′-methylenebis(6-methylphenolate) and 2,2′-methylenebis(6-isopropylphenolate) reported by Lehtonen and Sillanpää [12b].

In conclusion, the compounds described herein provide useful insight into the coordination environment afforded by the deprotonated forms of both bi- and tri-phenolate ligands. Further catalytic studies using these ligand systems will be published elsewhere.

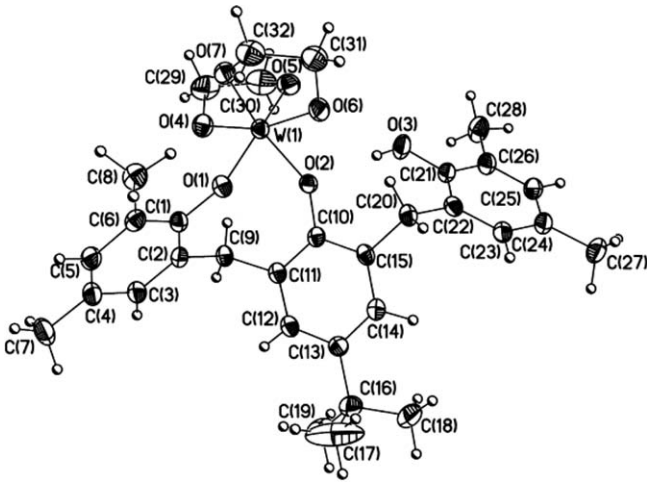

Fig. 7. Structural diagram of $[W(eg)_2(OAr^4CH_2Ar^3(O)CH_2Ar^4OH)]$ (**10**). Ellipsoids are shown at 50% probability levels.

3. Experimental

3.1. General

All manipulations were carried out under an atmosphere of nitrogen using standard Schlenk and cannula techniques or in a conventional nitrogen-filled glove-box. Solvents were refluxed over an appropriate drying agent, and distilled and degassed prior to use. Elemental analyses were performed by the microanalytical services of the Department of Chemistry at Durham and Medac Ltd. NMR spectra were recorded on a Varian VXR 400 S spectrometer at 399.9 MHz (^1H), and 161.9 MHz (^{31}P); chemical shifts are referenced to the residual protio impurity of the deuterated solvent; IR spectra (nujol mulls, CsI windows), Perkin–Elmer 577 and 457 grating spectrophotometers; $[WOCl_4]$, $[W(NPh)Cl_4(Et_2O)]$ and $[W(eg)_3]$ were prepared by literature methods [13–15]. Trimethylphosphine was prepared by the method of Wolfsberger and Schmidbaur [16]. The triphenol ligands **C**–**E** were prepared by the methods of Scott [7a]. All other chemicals were obtained commercially and used as received unless stated otherwise.

3.2. Preparation of $[WCl_4\{2,2'\text{-}CH_2\text{-}[4\text{-}Me,6\text{-}Bu^t\text{-}C_6H_2O]_2\}]$ (1)

$[WCl_6]$ (1.00 g, 2.52 mmol) and the diphenol **A** (0.93 g, 2.52 mmol) were combined in a dry-box. The system was then refluxed for 12 h in either CCl_4 or toluene (ca. 50 cm^3) to give a dark purple/black solid. This solid was washed with cold pentane (50 cm^3) and dried in vacuo. Yield: 1.24 g, 74%. Found: C, 42.1; H, 4.7%. $WCl_4O_2C_{23}H_{30}$ requires: C, 41.6; H, 4.6%. IR: 1599m, 1161w, 1140w, 1093bs, 1019bs, 917w, 871w, 865w, 799s. ^1H NMR ($CDCl_3$): δ 7.34 (d, 2H, $J_{HH} = 2.0$ Hz, aryl*H*), 7.25 (d, 2H, $J_{HH} = 1.5$ Hz, aryl*H*), 5.80 (d, 1H, $J_{HH} = 13.9$ Hz, CH_2), 3.99 (d, 1H, $J_{HH} = 13.9$ Hz, CH_2), 3.17 (s, 6H, CH_3), 1.57 (s, 18H, $(CH_3)_3C$).

3.3. Preparation of [WCl_4{2,2′-CH_3CH-[4,6-(Bu^t)$_2C_6H_2O$]$_2$}] (2)

[WCl_6] (3.39 g, 8.5 mmol) and the diphenol **B** (3.76 g, 8.6 mmol) were combined in a dry-box. The system was then refluxed for 12 h in either CCl_4 or toluene (ca. 50 cm^3) to give a dark purple/black solid. This solid was washed with cold pentane (50 cm^3) and dried in vacuo. Yield: 4.1 g, 62%. The compound can be crystallized from CH_2Cl_2 (−20 °C). Found: C, 46.9; H, 5.5%. $WCl_4O_2C_{30}H_{44}$ requires: C, 47.2; H, 5.8%. IR: 1583s, 1540w, 1363s, 1336w, 1261m, 1237m, 1200m, 1166s, 1157s, 1093s, 1022s, 927w, 908m, 885s, 875m, 800s, 769m, 759w, 749w, 723w, 684w, 657w, 628w, 565w, 444m, 357s, 318s, 308s. ^{1}H NMR ($CDCl_3$): δ 7.56 (d, 2H, J_{HH} = 2.0 Hz, aryl*H*), 7.37 (d, 2H, J_{HH} = 2.4 Hz, aryl*H*), 5.82 (q, 1H, J_{HH} = 6.8 Hz, C*H*), 1.57 (d, 3H, J_{HH} = 7.2 Hz, CH_3), 1.53 (s, 18H, (CH_3)$_3$C), 1.31 (s, 18H, (CH_3)$_3$C).

3.4. Preparation of [$WCl_2(PMe_3)_2${2,2′-CH_2-[4-Me,6-Bu^t-C_6H_2O]$_2$}] (3)

To a solution of **1** (1.00 g, 1.31 mmol) in toluene (40 cm^3) was added PMe_3 (0.31 cm^3, 3.0 mmol) and 0.2% sodium amalgam (0.09 g, 4.0 mmol). After stirring for 12 h, the suspension was filtered and the volatiles were removed in vacuo. The residue was dissolved in hexane (40 cm^3) and stored at 0 °C for 2 days to afford **3** as large red prisms. Yield: 0.47 g, 42%. Found: C, 46.3; H, 6.5%. $WCl_2P_2O_2C_{29}H_{48}$ requires: C, 46.7; H, 6.5%. IR: 1405m, 1286m, 1260s, 1229s, 1166m, 1120s, 1095bs, 1018bs, 953m, 918w, 900w, 861w, 848w, 831s, 796s, 737w, 722w, 567w.

3.5. Preparation of [$WCl_2(PMe_3)_2${2, 2′-CH_3CH-[4,6-(Bu^t)$_2C_6H_2O$]$_2$}] (4)

To a solution of **2** (2.00 g, 2.62 mmol) in toluene (ca. 50 cm^3) was added PMe_3 (0.6 cm^3, 5.3 mmol) and a 0.2% sodium amalgam (0.14 g Na, ca. 6 mmol). The mixture was stirred rapidly for 24 h, filtered and pumped dry in vacuo. Recrystallization from pentane at −20 °C gave a red crystalline solid. Yield: 1.45 g, 66%. Found: C, 50.8; H, 7.4%. $WCl_2P_2O_2C_{36}H_{62}$ requires: C, 51.2; H, 7.4%. IR: 1311s, 1284s, 1260s, 1236s, 1206s, 1186s, 1142s, 1122s, 1086s, 1023s, 952s, 913m, 872m, 853m, 828s, 812s, 773m, 741s, 728s, 670m, 647m, 633s, 600m, 550s. ^{31}P NMR ($CDCl_3$): δ −8.8 [s, with satellites $J_{(P-W)}$ 222 Hz].

3.6. Preparation of [$WOCl_2${2,2′-CH_2-[4-Me,6-Bu^t-C_6H_2O]$_2$}] (5)

To a solution of [$WOCl_4$] (1.00 g, 2.94 mmol) in diethyl ether (ca. 40 cm^3) at −78 °C was added the diphenol **A** (1.08 g, 2.94 mmol). After stirring the green solution at 25 °C (12 h), the volatiles were removed in vacuo and the solid residue was extracted with pentane. Filtration, reduction (to ca. 30 cm^3) and cooling (−20 °C) gave dark green cubes. Yield: 1.13 g, 63%. Found: C, 46.1; H, 5.2%. $WCl_2O_3C_{23}H_{30}$ requires: C, 45.3; H, 5.0%. IR: 1300w, 1261s, 1094bs, 1020bs, 986m, 941w, 930w, 800s, 722m. ^{1}H NMR ($CDCl_3$): δ 6.97 (d, 2H, $^4J_{HH}$ 2.0 Hz, aryl*H*), 6.95 (d, 2H, $^4J_{HH}$ 2.0 Hz, aryl*H*), 4.11 (d, 1H, $^2J_{HH}$ 16.1 Hz, CH_2), 3.72 (d, 1H, $^2J_{HH}$ 15.9 Hz, CH_2), 2.37 (s, 6H, 4-Me), 1.31 (s, 18H, (CH_3)$_3$C).

3.7. Preparation of [$WOCl_2${2,2′-CH_3CH-[4,6-(Bu^t)$_2C_6H_2O$]$_2$}] (6)

To a solution of [$WOCl_4$] (1.00 g, 2.94 mmol) in diethyl ether (ca. 40 cm^3) at −78 °C was added the diphenol **B** (1.29 g, 2.94 mmol). After stirring the green solution at 25 °C (12 h), the volatiles were removed in vacuo and the solid residue was extracted with pentane. Filtration, reduction (to ca. 30 cm^3) and cooling (−20 °C) gave dark green cubes. Yield: 1.14 g, 55%. Found: C, 54.1; H, 6.8%. $WCl_2O_3C_{35}H_{56}$ (pentane solvate) requires: C, 53.9; H, 7.2%. IR: 1589m, 1367s, 1261s, 1224s, 1200w, 1162w, 1109s, 1022s, 998s, 927m, 904w, 873s, 800s, 772m, 722w, 635w, 570w, 475w, 368m. ^{1}H NMR ($CDCl_3$): δ 7.16 (d, 2H, J_{HH} = 2.4 Hz, aryl*H*), 7.12 (d, 2H, J_{HH} = 2.0 Hz, aryl*H*), 3.76 (q, 1H, J_{HH} = 6.0 Hz, C*H*), 1.84 (d, 3H, J_{HH} = 6.4 Hz, CH_3), 1.31 (s, 18H, (CH_3)$_3$C), 1.21 (s, 18H, (CH_3)$_3$C).

3.8. Preparation of [$W(NPh)Cl_3${(1,1′-O,OH)-(2,2′-CH_3CH)[4,6-(Bu^t)$_2C_6H_2$]$_2$}] (7)

To a solution of [$W(NPh)Cl_4(Et_2O)$] (1.00 g, 2.0 mmol) in diethyl ether (ca. 40 cm^3) at −78 °C was added the diphenol **B** (0.9 g, 2.1 mmol). After stirring at 25 °C for 12 h, the volatiles were removed in vacuo and the residue was extracted with heptane. Concentration (to ca. 25 cm^3) and cooling (−20 °C) gave brown prisms. Yield: 0.69 g, 40%. Found: C, 49.9; H, 5.1; N, 1.7%; Calc. for $C_{36}H_{50}O_4NCl_3W$: C, 50.8; H, 5.9; N, 1.7%. IR: 3492m, 1595m, 1300m, 1260s, 1214s, 1170m, 1104s, 1027m, 924w, 882m, 864m, 804m, 761s, 726s, 681w. ^{1}H NMR ($CDCl_3$): δ 7.126 (m, 2H, aryl*H*), 7.47 (m, 2H, aryl*H*), 3.69 (q, 1H, J_{HH} 6.0 Hz, C*H*), 1.97 (d, 3H, J_{HH} 6.1 Hz, CH_3), 1.30 (s, 18H, (CH_3)$_3$C), 1.22 (s, 18H, (CH_3)$_3$C). O*H* obscurred.

3.9. Preparation of {$WOCl[OArCH_2Ar'(O)CH_2ArO]$}$_2$ Ar′ = 4-methylphenyl (8)

To a solution of [$WOCl_4$] (1.00 g, 2.94 mmol) in diethyl ether (ca. 40 cm^3) at −78 °C was added the triphenol **C** (1.60 g, 2.94 mmol). The system was refluxed for 12 h, volatiles were removed in vacuo, and the residue was extracted into warm MeCN (30 cm^3). Prolonged standing at ambient temperature (2–3 days), afforded purple needles of **8**. Yield: 0.98 g, 43%. Further crops can be obtained by concentration

of the mother-liquor. Total isolated yield 64%. Found: C, 60.8; H, 7.1%. Calc. for $C_{74}H_{104}O_8Cl_2W_2$: C, 61.6; H, 7.2%. IR: 1594w, 1359m, 1293w, 1261s, 1241w, 1218w, 1155m, 1095bs, 1019bs, 973s, 910w, 880w, 872w, 852m, 796s, 767m, 753w, 722w, 666w, 601w, 570m, 514w, 506w, 472w, 455w. ^{1}H NMR ($CDCl_3$): δ 7.27 (m, 8H, aryl*H*), 7.09 (s, 4H, aryl*H*), 5.07 (d, 4H, $^2J_{HH}$ 13.3 Hz, CH_2), 3.50 (d, 4H, $^2J_{HH}$ 13.3 Hz, CH_2), 2.27 (s, 6H, CH_3), 1.40 (s, 36H, C(CH_3)$_3$), 1.24 (s, 36H, C(CH_3)$_3$).

3.10. Preparation of {WOCl[OArCH$_2$Ar′(O)CH$_2$ArO]}$_2$ Ar′ = 4-tert-butylphenyl (9)

[W(NPh)Cl$_4$(Et$_2$O)] (1.00 g, 2.0 mmol) and triphenol **D** (1.01 g, 2.01 mmol) were refluxed in toluene (30 cm^3) for 12 h. On cooling, volatiles were removed in vacuo and the residue was extracted into hexane (30 cm^3). Cooling to −20 °C afforded brown blocks of **9** in 38% yield: 0.56 g. Alternatively, **9** can be prepared in ca. 60% yield using [WOCl$_4$] in the above procedure. Found: C, 54.8; H, 6.1%. Calc. for $C_{68}H_{86}O_8Cl_2W_2$: C, 55.6; H, 5.9%. IR: 1600w, 1293w, 1261s, 1206m, 1168m, 1096bs, 1019bs, 972m, 909w, 858m, 801s, 738m, 718m. ^{1}H NMR ($CDCl_3$): δ 7.21–7.24 (m, 4H, aryl*H*), 7.17 (s, 4H, aryl*H*), 7.10 (s, 4H, aryl*H*), 5.05 (d, 4H, $^2J_{HH}$ 13.4 Hz, CH_2), 3.52 (d, 4H, $^2J_{HH}$ 13.4 Hz, CH_2), 2.49 (s, 12H, CH_3), 1.42 (s, 36H, C(CH_3)$_3$), 1.19 (s, 18H, C(CH_3)$_3$).

3.11. Preparation of [W(eg)$_2$(OAr^{4}CH$_2$Ar^3(O)-CH$_2$Ar^{4}OH)] (10)

[W(eg)$_3$] (1.00 g, 2.75 mmol) and triphenol **E** (2.27 g, 5.49 mmol) were refluxed in toluene for 12 h. Volatiles were removed in vacuo and the residue was extracted into hot MeCN (40 cm^3). Prolonged standing at ambient temperature afforded **10** as orange needles. Yield: 1.08 g, 55%. Found: C, 52.9; H, 5.1%. Calc. for $C_{32}H_{40}O_7W$: C, 53.3; H, 5.6%. IR: 3367w, 1304m, 1248m, 1214s, 1146m, 1099w, 1049m, 1030s, 944w, 913s, 878m, 840m, 781w, 722m, 657s, 620s. ^{1}H NMR ($CDCl_3$): δ 7.11–7.58 (several m, 6H, aryl*H*), 5.91–6.01 (2× m, 4H, OCH_2), 5.53–5.74 (2× m, 4H, OCH_2), 4.29 (d, $^2J_{HH}$ 15.0 Hz, CH_2), 2.69 (s, 3H, CH_3), 2.32–2.58 (overlapping signals, 11H, 3x CH_3 + CH_2), 1.50 (s, 9H, C(CH_3)$_3$).

3.12. X-ray crystallography

Crystals were mounted on thin glass fibres using perfluoropolyether oil, which was frozen in situ by the cold nitrogen gas Cryostream flow. Data for compounds **1**, **3**, **5**, **8**, **9** and **10** were collected using an Enraf–Nonius Kappa CCD diffractometer using monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). Data was collected to $\theta_{max} \geqslant 27.5°$ for all structures with the exception of **5** ($\theta_{max} = 20.4°$), due to lack of high-angle diffraction from the sample. Cell refinement and data reduction was performed using the HKL SCALEPACK and DENZO [16] and COLLECT [17] utilities. Absorption corrections were made based on ψ- and ω-scans using the SORTAV program [18]. Structures were solved using direct methods and refined on F^2 using the program SIR-92 [19] and then refined using SHELXTL-97 software [20]. Geometrical restraints were applied to improve refinement of PMe_3 ligands in compound **3**; all P–C bond distances have been restrained using a single common free variable, while C···C distances were treated similarly, in order to obtain idealized (tetrahedral) geometries for these moieties. All non-hydrogen atoms were refined anisotropically for all structures. Aromatic H-atoms were fixed based on idealised positions and their values of U_{iso} set to 1.5 times that of the carrier atom [21]. See Table 1 for further crystallographic information.

of the higher field CD_2H quintet as the internal reference (δ 2.74 ppm, relative to $SiMe_4$). Time dependent visible (340–800 nm) and UV (220–320 nm) spectra and absorbance-time data generated from such data were recorded on a HP8453A diode array Vis/UV spectrophotometer thermostated to 25.0 ± 0.1 °C with use of a Lauda RM6 circulating water bath. Reported Vis/UV spectra for all compounds have been extrapolated to zero reaction time. Kinetic data were analysed by weighted non-linear regression on a Macintosh with the usual packages, or by importing the HP .kd files into Specfit® and carrying out Global Spectral Analysis (SVD data reduction) and subsequent fitting to either a single or double exponential integrated rate expression [14]. Carbon dioxide free Milli-Q® water was used for all physical measurements.

2.1. Synthesis and characterisation

$[Co(NH_3)_4(OCO_2)]NO_3 \cdot 0.5H_2O$ and $[Co(NH_3)_4(OCO_2)]Cl$ were prepared by two standard methods, the faster H_2O_2 oxidation procedure [15,16] being preferred over the aerial oxidation route [15,17]. $[Co(NH_3)_4(OCO_2)]_2SO_4 \cdot 3H_2O$ was made by the published procedure [10,18], as were *cis*-$[Co(NH_3)_4(OH_2)Cl]SO_4$ and *cis*-$[Co(NH_3)_4(OH_2)_2]_2(SO_4)_3 \cdot 3H_2O$ derived from it [15,18,19]. The carbonato sulfate was converted to the chloride by metathesis using the stoichiometric amount of $BaCl_2 \cdot 2H_2O$ to remove the sulfate and then crystallised by precipitation with methanol. *cis*-Diaqua sulfate was generated in situ from the carbonato sulfate with the required amount of H_2SO_4, and then treated with pyridine and $Na_2S_2O_6 \cdot 2H_2O$ to afford *cis*-$[Co(NH_3)_4(OH_2)OH]\ S_2O_6$ [20]. Much less pyridine (30 g) is required than that reported (85 g) for the synthesis on the same scale [20]. Dehydration of the latter product (130 °C, 3 h) yielded the *cis*-diol quantitatively [20]; the observed weight loss on dehydration was precisely that calculated. The resultant *cis–cis*-$[(NH_3)_4Co(OH)_2Co(NH_3)_4](S_2O_6)_2$ was converted to the chloride salt by trituration of a thin aqueous slurry with excess NH_4Cl, analogous to that described for the Cr(III) analogue [20]. The product was recrystallised from a saturated aqueous by addition of a fifth volume of saturated NH_4Cl and careful dilution with methanol. The product was collected, and washed with methanol and ether, and air dried.

2.1.1. *cis*-$[Co(NH_3)_4(OH_2)Cl]SO_4$

The crude material was recrystallised by adding sufficient conc. H_2SO_4 to a thick aqueous suspension of the crude sulfate salt to dissolve much of it, filtering rapidly, and then collecting the resultant crystals on cooling. The process was repeated to afford the pure sulfate. *Anal.* Calc. for $CoN_4H_{14}ClSO_5$: H, 5.30; N, 19.66; Cl, 12.27; S, 11.22. Found: H, 5.05; N, 19.99; Cl, 12.63; S, 11.29%.

2.1.2. *cis*-$[Co(NH_3)_4(OH_2)Cl]Cl_2$

cis-$[Co(NH_3)_4(OH_2)Cl]SO_4$ (10 g) was treated with conc. HCl (50 mL) at ambient temperature, and after stirring for 5 min was filtered, washed with ethanol and ether, and air dried. Two recrystallisations from a saturated aqueous solution by adding a third volume of conc. HCl and cooling yielded the pure chloride salt. *Anal.* Calc. for $CoN_4H_{14}Cl_3O$: H, 5.61; N, 22.29; Cl, 42.30. Found: H, 5.39; N, 22.04; Cl, 42.05%. Vis/UV spectrum (0.02 M $HClO_4$): 531 nm, ε(max) 57.5; 372 nm, ε(max) 49.0 $M^{-1}\,cm^{-1}$. ^1H NMR spectrum (D_2O, DCl): δ 4.30 (6H, *cis*-Cl, OH_2); δ 3.63 (3H, *trans*-OH_2); δ 3.20 ppm (3H, *trans*-Cl).

cis-$[Co(NH_3)_4(OH_2)Cl]S_2O_6 \cdot H_2O$ was obtained by adding aqueous $Na_2S_2O_6$ to a solution of the complex chloride. Crystals which formed on cooling overnight were washed with ice water, methanol and then ether and air dried. *Anal.* Calc. for $CoN_4H_{16}ClS_2O_8$: H, 4.50; N, 15.62; Cl, 9.88; S, 17.88. Found: H, 4.24; N, 15.63; Cl, 9.91; S, 17.50%.

2.1.3. *trans*-$[Co(NH_3)_5(OH_2)Cl]Cl_2$

trans-$[Co(NH_3)_5Cl_2]Cl_2 \cdot H_2O$ [18,21] (12.7 g, 50.5 mmol) was partly suspended/dissolved in a mixture of ice (150 g) and water (150 mL) acidified with a few drops of neat CF_3SO_3H or CF_3CO_2H while well-stirred in an ice bath. To this was added dropwise over 4–5 min an ice-cold suspension (yellow) of HgO (red; 10.9 g, 50.3 mmol, 1.0 equiv.) which had been well-stirred and cooled in ice (25 g)/water (10 mL) containing neat CF_3SO_3H (16 g, 107 mmol). The green salt gradually dissolved to yield a violet solution. Some unreacted green complex remained. The addition of a mixture of ice (25 g) and $HClO_4$ (70%; 25 mL) was added to ensure complete precipitation of the unreacted green substrate. The mixture was then filtered, and the residual green solid (<0.2 g) was washed with one bed volume of acetone (50 mL). The filtrate and washing was treated with ice (30 g)/conc. H_2SO_4 (20 mL), and acetone (75 mL) was added to the point of cloudiness. After further stirring on ice (ca. 3 min), the mixture was filtered to remove the precipitate of *cis*-$[Co(NH_3)_4(OH_2)Cl]SO_4$ (ca. 6 g) and washed with acetone (50 mL). The now lavender-grey filtrate was carefully diluted with acetone (ca. 125 mL) just to the point of permanent cloudiness. After 5 min stirring on ice and a then further addition of acetone (100 mL), the crystallisation of *trans*-$[Co(NH_3)_4(OH_2)Cl]SO_4$ was complete. It was removed by filtration, washed with acetone and ether, and air dried (5.1 g). A second crop (1.4 g) was obtained from the filtrate by diluting further with acetone (to 1 L total volume) and allowing to crystallise for 5 min.

The crude *trans* isomer was stirred in aqueous HCl (5 M) whence it transformed from a lavender grey to a fine grey-green Cl^- salt. It was filtered to remove the *cis* isomer which had selectively extracted. The extraction was repeated until the washings were virtually colorless and the residual solid had become a dull green. The purified *trans*-$[Co(NH_3)_4(OH_2)Cl]Cl_2$ was finally recrystallised from a minimum volume of ice water by filtering and quickly adding cold 5 M HCl. Shiny green-grey needles resulted, which were quickly collected, washed with methanol and

ether and air dried. *cis* Isomer is introduced if crystallisation is delayed. *Anal.* Calc. for $CoN_4H_{14}Cl_3O$: H, 5.65; N, 22.42; Cl, 42.55. Found: H, 5.64; N, 22.05; Cl, 41.68%. Vis/UV spectrum (0.02 M $HClO_4$): 593 nm, ε(max) 30.7; 470 nm, ε(max) 24.1; 367 nm, ε(max) 50.0; 530 nm, ε 20.4 $M^{-1}\,cm^{-1}$. ^1H NMR spectrum (D_2O, DCl): δ 4.36 ppm (6H, *cis*-Cl, OH_2).

An aqueous solution of the Cl^- salt yielded crystals of the SO_4^{2-} or $S_2O_6^{2-}$ using the appropriate precipitant (5 M H_2SO_4 or 5 M aqueous $Li_2S_2O_6$).

An alternative synthesis of the *trans*-aquachloro complex is via reaction of *trans*-$[Co(NH_3)_4Cl_2]Cl \cdot H_2O$ in neat triflic acid, as described for the bis(ethylenediamine) analogue [22]. The product mixture required fractionation of the sulfate salts, as described above.

2.1.4. *trans*-$[Co(NH_3)_4Cl_2]Cl \cdot H_2O$

This followed that described by Jørgensen, reaction of *cis*-$[Co(NH_3)_4(OH_2)_2]_2(SO_4)_3 \cdot 3H_2O$ in conc. H_2SO_4, followed by reaction with 37% HCl, all at ambient temperature [18,21]. By warming to 50–60 °C, the time scale of the synthesis can be reduced from 48 h to 30 min, and reduced further by using $[Co(NH_3)_4(OCO_2)]_2SO_4 \cdot 3H_2O$ directly rather than first converting it to the *cis*-diaqua complex using aqueous H_2SO_4. The grass-green product is reported to be the chloride salt, but it contains free sulfate and requires recrystallisation from H_2O/HCl to yield pure *trans*-$[Co(NH_3)_4Cl_2]Cl \cdot H_2O$. The perchlorate salt was obtained by metathesis in water using 5 M $HClO_4$ as precipitant. *Anal.* Calc. for $CoN_4H_{14}Cl_3O$: H, 5.61; N, 22.29; Cl, 42.30. Found: H, 5.38; N, 22.11; Cl, 42.13%. Vis/UV spectrum (0.02 M $HClO_4$): 634 nm, ε(max) 42.1; 538 nm, ε(min) 4.7; 467 nm, ε(max) 21.5; 377 nm, ε(max) 36.8; 370 nm, ε(max) 46.4 $M^{-1}\,cm^{-1}$. ^1H NMR spectra: DMF-d_7: δ 4.20 (12H, *cis*-Cl); D_2O, DCl: δ 4.06 ppm (12H, *cis*-Cl).

2.2. *cis*-$[Co(NH_3)_4Cl_2]ClO_4$

The following is a modification of Werner's procedure [1]. Concentrated HCl which had been saturated with HCl (g) at 0 °C was allowed to warm to ca. 15 °C and then 30 mL was added to *cis–cis*-$[(NH_3)_4Co(OH)_2Co(NH_3)_4]Cl_4$ (5.0 g) in a mortar and ground rapidly for ca. 40 s. The crystals that had quickly changed consistency and colour were filtered and the then chilled filtrate and ethanol washings (2 × 10 mL) were treated with cold $HClO_4$ (5 M; 1:1 70% mixed with ice). On scratching blue crystals deposited which were collected, washed with ethanol and ether and air dried. The original solid was extracted with small portions of ice water to give a red solution of the diaqua complex which contained a little of the *cis*-dichloro complex; this was again crystallised using 5 M $HClO_4$. The solid residue was crude blue *cis*-dichloro chloride which was extracted with sufficient ice water to dissolve it all, filtered, and treated with a fifth volume of cold $HClO_4$ (5 M). The three fractions of *cis*-$[Co(NH_3)_4Cl_2]ClO_4$ were combined and quickly recrystallised from water/$HClO_4$. Yield: 1.6 g (46%, based on diol). *Anal.* Calc. for $CoH_{12}N_4Cl_3O_4$: H, 4.07; N, 18.84; Cl, 35.76. Found: H, 4.34; N, 18.51; Cl, 35.32%. Vis/UV spectrum (0.02 M $HClO_4$): 594 nm, ε(sh) 54.2; 563 nm, ε(max) 57.1; 456 nm, ε(min) 9.5; 390 nm, ε(sh) 61.0 $M^{-1}\,cm^{-1}$. ^1H NMR spectrum: DMF-d_7: δ 4.25 (6H, *cis*-Cl); δ 2.74 (6H, *trans*-Cl); D_2O, DCl: δ 4.10 (6H, *cis*-Cl); δ 3.35 ppm (6H, *trans*-Cl).

trans-$[Co(NH_3)_4(NO_2)_2]Cl$ was synthesised as described [23]. It was recrystallised from a saturated aqueous solution by addition of a fifth volume of saturated NH_4Cl and careful dilution with methanol. The perchlorate salt was obtained by metathesis in water using $HClO_4$ as precipitant. Vis/UV spectrum (H_2O): λ(max) 441 and 347 nm. ^1H NMR spectrum (DMF-d_7): δ 3.82 (12H, *cis*-NO_2).

cis-$[Co(NH_3)_4(NO_2)_2]Cl$ was initially prepared as reported by aerial oxidation of Co(II) in the presence of excess NH_3 and NO_2^- [18]; the yield of pure material is poor. The high yield synthesis of *cis*-$[Co(NH_3)_4(NO_2)_2]NO_3$ has been reported [23]. We have made the Cl^- salt by warming *cis*-$[Co(NH_3)_4(OH_2)Cl]Cl_2$ with excess $NaNO_2$ (5 equiv.) after the addition of HCl to first generate the nitritochloro complex. The yellow product was reprecipitated from water with HCl, and then freed of a little *trans* isomer by extracting about 90% of the product with water and crystallising using HCl. This process was repeated to afford yellow needles of the pure *cis* salt. The perchlorate was obtained as described for the *trans* isomer. Vis/UV spectrum (H_2O): λ(max) 441 and 324 nm. ^1H NMR spectrum (DMF-d_7): δ 3.86 (6H, *cis*-NO_2); δ 3.60 ppm (6H, *trans*-NO_2).

An alternative synthesis, and one that gives cis isomer cleanly, is as follows. $[Co(NH_3)_4(OCO_2)]Cl$ in water was treated with sufficient H_2SO_4 to generate the *cis*-$[Co(NH_3)_4(OH_2)_2]^{3+}$ species, as described [20]. Addition of excess $NaNO_2$ (5 equiv.) was added, and the stirred mixture was allowed to stand 48 h to allow the nitrito species to isomerise to the nitro complex. Ethanol was added to precipitate the product, and the filtered material was recrystallised from hot water by addition of a fifth volume of saturated NH_4Cl and dilution with methanol. Fine yellow-orange crystals slowly deposited on cooling. Curiously, this material was much less soluble than the *cis*-dinitro chloride obtained as above, and proved to contain no chloride but rather anionic sulfate which had carried through from the H_2SO_4 plus carbonato chloride initial step.

cis-$[Co(NH_3)_4(NO_2)Cl]Cl$ was obtained by allowing a stirred, thin slurry of *cis*-$[Co(NH_3)_4(NO_2)_2]Cl$ in conc. HCl (1 g in 5 mL) to react for 18 h. The crude product was collected by filtration, washed with ethanol and ether, and air dried. This was extracted carefully with water to yield a claret solution and a green residue of the less soluble *trans*-$[Co(NH_3)_4Cl_2]Cl$. Addition of HCl precipitated the red-claret chloride salt which was recrystallised from water using HCl as precipitant to afford the Cl^- salt. Trituration of the Cl^- salt in a thin slurry with 70% $HClO_4$ removed Cl^- as HCl, and the filtered product was recrystallised from

water/$HClO_4$. ^1H NMR spectrum (DMF-d_7): δ 4.54 (6H, *cis*-NO_2, *cis*-Cl); δ 4.04 (3H, *cis*-Cl, *trans*-NO_2); δ 3.48 ppm (3H, *trans*-Cl).

trans-$[Co(NH_3)_4(NO_2)Cl]Cl$ was synthesised from *trans*-$[Co(NH_3)_4(NO_2)_2]Cl$ as described for the *cis* isomer above but allowing a 27 h reaction time. The *trans*-dinitro complex is not very soluble in HCl but cleanly transforms to the *trans*-nitrochloro product quantitatively, whereas the *cis* isomer partly dissolves in HCl and some loss of the second NO_2^- ligand occurs. The salmon pink *trans*-nitrochloro product was obtained as Cl^- and ClO_4^- salts. ^1H NMR spectrum (DMF-d_7): δ 3.70 ppm (12H, *cis*-NO_2, *cis*-Cl).

2.3. Kinetics of acid hydrolysis

Reactions were followed spectrophotometrically using a 8-cell compartment housed in an HP8453A diode array Vis/UV spectrophotometer and the in situ method described previously [24]. The solvent was 1.0, 0.1 or more usually 0.02 M $HClO_4$.

3. Results and discussion

3.1. Syntheses

trans-$[Co(NH_3)_4Cl_2]Cl \cdot H_2O$ was obtained by a modification of a published method [21]. It is much less soluble in water than the bis(ethylenediamine) analogue, and this is also true of methanol as solvent in which it is virtually insoluble. For the perchlorate salts, the water solubilities are reversed. The perchlorate counter ion does not precipitate the chloroaqua ions, and thus both *cis*- and *trans*-$[Co(NH_3)_4Cl_2]ClO_4$ are obtained free of the chloroaqua species which otherwise readily crystallise when Cl^-, SO_4^{2-} or $S_2O_6^{2-}$ are used as counterions.

Werner's classic *cis*-$[Co(NH_3)_4Cl_2]Cl$ complex was first synthesised by HCl cleavage of the *cis*-diol $[(NH_3)_4Co(\mu\text{-}OH)_2Co(NH_3)_4]Cl_4$ [1]. A 1:1 mixture of *cis*-$[Co(NH_3)_4Cl_2]Cl$ and *cis*-$[Co(NH_3)_4(OH_2)_2]Cl_3$ results. The HCl needs to be above the standard concentrated grade (11.7 M) or the yield of the dichloro complex from the bridge cleavage process is reduced. Treatment of *cis*-$[Co(NH_3)_4(NO_2)_2]Cl$ with concentrated HCl has been reported [18,25] as (rapidly) producing *cis*-$[Co(NH_3)_4Cl_2]Cl$, but in our hands it yielded (slowly) *cis*-$[Co(NH_3)_4(NO_2)Cl]Cl$, and on prolonged standing, *trans*-$[Co(NH_3)_4Cl_2]Cl$. Similarly, the *trans*-dinitro complex yielded *trans*-$[Co(NH_3)_4(NO_2)Cl]Cl$; these syntheses parallel the bis(ethylenediamine) chemistry [3]. Werner's alternative syntheses [3] of *cis*-$[Co(NH_3)_4Cl_2]Cl$ via reaction of $[Co(NH_3)_4(OCO_2)]Cl$ in aqueous or ethanolic HCl yielded only *cis*-$[Co(NH_3)_4(OH_2)Cl]Cl_2$ in our hands. Also, we found that the latter gives *trans*-$[Co(NH_3)_4Cl_2]Cl$ on prolonged reaction in HCl.

In hindsight, it is surprising that any of these syntheses for the *cis*-dichloro complex work, even the successful diol cleavage reaction! Werner envisaged the reaction as a simple *cis*-Co–O cleavage reaction, with such bond rupture occurring on the same Co centre. However, acid cleavage of the diol might have proceeded either way, as shown in Scheme 1.

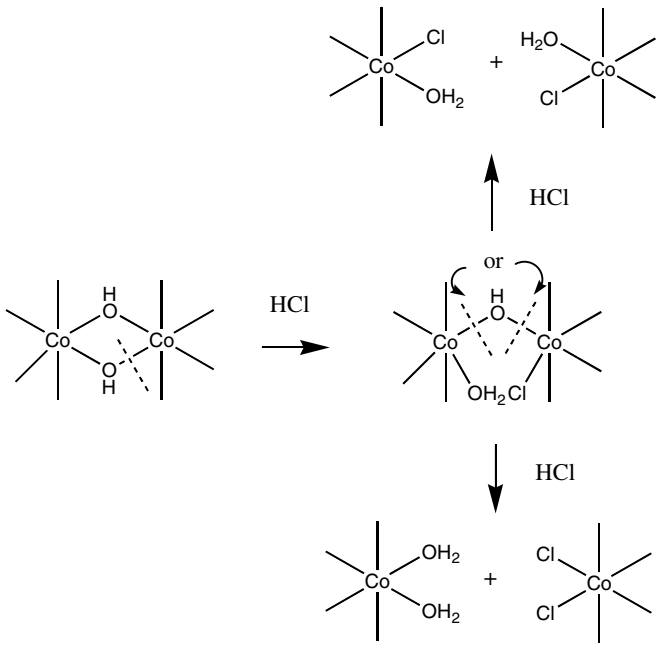
However, we can confirm that no observable *cis*-$[Co(NH_3)_4(OH_2)Cl]Cl_2$ is produced in the diol cleavage reaction. Similarly, the acid cleavage reactions of the carbonato and dinitro complexes, each reported to yield the *cis*-$[Co(NH_3)_4Cl_2]Cl$ complex, might have expected to yield aqua complexes, given the known modes of bond cleavage revealed through tracer studies [4,26], Scheme 2.

In our hands, no *cis*-dichloro complex was formed.

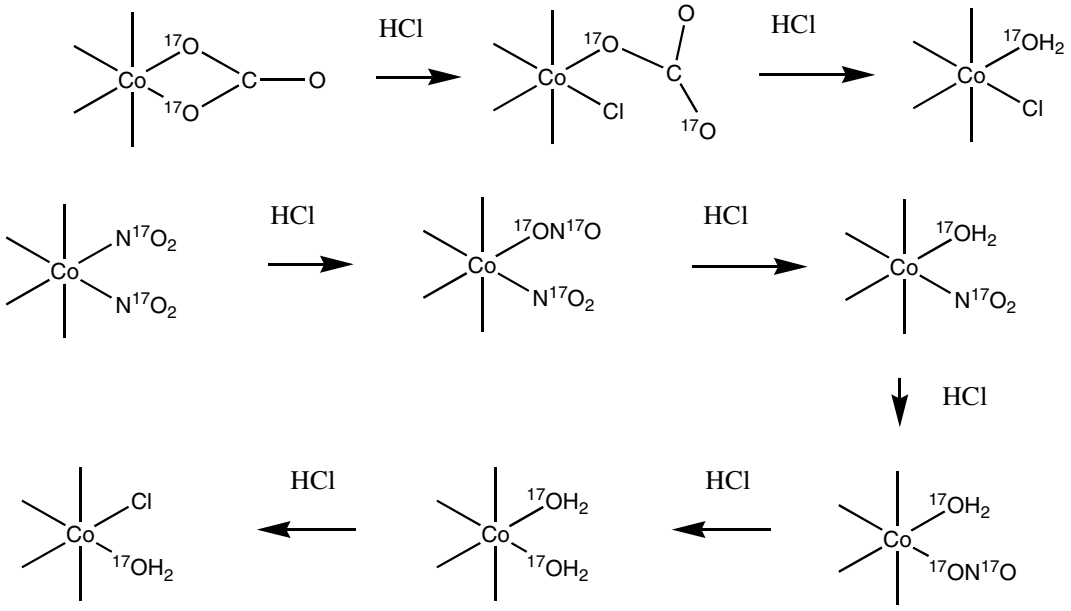
We have found that neither *cis*- nor *trans*-$[Co(NH_3)_4(OH_2)Cl]^{2+}$ yield *cis*-$[Co(NH_3)_4Cl_2]^+$ on reaction with HCl under a variety of conditions, nor does evaporation of an aqueous solution of the *trans*-dichloro chloride, a strategy successful in the bis(ethylenediamine) system.

Finally, the anation of either *cis*-$[Co(NH_3)_4(OSMe_2)_2](ClO_4)_3$ using Et_4Cl in either DMSO or DMF failed to yield appreciable *cis*-dichloro isomer, yet in the corresponding bis(ethylenediamine) systems [27] the *cis*-dichloro complex is formed and is strongly stabilised by ion-pairing in such dipolar aprotic media.

cis-$[Co(NH_3)_4(OH_2)Cl]SO_4$ and *cis*-$[Co(NH_3)_4(OH_2)Cl]S_2O_6 \cdot H_2O$ were too insoluble to be generally useful, while the more soluble *cis*-$[Co(NH_3)_4(OH_2)Cl]Cl_2$ as prepared by various published routes was not pure (^1H NMR). Conversion to the sulfate and back to the chloride removed these impurities. The chloride and sulfate salts were anhydrous; hydrates have been reported [13].



Scheme 1. Alternative modes of acid catalysed OH– bridge cleavage in the diol.



Scheme 2. Acid induced bond cleavage and rearrangement modes for carbonate and nitrite complexes of cobalt(III).

The *trans*-$[Co(NH_3)_4(OH_2)Cl]Cl_2$ complex is new. It was synthesised by Hg(II) induced aquation of *trans*-$[Co(NH_3)_4Cl_2]^+$, a method similar to that described for the bis(ethylenediamine) analogue [28]. It was also obtained [22] by reacting *trans*-$[Co(NH_3)_4Cl_2]Cl \cdot H_2O$ with triflic acid to yield $[Co(NH_3)_4(O_3SCF_3)Cl]CF_3SO_3$, which rapidly formed a *cis*-/*trans*-$[Co(NH_3)_4(OH_2)Cl]^{2+}$ mixture on hydrolysis, and this could be separated using the sulfate counter-ion. *cis*/*trans* Mixtures of salts of $[Co(NH_3)_4(OH_2)Cl]^{2+}$ proved virtually impossible to separate completely as the Cl^-, SO_4^{2-} or $S_2O_6^{2-}$ salts, due to the relatively rapid rate of trans to cis isomerisation and because, for SO_4^{2-} and $S_2O_6^{2-}$, the *trans* isomer is more soluble; the *cis* form then tends to co-crystallise. As the Cl^- salt, even small amounts of the *cis* form rendered the crystals grey, although they appeared homogeneous under the microscope. It could, however, be rendered completely free of it by successive extractions with small amounts of 1 M HCl until the extracts were a consistent pale violet colour. The residue was a dull green salt.

The four nitro complexes, of which *cis*- and *trans*-$[Co(NH_3)_4(NO_2)Cl]^+$ appear to be new, were reactants or products of the synthetic reactions described, and which did not proceed as reported. They are analogous to their bis(ethylenediamine) counterparts, and were characterised by their Vis/UV and ^1H NMR spectra; the characteristic difference between *cis* and *trans*-nitro species in the UV is noted.

3.2. Isomerisation of $[Co(NH_3)_4(OH_2)Cl]^{2+}$

The isomerisation of *trans*-$[Co(NH_3)_4(OH_2)Cl]^{2+}$ in dilute $HClO_4$ at 25 °C was followed in both the visible (340–700 nm) and UV (220–320, 270–300 nm) regions. In the visible region, two sharp isosbestic points were observed (589 nm, ε 30.7 $M^{-1}\,cm^{-1}$; and 473 nm, ε 23.8 $M^{-1}\,cm^{-1}$) and the absorbance changes were large (Fig. 1). Absorbance changes in the UV were much smaller (Figure 1S) because *cis*- and *trans*-$[Co(NH_3)_4(OH_2)Cl]^{2+}$ have very similar spectra throughout this region. Nonetheless, by working on the tail of the UV where the absorbance is low yet proportional absorbance changes are appreciable, and through raising the [Co] to take advantage of this, a sharp isosbestic point was observed at 284 nm (Figure 2S), and the absorbance-time data accurately fitted a single exponential ($k_{obsd} = 2.31 \times 10^{-3}\,s^{-1}$). The rate data obtained from the three spectral regions were in good agreement (Table 1), and k_{obsd} is not appreciably medium dependent (1.0, 0.1, 0.02 M $HClO_4$).

The *trans*/*cis* equilibrium, while it favours the *cis* side (88%), is not so far to that side that the rate could not be measured starting with the *cis* isomer. The spectral changes commencing with *cis* are small (Figure 3S) but sufficient to define the rate well (Table 1), and even the two isosbestic points (473 and 590 nm). The measured k_{obsd} should be the same since the sum of the forward and reverse rates are measured commencing with either isomer, and indeed this is born out by the results (Table 1).

Equilibrium $[Co(NH_3)_4(OH_2)Cl]^{2+}$ data are given in Table 2 and results are internally consistent for the four different starting materials. This result, $88 \pm 1\%$ *cis*, is not too different to that estimated by Linck's indirect method [10,13] ($90.5 \pm 1.0\%$ *cis*).

The ^1H NMR spectrum (Fig. 2) show the single line spectrum for the trans isomer in D_2O/DCl change into the 2:1:1 pattern expected for *cis*-$[Co(NH_3)_4(OH_2)Cl]^{2+}$, and confirm its presence at equilibrium to the extent of ca. 10%.

3.3. Aquation of *cis*-$[Co(NH_3)_4Cl_2]^+$

The hydrolysis rate for the *cis* isomer has never been measured. It has been described as 'very fast' by Pearson et al. [8], and that the aquation was very rapid was implied by Werner [1,3] in his experimental descriptions of poor recovery through rapid recrystallisation from water. It is a myth. It hydrolyses at about the same rate as the *trans*

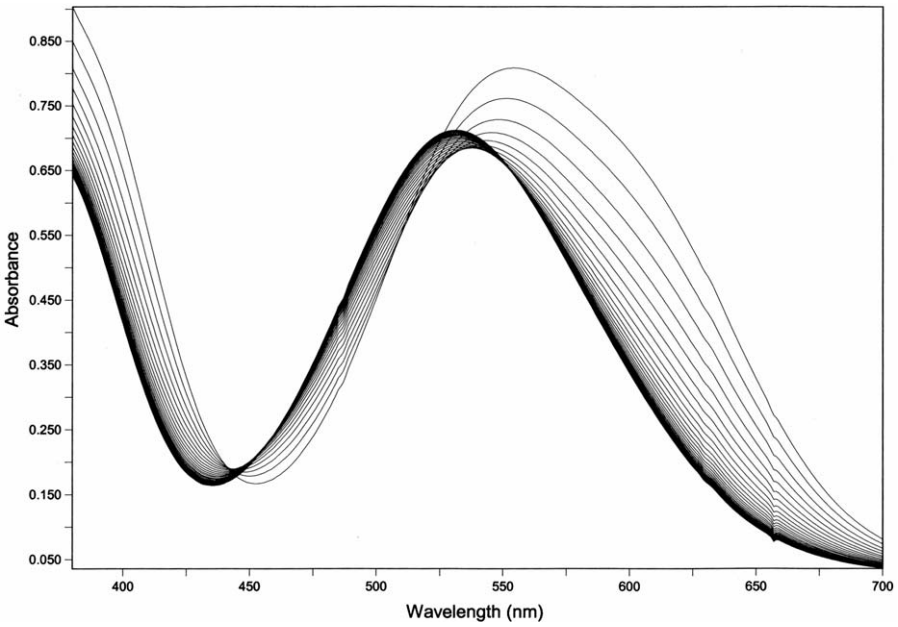

Fig. 3. Visible spectral changes for the hydrolysis of *cis*-$[Co(NH_3)_4Cl_2]^+$ in H_2O/H^+, 25 °C. The absorbance decreases with time at 600 nm.

isomer. The changes in visible spectra (340–700 nm; Fig. 3) with time hide the fact that there are two early sharp isosbestic points, one of which changes quickly with time (Fig. 4S. 440 nm, ε 13.0; 514 nm, ε 39.0 M^{-1} cm^{-1}). The first phase is loss of one Cl^- and the second is *cis*-/*trans*-$[Co(NH_3)_4(OH_2)Cl]^{2+}$ isomerisation. The final spectrum corresponds to a 88% *cis*/22% *trans* distribution (Table 2). The absorbance–time trace at 530 nm (Fig. 4) clearly indicates the biphasic behaviour, and in particular it shows that the second phase corresponds to *trans–cis* rather than *cis–trans* isomerisation, i.e., the initial hydrolysis reaction leads to not only both *cis*- and *trans*-$[Co(NH_3)_4(OH_2)Cl]^{2+}$ but an isomeric mixture which contains more *trans* isomer than does the equilibrium distribution.

The changes in the UV absorption spectra accompanying the hydrolysis of the *cis*-dichloro complex are relatively small (Figure 5S), but nonetheless sufficient to determine a rate constant for the hydrolysis. The data fitted a single exponential because in the region examined (280–320 nm) the absorbance changes for the secondary isomerisation process are much smaller, and negligible. The results (see below) bear this out – the visible and UV rate data agree.

The primary hydrolysis rate constant was determined by fitting the 589 nm data to a single exponential. The fits were good, since this wavelength is an isosbestic point for the secondary *trans*/*cis* isomerisation reaction. The 530 nm data (Fig. 4) were then fitted to two exponentials with the first exponential (k_1) fixed at the value determined from the 589 nm data. This yielded k_2 which is the aquachloro isomerisation rate, and the check on the correctness of the analysis is the reasonable agreement of this value and that determined independently for this reaction (Table 3; cf. Table 1).

It is evident that k_1 and k_2 are very similar in magnitude. Because of this, the global analysis of the visible absorption

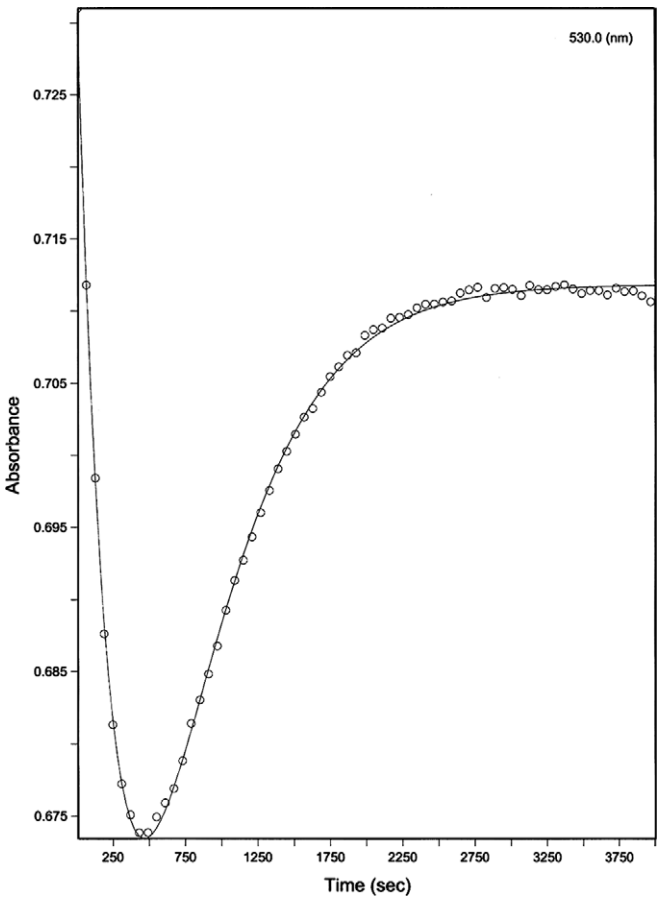

Fig. 4. Absorbance–time trace at 530 nm for the hydrolysis of *cis*-$[Co(NH_3)_4Cl_2]^{2+}$ in H_2O/H^+, 25 °C, illustrating the biphasic nature of the reaction.

spectral data (340–700 nm) involves a shallow minimum with considerable flexibility in the derived values for both k_1 and k_2 and the spectrum for the intermediate (kinetic)

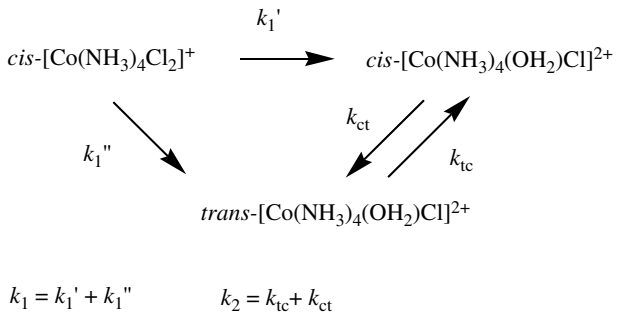
[b] Double exponential fit, with k_1 fixed at the value determined at 589 nm for the same run.
[c] Global fit (340–700 nm) double exponential fit with no restriction on k_1 or k_2, for selected data sets (>95% reaction).
[d] Double exponential fit with k_2 fixed at the independently determined value.

$[Co(NH_3)_4(OH_2)Cl]^{2+}$ isomer distribution. This is a general problem when $k_1 \sim k_2$ [14]. However, fitting to a single wavelength data set such as the fall-rise seen at 530 nm gives much better defined parameters when the two rates are similar, provided the data cover a time period in excess of 95% reaction.

The steric course for the primary substitution reaction was determined as described previously [29] by fitting the ε, t data to Eq. (1) which applies to Scheme 3 as shown:

$$\varepsilon_{obsd} = \varepsilon_\infty + \{(\varepsilon_A - \varepsilon_C) + (k_1(\varepsilon_B - \varepsilon_C)/(k_2 - k_1))\} \times \exp(-k_1 t) - \{(k_1(\varepsilon_B - \varepsilon_C)/(k_2 - k_1))\} \times \exp(-k_2 t). \quad (1)$$

Here 'B' is the first formed *cis*-/*trans*-aquachloro mixture and 'C' is the equilibrium mixture. The initial *cis*/*trans* ratio is best defined from absorbance data at around 530 nm where the component spectra differ the most. We also carried out a multiwavelength version of this analysis by globally fitting (Specfit®) the 340–700 nm data to a A → B → C scheme fixing the values of k_1 (determined at 589 nm, Table 3) and k_2 (independently determined, Table 1), and determining the full spectrum of the intermediate isomer mixture (Fig. 5). Note that even though we are dealing with first order reactions, absolute times must be used to get the correct spectrum of the intermediate B. The intermediate spectrum was fitted to the spectra of its two components and yielded a 55% *cis*, 45% *trans* kinetic distribution; similarly, the final spectrum corresponded to 88% *cis*, 12% *trans*.



Scheme 3. The sequential hydrolysis reaction for *cis*-$[Co(NH_3)_4Cl_2]^+$.

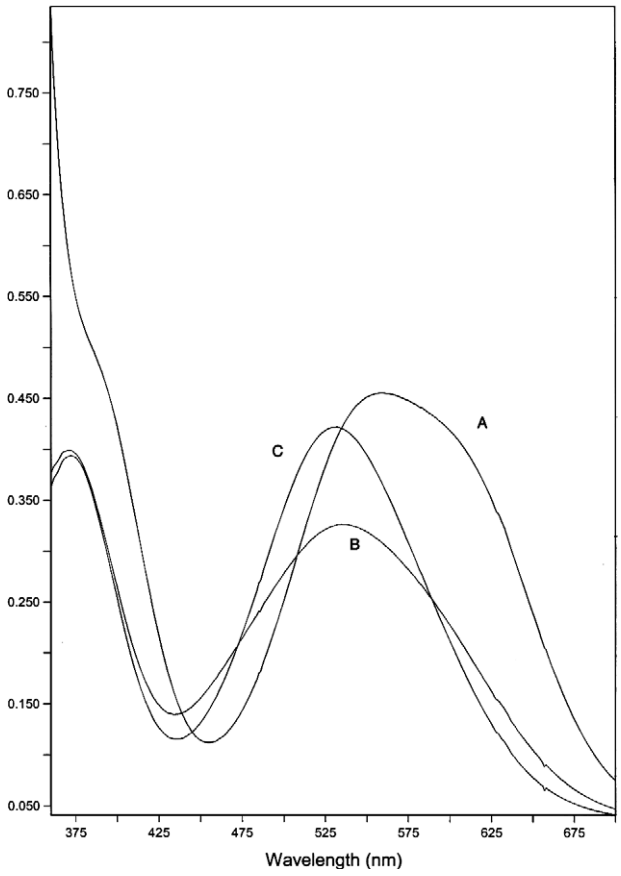


Fig. 5. Computed intermediate (B) and final (C) *cis*-/*trans*-$[Co(NH_3)_4(OH_2)Cl]^{2+}$ visible spectra, for the hydrolysis of *cis*-$[Co(NH_3)_4Cl_2]^+$ (A) in H_2O/H^+ at 25 °C. The vertical scale is absorbance, for an arbitrary [Co].

The 440 nm isosbestic point (ε 13.0; $\varepsilon(cis) = 11.0$, $\varepsilon(trans) = 19.3\ M^{-1}\ cm^{-1}$) is not very sensitive to the *trans*-/*cis*- product ratio but the 514 nm isosbestic is. The initial product distribution calculated from this (ε 39.0; $\varepsilon(cis) = 53.5$ and $\varepsilon(trans) = 19.7\ M^{-1}\ cm^{-1}$), while intrinsically less accurate, gives excellent agreement (57% *cis*). This shifts quite quickly with time, and it was important to define it using a number of scans collected within the first 40 s (10% reaction). After 2 min the isosbestic, still reasonably well defined, is at 516 nm (ε 40.5 $M^{-1}\ cm^{-1}$) and this corresponds to nearly 60% *cis* product. As the simulation shows (Table 4), for an initial 55% and final 88% *cis*, the 55% changes quickly in a system where k_1 and k_2 are very similar.

Fig. 6 shows the ^1H NMR spectra for the *cis*-dichloro complex hydrolysing in D_2O (pD 2, DCl) at ca. 21 °C. The *cis*- and *trans*-aquachloro ions grow in parallel, before ultimately the *trans* isomer decays back to the *cis*. The lowest field peak is *trans* (12H) and the next lowest is the major *cis* peak (6H), and from their areas the product distribution at 2–3 min reaction time is estimated as 60% *cis*, 40% *trans*, which is entirely in accord with the spectrophotometric determination.

Table 4
Changing product distribution with time for a consecutive reaction scheme for the *cis*-$[Co(NH_3)_4Cl_2]^+$ reactant and where $k_1 = 2.4 \times 10^{-3}\ s^{-1}$, $k_2 = 2.3 \times 10^{-3}\ s^{-1}$, and the initial and final *cis*-$[Co(NH_3)_4(OH_2)Cl]^{2+}$ product proportions are 55% and 88%

3.4. Aquation of *trans*-$[Co(NH_3)_4Cl_2]^+$

The UV absorption maximum at ca. 250 nm for the *trans*-dichloro ion [10] is associated with Co–Cl charge transfer absorption (ε ca. 15,000 $M^{-1}\ cm^{-1}$). It is roughly twice as intense and to lower energy than the corresponding absorption for the *trans*- and *cis*-monochloro ions (ca. 230 nm), and that, being associated with the Co–Cl charge transfer, is insensitive to the *cis* or *trans* stereochemistry. Thus the hydrolysis of the dichloro to monochloro ions involves a large absorption change in the UV region (Figure 6S) whereas the *trans*-/*cis*-isomerisation involves very little change. The latter change was sufficient, however, to easily determine the isomerisation rate spectrophotometrically (Table 1).

Although there is no isosbestic point for the isomerisation coincident with the isosbestic at 239 nm for the hydrolysis of *trans*-$[Co(NH_3)_4Cl_2]^+$ (the so-called triple isosbestic point), we have determined that the spectra for *cis*- and

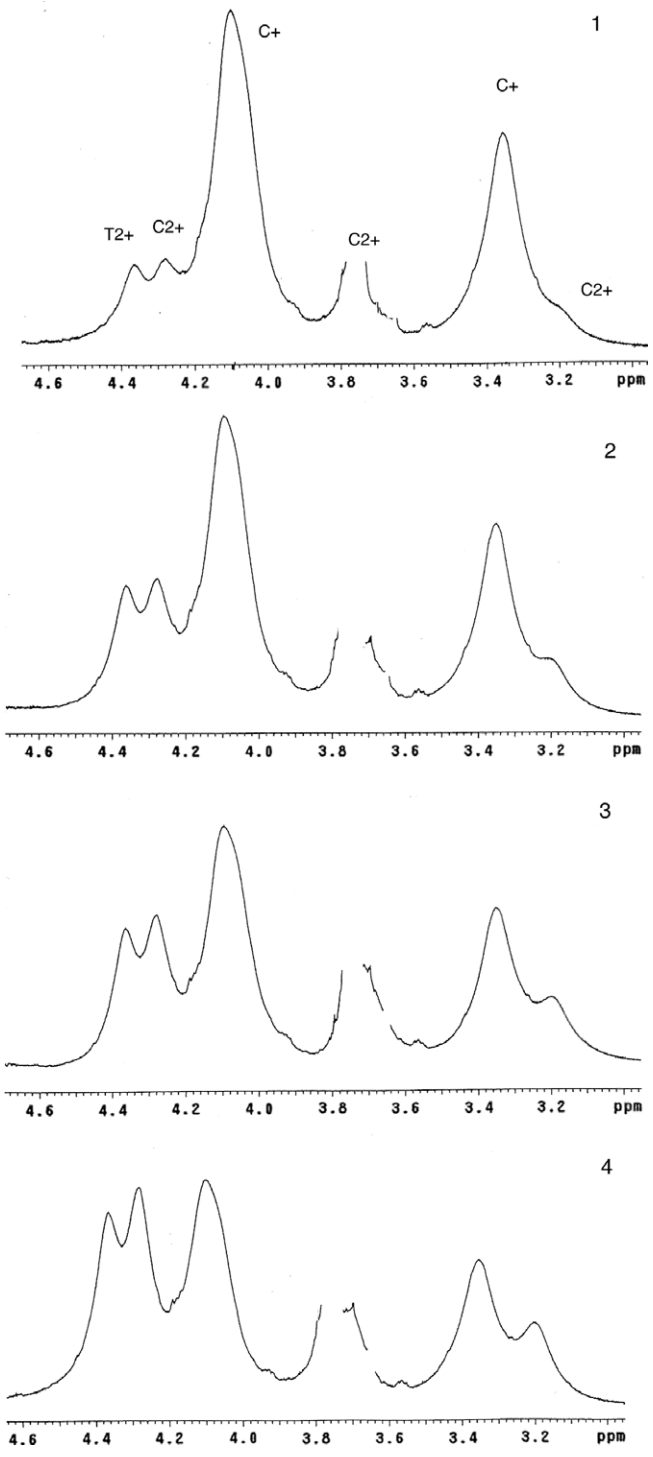

Fig. 6. ^1H NMR spectra (NH region) for the hydrolysis of *cis*-$[Co(NH_3)_4Cl_2]^+$ (C+) in D_2O/D^+ at ca. 21 °C; C2+ and T2+ denote the signals for *cis*- and *trans*-$[Co(NH_3)_4(OH_2)Cl]^{2+}$. Times increase, from 1 to 4.

trans-$[Co(NH_3)_4(OH_2)Cl]^{2+}$ are indeed very similar to each other and to the *trans*-$[Co(NH_3)_4Cl_2]^+$ ion in this region, and it confirms Linck's surmise [10] on this point, i.e., the persistence of the sharp isosbestic point at 239 nm for 10 $t_{1/2}$ of the primary reaction, despite the second step having essentially the same rate as the first step, the

primary aquation and secondary isomerisation reactions. Indeed, the small absorbance changes in the UV for the secondary reaction are the reason for the good single phase kinetics for the primary reaction as measured in the UV region at any wavelength. The rates obtained are all the same, and in particular the same as those determined from the UV data at 284 nm (Table 5), which is an isosbestic point for the *trans*-/*cis*-$[Co(NH_3)_4(OH_2)Cl]^{2+}$ isomerisation reaction (Figure 2S).

The reaction studied in the visible spectral region revealed four sharp isosbestic points: 353 nm, ε 43.4; 397 nm, ε 33.2; 467 nm, ε 21.5; 597 nm, ε 28.2 $M^{-1}\,cm^{-1}$ (Fig. 7). None were definitive of the steric course of substitution because the spectra of *cis*- and *trans*-$[Co(NH_3)_4(OH_2)Cl]^{2+}$ are very similar at each of these wavelengths (see Figs. 1 and 8).

Table 5
Rate data for the acid hydrolysis of *trans*-$[Co(NH_3)_4Cl_2]^+$ in 0.020 M $HClO_4$ at 25 °C

Region	$10^3 k_1$ (s^{-1})
UV	2.22 (12)[a]
Vis	2.22 (22)[b]
UV	2.23 (4)[c]

[a] Global analysis (UV: 220–320 nm) single exponential fit.
[b] Global analysis (Vis: 340–700 nm) double exponential fit, with k_2 fixed at $2.31 \times 10^{-3}\ s^{-1}$.
[c] Single exponential fit, for data collected at 284 nm, an isosbestic point for $[Co(NH_3)_4(OH_2)Cl]^{2+}$ isomerisation.

The data in the 340–700 nm visible range actually fit a single exponential quite well, but this is fortuitous, as discussed elsewhere [30]. The data were refitted to a double exponential, appropriate to a consecutive reaction scheme, with k_2 fixed at its known value $2.31 \times 10^{-3}\ s^{-1}$. The results for k_1 so obtained are presented in Table 5, and the value is in agreement with that determined in a more straightforward fashion from the UV data.

Quite remarkably, the hydrolysis rate for the *trans* isomer (k_1, $2.2 \times 10^{-3}\ s^{-1}$) is almost identical to that determined for the *cis* isomer ($2.4 \times 10^{-3}\ s^{-1}$), and also is essentially that for the subsequent isomerisation reaction ($2.3 \times 10^{-3}\ s^{-1}$).

The steric course of hydrolysis was determined as described above for the *cis* isomer – globally fitting the visible spectral data (340–700 nm) to a consecutive reaction scheme with the derived values for k_1 and k_2. The results are shown in Fig. 8. The average 530 nm result is $\varepsilon_B = 32.7\ M^{-1}\,cm^{-1}$ (22 determinations), which corresponds to 65% *trans* and 35% *cis* product. The error here is likely ±5%. Linck had estimated 45 ± 10% *trans* product by an indirect method [10,13].

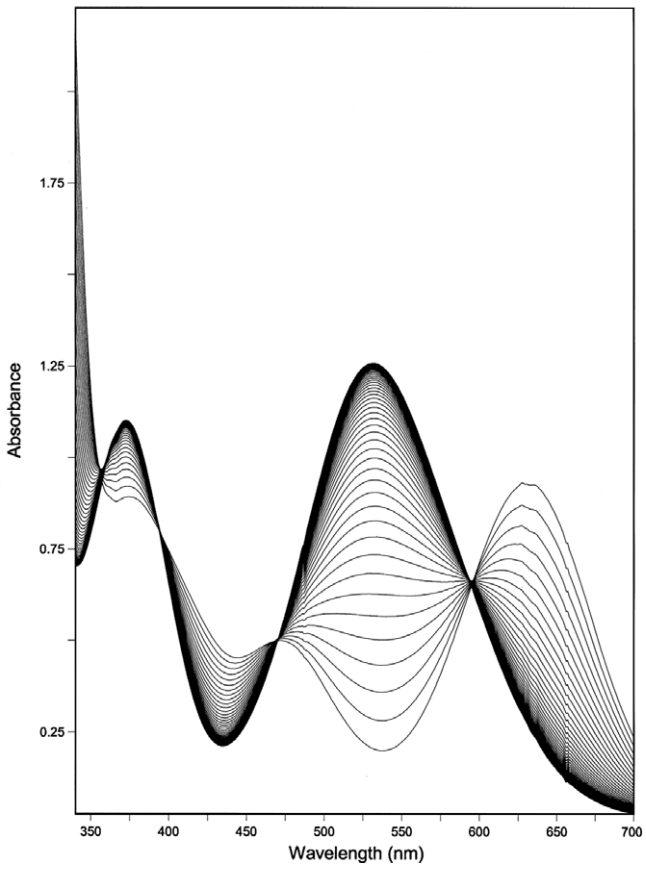

Fig. 7. Visible spectral changes for the hydrolysis of *trans*-$[Co(NH_3)_4Cl_2]^+$ in H_2O/H^+, 25 °C. The absorbance increases with time at 530 nm.

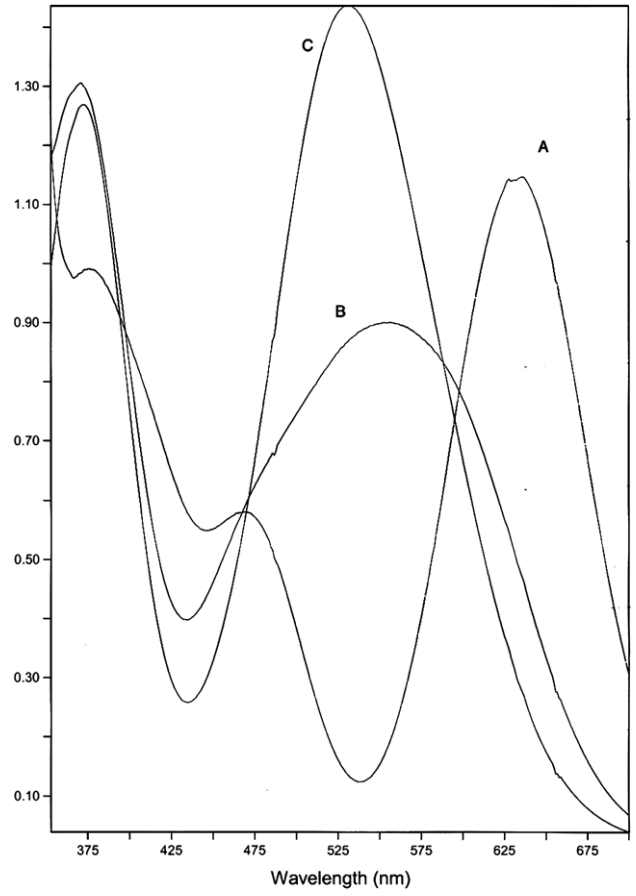

Fig. 8. Computed intermediate (B) and final (C) *cis*-/*trans*-$[Co(NH_3)_4(OH_2)Cl]^{2+}$ visible spectra, for the hydrolysis of *trans*-$[Co(NH_3)_4Cl_2]^+$ (A) in H_2O/H^+ at 25 °C. The vertical scale is absorbance, for an arbitrary [Co].

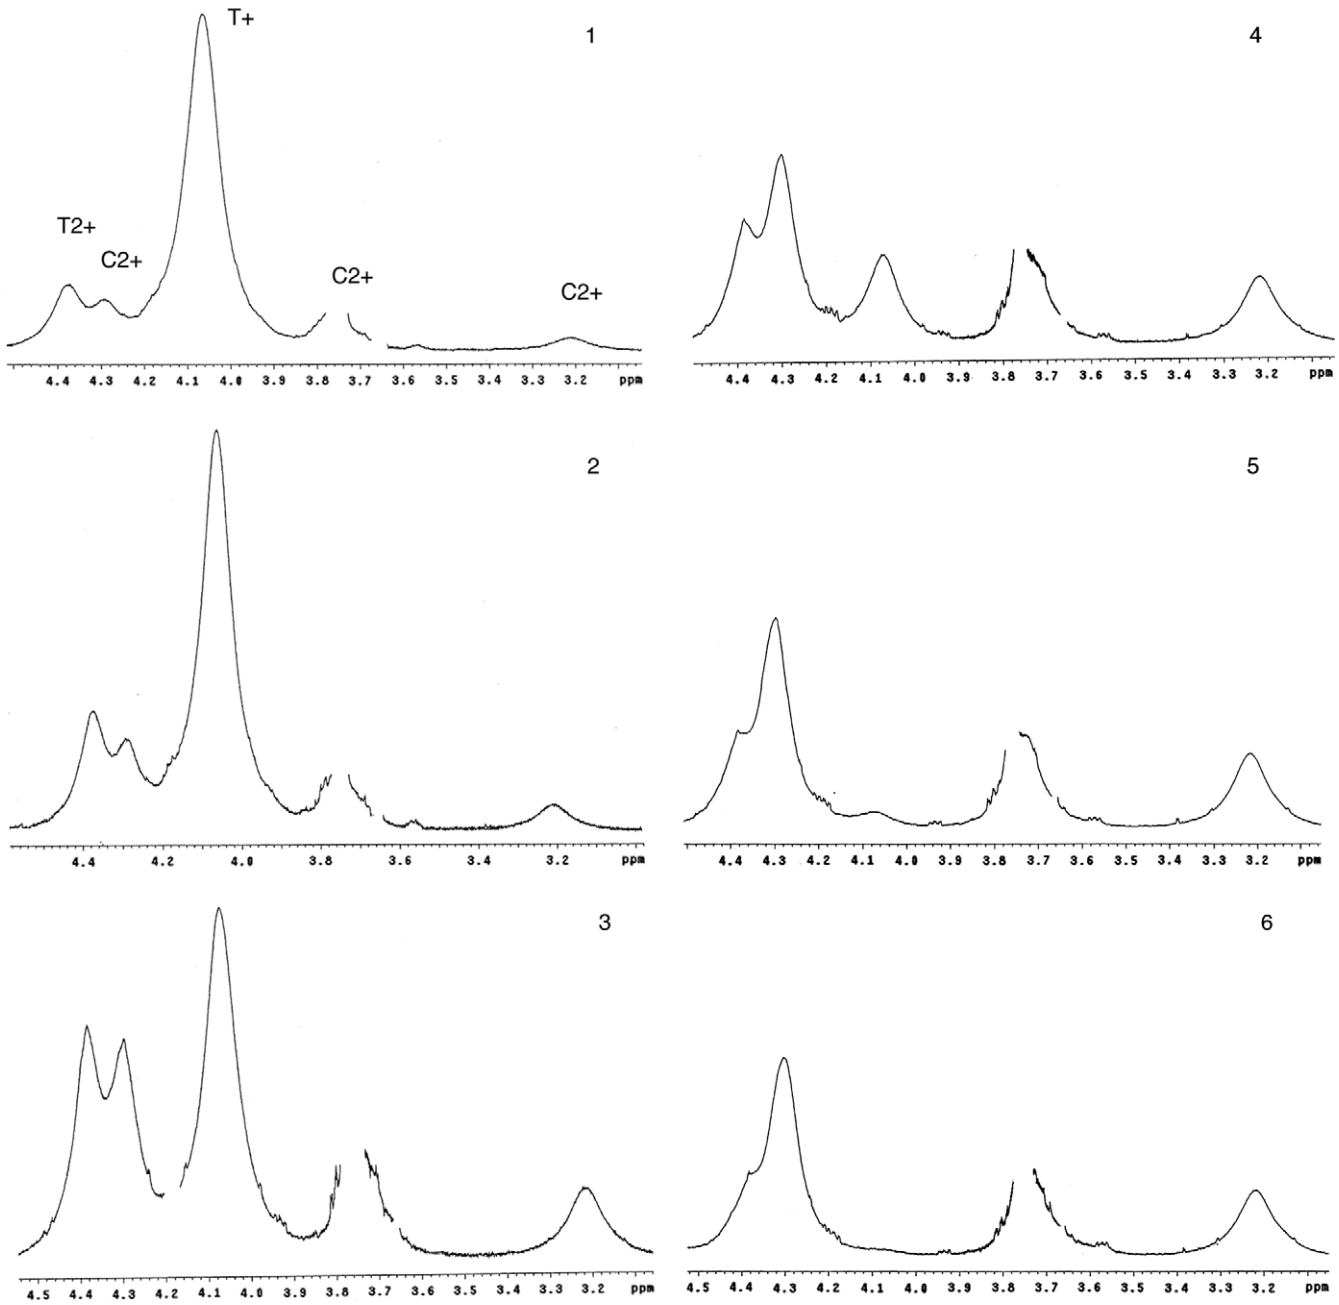

Fig. 9. ^{1}H NMR spectra (NH region) for the hydrolysis of *trans*-(T+) $[Co(NH_3)_4Cl_2]^+$ in D_2O/D^+ at ca. 21 °C; times increase from 1 to 6. C2+ and T2+ are *cis*- and *trans*-$[Co(NH_3)_4(OH_2)Cl]^{2+}$, respectively.

The ^{1}H NMR spectra for *trans*-$[Co(NH_3)_4Cl_2]^+$ reacting in D_2O/DCl are shown in Fig. 9. Compared to the corresponding changes for the *cis* isomer (Fig. 6), there is a little more *trans* product formed initially, estimated as 60% which is in good agreement with that determined spectrophotometrically.

4. Summary and conclusions

The *cis*- and *trans*-dichloro complexes hydrolyse at coincidentally the same rate. For the bis(ethylenediamine) analogues [7], the *cis* isomer is about sixfold more reactive than the *trans*, and both rates are between 10- and 50-fold smaller than the corresponding tetraammine rates; for the latter the *cis* isomer is about 10-fold more reactive than the *trans* isomer. The previous notion [8] that *cis*-$[Co(NH_3)_4Cl_2]^+$ hydrolyses extraordinarily rapidly is unfounded. Both isomers yield *cis*- and *trans*-$[Co(NH_3)_4(OH_2)Cl]^{2+}$ products directly, in different proportions, with the *trans* isomer showing more rearrangement (35% *cis* product; 65% rearrangement) than the *cis* form (55% *cis* product, 45% rearrangement). This also parallels the bis(ethylenediamine) chemistry, but there the extents of rearrangement are less (the *trans* reactant gives 74% *trans* product, the *cis* reactant gives 76% *cis* product; these numbers correspond to 26% and 24% rearrangement, respectively) [7]. The aquachloro

equilibrium isomer distributions in the two systems are also similar (en, 79% *cis*; NH_3, 88% *cis*).

The new stereochemical data for the tetraammine system again show that *cis* isomers are not universally retentive. It was once believed [4] the norm for the bis(ethylenediamine) complexes, but shown otherwise [6,29]. It thus seems unlikely that a study of the kinetics and stereochemistry of other $[Co(NH_3)_4AX]^{n+}$ complexes will uncover anything beyond what is described herein, notwithstanding the fact that the synthetic chemistry is not yet developed.

and the colorless solution was stirred for 5 min at room temperature. A solution of 0.650 g (0.1 mmol) NaN_3 in 5 ml CH_3OH was then added, and the stirring was continued for an additional 20 min. Slow evaporation of the solvent at 0 °C, gave colorless crystals of the title compound (**1**) suitable for X-ray analysis. The crystals were collected by filtration, washed with cold acetonitrile, and dried under vacuum. The yield was 0.539 g, 77%. *Anal.* Calc. for $C_{38}H_{35}AgN_5P$: C, 65.14; H, 5.03; N, 9.99. Found: C, 63.83; H, 4.72; N, 10.15%. IR (KBr pellet, 400–4000 cm^{-1}) 1628 (C=N), 2010 (N_3). UV [chloroform; λ_{max} in nm ($\log\varepsilon$ in L mol^{-1} cm^{-1})]: 343 (3.04), 277 (4.90) ^1H NMR ($CDCl_3$) 3.87 (s, 4H, NCH_2CH_2N); 6.87, (dd, 2H, C=CH–C); 6.98 (d, 2H, –CH=C); 7.26–7.49 (m, 25H, 2PhC=C, ArH); 8.14 (d, 2H, 2CH=N).

2.3. Synthesis of [Ag(ca$_2$en)(PPh$_3$)SCN] (2)

This complex was prepared in a manner similar to that of (**1**) using KSCN (0.980 g, 0.1 mmol). The crystals were collected by filtration, washed with cold acetonitrile and dried under vacuum. The yield was 0.608 g, 85%. *Anal.* Calc. for $C_{39}H_{35}AgN_3PS$: C, 65.36; H, 4.92; N, 5.86. Found: C, 65.20; H, 5.00; N, 5.80%. IR (KBr pellet, 400–4000 cm^{-1}) 1627 (C=N), 2085 (SCN). UV [chloroform; λ_{max} in nm ($\log\varepsilon$ in L mol^{-1} cm^{-1})]: 276 (4.96) ^1H NMR ($CDCl_3$) 3.86 (s, 4H, NCH_2CH_2N); 6.91 (dd, 2H, C=CHC); 6.99 (d, 2H, –CH=C); 7.26–7.50 (m, 25H, 2PhC=C, ArH); 8.15 (d, 2H, 2CH=N).

2.4. X-ray crystallography

Suitable single crystals of [Ag(ca$_2$en)(PPh$_3$)(N$_3$)] (**1**) and [Ag(ca$_2$en)(PPh$_3$)(SCN)] (**2**), were obtained by evaporation of solvent at 0 °C. The crystals were found to shatter easily when attempts were made to cut them, so large, well formed crystals were used without cutting. Data were collected on an Oxford Diffraction Xcalibur2 diffractometer using graphite-monochromated Mo Kα radiation ($\alpha = 0.71069$ Å). The data were corrected for Lorentz and polarization effects, and corrections were applied for absorption and scaling using data redundancy (SADABS [16]). The structures were solved by direct methods (SHELXS-97 [17]) and refined by full-matrix least squares using F^2 (SHELXL-97 [17]). All non-hydrogen atoms were refined anisotropically, and all H atoms were treated as riders with isotropic U values constrained to 1.2 times the equivalent isotropic U values of their respective parent atoms.

3. Results and discussion

3.1. Synthesis

The *N*,*N*′-bis(*trans*-cinnamaldehyde)1,2-diaminoethane, ca$_2$en, ligand was prepared as reported elsewhere [18]. These colorless complexes are stable in air in the solid state for 20 weeks. The stability of these complexes in solution depends on the solvent used. While these complexes are stable in acetonitrile solution at room temperature for 10 days, they remain unchanged for 5 days in methanol but only two days in dicholoromethane at 0 °C.

3.2. Crystal structures of [Ag(ca$_2$en)(PPh$_3$)(N$_3$)] (1) and [Ag(ca$_2$en)(PPh$_3$)(SCN)] (2)

A summary of the key crystallographic information for the two complexes are listed in Table 1. The molecular structures and atom numbering schemes of (**1**) and (**2**) are presented in Figs. 1 and 2, respectively. Selected bond distances, bond angles and torsion angles are given in Table 2. The pseudohalides, N_3 and SCN, are known to coordinate to metal ions in both terminal and bridging modes [19–22], and they act as terminal ligands in complexes (**1**) and (**2**). While a tetrahedral geometry might be expected for a four coordinated silver(I) center, the coordination sphere around the silver atom in (**1**) and (**2**) is distorted by the restricting bite angle of the chelating ligand ca$_2$en. The N–Ag–N angles in (**1**) and (**2**) are only 73.86(7)° and 72.49(5)°, respectively. The coordination environment around the metal ion in each complex is

pseudotetrahedral with large angular distortion, arising from the low intraligand N(1)–Ag(1)–N(2) chelate angle. This angle, fixed by the bite size of the ligand, is in the range found for ethylenediamine chelate compounds [76.3(6)°] [19]. The X–Ag(1)–P(1) angle is 118.33(6)° in (**1**) and 135.38(2)° in (**2**), being somewhat larger than the values for a tetrahedron. The dihedral angle between the best plane through the chelate ring and the plane defined by P(1)–Ag(1)–X, 85.05(8)° in (**1**) and 74.19(3)° in (**2**), are indicative of a deviation from idealized tetrahedral symmetry. The average Ag–N(ca_2en) distances of 2.365 in (**1**) and 2.390 Å in (**2**) are similar to those in the pseudotetrahedral (diimine) silver(I) complexes [22]. The Ag–N_3 bond length in (**1**) is 2.309(2) Å and that of Ag–S in (**2**) is 2.538(5) Å. The mode of coordination of the azide and thiocyanate anions to the transition metals is influenced by various factors such as the central metal and solvent polarity [20–22]. As expected, the SCN ligand is S-bonded in (**2**) due to the soft–soft interaction between Ag and S atoms. The terminal azido and thiocyanato ligands in these complexes are almost linear, with bond angles N–N–N, 177.33(3)° and S–C–N, 179.36(21)°. The geometries of the ca_2en ligand are as expected.

3.3. Spectral characterization

The IR spectrum of the free ligand exhibits the characteristic band of an imine C=N, which appears at 1634 cm^{-1} [18]. This band is shifted to lower frequencies (~1627 cm^{-1}) in the IR spectra of the complexes due to the coordination of the imine nitrogen.

It is well known that silver(I) compounds are diamagnetic and colourless. Since no d–d transitions are expected for a d^{10} complex, the absorption bands are either of CT or intraligand character. The first MLCT band is clearly observed only for complex **1** at 343 nm, however this transition may have been obscured by the intraligand transitions in **2**. This is presumably due to the fact that the first MLCT band of complex **2** is blue shifted because of a better π-back bonding between Ag and SCN relative to N_3. An absorption band at about 277 nm, which can be assigned to the π–π^* transition of the coordinated ligand, is observed in the spectra of both complexes.

The ^{1}H NMR spectral data and peak assignments for (**1**) and (**2**) are presented in the experimental section. The proton resonances of the coordinated ca_2en are commonly observed in the spectra. The aromatic protons of the coordinated PPh_3 ligands overlap to some extent with those of the phenyl protons of ca_2en. Aside from the aromatic protons (C=C–Ph, PPh_3), which appear at about 7.24–7.49 ppm, the two imine protons (N=CH–) appear as a doublet at about 8.15 ppm. The four ethylenic protons appear as a doublet of doublets at about 6.87 ppm (C–CH=C) and a doublet at 6.97 ppm (C=HC–Ph). The downfield shift of the imine protons in the spectra of the complexes relative to the free ligand can be attributed to the deshielding effect resulting from the coordination of the ligand. The sharp singlet at about 3.87 ppm is assigned to the N–CH_2–CH_2–N protons of the chelate ring. The ^{1}H NMR data support the existence of Ag(I) in these pesudotetrahedral complexes. The appearance of a unique signal for each type of proton in CD_3CN solution indicates that the symmetry of the molecules is retained in solution and the ca_2en ligand is in its endo configuration as indicated in the structures.

4. Supplementary material

Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Center, CCDC Nos. 275388 for (**1**) and 275389 for (**2**). Copies of the data can be obtained free of charge on application to The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK, fax: +44 1223 336 033, e-mail: deposit@ccdc.cam.ac.uk or http:www.ccdc.cam.ac.uk.

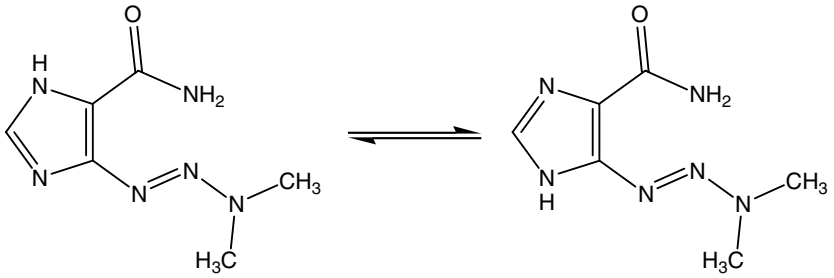

Fig. 1. Tautomeric forms of dacarbazine.

active against certain types of cancer and entered clinical studies [5,6]. In parallel, two gallium complexes: tris-(3-hydroxy-2-methyl-4*H*-pyran-4-onato)gallium(III) and tris(8-quinolinolato)gallium(III) (KP46, FFC11) have been evaluated in clinical studies to improve the bioavailability and increase the plasma concentration of orally administered gallium complexes in comparison with simple gallium salts [7–9].

The interaction between dacarbazine and metals has acquired clinical significance; in fact changes of reactivity, stability and transport properties can occur and increase the effectiveness of the compound. Several studies have been reported in the literature using different metals, like copper(II), iron(III), nickel(II), cobalt(II) and zinc(II), in order to synthesize and study dacarbazine complexes [10–12]. For example, both in vivo and in vitro studies of the anticancer activity of the dacarbazine-Fe(III) complex have shown that the iron(III) complex was more effective than dacarbazine itself: Multiplication of cells was inhibited and the tumor volume of BALB/c mice bearing sarcoma 180 was significantly reduced [11].

A powerful analytical tool for the characterization of metal complexes as well as to obtain information about molecular weight, charge and isotope distribution of molecules is electrospray ionization mass spectroscopy (ESI-MS). This method offers the advantage of consuming only a low sample amount (<μM) and permits the use of a variety of compatible solvent systems. ESI-MS is the softest desorption/ionization method and is therefore ideally suited to investigate the coordination behavior of transition metal complexes [13–15]. For example, ESI-MS was used to investigate both the coordination behavior of some heavy metal ions [e.g., mercury(II) and zinc(II)] towards thiacrown ether macrocycles [16] and also of Zn(II), Ag(II) and the hard alkali ions Li^+ and Na^+ towards ether and thioether-substituted ferrocenes [17]. Also, some metal complexes of ruthenium(II) with nitrogen-containing heterocyclic ligands [18] and the coordination of As(III), Sb(III), Cd(II), Hg(II), Tl(I), Pb(II) and Bi(III) towards polydentate ligands (e.g., glutathione) were characterized [19].

Dacarbazine with its seven donor atoms is expected to exhibit rich coordination chemistry. However, a crystallographic structure of the square-pyramidal dacarbazine–copper(II) complex, $[CuCl_2(dac)] \cdot 2CH_3OH$, showed that the ligand is bound bidentately through the oxygen of the carboxamide group and the nitrogen atom of the imidazole ring [10].

Herein, we report two approaches for characterization of metal complexes with dacarbazine: On the one hand, coordination compounds were isolated and characterized by classical analytical techniques. On the other hand, the complexes were allowed to form in situ and samples were characterized by ESI-MS.

2. Results and discussion

The complexation of dacarbazine was found to lead to promising tumor-inhibiting compounds [10–12]. Therefore, a series of transition metals was chosen: Representatives of groups VIII to X in the fourth period (Fe, Co, Ni) and for comparison purposes ruthenium as a member of the fifth period and VIIIth group were included in the studies. Also the influence of charge states and hardness of metal centers was taken into account: ions with oxidation states +2 (Ru, Co, Ni) and +3 (Fe) were evaluated for their binding properties towards dacarbazine.

cis-$[RuCl_2(dmso)_4]$, $CoCl_2$ and $NiCl_2$ were reacted with dacarbazine at a molar ratio of 1:2, while for the synthesis of the iron complex, comparable to previously published reports [11], a molar ratio of 1:1 ($FeCl_3$:dac) was chosen. The complexes were isolated by precipitation and analyzed by ^1H NMR and IR spectroscopy, elemental analysis and ESI-MS.

The NMR spectra of the products obtained from the paramagnetic ions Co(II), Ni(II) and Fe(III) were found to contain only rather broad peaks and it was not possible to assign the signals. Due to the large number of signals found in the spectrum of the Ru complex it is assumed that a compound of low symmetry was formed. Analysis of ^1H NMR spectra for all complexes made it evident that no uncoordinated dacarbazine was precipitated by the isolation process. However, NMR spectroscopy was found to be not suitable for the structural characterization of the obtained species. Only in the case of the Ni(II) complex (d^8) it can be concluded that the metal center does not have square planar geometry which would lead to diamagnetic properties.

The best fitting elemental analyses yielded: (i) a composition of Fe:dac:Cl = 1:1:3 with traces of solvent for the Fe

complex, (ii) $[RuCl_2(dac)_2(dmso)_2]\cdot H_2O$ for the reaction between *cis*-$[RuCl_2(dmso)_4]$ and dac, (iii) $[CoCl_2(dac)_2]$ impurified very probable with traces of $CoCl_2$ and methanol, as well as (iv) $[NiCl_2(dac)_2]$ containing the remaining unreacted $NiCl_2$ plus a trace of solvent. However, no structural information can be obtained. Note, the isolated Ru(II)-compound was found in a thermogravimetry experiment to be hygroscopic – one molecule of water was removed at 50 °C within 4 h and reincorporated at normal atmosphere within 1 h. This is in good accordance with the elemental analysis result.

Infrared spectroscopy results indicate that the amide-functionality might be involved into the coordination – a shift of the C=O-stretch vibration from 1655 cm^{-1} to 1635–1637 cm^{-1} was observed for all isolated complexes.

ESI-MS analysis in positive ion mode confirmed the proposed compositions of compounds based on elemental analysis data – the most abundant peaks for the Fe, Ru, Co and Ni complexes were assigned to $[FeCl(dac)_2]^+$, $[RuCl(dac)_2(dmso)]^+$, $[CoCl(dac)_2]^+$ and $[NiCl(dac)_2]^+$, respectively.

In order to investigate the influence of the incubation ratio, of the reaction time as well as of the isolation process, complexation studies by means of electrospray ionization mass spectrometry were performed. For this purpose, complexes of $FeCl_3$, *cis*-$[RuCl_2(dmso)_4]$, $CoCl_2$ and $NiCl_2$ with dacarbazine at both 1:1 and 1:2 ratios (metal:ligand) in methanol as solvent and at room temperature were prepared in situ and compared with the mass spectra of the isolated species. For the mass spectrometric study, the instrument was optimized in the positive ion mode on *m/z* 455.1 $[FeCl(dac)_2]^+$, 579.2 $[RuCl(dac)_2(dmso)]^+$, 458.1 $[CoCl(dac)_2]^+$ and 457.1 $[NiCl(dac)_2]^+$. In order to obtain comparable data, all mass spectra in the respective ion mode were recorded with the same parameter settings for each reaction.

3. The complexation of dacarbazine to iron(III)

With a sample taken from the incubation mixture with a molar ratio of 1:1 (Fe:dac) after 1 h of reaction the most intense peaks were found at *m/z* 455.0 ($[FeCl(dac)_2]^+$, 100%) and 387.1 ($[2dac+Na]^+$, 91%) (for assignment see Table 1). Giving the reaction 96 h to proceed, showed that only one major peak remained in the mass spectrum, at *m/z* 455.0 (see Fig. 2a). Increasing the dacarbazine content of the reaction mixture resulted in a spectrum with the peak at *m/z* 387.1 being the highest. Within 24 h of reaction again the signal assigned to $[FeCl(dac)_2]^+$, with Fe in the oxidation state 2+, was the most intense (see Fig. 2b), though $FeCl_3$ was used. Reduction is a common phenomenon during the electrospray process [20] and was also proven for other metals like Cu [21]. The mass spectra obtained from the isolated complex were relatively similar to that of the in situ-prepared ones after an incubation time of 24 h. In the negative ion mode spectra, the trichloroferrate(II)- and the tetrachloroferrate(III)-ions were identified beside a deprotonated species at *m/z* 453.2 $\{[FeCl(dac)_2-2H]^-\}$. No significant changes in the latter spectra were found over time.

Table 1
The theoretical *m/z* values for the highest peaks in positive mode mass spectra of the studied iron(III) complexes

m/z	Assignment
301.1	$[Fe(dac)(MeOH)_2-H]^+$
387.2	$[2dac+Na]^+$
425.9	$[Fe_2Cl_2(dac)(MeOH)_2-2H]^+$
455.1	$[Fe(dac)_2Cl]^+$
461.9	$[Fe_2Cl_3(dac)(MeOH)_2-H]^+$
486.0	$[FeCl(dac)_2(MeOH)-H]^+$
554.1	$[FeCl_2(dac)_2(MeOH)_2]^+$

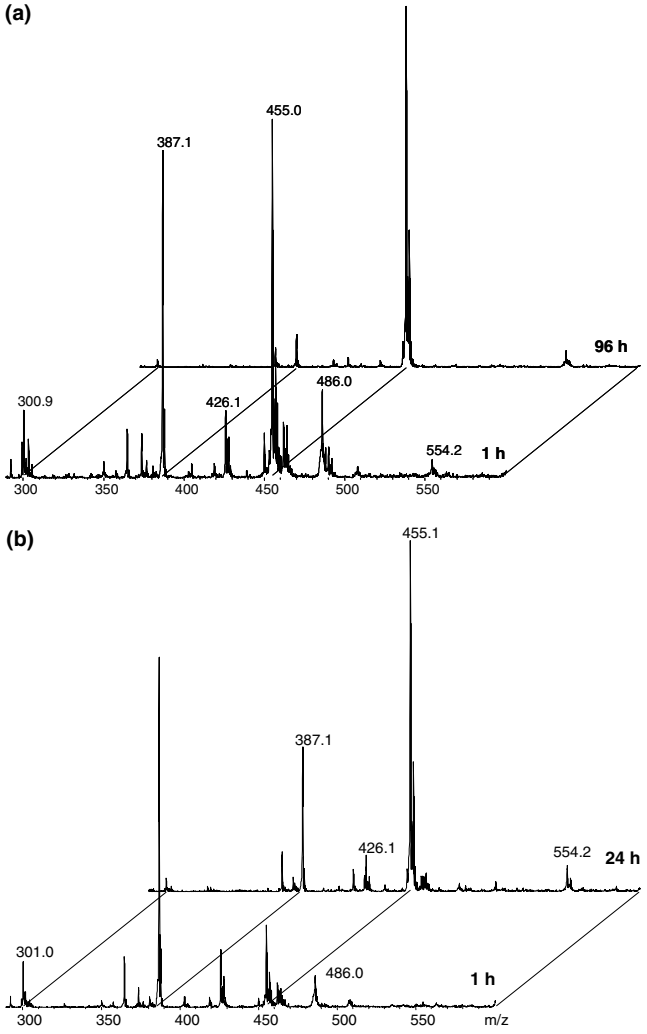

Fig. 2. Time resolved MS spectra of 1:1 (a) and 1:2 (b) incubation mixtures of $FeCl_3$ and dacarbazine.

Taking into account the information obtained by MS and elemental analysis leads to the conclusion that a species with the formula $[FeCl_2(dac)_2][FeCl_4]$ is formed if given an appropriate time period for the reaction. This is in contrast to the data published by Shukla and Pitre [11] who proposed as the reaction product of $FeCl_3$ with dacarbazine under the same conditions a species with the

formula [Fe^{III}(dac)]. The latter structure is quite implausible since no counterion was given in the publication and a threefold deprotonation of dacarbazine is not to be expected.

4. The complexation of dacarbazine to ruthenium(II)

Switching in the periodic table of elements from the 4th period into the 5th led us to compare the coordination behavior of iron with that of ruthenium.

The positive ESI-mass spectrum of the isolated Ru complex (Ru:dac = 1:2) yielded a peak at *m/z* 579.2 (100%) identified as $[RuCl(dac)_2(dmso)]^+$ and a further signal at 501.2 (15%) assignable to $[RuCl(dac)_2]^+$ (see Fig. 3a for comparison of the mass spectra of the isolated species and the in situ-prepared ones, for calculated *m/z*-values of the most important signals in the mass spectra see Table 2). The negative ion mode mass spectrum contained a main peak at *m/z* 136.0 ($[dac-H]^-$, 100%), and two less intense ones at *m/z* 499.0 and 579.1 identified as $[RuCl(dac)_2-2H]^-$ (42%) and $[RuCl(dac)_2(dmso)-2H]^-$ (31%), respectively. A peak at ca. *m/z* 530 (9%) might be a fragment ion after cleavage of the dacarbazine ligand, which could have been partly released from its metal-binding partner during the transfer from the liquid into the gaseous phase.

After 1 h of reaction of a *cis*-$[Ru(dmso)_4Cl_2]$ and dacarbazine mixture (1:1) the highest peak was found to be *m/z* 387.2 {$[2dac+Na]^+$}, changing within 48 h to 475.0 {$[RuCl(dac)(dmso)_2]^+$} (see Fig. 3b). Additionally, signals assigned to $[RuCl(dac)(dmso)_3]^+$ (95%), $[RuCl(dac)_2(dmso)]^+$ (82%), $[RuCl(dac)(dmso)_2(MeOH)_2-2H]^+$ (39%) and $[RuCl(dac)(dmso)]^+$ (17%) increased in abundance. Note that the oxidation states of the ruthenium centers in the $[RuCl(dac)(dmso)_2(MeOH)_2-2H]^+$- and $[RuCl_2(dac)(dmso)_3(MeOH)]^+$-ions are +4 and +3, respectively. These species might have been formed during the electrospray process (oxidation at the capillary tip) [22].

When freshly mixing two solutions of dacarbazine and the Ru-starting complex at a molar ratio of 2:1 (resembling the synthetic procedure), the mass spectrum in the positive ion mode showed as the highest peak a signal at *m/z* 387.2 (comparable to the 1:1 incubation) (see Fig. 3c). Additionally, less intense peaks (<5% relative intensity) were observed in the mass spectrum, having a rich isotope pattern. After 48 h the most intense signals were found to possess *m/z* 553.0 (100%) followed by 579.2 (48%), the latter having an increased relative intensity of 72% after a further 120 h of reaction.

Comparing the positive mode mass spectra of the isolated species with that of the in situ-prepared ones (reaction for 48 h) shows that the peak assigned to the Ru complex with one dacarbazine ligand is the highest one in the 1:1 incubation mixture, while in the other two mass spectra the peaks of compounds with two dacarbazine ligands significantly increase (see Fig. 3a). In the isolated species, the peak assigned to $[RuCl(dac)_2(dmso)]^+$ is nearly the exclusive one with a ruthenium isotope distribution.

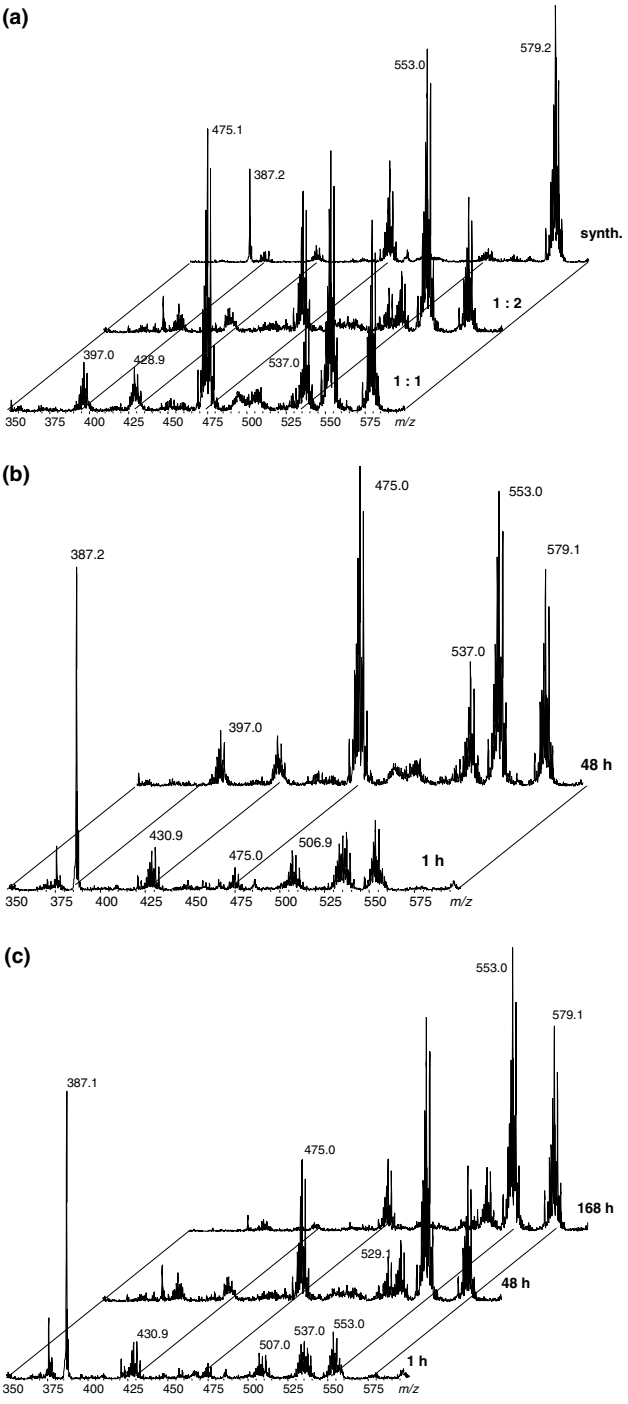

Fig. 3. (a) Comparison of in situ-synthesized Ru(II) complexes at incubation ratios of 1:1 and 1:2 (Ru:dac; after 48 h of incubation) with the synthesized complex and time resolved MS spectra of 1:1 (b) and 1:2 (c) incubation mixtures of *cis*-$RuCl_2(dmso)_4$ and dacarbazine.

In the negative ion mode mass spectra of all complexes, the peak at *m/z* 475.4 was found to have highest intensity, which correlates with calculated *m/z*-values for $[RuCl(dac)(dmso)-2H]^-$. Other signals could be assigned to $[RuCl(dac)_2(dmso)-2H]^-$ and $[RuCl_2(dac)(dmso)-H]^-$.

In contrast to the results obtained with iron(III) (data from MS experiments and elemental analysis indicates the formation of $[FeCl_2(dac)_2][FeCl_4]$), in the case of the

Table 2
The theoretical *m/z* values for the highest peaks in positive mode mass spectra of the studied ruthenium(II) complexes

m/z	Assignment
233.0	$[Ru(dac)_2]^{2+}$
387.2	$[2dac+Na]^+$
397.0	$[RuCl(dac)(dmso)]^+$
429.0	$[RuCl(dac)(dmso)(MeOH)]^+$
475.0	$[RuCl(dac)(dmso)_2]^+$
507.0	$[RuCl(dac)(dmso)_2(MeOH)]^+$
537.0	$[RuCl(dac)(dmso)_2(MeOH)_2-2H]^+$
553.0	$[RuCl(dac)(dmso)_3]^+$
579.1	$[RuCl(dac)_2(dmso)]^+$
607.0	$[RuCl(dac)(dmso)_3(MeOH)+Na-H]^+$
620.0	$[RuCl_2(dac)(dmso)_3(MeOH)]^+$
657.1	$[RuCl(dac)_2(dmso)_2]^+$

ruthenium complexes it is assumed that during the isolation process a species with the formula $[RuCl_2(dac)_2(dmso)_2]$ was obtained with the $[RuCl(dac)_2(dmso)]^+$-ion identified in the mass spectrum being probably a fragment of $[RuCl_2(dac)_2(dmso)_2]$. In general in mass spectrometric studies of synthesized (and characterized by other methods) Ru(II) and also of Ru(III) complexes, it has been recognized that these species frequently undergo fragmentation processes when transferred into the gaseous phase [23,24].

The isolation procedure might also have led to an enrichment of $[RuCl_2(dac)_2(dmso)_2]$ explaining the differences in the mass spectra (high abundance of ions assignable to ruthenium complexes with three dmso-ligands). Also it can be concluded that the reaction of dacarbazine with *cis*-$[RuCl_2(dmso)_4]$ proceeds rather slowly in comparison to other starting complexes (compare $CoCl_2$ and $NiCl_2$).

5. The complexation of dacarbazine to cobalt(II)

When incubating $CoCl_2$ and dacarbazine at a molar ratio of 1:2 and stirring for 2 h the coordination compound $[CoCl_2(dac)_2]$ was isolated by precipitation with diethylether. The elemental analysis showed that not only $[CoCl_2(dac)_2]$ but also unreacted $CoCl_2$ was precipitated during the isolation process.

Comparing the ESI mass spectra of the synthesized Co complex with that obtained after incubation of $CoCl_2$ with dacarbazine at molar ratios of 1:1 and 1:2 for 1 h at room temperature, which were also analyzed in both positive and negative ion modes, showed significant differences (see Fig. 4). While in all three mass spectra the most intense signal was found at *m/z* 458.0 and assigned to the $[CoCl(dac)_2]^+$-ion, the less abundant peaks varied significantly in regard in their abundance (for peak assignment see Table 3). For example, the peak at *m/z* 276.0 – the mono-dacarbazine complex – was much higher in the incubation mixtures than in the mass spectrum of the synthesized species. In contrast, signals derived from dacarbazine and higher adducts were more intense in the 1:2 sample and the isolated complex. Increasing the incubation time up to 24 h led only to minor changes in the mass spectra. The appearance of signals assignable to $[Co(dac)_2-NH(CH_3)_2-H]^+$ and $[Co(dac)_3-NH(CH_3)_2-3H]^+$ at *m/z* 377.1 and 577.1 (fragments of $[Co(dac)_2-H]^+$ and $[Co(dac)_3-H]^+$, respectively) indicates that the methylated amino group does not contribute to the coordination of the metal center to dacarbazine.

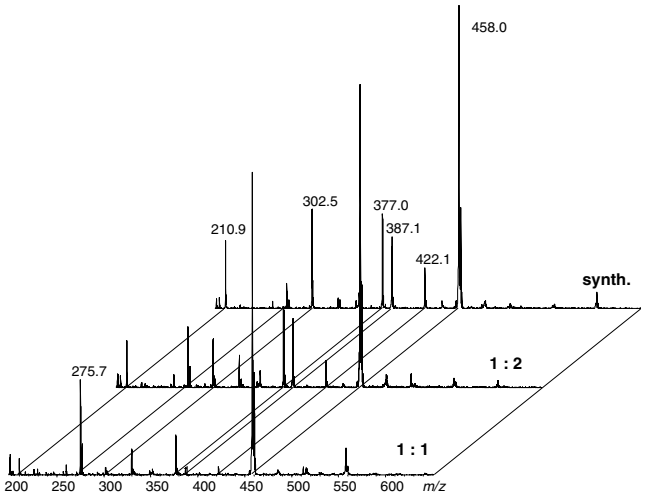

Fig. 4. Positive ion mode mass spectra for 1 h incubated $CoCl_2$–dacarbazine mixtures (1:1 and 1:2) and the isolated Co complex.

Table 3
The theoretical *m/z* values for the highest peaks in positive mode mass spectra of the studied cobalt(II) complexes

Positive ion mode (calculated) *m/z*	Assignment
211.6	$[Co(dac)_2]^{2+}$
276.0	$[CoCl(dac)]^+$
302.6	$[Co(dac)_3]^{2+}$
377.1	$[Co(dac)_2-NH(CH_3)_2-H]^+$
387.2	$[2dac+Na]^+$
422.1	$[Co(dac)_2-H]^+$
458.1	$[Co(dac)_2Cl]^+$
557.1	$[Co(dac)_3-NH(CH_3)_2-3H]^+$
604.2	$[Co(dac)_3-H]^+$

In the negative ion mode the species at *m/z* 163.8, 440.8 and 456.1 could be assigned to $[CoCl_3]^-$, a $[Co_2Cl_4(dac)-H]^-$ cluster and the $[CoCl(dac)_2-2H]^-$-anion, respectively. This might explain the rest of the unreacted $CoCl_2$ identified in the negative ion mode as the respective trichlorocobaltate(II) anion.

The data from elemental analysis and from mass spectrometric experiments led to the conclusion that the neutral complex $[CoCl_2(dac)_2]$ is the most favorable species to be formed between Co(II) and dacarbazine, independently of the molar ratio of incubation.

6. The complexation of dacarbazine to nickel(II)

Incubation of $NiCl_2$ with dacarbazine at a molar ratio of 1:2 yielded, after stirring for 2 h and precipitation with diethyl ether, $[NiCl_2(dac)_2]$ and a rest of unreacted $NiCl_2$. In the mass spectrum the main peak (100%) at *m/z* 457.2 was assigned to $[NiCl(dac)_2]^+$ (for assignment see Table 4).

Table 4
The theoretical *m/z* values for the highest peaks in positive mode mass spectra of the studied nickel(II) complexes

Positive ion mode (calculated) *m/z*	Assignment
211.1	$[Ni(dac)_2]^{2+}$
275.0	$[Ni(dac)Cl]^{+}$
302.1	$[Ni(dac)_3]^{2+}$
376.1	$[Ni(dac)_2-NH(CH_3)_2-H]^{+}$
387.2	$[2dac+Na]^{+}$
421.1	$[Ni(dac)_2-H]^{+}$
457.1	$[Ni(dac)_2Cl]^{+}$
515.1	$[Ni(dac)_3-2NH(CH_3)_2+H]^{+}$
556.1	$[Ni(dac)_3-NH(CH_3)_2-3H]^{+}$
603.2	$[Ni(dac)_3-H]^{+}$

Similar to the experiments with Co(II) the most abundant peaks were found to be $[NiCl(dac)_2]^{+}$ at *m/z* 457.1 and $[NiCl(dac)_2-2H]^{-}$ at *m/z* 455.1 in the positive and negative ion modes, respectively, for the isolated species and the 1:2 incubation mixture (Ni:dac) after an incubation period of 1 h, while in the 1:1 incubation mixture the peak at *m/z* 274.8 was the highest one $[NiCl(dac)]^{+}$ (see Fig. 5). After 24 h no significant changes in the mass spectra were found. Comparable to the cobalt complexes, in these experiments also fragment ions at *m/z* 376.1, 515.1 and 556.1 from the parent ions $[Ni(dac)_2-H]^{+}$ (*m/z* 421.1) or $[Ni(dac)_3-H]^{+}$ (*m/z* 603.2) were found which were assigned to $[Ni(dac)_2-NH(CH_3)_2-H]^{+}$, $[Ni(dac)_3-2NH(CH_3)_2+H]^{+}$ and $[Ni(dac)_3-NH(CH_3)_2-3H]^{+}$, respectively. Again, no involvement of the alkylated amino function in the binding was observed.

The negative ion mode spectrum of the isolated complex contained, beside the deprotonated species at *m/z* 455.3 $\{[NiCl(dac)_2-2H]^{-}\}$, a signal at *m/z* 311.4 $\{[NiCl_2(dac)]^{-}\}$ and another one at 164.4 ($[NiCl_3]^{-}$). In the 1:1 incubation mixture a cluster of two Ni ions with one dacarbazine ligand and chloride ions was the highest peak, accompanied by a $[NiCl_3]^{-}$ ion, while in the 1:2 reaction again the signal at *m/z* 455.3 was the most intense and the $[NiCl_3]^{-}$ ion was not detectable.

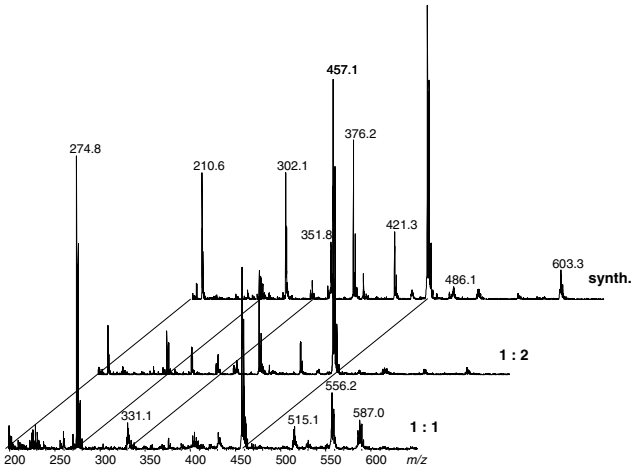

Fig. 5. Comparison of positive ion mass spectra for 1 h incubated $NiCl_2$–dacarbazine mixtures (1:1 and 1:2) and the isolated Ni complex.

In contrast to the Co complexes, it is assumed that $[NiCl_2(dac)_2]$ is the preferentially formed species only when incubating at a molar ratio of $NiCl_2$ to dacarbazine of 1:2, in the 1:1 incubation mixture the most intense signal was assigned to a [Ni(dac)]-type complex.

7. Conclusions

Dacarbazine and its metal complexes are of interest in antitumor chemotherapy. From the perspective of coordination chemists, attention is drawn to dacarbazine since it contains seven donor atoms representing potential coordination sites for transition metal ions. In order to study the coordination properties of this potential multidentate ligand, complexes with Fe, Ru, Ni and Co centers were synthesized and isolated or in situ characterized by electrospray ionization mass spectrometry.

It was found that Fe(III) forms, independently of the ratio between the iron salt and dacarbazine, at rather slow reaction kinetics exclusively a complex of the $[Fe(dac)_2]$ type. The also rather slow reaction between *cis*-$[Ru(dmso)_4Cl_2]$ with dacarbazine yields a mixture of [Ru(dac)] and $[Ru(dac)_2]$ type complexes. In contrast, the reactions with Ni(II) and Co(II) salts were observed to proceed much faster. While the reaction with Co(II) salts delivered only a $[Co(dac)_2]$ type complex, coordination compounds with Ni(II) were identified to be of [Ni(dac)] and $[Ni(dac)_2]$ types when being incubated at molar ratios Ni:dac of 1:1 or 1:2, respectively. Due to the paramagnetic character of most of the complexes no statement on the coordination geometry from NMR spectroscopy can be made. However, IR spectra elucidated the probable involvement of the amide functionality in the coordination process. This data were partly confirmed by MS data taking into account that the losses of $NH(CH_3)_2$ indicate that at least this nitrogen is not involved in the coordination processes.

8. Experimental

If necessary the reactions were carried out in dry solvents and under argon atmosphere. The NMR-spectra were recorded on a Bruker Avance DPX 400 instrument (Ultrashield™ Magnet) at 400.13 MHz (^{1}H).

Electrospray ionization mass spectra were recorded on a Bruker *esquire*$_{3000}$ ion trap mass spectrometer equipped with an orthogonal electrospray interface (Bruker Daltonics, Bremen, Germany). The Bruker Daltonics esquire 5.2 (Build 382) software bundle consisting of Bruker esquire Control 5.2 (Build 63.8) and Bruker Data Analysis 3.2 (Build 121) was used for acquiring spectra and data analysis, respectively. The samples were delivered at a flow rate of 4 μl/min using a syringe pump 74900 from Cole-Parmer Instrument Company (Vernon Hills, IL, USA) and N_2 was used as the drying (180 °C) and nebulizing gas (10 psi). The scan range was from 50 to 1200 *m/z*. The mass spectrometer was operated in both positive and negative ionization modes and the optimization was done to maximize the

Table 5
The operational MS parameters

Parameters	Fe	Ru	Co	Ni
HV capillary (V)	4500	2600	4500	3369
Dry gas flow (l min^{-1})	9	9	5	5

Skimmer 2 (V)	5.7	5.0	5.9	5.4
Octopole (V)	3.56	2.71	3.23	3.16
Trap drive	42.3	40.1	37.0	37.6

peak assignable to the most intense metal–dacarbazine adduct-signal in the positive ion mode (see Table 5 for measurement parameters). For MS studies, dacarbazine was incubated with the respective metal complexes at molar ratios of 1:1 and 2:1 by mixing methanol solutions yielding concentrations of about 0.1 mM. Measurements were done immediately after dissolution and repeated over a period of 4 days.

The thermogravimetric analyses were done on a Mettler Toledo TGA 850 and the elemental analyses by the Laboratory for Elemental Analysis of the Faculty of Chemistry, University of Vienna, with a Perkin–Elmer 2400 CHN Elemental Analyzer.

9. Syntheses of complexes

9.1. $FeCl_3 \cdot 6H_2O$

A solution of dacarbazine (50 mg, 0.27 mmol) in ethanol (6 mL) was added to a solution of $FeCl_3 \cdot 6H_2O$ (74 mg, 0.27 mmol) in ethanol (4 mL). The reaction mixture was refluxed for 2 h. Afterwards the solvent was removed and the dark solid was dried in vacuum (33.8 mg).

M.p. 178–180 °C. Elemental *Anal*. Calc. for $(C_{12}Cl_3FeH_{20}N_{12}O_2)_1(FeCl_3)_{1.15}(C_2H_5O)_{0.65}$: C, 21.50, H, 3.24, N, 22.62. Found: C, 21.45, H, 3.39, N, 22.54%. MS (ESI$^+$) m/z 489.9 $[Fe(dac)_2Cl_2]^+$.

9.2. *cis*-$RuCl_2(dmso)_4$

A solution of dacarbazine (200 mg, 1.1 mmol) in methanol (15 mL) was added to a solution of *cis*-$[RuCl_2(dmso)_4]$ (256 mg, 0.55 mmol) in methanol (15 mL). The reaction mixture was stirred for 4 h and diethyl ether (200 mL) was added. The solution was kept at 4 °C for 12 h and afterwards the precipitated product was isolated by filtration, washed with diethyl ether (3 × 20 mL), and dried in vacuum.

Yield: 265.3 mg (68%). M.p. 196–198 °C (decomp.). Elemental *Anal*. Calc. for $(C_{16}Cl_2H_{32}N_{12}O_4RuS_2)_1(H_2O)_1$: C, 27.04, H, 4.82, N, 23.65. Found: C, 26.89, H, 4.52, N, 23.76%. MS (ESI$^+$) m/z 579.3 $[Ru(dac)_2(dmso)Cl]^+$.

9.3. $CoCl_2 \cdot 6H_2O$

A solution of dacarbazine (50 mg, 0.27 mmol) in methanol (5 mL) was added to a solution of $CoCl_2 \cdot 6H_2O$ (33 mg, 0.14 mmol) in methanol (5 mL). The reaction mixture was stirred for 2 h and diethyl ether (50 mL) was added. Afterwards the precipitated product was isolated by filtration, washed with diethyl ether (3 × 10 mL), and dried in vacuum (38.1 mg).

M.p. 168–170 °C. Elemental *Anal*. Calc. for $(C_{12}Cl_2CoH_{20}N_{12}O_2)_1(CoCl_2)_{0.1}(CH_4O)_{0.4}$: C, 28.64, H, 4.19, N, 32.32. Found: C, 28.61, H, 4.20, N, 32.40%. MS (ESI$^+$) m/z 458.0 $[Co(dac)_2Cl]^+$.

9.4. $NiCl_2 \cdot 6H_2O$

A solution of dacarbazine (50 mg, 0.27 mmol) in methanol (5 mL) was added to a solution of $NiCl_2 \cdot 6H_2O$ (33 mg, 0.14 mmol) in methanol (5 mL). The reaction mixture was stirred for 2 h and diethyl ether (50 mL) was added. The solution was kept at 4 °C for 3 h and afterwards the precipitated product was isolated by filtration, washed with diethyl ether (3 × 10 mL), and dried in vacuum (39 mg).

M.p. 198–200 °C. Elemental *Anal*. Calc. for $(C_{12}Cl_2H_{20}N_{12}NiO_2)_1(NiCl_2)_{0.2}(CH_4O)_{0.5}(H_2O)_{0.4}$: C, 27.64, H, 4.23, N, 30.95. Found: C, 27.77, H, 4.29, N, 31.07%. MS (ESI$^+$) m/z 457.2 $[Ni(dac)_2Cl]^+$.

pK_a caused by the changes of the electronic and steric properties of the co-ordinated ligands L.

2. Experimental

All reagents were Aldrich or Fluka products in the highest available purity and were used without any further treatment. Solvents were dried using standard techniques.

2.1. Physical measurements

Infrared spectra (4000–400 cm^{-1}, KBr disks) were recorded on a Perkin–Elmer Spectrum One spectrophotometer. NMR spectra (^1H, $^{31}P\{^1H\}$, $^{31}P\{^1H\}$ with inverse-gated decoupling) were obtained either on AC 200 or AVANCE 300 Bruker spectrometers in CD_3NO_2 at temperatures comprised between 298 and 243 K. ^1H NMR spectra are referred to internal tetramethylsilane, while ^{31}P NMR chemical shifts are reported with respect to 85% H_3PO_4. SwaN-MR and MestRe-C software packages were used to treat the NMR data [2]. The conductivity of 1×10^{-3} mol dm^{-3} solutions of the new complexes in DMF at 25° was measured with a Radiometer CDM 83 instrument. Elemental analyses (C, H, N) were performed by the microanalytical laboratory at the Department of Pharmaceutical Sciences, University of Padua.

2.2. Computational details

Computational geometry optimisation of the complexes was performed using the restricted DFT B3PW91 method with the CEP-121G basis set (CEP-31G on the Pt atom). Geometry convergence was accelerated using the GDIIS algorithm and a first refinement of the structures was obtained using the restricted semi-empirical PM3 method. Geometry optimisation of the free nitrogen-donor ligands was obtained with restricted DFT B3LYP/6-311+G** calculations [3]. All calculations were carried out with computers equipped with Intel Pentium 4 Northwood processors operating at 2.6 GHz frequency or IBM G4 operating at 1.25 GHz. Software used were GAUSSIAN-98 and SPARTAN-02 [4].

2.3. Preparation of the complexes

The $[PtCl(triphos)]^+$ species has already been reported as the chloride salt [5], but we preferred to isolate it as the perchlorate salt following the procedure described below [6].

To a warm (ca. 50 °C) solution of *cis*/*trans*-$PtCl_2(SMe_2)_2$ [7] (0.390 g, 1.0 mmol) in methanol (25 mL) a stoichiometric amount of solid triphos (0.534 g, 1.0 mmol) was added in successive small portions. After 10 min the reaction mixture was allowed to cool to room temperature and a solution of an excess of $LiClO_4$ (0.202 g, 1.5 mmol) in methanol (10 mL) was slowly added. The white solid complex $[PtCl(triphos)](ClO_4)$ which separated out of the solution was filtered off, washed with methanol and diethylether and dried under vacuum (yield >90%).

2.4. *[Pt(4-R-py)(triphos)](ClO$_4$)$_2$ ($\mathbf{1}^R$)* *{R = CN, COOH, COOMe, MeCO, H, Me, NH$_2$}* *[Pt(4-R-an)(triphos)](ClO$_4$)$_2$ ($\mathbf{2}^R$)* *{R = NO$_2$, CN, Cl, H, Me, MeO}*

The complexes $[Pt(4\text{-}R\text{-}py)(triphos)](ClO_4)_2$ ($\mathbf{1}^R$) and $[Pt(4\text{-}R\text{-}an)(triphos)](ClO_4)_2$ ($\mathbf{2}^R$) have been prepared by adding the stoichiometric amount of solid $AgClO_4$ to a solution of $[PtCl(triphos)](ClO_4)$ in nitromethane. In a typical preparation, 0.021 g (0.1 mmol) of $AgClO_4$ were added to a 5 mL solution of $[PtCl(triphos)](ClO_4)$ (0.086 g, 0.1 mmol) in CH_3NO_2. After 12 h under stirring the AgCl formed was filtered off and a slight excess (1.5:1) of the appropriate pyridine or aniline was added. The resulting solution was heated to about 50 °C for 2 h and then filtered if necessary. By slow addition of diethylether the product which separated out was filtered, washed twice with diethylether and dried under vacuum (yield >70% in all cases).[1]

^{1}H NMR (ppm, 298 K): $\mathbf{1}^{COOMe}$ 3.93 (s, 3H, CH_3); $\mathbf{1}^{MeCO}$ 2.56 (s, 3H, CH_3); $\mathbf{1}^{Me}$ 2.36 (s, 3H, CH_3); $\mathbf{1}^{NH_2}$ (s, br, 2H, NH_2); $\mathbf{2}^{Me}$ 2.19 (s, 3H, CH_3); $\mathbf{2}^{OMe}$ 3.93 (s, 3H, CH_3).

^{31}P NMR chemical shifts and $^{1}J_{Pt-P}$ coupling constants are collected in Table 1. All the Λ_M values measured are comprised between 140 and 150 Ω^{-1} mol^{-1} cm^2, as expected for 2:1 electrolytes in DMF [8].

3. Results and discussion

3.1. Preparation of the complexes

The synthetic routes used for the preparation of the complexes $[PtCl(triphos)](ClO_4)$, $[Pt(4\text{-}R\text{-}py)(triphos)](ClO_4)_2$ ($\mathbf{1}^{R}$) and $[Pt(4\text{-}R\text{-}an)(triphos)](ClO_4)_2$ ($\mathbf{2}^{R}$) are outlined in Scheme 1 and the details are given in Section 2, so here only few comments are made. Although the isolation of the chloro-complex $[PtCl(triphos)]^{+}$ as chloride salt has already been reported [5], we have used an alternative method starting from the isomeric mixture of $PtCl_2(SMe_2)_2$, which we found very convenient for the synthesis of a wide variety of Pt(II) chloro-complexes with polydentate ligands [6]. Treatment of $[PtCl(triphos)](ClO_4)$ with silver perchlorate followed by the addition of the appropriate nitrogen-donor ligand afforded the desired $\mathbf{1}^{R}$ or $\mathbf{2}^{R}$ complex in pure form and in good yield. All the characterization data (IR, ^{1}H NMR, ^{31}P NMR, conductivity, elemental analyses) are in good agreement with the purposed formulations. Spectroscopic data of the $\mathbf{1}^{H}$ derivative have been also compared with those of the already known $[Pt(pyridine)(triphos)](CF_3SO_3)_2$ complex [9].

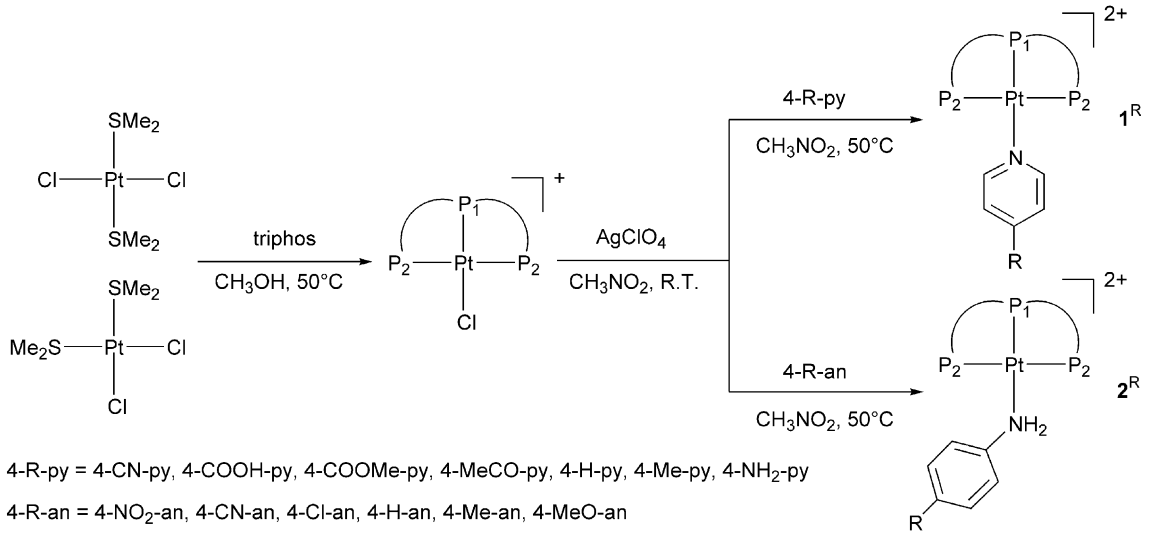
The pyridines and anilines, all *para*-substituted, were chosen to cover a wide range of basicity ($1.90 \leqslant pK_a$ pyridines $\leqslant 9.11$, $1.00 \leqslant pK_a$ anilines $\leqslant 5.34$). Moreover, the relationship between the basicity and the nucleophilic behaviour of some of the nitrogen-donor ligands considered has been already investigated and discussed in kinetic studies [10]. It is also known [11] that there is a linear relationship between the pK_a values and the proton affinity, PA (i.e., the enthalpy of a proton breaking-off in the gaseous phase) for the series of the considered pyridines and anilines, so the medium contribution to the pK_a determination is almost constant for both the types of nitrogen-donor ligands.

3.2. NMR and DFT studies

The ^{31}P {^{1}H} NMR spectra of all the $\mathbf{1}^{R}$ and $\mathbf{2}^{R}$ complexes consist of two sharp peaks, each with ^{195}Pt satellites. The J_{P1-P2} phosphorus–phosphorus couplings are unobservable for all the prepared complexes, but this is expected for square-planar triphos derivatives with all the phosphorus atoms co-ordinated to the same metal centre [9,12]. The ^{31}P NMR data of the $\mathbf{1}^{R}$ and $\mathbf{2}^{R}$ derivatives are reported in Table 1, together with the pK_a values [13] of the *para*-substituted pyridines and anilines.

There in no apparent regularity in the variation of the ^{31}P chemical shifts, while there are interesting trends for the coupling constants. For the *para*-substituted pyridines, a variation of pK_a in the range 1.90–9.11 leads to a linear variation of $^{1}J_{Pt-P1}$ (P_1 = phosphorus nucleus *trans* to N) from 2895 to 2768 Hz. The linear relationship $^{1}J_{Pt-P1} = 2918 \pm 4 - 16.9 \pm 0.9\ pK_a$ is followed, as shown in Fig. 1A. There is also a linear rise (42 Hz within the considered pK_a range) of the $^{1}J_{Pt-P2}$ couplings (P_2 = phosphorus nuclei *cis* to N) while the pK_a value increases (see Fig. 1B); the equation is $^{1}J_{Pt-P2} = 2371 \pm 1 + 5.8 \pm 0.2\ pK_a$. It is to be noted that the derivatives of 4-COOH-py and 4-COOMe-py, both having the same pK_a (3.26), give exactly the same *trans* and *cis* $^{1}J_{Pt-P}$ coupling constants.

The linear relationship between $^{1}J_{Pt-P1}$ and $^{1}J_{Pt-P2}$ coupling constants is given by the equation $^{1}J_{Pt-P1} = 9700 \pm 300 - 2.9 \pm 0.1\ ^{1}J_{Pt-P2}$. The variation of donor capability of the pyridines affects mostly the *trans* $^{1}J_{Pt-P}$ coupling constant, also considering that there are two *cis* phosphorus atoms and only one *trans* phosphorus atom.



Scheme 1. Synthesis of $[PtCl(triphos)]^+$, $[Pt(4\text{-R-py})(triphos)]^{2+}$ ($\mathbf{1}^R$) and $[Pt(4\text{-R-an})(triphos)]^{2+}$ ($\mathbf{2}^R$) complexes.

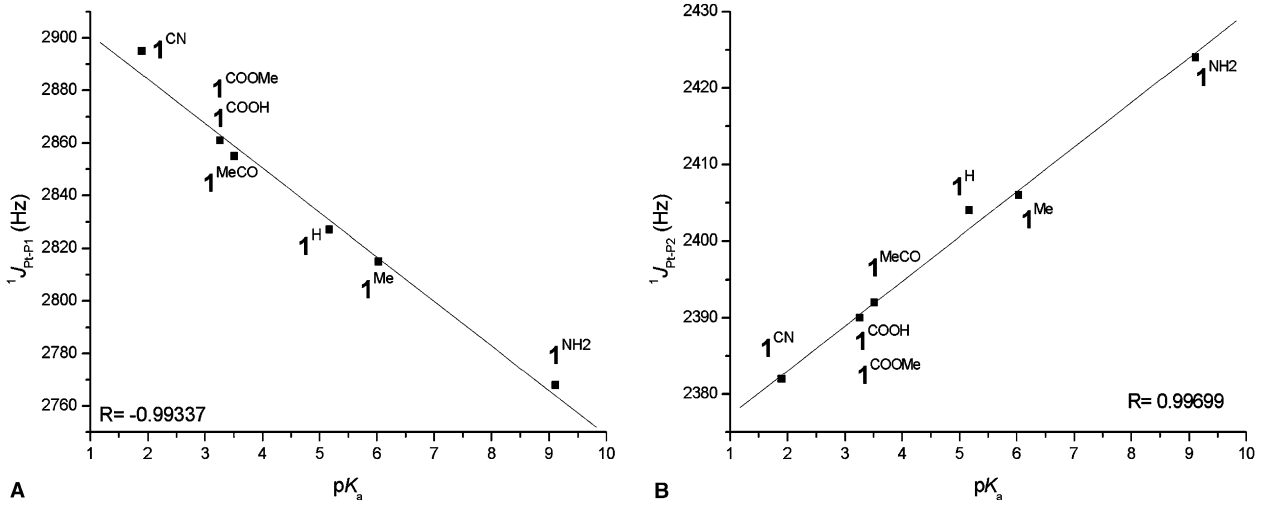


Fig. 1. Plot of $^1J_{Pt-P1}$ against pK_a (A) and of $^1J_{Pt-P2}$ against pK_a (B) for $\mathbf{1}^R$ complexes.

The use of 4-substituted pyridines allows to exclude steric effects due to the different R groups, so that the linear relationships between the pK_a and the $^1J_{Pt-P}$ values can be attributed only to electronic effects. It is generally assumed [1] that the magnitude of the $^1J_{Pt-P}$ coupling constant is dominated by the Fermi contact term, expressed by the following relation:

$$^1J_{Pt-P} \propto \frac{\gamma_{Pt}\gamma_P\alpha_{Pt}^2\alpha_P^2\left|\psi_{Pt(6s)}(0)\right|^2\left|\psi_{P(3s)}(0)\right|^2}{\Delta E}. \quad (1)$$

In the relation, γ_{Pt} and γ_P are the gyromagnetic ratios for the ^{195}Pt and ^{31}P isotopes, α_{Pt}^2 and α_P^2 represent the s-characters of the localized hybrid orbitals in a valence bond description, $|\psi_{Pt(6s)}(0)|^2$ and $|\psi_{P(3s)}(0)|^2$ are the electron densities of the s orbitals at nucleus, ΔE is an average singlet–triplet excitation energy. It is also assumed that the most important term for the variation of the magnitude of $^1J_{Pt-P}$ is α_{Pt}^2 so, following relation (1), the decrease of the *trans* $^1J_{Pt-P1}$ coupling constant with the increase of the pK_a represents primarily the change in 6s character of the hybrid orbital of platinum used in the bond with P_1. The increase of donor capability of the co-ordinated pyridine increase the Pt 6s character of the Pt–N bond at the expense of the *trans* Pt–P bond. The $^1J_{Pt-P2}$ trend suggests that the weakening of the Pt–P_1 bond strengthens the bonds between the metal centre and the other two phosphorus atoms in the *cis* positions.

Mather et al. have reported a correlation of the $^1J_{Pt-P}$ coupling constants with the Pt–P bond lengths in some trialkyl phosphine complexes of Pt(II) and Pt(IV) [14] and subsequent studies for Pt(0) complexes [15] have shown similar results, in which the shorter Pt–P distances are associated with larger values of $^1J_{Pt-P}$. We tried to correlate the $^1J_{Pt-P}$ coupling constants of the $\mathbf{1}^R$ complexes with the

bond lengths by optimising with DFT calculations the geometries of the derivatives of the pyridines with the greatest pK_a difference, the $[Pt(4\text{-CN-py})(triphos)]^{2+}$ ($\mathbf{1}^{CN}$) and $[Pt(4\text{-NH}_2\text{-py})(triphos)]^{2+}$ ($\mathbf{1}^{NH_2}$) cations. The difference in nucleophilicity between the two considered pyridines is well expressed by both the calculated dipolar moment μ (whose vector is oriented from the R group towards the pyridine-N atom) and the Mulliken charge on the pyridine-N atoms for the free species (see Table 2). Also the electrostatic potential surfaces on the pyridine-N atoms shown in Fig. 2 allow to understand the different nucleophilicity of the two pyridines.

The calculated r_{Pt-P1}, r_{Pt-P2} and r_{Pt-N} bond lengths for the $\mathbf{1}^{CN}$ and $\mathbf{1}^{NH_2}$ complexes are reported in Table 2; unfortunately, the differences between the corresponding bond lengths of the two derivatives are too small to be really significant, probably because of the relatively small difference of the $^1J_{Pt-P}$ couplings of the two complexes.

Also in the case of the complexes with the *para*-substituted anilines $\mathbf{2}^{R}$ a relationship between the pK_a values of the anilines and the $^1J_{Pt-P1}$ coupling constants of the $\mathbf{2}^{R}$ derivatives is observed (see Fig. 3), but this correlation is less linear in comparison with the one of the $\mathbf{1}^{R}$ derivatives. Moreover, for the $\mathbf{2}^{R}$ complexes there is an irregular trend of the $^1J_{Pt-P2}$ values against pK_a.

A possible explanation for the different behaviour of the $\mathbf{2}^{R}$ derivatives compared to $\mathbf{1}^{R}$ complexes is that steric effects due to the change of the 4-R group of the anilines cannot be completely excluded, as done in the case of the 4-substituted pyridines. In fact, by rotating the P_2–Pt–N–H dihedral angle in the optimised models of the $[Pt(4\text{-R-an})(triphos)]^{2+}$ cations, a steric interaction between the R group and the phenyl rings bonded to the P_2 atoms can be observed. If the steric hindrance between the phenyl rings bonded to the P_2 atoms and the aniline blocked the rotation around the Pt–N bond, two different rotamers at an energy minimum would be possible, with the phenyl ring bonded to the P_1 atom and the aryl group of the aniline in *Z* (*sin* rotamer) or *E* (*anti* rotamer) position, as shown in Fig. 4. The calculated energy difference between the two rotamers is quite small, about 5 kcal/mol.

As, on the contrary, the NMR spectra of the $\mathbf{2}^{R}$ derivatives show the signals of only one species in a temperature range between 298 and 243 K, there should be free rotation around the Pt–N bond. This means that the geometry in solution of the $\mathbf{2}^{R}$ derivatives in not affected only by the nucleophilicity of the aniline ligand, as observed for the $\mathbf{1}^{R}$ complexes, but also by the different bulk of the 4-R group. The sum of the electronic and the steric effects on the geometry of the $[Pt(4\text{-R-an})(triphos)]^{2+}$ cations

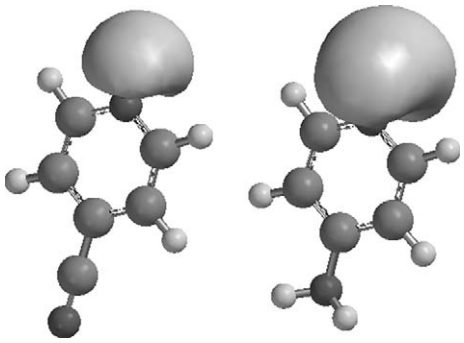

Fig. 2. Potential electrostatic surfaces on the pyridine-N atom for the 4-CN-py and 4-NH_2-py ligands.

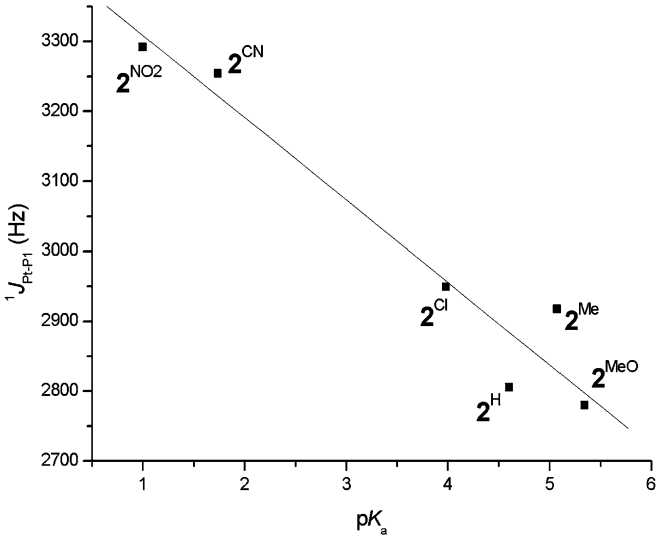

Fig. 3. Plot of $^1J_{Pt-P1}$ against pK_a for $\mathbf{2}^{R}$ complexes.

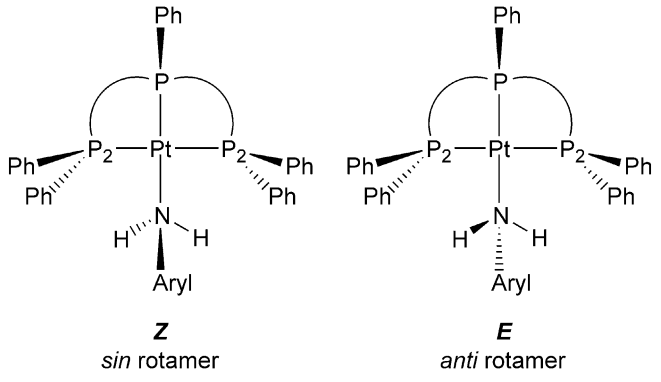

Fig. 4. Rotamers of the $[Pt(4\text{-R-an})(triphos)]^{2+}$ cations.

Table 2
Calculated r_{Pt-P} and r_{Pt-N} bond lengths for complexes $\mathbf{1}^{CN}$ and $\mathbf{1}^{NH_2}$, dipolar moment and Mulliken charge on the pyridine-N atom for the free ligands

Complex		r_{Pt-P1} (Å)	r_{Pt-P2} (Å)	r_{Pt-N} (Å)	Pyridine	μ (Debye)	N charge
$\mathbf{1}^{CN}$	$[Pt(4\text{-CN-py})(triphos)]^{2+}$	2.3258	2.4083	2.1070	4-CN-py	2.00	−0.060
$\mathbf{1}^{NH_2}$	$[Pt(4\text{-NH}_2\text{-py})(triphos)]^{2+}$	2.3270	2.4055	2.1023	4-NH_2-py	4.08	−0.112

explains the less linear correlation between the pK_a and the $^1J_{Pt-P1}$ values of these derivatives and the irregular trend of the $^1J_{Pt-P2}$ values.

4. Conclusions

In conclusion, the ^{31}P NMR spectroscopy of derivatives of the Pt(II)–triphos fragment allowed us to observe small changes of the electronic and steric properties of the co-ordinated ligands by measuring the $^1J_{Pt-P}$ coupling constants. Further investigations will be carried out in order to ascertain whether this approach could be an effective way for investigating and comparing other series of molecules with co-ordinating ability.

NBO analysis. The spin-allowed singlet–singlet electronic transitions of [Re(NO)Cl_2(PPh_3)(PPh_2py-P,N)] have been calculated with the time-dependent DFT method (TDDFT method), and the UV–Vis spectrum of the title complex has been discussed on this basis.

The calculations with the TDDFT method for open-shell organic, inorganic and organometallic molecules have supported the TDDFT method to be applicable for such systems giving good assignment of experimental spectra [24–27]. There are also several works performed with this method for 5d-metal (including rhenium complexes) in which good correlations between experimental and calculated results have been confirmed [28–34].

2. Experimental

2.1. General procedure

The reaction was carried out under argon atmosphere. All the reagents used to the synthesis of the complex are commercially available and were used without further purification. The [Re(NO)Cl_3(PPh_3)($OPPh_3$)] complex was prepared according to the literature method [17].

IR spectra were recorded on a Nicolet Magna 560 spectrophotometer in the spectral range 4000–400 cm^{-1} with the samples in the form of KBr pellets. Electronic spectra were measured on a spectrophotometer Lab Alliance UV–Vis 8500 in the range 900–200 nm in deoxygenated dichloromethane solution. Elemental analyses (C, H, N) were performed on a Perkin–Elmer CHN-2400 analyzer.

2.2. Preparation of [Re(NO)Cl_2(PPh_3)(PPh_2py-P,N)]

[Re(NO)Cl_3(PPh_3)($OPPh_3$)] (1 g, 1.15 mmol) and PPh_2py (0.3 g, 1.15 mmol) in chloroform (100 cm^3) were refluxed for 6 h. The volume was condensed to 20 cm^3 and dark orange microcrystalline solid was formed by an addition of 100 cm^3 of ethanol. The product was washed with cold ether, and dried in vacuo. The crystals suitable for X-ray investigation were obtained by recrystallization from $CHCl_3$–EtOH (yield 70%).

IR (KBr, cm^{-1}) 3063(m), 3049(w), 3055(w), 1683(vs), 1586(m) 1572(w), 1481(s), 1450(m), 1434(m), 1313(w), 1270(w), 1186(m) 1157(w), 1122(m), 1091(s), 1023(m), 998(w), 747(s), 726(w), 696(s), 617(w), 584(w), 532(sh), 522(s), 505(s), 433(m), 423(m).

2.3. Crystal structures determination and refinement

The X-ray intensity data of [Re(NO)Cl_2(PPh_3)(PPh_2py-P,N)] were collected on a KM-4-CCD automatic diffractometer equipped with CCD detector and 37 s exposure time was used. The unit cell parameters were determined from least-squares refinement of the setting angles of 14 536 strongest reflections. Details concerning crystal data and refinement are given in Table 1. Lorentz, polarization and numerical absorption corrections [35] were applied. The structure was solved by means of the Patterson method and subsequently completed by the difference Fourier recycling. All the non-hydrogen atoms were refined anisotropically using full-matrix, least-squares technique. The hydrogen atoms of the phenyl rings were treated as "riding" on their parent carbon atoms [d(C–H) = 0.96 Å] and assigned isotropic temperature factors equal 1.2 times the value of equivalent temperature factor of the parent carbon atom. SHELXS 97 [36], SHELXL 97 [37] and SHELXTL [38] programs were used for all the calculations. Atomic scattering factors were those incorporated in the computer programs.

Table 1
Crystal data and structure refinement for [Re(NO)Cl_2(PPh_3)(PPh_2py-P,N)]

Empirical formula	$C_{35}H_{29}Cl_2N_2OP_2Re$
Formula weight	812.6
Temperature (K)	293(2)

Absorption coefficient (mm^{-1})	3.995
F(000)	1600
Crystal size (mm)	0.29 × 0.27 × 0.22
θ Range for data collection (°)	3.20–25.13
Index ranges	$-13 \leqslant h \leqslant 13$, $-16 \leqslant k \leqslant 18$, $-22 \leqslant l \leqslant 22$
Reflections collected	35 191
Independent reflections [R_{int}]	5836 [0.0353]
Completeness to 2θ	99.6%
Maximum and minimum transmission	0.3254 and 0.0722
Data/restraints/parameters	5836/0/416
Goodness-of-fit on F^2	1.082
Final R indices [$I > 2\sigma(I)$]	$R_1 = 0.0177$, $wR_2 = 0.0370$
R indices (all data)	$R_1 = 0.0184$, $wR_2 = 0.0372$
Largest difference peak and hole (e Å^{-3})	0.831 and −0.694

2.4. Computational details

GAUSSIAN 03 program [39] was used in the calculations. The geometry optimization was carried out with the DFT method with the use of B3LYP functional [40,41]. The electronic spectrum was calculated with the TDDFT method [42]. The calculations were performed by using ECP basis set on the rhenium atom, the standard 6-31+G** basis for chlorine, oxygen and nitrogen, 6-31+G* for carbon and 6-31G basis for hydrogen atoms. The Xe core electrons of Re were replaced by an effective core potential and DZ quality Hay and Wadt Los Alamos ECP basis set (LANL2DZ) [43] was used for the valence electrons. Additional d function with exponent $\alpha = 0.3811$ and f function with exponent $\alpha = 2.033$ on the rhenium atom were added.

Natural bond orbital (NBO) calculations were performed with the NBO code [44] included in GAUSSIAN 03.

3. Results and discussion

3.1. Preparation

The complex $[Re(NO)Cl_2(PPh_3)(PPh_2py\text{-}P,N)]$ has been obtained in high yield in the reaction of $[Re(NO)Cl_3(PPh_3)(OPPh_3)]$ with diphenyl(2-pyridyl)phosphine in chloroform. Diphenyl(2-pyridyl)phosphine is a versatile ligand which can coordinate as a monodentate or chelating ligand depending on the requirements of the metal. In the title complex, P,N-coordination of the PPh_2py ligand is observed.

3.2. Crystal structure

The $[Re(NO)Cl_2(PPh_3)(PPh_2py\text{-}P,N)]$ complex crystallises in the orthorhombic space group $P2_12_12_1$ and its crystal structure is composed of the molecules located in general positions linked via weak intermolecular C(15)–H(15)···Cl(1) $(1/2 + x,\ 1/2 - y,\ -z + 2)$ hydrogen bonds [45,46]. Two intramolecular hydrogen bond linking C(12)–H(12)···Cl2(1) (D···A distance 3.291(5) Å and D–H···A angle 116.2°) and C(31)–H(31)···N(3) (D···A distance 3.337(12) Å and D–H···A angle 136.9°) provide additional stabilisation of the $[Re(NO)Cl_2(PPh_3)(PPh_2py\text{-}P,N)]$ molecule.

The structure of $[Re(NO)Cl_2(PPh_3)(PPh_2py\text{-}P,N)]$ has been modelled with the Cl(2), Cl(3) and NO ligands disordered over two sites using fractional occupancies equal 0.47 for Cl(3), N(2), O(2) atoms and 0.53 for Cl(2), N(3) and O(3). The rhenium atom is in a distorted octahedral environment with the triphenylphosphine molecule in *trans* geometry to the pyridine ring of the chelating ligand. Strong deviations of the rhenium coordination sphere from an ideal octahedron can be ascribed to the restricted bite angle of the four membered chelate ring. Fig. 1 shows a displacement ellipsoids plot of $[Re(NO)Cl_2(PPh_3)(PPh_2py\text{-}P,N)]$, and the selected bond lengths and angles of this compound are summarized in Table 2. The Re–NO and N–O bond lengths and the Re–N–O angles confirm the linear co-ordination of the distorted nitrosyl groups and they are compared with values previously found [1,14–23]. The Re–N_{py} of 2.187(3) Å is longer in comparison with the value obtained from the sum of the relevant covalent radii (2.08 Å) or average value of the Re–N_{py} distances (2.12 Å) in *mer*-$[ReX_3(py)_3]$ (X = Cl, Br) [47]. It can be attributed to the *trans* influence of the PPh_3 ligand. Similarly, the Re–Cl(1) bond length is considerable longer than Re–Cl(2) and Re–Cl(3) distances.

3.3. Infrared data and magnetochemical measurements

The IR spectrum of $[Re(NO)Cl_2(PPh_3)(PPh_2py\text{-}P,N)]$ exhibits strong band at 1683 cm^{-1} assignable to ν(NO).

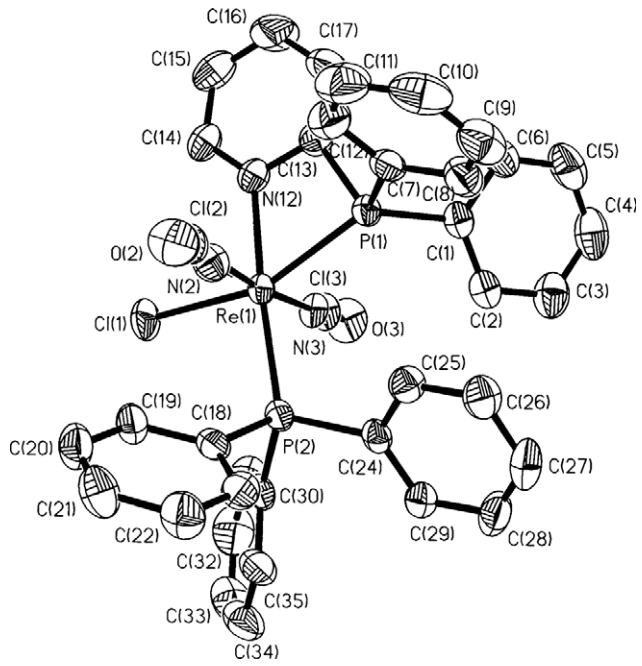

Fig. 1. Thermal ellipsoid plot of $[Re(NO)Cl_2(PPh_3)(PPh_2py\text{-}P,N)]$ showing the atom numbering scheme (50% probability ellipsoids).

The value of ν(NO) corresponds to linear NO range of Haymore and Ibers [ν(NO) above 1620–1610 cm^{-1} were assigned to linear M–N–O systems, while ν(NO) below 1610 cm^{-1} were assigned to bent M–N–O systems] [48]. The considerable lowering of the ν_{NO} of $[Re(NO)Cl_2(PPh_3)(PPh_2py\text{-}P,N)]$ in comparison with the starting $[Re(NO)Cl_3(PPh_3)(OPPh_3)]$ nitrosyl (1745 cm^{-1}) [17] is consistent with increase of electron number n in the $\{MNO\}^n$ unit. It results in an increased backdonation of electron density from the filled rhenium d orbitals into the π^* antibonding orbital of the NO group.

The characteristic bands of the C=C and C=N stretching modes are observed at 1586 and 1572 cm^{-1} [49].

3.4. Optimised geometry

The geometry of $[Re(NO)Cl_2(PPh_3)(PPh_2py\text{-}P,N)]$ was optimised in a singlet state by the DFT method with the B3LYP functional. The optimised geometric parameters are gathered in Table 2. The calculated bond lengths and angles are in agreement with the values based upon the X-ray crystal structure data, and the general trends observed in the experimental data are well reproduced in the calculations.

3.5. Charge distribution and spin densities

Table 3 presents the atomic charges from the natural population analysis (NPA) for $[Re(NO)Cl_2(PPh_3)(PPh_2py\text{-}P,N)]$. The calculated charge on the nitrogen atom of the nitrosyl group is positive, whereas the oxygen atom is negatively charged. The total charge on the NO group of the title complex is negative: −0.165. The calculated charge on the

Table 3
Atomic charges and spin densities of [Re(NO)Cl_2(PPh_3)(PPh_2py-P,N)]

Atom	Atomic charge
Re(1)	0.107
Cl(1)	−0.522
Cl(3)	−0.508
N(2)	0.167
O(2)	−0.332
P(1)	1.347
N(12)	−0.469
P(2)	1.409

rhenium atom of [Re(NO)Cl_2(PPh_3)(PPh_2py-P,N)] is far from the formal charge +1. It results from charge donation from the chloride ions and P-donor ligands. There are large positive charges on the P atoms, and the charges on the chloride ions are significantly smaller than −1. The charge on the pyridine nitrogen atom bonded with the rhenium is negative.

3.6. NBO analysis

Each natural bond orbital (NBO) σ_{AB} can be written in terms of two directed valence hybrids (NHOs) h_A and h_B on atoms A and B:

$$\sigma_{AB} = c_A h_A + c_B h_B$$

where c_A and c_B are polarization coefficients. Each valence bonding NBO must in turn be paired with a corresponding valence *anti*-bonding NBO:

$$\sigma^*_{AB} = c_B h_A - c_A h_B$$

to complete the span of the valence space. The Lewis-type (donor) NBOs are thereby complemented by the non-Lewis-type (acceptor) NBOs that are formally empty in an idealized Lewis picture. The interactions between 'filled' Lewis-type NBOs and 'empty' non-Lewis NBOs lead to loss of occupancy from the localized NBOs of the idealized Lewis structure into the empty non-Lewis orbitals, and they are referred to as 'delocalization' corrections to the zeroth-order natural Lewis structure. The stabilization energy ΔE_{ij} (kcal/mol) associated with delocalization is estimated by the second-order perturbative as:

$$\Delta E_{ij} = q_i(F(i,j)^2)/(\varepsilon_j - \varepsilon_i)$$

where q_i is the donor orbital occupancy, ε_i, ε_j are diagonal elements (orbital energies) and $F(i,j)$ is the off-diagonal NBO Fock or Kohn–Sham matrix element [50].

In the case of the [Re(NO)Cl_2(PPh_3)(PPh_2py-P,N)] complex, three natural bond orbitals were detected for the Re–N bond, and one orbital – for the N–O bond. The occupancies and hybridization of the calculated Re–N and N–O natural bond orbitals (NBOs) are given in Table 4. The Re–N bond orbital of σ-character is polarized towards the nitrogen atom and the s and d orbitals of Re take part in the bonding. The Re–N bond orbitals of π-character are insignificantly polarized toward the metal atom and only d-orbitals of Re are included into the

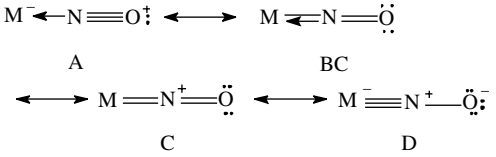
Table 4
The occupancies and hybridization of the calculated Re–N and N–O natural bond orbitals (NBOs) for [Re(NO)Cl_2(PPh_3)(PPh_2py-P,N)]

BD	Occupancy	Hybridization of NBO
Re–N	1.958 (0.385)	$0.499(sd^{2.63})_{Re} + 0.866(sp^{0.65})_N$
	1.964 (0.463)	$0.720(d)_{Re} + 0.694(p)_N$
	1.950 (0.453)	$0.738(d)_{Re} + 0.675(p)_N$
N–O	1.997 (0.015)	$0.673(sp^{1.81})_N + 0.740(sp^{2.35})_O$

BD denotes two-center bond.

bonding. The N–O bond orbital is slightly polarized towards the oxygen end. Table 5 presents the occupancies and atomic orbital compositions of the lone pairs (LP) orbitals detected on the oxygen atom of the nitrosyl group, as well as the character of the acceptor orbital and stabilization energies (ΔE_{ij}) for the corresponding donor–acceptor interactions. The oxygen atom of the nitrosyl ligand possesses three lone pair (LP) orbitals. The electron density from the LP orbitals described by p orbitals is strongly delocalized into π^*_{Re-N} orbitals (Table 5).

In the valence-bond treatment a linear bonding mode of the nitrosyl group may be represented by the following resonance forms [1]:



The results of the NBO analysis indicate that the resonance structure of D makes a significant contribution to the structure of the [Re(NO)Cl_2(PPh_3)(PPh_2py-P,N)] complex.

It is consistent with the charges on the nitrogen and oxygen atoms of the nitrosyl group and relatively low nitrosyl stretching frequency.

Table 5
The occupancies and atomic orbital compositions of the lone pairs (LP) detected on the oxygen atom of the nitrosyl group and the character of the acceptor orbital, as well as stabilization energies (ΔE_{ij}) for the corresponding donor–acceptor interactions

LP orbital	Occupancy of donor orbital	Acceptor orbital	ΔE_{ij} (kcal/mol)
$(sp^{0.42})_{O(2)}$	1.978	$0.866(sd^{2.63})_{Re} - 0.499(sp^{0.65})_N$	9.32
$(p)_{O(2)}$	1.634	$0.694(d)_{Re} - 0.720(p)_N$	10.59
		$0.675(d)_{Re} - 0.738(p)_N$	95.78
$(p)_{O(2)}$	1.607	$0.694(d)_{Re} - 0.720(p)_N$	80.45
		$0.675(d)_{Re} - 0.738(p)_N$	10.69

(For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

3.7. Electronic structure

The bonding of NO to the rhenium center involves a synergic interaction between the nitrosyl ligand orbitals and the metal orbitals. The Re–NO bond consists of two components: (i) a donation of electron density from a σ-type orbital on NO onto the metal orbital; and (ii) a donation of electron density from the occupied metal d-orbitals into the π^* antibonding orbitals of NO ligand. The occupied d_{xy} and d_{xz} rhenium orbitals participate in the backdonation from the central ion to the nitrosyl ligand in the [Re(NO)-Cl_2(PPh_3)(PPh_2py-P,N)] complex. The π_{Re-NO} bonding interaction makes the largest contribution into the H − 2 and H − 1 orbitals. Some participation of π_{Re-NO} orbitals, however, is also seen in other occupied molecular orbitals of [Re(NO)Cl_2(PPh_3)(PPh_2py-P,N)] (Fig. 2).

The π^*_{Re-NO} orbitals are distributed among several lowest unoccupied molecular orbitals. Their contribution is visible in L + 3, L + 4, L + 5, L + 6, L + 7, L + 8 and L + 9. The HOMO orbital of [Re(NO)Cl_2(PPh_3)(PPh_2py-P,N)] is composed of the d_{yz} metal orbital and chlorine π orbitals in anti-bonding arrangement. The LUMO orbital is mainly localised on the phenyl and pyridine rings of PPh_2py ligand. The d_z^2 orbital of Re atom makes the largest contribution into L + 13, whereas L + 15 has $d_{x^2-y^2}$–σ_{Cl}–σ_P–σ_N character. The selected HOMO and LUMO orbitals of [Re(NO)Cl_2(PPh_3)(PPh_2py-P,N)] are depicted in Fig. 2. The following orientation of the axes has been used for

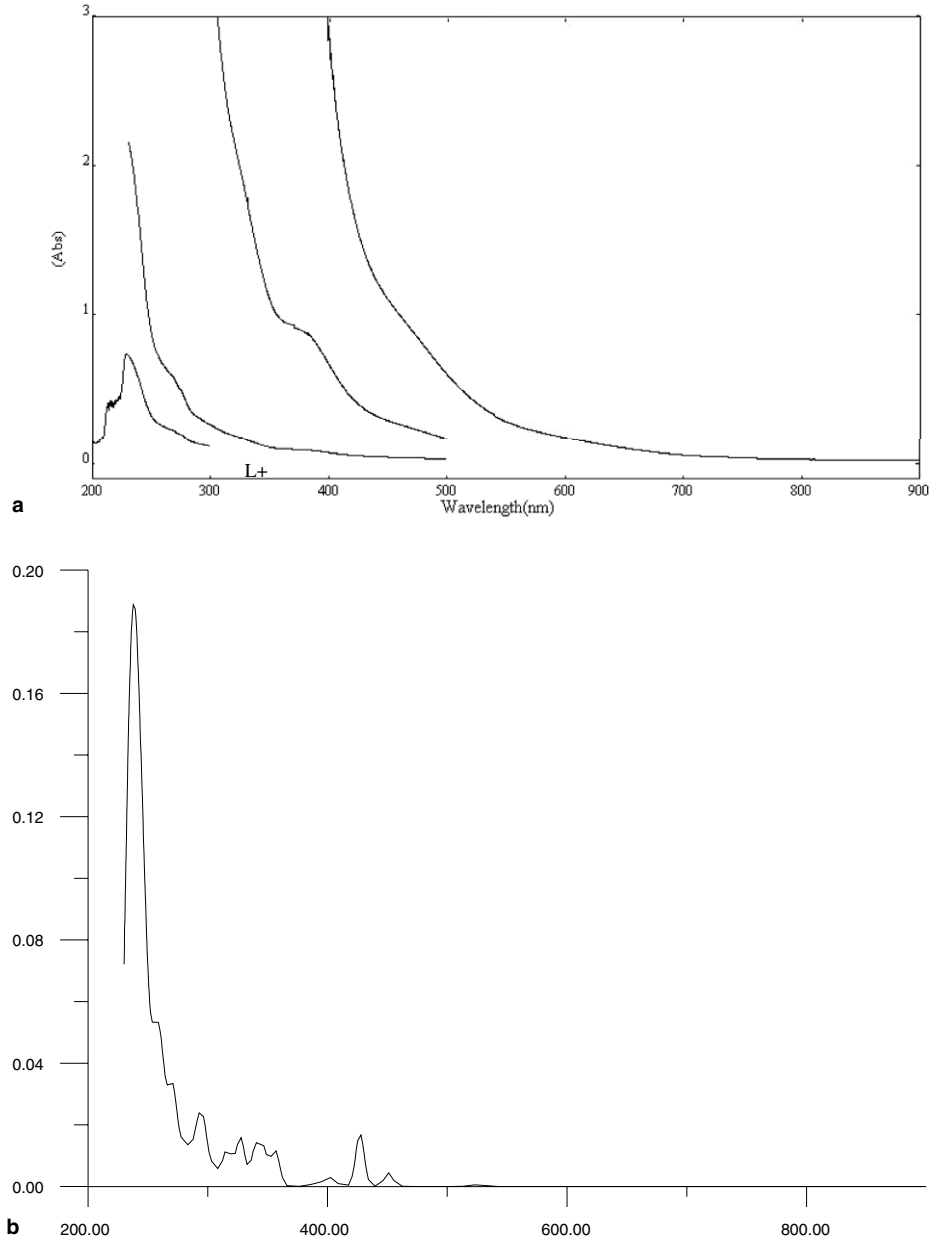


Fig. 3. The experimental (a) and calculated (b) electronic absorption spectrum of [Re(NO)Cl_2(PPh_3)(PPh_2py-P,N)].

determination of the MO characters: the z axis goes along Cl(1)–Re–P(1) linkage and y goes through the N(12)–Re–P(2) bonds.

3.8. Electronic spectra

The experimental and calculated electronic spectra of $[Re(NO)Cl_2(PPh_3)(PPh_2py\text{-}P,N)]$ are presented in Fig. 3. Each calculated transition in Fig. 3b was represented by a gaussian function with the height equal to the oscillator strength and width equal to 0.04.

Table 6 shows the spin-allowed singlet–singlet electronic transitions calculated with the TDDFT method for $[Re(NO)Cl_2(PPh_3)(PPh_2py\text{-}P,N)]$. For the high energy part of the spectrum (below 250 nm), only transitions with oscillator strengths larger than 0.010 are listed in Table 6.

A hundred electron transitions calculated by the TDDFT method do not comprise all the experimental

absorption bands. The UV–Vis spectrum of $[Re(NO)Cl_2(PPh_3)(PPh_2py\text{-}P,N)]$ was calculated to 230 nm, so the shortest wavelength experimental band cannot be assigned completely to the calculated transitions. Some additional intraligand and interligand transitions are expected to be found at higher energies in the calculation for $[Re(NO)Cl_2(PPh_3)(PPh_2py\text{-}P,N)]$.

The assignment of the calculated transitions to the experimental bands is based on the criterion of the energy and oscillator strength of the calculated transitions. In the description of the electronic transitions only the main components of the molecular orbital are taken into consideration. The bonding π_{Re-NO} orbitals are described as d orbitals, and the antibonding π^*_{Re-NO} orbitals – as π^*_{NO}.

The absorption experimental bands at 570, 380 and 335 nm are attributed to MLCT transitions occurring from the rhenium center to the π-antibonding orbitals of the nitrosyl, triphenylphospine or diphenyl(2-pyridyl)phosphine ligands. Considering the values of oscillator strengths, we can noticed that the transitions of $d \rightarrow \pi^*_{NO}$ are significantly weaker in comparison with the transitions of $d \rightarrow \pi^*_{py/Ph}(PPh_2py)$ and $d \rightarrow \pi^*_{Ph}(PPh_3)$ character. It means that $d \rightarrow \pi^*_{NO}$ transitions do not contribute significantly to the overall shape of the bands at 380 and 335 nm. They are hidden under the more intense MLCT transitions from Re ion to the π-antibonding orbitals of the PPh_3 and PPh_2py. A similar trend has been supported previously for $\{ReNO\}^5$ nitrosyls [51–53].

The absorption bands at 273.5 and 230.6 nm are assigned to the calculated transitions of LLCT with large oscillator strengths. The intra- and interligand transitions occur from the chlorine and phosphine ligand to the π-antibonding orbitals of the nitrosyl, triphenylphospine or diphenyl(2-pyridyl)phosphine ligands.

4. Conclusions

A novel $\{ReNO\}^6$ complex – $[Re(NO)Cl_2(PPh_3)(PPh_2py\text{-}P,N)]$ has been prepared and structurally as well as spectroscopically characterized. X-ray studies confirm linear coordination of the nitrosyl group and P,N-coordination of the diphenyl(2-pyridyl)phosphine. The Re–N and N–O bond lengths and ν(NO) indicates a strong backdonation of electron density from the filled rhenium d orbitals into the π^* antibonding orbital of the NO group. These results are in good agreement with the DFT and NBO studies. The Re–N bond can be considered as a triple one, whereas the N–O is a single bond. The π_{Re-NO} molecular orbitals results from overlapping between the occupied d_{xy} and d_{xz} rhenium orbitals and π-antibonding orbitals of the nitrosyl ligand.

5. Supplementary data

Supplementary data for $C_{35}H_{29}Cl_2N_2OP_2Re$ are available free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; fax: (internat.) +44 1223 336 033, e-mail: deposit@ccdc.cam.ac.uk] on request, quoting the deposition number 290236.

Acknowledgements

The GAUSSIAN 03 calculations were carried out in the Wrocław Centre for Networking and Supercomputing, WCSS, Wroc3aw, Poland. Crystallographic part was financed by funds allocated by the Ministry of Scientific Research and Information Technology to the Institute of General and Ecological Chemistry, Technical University of Łódź.

2. Results and discussion

New dirhodium(II) complexes: $[\mathbf{2}(HO_2CCF_3)_2]$ and $[\mathbf{3}(HO_2CEt)_2]\cdot HO_2CEt$ with orthometallated tris(*p*-methoxyphenyl)phosphine (PMP) were obtained by exchange of the acetato bridges in $[\mathbf{1}(HOAc)_2]$ by trifluoroacetato and propionato bridges, respectively (Scheme 1).

The reactions of adduct formation by [*cis*-Rh_2-(μ-$O_2CR)_2$(PMP-$C)_2$] with pyrazole or imidazole in $CHCl_3$ were followed by UV–Vis and NMR spectroscopies.

2.1. Molecular structures established with X-ray methods

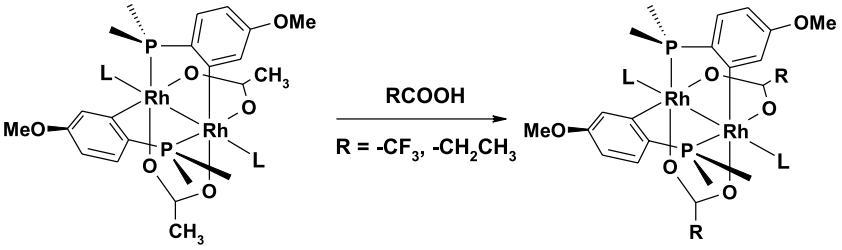
Crystal data for complexes: $[\mathbf{2}(H_2O)(PrOH)]\cdot PrOH$, $[\mathbf{3}(HO_2CEt)_2]\cdot HO_2CEt$, $[\mathbf{2}(Hpz)_2]$ and $[\mathbf{3}(Hpz)_2]$ are given in Table 1. Tables 2–5 present selected bond lengths and angles. Molecular structures of these complexes are shown in Figs. 1–6.

2.1.1. Structure of $[\mathbf{3}(HO_2CEt)_2]\cdot HO_2CEt$

The compound $[\mathbf{3}(HO_2CEt)_2]\cdot HO_2CEt$ crystallizes in the triclinic crystal system, space group $P\bar{1}$. The unit cell consists of two independent sets (A and B) of enantiomers of $[\mathbf{3}(HO_2CEt)_2]\cdot HO_2CEt$.

Each molecule of $[\mathbf{3}(HO_2CEt)_2]\cdot HO_2CEt$ consists of a binuclear rhodium core bridged by two propionato groups and two PMP ligands in which orthometallation has occurred at one of the phenyl rings. The phosphine ligands are in the *cis* position with a H–T (head–tail) structure. The axial sites are occupied by two molecules of propanoic acid. There are only slight differences between the structures of molecules A and B.

The molecular structures of both molecules exhibit distorted octahedral coordination around the central atoms. This complex is in a distorted eclipsed conformation. Torsion angles O1A–Rh1A–Rh2A–O2A and O3A–Rh1A–Rh2A–O4A of the propionato bridges in molecule A are 19.1° and 18.0°, respectively; while for molecule B: torsion angles O1B–Rh1B–Rh2B–O2B and O3B–Rh1B–Rh2B–O4B are 16.1° and 17.2°, respectively. The Rh1A–Rh2A and Rh1B–Rh2B distances are 2.504(1) and 2.506(1) Å, respectively, and indicate a rather strong single bond between the two metal atoms. Distances for Rh – equatorial atoms in molecules A and B are similar. The bond lengths between the phosphorus atom and carbon atom of the metallated rings are slightly shorter than those between the phosphorus atoms and carbon atoms of non-metallated rings. The structure of $[\mathbf{3}(HO_2CEt)_2]\cdot HO_2CEt$



Scheme 1. Schematic representation of $[\mathbf{1}(L)_2]$ and carboxylato bridges exchange.

is similar to the structure of $[cis\text{-}Rh_2(\mu\text{-}OAc)_2\{\mu\text{-}(C_6H_4)\text{-}PPh_2\}_2(HOAc)_2]$ [1].

The axial molecules of propanoic acid are rather weakly bound to the dirhodium core. The Rh1–O5 distances are 2.274(5) and 2.278(5) Å for A and B molecules respectively, Rh2–O7: 2.347(5) (A) and 2.334(5) Å (B). These distances are similar to the distances between the rhodium and axial oxygen atom found in complexes: $[cis\text{-}Rh_2(\mu\text{-}OAc)_2\{\mu\text{-}(C_6H_3\text{-}3\text{-}OMe)P(C_6H_4\text{-}3\text{-}OMe)_2\}_2(HOAc)(H_2O)]$ [21], $[cis\text{-}Rh_2(\mu\text{-}OAc)_2\{\mu\text{-}(C_6H_3\text{-}3\text{-}OMe)P(C_6H_4\text{-}3\text{-}OMe)_2\}_2(H_2O)_2]$ [23] and $[cis\text{-}Rh_2(\mu\text{-}OAc)_2\{\mu\text{-}(C_6H_4)PPh_2\}_2(HOAc)_2]$ [1]. The OH groups of axial molecules of HO_2CEt form strong hydrogen bonds with oxygen atoms (O3 and O2) of propionato bridges. Relatively strong asymmetry in coordinating axial molecules of propanoic acid ($d_{Rh1-O5} < d_{Rh2-O7}$) results probably because of the weak steric interaction of one axial HO_2CEt molecule with a crystallization molecule of propanoic acid, forming a hydrogen bond with the oxygen atom (O1) of the propionato bridge (EtC(O)OH···O1A and EtC(O)OH···O1B; Fig. 1.).

2.1.2. $[\mathbf{2}(H_2O)(PrOH)]\cdot PrOH$

The compound $[\mathbf{2}(H_2O)(PrOH)]\cdot PrOH$ crystallizes in the triclinic crystal system, space group $P\bar{1}$. The unit cell consists of two independent molecules of $[\mathbf{2}(H_2O)(PrOH)]\cdot PrOH$. Usually this kind of complex forms centrosymmetric unit cells (most frequently $P\bar{1}$ space group), like the complex $[\mathbf{3}(HO_2CEt)_2]\cdot HO_2CEt$ described above. The unit cell of the complex $[\mathbf{2}(H_2O)(PrOH)]\cdot PrOH$ contains two diastereoisomeric molecules A and B.

Symmetry transformations used to generate equivalent atoms: none = $[x, y, z]$, _1 = $[x, y, z-1]$, _2 = $[x, y+1, z]$, _3 = $[x, y, z+1]$.

The molecular structure of $[\mathbf{2}(H_2O)(PrOH)]\cdot PrOH$ is similar to the structure of $[\mathbf{3}(HO_2CEt)_2]\cdot HO_2CEt$ and consists of a binuclear rhodium core bridged by two trifluoroacetato groups and two orthometallated phosphine ligands. The axial sites are occupied by molecules of water and 1-propanol.

The complex exhibits a distorted eclipsed conformation. The torsion angles of the trifluoroacetato bridges in molecule A, O1A–Rh1A–Rh2A–O2A and O3A–Rh1A–Rh2A–O4A, are 17.7° and 18.5°, respectively, for molecule B, O1B–Rh1B–Rh2B–O2B and O3B–Rh1B–Rh2B–O4B are −15.8° and −18.4°, respectively, and these values are

Symmetry transformations used to generate equivalent atoms: none = [x, y, z], _1 = [$-x+1, -y+1, z$], _2 = [$-x, -y+1, z$].

similar to those found in [**3**(H_2O)(HO_2CEt)] · HO_2CEt. The Rh1A–Rh2A and Rh1B–Rh2B distances are 2.516(1) and 2.519(1) Å, respectively, and are longer than the Rh–Rh distances in [**3**(HO_2CEt)$_2$] · HO_2CEt. The Rh–P distances are also longer on comparing to those of [**3**(H_2O)(HO_2CEt)] · HO_2CEt.

The axial sites of the Rh–Rh core are occupied by molecules of water and 1-propanol. These molecules are rather weakly bound to the dirhodium core. The values of Rh–O^{PrOH} distances do not differ considerably from those found in other complexes described above.

The existence of two diastereoisomers, A and B, results mainly from different positions of the methoxy groups of the non-metallated phenyl rings, as shown in Fig. 3a. The torsion angles of the methoxy groups in the exo rings in molecule A are 12.8 (C63A–C64A–O64A–C76) and 0.5° (C33A–C34A–O34A–C73) and in molecule B, −179.0 (C63B–C64B–O64B–C86) and 3.0° (C33B–C34B–O34B–C83). In the endo rings, the torsion angles in molecule A are 179.0 (C53A–C54A–O54A–C75) and −15.6° (C23A–C24A–O24A–C72), and in molecule B, −2.2 (C53B–C54B–O54B–C85) and −3.5° (C23B–C24B–O24B–C82).

There are two crystallization molecules of 1-propanol in the unit cell. One molecule is bound to molecule A of [**2**(H_2O)(PrOH)] · PrOH via hydrogen bonds to the oxygen atom of the trifluoroacetato bridge (O1C–H1C···O3A) and to the axial water molecule (O5A–H5AA···O1C). The second molecule of 1-propanol is bound in the same way to molecule B. There are three intermolecular hydrogen bonds in the crystal. Two hydrogen bonds are formed between axial molecules of 1-propanol and oxygen atoms of the methoxy group of the metallated ring: O6A–H6A···O14B_1 and O6B–H6B···O14A_3 and third between the axial molecule of water and a crystallization molecule of 1-propanol: O5B–H5BA···O1C_2. This leads to the formation of a two-dimensional net.

2.1.3. [*3*(*Hpz*)$_2$]

The complex [**3**(Hpz)$_2$] crystallizes in the orthorhombic crystal system, space group *Fdd2*.

The molecular structure of [**3**(Hpz)$_2$] is similar to the structure of [**3**(HO_2CEt)$_2$] · HO_2CEt with the axial molecules of propanoic acid replaced with two molecules of pyrazole.

The main structural difference between [**3**(Hpz)$_2$] and [**3**(HO_2CEt)$_2$] · HO_2CEt results in the different space orientations of the $-CH_2CH_3$ groups of the propionato bridges, as shown in Fig. 5.

Coordination of pyrazole to the axial sites of the dirhodium core causes Rh–Rh bond lengthening: from 2.504(1) to 2.506(1) Å in [**3**(HO_2CEt)$_2$] · HO_2CEt to 2.5290(4) Å in [**3**(Hpz)$_2$]. This difference is smaller than that found in the acetic acid and pyridine adducts: [*cis*-Rh_2(μ-OAc)$_2$-{μ-(C_6H_4)PPh_2}$_2$($HOAc$)$_2$] and [*cis*-Rh_2(μ-OAc)$_2$-{μ-(C_6H_4)-PPh_2}$_2$(py)$_2$] [1] in which the Rh–Rh bond lengths are 2.508(1) and 2.556(2) Å, respectively, despite the similar donor properties of the pyrazole and pyridine ligands (proton affinities are 930 kJ/mol for pyridine and 894.1 kJ/mol for Hpz [24]). The bond lengths for the rhodium-equatorial ligands are approximately the same in [**3**(Hpz)$_2$] and [**3**(HO_2CEt)$_2$] · HO_2CEt. The O1–Rh1–Rh1_1–O1_1 tor-

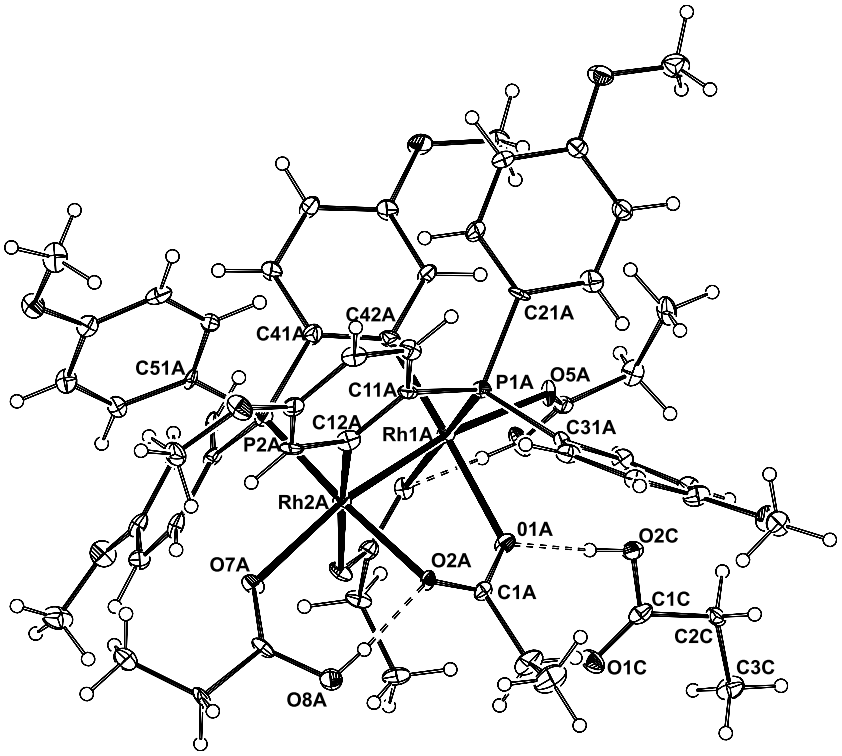

Fig. 1. Molecular structure of molecule A (an ORTEP view) of [**3**($HO_2CEt)_2$] · HO_2CEt with 25% thermal ellipsoids (the structure of molecule B is almost the same – with some exceptions discussed in the text).

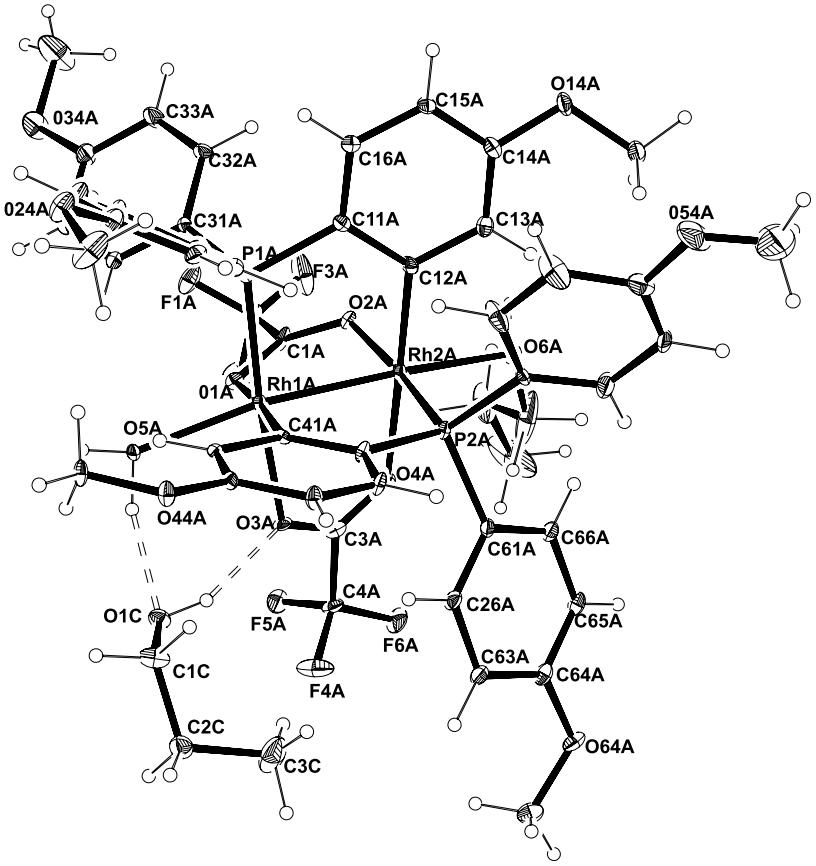

Fig. 2. Structure of molecule A of [**2**(H_2O)(PrOH)] · PrOH with 25% thermal ellipsoids (an ORTEP view).

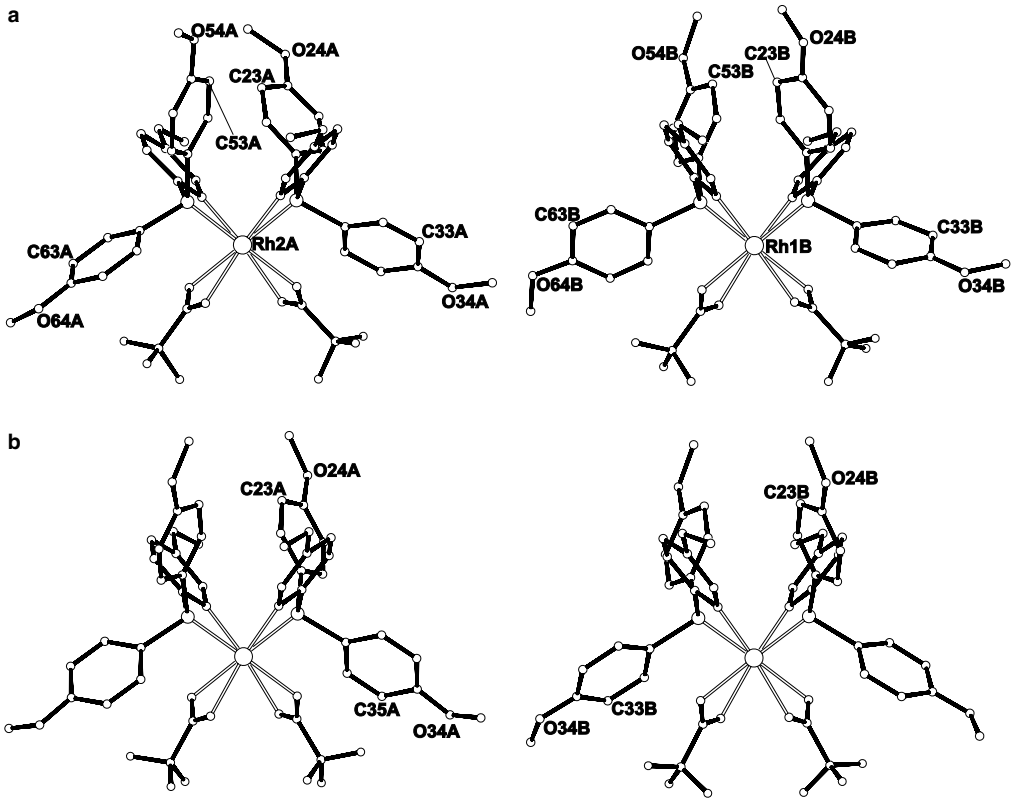

Fig. 3. View (PLATON) perpendicular to the Rh–Rh axis of diastereoisomers of [**2**(H_2O)(PrOH)] · PrOH (a) and [**2**($Hpz)_2$] (b). Hydrogen atoms and axial ligands are omitted for clarity.

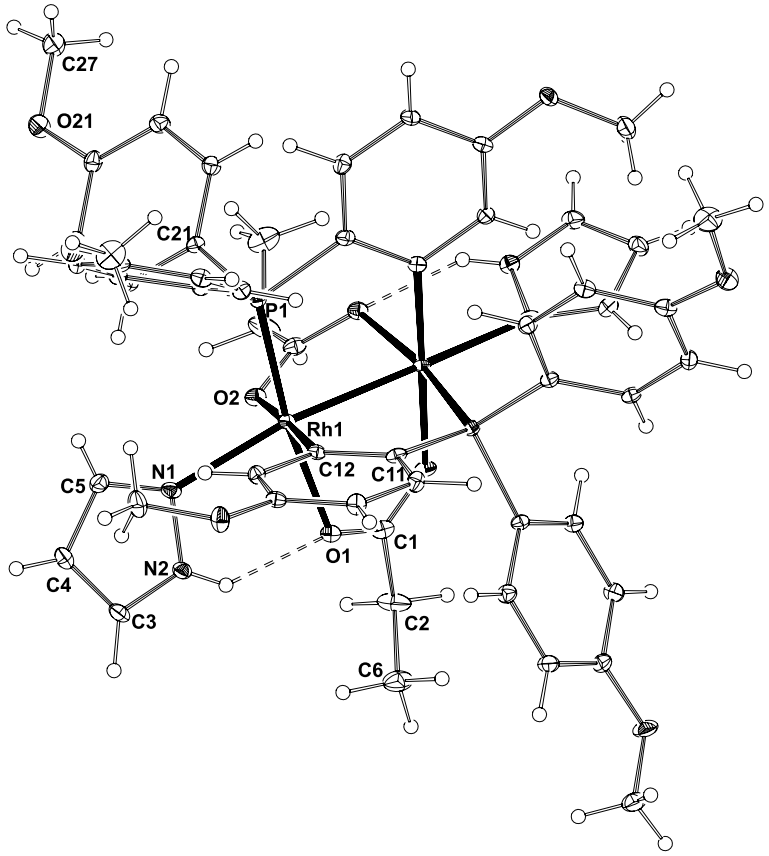

Fig. 4. ORTEP view of molecule A of [**3**($Hpz)_2$] with 25% thermal ellipsoids.

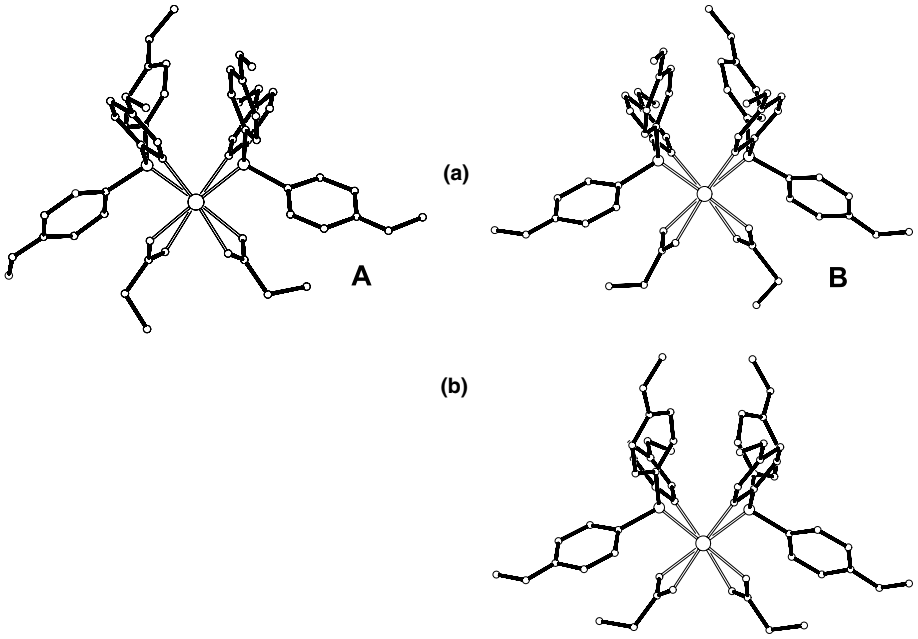

Fig. 5. View (PLATON) perpendicular to the Rh–Rh axis of diastereoisomers of $[\mathbf{3}(HO_2CEt)_2]\cdot HO_2CEt$ (a) and $[\mathbf{3}(Hpz)_2]$ (b). Hydrogen atoms and axial ligands are omitted for clarity.

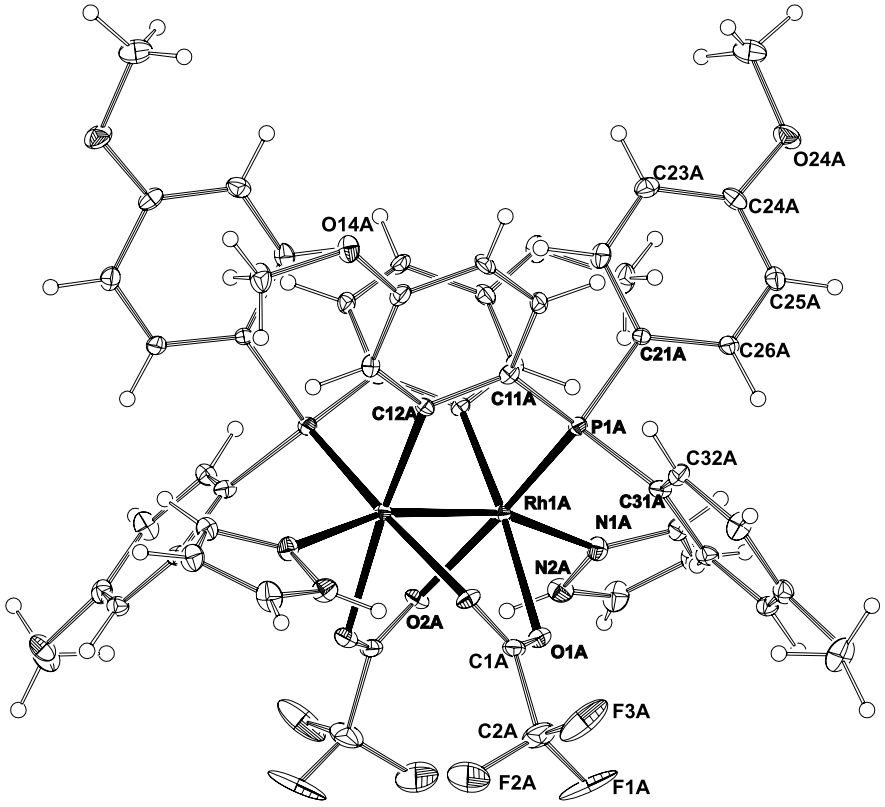

Fig. 6. ORTEP view of molecule A of $[\mathbf{2}(Hpz)_2]$ with 30% thermal ellipsoids.

sion angle in $[\mathbf{3}(Hpz)_2]$ is equal to 19.7° and is only slightly larger than the torsion angles in $[\mathbf{3}(HO_2CEt)_2]\cdot HO_2CEt$ (see Fig. 5).

The length of the rhodium – axial pyrazole ligand bond (Rh1–N1 = 2.250(2) Å) indicates a relatively strong bonding of pyrazole. The bonding of pyrazole is stronger than the bonding of propanoic acid (oxygen donor) in $[\mathbf{3}(HO_2CEt)_2]\cdot HO_2CEt$. The stronger coordination of the Hpz axial molecules in comparison with oxygen axial ligands leads to the increase in the Rh–Rh distance. The Rh1–N1 bond length is also shorter than the Rh–N bond length (2.281(9) Å) in the pyridine adducts [*cis*-Rh_2-

(μ-OAc)$_2${μ-(C$_6$H$_4$)PPh$_2$}$_2$(py)$_2$] [1] and [*cis*-Rh$_2$(μ-OOCCMe$_3$)$_2${μ-(C$_6$H$_4$)PMePh}$_2$(py)$_2$] [3]: 2.271(32) and 2.306(34) Å.

The molecule of pyrazole is almost planar; the deviations from the mean least-squares planes are very small. In contrast to the molecular structure of free pyrazole [25], which rather exhibits the betaine form, the carbon–carbon bond lengths indicate that the coordinated molecule of pyrazole is a neutral ligand. This is typical for most metal–pyrazole complexes (for example [NiCl$_2$(Hpz)$_4$] [26], [RhCl$_2$(Hpz)$_4$]Cl [27] and [RhCl$_2$(Hpz)$_4$][RhCl$_4$(Hpz)$_2$] [28]). The pyrazole molecule forms a hydrogen bond with the oxygen atom of the propionato bridge: N2–H2···O1. The H2 atom also forms a weak intermolecular hydrogen bond with the –OMe group of another complex molecule (N2A–H2A···O31_2).

2.1.4. [2(Hpz)$_2$]

The complex [**2**(Hpz)$_2$] crystallizes in the orthorhombic crystal system, space group *P*2(1)2(1)2. The unit cell consists of four molecules of [**2**(Hpz)$_2$]. There are two independent centrosymmetric molecules A and B in it. The structure of [**2**(Hpz)$_2$] is very similar to the structure of [**3**(Hpz)$_2$].

The torsion angles (molecule A: O1A–Rh1A–Rh1A_1–O2A = 22.3°, molecule B: O1B–Rh1B–Rh1B_2–O2B = −22.1°) show larger deviations from the eclipsed conformation than in [**2**(H$_2$O)(PrOH)] (Fig. 3). The Rh1A–Rh1A_1 and Rh1B–Rh1B_2 distances are 2.5374(9) and 2.5422(9) Å, respectively, and are longer than Rh–Rh distances in [**2**(H$_2$O)(PrOH)]. The lengths of the rhodium – axial pyrazole ligand bonds (Rh1A–N1A = 2.252(4), Rh1B–N1B = 2.218(4) Å) are similar to those in [**3**(Hpz)$_2$] (Rh1–N1 = 2.250(2) Å).

The pyrazole molecules form two intramolecular hydrogen bonds with oxygen atoms of trifluoroacetato bridges: N2A–H2A···O2A and N2B–H2B···O2B and one weak intermolecular hydrogen bond (N2A–H2A···O24B_1), leading to the formation of the two-dimensional structure.

In the complex [**2**(Hpz)$_2$], similarly as in [**2**(H$_2$O)(PrOH)], there are two diastereoisomeric molecules A and B in the unit cell. The differences in the diastereoisomeric molecules A and B (shown in the Fig. 3b) are, similarly as in [**2**(H$_2$O)(HO$_2$CEt)], caused by different orientations of the methoxy groups. For molecule A, the torsion angle C35A–C34A–O34A–C37 is −160.4° (exo) and C23A–C24A–O24A–C27 equals 2.1° (endo). In the case of molecule B, the torsion angle C33B–C34B–O34B–C67 is −10.9° (exo) and C23B–C24B–O24B–C57 is −5.2° (endo).

According to our best knowledge, crystals of [**2**(H$_2$O)(PrOH)] · PrOH and [**2**(Hpz)$_2$] are the first crystals grown in non-centrosymmetric space groups obtained from solutions of racemic mixtures of dirhodium(II) carboxylates with two molecules of metallated phosphines. Single crystals after dissolution give again a mixture of enantiomers.

2.2. Spectroscopic studies

2.2.1. Properties of [1(HOAc)$_2$], [2(HO$_2$CCF$_3$)$_2$] and [3(HO$_2$CEt)$_2$] · HO$_2$CEt

There are two bands in the electronic spectra of Rh$_2$(μ-O$_2$CR)$_4$ complexes in the visible region, which are assigned to the $\pi^*(Rh_2) \rightarrow \sigma^*(Rh_2)$ and $\pi^*(Rh_2) \rightarrow \sigma^*(Rh\text{–}O)$ transitions. The first band in the UV–Vis spectrum of [*cis*-Rh$_2$(μ-O$_2$CR)$_2$(μ-PMP-C)$_2$(HO$_2$CR)$_2$], corresponding to the $\pi^*(Rh_2) \rightarrow \sigma^*(Rh_2)$ transition [19], is observed at $\nu = 17\,990\ cm^{-1}$ ($\varepsilon = 308$) for [**3**(HO$_2$CEt)$_2$] · HO$_2$CEt, $\nu = 17\,860\ cm^{-1}$ ($\varepsilon = 362$) for [**1**(HOAc)$_2$] and $\nu = 17\,570\ cm^{-1}$ ($\varepsilon = 499$) for [**2**(HO$_2$CCF$_3$)$_2$] (Table 7). The second band is hidden under an intense P → Rh charge transfer transition. The energies of the $\pi^*(Rh_2) \rightarrow \sigma^*(Rh_2)$ transitions change in the following order: [**3**(HO$_2$CEt)$_2$] · HO$_2$CEt > [**1**(HOAc)$_2$] > [**2**(HO$_2$CCF$_3$)$_2$]. Thus they diminish with decreasing σ-donor properties of the appropriate acids (acid dissociation constants: $K_a(HO_2CEt) = 1.3 \times 10^{-5} < K_a(HOAc) = 1.8 \times 10^{-5} < K_a(HO_2CF_3) = 6.0 \times 10^{-1}$).

The chemical shifts in the $^{31}P\{^1H\}$ NMR spectra in $CDCl_3$ of the [*cis*-Rh$_2$(μ-O$_2$CR)$_2$(PMP-C)$_2$] complexes are 18.1 for [**3**(HO$_2$CEt)$_2$] · HO$_2$CEt, 17.4 for [**1**(HOAc)$_2$] and 14.1 ppm for [**2**(HO$_2$CCF$_3$)$_2$] (Table 6.) The signals in $^{31}P\{^1H\}$ NMR spectra are the AA′ part of an AA′XX′ or AA′MM′XX′ pattern, but they cannot be easily resolved due to broadening of the peaks. Thus the δ (^{31}P) values depend in the same manner on the acidity of carboxylic acids as the energy of $\pi^*(Rh_2) \rightarrow \sigma^*(Rh_2)$ transitions.

The ^{1}H NMR spectra of all the complexes are presented in Table 6. The chemical shifts of the methoxy substituents almost do not change with the change of the carboxylato bridges. Changes of chemical shifts and coupling constants of the aromatic protons also differ rather little in [**3**(HO$_2$CEt)$_2$] · HO$_2$CEt, [**1**(HOAc)$_2$] and [**2**(HO$_2$CCF$_3$)$_2$]. The only exception is the proton ($H^{3,m}$) of the metallated ring in the ortho position with respect to the Rh–C bond ([**3**(HO$_2$CEt)$_2$] · HO$_2$CEt: 6.41, [**1**(HOAc)$_2$]: 6.36, [**2**(HO$_2$CCF$_3$)$_2$]: 5.99 ppm). Thus these chemical shifts decrease with the increase of K_a of the carboxylic acid.

Generally there are two sets of signals (AA′MM′X type) for the protons of the non-metallated phenyl rings: A and B. A comparison of their chemical shifts (Table 6) with the analogous chemical shifts of the free phosphine (7.22 and 6.85 ppm [20]) suggests that A – type rings are most probably exo rings (in molecular structures established by X-ray methods: C31–C36 and C61–C66 rings) and B – type rings are in endo positions. On the same basis, the signals of OMe groups at 3.26 for [**3**(HO$_2$CEt)$_2$] · HO$_2$CEt, 3.28 for [**1**(HOAc)$_2$] and 3.30 ppm for [**2**(HO$_2$CCF$_3$)$_2$] can be assigned to metallated rings (for free PMP: δ(OMe) = 3.77 ppm).

2.2.2. Interactions of complexes with pyrazole and imidazole

The first band in the UV–Vis spectra of the dirhodium(II) complexes, assigned to the $\pi^*(Rh_2) \rightarrow \sigma^*(Rh_2)$ transition, is very sensitive to the nature of the axial ligand [22]. This is also true for dirhodium(II) carboxylates with

Table 6
NMR spectra of [**1**$(HOAc)_2$], [**2**$(HO_2CF_3)_2$] and [**3**$(HO_2CEt)_2]\cdot HO_2CEt$ complexes and their adducts with pyrazole: $[Rh_2] + x$Hpz (solvent: $CDCl_3$; chemical shifts (ppm); coupling constants (Hz))

two molecules of orthometallated phosphines [19,20]. Reactions of [*cis*-$Rh_2(\mu\text{-}O_2CR)_2(\mu\text{-PMP-C})_2$] with pyrazole or imidazole in $CHCl_3$ were followed by UV–Vis spectroscopy.

Analysis of the UV–Vis spectra (Table 7, Figs. 7 and 8) indicates that formation of monoadducts of imidazole (or pyrazole) proceeds very easily. One can observe the formation of monoadducts at a complex:ligand molar ratio equal to 1:1. The completion of the formation of bis-adducts with pyrazole or imidazole only at high pyrazole(imidazole)/complex ratios suggests rather weak and labile interactions of these molecules with the investigated complexes and a strong trans effect of the Rh–Rh bond.

The reactivities of the complexes with imidazole change in the following order: [**3**$(HO_2CEt)_2]\cdot HO_2CEt <$ [**1**$(HOAc)_2] <$ [**2**$(HO_2CCF_3)_2$] and differences between these reactivities are easy to distinguish (Fig. 7). Only for the complex [**2**$(HO_2CCF_3)_2$] is complete formation of imidazole biadducts observed. The same order of reactivities of the complexes can also be deduced from spectra at molar ratios equal to 1:2. It agrees with the order of the dissociation constants of the carboxylic acids.

For complexes $Rh_2L^N_2$, $Rh_2L^NL^O$ and $Rh_2L^O_2$ (where Rh_2 are complexes [**1**], [**2**] or [**3**]; L^O = HOAc, HOPr, $HOOCCF_3$, H_2O; L^N = , Him) the differences between the energies of the $\pi^*(Rh_2) \rightarrow \sigma^*(Rh_2)$ transitions $\Delta\nu_1 = \nu_1(Rh_2L^NL^O) - \nu_0(Rh_2L^O_2)$ and $\Delta\nu_2 = \nu_2(Rh_2L^N_2) - \nu_0(Rh_2L^O_2)$ are for [**3**]: 810 and 2590 cm^{-1}, for [**1**]: 870 and 3100 cm^{-1} and for [**2**]: 1120 and 3390 cm^{-1}. It follows that the Rh–Rh bond in **2** is the most influenced by coordination of imidazole.

Imidazole and pyrazole σ-donor properties, established as PA (proton affinity), are equal to 942.8 kJ/mol for Him and 894.1 for Hpz [24]. Therefore imidazole is a better σ-donor and should coordinate more strongly as an axial ligand, whilst the presented data indicate that the reactivities of the investigated complexes with pyrazole are generally higher than those with imidazole.

The reactivities of the complexes with pyrazole (as concluded from Fig. 8) are different than with imidazole and change in the following order: [**1**$(HOAc)_2] \leqslant$ [**2**$(HO_2CCF_3)_2] <$ [**3**$(HO_2CEt)_2]\cdot HO_2CEt$, and are much less distinct.

The influence of the pyrazole axial ligand on the electronic structure of monoadducts of complexes [**1**], [**2**] and [**3**] is different to that of imidazole because the $\Delta\nu_1$ values change in the series [**1**] (830 cm^{-1}) < [**2**] (1160 cm^{-1}) < [**3**] (1310 cm^{-1}). However the influence of pyrazole in biadducts is analogous with that of imidazole. In this case $\Delta\nu_2$ values increase in the series: [**3**] (3020 cm^{-1}) < [**1**] (3190 cm^{-1}) < [**2**] (3440 cm^{-1}).

The interactions leading to formation of mono- and bisadducts of [*cis*-$Rh_2(\mu\text{-}O_2CR)_2(\mu\text{-PMP-C})_2$] with Hpz were also followed by ^1H and $^{31}P\{^1H\}$ NMR spectroscopy in $CDCl_3$ solutions (Table 6). Mixtures of [*cis*-$Rh_2(\mu\text{-}O_2CR)_2(\mu\text{-PMP-C})_2$] with Hpz at molar ratios of 1:1 and 1:2 were prepared in situ.

The $^{31}P\{^1H\}$NMR signals were shifted to lower fields for all complexes. The largest changes were observed for [**2**$(HO_2CCF_3)_2$]: $\Delta\delta_1 = 3.9$ and $\Delta\delta_2 = 5.8$ ppm, where $\Delta\delta_x$ is defined as the difference between the chemical shift of the phosphorus atom in a mixture of the complex and pyrazole and the chemical shift in the starting complex ($\Delta\delta_x = \delta_{[Rh_2]+x\text{Hpz}} - \delta_{[Rh_2]}$). The changes of chemical shifts for [**1**$(HOAc)_2$] ($\Delta\delta_1 = 2.5$, $\Delta\delta_2 = 2.7$ ppm) and [**3**$(HO_2CEt)_2]\cdot HO_2CEt$ ($\Delta\delta_1 = 1.9$, $\Delta\delta_2 = 2.9$ ppm) are much smaller. Significant broadening of signals in all spectra reveals the dynamic nature of these interactions.

Detailed analysis of the ^1H NMR spectra of [**3**$(HO_2CEt)_2]\cdot HO_2CEt$ and its mixtures with pyrazole reveals some interesting features. With increasing Hpz concentration,

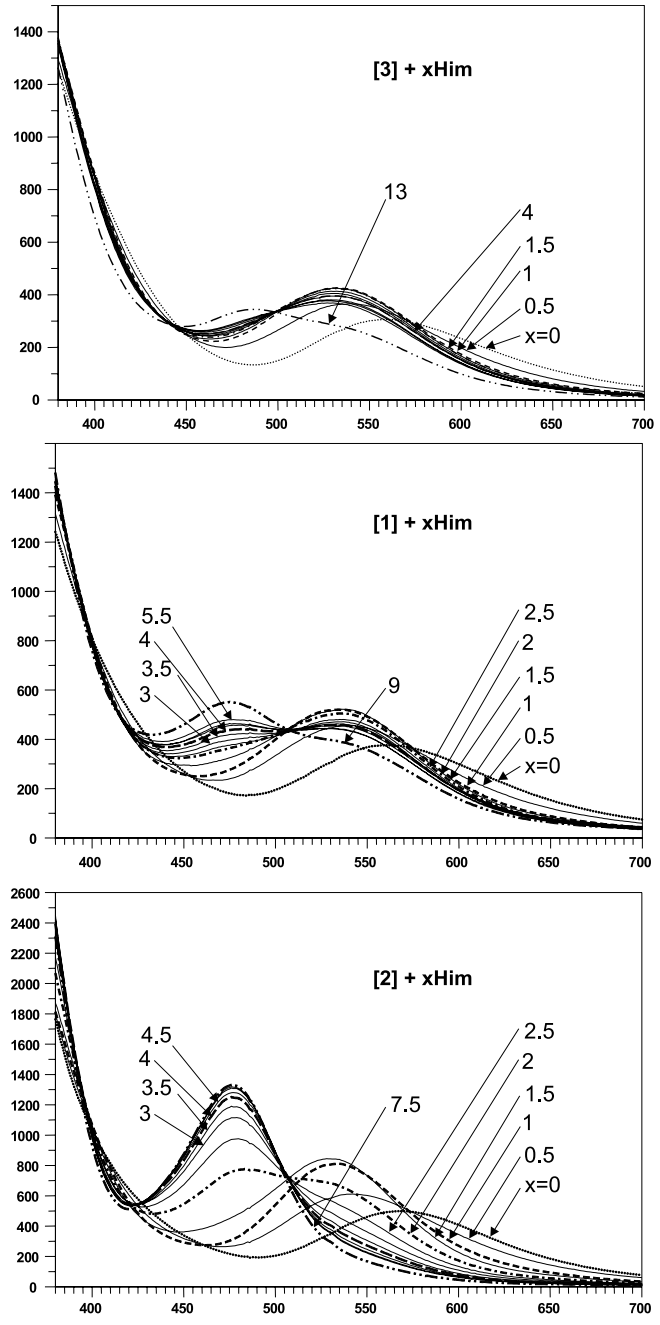

Fig. 7. UV–Vis spectra of mixtures of $[\mathbf{1}(HOAc)_2]$, $[\mathbf{2}(HO_2CCF_3)_2]$ and $[\mathbf{3}(HO_2CEt)_2]\cdot HO_2CEt$ complexes with imidazole (at room temperature; solvent: $CHCl_3$; X axis – λ (wavelengths) [nm], Y axis – ε (molar absorption coefficients) [$dm^3\,cm^{-1}\,mol^{-1}$]).

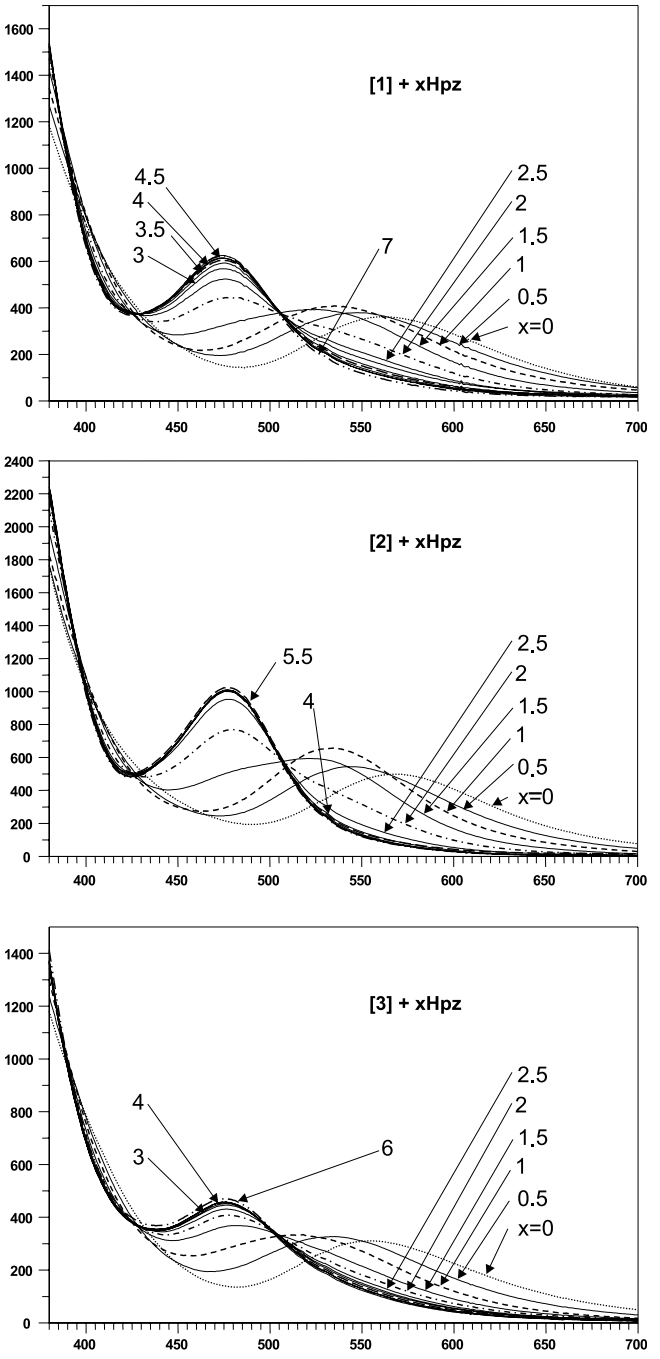

Fig. 8. UV–Vis spectra of mixtures of $[\mathbf{1}(HOAc)_2]$, $[\mathbf{2}(HO_2CCF_3)_2]$ and $[\mathbf{3}(HO_2CEt)_2]\cdot HO_2CEt$ complexes with pyrazole (at room temperature; solvent: $CHCl_3$; X axis – λ (wave lengths) [nm], Y axis – ε (molar absorption coefficients) [$dm^3\,cm^{-1}\,mol^{-1}$]).

the signals of the aromatic protons of the exo rings (A) remain almost unchanged. The signals of $H^{2,6}$ protons of endo (B) rings change their positions, lowering the difference between the chemical shifts of $H^{2,6}$ and $H^{3,5}$ almost to zero. The signals of protons of metallated rings are moved to higher fields. The largest changes are observed for $H^{3,m}$. The chemical shift of this proton changes from 6.41 to 5.66 ppm at a complex:Hpz ratio equal to 1:2. The signal of $H^{3,m}$ in $[\mathbf{1}(HOAc)_2]$ was less shifted (from 6.36 to 5.88 ppm), however in the case of $[\mathbf{2}(HO_2CCF_3)_2]$, the chemical shift of $H^{3,m}$ was changed very slightly (from 5.99 to 5.97 ppm). Thus the differences between the chemical shifts of $H^{3,m}$ in adducts with oxygen ligands and pyrazole adducts strongly depend on the acidity of the carboxylato bridging ligands.

Another interesting feature in these spectra is the signal of the $–CH_2–$ group in the propionato bridges. For the starting compound $[\mathbf{3}(HO_2CEt)_2]\cdot HO_2CEt$ one can observe a quartet for the CH_2 group at 1.17 ppm and a

triplet for the CH_3 group at 0.58 ppm (^3J(H–H) = 7.58 Hz). Owing to the coordination of the pyrazole these signals are shifted to lower fields and spectrum changes from an A_2X_3 type into an ABX_3 pattern. It indicates an unequivalency of the protons of the $–CH_2–$ group, caused by a slowing down of the rotation of the CH_3 groups. A similar, but much weaker, effect is observed in spectra of [**3**$(HO_2CEt)_2$] · HO_2CEt at lower temperatures.

3. Experimental

3.1. Procedures and materials

All solvents were deoxidized prior to use. UV–Vis spectra were measured on a Beckman DU 7500 spectrometer. ^1H NMR, $^{13}C\{^1H\}$ NMR and $^{31}P\{^1H\}$ NMR spectra were measured in $CDCl_3$ on a Bruker AMX 300 spectrometer with traces of $CHCl_3$ as an internal reference for ^1H ($\delta = 7.23$ ppm) and 85% H_3PO_4 in H_2O as an external standard for ^{31}P.

3.2. Syntheses

All operations were performed in dinitrogen or argon atmosphere using standard Schlenk techniques. [**1**$(HOAc)_2$] [21] was synthesized according to the literature methods.

3.2.1. [**2**$(HO_2CCF_3)_2$]

[**1**$(HOAc)_2$] (0.200 g) was dissolved in 3 cm^3 of CF_3COOH, heated to 50 °C and evaporated to dryness. The operation was repeated two times. The exchange of acetate bridges to trifluoroacetates occurred with 100% efficiency (proved by NMR spectra) after this procedure.

Crystals of [**2**(H_2O)(PrOH)] · PrOH suitable for X-ray structure determination were obtained by slow evaporation of a 1-propanol/water (5:1, v:v) solution of [**2**$(HO_2CF_3)_2$] in air.

3.2.2. [**3**$(HO_2CEt)_2$] · HO_2CEt

[**1**$(HOAc)_2$] (0.200 g) was dissolved in 3 cm^3 of HO_2CEt (propanoic acid), heated to 50 °C and evaporated to dryness. The operation was repeated two times. This procedure results in complete exchange (proved by NMR spectra) of acetate bridges to propionates. Crystals of [**3**$(HO_2CEt)_2$] · HO_2CEt suitable for X-ray structure determination were obtained by slow evaporation of a propanoic acid/acetone (1:1, v:v) solution of [**3**$(HO_2CEt)_2$] · HO_2CEt in air.

3.2.3. [**2**$(Hpz)_2$] and [**3**$(Hpz)_2$]

Spectroscopic studies were performed in situ.

Crystals of [**2**$(Hpz)_2$] suitable for crystallographic measurements were obtained by slow evaporation of a solution of [**2**$(HO_2CCF_3)_2$] in 1-propanol/water (5:1, v:v) with a large excess of pyrazole in air. The single crystals of [**3**$(Hpz)_2$] were prepared analogously from a mixture of water and ethanol (5:1, v:v).

3.3. X-ray structure determination

All measurements were made at 100(2) K on a Kuma KM4CCD κ-axis diffractometer with graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). Crystallization procedures are given in Section 3.2. The crystallographic data, together with data collection and structure refinement details, are given in Table 1. All the data were corrected for Lorenz and polarization effects but absorption and extinction were not applied. Data reduction and analysis were carried out with the Kuma Diffraction programs [29,30]. The structures were solved by direct methods and refined by full-matrix least-squares methods on F^2 [31]. The refinement was performed using the SHELXL program [32]. Non-hydrogen atoms were refined with anisotropic thermal parameters. The positions of hydrogen atoms were found from ΔF syntheses or geometrically and refined in rigid groups with the heavy atoms connected to them. Pictures were prepared with PLATON [33,34] or ORTEP-3 [35] software.

Appendix A. Supplementary data

Anisotropic displacement parameters and hydrogen atom parameters has been also deposited with the Cambridge Crystallographic Data Center, 12 Union Road, Cambridge CB2 1EZ, UK: CCDC 238033 – [**2**(H_2O)-(PrOH)] · PrOH; CCDC 238034 – [**2**$(Hpz)_2$]; CCDC 238035 – [**3**$(HO_2CEt)_2$] · HO_2CEt; CCDC 238036 – [**3**$(Hpz)_2$]. Copies of the data may be obtained free of charge upon request from The Director, Cambridge Crystallographic Data Centre, fax: +44 1223 336 033, e-mail: deposit@ccdc.cam.ac.uk; web: http://www.csdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2005.12.018.

networks [3b,10]. Cyano-bridged compounds have been reported to exhibit interesting electrochemical, magnetooptical, and zeolite properties [3,11]. In particular, some cyano-bridged compounds exhibit spontaneous magnetization at significantly higher temperatures [3,11a] to act as a molecular magnet.

Using $[Fe(CN)_6]^{3-}$ as a starting material, in most cases, the expected ferricyanide containing compounds have been isolated. Although in a few cases the ferricyanide anion has been reported to be reduced to ferrocyanide by nickel(II) or copper(II) compounds derived from cyclic or tertiary amines [5f,7d,10b], the species that is responsible for the reduction and the factors that affect the reduction process have not been explored.

Recently, the crystal structures and magnetic properties of a few nickel(II) and copper(II) bis-*trans*-1,2-diaminocyclohexane–ferricyanide systems have been reported [7a,7e,7f]. During the course of our studies with the nickel(II) system, we have noted that depending upon the reaction conditions, either exclusively ferricyanide or ferrocyanide compounds or their mixtures are formed. The present study is concerned with the isolation of the ferrocyanide complex, $[Ni^{II}L_2]_2[Fe^{II}(CN)_6]\cdot 5H_2O$ (**1**; L = *trans*-1,2-diaminocyclohexane), involving ferricyanide as the reactant, as well as the crystal engineering and magnetic properties of **1**. It has been shown from spectrophotometric titration that *trans*-1,2-diaminocyclohexane is responsible for the reduction of $[Fe(CN)_6]^{3-}$ to $[Fe(CN)_6]^{4-}$.

2. Experimental

2.1. Materials and physical measurements

All the reagents and solvents were purchased from commercial sources and used as received. Elemental (C, H, and N) analyses were performed on a Perkin–Elmer 2400 II analyzer. IR spectra were recorded in the region 400–4000 cm^{-1} on a Bio-Rad FTS40 infrared spectrophotometer in KBr disks. UV–Vis spectra were obtained with a Hitachi U-3501 spectrophotometer. Variable-temperature (2–300 K) magnetic susceptibility measurements under fixed field strength of 1 T were carried out with a Quantum Design MPMS SQUID magnetometer. Diamagnetic corrections were estimated from Pascals constants.

2.2. Syntheses

2.2.1. $[Ni^{II}L_2]_2[Fe^{II}(CN)_6]\cdot 5H_2O$ (1)

Method A: An aqueous solution (20 mL) of potassium ferricyanide (0.11 g, 0.33 mmol) was dropwise added to a pink aqueous solution (70 mL) containing nickel(II) chloride hexahydrate (0.119 g, 0.5 mmol) and *trans*-1,2-diaminocyclohexane (0.114 g, 1 mmol). The color of the mixture changed to brown. After a few hours, a brown crystalline compound **2** was deposited and filtered off. The green filtrate was kept undisturbed for several hours, during which time green diffraction quality single crystals of **1** were deposited and then collected by filtration. Yield: 0.055 g (25%) and 0.065 g (30%) for **1** and **2**, respectively. Anal. Calc. for $C_{30}H_{68}N_{14}O_5Ni_2Fe$ (**1**): C, 41.03; H, 7.80; N, 22.33. Found: C, 41.18; H, 7.70; N, 22.44%. Anal. Calc. for $C_{48}H_{88}N_{24}O_2Ni_3Fe_2$ (**2**): C, 43.64; H, 6.71; N, 25.44. Found: C, 43.86; H, 6.52; N, 25.32%. IR (**1**; KBr/cm^{-1}): ν(water), 3413m; ν_{as}(NH), 3336m; ν_s(NH), 3270m; ν_{as}(CH), 2930m; ν_s(CH), 2860w; ν(CN), 2033vs; δ(NH), 1589m; δ(CH), 1450w. IR (**2**; KBr/cm^{-1}): ν(water), 3513m; ν_{as}(NH), 3339s; ν_s(NH), 3279s; ν_{as}(CH), 2929s; ν_s(CH), 2859w; ν(CN), 2116s; δ(NH), 1593s; δ(CH), 1449w.

Method B: To an aqueous solution (25 mL) containing nickel(II) chloride hexahydrate (0.119 g, 0.5 mmol) and *trans*-1,2-diaminocyclohexane (0.114 g, 1 mmol), was added dropwise an aqueous solution (10 mL) of potassium ferrocyanide trihydrate (0.106 g, 0.25 mmol). After stirring for 10 min, the mixture was filtered to remove any suspended particles and the green solution was kept at room temperature. After few hours, the green crystalline compound **1** that deposited was collected by filtration. Yield: 0.16 g (73%). The IR spectrum of this compound is identical with that of **1** obtained by method A. In addition, the elemental analyses of the product obtained by method B agreed well with the molecular formula $C_{30}H_{68}N_{14}O_5Ni_2Fe$.

2.3. Crystal structure determination

Pertinent crystallographic data of **1** are summarized in Table 1. Diffraction data were collected on a Siemens P4 diffractometer in the ω–2ϑ scan mode using graphite monochromated Mo K_α radiation, having $\lambda = 0.71073$ Å. The accurate unit cell was obtained by means of least-squares fittings of 25 centered reflections. The intensity data were corrected for Lorentz and polarization effects, and semiempirical absorption corrections were made from

Table 1
Crystallographic data for **1**

Empirical formula	$C_{30}H_{68}N_{14}O_5Ni_2Fe$
Formula weight	878.25
Crystal system	monoclinic
Space group	*C*2/*c*
a (Å)	16.0621(12)
b (Å)	30.516(2)
c (Å)	8.9595(6)
β (°)	109.269(1)
V (Å^3)	4145.5(5)
Z	4
T (K)	294(2)
λ (Mo K_α) (Å)	0.71073
D_{calc} (g cm^{-3})	1.407
F(000)	1872
μ (mm^{-1})	1.298
R_1[a]/wR_2[b] ($I > 2\sigma(I)$ data)	0.0738/0.1451
R_1[a]/wR_2[b] (all data)	0.0942/0.1526

[a] $R_1 = [\sum \|F_o| - |F_c\|/\sum |F_o|]$.

[b] $wR_2 = \left[\sum w(F_o^2 - F_c^2)^2/\sum w(F_o^2)^2\right]^{1/2}$.

ψ-scans. A total of 11 160 reflections were collected for **1** in the range $2\vartheta = 3.68$–$50°$ with $0 \leqslant h \leqslant 10$, $-12 \leqslant k \leqslant 12$, $-13 \leqslant l \leqslant 13$, of which 3674 independent reflections ($R_{int} = 0.0453$) were used for structure determinations. During the development of the structure, it became obvious that both the cyclohexyl rings were highly disordered. For one ring, the four carbon atoms C(4), C(6), C(7), and C(9) are disordered over two sites with occupancies of 0.5, while the other two carbon atoms C(5) and C(8) remain in common positions. In the case of the second ring, all the carbon atoms C(10) to C(15) are distributed over two sites with the same occupancies. All disorders were treated using fully restrained refinement (site occupancies, coordinates, cycles planarity). The H atoms were geometrically fixed and allowed to ride on the atom to which they are attached. The structure was solved by direct and Fourier methods and refined by full-matrix least-squares methods based on F^2 using the programs SHELXS-97 and SHELXL-97 [12a,12b]. All programs used in the structure refinement were incorporated in the WINGX package [12c]. The final least-squares refinements (R_1) based on $I > 2\sigma(I)$ converged to 0.0738.

3. Results and discussion

3.1. Synthesis

Using *trans*-1,2-diaminocyclohexane as the blocking ligand and ferricyanide as the linker, three bimetallic assemblies all having the same composition, $[Ni^{II}(diamine)_2]_3[Fe^{III}(CN)_6]_2 \cdot 2H_2O$, have been reported recently [7a,7e,7f]. These three types of 2D assemblies differ in terms of their chiralities. They have been prepared by reacting either a mixture of enantiometrically pure $[Ni(diamine)_3](ClO4)_2 \cdot H_2O$, $[Ni(H_2O)_6](ClO4)_2$, and $K_3[Fe(CN)_6]$ in 1:1:1 stoichiometry in acetonitrile–water or a mixture of *trans*-1,2-diaminocyclohexane, $NiCl_2 \cdot 6H_2O$, and $K_3[Fe(CN)_6]$ in the ratio 1:1:0.65 in methanol–water. In all cases, the product was isolated as a brown material after standing.

During the course of our study, we have observed that the ratio of the reactants has profound effect on the composition of the product isolated. For example, if an aqueous solution of $K_3[Fe(CN)_6]$ (0.65 equivalent) is added to an aqueous solution containing 1 equivalent of $NiCl_2 \cdot 6H_2O$ and 2 equivalents of *trans*-1,2-diaminocyclohexane, within a few hours a brown colored compound is deposited first and from the filtrate on standing for further several hours a green colored product is obtained. The brown product has been identified to have the composition $[Ni^{II}(diamine)_2]_3[Fe^{III}(CN)_6]_2 \cdot 2H_2O$ and its IR spectrum is consistent with the presence of a ferricyanide moiety. The composition of the green compound is $[Ni^{II}(diamine)_2]_2[Fe^{II}(CN)_6] \cdot 5H_2O$ and its IR spectrum indicates that it contains a ferrocyanide moiety. If 0.65 equivalent of $K_3[Fe(CN)_6]$ is added to a mixture of 3 equivalents of *trans*-1,2-diaminocyclohexane and 1 equivalent of $NiCl_2 \cdot 6H_2O$, no brown compound formation takes place and the green compound is isolated exclusively in about 60% yield. Keeping the amount of other reactants the same but using 4 equivalents of the diamine, again only the green compound is isolated but in a slightly reduced yield (55%). Change of solvent composition, e.g., acetonitrile–water or methanol–water does not have any significant effect on the nature of the products, provided the reactant ratios remain the same. On the other hand, the concentration of the reactants affect the course of the reaction. For example, with the earlier mentioned ratio when both the brown and green products were obtained, only the brown compound is isolated if the reaction is carried out in half of the total volume. Conversely, if the total volume is 2.5-fold increased, then only the green product is obtained after standing for about 2 days.

As already reported and verified by us, the reaction involving $NiCl_2 \cdot 6H_2O$, *trans*-1,2-diaminocyclohexane, and $K_3[Fe(CN)_6]$ in the ratio 1:1:0.65 produces the brown product exclusively, while changing the reactants ratio to 1:3:0.65 gives rise to the formation of only the green colored ferrocyanide compound. It thus appears that the reduction of $[Fe(CN)_6]^{3-}$ to $[Fe(CN)_6]^{4-}$ is carried out by the non-coordinated diamine present in the solution.

3.2. IR spectrum

The IR spectra of the compounds **1** and **2** are shown in Fig. 1. It may be noted that **1** exhibits a single CN stretching at 2033 cm^{-1}, whereas this band appears at 2116 cm^{-1} for **2**. It is known that $K_4[Fe(CN)_6]$ exhibits ν_{CN} at

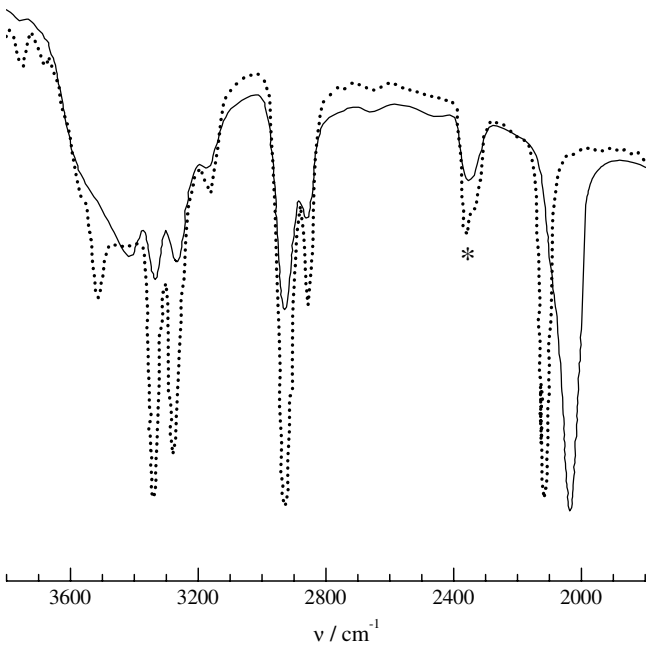

Fig. 1. A part of the IR spectra of **1** (solid lines) and **2** (dotted lines). The asterisk marked band indicates carbon dioxide vibration.

2044 cm^{-1}, while this band is observed at 2118 cm^{-1} for $K_3[Fe(CN)_6]$ [13]. Clearly, the green compound **1** contains a ferrocyanide unit, while the brown compound **2** contains a ferricyanide unit. Thus, the formation of **1** is accompanied by the reduction of the reactant ferricyanide. As will be seen, the structure of **1** contains both bridging and terminal cyanides. Generally, the stretching frequencies of terminal cyanides are observed at lower energies relative to those of bridging cyanides [13]. Therefore, **1** should have exhibited more than one CN vibrations. However, examples are known where for a similar situation only a single band has been observed [7f,9c]. Again, there are cases where more than one band have been observed for compounds with one type of cyano moiety [14].

3.3. Spectrophotometric titration

In order to verify that the reduction of $[Fe(CN)_6]^{3-}$ to $[Fe(CN)_6]^{4-}$ is accomplished by *trans*-1,2-diaminocyclohexane, a spectrophotometric titration of $K_3[Fe(CN)_6]$ has been carried out with the diamine. Fig. 2 shows the spectral changes for the solutions containing $[Fe(CN)_6]^{3-}$ and *trans*-1,2-diaminocyclohexane in the ratio of 1:0 to 1:4. It may be noted that the absorption maxima observed at 260, 302, 322, and 420 nm for $[Fe(CN)_6]^{3-}$ get depleted in intensity with the addition of *trans*-1,2-diaminocyclohexane in an increasing amount. When threefold or more amount of the diamine is added all the $[Fe(CN)_6]^{3-}$ bands practically vanish leaving a shoulder at 320 nm. The successive absorption curves pass through two isosbestic points at 285 and 350 nm. This clearly indicates that the redox reaction takes place smoothly. Further, as may be noted in Fig. 2, the position of the shoulder observed at 320 nm in the spectra of 1:3 or 1:4 ferricyanide–diamine solutions coincides with a similar absorption envelope observed for $[Fe(CN)_6]^{4-}$. Thus, it is clear that the formation of the green product takes place due to the reduction of $[Fe(CN)_6]^{3-}$ to $[Fe(CN)_6]^{4-}$ by the diamine.

3.4. Description of the Structure of *1*

An ORTEP view of **1**, demonstrating the coordination environment of the metal ions, is shown in Fig. 3, while the bridging pattern involved therein is illustrated in Fig. 4. The selected bond lengths and angles are summarized in Table 2. There are two crystallographically different nickel(II) centers (Ni(1) and Ni(2)), each of which is hexacoordinated. Two *trans* diequatorial 1,2-diaminocyclohexanes act as the blocking ligands for both the nickel(II) centers. For Ni(1), the remaining two coordination positions, which are *cis*, are occupied by the nitrile nitrogens of two different ferrocyanides, the *trans* cyanides of each link to two other Ni(1) centers resulting in one-dimensional chains that propagate along the crystallographic *c*-axis. Evidently, the *trans* cyanides of the hexacyanoferrate(II) bridge the *cis* positions of Ni(1) to result in these one-dimensional chains. In the case of Ni(2), the

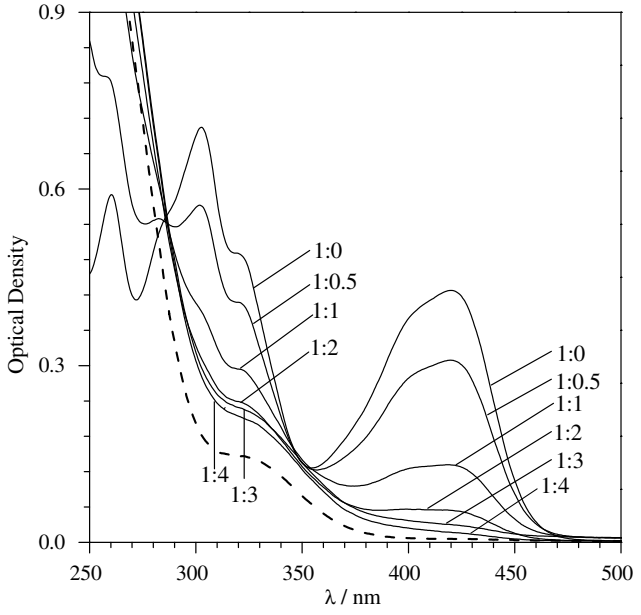

Fig. 2. Spectrophotometric titration of potassium ferricyanide (0.435 mM) with *trans*-1,2-diaminocyclohexane in water. The ferricyanide–diamine ratio has been indicated in the figure. The dashed lines are the absorption profile of an aqueous solution of potassium ferrocyanide (0.435 mM).

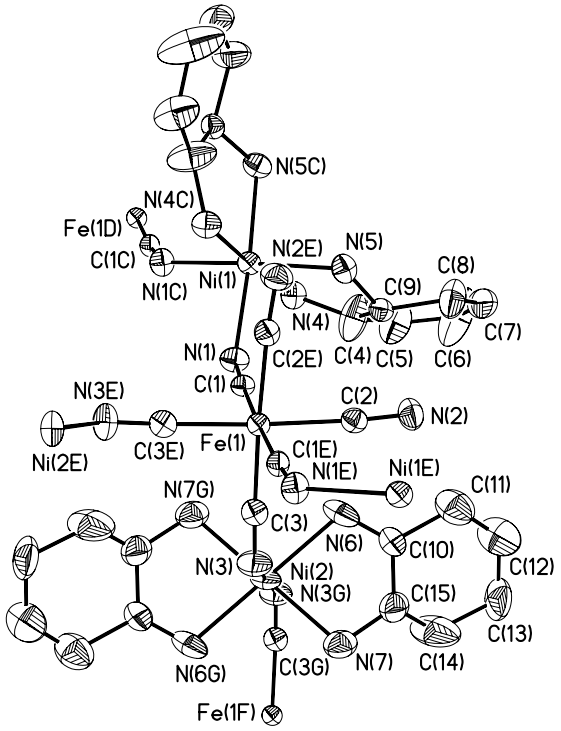

Fig. 3. ORTEP representation of $[Ni^{II}L_2]_2[Fe^{II}(CN)_6]\cdot 5H_2O$ (**1**) demonstrating the coordination environments of the iron(II) and two crystallographically different nickel(II) centers as well as the bridging pattern. Symmetry: C, $-x$, y, $2.5 - z$; D, x, y, $1 + z$; E, $-x$, y, $1.5 - z$; F, $0.5 + x$, $0.5 - y$, $0.5 + z$; G, $0.5 - x$, $0.5 - y$, $2 - z$.

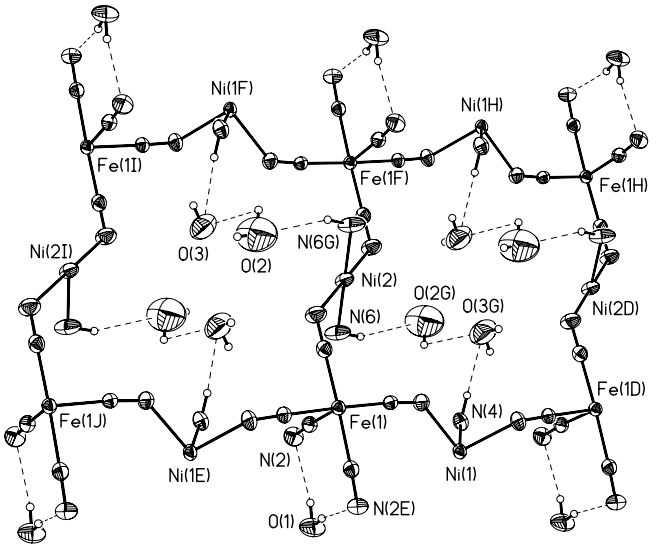

Fig. 4. A perspective view to demonstrate the grid-like bridging pattern of the cyanides as well as the hydrogen bonds between water and amine or non-coordinated cyanide nitrogens. The carbon atoms of the diamine and N(5) are omitted for clarity. Water hydrogens and the hydrogens that are involved in hydrogen bonds within the two-dimensional grids only are shown. Bridging of the *trans* cyanides to Ni(1) centers takes place along the crystallographic *c*-axis, while two *cis* cyanides coordinate to Ni(2) centers along the crystallographic *a*-axis. Symmetry: D–G, as in Fig. 3; H, $0.5 + x$, $0.5 - y$, $3 - z$; I, $0.5 - x$, $0.5 - y$, $1 - z$; J, x, y, $z - 1$.

N(4)–Ni(1)–N(5)	81.40(17)		

Symmetry: C, $-x$, y, $2.5 - z$; G, $0.5 - x$, $0.5 - y$, $2 - z$.

remaining two coordination positions are *trans* to each other and these are occupied by two cyanides of two different ferrocyanides, another *cis* cyanide of each then link to two other Ni(2) centers to result in a second type of one-dimensional chain that propagates along the crystallographic *a*-axis. The combination of these two types of one-dimensional chains generates a two-dimensional grid-like bridging network in compound **1**. The shortest metal···metal separations are: Ni(1)···Ni(1E) = 8.96 Å, Ni(1)···Ni(2) = 6.64 Å, and Ni(2)···Ni(2E) = 7.79 Å.

The coordination environment of both the nickel centers is a distorted octahedron. The Ni–N(cyanide) bond distances (Ni(1)–N(1) = 2.159(4) Å, Ni(2)–N(3) = 2.179 (5) Å) are slightly longer relative to the Ni–N(amine) distances (Ni(1)–N(4) = 2.090(4) Å, Ni(1)–N(5) = 2.123(4) Å, Ni(2)–N(6) = 2.106(5) Å, Ni(2)–N(7) = 2.089(5) Å). For the Ni(1) center, the *cisoid* and *transoid* angles lie in the range 81.40(17)–96.10(18)° and 171.22(17)–176.4(3)°, respectively. In contrast, for the Ni(2) center the *transoid* angles are 180° and the *cisoid* angles range from 81.6(2)° to 98.4(2)°. In the case of Ni(1), the average displacements of the nitrogen atoms forming the least-squares planes, N(1)N(1C)N(5)N(5C) and N(4)N(1C)N(5)N(4C), are 0.163 and 0.017 Å, respectively. The nickel(II) center, on the other hand, is exactly located in the first plane and only slightly displaced (0.029 Å) from the second plane. In case of the Ni(2) environment, the four donor nitrogens and the metal ion define exact planes. Evidently, the coordination environment of Ni(2) is less distorted from octahedral geometry.

The ferrocyanide moiety in **1** is almost free from distortion as evident from the facts that the *cisoid* (86.7(3)–92.0(2)°), *transoid* (177.3(2)–178.8(3)°) and Fe–C–N (175.6(5)–176.9(5)°) angles vary only to a small extent. The cyanide groups coordinate to the nickel(II) centers in a significantly bent way (Ni(1)–N(1)–C(1) = 133.2(4)°, Ni(2)–N(3)–C(3) = 126.0(4)°).

Among the three types of water molecules, two types, viz. $H_2O(2)$ and $H_2O(3)$, reside in the square blocks of the cyano-bridged assemblies by forming hydrogen bonds between each other and also with the amine nitrogens (Fig. 4). One water molecule, $H_2O(3)$, behaves as a bifurcated acceptor and interacts with H(21) and H(42F), which are bonded to O(2) and N(4F) (H(21)···O(3) = 2.457 Å, O(2)···O(3) = 2.736 Å, O(2)–H(21)···O(3) = 98.3°; H(42F)···O(3) = 2.534 Å, N(4F)···O(3) = 3.330 Å, N(4F)–H(42F)···O(3) = 147.8°), respectively. The second water molecule within the square blocks, $H_2O(2)$, in addition to being a donor to O(3), also acts as a single acceptor and makes hydrogen bond with H(63G) linked to N(6G) (H(63G)···O(2) = 2.534 Å, N(6G)···O(2) = 3.311 Å, N(6G)–H(63G)···O(2) = 145.0°).

The third water molecule, $H_2O(1)$, acts as a donor to two non-coordinated cyanides (Fig. 4; H(1)···N(2) = 2.086 Å, O(1)···N(2) = 2.965 Å, O(1)–H(1)···N(2) = 142.9°). The Fe(1)···N(2) and O(1)···N(2) distances (Fe(1)···N(2) = 3.079 Å, O(1)···N(2) = 2.965 Å) are very close and the internal angles (N(2)···Fe(1)···N(2E) = 83.4°, N(2)···O(1)···N(2E) = 87.4°, Fe(1)···N(2)···O(1) = 94.6°) in the Fe(1)N(2)O(1)N(2E) tetragon are deviated slightly from 90°. Thus, as the Fe(1)–C(2)–N(2) moiety is almost linear (175.6°), the donor and acceptor centers, along with the Fe–C–N moiety, form an approximate square. The dihedral angle between these hydrogen bonded squares with the cyanobridged square block, defined by the four iron(II) centers Fe(1), Fe(1F), Fe(1I), and Fe(1J) or Fe(1), Fe(1F), Fe(1H), and Fe(1D), is 97.1° indicating that the cyano-bridged and the hydrogen bonded squares are almost perpendicular; the later resides in the crystallographic *ab*-plane. Thus, the hydrogen bonded squares may be considered to be appended with the two-dimensional cyano-bridged grids.

As shown in Fig. 5, the two-dimensional cyano-bridged grids with the water molecules inside the square blocks are interlinked due to the intersheet hydrogen bonds between the hydrogens attached to one amine nitrogen (N(5L)) and the water molecule of the appended squares (H(53L)···O(1) = 2.314 Å, N(5L)···O(1) = 3.139 Å, N(5L)–H(53L)···O(1) = 152.3°). In Fig. 5, the two one-dimensional chains, ···Fe(1K)···Ni(1L)···Fe(1L)···Ni(1M)···Fe(1M)··· and ···Ni(1E)···Fe(1)···Ni(1)···Fe(1D)···Ni(1D)···, belong to two different two-dimensional cyano-bridged assemblies. An extended view down the crystallographic *c*-axis of the structure of **1** is shown in Fig. 6. The two-dimensional cyano-bridged grids look like waved sheets that are self-assembled into a three-dimensional network. Evidently, the grids are self-assembled into three dimensions due to the interlinking through the appended squares.

3.5. Magnetic properties

Variable-temperature (2–300 K) magnetic behavior of **1** is shown in Fig. 7 in the form of χ_M versus T and $\chi_M T$ versus T plots. The $\chi_M T$ value at 300 K is 2.35 $cm^3\,mol^{-1}\,K$. On lowering the temperature, the $\chi_M T$ values remain almost constant down to 20 K, and then decreases rapidly to 1.13 $cm^3\,mol^{-1}\,K$ at 2 K. The profile indicates that there may exist only a very weak antiferromagnetic interaction between the nickel(II) centers in **1**. As mentioned earlier, the paramagnetic centers in **1** are separated via five-atom bridges in two-dimensional cyano-bridged grids with the metal···metal separations of 6.64, 7.79, and 8.96 Å. Evidently, the extent of superexchange in this compound is expected to be very weak and the rapid decrease of $\chi_M T$ may be due to the single ion zero-field effect (ZFS) of the nickel(II) ions. Therefore, the susceptibility data have been simulated with the mononuclear model ($\mathbf{H} = D(\mathbf{S}_z^2 - 1/3\ S(S+1))$; Eq. (1)) that considers the zero-field effect of the nickel(II) ion

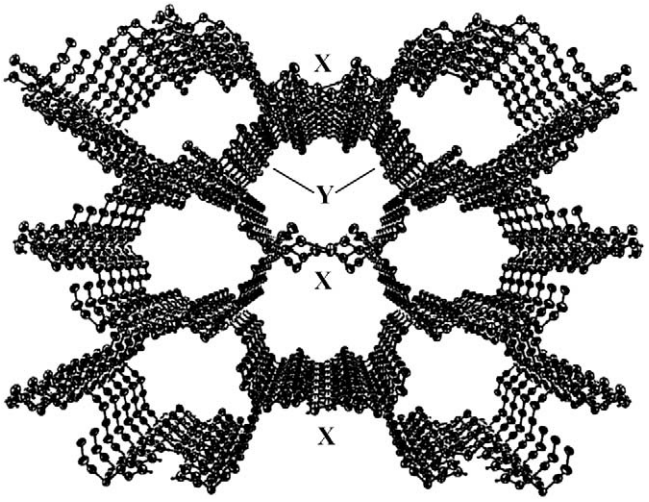

Fig. 6. A perspective view down the crystallographic *c*-axis to demonstrate the three dimensional structure that is generated due to the interlinking (region X; as in Fig. 5) of the waved sheets of the cyano-bridged grids (region Y). The carbon atoms, N(4), N(6), and N(7) of the diamines as well as O(2) and O(3) are omitted for clarity. Except the two hydrogens bonded to O(1) and one of the two hydrogens bonded to N(5), other hydrogen atoms are also omitted. Hydrogen bonds are shown by solid lines here.

$$\chi_M = \frac{4N\beta^2 g^2}{kT}\,\frac{e^{-D/kT}}{1+2e^{-D/kT}}. \qquad (1)$$

Least-squares fitting of the susceptibility data with Eq. (1) leads to $|D| = 1.9\ cm^{-1}$ and $g = 2.18$; the agreement factor (R) defined as $[\sum\{(\chi_M T)_{obs} - (\chi_M T)_{calc}\}^2 / \sum(\chi_M T)^2_{obs}]$ being 1.39×10^{-2}. The susceptibility data have been also simulated with the dinuclear model ($\mathbf{H} = -2J\mathbf{S_1}\cdot\mathbf{S_2} + D(\mathbf{S}_{1z}^2 + \mathbf{S}_{2z}^2)$) that considers superexchange as well

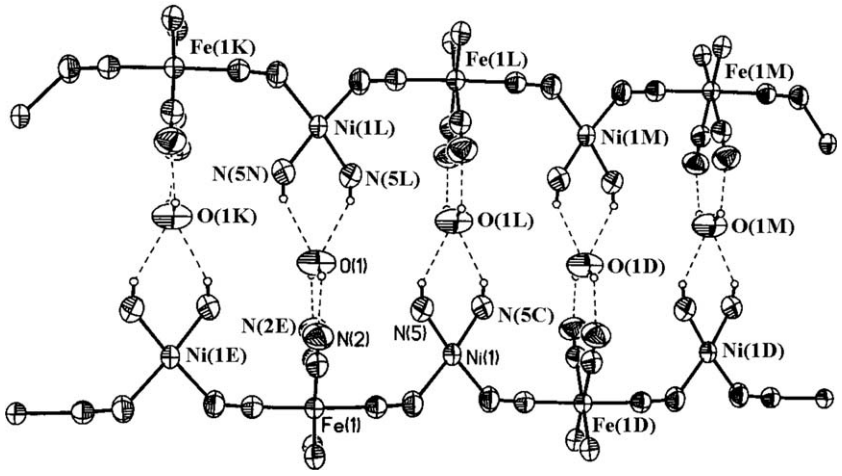

Fig. 5. A perspective view down the crystallographic *a*-axis to show the linking of two-dimensional sheets due to the hydrogen bonds between O(1) and the hydrogens of one amine nitrogen (N(5)). The Ni(2) center and the diamine coordinated to this metal ion, O(2), and O(3) atoms as well as the carbon and one nitrogen atoms of the diamine coordinated to Ni(1) center are omitted for clarity. Only those hydrogens participating in intersheet interactions are shown. Symmetry codes: D–G, as in Fig. 3; K, $-x, -y, 1-z$; L, $-x, -y, 2-z$; M, $-x, -y, 3-z$; N, $x, -y, z-0.5$.

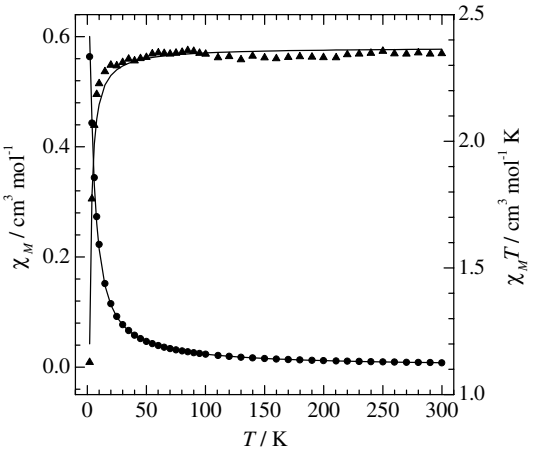

Fig. 7. Plots of χ_M (solid circles) and $\chi_M T$ (solid triangles) vs. T for **1**. Solid lines represent best least-squares fit of the experimental data with the theoretical equation (Eq. (1)) in the text).

as the single ion zero-field effect of nickel(II) [15]. The global minimization of the least-squares fittings (Fig. S1) takes place with $J = -0.3\ \mathrm{cm}^{-1}$, $g = 2.16$, and $|D| = 4.8\ \mathrm{cm}^{-1}$; the agreement factor ($R$), defined as $[\sum\{(\chi_M T)_{obs} - (\chi_M T)_{calc}\}^2 / \sum(\chi_M T)^2_{obs}]$, being 1.65×10^{-2}. On fixing the J value at zero, the simulation (Fig. S1) converges with $g = 2.15$, $|D| = 9.6\ \mathrm{cm}^{-1}$, and $R = 2.15 \times 10^{-2}$. Although the three simulations are almost superimposable, the rapid decrease of $\chi_M T$ at low temperatures are better defined in the mononuclear model as well as in the dinuclear model with imposed $J = 0$. However, the mononuclear model leads to more realistic estimate of the ZFS. From these simulations, it can be concluded that the superexchange interaction between the paramagnetic centers in **1** is negligible and the rapid decrease at low temperatures takes place due to the zero-field effect of the nickel(II) centers. It may be noted that the exchange interactions observed through the five-atom bridge, as in **1**, in the previously reported examples are only very weak ferromagnetic interactions [5d,10c]. Thus, the non-correlation between the paramagnetic centers in **1** is approximately consistent with the reported cases.

As mentioned earlier, three possible types of $[Ni^{II}(diamine)_2]_3[Fe^{III}(CN)_6]_2 \cdot 2H_2O$ (**2**) have been reported previously [7a,7e,7f]. All these three systems have similar two-dimensional structures. Magnetic properties of all these compounds are also similar and these exhibit ferromagnetic ordering at ca. 15 K.

cations to form stable complexes with general formula $[WM(RSn)_2(MW_9O_{34})_2]^{10-}$ where M = Co or Zn and R = CH_3, C_2H_5, *n*-C_4H_9.

The di-tin precursors α,ω-bis-(trichlorostannyl)alkanes with general formula $Cl_3Sn(CH_2)_nSnCl_3$ have previously been reported for the synthesis of organotin-oxo clusters [24]. In this paper, we report the use of $Cl_3Sn(CH_2)_4SnCl_3$ as a new polyoxometalate linker by reacting it with $[SiW_{11}O_{39}]^{8-}$ to connect two lacunary POMs and also to form linear oligomers from $[WZn(Zn(H_2O))_2(ZnW_9O_{34})_2]^{12-}$.

Although the nonaqueous synthesis of $[PhSnW_5O_{18}]^{3-}$ and $[PhGeW_5O_{18}]^{3-}$ from WO_4^{2-} and $PhMCl_3$ has been reported [25], we now show that reaction of $K_{10}[Ce(W_5O_{18})_2]$ and CH_3SnCl_3 yields $[CH_3W_5O_{18}]^{3-}$ in aqueous solution.

2. Experimental

The sodium salts of $[WM_3(H_2O)_2(MW_9O_{34})_2]^{12-}$ (M_5W_{19}) M = Co, Zn, $K_9[Ce^{III}(W_5O_{18})_2]\cdot nH_2O$ ($Ce(W_5)_2$) and $K_8[\alpha\text{-}SiW_{11}O_{39}]$ (SiW_{11}) were synthesized following published methods and identified by infrared spectroscopy and for Zn_5W_{19}, $Ce(W_5)_2$, and SiW_{11}, by ^{183}W NMR spectroscopy [17,18,26,27]. α,ω-Bis-(trichlorostannyl)butane ($Cl_3Sn(CH_2)_4SnCl_3$) was synthesized via α,ω-bis-(triphenylstannyl)butane [24,28]. Methyltintrichloride ($MeSnCl_3$), and butyltintrichloride ($BuSnCl_3$) (Aldrich) and ethyltintrichloride ($EtSnCl_3$) (Organometallics, Inc.) were used as supplied.

*$Cs_{10}[WZn(CH_3Sn)_2(ZnW_9O_{34})_2]\cdot 19.5H_2O$ (Cs_{10}**1**).* A solution of 5.0 g of $Na_{12}[WZn_3(H_2O)_2(ZnW_9O_{34})_2]\cdot nH_2O$ (0.9 mmol) in 10 mL water was heated to 80 °C and added to a solution of 0.43 g of CH_3SnCl_3 (1.8 mmol) in 10 mL of water. The resulting mixture was stirred at 80 °C for 30 min, 2.25 mL of 4 M CsCl solution was added and the mixture stored in the refrigerator overnight. The solid product was filtered off and recrystallized from 15 mL of hot (90–95 °C) water by adding 1 mL of 4 M CsCl solution. The fine crystals were filtered off and air-dried overnight. Yield: 4.6 g (77%). *Anal.* Calc. for $C_2H_{45}Cs_{10}O_{87.5}Sn_2W_{19}Zn_3$: C, 0.36; Cs, 19.8; Sn, 3.53; W, 51.9; Zn, 2.9. Found: C, 0.39; Cs, 20.4; Sn, 3.70; W, 56.1; Zn, 3.0%. IR (metal oxygen stretching region): 1203, 935, 880, 751, 658 cm^{-1}.

*$Cs_{10}[Co(CH_3Sn)_2(CoW_9O_{34})_2]\cdot 20H_2O$ (Cs_{10}**2**), $Cs_{10}[WZn(CH_3CH_2\ Sn)_2(ZnW_9O_{34})_2]\cdot 15H_2O$ (Cs_{10}**3**)* and *$Cs_{10}[WCo(CH_3CH_2Sn)_2(CoW_9O_{34})_2]\cdot 14H_2O$ (Cs_{10}**4**)* were prepared in a similar fashion.

*Cs_{10}**2***. Yield: 4.5 g (75%). *Anal.* Calc. for $C_2H_{46}Co_3Cs_{10}O_{88}W_{19}$: C, 0.36; Co, 2.63; Cs, 19.8; Sn, 3.54; W, 52.02. Found: C, 0.32; Co, 2.70; Cs, 19.6; Sn, 3.45; W, 54.8%. IR: 1203, 935, 885, 745, 660 cm^{-1}.

*Cs_{10}**3***. Yield: 3.9 g (65%). *Anal.* Calc. for $C_4H_{40}Cs_{10}O_{83}Sn_2W_{19}Zn_3$: C, 0.72; Cs, 19.9; Sn, 3.6; W, 52.4; Zn, 2.9. Found: C, 0.67; Cs, 19.6; Sn, 3.73; W, 52.9; Zn, 3.2%. IR: 1192, 933, 884, 750, 658, 539 cm^{-1}.

*Cs_{10}**4***. Yield: 3.6 g (60%). *Anal.* Calc. for $C_4H_{38}Co_3Cs_{10}O_{82}Sn_2W_{19}$: C, 0.72; Co, 2.7; Cs, 20.0; Sn, 3.6; W, 52.5. Found: C, 0.71; Co, 2.8; Cs, 20.3; Sn, 3.7; W, 55.1%. IR: 1190, 934, 883, 857, 751, 655, 538 cm^{-1}.

*$Cs_{10}[WZn(C_4H_9Sn)_2(ZnW_9O_{34})_2]\cdot 18H_2O$ (Cs_{10}**5**)* was prepared using the same procedure and quantity as above except that before and during the addition of the solution of $[WZn_3(H_2O)_2(ZnW_9O_{34})_2]^{12-}$ to the $C_4H_9SnCl_3$ the temperature was maintained at ca. 40 °C. After 5 min the temperature was slowly raised to 80 °C and kept there for 30 min. Yield: 3.0 g (50%). *Anal.* Calc. for $C_8H_{54}Cs_{10}O_{86}Sn_2W_{19}Zn_3$: C, 1.42; Cs, 19.6; Sn, 3.50; W, 51.5; Zn, 2.9. Found: C, 1.52; Cs, 19.4; Sn, 3.56; W, 51.9; Zn, 2.9%. IR: 1167, 1086, 936, 879, 752, 657, 600, 535 cm^{-1}

*$Cs_{10}[WCo(C_4H_9Sn)_2(CoW_9O_{34})_2]\cdot 17H_2O$ (Cs_{10}**6**)* was prepared using the same procedure used for **5**. Yield: 3.4 g (57%). *Anal.* Calc. for $C_8H_{52}Co_3Cs_{10}O_{85}Sn_2W_{19}$: C, 1.43; Co, 2.62; Cs, 19.7; Sn, 3.52; W, 51.8. Found: C, 1.45; Co, 2.71; Cs, 19.8; Sn, 3.63; W, 53.2%.

*$Cs_{10}[WCo(CH_3Sn)_2(ZnW_9O_{34})_2]\cdot 20H_2O$ (Cs_{10}**7**)*. To 20 mL of a warm solution (80 °C) of $Co(NO_3)_2\cdot 6H_2O$ (2.16 g, 9.1 mmol) was added 10 mL of a solution of $MeSn_2Zn_3W_{19}$ (10.5 g, 1.8 mmol). The solution changed color from pink to reddish brown and the resulting mixture was heated to near boiling for 2 h. The solution was then allowed to cool and passed through a cation exchange column (K^+) to remove excess unreacted cobalt. The eluate had a reddish green color. CsCl solution (4 M) was added to obtain a solid which was then recrystallized from the minimum amount of hot water (yield 6.5 g, 62%). *Anal.* Calc. for $C_2H_{46}CoCs_{10}O_{88}W_{19}Zn_2$: C, 0.36; Co, 0.88; Cs, 19.8; Sn, 3.53; W, 52.0. Found: C, 0.39; Co, 0.91, Cs, 20.2; Sn, 3.21; W 53.3%.

The isostructural but *achiral analogs* of **1**, **3** and **5**, $[(RSn)_2Zn_2(PW_9O_{34})_2]^{8-}$ (R = Me, Et, *n*-Bu) were also prepared for spectroscopic comparisons, see below and in Supplementary material.

*$K_{10}[SiW_{11}O_{39}Sn(CH_2)_4SnSiW_{11}O_{39}]\cdot H_2O$ (**8**)*. In 40 mL of DMF $Cl_3Sn(CH_2)_4SnCl_3$ (0.47 g, 0.93 mmol) and SiW_{11} (6 g, 1.9 mmol) were mixed and the slurry was heated at 100 °C overnight. The solution was filtered hot and 5 mL of a saturated solution of KCl was added first, followed by ethanol to yield a solid product which was recrystallized from the minimum of water. Yield: 5.4 g (90%).

Samples containing *$[(SnC_4H_8Sn)_{2n}\{WZn(ZnW_9O_{34})_2\}_n]^{10n-}$ (**9**)* were prepared as follows. A solution of $Cl_3SnC_4H_8SnCl_3$ (0.91 g, 1.8 mmol) in 40 mL of DMF was treated with solid Zn_5W_{19} (5 g, 0.9 mmol) and the slurry was heated at 100 °C overnight. After filtration to remove undissolved material, ethanol was added to precipitate 4.5 g (90%) of product.

2.1. Physical measurements

Infrared spectra were recorded in KBr pellets on a Spectrum One FT-IR spectrometer (Perkin–Elmer Instruments)

and electronic spectra on an Agilent 8453 UV–Vis spectrophotometer. Elemental analyses were performed by Schwarzkopf Microanalytical Lab Inc., Woodside, NY. and water content was determined by thermogravimetric analysis using a Q600 SDT DSC/TGA (TA Instruments, New Castle, Delaware). Cyclic voltammograms were recorded at room temperature on a BAS 100A instrument. A glassy carbon working electrode, platinum wire counter electrode, and Ag|AgCl reference electrode were used, and the measurements were carried out in sodium sulfate (pH 2 and 3), acetate/acetic acid (pH 4–6), and tris buffers (pH 7 and 8). All ^{183}W and ^{119}Sn NMR data were recorded on a Bruker AM-300WB spectrometer equipped with an Aspect 3000 computer or Tecmag DeSpect system. Proton NMR spectra were recorded on a Mercury 300 instrument with Varian VNMR software and carbon-13 spectra on an Oxford 500 MHz NMR with Varian Unity INOVA system. Resonance frequencies were 300.107 MHz for ^{1}H in 5 mm tubes, 125.68 MHz for ^{13}C in 5 mm tubes, 111.92 MHz for ^{119}Sn in 10 mm tubes, 12.505 MHz for ^{183}W NMR in 10 mm tubes. Chemical shifts are reported with respect to 2 M $NaWO_4$ (^{183}W) $(CH_3)_4Sn$ (^{119}Sn), and $(CH_3)_4Si$ (^{1}H, ^{13}C). Chemical shifts downfield of the references are reported as positive. All NMR measurements were made in 99.9% D_2O. For ^{183}W and ^{119}Sn, concentrations of 0.1–0.15 M were used. Cesium salts were treated with lithium perchlorate and subsequent removal of precipitated $CsClO_4$; potassium salts were soluble enough to require no ion exchange.

2.2. Crystal structure analysis

Crystals were grown from reaction mixtures as cesium, potassium, or sodium salts or as a combination of these cations. Structural analyses were performed on a Bruker-Siemens SMART CCD single-crystal diffractometer equipped with a Mo anode and graphite monochromator ($\lambda = 0.71073$ Å). The crystals were mounted on a glass fiber

and placed in a nitrogen stream at 173 K and an approximate sphere of data was collected using ω-scans. Following routine Lorentz and polarization correction, an empirical absorption correction was based on measured intensities of equivalent reflections at different ϕ and ω values [29,30]. All structures were solved using direct methods and refined against $|F^2|$ over all independent reflections. SMART, SAINT, SHELX-97, and X-SEED software were used to solve and refine the data [31–33]. As is frequently seen in polyoxometalate crystals there is extensive disorder of the cations and water molecules. In order to determine the occupancy of the disordered atoms their atomic displacement parameters were first set to be comparable to the corresponding non disordered atoms and their occupancies were refined. Then the occupancy numbers were held fixed and their atomic displacement factors were refined.

3. Results and discussion

Crystallographic data for structures containing $[(RSn)_2ZnW(ZnW_9O_{34})_2]^{10-}$ (R = CH_3), C_2H_5, and *n*-C_4H_9, are summarized in Table 1. The polytungstate skeleton is identical to that reported by Tourné and Zonnevijlle and consists of two α-B-$[ZnW_9O_{34}]^{12-}$ lacunary derivatives sandwiching Zn, W, and Sn(R) atoms as shown for the butyl derivative in Fig. 1. Although each anion has only C_2 symmetry, the belt W and Zn atom sites are disordered with 50% occupancy as a consequence of the centrosymmetric space group.

Tungsten-183 NMR spectra (Fig. 2) are similar to that reported for $[\{(H_2O)Zn\}_2ZnW(ZnW_9O_{34})_2]^{12-}$ with ten lines of relative intensity 1:2:2:2:2:2:2:2:2:2. Tungsten-183 and Tin-119 NMR data are summarized in Table 2.

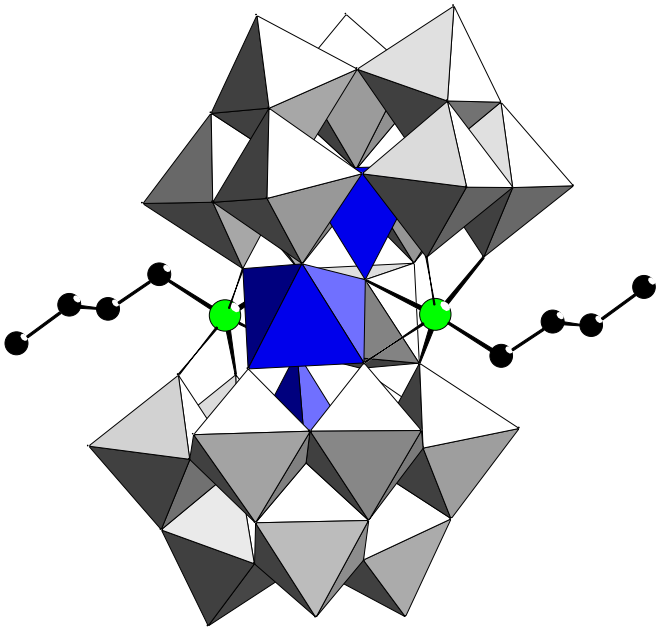

Fig. 1. Combination polyhedral and ball-and-stick representation of the structure of anion **5**.

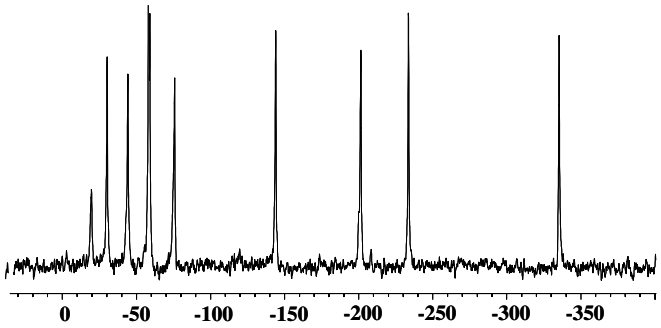

Fig. 2. Tungsten-183 NMR spectrum of anion **5**.

The proton NMR spectra of solutions of anions *3* and *5* reveal that the α-methylene protons are diastereotopic, see Fig. 3 and Table 3. We do not believe that this is a consequence of the chirality of the polyoxoanion structure for the following reasons: (1) the spectrum of the methyl derivative, **1**, is a singlet; (2) the spectra of *achiral* $[(RSn)_2Zn_2(PW_9O_{34})_2]^{8-}$ (R = Et, *n*-Bu) show similar splittings of the α-protons (Supplementary material). We tentatively suggest that the spectra result from restricted rotation about the Sn–C bond.

The well-known Keggin anion $[CoW_{12}O_{40}]^{6-}$ containing a tetrahedral cobalt(II) center within a rigid polytungstate shell is oxidizable to a stable cobalt(III) analog [34,35], a rare example of tetrahedral (high-spin) Co^{III}. Anions **2**, **4** and **6**, as well as the precursor Co_5W_{19} Tourné–Zonnevijlle species share a similar feature, although this does not seem to have been explored previously. Cyclic voltammograms of **2** and Co_5W_{19} (Fig. 4) show two reversible one-electron oxidations at pH 5–6. Solutions of the $Co^{II}Co^{III}$ and Co_2^{III} anions, both golden yellow, were easily generated by controlled potential electrolysis. In more acidic solutions the two one-electron waves coalesced into a single reversible two-electron feature, a consequence of the routinely-observed protonation effects in polyoxometalate electrochemistry [36]. The difference in oxidation potentials (ca. 300 mV, Table 4) between the two polyoxometalates is attributed to the anionic charge difference of 10– versus 12– [36].

3.1. Diplacement of cerium(III)

In earlier work we had shown that the pentatungstate anion in complexes such as $[Ce(W_5O_{18})_2]^{9-}$ had sufficient kinetic stability in aqueous solution to allow its transfer to other lanthanide polyoxometalates [37]. We have therefore considered the possibility of displacing the cerium atom by RSn^{3+} to generate $[RSnW_5O_{18}]^{3-}$. The only previously known examples of the latter structure, with phenyltin and phenylgermanium groups, were synthesized in non-aqueous solution from mononuclear tungstate [25].

In a preliminary investigation in aqueous solution $K_9[Ce(W_5O_{18})_2]\cdot nH_2O$ (3 g, 0.96 mmol) in 20 mL of water was added to one of $MeSnCl_3$ (0.46 g, 1.9 mmol) in 10 mL

5	0.32 (t, 3H), 0.79 (m, 2H), 1.42 (m, 2H), 2.02 (m, 1H), 2.18 (m, 1H)	13.01, 26.26, 28.86, 38.01

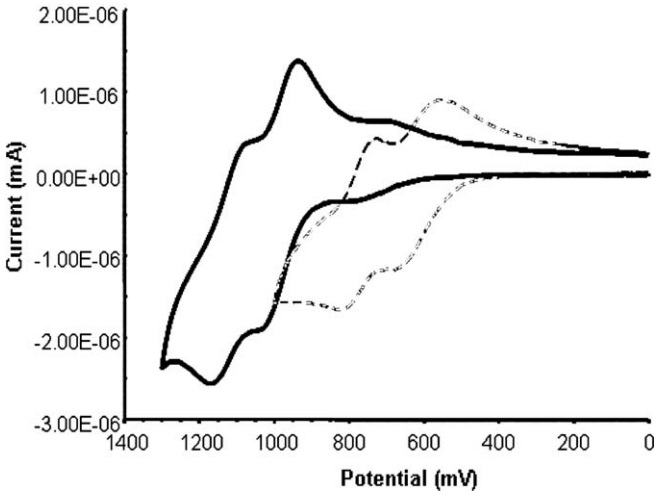

Fig. 4. Cyclic voltammograms of $[WCo_3(MeSn)_2(CoW_9O_{34})_2]^{10-}$ at pH 5 (solid line) and $[WCo_3(H_2O)_2(CoW_9O_{34})_2]^{12-}$ at pH 6 (broken line).

water, the pH of which had previously been adjusted to ca. 6. A white cloudy precipitate formed in about 5 min and the mixture was stirred for 1 h before filtration through a Millipore membrane (0.22 μm). The filtrate was concentrated to half volume by heating, and allowed to stand overnight. Orange block crystals (1 g). were separated manually and were confirmed to be the starting tungstocerate salt by X-ray analysis (and by NMR, see below). The pale yellow filtrate was treated with ethanol to yield a pale yellow solid (0.83 g, 28%). The product was characterized by IR (1414.9, 939.5, 839.7, 721.1, 579.6, 544.0, 418.7 cm^{-1}) and by ^{1}H and ^{183}W NMR spectroscopy, the results of which, δ(H) 1.36, $^{2}J_{H-Sn}$ 124 Hz; δ(W) −16.0 (1W), −20.3 (4W), are fully consistent with the formation of $[CH_3SnW_5O_{18}]^{3-}$. Prior to separation of crystals of the starting complex a ^{183}W NMR spectrum of the solution showed only signals for the product and for those of $[Ce(W_5O_{18})_2]^{9-}$ at +51.5 (1W) and +149.1 (4W) ppm.

3.2. Di-tin polyoxometalate linkers

The recent availability of (α,ω-bis(trichlorostannyl)alkanes, $Cl_3Sn(CH_2)_nSnCl_3$ [24], provides an opportunity to covalently link polyoxometalate units using the procedure described here. Two sets of initial experiments demonstrate the ease of this approach.

The dumbbell-shaped anion, $[SiW_{11}O_{39}Sn(CH_2)_4SnSiW_{11}O_{39}]^{10-}$, prepared in high yield as described in the experimental section, was identified by proton NMR which showed only two signals for the four sets of methylene protons, at 1.59 (with $^{2}J_{H-Sn} = 112$ Hz) and 2.15 ppm. Tungsten-183 and tin-119 NMR data are given in Table 5 with those of $[BuSnSiW_{11}O_{39}]^{5-}$ for comparison.

Preliminary light-scattering measurements[1] on aqueous solutions of the oligomers, $[(SnC_4H_8Sn)_{2n}\{WZn(ZnW_9O_{34})_2\}_n]^{10n-}$, described in the experimental section, indicate average *n*-values of about 4. Further synthetic and analytical work directed at longer chain-lengths is in progress and will be reported in due course.

[1] Measurements made by Dr. Guang Liu and Prof. Tianbo Liu.

4. Conclusions

The feasibility of incorporating organotin (and presumably organogermanium) groups into polyoxotungstates by displacement of transition metal centers from preformed heteropolyanions has been demonstrated. This opens new rational aqueous synthetic routes to organic derivatives of polyoxometalates. Coupling of polyoxometalate anions into "dimers" and oligomeric assemblies can be achieved through reaction with α,ω-bis-(trichlorostannyl)alkanes.

Acknowledgments

Acknowledgment is made to the Donors of the American Chemical Society Petroleum Research Fund for support of this research though Grant 39529-AC3. We thank Dr. Guang Liu and Professor Tianbo Liu (Lehigh University) for preliminary light-scattering measurements and advice.

Appendix A. Supplementary material

Synthesis and NMR spectra of $[(RSn)_2Zn_2(PW_9O_{34})_2]^{8-}$ anions. CIF files for all structure determinations have been deposited with the Cambridge Crystallographic Data Centre (288155–288158). Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2006.01.012.

fluorescence decay in aqueous solutions and that has been explained by the emission from non-interconverting rotamers which have different lifetimes due to different rates of intramolecular charge transfer [16].

DSC measurements on a L-tryptophanium hydrogen selenite powdered sample revealed the existence of a second-order transition at −82.5 °C.

We report here these DSC measurements and a thorough single-crystal X-ray diffraction study performed at room and low temperature to unravel the nature of the phase transition.

2. Experimental

2.1. Preparation of L-tryptophanium hydrogen selenite

A few drops of selenious acid were added to an aqueous solution of L-tryptophan. Within a few months transparent light brown crystals of prismatic shape grew from the solution.

2.2. Physical measurements

Single-crystal X-ray diffraction data for the title compound were collected both with a Mach3 diffractometer, equipped with a conventional detector at room temperature and another similar diffractometer equipped with an area detector at 80 K. The room temperature data were collected using ω–2θ scans and CuKα radiation ($\lambda = 1.5408$ Å). The unit cell parameters were determined by least-squares refinement of diffractometer angles ($21° < \theta < 37°$) for 25 automatically centered reflections.

The low temperature data were collected using φ and ω scans and Mo Kα radiation ($\lambda = 0.71073$ Å). The unit cell parameters were determined by least-squares refinement of diffractometer angles ($2.60° < \theta < 36.11°$) for 9018 automatically centered reflections.

For both temperatures the structure was solved by direct methods using SHELXS-97 [17] and refined anisotropically (non-H atoms) by full-matrix least-squares on F^2 using the SHELXL-97 program [17]. All the hydrogen atoms with the exception of that involved in the strong O1–H1···O3 hydrogen bond were allowed to ride on their parent atoms using SHELXL-97 defaults. H1 was freely refined with an isotropic displacement parameter multiple of the parent atom. The crystallographic details and selected interatomic distances and angles are given in Tables 1–4.

Thermal behaviour was studied using a power compensation differential scanning calorimeter DSC Pyris1, from Perkin–Elmer, equipped with a liquid nitrogen Cryofill

cooling unit. Purge was performed with a helium flux (20 mL/min). The crystalline product was powdered to obtain the sample and aluminum pans recommended for non-volatile substances were used for the sample and for the reference. An empty pan was used as the reference. Temperature calibration was performed with cyclohexane (Merck, GC, $x > 99.7\%$) and cyclopentane (Merck, GC, $x > 99.7\%$) [18]. DSC cooling and heating curves were traced at 10, 20 and 50 °C min^{-1} scanning rates, in the temperature range $-170\ °C \leqslant T \leqslant 25\ °C$.

3. Results and discussion

3.1. Structural properties

Tryptophan molecules can be divided in two parts: the hydrophobic ring and the hydrophilic amino-carboxylate tail. In cationic form the tail is positively charged with both the amine and carboxylic group protonated. The indole ring is practically planar, the five-membered ring has an average torsion angle of 0.36(14)° [0.96(9)° at 80 K] and the six-membered ring has an average torsion angle of 1.1(2)° [0.83(2)° at 80 K]. The least-squares plane of the indole ring makes an angle of 51.51(15)° [50.66(10)° at 80 K] with the carboxylic plane.

The stereographic projection about C_α–C_β (C2–C3) shows that the cation adopts a staggered conformation with N1 *gauche* to C4 that is *gauche* to C1. This conformation has been named the G+ conformer, according to Cao and Fisher [19]. This latter study, using ab initio molecular orbital calculations with a non-aqueous self-consistent reaction field (SCRF), identified three possible conformers of the zwitterionic aminoacid. The dominant conformer was found to be the one with N1 *gauche* to C4 that is *trans* to C1, determined by comparison of the predicted fundamental vibrational frequencies and intensities with the experimental IR spectra.

In the title compound the conformation of the positively charged aminoacid molecules practically does not change with the lowering of the temperature, as seen by the value of the torsion angles: N1–C2–C3–C4, 55.8(4)° and C1–C2–C2–C4 −65.8(4)° at room temperature and 55.2(2)° and −66.3(2)°, respectively, at low temperature.

The differences between the structure at room and low temperature are found in the geometry of the carboxylic group. While the length of the C–O double bond does not change significantly with temperature [1.232(4) Å and 1.237(2) Å for 80 K], the single C–O bond elongates from 1.278(4) Å to 1.288(3) Å as the temperature decreases. This suggests that the hydrogen atom in this group is closer to O1 at lower temperatures.

The geometry of the anion does not change much with the temperature as seen in Table 2. The $HSeO_3^-$ is pyramidal with one short Se–O bond, one long and another of intermediate length [Se–O3, 1.711(3) Å (at 293 K), 1.7224(16) Å (at 80 K)].

There is a hydrogen atom (H1) strongly shared between the anion (O3) and the cation (O1), in a strong H-bond

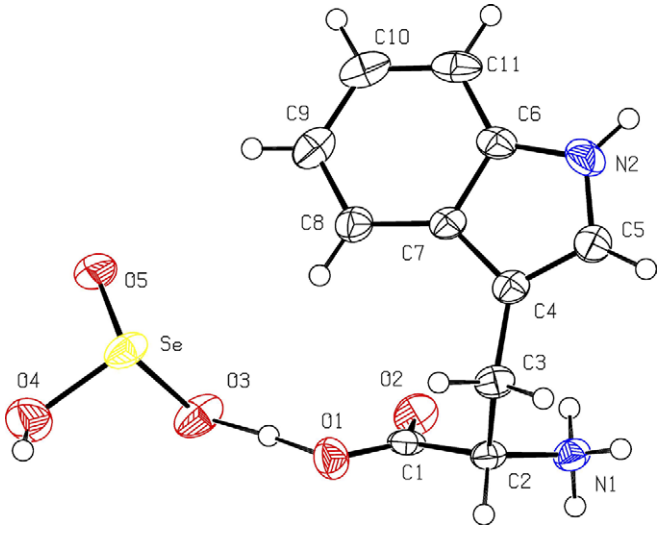

Fig. 1. ORTEPII plot of the title compound. Displacement ellipsoids are drawn at the 50% level.

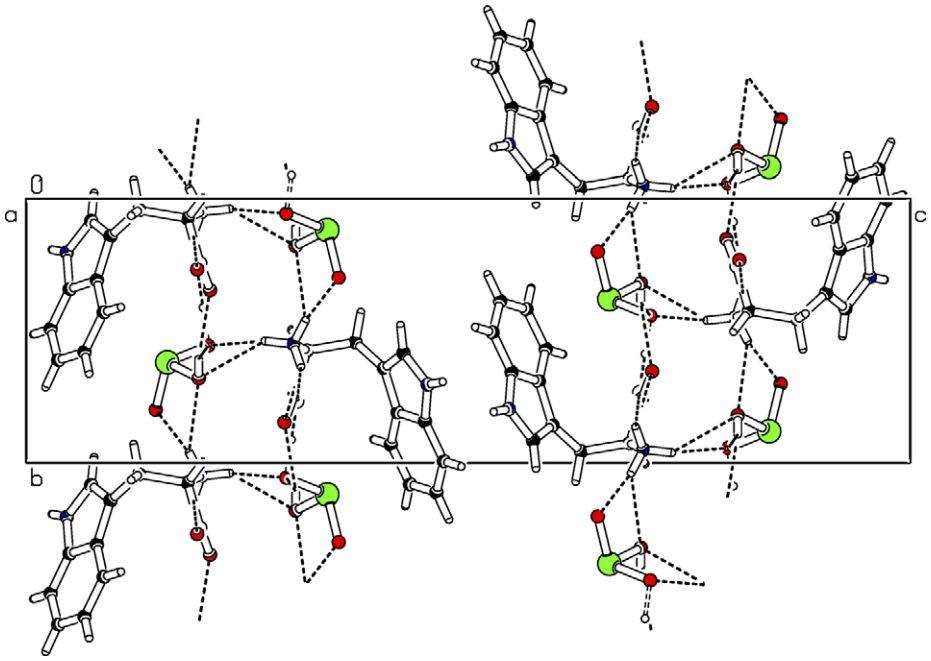

Fig. 2. Conventional hydrogen bond pattern viewed along the *a* axis.

(Fig. 1). The free refinement of this atom has shown that at room temperature H1 locates halfway between O1 and O3 as seen by the distances O1–H1 1.23(5) Å and O3–H1 1.26(5) Å. Difference electron density shows that the most likely explanation for such unusual O–H distances is that the proton is disordered between the O atoms. At low temperature O1–H1 decreases to 0.71(3) Å and O3–H1 increases to 1.82(3) Å, showing an ordering of the proton involved into an O1–H···O3 bond.

In the crystal, anions and cations assemble forming a vast 3-dimensional network of hydrogen bonds. The bond O4–H4···O3^{i} (i: $x-1,y,z$) links the selenite ions in chains along the *a*-axis. Also along the *a*-axis, the bond N1–H1C···O1^{ii} (ii: $x+1,y,z$) joins the cations in chains. Those chains are connected by other H-bonds between the anions and cations as described in Tables 3 and 4, where one can find bifurcated and trifurcated bonds.

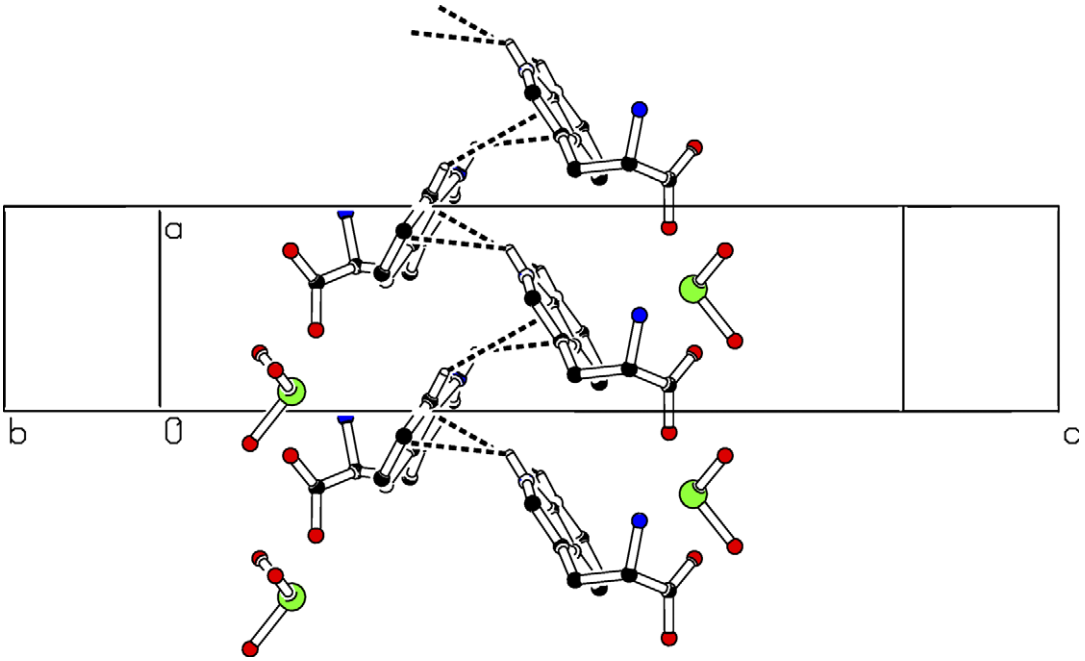

Fig. 3. X–H···π interactions shown as dashed lines. All hydrogen atoms not involved in these bonds were omitted for clarity.

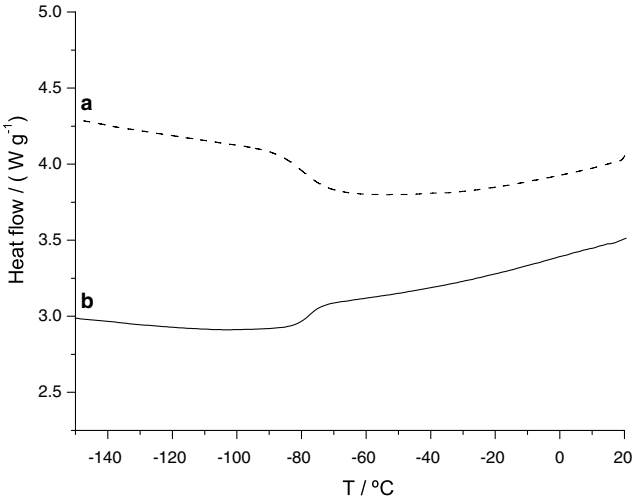

Fig. 4. Typical DSC L-tryptophanium hydrogen selenite (a) cooling curve and (b) heating curve, for the temperature range investigated.

Projecting the crystal packing down the *a*-axis one sees double layers of aminoacid tails and pyramidal anions strongly linked by hydrogen bonds (Fig. 2). Between those layers there are double layers of indole rings connected by N–H···π and C–H···π bonds, with the π electron system of the aromatic rings acting as the acceptor. The N2–H2 bond points towards the edge of the C6–C11 ring of a neighbouring molecule with the shared hydrogen situated above the centre ring. The H2-centroid distance is 2.681 Å, the interaction angle N2–H2···centroid is 127.83°, and the angle between the H2-centroid line and the ring perpendicular is 25.80°. This geometry is described as type III by Malone et al. [20]. The same geometry is seen in the intermolecular interaction, C11–H11···(N2–C6 centroid), with a slightly larger distance, 3.184 Å, and angle, 131.40°. Fig. 3 shows these intermolecular interactions joining the cations.

3.2. Thermal behaviour

The thermal behaviour of L-tryptophanium hydrogen selenite between $T = 25$ °C and $T = -170$ °C is illustrated in Fig. 4. For all scan rates investigated a second-order transition is observed on cooling. The behaviour is reversible on heating, with a transition temperature $T = -82.5$ °C. These observations are compatible with the existence of the hydrogen disorder at room temperature found in the X-ray experiments.

4. Conclusion

A new selenite compound has been synthesised and characterised by DSC and X-ray single crystal diffraction. The crystal structure of the L-tryptophanium hydrogen selenite has been solved at room and low temperature. An ordering of a hydrogen atom shared between the anion and the cation is seen and that is the probable cause of the DSC observed anomaly at −82.5 °C.

unsaturated, or contain readily exchangeable ligands, such as water or other solvent components [5].

The use of amino acid-derived Schiff bases as model systems has been mainly justified by the participation of these ligands in similar biological compounds in key biological reactions [2–10]. The magnetic, electrochemical and spectroscopic studies of the synthetic systems provide important information about redox and spin states of the metal centre(s), the magnitude of the exchange interaction, and the coordination environment which has a profound influence on the functional properties of the complexes. These models also allow structure and the magnetic, electronic, and optical properties of the metal sites present in biological systems to be correlated [11–15].

In a recent paper on $Fe_2(\mu\text{-carboxylate})_2(L_2)_2$ complexes, where L is a Schiff base derived from an α-amino acid and salycilaldehyde, we postulated that the dimeric iron(III) complexes are hexacoordinated, the metal ion being surrounded by water molecules, the salicylidenimine ligand and bridging carboxylate groups [16]. In this work, we report the synthesis of mixed valence dinuclear iron(II,III) complexes of the type $[Fe_2L_2(H_2O)_4](NO_3)(H_2O)_3$, where L is a Schiff base derived from an α-amino acids (glycine or L-isoleucine) and 5-bromosalicylaldehyde (Fig. 1). We have characterised these complexes using different spectroscopic techniques, plus magnetic susceptibility, conductivity, and electrochemical measurements.

2. Experimental

The reagents 5-bromosalicylaldehyde, glycine (Gly) and L-isoleucine (Ile) were purchased from Merck (analytical grade) and were used without further purification.

The ligands were synthesised as described by Paredes et al. [16] (yields 73–85%). Both ligands synthesised by this method are solids and were isolated as potassium salts. They were characterised by elemental analysis, and FTIR, UV–Vis and ^{1}H NMR spectroscopic methods.

The mixed valence complexes were prepared as described by Casella et al. [17]. The ligand (1 mmol) was dissolved in methanol at room temperature, and 1 mmol of potassium hydroxide was added. Finally, $Fe(NO_3)_3 \cdot 9H_2O$ (1 mmol), was added directly to the solution. The reaction mixture was left for 5–6 h at room temperature with continuous stirring under nitrogen. The KNO_3 formed was filtered off and the solution was concentrated; the product was precipitated with *n*-hexane and was dried under vacuum. The complexes synthesised by this method are dark violet amorphous solids with molecular formulae $[Fe_2L_2(H_2O)_4](NO_3)(H_2O)_3$ (yields 60–70%). In general, the complexes are highly insoluble in most low-polarity organic solvents and, unfortunately, single crystals suitable for X-ray diffraction were not obtained.

*$[Fe_2(BrSA\text{-}Ile)_2(H_2O)_4](NO_3)(H_2O)_3$ (**2**):* Yield: 76%. *Anal.* Calc. for $C_{26}H_{42}Br_2N_3O_{16}Fe_2$: C, 33.79; H, 4.58; N, 4.55; Fe, 12.08. Found: C, 34.71; H, 4.41; N, 4.67; Fe, 12.44%. Conductivity in DMF at 25 °C, $\Lambda = 64.0$ S cm^2 mol^{-1} L.

Microanalyses were performed with a Fisons elemental analyzer, model EA1108, and with a Shimadzu atomic absorption spectrophotometer, model AA-6200. The infrared spectra (KBr pellets) were recorded using a Bruker spectrophotometer, model AMX300. The Mössbauer spectra of these complexes, as fine powder samples, were obtained with a conventional spectrometer with constant acceleration. The source was 10 mCi ^{57}Co in a Pd matrix. The gamma ray detection was carried out with a Reutes–Stokes detector connected to an Ortec amplifying and selecting system. A 1024 channel Canberra multichannel analyser was used for the data acquisition. The Mössbauer spectra were recorded at 298 K in the absence of an external magnetic field. The reported isomer shift values are relative to sodium nitroprusside. Electrochemical studies were done with a PAR 173 potentiostat and PAR 175 programmer, equipped with a digital coulometer model 179. Polarographic measurements were done with a BAS CV27 cyclic voltammetry setup. Molar conductance was measured at 25 °C on a Radiometer conductimeter, model CDM-83 with a CDC-304 electrode. Cyclic voltammograms of the complexes were recorded in DMF with [TBA][PF_6] as supporting electrolyte in the potential range +1.3 to −1.8 V versus SCE. Ferrocenium was used as an internal reference. Electronic spectra were recorded on a Unicam II UV-Vis spectrophotometer. Variable temperature magnetic susceptibility data (5–300 K) were obtained with a CRYOGENICS Model S600 SQUID susceptometer–magnetometer, calibrated with Hg[$Co(SCN)_4$]. The diamagnetic corrections were calculated from Pascal's constants [18].

3. Results and discussion

The complexes can be considered as species with two six-coordinated iron centres, with the metal ions surrounded by water molecules, and the salicylaldimine ligand coordinated through the imine nitrogen and the phenolic oxygen, constituting a NO_5 donor set. Both metal ions are bridged by the carboxylate groups of the amino acids residues, Fig. 2.

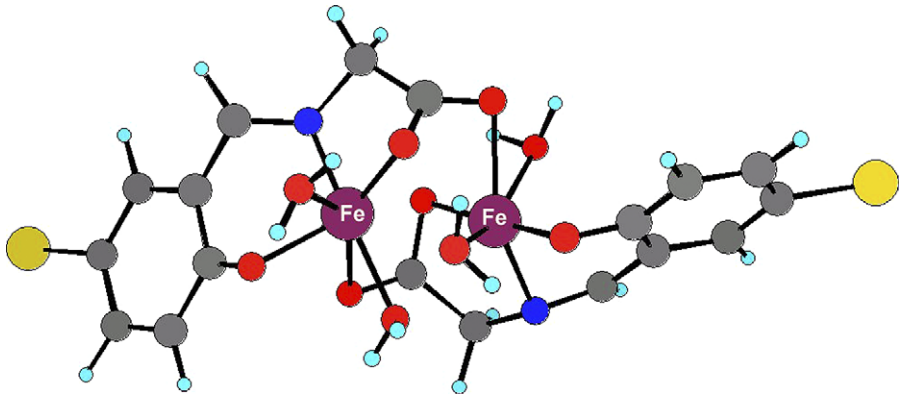

Fig. 2. Structures of dinuclear iron(II,III) complexes with Schiff bases derived from 5-bromosalicylaldehyde and α-amino acids (R = H, Sec-Bu).

3.1. Infrared and UV–Vis spectra

The mixed valence complexes show the same pattern for analogous vibrations. The vibration of the –C=N bond in the complexes is displaced towards lower energies, in comparison with the free ligand (15 cm^{-1} for (**1**) and 21 cm^{-1} for (**2**)). The $–C–O_{phenolic}$ group band is displaced to higher energies (~30 cm^{-1} in both complexes). Two strong bands at 1362–1372 and 1527–1529 cm^{-1}, associated with symmetric and asymmetric stretching absorptions of the carboxylate group, also show a decrease in energy in respect to the free ligand. The difference between these bands is correlated with the coordination mode of the carboxylate ligands. For the free ligands the differences between ν_a and ν_s ($\Delta\nu$) of the carboxylate groups are 224 and 230 cm^{-1} for the glycine and isoleucine Schiff base ligands, respectively. In the complexes, $\Delta\nu$ has a value of about 170 cm^{-1}, indicative of a bridging carboxylate group between the two metal atoms [19–21]. The spectra of the two complexes show a broad band at 3400 cm^{-1} due to coordinated water molecules. The single absorption at 1383 cm^{-1} is indicative of an ionic nitrate group [21].

In agreement with the infrared data and reported assignments for analogous diiron(III) complexes [16], it is possible to infer that each iron ion in these mixed valence complexes has a hexa-coordinated environment, in which the metal ion is coordinated to two water oxygens, a phenol oxygen, an imine nitrogen and two carboxylate oxygen atoms; the latter groups bridging both iron atoms (Fig. 2).

The electronic spectra of the complexes are strongly dominated by the electronic transitions due to the iron-salicylaldiminate cromophores. The charge transfer bands, from phenolate to the metal, are of intermediate intensity, appear near 450 nm, and are responsible for the red-purple colour of the complexes. These transitions can be assigned to a charge transfer from the pπ orbital of the phenolic oxygen to the dπ orbital of the iron centre [22,23].

3.2. Mössbauer spectroscopy

To assign the oxidation states of the iron centres in these dinuclear complexes, Mössbauer spectroscopy was used, since the isomer shift and the quadrupolar splitting can be related directly to populations of valence shell orbitals. Fig. 3 shows a representative spectrum and the fit of the data using least squares. The Mössbauer parameters obtained for the iron complexes are summarised in Table 1.

The Mössbauer spectra of both complexes exhibit two highly asymmetric quadrupole doublets. The integrated absorption intensities of the two spectral subcomponents show a 1:1 ratio, and therefore the relative amount of iron in both sites is the same.

For the first site of complex (**1**) the isomer shift (δ_1) is 0.51 mm s^{-1} and for complex (**2**) it is 0.56 mm s^{-1}. The quadrupolar splitting values (ΔE_{Q1}) are 0.91 mm s^{-1} for (**1**) and 0.96 mm s^{-1} for (**2**). These data correspond to high spin iron(III) ions ($S = 5/2$, $^6A_1$) [16,24–27]. For the second site, the chemical shifts (δ_2) are 1.40 mm s^{-1} for (**1**) and 1.41 mm s^{-1} for (**2**). The quadrupolar splitting (ΔE_{Q2}) is 2.68 mm s^{-1} for (**1**) and 2.65 mm s^{-1} for (**2**); these values correspond to high spin iron(II) ($S = 2$, $^5T_2$) [25–27].

On the other hand, complexes (**1**) and (**2**) have similar hyperfine parameters for site one. This allows us to assume that the coordination sphere and distortion of the octahedral geometry are the same for both complexes. The previous analysis can also be applied to the second site, since the hyperfine values for the two complexes are comparable. Furthermore, in these Fe(II,III) complexes, the iron(III) ion has a lower electronic density and a greater distortion of the octahedral geometry than in the analogous

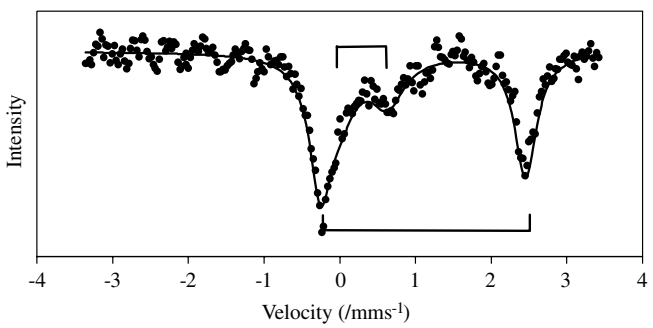

Fig. 3. Mössbauer spectrum for (**1**) at 300 K.

Table 1
Mössbauer parameters for dinuclear mixed valence complexes at 298 K

Complexes	I.S.[a] (mm s^{-1})		ΔE_Q[b] (mm s^{-1})		A_1/A_2[c]
	Site 1	Site 2	Site 1	Site 2	
(**1**)	0.51	1.39	0.91	2.67	1.05
(**2**)	0.56	1.41	0.96	2.65	1.32

The values of the chemical shifts are referred to sodium nitroprusside.
[a] Isomer shift.
[b] Quadrupolar splitting.
[c] Area ratio.

Fe(III,III) complexes ($\delta = 0.61$–0.66 mm s^{-1}, $\Delta E_Q = 0.70$–0.76 mm s^{-1}).

Lippard et al. have shown that high spin iron(II) dinuclear complexes with carboxylate bridges have a smaller isomer shift when the coordination number is lower [28]. For example, iron (II) sites with coordination number four tend to have a smaller isomer shift (1.0–1.1 mm s^{-1}) compared with those with coordination number six (1.3 mm s^{-1} approximately). The same authors also found that the carboxylate bridged diiron(II) species with a single N and variable number of O donor atoms present different isomer shifts. Iron(II) centres with a tetrahedral environment have an isomer shift of 1.04 mm s^{-1}. However diiron(II) complexes with an NO_4 environment in a square pyramidal geometry have an isomer shift of 1.12 mm s^{-1}, while in pentacoordinated complexes with a trigonal bipyramidal geometry the isomer shift is 1.19 mm s^{-1}. Finally, octahedral complexes with an NO_5 coordination sphere have an isomer shift of 1.35 mm s^{-1}. In our case, the Mössbauer data obtained for the two complexes show that the isomer shift for the iron(II) site is 1.40 mm s^{-1}, corroborating an octahedral arrangement for this type of iron centres. Consequently, it is correct to propose for complexes (**1**) and (**2**) a mixed valence (II,III) species with a pseudo-octahedral arrangement for each iron atom.

3.3. Cyclic voltammetry

The electrochemical behaviour of the dinuclear complexes was studied by cyclic voltammetry. The redox parameters are summarised in Table 2. The redox processes were observed at essentially identical potentials for complex (**1**) and complex (**2**). This result is indicative of a similar electronic environment for the metal ions in both complexes. Fig. 4 shows the voltammogram of mixed valence complex (**1**). In the first cycle (reduction sweep), only two redox processes are seen; the first peak at −0.51 V can be attributed to the Fe(II,III)/Fe(II,II) redox process and the second peak at −0.90 V, that involves more than one electron, may be assigned to the reduction of the Fe(II,II) species. In the oxidation sweep, it is possible to observe three processes: the first one at −1.00 V, can be assigned to the regeneration of the Fe(II,II) species; the second process at −0.53 V involves the formation of the Fe(II,III) species, and the third process at −0.18 V can be assigned to the formation of the Fe(III,III) species. In the second cycle a new reduction process at −0.18 V corresponding to the Fe(III,III)/Fe(II,III) reduction process is observed. In summary, in the first cycle it is possible to find only two reduction processes and three oxidation processes, while after this cycle, three reduction and three oxidation processes are detected, with half wave potentials at $E^1_{1/2} = -0.21$ V, $E^2_{1/2} = -0.48$ V and $E^3_{1/2} = -0.95$ V. Complex (**2**) shows a similar behaviour as complex (**1**), with half wave potentials at $E^1_{1/2} = -0.22$ V, $E^2_{1/2} = -0.50$ V and $E^3_{1/2} = -1.13$ V.

The redox processes are quasireversible and correspond to a diffusion-controlled process. It is important to remark that under the same experimental conditions, the cyclic voltammograms for the free ligands do not present any redox process, and therefore all the redox process observed can be attributed to the metal centres.

Previous work on the substituent effect on the electrochemical potentials was done for a series of [FeIII-(X–SA)$_2$trien]$^+$ complexes, (where SA = salicylaldehyde, trien = triethylamine, and X represents different substituents on the benzene ring, such as, H, NO_2, OCH_3, Br, Cl) [29,30]. The redox process in these complexes involves a one-electron transfer, which was assigned to the Fe(III)/Fe(II) reduction. The half wave potentials vary between −0.21 and −0.53 V versus SCE, depending on the substituent. For example, electron-donating groups such as OCH_3 make the metal centre more electron-rich thus hindering the reduction process. Electron-withdrawing groups, such as Cl, Br or NO_2, have an opposite effect on the reduction process [29–31].

A similar result is obtained for complexes (**1**) and (**2**) as seen in the second cycle; the bromine-substituted complexes have their redox processes at lower potentials than the analogous unsubstituted diiron(III) complexes. This difference may be attributed to the inductive effect of the bromine atom on the benzene ring. From the difference of the redox potentials, $E_2 - E_1 = (RT/F)\mathrm{Ln}K$, the conproportionation constant K at 293 K of the following reaction can be calculated.

$$Fe^{II}Fe^{II} + Fe^{III}Fe^{III} \rightarrow 2Fe^{II}Fe^{III}$$

Table 2
Electrochemical data for dinuclear mixed valence complexes[a]

Complexes	Redox wave	E_{pa}	E_{pc}	ΔE	$E_{1/2}$	i_{pa}/i_{pc}
(**1**)	I	−0.18	−0.24	0.04	−0.21	0.45
	II	−0.43	−0.53	0.10	−0.48	1.07
	III	−0.90	−1.00	0.10	−0.95	1.17
(**2**)	I	−0.20	−0.24	0.04	−0.22	0.63
	II	−0.44	−0.56	−0.12	−0.50	0.76
	III	−0.92	−1.24	0.32	−1.13	0.76

[a] Potential values are in volts and referred to SCE. E_{pa} and E_{pc} are the anodic and cathodic peak potentials respectively. $\Delta E = E_{pa} - E_{pc}$; $E_{1/2} = (E_{pa} + E_{pc})$.

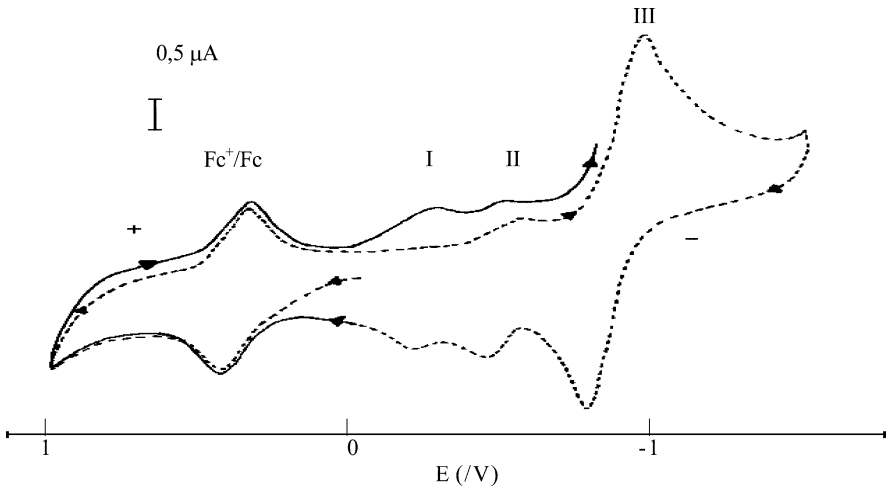

Fig. 4. Cyclic voltammogram of (**1**).

The K values obtained for the complexes were 3.7×10^4 and 5.4×10^4 for (**1**) and (**2**), respectively. These values are consistent with moderate electron coupling and charge delocalisation between the metal centres.

The degree of interaction between the two centres depends on the bridging ligand and on the nature of the metal. For example, a molybdenum complex with perfluorophthalate as bridging ligand presents a K value of 13. However, when the ligand is oxalate the K value is 5.4×10^4; the greater delocalisation is attributed to the shorter bridging group. On the other hand, when molybdenum is substituted by tungsten, in the oxalate complex, the K value is 1.3×10^{12}, that is, the extent of delocalisation is increased [32].

3.4. Magnetic susceptibilities

The magnetic susceptibilities of $[Fe_2(L_2(H_2O)_4](NO_3)\text{-}(H_2O)_3$ were recorded over the temperature range 5–300 K. The plot of the reciprocal molar susceptibility versus temperature for complex (**1**) is shown in Fig. 5, and corresponds to a Curie–Weiss behaviour. The glycine-derived Schiff base complex has an effective magnetic moment per molecule (μ_{eff}), which decreases from 6.82 μ_B at 300 K to 5.96 μ_B at 5 K. The trend is similar for (**2**), that is, μ_{eff} is 6.65 μ_B per molecule at 300 K and decreases to 5.96 μ_B at 5 K. For these complexes the μ_{eff} values at 300 K are lower than the expected spin-only value of 7.68 μ_B for the moment of two independent high spin iron(III) and iron(II) ions ($S = 5/2$, $S = 2$). The decrease of μ_{eff} at lower temperature indicates that the two iron centres are weakly antiferromagnetically coupled.

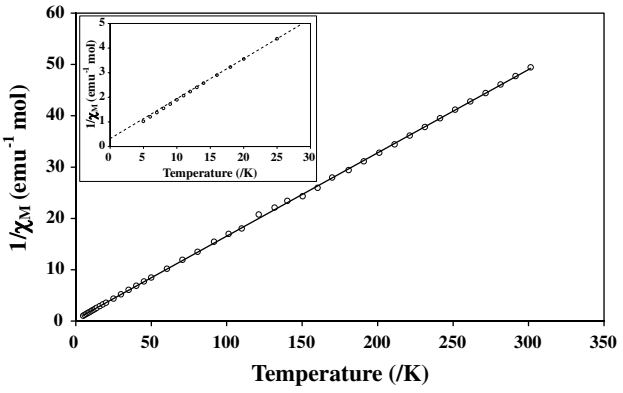

Fig. 5. Temperature dependence of the reciprocal molar susceptibility for (**1**).

The magnetic susceptibility of the mixed valence binuclear iron(II,III) complexes was analysed using the van Vleck equation, with a spin exchange Hamiltonian $\boldsymbol{H} = -2JS_1 \times S_2$, where $S_1 = 5/2$ and $S_2 = 2$. All the calculations were performed using a least-squares minimisation routine, where $\mathrm{SSQ} = \sum_i [(\chi_i^{obs} - \chi_i^{calc})/\chi_i^{obs}]^2$. The parameter $R = \mathrm{SSQ}/(n-p)$, where n is the number of experimental points and p is the number of parameters allowed to vary in the minimisation routine, is reported. The final magnetic parameters obtained for complexes (**1**) and (**2**) are $J = -0.17\ \mathrm{cm}^{-1}$, $g = 2.62$, $\theta = -2.50$ and $J = -\ 0.14\ \mathrm{cm}^{-1}$, $g = 2.53$ $\theta = -2.23$ K, respectively, indicating that the two iron ions are weakly antiferromagnetically coupled.

The results obtained for complexes (**1**) and (**2**), are comparable to those obtained for dinuclear iron(III) complexes with analogous ligands, in which the J values vary between -0.09 and $-0.21\ \mathrm{cm}^{-1}$ as reported in previous work, and as shown in Table 3 [16].

On the other hand, these values can be also compared with those reported for other carboxylate-bridged complexes, in which the magnetic properties of the diiron complexes depend significantly on metal–metal distances, as well as on the nature of the other bridging ligands [30]. Table 3 presents the J values for a series of different dinuclear iron complexes with carboxylates bridged. Nevertheless, according to these data, it is possible to infer that the weak antiferromagnetic coupling interaction exhibited by complexes (**1**) and (**2**) can be explained by a large distance

Table 3
Magnetic parameters for carboxylate-bridged iron complexes

Complexes	Distance Fe···Fe (Å)	J (cm^{-1})	Ref.

between both metal centres, and by the absence of a more efficient exchange pathway such as oxo, hydroxo or alkoxo bridges [16,19,33–39].

4. Conclusions

Two hexacoordinated mixed valence complexes, with an NO_5 coordination sphere, were obtained with Schiff base ligands derived from 5-bromosalicylaldehyde and glycine (**1**) or isoleucine (**2**). The FTIR data show that each ligand is coordinated to the metal centres through the imine nitrogen, phenolic oxygen and carboxylate groups, which also act as bridging ligands between both iron atoms. The remaining coordination positions are occupied by water molecules.

With Mössbauer spectroscopy it was possible to find two sites for the iron atoms. The isomer shifts and quadrupolar splittings for both sites correspond to high spin Fe(II) and Fe(III). The hyperfine values obtained for both complexes are comparable, and indicate that these complexes have a greater distortion than analogous Fe(III,III) complexes.

From cyclic voltammetry the presence of a mixed valence Fe(II,III) complex was confirmed. In the case of the studied bromine-substituted ligands, the complexes show lower values for all the redox potentials as compared to the complexes with unsubstituted ligands. This difference is attributed to the presence of the electron-withdrawing groups on the aromatic ring.

Magnetic susceptibility data for complexes (**1**) and (**2**) show that the two iron centres have a weak antiferromagnetic exchange coupling, which is principally attributed to three factors: (i) the strong distortion of the octahedral geometry, (ii) relatively large Fe-Fe distance and (iii) the absence of a more efficient exchange pathway. The J values obtained for both complexes are comparable to other dinuclear iron complexes with carboxylate bridges.

From the complete analyses done in this work, it is important to remark that when 5-bromosalicylaldehyde is used to form the Schiff base, a mixed valence species is obtained. Apparently the electronic effect of the bromine atom in the aromatic ring stabilises a mixed valence species.

addition, two silver complexes containing quinone ligand, which do not need redox stabilizing ligands, that are analogous to the title complexes have also been reported. In these cases, the Ag–O distances are long, 2.37–2.47 Å [9,14].

In light of these reports, and as part of our continuation of silver coordination chemistry investigation [15–19], we have endeavored to discover what catechol structures could be used to obtain stable, characterizable silver complexes and to better understand silver catechol reactivity. We now report that stable silver catechol complexes can be prepared but that the ability to obtain these complexes is limited to catechols having highly electron-withdrawing substituents (four halides, in these examples); yet they still require triphenylphosphine ligand stabilizers. The preparation and solid-state structures of these first stable silver catechol complexes, bis-triphenylphosphine-tetra-halocatechol silver, are described below.

2. Experimental

2.1. Preparation of $Ag(Br_4C_6(OH)O)(Ph_3P)_2$

Solution ligand exchange of the catechol with silver acetate was successfully utilized to isolate the title complex according to the following scheme:

$$Ag(O_2CCH_3)(Ph_3P)_2 + Br_4C_6(OH)_2 \rightarrow Ag(Br_4C_6(OH)O)(Ph_3P)_2 + HO_2CCH_3$$

To 134 mg of $Ag(O_2CCH_3)(Ph_3P)_2$ [20] was added 7 mL toluene and 88 mg tetra-bromocatechol, $Br_4C_6(OH)_2$ (Aldrich). A clear yellow solution resulted, which was layered with an equal volume of ether. Yellow crystals (0.12 g) grew overnight. DSC shows a single decomposition exotherm at 167 °C (the starting silver acetate phosphine complex shows this transition at 192 °C). For $C_{42}H_{31}O_2AgP_2Br_4$ elemental C, H (theory) C, H = 47.65 (47.70), 2.81 (2.93). The Raman spectrum is dominated by the triphenylphosphine ligand bands: primarily 998, 1025, and 1096 cm^{-1}. The silver tetra-bromo-catechol complex was submitted for NMR analysis to ascertain its molecular structure in solution (DMSO-d_6). While both the proton and P-31 spectra (supplementary data section) are suggestive of the proposed hydrogen-bonded dimer structure, long term C-13 analysis, due to inherent solution instability, is not.

2.2. Preparation of $Ag(Cl_4C_6(OH)O)(Ph_3P)_2$

Ag_2O as the deprotonating base for the catechol ligand, in place of acetate exchange from silver acetate, was also used to isolate the complex, according to the following scheme:

$$Ag_2O + 2Cl_4C_6(OH)_2 + 4Ph_3P \rightarrow 2Ag(Cl_4C_6(OH)O)(Ph_3P)_2 + H_2O$$

To 60 mg Ag_2O and 0.26 g Ph_3P in 5 mL toluene was added 128 mg tetra-chlorocatechol, $Cl_4C_6(OH)_2$ (Aldrich). Stirring at room temperature produced a nearly clear solution, which was colorless on filtration. A mixture of pink crystals in a slight oil remained after slow evaporation. The crystals (0.18 g) were removed after ether washing. DSC is completely similar to the bromine complex, an exotherm centered at 170 °C, preceded by a melting point endotherm at 155 °C. For $C_{42}H_{31}O_2AgP_2Cl_4$ elemental C, H (theory) C, H = 57.32 (57.34), 3.54 (3.53). The Raman spectrum is dominated by the triphenylphosphine ligand bands: primarily 998, 1025, and 1097 (1092 shoulder) cm^{-1}.

Differential scanning calorimetry (DSC) was obtained on a TAInstruments Model 910, heating at 10 °C/min under nitrogen flow (~50 mL/min).

Elemental analysis was obtained from Prevalere (8282 Halsey Road, Whitesboro, NY 13492).

Raman spectra were collected in micro mode with a JY Horiba LabRam, equipped with a CCD dectector, at 180 backscatter with a MSPlan 100× objective. The excitation wavelength was 785 nm with the laser power at approximately 300 mW, and the collection time was 100 s.

2.3. Single-crystal X-ray diffraction

Single-crystal structure determination by X-ray diffraction was performed on a Nonius KappaCCD [21] equipped with a normal focus, sealed-tube X-ray source. Data reductions were performed using DENZO-SMN [22]. The structures were solved and refined by using the SHELXTL [23]

3. Results and discussion

Our attempts to prepare silver complexes of various *ortho*-di-hydroxybenzenes under basic conditions rapidly resulted in metallic silver, regardless of the substituents. Using milder conditions, such as simple replacement of the acetate from water-soluble silver acetate, still resulted in rapid formation of metallic silver, again regardless of the derivative. The high reactivity of these catechols, coupled with the lack of silver catechol complexes reported in the literature, indicated that a different approach was clearly needed.

Organo-phosphines are known to act as good stabilizers of metal ions in unusual or unstable oxidation states [25,26]. Considering the high reactivity of Ag^+ with catechols, this ion might be thought of as a suitable candidate for stabilization with phosphine-based ligands. Two approaches were successful in the preparation of phosphine-stabilized silver catechol complexes, preparation of the complex from silver acetate or its Ph_3P derivative (acetic acid by-product), and silver oxide (water by-product):

$$Ag_2O + 4Ph_3P + 2catechol \rightarrow 2Ag(catechol)(Ph_3P)_2 + H_2O$$

$$[Ag(O_2CCH_3)]_2 + 4Ph_3P + 2catechol \rightarrow 2Ag(catechol)(Ph_3P)_2 + 2HO_2CCH_3$$

The triphenylphosphine complex of silver acetate, $Ag(O_2CCH_3)(Ph_3P)_2$, is well known whose structure has been reported [20]. Similar to the long-chain analog, C_{18} (stearate), $AgStearate(Ph_3P)_2$ [27], the acetate is chelated to the silver, and the two phosphines simply fill out the coordination sphere. For the catechol reactions, it was found that either the $Ag(O_2CCH_3)(Ph_3P)_2$ can be prepared separately, or it can be generated in situ.

Given that electron-rich catechols were found to be exceedingly reducing for Ag^+, even in the presence of the stabilizing ligand, highly electron-withdrawing groups were investigated as most likely to form stable silver catechol complexes. While these halogenated catechols do reduce silver acetate to metallic silver in the absence of the stabilizing ligand, in the presence of triphenylphosphine, however, rapidly cleared solutions were formed that slowly grew crystals suitable for X-ray structure analysis.

While the silver tetra-bromo-catechol complex was successfully obtained from silver acetate with triphenylphosphine as a stabilizing ligand, the tetra-chloro-catechol complex did not form suitable crystals under these reaction conditions. A second approach was taken to facilitate the complex formation and crystallization. In this case, we found that Ph_3P appears to partially "dissolve" Ag_2O, presumably a low molecular weight oligomer of $[Ph_3P–Ag–O]_x$, which should simply yield H_2O as a byproduct. Using this approach, well-formed crystals of the tetrachloro-catechol complex were obtained. This complex is seen to be completely structurally isomorphous with the bromine analog, Fig. 1, including the chelate function of the catechol via the O–Ag–Cl ring.

While normal Ag–O bonds between the silver and oxygen are observed in the $Ag(Br_4C_6(OH)O)(Ph_3P)_2$ and $Ag(Cl_4C_6(OH)O)(Ph_3P)_2$ complexes, 2.390(3) and 2.3575 (19) Å, two significant observations related to the Ag–O bonding can be made. First, unlike the normal catechol

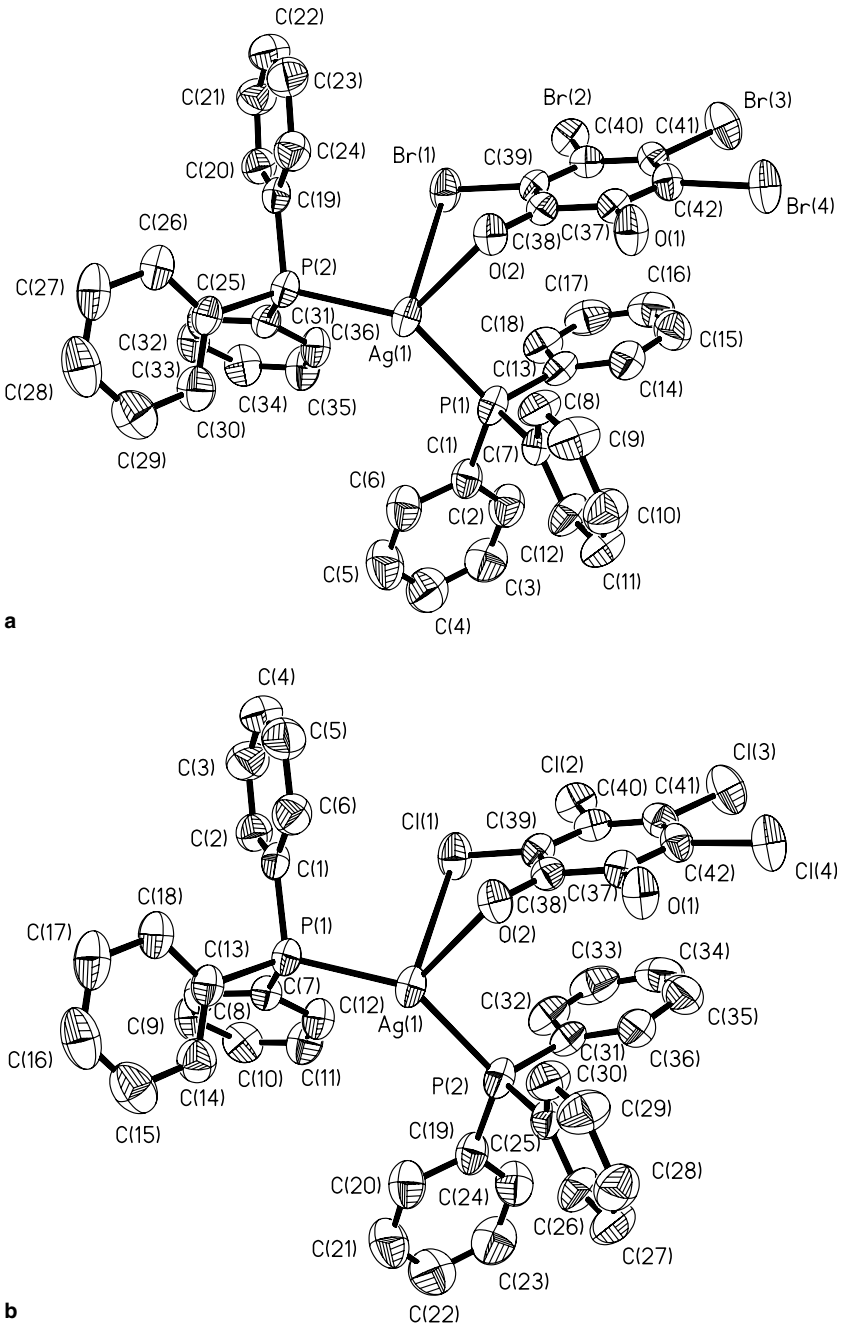

Fig. 1. ORTEP diagrams of: (a) $Ag(Br_4C_6(OH)O)(Ph_3P)_2$, and (b) $Ag(Cl_4C_6(OH)O)(Ph_3P)_2$ with 50% probability of thermal ellipsoids, showing atomic numbering schemes (hydrogen atoms omitted for clarity).

chelating functionality in which both oxygens are bound to the same metal ion, only one of the oxygens is bound to the silver. Second, similar to the silver–phenol complexes noted above, there is a significant Ag–X bond involving the halide ortho to the coordinated phenolic oxygen, Ag–Br = 3.1864(6) Å and Ag–Cl = 3.1838(9) Å. These are long Ag–X interactions compared to previously reported Ag–X–organic ligands (Ag–Br 2.7–3.0 Å [7–9], Ag–Cl 2.5–2.9 Å) [7,10,11]. The bond distances and crystallographically significant orientation makes it clear that the formation of an O–Ag–X chelated structure is more important than that of an O–Ag–O chelated structure.

An interesting unique feature of these structures is O–H···O hydrogen bonding interactions that result in crystal structure stabilization by formation of dimers as shown in Fig. 2. The available O(1)–H is bonded, about 2.60 Å, to the silver bound O(2) in the adjacent molecule.

In addition, when viewed in the solid-state crystal packing, Fig. 3, there are significant π–π interactions between aromatic rings of a phosphine phenyl group and the catechol. The stacking distance is about 3.41 Å, which is similar to that reported for other silver complexes [28].

Overall, the ability to prepare a stable silver catechol complex is limited to the highly electron-withdrawing

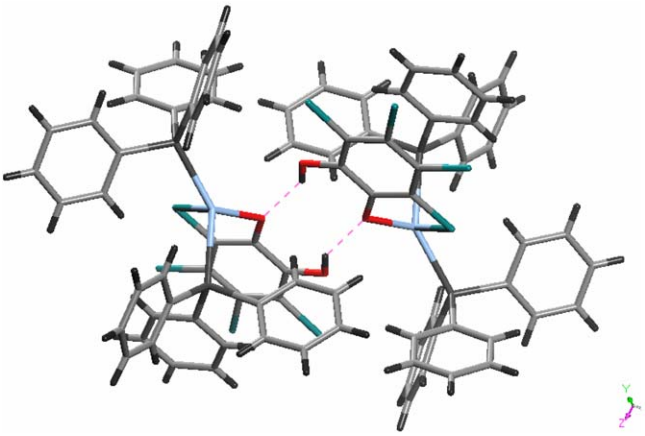

Fig. 2. Packing of $Ag(X_4C_6(OH)O)(Ph_3P)_2$ complexes in the unit cell showing hydrogen bonding associations between molecules forming a dimer in the solid-state lattice.

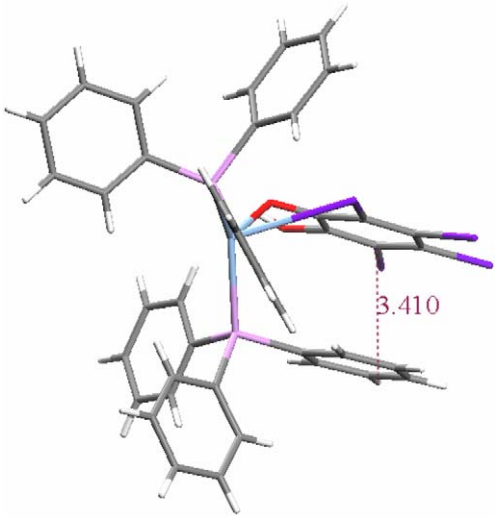

Fig. 3. Aromatic π–π interactions in $Ag(X_4C_6(OH)O)(Ph_3P)_2$.

tetra-halo-catechol in the presence of Ph_3P as a stabilizing ligand. All attempts to obtain silver catechol complexes having fewer halide groups on the catechol ligand, $BrH_3C_6(OH)_2$, $Br_2H_2C_6(OH)_2$, and $Br_3HC_6(OH)_2$, were unsuccessful, even using the triphenylphosphine stabilizing ligand.

4. Conclusions

The solid-state structures of the first verifiable silver complexes containing bound catechol ligands are reported. Only catechols containing highly electron-withdrawing groups, such as tetra-substituted catechols coupled with triphenylphosphine stabilizing ligands, can be used to obtain these complexes. Without these two key features, the silver is too readily reduced to the metal. In both complexes reported here, $Ag(Br_4C_6(OH)O)(Ph_3P)_2$ and $Ag(Cl_4C_6(OH)O)(Ph_3P)_2$, a single oxygen of the catechol is coordinated to the silver along with the *ortho*-halogen to form an O–Ag–X chelated structure. The second phenolic group is not involved with the coordination of the metal. Additional hydrogen bonding between the catechol groups provide for the formation of dimeric species in the solid state.

was prepared and used as a catalyst precursor for epoxide ring opening [16]. This reaction makes use of bulky 2,6 substituents to create a pocket in a similar manner to the designer Lewis acid catalysts based on aluminium tris-phenoxo complexes [17]. For these reactions the influence of local coordination environment is important and this can be varied more easily by changing substituents on the aromatic ring of phenoxo ligands than it can with the alkoxo ligands in the complexes $[TiCl(OR)_3]$ which also have an extensive use in organic synthesis [18]. However, chloro-tris-phenoxo complexes containing *ortho*-phenyl ring substituents are not well known. $[TiCl(OC_6H_2Me_3\text{-}2,4,6)_3]$ has been prepared [19,20] and some bis-amine adducts formed [20]. $[TiCl\{OC_6H_3(CHMe_2)_2\text{-}2,6\}_3]$ has been briefly described [20,21] and the X-ray structure of $[TiCl\{OC_6H_3(CMe_3)_2\text{-}2,6\}_3]$ obtained [22]. We report here work that is based on identifying pockets in chloro-tris-phenoxo complexes of titanium(IV) and investigate how this site topology may be retained.

2. Results and discussion

We have found that the best method for preparing the chloro-tris-phenoxo complexes even when there is a relatively large *ortho*-substituent on the phenyl ring is to simply thermalise the phenol and $[TiCl_4]$ in toluene (Eq. (1)).

$$[TiCl_4] + 3ArOH \rightarrow [TiCl(OAr)_3] + 3HCl \quad (1)$$

$$\begin{aligned} OAr = {} & OC_6H_4CMe_3\text{-}4, \\ & OC_6H_3Me_2\text{-}2,4, \\ & OC_6H_2Me_3\text{-}2,4,6, \\ & OC_6H_3(CHMe_2)_2\text{-}2,6, \\ & OC_6H_3(CMe_3)_2\text{-}2,4, \\ & OC_6H_4Ph\text{-}2. \end{aligned}$$

Obtaining very high yields relies on reaching the reaction end-point and this can be easily determined by monitoring the HCl exhaust gas production using amine hydrochloride cloud formation. This has been found to be successful for the general preparation of mono and bis-phenoxo complexes of titanium [23,24].

To ascertain the features associated with a chloro-tris-phenoxo complex in which there are no *ortho*-substituents on the phenyl ring, the reaction of 4-*tert*-butylphenol and $[TiCl_4]$ in a 3:1 ratio was undertaken. The production of HCl gas was vigorous at first but the reaction took 35 h for the last traces of HCl to be expelled. After removing the solvent, a non-crystalline material was obtained which failed to crystallise. Analytical data and the NMR spectra showed that even after extended periods of drying in vacuo, the complex retained toluene solvate and was characterised as $[TiCl(OC_6H_4CMe_3\text{-}4)_3] \cdot 0.5C_7H_8$ (**1**). Both the ^1H NMR and $^{13}C\{^1H\}$ NMR spectra showed the toluene as well-defined resonances whereas the 4-*tert*-butylphenoxo ligand resonances were broad suggesting solution dynamics [24]. In particular, the *ipso*-carbon resonance occurred at δ 164.5 which is upfield of that found for the mono-phenoxo complex $[TiCl_3(OC_6H_4CMe_3\text{-}4)]$ (δ 169.7) [23] and the bis-phenoxide complex $[TiCl_2(OC_6H_4CMe_3\text{-}4)_2]$ (δ 166.3) and is likely to represent a decrease in the π-bonding from each phenoxo ligand when the number of these ligands increases [24].

When $[TiCl_4]$ was reacted with 2,4-dimethylphenol using the standard conditions, a crystalline solid analysing as $[TiCl(OC_6H_3Me_2\text{-}2,4)_3]$ was obtained for which an X-ray crystal structure determination showed the dimeric phenoxo bridged complex **2**. The coordination geometry about each Ti is that of a trigonal bipyramid consisting of two bridging phenoxides, two terminal phenoxides and a terminal chloro ligand (Fig. 1a). Bond lengths and angles are shown in Table 1. The Ti–O(3) bond length [1.757(1) Å] is similar to that found in the mono-phenoxo complex $[TiCl_3\{OC_6H_2(CMe_3)_2\text{-}2,6\text{-}Me\text{-}4\}]$ [Ti–O bond length 1.750(2) Å] for which a theoretical study shows π-donation of both oxygen atom lone pairs to titanium and some π-bonding between the oxygen and the phenyl ring π-system [24]. The Ti–O(3)–C(31) bond angle [171.4(1)°] in **2** is more 'linear' than that found in $[TiCl_3\{OC_6H_2(CMe_3)_2\text{-}2,6\text{-}Me\text{-}4\}]$ [163.1(1)°] for which theoretical studies show significant changes in energy (and thus decrease in O_π–Ti_d donation) occur only after the Ti–O–C bond angle moves below ca. 160°. The Ti–O(2) bond length in **2** [1.794(2) Å] is significantly longer than the Ti–O(3) bond length and the Ti–O(2)–C(21) bond angle decreases to 138.8(1)° reflecting the decreased π-donation from the oxygen of this ligand. The Ti–O(1) bond length of 1.927(1) Å and Ti–O(1)–C(11) bond angle of 126.1(1)° suggest that there is minimal π-donation to Ti with the bridging phenoxo ligand. The bond length of the terminal chloro ligand [2.269(1) Å] is appreciably longer than that observed for the two terminal chloro ligands in the bridging phenoxo complex $[\{TiCl_2(OC_6H_4CMe_3\text{-}4)(\mu\text{-}OC_6H_4CMe_3\text{-}4)_2\}_2]$ [2.2186(11) and 2.2256(11) Å] [24] as a result of the lessened need for Cl_p–Ti_d π-donation when there is a third phenoxo ligand present.

For chloro-tris-phenoxo complexes, the local environment of the terminal chloro ligand is of importance when development of a pocket is considered since it is this ligand and any replacement that will be affected by local steric influences. Inspection of **2** and the space-filled model (Fig. 1b) shows that the orientation of the phenyl rings in the solid state is such that the methyl substituents in the *ortho*-positions of the three phenoxo ligands associated with each of the titanium atoms point up towards the terminal chloro ligand and as such start to build a 'wall' around one side of the upper Ti(1)–Cl bond but do not create a significant pocket. In fact the phenyl rings attached to the adjacent Ti atom create more of a wall but are further away from the chloro ligand. In solution, the influences playing on the chloro ligand would appear to be different from the solid state since the NMR spectra of **2** in $CDCl_3$ solution do not reflect the dimeric structure shown by the X-ray analysis but point to the three phenoxides being

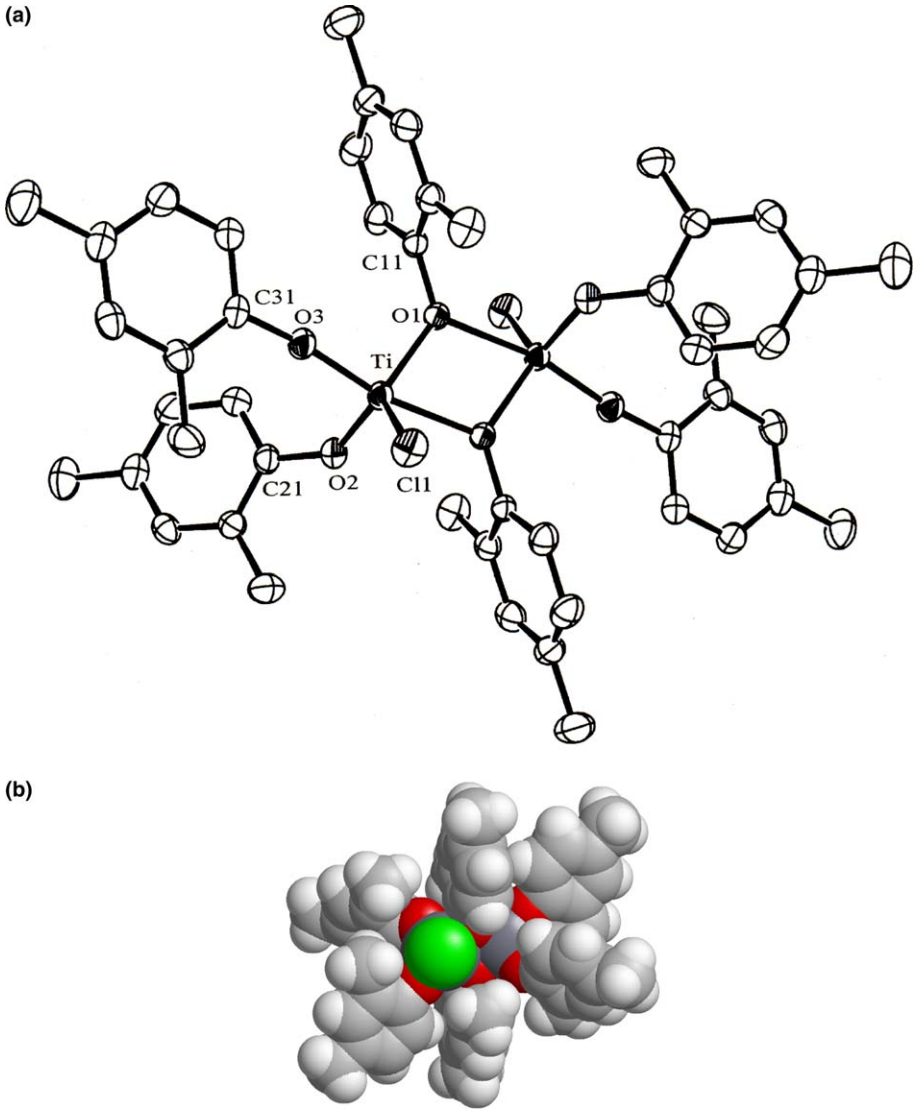

Fig. 1. (a) ORTEP diagram of [{TiCl($OC_6H_3Me_2$-2,4)$_2$(μ-$OC_6H_3Me_2$-2,4)}$_2$] (**2**) showing the molecular structure. Hydrogen atoms have been omitted for clarity. Only the major coordination site for Cl is shown. (b) Space-filling model looking down the Cl–Ti bond showing the position of the *o*-methyl groups on the Ti(1) phenoxo ligands and the phenoxo phenyl groups on Ti(2).

equivalent. The ^{1}H NMR spectrum shows a single set of sharp resonances for the *ortho* and *para*-methyls, a multiplet for the two *meta*-phenyl ring hydrogens and the $^{13}C\{^1H\}$ NMR spectrum a single set of resonances for the relevant phenoxide group carbons. The *ipso*-carbon resonance appears at δ 164.4 which is in a position similar to that found for **1** (δ 164.5). The absence of resonances for bridging and terminal ligands and the sharpened nature of the resonances suggest that solution dynamics are less important than for **1** so that the complex is likely to be monomeric in the NMR solvent and have a tetrahedral geometry in which the *ortho*-methyl groups all point up around the Ti–Cl bond. In comparison, the resonances of complex **1**, particularly those associated with the aromatic ring, were broad which may suggest monomer–dimer equilibria. We have found previously that [$TiCl_2(OAr)_2$] complexes without *ortho*-methyl substituents are dimeric in the solid state but are monomeric in solution. DFT calculations show that there is only a small dimerisation energy involved (-26.2 kJ mol^{-1}) [24].

Of fundamental importance in these systems is whether the structure of any pocket is maintained in the presence of other coordinating ligands. Addition of one or two equivalents of pyridine to **2** gave what appeared to be isomeric mixtures, which were difficult to distinguish by NMR spectroscopy. 4,4′-Dimethyl-2,2′-bipyridine (dmbipy) was used since isomeric mixtures can be more easily identified using this ligand [23,24]. Addition to **2** expanded the coordination number giving [TiCl($OC_6H_3Me_2$-2,4)$_3$(dmbipy)] (**3**) for which the NMR spectra showed one isomer. Based on a 2:1 ratio of phenoxo ligand resonances and a symmetrical dmbipy ligand shown by a singlet for the two methyl groups and a single set of resonances for the ring protons in the ^{1}H NMR spectrum and the required number of carbon resonances in the $^{13}C\{^1H\}$ NMR spectrum, dmbipy symmetric structure (a) rather than either of asymmetric

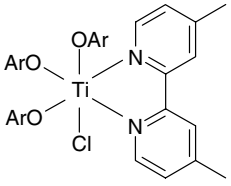
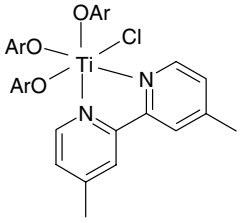
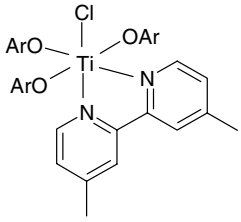
structures (b) and (c) is preferred. We have been unable to obtain suitable crystals to identify the absolute structure in the isomer but with one phenoxo ligand coordinating *trans*- to the chloro ligand the cavity structure about Cl is certainly destroyed.



Symmetric structure (a)



Asymmetric structure (b)



Asymmetric structure (c)

The structural features shown by the solid state structure of **2** indicate that one side of the titanium has become enclosed to some extent by the phenoxo ligand *ortho*-methyl groups so that the complex has the beginnings of a pocket with defined local structure. A more well-defined topology could arise if the complex were a tetrahedral monomer as suggested by the NMR spectra. However, analysis of the structure indicates that some rotation of the phenyl C–O bonds in the monomer or dimer forms may occur in solution taking the methyl groups away from the chloro ligand. Thus, 2,4,6-trimethylphenol and 2,6-di-*iso*-propylphenol were reacted with $TiCl_4$ using the standard conditions to form complexes in which phenoxo ligand C–O bond rotations are less likely to occur on account of the other *ortho*-position of the phenyl ring having a larger substituent than hydrogen. [TiCl($OC_6H_2Me_3$-2,4,6)$_3$] (**4**) [19] formed as a solid which, characterised by NMR spectroscopy, showed a single set of sharp resonances for the relevant hydrogens and carbons as found for complex **2** and with an *ipso*-carbon resonance in the $^{13}C\{^1H\}$ NMR spectrum at δ 163.9 suggesting a monomeric and thus tetrahedral complex. [TiCl{OC_6H_3-($CHMe_2$)$_2$-2,6}$_3$] (**5**) [20,21] was characterised by NMR spectral comparison with the product formed by thermalisation in benzene [21] as NMR analysis of the toluene reaction crude material indicated there was a significant amount of the phenol present as well as the *tetra*-phenoxide [Ti{$OC_6H_3(CHMe_2)_2$-2,6}$_4$] (identified by NMR spectral comparison with an independently prepared sample). Based on the single set of ligand resonances in the NMR spectra (in particular the *ipso*-carbon ^{13}C resonance at δ 163.1) **5** is also a tetrahedral monomer.

Of more importance than methyl or *iso*-propyl groups for pocket development are large *ortho*-substituents. The X-ray structures of [TiI{$OC_6H_3(CMe_3)_2$-2,6}$_3$] [22] and [TiCl($OC_6H_3Ph_2$-2,6)$_3$] [16] show cavity formation and would appear to be ideal molecules for cavity collapse studies. However, the former complex is difficult to prepare and the ligand for the latter is expensive. We therefore turned our attention to ligands that had a *tert*-butyl or phenyl substituent in only one of the phenoxide aryl ring *ortho*-positions. Reaction of 2,4-di-*tert*-butylphenol with [$TiCl_4$] under the standard conditions gave [TiCl{OC_6H_3-(CMe_3)$_2$-2,4}$_3$] (**6**) which could also be prepared in good yield by the reaction of 3 equivalents of $LiOC_6H_3$-(CMe_3)$_2$-2,4 with $TiCl_4$ dissolved in diethyl ether. The complex forms a crystalline mass that is analytically pure when the solvent is removed from the reaction mixture but may be recrystallised from petroleum spirit or diethyl ether. An X-ray crystal structure determination showed a distorted tetrahedron consisting of three terminal phenoxo ligands and a single terminal chloro ligand (Fig. 2a), the metal and chloro ligand lying along a threefold axis. Bond lengths and angle are shown in Table 2. The three identical Ti–O bond lengths [1.757(2) Å] are similar to the Ti–O(3) bond length in **2** which involves the most oxygen atom lone pair π-donation. The Ti–Cl bond length in **6** [2.240(2) Å] is slightly shorter than that observed in **2** [2.269(1) Å] resulting from the greater need for electron density at the metal with the lower coordination number. It is considerably shorter than the three terminal Ti–Cl bonds in [$TiCl_3${$OC_6H_2(CMe_3)_2$-2,6-Me-4}] [Ti–Cl bond length range 2.1822(8)–2.1945(9) Å] in which there is only one π-donating phenoxo ligand. In [$TiCl_4$] where each chloride must π-donate 2 electron pairs to attain an electron count of 16, the Ti–Cl bond lengths are 2.170(2) Å [25].

The Ti–O–C bond angles in **6** [158.8(2)°] are slightly smaller than those found in [$TiCl_3${$OC_6H_2(CMe_3)_2$-2,6-

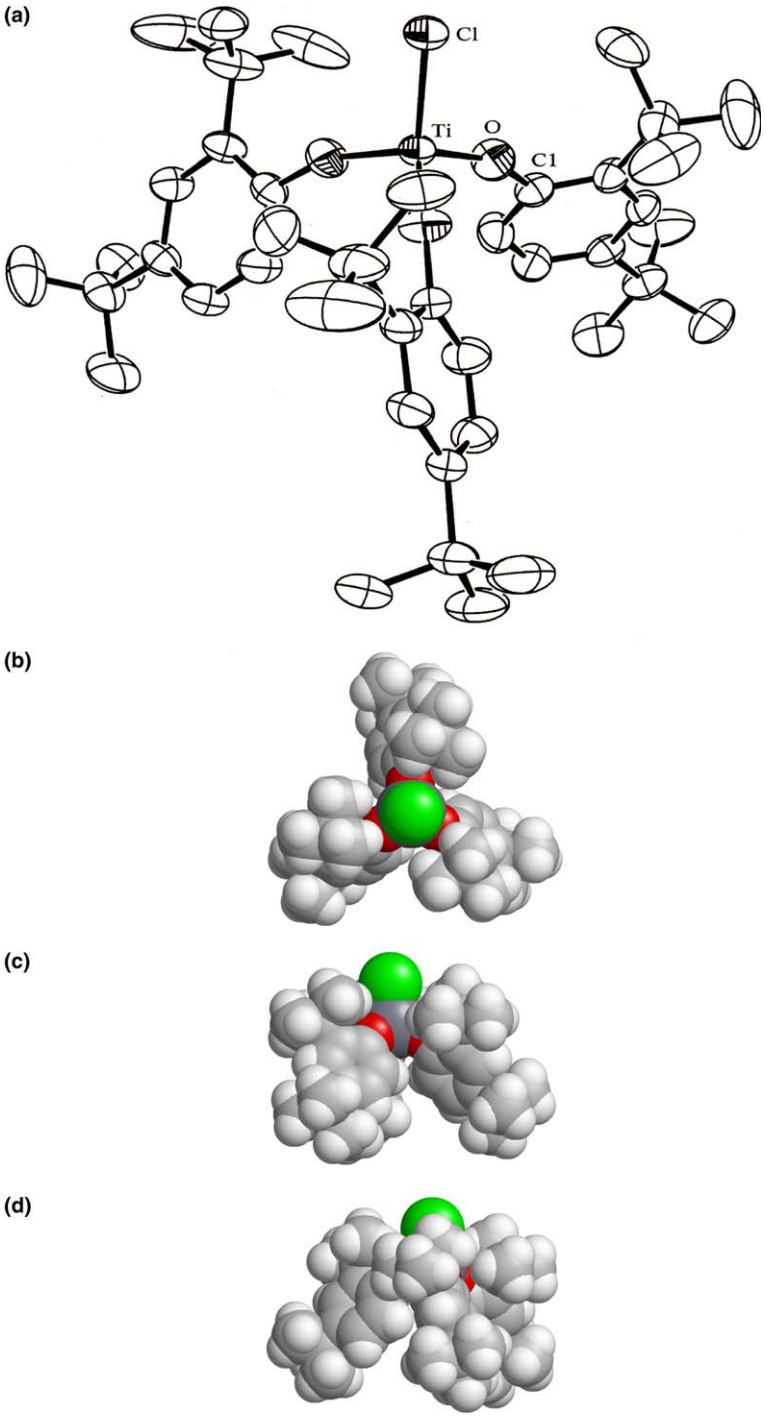


Fig. 2. (a) ORTEP diagram of $[TiCl\{OC_6H_3(CMe_3)_2\text{-}2,4\}_3]$ (**6**) showing the molecular structure. Hydrogen atoms are omitted for clarity. Only one of the disordered positions for the *tert*-butyl group is shown. (b) Space-filling model looking down the Cl–Ti bond showing the pocket arrangement about Cl. (c and d) Space-filling model, side-on view of the Ti–Cl bond showing the extent to which the *tert*-butyl group methyls cover the Cl atom.

Me-4}] [163.1(2)°] [23] and the Ti–O(3)–C(31) bond angle in complex **2** [171.4(1)°] but the angle in **6** is only a little less than the 160° for which theoretical studies with this type of ligand show a steep rise in energy when this value is reduced [23]. In $[TiI\{OC_6H_3(CMe_3)_2\text{-}2,6\}_3]$ where both phenyl ring *ortho*-positions have *tert*-butyl substituents the Ti–O–C bond angles range from 155.2(4)° to 158.2(4)° [22]. In **6** the O–Ti–O′ and O–Ti–Cl bond angles are 108.90(8)° and 110.03(8)°, respectively, hence the geometry does not deviate significantly from a tetrahedral arrangement. In $[TiI(OC_6H_3(CMe_3)_2\text{-}2,6)_3]$ the O–Ti–O bond angles range from 110.7(3)° to 114.9(3)° and the O–Ti–I bond angle range is 102.9(3)–108.6(3)° [22].

The phenyl rings in complex **6** orientate so that two of the methyl groups of the 2-*tert*-butyl group straddle the chloro ligand but lie slightly to the side of this ligand. The two closest methyl group carbon contacts with the chloro ligand are 3.13 and 3.11 Å which, taken with the

Table 2
Selected bond distances (Å) and angles (°) for [TiCl{$OC_6H_3(CMe_3)_2$-2,4}$_3$] (**6**)

Ti–Cl	2.240(2)
Ti–O(1)	1.757(2)
Ti–O(1)–C(1)	158.8(2)
Cl–Ti–O(1)	110.03(8)
O(1)–Ti–O(1)′	108.90(8)

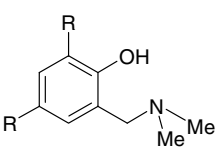
Ti–O–C(1) bond angles [158.8(2)°], and the near ideal tetrahedral geometry, indicate that the 2-*tert*-butyl substituent exerts little steric pressure. However, it is more constrained than its counterpart in the 4-position of the phenyl ring which is seen to occupy two disordered sites. No such disorder was observed for the 2-substituent. It provides something of a steric shield about the chloro ligand and thus creates a pocket for this fourth coordination site as the space filled models show (Fig. 2b–d). Molecular models indicate that if the Ti–O–C bond angles are maintained in solution near the solid state value of ca. 159° then rotation about the phenyl ring C–O bond is difficult. However, since this angle can flatten with little energy consequence [23] rotation may be possible although the C–O π-bond would need to be broken in this process.

The 4-coordination of complex **6** can be broken by the addition of dmbipy but whereas the *ortho*-methyl complex **2** gave one product which NMR spectroscopy showed to have a symmetric structure, reaction with **6** gave a product analysing as [TiCl{$OC_6H_3(CMe_3)_2$-2,4}$_3$(dmbipy)] (**7**) but the NMR spectra showed three products (ratio ca. 72:21:7) based on the easily distinguished features of the dmbipy hydrogens in the ^{1}H NMR spectrum. The major product, however, had spectral characteristics similar to complex **3** [symmetric structure (a)]. Of the three possible structures only (c) has the potential for three *tert*-butyl groups to surround Cl. We have also looked at the possibility of coordinating only one extra ligand to **6** by adding 1 equivalent of pyridine or various aldehydes but these reactions give gummy substances that are hard to purify. However, the NMR spectra show mainly single resonances for the phenoxo ligands indicating the ligands are equivalent which offers the possibility of a 5-coordinate structure (see later).

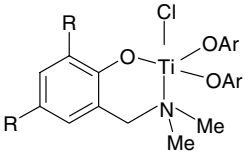
The structural features shown by complex **6** suggest that the chloro ligand would sit in a more effective pocket if the 2-*tert*-butyl substituent of the phenoxo ligands were replaced by a 2-phenyl substituent which, although less sterically demanding than the former, would protrude further out. Reaction of 2-phenylphenol with [$TiCl_4$] under the standard conditions gave an oil which failed to solidify but was identified as [TiCl(OC_6H_4Ph-2)$_3$] (**8**) on the basis of its NMR spectra. In particular, the more easily identified ^{13}C{^{1}H} NMR spectrum showed a single set of resonances for each of the carbons of the ligand and the *ipso*-carbon resonance (δ 163.6) was in a similar position to the other chloro-tris-phenoxide complexes prepared.

Reaction of [$TiCl_4$] with 3 equivalents of $LiOC_6H_4$Ph-2 in diethyl ether gave [TiCl(OC_6H_4Ph-2)$_3$(diethyl ether)] (**9**) which had nearly identical NMR spectral characteristics in the aromatic region to those shown by complex **8** with the *ipso*-carbon at δ 163.2. Interestingly, when complex **8** was dissolved and refluxed in diethyl ether the NMR spectra of the reaction product indicated that no diethyl ether was incorporated. This is probably related to the retention of coordinated ether during the reaction with the titanium starting material [$TiCl_4$(diethylether)$_2$]. An X-ray crystal structure determination of **9** showed a distorted trigonal bipyramidal coordination geometry with the diethyl ether ligand bound in a *trans* position to the chloro ligand and the three phenoxide ligands forming the equatorial plane (Fig. 3a). Bond lengths and angle are shown in Table 3. The Ti–O bond lengths lie in the range 1.790(1)–1.794(1) Å and, together with the Ti–Cl bond length [2.3067(6) Å], are much longer than the corresponding bonds in [TiCl{$OC_6H_3(CMe_3)_2$-2,4}$_3$] (**6**) [Ti–O and Ti–Cl are 1.757(2) and 2.240(2) Å, respectively]. This is a result of **9** having a reduced π-loading [26] requirement compared to **8** with the addition of the 2-electon donor diethyl ether ligand. Consequently, the Ti–O–C bond angles of 152.3(1)°, 155.0(1)° and 157.1(1)° relax a little in comparison with those in **6** where Ti–O–C bond angle is 158.8(2)°. The phenoxide oxygen atoms push away from the chloro ligand [O(1)–Ti–Cl, 96.12(4)°; O(2)–Ti–Cl, 95.90(5)°] but the O–Ti–O bond angles are close to the ideal trigonal angle [the range is 117.88(6)–119.99(6)°]. The phenyl rings are rotated into the equatorial plane to remove interaction with the diethyl ether ligand and this takes the 2-phenyl substituent on each phenoxo ligand away from the chloro ligand and destroys any substantial cavity present if the substituents all lie upright. The space-filling model looking down the Cl–Ti bond (Fig. 3b) shows the cavity effect which is different from that observed in [TiCl($OC_6H_3Ph_2$-2,6)$_3$] [16] where the substituents form an open-ended groove (Fig. 3c). This results from a face-to-face orientation of two of the phenyl substituents and an end wall in which the substituent has moved aside slightly. The extent to which the phenyl groups cover the chloro ligand in **9** is much less than in [TiCl($OC_6H_3Ph_2$-2,6)$_3$] (compare Fig. 3d and e) being somewhat similar to that found in [TiCl{$OC_6H_3(CMe_3)_2$-2,4}$_3$] (**6**) (compare Fig. 3d with Fig. 2c).

The structural features shown by complexes **6** and **9** indicate that the local cavity geometry is easily effected by the addition of another ligand. We therefore looked at tying back one of the three phenoxo ligands with a nitrogen donor using the benzylamine ligand structure (d) to form complexes of structural type (e).



Structure (d) (R = CMe_3)



Structural type (e) (R = CMe_3)

Only the major site of the coordinated ether ligand is shown. (b) Space-filling model of **9** looking down the Cl–Ti bond showing the collapsed *o*-phenyl group arrangement about Cl. (c) Space-filling model of [TiCl($OC_6H_4Ph_2$-2,6)$_3$] [16] showing the upright *o*-phenyl groups and the resulting groove (the 6-phenyl groups and the phenoxo ligand Hs have been removed for clarity). (d) Space-filling model, side-on view of **9** showing the extent to which the *o*-phenyl groups cover Cl. (e) Space-filling model, side-on view of [TiCl($OC_6H_4Ph_2$-2,6)$_3$] [16] showing the molecular groove (the 6-phenyl groups and the phenoxo ligand Hs have been removed for clarity).

This approach is then expected to produce one rigid phenoxo ligand and two more that are less rigid if the isomer with Cl *trans* to N is formed, allowing the influences made on the cavity ligand to be varied. Preliminary results of this work indicate that reaction of [$TiCl_2$($OC_6H_4CMe_3$-4)$_2$] [24] with $LiOC_6H_2(CMe_3)_2$-2,4-(CH_2NMe_2)-6 gives a solid analysing as the complex [TiCl($OC_6H_4CMe_3$-4)$_2$-{$OC_6H_2(CMe_3)_2$-2,4-(CH_2NMe_2)-6}] but the NMR spectra show the complex is made up of two isomers. Similarly, reaction of [$TiCl_4$] with two equivalents of $LiOC_6H_3$-(CMe_3)$_2$-2,4 in diethyl ether followed by one equivalent of $LiOC_6H_2(CMe_3)_2$-2,4-(CH_2NMe_2)-6 gives a complex analysing as [TiCl{$OC_6H_4(CMe_3)_2$-2, 4}$_2$($OC_6H_2(CMe_3)_2$-2,4-(CH_2NMe_2)-6)] which was also shown by the NMR spectra to consist of two isomers. The complexes do not appear to crystallise from solution so the structural details of any cavity formed in any of the isomers cannot as yet be assessed. The only success we have had with forming a single isomer complex using this type of tie-back is from a reaction of [$TiCl_2$({$OC_6H_2(CMe_3)$-2-Me-4}$_2CH_2$-6)] [27] with one equivalent of $LiOC_6H_2(CMe_3)_2$-2,4-(CH_2NMe_2)-6 which gives a product analysing as [TiCl({$OC_6H_2(CMe_3)$-2-Me-4}$_2CH_2$-6) ($OC_6H_2(CMe_3)_2$-2,4-(CH_2NMe_2)-6)]. The NMR spectra indicate the presence of only one isomer but crystals have not yet been obtained to identify the overall geometry by X-ray crystallography.

In further pursuing a non-collapsible coordination geometry about titanium, we have looked at the coordination properties of the tripodal ligand type tris(2-hydroxyphenyl)benzylamine, ($HOArCH_2$)$_3$N) for which the methyl and *tert*-butyl substituted compounds (HOC_6H_2-Me_2-2,4-CH_2-6)$_3$N [structure (f), R = Me] and

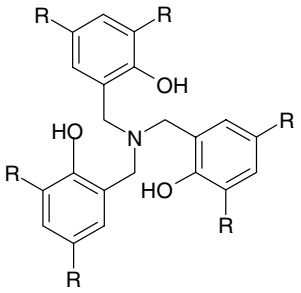
[HOC$_6$H$_2$(CMe$_3$)$_2$-2,4-CH$_2$-6]$_3$N [structure (f), R = CMe$_3$], respectively, should give the "tied back" versions of complexes **2** and **6**.



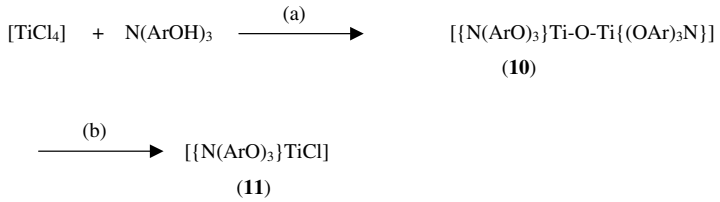
Structure (f) (R = Me, CMe$_3$)

Several alkoxo and phenoxo complexes of titanium containing these ligands have been reported [28–30]. In attempting to prepare chloro complexes, it was found that reactions of [TiCl$_4$] with either of these ligands in benzene in the presence of Et$_3$N gave mixtures which proved difficult to purify. This type of reaction is reported to give [TiCl{(OC$_6$H$_2$Me$_2$-2,4-CH$_2$-6)$_3$N}] in low yield but the complex has not been well characterised [31]. The complex was initially obtained via a circuitous route (Scheme 1).

We have noticed that when undried samples of (HOC$_6$H$_2$Me$_2$-2,4-CH$_2$-6)$_3$N, [(HOAr)$_3$N], are used in the reaction with [TiCl$_4$] and Et$_3$N, the oxo-bridged dimer [{N(ArO)$_3$}Ti–O–Ti{(OAr)$_3$N}]·1.5C$_6$H$_6$ (**10a**) is formed in good yield and this reacts with Me$_3$SiCl to give chloro complex **11**. There is an initial report of this dimer formed by the hydrolysis of [Ti(OCHMe$_2$){(OC$_6$H$_2$Me$_2$-2,4-CH$_2$-6)$_3$N}] in air [28] and the crystal structure of [{N(Ar′O)$_3$}Ti–O–Ti{(OAr′)$_3$N}]. [(OAr′)$_3$N = OC$_6$H$_2$-(CMe$_3$)$_2$-2,4-CH$_2$-6]$_3$N which is more resistant to hydrolysis has been obtained [30]. An X-ray crystal structure determination of the oxo-bridged dimer prepared in this work containing a pentane solvent molecule **10b** shows a distorted trigonal bipyramidal coordination geometry (Fig. 4) with bond lengths and angles (Table 4) which are similar to those found for the reported *tert*-butyl substituted analogue. The only significant difference between the two is the smaller Ti–O–Ti bond angle in **10b** [147.5(1)° cf. 155.5(1)°] which is apparently related to the smaller *ortho*-substituents providing less of a clash across the two sides of the molecule. In the *tert*-butyl substituted complex the *tert*-butyl groups are forced into close contact in the dimer with eight inter-titanium methyl–methyl contacts with C···C contacts shorter than the 4.0 Å sum of the van der Waals radii [30] but in **10b** there are no such close contacts.

[TiCl{(OC$_6$H$_2$Me$_2$-2,4-CH$_2$-6)$_3$N}] (**11**) was obtained more conveniently and in virtually quantitative yield by the reaction of the free ligand with [TiCl(OCHMe$_2$)$_3$] [18] prepared in diethyl ether from [TiCl$_4$] and 3 equivalents of [Ti(OCHMe$_2$)$_4$]. Complex **11** is not particularly soluble compared with the very soluble analogue [Ti(OCHMe$_2$){(OC$_6$H$_2$Me$_2$-2,4-CH$_2$-6)$_3$N}] [28]. The ^{1}H NMR spectrum shows a single set of resonances for the phenyl rings and the substituents while the benzylic CH protons form two very broad resonances. However, the ^{13}C{^{1}H}NMR spectrum shows only one CH$_2$ carbon resonance along with the other single set of carbon resonances. The *ipso*-carbon resonance appears at δ 160.2 which is upfield to that found for the non-tied-back analogue **2** (δ 164.4).

Addition of tris(3,5-di-*tert*-butyl-2-hydroxyphenyl)benzylamine to a diethyl ether solution of [TiCl(OCHMe$_2$)$_3$] gave the highly soluble complex [TiCl({OC$_6$H$_2$(CMe$_3$)$_2$-2,4-CH$_2$-6}$_3$N)]·diethyl ether (**12**) in virtually quantitative yield. The ^{1}H NMR spectrum showed a single set of resonances for the phenyl groups and the substituents and a well-defined AB spin system for the methylene protons. Although the structure has C_3-symmetry (see later for the X-ray structure) the methylene protons are non-equivalent due to the methylene carbon being pushed to one side in



Scheme 1. (a) NEt$_3$ in benzene, reflux 14 h; (b) Me$_3$SiCl in toluene, stir 8 h.

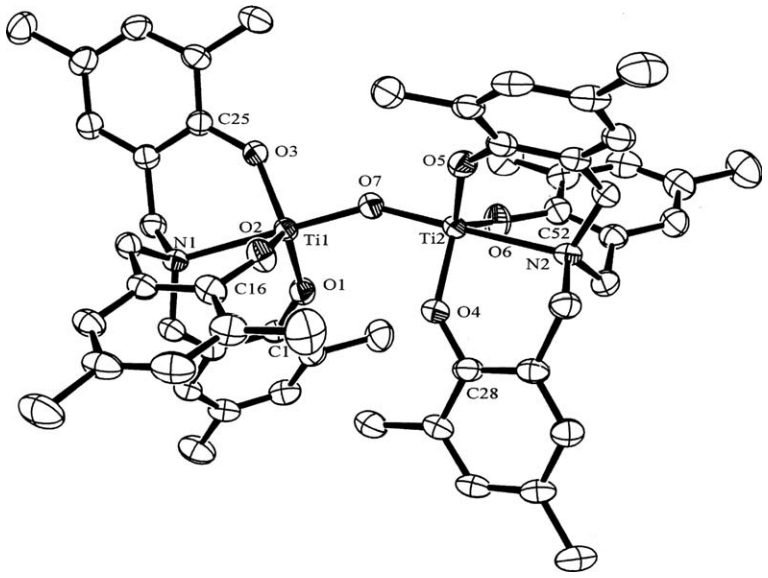


Fig. 4. ORTEP diagram of $[(Ti\{(OC_6H_2Me_2\text{-}2,4\text{-}CH_2\text{-}6)_3N\})_2O]\cdot n$-pentane (**10b**) showing the molecular structure. Hydrogen atoms are omitted for clarity. The *n*-pentane solvent molecule is not shown.

the six-membered ring. The AB system also indicates that rapid inversion of the structure does not occur on the NMR time scale [28]. In the $^{13}C\{^1H\}$ NMR spectrum there was a single set of resonances with the *ipso*-carbon resonances appearing at δ 160.8 which is similar to that found in methyl substituted complex **11** but lies upfield to the non-tied-back analogue 4-coordinate **6** (δ 164.4). An X-ray crystal structure of **12** showed a 5-coordinate distorted trigonal bipyramidal structure (Fig. 5a) in which the diethyl ether solvent molecule lies between the Ti complex molecules in the unit cell and is not coordinated. Bond lengths and angle are contained in Table 5.

The Ti–Cl bond [2.3074(7) Å] is similar to that found in the non-tied back trigonal bipyramidal $[TiCl(OC_6H_4Ph\text{-}2)_3\cdot(diethyl\ ether)]$ (**9**) [2.3067(6) Å] and both these bond lengths are longer than in tetrahedral $[TiCl\{OC_6H_3(CMe_3)_2 2,4\}_3]$ (**6**) [2.240(2) Å] which has a greater need for electron density at the metal. This electronic situation is further illustrated by the Ti–O bond lengths for the three molecules that are longer for the 5-coordinate complexes [ranges 1.809(2)–1.817(2) and 1.790(1)–1.794(1) Å for **12** and **9** cf. 1.756(2) Å for **6**]. In the trigonal bipyramidal complexes $[Ti(OCHMe_2)(\{OC_6H_2(CMe_3)_2\text{-}2,4\text{-}CH_2\text{-}6\}_3N)]$ [28] and $[Ti(OH)(\{OC_6H_2(CMe_3)_2\text{-}2,4\text{-}CH_2\text{-}6\}_3N)]$ [30] where there is an alkoxo or hydroxo ligand instead of Cl, the Ti–O bond lengths [ranges, respectively, 1.825(6)–1.866 Å and 1.783(2)–1.865(2) Å] are mostly longer than in **12** and **9** indicating that Cl is the poorer π-donor. This effect is also illustrated by comparison of the relative Ti–N bond lengths [2.216(2) Å in **12**; 2.334(5) and 2.364(2) Å, respectively, in the reported isopropoxo and hydroxo complexes] where the bond is shorter when N is trans to Cl. These features show there is a tightening of the Ti–O and Ti–N bonds when there is a less effective π-donor lying *trans* to the nitrogen atom.

In further comparisons of the relevant features of the coordination geometries for the complexes reported here, the O–Ti–Cl angles in the tied-back trigonal bipyramid (**12**) are similar to those in the non-tied-back trigonal bipyramid (**9**) [ranges 97.01(5)–97.18(5)° and 95.80(6)–96.12(4)°, respectively] as are the O–Ti–O bond angles [ranges 115.48(7)–120.72(7)° and 117.88(6)–119.99(6)°, respectively] showing that tying back has little effect on the trigonal bipyramidal geometry. However, for the tied-back trigonal bipyramidal geometry there is a significant effect for the Ti–O–C bond angles. In **12** the angles range from 143.5(2)° to 144.0(1)° whereas the angle widens in non-tied-back **9** [152.3(1)–157.1(1)°] (the complexes are expected to have similar electronic environments). In **6** where there is no tie-back constraint, the Ti–O–C bond angles are similar to those found for **9** [158.8(2)°]. There is obvious flexibility in this angle and this is even more pronounced in other complexes of this type of ligand. In the zwitterionic complex $[Zr\{(OC_6H_2Me_2\text{-}2,4\text{-}CH_2\text{-}6)_3NH\}_2]$ which has a low requirement for π-donation with six phenoxo ligands present and in which there is also room for a hydrogen atom on the inside of the cage at a non-agostic distance [2.688(3) Å], the angles range from 154(2)° to 160(2)° [32]. In $[W(O)(OCH_2CH_2OH)(\{OC_6H_2(CMe_3)_2\text{-}2,4\text{-}CH_2\text{-}6\}_3N)]$ where there is a similar low π-loading requirement for the phenoxo ligands the angles range from 126.0(2)–141.9(2)° [33]. For 1σ–2π donation from a phenoxo ligand, DFT calculations show there is a shallow minimum in the energy for the angle between about 160° and 180°, at 140° the energy is 20 kJ mol^{-1} and at 120° this energy rises to 60 kJ mol^{-1} [23].

Where the Ti–O–C bond angle is reduced it might be expected that the *tert*-butyl group would move away from the terminal Cl and create a wider but less well developed pocket about this ligand. However, inspection of the inter-

atomic distances between the central *tert*-butyl group carbons and Cl in **6** and **12** shows that this effect is minimal on changing from the tetrahedral structure (C···Cl distance 4.87 Å) to the trigonal bipyramid (C···Cl distances 4.87, 4.91 and 4.93 Å). Noticeable in the two structures is that the titanium atom lies 0.60 Å above the plain made by the three phenoxide oxygen atoms in the tetrahedron but only 0.22 Å above them in the trigonal bipyramid. This is, of course, to be expected but it results in the chloro ligand lying 2.15 Å above the central carbon atoms of the three *tert*-butyl groups in the tetrahedron and 1.69, 1.78 and 1.85 Å in the trigonal bipyramid. The net effect is that when the methyl groups are taken into account, the trigonal bipyramidal structure creates a slightly better pocket about Cl than does the tetrahedron. The pocket structure in **12** is shown by the space-filling models in Fig. 5b and c.

Given the trigonal bipyramidal nature of complex **12** and the relevance of coordination expansion in the present studies, an excess of pyridine was added to the complex resulting in the formation of [(TiCl({$OC_6H_2(CMe_3)_2$-2,4-CH_2-6)$_3$N})(NC_5H_5)] (**13**). The ^{1}H NMR spectrum shows the methylene protons as a broadened singlet for this 6-coordinate compound compared with the AB quartet found for the 5-coordinate parent. The pyridine resonances in both the ^{1}H and ^{13}C{^{1}H} NMR spectra were very well-defined suggesting that fluxional processes are absent or are fast on the NMR timescale. Suitable crystals of the complex for X-ray crystallography have not yet been obtained but the structure is expected to be octahedral with the pyridine ligand coordinating *trans* to one of the phenoxo ligands. For this geometry the chloro ligand would still be surrounded by the *tert*-butyl groups but the pocket would be opened up on one side by the pyridine ligand. Recently, reported X-ray crystal structures show that this type of coordination geometry can be obtained from bidentate oxygen and nitrogen ligands [34].

3. Conclusion

The results of this work indicate that substituents in the *ortho*-position of the phenoxo ligand ring in tetrahedral chloro-tris-phenoxo complexes of titanium are positioned so as to create a coordination pocket or cavity about the chloro ligand. Where the substituent is a methyl group the effect is minimal but a *tert*-butyl substituent gives rise to a more substantial pocket. Coordination expansion can occur when a further donor ligand is available which removes this special environment. A phenyl substituent creates a better pocket but this can also be reduced in size when a further ligand binds creating a trigonal bipyramidal structure in which the pocket collapses somewhat. The collapse is due to the need to remove interactions of the phenoxo ligand phenyl ring with the ligand lying *trans* to the chloro ligand. Where an octahedral structure forms by filling two coordination sites, the possibility of isomers complicates the issue producing structures in which not all the *ortho*-substituents influence the chloro ligand. Where the collapse needs to be prevented, the tied-back ligand system gives rise to a trigonal bipyramidal structure of a more robust nature. A further ligand may coordinate leading to an octahedral structure which is expected to be more open on one side but it is obvious that the nature of this ligand is important given that diethyl ether does not coordinate but pyridine does. Overall it is apparent that *tert*-butyl groups in these complexes do not cover Cl completely forming what is best described as a steric pressure pocket [10d] whereas substituents that reach further outwards would form a more enclosed pocket or cavity. Given the availability of a wide variety of phenol ligands substituted in the *ortho*-position, the chloro-tris-phenoxo approach to the molecular engineering of coordination pockets should have future potential. By varying the size of the substituent,

Hydrogen atoms have been removed for clarity. The diethyl ether solvent is not shown. (b) Space-filling model looking down the Cl–Ti bond showing the pocket arrangement about Cl. (c) Space-filling model, side-on view of the Ti–Cl bond showing the extent to which the *tert*-butyl group methyls cover the Cl atom.

collapsible through to non-collapsible complexes with different pocket characteristics may be realised.

4. Experimental

4.1. General methods and materials

All preparations and manipulations were carried out under dry oxygen-free nitrogen using standard bench-top techniques for air-sensitive substances. $[TiCl_4]$ and the phenols were used as received from commercial sources. 4,4′-Dimethyl-2,2′-bibyridyl (dmbipy) was dried under vacuum before use. Tris(2-hydroxy-4,6-di-*tert*-butylbenzyl)amine and tris(2-hydroxy-4,6-dimethylbenzyl)amine were prepared by the literature procedures [28]. Light petroleum (b.p. 40–60 °C) and toluene were distilled from sodium wire and dichloromethane from freshly ground CaH_2. ^1H and $^{13}C\{^1H\}$ NMR spectra were recorded at 400 and 100 MHz, respectively, on a Bruker AM400 spectrometer. $CDCl_3$ and CD_2Cl_2 were dried over, and distilled from, freshly ground CaH_2 and benzene-d_6 from sodium wire. C, H and N analyses were determined by Dr. A. Cunninghame and associates, University of Otago, New Zealand. The production of HCl gas in the thermalisation reactions was monitored by passing the exhaust gases from the nitrogen bubbler over *N*,*N*,*N*′,*N*′-tetramethylethylenediamine and observing the white cloud produced.

gas was produced (12 h). NMR spectroscopy at this stage confirmed that no 4-*tert*-butylphenol was present. The cooled solution was filtered, the solvent was removed and the residue held under vacuum for 2 h giving the complex as a deep-red flaky solid. Yield: 5.82 g, 97%. *Anal*. Calc. for $C_{33.5}H_{43}ClO_3Ti$: C, 69.73; H, 7.51. Found: C, 69.48; H, 7.58%. ^{1}H NMR: δ 1.27 (s, 27H, CMe_3), 2.40 [s, 1.5H, 0.5CH_3(toluene)], 7.11 (b, 12H, *o* and *m*-Hs), 7.22 and 7.30 (m, 2.5H, 0.5 aromatics (toluene). ^{13}C{^{1}H} NMR: δ 21.5 [Me(toluene)], 31.5 (CMe_3), 34.2 (C), 118.7 (b, *o*-C) 124.7 (toluene), 124.6 (b, *m*-C), 128.2 (toluene), 129.0 (toluene), 137.9 [*ipso*-C(toluene)], 145.8 (b, C), 164.6 (*ipso*-C).

4.2.2. [{TiCl($OC_6H_3Me_2$-2,4)$_2$(μ-$OC_6H_3Me_2$-2,4)}$_2$] (**2**)

2,4-Dimethylphenol (3.87 g, 31.7 mmol) in toluene (40 cm^3) was added to [$TiCl_4$] (2.0 g, 10.5 mmol) in toluene (40 cm^3) and the mixture was refluxed until no more HCl gas was produced (12 h). The cooled solution was filtered, the solvent was removed and the residue held under vacuum for 2 h giving a gum that formed the complex as a deep-red crystalline mass on standing overnight. Yield: 4.5 g, 96%. *Anal*. Calc. for $C_{24}H_{27}ClO_3Ti$: C, 64.51; H, 6.09. ^{1}H NMR: δ (s, 9H, Me), 2.20 (s, 9H, Me), 6.72–6.89 (m, 9H, *o* and *m*-Hs). ^{13}C{^{1}H} NMR: δ 16.6 (Me), 20.7 (Me), 119.5 (CH), 126.3 (C), 126.9 (CH), 131.0 (CH), 133.2 (C), 164.4 (*ipso*-C). Crystalline material was cut from the mass and used for the X-ray analysis.

4.2.3. [TiCl($OC_6H_3Me_2$-2,4)$_3$(dmbipy)] (**3**)

4,4′-Dimethyl-2,2′-bipyridine (0.4 g, 2.17 mmol) in CH_2Cl_2 (20 cm^3) was added to complex **2** (0.96 g, 2.15 mmol) in CH_2Cl_2 (20 cm^3) and the mixture was stirred for 1 h. The solution was filtered and the solvent removed to give the complex as an orange flaky solid. Yield: 1.30 g, 96%. *Anal*. Calc. for $C_{36}H_{39}ClN_2O_3Ti$: C, 68.52; H, 6.23, N, 4.44. Found: C, 67.80; H, 6.73, N, 4.68%. ^{1}H NMR: δ 1.67 (s, 3H, Me); 2.06 (s, 3H, Me); 2.24 (s, 6H, 2Me); 2.34 (s, 6H, 2Me); 2.40 (s, 6H, 2Me); 6.25 [d, ^3J(HH) 8.1, 1H, *o*-H]; 6.46 [dd, ^3J(HH) 8.1, ^4J(HH) 1.6, 1H, *m*-H]; 6.58 [d, ^4J(HH) 1.6, 1H, *m*-H]; 6.83 [dd, ^3J(HH) 8.1, ^4J(HH) 1.5, 2H, *m*-Hs]; 6.91 [d, ^4J(HH) 1.5, 2H, *m*-Hs]; 7.20 [d, ^3J(HH) 5.5, 2H, *m*-H dmbipy]; 7.38 [d, ^3J(HH) 8.1, 2H, *o*-Hs]; 7.81 [bd, 2H, *m*-Hs dmbipy]; 8.95 [d, ^3J(HH) 5.5, 2H, *o*-Hs dmbipy]. ^{13}C{^{1}H} NMR: δ 16.1 (1Me); 17.1 (2Me); 20.4 (1Me); 20.7 (2Me); 21.5 (2Me, dmbipy); 118.5 (1CH); 120.1 (2CH); 122.2 (*m*-CH, dmbipy); 126.3 (2C); 126.4 (1*m*-CH); 126.6 (2*m*-CHs, dmbipy); 127.0 (2*m*-CHs); 128.7 (1C); 128.9 (1C); 130.1 (2C); 130.3 (1*m*-CH); 130.7 (2*m*-CHs); 149.0 (2*o*-CHs, dmbipy); 150.7 (2Cs, dmbipy); 151.7 (2Cs, dmbipy); 162.7 (1 *ipso*-C); 163.51 (2 *ipso*-Cs).

4.2.4. [TiCl($OC_6H_2Me_3$-2,4,6)$_3$] (**4**)

2,4,6-Trimethylphenol (4.31 g, 31.7 mmol) in toluene (40 cm^3) was added to [$TiCl_4$] (2.0 g, 10.5 mmol) in toluene (40 cm^3) and the mixture was refluxed until no more HCl gas was produced (15.5 h). The cooled solution was filtered from a small amount of solid, the solvent was removed and the residue held under vacuum for 2 h giving a gum which formed the complex as a deep-red crystalline mass on standing overnight. Yield: 4.5 g, 87%. *Anal*. Calc. for $C_{27}H_{33}ClO_3Ti$: C, 66.33; H, 6.80. Found: C, 65.88; H, 6.70%. ^{1}H NMR: δ 2.19 (s, 9H, Me), 2.26 (bs, 18H, Me), 6.72 (bs, 6H, *m*-Hs). ^{13}C{^{1}H} NMR: δ 16.9 (*o*-Me), 20.6 (*p*-Me), 126.7 (*o*-C), 128.6 (CH), 132.4 (*p*-C), 163.9 (*ipso*-C).

4.2.5. [TiCl{$OC_6H_3(CHMe_2)_2$-2,6}$_3$] (**5**)

2,6-Di-*iso*-propylphenol (3.0 g, 16.8 mmol) in toluene (30 cm^3) was added to [$TiCl_4$] (1.0 g, 5.27 mmol) in toluene (30 cm^3) and the mixture was refluxed until no more HCl gas was produced (19.5 h). The cooled solution was filtered and the solvent removed giving an orange solid. NMR spectroscopy at this stage indicated the presence of unreacted phenol and two coordination products. The crude material was dissolved in toluene (50 cm^3), the volume reduced to ca. 30 cm^3 and the solution stood at −20 °C, giving the complex as a non-crystalline orange solid containing several large crystals of [Ti{$OC_6H_3(CHMe_2)_2$-2,6}$_4$] which were manually removed from the product. Yield: 1.30 g, 40%. *Anal*. Calc. for $C_{36}H_{51}ClO_3Ti$: C, 70.29; H, 8.36. Found: C, 70.78; H, 8.88%. ^{1}H NMR: δ 1.13 [d, ^3J(HH) 6.9, 36H, CMe_2], 3.42 [sept, ^3J(HH) 6.9, CH], 6.91 (t, 3H, *p*-Hs), 7.03 (m, 6H, *m*-Hs). ^{13}C{^{1}H} NMR: δ 23.2 (Me), 27.5 (CH), 123.0 (*m*-C), 123.8 (*p*-C), 137.4 (*o*-C), 163.1 (*ipso*-C). The NMR spectra are identical to that found for the complex prepared in refluxing benzene [20,21].

*4.2.6. [TiCl{$OC_6H_3(CMe_3)_2$-2,4}$_3$] (**6**)*

Method A: 2,4-Di-*tert*-butylphenol (9.8 g, 47.5 mmol) in toluene (60 cm^3) was added to [$TiCl_4$] (3.0 g, 15.8 mmol) in toluene (50 cm^3) and the mixture was refluxed until no more HCl gas was produced (14.5 h). After refluxing for a further 2 h, the cooled solution was filtered and the solvent removed giving a crystalline orange-red solid. Crude yield: 11.0 g, 99%. This material has a slight red tinge and NMR spectroscopy indicated the presence of a small amount of unreacted phenol (ca. 3–5%) but it was sufficiently pure for further use. The solid was washed with petroleum spirit (40 cm^3) giving the complex as an orange crystalline solid. Yield: 9.21 g, 83%. (Further complex can be obtained by cooling the petroleum spirit washings.) *Anal*. Calc. for $C_{42}H_{63}ClO_3Ti$: C, 72.13; H, 9.08. Found: C, 71.96; H, 9.26%. ^{1}H NMR: δ 1.29 (s, 27H, CMe_3), 1.46 (s, 27H, CMe_3), 7.10 (s, 6H, *o* and *m*-Hs), 7.29 [d, ^4J(HH) 1.3, 3H, *m*-H). $^{13}C\{^1H\}$ NMR: δ 30.3 (Me), 31.6 (Me), 34.6 (C), 35.1 (C), 122.7 (CH), 123.4 (CH), 124.0 (CH), 135.6 (C), 146.3 (C), 163.2 (*ipso*-C). On a larger scale, a reaction between 26.15 g of 2,4-di-*tert*-butylphenol (0.127 mol) and 8 g of [$TiCl_4$] (0.0422 mol) in 120 cm^3 of toluene produced 28.5 g (97%) of the crude product after refluxing for 21 h.

Method B: *n*-Butyl lithium (9.8 cm^3 of a 1.6 mol L^{-1} solution, 15.8 mmol) in hexane was added dropwise to a solution of 2,4-di-*tert*-butylphenol (3.26 g, 15.8 mmol) in diethyl ether (50 cm^3) cooled to −30°C and the solution was stirred with the cooling bath removed for 2 h. [$TiCl_4$] (1.0 g, 5.27 mmol) was added to a flask which was then cooled to −78 °C and diethyl ether (50 cm^3) was added. The solution was heated until all the yellow solid dissolved and then recooled to −78 °C and the lithium phenoxide solution added via a cannula. The cooling bath was removed and the solution stirred for 20 h, filtered and the solvent removed to give the crude complex as an orange crystalline solid (yield: 3.08 g) which was dissolved in diethyl ether (50 cm^3). The solution was filtered and the volume reduced to ca. 25 cm^3 giving the complex as yellow-orange crystals on standing. Yield: 1.24 g, 34%. *Anal*. Calc. for $C_{42}H_{63}ClO_3Ti$: C, 72.13; H, 9.08. Found: C, 72.14; H, 8.72%. The complex has identical NMR spectra to the sample prepared under method A. A single crystal from the mass was used for the X-ray analysis.

4.2.7. [TiCl{$OC_6H_3(CMe_3)_2$-2,4}$_3$(dmbipy)] (7)

4,4′-Dimethyl-2,2′-bipyridine (0.267 g, 1.45 mmol) in CH_2Cl_2 (20 cm^3) was added to complex **6** (1.014 g, 1.45 mmol) in CH_2Cl_2 (20 cm^3) and the mixture was stirred for 2 h. The solution was filtered and the solvent removed to give the complex as an orange flaky solid. Yield: 1.28 g, 99%. *Anal*. Calc. for $C_{54}H_{75}ClN_2O_3Ti$: C, 73.40; H, 5.56, N, 3.17. Found: C, 73.04; H, 5.76, N, 3.09%. The NMR spectra are very complicated due to the presence of isomers. Only the ^{1}H NMR of the distinguishable major isomer is reported: δ 1.28 (s, 18H, $2CMe_3$); 1.31 (s, 9H, CMe_3); 1.37 (s, 18H, $2CMe_3$); 1.51 (s, 9H, CMe_3); 2.31 (s, 6H, 2Me dmbipy); 6.96 [dd, ^3J(HH) 8.2, ^4J(HH) 2.4, 2H, *m*-Hs]; 6.98 (obscured dd, 1H, *m*-H); 7.09 [d, ^3J(HH) 5.6, 2H, *m*-Hs dmbipy]; 7.11 [d, ^3J(HH) 8.4, ^4J(HH) 2.3, 1H, *m*-H]; 7.23 [d, ^4J(HH) 2.4, 2H, *m*-Hs]; 7.29 [d, J(HH) 2.3, 1H, *m*-H]; 7.55 [bd, ^3J(HH) 8.2, 2H, *o*-Hs]; 7.91 (s, 2H, *m*-Hs dmbipy); 8.93 [d, ^3J(HH) 5.6, 2H, *o*-Hs dmbipy]. Easily distinguishable *ortho*-hydrogen resonances for the other isomers are at δ 8.79 and 8.53.

*4.2.8. [TiCl(OC_6H_4Ph-2)$_3$] (**8**)*

2-Hydroxybiphenyl (8.1 g, 47.6 mmol) in dichloromethane (50 cm^3) was added to [$TiCl_4$] (3.0 g, 15.8 mmol) in dichloromethane (50 cm^3) and the mixture was refluxed until no more HCl gas was produced (30 h). The cooled solution was filtered, the solvent was removed giving a dark red gum which failed to solidify on extended pumping. The complex was identified on the basis of NMR spectral characteristics that were similar to complex **9**. ^{1}H NMR: δ 6.58 [d, ^3J(HH) 7.4, 3H, *o*-H], 7.01 [t, ^3J(HH) 7.4, 3H, *p*-H], 7.07 [t, ^3J(HH) 7.4, 3H, *m*-H], 7.12–7.18 [m, 9H, *m* and *p*-Hs(phenyl substituent)], 7.20 [dd, ^3J(HH) 7.4, ^4J(HH) 1.4, 3H, *m*-H], 7.32 [d, ^3J(HH) 7.4, 6H, *o*-Hs(phenyl substituent)]. $^{13}C\{^1H\}$ NMR: δ 120.4 (CH), 124.0 (CH), 127.3 (CH), 128.2 (CH), 128.3 (CH), 129.2 (CH), 130.0 (CH), 130.6 (C), 137.3 (C), 163.6 (*ipso*-C).

*4.2.9. [TiCl(OC_6H_4Ph-2)$_3$(diethyl ether)] (**9**)*

n-Butyl lithium (15.3 cm^3 of a 1.6 mol L^{-1} solution, 24.4 mmol) in hexane was added dropwise to a solution of 2-hydroxybiphenyl (4.15 g, 24.4 mmol) in diethyl ether (80 cm^3) cooled to −30°C and the solution was stirred with the cooling bath removed for 2 h. [$TiCl_4$] (1.54 g, 8.1 mmol) was added to a flask which was then cooled to −78 °C and diethyl ether (80 cm^3) was added. The solution was heated until all the yellow solid dissolved and after cooling to room temperature, it was added via a cannula to the suspension of the lithium phenoxide cooled to −78 °C. The cooling bath was removed and the solution stirred for 20 h, filtered and the remaining solid washed with diethyl ether until it was no longer coloured orange. The combined filtrate and washings were kept hot while the volume was reduced to approximately half and on standing the complex formed as large ruby-red crystals. Yield: 1.8 g, 51%. *Anal*. Calc. for $C_{40}H_{37}ClO_4Ti$: C, 72.24; H, 5.61. Found: C, 71.91; H, 5.48%. ^{1}H NMR: δ 1.13 [t, ^3J(HH) 7.0, 6H, Me], 3.45 [q, ^3J(HH) 7.0, 4H, CH_2], 6.62 (d, 3H, aromatic-H), 6.99 (t, 3H, aromatic-H), 7.05 (t, 3H, aromatic-H), 7.09–7.20 (m, 12H, aromatic-Hs), 7.32 (d, 6H, aromatic-Hs). $^{13}C\{^1H\}$ NMR: δ 15.0 (Me), 66.0 (CH_2), 120.5 (CH), 123.6 (CH), 127.2 (CH), 128.2 (CH), 129.2 (CH), 130.0 (CH), 130.3 (C), 137.5 (*o*-C),163.2 (*ipso*-C). A single crystal from the mass was used for the X-ray analysis.

*4.2.10. [(Ti{($OC_6H_2Me_2$-2,4-CH_2-6)$_3$N})$_2$O] · 1.5C_6H_6 (**10a**)*

Undried tris(2-hydroxy-4,6-dimethylbenzyl)amine (1.77 g, 4.22 mmol) in benzene (40 cm^3) was added dropwise to

a stirred solution of [$TiCl_4$] (0.8 g, 4.28 mmol) in benzene (40 cm^3) and triethylamine (1.8 cm^3, 12.74 mmol) was added dropwise. The mixture was refluxed for 14 h, the cooled solution filtered and the solvent removed to give the complex as yellow crystalline solid which was washed with chilled diethyl ether (30 cm^3). Yield: 2.0 g, 100%. *Anal.* Calc. for $C_{54}H_{60}N_2O_7Ti_2 \cdot 1.5C_6H_6$: C, 71.25; H, 6.55; N, 2.64. Found: C, 71.39; H, 6.76; N, 2.90%. ^{1}H NMR: δ (C_6D_6) 2.15 (s, 9H, Me), 2.38 (s, 9H, Me), 2.8 (b, 3H, CH), 3.8 (b, 3H, CH), 6.54 (bs, 3H, *m*-CH), 6.73 (bs, 3H, *m*-CH), 7.28 (benzene). ^{13}C{^{1}H} NMR: δ 16.1 (Me), 20.7 (Me), 58.8 (CH_2),124.3 (C), 125.0 (C), 128.5 (CH), 129.3 (C), 131.0 (CH), 160.8 (*ipso*-C). A single crystal obtained from the mass produced on recrystallisation from *n*-pentane was used for the X-ray analysis [complex **10b**].

4.2.11. [TiCl{($OC_6H_2Me_2$-2,4-CH_2-6)$_3$N}] (**11**)

Method A: Chlorotrimethylsilane (2 cm^3, 1.34 mmol) was added via a syringe to [(Ti{($OC_6H_2Me_2$-2,4-CH_2-6)$_3$N})$_2$O] (0.6 g, 0.67 mmol) in toluene (30 cm^3) and the mixture was stirred for 8 h. The solution was filtered and the orange precipitate dried under vacuum. Yield: 0.49 g, 73%. *Anal.* Calc. for $C_{27}H_{30}ClNO_3Ti$: C, 64.87; H, 6.05, N, 2.80. Found: C, 64.82; H, 6.32; N, 2.97%. ^{1}H NMR (the complex is only slightly soluble in $CDCl_3$): δ 2.22 (s, 9H, Me), 2.25 (s, 9H, Me), 2.9 (b, 3H, CH), 3.9 (b, 3H, CH), 6.73 (bs, 3H, *m*-H), 6.88 (bs, 3H, *m*-H). ^{13}C{^{1}H} NMR: δ 15.8 (Me), 20.7 (Me), 58.5 (CH_2), 122.8 (C), 124.4 (C), 127.2 (CH), 131.1 (CH), 131.3 (C), 160.2 (*ipso*-C).

Method B: [$TiCl_4$] (0.29 g, 1.52 mmol) was cooled to −78 °C and diethyl ether (40 cm^3) was added. The solution was heated to dissolve the yellow solid, cooled to room temperature and added dropwise to [$Ti(OCHMe_2)_4$] (1.30 g, 4.57 mmol) in diethyl ether (30 cm^3). The mixture was stirred for 30 min [$TiCl(OCHMe_2)_3$] equivalent: (1.59 g, 6.08 mmol) and dry tris(2-hydroxy-4,6-dimethylbenzyl)amine (2.55 g, 6.08 mmol) in diethyl ether (40 cm^3) added dropwise. The mixture was stirred for 2 h and the orange precipitate filtered off and dried under vacuum. Yield: 2.92 g, 96%. *Anal.* Calc. for $C_{27}H_{30}ClNO_3Ti$: C, 64.87; H, 6.05, N, 2.80. Found: C, 65.31; H, 6.41; N, 2.81%. The complex had similar NMR spectra to the sample prepared under method A.

4.2.12. [TiCl({$OC_6H_2(CMe_3)_2$-2,4-CH_2-6}$_3$N)] · diethyl ether (**12**)

[$TiCl_4$] (0.234 g, 1.23 mmol) was cooled to −78 °C and diethyl ether (40 cm^3) was added. The solution was heated to dissolve the yellow solid, cooled to room temperature and added dropwise to [$Ti(OCHMe_2)_4$] (1.05 g, 3.69 mmol) in diethyl ether (30 cm^3). The mixture was stirred for 30 min ([$TiCl(OCHMe_2)_3$] equivalent: 1.286 g, 4.95 mmol) and dry tris(2-hydroxy-4,6-di-*tert*-butylbenzyl)amine (3.33 g, 4.96 mmol) in diethyl ether (40 cm^3) added dropwise. The mixture was stirred for 2 h, the solution filtered and the solvent removed to give an orange crystalline solid. Yield: 2.92 g, 96%. *Anal.* Calc. for $C_{45}H_{66}ClNO_3Ti$ (i.e., [{$N(ArO)_3$}TiCl]): C, 71.81; H, 8.84, N, 1.86. Found: C, 72.99; H, 8.76; N, 2.01%. The solid was dissolved in diethyl ether (120 cm^3) and the solvent kept hot and removed in vacuo until crystallisation could no longer be prevented. On standing, well formed orange crystals were formed. Further crystalline product was obtained by repeating this process. *Anal.* Calc. for $C_{49}H_{76}ClNO_4Ti$: C, 71.21; H, 9.27; N, 1.70. Found: C, 71.45; H, 9.36; N, 1.69%. ^{1}H NMR: δ 1.26 (t, 6H, diethyl ether),1.34 (s, 27H, CMe_3), 1.52 (s, 27H, CMe_3), 3.18 [d, ^2J(AB) 13.9, 3H, CH], 3.53 [d, ^2J(AB) 13.9, 3H, CH], 7.09 [d, ^3J(HH) 2.1, 3H, *m*-H], 7.31 [d, ^3J(HH) 2.1, 3H, *m*-H]. ^{13}C{^{1}H} NMR: δ 15.3 (Me, diethyl ether), 29.6 (CMe_3), 31.6 (CMe_3), 34.5 (C), 34.9 (C), 58.7 (CH_2), 65.8 (CH_2,diethyl ether), 123.3 (*o*-C), 123.5 (*m*-CH), 124.0 (*m*-CH), 135.7 (*p*-C), 144.3 (*o*-C), 160.8 (*ipso*-C). A single crystal from the mass was used for the X-ray analysis.

4.2.13. [TiCl{($OC_6H_2(CMe_3)_2$-2,4-CH_2-6)$_3$N}(NC_5H_5)] (**13**)

Pyridine (0.2 g, 2.5 mmol) in diethyl ether (10 cm^3) was added dropwise from a syringe to a rapidly stirred solution of complex **12** (0.373 g, 0.45 mmol) in diethyl ether and the mixture was stirred for 2 h. The solution was filtered and the brown microcrystalline solid dried in vacuo. Yield: 0.364 g, 97%. *Anal.* Calc. for $C_{50}H_{71}ClN_2O_3Ti$: C, 72.23; H, 8.61; N, 3.44. Found: C, 72.70; H, 9.27; N, 3.66%. ^{1}H NMR (CD_2Cl_2): δ 1.99 (t, 6H, Me), 1.32 (s, 27H, CMe_3), 1.49 (s, 27H, CMe_3), 3.47 (q, 4H, CH_2), 3.64 (bs, 6H, CH_2), 7.09 [d, ^3J(*HH*) 2.2, 3H, *m*-H], 7.31 [d, ^3J(*HH*) 2.2, 3H, *m*-H], 7.31–7.35 (obsm, 2H, *m*-H_{py}), 7.73 (td, ^3J(*HH*) 7.7, 1H, (*p*-H_{py})), 8.63 (bs, 2H, *o*-H_{py}). ^{13}C{^{1}H} NMR: δ 15.5 ($Me_{diethyl\ ether}$), 29.7 (CMe_3), 31.7 (CMe_3), 34.8 (C), 35.2(C), 59.0 (CH_2), 66.1 ($CH_{2diethyl\ ether}$), 123.9 (CH), 123.95 (*o*-C), 124.2 (*m*-CH_{py}), 135.8 (*p*-C), 136.4 (*p*-CH_{py}),144.8 (*o*-C), 150.1 (*o*-CH_{py}), 161.1 (*ipso*-C).

4.3. X-ray crystallography

Crystallographic and refinement data are given in Table 6. Data collected, with graphite monchromated Mo Kα X-radiation, were measured on a Siemens SMART CCD area detector diffractometer with the omega scan method. The data were corrected for Lorentz and polarisation effects and for absorption by the multi-scan method [35]. The structures were solved by direct methods [36] and refined by full-matrix least-squares methods [37] on F^2. Hydrogen atoms were placed in calculated positions and were refined with a riding model ($U_{iso} = 0.08$). Diagrams were prepared by ORTEP [38] and RASTOP [39]. Selected bond distances and angles are listed in Tables 1–5. Complex **2** is dimeric lying across a centre of symmetry. Some disorder was noted for the Cl (with a site occupancy ratio of ca. 90:10) and also for the H atoms in the Me group in the 4 positions of both terminal phenoxo ligands. The occupancies of these latter were fixed at 0.5. In **6** the *tert*-butyl group in the para

compounds [7,8] as precursors of heterocyclic molecules [9–11], including *N*-arylpyrazole derivatives have been studied by some of us owing to their wide applications in the pharmaceutical and agrochemical industries [12–14].

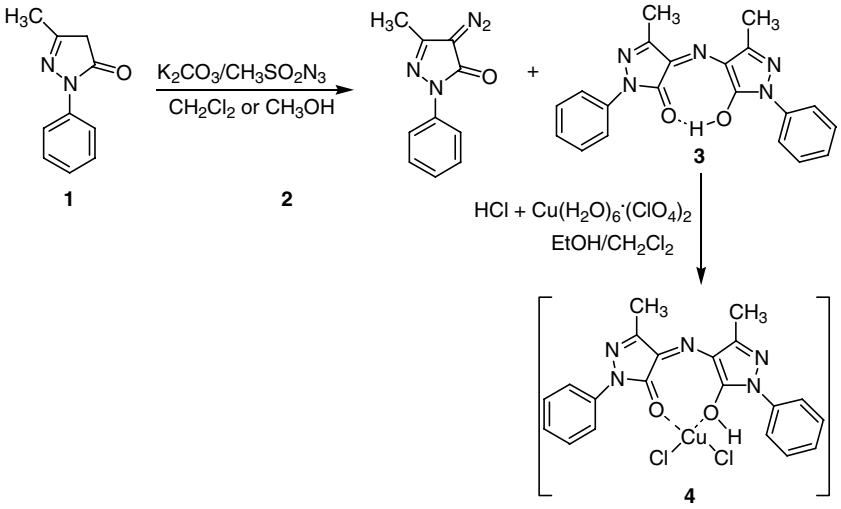
On the other hand, pyrazolyl and pyrazolyl-derived ligands can form relevant coordination compounds with different metal ions. Copper complexes have been extensively studied, especially dinuclear and polynuclear species, as mimics of the proteins hemocyanin and tyrosinase [15] or as compounds with interesting catalytic and magnetic properties [16–18]. In most of these complexes, copper ions are linked by *N*,*N*′-bridging pyrazolato anions, or coordinated by one nitrogen atom of the pyrazole ring [19]. However, recently an unusual coordination mode of this type of ligand was described, where nitrogen atoms of the pyrazole rings are not bound to copper, but involved in strong intramolecular hydrogen bonds [20]. Additionally, pyrazolone derivatives have interesting spectroscopic and structural properties owing to its keto-enol tautomerism [21]. Recently, some Schiff bases derived from 3-methyl-1-(4′-methylphenyl)-2-pyrazolin-5-one and aromatic amines were prepared and had their molecular structures determined. These ligands can exist in three tautomeric forms: keto-imine, imine-ol, and keto-amine, although the keto-amine form is predominant in the solid state [22]. Their corresponding mononuclear copper(II) complexes were also prepared and characterized by spectroscopic techniques, indicating a tetragonal geometry around the copper(II) ion, N,O coordinated.

Herein, we report a new method for preparing 4-(5-hydroxy-4-pyrazolylimino)-2-pyrazolin-5-one (**3**), from 2-pyrazolin-4,5-dione (**1**), in an one-step diazo-transfer process (see Scheme 1), and its corresponding crystal structure, that showed a near-linear intramolecular H-bonding. Further, since this compound shows different coordinating groups its binding ability towards copper(II) ions was investigated. A dark red complex **4** was obtained by reaction of **3** with copper(II) ions at stoichiometric ratio, in ethanol/water solution, at pH 4–5 adjusted with HCl. Compound **4** has been characterized as a neutral 1:1 species, [**3**:$CuCl_2$], involving tautomeric forms, by ESI-MS, ESI-MS/MS, IR, UV/Vis and EPR spectra, in addition to conductivity and elemental analysis. The deprotonation of **4**, in which the copper(II) ion is coordinated to ligand **3** solely by oxygen atoms, was monitored by UV/Vis, and a corresponding pK_a value was determined.

2. Experimental

2.1. Reagents and techniques

Melting points were determined on a Fisher–Johns apparatus and are uncorrected. Column chromatography was performed on silica gel 60 (Merck 70–230 mesh). Infrared spectra were recorded on Perkin–Elmer 1420 and BOMEM 3.0 instruments in the range 4000–400 cm^{-1}, in KBr pellets. NMR spectra were recorded with a Varian Unity Plus 300 spectrometer, operating at 300 MHz (^1H) and 75 MHz (^{13}C), with tetramethylsilane as the internal standard. Elemental analyses were performed at *Central Analítica* of the Instituto de Química-USP, using a Perkin–Elmer 2400 CHN Elemental Analyzer. Electronic spectra were recorded on an Olis modernized-Aminco DW 2000 instrument, using a thermostated cell compartment, and standard 1.00 cm quartz cells. The pH of the solutions was monitored using a Digimed DMPH-2 instrument, coupled to a combined pH electrode either from Ingold or Radiometer. Appropriate buffer solutions were used to calibrate the instrument. Conductivity experiments of 1 mmol dm^{-3} aqueous solutions were carried out on a Digimed DM-31 instrument, using a 10.0-mmol dm^{-3} KCl solution as standard (specific conductivity = 1412.0 μS cm^{-1} for aqueous solution, or 0.141 μS cm^{-1} for organic solutions, both at 298 K) [23]. EPR spectra were recorded



Scheme 1. Synthetic route used for obtaining compounds **2**–**4**.

on a Bruker EMX instrument, operating at X-band frequency, using standard Wilmad quartz tubes, at 77 K. DPPH (α,α′-diphenyl-β-picrylhydrazyl) was used as frequency calibrant ($g = 2.0036$) with samples in frozen CH_3CN:water (8:1, v/v) solutions, at 77 K. Usual conditions used in these measurements were 2.83×10^4 receiver gain, and 15G modulation amplitude. ESI mass and tandem mass spectrometric measurements were made using a Micromass (Manchester – UK) QTof instrument of ESI-QqTof configuration with 7.000 mass resolution in the TOF mass analyzer. The following typical operating conditions were used: 3 kV capillary voltage, 40 V cone voltage and dessolvation gas temperature of 100 °C. Tandem ESI-MS/MS spectra were collected after 15–20 eV collision induced dissociation (CID) of mass-selected ions with argon. Mass-selection was performed by Q1 using a unitary *m/z* window, and collisions were performed in the rf-only quadrupole collision cell, followed by mass analysis of product ions by the high-resolution orthogonal-reflectron Tof analyzer.

2.2. Synthetic procedures

2.2.1. 2-Diazo-3-methyl-1-phenyl-5-pyrazolone (2) and 2,4-dihydro-4-[(5-hydroxy-3-methyl-1-phenyl-1H-pyrazol-4-yl)imino]-5-methyl-2-phenyl-3H-pyrazol-3-one (3)

To a stirred suspension of potassium carbonate (2.5 mmol) in anhydrous dichloromethane (or methanol) (5 mL) under nitrogen at room temperature, was added a solution of **1** (1.0 mmol) in anhydrous dichloromethane (or methanol) (4 mL). After stirring the ice-cooled mixture for 0.5 h, a solution of mesyl azide (1.4 mmol) in dichloromethane (or methanol) (1 mL) was added dropwise. The reaction mixture was then stirred for other 3 h at room temperature, and the solvent was removed under vacuum to leave a red oily residue, which was separated by column chromatography on silica gel, using 40% dichloromethane in hexane as eluent to give **2** and **3**.

Compound **2**. ^{1}H NMR ($CDCl_3$) δ: 2.39 (s, Me), 7.20 (tt, 1H, *J* 1.2 and 7.5 Hz, H–Ar), 7.37–7.43 (m, 2H, H–Ar), 7.87–7.91 (m, 2H, H–Ar) . ^{13}C NMR ($CDCl_3$) δ: 13.9 (CH_3), 66.4 (C=N_2), 119.1(C-2′), 125.1 (C-4′), 128.7 (C-3′), 138.4 (C-1′), 141.8 (C-4), 163.0 (C=O). IR (KBr, cm^{-1}) $\nu_{C=O}$ 1681; ν_{N-N} 2133. EIMS (*m/z*) 200 [M^+, 100%]. UV/Vis (CH_2Cl_2, nm) λ_{max}: 251 ($\varepsilon_1 = 5.3 \times 10^4$), and 332 ($\varepsilon_2 = 2.3 \times 10^3$).

Compound **3**. M.p. 183–184 °C (lit. 183 °C). Elemental *Anal*. Calc. for $C_{20}H_{17}N_5O_2 \cdot 3H_2O$: C, 58.10; H, 5.61; N, 16.94. Found: C, 57.20; H, 5.04; N, 17.14%; ^{1}H NMR ($CDCl_3$) δ: 2.37 (s, 2Me), 7.30 (tt, 2H, *J* 1.2 and 7.5 Hz, H–Ar), 7.43–7.49 (m, 4H, H–Ar), 7.89–7.93 (m, 4H, H–Ar), 17.97 (s, 1H, OH). ^{13}C NMR ($CDCl_3$) δ: 11.8 (CH_3), 120.5 (C2′), 125.7 (C4), 126.7 (C4′), 128.8 (C3′), 137.4 (C1′), 152.1 (C3), 154.3 (C5). IR (KBr, cm^{-1}) $\nu_{C=O}$, 1729; ν_{OH} 2922, 2852. EIMS (*m/z*) 359 [M^+, 88%]. UV/Vis (CH_2Cl_2) λ_{max}/nm (ε/mol^{-1} dm^3 cm^{-1}): 250 ($\varepsilon_3 = 3.2 \times 10^3$), 359 ($\varepsilon_2 = 1.4 \times 10^3$) and 460 ($\varepsilon_1 = 1.3 \times 10^3$); UV/Vis ($CH_3CN$) λ_{max}/nm (ε/mol^{-1} dm^3 cm^{-1}): 204 (4.9×10^4), 240 (3.2×10^4), 368 (1.3×10^4) and 445 (2.6×10^4).

2.2.2. Preparation of the copper(II) complex (4)

A solution of $Cu(ClO_4)_2 \cdot 6H_2O$ (0.150 g, 0.4 mmol) in H_2O (0.5 mL) was added at room temperature and under stirring to a solution of **3** (0.165 g, 0.4 mmol) in ethanol (10 mL). The apparent pH of the reaction mixture was adjusted to 4–5 by dropwise addition of aqueous HCl solution (~1 M). After stirring for 6 h, tiny brownish-red crystals were collected, washed with cold ethanol and ether, and dried under reduced pressure over P_2O_5 to yield 0.122 g (60%) of the complex **4**.

Elemental *Anal*. Calc. for $[C_{20}H_{18}N_5O_2CuCl_2]$: C, 48.54; H, 3.67; N, 14.15; Cu, 12.84; Cl, 14.33. Found: C, 48.28/48.62; H, 3.34/3.59; N, 13.74/14.60; Cu, 11.88; Cl, 13.80%. $\Lambda_M = 21$ S cm^2 mol^{-1} in water solution, 17 S cm^2 mol^{-1} in CH_3OH, and 0 S cm^2 mol^{-1} in CH_2Cl_2. IR (KBr, cm^{-1}): ν_{OH}, 3432 (m); $\nu_{C_{sp3}-H}$, 3065 (w); $\nu_{C_{sp2}-C}$ 2924 (w); $\delta_{C_{sp2}-C}$, 995–775; $\nu_{C=O}$, 1614 (s); $\nu_{C=N}$, 1596 (m); ν_{C-N}, 1532 (w). UV/Vis (CH_3CN) λ_{max}/nm (ε/mol^{-1} dm^3 cm^{-1}): 203 (8.9×10^4), 255 (8.8×10^4), 348 (3.0×10^4) and 540 (2.4×10^4).

2.3. X-ray crystallography data collection and processing

Room temperature data were collected on a Bruker SMART area CCD diffractometer whilst low temperature date were collected on a Enraf Nonius KappaCCD diffractometer at the UK's EPSRC X-ray crystallographic service, based at the University of Southampton. The structure was solved by direct methods with SHELXS-97 and refined using SHELXL-97 [24] in the triclinic spacegroup $P\bar{1}$. Two dimers were present in each asymmetric unit to give **4** in the unit cell. The data completeness for the low temperature data set was somewhat lower than that of the room temperature set, as shown in Table 1, so discussion will concentrate on the room temperature data, although no major differences were discernable between the two results. All H atoms were located from difference maps and then treated as riding atoms, with C–H distances of 0.96 Å (methyl) or 0.93 Å (aromatic) and U_{iso}(H) values of $1.5U_{eq}$(methyl) or $1.2U_{eq}$(aromatic). The exceptions were the hydrogen atoms bridging two oxygen atoms, H11 and H31, which were allowed to refine freely. Conformational and H-bonding analysis was performed using PLATON [25].

3. Results and discussion

3.1. Compounds 2 and 3

Our synthetic route to **2**–**4** is shown in Scheme 1. Pyrazolone **1** on reaction with mesyl azide or tosyl azide in the presence of a base at room temperature furnished the diazo-pyrazolone **2** and the bis-pyrazole **3**. The diazo transfer reaction was attempted under a variety of conditions (Table 2), but most of the experimental conditions

provided the diazo-pyrazolone **2** in moderate to good yield (entries 1–7) with only traces of **3**. However, when the diazo transfer reaction was performed in methanol, only **3** was isolated in moderate yield (entry 8). Several other conditions were tested but led mostly to **2**. Mesyl azide appears to be a more convenient reagent than tosyl azide for **3** (entries 1–7).

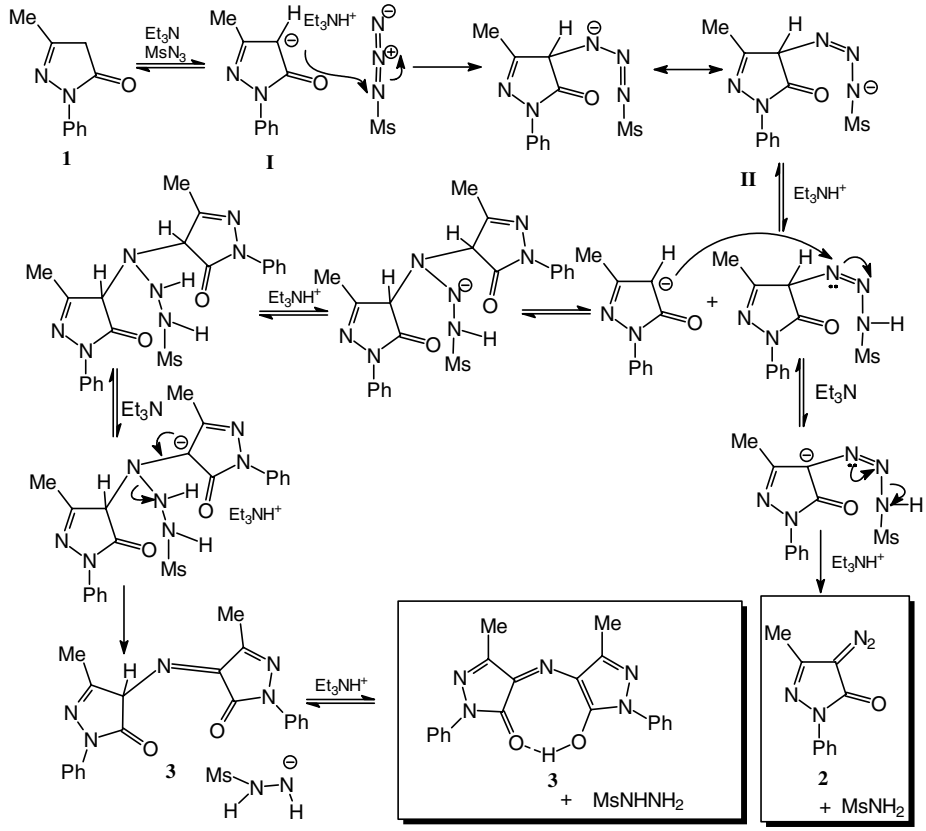
A different preparation of **3** was published by Hansel in 1976 [26], following a much earlier article in 1887 [27]. Hansel's synthesis employed **5** and 2-pyrazolin-4,5-dione (**6**) [28]. However, as only the m.p. of **3** was given, we present herein selected spectral details for **3** as well as its crystal structure.

Compounds **2** and **3** were characterized by IR, ^{1}H, ^{13}C NMR spectroscopies and ESI mass spectrometry. In the IR spectrum of **2**, the N=N absorption appears at 2133 cm^{-1} and the C=O stretch at 1682 cm^{-1} [29]. IR spectrum of **3** shows a reactively weak C=O absorption band at 1729 cm^{-1}, a cluster of bands between 2970 and 2850 cm^{-1}, with maxima at 2922 and 2851 cm^{-1}, the most intense bands in the spectrum, and a broad weak absorption band centered at 3400 cm^{-1}. The NMR spectrum of **3** indicates one set of chemical shifts for the two halves of the molecule. Of some significance is the δ^1H (OH) value in $CDCl_3$ solution at −50 °C of 17.95 ppm.

Usually, direct diazo transfers alpha to carbonyl are performed via reaction of sulfonyl azides on enolates [30,31]. Without success, we attempted to convert diazo-pyrazolone **2**–**3** under different reaction conditions. Therefore, we conclude that **3** must be formed from a different precursor. We speculate (Scheme 2) that **3** is produced by a second attack of the pyrazolone carbanion (**I**) on the intermediate (**II**). Participation of intermediate (**II**) in other side reactions has already been reported [32].

3.2. Crystallographic data for *3*

Fig. 1 shows the numbering scheme and atom arrangements for **3**. As shown by the selected data in Table 3, the two independent molecules exhibit only subtle differences in bond angles and lengths. Each molecule exhibits extensive delocalization and overall the molecule exhibits a structure almost midway between the two canonical



Scheme 2. Proposed mechanism for formation of **3**.

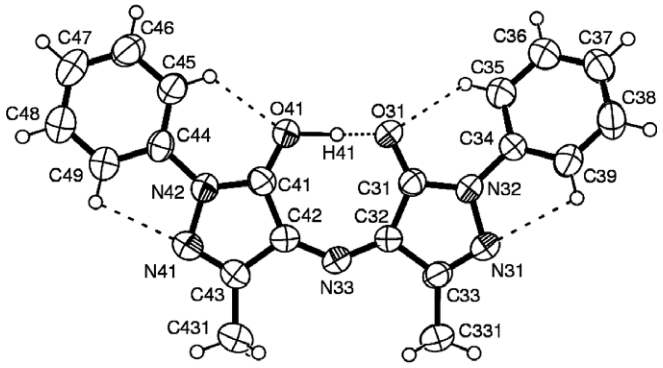


Fig. 1. Atom arrangements and the numbering scheme for the two independent molecules of **3**; probability ellipsoids are dawn at the 30% level. Intramolecular hydrogen bonds are shown as dotted lines.

forms IIIA and IIIB, Scheme 3, with a very strong, near linear O–H–O hydrogen bond closing a 8-membered central ring (see values in Table 3). This situation is similar to those found in several 3-aryl-pentane-2,4-diones, in which the 6-membered rings in the enol tautomers are remarkably symmetrical and with O---O distances of ca. 2.4–2.5 Å [33]. The C–O bond lengths in the two independent molecules of **3** are in the region 1.271(3)–1.290(3) Å – values between those expected for single and double bonds. Neither of the two molecules has a plane of symmetry in the solid state, but as shown by the single set of chemical

shift values for the atoms in the diazole rings in each of the ^{1}H and ^{13}C NMR spectra, in solution the molecule is symmetrical.

Further intramolecular C–H···O and C–H···N hydrogen bonds (Fig. 1) provide extra rigidity to the structure of **3**. Intermolecular interactions involve both the C16-H16···O11^{i} hydrogen bond, which forms a dimer centred on (0.5, 0.5, 0.5) with motif $R_4^2(10)$, Fig. 2, (symmetry operation: *i*: $-x+1$, $-y+1$, $-z+1$) and $\pi\cdots\pi$ interactions which lead to a "chain" of molecules along [1 0 0] as seen in Fig. 3. These involve the rings defined by N41–N42–C41–C42–C43 and C24–C25–C26–C27–C28–C29. There are also $\pi\cdots\pi$ interactions between the two molecules of the asymmetric unit.

Finally, the IR spectrum of **3** in KBr discs exhibits only a medium intensity band in the carbonyl region, at 1728 cm^{-1}.

3.3. Copper complex *4*

The complex **4** was obtained by the 1:1 reaction of **3** with copper(II) perchlorate hexahydrate in ethanol/aqueous HCl at pH 4–5, as tiny red-brown crystals. While in Scheme 1, complex **4** is drawn as a localized structure, it is considered much more likely to exist as a tautomeric compound, as shown in Scheme 3. Since suitable crystals for X-ray structure determination could not be grown, different spectroscopic techniques have been employed to characterize this complex. Confirmation of the presence of copper in the complex **4** came both from ESI-MS(/MS) data and from UV/Vis and EPR spectra.

The ESI mass spectrum of an acetonitrile solution of **4** reveals a cluster of four major isotopologue ions of *m*/*z* 463, 464, 465, and 466 with abundance ratios of

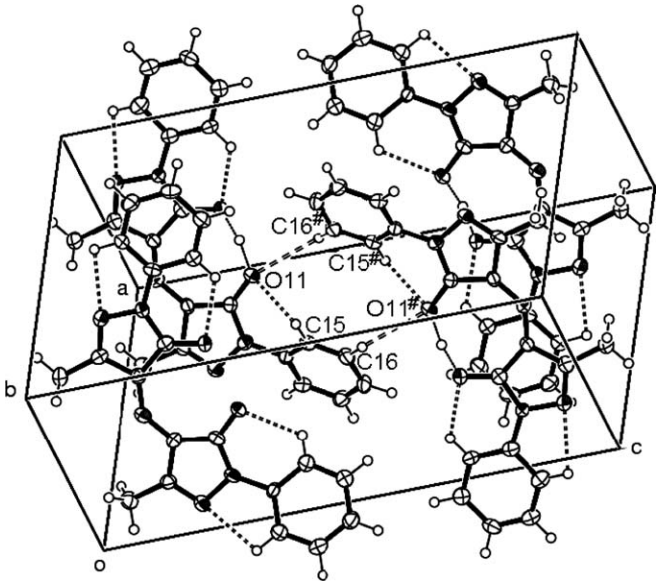

Fig. 2. Intra- and inter-molecular hydrogen bonds, shown as dotted lines, within the unit cell of **3** showing formation of a dimer. Geometric parameters are included as Supplementary Material.

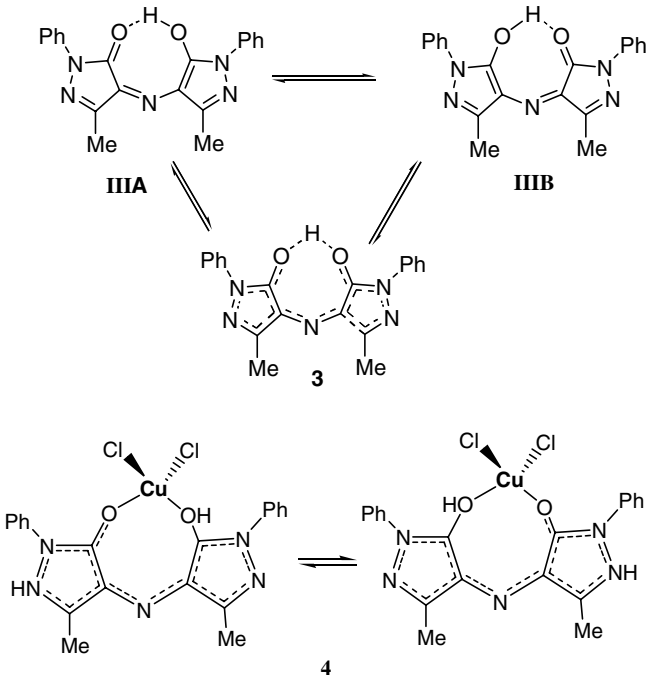

Scheme 3. Structures of **3** and **4**.

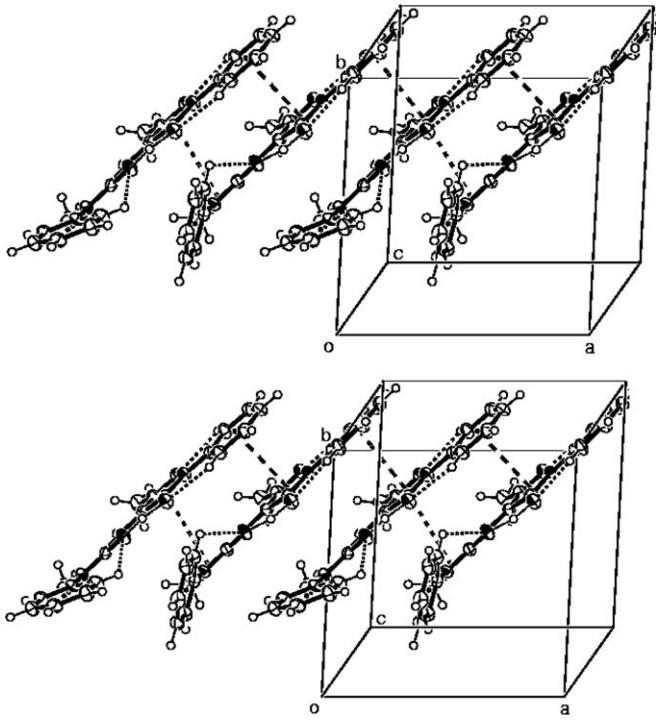

Fig. 3. π–π Interactions in **3**, forming a "chain" of molecules along [1 0 0].

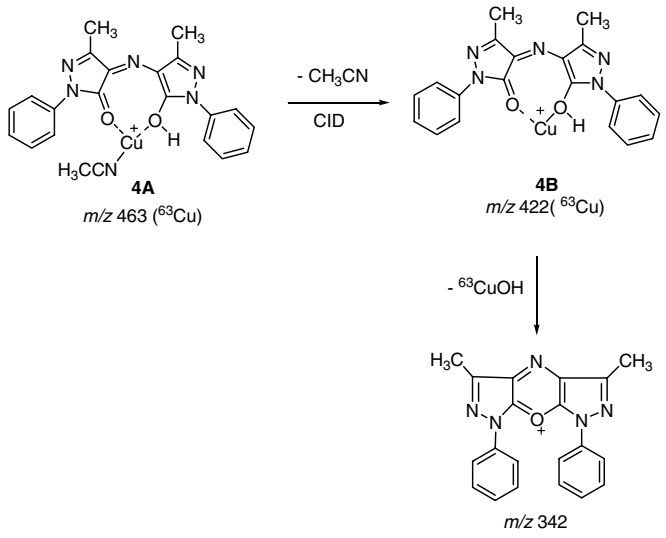
1:0.26:0.48:0.12 that is expected for a mono-nuclear Cu species of formula $[C_{22}H_{20}N_6O_2Cu]^{+}$, i.e., ion **4A** (Scheme 4), a chloride free Cu(I) complex coordinated to a single acetonitrile ligand. Collision-induced dissociation of the ^{63}Cu-isotopologue ion of *m*/*z* 463 shows that **4A** dissociates mainly by the loss of acetonitrile to form **4B** of *m*/*z* 422, and subsequently by the loss of a neutral species of



Scheme 4. Dissociation patterns for the singly charged ions of m/z 463 from ESI-MS/MS of **4**.

80 Da, ^{63}CuOH, to form the fragment ion of m/z 342 ion. This last fragmentation provides evidence for Cu–O coordination in **4**.

Conductivity measurements of solutions of **4** in CH_3OH and in CH_2Cl_2, at 298 K, indicate a non-electrolyte. Measurements in water are unexpected low, probably due to the very low solubility of this complex in aqueous solution. In the IR spectrum in KBr pellets, fail to observe strong bands near 1090 and 625 cm^{-1} suggests the absence of non-coordinated perchlorate ions. The addition of HCl to the reaction mixture during the synthesis of **4** clearly favored the involvement of Cl^- rather than ClO_4^- in the isolated complex. The C, H, N elemental analyses of solid **4** gave C, 48.28/48.62; H, 3.34/3.59; N, 13.74/14.60; Cu, 11.88; Cl, 13.80%, which is in excellent agreement with those expected for the complex, $[LCuCl_2]$, which requires C, 48.54; H, 3.67; N, 14.15; Cu, 12.84; Cl, 14.33%.

Other evidence that copper(II) ion binds to ligand **3** via oxygen atoms comes from the shift of the medium intensity band found at 1726 cm^{-1} in **3** to a much more intense band at 1614 cm^{-1} in **4**. Furthermore, the ν(C=N) bands at 1599 cm^{-1} for **3** and 1596 cm^{-1} for **4** suggest that Cu is not coordinated to the imine nitrogens. The bands at around 3074–2920 cm^{-1}, for both **3** and **4**, are assigned to $\nu(C_{sp3}–H)$ and $\nu(C_{sp2}–H)$, whereas the corresponding bending modes are observed in the 995–755 cm^{-1} range.

Analogously, a copper(II) complex with a new pyrazole-based ligand, $Na[Cu(bdmpb)_2(OOCCH_3)H_2O]$, where Hbdmpb = 1,3-bis(3,5-dimethylpyrazol-1-yl)-2-butanoic acid, has been recently prepared, and its crystal structure determined by X-ray analysis indicated that the nitrogen atoms of the pyrazole rings do not coordinate to the metal center. Instead, these nitrogen atoms are involved in strong intramolecular hydrogen bonds, and the copper ion is coordinated by four nearly coplanar oxygen atoms [20]. In this complex, as well as in our complex **4** there are methyl substituents that provide some steric hindrance around the nitrogen atoms in the pyrazole moiety.

Electronic spectra of **3** and **4** (Fig. 4) were obtained in CH_3CN solution. The absorption bands for the ligand **3** were observed at 204, 240, 368 and 445 nm (see Section 2). Analogous bands were observed for complex **4**; however, the maximum of the characteristic d–d band ($T_{2g} \leftarrow E_g$) for **4** is probably hidden under the dominant and overlapping LMCT transition band, at 540 nm. On the other hand, spectral changes in aqueous solution of **4** at different pHs were also verified, by appropriate addition of either HCl or NaOH solutions (0.1 mol dm^{-3}). The LMCT transition band for **4**, detected at 540 nm at pH $\geqslant$ 5.5, shift to the maximum absorption corresponding to free ligand transition at 445 nm, in more acidic medium (Fig. 5A), with an isosbestic point at 475 nm. A concomitant variation of the solution color was observed, from yellow to purple. A plot of pH versus log $[(A - A_{min})/(A_{max} - A)]$,

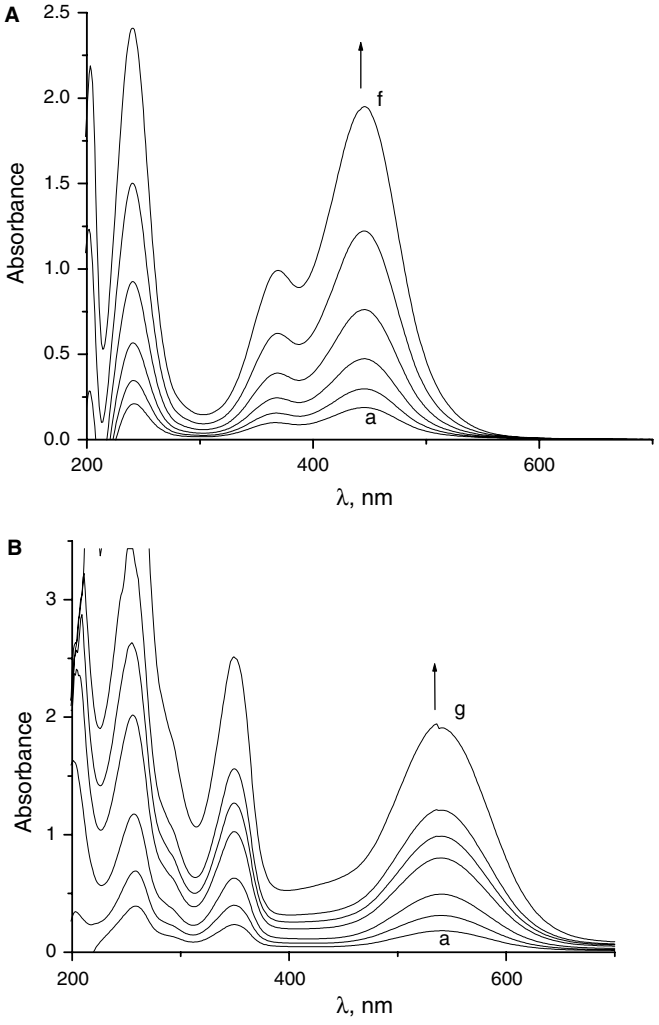


Fig. 4. Electronic spectra of: (A) compound **3** and (B) complex **4** in CH_3CN solution. For spectra in (A) a: 0.62×10^{-6}, b: 1.0×10^{-5}, c: 1.7×10^{-5}, d: 0.29×10^{-4}, e: 0.48×10^{-4}, f: 0.80×10^{-4} mol dm^{-3}. For spectra in (B) a: 4.0×10^{-5}, b: 0.81×10^{-5}, c: 0.16×10^{-4}, d: 0.32×10^{-4}, e: 0.46×10^{-4}, f: 0.65×10^{-4}, g: 1.3×10^{-4} mol dm^{-3}.

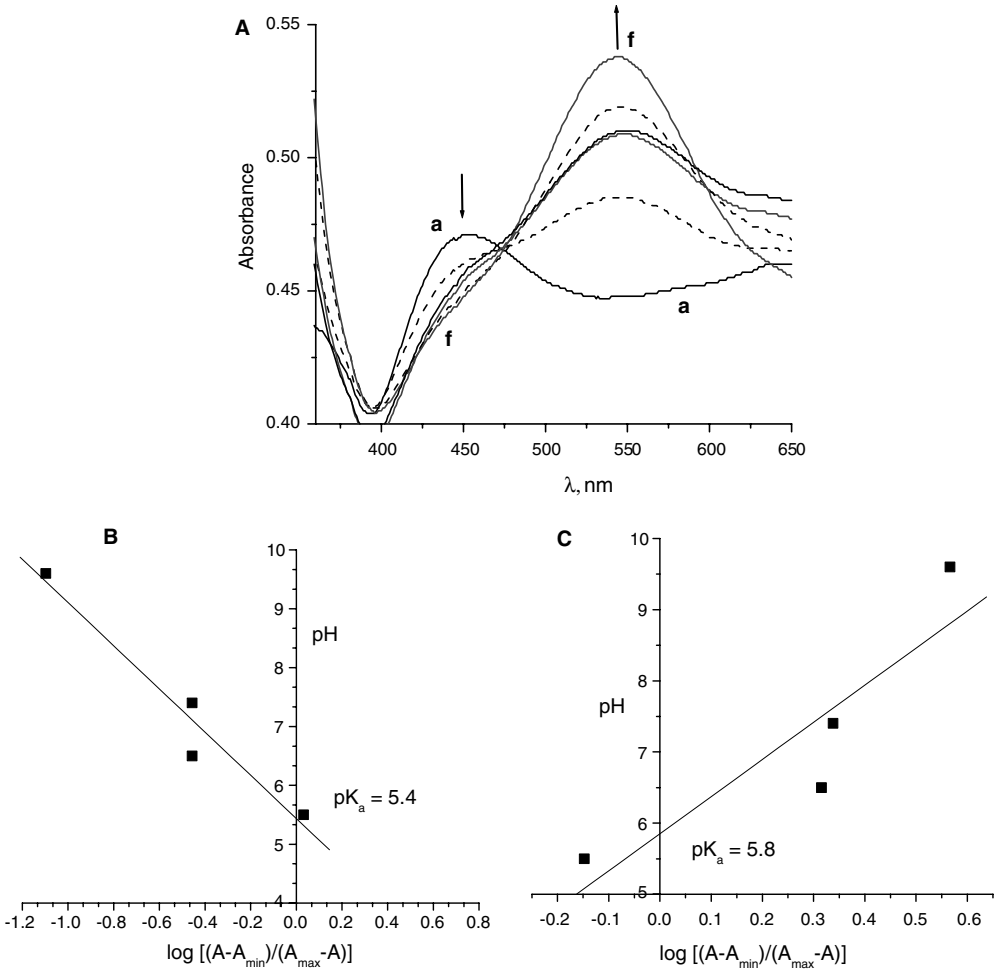

Fig. 5. (A) UV/Vis spectra of the complex **4** (20 μmol dm^{-3}), in water, at different pH values (a–f): (a) 3.0; (b) 5.5; (c) 6.5; (d) 7.3; (e) 9.6; (f) 10.5. (B) Plot of pH versus log $[(A - A_{min})/(A_{max} - A)]$, at $\lambda = 440$ nm. (C) Plot of pH versus log $[(A - A_{min})/(A_{max} - A)]$, at $\lambda = 540$ nm.

where A = absorbance of the band at $\lambda = 440$ nm (Fig. 5B) or at $\lambda = 540$ nm (Fig. 5C), led to the calculation of a p$K_a = (5.6 \pm 0.2)$ as expressed simplistically below:

$$[LCu]^{2+} + OH^- \leftrightharpoons [LH_{-1})Cu]^+ + H_2O \quad K_a$$

Similar equilibria have been recently observed with isatin-Schiff base copper(II) compounds, and for these complexes different tautomers were isolated, depending on the ligand [34]. On the other hand, the acid dissociation constants determined for acylpyrazolone derivatives indicated a pK_a around 4 [35].

The EPR spectrum of **4** (Fig. 6) in frozen CH_3CN:water solution (8:1, v:v) shows a characteristic profile of an axial environment around the copper(II) center, with $g_\parallel > g_\perp$. The EPR parameters were determined as $A_\parallel = 140.9 \times 10^{-4}$ cm^{-1}, $g_\parallel = 2.389$, $A_\perp = 12.7$ G and $g_\perp = 2.077$. The empirical ratio $g_\parallel/A_\parallel$ has been used to evaluate tetrahedral distortions in tetragonal structures of Cu(II) compounds, where a $g_\parallel/A_\parallel$ value close to 100 cm indicates a roughly square planar or tetragonal structure around the copper(II) ion, and values between 170 and 250 cm are indicative of a

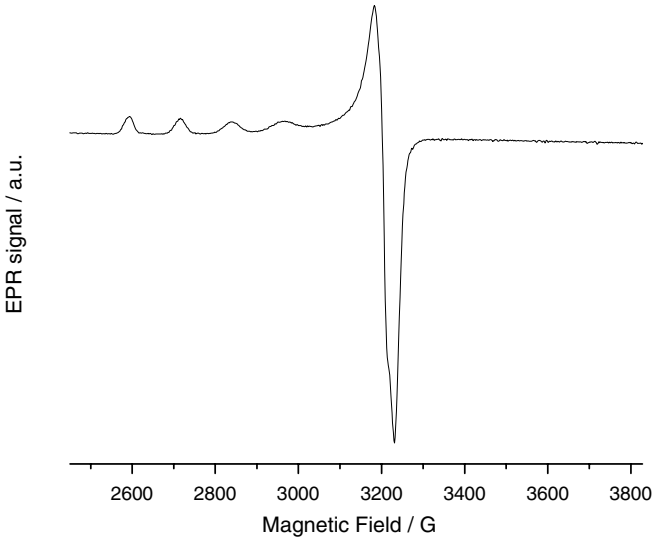

Fig. 6. EPR spectrum of the copper(II) complex **4** (0.5 mmol dm^{-3}), in CH_3CN:H_2O (8:1, v:v), at 77 K. Conditions: 2.83×10^4, receiver gain; 15 G, modulation amplitude; 20.48 s, time constant; 8 scans.

distorted tetrahedral copper(II) symmetry [36]. Based on these data, **4** exhibits a geometry closely to a distorted tetrahedron from the $g_{\|}/A_{\|}$ value of 169 cm. Evidence for substitution of chloride ligands by the CH_3CN solvent was obtained by inspection of EPR spectra. Duplication of copper hyperfine structure, $g_{\|} = 2.375$ and 2.343, with corresponding $A_{\|} = 149$ and 163×10^{-4} cm^{-1}, respectively, was observed at apparent pH $\geqslant 7$ (data not shown). Furthermore, evidence of a gradual reduction of Cu(II) to Cu(I) (an EPR silent ion) was detected at higher pH values, with consequent decreases in the intensity of the EPR signal, estimated by double integration of the bands, and concomitant oxidation of the ligand, similarly to what occurs during the ESI-MS/MS experiment (see Scheme 4). Reduction to provide the stable $[Cu^{I}(CH_3CN)_4]^{+}$ ion is a strong possibility [37].

4. Conclusions

A new route to 4-(5-hydroxy-4-pyrazolylimino)-2-pyrazolin-5-one, **3**, is reported, via an one-pot diazo transfer reaction of pyrazolin-5-one (**1**). The structure of **3** has been determined by X-ray crystallography and by NMR. Both in solution and in the solid state, **3** exhibits extensive delocalization with a very strong near-linear, near-symmetrical O–H–O hydrogen bond closing the central 8-membered ring. In the ^1H NMR spectrum in $CDCl_3$ solution the δ^1H (OH) value is 17.95 ppm. A mononuclear copper complex **4** was obtained on reaction of **3** with copper(II) ions in ethanol/water/HCl (pH 4–5) and structurally characterized as the complex $[LCuCl_2]$, via elemental analysis, FT-IR, UV/Vis, EPR, ESI-MS, and ESI-MS/MS spectra. IR spectra provided strong evidence for coordination of Cu(II) to ligand **3** via the C–O groups, replacing the bridging H atom. EPR data indicated a distorted tetrahedral environment to copper(II) ion. The pK_a value of **4**, determined by UV/Vis spectroscopy, was calculated to be (5.6 ± 0.2).

affect the ability of the platinum drug to block replication and transcription.

A series of DNA adducts with 1,2-diaminocyclohexane-Pt, 1,4-diaminocyclohexane-Pt, homopiperazine-Pt complexes have been reported by us previously [28–30]. In a continuous effort to investigate any correlation between anticancer activity and the DNA adduct profile, which may contribute to the understanding mechanism of action of such platinum-based anticancer agents, that are structurally and functionally distinct form cisplatin prompted us to report here the synthesis and characterization of a series of homopiperazine Pt(II) mono and diadducts with DNA bases and nucleosides along with the crystal structure of one of these complexes, [Pt^{II}(homopiperazine)-(9-ethylguanine)$_2$]$(NO_3)_2$.

2. Experimental

2.1. Chemicals

K_2PtCl_4 was purchased from Johnson Mathey (Seabrook, NH). Silver nitrate was purchased from Alfa Aesar (Ward Hill, MA). Homopiperazine (hmp), adenine (Ade), 9-ethylguanine (9-EtGua), 7-methylguanine (7-MeGua), cytosine (Cyt), 1-methylcytosine, (1-MeCyt), cytidine (Cytd), methylene chloride, and acetone were purchased from Aldrich Chemical Co. (Milwaukee, WI). Silver sulfate, silver nitrate, HCl, nitric acid, *N*,*N*-dimethylformamide (DMF), and potassium iodide (KI) were purchased from Fisher Scientific Co. (Houston, TX).

2.2. Physical measurements

Elemental analysis of the complexes was performed by Robertson Laboratories Inc. (Madison, NJ). ^1H, ^{13}C, and ^{195}Pt NMR spectra were recorded for complexes in solution with D_2O and DCl using a 300-MHz spectrometer. Shifts in the ^{195}Pt spectra were measured relative to an external standard of 0.2 M Na_2PtCl_6 in D_2O at 0.00 ppm.

2.3. Synthesis of platinum complexes

2.3.1. Preparation of [Pt^{II}(hmp)(Ade)Cl]NO_3 (**1**)

[Pt^{II}(hmp)Cl_2] was synthesized as described previously [28]. [Pt^{II}(hmp)Cl_2] was (1.00 g, 2.73 mmol) dissolved in 150 mL of *N*,*N*-dimethylformamide, and to this solution $AgNO_3$ (0.46 g, 2.73 mmol) was added. The reaction mixture was then continuously stirred in the dark for 24 h. The AgCl precipitate was filtered off, using celite as a filter. To the filtrate [Pt^{II}(hmp)(H_2O)Cl]NO_3, Ade (0.36 g, 2.73 mmol) was added. The reaction mixture was then stirred for 36 h at 45 °C. A pale yellow solution was obtained, concentrated to 10 mL under reduced pressure, and excess acetone was added. A pale yellow product [Pt^{II}(hmp)(Ade)Cl]NO_3 was obtained, filtered, washed with CH_2Cl_2, and acetone. The final product was dried in vacuo.

The same procedure was adopted for the preparation of complexes **3**, **5**, **7**, **9** and **11** using the corresponding bases.

2.3.2. Preparation of [Pt^{II}(hmp)(Ade)$_2$]$(NO_3)_2$ (**2**)

[Pt^{II}(hmp)Cl_2] (1.00 g, 2.73 mmol) was dissolved in 200 mL of dimethylformamide, and $AgNO_3$ (0.91 g, 5.46 mmol) was added to this solution. The reaction mixture was protected from light and stirred for 5 days at 45 °C. AgCl was filtered off, using celite as filter. To the filtrate [Pt^{II}(hmp)(H_2O)$_2$]$(NO_3)_2$, Ade (0.73 g, 5.46 mmol) was added, and the reaction mixture was then stirred continuously for 96 h. The pale yellow solution formed was filtered through celite, concentrated to 10 mL under reduced pressure, and precipitated with acetone. The product [Pt^{II}(hmp)(Ade)$_2$]$(NO_3)_2$ was filtered, washed with CH_2Cl_2 and acetone, and dried in vacuo.

The same procedure was adopted for the synthesis of complexes **4**, **6**, **8**, **10**, and **12**.

2.4. Crystallographic measurements

Each single crystal was glued to a glass fiber and mounted on a Bruker Smart 1000 diffractometer equipped with a CCD area detector. Graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) in the $\omega - 2\theta$ scanning mode was used. The data were collected at room temperature and corrected for Lorentz and polarization effects. An absorption correction was applied using the program SADABS. No decay of the crystal was detected during the data collection. Heavy atoms in the compounds were located using Patterson methods. The structures were solved using direct methods using SHELXTL software package and refined by full matrix least-square techniques on F^2. Hydrogen atoms were included in calculated positions and refined using riding model. All thermal ellipsoid are drawn at the 50% probability level (see Table 1).

3. Results and discussion

3.1. Chemistry

The synthesis of platinum(II) complexes is shown in Scheme 1. [Pt(hmp)Cl_2] was used as a precursor for both [Pt^{II}(hmp)(X)Cl]NO_3 and [Pt^{II}(hmp)X_2]$(NO_3)_2$ type of complexes. The reaction of [Pt^{II}(hmp)Cl_2] with 1 equiv. of $AgNO_3$ in DMF yielded [Pt^{II}(hmp)(H_2O)Cl]NO_3 (reaction A). The reaction of [Pt^{II}(hmp)(H_2O)Cl]NO_3 with 1 equiv. of the desired nucleobase in DMF produced [Pt^{II}(hmp)-(X)Cl]NO_3 type of complexes (reaction B). The reaction of [Pt^{II}(hmp)Cl_2] with 2 equiv. of $AgNO_3$ and the corresponding nucleobase produced [Pt^{II}(hmp)X_2]$(NO_3)_2$ type of complexes (reactions C and D).

3.2. Characterization of complexes

Structures of the platinum complexes are shown in Fig. 1. Elemental analysis showed a good correlation

Table 1
Crystal data and structure refinement for [Pt^{II}(homopiperazine)-(9-ethylguanine)$_2$]$(NO_3)_2$

Empirical formula	$C_{19}H_{28}N_{14}O_8Pt$
Formula weight	775.64
Temperature (K)	298(2)

Absorption correction	multiscan
Maximum and minimum transmission	1.000000 and 0.477532
Refinement method	full-matrix least-squares on F^2
Data/restraints/parameters	4738/0/379
Goodness-of-fit on F^2	1.034
Final R indices [$I > 2\sigma(I)$]	$R_1 = 0.0663$, $wR_2 = 0.1635$
R indices (all data)	$R_1 = 0.1572$, $wR_2 = 0.2147$
Largest difference in peak and hole (e Å^{-3})	2.042 and −1.207

between the theoretical and actual values. These values are displayed in Table 2.

Infrared spectroscopy was used to identify the functional groups of the ligands in compounds. A broad band between 3300 and 3100 cm^{-1} confirmed the N–H stretching vibrations in the spectra. The intense bands between 1690 and 1600 cm^{-1} for hmp and 1380 and 1200 cm^{-1} for nucleobase complexes were attributed to ν_{as}(C–O) and ν_s(C–O) vibration, respectively. Pt–N and Pt–Cl stretching frequencies gave rise to peaks around 580 and 360 cm^{-1}, respectively.

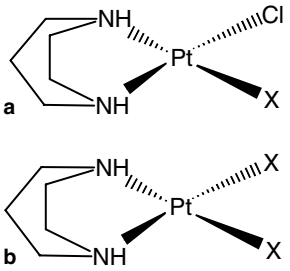

Fig. 1. (a) Structure of [Pt^{II}(hmp)XCl]NO_3, (b) Structure of [Pt^{II}(hmp)X_2]-$(NO_3)_2$ (where hmp = homopiperazine and X = adenine, 9-ethylguanine, 7-methylguaninine, cytosine, 1-methylcytosine, or cytidine).

All complexes were further characterized by ^{1}H, ^{13}C, and ^{195}Pt NMR spectroscopic techniques. The ^{1}H, ^{13}C, and ^{195}Pt NMR spectroscopic data given were most informative with respect to the structure of the complexes (Table 3). The peaks corresponding to homopiperazine were observed between 1.76–1.77 and 2.89–2.92 ppm. In complexes **1** and **2**, C_8H- and C_2H-proton resonance peaks of adenine were shifted downfield as compared with those of the free ligand. The shift of C_8H protons to the range of 0.08–0.30 ppm, as compared with that of C_2H protons to the ranged, 0.05–0.20 ppm, suggests that the site of coordination to the Pt metal ion is N7. The downfield shift of C_8–H proton to the range of 0.19–0.20 ppm observed for 9-ethylguanine complexes **3** and **4** and 0.46–0.51 ppm for 7-methylguanine complexes **5** and **6** complex supports the coordination of N7 or N9 with the metal ion. In cytosine, 1-methyl cytosine, and cytidine complexes (**7**–**12**), the two doublets corresponding to the C_5H protons exhibited a smaller shift than did the C_6H protons, which supports coordination through the N3 atom of the ligands. All of the peaks due to the ribose ring in cytidine complexes **11** and **12** were not shifted substantially; therefore,

Monoadducts

$$[Pt^{II}(hmp)Cl_2] + AgNO_3 \rightarrow [Pt^{II}(hmp)(H_2O)Cl]NO_3 + AgCl \quad (A)$$

$$[Pt^{II}(hmp)(NO_3)Cl] + X \rightarrow [Pt^{II}(hmp)(X)Cl]NO_3 + H_2O \quad (B)$$

Diadducts

$$[Pt^{II}(hmp)Cl_2] + 2AgNO_3 \rightarrow [Pt^{II}(hmp)(H_2O)_2](NO_3)_2 + 2AgCl \quad (C)$$

$$[Pt^{II}(hmp)(H_2O)_2](NO_3)_2 + 2X \rightarrow [Pt^{II}(hmp)X_2](NO_3)_2 + 2H_2O \quad (D)$$

X = adenine, 9-ethylguanine, 7-methylguanine, cytosine, 1-methylcytosine, or cytidine

Scheme 1.

[a] DCI.

in adenine complexes **1** and **2** and in (N9-substituted) 9-ethylguanine complexes **3** and **4** support the notion that N7 serves as a binding site. In complexes **5** and **6** the C_2, C_6, and C_8 carbons showed 2.5, 2.63, and 5.11 ppm shifts as compared with the 7-methylguanine suggesting that coordination site is N9 and not N7 because of the methyl substituent. X-ray diffraction and NMR studies of the complexes formed between platinum and N9- and N7-alkylated purines, N1-alkylated pyrimidines, nucleosides, and nucleotides have been used to elucidate the platinum binding sites. The preferred binding site is N7 for adenine and 9-ethylguanine and N9 for 7-methylguanine purine complexes, respectively, and N3 for pyrimidine complexes [31–35]. NH_2 is apparently not involved in coordination since there was only a negligible shift in NH_2 protons in DMF-d_7. This is further supported by the results of ^{195}Pt NMR spectroscopy.

In the ^{195}Pt NMR spectra, the Pt(II) complexes **1**, **3**, **5**, **7**, **9**, and **11** showed a signal in the range of −2514 to −2605 ppm for monoadducts and a signal in the range of −2641 to −2830 ppm for diadducts **2**, **4**, **6**, **8**, **10**, and **12**. Such chemical shifts are typical for square-planar Pt(II) complexes that contain three nitrogen and one chlorine donor for monoadducts and four nitrogen donors for diadducts, respectively. Fig. 1 shows the proposed structure of such complexes.

3.3. X-ray crystal structures

Fig. 2 shows a perspective view of the crystal structure of [Pt^{II}(homopiperazine)(9-ethylguanine)$_2$](NO$_3$)$_2$ along with its atom labeling. The selected bond lengths and bond angles are given in Table 4. The platinum atom was found to have a distorted square planar geometry due to a longer bite distance in the chelating ligand, hmp. The distortion is indicated by the contraction of the N_{11}–Pt_1–N_{12} angle in the hmp region to 77.2(7)° and contraction of the N_{4A}–Pt_1–N_{4B} angle in the 9-ethylguanine region to 89.2(6)°, similar to the N_1–Pt_1–N_2 and N_2–Pt_1–N_1 angles of 76.8(3)°, and 77.8(8)° as observed in [Pt(hmp)Cl$_2$] and [Pt(1-methylhomopiperazine)(methylmalonato)] · 2H$_2$O, respectively [28,36]. However, the same bond angle in the cisplatin adducts is about 90°, as reported previously for complexes *cis*-[(NH$_3$)$_2$Pt(9-ethylguanine)$_2$]SO$_4$ · 4H$_2$O (93.2°) [37], *cis*-[(NH$_3$)$_2$Pt(9-ethylguanine)$_2$][Pt(CN)$_4$] · 3H$_2$O (87.8°) [37], [Pt(NH$_3$)$_2$(9-ethylguanine)(1-methylcytosine)](ClO$_4$)$_2$ · nH$_2$O (90.0°) [33], and *cis*-[Pt(NH$_3$)$_2$(9-methyladenine)(9-ethylguanine)](NO$_3$)$_2$ (88.9°) [32]. The contraction of the bond angle is compensated for by expansion of the N_{11}–Pt_1–N_{4B} and N_{12}–Pt_1–N_{4A} bond angles to 97.6(6)° and 96.1(6)°, respectively. Homopiperazine forms a 5-membered chelate ring with the platinum atom.

C(5B)–N(4B)–Pt(1)	119.8(13)

Because of the unsymmetrical nature of the hmp ligand d(GpG) can coordinate in two ways with H8 atoms of the nucleobases disposed towards the two carbon chain of the hmp or toward the three carbon chain. Interconversions between two isomers cannot takes place with out breaking and reforming of coordinate Pt–N bonds [10]. The rotation about Pt–N7 (G) bond is restricted by the conformationally rigid nature of the hmp ligand. Therefore [Pt(hmp)d(GpG) adducts adopt any of the noninterconverting six geometries, two head-to-head and four head-to-tail [10]. In the crystal structure the two 9-ethylguanine ligands are oriented in such a way that the exocyclic oxygen atoms are on the opposite side of the platinum coordination plane in a head to tail fashion as shown in Fig. 2 [37]. The two 9-ethylguanine ligands are thus related by a pseudo C_2 axis. Rigorous C_2 symmetry for the molecule is not possible owing to the asymmetry in the homopiperazine ligand. The average angles for C(13)–N(12)–Pt(1) and C(15)–N(11)–Pt(1) are 106.2(2)° and 106.4(14)°, respectively, which are similar to those for [PtII(methylhomopiperazine)(methylmalonato)] · 2H$_2$O, and [Pt(hmp)Cl$_2$] and closer to the values seen in 1,2-DACH-platinum complexes

[30,40–44]. All Pt–N bond lengths were in the ranges normally observed for mono- or diadducts. The average Pt–N bond lengths of 2.047(15) Å [23] in the complexes are within the range normally observed for cisplatin-nucleobase adducts [38,33,37]. For example, the average bond length is 2.03(3) Å in [Pt^{IV}(*trans*-1*R*,2*R*-diaminocyclohexane)*trans*-(acetate)$_2$$Cl_2$], 2.038 Å in [Pt(*trans*-*R*,*R*-DACH-(*N*-Me-IDA))Cl]Cl, 2.06 Å in [Pt(*trans*-D,L-DACH)Cl_4], 2.04 Å in [Pt(*trans*-D,L-DACH(9-methylguanine)$_2$$Cl_2$]-$(NO_3)_2 \cdot 11H_2O$, 2.03 Å in [Pt(*cis*-1*R*,2*R*-DACH)*trans*-(Cl_2)(CBDCA)] · 1/2 MeOH, 2.01(1) Å in Pt–N(7) in *cis*-[$Pt(NH_3)_2$GC]$(ClO_4)_2$, 2.04(1) Å in [$Pt(NH_3)_2$(1-MeC)-(9-EtG)]$^{2+}$, and 2.006(8) Å in *cis*-[$(NH_3)_2$Pt(9-MA-N7)-(9-EtG-N7)]$NO_3 \cdot 1.5H_2O$ [29,31,33,39,42–44]. A stereoscopic view of the molecular packing of the crystals structures is shown in Fig. 3. The molecules in the crystal are held together by a system of hydrogen bonds between the amine hydrogen atom of one molecule and the carbonyl oxygen atom of the 9-ethylguanine. Homopiperazine and 9-ethylguanine ligands are attached to the platinum atom in a square planar configuration. The platinum and four attached nitrogen atoms are all within 0.08(1) Å of the least-squares plane defined by those five atoms. The planes of the 9-ethylguanine ligands lie at an 81.76° angle with respect to each other. Generally, all hydrogen bonds are formed through the interaction of the NH group on the 9-ethylguanine and homopiperazine with the nitrate or NH groups within or with other molecules. For example, N5A···N2B (3.220 Å) and N5A···N2B (3.220 Å) result from the intermolecular hydrogen bonds involving two 9-ethylguanine molecules related by symmetry. Similarly, the hydrogen bonds N11···O1B (3.263 Å) and N12···O10B (2.928 Å) are established through the interaction of the NH of homopiperazine with either a nitrate group or a 9-ethylguanine oxygen from a second molecule. The most abundant hydrogen bonds are those between the nitrate molecules that together generate an intricate network of intermolecular hydrogen bonds. The nitrate ions appear either in a bridged configuration via two oxygen atoms (O11A···N5B [2.871 Å] and O12A···N5A [3.166 Å]), in a simple hydrogen bond via one oxygen (N1B···O11B [2.866 Å]).

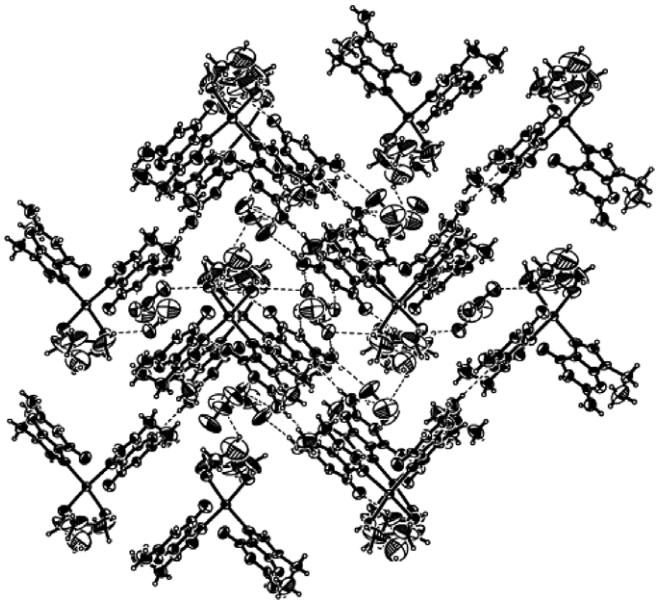

Fig. 3. A view of the molecular packing of [Pt^{II}(homopiperazine)-(9-ethylguanine)$_2$]$(NO_3)_2$.

4. Conclusions

A series of homopiperazine-Pt(II) mono adducts and diadducts formed with nucleobases and nucleosides, respectively, were synthesized and characterized by elemental analysis and NMR spectroscopic techniques. The crystal structure of [Pt^{II}(homopiperazine)(9-EtGua)$_2$]$(NO_3)_2$ was determined by X-ray crystallography.

but other bulk properties like magnetic susceptibility may depend both on the molecular structure as well as on the solid state packing of the molecular entities.

In this work we present the structural and magnetic study of a group of dinuclear copper(II) macrocycles $[Cu_2L]^{2+}$, obtained with different counteranions, and where LH_2 is the ligand derived from the condensation of 2,6-diformyl-4-methylphenol and 1,3-diamino-2-propanol with different counteranions. The influence of the counteranion on the solid state molecular structure and the crystal lattice which define the bulk magnetic properties will be discussed. We present also an example of a butterfly distortion in on of the macrocycles, which takes place along the axis joining both copper centres, and which is assumed to produce a decrease in the value of the magnetic exchange coupling. There are examples in the literature of some μ-hydroxo dinuclear copper(II) complexes presenting a similar distortion, but along the line joining both hydroxo oxygens in which a decrease of the magnetic exchange coupling is also observed [13].

2. Experimental

2.1. Physical measurements

The diffuse reflectance UV–Vis spectra were recorded using a Perkin–Elmer Lambda 20 UV–Vis spectrophotometer equipped with a Labsphere RSA-PE-20 diffuse reflectance accessory. Magnesium oxide was used as reference and the spectra were recorded in the range of 1.0 and 6.0 eV at room temperature. Reflectance measurements were converted to absorption spectra using the Kubelka-Munk function F(R8).

Solution spectra were obtained with a UV–Vis spectrometer, Unicam UV3. Infrared spectra were recorded in KBr pellets using a Bruker Vector 22 FTIR instrument in the range 250–4000 cm^{-1}.

The magnetic susceptibility measurements were carried out on polycrystalline samples at CEPEDEQ, University of Chile with a Cryogenics Susceptometer-Magnetometer SQUID S-600, and at the Servei de Magnetoquímica of the Universitat de Barcelona and University of Rennes-1 with a Quantum Design SQUID MPMS XL.

2.2. Preparations

All reagents and solvents from commercial sources were used without further purification. The macrocyclic copper(II) complexes **1**–**3** were synthesised by the template method. A general synthetic procedure was used to obtain these complexes. In 20 mL of methanol, 2 mmol of 2,6-diformyl-4-methylphenol and 2 mmol of the corresponding copper(II) salts ($CuCl_2 \cdot 2H_2O$, $Cu(acetate)_2 \cdot H_2O$,

$CuSO_4 \cdot 5H_2O$) were dissolved in methanol under nitrogen atmosphere. The green solution was refluxed for 2–3 h giving a green precipitate. Then 2 mmol of 1,3-diaminopropanol and 1 mL of triethylortoformiate were added to the reaction. The reaction mixture was refluxed for 8 h obtaining a green solution and a precipitate. The solid was filtered off and washed with small amounts of methanol. In the cases when no solid was obtained, a small amount of diethyl ether was added to induce the precipitation. All the complexes were dried under vacuum at 110 °C for 3 h. The microcrystalline solids were recrystallised from methanol.

The protonation of the sulfate anions is obviously due to the deprotonation of the phenolic groups during the complex formation reaction.

2.3. X-ray structure determination

Crystals of $[Cu_2LCl_2]\cdot 2H_2O$ (**1**); {$[Cu_2L(acetate)_2(H_2O)_2]$ $[Cu_2L(\mu_2\text{-acetate})]$}$(acetate)\cdot 6H_2O$ (**2a**,**2b**) and $[Cu_2L(H_2O)_2](SO_4H)_2\cdot 2H_2O$ (**3**) were glued with epoxy-resin on the tip of a capillary glass, and then mounted on a SMART-APEX Bruker diffraction system. Preliminary X-ray examination of the samples showed poor crystal quality, but cell determination was possible. A complete data set was measured for each compound [14], using 10 s by frame and 0.3° rotation between them. Reciprocal space exploration using RLATT [15] showed a main crystal plus secondary components for the complete series. The main component data was isolated and data reduction (SAINTPLUS [16]) and structure solution and refinement (SHELXTL [17]) was performed. Empirical absorption corrections were applied using SADABS [18]. Structures **2** and **3** present one of the amine-alcohol oxygen atoms disordered in two half-occupied positions (O13x and O13y in **2**, O12X and O12Y in **3**). Besides, in compound **2** there are a number of interstitial water molecules occupying depleted sites and whose occupations were refined and held constant in the last stages of refinement. Complex **3**, in turn presents a counterion with a severe rotational disorder. This was modelled using three partially occupied SO_4H moieties rotated around the sulphur centre and adding up to one complete sulphate unit.

In all cases hydrogen atoms attached to carbon were located at idealised positions. Some efforts were made in order to adequately find the position of those H atoms relevant for the H-bonding description. As a result, all those in structure **1** as well as a few (those pertaining to aqua molecules) in **2** and **3** could be trustfully inferred from a combined analysis of the Difference Fourier and the environment of potential acceptors for H-bonding. The resulting atoms were refined with metric restraints (O–H, 0.85(1) Å; H...H, 1.40(2) Å) and a riding isotropic displacement parameter. The remaining OHs could not be confidentially located and were accordingly disregarded from the model. Integrated information for all three

structures (**1**–**3**), are presented in Table 1 (data collection, crystallographic and refinement details), Table 2 (selected bond length and angles), Table 3 (hydrogen bonds and short O...O contacts) and Table 4 (π...π interactions).

3. Results and discussion

3.1. Description of structures

3.1.1. $[Cu_2LCl_2]\cdot 2H_2O$ (**1**)

Fig. 1 presents a molecular drawing with the atom numbering for **1**, selected bond distances and angles are given in Table 2. The molecular structure corresponds to a binuclear copper(II) species with a Cu_2O_2 plane, which presents an inversion centre. Each copper atom shows a square pyramidal geometry, where the basal plane is formed by two nitrogen atoms from the macrocyclic ligand and two oxygen atoms, which are shared by both metallic atoms (Cu1–N1, 1.965(6) Å; Cu1–N2#1, 1.957(5) Å; Cu1–O1, 1.959(4) Å; Cu1–O1#1, 1.976(4) Å). The best mean plane through these atoms presents a maximum deviation of 0.040(1) Å for O1#1. The axial chloride ligand is 2.529(2) Å from this mean plane, and the copper(II) atom is shifted in the same direction in 0.22 (1) Å.

The macrocyclic ligand is made up of two parallel, almost planar halves, respectively, defined by O1, O12, N1, N2, C1–C9 and their corresponding centrosymmetric counterparts. These two groups are planar within a mean deviation of 0.03 and a maximum departure of 0.095(1) Å for O1 (O1#1), and displaced 0.66(1) Å from one another. The non-planar part is to be found in the C10–C12 group, with C1 1 presenting the most significant deviation, 0.29 (1) Å. The two centrosymmetric chloride atoms lay at 2.33(1) Å from their respective planes, while each copper(II) atom is shifted by 0.11(1) Å.

The fact that all those hydrogen atoms intervening in H-bonding could be located allowed a neat description of the H-bonding scheme. The main interactions are presented in Table 3: the one defined by the alcoholic hydrogen (H12) defines chains of (H-bonded) dimers running along the crystallographic *a*-axis, while those mediated by the hydration water ones H1Wa and H1Wb join these chains into 2D structures parallel to (0 1 0). Finally, the protruding phenyl groups in the L ligands fit into the open spaces left in neighbouring arrays, in such a way as to have the aromatic rings (forced by symmetry to be strictly parallel to each other) at a π–π interacting distances from one another. The details are presented in Table 4.

3.1.2. $\{[Cu_2L(acetate)_2(H_2O)_2]$ (**2a**) $[Cu_2L(\mu_2\text{-acetate})](acetate)$ (**2b**)$\}\cdot 6H_2O$

The crystalline structure of the acetate macrocyclic complex consists of two molecular forms, **2a** and **2b**. One of the complex molecules **2a** corresponds to a planar species with a Cu_2O_2 plane which presents an inversion centre (Fig. 2a), similar to the one observed for **1**. The geometry around each copper(II) centre can be described as highly distorted octahedral. The basal plane is similar to the one described for **1**, with copper–nitrogen and copper–oxygen distances being Cu1a–N2a#3, 1.975(4) Å; Cu1a–N1a, 1.974(4) Å Cu1a–O1a#3, 1.967(4) Å; Cu1a–O1a, 1.982(4) Å. The axial ligands are a water molecule (Cu1a–O1W, 2.377(6) Å) and a monodentate acetate ion (Cu1a–O2a, 2.623(6) Å), coordinated to each metal centre in a *trans* arrangement relative to the basal plane and subtending a O1W–Cu1a–O2a angle of 170.8(2)°. The fact that the acetate oxygen atom lays at a semi-coordinating distance from the metal centre allows an

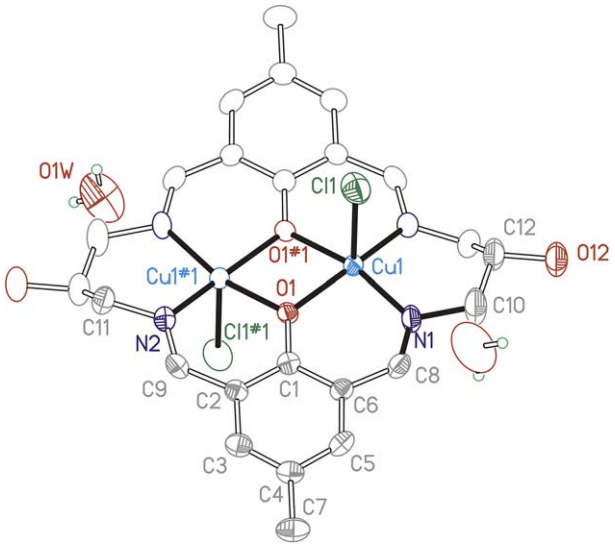

Fig. 1. Molecular diagram of **1**, with the independent and symmetry related parts, respectively, drawn as full and open displacement ellipsoids (40% probability level). In full solid bonds the copper coordination polyhedra. For symmetry codes, see Table 2 footnote.

alternative description of the environment around copper as being square-base pyramidal, with the aqua ligand occupying the apex.

As in the case of **1**, the macrocyclic ligand is composed of two planar sheets defined by O1a, N1a, N2a, C1a > C9a (and their centrosymmetric counterparts) parallel to each other at 0.30 Å from each other. Deviations from planarity of the individual halves are smaller than those found in **1** (with a maximum of 0.047 Å for O1a and a mean of 0.017 Å) as it is the shift between both planar moieties. The copper centres are "sandwiched" by these sheets, an lay at from 0.117(1) Å the nearest one.

The OH groups of the amine fragments of the planar macrocyclic complex **2** are axial and rest in a *trans* position with respect to the plane of the ligand. However, for complex **1** these same atoms are equatorial. A different ordering was reported from X-ray data by Tandon et al. [19], where a 4:1 equatorial to axial position of the hydroxo group of the diaminopropanol fragment of the macrocycle is mentioned.

The second binuclear copper(II) complex molecule **2b** (Fig. 2b) presents a folded macrocyclic ligand with a butterfly distortion [20]. Table 2 presents selected bond distances and angles. The acetate ligand bridges the copper(II) centres in a *syn–syn* mode, with two almost identical copper oxygen distances (Cu1b–O2b, 2.225(5) Å and Cu2b–O3b, 2.223(5) Å). This axial distance and the metal ligand atom distances are slightly shorter for the folded binuclear complex molecule, as compared to the planar one. A second acetate acts as counterion and balances

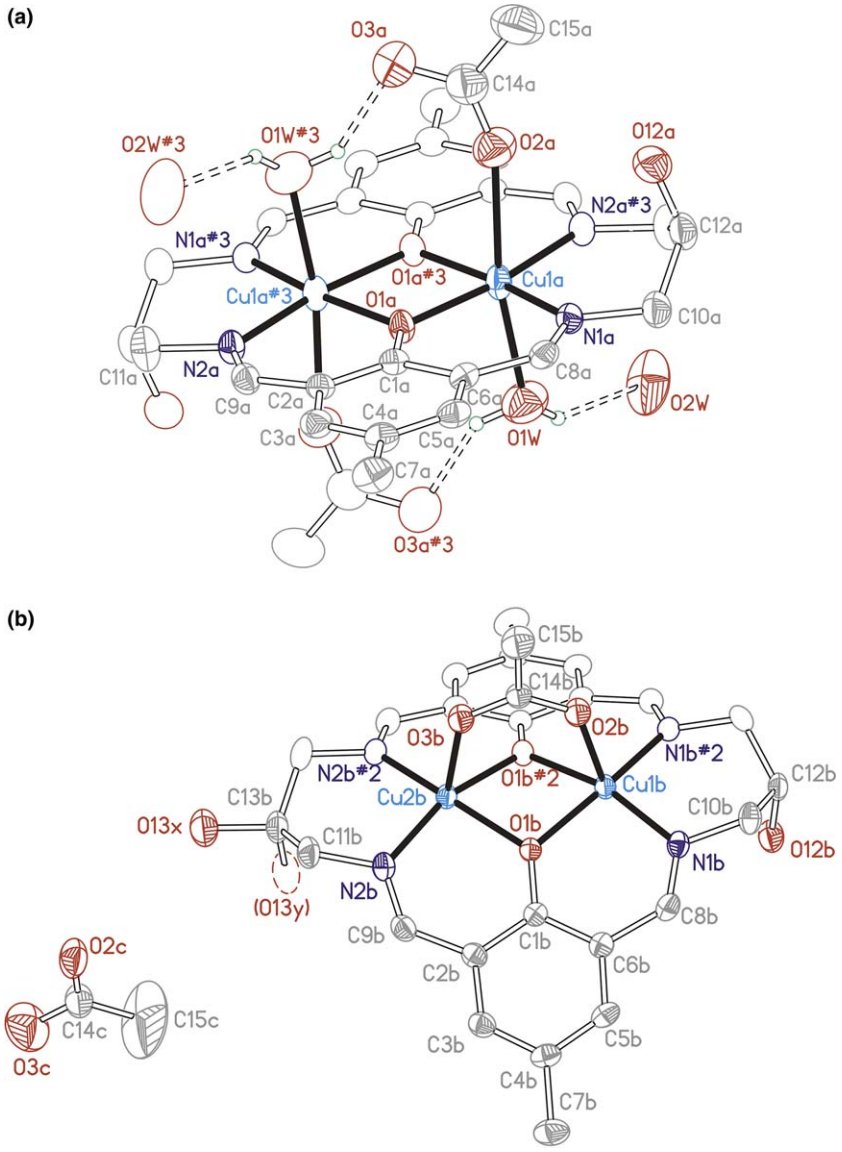

Fig. 2. Molecular diagram of **2**, with the independent and symmetry related parts, respectively, drawn as full and open displacement ellipsoids (40% probability level). In full solid bonds the copper coordination polyhedra. Disordered hydration water molecules not drawn, for clarity. For symmetry codes see Table 2 footnote. (a) Moiety **2a** $[Cu_2L(ac)_2(H_2O)_2]$: note the intramolecular H-bond connecting the aqua and the acetate groups. (b) Moiety **2b** $[Cu_2L(\mu_2\text{-ac})](ac)$: both positions for the split amine-alcohol oxygen shown, one of them in broken lines.

the charge of the complex species. The bond distances of copper oxygen and copper nitrogen atoms from the first coordination sphere are Cu1b–O1b, 1.963(3) Å and Cu1b–N1b, 1.961(4) Å.

The molecule possesses a crystallographic mirror plane containing the two copper atoms, the bridging acetate skeleton and the hydroxo groups of the diamine fragment of the macrocyclic ligand. This plane bisects the macrocycle, whose two planar halves (O1b, N1b, N2b, C1b > C9b, maximum deviation of 0.128(1) Å for O1b with a mean of 0.043(1) Å) are now far from parallel but define a dihedral angle of 46.9(1)°. Due to the intrinsic symmetry of the macrocycle, the molecule presents a non-crystallographic mirror plane, orthogonal to the former, which bisects the group along C7b, C4b, C1b, C14b, C15b, C7ba, C4ba, C1ba.

The crystal lattice presents six water molecules per molecule, disordered over several positions. The two unrelated dinuclear units organise as independent sets of columns, those containing Cu1a running along the *a*-axis, the remaining ones along *c*. These non-intersecting linear arrays define some kind of a 3D fabric, where the interleaving voids are filled by the free acetate anions as well as the disordered water molecules which act as connectors, via H bonding to the Os, OHs and water molecules in the columns. The existence of a large quantity of potentially good donors and acceptors for this type of interaction ensures a complex H-bonding scheme. Unfortunately, an accurate description of the H-bonding network was rendered impossible because of low data quality, which prevented finding many of the hydrogen atoms involved. An exception to this was the case of the aqua hydrogens, in particular H1Wb, the one making a strong intermolecular H-bond to the free O3c of the semi-coordinated acetate (Fig. 2b). The columns crossover is accomplished in such a way as to have the benzyl groups from the orthogonal, non-intersecting columns almost aligned along the *a* direction, with interplanar angles, centre to centre distances and slippage angles in the range 4–11°, 3.68(1)–4.37(1) Å and 20–40°, respectively. (For details see Table 4.) Thus the structure appears as stabilised by a large and varied quantity of non-bonding interactions.

3.1.3. $[Cu_2L(H_2O)_2](SO_4H)_2 \cdot 2H_2O$ (3)

Fig. 3 presents the molecular structure and atom numbering scheme for **3** and Table 2 presents selected bond distances and angles. For complex **3** the first coordination sphere of the copper atoms is square-base pyramidal, with the basal plane defined by the macrocycle (Cu1–N1, 1.960(5) Å; Cu1–N2#1, 1.935(5) Å; Cu1–O1, 1.961(4) Å; Cu1–O1#1, 1.959(3) Å) and the fifth position corresponding to the axial water ligand. This copper oxygen distance is 2.271(5) Å, being the shortest axial distance in the series of reported complexes. The least-square plane in the macrocyclic ligand is defined by N1–N2–O6–C1–C2–C3–C4–C5–C6–C7–C8–C9–C10 and the mean deviation of the atoms from this plane is 0.032 Å.

The crystalline structure presents isolated SO_4H counteranions, showing highly disordered oxygen atoms. These SO_4H groups form a chain along the *a*-axis. The existence of hydrogen bonds and van der Waals interactions, suggested by close contacts, stabilises the packing of the diaminopropanol fragment via hydrogen bonds.

Although the binuclear macrocyclic complex was prepared by the template reaction of 4-methyl-2,6-diformylphenol with 1,3-diamine-2-propanol in the presence of cupric sulphate, the counterions resulted to be two SO_4H species. The presence of two monovalent anions is evident by the experimental value of the percentage of the sulphur found for the complex, and X-ray diffraction data.

Again here the lack of precise information on some hydrogens, in addition to the severe disordered SO_4H counterions, turned the H-bonding description a rather speculative task, mainly based on the otherwise unexplainable short O...O contacts. Thus the counterion seems to serve as a double H-bonding bridge between neighbouring units, by accepting both an aqua (H1wa) and a diaminopropanol hydrogen. These interactions lead to the formation of H-bonded chains running along the *c*-axis, which present the benzyl group outwards, ready for a π–π interaction. This is achieved by the partial overlap of neighbouring chains when stacking along *a*. The resulting interaction is very similar to the ones already described (Table 4).

4. Spectral data

4.1. Infrared spectra

Selected IR data are presented in Table 5. All complexes show the same spectral pattern and the main differences

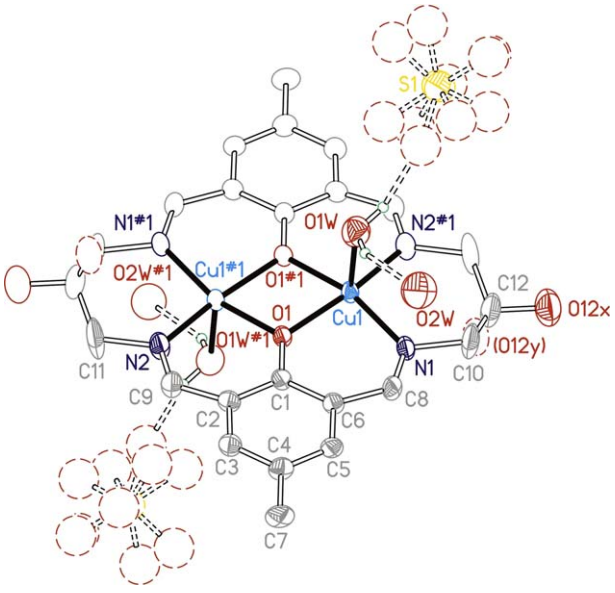

Fig. 3. Molecular diagram of **3**, with the independent and symmetry related parts, respectively, drawn as full and open displacement ellipsoids (40% probability level). In full solid bonds the copper coordination polyhedra. The disordered SO_4H counterions drawn as broken ellipsoids. Both depleted positions for the amine-alcohol oxygen shown, one of them in broken lines. For symmetry codes, see Table 2 footnote.

arise from absorptions due to the counteranions. Complex {**2a**,**2b**} shows stretching bands for the acetate ions at 1566 and 1408 cm^{-1}, corresponding to the asymmetric and symmetric absorptions of the carboxylate group, respectively. This allows to infer that the group is in its ionic form and also bridging the two metal atoms [21], in accordance to the structural data. Complex **3**, shows bands at 1113, 847 and 618 cm^{-1}; indicating the presence of the SO_4H species [21,22].

The complexes show the $\nu_{(C=N)}$ stretching bands in the range 1636–1639 cm^{-1} [23], and the $\nu_{C=C/C=N}$ ones between 1547 and 1568 cm^{-1}. The metal–ligand vibration zone shows three bands in all cases, one at 400 cm^{-1} assignable to the Cu–O stretching, and the remaining two at 350 and 370 cm^{-1} to the symmetric and asymmetric Cu–N vibrations [21].

4.2. Electronic spectra

All three reflectance spectra show a similar pattern, with strong electronic absorptions at 270, 390 and 420 nm attributed to the π–π^* ligand transitions [23]. The bands found at 352–363 nm are attributable to the phenolate-to-copper(II) charge-transfer band [2,5,24]. Much weaker, less defined absorption bands are found at lower energy (610–667 nm) associated to a d–d transitions [19].

Solution electronic spectra were recorded in methanol, and a similar pattern as for the reflectance spectra was obtained. All three copper(II) complexes show a very weak d–d transition band between 610–670 nm, indicative of a square pyramidal geometry [25–27]. Thus, it is possible to infer that the observed geometry of the binuclear copper(II) complexes in the solid state is maintained in solution.

5. Magnetic studies

Magnetic susceptibility measurements at variable temperature were performed for complexes **1**–**3**, in the temperature range 2–300 K. For compounds **1** and **3** measurements at different fields were also recorded. The results are summarised in Table 6, and presented as χ_M versus T plots in Figs. 4a and b (complexes **1** and **2**) and as χ'_M versus T plot in Fig. 4c (complex **3**). χ'_M corresponds to the molar magnetic susceptibility corrected by TIP.

The variable temperature–magnetic susceptibility data at 10 kOe for complex **1** were fitted with the Bleaney–Bowers equation, using the isotropic exchange Hamiltonian ($H = -2JS_1 \cdot S_2$) for the two interacting $S = 1/2$ centres [28]:

$$\chi_M(J,g,\rho,\theta) = \frac{2Ng^2\beta^2}{k(T-\theta)(3+e^{-2J/kT})}(1-\rho) + \frac{Ng^2\beta^2\rho}{4KT} + \mathrm{TIP} \quad (1)$$

where ρ is the fraction of paramagnetic impurity and θ corresponds to interdimer interactions.

The best fit to Eq. (1) gave $g = 2.175$, $2J = -1015$ cm^{-1}, $\rho = 0.025$, and $\theta = -5.0$ K ($10^3R = 5.9$). R is defined as $R = \left[\sum(\chi_{obs}-\chi_{calc})^2/\sum\chi^2_{obs}\right]^{1/2}$. A TIP value of 6×10^{-4} emu mol^{-1} was used. Complex **1** presents a stronger antiferromagnetic behaviour as compared to the analogue $[Cu_2(UPM)Cl_2]\cdot 6H_2O$ ($2J = -722$ cm^{-1}), where $UPMH_2$ is the macrocyclic ligand formed by the condensation of 4-methyl-2,6-diformylphenol with 1,3-diaminepropane [29]. This ligand lacks the secondary alcohol group present in LH_2, and the reported complex presents slightly different

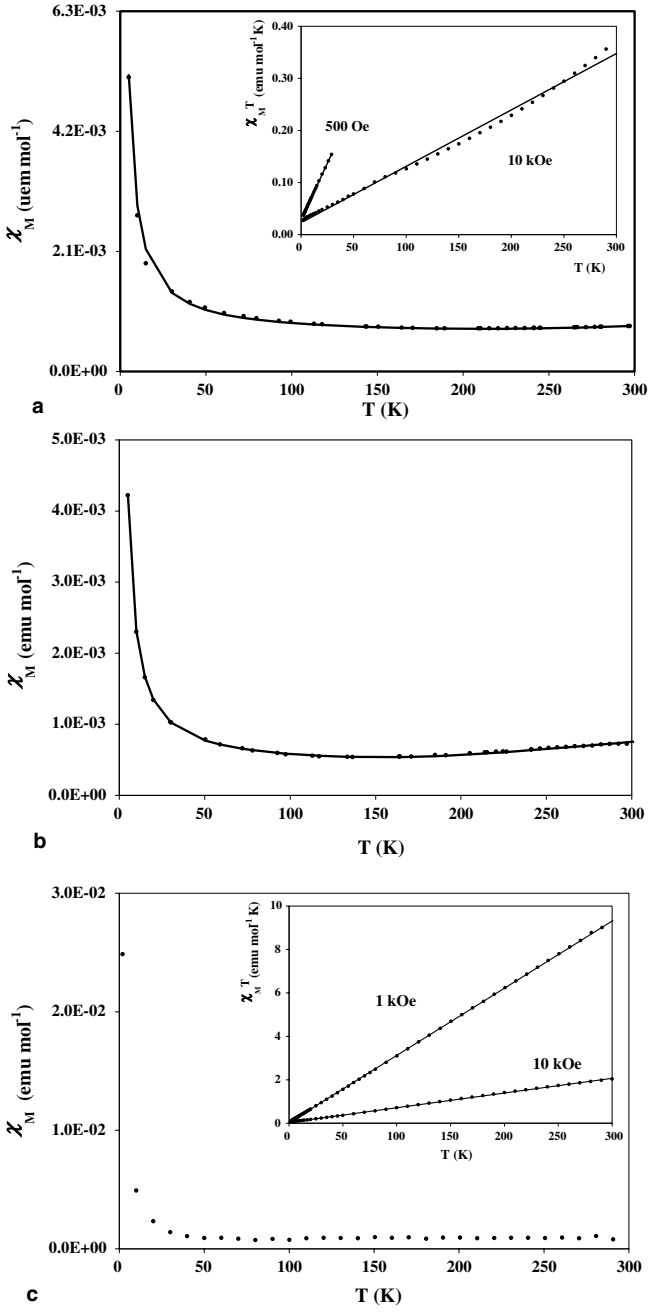

Fig. 4. Plots of χ_M vs. temperature for: (a) **1**; (b) **2a** and **2b**; (c) **3**. In (a) the solid line was calculated from Eq. (1), and in (b) the solid line was calculated from Eq. (2). In (c) $\chi'_M = (\chi_M - \text{TIP})$. Inset in (a) and (c) show a plot of $\chi_M \cdot T$ vs. T at different fields.

geometrical parameters: a copper–copper separation of 3.133 Å and a phenoxo bridge of 104.5°, as compared to 3.088 Å (Cu–Cu) and 103.34° (Cu–O–Cu) for **1**.

The magnetic data at 10 kOe for complex {**2a**,**2b**} was fitted with a modified Bleaney–Bowers equation, assuming that each binuclear macrocyclic copper(II) complex is characterised by a particular magnetic exchange constant, related to their different connectivities and distortions of the first coordination sphere. A TIP value of 3.8×10^{-4} emu mol^{-1} was considered for the fit of the data.

$$\chi^T_{MCu} = (\chi^1_M + \chi^2_M)(1-\rho) + \frac{N(g_1+g_2)^2\beta^2\rho}{4KT} + \text{TIP} \qquad (2)$$

For complex {**2a**,**2b**} the best fit to Eq. (2) gave $g_1 = 2.20$, $g_2 = 2.22$, $2J_1 = -306\ \text{cm}^{-1}$, $2J_2 = -921\ \text{cm}^{-1}$, $\rho = 0.021$, and $\theta = -15$ K ($10^2R = 1.2$).

Dihydroxo bridged dimers with butterfly distortions have been shown to present lower $2J$ parameters, than the completely planar systems [13]. In the reported dinuclear complexes the distortion occurs through the axis along both hydroxo oxygen atoms. This distortion produces a decrease in the overlap of the $d_{x^2-y^2}$ magnetic orbitals of the copper centres with the corresponding orbitals of the bridging phenoxo oxygen atoms, thus decreasing the antiferromagnetic interaction. This phenomenon has been explained theoretically by Kahn et al. [9]. In complex **2b** the distortion is induced by the μ-acetate coordination, along the axis through the copper centres. Therefore the intramolecular magnetic coupling in the non-planar $Cu_2O_{2(phenoxo)}$ system of complex **2b** should be described by the lower $2J$ value of $-306\ \text{cm}^{-1}$ and that of **2a** by the $2J$ value of $-921\ \text{cm}^{-1}$. The obtained parameters for **1** and **2a** are indicative of a strong antiferromagnetic coupling between the metal ions, which is commonly observed for this type of phenoxo bridged dicopper(II) complexes [5].

Complex **3** presents a high value for the measured susceptibility at 300 K. The inset of Fig. 4c shows the magnetic behaviour of this compound, which is assumed to correspond to temperature independent paramagnetism (TIP). The observed effect can not be attributed to paramagnetic impurities, since in such case the effect would have shown a behaviour independent of the applied field. However the observed phenomenon is shown to be dependent upon the magnitude of the applied field. The obtained TIP value from the $\chi_M T$ versus T plot is 308×10^{-4} emu mol^{-1} (1 kOe) and 68×10^{-4} emu mol^{-1} (10 kOe). From the corrected experimental susceptibility data, effective magnetic moments lower than the expected value for one unpaired electron (1.73 BM) per metal centre were obtained. It is important to remark that the Bleaney–Bowers equation was not used to fit the corrected susceptibility data for complex **3**, since this equation can fit the experimental data with different values for $2J$ and ρ parameters for extremely antiferromagnetic systems such as **3**.

Even though complex **3** and the reported $[Cu_2L(H_2O)_2](NO_3)_2$ [30] have similar pentacoordinated metal centres, with water molecules as axial ligands, the first is strongly antiferromagnetic with temperature independent paramagnetism, while the second has a pure intramolecular antiferromagnetic phenomenon with $2J = -631\ \text{cm}^{-1}$. The obtained magnetic data for **3**, together with aforementioned $2J$ value reported for the nitrate macrocyclic complex [30], clearly indicate that the lattice effects can play an important role on the magnitude of the magnetic exchange phenomenon.

A previous study of a family of compounds [29] with macrocyclic copper(II) complexes, derived from the

condensation of 4-methyl-2,6-diformylphenol with 1,3-diaminepropane and with different halogen axial ligands (Cl, Br, I) reports a trend of the intramolecular magnetic coupling with the nature of the coordinated halogen. Since the bulk geometry of the macrocycle is dependent on the nature of the halogen, it is not possible to infer that just the electronegativity of the axial ligand is responsible for the different magnetic behaviour. On the other hand, Tandon et al. [19] have also reported a rather high TIP value for a similar complex $[Cu_2L]$ with $Cu_2Cl_4^{2-}$ as counteranion.

We show in the present work that the nature of the counterion can play different roles, i.e., affecting the overall geometry of the macrocycle and acting, in some cases, as axial ligands. A dramatic example is observed in the acetate complex **2b** where the macrocycle is folded due to the presence of a bridging acetate anion. Therefore it is interesting to point out that the electronic and packing effects associated with the different anions can affect the bulk magnetic properties of the macrocyclic dinuclear copper(II) complexes.

6. Conclusions

While all the reported complexes can be described as pentacoordinated species with a square pyramidal geometry; the coordinated axial ligand depends on the nature of the counteranion of the used copper salt. The monodentate binding mode of the axial ligand generates planar macrocyclic complexes, while the *syn–syn* bridging mode of the acetate anion permits the formation of a folded macrocyclic moiety.

All the crystalline structures show the existence of a lattice with a great number of non-bonding interactions, such as hydrogen bonding and π–π stacking. All these interactions are due exclusively to the macrocyclic ligands, the solvate molecules and the different counteranions and not to the crystallisation conditions.

In the case of the planar species, the strongest antiferromagnetic exchange was observed for complex **3**, where the bisulphate anion is outside the first coordination sphere. The participation of the counteranion as axial ligand (compounds **1**, **2a**) produces a decrease in the antiferromagnetic exchange due to electronic interactions. Finally, dramatic distortions of the macrocycle are observed for compound **2b**, where the acetate anion is bridging the two metal centres and therefore the smallest $2J$ value is associated with this structure.

The reported binuclear complexes permit to asses that the existence of different bonding interactions of the anions, as those observed in the obtained crystalline structures, influence the bulk magnetic properties of the solid samples. Therefore counteranions should be considered relevant parameters for modulating magnetic properties.

uranium(III) trichlorides. Adjusting of water concentration enabled precipitation of three different compounds with formulas: $UCl_3 \cdot 2H_2O \cdot 2CH_3CN$, $UCl_3 \cdot 6H_2O$ and $UCl_3 \cdot 7H_2O$. The synthesis of these compounds is described and their crystal structures have been determined by single crystal X-ray measurements. The structures of hydrated uranium trichlorides are discussed and compared with analogues lanthanide compounds. We have not been able to prove the existence of $UCl_3 \cdot 5H_2O \cdot CH_3CN$ compound reported in Ref. [3].

Table 1
Compositions of the mother solutions used for the synthesis of the uranium trichloride hydrates

Compound	UCl_4 (g)	Methylcyanide (ml)	Propionic acid (ml)	Water (ml)
$UCl_3 \cdot 2H_2O \cdot 2CH_3CN$	1.15	25	0.47	0.25
$UCl_3 \cdot 6H_2O$	1.15	25	0.47	0.625
$3UCl_3 \cdot 7H_2O$	1.15	23	1.15	0.72

2. Experimental

2.1. Synthesis

For the synthesis of the single crystals three different solutions consisting of appropriate amounts of uranium tetrachloride, methylcyanide, propionic acid and water were prepared. The detailed compositions of the solutions are summarized in Table 1. The solutions were left standing for 24 h and afterward filtrated. Subsequently, 5 ml of the appropriate mother solution was placed together with 0.3 ml of a 2.4% liquid zinc amalgam in a glass ampoule, ~15 cm long and about 0.8 cm in diameter. The solutions were degassed by evaporation for 2–5 min in vacuum.

Subsequently, the ampoules with the degassed solutions were sealed under nitrogen and left standing motionless for 24 h at the room temperature. The accomplished slow reduction process yields good quality crystals of two new uranium(III) compounds of the formulas $UCl_3 \cdot 2H_2O \cdot 2CH_3CN$ and $UCl_3 \cdot 6H_2O$. In the case of $UCl_3 \cdot 7H_2O$, such reduction process did not lead to the precipitation of the compound but resulted in the formation of a separate uranium(III) oily-phase, only. In order to force the crystallization of the heptahydrate, the solution has been shaken for a few minutes with liquid zinc amalgam, which resulted in the immediate formation of a very fine crystalline precipitate. The crystals obtained in this way were of poor quality, but after leaving them in the mother solution for 1–2 days, some single crystals suitable for X-ray measurements could be selected from the coarse crystalline powder.

During the reduction process the colour of the solutions changes from olive-green to dark reddish-brown. The $UCl_3 \cdot 2H_2O \cdot 2CH_3CN$, $UCl_3 \cdot 6H_2O$ and $UCl_3 \cdot 7H_2O$ compounds crystallize as deep dark reddish needles, purple plates and greyish ink blue needles, respectively. The ampoules with the precipitated crystals were opened in an

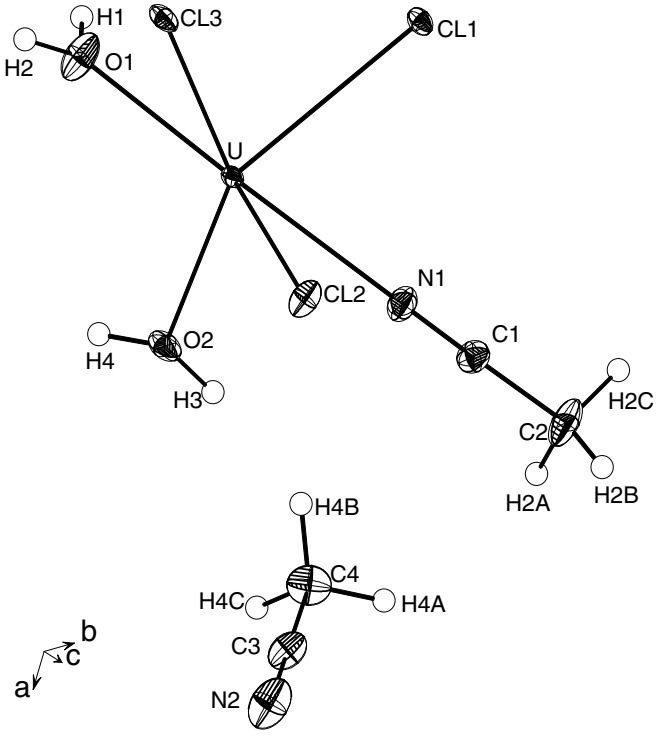

Fig. 3. The molecular structure of the asymmetric unit in the $[UCl_3 \cdot 2H_2O \cdot CH_3CN]_n \cdot [CH_3CN]_n$ polymeric chain. Displacement ellipsoids are shown at 50% probability level. The hydrogen atoms are shown as a small circle of arbitrary radii.

inert gas glove-box, drained off from the solvent and immediately immersed in a dry paraffin oil. Since uranium trichloride hydrates are moisture sensitive and they decompose very quickly in the contact with air, they were protected during X-ray measurements by a cold nitrogen gas stream.

2.2. Crystallographic experimental details

The crystallographic measurements of the uranium hydrates were performed on a Kuma KM4CCD diffractometer using graphite-monochromatized Mo Kα radiation. The data were collected at 100 K using in all cases the Cryosystem cooler. The conditions for the data collections as well as the used parameters of the structure refinements are summarized in Table 2.

The structure of the $UCl_3(H_2O)_2(CH_3CN)_2$ was solved by the heavy-atom method, using the SHELXS-97 program [12] and was refined by a full-matrix least-squares technique using the SHELXL-97 program [13] with anisotropic thermal parameters for non-H atoms.

The initial values of the co-ordinates of all non-H atoms for $UCl_3(H_2O)_6$ and $UCl_3(H_2O)_7$ were taken from the data reported for $AmCl_3(H_2O)_6$ [11] and $CeCl_3(H_2O)_7$ [14], respectively. The H-atoms were found from difference-Fourier maps and the C–H and O–H distances were constrained to 0.96 and 0.86 Å, respectively. All figures presented in the paper were prepared by using the XP program [15].

3. Results and discussion

The reduction of UCl_4 solutions in methylcyanide, with specific amounts of water and propionic acid, enabled the isolation of the three different uranium trichloride hydrates. From solutions containing 25 ml of methylcyanide, 1.15 g of UCl_4, 0.47 ml of propionic acid and 1–1.5% of water crystallizes $UCl_3 \cdot 2H_2O \cdot 2CH_3CN$. An increase of the water content to 2% results in the precipitation of a mixture of $UCl_3 \cdot 2H_2O \cdot 2CH_3CN$ and $UCl_3 \cdot 6H_2O$ crystals. Pure $UCl_3 \cdot 6H_2O$ crystals have been obtained from a solution containing 2.5% of water. An increase of the water content above this value leads to the formation of a separate uranium(III) oily-phase. The $UCl_3 \cdot 7H_2O$ crystals may be obtained from methylcyanide solution with a 2.5–5% water content, providing that the uranium tetrachloride and propionic acid concentrations have been also increased.

We have noticed differences in resistance of these hydrates against hydrolysis and oxidation processes. It was observed, that the quality of $UCl_3 \cdot 2H_2O \cdot 2CH_3CN$ as well as of $UCl_3 \cdot 6H_2O$ crystals, left in the mother solution in sealed glass ampoules filled with nitrogen, degraded

[a] Symmetry codes: (i) $-x+1, -y+2, -z+1$; (ii) $-x+1, -y+1, -z+1$; (iii) $-x+1/2, y, -z+1/2$; (iv) $-x, -y, -z+2$.

after about 48 h, and they usually decomposed within next 2–5 days, whereas the $UCl_3 \cdot 7H_2O$ crystals were relatively stable and could be kept in the mother solution for a few weeks.

The $UCl_3 \cdot 7H_2O$ and $UCl_3 \cdot 2H_2O \cdot 2CH_3CN$ crystals separated from solution and sealed under nitrogen in a glass tube were relatively stable and could be stored below 5 °C for a few months and a few weeks, respectively. In contrast to these, the $UCl_3 \cdot 6H_2O$ crystals underwent oxidation to green uranium(IV) products very easily and could not have been stored. Absorption spectra of $UCl_3 \cdot 6H_2O$ (not presented here) indicate that in the presence of air the compound initially attaches one water molecule forming $UCl_3 \cdot 7H_2O$ and afterward undergoes fast decomposition and oxidation.

3.1. Uranium trichloride bis(methylcyanide) dihydrate

Uranium trichloride bis(methylcyanide) dihydrate crystallizes with a structure that is, to our knowledge, unknown so far. The compound with the same formula and similar main features of the structure was reported only for the gadolinium(III) [16]. However, the authors have found gadolinium atoms in five slightly different positions.

The final atomic data of $UCl_3 \cdot 2H_2O \cdot 2CH_3CN$ are summarized in Table 3. The central U^{3+} ion is eight-coordinated by five chlorine anions, two water and one methylcyanide molecules, which are forming a distorted bicapped trigonal prism (see Fig. 1(a)).

The characteristic feature of this structure is the link of the uranium atoms through the two common edges of the Cl1 and Cl3 chlorine atoms into an infinite zigzag chain in the [0 1 0] direction. In Fig. 2, one may notice two planes, formed by the Cl1–U–$Cl1^{i}$–U^{i} [1] and Cl3–U–$Cl3^{ii}$–U^{ii} atoms, respectively. The angle between their normals is equal to 45.45(4)°. The torsion angle $Cl1^{i}$–U–Cl3–U^{ii} is equal to 123.73(5)° and the angle between the three neighboring uranium atoms (U^{i}–U–U^{ii}) amounts to 137.22(2)°.

The asymmetric unit is presented in Fig. 3. The U–Cl1 and U–Cl3 distances are equal to 2.867(2) and 2.901(2) Å, respectively. However, the distances between the uranium ion and bridging $Cl1^{i}$ and $Cl3^{ii}$ ions (Fig. 2) are somewhat larger and amount to 2.932(2) and 2.914(2) Å, respectively. The interatomic distances as well as the angles and torsion angles are presented in Table 4.

[1] Symmetry codes as in Table 4.

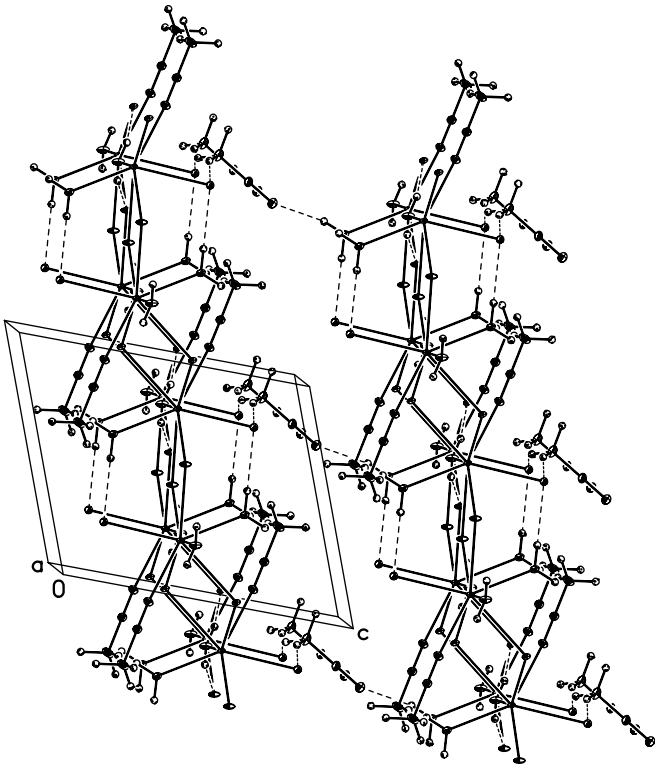

Fig. 4. The packing diagram of the $[UCl_3 \cdot 2H_2O \cdot CH_3CN]_n \cdot [CH_3CN]_n$ polymeric chains. The hydrogen bonds are shown as the dashed lines.

Although all crystals described in this paper, have been prepared from the methylcyanide solutions, molecules of this solvent are present only in the structure of $UCl_3 \cdot 2H_2O \cdot 2CH_3CN$ crystals. One of the two CH_3CN molecules is coordinated through the N atom to the uranium atom, while the second molecule is located between the main chains and link them through the hydrogen bonds – see Fig. 4.

The distances between the donor, acceptor and hydrogen atoms as well as the angles between them are listed in Table 5.

The polymeric structure has been reported for a number of uranium(III) compounds [7,17,18]. A comparison of the interatomic distances for selected uranium(III) chlorocomplexes with a polymeric structure is presented in Table 6. The U–Cl as well as the U···U distances in $UCl_3 \cdot 2H_2O \cdot 2CH_3CN$ are very similar to those in Rb_2UCl_5 and K_2UCl_5, but significantly shorter than those determined for $CsUCl_4 \cdot 3H_2O$. For the last compound the distances are among the longest of those found for the uranium(III) complex chlorides, comparable to distances observed for UCl_3 [19].

3.2. Uranium trichloride hexahydrate

We have not discerned any substantive qualitative differences between the crystal structures of uranium and americium trichloride hexahydrates [11] as well as their lanthanide analogues [10]. The found atomic coordinates for $UCl_3(H_2O)_6$ are summarized in Table 7.

[a] This paper.
[b] The bridging chlorine atoms.

The basic unit of the crystal structure are Cl^- anions and $[UCl_2(H_2O)_6]^+$ cations (Fig. 5). The U atom is eight-coordinated by the six water molecules and two chlorine atoms. The characteristic feature of this structure is the existence of hydrogen bonds, which link the uranium eight-coordinated polyhedra, forming a three-dimensional network.

The Cl1 atoms, which are located in gaps of the three-dimensional network, are octahedrally coordinated by the

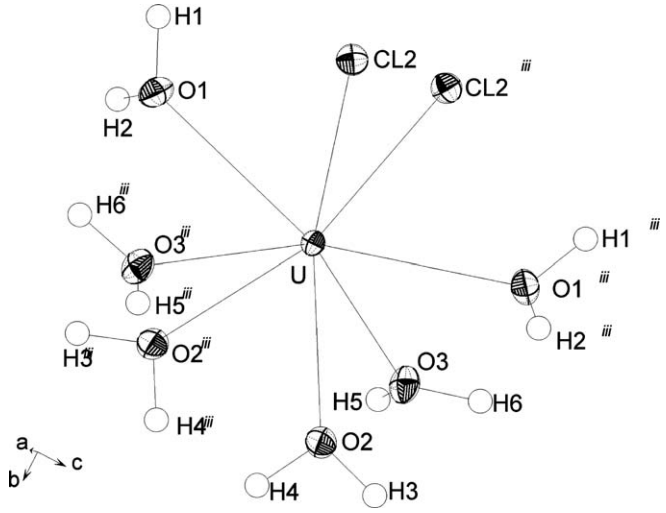

Fig. 5. The co-ordination of the U^{3+} in $UCl_2(H_2O)_6^+$ ion and labelling of the atoms.

water molecules through six hydrogen bonds (Fig. 6). It is worth noting that the same water molecules, which are hydrogen bonded to the Cl1 atoms, are also connected with the Cl2 by other hydrogen bonds. The packing diagram with the interatomic hydrogen bonds is shown in Fig. 7. The determined interatomic distances as well as bond angles are shown in Table 4, while the distances between donor, acceptor and hydrogen atoms as well as the appropriate angles are listed in Table 5.

The geometry around the eight-coordinated U^{3+} ion, which is located on the twofold axis, may be seen as a very distorted square antiprism, the bases of which are rhombuses folded along the shorter diagonal (see Fig. 1(b)).

A comparison of interatomic distances for $UCl_3 \cdot 6H_2O$ and selected chloro-complexes with a monomeric structure is presented in Table 8. The structure of $NH_4UCl_4 \cdot 4H_2O$ [8] is similar to that of uranium trichloride hexahydrate. As a consequence of this also the U–Cl as well as the U···U distances are for $UCl_3 \cdot 6H_2O$ close to those of $NH_4UCl_4 \cdot 4H_2O$. In Cs_2NaUCl_6 the U–Cl bonds are shorter, while the distance between two nearest uranium

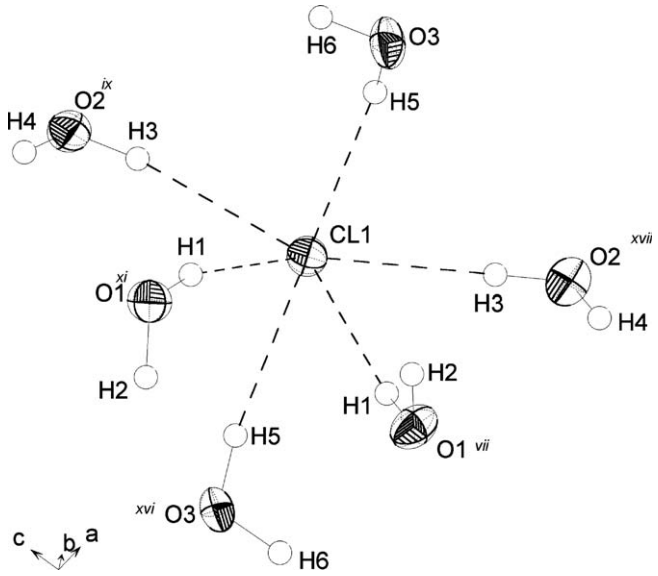

Fig. 6. The octahedral coordination sphere of the chloride anion in the $[UCl_2(H_2O)_6]Cl$ structure. The dashed line shows the hydrogen bond between chloride ions and water molecules. [Added symmetry codes are: (*xvi*) $3/2 - x$, y, $1/2 - z$; (*xvii*) $1/2 + x$, $-y + 1$, $1/2 + z$].

ions is considerably longer as compared with the hydrated monomeric forms.

3.3. Uranium trichloride heptahydrate

As has been mentioned above, $UCl_3 \cdot 7H_2O$ crystals suitable for X-ray measurements were obtained by recrystalization. Unfortunately, all of them turned out to be the penetration twins. Similarly, very small crystals, which could be found in the precipitate before submitting it to the recrystalization process, were also twinned. Therefore, the crystals for the crystal date collection were cut from larger ones.

Similarly, as in the case of the described above hexahydrate, we have not found any qualitative differences between the structure of uranium trichloride heptahydrate and its lanthanide analogue [9]. The atomic coordinates for $UCl_3(H_2O)_7$ are summarized in Table 9.

The uranium trichloride heptahydrate crystals are built up from separate $[U_2Cl_2(H_2O)_{14}]^{4+}$ and Cl^- ions. The characteristic feature of this structure are centrosymmetric dimers, formed by two U^{3+} ions connected by the (Cl1) bridging chlorine atoms. The shortest distance between uranium ions is equal to 4.652(2) Å, and remains in the range observed for other chloro-complexes with a polymeric structure – see Table 6.

The U^{3+} central metal ion is coordinated by two chloride anions and seven water molecules, forming a nine-coordinated dodecahedron. For the ML_9 type complexes the coordination polyhedron may be characterized as related to a D_{3h} tricapped trigonal prism or C_{4v} monocapped square antiprism, the first being energetically favorable [21].

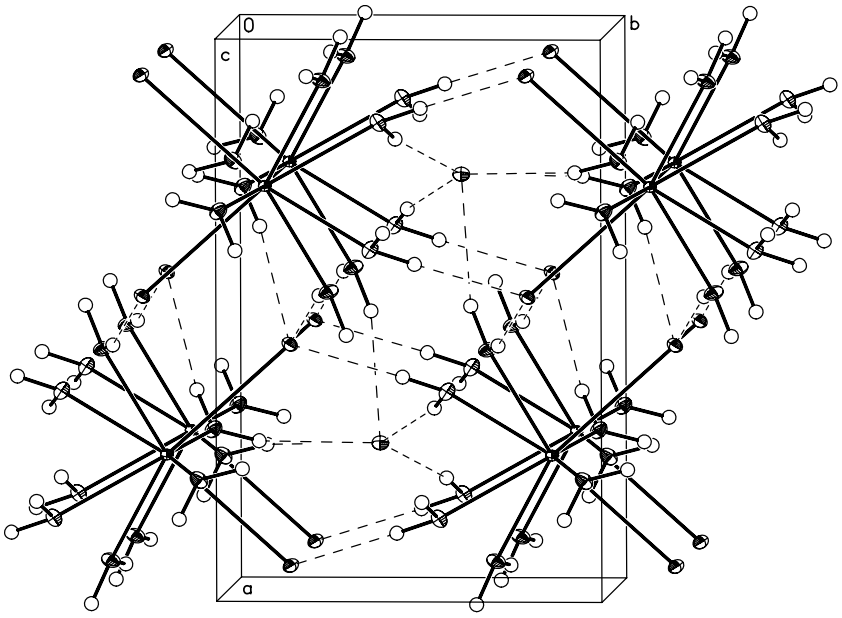

Fig. 7. The packing diagram of the $UCl_3 \cdot 6H_2O$. Dashed lines show the O–H···Cl hydrogen bonds in the crystal structure.

The coordination geometry of the $[La_2Cl_2(H_2O)_{14}]^{4+}$ ion was described by Bakakin et al. [9] as a highly disordered capped square antiprism. Similarly, Paterson et al. [22] described the dodecahedron observed for $CeCl_3 \cdot 7H_2O$ as an almost ideal capped square antiprism. The structure of $CeCl_3 \cdot 7H_2O$ was solved in the triclinic system in the space group $P1$, but it is essentially the same as that obtained in the space group $P\bar{1}$ for $LaCl_3 \cdot 7H_2O$ or $UCl_3 \cdot 7H_2O$.

The two polytopal forms, possible for uranium trichloride heptahydrate, are presented in Fig. 1(c) and (d). Since the D_{3h} form was found for most of ML_9 complexes as well as for boron and metal M_9 clusters [21], one may assume, that the coordination geometry of U^{3+} in $UCl_3 \cdot 7H_2O$ complex should be characterized as related to the tricapped trigonal prism (D_{3h}), rather than to a square antiprism.

In the $UCl_3 \cdot 7H_2O$ network the chloride anions are located in the gaps between the $[U_2Cl_2(H_2O)_{14}]^{4+}$ cations. The structure is held together by O–H···Cl hydrogen bonds. Furthermore, an intermolecular hydrogen bond is located inside the cation, between the oxygen atoms (O3–H6···O1^{iv}),[2] with the O3···O1^{iv} distance equal to 2.863(4) Å. In Table 4 interatomic distances as well as angles and torsion angles are shown, while the distances between the donor, acceptor and hydrogen atoms as well as the appropriate angles, are summarized in Table 5. The structure of the $[U_2Cl_2(H_2O)_{14}]^{4+}$ ion and the packing diagram of the ions in the unit cell are shown in Figs. 8 and 9, respectively.

For uranium trichloride heptahydrate the mean U–Cl and U–O distances are equal to 2.916 and 2.545 Å, respectively, and are somewhat longer as compared to those of

[2] Symmetry codes as in Table 5.

uranium trichloride hexahydrate and uranium trichloride bis(methylcyanide) dihydrate. Since $UCl_3 \cdot 7H_2O$ is the first dimeric uranium(III) hydrate with a known crystal structure, we could not perform for this type of compounds a comparison of the U–Cl or U–O distances. It is worth noting, that uranium(III) is, besides praseodymium(III) the only f-electron ion for which crystal structure has been determined both for hexa- and heptahydrated trichlorides [23,24]. Hence, one may compare the interatomic distances between hexa- and heptahydrates, as well as between the

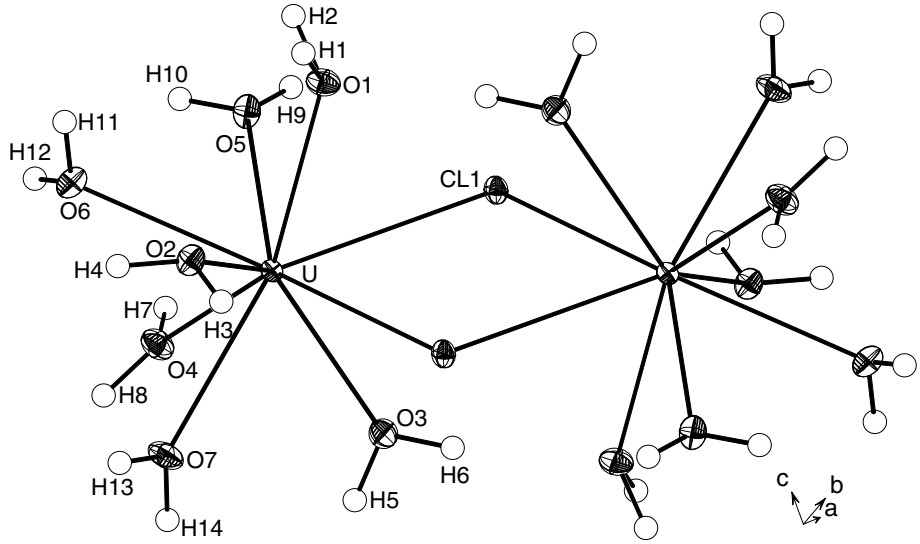

Fig. 8. The molecular structure of the $[U_2Cl_2(H_2O)_{14}]^{4+}$ cation. Displacement ellipsoids are shown at 50% probability. The hydrogen atoms are shown as a small circle of arbitrary radii.

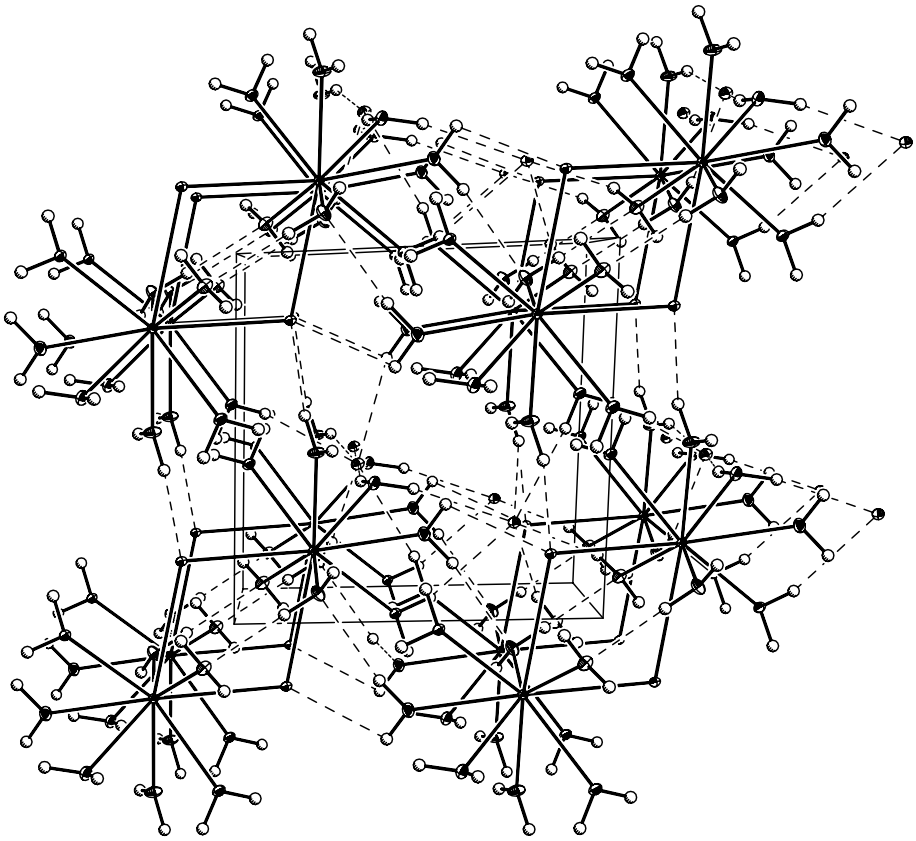

Fig. 9. The crystal packing diagram of the $UCl_3 \cdot 7H_2O$. The dashed lines show O–H···Cl and O–H···O hydrogen bonds.

actinide and lanthanide analogues. The mean M–Cl and M–O distances in lanthanide and actinide complexes are summarized in Table 10. As one may notice, for the uranium as well as for the praseodymium hexahydrated trichlorides, the M–O and M–Cl distances are shorter than for the heptahydrates. For praseodymium the differences of the M–O and M–Cl distances between the hexa- and heptahydrates amounts to 1.9% and 2.7%, while for uranium this changes are considerably smaller and are equal to 1.6% and 2.1%, respectively. For the hexa- as well as for the heptahydrates, both M–O and M–Cl distances are, as expected, larger for the uranium(III) than for praseodymium(III) compounds, what reflects the increase in the ionic radius of the M^{3+} metal ion (ionic radius: U^{3+} −116.5 pm, Pr^{3+} −108 pm).

4. Supplementary materials

Supplementary data are available from The Director, ICSD, FIZ Karlsruhe, Hermann-von-Helmholtz-Platz 1, 76344 Eggenstein-Leopoldshafen, Germany, by quoting the deposition numbers: 415442-$UCl_3 \cdot 6H_2O$, 415443-$UCl_3 \cdot 7H_2O$, 415444-$UCl_3 \cdot 2H_2O \cdot 2CH_3CN$ (fax: +49 7247 808 132; e-mail: crysdate@fiz-karlsruhe.de or http://www.fiz-karlsruhe.de).

of semi-coordinate bonds between adjacent dimers. The discussion of exchange pathways in these studies have focused on the through-bond intradimer and intrachain/stack interactions. Unfortunately, the discussion of the role of the close halogen–halogen (2H) contacts within these dimer structures has generally been ignored [7]. However, recently two neutron scattering studies in $A_2Cu_2Cl_6$ salts have shown that the 2H pathways are stronger than the intrachain/stack interactions [8]. Since this is true in chloride salts, it is expected that the 2H pathway will play an even more significant role in bromide salts.

This was observed to be the case in our recent study of the $(morpholinium)_2Cu_2Cl_{6-x}Br_x$ salts [9]. Here, semi-coordination of the morpholinium group to the copper ion results in the formation of isolated, essentially planar dimers. The morpholinium groups play an additional role; hydrogen bonding adjacent dimers together, forcing relatively short (3.92–4.07 Å) halide···halide contacts between dimers. In this way, magnetic exchange pathways between dimers are developed, defining in this manner, alternating AFM chains. Analysis of the magnetic susceptibility data showed that the magnitude of the larger exchange constants in the chain increased essentially linearly, and rapidly, as the fraction of bromide in the dimer increased. It was argued that this exchange constant represented the 2H pathway.

In this paper, we extend the above investigation by examining the structural and magnetic behavior in the $(BIPY)Cu_2Cl_{6-x}Br_x$ compounds, where BIPY denotes the 4,4′-bipyridinium cation. The previous studies of the chloro and bromo end members of these compounds showed extremely strong magnetic coupling [10]. These compounds assume the extended stack structure with bridging halides forming semi-coordinate bonds with the dimer directly above or below. N–H···X hydrogen bonds force very short X···X contacts between dimers, that can also produce effective magnetic exchange pathways. Thus, based on the assumption that the exchange coupling through the semi-coordinate bonds is weak, the compounds are expected to behave as alternating AFM chains, based on the through-bond intradimer coupling and the through-space halide–halide contact. In this study, the structural and magnetic properties of both the $(BIPY)Cu_2Cl_6$ and $(BIPY)Cu_2Br_6$ end members are reinvestigated and the properties of a series of mixed $(BIPY)Cu_2Cl_xBr_{6-x}$ compounds are reported.

2. Experimental

2.1. Synthesis

The compounds were grown from acidic aqueous solutions. The pH of these solutions is critical, since at very low pH, a dark brown precipitate is formed (presumably $(BIPY)CuX_4$), while at higher pH values, a green insoluble material is formed (presumably $CuX_2(bipy)$, bipy = 4,4′-bipyridine).

2.1.1. (4,4′-Bipyridinium)Cu_2Cl_6, (BIPY)Cu_2Cl_6 (**1**)

4,4′-Bipyridinium hydrochloride (0.457 g, 2 mmol) and copper chloride dihydrate (0.689 g, 4 mmol) were added to a mixture of 20 mL of 4 M hydrochloric acid, and 8 mL water. The red, pleochroic, nearly opaque crystals were collected after several days of evaporation, and allowed to dry (490 mg, 34% yield).

2.1.2. (4,4′-Bipyridinium)Cu_2Br_6, (BIPY)Cu_2Br_6 (**11**)

4,4′-Bipyridinium hydrobromide (0.636 g, 2 mmol) and copper bromide (0.893 g, 4 mmol) were added to a mixture of 15 mL of 4 M hydrobromic acid, and 28 mL water. The dark red, pleochroic, crystals were collected after several days of evaporation and allowed to dry (554 mg, 36% yield).

2.1.3. (4,4′-Bipyridinium)$Cu_2Cl_{6-x}Br_x$, (BIPY)$Cu_2Cl_{6-x}Br_x$ (**2**–**10**)

The compounds were synthesized by combining various ratios of 4,4′-bipyridinium hydrochloride/4,4′-bipyridinium hydrobromide (2 mmol total) salts and $CuCl_2\cdot 2H_2O/CuBr_2$ (4 mmol total). This was added to a mixture of the appropriate ratio of 4 M hydrochloric/hydrobromic acid (20 mL total). Water was slowly added to this solution until the brown precipitate dissolved (7–12 mL). The acidic solution was allowed to stir for 10 min. The red, pleochroic crystals were collected after several days of evaporation, and allowed to dry. Typical yields were 155–304 mg (21–34%).

2.2. Crystallography

Crystals were attached to a glass fiber using glue. Datasets were collected at 293(2) K, either using a Bruker/Siemens SMART 1K instrument or a Syntex $P2_1$ diffractometer upgraded to Bruker P4 specifications (Mo Kα radiation, $\lambda = 0.71073$ Å). Data obtained with the SMART system were measured using omega scans of 0.3° per frame for 30 s, and a half sphere of data were collected. The first 50 frames were recollected at the end of data collection to monitor for decay. Cell parameters were retrieved using SMART [11] software and refined using SAINT-PLUS [12] on all observed reflections. Data reduction and correction for Lp and decay were performed using the SAINT-PLUS software. Absorption corrections were applied using SADABS [13]. For the Syntex system, lattice dimensions were obtained from 25 accurately centered high angle reflections [14]. Data were corrected for absorption utilizing ψ-scan data assuming an ellipsoidal shaped crystal. The structures were solved by direct methods and refined by least squares method on F^2 using the SHELXTL program package [15]. No decomposition was observed during data collection. Structure refinements were straightforward in all cases and no disorder was observed. Further details are provided in the Supporting Information.

Crystallographic data on the mixed salts were collected on samples from nine different preparations (compounds

2–**10**, Table 1). The site occupancies for the three unique halide ion sites were refined independently, with the constraint that the site occupancies for each site should add to unity. The total site occupancy values obtained agreed well with the chemical analyses of the samples (Table 1). The fractions of Cl and Br found from the refinements correlates well with the unit cell constants and the unit cell volumes, as seen in Fig. 1. Consistent results were obtained between two refinement procedures: the first where the Cl and Br were constrained to be in the same location for each site; the second where the Cl and Br atoms were allowed to have different coordinates. Since the former process defines a unique average X···X distance for correlation with the magnetic data, it is those results that are reported here. Refinement information is available in the Supplementary Data.

2.3. Magnetic measurements

The susceptibility studies were done on crushed single crystals of samples **1**, **2**, **5**, **7**–**9** and **11** using a Quantum Design MPMS-XL SQUID Magnetometer. The magnetization of each sample was first determined at 1.8 K in fields between 0 and 5 T. The magnetization was linear with field up to at least 1 T for each compound. No hysteresis was detected for any of the compounds. For the determination of the molar magnetic susceptibility, χ_M, the magnetic moment of the compound in a field of 1000 Oe (0.1 T) was determined as a function of temperature between 1.8 and 325 K. Corrections for the small diamagnetic contribution of the sample holder were applied. Corrections to the molar susceptibility have been made for the temperature independent magnetization of the Cu(II) ion (60×10^{-6} emu/mol) and the diamagnetic contribution as calculated from Pascal's constants

3. Structure description

All of the $(BIPY)Cu_2X_6$ salts are isomorphous, containing planar $BIPY^{2+}$ dications linked to centrosymmetric pseudo-planar $Cu_2X_6^{2-}$ dimers through bifurcated N–H···X hydrogen bonds. The $Cu_2X_6^{2-}$ species are assembled into stacks via semi-coordinate Cu···X synthons, as shown in Fig. 2 for $(BIPY)Cu_2Cl_6$. This forces a distorted octahedral geometry around each Cu^{2+} ion. In addition, the N–H···X bonds (light lines in Fig. 3) link the stacks of $Cu_2X_6^{2-}$ dimers. In this manner, a two-dimensional structural network consisting of hydrogen bonded stacks is formed. These networks are tied together into the overall three-dimensional structure via a series of weaker C–H···X interactions (dotted lines in Fig. 3). As a consequence of these interactions between these structural networks, short X2···X2 contacts (heavy dashed lines in Fig. 3) are formed between dimers in adjacent layers.

Within the stacks of dimers, systematic changes in bond lengths occur as chloride ions are replaced by bromide ions. As seen in Fig. 4, the mean Cu–X distances increase nearly

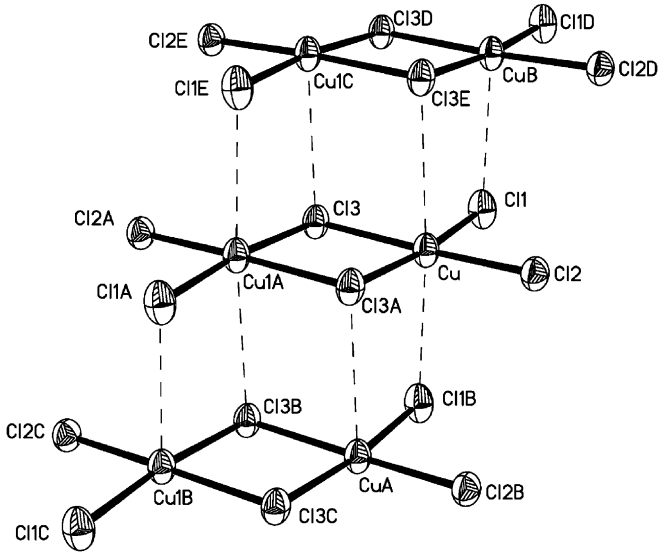

Fig. 2. Illustration of the stacking of dimers found in the (BIPY)Cu_2X_6 salts. The semi-coordinated bonds linking the dimers are shown as dashed lines.

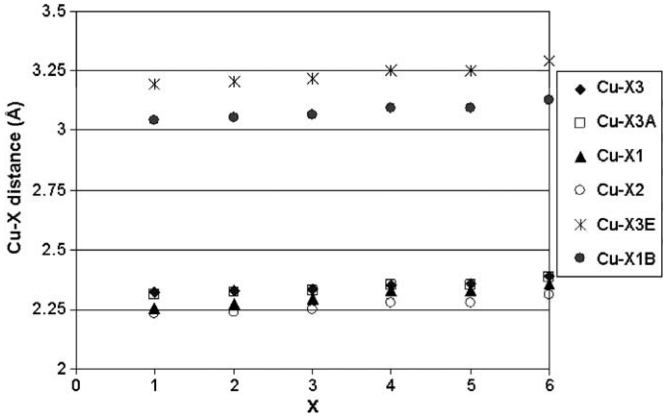

Fig. 4. Plot of Cu–X distances as a function of bromide ion content. Refer to Fig. 2 for label identification.

linearly with an increase of ~0.13 Å for the normal in-plane Cu–X bonds and ~0.16 Å for the semi-coordinate bonds. The bridging Cu–X bonds are significantly longer than the terminal bonds, as anticipated. In addition, it is seen that, for the terminal bonds, the mean Cu–X1 distances are ~0.02 Å longer than the mean Cu–X2 bond distances for the pure end members, and up to 0.05 Å longer for the mixed salts. The shortening of the Cu–X2 distances is a consequence of the electrostatic repulsion induced by the short X2···X2 contacts between layers. More significantly, it is also observed (Fig. 5) that the occupancy of the three independent halide ion sites is non-statistical for the mixed halide salts, with the X1 site preferentially occupied by the bromide ions. Again, this is anticipated based on electrostatic arguments.

As noted above, the weaker C–H···X interactions between layers force short, nearly linear X2···X2 contacts

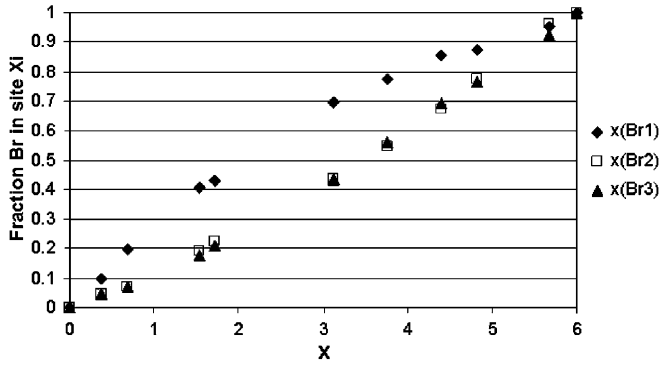

Fig. 5. Plot of the fractional occupancy of each halide ion site as a function of total Br content.

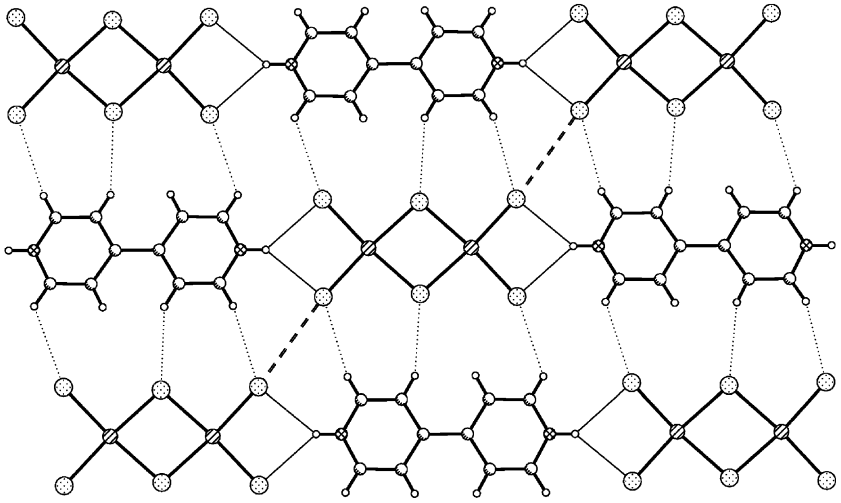

Fig. 3. Illustration of the hydrogen bonding network in the (BIPY)Cu_2X_6 salts. The view is perpendicular to the plane of the dimeric species. The N–H···X hydrogen bonds are shown as light solid lines, while the C–H···X interactions are shown as dotted lines. The resulting short X2···X2 contacts are shown as dashed lines.

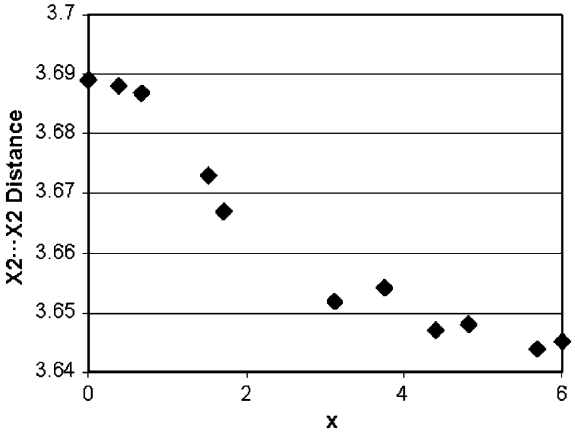

Fig. 6. Plot of the X2···X2 distance as a function of the total Br content.

between dimers in adjacent layers. These contacts will be crucial in the interpretation of the magnetic properties, thus the analysis of their structural properties is important. In the pure chloride salt, the contact distance (3.690 Å) is slightly larger than the sum of the Cl^- radii (3.6 Å), but in the bromide salt, the observed distance (3.645 Å) is substantially less than the sum of the Br^- radii (3.9 Å). Surprisingly, it is also noted that the contact distance for the bromide salt is less than that in the chloride salt. This is due to presence of the C–H···X interactions between the layers, which hold adjacent $Cu_2X_6^{2-}$ anions and $BIPY^{2+}$ cations in juxtaposition and keeps the Cu–X2···X2 contact interactions essentially linear. Given the increase in radii of ~0.15 Å when Cl^- is replaced by Br^-, it can be calculated that the X2···X2 distance must decrease by ~0.05 Å in order to retain the linear geometry. This is in good agreement with the observed decrease of 0.045 Å.

Another consequence of the non-random distribution for the halide ions is that the X2···X2 contact distance between the dimers varies non-linearly as the chloride ions are replaced by bromide ions, as shown in Fig. 6. Since the Br^- ions avoid the X2 site as their initial inclusion occurs, the primary type of contact will be of the Cl···Cl type in this composition regime. This means that the hydrogen bonding can more readily force the dimers closer together. For $x > 0.5$, the Br^- ions must now start to occupy the X2 site, so the contraction of the X2···X2 distance is much less.

4. Magnetic properties

As described above, the structures of both the chloride and bromide salts contain isolated $(BIPY)Cu_2X_6$ molecules that form stacks of $Cu_2X_6^{2-}$ dimers tied together by 4,4′-bipyridinium cations. Three possible exchange pathways exist: the intradimer pathway, J_d; the intrastack pathways via the semi-coordinate Cu···X bonds, J_{id}; and the 2H X···X contacts J_{2H}. Given the short X···X distances between dimers, it is expected that the 2H pathways will have relatively large AFM exchange couplings, even in the salts with high chloride content. In contrast, the intrastack interactions, which involve parallel planar arrangement of the magnetic orbitals, are expected to be relatively weak since the magnetic orbitals lie in the plane of the dimer. Thus, the significant exchange pathways are expected to be the intradimer coupling, J_d, and the 2H coupling between dimers, J_{2H}. These link the dimers together into magnetic chains with alternating exchange pathways containing J_d and J_{2H}. Given the structural characteristics discussed above, the magnetic behavior of both salts was modeled as alternating antiferromagnetic chains (AAFM) with exchange constants J_1 and J_2, characterized by the Hamiltonian $H = -2J_1\Sigma[s_i \cdot s_{i+1} + \alpha s_{i+1} \cdot s_{i+2}]$ with $0 < \alpha < 1$ and $J_2 = \alpha J_1$. The high temperature series expansion previously reported was used in the data analysis [16].

4.1. Magnetic properties of the pure compounds

Both the chloride and bromide salts exhibit dominant antiferromagnetic behavior as demonstrated by the continuously decreasing value of $\chi_M T$ versus T as the temperature is decreased. The results are in agreement with the experimental values reported earlier [10], with χ (max) occurring

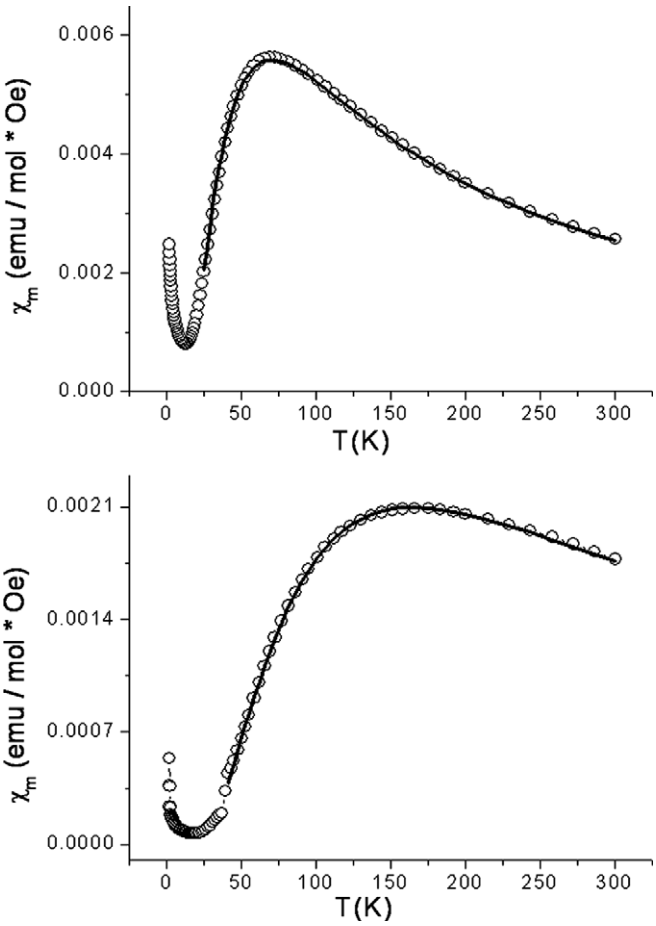

Fig. 7. Plot of χ_M vs. T for $(BIPY)Cu_2Cl_6$ (top) and $(BIPY)Cu_2Cl_5Br$ (bottom). Solid lines are calculated fits to the AAFM model with parameters given in text.

at substantially higher temperature for the bromide salt than the chloride salt. Data were fit with high temperature series expansions for χ_{AAFM} with a correction for the paramagnetic 'impurity' that is observed at very low temperatures, according to the equation $\chi_{dimer} = 2(1-f)\chi_{AAFM} + 2f(C/T)$, where f is the mole fraction impurity and C is the Curie constant for a spin 1/2 species. As with many other copper halide systems, the paramagnetic impurity is assumed to be intrinsic, due to defects in the crystal, rather than due to the presence of an impurity compound. The resulting fits are shown in Fig. 7 and the parameters given in Table 2. For the chloride salt, it is found that $J_1/k = -52.6(2)$ K and $J_2/k = -27(4)$ K, while the bromide salt has $J_1/k = -162(2)$ K and $J_2/k = -93(5)$ K. The fact that the exchange coupling in the bromide salt is substantially stronger than in the chloride analog, despite the isomorphous structures, is consistent with the previous report, with the general trend observed in isostructural copper halide dimers [6d], and with the observation in the diammonium layer perovskite system that the Br···Br exchange pathway is considerably stronger than the Cl···Cl pathway.

4.2. Magnetic properties of the $(BIPY)Cu_2Cl_{6-x}Br_x$ salts $(0 > x > 6)$

All these compounds assume the triclinic structure with a non-statistical distribution of halide ions. Qualitatively, the magnetic behavior of these salts is similar to that of the pure compounds, with the temperature at which χ_{max} occurs increasing monotonically as the fraction of bromide ion in the salts increased. Since the distribution of halide ions is disordered (although not completely random), these systems are, in principle, examples of spin 1/2 system random chains with dimerization ($\chi \sim T^{-\gamma}$, with γ varying continuously). However, for this to be observed, the width of the distribution of exchange parameters must be greater than twice the value of the average exchange coupling [17]. This is not the case here. Thus, the data were analyzed in the same manner as the pure salts, modeled as an AAFM chain with a relatively small paramagnetic impurity. The results are summarized in Table 2 and in Fig. 8. It is seen that J_1/k increases nearly linearly with the bromide content, to a maximum value near −163 K.

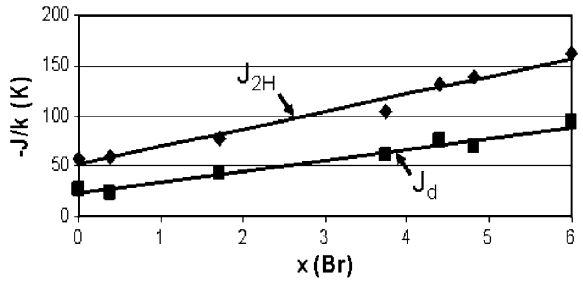

Fig. 8. Plot of the exchange constants for the alternating AFM chains. Solid lines are guides to the eye only.

5. Discussion

Although three possible exchange pathways can be identified from the structural analyses in these compounds, the analyses of the magnetic data clearly indicate that only two of these pathways contribute substantially to the magnetic behavior. Based on the arguments presented in the previous section, only two pathways will be considered here; the intradimer coupling, J_d, and the halide···halide coupling, J_{2H}. Unfortunately, the thermodynamic measurement of the magnetic susceptibility does not allow a definitive assignment correlation between the magnetic exchange parameters, J_1 and J_2, and the structural pathways, J_d and J_{2H}. Nevertheless, qualitative arguments can be made as to the appropriate assignment.

Structurally, it is observed that the Cu–X···X contacts are essentially linear, in contrast to other dimer systems where the effect of the 2H exchange pathways have been investigated [8]. This linear geometry is similar to that observed in the (diammonium)CuX_4 salts, where very strong AFM exchange is observed for X···X distances similar to those reported here [1–3]. In the latter, the AFM exchange arises through overlap of b_{1g}^* orbitals. It is known from EPR experiments that ~50% of the magnetic electron density in these orbitals is delocalized into the ligand p_σ orbitals. A similar delocalization into the p_σ orbitals of the terminal halide ions is anticipated in the pseudo-planar dimeric species. Thus, extremely strong AFM coupling is anticipated via the 2H pathways in these compounds.

It has been observed in studies of the 2H exchange in the diammonium layer perovskite salts, and in salts containing the distorted tetrahedral CuX_4^{2-} anions, that the 2H exchange coupling is typically 5–7 times larger for bromide salts than the corresponding chloride salts when the X···X distances are the same [1–3]. Table 2 shows that the X···X distances decrease slightly when the chloride ligand is replaced by bromide. Thus, for the (BIPY)$Cu_2Cl_{6-x}Br_x$ salts with substantial percentage Br, the larger exchange constant, J_1, is clearly associated with J_{2H}.

For the (BIPY)Cu_2Cl_6 salt the observed value of J_2 is consistent with the intradimer coupling observed in the spin liquid dimer system in $KCuCl_3$ [8b]. Thus, it is likely that for the pure chloride salt, that the intradimer coupling is associated with J_2 and the exchange in the 2H pathway is given by J_1. Thus, the association of exchange pathways with exchange parameters is as shown in Fig. 8.

In summary, this study has further elucidated the crucial role of the 2H exchange pathways in the determination of the magnetic behavior of copper halide dimers. The specific contribution of this study is the conclusion that the 2H pathway can become the dominant exchange pathway in the bromide dimers. Thus, discussions of the interpretation of the magnetic behavior of copper halide dimer systems must take this pathway into consideration.

substituted titanocenes as possible anti-cancer drugs using substituted benzyl lithium, benzyl substituted fulvenes and titanium tetrachloride, resulting in the formation of unbridged diarylmethyl substituted titanocenes. The optimised synthesis, underlined by quantum chemical calculations, and first results of very promising in vitro studies will be shown.

2. Experimental

2.1. General conditions

Titanium tetrachloride (1.0 M solution in toluene) and *tert*-butyl lithium (1.7 M solution in cyclohexane) were obtained commercially from Aldrich Chemical Co. THF was dried over Na and benzophenone and it was freshly distilled and collected under an atmosphere of argon prior to use. Manipulations of air and moisture sensitive compounds were done using standard Schlenk techniques, under an argon atmosphere. NMR spectra were measured on either a Varian 300 or a 500 MHz spectrometer. Chemical shifts are reported in ppm and are referenced to TMS. IR spectra were recorded on a Perkin–Elmer Paragon 1000 FT-IR Spectrometer employing a KBr disk. UV–Vis spectra were recorded on a Unicam UV4 Spectrometer.

2.2. Synthesis

6-(*p*-*N*,*N*-Dimethylanilinyl)fulvene (**3a**), 6-*p*-(methoxyphenyl)fulvene (**3b**) and 3,5-dimethoxyphenyl fulvene (**3c**) were synthesised according to the already published procedures [21,23].

2.3. Bis-[di-(p-N,N-dimethylaminophenyl)-methylcyclopentadienyl] titanium (IV) dichloride, $\{\eta^5\text{-}C_5H_4\text{–}CH\text{–}[C_6H_4\text{–}N(CH_3)_2]_2\}_2TiCl_2$ (*5a*)

To a Schlenk flask with 1.00 g (5.18 mmol) of 4-bromo-*N*,*N*-dimethylaniline (**1a**), 20 ml of THF was added until a transparent solution was formed, while stirring. The solution was cooled down to −78 °C for 15 min and 3.30 ml (5.57 mmol) of *tert*-butyl lithium was added. The solution was warmed up to 0 °C for 20 min, resulting in the formation of the yellow lithium intermediate (**2a**).

In a second Schlenk flask, 1.00 g (5.07 mmol) of 6-(*p*-*N*,*N*-dimethylanilinyl)fulvene (**3a**) was dissolved in 25 ml of THF and the resultant red solution was added via a *cannula* at −78 °C to the Schlenk flask containing the lithiated intermediate (**2a**). The reaction mixture was allowed to warm up to room temperature and left stirring for 40 min. Afterwards, 2.53 ml (2.53 mmol) of titanium tetrachloride was added at room temperature and the mixture was refluxed for 24 h. The solvent was removed under vacuum, resulting in a dark brown precipitate. This precipitate was dissolved in dichloromethane and filtered through celite to remove the LiCl, followed by two gravity filtrations. The solvent was removed under reduced pressure forming a shiny black solid (**5a**), which was washed with 150 ml of pentane and then dried in vacuo (2.05 g, 2.82 mmol, 55.1% yield).

UV–Vis (CH_2Cl_2/ε:[cm^2/mol]): λ 230 nm (ε 22 770), λ 402 nm (ε 2020), λ 509 nm (ε 210), λ_{max} 521 nm (weak).

2.4. Bis-[di-(p-methoxyphenyl)methylcyclopentadienyl] titanium (IV) dichloride, $\{\eta^5\text{-}C_5H_4\text{–}CH\text{–}[C_6H_4\text{–}O\text{–}CH_3]_2\}_2TiCl_2$ (*5b*)

To a Schlenk flask with 1.5 ml (5.43 μmol) of 4-bromoanisole (**1b**), 20 ml of THF was added until a transparent solution was formed, while stirring at room temperature. The solution was cooled down to −78 °C for 15 min and 5.3 ml (85.7 μmol) of *tert*-butyl lithium was added. The

solution was allowed to warm up to 0 °C for 20 min, resulting in the formation of the yellow lithium intermediate (**2b**).

In a second Schlenk flask, 1.00 g (5.43 mmol) of *p*-(methoxyphenyl)fulvene (**3b**) was dissolved in 25 ml of THF and the resultant red solution was added via a *cannula* at −78 °C to the Schlenk flask containing the lithiated intermediate. The reaction mixture was then allowed to warm up to room temperature and left for stirring for 40 min. Titanium tetrachloride (2.7 ml, 2.715 mmol) was added afterwards in situ at room temperature and the mixture was refluxed for 24 h. Subsequently, the solvent was removed under vacuum, resulting in the formation of a dark brown to black precipitate. This precipitate was dissolved in dichloromethane and filtered through celite to remove the LiCl, followed by two gravity filtrations. The solvent was removed under reduced pressure forming a shiny black solid (**5b**), which was washed with pentane and then dried in vacuo (3.83 g, 5.45 mmol, 43.5% yield).

Anal. Calc. for $C_{40}H_{38}O_4Cl_2Ti$: Theory: C, 68.50; H, 5.46; Cl, 10.11. Found: C, 68.34; H, 5.46; Cl, 10.09%.

UV–Vis (CH_2Cl_2/ε:[cm^2/mol]): λ 268 nm (ε 21 000), λ 393 nm (ε 1070) λ 404 nm (ε 1120), λ 509 nm (ε 210), λ_{max} 523 nm (weak).

2.5. Bis-[di-(3,5-dimethoxyphenyl)methylcyclopentadienyl] titanium (IV) dichloride, {η^5-C_5H_4–CH–[C_6H_4–$(OCH_3)_2$]$_2$}$_2$$TiCl_2$ (5c)

To a Schlenk flask with 1.32 g (4.66 mmol) of 1-bromo-3,5-dimethoxybenzene (**1c**), 20 ml of THF was added until a transparent solution was formed, while stirring at room temperature. The solution was cooled down to −78 °C for 15 min and 3.02 ml (5.13 mmol) of *tert*-butyl lithium was added. The solution was allowed to warm up to 0 °C for 20 min, resulting in the formation of the yellow lithium intermediate (**2c**).

In a second Schlenk flask, 0.92 g (4.66 mmol) of 3,5-dimethoxyphenylfulvene (**3c**) was dissolved in THF, and the resultant red solution was added via a *cannula* at −78 °C to the Schlenk flask containing the lithiated intermediate. The reaction mixture was then allowed to warm up to room temperature and left stirring for 40 min. Titanium tetrachloride (2.33 ml, 2.33 mmol) was added afterwards in situ at room temperature and the mixture was refluxed for 24 h. Subsequently, the solvent was removed under vacuum, resulting in the formation of a dark green oil that was dissolved in dichloromethane and filtered through celite to remove the LiCl. The black filtrate was filtered additionally twice by gravity filtration. The solvent was removed under reduced pressure forming a shiny black solid (**5c**), which was washed with 20 ml of pentane and then dried in vacuo (3.33 g, 4.05 mmol, 43.5% yield).

^{1}H NMR (δ ppm $CDCl_3$, 300 MHz): 7.18 [t, 4H, *J* 2.24 Hz, $C_6H_3(OCH_3)_2$]; 6.61 [dd, 4H, J_1 6.61 Hz, J_2 2.23 Hz, $C_6H_3(OCH_3)_2$]; 6.49 [dd, 4H, J_1 6.61 Hz, J_2 2.42 Hz, $C_6H_3(OCH_3)_2$]; 6.53 [d, 4H, *J* 2.23 Hz, C_5H_4–CH–$(C_6H_3(OCH_3)_2)$]; 6.52 [d, 4H, *J* 2.23 Hz, C_5H_4–CH–$(C_6H_3(OCH_3)_2)$]; 5.29 [s, 2H, C_5H_4–C*H*–$(C_6H_3(OCH_3)_2)$]; 3.72 [m, 24H, $C_6H_3(OCH_3)_2$].

^{13}C NMR (δ ppm $CDCl_3$, 500 MHz): 161.1, 160.7, 129.9, 122.9, 109.9, 109.6, 106.0, 100.2, 99.6 [C_5H_4 and C_6H_3]; 56.33, 56.26 [$C_6H_3(OCH_3)_2$]; 33.9 [Cp–*C*H–$(C_6H_3(OCH_3)_2)_2$]. (The rotation of the 3,5-dimethoxyphenyl group is hindered.)

IR absorptions (cm^{-1} KBr): 2931, 2832, 1606, 1509, 1461, 1425, 1299, 1174, 1108, 1031, 831.

Anal. Calc. for $C_{44}H_{46}O_8Cl_2Ti$: Theory: C, 64.32; H, 5.64; Cl, 8.62. Found: C, 64.14; H, 5.60; Cl, 8.57%.

UV–Vis (CH_2Cl_2/ε:[cm^2/mol]): λ 275 nm (ε 79 830), λ 378 nm (ε 17 830), λ 525 nm (ε 3820), λ 580 nm (weak), λ_{max} 685 nm (weak).

3. Results and discussion

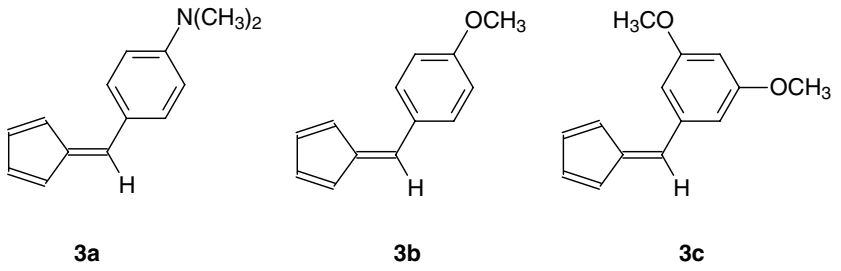
3.1. Synthesis

Fulvenes **3a**, **3b**, and **3c** were synthesised by reacting the corresponding benzaldehyde with freshly distilled cyclopentadiene in the presence of pyrrolidine as a base [21,23] and their structures are shown in Fig. 2.

The use of aryl lithium species for asymmetric addition in the synthesis of other metallocenes has been previously published [28–31]. This time, the method is used as a straightforward approach for the synthesis of diarylmethyl substituted metallocenes, as seen with titanocenes **5a**–**c** (Fig. 3).

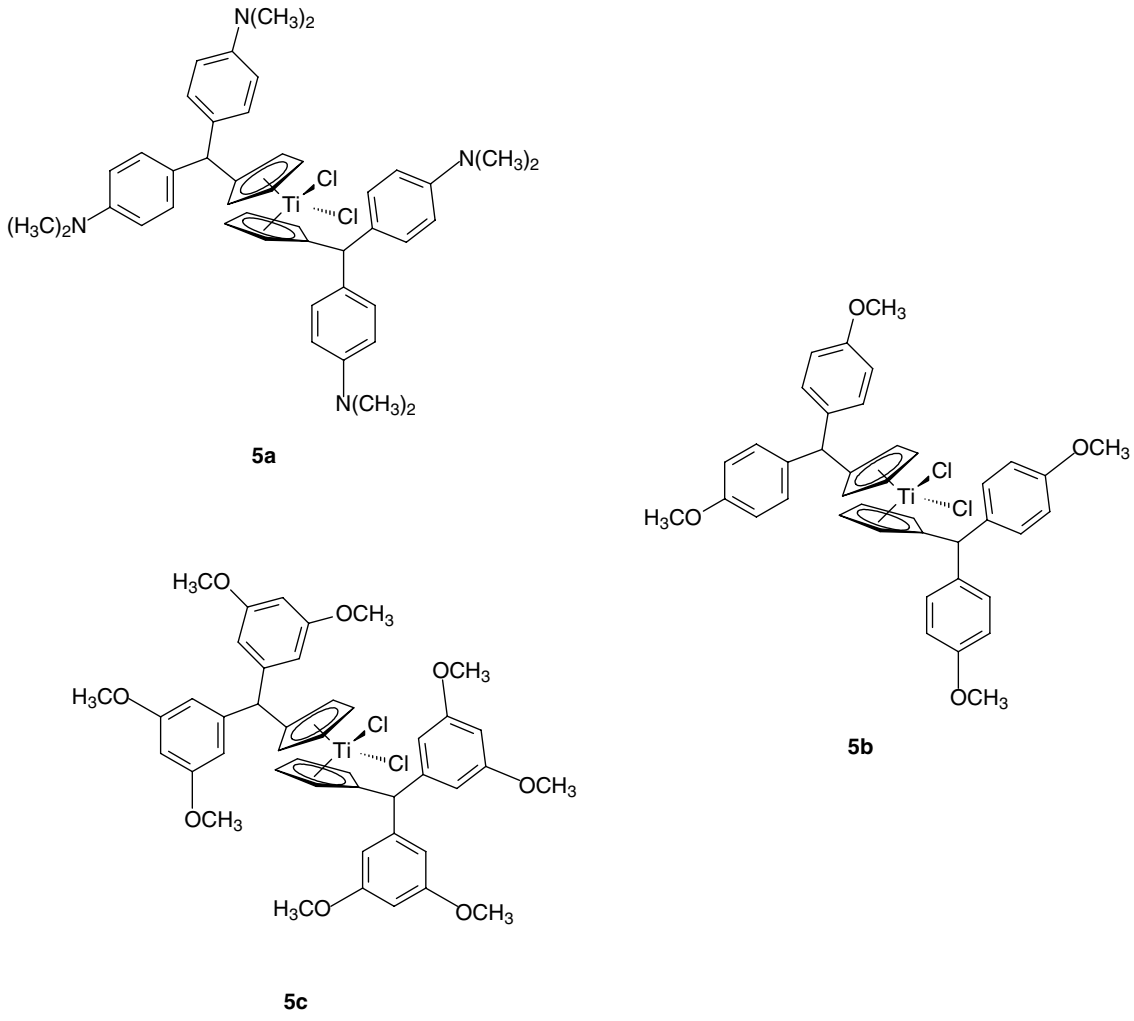
The first step of the reaction consists of a bromine–lithium exchange, in which the use of *tert*-butyl lithium resulted in the formation of the functionalised lithium intermediates **2a**–**c**, obtaining better yields and no side-reactions in comparison to *n*-butyl lithium. Side-reactions were also avoided by cooling down the reaction to −78 °C during the addition of *tert*-butyl lithium and subsequent warming up to 0 °C.

This step was followed by the nucleophilic addition of the lithiated intermediate to the double bond of the fulvenes **3a**, **3b** or **3c** at −78 °C. Then, the reaction mixture was allowed to warm up to room temperature and it resulted in the formation of the appropriate substituted lithium cyclopentadienyl intermediates, **4a**–**c**. After stirring the reaction mixture for 40 min, two molar equivalents of **4a, 4b** or **4c** underwent a transmetallation reaction when reacted with one molar equivalent of $TiCl_4$ in THF under reflux for 24 h, to give the appropriate unbridged



3a **3b** **3c**

Fig. 2. Structure of fulvenes **3a**–**c**.



5a **5b** **5c**

Fig. 3. Structure of Titanocenes **5a**–**c**.

substituted titanocenes, **5a**–**c**. The compounds obtained are shiny dark red to dark brown solids (Scheme 1).

3.2. Structural discussion

Despite our attempts to crystallise these three titanocenes, only one crystal structure for **5a** was obtained. Unfortunately, this crystal structure was not publishable. Nevertheless, the principal molecular structure of **5a** could be proven and even the pyramidal carbons 6 and 6′ could be observed (see Scheme 2), as the single methylic protons were sitting on their respective carbons.

In order to overcome the problem of missing crystal structures, density functional theory (DFT) calculations were carried out for titanocenes **5a** and **5b** at the B3LYP level using the 6-31G** basis set. Selected bond lengths of the optimised structures of these titanocenes are listed in Table 1 (for atom numbering, see Scheme 2). The molecular structures of **5a** and **5b** are presented in Fig. 4.

	1-5a	1-5b	1-5c
R_1	-$N(CH_3)_2$	-OCH_3	H
R_2	H	H	-OCH_3

Scheme 1. Synthesis of Titanocenes **5a**–**c**.

The length of the bond between the metal centre and the cyclopentadienyl carbons is similar for both titanocene structures. They vary between 237.9–249.9 pm for **5a** and 238.1–250.3 pm for **5b** with slightly different values for the different Cp rings. The same applies for the carbon–carbon bonds of the cyclopentadienyl rings with bond lengths between 141.0–141.9 pm for **5a** and 141.0–143.6 pm for **5b**. These values suggest that the titanocenes have a plane of symmetry bisecting the Cl–Ti–Cl plane and the calculated structures exhibit C_2 symmetry.

The bond length between the methylic carbon centre and the carbon centre of the Cp group is similar for both titanocenes within the range of 152.3–152.4 pm and the same occurs for the methylic carbon–aryl bond (153.0–153.7 pm).

The steric impediment of the aryls attached to the methylic carbons causes a lengthening of the bond, in order to relieve the resultant steric strain. The bond length between the methylic carbons is in both cases too large to suggest any bridge formation, 424.3 pm for **5a** and 432.7 pm for **5b**. As well the titanium–chlorine bond lengths are almost identical in both cases.

The Cl–Ti–Cl angle was calculated for **5a** to be 94.4° and 96.9° for **5b**. For **5a**, the angle formed by the bonds

between C(6), C(7) and C(7′) is 112.7°, and the angle formed between C(6′), C(7″) and C(7‴) is 111.4°. The corresponding calculated values for **5b** are 111.9° and 111.4°. The angle between C(1) or C(1′), the correspondent methylic atom, and C(7) or C(7‴), respectively, is smaller than the one formed by C(1) or C(1′), the correspondent methylic atom, and C(7′) or (C7″), respectively, by approximately 10° in both **5a** and **5b**, due to the steric impediment.

3.3. Cytotoxicity studies

The in vitro cytotoxicity of compounds **5a–c** was determined by MTT-based assays involving a 48 h drug exposure period, followed by 24 h of recovery time [32]. The compounds were tested for their activity on pig kidney carcinoma (LLC-PK) cells and the results are shown in Fig. 5. Compound **5a**, which contains dimethyl amino groups, has an IC_{50} value of 3.8×10^{-5} M, showing a higher cytotoxicity than its *ansa* and mono-benzyl substituted analogues. The *ansa* analogue of **5a**, compound Titanocene **X**, has an IC_{50} value of 4.5×10^{-4} M and the mono-benzyl substituted analogue has an IC_{50} value of 1.2×10^{-4} M. Compound **5b**, which contains *p*-methoxy groups, shows an IC_{50} value of 4.5×10^{-5} M, very similar to the value obtained for by the mono-benzyl substituted analogue Titanocene **Y**, that showed the most significant IC_{50} value of 2.1×10^{-5} M up to now. Compound **5c**, which we expected to have an increased aqueous solubility and consequently increased cytotoxicity due to the higher number of methoxy groups, has an IC_{50} value of 7.8×10^{-5} M, which shows a slight decrease in magnitude in comparison to **5a** and **5b**. It must also be noted that the cytotoxic action of **5a**, **5b** and **5c** differs from the mono-benzyl substituted analogue Titanocene **Y**: at lower concentrations the compounds show a less effective cell death induction than Titanocene **Y**.

The best compound in this series, titanocene **5a**, has an over 10-fold decrease in magnitude in terms of IC_{50} values when compared to the unsubstituted titanocene dichloride. Compared to the value for *cis*-platin, the IC_{50} value for these titanocenes shows an increase of approximately 6.4 in the order of magnitude when tested on the LLC-PK cell line.

Titanocenes **5a–c** presented in this paper do not have stereocentres and therefore stereoisomers do not exist, unlike their *ansa* analogues. But for **5c**, the rotation of the 3,5-dimethoxyphenyl groups was found to be hindered, which explains the NMR-spectroscopic results. In terms of in vivo and in vitro cell testing, this is advantageous. Previously, the presence of unseparated stereoisomers means that the issue of whether the compounds' cytotoxicities are related to specific isomers was not addressed. This is not of concern in the achiral bis-benzyl-substituted titanocenes **5a–c**.

4. Conclusions and outlook

The carbolithiation of 6-arylfulvenes with aryl lithium species followed by transmetallation offers a general way into the synthesis of achiral diarylmethyl substituted metallocenes. In the case of methoxy or dimethylamino substituents and titanium(IV) as the central metal, these

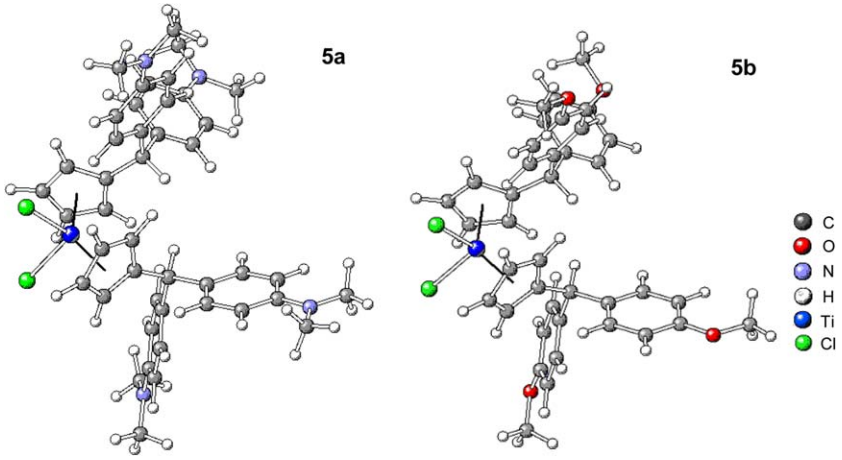

Fig. 4. DFT calculated structures of **5a** and **5b**.

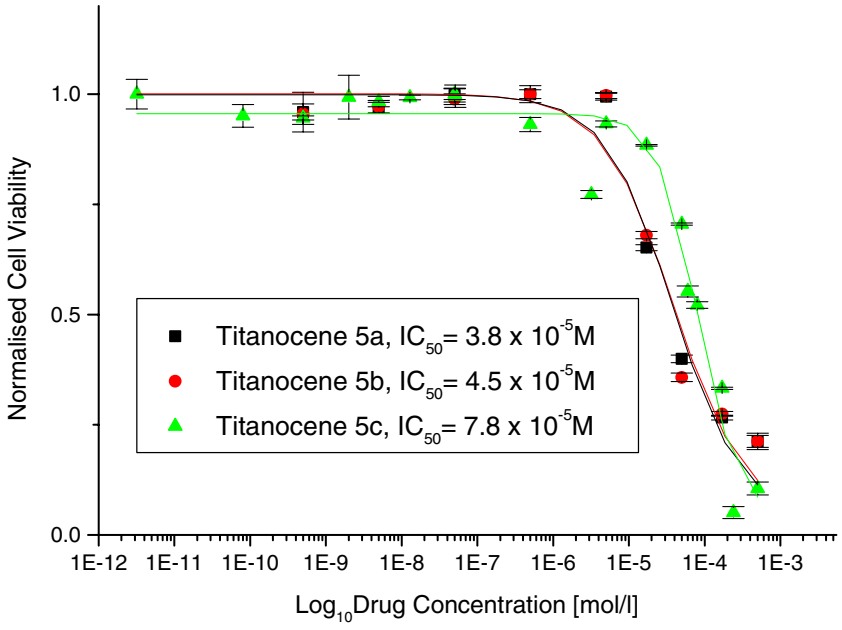

Fig. 5. MTT-based cytotoxicity curves show the effect of compounds **5a–c** on pig kidney carcinoma (LLC-PK) cells.

compounds exhibit significant cytotoxicity against kidney cancer cells with IC_{50} values in the 10^{-5} M region, which makes them already promising anti-cancer drugs. Nevertheless, it is intended to employ this carbolithiation method for future synthesis of titanocenes exhibiting cytotoxicities in the single digit μM region.

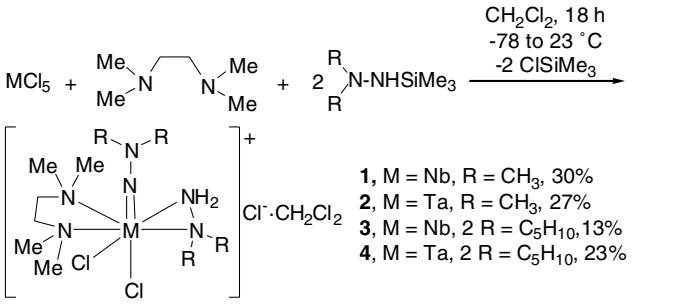
ligands [8,12], and only one tantalum complex has been structurally documented that contains an η^2-trimethylhydrazido(1−) ligand [10]. We are interested in the development of new metalorganic film growth precursors for TaN, and also seek to understand the mechanistic paths by which simple tantalum precursors are converted to TaN films in a CVD process. Within this context, we describe the synthesis and structural characterization of a series of niobium and tantalum complexes that are obtained upon treatment of the metal pentachlorides with 1,1-dialkylhydrazine derivatives. Depending upon the nature of the alkyl groups and the presence or absence of tetramethylethylenediamine (TMEDA), cationic complexes of the formula $[M(NNR_2)Cl_2(NH_2NR_2)(TMEDA)]^+Cl^-$ and $[M(NN(CH_2)_5)Cl_2(NH_2N(CH_2)_5)_2]^+Cl^-$ were obtained. These complexes were structurally characterized and possess several hydrazido ligand coordination modes.

2. Results and discussion

2.1. Treatment of niobium and tantalum pentachloride with 1,1-dialkyl-2-trimethylsilylhydrazines and TMEDA

Dichloromethane solutions of metal pentachloride/TMEDA (1 equivalent each) and 1,1-dialkyl-2-trimethylsilylhydrazine (2 equivalents, alkyl = CH_3, $0.5C_5H_{10}$) were mixed at −78 °C, allowed to warm to ambient temperature, and then stirred for 18 h. Workup entailed removal of the volatile components under reduced pressure to eliminate the chlorotrimethylsilane product, followed by fractional crystallization from concentrated dichloromethane solutions. In this way, $[Nb(NNMe_2)Cl_2(NH_2NMe_2)(TMEDA)]Cl \cdot CH_2Cl_2$ (**1**, 30%), $[Ta(NNMe_2)Cl_2(NH_2NMe_2)(TMEDA)]Cl \cdot CH_2Cl_2$ (**2**, 27%), $[Nb(NN(CH_2)_5)Cl_2(NH_2N(CH_2)_5)(TMEDA)]Cl \cdot CH_2Cl_2$ (**3**, 13%), and $[Ta(NN(CH_2)_5)Cl_2(NH_2N(CH_2)_5)(TMEDA)]Cl \cdot CH_2Cl_2$ (**4**, 23%) were isolated as yellow crystalline solids (Eq. (1)). The crude products revealed mixtures of **1**–**4** with either 1,1-dimethylhydrazinium chloride (**1**, **2**) or 1-ammoniumpiperidine chloride (**3**, **4**). There were no other products observed in the ^1H NMR spectra of the crude reaction mixtures, suggesting very clean reactions. Yields of the crude product mixtures, including the hydrazinium salts, were 95–98%. The solubility characteristics of **1**–**4** were similar to those of the hydrazinium chloride salts, but selective crystallization of **1**–**4** from dichloromethane could be achieved after most of the slightly less soluble hydrazinium salts had precipitated. However, the yields of crystalline **1**–**4** were low because of the stringent control required to achieve selective crystallization. The formulations of **1**–**4** were based upon spectral and analytical data, as well as X-ray crystal structure determinations. Complexes **1**–**4** are cationic monomers in the solid state with a chloride counterion. One equivalent of dichloromethane solvate per metal center was present in the crystals of **1**–**4**. The ^1H and $^{13}C\{^1H\}$ NMR data for **1**–**4** are uniquely consistent with retention of the solid state structures in solution. For example, all of the methyl groups in **1** and **2** exist in different chemical environments, and eight methyl signals were observed in the $^{13}C\{^1H\}$ spectra. The $^{13}C\{^1H\}$ NMR spectra of **3** and **4** reveal resonances for 16 carbon atoms, which is consistent with the solid state structures. The ^1H and $^{13}C\{^1H\}$ NMR spectra for **1**–**4** also show the expected resonances for the dichloromethane solvate.

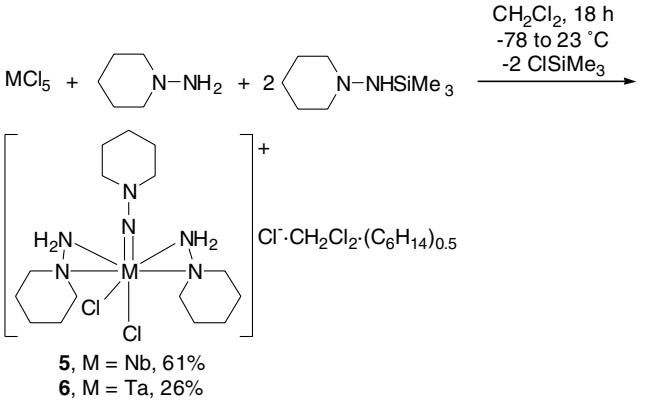


(1)

2.2. Treatment of niobium and tantalum pentachloride with 1-trimethylsilylaminopiperidine and 1-aminopiperidine

Experience gained from the syntheses of **1**–**4**, which showed that one equivalent of the neutral 1,1-dialkylhydrazine coordinates to the metal center to saturate the coordination sphere, suggested that stable complexes might be obtained without TMEDA if an additional equivalent of the 1,1-dialkylhydrazine was added to the reaction mixture. Accordingly, treatment of the metal pentachlorides with 1-trimethylsilylaminopiperidine (2 equivalents) and 1-aminopiperidine (1 equivalent) in dichloromethane at −78 °C, followed by stirring for 18 h at room temperature, afforded $[Nb(NN(CH_2)_5)Cl_2(NH_2N(CH_2)_5)_2]Cl \cdot [(CH_2Cl_2)(C_6H_{14})_{0.5}]$ (**5**, 61%) and $[Ta(NN(CH_2)_5)Cl_2(NH_2N(CH_2)_5)_2]Cl \cdot [(CH_2Cl_2)(C_6H_{14})_{0.5}]$ (**6**, 26%) as yellow crystalline solids (Eq. (2)). In **5** and **6**, two neutral 1-aminopiperidine ligands coordinate to the metal centers, which again leads to cationic complexes by elimination of a chloride ion from the inner coordination sphere. Like **1**–**4**, **5** and **6** were obtained as mixtures with the 1-ammoniumpiperidine salts. Accordingly, careful fractional crystallization was required to obtain pure materials, and reported yields are moderate to low. Structural assignments for **5** and **6** were based upon spectral and analytical data. An X-ray crystal structure determination was also performed for **5**. A low precision X-ray crystal structure analysis was performed on **6**, which confirmed a structure very similar to that of **5**. Complexes **5** and **6** both crystallize with one equivalent of dichloromethane and one-half equivalent of hexane in the asymmetric unit. The ^1H and $^{13}C\{^1H\}$ NMR spectra of **5** and **6** were consistent with the solid state structures. In **5** and **6**, there is a mirror plane that passes through the MCl_2 atoms, which makes the η^2-aminopiperidine ligands identical by symmetry. However, the five carbon atoms within each η^2-aminopiperidine ligand reside in different chemical environments, provided that exchange between the two faces of the piperidine fragment is slow on the NMR timescale. The ^1H

and $^{13}C\{^1H\}$ NMR spectra of **5** and **6** revealed sharp resonances for the 10 carbon atom sites, demonstrating that the exchange process for the η^2-aminopiperidine ligands is slow.



(2)

2.3. X-ray crystal structures of 1–5

X-ray crystal structures of **1**–**5** were determined to establish the geometry about the metal centers and the bonding modes of the hydrazine-derived ligands. Experimental crystallographic data are summarized in Table 1, selected bond distances and angles are given in Tables 2–6, and perspective views of **1**–**5** are presented in Figs. 1–5. Figs. 6 and 7 show intermolecular hydrogen bonding interactions that are present in **1** and **5**.

Complexes **1**–**4** adopt similar molecular structures, with monomeric formulations and approximate pentagonal bipyramidal geometry about each metal center. The axial sites contain one terminal, linear NNR_2 ligand and one chloride ion. The equatorial sites contain one chloride ion, one η^2-hydrazine ligand, and one η^2-TMEDA ligand. The $-NH_2$ fragments of the η^2-hydrazine ligands are situated *syn* to one of the TMEDA dimethylamino groups, apparently for steric reasons. The equatorial chloro ligand resides between one of the TMEDA dimethylamino groups and the $-NR_2$ fragment of the η^2-hydrazine ligands. The metal coordination sphere has an overall positive charge, and there is a chloride ion that serves to balance this charge. Each complex also crystallizes with one dichloromethane molecule per metal center. Since the niobium(V) and tantalum(V) ions are the same size ($r(Nb(V)) = 0.64$ Å, $r(Ta(V)) = 0.64$ Å for six-coordinate complexes [13]), the bond lengths of **1**–**4** can be directly compared. For the NNR_2 ligands, the metal–nitrogen bond lengths range from 1.773 to 1.785 Å, the nitrogen–nitrogen distances are between 1.32 and 1.36 Å, and the metal–nitrogen–nitrogen angles lie between 171.5° and 172.3°. The metal–nitrogen bond lengths associated with the neutral hydrazine ligands range between 2.179 and 2.190 Å for

The metal–chlorine distances for the chlorine atoms that are *cis* to the NNR_2 ligand range between 2.451 and 2.468 Å, while the related values for the chlorine atoms that are *trans* to the NNR_2 ligand lie between 2.521 and 2.550 Å. The latter bond lengths are longer than the former due to the strong *trans*-influence of the NNR_2 ligand.

The molecular structure of **5** is broadly similar to those of **1**–**4**. The cationic fragment in **5** is monomeric with approximate pentagonal bipyramidal geometry about the niobium center. The axial sites contain one terminal, linear NNR_2 ligand and one chloride ion. The equatorial sites contain one chloride ion and two η^2-aminopiperidine ligands. The –NH_2 fragments are *syn* to each other within the equatorial plane, which places the equatorial chloride ion in between the two piperidine groups. The imidopiperidine group has a niobium–nitrogen bond distance of 1.763(4) Å, a nitrogen–nitrogen bond length of 1.347(5) Å, and a niobium–nitrogen–nitrogen angle of 172.4(3)°. These values are within experimental uncertainty of those observed for **1**–**4**. The η^2-aminopiperidine ligands have niobium–nitrogen bond lengths of 2.184(4) and 2.188(4) Å for the –NH_2 fragments and 2.246(4) and 2.258(4) Å for the piperidine moieties. The asymmetry within the metal–nitrogen bond lengths for the η^2-aminopiperidine ligands in **5** (0.062–0.070 Å) is larger than the related values in **1**–**4** (0.021–0.040 Å), possibly due to the

Complexes **1**–**5** exhibit interesting crystal structures that contain hydrogen bonds between the hydrogen atoms of the coordinated neutral η^2-dimethylhydrazine and η^2-aminopiperidine ligands and the chloride counterions. In **1**–**4**, the nitrogen-bound hydrogen atoms of neutral η^2-hydrazine ligands of two adjacent cationic molecules form hydrogen bonds to two chloride counterions. This hydrogen bond network leads to an eight-membered $H_4N_2Cl_2$ ring, as depicted in Fig. 6 for **1**. In **1**–**4**, the nitrogen–chloride ion distances for the atoms involved in hydrogen bonding are separated by 3.11–3.23 Å. The hydrogen atom positions in **1** were calculated, resulting in nitrogen–hydrogen distances of 0.9 Å, hydrogen–chlorine distances of 2.25 and 2.37 Å,

and nitrogen–hydrogen–chlorine angles of 146° and 171°. There were no hydrogen bonds to the chlorine atoms of the dichloromethane solvate molecules. In **5**, the hydrogen bonding network is more complicated due to the presence of two neutral η^2-aminopiperidine ligands. As depicted in Fig. 7, there is an eight-membered $H_4N_2Cl_2$ ring similar to those observed in **1**–**4** that incorporates the four nitrogen-bound hydrogen atoms of the η^2-aminopiperidine ligands on two adjacent cationic molecules and two chloride counterions. The nitrogen–chloride ion distances for the atoms involved in the eight-membered ring are separated by 3.11–3.22 Å. The hydrogen atoms were placed in calculated positions with nitrogen–hydrogen distances of 0.90 Å, which afforded hydrogen–chlorine distances of 2.22 and 2.45 Å, and nitrogen–hydrogen–chlorine angles of 144° and 169°. One of the other η^2-aminopiperidine ligand hydrogen atoms on each metal center is engaged in hydrogen bonding to one of the chloride ions of the eight-membered $H_4N_2Cl_2$ ring, with nitrogen–chlorine distances of 3.15 Å, hydrogen–chlorine distances of 2.41 and 2.42 Å, and nitrogen–hydrogen–chlorine angles of 138° and 140°. Finally, the remaining η^2-aminopiperidine ligand hydrogen atom forms a hydrogen bond to the niobium-bound chloride ion that is *trans* to the NNR_2 ligand, and possesses a nitrogen–chlorine distances of 3.32 and 3.36 Å, hydrogen–chlorine distance of 2.45 and 2.47 Å, and nitrogen–hydrogen–chlorine angles of 164° and 169°.

2.4. Discussion

A significant aspect of the work described herein is the synthesis and structural documentation of **1**–**6**. There are very few crystallographically characterized niobium and tantalum complexes that contain hydrazine-derived

ligands. The complexes $(C_5H_4Me)_2NbCl(NNMe_2)$ (Nb–N 1.794(2) Å, N–N 1.340(3) Å, Nb–N–N 178.8(2)°) [8a], $CpNbCl_2(NNMe_2)(P(OMe)_3)$ (Nb–N 1.789(2) Å, N–N 1.338(2) Å, Nb–N–N 170.4(2)°) [8b], and $Cp_2Nb_2Cl_2(NNMe_2)_2$ (Nb–N 1.67(2) Å, N–N 1.38(2) Å, Nb–N–N 168.7(17)°) [8b] contain terminal dimethylhydrazido(2−) ligands. The complex $Cp_2Nb_2Cl_2(NNMe_2)_2$ also contains a μ:η^1,η^2-dimethylhydrazido(2−) ligand (Nb–N 1.88(1), 2.15(2), 2.28(1) Å; N–N 1.39(2) Å, Nb–N–N 127.9(10)°) [8b]. The complex $[NHEt_3]$- $[TaCl_4(NNC_9H_{18})_2]$ contains two linear 1-imido-2,2,6,6-tetramethylpiperidine ligands (Ta–N 1.865(7), 1.882(6) Å; N–N 1.283(9), 1.259(8) Å, Ta–N–N 176.4(5)°, 176.5(5)°) [12]. Complex $[Ta(S_2CNEt_2)_3(NMeNMe_2)]Br$ contains an η^2-1,1,2-trimethylhydrazido(1−) ligand [10], with tantalum–nitrogen distances of 1.932(12) and 2.209(16) Å and a nitrogen–nitrogen distance of 1.389(22) Å. Complexes **1**–**5** contain linear NNR_2 ligands with structural parameters that are very similar to previously reported neutral complexes containing similar ligands. Complexes **1**–**5** are the first niobium and tantalum complexes that contain neutral 1,1-dialkylhydrazine ligands. NMR studies for **1**–**5** in DMSO show that the η^2-hydrazine ligands exchange very slowly with the strong donor ligand DMSO at ambient temperature, and are thus strongly bound ligands. The complex $[NHEt_3][TaCl_4(NNC_9H_{18})_2]$ has longer tantalum–nitrogen bond lengths than those of **1**–**5** by about 0.1 Å, and also has nitrogen–nitrogen bond lengths that are about 0.05 Å shorter than those of **1**–**5**. The authors of this work suggested that this complex contains isodiazene ligands, rather than hydrazido(2−) ligands [12]. As outlined in Chart 1, isodiazene ligands are formally neutral donor ligands and contain a formal nitrogen–nitrogen double bond. In complexes containing isodiazene ligands, the metal–nitrogen bond lengths are longer and the nitrogen–nitrogen bond lengths are shorter compared to complexes containing hydrazido(2−) ligands. In **1**–**5**, the metal–nitrogen bond distances range from 1.76 to 1.79 Å, which is slightly shorter to about the same as in several of the neutral niobium cyclopentadienyl complexes described above. We have reported the structural characterization of a series of niobium and tantalum alkylimido complexes [14], and found metal–nitrogen bond lengths between 1.73 and 1.77 Å. The values in **1**–**5** are about the same to slightly longer than those of the alkylimido complexes. The nitrogen–nitrogen distances in the NNR_2 ligands of **1**–**5** were between 1.32 and 1.36 Å, while the corresponding values for the neutral hydrazine donor ligands in **1**–**5** ranged from 1.43 to 1.45 Å. The bond lengths in the latter ligands can be considered as a typical value for a nitrogen–nitrogen single bond. The combination of slightly longer metal–nitrogen bond lengths and short nitrogen–nitrogen bond lengths in **1**–**5** suggest at least some isodiazene character to the NNR_2 linkages.

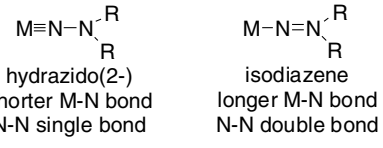

Chart 1. Hydrazido(2−) and isodiazene ligands.

Notably, since isodiazene ligands are formally neutral, the metal centers in complexes containing such ligands are formally reduced compared to complexes containing hydrazido(2−) ligands. A recent theoretical study has examined the bonding between metal ions and hydrazido(2−) ligands, and concluded that NNR_2 ligands have approximate charges of 1- in complexes of group 6 metals [15]. Accordingly, these ligands lead to a reduction in the formal oxidation state of the metal. We propose that the lower group 4 and 5 metal nitride film growth temperatures observed with hydrazine derivatives as coreactants, compared to similar film growth employing ammonia as the coreactant, are related to the formal reduction of the metal centers by isodiazene-like ligand intermediates that are formed in the film growth process. Complexes **1**–**5** represent models for the types of intermediates that could be formed in a film growth process from tantalum pentachloride and 1,1-dialkylhydrazines.

One of the goals of our work was to prepare new volatile complexes that might be employed as molecular precursors for the low temperature growth of TaN films. However, the cationic nature of **1**–**5** afforded essentially non-volatile complexes, which are not useful in film growth procedures employing conventional thermal precursor delivery. Attempts to replace the chloride ligands in **1**–**5** by salt metathesis reactions with lithium dimethylamide or potassium 3,5-di-*tert*-butylpyrazolate led to complex mixtures of products. Thus, **1**–**5** do not appear to be useful reagents for the preparation of niobium and tantalum complexes containing NNR_2 ligands. By contrast, complexes of the formula $M(NR)Cl_3py_2$ (M = Nb, Ta; R = alkyl; py = pyridine) are versatile starting materials for the synthesis of a range of niobium and tantalum imido complexes [16].

3. Experimental

3.1. General considerations

All manipulations were performed under an inert atmosphere of argon using either glovebox or Schlenk line techniques. Hexane was distilled from P_2O_5 and dichloromethane was distilled from calcium hydride. Niobium pentachloride, tantalum pentachloride, 1,1-dimethylhydrazine, 1-aminopiperidine, TMEDA, and chlorotrimethylsilane were purchased from Aldrich Chemical Company and were used as received. 1,1-Dimethyl-2-trimethylsilylhydrazine [17] and 1-trimethylsilyl-1-aminopiperidine [18] were prepared according to the literature procedures. ^1H and $^{13}C\{^1H\}$ NMR were obtained at 400, 300, 100, or 75 MHz in dichloromethane-d_2 or dimethylsulfoxide-d_6 as indicated. Infrared spectra were obtained using Nujol as the medium.

Elemental analyses were performed by Midwest Microlab, Indianapolis, Indiana. In spite of multiple submissions and addition of V_2O_5, satisfactory analyses could not be obtained for **1**, **2**, **5**, and **6**. Melting points were obtained on a Haake-Buchler HBI digital melting point apparatus and are uncorrected.

3.2. Preparation of *[Nb(NNMe$_2$)Cl$_2$(NH$_2$NMe$_2$)(TMEDA)]Cl · CH$_2$Cl$_2$ (**1**)*

A 100-mL Schlenk flask was charged with tantalum pentachloride (0.380 g, 1.06 mmol), dichloromethane (20 mL), and TMEDA (0.123 g, 1.06 mmol). The resultant mixture was stirred at ambient temperature for 0.5 h. The solution was then cooled to −78 °C, and was treated with a solution of 1,1-dimethyl-2-trimethylsilylhydrazine (0.281 g, 2.12 mmol) in dichloromethane (15 mL). The reaction mixture was allowed to warm to room temperature and was stirred for 18 h. The volatile components were removed under reduced pressure to afford a light orange powder. This powder was extracted with dichloromethane (25 mL) to afford an orange solution and a white precipitate. The dichloromethane extract was filtered through a 2-cm pad of Celite on a coarse glass frit to afford an orange-yellow solution. Storage of this solution at −20 °C for 24 h afforded **1** as yellow crystals (0.174 g, 27%): mp (dec) 139 °C; IR (Nujol, cm^{-1}) 3166 (w), 1582 (s), 1562 (w), 1283 (m), 1238 (w), 1204 (w), 1127 (m), 1075 (w), 1039 (w), 1000 (m), 944 (s), 893 (s), 844 (w); ^{1}H NMR (dichloromethane-d_2, 22 °C, δ) 11.55 (broad s, 1H, N*H*H′), 6.10 (broad s, 1H, NH*H*′), 3.44 (s, 3H, CH_3), 3.40 (s, 3H, CH_3), 3.29 (s, 3H, CH_3), 3.16 (s, 3H, CH_3), 3.10 (s, 6H, 2 CH_3), 2.97 (s, 3H, CH_3), 2.96 (s, 3H, CH_3), 2.4–2.9 (m, 4H, CH_2 of TMEDA); ^{13}C{^{1}H} NMR (dimethylsulfoxide-d_6, 22 °C, ppm) 58.79 (s, *C*H$_2$ of TMEDA), 58.14 (s, *C*H$_2$ of TMEDA), 54.97 (s, *C*H$_3$), 54.73 (s, *C*H$_3$), 54.60 (s, *C*H$_3$), 53.97 (s, *C*H$_3$), 52.38 (s, *C*H$_3$), 50.89 (s, *C*H$_3$), 49.38 (s, *C*H$_3$), 43.29 (s, *C*H$_3$).

Anal. Calc. for $C_{11}H_{32}Cl_5N_6Ta$: C, 21.78; H, 5.32; N, 13.85. Found: C, 24.60; H, 5.73; N, 12.57%.

3.3. Preparation of *[Ta(NNMe$_2$)Cl$_2$(NH$_2$NMe$_2$)(TMEDA)]Cl · CH$_2$Cl$_2$ (**2**)*

In a fashion similar to the preparation of **1**, treatment of niobium pentachloride (0.380 g, 1.41 mmol) with TMEDA (0.163 g, 1.40 mmol) and 1,1-dimethyl-2-trimethylsilylhydrazine (0.372 g, 2.81 mmol) afforded **2** as yellow crystals (0.262 g, 30%): mp (dec) 161 °C; IR (Nujol, cm^{-1}) 3168 (w), 1583 (s), 1565 (m), 1284 (m), 1231 (w), 1194 (w), 1120 (s), 1075 (m), 1041 (w), 1005 (s), 951 (s), 887 (s), 847 (w); ^{1}H NMR (dichloromethane-d_2, 22 °C, δ) 11.18 (d, 1H, $J = 7.8$ Hz, N*H*H′), 6.72 (d, 1H, $J = 7.8$ Hz, NH*H*′), 3.58 (s, 3H, CH_3), 3.48 (s, 3H, CH_3), 3.38 (s, 3H, CH_3), 3.27 (s, 3H, CH_3), 3.06 (s, 3H, CH_3), 3.03 (s, 6H, 2 CH_3), 2.96 (s, 3H, CH_3), 2.88 (m, 2H, CH_2 of TMEDA), 2.55 (m, 2H, CH_2 of TMEDA); ^{13}C{^{1}H} NMR (dimethylsulfoxide-d_6, 22 °C, ppm) 58.78 (s, *C*H$_2$ of TMEDA), 58.08 (s, *C*H$_2$ of TMEDA), 56.65 (s, *C*H$_3$), 54.97 (s, *C*H$_3$), 54.42 (s, *C*H$_3$), 52.46 (s, *C*H$_3$), 51.23 (s, *C*H$_3$), 49.26 (s, *C*H$_3$), 45.28 (s, *C*H$_3$), 42.24 (s, *C*H$_3$).

Anal. Calc. for $C_{11}H_{32}Cl_5N_6Nb$: C, 25.48; H, 6.22; N, 16.21. Found: C, 24.10; H, 5.80; N, 15.90%.

3.4. Preparation of *[Nb(NN(CH$_2$)$_5$)Cl$_2$(NH$_2$N(CH$_2$)$_5$)(TMEDA)]Cl · CH$_2$ Cl$_2$ (**3**)*

In a fashion similar to the preparation of **1**, treatment of niobium pentachloride (0.380 g, 1.41 mmol) with TMEDA (0.123 g, 1.06 mmol) and 1-trimethylsilyl-1-aminopiperidine (0.485 g, 2.81 mmol) afforded **3** as yellow crystals (0.168 g, 23%): mp (dec) 166 °C; IR (Nujol, cm^{-1}) 3190 (w), 3152 (w), 1575 (s), 1557 (w), 1539 (w), 1505 (w), 1353 (w), 1336 (w), 1317 (w), 1283 (m), 1271 (m), 1231 (s), 1204 (w), 1185 (w), 1178 (m), 1122 (m), 1078 (m), 1050 (s), 1006 (m), 998 (m), 986 (w), 968 (m), 951 (s), 907 (w), 890 (w), 872 (s), 865 (m), 853 (w), 846 (w), 811 (s), 778 (m), 762 (m), 702 (m), 671 (m), 661 (w); ^{1}H NMR (dimethylsulfoxide-d_6, 22 °C, δ) 9.32 (broad s, 1H, N*H*H′), 7.66 (s, 1H, NH*H*′), 3.12 (s, 3H, CH_3 of TMEDA), 3.01 (s, 3H, CH_3 of TMEDA), 2.75 (s, 3H, CH_3 of TMEDA), 2.74 (s, 3H, *C*H$_3$ of TMEDA), 1.2–3.7 (many multiplets, 24H, 2 $C_5H_{10}N$ + CH_2 of TMEDA); ^{13}C{^{1}H} NMR (dimethylsulfoxide-d_6, 22 °C, ppm) 58.80 (s, *C*H$_2$ of TMEDA), 58.33 (s, *C*H$_2$ of TMEDA), 57.40 (s, *C*H$_3$), 54.97 (s, *C*H$_3$), 54.52 (s, *C*H$_3$), 54.05 (s, *C*H$_3$), 52.70 (s, 2 N*C*H$_2$), 52.54 (s, N*C*H$_2$), 50.91 (s, N*C*H$_2$), 24.62 (s, 2 *C*H$_2$), 24.10 (s, *C*H$_2$), 23.28 (s, *C*H$_2$), 22.47 (s, *C*H$_2$), 22.04 (s, *C*H$_2$).

Anal. Calc. for $C_{17}H_{40}Cl_5N_6Nb$: C, 34.10; H, 6.73; N, 14.04. Found: C, 34.55; H, 6.78; N, 14.09%.

3.5. Preparation of *[Ta (NN(CH$_2$)$_5$)Cl$_2$(NH$_2$N(CH$_2$)$_5$)(TMEDA)]Cl · CH$_2$Cl$_2$ (**4**)*

In a fashion similar to the preparation of **1**, treatment of tantalum pentachloride (0.380 g, 1.41 mmol) with TMEDA (0.163 g, 1.40 mmol) and 1-trimethylsilyl-1-aminopiperidine (0.485 g, 2.81 mmol) afforded **4** as yellow crystals (0.109 g, 13%): mp (dec) 157 °C; IR (Nujol, cm^{-1}) 3208 (w), 3157 (w), 1578 (s), 1353 (w), 1338 (w), 1319 (w), 1283 (w), 1271 (w), 1223 (s), 1200 (w), 1172 (m), 1122 (m), 1081 (m), 1052 (m), 1044 (m), 1009 (w), 1001 (w), 974 (w), 954 (m), 905 (w), 891 (w), 871 (s), 848 (w), 810 (s), 775 (m), 764 (m), 701 (m), 673 (w), 660 (m); ^{1}H NMR (dimethylsulfoxide-d_6, 22 °C, δ) 9.50 (broad s, 1H, N*H*H′), 7.72 (broad s, 1H, NH*H*′), 3.22 (s, 3H, CH_3 of TMEDA), 3.13 (s, 3H, CH_3 of TMEDA), 2.85 (s, 3H, CH_3 of TMEDA), 2.83 (s, 3H, CH_3 of TMEDA), 1.2–3.7 (many multiplets, 24H, 2 $C_5H_{10}N$ + CH_2 of TMEDA); ^{13}C{^{1}H} NMR (dimethylsulfoxide-d_6, 22 °C, ppm) 58.79 (s, *C*H$_2$ of TMEDA), 58.28 (s, *C*H$_2$ of TMEDA), 57.39 (s, *C*H$_3$), 56.27 (s, *C*H$_3$), 54.97 (s, *C*H$_3$), 54.80 (s, *C*H$_3$), 54.64 (s, 2 N*C*H$_2$), 52.61 (s, N*C*H$_2$), 51.22 (s, N*C*H$_2$), 25.04 (s, *C*H$_2$), 23.91 (s, *C*H$_2$), 23.52 (s, *C*H$_2$), 23.05 (s, *C*H$_2$), 22.80 (s, *C*H$_2$), 21.87 (s, *C*H$_2$).

Anal. Calc. for $C_{17}H_{40}Cl_5N_6Ta$: C, 29.73; H, 5.87; N, 12.24. Found: C, 29.80; H, 5.83; N, 12.22%.

3.6. Preparation of $[Nb(NN(CH_2)_5)Cl_2(NH_2N(CH_2)_5)_2]Cl \cdot [(CH_2Cl_2)(C_6H_{14})_{0.5}]$ (5)

In a fashion similar to the preparation of **1**, treatment of niobium pentachloride (0.380 g, 1.41 mmol) with 1-aminopiperidine (0.141 g, 1.41 mmol) and 1-trimethylsilyl-1-aminopiperidine (0.485 g, 2.81 mmol) afforded **5** as yellow crystals after crystallization from dichloromethane/hexane at −20 °C (0.537 g, 61%): mp (dec) 121 °C; IR (Nujol, cm^{-1}) 3176 (w), 3152 (w), 1578 (s), 1549 (w), 1229 (s), 1124 (w), 1078 (w), 1031 (m), 1016 (w), 965 (m), 935 (w), 917 (w), 892 (w), 872 (m), 850 (w), 819 (w), 767 (m); ^{1}H NMR (dimethylsulfoxide-d_6, 22 °C, δ) 6.46 (broad s, 4H, N*HH′*), 2.8–3.4 (overlapping m, 12H, NCH_2), 1.1–2.1 (overlapping m, 18H, CH_2); ^{13}C{^{1}H} NMR (dichloromethane-d_2, 22 °C, ppm) 55.02 (s, 2 overlapping N*C*H_2), 54.33 (s, N*C*H_2), 53.84 (s, N*C*H_2), 25.18 (s, *C*H_2CH'_2CH''_2 of η^2-aminopiperidine ligand), 24.78 (s, CH_2*C*H'_2CH''_2 of η^2-aminopiperidine ligand), 25.51 (s, CH_2CH'_2*C*H''_2 of η^2-aminopiperidine ligand), 23.16 (s, *C*H_2CH'_2CH''_2 of imidopiperidine ligand), 22.99 (s, CH_2*C*H'_2CH''_2 of imidopiperidine ligand), 22.68 (s, CH_2CH'_2*C*H''_2 of imidopiperidine ligand).

Anal. Calc. for $C_{19}H_{43}Cl_5N_6Nb$: C, 36.47; H, 6.93; N, 13.43. Found: C, 35.21; H, 6.19; N, 14.12%.

3.7. Preparation of $[Ta(NN(CH_2)_5)Cl_2(NH_2N(CH_2)_5)_2]Cl \cdot [(CH_2Cl_2)(C_6H_{14})_{0.5}]$ (6)

In a fashion similar to the preparation of **1**, treatment of tantalum pentachloride (0.380 g, 1.06 mmol) with 1-aminopiperidine (0.106 g, 1.06 mmol) and 1-trimethylsilyl-1-aminopiperidine (0.366 g, 2.12 mmol) afforded **6** as yellow crystals after crystallization from dichloromethane/hexane at −20 °C (0.197 g, 26%): mp (dec) 143 °C; IR (Nujol, cm^{-1}) 3192 (w), 3145 (w), 1580 (s), 1575 (s), 1558 (w), 1237 (m), 1181 (w), 1155 (m), 1129 (w), 1109 (w), 1030 (m), 961 (s), 912 (w), 877 (s), 850 (m), 819 (m), 769 (s), 754 (w), 700 (w); ^{1}H NMR (dimethylsulfoxide-d_6, 22 °C, δ) 5.95 (broad s, 4H, N*HH′*), 2.8–3.6 (overlapping m, 12H, N*C*H_2), 1.1–2.1 (overlapping m, 18H, CH_2); ^{13}C{^{1}H} NMR (dichloromethane-d_2, 22 °C, ppm) 56.43 (s, N*C*H_2), 56.40 (s, N*C*H_2), 55.91 (s, N*C*H_2), 55.02 (s, 2 N*C*H_2), 25.11 (s, *C*H_2CH'_2CH''_2 of η^2-aminopiperidine ligand), 24.72 (s, CH_2*C*H'_2CH''_2 of η^2-aminopiperidine ligand), 25.60 (s, CH_2CH'_2*C*H''_2 of η^2-aminopiperidine ligand), 22.81 (s, *C*H_2CH'_2CH''_2 of imidopiperidine ligand), 22.07 (s, CH_2*C*H'_2CH''_2 of imidopiperidine ligand), 21.95 (s, CH_2CH'_2*C*H''_2 of imidopiperidine ligand).

Anal. Calc. for $C_{19}H_{43}Cl_5N_6Ta$: C, 31.97; H, 6.07; N 11.77. Found: C, 30.15; H, 5.63; N, 12.30%.

3.8. X-ray crystallographic structure determinations for 1–6

Crystalline samples of **1**–**6** were air-sensitive and were mounted in sealed thin walled capillaries under a nitrogen atmosphere for X-ray data collection. All datasets were collected at room temperature on a Bruker P4/CCD diffractometer equipped with Mo Kα radiation. For each collection, a full sphere of data was collected at 10 s/frame with 0.2° between each frame. The frame data were integrated with the manufacturer's SMART and SAINT software [19]. Absorption corrections were applied with Sheldrick's SADABS program [19] and the structures were solved and refined using the programs of SHELXL-97 [20]. All hydrogen atoms were placed in calculated positions.

Complex **1** crystallized as irregular yellow fragments. The asymmetric unit contains one complex cation, one chloride ion, and one dichloromethane solvate.

Complex **2** crystallized as yellow rods. The asymmetric unit contains one complex cation, one chloride ion, and one dichloromethane solvate. The dichloromethane molecule was disordered and was described with two partial carbon positions. This complex is isostructural with **2**.

Complex **3** crystallized as yellow triangles. The asymmetric unit contains one complex cation, one chloride ion, and one dichloromethane solvate molecule.

Complex **4** crystallized as yellow diamonds. The asymmetric unit contains one complex cation, one chloride ion, and one dichloromethane solvate molecule. This complex is isostructural with **3**.

Complex **5** crystallized as yellow irregular fragments. There are two niobium cationic complexes, two chloride ions, one dichloromethane molecule, and one-half hexane solvate in the asymmetric unit. The hexane was badly disordered on a twofold axis and was accounted for by using Spek's SQUEEZE program [21]. The organic portion of the ligands was also disordered and described by partial isotropic atoms. A network of hydrogen bonds exists between the amine hydrogen atoms and the chloride ions.

Complex **6** was isostructural with **5**. Its composition was clear but extensive disorder produced non-positive definite thermal parameters and unreasonable chemical parameters. Cell constants for **6** are $a = 16.827(1)$ Å, $b = 25.630(2)$ Å, $c = 12.189(1)$ Å, $\alpha = \beta = \gamma = 90°$ $V = 5257(1)$ Å^3, space group $P2_12_12$.

Acknowledgments

We are grateful to the US National Science Foundation (Grant No. CHE-0314615) for support of this research.

Appendix A. Supplementary material

Crystallographic data for the structural analyses have been deposited with the Cambridge Crystallographic Data Centre, quoting No. 288727 for **1**, No. 288728 for **2**, No. 288729 for **3**, No. 288730 for **4**, and No. 288731 for **5**. Here we describe the syntheses of the compounds $(Bu_4N)_2[Ni(R\text{-}SO_2N{=}CS_2)_2]$ (R = CH_3CH_2 (**1**), 4-IC_6H_4 (**2**), 2,5-$Cl_2C_6H_3$ (**3**)), which were characterized by IR, UV–Vis, ^1H NMR, ^{13}C NMR and by single crystal X-ray diffraction.

2. Experimental

2.1. Methods and materials

The solvents were purchased from Merck and used without further purification, except in the preparation of potassium *N*-2,5-dichlorophenyldithiocarbimate where DMF was dried over molecular sieves 4A. The ethanesulfonyl chloride, 4-iodobenzenesulphonyl chloride, 2,5-dichlorobenzenesulphonyl chloride and nickel(II) chloride hexahydrate were purchased from Aldrich. Carbon disulfide, potassium hydroxide and tetrabutylammonium bromide were purchased from Vetec, Merck and Carlo Erba, respectively. The ethane, 4-iodobenzene and 2,5-dichlorobenzene sulfonamides were prepared from the corresponding sulfonyl chlorides according to the methodology applied for the syntheses of similar compounds [10]. Melting points (m.p.) were determined with a Mettler FPS equipment. The IR spectra were recorded with a Perkin–Elmer 283 B infrared spectrophotometer using CsI pellets. The UV–Vis spectra were recorded with a Varian Cary 50 Conc spectrophotometer using a quartz cell of 1 cm path length in acetonitrile. The ^1H (300 MHz) and ^{13}C (75 MHz) NMR spectra were recorded with a Varian Mercury 300 spectrophotometer in D_2O for the dithiocarbimate potassium salts, $CDCl_3$ for compound **1** and DMSO-d_6 for compounds **2** and **3**. Microanalyses of C, H and N were obtained from a Perkin–Elmer 2400 CHN Elemental Analyzer. Nickel was analyzed by atomic absorption on a Hitachi Z-8200 Atomic Absorption Spectrophotometer.

2.2. Syntheses

2.2.1. Dithiocarbimate potassium salts

The *N*-ethanesulfonyldithiocarbimate and *N*-4-iodobenzenesulfonyldithiocarbimate potassium salts were prepared according to the methodology applied for the syntheses of similar compounds [11,12]: Carbon disulfide (0.02 mol) and potassium hydroxide (0.01 mol) were added to a solution of the corresponding sulfonamide (0.02 mol) in DMF (20 mL). The mixture was stirred at room temperature for 2 h previous to the addition of a second portion of potassium hydroxide (0.01 mol). After stirring for further 1 h, the yellow solid formed was filtered, washed with DMF, ethanol and ethyl acetate and dried under reduced pressure yielding the *N*-R-sulfonyldithiocarbimates (ca. 80% based on the sulfonamide). These salts were recrystallized in ethanol:water 1:1 mixture.

A variation of this methodology was used in the preparation of the potassium *N*-2,5-dichlorophenyldithiocarbimate: A slight excess of carbon disulfide (0.026 mol) was employed, the solution was more concentrated using 12 mL DMF only, previously dried over molecular sieves 4A and the reaction mixture temperature was kept between 4 and 8 °C. After 3 h of reaction, 10 mL of ice cold ethanol was added, the mixture was stirred for further 50 min and the temperature was allowed to rise up to room temperature. The yellowish solid was separated by filtration, washed with ethanol and ethyl acetate, dried under reduced pressure and used without further purification (ca. 63% based on the sulfonamide).

2.2.1.1. Potassium N-ethanesulfonyldithiocarbimate. IR (most important bands) (cm^{-1}): 3444 and 1630 (water), 1300 (νCN), 1251 (νSO_{2ass}), 1111 (νSO_{2sym}), 962 (νCS_{2ass}). ^1H NMR (δ), *J* (Hz): 1.19 (t, 3H, $J = 13.8$ Hz, CH_3), 3.41 (q, 2H, $J = 13.8$ Hz, CH_2). ^{13}C NMR (δ): 223.86 ($N{=}CS_2$), 45.43 (CH_2), 7.59 (CH_3).

2.2.1.2. Potassium N-4-iodophenylsulfonyldithiocarbimate. IR (most important bands) (cm^{-1}): 3435 and 1637 (water), 1280 (νCN), 1255 (νSO_{2ass}), 1134 (νSO_{2sym}), 971 (νCS_{2ass}). ^1H NMR (δ), *J* (Hz): 7.94 (d, $J = 8.4$, 2H), 7.58 (d, $J = 8.4$, 2H). ^{13}C NMR (δ): 225.62 ($N{=}CS_2$), 142.01 (C1), 128.84 (C2, C6), 138.31 (C3, C5), 98.65 (C4).

2.2.1.3. Potassium N-2,5-dichlorophenylsulfonyldithiocarbimate. IR (most important bands) (cm^{-1}): 3421 and 1621 (water), 1269 (νCN), 1246 (νSO_{2ass}), 1119 (νSO_{2sym}), 977 (νCS_{2ass}). ^1H NMR (δ), *J* (Hz): 7.31–7.34 (m, 2H), 7.83–7.82 (m, 2H). ^{13}C NMR (δ): 224.07 ($N{=}CS_2$), 141.25 (C1), 129.14 (C2), 132.43 (C3), 132.59 (C4), 132.20 (C5), 130.78 (C6).

2.2.2. Nickel complexes

A solution of nickel(II) chloride hexahydrate (1.0 mmol) and tetrabutylammonium bromide (2.0 mmol) in methanol (10 mL) was added to a solution of the appropriate potassium dithiocarbimate salt (2.0 mmol) in methanol:water 1:1 (10 mL) and the mixture was stirred for 1 h at room temperature. The green solid produced was filtered, washed with distilled water and dried under reduced pressure for one day, yielding $(Bu_4N)_2[Ni(C_2H_5SO_2N{=}CS_2)_2]$, $(Bu_4N)_2$-$Ni(IC_6H_4SO_2N{=}CS_2)_2]$ and $(Bu_4N)_2[Ni(2,5\text{-}Cl_2C_6H_4$-$SO_2N{=}CS_2)_2]$ (ca. 80%, based on nickel(II) chloride hexahydrate). Dark green crystals suitable for X-ray structure analyses were obtained by slow evaporation of their solutions in methanol: water (3:1) at room temperature.

*2.2.2.1. Tetrabutylammonium bis(ethanesulphonyldithiocarbimato)nickelate(II) (**1**).* Elemental *Anal.* Calc.: C, 50.15; H, 9.08; N, 6.16; Ni, 6.45. Found: C, 49.64; H, 9.00; N, 6.18; Ni, 6.50%. M.p. (°C): 129–132 (with decomposition). IR (most important bands) (cm^{-1}): 1399 (νCN), 1264 (νSO_{2ass}), 1117 (νSO_{2sym}), 939 (νCS_{2ass}), 394 (νNiS). UV–Vis [λ (nm), ε(L mol^{-1} cm^{-1})]: 233 (44 375) ($\pi \rightarrow \pi^*$ (NCS) + $\pi \rightarrow \pi^*$ (SCS)), 328 (37 188) ($n \rightarrow \pi^*$ (S)), 415 (7734) (CT), 618 (20) ($d \rightarrow d$). ^1H NMR (dithiocarbimate

anion signals) (δ), J (Hz): 3.12 (q, $J = 7.5$, 4H), 1.30 (t, $J = 7.2$, 6H). ^{13}C NMR (dithiocarbimate anion signals) (δ): 209.32 (N=CS_2), 47.83 (CH_2SO_2), 8.52 (CH_3).

*2.2.2.2. Tetrabutylammonium bis(4-iodophenylsulphonyldithiocarbimato)nickelate(II) (**2**).* Elemental *Anal.* Calc.: C, 43.92; H, 6.41; N, 4.45; Ni, 4.67. Found: C, 43.88; H, 6.43; N, 4.33; Ni, 4.73%. M.p. (°C): 173–175 (with decomposition). IR (most important bands) (cm^{-1}): 1382 (νCN), 1286 (νSO_{2ass}), 1141 (νSO_{2sym}), 940 (νCS_{2ass}), 386 (νNiS). UV–Vis [λ (nm), ε (L mol^{-1} cm^{-1})]: 235 (30659) ($\pi \rightarrow \pi^*$ (NCS)), 260 (29401) ($\pi \rightarrow \pi^*$ (SCS)), 347 (11165) ($n \rightarrow \pi^*$ (S)), 429 (5635) (CT), 604 (93) ($d \rightarrow d$). ^{1}H NMR (dithiocarbimate anion signals) (δ), J (Hz): 7.95–7.92 (m, 4H, H2, H6), 7.75–7.73 (m, 4H, H3, H5). ^{13}C NMR (dithiocarbimate anion signals) (δ): 210.38 (N=CS_2), 141.64 (C1), 135.37 (C3, C5), 127.52 (C2, C6), 96.64 (C4).

*2.2.2.3. Tetrabutylammonium bis(2,5-dichlorophenylsulphonyldithiocarbimato)nickelate(II) (**3**).* Elemental *Anal.* Calc.: C, 48.29; H, 6.87; N, 4.90; Ni, 5.13. Found: C, 48.44; H, 6.81; N, 4.59; Ni, 5.33%. M.p. (°C): 186–189 (with decomposition). IR (most important bands) (cm^{-1}): 1382 (νCN), 1294 (νSO_{2ass}), 1141, 1131 (νSO_{2sym}), 944 (νCS_{2ass}), 390 (νNiS). UV–Vis [λ (nm), ε (L mol^{-1} cm^{-1})]: 226 (60632) ($\pi \rightarrow \pi^*$ (NCS) + $\pi \rightarrow \pi^*$ (SCS)), 327 (30473) ($n \rightarrow \pi^*$ (S)), 413 (7619) (CT), 616 (22) ($d \rightarrow d$). ^{1}H NMR (dithiocarbimate anion signals) (δ), J (Hz): 8.13–8.11 (m, 6H, H3, H4 and H6). ^{13}C NMR (dithiocarbimate anion signals) (δ): 210.59 (N=CS_2), 141.37 (C1), 130.71 (C4), 130.49 (C3), 129.91 (C6), 129.11 (C5), 128.71 (C2).

All spectra (IR and NMR) showed the expected signals for the tetrabutylammonium cation. The integration curves in the ^{1}H NMR spectra were consistent with the 2:1 cation:complex anions.

2.3. X-ray diffraction experiments

The low temperature X-ray diffraction data collections for all crystals (φ scans and ω scans with κ offsets) were performed on an Enraf-Nonius Kappa-CCD diffractometer (95 mm CCD camera on κ-goniostat) using graphite monochromatic Mo Kα radiation (0.71073 Å). Data collections were made using the COLLECT program [13] up to 50° in 2θ with a redundancy of four. The final unit cell parameters were based on all reflections. The temperature was

controlled using an Oxford Cryosystem low temperature device. Integration and scaling of the reflections, correction for Lorentz and polarization effects were performed with the HKL Denzo-Scalepack system of programs [14]. Multi-scan absorption corrections were applied [15].

The structures were solved by direct methods with SHELXS-97 [16]. The models were refined by full-matrix least squares on F^2 using SHELXL-97 [17]. All the hydrogen atoms were stereochemically positioned and refined with the riding model. Hydrogen atoms of the CH and CH_2 groups were set isotropic with a thermal parameter 20% greater than the equivalent isotropic displacement parameter of the atom to which each one was bonded. This percentage was set to 50% for the hydrogen atoms of the CH_3 group. Data collections and experimental details for the compounds are summarized in Table 1. The programs SHELXL-97 [17] and ORTEP-3 [18] were used within WINGX [19] to prepare materials for publication.

3. Results and discussion

The potassium dithiocarbimates are soluble in water and insoluble in most organic solvents. To the best of our knowledge the spectroscopic data for these salts are not published elsewhere. The *N*-ethanesulfonyldithiocarbimate and *N*-4-iodobenzenesulfonyldithiocarbimate potassium salts were prepared (Scheme 1) by reaction of the corresponding sulfonamides, carbon disulfide (1 equiv.) and potassium hydroxide (2 equiv.) in DMF at room temperature. Attempts to prepare the potassium *N*-2,5-dichlorophenylsulfonyldithiocarbimate using the same conditions failed, yielding a white solid with a strong sulfurous odor. As described in the experimental section, it was necessary to use a dry solvent, low temperature and a more concentrated medium. The recrystallization of this salt was not possible and instead of the formation of the expected yellow crystals a white solid was produced. It is important to note that, although the other ditiocarbimates seem to be more stable, a white solid is also obtained from the aqueous solutions of potassium *N*-4-iodophenylsulfonyldithiocarbimate after some weeks at room temperature. When kept in the solid state at ambient temperature, these potassium salts were also converted in white solids after several months. The composition of these solids was not investigated yet.

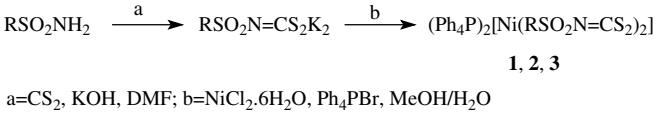
On the other hand, the compounds **1**–**3** are stable at the ambient conditions. They were obtained (Scheme 1) by the reaction of the appropriate potassium *N*-R-sulfonyldithiocarbimate ($RSO_2N{=}CS_2K_2$) with nickel(II) chloride hexahydrate in methanol/water and are considerably soluble in most of organic solvents and insoluble in water. However, compounds **2** and **3** are much less soluble in chloroform than compound **1**. Thus, their NMR spectra were obtained in dimethylsulfoxide-d_6.

The electronic spectra of the nickel complexes in acetonitrile showed four or five bands. The band V (ca. 615 nm) appeared in the same region of the d–d transition of the spectra of $(Bu_4N)_2[Ni(CH_3SO_2N{=}CS_2)_2]$ and $(Bu_4N)_2$-$[Ni(4\text{-}CH_3C_6H_4SO_2N{=}CSO_2)_2]$ [1,2]. The band around 420 nm was assigned to the charge transfer transition. These bands are also observed in the spectra of many other diamagnetic planar nickel(II) complexes that contain the NiS_4^{2-} chromophore [20]. The other bands were assigned to the internal transitions of the ligands [1,2].

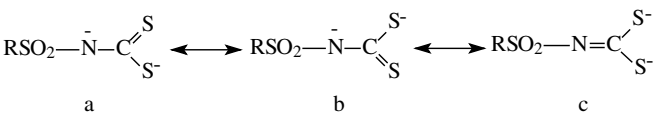
In the IR spectra of the potassium dithiocarbimates a prominent band is observed at ca. 3430 cm^{-1}. This band, associated to the one observed in the 1630 cm^{-1} region, indicates that these compounds are hydrated. It is known that some potassium dithiocarbimates crystallize with n lattice water molecules (*n* usually varying from 1 to 2) [12,21], which explains the observation of these bands. In the region of 1300–1245 cm^{-1} in the spectra of the dithiocarbimate potassium salts, two very intense bands were observed. The lower wavenumber band was assigned to the νSO_2 and the band of higher wavenumber was assigned to the νCN. Although these wavenumbers are rather low for a formal C=N band, possible hydrogen bonding with lattice water molecules might contribute to this effect. The SO_2 group neighbor to the nitrogen atom also explains the low values observed. This band is shifted to ca. 1385 cm^{-1} in the spectra of the complexes, which is explained both by the fact that the complexes are not hydrated and by the increased importance of the canonical form (c) upon complexation (Scheme 2). This band is observed at ca. 1440 cm^{-1} in the spectra of neutral complexes of general formula $[Ni(Ph_3P)_2(RSO_2N{=}CS_2)]$ where R = 2-$CH_3C_6H_4$, 4-$CH_3C_6H_4$ and 4-BrC_6H_4 [22].

The $\nu_{ass}CS_2$ were observed at higher frequencies in the spectra of the potassium dithiocarbimates (ca. 975 cm^{-1}) than in the spectra of the complexes (ca. 940 cm^{-1}). The shifts are also consistent with complexation by the sulfur atoms of the dithiocarbimate groups. The spectra of the complexes also show the expected medium/strong band in the 300–400 cm^{-1} range assigned to the NiS vibrations.

All the NMR spectra showed the expected signals for the tetrabutylammonium cation. The NMR spectra were typical for diamagnetic species and the integration curves on the ^1H NMR spectra were consistent with a



Scheme 1.



Scheme 2.

2:1 proportion between the tetrabutylammonium cation and the complex anions. In the ^{13}C NMR spectra of the complexes the signal due to the carbon of the dithiocarbimate moiety (N=CS_2, ca. 210 δ) is shifted upfield when compared to the correspondent signal in the potassium dithiocarbimates spectra (ca. 225 δ) as observed with analogous compounds [3]. In the neutral complexes [$Ni(Ph_3P)_2$-(RSO_2N=CS_2)] this signal is observed at (ca. 197 δ) [22].

Single crystal X-ray diffraction data confirmed that the compounds **1**–**3** are constituted by two tetrabutylammonium cations and one complex anion. The crystal structure shows that the nickel atom is coordinated by four sulfur atoms of two R-sulfonyldithiocarbimate ligands, in a distorted square-planar configuration. With the exception of

the compound **2**, in the other complexes the metal ion lies on an inversion center.

The crystal structure of the anions of the compounds **1**, **2** and **3** are illustrated in Figs. 1–3, respectively. The square planar geometry around the nickel atom, differently from the tetrahedral zinc complexes with similar ligands [23], indicate that the dithiocarbimates anions are strong field ligands enough to affect the spin pairing necessary for stabilization of the square planar arrangement.

Selected bond lengths and angles are listed in Tables 2 and 3. In all complexes the CS bond lengths, of the $N{=}CS_2$ fragments, are nearly equal and are slightly shorter than typical C–S single bond length (ca. 1.81 Å) due to partial π-delocalization in the S–C–S group. Similar behavior is observed for others nickel complexes of dithiocarbimates [3,22].

Both, the spectroscopic data and the X-ray experiments showed that the C–N bond lengths have a double bond character. However, the CN bonds in these anionic complexes are longer than in the neutral complexes $[Ni(PPh_3)_2(RSO_2N{=}CS_2)]$ [22]. This fact is probably due to a major negative charge on the Ni atom in the anionic complexes **1**–**3** in comparison to the neutral complexes. These data are consistent with the spectroscopic experiments results, which indicate the increase of importance of the canonical form (c) (Scheme 2) from the free ligands to the neutral complexes with similar ligands [22], passing through the anionic complexes.

The S1–C1–N1 angles of 131.9(2)°, 130.5(2)° and 131.0(3)° in the compounds **1**–**3**, respectively, are significantly greater than S2–C1–N1 [120.4(1)° in **1**, 121.7(2)° in **2** and 122.4(4)° in **3**] due to the repulsive interaction

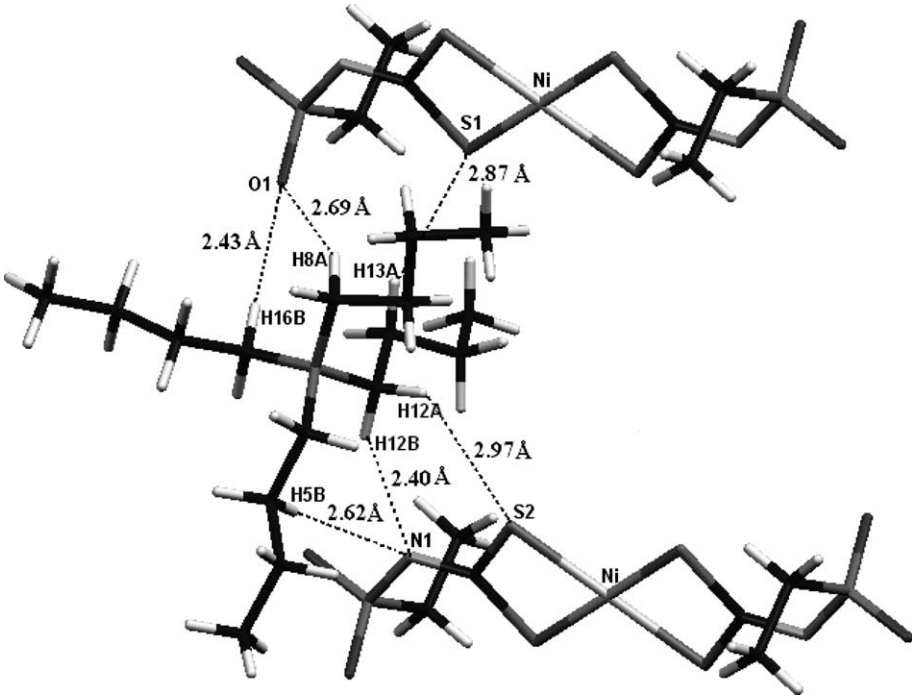

Fig. 4. Weak attractive C_{sp3}–H···O, C_{sp3}–H···N and C_{sp3}–H···S interactions between the cation and the complex anions in the crystal packing of the compound **1**.

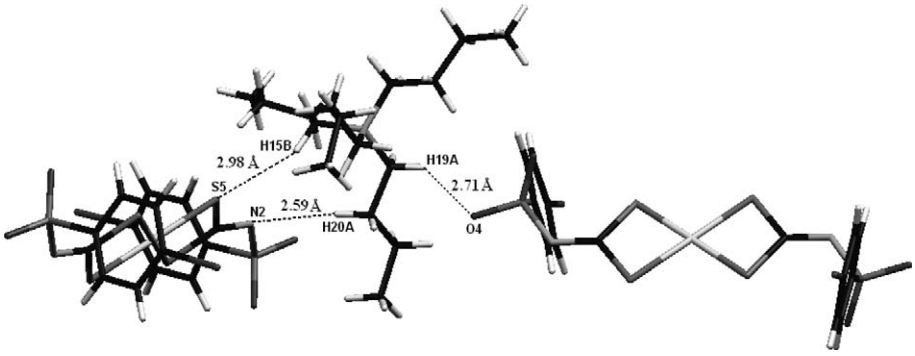

Fig. 5. Weak attractive C_{sp3}–H···O, C_{sp3}–H···N and C_{sp3}–H···S interactions between the cation and the complex anions in the crystal packing of the compound **2.**

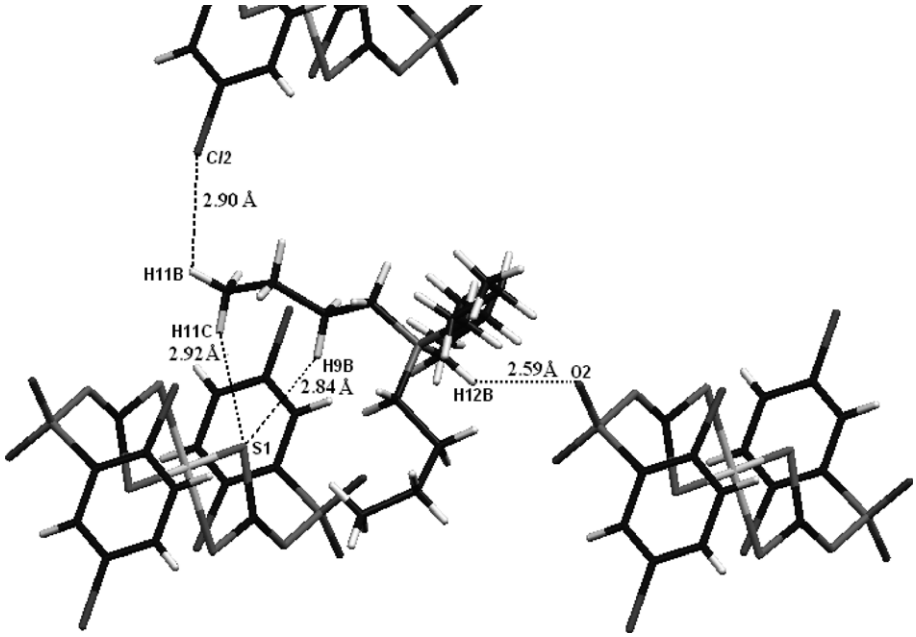

Fig. 6. Weak attractive C_{sp3}–H···O, C_{sp3}–H···S and C_{sp3}–H···Cl interactions between the cation and the complex anions in the crystal packing of the compound **3**.

between the SO_2R group and the S1 atom, which are in *cis* position in relation to the C1–N1 bond. This steric effect between the R-sulfonyl group and the S1 sulfur atom is greater than the repulsion between the lone-pair of the nitrogen N1 and sulfur S2 leading to an increase on the S1–C1–N1 bond angle.

The bond lengths and angles of the tetrabutylammonium cations are in agreement with expected values. However, the dihedral angles of some carbonic chains of the cations deviated from 180° due to the repulsive interaction between hydrogen atoms from neighbor carbonic chains (Table 4). Moreover, in the crystal packing are observed weak attractive C_{sp3}–H···X (X = O, N and/or S and Cl) interactions between the cation and the complex anions with donor–acceptor distances ranged from 3267(2) to 3911(4) Å (Figs. 4–6).

Therefore the competition between attractive and repulsive interactions may affect the conformation of the carbonic chains of the tetrabutylammonium cations.

4. Conclusion

Three new tetra-*n*-butylammonium salts of nickel(II) dithiocarbimates complexes were prepared and characterized by elemental analyses, UV–Vis, IR, ^{1}H NMR and ^{13}C NMR and by single crystal X-ray diffraction techniques.

In the IR spectra the wavenumbers of the *ν*CN are smaller for the ligands than for the compounds **1**–**3**. The NMR spectra show that the carbon atom of the dithiocarbimate moiety are more shielded in the complexes than in the parent ligands. The crystallographic data show that the CN bond are shorter in the complexes than in similar ligands [12]. The same tendency is observed when the data for the compounds **1**–**3** are compared with the data for neutral complexes of general formula $[Ni(PPh_3)_2(RSO_2N{=}CS_2)]$ [22]. Thus, the chemical shifts of the signal for the carbon atom of the $N{=}CS_2$ fragment is observed at lower field in the ^{13}C NMR spectra of compounds **1**–**3** if compared to these neutral complexes. The CN bonds are longer in the anionic complexes and the correspondent *ν*CN bands appear at lower wavenumbers in the IR spectra of **1**–**3** if compared to the neutral complexes [22]. These data pointed to an increase of the contribution of the canonical form (c) to the resonance hybrid from the ligands to the anionic complexes and from anionic complexes to analogous neutral complexes (Scheme 2).

of metal ions from solution and the activations of small molecules gave impetus to this endeavour [2–27]. The synthesis of organic substrates that preferentially interact with particular metal ions is of fundamental importance to many areas of chemistry [28–32]. For example, condensation between carbonyl and amine has played an important role in the development of synthetic macrocyclic ligands [33–43]. Usually such syntheses are carried out in the presence of a suitable metal ion, which serves to direct the steric course of the reaction preferentially towards cyclic rather than oligomeric or polymeric products.

The coordination geometry and properties of most transition metal complexes with 14-membered hexaaza macrocyclic ligands containing amine have been studied [1–43]. However, most of them contained tetraaza macrocyclic ligands, and 14-membered macrocyclic ligands containing six nitrogen atoms with a phenylene group's macrocyclic framework have not been reported yet. We have been interested in the synthesis of various types of polyaza macrocyclic complexes containing amino alkyl groups from in situ one-pot template synthesis (IOPTS). Metal template condensation reactions often provide selective routes towards products that are not obtainable in the absence of metal ions. Especially, template reactions involving formaldehyde and amines facilitate the preparation of saturated polyaza multidentate macrocyclic and macropolycyclic complexes. Metal template condensation reactions involving amines and formaldehyde have been employed in the preparation of various saturated polyaza macrocyclic complexes [1–43].

In this paper, we report the synthesis, characterization and properties of the new nickel(II) complexes of dibenzo-1,3,5,8,10,12-hexaazacyclotetradecane, [Ni(Bzo_2[14]aneN$_6$)]-(ClO_4)$_2$ (**1**); 3,10-dimethyl-, [Ni(Me_2Bzo_2[14]aneN$_6$)](ClO_4)$_2$ (**2**); 3,10-diethyl-, [Ni(Et_2Bzo_2[14]aneN$_6$)](ClO_4)$_2$ (**3**); 3,10-dibutyl-, [Ni(Bu_2Bzo_2[14]aneN$_6$)](ClO_4)$_2$ (**4**); 3,10-dibenzyl-, dibenzo-1,3,5,8,10,12-hexaazacyclotetradecane [Ni((benzyl)$_2$-Bzo_2[14]aneN$_6$)](ClO_4)$_2$ (**5**); [Ni(Bzo_2[14]aneN$_6$)](PF_6)$_2$ (**6**); [Ni(Me_2Bzo_2[14]aneN$_6$)](PF_6)$_2$ (**7**); [Ni(Et_2Bzo_2[14]aneN$_6$)]-(PF_6)$_2$ (**8**); [Ni(Bu_2Bzo_2[14]aneN$_6$)](PF_6)$_2$ (**9**); [Ni((benzyl)$_2$$Bzo_2$[14]aneN$_6$)]($PF_6$)$_2$ (**10**); [Ni(Bzo_2[14]aneN$_6$)Cl_2] (**11**); [Ni(Me_2Bzo_2[14]aneN$_6$)Cl_2] (**12**); [Ni(Et_2Bzo_2[14]-aneN$_6$)Cl_2] (**13**); [Ni(Bu_2Bzo_2[14]aneN$_6$)Cl_2] (**14**); [Ni((benzyl)$_2$$Bzo_2$[14]aneN$_6$)$Cl_2$] (**15**); [Ni($Bzo_2$[14]aneN$_6$)(NCS)$_2$] (**16**); [Ni($Me_2Bzo_2$[14]aneN$_6$)(NCS)$_2$] (**17**); [Ni($Et_2Bzo_2$-[14]aneN$_6$)(NCS)$_2$] (**18**); [Ni($Bu_2Bzo_2$[14]aneN$_6$)(NCS)$_2$] (**19**) and [Ni((benzyl)$_2$$Bzo_2$[14]aneN$_6$)(NCS)$_2$] (**20**) are given in Schemes 1 and 2.

2. Experimental

2.1. Materials and measurements

Safety note. Caution! Perchlorate salts of metal complexes are potentially explosive and due care must be employed when handling them. In particular, such compounds should never be heating as solids. All chemicals and solvents used in the syntheses were of reagent grade and were used without further purification. For the spectroscopic measurements, water was distilled and organic solvents were purified according to the literature method [44]. For electrochemical experiments, high-purity acetonitrile was obtained from Aldrich Chemical Co. and dried over 4 Å molecular sieves. Electronic absorption spectra were obtained with a Shimadzu UV–Vis scanning

spectrophotometer (Model 2101 PC), FTIR spectra with a Shimadzu Varian 4300 spectrophotometer, NMR spectra with a Varian Mercury 300 NMR spectrometer, and conductance measurements with a Metrohm Herisau conductometer E 518. The elemental analysis (carbon, hydrogen and nitrogen) of the complexes was obtained from Carlo ERBA Model EA 1108 analyzer. Magnetic moments were calculated from magnetic susceptibility data obtained by using a Johnson Matthey MK-1 magnetic susceptibility balance. The electrochemical data was obtained in acetonitrile with 0.1 M $(n\text{-Bu})_4NClO_4$ as supporting electrolyte. The working electrode was a platinum disk, the auxiliary electrode was a coiled platinum wire and the reference electrode was $Ag|AgClO_4$ (0.1 M in CH_3CN), which showed +0.24 V versus SCE. Atomic absorption spectra (AAS) were recorded on a Perkin–Elmer 4100-1319 spectrophotometer. FAB mass spectra were recorded on a Kratos MS50TC spectrometer.

2.2. Preparation of $[Ni(H_2Bzo_2[14]aneN_6)](ClO_4)_2$ (1)

To a stirred methanol solution (100 ml) of $Ni(ClO_4)_2 \cdot 6H_20$ (15.38 g, 42.07 mmol) was slowly added 1,2-phenylenediamine (9.11 g, 84.20 mmol), 36% formaldehyde (15 ml) and 25% ammonia (6.30 ml, 84.20 mmol). The mixture was heated at reflux for 24 h until a dark solution resulted. The solution was cooled to room temperature and filtered to remove nickel hydroxide. The deep yellow crystals were filtered, washed with methanol, and air-dried. The crystals were recrystallized from hot water. (Yield: ~46%; FAB mass (m/z): 456 ($[M - ClO_4]^+$)). *Anal.* Calc. for **1**: Ni, 10.56; C, 34.56; H, 3.99; N, 15.12. Found: Ni, 10.41; C, 34.40, H, 3.81; N, 15.24%.

2.3. Preparation of $[Ni(Me_2Bzo_2[14]aneN_6)](ClO_4)_2$ (2)

This compound was prepared by a method similar to that for the preparation of $[Ni(H_2Bzo_2[14]aneN_6)](ClO_4)_2$ except that methylamine (84.20 mmol, 10.47 ml) was used instead of ammonia. (Yield: ~54%; FAB mass (m/z): 484 ($[M - ClO_4]^+$)). *Anal.* Calc. for **2**: Ni, 10.05; C, 37.01; H, 4.49; N, 14.39. Found: Ni, 9.92; C, 36.88; H, 4.38; N, 14.55%.

2.4. Preparation of $[Ni(Et_2Bzo_2[14]aneN_6)](ClO_4)_2$ (3)

This complex was prepared by a method similar to that for $[Ni(H_2Bzo_2[14]aneN_6)](ClO_4)_2$ except that 50% ethylamine (8.72 ml, 84.20 mmol) was used instead of ammonia. (Yield: ~57%; FAB mass (m/z): 513 ($[M - ClO_4]^+$)). *Anal.* Calc. for **3**: Ni, 9.59; C, 39.24; H, 4.94; N, 13.73. Found: Ni, 9.47, C, 39.08; H, 4.81; N, 13.84%.

2.5. Preparation of $[Ni(Bu_2Bzo_2[14]aneN_6)](ClO_4)_2$ (4)

This complex was prepared by a method similar to that for $[Ni(H_2Bzo_2[14]aneN_6)](ClO_4)_2$ except that *iso*-butylamine (8.36 ml, 84.20 mmol) was used instead of ammonia. (Yield: ~44%; FAB mass (m/z): 568 ($[M - ClO_4]^+$)). *Anal.* Calc. for **4**: Ni, 8.79; C, 43.14; H, 5.73; N, 12.58. Found: Ni, 8.66; C, 43.02; H, 5.60; N, 12.65%.

2.6. Preparation of $[Ni((benzyl)_2Bzo_2[14]aneN_6)](ClO_4)_2$ (5)

This complex was prepared by a method similar to that for $[Ni(H_2Bzo_2[14]aneN_6)](ClO_4)_2$ except that benzylamine

(9.20 ml, 84.20 mol) was used instead of ammonia. (Yield: ~41%; FAB mass (*m*/*z*): 638 ($[M - ClO_4]^+$)). *Anal*. Calc. for **5**: Ni, 7.97; C, 48.94; H, 4.66; N, 11.42. Found: Ni, 7.81; C, 48.81; H, 4.53; N, 11.55%.

2.7. Preparation of $[Ni(R_2Bzo_2[14]aneN_6)](PF_6)_2$ (6–10)

To an acetonitrile (50 ml) suspension of $[Ni(R_2Bzo_2[14]aneN_6)](ClO_4)_2$ (0.50 g) was added excess NH_4PF_6, and white precipitates of NH_4ClO_4 were formed. NH_4ClO_4 was filtered off and the filtrate was concentrated to 25 ml. Water (25 ml) was added to the solution, and the mixture was kept in the refrigerator. The yellow precipitates were filtered, washed with a 6:1 mixture of water and acetonitrile, and dried in vacuum. (**6**, FAB mass (*m*/*z*): 502 ($[M - PF_6]^+$)). *Anal*. Calc. Ni, 9.07; C, 29.70; H, 3.43; N, 12.99. Found: Ni, 8.94; C, 29.58; H, 3.32; N, 13.04%. (**7**, FAB mass (*m*/*z*): 530 ($[M - PF_6]^+$)). *Anal*. Calc. Ni, 8.70; C, 32.02; H, 3.88; N, 12.45. Found: Ni, 8.57; C, 31.90; H, 3.75; N, 12.56%. (**8**, FAB mass (*m*/*z*): 558 ($[M - PF_6]^+$)). *Anal*. Calc. Ni, 8.35; C, 34.16; H, 4.30; N, 11.95. Found: Ni, 8.22; C, 34.02; H, 4.18; N, 12.06%. (**9**, FAB mass (*m*/*z*): 614 ($[M - PF_6]^+$)). *Anal*. Calc. Ni, 7.73; C, 37.97; H, 5.04; N, 11.07. Found: Ni, 7.60; C, 37.85; H, 4.91; N, 11.13%. (**10,** FAB mass (*m*/*z*): 682 ($[M - PF_6]^+$)). *Anal*. Calc. Ni, 7.10; C, 43.56; H, 4.14; N, 10.16. Found: Ni, 6.94; C, 43.44; H, 4.03; N, 10.24%.

2.8. Preparation of $[Ni(R_2Bzo_2[14]aneN_6Cl_2)]$ (11–15)

To a stirred methanol solution (100 ml) of $NiCl_2 \cdot 6H_2O$ (10.00 g, 42.07 mmol) were slowly added 1,2-phenylenediamine (9.11 g, 84.20 mmol), 36% formaldehyde (15 ml) and 25% ammonia (6.3 ml, 84.20 mmol). The mixture was heated at reflux for 24 h until a dark solution resulted. The solution was cooled to room temperature and filtered to remove nickel hydroxide. The dark brown crystals were filtered, washed with methanol and air-dried. The crystals were recrystallized from hot water. *Anal*. Calc. for **11**: Ni, 13.72; C, 30.18; H, 5.18; N, 19.64. Found: Ni, 13.58; C, 30.08; H, 5.10; N, 19.73%. *Anal*. Calc. for **12**: Ni, 12.87; C, 47.40; H, 5.75; N, 18.43. Found: Ni, 12.76; C, 47.29; H, 5.62; N, 18.56%. *Anal*. Calc. for **13**: Ni, 12.13; C, 49.62; H, 6.25; N, 17.36. Found: Ni, 12.01; C, 49.48; H, 6.18; N, 17.45%. *Anal*. Calc. for **14**: Ni, 10.87; C, 53.36; H, 7.09; N, 15.56. Found: Ni, 10.75; C, 53.22; H, 6.91; N, 15.64%. *Anal*. Calc. for **15**: Ni, 9.65; C, 56.24; H, 5.63; N, 13.82. Found: Ni, 9.54; C, 26.10; H, 5.48; N, 13.95%.

2.9. Preparation of $[Ni(R_2Bzo_2[14]aneN_6)(NCS)_2]$ (16–20)

To a saturated hot aqueous solution of the perchlorate salt of the appropriate "$[Ni(R_2Bzo_2[14]aneN_6)](ClO_4)_2$ (R = H, Me, Et, Bu, Benzyl)" was added excess KSCN dissolved in a minimum amount of hot water. The solution was allowed to stand at room temperature, and then the deep pink precipitate formed was filtered, washed with a 1:2 mixture of water and methanol, and dried in a vacuum. *Anal*. Calc. for **16**: Ni, 12.40; C, 45.68; H, 4.69; N, 23.68. Found: Ni, 12.29; C, 45.55; H, 4.56; N, 23.75%. *Anal*. Calc. for **17**: Ni, 11.71; C, 47.92; H, 5.23; N, 22.35. Found: Ni, 11.59; C, 47.80; H, 5.11; N, 22.46%. *Anal*. Calc. for **18**: Ni, 11.09; C, 49.92; H, 5.71; N, 21.17. Found: Ni, 10.91; C, 49.80; H, 5.58; N, 21.26%. *Anal*. Calc. for **19**: Ni, 10.03; C, 53.34; H, 6.54; N, 19.14. Found: Ni, 9.92; C, 53.21; H, 6.41; N, 19.23%. *Anal*. Calc. for **20**: Ni, 8.98; C, 58.81; H, 5.24; N, 17.15. Found: Ni, 8.83; C, 58.70; H, 5.12; N, 17.23%.

2.10. Preparation of $[Ni(Bzo_2[10]aneN_4)](ClO_4)_2$ (21)

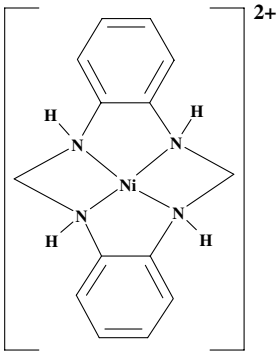
To a stirred methanol solution (100 ml) of $Ni(ClO_4)_2 \cdot 6H_20$ (15.38 g, 42.07 mmol) were slowly added 1,2-phenylenediamine (9.11 g, 84.20 mmol) and 36% formaldehyde (30 ml). The mixture was heated at reflux for 24 h until a dark yellow solution resulted. The solution was cooled to room temperature and filtered to remove nickel hydroxide. The dark yellow crystals were filtered, washed with methanol and air-dried. The crystals were recrystallized from hot water. (Yield: ~58%; FAB mass (*m*/*z*): 398 ($[M - PF_6]^+$)). *Anal*. Calc. for **21**: Ni, 11.78; C, 33.77; H, 3.24; N, 11.25. Found: Ni, 11.61; C, 33.58, H, 3.16; N, 11.37%.

2.11. Preparation of $[Ni((Allyl)_2Bzo_2[14]aneN_6)](ClO_4)_2$ (22)

This compound was prepared by a method similar to that for the preparation of $[Ni(H_2Bzo_2[14]aneN_6)](ClO_4)_2$ except that allylamine "3-amino-1-propene" (84.20 mmol, 4.81 g) was used instead of ammonia. (Yield: ~54%; FAB mass (*m*/*z*): 568 ($[M - PF_6]^+$)). *Anal*. Calc. for **23**: Ni, 8.78; C, 39.54; H, 5.13; N, 16.77. Found: Ni, 8.57; C, 39.38; H, 5.01; N, 16.83%.

3. Results and discussion

In situ one-pot template synthesis (IOPTS) of 1,2-phenylenediamine with formaldehyde, in the presence of the nickel(II) ion, was expected to produce of the mononuclear 14-membered hexaaza macrocycle complex "$[Ni(R_2Bzo_2[14]aneN_6)]^{2+}$". It was observed that the product obtained from the reactions was largely affected by the molar ratio of the reactants. The mononuclear hexaaza complex "$[Ni(R_2Bzo_2[14]aneN_6)](ClO_4)_2$ (**1**–**5**)" was readily prepared as the main product by the reaction of the nickel(II) ion, 1,2-phenylenediamine, CH_2O and amine in a 1:2:4:2 molar ratio. The crude product often contained a small amount of the 10-membered tetraaza macrocyclic nickel(II) complex (**21**) as a by-product (Section 2.10). However, the mononuclear complex could be readily isolated by fractional recrystallization of the product from ca. 0.05 M $HClO_4$ aqueous solutions.



21

The deep yellow complexes "$[Ni(R_2Bzo_2[14]aneN_6)](ClO_4)_2$ (**1**–**5**) and $[Ni(R_2Bzo_2[14]aneN_6)](PF_6)_2$ (**6**–**10**)" readily dissolve in polar solvents such as H_2O, CH_3CN, CH_3NO_2 and Me_2SO_2. However, PF_6^- salts of the complexes readily dissolve in nitromethane and water. The nickel(II) complexes are extremely stable in the solid state and in solution and are relatively stable against ligand dissociation even in highly acidic solutions. $[Ni(R_2[14]aneN_6)]^{2+}$ react with excess KSCN in aqueous solution to form tetragonal complexes $[Ni(R_2[14]aneN_6)(NCS)_2]$, whose IR spectra (Table 1) show that the nitrogen atoms of the NCS^- ligands are coordinated to the Ni(II) ion [45].

The molecular formulae of the complexes "$[Ni(R_2Bzo_2[14]aneN_6)](ClO_4)_2$, $[Ni(R_2Bzo_2[14]aneN_6)](PF_6)_2$, $[Ni(R_2Bzo_2[14]aneN_6)Cl_2]$ and $[Ni(R_2Bzo_2[14]aneN_6)(NCS)_2]$" have been assigned on the basis of the results of their elemental analyses and the molecular ion peaks in the mass spectra. All mass spectra showed molecular ion peaks for the 1:1 metal-to-ligand stoichiometry with no further peaks above them. A preliminary identification of the metal complexes was made on the basis of their IR spectra, which exhibited no bands characteristic of free primary amine, thus supporting the proposed macrocyclic skeleton (Scheme 1).

The IR spectra of all the complexes (Table 1) showed a single sharp absorption around $\sim$3230 cm^{-1} which may possibly arise from a secondary amine, ν_{N-H}, although its position has been found to be lower by 40–60 cm^{-1} than the analogous metal-free hexaaza ligands [46]. This suggests that the secondary amine nitrogens take part in coordination to the metal ions, which has been further confirmed by the appearance of bands in the 320–365 cm^{-1} region in all the complexes, corresponding to ν_{M-N} vibrations. A much higher ν_{N-H} value (3235 cm^{-1}) for $[Ni\{(CH_3)_2Bzo_2[14]aneN_6\}](ClO_4)_2$ than that (3220 cm^{-1}) for $[Ni\{(CH_3)_2[14]aneN_6\}](ClO_4)_2$ [57], indicates that the Ni–N interaction in **2** is much stronger than in the $[Ni\{(CH_3)_2[14]aneN_6\}](ClO_4)_2$ complex. The absorption bands in the 2850–3050 and 1400–1450 cm^{-1} regions observed in the complexes may reasonably correspond to CH stretching and CH bending vibrational modes. However, a medium intensity band at 280–290 cm^{-1} may unambiguously be assigned to the M–Cl stretching mode in complexes **11**–**15**.

The molar conductance values of **1**–**10** ($\sim$240 Ω^{-1} mol^{-1} cm^2), measured in water, correspond to 1:2 electrolytes.

Table 1
Spectral and conductance data for 14-membered hexaaza macrocyclic nickel(II) complexes

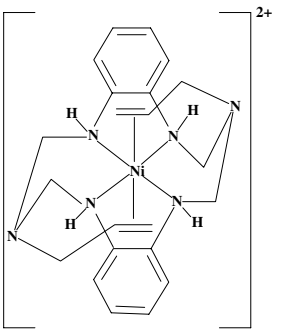
[a] In DMSO solution.

The observed low molar conductivities recorded (**10**–**20**) in DMSO indicate that these are non-electrolytes in nature. The overall geometries of all macrocycles have been deduced on the basis of the observed values of the magnetic moments and the band positions in the electronic spectra. The magnetic moments (−0.08 to −0.13 μ_B) of the nickel(II) complexes (**1**–**10**) measured in the solid state correspond to a square-planar coordination geometry of the complexes. The diamagnetic nature of the Ni(II) complex **7** has allowed its characterization by NMR spectrometry. ^{1}H NMR spectra of the Ni(II) complexes of **6**–**10** exhibit very broad peaks in D_2O, CH_3CN-d_3 and Me_2SO-d_6, but sharp resolvable peaks in CH_3NO_2-d_3. This indicates that a considerable amount of the paramagnetic octahedral species $[Ni(R_2Bzo_2[14]aneN_6)(Solvent)_2]^{2+}$ exists in the donating solvents, where as the Ni(II) complexes of "$R_2Bzo_2[14]aneN_6$" exist primarily as diamagnetic square-planar species in CH_3NO_2-d_3. The ^{1}H NMR spectra of the nickel complex "$[Ni\{((CH_3)_2Bzo_2[14]aneN_6)\}](PF_6)_2$" gave a singlet at 1.67 ppm corresponding to CH_3 (6H) protons. However, the ^{1}H NMR spectra of the complexes "$[Ni(R_2Bzo_2[14]aneN_6)](PF_6)_2$" showed a multiplet in the region 7.51–7.70 ppm, corresponding to the phenyl ring protons (8H). The ^{1}H NMR spectra of all the complexes showed a broad signal at 8.23–8.41 ppm and can be assigned to secondary amine protons (4H). A singlet for the complexes at 3.08–3.16 ppm corresponds to CH_2 (8H) protons adjacent to nitrogen. However, the spectra of all the complexes do not show any signal corresponding to free primary amine protons.

Nickel(II) complexes with the 14-membered hexaaza macrocyclic ligand "$R_2Bzo_2[14]aneN_6$" exist in aqueous solution as an equilibrium mixture of a yellow, square-planar, diamagnetic, low spin species and a blue, octahedral, paramagnetic, high-spin species. Solutions of hexaaza macrocyclic nickel(II) complexes in coordinating solvents (such as water, acetonitrile, etc.) show an absorption maximum at 450 nm, characteristic for square-planar yellow species, and at 350 and 500 nm, characteristic for blue octahedral species. Table 1 shows that the molar absorption coefficient of the ligand field transition band for complexes measured in water or acetonitrile is smaller than that in nitromethane, a non-coordinating solvent. These results are quite similar to those reported for other related polyaza macrocyclic complexes, indicating that the complex dissolves in water or acetonitrile to produce an equilibrium mixture of square-planar $[Ni\{R_2Bzo_2[14]aneN_6]^{2+}$ and octahedral *trans*-$[Ni(R_2Bzo_2$-$[14]aneN_6)(solvent)_2]^{2+}$; (solvent = H_2O or MeCN) [47–51]. Generally, the ligand structure, nature of the solvent and concentration of added electrolyte affect the equilibrium. The molar absorption coefficient of the ligand field transition band for $[Ni(R_2Bzo_2[14]aneN_6)]^{2+}$, measured in 3.0 M NaCl aqueous solutions, is somewhat higher than that in pure water (Table 1). A similar result was also observed in solutions containing NaBr, $NaNO_3$, or $NaClO_4$. This corresponds to the generally observed trend that neutral salts such as NaCl, dissolved in water from their hydrate, reduce the effective concentration of free water and thus increase the concentration of square-planar species [52,53]. The electronic spectra (Table 1) of the Ni(II) complexes are comparable to other square-planar tetraaza macrocyclic nickel(II) complexes, indicating that the hexaaza ligands of this study do not differ significantly from the tetraaza ligands with respect to the ligand field strength [1–43].

The absorption spectra of $[Ni((Allyl)_2Bzo_2[14]aneN_6)](ClO_4)_2$ and $[Ni(Bu_2Bzo_2[14]aneN_6)](ClO_4)_2$ were recorded and the results are given in Table 1 along with the spectral properties of analogous complexes. For aqueous solutions of the $[Ni(R_2Bzo_2[14]aneN_6)]^{2+}$ complexes, the ε value at $\lambda_{max} = 441$ nm increases from 56 to 67 $M^{-1}\,cm^{-1}$ as the alkyl chain length increases from methyl to butyl groups. Moreover, contrary to $[Ni(R_2Bzo_2[14]aneN_6)]^{2+}$ (R = H, Me, Et, Benzyl), both the $[Ni(Bu_2Bzo_2[14]aneN_6)]^{2+}$ and $[Ni((Allyl)_2Bzo_2[14]aneN_6)]^{2+}$ complexes exhibit the same ε value ($\varepsilon = 67\ M^{-1}\,cm^{-1}$) in nitromethane and water. This is probably due to the presence of butyl/propylene groups on the macrocyclic skeleton, which can exert a mechanical resistance towards the axial coordination and hence both $[Ni((Allyl)_2Bzo_2[14]aneN_6)]^{2+}$ and $[Ni(Bu_2Bzo_2[14]aneN_6)]^{2+}$ complexes seem to exist in the deep yellow, square-planar form in water and nitromethane. So it can be assumed that in aqueous solution $[Ni(Bu_2Bzo_2[14]aneN_6)]^{2+}$ and $[Ni((Allyl)_2Bzo_2[14]aneN_6)]^{2+}$ exist in the square-planar form and the propenyl/propyl groups of these complexes provide steric hindrance to the incoming water molecules for coordination [54,55]. The molecular models showed that the propylene group of $[Ni(Bu_2Bzo_2[14]aneN_6)]^{2+}$ and $[Ni((Allyl)_2Bzo_2[14]aneN_6)]^{2+}$ can block the axial positions for water molecules easily by tending towards the metal center (Scheme 3).

The 14-membered hexaaza macrocyclic nickel(II) complexes undergo intense color changes due to deprotonation of the macrocyclic ligand in the presence of amine bases such as pyridine and Et_3N. Similar N–H deprotonations have been observed with other metal complexes containing N–H linkages. For the nickel(II) complexes, Et_3N is sufficiently basic to facilitate formation of the molecular complexes. For preparation of the deprotonation form of $[Ni(Me_2Bzo_2[14]aneN_6)](ClO_4)_2$, Et_3N (0.5 cm^3) was added



Scheme 3.

to a deaerated solution of 200 mg of $[Ni(Me_2Bzo_2[14]aneN_6)](ClO_4)_2$ in 15 cm^3 of MeCN. The shiny-brown product, which began precipitating within minutes, was filtered after 0.5 h under a N_2 atmosphere, washed with anhydrous EtOH, and dried in a vacuum. IR. (KBr, cm^{-1}): 3214 (ν_{N-H}). $[Ni(C_{18}H_{24}N_6)]$ (**23**): Calc.: Ni, 15.18; C, 56.30; H, 6.16; N, 22.08. Found: Ni, 15.32; C, 56.43; H, 6.31; N, 21.94%. The N–H stretching frequency of this compound, $[Ni(C_{18}H_{24}N_6)]$, 3214 cm^{-1}, is reduced significantly from its dicationic precursor, $[Ni(Me_2Bzo_2[14]aneN_6)](ClO_4)_2$, 3235 cm^{-1}.

[a] Measured in acetonitrile solutions; 0.1 M $(n\text{-}Bu)_4NClO_4$; vs. SCE.
[b] Redox potential of this work and Ref. [56] were measured against a $Ag|Ag^+$ (0.1 M) reference electrode and converted to the values measured against the SCE by adding +0.24 V.

Cyclic voltammetry data are summarized in Table 2. Table 2 shows that the oxidation and reduction potentials of the Ni(II) complexes of **1**–**5** do not differ significantly from other [14]aneN$_4$ complexes. This suggests that macrocycles **1**–**5** have Lewis basicities and hole size similar to the [14]aneN$_4$ ligand in spite of the structural differences. A pronounced shift in oxidation state stability occurs when there is a change in the macrocyclic ring size. An increase in ring size promotes the ease of formation of Ni(I), while rendering the oxidation to Ni(III) more difficult. The difference between the $[(Ni[14]aneN_4)]^{2+}$ and $[Ni((CH_3)_6[16]1,4,12\text{-trieneN}_4)]^{2+}$ complexes is 0.3 V. Busch and co-workers suggested that this difference is primarily due to deviations from the ideal metal-donor atom distances accompanying the redox changes [56]. This concept of optimum fit between the coordinated metal ion and the "hole size" provided by the macrocyclic ligand is also in accord with theoretical conclusions and electronic spectral studies. The more common effect of ligand unsaturation also favors the formation of the lower valent states of the complexes and causes the Ni(II) to Ni(III) process to occur at higher energy. The effect of the Bzo function on the reduction reactions of the nickel macrocycles is very pronounced and the structures containing this moiety form the stable complexes in lower valence states under the influence of relatively mild potentials.

high nuclearity structure. The product we have obtained from the reaction is a new tetranuclear copper(II) complex $[Cu_4L_2(3\text{-ppz})_2]$ (**1**) which crystallizes in the hexahydrate form ($\mathbf{1}\cdot 6H_2O$). The crystal structure shows the presence of a discrete decanuclear water aggregate anchored onto two tetranuclear host units through hydrogen bonding interactions. Herein, we present the synthesis, crystal structure, magnetic properties of the complex along with the supramolecular structure of the water assembly. Stabilization of water aggregates of a larger size in metalloorganic hosts is of current interest to unravel their properties in restricted confinements as observed in crystal lattices and biological systems [8–14]. A detailed theoretical study of the variable-temperature magnetic susceptibility data of **1** shows the antiferromagnetic nature of the spin coupling in the complex.

2. Experimental

2.1. Materials

All reagents and chemicals were procured from commercial sources and used without further purification. The Schiff base *N*,*N*′-(2-hydroxypropane-1,3-diyl)bis(salicylaldimine) (H_3L) and 3-phenylpyrazole were prepared following literature methods [15,16]. The precursor complex $[Cu_2LBr]$ was prepared from the reaction of H_3L and $CuBr_2\cdot H_2O$ using a method that is similar to the one used for an analogous complex with a related Schiff base [15].

2.2. Measurements

The elemental analyses were done using a Heraeus CHN-O Rapid instrument. The electronic and infrared spectral data were obtained from Perkin–Elmer Lambda 35 UV–Vis and Bruker Equinox 55 spectrophotometers, respectively. Variable temperature magnetic susceptibility data in the temperature range 300–17 K were obtained for the polycrystalline sample using George Associates Inc. Lewis-coil-force magnetometer system (Berkeley, CA), equipped with a closed cycle cryostat (Air Products) and a Cahn balance. $Hg[Co(NCS)_4]$ was used as a standard. Experimental susceptibility data were corrected for diamagnetic contributions [$\chi_{dia} = -521.7\times10^{-6}\ cm^3\ M^{-1}$] [17]. The magnetic moments at various temperatures were calculated in μ_B units [$\mu_B = 9.274\times10^{-24}\ J\ T^{-1}$]. TGA analysis was done on a Mettler Toledo Star thermal analyzer.

2.3. Synthesis

$[Cu_2LBr]$ (0.4 g, 0.8 mmol) in MeCN (10 ml) was reacted with a methanol (10 ml) solution of 3-phenylpyrazole (0.12 g, 0.8 mmol) under refluxing conditions for 1 h. The solution was cooled to an ambient temperature and a green solid thus obtained was isolated, washed with a mixture of methanol and diethyl ether (1:1 v/v), and dried in vacuo over P_4O_{10} [Yield: 0.36 g (~78%)]. *Anal.* Calc. for $C_{52}H_{44}Cu_4N_8O_6$ (**1**): C, 55.21; H, 3.92; N, 9.91. Found: C, 55.09; H, 3.95; N, 9.75%. IR (KBr disc): 3415br, 1628s, 1601s, 1534m, 1464m, 1449s, 1396m, 1318m, 1195m, 1149w, 1132m, 1072w, 1042w, 981w, 860w, 759s, 694m cm^{-1} [s, strong; m, medium; w, weak; br, broad]. Electronic spectral data in MeOH [λ_{max}, nm (ε, $M^{-1}\ cm^{-1}$)]: 620 (340), 367 (19 100). Magnetic moment per molecule (μ_{eff}): 3.33 μ_B at 300 K; 0.56 μ_B at 17 K.

2.4. X-ray crystallography

Single crystals of $\mathbf{1}\cdot 6H_2O$ were obtained on slow evaporation of an aqueous methanol solution of the complex. A crystal of approximate size $0.25\times0.2\times0.14\ mm^3$ was mounted on a glass fiber with epoxy cement. The X-ray diffraction data were measured in frames with increasing ω (width of 0.3° per frame) at a scan speed of 8 s per frame using a Bruker SMART APEX CCD diffractometer, equipped with a fine focus sealed tube X-ray source. The SMART software was used for data acquisition and the SAINT software for data extraction [18]. Empirical absorption corrections were made on the intensity data [19]. The structure was solved by the heavy atom method and refined by full-matrix least-squares using the SHELX system of programs [20]. All non-hydrogen atoms of the complex except the positionally disordered solvent water molecule were refined anisotropically. All the hydrogen atoms belonging to the complex were generated, assigned isotropic thermal parameters and refined using the riding model. One water oxygen atom was found to be positionally disordered to

two sites that were refined as O(11) and O(11A) with site occupancy values of 0.6 and 0.4, respectively. The structure refinement gave a goodness-of-fit (GoF) value of 0.896. Selected crystallographic data are given in Table 1. The perspective view of the complex was obtained by ORTEP [21].

3. Results and discussion

3.1. Synthetic and general aspects

Dicopper(II) complexes of trianionic pentadentate Schiff base ligands have been studied for magneto-structural correlations that show a counter-complimentary spin coupling effect in the $\{Cu_2(\mu\text{-alkoxo})(\mu\text{-carboxylato})\}$ core [15,22–27]. The $\{Cu_2L\}$ unit has also been used in designing tricopper(II) complexes as models for multicopper oxidases, in the synthesis of high nuclearity clusters and for designing supramolecular host structures stabilizing different types of water clusters based on the carboxylate ligand used [6,7,28–31]. In the present work, we have attempted to synthesize a complex having a $\{Cu_2L\}$ unit using 3-phenylpyrazole as a linker to form either a binuclear complex with a $\{Cu_2(\mu\text{-alkoxo})(\mu\text{-pyrazolato})\}$ core or a higher nuclearity complex. The reaction of $[Cu_2LBr]$ with 3-ppz is found to form a discrete tetracopper(II) species $[Cu_4L_2(3\text{-ppz})_2]$ (**1**) in good yield (Scheme 1). The complex has been characterized from analytical and spectral methods, and by X-ray crystallography. It exhibits a d–d band at 620 nm in MeOH in its electronic spectrum. The complex shows antiferromagnetic behavior due to spin–spin coupling through alkoxo and pyrazolato bridges giving magnetic moment values of 3.33 and 0.56 μ_B at 300 and 17 K, respectively (Fig. 1). The magnetic behavior is similar to those of antiferromagnetically coupled dicopper(II) complexes having a $\{Cu_2(\mu\text{-alkoxo})(\mu\text{-carboxylato})\}$ core [15,22–27]. Thermogravimetric studies of $\mathbf{1}\cdot 6H_2O$ show loss of water (~8% weight loss) in the temperature range 30–140 °C followed by further weight loss due to 3-ppz and Schiff base decomposition. The gradual weight loss is observed till 250 °C, possibly due to the loss of 3-phenylpyrazole along with the water aggregate, thus, making it difficult for an accurate estimate of the water loss.

in Fig. 2. The structure consists of a tetranuclear copper(II) complex in which two dimeric $\{Cu_2L\}$ units are covalently linked by two mono-anionic 3-phenylpyrazole ligands. The trianionic Schiff base shows a pentadentate mode of coordination, providing the alkoxo-bridge. The coordination geometries at the copper centers are shown in Fig. 3. The Cu(1) and Cu(3) atoms have five-coordinate square-pyramidal geometry in which the nitrogen, alkoxo and phenoxo oxygen atoms are in the basal plane. The alkoxo oxygen atom belonging to the Schiff base displays the μ_3-mode of bonding with two equatorial bonds and one significantly long axial Cu–O bond. The Cu(2) and Cu(4) atoms have four-coordinate planar geometry. The four copper basal planes in the structure are not coplanar. The dihedral angle between the Cu(1) and Cu(2) planes is ~70° and the same for the Cu(3) and Cu(4) planes is ~68°. The alkoxo oxygen atoms are not planar due to the μ_3-bonding mode. The Cu···Cu distances are in the range 3.261(1)–3.492(1) Å. The Cu(1)···Cu(3) distance in the unit having axial–equatorial bridging alkoxo oxygen atoms is 3.261(1) Å. The Cu(1)–O(2)–Cu(2) and Cu(3)–O(5)–Cu(4) angles of ~120° are expected to give moderately strong antiferromagnetic spin-coupling involving two $\{d_{x^2-y^2}\}^1$ orbitals of the metal centers. In contrast, the other Cu–O–Cu angles of ~95° should promote ferromagnetism. However, magnetic interactions involving these super-exchange pathways are expected to be negligible as the $d_{x^2-y^2}$ and d_{z^2} orbitals of the metal centers are orthogonal to each other and the axial Cu–O bond is significantly longer than the equatorial ones.

The tetranuclear complex is involved in hydrogen bonding interactions with the lattice water molecules to form a supramolecular octanuclear copper(II) species in which two tetranuclear units are non-covalently linked by a decanuclear water cluster (Table 3 and Fig. 4). Besides, each complex is hydrogen bonded to an isolated lattice water molecule. The decanuclear water cluster is formed by hydrogen bonding interactions of two dimeric water aggregates with a cyclic hexameric water cluster that is anchored on two tetranuclear complexes involving four water molecules and four phenoxo oxygen atoms. Interestingly, the

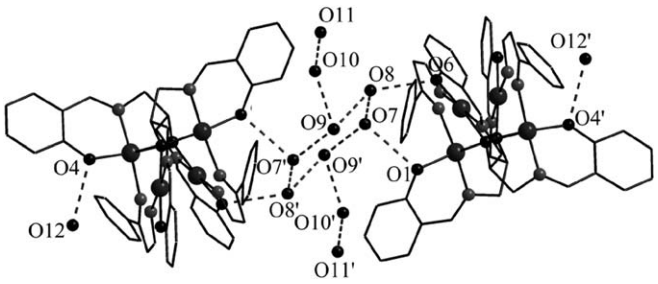

Fig. 4. A view of the discrete decanuclear water cluster anchored onto two tetracopper(II) units.

hexameric water aggregate resembles cyclohexane in its chair conformation. This rare and high-energy form of the cyclic hexameric structure is previously known in liquid helium droplets, organic supramolecular hosts and metal-organic framework structures [11,13,31]. The av. O···O···O angle of ~116.7° in the cyclic structure compares well to the value of 116.5° observed for water hexamers in organic hosts, but differ from the angle of 109.3° in hexagonal ice [13,32]. This could be due to the steric constraints imposed by the synthetic host. The O···O distances do, however, compare well with the corresponding distance of 2.759 Å reported for hexagonal ice (I_h) at −90 °C [33]. The important hydrogen bonding parameters are given in Table 3.

3.3. Magnetic properties

The temperature dependence of the magnetic susceptibility of the tetranuclear copper(II) complex is shown as a $\chi_M T$ versus T plot in Fig. 1. The $\chi_M T$ value decreases gradually in the beginning from 300 K and then rapidly, as the temperature is decreased below 150 K. The magnetic behavior shows that an antiferromagnetic interaction is predominant in the system. The structure of the {Cu_4} core shows that the Cu(1) and Cu(3) atoms are five-coordinate with a square-pyramidal geometry in which the nitrogen and phenoxo oxygen atoms are in the basal plane. The alkoxo oxygen atom belonging to the Schiff base displays the μ_3-mode of bonding with two short equatorial and one axially elongated Cu–O bond. The Cu(2) and Cu(4) atoms have a four-coordinated planar structure. The four basal planes in the structure are not coplanar giving dihedral angles of ~70°. The alkoxo oxygen atoms are not planar due to the μ_3-bonding mode. There are no bridging ligand atoms between Cu(2) and Cu(4) atoms and hence there is no exchange pathway between these two sites. Besides, the long Cu···Cu distances in the range 3.261(1)–3.492(1) Å precludes any direct bonding between the metal centers. Hence, the exchange constant for the magnetic interaction between Cu(2) and Cu(4) sites is zero. The Cu(1)···Cu(3) distance in the {$Cu_2(\mu\text{-}OR)_2$} unit is 3.261(1) Å. The presence of two axial–equatorial bridging alkoxo oxygen atoms in this unit is likely to make the exchange interaction (J_3) different from the other units. There exists only five exchange constants between the four magnetic Cu(II) ions in the complex. The symmetry of the molecule further reduces them to three unique exchange constants (Fig. 5). The Cu–O–Cu bond angles involving the pathway with exchange constant J_1 is 120.18° and that involving J_2 is 106.03°. This suggests that the interactions J_1 and J_2 are both expected to be antiferromagnetic [34]. The Cu(1)–O(2)–Cu(3) and Cu(1)–O(5)–Cu(3) bond angles for the pathway involving J_3 are 95.47° and 96.49° suggesting that this exchange interaction could be ferromagnetic [35]. The 3-phenylpyrazole ligands that act as linkers of the two binuclear units are unlikely to play any significant role in the magnetic exchange processes involving the copper(II) centers. The bond angles and bond lengths suggest that $|J_1| > |J_2| > |J_3|$. Based on the structural data, the magnetic interactions in the system are modelled using the Hamiltonian

$$\hat{H} = -J_1(\hat{S}_1\hat{S}_2 + \hat{S}_3\hat{S}_4) - J_2(\hat{S}_1\hat{S}_4 + \hat{S}_2\hat{S}_3) - J_3(\hat{S}_1\hat{S}_3) + g\mu_B H\sum_i \hat{S}_i^z - zJ'\langle S_{tot}^z\rangle\sum_i \hat{S}_i^z \quad (1)$$

where the positive and negative sign of J corresponds to ferromagnetic and antiferromagnetic interactions, respectively, and z is the number of nearest neighboring molecules. All the spin operators ($\hat{S}$s) correspond to spin-1/2 objects. The last term in the Hamiltonian takes into account intermolecular interactions in the system within the mean field approximation with $|J'| \ll \{|J_1|, |J_2|, |J_3|\}$ due to the large separation of the tetranuclear complexes from each other in the presence of the diamagnetic water cluster. Using the above model we can compute the square of the magnetization, $M^2(T)$, as a function of temperature

$$M^2(T) = \frac{\sum_S \sum_{M_s=-S}^{S} M_S^2 \exp(-E(S,M_S)/k_B T)}{\sum_S \sum_{M_s=-S}^{S} \exp(-E(S,M_S)/k_B T)} \quad (2)$$

where the eigenvalues $E(S, M_s)$ of $\hat{H}$ are given by $E(S, M_s) = E_o(S, M_s) + M_s(g\beta H - zJ'\langle S_z\rangle)$, $E_o(S, M_s)$ being the eigenvalues of the exchange Hamiltonian in the absence of an external magnetic field and intermolecular interactions. The temperature dependent magnetic susceptibility, $\chi_M(T)$ is then given by

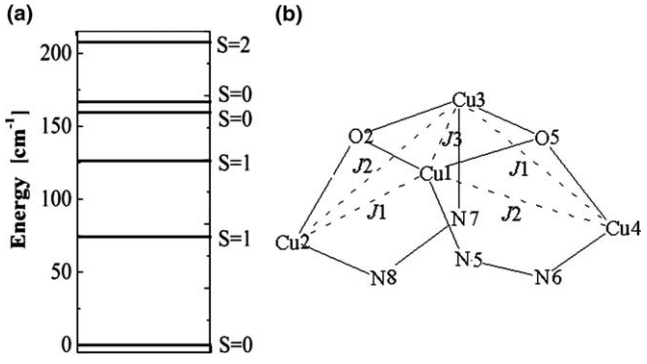

Fig. 5. (a) Energy levels of the {Cu_4} cluster from solving the Hamiltonian in Eq. (1) for the best-fit exchange constants. (b) The spin–spin coupling scheme in the complex.

$$\chi_M(T) = g^2M^2(T)/[T - zJ'M^2(T)] \quad (3)$$

where g is the gyromagnetic ratio. To account for trace concentrations of paramagnetic impurities present in the analytically pure sample, an additional Curie-like contribution to the magnetic susceptibility has been assumed and the total magnetic susceptibility is given by

$$\chi_{tot}(T) = \chi_M(T) + C/T \quad (4)$$

where C is the Curie constant. The error in the fit (R) is calculated from the expression,

$$R = \sum_i [(\chi_{obs}(T_i) - \chi_{cal}(T_i))^2/\chi_{obs}(T_i)^2] \quad (5)$$

where $\chi_{obs}(T_i)$ and $\chi_{cal}(T_i)$ are the observed and calculated magnetic susceptibilities at temperature T_i, respectively.

The magnetic data for the complex are fitted using the model Hamiltonian. The best fit gives J_1, J_2 and J_3 values as $-86.3\ cm^{-1}$, $-47.32\ cm^{-1}$ and $11.13\ cm^{-1}$, respectively. The intermolecular interaction (J') is weak and antiferromagnetic in nature, giving a value of $-0.765\ cm^{-1}$. The g value used for the theoretical fitting of the magnetic data are 2.02. The Curie constant obtained from the fit corresponds to an impurity concentration of 0.03 free-spins per tetranuclear unit. The error (R) of the fit is 1.7×10^{-4}. The energy levels of the copper cluster are shown in Fig. 5. The ground state is a low-spin singlet with a triplet state lying above because of the dominant antiferromagnetic interactions present in the system. The singlet triplet gap is $74.2\ cm^{-1}$ and the quintet state is $207.6\ cm^{-1}$ above the singlet ground state.

4. Conclusions

A new tetranuclear copper(II) complex showing a covalent linkage of two dicopper(II) units by two 3-phenylpyrazole ligands has been prepared and structurally characterized. The crystal structure shows the presence of a discrete decameric water aggregate that is formed from two dimeric and one cyclic hexameric water unit and the water assembly is stabilized by the host structure through hydrogen bonding interactions involving the phenoxo oxygen atoms of the Schiff base. The important role of the copper(II) complex containing a multidentate Schiff base as the host structure is observed in the stabilization of a large size water aggregate. The results are of significance considering the presence of hexameric water clusters in bulk water. The theoretical fitting of the magnetic data shows the presence of two dominant antiferromagnetic and one minor ferromagnetic exchange pathway, leading to the singlet magnetic ground state of the pseudo-linear tetranuclear copper(II) complex.

oxygen-sensitive, therefore an inert gas atmosphere was a requisite. Referring to labile gold trialkoxysilanethiolates, which were stable only in the presence of additional triphenylphosphine ligand [8], we expected that in the present case chelating heterocyclic N-donor bases like 2,2′-bipyridine may transform **1** not only to the more stable but also to less reactive manganese silanethiolate species.

Ligands containing the 2,2′-bipyridine fragment have found widespread use – recently they have been regarded as ideal for synthesizing complexes which exhibit a high luminescence quantum yield [9] and are being considered as promising candidates for non-linear optics [10]. So far, only three manganese(II) complexes with S-donor (albeit not thiolate) and heterocyclic chelating N-donor ligands simultaneously bonded to the same metal centre [11–13] have been described. Heteroleptic manganese(II) silanethiolate with chelating tetramethylethylenediamine as an additional ligand-[$Mn(SSiPh_3)_2$(tmeda)] has also been reported [14].

For our purposes 2,2′-bipyridine (bipy), 1,10-phenanthroline (phen) and 2,9-dimethyl-1,10-phenanthroline (neocuproine, neo) have been selected. The present paper reports our findings concerning the preparation, structure and properties of manganese silanethiolate complexes incorporating these ligands.

2. Experimental

2.1. Materials

Solvents and reagents were dried according to common procedures, degassed and distilled prior to use. Bis(tri-*tert*-butoxysilanethiolato)tetra(methanol)manganese(II) complex (**1**) was prepared as described elsewhere [7] using standard Schlenk techniques, vacuum line and inert gas atmosphere. Other chemicals were obtained from commercial sources and used as received. 1,10-Phenanthroline (phen) and 2,2-bipyridine (bipy) were purchased from POCh (Poland) and 2,9-dimethyl-1,10-phenanthroline (neo) from Aldrich Chemical.

2.2. Synthesis of complexes

Solutions of **1** [7] in methanol were mixed at room temperature under argon atmosphere with equimolar amounts of the ligand L (L = bipy, phen, neo) also dissolved in methanol. The products precipitated almost immediately as very fine microcrystals – orange [$Mn\{SSi(OBu^t)_3\}_2$(bipy)] (**2**), canary yellow [$Mn\{SSi(OBu^t)_3\}_2$(phen)] (**3**) and pale yellow [$Mn\{SSi(OBu^t)_3\}_2$(neo)] (**4**). They were collected, filtered off, washed with methanol and finally recrystallized from hot methanol.

Monocrystals of the compounds containing bipyridine and phenanthroline ligands of quality sufficient for X-ray measurements were obtained by dissolution of complexes **2** and **3** in methanol and slow crystallization at 5 °C. This simple procedure gave well-shaped crystals of complex **2**. Unexpectedly, when **3** was analogously recrystallized, the monocrystals of [$Mn\{SSi(OBu^t)_3\}_2$(phen)(MeOH)] (**3a**) were obtained. These were not stable and quickly became opaque (in a few minutes at RT and visibly faster when reduced pressure was applied) and then transformed to a yellowish powder of **3**. When, instead of MeOH, EtOH was used only microcrystalline **3** deposited. Attempts to prepare monocrystals of **4** (poorly soluble in MeOH) were unsuccessful.

3. Physical measurements

3.1. Elemental analysis

Elemental analysis of **2**–**4** for carbon, hydrogen, nitrogen and sulfur were performed using an automatic Elementary Analyser model EA 1108 (Carlo Erba Instruments, Italy).

3.2. Spectrometric measurements

IR spectra were recorded on a FTIR Mattson Genesis II Gold, externally controlled by WinFirst software. Spectra were registered in the solid state (KBr pellet) and in solution (CCl_4, KBr cuvette, 0.248 mm) in the range 4000–400 cm^{-1}.

UV spectra were recorded with Unicam UV300 spectrometer, externally controlled by Vision32 software. Methanol and quartz cuvettes were used.

3.3. Mass spectroscopy

MS spectra were recorded using LC Agilent 1100 Series chromatograph coupled with two-channel pump, automatic sampler, DAD detector, thermostat and MS detector with APCI (*atmospheric pressure chemical ionization*) and ES (*electrospray*) modes. Measurements were carried out at 30 °C with injection volume −20 μl, flow rate −0.5 ml/min and analysis time 3 min. A solution of acetic acid in methanol (0.1%) was used as the eluent. MS detection

resulted from either the ES or APCI ionization method. The positive ion mode was applied and fragmentation was performed with 20, 70 as well as 200 eV.

3.4. Thermal analysis

Thermal stability was determined with a Pyris 1 thermal analyzer (Perkin–Elmer). Measurements were made for samples of about 3–8 mg in the 50–500 °C range with 20 °C/min heating rate under an inert gas atmosphere (N_2). Differential scanning calorimetry measurements were performed with a DSC 7 (Perkin–Elmer). Samples of ca. 5 mg, encapsulated in aluminum containers, were melted and recrystallized at 20 °C/min rate under an inert gas atmosphere (N_2).

3.5. Crystal structure determination

Single crystals of **2** and **3a** were mounted on quartz capillaries using frozen epoxy resin. Experimental intensity data were collected at $T = 100(2)$ K on a KM4 diffractometer, goniometer equipped with a Sapphire 2 CCD detector (Oxford Diffraction) with monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at a crystal-detector distance of 50 mm. In both cases, data were collected in series of 152 frames at $\varphi = 0°$, 90°, 180° and 270°; ω scan with an increment of 0.75° and exposure time of 80 and 60 s per frame for **2** and **3a**, respectively. The unit cell dimensions, additional crystallographic data and refinement results for both complexes are given in Table 1.

The structures were solved by direct methods and refined by least-squares calculation in anisotropic approximation for non-hydrogen atoms. In these structures H atoms were added at idealized positions and refined using the riding model, except the H atom from the hydroxyl group of the methanol molecule in **3a** which was revealed from a difference electron-density map.

Data collection and editing, as well as refinement of unit cell parameters, was performed using CrysAlis 1.171 CCD (Oxford Diffraction, 2004). The structure solution and refinement (by full-matrix least-squares against F^2) were performed with the WINGX program package (ver.1.70.00, 2005) [15,16]. Selected bond lengths and angles for crystal structures of **2** and **3a** are listed in Tables 2 and 3.

4. Results and discussion

All manganese thiolates so far obtained have been found to be sensitive towards oxidation. This property may hamper significantly any potential applications. It also concerns silanethiolates. Since **1** was found to be labile and reactive towards oxygen its transformation into a more stable and less reactive manganese silanethiolate was considered. As it was previously mentioned we supposed that the exchange of the weakly bonded methanol into another, more strongly coordinating ligand could improve the stability

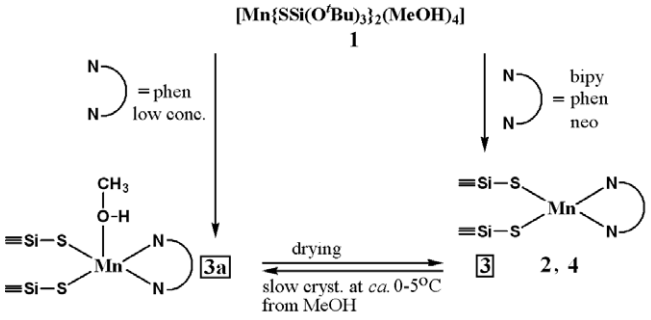
of the complex. Since manganese is regarded as an *a* class metal, N-donor ligands, especially strongly bonding chelating heterocyclic bases, seemed to be the most promising. We have selected 2,2′-bipyridine and, to exclude any possibility of twisting around the central C–C axis and thus coordination to two different metallic centres (a very rare case [17,18]) we have also used 1,10-phenanthroline. To see the influence (if any) of imposed steric hindrance we have also selected 2,9-dimethyl-1,10-phenanthroline.

Indeed, an equimolar amount of phenanthroline, bipyridine or neocuproine added to the solution of [Mn{SSi(OBu^t)$_3$}$_2$(MeOH)$_4$] (**1**) in methanol resulted in almost immediate formation of solid microcrystalline (as checked by XRD) products with a very good yield. Despite the similarities between all three ligands, the results of their reaction with **1** were, however, not always the same. With bipyridine and neocuproine stable products **2** and **4** were obtained, respectively. The stability of the product formed in the reaction of **1** with phenanthroline varied but finally we managed to obtain stable **3** and unstable **3a**, depending on the conditions used (Scheme 1). Then it became obvious that in the case of the phenanthroline containing complex we deal with two different products which may be quite easily converted into each other.

Elemental analysis of compounds **2**–**4** suggested a Mn{SSi(OBu^t)$_3$}$_2$(N–N) composition, where N–N represents the chelating ligand. FTIR spectra recorded in the solid state confirmed the presence of a silanethiolate substituent (e.g., strong bands at 1050–1000 cm^{-1} typical for Si–O and C–O vibrations) as well as bands typical for heterocyclic bases (C=C and C=N at around 1600–1550 cm^{-1}



Scheme 1.

and vibrations for bipyridine systems below 1000 cm^{-1}). For **4** also a band at 1450 cm^{-1}, characteristic for an asymmetric distortional vibration of the methyl group attached to an aromatic ring, can be noticed. For **3**, a Raman spectrum was also recorded.

Electronic spectra have also been examined. None of the complexes exhibited absorptions in the visible range. In the ultraviolet region **2**, **3** and **4** absorb at 204–215 nm, which is associated with σ(Si–S)) $\rightarrow \sigma^*$(Si–S) transitions in silanethiolate ligands [19]. Two absorption maxima at around 230 and 270 nm are caused by typical n $\rightarrow \pi^*$ transitions for heterocyclic compounds.

The mass spectra were similar in all cases and confirmed the composition of Mn{SSi(OBu^t)$_3$}$_2$(N–N). Although the parent ion could not be seen, the spectra allowed a hypothesis to be put forward concerning the main fragmentation pattern through elimination of OBu^t and Si–OBu^t

fragments from the tri-*tert*-butoxysilanethiolate substituent. Ions comprising a chelate ligand molecule (e.g., for **3**: *m/z* 296 $[(phen)MnSSi]^{\bullet+}$, 268 $[(phen)MnS]^{\bullet+}$, 236 $[(phen)Mn]^{\bullet+}$, 181 $[phen]^{\bullet+}$ and 155 $[C_{10}H_6N_2]^{\bullet+}$) can be easily traced in the lower mass part of the spectrum.

Compounds **2**–**4** are very stable in spite of being based on Mn(II). Thus the main goal of our work has been achieved. They may be stored in normal laboratory atmosphere without taking any precautions – after six months no signs of change were noticeable, even with additional irradiation with an UV lamp (40 W, 254 nm) for 5 h. All three compounds melt with decomposition which was confirmed using differential scanning calorimetry measurements. Thermogravimetric analysis indicated that the most stable complexes are those containing phenanthroline and neocuproine, which decompose to gaseous products with a maximum rate at 349 and 355 °C respectively.

IR spectra recorded in CCl_4 solution for **3** and **3a** differed. Bands at ca. 3500 cm^{-1}, characteristic for free ν(OH) can be seen for **3a**. Crystals of **3a** exposed to air became opaque after a few minutes so we anticipated the presence of MeOH (the reaction solvent) within the crystal structure. Compound **3a** required storage under inert gas atmosphere at temperatures near 0 °C. Any attempts to dry it, e.g., in a stream of argon, resulted in facile lost of methanol and formation of **3**.

The role of MeOH remained unknown until the structure was solved, and methanol was found in **3a** as a third type of ligand bonded to manganese. The outline of the reaction can be therefore summarized as shown in Scheme 1. One should note that the graphical representations of the products do not represent their structures.

Crystal and molecular structures have been determined for compounds **2** and **3a**. The structures are presented in Figs. 1 and 2. Selected bond lengths and angles are given in Tables 2 and 3. Both complexes represent quite uncommon structures, mainly because of the set of ligands bonded to manganese.

Looking at the structure of **2**, one can predict the reason of its stability. Complexation of Mn by three chelating ligands should visibly enhance the stability of the complex, however some favorable conditions must be met to reveal chelating properties of tri-*tert*-butoxysilanethiolato ligand. We know that the $(Bu^tO)_3SiS$ group can act as chelate [20,21] but it is not very usual situation. Comparison between **2** and any similar compound is difficult because related manganese complexes (or complexes for any other metal) have not yet been described, the closest one being bis(2-pyridinethiolato)(2,2′-bipyridine)-bis(tetrahydrofuran) europium with an $EuN_4O_2S_2$ kernel and eight-coordination at Eu [22]. Bond lengths and angles in **2** are unexceptional and similar to those in other silanethiolates. The only difference that can be seen between these bonds (and appropriate angles) relate to those which are or are not engaged in the formation of chelate rings.

Even more interesting is the structure of **3a**. Two thiolate ligands, a chelate nitrogen-donor ligand and a methanol molecule bonded to Mn form a structure which has no parallels among other complexes. When the structure of **3a** is compared to the structure of **2** some differences can be

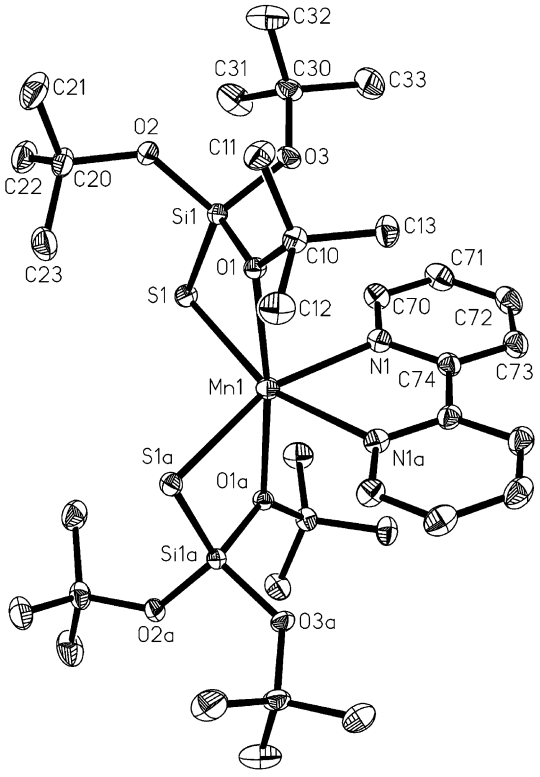


Fig. 1. Crystal and molecular structure of $[Mn\{SSi(OBu^t)_3\}_2(bipy)]$ (**2**). Hydrogen atoms are omitted for clarity. Thermal ellipsoids, 50%.

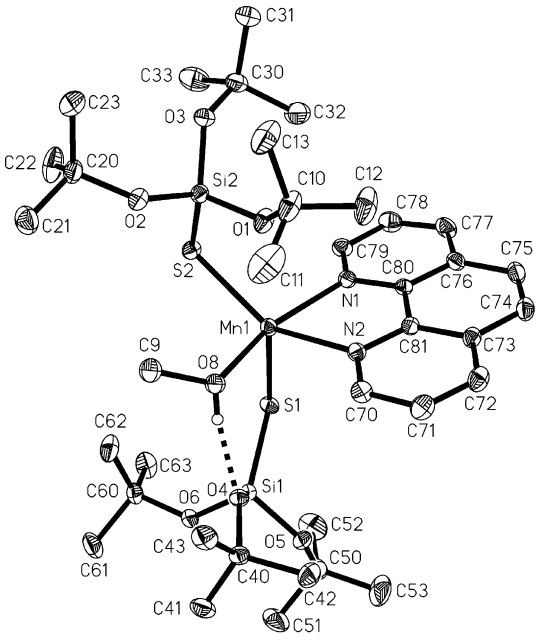

Fig. 2. Crystal and molecular structure of $[Mn\{SSi(OBu^t)_3\}_2(phen)\text{-}MeOH]$ (**3a**). Hydrogen atoms (except OH) are omitted for clarity. The O8–H···O4 hydrogen bond is shown as a broken line. Thermal ellipsoids, 50%.

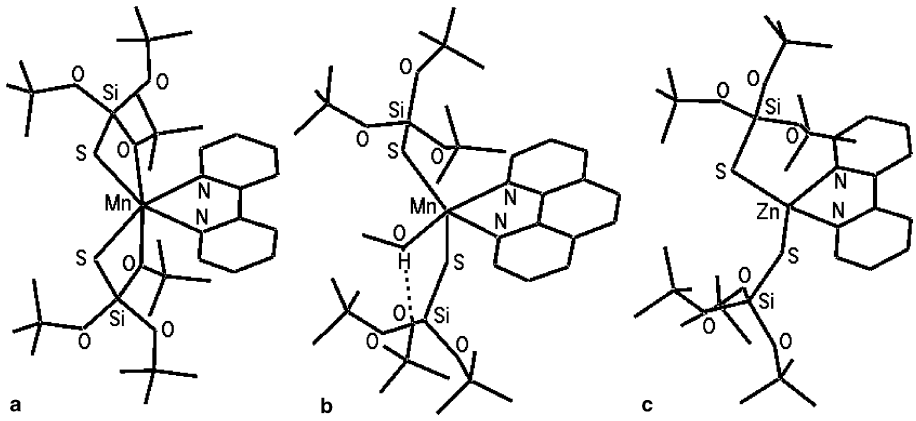

Fig. 3. (a) $[Mn\{SSi(OBu^t)_3\}_2(bipy)]$ $MnN_2O_2S_2$ (**2**); (b) $[Mn\{SSi(OBu^t)_3\}_2(phen)(MeOH)]$ MnN_2OS_2 (**3a**); (c) $[Zn\{SSi(OBu^t)_3\}_2(bipy)]$ MnN_2S_2 [21].

immediately noticed – the non-chelating nature of the silanethiolate ligand in **3a** and penta-coordination at Mn. Furthermore, there is a hydrogen bond between the O4 atom from one tri-*tert*-butoxysilanethiolate ligands and O8 from methanol (O4···O8 distance of 2.690 Å). Undoubtedly, the hydrogen bond should strengthen the complex and it may be the sole reason of sufficient stability of complex **3a**. Si–S bonds in **2** and **3a** are virtually the same and can be regarded as rather short. We also note the difference in Mn–O distances: $Mn–O_{SiOBu}$ 2.465 Å (part of the chelate ring in **2**) and $Mn–O_{MeOH}$ 2.210 Å (not restricted in **3a**), with Mn–O distances usually in the range 2.100–2.200 Å.

Are the structures of **3** and **4** similar to that of **2**? All three compounds show remarkable stability and their nitrogen-donor ligands are similar. However, we know only the structure of **3a**, not **3** and in the case of **4**, really hardly dissolving in all common solvents, we did not manage to obtain crystals suitable for diffraction measurement and the monometallic nature of the complex is not fully confirmed. All gathered data suggest that in **3** and **4** two silanethiolate ligands and a heterocyclic base coordinate to the same metal centre giving a monometallic species. We need to mention here the very stable zinc complex $[Zn\{SSi(OBu^t)_3\}_2(bipy)]$ [21], with tetra-coordinated Zn (ZnN_2S_2 kernel) lacking any secondary Zn–O interactions. Compared to complexes **2** and **3a**, it provides yet another, although closely related, structure type (Fig. 3).

It remains unknown how the silanethiolate ligands coordinate in **3** and **4**. Are they chelating as in **2** (CN = 6) or, according to greater steric hindrance introduced with neocuproine in **4**, only bonded through sulfur (CN = 4) as in the Zn silanethiolate (Fig. 3)? Of course a case with only one chelating silanethiolate ligand (CN = 5, as in **3a**) should be also considered.

Three silanethiolates of manganese(II) described in the present paper – in contrast to many other manganese(II) thiolates – are stable under normal conditions so that we can deliberate on their potential applications.

On the other hand, the preparation of labile **3a**, where methanol, thiolate ligands and heterocyclic base are bonded to the same metal centre, approaches the long studied problem of a complex of which the kernel should mimic the active centre $[ZnCys_2His(ROH)]$ of alcohol dehydrogenase [23–25]. So far, it has been impossible to prepare such a zinc compound where all four donor atoms (N, O, S, S) are provided by four independent ligands. Now, it seems that we can look for a very similar Mn-based complex starting with $[Mn\{SSi(OBu^t)_3\}_2(MeOH)_4]$ **1** as a substrate. Related work is now in progress.

Appendix A. Supplementary data

Crystallographic data for the structures have been deposited with the Cambridge Crystallographic Data Centre. Copies of the data can be obtained free of charge on application to The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, on full quoting the journal citation and deposition nos. CCDC 290752 (**2**), CCDC 290753 (**3a**). Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2005.12.030.

2.2. Physical measurements

C, H and N elemental analyses were carried out using a Heraeus Carlo Erba 1108 elemental analyzer. The IR spectra were obtained on a Jasco 5300 FT-IR spectrophotometer. Electronic spectra were recorded on a Shimadzu UV-240 spectrophotometer. NMR spectra were recorded by using a Bruker DPX 300 NMR spectrometer.

Single crystals of cyclopalladate **1** were grown by slow diffusion of a dichloromethane solution of **1** into *n*-hexane. A suitable single crystal was carefully selected under a polarizing microscope and glued to a thin glass fiber with cyanoacrylate adhesive. A single crystal structure determination by X-ray diffraction was performed on a Siemens Smart-CCD diffractometer equipped with a normal focus, 2.4 kW sealed tube X-ray source (Mo Kα radiation, $\lambda = 0.71073$ Å) operating at 50 kV and 40 mA. The structure was solved by direct methods using SHELXS-86 [36,37] and difference Fourier syntheses. An empirical absorption correction based on symmetry equivalent reflections was applied for the compounds using the SADABS [38] program. All the hydrogen positions for both compounds were initially located in the difference Fourier maps, and for the final refinement, the hydrogen atoms were placed geometrically and held in the riding mode. The last cycles of refinement included atomic positions for all the atoms, anisotropic thermal parameters for all non-hydrogen atoms and isotropic thermal parameters for all the hydrogen atoms. Full-matrix-least-squares structure refinement against $|F^2|$ was carried out using the SHELXTL-PLUS [39] package of programs.

2.3. Synthesis of [PdL(Pic)] (1)

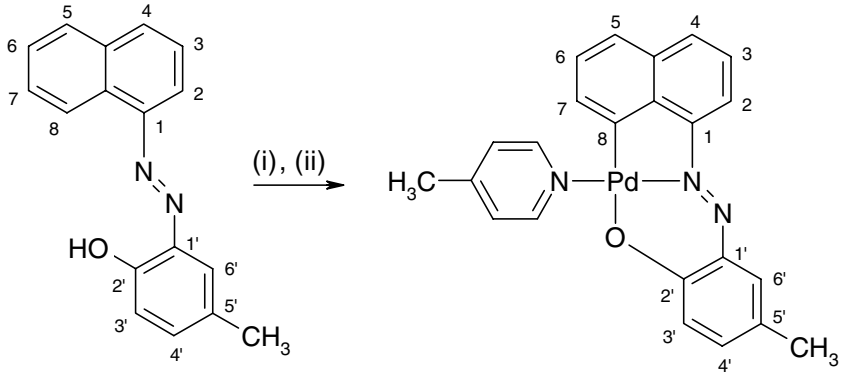
An orange-yellow ethanolic solution (10 mL) of H_2L, (0.03 g, 0.114 mmol) was slowly added to a brown solution of $Na_2[PdCl_4]$ (0.04 g, 0.136 mmol) in ethanol (10 mL). Immediately the colour of the mixture changed to deep red and the mixture was stirred for 2 h at room temperature. A solution of 4-picoline (0.02 g, 0.21 mmol) in benzene (5 mL) was added drop-wise to the above mixture. The mixture was further stirred for 0.5 h at room temperature and the colour changed to reddish pink. The solvent was removed by evaporation and the residue was thoroughly washed with water, ethanol and diethyl ether. The solid mass was dried and dissolved in dichloromethane. The solution was chromatographed on silica gel (60–120 mesh size). Initially an orange yellow band of H_2L was eluted by a mixture of petroleum ether and benzene (1:1, v/v) followed by a pink band of compound **1**, which was eluted by pure benzene. Red microcrystals of compound **1** were collected by the removal of solvent and finally dried in vacuo. (Yield: 0.025 g, 0.0544 mmol, 47.5%). *Anal.* Calc. for $C_{23}H_{19}N_3OPd$: C, 60.04; H, 4.13; N, 9.13. Found: C, 60.40; H, 4.22; N, 8.91%. $R_f = 0.3$; MP: 234 °C (decomp.). IR (KBr; ν/cm^{-1}): 1442 (N=N), 1190 (C–O). UV/Vis (CH_2Cl_2), λ/nm ($\varepsilon/dm^3\ mol^{-1}\ cm^{-1}$): 540(9500), 467(9200), 438(7800), 346(7900), 291 ^{sh}(16 000), 280(17 600). ^1H NMR in $CDCl_3$ (ppm): 2.25 (s, 3H, 5′-Me), 2.42 (s, 3H, 4-Pic), 6.7–8.8 (other aromatic protons). $^{13}C\{^1H\}$ NMR in $CDCl_3$ (ppm): 158.16 (C8), 156.95, 152.44, 150.75, 150.23, 138.70, 137.52, 134.15, 132.99, 130.39, 128.51, 126.15, 125.99, 124.55, 123.47, 122.93, 111.87, 21.27, 19.99.

Caution: *Benzene is a highly hazardous chemical. This should be handled with great care.*

3. Results and discussion

3.1. Synthesis and spectral properties

At room temperature 1-(2′-hydroxy-5′-methylphenylazo)-naphthalene (H_2L) reacts with disodium tetrachloropalladate in ethanol medium and slowly produces an insoluble mass which readily reacts with the neutral Lewis base 4-picoline and yields a soluble pink coloured monomeric cyclometallate [PdL(Pic)] (Scheme 1). The observed elemental analytical data (experimental section) of the compound is consistent with its proposed composition.



1

Scheme 1. (i) $Na_2[PdCl_4]$ (1 equivalent), EtOH, room temperature, 2 h; (ii) 4-picoline (2 equivalents), benzene, 30 min.

The IR absorption band of the phenolic group of HL at 3053 cm^{-1} indicates strong intra-molecular hydrogen bonding and it disappears on the formation of compound **1**. The IR spectrum of compound **1** shows absorptions at 1442 and 1190 cm^{-1} which are attributable to N=N (azo) [40,41] and the palladium(II) bound phenolato (C–O) [42,43] groups, respectively.

The cyclopalladate **1** is soluble in common organic solvents. The electronic spectrum of **1** shows strong absorptions in the visible region. These transitions are assigned to metal to ligand MLCT [d(Pd) → π (azo)] bands. The bands observed in the high-energy region with a high molar extinction coefficient arise from an intra-ligand charge transfer transition. The absorption in the ultraviolet region may be attributed to the usual n → π*, π → π* transitions occurring within the ligand orbitals [44].

The ^{1}H NMR signal at 12.97 ppm for the phenolic group of free HL disappears on complex formation. The methyl groups attached to the phenyl and picoline rings in **1** appear as singlets at 2.25 [42] and 2.42 ppm [42,45], respectively. The signals for the aromatic protons appear as a complex pattern in the region 6.7–8.8 ppm with the correct integration ratio. The $^{13}C\{^{1}H\}$ NMR spectrum of **1** shows a signal for the palladated C(8) of the naphthyl group at 158.16 ppm, which is in agreement with the reported values of chemical shifts for palladated carbons in the literature [32]. The signals for the methyl group of 4-picoline and 5′-methyl in **1** appear at 21.27 and 19.99 ppm, respectively.

3.2. X-ray structure of [PdL(Pic)] (1)

The molecular geometry of the cyclopalladate **1** along with the atomic numbering scheme is shown in Fig. 1. Significant crystal data and data collection parameters for **1** are listed in Table 1. Selected bond lengths and bond angles for **1** are given in Table 2.

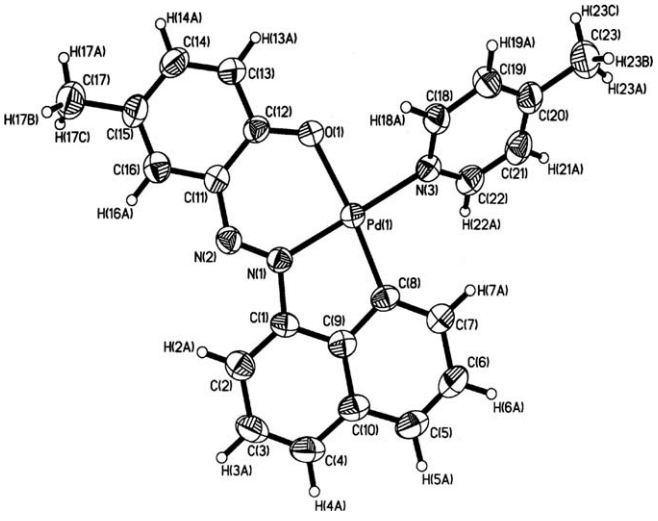


Fig. 1. Molecular structure of [Pd(L)(Pic)], **1**.

Table 1
Crystal data and structure refinement for [PdL(Pic)] (**1**)

Empirical formula	$C_{23}H_{19}N_3OPd$
Formula weight	459.81
Temperature (K)	293(2)
Wavelength (Å)	0.71073
Crystal system	monoclinic
Space group	$P2_1/c$
Unit cell dimensions

b (Å)	7.7345(2)
c (Å)	17.5364(4)
α (°)	90
β (°)	105.2080(10)
γ (°)	90
Volume (Å^3)/Z	1895.23(7)/4
Density (calculated) (Mg/m^3)	1.611
Absorption coefficient (mm^{-1})	0.998
$F(000)$	928
Crystal size (mm)	$0.35 \times 0.14 \times 0.14$
θ Range for data collection (°)	1.46 to 23.27
Limiting indices	$-12 \leqslant h \leqslant 16$, $-8 \leqslant k \leqslant 8$, $-19 \leqslant l \leqslant 17$
Reflections collected	7480
Independent reflections	2727 ($R_{int} = 0.0289$)
Maximum and minimum transmission	1.000000 and 0.756626
Refinement method	Full-matrix-least-squares on F^2
Data/restraints/parameters	2727/0/254
Goodness-of-fit on F^2	1.171
Final R indices [$I > 2\sigma(I)$]	$R_1 = 0.0330$, $wR_2 = 0.0908$
R indices (all data)	$R_1 = 0.0454$, $wR_2 = 0.0969$
Extinction coefficient	0.0130(8)
Largest difference in peak and hole (e Å^{-3})	0.622 and −0.540

Table 2
Selected bond lengths (Å) and angles (°) for [PdL(Pic)] (**1**)

Bond lengths	(Å)	*Bond lengths*	(Å)
Pd(1)–N(1)	1.976(4)	Pd(1)–C(8)	1.987(4)
Pd(1)–O(1)	2.062(3)	Pd(1)–N(3)	2.068(4)
C(1)–N(1)	1.430(5)	N(2)–C(11)	1.377(5)
N(1)–N(2)	1.271(5)	C(12)–O(1)	1.290(4)
Bond angles	(°)	*Bond angles*	(°)
N(1)–Pd(1)–C(8)	83.1(2)	N(1)–Pd(1)–O(1)	91.12(12)
C(8)–Pd(1)–O(1)	173.96(13)	N(1)–Pd(1)–N(3)	177.36(12)
C(8)–Pd(1)–N(3)	97.3(2)	O(1)–Pd(1)–N(3)	88.39(12)

The palladium(II) center is bonded to C8 (the *peri* position of the 1-azonaphthyl fagment), N1 of the diazo group, O1 of the phenolato function and N(3) of the picoline ligand. Therefore 1-(2′-hydroxy-5′-methylphenylazo)naphthalene binds palladium(II) as a dianionic terdentate [C, N, O] ligand.

The tetra-coordination around palladium is essentially planar and coplanar with the *peri* palladated naphthyl ring, but in a distorted square-planar geometry. The maximum deviation is represented by the 'bite' angle C(8)–Pd(1)–N(3) of 97.3(2)°. This type of deviation is observed for cyclopalladates [46]. The Pd–C8 bond length of 1.987(4) Å is in agreement with the reported palladium(II)–C8(naphthyl) bond length of 1.971(5) Å [31].

The shortening of the C(11)–N(2) bond, 1.377(5) Å, with respect to the C(1)–N(1) bond, 1.430(5) Å, reveals the presence of more π-electron density in the six membered diazapalladacycle than that present in the five membered azapalladacycle.

4. Conclusion

At room temperature 1-(2′-hydroxy-5′-methylphenylazo)naphthalene undergoes a cyclopalladation reaction with disodium tetrachloropalladate in ethanol and behaves as a dianionic terdentate [C, N, O] ligand. Palladium–carbon bond formation occurs at the C8 (*peri*-) position exclusively in contrast to the reported palladation of 1-phenylazonaphthalene which occurs at the C2 (*ortho*-) position. Thus the presence of the 2′-hydroxy group as an additional donor in the ligand frame influences the exclusive *peri*-palladation of the naphthyl group of 1-(2′-hydroxy-5′-methylphenylazo) naphthalene. The cyclopalladate has been isolated as a picoline adduct in the pure form and has been characterized by spectral and X-ray diffraction methods.

(**2**) with infinite 1D chain structures, and their magnetic properties have been investigated based on the simple tetranuclear model.

2. Experimental

2.1. Materials and synthesis

3-Carboxylsalicylidene was prepared by the literature method [20], 1-(2-hydroxybenzamido)-2-(amino) ethane was prepared by the literature method [13], the ligand H_4L and the copper precursor ($K_2CuL \cdot 1.5H_2O$) were prepared by the literature method [21]. Other chemicals were of reagent grade and obtained commercially without further purification.

2.1.1. Synthesis of the complex *1*

A methanol solution (100 mL) of $K_2CuL \cdot 1.5H_2O$ (0.25 g, 0.5 mmol) was gently poured into a methanol solution (100 mL) of Mn(II) acetate tetrahydrate (0.12 g, 0.5 mmol) at ambient temperature. The resulting solution was allowed to stand for several days. The poor light red crystals that formed were collected by filtration and dried in air. Yield based on [$CuLMn \cdot CuLMn(CH_3OH)(H_2O)$]: 90%. The crystals were only soluble in dimethyl sulfoxide (DMSO). Therefore, the single crystals suitable for X-ray analysis were grown by a slow diffusion method using a test-tube. 5 mL $Mn(OAC)_2 \cdot 4H_2O$ aqueous solution (5 mmol L^{1-}), 10 mL ethanol–water solution (3:1 V/V) and 5 mL $K_2CuL \cdot 1.5H_2O$ methanol solution (5 mmol L^{1-}) were carefully added in order to a 30 mL test-tube, and then the top of the tube was sealed. The light red single crystals of **1** were formed at the upper interface in one month. Calc. for $C_{36.5}H_{35}Cu_2Mn_2N_4O_{13}$: Cu, 13.04; Mn, 11.27; C, 44.98; H, 3.62; N, 5.75. Found: Cu, 12.75; Mn, 11.01; C, 44.82; H, 3.42; N, 5.58%. $\nu_{C=O}$ (amido moiety) at 1647 cm^{-1}.

2.1.2. Synthesis of the complex *2*

The compound **2** was prepared similarly to **1**. The yield based on [$CuLCo \cdot CuLCo\ (H_2O)_2] \cdot H_2O$: 93% Calc. for $C_{34}H_{30}Cu_2Co_2N_4O_{13}$: Cu, 13.40; Co, 12.43; C, 43.09; H, 3.19; N, 5.91. Found: Cu, 13.28; Co, 12.56; C, 43.22; H, 3.09; N, 5.80%. $\nu_{C=O}$ (amido moiety) at 1653 cm^{-1}.

2.2. Physical measurements

Elemental analyses for carbon, hydrogen and nitrogen were carried out on a Perkin–Elmer 2400II analyzer. The metal contents were determined by EDTA titration. The infrared spectra were recorded on an Avatar-360 spectrometer using KBr pellets in the range of 400–4000 cm^{-1}. UV–Vis spectra were recoded in DMSO (DMSO = dimethyl sulfoxide) with a UV-550 spectrometer in the range of 200–800 nm. The temperature-dependent magnetic susceptibilities in the temperature range of 5–300 K under a constant external magnetic field of 10 kG were measured with a MPMS-7 SQUID magnetometer.

2.3. Crystallographic studies

The single crystals used for data collection of the complexes **1** ($0.17 \times 0.13 \times 0.05$ mm^3) and **2** ($0.281 \times 0.125 \times 0.098$ mm^3) were selected and mounted on a Bruker Smart APEX diffractometer with a CCD detector using graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). Data were collected by the ω scan mode at 293(2) K to a θ_{max} of 25.00° with a total of 9790 reflections collected including 6568 independent reflections ($R_{int} = 0.0881$) for complex **1** and to a θ_{max} of 26.41° with a total 10403 reflections collected including 7113 independent reflections ($R_{int} = 0.0524$) for complex **2**. A summary of the crystallographic data is given in Table 1. Lorentz and polarization factors were made for the intensity data and absorption corrections were performed using the SADABS program [22]. The crystal structures were solved using the SHELXTL program and refined using full matrix least squares [23]. The positions of the hydrogen atoms were calculated theoretically and included in the final cycles of refinement in a riding model along with the attached carbons. For **1**, the uncoordinated CH_3OH and CH_3CH_2OH molecules appear to be disordered and their occupied factors are 0.5. Selected bond distances and angles are given in Table 2.

3. Results and discussion

3.1. Description of the crystal structures

The crystal structures were determined by single-crystal X-ray diffraction analyses. Their crystallographic data are summarized in Table 1. Selected bond distances and angles are shown in Tables 2 and 3. As their molecular structures are similar to each other, only the structure of **1** is described in detail. Each dissymmetrical unit of complex **1** consists of

#1 $-x+2, -y, -z+1$; #2 $-x+2, -y+1, -z$.

a dissymmetrical tetranuclear unit, a disordered methanol molecule and a disordered ethanol molecule (Fig. 1). The tetranuclear unit comprises two different neutral binuclear moieties Cu1Mn1L (Cu1Mn1L = **A**) and Cu2Mn2(H_2O)-(CH_3OH)L (Cu2Mn2 (H_2O)(CH_3OH)L = **B**), which are united together by the carboxylic group (O8C34O9) of **B** with a Mn1···Mn2 distance of 4.133 Å. The dihedral angle of the **A** and **B** moieties is 85.5°.

In moiety **A**, Cu1 has a square planar coordination geometry with N_2O_2 (N1, N2, O1, O2) donor atoms. The Cu–$N2_{(amido)}$ (1.899(7) Å) distance is considerably shorter than that of Cu–$N1_{Schiff}$ (1.916(7) Å). Both Cu–N and Cu–O distances are similar to the literature [3,12,13]. The Mn1 ions are coordinated by two bridged phenoxo atoms (O1, O2), one carboxylic oxygen atom (O3) from the **A** moiety, two carboxylic oxygen atoms (O8, O9) from the **B** moiety and one amido oxygen atom (O5#1) from the **A** moiety (**A**$^{\#}$) of an adjacent unit to form an octahedral coordination configuration, as shown in Figs. 1 and 2a. The Cu1 and Mn1 ions are bridged together by two

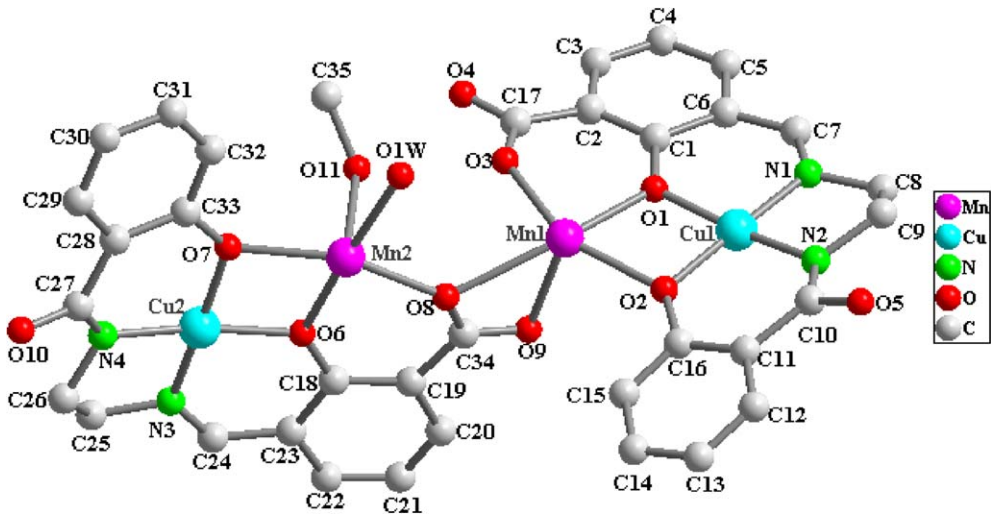

Fig. 1. Thee tetranuclear dissymmetrical unit of complex **1**, the hydrogen atoms, a disordered methanol molecule and a disordered ethanol molecule are omitted for clarity.

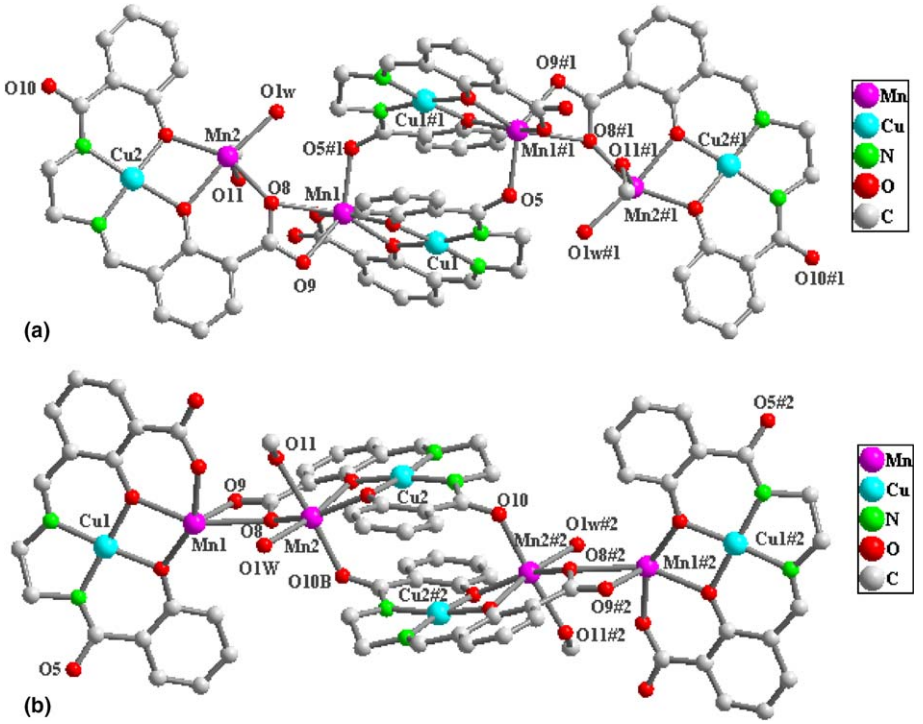

Fig. 2. (a) The tetranuclear cycle constructed by Cu1Mn1(H_2O)(CH_3OH)L moieties of two adjacent units and selected atom labelling scheme. (b) The tetranuclear cycle constructed by Cu2Mn2L moieties of two adjacent units and selected atom labelling scheme.

phenoxo atoms (O1, O2) with Cu1–O1 = 1.933(5) Å, O1–Mn1 = 2.173(5) Å, Cu1–O2 = 1.885(5) Å, O2–Mn1 = 2.138(6) Å, Cu1–O1–Mn1 = 99.8(2)°, Cu1–O2–Mn1 = 102.6(2)°; the Cu1···Mn1 distance is 3.145(2) Å. From Fig. 2a, we can also find that **A** and $\mathbf{A}^{\#}$ of the adjacent unit are bridged together through Mn1–O5#1and Mn1#1–O5 (2.114(6)?) to form a novel cyclic cylindrical tetranuclear structure (**AA**). From bond angles, the hexacoordinated Mn1 has four almost coplanar bonds Mn1–O3, Mn1–O1, Mn1–O2, Mn1–O8 with O3–Mn1–O1 = 81.0(2)°, O1–Mn1–O2 = 72.3(2)°, O2–Mn1–O8 = 123.0 (2)°, O8–Mn1–O3 = 82.7(2)°, O2–Mn1–O3 = 153.2(2)°, O1–Mn1–O8 = 153.8(2)° and two axial bonds Mn1–O5#1, Mn1–O9 with O9–Mn1–O5#1 = 140.3(2)°. Therefore, the Mn1 ions are located in a distorted octahedral configuration.

The structure of the **B** moiety is similar to that of **A** except as follows: (1) the Cu–$N4_{(adiom)}$ distance is considerably longer than that of Cu–$N3_{(Schiff)}$. (2) Although Mn2 is still a distorted octahedral coordination configuration, the coordination atoms are very different from Mn1. Mn2 ion is coordinated by two bridged phenoxo atoms (O6, O7), one carboxylic oxygen atom (O8), one oxygen atom (O1w) from a water molecule, one oxygen atom (O11) from a methanol molecule and an amido oxygen atom (O10#2) from the B moiety ($\mathbf{B}^{\#}$) of another adjacent unit, as shown in Figs. 1 and 2b. (3) The carboxylic group (O8C34O9) in moiety **B** acts as a bridge to coordinate to the Mn1 atom in the **A** moiety, as shown in Figs. 1 and 2. Similar to **A**, a cyclic cylindrical tetranuclear structure (**BB**) is also formed by the coordination bonds Mn2#2–O10 and Mn2–O10#2 (Fig. 2b). (4) The bond lengths and angles in the **B** moiety are slightly different from that of **A**, as shown in Table 2.

From the above discussion, the dissymmetrical tetranuclear unit forms two different tetranuclear cycles (**AA** and **BB**) through the coordination bonds Mn1–O5#1, Mn1#1–O5, Mn2#2–O10 and Mn2–O10#2. These dissymmetrical tetranuclear units are united together by these

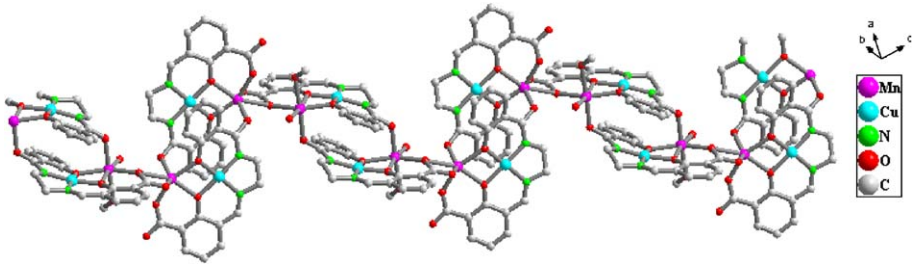

Fig. 3. Space filling representation of complex **1** showing the 1D chain.

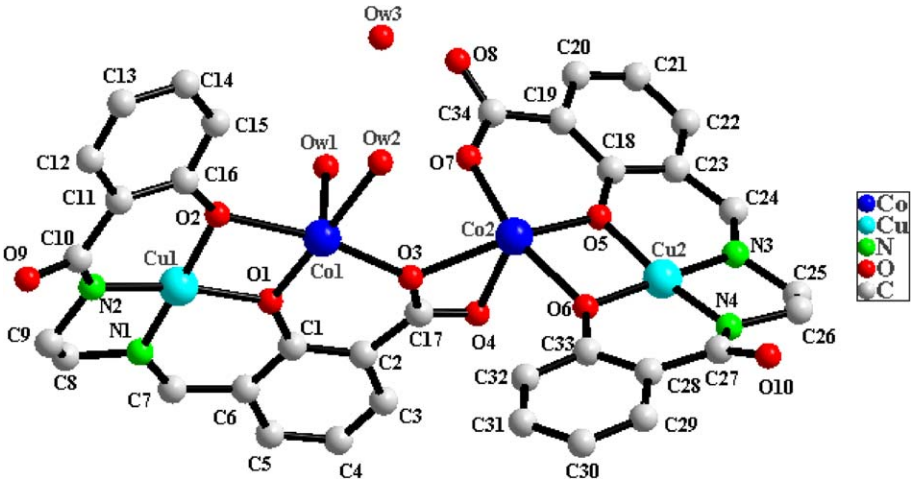

Fig. 4. The tetranuclear dissymmetrical unit of complex **2**, the hydrogen atoms are omitted for clarity.

coordination bonds between amido oxygen atoms and Mn^{II} ions to form a novel ...(**AA**)(**BB**)(**AA**)(**BB**)(**AA**)(**BB**)... 1D chain, as shown in Fig. 3. No hydrogen bonds are shown in the interchains (Fig. 3).

The structure of **2** is very similar to that of **1** except as follow: (1) Each dissymmetrical unit of **2** consists of a dissymmetrical tetranuclear unit and a solvent water molecule. (2) Two water molecules (O1w, O2w) coordinate to the same Co^{II} ion (Co1 ion) in the dissymmetrical tetranuclear unit. In a word, complex **2** not only has no methanol and ethanol solvent molecules, but also has no coordinated methanol molecule, as shown in Fig. 4.

3.2. Spectroscopic characterization

IR spectra of the ligand H_4L exhibits an intense absorption band assignable to the $\nu_{C=O}$ vibration of the amido moiety at 1638 cm^{-1} [24]; the band shifts to higher frequency by 6, 9 and 15 cm^{-1} in the IR spectra of $K_2CuL \cdot 1.5H_2O$, compound **1** and compound **2**, respectively. Owing to the conjugation of C=N group on the aromatic ring, the $\nu_{C=N}$ band of H_4L occurs at 1590 cm^{-1}. The band is shifted to higher frequency by 5, 8 and 7 cm^{-1} in the IR spectra of the $K_2CuL \cdot 1.5H_2O$, **1** and **2**, respectively. The COO^- asymmetrical vibration bands of **1** (or **2**), $\nu_{as(coo)}$, exhibits two intense absorption bands at 1578 cm^{-1} (or 1570 cm^{-1}) and 1538 cm^{-1} (or 1533 cm^{-1}), which may be attributed to $\nu_{as(coo)}$ bands of the monodentate and bidentate coordinated carboxyl groups, while the two intense absorption bands at 1395 cm^{-1} (or 1398 cm^{-1}) and 1428 cm^{-1} (or 1437 cm^{-1}) may be assigned to $\nu_{s(coo)}$, the symmetrical vibration bands of monodentate and bidentate coordinated carboxyl groups.

The d–d bands of $K_2CuL \cdot 1.5H_2O$ exhibit a very broad peak around 520 nm, which is consistent with the d–d bands of the Cu^{II} ion in a nearly square planar geometry. The electronic spectra of **1** show a broad band in the same region with a maximum absorption at 520 nm, a fact which indicates that the planarity of $[CuN_2O_2]$ in **1** is the same as that of $K_2CuL \cdot 1.5H_2O$. The d–d bands of Mn^{II}, due to spin-forbidden transitions, are all too weak to be observed or are overlapped by the d–d bands of Cu^{II}. The electronic spectra of **2** show a broad band in the region with a maximum absorption at 500 nm. Such a blue shift of the d–d band may be attributed to the d–d transitions of the Co^{II} ion in an octahedral field.

3.3. Magnetic properties

The variable temperature magnetic susceptibility data for a crystalline sample of the complexes **1** and **2** were measured on a MPMS-7 SQUID magnetometer over the temperature range of 5–300 K. The plots of μ_{eff} (where μ_{eff} is the effective magnetic moment) and χ_M versus T are shown in Fig. 5 (**1**) and Fig. 6 (**2**). For complex **1**, at 300 K, μ_{eff} is equal to 8.65 BM, a value a little lower than the expected one for two non-interacting $S = 5/2$ Mn^{II} centers and two $S = 1/2$ Cu^{II} centers (8.72 BM). For complex **2**, at 300 K, μ_{eff} is equal to 6.29 BM, a value slightly larger than that expected for two non-interacting $S = 3/2$ Co^{II} centers

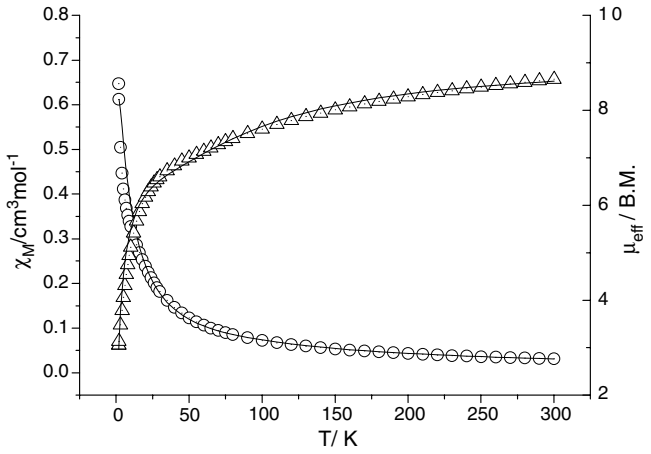

Fig. 5. The plots of μ_{eff} and x_M vs. T for complex **1**.

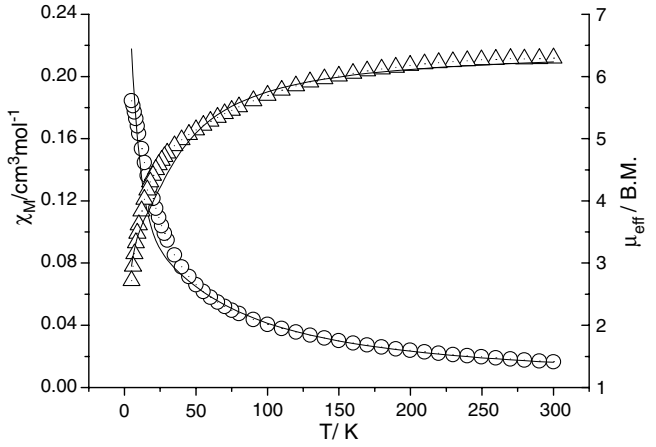

Fig. 6. The plots of μ_{eff} and x_M vs. T for complex **2**.

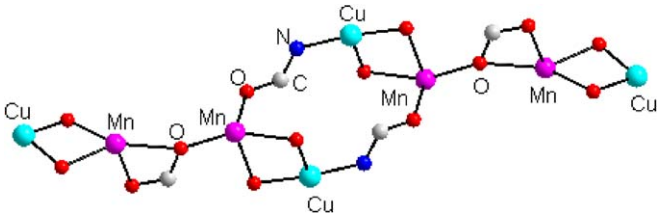

Scheme 1.

and two $S = 1/2$ Cu^{II} centers (6.0 BM). On decreasing the temperature, the μ_{eff} value decreases gradually to the value of 6.29 BM at 22 K for **1** and 4.41 BM at 20 K for **2**; then decreases sharply with the temperature being further lowered and approaches a minimum at around 5 K with $\mu_{eff} = 4.06$ BM for **1** and $\mu_{eff} = 2.95$ BM for **2**.

There are at least three kinds of magnetic interactions for the present systems, namely, (i) Cu^{II}–M^{II} through the phenoxo bridge, (ii) $Cu^{II}1M^{II}1$–$M^{II}2Cu^{II}2$ through the carboxylate oxygen bridge, and (iii) $Cu^{II}A$–M^{II} through the amido bridge, as shown in Scheme 1. These magnetic interactions compete to produce the magnetic properties of these complexes. It is difficult to find an appropriate model for this complicated situation and the difference of the bond angles between Cu1–O1–Mn1(99.8(2)°) and Cu2–O6–Mn2 (97.6(2)°) and between Cu1–O2–Mn1(102.6(2)°) and Cu2–O7–Mn2 (101.8(2)°) are small. As a preliminary treatment, we take these systems as isolated linear tetranuclear complexes with only (i) $Cu^{II}1$–$M^{II}1$ (or $Cu^{II}2$–$M^{II}2$) through the phenoxo bridge and (ii) $Cu^{II}1M^{II}1$–$M^{II}2Cu^{II}2$ through the carboxylate oxygen bridge, and take (iii) M^{II}–$Cu^{II}A$ (or $M^{II}A$–Cu^{II}) through the amido bridge into account in the θ value to deal with the magnetic interactions of the linear tetranuclear complexes. The magnetic analysis was then carried out by Eq. (1) for complex **1** and Eq. (2) for complex **2** derived from this model [25,26], previously reported, as shown in the following:

$$\mathrm{Cu}\overset{J}{-}\mathrm{Mn}\overset{j}{-}\mathrm{Mn}\overset{J}{-}\mathrm{Cu}, \quad X_M = \frac{Ng^2\beta^2}{K(T-\theta)}\frac{A}{B}, \tag{1}$$

where $A = 28 + 60\exp(4j/KT) + 10\exp(-3j/KT) + 2\exp(-5j/KT) + 420\exp(3J/KT) + 392\exp(6J/KT)$, $B = 7 + 9\exp(4j/KT) + 5\exp(-3j/KT) + 3\exp(-5j/KT) + \exp(-6j/KT) + 70\exp(3J/KT) + 49\exp(6J/KT)$.

$$\mathrm{Cu}\overset{J}{-}\mathrm{Co}\overset{j}{-}\mathrm{Co}\overset{J}{-}\mathrm{Cu}, \quad X_M = \frac{Ng^2\beta^2}{3K(T-\theta)}\frac{A}{B}, \tag{2}$$

where $A = 184\exp[(6J+4j)/KT] + 84\exp(6J/KT) + 30\exp[(6J-3j)/KT] + 6\exp[(6J-5j)/KT] + 168\exp[(4J+2j)/KT] + 60\exp[(4J-j)/KT] + 12\exp[(4J-3j)/KT] + 30\exp[(2J+j)/KT] + 6\exp[(2J-2j)/KT]$, $B = 9\exp[(6J+4j)/KT] + 7\exp(6J/KT) + 5\exp[(6J-3j)/KT] + 3\exp[(6J-5j)/KT] + \exp[(6J-6j)/KT] + 14\exp[(4J+2j)/KT] + 10\exp[(4J-j)/KT] + 6\exp[(4J-3j)/KT] + 5\exp[(2J+j)/KT] + 3\exp[(2J-j)/KT] + \exp[(2J-2j)/KT]$, J corresponds to the exchange integral between the M ion and the Cu ion, j stands for the exchange integral between two $Cu^{II}M^{II}$ units through carboxylic oxygen bridges. The best-fit parameters are $J = -41.6\ \mathrm{cm}^{-1}$, $g = 2.10$, $j = -0.12\ \mathrm{cm}^{-1}$, $\theta = -7.0$ K for **1** and $J = -25.1\ \mathrm{cm}^{-1}$, $g = 2.15$, $j = -1.12\ \mathrm{cm}^{-1}$, $\theta = -4.1$ K for **2**. The agreement factor $R = \sum(\chi_{obsd} - \chi_{cacld})^2/\sum\chi^2_{obsd}$ is equal to 5.76×10^{-3} for **1** and 9.52×10^{-3} for **2**, which corresponds to a reasonable agreement as can be seen in Figs. 5 and 6. The negative J and j values suggest that the magnetic interactions between the M^{II} and Cu^{II} ions through the phenoxo bridge, and between two $Cu^{II}M^{II}$ units through a carboxylic oxygen bridge are all antiferromagnetic, the $\theta < 0$ value indicates that the magnetic interaction between linear tetranuclear units is also antiferromagnetic.

The magnetic susceptibility data of complex **1** was well reproduced over the entire temperature range, while that of complex **2** was limited to the 50–300 K range. The interpretation of the magnetic properties of complex **2** is difficult due to the unquenched orbital momentum of the Co^{II} ion. The isotropic Heisenberg exchange model is not strictly applicable to octahedral Co^{II} complexes because of the strong spin–orbit coupling of the $^4T_{1g}$ ground term. Moreover, at low temperatures the states arising from the $^4T_{1g}$ term are split into two Kramer doublets by zero-field splitting, and the Heisenberg model may fail. Anyway, a reasonable fit could be performed in the higher temperature regions, neglecting the zero-field splitting.

4. Conclusion

The "bridging ligand complex" $K_2CuL \cdot 1.5H_2O$ plays a very important role during the construction of two heterometallic coordination polymers. Through the self-assembly method, two chain coordination polymers with carboxylate and amido bridges have been obtained. Complexes **1** and **2** do not dissolved in common organic and inorganic solvents, therefore, we employed the slow diffusion method in a test-tube to obtain the single crystals of the two compounds. Their magnetic properties were preliminary investigated by treating these systems as isolated linear tetranuclear systems.

5. Supporting material

CCDC-282749 and CCDC-282750 contain the supplementary crystallographic data for this paper. These data can be obtained, free of charge, from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (internat.) +44 1223 336 033; e-mail: deposit@ccdc.cam.ac.uk.

reported to our best knowledge. In this article, we have obtained two heteroleptic cyclometallated Rh(III) complexes. Both the photophysical and electrochemical properties of the two complexes have been thoroughly examined to probe the bonding information of their coordination chemistry.

2. Experimental

2.1. Instrumentation

Recording of NMR, IR, mass and absorption spectra have been detailed elsewhere [13]. Low temperature (77 K) emission spectra were obtained with a SLM 8000™ spectrofluorometer (SLM Instrument, Inc.) compact with photo-multiplier tubes which were used as detectors. An Xe–Hg lamp was utilized as the excitation source. Emission photoselection measurements of these complexes under study were obtained with the same instrument as the emission spectra, augmented with two additional sheets of polarizer placed in both the paths of the exciting light and emitting light. The luminescence lifetime was determined by a LN 3000 nitrogen laser with 337.1 nm pulses triggered and integrated by a SRS Model SR250 Gated Integrator (Standford Research Systems, Inc.) and Boxcar Average Module. Cyclic voltammetry (CV) and normal pulse voltammetry (NPV) experiments were carried out using a BAS-100B electrochemical analyzer (Bioanalytical Systems, Inc.) equipped with a three-electrode cell system. All experiments were conducted out under a N_2 atmosphere. A Pt working electrode (BAS Model MF-2103, 1.6 mm dia.), a Pt wire auxiliary electrode and a saturated calomel reference electrode (SCE) were used for voltammetric measurements. The ferrocenium/ferrocence redox couple was used as an internal standard, $E_{1/2}$ ($Fc^{+/0}$) = 0.40 V versus SCE. An H-type cell with a porous glass frit was used for controlled potential electrolysis (CPE) experiments using a Pt plate for the working and auxiliary electrodes.

2.2. Reagents

$RhCl_3 \cdot 3H_2O$ (Merck), 2,2′-bipyridine, 2-benzoylpyridine and 1,10-phenanthroline (Aldrich) were used as received. K[Rh(phen)Cl_4] was prepared according to the published procedure [14]. Me_2SO (Uvasol, Merck) was dried for spectroscopy. Et_4NClO_4 (TEAP), used as a base electrolyte, was obtained from Showa Chemical Co. and further purified by three recrystallizations from distilled H_2O. Laboratory grade solvents were used unless otherwise specified.

2.3. Synthesis

2.3.1. *[Rh(Hbzpy)(bzpy)Cl$_2$]*

[Rh(Hbzpy)(bzpy)Cl_2] was prepared according to the published procedure [12]. The orange-yellow product was characterized by its ^{1}H NMR spectrum which was consistent with the literature data [12].

2.3.2. *cis-[Rh(bzpy)(bipy)Cl$_2$] · 0.5H$_2$O (**1**)*

An intimate mixture of [Rh(Hbzpy)(bzpy)Cl_2] (0.324 g, 0.60 mmol) and bipy (0.562 g, 3.6 mmol) was placed in a ceramic boat (10 cm and 1.3 cm in length and width, respectively) and heated in an oven at 160 °C for 15 h. After cooling, the resulting reaction mixture was stirred for 2 h with 40 ml of methanol and then filtered. The precipitate was washed repeatedly with methanol and then dried under vacuum. 0.118 g (38%) of yellow crystalline product (**1**) was obtained. IR (cm^{-1}): ν(C=O) 1674; ν(Rh–Cl) 343, 324. δ_H(dmso-d_6) 9.19 (1H, d, $J = 5.6$ Hz, $H_{b'6}$) (b′ = bipy), 8.82 (1H, d, $J = 8.4$ Hz, $H_{b'3}$), 8.79–8.69 (3H, m, $H_{b6} + H_{b'6'} + H_{b3}$) (b = bzpy), 8.34 (1H, t, $J = 7.6$ Hz, $H_{b'4}$), 8.31 (1H, t, $H_{b'4'}$), 8.25 (1H, t, $J = 7.6$ Hz, H_{b5}), 8.15 (1H, d, $J = 7.6$ Hz, $H_{b'3'}$), 7.95 (1H, d, $J = 8.0$ Hz, $H_{b6'}$), 7.89–7.85 (2H, m, $H_{b'5} + H_{b'5'}$), 7.68 (1H, t, $J = 6.8$ Hz, H_{b4}), 7.66 (1H, d, $J = 7.6$, 1.2 Hz, $H_{b3'}$), 7.41 (1H, td, $J = 7.6$, 1.6 Hz, $H_{b5'}$), 7.25 (1H, t, $J = 7.2$ Hz, $H_{b4'}$), δ(dmso-d_6) 187.39 (CO), 163.75, 163.50, 157.37, 157.14, 154.54, 154.31, 153.29, 148.68, 140.77, 140.31, 139.84, 139.53, 129.65, 127.08, 126.93, 126.82, 126.27, 125.09, 123.86, 123.56, 123.47. *Anal.* Calc. for $C_{22}H_{17}N_3O_{1.5}Cl_2Rh$: C, 50.70; H, 3.29; N, 8.06; Cl, 13.60. Found: C, 50.62; H, 3.38; N, 8.17; Cl, 13.72%.

2.3.3. *cis-[Rh(bzpy)(phen)Cl$_2$] · 0.5H$_2$O (**2**)*

An intimate mixture of K[Rh(phen)Cl_4] (0.464 g, 1.0 mmole) and Hbzpy (0.660 g, 3.6 mmole) was placed in a ceramic boat (10 and 1.3 cm in length and width, respectively) and heated in an oven at 210 °C for 15 h. After cooling, the resulting reaction mixture was stirred overnight with 50 ml of methanol/H_2O (1:1, v/v) solution and then filtered. The yellow-brown filtrate was evaporated to dryness, followed by washing with dichloromethane. A deep yellow-green precipitate was obtained and washed repeatedly with acetone. After drying under vacuum, 0.169 g (31%) of yellow-green crystalline product (**2**) was obtained. IR (cm^{-1}): ν(C=O) 1666; ν(Rh–Cl) 342, 325. δ_H(dmso-d_6) 9.97 (1H, d, $J = 5.6$ Hz, H_{b6}) (b = bzpy), 9.55 (1H, d, $J = 4.8$ Hz, H_{p2}) (p = phen), 9.00 (1H, d, $J = 8.0$ Hz, H_{p4}), 8.92 (1H, d, $J = 8.0$ Hz, H_{p5}), 8.44–8.29 (5H, m, $H_{b3} + H_{b4} + H_{p7} + H_{p8} + H_{p9}$), 8.16 (1H, dd, $J = 8.0$, 2.8 Hz, H_{p3}); 7.99–7.88 (2H, m, $H_{b5} + H_{p6}$), 7.67 (1H, d, $J = 7.6$ Hz, $H_{b6'}$), 6.94 (1H, t, $J = 7.2$ Hz, $H_{b5'}$), 6.67 (1H, t, $J = 7.2$ Hz, $H_{b4'}$), 5.86 (1H, d, $J = 8.0$ Hz, $H_{b3'}$), δ_C(dmso-d_6) 189.55 (CO), 156.44, 155.29, 154.99, 152.27, 151.13, 146.55, 140.30, 138.86, 138.76, 138.34, 137.91, 133.66, 130.90, 130.77, 129.21, 128.29, 127.86, 127.69, 126.93, 126.24, 126.13, 125.98, 124.02. *Anal.* Calc. for $C_{24}H_{17}N_3O_{1.5}Cl_2Rh$: C, 52.87; H, 3.14; N, 7.71; Cl, 13.01. Found: C, 52.76; H, 3.21; N, 7.84; Cl, 13.15%.

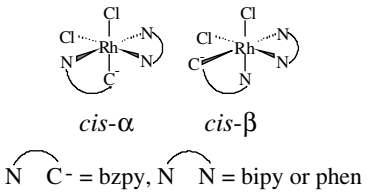
3. Results and discussion

3.1. Synthesis and assessment of structure

First [Rh(Hbzpy)(bzpy)Cl_2] was prepared according to published procedures [12] at this laboratory. Complex **1** was then prepared by heating the intimate mixture of [Rh(Hbzpy)(bzpy)Cl_2] and bipy in an oven at 160 °C for 15 h. Elimination of Hbzpy had been ascribed to the cleavage of the rather weak Rh–O bond, which led to a loss of stabilization due to the chelate effect [12]. Replacement of Hbzpy by phen under the same conditions, however, generated a mixture of at least two isomers, which we were unable to separate. The synthesis of complex **2** was accomplished by heating an intimate mixture of K[Rh(phen)Cl_4] and Hbzpy in an oven at 210 °C for 15 h. Attempts to get complex **1** by the latter procedure failed since a mixture of isomers was obtained again. The synthetic studies of the two different routes in connection with the stereochemistry of complexes **1** and **2** remain unknown to the authors to date.

The base peaks in the mass spectra of complexes **1** and **2** are *m*/*z* 512 and 536, corresponding to the molecular mass of *cis*-[Rh(bzpy)(bipy)Cl_2] and *cis*-[Rh(bzpy)(phen)Cl_2], respectively. The infrared spectra of the two complexes exhibit the ν(C=O) stretching bands in the vicinity of 1666 cm^{-1}. On the basis that the ν(C=O) stretching bands of complexes **1** and **2**, as well as the free Hbzpy ligand (ca. 1668 cm^{-1}), are almost the same, it is evident that the chelated bzpy ligand forms a six-member *N*,*C* metallacycle, not a five-member *N*,*O* metallacycle. The stereochemistry of the $RhCl_2$ moiety in these complexes has been determined by IR data. Both complexes show two ν(Rh–Cl) bands near 342 and 324 cm^{-1}, indicating that the two chlorides are *cis* to each other [15].

The proton peaks in the ^{1}H NMR spectrum of each complex show sixteen chemically different protons. From the ^{13}C spectra, complexes **1** and **2** exhibit 22 and 24 carbons, respectively. In addition, the ^{13}C DEPT of complexes **1** and **2** exhibit six and eight non-protonated carbon peaks, respectively. As a further confirmation of the double bond character of the C=O bond in the N,O ligands, δ_{CO} falls close to 200 ppm [8]. On the basis that δ_{CO} of complexes **1** and **2** relative to free Hbzpy ($\delta_{CO} = 193.5$ ppm) are almost the same, the NMR data are inconsistent with *N*,*O*-coordination of 2-benzoylpyridine. Due to the IR and NMR data, complexes **1** and **2** are consistent with the *N*,*C*-coordination of 2-benzoylpyridine. There are two possible isomers for [Rh(bzpy)(NN)Cl_2] (NN = bipy or phen) deduced from the hetero-bischelated complexes as displayed below.



In the *cis*-α conformation, $H_{b3'}$ of the phenyl moiety of the bzpy ligand is located above (or below) the pyridine of the bipy/phen ligand (see Fig. 1). For complex **1**, the resonance position of $H_{b3'}$, $\delta = 7.66$, is somewhat deshielded compared to that of $H_{b4'}$, $\delta = 7.25$, as presented in Section 2. This is therefore inconsistent with the NMR chemical shift data since this hydrogen would indeed be more shielded due to the π-electron ring current of pyridine. In the *cis*-β isomer, however, H_{b6} of the pyridyl moiety of the bzpy ligand is located below the plane of the pyridine of the bipy/phen ligand, which exhibit significant upfield shifts as expected due to the shielding effect of the ring current. For complex **1**, the resonance position of H_{b6}, $\delta = 8.79$, is more shielded compared to $H_{b'6}$ in the plane of the pyridine of the bipy ligand, $\delta = 9.19$, as expected by the shielding effect of the ring current. Therefore, the NMR chemical shift data of complex **1** are consistent with

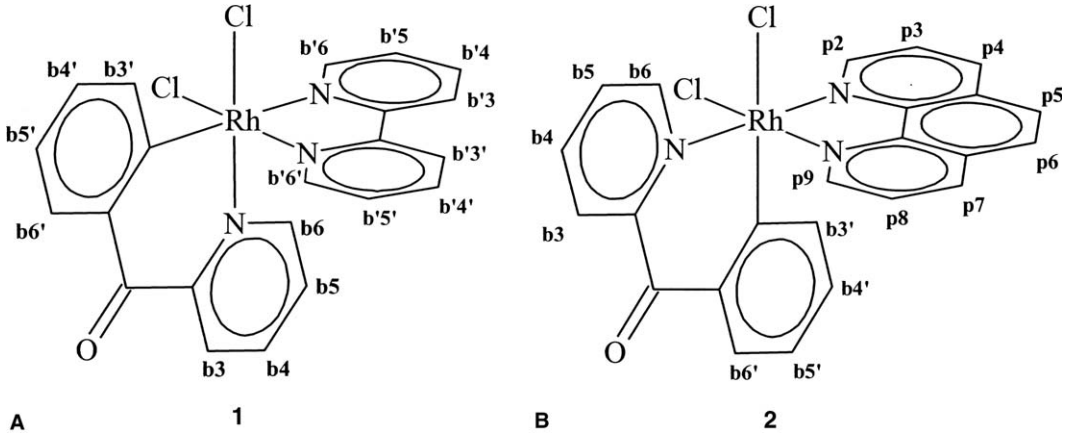


Fig. 1. The proposed structures of *cis*-[Rh(bzpy)LCl_2]: (A) *cis* β-[Rh(bzpy)(bipy)Cl_2] (**1**); (B) *cis* α-[Rh(bzpy)(phen)Cl_2] (**2**).

the *cis*-β structure as illustrated in Fig. 1. The conformer of complex **1** is further evidenced by the NOESY experiment, available in the supplementary material. $H_{b'6}$ (b′ = bipy) is spatially correlated with H_{b6} of pyridine in bzpy as demonstrated in the same figure.

For complex **2**, the chemical shift of $H_{b3'}$, $\delta = 5.86$, more upfield than that of $H_{b6'}$, $\delta = 7.67$, is due to the anisotropic effect resulting from the inductive ring current of the pyridyl ring. $H_{b3'}$ is located just above (or below) the pyridine of the phen ligand, and hence corresponds to the relative location of protons in space for the *cis*-α structure as illustrated in Fig. 1. The appearance of the chemical shift of $H_{b'6}$ for complex **1**, $\delta = 9.19$, more upfield than that of H_{p2} for complex **2**, $\delta = 9.55$, is due to the π-donor ability of the metallated phenyl ring, which is located *trans* to $H_{b'6}$, as demonstrated in the same figure.

Further assignments of the ^{1}H NMR spectra for complexes **1** and **2** have been done through ^{1}H COSY NMR experiments, available in the supplementary material.

3.2. Absorption spectra

The free Hbzpy ligand exhibits one intense ($\varepsilon \sim 10^4\ cm^{-1}\ M^{-1}$) absorption at about $3.78 \times 10^4\ cm^{-1}$, arising from the spin-allowed π–π* transition. The weaker ($\varepsilon \sim 10^2\ cm^{-1}\ M^{-1}$) absorption band observed at about $2.84 \times 10^4\ cm^{-1}$ is assigned as the carbonyl n–π* transition on the basis that the energy of this absorption peak exhibits a hypsochromic shift when the solvent polarity is increased [7]. The room temperature absorption spectra for complexes **1** and **2** are presented in Fig. 2A. Both shows an intense ($\varepsilon \sim 10^4\ cm^{-1}\ M^{-1}$) absorption in the 3.1–$3.9 \times 10^4\ cm^{-1}$ region which most likely arise from a spin-allowed π–π* absorption of the coordinated ligands [7,16]. Each complex also exhibits an intermediate ($\varepsilon \sim 10^3\ cm^{-1}\ M^{-1}$) absorption in the 3.0–$2.7 \times 10^4\ cm^{-1}$ region. According to the absorption spectra of the related free ligands [7,16] and *cis*-$[Rh(dpk)_2Cl_2]^+$ (dpk = di-2-pyridyl ketone) [17], this absorption can be assigned as a carbonyl n–π* band [18], which was not observed for *cis*-$[Rh(bipy)_2Cl_2]^+$ and *cis*-$[Rh(phen)_2Cl_2]^+$ [19]. It is noted that the absorption band profile extended to lower energy (below $2.6 \times 10^4\ cm^{-1}$), which was not observed for the related ligands either. This might be the tail of the carbonyl n–π* band in combination with a rather weak dd* absorption.

The excitation polarization spectrum of complex **1** is shown in Fig. 2B. The excitation polarization spectrum of complex **2** is very similar to that of complex **1**. The symmetry of each complex is lower than C_{2V} and hence only a singly symmetric species is considered in the analysis of the electronic spectrum. In other words, the polarization limits pertaining to planar oscillators will not be pertinent here. The calculated limits are 0.5 and −0.33 [20], resulting from the combination of a linear absorption and a linear emission oscillator. The polarizations in the π–π* region of the two complexes are quite similar, showing little structure having minima (−10% for complex **1**; −14% for complex **2**) in the polarization spectra. These data also reveal that the absorption and emission are both linear oscillators [20]. Deviation of the polarization from −0.33 may be explained by the existence of other states having similar energies in the region [21].

The slightly structured shape and increased value for the excitation polarization spectrum in the $3.3–2.5 \times 10^4\ cm^{-1}$ region suggest that there may be more than one absorption mode involved in this region, consistent with the carbonyl n–π* transitions assignment. The polarization spectra increase sharply to about 0.20 in the lowest energy wavelength region (below $25 \times 10^4\ cm^{-1}$) for both complexes. The magnitude that approaches the limit value 0.5 is expected for a linear absorber-linear emitter case [20]. Therefore, involvement other transitions is implied and one could reasonably conclude that the dd* absorption is buried in this low-energy region. Therefore, the carbonyl n–π* transition must be involved and in which all spin-forbidden dd* transitions were likely buried, similar to that of *cis*-$[Rh(dpk)_2Cl_2]^+$ [17].

3.3. Luminescence properties

Hbzpy shows a structural emission with a single vibrational progression of $1650\ cm^{-1}$, assigned as an n–π* transition [22]. The emission spectra recorded in ethanol/

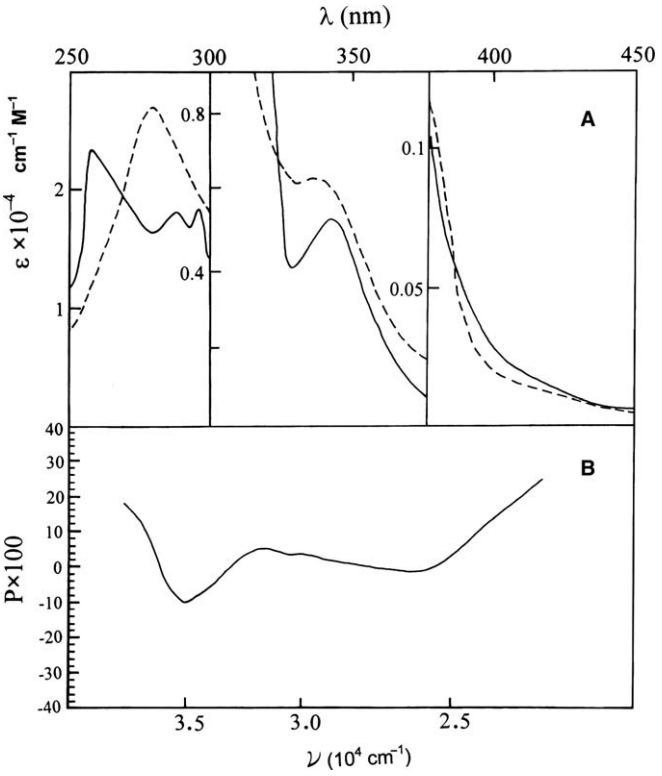

Fig. 2. Absorption and excitation polarization spectra: (A) absorption spectra (room temperature): *cis* β-$[Rh(bzpy)(bipy)Cl_2]$ (**1**) (——); *cis* α-$[Rh(bzpy)(phen)Cl_2]$ (**2**) (– –). (B) excitation polarization spectrum of *cis* β-$[Rh(bzpy)(bipy)Cl_2]$ (**1**) (77 K, 689 nm emission).

methanol (9:1, v/v) at 77 K of complexes **1** and **2** are presented in Fig. 3. No emission behavior is observed at room temperature. Contained in Table 1 are the luminescent data of these complexes. The red emissions ($1.2–1.7 \times 10^4$ cm^{-1}) recorded for complexes **1** and **2** are broad (with around 2.2×10^3 cm^{-1} in half-width) and both are symmetric and structureless, as seen in Fig. 3. The lifetimes measured at the emission maximum are respectively 58 and 60 μs for complexes **1** and **2** (see Table 1). The energy of the emission peak is unaffected by changing the solvent from ethanol/methanol to DMSO. In comparison with the band shape, lifetime and peak position studies performed on the cyclometallated Rh(III) complexes [3], the emission types of complexes **1** and **2** have excluded the possibilities of ^{3}MLCT, ^{3}SBLCT or $^3\pi\pi^*$ emissions and hence are classified as a dd* phosphorescence [17,23].

The emission polarization spectra of both complexes, excited at 313 and 365 nm, are flat with a vanished slope. This observation indicates that the combination of absorber and emitter(s) gives the same polarization across the emission band. Therefore, it is reasonable to conclude that there is no other emission buried in the observed emission band. In other words, both complexes show a band of single emissions rather than multiple ones.

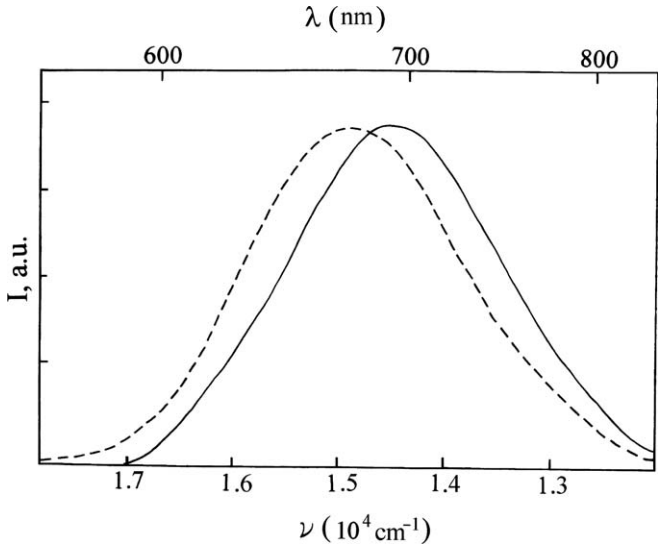

Fig. 3. Emission spectra of *cis* β-[Rh(bzpy)(bipy)Cl_2] (**1**) (——) and *cis* α-[Rh(bzpy)(phen)Cl_2] (**2**) (––) (77 K, 313 nm excitation).

Table 1
Phosphorescence data and lifetime (τ) for Rh(III) complexes at 77 K

Complex	Phosphorescence[a]	
	ν_{max} ($\times 10^4$ cm^{-1})	τ_p (μs)
1	1.45	58
2	1.49	60
cis-[Rh(bipy)$_2$$Cl_2$]$^+$	1.42[b]	47[b]
cis-[Rh(phen)$_2$$Cl_2$]$^+$	1.41[b]	41[b]

[a] In EtOH/MeOH (9:1).
[b] Ref. [16].

No emission could be detected from [Rh(Hbzpy)(bzpy)Cl_2] [12], but emission could be obtained from *cis*-[Rh(bzpy)(NN)Cl_2] (NN = bipy/phen). On one hand, it might be possible that the emission is occurring but is beyond the detection limits of our equipment [24]. On the other hand, it is possible that the phenyl ring of chelated Hbzpy can undergo rotation and then facilitate the non-radiative energy loss in this complex [25]. The bipyridyl-like ligands are more rigid than the *N*,*O*-coordinated Hbzpy ligand. When the N,O ligand (Hbzpy) is substituted by bipy/phen (a more rigid ligand), the emission could be observed. The latter reason at least is therefore supported by our results.

The metallated phenyl ring of bzpy is a weaker π-acceptor and a stronger-donor compared to bipy or phen. A strong-donor can move the metal d*(e_g) orbitals to a higher energy, but a strong π-acceptor can lead to the lowering of the metal d(t_{2g}) orbitals. Therefore, the dd* emission of complexes **1** and **2** were observed at a higher energy than that of *cis*-[Rh(bipy)$_2$$Cl_2$]$^+$ and *cis*-[Rh(phen)$_2$$Cl_2$]$^+$ (see Table 1) [16]. It is examined that the degree of raising of the metal d*(e_g) orbitals for complexes **1** and **2** is more than the degree of lowering of the metal d(t_{2g}) orbitals for *cis*-[Rh(bipy)$_2$$Cl_2$]$^+$ and *cis*-[Rh(phen)$_2$$Cl_2$]$^+$, which results in the higher energy gap of the ^{3}d–d* excited state for complexes **1** and **2**. In other word, bzpy exhibits a higher ligand field strength compared with that of bipy or phen.

3.4. Electrochemical properties

Electrochemical studies were conducted in 0.10 M TEAP/DMSO solutions containing the corresponding Rh(III) complexes. Cyclic voltammetric data such as the peak potentials are collected in Table 2. No oxidation wave was observed when the potential was scanned from 0.0 to +2.0 V.

3.4.1. Electrochemistry of complexes *1* and *2*

The cyclic voltammograms of complexes **1** and **2** have similar patterns, showing two reduction waves, c_I and c_{II} (see Table 2), and no corresponding oxidation wave appeared upon scan reversal with respect to c_I. The number

Table 2
Cyclic voltammetric reduction potentials for Rh(III) complexes[a]

Complex	ν (V/s)	$(E_{pc})_I$	$(E_{pc})_{II}$
1	0.1	−1.19	−1.64
	2.0	−1.24	−1.67
2	0.1	−1.16	−1.65
	2.0	−1.22	−1.69
cis-[Rh(bipy)$_2$$Cl_2$]$^+$	0.1	−0.84[b]	−1.46[b]
cis-[Rh(phen)$_2$$Cl_2$]$^+$	0.1	−0.85[c]	−1.46[c]

[a] Results for 1.2 mM samples in 0.10 M TEAP/DMSO solutions at a Pt electrode. E_{pc} in V vs. SCE.
[b] Ref. [31].
[c] Ref. [32].

of electrons transferred at the wave c_I, estimated from controlled-potential electrolysis experiments at −1.20 and −1.15 V $(E_{pc})_I$, were found to be 1.80 and 1.85 for complexes **1** and **2**, respectively, indicating that wave c_I for both complexes involved essentially a two-electron charge transfer process. An oxidation wave due to oxidation of the chloride ion was also observed at 1.07 V in the voltammograms obtained for the solutions after the electrolysis. For each complex, the ratio of the peak current of the chloride ion to that of wave c_I is close to one, indicating that two chlorides had been eliminated from the complex after electrolysis at wave c_I. It has also been reported that electrochemical reduction of halide-coordinated complexes will generate products via dissociation of halide(s) [26–30]. As stated earlier, the emission of the two complexes is confirmed to be a dd* transition. The two-electron transfer reduction (wave c_I) results in higher electron density on the metal and, hence, destabilizes these complexes. This can rationalize the transfer of two electrons, in which the chemical reaction involves the loss of two chloride ions, and lead to the irreversible process at wave c_I.

The more negative values of $(E_{pc})_I$ obtained for complexes **1** and **2** compared to those reported for *cis*-$[Rh(bipy)_2Cl_2]^+$ and *cis*-$[Rh(phen)_2Cl_2]^+$, as shown in Table 2, may be ascribed to the higher electron densities on the metal. This is well understood based on the nature of the negatively charged bzpy ligand, which is a better σ-donor but a poorer π-acceptor (vide supra). On the whole, reductions of the neutral species are more demanding than those for the cationic complexes.

Normal pulse voltammograms (NPV) were also recorded for the two complexes. Similar to the cyclic voltammograms, the NPV also exhibited reduction waves c_I and c_{II} for each complex. It was found that the ratio of the limiting current of waves c_I and c_{II} is 2:1. Furthermore, the ratio of the peak current of wave c_I to that of wave c_{II} is also close to two at relatively high scan rates. Because wave c_I is a two-electron charge transfer process, this result suggests that wave c_{II} is possibly a one-electron charge transfer process. When phenol was added into the solutions as the proton donor, no significant changes were observed for wave c_I in the cyclic voltammograms of the complexes, suggesting that wave c_I is due to the reduction at the metal-localized orbitals. On the other hand, the addition of phenol resulted in an evident potential shift and peak current increased for wave c_{II}. Based on the influence of phenol, the reduction at wave c_{II} can be assigned to be localized at the carbonyl π* orbital of bzpy. The same result was observed for the pik-coordinated or dpk-coordinated complexes of rhodium(III) [13,17].

4. Conclusions

In this study, two heteroleptic cyclometallated Rh(III) complexes, *cis*-$[Rh(bzpy)(bipy)Cl_2]$ (**1**) and *cis*-$[Rh(bzpy)(phen)Cl_2]$ (**2**), have been synthesized and characterized. The anionic bzpy ligand is *N*,*C* coordinated to Rh(III) based on IR and NMR data. Through analysis of NMR chemical shifts, structures of complexes **1** and **2** are consistent with *cis*-β and *cis*-α conformers, respectively. Each complex shows high intensity bands in the UV region, assigned as spin-allowed π–π* transitions. The medium-intensity absorption band profile in the lower energy region can be explained by convolution of carbonyl n–π* and d–d* transitions. At 77 K, each complex shows a broad, symmetric and structureless red emission with microsecond lifetime, assigned as dd* phosphorescence. The electrochemical data also provide evidence in support of the assigned dd* emissions of the two complexes. The first two-electron reduction process occurs at the metal and is coupled with the elimination of two chlorides. Through examination of the influence of phenol on the reduction potentials, the redox orbital involved in the second reduction is assigned as the π* orbital localized at the carbonyl fragment of bzpy.

5. Supplementary material

2D NMR for complexes **1** and **2** are available from the author on request. Copies of the data can be obtained free of charge on application to The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK, fax: +44 1223 336033, e-mail: deposit@ccdc.cam.ac.uk or http:www.ccdc.cam.ac.uk.

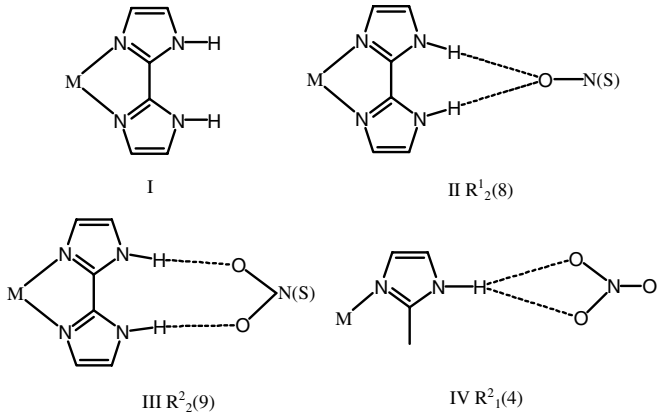

Scheme 1. Three supramolecular synthons (II–IV) formed by M(H_2biim) (I) and SO_4^{2-}(NO_3^-).

elemental analyzer. IR spectra were recorded on a Magna 750 FT-IR spectrometer photometer as KBr pellets in the 4000–400 cm^{-1}. Fluorescent spectra were measured with a PE LS55 fluorescent analytical instrument.

2.1. Synthesis of $[Zn(H_2biim)_3]SO_4$ (1)

A mixture of $ZnSO_4 \cdot 7H_2O$ (0.144 g, 0.5 mmol) and H_2biim (0.134 g, 1 mmol) in H_2O (16 ml) was heated at 160 °C for three days under autogenous pressure. Colorless single crystals were isolated after the reaction solution was cooled gradually. Yield: 35%. *Anal*. Calc. for $C_{18}H_{18}N_{12}O_4SZn$: C, 38.34; H, 3.22; N, 29.81. Found: C, 38.39; H, 3.28; N, 29.61%. IR (KBr; cm^{-1}): 3450m, 3153m, 3123m, 3069m, 3001m, 2900m, 2815m, 2782m, 2739m, 2686m, 2651m, 1630w, 1544m, 1426m, 1406w, 1384w, 1331w, 1312w, 1148s, 1131s, 1115s, 1106s, 1050s, 988s, 891w, 773m, 759s, 691s, 624m, 617m.

2.2. Synthesis of $[Cu(H_2biim)_2(H_2O)]SO_4 \cdot 3H_2O$ (2)

A mixture of $CuSO_4 \cdot 5H_2O$ (0.063 g, 0.25 mmol) and H_2biim (0.067 g, 0.5 mmol) in H_2O (16 ml) was heated at 160 °C for about five days under autogenous pressure. The resulting mixture was filtered off after the reaction solution was cooled down gradually. The filtrate was left in air to evaporate the solvent, and crystals were obtained after one week. The product was collected by filtration, washed with ethanol and dried in air. Yield: 34%. *Anal*. Calc. for $C_{12}H_{20}CuN_8O_8S$: C, 25.56; H, 3.58; N, 19.88. Found: C, 25.73; H, 3.65; N, 19.99%. IR (KBr; cm^{-1}): 3436m, 3121m, 2994m, 2916m, 1628w, 1524s, 1429m, 1384w, 1324m, 1179s, 1134s, 1107s, 1002w, 851w, 802w, 758m, 681m, 617m.

2.3. Synthesis of $[Cd(H_2biim)_2(NO_3)(H_2O)]_4(NO_3)_4$ (3)

A suspension of H_2biim (0.143 g, 1 mmol) in water (20 ml) was added slowly to $Cd(NO_3)_2 \cdot 4H_2O$ (0.308 g, 1 mmol) dissolved in water (20 ml), with stirring. The mixture was stirred at 80 °C for 30 min. The resulting solution was filtered. The filtrate was left in air to evaporate and crystals were obtained after a few days. Colorless crystals were collected by filtration, washed with water and dried under vacuum. Yield: 42%. *Anal*. Calc. for $C_{48}H_{56}Cd_4N_{40}O_{28}$: C, 27.57; H, 2.70; N, 26.80. Found: C, 27.59; H, 2.81; N, 26.77%. IR (KBr; cm^{-1}): 3245m, 3204m, 3144m, 3122m, 3076m, 3001m, 2898m, 2807m, 1632w, 1547m, 1524m, 1384s, 1218w, 1172w, 1105s, 1094s, 988w, 940m, 888w, 832w, 762m, 748m, 689w, 669m.

2.4. Synthesis of $[Zn(H_2biim)_2(H_2O)](NO_3)_2$ (4)

A suspension of H_2biim (0.268 g, 2 mmol) in water (30 ml) was added slowly to $Zn(NO_3)_2 \cdot 6H_2O$ (0.297 g, 1 mmol) dissolved in water (20 ml), with stirring. The mixture was stirred at 353 K for 30 min. The resulting solution was filtered. The filtrate was left in air to evaporate and crystals were obtained after a few days. Colorless crystals were collected by filtration, washed with water and dried under vacuum. Yield: 75%. *Anal*. Calc. for $C_{12}H_{14}N_{10}O_7Zn$: C, 30.30; H, 2.97; N, 29.45. Found: C, 30.45; H, 3.05; N, 29.40%. IR (KBr; cm^{-1}): 3251m, 3153s, 3128s, 3048m, 3005m, 2936w, 2767w, 1646w, 1624w, 1529s, 1513w, 1426m, 1384s, 1312s, 1176s, 1130s, 1105s, 1048w, 997w, 936w, 833w, 769s, 753s, 716w, 683s.

2.5. X-ray single-crystal determination

Suitable single crystals of complexes **1**–**4** were mounted on a Siemens Smart CCD diffractometer equipped with graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at 298 K. All absorption corrections were performed using the SADABS program. All structures were solved by direct methods and refined by full-matrix least-squares fitting on F^2 by SHELXTL-97 [6]. All non-hydrogen atoms were refined with anisotropic thermal parameters. Hydrogen atoms were located at geometrically calculated positions and treated by a mixture of independent and constrained refinement. Crystallographic data and structural refinements for compounds **1**–**4** are summarized in Table 1. Selected bond distances and angles are listed in Table 2.

3. Results and discussions

3.1. $[Zn(H_2biim)_3]SO_4$ (1)

The asymmetric unit of **1** consists of half of $[Zn(H_2biim)_3]^{2+}$ and SO_4^{2-}. The structure of the cation is shown in Fig. 1. It has crystallographic C_2 symmetry with the twofold rotation axis going through Zn^{2+} and the middle of the C8–C8′ bond. The coordination geometry of the zinc(II) center can be described as a distorted $[ZnN_6]$ octahedron with the six nitrogen atoms from the chelating H_2biim ligands. A comparable example is $[Zn(H_2biim)_2]_2$-(μ-H_2biim) [8] reported by Krebs et al. wherein Zn^{2+} is

Symmetry code: **1**: #1: $-x+1$, $-y+2$, z; **4**: #1: $-x$, y, $-z+1/2$.

five-coordinated. The Zn–N distances [Zn–N1, 2.16(1); –N3, 2.22(1); –N5, 2.20(1) Å] are similar to those of the reported Zn–H_2biim complexes (Zn–N, 2.030–2.240 Å) [7,8]. The bond angles around Zn^{2+} deviate appreciably from the ideal octahedral values with the maximum deviations being, as expected, due to the chelating 'bite' of H_2biim. The N–Zn–N bite angles (av. 76.9°) are slightly smaller than in the known Zn–H_2biim complexes (78.2–80.0°) [4d,8].

Each sulfate anion interacts with the surrounding three $[Zn(H_2biim)_3]^{2+}$ units via six hydrogen bonds, as shown in Fig. 1 (type III, Scheme 1), with the N···O separations

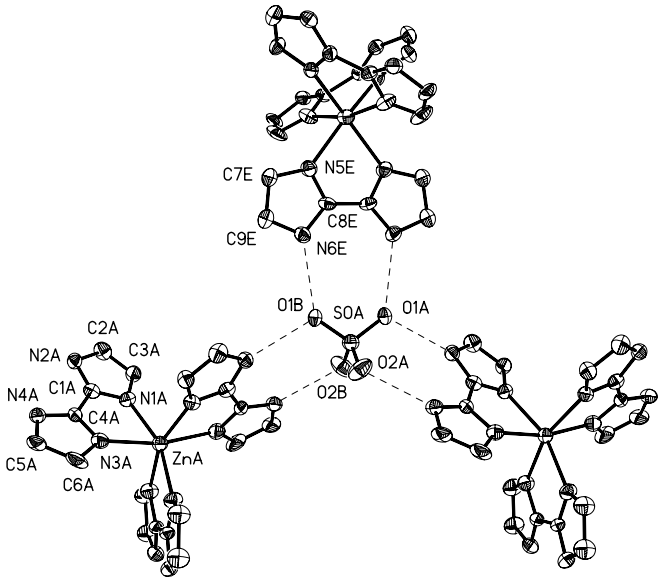

Fig. 1. Hydrogen bonds between $[Zn(H_2biim)_3]^{2+}$ and SO_4^{2-}.

ranging from 2.70(2) to 2.77(2) Å. Each cation is correspondingly linked to three sulfate anions (Fig. 2) to form a supramolecular framework structure as depicted in Fig. 1S in the supplementary material.

3.2. $[Cu(H_2biim)_2(H_2O)]SO_4 \cdot 3H_2O$ (2)

The asymmetric unit of **2** consists of $[Cu(H_2biim)_2(H_2O)]^{2+}$, one SO_4^{2-} and three lattice water molecules. The coordination environment around Cu^{2+} can be described as a distorted square pyramidal geometry (Fig. 3). Four nitrogen atoms of two chelating H_2biim ligands form the basal plane of the pyramid, and the metal is displaced by 0.189 Å from this plane towards the apical ligand, where the apical position is occupied by one water molecule. The Cu–N distances [Cu–N1 = 2.009(2) Å, Cu–N3 = 2.014(2) Å, Cu–N5 = 2.006(2) Å, Cu–N7 = 2.015(2) Å] are shorter than the apical Cu–O distance [2.198(1) Å]. These distances and those of the biimidazole ligand lie in the range observed for biimidazole-Cu complexes retrieved from the CSD [7]. The N–Cu–N bite angles (av. 82.32(8)°) are found in the upper limit of the range registered in the CSD so far (range: N–Cu–N: 78.6–81.6°) [7]. The chelating H_2biim ligands are almost planar, with dihedral angles of 4.6° and 0.7°.

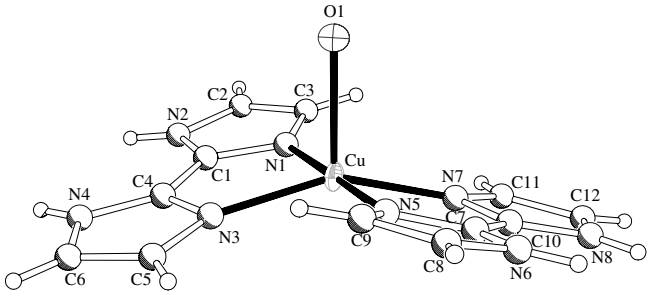

Fig. 3. ORTEP drawing of $[Cu(H_2biim)_2(H_2O)]^{+}$.

Unlike in the case of compound **1**, the hydrogen bond donors of **2** ($[Cu(H_2biim)_2(H_2O)]^{2+}$) have two *trans* H_2biim groups that are nearly coplanar. As a consequence, a hydrogen bonded dimeric structure (Fig. 4) through type II hydrogen bonds (Scheme 1) has been observed for **2** instead of the 3D framework found in **1**. The N···O distances range from 2.762(3) to 3.272(3) Å. It is interesting that the three lattice water molecules that are linked together by hydrogen bonds (2.743–2.780 Å) generate a hexanuclear water cluster through a twofold rotation axis. The water hexamer has an unprecedented open structure consisting of a cyclic water tetramer rather than the cage structure with an energy minimum [9]. The hexameric cluster is stabilized by hydrogen bonding to the sulfate (O1w···O3, 2.716; O1w···O5, 2.778 Å) forming the sulfate-

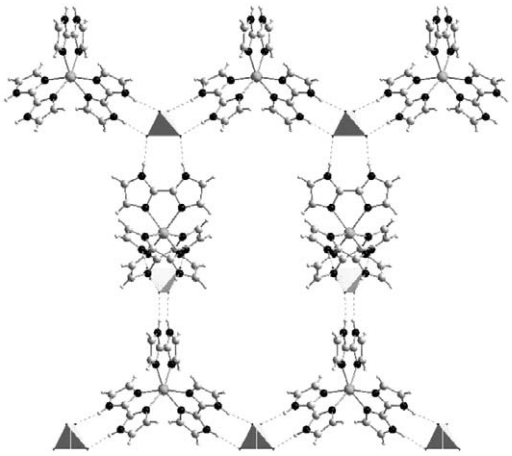

Fig. 2. Extended hydrogen bond network of **1**.

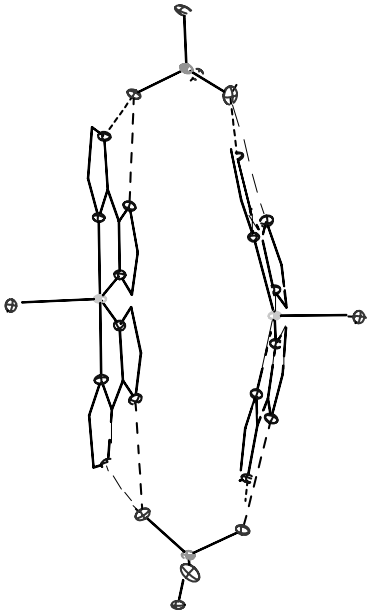

Fig. 4. Hydrogen bonded dimeric structure of $[Cu(H_2biim)_2(H_2O)]SO_4$.

assisted sheet (Fig. 5). There are extensive hydrogen bonds between sulfate and water molecules of coordination and lattice origin, which leads to the formation of the framework structure of **2** (Fig. 6).

3.3. *[Cd(H$_2$biim)(NO$_3$)(H$_2$O)]$_4$(NO$_3$)$_4$ (**3**)*

The molecule of **3** consists of four independent $[Cd(H_2biim)(NO_3)(H_2O)]^+$ cations and four nitrate anions. The bond lengths and angles in the four cations are similar to each other and thus only one set of the selected bond distances and angles are given in Table 2. The cadmium atom has a [CdO2N4] octahedral coordination environment with the four nitrogen atoms from the two H_2biim ligands in equatorial positions and the two oxygen donor atoms from nitrate and water molecules in apical sites (Fig. 7). The Cd–N distances range from 2.279(6) to 2.326(6) Å, slightly shorter than the Cd–O distances (2.364(5), 2.355(6) Å). The N–Cd–N bite angles are 73.9(2)° and 75.0(2)°, smaller than those observed for **1** and **2** as expected for longer Cd–N distances. The two rings of each H_2biim ligand are slightly twisted with dihedral angles of 3.2° and 6.4°.

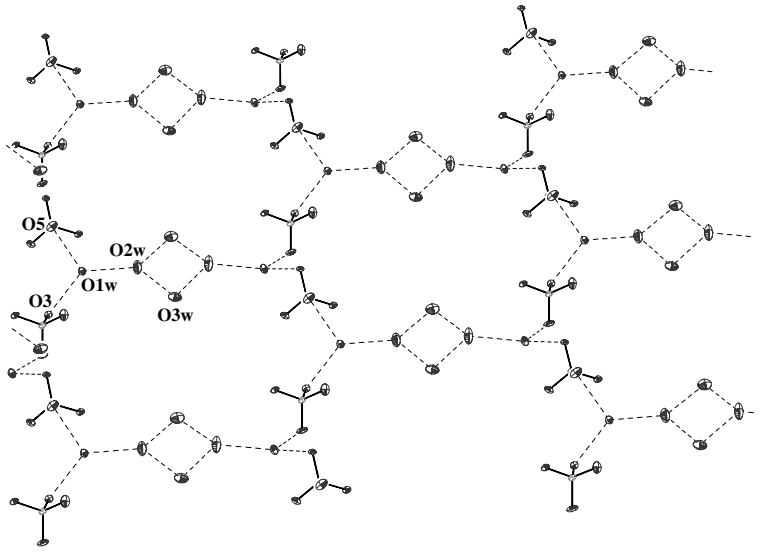

Fig. 5. Sulfate-assisted sheet of the water hexamer.

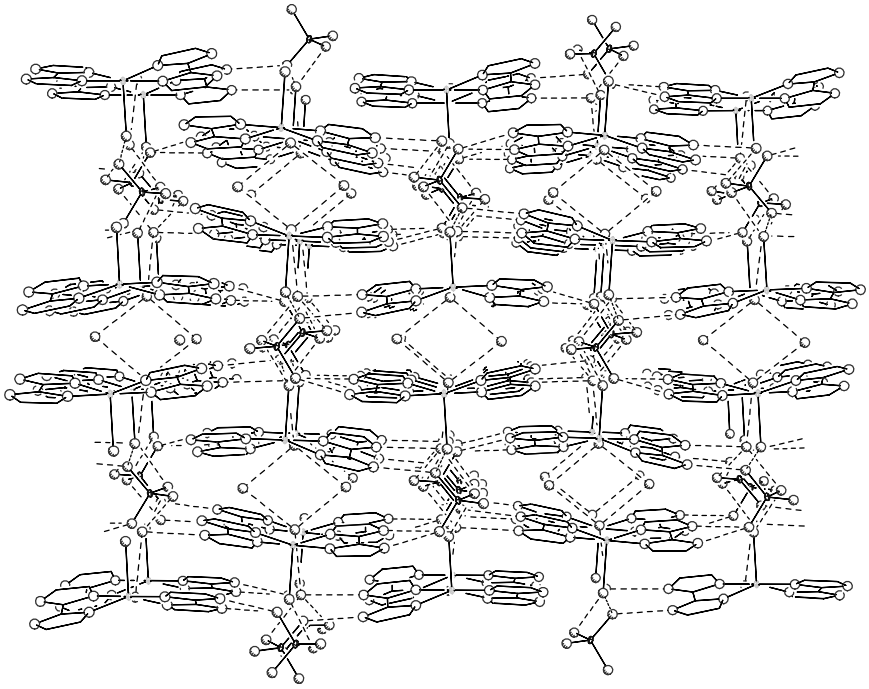

Fig. 6. Supramolecular framework structure of **2**.

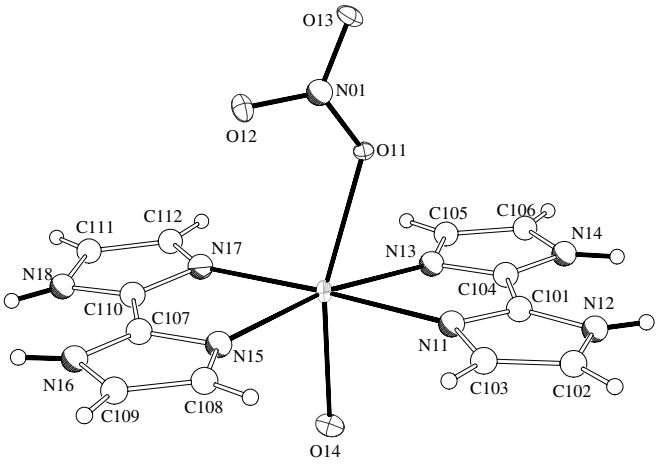

Fig. 7. Molecular structure of one independent $[Cd(H_2biim)_2(H_2O)(NO_3)]^+$.

Although the hydrogen bond donors (cationic H_2biim metal complexes) of **2** and **3** have a similar geometry of donor atoms, the different geometry of the counter-anions leads to their distinct hydrogen bonded structures. Fig. 8 shows the hydrogen bonds between $[Cd(H_2biim)_2(NO_3)(H_2O)]^+$ and nitrate. There are two types of hydrogen bonds ($R_2^1(8)$ and $R_2^2(9)$) that link the cations and counter-anions into a one-dimensional structure. The N···O separations range from 2.829(9) to 3.017(8) Å. The hydrogen bonds (2.749–3.121 Å) between the free nitrate and the apical oxygen donor atoms are responsible for the two-dimensional structure (see Fig. 9). The further hydrogen bonds (2.730–3.070 Å) between the coordinated nitrate and water molecules interconnect the layers into the network structure as illustrated in Fig. 10.

3.4. $[Zn(H_2biim)_2(H_2O)](NO_3)_2$ (**4**)

Complex **4** consists of two $[Zn(H_2biim)_2(H_2O)]_{1/2}$ and two nitrate anions. $[Zn(H_2biim)_2(H_2O)]^{2+}$ shown in Fig. 11 has C_2 symmetry with the twofold rotation axis going through the Zn^{2+} ion and apical oxygen donor atom. The coordination environment around the Zn^{2+} ion can be described as a distorted square pyramidal geometry. The four nitrogen atoms of the two chelating H_2biim ligands form the basal plane of the pyramid (mean plane: 0.2994 Å) [Zn1–N1 = 2.055(5) Å, Zn1–N3 = 2.154(5) Å]. The Zn–O distances are slightly different (Zn1–O1 = 2.032(8) Å). These values and those in the H_2biim ligands are comparable with those registered for biimidazole-Zn complexes in the CSD [Zn–N, 2.030–2.240 Å]. The bite angles [N1–Zn1–N3 = 81.8(2)°] lie in the upper limit of the range registered in the CSD so far (range: 76.9–81.6°).

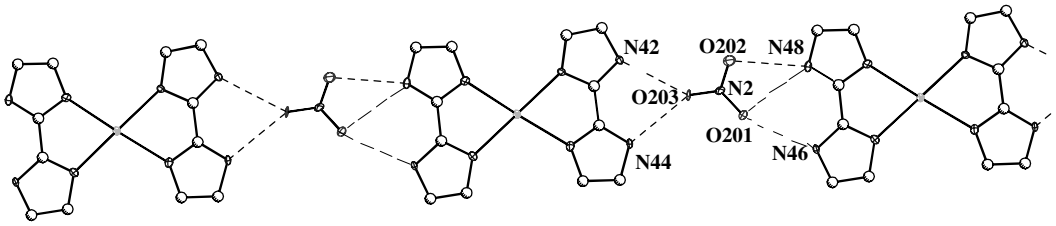

Fig. 8. Hydrogen bonded ribbon structure of $[Cd(H_2biim)_2(H_2O)(NO_3)]NO_3$.

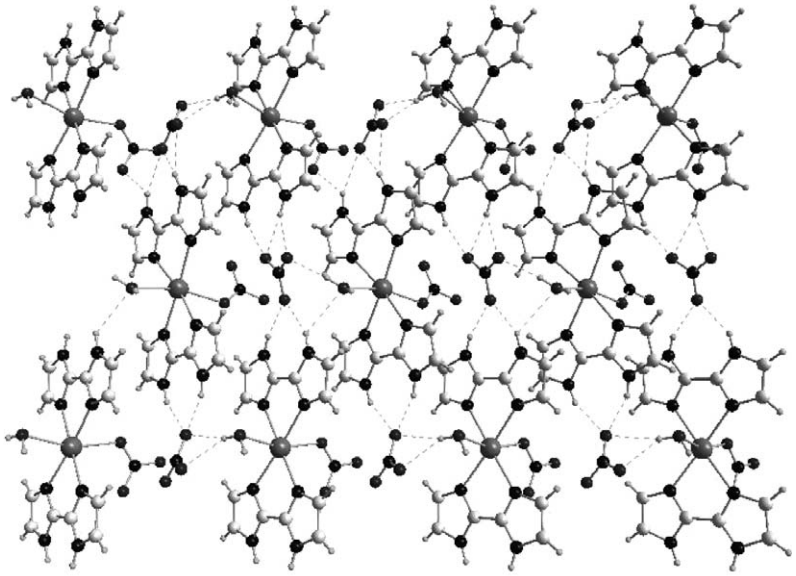

Fig. 9. Two dimensional structure of **3**.

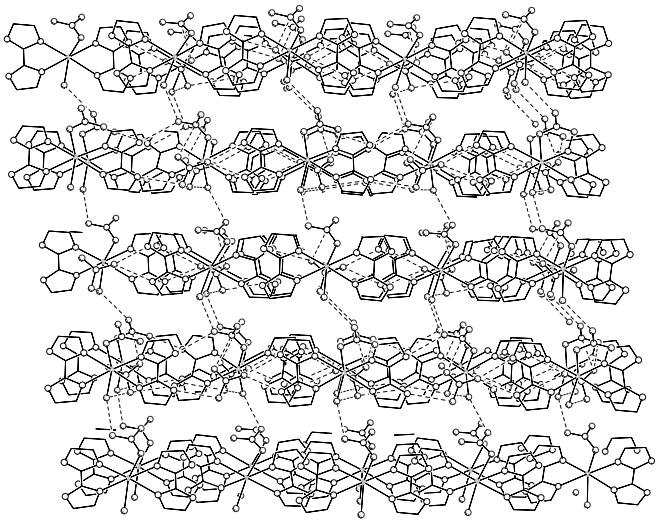

Fig. 10. Network structure of **3**.

Although the hydrogen bond donor $[Zn(H_2biim)_2(H_2O)]^{2+}$ of **4** has two *trans* H_2biim groups, as in the case of **3**, the hydrogen bonding patterns between the donors and acceptors are quite different. In compound **4**, the acceptors are hydrogen bonded to the only one donor via Type II ($R_2^1(8)$) hydrogen bonds to form a discrete structure. This may be attributed to the two non-coplanar H_2biim groups in **4** with the dihedral angle of 32°. The N···O separations range from 2.801(8) to 2.815(8) Å. Additional hydrogen bonds between nitrate and the apical oxygen atoms (O···O, 2.719(7) and 3.079(7) Å) account for the formation of an infinite tape structure with a pitch of 12.29 Å running along the *c* axis (Fig. 11). A single hydrogen bond between H_2biim and nitrate (N···O, 3.168(8) Å) interconnect the tapes into a three-dimensional architecture as shown in Fig. 2S in the supplementary material.

3.5. Fluorescent properties

The emission and excitation spectra of H_2biim and compounds **1**–**4** in the solid state at room temperature are shown in Fig. 3S in the supplementary material. Compounds **1**, **3** and **4** have the same ligands and thus a comparison of the fluorescence spectra of H_2biim, **1**, **3** and **4** are suggestive of the emission origin and influence of metal coordination. H_2biim exhibits a broad photoluminescence emission at 334 nm ($\lambda_{ex} = 431$ nm) similar to that of Me_2biim ($\lambda_{em} = 330$ nm, $\lambda_{ex} = 305$). [9] The single emission maximum at 425 nm ($\lambda_{ex} = 350$ nm) in **1** with three chelating H_2biim is similar to those in free H_2biim. Compounds **3** and **4** with the two chelating H_2biim ligands exhibit very similar fluorescence spectra [422 and 485 nm ($\lambda_{ex} = 350$ nm) for **3**, and 426 and 470 nm ($\lambda_{ex} = 340$ nm) for **4**], that are independent of the metal center and the axial coordination. It is obvious that the axial coordination makes significant influence on the photoluminescence.

4. Conclusion

A systematic study of the hydrogen bonded system constructed by cationic M–H_2biim fragments as donors and inorganic counter-anions (sulfate, nitrate) as acceptors has been established. The M–H_2biim moieties can serve as effective hydrogen bonding donors to construct supramolecular structures via strong hydrogen bonding with inorganic counter-anions. Three types of supramolecular synthons (Type II ($R_2^1(8)$), III ($R_2^2(9)$), IV ($R_1^2(4)$)) have been observed. Those with six peripheral donor atoms such as $[Zn(H_2biim)_3]^{2+}$ in **1** can form a 3D hydrogen bonded framework with spherical inorganic counter-anions such as SO_4^{2-}. The cationic donors with *trans* H_2biim groups can form discrete, dimeric and 1D hydrogen bonded structures depending on the shapes of the counter-anions and the coplanarity of the two H_2biim groups. The coplanar arrangement of the H_2biim groups favors the 1D hydrogen bonded structure. These hydrogen bonded structures may allow the presence of unusual water clusters as observed in **2**.

the coordination around the metal centre is approximately octahedral.

The molecular heterometallic iron-containing trinuclear carboxylates $[Fe_2MO(RCOO)_6(L)_3]$, where M is a bivalent 3d transition metal, attract special attention due to being able to provide an opportunity to study many spin-coupling interactions in the system with the same configuration [18]. A considerable number of such complexes containing either heterometallic $[Fe_2MnO]^{6+}$ [18,19], $[Fe_2CoO]^{6+}$ [20,21], $[Fe_2NiO]^{6+}$ [18,22], $[Fe_2ZnO]^{6+}$ [23,24] or homometallic mixed-valence $[Fe_2FeO]^{6+}$ [4,25–34] cores, has been investigated by various methods.

All of the above-mentioned complexes contain iron (III) and bivalent 3d metals: Mn, Fe, Co, Ni, Zn. The difference in the atomic radii of iron and the other 3d elements is negligible. For example, the atomic radius of high-spin iron (III) is equal to 0.65 Å, while the atomic radii for 3d bivalent elements Mn(II), Fe(II), Co(II), Ni(II) range from 0.75 to 0.80 Å. This difference does not essentially influence the stability of the trinuclear $[Fe_2MO]$ core. A survey of the CCDC [35] revealed that in neutral complexes which include a $\{Fe_2^{III}Fe^{II}O\}$ core, the average Fe···Fe separation is equal to 3.280(2) Å (Fe–O(μ_3) 1.875(3) Å, Fe–O_{carb} 2.040(3) Å). In ionic compounds with a $\{Fe_3^{III}O\}$ core, the corresponding distances adopt the values 3.290(2), 1.890(2) and 2.025 Å, respectively. These values suggest a skeleton of the molecular structure with a symmetry close to D_{3h}.

Previously reported was the preparation and the study of complexes containing the $[Fe_2MgO]^{6+}$ core [22]. In the compound $[Fe_2MgO(CCl_3COO)_6(Py)_3]\cdot CH_3C_6H_5$, one iron atom occupies a special position on the mirror plane, while the other iron and the magnesium atom of the Fe_2MgO core occupy the known general position with equal probability (50%). This arrangement occurs in spite of a different mode of interaction of the coordination environment with the d(Fe) and s(Mg) metals. The rather different ionic radii of Fe(III) 0.65 Å and Mg(II) 0.72 Å conserved a practically equilateral triangle of the three metal atoms. The geometric rather than the electronic factor, probably, avoid any dramatic rearrangements in the trinuclear cluster.

The present study describes the results obtained with the alkaline-earth elements Ca (ionic radius 1.00 Å), Sr (1.18 Å) and Ba (1.35 Å) and the way to synthesize new iron-containing molecular μ_3-oxo clusters.

2. Experimental

2.1. General

The carbon and hydrogen content was determined by standard micro-methods. Atomic absorption spectroscopy was used to determine the Fe(III), Ca(II), Sr(II) and Ba(II) content.

IR spectra of polycrystalline samples were recorded as oil mulls on a Specord M-75 spectrophotometer.

TG studies were performed on a Paulik–Paulik–Erdey derivatograph in air, with Al_2O_3 as the standard calibration. DTG – 1/5; DTA – 1/10; TG – 100/100. T_{max} = 1000 °C for **1** and **3**, and 500 °C for **2**.

Magnetic measurements of **1** and **3** were performed using the Gouy method in the temperature range 110.0–293.0 K. The temperature of the sample was determined with ±1.5 K accuracy using the Cu–Constantan thermocouple. The variable temperature susceptibility of **2** was measured with an Oxford Instruments Vibrating Sample Magnetometer (VSM) working between 0 and 12 T and in the 1.5–350.0 K temperature range. Diamagnetic Pascal's constants were used to correct the magnetic values [36].

The Mossbauer spectrum for **1** was acquired using a constant acceleration system with a symmetrical waveform. A ^{57}Co (1.0 MBq) source in a Rh matrix was used, but the isomer shift refers to α-Fe.

2.2. Synthesis

Most of the precursors, except $Ca(CCl_3COO)_2\cdot 4H_2O$, $Sr(CCl_3COO)_2\cdot 4H_2O$ and $Ba(CCl_3COO)_2\cdot 4H_2O$, which were synthesized by the reaction between $CaCO_3$, $SrCO_3$or $BaCO_3$ with trichloroacetic acid, were commercially obtained and used without any further purification.

All the products are air stable and also soluble in common organic solvents such as MeOH, EtOH, THF, CH_3CN and DMSO. Single crystals suitable for X-ray crystallography for **1** and **3** were obtained by slow evaporation of their THF solutions, at room temperature.

2.2.1. Synthesis of $[Fe_2CaO(CCl_3COO)_6(THF)_4]\cdot THF$ (**1**)

A mixture of $Fe(NO_3)_3\cdot 9H_2O$ (0.808 g, 2.00 mmol) and $Ca(CCl_3COO)_2\cdot 4H_2O$ (1.748 g, 4.00 mmol) in 30 ml of methanol was heated on a water bath (~70 °C) with permanent stirring until dryness. The solid product was extracted with three small portions (10 ml) of THF. After 2 days a light red microcrystalline material precipitated from the THF solution, which was filtered off, washed with hexane and finally dried in air. Yield: 65% (on iron basis). *Anal.* Calc. for $C_{32}H_{40}Cl_{18}O_{18}CaFe_2$: C, 25.58; H, 2.68; Fe, 7.43; Ca, 2.67. Found: C, 25.27; H, 2.54; Fe, 7.32; Ca, 2.48%. IR data (oil mulls, cm^{-1}): 3650 m, 3470 mb, 1700 m, 1673 msh, 1645 s, 1593 s, 1590 m, 1380 s, 1340 s, 1010 w, 940 w, 832 s, 826 s, 748 sh, 720 m, 675 m, 670 s, 469 m, 440 m.

2.2.2. Synthesis of $[Fe_2SrO(CCl_3COO)_6(THF)_6]\cdot 0.5THF\cdot 0.5H_2O$ (**2**)

The light red coloured complex **2** was synthesized identically to **1**, but using $Sr(CCl_3COO)_2\cdot 4H_2O$ instead of $Ca(CCl_3COO)_2\cdot 4H_2O$. Yield: ~ 52% (on iron basis). *Anal.* Calc. for $C_{38}H_{53}Cl_{18}O_{20}Fe_2Sr$: C, 27.37; H, 3.20; Fe, 6.70; Sr, 5.25. Found: C, 27.11; H, 3.17; Fe, 6.31; Sr, 5.01%. IR data (oil mulls, cm^{-1}): 3650 m, 3540 mb, 3180 wb, 1690 s,

1675 ssh, 1660 s, 1380 s, 1340 ssh, 1030 w, 1015 w, 950 w, 910 w, 830 ssh, 820 s, 740 s, 730 msh, 690 msh, 675 s, 460 m, 430 w.

2.2.3. Synthesis of $[Fe_2BaO(CCl_3COO)_6(THF)_6]\cdot 0.5THF\cdot 0.5H_2O$ (3)

A mixture of $Fe(NO_3)_3\cdot 9H_2O$ (0.808 g, 2.00 mmol) and $Ba(CCl_3COO)_2\cdot 4H_2O$ (2.136 g, 4.00 mmol) in 50 ml of methanol was heated on a water bath (~70 °C) with stirring for 3 h. The solution was filtered to remove insoluble $Ba(NO_3)_2$ and evaporated at room temperature. The solid product was dissolved in 50 ml THF. After 1 week, as a result of very slow evaporation, a dark red crystalline material was filtered off, washed with hexane and air dried. It is necessary to mention that using this procedure crystals up to ~0.5 cm^3 were obtained. Yield: ~83% (on iron basis). *Anal*. Calc. for $C_{38}H_{53}Cl_{18}O_{20}BaFe_2$: C, 26.58; H, 3.11; Fe, 6.50; Ba, 8.00. Found: C, 25.88; H, 2.91; Fe, 6.60; Ba, 7.68%. IR data (oil mulls, cm^{-1}): 3460 mb, 1675 s, 1630 s, 1380 s, 1340s, 1120 vw, 1020 m, 940 w, 890 vw, 860 sh, 832 s, 820 s, 720 m, 690 m, 670 s, 465 m, 445 w.

2.3. Crystallographic data

The structural parameters together with details of data collection and refinement for compounds **1** and **3** are given in Table 1.

The X-ray intensity data for **1** were collected at 150 K on a Nonius Kappa CCD diffractometer equipped with graphite monochromated Mo Kα radiation using ω rotation with a sample-to-detector distance of 40 mm. Unit cell parameters were obtained and refined using the whole data set. Frames were integrated and corrected for Lorenz and polarization effects using DENZO [37]. The scaling, as well as the global refinement of the crystal parameters, was performed by SCALEPACK [38]. Reflections, which were partly measured on previous and subsequent frames, were used to scale these frames on each other. The absorption correction for **1** and **3** were introduced by a semi-empirical method based on symmetry equivalent reflections [37].

Data collection for **3** was performed on a KUMA KM-4 CCD diffractometer equipped with graphite monochromated Mo Kα radiation at 100 K. The unit cell determination and data integration were carried out using the CrysAlis package of Oxford Diffraction [39]. Intensity data were corrected for Lorentz and polarization effects. The mean value of 0.693 for $|E^2-1|$ suggested a non-centrosymmetric space group, but taking into consideration the R_{int} 0.071 value for the Laue group $4/m$ and systematic absences, the structure settlement with SHELXS-97 [40] was initially envisaged by using the $P4_2/nmc$ space group. The $M_3O(COO)_6$ core was easily recognized on the Fourier map though further calculations of the ΔF maps did not allow a better value of R than 0.12 to be obtained. In subsequent attempts, the structure was successfully solved via SHELXL-97 [40] using a twinning approach by introducing the instruction TWIN 0 1 0 1 0 0 0 0 $\bar{1}$. The fractional contributions of the two twin domains in structure **3** are in a 1:1 ratio. Refinement of the structures revealed that THF (coordinated to Fe) in compound **1**, one of the two THF

(coordinated to Ba), as well as solvated THF molecules in **3** occupy two positions each with 50% probability. Only one of the three asymmetrical $-CCl_3$ groups was found to be disordered into two resolute positions, in both complexes **1** and **3**.

3. Results and discussion

To date, various heterotrinuclear complexes with chloro containing acetic acids have been synthesized and structurally characterized [19,20,22,23]. Most of these complexes were synthesized through a step concerning treatment of basic acetates of d-elements with the corresponding acids in aqueous solutions. It is worth mentioning that complexes **1**–**3** were prepared by a self-assembly reaction of $Fe(NO_3)_3 \cdot 9H_2O$ with trichloroacetates of alkaline earth metals in methanol.

3.1. Molecular structures of *1* and *3*

The X-ray study revealed that the compounds **1** and **3**, containing Ca and, respectively, Ba, belong to molecular complexes with THF solvated molecules placed in the external coordination sphere. It has to be mentioned that compound **3** includes solvated water molecules too. As in the case of the complex $[Fe_2MnO(CHCl_2COO)_6(THF)_2 \cdot H_2O]$ [19], the character of distribution of the metal cations in the various M_3–μ_3-O cores was unambiguously demonstrated. It appeared possible even in the case of an essential difference in the values of ionic radii of the metals used, M^{2+} (Ca, Ba) and Fe^{3+}. This difference produced the formation of an isosceles triangle of C_2 symmetry (Fig. 1a and b), with the lateral equivalent distances Ca···Fe 3.750(1) Å for **1** (Ba···Fe 4.177(1) Å for **3**) and the basal distance Fe···Fe 3.229(2) Å for **1** and 3.201(1) Å for **3**. The data show that this difference in the length of the sides of the triangle could be dictated by the stability of the molecular core, $[M_3O(R–COO)_6]$. The character of the bridges forming this core was not essentially changed in comparison with the classic μ_3-oxo-iron complexes. The stability of the trinuclear core is dictated by the μ_3-bridge oxygen atom O^{2-} and by six carboxylate anions joint in a *syn–syn* mode along the sides of the triangle. Although the general architecture of the core remains the same, the locations in the first coordination sphere of the metal differ essentially.

3.1.1. Compound $[Fe_2CaO(CCl_3COO)_6(THF)_4] \cdot THF$ (*1*)

Fig. 1a presents the molecular trinuclear complex structure. The geometric characteristics of the coordination core (Table 2) denoted by iron(III) metals in compound **1** do not differ essentially from those reported in [35]. The coordination number of Fe(1) atoms equals 6, and represent a weakly distorted octahedron. Four oxygen atoms of four carboxylic groups occupy the equatorial plane with Fe–O distances ranging from 1.996(2) to 2.065(2) Å. The coordination is completed by oxygen atom O(1) and oxygen atom O(9) of THF molecules at the distances of 1.827(1) Å and, respectively, 2.155(2) Å. Atom Fe(1) is out of the plane of the four carboxyl oxygen atoms in the direction of the μ_3-oxygen at a distance of 0.286(2) Å.

The Ca^{2+} local arrangement differs essentially from the surrounds of the Fe(1) atom: the coordination number of calcium is 7; the coordination sphere includes four carboxylic oxygen atoms at distances in the range 2.336(2)–

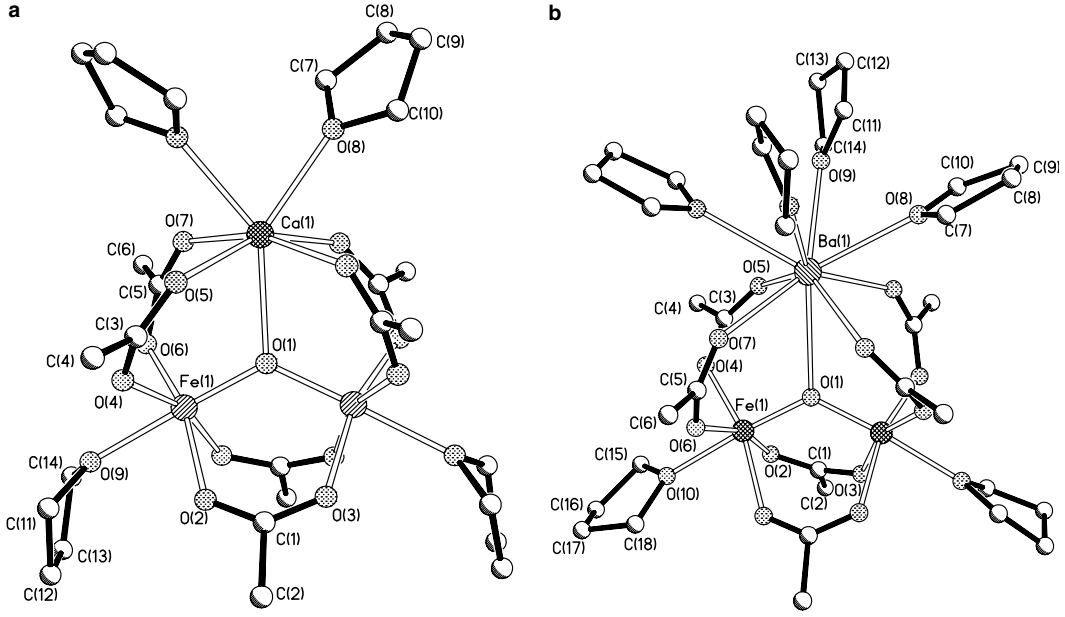

Fig. 1. Structures of the molecular complexes: (a) $[Fe_2CaO(CCl_3COO)_6(THF)_4]$ (**1**); (b) $[Fe_2BaO(CCl_3COO)_6(THF)_6]$ (**3**). Chlorine atoms are omitted for clarity.

Table 2
Interatomic distances (Å) in coordination polyhedra of Ca, Ba and Fe in **1** and **3**

Compound **1**		Compound **3**	
Ca(1)–O(1)	2.530(3)	Ba(1)–O(1)	3.000(7)
Ca(1)–O(5)	2.353(2) × 2	Ba(1)–O(5)	2.697(6) × 2
Ca(1)–O(7)	2.336(2) × 2	Ba(1)–O(7)	2.688(7) × 2
Ca(1)–O(8)	2.424(2) × 2	Ba(1)–O(8)	2.850(7) × 2
		Ba(1)–O(9)	2.803(7) × 2
Fe(1)–O(1)	1.827(1)	Fe(1)–O(1)	1.816(3)
Fe(1)–O(2)	2.065(2)	Fe(1)–O(2)	2.078(6)
Fe(1)–O(3)$^{(1)}$	2.060(2)	Fe(1)–O(3)$^{(2)}$	2.065(6)
Fe(1)–O(4)	1.996(2)	Fe(1)–O(4)	1.997(7)
Fe(1)–O(6)	2.003(2)	Fe(1)–O(6)	1.993(6)
Fe(1)–O(9)	2.155(2)	Fe(1)–O(10)	2.178(6)

Symmetry transformations: (1) $-x, y, -z + 0.5$; (2) $-x + 0.5, -y + 0.75, z$.

2.353(2) Å, two oxygen atoms of THF ligands (Ca(1)–O(8) 2.424(2) Å) and μ_3-O at 2.530(3) Å. The difference in the M–O(1) distances (Ca–O and Fe–O) is 0.703(2) Å, which exceeds the difference in the ionic radii of Ca^{2+} (1.00 Å) and Fe^{3+} (0.65 Å). The Ca atom deviates by 0.443 Å from the plane of the four oxygen atoms in the direction of the neutral ligands. Concluding, the main result of the X-ray study is related to reliable information about the magnetic moiety that includes two iron(III) atoms interacting via Fe–O–Fe and two *syn–syn* carboxylic groups bridges.

The X-ray study of the compounds $[Fe_2SrO(CCl_3COO)_6(THF)_6]\cdot 0.5H_2O\cdot 0.5THF$ (**2**) and $[Fe_2BaO(CCl_3COO)_6(THF)_6]\cdot 0.5H_2O\cdot 0.5THF$ (**3**) has shown that they are isostructural. In the following, as an example, is described in detail the structure of **3**, for which a complete X-ray single crystal investigation was carried out.

The main distinction between compound **3** and compound **1** consists of a different coordination geometry for the s elements. There is a 9-coordination number for Ba^{2+} and its environment includes four THF ligands (Fig. 1b). The Ba atom deviates considerably, at 1.003(6) Å, from the plane of four coordinated oxygen atoms of carboxylate groups towards neutral ligands. The coordination polyhedron of Fe^{3+} is similar to that observed in **1**. The deviation of the Fe(1) atom from the main plane of four carboxylate oxygen atoms was found to be 0.304(7) Å in the direction of O(1) oxygen.

The crystal packing for both **1** and **3** compounds was derived from the arrangement of the corresponding neutral complexes $[Fe_2CaO(CCl_3COO)_6(THF)_4]$ and $[Fe_2BaO(CCl_3COO)_6(THF)_6]$ according to the Cl···Cl intermolecular contacts, which adopt the shortest values of 3.566 Å for **1** and 3.522 Å for **3**. All other intermolecular separations are not smaller than the sum of Van der Waals radii. The disordered solvate THF and water molecules are accommodated within the free space formed by the packing of the bulky trinuclear complexes (Figs. 2 and 3). These spaces represent closed cavities formed by staggered two-dimensional layers in structure **1** (Fig. 2) and the channels propagated along the *c*-crystallographic axes in structure **3** (Fig. 3).

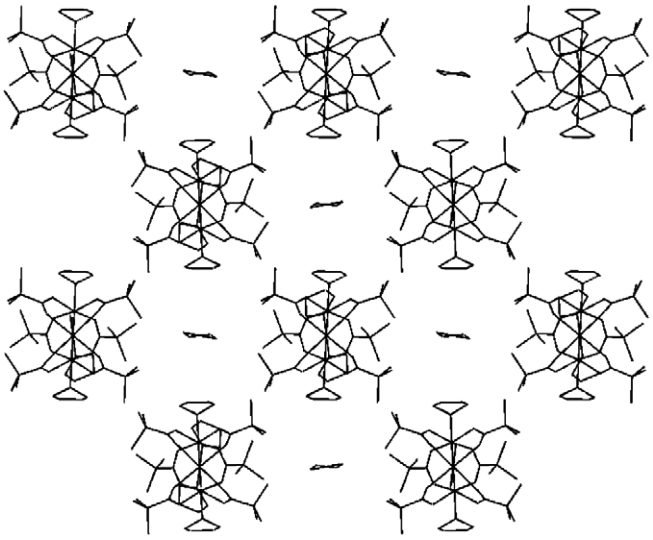

Fig. 2. Structure of the 2D layer in **1**.

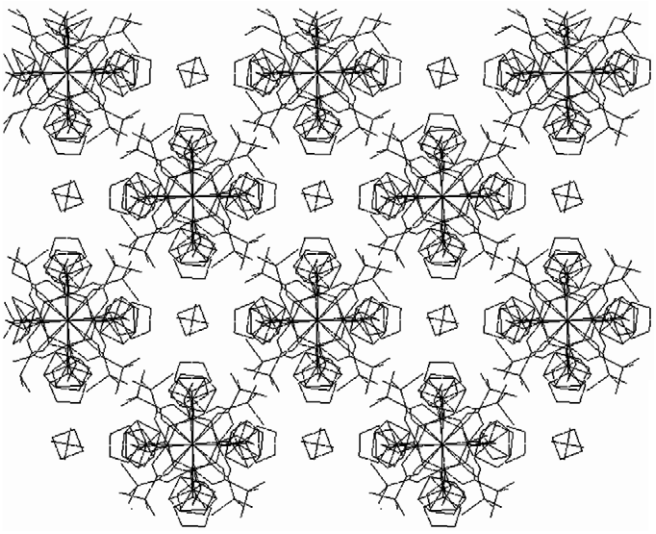

Fig. 3. Projection of the crystal structure **3** along the *c*-axis.

3.2. Infrared spectra

The solid state IR spectra of complexes **1**–**3** indicate the presence of carboxylate, THF and $\{Fe_2MO\}$ groups. The characteristic vibration frequencies for THF groups appear at ~3450–3600 and 2800–3000 cm^{-1}. The IR data for compounds **1**–**3** show a single pair of carboxylate stretching vibrations at 1645 and 1380 cm^{-1} for **1**, 1670 and 1380 cm^{-1} for **2** and 1675 and 1380 cm^{-1} for **3** assigned to ν_{as}(COO) and ν_s(COO), respectively, suggesting the existence of only one type of carboxylate group in their crystal structures. These bands are shifted to lower energy by 45–75 cm^{-1} relative to the trinuclear basic acetates [4] due to the replacement of the CH_3 radical by the much more powerfully electron-accepting CCl_3 moieties which weaken the $M–O_{carb}$ force constant.

In Table 3, some band assignments for (COO), (CCl), (CH) and (CC) groups for μ_3-oxo heterotrinuclear clusters

Table 3

$CCl_3COO \equiv$ TCA; s – strong; v – very; m – medium; w – weak; sh – shoulder; ν – stretching.
[a] Data from [42].

according to [41,42] are given. It is worth mentioning that the band corresponding to $\nu_{as}(Fe_3O) = 595\ cm^{-1}$ from homotrinuclear basic acetates is missing in IR spectra of compounds **1**–**3**. This band is replaced by another two bands at ~690–675 cm^{-1}, corresponding to $\nu_{as}(Fe_2MO)$ (A_1), and at 465–460 cm^{-1}, corresponding to $\nu_{as}(Fe_2MO)$ (B_2) according to [4]. Cannon and co-workers [43–45] have examined the Fe_2M–O vibration modes and such bands have been found for a number of $[Fe_2M^{II}(\mu_3\text{-}O)(RCOO)_6(L)_3]$ complexes. Such behaviour was expected because of symmetry lowering of the complexes from D_{3h} to C_{2v} [4,46].

3.3. TG study

A specific feature of the investigated complexes is related to their low temperature stability. Already at temperatures higher than 50–70 °C *exo* and *endo* effects accompanied by weight loss have been registered.

On TG and DTG curves of the investigated compounds, it is possible to notice that the basic processes of decomposition finishes in the range 300–360 °C.

The first endothermic stage of decomposition corresponds to removal of solvent molecules (THF, or THF and H_2O) and some quantity of intrasphere THF (1.5 for **1**, and 0.5 for **2** and **3**).

It is very probably the removal of intrasphere molecules of THF is accompanied by reorganisation of the cluster in such a way to assure all coordination places of the s-metal ion by changing the *syn–syn* mode of coordination of the carboxylic ligands to a cyclo-bridged one [8,9].

The subsequent second process for all three clusters is characterised by several superpositioned processes: removal of coordinated molecules of THF, decomposition of trichloroacetic acid anions and reorganisation of the complexes with the formation of the final product, Fe_2MO_4, with a small quantity of impurities.

3.4. Mössbauer spectrum

The Mössbauer spectrum of compound **1** at room temperature presents only one doublet with slightly asymmetric lines (Fig. 4). The value of the isomer shift parameter δ_{Fe} is 0.46 mm/s and that of the quadrupole splitting parameter ΔE_Q is 1.11 mm/s. These parameters indicate the presence of iron(III) in a high spin state ($S = 5/2$). There are rather insignificant changes in δ_{Fe} and ΔE_Q values related to the substitution of one trivalent Fe^{3+} cation [47] by a bivalent Ca^{2+}.

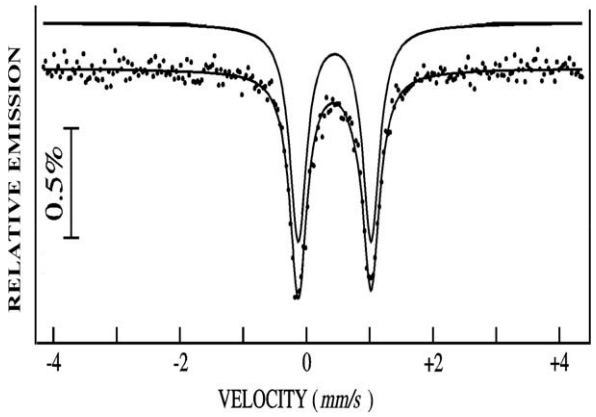

Fig. 4. Fe^{57} Mössbauer spectrum of **1** at room temperature; the solid line is the least-squares fit; isomer shifts are referred to α-iron at room temperature.

3.5. Magnetic properties

The magnetic properties of compounds **1**–**3** have been measured in different ranges of temperatures: 300–110 K for **1** and **3**, and 300–2.9 K for **2**. All three substances are characterized by a gradual reduction of the $\chi_M T$ value with the lowering of temperature, thus indicating an antiferromagnetic interaction between the iron (III) ions. It is evident that ions of s-metals do not contribute to the magnetic exchange. In order to describe the magnetic properties of the investigated complexes the following spin–spin interaction Hamiltonian was used [36]:

$$\mathbf{H}_{exch} = -2\mathbf{J}_{12}\mathbf{S}_1 \cdot \mathbf{S}_2. \quad (1)$$

The energy levels of Hamiltonian (1) are given by the following expression:

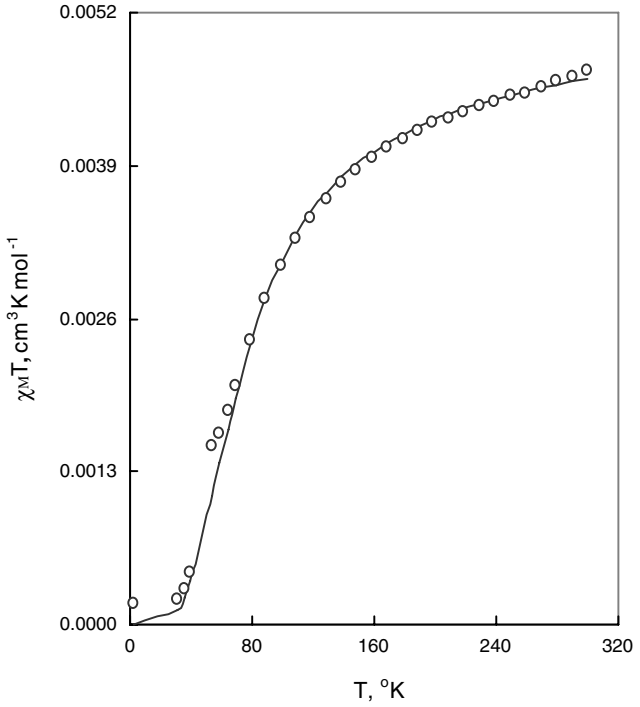

Fig. 5. Temperature dependence of the magnetic susceptibility of **2**, plotted as $\chi_M T$ vs. T; the solid line is the least-squares fit.

$$E(S') = -J_{12}[S'(S'+1) - S_1(S_1+1) - S_2(S_2+1)], \qquad (2)$$

where S' is the total spin of the system. $S' = (S_1 + S_2), (S_1 + S_2 - 1), \ldots |S_1 - S_2|$; $S_1 = S_2$ is the iron(III) ion spin, equal to 5/2. For the investigated systems the values of S' are: 5, 4, 3, 2, 1, 0. The expression for molar magnetic susceptibility χ_M could be presented as

$$\chi_M = \frac{3g^2}{4T} \frac{[55\exp(30x) + 30\exp(20x) + 14\exp(12x) + 5\exp(6x) + \exp(2x)]}{[11\exp(30x) + 9\exp(20x) + 7\exp(12x) + 5\exp(6x) + 3\exp(2x) + 1]}, \qquad (3)$$

where g is the Lande factor of splitting, $x = J_{12}/(kT)$.

Using the fitting program MAGMUN [48], the parameters of magnetic exchange J_{12} have been determined, giving the following values: $J_{12} = J_{Fe-Fe} = -58.9 \pm 0.5\ cm^{-1}$ for **1**; $-75.4 \pm 0.8\ cm^{-1}$ for **2**; $-60.4 \pm 0.4\ cm^{-1}$ for **3**; g is equal to 2.0 for **1** and **3**, and 2.14 for **2** (see Fig. 5).

From the acquired data, it is obvious that the absolute value of the magnetic exchange parameter J_{12} changes from complex to complex. At the same time it is useful to note that the values of the parameter of exchange between iron (III) ions in the discussed trinuclear clusters are significantly larger in their absolute values compared to similar homonuclear carboxylates of iron (III) [16,36,49], but they are practically the same for heteronuclear acetates with $\{Fe_2MO\}$ cores, where M is a 3d-element [18]. From the comparison of L(Fe–Fe) and $|J_{Fe-Fe}|$ values for **1** and **3**, one can see that they have a certain mutual correlation. The fact that the value $|J_{Fe-Fe}|$ for **2** is considerably different from those of **1** and **3** probably is the result of the different temperature ranges in which the susceptibility curves have been measured and the different values of the fitted g factor.

4. Conclusions

Three new μ_3-oxo heterotrinuclear iron and s-metal containing carboxylates of the composition $[Fe_2M(Ca, Sr, Ba)O(RCOO)_6(L)_n]$, where R = CCl_3, L = tetrahydrofuran (THF), have been synthesized.

For the first time the possibility to obtain a trinuclear core $[Fe_2MO(R–COO)_6]$ with M differing in both electronic property (Fe – alkaline-earth metals) and dimension (Fe/Ba, Fe/Sr, Fe/Ca) was demonstrated. The positions of paramagnetic and diamagnetic centres in the core of the trinuclear molecule have been assigned unambiguously. This allows an analysis of the magnetic interactions in the Fe–Fe fragment where the iron atoms are connected by two different bridges.

The absolute value of the antiferromagnetic interaction between iron(III) ions (magnetic exchange parameter $-58.9 \pm 0.5\ cm^{-1}$ for **1**, $-75.4 \pm 0.8\ cm^{-1}$ for **2**, $-60.4 \pm 0.4\ cm^{-1}$ for **3**) is higher than the analogous parameter in homo-iron carboxylates, but they are practically the same for heteronuclear acetates with $\{Fe_2MO\}$ cores, where M is a 3d-element.

5. Supplementary material

Crystallographic data (excluding structure factors) for **1** and **3** have been deposited with the Cambridge Crystallographic Data Centre as a supplementary publication, CCDC reference number 247520 for **1** and 247519 for **3**. Copies of the data can be obtained, free of charge, on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [fax: +44 1223 336 033 or e-mail: deposit@ccdc.cam.ac.uk].

are markedly influenced by the steric demand of the substituents on the pendant silicon atom as well as by the alkyl chain length of the carbosilyl groups bonded to skeletal silicon backbone. As a part of this ongoing research, it has been our endeavor to understand structural features of new disilaalkanes which can be utilized as precursors in the synthesis of a variety of silicon polymers. We report herein the synthesis and characterization of some hitherto unknown asymmetrically substituted disilaalkanes $Ph_3SiCH_2CH_2SiRR'_2$ [R = Me, R′ = Cl (**1**); R = Ph, R′ = Cl (**2**); R = R′ = Cl (**3**), Ph (**4**), OEt (**5**), H (**6**)]. The crystal structures of **1** and **4** reveal the presence of C–H···Cl and/or C–H···π interactions which afford 3-D supramolecular assemblies.

2. Results and discussion

2.1. Synthesis and spectral studies

As evident from Scheme 1, the hydrosilylation reaction between equimolar quantities of triphenylsilane and dichloromethyl/dichlorophenyl/trichlorovinylsilane in the presence of Karstedt's catalyst (10^{-5} mol of Pt/mol of silane) affords the corresponding disilaalkanes, $Ph_3SiCH_2CH_2SiRR'_2$ [R = Me, R′ = Cl (**1**); R = Ph, R′ = Cl (**2**); R = R′ = Cl (**3**)] along with minor amounts of 1,1,1,4,4,4-hexaphenyl-1,4-disilabutane (**4**; yield: 4.4–8.8%) in each case. The isolation of these disilaalkanes as analytically pure products from the mixture has been accomplished by taking advantage of the preferential solubility of **1**–**3** in *n*-hexane. By analogy with the literature precedence [13], the formation of **4** in these reactions is believed to arise from a ligand-exchange phenomenon involving vinyl/H groups in the precursors under Pt-catalyzed conditions (Eq. (1)). The resulting triphenylvinylsilane subsequently undergoes hydrosilylation with triphenylsilane to yield compound **4**

$$Ph_3SiH + CH_2{=}CHSiRCl_2 \rightleftarrows CH_2{=}CHSiPh_3 + HSiRCl_2 \quad (1)$$

On the other hand, the reaction between triphenylsilane and triethoxyvinylsilane under similar conditions proceeds regioselectively to yield the disilaalkane **5** as the exclusive product, which upon subsequent treatment with lithium aluminum hydride affords **6** with a SiH_3 end group.

The disilaalkanes obtained herein are white solids or a viscous liquid (for **2**) and are soluble in common organic solvents such as dichloromethane, chloroform, toluene, THF etc. The identity of these compounds has been established by IR as well as ^1H, $^{13}C\{^1H\}$ and $^{29}Si\{^1H\}$ NMR spectroscopy. ^1H NMR spectra of **1**–**3**, **5** and **6** reveal two distinct multiplets in the region δ 1.58–0.73 due to methylene groups. The 2D-TOCSY spectra confirm these spectral features to arise from both geminal and vicinal coupling of non-equivalent CH_2 protons. For **4**, a singlet at δ1.43 for the methylene protons is in accord with the symmetrical structure and is supported by a single $^{29}Si\{^1H\}$ NMR resonance at δ −8.5 due to Ph_3Si groups. $^{29}Si\{^1H\}$ NMR spectra of all other silaalkanes display an additional singlet at the chemical shift values which are characteristic of the functionally substituted silicon moieties (see Section 3).

2.2. X-ray crystal structures

Single crystals suitable for X-ray structure analysis were obtained upon cooling the solution of the compounds in dichloromethane (for **1**) and dichloromethane/toluene (80:20) (for **4**). The molecular structure of **1**, along with atomic labelling scheme, is shown in Fig. 1, while the crystal data and selected bond lengths and angles are listed in Tables 1 and 2, respectively. The molecule adopts a *trans*-planar conformation of the Si–C–C–Si unit (torsional angle −178.4(1)°), similar to related symmetrically substituted 1,4-disilabutanes known earlier [5,8,9]. However, the Si–C–C angles subtended by the methylene groups [117.0(1)°;

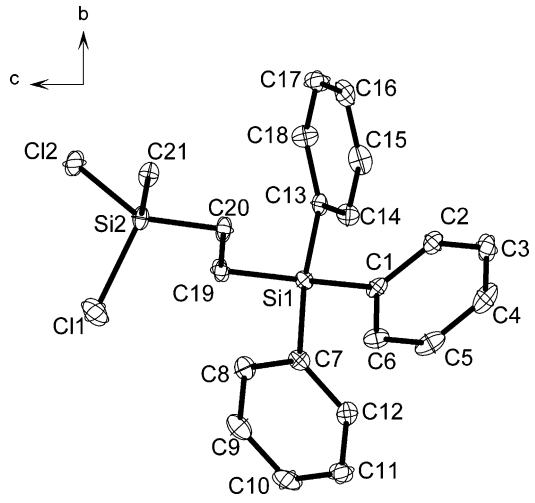

Fig. 1. ORTEP view of **1**. Thermal ellipsoids are shown at 50% probability. Hydrogen atoms are omitted for clarity.

116.7(1)°] are found to be the largest known so far, as might be expected in a sterically congested system. The influence of the bulky Ph_3Si group is also reminiscent in the observed Si1–C19 bond length, 1.899(2) Å, which lies at the upper end of the normal range accepted for the Si–C bond (1.86–1.91 Å) [14]. In addition, a large deviation from a tetrahedral geometry around the Si2 atom is discernible from a considerable reduction of Cl1–Si2–Cl2 [105.4(3)°] and a concomitant increase of C21–Si2–C20 [114.9(9)°] angles. The observed deformation in the Cl–Si–Cl angle is in contrast to those found in the solid state structures of related compounds such as $Cl_3SiCH_2CH_2SiCl_3$ [107.1(3)–108.5(3)°] [8] and H_2SiCl_2 [109.0(1)°], but is close to that of the adduct $[(H_3C)_2O \cdot H_2SiCl_2]_2$ [104.7(1)°] [15] in which the silicon atom adopts a hexacoordinate structure. A consequence of this structural deformation also results in significant deviation of the Cl1–Si2–C20–C19 moiety from an ideal gauche conformation (torsion angle, −52.1(1)°). The triphenylsilyl fragment in the molecule adopts a propeller-shape conformation [16,17] in order to relieve the steric strain due to interactions between the *ortho*-hydrogen atoms of the adjacent phenyl groups. A qualitative interpretation of the extent of propeller-twist distortion is obtained by an examination of the dihedral angles C_{ipso}–Si–C'_{ipso}–C'_{ortho} subtended between the phenyl rings. The mean distortion of these dihedral angles has been found to be 39.9° in comparison to the idealized value of 30° expected in the absence of an *ortho–ortho* interaction between the phenyl groups [17]. A detailed analysis of the X-ray structure of **1** reveals the existence of weak hydrogen bonding involving C–H···Cl [18] and C–H···π [19] interactions, leading to a 3-D supramolecular network. A perspective view of the self assembly is shown in Fig. 2. Noticeably, the Cl(2) atom is involved in a bifurcated C–H···Cl interaction involving CH (arene) and CH_2 (methylene) hydrogens of the two neighboring molecules, while Cl(1) atom is intramolecularly associated with H19A of the methylene group. The crystallographic numbering scheme represents the corresponding parameters as follows [H10–Cl2 = 3.12 Å, C10–Cl2 = 3.99 Å, C10–H10–Cl2 = 158.3°; H20B–Cl2 = 3.07 Å, C20–Cl2 = 3.90 Å, C20–H20B–Cl2 = 143.2°, H19A–Cl1 = 3.12 Å, C19–Cl1 = 3.58 Å, C19–H19A–Cl1 = 111.3°]. In addition, one of the arene hydrogens, H16, is involved in an intermolecular CH···π interaction with a H16–centroid distance of 3.05 Å, the corresponding C16–centroid distance being 3.84 Å and the associated C16–H16–centroid angle 144.2°. The 2-D structure thus formed along the *bc* plane self assembles into a 3-D network by intermolecular C–H···Cl and C–H···π interactions, with the Cl1 atom involved in bifurcated H-bonding. The metric parameters involved are H19A–Cl1 = 3.06 Å; C19–Cl1 = 3.97 Å, C19–H19A–Cl1 = 156.9°; H21C–centroid = 3.05 Å, C21C–centroid = 3.69 Å, C21C–H21C–centroid angle = 125.6°. The overall structure adopts stacked layers along the crystallographic *a* axis.

The molecular structure of **4** comprises two independent molecules in the unit cell, of which only one is shown in Fig. 3. The crystal data are summarized in Table 1 and selected bond lengths and angles are listed in Table 3. Each molecule lies on a crystallographic inversion centre and adopts a *trans*-planar conformation of the Si–C–C–Si unit with nearly identical metrical parameters [Si1–C19 1.881(5) Å, Si2–C38 1.879(4) Å, C19–C19 1.538(9) Å, C38–C38 1.537(8) Å, C19–C19–Si1 116.5(4)°, C38–C38–Si2 117.0(4)°]. However, there are subtle structural differences in the relative orientations of various phenyl rings with respect to the C–Si–C_{ipso} plane, as evident from the dihedral angles C–Si–C_{ipso}–C_{ortho} (Table 3), the largest observed deviation being 3.9°. These results are in conformity with the superposition plot shown in Fig. 4. The Ph_3Si fragments in each molecule also exhibit propeller twist distortion with a mean value of the dihedral angles

C_{ipso}–Si–C'_{ipso}–C'_{ortho} of 32.6° for the Si1 molecule and 35.3° for the Si2 molecule. In addition, extensive CH···π interactions between the arene rings have been observed which results in the formation of a 3-D supramolecular assembly (Fig. 5). A view along the crystallographic *a* axis reveals that one of the asymmetric molecules, designated with the Si1 atom, involves H5 and H11 atoms for CH···π interactions with the adjacent arene molecules. Similar characteristic CH···π interactions are also evident for the Si2 molecule, involving H24 and H34 atoms [H5–centroid = 2.83 Å, C5–centroid = 3.56 Å, C5–H5–centroid angle = 134.5°; H11–centroid = 2.89 Å, C11–centroid = 3.53 Å, C11–H11–centroid angle = 125.9°; H24–centroid = 2.83 Å, C24–centroid = 3.61 Å, C24–H24–centroid angle = 139.5°; H34–centroid = 3.04 Å, C34–centroid = 3.69 Å, C34–H34–centroid angle = 127.6°]. The Si2 mole-

cules are associated along the *bc* plane via a C35–H35···π interaction with a H35–centroid distance of 2.58 Å and C35–H35–centroid angle of 157.4°, while Si1 molecules are devoid of such interactions. The two asymmetric molecules are interconnected via a CH···π interaction involving the H10 atom of one molecule with the arene moiety of the other [H10–centroid = 2.95 Å, C10–centroid = 3.78 Å, C10–H10–centroid angle = 146.3°].

In conclusion, the disilaalkanes **1**–**6** have been synthesized by the hydrosilylation reaction between triphenylsilane and the corresponding vinylsilanes in the presence of Karstedt's catalyst. The formation of **4** in these reactions has been rationalized by invoking a redistribution of the vinyl and H groups in the precursors under the catalyzed conditions. The molecular structures of **1** and **4** reveal a considerable increase in the Si–C bond lengths and Si–C–C bond angles in order to relieve the steric strain imposed by the bulky triphenylsilyl group. The formation of a 3-D supramolecular assembly in these structures is mediated through extensive C–H···Cl (for **1**) and C–H···π interactions. To our knowledge, there is no such precedence of supramolecular aggregation in the family of disilaalkanes. The implications of these structural characteristics on the electronic properties of the resulting polysilanes derived from the disilaalkane precursors are currently under investigation.

3. Experimental

3.1. General comments

All operations were carried out using standard schlenk line techniques under dry nitrogen atmosphere. Solvents were freshly distilled under inert atmosphere over P_2O_5 (dichloromethane and *n*-hexane) or sodium benzophenone (toluene) before use. Glassware were dried in an oven at 100–120 °C and further flame dried under vacuum prior to use. Dichloromethylvinylsilane, trichlorovinylsilane and triethoxyvinylsilane (Aldrich) were freshly distilled before use. Karstedt's catalyst (platinum(0)-1,3-divinyl-1,1,3,3-tetramethyldisiloxane complex), triphenylsilane (Aldrich) were used as received. Dichlorophenylvinylsilane was prepared by the literature method [20].

Infrared spectra were obtained as thin films on KBr pellets on a Nicolet FT-IR (Protégé) spectrophotometer. ^{1}H, $^{13}C\{^{1}H\}$ and $^{29}Si\{^{1}H\}$ NMR spectra were recorded in $CDCl_3$ on a Bruker spectrospin DPX 300 MHz instrument at frequency 300, 75.5, 59.6 MHz, respectively, and chemical shifts are quoted relative to Me_4Si. 2-D TOCSY (Total Correlation Spectroscopy) experiments using the standard pulse sequence were carried out in $CDCl_3$. The mixing time used for these experiments were 4 and 80 ms. A total of 32 scans containing 1 K data points were accumulated for 512 experiments with a delay time of 2 s. Elemental analysis (C, H and N) was performed on a Perkin–Elmer model 2400 CHN elemental analyzer.

3.2. Synthesis of disilaalkanes *1*–*6*

Dichloromethyl/dichlorophenyl/trichlorovinylsilane (16.19 mmol) was added dropwise to a melt of triphenylsilane (15.61 mmol) containing a catalytic amount of Karstedt's reagent (10^{-5} mol of Pt/mol of silane) at 50 °C. No induction period was observed during the complete addition. The reaction mixture was heated at 75 °C for 12 h. The contents were cooled and *n*-hexane (50 ml) was added to afford 1,1,1,4,4,4-hexaphenyl-1,4-disilabutane (**4**) as a white solid, which was filtered and dried under vacuum.

The filtrates obtained from these reactions were concentrated under vacuum to yield the corresponding disilaalkanes **1**–**3**.

*3.2.1. $Ph_3SiCH_2CH_2SiMeCl_2$ (**1**)*

Yield: (4.72 g, 75.4%), m.p. 94–95 °C. *Anal.* Calc. for $C_{21}H_{22}Cl_2Si_2$: C, 62.84; H, 5.48. Yield: (4.4–8.8%), m.p. 195–196 °C. *Anal.* Calc. for $C_{38}H_{34}Si_2$: C, 83.51; H, 6.22. Found: C, 83.32; H, 6.15%. ^{1}H NMR 7.47–7.30 (m, 30H, *Ph*), 1.43 (s, 4H, CH_2). ^{13}C{^{1}H} NMR 135.73, 134.85, 129.41, 127.85 (Si–*Ph*), 5.64 (*C*H$_2$). ^{29}Si{^{1}H} NMR −8.50 (Ph$_3$*Si*).

*3.2.5. $Ph_3SiCH_2CH_2Si(OEt)_3$ (**5**)*

The title compound was prepared using triphenylsilane (3.67 g, 14.09 mmol) and triethoxyvinylsilane (2.70 g, 3.0 ml, 14.23 mmol) by following a similar procedure as described above. Compound **5** was obtained as a low melting solid. Yield: (4.69 g, 73.2%), m.p. 46–48 °C. *Anal.* Calc. for $C_{26}H_{34}Si_2O_3$: C, 69.33; H, 7.55. Found: C, 69.10; H, 7.43%. ^{1}H NMR 7.47–7.27 (m, 15H, *Ph*), 3.74–3.63 (q, 6H, CH_2(Et), $^3J_{HH} = 6.88$ Hz), 1.36–1.30 (m, 2H, Ph$_3$SiCH_2), 1.12 (t, 9H, CH_3(Et), $^3J_{HH} = 6.93$ Hz), 0.66–0.60 (m, 2H, CH_2Si(OEt)$_3$). ^{13}C{^{1}H} NMR 135.66, 134.90, 129.34, 127.79 (Si–*Ph*), 58.38 (*C*H$_2$(Et)), 18.27 (*C*H$_3$(Et)), 4.31 (Ph$_3$Si*C*H$_2$), 2.83 (*C*H$_2$Si(OEt)$_3$). ^{29}Si{^{1}H} NMR −8.30 (Ph$_3$*Si*), −44.92 (*Si*(OEt)$_3$).

*3.2.6. $Ph_3SiCH_2CH_2SiH_3$ (**6**)*

A solution of **5** (3.84 g, 7.74 mmol) in diethylether was added dropwise to a dispersion of $LiAlH_4$ (0.45 g, 11.84 mmol) in same solvent at 0 °C. The reaction mixture was gently refluxed for 5–6 h. Thereafter, the contents were treated with 1 N HCl, then the ether layer was extracted and dried over anhydrous Na_2SO_4. The solvent was removed under vacuum to afford **6** as a white solid. Yield: (1.52 g, 61.7%), m.p. 95–96 °C. *Anal.* Calc. for $C_{20}H_{22}Si_2$: C, 75.47; H, 6.91. Found: C, 75.21; H, 6.68%. ^{1}H NMR 7.53–7.34 (m, 15H, *Ph*), 3.50 (t, 3H, Si*H*, $^3J_{HH} = 3.63$ Hz), 1.45–1.39 (m, 2H, Ph$_3$SiCH_2), 0.86–0.79 (m, 2H, CH_2SiH$_3$). ^{13}C{^{1}H} NMR 136.36, 135.63, 129.47, 127.87 (Si–*Ph*), 9.00 (Ph$_3$Si*C*H$_2$), −0.60 (*C*H$_2$SiH$_3$). ^{29}Si{^{1}H} NMR −8.95 (Ph$_3$*Si*), −55.6 (*Si*H$_3$).

3.3. X-ray crystallography

The suitable crystals of **1** and **4** were mounted lengthways with the largest dimension in sealed capillaries and were used for data collection. The intensity data were collected on a Bruker SMART APEX diffractometer equipped with a molybdenum sealed tube and a highly orientated graphite monochromator. The structures were solved by direct methods and refined using the SHELXTL package [21,22]. Non-hydrogen atoms were refined anisotropically by the full-matrix least square method while the hydrogen atoms were constrained by a rigid model. All calculations were done on an IBM compatible PC using SMART [23], SAINT [24] and SADABS [25]. Details of crystallographic data are given in Table 1.

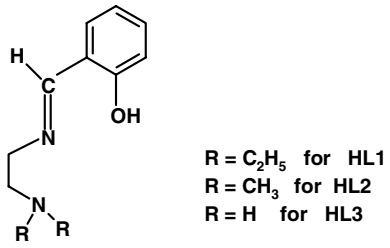

Scheme 1.

certainly influence the structural diversity of metal assembled complexes. Recently, we have reported a structurally characterized tetranuclear copper (II) azido complex containing salen (salenH$_2$ = *N*,*N*′-bis-(salicylidehyde)-ethylenediimine) as co-ligand [10]. An end-on azido group and a monophenoxo group from salen bridged four copper (II) centers to form a tetranuclear moiety. On changing the co-ligand salen to a tridentate Schiff base viz. HL3 (Scheme 1), the copper (II) azido system afforded a dinuclear moiety where copper (II) ions are bridged by two end-on azido groups [11]. In fact structurally characterized metal azido systems containing Schiff base co-ligands were not so well documented before our reports [12,13].

We now report our investigation on the synthesis, characterization and the crystal structure analysis of two copper (II) azido systems in which 1-(*N*-salicylideneimine)-2-(*N*,*N*-diethyl)-aminoethane (HL1) and 1-(*N*-salicylideneimine)-2-(*N*,*N*-dimethyl)-aminoethane (HL2) are two different tridentate Schiff base ligands acting as co-ligand. Interestingly, while a monomeric complex [Cu(L1)(N$_3$)] (**1**) is obtained in case of HL1, HL2 afforded a polymeric ID chain, [Cu(L2)(N$_3$)]$_n$ (**2**), containing end-to-end azido bridges. The present work constitutes a part of our continuing study on metal-azido complexes of tridentate Schiff base ligands based on substituted ethylenediamines.

2. Experimental

2.1. General

All chemicals and solvents used during the synthesis were of AR grade and used as received. Elemental analyses (CHN) were performed using a Perkin–Elmer 240 elemental analyzer. IR spectra were recorded on a Nicolate Magna IR 750 Series II FT-IR spectrophotometer. The instruments used for other measurements were reported earlier [10].

2.1.1. Synthesis of the complex [Cu(Ll)(N$_3$)] (*1*)

A methanolic solution (20 ml) of *N*,*N*-diethyl-ethylenediamine (1 mmol, 0.106 g) was added to a methanolic solution (20 ml) of salicylaldehyde (1 mmol, 0.122 g). The reaction mixture was then stirred for 30 min. To this copper (II) nitrate trihydrate (1 mmol, 0.241 g) dissolved in methanol was added and was stirred for 10 min. Finally, 5 ml aqueous solution of NaN_3 (2 mmol, 0.130 g) was added drop-wise to the mixture with continuous stirring and the resulting solution was then filtered. The green filtrate was then kept in air. From the green solution black crystals were formed within few days. They were then collected by filtration and dried in a desiccator. A suitable crystal was selected for X-ray crystallographic analysis. (Yield ca. 60%). *Anal.* Calc. for $C_{13}H_{19}CuN_5O$: C, 48.0; H, 5.8; N, 21.5. Found: C, 48.2; H, 5.9; N, 22.0%. IR (KBr): $\nu_{as}(N_3)$, 2020 cm^{-1}; $\nu_s(N_3)$, 1320 and 1340 cm^{-1}; $\delta(N_3)$, 610 cm^{-1}; ν(C=N), 1630 cm^{-1}, $\mu_{eff} = 1.83$ BM.

2.1.2. Synthesis of the complex [Cu(L2)(μ-1, 3-N$_3$)]$_n$ (*2*)

This complex was prepared by refluxing a methanolic solution (20 ml) of *N*,*N*-dimethyl-ethylenediamine (1 mmol, 0.088 g) and a methanolic solution (20 ml) of salicylaldehyde (1 mmol, 0.122 g) for 1 h and evaporated on a water-bath until the volume reduced is to ca. 10 ml to obtain a viscous liquid which was added to the methanolic solution (10 ml) of copper (II) nitrate trihydrate (1 mmol, 0.241 g). The resulting mixture was refluxed for 15 min. To it, an aqueous solution of NaN_3 (2 mmol, 0.130 g) was added drop-wise with continuous stirring and the resulting solution was filtered. Black single crystals suitable for structure determination were obtained by slow evaporation of the resulting green solution in the air. (Yield ca. 67%). *Anal.* Calc. for $C_{11}H_{15}CuN_5O$: C, 44.5; H, 5.0; N, 23.6. Found: C, 45.2; H, 5.8; N, 23.7%. IR (KBr): $\nu_{as}(N_3)$, 2030 cm^{-1}; $\nu_s(N_3)$, 1330 and 1345 cm^{-1}; $\delta(N_3)$, 620 cm^{-1}; ν(C=N), 1640 cm^{-1}.

Caution! Although our samples never exploded during handling, metal azido complexes are potentially explosive: only a small amount of material should be prepared and it should be handled with care.

2.2. X-ray crystallography

The crystal data, intensity data collection and refinement details of (**1**) and (**2**) are given in Table 1. A chip of black single crystal of complex (**1**) and a rectangular block single crystal of complex (**2**) were selected for collecting X-ray data. All measurements were made on a Rigaku AFC7 diffractometer using graphite monochromated Mo Kα radiation ($\lambda = 0.71070$ Å) equipped with a Rigaku Mercury CCD detector. The unit cell parameters and orientation matrix were determined by least square refinements. Of the 24126 and 82332 reflections that were collected, 3533 ($R_{int} = 0.022$) and 6561 ($R_{int} = 0.040$) were unique for complex (**1**) and (**2**), respectively. The collected intensity data were corrected for Lorentz and polarization effects and an empirical absorption correction was also employed. Data were collected and processed using CrystalClear (Rigaku) program [14]. The structures were solved by direct methods (SIR 97) [15] and expanded using Fourier techniques. The non-hydrogen atoms were refined anisotropically. Hydrogen atoms were refined isotropically for complex (**1**) while they were refined using the riding model for complex (**2**). All calculations were carried out using the CrystalStructure [16], CRYSTALS [17] and PLATON [18].

3. Results and discussion

3.1. Synthesis and spectroscopic studies

Elemental analyses of the complexes convincingly demonstrate that (**1**) and (**2**) can be formulated as [Cu(L1)(N_3)] and [Cu(L2)(N_3)], respectively. IR spectral measurements of (**1**) and (**2**) show a strong band in the range 1630–1630 attributable due to the azomethine group [19]. The ν_{as} band for azide group appears around 2020 and 2030 cm^{-1} for complex (**1**) and (**2**), respectively. Similar characteristic bands for azides have been observed in a number of mononuclear and azido bridged polynuclear complexes [5,10,11]. The electronic spectra of the complex (**1**) and (**2**) have been measured in methanolic solution. A relatively weak band appears at around 610 nm for both the complexes can be assigned as d–d transition while a broad intense band centered at around 365 nm for (**1**) and (**2**) attributable due to the ligand metal charge transfer.

3.2. Description of structures

3.2.1. [Cu(Ll)(N_3)] (1)

The principal structural features of complex (**1**) are given in Fig. 1. The structure consists of discrete molecules of [(CuLl)(N_3)]. The copper ion occupies the central position of a regular square planar arrangement. Out of its four coordination sites three positions are occupied by the tridentate Schiff base through two nitrogen (amino and imino) atoms and while other one is occupied by de-protonated phenoxo group. The remaining fourth coordination is satisfied by an azido ligand. The Cu–N bond lengths are found to be Cu(1)–N(1) = 1.935(2); Cu(1)–N(2) = 2.063(2); Cu(1)–N(3) = 1.946(2) Å while the Cu(1)–O(1) bond length is 1.888(2) Å. The azide group, which acts as a monodentate ligand is slightly asymmetric [N(3)–N(4) = 1.184(3) and N(4)–N(5) = 1.141(3) Å] and linear within the experimental error [N(5)–N(4)–N(3) = 175.6(2)]. The other bond lengths and angles are gathered in Table 2. The distance between the central Cu(1) ion and the unused terminal N atom of the azide ligand of the symmetry related moieties are found to be ca. 5.735 Å. The bond lengths and bond angles determined from X-ray measurements are in agreement with the other similar reported systems. The structure of the complex (**1**), however, differs from the other X-ray crystallographically investigated copper (II) azide complexes containing terminal azido ligand [20]. In most of the cases the coordination geometry around copper ions are either pseudo octahedral or distorted trigonal bipyramidal while square planar is not so common. The present complex acquires a square planar environment around the copper ion probably due to the presence of two ethyl groups attached to the N atom in 1,1 position of the ethylenediamine backbone of Schiff base ligand.

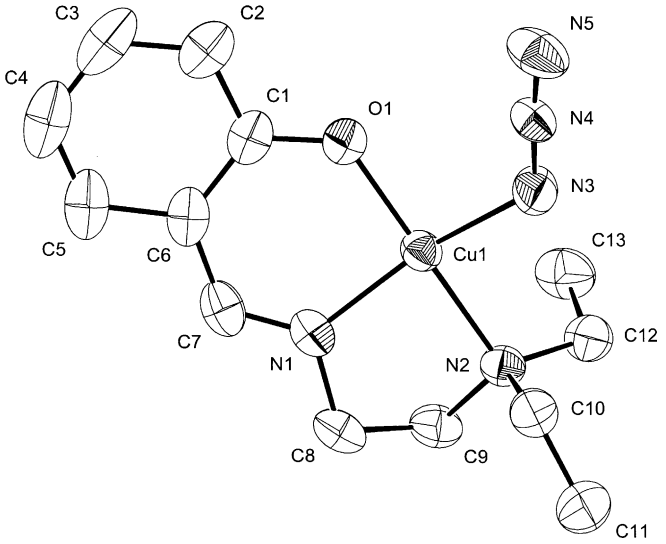

Fig. 1. ORTEP diagram of complex **1** showing atom numbering scheme.

3.2.2. [(CuL2)(μ-1,3-N_3)]$_n$ (2)

The structure determination reveals that the neutral [Cu(L2)(N_3)] units in complex (**2**) are connected by the single (μ-1,3-azido ligands) to form an infinite 1D polymeric chain. The tridentate NNO donor Schiff base ligand acts as a chelating ligand. An ORTEP [21] drawing of the chain with atom labeling scheme is shown in Fig. 2. The copper (II) ion in complex (**2**) is pentacoordinated. Of them two nitrogen atoms and one oxygen atom of the Schiff base ligand and one nitrogen atom of the bridging azido ligand define the basal plane around the copper (II) ion in this

Symmetry codes (i) = $3/2 - x$, $1/2 + y$, z; (ii) = $3/2 - x$, $-1/2 + y$, z.

complex. A nitrogen atom of azido ligand from the symmetry related unit (symmetry operation $3/2 - x$, $1/2 + y$, z) occupies the remaining fifth position of the coordinated polyhedra. Azido ligand bridges Cu(1) with Cu(2) through basal-apical linkage in this complex. The bond lengths and bond angles of complex (**2**) is given in Table 2. The Cu-azido-Cu chains are propagated along the crystallographic *b*-axis while chains are stacked one upon another along crystallographic *c*-axis (Fig. 3). No appreciable inter-chain interaction is apparent from the crystallographic study. The trigonality index $\tau(=(\phi_1 - \phi_2)/60$, where ϕ_1, ϕ_2 are the two largest L–M–L angles of the coordination sphere) has been calculated for the pentagonal copper sites [22]. The τ values are found to be 0.24 and 0.16 for Cu1 and Cu2, respectively, confirming the square pyramidal character of both sites ($\tau = 0$ infers a perfect square pyramid, and a $\tau = 1$ a perfect trigonal bipyramid). The apical Cu–N bond lengths are little longer than usual [Cu(1)–N(10) = 2.473(4) and Cu(2)–N(5^{i}) = 2.457(4)]. The other bond distances and angles are close to the expected values. The intra-chain Cu–Cu distance is found to be 5.318(3) Å. Jiang et al. have reported a μ-1,3-azido complex containing the same co-ligand as that in complex (**2**), but structurally they are different [23]. Therefore, present complex can be considered as a polymorph of the former one.

3.3. Magnetic properties of [Cu(Ll)(N_3)] (**1**) and [(CuL2)(μ-1,3-N_3)]$_n$ (**2**)

The temperature dependence of the molar magnetic susceptibility, χ_M, for complex (**2**) in the 4–300 K temperature range was measured with a superconducting quantum interference device (SQUID) magnetometer, under magnetic fields of 20 kG and is shown in Fig. 4. The χ_M value of 5.5×10^{-3} cm^3 mol^{-1} at 300 K for complex (**2**) is slightly higher than the value expected for an isolated magnetically uncoupled copper (II) ion ($\chi_M = 1.25 \times 10^{-3}$ cm^3 mol^{-1} for

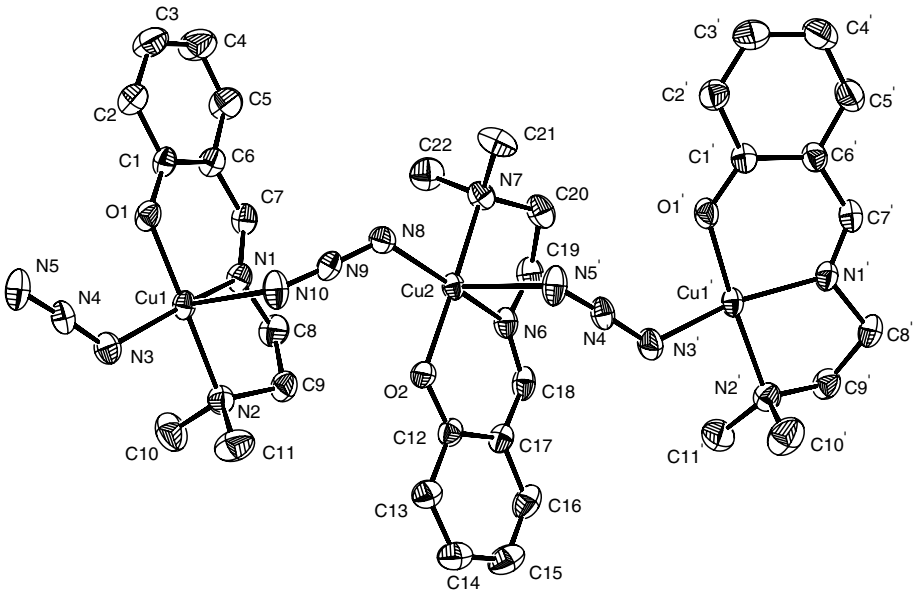

Fig. 2. ORTEP diagram of complex **2** showing part of the 1D infinite chain with atom numbering scheme. Symmetry code for primed atoms is $3/2 - x$, $1/2 + y$, z.

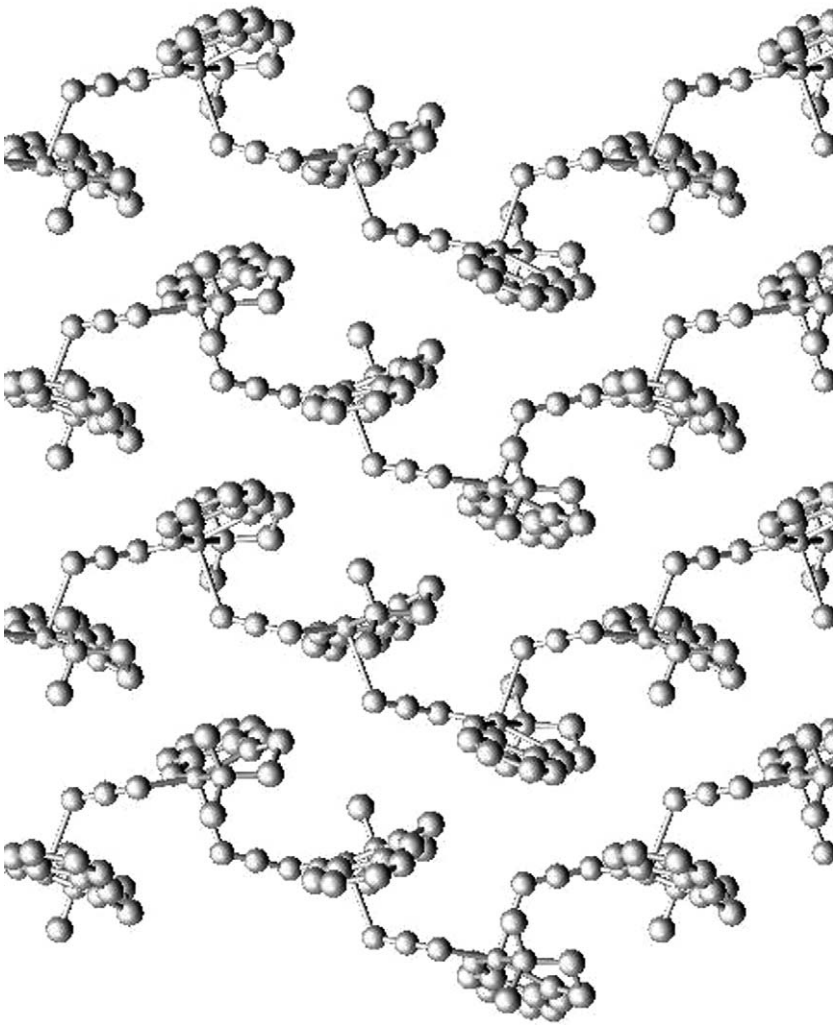

Fig. 3. Diagram showing stacking of 1D chains of complex **2**.

$g = 2.0$). Upon cooling the χ_M value for complex (**2**) increases gradually with temperature until ca. 125 K, and then rapidly, reaching a maximum of 3.7×10^{-2} cm^3 mol^{-1} at ca. 22 K. The typical folded-knee shaped χ_M versus T curve indicates a bulk antiferromagnetic interaction is operative in the complex (**2**). The $\chi_M T$ value for complex (**1**) is equal to 0.37 ± 0.01 cm^3 mol^{-1} K over the whole temperature range (4–300 K), confirming the paramagnetic nature of this mononuclear species.

In order to explain the magnetic properties of complex (**2**), a simplest case of isotropic infinite chain model that is provided by an array of equally spaced copper (II) ions bridged through μ-1,3-azido ligands with $S = 1/2$ local spins has been considered. The spin Hamiltonian of such a system considering isotropic interaction between nearest neighbour ions is

$$H = -J \sum_{i=1}^{n-1} S_{A_i} \cdot S_{A_{i+1}} \quad (1)$$

where summation runs over the n site of the chain. For the condition $n \to \infty$ no analytical method is available so as to determine the energies of low-lying states and magnetic susceptibility. Nevertheless, the problem can be dealt with numerical solution of the Hamiltonian by considering ring chains of increasing size and extrapolating for the case

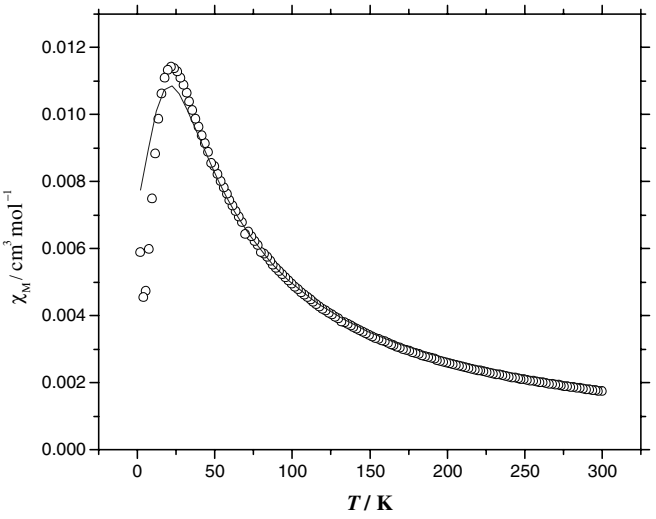

Fig. 4. χ_M vs. T(Δ) plot for complex **2**. Solid lines represent the best fit of the data with the model described in the text.

where n becomes infinite. The ring structure permits the limiting condition as follows [24,25]:

$$S_{A_{i+n}} = S_{A_i} \quad \text{for any } n \tag{2}$$

Finally, a numerical expression can be used to fit magnetic susceptibility data are given by [26]:

$$\chi_M = \frac{Ng^2\beta^2}{kT}\,\frac{0.25 + 0.074975x + 0.075235x^2}{1.0 + 0.9931x + 0.172135x^2 + 0.757825x^3} \tag{3}$$

where

$$x = |J|/kT \tag{4}$$

Fitting of the magnetic susceptibility data considering the Eq. (3) yielded the parameter values $J = -22.5(\pm 0.2)\ \mathrm{cm}^{-1}$, $g = 2.2(\pm 0.01)$, with an agreement factor $R = 7.2 \times 10^{-6}$. Fig. 4 shows the result of this fit.

4. Conclusions

It is evident from the above discussion that we have successfully isolated a series of copper (II) azido complexes with diverse structural motifs using NNO donor Schiff bases. Copper azido complexes with these types of Schiff bases are not so well documented in the literature. In an earlier attempt we were successful in isolating rather a rare variety of asymmetric double μ-1,1-azido copper (II) dimer using a tridentate Schiff base HL3 as co-ligand where ethylenediamine substructure of the Schiff base has no substitution [11]. The present study shows that by introducing the simple substitutions in the amine nitrogen of the diamine from which Schiff base is derived structural diversity can be achieved. The copper-azido complex containing Schiff base HL3 gives a double μ-1,1-azido bridged dimeric moiety while Schiff base HL2 gives a 1D polymeric chain bridged through a single μ-1,3-azido group. On the other hand, a mononuclear species having only terminal azido group is formed with co-ligand HL1. Magnetic measurement shows while complex (**2**) is showing bulk antiferromagnetism, complex (**1**) is a paramagnet. This type of studies certainly has relevance in designing newer molecular architecture for synthesizing novel molecular materials.

(bpy) and 1,10-phenanthroline (phen) and have isolated several new phases in such organic–inorganic metal-phosphate systems. In the present study, two novel examples of the chelating didentate amines-phosphate system, $[Cu_2(bpy)_2(\mu,\eta^2\text{-}HPO_4)(\mu,\eta^1\text{-}H_2PO_4)(\mu,\eta^2\text{-}H_2PO_4)]_n$ (**1**) and $[Cu_4(phen)_4(\mu_3,\eta^2\text{-}HPO_4)_2(\mu,\eta^2\text{-}H_2PO_4)_2(H_2PO_4)_2]\cdot(H_2O)_4$ (**2**) are reported, and their structural, spectroscopic and magnetic properties are discussed.

2. Experimental

All reagents were commercial grade materials and were used without further purification. Elemental analyses (C, H and N) were performed by the Microanalytical Service of Science and Technological Research Equipment Centre, Chulalongkorn University on a Perkin–Elmer PE2400 CHNS/O analyzer. IR spectra were recorded on a Perkin–Elmer spectrum One FT-IR spectrophotometer as KBr disc in the 4000–450 cm^{-1} spectral range. Solid-state (diffuse reflectance) electronic spectra were measured as polycrystalline samples on a Perkin–Elmer Lambda2S spectrophotometer, within the range 8000–18 000 cm^{-1}. The X-band powder EPR spectra were obtained on polycrystalline samples at room temperature and 77 K with a JEOL RE2X electron spin resonance spectrometer with DPPH ($g = 2.0036$) as a reference. Magnetic susceptibility measurements were carried out using a Quantum design MPMS-5S SQUID magnetometer (measurements carried out at 1000 G). Data were corrected for magnetization of the sample holder and for diamagnetic contributions, which were estimated from the Pascal constants.

2.1. Synthesis of the compounds

2.1.1. Synthesis of $[Cu_2(bpy)_2(\mu,\eta^2\text{-}HPO_4)(\mu,\eta^1\text{-}H_2PO_4)(\mu,\eta^2\text{-}H_2PO_4)]_n$ (1)

A solution of bpy (0.16 g, 1.0 mmol) in dimethyl sulfoxide (5 ml) was slowly added to a solution of $Cu(NO_3)_2\cdot 3H_2O$ (0.24 g, 1.0 mmol) in dimethyl sulfoxide (10 ml) after which a solution of KH_2PO_4 (0.27 g, 2.0 mmol) in water (5 ml) was added resulting blue green solution. Bluish-green crystals of **1** were deposited after two weeks, which were collected by filtration. Yield: 60%. *Anal*. Calc. for $C_{20}H_{21}Cu_2N_4O_{12}P_3$: C, 32.93; H, 2.90; N, 7.67. Found: C, 32.71; H, 2.91; N, 7.46%.

2.1.2. Synthesis of $[Cu_4(phen)_4(\mu_3,\eta^2\text{-}HPO_4)_2(\mu,\eta^2\text{-}H_2PO_4)_2(H_2PO_4)_2](H_2O)_4$ (2)

The complex **2** was prepared by adding an aqueous solution (10 ml) of $Cu(NO_3)_2\cdot 3H_2O$ (0.24 g, 1.0 mmol) to a solution of phen (0.18 g, 1.0 mmol) in methanol (15 ml) after which an aqueous solution (5 ml) of KH_2PO_4 (0.27 g, 2.0 mmol) was added. The blue-green solution was slowly evaporated at room temperature. Green crystals of **2** were collected from the solution by filtration after several days. Yield: 65%. *Anal*. Calc. for $C_{48}H_{50}Cu_4N_8O_{28}P_6$: C, 35.43; H, 3.09; N, 6.89. Found: C, 36.38; H, 3.12; N, 6.92%.

2.2. Crystallography

The X-ray single-crystal data for compounds **1** and **2** were collected at 293 K on a 1 K Bruker SMART CCD area detector diffractometer using graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at a detector distance of 4.5 cm and swing angle of −35°. A hemisphere of the reciprocal space was covered by combination of three sets of exposures; each set had a different ϕ angle (0°, 88°, and 180°) and each exposure of 40 s covered 0.3° in ω. Data reduction and cell refinements were performed using the program SAINT [9]. An empirical absorption correction by using the SADABS [10] program was applied, which resulted in transmission coefficients ranging from 0.708 to 1.000 for compound **1** and 0.737 to 1.000 for compound **2**. The structures were solved by direct methods and refined by full-matrix least-squares method on $(F_{obs})^2$ with anisotropic thermal parameters for all non-hydrogen atoms using the SHELXTL-PC v 6.12 software package [11]. All hydrogen atoms were located geometrically and refined isotropically except two hydrogen atoms of dihydrogenphosphate group in compound **1**. The molecular graphics were created by using the SHELXTL-PC [11] package. The crystal and refinement details for compounds **1** and **2** are listed in Table 1. Selected bond lengths and angles are given in Tables 2 and 3.

3. Results and discussion

3.1. Crystal structure of $[Cu_2(bpy)_2(\mu,\eta^2\text{-}HPO_4)(\mu,\eta^1\text{-}H_2PO_4)(\mu,\eta^2\text{-}H_2PO_4)]_n$ (1)

The structure showing several repeat units is depicted in Fig. 1 together with the numbering scheme. Selected bond distances and angles are listed in Table 2. The structure consists polymeric chains of $[Cu_2(bpy)_2(\mu,\eta^2\text{-}HPO_4)(\mu,\eta^1\text{-}H_2PO_4)(\mu,\eta^2\text{-}H_2PO_4)]$ bridged by $\mu,\eta^2\text{-}HPO_4$, $\mu,\eta^1\text{-}H_2PO_4$ and $\mu,\eta^2\text{-}H_2PO_4$ groups with different coordination modes. Two nearest Cu(II) ions are doubly-bridged by $\mu,\eta^2\text{-}HPO_4$ and $\mu,\eta^1\text{-}H_2PO_4$ ligands, and singly-bridged by a $\mu,\eta^2\text{-}H_2PO_4$ ligand to another copper(II) ion, providing a chain of distorted square-pyramidal geometries for CuN_2O_2O' chromophores with τ values of 0.03 for Cu(1) and 0.30 for Cu(2) (The τ value describes the relative amount of trigonality; $\tau = 0$ for square pyramid and $\tau = 1$ for trigonal bipyramidal [12]). Hence, the Cu(II) ions are alternatively doubly-bridged and singly-bridged along the polymeric chain. The dihydrogenphosphato ligands exhibit different coordination modes. One is in a O–P–O-bridging mode with an *antisyn–syn* configuration and the other is in a monoatomic-O-bridging mode, while the hydrogenphosphato ligand is in a O–P–O-bridging mode with a *syn–syn* configuration. The $\mu,\eta^2\text{-}HPO_4$ ligand joins two copper(II) ions in an equatorial–equatorial configuration, while the $\mu,\eta^1\text{-}H_2PO_4$ and $\mu,\eta^2\text{-}H_2PO_4$ ligands join in an axial–equatorial configuration. The Cu···Cu separation are 3.322(1) and 5.283(1) Å for a double bridge and a single bridge, respectively.

Symmetry code: A = $x + 1/2$, $y - 1/2$, z.

Both copper ions have a planar square base with a CuN_2O_2 chromophore consisting of two oxygen atoms of bridging HPO_4^{2-} and $H_2PO_4^-$ groups with Cu–O distances vary from 1.914(1) to 1.986(1) Å and two nitrogen atoms of a bpy ligand with Cu–N distances vary from 2.001(2) to 2.027(2) Å. An oxygen atom of the O–P–O-bridged and monoatomic-bridged dihydrogenphosphato ligands for Cu(1) and Cu(2), respectively completes the five-coordination of a square-pyramidal geometry with Cu(1)–O(9) distance of 2.203(1) Å and Cu(2)–O(5) distance of 2.420(1) Å. The four basal atoms show a small tetrahedral distortion with a dihedral angle of 18.5° and 21.9° formed between the CuO_2 and the CuN_2 planes, while the copper atoms are displaced by 0.23 and 0.21 Å from the basal planes toward the O(9) and O(5) atoms, respectively. Details of the hydrogen bondings are also listed in Table 2.

3.2. Crystal structure of $[Cu_4(phen)_4(\mu_3,\eta^2\text{-}HPO_4)_2(\mu,\eta^2\text{-}H_2PO_4)_2(H_2PO_4)_2](H_2O)_4$ (**2**)

A thermal ellipsoid plot of the structure is depicted in Fig. 2 with selected bond distances and angles given in Table 3. The crystal structure consists of a centrosymmetric tetranuclear $[Cu_4(phen)_4(\mu_3,\eta^2\text{-}HPO_4)_2(\mu,\eta^2\text{-}H_2PO_4)_2$-

Table 3

O(12)–H(26)···O(7)	0.60(1)	1.99(3)	2.590	175(3)

Symmetry code: A = −x, −y, −z.

$(H_2PO_4)_2$] unit and four molecules of lattice water. The four copper ions of the tetranuclear identity are linked through a double hydrogenphosphate bridge in an equatorial–equatorial and a double dihydrogenphosphate bridge in an equatorial–axial configuration with a double terminal dihydrogenphosphate group. The Cu···Cu distances varying from 3.162(1) to 5.060(1) Å. The tetranuclear unit has an inversion centre located between the Cu(2) and Cu(2)A atoms. The geometry around the copper atom is square pyramidal, having a CuN_2O_2O' chromophore and with τ values of 0.03 for Cu(1)and 0.13 for Cu(2), respectively. The basal plane consists of two oxygen atoms from each bridging dihydrogenphosphato and hydrogenphosphato group, with Cu–O distances vary from 1.923(1) to 1.949(1) Å and of phen ligand coordinated almost symmetrically through two nitrogen atoms, with Cu–N distances vary from 2.010(2) to 2.031(2) Å. The fifth (axial) coordination site is occupied by an oxygen atom of a non-bridging monodentate dihydrogenphosphato group at a distance of 2.217(1) Å for the terminal chromophore and an oxygen atom of the bridging hydrogenphosphato group at a Cu–O distance of 2.247(1) Å for the inner chromophores. The square bases are essentially planar with only a small tetrahedral twist (dihedral angles between the CuN_2 and CuO_2 planes are 22.6° and 13.1°). The Cu atom lies 0.27 and −0.14 Å above these planes towards O(1) and O(6A), respectively.

Consequently, the Cu(2) and Cu(2A) ions are doubly bridged by a monoatomic-bridged μ_3,η^2-HPO_4 anion in an equatorial–axial configuration. Both hydrogenphosphate ligands exhibit a unique tridentate anion displaying a dual nature, i.e., triatomic-O–P–O and monoatomic-O bridges. Details of the hydrogen bondings are also listed in Table 3.

For both compounds several moderate to strong intermoleculrar H bonds are observed; these are not further discussed.

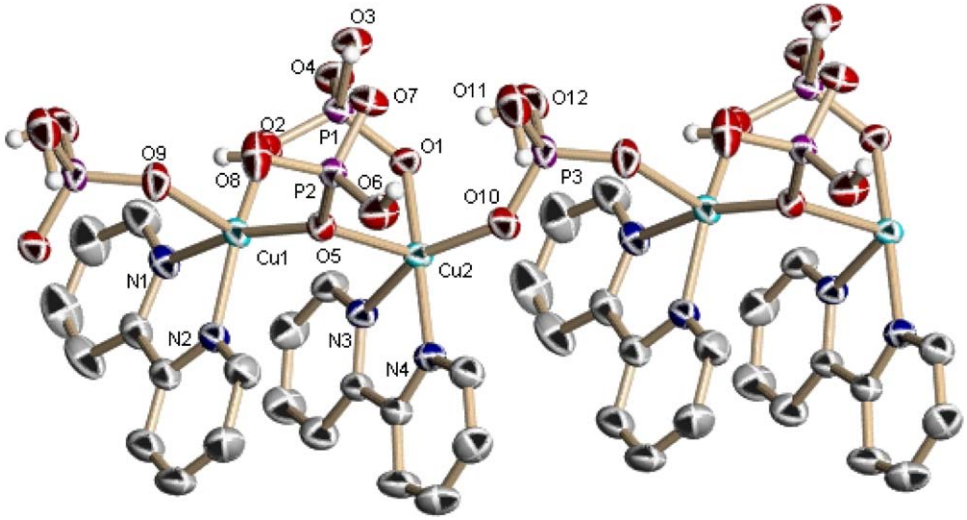

Fig. 1. Thermal ellipsoid plot (50% probability) of two units of [Cu_2(bpy)$_2$(μ,η^2-HPO_4)(μ,η^1-H_2PO_4)(μ,η^2-H_2PO_4)]$_n$ (**1**). The hydrogen atoms of pyridine ring are omitted for clarity.

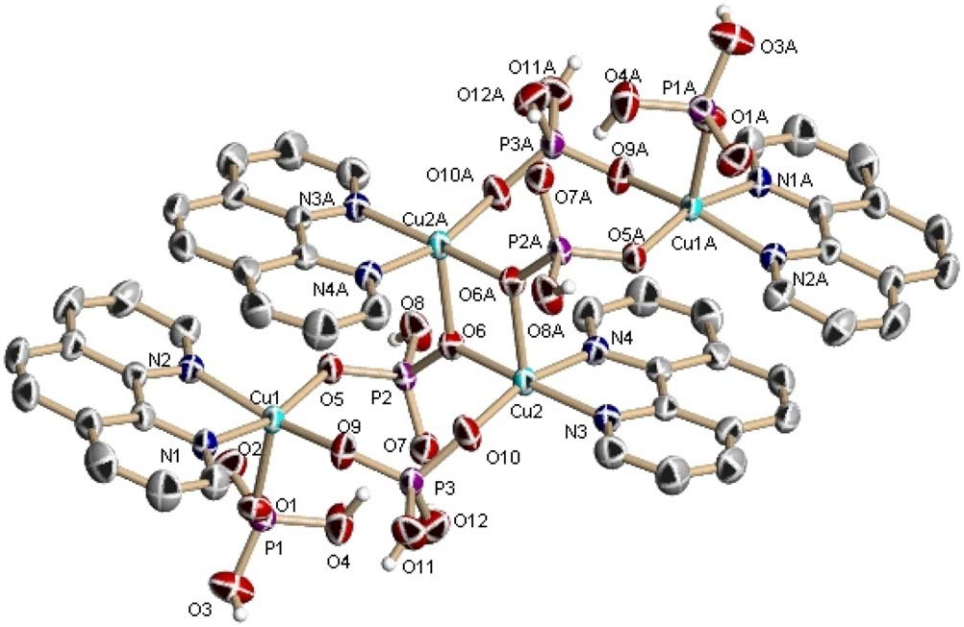

Fig. 2. Thermal ellipsoid plot (50% probability) plot of $[Cu_4(phen)_4(\mu_3,\eta^2\text{-}HPO_4)_2(\mu,\eta^2H_2PO_4)_2(H_2PO_4)_2](H_2O)_4$ (**2**). Atoms with an "A" are generated by an inversion centre and hydrogen atoms of pyridine ring are omitted for clarity.

3.3. Structure comparisons

The polymeric structure of complex **1** is comparable to those of earlier reported complexes with chelate didentate amine-phosphate system, $\{[Cu_3(dpyam)_3(\mu_3,\eta^3\text{-}HPO_4)(\mu_3,\eta^4\text{-}PO_4)(H_2O)](PF_6)\cdot 3H_2O\}_n$ (**3**) [13], $[Cu(dpyam)(\mu,\eta^3\text{-}HPO_4)]_n$ (**4**) [14] and $[Cu(phen)(\mu\text{-}HPO_4)(H_2O)_2]$ (**5**) [15] (see Table 4) all having a polymeric structure with bridging polyvalent hydrogenphosphate groups. The Cu atoms of **3** are bridged unsymmetrically through mixed 3M,3L (where M = metal and L = ligand) hydrogenphosphate and 3M,4L phosphate coordination modes. The bridging HPO_4^{2-} and PO_4^{3-} groups join copper(II) ions in an equatorial–equatorial and axial– equatorial configurations between two distorted square-pyramidal chromophores and two different geometry chromophores. The copper(II) ions in compound **4** are bridged by tridentate hydrogenphosphato ligands giving a 2M,3L coordination mode with the HPO_4 bridge linking Cu(II) ions in an equatorial–equatorial and axial–equatorial configurations. While those of compound **5** are bridged by didentate hydrogenphosphato ligands, giving a 2M,2L coordination mode, joining two copper(II) ions in an axial–axial configuration. However, compound **1** is also comparable to the $[Cu(dpyam)(\mu,\eta^2\text{-}H_2PO_4)(H_2PO_4)]_2$ (**6**) complex containing the monovalent dihydrogenphosphate group [14], Cu(II) ions being doubly bridged by two didentate dihydrogenphosphato anions with the 2M,2L coordination mode. The bridging oxoanion ligand joins two copper(II) ions in an equatorial–equatorial configuration (see Table 4).

The square-pyramidal CuN_2O_2O' chromophore of complex **2** corresponds to the copper environments of the known tetranuclear structures; $[Cu_4(dpyam)_4(\mu_4,\eta^3\text{-}HPO_4)_2(\mu\text{-}Cl)_2](Cl)_2\cdot 6H_2O$ (**7**) [16], $[Cu_4(dpyam)_4(\mu_4,\eta^3\text{-}HPO_4)_2(\mu\text{-}Br)_2](Br)_2\cdot 6H_2O$ (**8**) [16] and $[Cu_4(dpyam)_4(\mu_3,\eta^3\text{-}HPO_4)_2(NO_3)_2(H_2O)_2](NO_3)_2\cdot 2H_2O$ (**9**) [17] (see Table 5). Complexes **7** and **8** involve two pairs of five-coordinated copper(II) ions bridged by two tetrahedral, tridentate hydrogenphosphato groups in each molecules. All copper (II) ions are linked to each other via double-bridged HPO_4^{2-} groups in an equatorial–equatorial configuration giving a 4M,3L coordination mode. While four copper ions of complex **9**, are linked through a double hydrogenphosphate bridge, they give a 3M,3L coordination mode. Each chromophore is linked to another Cu(II) via a HPO_4^{2-} group in an equatorial–equatorial configuration between square pyramidal chromophores and in an axial–equatorial configuration between different geometry chromophores.

3.4. Spectroscopic properties

The electronic diffuse reflectance spectra of **1** and **2** show a broad band at 14000 and 14410 cm^{-1}, respectively. This observed single broad peak is consistent with the square pyramidal stereochemistry and assigned to be d_{z^2}, d_{xy}, d_{xz}, $d_{yz} \rightarrow d_{x^2-y^2}$ transition [18].

The infrared spectrum of complex **1** displays the characteristic bands of δ(P–O–(H)) in-plane deformation, ν_{as}(P–O), ν_s(P–O), δ(P–O–(H)) out-of-plane deformation and δ(O–P–O) at about 1317 and 1247; 1158–1024; 977; 878 cm^{-1}; and 527 and 487 cm^{-1}, respectively, which corresponds to those reported in the literature [19–22]. The IR spectrum of complex **2** shows bands at about 1320 and 1259; 1156–1065; 975 cm^{-1}; and 852 cm^{-1} characteristic

3.5. EPR and magnetic properties

The EPR spectrum of the powdered compounds reveals at room temperature and at 77 K an axial signal with $g_\perp = 2.09$ and an unresolved $g_\parallel = 2.28$ for compound **1** and $g_\perp = 2.04$ and an unresolved $g_\parallel = 2.26$ for compound **2**. The signals are consistent with the $d_{x^2-y^2}$ ground state and the planar based geometry [18]. No triplet signal has been observed.

The magnetic susceptibility of a powdered sample of compound **1** was measured from 5 to 350 K. The magnetic properties of the compound are depicted in Fig. 3 in the form of a plot of $\chi_m T$ versus T. At 350 K the $\chi_m T$ value is 0.83 $cm^3\,mol^{-1}$ K, slightly higher from that expected for two uncoupled Cu(II) centres ($\chi_m T = 0.75\ cm^3\ mol^{-1}$ K, with $g = 2$). With decreasing temperature the $\chi_m T$ value remains constant until at about 20 K, where it starts to decrease until 0.46 $cm^3\,mol^{-1}$ K at 5 K. This behaviour agrees with a weak antiferromagnetic interaction.

The chain-like structure can be considered as formed by dinuclear units bridged by hydrogenphosphato anions. The Cu–Cu distance between the copper dinuclear units bridged by the hydrogenphosphato anion is 5.28 Å and is large enough to consider these dinuclear units as being independent and any interaction between these dinuclear units as intermolecular.

The theoretical expression for the magnetic susceptibility for two interacting $S = 1/2$ centres, which is based on the general Hamiltonian [25] is: $H_{ex} = -JS_1S_2$, in which the exchange parameter J, is negative for antiferromagnetic and positive for ferromagnetic interaction. The magnetic data were fitted to the equation given in the literature for dinuclear copper compounds [25]: $\chi_m = 2Ng^2\beta^2[kT - 2zJ'/(3 + \exp(-J/kT)]^{-1}[3 + \exp(-J/kT)]^{-1}) \cdot (1 - p) + (Ng^2\beta^2/2kT) \cdot p + \mathrm{TIP}$, in which N, g, β, k and T have their usual meanings [25]. The parameter p denotes the fraction of paramagnetic impurity in the sample and zJ' the interaction between the neighbouring dinuclear units.

The best fit, depicted in Fig. 3 as a solid line, was obtained (fixing the TIP, temperature independent paramagnetism, to $140 \times 10^{-6}\ cm^3\,mol^{-1}$ K) for $J = -5.3\ cm^{-1}$, $g = 2.05$, $zJ' = 0.28\ cm^{-1}$, $p = 0$. As the two copper centres are in a square pyramidal (SP) geometry, their magnetic orbital is the $d_{x^2-y^2}$. One of the hydrogenphosphato anions is bridging the two centres through two of its oxygen atoms, which are coordinated to the metals in the basal plane. This path allows a weak antiferromagnetic interaction to occur between the coppers. The magnitude of the interaction is explained by the fact that the two basal planes of the copper atoms are almost parallel to each other and thus their overlap will be small. The other hydrogenphosphato anion bridges the two centres through a non-magnetic orbital of one of the coppers (d_{z^2}), and any type of interaction will be weak and thus masked by the major one. The zJ' value points to a weak interdimer ferromagnetic interaction. If $z = 2$, as it is a 1-D polymer, then $J' = 0.14$.

The distance between the coppers and the fact that one of the orbitals involved in the overlapping is non-magnetic, account for the weakness of the interaction. The ferromagnetic character of the interaction is evidenced by the perpendicularity of the d_{z^2} and the $d_{x^2-y^2}$ orbitals involved in this bridge. An "overall" antiferromagnetic behaviour determined by the intradimer interaction is observed for compound **1**.

The magnetic susceptibility of a powdered sample of compound **2** was measured from 5 to 200 K. The magnetic properties of the bulk compound are depicted in Fig. 4 in the form of a plot of $\chi_m T$ versus T and χ_m versus T.

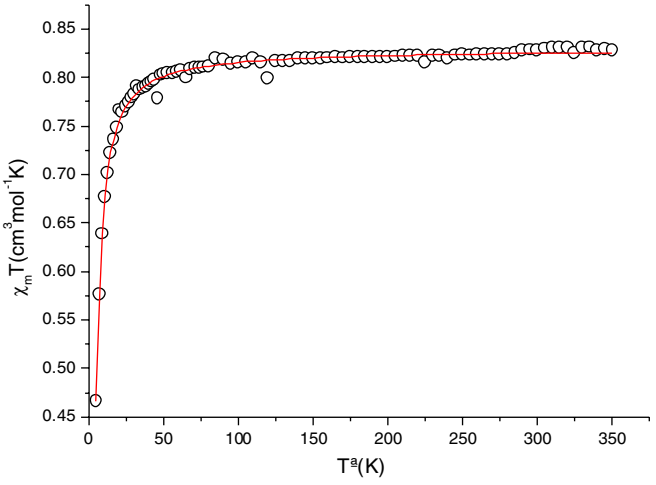

Fig. 3. A plot of the temperature dependence of $\chi_m T$ vs. T for compound **1**. The solid line represents the calculated curve for the parameters $J = -5.3\ cm^{-1}$, $g = 2.05$, $zJ' = 0.28\ cm^{-1}$ (see text).

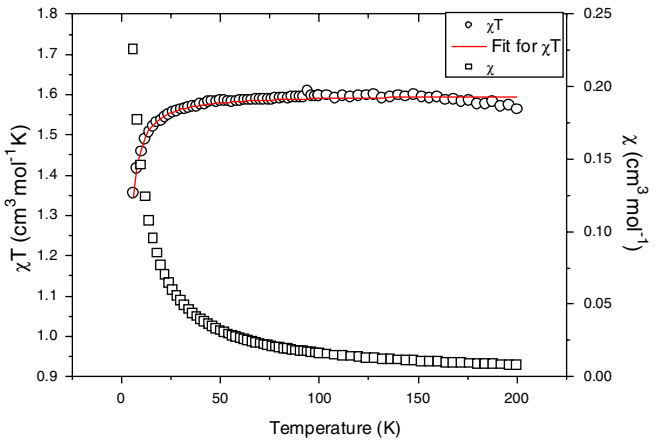

Fig. 4. The χ_m vs. T (□) and $\chi_m T$ vs. T (○) plots for compound **2**. The solid line represents the calculated curve for the parameters given in the text.

At 200 K the $\chi_m T$ value is 1.58 $cm^3\ mol^{-1}\ K$, which corresponds to the value for four uncoupled Cu(II) centres ($\chi_m T = 1.5\ cm^3\ mol^{-1}\ K$, with $g = 2$). With lowering temperature the $\chi_m T$ value remains constant until at about 16 K, where it starts to decrease to 1.35 $cm^3\ mol^{-1}\ K$ at 5 K. This behaviour agrees with an overall weak antiferromagnetic interaction.

For a tetranuclear compound with the present topology (see Scheme 1), the following Hamiltonian can be used [15,26,27].

$$\begin{aligned} H = &-2\cdot J_1(\mathbf{S}_2\mathbf{S}_{2a}) - 2\cdot J_2(\mathbf{S}_2\mathbf{S}_1 + \mathbf{S}_{2a}\mathbf{S}_{1a}) \\ &- 2\cdot J_3(\mathbf{S}_2\mathbf{S}_{1a} + \mathbf{S}_{2a}\mathbf{S}_1) - 2\cdot J_4(\mathbf{S}_{1a}\mathbf{S}_1) \end{aligned}$$

Considering the energy levels and the spin quantum numbers as follows:

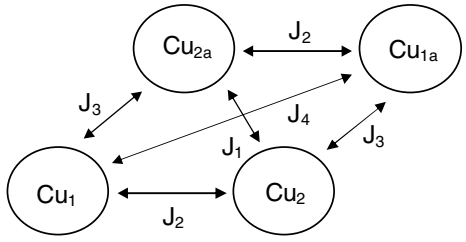
$$\begin{aligned}
&S_1 = 2, \quad E_1 = -J_1 - J_2/2 - J_3 - J_4/2 \\
&S_2 = 1, \quad E_2 = -J_1 - J_2/2 + J_3 - J_4/2 \\
&S_3 = 1, \quad E_3 = (J_2 + J_4)/2 + [(J_2 - J_4)^2 + (J_3 - J_1)^2]^{1/2} \\
&S_4 = 1, \quad E_4 = (J_2 + J_4)/2 - [(J_2 - J_4)^2 + (J_3 - J_1)^2]^{1/2} \\
&S_5 = 0, \quad E_5 = J_1 + J_3 + (J_2 + J_4)/2 + [4(J_1^2 + J_3^2) + J_2^2 + J_4^2 - 2J_1(J_2 + 2J_3 + J_4) - 2J_2(J_3 - J_4) - 2J_3J_4]^{1/2} \\
&S_6 = 0, \quad E_6 = J_1 + J_3 + (J_2 + J_4)/2 - [4(J_1^2 + J_3^2) + J_2^2 + J_4^2 - 2J_1(J_2 + 2J_3 + J_4) - 2J_2(J_3 - J_4) - 2J_3J_4]^{1/2}
\end{aligned}$$

Then the expression for the magnetic susceptibility per tetranuclear unit is described by:

$$\begin{aligned} \chi_M = &(N_A g^2\beta^2/k_B T)[10\exp(-E_1/K_B T) + 2\exp(-E_2/K_B T) \\ &+ 2\exp(-E_3/K_B T) + 2\exp(-E_4/K_B T)] \\ &/[5\exp(-E_1/K_B T) + 3\exp(-E_2/K_B T) \\ &+ 3\exp(-E_3/K_B T) + 3\exp(-E_4/K_B T) \\ &+ \exp(-E_5/K_B T) + \exp(-E_6/K_B T)] + \mathrm{TIP} \end{aligned}$$

The values of N, g, β, k and T have their usual meanings and the TIP was fixed to $60\times10^{-6}\ cm^3\ mol^{-1}\ K$ per copper atom [25]. An impurity factor (p) was considered to account for any paramagnetic impurity. When fixing $J_4 = 0$, the best set of parameters were obtained as: $g = 2.06$, $J_1 = 0.12\ cm^{-1}$, $J_2 = -1.32\ cm^{-1}$, $J_3 = 0.1\ cm^{-1}$ and $p = 0.001$.

The values obtained indicate that the overall magnetic behaviour is dominated by the interaction parameter J_2. The lack of a clear path for any interaction to occur can justify the weakness of the coupling constants. The parameter J_1, the coupling constant between the two central copper centres (see Scheme 1), is weak ferromagnetic. Both metal centres have SP geometry, thus both have the $d_{x^2-y^2}$ as their magnetic orbital. In each case the path to communicate implies the magnetic orbital of one metal centre ($d_{x^2-y^2}$) with a non-magnetic orbital of the other copper (d_{z^2}), hindering the interaction. The low electronic-paramagnetic density of the d_{z^2} and its perpendicularity with respect to the $d_{x^2-y^2}$ makes the small value for J_1 reasonable. A negative value for the interaction parameter J_2 is obtained, pointing at a weak antiferromagnetic interaction between the central and the external coppers ($Cu_1\cdots Cu_2$, 5.06 Å). This is in agreement with the relative positions of the magnetic orbitals of the metal centres. With respect to the previous constant, in this case both orbitals implied are magnetic, and a much stronger interaction could be expected. The long distance between the coppers, created by the anion (5.06 Å), can account for the weakness of the interaction [12]. The parameter J_3, like J_1, is ferromagnetic. The μ-O-hydrogenphosphato anion bridges Cu1 and Cu2a (J_3) with a hydrogenphosphato-O,O mode. The interaction occurs between two perpendicular orbitals in which one of them is non-magnetic, explaining both sign and intensity of the interaction. Moreover, the long distance between the coppers, due to the hydrogenphosphato-O,O bridge mode, makes the interaction almost negligible. In previous cases, the distortion of the copper geometry and the subsequent diminish of the electron delocalization, was pointed as a plausible explanation of the weak interaction [12,16]. In the present case the compound's fairly regular SP geometry of the copper discards this possibility. The long distances between coppers created by the hydrogenphosphato-O,O-bridge mode or the involvement of a non-magnetic orbital in the communication path, must account for this weak bulk magnetic interaction.



Scheme 1. Scheme of the magnetic interactions in the tetranuclear compound **2**.

4. Conclusions

The crystal structure determination of the two new hydrogenphosphate-bridged Cu(II) compounds, a dinuclear compound bridged by hydrogenphosphate molecules to form a polynuclear identity **1** and a tetranuclear compound **2**. In all cases the Cu–Cu distances are fairly large and the magnetic interaction must occur via the hydrogenphosphate molecules.

As can be seen from Table 4, which shows a number of compounds related to compound **1**, the magnetic interaction in these compounds is in general weakly antiferromagnetic.

In Table 5 a number of compounds are shown which are related to compound 2 and as can be seen from these the magnetic interaction is rather complicated and varies from a weak antiferromagnetic to a weak ferromagnetic interaction.

complex **1** became Ni(tpp-*N*-O) (**2**) [12]. However, until now there has been no X-ray structural data available for the diamagnetic and bridged metal [M(III)] porphyrin complexes with an oxygen atom being inserted between one metal–N unit and with a coordination number (CN) above 4 (i.e., with CN $\geqq$ 5).

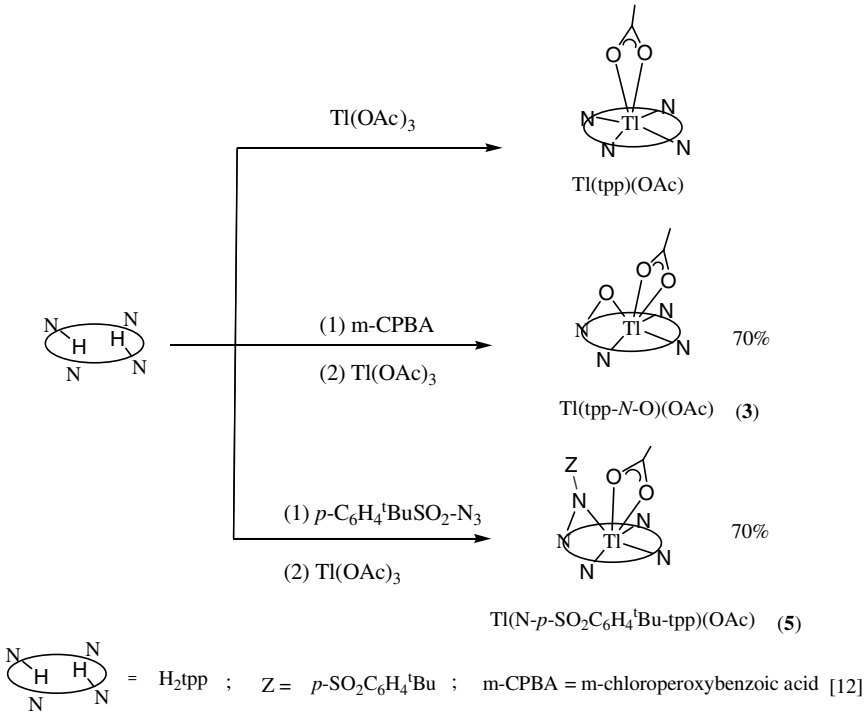
In order to investigate the range of metal ions that can be inserted into H_2(tpp-*N*-O), we present the results upon replacing Ni(II) with Tl(III) in Ni(tpp-*N*-O) (**2**) forming a new complex Tl(tpp-*N*-O)(OAc) (**3**). This replacement increases the coordination number (CN) from four for **2** to six for Tl(tpp-*N*-O)(OAc) (**3**). The presence of acetate ligands in **3** plays a potential role in increasing the coordination number.

In order to figure out the structural features of oxygen and nitrogen inserted into the Tl–N bond, we also describe the synthesis and X-ray structural investigation on the metallation of 21-(4-*tert*-butyl-benzensulfonamido)-5,10,15,20-tetraphenylporphyrin [N-*p*-$HNSO_2C_6H_4{}^t$Bu-Htpp (**4**)], leading to the mononuclear complex *cis*-acetato-N-*p*-*tert*-butylbenzensulfonylimido-*meso*-tetraphenylporphyrinato-thallium(III) Tl(N-*p*-$NSO_2C_6H_4{}^t$Bu-tpp)(OAc) (**5**). Because of the large size of Tl^{3+} (r_{ion} = 1.025 Å) [13] the relative position of acetate and the 4-*tert*-butylbenzensulfonyl (^{t}BuBS) group coordinated to the Tl atom might lead to a *cis* configuration in **5** [5,8,9]. Prompted by earlier studies on the acetato exchange of Tl(tpp)(OAc) and Tl(N-NTs-tpp)-(OAc) in CD_2Cl_2(NTs = tosylimido) [8,14,15], we investigated a similar intermolecular acetato exchange for **3** and **5** in CD_2Cl_2 by ^{1}H and ^{13}C dynamic NMR methods. Thallium shows rich coupling patterns to the nuclei of the porphyrin core and to the porphyrin substituents and axial ligands. Many long-range Tl–C and Tl–H couplings to the porphyrin substituents and to the axial ligands are observed [16,17]. Moreover, there is no precedence in the literature that the magnitude of two- and three-bond thallium–carbon spin–spin coupling constants between the Tl atom and the OAc^- group of **3** and **5** depends on the electronegative substituents X (i.e., X = O in **3** and N in **5**) attached to the thallium atom. Thus, the electronegative dependence of spin–spin coupling constants $^nJ(Tl-{}^{13}C)$ (n = 2, 3) for the OAc^- ligand of **3** and **5** will be studied for the first time in the chemistry of thallium porphyrins. The compound **3** is the first thallium porphyrin complex with a Tl–O–N(Por) linkage and **5** represents the fourth thallium complex with a Tl–N(R)–N(Por) linkage reported in the literature [5,8,9].

2. Experimental

2.1. Tl(tpp-*N*-O)(OAc) (3)

A mixture of H_2(tpp-*N*-O) (0.063 g, 0.1 mmol) in CH_2Cl_2 (20 cm^3) and $Tl(OAc)_3$ (0.08 g, 0.2 mmol) in MeOH (10 cm^3) was refluxed for 3 h (Scheme 1) [12]. After concentrating, the residue was redissolved in CH_2Cl_2, dried with anhydrous Na_2SO_4, and filtered. The filtrate was concentrated and recrystallized from CH_2Cl_2–MeOH [1:2 (v/v)] yielding the blue solid of **3** (0.062 g, 7×10^{-2} mmol, 70%). Compound **3** was dissolved in toluene to crystallize out as blue crystals for single-crystal X-ray analysis. ^{1}H NMR (599.95 MHz, $CDCl_3$, 20 °C): δ 9.18 [dd, 2H, H_β



Scheme 1.

(2, 13), ^4J(Tl–H) = 13 Hz and ^3J(H–H) = 4.8 Hz], H_β (a, b) represents the 2 equiv. β-pyrrole protons attached to carbons a and b, respectively; 8.93 [dd, 2H, H_β (3, 12), ^4J(Tl–H) = 20 Hz and ^3J(H–H) = 4.8 Hz]; 8.79 [d, 2H, H_β (7, 8), ^4J(Tl–H) = 79 Hz]; 6.65 [s, 2H, H_β (17, 18)]; 8.45 [d, 2H, *o*-H (26, 28), ^3J(H–H) = 4.4 Hz], *o*-H represents *ortho* phenyl protons; 8.07 [s, 2H, *o*-H (22, 32)]; 7.72–7.81(m, 12H) for *meta* and *para* phenyl protons (*m*-, *p*-H); 0.54 (s, 3H, OAc). FAB MS, *m*/*z* (assignment, rel. intensity): 154 ($[NBA + H]^+$, 100), 614 ($[H_2tpp]^+$, 36.31), 630 ($[H_2tpp\text{-}N\text{-}O]^+$, 40.13), 631 ($[H_2tpp\text{-}N\text{-}O + H]^+$, 42.67), 833 ($[Tl(tpp\text{-}N\text{-}O)]^+$, 64.31), UV/Vis spectrum, λ/nm [$\varepsilon \times 10^{-3}$ ($M^{-1}\,cm^{-1}$)] in CH_2Cl_2: 333.2 (17.1), 477.2 (173.0), 584.4 (9.1), 626.0 (10.9).

2.2. Tl(N-*p*-$NSO_2C_6H_4{}^t$Bu-tpp)(OAc) (5)

A mixture of $Tl(OAc)_3$ (0.05 g, 1.31×10^{-4} mol) in MeOH (20 cm^3) and N-*p*-$HNSO_2C_6H_4{}^t$Bu-Htpp (0.05 g, 6.06×10^{-5} mol) in CH_2Cl_2 (50 cm^3) was refluxed for 3 h (Scheme 1) [9]. After concentrating, the residue was dissolved in CH_2Cl_2, dried with anhydrous Na_2SO_4, and filtered. The filtrate was concentrated and recrystallized from CH_2Cl_2–MeOH [1:3 (v/v)] yielding the bluish-purple solid of **5** (0.046 g, 4.23×10^{-5} mol, 70%) which was again dissolved in CH_2Cl_2 and layered with MeOH to get purple crystals for single crystal X-ray analysis. ^{1}H NMR (299.95 MHz, CD_2Cl_2, 20 °C): δ 9.05 [dd, 2H, H_β (10, 19), ^4J(Tl–H) = 17.1 Hz and ^3J(H–H) = 4.8 Hz]; 8.92 [dd, 2H, H_β (9, 20), ^4J(Tl–H) = 10.4 Hz and ^3J(H–H) = 4.8 Hz]; 8.69 [d, 2H, H_β (4, 5), ^4J(Tl–H) = 76.5 Hz]; 8.38 [d, 2H, ^3J(H–H) = 7 Hz] and 8.10 [d, 2H, ^3J(H–H) = 7 Hz] for *ortho* protons; 7.85–7.76 (m, 12H, for *meta* and *para* protons); 7.07 [d, 2H, ^{t}BuBS-$H_{3,5}$ or H (49, 51), ^3J(H–H) = 8 Hz]; 6.94 [s, 2H, H_β (14, 15)], 6.09 [d, 2H, ^{t}BuBS-$H_{2,6}$ or H (48, 52), ^3J(H–H) = 8 Hz]; 1.15 (s, 9H, *t*-butyl protons); 0.62 (s, 3H, OAc). ESI–MS, *m*/*z* (assignment, rel. intensity): 1087 ($[Tl(N\text{-}p\text{-}NSO_2C_6H_4{}^t$Bu-tpp)(OAc)$]^+$, 12.26), 1086 ($[Tl(N\text{-}p\text{-}NSO_2C_6H_4{}^t$Bu-tpp)(OAc)-H$]^+$, 16.34), 1030 ($[Tl(N\text{-}p\text{-}NSO_2C_6H_4{}^t$Bu-tpp) + 2 H$]^+$, 100), 1028 ($[Tl(N\text{-}p\text{-}NSO_2C_6H_4{}^t$Bu-tpp$)]^+$, 74.18). UV/Vis spectrum, λ/nm [$\varepsilon \times 10^{-3}$ ($M^{-1}\,cm^{-1}$)] in CH_2Cl_2: 332 (23.0), 446 (354), 555 (8.4), 609 (19.1).

2.3. Spectroscopy

Proton and ^{13}C NMR spectra were recorded at 299.95 (or 599.95) and 75.43 (or 150.87) MHz, respectively, on Varian VXR-300 (or Varian Unity Inova-600) spectrometers locked on deuterated solvent, and referenced to the solvent peak. Proton NMR is relative to CD_2Cl_2 or $CDCl_3$ at $\delta = 5.30$ or 7.24 and ^{13}C NMR to the center line of CD_2Cl_2 or $CDCl_3$ at $\delta = 53.6$ or 77.0. HMQC (heteronuclear multiple quantum coherence) was used to correlate protons and carbon through one-bond coupling and HMBC (heteronuclear multiple bond coherence) for two- and three-bond proton–carbon coupling. Nuclear Overhauser effect (NOE) difference spectroscopy was employed to determine the ^{1}H–^{1}H proximity through space over a distance of up to about 4 Å.

Positive ion mode ESI mass spectra were acquired at room temperature on a ThermoFinnigan LCQ Advantage mass spectrometer. The positive-ion fast atom bombardment mass spectrum (FAB MS) was obtained in a nitrobenzyl alcohol (NBA) matrix using a JEOL JMS-SX/SX 102A mass spectrometer. UV/Vis spectra were recorded at 20 °C on a HITACHI U-3210 spectrophotometer.

2.4. Crystallography

Table 1 presents the crystal data as well as other information for **3** and **5**. Measurements for **3** were taken on a Nonius Kappa CCD diffractometer using monochromatized Mo Kα radiation ($\lambda = 0.71073$ Å) at a temperature of 100(1) K. Measurements for **5** were taken on a Bruker AXS SMART-1000 diffractometer using monochromatized Mo Kα radiation ($\lambda = 0.71073$ Å) at a temperature of 100(2) K. Muti-scan absorption corrections were made for **3** and empirical absorption corrections were made for **5**. The structures were solved by direct methods (SHELXL-97) [18] and refined by the full-matrix least-squares method. The OAc group within **3** is disordered with an occupancy factor of 0.6 for O(2)O(3)C(45)C(46) and 0.4 for O(2′)O(3′)C(45′)C(46′). These four atoms (i.e., O(2), O(3), C(45) and C(46)) were refined with isotropic displacement parameters. All non-hydrogen atoms, except the

above four atoms, were refined with anisotropic thermal parameters, whereas all hydrogen atoms were placed in calculated positions and refined with a riding model. Table 2 lists selected bond distances and bond angles for complexes **3** and **5**.

3. Results and discussion

3.1. Molecular structures of 3 and 5

The X-ray molecules are depicted in Fig. 1a for the complex Tl(tpp-*N*-O)(OAc) (**3**) and in Fig. 1b for Tl(N-*p*-$NSO_2C_6H_4{}^t$Bu-tpp)(OAc)**5**. The complex **3** co-recrystallizes with 1 equiv. of CH_2Cl_2 solvent molecule in the triclinic space group $P\bar{1}$, and complex **5** recrystallizes in the monoclinic space group $P2_1/n$. In both **3** and **5**, it is obvious that the oxygen and $NSO_2C_6H_4{}^t$Bu moieties have been inserted into the Tl–N bond of acetato(*meso*-tetraphenylporphyrinato)thallium(III) Tl(tpp)(OAc) (see Scheme 1) [15].

The metal–ligand bond distances and the bond angles are summarized in Table 2. The bond distance (Å) are Tl–O(2) = 2.357(9), Tl–O(3) = 2.348(8) and Tl–O(1) = 2.126(4) and the mean Tl–N(*p*) = 2.264(4) for **3**; for **5** the values are Tl(1)–O(1) = 2.337(2) and Tl(1)–O(2) = 2.350(2) and the mean Tl(1)–N(*p*) = 2.241(2). Since the acetate of **3** was disordered, data reported involving O(2) and O(3) refer to the acetate at the higher occupancy factor of 0.6.

The geometry around Tl^{3+} is described as a distorted square-based pyramid in which the apical site is occupied

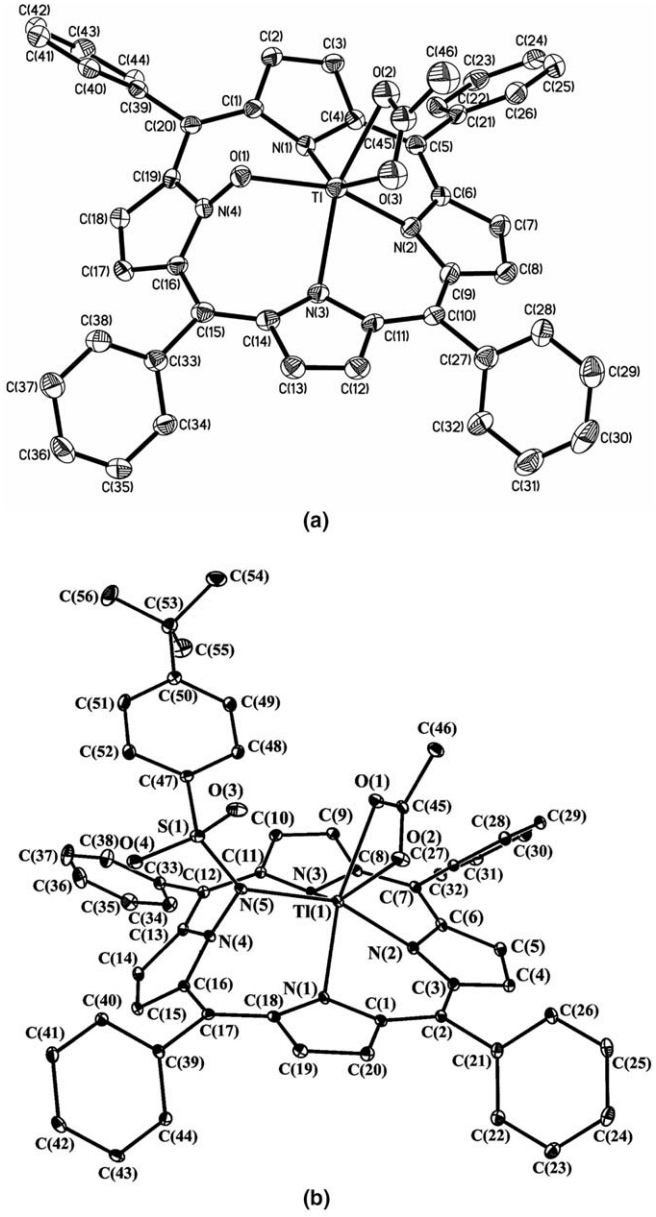

Fig. 1. Molecular configuration and atom labelling scheme for (a) Tl(tpp-*N*-O)(OAc) (**3**), (b) Tl(N-*p*-$SO_2C_6H_4{}^t$Bu-tpp)(OAc) (**5**), with ellipsoids drawn at 50% probability for **3** and at 30% probability for **5**. Hydrogen atoms for all compounds are omitted for clarity.

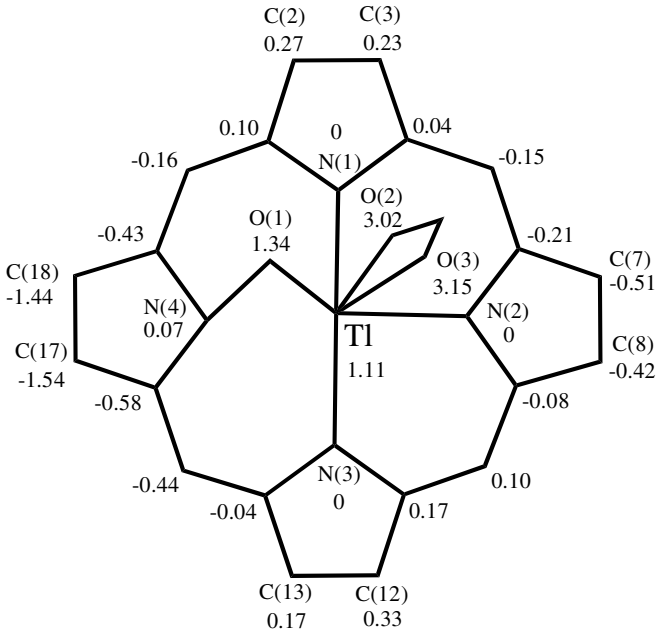
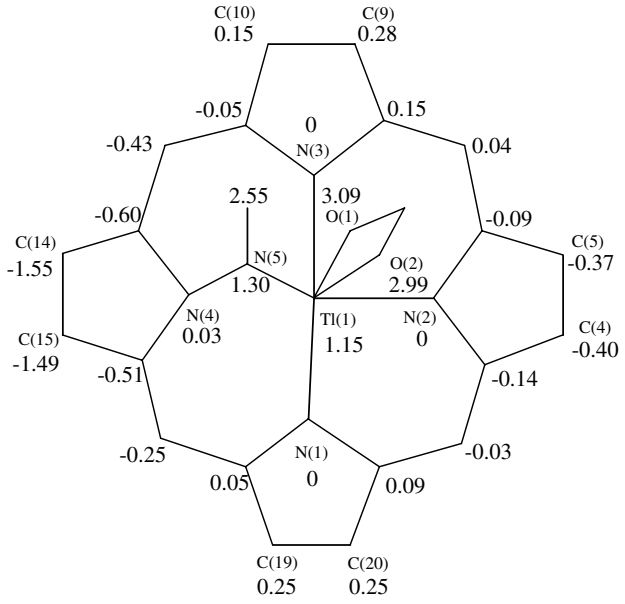
by a bidentate chelating OAc^- group for **3** and **5**. Fig. 2 shows the actual porphyrin skeleton of **3** and **5**. The pyrrole nitrogens N(4) (in **3** and **5**) are no longer bonded to the thallium as indicated by their longer internuclear distances, 2.831(4) Å for N(4)···Tl (in **3**) and 2.899(2) Å for N(4)···Tl(1) (in **5**). The plane of three strongly bound pyrrole nitrogen atoms (i.e., N(1)–N(3) for **3** and **5**) is adopted as a reference plane 3*N*. It is noted that the ionic radius increases from 0.63 Å for Ni^{2+} to 1.025 Å for Tl^{3+} [1,13]. Because of the larger size of Tl^{3+}, Tl and O(1) lie 1.11 and 1.34 Å, respectively, above the 3*N* plane in **3**, compared to 1.15 Å for Tl(1) and 1.30 Å for N(5) in **5** (cf. 0.05 Å for Ni(II) in Ni(OEP-*N*-O)) (Fig. 2) [1].



(a) Tl(tpp-*N*-O)(OAc) **3**



(b) Tl(N-*p*-$NSO_2C_6H_4{}^t$Bu-tpp)(OAc) **5**

Fig. 2. Diagram of the porphyrinato core ($C_{20}N_4$, M, O, ^{t}BuBS and OAc^-) of (a) **3** · CH_2Cl_2 and (b) **5**. The values represent the displacements (in angstroms) of the atoms from the mean 3*N* plane (i.e., N(1)–N(3) for **3** · CH_2Cl_2 and **5**).

The porphyrin macrocycle is indeed distorted because of the presence of the oxygen [O(1)] and the $NSO_2C_6H_4{}^t$Bu group in **3** and **5**, respectively (Fig. 2). Thus, N(4) in the **3** and **5** pyrrole rings bearing the oxygen and the $NSO_2C_6H_4{}^t$Bu group is deviated most from the 3*N* plane and oriented separately with a dihedral angle of 47.3° and of 46.7°, whereas small angles of 7.0°, 13.1° and 9.0° occur with N(1), N(2) and N(3) pyrroles for compound **3** and 6.8°, 10.8° and 7.9° with N(1), N(2) and N(3) pyrroles for compound **5**. The dihedral angles between the mean plane of the skeleton (3*N*) and the plane of the phenyl group are 49.8° [C(24)], 53.1° [C(30)], 44.7° [C(36)] and 44.0° [C(42)] for **3** and the corresponding angles are 49.4°, 57.4°, 45.0° and 53.1° for **5**.

Table 3
Comparison of distances (Å) and bond angles (°) in **3** and **5** with oxygen and nitrogen units (X) inserted between one Tl–N unit

Parameters	X = O (**3**)	Parameters	X = $NSO_2C_6H_4{}^t$Bu (**5**)
3		**5**	
O(1)–Tl	2.126(4)	Tl(1)–N(5)	2.128(2)
N(1)–Tl	2.306(4)	Tl(1)–N(1)	2.320(2)
N(2)–Tl	2.150(4)	Tl(1)–N(2)	2.153(2)
N(3)–Tl	2.335(4)	Tl(1)–N(3)	2.364(2)
N(4)···Tl	2.831(4)	Tl(1)···N(4)	2.899(2)
N(4)–O(1)	1.369(5)	N(4)–N(5)	1.386(3)
O(1)–Tl–N(2)	155.45(16)	N(5)–Tl(1)–N(2)	151.74(9)
N(1)–Tl–N(3)	121.28(15)	N(3)–Tl(1)–N(1)	118.84(8)

Table 3 contains some comparative data. The N(4)–O(1) distance of 1.369(5) Å in **3** is comparable to that in Ni(OEP-*N*-O) [1.363(6) Å] [1]. The *trans* O(1)–Tl–N(2) and N(1)–Tl–N(3) angles [155.45(16)° and 121.28(15)°] in **3** and the corresponding N(5)–Tl(1)–N(2) and N(1)–Tl(1)–N(3) angles [151.74(9)° and 118.84(8)°] in **5** indicate that both complexes are severely distorted from linearity.

In compound **3**, such a large deviation from planarity for the N(4) pyrrole is also reflected by observing a 19–22 ppm upfield shift of the C_β (C17, C18) at 112.9 ppm compared to 135.2 ppm for C_β (C2, C13), 133.7 ppm for C_β (C3, C12) and 131.8 ppm for C_β (C7, C8). In compound **5**, a similar deviation is also found for the N(4) pyrrole by observing a 16–21 ppm upfield shift of the C_β (C14, C15) at 115.7 ppm compared to 136.4 for C_β (C10, C19), 133.7 ppm for C_β (C9, C20) and 132.2 ppm for C_β (C4, C5). Similarly, the non-planarity of the porphyrins causing upfield shifts of C_β resonances were also observed with a magnitude of 16–21 ppm for Tl(N-NTs-tpp)(OAc) [8].

3.2. ^1H and ^{13}C NMR for **3** and **5** in CD_2Cl_2 and $CDCl_3$

Complexes **3** and **5** were characterized by ^{1}H (Fig. 3) and ^{13}C NMR analysis. In solution, the molecules have effective C_s symmetry with a mirror plane running through the N(2)–Tl–O(1)–N(4) unit for **3** and the N(2)–Tl(1)–N(4)–N(5) unit for **5**. There are four distinct β-pyrrole protons H_β, four β-pyrrole carbons C_β, four α-pyrrole carbons C_α, two different *meso* carbons C_{meso} and two phenyl-C_1 carbons for both the complexes.

The NMR study of **3** showed four different types of Tl–H coupling constants for H_β in CD_2Cl_2 at 20 °C (Fig. 3a). The doublet at 8.70 ppm is assigned as H_β (7, 8) with ^4J(Tl–H) = 78 Hz and the singlet at 6.64 ppm is due to H_β (17, 18). The doublet of a doublets at 9.18 ppm is due to H_β (2, 13) with ^4J(Tl–H) = 14 Hz and ^3J(H–H) = 4.2 Hz and the doublet of a doublets at 8.93 ppm is due to H_β

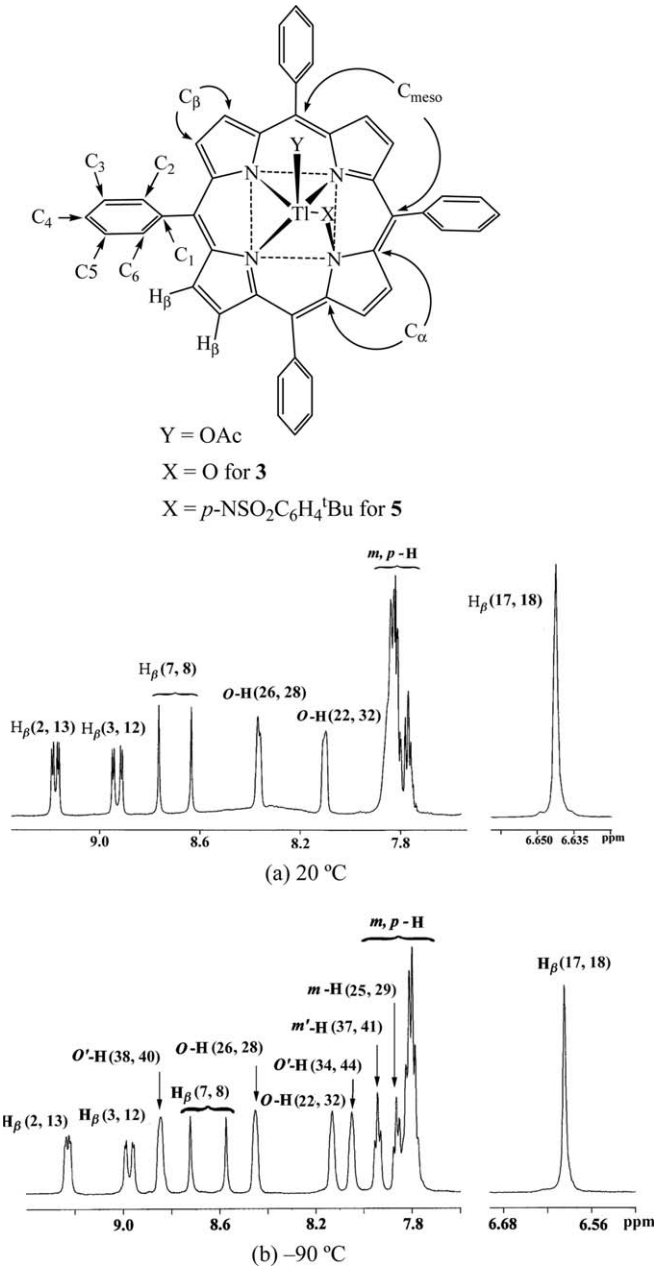


Fig. 3. ^{1}H NMR spectra for Tl(tpp-*N*-O)(OAc) at 599.95 MHz in CD_2Cl_2 showing four different β-pyrrole protons H_β and phenyl protons (*o*-H, *m*, *p*-H): (a) 20 °C; (b) −90 °C.

(3, 12) with ^4J(Tl–H) = 20 Hz and ^3J(H–H) = 4.2 Hz. Likewise, there were also four different types of Tl–^{13}C coupling constants for C_β **3** in $CDCl_3$ at 20 °C. The doublet at 131.8 ppm is due to C_β (C7, C8) with ^3J(Tl–^{13}C) = 156 Hz and the singlet at 133.7 ppm is due to C_β (C3, C12). The doublet at 135.2 ppm is due to C_β (C2, C13) with ^3J(Tl–^{13}C) = 44 Hz and the doublet at 112.9 ppm is due to C_β (C17, C18) with ^4J(Tl–^{13}C) = 80 Hz.

The NMR study of **5** showed four different types of Tl–H coupling constants for H_β in CD_2Cl_2 at 20 °C. The doublet at 8.69 ppm is assigned as H_β (4, 5) with ^4J(Tl–H) = 76.5 Hz and the singlet at 6.94 ppm is due to H_β (14, 15). The doublet of a doublets at 9.05 ppm is due to H_β (10, 19) with ^4J(Tl–H) = 17.1 Hz and ^3J(H–H) = 4.8 Hz and the doublet of a doublets at 8.92 ppm is due to H_β (9, 20) with ^4J(Tl–H) = 10.4 Hz and ^3J(H–H) = 4.8 Hz. Likewise, there were also four different types of Tl–^{13}C coupling constants for C_β **5** in CD_2Cl_2 at 20 °C. The doublet at 132.2 ppm is due to C_β (C4, C5) with ^3J(Tl–^{13}C) = 165 Hz and the doublet at 136.4 ppm is due to C_β (C10, C19) with ^3J(Tl–^{13}C) = 37 Hz. The singlet at 133.7 ppm supposedly due to C_β (C9, C20) with ^3J(Tl–^{13}C) is not observed and the doublet at 115.7 ppm is due to C_β (C14, C15) with ^4J(Tl–^{13}C) = 78 Hz. The ^{1}H NMR spectra reveal that the aromatic protons of the ^{t}BuBS group appear as a doublet at 6.94 (^{t}BuBS-$H_{3,5}$) and a doublet at 6.09 ppm (^{t}BuBS-$H_{2,6}$) for **5**. Due to the porphyrin ring current effect, all $NSO_2C_6H_4{}^t$Bu and acetato protons are shifted upfield compared to their counterparts in free $NSO_2C_6H_4{}^t$Bu and OAc^-. The above ring current effect indicates that both the $NSO_2C_6H_4{}^t$Bu and acetate ligands are bonded to Tl in **5** in the solution phase. The $NSO_2C_6H_4{}^t$Bu bonding argument is further confirmed by the result that the ^{t}BuBS–C_1 (i.e., C(47)) peak in **5** was observed at 137.6 ppm with ^3J(Tl–C) = 46 Hz. X-ray diffraction analysis unambiguously confirms that **5** is a bidentate complex in the solid phase.

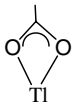
Fig. 3 depicts representative ^{1}H spectra for **3** in CD_2Cl_2 at 20 and −90 °C. At 20 °C, the rotation of the phenyl group along the C_1–C_{meso} [C(5)–C(21) or C(10)–C(27)] bond is intermediately slow [19]. This intermediately slow rotation is supported by the two broad singlets at 8.36 and 8.10 ppm for the *ortho* protons *o*-H (26, 28) and *o*-H (22, 32), respectively. Moreover, the rotation of the phenyl group along the C(15)–C(33) [or C(20)–C(39)] bond is at the intermediate exchange region [21]. In this intermediate exchange region, the signals are broadened beyond detection. Hence, no signals of *o*′-H (34, 44) and *o*′-H (38, 40) have been found at 20 °C (Fig. 3a). At −90 °C, this rotation is extremely slow. Hence, the rate of intramolecular exchange of the *ortho* protons for **3** in CD_2Cl_2 is also extremely slow. The singlet at 8.85 ppm is assigned to *ortho* protons *o*′-H (38, 40) (Fig. 3b). The other singlet at 8.05 ppm is due to *ortho* protons *o*′-H (34, 44). Likewise, the singlet at 8.45 ppm is due to the *ortho* protons *o*-H (26, 28) and singlet at 8.13 ppm is due to the *ortho* protons *o*′-H (22, 32) (Fig. 3b). In a similar way, the *meta* and *para* protons appearing as multiplet (7.76–7.84 ppm) at 20 °C (Fig. 3a) changed to 7.94 [t, *m*′-H (37, 41)], 7.86 [t, *m*-H (25, 29)], 7.82 [m, *m*′-H (35, 43)], 7.81 [m, *p*′-H (36, 42)] and 7.80 [m, *m*-H (23, 31) and *p*-H (24, 30)] ppm at −90 °C (Fig. 3b). The interpretation of these data was confirmed by NOE difference spectroscopy for **3** in CD_2Cl_2 at 20 and −90 °C.

In a similar fashion, the rotation for the phenyl group of **5** in CD_2Cl_2 at 20 °C along the C(2)–C(21) [or C(7)–C(27)] bond is slow and that rotation along C(12)–C(33) [or C(17)–C(39)] is at the intermediate region. Hence, the ^{1}H resonances for the *ortho* protons of **5** were observed with two sets of doublets: one doublet at 8.38 ppm is assigned

to *ortho* protons *o*-H (26, 28) with ^3J(H–H) = 7 Hz and the other doublet at 8.10 ppm is due to *ortho* protons *o*-H (22, 32) with ^3J(H–H) = 7 Hz. Moreover, no signals of *o*′-H (38, 40) and *o*′-H (34, 44) of **5** have been detected at 20 °C.

3.3. Dynamic NMR of 3 and 5 in CD_2Cl_2

Upon cooling of a 0.02 M CD_2Cl_2 solution of **3**, the methyl proton signal of OAc^-, being a single peak at 20 °C ($\delta = 0.45$ ppm), first broadened (coalescence temperature $T_c = -89$ °C) and then split into two peaks with a separation of 12 Hz at $\delta = 0.35$ ppm at −100 °C. As the exchange of OAc^- within **3** is reversible, the results at 599.95 MHz confirm the separation as a coupling of ^4J (Tl–H) rather than a chemical shift difference. The most likely cause of loss of coupling is due to the reversible dissociation of acetate with a small dissociation constant.



3

$$\xrightarrow[\rightleftharpoons]{CD_2Cl_2} \text{Tl(tpp-}N\text{-O)}^+ + OAc^- \qquad (1)$$

Such a scenario would lead to the change in the chemical shift with temperature and no detectable free OAc^- and Tl(tpp-*N*-O)$^+$ at low temperature, but would lead to the loss of coupling between acetate and thallium at higher temperature [20]. The chemical shift in the high-temperature limit is the average of the two species (i.e., Tl(tpp-*N*-O)(OAc) and OAc^-) in Eq. (1) weighted by their concentration. The free energy of activation $\Delta G^{\ddagger}_{184} = 39.3$ kJ/mol is therefore determined for the intermolecular exchange of OAc^- in **3**. The free energy of activation at the coalescence temperature T_c for a similar OAc^- exchange of **5** in CD_2Cl_2 is determined to be $\Delta G^{\ddagger}_{208} = 44.1$ kJ/mol. At 20 °C, intermolecular exchange of the OAc^- group for **3** is rapid as indicated by the appearance of singlet signals due to carbonyl carbons at 175.8 ppm and methyl carbons at 18.9 ppm. At −100 °C, the rate of intermolecular exchange of OAc^- for **3** in CD_2Cl_2 is slow. Hence, at this temperature, the methyl and carbonyl carbons of OAc^- are observed at δ 18.5 ppm [with ^3J(Tl–C) = 135 Hz] and 176.0 ppm [with ^2J(Tl–C) = 156 Hz] as doublets, respectively. These ^{13}C resonances are quite close to that of **5** in which the two corresponding carbons were observed in CD_2Cl_2 at δ 18.6 ppm [with ^3J(Tl–C) = 221 Hz] and 176.4 ppm [with ^2J(Tl–C) = 205 Hz] as doublets at −90 °C, but with different $^{2,3}J$(Tl–C) coupling constants. The bulky ^{t}Bu group in **5** increases the free energy of activation for the intermolecular OAc^- exchange in CD_2Cl_2 from $\Delta G^{\ddagger}_{171} = 36.0$ kJ/mol for Tl(N-NTs-tpp)(OAc) to $\Delta G^{\ddagger}_{208} = 44.1$ kJ/mol for **5** [8].

3.4. O(1) and N(5) atoms connected to α-thallium

The effect of a different electronegative atom O(1) [or N(5)] attached to the thallium(III) in **3** (or **5**) on ^2J(Tl–C) and ^3J(Tl–C) of the OAc^- ligand was studied. The importance of the thallium carbon coupling comes mainly from the Karplus-type dependence of ^3J(Tl–C) on the torsion angle $\Phi_{Tl\alpha-C\delta}(Tl_\alpha–O_\beta–C_\gamma–{}^{13}C_\delta)$ [21–23]. Hence, the complexity of the ^3J(Tl–C) coupling is primarily due to the angular dependence on Φ and also due to the substituent effects arising from the nature, position and orientation. The substituents (X) bonded to the coupled Tl_α thallium induces an additional angular dependence on the torsion angle $\Psi_{X-C\gamma}(X–Tl_\alpha–O_\beta–C_\gamma)$. Experimentally, the dependence of the ^3J(Tl–C) coupling on the torsion angles Φ, Ψ and electronegativity (χ) for **3** and **5** is shown in Table 4. Analytically, the effect upon ^nJ(Tl–C) ($n = 2, 3$) of a substituent X (X = O, N) attached to a thallium atom is defined by the difference Δ^nJ(Tl–C, X) = ^nJ(Tl–C, X)–^nJ(Tl–C, P), where ^nJ(Tl–C, X) and ^nJ(Tl–C, P) are the ^nJ(Tl–C) coupling for the X-monosubstituted Tl(tpp)(OAc) and for the parent molecule of Tl(tpp)(OAc), respectively [21]. In Table 4, the coupling constants from our study and the published ones for thallium porphyrin derivatives are provided for a comparison of the experimental Δ^nJ(Tl–C, X) values [5,8,14]. A maximum positive contribution to ^3J(Tl–C) is expected in the *transoid* arrangement ($\Phi = 180°$ and $\Psi = 180°$). The absolute values of Φ and Ψ are observed to be approximately constant around 180° and 80.1 6.8° for complexes **3**, **5** and their homologue, respectively (Table 4), therefore the magnitude of ^3J(Tl–C) in the system X–Tl_α–O_β–C_γ–$^{13}C_\delta$ shows a strong dependence on the electronegativity (χ) of the substituent X. A large negative value of Δ^3J(Tl–C, O) = −145 Hz is observed for **3** while a small negative values of Δ^3J(Tl–C, N) = −57 ± 3 Hz are assessed for **5**, **6** and **7** (Table 4) [5,8]. Likewise, the magnitude of the geminal thallium–carbon coupling constant, ^2J(Tl–C), for the OAc^- of **3** and **5** in the system X–Tl_α–O_β–$^{13}C_\gamma$ depends on the electronegativity (χ) of X (Table 4). Experimentally, a large negative value of Δ^2J(Tl–C, O) = −79 Hz is observed for **3** while a small negative value of Δ^2J(Tl–C, N) = −28 ± 3 Hz is calculated for **5**, **6** and **7** (Table 4) [5,8]. Owing to the magnitude of Δ^nJ(Tl–C, X) ($n = 2, 3$) increasing with increasing electronegativity of X, the smaller electronegativity of N(5)–$SO_2C_6H_4{}^t$Bu (with χ [N(5) = 2.98]) for **5** than the O(1) atom (with χ [O(1) = 3.44]) for **3** [24,25] results in the magnitude of $|\Delta^3J$(Tl–C, N)| = 59 Hz in **5** being smaller than that of $|\Delta^3J$(Tl–C, O)| = 145 Hz in **3** (Table 4). In a similar case, the absolute value of $|\Delta^2J$(Tl–C, N)| = 30 Hz in **5** is smaller than that of $|\Delta^2J$(Tl–C, O)| = 79 Hz in **3** (Table 4).

4. Conclusions

We have investigated two new diamagnetic and mononuclear thallium(III) porphyrin complexes **3** and **5** and their X-ray structures are established. NOE difference spectroscopies, HMQC and HMBC were employed for the unambiguous assignment of the ^{1}H and ^{13}C NMR resonances of **3** and **5** in $CDCl_3$ at 20 °C and in CD_2Cl_2 at 20 and −90 °C. In brief, the electronegativity (χ) of the X atom attached to the α-thallium nucleus correlates to the

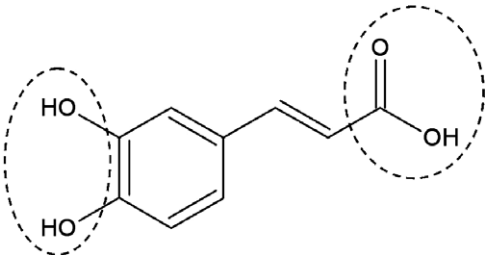

Fig. 1. Structure of caffeic acid with its two complexing sites in competition.

H^+–Al^{3+}–caffeic acid system has already been reported in the literature. Notably, Adams et al. [15] reported the equilibrium constants of complexation of various species such as $AlHL^+$, AlL^0, $Al(OH)L^-$, AlL_2^{3-}, $Al(OH)L_2^{4-}$ and AlL_3^{6-}, where L is the fully deprotonated ligand. These results were obtained from potentiometric titrations (25 °C, 0.10 M KCl) and allow the metal speciation versus pH. On the other hand, Sikora and McBride [16] have found a 1:1 complex by UV–Vis spectroscopy for this same system; however, the electronic absorption spectrum of the complex was not reported. The main aim of this work is to obtain a spectral characterization of the different species formed during the complexation of Al(III) by caffeic acid. This mechanism was followed by both UV–Vis absorption and synchronous fluorescence spectroscopic techniques combined with chemometric methods in order to determinate the stoichiometry and to estimate the stability constants of the different complexes at pH 5 and 6.5. However, in a first step of our study, we have applied these methods to the determination of the first acidity constants of caffeic acid and have compared the results with those found in the literature.

2. Experimental

2.1. Materials and methods

Sample of caffeic acid (*trans*-3-(3′,4′-dihydroxyphenyl)propenoic acid) was obtained commercially from Sigma. Al^{3+} stock solutions were prepared from aluminium chloride $AlCl_3 \cdot 6\,H_2O$. For all working solutions, sodium chloride has been added to give a constant ionic strength of 0.10 M. The molar ratio method [17] has allowed the determination of the complexes composition in solution from UV–Vis or fluorescence spectra. In this method, the electronic spectra of solutions containing a constant concentration of caffeic acid in water (5×10^{-5} M for UV–Vis and 2×10^{-5} M for fluorescence measurements) and variable concentration of $AlCl_3$ were recorded. The titrations were effected by incremental additions of aluminium chloride and additions of NaOH to keep a constant pH. A Minipuls II (Gibson) peristaltic pump was used to circulate solution from the thermostated titration cell (25 °C) to the flow cell (Hellma) for both absorption and fluorescence measurements. Due to the dilution of the ligand solution, all the electronic spectra were corrected before exploitation.

2.2. Instrumentation

UV–Vis spectra were run on a double-beam spectrophotometer (Cary 100-Varian) using cells of 1 cm path length. Fluorescence spectra were recorded using a Fluoromax-3 (Jobin-Yvon) spectrofluorimeter with slits width of 5 nm. Three-dimensional spectra were acquired to obtain excitation–emission matrix (EEM) plots, the excitation wavelengths are plotted on the *y*-axis and the emission wavelengths are plotted on the *x*-axis, the third dimension represents the relative intensity.

2.3. Chemometrics methods

The different pK_a and the formation constants of the Al(III) complexes with caffeic acid were estimated by using a multivariate data analysis program for modelling and fitting equilibrium titration 3D data sets obtained from experimental measurements. The UV–Vis absorption and fluorescence spectra were refined using the SPECFIT software (version 3.0.32) [18]. The set of spectra obtained at variable pH or variable Al(III) concentration were treated by evolving factor analysis (EFA) [19] in order to determine the number of different species in the system and the pure spectrum of each species. The SPECFIT software has also been used to estimate the apparent stability constants (β) of the complexes and the standard deviation (σ) of each value.

3. Results and discussion

3.1. Acidobasic properties of caffeic acid

Fig. 2A shows the absorption spectra of caffeic acid in aqueous solution at different pH (from 2 to 10). UV–Vis spectra clearly present two isosbestic points at 291 and 320 nm within the studied pH region, reflecting the successive presence of two acid–base equilibriums. The first one corresponds to an equilibrium between the fully protonated H_3CA and singly-deprotonated H_2CA^- forms (with a deprotonation of the COOH group). The second one relates to the deprotonation of a hydroxyl group of the catechol (H_2CA^-/HCA^{2-} equilibrium). Oxidation processes of the molecule for high pH values (>9) prevent the observation of the third equilibrium corresponding with a complete deprotonation of the hydroxyl functions to give the CA^{3-} species. The set of spectra treated by evolving factor analysis (EFA) has allowed the determination of the pure absorption spectrum of each form of caffeic acid (Fig. 2B). The acidic form presents a spectrum characterized by a double band located at 320 and 295 nm and absorption under 250 nm. The deprotonation of the carboxylic function leads to a hypsochromic shift of the double band to 309 and 284 nm. A bathochromic shift is then observed with the first deprotonation of the catechol group

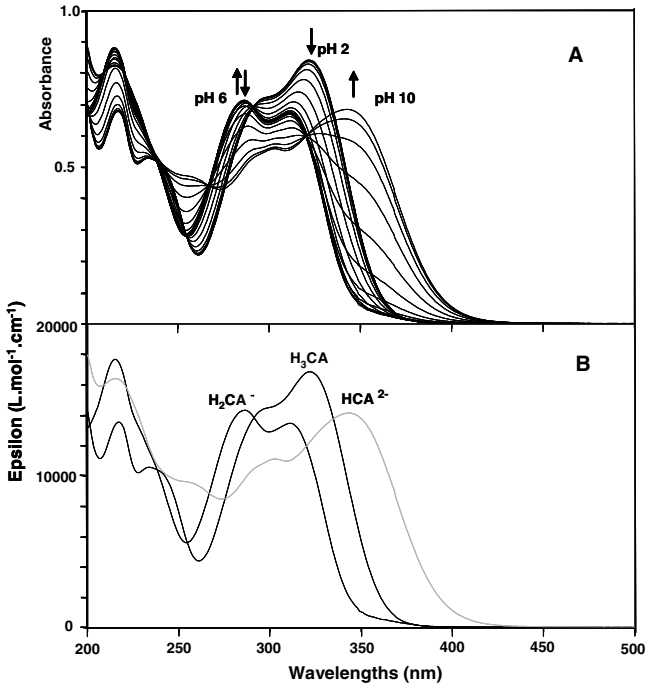

Fig. 2. Variation of the UV–Vis spectra of caffeic acid with the pH in the range 2–10 (A) and absorption spectra of the pure species (B).

(341 and 298 nm). The same experiments have been carried out using synchronous fluorescence spectroscopy with a constant wavelength difference between excitation and emission of 112 nm. The evolution of fluorescence spectra with the pH are illustrated in Fig. 3A. In a same way, the pure synchronous fluorescence spectra of the three forms of caffeic acid have been determined using the SPECFIT program and are reported in Fig. 3B. The fluorescence spectrum of caffeic acid presents a low intensity ($<4\times10^4$ cps) compared with the other spectra, and is characterized by a large band with a maximum for $\lambda_{ex}=322$ nm. Caffeate fluorescence spectrum is more intense and presents a maximum for $\lambda_{ex}=313$ nm. The second deprotonation leads to a large enhancement of the emission intensity (40 times more important than caffeic acid) and gives rise to a band located at $\lambda_{ex}=375$ nm.

From absorption and emission spectra sets, the two first acidity constants were calculated and refined with the SPECFIT program. The estimated values of the dissociation constants with their uncertainties are shown in Table 1, along with the values obtained by potentiometric titrations and reported in the literature. Satisfactory agreement of protonation constants obtained from UV–Vis experiments with those found in the literature was reached. However,

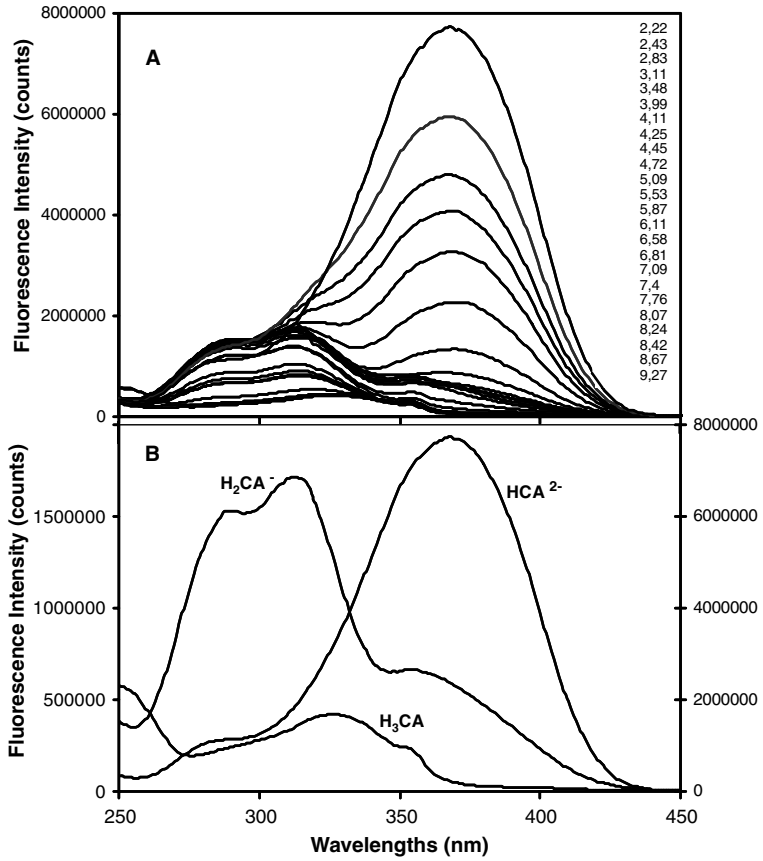

Fig. 3. Variation of the synchronous fluorescence spectra (offset: 112 nm) of caffeic acid with the pH (A) and synchronous fluorescence spectra of the pure species (B) the left scale is relative to H_3CA and H_2CA^- forms whereas the right scale is relative to the bi-deprotonated form.

Table 1

the values obtained from synchronous fluorescence spectroscopy are slightly lower than those obtained from UV–Vis measurements. This observation may be explained by the fact that the value obtained reflects the acido-basic properties of the excited state involved in the emission process.

3.2. Complexation of Al(III) by caffeic acid

The complexation of Al(III) by caffeic acid was investigated at pH 5 and 6.5 under constant ionic strength of 0.1. The pH was chosen in the range where no precipitation of metal hydroxide takes place, and for values close to the pH generally found in the soils. At pH 5, the solution is mixture of caffeic acid (26%) and caffeate (74%), whereas at pH 6.5 caffeate ion (H_2CA^-) is the only species present in the solution.

It should be noticed that, in spite of the use of a system ensuring the circulation of the solution, the acid caffeic molecule undergoes a photodegradation under the action of the excitation beam of fluorescence. This phenomenon is particularly visible on the EEM recorded on a caffeic solution at pH 6.5 (Fig. 4(1)). The broad signal A made up of two fluorescence bands at 281/419 nm and 310/419 nm ($\lambda_{ex}/\lambda_{em}$) is characteristic of caffeic acid, whereas the signal noted B at 383/471 nm corresponds to a photo-product. However, the appearance of this photo-product is not instantaneous (several hours were necessary to record fluorescence EEM) and this last is not highlighted on the emission spectrum when a caffeic acid solution freshly prepared is excited at 383 nm. To complete the assignment of the fluorescence EEM, one can observed the first and second-order Raman bands of water (bands C and D, respectively). A fluorescence EEM of the 3,4-dimethoxycinnamic acid (Fig. 4(2)) does not present the signal B. In this case, the substitution of the hydroxyls of the catechol moiety by –OCH_3 functions prevents the deprotonation of the catechol and so a photo-oxidation of the molecule. Fig. 4(3) presents the fluorescence EEM of a caffeic acid solution (pH 6.5) in the presence of Al(III) for a molar ratio of 1. A new intense signal appears at 338/508 nm corresponding to the formation of the complexed species whereas the signal A is less intense than this observed in Fig. 4(1) but still present. In opposition the photo-product has totally disappeared of the EEM, that

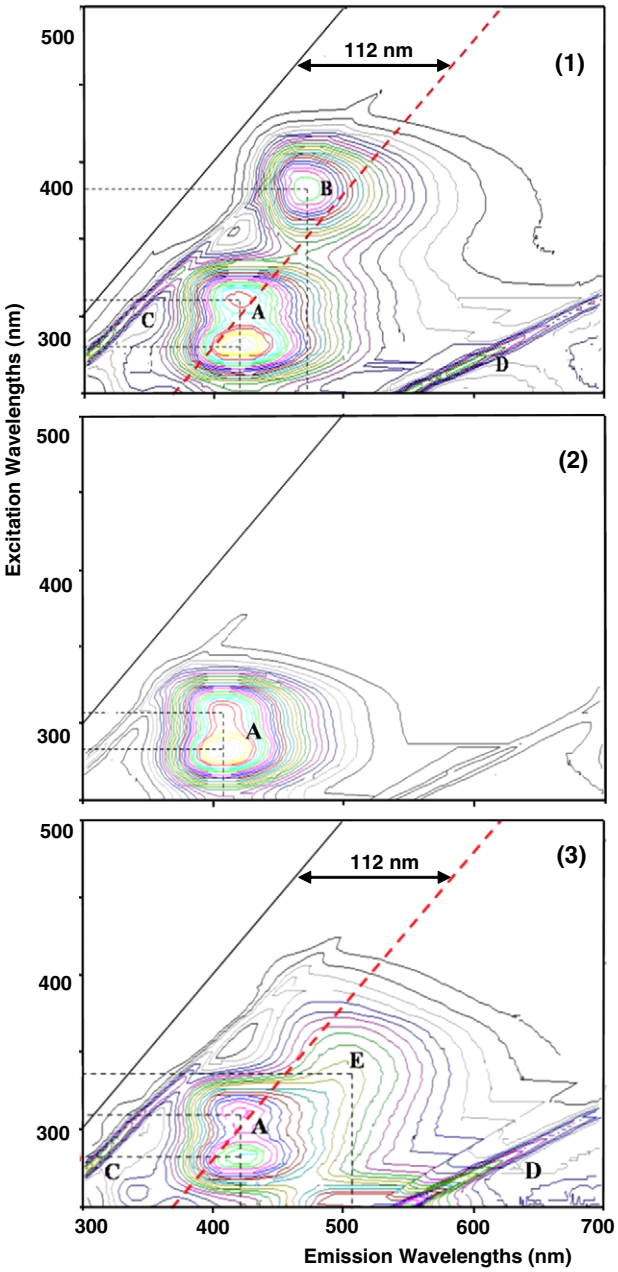

Fig. 4. 3D fluorescence excitation–emission matrix (EEM) plots are shown for caffeic acid at pH 6.5 (1), 3-4-dimethoxycinnamic acid (2) and the Al–caffeic acid system with a molar ratio of 1 (3).

reinforces the assumption of a chelation of Al(III) on the catechol group combined with a complete deprotonation of the hydroxyl functions [13,15]. One can observe in Fig. 4 that an offset of 112 nm between the excitation and emission wavelengths is well adapted to observe simultaneously the evolution of the fluorescence signal of both free and complexed forms of caffeic acid upon complexation.

3.2.1. Complexation at pH 5

Fig. 5A illustrates the evolution of the UV–Vis spectra of the caffeic acid–Al(III) system at pH 5 for different [Al(III)]/[Caf] molar ratios from 0 to 25. The intensity of

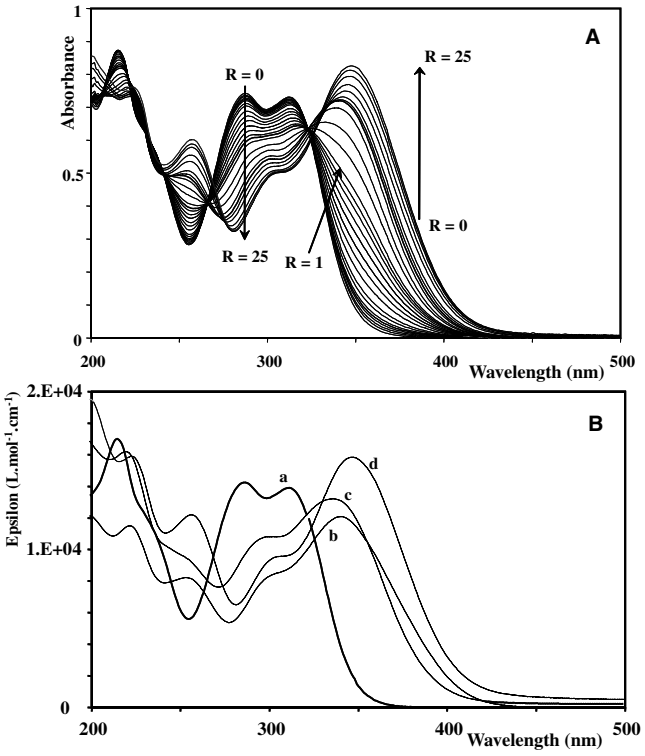

Fig. 5. UV–Vis absorption spectra of caffeic acid in absence and in presence of $AlCl_3$. [Al(III)]/[CA] molar ratio vary from 0 to 25, in aqueous solution at pH 5 (A). Absorption spectra of pure species (B): caffeic acid (a), complex 1:2 (b), complex 1:1 (c) and complex 2:1 (d).

the double band characteristic of the caffeic acid decreases with the amount of $AlCl_3$ added, whereas a new band appears in the higher wavelengths range. The maximum of this band moves towards the high wavelengths with the increase of the molar ratio. The absence of a single isosbestic point shows that several complexed species are formed simultaneously and/or successively during the complexation process. Using the molar ratio method, the curves of absorbance variations versus [Al(III)]/[Caf] molar ratio plotted at 348 nm (λ_{max} of complexed form) and 285 nm (λ_{max} of free form) allow us to observe the formation of five species of stoichiometry (Al:AC) 1:6, 1:3, 1:2, 1:1 and 2:1. Our previous works, as well as the results found in the literature [13,15,16], show that the chelation of aluminium takes place at the level of the catechol site with a complete deprotonation of the hydroxyl groups. Under these conditions, the formation of the complex 1:6 would be obtained with the coordination to an aluminium ion of three dimers of caffeic acid. From the UV–Vis spectra set, the determination of the number of different absorbing species was estimated by the EFA method. With this method, only three complexed forms could be detected and the absorption spectra of the corresponding pure species are represented in Fig. 5B (spectra b, c and d). This result suggests that among the five complexes obtained with the molar ratios method, two of them are minority species, which either present very weak concentrations, or are present in the mixture only at the beginning of the dosage. To determine the stoichiometry of the three major complexes and to estimate their stability constants, a numerical treatment of the UV–Vis spectra has been carried out implicating the different possible models. The model best-fitting the experimental data involves the complexes of stoichiometry 1:2 ($\lambda_{max} = 340$ nm, spectrum b), 1:1 ($\lambda_{max} = 335$ nm, spectrum c) and 2:1 ($\lambda_{max} = 347$ nm, spectrum d). The spectrum a (Fig. 5B) corresponds to the sum of the absorbance of H_3CA and H_2CA^- forms. The apparent stability constants of the three major complexes are reported in Table 2. This result comes from the following reaction between aluminium and the ligand (L) both protonated and mono-deprotonated:

$$aAl + bL \leftrightarrow Al_aL_b$$

with the corresponding apparent stability constant:

$$\beta = \frac{[Al_aL_b]}{[Al]^a[L]^b}.$$

It can be concluded, that the complexes of stoichiometry 1:6 and 1:3 are present at very low concentration in the solution only for very low amount of $AlCl_3$ added.

The complexation of aluminium (III) by caffeic acid at pH 5 has been also followed by fluorescence emission spectroscopy ($\lambda_{exc} = 320$ nm) and by synchronous fluorescence spectroscopy (offset of 112 nm). Only the results obtained by this last technique will be presented in details. The synchronous fluorescence spectra of caffeic acid at pH 5 with different amounts of $AlCl_3$ are reported in Fig. 6A. As already observed in UV–Vis spectroscopy, no distinct isoemissive point is detected, indicating the simultaneous formation of several complexes. The chemometric methods applied to the data set have allowed the determination of

Table 2
Stability constants estimated from different spectroscopic methods for the main complexes of the Al(III)–caffeic acid system at pH 5 and 6.5 in aqueous solution

	Stoichiometry	1:6	1:3	1:2	1:1	2:1
	Formulae	$[AlCaf_6]^{9-}$	$[AlCaf_3]^{6-}$	$[AlCaf_2]^{3-}$	[AlCaf]	$[Al2Caf]^{3+}$
pH 5	UV–Vis			8.4 ± 0.3	5.6 ± 0.1	9.3 ± 0.1
	fluo ($\lambda_{ex} = 320$ nm)			8.97 ± 0.07	5.04 ± 0.02	8.95 ± 0.08
	fluo synchronous			8.64 ± 0.07	4.83 ± 0.02	8.85 ± 0.07
pH 6.5	UV–Vis		12.9 ± 0.1	8.6 ± 0.2		
	fluo ($\lambda_{ex} = 320$ nm)		13.40 ± 0.08	8.96 ± 0.04		
	fluo synchronous		13.41 ± 0.09	8.6 ± 0.1		

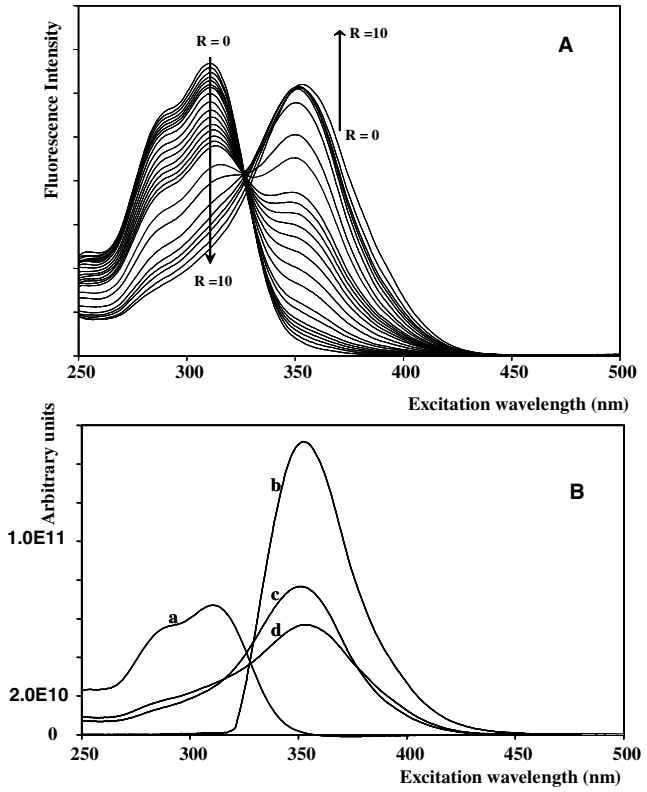

Fig. 6. Synchronous fluorescence spectra of caffeic acid in absence and in presence of $AlCl_3$. [Al(III)]/[CA] molar ratio vary from 0 to 10, in aqueous solution at pH 5 (A). Synchronous fluorescence spectra of pure species (B): caffeic acid (a), complex 1:2 (b), complex 1:1 (c) and complex 2:1 (d).

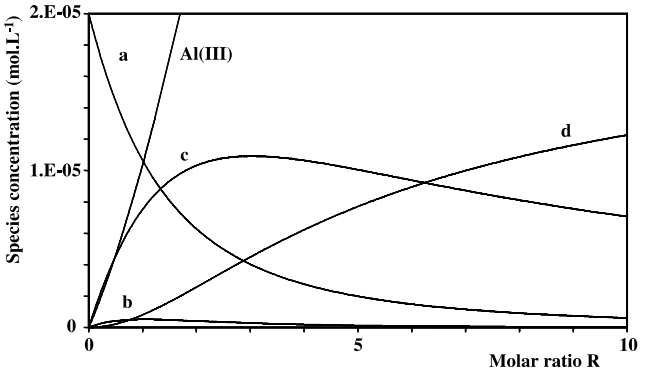

Fig. 7. Distribution curves of the concentration of aluminium complexes with caffeic acid at pH 5 as a function of the [Al(III)]/[CA] molar ratio. Caffeic acid (a), complex 1:2 (b), complex 1:1 (c) and complex 2:1 (d).

four pure species, whose spectra are presented in Fig. 6B. The spectrum a is relative to caffeic acid, and spectra b, c and d can be assigned to the complexes of stoichiometry 1:2, 1:1 and 2:1, respectively. One can notice that the maximum of the three synchronous fluorescence spectra of complexes are very close. In the same way as the results obtained by UV–Vis spectroscopy, the 1:6 and 1:3 species were highlighted by the molar ratios method, but not by the EFA method. The stability constants obtained from fluorescence measurements, reported in Table 2, stand comparison with those estimated from UV–Vis measurements. However, on can notice that the value of the 1:2 complex stability constant is calculated slightly higher with the fluorescence techniques than with the absorption technique; while the situation is reversed for the 1:1 and 2:1 complexes. The concentration variations of the free and complexed ligands versus quantity of aluminium added (molar ratios) is illustrated in Fig. 7. Both absorption and fluorescence measurements lead to obtaining the same variations. The curves show that the 1:2 and 1:1 complexes are simultaneously formed from the beginning of the aluminium addition, however, the 1:1 species is largely predominant (curve c). The formation of very weak amounts of the 1:2 complex observed on this curve, suggests that the 1:3 and 1:6 species must present concentrations even weaker and consequently explains why they were not easily detected. This result is consistent with this obtained by Sikora and McBride that found only the 1:1 species between pH 3.8 and 4.5 [16]. The 2:1 complex starts to be formed for molar ratios higher than 0.1. This fact indicates that the second complexation site, in this case the carboxylic function, is implied in the coordination of aluminium relatively quickly, whereas less than 10% of the catechol sites are occupied. That shows that, even if the carboxylic and carboxylate functions have less affinity than the catechol group with respect to Al(III), these two sites have rather close chelating powers, at pH 5. Simultaneous coordination of metal ions to both the carboxylic and catechol sites has been already observed for the binding of caffeic acid to various divalent metal [23].

3.2.2. Complexation at pH 6.5

At pH 6.5, the precipitation of aluminium hydroxide prevents obtaining high concentrations of Al(III) in solution. In this study, we limited ourselves to a molar ratio value of 2, in order to not observe a continuous background on the electronic spectra, as illustrated in the two last spectra (not included in the calculations) that show the $Al(OH)_3$ precipitation. At pH 6.5, the follow-up of dosage by spectroscopy shows a very different evolution of the data sets with the addition of aluminium compared to the results obtained at pH 5. The UV–Vis spectra obtained for different molar ratios (Fig. 8A) show the formation of several complexes insofar as no isosbectic point is observed. The molar ratio method applied to the spectral data allows the determination of three species of stoichiometry 1:6, 1:3 and 1:2. Once again, the complex 1:6 is a minority species and was not detected by EFA method. The spectra of the complexes 1:3 and 1:2 are presented in Fig. 8B (spectrum b and c, respectively). The same conclusions can be drawn from the data obtained by synchronous fluorescence spectroscopy (Fig. 9A), where only the complexes 1:3 and 1:2 are highlighted (Fig. 9B) by the chemometric methods. The stability constants of the two found complexes are reported in Table 2 for the different techniques. One can observe slight differences between the values of the constants according to the spectroscopic

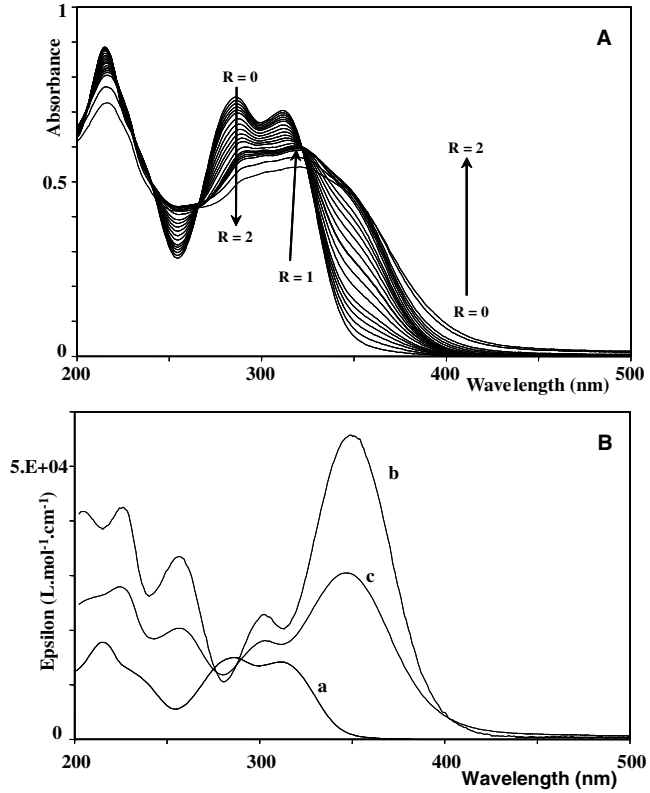

Fig. 8. UV–Vis absorption spectra of caffeic acid in absence and in presence of $AlCl_3$. [Al(III)]/[CA] molar ratio vary from 0 to 2, in aqueous solution at pH 6.5 (A). Absorption spectra of free species (B): caffeic acid (a), complex 1:3 (b) and complex 1:2 (c).

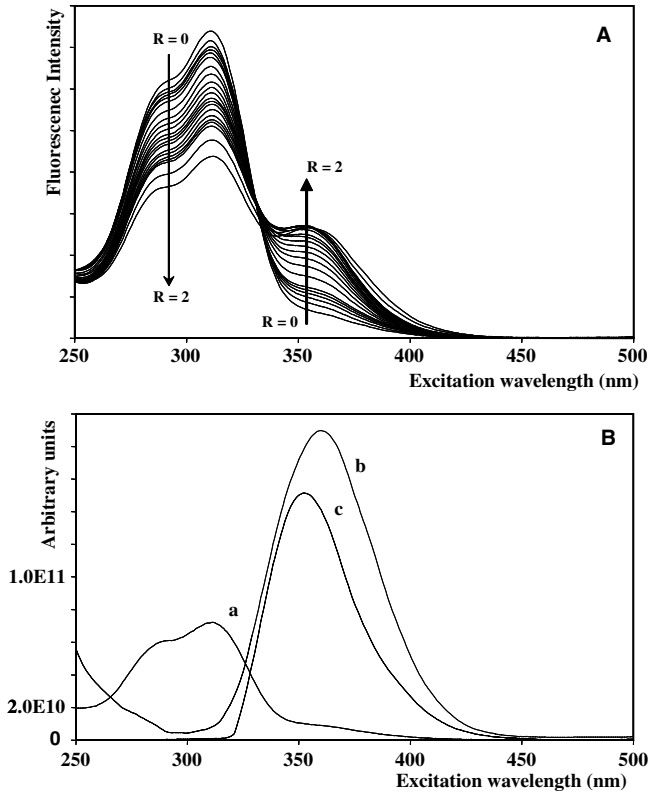

Fig. 9. Synchronous fluorescence spectra of caffeic acid in absence and in presence of $AlCl_3$. [Al(III)]/[CA] molar ratio vary from 0 to 2, in aqueous solution at pH 6.5 (A). Synchronous fluorescence spectra of free species (B): caffeic acid (a), complex 1:3 (b) and complex 1:2 (c).

technique used, but the magnitude order is preserved. It should be noted that, for the 1:2 complex which is common to the experiments at pH 5 and 6.5, the EFA method leads to the obtaining of the same electronic spectra of this species at both pH. As the concentration evolution of the various species according to the molar ratio shows it (Fig. 10), the two chelates are formed simultaneously and in the same proportions. For a molar ratio of 3, one observes neither the formation of the complex 1:1, nor that of the complex 2:1; thus even for large quantity of added metal, only one complexation site is involved. It is obvious that the chelating power of the ligand towards Al(III) increases with pH. On the one hand, complexes of higher stoichiometry are obtained at pH 6.5 than at pH 5 and, on the other hand, the formation of the 1:2 complex slightly increases with the pH.

If this study has allowed the spectroscopic characterization, both in absorption and fluorescence, of the 1:3, 1:2, 1:1 and 2:1 complexes of Al(III) with caffeic acid, it did not permit the determination of the protonation state of these complexes. Indeed, for instance, only one spectrum could be highlighted by the spectroscopic techniques for the 1:1 complex, whereas Adams et al. reported, for this one, the existence of three possible species: $AlHL^+$, AlL^0 and $Al(OH)L^-$ with different stability constants. These three species must present very close electronic spectra

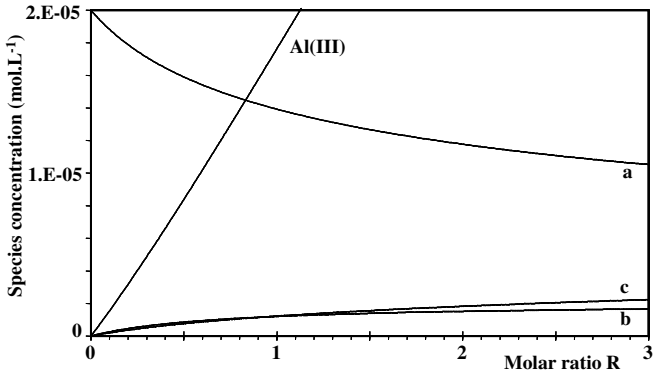

Fig. 10. Distribution curves of the concentration of aluminium complexes with caffeic acid at pH 6.5 as a function of the [Al(III)]/[CA] molar ratio. Caffeic acid (a), complex 1:3 (b) and complex 1:2 (c).

which it is impossible to distinguish by spectral decomposition. Thus, the conditional equilibrium constant calculated in this study for the 1:1 complex is not directly comparable with those obtained by potentiometric methods.

The presence of the CH=CH–COOH function on the 1-2-dihydroxybenzene seems not very affected the chelation ability of the catechol function. Indeed, the stability constants which one can calculate starting from the results of Adams et al. (16.25) [15] or Sikora and McBride (15.06)

[16] for the AlL^0 complex of caffeic acid are very close to that obtained for the pyrocatechol (16.20) [24]. Thus, this chemical function has an effect definitely weaker than the nitro group, which significantly decreases the complexing capacity of catechol, since the AlL^0 complex obtained with nitrocatechol presents a stability constant of 13.80 [25].

The iron(II)–caffeic acid system studied by absorption spectroscopy leads to the formation of a 1:1 complex presenting an equilibrium constant of 8.12 [26]. The comparison of this value with that calculated in this study for the Al 1:1 complex (average: 5.15) shows that caffeic acid presents a greater chelating power towards Fe(II) than Al(III).

4. Conclusion

The aqueous solution chemistry of Al(III)–caffeic acid system has been examined using both UV–Vis and synchronous fluorescence spectroscopic techniques. The experiments show that, at pH 5, the 1:1 complex largely predominates in solution, however, the protonation of this complex could be given neither by absorption spectroscopy nor by fluorescence spectroscopy. It is interesting to note that small amounts of metal ions are necessary to obtain a binuclear complex, where the two sites in competition are involved. At pH 6.5, only one site, the catecholate group, coordinates to Al(III) leading to the formation of 1:2 and 1:3 complexes. This study confirms ours previous results concerning the competition of carboxylic and catechol functions to complex aluminium ions. It is patent that the catechol group presents a chelating capacity higher than that of the carboxylic or carboxylate functions with respect to Al(III). This complexing capacity increases, as one could expect it, with the pH. The polyphenolic functions omnipresent in the humic substances have a considerable role in the retention of metal traces in the soil and are in favourable competition with respect to the more acid groups in the coordination of aluminium. It is obvious that in the natural environments, the metal/potential complexing sites ratios are very weak and very largely lower than the ratios used in this study, therefore, only the species formed for small added amounts of Al(III) are of interest within this framework.

spectrophotometer using KBr discs in the range of 4000–400 cm^{-1}. Electronic spectra were recorded on a Systronics 119 UV–Vis spectrophotometer using methanol as solvent. Elemental analyses were performed with a Vario EL III Elementar analyzer. Room temperature EPR spectra were recorded using an E-112 Varian model instrument. Cyclic voltammetric experiments were carried out using BAS CV-27 electrochemical analyzer with a glassy carbon working electrode. A platinum wire and silver–silverchloride electrode were used as counter- and reference electrodes, respectively. Melting points were recorded with a Lab India apparatus.

2.3. Crystallography

Single crystals of [Ru(dipic)$(PPh_3)_2$Cl] suitable for X-ray diffraction studies were obtained from slow evaporation of a solution of the complex in benzene/ethanol mixture. Intensity data were collected on a Nonius MACH 3 four circle diffractometer equipped with graphite monochromated Mo Kα radiation ($\lambda = 0.7107$ Å). The structure was solved by the direct method. All non-hydrogen atoms were refined anisotropically by full-matrix least-squares, with a ridging model for the hydrogen atoms, using the SHELXTL/PC package [30].

2.4. Synthesis of [Ru(dipic)$(EPh_3)_2X$] (X = Cl, Br; E = P, As)

All the new ruthenium(III) complexes were prepared by the following general procedure. A benzene (20 ml) solution of [$RuX_3(EPh_3)_3$] (where E = P, As; X = Cl, Br) (0.1 mmol) was added to a refluxing solution of dipicolinic acid (0.1 mmol) in ethanol (20 ml). The mixture was heated under reflux for 6 h. The solution was filtered while hot, reduced to half of its volume and left for slow evaporation. The crystalline product that separated out was filtered off, washed with ethanol and dried under vacuum. The product was recrystallized from benzene/ethanol mixture.

[Ru(dipic)$(PPh_3)_2$Cl] (**1**) was prepared from [$RuCl_3(PPh_3)_3$] (0.0994 g, 0.1 mmol) and dipicolinic acid (0.018 g, 0.1 mmol) as reddish brown crystals. Yield: 75%. *Anal*. Calc. for $RuC_{43}H_{33}NO_4ClP_2$: C, 62.51; H, 4.02; N, 1.69. Found: C, 62.04; H, 4.51; N, 1.74%. IR: 1659, 1352, 1431, 1091, 697 cm^{-1}. UV: λ_{max}: 268(4236), 405(9219) nm(dm^3/mol/l); m.p. >230 °C.

[Ru(dipic)$(AsPh_3)_2$Cl] (**2**) was prepared from [$RuCl_3(AsPh_3)_3$] (0.112 g, 0.1 mmol) and dipicolinic acid (0.018 g, 0.1 mmol) as shining red crystals. Yield: 80%. *Anal*. Calc. for $RuC_{43}H_{33}NO_4ClAs_2$: C, 56.44; H, 3.63; N, 1.53. Found: C, 56.17; H, 3.82; N, 1.60%. IR: 1671, 1344, 1434, 1077, 692 cm^{-1}. UV: λ_{max}: 268(4767), 315(6296), 530(964) nm(dm^3/mol/l); m.p. >290 °C.

[Ru(dipic)$(AsPh_3)_2$Br] (**3**) was prepared from [$RuBr_3(AsPh_3)_3$] (0.125 g, 0.1 mmol) and dipicolinic acid (0.018 g, 0.1 mmol) as brown crystals. Yield: 85%. *Anal*. Calc. for $RuC_{43}H_{33}NO_4BrAs_2$: C, 59.32; H, 3.82; N, 1.60. Found: C, 59.27; H, 3.94; N, 1.58%. IR: 1673, 1350, 1434, 1077, 692 cm^{-1}. UV: λ_{max}: 268(4706), 315(5652), 416(10 184), 534(590) nm(dm^3/mol/l); m.p. >270 °C.

[Ru(dipic)$(PPh_3)_2$Br] (**4**) was prepared from [$RuBr_3(PPh_3)_2$(MeOH)] (0.0897 g, 0.1 mmol) and dipicolinic acid (0.018 g, 0.1 mmol) as orange brown crystals. Yield: 75%. *Anal*. Calc. for $RuC_{43}H_{33}NO_4BrP_2$: C, 53.82; H, 3.46; N, 1.45. Found: C, 53.79; H, 3.63; N, 1.39%. IR: 1666, 1347, 1440, 1080, 690 cm^{-1}. UV: λ_{max}: 268(4344), 416(9180) nm(dm^3/mol/l); m.p. >240 °C.

2.5. Catalytic oxidation

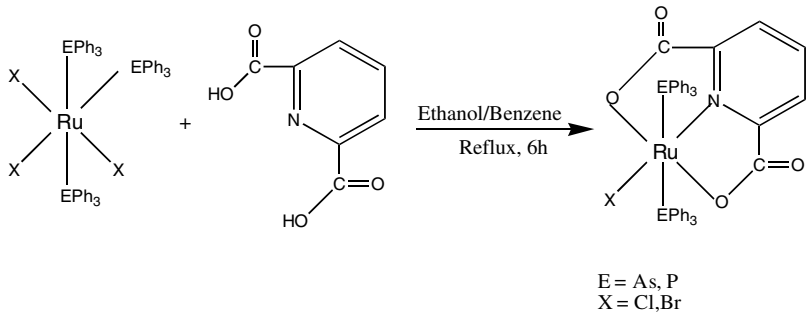
To a solution of the alcohol (1 mmol) in CH_2Cl_2 (20 ml), *N*-methyl morpholine-*N*-oxide (3 mmol) and ruthenium complex (0.01 mmol) were added. The solution was heated under reflux for 3 h. The mixture was evaporated to dryness and extracted with petroleum ether (60–80 °C). The combined petroleum ether mixture was filtered and evaporated to give the corresponding aldehyde, which was then quantified as its 2,4-dinitrophenyl hydrazone derivative [31].

3. Results and discussion

New hexa-coordinated Ru(III) complexes of the type [Ru(dipic)$(EPh_3)_2$X] have been prepared by reacting 2,6-pyridine dicarboxylic acid (dipicolinic acid, H_2dipic) with [$RuCl_3(PPh_3)_3$], [$RuCl_3(AsPh_3)_3$], [$RuBr_3(AsPh_3)_3$] and [$RuBr_3(PPh_3)_2$(MeOH)] in a 1:1 mole ratio. The ligand replaces one EPh_3 and two X atoms, (E = As or P; X = Cl or Br), from the starting complex to yield [Ru(dipic)-$(EPh_3)_2$X] (Scheme 1). Dipicolinic acid acts as a dibasic tridentate ligand in all the complexes. The analytical data conform to the stoichiometry of the ruthenium(III) complexes as [Ru(dipic)$(EPh_3)_2$X].

3.1. Infrared spectroscopy

The IR spectrum of the free ligand (H_2dipic) shows a strong band around 1700 cm^{-1} assignable to ν(C=O) of COOH moiety [7]. In all the complexes, the band due to $\nu_{as}(COO^-)$ was observed in the region 1675–1610 cm^{-1} and that due to $\nu_s(COO^-)$ in the region 1352–1344 cm^{-1}. A large difference of 327–307 cm^{-1} between ν_{as} and ν_s vibrations indicates a monodentate coordination of the carboxylic group in all the complexes [32]. A broad band observed in the region 3340–2500 cm^{-1} region due to ν(O–H) of the carboxyl group in the free ligand disappeared in all the complexes indicating the deprotonation and subsequent coordination through oxygen donor atom. The absence of any peak around 1700 cm^{-1} reveals that both COOH groups are involved in coordination. All the characteristic peaks due to PPh_3/$AsPh_3$ were observed in the usual regions [31].



Scheme 1.

3.2. EPR spectroscopy

The EPR spectra of the powdered samples were recorded at room temperature at X-band frequencies. The nature of the spectra revealed the absence of any hyperfine splitting due to interaction with any other nuclei present in the complexes. Complexes **1** and **4** showed two lines with two different '*g*' values ($g_x = g_y \neq g_z$) indicating magnetic anisotropy and suggestive of tetragonal distortion in octahedral geometry [33]. However, complexes **2** and **3** showed three lines with three different '*g*' values ($g_x \neq g_y \neq g_z$) indicating rhombic distortion [34]. The '*g*' values are in the range 2.12–2.21. The nature of spectra obtained is in good agreement with that of the previously reported Ru(III) complexes [35]. A representative case is depicted in Fig. 1.

3.3. Electrochemistry

The redox behavior of the complexes was studied using cyclic voltammetry at a glassy carbon working electrode at a scan rate of 100 mV s^{-1}. $[NBu_4]BF_4$ (0.1 M) was used as supporting electrolyte in acetonitrile solution of 0.001 M of complex. The cyclic voltammetric data are given in Table 1 and a representative cyclic voltammogram is displayed in Fig. 2. The $E_{1/2}$ of the oxidation process was in the range from 0.71 to 0.79 V and reduction process was in the range from −0.73 to −0.80 V. The oxidation and reduction waves

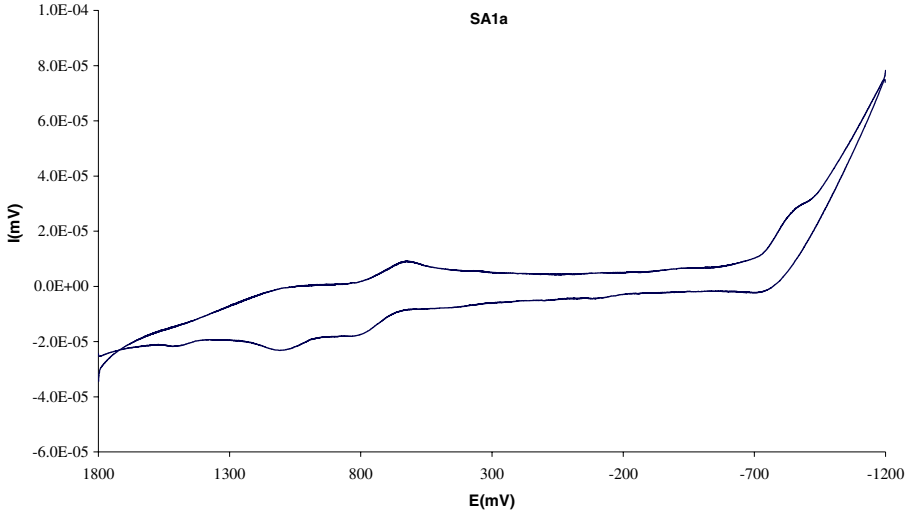

Fig. 2. Cyclic voltammogram of **1**.

are due to the metal centered Ru(III) → Ru(IV) and Ru(III) → Ru(II) processes, respectively. Any redox behavior of the ligand in the range 0.71 to −0.80 V is ruled out because dipicolinic acid showed quasi-reversible and irreversible processes only around −1.58 V in its complexes [36]. Moreover, potential difference between the two successive oxidation processes is ≈1.5 V which agrees well with the average potential difference between the redox processes of the ruthenium center ($Ru^{II/III}$–$Ru^{III/IV}$) (≈1.0–1.5 V) observed for other mononuclear complexes [37]. All the complexes exhibit quasi-reversible oxidative couples with peak to peak separations (ΔE_p) of 120–236 mV [38]. Replacement of PPh_3 by $AsPh_3$ showed no much variation in the redox potential. It has been observed from the electrochemical data that the present ligand system is ideally suitable for stabilizing the higher oxidation state of the ruthenium ion [39–41].

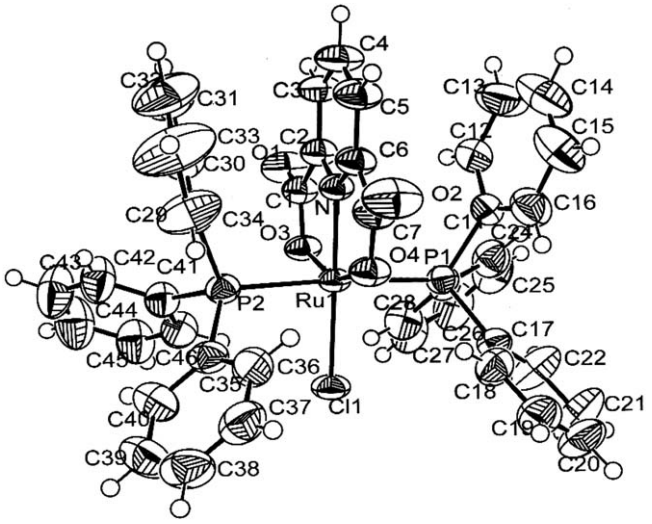

Fig. 3. ORTEP diagram [Ru(dipic)(PPh_3)$_2$Cl] (**1**).

3.4. Crystal structure of [Ru(dipic)(PPh_3)$_2$Cl]

The ORTEP diagram of [Ru(dipic)(PPh_3)$_2$Cl] is shown in Fig. 3. The crystal data and refinement parameters are summarized in Table 2. Selected bond lengths and bond

Table 2
Crystal data and structure refinement parameters for [Ru(dipic)(PPh_3)$_2$Cl]

Empirical formula	$C_{43}H_{33}ClNO_4P_2Ru$
Formula weight	826.16
Temperature (K)	293(2)
Wavelength (Å)	0.71073
Crystal system, space group	monoclinic, *C*2/*c*
Unit cell dimensions	
a (Å)	34.882(14)
b (Å)	9.998(4)
c (Å)	29.132(12)
α (°)	90
β (°)	121.32(3)
γ (°)	90
Volume (Å^3)	8679(6)
Z, calculated density (Mg/m^3)	8, 1.265
Absorption coefficient (mm^{-1})	0.535
F(000)	3368
Crystal size (mm)	0.22 × 0.19 × 0.14
θ Range for data collection (°)	2.15–24.98
Limiting indices	$0 \leqslant h \leqslant 41$, $-1 \leqslant k \leqslant 11$, $-34 \leqslant l \leqslant 29$
Reflections collected/unique (R_{int})	8653/7584 (0.0171)
Completeness to θ = 24.98 (%)	99.4
Absorption correction	ψ-scan
Maximum and minimum transmission	0.9998 and 0.9647
Refinement method	full-matrix least-squares on F^2
Data/restraints/parameters	7584/0/469
Goodness-of-fit on F^2	1.057
Final *R* indices [$I > 2\sigma(I)$]	$R_1 = 0.0327$, $wR_2 = 0.0913$
R indices (all data)	$R_1 = 0.0517$, $wR_2 = 0.1055$
Largest difference in peak and hole (e A^{-3})	0.530 and −0.603

angles are given in Table 3. The N(1)–Ru(1)–Cl(1) bond angle is 178.95(9)° showing that Cl atom lies *trans* to ring nitrogen. The bite angles around Ru(III) are N(1)–Ru(1)–O(4) = 77.42(10)°; N(1)–Ru(1)–O(3) = 77.28(9)°; O(4)–Ru(1)–Cl(1) = 103.60(7)° and O(3)–Ru(1)–Cl(1) = 101.70(6)°, summing up the in-plane angle to be exactly 360°. This shows the high planarity of the Cl and O, N, O donor atoms of dipicolinic acid. This is further supported by the other *cis* angles mentioned in Table 3. Thus, the acid occupies the equatorial plane around the Ru(III) octahedron, along with Cl. The bond angle P(1)–Ru(1)–P(2) = 175.62(3)° shows that the two PPh_3 groups are trans to each other occupying the axial positions. The two Ru–P bonds are slightly bent away from the dipicolinic acid towards the Cl atom which is evident from the P(1)–Ru(1)–Cl(1) bond angle is 88.84° which is smaller than P(1)–Ru(1)–N(1) = 91.41° and P(2)–Ru(1)–N(1) = 92.51° [42]. The Ru–P, Ru–O, Ru–N and Ru–Cl bond lengths found in the complex agree well with that reported for similar ruthenium complexes [3,7,43,44].

3.5. Catalytic activity

The oxidation of benzyl alcohol and cinnamyl alcohol to benzaldehyde and cinnamaldehyde was carried out with the new ruthenium(III) complexes as catalysts in the presence of *N*-methyl morpholine-*N*-oxide as co-oxidant in CH_2Cl_2. After 3 h of reflux the aldehydes formed were quantified as their 2,4-dinitrophenyl hydrazone derivatives [25]. The results obtained are given in Table 4. In cinnamyl alcohol, only the alcoholic group gets oxidized selectively without affecting the double bond. The relatively higher yield of cinnamaldehyde when compared to benzaldehyde is due to the fact that α-CH unit of cinnamyl alcohol is more acidic than benzyl alcohol [45]. The replacement of PPh_3 by $AsPh_3$ group in the complexes did not result in much. On comparing the catalytic activity of these complexes with that of the other reported ruthenium(III) complexes, it is found that theses complexes exhibit comparatively lower activity [31,46]. This may be due to the stronger chelation of the ligand which may hinder the formation of catalytically active species.

Table 3
Selected bond lengths (Å) and bond angles (°) for [Ru(dipic)(PPh_3)$_2$Cl]

Bond lengths	
Ru(1)–Cl(1)	2.3340(12)
Ru(1)–O(4)	2.050(2)
Ru(1)–N(1)	1.996(3)
Ru(1)–P(1)	2.3945(12)
Ru(1)–O(3)	2.053(2)
Ru(1)–P(2)	2.4052(12)
Bond angles	
N(1)–Ru(1)–O(4)	77.42(10)
O(3)–Ru(1)–P(1)	90.81(8)
N(1)–Ru(1)–O(3)	77.28(9)
Cl(1)–Ru(1)–P(1)	88.84(3)
O(4)–Ru(1)–O(3)	154.70(8)
N(1)–Ru(1)–P(2)	92.57(8)
N(1)–Ru(1)–Cl(1)	178.95(9)
O(4)–Ru(1)–P(2)	89.36(8)
O(4)–Ru(1)–Cl(1)	103.60(7)
O(3)–Ru(1)–P(2)	91.85(8)
O(3)–Ru(1)–Cl(1)	101.70(6)
Cl(1)–Ru(1)–P(2)	87.22(3)
N(1)–Ru(1)–P(1)	91.41(8)
P(1)–Ru(1)–P(2)	175.62(3)
O(4)–Ru(1)–P(1)	89.72(8)

Table 4
Catalytic activity of new Ru(III) complexes

Complex	Substrate	Yield[a] (%)	Turnover number[b]
1	benzyl alcohol	56	57
	cinnamyl alcohol	60	59
2	benzyl alcohol	36	37
	cinnamyl alcohol	60	59
3	benzyl alcohol	30	30
	cinnamyl alcohol	67	66
4	benzyl alcohol	39	40
	cinnamyl alcohol	62	61

[a] Yield based on substrate.
[b] Moles of product per mole of catalyst.

4. Conclusion

Dipicolinic acid can coordinate to the metal in a number of fashions. In spite of this variable ligating ability, it acts as tridentate dibasic chelating ligand forming only mononuclear complex irrespective of the metal-to-ligand ratio.

metal cations and therefore the biological activities of its metal complexes should be significantly altered. The most salient feature of these isomorphous crystal structures is that the individual ionic subunits self-assemble via π–π stacking and extensive intermolecular hydrogen bonding, resulting in a 3D supramolecular architecture.

2. Experimental

2.1. Materials

High purity 5-nitrosalicylic acid, anhydrous magnesium chloride, zinc sulfate heptahydrate, cobalt sulfate heptahydrate and nickel chloride hexahydrate were purchased from Acros (USA) and used without further purification.

2.2. Physical measurement

Elemental analyses (C, H and N) were performed on a Perkin–Elmer 2400 analyzer. Thermal analysis (TG-DTA) was carried out using a TGA7 Perkin–Elmer thermal analyzer under N_2. The ^1H NMR spectra were recorded with Bruker AC 200 P (200 MHz) spectrometer; the chemical shifts are expressed in terms of ppm. The IR spectra were recorded with Bruker Vector 22 spectrometer.

2.3. Preparation of the complexes

2.3.1. $[Mg(H_2O)_5(5\text{-nsa})]^+(5\text{-nsa})^- \cdot H_2O$ (1)

Sodium 5-nitrosalicylate was prepared by neutralizing 5-nitrosalicylic acid (0.915 g, 5 mmol) with 5 ml of 1 M NaOH. To this solution was added anhydrous $MgCl_2$ (0.238 g, 2.5 mmol) in 3 ml of water. After a few days **1** was filtered, crystallized in water and dried over calcium chloride. Yield: 0.620 g (64%). *Anal.* Calc. for $C_{14}H_{20}N_2O_{16}Mg$ (**1**): C, 33.85; H, 4.07; N, 5.64. Found: C, 33.60; H, 3.96; N, 5.55%. Thermal study (TG-DTA) reveals a weight loss of 20.5% (Calc. 21.7%) at 75–230 °C, corresponding approximately to loss of six crystalline water molecules (both crystallization and coordination water). IR (neat, cm^{-1}): 3423(m), 1624(m), 1590(s), 1475(s), 1450(s), 1386(m), 1332(s), 1150(s), 1074(m), 926(m), 842(m), 808(m), 751(m), 698(s), 639(m).

2.3.2. $[Zn(H_2O)_5(5\text{-nsa})]^+(5\text{-nsa})^- \cdot H_2O$ (2)

Sodium 5-nitrosalicylate was prepared by neutralizing 5-nitrosalicylic acid (0.915 g, 5 mmol) with 5 ml of 1 M NaOH. To this solution was added $ZnSO_4 \cdot 7H_2O$ (0.720 g, 2.5 mmol) in 3 ml of water. After a few days **2** was filtered, crystallized in water and dried over calcium chloride. Yield: 1.076 g (80%). *Anal.* Calc. for $C_{14}H_{20}N_2O_{16}Zn$ (**2**): C, 31.27; H, 3.76; N, 5.21. Found: C, 31.16; H, 3.99; N, 5.25%. Thermal study (TG-DTA) reveals a weight loss of 19.7% (Calc. 20.1%) at 55–160 °C, corresponding to loss of six crystalline water molecules (both crystallization and coordination water). ^1H NMR (D_2O, 200 MHz) δ: 8.62 (d, $J = 2.6$ Hz, 1H, H-6), 8.24 (dd, $J = 9.3$, 2.6 Hz, 1H, H-4), 6.99 (d, $J = 9.3$ Hz, 1H, H-3). IR (neat, cm^{-1}): 3407(m), 1623(m), 1588(s), 1503(m), 1475(s), 1447(s), 1386(s), 1333(s), 1287(s), 1151(s), 1074(m), 926(m), 888(m), 844(m), 807(m), 750(m), 710(m), 640(m).

2.3.3. $[Co(H_2O)_5(5\text{-nsa})]^+(5\text{-nsa})^- \cdot H_2O$ (3)

Sodium 5-nitrosalicylate was prepared by neutralizing 5-nitrosalicylic acid (0.915 g, 5 mmol) with 5 ml of 1 M NaOH. To this solution was added $CoSO_4 \cdot 7H_2O$ (0.702 g, 2.5 mmol) in 3 ml of water. After a few days **3** was filtered, crystallized in water and dried over calcium chloride. Yield: 0.888 g (67%). *Anal.* Calc. for $C_{14}H_{20}N_2O_{16}Co$ (**3**): C, 31.65; H, 3.80; N, 5.27. Found: C, 31.46; H, 3.91; N, 5.16%. Thermal study (TG-DTA) reveals a weight loss of 20.2% (Calc. 20.3%) at 75–165 °C, corresponding to loss of six crystalline water molecules (both crystallization and coordination water). IR (neat, cm^{-1}): 3403(m), 1624(m), 1589(s), 1503(m), 1475(s), 1448(s), 1386(m), 1332(s), 1288(s), 1150(s), 1073(m), 926(m), 895(m), 843(m), 808(m), 750(m), 710(m), 698(m), 640(m).

2.3.4. $[Ni(H_2O)_5(5\text{-nsa})]^+(5\text{-nsa})^- \cdot H_2O$ (4)

Sodium 5-nitrosalicylate was prepared by neutralizing 5-nitrosalicylic acid (0.915 g, 5 mmol) with 5 ml of 1 M NaOH. To this solution was added $NiCl_2 \cdot 6H_2O$ (0.594 g, 2.5 mmol) in 3 ml of water. After a few days **4** was filtered, crystallized in water and dried over calcium chloride. Yield: 0.887 g (67%). *Anal.* Calc. for $C_{14}H_{20}N_2O_{16}Ni$ (**4**): C, 31.66; H, 3.80; N, 5.27. Found: C, 31.44; H, 3.75; N, 5.14%. Thermal study (TG-DTA) reveals a weight loss of 20.1% (Calc. 20.3%) at 70–190 °C, corresponding to loss of six crystalline water molecules (both crystallization and coordination water). IR (neat, cm^{-1}): 3406(m), 1624(m), 1589(s), 1503(m), 1475(s), 1448(s), 1386(s), 1332(s), 1287(s), 1151(s), 1074(m), 927(m), 890(m), 844(m), 809(m), 750(m), 710(s), 697(s), 640(m).

2.4. X-ray diffraction study

Diffraction data were collected on a Bruker-SMART three axis diffractometer equipped with a SMART 1000 CCD area detector using graphite monochromated Mo Kα X-radiation (wavelength $\lambda = 0.71073$ Å) at 100.0(1) K. The low temperature was reached by an evaporated liquid nitrogen stream over the crystal, provided by the Oxford Cryosystem device. Data collection and processing were carried out using Bruker SMART programs [3] and empirical absorption correction was applied using SADABS computer program [3]. The structure was solved by direct methods SIR97 [4], and refined by full-matrix least-squares based on F using CRYSTALS software [5]. All non-hydrogen atoms were anisotropically refined. The hydrogen atoms were located in difference Fourier maps. H atoms were refined isotropically with $U_{iso} = 1.20\ U_{eq}$

where U_{eq} is the equivalent isotropic atomic displacement parameter of the attached atom. The crystal parameters, data collection and the refinement details of compounds **1**, **2**, **3** and **4** are reported in Table 1.

3. Results and discussion

The structure determinations show that all these complexes are isomorphous and crystallize in *Pna2₁* orthorhombic space group. The asymmetric unit can be represented by the general formula: $[M_1(H_2O)_5(5\text{-nsa})]^+(5\text{-nsa})^- \cdot H_2O$ where M_1 = magnesium, zinc, cobalt or nickel. Since complexes **1**–**4** are isomorphous, no notable differences were observed between their structural parameters. For that reason, only the details of the X-ray structure of Ni(II) complex (**4**), arbitrarily chosen, were reported and discussed in the present paper. The canonical drawing and the CAMERON [6] molecular structure of the Ni(II) complex (**4**) are represented in Figs. 1 and 2, respectively, with the atom numbering system used in Table 2, which lists the most relevant bond distances and angles.

The structure of $[Ni(H_2O)_5(5\text{-nsa})]^+(5\text{-nsa})^- \cdot H_2O$ (**4**) consists of one $[Ni(H_2O)_5(5\text{-nsa})]^+$ cation, one $(5\text{-nsa})^-$ serves as a counter-anion and one water molecule exists as solvate molecule. The cation is a monomeric complex in which Ni(II) is coordinated to five aqua ligands and the carboxylato O(36)-atom from the 5-nitrosalicylato ligand, forming a slightly distorted octahedron. The *cis* angles around the Ni center vary between 86.13(6)° and 94.32(7)° while the *trans* angles vary from 173.22(6)° to 176.29(7)°. The Ni–O(36) distance [2.026(2) Å] is notably shorter than those for Ni–O(10), Ni–O(11), Ni–O(12), Ni–O(13), Ni–O(14), [2.040(2), 2.095(2), 2.086(2), 2.067(2), 2.043(2) Å, respectively]. These bonds are probably quite dependent on the H-bonding system, which is very important in this structure. The presence of six water molecules leads to a very extensive and complicated H-bonding network. All the aqua ligands and the solvate water molecule form strong H-bonds between themselves, with the carboxylato O-atoms, the nitro O-atoms and the phenoxo O-atoms. A list of the most probable atoms involved in H-bonds with their related angles is given in Table 3. Fig. 3 shows the H-bonding association in the asymmetric unit. The H-bonds are extended in all directions

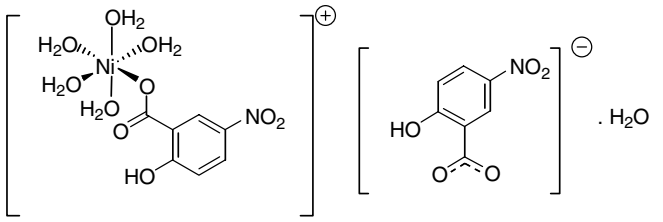

Fig. 1. Canonical representation of $[Ni(H_2O)_5(5\text{-nsa})]^+(5\text{-nsa})^- \cdot H_2O$ (**4**).

forming a H-bonded 3D network, as illustrated in Fig. 4. The crystal cohesion is thus ensured by fourteen hydrogen bonds per asymmetric unit: three intramolecular, two intermolecular intra-asymmetric unit and nine intermolecular inter-asymmetric unit (Figs. 3 and 4).

In both aromatic units, the 5-nitro group is roughly coplanar with the adjacent phenyl ring [torsion angle C(23)–C(24)–N(24)–O(24): 174.13° (non-ligating aromatic moiety); torsion angle C(33)–C(34)–N(34)–O(34): 174.36° (metal-bonded aromatic moiety)]. However, a notable dissymmetry was observed between the N–O lengths of each

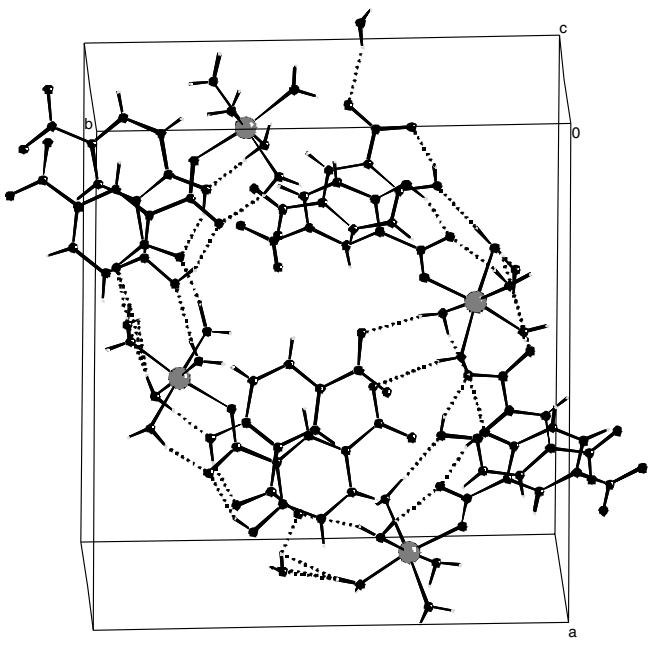

Fig. 4. Perspective diagram of packing of $[Ni(H_2O)_5(5\text{-nsa})]^+(5\text{-nsa})^- \cdot H_2O$ (**4**) in the unit cell showing the extensive 3D H-bonded network (dashed lines). Ni centers are symbolized by large gray tone circles.

aromatic moiety [N(24)–O(24): 1.228(3) Å, N(24)–O(25): 1.241(3) Å; N(34)–O(34): 1.241(3) Å, N(34)–O(35): 1.221(3) Å]. This can be rationalized by invoking that O(25) and O(34) are both implicated in intermolecular hydrogen bonds [with H(142) and H(112), respectively], Fig. 3. Similarly, the carboxylate group of each aromatic unit is essentially coplanar with the adjacent phenyl ring [torsion angle C(21)–C(20)–C(26)–O(26): 178.48° (non-ligating aromatic moiety); torsion angle C(31)–C(30)–C(36)–O(36): 176.95° (metal-bonded aromatic moiety)] with a marked dissymmetry between the C–O lengths [C(26)–O(26): 1.256(3) Å, C(26)–O(27): 1.274(3) Å; C(36)–O(37): 1.277(3) Å, C(36)–O(36): 1.252(3) Å]. This dissymmetry is typical of asymmetrically-bonded (unidentate) carboxylato ligands, and is seen in the crystal structure of a variety of (salicylato) metal complexes [2e,2f]. Another salient geometrical feature of this structure is that the non-ligating 5-nsa moiety [C(20) to C(25) plane, denoted P(1)] and the metal-bonded one [C(30) to C(35) plane, denoted P(2)] are pairwise linked by π–π stacking interactions (Figs. 5 and 6). Remarkably, this stacking implicates a *syn*-facial arrangement of the aromatic nuclei (superimposition of the same faces); in sharp contrast, Smith and co-workers have observed an *anti*-facial arrangement of the π-bonded 5-nsa ligands (superimposition of the opposite faces) in the proton-transfer compounds with a variety of Lewis bases [7]. The dihedral angle between mean planes P(1) and P(2) is 5.86(6)°. The two 5-nsa rings have a centroid separation *Cg*P(1)…*Cg*P(2) of 3.847 Å and a mean interplanar spacing of 3.400 Å [orthogonal projection of *Cg*P(2) on P(1)] corresponding to a ring-centroid offset of 1.800 Å (Table 4). Although this offset is quite large, a notable π-overlapping exists between the two aromatic nuclei (Fig. 5). On the other hand, the metal-bonded nucleus is slightly rotated counterclockwise around C(32)–C(35) axis (by ca. 1°) relatively to the non-ligating nucleus plane, as highlighted in Fig. 6. Besides the anchoring of the metal-bonded cationic moiety to the non-ligating anionic counterpart through π–π interaction, these are connected by two types of intermolecular hydrogen bonds: seven inter-asymmetric unit bonds [$O(26)^{i}$…H(102)–O(10)–Ni, $O(26)^{ii}$···H(121)–O(12)–Ni, $O(200)^{ii}$···H(101)–O(10)–Ni, $O(200)^{i}$···H(131)–O(13)–Ni, H(202)···$O(12)^{iii}$–Ni, $O(27)^{i}$···H(141)–O(14)–Ni, $O(25)^{iv}$···H(142)–O(14)–Ni] and one intra-asymmetric unit bond [O(21)···H(132)–O(13)–Ni] (Fig. 3).

4. Conclusion

We have shown that the individual ionic subunits of the 5-nsa complexes with Mg(II), Zn(II), Co(II) and Ni(II) self-assemble via π–π stacking and extensive hydrogen bonding involving water molecules, leading to a 3D supramolecular architecture. The propensity for the 5-nsa ligand to be paired via π–π stacking interaction, already reported by Smith and co-workers [7], is noteworthy. In sharp contrast, the isomorphous 4-nsa complexes of Zn(II), Co(II) and Ni(II) reported par Ulkü and co-workers [2e], regioisomers of complexes **2**, **3** and **4**, respectively, consist of centrosymmetric monomers with the metal atom occupying the two inversion centers at $0,0,0$ and $0,1/2,1/2$ of a monoclinic unit cell. This work is being continued in two directions. First, the biological activities of complexes **1**–**4** are currently under evaluation in connection with the elaboration of potent (salicylato) metal complexes-based drugs. Secondly, the original metallo-organic framework of these complexes consisting of cationic/anionic aromatic moieties linked together through π-stacking and hydrogen bonding might be of peculiar interest in the design of functional materials. For instance, the π–π stacking interactions have been utilized in several research areas such as molecular conductors [8] and electronics [9]. In other respects, since the five shortest separations between Ni centers in **4** are 6.78, 7.14, 9.25, 10.66 and 11.76 Å, long-range magnetic interactions are expected, which could be exploited to elaborate molecular-based magnetic materials [10].

5. Supplementary data

Crystallographic data for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Center as supplementary publication Nos. CCDC 286184 (**3**) – CCDC 286185 (**1**) – CCDC 28186 (**4**) – CCDC 28187 (**2**). Copies of this information can be obtained free of charge from The Director, CCDC, 12, Union Road, Cambridge CB2 1EZ, UK (fax: +44 1223 336033; e-mail: deposit@ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk).

Acknowledgements

This paper is dedicated to Professor John R.J. Sorenson (University of Arkansas, USA). Financial support of Université Paris XI, CNRS and Ecole Centrale Paris is gratefully acknowledged. The authors thank Mrs. S. Mairesse-Lebrun for performing elemental analyses and Mr. M. Sghaier for performing DTA analyses.

L = ethanol and 2-amimopyrimidine (abbreviated as ampym)), $[Mn(dca)_2(C_2H_5OH)_2]_n$ (**1**) and $[Mn(dca)_2(ampym)_2]_n$ (**2**), together with spectroscopic and magnetic observations.

2. Experimental

2.1. Synthesis of the compounds

All chemicals were purchased from commercial sources and used as received.

$Mn(dca)_2(C_2H_5OH)_2]_n$ (**1**): 0.5 mmol $MnCl_2$ in ethanol and 1.0 mmol sodium dicyanamide in ethanol plus a small amount of water were carefully mixed together and filtered to remove any solid particles. Colourless crystals were obtained by diffusion into ether. When crystals are taken out of the solvent mixture and remain in open air, solvent is lost rapidly within a few hours to form $Mn(dca)_2$, which was confirmed by elemental analysis and infrared spectroscopy (vide infra). Such a decomposition in open air was also observed earlier in the literature for other related $Mn(dca)_2$ compounds [5c]. For IR and X-ray measurement freshly prepared crystals were used.

$[Mn(dca)_2(ampym)_2]_n$ (**2**): 0.5 mmol $Mn(CF_3SO_3)_2$ and 1 mmol ampym were each dissolved in an ethanol/water (1:1) mixture and warmed up until about 50 °C. To this solution, an aqueous solution of 1 mmol sodium dicyanamide was added dropwise. The white solution was filtered and left to evaporate at room temperature. White-yellowish crystals were obtained in a few days. (yield 48%); *Anal.* Calc. for $C_{12}H_{12}N_{12}Mn$: C, 38.0; H, 3.2; N, 44.3. Found: C, 37.9; H, 3.1; N, 44.3%.

2.2. Physical techniques

C, H, N determinations were performed on a Perkin Elmer 2400 Series II analyzer.

FTIR spectra were obtained on a Perkin Elmer Paragon 1000 FTIR spectrophotometer equipped with a Golden Gate ATR device, using the reflectance technique (4000–300 cm^{-1}, res. 4 cm^{-1}). X-band EPR spectra were recorded on polycrystalline samples at RT at 77 K with a Jeol RE2X electron spin resonance spectrometer using DPPH ($g = 2.0036$) as a standard. Magnetic susceptibility measurement (5–300 K) were carried out using a Quantum Design MPMS-5S SQUID magnetometer (measurements carried out at 0.1 T). Data were corrected for magnetisation of the sample holder and for diamagnetic contributions, which were estimated from Pascal constants.

2.3. Crystallography

Freshly prepared crystals suitable for structure determination were mounted on Lindemann-glass capillaries and transferred into the cold nitrogen stream of a Nonius KappaCCD diffractometer on rotating anode (Mo Kα radiation, graphite monochromator, $\lambda = 0.71073$). The intensity data were corrected for Lorentz and polarisation effects, for absorption and extinction. The structures were solved by direct methods. The programs COLLECT [6a], SHELXS-97 [6b], SHELXL-97 [6c] were used for data reduction, structure solution and structure refinement, respectively. All non-hydrogen atoms were refined anisotropically. All H atoms were introduced in calculated positions and refined with fixed geometry with respect to their carrier atoms. Crystallographic data of the compounds are listed in Table 1.

3. Results and discussion

3.1. Structures

3.1.1. Crystal structure of $[Mn(dca)_2(C_2H_5OH)_2]_n$ (1)

A plot showing the numbering scheme is given in Fig. 1 and selected bond distances and angles are given in Table 2. The structure of **1** contains 1D linear chains with double-bridged $\mu_{1,5}$-bridging dca molecules. The geometry of the Mn ion is octahedral and the octahedron is formed by four

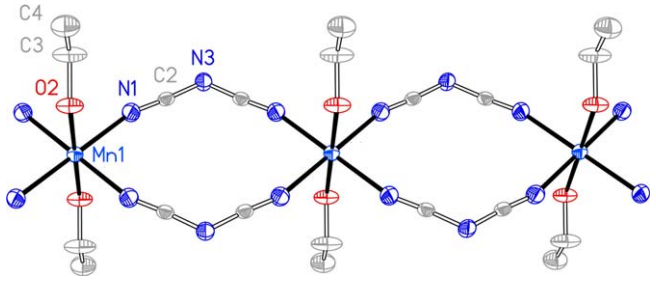

Fig. 1. Atomic displacement plot (50% probability) of structure $[Mn(dca)_2(C_2H_5OH)_2]_n$ (**1**). H atoms are omitted for clarity.

Table 2
Selected bond lengths (Å) and angles (°) for $[Mn(dca)_2(C_2H_5OH)_2]_n$ (**1**)

Mn(1)–O(2)	2.216(3)	Mn(1)–N(1)	2.217(2)
Mn(1)–Mn(1)A	7.506(3)		
O(2)–Mn(1)–N(1)	89.12(8)	O(2)–Mn(1)–N(1)A	90.88(8)
N(1)–Mn(1)–N(1)B	88.52(13)	N(1)A–Mn(1)–N(1)B	91.48(13)

Relevant hydrogen bonds:

	D–H	H···A	D···A	D–H···A
N3–H31···O2 [−1/2 + x, −1/2 + y, z]	0.88	2.10	2.855(6)	143

$A = -x + 1, -y + 1, -z + 1$, $B = -x + 1, y, -z + 1$.

nitrogen atoms of four different dca molecules with a Mn–N distance of 2.217(2) Å and two oxygen atoms of two *trans*-ethanol molecules with a Mn–O distance of 2.216(3) Å. The Mn–Mn distance is 7.506. A hydrogen-bonding network is formed by the hydrogen atom of the nitrile nitrogen atom of the bridging dca molecule to an oxygen atom of a neighbouring ethanol molecule with a N3···O2 distance of 2.855(6) Å. Further details of the hydrogen bonding are listed in Table 2. This compound **1** can be considered as an isomer of the compound $\{[Mn(dca)_2(C_2H_5OH)_2]\ ((CH_3)_2CO)\}_n$ [5c]; however, this last compound does form a sheet like structure and, due to the fact that an acetone molecule is present in the lattice, has a different hydrogen bond structure.

3.1.2. Crystal structure of $[Mn(dca)_2(ampym)_2]_n$ (2)

A plot showing the numbering scheme is given in Fig. 2 and selected bond distances and angles are given in Table 3.

The structure of **2** contains 1D linear chains with double-bridged $\mu_{1,5}$-bridging dca molecules. The geometry of the Mn ion is octahedral and the octahedron is formed by four nitrogen atoms of four different dca anions with a Mn–N distance of 2.2193(13) Å and two nitrogen atoms of two *trans*-ampym molecules with a Mn–N distance of 2.3191(18) Å. The Mn–Mn distance is 7.580 Å. A hydrogen-bonding network is formed by the hydrogen atom of an amino nitrogen atom of the ampym ligand to a nitrile nitrogen atom of a neighbouring dca molecule with a N···N distance of 3.303(3) Å. The crystal lattice is further stabilised by an H-bonding system (Watson-Crick type) between the amino nitrogen N7 and the uncoordinated pyrimidine nitrogen atom N3 of a neighbouring ampym ligand (N3···N7 3.085(3) Å). A similar H-bonding pattern was reported earlier for compounds containing ampym as a ligand [7]. Furthermore some weak intramolecular H-bonds occur, and more details are given in Table 2.

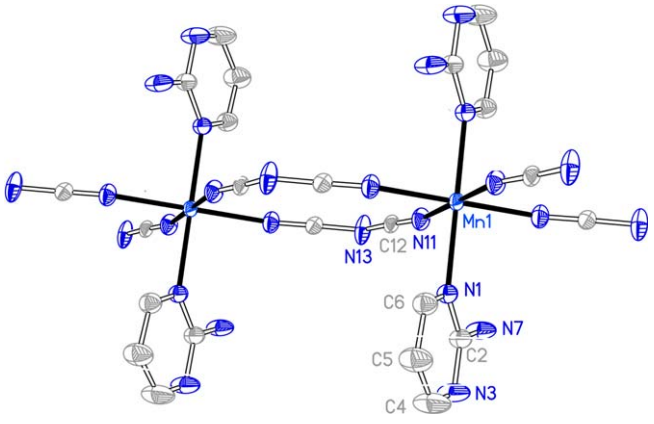

Fig. 2. Atomic displacement plot (50% probability) of structure $[Mn(dca)_2(ampym)_2]_n$ (**2**). H atoms are omitted for clarity.

3.2. Infrared spectra

Both compounds exhibit a strong absorption in the 2370–2150 cm^{-1} region corresponding to the modes of vibration of dca anion. These bands are characteristic of the $\nu_{s(C-N)} + \nu_{as(C-N)}$ and $\nu_{(C\equiv N)}$ vibrations, for which the first band is diagnostic for the metal binding mode [8]. In compound **1**, the bands are observed at 2290, 2248 and 2178 cm^{-1} for a freshly prepared sample. After staying in open air for a short time compound **1** decomposes into $Mn(dca)_2$ and IR vibration are observed at 2363, 2338, 2294, 2258 and 2188 cm^{-1}, which compare to observations made in the literature [5c]. Compound **2** exhibits IR bands similar as compound **1** at 2305, 2245 and 2172 cm^{-1}. The observed IR bands are in agreement with the literature for coordinated dca and ampym ligands [8].

3.3. Magnetic properties

Due to the decomposition of compound **1** (see Section 2), only from compound **2** an EPR spectrum and magnetic susceptibility measurements could be obtained. The EPR spectrum of compound **2**, measured as a polycrystalline powder at RT, shows an isotropic very broad signal centred at $g = 2.01$, in accordance to observations in the literature [5f].

The magnetic susceptibility of a powdered sample **2** was measured from 5 to 300 K. The temperature dependence of $\chi_M T$ versus T is shown in Fig. 3. The $\chi_M T$ value at 300 K is 4.266 $cm^3\ K\ mol^{-1}$, a value which is closed to the value expected for one isolated manganese(II) ion of spin $S = 5/2$ ($\chi_M T = 4.375\ cm^3\ K mol^{-1}$), with g equal to 2. This value stays almost constant till about 50 K, from which it slowly decreases to 2.734 $cm^3\ K\ mol^{-1}$ at 5 K. The behaviour is indicative for a weak antiferromagnetic coupling between Mn(II) ions. The variable temperature magnetic susceptibility data follow the Curie-Weiss law with $\Theta = -2.9$ K and $C = 4.309\ cm^3\ K\ mol^{-1}$.

Table 3
Selected bond lengths (Å) and angles (°) for $[Mn(dca)_2(ampym)_2]_n$ (**2**)

Mn(1)–N(1)	2.3191(18)	Mn(1)–N(11)	2.2193(13)
Mn(1)–Mn(1)A	7.580(3)		
N(11)–Mn(1)–N(11)B	87.31(7)	N(11)–Mn(1)–N(11)C	92.69(7)
N(11)A–Mn(1)–N(1)A	91.50(5)	N(11)–Mn(1)–N(1)A	88.50(5)

Relevant hydrogen bonds:

	D–H	H···A	D···A	D–H···A
N3–H3A···N7 [$-x$, $-1-y$, z]	0.88	2.21	3.085(3)	180
N7–H7A···N3 [$-x$, $-1-y$, z]	0.88	2.21	3.085(3)	178
N7–H7B···N13 [$-x$, y, $1/2-z$]	0.88	2.60	3.303(3)	138

$A = -x+1/2, -y+1/2, -z+1$; $B = -x+1/2, -y+1/2, z$; $C = x, y, -z+1$.

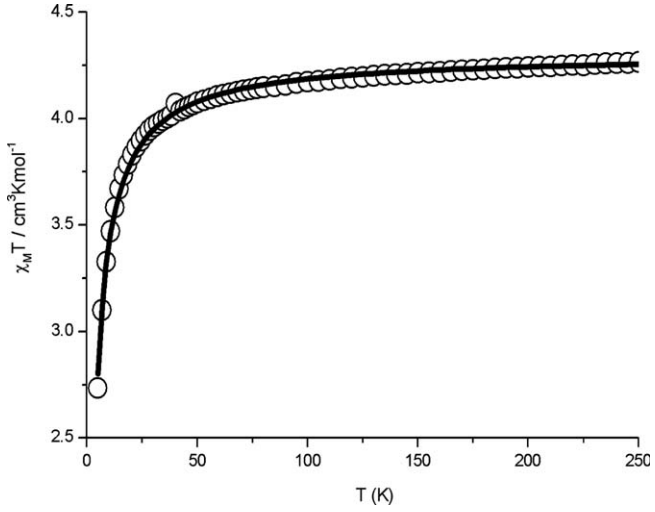

Fig. 3. A plot of the temperature dependence of χ_M. T vs. T for compound **2**. The solid line represents the calculated curve for $g = 2.00$ and $J = -0.22\ cm^{-1}$ (see text).

The magnetic susceptibility can be described using the 1D antiferromagnetic chain model for classical $S = 5/2$ spins derived by Fischer from the Heisenberg model [9], with the Hamiltonian used: $H = -J\sum S_i S_{i+1}$, where J is the magnetic exchange coupling between two adjacent paramagnetic metal ions. The best fit parameters obtained were $J = -0.22\ cm^{-1}$, $g = 2.00$ with $R = 1.2 \times 10^{-4}$ (see solid line in Fig. 3). The large Mn–Mn distance agrees with the weak magnetic exchange.

4. Conclusions

Two new polymeric Mn(II) compounds with doubly bridged $\mu_{1,5}$-dca molecules which forms an 1D array. The magnetic interaction of compound (**2**) is very weakly antiferromagnetic. In Table 4 a number of related relevant compounds together with their magnetic properties are presented. As can be seen from this table in all compounds the antiferromagnetic interaction is very weak, clearly due to the fact that the Mn–Mn distance is large (about 7.5 Å) and no serious overlap of the magnetic metal orbitals can take place via the dca ligands. The same kind of weak interaction ($J < 1\ cm^{-1}$) is also observed for a number of polymeric dca-bridged Cu(II) compounds [8c].

5. Supplementary material

Crystallographic data (excluding structure factors) for the structure reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication nos. CCDC-284104 and 284105, for compounds **1** and **2**, respectively. Copies of this information can be obtained free of charge from The Director, CCDC, 12, Union Road, Cambridge CB2 1EZ, UK (fax:

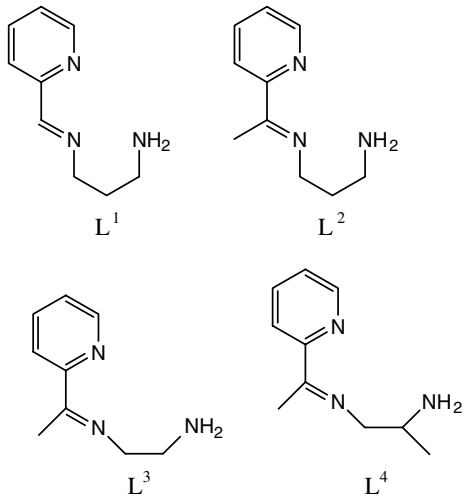
group [2]. The azide ion usually bridges the metal centers in end-on, end-to-end or a combination of both modes to yield dinuclear, tetranuclear, cubane, 1-D, 2-D and 3-D compounds [3–11]. Focusing on Cu(II) systems, both type of bridges can be either symmetrical or unsymmetrical due to active Jahn–Teller effects on the metal centre which make the structures even more versatile [12]. The magnetic exchange via the azide bridge can be ferro- or antiferromagnetic depending upon the bridging mode and bonding parameters. For example, when the azido ligand bridges two Cu(II) ions in an end-on, basal–basal manner, the nature of the exchange coupling changes from ferromagnetic to antiferromagnetic when the Cu–N–Cu angle is around 108° [13]. On the other hand, for basal–apical coordination, no such theoretical calculation has been reported. The literature data for this bridging mode are limited and the J values with regard to Cu–N–Cu angles are so dispersed that no meaningful correlation can be done [14–27]. Therefore, new complexes need to be prepared with this kind of coordination to be able to draw clearer magneto-structural conclusions. A tridentate blocking ligand and one azide ion should be an ideal combination to produce such complexes. Recently, we have found that a group of mononegative N,N,O donor tridentate Schiff base ligands indeed yielded double EO azido bridged basal–apical dimers in all cases [28]. Interestingly, it was found that very subtle differences in the H-bonding network and structural parameters could be responsible for drastic changes in the magnetic behavior of such complexes.

In order to introduce variation in such complexes, we intend to use neutral N,N,N donor tridentate Schiff base blocking ligands. As in the case of NNO donor ligands [28], we want to keep one of the primary amine groups of the diamine free to allow it to form H-bonds. In this paper, we describe a very easy and convenient method to synthesize four new complexes of the general formula $CuL(N_3)(ClO_4)$, where L^1–L^4 are four different monocondensed, tridentate N,N,N donor Schiff base ligands (Scheme 1), their crystal structures and magnetic properties.



Scheme 1.

2. Experimental

All chemicals were of reagent grade, purchased from commercial sources and used without further purification.

Caution!!! All the complexes contain azide and perchlorate groups and are potentially explosive. Only a small amount of the material should be prepared and it should be handled with care.

2.1. Preparations

2.1.1. Synthesis of the ligands N^1-pyridin-2-yl-methylene-propane-1,3-diamine (L^1), N^1-(1-pyridin-2-yl-ethylidene) propane-1,3-diamine (L^2), N^1-(1-pyridin-2-yl-ethylidene) ethane-1,2-diamine (L^3) and N^1-(1-pyridin-2-yl-ethylidene) propane- 1,2-diamine (L^4)

All four tridentate Schiff base ligands L^1, L^2, L^3 and L^4 were synthesized in a similar way by refluxing the respective diamine (10 mmol) with pyridine-2-carboxaldehyde or 2-acetyl pyridine (10 mmol) in methanol solution (20 ml) for ca. 3 h. The ligands were not isolated. The methanolic solutions were used for the syntheses of the complexes.

L^1 and L^2 were synthesized by refluxing 1,3-propanediamine (10 mmol, 0.84 cm^3) with pyridine-2-carboxaldehyde (10 mmol, 0.98 cm^3) and 2-acetylpyridine (10 mmol, 1.2 cm^3), respectively. L^3 and L^4 were synthesized by refluxing 1,2-ethanediamine (10 mmol, 0.67 cm^3) and 1,2-propanediamine (10 mmol, 0.76 cm^3), respectively, with 2-acetylpyridine (10 mmol, 1.2 cm^3).

2.1.2. Synthesis of complexes $[(CuL^1N_3)_2](ClO_4)_2$ (**1**), $[(CuL^2N_3)_2](ClO_4)_2$ (**2**), $[CuL^3(N_3)(ClO_4)]_n$ (**3**) and $[CuL^4(\mu\text{-}1,1\text{-}N_3)(\mu\text{-}1,3\text{-}N_3)(ClO_4)]_n$ (**4**)

To prepare complexes **1**, **2**, **3** and **4**, a methanol solution (20 ml) of copper(II) perchlorate hexahydrate (10 mmol, 3.7 g) was added to the ligand solution (10 mmol) of HL^1, HL^2, HL^3 and HL^4, respectively, and refluxed for 1 h. A solution of NaN_3 (10 mmol, 0.37 g) in methanol was then added to it with constant stirring. For complex **1** a deep blue precipitate separated out immediately and was collected by filtration. Diffraction quality single crystals were obtained after a few days by slow evaporation of a dark green acetonitrile solution of the compound in open atmosphere. In the case of complex **2**, there was no immediate separation of a compound. Crystalline compounds started to separate after ca. 2 h and were collected by filtration after ca. 5 h. Single crystals suitable for X-ray diffraction were obtained from the filtrate by slow evaporation in a refrigerator. For both complexes **3** and **4**, deep blue solids separated out immediately after addition of azide and were separated by filtration. Deep blue parallelepiped-shaped single crystals of **3** suitable for X-ray diffraction were obtained from a CH_3CN solution of the compound by slow evaporation in air. For complex **4** deep

2.2. Physical measurements

Elemental analysis (carbon, hydrogen and nitrogen) was performed using a Perkin–Elmer 240C elemental analyzer. IR spectra in KBr (4500–500 cm^{-1}) were recorded using a Perkin–Elmer RXI FT-IR spectrophotometer. Electronic spectra in acetonitrile (1200–350 nm) were recorded in a Hitachi U-3501 spectrophotometer. The magnetic measurements were carried out in the "Servei de Magnetoquimica (Universitat de Barcelona)" on polycrystalline samples (20 mg) with a Quantum Design SQUID MPMSXL susceptometer in the temperature range of 2–300 K and the magnetic field was 1 T. Magnetization measurements were made in the same SQUID at 2 K. EPR spectra were recorded on powder samples at X-band frequency with a Bruker 300E automatic spectrometer, varying the temperature between 4 and 300 K.

2.3. X-ray crystallography

Data for all four crystals were measured with Mo Kα radiation using the MAR research Image Plate System. The crystals were positioned at 70 mm from the Image Plate. 100 frames were measured at 2° intervals with a counting time of 2 min. Data analysis was carried out with the XDS program [29]. The structures were solved using direct methods with the SHELX-86 program [30]. Non-hydrogen atoms were refined with anisotropic thermal parameters. The hydrogen atoms were included in geometric positions and given thermal parameters equivalent to 1.2 times those of the atom to which they were attached. Empirical absorption corrections were carried out using DIFABS [31]. The structures were refined on F^2 using SHELXL [32]. A summary of the crystallographic data are given in Table 1. The poor quality of the crystals of **4** gave rise to misshapen large spots in the diffraction pattern which in turn led to high R values. The crystallographic illustrations were prepared using ORTEP-3 [33].

3. Results and discussion

3.1. Syntheses

All four Schiff base ligands and their complexes were synthesized in a very facile and essentially identical way. The respective diamine and the carbonyl compound were

mixed in a 1:1 stoichiometric ratio in methanol and refluxed. The methanolic solution of the Schiff base ligand thus prepared was added to a methanolic solution of copper perchlorate, refluxed for 1 h and then a stoichiometric amount of sodium azide was added when the desired complexes were separated. It is to be noted that there is a possibility that the diamines may undergo condensation at both ends to produce a tetradentate di-Schiff base. We, therefore, repeated the syntheses several times and found that as long as the stoichiometry of the diamine and carbonyl compound are strictly maintain as 1:1, no compound other than that of monocondensed tridentate ligand is separated. If the amount of carbonyl compound is increased, however, a compound of the tetradentate ligands starts to separate together with the desired complex. A similar approach was adopted earlier for the syntheses of mononuclear Zn(II) and Ni(II) complexes of N_3-donor tridentate Schiff base ligands [34].

The four tridentate Schiff base blocking ligands are very similar; all the complexes have the same general formula $CuL(N_3)(ClO_4)$, yet the bridging topologies are drastically different. The complexes of the ligands L^1 and L^2 are double azido bridged dimers, that of L^3 is a 1-D chain bridged by perchlorate ions and the complex of L^4 is a 1-D chain with alternate single EO and EE azido bridges. Two 1-D chains of complex **3** are linked by H-bonds, which play all important roles in magnetic interactions. The structure of the complex of L^4 is very interesting as the occurrence of alternate single EO and EE bridges between two metal ions is very rare. To our knowledge, only two such compounds have been reported to date and the magnetic interactions mediated by the bridges in the two complexes are opposite to each other [25,26].

3.2. IR and electronic spectra

The most important aspects concerning the infrared spectra of the four compounds **1**, **2**, **3** and **4** deal with the possibility of characterizing the different coordination modes for the azido ligand to a transition metal, which is usually detected by the intense IR band due to $\nu_{as}(N_3)$ that occurs above 2000 cm^{-1}. In general, it appears above 2055 cm^{-1} for the bridging azide and below 2055 cm^{-1} for the terminal ion [13a]. In the same way, the presence of the $\nu_s(N_3)$ vibration mode in the region of 1360–1280 cm^{-1} is related to the existence of the terminal or end-on bridging azide, not appearing for the end-to-end bridging mode [35].

The two complexes **1** and **2** show only a single absorption band, consistent with the presence of only one type of azide ion in the structures. However, all of them appear at lower frequencies viz. 2044 and 2047 cm^{-1}, respectively, than usually expected for μ_2-1,1-azide bridging and this may be attributed to the highly asymmetrical nature of the azide bridges in the present complexes (vide structure description). For compound **3**, the $\nu_{as}(N_3)$ stretching vibration of the azido group appears at 2054 cm^{-1} and the band at 1320 cm^{-1} is attributed to the $\nu_s(N_3)$ vibration mode corresponding to the presence of terminal azido ligand as confirmed by the crystal structure for the compound **3**. Complex **4** shows a strong absorption band at 2062 cm^{-1}. Although the compound contains two types of azide bridges the appearance of single peak can be attributed to the very weak coordination mode of the EE bridge and asymmetric nature of the EO bridge.

All four complexes show two bands above 3000 cm^{-1} at 3309 and 3263 cm^{-1} for complex **1**, 3322 and 3263 cm^{-1} for complex **2**, 3310 and 3246 cm^{-1} for complex **3** and 3285 and 3127 $cm^{-1}$for complex **4**. These bands can be attributed to the ν_{NH_2} frequency. The band corresponding to the azomethine (C=N) group is distinct in all the four complexes; it occurs at 1599, 1593, 1583 and 1596 cm^{-1} for complexes **1**, **2**, **3** and **4**, respectively. Concerning the ClO_4^- anions, the ν_3 mode at 1098, 1088 and 1095 cm^{-1} for **1**, **2** and **4**, respectively, is somewhat broadened but the ν_4 band at 620, 619 and 621 cm^{-1}, respectively, is devoid of any splitting and are consistent with the IR-active normal modes for T_d symmetry suggesting that these anions are not coordinated to the copper atoms as substantiated by the crystal structures. The splitting of the band at 1092 cm^{-1} for **3** is indicative of coordinated perchlorate ions.

The electronic spectra of **1**, **2** and **4** in acetonitrile solution display a single absorption band 603, 600 and 606 nm, respectively. The positions of these bands are consistent with the observed square-pyramidal geometry around the copper centers [36]. The octahedral nature of complex **3** is evident by the appearance of a single broad peak at 587 nm, a position somewhat lower than the square-pyramidal geometry [37].

3.3. Description of the structures

3.3.1. Complexes $[(CuL^1N_3)_2](ClO_4)_2$ (1) and $[(CuL^2N_3)_2](ClO_4)_2$ (2)

The structure determination reveals that both complexes **1** and **2** consist of a discrete, centrosymmetric dinuclear complex cation $[(CuLN_3)_2]^{2+}$ and two non-coordinated perchlorate anions. In complex **2** there are two independent centrosymmetric dimers (A and B) with equivalent geometry. A view of the complex species is given in Fig. 1 for complex **1** (complex **2** has very similar molecular structure: Figure S1 for dimer A, Supporting Information). Selected bond lengths and angles for **1** and **2** are summarized in Tables 2 and 3, respectively. In the dimers of both complexes **1** and **2**, two distorted square-pyramidal copper(II) centers are bridged by the two centrosymmetrically related azide ions in asymmetric, basal–apical, end-on fashion leading to relatively small Cu···Cu distances (3.285(3) Å for **1**). Within the dimeric units each of the two trigonally distorted square-pyramidal copper(II) centers is coordinated equatorially by three ligating nitrogen atoms, N(1), N(2) and N(3), of the corresponding tridentate Schiff base ligand and a nitrogen atom, N(11), of one of the bridging

azides; this comprises the basal plane. A second nitrogen atom, N(11)′, from the centrosymmetrically related bridging azide coordinates axially at a rather long distance furnishing an elongated square-pyramidal $(4 + 1)$ geometry for each copper(II) center in the two complexes.

In the two crystallographically independent dimers of **2** there are minor variations in their bond lengths and bond angles. The intradimeric Cu···Cu distances are 3.244(3) and 3.335(3) Å in A and B, respectively. The axial Cu–N distances, 2.318(5) and 2.477(5) Å and bridging Cu–N–Cu angles, 97.5(2)° and 83.8(2)°, respectively, for dimer A and B are considerably different. As usual for a square-pyramid structure, the copper atom for each model is slightly pulled out of the mean squares plane towards the apical donor atom at a distance 0.085(1) Å, 0.194(1) Å and 0.015(1) Å in **1**, A and B of **2**, respectively. The addition parameter (τ) for complex **1** is 0.14; but these values are 0.33 and 0.01 for dimer A and B, respectively, for complex **2** indicating that the distortion towards trigonal-bipyramidal geometry is more pronounced for dimer A [38]. The six-membered chelate ring within each dimer incorporating the trimethylene fragment from the starting diamine assumes a twist-boat conformation with puckering parameters [39] $q = 0.515(7)$, 0.535(6) and 0.520(6) Å, $\phi = 14.4(16)°$, 4.1(2)° and 12.5(9)° and $\theta = 154.1(7)°$, 159.3(5)° and 142.1(6)°, respectively, in complex **1** and in dimer A and B of complex **2**.

The bridging Cu_2N_2 network is exactly planar as dictated by symmetry. Due to formation of basal–apical μ_2-1,1-N_3 bridging, the bridging Cu–N bond lengths are significantly different ($\Delta d = 0.58$, 0.33 and 0.49 for complex **1** and for A and B of **2**, respectively). The bridging N_3^- anions are quasi-linear; the N–N–N angles are 175.9(5)° for **1** and 177.5(6)° and 175.2(5)° for A and B of **2**, respectively.

The two crystal structures exhibit different hydrogen bonding patterns (Table 4). Perchlorate ions play a

significant role in the hydrogen bonding network. Both H(1a) and H(1b) of **1** and dimer A of **2** are involved in strong N–H···O hydrogen bonding with the perchlorate oxygen atoms giving a one-dimensional supramolecular entity. The one-dimensional structure for complex **1** is shown in Fig. 2. Dimer B of **2** does not form any such H-bonded one-dimensional structure.

3.3.2. Complex $[CuL^3(N_3)(ClO_4)]_n$ (3)

The structure of complex **3** consists of a quasi-one-dimensional infinite chain system with the repeating unit $[CuL^3N_3]^+$ bridged by perchlorate anions. The perspective view with the atom labelling scheme of the monomeric unit of $[CuL^3(N_3)(ClO_4)]_n$ is shown in Fig. 3. A view of the extended chain and the supramolecular hydrogen-bonded array of complex **3** is displayed in Fig. 4. Selected bond lengths and angles are summarized in Table 2. The copper atom is six-coordinated, being bonded to three ligating nitrogen atoms N(1), N(2) and N(3) from the tridentate Schiff base ligand L^3, another nitrogen N(11) of the terminal azide anion in the base plane and two oxygen atoms O(10) and O(13)* from two different perchlorate ions in the two apical positions. Thus, the six coordinated copper(II) center in this complex assumes a tetragonally distorted octahedron. In the complex reported here the two Cu–O distances with the perchlorate oxygen atoms are distinguishable and the bond Cu–O(10) is 2.430(5) Å whereas Cu–O(13)* is 2.633(5) Å, which may be considered as "semicoordinated" as proposed by Hathaway [40]. The azide ion is nearly linear with a N(11)–N(12)–N(13) angle of 176.0(4)°. The N–N distances within the azide ion are not equal [N(11)–N(12) = 1.198(5) Å and N(12)–N(13) = 1.151(5) Å] and the difference between them is 0.047 Å. The copper–copper repeating distance is 7.336 Å along the chain.

The pyridine ring can be considered as practically planar and the five membered chelate ring Cu–N(1)–C(1)–C(2)–N(2) has an envelope conformation on C(1) with puckering parameters [39] $q_2 = 0.418(4)$ Å and $\phi_2 = 107.2(4)°$.

An interesting feature of this complex is the joining of two neighbouring Cu-containing chain fragments via hydrogen bonds (Table 4, Fig. 4). There are two available hydrogen atoms [H(1a) and H(1b)] for hydrogen bond formation, both of which are involved in strong hydrogen bonding with the symmetry related units. H(1b) is engaged in bifurcated hydrogen bond formation with the coordinating nitrogen N(11′) of the pendant azide ion and O(11′) of the perchlorate anion from same crystallographically related unit $(2 - x, -y, -z)$. But H(1a) is involved in N–H···N hydrogen bond formation with the terminal nitrogen N(13′) of the pendant azide ion from another crystallographically related unit $(2 - x, 1 - y, -z)$. The shortest copper–copper distance between the two H-bonded chains is 5.170 Å. It is to be noted here that although there are several examples where a perchlorate ion bridges Cu^{II} centres to form one-dimensional chains [41], only one other complex has been reported to date in which a perchlorate ion bridges the Cu(II) centres in spite of the presence of a versatile bridging azide ion as a monodentate ligand [14]. In that structure, however, the linking of neighbouring chains by H-bonding, which plays a very important role in the magnetism of **3** (see magnetic studies), has not been observed.

3.3.3. Complex $[CuL^4(\mu\text{-}1,1\text{-}N_3)(\mu\text{-}1,3\text{-}N_3)(ClO_4)]_n$ (4)

An ORTEP drawing of the one-dimensional complex $[CuL^4(N_3)(ClO_4)]_n$, with the atom labelling scheme, is shown in Fig. 5. Selected bond lengths and angles are

summarized in Table 3. The structure determination reveals that the copper atoms are bridged singly and alternately by end-on and end-to-end azido ligands with the occurrence of a 1-D polymeric infinite chain. Two independent copper atoms Cu(1) and Cu(2), having different environments, possess distorted square-pyramidal geometries. Each copper center is linked to one neighboring copper center by an azide in an end-on fashion and another copper atom through end-to-end fashion to form the 1-D alternate chain. Cu(1) is coordinated equatorially by three ligating nitrogen atoms, N(1), N(2) and N(3), of the tridentate Schiff base ligand L^{4} and a nitrogen atom, N(21), of the end-to-end bridged azido ligand; this defines the basal plane. The apical position is occupied by one nitrogen atom N(11) of the end-on bridged azido ligand. Similarly for Cu(2), the three coordinating nitrogen atoms N(4), N(5) and N(6) of the tridentate Schiff base and one nitrogen atom N(11) of the end-on bridged azido ligand comprises the basal plane and here the apical position is occupied by the nitrogen atom N(23)′ of the another end-to-end bridged azido ligand from a crystallographically related unit. Thus, both EO and EE bridges assume an

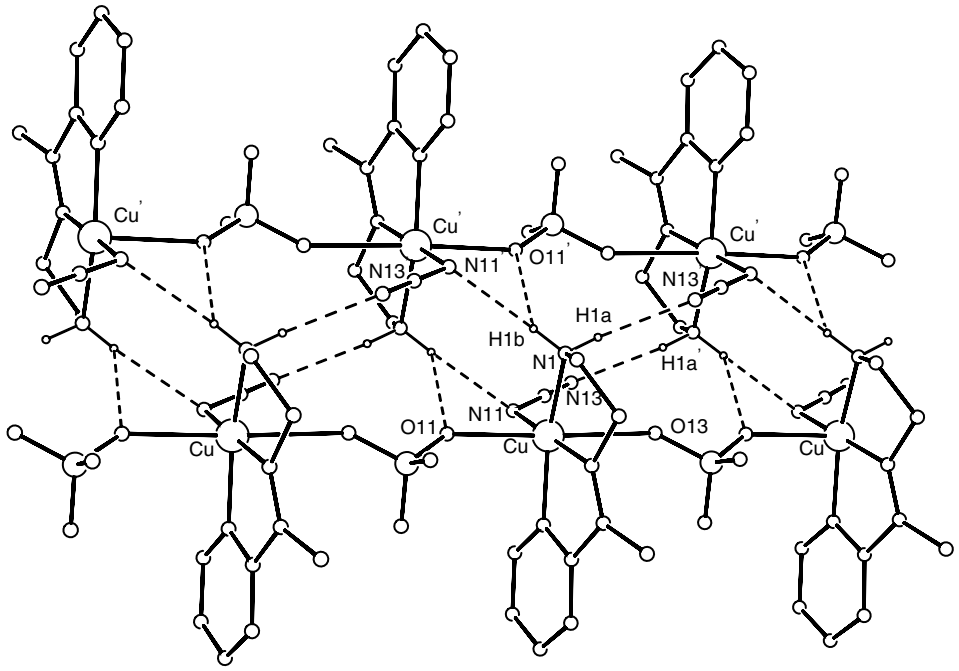

Fig. 4. Extended chain structure and two-dimensional array of $[CuL^3N_3(ClO_4)]_n$ (**3**) formed by an intermolecular hydrogen bonding network.

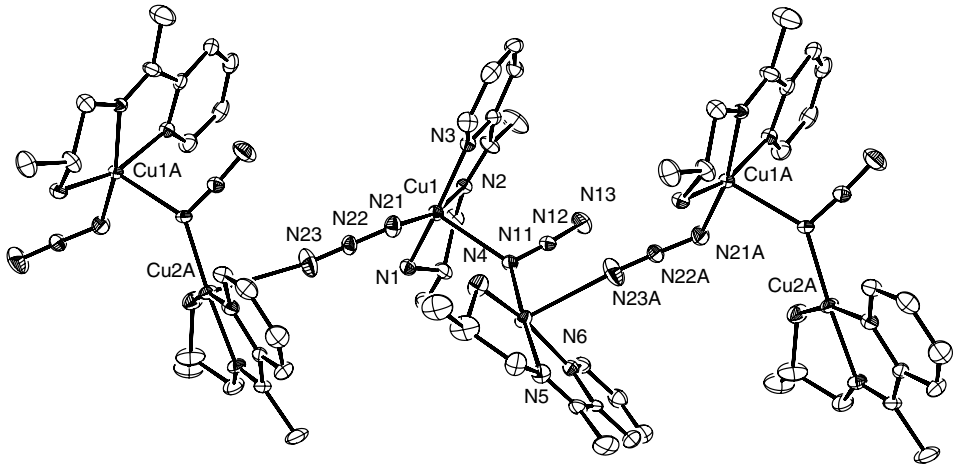

Fig. 5. ORTEP-3 diagram of $[CuL^4(\mu\text{-}1,1\text{-}N_3)(\mu\text{-}1,3\text{-}N_3)(ClO_4)]_n$ (**4**) with the atom labelling scheme, showing 30% probability thermal ellipsoids for all non-hydrogen atoms.

asymmetric apical–basal disposition between neighboring Cu(II) ions; i.e., the same azido bridge resides on the apical position of one copper but in the basal plane of the neighboring copper, with the apical Cu–N distance being significantly longer than the basal one; specially the distance Cu(2)–N(23) (2.643 Å) is very long and should be considered as semicoordinated. If it is not considered as a bond, compound **4** would be a very unusual singly EO azide bridged dimer (as substantiated by magnetic properties) with the two copper atoms having different coordination spheres – Cu(1) is five-coordinate square-pyramidal while Cu(2) is four-coordinate square planar. The Cu(1)–N(11)–Cu(2) bond angle for the end-on azido bridging mode is 131.6(4)° which is the highest among the EO bridging azides with Cu(II) reported to date. The angles of other two known singly EO bridged azides in similar alternating EE and EO bridged structures are 130.0° [25] and 116.6° [26].

The τ values are 0.07 and 0.22 for Cu(1) and Cu(2), respectively [38]. Deviation of the Cu(1) and Cu(2) atoms from the mean plane towards the apical donor atom is about 0.188(1) and 0.029(2) Å, respectively. The bridging N_3^- anions for both end-on and end-to-end modes are quasi-linear; the N–N–N angles are 176.0(11)° and 177.7(12)° for end-on and end-to-end bridging, respectively. The intrachain Cu···Cu distance is 3.947(3) and 6.372 Å in the end-on and end-to-end bridges, respectively. The five-membered chelate ring [Cu(1)–N(1)–C(1)–C(2)–N(2)] connected with Cu(1) assumes a half-chair conformation twisted on N(1)···C(1) whereas a similar type chelate ring formed by the same diamine with Cu(2), [Cu(2)–

N(4)–C(9)–C(10)–N(5)], is envelope on C(9) with puckering parameters [39] $q_2 = 0.432(11)$ and 0.381(13) Å, $\phi = 237.9(12)°$ and 67.7(16)°, respectively.

In this one-dimensional polymeric chain, different asymmetric units are also linked by strong hydrogen bonds via perchlorate ions (Table 4). There are four available hydrogen atoms [H(1a), H(1b), H(4a) and H(4b)] for hydrogen bond formation in each asymmetric unit. H(1a) and H(1b) of the nitrogen N(1) coordinated with Cu(1) are involved in strong N–H···O hydrogen bond formation with the oxygen atoms O(12) and O(21), respectively, from two different perchlorate ions. H(4b) of N(4) coordinated with Cu(2) forms a strong N–H···N hydrogen bond with N(21) of the end-to-end bridging azide. H(4a) of the similar nitrogen forms an intramolecular hydrogen bond between the different units via O(21)′ of the symmetry related perchlorate ions.

3.4. Magnetic properties

Variable temperature (2–300 K) magnetic susceptibility data were collected for microcrystalline samples of compounds 1–4. The agreement factor R is defined as $R = \sum_i[(\chi_M T)_{obsd} - (\chi_M T)_{calcd}]^2/\sum_i[(\chi_M T)_{obsd}]$. The temperature-independent paramagnetism (TIP) was taken as 60×10^{-6} cm^3 mol^{-1} K, for each copper(II) atom in all cases.

3.4.1. Complex *1*

A $\chi_M T$ versus T plot (χ_M is the molar susceptibility for two Cu^{II} ions) for complex **1** is shown in Fig. 6 top. The value of $\chi_M T$ for **1** at 300 K is 0.83 cm^3 mol^{-1} K, which is as expected for two magnetically quasi-isolated spin doublets ($g > 2.00$). The $\chi_M T$ values decrease very slowly and then abruptly at low temperatures, reaching a value of 0.083 cm^3 mol^{-1} K at 2 K. In Fig. 6 top (inset), the χ_M versus T plot is shown. The plot displays the occurrence of a maximum at 10 K in χ_M, which is a signature of antiferromagnetic coupling. At 3.7 K, an increase in the χ_M values appears due to the presence of a small amount of paramagnetic impurity, as pointed in the study of the EPR spectra at low temperatures. So the fit of the experimental data was performed until 10 K, and the possible interactions through the dinuclear entities, that are important at low temperatures, are not evaluated. The Bleaney–Bowers formula for a dinuclear $S = 1/2$ system was used [1d,42] The Hamiltonian employed is $H = -JS_1S_2$. The best-fit parameters were: $J = -12.18 \pm 0.09$ cm^{-1}, $g = 2.12 \pm 0.00$ and $R = 4 \times 10^{-5}$. The field dependence of magnetization at 2 K is displayed in Fig. 6 bottom. The reduced molar magnetization tends to $0.3N\mu_B$ when the field approaches 5 T. The value of the molar magnetization at 5 T is far from the expected value for two isolated copper(II) complexes, indicating a global antiferromagnetic coupling. The powder EPR spectra from 298 to 4 K show the typical pattern for a square-pyramidal geometry, $g_\parallel = 2.22$ and $g_\perp = 2.07$ ($g_{av} = 2.12$).

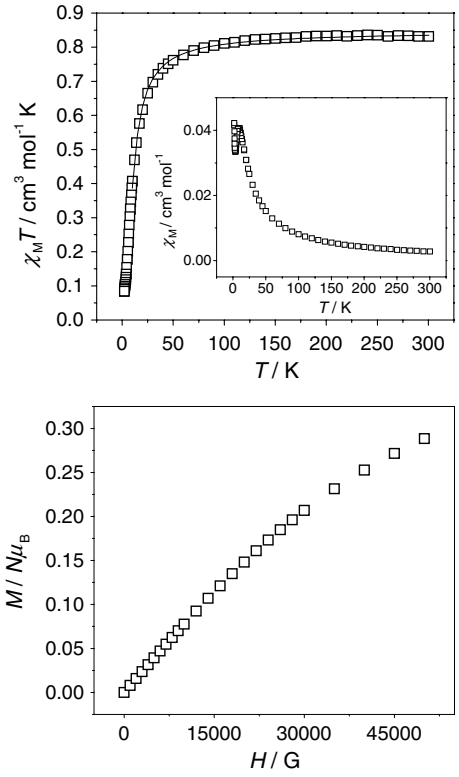

Fig. 6. Top: A plot of χ_M (inset) and $\chi_M T$ vs. T for complex **1**. The solid lines represented the best fit and the square the experimental date. Bottom: A plot of $M/N\mu_B$ vs. H at 2 K.

3.4.2. Complex *2*

The $\chi_M T$ and χ_M (inset) versus T plots (χ_M is the molar magnetic susceptibility for 2 Cu^{II} ions) are shown in Fig. 7. The value of $\chi_M T$ at 300 K is 0.79 cm^{3}mol^{-1} K, which is as expected for two magnetically quasi-isolated spin doublets ($g > 2.00$). The $\chi_M T$ values decrease very slowly and then abruptly at low temperatures, reaching a value of 0.026 cm^3 mol^{-1} K at 2 K. No maximum was found in the χ_M versus T plot. The global feature is characteristic of weak antiferromagnetic coupling. According to the structural data, there are two crystallographically independent dimers, A and B, with different values on their geometrical parameters (see structure description of complex **2**). Focusing in the inter-dimer interactions, isomer A forms a supramolecular structure in which the dinuclear entities are linked by strong hydrogen bonds resulting in a one-dimensional system whereas isomer B is a one-dimensional system formed by quasi-isolated dinuclear entities linked only by van der Waals forces. Taking into account these features, the intra-dinuclear magnetic coupling through the azide ligand and the possible interactions through the dinuclear entities in the two dimers must be different. So the possible interactions were evaluate in a global J value by the Bleaney–Bowers formula for a dinuclear $S = 1/2$ system. The Hamiltonian employed is $H = -JS_1S_2$. The best-fit parameters were: $J = -4.43 \pm 0.1$ cm^{-1}, $g = 2.07 \pm 0.00$ and $R = 1.8 \times 10^{-4}$. The reduced

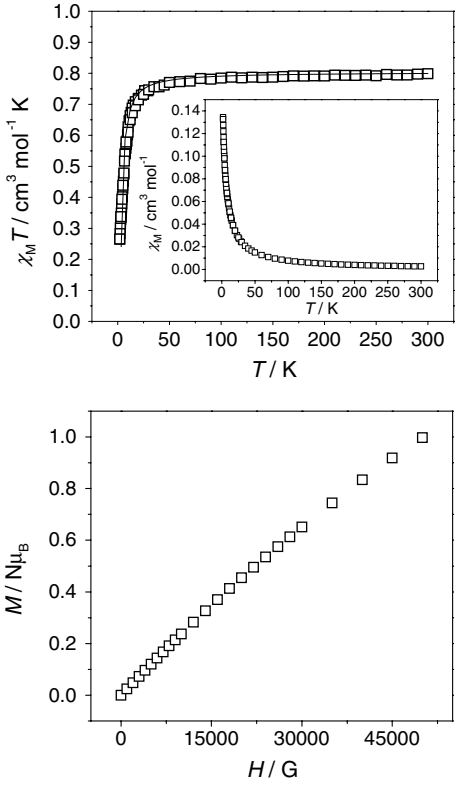

Fig. 7. Top: A plot of χ_M (inset) and $\chi_M T$ vs. T for complex **2**. The solid lines represented the best fit and the square the experimental date. Bottom: A plot of $M/N\mu_B$ vs. H at 2 K.

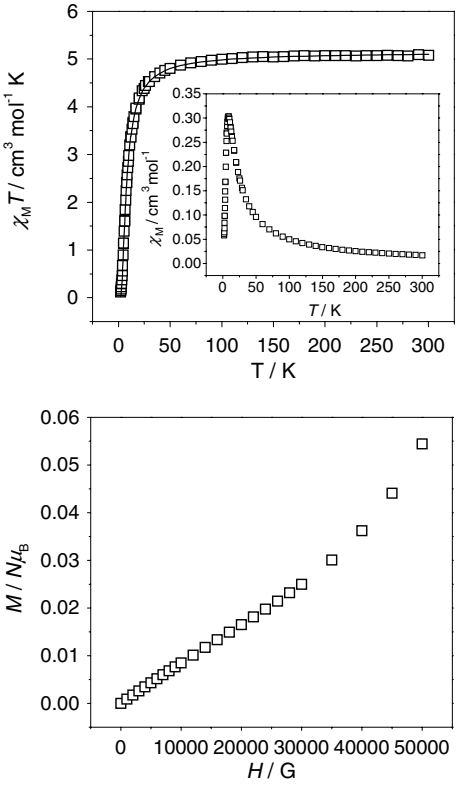

Fig. 8. Top: A plot of χ_M (inset) and $\chi_M T$ vs. T for complex **3**. The solid lines represented the best fit and the square the experimental date. Bottom: A plot of $M/N\mu_B$ vs. H at 2 K.

molar magnetization tends to $1N\beta$ when the field reaches 5 T (Fig. 7 bottom) clearly indicating that the global coupling is less antiferromagnetic than that for complex **1**. The EPR spectra show a broad band centered at 2.6 and a shoulder at 2.1.

3.4.3. Complex *3*

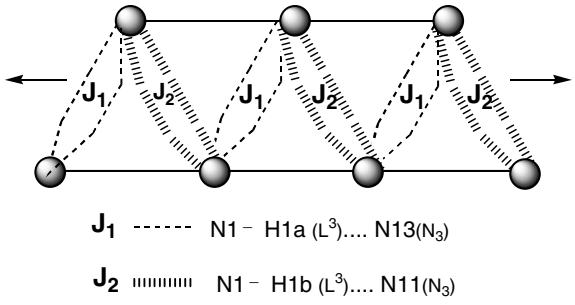
The $\chi_M T$ and χ_M (inset) versus T plots (χ_M is the molar magnetic susceptibility for 12 Cu^{II} ions) are shown in Fig. 8 top. The value of $\chi_M T$ at 300 K is 5.10 $cm^3\ mol^{-1}$ K, which is as expected for 12 magnetically quasi-isolated spin doublets ($g > 2.00$). The $\chi_M T$ values decrease very slowly and then abruptly at low temperatures reaching a value of 0.02 $cm^3\ mol^{-1}$ K at 2 K. The χ_M versus T plot displays the occurrence of a maximum at 9 K, which is a signature of an overall antiferromagnetic coupling. The structure of complex **3**, as can be seen from the crystal structure, consists of a double one-dimensional chain derived from mononuclear units linked by hydrogen bonds that involve perchlorate ions and azide groups (Fig. 4). The perchlorate anion acts as a pseudo-bridge between two copper(II) ions through two of their oxygen atoms, O11 and O13, giving a 1-D supramolecular structure. The distance from the oxygen O13 of the pseudo-coordinated perchlorate anion and the Cu (II) ion is 2.633 Å. Taking into account this large distance and the small efficient transmission of the magnetic interaction of the perchlorate ion we could consider these interactions as nil.

Each of these mononuclear entities is bridged to two other mononuclear entities of the neighboring chain by four hydrogen bonds (2 + 2) giving the double chain structure (Scheme 2). Each $[CuL^3N_3]$ mononuclear entity is bridged, asymmetrically, to two other mononuclear units of the neighboring chain. In both cases the bridge occurs through a pair of equivalent hydrogen bonds. The first pair involved the N1 atom (from L^3) of one monomer and the N11 (from the N_3) of a neighboring monomer and vice-versa. The second pair of hydrogen bonds takes place between the N1 atom (from L^3) of one monomer and the N13 (from the N_3), respectively, of the corresponding monomers.

From the magnetic point of view we considered the structure as an alternating zig-zag chain (Scheme 2). To fit the experimental data we have assumed a chain of 12 copper(II) atoms, which should describe the behavior of the infinite chain. The fit to the experimental data were performed according to the following Hamiltonian:

$$H = -J_1(S_1S_2 + S_3S_4 + S_4S_5 + S_5S_6 + S_7S_8 + S_9S_{10} + S_{11}S_{12}) - J_2(S_2S_3 + S_4S_5 + S_6S_7 + S_8S_9 + S_{10}S_{11}).$$

The free parameters were J_1, J_2 and g (average). The fit made by the irreducible tensor operator formalism (ITO), using the CLUMAG program [43], gave the following results: $J_1 = -9.69 \pm 0.03\ cm^{-1}$, $J_2 = 1.00 \pm 0.01\ cm^{-1}$, $g = 2.12 \pm 0.05$ and $R = 5.3 \times 10^{-5}$. Each J value involved the two



Scheme 2.

kinds of equivalent hydrogen bonds (see Scheme 2). We could not conclude the assignment of each J value for each different magnetic interaction through the two kinds of hydrogen bonds. The field dependence of magnetization at 2 K is displayed in Fig. 8 bottom. The reduced molar magnetization tends to 0.06 $N\mu_B$ when the field approaches 5 T. The value of the molar magnetization at 5 T is far from the expected value for one isolated copper(II) complex, indicating a global antiferromagnetic coupling.

The powder EPR spectra from 298 to 4 K show the typical pattern for a square-pyramidal geometry, $g_{\parallel} = 2.21$ and $g_{\perp} = 2.06$ ($g_{av} = 2.11$).

3.4.4. Complex 4

The structure determination reveals that the copper atoms are bridged singly and alternately by end-on and end-to-end azido ligands with the occurrence of a 1-D polymeric infinite chain. Only intramolecular hydrogen bonds are present in the structure. The susceptibility measurements (for 2 copper atoms) are shown in Fig. 9 (top).

The $\chi_M T$ value at 300 K is 0.84 $cm^3\ mol^{-1}\ K$, which is as expected for two magnetically quasi-isolated spin doublets ($g > 2.00$). Upon cooling, $\chi_M T$ slightly increases when the temperature is lowered, after 35 K increases quickly and reaches a value of 1.04 $cm^3\ mol^{-1}\ K$ at 2 K. This behavior indicates an overall ferromagnetic interaction between the Cu(II) ions within the chain. The χ_M values increase monotonically when the temperature decreases (Fig. 9 top inset). The presence of two kinds of bridges (1,1-N_3) and (1,3-N_3) is consistent with the presence of two different exchange-coupling parameters. The fit of the magnetic data have been carried out with the CLUMAG program [43], with the same conditions as for complex **3**. The best-fit parameters obtained with this computing program are $J_1 = 1.91\ cm^{-1}$, $J_2 = -0.38 \times 10^{-2}\ cm^{-1}$, $g = 2.12$ and $R = 6.1 \times 10^{-6}$. Since the EE bridging moiety has three atoms between the metal ions, the distances Cu1···Cu2 (6.372 Å) and Cu2···N23 (2.643 Å) are longer, we assign J_1 and J_2 to the EO and EE bridges, respectively. Considering the low J_2 value as practically nil, a fit using the Bleaney–Bowers formula for a dinuclear $S = 1/2$ system was used [1d,42]. The Hamiltonian employed is $H = -JS_1S_2$. The best-fit parameters were $J = 1.91 \pm 0.01\ cm^{-1}$, $g = 2.12 \pm 0.00$ and $R = 5.6 \times 10^{-6}$ (Fig. 9 top). Therefore, from the magnetic point of view we can conclude that complex **4** is a ferromagnetic dinuclear complex. The reduced magnetization value (Fig. 9, bottom) at 5 T clearly tends to $2N\mu_B$, the expected value for two isolated (or ferromagnetically coupled) copper(II) ions. The shape of the curve formed by the experimental points does not follow the Brillouin formula, but the tendency to reach the value of $2N\mu_B$ is more pronounced which is the typical signature of ferromagnetic coupling. To our knowledge, only two compounds consisting of 1-D chains in which the copper atoms with square-pyramidal geometry are alternately bridged containing single end-to-end (EE) and single end-to-on (EO) azido ligands, both adopting a basal–apical disposition, are found in the literature (**5** [25], **6** [26]). In complex **6**, the interchain interactions are ferromagnetic, compounds **5** is just the opposite, while in complex **4** the interaction through the EO azide bridge is ferromagnetic and through the EE azide bridge is negligible (Table 5). The powder EPR spectra show a signal centered at 2.11.

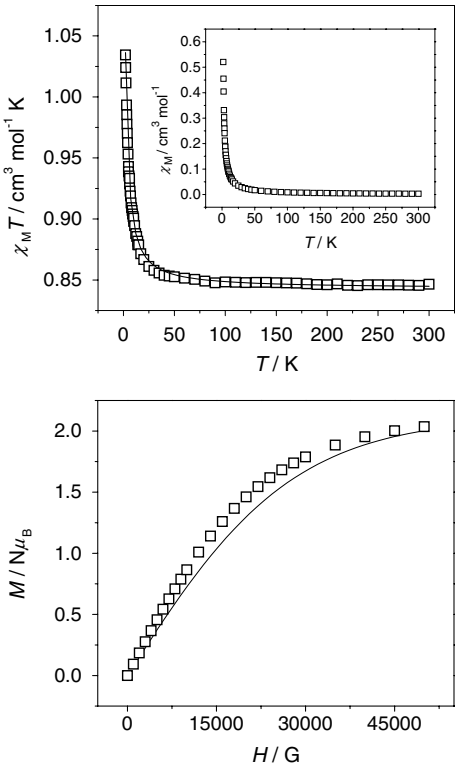


Fig. 9. Top: A plot of χ_M (inset) and $\chi_M T$ vs. T for complex **4**. The solid lines represented the best fit and the square the experimental date. Bottom: A plot of $M/N\mu_B$ vs. H at 2 K. The solid line represents the simulation of the Brillouin function for two copper(II) ions with $g = 2.12$.

3.4.5. Discussion

In complexes **1**, **2** and **4** (considering it from the magnetic point of view as dinuclear species), the copper(II) ions are in square-pyramidal geometries with an axially elongated bond length, and the end-on azido group bridges the copper centers in a basal–apical fashion. The magnetic orbital describing the single electron in the two copper

Table 5
Structural and magnetic parameters for alternating 1-D compounds, containing single end-to-end and single end-to-on azido ligands

Compound	$\tau^{(a)}$		EE			EO				J values	
	Cu1	Cu2	Cu–Cu (Å)	Cu–azido-basal (Å)	Cu–azido-apical (Å)	Cu–N–Cu (°)	Cu–Cu (Å)	Cu–azido-basal (Å)	Cu–azido-apical (Å)	J_{EE} (cm^{-1})	J_{EO} (cm^{-1})
4 (this work)	0.07	0.22	6.372	1.964	2.643	131.61	3.974	1.983	2.342	0	1.91

atoms are mainly of a $d_{x^2-y^2}$ orbital lying in the basal plane of the copper atoms and have only small contribution on the axis perpendicular to the basal plane. The consequence is the good delocalization of the electron density of one copper(II) towards the bridging azido, while the delocalization is poor in the second copper atom because the azide occupies an axial position of it, with a longer distance, and so an extremely weak interaction should be expected, as observed experimentally. In these kinds of complexes (azide bridged acting in basal–apical fashion), the variations in the J parameter are small and consequently, it is difficult to establish clear trends connecting theoretical parameters to variation in J. Theoretical calculations demonstrate that J can be antiferromagnetic or ferromagnetic depending mainly on the Cu–N_3–Cu angle when the azido bridge is in a basal–basal position [13]. This reasoning is not valid when the azido bridges are in basal–apical coordination, although too many papers devoted to this kind of coupling try to relate this angle with the J parameter. Looking in the literature for: (a) structural and magnetic data for both single and double asymmetric EO azide bridges in copper (II) complexes [13a,17,19,21,25–28], and (b) copper (II) species with single EE bridges [11,25,26,44,45], it would be difficult to establish clear trends connecting structural parameters to variation in J. This difficulty is due to: (a) the small values of J coupling for the basal–apical fashion of the azide ligand and (b) the dispersion of these J values with regard to several geometrical parameters.

4. Conclusion

Four Cu^{II} complexes having very similar, singly condensed tridentate blocking ligands and having both azide and perchlorate as anions have been synthesized in a very facile way. The bridging topologies of the complexes are drastically different with a small change in the blocking ligands. Complexes **1** and **2** are double azido bridged dimers, **3** is a 1-D chain, bridged by perchlorate ions and **4** is best described as a 1-D chain with alternate single EO and EE azido bridges. However, from the magnetic point of view **4** is a dinuclear complex since interaction through the EE bridge is practically nil due to a very long Cu···N distance (axial bond). Complexes **1** and **2** are antiferromagnetically coupled as is usual for this kind of complex. The EO bridge in complex **4** shows a ferromagnetic interaction. Comparison of Cu–N–Cu bond angles of **4** and two other reported compounds clearly indicates that the accidental orthogonality for this kind of bridging mode does not depend upon this angle as the compound having lowest and highest angles (**4** and **6**) are ferromagnetic while the other with an intermediate angle (**5**) is antiferromagnetic. The magnetic interaction in compound **3** is mediated solely through H-bonds. It is well known that hydrogen bonds play an important role in the transmission of magnetic interactions. For many years, hydrogen bonds have been reported to propagate essentially antiferromagnetic interactions between metal centers, but presently, the number of ferromagnetically coupled hydrogen-bonded systems is growing. Magnetism of complex **3** is interesting in that of two kinds of H-bonds are present in it, one transmits antiferromagnetic while the other ferromagnetic interactions.

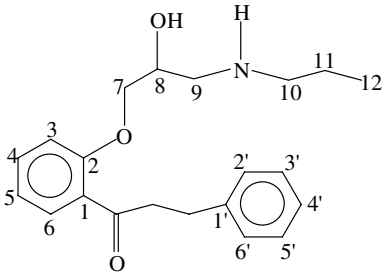
have higher activity [3,11,23] or/and prolonged action as compared to the free ligand [21].

The present paper is part of this systematic study and it is dedicated to complex formation between copper(II) and 1-[2-[2-hydroxy-3-(propylamino)propoxy]phenyl]-3-phenyl-1-propanone, propafenone. The latter is an effective antiarrythmic agent with a moderate β-blocking activity and an acceptable side effect profile for the acute and long-term treatment of supraventricular arrythmias. From a chemical point of view it represents an aminoalcohol and therefore it is of interest to compare its behaviour as a ligand with that of another group of aminoalcohol medications – that of the β-blockers, which easily form stable complexes with copper(II) [16–22]. Some of these complexes exhibit even better pharmacological effects in comparison with the non-coordinated free drugs that offer good perspectives for their clinical application [3,11,21,22].



Propafenone, HPr

The aminoalcohol chain in propafenone is linked to the phenyl ring through an oxygen atom as in the β-blockers and thus one might expect to find similar coordination ability of these ligands. We have already discussed the role of the oxygen for the chemical and biological properties of other aminoalcohol drugs such as effortil, clenbuterol, salbutamol and sotalol [1,2,14,22]. On the other hand the presence of bulky substituents in the aromatic ring of propafenone could create steric hindrance and decrease to some extent the complexation with copper. Therefore, a comparison between the coordination ability of propafenone and the other aminoalcohol drugs mentioned above seems to be of interest.

We have found that, like many other aminoalcohols, propafenone forms mono- and binuclear complexes, depending mainly on the molar metal-to-ligand ratio in the reaction system. Due to the relatively lower solubility of the ligand in water, we used methanol as a reaction medium for the synthesis of the complexes. In alkaline methanolic solution and with an excess of the ligand ($M{:}HPr \cdot HCl \leqslant 1{:}10$; $HPr \cdot HCl{:}NaOH \leqslant 1{:}2$) the violet mononuclear complex **1** was obtained, in which copper(II) is coordinated via the NH and the deprotonated OH groups of the ligand, forming a stable five-membered chelate ring. With comparable amounts of the reagents ($M{:}HPr \cdot HCl$ from 1:2 to 2:1) and the same alkalinity ($HPr \cdot HCl{:}NaOH \leqslant 1{:}2$) the green binuclear complex **2** was formed with participation of the same donor groups of the ligand.

2. Experimental

2.1. Materials and synthesis

Propafenone was obtained from Sigma, Germany as the hydrochloric salt, $HPr \cdot HCl$ and was used without further purification. The metal salt $CuCl_2 \cdot 2H_2O$ and NaOH were supplied by Riedel E. de Haën AG and MeOH from Fluka. All reagents and solvents used were of analytical grade.

The mononuclear complex **1** was obtained at room temperature when 1.00 cm^3 0.025 M solution of $CuCl_2 \cdot 2H_2O$ (0.0426 g $CuCl_2 \cdot 2H_2O$ in 10.0 cm^3 MeOH) was added to 10.00 cm^3 0.025 M of the ligand in the same solvent (0.0945 g $Pr \cdot HCl$ in 10.0 cm^3 MeOH). Dropwise addition of 5.0 cm^3 0.10 M NaOH (0.0800 g NaOH in 20.0 cm^3 MeOH) to the reaction solution resulted in a violet coloration. From this solution violet crystals precipitated after 5 days. The crystals were filtered, washed with methanol, recrystallized from EtOH and dried over P_2O_5 (yield ca. 35%). *Anal.* Calc. for $CuPr_2$: C, 67.76; H, 7.04; N, 3.76; Cu, 8.54. Found: C, 67.24; H, 6.86; N, 3.92; Cu, 8.45%. M.p.: 146 °C.

The binuclear complex **2** was synthesized at ambient temperature when 10.00 cm^3 0.025 M solution of $Pr \cdot HCl$ (0.0945 g $Pr \cdot HCl$ in 10.0 cm^3 MeOH) was mixed with 10.00 cm^3 0.025 M solution of $CuCl_2 \cdot 2H_2O$ (0.0426 g $CuCl_2 \cdot 2H_2O$ in 10.0 cm^3 MeOH). The dropwise addition of 5.0 cm^3 0.10 M NaOH (0.0800 g NaOH in 20.0 cm^3 MeOH) resulted in the formation of a green precipitate, that was filtered, washed with MeOH and dried over P_2O_5 (yield ca. 60%). *Anal.* Calc. for $Cu_2Pr_2Cl_2$: C, 57.40; H, 5.96; N, 3.19; Cl, 8.07; Cu, 14.46. Found: C, 57.31; H, 5.91; N, 3.28; Cl, 8.26; Cu, 14.06%. M.p.: 158 °C. Unfortunately, we were not able to obtain crystals of proper size and quality in order to perform a direct X-ray single crystal structure determination of complex **2**.

2.2. Instrumentation and analysis

Electronic spectra were obtained on a Specord UV–Vis (Carl-Zeiss, Jena) instrument. IR spectra were recorded in the range 4000–400 cm^{-1} on a Specord-75 IR spectrometer, and in the range 500–75 cm^{-1} on a Bruker 113 V instrument in polyethylene. Thermogravimetric analyses were performed using a Perkin–Elmer TGS-2 instrument. The EPR spectra in the X-band were obtained with an ERS 220/Q instrument, using Mn/ZnS standard. Magnetic measurements were carried out under a helium atmosphere on a SQUID magnetometer with a sensitivity of $\sim 2 \times 10^{-5}$ emu. The magnetic susceptibility was measured with an increment of 2 K over the whole temperature range 2–300 K and the validity of the Curie–Weiss law was estimated using the correlation coefficient, with values higher than 0.9900. Elemental analyses were performed

according to classical methods: C, H were determined as CO_2 and H_2O, N through the Dumas' method, chlorine by titration with $Hg(NO_3)_2$ after wet digestion of the sample. Copper was determined by atomic absorption after wet digestion of the sample. The NMR spectra were recorded in $CDCl_3$ solutions on a JEOL EX-400 instrument (^{13}C at 100 MHz, ^{1}H at 400 MHz) and on a Varian 300 (^{13}C at 75 MHz, ^{1}H at 300 MHz).

For the structure determination of **1**, a transparent needle shaped pink crystal was mounted on a SIEMENS SMART X-ray diffractometer with a 1 K CCD area detector. Data were collected at room temperature using graphite-monochromatized Mo Kα radiation ($\lambda = 0.71073$ Å). A hemisphere of data (1271 frames at 5 cm detector distance) was collected using a narrow-frame method with scan widths of 0.30° in ω and an exposure time of 30 s/frame. The first 50 frames were measured again at the end of the data collection to monitor instrument and crystal stability. The data were integrated using the Siemens SAINT program [23]. The program SADABS was used for the absorption correction [24]. The structure was solved by direct methods and refined by full-matrix least-squares techniques with the SHELX97 software package [25]. All non-hydrogen atoms have been located and assigned directly from the Fourier maps. The hydrogen atoms have been introduced as riding models and their thermal parameters refined isotropically [25]. The main crystallographic details are summarized in Table 1.

Table 1
Crystal data and structure refinement for $CuPr_2$ (**1**)

Complex **1**	
Empirical formula	$C_{16.80}H_{17.60}Cu_{0.40}N_{0.80}O_{2.40}$
Formula weight	294.39

a (Å)	4.7106(9)
b (Å)	12.507(2)
c (Å)	31.979(6)
α (°)	90
β (°)	92.858(4)
γ (°)	90
Volume (Å^3), Z	1881.7(6), 5
Calculated density (g cm^{-3})	1.338
$F(000)$	794
Crystal size (mm)	$0.44 \times 0.09 \times 0.06$
θ Range for data collection (°)	1.28–22.50
Limiting indices	$-5 \leqslant h \leqslant 5$, $-13 \leqslant k \leqslant 13$, $-34 \leqslant l \leqslant 34$
Reflections collected/unique	11 218/2439
Refinement method	full-matrix least-squares on F^2
Data/parameters	2439/239
Goodness-of-fit on F^2	1.424
Final R indices [$I > 2\sigma(I)$][a,b]	$R_1 = 0.1080$, $wR_2 = 0.2681$
R indices (all data)	$R_1 = 0.1111$, $wR_2 = 0.2709$

[a] $R_1 = \sum||F_o| - |F_c|/\sum|F_o|$ (based on reflections with $I > 2\sigma(I)$).

[b] $wR_2 = \left[\sum w(|F_o| - |F_c|)^2/\sum w|F_o|2\right]^{1/2}$; $w = 1/[\sigma^2(F_o^2) + (0.0533P)^2 + 28.15P]$; $P = [\max(F_o^2, 0) + 2F_c^2]/3$ (all data).

3. Results and discussion

3.1. Mononuclear $CuPr_2$ complex *1*

3.1.1. X-ray data and crystal structure

The asymmetric unit of the title compound consists of one copper atom and one propafenone molecule (Fig. 1). The copper atoms are located on inversion centers occupying one special (2*a*: 0, 0, 0) position while all other atoms occupy general (4*e*: *x*, *y*, *z*) positions. Each copper atom is coordinated by two propafenone molecules acting as bidentate ligands through O1 and N1 (Fig. 2). All five atoms of the resulting CuO_2N_2 unit lie in the same plane with Cu—O1 and Cu—N1 distances of 1.900(6) and 2.024(7) Å, respectively, and a O1—Cu—N1 angle of 86.9(3)° (Table 2). Hence, the copper coordination could be described as a plain squared one (Fig. 2). All C—O, C—N and C—C distances and angles in the propafenone molecule are well within the corresponding limits.

The $CuPr_2$ complexes are packed on top of each other forming slabs that run parallel to the *a*-axis (Fig. 3). The shortest intermolecular O···H distances are of order of 2.4 Å (O3···H11 = 2.35 Å, O2···H14 = 2.39 Å and O2···H10 = 2.45 Å) indicating the presence of only a small number of weak hydrogen bonds. No solvent molecules have been detected in the structure.

3.1.2. Electronic and IR spectra

The electronic spectrum of the mononuclear complex **1** in methanol shows one broad asymmetric absorption band at 520 nm ($\varepsilon \approx 100$ l mol^{-1} cm^{-1}), and a shoulder at 650 nm, due to the d–d transition in the distorted octahedral structure of the Cu(II) complex, where copper is bound with nitrogen and oxygen donor atoms.

The IR spectrum of the ligand shows two bands at 3295 and 3160 cm^{-1} assigned to the stretching vibrations of the NH and OH groups, respectively, engaged in the formation of H-bonds, as follows from the absorbance in the 2800–

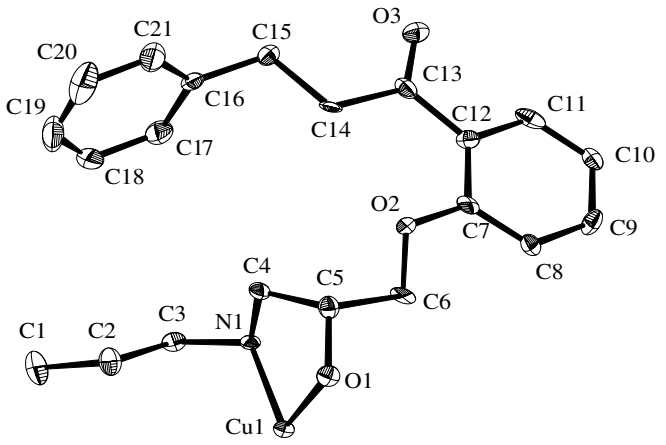

Fig. 1. Asymmetric unit, 50% thermal ellipsoids and labelling scheme in complex **1**.

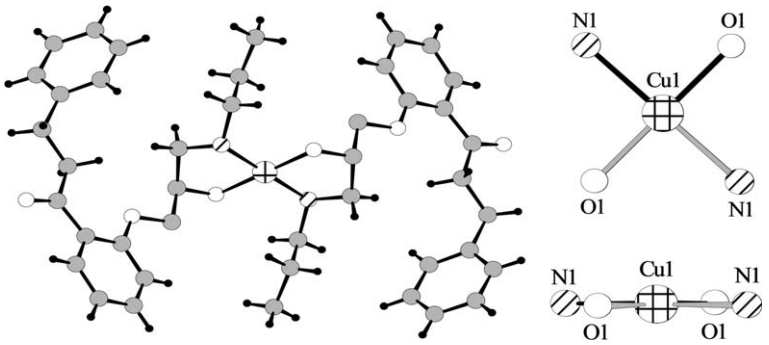

Fig. 2. Cu coordination in complex **1**. Copper, nitrogen, oxygen, carbon and hydrogen atoms are shown as cross-hatched, hatched, open, filled and black circles, respectively.

Symmetry transformations used to generate equivalent atoms: (#1) $-x, -y, -z$; (#2) $-x+1, -y, -z$.

2300 cm^{-1} range. The coordination of the ligand with Cu(II) and the formation of **1** lead to disappearance of the ν(OH) stretching vibration as a result of deprotonation of the hydroxyl group and to a shift of the ν(NH) to the 3000–2800 cm^{-1} range, where the bands due to $\nu(Ar_{C-H})$ of the aromatic ring are also present. At the same time two new bands are observed in the far IR-spectrum at 600 and 430 cm^{-1}, assigned to the stretching vibrations of ν(Cu—N) and ν(Cu—O) in the complex [26].

3.1.3. EPR data

The X-band EPR spectrum of complex **1** in a methanolic solution frozen at 113 K presents an anisotropic signal with $g_{\|} = 2.212$, $A_{\|} = 170$ G and an unresolved perpendicular component. Qualitatively, these parameters and the relation $g_{\|} > g_{\perp}$ indicate that the unpaired d-electron is located mainly on the $d_{x^2-y^2}$-orbital and a considerable axial deformation is realized, leading practically to a square-planar complex. The same spectra also exhibit an unresolved SHSF from ^{14}N in the perpendicular magnetic field, due to the coordination of the NH-function to copper. A solid sample of complex **1** at the same temperature (113 K) shows a broad signal for a magnetically concentrated sample of a paramagnetic copper(II) complex.

These experimental EPR data are in a good accordance with those for other similar copper(II) complexes [1,22].

3.1.4. Magnetochemical data
