We were interested of see whether changing the bulk of the orthometallated ligand would have any bearing on the geometry of the tricyclohexylphosphine adducts. Therefore, the complexes **2b–d** were prepared in an analogous fashion to **2a**. In all cases the only product obtained is that in which the two P-donors are *cis* as evidenced by ^{31}P NMR spectroscopy. The mutual $^2J_{pp}$ couplings in complexes **2c** and **2d** (~41 Hz) are identical to that reported for complex **2a** [7], suggesting that steric bulk has very little effect on the coordination environment. By contrast complex **2b** shows a lower coupling of 36.45 Hz. We previously showed that the tri-*tert*-butylphosphine is too bulky to produce an adduct of complex **1a** [7]. Attempts to produce such adducts with the smaller complexes **1c** and **1d** gave only starting materials as adjudged by ^{31}P NMR analysis of the crude product mixtures. While the triphenylphosphite-based analogue **1b** does appear to react with P^tBu_3, this leads to a complex mixture of phosphorus-containing species.

2.4. An unusual solvolysis reaction

During the course of the synthetic studies we noticed that while complex **4g** can be prepared in the same manner as complexes **4a–f**, it is necessary to avoid the addition of methanol during work-up otherwise the isolated compound is quite obviously not the desired product. The ^{31}P NMR spectrum of the white powder precipitated over several hours in this instance shows a singlet δ 98.1 ppm, quite distinct from those of complexes of the general formula **4** which fall in the range 76.6–85.2 ppm. Furthermore, the ^1H NMR spectrum shows no aromatic signals; rather the only peak observed is a non-first-order multiplet at δ 3.83 ppm. Elemental analysis[1] is consistent with the formation of the known complex *cis*-$[PdCl_2\{P(OMe)_3\}_2]$ (**8**). Accordingly, we synthesized a genuine sample of complex **8** and found its ^1H and ^{31}P NMR spectroscopic data to be identical with those obtained above. This implies that either the complex **4g** undergoes facile methanolysis, or that the triarylphosphite ligands are labile and undergo methanolysis away from the palladium centre. The ^{31}P NMR spectrum of a $CDCl_3$/MeOH solution of ligand **3g** shows that partial methanolysis occurs within 20 h at room temperature to give an approximately 4:1 mixture of **3g** and $P(OMe)_3$ along with several other minor species. Treatment of complex **4g** with methanol under the same conditions gives a number of phosphorus-containing species as adjudged by ^{31}P NMR spectroscopy, which shows a range of peaks between 90 and 95 ppm only. While there does not appear to be any peaks corresponding to complex **8**, the lack of any signal for the starting complex **4g** and the chemical shift values for the products obtained,[2] imply that complete conversion of the starting material to partially methanolysed complexes of the form $[PdCl_2\{P(OMe)_n(OAr)_{3-n}\}\{P(OMe)_m(OAr)_{3-m}\}]$ has occurred.

While we have observed a similar alcoholysis reaction previously with a palladium–phosphinite complex [15], the facile nature of this particular reaction appears to be ligand specific; none of the other complexes **4a–f** appear to be susceptible to methanolysis under the same conditions.

3. Summary

In summary, we have shown that the stereochemistry of complexes of the type $[PdCl_2\{P(OAr)_3\}_2]$ is dependent on the size of *ortho*-substituents with bulky groups forcing the complexes to adopt the electronically less preferable *trans* configuration. In contrast, variation in the bulk of the *meta*-groups does not appear to have any significant influence on geometry. The bulk of the phosphite ligand also has implications in the choice of synthetic methodology adopted for the formation of orthopalladated dimers and their geometry in the solid state.

4. Experimental

4.1. General

All reactions were performed under nitrogen using standard schlenk techniques. All solvents were distilled from appropriate drying reagents prior to use. Ligand **3c** was prepared according to the literature method [16], while the known ligands **3d** and **3e** were prepared in a similar manner. Complexes **4a** and **8** were prepared according to the literature methods [8,17]. All other materials were obtained commercially and used as received.

[1] $[PdCl_2\{P(OMe)_3\}_2]$ requires C, 16.9; H, 4.25. Found: C, 16.9; H, 4.3%.

[2] Palladium aryldiethylphosphite complexes of the type $[PdCl_2\{P(OEt)_2(OAr)\}_2]$ show chemical shifts of ~ 90 ppm in their ^{31}P NMR spectra. See Refs. [8,11].

4.2. Synthesis of $P(OC_6H_3\text{-}3,5\text{-}OMe_2)_3$ (**3d**)

PCl_3 (0.87 ml, 10 mmol) was added to a solution of 3,5-dimethoxyphenol (4.625 g, 30 mmol) and *N*,*N*-dimethyl-*p*-toluidine (0.144 ml, 1.0 mmol) in 10 ml of xylene. The mixture was then heated at reflux, while N_2 was passed through to expel the HCl formed. After 2 h, the xylene was removed under reduced pressure and the residue was kept at 180 °C overnight in vacuo to yield the product as an orange oil that was not purified further (87% yield). *Anal.* Calc. for $C_{27}H_{33}O_3P$: C, 74.3; H, 7.6. Found: C, 73.7; H, 7.85%. NMR ($CDCl_3$): δ_H (300 MHz) 6.18 (s, 6H, aryl H2 and H6); 6.06 (s, 3H, aryl H4); 3.49 (s, 18H, Me). δ_P (121.5 MHz) 130.6.

4.3. General method for the synthesis of the complexes cis/trans-$[PdCl_2\{P(OAr)_3\}_2]$ (**4**)

A solution of $[PdCl_2(NCMe)_2]$ (0.5 mmol) and the appropriate triarylphosphite **3** (1.0 mmol) in dichloromethane (15 ml) was stirred at room temperature for 1.5 h. Methanol (20 ml) was then added and the mixture concentrated under reduced pressure to induce precipitation of the product.

4.4. trans-$[PdCl_2\{P(OC_6H_4\text{-}2\text{-}^tBu)_3\}_2]$ (**4c**)

Yellow solid (72% yield). *Anal.* Calc. for $C_{60}H_{78}Cl_2O_6P_2Pd$: C, 63.5; H, 6.9. Found: C, 63.0; H, 7.1%. NMR ($CDCl_3$): δ_H (300 MHz) 7.27 (d, 6H, $^3J_{HH} = 9$ Hz), 7.22 (d, 6H, $^3J_{HH} = 6$ Hz), 6.92 (t, 6H, $^3J_{HH} = 6$ Hz), 6.81 (t, 6H, $^3J_{HH} = 9$ Hz). δ_P (121.5 MHz) 85.20. IR (Nujol mull, polythene film): ν(Pd–Cl) 382 cm^{-1}.

4.5. cis/trans-$[PdCl_2\{P(OC_6H_4\text{-}2\text{-}^iPr)_3\}_2]$ (**4d**)

Yellow solid (63% yield). *Anal.* Calc. for $C_{54}H_{66}Cl_2O_6P_2Pd$: C, 61.75; H, 6.3. Found: C, 61.25; H, 6.2%. NMR ($CDCl_3$): δ_H (300 MHz) (most of the minor isomer peaks are coincident with or obscured by the major isomer): 7.29 (d, 6H, $^3J_{HH} = 9$ Hz), 7.10 (d, 6H, $^3J_{HH} = 9$ Hz), 7.01 (t, 6H, $^3J_{HH} = 9$ Hz), 6.93 (td, 6H, $^3J_{HH} = 9$ Hz, $^4J_{HH} = 3$ Hz), 3.22 (m, 6H), 1.00 (d, 36H, major, $^3J_{HH} = 6$ Hz), 0.93 (d, 36H, minor, $^3J_{HH} = 6$ Hz). δ_P (121.5 MHz) 84.42 (s, major isomer) and 80.46 (minor isomer). IR (Nujol mull, polythene film) ν(Pd–Cl): 375 (*trans* isomer).

4.6. cis-$[PdCl_2\{P(OC_6H_4\text{-}3,5\text{-}^tBu_2)_3\}_2]$ (**4e**)

Attempts to precipitate the product from dichloromethane solution by addition of methanol, ethanol, pentane, hexane or diethyl ether proved unsuccessful in this instance due to the high solubility of the product. Therefore, the solvent was removed in vacuo and the product was not purified further.

NMR ($CDCl_3$): δ_H (300 MHz) 7.06 (s, 6H, H4), 6.92 (s, 12H, H2 and H6), 1.06 (s, 108H, ^{t}Bu). δ_P (121.5 MHz) 76.60. IR (Nujol mull, polythene film) ν(Pd–Cl): 322 and 340 cm^{-1}.

4.7. cis-$[PdCl_2\{P(OC_6H_4\text{-}3,5\text{-}OMe_2)_3\}_2]$ (**4f**)

Pale yellow solid (26% yield). *Anal.* Calc. for $C_{48}H_{54}Cl_2O_{18}P_2Pd$: C, 49.8; H, 4.7. Found: C, 48.5; H, 4.4%. NMR ($CDCl_3$): δ_H (300 MHz) 6.35 (s, 12H, H2 and H6), 6.16 (s, 6H, H4), 3.59 (s, 36H, Me). δ_P (121.5 MHz) 83.49 ppm. IR (Nujol mull, polythene film) ν(Pd–Cl): 315 and 339 cm^{-1}.

4.8. cis-$[PdCl_2\{P(OC_6H_4\text{-}3,5\text{-}Me_2)_3\}_2]$ (**4g**)

Diethyl ether was used in place of methanol to induce precipitation. Pale yellow solid (75% yield). NMR ($CDCl_3$): δ_H (400 MHz) 6.74 (s, 12H, H2 and H6), 6.70 (s, 6H, H4), 2.10 (s, 36H, Me). δ_P (121.5 MHz, $CDCl_3$) 79.70 ppm. IR (Nujol mull, polythene film) ν(Pd–Cl): 305 and 334 cm^{-1}.

4.9. Synthesis of trans-$[\{Pd(\mu\text{-}Cl)(\kappa^2\text{-}P,C\text{-}P(OC_6H_3\text{-}2\text{-}^tBu)(OC_6H_4\text{-}2\text{-}^tBu)_2)\}_2]$ (**1c**)

A mixture of palladium dichloride (0.0745 g, 0.42 mmol) and ligand **3c** (0.200 g, 0.42 mmol) in 2-methoxyethanol (10 ml) was heated at reflux temperature for 2 h. The resultant solution was filtered through celite, ethanol (15 ml) was added and the solution concentrated in vacuo to give the product as a white solid (62% yield). *Anal.* Calc. for $C_{60}H_{78}Cl_2O_6P_2Pd_2$: C, 58.2; H, 6.2. Found: C, 57.6; H, 6.1%. NMR ($CDCl_3$): δ_H (300 MHz) 7.47 (s, 2H, orthometallated ring), 7.33 (s, 2H, orthometallated ring), 7.25 (d, 4H, free ring, $^3J_{HH} = 6$ Hz), 7.02 (d, 4H, free ring, $^3J_{HH} = 6$ Hz), 6.97–6.87 (m, 8H, free ring), 6.80 (s, 2H, orthometallated ring), 1.32 (s, 36H; free ring), 1.07 (s, 18H; orthometallated ring). δ_P (121.5 MHz) 120.96.

4.10. Synthesis of cis/trans-$[\{Pd(\mu\text{-}Cl)(\kappa^2\text{-}P,C\text{-}P(OC_6H_3\text{-}2\text{-}^iPr)(OC_6H_4\text{-}2\text{-}^iPr)_2)\}_2]$ (**1d**)

A mixture of complex **4d** (0.244 g, 0.23 mmol) and $PdCl_2$ (0.043 g, 0.24 mmol) in toluene (10 ml) was heated at reflux temperature for 5 h. The resultant solution was filtered through celite and the solvent was removed under reduced pressure. The residue was then recrystallised from CH_2Cl_2/MeOH to give the product as a white powder (98% yield). *Anal.* Calc. for $C_{54}H_{64}Cl_2O_6P_2Pd_2$: C, 56.2; H, 5.6. Found: C, 55.35; H, 5.5%. NMR ($CDCl_3$): δ_H (300 MHz) (most of the minor isomer peaks are coincident with or obscured by the broad major isomer peaks): 7.38 (d, $^3J_{HH} = 9$ Hz), 7.2 (br s) 7.13 (br m), 7.03–6.91 (br m) 6.78–6.76 (br m), 3.31 (br m, 2H, major isomer C*H*(CH_3)$_2$), 3.04 (br m, 2H, minor isomer, C*H*(CH_3)$_2$), 1.07 (Br d, CH(C*H*$_3$)$_2$). δ_P (121.5 MHz) 122.07 (major isomer), 120.29 (minor isomer).

4.11. General method for the synthesis of PCy_3 adducts of phosphite-based palladacycles (2)

A mixture of the appropriate complex **1** (0.1 mmol) and PCy_3 (0.3 mmol) in acetonitrile (10 ml) was stirred at room temperature for 5 h. The resultant solution was concentrated in vacuo and the product was precipitated by addition of an appropriate co-solvent.

4.12. [Pd(Cl){κ^2-P,C-P(OC_6H_3-2-^{t}Bu)-(OC_6H_4-2-^{t}Bu)$_2$}PCy_3] (2b)

Product precipitated as a white solid on addition of hexane (24% yield). *Anal.* Calc. for $C_{48}H_{71}ClO_3P_2Pd$: C, 64.1; H, 7.95. Found: C, 62.9; H, 8.3%. NMR ($CDCl_3$): δ_H (300 MHz) 8.42 (br m, 1H), 7.81 (br d, 2H, $^3J_{HH} = 6$ Hz), 7.285 (br d, 2H, $^3J_{HH} = 9$ Hz), 6.91 (m, 6H), 2.34 (br, 3H, Cy), 1.80 (br d, 9H, Cy), 1.49 (s, 18H, ^{t}Bu), 1.4, 1.1 and 0.8 (3 × m, 21H, Cy), 0.86 (s, 9H, ^{t}Bu). δ_P (121.5 MHz) 136.6 (d, phosphite, $^2J_{PP} = 36.5$ Hz), 28.4 (d, PCy_3, $^2J_{PP} = 36.5$ Hz).

4.13. [Pd(Cl){κ^2-P,C-P(OC_6H_3-2-^{i}Pr)-(OC_6H_4-2-^{i}Pr)$_2$}PCy_3] (2c)

This complex could not be obtained as a pure solid but as an impure oil (yield and elemental analysis were not determined). NMR ($CDCl_3$): δ_H (300 MHz) 8.20 (br dd, 2 × $J_{HH} = 6$ Hz), 7.30 (d, 2H, $J_{HH} = 9$ Hz), 2.20 (d, 2H, $J_{HH} = 6$ Hz), 7.08–6.95 (2 × m, 4H), 6.88 (m, 1H), 6.79 (m, 1H), 3.29 (m, 3H), 2.49 (m, 4H), 1.94 (m, 6H), 1.6, 1.2, 1.05 (3 × m, 32H), 0.85 (m, 3H) and 0.67 (d, $J_{HH} = 9$ Hz). δ_P (121.5 MHz) 131.43 (d, phosphite, $^2J_{PP} = 41.3$ Hz), 28.08 (d, PCy_3, $^2J_{PP} = 40.1$ Hz).

4.14. [Pd(Cl){κ^2-P,C-P(OC_6H_4)(OPh)$_2$}PCy_3] (2d)

Product precipitated as a white solid on addition of ethanol and cooling at −20 °C overnight (60% yield). *Anal.* Calc. for $C_{36}H_{47}ClO_3P_2Pd$: C, 59.1; H, 6.55. Found: C, 57.2; H, 6.4%. NMR ($CDCl_3$): δ_H (300 MHz) δ 8.42 (br d, 1H, $J_{HH} = 6$ Hz), 7.24 (m, 5H), 7.12 (m, 5H), 7.01 (m 2H), 6.72 (br s, 1H), 2.39 (br m, 3H, Cy), 1.86 (br s, 6H, Cy), 1.65 (br s, 9H) 1.49 (br m, 6H), 1.17 (br s, 9H). δ_P (121.5 MHz) 131.00 (d, phosphite, $^2J_{PP} = 41.3$ Hz), 29.00 (d, PCy_3, $^2J_{PP} = 42.5$ Hz).

5. Crystallography

Suitable single crystals were selected and data collected on a Bruker Nonius KappaCCD Area Detector at the window of a Bruker Nonius FR591 rotating anode ($\lambda_{Mo\,K\alpha} = 0.71073$ Å) driven by COLLECT [18] and DENZO [19] software at 120 K. The structure was determined in

and this manuscript reports on studies involving choline and triethylammonium organotriboroxinate derivatives.

2. Results and discussion

The choline tetraorganotriboroxinate salt $[Me_3NCH_2CH_2OH][Ph_4B_3O_3]$ (**1**) was prepared by the reaction in methanol solution of phenylboronic acid, diphenylborinic acid anhydride and choline hydroxide in appropriate stoichiometry (Eq. (1)). A similar procedure has been reported previously [7] for the synthesis of $[NMe_4][Ph_4B_3O_3]$. The product rapidly precipitated out of solution as an air-stable white solid which could be easily isolated by filtration, and purified by re-crystallization from acetone.

$$Ph_2BOBPh_2 + 4PhB(OH)_2 + 2[Me_3NCH_2CH_2OH][OH] \rightarrow 2[Me_3NCH_2CH_2OH][Ph_4B_3O_3](\mathbf{1}) + 5H_2O \quad (1)$$

Compound **1** was characterized by m.p. ^{11}B NMR and IR spectroscopy and gave satisfactory elemental analysis. The ^{11}B spectrum showed two signals at +29.1 and +4.2 ppm with the high frequency signal (3-coordinate B) twice the intensity of the low frequency (4-coordinate B) signal. The solid-state structure of compound **1** was obtained from a single-crystal X-ray diffraction study.

The solid-state structure of **1** reveals that the anions and cations are held together as discrete ion-pairs via a H-bond interaction between an hydroxyl O atom of the cation, O4, and a ring O atom of the anion, O3 (Fig. 1). The O4···O3 distance at 2.845(5) Å indicates a moderately strong H-bond interaction. Bond angle and bond distance data for the $[Ph_4B_3O_3]^-$ anion are summarized in the caption to Fig. 1; these data are very similar to those reported for $[Me_4N][Ph_4B_3O_4]$ [7]. It should be noted that the anion is also isoelectronic with Lewis base adducts of triorganylboroxines ($R_3B_3O_3 \cdot L$), and many of which e.g., $2(Ph_3B_3O_3) \cdot 3(p\text{-}H_2NC_6H_4NH_2)$, $2(Ph_3B_3O_3) \cdot N(CH_2CH_2)_3N$, $Ph_3B_3O_3 \cdot Me_2NCH_2CH_2NMe_2$, $Ph_3B_3O_3 \cdot py$, $(4\text{-}MeC_6H_4)_3B_3O_3 \cdot C_6H_{12}NH_2$, $(4\text{-}MeC_6H_4)_3B_3O_3 \cdot$ (4-picoline), $(4\text{-}BrC_6H_4)_3B_3O_3 \cdot$ (3-picoline), and $Me_3B_3O_3 \cdot NH_2{}^iPr \cdot MeB(OH)_2$ have been structurally characterized [9–15]. These boroxine ring structures, each of which contain one 4-coordinate and two 3-coordinate B atoms, show similar, significant, and systematic variations in BO bond lengths. This is also the case for **1** were the average BO distance involving the 4-coordinate B {1.507(5) Å} > average BO distance involving the O atom remote from the 4-coordinate B {1.396(5) Å} > the average remaining 2 BO distances {1.339(5) Å}, and reflecting the expected bond orders. The

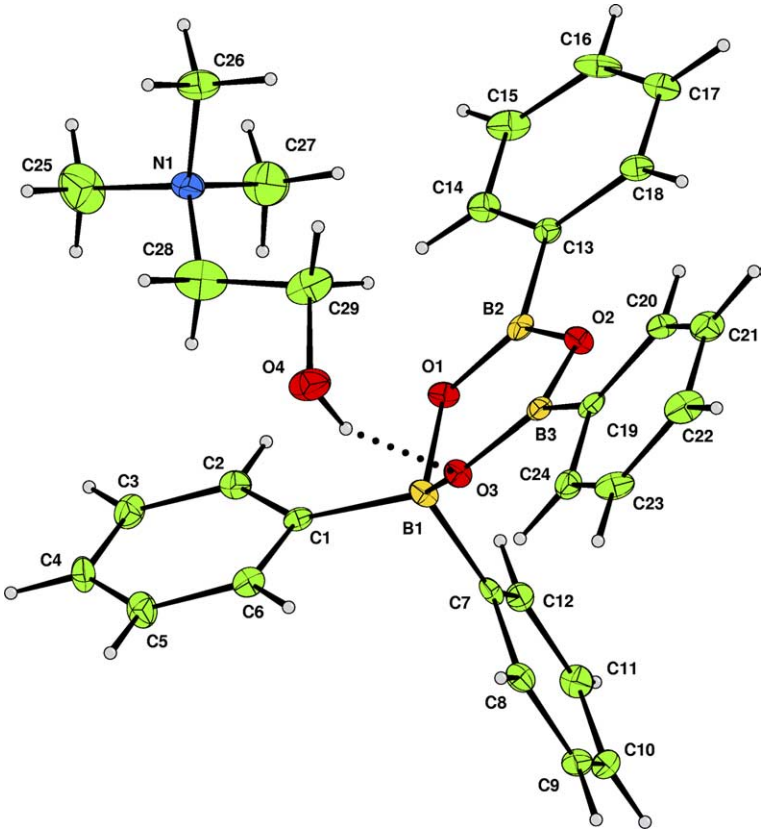

Fig. 1. Molecular structure of $[Me_3NCH_2CH_2OH][Ph_4B_3O_3]$ (**1**) showing atomic numbering scheme. Selected internuclear angles (°) and internuclear distances (Å) with esd's in parenthesis are: B1–O1 1.498(5), B1–O3 1.517(5), B1–C7 1.618(6), B1–C1 1.624(5), B2–O1 1.337(5), B2–O2 1.401(5), B2–C13 1.564(6), B3–O3 1.341(4), B3–O2 1.391(5), B3–C19 1.573(5); and O1–B1–O3 108.8(3), O1–B1–C7 110.4(3), O3–B1–C7 108.8(3), O1–B1–C1 108.6(3), O3–B1–C1 109.6(3), C7–B1–C1 110.7(3), O1–B2–O2 120.9(3), O1–B2–C13 120.9(3), O2–B2–C13 118.1(3), O3–B3–O2 121.9(3), O3–B3–C19 120.4(3), O2–B3–C19 117.7(3), B2–O1–B1 121.4(3), B3–O2–B2 118.2(3), B3–O3–B1 119.4(3). H-bond interaction: O4–H–O3 154.7, O4–H 0.84, H···O3 2.06, O4···O2 2.845(4).

B (sp^3)-C bonds {av. 1.621(6) Å} are significantly longer than the B (sp^2)-C bonds {av. 1.569(6) Å} due to π-overlap of the phenyl ring with the trigonal B centres. The ring-angle at the 4-coordinate B(1) is 108.8(3)°, whereas the 3-coordinate B(2) and B(3) centers have ring-angles averaging 121.4(3)°. The O ring-angles are in the range 118.2(3)–121.4(2)° with the angle opposite the tetrahedral B the smallest. The ring is almost planar with the rms deviation from the least squares plane being 0.128(7) Å. However, the conformation could be described as a 'shallow' boat with B1 and O2 deviating from the least squares plane of O1, B2, O3, B3 by 0.383(6) and 0.136(5) Å, respectively. The H-bond interaction is to one of the O atoms {O3} adjacent to the 4-coordinate B atom {B1}, rather than to the remote O atom {O2}. With the exception of the slight contraction of the ring angle at O3, the other bond angles and distances involving O3 are not significantly different from those of the non H-bonded, but otherwise chemically equivalent O1. The location of the H-bond acceptor site is possibly an indication of increased electron density at the O atoms adjacent to the formally negatively charged tetrahedral B atom. A H-bond interaction to this adjacent position has also been previously observed in $Me_3B_3O_3 \cdot NH_2{}^iPr \cdot MeB(OH)_2$ [14] and in that system the H-bond is essentially co-planar with the boroxine ring. This contrasts with **1** where the H-bond is at a substantial angle (such that the non-bonded angle B2 O3 H4A from the hydrogen of the donor to the cross ring vector is 118.52(4)°). It is possible that crystal-packing and steric effects play a substantial and largely unpredictable role in the H-bond location.

It was of interest to investigate whether analogous mixed-aryl anions e.g., $[(Ph_2BO)(ArBO)_2]^-$ might be prepared following a similar procedure. White solid products were obtained from reaction in methanol solution of diphenylborinic anhydride/choline hydroxide with various arylboronic acids {Ar = 4-$MeOC_6H_4$, 3-$MeOC_6H_4$, 2-$MeOC_6H_4$, 4-BrC_6H_4, $CpFe(C_5H_4)$ but these products, even when dissolved in acetone and re-precipitated with pet. ether, did not give satisfactory elemental analysis. ^{11}B NMR of these 'white products' showed the expected 3- and 4-coordinate boron signals of correct intensities, but it is likely that these materials were mixtures rather than pure compounds. From an attempted re-crystallization of a white solid isolated from the 4-$MeOC_6H_4$-$B(OH)_2/Ph_2BOBPh_2/[Me_3NCH_2CH_2OH][OH]$ (4:1:2) reaction mixture we isolated a few single-crystals of a compound which were subsequently identified by X-ray diffraction as the triarylboroxine, $(4\text{-}MeOC_6H_4)_3B_3O_3$ (**2**). This compound is well known but surprisingly its crystal structure has not been previously reported. A schematic drawing of the molecular structure of **2** is shown in Fig. 2 and pertinent bond-lengths and bond-angles are given in the

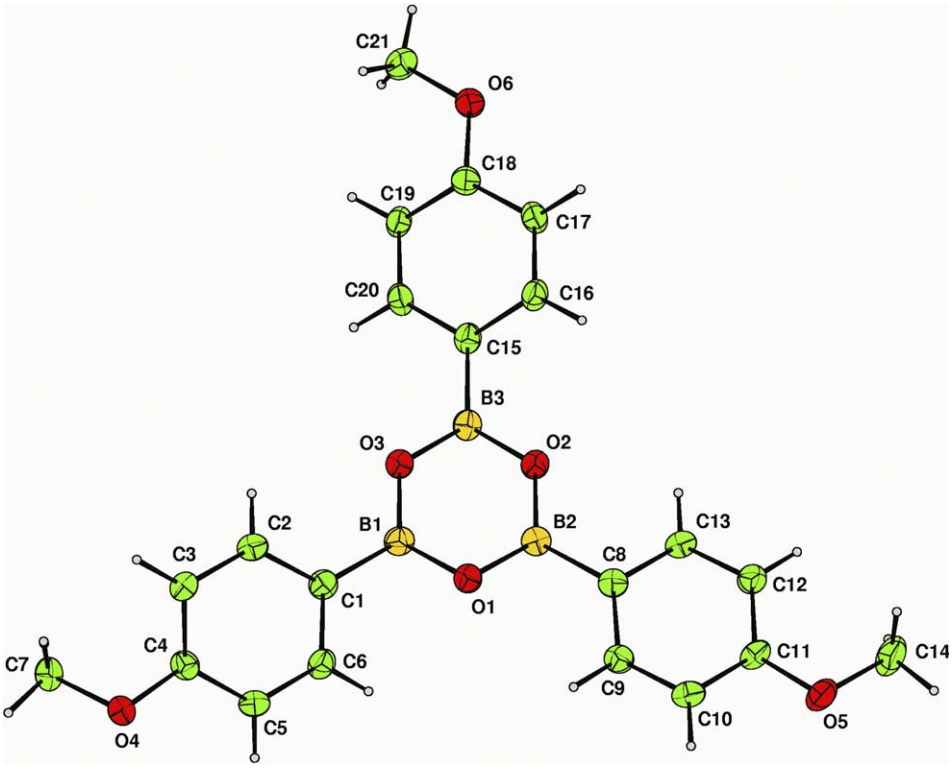

Fig. 2. Molecular structure of $(4\text{-}MeOC_6H_4)_3B_3O_3$ (**2**) showing atomic numbering scheme. Selected internuclear distances (Å) and bond angles (°) with esd's in parenthesis are: B1–O1 1.378(2), B1–O3 1.384(2), B2–O1 1.380(2), B2–O2 1.380(2), B3–O2 1.377(2), B3–O3 1.383(2), C1–B1 1.543(2), C8–B2 1.539(2), C15–B3 1.545(2); and O1–B1–O3 119.24(15), O1–B1–C1 120.46(14), O3–B1–C1 120.29(14), O1–B2–O2 119.02(14), O1–B2–C8 121.42(14), O2–B2–C8 119.55(14), O2–B3–O3 118.78(14), O2–B3–C15 120.41(14), O3–B3–C15 120.81(14), B1–O1–B2 120.74(13), B3–O2–B2 121.31(13), B3–O3–B1 120.80(13).

caption to the Figure. Previously determined single-crystal X-ray diffraction studies of boroxines include $Et_3B_3O_3$ and $Ar_3B_3O_3$, (Ar = Ph, 4-MeC_6H_4, 4-BrC_6H_4) [12,16–18]. In common with the other structurally characterized $Ar_3B_3O_3$ derivatives, the *p*-methoxyphenyl rings and the alternating B_3O_3 boroxine ring in **2** are essentially co-planar, with bond distances and angles similar to those previously reported. The B–O distances are in the range 1.377(2)–1.384(2) Å [av. 1.380(2) Å] with the boroxine ring angles close to that expected for sp^2 hybridized atoms with the B–O–B angles [120.74(13)–121.33(13)°, av. 120.96(13)°] slightly larger than the O–B–O angles [118.78(14)–119.24(15)°, av. 119.01°].

A hybrid hydroxy/triorganotriboroxinate salt, $[NEt_3H][Ph_3B_3O_3(OH)]$ (**3**), closely related to the tetraorganoboroxinate salt (**1**), was obtained in reasonable yield from the reaction of Et_3N with 3 equiv. of $PhB(OH)_2$ in anhydrous Et_2O (Eq. (2)). Compound **3** was characterized by elemental analysis, IR and ^{11}B NMR spectroscopy, and by a single-crystal X-ray diffraction study. Its ^{11}B NMR spectrum showed the expected 2 signals of relative intensity 2:1 at +29.8 and +4.6 ppm corresponding to the 3- and 4-coordinate B environments. A plausible mechanism for the formation of this novel hybrid structure might involve initial condensation of the $PhB(OH)_2$ to yield the triphenylboroxine, $Ph_3B_3O_3$, and 3 equiv. of water. Subsequent proton abstraction from the water by the Et_3N to yield the hydroxide salt $[Et_3N][OH]$ followed by addition to $Ph_3B_3O_3$ would lead to formation of the hydroxide adduct, **3**. $Ph_3B_3O_3 \cdot py$ is reported to be formed from py and $PhB(OH)_2$ under similar conditions [18] and the differing reactivity of Et_3N and py may be attributed to its increased basicity of the former.

$$Et_3N + 3PhB(OH)_2 \rightarrow [NEt_3H][Ph_3B_3O_3(OH)]\ (\mathbf{3}) + 2H_2O \quad (2)$$

A drawing of the anion and cation of **3**, showing atomic numbering scheme, is shown in Fig. 3; relevant bond angle and bond distance data are described within the caption to this figure. The solid-state dimeric structure of **3** is clearly demonstrated in Fig. 4, where short H-bond interactions (D···A, <2.9 Å) are shown. The solid-state structure has H-bond interactions between the cation and anion (N1H···O4) which exist as an ion-pair, and also anion–anion (O4H···O2) interactions which form the dimeric structure. The hydroxyl O atom, O4, is involved in both acceptor and donor H-bond interactions, with the hydroxyl hydrogen bridging across to O2 in the neighbouring anion's boroxinate ring. The heavy atoms of the dimeric anions (B3O2O4) adopt a centro-symmetric pseudo chair-like conformation with O4H···O2 angle at 166(2)°. There is also a weaker longer range H-bond interaction involving N1H and O3. Here, the N1–H···O3 angle is smaller at 122.8(1)°, and the internuclear distances are N1–H 1.04(2) Å, O3···H 2.570(19) Å, and N1···O3 3.245(18) Å. As was noted above for the tetraorganoboroxinate anion **1**, and previously for Lewis base adducts of boroxines, there is again a systematic variation of B–O bond-lengths

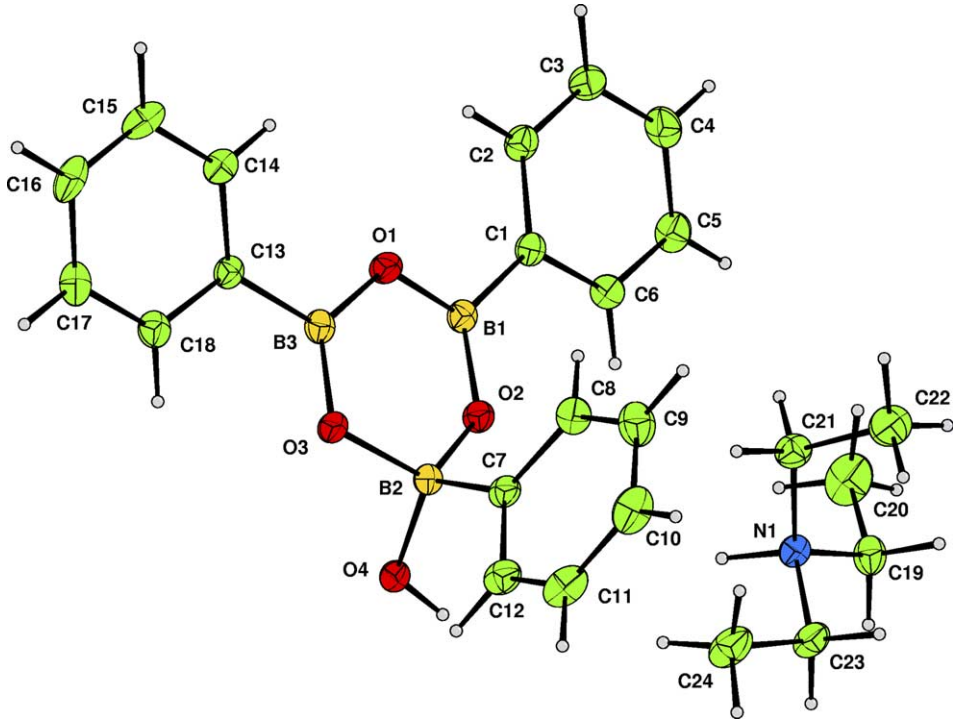

Fig. 3. Molecular structure of $[NEt_3H][Ph_3B_3O_3(OH)]$ (**3**) showing atomic numbering scheme. Selected internuclear distances (Å) and bond angles (°) with esd's in parenthesis are:B1–O2 1.344(2), B1–O1 1.396(2), B1–C1 1.567(3), B2–O4 1.456(2), B2–O3 1.490(2), B2–O2 1.507(2), B2–C7 1.617(3), B3–O3 1.337(2), B3–O1 1.391(2), B3–C13 1.571(2); and O2–B1–O1 120.80(16), O2–B1–C1 121.08(15), O1–B1–C1 118.09(16), O4–B2–O3 105.04(14), O4–B2–O2 109.48(14), O3–B2–O2 108.90(14), O4–B2–C7 113.43(14), O3–B2–C7 110.12(13), O2–B2–C7 109.71(14), O3–B3–O1 121.39(15), O3–B3–C13 120.14(15), O1–B3–C13 118.47(15), B3–O1–B1 119.07(14), B1–O2–B2 122.16(13), B3–O3–B2 122.19(14).

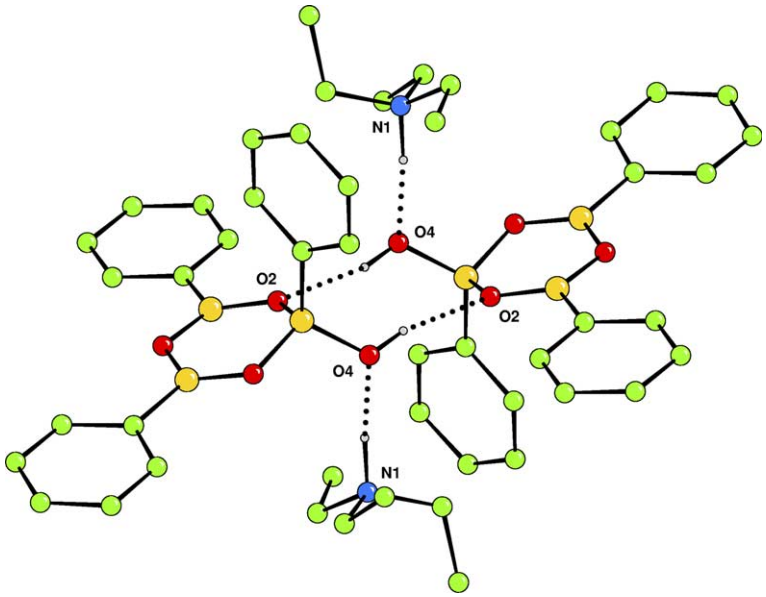

Fig. 4. Dimeric solid-state structure of **3** showing short range H-bond interactions. Internuclear angles (°) and internuclear distances (Å) with esd's in parenthesis are: O4–H–O2 166(2), O4–H 0.87(2), O2···H 1.99(2), O4···O2 2.8425(17) , and N1–H–O4 173.8(18), N1–H 1.04(2), O4···H 1.59(2), N1···O4 2.6283(19).

within the hydroxytriorganoboroxinate ring of **3**. Thus, the average BO distance involving the 4-coordinate B {1.499(2) Å} > average BO distance involving the O atom remote from the 4-coordinate B {1.394(2) Å} > the average remaining 2 BO distances {1.341(2) Å}. The *exo* ring B2–O4 distance of 1.456(2) Å is significantly shorter than the two ring O–B2 distances, indicative of a stronger bond. The B (sp^3)-C7 bond length and the B (sp^2)-C bond lengths {av. 1.569(3) Å} in **3** are not significantly different from those observed for **1**. The ring-angle at the 4-coordinate B(2) is 108.90(14)°, whereas the 3-coordinate B(1) and B(3) centers have ring-angles averaging 121.10(16)°. The O ring-angles are in the range 119.07(14)–122.19(14)°. Angles involving the B2O4 vector to O3, O2 and C7 range from 105.04(14)–113.43(14)° [av. 109.31(14)°]. The B_3O_3 ring conformation is best described as an envelope with the tetrahedrally coordinated B2 forming the flap. The rms deviation of the 5 atoms from planarity is 0.0196(7) Å and the flap of B2 is 0.334(2) Å out of the plane.

3. Experimental

3.1. General

Reactions were carried out under N_2. IR spectra were recorded on a Perkin–Elmer FT-IR 1600 spectrometer. ^{11}B NMR spectra were recorded on a Bruker 500 AVANCE spectrometer operating at 160.5 MHz. Chemical shifts are given in ppm with positive values towards high-frequency from $BF_3 \cdot OEt_2$. Elemental analysis were obtained on a Carla Erba MOD-1106 instrument using He as carrier gas. Ph_2BOPh_2 was prepared by the literature method [19] from commercially available $Ph_2BOCH_2CH_2NH_2$. The aryl boronic acids [$PhB(OH)_2$, 4-$MeOC_6H_4B(OH)_2$, 3-$MeOC_6H_4B(OH)_2$, 2-$MeOC_6H_4B(OH)_2$, 4-$BrC_6H_4B(OH)_2$, $CpFe(C_5H_4)B(OH)_2$] were obtained commercially.

3.2. Synthesis of $[Me_3NCH_2CH_2OH][Ph_4B_3O_3]$ (1)

To MeOH (5 cm^3) was added, with stirring, a methanolic solution of choline hydroxide (45% w/w, 0.31 g, 1.16 mmol), solid Ph_2BOBPh_2 (0.20 g, 0.58 mmol) and solid $PhB(OH)_2$ (0.28 g, 2.29 mmol). The solids initially dissolved to give a clear solution, and then after a few minutes the product precipitated as a white solid. The product was isolated by filtration and recrystallized from acetone. Yield: 0.28 g (52%). M.p. 189 °C. *Anal.* Calc. for $C_{29}H_{34}B_3NO_4$: C, 70.7; H, 6.9; N, 2.8. Found: C, 70.4; H, 6.6; N, 2.5%. NMR δ (^{11}B)(acetone-d_6): +4.2 (1B), +29.1 (2B). IR (ν_{max}/cm^{-1} as nujol mull, all strong): 3384, 1598, 1444, 1414, 1385, 1272, 1236, 1146, 1109, 954, 872, 706. Crystals suitable for X-ray diffraction were obtained from an acetone solution of the compound layered with pentane.

3.3. Synthesis of $[Et_3NH][Ph_3B_3O_3(OH)]$ (3)

Et_3N (0.20 g, 2.0 mmol) and $PhB(OH)_2$ (0.732, 6.0 mmol) were dissolved in Et_2O (5 cm^3). After a few minutes the solvent was evaporated and the remaining white solid recrystallized from Et_2O. Yield: 0.41 g (47%). M.p. 96 °C. *Anal.* Calc. for $C_{24}H_{32}B_3NO_4$: C, 66.9; H, 7.5; N, 3.3. Found: C, 67.2; H, 7.2 ; N, 3.0%. NMR δ (^{11}B)(acetone-d_6): +4.6 (1B), +29.8 (2B). IR (ν_{max}/cm^{-1}as nujol mull, all strong): 3424, 1600, 1446, 1377, 1252, 1175,

1114, 1027, 968, 923, 750, 704. Crystals suitable for X-ray diffraction were grown from Et_2O at 6 °C.

3.4. X-ray structures of *1*, *2*, and *3*

Data for all structures were collected using Phi and omega scans on a Bruker Nonius Kappa CCD area detector diffractometer with a rotating Mo (0.71073 Å) anode following standard procedures. Data were corrected for absorption using SORTAV [20,21]. Structure solution was performed using SHELXS-97 [22] and refinement carried out on F^2 using SHELXL 97 [23]. Hydrogen atoms were placed in idealised positions and refined using a riding model. Crystal data for **1**, **2** and **3** and their structural refinement parameters are given in Table 1.

4. Supplementary material

Crystallographic data for the structure analysis has been deposited with the Cambridge Crystallographic Data Centre CCDC Nos. **1** (CCDC275669), **2** (CCDC275668), and **3** (CCDC275667). Copies of this information may be obtained free of charge from the Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ (fax: +44 1223 336033) or e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk.

Fig. 1. Bisphosphonate structure.

2. Results and discussion

The bisphosphonic acids 4-amino-1-hydroxy-1,1-butylidenebisphosphonic acid (H_4L^2) and 6-amino-1-hydroxy-1,1-hexylidenebisphosphonic acid (H_4L^3) were synthesised as described in the patent literature [19]. We screened reactions of H_4L^2 and H_4L^3 with a range of hydrated divalent transition metal nitrates, metal = Mn, Fe, Co, Ni, Cu, Zn, Cd and vanadyl sulfate. The metal:ligand stoichiometries 0.75:1, 1:1, 1:1.5 and 1:2 were explored including reactions where the bisphosphonic acids were initially treated with 1–4 molar equivalents of NaOH. Apart from those cases employing metal:protonated ligand ratio of 0.75:1 (for, Co **1**, **6**, Ni **2**, Zn **3**, Mn **4**, and Cd **5** derivatives), the products of these reactions were otherwise very fine polycrystalline powders, not readily amenable to study by single crystal diffraction methods. The structurally characterised compounds had metal:ligand ratios of 1:2. They were insoluble in common organic solvents and water and did not melt below 290 °C.

3. X-ray crystal structures of 1–6

The structures of compounds **1**–**6** are shown in Fig. 2 along with atom numbering schemes.

The single crystal data are summarised in Section 5 while selected bond distances and angles are given in Tables 3 and 4 and selected hydrogen bonding is shown in Tables 5–11.

In common with known metal hydroxyaminoalkanebisphosphonates the ligands in compounds **1**–**6** are zwitterionic having a positively charged ammonium terminus balanced by one of the negatively charged phosphonate oxygens. In the present work further deprotonation at the second phosphonic acid group provides a bidentate dianionic ligand where each phosphonate is of the form ~P=O(O^-)(OH) with tetrahedral phosphorus and where the ligand adopts simple chelate (seen in all compounds **1**–**6**) and additionally, chelate bridging (in **4**–**6**) coordination modes. Metal coordination is roughly octahedral in all compounds **1**–**6**. Both ligand coordination modes have been reported previously for metal derivatives of H_4L, H_4L^2 (see Tables 1 and 2) but only the former for H_4L^3 [20]. The P=O (average 1.507 Å) and P–O(H) (average 1.567 Å) distances are clearly distinguished in all cases. The former are close to both chelate P–O(M) (average 1.509 Å) and bridging P–O(M) (average P–O(M) 1.499 Å). Two of the P–O(M) bonds in **4**, **5**, and **6** should be formally P=O(M) but its not possible from the data to assign these to specific bridging or chelate groups.

Compounds **1**–**3** are rare examples of mononuclear bisphosphonates with the 6-amino-1-hydroxy-1,1-hexylidene, C_6, fragment. The cupric ion derivative of H_4L^3 has previously been structurally characterised [20] and **1**–**3** are essentially isostructural with this copper compound. In the case of the Zn compound **3** we observed a doubling of the *a*-axis parameter and loss of symmetry on the molecule at 160 K (**3a**) compared to room temperature (**3b**). In **3a** the two halves of the molecule are no longer related by an inversion centre (as in **1**, **2** and **3b**). This indication of a phase transition is probably due to changes in hydrogen bonding at the lower temperature. The detail and more general occurrence of this type of phase transition in these systems requires further study but it is noteworthy that since compounds **1** and **2** are centrosymmetric at low temperature, the effect may be metal dependent.

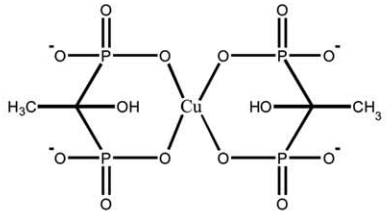
There is an extensive network of intra and intermolecular hydrogen bonds between the molecular units, which includes lattice bound water, in all of these structures. In the mononuclear structures, for example, intramolecular H-bonds include the alkyl hydroxy group and coordinated water molecules while intermolecular bonds extend from the P–OH, P=O the terminal ammonium groups and coordinated water (see Fig. 3 and Tables 5–8). In the dinuclear structures **4** and **5** hydrogen bonding is primarily intermolecular and again extends from the P–OH, P=O, C–OH, terminal ammonium groups and coordinated water. A pair of P–OH–O=P intramolecular bonds can be seen between the bridging ligands (see Fig. 4 and Tables 9 and 10).

In contrast to **4** and **5** there is extensive intramolecular H-bonding in dinuclear compound **6** (Table 11).

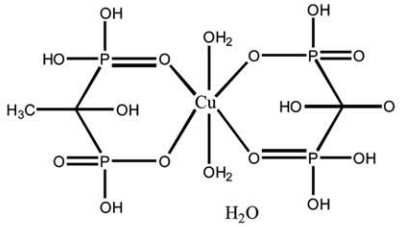
This involves H–O bonds between C–OH–HO–P groups where both are part of the same bridging ligand and between C–OH–(Co)O–P groups from bridging to terminal ligands. Further intramolecular H-bonding of type NH_3^+–(Co)O–P from bridging to terminal ligands is also present.

Compounds **1** and **6** are the first examples Co^{2+} derivatives of H_4L^3 and H_4L^2 to be structurally characterised. The observed aggregation patterns, mononuclear for **1**, $[Co(H_3L^3)_2 \cdot 2H_2O]$ $2H_2O$ and dinuclear for **6**, $[Co(H_3L^2)_2 \cdot H_2O]_2$ $2H_2O$ follow those previously observed for the analogous Cu^{2+} derivatives [18,20]. This pattern is also seen in the mononuclear structure of $[Zn(H_3L^3)_2 \cdot 2H_2O]$ $2H_2O$ **3** and the previously described dinuclear compound $[Zn(H_3L^2)_2 \cdot H_2O]_2$ $2H_2O$ [18]. Others postulated that the aminoalkylidene chain length plays a role in determining aggregation [20]. The dinuclear Mn^{2+}, **4** and Cd^{2+}, **5** derivatives of H_4L^3 are apparently the first examples of dinuclear derivatives of H_4L^3. There are striking differences between the dinuclear structures derived from H_4L^3 and those derived from H_4L^2. These are discussed below in relation to dinuclear compounds

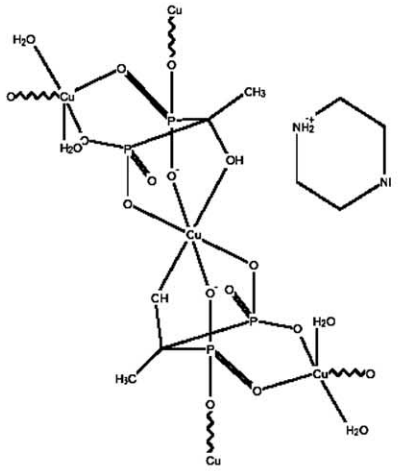
Table 1
Coordination modes exhibited by etidronate (H_4L) (taken from the CCSD Cambridge Crystallographic Structure Data Base)



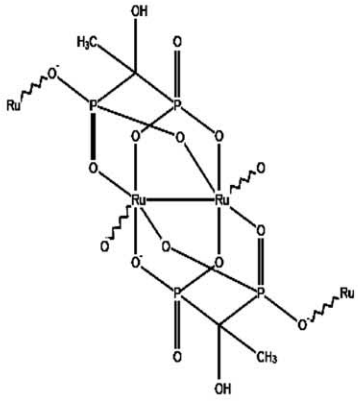
Tetrapotassium disodium bis(1-hydroxyethylidene-1,1-diphosphonate-O,O',O'')-copper(II) dodecahydrate [8]



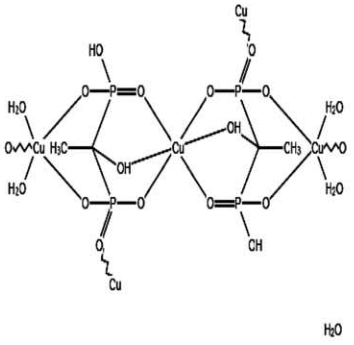
Diaqua-bis(1-hydroxyethylidene-diphosphonato)-copper(II) trihydrate [9]



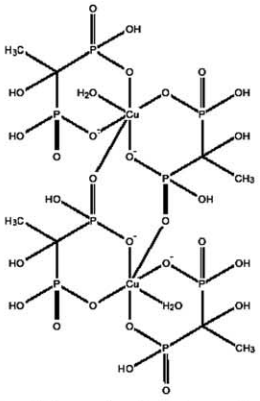
catena-(piperazinium bis(μ_3-1-hydroxyethylidene diphosphonato)-tetraaqua-tri-copper(II)) [12]



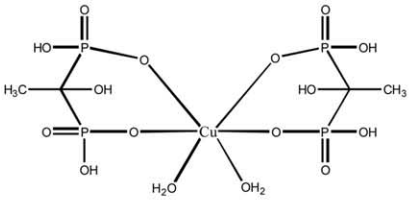
catena-(Triammonium bis(μ_3-1hydroxyethylidene diphosphonato)-diruthenium(II,III) dihydrate [13]



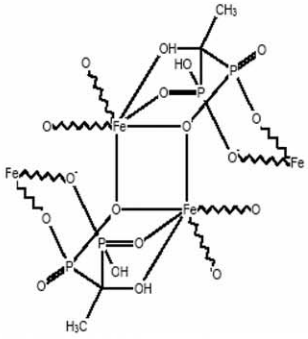
catena-(bis((μ_3-1-Hydroxyethane-1,1-diphosphonato-O,O',O'',O''',O'''',O''''')-diaqua)-tri-copper(II) dihydrate) [10]



Tetra-potassium bis(aqua-(μ_2-(1-hydroxyethane-1,1-diphosphonato-O,O'))-(1-hydroxyethane-1,1-diphosphonato-O,O)-copper(II) tetrahydrate [11]

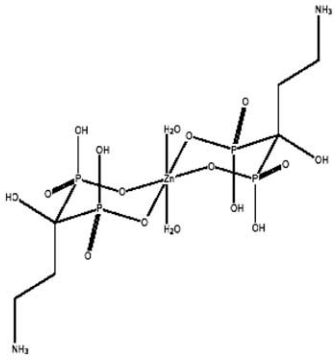


Bis(diethylammonium) diaqua-bis(1-hydroxyethylidene-1,1-diphosphonato)-cobalt(II) [14]

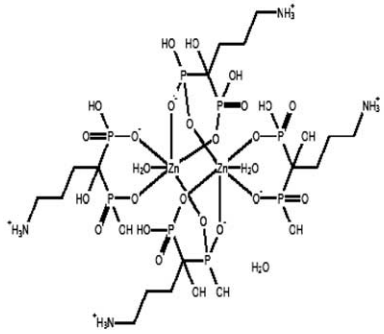


catena-(butane-1,4-diammonium bis(μ_3-1-hydroxy-1-(hydrogenphosphonate)-1-(phosphonato)ethane)-di-iron(II) dihydrate) [15]

Table 2
Coordination modes exhibited by aminohydroxyalkylidenebisphosphonate compounds



bis(3-Ammonio-1-hydroxypropylidene-1,1-bisphosphonate-O,O')-diaquazinc [17]



bis(μ_2-4-Amino-1-hydroxybutylidene-1,1-biphosphonite)-diaqua-bis(4-amino-1-hydroxybutylidene-1,1-biphosphonite)-di-zinc dihydrate [18]

4 and **6** with C_6 and C_4 chains, respectively. The central coordination cores are essentially the same with the pseudo-octahedral metal environments occupied by water, terminal chelating and chelate bridging bisphosphonates. The ammonium terminated C_6 and C_4 chains of the terminal ligands extend away from the dinuclear core in both cases. In the case of the bridging ligands, the C_4 chain in **6** bends in the direction of the central dinuclear core to facilitate intramolecular hydrogen bonding between the ammonium terminus and the ligating as well as non-ligating phosphonate oxygens. In contrast the C_6 chains of the bridging ligands in **4** and **5** extend away from the central dinuclear core (like the terminal ligands) so that intramolecular hydrogen bonding from the ammonium terminus is prohibited in this case (Fig. 4). However, it should be noted that there is significantly more puckering in the C_6 chains of the bridging ligands compared to those of the terminal ligands in **4** and **5**. This structural difference between dinuclear metal derivatives of L_4H^2 and L_4H^3 results in different intramolecular hydrogen bonding patterns and different overall extended structures for the hydrogen-bonded assemblies. Thus, if we consider structure directing effects of the aminoalkyl chains only, we see in **6** chain assemblies of hydrogen-bonded dimers while in **4** we see sheet-like assemblies of hydrogen bonded dimers.

The isolation of dinuclear compounds **4** and **5** with C_6 chains and extended sheet-type H-bonded structures, shows that these ligands display more versatile structure directing ability than previously seen. The different structural types, mononuclear or dinuclear, for H_4L^3 derivatives of different metals suggests the metal ions themselves may be important in determining this feature. In the present work it is noteworthy that the dinuclear structures **4** and **5** are formed by the two largest metal ions of the series used (Mn^{2+} 91pm, Cd^{2+} 103pm) while mononuclear structures were afforded by the rest (Co^{2+} 82pm, Ni^{2+} 78pm, Cu^{2+} 72pm, [20], Zn^{2+} 83pm). As mentioned earlier, divalent metal ions (Co^{2+}, this work, Cu^{2+} [20], Zn^{2+}, this work and [18]) which formed a mononuclear 1:2 derivative from H_4L^3 (C_6) gave a dinuclear 1:2 derivative with H_4L^2 (C_4). It is interesting in this context that while we report here on a dinuclear 1:2 derivative of H_4L^3 for Cd^{2+} **5**, others have reported a 1:1 complex from Cd^{2+} and H_4L^2 that has polymeric chain structure [18].

4. Conclusion

This work provides further evidence of a relationship between aggregation and alkylammonium chain length which is also linked to the size of metal ions. Additionally, the alkylammonium chain length is clearly important in determining the features of the supramolecular structures of these compounds.

5. Experimental

The compounds 4-amino-1-hydroxy-1,1-butylidenebisphosphonic acid (H_4L^2) and 6-amino-1-hydroxy-1,1-hexylidenebisphosphonic acid (H_4L^3) were prepared according to the methods described in the patent literature [19]. Reagents were purchased from Aldrich. All of the new compounds **1**–**6** displayed the infra red vibrational modes ν_{O-H} 3400, ν_{N-H} 2800, $\nu_{P=O}$ 1150, ν_{P-O-H} 980, and ν_{P-C} 770–650 cm^{-1}.

5.1. Diaqua-bis(6-hydroxyhexylidene-1,1-bisphosphonate)-cobalt dihydrate (*1*)

A bright pink solution from H_4L^3 (1.18 g, 4.23 mmol) in water 70 mL and $Co(NO_3)_2 \cdot 6H_2O$ (0.79 g, 3.08 mmol) in water 5 mL was heated in a sealed Teflon reactor held

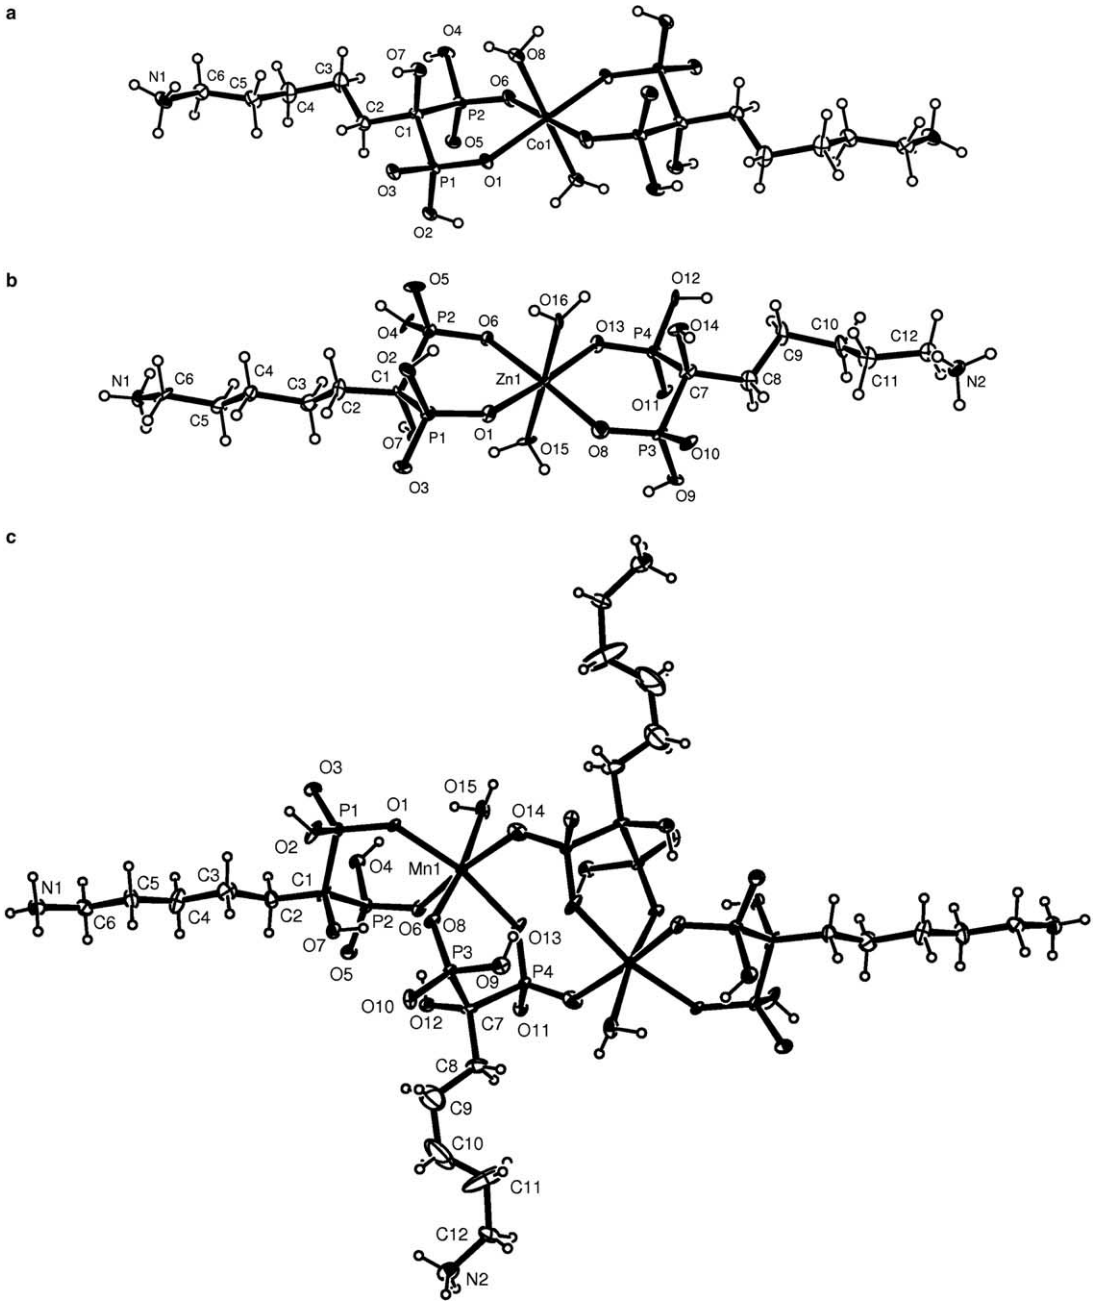


Fig. 2. Crystal structures of compounds **1**–**6**. (a) Crystal structure and atom numbering scheme for (**1**) (same scheme applies for isostructural compound (**2**) and (**3b**)). (b) Crystal structure and atom numbering scheme for (**3a**). (c) Crystal structure and atom labelling scheme for (**4**). (d) Crystal structure and atom labelling scheme for (**5**). (e) Crystal structure and atom labelling scheme for (**6**).

in an oil bath at 130 °C for 70 h and then allowed to cool to room temperature. Pink crystals of compound **1** were extracted from the walls of the Teflon reactor.

*5.2. Diaqua-bis(6-hydroxyhexylidene-1,1-bisphosphonate)-nickel dihydrate (**2**)*

Compound **2** was prepared as for **1** by combining $Ni(NO_3)_2 \cdot 6H_2O$ 1.51 mmol in 5 mL water and H_4L^3 1.98 mmol in 40 mL water at 130 °C for 130 h as pale green crystals.

*5.3. Diaqua-bis(6-hydroxyhexylidene-1,1-bisphosphonate)-zinc dihydrate (**3**)*

Compound **3** was prepared as for **1** from $Zn(NO_3)_2 \cdot 6H_2O$ 1.98 mmol in water 5 mL and H_4L^3 1.5 mmol in water 40 mL at 130 °C for 70 h and as colourless crystals.

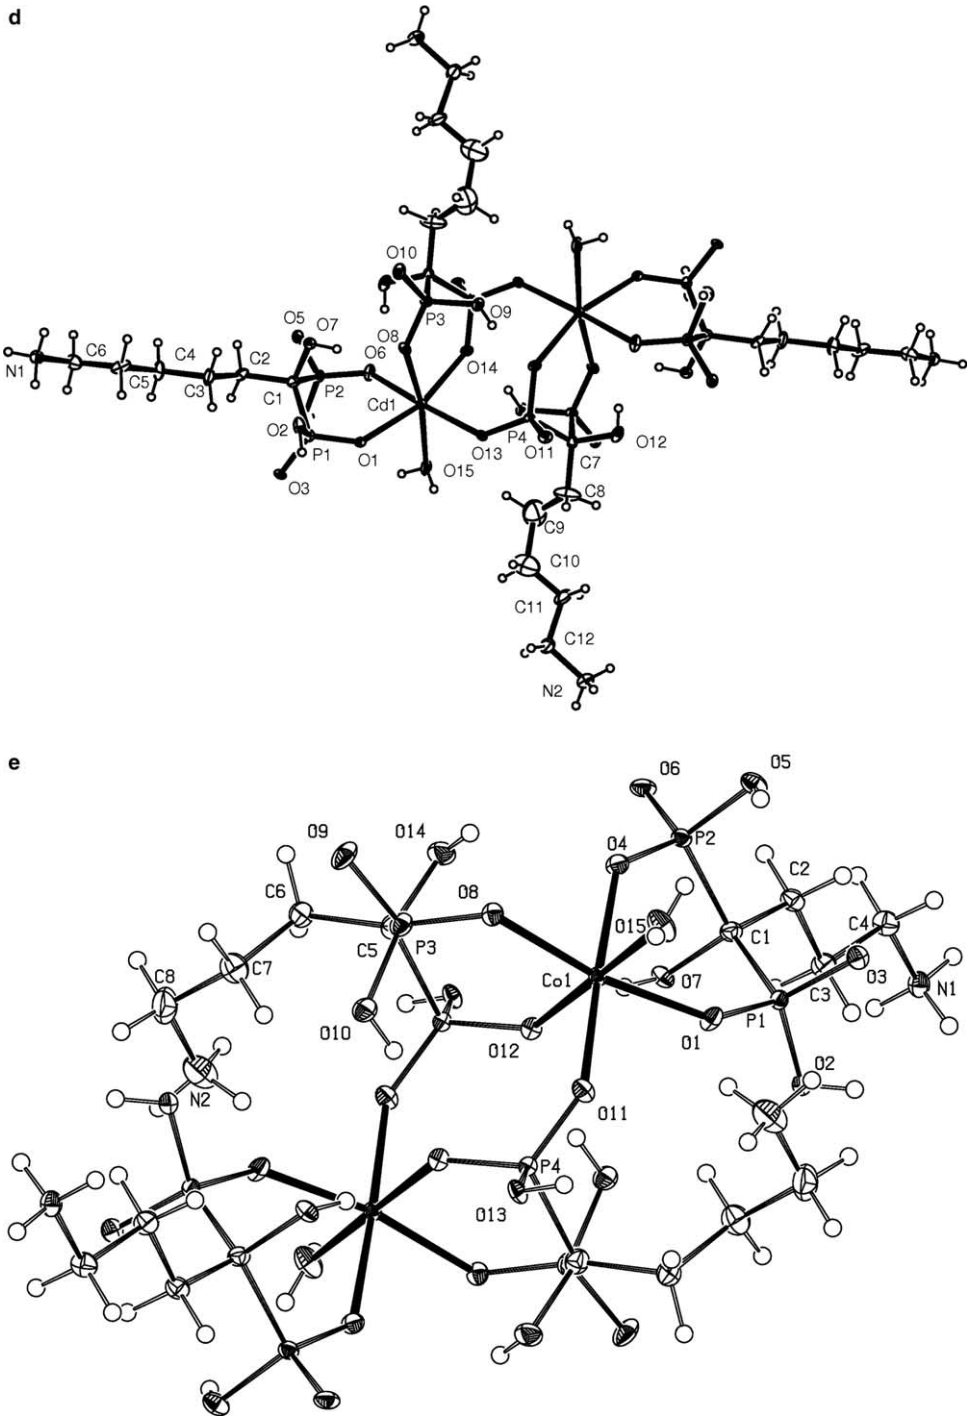

Fig. 2 (*continued*)

*5.4. Bis(μ2-6-amino-1-hydroxyhexylidene-1,1-bisphosphonate)-diaqua-bis(4-amino-1-hydroxyhexylidene-1,1-bisphosphonate)-di-manganese dihydrate (**4**)*

Compound **4** was prepared as for **1** from $Mn(NO_3)_2 \cdot 6H_2O$ 4 mmol in water 5 mL and H_4L^3 3 mmol in water 45 mL at 130 °C for 70 h as colourless crystals.

*5.5. Bis(μ2-6-amino-1-hydroxyhexylidene-1,1-bisphosphonate)-diaqua-bis(4-amino-1-hydroxyhexylidene-1,1-bisphosphonate)-di-cadmium dihydrate (**5**)*

Compound **5** was prepared as for **1** from $Cd(SO_4)$ 4.26 mmol in 10 mL H_2O and H_4L^3 3 mmol in water 80 mL at 130 °C for 70 h as colourless crystals.

*5.6. Bis(μ2-6-amino-1-hydroxybutylidene-1,1-bisphosphonate)-diaqua-bis(4-amino-1-hydroxybutylidene-1,1-bisphosphonate)-di-cobalt dihydrate (**6**)*

Compound **6** was prepared as for **1** from $Co(NO_3)_2 \cdot 6H_2O$ 4 mmol in 5 mL water and H_4L^2 3 mmol in water 45 mL at 130 °C for 70 h and isolated as pink crystals 0.67 g.

5.7. X-ray crystallography

The intensity data for **1**, **3a**, **3b**, **4** and **6** were collected on a CAD-4 diffractometer using Mo Kα radiation (λ 0.71069 Å) and ω-2θ scans at 160 or 293 K (see data for individual compounds). The unit cell parameters were determined by least-squares refinement on diffractometer angles for 25 automatically centred reflections [21]. Data

#8 $x-1, -y+1/2, z-1/2$.

for compounds **1**, **3a**, **3b**, **4** and **6** were corrected for absorption by empirical methods (ψ scan) [22] and for Lorentz-polarization effects by XCAD4 [23]. The structures were solved by heavy-atom methods using SHELXS-97, [24] and DIRDIF-99 programs, [25] and were refined anisotropically (non-hydrogen atoms) by full-matrix least-squares on F^2 using SHELXL-97 [24]. The H atoms were calculated geometrically and refined with a riding model except for the hydrogens in the water molecules. These were taken from the difference map and the O–H distances were restrained by DFIX facility in the SHELXL-97 programme [24].

Data for **2** and **5** were collected at 120 K using a Nonius Kappa CCD area detector diffractometer mounted at the window of molybdenum rotating anode (50 kV, 90 mA, $\lambda = 0.71069$ Å). The crystal-to-detector distance was

#7 $x-1, -y+1/2, z-1/2$;
#8 $x-1, y, z$;
#9 $x+1, y, z+1$.

30 mm and ϕ and Ω scans (2.0° increments, 12 s exposure time) were carried out to fill the Ewald sphere. Data collection and processing were carried out using the COLLECT [26], DENZO [27] and maXus [28] and empirical absorption correction was applied using SORTAV [29,30]. The structure was solved by heavy-atom method using DIRDIF99 [25] and refined anisotropically (non-hydrogen atoms) by full-matrix least-squares on F^2 using the SHELXL-97 [24] program. The H atoms were calculated geometrically and refined with riding model.

The programs ORTEP-3 [31] and Platon [32] was used for diagrams and WINGX [33] was used to prepare material for publication. Crystal data and refinement details are given below.

synthesis and characterization of $\mathbf{L}^1$, related ligand $\mathbf{L}^2$ and their metal complexes (with Pt(II), Pd(II) and Hg(II)). Like platinum(II), a 20-membered metallomacrocycle is also formed by palladium(II) with $\mathbf{L}^1$. Its crystal structure is also solved and described in this paper. Moreover, macrocyclic ligands containing Te (Te/S, Te/O type) and their metal complexes are also not unknown [10b]. Metal complexes of nitrogen, oxygen, sulfur and/or phosphorus ligands containing large size chelate ring (i.e., metallomacrocycles) are well known [11–17]. The complexes $[Cu_2(\mu\text{-dppy})_3(MeCN)][BF_4]_2$ (where dppy = 2-(diphenylphosphino)pyridine) [11], *trans*-[1,8-bis(diphenylphosphino)-3,6-dioxaoctane-*P*,*P*′]carbonyl(ethanol)rhodium(I)hexaflurophosphate [12], *trans*-[1,5-bis(diphenylphosphino)-3-oxapentane-*P*,*P*′]carbonylchlororhodium(I) dimer [12], di-μ-[glutaraldehydebis(dimethylhydrazone)]-bis[dichloropalladium(II)] [13], $[\{CoCl_2Ph_2P(O)CH_2CH_2P(O)Ph_2\}_2]$ [14] and dinuclear platinum(II) complex of the dithioether ligand 1,5-bis(*n*-propylthio)pentane [15] are some examples containing 8–16-membered chelate ring. Two known examples of metallomacrocycles containing telluroether ligands are the polymeric silver(I) complex of $MeTe(CH_2)_3TeMe$ [16] and the mononuclear Hg(II) complex of 1,6-bis-2-butyltellurophenyl-2,5-diazahexa-1,5-diene [17] with 24- and 13-membered rings, respectively. Moreover, the hybrid macrocyclic ligands (P/S, P/N, P/O) and their complexes are also well document [17b].

2. Experimental

The C and H analyses were carried out with a Perkin–Elmer elemental analyzer 240 C. Tellurium was estimated by atomic absorption spectrometer. The ^1H and ^{13}C $\{^1H\}$ NMR spectra were recorded on a Bruker Spectrospin DPX-300 NMR spectrometer at 300.13 and 75.47 MHz, respectively. IR spectra in the range 4000–250 cm^{-1} were recorded on a Nicolet Protége 460 FT-IR spectrometer as KBr and CsI pellets. The conductance measurements were made in acetonitrile (concentration ~1 mM) using an ORION conductivity meter model 162. The molecular weights (concentration ~5 mM) in chloroform were determined with a Knauer vapour pressure osmometer model A0280. The melting points determined in open capillary are reported as such. 2-[3-(2-Chloroethoxy)propyl]-6-methylpyridine was prepared by chlorination of corresponding alcohol with thionyl chloride [18].

2.1. X-ray crystallography

The X-ray data for **1** was collected (at 120 K) on an Bruker Nonius Kappa CCD area detector diffractometer, with φ and ω scans chosen to give a complete asymmetric unit. An absorption correction was applied [19]. The structure was solved by direct methods [20] and was refined using the WINGX version [21] of SHELX-97 [22]. The final cycle of full-matrix least-squares refinement was based on 8483 observed reflections (6690 for $F^2 > 4\sigma(F^2)$) and 536 variable parameters and converged (largest parameter shift was 0.001 times its esd). All of the non-hydrogen atoms were treated anisotropically. Hydrogen atoms were included in idealized positions with isotropic thermal parameters set at 1.2 times that of the carbon atom to which they were attached. Table 1 lists the experimental parameters used for single crystal structure analysis and crystal data. Selected bond lengths and angles are given in Table 2. The slightly high residual electron density may ascribed to the shape of crystals (very thin plates).

2.2. Synthesis of 1-(4-methoxyphenyltelluro)-2-[3-(6-methyl-2-pyridyl)propoxy]ethane ($\mathbf{L}^1$)

Bis(4-methoxyphenyl)ditelluride (0.46 g, 1.0 mmol) was dissolved in 30 cm^3 of ethanol and the solution set to reflux under nitrogen atmosphere. A solution of sodium borohydride (0.07 g, 2.0 mmol) made in 5 cm^3 NaOH (5%) was added drop wise to the refluxing solution of the ditelluride under nitrogen atmosphere until it became colourless due to the formation of $ArTe^-$ Na^+. 2-[3-(2-Chloroethoxy)-propyl]-6-methylpyridine (0.42 g, 2.0 mmol) dissolved in 10 cm^3 of ethanol was added to this solution with constant stirring. The reaction mixture was refluxed further for 2–3 h, cooled to room temperature and poured into ice cold

Table 1
Crystal data and structure refinement for $[PdCl_2\mathbf{L}^1]_2 \cdot 1.5C_6H_6$

water (100 cm^3) in which 0.1 g of NaOH was dissolved. The ligand was extracted into chloroform (4×50 cm^3) from this aqueous mixture. The extract was washed with water (2×20 cm^3) and dried over anhydrous sodium sulphate. The solvent was evaporated off under reduced pressure on a rotary evaporator, resulting in red oil, which was extracted with hexane (30 cm^3). On removing hexane from the extract under reduced pressure on a rotary evaporator ligand $\mathbf{L}^1$ was obtained as yellow viscous oil. Yield: ~70%; ^{1}H NMR ($CDCl_3$, 25 °C) (δ versus TMS): 1.91–2.01 (m, 2H, H_4), 2.52 (s, 3H, H_{11}), 2.71–2.82 (t, 2H, H_1), 2.95–3.00 (t, 2H, H_5), 3.43–3.47 (t, 2H, H_3), 3.66–3.70 (t, 2H, H_2), 3.78 (s, 3H, OCH_3), 6.73–6.76 (d, 2H, *m* to Te), 6.93–6.96 (d, 2H, H_7 and H_9), 7.43 7.48 (t, 1H, H_8), 7.65–7.70 (d, 2H, *o* to Te). ^{13}C {^{1}H} NMR ($CDCl_3$, 25 °C) (δ versus TMS) 8.1 (C_1), 24.1 (C_{11}), 28.9 (C_4), 34.5 (C_5) 54.7 (OCH_3), 69.4 (C_2), 71.8 (C_3), 99.8 (ArTe–C), 114.8 (C_9), 119.3 (ArC *m* to Te), 120.1 (C_7), 136.4 (C_8), 140.6 (ArC *o* to Te), 157.3 (C_{10}), 160.5 (ArC *p* to Te), 161.1 (C_6).

2.3. Synthesis of 2-methyl-6-{3-[2-({2-[3-(6-methyl-2-pyridyl)propoxy]ethyl}telluranyl)ethoxy]propyl}pyridine ($\mathbf{L}^2$)

Tellurium powder (0.65 g, 5.0 mmol) and sodium borohydride (0.38 g, 10.0 mmol) solution (made in 10 cm^3 of 2.0 M NaOH) were mixed in 50 cm^3 of water. The mixture was refluxed for 2 h under nitrogen atmosphere. To the resulting colourless thin slurry of Na_2Te kept under reflux, a solution of 2-[3-(6-methyl-2-pyridyl)propoxy]ethyl chloride (2.13 g, 10.0 mmol) made in 10 cm^3 of ethanol was added drop wise with constant stirring under nitrogen atmosphere. The mixture was cooled to room temperature and poured into 100 cm^3 of water. The ligand $\mathbf{L}^2$ was extracted into diethyl ether (4×30 cm^3) from the aqueous phase. The ether extract was washed with distilled water (2×15 cm^3) and dried over anhydrous sodium sulphate. On evaporating off ether under reduced pressure on a rotary evaporator $\mathbf{L}^2$ (2-methyl-6-{3-[2-({2-[3-(6-methyl-2-pyridyl)propoxy]ethyl}telluranyl)ethoxy]propyl}-pyridine) was obtained as a reddish yellow viscous liquid that was unstable as it showed the sign of decay within few days. Yield: ~75%; ^{1}H NMR ($CDCl_3$, 25 °C) (δ versus TMS) 1.96–2.00 (m, 2H, H_4), 2.51 (s, 3H, H_{11}), 2.79–2.84 (m, 4H, H_5 and H_1), 3.45–3.51 (m, 2H, H_3), 3.70–3.76 (m, 2H, H_2), 6.94–6.96 (m, 2H, H_8 and H_9), 7.427.46 (m, 1H, H_7) ^{13}C {^{1}H} NMR ($CDCl_3$, 25 °C) (δ versus TMS) 3.1 (C_1), 23.9 (C_{11}), 29.3 (C_4), 34.2 (C_5), 69.8 (C_2), 76.5 (C_3), 119.0 (C_9), 119.8 (C_7), 135.8 (C_8), 157.0 (C_6), 160.3 (C_{10}).

2.4. Synthesis of $[PdCl_2(\mathbf{L}^1)]_2$ (1)

To a solution of $\mathbf{L}^1$ (0.20 g, 0.50 mmol) made in 10 cm^3 of acetone was added $Na_2[PdCl_4]$ (0.14 g, 0.50 mmol) dissolved in 10 cm^3 of water. The resulting mixture was stirred for 2 h at room temperature and poured into 100 cm^3 of water. The complex was extracted into chloroform (4×25 cm^3). The extract was dried over anhydrous sodium sulphate, concentrated to ~5 cm^3 and mixed with hexane (20 cm^3). The resulting yellow solid was filtered, washed with hexane and dried in vacuo. The single crystals of the complex **1** were grown from benzene. The **1** crystallizes with 1.5 mol of benzene per mole. Yield: 78%; m.p. 125 °C; Λ_M (Ω^{-1} cm^2 mol^{-1}) 5.8. *Anal.* Calc. for $C_{36}H_{46}N_2O4Te_2Pd_2Cl_4$: C, 36.60; H, 3.97; N, 2.31; Te, 21.62. Found: C, 36.24; H, 3.89; N, 2.31; Te, 21.24%. Mol. wt.: 1144.6 (Calc. 1180.0). ^{1}H NMR ($CDCl_3$, 25 °C) (δ versus TMS) 2.20–2.27 (m, 2H, H_4), 3.30–3.31 (m, 4H, H_{11} and H_3), 3.54–3.66 (m, 2H, H_5 and H_3), 3.77–3.78 (m, 4H, $CH_3O + H_5$), 3.78–3.81 (t, 2H, H_2), 4.10–4.22 (m, 2H, H_1), 6.89–6.94 (m, 2H, ArH *m* to Te), 7.12–7.14 (m, 2H, H_7 and H_9), 7.36 (s, 1H, $CHCl_3$), 7.56–7.61 (m, 1H, H_8), 7.99–8.06 (m, 2H, ArH *o* to Te). ^{13}C {^{1}H} NMR ($CDCl_3$, 25 °C) (δ versus TMS) 21.8 (C_1), 27.0 (C_{11}), 29.4 (C_4), 36.6 (C_5), 55.2 (OCH_3), 66.7 (C_2), 70.3 (C_3), 103.9 (Ar–C–Te), 115.5 (C_9), 121.6 (Ar–C *m* to Te), 123.2 (C_7), 138.4 (C_8), 140.6 (Ar–C *o* to Te), 158.9 (C_{10}), 161.1 (Ar–C *p* to Te), 162.2 (C_6).

2.5. Synthesis of $[PtCl_2(\mathbf{L}^1)]_2$ (2)

A solution of $\mathbf{L}^1$ (0.20 g, 0.50 mmol) made in 10 cm^3 of acetone was added to $K_2[PtCl_4]$ (0.20 g, 0.50 mmol) dissolved in 10 cm^3 of water. The resulting mixture was stirred for 3 h at room temperature and poured into 100 cm^3 of water. The complex was extracted into chloroform (4×25 cm^3). The chloroform extract was dried over anhydrous sodium sulphate, concentrated to ~5 cm^3 on a rotary evaporator, and mixed with hexane (20 cm^3). The

resulting yellow coloured compound was filtered, washed with hexane. The single crystals suitable for diffraction were grown from chloroform:hexane (1:1) mixture. The **2** crystallizes with 2 mol of chloroform per mole. Yield: 75%; m.p. 126 °C; Λ_M (Ω^{-1} cm^2 mol^{-1}) 10.5. *Anal.* Calc. for $C_{36}H_{46}N_2O_4Te_2Pt_2Cl_4$: C, 31.82; H, 3.32; N, 2.00; Te, 18.80. Found: C, 32.91; H, 3.39; N, 2.06; Te, 18.92%. Mol. wt.: 1324.2 (Calc. 1357.3). ^{1}H NMR ($CDCl_3$, 25 °C) (δ versus TMS) 2.22–2.30 (m, 2H, H_4), 3.26–3.32 (m, 4H, H_{11} and H_3), 3.55–3.67 (m, 2H, H_5 and H_3), 3.81–3.84 (m, 4H, $CH_3O + H_5$), 3.90–3.92 (t, 2H, H_2), 4.12–4.14 (m, 1H, H_1), 4.26–4.41 (m, 1H, H_1), 6.87–6.94 (m, 2H, ArH *m* to Te), 7.10–7.13 (m, 2H, H_7 and H_9), 7.26–7.28 (s, 2H, $CHCl_3$), 7.53–7.61 (m, 1H, H_8), 7.80–7.83 (d, 1H, ArH *o* to Te), 8.00–8.06 (m, 1H ArH *o* to Te). ^{13}C {^{1}H} NMR ($CDCl_3$, 25 °C) (δ versus TMS) 18.9 (C_1), 26.8 (C_{11}), 28.0 (C_4), 36.3 (C_5), 55.3 (OCH_3), 66.9 (C_2), 70.6 (C_3), 99.8 (Ar–Te–C), 115.2 (C_9), 122.7 (Ar–C *m* to Te), 123.8 (C_7), 138.4 (C_8), 140.6 (Ar–C *o* to Te), 160.0 (C_{10}), 160.6 (Ar–C *p* to Te), 161.2 (C_6).

2.6. Synthesis of [$HgBr_2$(**L**^{1})] (**3**)

$HgBr_2$ (0.20 g, 0.55 mmol) dissolved in acetone (20 cm^3) was mixed with a solution of **L**^{1} (0.22 g, 0.55 mmol) made in chloroform (20 cm^3). The resulting mixture was stirred at room temperature until the ligand **L**^{1} was consumed (as monitored by TLC). The solvent was removed from the mixture on a rotary evaporator. The resulting residue was dissolved in 20 cm^3 of chloroform and filtered through celite. The filtrate was concentrated to 10 cm^3 and mixed with 20 cm^3 of hexane. A white complex was separated, filtered, dried in vacuo and recrystallized from acetone–hexane (2:1) mixture. Yield: 80%; m.p. 130 °C (d); Λ_M (Ω^{-1} cm^2 mol^{-1}) 7.8 *Anal.* Calc. for $C_{18}H_{23}NO_2TeHgBr_2$: C, 27.97; H, 2.97; N, 1.81; Te, 16.50. Found: C, 27.71; H, 2.91; N, 1.76; Te, 16.36%. Mol. wt.: 770.34 (Calc. 773.10). ^{1}H NMR ($CDCl_3$, 25 °C) (δ versus TMS) 1.86–1.89 (m, 2H, H_4), 2.46 (s, 3H, H_{11}), 2.71–2.75 (t, 2H, H_1), 3.37 (t, 2H, H_5), 3.46 (bs, 2H, H_3), 3.65–3.68 (m, 5H, H_2 and OCH_3), 6.74–6.77 (d, 2H, *m* to Te), 6.93–6.97 (m, 2H, H_7 and H_9), 7.47–7.52 (t, 1H, H_8), 7.68–7.71 (d, 2H, *o* to Te), ^{13}C {^{1}H} NMR ($CDCl_3$, 25 °C) (δ versus TMS) 24.4 (C_1), 24.8 (C_{11}), 28.9 (C_4), 34.8 (C_5), 55.2 (OCH_3), 66.9 (C_2), 70.4 (C_3), 99.8 (ArTe–C), 114.7 (C_9), 116.2 (Ar–C *m* to Te), 120.9 (C_7), 137.1 (C_8), 139.3 (ArC *o* to Te), 157.3 (C_{10}), 160.5 (Ar–C *p* to Te), 161.1 (C_6).

2.7. Formation of $MeOC_6H_4HgBr$ (**4**) and [RTe^+–$HgBr_2$]Br^- (R = –$CH_2CH_2OCH_2CH_2CH_2$-(2-(6-CH_3–C_5H_3N))) (**5**)

$HgBr_2$(**L**^{1}) (**3**) (0.07 g, 0.09 mmol) was dissolved in acetone–hexane (2:1) mixture and kept for slow evaporation at 25°C. After 7 days, crystals of **4** were obtained. The mother liquor was mixed with chloroform (20 ml) and refluxed for 3 h. The **5** was obtained as solid. It was filtered, washed with chloroform (2 × 5 cm^3) and dried in vacuo. **4**: Yield: 18%; m.p. 115 °C (d); Λ_M (Ω^{-1} cm^2 mol^{-1}) 6.4. *Anal.* Calc. for C_7H_7OHgBr: C, 27.70; H, 1.80. Found: C, 27.71; H, 1.82%. Mol. wt.: 379.3 (Calc. 387.6) ^{1}H NMR (DMSO-d^6, 25 °C) (δ versus TMS) 3.71 (s, 3H, OCH_3), 6.89–6.91 (d, 2H, ArH *m* to Hg), 7.34–7.37 (ArH *o* to Hg).

2.8. Synthesis of [$PdCl_2$(**L**^{2})]$_2$ (**6**)

The freshly prepared sample of **L**^{2} (0.24 g, 0.50 mmol) dissolved in 10 cm^3 of acetone was added to $Na_2[PdCl_4]$ (0.14 g, 0.50 mmol) dissolved in 10 cm^3 of water. The resulting mixture was stirred for 3 h at room temperature and poured in 100 cm^3 of water. The complex was extracted with chloroform (4 × 25 cm^3). The chloroform extract was dried over anhydrous sodium sulfate and concentrated to ~10 cm^3 on a rotary evaporator, and mixed with hexane (20 cm^3). The resulting orange coloured compound was filtered, washed with hexane and recrystallized from chloroform:hexane (1:1) mixture. Yield: 79%; m.p. 139 °C (d); Λ_M (Ω^{-1} cm^2 mol^{-1}) 7.6. *Anal.* Calc. for $C_{22}H_{32}N_2O_2TePdCl_2$: C, 39.68; H, 4.84; N, 4.20; Te, 19.30. Found: C, 39.90; H, 4.53; N, 4.34; Te, 19.12%. Mol. wt.: 658.1 (Calc. 661.0). ^{1}H NMR ($CDCl_3$, 25 °C) (δ versus TMS) 1.69 (m, 2H, H_4), 2.02–2.04 (m, 2H, H'_4), 2.38–2.42 (m, 3H, H'_{11}), 2.54 (m, 3H, H_{11}), 2.84–2.97 (m, 4H, $H_5 + H'_5$), 3.35 (m, 2H, H_3), 3.53–3.65 (m, 2H, H'_3), 3.73–3.75 (m, 2 H H_2), 3.77–3.79 (m, 2H, H2′), 3.90–4.05 (m, 2H, H_1), 6.99–7.15 (m, 2H, $H_8 + H_9$), 7.47–7.52 (m, 2H, $H'_8 + H'_9$), 7.55–7.58 (m, 1H, H'_{10}) 7.60 (m, 1H, H_{10}). ^{13}C {^{1}H} NMR ($CDCl_3$, 25 °C) (δ versus TMS) 14.0 (C_1), 26.0 (C'_{11}), 26.6 (C_{11}), 28.9 (C'_4), 29.8 (C_4), 34.6 (C'_5), 35.8 (C_5), 68.2 (C'_2), 70.3 (C_2), 76.9 (C_3), 119.0 (C'_9), 120.6 (C_9), 121.0 (C'_7), 122.2 (C_7), 138.5 (C_8), 136.8 (C'_8), 159.0 (C_6), 162.9 (C_{10}) [primes indicate the pendent arm proton or carbon atoms].

2.9. Synthesis of [$PtCl_2$(**L**^{2})]$_2$ (**7**)

The freshly prepared sample of **L**^{2} (0.24 g, 0.50 mmol) dissolved in 10 cm^3 of acetone was added to $K_2[PtCl_4]$ (0.20 g, 0.50 mmol) dissolved in 10 cm^3 of water. The resulting mixture was stirred for 3 h at room temperature and poured into 100 cm^3 of water. The complex was extracted into chloroform (4 × 25 cm^3). The chloroform extract was dried over anhydrous sodium sulphate,

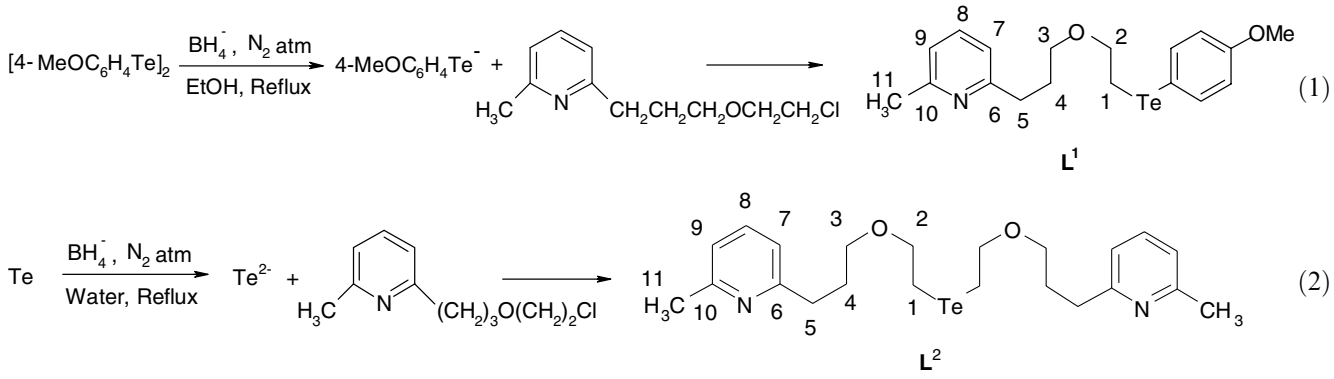
concentrated to ~10 cm^3 on a rotary evaporator, and mixed with hexane (20 cm^3). The resulting yellow coloured compound was filtered, washed with hexane and recrystallized from chloroform:hexane (1:1) mixture. Yield: 75%; m.p. 147 °C (d); Λ_M (Ω^{-1} cm^2 mol^{-1}) 9.0. *Anal.* Calc. for $C_{22}H_{32}N_2O_2TePtCl_2$: C, 35.21; H, 4.26; N, 3.73; Te, 17.02. Found: C, 35.12; H, 4.21; N, 3.12; Te, 16.17%. Mol. wt.: 739.2 (Calc. 749.6). ^{1}H NMR ($CDCl_3$, 25 °C) (δ versus TMS) 1.89 (m, 2H, H_4), 2.02–2.08 (m, 2H, H'_4), 2.35–2.40 (m, 3H, H'_{11}), 2.53–2.54 (m, 3H, H_{11}), 2.86–2.97 (m, 4H, $H_5 + H'_5$), 3.20–3.27 (m, 2H, H_3), 3.34–3.40 (m, 2H, H'_3), 3.56–3.62 (m, 2H, H'_2), 3.78–3.79 (m, 2H, H_2), 3.84 (m, 2H, H_1), 6.69 (m, 2H, $H_8 + H_9$), 6.99–7.15 (m, 2H, $H'_8 + H'_9$), 7.48–7.49 (m, 1H, H'_{10}), 7.50–7.58 (m, 1H, H_{10}). ^{13}C {^{1}H} NMR ($CDCl_3$, 25 °C) (δ versus TMS) 16.7 (C_1), 24.0 (C'_{11}), 27.6 (C_{11}), 28.8 (C_4), 29.3 (C'_4), 34.7 (C'_5), 36.4 (C_5), 69.7 (C'_2), 70.4 (C_2), 77.0 (C_3), 119.0 (C'_9), 120.6 (C_9), 121.6 (C'_7), 123.5 (C_7), 136.7 (C'_8), 138.4 (C_8), 161.5 (C_6), 164.0 (C_{10}) [primes indicate the pendent arm proton or carbon atoms].

2.10. Synthesis of [($PdCl_2$)$_3$(L^2)$_2$] (8)

The freshly prepared sample of L^2 (0.24 g, 0.50 mmol) dissolved in 10 cm^3 of acetone was added to $Na_2[PdCl_4]$ (0.22 g, 0.75 mmol) dissolved in 10 cm^3 of water. The resulting mixture was stirred for 3 h at room temperature and poured in to 100 cm^3 of water. The complex was extracted with 4×25 cm^3 of chloroform. The combined chloroform layer was dried over anhydrous sodium sulfate and concentrated to ~10 cm^3 on a rotary evaporator, and mixed with hexane (20 cm^3). The resulting orange colored compound was filtered, washed with hexane and recrystallized from chloroform:hexane (1:1) mixture. Yield: 72%; m.p. 141 °C (d); Λ_M (Ω^{-1} cm^2 mol^{-1}) 8.7 *Anal.* Calc. for $C_{44}H_{64}N_4O_4Te_2Pd_3Cl_6$: C, 35.21; H, 4.26; N, 3.73; Te, 17.01. Found: C, 35.16; H, 4.24; N, 3.71; Te, 17.00%. Mol. wt.: 1487.2 (Calc. 1499.4). ^{1}H NMR ($CDCl_3$, 25 °C) (δ versus TMS) 2.36–2.43 (m, 4H, H_4 and H_{11}), 3.13–3.19 (m, 2H, H_5), 3.31–3.42 (m, 1H, H_3), 3.68–3.94 (m, 5H, H_3, H_2, H_1), 7.11–7.12 (m, 2H, H_8 and H_9), 7.55–7.60 (m, 1H, H_7) ^{13}C {^{1}H} NMR ($CDCl_3$, 25 °C) (δ versus TMS) 17.3 (C_1), 27.6 (C_{11}), 28.9 (C_4), 36.4 (C_5), 69.7 (C_2), 77. 4 (C_3), 121.6 (C_9), 123.7 (C_7), 138.5 (C_8), 161.5 (C_6), 164.0 (C_{10}).

3. Results and discussion

The ligands L^1 and L^2 were prepared according to Eqs. (1) and (2) given below. The ligand L^1 was found stable for two months under ambient conditions. Thereafter, deposition of white solid starts in the oil, which is most likely a tellurium dioxide formed by its oxidative decomposition. However, on storing L^2 for only eight days at room temperature under ambient conditions TeO_2 deposits appear. In N_2 atmosphere it may be stored for one month without any sign of decomposition.



(1)

(2)

The Pd(II), Pt(II), Hg(II) complexes of L^1 and L^2 were prepared according to Eqs. (3)–(8) given below. The **1** crystallizes with 1.5 mol of benzene per mole whereas **2** with 2 mol of chloroform. The complexes **1**–**3**, **6**, **7**, and **8** can be stored at room temperature for two months easily. Single crystals of **6**–**8** suitable for X-ray diffraction could not be grown.

$$2Na_2PdCl_4 + 2L^1 \rightarrow [PdCl_2(L^1)]_2\ (\mathbf{1}) + 4NaCl \quad (3)$$

$$2K_2PtCl_4 + 2L^1 \rightarrow [PtCl_2(L^1)]_2\ (\mathbf{2}) + 4KCl \quad (4)$$

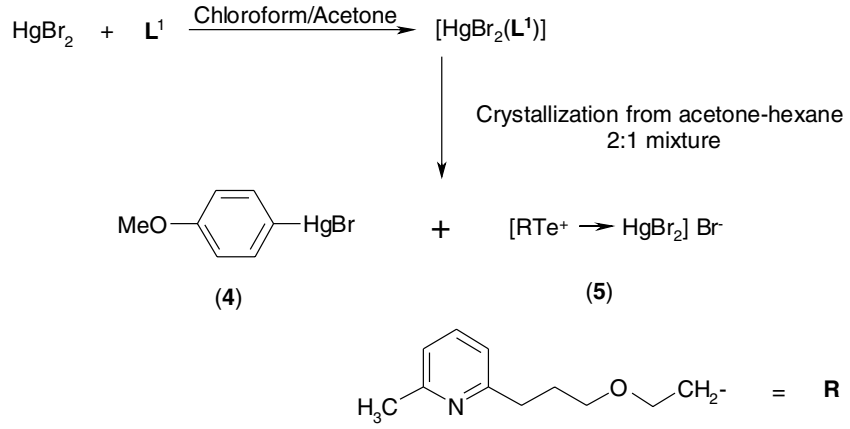
$$HgBr_2 + L^1 \rightarrow [HgBr_2(L^1)]\ (\mathbf{3}) \quad (5)$$

$$2Na_2PdCl_4 + 2L^2 \rightarrow [PdCl_2(L^2)]_2\ (\mathbf{6}) + 4NaCl \quad (6)$$

$$2K_2PtCl_4 + 2L^2 \rightarrow [PtCl_2(L^2)]_2\ (\mathbf{7}) + 4KCl \quad (7)$$

$$3Na_2PdCl_4 + 2L^2 \rightarrow [(PdCl_2)_3(L^2)_2]\ (\mathbf{8}) + 6NaCl \quad (8)$$

Both L^1 and L^2 and their complexes are highly soluble in chloroform and dichloromethane and moderately soluble in acetone. In methanol, ethanol and hexane the two ligands L^1 and L^2 are sparingly soluble. However on crystallization of **3** in acetone:hexane (2:1) mixture, the cleavage of L^1 occurs resulting in MeO C_6H_4HgBr (**4**) and [RTe^+–$HgBr_2$]Br^- (R = –$CH_2CH_2OCH_2CH_2CH_2$-(2-(6-CH_3-C_5H_3N))) (**5**) as shown in Eq. (9) given below.



(9)

The compound **4** is soluble in common organic solvents such as chloroform, dichloromethane whereas **5** is insoluble in organic solvents. The crystal structure of **4** is solved and reported earlier [24]. The molar conductance values Λ_M of the complexes **1**–**3**, **6**, **7**, and **8** in acetonitrile at ~1 mM concentration level have been recorded. The found values are much lower than the values expected for a 1:1 electrolyte. This suggests that all the complexes **1**–**3**, **6**, **7** and **8** are non–electrolytes. The molecular weights of complexes **1**–**3**, **6**, **7** and **8** determined in chloroform by vapour pressure osmometric method were found to be very close to the values calculated from their molecular formulae. This indicates that there is no appreciable dissociation of any of these complexes in the solution. The existence of metallomacrocycles in solution may be further strengthened with ^{125}Te NMR but inadequate solubility of **1** and **2** has restricted us.

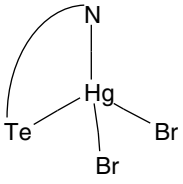
3.1. Infrared spectra

In the IR spectrum of $\mathbf{L}^1$ the bands appearing at 3060 cm^{-1} are due to C–H (aromatic) vibrations and those in the region 1456–1588 cm^{-1} due to C–C (aromatic) vibrations. The C–H (aliphatic) stretching vibrations appear at 2857–2936 cm^{-1} whereas ν(Te–C (aliphatic)) appears at 510 cm^{-1}. In IR spectrum of $\mathbf{L}^2$, the bands for C–H (aromatic) vibrations are observed at 3058 cm^{-1} while C–H (aliphatic) vibrations at 2854–2940 cm^{-1}. The band at 495 cm^{-1} seems to originate from ν(Te–C (aliphatic)). In the IR spectrum of **1**, ν(Te–C (aliphatic)) shows red shift as it appears at 478 cm^{-1}. The ν(Pd–Cl) in this spectrum appears at 357 cm^{-1} and is characteristic of a *trans* Cl–Pd–Cl system. In the IR spectrum of **2**, the bands appearing at 331 cm^{-1} may be assigned to the asymmetric stretching of *trans* Cl–Pt–Cl system. The band at 472 cm^{-1} seems to arise from Te–C (aliphatic) vibrations and show red shift of ~23 cm^{-1}. In the IR spectra of **3**, **4** and **5** a band is observed around 295 cm^{-1} which may be assigned to Hg–C/N vibrations. This indicates that in **5**, pyridine N interacts with Hg as shown for **3**. In the IR spectra of complexes **6** and **7**, the ν(M–Cl) appears at 351 and 334 cm^{-1}, respectively, indicating the presence of two *trans* M–Cl bonds (M = Pd or Pt) of a square planar complex. In the IR spectra of complexes **6** and **7** also, ν(Te–C (aliphatic)) appears at lower frequency (458 and 443 cm^{-1}, respectively) when compared to that of free ligand ($\mathbf{L}^2$). In the IR spectrum of **8**, the ν(M–Cl) due to two *trans* Pd–Cl appears at 351 cm^{-1} while the band at 481 cm^{-1} may be assigned to Te–C (aliphatic) vibrations. A red shift in this band in comparison to that of free $\mathbf{L}^2$supports the formation of M–Te bond. Similar red shifts in ν(Te–C (aliphatic)) band in the IR spectra of complexes **1**–**3** and **6** and **7** (described above) support the involvement of Te in coordination of the two ligands $\mathbf{L}^1$ and $\mathbf{L}^2$ with the metal ions.

3.2. ^{1}H NMR spectra

In the ^{1}H NMR spectrum $\mathbf{L}^1$, H_1 appears deshielded by ~1.2 ppm as compared to that of 2-[3-2-(chloroethoxy)propyl]-6-methylpyridine as the chlorine is replaced by a tellurium moiety. In the ^{1}H NMR spectrum of $\mathbf{L}^2$, H_1 protons merge with H_5 protons and appear as a multiplet with a deshielding of ~1.1 ppm as compared to 2-[3-(2-chloroethoxy)propyl]-6-methylpyridine again due to substitution of chlorine with tellurium moiety. In case of $\mathbf{L}^1$ the aromatic protons *ortho* to Te appear more deshielded as a doublet than expected as compared to *para* to Te which also appear as doublet. The pyridyl protons H_7 and H_9 in ^{1}H NMR spectrum of $\mathbf{L}^1$ appear merged as a multiplet whereas the H_8 appears as a triplet. In case of $\mathbf{L}^2$ also H_7 and H_9 appear as multiplet while H_8 appears as a triplet. The ^{1}H NMR spectrum of **1** and **2** were found to be similar and somewhat complex in the alkyl region. In the ^{1}H NMR spectrum of **2**, the two singlets at 7.26–7.28 are due to two chloroform molecules identified in the lattice of its single crystals. The H_1 proton appears to be maximum deshielded (~1.14–1.41 ppm) with respect to that of free ligand $\mathbf{L}^1$ as it coordinates through Te. Similarly, deshielding of H_5 with respect to free ligand is also large (~0.85 ppm) because

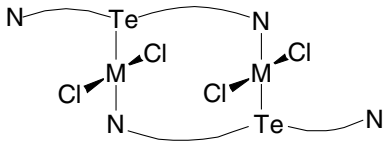
the ligand also coordinates via pyridine nitrogen, which is also reflected in the deshielding of H_{11} by ~1.1 ppm as compared to free $\mathbf{L}^1$. All other CH_2 protons also exhibit deshielding (~0.1–0.3 ppm). Some of them become non equivalent (viz. H_1, H_3 and H_5) also. Pyridine and aryl protons also appear deshielded (~0.1–0.3 ppm). In the proton NMR spectrum of **1** also maximum deshielding occurs for H_1 (~1.31–1.44 ppm) as compared to free ligand. The broad singlet at 7.24 is due to benzene molecule identified in the lattice of its single crystal. The signal for H_5 and H_{11} appear deshielded by ~0.6 and 0.3 ppm respectively, thereby indicating the binding of ligand through nitrogen pyridine also as in the case of **2**. The rigidity in the complex as compared to free ligand is probably responsible for the complexity observed in the proton NMR spectrum of complexes **1** and **2** in the alkyl region. In the proton NMR spectrum of **3**, the coordination shifts are not found to be significant as expected for a d^{10} system. Thus H_1 protons are not deshielded as expected for a d^{10} system. However H_5 protons appear to be deshielded by ~0.3 ppm as compared to that of free ligand $\mathbf{L}^1$, there by indicating the binding of pyridyl nitrogen to the metal centre. All the other protons viz. H_1, H_3, H_4 and the aromatic protons of pyridyl ring and methoxy phenyl group appear at almost the same position as that of free ligand $\mathbf{L}^1$.



(**3**) ($\mathbf{L^1}$ = Te~N)

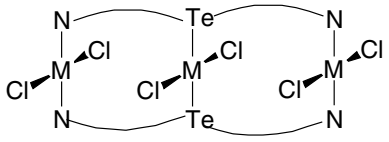
Most probably **3** has a tetrahedral structure given above which is corroborated by ^{13}C NMR and terminal ν(Hg–Br) bands observed in its IR spectrum.

The proton NMR spectrum of **4** and **5** are also characteristic. In the spectrum of **4** aromatic protons *ortho* and *meta* to Hg appear as doublet while OCH_3 protons appear as a singlet. In case of **5** the H_1 protons appear as multiplet and are deshielded by ~1.0 ppm as compared to those of ligand $\mathbf{L}^1$. This kind of decomposition by which **3** gives **4** and **5** is reported earlier also in tellurium chemistry [23]. The signals in the proton NMR spectra of **6** and **7** are broad in the aliphatic as well as aromatic region. Additional signals are also observed in proton NMR spectrum of **6** and **7** in the aromatic as well as aliphatic region. These additional signals are similar to those of free ligand $\mathbf{L}^2$. The multiplication of the signals may be due to free uncoordinated arm of the ligand $\mathbf{L}^2$ in **6** and **7**. The broadness of these signals may arise due to exchange between pendant and coordinated arms of $\mathbf{L}^2$. The most plausible structure of **6** and **7** may be presumed to be dimeric as shown below:



6 / 7 (M = Pd/ Pt)

On reacting $\mathbf{L}^2$ with Pd (II) according to Eq. (8), complex **8** results. The additional peaks like that of proton NMR spectra of **6** and **7** are not observed in its ^1H NMR spectrum. The spectrum not only becomes cleaner as compared to those of **6** and **7** but the signals also become sharp when compared with those of ^1H NMR spectrum of **6** and **7**. The aromatic protons show a deshielding (~0.12 ppm). These observations indicate that the free arm of ligand $\mathbf{L}^2$ present in **6/7** coordinates to third Pd atom to give a structure which is shown below.



(8)

3.3. ^{13}C $\{^1H\}$ NMR spectra

The ^{13}C $\{^1H\}$ NMR for **4** and **5** could not be recorded because of their low solubilities. In the carbon-13 NMR of **1**, the C_1 signal exhibits a deshielding of ~13 ppm with respect to that of $\mathbf{L}^1$ thereby indicating the coordination through Te. In the carbon-13 NMR spectrum of **2** also, the C_1 signal shows ~10 ppm deshielding with respect to that of $\mathbf{L}^1$ while the other carbons are deshielded to a lesser extent (<4 ppm). In the spectrum of **3**, the C_1 signal appears ~16 ppm deshielded with respect to free $\mathbf{L}^1$ which may be due to the coordination of Te to the metal centre. Additional signals are observed in carbon-13 NMR spectrum of **6** in the aliphatic and aromatic regions at δ 26.0, 28.9, 34.6, 68.2, 119.0, 121.0, 130.8. Similarly in the carbon-13 NMR spectrum of **7** also, additional peaks are observed at δ 24.0, 29.3, 34.7, 69.1, 119.0, 121.6, 136.7 ppm. These extra signals are due to pendant arm of $\mathbf{L}^2$ and are corroborated by the proton NMR spectra **6/7**. The carbon-13 NMR spectrum of **8** does not have additional signals as observed in the case of **6** and **7**. This may be due to the binding of uncoordinated arm of $\mathbf{L}^2$ of **6/7** with the metal centre in **8**, which is corroborated by its ^1H NMR spectrum. However, the compounds **6**,**7** and **8** do not have adequate solubility for ^{125}Te NMR. Moreover, failure to grow their single crystals suitable for X-ray diffraction has compelled us to propose structures with limited evidences.

3.4. Crystal structure

The details of the crystal structures of **2** and **4** have already been reported by us [10,24] and their molecular structures are shown in Figs. 2 and 3 for comparative purposes. The data for crystal and structure refinement of **1** are given in Table 1, selected bond lengths and angles in Table 2 and the molecular structure in Fig. 1. The immediate environment around Pd in **1** is essentially square planar consisting of the two *trans* Cl atoms along with the Te atom of one bridging ligand and the N atom of the other. This results in the formation of a 20-membered metallomacrocycle ring as has been reported for **2** (Fig. 2).

The Pd–Cl bond lengths 2.313(2)/2.295(2) Å are comparable to those (2.131(11) ave. Å) reported for three *trans* $PdCl_2L_2$ complexes, where L represents ligands bonding to Pd through Te [25,26]. In **1**, where a pyridine nitrogen is *trans* to Te, the Pd–Te bond lengths of 2.530(1)/2.5313(9) Å are considerably shorter than the sum of the respective covalent radii of 2.63 Å [1.31 Å square planar Pd(II) and 1.32 Å (tetrahedral Te)] and also shorter than those reported earlier (2.594(8) ave. Å) for the three compounds with two *trans* Te-ligands [25,26]. Conversely, the Pd–N bond lengths of 2.097(4) and 2.101(4) Å in **1** are longer than the sum of the respective covalent radii, 2.06 Å and also longer than that reported (2.086(2) Å) for a Pd–Te bond *cis* to Te [8]; also consistent with the strong *trans* influence of tellurium. The bond angles at Te and nitrogen are as expected for trigonal pyramidal and trigonal planar geometry, respectively. The Te–C(aryl) bond lengths 2.114(6)/2.118(5) Å are shorter than Te–C(alkyl) bond lengths 2.132(6)/2.138(5) Å and close to the earlier reported values of 2.116(20) and 2.158(30) Å [27], respectively.

A distinguishing feature of the 20-membered metallomacrocycle ring can be described as an approximate rectangle (or tetragon) denoted by the four sides Te(1)···N(2), N(2)···Te(2), Te(2)···N(1), and N(1)···Te(1) with distances of 4.625(5), 8.921(5), 4.630(5), and 9.081(5) Å, respectively. However, the rectangle is twisted such that the dihedral angles for Te(1)–Pd(1)···Pd(2)–N(1) and N(1)–Pd(1)···Pd(2)–Te(2) are 31.2(2)° and 31.7(2)°, respectively, when viewed down the Pd(1)···Pd(2) vector (8.905(2) Å). The related Cl(1)–Pd(1)···Pd(2)–Cl(3) and Cl(2)–Pd(1)···Pd(2)–Cl(4) dihedral angles are 26.8(2)° and 26.0(2)°, respectively. The C_3OC_2 chain of the long sides of the macrocyclic rectangle are arranged so that the C_3O section forms a roughly regular zig-zag chain but the final C_2 section deviates from this forming a trough-like arrangement at Te. This can be expressed by looking at the torsion angle of C(9)–O(2)–C(10)–C(11) which is −77.6(6)° as opposed to that

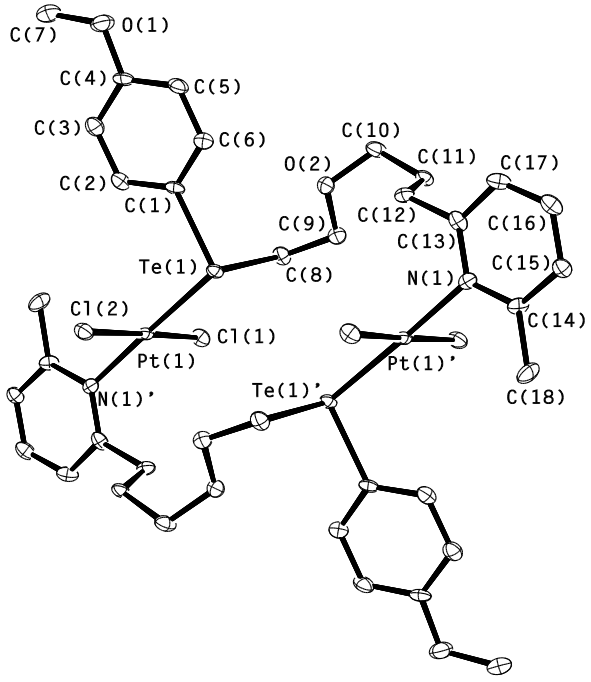


Fig. 2. Molecular structure of $[PtCl_2(\mathbf{L}^1)]_2 \cdot 2CHCl_3$ (**2**).

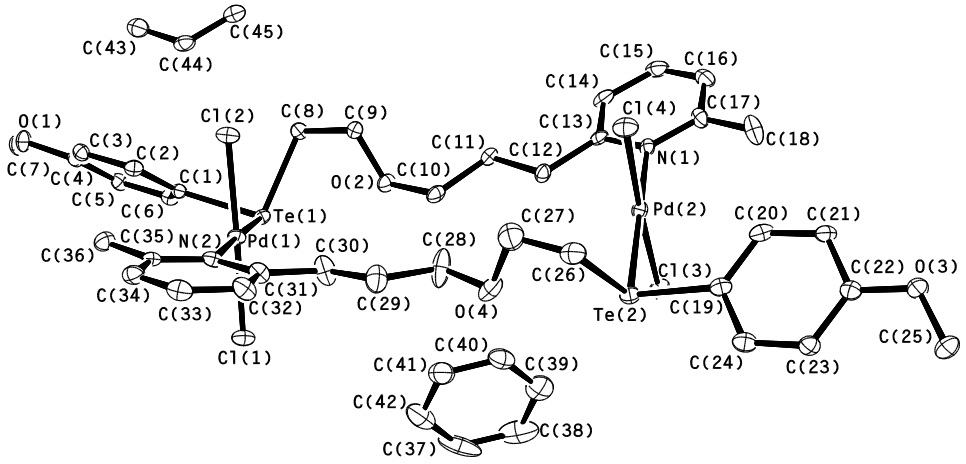

Fig. 1. Molecular structure of $[PdCl_2(\mathbf{L}^1)]_2 \cdot 1.5C_6H_6$ (**1**).

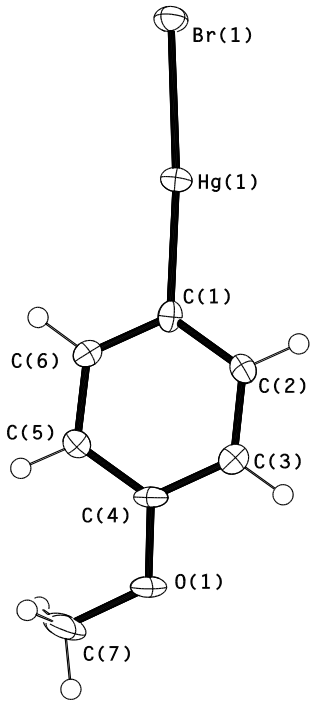

Fig. 3. Molecular structure of 4-$MeOC_6H_4HgBr$ (**4**).

of −176.7(6)° for the zig-zag section of C(12)–C(11)–C(10)–O(2). A similar geometry is observed along the other long edge with both troughs pointing in the same direction.

The relationship between the macrocycle and the solvate is such that one benzene molecule slots into the base of the macrocycle so that pairs of CH groups appear to be associated with two chlorine atoms H(39)···Cl(3), H(40)···Cl(3) and H(41)···Cl(1), H(42)···Cl(1) and also with that of an adjacent macrocycle below H(37)···Cl(1)′, H(38)···Cl(1)′. However the contact distances are all greater than 3.0 Å (CH···Cl distances being in the range 3.03–3.81 Å) and hence beyond the sum of the van der Waals radii. The other benzene molecule is sandwiched, side-on, between two phenyl (C_1–C_6) rings of adjacent macrocycles.

4. Conclusion

The potentially multidentate ligands 1-(4-methoxyphenyltelluro)-2-[3-(6-methyl-2-pyridyl)propoxy]ethane ($\mathbf{L}^1$) 2-methyl-6-{3-[2-({2-[3-(6-methyl-2-pyridyl)propoxy]ethyl}-telluranyl)ethoxy]propyl}pyridine ($\mathbf{L}^2$) have been synthesized. The $\mathbf{L}^1$ is used to design 20-membered metallomacocycles with Pd(II) and Pt(II). The **1** and **2** are the first examples of the formation of 20-membered metallomacrocycle ring by a hybrid organotellurium ligand. The decomposition of $\mathbf{L}^1$ in its mercury complex appears to be metal promoted. The **4** is the first linear ArHgX system characterized fully by X-ray diffraction on its single crystals.

5. Supplementary material

CCDC-285432 contains the supplementary crystallographic data for **1**. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; fax: (internat.) +44 1223 336 033, e-mail: deposit@ccdc.cam.ac.uk].

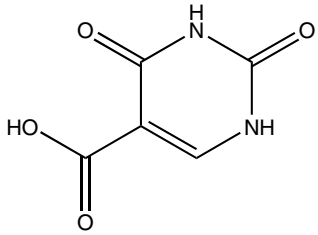

Scheme 1. Uracil-5-carboxylic acid.

sites. Additionally, it has two N–H sites which can act either protonated as hydrogen bond donor sites, or deprotonated as coordination sites. With this versatility in mind we carried out the synthesis in aqueous solution and crystallographic characterisation of alkali metal (Na–Cs) complexes of U5CAH to examine both the coordination behaviour at the metal centre and the hydrogen bonding geometries in each compound.

We succeeded in obtaining compounds for all four metal ions. By varying the reaction stoichiometry and crystallisation conditions we were able to obtain two separate rubidium compounds, one with coordinated water and one with uncoordinated but hydrogen-bonded water as solvent of crystallisation. The remaining reaction systems are unaffected by changing the method of crystallisation. In the case of potassium a neutral ligand is also coordinated. All compounds are polymeric, as would be expected with a ligand containing extensive coordination and hydrogen bonding sites. In the case of the potassium complex **2** and one of the rubidium complexes **4** the crystals were too weakly diffracting for adequate data collection using a standard laboratory X-ray source. Data for these compounds were collected at Station 9.8 of the SRS at Daresbury Laboratory, Cheshire, England, as part of the EPSRC National X-ray Crystallography Service.

The compounds presented here are: $[Na(C_5H_3N_2O_4)(H_2O)]_\infty$ (**1**); $[K(C_5H_3N_2O_4)(C_5H_4N_2O_4)]_\infty$ (**2**); $[Rb\{H(C_5H_3N_2O_4)_2\}\cdot 2H_2O]_\infty$ (**3**); $[Rb(C_5H_3N_2O_4)(H_2O)]_\infty$ (**4**); $[Cs\{H(C_5H_3N_2O_4)_2\}(H_2O)_2]_\infty$ (**5**).

2. Experimental

U5CAH monohydrate was purchased from Avocado Chemicals and used without purification. Elemental analyses were not always possible, due to the very small amount of product obtained, or due to rapid solvent loss when the crystals were separated from the mother liquor. Since the principal aim of the study was crystallographic, we developed procedures to obtain crystals of the compounds for X-ray analysis and did not attempt to optimise the synthetic methods, and therefore the yields are rather low.

2.1. Synthesis

2.1.1. $[Na(C_5H_3N_2O_4)(H_2O)]_\infty$ (1)

0.172 g (1 mmol) of U5CAH was dissolved in 20 cm^3 of distilled water. To this was added a solution of 0.05 g (0.5 mmol) Na_2CO_3 in 10 cm^3 distilled water. The mixture was boiled until around 15 cm^3 remained and the solution was then transferred to a separate vial, sealed and stored at

approximately 5 °C. After 1 week a very small amount of crystals of **1** had formed. As a result of this it was not possible to obtain further analytical data for **1**.

2.1.2. $[K(C_5H_3N_2O_4)(C_5H_4N_2O_4)]_\infty$ (**2**)

0.184 g (1 mmol) of U5CAH was dissolved in 20 cm^3 of distilled water. To this was added a solution of 0.06 g (0.5 mmol) K_2CO_3 dissolved in 10 cm^3 distilled water. The mixture was boiled until around 15 cm^3 remained and the solution was transferred to a separate sealed vial. After 1 h of standing at room temperature a large mass of lath-shaped colourless crystals of **2** was obtained; yield 0.072 g, 20%. *Anal.* Calc. for **2**: C, 34.50; H, 2.00; N, 15.50. Found: C, 34.70; H, 2.35; N, 15.65%.

2.1.3. $[Rb\{H(C_5H_3N_2O_4)_2\}\cdot 2H_2O]_\infty$ (**3**)

0.171 g (1 mmol) of U5CAH was dissolved in 20 cm^3 of distilled water. To this was added a solution of 0.121 g (0.5 mmol) Rb_2CO_3 dissolved in 10 cm^3 distilled water. The mixture was boiled until around 15 cm^3 remained and the solution was transferred to a separate sealed vial. After 1 h of standing at room temperature a large mass of needle-shaped colourless crystals of **3** was obtained; yield 0.130 g, 31%. *Anal.* Calc. for **3**: C, 27.90; H, 2.55; N, 12.55. Found: C, 27.80; H, 2.60; N, 12.80%.

2.1.4. $[Rb(C_5H_3N_2O_4)(H_2O)]_\infty$ (**4**)

0.174 g (1 mmol) of U5CAH was dissolved in 20 cm^3 of distilled water. To this was added a solution of 0.238 g (1 mmol) Rb_2CO_3 dissolved in 10 cm^3 distilled water. The mixture was boiled until around 15 cm^3 remained and the solution was transferred to a separate sealed vial. Standing for several months at 5 °C failed to induce crystallisation, so the method of slow solvent evaporation was tried. After

around 2 weeks the solvent had evaporated to leave a very small amount of plate-shaped crystals. The amount of crystals produced was too small to enable any further analysis to be carried out.

2.1.5. $[Cs\{H(C_5H_3N_2O_4)_2\}(H_2O)_2]_\infty$ (5)

0.179 g (1 mmol) of U5CAH was dissolved in 20 cm^3 of distilled water. To this was added a solution of 0.162 g (1 mmol) $Cs(OH)\cdot H_2O$ dissolved in 10 cm^3 distilled water. The mixture was boiled until around 15 cm^3 remained and the solution was transferred to a separate sealed vial. After 1 h of standing at room temperature a large mass of small needle-shaped colourless crystals of **5** was obtained; yield 0.135 g, 29%. *Anal.* Calc. for **5**: C, 25.10; H, 2.10; N, 11.30. Found: C, 25.15; H, 2.35; N, 11.40%.

2.2. X-ray crystallography

Experimental conditions and crystallographic data parameters for all compounds are summarised in Table 1. For **1** and **5** data collection was carried out by using COLLECT [17], with cell refinement and integration using EVALCCD [18]. For **2** and **4** data collection was carried out with APEX2 [19], with cell refinement and integration by SAINT [20]. For **3** data collection was by SMART [21], with cell refinement and integration by SAINT. Semi-empirical absorption corrections, based on symmetry-equivalent and repeated reflections, were applied to all datasets using SADABS [22]. Structure solution was by direct methods using either SIR-2002 [23] (**2**, **3** and **5**) or SHELXTL [24]. For all compounds refinement was by full-matrix least-squares on F^2 using SHELXTL, with all non-hydrogen atoms refined anisotropically. All molecular diagrams were produced with DIAMOND-3 [25]. Details of hydrogen atom treatment and non-standard individual refinement strategies (where appropriate) are given below.

2.2.1. Hydrogen atom treatment

2.2.1.1. Compound ***1***. Hydrogen atoms were all located in a difference Fourier map. The C–H hydrogen atom was then constrained as riding, with a C–H bond length of 0.95 Å and $U_{iso}(H) = 1.2U_{eq}(C)$. The N–H and water hydrogen atoms were refined with $U_{iso}(H) = 1.2U_{eq}(N,O)$ but there were no constraints on the geometry.

2.2.1.2. Compound ***2***. Hydrogen atoms were all located in a difference Fourier map. The C–H hydrogen atoms were treated as above. The N–H hydrogen atoms were refined with $U_{iso}(H) = 1.2U_{eq}(N)$ and the N–H bond lengths were

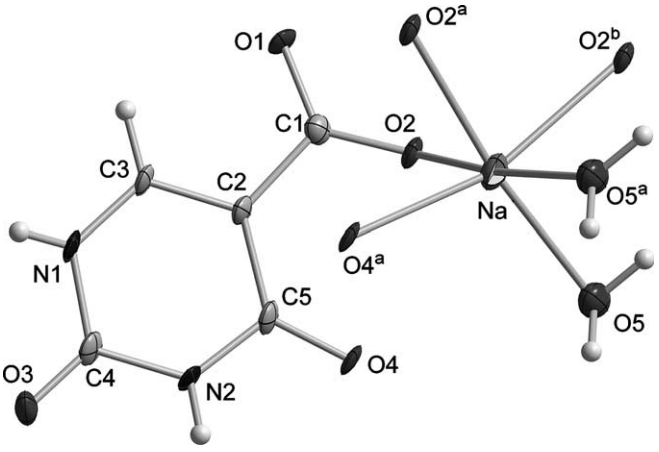

Fig. 1. The asymmetric unit of **1** (50% displacement ellipsoids) expanded to show the Na coordination sphere. Symmetry operators: a, $x-1$, y, z; b, $-x+1$, $-y+1$, $-z+2$.

restrained to 0.85(2) Å. The O–H hydrogen atom position was freely refined.

*2.2.1.3. Compounds **3** and **4**.* Hydrogen atoms were all located in a difference Fourier map. The C–H hydrogen atom was treated as above. The N–H bond lengths were restrained to 0.85(3) Å; all other parameters for these and the remaining hydrogen atoms were freely refined.

*2.2.1.4. Compound **5**.* Hydrogen atoms were all located in a difference Fourier map. The C–H hydrogen atom was treated as above. The water and N–H hydrogen atoms were refined with $U_{iso}(H) = 1.2U_{eq}(N,O)$ and the water O–H bond lengths were restrained to 0.85(1) Å with the H···H distance restrained to 1.35(2) Å. The H atom on an inversion centre was constrained to this position, but its displacement parameter was freely refined.

3. Results and discussion

The structural discussions refer to hydrogen bonding motifs described in graph set notation [26,27]. This takes the general form $R_d^a(n)$ where R = ring motif, a = number of hydrogen bonding acceptor sites, d = number of hydrogen bonding acceptor sites, and n = total number of atoms making up the motif. Selected geometrical parameters for all compounds are given in Table 2, with hydrogen bonding geometry given in Table 3.

3.1. $[Na(C_5H_3N_2O_4)(H_2O)]_\infty$ (**1**)

The asymmetric unit of **1**, expanded to show the full coordination sphere of the Na centre, is shown in Fig. 1. It consists of one Na^+ cation, one U5CA$^-$ anion and a coordinated water molecule. The Na centre is six-coordinate and has distorted octahedral geometry with only O2, O4 and O5 coordinating. In the crystal packing, O2 bridges three centres, O5 (the water molecule) bridges two centres and O4 is terminally coordinating. O1 and O3 coordinate to no Na centre but are instead involved in hydrogen bonding (discussed below). The result of this coordination is a ladder packing motif (Fig. 2) formed by dimerisation of the asymmetric unit about the crystallographic inversion centre; these dimers then extend by metal–ligand coordination in one direction only to give a polymeric chain.

There is no cross-coordination between the individual separate chains, as O1 and O3 do not coordinate, and so there is only hydrogen bonding to hold the different chains together to form the overall crystal structure. The extent of hydrogen bonding is most easily appreciated by considering two *a*-axis packing diagrams (looking along the chains), one with the hydrogen bonds omitted and a second with them included (Fig. 3). The hydrogen bonding is extensive, with O1, O3 and O4 all acting as acceptor sites (O1 and O3 are both bifurcated acceptors). An $R_2^2(8)$ motif links together the amide groups of two ligands, a very common hydrogen bonding interaction in structures featuring this type of molecule. There is also strong evidence to suggest a C–H···O interaction is present in this structure; the relevant hydrogen bonding parameters are in good agreement with typical values for a weak C–H···O interaction [28]. Finally, both hydrogen atoms of the water molecule are donor sites, but the water does not act as a hydrogen bond acceptor in this structure, since it bridges two Na centres.

Covalent bonding within the structure is unexceptional; the uracil ring is planar and the carboxylate group is twisted slightly out of the ring plane [the O2–C1–C2–C5 torsion angle is −11.3(5)°].

3.2. $[K(C_5H_3N_2O_4)(C_5H_4N_2O_4)]_\infty$ (**2**)

Despite the reasonable size of the crystals obtained of this compound, they proved to be rather weakly diffracting. Data collected using a standard X-ray tube with very long

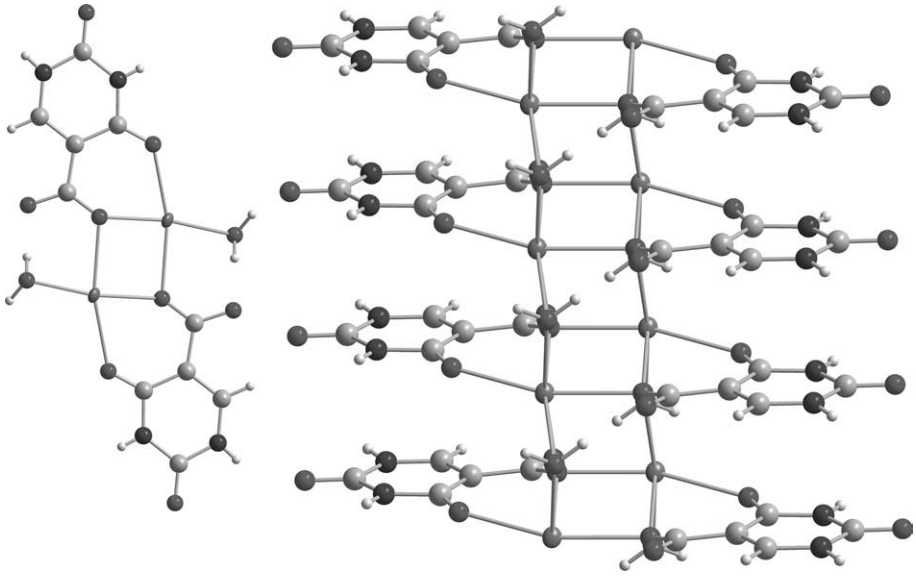

Fig. 2. The dimer and the ladder-like chain packing motif in **1**.

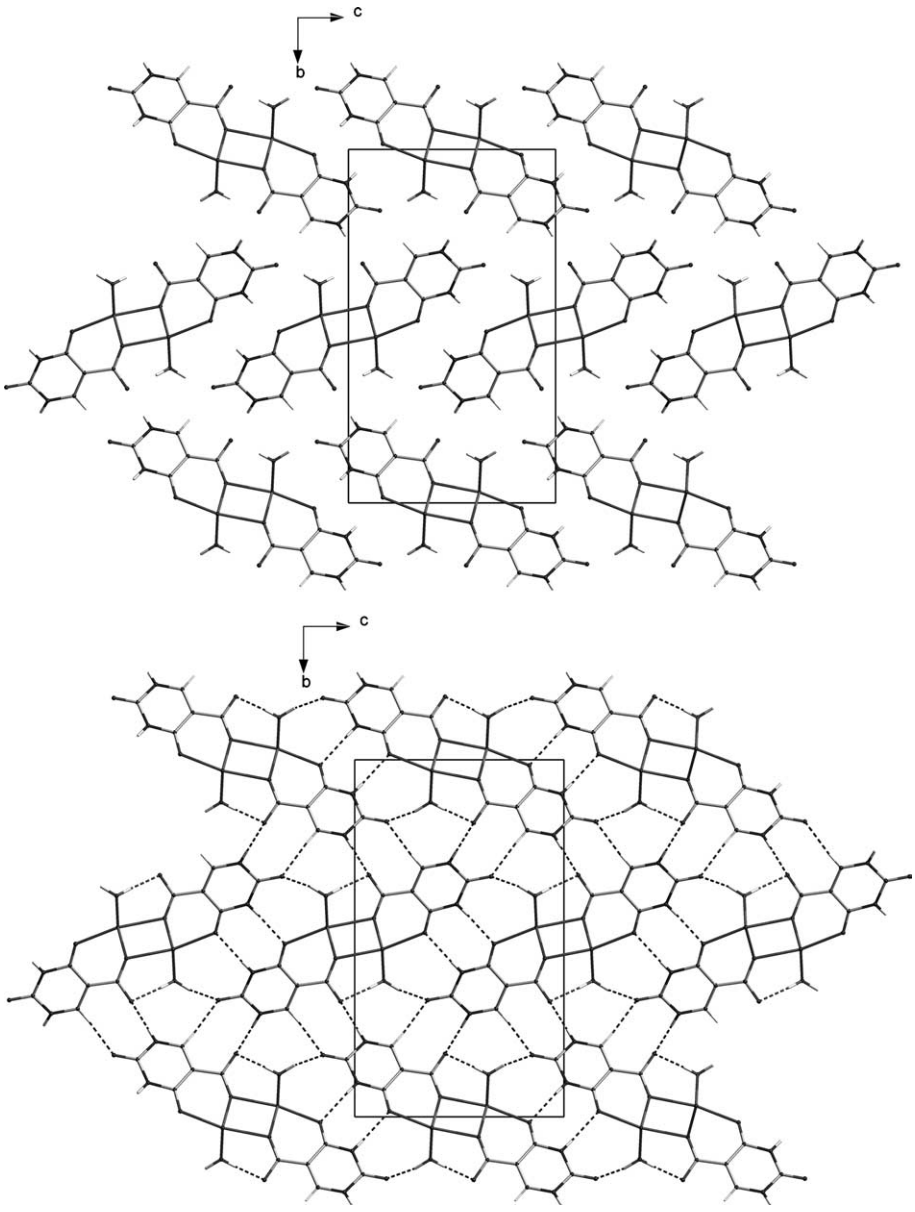

Fig. 3. Two *a*-axis packing views of **1**. The top view shows the packing without hydrogen bonding, the bottom view is identical but has the hydrogen bonding indicated by dashed lines.

exposure times (150 s per frame) were sufficient to allow structural solution and to define molecular connectivity. However, they were too weak to allow satisfactory refinement of the structure. Therefore, data were collected with synchrotron radiation, and were of much greater intensity and quality than could ever have been obtained with laboratory equipment. The structure of this compound is presented in space group *Cc*. The ADDSYM function of PLATON [29] detects a possible missed symmetry element (twofold rotation) and suggests that the true space group is actually *C*2/*c*. *Cc* and *C*2/*c* are indistinguishable from one another purely on the basis of the systematic absences in the diffraction data, so it is generally the case that an identified additional twofold rotation in space group *Cc* indicates that the true space group is *C*2/*c* [30]. However, refinement in *C*2/*c* requires that the ligand be disordered and that the K^+ ion and the O–H hydrogen atom lie on special positions in order that the charges balance. The final $R = 0.072$ in space group *C*2/*c* is much poorer than the final value in space group *Cc* (0.042), and refinement of the enantiopole parameter gives a value of 0.19(8), much closer to zero than to 0.5 [31]; these observations, combined with the fact that the structure is ordered in *Cc*, leads us to believe that, in this instance, the correct space group is *Cc*.

The asymmetric unit of **2**, expanded to show the full coordination sphere of the K centre, is shown in Fig. 4. There is no water present and the asymmetric unit consists of one K^+ cation, one $U5CA^-$ anion and one neutral U5CAH molecule. This is despite the reaction stoichiome-

try, which was deliberately kept at 1:1 K:U5CAH in an attempt to prevent an excess of unreacted ligand being incorporated into the structure. The K centre is seven-coordinate and K–O bond lengths are unexceptional. The coordination geometry is perhaps best described as being square antiprismatic (as is found with eight-coordinate complexes) with one of the vertices removed, rather than a 4:3 piano stool-type geometry which is found in seven-coordinate transition metal complexes. There is some distortion in the angles around the K centre when compared to a square antiprism, but much less than for a piano stool geometry. For example, the O6–K–O8[a] angle is 159.08(10)°, much larger than typical square antiprismatic bond angles. O5 and O8 also act together to chelate the K centre. Within each ligand molecular dimensions agree with expected values [13] and the carboxylate groups of both ligands are essentially coplanar with the uracil ring (RMS deviations of mean planes fitted through all non-H atoms are 0.041 and 0.047 Å for the neutral and deprotonated ligands, respectively).

As with compound **1** there is extensive hydrogen bonding in this structure. The crystal packing consists of roughly planar sheets of hydrogen-bonded U5CA$^-$ anions and U5CAH molecules. The sheet structure is shown in Fig. 5 and it consists of hydrogen-bonded ribbons which run parallel to the *b* and *c* axes; these ribbons are hydrogen bonded together to form the 2D grid-like arrangement in the sheet structure. Running parallel to the *b*-axis the ligands are held together by two very common hydrogen bonding motifs: the $R_2^2(8)$ motif between the amide groups and the single short strong O–H···O interaction between the carboxylate and carboxylic acid groups, a fairly common observation in hydrogen-bonded carboxylic acid structures. These are then linked by further hydrogen bonding parallel to the *c*-axis; the motifs observed in this direction are rather less common and are generally longer and weaker. The remaining amide group acts as a bifurcated donor forming two rather bent hydrogen bonds and, as was observed in **1**, there is evidence to support the presence once again of a C–H···O interaction. This is part of an $R_2^2(9)$ motif, somewhat rarer than the $R_2^2(8)$ motif observed parallel to the *b*-axis.

These hydrogen-bonded sheets are coordinated to and separated by the K$^+$ cations, which do not lie in the hydrogen-bonded plane (Fig. 6). The inter-sheet separation distance is about 3.22 Å; overlapping rings are laterally displaced by approximately half a ring diameter, as is usually found in stacked aromatic systems, so that the shortest distance between the centroids of neighbouring rings is 3.72 Å; these rings are not symmetry-related to each other, so they are not precisely parallel. These are characteristics of π stacking, which contributes to the cohesion of this structure in addition to the polymeric coordination network and the hydrogen bonding.

3.3. $[Rb\{H(C_5H_3N_2O_4)_2\}\cdot 2H_2O]_\infty$ (**3**)

There are three particularly unusual aspects of this compound in the series. The first is the sensitivity of the reaction to stoichiometry, as a second rubidium complex was also obtained and is discussed below (compound **4**). Second, the water molecule is present as hydrogen-bonded solvent of crystallisation and is not coordinated to the rubidium centre. Finally, there is peculiar behaviour of

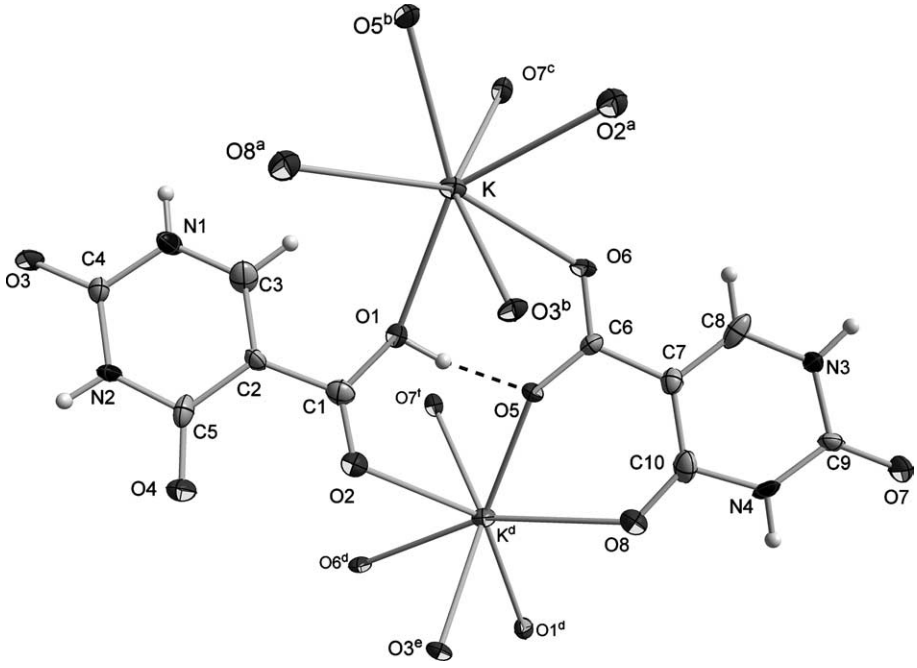

Fig. 4. The asymmetric unit of **2** (50% displacement ellipsoids) expanded to show the K coordination and the chelating nature of the UC5A$^-$ ligand. Symmetry operators: a, $x, -y+1, z+1/2$; b, $x-1/2, y-1/2, z$; c, $x+1/2, y-1/2, z+1/2$; d, $x, -y+1, z-1/2$; e, $x-1/2, -y+3/2, z-1/2$; f, $x+1/2, y+1/2, z$.

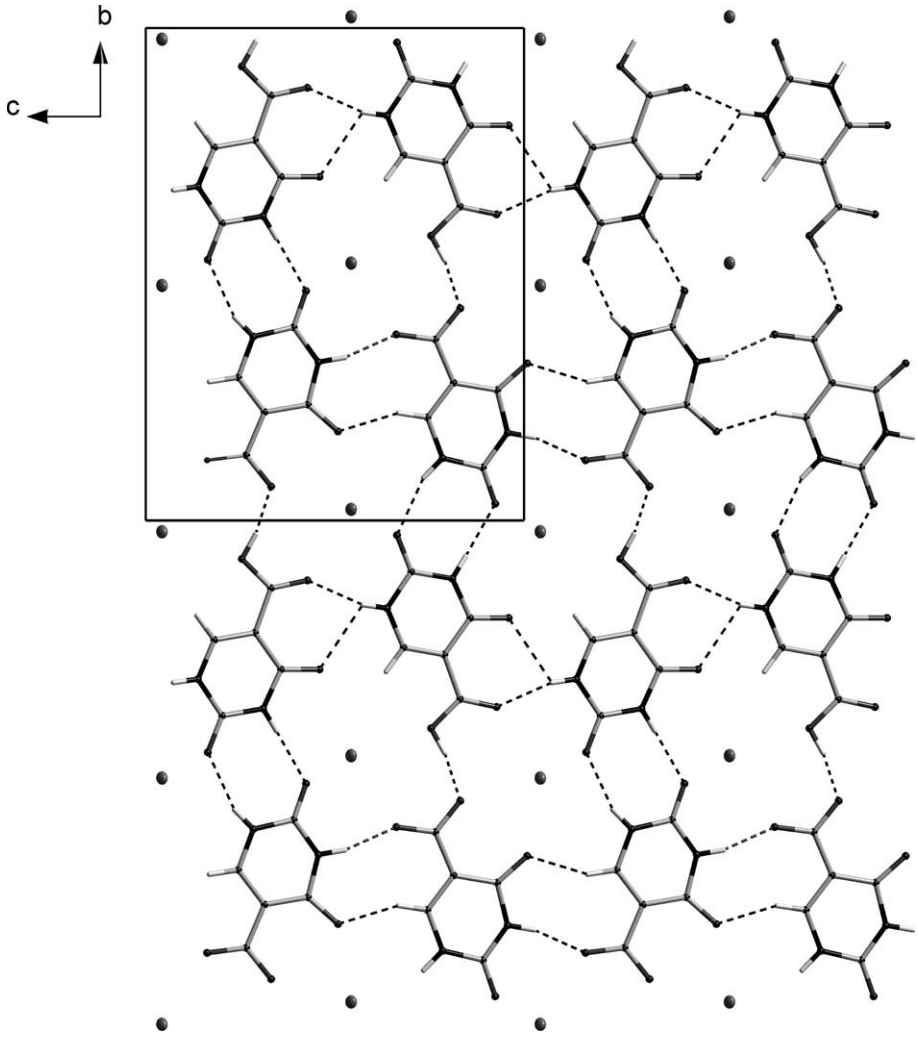

Fig. 5. The sheet structure formed by hydrogen bonding between the ligands of **2**. Coordination bonds to K have been removed for clarity of viewing and hydrogen bonding is denoted by dashed lines. It should be noted that the K^+ ions do not lie in the hydrogen-bonded plane.

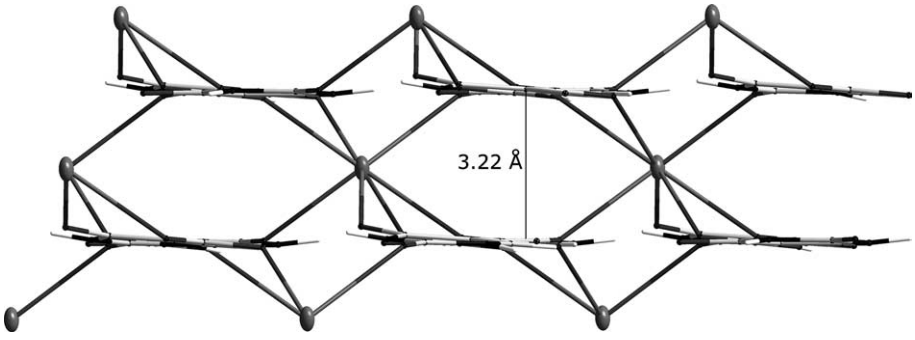

Fig. 6. The coordination of K^+ by the hydrogen-bonded ligand sheets in **2** with the short inter-sheet distance marked in Å. Note that the ligands of each sheet do not directly overlap.

the carboxylic acid group, which is only partially deprotonated and results in a hydrogen atom symmetrically shared between two carboxylate groups.

The asymmetric unit of **3**, expanded to show the full coordination of the rubidium centre, is shown in Fig. 7. The Rb centre is eight-coordinate and the eight coordinating oxygen atoms are located approximately on the eight corners of a cube with Rb at its centre, unusual in the sense that square antiprismatic geometry is more typical of an eight-coordinate complex. The ligand is chelating to the Rb centre via O1 and O3; Rb–O lengths are unexceptional, the uracil ring is essentially planar and the carboxylate group is twisted slightly out of the ring plane [the O1–C1–C2–C3 torsion angle is 6.8(5)°].

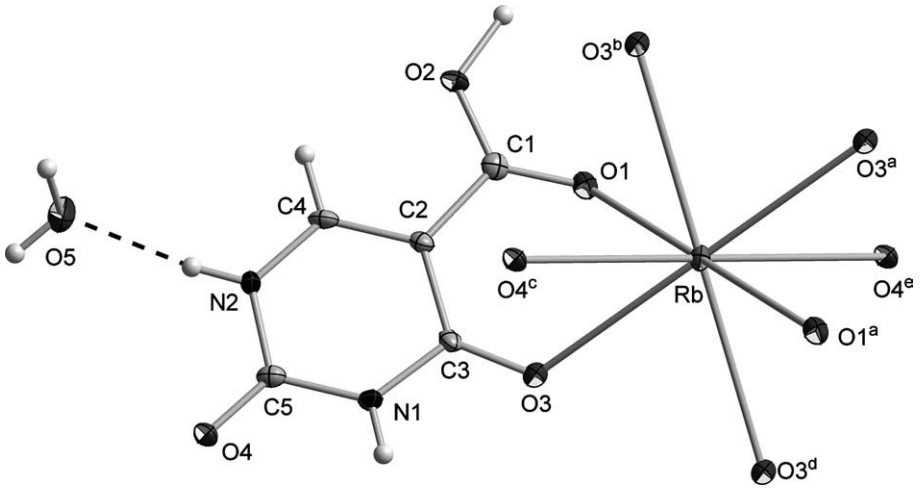

Fig. 7. The asymmetric unit of **3** (50% displacement ellipsoids) expanded to show the Rb coordination. Symmetry operators: a, $-x$, $-y$, $-z$; b, $x-1$, y, z; c, $-x+1$, $-y+1$, $-z$; d, $-x+1$, $-y$, $-z$; e, $x-1$, $y-1$, z.

The stoichiometry used in this reaction was 1:1 Rb:U5-CAH with the intention that the ligand be fully deprotonated, leaving no neutral ligand in solution. However, as was seen in **2**, this is not this case here. Unlike **2**, where separately identifiable fully deprotonated and neutral U5CAH molecules are present in the structure, here the ligands are all crystallographically equivalent. We can be certain that only partial deprotonation has occurred, since the Rb^+ cation and the O–H hydrogen atom are both located on crystallographic inversion centres. This means that both carry an effective charge of 0.5+ in the asymmetric unit, which together balance out the negative charge of the $U5CA^-$ anion. The H atom on the inversion centre is bonded symmetrically to carboxylate oxygen atoms of two ligands (Fig. 8). This gives O–H bond lengths of 1.210(2) Å, too long for a standard O–H covalent bond and shorter than an O···H hydrogen bond interaction. Such a symmetrical hydrogen bond is usually associated with a very short O···O distance, which here is 2.420 Å. Attempts to refine the hydrogen atom as disordered on either side of the inversion centre were unsuccessful; it always moved back to the inversion centre. It is always difficult to draw firm conclusions about the position of a hydrogen atom based on X-ray diffraction data alone. However, based on our other observations about the inter-oxygen distance and the hydrogen atom behaviour during refinement we can be confident about the location of this hydrogen atom and we can draw the conclusion that only partial deprotonation of U5CAH has occurred in **3**.

The crystal packing in **3** is characterised by the coordination of the ligand to the metal centre to form a 2D layer network in the *ab*-plane. Within this network is a hydrogen-bonded water molecule; both hydrogen atoms are hydrogen bond donors and the water also acts as a single hydrogen bond acceptor. A projection along the *b*-axis (Fig. 9) shows how these 2D networks are linked together. There is only one interaction and that is the O···H···O hydrogen bonding which joins the 2D networks together into an overall 3D structure. There is no other type of interaction, including any C–H···O bonding, linking the 2D networks together.

3.4. $[Rb(C_5H_3N_2O_4)(H_2O)]_\infty$ (**4**)

As was commented upon in the structural discussion of **3**, the Rb/U5CAH reaction system is sensitive to the stoichiometry used. For the synthesis of this compound the Rb:U5CAH ratio was 2:1 and this led to full deprotonation of U5CAH and not the partial deprotonation observed in **3**. The method of crystallisation was also quite different; whilst crystals of **3** grew as the reaction mixture cooled, crystals of **4** had to be obtained by subsequent solvent evaporation. The crystals were too small for analysis with a standard laboratory X-ray source so data were collected with synchrotron radiation.

Whilst having the same empirical formula as **3**, compound **4** has a rather different structure. The asymmetric unit of **4** is shown in Fig. 10 and immediately the structural

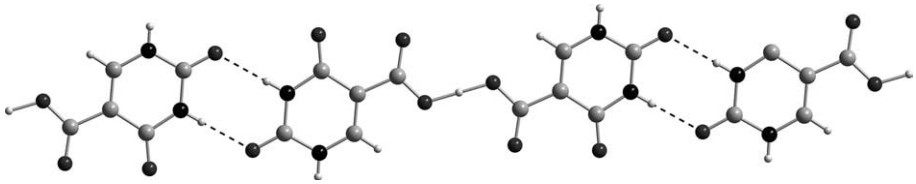

Fig. 8. The hydrogen-bonded ligand tape structure in **3**. Note the centrosymmetric hydrogen atom between the two carboxylate groups.

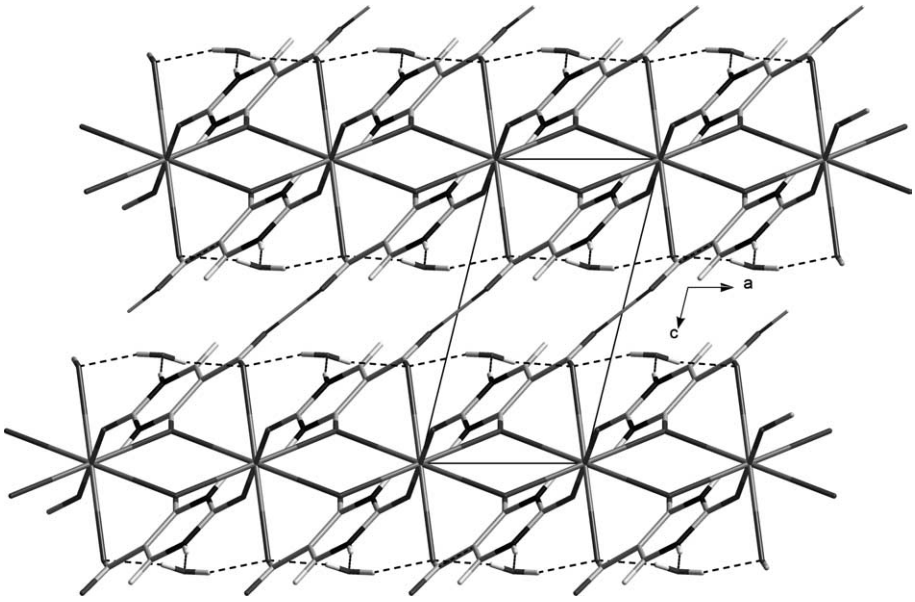

Fig. 9. A projection along the *b*-axis of **3** showing how the single centrosymmetric O···H···O interaction links the 2D networks together.

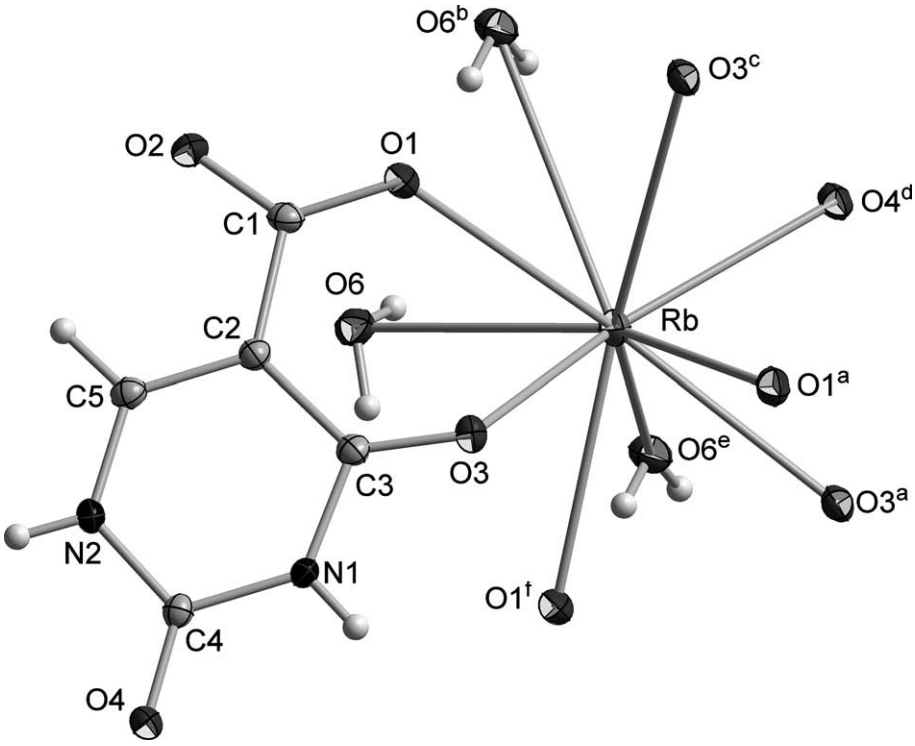

Fig. 10. The asymmetric unit of **4** (50% displacement ellipsoids) expanded to show the full coordination Rb sphere. Symmetry operators: a, $-x$, $y + 1/2$, $-z + 1/2$; b, $-x + 1$, $y - 1/2$, $z - 1/2$; c, $-x$, $y - 1/2$, $-z + 1/2$; d, x, $-y + 3/2$, $z - 1/2$; e, $-x + 1$, $y + 1/2$, $-z + 1/2$; f, x, $y + 1$, z.

differences are clear. The Rb centre is now 10-coordinate, with the water molecule also coordinated (cf. eight-coordinate and non-coordinated water in **3**). The range of Rb–O bond lengths is much wider, from the short 2.7577(12) Å to the very long 3.5046(14) Å. As seen in **2** and **3**, the ligand is chelating, with the carboxylate group essentially coplanar with the uracil ring.

Hydrogen bonding is once again extensive in the crystal packing. The ligands form hydrogen-bonded tapes (Fig. 11) with the familiar $R_2^2(8)$ motif between the amide groups again present; as with **1** and **2** there is also evidence of a weak C–H···O interaction forming part of the tape, something absent in **3**. The tapes are linked together by hydrogen bonding through the water molecule and by substantial coordination to the Rb centre. Unlike the previous examples the tapes are not coplanar and do not form sheets. Instead they pack as stacked tapes in two different orientations (Fig. 12). The angle between two mean planes fitted

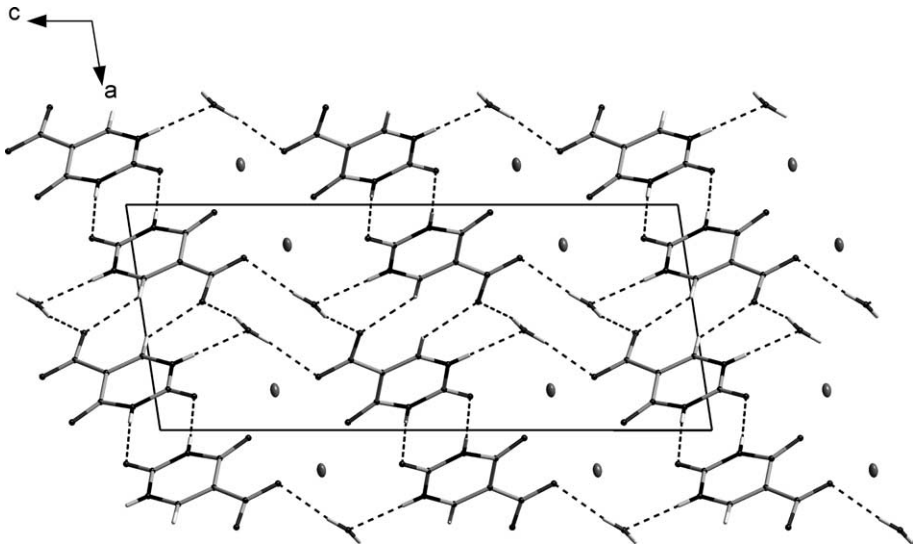

Fig. 11. A *b*-axis projection of the crystal packing of **4**. Coordination bonds to the Rb centre are not shown for clarity.

through two uracil molecules in these different orientations is approximately 74°. Fig. 12 also suggests that there are some weak stacking interactions between the uracil molecules in the stacked tapes. The distance between the tapes is approximately 3.9 Å and at this distance it is unlikely that any stacking interaction has a real influence on the crystal packing; it is probably a consequence, rather than a cause of the structure.

3.5. $[Cs\{H(C_5H_3N_2O_4)_2\}(H_2O)_2]_\infty$ (**5**)

The final compound in this series combines in one structure some of the structural motifs and features observed in previous compounds. Like **2**, the ligands take the form of hydrogen-bonded sheets and, as in **3**, we see again only partial deprotonation of the ligand, which leads to centrosymmetric hydrogen bonding between the carboxylate groups. The asymmetric unit of **5**, expanded to show the full Cs coordination sphere, is shown in Fig. 13. As with **4**, the Cs centre is 10-coordinate, although the Cs–O bond length range [3.1457(19)–3.498(2) Å] is not quite as wide as the Rb–O range in **4**. The carboxylate group is essentially coplanar with the uracil ring and the ligand again is chelating.

As with **3** the partial deprotonation of U5CAH creates a similar charge-balance issue, with the Cs^+ cation and the O···H···O hydrogen atom both located on crystallographic inversion centres. For the reasons discussed in **3**

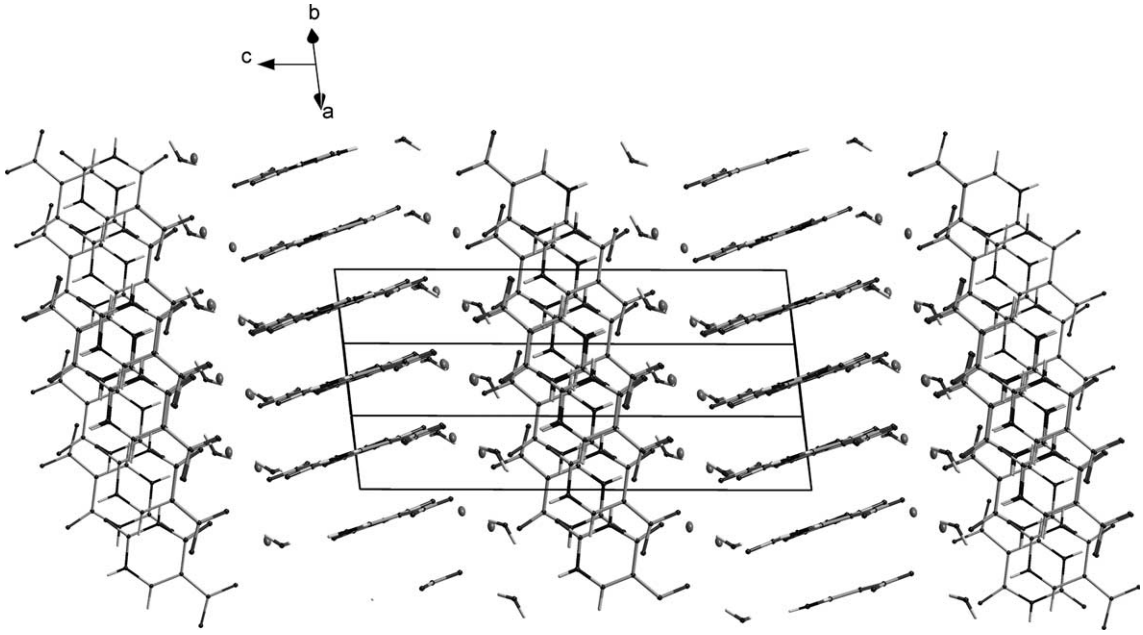

Fig. 12. An alternative view of the crystal packing of **4** showing the two different packing orientations of the hydrogen bonded tapes. Coordination to the Rb centres and hydrogen bonding interactions are not shown for clarity.

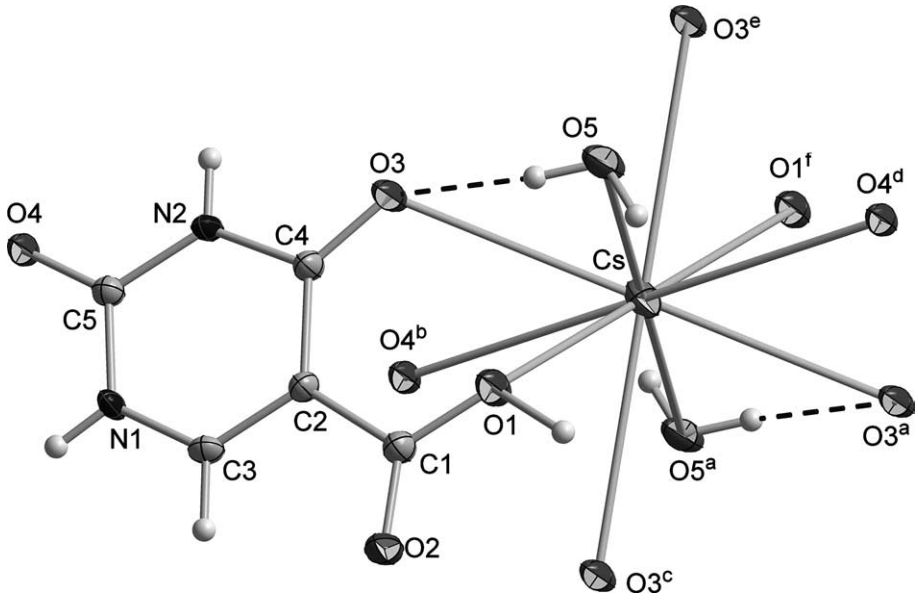

Fig. 13. The asymmetric unit of **5** (50% probability displacement ellipsoids) expanded to show the full coordination sphere of Cs. Dashed lines denote hydrogen bonds. Symmetry operators: a, $x-1, -y, z-1$; b, $-x, -y, -z+2$; c, $x+1, y, z$; d, $x+1, y, z-1$; e, $-x, -y, -1+z$; f, $-x+1, -y, -z+1$.

relating to the very short O···O distance and the behaviour of the hydrogen atom during refinement, we are satisfied that this atom is centrosymmetrically located between two carboxylate groups. The reaction stoichiometry used was Cs:U5CAH 1:1; use of an excess of base failed to give any product despite several different methods of synthesis and crystallisation.

Unlike the denser network structures formed in **3** and **4**, the crystal packing of **5** is much simpler and shares similarities with **2**. Fig. 14 gives a representation of the hydrogen bonding motifs formed between the ligand and water molecules. As we have observed throughout this study, weak C–H···O interactions play an important role in the hydrogen bonding of these compounds, and here once again we have evidence suggesting a C–H···O interaction is present. The ligand and water molecules hydrogen bond together to form approximately planar sheets featuring a quasi-rosette-shaped motif with a central cavity occupied by the Cs^+ cation. Compound **3** also features a sheet structure formed by hydrogen bonding, but the K^+ cations were situated in the inter-sheet spacing. In compound **5** the cavity formed by the rosette motif is large enough to accommodate the

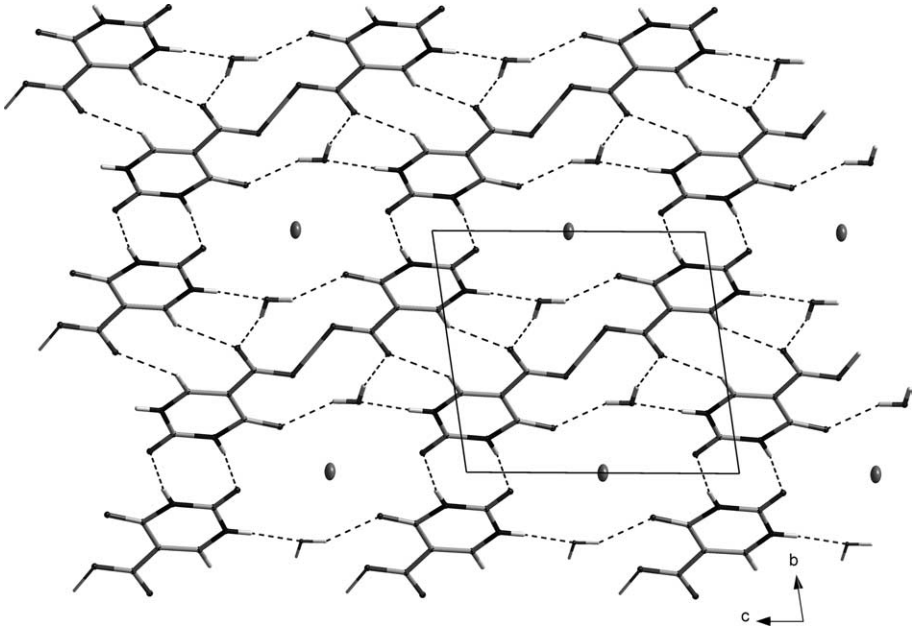

Fig. 14. The hydrogen-bonded sheet formed by the U5CA and water molecules. Note the rosette-like motif formed by the hydrogen bonding. Cs–O coordination bonds are not shown for clarity.

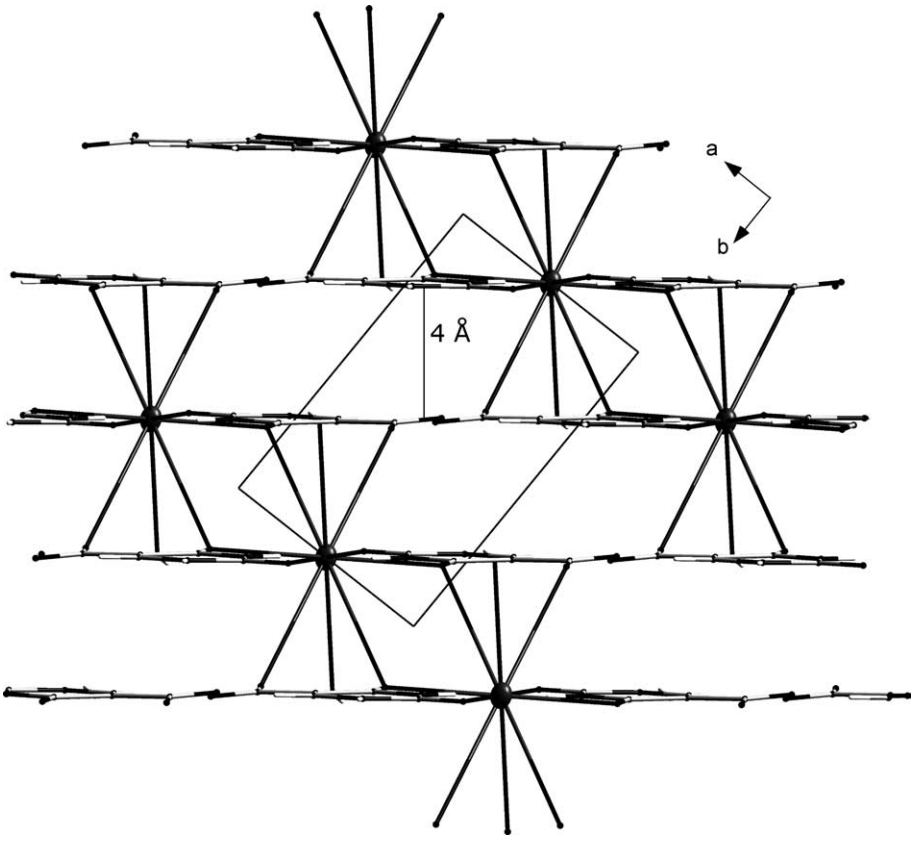

Fig. 15. A projection along the *c*-axis of **5**. The Cs^+ cations are situated in the cavities of the sheet structure created by the ligand hydrogen bonding, and are in the plane of the sheet.

Cs^+ cation neatly and it lies in the plane of the hydrogen-bonded sheet (Fig. 15). The stacking distance between the sheets is approximately 4 Å and, as was discussed for **4**, this is too long for stacking interactions to be the rational driving force behind the crystal packing.

4. Conclusion

A systematic study of alkali metal (Na–Cs) complexes of uracil-5-carboxylic acid reveals some interesting patterns in the coordination behaviour of the metal centres and hydrogen bonding of the ligands and water molecules. By using equimolar amounts of metal and ligand we were able to produce two complexes (**3** and **5**) in which the ligand was only partially deprotonated. By using an excess of base we were able to convert **3** into **4**, where the ligand is fully deprotonated; however, this synthetic behaviour could not be repeated for any of the other reaction systems.

The coordination behaviour of the different metal centres is largely unexceptional. In all cases coordination is via the oxygen atoms of the ligand and, in some cases, the water molecules. This is typical of hard centre alkali metal coordination. It was, however, surprising to note in **3** that the water molecule does not coordinate to the Rb centre but instead forms part of the hydrogen-bonded ligand network.

The hydrogen bonding between the ligands and the water molecules is of particular note, showing the versatility of U5CAH in forming different types of hydrogen bond motifs. Tapes, sheets, 2D and 3D networks are all present in these structures. The centrosymmetric sharing of a hydrogen atom between two carboxylate groups, giving a short and strong hydrogen bond, is one of the key observations in this study. Another is the observation that in four of the five compounds (not compound **3**) C–H···O hydrogen bonding interactions are observed. There is strong evidence in the H···O distances and angles to support this, and the interactions form a key part of the hydrogen bonding networks.

2. Experimental

Hydrated lanthanoid nitrates, 2,4,6-tri-α-pyridyl-1,3,5-triazine, and solvents were obtained as commercial products (Aldrich) and were used without purification.

2.1. Synthesis of $[Ln(tptz)(NO_3)_3(H_2O)]\cdot 2C_2H_5OH$ (4–16)

The complexes $[Ln(tptz)(NO_3)_3(H_2O)]$ were prepared essentially by the literature method [1], as is described in detail for $[Er(tptz)(NO_3)_3(H_2O)]\cdot 2C_2H_5OH$ (**14**) here. A hot solution of hydrated erbium nitrate (0.07 g., 0.18 mmol) in ethanol (5 ml) was mixed with a solution of 2,4,6-tri-α-pyridyl-1,3,5-triazine (0.05 g; 0.16 mmol) in ethanol (25 ml) and allowed to stand overnight, when well-formed pink crystals were obtained.

The other complexes were obtained similarly, with appropriate variation of lanthanoid and choice of solvent. Crystals of $[Yb(tptz)(NO_3)_3(H_2O)]\cdot 2C_2H_5OH$ (**16**) and $[Yb(tptz)(NO_3)_3\cdot C_2H_5OH]\cdot C_2H_5OH$ (**17**) were obtained from the same reaction mixture. Crystals of $[La(tptz)(NO_3)_3(H_2O)]\cdot Me_2CO$ (**2**) were obtained by recrystallisation of $[La(tptz)(NO_3)_3(H_2O)]\cdot 2C_2H_5OH$ from propanone using a microwave oven.

Analyses were obtained for a representative sample of compounds. Carbon analyses tended to be low, despite the use of oxidant.

2.2. X-ray crystallography

The crystal data, data collection parameters, and structure solution and refinement details for the crystal structures determined are summarised in Table 1. Data collections were carried out on a Nonius Kappa CCD diffractometer, using graphite monochromated Mo Kα radiation, except for that for $[La(tptz)(NO_3)_3(H_2O)]\cdot 2EtOH$ (**4**) which was collected on a Bruker AXS SMART diffractometer, at Station 9.8 of the CCLRC Daresbury Laboratory. Both diffractometers were equipped with an Oxford Cryostream cooling apparatus. The data sets were corrected for Lorentz and polarisation effects and for absorption using SORTAV [12] or SADABS [13] (for $[La(tptz)(NO_3)_3(H_2O)]\cdot 2EtOH$ (**4**)), except for the structures of $[Ln(tptz)(NO_3)_3(H_2O)]2EtOH$ (Ln = Eu (**9**), Ho (**13**) and Yb (**16**)) where numerical methods, based of the faces of the crystals were used. Structure solution was achieved by Patterson methods (DIRDIF-99 [14]) and refined by full-matrix least-squares on F^2 (SHELXL-97 [15]) with all ordered non-hydrogen atoms assigned anisotropic displacement parameters. Hydrogen atoms attached to carbon atoms were placed in idealised positions and allowed to ride on the relevant carbon atom. In the final cycles of refinement a weighting scheme that gave a relatively flat analysis of variance was introduced and refinement continued until convergence was reached.

3. Discussion

Reaction of the 2,4,6-tri-α-pyridyl-1,3,5-triazine (tptz) ligand with the hydrated lanthanoid nitrates in ethanolic solution gave crystals of $[Ln(tptz)(NO_3)_3(H_2O)]\cdot 2C_2H_5OH$ (Ln = La–Yb (**4**–**16**) except Pm) and $[Lu(tptz)(NO_3)_3(C_2H_5OH)]$ (**18**) that proved suitable for X-ray diffraction. In the case of ytterbium, mixtures of two crystalline compounds were obtained, $[Yb(tptz)(NO_3)_3(H_2O)]\cdot 2C_2H_5OH$ (**16**) and $[Yb(tptz)(NO_3)_3(C_2H_5OH)]$ (**17**). Microcrystals of the product of reaction using lanthanum nitrate, on recrystallisation from propanone, afforded $[La(tptz)(NO_3)_3(H_2O)]\cdot Me_2CO$ (**2**), and synthesis of the lanthanum complex in methanol afforded $[La(tptz)(NO_3)_3(CH_3OH)_2]$ (**1**). Reaction of tptz with lutetium nitrate in acetonitrile or methanol led to the formation of $[Lu(tptz)(NO_3)_3(H_2O)]\cdot MeCN$ (**19**) or $[Lu(tptz)(NO_3)_2(H_2O)_2]NO_3\cdot 3MeOH$ (**20**), respectively.

While this work was in progress, other workers reported [16] considerable difficulty in obtaining crystals of the lanthanoid nitrate complexes of tptz using MeCN as a solvent, though subsequently they reported the crystal structure of

$[Sm(tptz)(NO_3)_3(H_2O)] \cdot 2H_2O$, obtained by this route [17]. They also studied a large number of complexes of the related terdentate ligand 4-amino-bis(2,6-(2-pyridyl))1,3,5-triazine (abptz) formed by reacting the lanthanide nitrate with 1 mol of abptz in MeCN [16]. They obtained complexes with a wide range of compositions, $[La(abptz)(NO_3)_3(H_2O)_2]$ (11 co-ordinate), $[Ln(abptz)(NO_3)_3(H_2O)]$ (Ln = La, Pr–Sm; 10 co-ordinate), $[Ln(abptz)(NO_3)_3(H_2O)]$ (Ln = Yb, Y; nine co-ordinate, with one monodentate nitrate), $[Ln(abptz)(NO_3)_2(H_2O)_3]NO_3$(Ln = Nd, Sm; 10 co-ordinate) and $[Ln(abptz)(NO_3)_2(H_2O)_2]NO_3$ (Ln = Eu–Lu; nine co-ordinate), which have all been crystallographically characterised. Our fortuitous success in obtaining crystals of the tptz complexes using ethanol for the syntheses may possibly be due to a favourable hydrogen-bonding network present in the crystalline state.

Two other lanthanoid complexes of tptz have also been characterised crystallographically [18]. Tptz acts as a tridentate ligand in the structures of $[Eu(tptz)Cl_3(MeOH)_2] \cdot 2$ MeOH (eight co-ordinate) and $[Pr(tptz)(OAc)_3]_2 \cdot 2$ MeOH (10 co-ordinate). The latter features the presence of double (η^2,μ-1,1) acetate bridges increasingly familiar in other lanthanide carboxylates and their complexes [19–21].

In contrast to the situation with the abptz ligand, we have obtained isomorphous and isostructural tptz complexes covering the whole lanthanoid series, save one extreme member. This is a rarity, although both the isostructural families $[Ln(bipy)_2(NO_3)_3]$ and $[Ln(phen)_2(NO_3)_3]$ exist for La–Lu and Y (bipy = 2,2′-bipyridyl; phen = 1,10-phenanthroline) [22].

3.1. The crystal structure of $[La(tptz)(NO_3)_3(CH_3OH)_2]$ (*1*)

This compound contains 11 co-ordinate lanthanum, with three bidentate nitrate groups and two co-ordinated methanol molecules and the tridentate tptz ligand (Fig. 1). The nitrate groups are essentially planar, and the three coordinated six-membered rings of the tptz ligand are close to being co-planar, with the dihedral angle between the ring N(1)C(1)C(2)C(3)C(4)C(5) (ring A, Fig. 1) and the ring N(2)N(3)N(4)C(6)C(7)C(13) (ring B, Fig. 1) of 4.2° and that between the ring N(2)N(3)-N(4)C(6)C(7)C(13) and the ring N(5)C(14)C(15)C(16)-C(17)C(18) (ring C, Fig. 1) is 1.4°. The dihedral angle between the central triazine ring and the back, uncoordi-

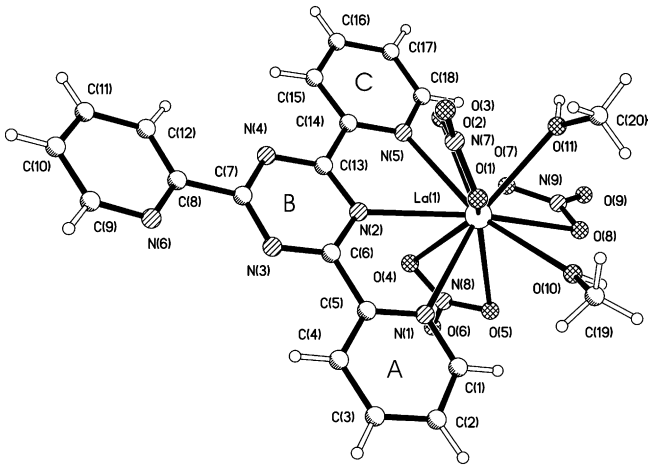

Fig. 1. The molecular structure of $[La(tptz)(NO_3)_3(CH_3OH)_2]$ (**1**) showing the atom numbering scheme.

nated pyridine ring is somewhat larger, at 10.6°. In the crystal, the molecules are linked through hydrogen bonds involving the methanolic O–H groups as hydrogen bond donors, and either a nitrate oxygen or a ring nitrogen as acceptors. The three most significant hydrogen bonds are O(10)–H(10A)···O(5) (related by $-x$, $-y+1$, $-z+1$), with parameters of H(10A)···O(5) 2.09 Å and O(10)–H(10A)···O(5) 156.6°; and a bifurcated hydrogen bond O(11)–H(11A)···N(6) (related by $x-1$, y, z), with parameters H(11A)···N(6) 2.14 Å, O(11)–H(11A)···N(6) 128.3°; and H(11A)···N(3) (related by $x-1$, y, z), with parameters H(11A)···N(3) 2.56 Å, O(11)–H(11A)···N(3) 145.1°.

Although we have not been successful in isolating the analogous $[La(tptz)(NO_3)_3(H_2O)_2]$, it is most likely that it exists in solution and the methanol complex is a surrogate for it.

The structures of two related complexes have been described in the literature, $[La(terpy)(NO_3)_3(CH_3OH)_2]$ [5] and $[La(abptz)(NO_3)_3(H_2O)_2]$ [16]. In comparison with $[La(terpy)(NO_3)_3(CH_3OH)_2]$, the tptz complex has rather longer La–N distances, averaging 2.758 Å against 2.701 Å in the case of the terpyridyl complex, whilst the La–O (CH_3OH) distances are also slightly longer, averaging 2.609 Å for $[La(tptz)(NO_3)_3(CH_3OH)_2]$ versus 2.570 Å for the terpyridyl complex. In contrast, the La–O (nitrate) distances are shorter for $[La(tptz)(NO_3)_3(CH_3OH)_2]$, they range from 2.569(2) to 2.761(2) Å, with an average of 2.636 Å, whereas for $[La(terpy)(NO_3)_3(CH_3OH)_2]$ they range from 2.596(2) to 2.926(2) Å (the last named being 0.199 Å longer than the next longest (2.727 Å)), the average La–O distance being 2.698 Å. In $[La(tptz)(NO_3)_3(CH_3OH)_2]$, the two longest La–O distances are 2.714(2) and 2.761(2) Å, a much smaller discrepancy. It is difficult to escape the conclusion that in the terpyridyl complex the congestion in the co-ordination sphere is such that it is relieved with a "sesquidentate" nitrate group, whereas in the tptz complex the co-ordination of the three nitrate groups is more symmetrical. Examining $[La(abptz)(NO_3)_3(H_2O)_2]$, the La–N distances average 2.710 Å (against 2.758 for the tptz complex) and the La–O (H_2O) distances average 2.600 Å, very similar to the value of 2.609 Å for La–O (CH_3OH) in $[La(tptz)(NO_3)_3(CH_3OH)_2]$. The shorter La–N distances in the abptz complex are counterbalanced by it having longer La–O distances involving the nitrate groups, ranging from 2.628(4) to 2.805(6) Å, averaging 2.685 Å. The longest La–O distance in the abptz complex is 0.103 Å longer than the next longest one, so again there is some suggestion of congestion being released. However, variation of the La–N distance between similar complexes of tptz and abptz having the same stoichiometry suggests that there may be some degree of steric determination in bond length.

3.2. The crystal structure of $[La(tptz)(NO_3)_3(H_2O)] \cdot Me_2CO$ (2)

This complex has 10 co-ordinate lanthanum, with a tridentate tptz ligand, three bidentate nitrates and one co-ordinated water molecule (Fig. 2), and has a geometry very similar to $[La(tptz)(NO_3)_3(H_2O)] \cdot 2C_2H_5OH$ (**4**). Comparing bond lengths in $[La(tptz)(NO_3)_3(H_2O)] \cdot Me_2CO$ (**2**) and $[La(tptz)(NO_3)_3(H_2O)] \cdot 2C_2H_5OH$ (**4**), respectively, the average La–N distances are 2.698 and 2.687 Å; the respective average La–O distances are 2.601 and 2.605 Å, whilst the corresponding Ln–O (OH_2) distances are 2.477(4) and 2.452(1) Å (Table 2). In **2** the nitrate groups are essentially planar whereas the tptz ligand shows some deviation from planarity. The pyridine ring A (as defined in Fig. 1) makes an angle of 5.2° with the central trazine ring (ring B as defined in Fig. 1) while the angle between this ring and the third coordinated pyridine ring (ring C as defined in Fig. 1 is 8.0°). As in the case of **1** the dihedral angle between the central triazine ring and the uncoordinated ring N(6)C(9)C(10)C(11)C(12)C(13) is a little greater, at 11.4°. In the crystal structure of **2** there is a relatively

strong hydrogen bond between the coordinated water hydrogen and the oxygen atom of the acetone solvent molecule; the hydrogen bonding parameters are H(10B)···O(11) 1.80 Å and O(10)–H(10B)···O(11) 167.3° where O(11) is related by the symmetry operation x, $y+1$, z.

3.3. The crystal structures of $[Ln(tptz)(NO_3)_3(H_2O)] \cdot 2C_2H_5OH$ (Ln = Y (**3**), La–Yb (**4**–**16**) except Pm)

3.3.1. General points

This series of isostructural complexes is 10 co-ordinate, with a tridentate tptz ligand, three bidentate nitrates and one co-ordinated water molecule. Selected bond lengths are presented in Table 2. The lanthanum complex **4** is illustrated in Fig. 3. As has already been indicated the geometry of the complex **4** is very similar to that of complex **2**. In this case the dihedral angle between ring A and ring B is 3.9°, that between the central triazine ring (ring B) and ring C is also 3.9°, while the dihedral angle between the triazine ring and the uncoordinated pyridine ring is only 7.7°. As with the whole series the two ethanol molecules of crystallisation are hydrogen bonded to the coordinated water molecule, with the ethanolic oxygens acting as the hydrogen bond acceptors; H(10A)···O(11) 1.747(3) Å, O(10)–H(10A)···O(11) 176(3)°, H(10B)···O(12) 1.777(4) Å, O(10)–H(10B)···O(12) 173(3)°. In addition, the ethanolic O(12)–H(12A) group acts as a hydrogen bond donor to the pyridyl nitrogen N(4) of the uncoordinated pyridine ring of the tptz ligand with H(12A)···N(4) 1.95 Å and O(12)–H(12A)···N(4) 175°, with N(4) related by the symmetry operation $-x-1$, $-y$, $2-z$. There is also a short contact between the other ethanol and a nitrate group, H(11A)···O(4) 2.00 Å, O(11)–H(11A) 169.7°, with O(4) related by the symmetry operation $-x$, $-y$, $1-z$.

The same pattern is seen in the next member of the series $[Ce(tptz)(NO_3)_3(H_2O)] \cdot 2EtOH$ (**5**). The Ce–N distances vary from 2.660(4) Å [Ce(1)–N(1)] to 2.696(4) Å [Ce(1)–N(3)] for the tptz ligand, while the Ce–O distances for

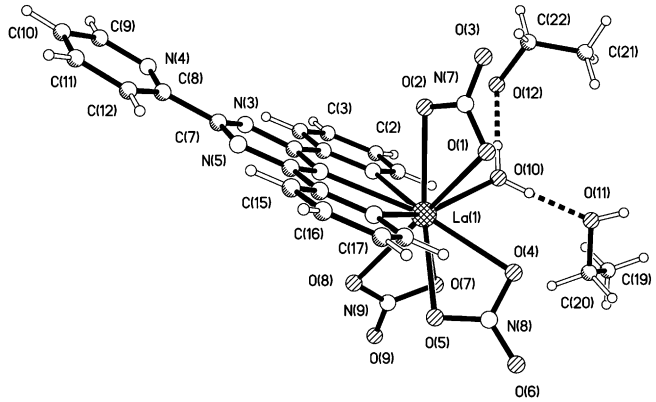

Fig. 3. The molecular structure of $[La(tptz)(NO_3)_3(H_2O)] \cdot 2EtOH$ (**4**) showing the hydrogen bonding of the hydrogen bonding of the two ethanol molecules to the complex.

the nitrate groups vary from 2.549(4) Å [Ce(1)–O(1)] to 2.618(4) Å [Ce(1)–O(6)] averaging 2.588 Å. The shortest Ce–O bond is that of the coordinated water molecule at 2.424(4) Å.

Also, the hydrogen bonding network in **5** is the same as in **4** with hydrogen bonding between the complex and the solvent molecules. In **5** the water hydrogen H(10A) forms a hydrogen bond with an ethanolic oxygen O(12) (O(10)–H(10A)···O(12)) at distances of 1.84 Å and an angle of 173°, while the other hydrogen H(10B) interacts with the other ethanolic oxygen O(11) [O(10)–H(10b)···O(11)] at a distance of 1.65 Å and an angle of 169°. Meanwhile the ethanolic hydrogen H(11A) forms an interaction with O(4) from the nitrate group [O(11)–H(11A)···O(4)] with a distance of 2.06 Å and at an angle of 154°. They are related by the symmetry operator $1 + x, y, z$. The other ethanolic hydrogen H(12A) also forms a hydrogen bond, this time with a nitrogen in the uncoordinated pyridine group [O(12)–H(12A)···N(6)] at a distance of 2.29 Å and an angle of 169° related by the symmetry operation $x, y, 1 + z$.

In the series there is also evidence for weak graphitic π–π interactions between the pyridine end groups of the tptz ligand in adjacent molecules, with centroid–centroid ring distances in the range 4.0–4.084 Å.

Comparing the family of complexes $[Ln(tptz)(NO_3)_3(H_2O)]\cdot 2EtOH$, perusal of Table 2 reveals a steady decrease in bond length with increasing atomic number, and decreasing ionic radius, of the lanthanoid ion, and the trends are illustrated in Fig. 4. Comparing the first and last members of the series, the lanthanum and ytterbium compounds, the average Ln–N distances are 2.687 Å (La) and 2.514 Å (Yb); the average Ln–O (nitrate) distances are 2.606 Å (La) and 2.457 Å (Yb); and the Ln–O (water) distances are 2.452(1) Å (La) and 2.270(2) Å (Yb). The decreases on traversing the series La–Yb are, respectively, 0.173, 0.149 and 0.182 Å. Although an ionic radius for 10 co-ordinate La^{3+} and Yb^{3+} is not given in the best literature compilation [23], ionic radii of 1.216 and 1.042 Å are given for nine co-ordinate La^{3+} and Yb^{3+}, respectively, indicating that a decrease of around 0.174 Å would be expected.

As already remarked, it is unusual for the same co-ordination number to be observed for a family of compounds across the whole lanthanide series, since there is a significant decrease of some 16% in ionic radius. The occurrence of the $[Ln(H_2O)_9]^{3+}$ ion in many solid salts of the later lanthanides (which form $[Ln(H_2O)_8]^{3+}$ ions in solution) is due to its stabilisation in the solid state by hydrogen-bonding [24], whilst many LnX_3 display decreases in co-ordination number, such as a change from 9 in $LaCl_3$ to 6 in $LuCl_3$ [25]. One feature that indicates a build-up of strain in the co-ordination environment of the lanthanide ion in these compounds is the range of Ln–O (nitrate) distances. In $[La(tptz)(NO_3)_3(H_2O)]\cdot 2C_2H_5OH$ (**4**), the La–O (nitrate) distances range from 2.570(1) to 2.631(1) Å, a spread of values of 0.061 Å, this value increasing fairly smoothly with increasing atomic number to successive values of 0.119, 0.128, 0.143 and 0.138 Å for the Dy (**12**), Ho (**13**), Er (**14**) and Tm (**15**) compounds, respectively, then *suddenly* increasing to 0.180 Å in $[Yb(tptz)(NO_3)_3(H_2O)]\cdot 2C_2H_5OH$ (**16**). The view that this reflects increasing congestion in the co-ordination sphere is supported by the fact that we were unable to isolate a lutetium member of this family, nine co-ordinate $[Lu(tptz)(NO_3)_3(C_2H_5OH)]$ (**18**) being obtained instead. Further, the isolation of crystals of $[Yb(tptz)(NO_3)_3\cdot(C_2H_5OH)]$ (**17**) (Table 3) from

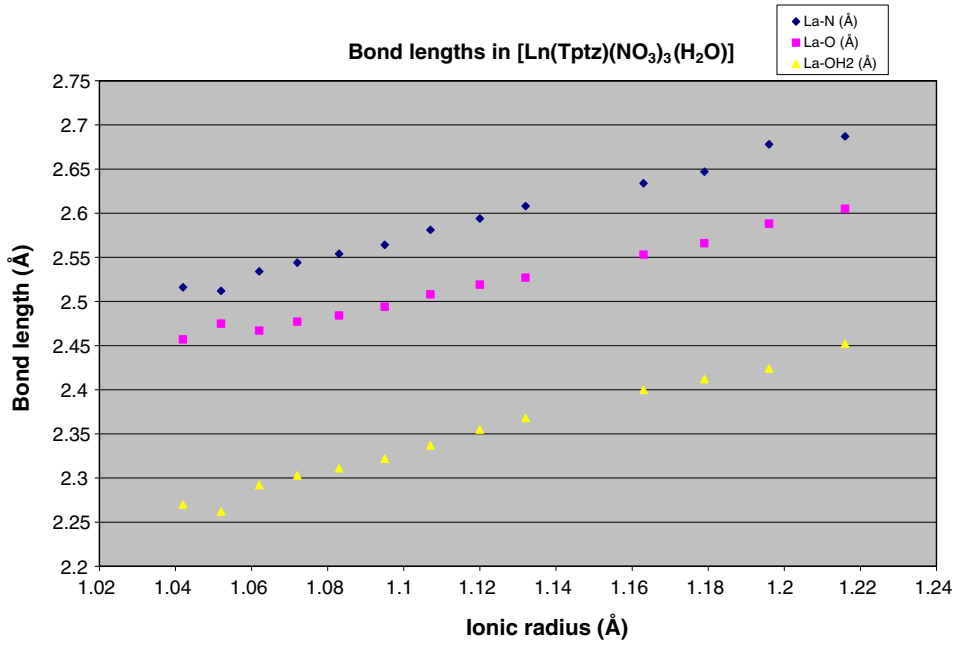

Fig. 4. A plot of the Ln–N (tptz), Ln–O (nitrate), and Ln–O (water) distances for the series $[Ln(tptz)(NO_3)_3(H_2O)]\cdot 2EtOH$ (La–Yb) showing the lanthanide contraction.

the same reaction that affords [Yb(tptz)$(NO_3)_3(H_2O)]\cdot 2C_2H_5OH$ (**16**) tends to suggest that the latter compound approaches the borderline of stability.

Another way in which the co-ordinated nitrate groups can serve as an index of increasing congestion in the co-ordination sphere in these compounds can be seen in examining the asymmetry within each co-ordinated nitrate group. In the lanthanum complex (**4**), the discrepancies in La–O distance between the three pairs of bidentate nitrate groups are 0.036, 0.047 and 0.053 Å (for a symmetrically bidentate group, the values would, obviously, be zero), averaging 0.045 Å; in the cerium complex (**5**), the discrepancies in Ce–O distance between the three pairs of bidentate nitrate groups are 0.026, 0.049 and 0.053 Å, averaging 0.043 Å. In the ytterbium compound (**16**), the discrepancies are 0.069, 0.127 and 0.168 Å. Though this is not a smooth trend, the individual values for the Tm complex (**15**) being 0.091, 0.101 and 0.138 Å, yet giving a smaller total discrepancy in bond length, as befits the argument, the point is made.

A comparison is possible between bond lengths in [Nd(tptz)$(NO_3)_3(H_2O)]\cdot 2C_2H_5OH$ (**7**) (this paper) and the compounds [Nd(abptz)$(NO_3)_3(H_2O)$] [16] and [Nd(terpy)$(NO_3)_3(H_2O)$] [3]. Respective average Nd–N bond lengths are 2.634, 2.605 and 2.638 Å; Nd–O (nitrate) bonds average 2.553, 2.568 and 2.567 Å; and Nd–O (water) are 2.400, 2.470 and 2.488 Å. These values, apart from the metal–water bonds, which seem more susceptible to hydrogen-bonding forces, are closely comparable.

3.3.2. A comparison of $[Sm(tptz)(NO_3)_3(H_2O)]\cdot 2C_2H_5OH$ (*8*) and $[Sm(tptz)(NO_3)_3(H_2O)]\cdot 2H_2O$

In these complexes with identical coordination spheres, respective average Sm–N bond lengths are 2.608 and 2.615 Å [17]; Sm–O (nitrate) bonds average 2.527 and 2.533 Å; and Sm–O (water) are 2.368(2) and 2.420(2) Å. Despite the presence of different solvent molecules in the lattice, these values are in good agreement, within experimental error, apart from the metal–water bonds, which seem more susceptible to hydrogen-bonding forces.

3.4. Structures of the lutetium complexes

3.4.1. $[Lu(tptz)(NO_3)_3\cdot(C_2H_5OH)]$ (*18*)

The crystal structure of [Lu(tptz)$(NO_3)_3(C_2H_5OH)$] (**18**) shows that it is nine co-ordinate, with a tridentate tptz ligand, two bidentate nitrates, one monodentate nitrate and one co-ordinated water molecule (Fig. 5). Selected bond lengths for **18** are shown in Table 3. The initially bidentate nitrate (in the earlier elements of the series) is replaced by a monodentate nitrate and an ethanol molecule. The free ethanol molecule in the lattice (not shown in Fig. 5) is disordered over two positions. Individual atomic sites were refined with 66%:34% occupancies and the atomic coordinates and displacement parameters tied together

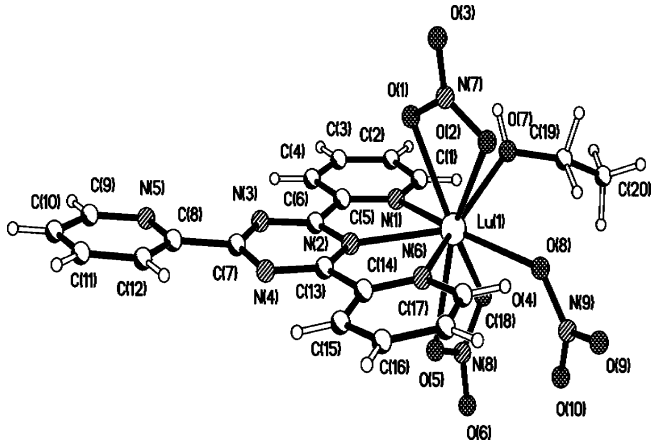

Fig. 5. The molecular structure of [Lu(tptz)$(NO_3)_3$(EtOH)] (**18**) showing the atom numbering scheme adopted. The disordered, uncoordinated EtOH solvent molecule is not shown.

and summed to unity. The oxygen atom, O(11), of the disordered lattice ethanol solvent molecule is hydrogen bonded to the OH group of the coordinated ethanol, with parameters H(7A)···O(11) 1.79 Å, O(7)–H(7A)···O(11) 172°, with O(11) related by the symmetry operation $1-x$, $-y$, $1-z$. As observed with the earlier group of lanthanoid complexes, there is also some evidence of weak graphitic packing between the coordinated pyridine rings of the tptz ligands in adjacent molecules. The centroid–centroid distances lie in the range 4.167–3.978 Å. The conformation of the tptz ligand is similar to that observed in the earlier lanthanoid complexes, **1**, **2**, and **4** with the dihedral angle between the pyridine ring (ring A) and the triazine ring (ring B) of 1.8°, that between the triazine ring and the other coordinated pyridine ring (ring C) of 8.3°, and that between the triazine ring and the uncoordinated pyridine ring of 5.9°. The complex [Yb(tptz)-$(NO_3)_3(C_2H_5OH)$] (**17**) is isostructural.

The Lu–N distances in **18** vary from 2.453(3) Å [Lu(1)–N(2)] to 2.510(3) Å [Lu(1)–N(6)] for the tptz ligand, while the Lu–O distances for the nitrate groups vary from 2.269(3) Å [Lu(1)–O(8)], the monodentate nitrate to 2.464(4) Å [Lu(1)–O(2)] averaging 2.371 Å. Comparing it with [Lu(terpy)$(NO_3)_3(C_2H_5OH)$] [2b], which it closely resembles, average bond lengths are Lu–N 2.484 and 2.457 Å (tptz complex first); Lu–O (bidentate nitrate) 2.396 and 2.414 Å; Lu–O (monodentate nitrate) 2.269(3) and 2.279(3) Å; and Lu–O (ethanol) 2.271(3) and 2.297(3) Å.

3.4.2. The structure of $[Lu(tptz)(NO_3)_3(H_2O)]\cdot MeCN$ (**19**)

The structure of [Lu(tptz)$(NO_3)_3(H_2O)]\cdot$MeCN (**19**) closely resembles that of [Lu(tptz)$(NO_3)_3(C_2H_5OH)$] (**18**) in having a tridentate tptz ligand, two bidentate nitrates, one monodentate nitrate and one co-ordinated oxygen atom from a neutral donor (Fig. 6); average bond lengths of Lu–N of 2.455 Å, Lu–O (bidentate nitrate) 2.396 Å; Lu–O (monodentate nitrate) 2.270 (3) Å; and Lu–O (H_2O) 2.293 (3) Å are closely comparable (Table 3). As in all the previous examples, hydrogen bonds contribute to the packing of the molecules in solid state with an intermolecular interaction involving O(10). The atom O(10) acts as a hydrogen bond acceptor in an interaction with the aromatic hydrogen H(16) at a distance of 1.87 Å and an angle of 151° (related by $x-1/2$, $1/2-y$, $z-1/2$). In addition, there is graphitic stacking now between the central trazine ring and the uncoordinated pyridine ring in an adjacent molecule at a centroid–centroid distance of 3.789 Å. The MeCN solvent molecule is not involved in hydrogen bonding. The ring conformations within the tptz ligand are similar to those observed in the other complexes with the dihedral angle between the coordinated pyridine ring (ring A) and the central triazine ring (ring B) of 12.8°, that between the triazine ring and the other coordinated pyridine ring (ring C) of 4.6°, and that between the triazine ring and the uncoordinated pyridine ring of 6.6°.

Two similar abptz complexes, [Ln(abptz)$(NO_3)_3(H_2O)$] (Ln = Y, Yb) have been reported [16].

3.4.3. The structure of $[Lu(tptz)(NO_3)_2\cdot(H_2O)_2]\cdot NO_3\cdot 3MeOH$ (**20**)

Isolated from the reaction of lutetium nitrate and tptz in methanol, this compound differs from the other two lutetium complexes in having an ionic structure (the cation is shown in Fig. 7), in which complete solvolysis of a co-ordinated nitrate group has occurred. The cation, containing two bidentate nitrate groups as well as two co-ordinated water molecules, strongly resembles that found in $[Lu(terpy)(NO_3)_2(H_2O)_2]NO_3\cdot 2H_2O$ [5] and terpy analogues with other heavy lanthanides. As in the case of the terpy complexes, it is the nitrate group *trans* to the terdentate N-donor that has undergone solvolysis (at least in the final product). The conformation of the tptz ligand is similar to that of the other complexes, with the dihedral angle

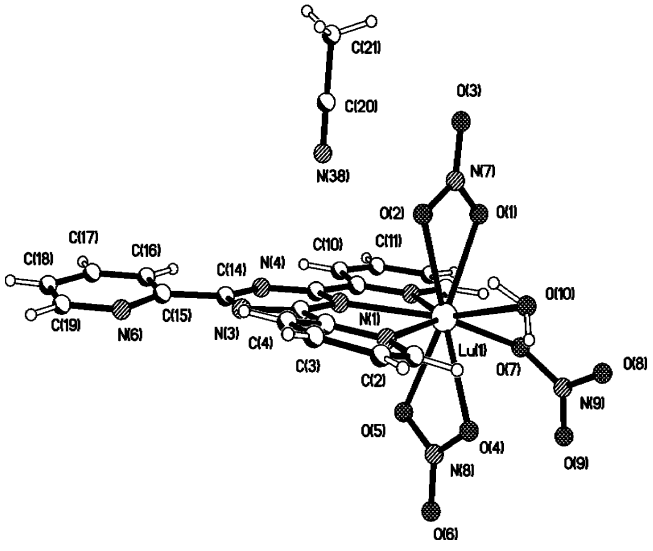

Fig. 6. The molecular structure of [Lu(tptz)$(NO_3)_3(H_2O)]\cdot$MeCN (**19**) showing that the MeCN solvent molecule is not involved in hydrogen bonding to the complex.

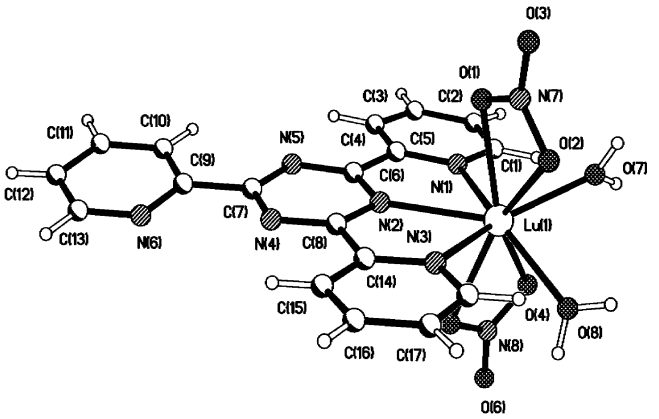

Fig. 7. The structure of the cation $[Lu(tptz)(NO_3)_2(H_2O)_2]^+$ showing the atom numbering scheme adopted.

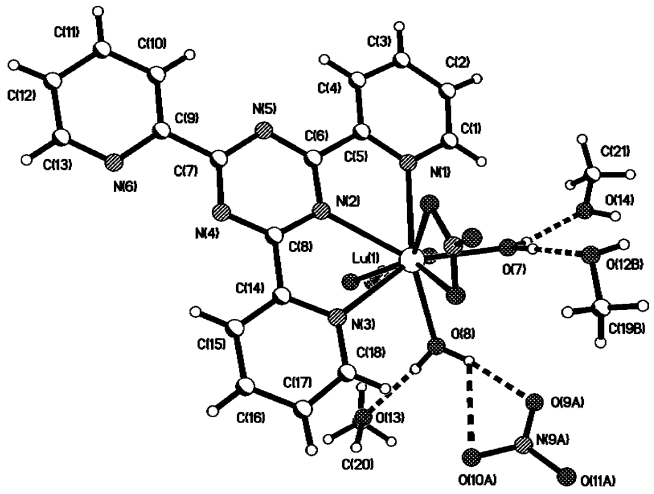

Fig. 8. The structure of $[Lu(tptz)(NO_3)_2(H_2O)_2]NO_3 \cdot 3MeOH$ (**20**) showing the hydrogen bonding network in the solid-state structure.

between ring A and the central triazine ring (ring B) being 5.1°, while that between this central ring and the other coordinated pyridine ring (ring C) is 2.8°, and the dihedral angle between the triazine ring and the uncoordinated pyridine ring is 4.3°. Corresponding average bond lengths (Table 3) (values for the tptz complex first) are: Lu–N 2.488 and 2.472 Å, Lu–O (nitrate) 2.400 and 2.411 Å and Lu–O (water) 2.266 and 2.266 Å, the latter being closely comparable to that of the other coordinated solvent molecules.

The free uncoordinated solvent molecules within the crystal lattice contribute to extensive hydrogen bonding (Fig. 8). The methanolic oxygens O(13) and O(14) both act as hydrogen bond acceptors to the coordinated water molecules. The interactions between O(13)···H(8A) and O(14)···H(7A) are 1.80 Å (O(8)–H(8A)···O(13) 163°) and 1.92 Å (O(7)–H(7A)···O(13) 153°), respectively. Meanwhile, the symmetry related nitrate anion acts as a hydrogen bond acceptor to two methanol solvent molecules. The distances between H(12A) and O(9) is 2.075 Å at an angle of 151° (related by $1-x$, $1-y$, $1-z$), while O(11) and H(14) are 2.05 Å apart, at an angle of 148.30° (related by $1-x$, $-y$, $1-z$). The hydrogen H(7B) on the coordinated O(7) acts as a hydrogen bond donor to O(12) with distances between O(12) and H(7B) at 1.81 Å and at an angle of 176° (related by x, $y-1$, z).

4. Conclusions

The structures of the complexes isolated display the expected trends in decreasing co-ordination number with decreasing ionic radius of the Ln^{3+} ion and moreover include three structural types already described for lanthanoid complexes of terpy. It has been suggested [16] that use of MeCN for syntheses can favour inclusion of nitrate in the co-ordination sphere of the metal rather than water; we note here that the same samarium complex is obtained carrying out the synthesis in ethanol or acetonitrile.

The pK_{a1} values for terpy and tptz are 4.9 and 4.5, respectively [26], showing that terpy is a stronger base [17]. For the complexes described here, Ln–N bond lengths tend in general to be greater in tptz complexes than in the terpy analogues, as noted by others [14] in some cases, which would be expected if strength as a Lewis base correlated with strength of bond in a complex, though steric factors may also operate here too.

In this study, the complex isolated for most lanthanoids is $[Ln(tptz)(NO_3)_3(H_2O)] \cdot 2C_2H_5OH$ though a species $[Ln(tptz)(NO_3)_3(C_2H_5OH)]$ is presumably present in the solutions from which it crystallises, and in the case of ytterbium and lutetium an ethanol complex $[Ln(tptz)(NO_3)_3(C_2H_5OH)]$, albeit with a lower co-ordination number, is actually isolated.

We have described structural evidence for crowding in the $[Yb(tptz)(NO_3)_3(H_2O)]$ (**17**) molecule in particular, but this does not in itself explain why crowding is not relieved by expulsion of a water molecule and why the lutetium complex isolated is not nine co-ordinate $[Lu(tptz)(\eta^2\text{-}NO_3)_3]$ with three bidentate nitrate groups, since terpyridyl analogues $[Ln(terpy)(\eta^2\text{-}NO_3)_3]$ (Ln = Yb, Lu) have been fully characterised [2b,3]. This is not a singular phenomenon as similar terpyridyl complexes $[Ln(terpy)(\eta^2\text{-}NO_3)_2(\eta^1\text{-}NO_3)(C_2H_5OH)]$ (Ln = Er, Yb, Lu) have been described [2a,2b], also aqua complexes $[Tm(terpy)(\eta^2\text{-}NO_3)_2(\eta^1\text{-}NO_3)(H_2O)]$ [3] and $[Ln(abtpz)(\eta^2\text{-}NO_3)_2(\eta^1\text{-}NO_3)(H_2O)]$ (Ln = Y, Yb) [17].

Bidentate nitrates would be favoured by the chelate effect and it would also be expected that a bidentate nitrate group would take up less space than a monodentate nitrate group and a co-ordinated ethanol (or water) molecule. Evidently this is counterbalanced by the formation of strong bonds to the monodentate donors and also by the intramolecular hydrogen bonds between an unbound oxygen of the monodentate nitrate and a hydrogen from H_2O or C_2H_5OH. In addition, an analysis of the N–Ln–N angles, for the two coordinated pyridine rings of the tptz group show a smooth increase from 120.62(4)° for the La complex (**4**) to 128.05(7)° for the Yb complex (**16**), consistent with the shortening of the Ln–N bond length across the series. This angle in **16** is slightly narrower than that found in **17** (129.47(17)°) where the Yb atom is nine coordinate instead of 10 coordinate. Thus, the tptz ligand does not seem to be sensitive to any potential strain around the lanthanoid ion centre. However, it should also be borne in mind that our conclusions are based on the species isolated in the solid state.

Ab initio quantum mechanical calculations [27] on $Ln(NO_3)_n$ and $Ln(NO_3)_n(H_2O)_m$ ($n = 1$–3, $m = 4$–6) species indicate that bidentate behaviour of the nitrate group is preferred less over monodentate binding as more nitrate groups attach themselves to the metal ion. Water binding to the lanthanide may shift binding of the nitrate group in favour of monodentate behaviour whilst bidentate binding may be favoured by entropy effects so that several different species may be present in solution. Moving to the solid state, the balance may further be altered by crystal packing

and intermolecular forces. It should also be borne in mind that the complexes obtained in the solid state are not necessarily the most abundant species in solution, as solubility is a key important factor in deciding which species is obtained in the solid state. NMR studies on the $La(NO_3)_3$/terpy system in MeCN indicated the presence of at least seven different La-containing species in the complexation process [4].

5. Supplementary material

Crystallographic supplementary data are available from The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44 1223 336 033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk) quoting the deposition numbers CCDC 284755–284774.

Acknowledgements

We are grateful to the University of Bath for a studentship (to L.L.O.), and to the EPSRC for funding for the purchase of the X-ray diffractometer. We acknowledge the support of the CCLRC Daresbury Laboratory through the award of beamtime. We are also grateful to Mr. T.J. Spencer for microanalyses and to Professor J.C. Anderson of Nottingham University for arranging for the analyses to be carried out.

and **2** are previously reported [13–15]. Cation **1** and related compounds are of interest as synthons for compounds likely to be of utility in boron neutron capture therapy (BNCT) for the treatment of cancerous tumours [16–18]. Although isostructural, the two species **1** and **2** differ in the centres of their charge location: in cation **1** the positive centre resides on the alkylammonium residue and in anion **2** the negative charge is delocalised over the monocarbaborane cluster.

The $[1\text{-}(H_3NCH_2)\text{-}closo\text{-}1,2\text{-}C_2B_{10}H_{11}]^+$ cation **1** was prepared by the previously reported route from [*closo*-1,2-$C_2B_{10}H_{12}$], via the neutral (phthalimidomethy1)-*closo*-1,2-dicarborane $[1\text{-}\{C_6H_4(CO)_2NCH_3\}\text{-}closo\text{-}1,2\text{-}C_2B_{10}H_{11}]$ and isolated as its Cl^- salt **1a** [13]. The $[1\text{-}(H_3CCH_2)\text{-}closo\text{-}1\text{-}CB_{11}H_{11}]^-$ anion **2** was made by the following variant of the published procedure [19], and isolated as its $[NEt_4]^+$ salt. Thus, the $[NEt_4]^+$ salt of the [*closo*-1-$CB_{11}H_{12}]^-$ anion (made as in Ref. [19]; 1.6 g, 5.8 mmol) was dissolved in dry thf (30 ml) and a solution of *n*-BuLi in *n*-hexane (1.6 M, 12 ml, corresponding to ca. 20 mmol of *n*-BuLi) was added dropwise. After stirring for one hour at ambient temperature, CH_3CH_2I (2 ml, ca. 24 mmol) was added dropwise and the reaction was allowed to stir for three hours. H_2O (100 ml) was then added and the thf was removed by use of a rotary thin-film evaporator. The remaining aqueous solution was extracted with diethyl ether (3×30 ml), and the combined ether layers evaporated by use of a rotary thin-film evaporator. The residual colourless oil was dissolved in H_2O (50 ml), the solution filtered, and $[NEt_4]^+Br^-$ (2.1 g, 10 mmol) slowly added to the stirred filtrate. After further stirring, the white precipitate was filtered off and dried in vacuo, to yield the $[NEt_4]^+$ salt **2a** of the $[1\text{-Et-}closo\text{-}1\text{-}CB_{11}H_{11}]^-$ anion **2** (1.25 g, 4.2 mmol, 72%). Measured NMR data for [1-Et-*closo*-1-$CB_{11}H_{11}]^-$ salt **2a**, in $(CD_3)_2CO$ at 298–300 K, ordered as assignment $\delta(^{11}B)$/ppm [δ (^1H)/ppm in square brackets] are: BH(12) −10.0 [+1.61], BH(2,3,4,5,6) −13.6 [+1.56] and BH(7,8,9,10,11) −13.6 [+1.77]; additionally δ (^1H)(BEt) at +1.87 (2H, quartet), +0.89 (3H, triplet), δ (^1H)(NEt_4) at +3.51 (8H, quartet), +1.42 (12H, triplet); additionally $\delta(^{13}C)(NEt_4)$ +52.4 and +7.0, with $\delta(^{13}C)$(cluster-bound Et) +32.5 and +14.3. A sample of the $[NEt_4]^+$ salt **2a** of anion **2** (150 mg, 500 μmol) was then dissolved in aqueous nitric acid (5%, 60 ml) and extracted with Et_2O (3×20 ml). H_2O (50 ml) was then added, and then the Et_2O was removed using a rotary thin-film evaporator. The resulting aqueous solution was cooled to 0 °C, and then $AgNO_3$ (850 mg, 500 μmol) was added with stirring. The $[Ag]^+$ salt **2b** of anion **2** precipitated as a white solid (700 mg, 252 μmol, 51%). Crystals suitable for single-crystal X-ray diffraction analysis were obtained by the slow diffusion of Et_2O into a concentrated solution of **2b** (Fig. 1) in acetone. Addition of the $[Cl]^-$ salt of **1** to the $[Ag]^+$ salt **2b** in dichloromethane, followed by overnight stirring, filtration, and subsequent evaporation of the solvent, led quantitatively to the formation of the desired $[1\text{-}(H_3NCH_2)\text{-}closo\text{-}1,2\text{-}C_2B_{10}H_{11}][1\text{-}(H_3CCH_2)\text{-}closo\text{-}1\text{-}CB_{11}H_{11}]$ salt **3**. The 1:1 water solvate **3a** of the salt **3** was then identified by single-crystal X-ray diffraction analysis (Fig. 2), for which crystals were obtained by the slow diffusion of *n*-hexane into a concentrated solution of the $[1\text{-}(H_3NCH_2)\text{-}closo\text{-}1,2\text{-}C_2B_{10}H_{11}][1\text{-}(H_3CCH_2)\text{-}closo\text{-}1\text{-}CB_{11}H_{11}]$ salt **3** in dichloromethane in air. We understand that an *ortho*-dicarborane derivative with an $\{NH_3\}$ moiety has not been structurally characterised before, and, as such, the result may be of interest to chemists involved in BNCT research [16–18] (we thank a referee for pointing this out).

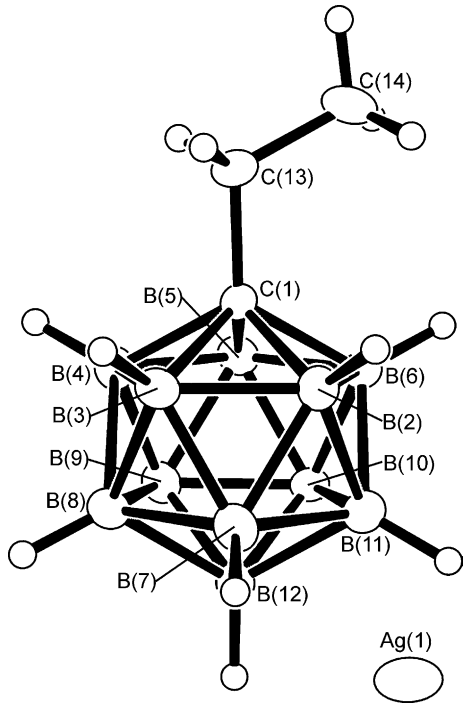

Fig. 1. ORTEP-type illustration of the basic unit of the crystallographically determined structure of $[Ag]^+[1\text{-}(H_3CCH_2)\text{-}closo\text{-}1\text{-}CB_{11}H_{11}]^-$ (species **2b**). Distances from C(1) to boron range from 1.713(2) to 1.735(2) Å; C(1)–C(13) is 1.533(1) and C(13)–C(14) is 1.509(2) Å. The $[Ag]^+$ cation is close to H(7) at 2.078 Å; the associated distance Ag(1)–B(7) is 2.666 Å. In the extended crystal lattice the $[Ag]^+$ cation is associated with three $[1\text{-Et-}closo\text{-}1\text{-}CB_{11}H_{11}]^-$ anions (Fig. 6). Crystallographic data for $Ag[1\text{-}(H_3CCH_2)\text{-}closo\text{-}1\text{-}CB_{11}H_{11}]$ species **2b**, $[Ag][1\text{-}(H_3CCH_2)\text{-}closo\text{-}1\text{-}CB_{11}H_{11}]$, $C_3H_{16}AgB_{11}$, $M = 278.94$, monoclinic ($0.26 \times 0.20 \times 0.13$ mm, colourless prism from diffusion of diethyl ether into a solution in acetone), space group $P2_1/c$, $a = 11.7166(4)$, $b = 9.8206(3)$, $c = 9.5221(3)$ Å, $\beta = 92.879(2)°$, $U = 1094.27(6)$ Å^3, $D_{calc} = 1.693$ Mg m^{-3}, $Z = 4$, Mo Kα, $\lambda = 0.71073$ Å, $\mu = 1.783$ mm^{-1}, $T = 150(2)$ K, $R_1 = 0.0947$ for 1837 reflections with $I > 2\sigma(I)$, and $wR_2 = 0.2872$ for all 2138 unique reflections; CCDC 280664, Crystallographic methods and programmes were standard; coordinates, etc., can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from The Director, CCDC, 12, Union Road, Cambridge CB2 1EZ, UK (fax: +44 1223 336033; e-mail: deposit@ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk)].

We have not been able to obtain crystals of **3** without solvent. Such a solvation problem may not be a problem with the as yet unsynthesised salt $[C_3B_9H_{12}]^+$ $[CB_{11}H_{12}]^-$ because, presumably, the non-substituted spherical anions would mutually pack more efficiently, and therefore, perhaps, in their solid-state properties mimic the very high melting points of the neutral [*closo*-$C_2B_{10}H_{12}$] isomers that

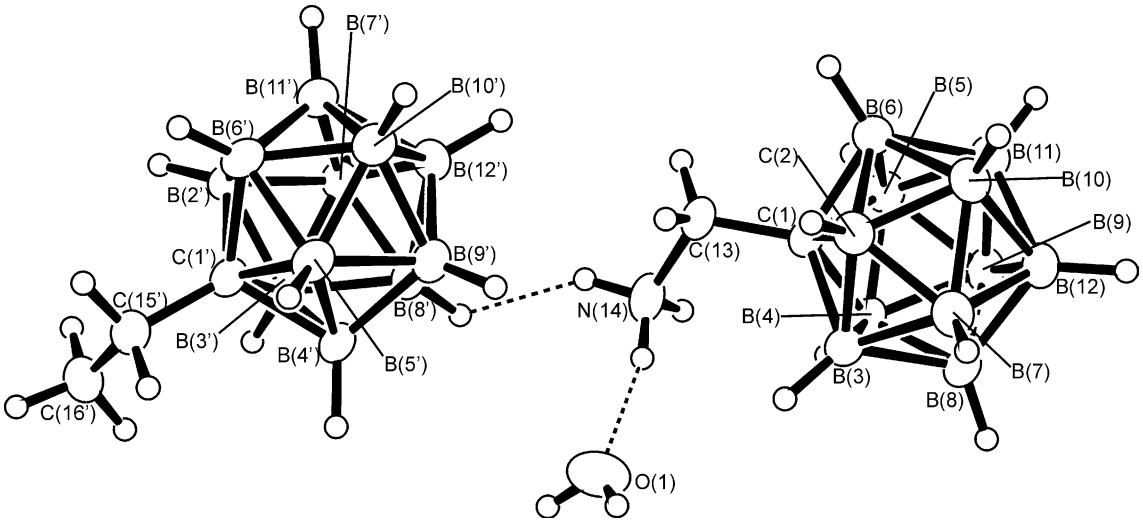

Fig. 2. ORTEP-type illustration of the basic unit of the crystallographically determined structure of $[1\text{-}(H_3NCH_2)\text{-}closo\text{-}1,2\text{-}C_2B_{10}H_{11}]^+[1\text{-}(H_3CCH_2)\text{-}closo\text{-}1\text{-}CB_{11}H_{11}]^-[H_2O]$ (species **3a**). The hatched lines represent hydrogen bonds and dihydrogen bonds. Interatomic distances associated with these bonds are C(13)–N(14) 1.471(3), N(14)–B(8′) 3.346(3), N(14)–O(1) 2.755(3), H(8′)–H(14B) 1.90 and O(1)–H(14A) 1.89 Å; N–H–H and B–H–H angles are 110° and 146° respectively. Within the $[1\text{-}(H_3CCH_2)\text{-}closo\text{-}1\text{-}CB_{11}H_{11}]^-$ anion (left) selected interatomic distances are C(1′)–C(15′) 1.532(3) and C(15′)–C(16′) 1.523(3) Å with distances from C(1′) to boron ranging from 1.705(3) to 1.729(3) Å. Angle C(1′)C(15′)C(16′) is 115.2(2)°. Within the $[1\text{-}(H_3NCH_2)\text{-}closo\text{-}1,2\text{-}C_2B_{10}H_{11}]^+$ cation (right) selected interatomic distances are C(1)–C(2) 1.640(2), C(1)–C(13) 1.517(2) and C(13)–N(14) 1.471(3) Å, with distances from C(1) to boron ranging from 1.705(3) to 1.729(3) Å. Angle C(1)C(13)N(14) is 113.5(2)°. Crystallographic methods and programmes were standard; coordinates, etc., can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from The Director, CCDC, 12, Union Road, Cambridge CB2 1EZ, UK (fax: +44 1223 336033; e-mail: deposit@ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk)], Crystallographic data for $[1\text{-}(H_3NCH_2)\text{-}closo\text{-}1,2\text{-}C_2B_{10}H_{11}]$ $[1\text{-}(H_3CCH_2)\text{-}closo\text{-}1\text{-}CB_{11}H_{10.935}Cl_{0.065}]$ $[H_2O]$ **3a**: $C_6H_{33.935}B_{21}NOCl_{0.065}$, $M = 365.76$, monoclinic ($0.79 \times 0.33 \times 0.20$ mm, colourless prism from diffusion of hexane into a solution in CH_2Cl_2), space group $P2_1/c$, $a = 16.2035(3)$, $b = 10.3111(2)$, $c = 13.8135(2)$ Å, $\beta = 106.4920(10)°$, $U = 2212.95(7)$ Å^3, $D_{calc} = 1.091$ Mg m^{-3}, $Z = 4$, Mo $K\alpha$, $\lambda = 0.71073$ Å, $\mu = 0.051$ mm^{-1}, $T = 150(2)$ K, $R_1 = 0.0725$ for 3419 reflections with $I > 2\sigma(I)$, and $wR_2 = 0.2084$ for all 4325 unique reflections; CCDC 280665.

do not exhibit solvent inclusion. Another manifestation of solvent behaviour in the present system arose from the reactivity of the alkylammonium residue on the $[(H_3NCH_2)C_2B_{10}H_{11}]^+$ cation **1**. Cation **1** very readily formed the cationic iminium derivative $[(CH_3)C{=}NH\text{-}CH_2C_2B_{10}H_{11}]^+$ **4** in preliminary crystallisation attempts involving acetone as solvent. In fact, in the present system, anion **1** proved to be a relatively efficient scavenger of any acetone residues during crystallisation attempts using a variety of solvent systems if apparatus was insufficiently purged of traces of residual acetone that has been used for cleaning purposes, and salts of **4** rather than of **1** were thence often obtained as products. The phenomenon has been noted previously in the formation of the 'globule–globule assembly' $[C_2B_{10}H_{11}CH_2NH{=}CH(CH_3)_2]_4[W_{10}O_{32}][H_2O]_2[(CH_3)_2CO]_4$ [9]. Arising from this behaviour, as part of this current report we now are also able to describe the crystallographically determined structure of the $[1\text{-}(H_3CCH_2)\text{-}closo\text{-}1\text{-}CB_{11}H_{11}]^-$ salt **4a** of the iminium cation **4** (Fig. 3). Crystals suitable for single-crystal X-ray diffraction analysis were obtained by the slow diffusion of Et_2O into a concentrated solution of the $[1\text{-}(H_3NCH_2)\text{-}closo\text{-}1,2\text{-}C_2B_{10}H_{11}][1\text{-}(H_3CCH_2)\text{-}closo\text{-}1\text{-}CB_{11}H_{11}]$ salt **3** in acetone.

One reason for the developing interest in these types of species is the examination for intermolecular interactions. In this context it may be noted that cage CH···X interactions in the solid-state structures of icosahedral carbaboranes are recently reviewed [20]. It is apparent from the basic structural unit of the $[1\text{-}(H_3NCH_2)\text{-}closo\text{-}1,2\text{-}C_2B_{10}H_{11}]^+[1\text{-}(H_3CCH_2)\text{-}closo\text{-}1\text{-}CB_{11}H_{11}]^-[H_2O]$ salt **3a** (Fig. 2) that interionic interaction occurs. As mentioned above, although the cation and anion in this salt are isostructural, the two species differ in the centres of their charge location: the positive charge of the $[1\text{-}(H_3NCH_2)\text{-}closo\text{-}1,2\text{-}C_2B_{10}H_{11}]^+$ cation is located on the alkylammonium residue whereas the negative charge for the $[1\text{-}(H_3CCH_2)\text{-}closo\text{-}1\text{-}CB_{11}H_{11}]^-$ anion is delocalised over the monocarbaborane cage, albeit with some dipolar character with the more negative end of the charge distribution around the pentagonal pyramidal $\{B_6H_6\}$ cap distal from the C(1) vertex [14,21]. The positively charged alkylammonium residue contributes to the presence of the hydrogen bonding observed between the {NH} hydrogen atom in position 14B and the oxygen atom in the water molecule, as well as to the presence of the intermolecular dihydrogen bond seen between the hydrogen atoms in {BH} position 8 in the anion and in {NH} position 14A in the cation. The hydrogen bond and the dihydrogen bonds are marked in Fig. 2 as hatched lines.

The hydrogen-bond distance of 1.89 Å from the oxygen atom O(1) in the water molecule to the alkylammonium hydrogen atom, {NH} position 14A, is well within the range for typical hydrogen bonds. The distance from the

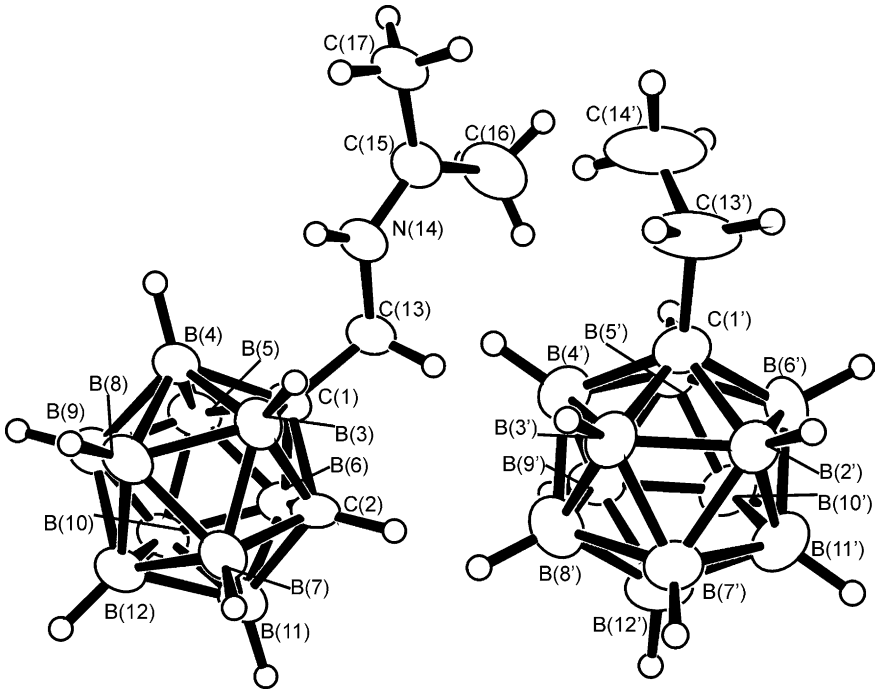

Fig. 3. ORTEP-type illustration of a basic unit of the crystallographically determined structure of [1-{$(CH_3)_2C{=}NHCH_2$}-*closo*-1,2-$C_2B_{10}H_{11}$]$^+$-[1-(H_3CCH_2)-*closo*-1-$CB_{11}H_{11}$]$^-$ (species **4a**). Within the [1-{$(CH_3)_2C{=}NHCH_2$}-*closo*-1,2-$C_2B_{10}H_{11}$]$^+$ cation (left) selected interatomic distances are C(1)–C(13) 1.498(5), C(13)–N(14) 1.457(5) and N(14)–C(15) 1.285(5) Å, with distances from C(1) to boron ranging from 1.700(6) to 1.723(6) Å. Angles C(1)C(13)N(14) C(13)N(14)C(15) are 112.5(3)° and 126.8(4)° respectively. Within the [1-Et-*closo*-1-$CB_{11}H_{11}$]$^-$ anion (right) selected interatomic distances are C(1′)–C(13′) 1.514(6) and C(13′)–C(14′) 1.421(6) Å, with distances from C(1′) to boron ranging from 1.706(6) to 1.734(7) Å. Note that in this projection the second hydrogen atom on the C(13′) {CH_2} grouping is hidden. Crystallographic methods and programmes were standard; coordinates, etc., can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from The Director, CCDC, 12, Union Road, Cambridge CB2 1EZ, UK (fax: +44 1223 336033; e-mail: deposit@ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk)], Crystallographic data for [$(CH_3)C{=}NHCH_2C_2B_{10}H_{11}$][1-($H_3CCH_2$)-*closo*-1-$CB_{11}H_{11}$] **4a**: $C_9H_{36}B_{21}N$, $M = 385.4$, orthorhombic ($0.43 \times 0.13 \times 0.13$ mm, colourless prism from diffusion of diethyl ether into a solution in acetone), space group $P2_12_12_1$, $a = 7.2355(4)$, $b = 16.1780(9)$, $c = 20.4799(14)$ Å, $U = 2397.3(2)$ Å^3, $D_{calc} = 1.068$ Mg m^{-3}, $Z = 4$, Mo Kα, $\lambda = 0.71073$ Å, $\mu = 0.047$ mm^{-1}, $T = 150(2)$ K, $R_1 = 0.0607$ for 1896 reflections with $I > 2\sigma(I)$, and $wR_2 = 0.1580$ for all 3114 unique reflections; CCDC 280666.

hydrogen donor N(14) to hydrogen acceptor O(1) is 2.755 (3) Å, short when compared to a mean typical NHO hydrogen-bonded distance of 2.89 Å [22]. The positive charge associated with the alkylammonium residue will contribute to this stronger bonding; the hydrogen bonding will also be increased by the negative charge on the anion **2**, enhanced by the intracluster polarity mentioned in the previous paragraph. For similar reasons the NH–HB dihydrogen-bond distance of 1.90 Å is also towards the shorter end of the range of dihydrogen-bonding distances, typical such distances being held to range from 1.7 to 2.2 Å, with an average distance of 1.96 Å [23]. The N–H–H angle is also larger than the H–H–B angle, confirming the presence of a true dihydrogen bond, these angles being 146° and 110° respectively. A fragment of the extended solid-state structure of [1-(H_3NCH_2)-*closo*-1,2-$C_2B_{10}H_{11}$]$^+$[1-(H_3CCH_2)-*closo*-1-$CB_{11}H_{11}$]$^-$[H_2O] **3a** is illustrated in Fig. 4. There are no coordination polymers or networks as the hydrogen bonding and dihydrogen bonding only occur among the water molecule, the cation and the anion within a single asymmetric unit as in Fig. 2.

By contrast, in the extended crystal structure of the [1-{$(CH_3)_2C{=}NHCH_2$}-*closo*-1,2-$C_2B_{10}H_{11}$]$^+$[1-(H_3CCH_2)-*closo*-1-$CB_{11}H_{11}$]$^-$ salt **4a** there appear to be no significant

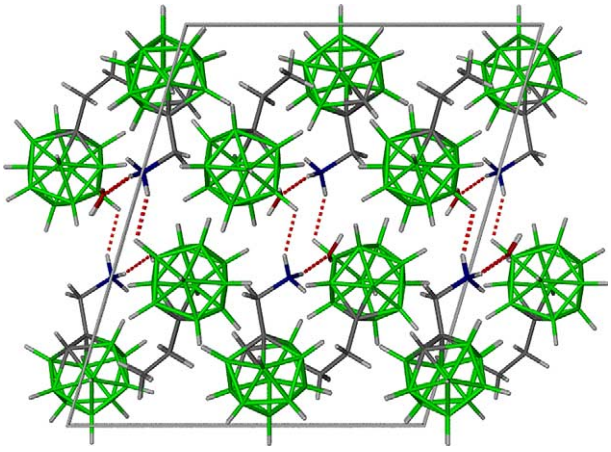

Fig. 4. Illustration of a fragment of the extended solid-state structure of [1-(H_3NCH_2)-*closo*-1,2-$C_2B_{10}H_{11}$]$^+$[1-(H_3CCH_2)-*closo*-1-$CB_{11}H_{11}$]$^-$ · H_2O (species **3a**). The view is looking directly down the *b*-axis of the unit cell. The unit cell is marked on as a grey box and the dotted red lines show the hydrogen and dihydrogen interactions. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

specific cation–anion interionic interactions of note. The basic unit of the structure of **4a** is shown in Fig. 3 above. The lattice can be regarded as being made up of layers of

cations with the anions packed between the layers (Fig. 5, upper diagram). A referee has suggested that CH···HB interactions [20] can contribute strongly to the observed cage ordering in **4a** and also in **3a** above. It is of interest that the pattern of layer assembly in the crystallographic *bc* plane that is evident from Fig. 5 closely resembles the packing of anions within the anionic layers of on the crystal structures of the $[NEt_4]^+$ salts of several of the smaller C-phenyl monocarbaborane anions $[PhCB_nH_n]^-$. Specifically the $[NEt_4]^+$ salts of the $[PhCB_6H_6]^-$, $PhCB_7H_7]^-$ and $[PhCB_8H_8]^-$ anions crystallise with alternate layers of $[NEt_4]^+$ cations and $[PhCB_nH_n]^-$ anions [11,12]. Within the anion layers, exemplified by the structure of $[NEt_4]^+[PhCB_6H_6]^-$ (Fig. 5, lower diagram), the phenyl groups pack among the carbaborane units in a very similar manner to the $\{CH_2CH_3\}$ and $\{CH_2NH_3\}$ groups in compound **4a** (Fig. 5, upper diagram).

There is considerable contemporary interest in the interaction of the Ag^+ cation with monocarbaborane anions [14,24–35]. In this regard, aspects of the extended solid-state structure of the precursive $[Ag]^+$ salt **2b** of the $[1\text{-}(H_3CCH_2)\text{-}closo\text{-}1\text{-}CB_{11}H_{11}]^-$ anion **2** also merit brief comment. The salt **2b** crystallises in a monoclinic crystal system and is solved in space group $P2_1/c$. The basic $[Ag]^+[1\text{-}(H_3CCH_2)\text{-}closo\text{-}1\text{-}CB_{11}H_{11}]^-$ unit is shown in Fig. 1 above. In the crystal lattice the Ag^+ cation coordinates to three separate monocarbaborane anions (Fig. 6). Coordination occurs via monocarbaborane hydrogen atoms, with the first anion (the one in Fig. 1) coordinating via a single hydrogen atom in its {BH} position 7, the second anion coordinating via a hydrogen atom in its {BH} position 10, and with the third anion coordinating via two adjacent hydrogen atoms in its {BH} positions 8 and 9. These together result in a fourfold coordination sphere around the Ag^+ cation that is distorted slightly from regular tetrahedral geometry. The Ag–H interatomic distances to the first two anions, Ag(1)–H(7) at 2.078 and Ag(1)–H(10) at 1.943 Å, of which each exhibits only one such interaction to a particular Ag^+ cation, are within an atom-radius sum of 2.34 [cationic tetrahedral silver(I) at 1.14 Å and a hydrogen Van der Waals radius of, say, 1.20 Å], implying significant attractive interaction. The attractions to the doubly-coordinating anion are somewhat weaker, with the two somewhat longer distances Ag(1)–H(8) of 2.352 and Ag(1)–H(9) of 2.301 Å.

The extended solid-state structure of **2b** is characterised by layers that pack parallel to the *bc* plane of the unit cell. These layers are two asymmetric units in width and are held together by the Ag–H interactions detailed in Fig. 6 and discussed in the previous paragraph. The polar interactions between the Ag^+ cations and the monocarbaborane anions dictate each of these layers, each consisting of

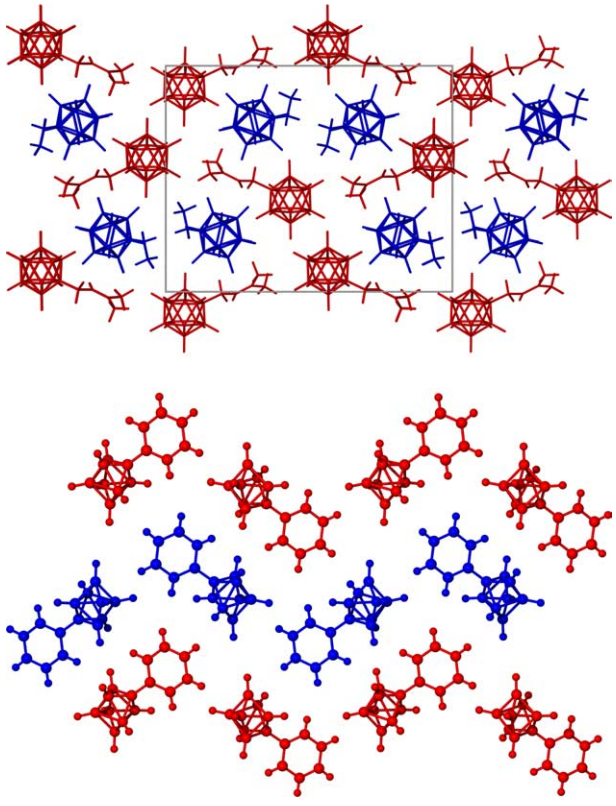

Fig. 5. *Upper diagram:* Illustration of a fragment of the extended solid-state structure of $[1\text{-}\{(CH_3)_2CNHCH_2\}\text{-}closo\text{-}1,2\text{-}C_2B_{10}H_{11}]^+$-$[1\text{-}(H_3CCH_2)\text{-}closo\text{-}1\text{-}CB_{11}H_{11}]^-$ (species **4a**). The view is looking directly down the *a*-axis of the unit cell. The unit cell is drawn as a grey box. Cations are coloured red and anions are coloured blue. *Lower diagram*: Illustration of a fragment of the extended solid-state structure of $[NEt_4]^+[PhCB_7H_7]^-$ (data from reference [11]; CCDC 164852) to illustrate the similarities in packing with species **4a**. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

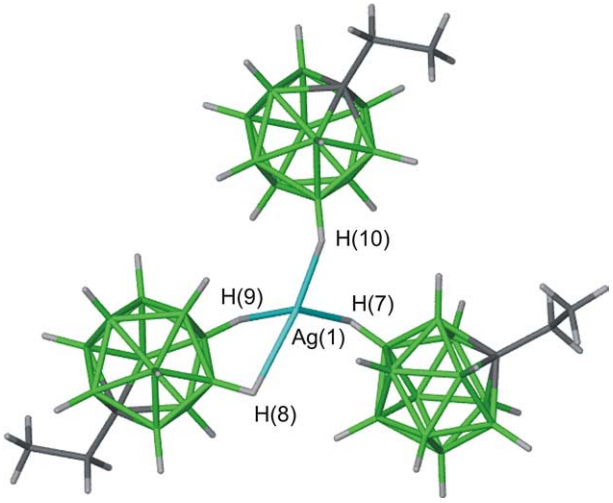

Fig. 6. Illustration to show the silver cation environment in the solid-state structure of $[Ag]^+[1\text{-}(H_3CCH_2)\text{-}closo\text{-}1\text{-}CB_{11}H_{11}]^-$ (species **2b**). The Ag^+ cation is coordinated to four hydrogen atoms in a fourfold coordination mode that is slightly distorted from regular tetrahedral geometry. Relevant interatomic distances are Ag(1)–B(7) 2.666(13), Ag(1)–B(8) 2.713(11), Ag(1)–B(9) 2.689(12), Ag(1)–B(10) 2.764(12), Ag(1)–H(7) 2.078, Ag(1)–H(8) 2.352, Ag(1)–H(9) 2.301 and Ag(1)–H(10) 1.943 Å. The H–Ag–H angles are 76.4°, 79.7°, 104.1°, 110.0°, 128.1° and 140.7°.

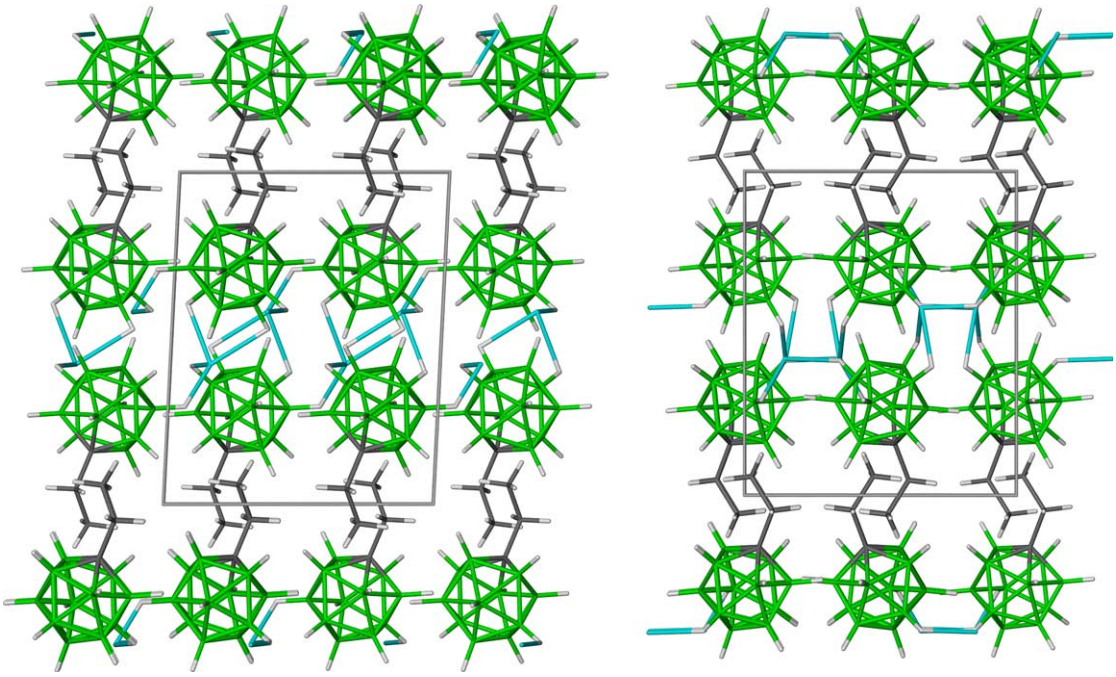

Fig. 7. Views showing fragments of the extended crystal structure for $[Ag]^+[1\text{-Et-}closo\text{-}1\text{-}CB_{11}H_{11}]^-$ (species **2b**): left, viewed down the *b*-axis, and right, viewed down the *c*-axis. The unit cell is marked on the diagrams as a grey box and the Ag^+ cations are shown in blue. The dotted red lines distinguish where the parallel double layers of anions mesh together with their lipophilic C-ethyl groups interlocking. The two-sub-layers of anions in the double layers are held together internally by B–H–Ag interaction with the central core of $[Ag]^+$ cations (see Fig. 6).

Ag^+ cations held between two sub-layers of anions. The layers then stack by means of lipophilic ethyl–ethyl interactions between ethyl groups from adjacent layers. Illustrative fragments of the extended solid-state structure are represented in Fig. 7.

Interestingly in the context of these solid-state silver-to-cluster interactions is that negative-ion electrospray mass-spectrometry results for liquid solutions of **2b** show not only an isotopomer mass-envelope with an intensity maximum of *m/z* 171.1, corresponding to the uncoordinated $\{C_3B_{11}H_{16}\}^-$ anion **2**, but also a mass-envelope with an intensity maximum of *m/z* 450.0, which corresponds to two anions **2** coordinated to the $[Ag]^+$ cation, viz. an $\{Ag(C_3B_{11}H_{16})_2\}^-$ assembly. This suggests that the associations between the $[Ag]^+$ cations and monocarbaborane anions may well persist to a significant extent in solution. We are currently examining a series of several silver salts of the monocarbaboranes for this type of anion–cation interactive behaviour.

Acknowledgements

We thank the Basque Government for financial support, and the UK DTI for support of our monocarbaborane work. We also acknowledge support from the UK EPSRC for equipment grants (J/56929, L/49505 and R/61949) and for contributions to a Research DTA for M.J.C. We also thank Ian Moss and Richard Taylor of Dow Corning Ltd. for their good offices, and Colin Kilner for assistance with X-ray crystallography.

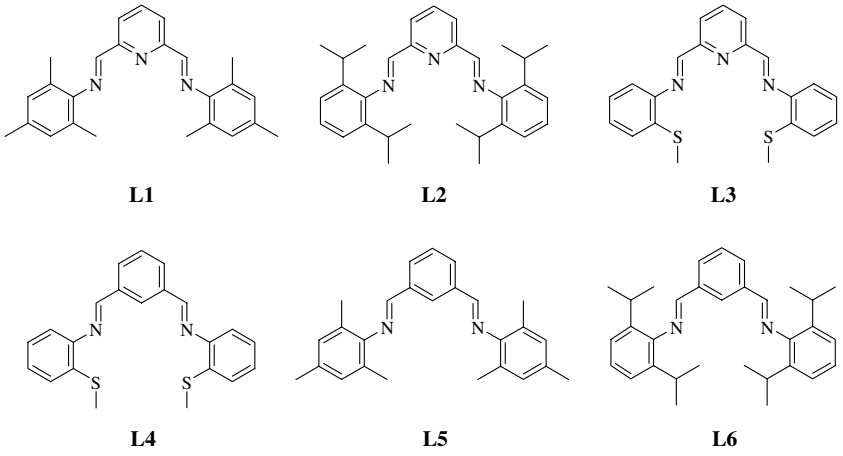
complexes of bis(benzimidazolyl)-thioether donors with N_2S [5–7], N_2S_2 [8–12] and N_2S_3 [13–17] donor sets have been synthesized as models for the active sites in proteins and their structures, spectra and redox behaviour have been investigated with the goal of relating the electronic structure properties to the active site reactivity.

In our laboratory we have undertaken a systematic structural, spectroscopic and electrochemical study on a series of mononuclear copper(II) complexes of linear polydentate bis(benzimidazolyl)-thioether/amine/pyridine ligands [7,18–20] offering N and S donor atoms. The copper(II) complexes of nitrogen and sulfur containing Schiff base ligands have been demonstrated as valid models for blue copper proteins. Also, there is a continuing interest in investigating the relationship between the redox potentials and other electrochemical parameters and the spectral/geometrical parameters of Schiff base metal complexes, which could be the result of steric and electronic effects [21]. In this report, we describe the synthesis of copper(II) complexes of di-, tri-, tetra- and pentadentate ligands (Scheme 1) containing heterocyclic N, imine N and thioether S donors with different and varying steric demands. The 3N ligands **L1** and **L2** have been designed as they have the ability to form copper(II) complexes in a meridional rather than facial coordination mode. Two thioether sulfur atoms have been incorporated into the 3N framework of **L1/L2** to offer a N_3S_2 donor set (**L3**). The ligand **L4** has been synthesized to generate a novel CuN_2S_2 coordination geometry with steric constraints, to help in understanding the role of the central pyridine nitrogen in **L3**. The 2N ligands **L5** and **L6** are sterically constrained to impose geometric distortions in bis-complexes of copper(II). The X-ray crystal structure of the copper(II) complex of **L2** has been successfully determined. The spectral and electrochemical properties of the complexes have been studied and the results discussed.

2. Results and discussion

2.1. Synthesis

A series of systematically varied ligands have been synthesized with the aim to understand the effect of ligand electronic and steric factors upon the structure and spectra of the copper(II) complexes. The ligands **L1**, **L2** and **L3** have been synthesized using the reported procedure with slight modifications, by condensing 2,6-pyridinedicarboxaldehyde [22] with 2,4,6-trimethylaniline, 2,6-diisopropylaniline and 2-(methylthio)aniline, respectively. The ligands **L4**, **L5** and **L6** have been obtained by the condensation of isophthalaldehyde with the corresponding sterically hindered anilines. The results of elemental analyses of **L1**–**L6** were satisfactory and the ^1H and ^{13}C NMR confirmed the identity of the ligands. All the Schiff base ligands, except **L6**, readily form complexes on treating one or two equivalents of them with copper(II) salts in methanol at room temperature. The perchlorate complexes were synthesized in order to avoid the competing coordination of chloride ions to copper(II) in the presence of weakly coordinating thioether sulfur donors. Our attempt to synthesize $[Cu(L6)_2]^{2+}$ was unsuccessful and no pure solid product could be isolated from the brown solutions obtained on mixing the ligand **L6** and copper(II) perchlorate. The stoichiometries of the complexes were derived from elemental analysis and conductivity studies and that of complex **2** was confirmed by determining its X-ray crystal structure. The observed values of molar conductance suggest [23] that the complexes **1**, **2** and **4a** (30–60 Ω^{-1} cm^2 mol^{-1}) behave as neutral species, while the complexes **3**–**5** (160–205 Ω^{-1} cm^2 mol^{-1}) exist as 1:2 electrolytes in solution. The molar conductance (90 Ω^{-1} cm^2 mol^{-1}) of **3a** suggests that it behaves as 1:1 electrolyte in solution. The IR spectral data of the complexes support the coordination of the ligands to copper(II). The C=N (1700–1580 cm^{-1}) and C–S (**L3**, 690; **L6**,



Scheme 1.

685 cm^{-1}) stretching vibrations of the ligands are shifted to lower frequencies (ν(C=N), 1600–1470 cm^{-1}; ν(C–S), 645–635 cm^{-1}) upon complex formation. The intense bands observed around 1095 and 625 cm^{-1} for the perchlorate complexes are due to ν(Cl–O) of uncoordinated perchlorate anions.

2.2. Description of the structure of [Cu(L2)Cl_2] (2)

The ORTEP representation of the structure of the complex including the atom numbering scheme is shown in Fig. 1. The crystallographic data are given in Table 1 while the bond lengths and bond angles are collected in Table 2. The structure of the complex molecule involves a five-coordinate CuN_3Cl_2 chromophore constituted by two imine (N9, N23) and one pyridine (N2) nitrogen of the tridentate ligand **L2** and two chloride ions. The geometry around copper(II) is best described as distorted square pyramidal [24], as evident from the value of the trigonal index [11] τ of 0.18 [$\tau = (\beta - \alpha)/60$, where α = N2–Cu1–Cl36 = 160.42(5)° and β = N23–Cu1–N9 = 149.63(7)°; for perfect square pyramidal and trigonal bipyramidal geometries the τ values are zero and unity, respectively]. The N9, N23 and N2 nitrogen atoms of the meridionally coordinated **L2** ligand and one of the chloride ions (Cl36) occupy the corners of the square plane. The other chloride ion (Cl37) is axially coordinated at an average angle of 99.43° to the CuN_3Cl plane. The Cu–N_{py} (1.9523 Å) and Cu–N_{imine} bond distances (2.1203, 2.1482 Å) fall in the range of values found for similar complexes [25,26]. The axial chloride ion is located at a distance (2.391 Å) longer than the equatorially located chloride ion (2.203 Å). The two phenyl rings are almost parallel to each other as in this arrangement the steric interaction between them is minimized. Also, interestingly, the bulky isopropyl substituents on the phenyl rings are pushed away from the chloride ions and hence there is no steric clash between them.

2.3. Spectral properties

The solid-state reflectance spectra of all the complexes display either one broad or two poorly separated ligand-field bands (11 900–15 800 cm^{-1}) in the visible region, which is typical of Cu(II) located in a weakly tetragonal field [27]. On dissolution in methanol or acetonitrile no

appreciable change in the ligand field bands is observed for the complexes **1**, **2** and **4** (Table 3). However, noticeable changes in the ligand field features are observed for the complexes **3** and **5**. For the complexes **1** and **2** two more absorption bands are observed at higher energies (**1**, 23 900 and 26 200 cm^{-1}; **2**, 26 300 and 28 000 cm^{-1}), which are presumably derived from nitrogen to copper(II) charge transfer (CT) transitions. Replacing the methyl groups in **1** by the more sterically demanding isopropyl groups, as in **2**, would be expected to effect distortions in the copper(II) coordination geometry and hence lower the LF energy, but no significant spectral differences are observed. Obviously, the free rotation of the phenyl rings in the complexes (cf. above) minimize the steric constraints around copper(II), which is independent of the phenyl ring substituents and hence similar LF features are observed for **1** and **2**. For complex **3**, two ligand to metal charge transfer (LMCT) bands, characteristic of $S(\sigma) \rightarrow Cu(II)$ and $N(\pi) \rightarrow Cu(II)$ transitions, are observed (33 200 and 32 700 cm^{-1}). Complex **4** in acetonitrile solution shows an absorption band (13 500 cm^{-1}) with enhanced absorptivity (2340 $M^{-1}\,cm^{-1}$) in the visible region, which may be attributed to intensity borrowing [28] from the $S(\sigma) \rightarrow Cu(II)$ LMCT band, providing strong evidence for thioether coordination to copper(II) in solution. The noteworthy observation is that the LF band energy of **4** is lower than that of **3**, with the absorptivity of **4** being 30-fold higher than that of **3** (Table 3). This suggests the presence of an axial interaction by solvent and/or distortion around copper(II) effected by the N_2S_2 donor set of the **L4** ligand, which is unfavourable for square planar coordination. The difference in electronic spectra of **3** and **4** in methanol solution indicates that complex **4** experiences partial or complete replacement of one or two weakly coordinated thioether donors by coordinating solvents. The chloride complex **4a** exhibits a spectral pattern closely similar to **4**, but with very low absorptivity (Table 3). The bis-complex **5**, which does not have a pyridine donor as in **L1**–**L3**, exhibits a broad LF band around 13 900 cm^{-1} with a shoulder around 18 900 cm^{-1}, implying a distorted square based coordination geometry. This is expected as copper(II) complexes with a N_4 donor set display a LF band in the range 14 000–19 000 cm^{-1} [7,27].

The polycrystalline EPR spectra of complexes **2**, **4a** and **5** are isotropic while those of complexes **3** and **3a** are axial. Interestingly, the complexes **1** and **4** show rhombic spectra with R values greater than unity [$R = (g_3 - g_2)/(g_2 - g_1) =$ 1.2 (**1**); 1.1 (**4**), Table 3]. The rhombicity is more likely to arise from the interaction between differently oriented Cu(II) complexes rather than a d_{z^2} ground state for copper(II) in the solid state [29,30]. The cryogenic solution EPR spectra of all the complexes are axial [$g_\parallel > g_\perp > 2.0$, $G = (g_\parallel - 2)/(g_\perp - 2) = 3.0$–4.5], suggesting the presence of a $d_{x^2-y^2}$ ground state for copper(II) located in square based geometries [31,32]. The complex $[Cu(L2)Cl_2]$ (**2**) shows $g_\parallel$ (2.254) and $A_\parallel$ ($133 \times 10^{-4}\,cm^{-1}$, Fig. 2) values, which are consistent with the '$CuN_3Cl + Cl$' chromophore as observed in the X-ray crystal structure. The complex $[Cu(L)(H_2O)_2](ClO_4)_2.(H_2O)_2$ (L = bis(benzimidazol-2-yl) methylamine) [30] with the CuN_3O_2 chromophore shows similar $g_\parallel$ (2.268) and $A_\parallel$ ($140 \times 10^{-4}\,cm^{-1}$) values. However, copper(II) complexes of tridentate ligands with a CuN_3Cl_2 coordination sphere, synthesized in our laboratory very recently [33], exhibit $g_\parallel$ and $A_\parallel$ values in the range 2.21–2.25 and 179–184 $\times 10^{-4}\,cm^{-1}$, respectively. Though the $g_\parallel$ value of complex **2** falls within this range, the very low $A_\parallel$ value observed indicates a large deviation from axial symmetry, which is evident from its crystal structure. It is interesting to compare the complexes **1** and **2**, which are expected to have similar coordination geometries. On replacing isopropyl groups in **2** by methyl groups as in **1** the $g_\parallel$ value decreases and the $A_\parallel$ value increases suggesting a decrease in geometric distortion or axial interaction with copper(II). This is supported by the lower $g_\parallel/A_\parallel$ quotient (131 cm) of complex **1**, which falls in the range 105–135 cm, as expected [34] for square-planar copper(II) complexes. The $g_\parallel$ and $A_\parallel$ values of **2**, which are higher and lower, respectively, than **1**, suggest that the former possesses a coordination geometry distorted ($g_\parallel/A_\parallel$, 169 cm) more than **1** because of the sterically demanding isopropyl groups, rather than an axial interaction [35]. This is in contrast to the similar electronic spectral parameters of **1** and **2** suggesting the usefulness of EPR spectroscopy in detecting even small differences in coordination geometries.

The copper(II) complexes containing bis(benzimidazolyl)-thioether ligands [19] offering a N_3S_2 donor set display $g_\parallel$ and $A_\parallel$ values in the range 2.24–2.29 and 138–187 $\times 10^{-4}\,cm^{-1}$, respectively. Complex **3**, also with a N_3S_2 donor set, exhibits a $g_\parallel$ value of 2.249 and an $A_\parallel$ value of $140 \times 10^{-4}\,cm^{-1}$ (Fig. 2). The relatively low $A_\parallel$ value of complex **3** supported by the relatively low value of LF band energy indicates the presence of strong geometric distortion or strong axial interaction in the square-based coordination geometry. The EPR spectral features of **3a** are very similar to that of **3**; however, a lower $g_\parallel/A_\parallel$ value is observed for **3a**. On replacing the pyridine ring in the **L3** complex by a benzene ring as in complex **4**, the $g_\parallel$ (2.382) and $A_\parallel$

[a] Concentration, 2×10^{-3} M for ligand field and 2×10^{-5} M for ligand based transitions.
[b] $A_\parallel$ in 10^{-4} cm^{-1}.
[c] The species $[Cu(solvent)_4]^{2+}$ is also present ($g_\parallel$ 2.418; $A_\parallel$, 148×10^{-4} cm^{-1}).
[d] Values in methanol, $g_\parallel$ 2.408; $A_\parallel$ 134×10^{-4} cm^{-1}; $g_\perp$ 2.099.
[e] Values in DMF, $g_\parallel$ 2.404; $A_\parallel$ 131×10^{-4} cm^{-1}; $g_\perp$ 2.089.

(148×10^{-4} cm^{-1}) values are enhanced (Table 3). This reveals the presence of a severely distorted square planar stereochemistry around copper(II) in **4** effected by the N_2S_2 donor atoms, the geometrical disposition of which are unfavourable for square planar coordination around Cu(II).

2.4. Redox chemistry

The electrochemical data obtained in methanol or acetonitrile solution of the present complexes using TBAP as a supporting electrolyte are collected in Table 4. For all the complexes the one electron reduction peak (E_{pc}) corresponding to Cu(II) to Cu(I) reduction occurs in the potential range 0.508–0.208 V, with a directly associated reoxidation peak (E_{pa}) in the reverse scan, whose potential values fall within the range 0.702–0.296 V (Table 4). Further, the original Cu(II) complex species undergoing reduction are completely regenerated following electrochemical oxidation (the ratio of peak currents, $i_{pa}/i_{pc} \sim 1.0$, Table 4) suggesting a chemically reversible Cu^{II}/Cu^{I} couple. However, the value of the limiting peak-to-peak separation (ΔE_p, 86–226 mV) is higher than that for the Fc/Fc^+ couple (ΔE_p, 84 mV; $E_{1/2}$, 0.414 V) under identical conditions.

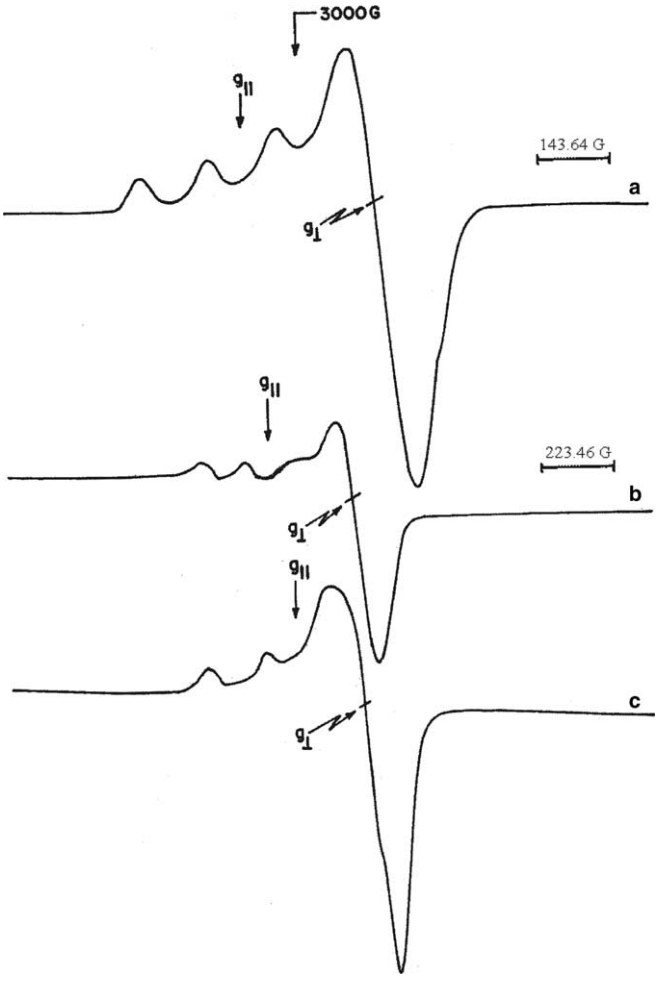

Fig. 2. X-band EPR spectra of the complexes $[Cu(L2)Cl_2]$ (**2**) (a) in methanol/acetone and $[Cu(L3)](ClO_4)_2$ (**3**) (b) and $[Cu(L5)_2](ClO_4)_2$ (**5**) (c) in acetonitrile/acetone solution at 77 K.

This suggests that the heterogeneous electron-transfer process in most of the present complexes is far from reversible and that on electron transfer considerable stereochemical reorganization of the coordination sphere occurs. However, quantitative conclusions on the extent of such reorganization are difficult to estimate [36]. Interestingly, the complexes **1** (Fig. 3) and **2** (Fig. 4(a)) have a minimal reorganizational energy barrier (ΔE_p, **1**, 88; **2**, 86; Fc/Fc^+, 84 mV) indicating that the structural reorganization between the two oxidation states is minimum and hence electron transfer in these complexes is facile. It is relevant to note that in naturally occuring electron transfer copper proteins the redox is facile because of minimal structural changes between the redox pairs.

Complex **2** exhibits a one electron reduction at 0.268 V and the corresponding oxidation occurs at 0.348 V. Interestingly, an additional anodic peak at 0.484 V is observed (Fig. 4(a)), which can be explained by assuming a square scheme (Scheme 2). As the conductance of **2** is 30 Ω^{-1} cm^2 mol^{-1} it is probable that the complex is present as a $[CuLCl]^+$ species. The additional peak may arise from the oxidation of a trigonal planar (tp) Cu(I) species. Thus, when the scan rate is increased from 50 to 500 mV the additional peak grows in height suggesting that at higher scan rates the tp Cu(I) species is preferentially formed immediately on reducing the square planar (sp) $[CuLCl]^+$ species. Further, on addition of Cl^- ions (LiCl), the height of the additional anodic peak decreases illustrating that the tp Cu(I) species combine with the Cl^- ion to form a tetrahedral Cu(I) species, decreasing its concentration. It may be noted that the tp Cu(II) species corresponding to the tp Cu(I) species could not be detected, obviously because the isopropyl substituents on the phenyl rings in the Cu(II) species would be brought closer to exhibit strong steric clashes leading to

its destability. Thus, in the X-ray structure of the tp Cu(I) complex $[Cu(bbtmp)](NO_3)$ [bbtmp = 2,6-bis (benzimidazol-2′-ylthiomethyl)pyridine] the benzimidazole rings are closer to each other than in the corresponding tetrahedral [Cu(bbtmp)Cl] species [17]. From the difference in E_{pa} values (ΔE_{pa}) for the oxidation of the two Cu(I) species, the $\Delta E_{1/2}$ values for the redox of [Cu(L2)Cl] and $[Cu(L2)]^+$ species was estimated assuming reversibility, from which the K_1/K_2 value was calculated [37] as 7.9×10^{-3}. The magnitude of K_1/K_2 illustrates that the tp Cu(II) species rather than the tp Cu(I) species readily combines with Cl^- ions leading to the non-detection of the tp Cu(II) species. Similarly, the tp Cu(I) species shows a reluctance to bind to the Cl^- ion illustrating the above observation that the tp Cu(I) species are directly formed from square planar $[Cu(L2)Cl]^+$ species on reduction. The decreased steric constraints in the tp Cu(II) species of **1** leads to its detection in the CV (E_{pc}, 0.391 V), in contrast to **2**. Similarly, the tp Cu(I) species for **1** will be more stable than that for **2** and hence combine with Cl^- less strongly (K_1/K_2, 1.8×10^{-3}, calculated from the two $E_{1/2}$ values (Table 4) obtained from differential pulse voltammetry (DPV)). As for **2**, an increase in scan rate leads to the formation of more tp Cu(I) species, as seen from the increase in height of the additional anodic peak with increase in scan rate. The tp Cu(II) species of **1** is more stable because the steric clash between the two phenyl rings carrying the methyl groups is less compared to the corresponding tp Cu(II) species of **2** and hence its detection in the CV.

Complex **3**, bearing a CuN_3S_2 coordination sphere, shows a positive redox potential of 0.395 V (Fig. 4(b)). The incorporation of two sulfur atoms into **1** as in complex **3** leads to a Cu(II)/Cu(I) redox potential higher than **1/2** suggesting the involvement of thioether coordination in **3** [38]. The higher $E_{1/2}$ value (0.403 V) observed for the chloro complex **3a** is almost the same as for **3** but, interestingly, the ΔE_p value of complex **3a** (226 mV) is higher than **3** (114 mV). This suggests that the chloride ion coordinates to copper(II), as shown by the lower conductance (90 Ω^{-1} cm^2 mol^{-1}) of **3a**. Further, the addition of excess LiCl shifts the cathodic peak to a more

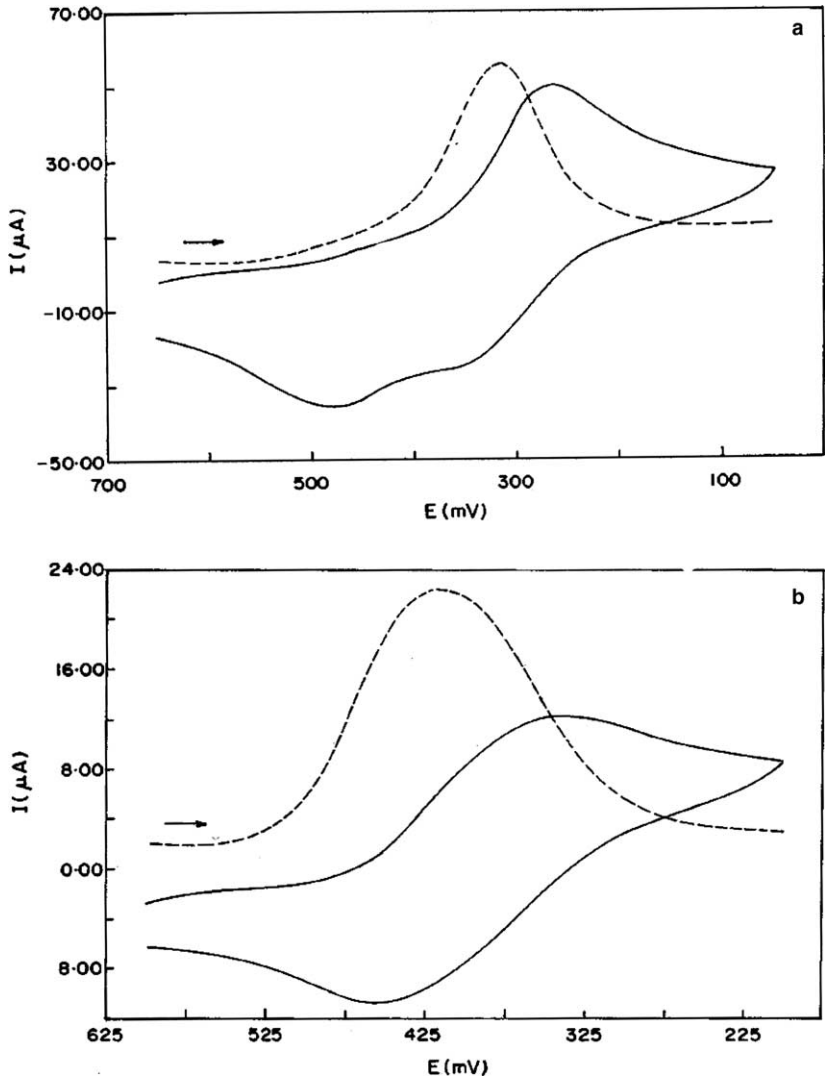

Fig. 4. Cyclic (——) and differential pulse (-----) voltammograms of the complexes $[Cu(L2)Cl_2]$ (**2**) (a) and $[Cu(L3)](ClO_4)_2$ (**3**) (b) and methanol solution at 25 °C at 0.05 V s^{-1} scan rate.

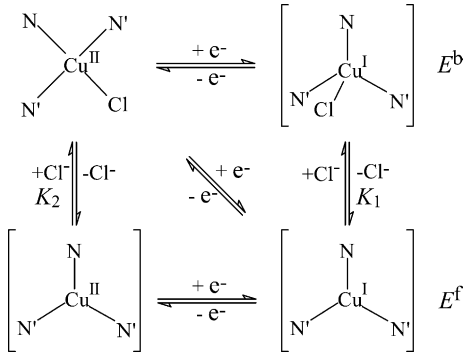
negative value confirming the coordination of the chloride ion to copper(II), which renders the reduction more difficult.

The complexes **4** and **4a** display redox potentials higher than complexes **3** and **3a**, which is expected with the incorporation of hard N donors into the CuN_2S_2 coordination sphere of **4** and **4a**. An interesting electrochemical behaviour was observed for the chloro complex **4a**, which undergoes reduction at a very low positive potential of 0.230 V with a shoulder around 0.438 V. The high ΔE_p value (318 mV) and the observation of two waves in DPV at different potentials suggest the coordination of Cl^- ion as illustrated above for **2**. A well-defined CV with a low ΔE_p value of 90 mV was obtained after the addition of excess of LiCl, supporting the dissociation of chloride ions as proposed above. It should be noted that all these proposals are only speculative in the absence of crystal structures of the complexes. The bis-complex **5** also exhibits positive redox potentials (0.438 V) because of the bulky *N*-phenyl groups, which would favour the formation of tetrahedral copper(I) species more than complex **1**, which may be



Scheme 2.

due to the presence of hard N donors in the latter complex as discussed above. The high redox potential (0.592 V versus Ag/Ag^+) for the Cu(II)/Cu(I) couple of complex **4** may be attributed to tetrahedral distortion from a regular square-based geometry.

3. Conclusions

The distinct spectral and electrochemical behaviour of copper(II) complexes of five sterically hindered Schiff base ligands have been studied. The 1:1 copper(II) complex of 2,6-bis(2,6-diisopropylphenyliminomethyl)pyridine adopts a distorted square pyramidal geometry. The replacement of isopropyl groups in this complex by the less sterically demanding methyl groups leads to a similar coordination geometry as revealed by their similar spectral and electrochemical features. However, the redox potential of the isopropyl complex is higher than the methyl complex, which is consistent with the higher $g_{\|}$ value [39] of the former complex, illustrating the importance of sterically demanding isopropyl groups in distorting the coordination geometry around copper(II). Further, the interaction of a thiolate moiety with the methyl/isopropyl complexes would be expected to generate a Cu(I) trigonal pyramidal-like or tetrahedral-like coordination geometry, which would be a better copper(II) model for the active sites of electron transfer copper proteins. Thus, Holland and Tolman [40] have recently reported four-coordinate copper(II) complexes with a thiolate and thioether containing chelating ligand and a bidentate β-diketiminate as an auxiliary ligand and these complexes are believed to be close structural mimics for the type I copper proteins. However, these complexes fail to reproduce the positive redox potential of the blue copper proteins.

The copper(II) complexes of sterically constrained ligands providing N_3S_2 and N_2S_2 donor sets, which are unfavourable for square planar coordination, have also been synthesized and characterized. The spectral and electrochemical properties of these complexes suggest the presence of thioether coordination in solution. The incorporation of a pyridine nitrogen donor into the CuN_2S_2 complexes leads to a higher LF band energy but with lower absorptivity, suggesting lesser distortion in the coordination sphere. Both the CuN_3S_2 and CuN_2S_2 complexes show positive redox potentials suggesting the coordination of at least one thioether sulfur. The bis-complex of a sterically hindering bidentate ligand also shows a positive redox potential suggesting that the distortion in the coordination sphere is significantly large.

4. Experimental

4.1. Materials

Copper(II) chloride dihydrate, copper(II) perchlorate hexahydrate, 2,6-pyridinedimethanol, 2,4,6-trimethylaniline, 2,6-diisopropylaniline, selenium dioxide (Aldrich), isophthaladehyde (Lancaster) were used without further purification.

4.2. Synthesis of ligands

4.2.1. 2,6-Bis(2,4,6-trimethylphenyliminomethyl)pyridine (*L1*)

2,6-Pyridinedicarboxaldehyde (0.68 g, 5.0 mmol) and 2,4,6-trimethylaniline (1.35 g, 10.0 mmol) were refluxed [26] in methanol (25 mL) for 2 h over molecular sieves (4 Å). The reaction mixture was filtered while hot. The yellow crystals of **L1** (1.64 g, 89%) obtained upon cooling the reaction mixture were filtered off and dried. *Anal*. Calc. for $C_{25}H_{27}N_3$: C, 81.3; H, 7.4; N, 11.4. Found: C, 81.4; H, 7.5; N, 11.4%. ^{1}H NMR ($CDCl_3$, 400 MHz): δ, ppm 8.39 (s, 2H, *H*C=N), 8.38 (d, $J = 7.8$, 2H, *H*Py), 7.97 (t, $J = 7.6$, 1H, *H*Py), 6.91 (s, 4H, *H*Ph), 2.30 (s, 6H, H_3C–PhC_4), 2.16 (s, 12H, H_3C–PhC_2). ^{13}C NMR (CDCl3, 100 MHz): δ, ppm 163.6 (*C*H=N), 155.0, 148.2, 137.7, 134.0, 129.3, 127.2, 123.0 (*C*Py, CPh), 21.2 (CH_3–C_4), 18.7 (CH_3–C_2). IR (KBr): ν, cm^{-1} 2971s, 2914s, 2914s, 1640vs, 1481s, 1205vs, 1140s, 835s, 733s.

4.2.2. 2,6-Bis(2,6-diisopropylphenyliminomethyl)pyridine (*L2*)

The ligand **L2** was synthesized by the reported procedure [41]. To a solution of 2,6-pyridinedicarboxaldehyde (0.68 g, 5.0 mmol) in ethanol (25 mL) were added 2,6-diisopropylaniline (1.77 g, 10.0 mmol) and one drop of glacial acetic acid, and the resulting mixture was refluxed over molecular sieves (4 Å). After 24 h the reaction mixture was filtered and the ligand (1.78 g, 78%) was obtained upon cooling. *Anal*. Calc. for $C_{31}H_{39}N_3$: C, 82.1; H, 8.7; N, 9.3. Found: C, 81.5; H, 8.9; N, 9.5%. ^{1}H NMR ($CDCl_3$, 400 MHz): δ, ppm 8.41 (d, $J = 7.8$, 2H, *H*Py), 8.39 (s, 2H, *H*C=N), 8.01 (t, $J = 7.8$, 1H, *H*Py), 7.21–7.10 (m, 6H, *H*Ph), 3.00 (sep, $J = 6.8$, 4H, $HC(H_3C)_2$), 1.20 (d, $J = 6.8$, 24H, $(H_3C)_2C$). ^{13}C NMR ($CDCl_3$, 100 MHz): δ, ppm 162.8 (*C*H=N), 154.6, 148.4, 137.5, 137.3, 124.7, 123.2, 122.9 (*C*Py, *C*Ph), 28.1 ($CH(H_3C)_2$), 23.6 ($(CH_3)_2C$). IR (KBr): ν, cm^{-1} 3065w, 2961vs, 1585vs, 1566w, 1456w, 1319s, 1184s, 748s.

4.2.3. 2,6-Bis(2-methylthiophenyliminomethyl)pyridine (*L3*)

A mixture of 2,6-pyridinedicarboxaldehyde (0.68 g, 5.0 mmol) and 2-(methylthio)aniline (1.47 g, 10.5 mmol) were refluxed in benzene (20 mL) for 36 h. The reaction mixture was filtered under hot conditions. Fine yellow crystals of **L3** (1.16 g, 62%) were obtained on recrystallization in benzene, which was filtered off and dried. *Anal*. Calc. for $C_{21}H_{19}N_3S_2$: C, 66.8; H, 5.1; N, 11.1. Found: C, 66.9; H, 5.1; N, 11.2%. ^{1}H NMR ($CDCl_3$, 400 MHz): δ, ppm 8.63 (s, 2H, *H*C=N), 8.41 (d, $J = 7.8$, H, *H*Py), 7.95 (t, $J = 7.8$, 1H, *H*Py), 7.36–7.11 (m, 8H, *H*Ph), 2.49 (s, 6H, H_3C). ^{13}C NMR ($CDCl_3$, 100 MHz): δ, ppm 159.7 (*C*H=N), 154.7, 147.8, 137.5, 135.1, 127.5, 125.4, 124.7, 123.6, 117.5 (*C*Py, *C*Ph), 14.9 (CH_3). IR (KBr): ν, cm^{-1} 3050w, 2978w, 2913s, 1619vs, 1570w, 1468s, 1331s, 800s, 724vs.

4.2.4. 1,3-bis(2-methylthiophenyliminomethyl)benzene (*L4*)

The ligand **L4** was synthesized by the same method adopted for **L3**, using isophthalaldehyde (0.67 g, 5.0 mmol). The yellow solid precipitated was filtered off and dried (1.43 g, 76%). *Anal*. Calc. for $C_{22}H_{20}N_2S_2$: C, 70.2; H, 5.4; N, 7.4. Found: C, 70.2; H, 5.3; N, 7.5%. ^{1}H NMR ($CDCl_3$, 400 MHz): δ, ppm 8.50 (s, 2H, *H*C=N), 8.41 (s, 1H, *H*Ph), 8.14 (d, $J = 7.8$, 1H, *H*Ph), 8.13 (d, $J = 7.6$, 1H, *H*Ph), 7.59 (t, $J = 7.6$, 1H, *H*Ph), 7.24–7.03 (m, 6H, *H*Ph), 7.01 (d, $J = 7.6$, 2H, *H*Ph), 2.48 (s, 6H, H_3C). ^{13}C NMR ($CDCl_3$, 100 MHz): δ, ppm 159.3 (*C*H=N), 148.9, 136.9, 134.3, 131.5, 130.2, 129.4, 126.8, 125.4, 124.7, 117.7 (*C*Ph), 14.9 (CH_3). IR (KBr, ν, cm^{-1}): 3050w, 2978w, 2905w, 1614vs, 1570s, 1466s, 1436s, 1351s, 1268s, 1071s, 804s, 754vs, 691s.

4.2.5. 1,3-bis(2,4,6-trimethylphenyliminomethyl)benzene (*L5*)

The ligand **L5** was prepared by refluxing isophthalaldehyde (0.67 g, 5.0 mmol) and 2,4,6-trimethylaniline (1.42 g, 10.5 mmol) in benzene (20 mL) for 36 h over molecular sieves (4 Å). The reaction mixture was filtered and the solvent removed under vacuum. The excess amine was evaporated on warming gently under high vacuum. The ^{1}H NMR spectrum of the residue showed that the product was sufficiently pure (1.62 g, 88%). *Anal*. Calc. for $C_{26}H_{28}N_2$: C, 84.7; H, 7.7; N, 7.6. Found: C, 84.8; H, 7.7; N, 7.7%. ^{1}H NMR ($CDCl_3$, 400 MHz): δ, ppm 8.36 (s, 1H, *H*Ph), 8.31 (s, 2H, *H*C=N), 8.10 (d, $J = 7.6$, 1H, *H*Ph), 8.09 (d, $J = 7.8$, 1H, *H*Ph), 7.63 (t, $J = 7.6$, 1H, *H*Ph), 6.91 (s, 4H, *H*Ph), 2.31 (s, 6H, H_3C–C_4), 2.15 (s, 12H, H_3C–C_2). ^{13}C NMR ($CDCl_3$, 100 MHz): δ, ppm 162.1 (*C*H=N); 148.6, 136.9, 133.3, 130.9, 129.4, 128.9, 128.8, 127.1 (*C*Ph), 20.9 (CH_3–C_4), 18.4 (CH_3–C_2).

4.2.6. 1,3-bis(2,6-diisopropylphenyliminomethyl)benzene (*L6*)

The ligand **L6** was prepared using the method adopted for **L5**. After the evaporation of the solvent the solid obtained was washed with hexane to yield **L6** (1.89 g, 83%). *Anal*. Calc. for $C_{32}H_{40}N_2$: C, 84.9; H, 8.9; N, 6.2. Found: C, 85.0; H, 9.0; N, 6.2%. ^{1}H NMR ($CDCl_3$, 400 MHz): δ, ppm 8.36 (s, 1H, *H*Ph), 8.32 (s, 2H, *H*C=N), 8.15 (d, $J = 7.8$, 1H, *H*Ph), 8.14 (d, $J = 7.6$, 1H, *H*Ph), 7.68 (t, $J = 7.6$, 1H, *H*Ph), 7.21–7.15 (m, 6H, *H*Ph), 3.02 (sep, $J = 6.8$, 4H, *H*C(H_3C)$_2$), 1.21 (d, $J = 6.8$, 24H, (H_3C)$_2$C). ^{13}C NMR ($CDCl_3$, 100 MHz): δ, ppm 161.8 (*C*H=N); 149.4, 137.9, 137.2, 131.5, 129.9, 129.5, 124.8, 123.5 (*C*Py, *C*Ph), 28.4 (*C*H(H_3C)$_2$), 23.9 ((*C*H_3)$_2$C). IR (KBr): ν, cm^{-1} 3057w, 2964vs, 2869s, 1636vs, 1581s, 1456w, 1361s, 1321s, 1147s, 840s, 762vs, 692s.

4.3. Synthesis of copper(II) complexes

The copper(II) complexes **1**–**4** of the ligands **L1**–**L4** were prepared by adding the corresponding copper(II) salt in methanol to a methanolic solution of the ligand in a 1:1 mole ratio. The volume of the solvent was reduced by rotary evaporation and then cooled. The product formed was filtered off, washed with small amounts of cold methanol and then dried under vacuum. Single crystals of [Cu(L2)Cl_2] (**2**) suitable for X-ray diffraction were obtained by diffusion of ether vapour into an acetonitrile solution of **2**. The complex **5** was obtained by mixing the ligand **L5** and copper(II) perchlorate hexahydrate in a 2:1 (ligand:metal) mole ratio.

*[Cu(L1)Cl_2](**1**)*. Yield: 86% (0.43 g). *Anal*. Calc. for $C_{25}H_{27}N_3Cl_2Cu$: C, 59.6; H, 5.4; N, 8.3. Found: C, 59.6; H, 5.5; N, 8.4%.

*[Cu(L2)Cl_2](**2**)*. Yield: 88% (0.52 g). *Anal*. Calc. for $C_{31}H_{39}N_3Cl_2Cu$: C, 63.3; H, 6.7; N, 7.1. Found: C, 63.4; H, 6.7; N, 7.2%.

4.4. Data collection and structure refinement

Single crystals of [Cu(L2)Cl_2] were chosen for X-ray data collection after careful examination under an optical microscope. The X-ray diffraction intensities were measured by ω and ϕ scans using a Nonius Kappa CCD four-circle diffractometer fitted with a CCD area detector and a graphite monochromator for the Mo Kα radiation. The unit cell parameters and the orientation matrix of the crystal were determined using all data. Data reduction was performed using the DENZO program [42], and a semi-empirical multi-scan absorption correction was applied using the program SORTAV [43]. The structures were solved by direct methods using the SHELXS-97 program [44] and refined by the full-matrix least-squares method on F^2 using SHELXL-97 [45]. While three of four isopropyl groups showed slightly higher thermal parameters, indicative of librational motion, in only one of those were the ellipsoids large enough to merit a disorder model. This was refined over two equally occupied orientations, C(33A)–C(35A) and C(33B)–C(35B). All disordered C–C bond lengths were restrained to 1.53(2) Å, and non-bonded 1,3-C$\cdots$C distances between methyl groups on each disordered orientation to 2.50(2) Å. All non-H atoms except the disordered C atoms were refined anisotropically, while all sp^2-H atoms were placed in calculated

positions and refined using a riding model. Methyl H atoms were treated as idealised groups with freely refined torsions about their C–C bonds.

5. Supplementary data

Full crystallographic data for **2** are available from the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK on request, quoting the deposition number 255046.

nol solvent molecules (brown form). Guest methanol molecules force the complex to adopt a more planar coordination environment in the solid state. In addition, absorption spectra in various organic solvents have been measured and a relationship is found between the features of absorption spectra and polarity of solvents as chemical external perturbations (Scheme 1).

2. Experimental

2.1. General

Chemicals of the highest commercial grade available (Aldrich and Wako) were used as received without further purification. Elemental analyses (C, H, N) were carried out on an Elementar Vario EL analyser at Keio University. Infrared spectra were recorded as KBr pellets on a JASCO FT-IR 660 plus spectrophotometer in the range of 4000–400 cm^{-1} at 298 K. Thermal analysis was performed on a SHIMADZU DSC-60 differential scanning calorimeter (DSC), where the heating rate was 10 K min^{-1} in the range 313–673 K. Diffuse reflectance spectra were measured on a JASCO V-560 spectrophotometer equipped with an integrating sphere in the range 850–220 nm at 298 K. Absorption spectra were measured on a JASCO V-560 spectrophotometer in the range 900–200 nm at 298 K. Magnetic susceptibility was measured with a Sherwood Scientific magnetic susceptibility balance at 298 K. Magnetic data were corrected for the magnetization of diamagnetic contributions, which were estimated from Pascal constants. XRD were recorded on a Rigaku RAD-C diffractometer with Cu Kα radiation ($\lambda = 1.5418$ Å). Semi-empirical molecular orbital calculations were performed the program ZINDO in a CAChe software package based on the crystal structures determined.

2.2. Synthesis

Treatment of an equimolar amount of copper(II) acetate (0.91 g, 5.00 mmol), salicylaldehyde (1.22 g, 10.0 mmol) and 1,2-diphenylethylamine (1.97 g, 10.0 mmol) in ethanol (100 mL) at 318 K for 3 h gave rise to brown crude precipitates. Recrystallization from an acetone solution at 298 K over a period of several days yielded green plate-like crystals suitable for X-ray crystallography, green form (**1**). *Anal.* Calc. for $C_{42}H_{36}CuN_2O_2$: C, 75.94; H, 5.46; N, 4.22. Found: C, 75.68; H, 5.37; N, 4.17%. IR (KBr): 1610 cm^{-1} (imine C=N stretching band). M.p. 572 K (decomposition). $\mu_{eff} = 1.52$ BM at 298 K. On the other hand, recrystallization from methanol–acetone mixed solution (1:1, v/v) at 298 K over a period of several days yielded a brown precipitate. *Anal.* Calc. for $C_{42}H_{36}CuN_2O_2$: C, 75.94; H, 5.46; N, 4.22. Found: C, 75.84; H, 5.46; N, 4.12%. IR (KBr): 1609 cm^{-1} (imine C=N stretching band). M.p. 559 K (decomposition). $\mu_{eff} = 1.43$ BM at 298 K. Well-grown brown prismatic single crystals suitable for X-ray crystallography contain methanol molecules, brown form (**2**).

2.3. X-ray crystallography

Intensity data were collected on a Rigaku AFC-7R four-circle diffractometer. The structures were solved by direct methods using SIR92 [34] and expanded by Fourier techniques. The structures were refined on F^2 anisotropically for non-hydrogen atoms by full-matrix least-squares methods with SHLEXL-97 [35] of the teXsan program package [36]. Empirical absorption corrections were applied based on ψ scans; transmission factors for **1** and **2** were 0.726–0.933 and 0.919–0.999, respectively. No significant decay in the intensity of three standard reflections was observed throughout the data collection. The hydrogen atoms were located at geometrically calculated positions, C–H = 0.950 Å, and refined isotropically. All the non-hydrogen atoms were refined anisotropically. As for **2**, C8(H6A)–C9A(H7A, H8A) and C8(H6B)–C9B(H7B, H8B) were treated as a positional disorder with 0.5 occupancy. Crystallographic data for **1** and **2** are summarized in Table 1.

3. Results and discussion

3.1. Description of structures

The molecular and crystal structures of **1** and **2** are depicted in Figs. 1–4, respectively. Selected bond distances and angles, and torsion angles of **1** and **2** are given in Tables 2 and 3, respectively.

The green form (**1**) affords a compressed tetrahedral *trans*-[CuN_2O_2] coordination geometry, in which the bidentate chelate ligands coordinate to the copper ion through phenolate oxygen atoms and imine nitrogen atoms. The Cu–N bond distances are 1.959(10) and 1.990(9) Å, while the Cu–O bond distances are 1.877(7) and 1.885(8) Å. These values are comparable to related non-planar or distorted tetrahedral complexes [16,17,19,22]. The *trans*-N–Cu–N and *trans*-O–Cu–O bond angles are 157.0(4)° and 151.1(3)°, respectively. The dihedral angle between the O1/Cu1/N1 plane and the O2/Cu1/N2 plane is 36.46(1)°,

which results from two skewed ligands at opposite sides. This distorted coordination geometry is mainly ascribed to the steric hindrance of the bulky 1,2-diphenylethylamine moieties [29]. One of two 1,2-diphenylethylamine moieties of 1 is folded up, being close to the inner side of the molecule, while another one is expanded on the outside of the molecule. The corresponding torsion angles are N1–C8–C9–C16 = 65(1) and N2–C29–C30–C37 = −160.9(8)°. The imine C=N double bond lengths are 1.27(1) and

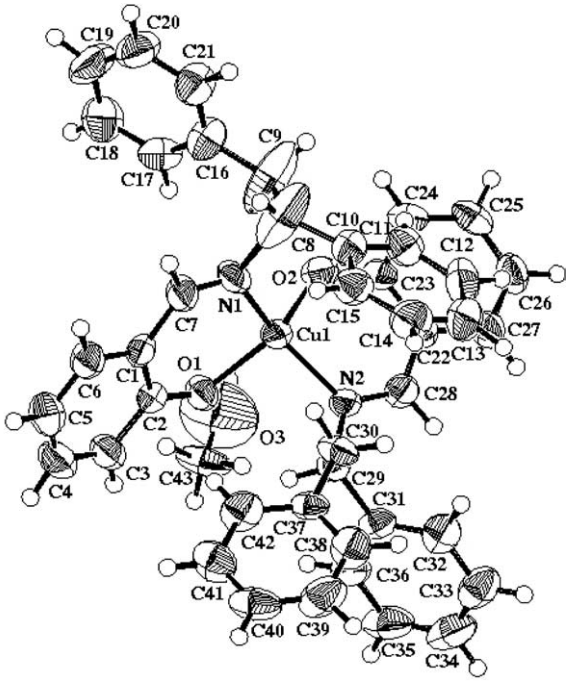

Fig. 3. The molecular structure of **2** showing the atom-labelling scheme. Displacement ellipsoids are drawn at the 50% probability level. Disordered atoms are omitted for clarity.

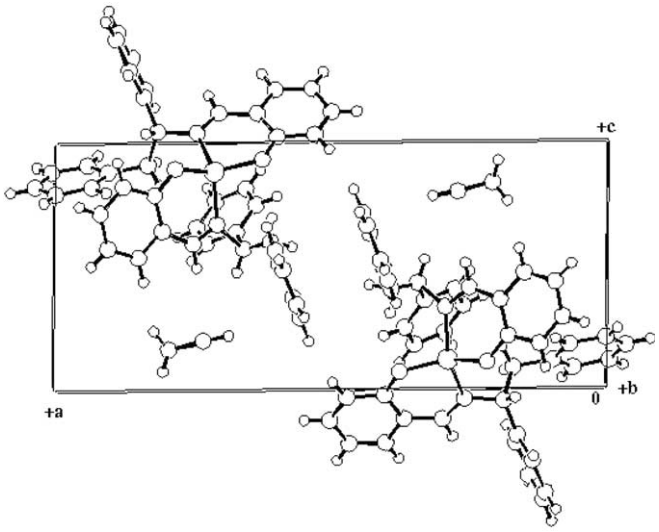

Fig. 4. Crystal packing of **2** viewed from the crystallographic *b* axis.

1.28(1) Å, which indicates that there is a sufficient decrease of the electronic distribution of dπ–pπ character through the π-conjugated system to cause distortion towards a tetrahedral environment [37]. The rest of the geometric parameters are unremarkable among analogous copper(II) complexes. No specific intramolecular hydrogen bonds could be detectable within van der Waals radii [38].

On the other hand, its crystal packing does not reveal remarkable intermolecular interactions, hence the crystals are estimated to be aggregated by weak van der Waals forces. In the crystal of **1**, the phenyl groups of one of the two 1,2-diphenylethylamine moieties face the inner side of the crystal lattice. A parallel arrangement of the molecules attribute to form molecular alignment along the crystallographic *a* axis. It should be noted that there is no space to include additional small molecules.

C7–N1–C8–C10	116.0(8)	C28–N2–C29–C31	−22.9(8)

In contrast to **1**, the brown form (**2**) contains methanol molecules as crystalline solvent. Individual molecules of **2** also afford a compressed tetrahedral *trans*-[CuN_2O_2] coordination geometry. The Cu–N bond distances are 1.977(5) and 1.973(5) Å and the Cu–O bond distances are 1.906(5) and 1.875(4) Å. These values are also comparable to the related non-planar complexes [16,17,19,22]. The *trans*-N–Cu–N and *trans*-O–Cu–O bond angles are 141.3(3)° and 139.9(2)°, respectively. The dihedral angle between the O1/Cu1/N1 plane and the O2/Cu1/N2 plane is 54.46(1)°. These figures suggest that the degree of tetrahedral distortion deviated from square planar of **2** is larger than that of **1**. Although the main part of **1** and **2** is identical, the structural differences are ascribed to methanol solvent

and conformation and arrangement of the ligands, especially the 1,2-diphenylethylamine moieties. As for **2**, all phenyl groups of 1,2-diphenylethylamine moieties in the ligands are expanded outside of the molecule. The torsion angles are N1–C8–C9A–C16 = 120(1) and N2–C29–C30–C37 = 165.6(5)°. The imine C=N double bond lengths of 1.259(9) and 1.286(8) Å are similar to the corresponding values for **1** regardless of the degree of distortion [26–28].

Nevertheless, **2** contains methanol molecules as solvent, neither intramolecular nor intermolecular hydrogen bonds could be detectable in the crystals. However, a pair of phenyl groups, with a distance between them of about 4.2 Å, are faced as if they formed π–π stacking. The methanol solvent molecules are included in the void space between these quasi-stacking phenyl groups and its parent salicydenaminano moiety to stabilize crystal packing.

Recently, metal-organic frameworks for nano-scaled pores [39–43] and structural tuning by containing guest solvent molecules [44–48] have been studied widely in the field of supramolecular chemistry. In contrast to many of these metal-organic frameworks, the present complexes, **1** and **2**, are flexible mononuclear complexes without bridging ligands or intermolecular interactions. Interestingly, **1** (and **2**) may be a rare example which can vary its individual molecular structure as well as overall crystal structure to fit, or be induced by, solvent methanol molecules. The crystal lattice differences are also supported by XRD patterns for **1** and **2** (Fig. 5). The results are also consistent with simulated XRD patterns derived from the analyses of single crystal structures qualitatively.

3.2. IR and electronic spectra in the solid state

The IR spectra of **1** and **2** show bands at 1610 and 1609 cm^{-1}, respectively, which are ascribed to a stretching vibration of the imine C=N groups. The IR spectra of both complexes studied are in agreement with previous reports of analogous complexes (around 1620 cm^{-1}). However, the slight difference in distortion of coordination environment between **1** and **2** is not detectable by IR spectra.

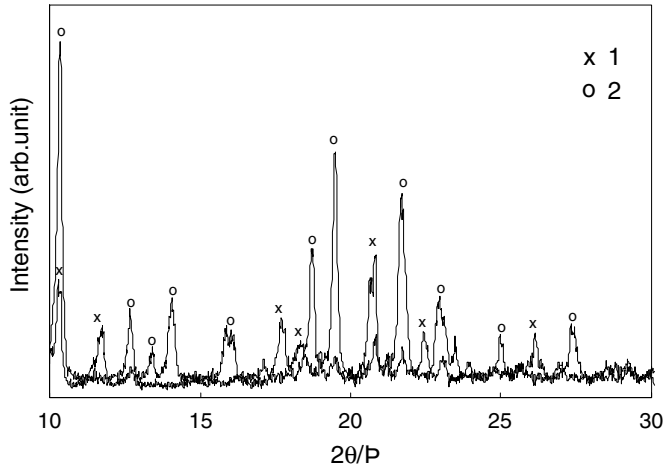

Fig. 5. XRD patterns of **1** and **2**.

The diffuse reflectance electronic spectra of **1** and **2** were recorded in the solid state. Both complexes exhibit a broad band in the region 15 000–20 000 cm^{-1} and another strong band in the region 21 000–24 000 cm^{-1}. The former broad d–d bands are attributed to a ligand field transition of the $3d^9$ copper(II) ion. In general for copper(II) complexes in C_2 symmetry, the free copper(II) ion of $3d^9$ configuration with the ^2D state splits into $^2A_1$, $^2A_2$, $^2B_1$ and $^2B_2$ levels. For this splitting, three transitions, $^2A_1 \rightarrow {}^2A_1$, $^2A_1 \rightarrow {}^2B_1$ and $^2A_1 \rightarrow {}^2B_2$, can be expected to be allowed, and the broad band is due to a combination of the three allowed transitions. A slight difference in the spectral features and apparent colors of **1** and **2** are caused by the ligand field splitting derived from the distortion of the coordination environment. Indeed, there is a tendency that tetrahedral complexes show a d–d band at lower energies, which shifts to higher energies on distorting from tetrahedral to square planar [23]. On the other hand, the strong band found at higher energies is due to overlap of a π–π* transition [49,50] and ligand (phenolate O) to copper(II) metal charge transfer (LMCT) transition. The peaks of these transitions are related to not only *trans*-$[CuN_2O_2]$ coordination geometries but also the net atomic charge on the coordinating atoms (O and N) of the ligands.

3.3. Calculations

The main results of semi-empirical calculations (ZINDO) [51,52] are summarized in Table 4. Single point calculations of heat of formation of the crystal structures determined show a difference of 5.7 kJ mol^{-1} between **1** and **2**. The fact that the energy of the green form (**1**), close to tetrahedral, is higher than that of the brown one (**2**), close to square planar. This indicates that the structural conformation of the ligands in individual molecules of **2** is more stable thermodynamically. In other words, providing external energy may be necessary to convert from the stable form **1** into the unstable form **2**.

The formal charges on the coordinating O and N atoms of the ligands and copper(II) ions have been calculated and the net atomic charges thus obtained have been averaged. The formal charges on copper(II) ions are 0.190 and 0.141 for **1** and **2**, respectively, which indicates that the more tetrahedrally distorted coordination environment prevents charge distribution through the coordination bonds. This tendency is qualitatively consistent with conventional interpretation; distortion from regular planar to tetrahedral leads to a weakening of both σ- and π-characters of coordination bonds. As the ligands of **1** and **2** are identical, the difference can be ascribed to purely coordination geometries. However, the correlation between the average negative charge of the coordinating atoms and the peaks may not be simple, because the electronic spectra consist of several types of transitions.

Table 4
Summary of calculated values of several properties for **1** and **2**

	1	**2**
Heat of formation (kJ mol^{-1})	358.1	352.4
Dipole moment (Debye)	4.96	6.96
Formal charge Cu	0.190	0.141
N	−0.173	−0.237
O	−0.477	−0.230
The lowest π–π* transition	29200	26100
Calculated (cm^{-1})	(LUMO → HOMO − 1)	(LUMO + 4 → HOMO − 1)

The dipole moments of **1** and **2** were evaluated to be 4.96 and 6.96 Debye, respectively. These values can be considered as an indication of the polarity of the molecules in their given conformations. Since **1** and **2** are distortion isomers, the larger dipole moment of **2** can be attributed to the conformation of the ligands.

3.4. Absorption spectra in various solvents

As shown in Fig. 6, the absorption spectra of **1** in the range 18000– 30000 cm^{-1} are characterized by a strong band around 27000 cm^{-1} band, and a weak shoulder-like band around 24000 cm^{-1}. The former is assigned to a π–π* transition in the ligands, while the latter is a d–d band reflecting the coordination environment. The π–π* peaks (wavenumber) and their intensity (log ε) are solvent dependent, as well as occasionally allowing the slight appearance of the shoulder-like band shape of the d–d region to shift. The shift of the π–π* region is as follows: acetone (27000 cm^{-1}, 4.16), chloroform (26900 cm^{-1}, 4.08), methanol (27100 cm^{-1}, 4.04), toluene (27000 cm^{-1}, 4.17) and DMF (26900 cm^{-1}, 4.06). The dipole moment (μ, Debye) and dielectric constant (ε) of the solvents used are: acetone (μ = 3.11, ε = 20.7), chloroform (μ = 1.11, ε = 4.81), methanol (μ = 2.97, ε = 32.6), toluene (μ = 0.37, ε = 2.44) and DMF (μ = 3.82, ε = 36.7). The π–π* bands exhibit a slight tendency of negative solvatochromism, namely the peaks of the bands shift to higher energies in solvents of increasing polarity. The results of the molecular orbital calculations above suggest that tetrahedrally distorted molecules indicate larger polarity. However, weak d–d bands are less sensitive to the polarity of solvents.

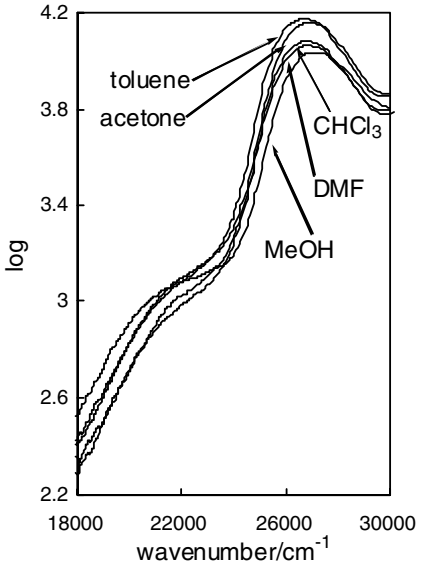

Fig. 6. Absorption electronic spectra of **1** in 1 mM solutions (acetone, chloroform, methanol, toluene and DMF) at room temperature.

In view of the theory of dielectric polarization [8], negative solvatochromism is expected for transitions from a higher dipole moment state to a smaller one. Generally, the LMCT transition moment lies antiparallel to the ground state dipole moment, when the ground state is more polar than the excited state. In this case, the ground state is stabilized by polar solvents and its transition energies are increased. On the other hand, in the cases where the peak of a band for a certain type of transition can shift in accordance with intermolecular interactions between the dipole moment of solutes and solvents, we should consider induced short-range specific interactions such as hydrogen bonds and π–π stacking.

For the present case, however, the correlation between the dipole moment of the complexes and the physical properties of solvents do not allow us to draw a conclusion that the various solvents attribute to the shift of the LMCT transitions of the complexes. We consider only the dipole–dipole part of the van der Waals solute–solvent interactions, neglecting dipole-induced dipole interactions and London's dispersion force, which is a complicated matter that we should study furthermore.

4. Concluding remarks

The syntheses, structural characterization and spectroscopic data have been reported for both the green form of solvent free and the brown form containing methanol solvent of the present copper(II) complex. It is revealed that methanol molecules as solvents in the crystals play an important role in tuning not only crystal packing but also the individual molecular conformation of this flexible mononuclear copper(II) complex without remarkable intermolecular interactions. The ZINDO calculations based on the crystal structures elucidated thermodynamical stability and difference in energy for both forms. The absorption

spectra in various solvents exhibit a relationship between molecular structures and dipole moments. Further studies on other related compounds and the development of photo-induced switching mechanisms are currently ongoing.

5. Supplementary material

Crystallographic data for the structural analyses are deposited with the Cambridge Crystallographic Data Centre, CCDC with deposition numbers 260175 and 260176 for **1** and **2**, respectively. Copies of this information can be obtained from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44 1223 336033; deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

report also includes the analysis of the possible influence of this and other structural features on the final geometry of the complex molecule. The results are compared with those found for the previously reported Co(II) complexes of acetone *S*-methylisothiosemicarbazone [11,12] and with the similar five-coordinate bis(bidentate)–Co(II) and –Co(III) complexes containing five-membered chelate rings. In the aim of the determination of the main factors influencing the preferable geometry in these complexes, we analyzed all five-coordinate bis(bidentate)–Co complexes available in the literature. In addition to the structural determination of the complexes **1** and **2**, a study of their spectroscopic and magnetic properties has been carried out together with that of third complex with the same ligand, [CoL_2Br]Br (**3**).

2. Experimental

2.1. Synthesis of the complexes

Acetone *S*-methylisothiosemicarbazone (L) was prepared according to the procedure described in [14]. The details of the synthesis are as follows: an acetone-ethanolic solution (50 and 20 cm^3, respectively) of 23.0 g (0.1 mol) *S*-methylisothiosmicarbazide hydrogeniodide and 15 g (0.05 mol) $Na_2CO_3 \cdot 10H_2O$ were heated with refluxing. After completing the reaction (3 h), the solution was filtered and its amount reduced to a small volume by heating with warm air. The yellowish crystals of the ligand were filtered out and washed with ether and ethanol. Yield: 8.7 g.

2.1.1. [CoL_2Cl]I (**1**)

0.24 g (1 mmol) of $CoCl_2 \cdot 6H_2O$ was added with stirring to a methanolic-acetone mixture (8 and 4 cm^3, respectively) of 0.46 g (2 mmol) *S*-methylisothiosemicarbazide hydrogeniodide and 0.29 g (1 mmol) $Na_2CO_3 \cdot 10H_2O$. The mixture was heated with stirring for 15 min. The product was filtered off and the solution was allowed to stand. Violet crystals of the complex appeared after 24 h. Yield: 0.62 g, m.p. 199 °C *Anal.* Calc. for $C_{10}H_{22}ClCoIN_6S_2$ ($M = 511.74$ g mol^{-1}): C, 23.45; H, 4.30; N, 16.41; S, 12.51. Found: C, 23.21; H, 4.26; N, 16.44; S, 12.48%.

2.1.2. [$CoLBr_2$] (**2**)

0.14 g (1 mmol) of solid acetone *S*-methylisothiosemicarbazone [14] was added to a solution of 0.33 g (1 mmol) $CoBr_2 \cdot 6H_2O$ in 5 cm^3 acetone. The mixture was heated with stirring for about 15 min. After 8 h of crystallization, the product was filtered off and washed with acetone. Yield: 0.54 g, m.p. 241 °C *Anal.* Calc. for $C_5H_{11}Br_2CoN_3S$ ($M = 363.98$ g mol^{-1}): C, 16.48; H, 3.02; N, 11.54; S, 8.79. Found: C, 16.39; H, 3.05; N, 11.50; S, 8.74%.

2.1.3. [CoL_2Br]Br (**3**)

0.28 g (2 mmol) of solid acetone *S*-methylisothiosemicarbazone was added to a solution of 0.33 g (1 mmol) $CoBr_2 \cdot 6H_2O$ in 5 cm^3 ethanol. The mixture was heated with stirring for about 15 min. After 8 h of crystallization, the product was filtered off and washed with ethanol. Yield: 0.38 g, m.p. 191 °C, *Anal.* Calc. $C_{10}H_{22}CoBr_2N_6S_2$ ($M = 509.24$ g mol^{-1}): C, 23.56; H, 4.23; N, 16.50; S, 12.56. Found: C, 23.52; H, 4.18; N, 16.56; S, 12.50%.

2.2. Physical methods

Elemental (C, H, N) analysis of the air-dried compounds was carried out by standard micromethods at the Center for Instrumental Analysis, Faculty of Chemistry, Belgrade. Infrared spectra in KBr pellets (400–4000 cm^{-1}) were recorded by a FT-IR spectrophotometer. Magnetic measurements of powdered samples were carried out in the temperature range 5–200 K at an applied magnetic field of 500 Oe using a Quantum Design MPMS-XL-5 SQUID magnetometer. Diamagnetic corrections are estimated from Pascal tables.

2.3. X-ray crystallography

Crystal and structure refinement data for [CoL_2Cl]I and [$CoLBr_2$] are summarized in Table 1. The diffraction data for both complexes were collected on an Enraf-Nonius CAD4 diffractometer by using graphite-monochromated Mo Kα (0.71073 Å) radiation at 293(2) K. The data were corrected for Lorentz and polarization effects [15,16]. The absorption correction was neglected in [CoL_2Cl]I in view of the small crystal dimensions, while in the case of [$CoLBr_2$] a gaussian-type absorption correction [17,18] based on the crystal morphology was applied. Both structures were solved by heavy atom method and difference

Fourier methods and refined on F^2 by the full-matrix least-square method [19,20]. H atoms were included in the model at geometrically calculated positions with fixed C–H and N–H distances of 0.96 and of 0.86 Å, respectively, and isotropic displacement parameters equal to 1.5 and 1.2 times the equivalent isotropic displacement parameters of the C and N atoms.

3. Results and discussion

The molecular structures of $[CoL_2Cl]I$ (**1**) and $[CoLBr_2]$ (**2**) along with their crystal packing are shown in Figs. 1 and 3, respectively. The selected bond lengths and bond angles for complexes **1** and **2** are given in Tables 2 and 4, respectively. Table 3 lists the similar five coordinate bis(bidentate)–Co(II) and bis(bidentate)–Co(III) complexes containing nitrogen donating chelates, and their corresponding τ values.

3.1. Crystal structure of $[CoL_2Cl]I$ (1)

Fig. 1A shows the molecular structure of the complex molecule and the atom numbering scheme. The coordination polyhedron around Co(II) is best described in terms of the trigonal bipyramidal geometry. According to the value of 0.84 found for the geometrical parameter $\tau = (\beta - \alpha)/60$ [21], where $\alpha =$ N3a–Co–N3b and $\beta =$ N1a–Co–N1b, the structure is less than 20% distorted from an ideal trigonal bipyramid. This polyhedron comprises of one chlorine atom and two thioamide nitrogens (N3a and N3b) of the Schiff base in the equatorial positions and two terminal hydrazine nitrogens (N1a and N1b) in the axial sites. Table 2 lists selected bond lengths and angles for **1**. The interatomic Co–N and Co–Cl distances are consistent with those reported for similar Co(II) structures [11,12,22].

Table 2
Selected bond lengths (Å) and angles (°) in complex cation of $[CoL_2Cl]I$ compared with those in $[CoL_2Cl]_2[CoCl_4]$ [12]

It should be noted that depending of their carbonyl moiety, the majority of the thiosemicarbazone ligands contain more or less delocalized π electron density throughout the Schiff base, however among the over one hundred reported isothiosemicarbazide-based ligands the acetone *S*-methylisothiosemicarbazone is the only one which contains a

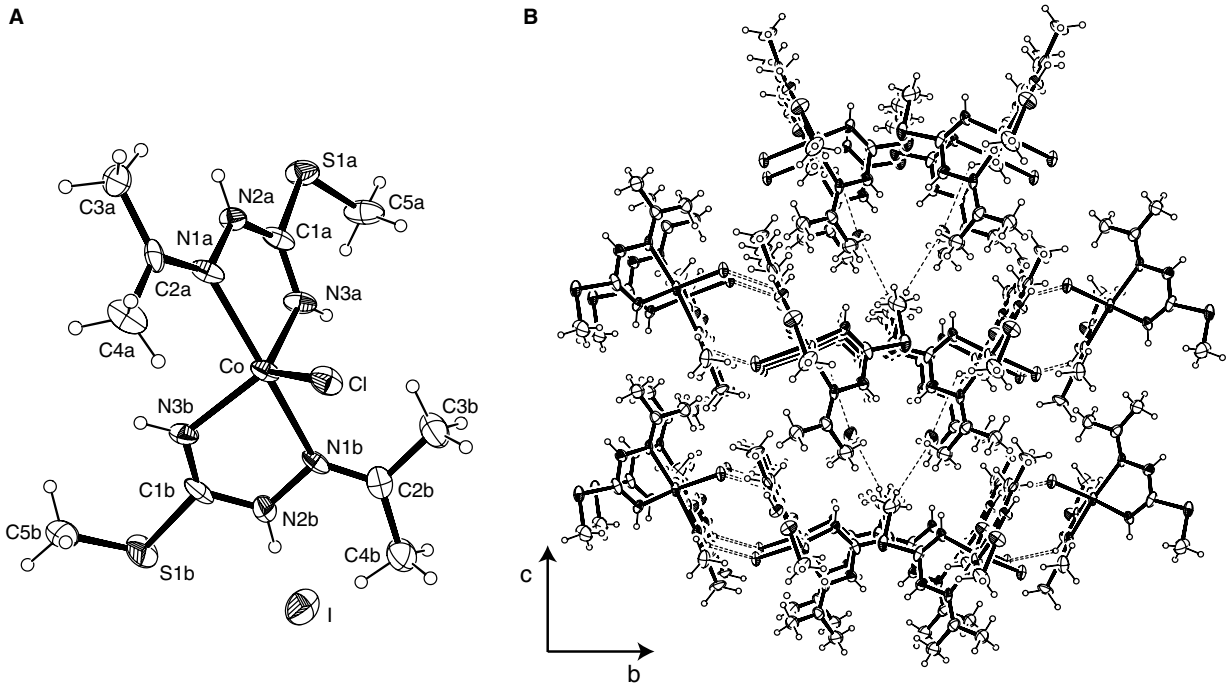

Fig. 1. (A) Molecule structure of **1**. (B) Packing arrangement (viewed down the *a*-axis) showing the N–H···Cl hydrogen bonds and C–H···I interactions.

completely localized double bond between hydrazine N1 and carbonyl C2 atoms. This is confirmed by the corresponding bond lengths N1a–C2a = 1.292(18) Å and N1b–C2b = 1.298(17) Å and by the fact that each of the sp^2 hybridized C2 atoms bind two methyl groups through two single bonds. The localized π electron density prevents any rotation around the N1–C2 bond and favors the planarity of the ligand. The corresponding torsion angles N2–N1–C2–C3 and N2–N1–C2–C4 are 176.8° and −0.7°, −178.8° and 3.4° for branches *a* and *b*, respectively.

The hydrazine nitrogen atoms N2a and N2b are almost equivalently positioned regarding the Cl anion, however they have quite different roles in the crystal packing. The N2a–H2a moiety is involved in the hydrogen bond with the chlorine of the centrosymmetrically related complex molecule [N2a–H2a = 0.86 Å, H2a···Cl = 2.61 Å, N2a···Cl = 3.35(2) Å, N2a–H2a···Cl^{i} = 144°, (i) $-x+1$, $-y+1$, $-z+1$], while the other hydrazine moiety N2b–H2b finds the appropriate acceptor, the iodine atom, at a distance of 3.11 Å which is close to the sum of the van der Waals radii for H and I [1.20(H) + 1.98(I) = 3.18 Å] [23]. Probably as a consequence of the engagement of N2a in the hydrogen interaction, the chelate ring containing this atom shows less planarity then the other one, the corresponding N1a–N2a–C1a–N3a and N1b–N2b–C1b–N3b torsion angles are −4.4° and −0.5°, respectively. It is worth noticing that, surrounded with five methyl groups in the radius of 4 Å, the iodine atom forms contacts with both –S–CH_3 moieties where the C–H···I distances are shorter than the sum of the van der Waals radii for these two atoms H5b···I = 3.01 Å, C5a···I = 3.90(2), C5a–H5a···I^{ii} = 154°, (ii) x, y, z; H5d···I = 3.06 Å, C5b···I = 3.64(2), C5b–H5d···I^{iii} = 121°, (iii) $1+x$, y, $1+z$ (Fig. 1B).

3.2. Coordination geometry of five-coordinate bis(bidentate)–Co(II) and bis(bidentate)–Co(III) complexes containing two five-membered chelate rings

The geometrical characteristics of the complex molecules and the factors determining the degree of their deformation from the ideal geometry always deserve special attention. In the case of five coordinate complexes which could exist in two ideal geometrical forms, square pyramidal and trigonal bipyramidal, an additional problem emerges, that is to find the preferable configuration and then to search for the causes of its deformation. Considering that the nature of the complexes depends on many different factors [24], we tried to explore the effects of several, which we found most important, on the coordination geometry of the five coordinate bis(bidentate)–Co(II) and –Co(III) complexes containing two five-membered chelate rings.

3.2.1. Coordinational preference of the metal

It is well known that cobalt forms numerous complexes of various stereochemical types in both oxidation states Co(II) and Co(III), although it has been found that in complex molecules the state Co(III) is more stable relative to the state Co(II). For both oxidation states an octahedral disposition of the donor atoms around the Co ion is the most typical. The number of tetrahedral structures is also significant, particularly in the case of divalent cobalt, while the coordination number five within a trigonal bipyramidal or a square-pyramidal ligand arrangement is less common for either oxidation state [23]. Limiting our investigation to bis(bidentate)–Co(II) and –Co(III) complexes containing five-membered chelate rings with nitrogen donors we found only 15 structures whose crystal structures were reported. These compounds are listed in Table 3.

3.2.2. Bite angle of the chelating ligand

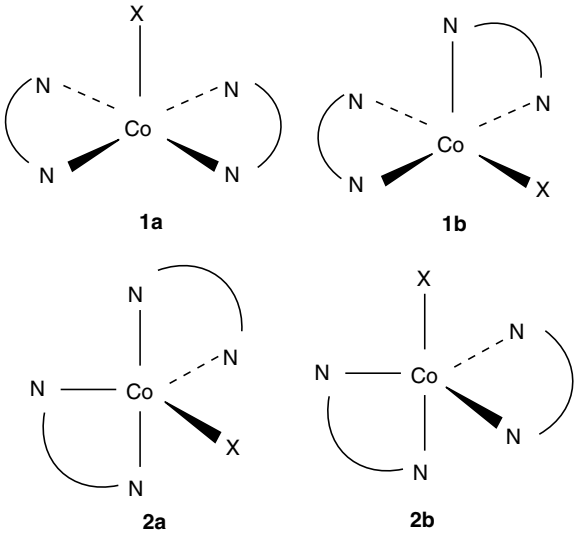
The theoretically possible arrangements of two bidentate ligands within the square pyramidal and trigonal bipyramidal complexes are represented in Scheme 1. Considering whether the ligand bridges two equatorial or equatorial and axial positions, the complexes could be distributed in four theoretically possible arrangements, (two for each geometry). However, the corresponding τ values which were calculated for each of the bis(bidentate) Co complexes (Table 3) showed that in most of the cases the geometry of the complexes is closer to square pyramidal (SP) (11 structures with τ less than 0.21) than to trigonal bipyramidal (TBP) (3 structures). Between the two possible arrangements of ligands within the SP geometry shown in Scheme 1, 1a was the only one found. This is in agreement with the fact that N–Co–N coordination angles of the small bidentate ligands, whose average value is $\langle 80.1° \rangle$, are much more in accordance with the value of 88.4°, characteristic for the equatorial part of the SP geometry than to an angle of 100° formed between the axial and equatorial sites of a SP structure (1b) [25]. The few complexes whose geometry is closer to TBP rather adopt the arrangement labelled as 2a. The angle spanned by the chelate is somewhat larger (90°) than in the previous case, which could be the reason for the smaller number of TBP structures, but it is again much more in accordance with its small bite than the case 2b where one of the bidentate ligands occupies the equatorial sites at 120°.

3.2.3. Steric and geometrical requirements of the ligands

Inspection of the tabulated square-pyramidal complexes of Co(II) and Co(III) showed two types of chelates present in their basal plane: (1) chelates without the large substituents on the donor atoms and thus without steric hindrance in the basal planes; (2) chelates which contain large substituents on the donor atoms but are able to avoid steric repulsion by the rotation of the substituents. The example for the later is the square-pyramidal complex $[CoL^8{}_2I]$, L^8 = *S*-methyl-1-phenylthiosemicarbazide [33], where the large phenyl group is attached to *S*-methylisothiosemicarbazide. However, the single bond which connects these moieties (N1–C2 = 1.43 Å) allows free rotation of the phenyl ring and formation of the basal plane of the quite regular SP structure ($\tau = 0.02$). Similarly, the corresponding N–C bonds in other SP complexes containing substitutents on the donor atoms range from 1.42 to 1.44 Å.

Among the complexes whose structure is closer to TBP, two were products of L, thus the fact that the novel complex with the same ligand also belongs to the less favorable TBP group indicates the importance of the ligand's structural features and possible steric interaction in the SP geometry. To explore this fact we analyzed the hypothetical complex molecule which contains two L ligands in the base of a SP structure (Fig. 2). The geometry of this molecule is based on the experimental data obtained for complex **1**. According to it, even in a *trans* mutual arrangement the two molecules of L, due to their steric repulsion, could not form the basal plane for a SP geometry. Since the double bond hinders the rotation of the ketone moiety around N1–C2, the hydrogen atoms of the methyl and thioamide groups are directed to each other forming too short a H···H distance of 1.46 Å (Fig. 2).

One can conclude that the final configuration of **1** is the result of the geometrical restrictions of the bidentate ligand, which besides the small bite angle also include its favored planarity caused by a pure double bond between the thiosemicarbazide and ketone moieties. The compromise between the produced steric hindrance and the maximal separations of the donor atoms eventually gives rise to the quite uniform distribution of the donor atoms within this trigonal-bipyramid [N3a–Co–N3b = 121.1 (5)°, N3a–Co–Cl = 119.7 (5)°, N3b–Co–Cl = 119.2 (5)°, N1a–Co–Cl = 94.8 (3)°, N1b–Co–Cl = 93.2 (3)°]. In the TBP complexes listed in Table 3 the corresponding N–C bonds range from 1.27 to 1.29 Å; the exception is $[Co(L^1)_2H_2O]\cdot$



Scheme 1.

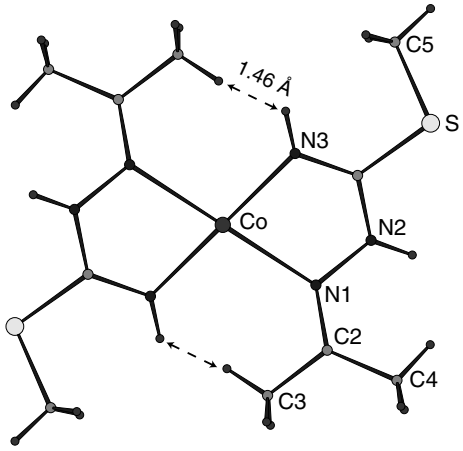


Fig. 2. The hypothetical complex molecule containing two L ligands in the base plane of a square-pyramid; the axial ligand is omitted for clarity.

H_2O [26] (N–C = 1.43 Å) whose chelate contains a phenyl group on either donor atom.

3.2.4. Interligand repulsion

According to the τ value, the geometry of the complex $[CoL_2CH_3COO]I$ [11], containing the same ligand, is almost in the middle of two terminal five coordinate structures ($\tau = 0.44$). However, viewed as SP the structure shows the less favorable distribution 1b with L bridging the axial and equatorial positions of the complex, while viewed as TBP this structure shows the common arrangement 2a in which L spans the equatorial and axial positions of the TBP structure. Similarly to **1**, the geometric requirements of the ligand prevent the formation of the basal plane of a SP geometry. On the other hand, the stronger electrostatic repulsion between the uncoordinated oxygen atom of the acetate ligand and the nitrogen donors prevents the formation of the regular TBP arrangement as found in **1**. The final geometry of $[CoL_2CH_3COO]I$ is thus markedly distorted, which can be seen from the corresponding angles: N3a–Co–N3b = 113.8°, N3a–Co–O1 = 141.1°, N3b–Co–O1 = 104.2°, N1a–Co–O1 = 105.0°, N1b–Co–O1 = 87.4°.

3.2.5. Packing considerations in the crystal lattice

Another previously reported complex of L, $[CoL_2Cl]_2$-$[CoCl_4]$ [12] contains the identical complex cation as for **1**. Comparison of their resulting geometrical parameters (Table 2) shows a considerable similarity. With N1a–Co–N1b assigned as β and N3a–Co–Cl assigned as α, the τ parameter of $[CoL_2Cl]_2[CoCl_4]$ has a value 0.80. However, since the cations of $[CoL_2Cl]_2[CoCl_4]$ and **1** are essentially identical we found it necessary to compare the τ values calculated using the same type of angles for both compounds. Thus, if we assign α to N3a–Co–N3b and β to N1a–Co–N1b we obtained the value 0.82 which is still very similar to the value of 0.84 found for **1**. The similarity of the coordination geometries of the two complexes cations is therefore evident. On the other hand the anions of the two complex molecules are rather different in size and complexity which cause considerable differences in the corresponding molecule arrangements. Since the complex cations preserve the very similar TBP geometry regardless of the different intermolecular interactions existing in the corresponding crystal structures it could be suggested that the crystal packing is not a factor of particular influence on the final geometry of these coordination polyhedrons.

3.2.6. Bidentate ligands with other donor sets

It should be mentioned that among the five coordinate bis(bidentate)–Co(II) and –Co(III) complexes with five-membered chelates containing other donor sets (NS, SS, NO and PP), the SP geometry also prevails. The TBP geometry is observed in the case of Co(II) complexes containing the bulky PPh_3 donor [38] and in the case of the thiosemicarbazide analogue of complex **1**, $[Co(TSCAc)_2Cl]Cl$, where TSCAc = acetone thiosemicarbazone [13]. Similar to L, the localized double bonds of this Schiff base (N1a–C2a = 1.29 Å N1b–C2b = 1.27 Å) prevent the rotation of the carbonyl moieties, producing steric repulsion between the planar neighboring ligands in the basal plane. The τ parameter for this complex has a value of 0.74.

According to above analysis it could be suggested that if there is no steric hindrance between the chelates in the basal plane, the SP geometry is more favorable for five coordinate Co-complexes containing two five-membered chelate rings. In these structures the bidentate ligands always coordinate in the form shown in 1a with a mutual *trans* disposition. If the steric repulsion in the basal plane cannot be avoided the coordination is TBP, and always in the form shown in 2a. This is the case described with Co(II) complexes with acetone *S*-methylisothiosemicarbazone, which due to the rigid and planar configuration of the ligand and consequent steric interactions prefer a trigonal bipyramidal arrangement.

3.3. $[CoLBr_2]$

The crystal structure of **2** consists of discrete neutral units. The Co(II) atom is placed at the center of the severely distorted tetrahedron with two Br atoms and two N atoms of the L molecule in the apices. Table 4 lists selected bond lengths and angles for **2**. Due to the different coordination geometry around the cobalt atom, the Co–N bonds in **2** are shorter than the corresponding ones in **1**, however the difference in Co–N3 bond lengths for these two complexes are less pronounced [Co–N3a = 1.987(11), Co–N3b = 1.999(11) Å in **1**, Co–N3 = 1.959(13) Å in **2**] than the difference in the corresponding Co–N1 bonds [Co–N1a = 2.167(12), Co–N1b = 2.178(12) Å in **1**, Co–N1 = 2.075(13) Å in **2**]. This is probably due to the fact that the axial and equatorial components of the pentacoordinate structure contain different contributions of p orbitals and consequently additionally longer axial bonds. In the tetrahedral structures the sp^3 orbitals are equivalent, thus the difference between the two types of Co–N bonds is less marked and it is only a consequence of the different hybridization of the nitrogen atoms. Since L keeps a constant distance between the donor atoms (2.6 Å) the resulting coordination angle is somewhat larger [N1–Co–N3 = 80.2(5)°] than in the previous five coordinate structure **1**. The distortion from the idealized stereochemistry is mainly attributed to the restricted bite angle of the Schiff base, however the other angles involving the Co atom also show marked differences from the ideal value of 109°. The largest angle in the structure is N3–Co–Br2 [119.2(5)°], while the angle between the two largest donor atoms Br1–Co–Br2 is less distorted [111.7(5)°].

The atoms of the five-membered chelate ring are practically planar with a mean plane deviation of 0.005 Å. As a consequence of the planarity, the sums of the respective internal angles is in good agreement with the ideal value of 540°. The ketone moiety slightly deviates from the plane of the chelate ring. The dihedral angle formed between the corresponding mean planes is 4.1°. On the other hand

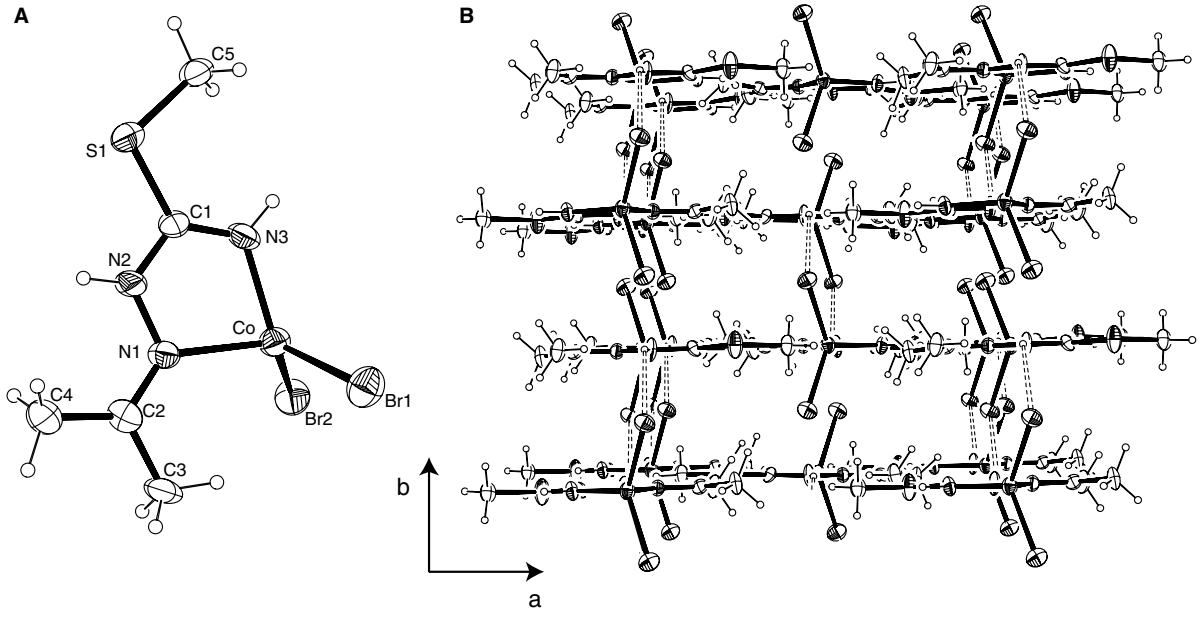

Fig. 3. (A) Molecule structure of [$CoLBr_2$]. (B) Packing arrangement as viewed down the *b*-axis.

the dihedral angle formed between least-square planes of the chelate ring and the Br1–Co–Br2 moiety is nearly orthogonal, 89.3°, thus viewing the crystal arrangement down the *b*-axis we can recognize the distinct regions containing planar isothiosemicarbazone moieties separated by the mutually crossed Br anions (Fig. 3B). The single intermolecular hydrogen bond present in the structure is formed between the hydrazine nitrogen and Br2 bromine atom, N2–H2 = 0.86 Å, N2···Br2 = 3.54(2) Å, H2···Br2 = 2.89 Å, N2–H2···$Br2^{i}$ = 133°, (i) $-x+1, -y, -z$.

3.4. Infrared spectra

The selected IR spectral assignments are listed in Table 5. The two highest energy bands found in the ligand spectrum at 3284 and 3143 cm^{-1} could be attributed to *ν*(N–H) vibrations. In the spectra of the complexes these bands are found at higher frequencies. The strong band at 1560 cm^{-1} in the spectrum of the free ligand, assigned to *ν*(C=N) vibrations, undergoes a shift from its position to lower energies in the spectra of all the metal complexes indicating coordination through the imine nitrogen. It also splits to two near bands probably as a consequence of a slightly increased energy difference between the two C=N bonds upon the ligand coordination. Absorptions in the region 1430–1300 cm^{-1} are found in the spectra of all compounds and are associated with deformation C–H vibrations of the methyl groups. A shifting of *ν*(N–N) to higher frequencies in the spectra of the complexes confirms the coordination through the azomethine nitrogen. The similar positions of the absorption bands in the spectra of [CoL_2Cl]I and [CoL_2Br]Br indicate similar structural features of these two complexes, and suggest a five coordinated geometry for [CoL_2Br]Br.

3.5. Magnetic studies

The temperature dependent magnetic susceptibilities of **1** (19.01 mg), **2** (31.27 mg) and **3** (37.66 mg) have been

1	2.32	−6.33	4.31
2	2.65	−7.55	4.60
3	2.38	−3.88	4.38

studied in the range of 5–200 K. The plot of the χ^{-1} and χT versus temperature (with χ being the magnetization per cobalt (II) ion) is shown in Fig. 4. A similar magnetic behavior was observed for all three Co(II) complexes and consequently only the molar susceptibility curve of compound **2** is given. In all cases the magnetic measurements obey the Curie–Weiss law. A fitting of the linear part of the χ^{-1} versus T curves resulted in the corresponding Curie constants (Cm) and Curie–Weiss temperatures (θ) which are listed in Table 6. The Curie constants correspond to g values of 2.37, 2.26 and 2.22 for compounds **1**, **2** and **3**, respectively. The values of the effective magnetic moment (μ_{eff}) [39] per cobalt (II) are slightly higher than the values expected for the spin-only $S = 3/2$ systems (3.87 μ_B) [23].

4. Conclusion

Three novel complexes of Co(II) with acetone *S*-methylisothiosemicarbazone have been synthesized and characterized by different physicochemical methods. The crystal structure analyses of compounds **1** and **2** reveal trigonal bipyramidal and tetrahedral geometries, respectively. In both structures the ligand has a planar and rigid conformation due to the prevented rotation around the localized $C^2{=}N^1$ double bond. It has been suggested that this feature of the ligand is the main reason why complex **1** adopts a trigonal bipyramidal geometry. After a full analysis of all the five coordinate bis(bidentate)–Co complexes it is clear that if there is no steric interaction in the basal plane, the SP geometry is the preferential form for this type of complex. A similar disposition of the absorption bands within the IR spectra of compounds **1** and **3** leads to the conclusion that compound **3** also adopts the less favorable trigonal bipyramidal arrangement of ligands.

SmI_2 reacts only in the presence of HMPA, which increases the reductive potential of the samarium salt [9].

The triorganochlorosilanes were reported [10] to react with SmI_2 in THF at room temperature to give the respective disilanes R_3SiSiR_3 in high yield, except for Me_3SiCl for which the maximum conversion was only 5%, independent of the reaction conditions.

To get more insight into the reactivity of one of the mentioned diiodides and to evaluate its advantages and limitations as a synthon compared to SmI_2 and alkali metals, we have studied the reactions of **1** with some alkyl(aryl) halides and chlorotrimethylsilane in solvating and non-solvating media.

2. Results and discussion

2.1. Reactions in THF

One of the most unusual properties found for **1** and DyI_2 is their liability to disproportionation in THF or DME solutions, caused by addition of benzene, its derivatives or some other compounds [11]. In the case of **1** this process leads to formation of NdI_3 and a mixture of NdIRR′ products (R, R′ – fragments of split solvent). The aromatic substrate is incorporated into the products to a negligible extent. The addition of phenol at −100 °C promotes similar conversions while at 20 °C the reaction proceeds as an ordinary single electron redox process to give $PhONdI_2(THF)$ [11].

In the reaction of **1** with iodobenzene in THF, independent of temperature, the main product is benzene, the yield of which reaches 84% (Table 1). Most of the benzene (73%) is formed directly in the reaction and can be separated from the non-volatile products together with the solvent by condensation in vacuum. The rest of the C_6H_6 (11%) is isolated after hydrolysis of the solid residue, indicative of the presence in the products of phenylneodymium derivatives of the type $PhNdI_2$. In addition to benzene in the reaction mixture, a small amount of biphenyl (1%) and a few unidentified products were found by HPLC. When **1** interacts

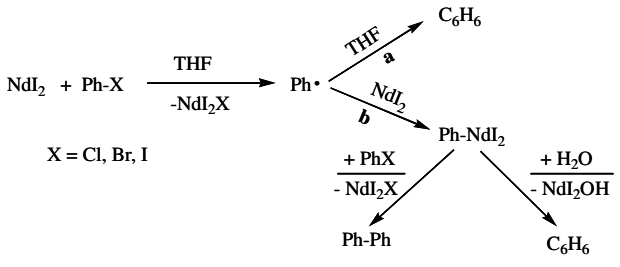
with bromobenzene, the yield of benzene, most of which is formed directly in the reaction, noticeably decreases (56%). In the case of PhCl, the yield of benzene after hydrolysis reaches 21%, but directly in the reaction only 35% of it is formed. The yield of biphenyl decreases to 0.4%.

We believe that the scheme of these reactions is similar to that of SmI_2 and includes in the first stage the electron transfer from **1** to PhX, formation of trihalide NdI_2X and phenyl radical, which splits hydrogen from THF to give benzene (Scheme 1, direction *a*) or interacts with **1** yielding the σ-complex $PhNdI_2$ (direction *b*). The latter can react with the aryl halide starting material affording biphenyl. A part of $PhNdI_2$ remains in the solution and after hydrolysis gives additional benzene.

In all the reactions after 2–3 min the mixture turned dark brown, a precipitate of neodymium trihalide deposited, and evolution of a minor amount of gas was observed. These transformations, similar to those in the reactions with benzene [11], indicate that the disproportionation of **1** mentioned above also takes place in the reactions with PhX. However in this case, such a process does not play an important role.

Unfortunately, we could not find the conditions of chromatographic analysis for consistent identification of the small amounts of benzene formed from C_6H_5F. According to the ^1H NMR spectra, fluorobenzene is also reduced in the reaction with **1,** but the yield of C_6H_6 does not exceed 8–10%. The significant amount of NdI_3 and NdIRR′ products (R, R′ = fragments of split solvent) formed in this reaction show that the halide function of C_6H_5F is negligibly involved into the transformations and that the main direction of the reaction is the same as in the reaction with benzene [11].

Unlike PhX the benzyl chloride reaction with **1** produces mainly the coupling product $PhCH_2CH_2Ph$, the yield of which reaches 82%. The yield of toluene generated directly in the reaction is 15%, but hydrolysis of the solid residue remaining after removal of volatiles affords only 1% of $PhCH_3$. Besides these products, a significant amount of $PhCH_2I$ and a few unidentified compounds were detected in the reaction mixture. These data reveal that the reaction of **1** with $PhCH_2Cl$ includes additionally I/Cl exchange beyond the stages indicated in Scheme 1. An attempt to carry out the cross-coupling reaction between PhI and benzyl chloride failed. Only benzene, toluene and bibenzyl were found in the reaction mixture formed after treatment of **1** with a mixture of iodobenzene and benzyl chloride.



Scheme 1.

The GLC analysis of volatile products from the reactions of **1** with 1-bromoheptane and cyclohexyl chloride, which easily proceeded in THF at room temperature, revealed the presence of the respective hydrocarbons which are formed directly in the reactions in ca. 25% yield. The reaction with *tert*-butyl chloride under the same conditions afforded a mixture of isobutane and isobutylene. Coupling products also were not found in any of the three cases. Hydrolysis of the solid products remaining after separation of the volatiles from these reactions did not yield additional amounts of RH, indicative of the absence of compounds of the type $RNdI_2$ in the mixture. This is consistent with the well-known fact that σ-alkyllanthanide complexes have low stability.

In contrast to SmI_2, the iodide **1** in THF vigorously interacts with trimethylchlorosilane at room temperature. The reaction proceeds with evolution of gaseous trimethylsilane and is completed in 30 min to give 10% of Me_3SiH, hexamethyldisilane (8%) and trimethylsilylbutoxide as the main product (31%). In addition, significant amounts of organosilicon compounds were found by IR spectroscopy in the solid residue remaining after removal of the volatiles. The work on identification of this product is currently in progress. If the reaction is carried out at −60 °C, the yields of trimethylsilane and $Me_3SiSiMe_3$ drop down to 1% and 3%, respectively, but the yield of $Me_3SiO(CH_2)_3CH_3$ increases up to 88%. Formation of this product can be explained by addition of Me_3SiCl to THF in the presence of a neodymium salt (NdI_2 or NdI_2Cl) with generation of $Me_3SiO(CH_2)_3CH_2Cl$ and subsequent reduction of it by **1** like other alkyl chlorides. The similar addition of organochlorosilanes into the C–O bond of THF in the presence of $ZnCl_2$ has been described earlier [12].

2.2. Reactions in benzene

All of the above reactions of LnI_2 (Nd, Dy, Tm) were carried out in solvating media such as THF or DME in which these salts are soluble. But recently with an example of the reactions of DyI_2 with VCl_4 or vanadocene we have established that the mentioned diiodides can readily react with substrates in benzene under heterogeneous conditions [13]. This property of LnI_2 has also revealed itself in the reactions of **1** with cyclohexyl chloride, *n*-BuCl and benzyl chloride which proceed in benzene at 80 °C. However in this case, in contrast to the reactions in THF, reduction of RX is not the result. Instead, alkylation of the aromatic solvent takes place, i.e. the reactions are similar to Friedel–Crafts processes. The main organic product in the reaction with benzyl chloride is diphenylmethane, the yield of which in 8 h reaches 66%. The reactions with butyl chloride and cyclohexyl chloride result in the formation of near equal amounts of mono- and 1,4-dialkylation products. The reaction with *n*-BuCl is accompanied by isomerization of the butyl radical into the *tert*-butyl form that is characteristic

for the Friedel–Crafts alkylation. Besides the indicated products in all of the reactions, the neodymium trihalide NdI_2Cl, hydrogen and HCl are formed. The side process of I/Cl exchange and decomposition of generated HI leads as well to the isolation of a minor amount of iodine

$$NdI_2 + R\text{-}Cl \xrightarrow[-NdI_2Cl,-H_2,-HCl]{C_6H_6} R\text{-}C_6H_5 + 1,4\text{-}R_2C_6H_4$$

$$R = CH_2Ph, \textit{cyclo}\text{-}C_6H_{11}, t\text{-}Bu$$

It is known [14] that lanthanide trichlorides and tribromides catalyze the alkylation and acylation of aromatic compound similar to other Lewis acids. The sets of products of these reactions indicate that the reactions with divalent salt **1** also proceed similarly to Friedel–Crafts transformations. However in this case, the process includes an additional stage – oxidation of neodymium to the trivalent state and liberation of hydrogen. The NdI_2Cl formed in this stage evidently plays the role of catalyst in the subsequent alkylation. Catalytic transformations with **1** are less probable because of its high reductive potential, which stipulates quick oxidation of **1** by RX or HCl. It is interesting to note that the catalytic activity of NdI_3 in the benzylation of benzene is very low: only 1% of Ph_2CH_2 was obtained after heating of this iodide with benzyl chloride in benzene at 80 °C for 5 h.

In all of these reactions of **1** with RX in benzene, a significant amount of the salt was used because of its insolubility in this solvent. Therefore the yields of the products under the given conditions are rather low (20–30% calculated on **1**) and the reactions look like they are stoichiometric. Evidence that these processes can be catalytic is obtained by the reaction of **1** with benzyl chloride in the absence of solvent. The oligomers $PhCH_2(C_6H_4CH_2)_nC_6H_4CH_2Cl$ (*n* found by terminal group analysis is close to 28) were isolated in this case as a white non-crystalline solid. According to the ^1H and ^{13}C NMR data, it has mainly linear 1,4-arrangements, but 1,3-substituted fragments are also present in the product. Conversion of $PhCH_2Cl$ in 3.5 h at 80 °C was 59% where the yield of the oligomers reached 111% calculated on the amount of **1** used.

Surprisingly, both Me_3SiCl and Me_3SiCH_2Cl as well as PhI and PhBr turned out to be quite inert toward **1** in benzene.

3. Conclusion

These studies show that the reactions of neodymium diiodide **1** with alkyl(aryl) halides in THF solution are similar to those of alkali metals, but have some essential differences. The most important are: (i) formation of a significant amount of the corresponding hydrocarbons RH directly in the reaction; (ii) the reduced yield of coupling products in the case of aryl halides. In addition, the tendency of **1** to disproportionate in solvating medium in the presence of aromatic compounds causes side processes, which are not characteristic of the reactions with sodium. Probably the most substantial difference in chemical behavior between **1** and alkali metals is the ability of neodymium diiodide to catalyze the alkylation of aromatic compounds with alkyl halides when the reactions are carried out in non-solvating medium. These processes are similar to Friedel–Crafts alkylation but have an additional redox stage – oxidation of Nd(II) to Nd(III) and reduction of hydrogen.

4. Experimental

4.1. General

All the reactions were carried out in a vacuum in sealed tubes using standard Schlenk techniques. To purify and dry, THF was refluxed over NaOH and treated with **1** for 30 min before use (2 g of **1** for 100 ml THF). The solvent was collected into a reaction vessel by condensation in a vacuum from the formed solution. Benzene was dried by refluxing over sodium and treated with **1** for 30 min before use. Diiodide **1** was prepared as described in [15]. The commercial organohalides were purified according to known procedures. The ^1H and ^{13}C NMR spectra were recorded on a Bruker DPX 200 spectrometer at 20 °C. The IR spectra were recorded on a Specord M-75 spectrometer. The samples were placed as films between KBr glasses. The HPLC analysis was performed on a "Knauer" liquid chromatograph equipped with a UV-spectrophotometer ($\lambda = 254$ nm) and glass columns 150×3 mm filled with adsorbent Separon SGX C18 ("Lachema"), 5 μm granules were used. Methanol/water (80:20) solution served as an eluent at a flow-rate of 0.4 ml/min at 20 °C. Chromatographic analysis of volatile products was carried out on a "Tsvet-800" gas chromatograph equipped with a thermal conductivity detector and a stainless-steel column (3 m long and 3 mm OD). In these analysis 5% SE-30 on Chromaton N-AW (0.2–0.25 mm granules) as an adsorbent was used. A flow-rate of the carrier gas (helium) was 30 ml/min. Quantitative analysis of the reaction mixtures have been performed by the method of absolute calibration.

4.2. Reaction of *1* with PhI

To the solution of iodobenzene (0.639 g, 2.83 mmol) in 10 ml THF 0.557 g (1.5 mmol) of **1** was added at room temperature with stirring. Gradually color of the mixture changed to brown and the microcrystalline precipitate of neodymium triiodide deposited. Evolution of a small amount of gaseous products was observed. After 10 h the solvent and volatile products were removed by condensation in a vacuum and 2 ml of water was added to the residue. The obtained mixture was extracted with ether (2×7 ml) and then the extract was separated and dried with $CaCl_2$. HPLC analysis of the extract revealed the presence of 12 mg (11%) of benzene and 1 mg (1%) of biphenyl. In the volatiles 80 mg (73%) of benzene was found by GLC analysis.

The reactions of **1** with PhBr, PhCl and PhF were carried out analogously.

4.3. Reaction of *1* with $PhCH_2Cl$ in THF

A solution of benzyl chloride (2.948 g, 7.41 mmol) in 15 ml THF was added to 2.471 g (19.52 mmol) of **1**. The mixture was stirred for 1 h and left for a night at room temperature. Solvent, excess of $PhCH_2Cl$ and volatile products were removed by condensation in a vacuum and the residue was hydrolyzed by 5 ml of water. The obtained mixture was extracted with ether (2×8 ml) and then the extract was dried over $CaCl_2$ and analyzed by HPLC. Toluene (7 mg, 1%), 1.2-diphenylethane (0.56 g, 82%) and 027 g (17%) of $PhCH_2I$ were found among the products. HPLC of the volatiles revealed the presence of 0.1 g (15%) of toluene and 93 mg (6%) of benzyl iodide. The total yield of toluene was 0.107 mg (16%).

4.4. Reaction of *1* with $C_7H_{15}Br$ in THF

0.165 g (0.92 mmol) of 1-bromoheptane and 4 ml THF were condensed into an ampoule containing 0.842 g (2.11 mmol) of **1**. The mixture was stirred for 1 h at ambient temperature. Benzene and volatile products were removed by condensation in a vacuum. The solid residue was hydrolyzed by diluted HCl and the obtained solution was extracted with 4 ml of ether. GLC analysis of the ether revealed an absence of heptane or tetradecane. In the volatile fraction, besides benzene and $C_7H_{15}Br$, 20 mg (22%) of heptane was found.

The reaction of **1** with cyclohexyl chloride was carried out analogously.

4.5. Reaction of *1* with t-BuCl in THF

A mixture of *t*-BuCl (0.54 g, 5.83 mmol), **1** (0.693 g, 1.78 mmol) and 6 ml THF was stirred in a sealed ampoule for 8 h at room temperature. The solvent and volatile products were separated by condensation in a vacuum from the formed grey precipitate of NdI_2Cl. In the condensate isobutane (28 mg, 27%) and isobutylene (63 g, 63%) were found by GLC.

4.6. Reaction of *1* with Me_3SiCl in THF

At room temperature. To an evacuated 100 ml ampoule containing 3.82 g (9.6 mmol) of **1** in 5 ml THF, 0.939 g (8.6 mmol) of Me_3SiCl in 5 ml THF was added at −60 °C. The mixture was allowed to warm to room temperature and stirred for 30 min. The initial dark violet precipitate of **1** gradually disappeared but a grey precipitate of NdI_2Cl was formed. Evolution of a gaseous product and a slight warming of the mixture was observed. After completion of the reaction, THF and volatile products were transferred by condensation at 100 °C in a vacuum into an ampoule of 20 ml volume. The solution was warmed to ambient temperature and a volume of evolved gaseous Me_3SiH (16 ml, identified by GLC) was measured with a gas burette. An additional 12 mg of Me_3SiH were found in the solution by GLC. The total yield of trimethylsilane was 65 mg, (10%). In the solution 50 mg (8%) of Me_3Si-$SiMe_3$ and 0.4 g (31%) of $Me_3SiO(CH_2)_3CH_3$ were found by GLC. The butoxitrimethylsilane was isolated from the solution by distillation at normal pressure. Its characteristics, b.p. (123–125 °C), α_D^{20} (1.395), IR and ^1H NMR spectra, correspond to the literature data [16].

The low temperature reaction was carried out in the same manner but before warming to room temperature the reaction mixture was stirred at −60 °C for 5 h.

4.7. Reaction of *1* with $PhCH_2Cl$ in benzene

A mixture of 2.667 g (5.08 mmol) of **1**, 0.643 g (5.08 mmol) of benzyl chloride and 8 ml of benzene was stirred for 8 h at 80 °C in a sealed ampoule. The evolved gaseous products were released into the atmosphere, the organic layer was separated by decantation from the crystalline precipitate of neodymium trihalide and the solvent and volatile products were removed by condensation in a vacuum. The remained viscous substance was hydrolyzed by 4 ml of water and extracted with ether (2×4 ml). In the extract 0.606 g (3.6 mmol) of Ph_2CH_2, 0.015 g (0.19 mmol) of benzene, trace amounts of iodine, iodobenzene and biphenyl were found by means of HPLC and GLC.

4.8. Reaction of *1* with cyclo-$C_6H_{11}Cl$ in benzene

Under the conditions of the previous experiment, a mixture of *cyclo*-$C_6H_{11}Cl$ (1.085 g, 9.148 mmol), **1** (2.1 g, 5.269 mmol) and 5 ml of benzene was heated for 8 h. The light pink solution was separated from a grey precipitate by decantation and the precipitate was washed with benzene (2×5 ml). The reaction solution and benzene washings were combined and then washed with a diluted solution of ammonia, and dried over $CaCl_2$. Distillation of the solution afforded 0.51 g (3.18 mmol) of cyclohexylbenzene, b.p. 238–240 °C (identified by HPLC, IR, ^1H NMR). The oily non-volatile residue solidified at room temperature and was recrystallized from methanol to give 0.4 g (1.65 mmol) of 1,4-(*cyclo*-$C_6H_{11})_2C_6H_4$ with m.p. 239 °C (identified HPLC, IR, ^1H NMR). In the gaseous products H_2 and HCl were identified by GLC analysis.

4.9. Reaction of *1* with n-BuCl in benzene

To 2.97 g (7.46 mmol) of **1** a solution of *n*-BuCl (1.07 g, 11.56 mmol) in 5 ml of benzene was added. The mixture was stirred for 36 h at 80 °C. The evolved gaseous products were periodically released into the atmosphere. Then the reaction mixture was hydrolyzed with dilute HCl and extracted with ether. The extract was analyzed by HPLC and GLC. Among the products 0.4 g (2.98 mmol) of

s-BuC_6H_5 and 0.64 g (3.35 mmol) of 1,4-(*s*-Bu)$_2C_6H_4$ were found.

The reactions of **1** with PhI, PhBr, *cyclo*-$C_6H_{11}Cl$, Me_3SiCH_2Cl and Me_3SiCl were carried out using the same conditions.

4.10. Reaction of **1** with $PhCH_2Cl$ without solvent

Under the conditions of the previous experiment, a mixture of **1** (2.124 g, 5.3 mmol) and benzyl chloride (5.5 g, 43.5 mmol) was heated for 3.5 h. The reaction solution was separated from a black precipitate, the latter was washed with 5 ml of $PhCH_2Cl$ and the extract was joined to the reaction solution. Benzyl chloride and volatile products were removed by condensation in a vacuum to give a yellow-greenish oil, which gradually solidified at room temperature. Reprecipitation of the product by methanol from benzene resulted in formation of the oligomer $PhCH_2(C_6H_4CH_2)_{28}C_6H_4CH_2Cl$ as a white solid, melting above 70 °C; yield 2.353 g (conversion 59%). ^{1}H NMR (200 MHz, C_6D_6): $\delta = 3.73$ (CH_2), 4.07 (CH_2Cl), 6.99 (C_6H_4). ^{13}C NMR (50 MHz, C_6D_6) contains 28 signals, the most intensive of which are: $\delta = 141.6$, 139.3, 131.2, 131.0, 126.9, 126.3 (C_6H_4), 41.8, 41.5, 39.0 (CH_2). IR 3080w, 3050w, 3020w, 1600m, 1509m, 1493m, 1417m, 727s, 696m cm^{-1}. *Anal.* Calc. for $C_{216}H_{185}Cl$: C, 92.16; H, 6.58; Cl, 1.26. Found: C, 92.02; H, 6.75; Cl, 1.23%.

adds to acetone yielding $C_3H_3N_2C(CH_3)_2OH$ adduct, which reacts with the starting oxo complex [14].

The factors determining the formation of the $Re_2O_3^{4+}$ complexes have not been formalised. All the reactions were carried out in a system open to the atmosphere, and water seems to be the source of the bridging oxo group. It is presumed that the formation of intermediate hydroxo-species is crucial [15,16].

This findings prompted us to explore the reactions of $[ReOCl_3(OAsPh_3)(AsPh_3)]$ and $[ReOCl_3(PPh_3)_2]$ with pyrazole in tetrahydrofurane at room temperature. In these cases the mononuclear $[ReOCl_2(pzH)_2(OAsPh_3)](ReO_4)$ (**1**) and dinuclear $[\{ReCl_2(pzH)_2\}_2(\mu\text{-}O)]$ (**2**) oxocomplexes have been isolated.

Here, we present the crystal, molecular and electronic structures of **1** and **2**. The electronic structures of **1** and **2** have been determined basing on the results of the density functional theory (DFT) calculations. The spin-allowed singlet–singlet electronic transitions of the $[ReOCl_2(pzH)_2(OAsPh_3)]^+$ cation, ReO_4^- anion and $[\{ReCl_2(pzH)_2\}_2(\mu\text{-}O)]$-complex have been calculated with the the time-dependent DFT method (TDDFT), and the UV–Vis spectra of the title compounds have been discussed on this basis.

2. Experimental

2.1. General procedure

All the reagents used to the synthesis were commercially available and were used without further purification. The $[ReOCl_3(AsPh_3)(OAsPh_3)]$ and $[ReOCl_3(PPh_3)_2]$ complexes were prepared according to the literature methods [17,18].

IR spectra were recorded on a Nicolet Magna 560 spectrophotometer in the spectral range 4000–400 cm^{-1} with the samples in the form of KBr pellets. Electronic spectra were measured on a spectrophotometer Lab Alliance UV–VIS 8500 in the range 800–200 nm in deoxygenated dichloromethane solution. ^1H NMR spectra were obtained at room temperature in $CDCl_3$ using INOVA 300 spectrometer. Magnetic susceptibilities were measured at 296 K by the Faraday method. Elemental analyses (C H N) were performed on a Perkin–Elmer CHN-2400 analyzer.

2.2. Preparation of $[ReOCl_2(pzH)_2(OAsPh_3)](ReO_4)$ (1)

$[ReOCl_3(AsPh_3)(OAsPh_3)]$ (0.5 g, 0.53 mmol) was suspended in tetrahydrofurane (30 ml) and pzH (0.14 g, 2 mmol) in THF (5 ml) was added dropwise to the stirred suspension. The mixture was stirred for 1 h at room temperature. The solvent was evaporated and the resulting residue was extracted with ethanol and diethyl ether (50 ml) was added. The blue crystals of $[ReOCl_2(pzH)_2(OAsPh_3)](ReO_4)$ were formed overnight. Yield: 30%.

IR (KBr, cm^{-1}) 3204 (m), 3134 (m), 3059 (w), 1587 (w), 1520 (w), 1480(s), 1443 (s), 1405 (m), 1342 (m), 1272 (w), 1188 (w), 1165 (w), 1121 (s) 1088 (m), 1072 (m), 1051 (s), 999 (m), 922 (vs), 906 (vs), 852 (vs), 792 (m), 769 (m), 745 (s), 689 (s), 606 (m), 480 (s), 454 (m), 415 (w). ^1H NMR ($CDCl_3$, ppm): $\delta = 6.59$, 7.78, 8.08 and 8.65 (br, 4H, C(21)–H, C(23)–H, C(31)–H and C(33)–H); 7.28 (m, 15H, C_6H_5); 7.55 and 7.69 (pseudo-triplets, 2H, C(22)–H, C(32)–H) and 13.16 ppm (s, 1H, NH). *Anal.* Calc. for $C_{24}H_{23}AsCl_2N_4O_6Re_2$: C, 29.36; H, 2.36; N, 5.71. Found: C, 29.45; H, 2.40; N, 5.80%.

2.3. Preparation of $[\{ReCl_2(pzH)_2\}_2(\mu\text{-}O)]$ (2)

$[ReOCl_3(PPh_3)_2]$ (0.83 g, 1 mmol) was suspended in tetrahydrofurane (30 ml) and pzH (0.28 g, 4 mmol) in THF (5 ml) was added dropwise to the stirred suspension. The mixture was stirred for 24 h at room temperature. The solvent was evaporated and the resulting residue was extracted with acetonitrile. The blue crystals of $[\{ReCl_2(pzH)_2\}_2(\mu\text{-}O)]$ were formed during several days. Yield: 55%.

2.4. Crystal structures determination and refinement

The X-ray intensity data of **1** and **2** were collected on a KM-4-CCD automatic diffractometer equipped with CCD detector, 55 and 20 s exposure time was used respectively and all reflections of the of Ewald sphere up to $2\theta = 50°$ was collected. The unit cell parameters were determined from least-squares refinement of the setting angles of 7336 and 6418 strongest reflections, respectively. Details concerning crystal data and refinements are given in Table 1. Lorentz, polarization and numerical absorption corrections [19] were applied. The structure were solved by the Patterson method and subsequently completed by the difference Fourier recycling. All the non-hydrogen atoms were refined anisotropically using full-matrix, least-squares technique. The hydrogen atoms were found on difference Fourier synthesis and next refined as "riding" on their parent carbon atoms [d(C–H) = 0.96 Å] and assigned isotropic temperature factors equal 1.2 times the value of equivalent temperature factor of the parent carbon atom. The crystal of 2 was racemically twinned with 7:3 participation of domains. SHELXS-97 [20], SHELXL-97 [21] and SHELXTL [22] programs were used for all the calculations. Atomic scattering factors were those incorporated in the computer programs.

3. Computational details

GAUSSIAN-03 program [23] was used in the calculations. The geometry optimisations of the $[ReOCl_2(pzH)_2(OAsPh_3)]^+$ cation, ReO_4^- anion and $[\{ReCl_2(pzH)_2\}_2(\mu\text{-}O)]$ complex were carried out with the DFT method with

the use of B3LYP functional [24,25]. The electronic spectra the $[ReOCl_2(pzH)_2(OAsPh_3)]^+$ cation, ReO_4^- anion and $[\{ReCl_2(pzH)_2\}_2(\mu\text{-}O)]$ complex were calculated with the TDDFT method [26].

LANL2DZ basis set [27] with additional d (with exponent $\alpha = 0.3811$) and f (with exponent $\alpha = 2.033$) functions was used on the rhenium atom, 6-31G(d) on the chlorine, nitrogen, arsenic, oxygen and carbon atoms and 6-31G basis on the hydrogen atoms.

Natural bond orbital (NBO) calculations were performed with the NBO code [28] included in GAUSSIAN-03.

4. Results and discussion

4.1. Preparation of complexes

The $[ReOCl_2(pzH)_2(OAsPh_3)](ReO_4)$ complex has been isolated in the reaction of $[ReOCl_3(AsPh_3)(OAsPh_3)]$ with an excess of pyrazole in wet tetrahydrofurane at room temperature. In contrast to the analogous reactions of $[ReOX_3(AsPh_3)(OAsPh_3)]$ (X = Cl, Br) with 3,5-dimethylpyrazole (L) in acetone, dimerization and formation of dinuclear $[Re_2O_3X_4L_4]$ compounds do not occur. The presence of perrhenate anion in **1** could seem to be surprising and somewhat unexpected. However, the formation of ReO_4^- ion during synthesis of rhenium compounds has been observed previously [29].

Dimerization and formation of a dinuclear compound is observed for the reaction of $[ReOCl_3(PPh_3)_2]$ with pyrazole in tetrahydrofurane. In this case, the $[\{ReCl_2(pzH)_2\}_2(\mu\text{-}O)]$ complex has been isolated from the reaction system. However, in contrast to the previously characterised $[\{Re(O)X_2(3,5\text{-}Me_2pzH)_2\}_2(\mu\text{-}O)]$ compounds with *cis*,*cis*-ReX_2N_2 arrangement, the $ReCl_2(pzH)_2$ units in **1** are found to be *trans*,*trans*. Only two $[\{ReOX_2L_2\}_2(\mu\text{-}O)]$ complexes with a *trans* arrangement of monodentate heterocycle ligands L in the ReX_2L_2 planes have been characterised so far, $[\{ReOX_2(py)_2\}_2(\mu\text{-}O)]$ [6] and $[\{ReOX_2(1\text{-}Meim)_2\}_2(\mu\text{-}O)]$ [30].

4.2. Crystal structure of *1*

The molecular structure of **1** is shown in Fig. 1. There are no significant contacts involving either cation or anion, with the possible exception of some rather weak hydrogen bonds from the perrhenate anion to the pyrazole or phenyl

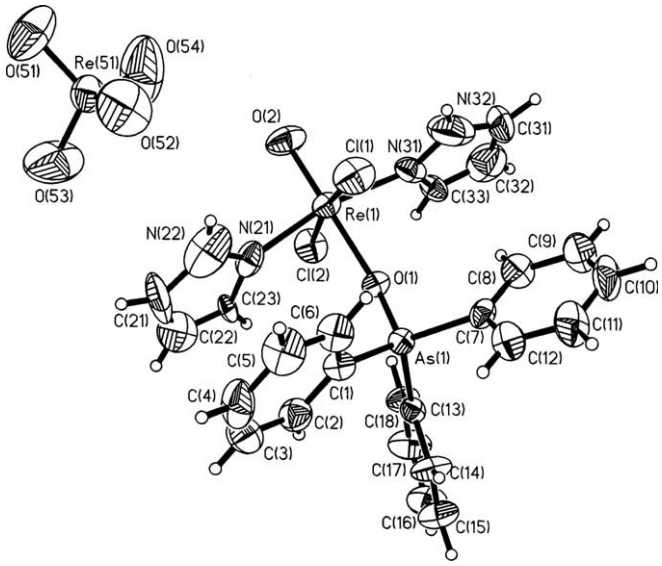

Fig. 1. The molecular structure of $[ReOBr_2(pzH)_2(OAsPh_3)](ReO_4)$.

rings. The weak intramolecular and intermolecular hydrogen bonds [31,32] of **1** are presented in Table 2.

The rhenium atom of the $[ReOCl_2(pzH)_2(OAsPh_3)]^+$ cation has a distorted octahedral environment with the *trans* arranged pyrazole ligands and oxo ion lying in *trans* position to the $OAsPh_3$ molecule. The *cis*-location of π-acid ligands (the pyrazole ligands) in relation to the oxo group seems to be dominated by electronic influence of the multiply bonded ligand, which forces the metal nonbonding d electrons to lie in the in the plane perpendicular to the M–O bond axis. This general rule appears to hold for isonitrile, carbonyl, olefin, acetylene, thioether and often phosphine ligands [33–36]. The most important bond lengths and angles for **1** are reported in Table 3. The major distortion – an increase in the O(2)–Re–Cl/N angles – appears due to the electronic factors interactions with the oxo ligand, and it is commonly observed in octahedral complexes containing a multiply bonding ligand [33,34]. The $Re–O_{oxo}$ bond in $[ReOCl_2(pzH)_2(OAsPh_3)]^+$ is a typical example of reported terminal multiple $Re–O_{oxo}$ distances in mononuclear $[ReO]^{3+}$ compounds: 1.691 Å in $[ReOCl_3(OPPh_2CH_2PPh_2)]$ [37], 1.663 Å in *trans*-$[ReOCl_3(PPh_3)_2]$ [38] and 1.673 Å in $[ReOMe_2Cl(PMe_3)_2]$ [39].

The $Re–OAsPh_3$ and the As–O bond lengths in $[ReOCl_2(pzH)_2(OAsPh_3)]^+$ are in good agreement with the values found for $[ReOBr_3(AsPh_3)(OAsPh_3)]$ (Re–O = 2.010(7) Å, As–O = 1.675(7) Å) and $[ReOCl_3(AsPh_3)(OAsPh_3)]$ (Re–O = 2.019(8) Å, As–O = 1.643(9) Å [17]). The bond distances and angles in the pyrazole rings are also unexceptional, and they agree well with appropriate values found previously [13,14].

4.3. Crystal structure of **2**

The molecular structure of **2** is presented in Fig. 2, and the most important bond lengths and angles are reported in Table 4. The $[\{ReCl_2(pzH)_2\}_2(\mu\text{-}O)]$ complex takes a dinuclear structure in which two rhenium atoms are bridged by the oxo ligand. The bridging oxygen atom lies in special position *a* of $P2_12_12$ space group with site symmetry 2. Each rhenium ion of **2** exhibits a distorted octahedral coordination geometry with the oxygen atoms in the axial positions and *trans* arrangement of monodentate pyrazole ligands in the $ReX_2(pzH)_2$ planes. The Re–O–Re angle is almost linear [177.5(5)°], and two halves of the dinuclear compound are rotated about 54.8° along the line linking Re···Re atoms. The torsion

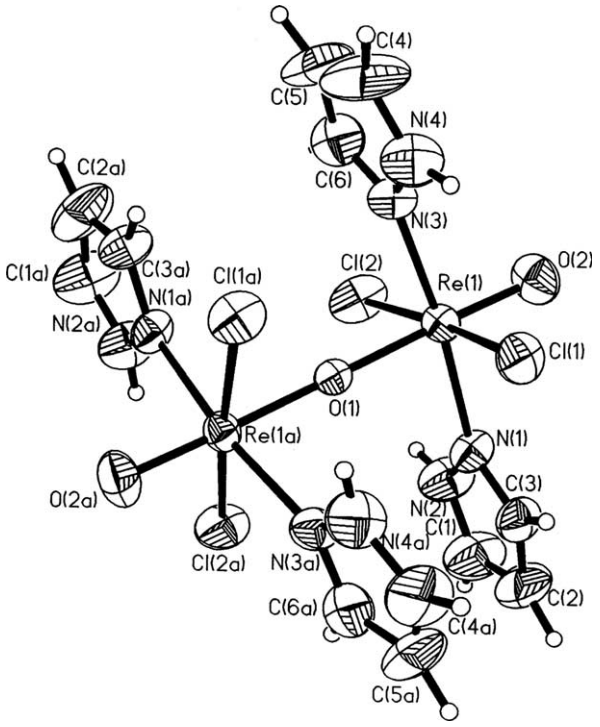

Fig. 2. The molecular structure of $[\{ReCl_2(pzH)_2\}_2(\mu\text{-}O)]$.

Cl(1)–Re(1)···Re(1#)–Cl(1#)/Cl(2#)/N(1#)/N(3#) angles are equal to 55.03(11), −125.20(8), 145.0(2) and −35.3(2)°, respectively (# indicate the $-x+2$, $-y$, z symmetry transformation). This conformation allows stacking interactions to occur between the two pairs of the heterocyclic ligands (Fig. 2; Cg···Cg# distance 4.578(15) Å, angle between Cg···Cg# vector and normal to plane Cg equal to 43.8(9)° and perpendicular distance of Cg on ring Cg# 3.538(5) Å), and succeeding intermolecular stacking interaction between pyrazole substituents indicated by N(3) atom (Cg···Cg$ distance 3.346(16) Å, angle between Cg···Cg$ vector and normal to plane Cg equal to 12.7(9)° and perpendicular distance of Cg on ring Cg$ 3.557(5) Å; $ indicate the $-x+1$, $-y$, z symmetry transformation) linking the molecules to the one dimensional chain. The structure is assembled via strong and weak hydrogen bonds (Table 5) to the three dimensional net. The Re–N, Re–Cl, Re–O_t, and Re–O_b bond lengths in **2** agree well with appropriate values found previously in similar rhenium compounds containing the O=Re–O–Re=O framework [4–12,30]. The Re–O_t bond length of **2** is slightly longer than Re–O_t distance of **1**, but it falls in the range typical of mononuclear complexes of rhenium(V) having $[ReO]^{3+}$ core. The Re–O_b bond distance is also significantly shorter than a single Re–O length. An ideal single Re–O bond distance, predicted by the use of Pauling's covalent

radius for oxygen and Cotton and Lippard's value for the octahedral covalent radius of rhenium(V), should be ca. 2.04 Å [40]. It indicates some redistribution of the d_{π}–p_{π} interaction along the O_t–Re–O_b unit in the dinuclear rhenium complex.

4.4. Spectroscopic characterization

The IR spectrum of $[ReOCl_2(pzH)_2(OAsPh_3)](ReO_4)$ shows a band at 999 cm^{-1} assignable to Re=O stretching vibration of the $[ReOCl_2(pzH)_2(OAsPh_3)]^+$ cation and two intense bands at 922 and 906 cm^{-1} caused by ν(ReO) vibrations of the perrhenate ion. A strong band corresponding to the ν(As=O) vibration appears at 852 cm^{-1}. The IR spectrum of **2** shows a band at 954 cm^{-1} assignable to the symmetric Re=O stretch and a strong multicomponent ν(Re–O–Re) band at 704 $cm^{-1}$with the same shape illustrated in the article of Cotton et al. [41]. The bands of C=C and C=N stretching modes observed at ca. 1640 and 1558 cm^{-1} in uncomplexed pyrazole are shifted to considerable lower frequencies for **1** and **2** complexes. The presence of bands in the range assignable to N–H vibrations in the spectra of **1** and **2** is consistent with the coordination of pyrazole ligands in neutral monodentate form.

The protons of $OAsPh_3$ ligand are readily identified from integrations, they appear as a multiplet at 7.28 ppm. Two pseudotriplets at 7.55 and 7.69 ppm correspond to the protons bound to C(22) and C(32) atoms. Four signals in the range 6.50–8.65 ppm are associated with the other pyrazolyl CH protons, whereas the signal at 13.16 ppm is attributed to NH protons of the pyrazole ligands.

4.5. Geometry optimisation

The geometries of the $[ReOCl_2(pzH)_2(OAsPh_3)]^+$ cation, ReO_4^- anion and $[\{ReCl_2(pzH)_2\}_2(\mu\text{-}O)]$ complex were optimised in a singlet state using the DFT method with the B3LYP functional. For both compounds, a good agreement with the experimental values can be noticed for the Re–O and Re–N bond lengths. The optimised Re–N distances differs by about 0.01 Å from the experimental

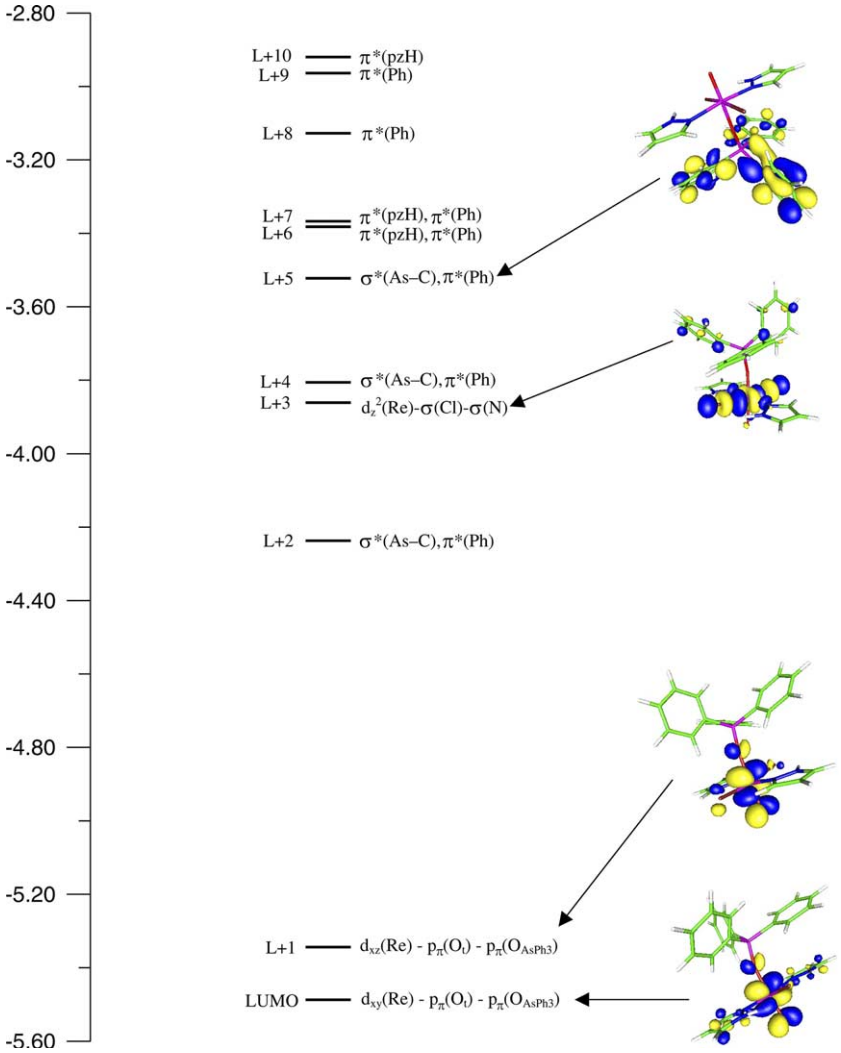

Fig. 3a. The energy (eV), character and some contours of the unoccupied molecular orbitals of $[ReOCl_2(pzH)_2(OAsPh_3)]^+$.

ones. The computed Re–O bond length of the $[ReOCl_2(pzH)_2(OAsPh_3)]^+$ cation (1.660 Å) is almost the same as the experimental value (1.664(5) Å). The optimised Re–$O_{terminal}$ distances (1.679 Å) of $[\{ReCl_2(pzH)_2\}_2(\mu\text{-}O)]$ are insignificantly shorter than the experimental values (1.692(6) Å), whereas the computed Re–$O_{bridging}$ bond lengths are little overestimated in comparison with the experimental ones. The largest differences between the experimental and optimised values are found for Re–Cl distances, the maximum deviations Re–Cl bond lengths are equal to 0.127 and 0.065 Å for **1** and **2**, respectively. Similar elongation of the rhenium–chlorine bond lengths (up to 0.25 Å) in the B3LYP with different basis sets has been found in other rhenium complexes [42]. A good agreement with the experimental values is also found for bond angles, and general trends observed in the experimental geometries are well reproduced in the calculated structures.

4.6. Charge distribution

Table 6 presents the atomic charges from the Natural Population Analysis (NPA) for **1** and **2** complexes. The calculated charges on the rhenium atoms are considerable lower than the formal charge +5. This is a result of significant charge donation from oxo ligands, chlorine ions and *N*-heterocyle molecules. For complex **2**, the considerable difference in values of charges is observed for the terminal and bridging oxo ligands – less negative are the terminal oxo ligands, which indicates the higher electron density delocalization from the terminal ligands towards the rhenium centers and corresponds to differences in the Re–O_t and Re–O_b bonds lengths.

4.7. Electronic structure

The energies, characters and contours of the selected unoccupied and occupied molecular orbitals of the $[ReOCl_2(pzH)_2(OAsPh_3)]^+$ cation are shown in Figs. 3a and 3b, respectively. The rhenium atom in $[ReOCl_2(pzH)_2(OAsPh_3)]^+$ possess the d^2 configuration, the highest MO of the cation is of d_{yz} type with an antibonding contributions from p_π chlorine orbitals. The remaining four d-type orbitals of rhenium are found among unoccupied MOs. The rhenium–oxygen interaction in the $[ReOBr_2(pzH)_2(OAsPh_3)]^+$ cation is described as a triple bond. The $\pi_{Re\equiv O}$

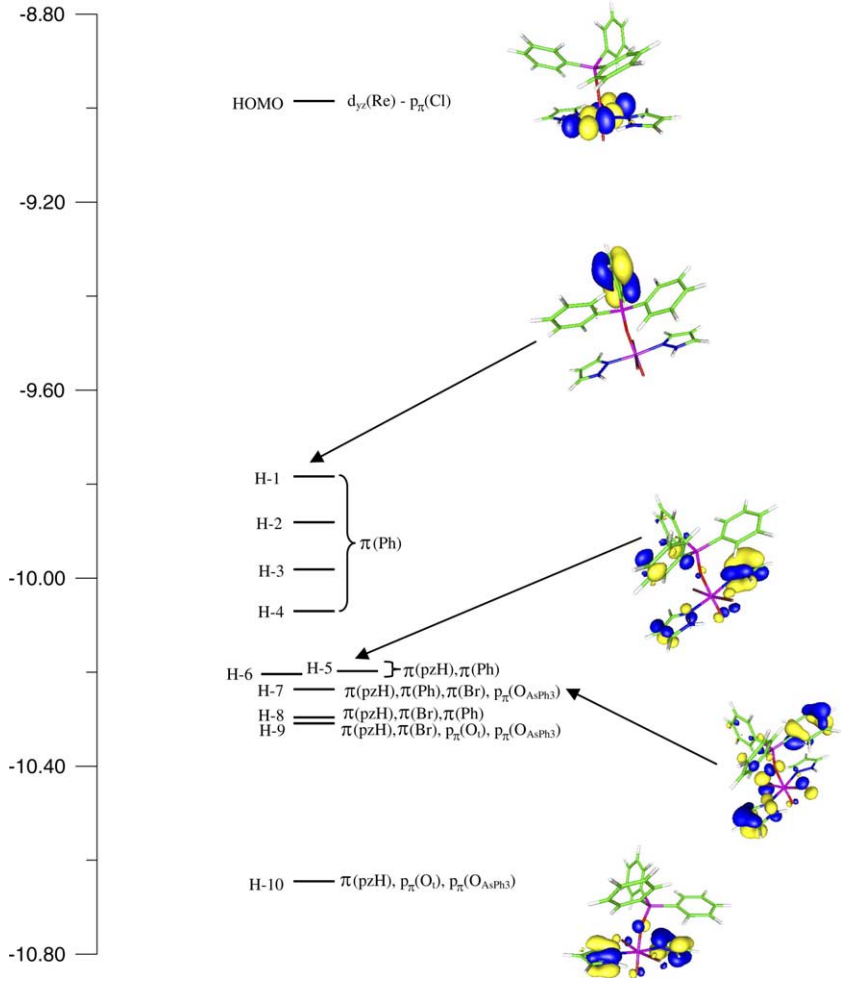

Fig. 3b. The energy (eV), character and some contours of the occupied molecular orbitals of $[ReOCl_2(pzH)_2(OAsPh_3)]^+$.

bonds arise from overlap of the two occupied oxygen p_π orbitals with the empty d_{xy} and d_{xz} metal orbitals. The LUMO and LUMO + 1 are ascribed as π-antibonding rhenium–oxygen molecular orbitals. The LUMO + 3 and LUMO + 11 of the $[ReOBr_2(pzH)_2(OAsPh_3)]^+$ cation are predominantly of d_{z^2} and $d_{x^2-y^2}$ rhenium orbital character, respectively. The LUMO + 2, LUMO + 4, LUMO + 5, LUMO + 8 and LUMO + 9 are mainly composed of π-antibonding phenyl rings, whereas π-antibonding pyrazole rings are mainly contribute to the LUMO + 6, LUMO + 7 and LUMO + 10.

The energies, characters and contours of the selected unoccupied and occupied molecular orbitals of complex **2** are presented in Figs. 4a and 4b, respectively. The rhenium atoms of **2** possess the d^2 configuration; the two highest MOs of the dinuclear complex are of d_{xz} type with an antibonding contribution from p_π chlorine orbitals. The remaining eight d-type orbitals of rhenium are found among unoccupied MOs. The d_{yz} and d_{xy} orbitals of both rhenium ions interact with the filled p_π orbitals of the terminal and bridging oxo ligands to give four π-bonding, two π-nonbonding and four π-antibonding molecular orbitals. The LUMO, LUMO + 1, LUMO + 2 and LUMO + 3 are ascribed as π-antibonding rhenium–oxygen molecular orbitals. The LUMO + 4 and LUMO + 5 are of d_{z^2}-σ_{Cl}–σ_N character. The $d_{x^2-y^2}$ rhenium orbitals make the largest contribution into the LUMO + 10 and LUMO + 11 orbitals. As the complex **2** have C_2 symmetry each molecular orbital is plus or minus combination of the symmetry equivalent d orbitals of the two Re atoms.

4.8. NBO analysis

Table 7 presents the occupancies and hybridization of the calculated natural bond orbitals (NBOs) between the rhenium and the oxo ligands for the $[ReOCl_2(pzH)_2(OAsPh_3)]^+$ cation and $[\{ReCl_2(pzH)_2\}_2(\mu\text{-}O)]$ complex. Table 8 shows the occupancies and atomic orbital compositions of the detected lone pairs (LP) orbitals of the O_b ligand, as well as the character of the acceptor orbital and stabilization energies (ΔE_{ij}) for the corresponding

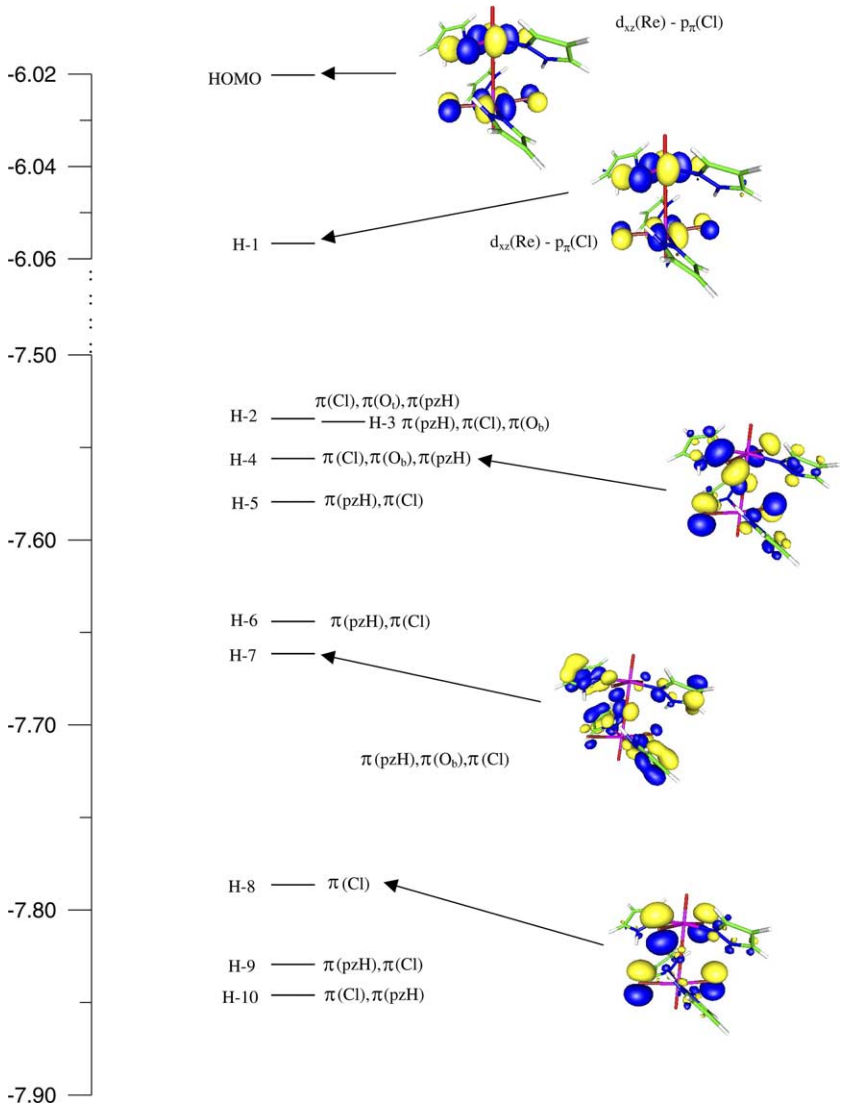

Fig. 4b. The energy (eV), character and some contours of the occupied molecular orbitals of **2**.

Table 7
The occupancies and hybridization of the calculated natural bond orbitals (NBOs) between the rhenium and the oxo ligands for $[ReOCl_2(pzH)_2(OAsPh_3)]^+$ and $[\{ReCl_2(pzH)_2\}_2(\mu\text{-}O)]$

BD	Occupancy	Hybridization of NBO
$[ReOCl_2(pzH)_2(OAsPh_3)]^+$		
Re–O_t	1.983	$0.509(sd^{14.16})_{Re} + 0.861(sp^{2.09})_O$
Re–O_t	1.993	$0.579(d)_{Re} + 0.815(p)_O$
Re–O_t	1.990	$0.572(d)_{Re} + 0.820(p)_O$
Re–O_t[a]	0.327	$0.861(sd^{14.16})_{Re} + 0.509(sp^{2.09})_O$
Re–O_t[a]	0.240	$0.815(d)_{Re} - 0.579(p)_O$
Re–O_t[a]	0.219	$0.820(d)_{Re} - 0.572(p)_O$
$[\{ReCl_2(pzH)_2\}_2(\mu\text{-}O)]$		
Re–O_t	1.959	$0.466(sd^{3.37})_{Re} + 0.885(sp^{1.75})_O$
Re–O_t	1.993	$0.574(d)_{Re} + 0.819(p)_O$
Re–O_t	1.988	$0.573(d)_{Re} + 0.820(p)_O$
Re–O_t[a]	0.288	$0.885(sd^{3.37})_{Re} - 0.466(sp^{1.75})_O$
Re–O_t[a]	0.263	$0.819(d)_{Re} - 0.574(p)_O$
Re–O_t[a]	0.237	$0.820(d)_{Re} - 0.573(p)_O$

BD denotes 2-center bond.
[a] Denotes antibond NBO.

Table 8
Stabilization energies associated with delocalisation from the lone pair orbitals of the bridging oxo ligand for $[\{ReCl_2(pzH)_2\}_2(\mu\text{-}O)]$

Donor orbital	Occupancy of donor orbital	Acceptor orbital	ΔE_{ij} (kcal/mol)
$s_{O(1)}$	1.772	$0.885(sd^{3.37})_{Re} - 0.466(sp^{1.75})_O$	83.90
$p_{O(1)}$	1.756	$0.885(sd^{3.37})_{Re} - 0.466(sp^{1.75})_O$	43.85
$p_{O(1)}$	1.660	$0.819(d)_{Re} - 0.574(p)_O$	33.75
$p_{O(1)}$	1.653	$0.820(d)_{Re} - 0.573(p)_O$	32.14

donor–acceptor interactions for complex **2**. The interactions between 'filled' (donor) Lewis-type NBOs and 'empty' (acceptor) non-Lewis NBOs lead to loss of occupancy from the localized NBOs of the idealized Lewis structure into the empty non-Lewis orbitals, and they are referred to as 'delocalization' corrections to the zeroth-order natural Lewis structure. The stabilization energy ΔE_{ij} (kcal/mol) associated with delocalization is estimated by the second-order perturbative as:

$$\Delta E_{ij} = q_i(F(i,j)^2)/(\varepsilon_j - \varepsilon_i),$$

where q_i is the donor orbital occupancy, ε_i, ε_j are diagonal elements (orbital energies) and $F(i,j)$ is the off-diagonal NBO Fock matrix element [43].

For each Re atom of **2**, three natural Re–O_t bond orbitals were detected. Due to C_2 symmetry of complex **2**, the Re(1)–O(2) and Re(2)–O(3) natural orbitals have the same character, and the values of stabilization energies (ΔE_{ij}) are equal for Re(1) and Re(2) centers. The Re–O_t bonds are all strongly polarized towards the oxygen atom. The s and p oxygen orbitals and s and d rhenium orbitals take part in the σ_{Re-Ot} bond formation, whereas the π_{Re-Ot} bond orbitals result from overlapping of the empty d_{xy} and d_{yz} rhenium orbitals with the occupied p_x and p_z orbitals of the terminal oxygen ligands. Each terminal oxo ligand of **2** has one lone pair with occupancy close to 2. The Re–O_b bonds were not detected indicating a predominant Coulomb-type interaction between the central ion and the bridging oxo ligand [44]. The bridging oxygen ligand has four lone pairs orbitals (LP) and electron density from the LP orbitals is strongly delocalized into the antibonding Re–O_t bond orbitals – the occupancy of the LP orbitals of bridging oxygen are significantly lower than ~2 (Table 8).

Three natural bond orbitals were also detected for the Re–O_t bond in the $[ReOCl_2(pzH)_2(OAsPh_3)]^+$ cation. Similar to complex **2**, the and πRe–O bonds are clearly polarized towards the oxygen end.

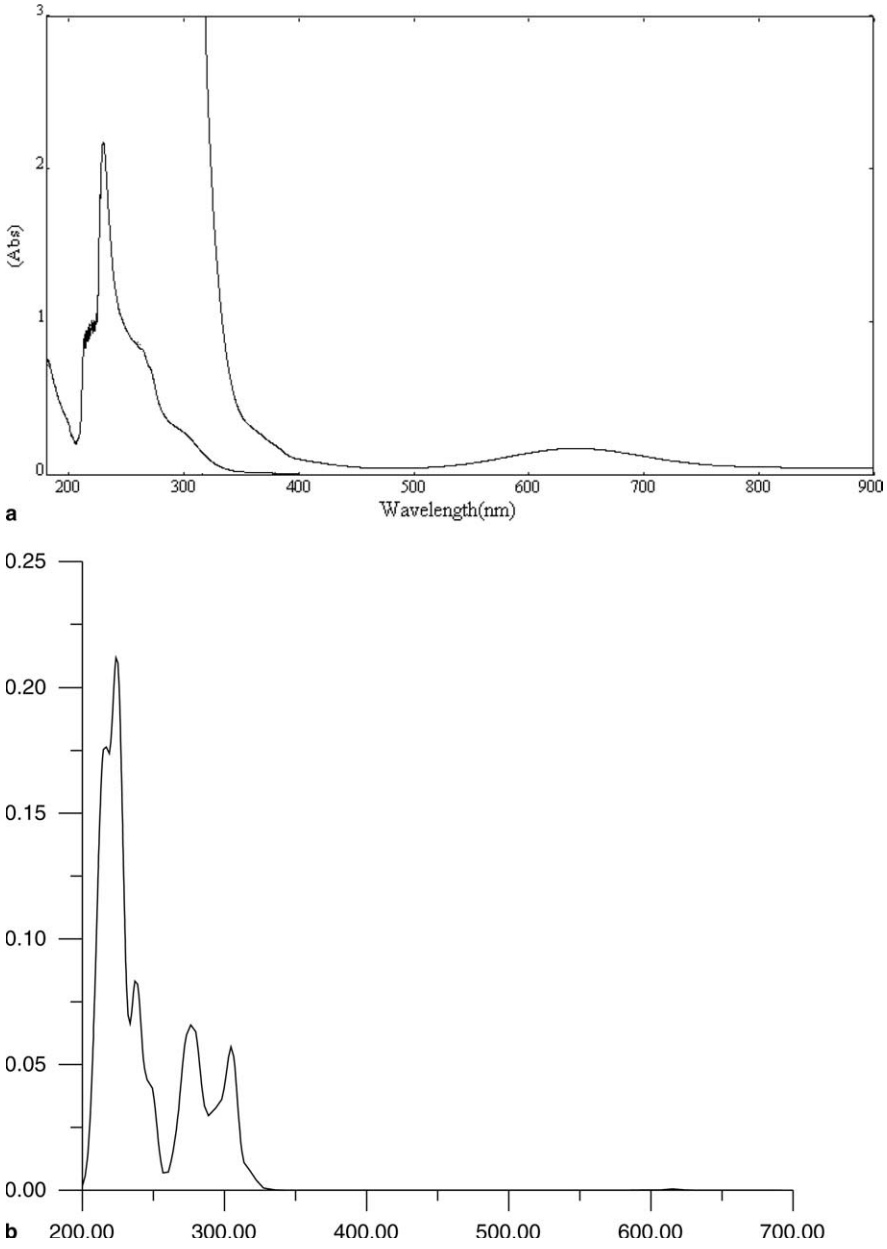

Fig. 5. The experimental (a) and calculated (b) electronic absorption spectrum of **1**.

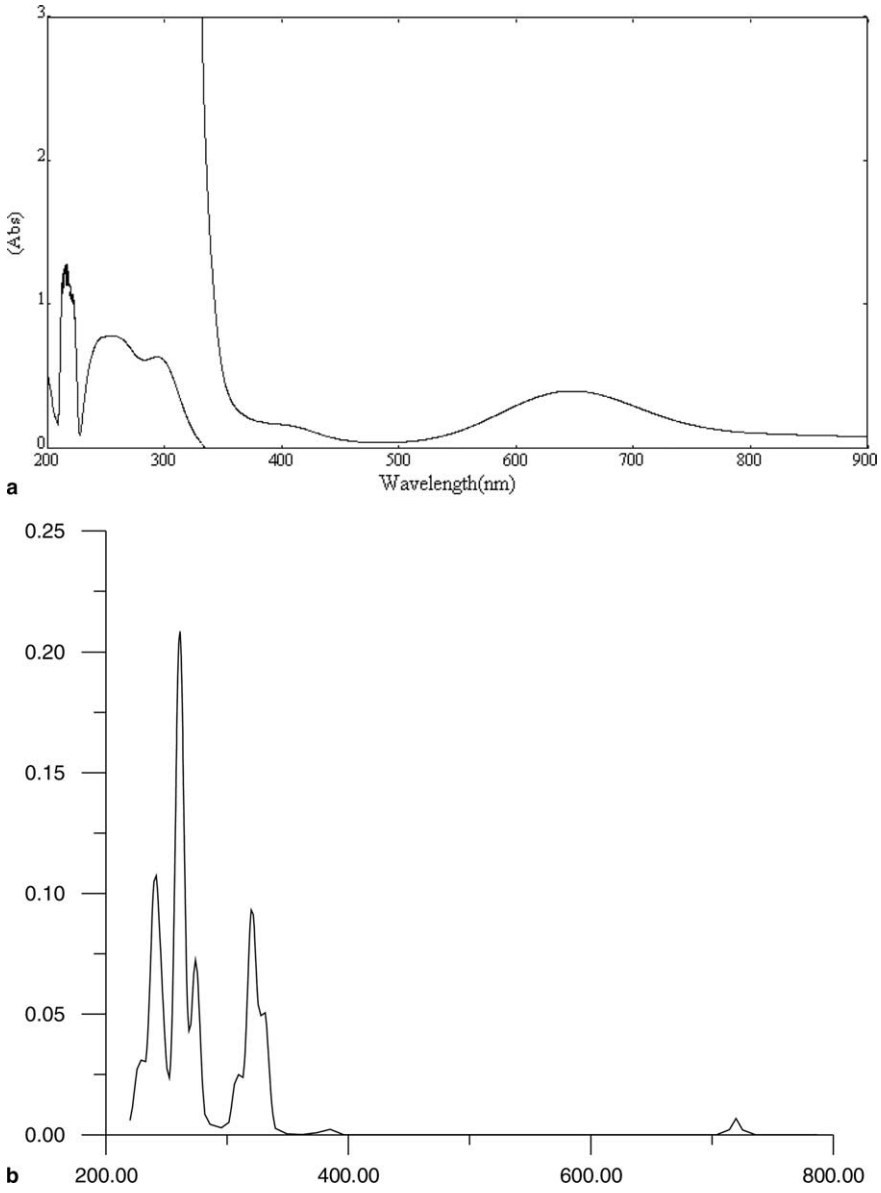

Fig. 6. The experimental (a) and calculated (b) electronic absorption spectrum of **2**.

4.9. Electronic spectra

The experimental and calculated electronic spectra of **1** and **2** are presented in Figs. 5 and 6, respectively. Each calculated transition in Figs. 5 and 6(b) was represented by a gaussian function with the height equal to the oscillator strength and width equal to 0.04.

Tables 9 and 10 present the position of the experimental absorption bands and the spin-allowed singlet–singlet electronic transitions calculated with the TDDFT method for **1** and **2**, respectively. The calculations result in many transitions with very small oscillator strengths. Except for the low energy part of the spectrum, only transitions with oscillator strengths larger than 0.010 are listed for **1** and **2**, respectively. The assignment of the calculated transitions to experimental absorption bands was based on the criterion of the energy and oscillator strength of the calculated transition. The assignment for the complex **2** is not complete. Some additional intraligand and interligand transitions are expected to be found at higher energies in the calculations for **2**.

The UV–Vis spectrum of **1** exhibits a few intense absorption bands in the range 350–200 nm and a weak absorption in the low energy range – at 651.4 nm.

The longest wavelength experimental band at 651.4 nm is attributed to the transitions of $d \rightarrow d$ character with small oscillator strengths calculated at 615.7 and 595.1 nm.

The absorption bands at 300 and 263 nm correspond mainly to the LMCT transitions that occur from the chlorine, oxygen, triphenylarsine oxide and pyrazole orbitals to the d rhenium orbitals.

Table 9
The position of experimental absorption bands and electronic transitions calculated with the TDDFT method $[ReOCl_2(pzH)_2(OAsPh_3)]^+$

H-2 → L + 6	π(Ph) → π*(Ph)/π*(pzH)	207.1	5.99	0.0137	
H-2 → L + 6	π(Ph) → π*(Ph)/π*(pzH)	206.4	6.01	0.0129	

The next band at 230 nm is assigned to the LMCT (π(O) → d) transitions calculated for perrhenate anion at ~225 nm and LLCT transitions calculated for the $[ReOCl_2(pzH)_2(OAsPh_3)]^+$ cation in the range 230–220 nm. The last ones occur from the chlorine, oxygen, triphenylarsine oxide and pyrazole orbitals to the π^*_{pzH} orbitals and π-acceptor orbitals of the arsine ligand.

Two longest wavelength experimental bands of **2** at 651.8 and 401.6 nm are attributed to the transitions of d → d character with small oscillator strengths calculated at 719.9 nm and in the range 390–365 nm, respectively.

The next experimental band at 300.0 nm corresponds to the electronic transitions calculated between 335 and 280 nm. These transitions are mainly of LMCT (π(Cl)/$\pi(O_b)$ → d and π(pzH)/π(Cl) → d character.

The transitions calculated between 275 and 230 nm are ascribed to the experimental band at 257.6 nm. They are of LMCT (π(Cl)/$\pi(O_b)$/$\pi(O_t)$/π(pzH) → d and MLCT (d → π^*_{pzH}).

5. Supplementary data

Supplementary data for $C_{24}H_{23}AsCl_2N_4O_6Re_2$ and $C_{12}H_{16}Cl_4N_8O_3Re_2$ are available from the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK on request, quoting the deposition numbers 260099 and 271895.

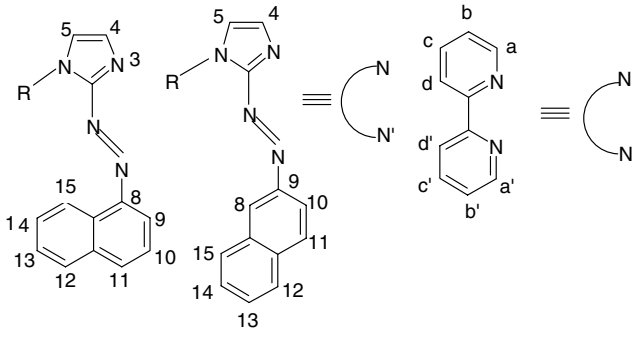
technique of diazo coupling reaction to incorporate Ar–N=N–$^{+}$ into imidazole backbone and have synthesized 2-(arylazo)imidazole [23]. These molecules are π-deficient and can stabilize low metal redox state and exhibit MLCT transitions in their transition metal complexes. Heterocyclic ring size, number of heteroatoms, substituents in the ring and side arm to azo function can significantly modify the physical and chemical properties of the complexes [31,32]. The exobidentate behaviour of imidazole has been eliminated by alkylation to give 1-alkyl-2-(arylazo)imidazoles. The modification of pendant aryl group may be carried out by substituting with sterically more crowded, electronically more susceptible naphthyl group to get 2-(naphthylazo)imidazoles [25]. On considering the importance of ruthenium-bipyridine system we are interested, in the present work, in developing new hetero tris-complexes of the type $[Ru(bpy)_2(L)]^{2+}$ (L = 1-alkyl-2-(naphthylazo) imidazoles). Detail synthesis, spectroscopic characterization and structural studies are reported herewith.

2. Results and discussion

2.1. The complexes

1-Alkyl-2-(naphthyl-α/β-azo)imidazoles (α/β-NaiR) (**3**, **4**; R = Me (a), Et (b), CH_2Ph (c)) are used as ligands (Scheme 1). They are unsymmetric *N*,*N*′-chelating ligands and the donor centres are abbreviated as *N*(imidazole), *N* and *N*(azo), *N*′. The complexes are isolated as perchlorate salt, $[Ru(bpy)_2(\alpha/\beta\text{-NaiR})](ClO_4)_2$, (**5**, **6**) by nucleophilic substitution of chloride from *cis*-$Ru(bpy)_2Cl_2$ by α/β-NaiR via Ag^{+}-assisted route (Eq. (1)). The synthesis may also be carried out by reacting $Ag(\alpha/\beta\text{-NaiR})_2^{+}$ with *cis*-$Ru(bpy)_2Cl_2$ (Eq. (2)).

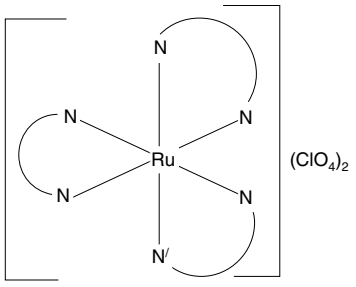
$$Ru(bpy)_2Cl_2 + \alpha/\beta\text{-NaiR} \xrightarrow[(2)\ NaClO_4]{(1)\ Ag^{+},\ MeOH,\ reflux} [Ru(bpy)_2(\alpha/\beta\text{-NaiR})](ClO_4)_2 + 2AgCl\downarrow \quad (1)$$



α-NaiH (**1**), α-NaiMe (**3a**), α-NaiEt (**3b**), α-NaiCH$_2$Ph (**3c**);
β-NaiH (**2**), β-NaiMe (**4a**), β-NaiEt (**4b**), β-NaiCH$_2$Ph (**4c**)

Scheme 1.

$$Ru(bpy)_2Cl_2 + [Ag(\alpha/\beta\text{-NaiR})_2]^{+} \xrightarrow[(2)\ NaClO_4]{(1)\ MeOH,\ reflux} [Ru(bpy)_2(\alpha/\beta\text{-NaiR})](ClO_4)_2 + \alpha/\beta\text{-NaiR} + 2AgCl\downarrow \quad (2)$$



$[Ru(bpy)_2(\alpha\text{-NaiMe})](ClO_4)_2$ (**5a**), $[Ru(bpy)_2(\beta\text{-NaiMe})](ClO_4)_2$ (**6a**)
$[Ru(bpy)_2(\alpha\text{-NaiEt})](ClO_4)_2$ (**5b**), $[Ru(bpy)_2(\beta\text{-NaiEt})](ClO_4)_2$ (**6b**),
$[Ru(bpy)_2(\alpha\text{-NaiCH}_2Ph)](ClO_4)_2$ (**5c**) $[Ru(bpy)_2(\beta\text{-NaiCH}_2Ph)](ClO_4)_2$ (**6c**)

The reaction in Eq. (2) is mainly used for the synthesis of heteroleptic tris-chelates. The products were purified by chromatographic process. Tris-chelates may exist in different isomeric forms [33–35], but we have not been able to separate them by chromatography. The complexes are expectedly diamagnetic (d^6) and 1:2 electrolyte in MeCN. The composition of the compounds was formulated by elemental analyses (vide experimental section).

2.2. Spectral studies

The complexes show *ν*(N=N) and *ν*(C=N) at ca. 1360 and 1500 cm^{-1}, respectively. Very strong sharp stretching at ca. 1085 cm^{-1} is due to perchlorate (ClO_4) along with a weak band at 625 cm^{-1}.

The electronic spectra of NaiR were recorded in MeCN in the UV–VIS region (200–900 nm). Multiple transitions are observed in UV region those are referred to transitions in the coordinated ligand sites viz., bpy and NaiR. The transitions in the visible region are of typical metal-to-ligand charge transfer type (MLCT) in the range 410–480 nm with high molar extinction coefficients ($\varepsilon \sim 10^4$ dm^3 mol^{-1} cm^{-1}) (Table 1). A weak absorption is also observed ($\varepsilon \sim 10^3$ dm^3 mol^{-1} cm^{-1}) at ca. 625 nm. The spectra of the complexes are comparable to that of other $[Ru(bpy)_2(L)]^{2+}$ (L = bpy, aryl-(2-pyridylmethylene)amine [33]/2-(arylazo)pyridine [34], 1-alkyl-2-(arylazo)imidazole [35] (RaaiR′)). It is concluded that the absorption at 400–420 nm is attributed to dπ(Ru) → π*(bpy) and at 450–480 nm is assigned to dπ(Ru) → π*(NaiR) transition. The transition corresponding to 625 nm may be assigned to a state originated from mixing of singlet and triplet configuration in the excited state via spin orbit coupling in a low symmetry environment about the metal ion [36]. The MLCT transition appears at shorter wavelength in $[Ru(bpy)_2(NaiR)]^{2+}$ (λ_{max}, ca. 470 nm) compared to $[Ru(bpy)_2(RaaiR')]^{2+}$(λ_{max} ca. 500 nm). This implies that the

[c] Solvent: MeCN, Platinum disk milli electrode, SCE reference, $[Bu_4N][ClO_4]$ supporting electrolyte, scan rate 50 mV s^{-1}.

LUMO which has been π*(azo) characterized is shifted to higher energy in present series of complexes than that of $[Ru(bpy)_2(RaaiR')]^{2+}$ analogue. Naphthyl group is more delocalised, polarisable, less π-acidic, sterically crowded than aryl group and may be responsible to make difference in energy and composition of MOs of the orbitals in $[Ru(bpy)_2(NaiR)]^{2+}$ and $[Ru(bpy)_2(RaaiR')]^{2+}$.

The ^1H NMR spectra were collected in CD_3CN. The proton numbering pattern is shown in the structures in Scheme 1 and the spectral data are given in Table 2. The NMR signals have been assigned by comparing with free ligand values and ruthenium-naphthylazoimidazoles [25]. The 1-Me in $[Ru(bpy)_2(NaiMe)](ClO_4)_2$ (**5a**, **6a**) signal appears at 4.1–4.2 ppm and is downfield shifted by ~0.2 ppm compared to free ligand values (free ligand δ(Me): 4.0 ppm) [25]. In $[Ru(bpy)_2(NaiCH_2CH_3)](ClO_4)_2$ (**5b**, **6b**) the 1-CH_2CH_3 show complex multiplet for $–CH_2–$ (ca. 4.5 ppm) and triplet for $–CH_3$ (1.50 ppm). The $[Ru(bpy)_2(NaiCH_2Ph)]^{2+}$ show quartet (AB type, Fig. 1(b)) for methylene protons, $–CH_2–(Ph)$, (H7a, H7b) at ca. 5.5 and 5.8 ppm ($J = 18.0$ Hz). The complexes do not possess neighbouring chiral centres but there exist a distorted coordination around the metal ion (vide supra, X-ray structure, Fig. 2). This overall distortion leads to the molecular dissymmetry [23,25]. The imidazolic 4- and 5-H protons appear at 7.4 and 7.3 ppm, respectively. The singlet nature of the proton signal may be due to rapid proton exchange with CH_3CN, which is generated by rapid hydrolysis of CD_3CN upon exposure to moisture in air. The naphthyl protons (8-H to 15-H) appear at upper field side and bpy protons (a-d –H and a′-d′-H) are observed at down field portion of the spectra.

2.3. Molecular structure of $[Ru(bpy)_2((\alpha\text{-NaiEt})](ClO_4)_2$ (**5b**)

View of the molecular unit $[Ru(bpy)_2((\alpha\text{-NaiEt})]^{2+}$ is shown in Fig. 2 and the bond parameters are given in Table 3. The distorted RuN_6 octahedron is generated by the coordination of two N-donor centres of chelated 1-ethyl-2-(naphthyl-α-azo)imidazole and four N-donor centres from two chelated bpy units. The three atomic groups Ru, N(1), C(5), C(6), N(2); Ru, N(3), C(15), C(16), N(4) and Ru, N(8), N(7), C(21), N(5) separately constitute three chelate planes (mean deviation <0.02 Å). The planes are mutually orthogonal (dihedral angle 86–90°). The chelate angles are N(1)–Ru(1)–N(8), 78.7(2); N(3)–Ru(1)–N(4) 78.0(2) and N(5)–Ru(1)–N(8), 76.3(2)°. The N–N distance is 1.287(6) Å and is slightly elongated than free azo bond length (1.266(3) Å [37]). The increase in bond length is undoubtedly due to coordination of N(azo) to ruthenium center which insists $d\pi(Ru) \rightarrow \pi^*(azo)$ charge transition. The average Ru–N(bpy) distance (av. 2.07 Å) is longer than Ru–N(imidazole) (2.036(6) Å) and Ru–N(azo) (1.987(5) Å) distances. The shortening of Ru–N(azo) distance than the Ru–N(imidazole)/Ru–N(bpy) is the indication of metal–ligand π-interaction that is localised in the

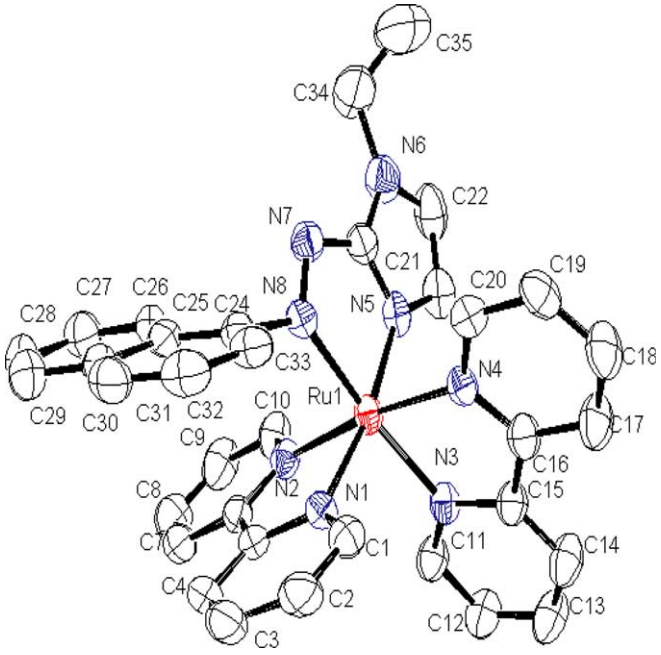

Fig. 2. ORTEP plot of $[Ru(bpy)_2(\alpha\text{-NaiEt})]^{2+}$ (30% probability ellipsoids).

M-azo fragment. The perchlorate ions hydrogen bond (C–H–O) to the ligands of the cation while at the same time forming O_3Cl–O–H–C (bpy) bonds resulting in the construction of an extended 3-D network structure (Table 4, Fig. 3). A hydrogen bonded dimer is described when naphthyl-C(26)-H–O–ClO_3 interaction is observed (Fig. 3). Each hydrogen bonded dimer then provide an opportunity to incorporate O_3Cl–O–π (Cg of N(4), C(16), C(17), C(18), C(19), C(20); 3.04 Å) interaction and forms a dimer-of-dimer.

2.4. Electrochemistry

The voltammograms display Ru(III)/Ru(II) couple at the positive side and the ligand reductions at the negative side to reference electrode, SCE. The results are given in

Table 1, and a representative voltammogram is shown in Fig. 4.

In the potential range 0.0–1.8 V at the scan rate 50 mV s^{-1} in MeCN a reversible to quasireversible (peak to-peak separation $\Delta E = 70$–120 mV) oxidative response is observed corresponding to the redox reaction (Eq. (3)).

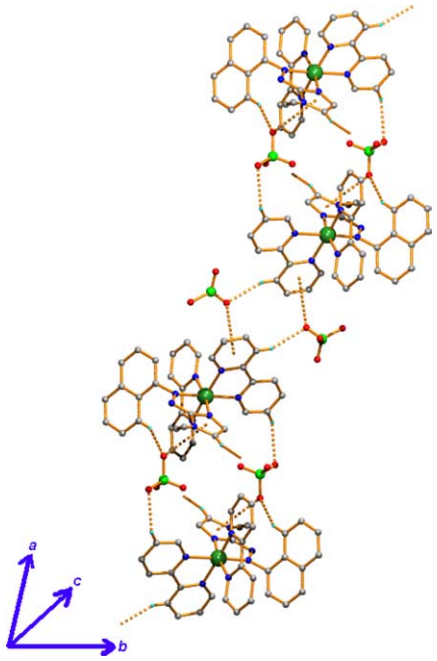

Fig. 3. Hydrogen bonded dimer-of-dimer generated by Cl–O–π interactions.

$$[Ru(bpy)_2(NaiR)]^{3+} + e \rightleftharpoons [Ru(bpy)_2(NaiR)]^{2+} \quad (3)$$

$$[Ru(bpy)_2(NaiR)]^{2+} + e \rightleftharpoons [Ru(bpy)_2(NaiR^-)]^{2+} \quad (4)$$

$$[Ru(bpy)_2(NaiR)]^{2+} + e \rightleftharpoons [Ru(bpy)(bpy^-)(NaiR^-)]^{2+} \quad (5)$$

$$[Ru(bpy)(bpy^-)(NaiR^-)]^{2+} + e \rightleftharpoons [Ru(bpy^-)(bpy^-)(NaiR^-)]^{2+} \quad (6)$$

Voltammetric profile pattern remains unchanged with in scan range 50–500 mV s^{-1}. The i_{pa}/i_{pc} ratio (i_{pa} = anodic peak current and i_{pc} = cathodic peak current) is close to 1.0, as expected for reversible couples. The Ru(III)/Ru(II) redox potential ($E^M_{1/2} = 1.2$ V, Table 1) is expectedly higher than that of $Ru(NaiR)_2Cl_2$ (0.5–0.6 V vs. SCE [25]) which

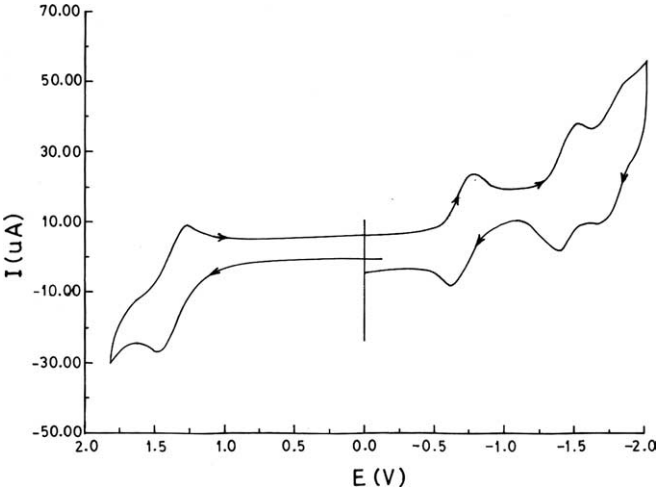

Fig. 4. Cyclic voltammogram of $[Ru(bpy)_2(\alpha\text{-NaiEt})](ClO_4)_2$ in MeCN.

are due to higher π-acidity of azoimine or diimine groups than chlorides. Some Ru(III)/Ru(II) formal potential data in tris-chelates $[Ru(bpy)_2(L)]^{2+}$ for L = *N*,*N*-bidentate neutral donor are as follows: $Ru(bpy)_3{}^{2+}$ in CH_2Cl_2 1.29 V [38]; $[Ru(bpy)_2$(2-(arylazo)pyridine)$]^{2+}$in MeCN 1.60 V [34]; $[Ru(bpy)_2$(1-alkyl-2-(arylazo)imidazole)$]^{2+}$ in MeCN 1.4 V [35]; $[Ru(bpy)_2$(*N*-phenylthiosalicylaldimine)$]^{+}$ in MeCN, 0.3 V [10]. The relative values of the potential suggest that the π-acidity order is *N*-phenylthiosalicylaldimine < bipyridine < naphthylazomidazole < arylazoimidazoles < arylazopyridines. On comparing Ru(III)/Ru(II) couple of $[Ru(bpy)_2$(1-alkyl-2-(arylazo)imidazole)$]^{2+}$ with present group of complexes it is concluded that the metal dominated redox orbital (HOMO) is less stable in present case and Ru(III)/Ru(II) couple appears at lower potential data (lowering by ~0.2 V).

In the potential range 0.0 to −2.0 V three successive reductive responses are observed under similar conditions. The interpretation of CV data may be carried out on comparison with the redox properties of *cis*-$Ru(bpy)_2Cl_2$[38], $[Ru(bpy)_2(L)]^{2+}$ (L = 2-(arylazo)pyridines [34], aryl-(2-pyridylmethylene)amine [33], 1-alkyl-2-(arylazo)imidazle [35]), and $Ru(NaiR)_2Cl_2$ [25]. These are assigned to reductions of the coordinated ligands. Redox data in Table 1 reveal that the first reduction potential of the coordinated ligand occurs at a much less negative potential than that of other two responses. The first reduction may be expected to involve the ligand having the most stable lowest unoccupied molecular orbital (LUMO) [11,23–26], which is dominated by azo function of naphthylazoimidazole than bpy (Eq. (4)). The potential of (–N=N–)/(–N=N–)$^-$ is less negative by ~0.1 V than that of data reported for $Ru(NaiR)_2Cl_2$ [25]. This may be due to coligand effect of π-acidic bpy groups. However, the (–N=N–)/(–N=N–)$^-$ couple appears at more negative value by ~0.1 V in present compounds than that of $[Ru(bpy)_2$(1-alkyl-2-(arylazo)imidazle$]^{2+}$ [35]. The presence of electron rich naphthyl group (in NaiR) may shift ligand dominated orbitals (LUMOs) to higher energy side than aryl group in RaaiR′. In the potential range −1.4 to −1.8 V two reductive responses are observed. These are referred to the reductions of bpy in $Ru(bpy)_2$–motif (Eqs. (5) and (6)). The one-electron nature of these processes was assigned from the comparison of current height with couple (3).

3. Experimental

3.1. Materials

$RuCl_3 \cdot nH_2O$ was obtained from Arrora Matthey, Calcutta and was digested thrice with concentrated HCl before use. 1-Alkyl-2-(naphthylazo)imidazoles (NaiR) and $[Ag(NaiR)_2](ClO_4)$ were synthesized as before [39]. *cis*-$Ru(bpy)_2Cl_2$ was prepared by published procedure [38]. All other chemicals and solvents used for the preparative work were of reagent grade and were used as received.

3.2. Physical measurements

Microanalytical data (C, H, N) were collected using a Perkin–Elmer 2400 CHN elemental analyser. Solution electronic spectra were recorded on a JASCO UV–VIS–NIR V-570 spectrophotometer. Infrared (IR) spectra were obtained using a JASCO 420 spectrophotometer (using KBr disks, 4000–200 cm^{-1}). The ^1H NMR spectra in CD_3CN were obtained on a Bruker 300 MHz FT NMR spectrometer using $SiMe_4$ as internal reference. Solution electrical conductivities were measured using Systronics 304 conductivity meter with solute concentration ~10^{-3} M in acetonitrile. Electrochemical work was carried out using EG & G PARC Versastat computer controlled 250 electrochemical system. All experiments were performed under a dry N_2 atmosphere at 298 K using a Pt-disk milli working electrode in the potential range +1.8 to −2.0 V. All results were referenced to a saturated calomel electrode (SCE). Reported potentials are uncorrected for junction effect.

3.3. Preparation of complexes

3.3.1. Bis(2,2′-bipyridine)[1-methyl-2-(naphthyl-α-azo)imidazole]ruthenium(II) perchlorate [Ru(bpy)$_2$(α-NaiMe)](ClO$_4$)$_2$ (**5a**)

To a suspension of $Ru(bpy)_2Cl_2$ (50 mg, 0.103 mmol) in acetone (15 ml) was added aqueous solution of $AgNO_3$ (2 mmol) and was refluxed for 15 min, AgCl so precipitated was filtered off by G-4 crucible. The acetone solution (10 ml) of α-NaiMe (25 mg, 0.106 mmol) was then added and the resulting mixture was heated to reflux for 1 h under nitrogen atmosphere. The solution volume was then evaporated to half of its original volume by N_2 bubbling and an aqueous solution of $NaClO_4$ (ca. 0.5 g in 10 ml water) was added. The reddish brown precipitate thus obtained was filtered and dried in vacuo over P_4O_{10}. The dry mass was then dissolved in minimum vol. of CH_2Cl_2 and was subjected to column chromatography on a silica gel column (60–120 mesh). A reddish brown band was eluted with C_6H_6-MeCN (3:2, v/v). It was collected and evaporated. Crystals were collected layering a solution of the complex in CH_2Cl_2 with hexane. Yield, 52 mg, 61%.

3.3.2. Reaction of Ru(bpy)$_2$Cl$_2$ with [Ag(NaiMe)$_2$](ClO$_4$)

General procedure for synthesis of $[Ru(bpy)_2$((α-*NaiMe*)$](ClO_4)_2$ is given below. To a methanolic suspension of $Ru(bpy)_2Cl_2$, (50 mg, 0.103 mmol in 10 ml MeOH) $[Ag(NaiMe)_2](ClO_4)$ (140 mg, 0,206 mmol in 25 ml in acetone) was added and refluxed for 1h under nitrogen atmosphere. Solution was filtered through a G-4 sintered glass funnel. Insoluble AgCl was filtered, the solution was evaporated to dryness and washed thoroughly with cold water (20 ml × 4). The dried mass was dissolved in methanol and an aqueous solution of $NaClO_4$ (ca. 1 g in 15 ml) was added. The reddish brown product was filtered and purified as before. Yield: 64 mg, 75%.

All other complexes were prepared similarly (yield: 70–80%).

Microanalytical data of the complexes are as follows: $[Ru(bpy)_2(\alpha\text{-NaiMe})](ClO_4)_2$, (**5a**): *Anal.* Calc. for $C_{34}H_{28}N_8O_8Cl_2Ru$: C, 48.11; H, 3.30; N, 13.21. Found: C, 48.03; H, 3.25; N, 13.26%. $[Ru(bpy)_2(\alpha\text{-NaiEt})](ClO_4)_2$, (**5b**) *Anal.* Calc. for $C_{35}H_{30}N_8O_8Cl_2Ru$: C, 48.72; H, 3.48; N, 12.99. Found: C, 48.78; H, 3.45; N, 13.06. $[Ru(bpy)_2(\alpha\text{-NaiCH}_2Ph)](ClO_4)_2$ (**5c**): *Anal.* Calc. for $C_{40}H_{32}N_8O_8Cl_2Ru$: C, 51.95; H, 3.46; N, 12.12. Found: C, 52.00; H, 3.50; N, 12.07%. $[Ru(bpy)_2(\beta\text{-NaiMe})](ClO_4)_2$, (**6a**): *Anal.* Calc. for $C_{34}H_{28}N_8O_8Cl_2Ru$: C, 48.11; H, 3.30; N, 13.21. Found: C, 48.70; H, 3.53; N, 13.03%. $[Ru(bpy)_2(\beta\text{-NaiCH}_2Ph)](ClO_4)_2$ (**6c**): *Anal.* Calc. for $C_{40}H_{32}N_8O_8Cl_2Ru$: C, 51.95; H, 3.46; N, 12.12. Found: C, 52.02; H, 3.50; N, 12.18%.

Caution! Perchlorate salts of metal complexes are generally explosive. Care should be taken in handling the samples.

3.4. X-ray crystallography

Crystal suitable for X-ray work was grown by slow diffusion of hexane–benzene (1:1, v/v) into dichloromethane solution of $[Ru(bpy)_2(\alpha\text{-NaiEt})](ClO_4)_2$ (**5b**). Crystal size was $0.3 \times 0.2 \times 0.15$ mm^3. Data were collected on a Bruker SMART 1K CCD diffractometer with graphite monochromatized Mo Kα radiation ($\lambda = 0.71073$ Å) at 293(2) K. Crystal data and collection parameter are listed in Table 5. The data were corrected for absorption effects by empirical method using XPREP [40]. Systematic absences led to the identification of space group $C2/c$ in the range of 2θ of 2.16–56.6°. Of the 22,592 collected reflections 8607 were independent (3815 reflections $I > 2(I)$). The structure was solved by conventional heavy-atom method and refined by full-matrix least-squares refinements on F^2 using SHELXL-97 [41] with anisotropic displacement parameters for all non-hydrogen atoms. Hydrogen atoms were included in calculated positions with isotropic thermal parameters 1.2 times the equivalent isotopic thermal parameters of their parent carbon atoms. All calculations were carried out using SHELXS-97 [41], PLATON [42], ORTEP-32 [43].

Table 5
Crystallographic data of **5b**

Chemical formula	$C_{35}H_{30}Cl_2N_8O_8Ru$
Formula weight	862.64
T (K)	293 (2)
Crystal system	monoclinic
Space group	$C2/c$
μ (mm^{-1})	0.613
a (Å)	37.714 (5)
b (Å)	14.390(2)
c (Å)	14.0322(19)
β (°)	91.807(3)
Unit cell volume (Å^3)	7611.6(18)
Z	8
μ (cm^{-1})	6.13
ρ_{calc} (gm cm^{-3})	1.506
Measured reflections	22592
Independent reflection (R_{int})	8607 (0.0790)
R^a ($I > 2(I)$)	0.0743
wR^b	0.1770
Goodness-of-fit[c]	1.005

[a] $R = \sum|F_o - F_c|/\sum F_o$.
[b] $wR = [\sum w(F_o^2 - F_c^2)/\sum wF_o^4]^{1/2}$; $w = 1/[\sigma^2(F_o^2) + (0.0928P)^2]$, $P = (F_o^2 + 2F_c^2)/3$.
[c] GOF (Goodness-of-fit) is defined as $[w(F_o - F_c)/(n_0 - n_v)]^{1/2}$ where n_0 and n_v denote the numbers of data and variables, respectively.

4. Conclusion

In this work we have synthesised mixed tris-chelates of type $[Ru(bpy)_2(\alpha\text{-/}\beta\text{-NaiR})](ClO_4)_2$. Ligands, α-/β-NaiR (1-alkyl-(naphthyl-α-/β-azo)imidazole) belong to azoimine chelating group, –N=N–C=N–. The complexes show strong MLCT transition in the visible region. They have been characterised by spectroscopic data and in one case by single-crystal X-ray diffraction study. Cyclic voltammetry shows metal centred oxidation and ligand centred reductions.

5. Supplementary material

Crystallographic data for the structures have been deposited with the Cambridge Crystallographic data center, CCDC No. 274227. Copies of this information may be obtained free of charge from the Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (e-mail: deposit@ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk).

strikingly different reactivity behaviors towards triarylphosphines [5]. In order to further examination of the effect of *tert*-butyl groups on the structural properties and redox reactivity of the Cu(II) salicylaldiminates we have carried out the synthesis of bis(N-3,5-Bu$^t_2$-phenyl-R-sal)copper(II) complexes, where R = H, OH, OCH_3, *t*-Bu, and their spectroscopic, structural and redox reactivity properties were studied.

In the present work, the preparation, spectroscopy, electrochemical and chemical redox properties of bis(N-3,5-Bu$^t_2$phenyl-R-sal)copper(II) complexes, (**X**), derived from 3,5-Bu$^t_2$aniline and salicylaldehyde derivatives, i.e.: bis(N-3,5-Bu$^t_2$phenyl-sal)copper(II) (**1**), bis(N-3,5-Bu$^t_2$phenyl-3-methoxy-sal)-copper(II) (**2**), bis(N-3,5-Bu$^t_2$phenyl-4-methoxy-sal)copper(II) (**3**), bis(N-3,5-Bu$^t_2$phenyl-3-hydroxy-sal)copper(II) (**4**), bis(N-3,5-Bu$^t_2$phenyl-4-hydroxy-sal)copper(II) (**5**), bis(N-3,5-Bu$^t_2$phenyl-3,5-Bu$^t_2$-sal)copper(II) (**6**) and crystal structural analysis of **1** are reported.

2. Experimental

2.1. Chemicals

All solvents, $Cu(ac)_2 \cdot H_2O$, $(NH_4)_2Ce(NO_3)_6$, n-Bu_4NClO_4, PPh_3, 3,5-di-*tert*-butylaniline, salicylaldehyde and its 3-HO, 4-HO, 3-OCH_3, 4-OCH_3 derivatives were purchased from Aldrich Chemical Co. and were used without further purification. 3,5-di-*tert*-butylsalicylaldehyde was prepared according to the procedure described by Jacobsen and his co-workers [3d].

2.2. Ligands

N-3,5-di-*tert*-butylphenyl-R-sal (**L$_x$H**) were prepared in good yields by the condensation of 3,5-di-*tert*-butylaniline and appropriate salicylaldehydes in refluxing methanol. The yellow imines were recrystallized from methanol. Yields of the **L$_x$H** are in the range 75–88%. Compound **L$_1$H**: yield % 78; m.p. 114 °C; selected IR (cm^{-1}, KBr): 1618 (CH=N), 2902–2964 (C–H, Bu^t); ^{1}H NMR (200 MHz, $CDCl_3$): δ 13.47 (s, 1H, O*H*), 8.64 (s, 1H, C*H*=N), 7.44–7.34 (m, 3H, Ar*H*), 7.13–6.91 (m, 4H Ar*H*), 1.37 (s, 18 H, *t*-Bu); ^{13}C NMR (50 MHz, $CDCl_3$): δ 162.1 (*C*H=N), 152.2, 132.9, 132.2, 121.1, 118.9, 117.3, 115.4, 35.1, 31.5; UV/Vis (EtOH): λ ($\log\varepsilon$ 1 cm^{-1} M^{-1}): 210(sh), 230(4.40), 268(4.25), 341(4.26), 438(2.36) nm; *Anal.* Calc. for $C_{21}H_{27}NO$: C, 77.50; H, 8.36; N, 4.30. Compound **L$_6$H**: yield % 85; m.p. 119 °C; Selected IR (cm^{-1}, KBr): 1619 (CH=N), 2902–2964 (C–H, Bu^t); ^{1}H NMR (200 MHz, $CDCl_3$): δ 13.97 (s, 1H, O*H*), 8.60 (d, J = 6.0 Hz, 1H, C*H*=N), 7.49–7.15 (m, 4H, Ar*H*), 1.54–1.37 (m, 36 H, *t*-Bu); ^{13}C NMR (50 MHz, $CDCl_3$): δ 163.2 (*C*H=N), 158.3, 152.1, 148.2, 140.5, 136.9, 127.8, 126.7, 120.8, 118.5, 115.5, 35.1, 34.2, 31.6, 29.5; UV/Vis (EtOH): λ ($\log\varepsilon$ 1 cm^{-1} M^{-1}): 210(sh), 230(4.40), 268(4.25), 341(4.26), 438(2.36) nm; *Anal.* Calc. for $C_{29}H_{43}NO$: C, 82.61; H, 10.28; N, 3.32. Found: C, 82.42; H, 9.87; N, 3.42%.

2.3. Complexes

The complexes **X** were prepared by refluxing methanolic solutions of $Cu(ac)_2 \cdot H_2O$ (0.25 mmol) and **L$_x$H** (0.5 mmol) in a 1:2 molar ratio for 1.0–1.5 h. The volume of the resulting solution was reduced to one half and left at room temperature without stirring. The precipitate microcrystals were collected by filtration, washed with a small amount of cold methanol and dried on air (yields 68–85%). Recrystallization of **1** from methanol afforded X-ray suitable crystals. Yield: 76%. M.p. 196 °C. $\mu_{eff} = 1.76\mu_B$; UV/Vis ($CHCl_3$): λ ($\log\varepsilon$) = 294(4.79), 400(4.41), 500(sh), 670-(2.43); IR (KBr, cm^{-1}): ν = 1608 (CH=N), 2864–2956 (C–H in Bu^t). $C_{42}H_{52}N_2O_2Cu$: Calc.: C, 74.2; H, 7.7; N, 4.1. Found: C, 74.3; H, 7.6; N, 4.2%. Elemental analysis, physico-chemical, electronic spectral and IR data of **X** complexes are summarized in Table 1.

Table 1

2.4. Physical measurements

Elemental analyses were carried out using a LECO CHNS 932 elemental analyzer. The magnetic susceptibilities of powdered samples were measured in a Sherwood Scientific Magnetic Susceptibility Balance (Model MK 1) magnetometer at r.t. Electronic spectra were measured on a Shimadzu 1601 UV–Vis spectrophotometer in various solvents. The IR spectra were recorded on a Perkin–Elmer FTIR spectrometer using KBr discs. ^1H and ^{13}C NMR spectra were recorded on a Bruker Spectro spin Avance DPX-400 Ultra Shield Model NMR or on a BRUKER AC 200 using TMS as an internal standard in $CDCl_3$. The ESR spectra were recorded on a Varian E-109 C model X-band spectrometer with 100 kHz modulations. The X-band EPR spectra at 300 and 113–133 K were recorded on a Varian E109 C model EPR spectrometer with 100 kHz frequency modulation using DPPH ($g = 2.0036$) as standard. Errors in g_{iso}, $g_{\|}$ and $g_{\perp}$ are ± 0.0005; errors in A_{iso}, $A_{\|}$ and $A_{\perp}$ are 0.5, 1.0 and 1.0 G, respectively.

An EcoChemie Autolab-12 potentiostat with the electrochemical software package GPES 4.9 (Utrecht, The Netherlands) was used for voltammetric measurements. A three electrode system was used: a Pt counter electrode, an Ag/AgCl reference electrode and a 2-mm sized Pt disc as working electrode. The potentiostat/galvanostat has an IR-compensation option. Therefore, the resistance due to the electrode surface was compensated throughout the measurements. Oxygen-free nitrogen was bubbled through the solution before each experiment. All experiments were carried out at room temperature.

2.5. X-ray crystallography

A suitable single crystal was mounted on a glass fiber and data collections were performed on a STOE IPDSII image plate detector using Mo Kα radiation ($\lambda = 0.710690$ Å). Intensity data were collected in the θ range 1.93–29.38° at 298 (2) K. Crystallographic data are listed in Table 2. Data collection: Stoe X-AREA [7]. Cell refinement: Stoe X-AREA [7]. Data reduction: Stoe X-RED [7]. The structure was solved by direct-methods using SIR97 [8] and anisotropic displacement parameters were applied to non-hydrogen atoms in a full-matrix least-squares refinement based on F^2 using SHELXL-97 [9]. All hydrogen atoms were positioned geometrically and refined by a riding model with U_{iso} 1.2 times that of attached atoms. Molecular drawings were obtained using ORTEP-III [10].

3. Results and discussion

Except **5** (R = 4-OH) all **X** complexes are soluble in chloroform, dichloromethane, but less soluble in solvents such as alcohols, tetrahydrofuran and DMSO. The elemen-

tal analyses were satisfactory, indicating that the complexes have a ligand-to-metal ratio of 2:1.

It is well known that tetra coordinated copper(II)-Schiff base complexes derived from bidentate *N*-aryl(alkyl)-R-sal ligands with CuN_2O_2 coordination sphere usually display *trans* square planar, distorted square planar or tetrahedral arrangement [2–4c,11]. At the same time, recently reported X-ray structural studies of the solvated Cu(*N*-Ph-5-Cl-sal)$_2 \cdot 1/2CH_2Cl_2$ [3a] and Cu(*N*-*p*-CH_3Ph-sal)$_2 \cdot$ DMF [12] revealed that in these complexes the ligands are coordinated in a *cis*-N_2O_2 planar configuration. Interestingly, in the present unsolvated complex **1** the copper atom has a tetrahedrally distorted square planar geometry with two 3, 5-di-Bu$^t_2$phenyl-sal ligands in a *cis*-N_2O_2 arrangement.

3.1. Description of the structure of *1*

The molecular structure of complex **1** is illustrated in Fig. 1. Details of the crystal and data collection are outlined in Table 2. The selected bond lengths and bond angles are listed in Table 3. The X-ray diffraction analysis of **1** show that the copper ion is bonded to the oxygen and nitrogen donor atoms of the two bidentate ligand molecules in the unusual a *cis*-N_2O_2 arrangement. The geometry of **1** is distorted square planar where the dihedral angle between the two coordination planes defined by O1′Cu1N1′ and O1CuN1 is 36.91(6)° (Fig. 1). The compound has crystallographic C_2 2-fold axes passing through the copper atom. The crystal structure of **1** is built from pairs of molecules orientated in the *trans* position respect to each other and the two salicylidene groups of the neighboring mole-

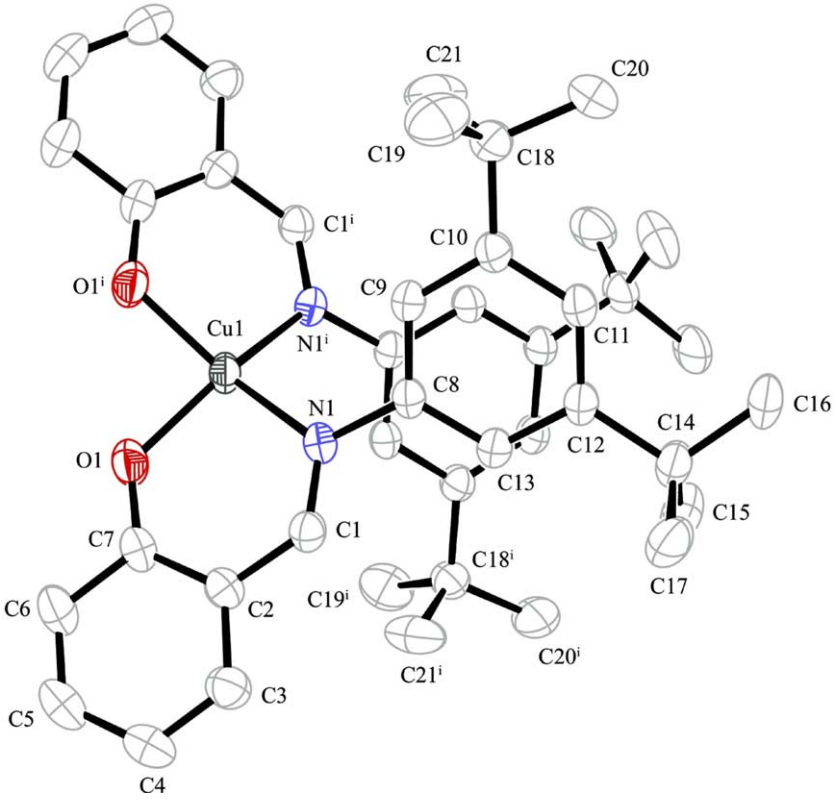

Fig. 1. An ORTER diagram of **1**. Displacement ellipsoids are drawn at the 40% probability level. H atoms are omitted for clarity.

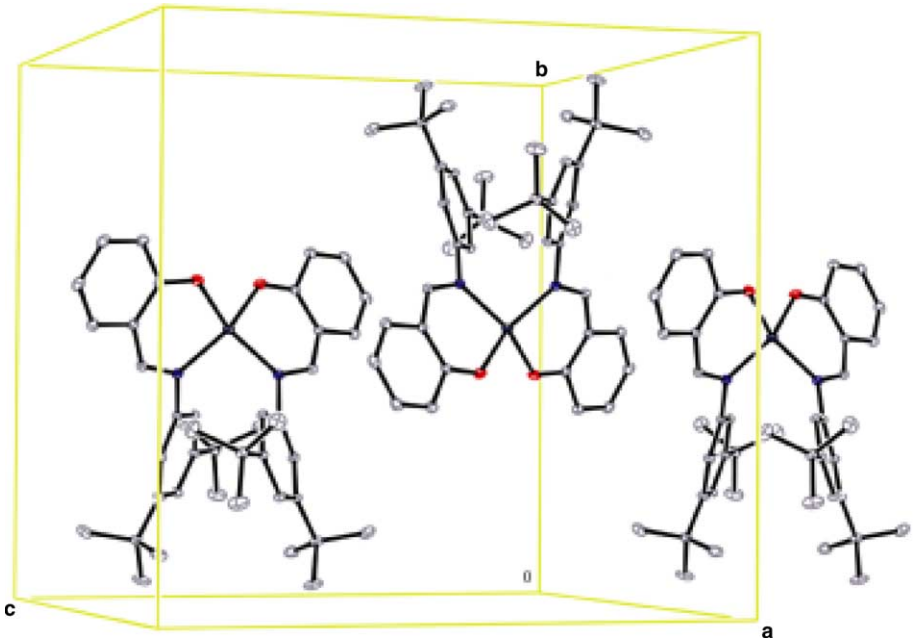

Fig. 2. View of the packing in **1** along the *a*-axis showing the possible π···π and C–H···π contacts at 10% probability displacement ellipsoids.

cules are oriented nearly parallel to each other as shown in Fig. 2. Although the centroids of the two di-tertbutylphenyl rings are indeed too far apart for any π–π interactions [the distances between the centroids of the aromatic rings of the neighboring SA molecules are 4.791(2) and 4.568(2) Å, a distances that are longer than the sum of the van der Vaals radii of two carbon atoms (3.4–3.6 Å)], the rings are not parallel, and C8···C9′ and C9···C8′ are only 3.413(3) Å, indicating quite strong interactions between these two carbons in both rings [11]. The Cu–Cu distance between the neighboring complexes units is so large (8.392 Å) that intermolecular interaction can be excluded. The copper center in **1** is in a distorted square planar environment with O1–Cu1–N1^{i}, N1–Cu1–N1^{i}, and O1–Cu1–O1^{i} (symmetry code: (i) x, y, $-z+0.5$), angles of 152.81(8)°, 97.13(9)° and 87.70(10)°, respectively. The dihedral angles between two phenyl rings and between the two salicylidene benzene rings are 27.40(9)° and 28.49(8)°, respectively. The Cu1–N1 and Cu1–O1 bond distances of 1.9706(16) and 1.8850(16) Å, respectively, agree well with the corresponding distances founded in bis(*N*-phenyl-SA)copper(II) [Cu1–N1 (1.99) and Cu1–O1 (1.88) Å [6a], bis(*N*-*p*-methylphenyl-SA)copper(II) [Cu1–N1 1.965 (3) and Cu1–O1 1.895(2) Å] [13b] and bis[*N*-*p*-$(CH_3)_2$N-phenyl-SA]copper(II) [Cu–N 1.996 (6) and Cu–O 1.885(5) Å] [6b] and in many *N*-alkyl substituted bis-SA and bis-naphthaldimine–Cu^{II} complexes [13,15,16]. Surprisingly, although, the present complex **1** differs from bis(*N*-3, 5-Bu$^{t}_{2}$-4-OCH_3-phenyl-SA)Cu^{II} (**II**) complexes [4c] only with the absence of a OCH_3 group in the 4-position of aniline ring of **1**, the latter complex has practically undistorted a *trans*-N_2O_2 square-planar geometry around Cu(II) center with Cu1–N1 and Cu1–O1 distances of 2.029 and 1.900 Å, respectively [4c]. From a chemical point of view the most significant aspect of the present structure is that it demonstrates the possibility coordination of the bidentate *N*-aryl-SA ligands to copper atom in the sterically unfavorable a *cis*-N_2O_2 arrangement configuration. The reasons that the *cis*-configuration is preferred for complex **1** are not clear.

3.2. IR, ^{1}H NMR and ^{13}C NMR spectra

In the IR spectra of the ligands along with characteristic bands in the 1619–1626 and 2550–2800 cm^{-1} regions (Section 2.2) due to ν(C=N) and intramolecularly H-bonded ν(OH), respectively, a strong narrow peak at 3452 cm^{-1} in $\mathbf{L_4H}$ and a broad strong peak at 3259 cm^{-1} in $\mathbf{L_5H}$ attributed to ν(OH) stretching of 3-OH group and intermolecularly H-bonded 4-OH, respectively, were observed.

In the spectra of **X** complexes the ν(C=N) band of the ligands undergoes small shift to lower frequencies (1598–1616 cm^{-1}), indicating that the ligands are coordinated through the imine nitrogen atoms. The disappearance of the broad band at 2600–2800 cm^{-1} and the appearance of new medium intensity bands in the region 450–600 and a strong band centered at 1523–1552 cm^{-1} which appeared only in the spectra of **X** can be assigned to ν_{Cu-N}, ν_{Cu-O} and $\nu_{C=C}$ (Table 1), respectively, as described in similar complexes [14]. The medium intensity bands detected at 3488 and 3438 cm^{-1} in the spectra of **2** and **3**, respectively, assigned to ν_{OH} of lattice water molecules.

The ^{1}H NMR and ^{13}C NMR spectral results obtained for $\mathbf{L}_x\mathbf{H}$ ligands in $CDCl_3$, with their assignments are given in Section 2. ^{1}H NMR signals were assigned on the basis of their integral intensity, spin–spin coupling patterns and chemical shift values.

3.3. Electronic spectra

Electronic spectral data of the $\mathbf{L}_x\mathbf{H}$ ligands in EtOH solution are presented in the Experimental Section. The electronic spectra of **X** in $CHCl_3$ solutions (Table 1) along with intraligand absorptions originated from $\pi \rightarrow \pi^*$ and $n \rightarrow \pi^*$ transitions also exhibited three visible bands at 400–450, 500(sh) and 660–710 nm which are assigned to the following transitions in order of decreasing energy the MLCT transition (CT band from filled d_π orbitals of Cu^{II} to the antibonding π^* orbitals of phenoate), $d_{xy} \rightarrow d_{x^2-y^2}$, and $d_{z^2} \rightarrow d_{x^2-y^2}$, respectively, in a distorted square planar geometry around copper(II) ion [17,18a].

3.4. EPR and magnetic properties

The room temperature effective magnetic moments of **1**, **5**, and **6** (1.73, 1.76 and 1.70μ_B) (Table 4) are close to the spin only value of 1.73μ_B expected for $3d^9$ systems. The similar magnetic behaviors are noticed in the magnetically dilute systems; therefore this indicates the absence of any coupling in the solid state [18a]. Indeed, our present X-ray study revealed that the nearest Cu···Cu distance in **1** is 8.386 Å. The complexes **2**, **4** and **3** exhibit magnetic moments (1.83 and 1.97μ_B) typical for square planar or pseudo-tetrahedral mononuclear copper(II) complexes with a $S = 1/2$ spin state [19,20].

The spin Hamiltonian parameters of **X** complexes is listed in Table 4. The EPR spectra of powder of all **X** at 300 and 113 K exhibit an axial signal with copper-hyperfine splitting with $g_\parallel > g_\perp > g_e$ pattern typical for a slightly distorted square planar or square planar geometries with a $d_{x^2-y^2}$ ground state [18]. Selected spectra are shown in Fig. 3. Spectral features for **1**, **4**, **5**, were significantly different from those for **2**, **3** and **6** for which in $g_\parallel$ region two [($A_\parallel = 172$ G (for **2**), 164 G (for **3**)] and three components ($A_\parallel = 119$ for **6**) of the four parallel copper hyperfine features were resolved (Fig. 3). When EPR spectra of **2**, **3** and **5** were scanned from 293 to 113 K without any changes in the line widths and *g*-factors, the linearly increasing in intensity of the high field doublet spectrum which follows the Curie law ($I = C/T$) were detected. The similar behavior is consistent with $J > 0$ (ferromagnetic coupling) or $J = 0$ [21].

The solution EPR spectra except **5** of all **X** in $CHCl_3$ at 300 K display the expected typical 4-line pattern from coupling to nuclei of ^{65}Cu ($I = 3/2$) isotopes, without ^{14}N-shfs resolutions on the high-field $m_I = 3/2$ line component. Complex **4** displays a five-line superhyperfine structure on high field copper component with $A^N_{iso} = 8.8$ G due to coupling with two ^{14}N ($I = 1$) nuclei. The resonances show m_I dependent line widths with the high field line being narrower and more intense than the low field line. According to spectral parameters obtained from frozen glass spectra of **X** (Table 4) at 133 K the complexes exhibit axial symmetry feature with $g_\parallel > g_\perp > 2.03$ indicating a $d_{x^2-y^2}$ or d_{xy} ground state in a tetragonal copper centers [18b]. The quotient $g_\parallel/A_\parallel$ value of 146–167 cm for **X**, lying between 140 and 250 cm again indicates a slightly distorted environment for Cu(II) centers [22]. It is interesting that according to $g_\parallel/A_\parallel$ value (Table 4) complex **1** prepared from unsubstituted salicylaldehyde exhibits significantly more tetrahedral distortion than **6** prepared from sterically bulky 3,5-Bu^t_2salicylaldehyde. Another interesting feature consist of significant difference between $g_\parallel/A_\parallel$ ratio for **6** determined from its powdered spectrum (192 cm) and frozen glass spectrum (146 cm), indicating changes its geometry from strongly distorted tetrahedral to a slightly distorted planar in solution.

3.5. Reduction of X complexes with PPh_3

In our early works, it has been demonstrated that some copper(II) complexes with salicylaldimine, 2-hydroxybenzylamine and β-ketoamine ligands bearing sterically hindered 2,6-di-*tert*-butylphenyl fragment unlike their unhindered analogs, undergo one-electron transfer reactions in the interactions with triarylphosphines giving corresponding metal-stabilized radical intermediates [5a,5b,5c,5d,5e]. When some copper(II) bis-chelates with *N*-2,5-di-Bu^t_2pheny-R-sal, structural isomers of the present complexes, was treated with a 2–3-fold excess of PPh_3 in various solvents the decreasing of the intensity of copper EPR signals and immediate appearance of radical signals with $g = 2.005$–2.0082 for R = 3-OH, 3-OCH_3, and 5-OH complexes were detected [23]. At the same time, no reduction process were observed for similar **II** complexes even in the interaction with 10-fold excess of PPh_3. Similar treat-

[a] A_{iso}, $A_\parallel$ and $A_\perp$ values are given in units of G (Gauss).

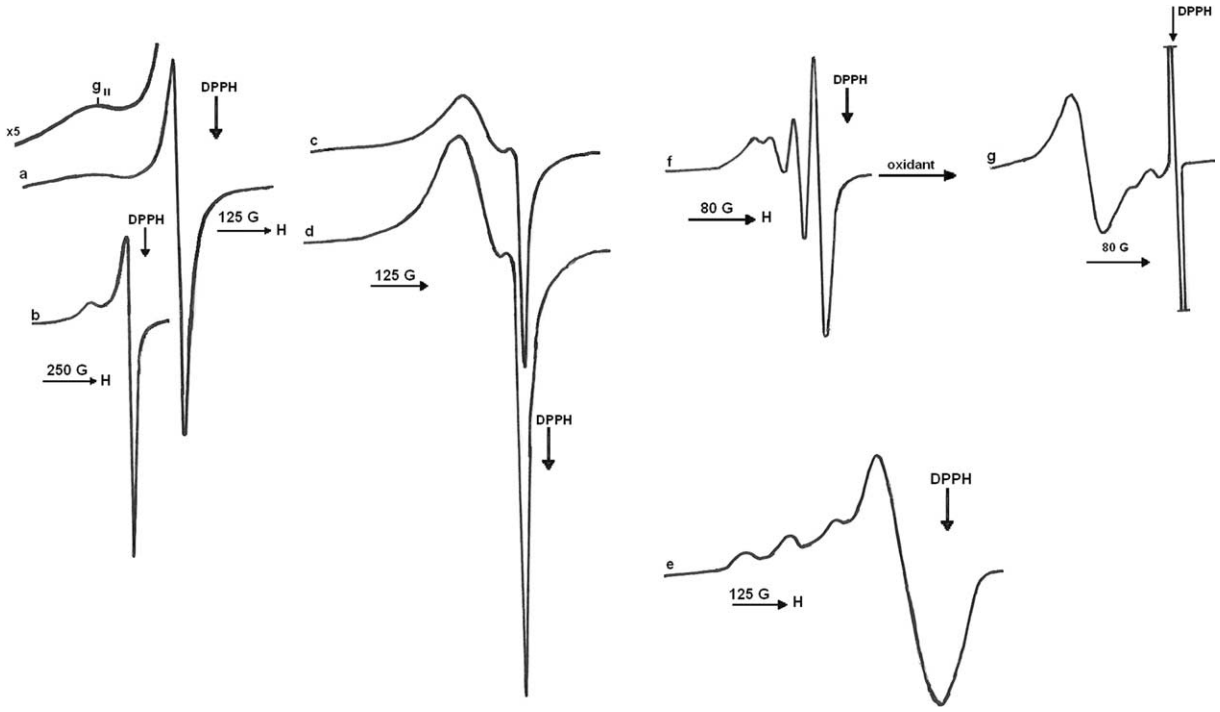

Fig. 3. ESR spectra of some **X** complexes: microcrystalline solids (a) **1** and (b) **5** at r.t., (c) powdered solid **4** at 293 K and (d) at 113 K; (e) powdered **6** at 293 K; (f) solution spectrum **6** in $CHCl_3$ and (g) oxidized **6** at r.t. under identical scanning conditions.

ment of the present **X** complexes revealed that upon addition of 3–4-fold excess of PPh_3 to $CHCl_3$ solution of **1**, **2, 4** and **6** complexes at r.t., during 3–6 h their black color changed to orange-yellow and their absorption peaks within the range of 450–700 nm were disappeared. Under similar conditions the dark brown color of **3**, during even 3 days has not changed practically [(340, 390(sh), 420(sh). 500(sh) and 670 nm(sh) (**3** + PPh_3)]. In the EPR monitoring of **X** + PPh_3 (**X** = **1**, **2**, **4**, **6**) systems during reaction process in air or in vacuum only slowly decreasing in the intensity of their spectra without appearance of any radical signals were detected.

3.6. Chemical oxidation of the complexes

Our recent studies demonstrated that in the chemical oxidation of bis[*N*-alkyl(aryl)-3, 5-Bu^t_2sal]copper(II) complexes with one-electron oxidant $(NH_4)_2[Ce(NO_3)_6]$ (CAN) in $CHCl_3$, along with decreasing of the Cu(II) signal intensity, the generation of directly coordinated phenoxyl radical complexes are also detected [23]. The present investigation of the oxidative behavior of **X** complexes at r.t. and in air conditions, revealed that when they are treated with of three to 5-fold excess amount of CAN along with color change from black or dark brown to light brown or light yellow, the disappearance of the EPR spectra of **X** and appearance new broad lines (peak-to-peak about $\Delta H = 92$–108 G) at $g = 2.169$–2.189 were detected. For complexes **5** and **6** besides broad singlets at 2.169 and 2.189 the strong radical signals at $g = 2.0055$ and $g = 2.0052$ were observed (Figs. 3(f) and (g)). The decreasing of the signal intensity of **X** + CAN system suggest that one-electron oxidation results in the generation of a Cu^{II}-phenoxyl radical complex and there is antiferromagnetic coupling between an $S = 1/2 Cu^{II}$ and an $S = 1/2$ phenoxyl radical. We suggest that the detected radical signals more probably originate from $Cu(L^{\bullet}_x)_2$ type diradical species in which one radical center is fully antiferromagnetically coupled with Cu(II).

The spectral changes for **X** + CAN systems were also monitored by UV–Vis spectroscopy during the progress of the oxidation of **X** complexes with ACN in $CHCl_3$. Since the oxidant is insoluble in $CHCl_3$ the reaction system was heterogeneous. However, the solution **X** + CAN system was mixed using a spatula for 5–6 s prior to each scanning. When three to five excess of CAN was added to the solution of **X** in $CHCl_3$ at r.t., the black solution turns to brown or light yellow with the disappearance of the original bands of visible bands at 450–700 nm.

3.7. Electrochemistry

Electrochemical properties of the complexes **X** except **5** due to its poor solubility were studied on a Pt disc electrode in dimethylsulfoxide containing 0.05 M *n*-Bu_4NClO_4 as the supporting electrolyte. Table 5 summarizes the electrode potentials for all complexes in dimethylsulfoxide. A cyclic voltammogram of **1** is given in Fig. 4. This complex displays a reduction peak at $E^1_{pc} = 0.14$ V with a corresponding oxidation peak at $E^1_{pa} = 0.26$ V. The peak separation of

Supporting electrolyte = 0.05 M n-Bu_4NClO_4, scan rate = 100 mV/s.
Potentials are presented in volts.

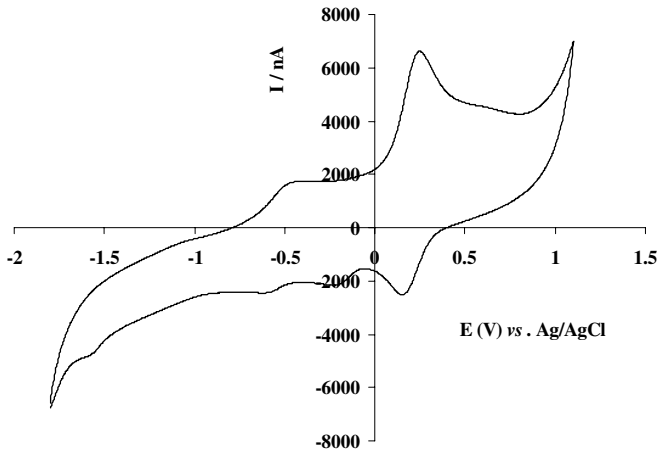

Fig. 4. A cyclic voltammogram of **1** in dimethylsulfoxide containing 0.05 M n-Bu_4NClO_4 as supporting electrolyte. Scan rate = 100 mV/s.

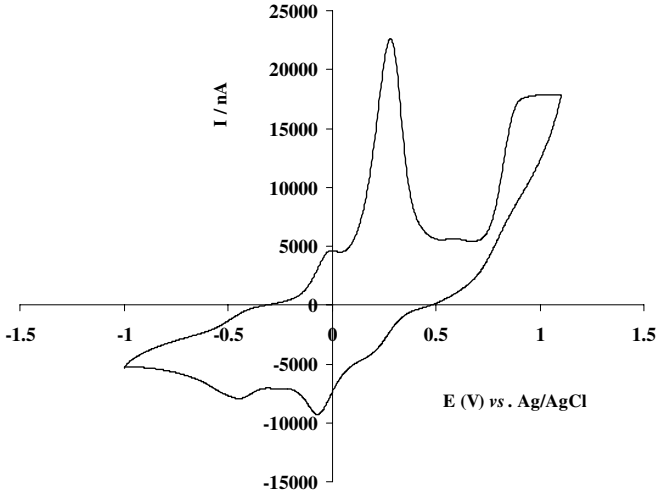

Fig. 5. A cyclic voltammogram of **4** in dimethylsulfoxide containing 0.05 M n-Bu_4NClO_4 as supporting electrolyte. Scan rate = 100 mV/s.

this couple (ΔE_p) is 0.12 V at 0.1 V/s and increases with scan rate. The most significant feature of this redox couple is the 1e-transfer electrochemical process of the formation of Cu(II)/Cu(I). The difference between forward and backward peak potentials can provide a rough evaluation of the degree of the reversibility of one electron transfer reaction. The analysis of cyclic voltammetric responses with the scan rate varying 50–300 mV/s gives the evidence for a quasi-reversible one electron oxidation. The ratio of cathodic to anodic peak height was less than one. However, the peak current increases with the increase of the square root of the scan rate. The $I_p/v^{1/2}$ value is almost constant for all scan rates. This establishes the electrode process as diffusion controlled [24]. The separation in peak potentials increases at higher scan rates. These characteristic features are consistent with the quasi-reversibility of Cu(II)/Cu(I) couple. The other oxidation or reduction peaks are listed in the Table 5 and are probably due to the ligand moiety of complex. The electrode potentials of the rest of the copper(II) complexes are given in Table 5.

A cyclic voltammogram of the complex **4** is given in Fig. 5. The complex **4** exhibits a reduction peak at $E^1_{pc} = 0.21$ V with a directly re-oxidation peak at $E^1_{pa} = 0.29$ V corresponding to the formation of Cu(II)/Cu(I) couple. The peak separation of this couple (ΔE_p) is 0.08 V. This redox couple also have quasi-reversible character as the separation in peak potentials are higher than 59 mV and the peak currents rises with increasing $v^{1/2}$. Diagnostic test for the complex **4** indicated that the electrode process is controlled by diffusion. The separation in peak potentails (ΔE_p) for complexes are in order **4** < **3** < **2** < **1** < **6**. The difference between forward and backward peak potentials can provide a rough evaluation of the degree of the reversibility. This shows that the electrochemical process of complex **4** is faster than that of the other complexes. This behavior may suggest that in complex **4**, both the Cu(II) and Cu(I) forms appear in a similar geometrical configuration, so the electron transfer does not require larger reorganization of the complex coordination geometry.

In conclusion, the present work indicates that a small changes of the substituents on the ligands of the bis(N-3, 5-Bu^t_2phenyl-R-sal)copper(II) type complexes results in striking changes both in the molecular structure of the complexes and their chemical redox reactivity. Surprisingly, in complex **1** with R = H unlike its structurally characterized bis(N-aryl(alkyl)-sal) analogs copper center exhibits a tetrahedrally distorted *cis*-N_2O_2 square planar geometry. Chemical oxidation of some complexes leads to the formation of the coordinated Cu(II)-phenoxyl radical complexes. As supported by EPR and electronic spectral studies their reduction with PPh_3 proceeded slowly without generation any radical species. The electrochemical measurements have indicated that complexes showed quasi-reversible 1e-electron transfer reduction to Cu(I) along with the reduction and oxidation of the ligand moiety of the complexes. The results also indicated that **4** has the highest

electrochemical rate assuming that the both couples have similar geometrical configuration, so the electron transfer does not require larger reorganization of the complex.

4. Supplementary data

Crystallographic data (excluding structure factors) for the structure in this paper have been deposited with the Cambridge Crystallographic Data Centre as the Supplementary Publication No. CCDC 253758. Copies of the data can be obtained, free of charge, on application to CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK, fax: +44 1223 366 033, e-mail: deposit@ccdc.ac.uk or on the web www: http://www.ccdc.cam.ac.uk.

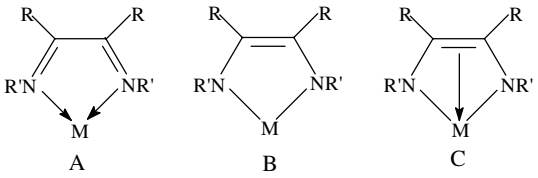

Fig. 1. Coordination modes of diazadiene ligands.

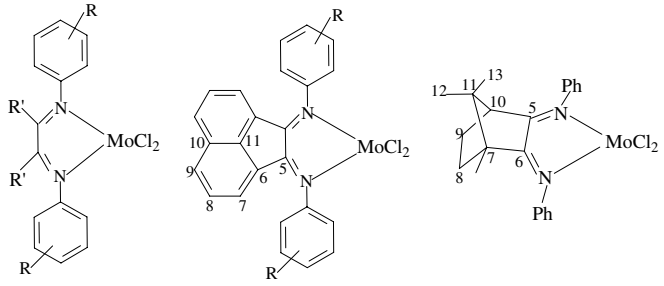
the use of sodium as the reducing agent and their octahedral geometry. These other derivatives of $MoCl_2$, however, were not structurally characterized and no details of their stereochemistry were evident from the spectroscopic studies. Therefore, an alternative synthetic methods of new diazadiene molybdenum complexes were explored.

Molybdenum complexes [**3ai**, **3bi**, **3c**] (Scheme 1) crystallize as green crystals for **3ai**, **3c**, and orange brown for **3bi** from CH_2Cl_2/*n*-hexane. All these compounds are soluble in methylene chlorid, dimethylsulfoxid, acetone and acetonitrile. They are air-sensitive and non-soluble in unpolar solvents. These compounds have been characterised by ^1H, ^{13}C NMR and IR spectroscopy.



Scheme 1.

The new complexes (dad)$MoCl_2$, exhibit spectroscopic data in accord with the proposed structure.

The NMR properties unambiguously establish the diamagnetic nature of these compounds. In fact the substituent on the aryl groups of the dad ligand are all equivalent as expected for the C_{2v}-symmetric isomer. Chemical shifts of the R′N=C(R)–C(R)=NR′ subunit in the complexes [**3ai**, **3bi**, **3c**] are slightly shielded in comparison to those of the free ligands similar to other complexes [21]. The C=N carbon appears between 163 and 179 ppm.

In the IR spectra of the complexes (as KBr pellets), the C=N stretching vibration is observed at 1601–1640 cm^{-1}, i.e., shifted by 10–20 cm^{-1} to lower frequency as compared to the free ligands.

Single crystal of **3a2** was grown from a mixture of $CH_2Cl_2$and hexane solution at room temperature.

The Ortep diagram of **3a2** is shown in Fig. 2, with details of the structure determination, including unit-cell data, summarized in Table 1 and relevant bond distances and bond angles in Table 2.

The structural analysis confirms the identity of the molecule. The coordination sphere of the molybdenum center is composed of the two nitrogen atoms of the chelating diazadiene ligand and the two dichloride atoms. The coordination geometry of the molybdenum atom can be described as slightly distorted tetrahedral. This distortion is explained by the 78.17(19)° bite angle measured for the bidentate diazadiene ligand [N2–Mo–N1]. This angle are similar to the value of 72.6(3)° measured for [$W(CO)_3$(dad: R = H; R′ = *i*-Pr)(η^2-eco)] {eco = (*E*)-cyclooctene} [22].

The Mo–N distances are considerably shorter than in the structurally related complex [MoO_2Cl_2(dad: R = H; R′ = *t*-Bu)] [2.399(2) and 2.388(2) Å] [23].

The ligand and metal in this structure are essentially coplanar consistent with the π-backbonding of this ligand. The N1–C19, N2–C20 and C19–C20 bond distances of 1.267(8), 1.258(8) and 1.523(9) Å, respectively, confirm the conjugated diimine nature of this ligand and with those

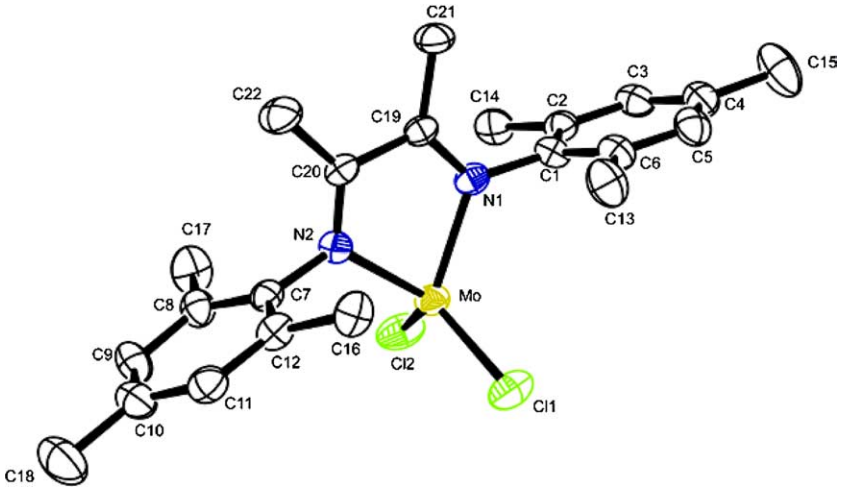


Fig. 2. ORTEP diagram of **3a2** · CH_2Cl_2. Thermal ellipsoids are at 50% probability. Hydrogen are omitted for clarity.

of complexes to with the bonding mode A can be clearly assigned (N–C: 1.26–1.30 Å; C–C: 1.40–1.55 Å) [1]. These distances are similar to those observed in $Mo(CO)_4$(dad) complex [24].

The metal-chelate ring (Mo–N2–C20–C19–N1) in complex (**3a2**) is almost flat as indicated by the torsion angles of −1.96 (0.87)°, 5.21 (0.71)° and −2.40(0.71)° for N2–C20–C19–N1, Mo–N1–C19–C20 and Mo–N2–C20–C19, respectively, which are very closer for other platinum (II) complexes [25].

Table 2
Selected interatomic distances and angles for [2,4,6-Me_3-dad]$MoCl_2$ (**3a2**)

Bond distances (Å)		Bond angles (°)	
Mo–N1	2.089(5)	N1–Mo–N2	78.17(19)

		N1–C19–C20	116.5(5)

The o-methylphenyl groups makes an angle of approximately 90° to the plane of the C=N bonds, due to the presence of the o-methyl substituents as appears from the torsion angles of 93.64 (0.79)°, −88.83 (0.76)°, 85.51 (0.84)° and −92.75 (0.79)° for C20–N2–C7–C8, C20–N2–C7–C12, C19–N1–C1–C6 and C19–N1–C1–C2, respectively.

In conclusion, we have described a convenient synthetic procedure for the preparation of the new diazadiene molybdenum (II) complexes. The application of these complexes in catalytic reactions such as oligomerization and polymerisation of alkenes (ethylene, propylene) and functional alkenes (methylacrylate) is in progress.

3. Experimental

All manipulations are carried out under an atmosphere of dry and oxygen-free argon with standard schlenck techniques. Diethylether was purified by reflux over sodium benzophenone ketyl and distilled under argon prior to use. Methylene chloride and *n*-hexane were purified from P_2O_5 and distilled under argon.

The diazadiene ligands: dab [26], Ar-BIAN, Ph-BIC [27]; $MoCl_4(thf)_2$ [19] were obtained according to the literature procedures.

All routine NMR experiments were carried out on a Bruker AM 300 and infrared spectra on a Bio-Rad FTS-6000 spectrophotometer.

3.1. General procedure for the preparation of [dad]$MoCl_2$

In an inert atmosphere, $MoCl_4(thf)_2$ (1 equiv.) was added to diazadiene ligand (3 equiv.) in 20 ml of anhydrous CH_2Cl_2. Zinc was added (5 equiv.) as a reducing agent. The solution was stirred at room temperature for two days. The supernatant was separated by filtration, and the solvent was removed under vacuum until 3 ml. Addition of hexane precipitate the product. Pure compound was isolated as a solid by crystallization from methylene chloride/hexane solution at −30 °C. Yields ranged from 52% to 83%.

3.2. [2,4,6-$(CH_3)_3$-$C_6H_2NC(H)C(H)NC_6H_2$-2,4,6-$(CH_3)_3$]$MoCl_2$ (**3a1**)

Following general procedure, from $MoCl_4(thf)_2$ (0.57 mmol, 0.22 g), [2,4,6-$(CH_3)_3$-$C_6H_2NC(H)C(H)$-NC_6H_2-2,4,6-$(CH_3)_3$] (1.7 mmol, 0.505 g). Zinc (2.85 mmol, 0.186 g) in 20 ml of methylene chloride was obtained 0.178g (yield 68%) of **3a1** as a green solid after crystallization from a mixture *n*-hexane/CH_2Cl_2 (8/2). Decomposition = 310 °C; IR ($\nu_{C=N}$ = 1615 cm^{-1}).

^{1}H NMR (300 MHz, $CDCl_3$, 25 °C, δ [ppm]): δ = 2.30 (s, 12H, *ortho*,*ortho*′-CH_3), 2.49 (6H; *para*-CH_3); 6.936 (s, 4H, Har); 8.76 (1, 2H, H–C=N).

^{13}C NMR (75.5 MHz, $CDCl_3$, 25 °C, δ [ppm]): $\delta = 19.5$ (*ortho*-CH_3); 21.5 (*para*-CH_3); 130.75 (C_{ortho}); 132 (C_{meta}); 137, 75 (C_{para}); 144 (C_{ipso}); 176.5 (C=N).

3.3. [2,4,6-$(CH_3)_3$-$C_6H_2NC(Me)C(Me)NC_6H_2$-2,4,6-$(CH_3)_3$]$MoCl_2$ (**3a2**)

Following general procedure, from $MoCl_4(thf)_2$ (0.44 mmol, 0.17 g), [2,4,6-$(CH_3)_3$-$C_6H_2NC(Me)C(Me)$-NC_6H_2-2,4,6-$(CH_3)_3$] (1.3 mmol, 0.427 g). Zinc (2.2 mmol, 0.143 g) in 20 ml of methylene chloride was obtained 0.178g (yield 83%) of **3a2** as a green solid after crystallization from a mixture *n*-hexane/CH_2Cl_2 (8/2). Decomposition = 367 °C; IR ($\nu_{C=N} = 1650$; 1607 cm^{-1}).

^{1}H NMR (300 MHz, CD_3CN, 25 °C, δ [ppm]): $\delta = 2.26$–2.36 (m, 24H, *ortho*,*ortho'*,*para*-$CH_3 + CH_3$–C=N); 7.09 (s, 4H, Har).

^{13}C NMR (75.5 MHz, CD_3CN, 25 °C, δ [ppm]): $\delta = 17.38$ (CH_3–C=N); 18.20 (*ortho*,*ortho'*-CH_3); 19.35 (*para*-CH_3); 128.43 (C_{ortho}); 129.29 (C_{meta}); 136.91 (C_{para}); 139.79(C_{ipso}); 172.16 (C=N).

3.4. [2,6-*i*-Pr_2-$C_6H_3NC(Me)C(Me)NC_6H_3$-2,6-*i*-Pr_2]$MoCl_2$ (**3a3**)

Following general procedure, from $MoCl_4(thf)_2$ (0.6 mmol, 0.23 g), [2,6-*i*-Pr_2-$C_6H_3NC(Me)C(Me)NC_6H_3$-2,6-*i*-Pr_2] (1.8 mmol, 0.731 g). Zinc (3 mmol, 0.196 g) in 20 ml of methylene chloride was obtained 0.260g (yield 67%) of **3a3** as a brown solid after crystallization from a mixture *n*-hexane/CH_2Cl_2 (9/1). Decomposition = 355 °C; IR ($\nu_{C=N} = 1654$; 1607 cm^{-1}).

^{1}H NMR (300 MHz, DMSO-d, 25 °C, δ [ppm]): $\delta = 1.16$–1.08 (m, 24H, Me); 1.98 (s, 6H, CH_3–C=N); 2.50 (sept, 4H, CH–*i*-Pr); 7.18–6.85 (m, 6H, Har).

^{13}C NMR (75.5 MHz, DMSO-d, 25 °C, δ [ppm]): $\delta = 16.63$ (CH_3–C=N); 23, 18, 23, 56 (CH_3–*i*-Pr); 27.99 (CH–*i*-Pr); 122.50 (C_{meta}); 124.15 (C_{para}); 134.76 (C_{ortho}, $C_{ortho'}$); 145.99 (C_{ipso}); 168.23 (C=N).

3.5. [2,6-*i*-Pr_2-C_6H_3-acenaphtene]$MoCl_2$: 3b1 {Ar-BIAN, Ar = 2,6-*i*-Pr_2-C_6H_3}

Following general procedure, from $MoCl_4(thf)_2$ (0.54 mmol, 0.21 g), [2,6-*i*-Pr_2-acenaphtene] (1.6 mmol, 0.785 g). Zinc (2.7 mmol, 0.176 g) in 20 ml of methylene chloride was obtained 0.262g (yield 75%) of **3b1** as orange brown solid after crystallization from a mixture *n*-hexane/CH_2Cl_2 (9/1). Decomposition = 375 °C; IR ($\nu_{C=N} = 1640$; 1601 cm^{-1}).

^{1}H NMR (300 MHz, $CDCl_3$, 25 °C, δ [ppm]): $\delta = 0.82$ (d, 12H, CH_3–*i*-Pr); 1.32 (d, 12H, CH_3–*i*-Pr); 3.26 (sept, 4H, CH–*i*-Pr); 6.65 (d, 2H; H_7); 7.55–7.3 (m, 6H, $H_{meta,meta',para}$); 8.101 (d, 2H, H_9)

^{13}C NMR (75.5 MHz, $CDCl_3$, 25 °C, δ [ppm]): $\delta =$ 24.802 (Me-*i*-Pr); 29.34 (CH–*i*-Pr); 125.43 (C_7); 126.02 (C_{meta}); 127.39 (C_{para}); 128.69 (C_8); 129.27(C_9); 131.44 (C_6); 133.12 (C_{10}); 139.87 (C_{ortho}); 140.70 (C_{11}); 145.06 (C_{ipso}); 165.63 (C=N).

3.6. [o-Me-C_6H_4-acenaphtene]$MoCl_2$ (**3b2**) {Ar-BIAN, Ar = o-Me-C_6H_4}

Following general procedure, from $MoCl_4(thf)_2$ (0.39 mmol, 0.15 g), [*o*-Me-acenaphtene] (1.1 mmol, 0.424 g). Zinc (1.95 mmol, 0.127 g) in 20 ml of methylene chloride was obtained 0.178g (yield 86%) of **3b2** as orange solid after crystallization from a mixture *n*-hexane/CH_2Cl_2 (9/1). Decomposition = 336 °C; IR ($\nu_{C=N} = 1631$, 1591 cm^{-1}).

^{1}H NMR (300 MHz, DMSO-d, 25 °C, δ [ppm]): $\delta =$ 2.18 (s, 6H, CH_3); 6.83 (d, 2H, H_7); 6.92 (d, 2H, $H_{ar\,meta}$) 7.92–7.05 (m, 10H, $6H_{ar\,9,10,11}$ and $4H_{8,9}$).

^{13}C NMR (75.5 MHz, DMSO-d, 25 °C, δ [ppm]): $\delta = 17.15$ (MeC=N); 119.75 (C_{ortho}); 120.01 (C_7); 124.55 (C_{para}); 125.43 (C_{ortho}); 126.89 (C_{meta}), 127.36 (C_8), 128,37 (C_9); 130.27 (C_{10}); 130.96 ($C_{meta'}$): 131.98 (C_6); 142.69(C_{11}); 144.30 (C_{ipso}); 163.23 (C=N).

3.7. [(Ph-Bic)]$MoCl_2$ (**3c**)

Following general procedure, from $MoCl_4(thf)_2$ (0.7 mmol, 0.28 g), [(Ph-BIC)] (2.1 mmol, 0.694 g). Zinc (3.5 mmol, 0.228 g) in 20 ml of methylene chloride was obtained 0.165g (yield 52%) of **3c** as green solid after crystallization from a mixture *n*-hexane/CH_2Cl_2 (9/1). Decomposition = 318°C; IR ($\nu_{C=N} = 1675$; 1631; 1595 cm^{-1}).

^{1}H NMR (300 MHz, acetone-d, 25 °C, δ [ppm]): $\delta = 0.68$; 0.86; 0.98 (s, 3H chacun, $H_{12,13,14}$); 1.55–1.179 (m, 4H, $H_{8,9}$); 3.15 (d, 1H, H_{10}); 7.18–7.40 (m, 10H, Har).

^{13}C NMR (75.5 MHz, acetone-d, 25 °C, δ [ppm]): $\delta = 11.37$; 17.02; 21.20 ($C_{12,13,14}$); 23, 86, 32, 69 ($C_{8,9}$); 49, 11 (C_7); 49.97 (C_{10}); 56.04 (C_{11}); 121.54, 123.14 (C_{ortho}); 127.76 (C_{para}); 129.06, 129.78 (C_{meta}); 174.13; 176.10 (C=N).

4. X-ray structure determination

A crystal ($0.11 \times 0.31 \times 0.64$ mm) suitable for X-ray intensity data collection was selected. X-ray intensity data were collected on a MACH3 Enraf Nonius diffractometer using monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at 293 K. Accurate unit cell parameters and orientation matrix were determined from 25 reflections in the range 13–15°. Intensity data were collected by using the ω–2θ scan mode with a range of $2 < \theta < 27°$. All the intensity data were corrected for Lorentz and polarization effects. The crystal structure solution carried out with direct methods from the SHELXS-97 permitted the location of all non-hydrogen atoms. After anisotropic least-squares refinement, hydrogen atoms were placed at their geometrically calculated positions and refined riding on the corresponding atoms with isotropic thermal parameters. Final refinement based on the reflections [$I > 2\sigma(I)$] converged at $R_1 = 0.0808$, $wR_2 = 0.2265$ and goodness-of-fit = 0.996.

The experimental conditions of data collection, strategy followed for the structure determination, and final results are given in Table 1.

5. Supporting information

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 268891. Copies of this information may be obtained free of charge from the Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK; fax: +44 1223 336 033 or deposit@ccdc.cam.ac.uk.

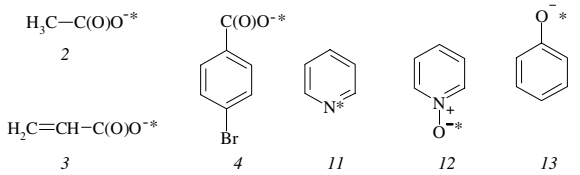
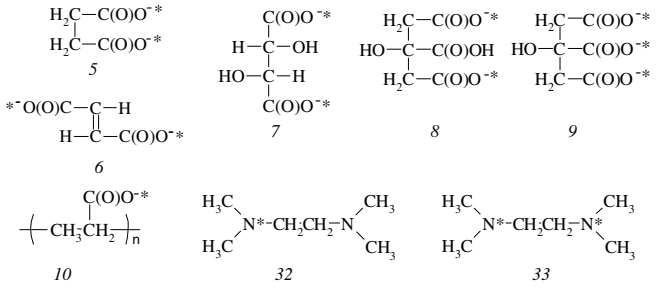
Table 1
Ligands substituted for H_2O in $(CO)_3(dppe)Mn(OH_2)$ (* indicates atom(s) attached to Mn)

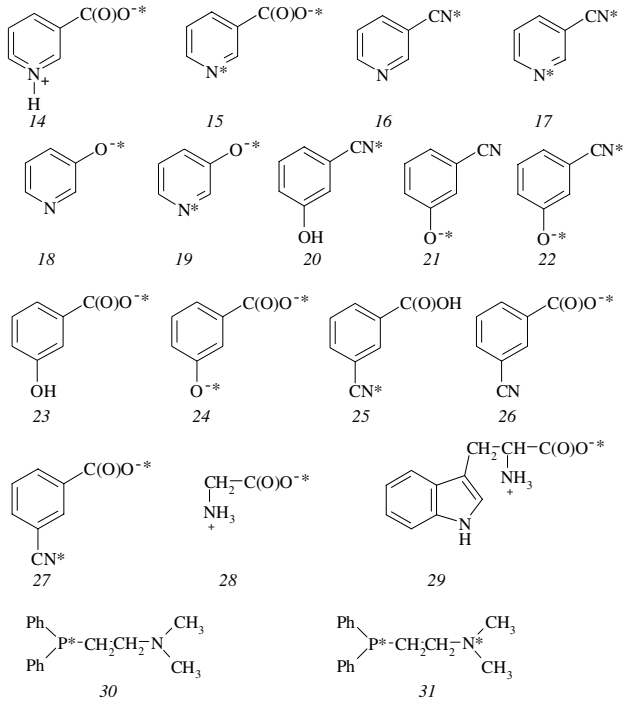
A. Monodentate ligands



B. Polydentate ligands



C. Ambident ligands



a magnetic stirrer and all involved the simple replacement of the aqua ligand of **1** by a new ligand. If the new ligand is neutral, it is used as a solution in $CHCl_3$, and if acidic, it is dissolved either in a few milliliters of water or in aqueous alkali. The general procedure was as follows: To a $CHCl_3$ solution of about 40–100 mg of **1** in about 20 mL $CHCl_3$, a solution of an equimolar quantity of the new ligand is added drop-wise. The order of addition is reversed when ambident ligands are used. After addition, stirring is continued for 10–20 min, the $CHCl_3$ solution is separated, washed with water, dried and evaporated. The resulting yellow to brown solids are thoroughly washed with hexane, dried in vacuo, collected and weighed. The yield of recovered product is 80–90%; the loss of material is incurred in handling the very small quantities involved. Only deviations form the general procedure are included in the experimental details. Our characterization of the new complexes, after ascertaining purity by TLC, relies very heavily on three techniques: high-resolution mass spectra (identification of the exact mass of the molecular ion and some significant daughter ions); close inspection of infrared spectra (carbonyl and nitrile stretching frequencies); and ^1H NMR spectra (particularly the chemical shifts of the dppe methylene protons). High-resolution mass spectra were obtained using a Kratos MS-25 high performance mass spectrometer fitted with an electrospray ionization (ESI) attachment. IR spectra were recorded on a P-E spectrum One FT-IR employing a 5-mm CaF_2 liquid cell. ^1H NMR data were obtained with $CDCl_3$ solutions using a Bruker AC-400 MHz spectrometer with the chemical shifts recorded relative to TMS $[Si(CH_3)_4]$. Ultimate analyses were not routinely determined, because, in addition to being less definitive for the characterization of pure compounds than exact mass spectra, such analyses are frequently unreliable and are further complicated by the tendency of many of these types of complexes to crystallize with non-integral molecules of solvent, which resist efforts to remove, and whose reported content must be adjusted in order to conform with results of ultimate analysis.

2.1. Reaction of *1* with monocarboxylic acids

2.1.1. Acetic acid complex, $[(CO)_3(dppe)MnOC(O)CH_3]$ (*2*)

Data ***2***: m.p.: softens at about 172 °C and decomposes above 178 °C; IR (cm^{-1}, $CHCl_3$): ν(CO) 2026, 1959 and 1910; ^1H NMR (δ, $CDCl_3$): 7.8–7.3 (m, 20H, Ph), 2.92 (m, 2H) and 2.74 (m, 2H) both from dppe, 2.18 (s, 3H, CH_3); High-resolution MS (m/z): 597.084, calc. for $[(CO)_3(dppe)MnOC(O)CH_3 + H]^+$, $C_{31}H_{28}O_5P_2Mn$, 597.079; 537.060, calc. for $[(CO)_3(dppe)Mn]^+$, $C_{29}H_{24}O_3P_2Mn$, 537.058.

The reversibility of the reaction was demonstrated by the following experiment. One drop of HBF_4 was added to the acetic acid complex **2**, dissolved in $CHCl_3$ and then stirred for 1 min. The IR of the solution showed the spectrum characteristic of the aqua complex **1**.

2.1.2. Acrylic acid complex, $[(CO)_3(dppe)MnOC(O)CH{=}CH_2]$ (*3*)

Data ***3***: m.p.: the color of the solid product changes from pale yellow at room temperature to white at 276–280 °C and decomposes at 372–378 °C; IR (cm^{-1}, $CHCl_3$): ν(CO) 2026, 1960 and 1911; ^1H NMR (δ, $CDCl_3$): 7.9–7.2 (m, 20H, Ph), 5.65 (t, 1H, CH), 4.97 (d, 2H, CH_2 attached to double bond), 2.91 (m, 2H), and 2.82 (m, 2H) both from

dppe; High-resolution MS (*m*/*z*): 609.0764, calc. for $[(CO)_3(dppe)MnOC(O)CH{=}CH_2 + H]^+$, $C_{32}H_{28}O_5P_2Mn$, 609.0792, 537.0335, calc. for $[(CO)_3(dppe)Mn]^+$, $C_{29}H_{24}O_3P_2Mn$, 537.058.

2.1.3. p-Bromobenzoic acid complex, [(CO)$_3$(dppe)MnOC(O)C$_6$H$_4$Br] (4)

The reaction was carried out using an aqueous solution of *p*-bromobenzoic acid.

Data **4**: m.p.: softens at about 192 °C and decomposes at above 225 °C; IR (cm^{-1}, $CHCl_3$): *v*(CO) 2027, 1959 and 1913; ^1H NMR (δ, $CDCl_3$): 7.9–7.2 (m, 24H, Ph), 2.99 (m, 2H) and 2.89 (m, 2H) both from dppe; High-resolution MS (*m*/*z*): 772.9814, calc. for $[(CO)_3(dppe)Mn{-}OC(O)C_6H_4Br\text{-}p + Cl]^-$, $C_{36}H_{28}O_5P_2BrClMn$, 772.9646 (Cl^- originated from the chloroform solvent used in the electrospray).

2.2. Reaction of 1 with dicarboxylic acids

Unless otherwise noted, aqueous solutions of the sodium salts of the acids were used.

2.2.1. Succinic acid complex, [(CO)$_3$(dppe)MnOC(O)CH$_2$CH$_2$C(O)OMn(dppe)(CO)$_3$] (5)

Data **5**: m.p.: softens at about 268 °C and decomposes above 298 °C; IR (cm^{-1}, $CHCl_3$): *v*(CO) 2025, 1958 and 1907; ^1H NMR (δ, $CDCl_3$): 7.9–7.2 (m, 40H, Ph), 2.86 (m, 4H, from dppe), 2.68 (m, 4H, from dppe), 2.52 (m, 2H, from succinic acid), 2.27 (m, 2H, from succinic acid); High-resolution MS (*m*/*z*): 1191.1299, calc. for $[(CO)_3(dppe)Mn{-}OC(O)CH_2CH_2C(O)O{-}Mn(dppe)(CO)_3 + H]^+$, $C_{62}H_{53}O_{10}P_4Mn_2$, 1191.135.

2.2.2. Fumaric acid complex, [(CO)$_3$(dppe)MnOC(O)CH=CHC(O)OMn(dppe)(CO)$_3$] (6)

Data **6**: m.p.: softens at about 145 °C and decomposes above 160 °C; IR (cm^{-1}, $CHCl_3$) *v*(CO) 2027, 1959 and 1914; ^1H NMR (δ, $CDCl_3$): 7.9–7.2 (m, 40H, Ph), 6.5 (s, 2H, from two CHs of fumaric acid moiety), 3.05 (m, 4H, from dppe), 2.84 (m, 4H, from dppe); High-resolution MS (*m*/*z*): 1189.200, calc. for $[(CO)_3(dppe)MnOC(O)CH{=}CHC(O)OMn(dppe)(CO)_3 + H]^+$, $C_{62}H_{51}O_{10}P_2Mn_2$, 1189.1188.

2.2.3. D-Tartaric acid complex, [(CO)$_3$(dppe)MnOC(O)(CHOH)$_2$C(O)OMn(dppe)(CO)$_3$] (7)

Data **7**: m.p.: softens at about 131 °C and decomposes above 154 °C; IR (cm^{-1}, $CHCl_3$) *v*(CO) 2029, 1962 and 1916; ^1H NMR (δ, $CDCl_3$): 7.9–7.2 (m, 40H, Ph), 2.95 (m, 4H, from dppe), 2.84 (m, 4H, from dppe); High-resolution MS (*m*/*z*): 1223.1241, calc. for $[(CO)_3(dppe)Mn{-}OC(O)(CHOH)_2C(O)O{-}Mn(dppe)(CO)_3 + H]^+$, $C_{62}H_{53}O_{12}P_2Mn_2$, 1223.1248.

2.3. Reaction of 1 with polycarboxylic acids

2.3.1. Preparation of citric acid complex, K^1(O),K^1(O)[(CO)$_3$(dppe)MnOC(O)CH$_2$–C(OH)(COOH)CH$_2$C(O)OMn(dppe)(CO)$_3$] (8)

8.2 mg (0.039 mM) of citric acid (99%, Aldrich) was suspended in a solution of **1** (75 mg, 0.117 mM) in 25 mL $CHCl_3$. After stirring for approximately 45 min, the solvent was removed by rotary evaporator. The residue was chromatographed on a column of neutral alumina gel with hexane and ethyl acetate as gradient eluents to give **8** as a yellow solid.

Data **8**: m.p.: softens at 205 °C and decomposes above 220 °C; IR (cm^{-1}, $CHCl_3$) *v*(CO) 2027, 1959 and 1916; ^1H NMR (δ, $CDCl_3$): 7.9–7.2 (m, 40H, Ph), 2.92 (m, 4H, from dppe), 2.72 (m, 4H, from dppe), 2.51 (s, 4H, CH_2); High-resolution MS (*m*/*z*): 1265.1896, calc. for $[(CO)_3(dppe)MnOC(O)CH_2C(OH)(COOH)CH_2C(O)OMn(dppe)(CO)_3 + H]^+$, $C_{64}H_{55}O_{13}P_4Mn_2$, 1265.19. *Anal.* Calc. for $C_{64}H_{54}O_{13}P_4Mn_2 \cdot 2H_2O \cdot C_6H_{14}$: C, 60.61; H, 5.23. Found: C, 59.34; H, 5.28% (NMR showed both water and hexane; the stoichiometry of the associated solvents is adjusted to conform with the hydrogen analysis). It is assumed that the manganese coordinates at the terminal carboxylic groups.

2.3.2. Preparation of citric acid complex, K^1(O),K^1(O),K^1(O)[(CO)$_3$(dppe)Mn–OC(O)CH$_2$C(OH)C(O)OMn(CO)$_3$(dppe)CH$_2$C(O)OMn(dppe)(CO)$_3$] (9)

A solution of **1** (75 mg, 0.117 mM) in 25 mL of $CHCl_3$ was added drop-wise to 3.9 mL of an aqueous solution containing 8.2 mg of citric acid (0.039 mM) and 4.68 mg of NaOH (0.117 mM). After stirring the mixture for approximately 75 min, the product was isolated in the usual manner.

Data **9**: m.p.: softens at 176 °C and decomposes above 200 °C; IR (cm^{-1}, $CHCl_3$) *v*(CO) 2026, 1955 and 1909; ^1H NMR (δ, $CDCl_3$): 7.9–7.2 (m, 40H, Ph), 2.96 (m, 6H, from dppe), 2.71 (m, 6H, from dppe), 2.51 (s, 4H, CH_2); High-resolution MS (*m*/*z*): 1802.2294 calc. for $[(CO)_3(dppe)MnOC(O)CH_2C(OH)C(O)OMn(CO)_3(dppe)CH_2C(O)OMn(dppe)(CO)_3 + H]^+$, $C_{93}H_{78}O_{16}P_6Mn_3$, 1802.19.

2.3.3. Na-polyacrlyate polymer complex, –[–CH$_2$–CH–[C(O)OMn(CO)$_3$(dppe)]]$_n$– (10)

A solution of the aqua complex, **1** (67.2 mg, 0.105 mM) in 25 mL of MeOH was placed in a round-bottom flask. A solution of sodium polyacrylate (10 mg, 0.005 mM) in 10 mL water was added drop-wise to the solution of **1** and the resulting solution was stirred for 2 h. During this time, the original clear solution became turbid. Stirring was continued overnight. The reaction mixture was evaporated to dryness with a rotary evaporator. The resulting solid was washed with 20 mL of $CHCl_3$ and 10 mL of CH_3OH leaving an orange solid, which was dried in vacuum. Yield 67%.

*Data **10***: m.p.: decomposes without melting at about 350 °C; IR (cm^{-1}, KBr): ν(CO) 2025, 1953 and 1910; *Anal*. Calc. for one unit of polymer, $C_{31}H_{27}O_5P_2Mn$: C, 62.42; H, 4.56; P, 10.38. Found: C, 60.25; H, 5.12; P, 9.86%. The calculated atomic C/P for one unit of polymer is 15.8; Found: 16.0, indicating that approximately each unit of the polyacrylate polymer is bonded to an Mn atom.

2.4. Reaction of **1** with pyridine and pyridine-N-oxide

2.4.1. Pyridine complex, $K^1(N)[(CO)_3(dppe)MnNC_5H_5]^+BF_4^-$ (**11**)

*Data **11***: m.p.: softens at about 103 °C and decomposes above 116 °C; IR (cm^{-1}, $CHCl_3$): ν(CO) 2030, 1957 and 1944; ^{1}H NMR (δ, $CDCl_3$): 7.90–6.65 (m, 20H, from Ph, 5H, from pyridine), 3.65 (m, 2H) and 3.25 (m, 2H) both from dppe; Low temperature (−53 °C) ^{1}H NMR gave the same two signals with the same intensity. High-resolution MS (*m*/*z*): 616.0856, calc. for $[(CO)_3(dppe)MnNC_5H_5]^+$, $C_{34}H_{29}NO_3P_2Mn$, 616.0921.

2.4.2. Pyridine-N-oxide complex, $K^1(O)[(CO)_3(dppe)MnONC_5H_4]^+BF_4^-$ (**12**)

*Data **12***: m.p.: softens at about 82 °C and decomposes above 90 °C; IR (cm^{-1}, $CHCl_3$): ν(CO) 2025, 1950 and 1925; ^{1}H NMR (δ, $CDCl_3$): 7.8–6.8 (m, 20H, from dppe Ph, 5H, from pyridine-*N*-oxide), 3.41 (m, 2H), 2.88 (m, 2H) both from dppe CH_2; High-resolution MS (*m*/*z*): 632.0970, calc. for $[(CO)_3(dppe)MnONC_5H_5]^+$, $C_{34}H_{29}NO_4P_2Mn$, 632.0952, 537.0581, calc. for $[Mn(dppe)(CO)_3]$, $C_{29}H_{24}O_3P_2Mn$, 537.0581.

2.4.3. Reaction of **1** with 1:1 mixture of pyridine and pyridine-N-oxide

Data: ^{1}H NMR (δ, $CDCl_3$): 7.8–6.8 (m, 40H, from dppe Ph, 5H, from pyridine and 5H, from py-*N*-oxide), 3.62 (m, 2H, from pyridine complex), 3.41 (m, 2H, from pyridine-*N*-oxide complex), 3.25 (m, 2H, from pyridine complex), 2.89 (m, 2H, from pyridine-*N*-oxide complex) These data (Table 2) for the dppe CH_2 indicate that both ligand complexes were present; from the relative intensities it was estimated that they were present in approximately equal quantities.

2.5. Reaction of **1** with phenolate anion

2.5.1. Preparation of phenol complex, $[(CO)_3(dppe)MnOC_6H_5]$ (**13**)

The reaction was carried out either by using pure phenol, or more rapidly, by adding complex **1** in $CHCl_3$ to an aqueous NaOH solution of phenol.

*Data **13***: m.p.: softens at about 128 °C and decomposes above 142 °C; IR (cm^{-1}, $CHCl_3$): ν(CO) 2017, 1942 and 1906; ^{1}H NMR (δ, $CDCl_3$): 7.8–7.1 (m, 25H, Ph), 2.97 (m, 2H) and 2.83 (m, 2H) both from dppe; High-resolution MS (*m*/*z*): 630.19, calc. for $[(CO)_3(dppe)Mn–OC_6H_5 + H]^+$, $C_{35}H_{30}O_4P_2Mn$, 630.20; 537.028, calc. for $[Mn(CO)_3\text{-}(dppe)]^+$, $C_{29}H_{24}O_3P_2Mn$, 537.058.

2.6. Reaction of **1** with ambident ligands

2.6.1. Derivatives of pyridine

2.6.1.1. $K^1(O)$ complex with pyridine-3-carboxylic acid, (nicotinic acid), $[(CO)_3(dppe)MnOC(O)C_5H_4N]$ (**14**).

*Data **14***: m.p.: softens at about 108 °C and decomposes above 135 °C; IR (cm^{-1}, $CHCl_3$): ν(CO) 2027, 1960 and 1914; ^{1}H NMR (δ, $CDCl_3$): 7.9–7.2 (m, 24H, Ph), 3.02 (m, 2H) and 2.87 (m, 2H) both from dppe; High-resolution MS (*m*/*z*): 660.105, calc. for $[(CO)_3(dppe)MnNC_5H_4\text{-}C(O)OH]^+$, $C_{35}H_{29}NO_5P_2Mn$, 660.112.

2.6.1.2. $K^1(N),K^1(O)$ dinuclear Mn complex with pyridine-3-carboxylic acid, (nicotinic acid), $[(CO)_3(dppe)MnN\text{-}C_5H_4C(O)OMn(dppe)(CO)_3]^+BF_4^-$ (**15**).

Pure **15** was obtained by column chromatography on neutral alumina using hexane and ethyl acetate as gradient eluents.

*Data **15***: m.p.: softens at 110 °C and decomposes above 150 °C; IR (cm^{-1}, $CHCl_3$): ν(CO) 2027 (broad), 1960 (broad) and 1939 (shoulder) and 1913; ^{1}H NMR (δ, $CDCl_3$): 8.73 (m), 8.35 (m, H) and 7.98 (m, H) all from nicotinic acid moiety, 7.9–7.2 (m, 40H, from Ph) 6.97 (m, H, from nicotinic acid), 3.63 (m, 2H, from dppe bonded to the Mn attached to N), 3.20 (m, 2H, from dppe bonded to the Mn attached to N), 3.01 (m, 2H, from dppe bonded to the Mn attached to the acid group), 2.85 (m, 2H, from dppe bonded to the Mn attached to the acid group); High-resolution MS (*m*/*z*): 1196.1440, calc. for $[(CO)_3\text{-}(dppe)Mn–NC_5H_4C(O)O–Mn(dppe)(CO)_3]$ $C_{64}H_{52}NO_8\text{-}P_4Mn_2$, 1196.1404; 537.0581, calc. for $[Mn(dppe)(CO)_3]$, $C_{29}H_{24}O_3P_2Mn$, 537.0581. This complex was also prepared by adding 2 molar equivalents of aqua complex to 1 mol of nicotinic acid.

2.6.1.3. $K^1(NC)$ complex with 4-cyanopyridine, $[(CO)_3\text{-}(dppe)MnNCC_5H_4N]^+BF_4^-$ (**16**).

The product was chromatographed on a column of neutral alumina with hexane and ethyl acetate as gradient eluents to give pure **16**.

*Data **16***: m.p.: softens at about 85 °C and decomposes above 108 °C; IR (cm^{-1}, $CHCl_3$): ν(CO) 2039, 1971 and 1961: ^{1}H NMR (δ, $CDCl_3$): 7.8–6.8 (m, 20H, from dppe Ph, 4H, from 4-cyanopyridine), 3.48 (m, 2H), 3.05 (m, 2H) both from dppe CH_2; High-resolution MS (*m*/*z*): 641.0930, calc. for $[(CO)_3(dppe)MnNCC_5H_4N]^+$, $C_{35}H_{28}\text{-}N_2O_3P_2Mn$, 641.0956, 537.0316, calc. for $[Mn(dppe)(CO)_3]$, $C_{29}H_{24}O_3P_2Mn$, 537.0581.

2.6.1.4. Preparation of $K^1(NC),K^1(N)$ dinuclear Mn complex with 4-cyanopyridine, $[(CO)_3(dppe)MnNCC_5H_4\text{-}N–Mn(dppe)(CO)_3]^{2+}2BF_4^-$ (**17**).

The crude product was chromatographed on neutral alumina with hexane and ethyl acetate as gradient eluents to give pure **17**.

*Data **17***: m.p.: softens at about 105 °C and decomposes above 128 °C; IR (cm^{-1}, $CHCl_3$): ν(CO) 2039, 2027

Table 2
Chemical shift of dppe CH_2 protons (ppm) and IR spectra (cm^{-1}, in $CHCl_3$) of $(CO)_3$(dppe)MnZ

Complex No.	Attached to Mn		DPPE methylene protons (δ) ppm			Stretching frequencies

[a] Assumed to be "*trans*" to apical CO.
[b] Assumed to be "*cis*" to apical CO.
[c] CO stretching frequencies essentially the same for each set of carbonyls.
[d] Integrates for four protons for each signal.
[e] Integrates for six protons for each signal.
[f] IR spectra of Na-polyacrylate complex was taken by using Kbr pellet.
[g] This complex is excluded from the generalizations discussed below.
[h] K^2(N) complex.

(shoulder) 1971, 1961 (broad) and 1939 shoulder; ^{1}H NMR (δ, $CDCl_3$): 7.8–6.8 (m, 40H, from dppe Ph, 4H, from 4-cyanopyridine), 3.50 (broad, m, 4H), 3.11 (broad, m, 4H) both from dppe CH_2; High-resolution MS (*m*/*z*): 1178.1601, calc. for $[(CO)_3(dppe)MnNCC_5H_4N–Mn(dppe)(CO)_3]^{2+}$, $C_{64}H_{62}N_2O_6P_4Mn_2$, 1178.1537. This complex was also prepared by adding one mole of **1** to a solution of **17**.

*2.6.1.5. Preparation of $K^1(O)$ complex with 3-hydroxypyridine, $[(CO)_3(dppe)Mn–OC_5H_4N]$ (**18**).* A solution of **1** was added drop-wise to a solution containing an equimolar

quantity of 3-hydroxypyridine dissolved in aqueous NaOH.

*Data **18***: m.p.: softens at about 75 °C and decomposes above 88 °C; IR (cm^{-1}, $CHCl_3$): ν(CO) 2025, 1948 and 1922: ^1H NMR (δ, $CDCl_3$): 7.8–6.8 (m, 20H, from dppe Ph, 4H, from 3-hydroxypyridine), 3.07 (m, 2H), 2.92 (m, 2H) both from dppe CH_2; High-resolution MS (*m*/*z*): 632.1005, calc. for $[(CO)_3(dppe)MnOC_5H_4N + H]^+$, $C_{34}H_{29}NO_4P_2Mn$, 632.0952, 537.0556, calc. for $[Mn(dppe)(CO)_3]$, $C_{29}H_{24}O_3P_2Mn$, 537.0581.

*2.6.1.6. $K^1(O),K^1(N)$ dinuclear Mn complex with 3-hydroxypyridine, $[(CO)_3(dppe)MnOC_5H_4NMn(dppe)(CO)_3]^+BF_4^-$ (**19**).* The reaction was carried out in $CHCl_3$ using an equimolar solution of **1** and **18**.

*Data **19***: m.p.: softens at about 89 °C and decomposes above 112 °C; IR (cm^{-1}, $CHCl_3$): ν(CO) 2028 (broad), 1955 (broad), 1940 (shoulder) and 1918; ^1H NMR (δ, $CDCl_3$): 7.8–6.8 (m, 40H, from dppe Ph, 4H, from 3-hydroxypyridine), 3.59 (m, 2H, from dppe bonded to the Mn attached to N), 3.23 (m, 2H, from dppe bonded to the Mn attached to N), 3.05 (m, 2H, from dppe bonded to the Mn attached to O), 2.89 (m, 2H, from dppe bonded to the Mn attached to O); High-resolution MS (*m*/*z*): 1168.1505, calc. for $[(CO)_3(dppe)MnOC_5H_4N–Mn(dppe)(CO)_3]^+$, $C_{63}H_{62}NO_7P_4Mn_2$, 1168.1454, 537.0567, calc. for $[Mn(dppe)(CO)_3]$, $C_{29}H_{24}O_3P_2Mn$, 537.0581. This complex was also prepared by using 2 molar equivalents of **1** to one of 3-hydroxypyridine.

2.6.2. Derivatives of phenol

*2.6.2.1. Preparation of $K^1(N)$ complex with 3-cyanophenol, $[(CO)_3(dppe)Mn–NCC_6H_4OH]^+BF_4^-$ (**20**).* The reaction was carried out in $CHCl_3$ using equimolar amounts of **1** and ligand.

*Data **20***: m.p.: softens at about 155 °C and decomposes above 163 °C; IR (cm^{-1}, $CHCl_3$): ν(CO) 2038, 1971 and 1959: ^1H NMR (δ, $CDCl_3$): 7.8–6.2 (m, 20H, from dppe Ph, 5H, from 3-cyanophenol), 3.39 (m, 2H), 3.04 (m, 2H) both from dppe CH_2; High-resolution MS (*m*/*z*): 656.0961, calc. for $[(CO)_3(dppe)MnNCC_6H_4OH]^+$, $C_{36}H_{29}NO_4P_2Mn$, 656.0952, 537.0461, calc. for $[Mn(dppe)(CO)_3]$, $C_{29}H_{24}O_3P_2Mn$, 537.0581.

*2.6.2.2. Preparation of $K^1(O)$ complex with 3-cyanophenol, $[(CO)_3(dppe)MnOC_6H_4CN]$ (**21**).* The reaction was carried out using a $CHCl_3$ solution of **1** and a molar equivalent of 3-cyanophenol in aqueous NaOH.

*Data **21***: m.p.: softens at about 167 °C and decomposes above 181 °C; IR (cm^{-1}, $CHCl_3$): ν(CO) 2019, 1945 and 1911; ^1H NMR (δ, $CDCl_3$): 7.8–6.2 (m, 20H, from dppe Ph, 5H, from 3-cyanophenol), 2.99 (m, 2H), 2.83 (m, 2H) both from dppe CH_2; High-resolution MS (*m*/*z*): 656.0991, calc. for $[(CO)_3(dppe)MnOC_6H_4CN + H]$, $C_{36}H_{29}$-NO_4P_2Mn, 656.0952, 537.0603, calc. for $[Mn(dppe)(CO)_3]$, $C_{29}H_{24}O_3P_2Mn$, 537.0581. In the absence of alkali but in the presence of water, **20**, and an almost equal quantity of **21** were formed.

*2.6.2.3. Preparation of $K^1(N),K^1(O)$ dinuclear Mn complex with 3-cyanophenol, $[(CO)_3(dppe)MnNCC_6H_4OMn(dpp)(CO)_3]^+BF_4^-$ (**22**).* A $CHCl_3$ solution of two molar equivalents of **1** is added to an aqueous NaOH solution of one molar equivalent of 3-cyanophenol. Compound **22** was also prepared by adding molar equivalents of **1** to either **20** or **21**.

*Data **22***: m.p.: softens at about 162 °C and decomposes above 178 °C; IR (cm^{-1}, $CHCl_3$): ν(CO) 2038, 2021, 1971, broad 1957 (1959 due to CN, and 1956 due to OH merged) and 1912; ^1H NMR (δ, $CDCl_3$): 7.8–6.2 (m, 40H, from dppe Ph, 4H, from 3-cyanophenol), 3.36 (m, 2H), 3.04 (m, 2 H) both from dppe CH_2 Mn attached to N; 3.01 (m, 2H), 2.85 (m, 2H) both from dppe CH_2 of Mn attached to O; High-resolution MS (*m*/*z*): 1192.1501, calc. for $[(CO)_3(dppe)MnNC$-$C_6H_4OMn(dppe)(CO)_3]^+$, $C_{65}H_{52}O_5P_2Mn_2$, 1192.1454, 656.0961, calc. for $[(CO)_3(dppe)MnNCC_6H_4OH]^+$, $C_{36}H_{29}NO_4P_2Mn$, 656.0952; 537.0461, calc. for $[Mn(dppe)$-$(CO)_3]$, $C_{29}H_{24}O_3P_2Mn$, 537.0581.

2.6.3. Derivatives of benzoic acid

*2.6.3.1. Preparation of $K^1(OCO)$ complex with 3-hydroxybenzoic acid, $[(CO)_3(dppe)Mn–OC(O)C_6H_4OH]$ (**23**).* The reaction was carried out by adding a $CHCl_3$ solution of **1** to an equimolar quantity of 3-hydroxybenzoic acid in aqueous $NaHCO_3$.

*Data **23***: m.p.: softens at about 114 °C and decomposes at above 124 °C; IR (cm^{-1}, $CHCl_3$): ν(CO) 2027, 1960 and 1911; ^1H NMR (δ, $CDCl_3$): 7.9–6.8 (m, 20H, from dppe Ph, 4H, from 3-hydroxybenzoic acid), 3.00 (m, 2H) and 2.85 (m, 2H) both from dppe CH_2; High-resolution MS (*m*/*z*): 673.0842, calc. for $[(CO)_3(dppe)Mn–OC_6H_4$-$COOH + H]$, $C_{37}H_{30}O_6P_2Mn$, 674.0820.

*2.6.3.2. Preparation of $K^1(OCO),K^1(O)$ complex of 3-hydroxybenzoic acid, $[(CO)_3(dppe)Mn–OC(O)C_6H_4$-$O–Mn(dppe)(CO)_3]$ (**24**).* A $CHCl_3$ solution of two molar equivalents of **1** is added to one molar equivalent of an aqueous NaOH solution of 3-hydroxybenzoic acid.

*Data **24***: m.p.: softens at about 118 °C and decomposes above 133 °C; IR (cm^{-1}, $CHCl_3$): ν(CO) 2027, 1959 and 1916; ^1H NMR (δ, $CDCl_3$): 7.9–7.2 (m, 40H, from dppe Ph, 4H, from 3-hydroxybenzoic acid), 3.03 (broad, m, 4H) and 2.85 (broad, m, 4H) both from dppe CH_2; High-resolution MS (*m*/*z*): 1211.1406, calc. for $[(CO)_3(dppe)$-$Mn–OC(O)C_6H_4O–Mn(dppe)(CO)_3 + H]^+$, $C_{65}H_{53}O_9P_4Mn_2$, 1211.1401.

*2.6.3.3. Preparation of $K^1(N)$ complex with 3-cyanobenzoic acid, $[(CO)_3(dppe)Mn–NCC_6H_4COOH]^+BF_4^-$ (**25**).* The reaction is carried out in carefully dried MeOH. The yellow solid consisted of two complexes, which were separated by chromatography on a neutral alumina column. Based on spectroscopic data, the composition of the

mixture was estimated to consist of about 85% of **25** and 15% of **26**.

*Data **25***: m.p.: softens at about 106 °C and decomposes at above 112 °C; IR (cm^{-1}, $CHCl_3$): ν(CO) 2038, 1969 and 1960; ^1H NMR (δ, $CDCl_3$): 7.9–7.2 (m, 20H, from dppe Ph, 4H, from 3-cyanobenzoic acid), 3.27 (m, 2H) and 2.86 (m, 2H) both from dppe; High-resolution MS (*m*/*z*): 684.0953, calc. for $[(CO)_3(dppe)Mn–NCC_6H_4COOH]^+$, $C_{37}H_{29}O_5P_2NMn$: 684.0901.

*2.6.3.4. Preparation of $K^1(O)$ complex with 3-cyanobenzoic acid, $[(CO)_3(dppe)Mn–O(O)CC_6H_4CN]$ (**26**).* A $CHCl_3$ solution of **1** is added to an equimolar quantity of 3-cyanobenzoic acid in aqueous NaOH.

*Data **26***: m.p.: softens at about 112 °C and decomposes at above 120 °C; IR (cm^{-1}, $CHCl_3$): ν(CO) 2028, 1961 and 1914; ^1H NMR (δ, $CDCl_3$): 7.9–7.2 (m, 20H, from dppe, 4H, from 3-cyanobenzoic acid), 3.00 (m, 2H) and 2.83 (m, 2H) both from dppe; High-resolution MS (*m*/*z*): 684.0961, calc. for $[(CO)_3(dppe)Mn–O(O)CC_6H_4CN + H]^+$, $C_{37}H_{29}O_5P_2NMn$, 684.0901.

*2.6.3.5. Preparation of $K^1(O),K^1(N)$ dinuclear Mn complex with 3-cyanobenzoic acid, $[(CO)_3(dppe)Mn–O(O)-CC_6H_4CN–Mn(dppe)(CO)_3]^+BF_4^-$ (**27**).* A $CHCl_3$ solution of two molar equivalents of **1** is added to one molar equivalent of 3-cyanobenzoic acid in aqueous NaOH solution.

*Data **27***: m.p.: softens at about 118 °C and decomposes above 124 °C; IR (cm^{-1}, $CHCl_3$): ν(CO) 2038, 2027 and 1969, cyanobenzoic acid, 3.26 (m, 2H), 2.86 (m, 2H) both from dppe CH_2 Mn attached to N; 3.00 (m, 2H), 2.74 (m, 2H) both from dppe CH_2 Mn attached to O; High-resolution MS (*m*/*z*): 3.36 (m, 2H), 3.04 (m, 2H); 3.01 (m, 2H), 2.85 (m, 2H) both from dppe CH_2 of Mn attached to O; High-resolution MS (*m*/*z*): 1220.1394, calc. for $[(CO)_3(dppe)Mn-OC(O)C_6H_4CN–Mn(dppe)(CO)_3]^+$, $C_{65}H_{62}O_8P_4NMn_2$, 1220.140.

*2.6.4. Reaction of **1** with amino acids*

*2.6.4.1. Preparation of $K^1(O)$ complex with glycine, $[(CO)_3(dppe)MnOC(O)CH_2NH_2]$ (**28**).* A $CHCl_3$ solution of **1** is added to an equimolar aqueous solution of glycine.

*Data **28***: m.p.: softens at about 130 °C and decomposes above 138 °C; IR (cm^{-1}, $CHCl_3$): ν(CO) 2026, 1953.7 and 1908; ^1H NMR (δ, $CDCl_3$): 7.9–7.2 (m, 20H, from dppe, 4H, from 3-cyanobenzoic acid), 3.03 (m, 2H) and 2.87 (m, 2H) both from dppe; High-resolution MS (*m*/*z*): 612.0921, calc. for $[(CO)_3(dppe)Mn–OC(O)CH_2NH_2 + H]^+$, $C_{31}H_{29}O_5P_2NMn$, 6121.0903.

*2.6.4.2. $K^1(O)$ complex with tryptophan, $[(CO)_3(dppe)-Mn–OC(O)CHCH_2(NH_2)C_8H_5N]$, (**29**).* The reaction is carried out in MeOH.

*Data **29***: m.p: softens at about 138 °C and decomposes above 160 °C; IR (cm^{-1}, $CHCl_3$): ν(CO) 2026, 1955 and 1910; ^1H NMR (δ, $CDCl_3$): 7.9–7.2 (m, 20H, from dppe, 4H, from 3-cyanobenzoic acid), 5.1 (broad peak due to NH_3^+ zwitter ion), 3.15 (m, 2H), and 2.95 (m, 2H) both from dppe; 2.5 (m, 2H) from CH_2 of tryptophan, 2.25 (t, H) from CH of tryptophan; High-resolution MS (*m*/*z*): 726.138, calc. for $[(CO)_3(dppe)Mn–OC(O)CHCH_2(NH_2)-C_8H_5N + H]^+$, $C_{40}H_{35}O_5P_2NMn$, 726.1372.

*2.6.5. Reaction of **1** with $Ph_2PCH_2CH_2N(CH_3)_2(pn)$*

*2.6.5.1. Preparation of $K^1(P)[(CO)_3(dppe)MnP(Ph)_2-CH_2CH_2N(CH_3)_2]^+BF_4^-$ (**30**).* The reaction is carried out by adding a $CHCl_3$ solution of **1** to a $CHCl_3$ solution of half the molar equivalent of pn.

*Data **30***: m.p.: softens at about 87 °C, decomposes above 104 °C; IR (cm^{-1}, $CHCl_3$): ν(CO) 2027, 1958 and 1917; ^1H NMR (δ, $CDCl_3$): 8.0–7.0 (m, 30H, Ph), 3.34 (m, 2H), 3.09 (m, 2H), 3.02 (m, 2H attached to P of pn), 2.72 (2H, CH_2 attached to N), 2.27 (s, 6H, CH_3 attached to N); High-resolution MS (*m*/*z*): 794.1915, calc. for $[(CO)_3Mn(dppe)P(Ph)_2CH_2CH_2\ N(CH_3)_2]$, $C_{45}H_{44}NO_3P_3Mn$, 794.1910; 537.023, calc. for $[(CO)_3Mn(dppe)]$, $C_{29}H_{24}O_3P_2Mn$, 537.058.

*2.6.5.2. $K^1(P),K^1(N)[(dppe)(CO)_3MnP(Ph)_2(CH_2)_2N-(CH_3)Mn(CO)_3(dppe)]^{2+}2BF_4^-$ (**31**).* A $CHCl_3$ solution of equimolar quantities of **1** and **30** was used.

*Data **31***: m.p.: softens at 144 °C, decomposes above 210 °C; IR (cm^{-1}, $CHCl_3$): ν(CO) 2031(broad), 1957(broad), 1913 (broad) and 1916; ^1H NMR (δ, $CDCl_3$): 8.00–7.00 (m, 50H, Ph), 3.39 (m, 2H, from dppe bonded to the Mn attached to N), 3.10 (m, 2H, from dppe, bonded to the Mn attached to P of pn), 3.01 (m, 4H, CH_2 attached to P of pn), 2.97 (m, 2H, from dppe bonded to the Mn attached to N), 2.80 (m, 2H, from dppe bonded to the Mn attached to N), 2.79 (m, 2H, CH_2 attached to N), 2.60 (s, 6H, $2CH_3$ attached to N); High-resolution MS (*m*/*z*): 1418.2647, calc. for $[(dppe)(CO)_3Mn–P(Ph)_2(CH_2)_2N(CH_3)_2–Mn(CO)_3(dppe)]^{2+}BF_4^-$, 1418.2530; 822.2166, calc. for $[(dppe)(CO)_3Mn–P(Ph)_2(CH_2)_2N-(CH_3)_2H]^{2+}BF_4$, 882.2029, 794.1882, calc. for $[(CO)_3-Mn(dppe)P(Ph)_2CH_2CH_2N(CH_3)_2]$, $C_{45}H_{44}NO_3P_3Mn$, 794.1915, 537.047, calc. for $[(CO)_3Mn(dppe)]$, $C_{29}H_{24}O_3-P_2Mn$, 537.058.

2.7.2. $K^1(N)$, $K1(N)[(CO)_3(dppe)MnN(CH_3)_2$-$CH_2CH_2N(CH_3)_2Mn(CO)_3(dppe)]^{2+}2BF_4^-$ (**33**)

A $CHCl_3$ solution of TMED is added to an equimolar $CHCl_3$ solution of **1** and the product recrystallized from $CHCl_3$/hexane.

Data ***33***: m.p.: softens at about 120 °C and decomposes above 142 °C; IR (cm^{-1}, $CHCl_3$): *ν*(CO) 2025, 1951 and 1906; ^1H NMR (*δ*, $CDCl_3$): 8.00–7.00 (m, 40H, Ph), 3.07 (m, 4H, from dppe), 2.91 (m, 4H, from dppe) 2.79 (s, 6H, $2CH_3$ attached to N), 2.73 (s, 6H, $2CH_3$ attached to N), 2.52 (m, 2H, attached to N), 2.51 (s, 2H, attached to N); High-resolution MS (*m/z*): 1277.1953; calc. for [$(CO)_3$(dppe)MnN$(CH_3)_2CH_2CH_2N(CH_3)_2Mn(CO)_3$(dppe)]$^+$ BF_4^-, $C_{64}H_{64}N_2O_6P_4Mn_2BF_4$, 1277.2505, 1191.1655, calc. for [$(CO)_3$(dppe)Mn–N$(CH_3)_2CH_2CH_2N(CH_3)_2$–Mn$(CO)_3$(dppe) + H]$^+$, $C_{64}H_{65}N_2O_6P_4Mn_2$, 1191.2554.

2.7.3. $[K^2(N,N\text{-}TMED)]Mn(CO)_3Br$ (**34**)

To a solution of $Mn(CO)_5Br$ [6] (0.274 g, 1.0 mmol), in 20 mL of toluene in a round-bottom flask equipped with a condenser, 0.150 mL (1.0 mmol) of TMED dissolved in 20 mL of toluene is added drop-wise. The solution is refluxed for 3 h and the toluene is removed via rotary evaporator to give a brown solid, which is dissolved in benzene, stirred for 5 min and filtered. The filtrate is evaporated via rotary evaporator. The brown solid is recrystallized from 1:1 CH_2Cl_2/hexane, giving orange crystals of **34**. Yield 75%.

Data ***34***: m.p.: 154–158 °C, IR (cm^{-1}, CH_2Cl_2): *ν*(CO) 2015, 1919, 1893 and 1895 as a doublet; ^1H NMR (*δ*, $CDCl_3$): 2.98 (s, 6H, CH_3), 2.92 (s, 6H, CH_3), 2.7 (m, 2H), 2.58 (m, 2H); High-resolution MS (*m/z*): 333.9628, calc. for $Mn(CO)_3$(TMED)Br, 334.0189; 249.9882, calc. for [Mn(TMED)Br], 249.9877; 171.07, calc. for [Mn(TMED)], 171.0694. *Anal.* Calc. for [$Mn(CO)_3$(TMED)Br]: C, 32.26: H, 4.81. Found: C, 32.6; H, 4.85%.

3. Results and discussion

The octahedral Mn(I) complex *fac*-[$(CO)_3$(dppe)-$MnOH_2]^+BF_4^-$ (**1**) central to this study, is easily prepared in high yield by a two-step process from readily available starting materials [2,3]. Replacement of the aqua ligand is achieved by simply stirring a solution of **1** with the desired ligand, Z. Thus derivatives of **1** have been reported, where Z represents the following anions: CN; OMe; NO_3; OC(O)-CH_3; OTf; N_3 [4]; and F [6]. (In the case of the azide, further reaction of the coordinated N_3 by 1,3-dipolar addition, either to acetylenic compounds or to nitriles, gave new manganese-bonded triazoles and tetrazoles, respectively [3]). With neutral ligands [4], the corresponding ionic complexes [$(CO)_3$(dppe)MnZ]BF_4 were prepared, where Z = PhCN, CH_3CN, CH_2=CHCN, *m*-xylylNC, PPh_3 and CO [7].

We have reported [2], that the hydride, $(CO)_3$(dppe)-MnH, precursor to the corresponding aqua complex, reacts not only with HBF_4 but also with a variety of other strong acids. These reactions result in the liberation of dihydrogen and the direct formation of the neutral complex containing the anion of the acid as a new ligand. However, weaker acids such as acetic acid and phenol do not react in this fashion. We now report that such weaker acids do react with the aqua complex resulting in the replacement of the aqua ligand by the anion (conjugate base) of the weak acid thus making available a new route to the corresponding neutral complexes. Water-soluble carboxylic acids can be used in a two-phase system without added alkali, but others require the presence of base to speed the reaction. Amino acid ligands in methanol solution react in their zwitter ion form. Complexes have been prepared from both aliphatic and aromatic carboxylic acids, as well as from phenol. The reaction with succinic and fumaric acids leads to complexes containing two Mn atoms. The reaction with citric acid gives either the 2:1 complex, presumably involving the two terminal carboxyl groups, or when alkali is present, a 3:1 complex. Stirring an excess of the aqua complex with sodium acrylate polymer (Aldrich, av. mol wt. 2100) gives a product that is insoluble in all common solvents and thus resists conventional methods of characterization. The ultimate analysis of the polymer and the calculated C/P ratio from that analysis, (see supra) indicates that almost every –[–CH_2–CH–(CO_2^-)–]– unit of the acrylate polymer is attached to a separate Mn atom, giving a new polymer, **10**, of the approximate formula: –[–CH_2–CH–[C(O)OMn$(CO)_3$(dppe)]]$_n^-$. This appears to be a unique type of polymer, one highly loaded with a transition metal, and it merits further investigation. Attempts to prepare a similar polymer by initiating polymerization of [$(CO)_3$(dppe)Mn(NCCH=CH_2)]BF_4 with benzoyl peroxide or AIBN were unsuccessful.

3.1. ^1H NMR studies

3.1.1. Aqua complex *1*

The signals associated with the protons of the dppe-Mn metallacycle are of particular interest. Unlike the other related dppe complexes, which all show two signals, **1** in $CDCl_3$ at room temperature shows a single signal (*δ* 2.95, m, 4H) for these four protons. The crystal structure [3] of **1** shows a puckered metallacycle, similar to that of other dppe complexes. Apparently the rapid reversible dissociation of the aqua ligand of **1**, which may involve a concomitant rearrangement to an intermediate 5-coordinate trigonal bipyramidal structure, results in all the protons appearing equivalent on the NMR timescale. However, at −53 °C, this signal is split into two distinct methylene signals (m, *δ* 2.67, 2H; m, *δ* 3.1, 2H) owing to the slowing of dissociation of the aqua ligand at low temperature. However, even at this low temperature it appears that

axial–equatorial interconversions of the puckered structure continue, leading, on average, to an essentially planar, 5-membered ring (see Graphical Abstract). Such a planar C_s structure results in a pair of equivalent protons on adjacent carbon *cis* to the apical CO and a pair that is *trans* to this CO, giving rise to the two signals characteristic of the ^{1}H NMR of the dppe-metallacyle.

3.1.2. Hydrido and nitrato derivatives of *1*

In an attempt to obtain evidence for ligand dissociation, the ^{1}H NMR of the hydrido (the smallest ligand) and nitrato (with a long Mn–O bond) complexes [2,4] was examined in the temperature range 100 to 120 °C. However, the chemical shifts remained unchanged (m, 2H, 2.51 and m, 2H, 2.23 for hydrido, m, 2.97, 2H and m, 2.80, 2H for nitrato) indicating no dissociation under these conditions.

3.1.3. The dppe-Mn metallacycle

The chemical shifts of the methylene protons provide valuable evidence for the preferred site of mono-coordinated ambident ligands. One of the most instructive ^{1}H NMR studies [8] of this system involved the dppe complex, 6-exophenylcyclohexadienylmanganese(I), $[PhC_6H_6(dppe)Mn(NO)]PF_6$. At 25 °C, this complex showed the CH_2 protons of the dppe as two signals (δ 3.53 and 3.02) as expected. However at −75 °C four different signals were observed, which the authors ascribe to two non-equivalent axial and two non-equivalent equatorial protons, in accordance with a stable puckered C_1 structure. We examined the ^{1}H NMR of our pyridine complex, **11**, at −50 °C, but the two signals observed at room temperature remained essentially unchanged at the lower temperature.

The chemical shift data (Table 2) of the methylene protons on the dppe ligand, provide valuable diagnostic information as to the site (Table 1) of mono-coordination of ambident ligands. These data show a consistent pattern, particularly, with respect to the difference between the chemical shifts of the two sets of protons. For the 21 related complexes in which the Mn is coordinated to an oxygen atom, this difference ranges from 0.09 to 0.19 ppm or an average of 0.14 ppm. For the 10 complexes in which the Mn is attached to a nitrogen atom, either that of a pyridine or a nitrile nitrogen, this difference ranges from 0.32 to 0.43 ppm or an average of 0.39 ppm.

3.2. Infrared studies

In a previous paper [9], we analyzed the carbonyl stretching frequencies of 38 $[(CO)_3(dppe)MnZ]$ complexes. We were able to assign symmetry species A′, A″, and A′ in decreasing order of frequency, to the three carbonyl stretches in each of these related C_s complexes. The partial positive charge on the carbon atom of coordinated CO is the most important factor affecting the frequency; the more positive this charge, the larger the force constant and the higher the frequency. Data for the new complexes are shown in Table 2. These 29 complexes may be grouped into four categories (Table 3) depending on the nature of the ligand atom that is bonded to the Mn, namely cyano-nitrogen, pyridine-nitrogen, carboxyl-oxygen and phenolic-oxygen. This order is the descending order of frequencies (with one minor exception) for all three A′, A″, and A′ bonding modes. The largest difference in frequencies between the four categories of bonding types occurs with the lower A′ mode, which involves the equatorial COs moving in phase with respect to each other and out of phase with respect to the axial CO. The group of complexes with the highest frequencies of the four groups is the category in which a nitrile nitrogen atom is bonded to the Mn. The six complexes having such coordination have the relevant A′ stretching frequencies in the narrow range 1957–1961 cm^{-1} (noticeably shifted, as expected, from the values observed with ligands having free nitrile groups). The nitrile group's π* orbitals probably compete with the carbonyl π* orbitals in accepting back-donation from the Mn d-electrons, thus increasing the partial positive charge on the carbonyl carbon atoms with the net effect of increasing the carbonyl frequencies as compared to those with pyridine or oxygen-bonded ligands.

3.3. Competition for coordination sites on ambident ligands

Previous evaluations of the relative coordinating ability of some monodentate ligands have relied on the determination of equilibrium studies of substitution reactions, e.g., $(amine)W(CO)_5 + L \rightleftarrows LW(CO)_5 + amine$ [10]. The determination of the equilibrium constants by such studies is, however, rather limited and have to be carefully chosen because of analytical difficulties. The interest in unsymmetrical chelation in ambident ligands stems from their potential use in transition metal-catalyzed homogeneous reactions. The K^2 chelation of such ligands affords stability, but if one of the donor atoms is more easily dissociated than the other, the resulting vacated site on the K^1 complex may then be occupied by a substrate molecule, followed by a desired insertion reaction and a subsequent reconstitution of the original K^2 complex. One of the most frequently used ligand for such reactions is the bidentate P,N ligand,

Table 3

$(CH_3)_2NCH_2CH_2PPh_2$, (pn). It has been found, for example [11] that the rhodium-catalyzed hydroformylation of styrene gives a substantially better yield of aldehydes when pn rather than dppe is used as a chelating ligand and a similar result was found [12,13] in the case of the carbonylation of a Pt-K^2(N,P) pn complex. Studies of Ni [14], Ru [15], and heteronuclear Pt complexes [16] containing the pn ligand in its K^2(N,P) form have shown that the nitrogen site is more easily dissociated from the metal than the phosphorous atom.

Most studies involving mixed bidentate ligands, such as the ones cited above, have been devoted to investigating selective dissociation of the chelated K^2-complex to a corresponding K^1-complex. The results of such studies are generally consistent with hard-acid, soft-base (HASB) theory, with the central cationic metal acting as the hard acid, and the ligand, with two competing heteroatoms of differing hardness/softness, as the base [17]. In the case of a the K^2(N,P) pn complexes, the metal–N bond, as expected, and as the cited references show, dissociates preferentially. Although it may be reasonable to assume that preferred coordination is the reverse of preferred dissociation, it was nevertheless thought to be instructive to ascertain the preferred coordination site in the case of pn by reacting it with one mole of **1**.

Our studies show that when a solution of **1** is added dropwise to an equimolar solution of pn, the K^1(P) complex, **30**, is formed, essentially in quantitative yield. For purposes of comparing their ^{1}H NMR spectra, complexes **32** and **33** were also prepared. The difference in δ of the methyl protons attached to the trivalent and tetravalent N atoms in the complexes allows one to ascertain when and if the N is involved in the coordination of pn to the Mn. The fact that P of pn is preferred on coordination is consistent with the dissociation studies, which found that N dissociates before P in pn K^2 (P,N) complexes.

Our studies compare relative ligating ability of ambident ligands possessing combinations of carboxylate, phenolic, pyridine and nitrile groups competing for a single coordination site. When present as anions, usually in a two-phase system, the carboxylate (including the zwitter ions of amino acids) and phenolic ligands are preferred over the other type ligands. By using $NaHCO_3$ it is possible to coordinate 3-hydroxybenzoic acid exclusively at the carboxyl group, **23**, while with NaOH both functional groups are coordinated, **24**. The synthesis of **16** from 4-cyanopyridine indicates coordination at nitrile nitrogen in preference to pyridine nitrogen. In the absence of alkali or water, the nitrile group coordinates more rapidly than carboxyl of 3-hydroxybenzoic acid (**25**) or the hydroxyl of 3-cyanophenol (**20**). It would appear that a useful ambident chelating ligand for certain catalytic reactions might consist of a pyridine derivative having a suitably situated nitrile group, or one containing CN and $N(CH_3)_2$ groups. We have no plans to pursue this area of research.

Acknowledgments

We thank Prof. A. Pinhas and Dr. J.K. Bauer for valuable discussions and Drs. Tom Becker and K. Jayasimhulu for help with experimental work.

Molecule-based magnets made with $V^0(CO)_6$ are based upon its redox reaction with a neutral electron acceptor, i.e., $Ni(mnt)_2$, $\mathbf{1a}^0$. While innumerable salts of $\mathbf{1a}^n$ ($n = 1$-, 2-) have been reported, neutral $\mathbf{1}^0$ has yet to be isolated. Nonetheless, $\mathbf{1a}^0$ has been electrochemically generated in situ [20] and formation of $V[Ni(mnt)_2]_2$, **2**, was sought via

$$V^0(CO)_6 + 2Ni(mnt)_2 \rightarrow V[Ni(mnt)_2]_2\ (\mathbf{2}). \quad (1)$$

In addition to formation of **2**, we sought molecule-based magnets based on $S = 1/2$ $[M(mnt)_2]^{2-}$ [M = Co (**1b**); Cu (**1c**)]. Due **1b** and **1c** being dianions, materials of the composition of $M^{II'}[M(mnt)_2]$ (M = Co, Cu; M′ = V, Cr, Mn, Fe, Co, Ni) (**3**) were sought via

$$[M^{II'}(NCMe)_6]^{2+} + [M(mnt)_2]^{\bullet 2-} \rightarrow M^{II'}[M(mnt)_2]\ (\mathbf{3}). \quad (2)$$

2. Experimental

2.1. Synthesis

$[NBu_4][Ni(mnt)_2]$ [10a], $[NBu_4]_2[M(mnt)_2]$ (M = Co, Cu) [10e], $[M'(NCMe)_6][BF_4]_2$ (M′ = V, Mn, Fe, Co, Ni) [10g], $[Cr(NCMe)_6][B(C_6H_3(CF_3)_2)_4]_2$ [10i], and $V^0(CO)_6$ [10j] were prepared as previously reported. The supporting electrolyte, tetrabutylammonium hexafluorophosphate, was recrystallized from ethanol, which was dried and distilled under N_2. All other solvents used were also dried and distilled under nitrogen, along with the reaction being preformed under a nitrogen atmosphere. All the products are dark blue-black in color.

2.2. V[Ni(mnt)$_2$]$_2$ (2)

The $[NBu_4][PF_6]$ supporting electrolyte (1.952 g, 5.04 mmol) was dissolved in 50.0 mL of CH_2Cl_2. Twenty-five milliliters of this solution was used to dissolve $\mathbf{1a}^-$ (0.0120 g, 1.20 mmol). The solution of $\mathbf{1a}^-$, along with the $Ag/AgNO_3$ reference electrode and the Pt mesh working electrode (6.25 × 2.25 cm), were placed into one side of a two-chambered flask, and separated by sintered glass. The other side had the remainder of the electrolyte solution, along with the Pt mesh basket (1 cm diameter × 3 cm) with a 6 × 2.65 cm piece of Pt mesh rolled up inside to increase the surface area. A controlled potential electrolysis was run for 30 min at 1200 mV, following the literature procedure [20]. The electrolysis was monitored using UV–Vis spectroscopy, with the characteristic peak at 800 nm, along with the blue color of the solution, being present as early as 10 min into the electrolysis. After the complete conversion of $\mathbf{1a}^-$ to $\mathbf{1a}^0$, a solution of $V(CO)_6$ (2.5 mg, 11.4 μmol), dissolved in minimal CH_2Cl_2, was then added to the blue solution of $\mathbf{1a}^0$, turning it immediately brown and forming a precipitate. The black precipitate was filtered, and the filtrate was clear. *Anal.* Calc for $V[Ni(S_2C_2(CN)_2)_2]_2 \cdot 2.7(CH_2Cl_2) \cdot 0.36[NBu_4][PF_6]$ C, 26.76; H, 1.69; N, 10.67. Found: C, 26.68; H, 2.07; N, 10.91%. IR (KBr: cm^{-1}): $\nu_{C\equiv N}$ 2202 cm^{-1}.

2.3. Mn^{II}[Co(mnt)$_2$]

A 300-mL round bottom flask was charged with 218.3 mg (0.265 mmol) of $[NBu_4]_2[Co(mnt)_2]$, to which 200 mL of CH_2Cl_2 was added. The flask was outfitted with a stir bar, a Soxhlet extractor,[1] a double walled condensing column, and a vacuum adaptor. $[Mn(NCMe)_6][BF_4]_2$ (130.0 mg, 0.273 mmol) was placed into a thimble and then into the Soxhlet extractor. With stirring, the flask was gentled heated until refluxing, and extracted overnight. The solution was then cooled to room temperature and filtered. The fine black precipitate was dried under vacuum for one hour and then placed into a thimble and into a Soxhlet extractor with the same set-up as described above, except that 1,2-dichloroethane was the extracting solvent. The system was allowed to reflux for 2–3 days, then brought to room temperature, and the solids were collected from the thimble (yield 96%). *Anal.* Calc. for $Mn[Co(mnt)_2] \cdot 1.1(C_2H_4Cl_2)]$: C, 24.34; H, 0.94; N, 11.14. Found: C, 24.33; H, 0.99; N, 10.76%. IR (KBr: cm^{-1}): $\nu_{C\equiv N}$ 2209 cm^{-1}.

The rest of the series was made in a similar manner, taking care to keep a 1:1 molar ratio between the $[M^{III}(mnt)_2]^{2-}$ anion and the M^{II} cation {yield: ⩾95% for $[NBu_4]_{0.5}[Ni(Cu(mnt)_2)_{1.25}] \cdot 0.5MeCN$: C, 32.24; H, 2.78; N, 11.87. Found: C, 32.29; H, 2.76; N, 11.83%. IR (KBr: cm^{-1}): $\nu_{C\equiv N}$ 2238sh, 2220 cm^{-1}; $Mn[Cu(mnt)_2]$: C,

[1] Soxhlet extraction was used due to the limited solubility of some of the cations used. Although readily soluble in MeCN, along with the anions, use of MeCN could lead to possible its coordination, and undesired products. Instead, non-coordinating dichloromethane was used as the $[M(mnt)_2]^{2-}$ salts are readily soluble in it. However, the cations have different degrees of solubility; from easily soluble $[Cr(NCMe)_6][B(C_6H_3(CF_3)_2)_4]_2$ and $[Ni(NCMe)_6][BF_4]_2$ to poorly soluble for the $[V(NCMe)_6][BF_4]_2$ and $[Co(NCMe)_6][BF_4]_2$. Thus, the reaction could take a day to a week to complete, or, in the later cases of the $[V(NCMe)_6]^{2+}$ and $[Co(NCMe)_6]^{2+}$, completion does not occur. However, product was recovered from all reactions, except for the reaction of $[Co(mnt)_2]^{2-}$ with $[V(NCMe)_6][BF_4]_2$. After collecting the product via filtration, it was dried under vacuum for 1 h. Each product was cleaned by placing the solid into a Soxhlet extractor, and using dichloroethane as the solvent. This redissolves any counter-ions, but not the compound, leading to the reduction of any $[NBu_4]^+$, $[BF_4]^-$, or $[B(C_6H_3(CF_3)_2)_4]_2^-$ peaks that may have been present in the initial IR spectra.

2.4. Physical properties

Thermal properties were studied on a TA Instruments Model 2050 thermogravimetric analyzer (TGA) equipped with a TA-MS Fison triple filter quadrupole mass spectrometer, to identify gaseous products with masses less than 300 amu. This instrument is located in a Vacuum Atmospheres DriLab under nitrogen to protect air and moisture sensitive samples. Samples were placed in an aluminum pan and heated at 20 °C/min under a continuous 10-mL/min-nitrogen flow. The 2–300 K magnetic susceptibility was determined on a Quantum Design MPMS-5XL 5 T SQUID (sensitivity = 10^{-8} emu or 10^{-12} emu/Oe at 1 T) as previously described [21]. In addition to correcting for the diamagnetic contribution from the sample holder, core diamagnetic corrections based on summing Pascal's constants were used. Infrared spectra (600–4000 ± 1 cm^{-1}) were obtained on a Bruker Tensor 37 FT IR-40 spectrophotometer as KBr pellets. Elemental analyses were performed by Complete Analysis Laboratories Inc. of Parsippany, NJ.

3. Results and discussion

The addition of 0.5 equiv. of $V^0(CO)_6$ to in situ generated Ni(mnt)$_2^0$ results in an immediate precipitate, **2**. The IR of **2** shows a characteristic stretch of the CN group [ν_{CN} at 2202 cm^{-1}], which is broadened with respect to **1a**$^-$, indicative of coordination through the CN group. There is also an absence of a ν_{CO} absorption that would be found for a vanadium carbonyl. Peaks characteristic of $[NBu_4]^+$ as well as $[PF_6]^-$ are also present. Hence, the supporting electrolyte is occluded upon the rapid precipitation of **2**. This is also noted as the elemental analysis that fits $V^{II}\{[Ni(mnt)_2]^-\}_2 \cdot 2.7(CH_2Cl_2) \cdot 0.36[NBu_4][PF_6]$.

Evidence that the reaction products were of M′[M-(mnt)$_2$] composition were obtained from line broadening and shifts in the position of the ν_{CN} absorption. This is indicative of coordination through the nitrile on the $[M'(mnt)_2]^{2-}$. The IR spectra also showed an absence of $[BF_4]^-$, coordinated MeCN and $[B(C_6H_3(CF_3)_2)_4]^-$ peaks, indicating that these were not present in the final product, and that the desired metathesis reaction occurred.

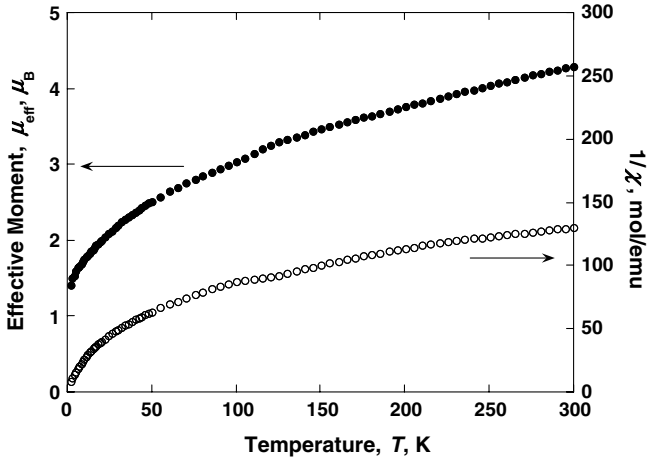

Fig. 1. The 5–300 K $\mu_{eff}(T)$ and $\chi^{-1}(T)$ for V[Ni(mnt)$_2$]$_2 \cdot 2.7(CH_2Cl_2) \cdot 0.36[NBu_4][PF_6]$ (**2**).

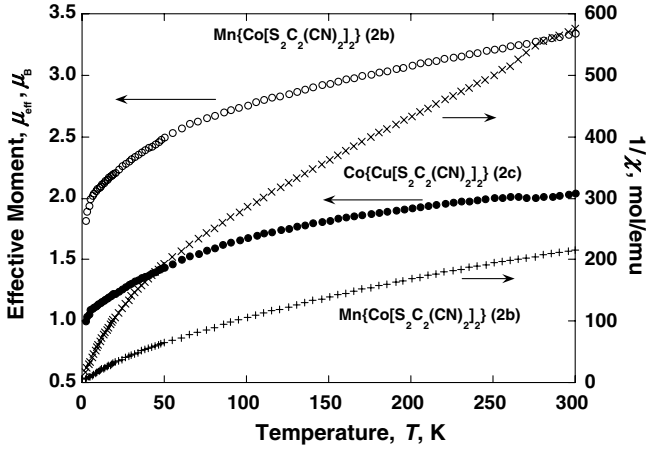

Fig. 2. The 5–300 K $\mu_{eff}(T)$ and $\chi^{-1}(T)$ for Mn[Co(mnt)$_2] \cdot 1.10(C_2H_4Cl_2)$ (○, +), and Co[Cu(mnt)$_2] \cdot 1.10(MeCN) \cdot 0.2(C_2H_4Cl_2)$ (●, ×).

The 5–300 K magnetic susceptibility, $\chi(T)$, was determined and is reported as $\mu_{eff}(T)[\equiv(8\chi T)^{1/2}]$, and $\chi^{-1}(T)$, Figs. 1 and 2, for V[Ni(mnt)$_2$]$_2$ and M′[M(mnt)$_2$] (M = Co, M′ = Mn; M = Cu, M′ = Co), respectively. For **2** $\mu_{eff}(T)$ increases with increasing temperature and at 300 K is 4.3 μ_B and still increasing. This is in accord with expected moment of 4.58 μ_B for uncoupled $S = 3/2$ V(II) and two $S = 1/2$ $[Ni(mnt)_2]^{\bullet-}$ spin sites.[2] The reduced moment is indicative of antiferromagnetic coupling that is expected. The $\mu_{eff}(T)$ above 160 K could be fit to the Curie–Weiss expression, $\chi \propto (T-\theta)^{-1}$, with $\theta \sim -400$ K indicative of strong antiferromagnetic coupling. Magnetic ordering, however, is not

[2] The alternative formulations of either $V^{III}[Ni(mnt)_2]^{2-}[Ni(mnt)_2]^-$ or $V^{IV}\{[Ni(mnt)_2]^{2-}\}_2$ would have room temperature moments of 3.31 and 1.73 μ_B, respectively. These are too low with respect to the observed value.

evident from either the magnetization, or in-phase, $\chi'(T)$, and out-of-phase, $\chi''(T)$, AC susceptibility studies.

For Mn[Co(mnt)$_2$] and Co[Cu(mnt)$_2$], $\mu_{eff}(T)$ increases with increasing temperature and is 3.36 μ_B at 300 K for Mn[Co(mnt)$_2$], and 2.00 μ_B at 250 K for Co[Cu(mnt)$_2$], and still increasing. This is in accord with uncoupled $S = 5/2$ Mn(II) and $S = 1/2$ [Co(mnt)$_2$]$^{2-}$ spins for Mn[Co(mnt)$_2$], and $S = 3/2$ Co(II) and $S = 1/2$ [Cu(mnt)$_2$]$^{2-}$ spins for Co[Cu(mnt)$_2$]. The reduced moment is indicative of antiferromagnetic coupling that is expected. The $\mu_{eff}(T)$ above 100 K for Mn[Co(mnt)$_2$] and 145 K for Co[Cu(mnt)$_2$] could be fit to the Curie–Weiss expression with $\theta \sim -115$ and -100 K, respectively, indicative of strong antiferromagnetic coupling for Mn[Co(mnt)$_2$] and Co[Cu(mnt)$_2$], respectively. None of the compounds showed evidence of magnetic ordering. Similar results are observed for the other members of these families.

Hence, unlike M[TCNE]$_x$ (M = V, Mn, Fe, Co, Ni) which magnetically order as a ferrimagnets at temperatures as high as room temperature (M = V), neither V[Ni(mnt)$_2$]$_2$ nor M$^{II'}$[M(mnt)$_2$] as well as M[Ni(mnt)$_2$]$_2${M = V, Cr, Mn, Fe, Co, Ni} [22a] magnetically order. Nonetheless, V[Ni(mnt)$_2$]$_2$ and M$^{II'}$[M(mnt)$_2$] {as well as M[Ni(mnt)$_2$]$_2$ {M = V, Cr, Mn, Fe, Co, Ni} exhibit significant antiferromagnetic coupling. We attribute the poor spin coupling of the bridging $S = 1/2$ [Ni(mnt)$_2$]$^{\bullet -}$ or [M(mnt)$_2$]$^{\bullet 2-}$ (M = Co, Cu) to the low spin density of the terminal N's (~1%) [14] for [Ni(mnt)$_2$]$^{\bullet -}$ and less for [Co(mnt)$_2$]$^{\bullet 2-}$ [22b] with respect to [TCNE]$^{\bullet -}$ (~13%) [23].

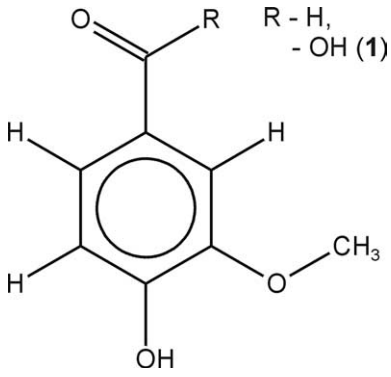

Scheme 1. Two lignin model compounds vanillin ($C_8H_8O_3$) and vanillic acid ($C_8H_8O_4$) (**1**).

on benzene ring, present in simple lignin model compounds (Scheme 1).

A dinuclear heterocarboxylate copper *paddle-wheel* compound with vanillic and acetic acid anions $[Cu_2(C_8\text{-}H_7O_4)_2(O_2CCH_3)_2(CH_3OH)_2]$ was synthesized and characterized. It was compared to a related homocarboxylate complex $[Cu_2(C_8H_7O_4)_4(H_2O)_2]$.

2. Experimental

2.1. Synthesis

All starting compounds and solvents were used as purchased, without any further purification. The single crystals of vanillic acid ($C_8H_8O_4$) (**1**), suitable for X-ray analysis, were obtained by a recrystallization from ethylacetate.

$[Cu_2(C_8H_7O_4)_2(O_2CCH_3)_2(CH_3OH)_2]$ (**2**), $[Cu_2(C_8H_7O_4)_2(O_2CCH_3)_2(H_2O)_2]$ (**2a**): Vanillic acid (0.061 g; 0.36 mmol) was added to a hot methanol solution (10.0 mL) of $[Cu_2(O_2CCH_3)_4(H_2O)_2]$ (0.040 g; 0.10 mmol). Next day, a dark green precipitate of **2** was filtered off, washed three times with methanol and then left for a day on air, yielding **2a**. Yield 80%. *Anal*. Calc. for $C_{20}H_{24}Cu_2O_{14}$ (**2a**): C, 39.0; H, 3.93; Cu, 20.7. Found: C, 38.9; H, 4.17; Cu, 20.7%. UV–Vis–NIR (DMSO) λ_{max}, 260, 290, 450(sh), 720 nm; (mull) λ_{max}, 230, 265, 290, 360(sh), 695 nm. IR, 3420 ν(O–H), 1623 $\nu_{as}(CO_2)$, 1602, 1591 $\nu_{as}(CO_2)$, 1518, 1417 $\nu_s(CO_2)$, 1398 $\nu_s(CO_2)$, 780 cm^{-1}. EPR (298 K), $g_\perp = 2.09$, $g_\parallel = 2.36$, $D = 0.329\ cm^{-1}$, $2J = 278\ cm^{-1}$; (116 K), $g_\perp = 2.07$, $g_\parallel = 2.36$, $A_{z1} = 5.6$ mT, $D = 0.326\ cm^{-1}$, $2J = 237\ cm^{-1}$. μ_{eff} (298 K), 1.48 BM. The single crystals of **2**, suitable for X-ray analysis, were obtained by a similar procedure, but at lower concentration of the starting compounds. The crystals were frozen immediately after removal from mother-liquid, to prevent their decomposition due to evaporation of methanol and its probable replacement with water molecules (elemental analysis, IR).

$[Cu_2(C_8H_7O_4)_4(H_2O)_2]$ (**3**): The starting compounds and a procedure was different as already described [8]. 0.160 g (0.40 mmol) of $[Cu_2(O_2CCH_3)_4(H_2O)_2]$ was dissolved in 10 mL of hot water. The solution was added to 0.244 g (1.45 mmol) of vanillic acid. Green crystallites were filtered off next day and then dried one day in a desiccator. Yield 80%. *Anal*. Calc. for $C_{32}H_{32}Cu_2O_{18}$ (**3**): C, 46.2; H, 3.88; Cu, 15.3. Found: C, 46.0; H, 4.18; Cu, 15.2. UV–Vis–NIR (DMSO) λ_{max}, 260, 290, 450(sh), 720 nm; (mull) λ_{max}, 230, 265, 300, 380(sh), 690 nm. IR, 3456 ν(O–H), 1615, 1596, 1570 $\nu_{as}(CO_2)$, 1518, 1455, 1426 $\nu_s(CO_2)$, 1394 $\nu_s(CO_2)$, 774 cm^{-1}. EPR (298 K), $g_x = 2.05$, $g_y = 2.06$, $g_z = 2.34$, $D = 0.306\ cm^{-1}$, $E = 0.0025\ cm^{-1}$, $2J = 241\ cm^{-1}$; (116 K), $g_x = 2.05$, $g_y = 2.06$, $g_z = 2.35$, $A_{z1} = 7.0$ mT, $D = 0.303\ cm^{-1}$, $E = 0.0030\ cm^{-1}$, $2J = 231\ cm^{-1}$. μ_{eff} (298 K), 1.56 BM. The single crystals of **3**, suitable for X-ray analysis, were obtained by a similar procedure, but at lower concentration of the starting compounds.

2.2. X-ray structure analysis

Details of the crystal data, data collection and refinement parameters for **1**, **2** and **3** are listed in Table 1. The selected distances and angles are presented in Table 2. A colorless plate of compound **1** was glued, while green prisms of compounds **2** and **3** were greased on a glass thread. The diffraction data for **1**–**3** were collected on a Nonius Kappa CCD diffractometer with graphite monochromated Mo Kα radiation. A Cryostream Cooler (Oxford Cryosystems) was used for cooling the samples of **2** and **3**. The data were processed using DENZO [13]. Structures of **1** and **2** were solved by direct methods using SIR97 [14] and refined using XTAL 3.6 [15] by a full-matrix least-squares procedure based on *F*. Structure of **3** was solved by direct methods implemented in SHELXS-97 [16] and refined by a full-matrix least-squares procedure based on F^2 (SHELXL-97) [17]. All of the non-hydrogen atoms were refined anisotropically. The positions of hydrogen atoms in **1** and **2** were obtained from the difference Fourier maps. Positional parameters of H atoms for **1**, while positional and isotropic displacement parameters of H atoms for **2**, were refined. The water hydrogen atoms in **3** were visible in the last stages of the refinement and were refined freely, while the other hydrogen atoms were included in the model at geometrically calculated positions and refined using a riding model.

2.3. Physical measurements

Metal analysis was carried out electrogravimetrically with Pt electrodes. C,H analysis was performed with a Perkin–Elmer, Elemental Analyzer 2400 CHN. The magnetic susceptibility of the substances was determined at room temperature by powdered samples with a Sherwood Scientific MSB-1 balance. Diamagnetic corrections were estimated from Pascal's constants [18]. Infrared spectra were measured on mineral mulls, using a Perkin–Elmer FT-IR 1720X spectrometer. Electronic spectra were recorded as nujol mulls and DMSO solutions with a Perkin–Elmer

UV/Vis/NIR spectrometer Lambda 19. EPR spectra of the powdered samples were recorded by a Bruker ESP-300 spectrometer, operating at X-band (9.59 GHz) at room temperature and at 116 K. The values of parameters g, A, D, E and $2J$ were calculated directly from the signal positions in the spectra [19–21].

3. Results and discussion

3.1. The structure of free vanillic acid $C_8H_8O_4$ (1)

Two molecules of free vanillic acid are strongly H-bonded by two mutual H-bonds between their carboxylate

groups (O1–H···O2′ 2.642(3) Å), thus forming a centrosymmetrical dimeric unit (Fig. 1), as often found at carboxylic acids. Another H-bond is intramolecular, formed by the hydroxy group and the methoxy group (O4–H···O3 2.631(3) Å). A comparison to the structure of related lignin model compound vanillin (Scheme 1) [22] reveals significantly different intermolecular H-bonding, due to the aldehyde group instead of the carboxylic group. The vanillin molecules are packed in chains, where strong H-bonds connect aldehyde and phenolato groups on positions 1 and 4 of the benzene ring (O–H···O 2.712(2)–2.743(3) Å).

3.2. The structure of bis(μ-(4-hydroxy-3-methoxybenzoato-O:O′))bis(μ-(acetato-O:O′))bis(methanol) dicopper(II) (2)

The centrosymmetric *paddle-wheel* central core $[Cu_2(C_8H_7O_4)_2(O_2CCH_3)_2(CH_3OH)_2]$ (**2**) is of copper(II) acetate hydrate type, however with two different carboxylates (two acetates and two vanillic acid anions) in *trans* orientation, while methanol molecules occupy the apical positions (Fig. 2). The phenolate group is involved in all three hydrogen bonds, either intra-molecularly to methoxy oxygen atom (O4–H···O3 2.707(2) Å), or inter-molecularly to methanol molecule (O7–H···O4 2.735(2) Å) and acetate group (O4–H···O6 2.751(2) Å).

3.3. The structure of tetrakis(μ-(4-hydroxy-3-methoxybenzoato-O:O′))bis(aqua) dicopper(II) (3)

The structure of complex $[Cu_2(C_8H_7O_4)_4(H_2O)_2]$ (**3**) was already reported [8], but was redetermined due to unavailability of the atom positions from the CSD [25]. Complex **3** is of $[Cu_2(O_2CCH_3)_4(H_2O)_2]$ type with four identical carboxylate ligands. Similar pattern, as in **2**, is found in the vanillic acid anion, with the phenolate group involved in all H-bonds and an intra-molecular H-bond between hydroxy and methoxy groups. Each hydroxy group is H-bonded also inter-molecularly to axially coordinated water molecules (O6–H1···O10 2.876(6) Å, O6–H2···O9 2.958(6) Å), giving two H-bonds with each water molecule.

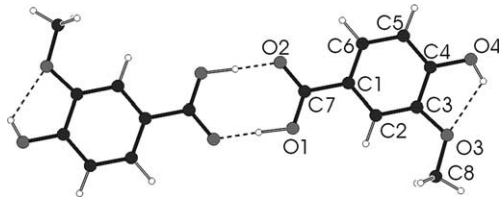

Fig. 1. The dimeric structure of free vanillic acid with two hydrogen-bonds between the carboxylic groups of the vanillic acid molecules [23,24].

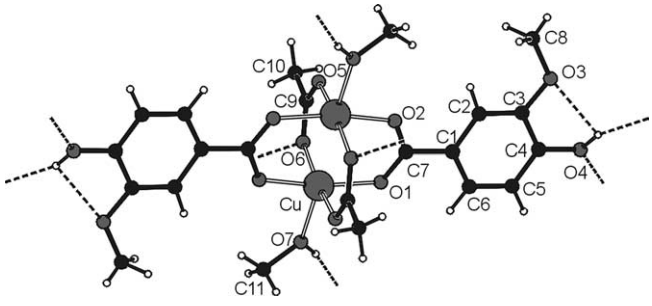

Fig. 2. Two types of carboxylate anions in a dinuclear copper(II) tetracarboxylate complex $[Cu_2(C_8H_7O_4)_2(O_2CCH_3)_2(CH_3OH)_2]$ (**2**) [23,24]. The intermolecular H-bonds are connecting the phenolate group (O4) with the acetate anion (O6) and methanol molecules (O7).

Two H-bonds (**3**) to the axial ligand instead of one (**2**) and better volatility of methanol (**2**) than water (**3**) may be the main reasons for better stability of **3** than **2** outside mother-liquid. Interestingly, only two vanillic acid anions in **3** are forming another H-bond to carboxylate oxygen atom (O10–H10···O5 2.873(5) Å), while for another two, no such connections were found, probable due to steric reasons. This is very probable reason that only two vanillic acid anions are replaced with acetates in **2**. Small acetates enable stronger (shorter) inter-molecular H-bonds, possibly due to less steric hindrance (see Table 2). Additionally, stronger stabilization in **3** than in **2** is found also in π-stacking interaction (mean inter-planar separation 3.30 Å (3.37 Å) for **3** (**2**), centroid···centroid distance 3.94 Å (4.22 Å) for **3** (**2**)). It seems that the decisive factors for the competition between the homocarboxylate (**3**) and heterocarboxylate (**2**) are inter-molecular interactions. Either weaker H-bonds, stronger π-stacking and two H-bonds to the axial ligand (**3**), or stronger H-bonds, weaker π-stacking and one H-bond to the axial ligand (**2**).

3.4. Spectroscopic and magnetic analysis

Although the compound **2** is not stable outside mother-liquid, yielding **2a**, the μ_{eff} 1.48 BM (**2a**) suggests only partial decomposition of **2** and a retainment of the dinuclear tetracarboxylate central core in the compound **2a** (1.55 BM for **3**). This is in agreement with almost identical solution or mull UV–Vis–NIR spectra for **2a** and **3**, respectively, and with EPR spectra, where typical signals (H_{z1}, $H_{\perp 2}$, H_{z2} [19], Fig. 3) for the triplet state $S = 1$ of $[Cu_2(O_2CCH_3)_4(H_2O)_2]$ type of compounds may be observed at room temperature and at 116 K (see Section 2). In the low temperature EPR spectra, the splitting of a H_{z1} signal to septet, $H_{\perp 2}$ to H_{x2} and H_{y2} and an appearance of the signal of mononuclear species H_{mono} at 330 mT were noticed. Such phenomena are often found in the low temperature spectra of the dinuclear copper(II) tetracarboxylates. Differences in the H_{z1} splitting, the hyperfine constant A_{z1} (5.6 mT; 7.0 mT), and the $H_{\perp 2}$ separation for the spectra of **2a** and **3** may be related to a different role of the bridging anions present in both complexes, and/or replacement of the apical ligand (**2** → **2a**) that might not enable full equivalency of both Cu ions in the dinuclear unit after rearrangement. Close to the H_{z1} signal in the spectra of **3**, an additional distinctive signal may be observed at 80 mT (Fig. 3). This signal is assigned as $H_{\perp 1}$ (H_{x1}, H_{y1}) that is observable, since $D < h\nu$, and may be described by the equations [19–21]:

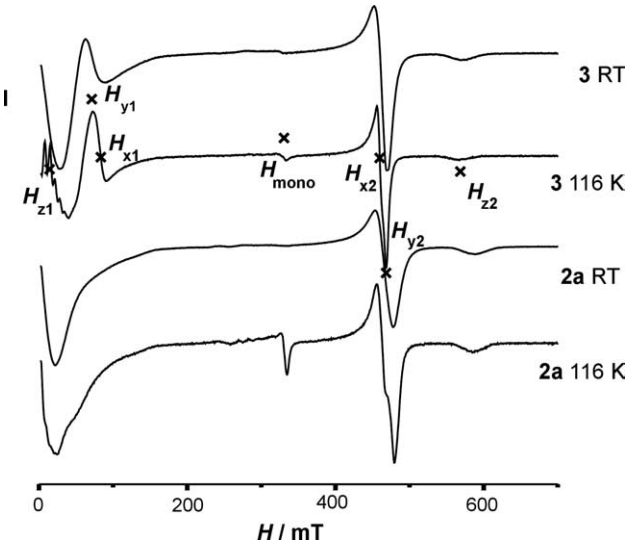

Fig. 3. Three signals H_{z1}, $H_{\perp 2}$ (H_{x2}, H_{y2}) and H_{z2}, characteristic for $[Cu_2(O_2CCH_3)_4(H_2O)_2]$ type of compounds for **2a** and **3**, and an additional signal $H_{\perp 1}$ (H_{x1}, H_{y1}) at 80 mT, in the spectra of **3** at room temperature (RT) and at 116 K.

$$H_{x1}^2 = \left(\frac{g_e}{g_x}\right)^2 (H_0 - D' + E')(H_0 + 2E'), \quad (1)$$

$$H_{y1}^2 = \left(\frac{g_e}{g_y}\right)^2 (H_0 - D' - E')(H_0 - 2E'), \quad (2)$$

$$H_0 = h\nu/g_e\beta, \quad D' = D/g_e\beta, \quad E' = E/g_e\beta.$$

Such signal and its assignment was, up to our knowledge, so far not reported for dicopper(II) tetracarboxylates, but only for $[Cu_2(O_2CCH_3)_2L_2(dmf)_2]$, with two O–C–O and two N–C–N bridges in Cu tetracarboxylate analogue [26]. Similar signal was noticed also in the spectra of copper(II) dinuclear complex with four O–C–N bridges in $[Cu_2(chp)_4]$ [27]. The partial coordination sphere in these two complexes is distorted square-planar CuO_2N_2 (only coordination atoms from bridges and without the axial ligand). The presence of the $H_{\perp 1}$ signal for these two tetracarboxylate analogues is in agreement with low D values (0.265; 0.275 $cm^{-1} \Rightarrow D < h\nu$). Structurally, the complex **3** is related to these two complexes by a relatively large torsion angle 6.0° for two *trans* O–Cu···Cu–O moieties (both O atoms are from the same carboxylate group; Fig. 4). For $[Cu_2(chp)_4]$, the O–Cu···Cu–N torsion angle is 5.1–8.6°, while for $[Cu_2(O_2CCH_3)_2L_2(dmf)_2]$, O–Cu···Cu–O 3.4° and N–Cu···Cu–N 0.9°, respectively. Comparable angles for **2** and for $[Cu_2(O_2CCH_3)_4(H_2O)_2]$ are significantly smaller (<1.2°, <2°) [28]. The Cu···Cu distances for both complexes **2** and **3** (2.608(1), 2.611(1) Å) are similar and typical for dicopper tetracarboxylates [29], therefore this distance can not be directly correlated to the appearance of the $H_{\perp 1}$ signal in the EPR spectra of **3**.

Since herein, the complex **3** is structurally characterized with **2**, and with **2a** by EPR, this correlation may not be absolutely exact. Maybe some additional information from the EPR spectra of the undecayed **2** (powder inside traces of mother solution) or from the frozen solution spectra could be obtained.

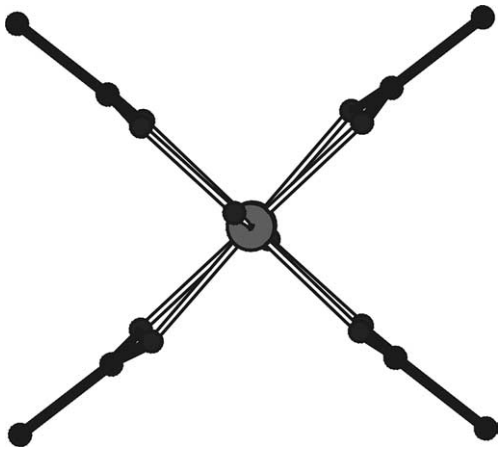

Fig. 4. Torsion in the O–Cu···Cu–O angles in **3** [23–25]. The second central copper ion is positioned behind the first one. All hydrogen atoms and aromatic rings are omitted for clarity.

A broad band at 3600–3300 cm^{-1} in the IR spectrum of **2a** agrees with the presence of water instead of methanol (a narrow band for O–H bond would be expected for **2**). One strong band in the region 1650–1550 cm^{-1} found for **3** (1570 cm^{-1}) and two strong bands in the spectrum of **2a** (1623, 1591 cm^{-1}) are probably due to the asymmetric stretching vibration [30] of one (vanillic acid anion) and two (acetate, vanillic acid anion) types of carboxylate anions in the compounds **2a** and **3**, respectively. Since in $[Cu_2(O_2CCH_3)_4(H_2O)_2]$, an acetate analogue of **3**, $\nu_{as}(CO_2)$ was observed at 1605 cm^{-1} [31], the higher energy band at 1623 cm^{-1} in the spectrum of **2a** is assigned to the acetate, while the 1591 cm^{-1} band to the vanillic acid anion.

4. Concluding remarks

The compounds $[Cu_2(C_8H_7O_4)_2(O_2CCH_3)_2(CH_3OH)_2]$ (**2**) and $[Cu_2(C_8H_7O_4)_4(H_2O)_2]$ (**3**) precipitate from the solution of the same starting compounds $[Cu_2(O_2CCH_3)_4(H_2O)_2]$ and vanillic acid, however in different polar solvent methanol or water for **2** or **3**, respectively. Heterocarboxylate compound $[Cu_2(C_8H_7O_4)_2(O_2CCH_3)_2(CH_3OH)_2]$ (**2**) is unstable outside mother-liquid. Its decomposition is partial, since the central carboxylate cage remains, however water molecules replace the apical methanol molecules. On the other hand, the homocarboxylate compound $[Cu_2(C_8H_7O_4)_4(H_2O)_2]$ (**3**) is stable also in air, probably due to two H-bonds to the axial ligand instead of one (**2**) and less volatile water (**3**) than methanol (**2**). Significant differences were found in the EPR spectra, resulting in an unexpected signal at 80 mT in the spectra of **3**, next to H_{z1}, $H_{\perp 2}$ and H_{z2}, typical for $S = 1$ spin state. This signal is assigned as $H_{\perp 1}$, due to low D axial zero field splitting parameter value ($D < h\nu$). The appearance of this signal is probably related to a relatively large torsion angle O–Cu···Cu–O, found in compound **3**, and not with the Cu···Cu distance

inside a dinuclear molecule. Coordination of the acetates, together with vanillic acid anions, in **2** and **2a**, yields stronger H-bonds and much less torsion in dicopper tetracarboxylate central core than in **3**, and seems to be an appropriate alternative to more extensive H-bonding with the axial ligand and more effective π-stacking in homocarboxylate complex **3**.

Acknowledgments

The financial support of the Ministry of Education, Science and Sport, Republic of Slovenia, through Grants MŠZŠ P-6209-124, P1-0175-103 and X-2000, is gratefully acknowledged. We thank Dr. M. Šentjurc, EPR center, 'Jožef Stefan' Institute, Ljubljana, for EPR spectra.

Appendix A. Supplementary data

The final atomic and geometrical parameters, crystal data and details concerning data collection and refinement for all three compounds have also been deposited with the Cambridge Crystallographic Data Center as supplementary material with the deposition numbers 277423 (**1**), 277424 (**2**) and 277425 (**3**), respectively. These data can be obtained, free of charge via http://www.ccdc.cam.ac.uk/const/retrieving.html. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2005.08.031.

$Ir(F_2HexO/F_2{}^tBuppy)_2(pic)$ complexes, their photophysical behaviors and redox properties, the X-ray single-crystal structure analyses of $Ir(F_2{}^tBuppy)_2(acac)$ and $Ir(F_2{}^tBuppy)_2(pic)$ and the applications of $Ir(F_2{}^tBuppy)_2(pic)$ as a dopant in the emitting layer of an EL device.

2. Experiments

2.1. Materials

$IrCl_3 \cdot 3H_2O$ was purchased from Alfa Aesar, USA, 2,4-difluoroboronic acid, picolinic acid, 1-hexanol and glycerol from Aldrich Chemicals, USA, phosphorousoxytrichloride from FERAK Laborat GMBH, Berlin (west), sodium hydride from Lancaster and the rest of the compounds from Tokyo Kasei Kogyo Co. Ltd., Japan, and all materials were used as received.

2.2. Syntheses

2-Chloropyridine-*N*-oxide, 2-chloro-4-nitropyridine-*N*-oxide and 2-chloro-4-nitro pyridine were prepared by following the methods described in the literature [3]. The synthetic routes of the ligands and the complexes are shown in Scheme 1.

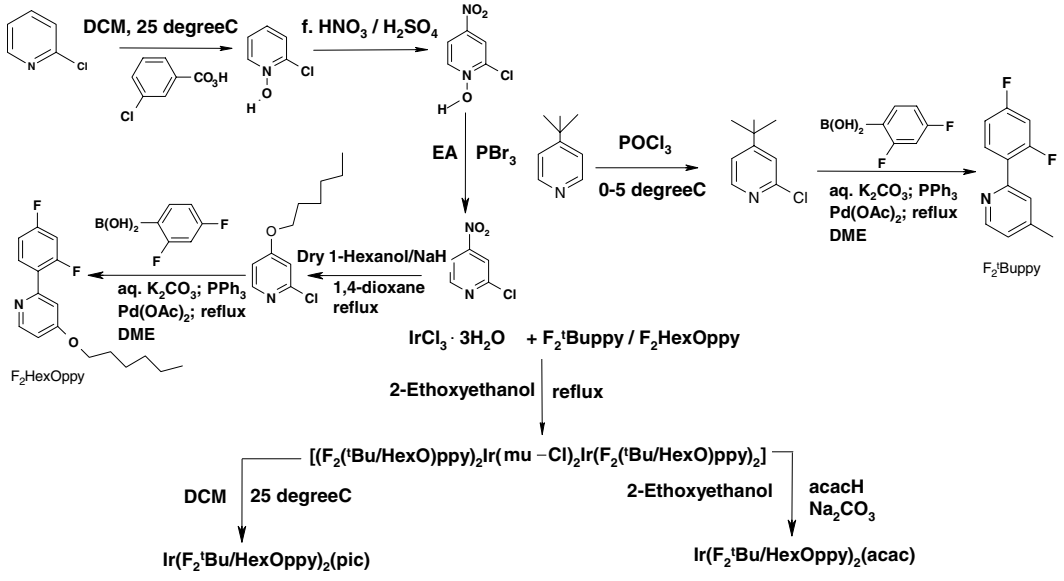
2-Chloro-4-oxyhexylpyridine (yield: 53%): 2-Chloro-4-nitropyridine (1 eq) was added to a mixture of dry 1-hexanol (1.1 eq) and sodium hydride (1.5 eq) in dioxane as the solvent. The resulting solution was refluxed for 12 h. The reaction mixture was cooled to room temperature and poured into water. The organic layer separated out and the aqueous layer was washed by ethyl acetate. The combined organic extracts were dried and evaporated to dryness. The compound was purified by column chromatography. ^1H NMR (300 MHz, $CDCl_3$): δ, 8.07 (d, 1H, $J = 5.7$ Hz), 6.93 (d, 1H, $J = 3.0$ Hz), 6.71 (dd, 1H, $J = 2.1$, 6.0 Hz), 3.98 (dd, 2H, $J = 7.3$, 13.5 Hz), 1.72 (m, 2H), 1.45 (m, 2H), 1.25 (m, 4H), 0.82 (m, 3H). EIMS, m/z: 214, calc. 213.5.

2-(2′,4′-difluorophenyl)-4-oxyhexylpyridine (yield 75%): It was prepared by employing the method described in the literature [3]. 2-Chloro-4-oxyhexylpyridine was taken instead of 2-chloro-4-methoxypyridine as the starting material. ^1H NMR (300 MHz, $CDCl_3$): 8.51 (d, 1H, $J = 5.7$ Hz), 7.98 (m, 1H), 7.26 (t, 1H, $J = 2.1$ Hz), 6.94 (m, 2H), 6.78 (dd, 1H, $J = 2.4$, 5.7 Hz), 4.06 (m, 2H), 1.84 (m, 2H), 1.65 (m, 2H), 1.37 (m, 2H), 1.22 (m, 2H), 0.85 (m, 3H). EIMS, m/z: 221, calc. 221.

2-Chloro-4-*tert*-butylpyridine (yield 60%): 4-*tert*-Butylpyridine was chlorinated by the reaction with phosphorousoxytrichloride at low temperature (0–5 °C), it was stirred for 1h at 0 °C and then a further 1h at room temperature (25 °C). Then the reaction mixture was poured slowly into ice-cold water. The product was extracted by ethyl acetate and purified through column chromatography. ^1H NMR (300 MHz, $CDCl_3$): δ, 8.16 (d, 1H, $J = 6.0$ Hz), 7.27 (d, 2H, $J = 5.1$ Hz), 1.21 (s, 9H). EIMS, m/z: 170, calc. 169.5.

2-(2′,4′-Difluorophenyl)-4-*tert*-butylpyridine (yield 72%): This was prepared by a similar method to that described in the literature [3]. ^1H NMR (300 MHz, $CDCl_3$): δ, 8.60 (d, 1H, $J = 5.1$ Hz), 7.94 (dd, 1H, $J = 2.1$, 8.7 Hz), 7.72 (s, 1H), 7.25 (dd, 1H, $J = 1.8$, 5.4 Hz), 6.93 (m, 2H), 1.28 (s, 9H). EIMS, m/z: 247, calc. 247.

$(F_2{}^tBuppyppy)_2Ir(\mu\text{-}Cl)Ir(F_2{}^tBuOppyppy)_2$ (yield 70–75%): A solution of $IrCl_3 \cdot 3H_2O$ (1 mmol) and 2-(2′,4′-difluorophenyl)-4-methoxypyridine (3 mmol) in 2-ethoxyethanol (30 ml) was refluxed for 24 h. The pale green mixture was cooled to room temperature and 20 ml of 1 M HCl was added to precipitate the product. The mixture was filtered and washed with 100 ml of 1 M HCl, followed by 50 ml of methanol and then dried. The prod-



Scheme 1.

uct was obtained as a light green powder. ^{1}H NMR (300 MHz, $CDCl_3$): 9.04 (d, 4H, $J = 6.0$ Hz), 8.33 (s, 4H), 6.87 (d, 4H, $J = 6.0$ Hz), 6.32 (t, 4H, $J = 9.6$ Hz), 5.16 (d, 4H, $J = 7.2$ Hz), 1.58 (s, 36H). FABMS: *m/z*: 1439, fragmented masses, 1403 (–Cl), 1159 (–1 ligand); Calc. 1439.

$(F_2HexOppyppy)_2Ir(\mu\text{-}Cl)Ir(F_2HexOppy)_2$ (yield 70–75%): This has been synthesized by following the same method as described above. ^{1}H NMR (300 MHz, $CDCl_3$): 8.90 (d, 4H, $J = 5.7$ Hz), 7.79 (s, 4H), 6.35 (m, 8H), 5.41 (d, 4H, $J = 7.5$ Hz), 4.21 (d, 8H, $J = 6.0$ Hz), 2.05 (s, 8H), 1.69 (s, 8H), 1.31 (s, 16 H), 0.99 (s, 12H). FABMS: *m/z*: 1615, fragmented masses, 808 (–IrCl(ligand)$_2$), 773 (–Cl), calc. 1615.

$Ir(F_2HexOppy)_2(acac)$ (yield 80%) (**1a**) [1e,4]. $(F_2HexOppy)_2Ir(\mu\text{-}Cl)Ir(F_2HexOppy)_2$ (1 mmol), acetylacetone (3 mmol) and sodium carbonate (10 mmol) were mixed in 10 ml of 2-ethoxyethanol. The mixture was refluxed under nitrogen for 12 h. The reaction mixture was then cooled and the pale green precipitate was filtered off. The product was washed by methanol several times, followed by hexane. Then it was recrystallised from a mixture of dichloromethane and methanol (1:1). ^{1}H NMR (300 MHz, $CDCl_3$): 8.17 (d, 1H, $J = 6.3$ Hz), 7.73 (s, 1H), 6.73 (s, 1H), 6.32 (d, 1H, $J = 11.7$ Hz), 5.72 (d, 1H, $J = 6.0$ Hz), 5.22 (s, 1H), 4.15 (s, 2H), 1.87 (m, 8H), 1.39 (m, 6H), 0.93 (s, 3H). FABMS: *m/z*: 871, fragmented masses, 771 (–acetylacetonate); Calc. 871.

$Ir(F_2{}^tBuppy)_2(acac)$ (yield 80%) (**2a**). This has been prepared by adopting a similar method as described above. ^{1}H NMR (300 MHz, $CDCl_3$): 8.28 (m, 4H), 7.22 (d, 2H, $J = 6.0$ Hz), 6.32 (t, 2H, $J = 10.8$ Hz), 5.66 (d, 2H, $J = 8.4$ Hz), 5.24 (s, 1H), 1.81 (s, 6H), 1.44 (s, 18H), fragmented masses, 684 (–acetylacetonate); FABMS: *m/z*: 783, calc. 783.

$Ir(F_2HexOppy)_2(pic)$ (yield 88%) (**1b**) [1e,4]. 2.2 mmol of picolinic acid was added to a solution of 0.8 mmol of $(F_2{}^tBuppy)_2Ir(\mu\text{-}Cl)Ir(F_2{}^tBuppy)_2$ in 60 ml of dichloromethane at ambient temperature. The mixture was refluxed under nitrogen in an oil bath for 16 h. The reaction mixture was cooled to room temperature and a pale yellow precipitate was filtered off. The pure product was obtained by flash chromatography. ^{1}H NMR (300 MHz, $CDCl_3$): 8.44 (s, 1H), 8.30 (d, 1H, $J = 6.3$ Hz), 7.90 (s, 1H), 7.73 (m, 3H), 7.38 (s, 1H), 7.14 (s, 1H), 6.69 (s, 1H), 6.40 (m, 3H), 5.88 (d, 1H, $J = 8.4$ Hz), 5.65 (d, 1H, $J = 7.8$ Hz), 4.09 (s, 4H), 1.82 (s, 4H), 1.47 (s, 4H), 1.29 (s, 8H), 0.91 (s, 6H). FABMS: *m/z*: 894, fragmented masses, 772 (–picolinate); Calc. 894.

$Ir(F_2{}^tBuppy)_2(pic)$ (yield 92%) (**2b**). This has been synthesized by following the method as described above. ^{1}H NMR (300 MHz, $CDCl_3$): 8.59 (d, 1H, $J = 4.2$ Hz), 8.29 (m, 3H), 8.24 (s, 1H), 7.77 (s, 1H), 7.41 (s, 1H), 7.17 (d, 1H, $J = 4.2$ Hz), 7.00 (d, 1H, $J = 6.0$ Hz), 6.45 (m, 2H), 5.87 (d, 1H, $J = 9.0$ Hz), 5.57 (d, 1H, $J = 8.1$ Hz), 5.30 (s, 1H), 1.38 (s, 18H). FABMS: *m/z*: 806, fragmented masses, 685 (–picolinate), 651 (–Cl); Calc. 806.

$Ir(F_2MeOppy)_2(acac)$ (**3a**) and $Ir(F_2MeOppy)_2(pic)$ (**3b**). The syntheses of these complexes have been described in our previous paper [3].

$Ir(F_2ppy)_2(acac)$ (**4a**) and FIrpic (**4b**). The syntheses of these complexes have also been described previously [5].

2.3. Crystallography

Single-crystal diffraction data for $Ir(F_2{}^tBuppy)_2(acac)$ and $Ir(F_2{}^tBuppy)(pic)$ were collected on a Bruker SmartCCD diffractometer equipped with a normal focus, 3 kW sealed-tube X-ray source ($\lambda = 0.71073$ Å). The intensity data were collected in the ω scan mode (width of 0.3/° frame) and corrected for *Lp* and absorption effects by using the SAINT [6] program. Cell refinement and data reduction were carried out using the program Bruker SHELXTL [7] and the crystal structure was solved by direct methods using the SHELXTL [7] version 5.1 software packages. The structure was further refined by full-matrix least-square methods based on F^2 using SHELXTL version 5.1 [7]. Positions of non-hydrogen atoms were refined anisotropically, whereas the hydrogen positions were not refined.

2.4. Optical measurements and composition analyses

The ultraviolet–visible (UV–Vis) spectra of the phosphorescent iridium(III) complexes were measured on an UV–Vis spectrophotometer (Agilent Model 8453) and corrected for background due to solvent absorption. Photoluminescence (PL) spectra were carried out with a spectrophotometer (Jobin-Yvon Spex, Model Fluorolog-3). Emission quantum yields were measured by the method of Demas and Crosby [8] using *fac*-$Ir(ppy)_3$ as a reference [9]. NMR spectra were recorded on Varian 300 MHz. MS spectra (EI and FAB) were taken by micromass TRIO-2000. Cyclic voltammetry (CV) analyses were performed using CHI 2.05; dichloromethane was used as the solvent in an inert atmosphere and 0.1 M tetra(*n*-butyl)ammonium tetrafluoroborate was used as the supporting electrolyte. A glassy carbon rod was used as the working electrode, platinum was used as the counter electrode, and a silver wire was used as a pseudo-reference electrode. The TG-DTA analysis was carried out using a thermal analyzer (SEIKO 1TG/DTA Model 200). Luminescence lifetimes were obtained by exponentially fitting the emission decay curves recorded on a Continuum Model NY61 spectrofluorometer.

2.5. OLED fabrication and testing

In the fabrication of OLEDs, organic layers were thermally evaporated onto a glass substrate precoated with an indium-tin-oxide (ITO) layer with a sheet resistance of 20 Ω under high-vacuum. Prior to use, the ITO surface was ultrasonicated in a detergent solution followed by rinsing with deionized (DI) water, dipped into acetone, trichloroethylene and 2-propanol, and then degreased with a vapor of 2-propanol. After degreasing, the substrate was

oxidized and cleaned in a UV-ozone chamber before it was loaded into an evaporator. In a vacuum chamber at a pressure of 10^{-6} Torr, different layers (discussed in the EL discussion) were sequentially deposited onto the substrate to give the device structure. The current–voltage (*I–V*) profiles and light intensity characteristics for the above-fabricated devices were measured in a vacuum chamber of 10^{-6} Torr at ambient temperature using a Keithley 2400 Source Meter/2000 Multimeter coupled to a PR 650 Optical Meter.

3. Results and discussion

3.1. Syntheses

The syntheses of two new cyclometalated ligands, 2-(2′,4′-difluorophenyl)-4-oxyhexylpyridine and 2-(2′,4′-difluorophenyl)-4-*tert*-butylpyridine were carried out. The incorporation of an oxyhexyl group into the pyridyl moiety of 2-(2′,4′-difluorophenyl)-4-pyridine follows an almost similar method as described previously [3], except for step 4, where the nitro substituent was replaced by using dry 1-hexanol and sodium hydride as the base. The oxyhexyl substituent was incorporated into the pyridyl moiety of 2-(2′,4′-difluorophenyl)-4-pyridine in six steps, whereas the *tert*-butyl substituent just took two steps. Syntheses of cyclometalated complexes of iridium(III) were performed as described previously [3] using the oxyhexyl/*tert*-butyl-substituted ligands as the cyclometalated ligands and acetylacetone/picolinic acid as ancillary ligands. The thermogravimetric analysis of these complexes showed that the picolinate-Ir complexes are more stable than their corresponding acetylacetonate analogues (decomposition temperature (T_d): **1a**, 268 and **1b** 370; **2a**, 290 and **2b**, 310; **4a**, 216 and **4b** 344 °C) (Fig. 1). It is assumed that the free oxygen atom present in the picolinate of the Ir–picolinate complexes is responsible for making strong intermolecular H-bonding and hence increases the decomposition temperature. This fact is supported by the H-bonding obtained from the crystal structure of **1b**, i.e., O2···H1A′-C1A′ 2.607 Å and 120°.

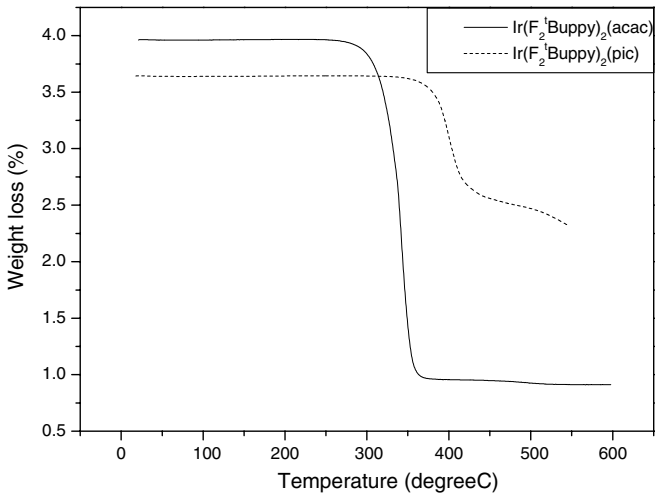


Fig. 1. Thermogravimetric analysis shows the decomposition temperature of [Ir(F_2′Buppy)$_2$(acac)] (**2a**) and [Ir(F_2′Buppy)$_2$(pic)] (**2b**).

3.2. Description of the X-ray structures

ORTEP plots of (F_2′Buppy)$_2$Ir(acac) and (F_2′Buppy)$_2$Ir(pic) molecules are shown in Fig. 2(a) and (b), respectively. Crystallographic data are given in Table 1, and selected bond lengths (Å) and angles (°) for these complexes are presented in Table 2. Single crystals of (F_2′Buppy)$_2$Ir(pic) were of lower quality than those of (F_2′Buppy)$_2$Ir(acac), which is reflected in the poor agreement factor for the (F_2′Buppy)$_2$Ir(pic) complex (Table 1). Both the complexes have octahedral geometry around iridium with *cis*-C,C *trans*-*N*,*N* chelate disposition. The Ir–C and Ir–N bond lengths are within the normal ranges expected for cyclometalated iridium(III) complexes [1b,4]. The Ir–O bond lengths are longer than the mean value of 2.088 Å reported in the Cambridge Crystallographic Database and reflect the large *trans* influence of the phenyl groups. All other bond lengths and angles within the chelate ligands are typical for cyclometalated complexes with ppy and acac/pic ligands bound to iridium(III) [2c,4,10].

3.3. Photoluminescence spectra

Fig. 3(a) and (b) shows mainly the lowest energy absorption bands for the acetylacetonate and picolinate analogues, respectively. The bands observed in the range 350–440 nm can be assigned as intraligand (IL) (π–π*) transitions (ppy^-) and metal-to-ligand charge-transfer (^{1}MLCT) (dπ (Ir) → π* (ppy^-)) transitions. Additionally, the spectra of all these complexes exhibit weaker absorption tails towards lower energy regions (440–480 nm), which may be attributed to triplet metal-to-ligand charge-transfer transitions (^{3}MLCT). As observed in Fig. 3(a) and (b), the picolinate analogues show significantly higher MLCT transitions with respect to their corresponding acetylacetonate analogues. If the comparison is confined to a particular series of complexes, either picolinate or acetylacetonate, the trend of blue-shifting of MLCT states is as follows: unsubstituted complex (FIrpic) < *tert*-butylsubstituted complex < methoxy-substituted complex ∼ oxyhexyl-substituted complex. The observed shift toward higher energy indicates an increase in energy separation between the metal d- and π*-orbitals and the strong electron-releasing effects of the substituents raise the π* orbitals of the cyclometalated ligand. These lowest excited states show solvatochromic effects and are shifted hypsochromically with increasing polarity of the solvents. As shown in Fig. 4(a), the decreasing order of maximum emission wavelength of a thin-film acetylacetonate sample is as follows: **1a** = **3a** > **2a** > **4a**. The same trend has also been observed in the picolinate thin-film analogues (Fig. 4(b)). The results reveal that the strongest electron releasing substituents, methoxy and oxyhexyl groups, shift the emission wave-

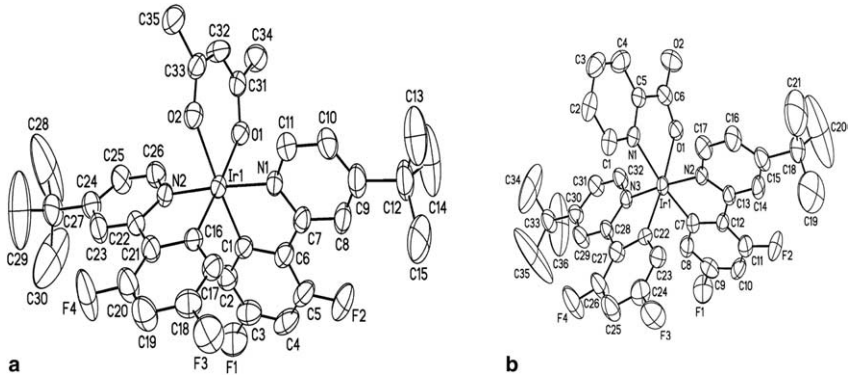

Fig. 2. ORTEP diagrams of: (a) [Ir(F_2'Buppy)$_2$(acac)] (**2a**) and (b) [Ir(F_2'Buppy)$_2$(pic)] (**2b**) (showing 50% thermal probability).

length to the most blue region (458 nm), followed by the *tert*-butyl (462 nm) and then the unsubstituted (466 nm) complexes. This fact indirectly supports that the positions of the substituents in the ligand (pyridyl moiety) contains the LUMO states for these complexes. It also corroborate that the oxy-alkyl substituents exert stronger electronic effects relative to that of *tert*-butyl substituent. The shifting of the maximum emission wavelength is independent of the chain lengths of –OCH_3 and –O–CH_2–$(CH_2)_4$–CH_3 substituents. Solution PL emission spectra of the acetylacetonate analogues show the same trend of shifting emission wavelength (Fig. 5(a)) as is observed for the thin-film samples (Fig. 4(a)), while a different trend is observed for the solution picolinate complexes, i.e., **2b** > **4b** > **3b** > **1b** (Fig. 5(b)). The solution spectra of the oxy-alkyl substituted complexes show red-shifted and broad emission spectra relative to that of their thin-film samples. This observation prompted us to study the emissive characteristics of all the available acetylacetonate and picolinate complexes in different solvents with increasing polarities, that is systematic changes in polarity. Hence, the measurement of the solution emission spectra of these complexes were conducted in the following solvents of different polarities, toluene < chloroform < acetone < acetonitrile < methanol.

The solution spectra of the picolinate complexes are highly affected by the solvent polarity (Fig. 6(a)–(d)). In general, the broad and red-shifted emission is observed with increasing order of polarity. Again, the oxy-alkyl subsitituted complexes are mostly affected by solvents followed by the *tert*-butyl substituted and the unsubstituted complexes. The emission profile of the acetylacetonate complexes, however, remains almost unaffected (Fig. 7(a) and (b)). Presumably, the lowest excited state of the Ir–picolinate complexes has a significant contribution from the excited states of picolinate which is highly affected by solvent polarity. The PL quantum yields were obtained relative to [Ir(ppy)$_3$] ($\phi_{PL} = 0.4$) and the maximum value were found for the Ir(F_2'Buppy)$_2$(acac) complex (Table 3).

3.4. Cyclic voltametric studies

Analysis by cyclic voltammetry shows that all these acetylacetonates and picolinates undergo a reversible one-electron oxidation; no reduction processes were observed in chloroform. As shown in Table 3, the oxidation potentials are slightly affected by the type of ancillary ligand (acetylacetonate and picolinate; ~125 mV) for each pair of complexes, but they vary significantly between complexes with different substitutions (*tert*-butyl and oxyhexyl; ~350 mV). Oxyhexyl-substituted complexes show lower oxidation potentials with respect to their corresponding *tert*-butyl-substituted analogues, indicating the relative ease of oxidation.

3.5. Electroluminescence

The electroluminescent (EL) properties of the complex **2b** were investigated. The EL device performance was investigated by using **2b** as a dopant and CBP [4,4′-bis(9-carbazolyl)-1,1′-biphenyl] as the host in the emitting zone (D-**I**). The device structure adopted in this work is a typical multi-layer, employing indium tin oxide (ITO) as the anode, polyfluoro carbon (CF_x) as the hole injecting material, 4,4′-bis[(1-naphthyl)(phenyl)amino]-1,1-biphenyl (NPB) as the hole transporting material, **2b** as the dopant and CBP as the host, 2,6-dimethyl-4,7-diphenyl-1,10-phenanthroline (BCP) as the hole blocking material, aluminium *tris*(8-quinolinolate) (Alq_3) as the electron-transport material, LiF as the electron-injection layer and aluminum as the cathode, as shown in Fig. 8 (inset). The complex emits a greenish-blue emission in the EL spectra (Fig. 8), which are well matched to that observed in the PL spectra in solution. There are no characteristic emission peaks from Alq_3 or CBP, except a very weak emission from the NPB layer (weak emission ~425 nm in Fig. 8), indicating the emission originates from the dopant in the emitting layer. Furthermore, these results support that the effective energy transfer from the host (CBP) to the dopant (Ir complex) occurs in the emissive layer. The fabrication of another two devices

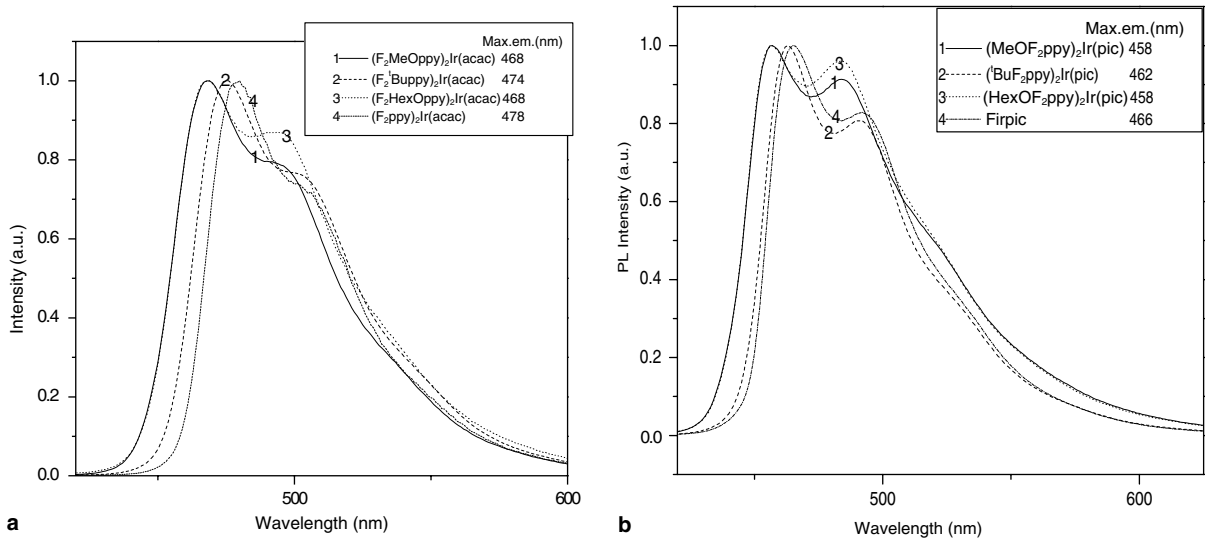

Fig. 4. Solid thin-film emission spectra of the series of acetylacetonate (a) and picolinate (b) iridium(III) complexes.

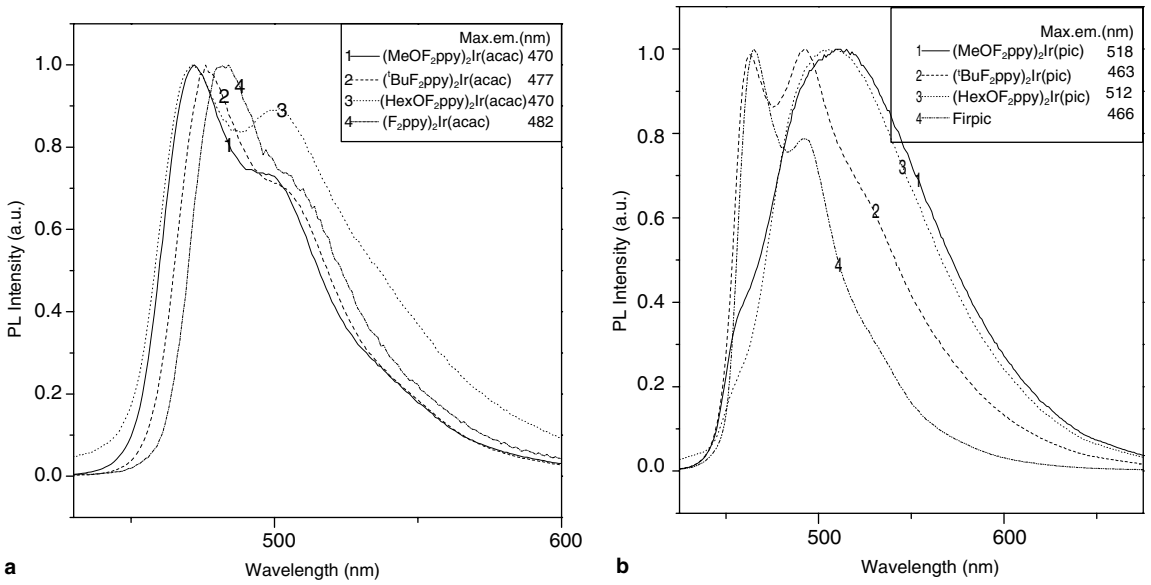

Fig. 5. Solution emission spectra (chloroform) of the series of acetylacetonate (a) and picolinate (b) iridium(III) complexes.

was also carried out, using $Ir(F_2MeOppy)_2(acac)$ [3] (D-**II**) and FIrpic (D-**III**), **3** dopants in a similar device structure as mentioned above to make a comparative study of EL performances. The lowest unoccupied molecular orbitals (LUMO) primarily lie on the pyridyl moiety [11] of the cyclometalated ligand in **2b** and it contains the electron releasing substituent *tert*-butyl (^{t}Bu). The electronic effect of the *tert*-butyl (^{t}Bu) substituent in the pyridyl moiety uplifts the LUMO state and a hypsochromically shifted emission is observed subsequently with respect to the unsubstituted Firpic complex in EL emission (472 nm → 468 nm; Fig. 8). The EL device containing the dopant $Ir(F_2MeOppy)_2(acac)$ shows the maximum emission at 472 nm, where the ancillary ligand (acac) is different from that of FIrpic and **2b**. The turn-on voltages of D-**I**, D-**II** and D-**III** are 5.6, 5.9 and 6.9, respectively (Fig. 9). The intermolecular interactions (e.g., π–π stacks in the molecular crystals) in the solid state and the ability to trap charges in the emissive layer are considered to be the most important factors in determining the operating voltage. The strong electronic coupling and intermolecular interactions in the molecular crystals contribute to effective injections and transport of charges, leading to lower operating voltages [12]. On the other hand, effective charge-trapping by the dopants gives rise to increasing driving voltages in OLEDs [13]. If the dopant material functions as a hole trap, the HOMO level of the dopant could be above that of the host material. Hence, materials having a lower oxidation potential can function as effective hole traps in OLEDs. Therefore, the observed higher operating voltages for D-**III** relative to D-**I** are predominantly caused due to effective hole trapping, which is consistent with the electro-

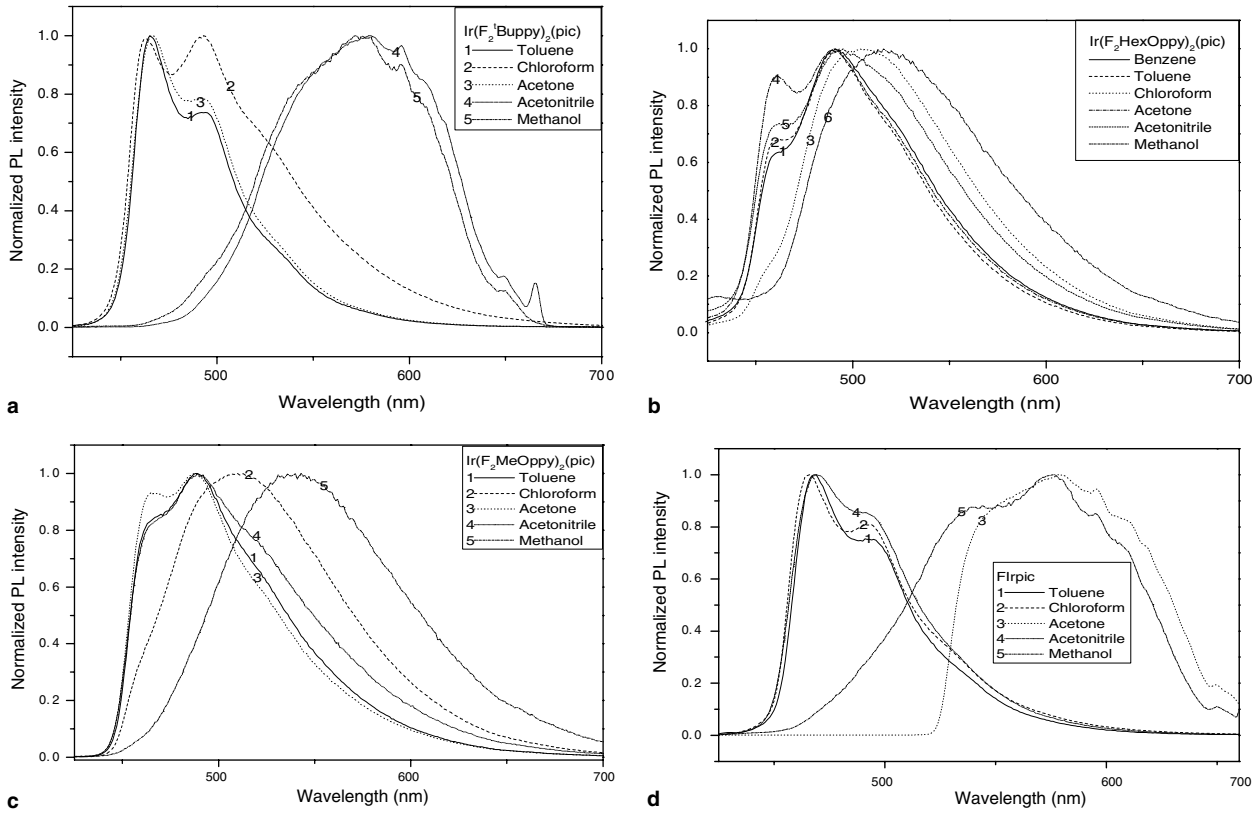

Fig. 6. Solvent dependent emission spectra of the iridium(III)-picolinate complexes: [Ir(F_2'Buppy)$_2$(pic)] (shown in a), [Ir(F_2HexOppy)$_2$(pic)] (shown in b), [Ir(F_2MeOppy)$_2$(pic)] (shown in c) and [Ir(F_2ppy)$_2$(pic)] (shown in d).

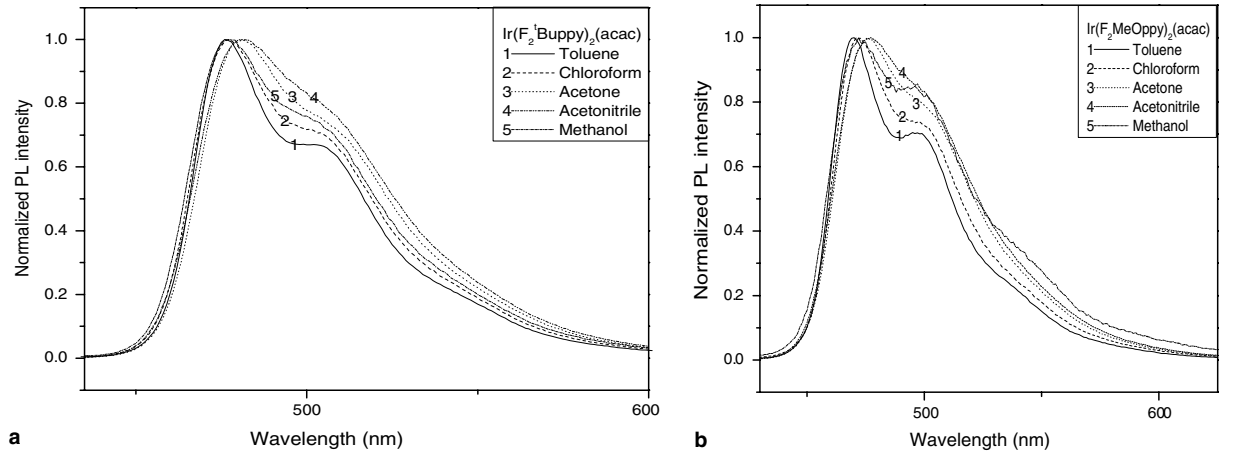

Fig. 7. Solvent dependent emission spectra of the iridium(III)-acetylacetonate complexes: [Ir(F_2'Buppy)$_2$(acac)] (shown in a) and [Ir(F_2'Buppy)$_2$(acac)] (shown in b).

chemical behavior of the dopants used in these devices (i.e., E^{ox} of **2b** (dopant in D-**I**) 0.866 V; E^{ox} of FIrpic (dopant in D-**III**) 0.586 V). The electrochemical behavior of the dopant used in D-**II** (E^{ox} of Ir(F_2MeOppy)$_2$(acac) (dopant in D-**II**) 0.506 V) is almost similar to that of D-**III**, but the observed operating voltage is significantly smaller than that of D-**III**. Presumably, the dopant used in D-**II** has relatively strong intermolecular interactions (MeO-substituent present; π–π stacks) as compared to that of the dopant used in D-**III**, which is responsible for better injection of charges and hence correspondingly lowering of driving voltages. The comparative EL performances of the devices are shown in Table 4. The luminance yield for D-**III** is superior to the remaining devices described herein. Poor solution PL luminance yield is observed (Table 3) for the substituted dopants relative to that of FIrpic, reflecting the comparatively poor EL luminance yield observed for D-**I** and **II** devices. These experiments further prompt us that there is no

Table 3

inherent tendency of the substituted dopants which results in abnormal worsening of EL performances.

Assuming that the emitting state of a complex is formed with unit efficiency, based on the $k_r = \phi_{PL}/\tau$ and $\phi_{PL} = k_r/(k_r + k_{nr})$ relationships, the calculations of radiative (k_r) and non-radiative (k_{nr}) rate constants of $Ir(F_2{}^tBuppy)_2(acac)$ ($\phi_{PL} = 0.78$; $\tau = 0.11$ μs; $k_r = 7.1 \times 10^6$; $k_{nr} = 2.0 \times 10^6$), $Ir(F_2MeOppy)_2(acac)$ ($\phi_{PL} = 0.60$; $\tau = 0.097$ μs; $k_r = 6.2 \times 10^6$; $k_{nr} = 4.0 \times 10^6$) and FIrpic ($\phi_{PL} = 0.99$; $\tau = 0.11$ μs; $k_r = 9 \times 10^6$; $k_{nr} = 9 \times 10^4$) were performed. The radiative rate constants for these complexes show almost similar order (10^6), but the non-radiative rate constants for FIrpic are less than two orders of magnitude smaller than those of substituted dopants. The non-radiative rate constant is a sum of rates for several processes that quench emission. It appears that a new luminescent quenching mechanism comes into play as the energy of the triplet states increases (for the case of substituted dopants). It may involve a self-quenching mechanism or perhaps thermal activation to a competing MLCT state on the ancillary ligand.

4. Conclusion

Syntheses of new blue-emitting iridium(III) based phosphorescent materials have been carried out. Systematic changes of emission wavelengths have been demonstrated by various ligands with different electronic properties to form a series of Ir complexes. Solution photoluminescence behavior of iridium(III)-acetylacetonate/picolinate complexes were also investigated. Comparative EL performances were also examined using three similar types of dopants described herein with the same device configuration, and the observed poor device performances for the device containing a substituted dopant with respect to the device which contains a dopant without a substituent was rationalized.

Table 4
Comparative EL performances for devices D-**I**, **II** and **III**

Dopants used (Device)	Current density (mA cm^{-2})	Drive voltage (V)	Luminance (cd m^{-2})	Luminance yield (cd A^{-1})	CIE		λ_{max} (nm)	Quantum efficiency (%)
					x	*y*		
$(F_2{}^tBuppy)_2Ir(pic)$ (D-**I**)	20	9.1	402	2.0	0.17	0.30	468	1.0

2. Experimental

2.1. Materials and general methods

1-(1′-Naphthylazo)naphthalene [65] were synthesised following published method with minor modifications. Thallium(I) cylopentadienide was prepared according to a reported method [66].

The IR spectra were recorded either on Perkin–Elmer 783 or on Perkin–Elmer 983 (with DS system) spectrophotometer as KBr disks. NMR spectra were obtained using either JEOL GSX 400 NB or VXR 300 S Varian Supercon spectrometer. Electronic spectra were recorded on a Shimadzu UV-240 spectrophotometer.

2.2. Di-(μ-chloro)-bis(1-(1′-naphthylazo)naphthyl-C(2), N_β)dipalladium(II) (**1a**)

A hot ethanolic solution (50 ml) of 1-(1′-naphthylazo)naphthalene (0.14 g, 0.496 mmol) was added to an ethanolic solution (20 ml) of $Na_2[PdCl_4]$ (0.14 g, 0.475 mmol). The solution was kept at room temperature for 24 h. **1a** was separated as red precipitate, thoroughly washed with water and ethanol and finally dried in vacuo. Yield: 0.157 g (75%). *Anal*. Calc. for $C_{40}H_{26}N_4Pd_2Cl_2$: C, 56.7; H, 3.1; N, 6.6. Found: C, 56.5; H, 3.0; N, 6.5%. UV/VIS (MeCN), λ/nm (ε/dm^3 mol^{-1} cm^{-1}): 500 (9250), 398 (16600), 222 (71540).

2.3. Di-(μ-acetato)-bis(1-(1′-naphthylazo)naphthyl-C(2), N_β)dipalladium(II) (**1b**)

A solution of 1-(1′-naphthylazo)naphthalene (0.25 g, 0.886 mmol) in chloroform (15 ml) was added to a solution of palladium(II)acetate (0.2 g, 0.891 mmol) in the same solvent (25 ml). The reaction mixture was kept for 48 h. at room temperature. The volume of the reaction mixture was reduced to 15 ml and was chromatographed on silica gel (60–120 mesh size). The free ligand was first eluted with benzene. **1b** was eluted as a red band by a mixture of benzene and acetonitrile (4:1 v/v) as an eluant. Removal of the solvent afforded **1b** as red crystalline powder. Yield: 0.198 g (50%). *Anal*. Calc. for $C_{44}H_{32}N_4Pd_2O_4$: C, 59.1; H, 3.6; N, 6.3. Found: C, 59.0; H, 3.6; N, 6.2%. IR (KBr; ν/cm^{-1}): 1554, 1424 (CH_3COO). UV/VIS (MeCN), λ/nm (ε/dm^3 mol^{-1} cm^{-1}): 500 (11200), 410 (18730), 280 (35100). ^{1}H NMR in DMSO-d_6 (ppm): 2.54 (s, 3H, Me), 7.34 (br s,1H, H–C(3)), 7.48–8.57 (Ar). ^{13}C {^{1}H} NMR in DMSO-d_6 (ppm):158.23 (C–2), 156.02–117.78 (Ar), 29.69 (Me).

2.4. (η^5-Cyclopentadienyl)(1-(1′-naphthylazo)naphthyl-C(2), N_β)palladium(II) (**2**)

To a suspension of **1a** (0.07 g, 0.083 mmol) in dry benzene (20 ml) was added solid TlCp (0.067 g, 0.248 mmol) with stirring. The mixture was further stirred for 4 h at room temperature. The colour of the solution became dark violet. The precipitate of TlCl was removed by filtration through a glass sintered (G-4 frit) funnel. The filtrate was evaporated to dryness in vacuo. The solid residue was taken up in CH_2Cl_2 and chromatographed on alumina column. Compound **2** was eluted as deep violet band using benzene as an eluant. Removal of the solvent afforded **2** as deep violet microcrystals. Yield: 0.045 g (60%). *Anal*. Calc. for $C_{25}H_{18}N_2Pd$: C, 66.3; H, 4.0; N, 6.2. Found: C, 66.1; H, 3.9; N, 6.1%. UV/VIS (MeCN), λ/nm (ε/dm^3 mol^{-1} cm^{-1}): 550 (8170), 470 (9600), 265 (33660), 230 (44880). ^{1}H NMR in $CDCl_3$ (ppm): 5.7 (s, 5H, Cp), 7.42–8.79 (Ar). ^{13}C {^{1}H} NMR in $CDCl_3$ (ppm): 190.08 (C–2), 155.60–121.13 (Ar), 96.66 (Cp).

2.5. Reaction of complex (**1a**) with m-chloroperbenzoic acid

Acetonitrile solution (5 ml) of *m*-chloroperbenzoic acid (0.025 g, 0.144 mmol) was added dropwise with stirring to a suspension of **1a** (0.04 g, 0.047 mmol) in acetonitrile (40 ml). The reaction mixture was further stirred for 24 h at room temperature The colour of the solution was gradually turned into violet. The solvent was removed under reduced pressure and the solid mass was repeatedly washed with aqueous ethanol (1:1, v/v) followed by Et_2O to remove the organic acids and finally it was extracted with chloroform (10 × 10 ml). Removal of the solvent in vacuo afforded **3a** as maroon microcrystals Yield: 0.018 g (45%). *Anal*. Calc. for $C_{40}H_{26}N_4O_2Pd_2$ Cl_2: C, 54.7; H, 3.0; N, 6.4. Found: C, 54.6; H, 3.0; N, 6.2%. IR (KBr;ν/cm^{-1}): 1141 ν (C–O). UV/VIS ($CHCl_3$), λ/nm (ε/dm^3 mol^{-1} cm^{-1}): 550 (30170), 510 (28640), 380 (10970), 360 (10315), 260 (59250), 240 (76150).

2.6. Reaction of complex (**1b**) with m-chloroperbenzoic acid

Acetonitrile solution (10 ml) of *m*-chloroperbenzoic acid (0.029 g, 0.168 mmol) was added dropwise with stirring to **1b** (0.05 g, 0.056 mmol) suspended in acetonitrile (35 ml). The colour of the reaction mixture was gradually turned

into violet and the stirring was continued for 3 h. The solvent was removed under reduced pressure and the residue was washed with aqueous ethanol (1:1 v/v) thrice to remove the organic acids. The residue was dissolved in chloroform (5 ml) and chromatographed on silica gel (60–120 mesh). A red violet band was eluted by a mixture of benzene and acetonitrile (25:1 v/v). Removal of the solvent afforded pure **3b**. Yield: 0.015 g (30%). *Anal*. Calc. for $C_{44}H_{32}N_4Pd_2O_6$: C, 57.1; H, 3.5; N, 6.1. Found: C, 56.9; H, 3.4; N, 5.9%. IR (KBr; ν/cm^{-1}): 1550, 1424 (CH_3COO), 1150 (C–O). UV/VIS ($CHCl_3$), λ/nm ($\varepsilon/dm^3\ mol^{-1}\ cm^{-1}$): 545 (33 180), 510 (29 550), 380 (10 160), 360 (9870), 260 (55 158), 240 (63 140). ^1H NMR in $CDCl_3$ (ppm): 2.53 (s, 3H, Me), 6.22 (d, 1H, H–C(3)), 6.51–8.63 (other aromatic protons). $^{13}C\{^1H\}$ NMR in $CDCl_3$ (ppm): 137.19 (C-2), 131.00–111.95 (Ar), 29.69 (Me).

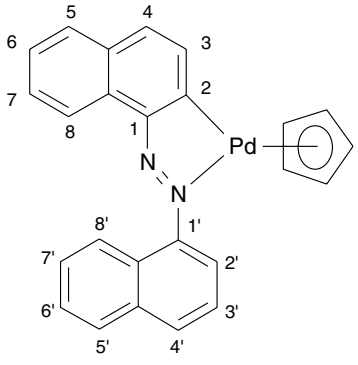
Caution: Thallium compounds and benzene are highly hazardous chemicals. These should be handled with great care.

3. Results and discussion

3.1. Synthesis

1-(1′-Naphthylazo)naphthalene (HL) smoothly reacts with $Na_2[PdCl_4]$ in ethanol at room temperature and yields cyclopalladated chloro-bridged binuclear **1a** as red crystalline solid. Similarly palladium(II) acetate yields acetato-bridged binuclear **1b** in chloroform at room temperature. The conversion of **1b** into **1a** is readily achieved by treating **1b** with LiCl in a dioxane–water mixture. P. Rys et al. [53,54] have thoroughly studied the cyclopalladation reaction of azonaphthyl group of 1-(1′-phenylazo)naphthalene and established that the palladium–carbon bond formation occurs at C2 exclusively. The chloro-bridge of the cyclopalladated compound **1a** is cleaved by solid TlCp in benzene at room temperature to afford air stable monomeric **2**.

The IR spectrum of **1b** shows two bands at 1554 and 1424 cm^{-1} characteristic of acetato-bridged cyclopalladated compounds [67]. The strong absorption around 764 cm^{-1} of **2** is attributed to π-bonded cyclopentadienyl ring to palladium(II) centre [68].

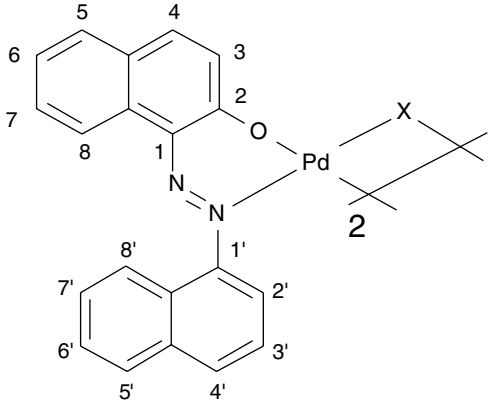


2

The strong absorption band of **1** at 500 nm is believed [36,69] to originate from $\pi \rightarrow \pi^*$ transition localised on the palladated azonaphthalene fragment L. The allowed metal to ligand charge transfer band for **2** is observed around 550 nm [61]. In contrast to the poor solubility of chloro-bridged **1a**, the acetato-bridged **1b** is suitable for ^1H and ^{13}C NMR investigations. The signal for aromatic 3-H proton of **1b** appears as broad peak at 7.34 ppm separated from other aromatic protons signals in the region of 7.48–8.57 ppm. The high field shift of H–C3 on *ortho*-metallation is well known [44,53]. The $^{13}C\{^1H\}$ NMR spectrum of **1b** exhibits the metallated carbon C(2) at 158.23 ppm and such low-field shift of aromatic carbon on metallation is well documented [53]. The ^1H NMR spectrum of **2** display a single sharp signal at ca. 5.7 ppm due to the η^5-binding of cyclopentadienyl group (Cp) to palladium(II) [70]. The equivalence of all the five carbon atoms of metal bound cyclopentadienyl group in **2** is also evident from the signal at 96.66 ppm in the $^{13}C\{^1H\}$ NMR spectrum of **2**. The signal for palladated carbon (C-2) appears at 190.08 ppm and such low field shift (31.8 ppm) of palladated carbon in presence of Cp as coligand is well known [61].

3.2. Metaloxylation Reaction of complexes (*1*) with *m*-chloroperbenzoic acid

Azoxy-naphthalene is the sole product of the reaction between 1-(1′-naphthylazo)naphthalene and *m*-chloroperbenzoic acid in non-aqueous media [65]. But the reaction of cyclopalladated complexes **1** with *m*-chloroperbenzoic acid in acetonitrile medium at room temperature results in the oxygen insertion into Pd–C(naphthyl) bond and affords **3**. The reaction virtually goes to completion within 3 h. Complexes **3** have been isolated using chromatographic technique.



3a: X = Cl
3b: X = OAc

The strong absorptions of **3** around 545 and 515 nm are assigned [40,60] as LMCT bands. These bands appear to be a characteristic [60] of palladium(II) bound to one azonaphtholato fragment.

The IR spectrum of **3b** displays two bands at 1550 and 1424 cm^{-1} characteristic [68] of acetato-bridged compound. Both the metaloxylated **3a** and **3b** show ν(C–O) stretch [40] at ca. 1140 cm^{-1} in the IR spectra.

The ^1H NMR spectrum of **3b** shows high field shift of aromatic proton signals specially of metaloxylated ring. The effect is most dramatic in the case of H–C3 proton. The H–C3 proton of **3b** appears at 6.22 ppm. This corresponds to a high-field shift of about 1.12 ppm compared with the chemical shift of H–C3 of **1b**. This may be due to the electron releasing properties of naphtholic oxygen [36]. The $^{13}C\{^1H\}$ NMR spectrum of **3b** shows the signal for C2 at 137.19 ppm. The insertion of oxygen atom into palladium–C(naphthyl) bond shifts the signal for C2 to high field region.

3.3. Metaloxylation of (2) with m-chloroperbenzoic acid

The presence of both σ- and π-types palladium–carbon bonds [71] in **2** makes it worthy to examine its reactivity towards oxygen transfer reagent [61]. At room temperature, *m*-CPBA is added in (1:1) mole ratio to the deep violet solution of **2** in chloroform and the colour of the reaction mixture immediately turns into red violet (Fig. 1). The characteristic absorption bands of **2** at 470 and 550 nm disappear and new absorption bands develop at ca. 515 and 545 nm. The profile of the absorption spectrum with maxima at 515 and 545 nm in chloroform is very similar to those of **3** and indicates the existence [60] of one 1-(1′-naphthylazo)-2-naphtholato chelate ring per palladium(II) centre. The above reaction in $CDCl_3$ was also monitored by ^1H NMR spectroscopy. On addition of *m*-CPBA, the signal for H–C3 proton of complex **2** is shifted from 7.42 (*d*) ppm to 6.57 (*d*) ppm. The 0.85 ppm upfield shift of H–C3 is attributed to the conversion of M–C bond to M–O–C bond and the shift is due to electron releasing properties of naphtholic oxygen atoms [36]. The signal for the five protons of cyclopentadienyl ring appears at 5.7 ppm as in **2**. Therefore, the cyclopentadienyl group binds the naphthylazonaphtholato palladium(II) in η^5 fashion [70] and remains unaffected during and after metaloxylation. Chakravorty et al. [40] suggested that the metaloxylation of cyclopalladates by *m*-CPBA become more facile with the increase in the electrophillicity of palladium centres. In **2** naphthyl bound palladium centre becomes more electrophillic due to the presence of Cp as a coligand which has been reflected in the $^{13}C\{^1H\}$ NMR spectrum of **2**. The spectral studies of the reaction of **2** with *m*-CPBA establish that *m*-CPBA selectively metaloxylates the Pd–C(naphthyl) bond without affecting the cyclopentadienyl moiety in solution. The isolation of analytically pure metaloxylated compound is under progress.

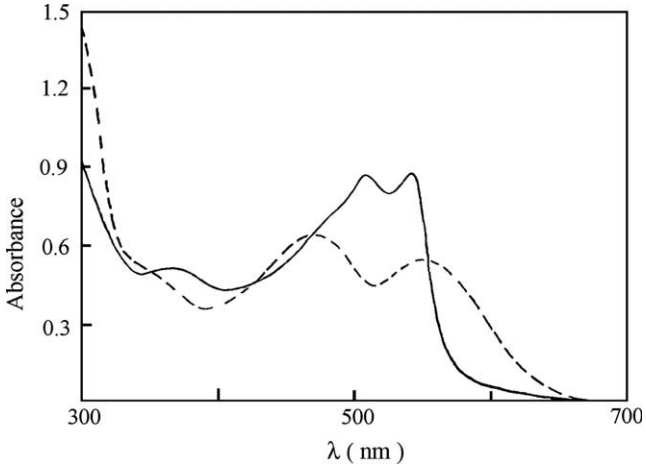


Fig. 1. Electronic spectra of pure **2** (6.68×10^{-4} M) (--------) and after metaloxylation (————) in $CHCl_3$ at 298 K.

R = C_6F_{13} (**V**), H (**VI**)

Fig. 1. Fluoroalkylated BINAP and MonoPhos ligands.

(*R*)- and (*S*)-enantiomers of the ligands were used in the synthesis of complexes and the data obtained was identical in all cases apart from optical rotation values, which were equal in magnitude but opposite in sign; data for only the (*R*)-enantiomers is presented here.

2.1. General procedure for the formation of platinum complexes of BINAP-based ligands

cis-[$PtCl_2(MeCN)_2$] (0.033 g, 9.5×10^{-5} mol) and the BINAP ligand (9.5×10^{-5} mol) were dissolved in dry and degassed dichloromethane (35 ml) and the mixture heated to reflux under nitrogen for 3 h. Upon cooling, approximately 30 ml of the solvent was removed under reduced pressure and the product precipitated from solution by the addition of petroleum ether (b.p. 40–60 °C, 10 ml). The crude product was collected by filtration and recrystallised from dichloromethane/hexane.

2.1.1. [$PtCl_2${(*R*)-R_{f6}-BINAP}] (**VII**) (68% yield)

M.p. 186–188 °C. *m/z* (FAB) 1489 $[M-Cl]^+$ (97%), 1453 $[M-2Cl]^+$ (100%). $[\alpha]_D$ ($CHCl_3$) 264.6° ($c=1.6$). *Anal.* Calc. for $C_{56}H_{30}Cl_2F_{26}P_2Pt$: C, 44.09; H, 1.97. Found: C, 43.89; H, 1.91%. ^1H ($CDCl_3$) 6.62 (6H, m, PhH), 6.75 (4H, m, ArH), 7.22 (2H, d, $^3J_{HH}=9.0$ Hz, ArH), 7.37–7.51 (10H, m, PhH), 7.62 (2H, d, $^3J_{HH}=8.4$ Hz, ArH), 7.74 (4H, m, PhH), 7.82 (2H, s, ArH). $^{19}F\{^1H\}$ −81.12 (6F, t, $^4J_{FF}=10.4$ Hz, CF_3), −111.11 (4F, m, α-CF_2), −121.32 (4F, m, CF_2), −122.69 (4F, m, CF_2), −123.18 (4F,m, CF_2), −126.49 (4F, m, CF_2). $^{31}P\{^1H\}$ 10.79 (s, $^1J_{Pt-P}=3636$ Hz).

2.1.2. [$PtCl_2${(*R*)-R_{f6}-C_2H_2-BINAP}] (**VIII**) (69% yield)

M.p. 189–191 °C. *m/z* (FAB) 1541 $[M-Cl]^+$ (35%), 1505 $[M-2Cl]^+$ (31%). $[\alpha]_D$ ($CHCl_3$) 153.13° ($c=0.8$). *Anal.* Calc. for $C_{60}H_{34}Cl_2F_{26}P_2Pt$: C, 45.69; H, 2.16. 2.6. Crystal structure determination of [Cp*RhCl$_2${(R)-MonoPhos}] (XVII)

Crystals suitable for single crystal structural analysis were grown by slow evaporation from a 1:5 dichloromethane/hexane solution.

2.7. Crystal data

$C_{32}H_{33}Cl_2NO_2PRh.1/2CH_2Cl_2$, $M = 710.84$, orthorhombic, $a = 17.8135(7)$ Å, $b = 22.7127(9)$ Å, $c = 7.6566(3)$ Å, $U = 3097.8(2)$ Å^3, $1.79 < \theta < 25.00°$, $T = 150(2)$ K, space group $P2_12_12$, graphite-monochromated Mo Kα radiation, $\lambda = 0.71073$ Å, $Z = 4$, $D_{calc} = 1.524$ g cm^{-3}, $F(000) = 1452$, dimensions $0.18 \times 0.16 \times 0.11$ mm^3, μ (Mo Kα) $= 0.8933$ mm^{-1}, empirical absorption correction based on ψ scans, maximum and minimum transmission factors of 0.928 and 0.710, respectively, Bruker APEX 2000 CCD diffractometer, ω scans, data collection range $1.79 < \theta < 25.00°$, $-21 \leqslant h \leqslant 21$, $-27 \leqslant k \leqslant 26$, $-9 \leqslant l \leqslant 8$; 22 576 reflections were measured, and 5439 were unique ($R_{int} = 0.0329$). The data were corrected for Lorentz and polarisation effects.

2.8. Structure solution and refinement

Structure solution was by Patterson methods. The structure refinement on F^2 employed SHELXTL version 6.10 (SHELXTL, an integrated system for solving, refining and displaying crystal structures). For all structures hydrogen atoms were included in calculated positions (C–H = 0.96 Å) riding on the bonded atom with isotropic displacement parameters set to 1.5 U_{eq}(C) for methyl H atoms and 1.2 U_{eq}(C) for all other H atoms. All non-H atoms were refined with anisotropic displacement parameters. Final refinement cycles included one molecule of lattice CH_2Cl_2 with half occupancy. Final $R_1 = 0.0318$, $wR_2 = 0.0826$ (0.0326 and 0.0833, respectively, for all data) for 360 variables. The final residual Fourier map showed peaks of 1.038 and −0.891 e Å^{-3}.

3. Results and discussion

We have previously shown that the introduction of perfluoroalkyl substituents does not impact substantially on the application of these ligands in catalysis. However, in order to properly evaluate the electronic environment around the coordinating phosphorus centres, the air- and moisture-stable complexes *cis*-[$PtCl_2$(L)] and *cis*-[$PdCl_2$(L)] (L = R_{f6}-BINAP, R_{f6}-C_2H_2-BINAP and R_{f6}-C_2H_4-BINAP) and *cis*-[$PtCl_2$(L′)$_2$], *trans*-[$PdCl_2$(L′)$_2$] and [Cp*$RhCl_2$(L′)] (L′ = MonoPhos, R_{f6}-MonoPhos) were prepared; such complexes are well-established probes for ligand coordination chemistry and are readily prepared by displacement of weakly coordinating ligands or cleavage of halide-bridged dinuclear complexes. The ^1H and ^{19}F NMR data are unremarkable, beyond the virtual triplet for the NMe_2 protons for *trans*-[$PdCl_2$(MonoPhos)$_2$] (**XV**, **XVI**) that confirm the *trans*-arrangement for the two phosphorus(III) ligands in these complexes. The ^{31}P NMR data (Table 1) reveals, as we have shown previously, that the phosphorus chemical shift is not a particularly good probe for the electronic properties of these ligands but that, in particular, $^1J_{Pt-P}$ does reveal subtle variations in σ-donor properties. These coupling constant data reveal that even the binaphthyl rings in these ligands do not completely ameliorate the electronic influence of perfluoroalkyl substituents in the 6,6′-positions, and this is only achieved with an additional, aliphatic, C_2H_4 spacer unit. Interesting, this is equivalent to the eight-carbon unit highlighted by Gladysz et al. [13] as necessary to totally shield donor atoms, and electronic effects are even felt through a conjugated eight-carbon unit, such as in the alkenyl-binaphthyl ligand Rf-C_2H_2-BINAP.

Single crystals of [Cp*$RhCl_2${(*R*)-MonoPhos}] (**XVII**) suitable for X-ray structural determination were obtained by slow evaporation of a 5:1 hexane/dichloromethane solution. Selected bond lengths and bond angles, together with data for closely related rhodium(III) complexes, are given in Table 2 and the molecular structure shown in Fig. 2. The complex adopts the anticipated pseudo-piano stool structure in which the bond lengths and angles are consistent with the electronic properties of the phosphoramidite ligand. In particular, the Rh–P bond distance is comparable to those for Rh(III)-phosphonite complexes

[14] and significantly shorter than the analogous Rh–P distances in Cp*Rh-phosphinite or -phosphine complexes [6,14]. In contrast, the steric bulk of the phosphoramidite ligand, as evidenced by the relative size of the Cl–Rh–Cl angle opposite the ligand, is much greater than that for the phosphonite ligands and more comparable to that of a phosphine.

4. Conclusions

Coordination complexes of fluoroalkylated BINAP and MonoPhos ligands have been readily prepared and characterised. Analysis of the ^{31}P NMR data for the complexes shows that the addition of perfluoroalkyl ponytails to the binaphthyl backbone has only a small effect on the electronic environment around the coordinating phosphorus centres and that this effect can be almost totally overcome by the inclusion of an extra ethyl-insulating unit.

5. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC no. 269719. Copies of this information may be obtained from the Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: + 44 1233 336033, email: deposit@ccdc.cam or www: http://www.ccdec.cam.ac.uk.

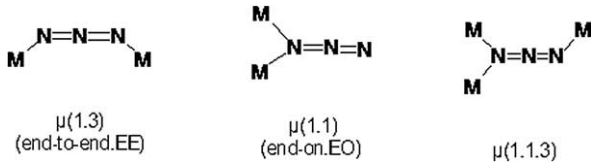
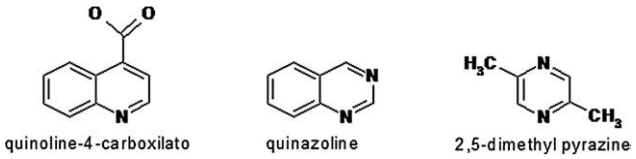


Scheme 1. Different bridging modes of the azido ion.



Scheme 2. Some pyridyl-based ditopic ligands.

only few known crystal structures. 2,5-dimethyl pyrazine as simultaneously bridging ligand through its μ(*N*,*N*′) atoms was found in some copper(II) complexes [7–9], nickel(II) complex [10] and silver(I) complex [11] or coordinated through only one hetero nitrogen atom as in Ru(II) complex [12]. Also quinazoline was presented as μ(*N*,*N*′) bridging in Cu(II) and Cu(I) halide complex [13]. While quinoline-4-carboxylato shows an enormous amount of complexes in the literature, although very few solved structures appear in the CCDC with Sn(II) and Re(II) [14]. Therefore, we extend our work to explore the different possible systems arising with these ligands. As part of our investigation on metal azides, we have recently reported a number of cadmium(II) azido and thiocyanato coordination polymers with some pyridine derivative ligands containing different bridging modes of $[Cd(N_3)_2]_n$ and $[Cd(NCS)_2]_n$ chains to construct coordination supramolecular frameworks [15–17]. Compared to the relatively large number of the azido-bridged polymers with Mn(II), Ni(II) and Cu(II) reported in the literature, the Cd(II) polymers are still very rare. Although diamagnetic, the cadmium systems are interesting from the structural point of view, since the systems can exhibit novel bridging networks different from other metal complexes [18]. Here, we present the reactions of cadmium(II) ions with quinoline-4-carboxylic acid, quinazoline and 2,5-dimethylpyrazine in presence of azide ions, and we isolated three complexes; 1:2:1 Cd:quinoline-4-carboxylato:H_2O (**1**), 1:2:2 Cd:quinazoline:azide (**2**) and a 1:1:2 Cd:dimethylpyrazine:azide (**3**) complexes.

2. Experimental

2.1. Material and instrumentation

Elemental analyses C, H, N were carried out using a Perkin–Elmer analyzer, Cd^{2+} was analyzed by a Perkin–Elmer Analyst 300, AAS atomic absorption spectrometer. Infrared spectra were recorded on a Bruker IFS-125 model FT-IR spectrophotometer as KBr pellets. Quinoline-4-carboxylic acid, quinazoline and 2,5-dimethylpyrazine were purchased from Aldrich Company and other chemicals were of analytical grade quality and used as received.

Caution: Metal azide complexes are potentially explosives. Only a small amount of material should be prepared and should be handled with caution.

2.2. Synthesis

The complexes **1**, **2** and **3** have been synthesized in a similar way as reported [17], where an aqueous solution (20 cm^3) of $3CdSO_4 \cdot 8H_2O$ (0.77 g, 1.0 mmol, 3 mmol in Cd^{2+}) was prepared then the organic ligand (0.34 g, 2 mmol, Qux, 0.26 g, 2 mmol, Quz or 0.22 g, 2 mmol, dmpz) dissolved in ca. 15–20 cm^3 of methanol or (methanol/water) were added, followed by a dropwise addition of aqueous solution of NaN_3 (0.65 g, 10 mmol) with continuous stirring. The turbid mixtures were heated, filtered off, boiled again and the final clear mixtures were allowed to cool gradually to room temperature then placed in a refrigerator for several days. Colourless crystals of **1** and **2** with a yield (0.14 g, ~30% and 0.23 g, ~50%), respectively and pale yellow crystals of **3** with a yield (0.49 g, ~80%) with respect to the ligand, suitable for X-ray measurements were collected and dried in air. *Anal.* Calc. for complex **1**: C, 50.60; H, 2.97; N, 5.90; Cd, 23.67. 2.3. X-ray crystallography

All diffraction data were collected using a Siemens SMART CCD diffractometer with Mo Kα radiation ($\lambda = 0.71073$ Å, graphite monochromator). The crystals were cooled to 173(2) K by a flow of nitrogen gas using the LT-2A device. Full spheres of reciprocal lattices were scanned by 0.3° steps in ω with a crystal-to-detector

distance of 3.97 cm. Preliminary orientation matrices were obtained from the first frames using SMART [19]. The collected frames were integrated using the preliminary orientation matrices which were updated every 100 frames. Final cell parameters were obtained by refinement on the positions of reflections with $I > 10(I)$ after integration of all the frames using SAINT [19]. The data were empirically corrected for absorption and other effects using SADABS program [20]. The structures were solved by direct methods and refined by full-matrix least-squares on all F^2 data using SHELXTL [21]. The non-H atoms were refined anisotropically, while hydrogen atoms were refined isotropically with use of geometrical restraints. The crystallographic and refinement data are summarized in Table 1. Tables 2, 4 and 5 list the selected bond distances and angles for complexes **1**, **2** and **3**, respectively. Molecular graphics were prepared using Diamond [22].

Symmetry transformations used to generate equivalent atoms: (i): $x, -y, z - 1/2$; (ii): $-x, y, -z + 1/2$; (iii): $-x, -y, -z$; (iv): $-x, y, -z - 1/2$.

3. Results and discussion

Three new complexes $[Cd(Qux)_2(H_2O)]_n$ (**1**), $[Cd(Quz)_2(N_3)_2]_n$ (**2**) and $[Cd(dmpz)(N_3)_2]_n$ (**3**) (Qux = quinoline-4-carboxylato anion, Quz = quinazoline, dmpz = 2,5-dimethylpyrazine) have been synthesized and found by X-ray crystallography to have 1D, 2D and 3D topologies, respectively. Although azide ion was introduced in all reactions it is present in complexes **2** and **3** but it is absent in complex **1**. These complexes are insoluble in many polar solvents, e.g., water, MeOH, and EtOH, suggesting their polymeric nature, and they are sparingly soluble in DMSO. IR spectra of these complexes confirm the coordination and the bridging nature of the azido ligand in **2** and **3** and also the carboxylato group in complex **1**.

3.1. Structures

3.1.1. $[Cd(Qux)_2(H_2O)]_n$ (1)

The structure at room temperature of complex **1** has been reported [23] but no coordinates are available. There was also no reply from authors to request for data from

CCDC (refcode XUXRUD). Thus, we present our results here. The low temperature single-crystal X-ray structure analysis of **1** indicates a 1D topology where the coordination geometry around the central Cd(II) atom is slightly distorted octahedral geometry CdO_6 as presented in Fig. 1. The two μ_2-OH_2 axially coordinated to the Cd(II) are related by a symmetry center, where the Cd(II) ion lies. Further the equatorially bonded four oxygen atoms from four different quinoline-4-carboxylato ligands at distances 2.213(2)–2.300(2) Å (see Table 2) which is very close to that of Cd–O_{carb} distances (2.283–2.284 Å) of $[Cd_3(\mu_3\text{-}OH)L_3(py)_6](ClO_4)_2$, (L = 4-[2-(4-pyridyl)ethenyl] (benzoate) [24] and $[Cd_3(nic)_4(N_3)_2(H_2O)]_n$, (nic = nicotinato anion) [17b]. Due to bridging nature of the μ_2-OH_2, the Cd–O_w distances (2.357(1) Å) in the apical positions is longer than that of Cd–O_{carb} in the equatorial position. Although the bond angles O–Cd–O are 180.0° for the atoms related by inverse center in both apical and equatorial planes, the bond angles around the Cd center range from 86.54(7) to 92.56(5)°, and deviate less than 3.5° from those expected for an ideal octahedron. This is different from the one-dimensional platinum system consisting of carboxylate-bridged *cis*-diammineplatinum dimers [25], as for compound **1** the cadmium centers are linked by triple bridges between the adjacent cadmium centers resulting in a one-dimensional linear chain Fig. 2. Each Cd(II) atom is triply bridged on both sides to two adjacent Cd atoms through two μ(O,O′)-carboxylato groups on each side and two μ_2-OH_2. The Cd···Cd distance is 3.8888(1) Å, indicative of no metal–metal interaction and distinguished from those one-dimensional metal chain complexes having infinite metal–metal interactions or bonds [26]. The structure of **1** represents a strong supramolecular interactions through the (O_w-H···N, 2.714(2) Å), where the hetero nitrogen atom of the quinoline group is hydrogen bonded to the bridging water molecules, see Fig. 3 and Table 3 for hydrogen bonding.

Symmetry transformations used to generate equivalent atoms: (v): $-x+1/2, -y+1/2, -z$.

3.1.2. $[Cd(Quz)_2(N_3)_2]_n$ (**2**)

The low temperature X-ray single crystal structure determination for complex **2**, see numbering scheme

Fig. 4, reveals that it has a 2D structure consisting of parallel planes connected through di-EE azido groups and two terminal quinazoline ligands as shown in Fig. 5. The azide ligand bridging in *c*-direction is placed with its central atom at 2-fold axis. The azide ligands binding in *b*-direction are statistically disordered with two different positions (1:1), sharing the central N-atom at inverse center and this relative orientations differ around 30°. The cadmium atoms, positioned at 2-fold axis, are placed in a slightly distorted octahedral geometry CdN_6 linked to four azides in the equatorial plane and to two terminal quinazoline groups, coordinated through the *meta* N atoms only, in the apical positions. The distances Cd–N(azide) (see Table 4) range from 2.349(2) to 2.355(3) Å, while Cd–N(Quz) are

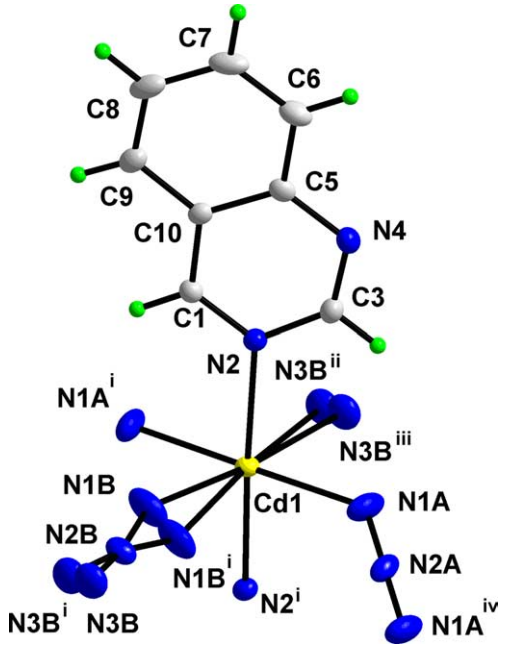

Fig. 4. Numbering scheme and atomic displacement ellipsoids of $[Cd(Quz)_2(N_3)_2]_n$ (**2**) drawn at 50% probability level. Symmetry codes as in Table 4. Note the disordered azide.

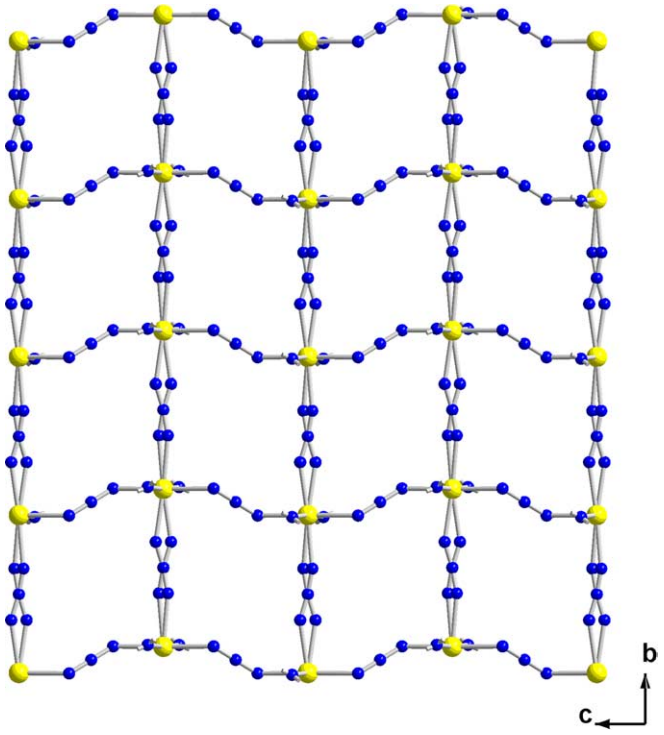

Fig. 5. Projection of the structure of $[Cd(Quz)_2(N_3)_2]_n$ (**2**) along *a*-axis. Only N-atoms of Quz are shown for simplicity.

Symmetry transformations used to generate equivalent atoms: (i): $-x$, y, $-z+3/2$; (ii): $-x$, $y+1$, $-z+3/2$; (iii): x, $y+1$, z; (iv): $-x$, $-y$, $-z+1$; (v): x, $y-1$, z.

2.343(1) Å. The bond angles in the equatorial plane range from 83.5(1) to 97.5(1)° and 167.1(2) to 179.04(8)°, while N(Quz)-Cd–N(azide) range from 87.2(4) to 96.5(1)° and N(Quz)-Cd–N(Quz) is 175.97(5)°. The azido ligands have Cd–N–N bond angle of 133.3(1)° for the azide placed in the 2-fold axis, while for the disordered azide placed on the inversion center, the Cd–N–N bond angles are 154.5(2) and 164.2(5)°. The Cd···Cd distances are within the 2D sheet 6.4516(1) and 6.5355(1) Å in the *b*- and *c*-directions, respectively.

3.1.3. $[Cd(dmpz)(N_3)_2]_n$ (3)

A labeled ORTEP-like plot of the structure is shown in Fig. 6, selected distances and angles are listed in Table 5. The structure of this complex can be described as a 3D network structure consisting of Cd(II) ions, each surrounded by four (EE) azido groups and two bridging μ(*N*,*N*′) dimethylpyrazine groups as shown in Figs. 7 and 8. The Cd atoms, placed at inversion center, have an octahedral slightly distorted environment CdN_6 linked to four azides in the equatorial plan with two dmpz in the apical positions. The distances Cd–N(azide) are 2.3081(9) and 2.3613(9) Å (two each), while the distances Cd–N(dmpz) are 2.407(1) Å, which is quite similar to the reported Ag–N(dmpz), 2.402(5) Å for $[Ag(CF_3CO_2)(dmpz)]_n$ [11]. The bond angles in the equatorial plane of Cd octahedra range from 83.53(4) to 96.47(4)° and from 85.73(3) to 94.26(3)° between the apical N and the equatorial ones apart from those of 180° imposed by symmetry. The azido ligands have Cd–N–N bond angle of 117.87(11)° and 133.56(8)° respectively, see Fig. 7. The dmpz ring is planar with $\chi^2 = 4.9$ and maximal departure from the mean last-square plane of 0.001(2) Å for the atoms in the ring and 0.029(1) Å for the C-methyl atoms. The Cd···Cd distances are 5.8919(1) Å via azide bridges, significantly different from the corresponding value 6.086(2) Å given for the di(EE) azide separation in the two dimensional

complex $[Cd(4\text{-}Acpy)_2(N_3)_2]_n$ [15c], and 7.5793(1) Å via dmpz bridges in **3**.

3.2. Spectra

The room temperature IR spectrum of the crystalline complex $[Cd(Qux)(H_2O)]_n$ **1** as a KBr pellet shows no bands around 2000–2100 cm^{-1}, indicating the absence of the azide ion. The expected bands of the ν(C=O) and ν_{as}(–COO^-) around 1710–1720 and 1640–1660 cm^{-1} for the free acid are absent in the IR spectrum of **1**, instead, strong and broad bands around 1601, 1577 and 1403 cm^{-1} appeared indicating that only carboxylato anions are coordinated to the Cd(II) ion [27]. In the high energy region complex **1** exhibits a strong broad band around 3573 cm^{-1} corresponding to the water molecules coordinated to the Cd(II) ions bridging the 1D chain in complex **1**. Hydrogen bonding of the type (O–H···N) is indicated in the spectrum by the presence of broad, medium strong bands near 2450 cm^{-1} (IR) [28]. The vibration frequencies at 2068 vs, 2036 vs and 1254 w cm^{-1} for complex **2** and at 2064 vs, 2006 w and 1269 br cm^{-1} for complex **3** were assigned as (ν_{as}-N_3) and (ν_s-N_3), respectively and simply attributable to the EE bridge [29]. This is not in agreement with the symmetric nature of the bridging ($\mu_{1,3}$-N_3) groups N1A–N2A and N2A–$N1A^{iv}$ both distances are 1.1736(14) Å as imposed by symmetry. While the asymmetric disordered ($\mu_{1,3}$-N_3) group, N1B–N2B 1.189(3) and N2B–N3B 1.149(3) Å explains these bands in the spectrum of complex **2**. In complex **3** the azido groups are asymmetric [N1A–N2A, 1.1822(12) and N2A–N3A, 1.1789(13) Å] and in agreement with the experimental data. The bands related to the organic ligands, quinoline-4-carboxilato anion, quinazoline and 2,5-dimethylpyrazine in the spectra of **1**, **2** and **3** show some systematic shifts according to the coordination to the metal ion in accordance to those found for pyridine related complexes [30].

4. Supplementary material

Supplementary data are available from the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK on request, quoting the deposition number(s) CCDC-280747, CCDC-280746 and CCDC-258680 (excluding structure factors) for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or fax: (internat.) +44 1223/336 033; E-mail: deposit@ccdc.cam.ac.uk.

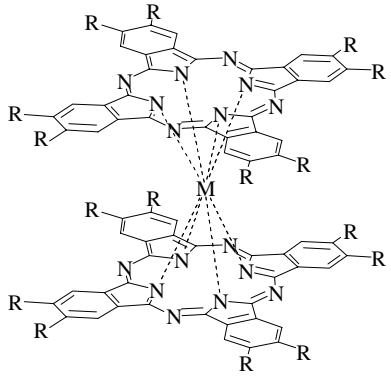
of advanced molecular materials [1]. Some proposed fields of application include molecular electronic, optronic and iono-electronic devices [1,2]. Vibrational spectroscopies have proved to be versatile methods among various techniques for characterizing thin films of phthalocyanines in solid state devices. In the past several years, the vibrational (IR and Raman) characteristics of (na)phthalocyanine in a wide range of bis[(na)phthalocyaninato] and mixed (porphyrinato)[(na)phthalocyaninato] rare earth complexes have been systematically investigated mainly by Jiang and Arnold [3,4], following the precedent studies of Aroca, Homborg, and Tran-Thi [5–7]. As summarized in our recent papers concerning the vibrational spectroscopic characteristics of sandwich tetrapyrrole rare earth complexes, several series of recently developed novel sandwich double-decker complexes with the whole series of rare earth metals, namely M(TClPP)(Pc) [4g], M(OEP)(Nc) [4d], M(TBPP)(Nc) [4e], M[Nc(tBu)$_4$]$_2$ [4c], and M(Pc)[Pc(α-OC$_5$H$_{11}$)$_4$] [4f] [M = Y, La$\cdots$Lu except Pm; H_2TClPP = 5,10,15,20-tetra(4-chloro)phenylporphyrin, H_2OEP = 2,3,7,8,12,13,7,18-octaethylporphyrin, H_2TBPP = 5,10,15,20-tetra(4-t-butyl)phenylporphyrin, H_2Nc(tBu)$_4$ = 3(4),12(13),21(22),30(31)-tetrakis(t-butyl)-2,3-naphthalocyanine, H_2Pc-(α-OC$_5$H$_{11}$)$_4$ = 1,8,15,22-tetrakis(3-pentyloxy)phthalocyanine] have been systematically studied by the Raman technique using laser excitations emitting at 633 and 785 nm, in order to achieve a complete understanding of their intrinsic properties. In contrast, investigation at the same excitation wavelengths of the Raman properties of the most common counterparts, the basic unsubstituted and peripherally octa(alkoxy)-substituted homoleptic bis(phthalocyaninato) rare earth complexes (Fig. 1), are still limited to scattered species such as M(Pc)$_2$ (M = Ce, Eu), Eu[Pc(OC$_5$H$_{11}$)$_8$]$_2$, and M[Pc(OC$_8$H$_{17}$)$_8$]$_2$ (M = Ce, Gd, Tb) (λ_{ex} = 633 nm) [4a]. It thus seems opportune to study systematically the Raman spectroscopic properties of these complexes by means of excitation with laser sources emitting at 633 and 785 nm, as for the other series mentioned above. The present work reports these studies.



R = H, OC$_8$H$_{17}$

Fig. 1. The schematic molecular structure of bis(phthalocyaninato) rare earth sandwich complexes M(Pc′)$_2$ [Pc′=Pc, Pc(OC$_8$H$_{17}$)$_8$].

It is worth noting that we have previously recorded the Raman spectra of the bis(phthalocyaninato) compounds of Ce and Eu, namely M(Pc)$_2$ (M = Ce, Eu) and Ce[Pc(OC$_8$H$_{17}$)$_8$]$_2$, under excitation by 633 nm radiation [4a]. For the purpose of systematic comparison with those under 785 nm laser excitation, the spectra of the complete set of compounds discussed in this paper were re-measured under 633 nm excitation. Note that the Raman spectra of Ce(Pc)$_2$ and Ce[Pc(OC$_8$H$_{17}$)$_8$]$_2$ recorded this time under 633 nm excitation correspond well in band positions, but the relative intensities of some bands differ, compared with those recorded previously [4a]. Nevertheless, the results reported here are confirmed by the systematic and comparative spectra of the whole series of rare earth bis(phthalocyaninato) compounds M(Pc)$_2$ and M[Pc(OC$_8$H$_{17}$)$_8$]$_2$ (M = Y, La$\cdots$Lu except Ce and Pm), in which the one for Eu(Pc)$_2$ is in good accordance with the previous measurements [4a]. The conclusions are further reinforced by the fact that the Raman spectrum of Ce[Pc(OC$_8$H$_{17}$)$_8$]$_2$ corresponds well with that of Ce(Pc)$_2$ recorded under 633 nm excitation, the former of which is also in line with the previous measurement under excitation by 647 nm radiation [4b].

2. Experimental

Homoleptic bis(phthalocyaninato) rare earth complexes M(Pc)$_2$ and M[Pc(OC$_8$H$_{17}$)$_8$] (M = La–Lu except Pm, Y) were prepared according to published procedures [8]. Their sandwich nature has been well established through a series of spectroscopic methods including high resolution mass, UV–Vis, near-IR, and NMR techniques. Resonance Raman spectra were recorded on a few grains of the solid samples with ca. 4 cm^{-1} resolution using a Renishaw Raman Microprobe, equipped with a Spectra Physics Model 127 He–Ne laser excitation source emitting at a wavelength of 633 nm and a Renishaw diode laser emitting at 785 nm, and a cooled charge-coupled device (CCD) camera. An Olympus BHZ-UHA microscope was attached, and for these experiments the 10× objective was employed giving a spot size on the sample of about 5 μm. Laser power at the sample was approximately 0.08 mW. Spectra of excellent quality were obtained in approximately 3 min, with the exceptions noted below.

3. Results and discussion

In bis(phthalocyaninato) rare earth complexes M(Pc)$_2$, the single crystal X-ray diffraction structural data have shown that the rare earth cation is at the center of two Pc ligands facing each other in a staggered arrangement [1,2]. In the solid state, these compounds can be assumed to belong to the D_4 or D_{4d} point-groups depending on the skew angle between the two macrocyclic rings. There has been no crystallographic report on the molecular structure of peripherally octa(alkoxy)-substituted homoleptic bis(phthalocyaninato) rare earth complexes thus far. However,

according to the recently reported molecular structures of peripherally octa(hexylthio)- and 15-crown-5 ether-substituted bis(phthalocyaninato) rare earth analogues Lu[Pc(SC_6H_{13})$_8$]$_2$ and Yb[Pc(15C5)$_4$]$_2$[H_2Pc(SC_6H_{13})$_8$ = 2,3,9,10,16,17,23,24-octakis(hexylthio)phthalocyanine, H_2Pc(15C5)$_4$ = 2,3,9,10,16,17,24,25-tetrakis(15-crown-5)phthalocyanine] [9], the skew angle between the two phthalocyanine macrocyclic ligands is 42° and 42.5°, respectively, for these two compounds. The equilibrium geometry of Lu[Pc(SC_6H_{13})$_8$]$_2$ and Yb[Pc(15C5)$_4$]$_2$ is therefore D_4. This should also be true for the present alkoxy-substituted analogues M[Pc(OC_8H_{17})$_8$]$_2$.

It has been found that in the Raman spectra of Zr[Pc(*t*Bu)$_4$]$_2$, M[Nc(*t*Bu)$_4$]$_2$, and M(Pc)[Pc(α-OC_5H_{11})$_4$] [4c,4f,5], only frequencies corresponding to the characteristic fingerprint vibrations of the Pc or Nc macrocycle were observed and side chain vibrations were very weak or absent. This is also true in the present case since both laser lines used in our experiments appear to enhance modes associated with the aromatic macrocycles (see below).

Similar to other large conjugated systems, one-to-one matching of observed vibrational frequencies to the internal vibrations cannot be achieved in the vibrational spectra of homoleptic bis(phthalocyaninato) rare earth compounds due to the existence of strong couplings of some vibrational coordinates [3–7]. Therefore, the Raman spectra of these homoleptic bis(phthalocyaninato) double-decker complexes are still composed of a relatively small number of fundamentals despite the large number of Raman active vibrational modes.

3.1. Raman characteristics of M(Pc)$_2$ and M[Pc(OC_8H_{17})$_8$]$_2$ (M = Y, La–Lu except Pm) with excitation by laser line at 633 nm

The electronic absorption spectra of M(Pc)$_2$ and M[Pc(OC_8H_{17})$_8$]$_2$ (M = Pr, Tb, Tm) which are typical representatives of the UV–Vis spectra for the complexes of tervalent rare earths in each series are shown in Figs. 2 and 3, respectively [8]. All the spectra of M(Pc)$_2$ (M = Y, La–Lu except for Ce and Pm) show a typical B band at 316–325 nm with a very weak shoulder peak at the lower energy side of 342–358 nm [10]. The *Q* bands for these compounds appear as a strong absorption in the range of 658–689 nm together with the weak vibronic components at 570–596 and 595–618 nm. In addition, a weak band related with the π-radical anion at 420–458 nm is also observed. For the series of M[Pc(OC_8H_{17})$_8$]$_2$ compounds containing tervalent rare earth metal, the B absorption splits into two bands at 331–343 and 369–378 nm due to the influence of eight octyloxy groups on the phthalocyaninato rings [8d]. Their *Q* bands appear at 668–699 nm with weak vibronic absorptions at 579–601 and 604–630 nm, respectively. The weak π-radical anion band is seen at 485–513 nm. For both series of compounds, the energies of all the absorption bands mentioned above are sensitive to the metal center. In particular, along with the lanthanide contraction, the *Q* absorption band for both M(Pc)$_2$ and M[Pc(OC_8H_{17})$_8$]$_2$ blue-shifts in the same order [8d,10]. These characteristics in their electronic absorption form the basis for the fact that systematic changes are observed in both the frequencies and appearance of the Raman spectra of M(Pc)$_2$ and M[Pc(OC_8H_{17})$_8$]$_2$ along with the change in the central metal ionic size, as detailed below.

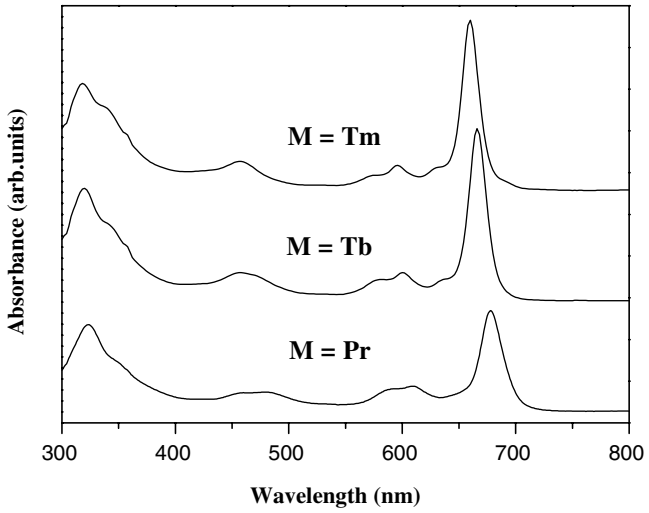


Fig. 2. The UV–Vis spectra of M(Pc)$_2$ (M = Pr, Tb, Tm) in $CHCl_3$.

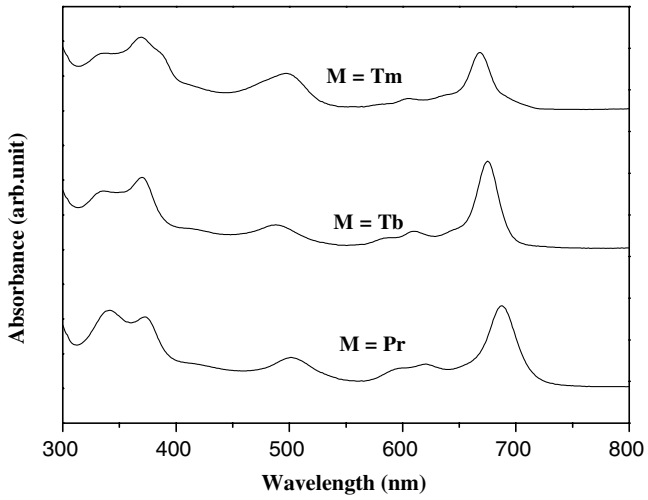

Fig. 3. The UV–Vis spectra of M[Pc(OC_8H_{17})$_8$]$_2$ (M = Pr, Tb, Tm) in $CHCl_3$.

It is worth noting that the Raman spectra of La(Pc)$_2$ and Dy[Pc(OC_8H_{17})$_8$]$_2$ with excitation at 633 nm were of poor quality due to the strong fluorescence. Figs. 4 and 5, respectively, compare the Raman spectra of three compounds M(Pc)$_2$ and M[Pc(OC_8H_{17})$_8$]$_2$ for M = Pr, Tb, and Tm under excitation by 633 nm light. As can be seen, the Raman spectra for both series of compounds M(Pc)$_2$ and M[Pc(OC_8H_{17})$_8$]$_2$ seem to be much simpler in comparison with those of M(Pc)[Pc(α-OC_5H_{11})$_4$] [4f], revealing the relatively higher molecular symmetry of these compounds than the heteroleptic analogues. In particular, the Raman

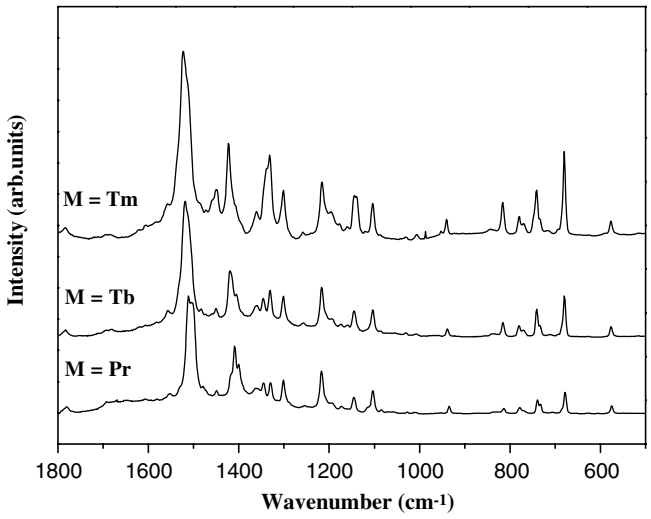

Fig. 4. Raman spectra of $M(Pc)_2$ (M = Pr, Tb, Tm) in the region of 500–1800 cm^{-1} with excitation at 633 nm.

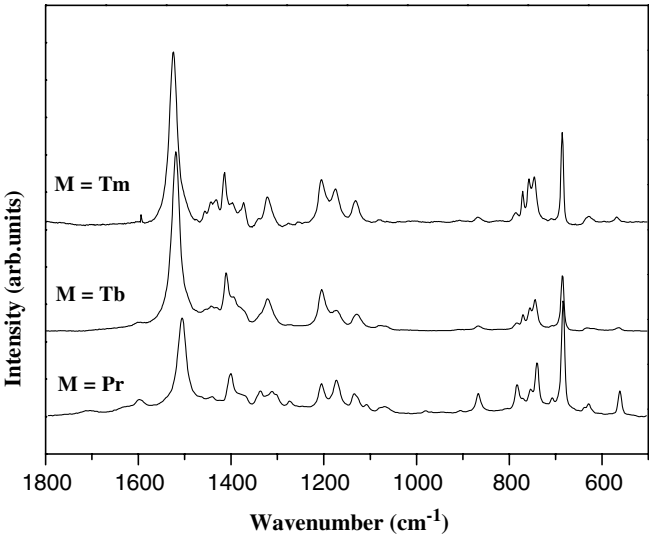

Fig. 5. Raman spectra of $M[Pc(OC_8H_{17})_8]_2$ (M = Pr, Tb, Tm) in the region of 500–1800 cm^{-1} with excitation at 633 nm.

spectra for the peripherally octa(octyloxy)-substituted bis(phthalocyaninato) rare earth complexes appear to be as simple as, or even simpler than, the corresponding unsubstituted counterparts $M(Pc)_2$, indicating again that only frequencies corresponding to the characteristic fingerprint vibrations of the Pc macrocycle in $M[Pc(OC_8H_{17})_8]_2$ were observed. Side chain vibrations were very weak or absent under excitation with laser line of 633 nm, and this is also true when using laser excitation emitting at 785 nm (see below). The observed Raman spectroscopic bands of phthalocyanine for these new homoleptic bis(phthalocyaninato) rare earths were partially assigned in Tables 1 and 2, respectively. Note that the assignments given in Tables 1 and 2 are restricted to characteristic fundamentals based on the previous description of normal modes for phthalocyaninato and especially bis(phthalocyaninato) metal derivatives [4,11]. Recent calculations on the vibrational characteristics of monomeric phthalocyanine derivatives also benefit the present assignments [12]. Due to the similar electronic structure and electronic absorption properties among the whole series of bis(phthalocyaninato) rare earth compounds, all members of each series $M^{III}(Pc)_2$ and $M^{III}[Pc(OC_8H_{17})_8]_2$ (M = Y, La–Lu except Ce and Pm) show similar Raman characteristics.

With laser excitation at 633 nm, which is nearly in resonance with the *Q* band absorptions of both series of bis(phthalocyaninato) rare earth complexes, respectively, at 658–689 and 668–699 nm, vibrational frequencies in the range of 1300–1600 cm^{-1} derived from isoindole ring stretchings and the aza group stretching are selectively intensified. For $M^{III}(Pc)_2$, the weak Raman bands at ca. 574–577 and 812–817 cm^{-1} and a band at 678–680 cm^{-1} with medium or strong intensity are attributed to phthalocyanine breathing [4,11], and the frequencies of all these modes seem to show a dependence on the rare earth size, slightly blue-shifted along with the lanthanide contraction. The medium band at ca. 740 cm^{-1} is due to aromatic phthalocyanine C–H wagging of $M(Pc)_2$ [4]. In the range of 1000–1300 cm^{-1}, there are several weak or medium bands lying at ca. 1006, 1030, 1103, 1174, 1196, 1215 and 1301 cm^{-1}, which are assigned to aromatic C–H bending. The pyrrole breathing presents two bands in the region of around 1140 and 1500 cm^{-1}. The former comprises a single peak with medium intensity at ca. 1138–1145 cm^{-1}, whereas the latter overlaps with the aza stretching vibration in the same region to form a broad band at 1495–1525 cm^{-1} for the whole series of compounds $M^{III}(Pc)_2$. For the double-deckers with early lanthanide metals, the aza stretching band appears as an unresolved shoulder on the *higher* energy side of the peak. In contrast, for the double-deckers with medium and late lanthanides, the pyrrole breathing band appears as an unresolved shoulder peak on the *lower* energy side of the more intense aza stretching peak. The intense band in the range 1409–1423 cm^{-1} and the weak band in the range 1444–1451 cm^{-1} are attributed to isoindole stretchings. The former intense band discussed above, together with the aza stretching band at 1512–1525 cm^{-1}, show dependence on the rare earth radius, shifting to higher energy along with the rare earth contraction. This is not surprising considering the blue-shifted trend of the *Q* absorptions at 658–689 nm in the same order.

As shown in Fig. 5 and organized in Table 2, the Raman spectroscopic frequencies of the phthalocyanine core in $M[Pc(OC_8H_{17})_8]_2$ have been similarly assigned by analogy with those of unsubstituted counterparts $M(Pc)_2$. The Raman spectra observed for $M[Pc(OC_8H_{17})_8]_2$ are even simpler than those of corresponding $M(Pc)_2$. This is probably due to the fact that the excitation at 633 nm is slightly further away from resonance with the main *Q* bands of $M[Pc(OC_8H_{17})_8]_2$ (668–699 nm) than with those of $M(Pc)_2$. This leads to an increased resolution in the Raman spectra of $M[Pc(OC_8H_{17})_8]_2$, which further benefits

the assignments of the frequencies. For instance, unlike for the series of $M^{III}(Pc)_2$, a very good linear correlation can be established between the frequency of the coupled pyrrole and aza stretching modes of $M^{III}[Pc(OC_8H_{17})_8]_2$ at 1504–1527 cm^{-1} and the tervalent rare earth ionic radii, as shown in Fig. 6. In addition, the band positions of the Pc breathing modes at 561–568 and 683–686 cm^{-1}, the C=N stretch at 782–787 cm^{-1}, the coupled C=C pyrrole and benzene stretching at 1312–1322 cm^{-1} and the isoindole stretching at 1400–1415 cm^{-1} show dependence on the rare earth ionic size. They all shift to higher energy along with the rare earth contraction as for their unsubstituted analogues.

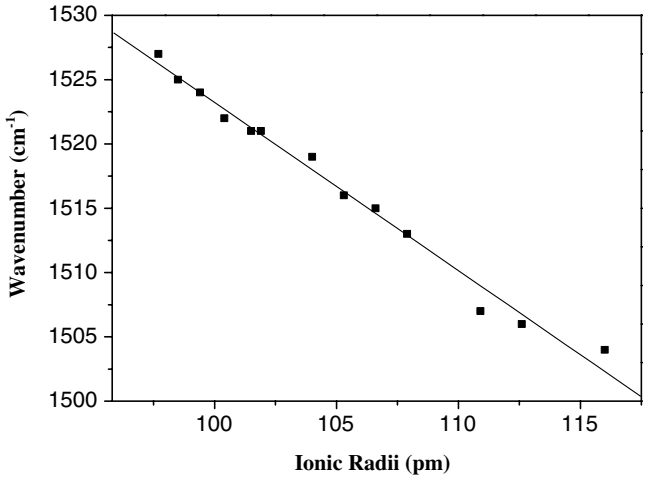

Fig. 6. Plot of wavenumber of the coupling of pyrrole and aza stretching scattering of $M[Pc(OC_8H_{17})_8]_2$ at 1504–1527 cm^{-1} with excitation at 633 nm as a function of the ionic radius of M^{III}.

The tervalent yttrium double-deckers are noteworthy. The frequencies of some above-mentioned bands for both $Y^{III}(Pc)_2$ and $Y^{III}[Pc(OC_8H_{17})_8]_2$ deviate from the linear relationship established for the other tervalent rare earth complexes (Tables 1 and 2), due probably to the intrinsic difference between yttrium and the lanthanides, namely the absence of f electrons. This is also true for these two yttrium complexes when using laser excitation emitting at 785 nm, Tables 3 and 4.

As can be expected from the previous studies [4a,4b,4d,4e,4f,8d], both $Ce(Pc)_2$ and $Ce[Pc(OC_8H_{17})_8]_2$ show different Raman spectroscopic characteristics from those of the rest of the rare earth series, which is related to the different electronic absorption spectra of these cerium complexes. As indicated by the ^1H NMR spectra, both phthalocyanine rings exist as dianions in $Ce(Pc)_2$ and $Ce[Pc(OC_8H_{17})_8]_2$, despite the XANES results that suggest a valence state intermediate between III and IV for the cerium [13]. These complexes therefore differ from other analogues that have the form $M(Pc'^{2-})Pc'^{\bullet-}$ [$Pc' = Pc, Pc(OC_8H_{17})_8$]. A comparison of the Raman spectra of $Ce(Pc)_2$ and $Ce[Pc(OC_8H_{17})_8]_2$ with those of the rest of the series shows that these cerium complexes contain most of the frequencies found for the other complexes, however the relative intensities are different. For example, a strong band appears at 1173 cm^{-1} for $Ce[Pc(OC_8H_{17})_8]_2$ (Table 2) corresponding to C–H bending, but for the other complexes, only a weak band in the same region is observed. Moreover, the marker Raman band of Pc^{2-} and $[Pc(OC_8H_{17})_8]^{2-}$ at

1499 and 1501 cm^{-1} with contributions from pyrrole C=C, aza C=N and isoindole stretches is observed as the strongest scattering in the Raman spectra of $Ce(Pc)_2$ and $Ce[Pc(OC_8H_{17})_8]_2$. As noted above, a similar strong band due to $Pc^{\cdot-}$ and $[Pc(OC_8H_{17})_8]^{\cdot-}$ has been found to upshift to 1502–1509 and 1504–1527 cm^{-1} in the Raman spectra of $M^{III}(Pc)_2$ and $M^{III}[Pc(OC_8H_{17})_8]_2$.

3.2. Raman characteristics of $M(Pc)_2$ and $M[Pc(OC_8H_{17})_8]_2$ (M = Y, La–Lu except Pm) with excitation by laser line at 785 nm

Strong fluorescence occurred when trying to record the Raman spectra of $M(Pc)_2$ (M = La, Ce, Lu) using excitation at 785 nm, so these data do not appear in Table 3.

Using the excitation laser line at 785 nm that is far away from resonance with the *Q* absorption bands, as shown in Fig. 7 and summarized in Table 3, the macrocyclic ring deformation and ring radial vibrations between 500 and 1000 cm^{-1} in the Raman spectra of $M(Pc)_2$ are selectively intensified. This is in good accordance with the Raman characteristics of homoleptic $M(Pc)_2$ reported by Homborg [6b], especially with excitation at 1064 nm. The Pc breathing at 675–679 cm^{-1} and the aromatic C–H wagging at ca. 739 cm^{-1} are the most intense bands. The band locating at 1327–1329 cm^{-1} with medium intensity is assigned to the pyrrole C=C stretchings coupled with benzene C=C stretchings and the weak one at about 1342 cm^{-1} to the isoindole stretchings. Similar to those excited with 633 nm laser line, the frequencies of the coupled pyrrole C=C and aza C=N stretchings in the region of 1507–1521 cm^{-1} overlap to form a broad, unresolved envelope. The vibrations of $M(Pc)_2$ at 675–679 cm^{-1} assigned to the Pc breathings, at 1407–1422 cm^{-1} attributed to the isoindole stretchings, and at 1508–1521 cm^{-1} due to the coupling of aza and pyrrole stretchings are found to shift to higher energy along with the ionic radius contraction.

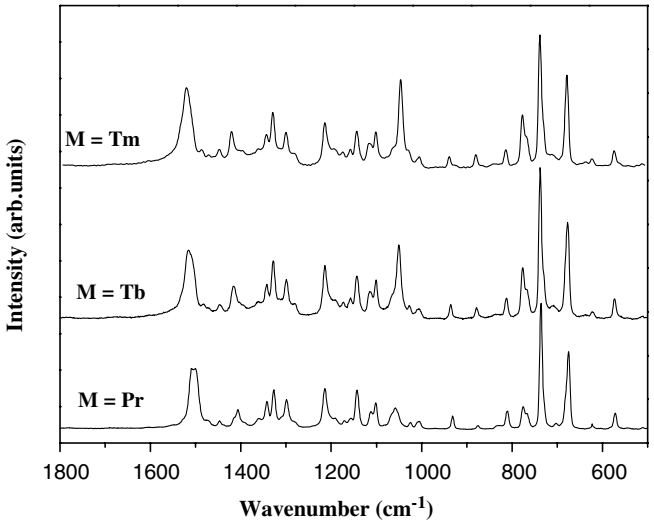

Fig. 7. Raman spectra of $M(Pc)_2$ (M = Pr, Tb, Tm) in the region of 500–1800 cm^{-1} with excitation at 785 nm.

Under the same laser line excitation of 785 nm, the Raman spectra for the octa(octyloxy)-substituted bis(phthalocyaninato) rare earth analogues $M[Pc(OC_8H_{17})_8]_2$ basically take the same spectroscopic features with corresponding unsubstituted counterparts $M(Pc)_2$. Their Raman spectroscopic frequencies with assignments are tabulated in Table 4.

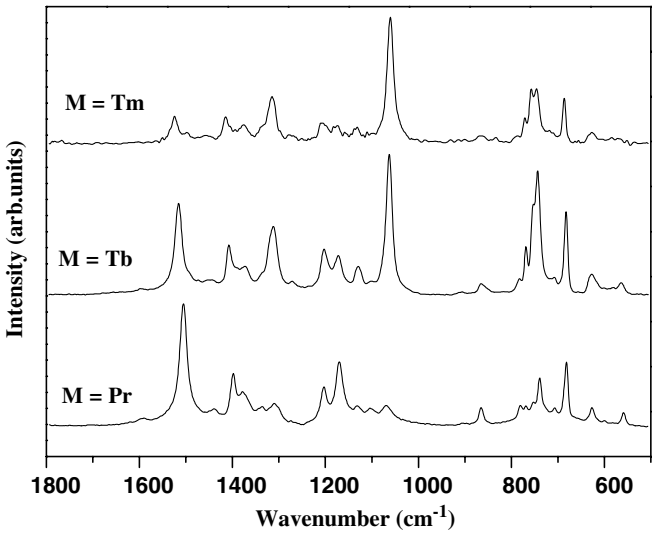

Fig. 8. Raman spectra of $M[Pc(OC_8H_{17})_8]_2$ (M = Pr, Tb, Tm) in the region of 500–1800 cm^{-1} with excitation at 785 nm.

However, this time a systematic but rather more dramatic change could be seen in the appearance of the Raman spectra across the series. Along with the decrease in the ionic size from La to Lu, the band at 1502–1528 cm^{-1} contributed from the coupling of the pyrrole and aza stretchings gradually loses some intensity, changing from a very strong scattering for the light rare earth compounds to a medium and weak one for the heavy rare earth complexes. In the same order, the band at ca. 1060 cm^{-1} assigned to the C–H bendings in contrast gradually gains some intensity to change from a weak band to an intense band. It is worth noting that similar change in the intensity of the latter band at ca. 1050 cm^{-1} due to the C–H bendings was also observed in the Raman spectra of $M^{III}(Pc)_2$ under the same laser line excitation. However, the change in the intensity of the former band for $M^{III}(Pc)_2$ was not so significant. All these results can be clearly exemplified by the Raman spectra of the Pr, Tb, and Tm complexes of the two series shown in Figs. 7 and 8.

When exciting the Raman spectrum of $Ce[Pc(OC_8H_{17})_8]_2$ with 785 nm laser line, similar to the case by means of 633 nm laser line, a Raman spectrum with different characteristics from those of the rest of the rare earth series was obtained. The intense band at 1498 cm^{-1} with contribution from both pyrrole C=C and aza C=N stretches together with isoindole stretchings is the marker Raman band of $[Pc(OC_8H_{17})_8]^{2-}$, which compares with that of $[Pc(OC_8H_{17})_8]^{\bullet-}$ at 1502–1528 cm^{-1} in the Raman spectra of $M^{III}[Pc(OC_8H_{17})_8]_2$ under the same excitation.

4. Conclusions

The Raman spectra for two series of homoleptic bis(phthalocyaninato) rare earth complexes $M(Pc)_2$ and $M[Pc(OC_8H_{17})_8]_2$ have been recorded under excitation with 633 and 785 nm laser lines. The present results are in line with those reported for related series of complexes, namely $M(Pc)[Pc(\alpha\text{-}OC_5H_{11})_4]$ and M(TClPP)(Pc), recorded under similar laser line excitations, in terms of the Raman spectroscopic characteristics of phthalocyanine ligand and the relationship between the phthalcyanine Raman characteristics and the rare earth ionic size. They also provide a good and, more importantly a systematic, experimental basis for further investigation by theoretical chemists in this field.

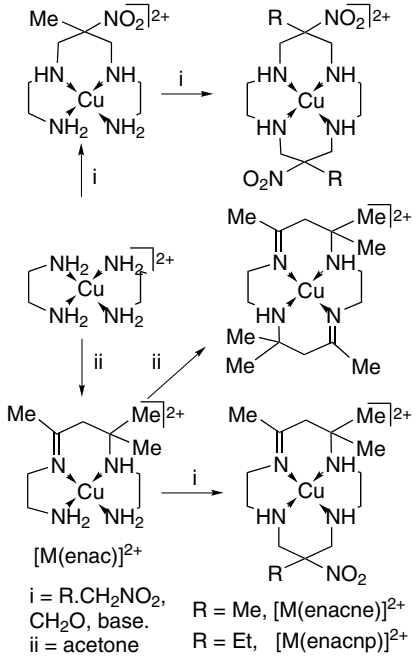

Scheme 1. Reactions of $[Cu(en)_2]^{2+}$ and $[Cu(enac)]^{2+}$ with methanal plus nitroethane [4] or nitropropane (i) or with acetone (ii) [21–25].

Terminal primary amine functions of bis(diamine) and linear tetraamine complexes of copper(II) and nickel(II) can also be linked by reaction with acetone (or related carbonyl compounds) [21]. Reactions of bis(ethane-1,2-diamine) compounds with acetone initially form compounds of the 2,3,2-tetradentate imine-triamine ligand 4,6,6-trimethyl-3,7-diazanon-3-ene-1,9-diamine, enac [22–25]. Structures of $[Cu(enac)][ZnCl_4]$ [26] and $[Ni(enac)(NO_2)]ClO_4$ have been reported [25]. Further reactions with acetone lead to hexamethyl substituted diamine diimine azamacrocycle compounds.

This communication reports reactions of $[Cu(enac)]^{2+}$ with methanal and nitroethane (or nitropropane) to form the 13-methyl-13-nitro- and 13-ethyl-13-nitro-substituted 1,8,11-tri-(secondary amine)-4-imine macrocycle cations 5,7,7,13-tetramethyl-13-nitro-1,4,8,11-tetraazacyclotetradec-4-ene, $[Cu(enacne)]^{2+}$ (or the 13-ethyl-5,7,7-trimethyl-13-nitro-homologue, $[Cu(enacnp)]^{2+}$). The structure of $[Cu(enacnp)(H_2O)](ClO_4)_2$ is reported. Structures of copper(II) compounds with 13 [5], 14 [3], 15 and 16 [5,7] membered nitro-substituted azamacrocycles formed by reaction of copper(II) compounds of linear tetraamines, methanal and nitroethane have been described. The structure of a tetracyanonickelate(II) compound of $[Cu(enacnp)]^{2+}$ has been reported [27].

An improved preparation of the $[Cu(enac)](ClO_4)_2$ starting material is reported.

2. Results

$[Cu(enac)](ClO_4)_2$ reacts with methanal plus nitroethane or nitropropane in water, or methanol, with base to form nitro-substituted imine-triamine macrocyclic products (see Scheme 1). These have properties similar to those of previously reported imine-amine azamacrocycle compounds, in particular their resistance to acid demetallation.

The macrocyclic cations form orange perchlorate salts, which also occur as blue-mauve ammine adducts and hydrates; the structural study of $[Cu(enacnp)(H_2O)](ClO_4)_2$ (below) shows an axial interaction with the water molecule. Blue-mauve colours of the tetrachlorozincate salts and of compounds $[Cu(L)(X)]ClO_4 \cdot xH_2O$ $(X^- = NCS^-, NO_2^-)$ are also indicative of axial interactions.

2.1. Structural study

The structure of $[Cu(enacnp)(H_2O)](ClO_4)_2$ was determined by X-ray diffractometry, see Section 5 for details. The cation, (Cu1), is shown in Fig. 1. The C4–N5 distance (see Table 1) and the angles about these atoms confirm the presence of the imine function. The copper(II) ion is in square-planar coordination by the imine, N4, and three secondary amine, N1, N8 and N11, nitrogen atoms of the enacnp azamacrocycle, with water oxygen O3 weakly, and perchlorate oxygen atom O11 very weakly, interacting in the axial sites.

The structure of a compound of formal composition $[Cu(enacnp)] \cdot [Ni(CN)_4] \cdot 2.5H_2O$ has been reported [26]. This has as asymmetric unit two centrosymmetric trinuclear cations $[(enacnp)Cu–\mu(NC)–Ni(CN)_2–\mu(CN)–Cu(enacnp)]^{2+}$, (Cu2), and $[(H_2O)(enacnp)Cu–\mu(NC)\text{-}Ni(CN)_2–\mu(CN)–Cu(enacnp)(OH_2)]^{2+}$, (Cu3), plus independent $[Ni(CN)_4]^{2-}$ anions and water molecules. All three $[Cu(enacnp)]^{2+}$ cations (Cu1), (Cu2) and (Cu3), have the copper(II) ion in flattened square pyramidal coordination by the imine and three secondary amine nitrogen atoms of the macrocycle, with weak axial coordination: by water and perchlorate oxygen atoms for cation (Cu1), by an isocyano bridging nitrogen atom and perchlorate oxygen atom for cation (Cu2) and by water oxygen and the isocyano bridging nitrogen atom for cation (Cu3). The principal dimensions of these three cations are shown in Table 1. The Cu–N distances for the cations are in good agreement, with the $Cu–N_{imine}$ distance ca. 0.03 Å shorter than the mean of

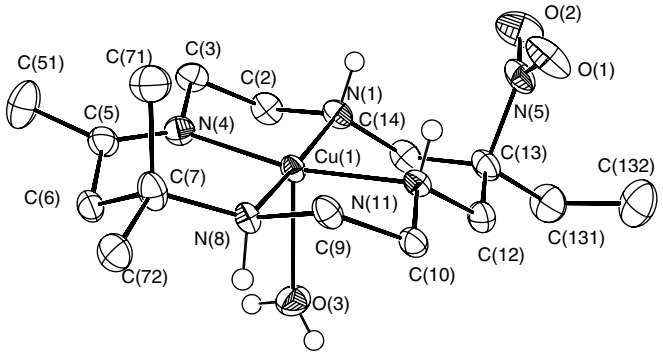

Fig. 1. The cation $[Cu(enacnp)(H_2O)]^{2+}$, drawn [28] with displacement ellipsoids at the 50% confidence level. Hydrogen atoms are shown as circles of arbitrary radius.

Table 1
Geometric parameters (Å, °) for $[Cu(enacnp)(H_2O)](ClO_4)_2$ {cation (Cu1)} and $[\{Cu(enacnp)\}_2Ni(CN)_4]$[j] $[\{Cu(enacnp)(H_2O)\}_2Ni(CN)_4]$[k] · $2[Ni(CN_4)] \cdot 8H_2O$

Dimension	Cation (Cu1)	Cation (Cu2)	Cation (Cu3)

[c] Distance to N of bridging cyanide.
[d] Distance to O of water.
[e] Distance Cu to further atom in axial position.
[f] Distance to O of perchlorate.
[g] Distance to O of water.
[h] Mean displacement from least squares plane of the imine and three amine N atoms.
[i] Displacement of Cu from the N_4 plane in 'mean displacement from least squares plane of the imine and three amine N atoms' towards the closer axial donor atom.
[j] {Cation (Cu2)}.
[k] {Cation (Cu3)} [26].

the Cu–N_{amine} distances. The distances and angles within the CuN_4 coordination group are consistent for the three differing axial environments, the most significant variation being in the extent of tetrahedral twisting of this group. Cations Cu(1) and Cu(2) have one closer and one very distant axial interaction, with similar closer axial donor distances {Cu–O for (Cu1) and Cu–N_{axial} for (Cu2)}. Cation (Cu3) has a more symmetrical axial environment with Cu–O and Cu–N_{axial} distances, intermediate to those of (Cu1) and (Cu2). The three cations have the same 1*RS*,8*RS*,11*SR* configuration and similar conformations of the azamacrocycles, with one methyl of the gem-dimethyl group axially oriented on the same side of the CuN_4 "plane" as the nitro-group (Table 2). The closer axial ligands for the three cations are coordinated on the other, less crowded side, of the plane.

Table 2
Displacements of atoms from CuN_2 planes for chelate rings for $[Cu(enacnp)(H_2O)](ClO_4)_2$

Atoms defining plane	Displacement (Å)
Cu,N1,N4	C2 0.480(4); C3 −0.200(4)
Cu,N8,N11	C9 −0.398(4); C10 0.332(3)
Cu,N4,N8	C5 0.082(4); C6 0.480(4); C7 −0.354(4); C51 −0.040(6); C71 −1.87(4); C72 −0.060(5)
Cu,N8,N11	C12 0.937(4); C13 0.804(4); C14 0.974(4); C131 1.834(5); C132 1.662(7); N5 −0.569(4)

Table 3
Hydrogen bonding parameters for $[Cu(enacnp)(H_2O)](ClO_4)_2$ (Å, °)

Atoms	D–H	H···A	D···A	D–H···A
N11–H11···O1	0.91	2.32	2.910(3)	123
N11–H11···O1[i]	0.91	2.33	3.068(3)	138
N1–H1···O11	0.91	2.11	3.014(3)	170
N8–H8···O22	0.91	2.44	3.201(3)	141
N11–H11···O14	0.91	2.47	3.072(3)	124
O3–H3A···O11[ii]	0.82	1.97	2.783(3)	169
O3–H3B···O21[iii]	0.81	2.04	2.810(3)	158

Symmetry operations: i: $-x+2, -y, -z+1$; ii: $x, -y+1/2, z-1/2$; iii: $-x+2, -y, -z$.

For all three cations the six-membered chelate ring including Cu,N1,N11 has a chair conformation with the NO_2 substituent axially oriented (see Table 2). The six-membered amine-imine chelate ring including Cu,N5,N8 has a half-chair conformation with one component of the gem-dimethyl group axially oriented, on the same side of the CuN_4 plane as the nitro group. The five-membered chelate rings have gauche conformations.

For $[Cu(enacnp)(H_2O)](ClO_4)_2$ the nitro-group oxygen O1 is linked to N11–H11 by an intramolecular hydrogen bond and to N11–H11 ($-x+2, -y, -z+1$) by an intermolecular hydrogen bond. All NH and water OH groups hydrogen bond to perchlorate oxygen atoms to form an H-bonding network (see Table 3).

The structure of a compound obtained from the reaction of (3,7-diazanonan-1,9-diamine)copper(II) perchlorate with methanal and nitroethane has been reported [3]. This has a chain polymeric structure, with alternating square-planar (6-methyl-6-nitro-1,4,8,11-tetraazacyclotetradecane)copper(II) and (3,7-diazanonane-1,9-diamine) copper(II) cations, linked by perchlorate ions. The Cu–N distances for the azamacrocycle cation are 2.013(6) and 2.017(5) Å (nitro-substituted chelate ring) and 1.995(6) and 1.999(6) Å (unsubstituted chelate ring), with axial Cu–O distances 2.539(7) and 2.577(6) Å.

3. Conclusions

The facile reaction of $[Cu(enac)]^{2+}$ with nitroalkyls plus methanal to form the nitro-substituted imine-triamine macrocycles completes a set of azamacrocycle compounds formed by cyclization of the bis(ethane-1,2-diamine)copper(II) cations by condensations with acetone or with methanal/nitroalkyls, as represented in the reaction scheme.

4. Experimental

4.1. Preparations of compounds

The perchlorate compounds described are potentially explosive and should be treated with caution, particularly the ethanediamine starting material. However, the enac, enacne and enacnp compounds have shown no indication of shock sensitivity and decompose non-violently if strongly heated.

4.1.1. (4,6,6-Trimethyl-3,7-diazanon-3-ene-1,9-diamine)-copper(II) perchlorate, [Cu(enac)](ClO$_4$)$_2$

Improvements have been made to the reported [21–23] preparations of [Cu(enac)](ClO$_4$)$_2$. [Cu(en)$_2$](ClO$_4$)$_2$ (20 g), 2-aminoethanol (0.5 g), methanol (50 cm^3) and acetone (50 cm^3) were heated near boiling for ca. 24 h. The solution was filtered through activated charcoal and rotary evaporated. The resulting purple gum was dissolved in water (50 cm^3), filtered through charcoal and again evaporated, to leave a purple gum. Methanol (30 cm^3) was added when the purple product slowly crystallized (nucleation with the preformed compound speeds this process). The product was filtered off and washed with ethanol, yield ca. 90%. The product so prepared was satisfactory for the preparations below but could be recrystallised from hot methanol. The use of 2-aminoethanol in the preparation of [Cu(enac)]Cl$_2$ has been reported [29].

4.2. Macrocyclic compounds

The macrocyclic cations are resistant to acid demetallation (but are rapidly oxidized by nitric acid). They are slowly degraded in alkaline solution. The infrared spectra all show ν(NH) band(s) near 3200 cm^{-1}, and sharp peaks assigned to ν(N=C) near 1665 cm^{-1} and ν(NO$_2$) (more intense) near 1550 cm^{-1}.

4.2.1. (5,7,7,13-Tetramethyl-13-nitro-1,4,8,11-tetraazacyclotetradec-4-ene)copper(II) perchlorate, [Cu(enacne)](ClO$_4$)$_2$

[Cu(enac)](ClO$_4$)$_2$ (9.26 g), nitroethane (1.6 g), methanal (formaldehyde, 3.5 cm^3 of 37% aqueous solution 1: 1.5: 3 mol ratios) and sodium hydrogen carbonate (0.5 g) were heated in water (100 cm^3) at ca. 80 °C. for 2 h. The solution was filtered while hot through activated charcoal and perchloric acid (1 g of 60% aqueous solution, sufficient to neutralise the NaHCO$_3$) was added. The product was filtered from the cold solution and washed with ethanol. The filtrate was rotary evaporated to leave a purple gum that was triturated with hot ethanol (25 cm^3) when more product crystallised. The magenta coloured *product* was recrystallised from hot acetonitrile (in which it is very soluble)/propan-2-ol or acetone: water (10:1)/propan-2-ol. Yield: 85%. *Anal.* Calc. for C$_{14}$H$_{29}$Cl$_2$CuN$_5$O$_{10}$: C, 29.9; H, 5.3; N, 12.3. Found: C, 30.0; H, 5.3; N, 12.3%. Visible spectrum in water {λ_{max}/nm (ε/dm^3 mol^{-1} cm^{-1})}: 514 (129). IR spectrum (ν_{max}/cm^{-1}): ν(NH) 3236; ν(C=N) 1663; ν(NO$_2$) 1553. A purple ammine adduct which crystallised from concd. aqueous ammonia retained the ammonia at 110 °C.

4.2.2. (13-Ethyl-5,7,7-trimethyl-13-nitro-1,4,8,11-tetraazacyclotetradec-4-ene)copper(II) perchlorate (and hydrate), [Cu(enacnp)](ClO$_4$)$_2$ and [Cu(enacnp)(H$_2$O)](ClO$_4$)$_2$

This compound was prepared as for the previous compound by using 1.9 g of nitropropane in place of the nitroethane. It crystallized in similar yield, as a mono-hydrate from solvent mixtures containing water or as the unhydrated salt from dry solvents. *Anal.* Calc. for C$_{15}$H$_{33}$Cl$_2$CuN$_5$O$_{11}$: C, 30.4; H, 5.8; N, 11.3. Found for hydrate: C, 30.4; H, 5.7; N, 11.3%. Visible spectrum in water {λ_{max}/nm (ε/dm^3 mol^{-1} cm^{-1})}, 447 (129). IR spectrum (ν_{max}/cm^{-1}): ν(NH) 3236; ν(C=N) 1663; ν(NO$_2$) 1553.

4.2.3. (5,7,7,13-Tetramethyl-13-nitro-1,4,8,11-tetraazacyclotetradec-4-ene)copper(II) tetrachlorozincate, [Cu(enacne)][ZnCl$_4$]

Zinc chloride was added to a hot solution of [Cu(enacne)](ClO$_4$)$_2$ in acetonitrile, followed by propan-2-ol. The mauve product was filtered off, washed with ethanol and recrystallised from hot methanol. *Anal.* Calc. for C$_{14}$H$_{29}$Cl$_4$CuN$_5$Zn: C, 29.5; H, 5.1; N, 12.3. Found: C, 29.6; H, 5.0; N, 12.1%.

4.2.4. (5,7,7,13-Tetramethyl-13-nitro-1,4,8,11-tetraazacyclotetradec-4-ene)thiocyanatocopper(II) Perchlorate Hydrate, [Cu(enacne)(NCS)]ClO$_4$ · H$_2$O

Sodium thiocyanate was added to a hot aqueous solution of [Cu(enacne)](ClO$_4$)$_2$. The blue product was filtered from the cold solution and recrystallised from hot methanol. *Anal.* Calc. for C$_{15}$H$_{31}$ClCuN$_6$O$_5$S: C, 35.6; H, 6.2; N, 16.6. Found: C, 35.2; H, 6.0; N, 16.8%. IR spectrum (ν_{max}/cm^{-1}): ν(OH) 3470; ν(NH) 3262, 3232; ν(C≡N) 2060vs; ν(C=N) 1662; δ (HOH) 1644; ν(NO$_2$) 1539.

4.2.5. Nitrito(5,7,7,13-tetramethyl-13-nitro-1,4,8,11-tetraazacyclotetradec-4-ene)copper(II) perchlorate, [Cu(enacne)(ONO)]ClO$_4$

This mauve coloured compound was prepared as for the thiocyanate, by using sodium nitrite. *Anal.* Calc. for C$_{15}$H$_{29}$ClCuN$_6$O$_6$: C, 33.1; H, 5.7; N, 16.5. Found: C, 33.2; H, 5.7; N, 16.6%. IR spectrum (ν_{max}/cm^{-1}): ν(NH) 3205, 3114; ν(C=N) 1669; ν(NO$_2$) 1540; ν_{as}(NO$_2^-$) 1272.

5. Crystallography

Diffraction data were collected for a dark purple plate (0.32 × 0.23 × 0.12 mm) of aqua-(13-ethyl-5,7,7-trimethyl-13-nitro-1,4,8,11-tetraazacyclotetradec-4-ene)copper(II) perchlorate, grown from water, [Cu(enacnp)(H$_2$O)](ClO$_4$)$_2$, C$_{15}$H$_{33}$Cl$_2$CuN$_5$O$_{11}$, M_r = 593.91. The crystal was monoclinic, space group $P2_1/c$, a = 11.247(3) Å, b = 15.321(5) Å, c = 14.323(6) Å, β = 97.22(2)°. Data were collected at 120(2) K, by using a SMART 1K CCD diffractometer [30] with fine focus sealed tube Mo Kα radiation (λ = 0.71073 Å) using ω scans. Multi-scan absorption corrections [31] were applied T_{min} = 0.617, T_{max} = 0.773. About 26 288 reflections (average R_{equiv} = 0.0467) were collected, $-14 < h < 14$; $-19 < k < 19$; $-18 < l < 18$; $1.83 < \theta < 27.48°$; with 5615 unique reflections, 4947 reflections with $I > 2\sigma(I)$. The structure was solved and refined on F^2 using SHELXTL [32], with H(C) and H(N) atoms in calculated positions and riding. H(O) atoms were located and their positions refined with restrained O–H distances. R_1 ($2\sigma(I)$) = 0.037, R_1 (all) = 0.043, R_w ($2\sigma(I)$) = 0.090, R_w (all) = 0.095

$(w = 1/[\sigma^2(F_o^2) + (0.0417P)^2 + (3.54P)]$ where $P = (F_o^2 + 2F_c^2)/3)$.

Appendix A. Supplementary data

Crystallographic data have been deposited with the Cambridge Crystallographic Data Centre for this structure; CCDC 277465. Copies may be obtained free of charge from the Director, CDCC, 12 Union Road, Cambridge CBZ 1EZ, UK (fax: +44 1223 336 033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.uk). Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2005.08.037.

use the diamagnetic gold complex, bis(cyanoimidodithiocarbonate)aurate(III), abbreviated as $Au(cdc)_2$, which was previously used in the preparation of a molecular conductor, by combination with perylene [7].

2. Experimental

2.1. Synthesis and electrocrystallisation

Single crystals of (bedt-ttf)[$Au(cdc)_2$] were obtained by electrocrystallisation from solutions of n−Bu_4N[$Au(cdc)_2$] and bedt-ttf ($\approx 10^{-3}$ M) in different solvents: dichloromethane (A), 95% trichloroethane-5% ethanol v/v (B), trichloroethane (C) and 75% trichloroethane-25% THF (D). The gold complex of cyanoimidodithiocarbonate (also known as cyanodithiocarbimate) was prepared according to the procedure of Cotton and McCleverty [8], and recrystallised from acetone. bedt-ttf was synthesised according to the method of Larsen and Lenoir [9]. Solvents were dried and distilled following standard procedures. The electrocrystallisation was carried out in a two-compartment cell with platinum electrodes under galvanostatic conditions using a current density 15 μA cm^{-2} at 30 °C for A and with different current densities at 50 °C for the three other preparations. After ≈7 days, the dark metallic-looking plate-shaped crystals obtained on the anode were filtered off and washed with dichloromethane (trichloroethane for B, C and D). The elemental analyses of the crystalline solids obtained in all batches are within experimental error the same. In a typical elemental analysis performed in a Perkin–Elmer 240 elemental analyser at the analytical service of Instituto Tecnológico e Nuclear was found: C, 21.02; N, 6.62; H, 0.99; Au, 24.2% ($C_{14}H_8AuN_4S_{12}$ requires C, 20.66; N, 6.88; H, 0.99; Au, 24.2%).

2.2. Spectroscopy

Infrared spectra were obtained with a Nicolet SDXC spectrophotometer with FT in the range 4000–200 cm^{-1}. Most intense bands were 2192 (cdc), 1488 (bedt-ttf), 1404 (bedt-ttf), 1024 (cdc), 960 (cdc), 880 (bedt-ttf) cm^{-1}.

2.3. X-ray crystallography

A black crystal from batch A with approximate dimensions $0.25 \times 0.06 \times 0.031$ mm^3 was mounted in a glass capillary on a goniometer head. X-ray data were collected at room temperature on an Enraf-Nonius CAD-4 automatic diffractometer equipped with graphite monochromated Mo Kα radiation ($\lambda = 0.71069$ Å) in the ω-2θ scan mode. Unit cell dimensions and a crystal orientation matrix were obtained from least-square refinement of the setting angles of 25 reflections in the $8° < \theta < 10°$ range.

The unit cell was identified as monoclinic, space group $P2_1/n$. This choice was confirmed by the solution and the successful refinement of the structure. The intensities were corrected for Lorentz and polarisation effects, and an empirical absorption correction (ψ scan) was made. The structure was solved by direct methods using SIR97 [10] and refined by full-matrix least-squares methods using the program SHELXL97 [11] and the winGX software package [12]. All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were placed in calculated positions. Molecular graphics were prepared with ORTEP-3 [13] and SCHAKAL-97 [14]. Crystal data and structure refinement are summarised in Table 1.

2.4. ESR measurements

All ESR signals were recorded as first derivative absorption lines in an X-band Bruker ESP300E spectrometer, equipped with an Oxford Instruments flow cryostat and a goniometer. Anisotropy was studied at room temperature, recording signals at 10° intervals for the three cartesian axis of at least two crystals from each of the four different batches. Then, for chosen orientations, signals were recorded at different temperatures in the range 4.2–300 K. However, variable temperature measurements for samples of two different batches (C and D) could not be obtained because the crystals splintered during cooling.

2.5. Magnetic susceptibility

A powdered sample of batch A was placed into a teflon bucket previously measured and magnetisation data were obtained with an Oxford Instruments Faraday balance system, at a static field of 3.5 T and a gradient of 5 T m^{-1}, in the temperature range 10–300 K

2.6. Electrical resistivity

Demetron 308A platinum paint were measured with an Keithley 619 electrometer in the temperature range 250–350 K, with a current of 0.1 μA. On large crystals, four gold electrodes were attached in a rectangular configuration, in order to use the Montgomery method [15] to test the anisotropy of resistivity.

3. Results

3.1. Crystal structure

The unit cell belongs to the space group $P2_1/n$, with two formula units. The anionic species $[Au(cdc)_2]^-$ was centred at the origin and the bedt-ttf radical cation placed at an inversion centre located midway the central C–C double bond (Fig. 1). The gold dithiocarbimate complex is planar with average deviations from the mean plane of 0.02 Å, with a similar geometry to other complexes of the same ligand [16]. The gold atom is coordinated to four sulphur atoms in a square planar configuration with S–Au bond distances of 2.330 and 2.337 Å, and the S1–Au–S2 angles of 75.22(5)°. The four-membered ring is responsible for this angle being significantly smaller than that of almost 90° usually found in metal bisdithiolates with five-member rings, e.g., $Au(mnt)_2$, [17].

As expected for a Au(III) complex, the C–S bond lengths are typical of single carbon–sulphur bonds. In the cdc ligand, the N(1)–C(2)–N(2) is almost linear – the angle is 175.8(7)° – with bond lengths typical of triple bond for C(2)–N(2), single for C(2)–N(1) and double for C(1)–N(1) (see Table 2).

The bedt-ttf cationic species has a planar central skeleton and terminal ethylene groups deviating from this plane −0.44 Å for C(6) and 0.42 Å for C(7), as it is usual for this molecule, but without positional disorder.

The anionic and cationic species are alternately packed along the *c*-axis (Fig. 2). The bedt-ttf and $Au(cdc)_2$, units are essentially parallel and their best planes almost perpendicular to the *c*-axis, the angle with their planes being of 89.67° and 89.68°, respectively. Multiple short distance contacts between bedt-ttf and the metal complex are noticed (Table 3). Further short contacts between bedt-ttf's H atoms and the anions' N atoms (Table 4) are responsible for the absence of positional disorder of the bedt-ttf ethylene group. Between bedt-ttf units of neighbour columns there are also several short contacts along the *a* direction (Fig. 2).

[A] Normalised values according to [19,20].

The analysis of the bedt-ttf bond lengths in the present compound leads to a δ parameter as proposed by Guionneau et al. [18], $\delta = 0.72$, a value typical of a +1 charge, as inferred from the 1:1 stoichiometry.

3.2. Electrical resistivity

The electrical resistivity is $6.5 \times 10^3\ \Omega$ cm at room temperature and it shows a thermally activated behaviour, from which an energy gap $2\Delta = 0.51$ eV was derived. No significant conductivity anisotropy could be measured by the Montgomery method.

3.3. ESR results

First, we analyse the room temperature anisotropy of the ESR signal. Data collected from the four batches, indicated some differences in the spread of the linewidth between minimum and maximum, although obeying always to a common pattern with a shape of simple Lorentzian line. Samples from batches A and B had linewidth varying between 9 and 15 G, whereas samples from batches C and D, for some orientations, had lines wider than 20 G.

ESR is often used as a non-destructive and easy way to test different phases, which can be present even in the same preparative batch. In the case of many bedt-ttf salts different phases can be discriminated just by the linewidths [1].

To evaluate whether or not we were in the presence of two phases, samples from different batches were checked afterwards by X-ray diffraction. The automatic CAD4 routine always recognised the same unit cell parameters, although in some cases, mainly for batches C and D, the crystals were twinned. Therefore the broader absorption EPR lines are ascribed to this fact, which in turn may depend on the solvent and preparative conditions. Full determination of the crystal structure was made for a sample of batch A, showing no presence of solvent molecules, as discussed above.

As all batches yielded consistently the same elemental (C, H and N) analysis within experimental error, these differences are not attributed to solvent molecules incorporated in the structure.

Anisotropy plots of linewidth and g-value are given in Fig. 3 for rotations around three orthogonal axes indicated. The g-value anisotropy has a simple sinusoidal dependence with an 180° period, different from the linewidth dependence with two maxima in one of the 180° rotation. These two contributions became more visible upon cooling. Indeed below about 50 K at some orientations it is possible to observe two separate lines.

As expected since $Au(cdc)_2^-$ is a diamagnetic anion, the observed g-values are typical of bedt-ttf where the principal values of the g tensor in a static magnetic field are 2.011–2.012 parallel to the molecular long axis, 2.006–2.007 for the short axis and 2.002–2.003 for the normal to the molecular plane [21]. The two lines are attributed to the different orientations of the two bedt-ttf cations within the unit cell

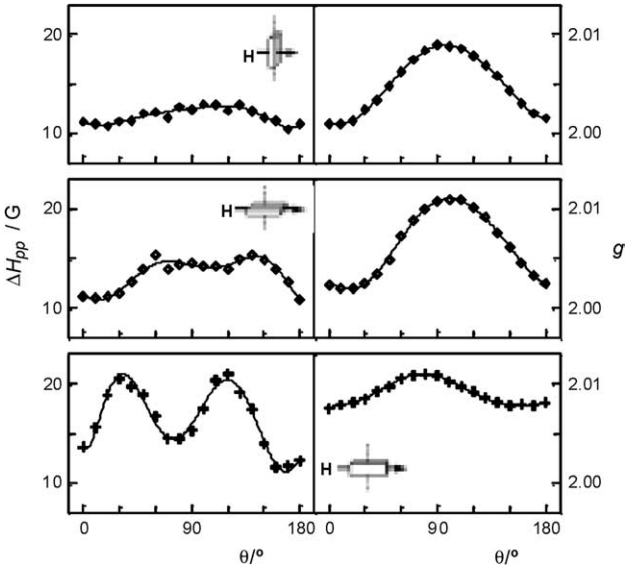

Fig. 3. Linewidth (left) and g-value (right) anisotropy of ESR signal at room temperature.

relative to the magnetic field, which become equivalent only for particular orientations.

We have chosen one orientation for which apparently only a single line is observed and recorded the signals as a function of temperature for different orientations rotated in 45° steps around the same axis. The thermal dependence of *g*-value is shown in Fig. 4 and of the linewidth in Fig. 5, where the data for (+90°) were omitted as they are within error bars coincident with those for 0°.

3.4. Magnetic susceptibility measurements

Results of paramagnetic susceptibility calculated from Faraday balance measurements assuming a diamagnetism estimated as -3.05×10^{-4} emu/mol, from tabulated Pascal's constants are displayed in Fig. 6, together with the integrated signal intensity from ESR measurements of two different crystals, from batches A and B, at the same orientation, which were normalised at room temperature as being equal to the value of the static paramagnetic susceptibility. Slightly different temperature dependences are noticed only below ~60 K. Such differences may come from a variable contributions to the Curie tail, that is larger for crystal B and the polycrystalline sample used in Faraday balance (from batch A).

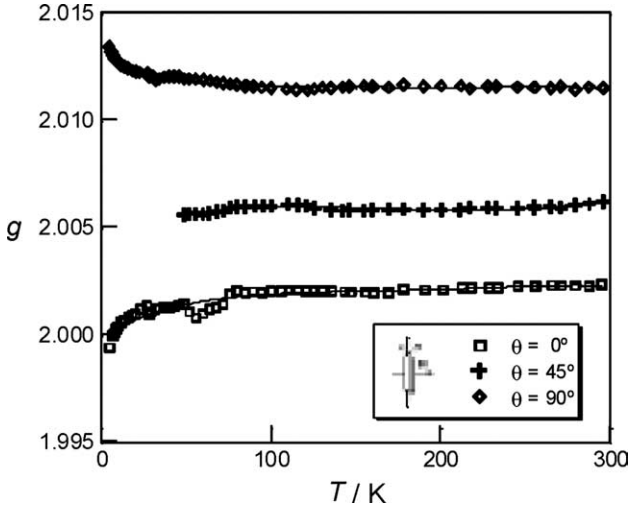

Fig. 4. Temperature dependence of the *g*-value for three different crystal orientations.

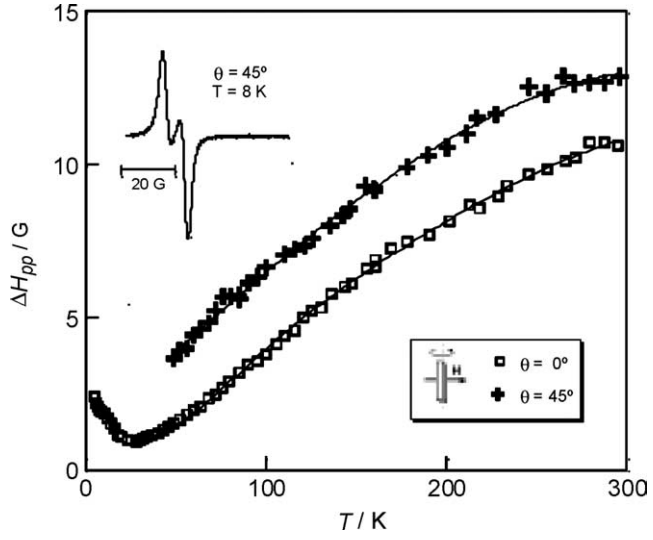

Fig. 5. Thermal dependence of ESR signal linewidth for two orientations. At 45°, two lines are observed below 50 K.

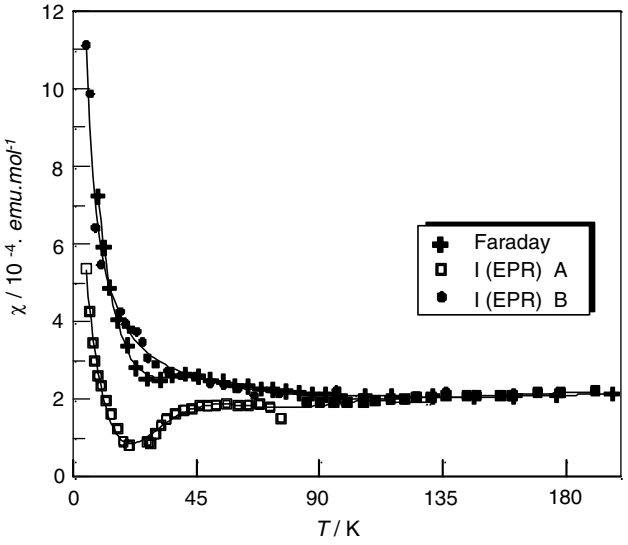

Fig. 6. The thermal dependence of the static magnetic susceptibility (crosses) compared with the ESR signal intensity (normalised) for two samples.

Assuming that the susceptibility has two contributions, one intrinsic and another a Curie tail due to impurities with different extent from sample to sample, we removed this last contribution from the different measurements and obtained for the intrinsic susceptibility always a similar behaviour with an exponential decay below 40 K corresponding to a magnetic excitation gap of $\Delta/k_B = 87 \pm 3$ K.

It is worth noting that at higher temperatures ($T > 50$ K) the paramagnetic susceptibility, is rather small ($\sim 2.5\times10^{-4}$ emu/mol at room temperature) and almost temperature independent. This is reminiscent of the Pauli contribution characteristic of conducting systems. However, the low value of the electrical conductivity ($1.5\times10^{-4}\ \Omega^{-1}\,cm^{-1}$) and its semiconducting behaviour with a large energy gap (0.51 eV) rule out such assignment. It should be also mentioned in this respect that similar high temperature behaviours were found in other non-conducting systems [22]. Amongst the bedt-ttf insulators this is a very low room temperature value of χ_p, which are mostly closer to 10^{-3} emu/mol, although a lower value of 10^{-4} emu/mol was found for (bedt-ttf)$HgBr_3$ [23].

4. Discussion and conclusions

The results show that we are in presence of a semiconducting system, and the poor electrical conductivity is

mainly a consequence of the alternated packing of bedt-ttf radical cations and bis-dithiolate anions. Even if the different short (bedt-ttf) contacts, namely along *a*, would lead to significant electronic interactions and a reasonable bandwidth, the stoichiometry makes the system half filled, a situation where an insulating regime is always expected as a consequence of the strong correlation effects dominated by large on-site Coulomb repulsions.

The metallic behaviour, sometimes with superconducting transitions at low temperatures, occurs in bedt-ttf salts where the donor molecules are partially oxidised and well segregated, usually in layers. The alternated stacking seems to stabilise the full oxidation of bedt-ttf in 1:1 salts. This is also the case of other bedt-ttf salts with metal-bis(dithiolates) such as $Ni(mnt)_2$ or $Ni(dmit)_2$, which nevertheless present differences in the packing mode. In spite of the lower symmetry of $Au(cdc)_2$, its salt is of higher symmetry (monoclinic), whereas it is triclinic in the former cases. As in the $Ni(dmit)_2$ compound, the bedt-ttf and the dithiolate species are almost parallel [24], at variance with the $Ni(mnt)_2$ compound [25] where the angle between the mean planes of radical cation and anion moieties is ca. 50°.

We have seen above that a consequence of short distance contacts between the radical cations and the anionic species through peripheral sulphur atoms inhibits the positional disorder of methylene groups characteristic of many bedt-ttf compounds. These short contacts are also responsible for the observed magnetic properties. In fact, in the absence of significant interactions, a Curie–Weiss type magnetic susceptibility due to localised $S = 1/2$ spins in each bedt-ttf cation would be expected. This is not the case and the small and almost temperature independent paramagnetism observed denotes the existence of a complex 3D network of antiferromagnetic interactions. These antiferromagnetic interactions can be either mediated through the alternating anions, mainly along *c*, and also associated with the network of short contacts between cations in neighbouring columns along *a*. There are a few cases where the antiferromagnetic interactions (J values) were estimated from the intermolecular overlap integrals [26]. This was done for 2:1 bedt-ttf salts in the Mott insulator regime. A similar study for 1:1 insulators is worth to be fulfilled, but it is beyond the scope of the present article.

The variation of the extreme *g*-values, the increase of linewidth and the exponential decay of susceptibility, all observed below 25 K can be associated with a structural modification involving small alteration of the bedt-ttf packing.

Finally, it should be mentioned that the present study shows that the small temperature independent paramagnetism in molecular compounds is not an exclusive attribute of metallic systems and it can be found also in insulators.

Supplementary crystal structure data was deposited in CCDC under No. 207760, and are available on request to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: (internat.) +44 1223/336 033; e-mail: deposit@ccdc.cam.ac.uk).

structures containing this ligand [7]. Of these the 1,6-bridging mode, which favors the formation of the coordination polymers, is the most common. The phthalate ligand can also take part in additional weak hydrogen bonding, which stabilizes the polymeric structures by forming two- and three-dimensional networks. We have shown that a successful preparation of coordination polymers is based on a suitable choice of combinations of the phthalate bridging ligand and different amines, such as pyridine, imidazole and its derivatives, 2,2′-bipyridine, and 1,10-phenanthroline, which act as terminal ligands. Depending on both the nature of the amines and the stoichiometric ratio metal:acid:amines, infinite linear [4], zigzag [5,6] or helical [8,10] chains are formed.

Oxidation reactions have synthetic applications in both the chemical and pharmaceutical industries. The catalytic oxidation of alkenes has potentially important industrial applications since the selective oxidation products serve as starting materials for the production of many fine chemicals. Oxidation can be carried out with many different oxidants, but from an economic point of view H_2O_2 is ideally suitable. It is cheap, readily available and environmentally benign. A large effort is thus currently in progress to try to find active catalysts for the oxidation reactions using this oxidant. Several families of catalysts are known, mainly based on various transition-metal complexes as titanium, vanadium, molybdenum, manganese, tungsten and rhenium complexes [49]. The cobalt-catalyzed decomposition of hydroperoxides has also been extensively studied [50], but catalytic oxidation catalyzed by copper complexes is comparatively rare. Recently, a series of reports have been published showing that β-carbonylenolate, β-diketonate and β-ketamidate copper(II) complexes [51,52] and mixed-ligand salicylaldehyde copper(II) complex [53] can be used for catalytic oxidation cyclohexene under Mukaiyama's conditions. Some copper-based catalysts have also been reported to be active in the presence of H_2O_2 [54,55].

The present work reports the synthesis of two phthalate based copper(II) and cobalt(II) coordination polymers using imidazole (Im) as the amine, $\{[Cu(Pht)(Im)_2]\cdot 1.5H_2O\}_n$ (**1**) and $[Co(Pht)(Im)_2]_n$ (**2**), their crystal structures and presents a preliminary investigation into the catalytic activity of **1** and **2** towards the oxidation of cyclohexene using hydrogen peroxide as oxidant under aerobic conditions.

2. Experimental

2.1. Materials and methods

All the starting materials were reagent grade and used as purchased. Hydrogen peroxide (30% aqueous solution) was used as received from Acros. The infrared spectra were recorded on a Perkin–Elmer Spectrum One spectrometer using KBr pellets in the region 4000–400 cm^{-1}. Gas chromatographic analyses were carried out with a HP 5890 instrument on a RTX-5 column 30 m × 0.25 mm × 0.5 μm fitted with a flame ionization detector, and hydrogen gas pressure was 0.4 bar.

2.2. Synthesis of complexes

2.2.1. Synthesis of $\{[Cu(Pht)(Im)_2]\cdot 1.5H_2O\}_n$ (1)

Method A. To a hot suspension of *o*-phthalic acid (0.66 g, 4 mmol) and $CuCO_3\cdot Cu(OH)_2$ (0.44 g, 2 mmol) in 40 ml H_2O was added Im (0.55 g, 8 mmol). The resulting blue mixture was stirred and refluxed for 30 min and then filtered. The filtrate was allowed to stand at room temperature. Blue crystals, suitable for X-ray analysis, were filtered off the next day, washed with water, ethanol and acetone, and dried in air. Yield: 0.87 g (56%). *Anal*. Calc. for $C_{28}H_{26}Cu_2O_{11}N_8$: C, 43.02; H, 3.87; N, 14.33; Cu, 16.26. Found: C, 43.09; H, 3.71; N, 14.08; Cu, 16.20%. IR data (KBr, cm^{-1}): 3479m, 3380m, 3137s, 3067m, 2959m, 2871m, 1616vs, 1587vs, 1570vs, 1539sh, 1506sh, 1485m, 1443m, 1385vs, 1370vs, 1330m, 1263w, 1182w, 1148w, 1071s, 955w, 859m, 829m, 750s, 719m, 705m. The compound is insoluble in alcohol, acetone, acetonitrile, chloroform, and poorly soluble in water.

Method B. To a hot solution of *o*-phthalic acid (0.83 g, 5 mmol) and Im (0.69 g, 10 mmol) in 20 ml H_2O was added $Cu(CH_3COO)_2\cdot H_2O$ (0.99 g, 5 mmol). The resulting blue solution was heated for 10 min and allowed to stand at room temperature. Blue crystals formed after 1–2 days. They were filtered off, washed with water, ethanol and acetone, and dried in air. Yield: 0.82 g (42%). It was identified by comparing its IR spectrum with the crystallographically characterized precipitate from Method A, and elemental analysis. *Anal*. Found for the title compound: C, 42.69; H, 3.77; N, 13.80; Cu, 15.72%.

2.2.2. Synthesis of $[Co(Pht)(Im)_2]_n$ (2)

To a hot solution of H_2Pht (0.83 g, 5 mmol) and Im (0.69 g, 10 mmol) in water (15 ml) $Co(O_2CMe)_2\cdot 4H_2O$ (1.25 g, 5 mmol) was added. The resulting mixture was stirred and heated for 20 min. The lilac precipitate so formed was filtered off from hot solution, washed with hot water, ethanol and acetone and dried in air. Yield: 0.84 g (46.8%). *Anal*. Calc. for $C_{14}H_{12}CoN_4O_4$: C, 46.81; H, 3.37; N, 15.60; Co, 16.41. Found: C, 46.72; H, 3.32; N, 15.49; Co, 16.33%. IR data (KBr, cm^{-1}): 3137s, 3062m, 2970m, 2880m, 1612s, 1589vs, 1579sh, 1486m, 1460m, 1444m, 1394s, 1373vs, 1329m, 1267m, 1144m, 1107m, 1075vs, 957m, 914w, 840m, 752s, 702m, 656vs, 620m, 606w, 573w, 482m. Single crystals suitable for diffraction studies were obtained by recrystallization of **2** from hot aqueous solution.

2.3. Crystal structure determinations

Experimental data were collected on Bruker-Nonius KappaCCD and KUMA KM4CCD-κ-axis diffractometers using graphite monochromated Mo Kα radiation at 100 K for **1** and 293 K for**2**. The crystals were located 40 mm (**1**)/ 60 mm (**2**) from the CCD camera. 446/444 Frames were collected in 2/4 runs with a 0.5/0.5° scan width and 150 s/10 s per frame. The data were processed using the SAINT program from Bruker-Nonius (Madison, USA) and KUMA diffraction (Wroclaw, Poland) software. Crystal data, details of data collections and refinement for **1** and **2** are given in Table 1. The structures were solved by direct methods (SHELXS-97 [56]) and refined on F^2 (SHELXL-97 [57]) using anisotropic displacement parameters for non-H atoms. Except for the solute water molecules in **1**, H atoms were located from difference electron density syntheses and refined using a riding model. Selected bond distances and angles are listed in Table 2.

3. Results and discussion

3.1. Crystal structures

3.1.1. The structure of $\{[Cu(Pht)(Im)_2]\cdot 1.5H_2O\}_n$ (1)

Fig. 1 shows a view of crystallographically independent structure fragment of complex **1**. The crystal structure of **1** is characterized by $[Cu(Im)_2]$ entities linked into infinited chains by bridging phthalate anions. The observed chain structure (Fig. 2) is not unusual and has been found in the crystal structures of the catenates (μ_2-*o*-phthalato)-*bis*(pyridine)-copper(II) [16], ethylenediamine-(μ_2-*o*-phtha-

lato)-copper(II) [17], aqua-(1,10-phenanthroline)-(μ_2-*o*-phthalato)-copper(II) [18], (μ_2-*o*-phthalato)-*bis*(piperidine)-copper(II) [20], *bis*(μ_2-*o*-phthalato)-aqua-*tetrakis*(4-methylpyridine)-di-copper(II) [2], diammine-(μ_2-*o*-phthalato)-copper(II) [8], and (1-methylimidazole)-(μ_2-*o*-phthalato)-copper(II) [6] and aqua-(4-methylimidazole)-(μ_2-*o*-phthalato)-copper(II) [7] among others. The mode of attachment of the phthalate dianion to the metal is not always the same. In some cases, the carboxylic acid groups are attached by both oxygen atoms and in others by one oxygen atom.

There are two crystallographically independent Cu(II) centers within chains and both Cu(II) atoms have approximately square-planar N_2O_2 coordination. The O–Cu–O angles range from 167.3(1)° (O(1)–Cu(1)–O(5)) to 176.3(1)° (O(4)–Cu(2)–O(7)) and the N–Cu–N angles vary from 168.7(1)° (N(5)–Cu(2)–N(7)) to 171.6(1)° (N(1)–Cu(1)–N(3)). The different arrangement of the C=O bonds of the carboxylic acid groups relative to the coordination planes of the two independent Cu atoms indicate that the chain is relatively flexible and successive Cu···Cu distances in the chain are 6.045(1) and 6.468(1) Å. Whereas the Cu–X distances vary significantly for Cu(1) [Cu(1)–N(1) 1.956(3), Cu(1)–N(3) 1.980(2), Cu(1)–O(1) 1.999(2), Cu(1)–O(5) 1.965(2) Å], this is not the case for Cu(2) [Cu(2)–N(5) 1.972(3), Cu(2)–N(7) 1.978(3) Å, Cu(2)–O(4)

1.971(2), Cu(2)–O(7)* 1.972(2) Å]. Note, the Cu(1) and Cu(2) atoms additionally form two long contacts: Cu(1)–O(2) 2.559(2), Cu(1)–O(6) 2.894(2) Å with uncoordinated oxygen atoms of both carboxylic groups; Cu(2)–O(1w) is 2.644 and Cu(2)–O(3) is 2.861 Å. Consequently, the coordination of both Cu atoms can be described as 4 + 1 + 1.

All of the four independent imidazole ligands in **1** are involved in N–H···O hydrogen bonding interactions, of which only one is intramolecular. Thus, N(6) forms an intramolecular H bonding interaction with the free carbonyl O atom of a phthalate ligand further along the chain. The distance N(6)···O(2) is 2.793(4) Å and this is comparable to the distance N(8)···O(2w) (2.787(4) Å) between the *trans* imidazole group N–H group and a solute water molecule. There is also an additional intermolecular contact between N(2) and the water molecule O(1w) of 3.040(4) Å such that N(2) forms a bifurcated hydrogen bond to O(7) and O(1w). The remaining two independent imidazole groups, both of which are attached to Cu(1), form direct interchain N–H···O–Cu hydrogen bonds to the O atoms of the phthalate groups bonded to the Cu atoms in neighboring chains. The corresponding interatomic distances are N(4)···O(4) = 2.785(3) and N(2)···O(7) = 3.109(4) Å. This extended hydrogen bonding network stabilizes a 3D structure in complexes **1**. Fig. 2 presents a fragment of packing arrangement in **1**.

3.1.2. The structure of $[Co(Pht)(Im)_2]_n$ (2)

The structure of **2** comprises $[Co(Im)_2]$ units linked into zigzag polymeric chains by bridging phthalate anions. Fig. 3 shows a fragment of the chain in compound **2**, together with the atomic labeling scheme. The crystals are isostructural with the analogous Zn(II) complex [6]. Each Co atom adopts a tetrahedral N_2O_2 geometry, being coordinated by a pair of imidazole ligands [Co(1)–N(1a) = 2.002(3) and Co(1)–N(1b) = 2.001(2) Å] and a pair of monodentate carboxylate groups [Co(1)–O(1)* = 1.980(2) and Co(1)–O(4) = 1.952(2) Å]. The bond angles at Co(1) atom range from 92.8(1)° to 121.7(1)° (Table 2). As expected, distances and angles in coordination polyhedron agree well with those in $[Zn(Pht)(Im)_2]_n$ [6]. The nearest Co···Co distances in the chain are at 6.017(2) Å. The dihedral angles between the planes through the carboxylate groups [O(1)C(11)O(2) and O(3)C(22)O(4)] and the aromatic ring are 61.9(2)° and 33.7(2)°, respectively. For Pht ligand, the C–C bonds within the aromatic ring range from 1.373(5) to 1.404(4) Å and are similar to those in complex **1** and other Cu(II) phthalate complexes [3,7,8]. The bond distances and angles of the imidazole molecules also fall in the range of values found in other complexes, containing the coordinated imidazole [58,59].

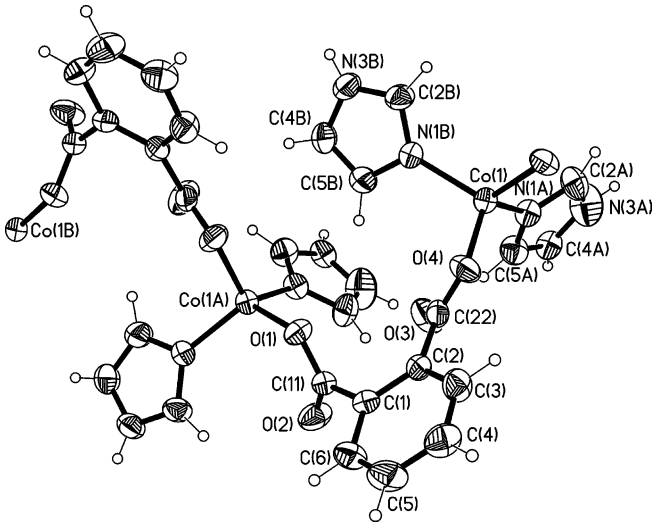

Fig. 3. Polymeric chain in compound **2** with numbering scheme. The atomic displacement ellipsoids are drawn at the 50% probability level.

The chains lie parallel along the [1 0 1] direction. The N(3b)–H(3b)···O(2) [x, $y+1$, z] = 2.754(4) Å hydrogen bonds connect the chains into layers (Fig. 4) and N(3a)–H(3a)···O(1) [$x+1$, y, z] = 2.812(4) Å interactions combine neighboring layers into a 3D network. Interestingly, in contrast to **1**, the crystal structure of **2** contains no solute water, even though the crystals of **2** were grown from hot aqueous solution.

3.2. Spectroscopic properties

IR spectra of compounds **1** and **2** showed absorptions due to N–H bond stretching of imidazole ligands and C–H bonds of aromatic rings in the range 3380–2871 cm^{-1}. Strong bands in the 1616–1570 and 1385–1370 cm^{-1} regions were assigned to the asymmetric and symmetric stretching modes of carboxylate groups, respectively [60,61]. The separations between the asymmetric and symmetric stretching frequencies, $\Delta\nu$ (ν_{asym}–ν_{sym} ranges from 246 to 185 cm^{-1}), are indicative of the fact that COO^- groups from phthalate groups have bridging O atoms [62]. Such absorptions have already been reported for other phthalate complexes with aromatic amines (1620–1520 cm^{-1}) [21,22]. IR spectrum of complex **1** also showed a strong and broad ν(O–H) stretching band around 3479 cm^{-1} confirming the presence of the water solute molecules.

3.3. Catalytic oxidation of cyclohexene

Choosing cyclohexene as a model substrate, oxidation reactions were carried out in acetone at room temperature under magnetic stirring in the presence of **1** and **2** as the catalyst using 30% H_2O_2. The evolution of the reactions was monitored by GC analysis of solution samples taken periodically to determine the concentrations of the various oxidation products. In a typical experiment, 1 ml of hydrogen peroxide (30%) was added to the reaction mixture containing cyclohexene (1 ml) and catalyst (39 mg) in 1 ml acetone. The results of the investigations are summarized in Table 3. In the case of **1** the distribution of the products was strongly dependent on the ratio of $[C_6H_{10}]$ to $[H_2O_2]$.

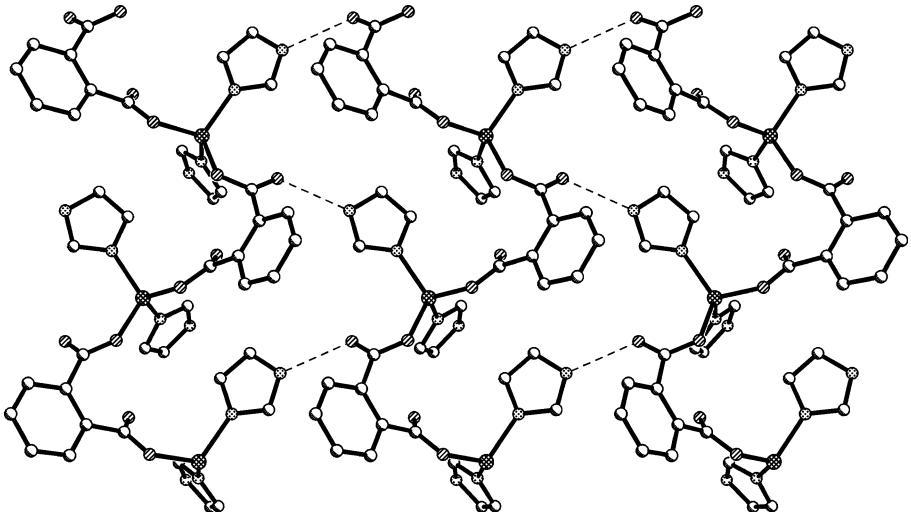

Fig. 4. Fragment of the layer formed through N–H···O interactions in structure **2**. Hydrogen atoms are omitted for clarity and hydrogen bonds are indicated by dotted lines.

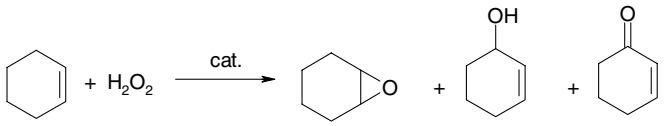
Table 3
Catalytic oxidation of cyclohexene with H_2O_2[a]

Catalyst	Run	Ratio C_6H_{10}:H_2O_2	Products (%)[b]			
			Alkene	Epoxide	Alcohol	Ketone
1	1[c]	1:12	0.76	0.49	5.32	93.4
	2[c]	1:9	6.13	1.49	6.78	85.6
	3[c]	1:4.5	40.5	4.67	11.4	43.4
	4[d]	1:9	0.85	8.39	3.06	87.7
	5[e]	1:9	2.01	11.3	11.5	75.2
2	6[e]	1:9	38.8	1.94	18.7	40.6

[a] Reaction conditions: substrate (1 mmol), catalyst (0.1 mmol), temperature (22 °C).
[b] Ratio of the different products in the reaction was determined by GC analysis. Products were identified by GC–MS.
[c] Acetone – 1 ml, 48 h.
[d] Acetone – 0.5 ml, 1 h.
[e] Acetone – 1 ml, 1 h.

The largest specificity was obtained using catalyst **1** and a concentration ratio of 1:12. Under these experimental conditions the allylic hydrogen is more reactive than the C=C double bond, and the reaction proceeds to give mainly the 2-cyclohexen-1-one as the main product and cyclohexene epoxide with the lowest yield (entry 1, Table 3). In control experiments, using cyclohexene under identical experimental conditions, but excluding metal complex, or in the presence of $Cu(CH_3COO)_2 \cdot H_2O$, did not give any oxidation products.



4. Conclusion

Two new copper(II) and cobalt(II) coordination polymers based on *o*-phthalic acid and imidazole have been synthesized and characterized by X-ray crystallography. The compounds have a polymeric chain structure with metal atoms linked by 1,6-bridging Pht^{2-} ligands. Preliminary catalytic investigations of the complexes for the oxidation of cyclohexene with H_2O_2 have been undertaken. The major oxidation product is 2-cyclohexen-1-one with appreciable amounts of 2-cyclohexen-1-ol depending on the reaction conditions. The yield of ketone is higher in the case of the copper complex. A systematic investigation on the use of the phthalate linker in the synthesis of 3d-metal coordination polymers and their magnetic and catalytic properties is currently underway.

5. Supplementary material

Crystallographic data for the structural analyses have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 271720 (**1**) and 275123 (**2**). Copies of this information may be obtained from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44 1233 336033; e-mail: deposit@ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk). Structure factors for **1** and **2** are available from the authors on request.

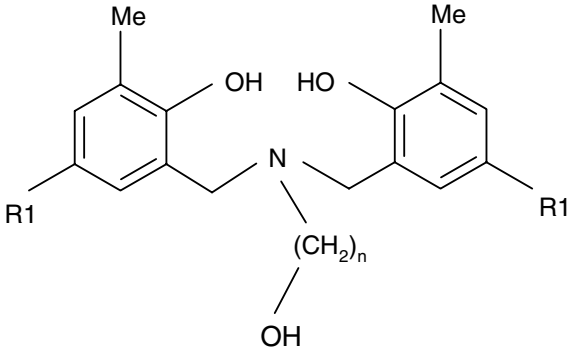
like hydroxypyridones [3,4,10] and -pyrones [10]. Calixarenes and modified calixarenes have also been prepared for uranyl extraction [1,2]. The uranyl complexes of calixarenes possess several phenolato ligands and many such complexes have been prepared and their structures have been reviewed recently [11]. It seems in many cases though, that these ligands are too rigid for optimal complex formation and more flexible ligands are required. Homoatsa and homo-oxa modified calixarenes are not as rigid as ordinary calixarenes [12,13], but the problem of the uranyl ion fitting neatly inside the cage still seems to be present. A distinct disadvantage is that the formed complexes are generally anionic and cations are required for charge balance. Homoatsacalixarenes, though, can potentially form a neutral zwitterion with uranyl ion, and an example is the ligand *p*-methyl-*N*-benzyltetrahomo-diazacalix[5]arene [13]. Open-chain, *ortho*-methylene linked di- and triphenols also form complexes with uranyl ion in a 1:2 molar ratio (U to L) in the presence of DABCO (1,4-diazabicyclo[2.2.2]octane) [14].

We have earlier used [O,N,O] type diphenoxo ligands for the complexation of W(VI) [15] and Mo(VI) ions [16]. In this work we prepared four (two are new), similar ligands for uranyl ion complexation by combining the features of the previously described ligands and we herein report the results of our studies. In this case, the ligands contain two phenol oxygens, one alcohol oxygen and one ammine nitrogen, thus there is the possibility of the ligand functioning as up to a tetradentate ligand. In Scheme 1 are depicted the ligand family in use. With these ligands we hope to offer optimal coordination conditions for the uranyl ion.



R1= methyl or *tert*-butyl

Ligand	*R1*	*n*
H_3L1	Me	2
H_3L2	*t*-Bu	2
H_3L3	Me	3
H_3L4	*t*-Bu	3

Scheme 1. The ligands under study.

2. Experimental

2.1. General information

2-Aminoethanol (Aldrich), 3-amino-1-propanol, 4-*t*-butyl-2-methylphenol (Fluka), triethylamine (Riedel), 2,4-dimethylphenol, 37% formaldehyde and uranyl nitrate hexahydrate (Merck) were used as supplied. The ligands H_3L1–H_3L4 were synthesized by following in the main a procedure for methylamino-*N*,*N*-bis(1-methylene-2-naphthol) [17]. Details of the syntheses, not optimized, are described below. NMR spectra were recorded on a Bruker AVANCE DPX 250 FT NMR spectrometer. ^{1}H and ^{13}C NMR spectra were recorded either in $CDCl_3$ or d_6-DMSO at 30 °C and chemical shifts are reported in ppm relative to $CDCl_3$ (δ 7.26, ^{1}H NMR; δ 77.0, ^{13}C NMR) or d_6-DMSO (δ 2.50, ^{1}H NMR; δ 39.50, ^{13}C NMR). Mass spectrometric measurements were performed using a Micromass LCT time of flight (TOF) mass spectrometer with electrospray ionization (ESI-MS). Elemental analysis was performed using a VarioEl III elemental analyzer.

2.2. H_3L1 {(*N*,*N*-bis(2-hydroxy-3,5-dimethylbenzyl)-2-aminoethanol) · 1/3toluene}

This compound has been earlier prepared without toluene slightly in different conditions [18a,18b]. To a solution of 2,4-dimethylphenol (2.44 g, 0.020 mol) in methanol (13 mL) was added aqueous formaldehyde (37%, 1.63 g, 0.020 mol) and 2-aminoethanol (0.61 g, 0.010 mol) with stirring. The resulting solution was refluxed for 24 h after which the solvent was evaporated off and the resulting oil left to stand at room temperature for two weeks. The small crystals that had formed in the oil were filtered off and recrystallized from toluene (8 mL) after which the white crystals were collected and washed with cold toluene (5 mL). Yield: 1.41 g (43%). Mp: 108–110 °C. ^{1}H NMR ($CDCl_3$, 250 MHz): 2.20 (d, $J = 2.3$ Hz, 12H, aryl CH_3), 2.69 (t, $J = 5.3$ Hz, 2H, NCH_2CH$_2$), 3.73 (s, 4H, NCH_2-aryl), 3.87 (t, $J = 5.3$ Hz, 2H, OCH_2CH$_2$), 6.70 (s, 2H, aryl), 6.85 (s, 2H, aryl). ^{13}C NMR ($CDCl_3$, 63 MHz): 15.9, 20.3 (aryl *C*H$_3$), 53.7, 57.0, 60.5 (N*C*H$_2$CH$_2$, N*C*H$_2$-aryl, O*C*H$_2$CH$_2$), 121.1, 124.9, 128.3, 128.5, 131.4, 151.9 (aryl). The NMR data were in agreement with the literature [18b]. ESI-MS *m*/*z*: 330.23 $[H_3L1 + H]^+$. The calculated value for H_3L1 was: $m/z = 330.21$ $[H_3L1 + H]^+$. Elemental *Anal*. Calc. for $C_{20}H_{27}NO_3 \cdot 1/3C_7H_8$: C, 74.48; H, 8.30; N, 3.89. Found: C, 74.57; H, 8.33; N, 3.75%.

2.3. H_3L2 {*N*,*N*-bis(2-hydroxy-5-t-butyl-3-methylbenzyl)-2-aminoethanol}

To a solution of 4-*t*-butyl-2-methylphenol (3.28 g, 0.020 mol) in methanol (13 mL) and water (5 mL) was added aqueous formaldehyde (37%, 1.63 g, 0.020 mol) and 2-aminoethanol (0.61 g, 0.010 mol) with stirring. The solution was refluxed for 30 h and then left to stand at

room temperature. Within a week, a white solid had formed which was separated by filtration, washed with cold methanol (5 mL) and recrystallized from methanol–water (9:1). Yield: 1.80 g (44%). Mp: 121–122 °C. ^{1}H NMR ($CDCl_3$, 250 MHz): 1.27 (s, 18H, aryl C(CH_3)$_3$), 2.23 (s, 6H, aryl CH_3), 2.72 (t, $J = 5.3$ Hz, 2H, NCH_2CH$_2$), 3.77 (s, 4H, NCH_2-aryl), 3.89 (t, $J = 5.3$ Hz, 2H, OCH_2CH$_2$), 6.89 (s, 2H, aryl), 7.05 (s, 2H, aryl).^{13}C NMR ($CDCl_3$, 63 MHz): 16.3 (aryl CH_3), 31.6 (aryl C(CH_3)$_3$), 33.9 (aryl C(CH$_3$)$_3$), 53.8, 57.1, 60.4 (NCH$_2$CH$_2$, NCH$_2$-aryl, OCH$_2$CH$_2$), 120.1, 124.4, 124.8, 127.7, 142.0, 151.9 (aryl). ESI-MS m/z: 414.29 $[H_3L2 + H]^+$. The calculated value for H_3L2 is: $m/z = 414.30$ $[H_3L2 + H]^+$. Elemental *Anal.* Calc. for $C_{26}H_{39}NO_3$: C, 75.50; H, 9.50; N, 3.39. Found: C, 74.45; H, 9.45; N, 3.45%.

2.4. H_3L3 {*N,N*-bis(2-hydroxy-3,5-dimethylbenzyl)-3-amino-1-propanol}

The preparation of the compound is reported in patent literature [18a]. To a solution of 2,4-dimethylphenol (24.5 g, 0.2 mol) in ethanol (40 mL) was added aqueous formaldehyde (37%, 17.0 g, 0.21 mol) and 3-amino-1-propanol (7.52 g, 0.1 mol) with stirring. The resulting solution was refluxed for 24 h after which most of the solvent was evaporated off and the residue taken up in toluene (15 mL) and then left to stand at −25 °C for one week. The crystals that formed were separated by filtration and the filtrate returned to cold storage for the harvesting of a second crop of crystals after a further week of storage. Total yield 1.77 g (5.2%). Mp: 126–127 °C. ^{1}H NMR ($CDCl_3$, 250 MHz): 1.88 (m, 2H, NCH$_2$CH_2CH$_2$), 2.19 (d, $J = 10.9$ Hz, 12H, aryl CH_3), 2.61 (t, $J = 6.6$ Hz, 2H, NCH_2CH$_2$), 3.63 (s, 4H, NCH_2-aryl), 3.76 (t, $J = 5.7$ Hz, 2H, OCH_2CH$_2$), 6.71 (s, 2H, aryl), 6.85 (s, 2H, aryl). ^{13}C NMR ($CDCl_3$, 63 MHz): 15.9, 20.3 (aryl CH_3), 28.6 (OCH$_2$$CH_2$), 51.6, 56.3, 61.4 (NCH$_2CH_2$, NCH$_2$-aryl, OCH$_2CH_2$), 121.6, 124.6, 128.3, 128.6, 131.0, 151.8 (aryl). ESI-MS m/z: 344.23 $[H_3L3 + H]^+$. The calculated value for H_3L3 is: $m/z = 344.22$ $[H_3L3 + H]^+$. Elemental *Anal.* Calc. for $C_{21}H_{29}NO_3$: C, 73.44; H, 8.51; N, 4.08. Found: C, 73.49; H, 8.54; N, 4.01%.

2.5. H_3L4 {(*N,N*-bis(2-hydroxy-5-t-butyl-3-methylbenzyl)-3-amino-1-propanol) · HCl}

To a solution of 4-*t*-butyl-2-methylphenol (8.21 g, 0.050 mol) in methanol (60 mL) was added aqueous formaldehyde (37%, 4.47 g, 0.055 mol) and 3-amino-1-propanol (2.10 g, 0.028 mol) with stirring. The resulting solution was refluxed for 9 h after which the solvent was removed and the resulting oil taken up in CH_3CN (10 mL) followed by the addition of 6 M HCl (6 mL, 36 mmol). The solvent was again removed and the resulting mixture of white solid and oil dissolved in CH_2Cl_2 (20 mL) with warming and left to stand at room temperature in an open vessel. The small crystals that formed during the evaporation process were separated by filtration and recrystallized from toluene. The white crystals were collected by filtration and washed with cold toluene (5 mL). Yield: 1.94 g (17%). Mp: 188–191 °C. ^{1}H NMR ($CDCl_3$, 250 MHz): 1.26 (s, 18H, aryl C(CH_3)$_3$), 2.07 (m, 2H, NCH$_2$CH_2CH$_2$) 2.40 (s, 6H, aryl CH_3), 3.26 (t, $J = 6.2$ Hz, 2H, NCH_2CH$_2$), 3.79 (t, $J = 5.7$ Hz, 2H, OCH_2CH$_2$), 4.20 (s, 4H, NCH_2-aryl), 6.96 (s, 2H, aryl), 7.19 (s, 2H, aryl). ^{13}C NMR ($CDCl_3$, 63 MHz): 17.03, 25.47, 31.47, 33.98 (aryl CH_3, aryl C(CH_3)$_3$, aryl C (CH$_3$)$_3$, NCH$_2$$CH_2$), 52.42, 56.55, 58.75 (NCH$_2$CH$_2$, NCH$_2$-aryl, OCH$_2$CH$_2$), 115.89, 125.46, 126.38, 130.39, 143.60, 151.26 (aryl). ESI-MS m/z: 428.27 $[H_3L4 + H]^+$. The calculated value for H_3L4 is: $m/z = 428.32$ $[H_3L4 + H]^+$. Elemental *Anal.* Calc. for $C_{27}H_{42}NO_3Cl$: C, 69.88; H, 9.12; N, 3.02. Found: C, 69.11; H, 9.13; N, 3.11%.

2.6. $[(UO_2)_2(H_2L1)_2(NO_3)_2]$ (**1**)

The complex **1** was prepared by dissolving together H_3L1 (0.062 g, 0.17 mmol) and $UO_2(NO_3)_2 \cdot 6H_2O$ (0.050 g, 0.10 mmol) in CH_3CN (5 mL). The resulting red solution was kept at room temperature for four days leading to the formation of crystals. The red crystals were filtered off, washed once with diethyl ether (5 mL) and then air dried. Yield: 0.025 g (38%). ^{1}H NMR (250 MHz, d_6-DMSO) 2.09, 2.15, 2.31, 2.60 (s, 24H, aryl CH_3), 2.97, 3.06 (t, 4H, NCH_2CH$_2$), 3.57, 4.19 (t, 4H, OCH_2CH$_2$), 3.65, 4.32, 4.38 (s, 8H, NCH_2-aryl), 4.83 (s, 2H, CH$_2$OH), 6.74, 6.79, 6.92, 6.98, 7.12 (s, 8H, aryl), 9.34 (s, 2H, CH$_2$NH^+). ^{13}C NMR (63 MHz, d_6-DMSO): 16.05, 16.50, 17.03, 20.07 (aryl CH_3), 51.96, 54.22, 54.82, 55.01, 57.23, 60.51 (NCH$_2$CH$_2$, NCH$_2$-aryl, OCH$_2$CH$_2$), 122.55–164.60 (aryl). Elemental *Anal.* Calc. for $C_{40}H_{52}N_4O_{16}U_2$: C, 36.37; H, 3.97; N, 4.24. Found: C, 35.73; H, 3.98; N, 4.22%. Molecular ion species were not observed by ESI-MS. Single-crystal X-ray analysis was performed on one of the crystals.

2.7. $[UO_2(H_2L1)_2] \cdot 2H_2O$ (**2**)

The complex **2** was prepared by dissolving together H_3L1 (0.054 g, 0.15 mmol), $UO_2(NO_3)_2 \cdot 6H_2O$ (0.0375 g, 0.075 mmol) and Et_3N (0.015 g, 0.15 mmol) in CH_3CN (16 mL). The resulting red solution was kept at room temperature for one week leading to the formation of crystals. The red crystals were filtered off, washed twice with diethyl ether (5 mL) and then air dried. Yield: 0.032 g (44%). ^{1}H NMR (250 MHz, d_6-DMSO): 2.09, 2.15, 2.31, 2.60 (s, 24H, aryl CH_3), 2.54, 3.06 (t, 4H, NCH_2CH$_2$), 3.56, 4.19 (t, 4H, OCH_2CH$_2$), 3.65, 4.38 (s, 8H, NCH_2-aryl), 4.83 (s, 2H, CH$_2$OH), 6.74, 6.79, 6.92, 6.98 (s, 8H, aryl), 9.34 (s, 2H, CH$_2$NH^+). ^{13}C NMR (63 MHz, d_6-DMSO): 16.03, 17.02, 20.07 (aryl CH_3), 51.97, 54.20, 54.82, 55.05, 58.23, 60.49 (NCH$_2$CH$_2$, NCH$_2$-aryl, OCH$_2$CH$_2$), 122.57–164.60 (aryl). 2.8. $[UO_2(H_2L2)_2] \cdot 2CH_3CN$ (**3**)

The complex **3** was prepared by dissolving together H_3L2 (0.038 g, 0.09 mmol), $UO_2(NO_3)_2 \cdot 6H_2O$ (0.023 g, 0.045 mmol) and Et_3N (0.009 g, 0.09 mmol) in CH_3CN (5 mL). The resulting light-red solution was kept at room temperature for two weeks leading to the formation of crystals. The light-red crystals were filtered off, washed once with diethyl ether (5 mL) and then air dried. Yield: 0.021 g (41%). ^{1}H NMR (250 MHz, d_6-DMSO): 1.22, 1.28 (s, 36H, aryl C(CH_3)$_3$), 2.13, 2.62 (s, 12H, aryl CH_3), 2.55, 3.08 (t, 4H, NCH_2CH$_2$), 3.59, 3.68, 4.14 (t, 4H, OCH_2CH$_2$), 3.68, 4.43 (s, 8H, NCH_2-aryl), 4.83 (s, 2H, CH$_2$O*H*), 6.95, 6.99, 7.12, 7.18 (s, 8H, aryl), 9.44 (s, 2H, CH$_2$NH^+). ^{13}C NMR (63 MHz, d_6-DMSO): 16.37, 17.40 (aryl CH_3), 31.38, 31.93, 33.16, 33.47 (aryl C(CH_3)$_3$), 52.41, 54.45, 54.93, 55.15, 58.33, 60.94 (NCH_2CH$_2$, NCH_2-aryl, OCH_2CH$_2$), 121.96–164.43 (aryl). Elemental *Anal*. Calc. for $C_{52}H_{76}N_2O_8U$: C, 57.03; H, 6.99; N, 2.56. Found: C, 55.39; H 6.64; N, 2.66%. Molecular ion species were not observed by ESI-MS. Single-crystal X-ray analysis was performed on one of the crystals.

2.9. $[UO_2(H_2L3)_2]$ (**4**)

The complex **4** was prepared by dissolving together H_3L3 (0.052 g, 0.15 mmol), $UO_2(NO_3)_2 \cdot 6H_2O$ (0.0375 g, 0.075 mmol) and Et_3N (0.015 g, 0.15 mmol) in CH_3CN (20 mL). The resulting red solution was kept at room temperature for two weeks allowing the formation of crystals. The red crystals were filtered off, washed once with diethyl ether (5 mL) and then air dried. Yield: 0.051 g (71%). ^{1}H NMR (250 MHz, d_6-DMSO): 1.68 (m, 4H, OCH$_2$CH_2CH$_2$), 2.09, 2.14, 2.31, 2.59 (s, 24H, aryl CH_3), 2.47, 2.92 (t, 4H, NCH_2CH$_2$), 2.98, 3.33 (t, 4H, OCH_2CH$_2$), 3.60 (s, 8H, NCH_2-aryl), 4.21 (s, 2H, CH$_2$O*H*), 6.72, 6.78, 6.90, 6.98 (aryl). ^{13}C NMR (63 MHz, d_6-DMSO): 16.09, 17.02, 20.08 (aryl CH_3), 23.12, 28.61 (OCH$_2$$CH_2CH_2$), 47.19, 50.00, 54.49, 59.21, 59.60 (NCH_2CH$_2$, NCH_2-aryl, OCH_2CH$_2$), 122.66–164.76 (aryl). Elemental *Anal*. Calc. for $C_{42}H_{56}N_2O_8U$: C, 52.83; H, 5.91; N, 2.93. Found: C, 52.86; H, 5.95; N, 3.36%. ESI-MS *m/z*: 955.23 $[M + H]^+$, 977.25 $[M + Na]^+$, 993.21 $[M + K]^+$. The calculated values for **4** were: $m/z = 955.46$ $[M + H]^+$, 977.44 $[M + Na]^+$, 993.42 $[M + K]^+$. Single-crystal X-ray analysis was performed on one of the crystals.

2.10. $[UO_2(H_2L4)_2]$ (**5**)

The complex **5** was prepared by dissolving together $H_3L4 \cdot HCl$ (0.042 g, 0.09 mmol), $UO_2(NO_3)_2 \cdot 6H_2O$ (0.0225 g, 0.045 mmol) and Et_3N (0.018 g, 0.18 mmol) in CH_3CN (5 mL). The resulting red/orange solution was kept at room temperature for two days leading to the formation of crystals. The red crystals were filtered off, washed once with diethyl ether (5 mL) and then air dried. Yield: 0.038 g (75%). ^{1}H NMR (250 MHz, d_6-DMSO): 1.22, 1.28 (aryl C(CH_3)$_3$), 1.71 (m, 4H, OCH$_2$CH_2CH$_2$), 2.13, 2.62 (s, 12H, aryl CH_3), 2.47, 2.83 (t, 4H, NCH_2CH$_2$), 2.96, 3.36 (t, 4H, OCH_2CH$_2$), 3.64 (s, 8H, NCH_2-aryl), 4.14 (s, 2H, CH$_2$O*H*), 6.93, 6.99, 7.11, 7.19 (aryl). ^{13}C NMR (63 MHz, d_6-DMSO): 16.39, 17.37 (aryl CH_3), 31.36, 31.90, 33.15, 33.45 (aryl C(CH_3)$_3$), 47.06, 50.04, 54.48, 59.19, 59.58 (NCH_2CH$_2$, NCH_2-aryl, OCH_2CH$_2$), 122.03–164.72 (aryl). Elemental *Anal*. Calc. for $C_{54}H_{80}N_2O_8U$: C, 57.74; H, 7.18; N, 2.49. Found: C, 57.72; H, 6.98; N, 2.89%. Molecular ion species were not observed by ESI-MS. Single-crystal X-ray analysis was performed on one of the crystals.

2.11. Uranyl extraction

Two-phase extraction studies were performed to determine the UO_2^{2+} cation uptake from water layer to CH_2Cl_2 layer by the ligands, H_3L1, H_3L2, H_3L3 and H_3L4. The experimental setup was following: to the bottom of a test tube was placed 3 mL of CH_2Cl_2 with ligand (0.420 mmol) and at the top of this layer was placed 2 mL of water with uranyl nitrate (c(U) = 12.5 mg/mL, n(U) = 0.105 mmol) leading to ratio of U to ligand 1:4. Furthermore, one test tube with CH_2Cl_2 containing no ligand was prepared. The samples for ICP ($V = 50$ μL, diluted to 20 mL) were taken from water layer over three days period of time. The samples were analyzed with ICP-OES at 385.958 nm using Perkin–Elmer Optima 4300DV instrument.

2.12. X-ray crystallography

Crystals suitable for single-crystal X-ray measurements were obtained directly from the reaction vessels. The crystal data for compounds **1**–**5** along with other experimental details, are summarized in Table 1. The crystallographic data were collected at 173 K on an Enraf Nonius Kappa CCD area-detector diffractometer using graphite monochromatized MoK_α radiation ($\lambda = 0.71073$ Å). Data collection was performed using φ and ω scans and the data processed using DENZO-SMN v0.93.0 [19]. SHELXA [20] absorption correction was applied to the data of **1**–**5**. The structures were solved by direct methods using the SHELXS-97 program [21] and full-matrix least-squares refinements on F^2 were performed using the SHELXL-97 program [21]. For all compounds the heavy atoms were refined anisotropically (except for C-1 in **3** and the disordered carbon atoms in **5**). The CH hydrogen atoms were included at fixed distances using fixed displacement parameters from their host atoms whilst other H atoms were refined using fixed displacement parameters. Structure figures were drawn using ORTEP-3 for Windows [22].

3. Results and discussion

3.1. Syntheses of ligands and uranyl complexes

The details of the ligand syntheses are described in Section 2. Generally, the yields of the ligands were quite low. One reason for this is the fact that the solubility properties of the product and the phenol in question are quite similar and, in some cases, a crystalline adduct, containing both, was formed. Thus, the separation of the product from the sticky oil, which was generally formed at the end of the reaction, was quite difficult and as a result part of the product was lost together with the starting phenol during the separation process. The second reason for the low yield is that the reaction itself does not readily go to completion and intermediates with only one phenol moiety attached to the aminoalcohol were present. In two cases (H_3L3 and the di-*t*-butyl derivative, also prepared but not reported as it did not form solid complexes with uranyl ion), such products were able to be identified (using ^{1}H NMR) though it is likely that this happens in every case. Due to similarities in the solubilities of the product and the phenol in question, the reaction mixture of H_3L4 was treated with HCl (6 M) in order to render the product more polar with respect to the phenol. This proved to be a successful tactic as it rendered the separation process much easier.

Generally, the crystals of the complexes formed quite easily following the dissolution of the uranyl nitrate hexahydrate in acetonitrile together with an appropriate amount of the ligand. The formation of the complex was clearly indicated by the change in color of the solution from the yellow of uranyl nitrate to red. The reactions, however, were left to stand at room temperature for between two days to up to two weeks to allow the formation of crystals. The filtrates, though, were still red in color after removal of the crystals indicating that crystallization was incomplete.

H_3L1 formed solid dinuclear (**1**) or mononuclear (**2**) complexes from acetonitrile solution depending on the stoichiometry and the use of base. If the U to ligand molar ratio is 1:2 (or under 2 for ligand) complex **1** is obtained, but using the same molar ratio, 1:2, in the presence of 2 moles of triethylamine results in the formation of complex **2**. If the U to ligand molar ratio is 1:3 or more without extra base, only complex **2** forms. Complexes **1** and **2** both dissolve in DMSO and in acetone. The ^{1}H and ^{13}C NMR spectra in d_6-DMSO for compounds **1** and **2** were, accordingly, identical, so it appears that in DMSO solution compound **1** decomposes and coordinates with DMSO in the same manner as compound **2**, i.e., it forms the same species.

Ligands H_3L2, H_3L3 and H_3L4 (actually, $H_3L4 \cdot HCl$) formed complexes **3**–**5**, respectively, with $UO_2(NO)_3$ of general formula $[UO_2(H_2Lx)_2]$ (where $x = 2$, 3 or 4 and where **3** also contains two acetonitrile molecules in the unit cell). Complex **3** dissolves in DMSO, acetone, THF and CH_2Cl_2, and as such it has the best solubility properties. The acetonitrile molecules bound in the crystals of compound **3**, however, are able to escape readily from the crystalline matrix rendering the crystals prone to decay relatively soon after their removal from solution. The preparation of complex **5** using $H_3L4 \cdot HCl$ as starting material did not create any problems-the amount of the base was appropriately doubled-and this tactic of using the ligand hydrochloride seems to be a good practical method for the syntheses of these kind of complexes. The complexes

4 and **5**, though, dissolve effectively only in DMSO. For uranyl extraction studies, good solubility of the complex in organic solvents is essential, a demand which is not totally fulfilled with these present ligands. We believe, however, that these ligands can be modified accordingly such that their complex solubilities can be improved for organic, water-immiscible solvents. In order to do just this, the di-*t*-butyl ligand derivative was also prepared, but unfortunately it did not form a solid complex with uranyl ion due to the steric repulsion arising in the complex (vide infra).

3.2. Structural studies of the uranyl complexes

The solid-state structures of compounds **1**–**5** were verified by single-crystal X-ray analysis. Crystals of **1**, obtained from acetonitrile solution without the addition of base at room temperature, were comprised of neutral dinuclear UO_2 complex units in which one H_3L1 ligand binds to a UO_2^{2+} ion via one phenolato and one alkoxo oxygen donor bond (Fig. 1). The latter also forms a bond to the neighboring UO_2 unit to form a dinuclear unit. Selected bond lengths and angles for **1** are presented in Table 2. The alkoxo oxygens that bridge the two uranium ions have U–O bond lengths of 2.360(6) and 2.389(5) Å and 2.361(6) and 2.381(6) Å whilst the U–O(phenolato) bond lengths are 2.203(6) and 2.184(6) Å. The nitrate ion bonds bidentately to a single UO_2 unit and the nitrate oxygen atoms are at an average distance of 2.497 Å from the U atom. One phenol OH does not take part in bonding to U and the N atom acts as a base accepting a proton. The approximate coordination spheres around both U(VI) ions are distorted pentagonal bipyramidal with trans UO_2 groups. However, the plane of five coordinated atoms resembles a four-coordination plane if the nitrate group is taken as a single donor as the oxygen atoms of the nitrate ions and

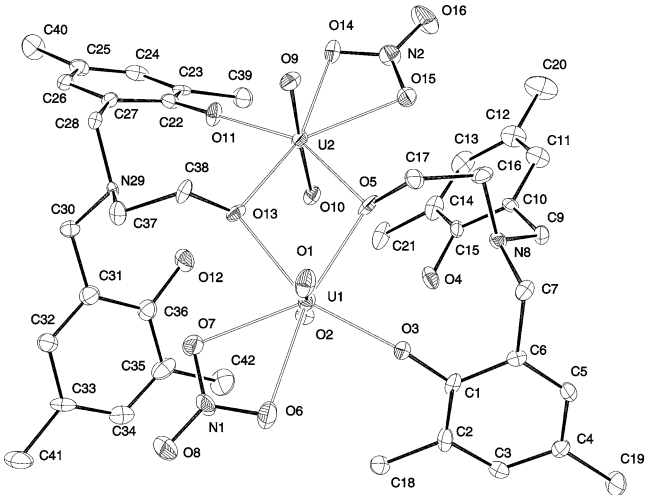

Fig. 1. Molecular structure of $[(UO_2)_2(H_2L1)_2(NO_3)_2]$ (**1**). Thermal ellipsoids have been drawn at 30% probability level. The hydrogen atoms have been omitted for clarity.

Table 2
Selected bond lengths (Å) and angles (°) for **1**

U1–O13–U2	104.8(2)
C1–O3–U1	157.0(5)
C22–C11–U2	170.1(5)

the uranium ions (O–U–O) only form very small angles {51.1(2)° and 50.7(2)°}. The main features of this structure are the following: (1) the oxo donors are located in trans positions {the O–U–O angles are 177.5(3)° and 177.1(3)°}, (2) the O(alcoholato)–U–O(phenolato) angles are 85.1(2)° and 85.7(2)°, and (3) the bridging U–O–U angles are 105.1(2)° and 104.8(2)°. Of note, dinuclear alkoxo bridged complexes have been reported earlier [23] (see Table 2).

Red crystals of **2**–**5** were obtained from acetonitrile solution by the addition base (triethylamine). The complexes have a centrosymmetrical structure in which the uranium ion has a compressed octahedral symmetry (Figs. 2–5). The asymmetric unit of all compounds contains a UO unit with a negative H_2L^- ligand, which binds to the UO unit via two phenoxide groups. Selected bonding parameters for these four molecules are compared in Table 3. The aliphatic nitrogen atom bears an accepted proton and does not form a bond with the U(VI) ion. The proton on the nitrogen atom, however, forms weak H-bonds to O-2 and O-3 (and also to O-4 in **4**). The complexes are neutral zwitterionic units with two negative charges on oxygen atoms

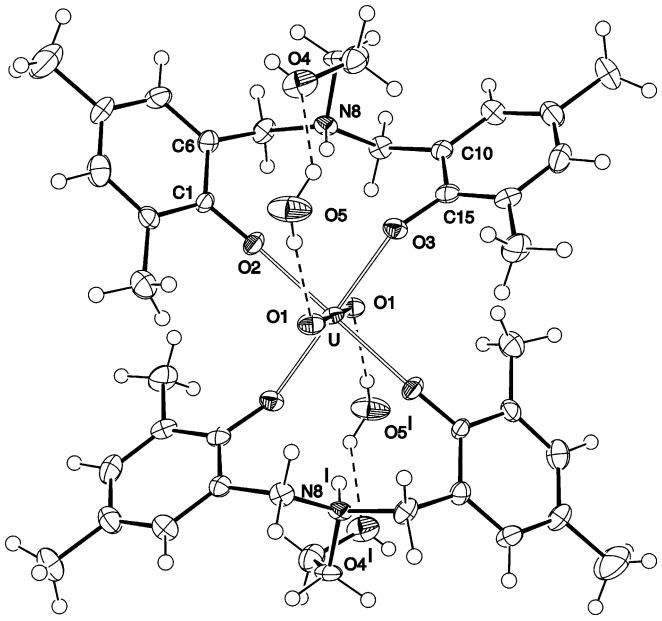

Fig. 2. Molecular structure of $[UO_2(H_2L1)_2]\cdot 2H_2O$ (**2**). Thermal ellipsoids have been drawn at 30% probability level. Symmetry operation i: $-x, -y, -z$.

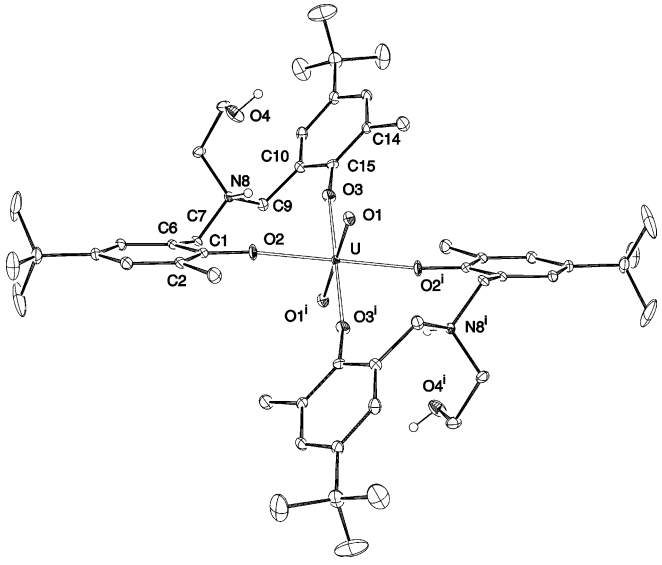

Fig. 3. Molecular structure of $[UO_2(H_2L2)_2]\cdot 2CH_3CN$ (**3**). Thermal ellipsoids have been drawn at 30% probability level. Acetonitrile molecules are not shown and the CH hydrogen atoms have been omitted for clarity. Symmetry operation i: $-x, -y, -z$.

and a positive charge on each nitrogen atom. The aliphatic alcohol groups do not take part in bonding with uranyl ion, but do form H-bonds in all compounds. The overall structure is similar to the uranyl homoazacalixarene complex [13], where the uranyl ion is located inside the cage.

The U–O(phenoxide) distances in **4** are 2.214(3) and 2.256(3) Å and in **2**–**5** they lie in the range 2.221(2)-2.241(3) Å. These bond distances are near the estimated "ideal" value of 2.2 Å found in U(VI) compounds with unrestricted, unidentate alkoxide ligands [11a]. This suggests that these ligands bind to the UO_2^{2+} ion quite effectively. The larger difference in the U–O(phenoxide) bond distances in **4** (0.04 Å) compared to **2**–**5** (0.02 Å) is possibly due to packing reasons (vide infra) and which, for example,

can cause distortion of the U–O–C angle. Generally, the larger the U–O–C angle is, the shorter the U–O bond distance becomes.

In all molecules, the coordination mode of aminobis(phenolate) is rather similar, but the aminoalcohol group behaves differently in its H-bond formation. In complex **2**, water molecules are present which are H-bonded to the oxo atom of the uranyl ion and the aminoalcohol oxygen atom (see Fig. 2). The hydrogen at the aminoalcohol oxygen also bonds to a water molecule. In **3**–**5**, the hydrogen of the aminoalcohol hydroxyl bonds to the uranyl oxo group. Complex **5** possesses both the shortest intermolecular O1···O4 distance {2.741(5) Å} and the longest U=O bond {1.817(3) Å} as a H-bond to the uranyl oxygen atom is known to increase the U=O bond length. But on the other hand, strong donor ligands that coordinate in an equatorial plane to the uranyl ion have been found to labilize U=O bonds [24] and thus it is not easy to distinguish between these two effects.

Conformational differences of the coordinated ligands in **2**–**5** were evident by analysis of the torsional or dihedral angles in the structures. In particular, the dihedral angles between the phenyl rings (formed by the atoms C1···C6 and C10···C15) vary and the angles between these planes in **2**–**5** are 52.9(2)°, 50.0(1)°, 35.2(2)° and 66.4(1)°, respectively. These deviations indicate that the frameworks of the ligands are flexible and that they have enough freedom to accommodate slightly different arrangements in the solid state for packing reasons.

Uranyl ion complexation with a ligand in which the methyl groups in positions 3 and 3′ of H_3L2 was replaced with *t*-butyl groups, i.e., using the ligand, *N*,*N*-bis(2-hydroxy-3,5-di-*t*-butyl-benzyl)-2-aminoethanol, was also attempted. However, a solid complex could not be crystallized out from solution although the uranyl solution did turn red indicating at least some ligand complexation. Steric constraints can account for this inability to obtain a solid complex. In the solid state of the uranyl complexes, the *t*-butyl groups at position 3 would come so close to each other that the complex is unstable (in **2** and **3**, the two relevant methyl groups are at distances of 4.013 and 4.015 Å from each other, respectively). So replacement of the methyl groups at position 3 by *t*-butyl groups simply prevents complex formation on steric hindrance grounds. Steric constraints are known, in fact, to control the formation of isomers in uranyl phenoxo complexes [25].

3.3. Uranyl ion extraction studies

The results of uranyl ion extraction studies at room temperature (22–23 °C) with the ligands H_3L1 and H_3L3 are shown in Fig. 6. The ratio of the ligand to the uranyl ion was 4:1. The concentration of the uranyl ion in the water layer of the control sample was constant during the three days follow up. The transfer of the uranyl ion from water layer to CH_2Cl_2 with H_3L_3 was 93% and with H_3L1 85% during 48 h. Already after 4 h extraction with H_3L3 84% of uranyl ions were in CH_2Cl_2 while with H_3L1 we needed 30 h to reach the same uranyl extraction level. So the H_3L3 ligand is much better extractor than H_3L1. With both ligands, H_3L1 and H_3L3, red crystals formed into and under the CH_2Cl_2 layer. These crystals were analyzed with single-crystal X-ray diffraction and they turned out to be compounds **2** and **4**, respectively. The mass% of uranyl complex **4** in CH_2Cl_2 was 78% measured from the initial level of uranyl ions in H_2O layer and 84% measured from the uranyl ions extracted to CH_2Cl_2 layer and the amount of uranyl complex **2** was 52% measured from the initial level of uranyl ions in H_2O layer and 62% measured from the uranium extracted to CH_2Cl_2 layer. The extraction system gained balance at the uranium concentration about 1 mg/mL. In order to improve the extraction of the uranyl ion, we must be able to control very complicated process in which the complexation of the uranyl ion with the ligands is one of the most important factor. The solubility of the formed

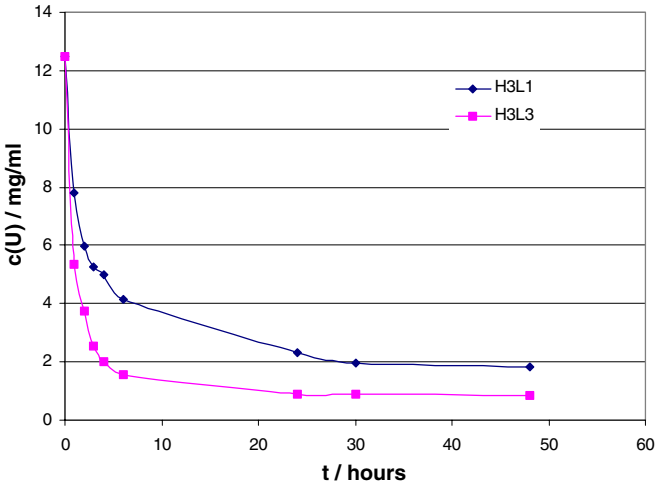

Fig. 6. The decrease of the uranium concentration as a function of time in the water layer during two-phase extraction study with ligands H_3L1 and H_3L3.

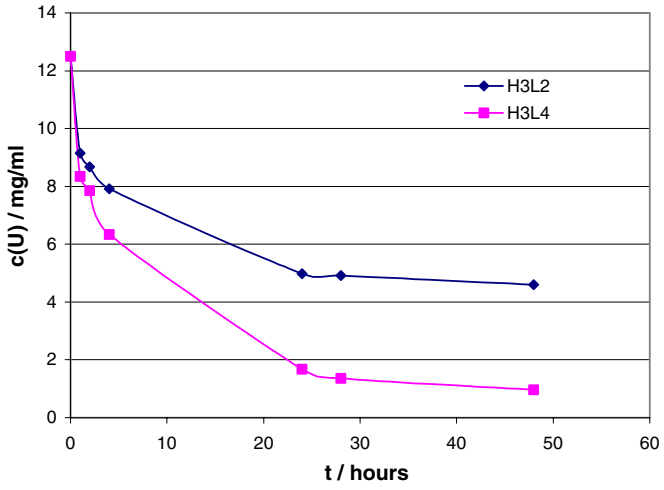

Fig. 7. The decrease of the uranium concentration as a function of time in the water layer during two-phase extraction study with ligands H_3L2 and H_3L4.

uranyl complex in the organic solvent is a second important factor and the crystallization of the uranyl complex from the organic solvent is a third one. Thus, the modification of the ligand is one of the useful ways to proceed.

The results of uranyl ion extraction studies with the ligands H_3L2 and H_3L4 are shown in Fig. 7. The uranyl ion do not crystallize with H_3L2 from dichloromethane without acetonitrile and thus the ability of H_3L2 to remove uranyl ion from water is worst. H_3L4 is slower and slightly worse than H_3L3 possibly because *t*-butyl group at position 5 increases the solubility of this uranyl complex in dichloromethane.

We are currently working in the field of the ligand modification trying to get more effective ligands for uranyl ion extraction. The pH of the water phase plays also important role during the extraction and this must also be studied. We have not yet studied how selectively this ligand family extracts the uranyl ion in the presence of other metal ions. This is an important matter, which will be also studied later.

4. Conclusion

In conclusion, we have found that $UO_2(NO_3)_2 \cdot 6H_2O$ in CH_3CN reacts with phenolic ligand precursors *N*,*N*-bis(2-hydroxy-3,5-dimethylbenzyl)-2-aminoethanol (H_3L1), *N*,*N*-bis(2-hydroxy-5-*t*-butyl-3-methylbenzyl)-2-aminoethanol (H_3L2), *N*,*N*-bis(2-hydroxy-3,5-dimethylbenzyl)-3-amino-1-propanol (H_3L3) and *N*,*N*-bis(2-hydroxy-5-*t*-butyl-3-methylbenzyl)-3-amino-1-propanol (H_3L4) to form dioxouranium(VI) complexes of the type $[UO_2(H_2L\text{-}x)_2] \cdot y$S (where $x = 1$–4, $y = 0$ or 2 and S = water or acetonitrile), and all with the similar compressed octahedral coordination spheres around U(VI). The ligand H_3L1 also formed a dinuclear complex with the uranyl ion. The neutral uranyl complexes form structures in which uranyl ion is almost ideally bonded to two ligands and the complex itself is zwitterionic. Although the yields of the ligand syntheses are poor, compared to calixarenes, these ligands are reasonably easy to prepare, and furthermore, the complexation of the new ligands mainly produce only one complex with a centrosymmetric structure.

For uranyl extraction studies, good solubility of the uranyl complexes in organic solvents is important. This is a condition that is not totally fulfilled with the present complexes, but on the other hand crystallization of the complex from the organic solvent can improve the extraction process. Thus, the ligands, H_3L1, H_3L3 and H_3L4 worked quite well in the extraction process: H_3L3 was the best one. We hope to increase our knowledge about the extraction system by preparing new ligands, which shall improve solubility of uranyl complexes in organic, water-immiscible solvents. We hope that, for example, the changing of the aminoalcohol to a simple alkyl amine will provide a solution to the problem of solubility. The selectivity of the ligands prepared in this work towards uranyl ion in the presence of other metals has not yet been studied. However, we believe that the complexes described here and their modified relatives open up new possibilities for uranyl ion extraction and the elimination of uranyl ions for ex. from biological systems.

5. Supplementary data

Crystallographic data (excluding structure factors) for the structure(s) reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication nos. CCDC 277291–277295 for **1**–**5**. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: (internat.) +44 1223 336 033; e-mail: deposit@ccdc.cam.ac.uk).

Acknowledgments

We are grateful to Dr. Karel D. Klika for correction of the language, to Elina Hautakangas for her help in the synthetic work and performing the elemental analysis and to Dr. Ari Väisänen for doing the ICP measurements.

2. Experimental

All reagents were used as purchased. $K_4Re_4S_{4-x}Te_x(CN)_{12}$ was synthesized through the reaction of $Re_4S_{4-x}Te_x(TeCl_2)_4Cl_8$ with KCN in water by technique reported for $K_4Re_4Se_4(CN)_{12}\cdot 6H_2O$ [10]. $Re_4S_{4-x}Te_x(TeCl_2)_4Cl_8$ was obtained through the reaction of $ReCl_5$ with a mixture of elemental S and Te [14]. FT-IR: Scimitar FTS 2000 – Elementary analyses: Vario EL of Elementar Analysensysteme GmbH, Z8000 (Hitachi).

2.1. Synthesis of $[\{Cu(en)_2\}_2Re_4S_{3.83}Te_{0.17}(CN)_{12}]\cdot H_2O$ (1)

A solution containing $CuSO_4\cdot 5H_2O$ (0.072 g) and en (0.03 ml) in concentrated aqueous ammonia (5 ml) was mixed with a solution of $K_4Re_4S_{4-x}Te_x(CN)_{12}$ (0.005 g) in water (5 ml). The resultant solution was kept for two weeks in a vessel covered by a watch glass. Dark red crystals formed during this time were filtered off and dried on filter paper. Yield: 0.0053 g. *Anal.* Calc. for $C_{20}H_{34}Cu_2N_{20}ORe_4S_{3.83}Te_{0.17}$: C, 30.2; H, 3.85; N, 32.8; S, 14.23. Found: C, 28.8; H, 4.11; N, 33.6; S, 14.7%. IR (KBr, cm^{-1}): $\nu_{CN} = 2154$(s), 2181(w).

2.2. Synthesis of $[\{Zn(en)_2\}_2Re_4S_{3.60}Te_{0.41}(CN)_{12}]\cdot 3.75H_2O$ (2)

A solution containing $ZnCl_2$ (0.037 g) and en (0.03 ml) in concentrated aqueous ammonia (3 ml) was mixed with a solution of $K_4Re_4S_{4-x}Te_x(CN)_{12}$ (0.005 g) in water (2 ml). The resultant solution was kept for two weeks in a vessel covered by watch glass. Dark-red crystals formed during this time were filtered off and dried on filter paper. Yield: 0.0034 g. *Anal.* Calc. for $C_{20}H_{39.50}Zn_2N_{20}O_{3.75}Re_4S_{3.60}Te_{0.41}$: C, 14.4; H, 2.39; N, 16.8; S, 6.94. Found: C, 14.9; H, 2.85; N, 16.9; S, 6.32%. IR (KBr, cm^{-1}): $\nu_{CN} = 2153$(s), 2191(w).

2.3. Synthesis of $[\{Cu(dien)(NH_3)\}Re_4S_{3.45}Te_{0.55}(CN)_{12}]\cdot 3H_2O$ (3)

A solution containing $CuSO_4\cdot 5H_2O$ (0.06 g) and dien (0.024 ml) in concentrated aqueous ammonia (3 ml) was mixed with a solution of $K_4Re_4S_{4-x}Te_x(CN)_{12}$ (0.005 g) in water (2 ml). The resultant solution was kept for one week in a vessel covered by watch glass. Dark-red plate-like crystals formed during this time were filtered off and dried on filter paper. Yield: 0.0056 g. *Anal.* Calc. for $C_{20}H_{38}Cu_2N_{20}O_3Re_4S_{3.64}Te_{0.36}$: Te, 3.02; Cu, 7.66. Found: Te, 2.80; Cu, 7.74%. IR (KBr, cm^{-1}): ν(CN) = 2170(w), 2162(w), 2154(s).

2.4. X-ray structural analyses

The structures of **1**–**3** were solved by X-ray structural analysis. Single-crystal X-ray diffraction data were collected with the use of graphite monochromatized Mo Kα radiation ($\lambda = 0.71073$ Å) at 293 K on a Bruker Nonius X8Apex diffractometer equipped with a 4K CCD area detector. The data were collected at 293 K. The φ-scan technique was employed to measure intensities. Decomposition of the crystals did not occur during data collection. Corrections were applied for Lorentz and polarization effects and for absorption [15]. The structures were solved by direct methods with employing difference Fourier

syntheses and refined anisotropically by full-matrix least-squares techniques on F^2 using the SHELXL-97 Release 97-2 software package [16]. Hydrogen atoms from the water molecules are not located. Hydrogen atoms from the organic ligands and ammonia are located by hydrogen bonds. ORTEP drawings were made using ORTEP III for Windows [17]. Crystallographic data as well as details of data collection and refinement for complexes **1**–**3** are listed in Table 1.

2.5. DFT calculations

Density functional theory calculations were carried out on different $[Re_4S_3Q(CN)_{12}]^{4-}$ (Q = S, Se, Te) models with full optimizations using the ADF2002 code [18]. The density functional consisted from LDA and GGA parts [19–21]. The STO basic set (TZ2P) without core-potentials was used for all atoms. The ZORA (zeroth-order relativistic approximation) method was used to account for the scalar relativistic effects [22]. The electronic binding energy (ΔE) are computed from the reaction $4Re + 3S + Q + 12C + 12N + 4e^- \rightarrow [Re_4S_3Q(CN)_{12}]^{4-}$. The atomic net charges for several $[Re_4S_3Q(CN)_{12}]^{4-}$ complexes obtained using the Hirshfeld analysis [23].

3. Results and discussion

3.1. Syntheses

$K_4[Re_4S_{4-x}Te_x(CN)_{12}]$ cluster compound has been synthesized accidentally during preparation of $K_4Re_4S_4(CN)_{12}$ cluster from $Re_4S_4(TeCl_2)_4Cl_8$ by boiling with KCN as described for $K_4Re_4Se_4(CN)_{12} \cdot 6H_2O$ [10]. According to elemental analysis the compound obtained contains the tellurium. This could be caused of sulfur shortage during the preparation of $Re_4S_4(TeCl_2)_4Cl_8$ from $ReCl_5$, S and Te [14]. Using $K_4[Re_4S_{4-x}Te_x(CN)_{12}]$, that may be described as solid solution between $K_4[Re_4S_4(CN)_{12}]$ and $K_4[Re_4S_3Te(CN)_{12}]$, copper or zinc salts and polydentate ligands, namely, ethylenediamine and diethylenetriamine, we have synthesized three new cluster compounds. All three compounds have been characterized by single-crystal X-ray diffraction method.

The two-dimensional compound **1** was synthesized by the reaction of an aqueous solution of the cluster $K_4[Re_4S_{4-x}Te_x(CN)_{12}]$ with an ammonia solution containing $CuSO_4$ and *en* in molecular ratio 1:2. The polymeric complex **2** was obtained in a similar manner using $ZnCl_2$ as a starting compound. Analogously, the molecular complex **3** was prepared using $CuSO_4$ and diethylenetriamine in ratio 1:1.

3.2. Structures

According to X-ray diffraction analysis there are two different cluster anions in compounds with compositions $[Re_4S_4(CN)_{12}]^{4-}$ and $[Re_4S_3Te(CN)_{12}]^{4-}$. The structure of $[Re_4S_4(CN)_{12}]^{4-}$ anion is similar to that in the related compounds. It contains Re_4S_4 cubane-like cluster core formed from nearly regular Re_4, with Re–Re and Re–(μ_3-S) distances in the ranges 2.7554(4)–2.7651(3) Å and 2.3497(13)–2.358(3) Å for **1**, 2.7599(7)–2.7748(8) Å and 2.345(18)–2.376(3) Å for **2**, 2.7431(13)–2.7820(14) Å and 2.34(2)–2.400(5) Å for **3**, respectively. Each Re atom is further ligated by three cyano-ligands. The structure of $[Re_4S_3Te(CN)_{12}]^{4-}$ looks like thiocyanide cluster, but one sulfur atom is substituted by the tellurium atom. The Re–(μ_3-Te) distances are in range 2.591(8)–2.654(5) Å for **1**, 2.627(5)–2.635(6) Å for **2** and 2.613(6)–2.621(4) Å for **3**. These values are similar to that found for $[Re_4Te_4(CN)_{12}]^{4-}$ anion. It is to be noted that these data are the first examples for cubane-like rhenium mixed chalcogenide cluster core Re_4S_3Te.

In structures of all three compounds, the Re_4S_4 and Re_4S_3Te cluster cores are ordered in such a way, that three position of Q_4 tetrahedron are equivalent and occupied with only sulfur atoms, but the fourth position is occupied with either sulfur or tellurium atoms.

Compound **1** has a polymeric grid structure in which the $[Re_4S_{3.83}Te_{0.17}(CN)_{12}]^{4-}$ cluster anions are situated in cross-points of this lattice and linked by $[Cu(en)_2]^{2+}$ cationic units as depicted in Fig. 1(a). Each Cu atom in the cationic part has 4 + 2 coordination environment and coordinated by four NH_2 groups of two ethylenediamine units in equatorial plane (Cu–N distances ranging from 2.008(5) to 2.028(5) Å), and by two N atoms of CN^- ligands of different cluster anions with a Cu–N distances, one of which is equal to 2.367(4) Å, and other one is longer (2.759(5) Å), but also can be considered as weak interaction.

Compound **2** also has a polymeric grid structure with $[Re_4S_{3.60}Te_{0.41}(CN)_{12}]^{4-}$ cluster anions in cross-points and $[Zn(en)_2]^{2+}$ moieties on the edges (Fig. 1(b)). However, two these lattices are differently arranged. In the case of **1** four CN^- groups of two rhenium atoms (2 + 2) take part in binding; on the other hand four CN^- ligand from three Re atoms (2 + 1 + 1) of cluster anion is in formation of polymeric structure in case of **2**. In this context, the different bridging modes have a crucial influence on the packing characteristics. The bent bridging modes in **1** resulted in the formation of wavy layers (Fig. 2(a)), whereas the tentatively flat binding of **2** generates approximately plane layers (Fig. 2(b)). There are two crystallographically independent zinc atoms in cationic part of **2**. Once again, every zinc atom has a similar environment as a copper atoms in **1**, namely, it is coordinated by amino groups of two ethylenediamines (Zn–N distances ranging from 2.093(15) to 2.143(13) Å) and by two N atoms of CN^- ligands of different cluster anions with a Zn–N with similar distances 2.221(13) and 2.334(13) Å.

In the molecular structure of compound **3**, two $[Cu(dien)(NH_3)]^{2+}$ cations are coordinated by the N atoms of CN^- ligands, that belong to one rhenium atom of the $[Re_4S_{3.45}Te_{0.55}(CN)_{12}]^{4-}$ anion (Fig. 3). Each Cu atom is coordinated by the 3N atoms of the dien ligand with

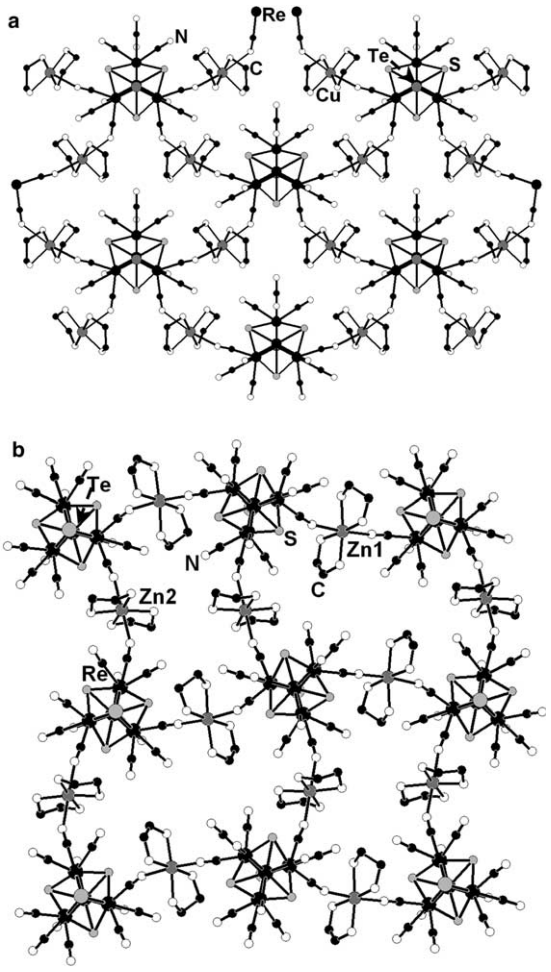

Fig. 1. Ball-and-stick representations of the $[\{M(en)_2\}_2\{cluster\}]_\infty$ layer of (a) **1** and (b) **2**. Hydrogen atoms and water molecules are omitted.

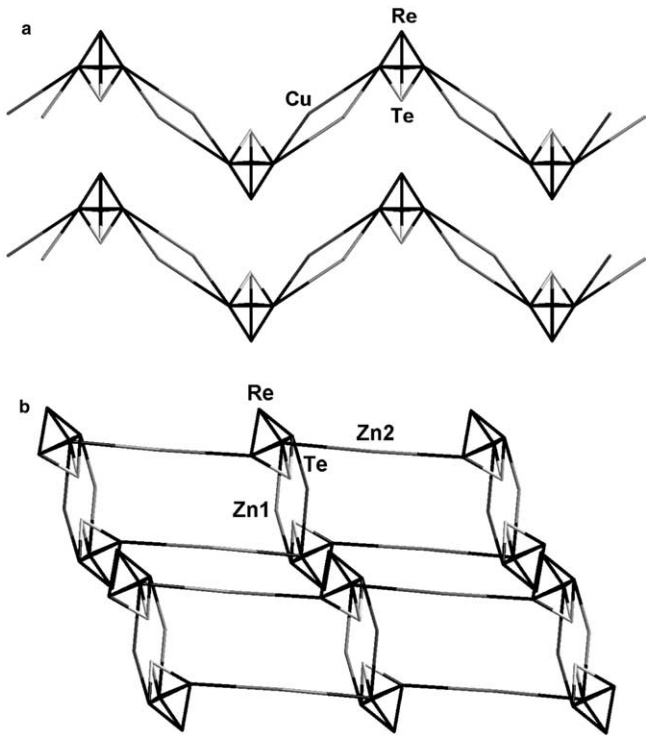

Fig. 2. Views of the stacking of layers in **1** (a) and **2** (b) using a stick model. Hydrogen, nitrogen, carbon, sulfur atoms are omitted for clarity.

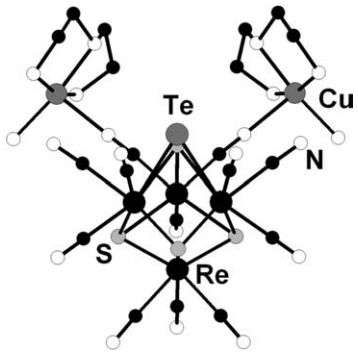

Fig. 3. View of the $[\{Cu(dien)(NH_3)\}_2Re_4S_{3.45}Te_{0.55}(CN)_{12}]$ molecule in compound **3**. Hydrogen atoms are omitted.

Cu–N distances ranging from 1.982(17) to 2.01(2) Å, by one NH_3 ligand with Cu–N distance of 1.979(19) Å and by N atom of a bridging CN^- ligand of the cluster anion with Cu–N distance 2.297(19) Å. Thus the coordination number of each Cu is equal to 5 and the copper atoms exhibit square–pyramidal coordination spheres with cyanide nitrogen in axial position.

It should be noted, that in all three structures metal cations have chosen CN groups which are the closest to tellurium atom position. To understand a reason of similar coordination the density functional theory calculations were carried out on different $[Re_4S_3Q(CN)_{12}]^{4-}$ (Q = S, Se, Te) cluster anions using ADF program. According to these calculations, there are several types of CN ligands in $[Re_4S_3Q(CN)_{12}]^{4-}$ (Q = Se, Te) cluster anions. Let's consider each Re atom to be octahedrally coordinated (without taking Re–Re bonds into account). First of all, there are three CN groups, which are bonded with ReS_3 fragment; this is the first type of ligands; remained CN ligands are coordinated to three ReS_2Q (Q = Se, Te) fragments. Within $ReS_2Q(CN)_3$ units one CN group is more distant from Q atom then another two groups (the ligands of

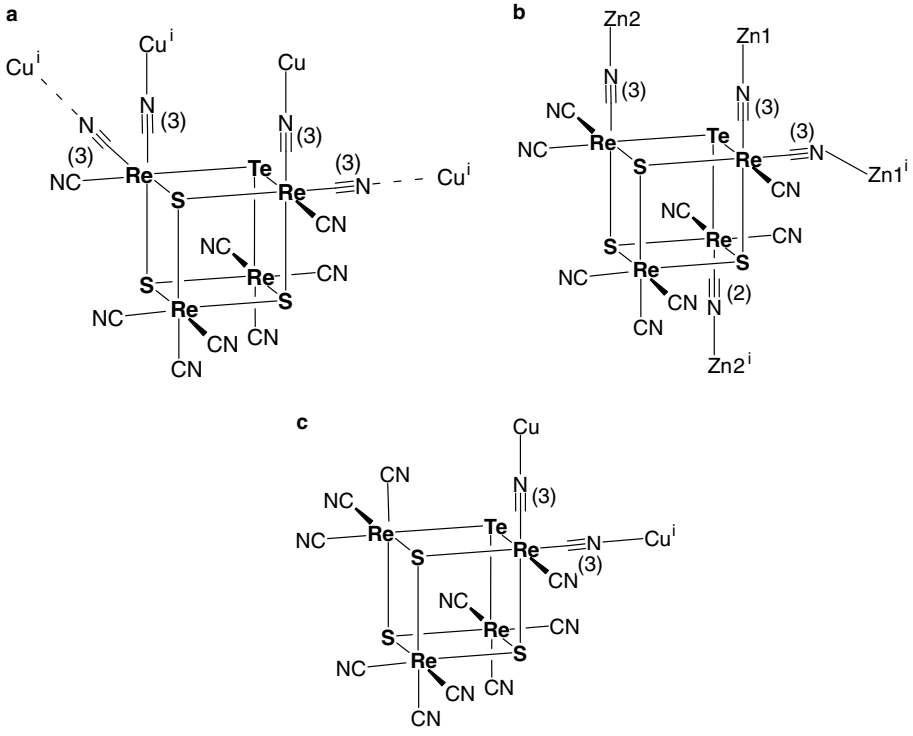

Scheme 2.

2 and 3 types, correspondingly) (Scheme 1). For CN ligands of types 1 and 2 the changes are negligible, but for six CN groups of the third type that are considerable and rise with decreasing of electronegativity of chalcogen atoms (Table 2). We propose that increasing of negative charge on N atoms of type 3 results in considerable preferences of metal ions in coordination to these atoms.

In the case of compound **1** all copper atoms are coordinated by CN groups of third type giving polymeric structure (Scheme 2a). It slightly differs from compound **2**, in which Zn1 atoms are coordinated by two CN groups of third type; whereas Zn2 cations are linked with CN groups of both second and third types. To put it another way only three of four bridged CN ligands of one cluster anion are of type 3, while the fourth one is of type 2 (Scheme 2b). In molecular compound **3**, two bridged CN groups also belong to the third type (Scheme 2c).

The received date supplement the previous research and show that substituting one sulfur atom by tellurium atom in cluster core Re_4S_4 we thus activate six CN groups of cluster anion for interaction with cation; all these groups are the nearest to Te atom.

4. Supplementary data

Supplementary data are available from the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK on request, quoting the Deposition Nos. CCDC 271383 (**1**), 271384 (**2**) and 271385 (**3**).

structures but also make the complexes have particular characters [6]. Herein, we report the syntheses and characterizations of four new complexes, $[Cd(hpht)(phen)]_n$ (**1**), $[Cd(hpht)(2,2'\text{-bpy})]_n$ (**2**), $[Cd(hpht)(2,2'\text{-bpy})(H_2O)]_n \cdot 2nH_2O$ (**3**), and $[Cd(hpht)(4,4'\text{-bpy})]_n \cdot nH_2O$ (**4**).

2. Experimental

2.1. Materials and analyses

All chemicals are used as purchased without further purification. Thermogravimetric analyses were carried out with a NETZSCH STA 449C unit at a heating rate of 15 °C min^{-1} under nitrogen. IR spectra were recorded on a Magna 750 FT-IR spectrophotometer as KBr pallets. Elemental analyses were carried out on an Elementar Vario EL III analyzer. Fluorescence spectroscopy was performed on an Edinburgh Analytical instrument FLS920.

2.2. Syntheses

2.2.1. $[Cd(phen)(hpht)]_n$ (**1**)

H_2hpht (0.055 g, 0.3 mmol), phen (0.060 g, 0.3 mmol), and $Cd(CH_3COO)_2 \cdot 2H_2O$ (0.12 g, 0.45 mmol) were put in a mixed solution of 8 mL distilled H_2O and 2 mL ethanol, and the pH was adjusted to about 5.6 by diluent HCl aqueous solution. Then, the mixture was sealed in 25 mL Teflon-lined reactor and heated to 160 °C for 3 days, and then slowly cooled to room temperature. Colorless prism crystals of **1** were collected and washed with distilled water (yield: 67%). Complex **1** was also obtained by using $Cd(NO_3)_2 \cdot 4H_2O$ (pH 4.7, 58% yield), $CdCl_2$ (pH 5.6, 43% yield), or $CdSO_4$ (pH 5.4, 47% yield). *Anal.* Calc. for **1**: H, 3.00; C, 53.58; N, 5.95. Found: H, 3.08; C, 53.47; N, 5.98%. IR(KBr) 3067m, 3011m, 2992m, 1575vs, 1548vs, 1509vs, 1389vs, 1295s, 1146m, 1097m, 844vs, 828m, 774m, 731vs, 677vs.

2.2.2. $[Cd(hpht)(2,2'\text{-bpy})]_n$ (**2**)

The synthetic procedure of **2** is essentially the same as that for **1**, while $Cd(NO_3)_2 \cdot 4H_2O$ and 2,2′-bpy were used, and the pH was adjusted to about 5.3 by diluent NaOH aqueous solution. Colorless prism crystals of **2** were collected and washed with distilled water (yield: 76%). *Anal.* Calc. for **2**: H, 3.16; C, 51.08; N, 6.27. Found: H, 3.50; C, 50.89; N, 6.32%. IR(KBr) 3112m, 3077m, 3062m, 3027m, 2956m, 1590vs, 1544vs, 1485s, 1443vs, 1415vs, 1380vs, 1287s, 1061m, 1018s, 855m, 832m, 758vs, 723vs, 688s, 645m.

2.2.3. $[Cd(hpht)(2,2'\text{-bpy})(H_2O)]_n \cdot 2nH_2O$ (**3**)

The synthetic procedure is the same as that for **2**, and the pH was adjusted to about 5.5 by diluent NaOH aqueous solution. Colorless prism crystals of **3** were collected

2.3. X-ray data collection and structure determination

The intensity data of **1**, **3**, **4** were collected on a Rigaku CCD diffractometer with graphite-monochromatized Mo Kα ($\lambda = 0.71073$ Å) radiation at 173 K, and the empirical absorption corrections were performed using the CRYSTALCLEAR program [7]. The intensity data of **2** were collected on a SIEMENS SMART CCD diffractometer with graphite-monochromatized Mo Kα ($\lambda = 0.71073$ Å) radiation at room temperature. The absorption correction was performed using the SADABS program [8]. The structures were solved by direct methods and refined on F^2 by full-matrix least-squares using the SHELXTL-97 program package [9]. All non-hydrogen atoms were refined anisotropically. The organic hydrogen atoms were generated geometrically (C–H = 0.95 Å). The H atoms of water were located from *E*-map, but those of the lattice water (O7) in **3** could not be located and were not taken into consideration, and the hydrogen atoms of the water in complex **4** were refined with AFIX 3 constraints on the O–H bonds. The crystallographic data for four complexes are listed in Table 1.

3. Results and discussion

3.1. Syntheses

As shown in Scheme 1, the coordination modes of $hpht^{2-}$ ligand are different in the four complexes. Andrew and co-workers have reported the second coordination mode, while the other two modes are new. As known, solvothermal reaction is complicated, and it is quite difficult to know what controls the coordination modes of $hpht^{2-}$ ligand and the formation of the complexes. In this work, we primarily studied the influence from auxiliary ligand, pH value, counter ion, and ratio of the starting materials.

The employment of terminal ligands 2,2′-bpy and 1,10-phen prevents complexes **1**–**3** from being extended to 2D or 3D architectures, but yields infinite 1-D chain structures of the three complexes. When bridging ligand 4,4′-bpy was used, 2D network **4** was obtained. Unfortunately, when 1,3-di(4-bpy)propane and piperazine were used as bridging ligands, the experiments were failed. The pH value plays a crucial role for the formation of the complexes. It is only within the specific pH range that complexes **1**–**4** can be obtained and different pH values lead to different yields of the products. More interestingly, although the starting materials and reaction conditions are quite similar, the structures of **2** and **3** are significantly different, the slightly different of the pH values of the reaction medium might play important role, although detailed reaction mechanism still remains unclear. We also studied the influence from counter ions and the mole ratio of starting materials. The results illustrate that the two factors only induce different yields of the products and may be not the key factors for the synthetic reactions.

3.2. Crystal structures

3.2.1. Crystal structures of complexes *1* and *2*

The selected bond lengths and angles of complex **1** are listed in Table 2. The asymmetric unit of **1** consists one Cd(II) ion, a phen ligand and a $hpht^{2-}$ ligand. The Cd(II) ion is six-coordinated by two nitrogen atoms from phen and four oxygen atoms from three $hpht^{2-}$ ligands in a distorted octahedron coordination geometry, as shown in Fig. 1. The Cd–O(N) bond distances are in the range 2.275–2.418 Å, with an average value of 2.350 Å. The $hpht^{2-}$ ligand links three Cd(II) ions, in which the carboxylate group chelates a Cd(II) ion and the ethylic carboxylate group bridges two Cd(II) ions (Scheme 1(a)). The two Cd(II) ions connected by two bridging ethylic carboxylate groups with interatomic distance of 4.023 Å form the basic building unit, $Cd_2(hpht)_2(phen)_2$, of the whole structure. Each two of such units are connected together through sharing the $hpht^{2-}$ ligands to form the final double chain structure. Two kinds of macrocyclic rings, one is 16-member ring (A) and the other is 8-member ring (B), are observed in the double chain (Fig. 2). Phen ligands are

alternately attached to the two sides of the double-chain, and the vertical distance of the two adjacent phen planes at the same side is 6.897 Å. The double-chains are further stacked by π–π interaction of phen (about 3.43 Å) to form the final layer structure, and the benzene planes of $hpht^{2-}$ anions from two layers are meshed (Fig. 3). Since the previously reported homophthalate complexes are all 0-D dimmers [5], to our knowledge, **1** is the first example of homophthalate complexes with 1-D chain structure. The selected bond lengths and angles of complex **2** are listed in Table 3. The structure of **2** is quite similar to that of **1**, only 2,2′-bpy ligands replace the phen ligands. Detailed discussion of the structure will not be made here.

3.2.2. Crystal structure of complex *3*

The selected bond lengths and angles of complex **3** are listed in Table 4. The asymmetric unit of **3** consists one

Symmetry transformations used to generate equivalent atoms: #1 $-x+1,-y+1,-z$; #2 $x-1, y, z$.

Cd(II) ion, a 2,2′-bpy ligand, a $hpht^{2-}$ ligand, a coordinated water molecule and two guest water molecules. Cd(II) ion is seven-coordinated by two nitrogen atoms from 2,2′-bpy and five oxygen atoms, four of which from two $hpht^{2-}$ ligands and one from coordinated water in a highly distorted pentagonal bipyramid coordination geometry, with O3A and N2 in the axial positions (Fig. 4). The Cd–O(N) bond distances are in the range 2.287–2.5l0 Å with an average value of 2.373 Å, slightly longer than those in complex **2**. Both carboxylate groups in $hpht^{2-}$ ligand adopt chelating coordination mode (Scheme 1(b)). The connections of Cd(II) ions and $hpht^{2-}$ ligands alternately along the *a*-axis lead to the formation of 1-D linear chain, as shown in Fig. 4. All the 2,2′-bpy ligands arrange in the same side of the chain and all the $hpht^{2-}$ ligands in the other side, which is significantly different from **1** and **2**. There are four types of hydrogen bondings in **3**. Two types of them (O5–H20···O1 and O5–H21···O4) link linear chains to form the double-chains, and the other two types (O6–H22···O2 and O6–H23···O3) link the double-chains to form the final 2-D network structure, as shown in Fig. 5. The 2-D network is corrugated because different double-chains are parallel but not in a plane. Different layers are stacked to produce the 3-D structure by the π–π weak interaction of 2,2′-bpy ligands along the *a*-axis, and the vertical distance between two 2,2-bpy ligands is about 3.467 Å. The free guest H_2O molecules are hold in the channels that formed by π–π interaction and hydrogen bonding, as shown in Fig. 6.

3.2.3. Crystal structure of complex *4*

The selected bond lengths and angles of complex **4** are listed in Table 5. The asymmetric unit of **4** consists a Cd(II) ion, a $hpht^{2-}$ ligand, a 4,4′-bpy ligand, and a guest water molecule. Cd(II) ion is seven-coordinated by two nitrogen atoms from two 4,4′-bpy ligands and five oxygen atoms from three $hpht^{2-}$ anions in a slightly distorted pentagonal bipyramid coordination geometry (Fig. 7). Each $hpht^{2-}$ ligand links three Cd(II) ions, in which the methyl carboxylate group adopts bridging mode and the ethyl carboxylate adopts bridging-chelating mode (Scheme 1(c)). Two Cd(II) ions connected by two ethyl carboxylate groups with interatomic distance of 4.318 Å, $Cd_2(hpht)_2$, form the basic building unit of the whole structure. Each two of such units are connected together through the bridging carboxylate groups to form the 1-D chains, with benzene planes arrange on two sides of the chains reversely, which make the chain like long bench, as shown in Fig. 8. The 4,4′-bpy ligands link 1-D chains to form the final 2-D layer structure and to complete the coordination sphere of

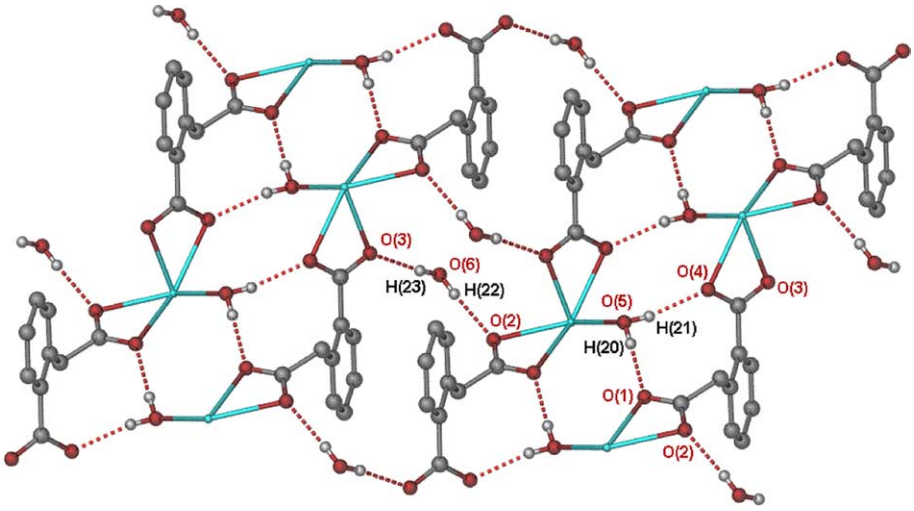

Fig. 5. View of the corrugated 2-D network in complex **3**. All the 2,2′-bpy and free guest water molecules are omitted for clarity, as well as the H atoms bonded to C atoms.

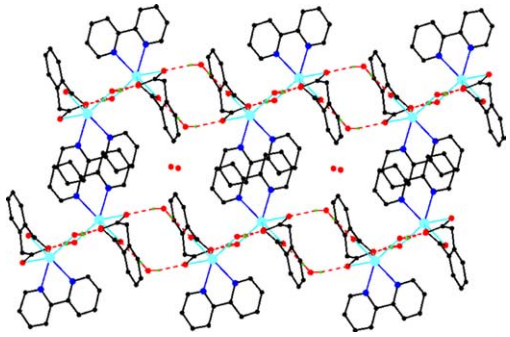

Fig. 6. View of the 3-D structure of complex **3** along *a*-axis. All the H atoms bonded to C atoms are omitted for clarity.

Cd(II) ions, and the free water molecules are hold between layers, as shown in Fig. 9.

3.3. Thermal gravimetric analysis

Thermal gravimetric analysis (TGA) diagram revealed that **1** was stable up to 317 °C, and then decomposed rapidly by the oxidation of the organic component. Complex **2** was stable up to 243 °C, and then the structure collapsed rapidly. For **3**, the first weight loss of 11.07% from 81 to 294 °C is attributed to the release of all water molecules (Calc. 10.78%). We note that the crystallization guest water is released at the same time as the coordinated water, supporting the structural evidence of hydrogen bonding in **3**. Complex **4** loses 3.78% of total weight in a range of 120–170 °C, corresponding to the loss of the free guest water (Calc. 3.87%), the framework is stable till 234 °C and then decomposed.

3.4. Fluorescence

The emission spectra of complexes **1**–**4** in the solid state at room temperature are shown in Fig. 11. It can be seen

Symmetry transformations used to generate equivalent atoms: #1 $x-1/2,-y+1/2,z-1/2$; #2 $-x+1,-y+1,-z$; #3 $-x+1,-y,-z$.

that **1** exhibits an intense blue photoluminescence emission at $\lambda_{max} = 406$ nm and a very weak band at $\lambda_{max} = 524$ nm ($\lambda_{ex} = 350$ nm). The emission of **1** probably can be assigned to the intraligand fluorescent emission since very similar emissions are also observed for free H_2hpht (Fig. 10, $\lambda_{ex} = 274$ nm) and phen ligands [10].

Complex **2** exhibits an intense blue emission band ($\lambda_{max} = 422$, 498 nm, with a shoulder at 530 nm) from

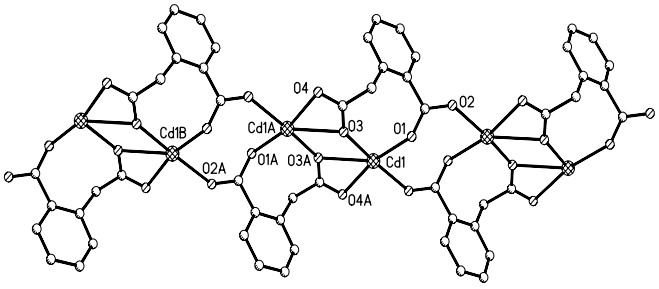

Fig. 8. View of the chain formed by Cd(II) ions and $hpht^{2-}$ ligands in complex **4**. All the H atoms are omitted for clarity.

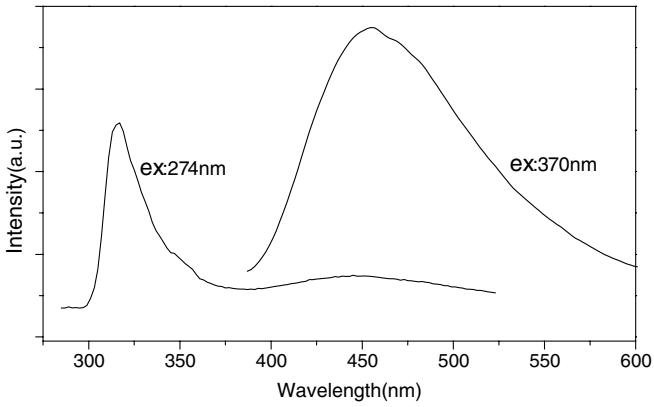

Fig. 10. Emission spectrum of homophthalic acid in the solid state.

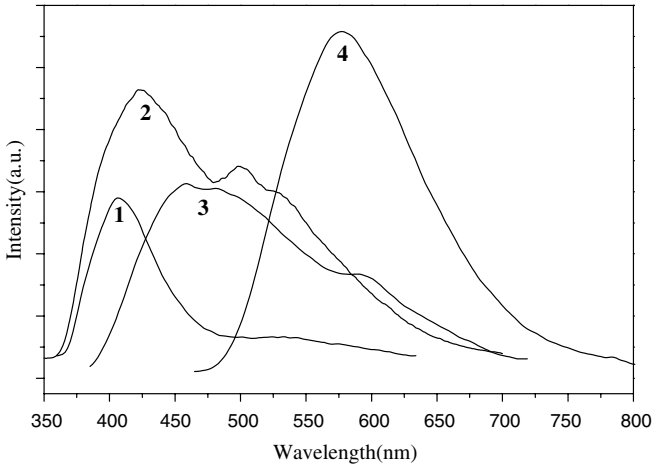

Fig. 11. Emission spectrum of complexes **1**–**4** in the solid state.

375 to 650 nm on excitation at 310 nm (Fig. 11). The peak at 422 nm can be assigned to the intraligand emission of H_2pht, since the free H_2pht ligand exhibits intense emission at $\lambda_{max} = 455$ nm upon excitation at 370 nm (Fig. 10), and the coordination of the ligand may lead to the blue-shift. The peak at 498 nm may be attributed to the intraligand emission from the 2,2′-bpy ligand [11]. It is known that the free 2,2′-bpy molecule displays a weak luminescence at ca. 535 nm. The enhancement and significant blue-shift of the photoluminescence of the coordinated 2,2′-bpy ligand compared to that of the free 2,2′-bpy molecule may, therefore, be attributed to the chelating of the 2,2′-bpy ligand to the metal ion, which effectively increases the rigidity of the ligand and reduces the loss of energy by radiationless decay of the intraligand emission excited state [12]. The shoulder emission at 530 nm may be assigned as ligand-to-metal-charge-transfer (LMCT) [13].

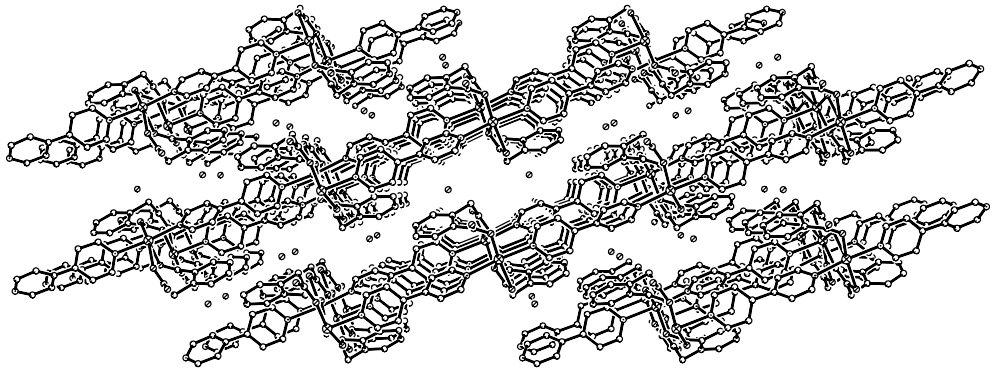

Fig. 9. View of the layer structure of complex **4** along *b*-axis. All the H atoms are omitted for clarity.

Complex **3** exhibits a broad green emission band ($\lambda_{max} = 459$, 481 nm, with a shoulder at 603 nm) from 385 to 700 nm on excitation at 372 nm (Fig. 11). We noted that the photoluminescence of **3** is similar to that of **2**, and the peaks can be assigned similarly. Compared with their analogs, both the peak at 459 nm and the shoulder red-shift and have lower intensity, which may be attributed to the different coordination mode of the ligand and different coordination environment of metal ions.

Complex **4** exhibits a very intense red photoluminescence emission at $\lambda_{max} = 577$, upon excitation at 455 nm, which has rarely been reported for cadmium complexes. While a very similar emission band of the free 4, 4′-bpy molecule with $\lambda_{max} = 432$ nm ($\lambda_{ex} = 344$ nm) is observed, the emission may be assigned to the ligand-to-metal charge transfer (LMCT) [14].

In a word, the photoluminescence properties of complexes **1**–**4** exhibit a broad range of visible light. Since complexes **1**–**4** are insoluble in common solvents and thermally stable, they may be potential candidates for photoactive materials.

4. Conclusion

In conclusion, four new complexes, **1**–**4**, have been successfully synthesized from the solvothermal reactions of cadmium salts, H_2phth and different auxiliary diimine ligands. The four complexes are stable and have particular fluorescence properties, and they may have promising application in photophysical chemistry.

5. Supplementary material

For the four complexes, full list of atomic coordinates, isotropic thermal parameters, bond lengths and angles are available from the authors on request. Crystallographic data for the structural analyses have been deposited with the Cambridge Crystallographic Data Center, CCDC Nos. 278028–278031 for complexes **1**–**4**, respectively. Copies of the data can be obtained from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; Fax: (internet.) +44 1223 336 033; e-mail: deposit@ccdc.cam.ac.uk.

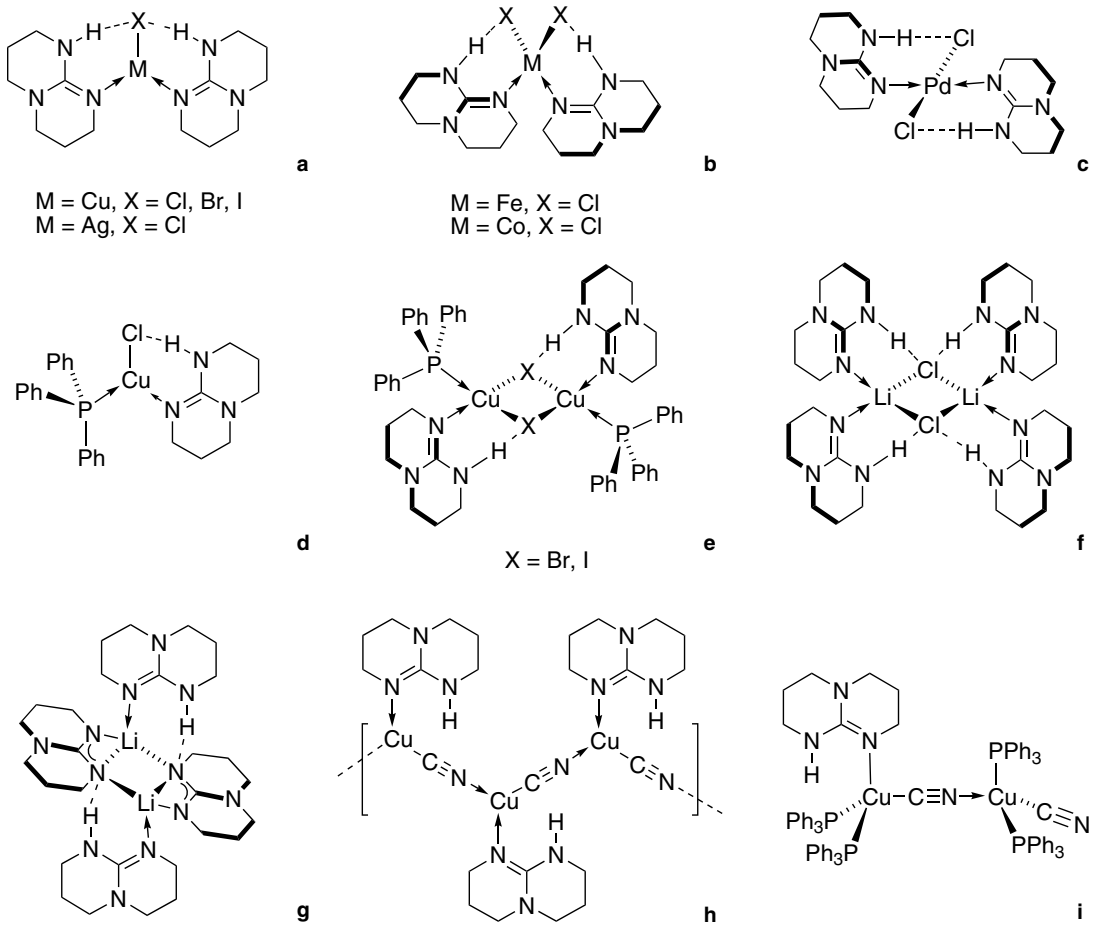

Fig. 1. Examples of compounds containing the neutral bicyclic guanidine, hppH, as a ligand.

more recently in a square-planar palladium complex (**c**) [11]. We have shown that the extent of aggregation differs in the mixed phosphine/guanidine copper(I) halides (**d**) and (**e**), where the chloride was isolated as the monomer and the heavier congeners formed μ,μ′-dihalobridged dimers [9]. In contrast to complexes of type (**a**), the bis-ligand, monovalent metal halide species formed with lithium chloride is dimeric in the solid-state, comprised of chloride bridges and tetrahedral metal centres (**f**) [9].

Hydrogen bonding between tetrasubstituted guanidines and atoms other than the halides has also been observed, albeit less frequently. The acyclic guanidine, $Me_2NC\{N^iPr\}\{NH^iPr\}$, forms intramolecular N*H*···O bonds within the monomeric zinc complexes $Zn(OAr)Me(Me_2NC\{N^iPr\}\{NH^iPr\})$ ($Ar = 2,6\text{-}^tBu_2C_6H_3$) [12] and the guanidinate/boroxide species, $Zn(OBmes_2)(Me_2NC\{N^iPr\}_2)(Me_2NC\{N^iPr\}\{NH^iPr\})$ [13]. Intramolecular hydrogen bonding by hppH to nitrogen is restricted to the mixed guanidine/guanidinate dimer, $[Li(hpp)(hppH)]_2$ (**g**) [14].

Finally, examples have been structurally characterized in which the coordinated guanidine does not undergo further interaction with the metal fragment. This situation was first noted by Bailey and co-workers with the tri-substituted guanidine, $PhN=C\{NHPh\}_2$, in the cationic silver species $Ag[PhN=C(NHPh)_2]_2[OTf]$ [15]. In this case, however, the preferential formation of *inter*molecular hydrogen bonds to the triflate anion are observed, via two S=O oxygen atoms. We have shown that the hppH ligand is monodentate in the polymeric copper(I) cyanide complex, $[CuCN(hpp)]_\infty$ (**h**), and bimetallic complex, $(Ph_3P)_2(hppH)Cu(\mu\text{-}CN)Cu(PPh_3)(CN)$ (**i**), where no readily available groups are present to interact with the N*H* atom.

In all cases discussed above, bonding occurs exclusively through donation of the imine lone pair to an orbital of suitable symmetry and energy on the metal in question. In this contribution we report the synthesis and structural analysis of series of divalent tetrahedral metal complexes of general formula $MX_2(hppH)_2$ (M = Mn, Fe, Ni, Zn; X = Cl, Br). We also report the solid-state structure of the dimeric lithium siloxide species, $[Ph_3SiOLi(hppH)(THF)]_2$, which contains an intramolecular N*H*···O hydrogen bond.

2. Experimental

2.1. General experimental procedures

All manipulations were carried out under dry nitrogen using standard Schlenk line and cannula techniques, or in a conventional nitrogen-filled glovebox operating at

<1 ppm oxygen. Solvents were dried over the appropriate drying agent and degassed prior to use. The reagents hppH (Fluka), $MnCl_2$ (Aldrich), $FeCl_2$ (Aldrich), $CoCl_2$ (Aldrich), $NiCl_2$ (Aldrich), $CuCl_2$ (Aldrich) and $ZnBr_2$ (Aldrich) were purchased from commercial sources and used as received. The compound $NiCl_2(Py)_4$ was synthesised according to literature procedures [16] and kindly donated by Dr. A.K. de K. Lewis; $(hpp)_3SiMe$ was made according to our previously reported procedure [17]. NMR spectra were recorded in $[^2H]_6$-benzene at 293 K (unless stated otherwise) using a Bruker Avance DPX 300 MHz spectrometer at 300 (^1H) and 75 ($^{13}C\{^1H\}$) MHz. Proton and carbon chemical shifts were referenced internally to residual solvent resonances. Elemental analyses were performed by S. Boyer at London Metropolitan University.

2.1.1. $MnCl_2(hppH)_2$ (1)

A solution of hppH (0.500 g, 3.59 mmol) in THF (10 mL) was added dropwise to a slurry of $MnCl_2$ (0.226 g, 1.80 mmol) in THF (10 mL). The mixture was stirred for 48 h at room temperature with gradual dissolution of the manganese dichloride and formation of a pale pink precipitate. Recrystallization from slow cooling of a warm (~70 °C) toluene solution afforded colourless crystals of **1** suitable for X-ray diffraction analysis. Yield: 0.450 g (62%). *Anal.* Calc. for $C_{14}N_6H_{26}MnCl_2$ (404.24): C, 41.60; H, 6.48; N, 20.79. Found: C, 41.72; H, 6.68; N, 20.85%.

2.1.2. $FeCl_2(hppH)_2$ (2)

Compound **2** was prepared according to the procedure described for compound **1**, using 0.500 g, hppH (3.59 mmol) and 0.228 g $FeCl_2$ (1.80 mmol). Recrystallization by slow cooling of a MeCN solution afforded light brown crystals of analytically pure **2**. Yield: 0.418 g (57%). *Anal.* Calc. for $C_{14}N_6H_{26}FeCl_2$ (405.15): C, 41.50; H, 6.47; N, 20.74. Found: C, 41.37; H, 6.65; N, 20.43%.

2.1.3. $NiCl_2(hppH)_2$ (3)

A solution of hpp_3SiMe (0.100 g, 0.22 mmol) in toluene (5 mL) was added dropwise to a slurry of $NiCl_2(Py)_4$ (0.097 g, 0.22 mmol) in toluene (10 mL) at room temperature. An immediate colour change from pale blue to purple was observed. The mixture was stirred for 24 h at room temperature and then filtered. Recrystallization from hot toluene afforded dark blue crystals of analytically pure **3**. Yield: 0.033 g (37%). *Anal.* Calc. for $C_{14}H_{26}N_6NiCl_2$ (408.02): C, 41.21; H, 6.42; N, 20.60. Found: C, 41.37; H, 6.60; N, 20.36%.

2.1.4. $ZnBr_2(hppH)_2$ (4)

Compound **4** was prepared according to the procedure described for compound **1**, using 0.500 g, hppH (3.59 mmol) and 0.400 g $ZnBr_2$ (1.78 mmol). The solid was collected after removal of the volatiles in vacuo and then washed with toluene to remove any unreacted hppH. Crystals suitable for X-ray diffraction analysis were grown from an acetonitrile solution.

^1H NMR. δ 7.44 (br, 1H, N*H*), 3.40 (m, 2H, CH_2), 2.54 (m, 2H, CH_2), 2.29 (m, $J_{HH} = 6.1$, 2H, CH_2), 2.10 (m, $J_{HH} = 6.2$, 2H, CH_2), 1.44 (m, 2H, CH_2), 0.96 (m, 2H, hpp-CH_2). $[^2H]_2$-dichloromethane: δ 6.49 (br, s, 1H, N*H*), 3.20 (m, 8H, CH_2), 1.84 (m, $J_{HH} = 5.9$, 4H, hpp-CH_2). ^{13}C NMR data were not obtained due to the low solubility of the product.

2.1.5. $hppSiPh_3$ and $[Ph_3SiOLi(hppH)(THF)]_2$ (5)

The synthesis of $hppSiPh_3$ was carried out using the procedure described for $hppSiMe_3$, [18] using 0.200 g hppH (1.44 mmol),^{n}BuLi (0.6 mL of a 2.5 M solution in hexane, 1.51 mmol) and Ph_3SiCl (0.42 g, 1.44 mmol). Removal of the volatiles afforded a white crystalline solid. Washing the solid with toluene gave two products that analyzed as $hppSiPh_3$ and $[Ph_3SiOLi(hppH)(THF)]_2$ (**5**). Crystallization of **5** from THF at 0 °C afforded crystals suitable for X-ray diffraction analysis.

$hppSiPh_3$. Anal. Calc. for $C_{25}H_{27}N_3Si$ (397.59): C, 75.52; H, 6.84; N, 10.57. Found: C, 75.71; H, 6.74; N, 10.27%. ^1H NMR: δ 8.00 (m, 6H, *o*-C_6H_5), 7.23 (m, 9H, *m,p*-C_6H_5), 2.52 (br m, 4H, CH_2), 2.23 (br m, 4H, CH_2), 1.13 (br m, 4H, CH_2).

$[Ph_3SiOLi(hppH)(THF)]_2$. Anal. Calc. for $C_{29}H_{36}N_3LiO_2Si$ (493.65): C, 70.56; H, 7.35; N, 8.51. Found: C, 70.49; H, 7.40; N, 8.44%. ^1H NMR $[^2H]_3$-acetonitrile: δ 8.00 (m, 6H, *o*-C_6H_5), 7.24 (m, 9H, *m,p*-C_6H_5), 3.64 (m, 4H, C_4H_8O), 2.97 (m, 8H, hpp-CH_2), 1.80 (m, 4H, C_4H_8O), 1.71 (br m, 4H, hpp-CH_2). ^{13}C NMR $[^2H]_3$-acetonitrile: δ 152.3 (*C*N_3), 144.6 (*C*$_6H_5$), 136.0 (*C*$_6H_5$), 128.7 (*C*$_6H_5$), 127.9 (*C*$_6H_5$), 68.2 (*C*$_4H_8O$), 48.5 (hpp-*C*H_2), 41.6 (hpp-*C*H_2), 26.2 (*C*$_4H_8O$), 23.7 (hpp-*C*H_2).

2.2. X-ray diffraction data

Crystals were covered in oil and suitable single crystals were selected under a microscope and mounted on a Kappa CCD diffractometer. The structures were refined with SHELXL-97 [19]. Details of the crystal data, intensity collection and refinement for complexes **1**–**4** are listed in Table 1 and for compound **5** in Table 3; selected bond lengths and angles for **1**–**4** in Table 2, and for **5** in Table 4. Additional features of note associated with individual data sets are listed below:

2.2.1. $MnCl_2(hppH)_2$ (1)

The molecule lies on a twofold rotation axis. The hydrogen atom on N(2) was located in the difference map and refined; other hydrogens were in riding mode. Disorder in both rings of the ligand was modeled (relative occupancies: a 0.72, b 0.75, c 0.28, d 0.25), with the lower occupancy carbon sites left isotropic.

2.2.2. $FeCl_2(hppH)_2$ (2)

As described for **1** (relative occupancies in disordered rings: a 0.72, b 0.28).

Table 1

2.2.3. $ZnBr_2(hppH)_2$ (**4**)

As described for **1** (relative occupancies in disordered rings: a 0.74, b 0.26, c 0.78, d 0.22).

2.2.4. $[Ph_3SiOLi(hppH)(THF)]_2$ (**5**)

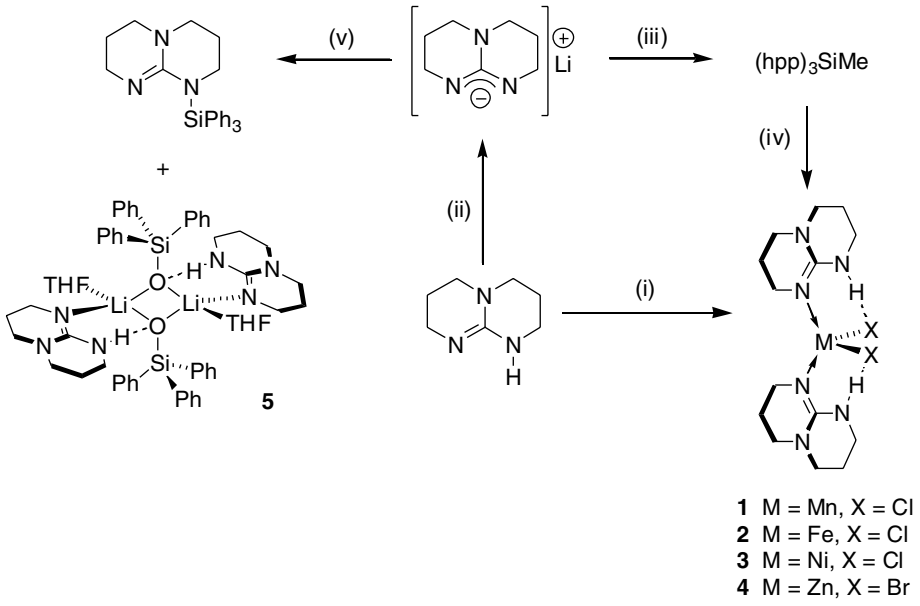
The hydrogen atom on N(2) was refined; other hydrogens were in riding mode. C(3) is disordered.

3. Results and discussion

3.1. $MX_2(hppH)_2$

The synthesis of the hppH adducts, $MnCl_2(hppH)_2$ (**1**), $FeCl_2(hppH)_2$ (**2**) and $ZnBr_2(hppH)_2$ (**4**) was achieved in a straight forward manner by combining the correct ratio of guanidine and metal salt in THF, with the exclusion of air/moisture (Scheme 1). The previously reported synthesis of **2** and the cobalt analogue, $CoCl_2(hppH)_2$, employed toluene as solvent and the mixture was refluxed to ensure complete reaction had occurred. Using our modification, each reaction proceeded with gradual dissolution of the metal starting reagent, coincident with precipitation of the product, indicating similar solubility properties. Recrystallization by slowly cooling a saturated solution (**1**, toluene; **2** and **4**, acetonitrile) to room temperature afforded analytically pure products.

Attempted synthesis of $NiCl_2(hppH)_2$ (**3**), using the direct combination of reagents analogous to the procedure



Scheme 1. (i) 1/2 MX_2, THF; (ii) ^{n}BuLi; (iii) 1/3 $SiCl_3Me$; (iv) $NiCl_2(Py)_4/H_2O$; (v) $SiPh_3Cl/H_2O$ (trace).

described above were unsuccessful. The desired product was, however, repeatedly isolated in moderate yield from the reaction between $NiCl_2(Py)_4$ and $(hpp)_3SiMe$ [17] (Scheme 1). Clearly, to give the product in this case, protonolysis of the silylated reagent must have occurred, forming the parent hppH reagent during the course of the reaction. We feel that it is unlikely that this was the result of accidental exposure to a moist atmosphere and a more likely explanation is residual water present in the nickel starting reagent (which was synthesized from the hydrate) [16].

NMR analysis of the manganese, iron and nickel complexes gave broad resonances commensurate with paramagnetic species; attempts at determining the magnetic moment using Evan's method were frustrated by limited solubility. ^{1}H NMR analysis of the diamagnetic zinc complex **4** suggested a static structure in solution, indicated by the presence of six resonances for the methylene groups within the bicyclic framework. This situation is in contrast to the three coordinate copper and silver complexes, $MCl(hppH)_2$, [8,9] in which a fluxional process occurs in solution equating the two dissimilar rings of the bicyclic framework, but has recently been noted in the palladium adduct, $PdCl_2(hppH)_2$ [11]. In the absence of further solution-state measurements for these systems, it is premature to definitively allocate the causes of these differences to purely steric or electronic factors. It does, however, suggest that intramolecular hydrogen bonding is an important feature of solution-state stability of complexes of this general type, which will become central in any proposed catalytic applications of these species in solution.

X-ray structural analyses of compounds **1**–**4** were conducted, primarily in order to acquire information about the nature of any hydrogen bonding involving the guanidine N*H* atom. The molecular structures are illustrated in Figs. 2–5; crystal structure and refinement data are given in Table 1 and selected bond lengths and angles in Table 2.

To complete the analogous series of $MCl_2(hppH)_2$ compounds where M is a metal from groups 7 to 10, the results from this study have been compared with the previously reported cobalt complex, $CoCl_2(hppH)_2$[1] [10]. Despite repeated attempts, the corresponding copper(II) chloride complex was unattainable, precluding extension of this series through to group 12. It is also noted that the presence of bromides in place of the chlorides in **4** will necessarily affect bond lengths and angles within the zinc complex and comparisons with the structure of **4** should therefore be treated accordingly.

The manganese, iron and cobalt complexes are isostructural, each crystallizing in the orthorhombic crystal system (space group *Fdd*2), whilst the nickel and zinc compounds crystallize in the monoclinic form (space groups $P2_1/n$ and $C2/c$, respectively). The former molecules each lie on a two-fold rotation axis which relates the two halves of the molecule, as does the zinc complex; the two halves of the nickel species are crystallographically distinct. The guanidine rings in compounds **1**, **2** and **4** exhibit varying degrees of disorder and were modelled accordingly (see Section 2); again due caution must therefore be exercised when discussing bond distances and angles.

In each case a monomeric, distorted tetrahedral complex forms consisting of two imine-bound guanidine ligands about the metal dihalide fragment. The metal nitrogen dis-

[1] The crystal structure of the cobalt complex, $CoCl_2(hppH)_2$, has been previously reported by Cotton and co-workers. However, the crystallographic data has not been deposited, as stated in the publication, and is therefore unavailable from the Cambridge Structural Database. We have independently synthesized and characterized the complex by X-ray diffraction studies and have deposited the data with this publication.

tances are, in general, shorter than in related formamidine and benzamidine complexes of the dihalides, [20–22] in agreement with greater electron donation by the guanidine. The angles about the metal in the Mn, Fe and Co compounds are not substantially distorted from the predicted tetrahedral value [ranges: **1**, 107.97(4)° to 110.77(5)°; **2**, 107.52(9)° to 111.63(3)°; $CoCl_2(hppH)_2$, 107.6(2)° to 110.00(7)°], whilst the range is appreciably greater in the nickel [103.81(10)° to 116.08(3)°] and zinc [103.92(18)° to 113.11(16)°] analogues. In the latter two examples, this distortion manifests itself further in different orientations of the neutral donor ligand and halide atoms with respect to

the metal centre (illustrated in Fig. 6 for the 'CN_3' core of the Δ isomers – vide infra). Thus, the guanidine ligands are aligned almost parallel to the nickel-halide vector in **3**, while a pronounced twist between the 'Br–Zn–Br' and 'N–Zn–N' planes is observed in **4**. These observations serve to illustrate a degree of flexibility in the geometry generated at the metal upon coordination, dependant on the position of the metal in the periodic table and the nature of the halide atom present in the complex.

The carbon–nitrogen distances within the guanidine are consistent with the presence of single and double bonds in which partial delocalization has occurred (Δ_{CN} values: [23] **1**, 0.029 Å; **2**, 0.032 Å; $CoCl_2(hppH)_2$, 0.014 Å; **3**, 0.041 and 0.043 Å; **4**, 0.035 Å). The E_{anti} configuration about the amidine component of hppH, enforced by the bicyclic framework, encourages hydrogen bonding to the halide atoms (Table 2). In each complex, the amine hydrogen atoms were located and refined indicating interaction with

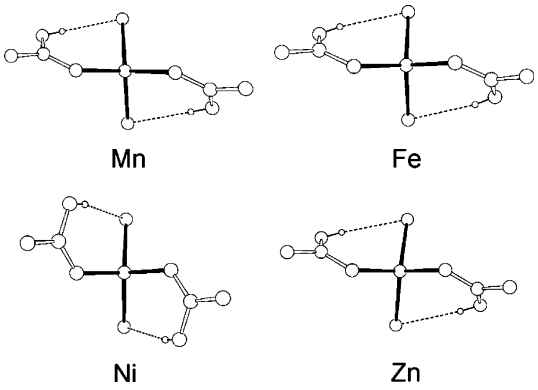

Fig. 6. Core structures of the *Δ* isomers of compounds **1**, **2**, **3** and **4** (viewed along the N–M–N plane with the guanidine ligands facing out and the halides facing into the page).

the chloride and bromide, with H···X distances in the range 2.45–2.59 Å.

The presence of these intramolecular hydrogen-bonds in the solid-state generates chiral molecules which, by analogy with D_3-tris(chelate) octahedral complexes, are assigned as the *Δ* or *Λ* isomer (Fig. 7). All of the compounds crystallise as the racemic mixture; however the way in which these molecules are arranged within the unit cell differs depending to which space group they belong. Thus, in the non-centrosymmetric space group *Fdd*2 (compounds **1**, **2** and the cobalt analogue) molecules with the *Δ* and *Λ* configuration are related by a *d*-glide perpendicular to *a*, while in the centrosymmetric space groups $P2_1/n$ (**3**) and $C2/c$ (**4**) either a centre of inversion and/or a glide plane relates the isomers.

3.2. $[Ph_3SiOLi(hppH)(THF)]_2$

During the synthesis of the triphenylsilyl-substituted guanidine, $hppSiPh_3$, using a procedure analogous to that used to generate the trimethylsilyl derivative, [18] a small amount of colourless crystalline material was isolated, identified by X-ray crystallography as the base stabilized siloxide, $[Ph_3SiOLi(hppH)(THF)]_2$ (**5**). We assume that the origin of **5** is due to the reaction between 'hppLi' with a small amount Ph_3SiOH, generated from hydrolysis of the silylchloride by adventitious water. The lithiated guanidinate is therefore a sufficiently strong base to deprotonate the silanol, with concomitant formation of the neutral guanidine which, in combination with THF solvent, stabilizes the siloxide anion, $[Ph_3SiO]^-$, in the solid-state. The product was analyzed by elemental analysis and X-ray diffraction and since one of the aims of this work is to further the understanding of intramolecular hydrogen bonding involving hppH, we feel that a brief discussion of the molecular structure of **5** is warranted (Fig. 8, Tables 3 and 4).

Compound **5** crystallizes as the symmetry related dimer in which the lithium cations and siloxide anions form a rhombohedral 'Li_2O_2' core, commonly observed with lithiated alkoxides [24,25], boroxides [25–28] and siloxides [29,30] (provided sufficient bulk is present to prevent further aggregation). Within the central ring, the angles are obtuse at lithium and acute at oxygen [99.24(15)° and 80.76(15)°, respectively], with essentially equal Li–O bond

distances (within 3σ) to each oxygen. A similar trend has been reported in the closely related dme adduct, $[Ph_3SiO\text{-}Li(dme)]_2$ [30]. Overall, each lithium atom is distorted tetrahedral, with the coordination sphere being completed by a molecule of THF and an N_{imine} bound neutral hppH; the three coordinate siloxide oxygen atoms show significant pyramidalization [$\Sigma_{angles} = 350.06°$]. The hppH molecule is oriented approximately parallel to the Li–O vector and therefore effectively bridges this unit, with a resultant intramolecular hydrogen bond distance of 2.04 Å. This is the first reported example of an intramolecular N*H*···O bond involving the neutral hppH guanidine.

4. Summary

The series of bis-hppH adducts of the first row transition metal dihalides has been extended, showing a common bonding pattern in which intramolecular hydrogen bonding is evident. The compounds each crystallize as the racemic mixture of Δ and Λ isomers within the crystal, and it is noted that the long range order of how these isomers are arranged with respect to each other differs depending on the crystal system. The molecular structure of the lithiated siloxide $[Ph_3SiOLi(hppH)(THF)]_2$ reveals a dimer in the solid-state, in which the N*H* hydrogen bonds to the siloxide oxygen atom.

5. Supplementary material

Crystallographic data for the structural analyses have been deposited with the Cambridge Crystallographic Data Centre, CCDC nos. **1** (276689), **2** (231326) $CoCl_2(hppH)_2$ (276693), **3** (276690), **4** (276691) and **5** (276692). 2. Experimental

2.1. Materials and synthesis

1,4,7,10-tetraazacyclododecane, $K_2[Ni(CN)_4]\cdot xH_2O$ and $K_2[Pt(CN)_4]\cdot 3H_2O$ were obtained from Strem. All chemicals and solvents were of reagent grade and were used as received.

$[Ni(cyclen)]_2[Pt(CN)_4]_2\cdot 6H_2O$ (**1**) was synthesized by a slow diffusion method. $K_2[Pt(CN)_4]\cdot 3H_2O$ (108 mg, 0.25 mmol), cyclen (86 mg, 0.5 mmol) and $Ni(CH_3COO)_2\cdot 4H_2O$ (124 mg, 0.5 mmol) contained in three separate sample tubes (10 ml) were placed together in a 200 ml beaker. The sample tubes and the beaker were then carefully filled with water such that the three sample tubes were immersed in the beaker of water but the contents were not mixed together. Purple needle-shaped crystals were obtained after leaving the beaker undisturbed at room temperature for a week. Yield: 65%. *Anal*. Calc. for $Pt_2Ni_2N_{16}C_{24}O_6H_{52}$: C, 24.67; H, 4.49; N, 19.18. Found: C, 24.55; H, 4.60; N, 19.30%. IR ν_{CN} (KBr/cm^{-1}): 2184sh, 2172s, 2138vs.

The synthesis of $[Ni(cyclen)]_2[Ni(CN)_4]_2\cdot 6H_2O$ (**2**) was similar to that of **1**. $K_2[Ni(CN)_4]\cdot xH_2O$ (120 mg, 0.5 mmol), cyclen (86 mg, 0.5 mmol) and $Ni(CH_3COO)_2\cdot 4H_2O$ (124 mg, 0.5 mmol) were used as starting materials. Purple needle-shaped crystals were obtained after one week. Yield: 65%. *Anal*. Calc. for Ni_4N_{16}-$C_{24}O_6H_{52}$: C, 32.19; H, 5.85; N, 25.02. Found: C, 32.20; H, 6.10; N, 25.05%. IR ν_{CN} (KBr/ cm^{-1}): 2165s, 2126vs.

For the synthesis of $[Mn(cyclen)]_2[Ni(CN)_4]_2\cdot 6H_2O$ (**3**), $K_2[Ni(CN)_4]\cdot xH_2O$ (60 mg, 0.25 mmol) in 5 ml H_2O was added to a solution of $Mn(ClO_4)_2\cdot 6H_2O$ (181 mg, 0.5 mmol) and cyclen (86 mg, 0.5 mmol) in 10 ml H_2O. After stirring the mixture for a few minutes, the solution was filtered to remove a white precipitate. Slow evaporation of the green filtrate in the dark gave pink crystals after one week. Yield: 10%. *Anal*. Calc. for $Mn_2Ni_2N_{16}C_{24}$-O_6H_{52}: C, 32.46; H, 5.90; N, 25.24. Found: C, 32.50; H, 6.02; N, 24.56%. IR ν_{CN} (KBr/cm^{-1}): 2157s, 2133s.

2.2. Physical measurements

Infra-red spectra (KBr pellets) were recorded on a Perkin–Elmer model 1600 FTIR spectrophotometer. Elemental analysis were performed on a Vario EL elemental analyzer. Variable-temperature magnetic susceptibility measurements were performed on crystalline samples of the title compounds in the range of 2–200 K on an Oxford Instruments Maglab2000 magnetometer. Susceptibilities were corrected for diamagnetism using Pascal's constants.

2.3. Crystallography

Crystallographic data was collected on a Rigaku AFC7R diffractometer with graphite-monochromated Mo Kα radiation ($\lambda = 0.71069$ Å) for **1** at 301 K and Bruker SMART CCD area detector with graphite monochromated Mo Kα radiation ($\lambda = 0.71069$ Å) for **2**–**3** at 298 K. The structures were solved by direct method SHELXS 86 [15] for **1** and SIR 92 [16] for **2** and **3**, and refined by full-matrix least squares technique based on F using TEXSAN crystallographic software package [17] for **1** and **2** and using CRYSTALS [18] for **3**. The intensity data were corrected

for Lorentz and polarization effects. Empirical absorption corrections were also applied. All the non-hydrogen atoms were refined anisotropically. Hydrogen atoms were included but not refined. The hydrogen atoms of the water solvates for **3** were not located. The crystallographic data is collected in Table 1.

3. Results and discussion

3.1. Description of the structures

The X-ray structure of $[Ni(cyclen)]_2[Pt(CN)_4]_2 \cdot 6H_2O$ (**1**) (Fig. 1) shows that each Ni(II) centre is octahedrally coordinated to the four nitrogen atoms of a cyclen ligand and two cyano nitrogen atoms in a *cis* configuration. Two $[Ni(cyclen)]^{2+}$ units are linked by two $[Pt(CN)_4]^{2-}$ units via bridging cyano groups to produce a slightly puckered 12-membered molecular square structure. The deviation from the mean plane of the square structure is ±0.169 Å. This is because the Ni—N≡C unit is slightly bent with an Ni*–N(3)–C(3) angle of 173.1(6)° and an Ni–N(4)–C(4) angle of 166.7(6)°. Two of the Ni–N(cyclen) bonds [2.140(5) and 2.143(5) Å] are slightly longer than the other Ni–N(cyclen) bonds [2.072(5)–2.088(5) Å] and the Ni—N(≡C) bonds [2.064(5) and 2.096(6) Å]. All terminal and bridging C≡N distances are similar [1.134(7)–1.148(8) Å] and comparable to those found in $[Cu(bpy)(H_2O)Pt(CN)_4]_2 \cdot 2H_2O$ [1.114(11)–1.145(10) Å] [19] (Table 2). The intramolecular Ni···Ni separation is 7.462 Å and the closest intermolecular Ni···Ni separation is 7.943 Å. The tetranuclear square structures are arranged in a herring bone fashion, with a dihedral angle between the neighbouring square structures of 60.08°. Taking the Ni–Pt–Ni–Pt as the mean plane, the inter-planar distance between the squares is 3.752 Å and the Pt···Pt distance is 3.822 Å, indicating the presence of weak interactions between the Pt atoms. The void area of the tetranuclear square structure is capped on both sides by water solvates, O(1)/H(21)/H(22). Extensive intermolecular hydrogen bonding was observed between the tetranuclear square structures and the water solvates (Table 5 and Fig. 4).

Symmetry transformation used to generate equivalent atom (*): $1-x, -y, 2-z$.

The X-ray structure of $[Ni(cyclen)]_2[Ni(CN)_4]_2 \cdot 6H_2O$ **2** (Fig. 2) shows that it is isostructural with **1**, each Ni(II) centre is octahedrally coordinated to the four nitrogen atoms of a cyclen ligand and two cyano nitrogen atoms of $[Ni(CN)_4]^{2-}$ in a *cis* configuration forming a slightly puck-

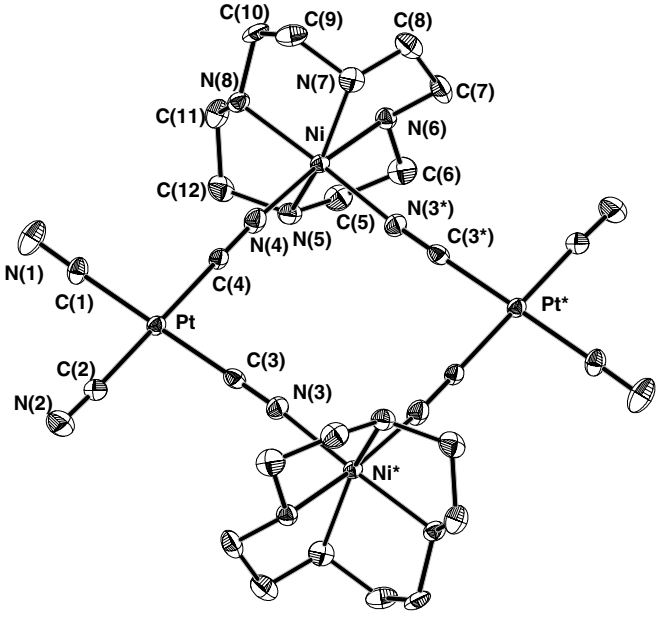

Fig. 1. An ORTEP diagram of $[Ni(cyclen)]_2[Pt(CN)_4]_2 \cdot 6H_2O$ with atom labelling scheme. The water solvates and H atoms were omitted for clarity.

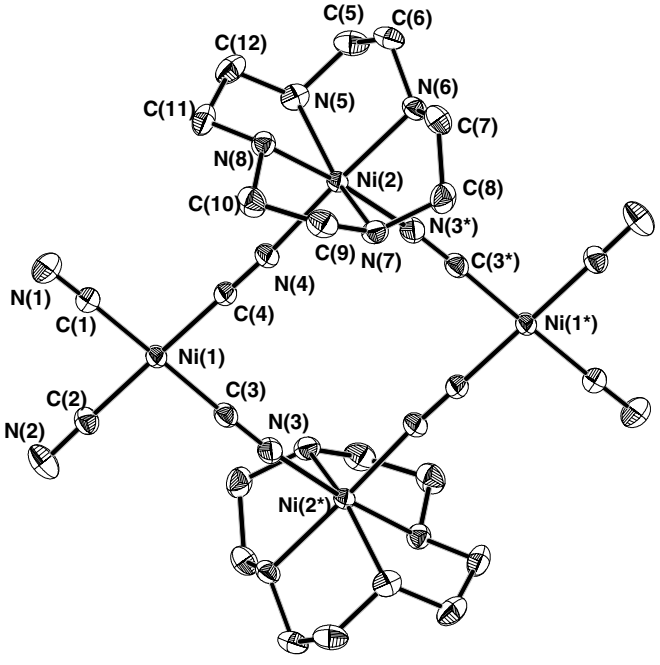

Fig. 2. An ORTEP diagram of $[Ni(cyclen)]_2[Ni(CN)_4]_2 \cdot 6H_2O$ with atom labelling scheme. The water solvates and H atoms were omitted for clarity.

ered 12-membered tetranuclear square structure. The deviation from the mean plane of the square structure is ±0.203 Å. This is because two of the Ni—N≡C units are almost linear with an Ni(2)–N(4)–C(4) angle of 176.0(2)° but the other two units are bent with an Ni(2*)–N(3)–C(3) angle of 164.0(2)°. Two of the Ni–N(cyclen) bonds [2.134(2) and 2.136(2) Å] are slightly longer than the other Ni–N(cyclen) bonds [2.070(2)–2.096(2) Å] and the Ni—N(≡C) bonds [2.064(2) and 2.091(2) Å]. All the terminal and bridging C≡N distances are similar [1.137(3)–1.152(3) Å] and comparable to those found in **1** (Table 3). The intramolecular Ni(cyclen)···Ni(cyclen) separation is 7.245 Å and the closest intermolecular Ni(cyclen)···Ni(cyclen) separation is 7.855 Å. The tetranuclear square structures are also arranged in a herring bone fashion, with a dihedral angle between the neighbouring square structures of 54.66°. Taking the four Ni atoms as the mean plane, the inter-planar distance between the squares is 3.849 Å and the shortest Ni(cyanide)···Ni(cyanide) distance is 3.944 Å, indicating the presence of weak interactions between the Ni atoms. The void area of the tetranuclear square structure is capped on both sides by water solvates, O(2)/H(23)/H(24). Extensive intermolecular hydrogen bonding is also observed in the crystal lattice (Table 6 and Fig. 5).

The X-ray structure of $[Mn(cyclen)]_2[Ni(CN)_4]_2 \cdot 6H_2O$ (**3**) (Fig. 3) shows that it is also a molecular square and is isostructural to **1** and **2**. Each Mn(II) centre is octahedrally coordinated to the four nitrogen atoms of a cyclen ligand and two cyano nitrogen atoms in a *cis* configuration forming a puckered 12-membered tetranuclear square structure. The deviation from the mean plane of the square structure is ±0.204 Å. This is because one of the Mn—N≡C unit is almost linear with a Mn(2)–N(4)–C(4) bond angle of 175.5(4)° while the other is bent with a Mn(1*)–N(3)–C(3) bond angle of 164.7(4)°. Two $[Mn(cyclen)]^{2+}$ units are linked by two $[Ni(CN)_4]^{2-}$ units via bridging cyano groups to form a molecular square. Three of the Mn–N(cyclen) bonds [2.101(4)–2.139(4) Å] are slightly longer than the other Mn–N(cyclen) bonds [2.081(4) Å] and the Mn—N(≡C) bonds [2.063(4)–2.093(4) Å]. All the bond distances of terminal and bridging cyano groups (C≡N) are similar [1.146(8)–1.150(7) Å] and comparable to those found in the structure **1** and **2** (Table 4). The intramolecular Mn···Mn separation is 7.231 Å and the closest intermolecular Mn···Mn separation is 7.871 Å. The tetranuclear square structures are also arranged in a herring bone fashion, with

The void area of the tetranuclear square structure is capped on both sides by water solvates, O(2). Although the hydrogens of the water solvates were not located, it is expected that extensive intermolecular hydrogen bonding should also exist in the crystal lattice as in **1** and **2**.

3.2. Magnetic properties

The variable-temperature magnetic susceptibility of **1** was measured in the range of 2–200 K. The data obey Curie–Weiss Law $[\chi_m = C/(T-\theta)]$ with $\theta = +0.67$ K and $C = 2.36\ cm^3\ mol^{-1}\ K$ (Fig. 6). The very small positive Weiss constant suggests that there might be an overall very small ferromagnetic interaction between the Ni^{II} centres through the diamagnetic $[Pt(CN)_4]^{2-}$ bridge. The variable-temperature magnetic susceptibility of **2** was also measured in the range of 2–200 K. The data obey Curie–Weiss Law $[\chi_m = C/(T-\theta)]$ with $\theta = +0.14$ K and $C = 2.24\ cm^3\ mol^{-1}\ K$ (Fig. 7). Similar to **1**, the very small positive Weiss constant suggests that there might be an overall very weak ferromagnetic interaction between the Ni^{II} centres through the diamagnetic $[Ni(CN)_4]^{2-}$ bridge. To estimate the magnitude of the intradimer exchange coupling constant (J) and the interdimer magnetic interaction (zJ'),

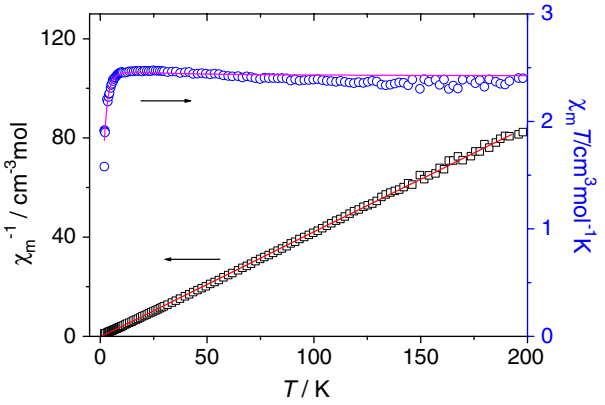

Fig. 6. Temperature dependence of χ_m^{-1} (□) and $\chi_m T$ (○) for $[Ni(cyclen)]_2[Pt(CN)_4]_2 \cdot 6H_2O$ (**1**), lines represent the fitting results using Curie–Weiss law and Ni-dimer model (see text).

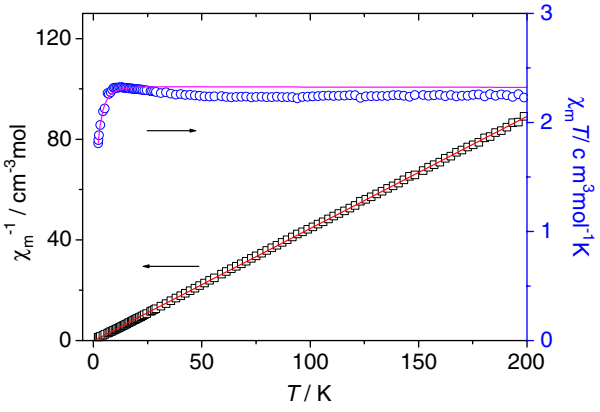

Fig. 7. Temperature dependence of χ_m^{-1} (□) and $\chi_m T$ (○) for [Ni(cyclen)]$_2$[Ni(CN)$_4$]$_2 \cdot 6H_2O$ (**2**), lines represent the fitting results using Curie–Weiss law and Ni-dimer model (see text).

the experimental data were initially fitted to a simple analytical expression based on the Hamiltonian $H = -2JS_1S_2$ with an isotropic interaction between the two Ni(II) ions and taking into account the molecular field effect. The best fit parameters are: for **1**, $J = 0.8(2)$ cm^{-1}, $zJ' = -0.33(1)$ cm^{-1}, and $g = 2.21(4)$; for **2**, $J = 0.48(4)$ cm^{-1}, $zJ' = -0.313(4)$ cm^{-1}, and $g = 2.175(6)$. When the zero-field splitting D of the Ni(II) ion was considered, a magnetic model derived by Ginsberg et al. [20] and corrected by Wen [21] has been used to fit the magnetic data, resulting in the following parameters: for **1**, $J = 0.6(1)$ cm^{-1}, $zJ' = -0.111(6)$ cm^{-1}, $D = 6$ cm^{-1}, and $g = 2.19(3)$ with $R = 2 \times 10^{-3}$; for **2**, $J = 0.23(3)$ cm^{-1}, $zJ' = -0.060(8)$ cm^{-1}, $D = 6$ cm^{-1}, and $g = 2.154(4)$ with $R = 8 \times 10^{-5}$ ($R = \sum(\chi_{obs} - \chi_{cal})^2/\sum(\chi_{obs})^2$). The fitted results suggest a very weak ferromagnetic intradimer interaction and an even weaker interdimer antiferromagnetic coupling. This is likely due to the relatively long intramolecular Ni···Ni separation (7.462 Å in **1** and 7.245 Å in **2**) and intermolecular Ni···Ni separation (7.943 Å in **1** and 7.855 Å in **2**). The magnetic behaviour of **3** was not investigated since it was expected to be similar to that of **1** and **2**.

In conclusion, we demonstrate that the use of a cyclen-capped metal complex in conjunction with a square planar tetracyanometalate $[M(CN)_4]^{2-}$ provides a general method for the synthesis of molecular squares. The 12-membered cyclen ring allows only *cis*-coordination, while the square tetracyanometalate is a good linker. This approach is potentially useful for the synthesis of other structures such as pentagons and hexagons.

4. Supplementary material

X-ray crystallographic files, in CIF format, for the structure **1**, **2** and **3** are available from the Cambridge Crystallographic Data Center, 12 Union Road, Cambridge CB2 1EZ, UK, fax: (internat.) +44 1223 336 033; e-mail: deposit@ccdc.cam.ac.uk, or via www.ccdc.cam.ac.uk/data_request/cif, by emailing data_request@ccdc.cam.ac.uk upon request, quoting the deposition numbers, CCDC-275688 (1), -275689 (2), and -275690 (3), respectively.

Cu(II) takes place [17]. When the template is made of interconnected cylinders, long rods of copper are obtained. Slight changes in the experimental conditions induce distinct modifications of the shape and size of the nanorods [14,17].

However, despite numerous reports, as per our knowledge, this is the first report of copper nanorod synthesis without the addition of any other extra stabilizer or capping agent from outside. In this synthesis, glucose is performing multiple tasks. It not only reduces the copper(II) ions but is also responsible for the in situ stabilization of the evolved particles and acts as a capping agent to the copper metal. It is also shown that at a particular concentration of the reducing agent (glucose) well-defined nanorods were obtained. Slight changes in the experimental conditions induce distinct modifications of the shape and size of the nanorods. This reaction is very simple, reproducible and has to be carried out in alkaline medium. The morphology of the evolved particles can be controlled simply by varying its concentration but keeping other parameters constant. The evolved particles remained stable for ~7 days and were characterized by UV–Vis spectroscopy, TEM and XRD studies. Again, shape selective catalysis by the rod shaped copper nanoparticles has been demonstrated for 1,1′ coupling of 2-naphthol via oxidative phenol coupling (OPC) reaction.

2. Experimental

2.1. Reagents

All the reagents were of analytical reagent grade. Copper sulfate (Aldrich) was used as received. Aqueous solution (10^{-2} M) of the salt was used as stock solution. Glucose, anion exchange resin, Amberlite IRA 400 and sodium thiocyanate were purchased from S.D. Fine Chemicals, India, 2-naphthol was purchased from Loba Chemie, India. Milli-Q water was used throughout the experiment. Sodium hydroxide (Merck) was used as received. Aqueous solution (1.0 M) of NaOH was used as stock solution.

2.2. Instruments

The absorption spectra were recorded in a Chemito Spectrascan UV 2600 doubled beam spectrophotometer taking the solutions in a quartz cuvette of path length 1 cm. All the spectral measurements were done at room temperature. TEM measurements of the metal sols were performed in a Hitachi H-9000 NAR instrument on samples prepared by placing a drop of fresh metal sols on Cu grids precoated with carbon films, followed by solvent evaporation under vacuum. The particle size was measured using a JEOL-100CXII transmission electron microscope (TEM). X-ray diffraction (XRD) measurement was performed by PW1840 diffractometer Philips, using Co-target at working voltage 40 kV, 20 mA. The samples were centrifuged and washed with methanol. Finally, the samples were dried under vacuum and X-ray diffraction (XRD) was undertaken for all the three samples.

2.3. Preparation of samples

Three different sets of solutions namely C_1, C_2 and C_3 were prepared by dissolving 0.2, 0.3 and 0.4 g of glucose, respectively, in 5.0 ml of water. Then, 10 μL NaOH (1.0 M) was added to it and the solution was warmed to a temperature of 60 °C. Finally, 200 μL $CuSO_4$ (10^{-2} M) was introduced to each set and the final mixture was warmed for 3 min to a temperature of ~80 °C. The solutions turned light yellow in all the three sets indicating the formation of Cu(0) with the characteristic plasmon band in the visible range. The whole reaction was carried out in nitrogen atmosphere to prevent the oxidation of copper nanoparticles. The UV–Vis spectra due to the plasmon resonance arise with a significant contribution from interband transition, which produces yellow color hydrosol [18]. A drop of solution from all the three reaction mixtures was deposited on three different copper grids precoated with carbon black. To prevent surface oxidation of the Cu(0), the TEM samples were then transported to the instrument under an argon atmosphere. The TEM images indicates well-defined, nanorods (average length of ~116 nm and width 46 nm for C_2) and nanospheres (diameter for $C_1 \sim 20$ nm and for $C_3 \sim 4$ nm), respectively. The XRD analysis was carried out for the all three samples.

3. Results and discussions

3.1. UV–Vis study

In spheroidal or rod-shaped copper nanoparticles, the first distinct difference relative to spherical particle is the appearance of a surface plasmon band at lower energies [19]. Fig. 1 shows the absorption spectrum of the copper nanoparticles prepared in three different sets. The prepared spherical nanoparticles (C_1) display an absorption peak at ~499 nm which can be assigned to the absorption peak of spherical copper nanoparticles. Aqueous suspensions of the rod shaped particles (C_2) have a sharp peak at 472 nm in the UV–Vis spectra, corresponding to the transverse plasmon band of the copper nanorods and the plasmon band 740 nm is assigned to the longitudinal one. The longitudinal and transverse peak position shifted to some extent due to the dielectric constant of the medium which is again temperature dependent [20]. The solution (C_3) having higher concentration of glucose showed one peak at 463 nm (λ_{max}) only. The optical path length is 1 cm and the extinction coefficient per atom was calculated to be $1.7 \times 10^3\ l\ M^{-1}\ cm^{-1}$which is slightly lower than the literature value [13]. The whole synthetic procedure and the corresponding UV–Vis spectra is given in Scheme 1. The synthesized particles were stable for ~7 days. This kind of stabilization of Cu nanoparticles was due to the capping

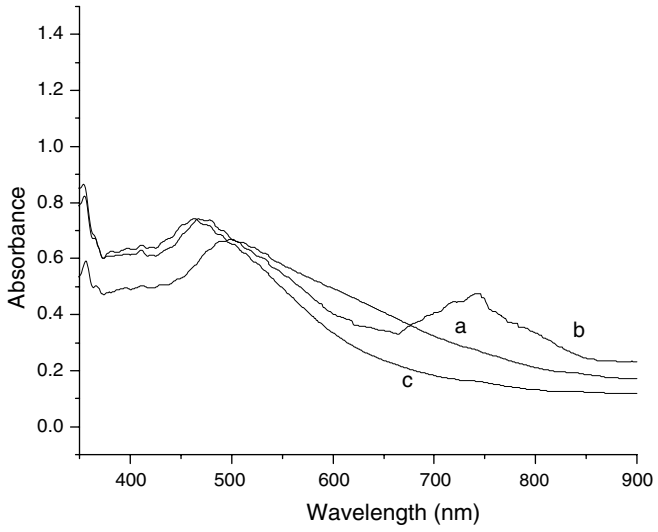

Fig. 1. UV–Vis spectra of the copper nanospheres and nanorods, (a) UV–Vis spectra of the spherical particles (C_1), (b) UV–Vis spectra of the nanorods (C_2), (c) UV–Vis spectra of the spherical particles (C_3). Conditions: $[CuSO_4] = 3.84 \times 10^{-4}$ M, $[NaOH] = 2 \times 10^{-3}$ M [glucose] = 5.78×10^{-3} M for a, 8.68×10^{-3} M for b and 1.16×10^{-2} M for c.

of particles by glucose and/or by gluconic acid in alkaline condition. The arrangement of capping agent, glucose/gluconic acid surrounding the nanoparticles is size dependent. After a few days, slow oxidation of copper particles sets in with the disappearance of absorption peaks [21] and finally the solution becomes colorless. However, the solution on a spot plate produces a distinct black coloration with ethanolic solution of rubeanic acid (0.5%) due to the formation of copper rubeanate. The test authenticates the evolution of Cu(II) ions from Cu(0).

3.2. TEM analysis

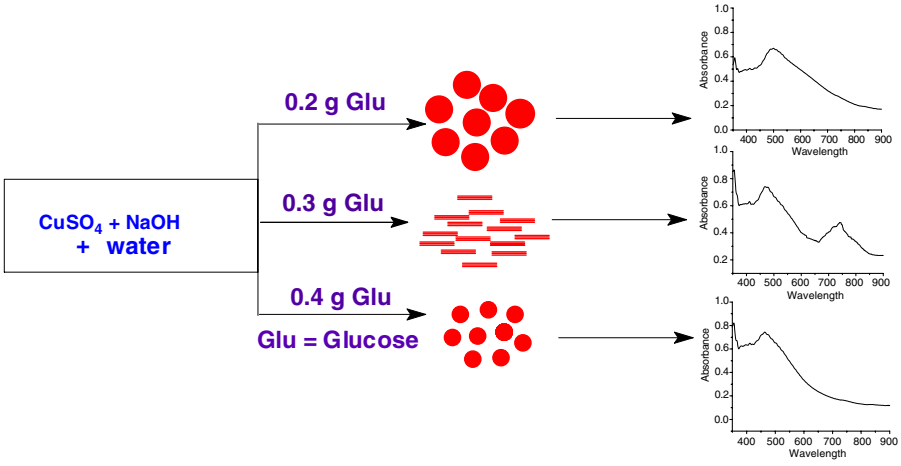
The TEM microstructures for the prepared copper nanoparticles are shown in Fig. 2(a)–(c) and the inset shows the histogram for the copper nanorods. Fig. 2(a) shows the TEM images of spherical copper particles (C_1) size of ~20 nm. Fig. 2(b) reveals the large copper nanorods (C_2) having an average length ~116 nm and diameter in the range ~46 nm with an aspect ratio of ~2.5. Fig. 2(c) describes the TEM images of the fine particles of copper having size ~4 nm (C_3) with a very few number of nanorods.

3.3. X-ray diffraction pattern

Fig. 3 shows an XRD pattern of the copper nanorods (C_2). The product exhibits a high crystallinity and no indication of impurities such as copper oxide (CuO) and cuprous oxide (Cu_2O), can be detected in the pattern. The reflection peaks at $2\theta = 43.4°$, 50.6° and 74.2° are indexed as [1 1 1], [2 0 0] and [2 2 0] planes of copper with cubic symmetry, respectively. These reflection peaks of copper nanorods have been compared with the literature values [22].

3.4. Mechanism of particle growth and the effect of OH^- ion

In presence of alkali α-glucose transforms into β-glucose through the open chain structure, which is reactive, and this phenomenon is known as mutarotation. In open chain form, the free –CHO group is available which causes the reduction of the Cu(II) to Cu(0) in the alkaline pH and at the elevated temperature. As a consequence of the reduction the –CHO group oxidizes to the corresponding –COOH which offers stability to the generated particles under alkaline condition [23]. The particle formation reaction and the mechanism are given in Scheme 2. The pH of the solution was measured at the end of the reaction. In all the three sets though the volume of added NaOH is same but the pH varies (~8.0 ± 0.5) to some extent due to the variable amount of added glucose. The base is partly neutralized by the evolved gluconic acid and hence the pH remains somewhat less than the expected value. Again, under the alkaline condition basic copper hydroxide is formed and this is responsible for nucleation and successive growth. Therefore, the OH^- ion has formidable influence



Scheme 1. The schematic representation of the synthetic procedure.

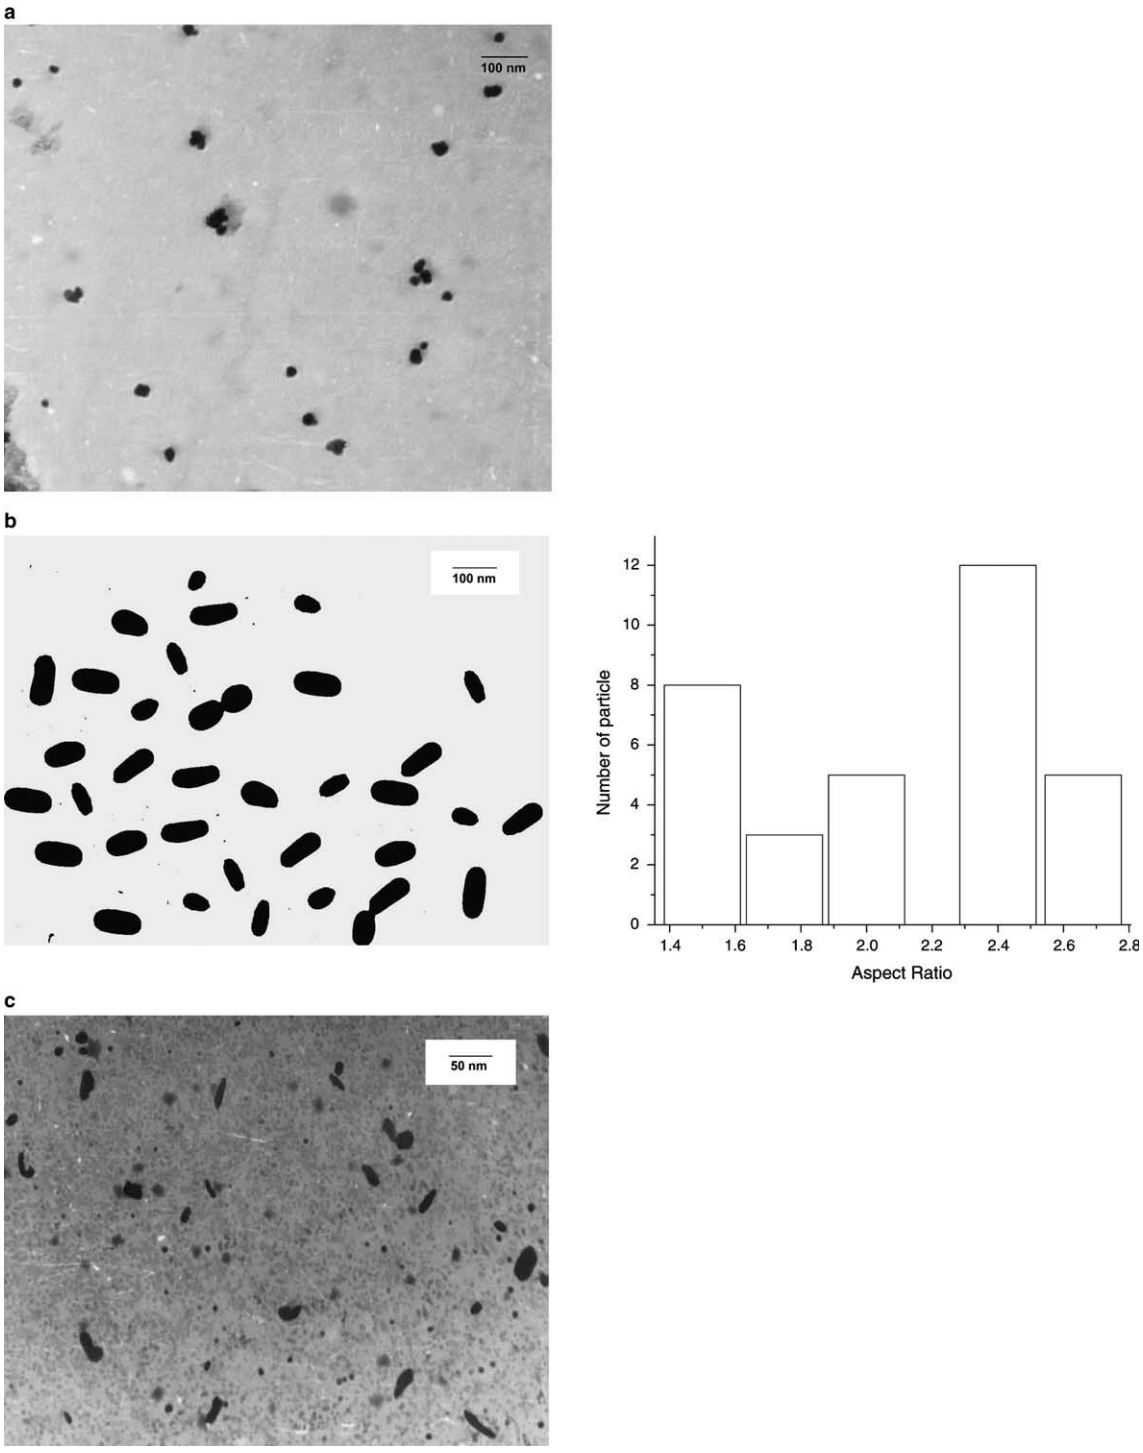


Fig. 2. TEM images of the copper nanoparticles. (a) TEM images of the spherical particles (C_1). (b) TEM images of the nanorods (C_2) and its corresponding histogram. (c) TEM images of the spherical particles (C_3). Conditions: $[CuSO_4] = 3.84 \times 10^{-4}$ M, $[NaOH] = 2 \times 10^{-3}$ M [glucose] $= 5.78 \times 10^{-3}$ M for a, 8.68×10^{-3} M for b and 1.16×10^{-2} M for c.

on the particle morphology and the directional growth as reported earlier [24].

Controlled reactions could not produce any copper nanoparticle in which no NaOH was added. Therefore, we concluded that hydroxide ion is important for particle growth. Since the concentration of NaOH is same in all the three cases so the numbers of Na^+ ions remained same but the available OH^- is different due to the variable amount of glucose for different sets. Like the previous reports [24,25] we observed that simple OH^- ions could direct the growth of Cu nanoparticles into different shapes, highlighting the importance of OH^- ions. Recently, enhanced coordination ability of the sugar molecules in alkaline medium has been well documented due to the

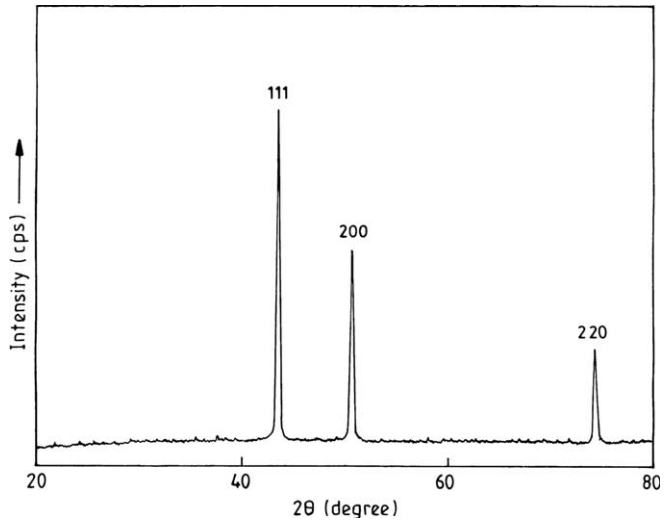

Fig. 3. X-ray diffraction pattern of the nanorods (C_2). Conditions: $[CuSO_4] = 3.84 \times 10^{-4}$ M, $[NaOH] = 2 \times 10^{-3}$ M, $[glucose] = 8.68 \times 10^{-3}$ M.

formation of deprotonated sugar anions [26,27]. In the present case, the coordinatively unsaturated surface atoms of copper particles get stabilized by the anionic sugar moiety. Furthermore, it was also observed that KOH and NH_4OH in lieu of NaOH produced similar results.

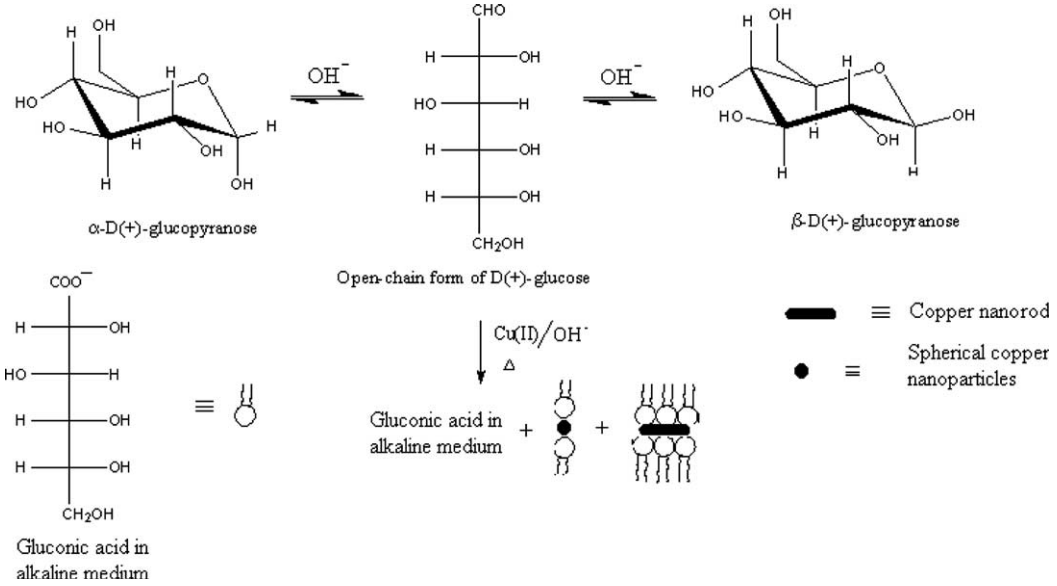
A distinct transition from the spheres to the rod shaped growth has been observed at a higher temperature (>80 °C). The evolved particles happen to be resistant to oxidation, no matter whether the produced particles are spheres or rods. Another plausible mechanism of nanorod formation lies with the stabilization of chelate of Cu(II) with the –OH groups of the glucose (at a particular concentration) that eventually produced a void space that might act as a template for particle growth. This kind of chelation of Cu(II) ions in alkaline medium and the mechanism seems analogous to the Fehling's test of glucose solution. Furthermore, gluconic acid under the experimental condition advances the stabilization process of the nanorods through effective capping [28].

3.5. Interaction with anion exchange resin

Gluconic acid, an oxidized product of glucose, produced in the reaction mixture bears a negative charge in the alkaline solution and it imparts stability to the evolved Cu(0) particles acting as a capping agent. Therefore, no extra capping agent or stabilizing agent is required and the copper nanoparticles become negatively charged. The negative charge on the surface of the evolved particles was confirmed by the ready exchange of the negatively charged copper particles with the chloride form of an anion exchange resin, Amberlite IRA 400.

3.6. Thiocyanate dissolution study: reactivity of the particles

Interaction of a diffusing ion, SCN^- with copper nanoparticles further authenticated the stability of the evolved nanorods. Same amount of SCN^- was introduced (added as NaSCN in the μM concentration) into three different sets (C_1, C_2 and C_3) of solution containing copper nanoparticles and were shaken for ~5 min considering the more diffusing nature of SCN^- ion than the capping agent, gluconic acid. From the UV–Vis spectra, 6 and 10 nm blue shift of the λ_{max} values were observed for set C_1 and C_3, respectively. Finally, increased concentration of NaSCN dissolved copper nanoparticles under ambient condition. Surprisingly, the absorption peaks of the nanorods (C_2) at lower energy region disappeared and the peak at the higher energy gradually blue shifted by the addition of aqueous SCN^- solution in portion. The corresponding



Scheme 2. The schematic presentation of the mechanism of the reaction.

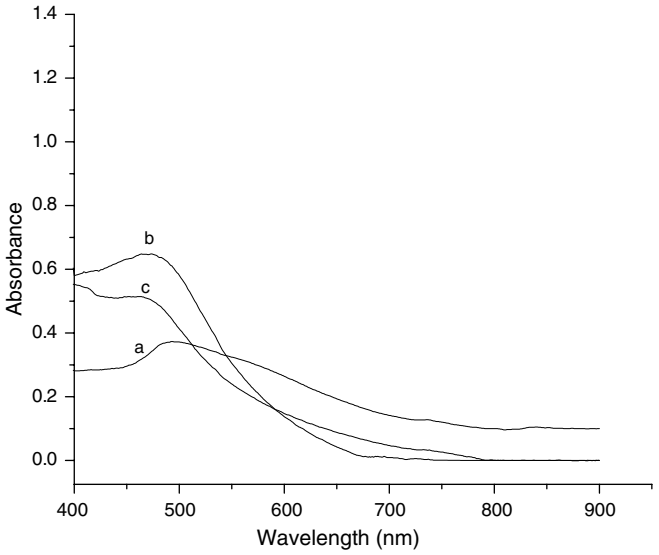


Fig. 4. The UV–Vis spectra of the evolved copper nanoparticles (rods and spheres) after addition of SCN^-. (a) UV–Vis spectra of the spherical particles after addition of SCN^- (C_1). (b) UV–Vis spectra of the nanorods after addition of SCN^- (C_2). (c) UV–Vis spectra of the spherical particles after addition of SCN^- (C_3). Conditions: $[CuSO_4] = 3.84 \times 10^{-4}$ M, $[NaOH] = 2 \times 10^{-3}$ M $[SCN^-] = 1.9 \times 10^{-6}$ M [glucose] $= 5.78 \times 10^{-3}$ M for a, 8.68×10^{-3} M for b and 1.16×10^{-2} M for c.

UV–Vis spectrum is shown in Fig. 4. On the other hand, the blue shift of the λ_{max} corroborates the shift of Fermi levels of the nanoparticles towards more negative potential and making them vulnerable to dissolution [29]. It is thus concluded that the smaller particle has greater tendency towards SCN^- attack (after pronounced blue shifting) rather than the larger one and nanorods eventually break down to the spherical particles when it reacted with the SCN^- [30,31]. Stepwise blue shifts of the λ_{max} position were noticed by the controlled addition of NaSCN solution. Again, similar shifts of λ_{max} values were noticed while $NaBH_4$ and NaCN were introduced in the μM concentrations. However, gradual increase in NaCN concentration produced a colorless solution due to the formation of $[Cu(CN)_4]^-$ species but other diffusing ions left black precipitate on standing.

3.7. Catalytic application

The evolved copper nanoparticles (rods and spheres) were individually exploited as viable catalyst for C–C bond formation via oxidative phenol coupling (OPC) between two 2-naphthol moieties [31,32]. In a round bottom flask 30 mL of the copper nanorods solution was taken and then 0.01 g of solid 2-naphthol was introduced into it. The solution was stirred at room temperature (25 °C) for ~7 days under aerated condition. Finally the product was extracted with chloroform. The product was extracted from water and separated by column chromatography using petroleum ether–EtOAc (10:1) as eluant. It was found that the rod shaped particles selectively catalyze the coupling to produce 1,1′ coupled product with a good yield (76%). The separated bi-naphthol was characterized unambiguously by TLC, UV, IR, ^1H NMR and mass spectroscopic studies. The melting point of bi-naphthol is 235 °C and the M^+ is 286. The UV–Vis spectral data shows a peak at 270 nm ($\log \varepsilon$ 4.20). IR analysis shows two broad bands at 3400 and 3500 cm^{-1} due to –OH functionality and peaks at 1620, 1600, 830, 820, 780 and 750 cm^{-1} due to the aromatic nucleus. The ^1H NMR study gives d (DMSO-d_6 + $CDCl_3$) 7.2–8.0 (12H, m, Ar–H), 8.7 (disappeared on deuteration, Ar–OH). However, we failed to detect any coupled product out of the OPC reaction involving spherical copper particles. The detailed reaction involving other phenols has been reported elsewhere [32]. It has been reported that the reactivity and stability of nanoparticles depend on the aspect ratio and spheroids are more reactive than spheres [33]. During the reaction, the spheroids transforms into spheres whereas the spheres do not react. So in our case this OPC might be due the preferential adsorption of 2-naphthol onto the copper nanorod surfaces and higher catalytic activity of the rod shaped particles are observed in comparison to spheres.

4. Conclusion

In conclusion, the novelty of this one step method for the generation of copper nanoparticles lies in its simplicity and simultaneous control of both size and shape of the particles, without employing any stabilizing agent, capping agent or any template. This surfactantless one pot synthetic procedure may be useful for producing particles of desired size and shapes. Moreover, this procedure is highly reproducible and does not involve any toxic reagents. The particles are stable for about a week at room temperature. The evolution of the copper nanorods has been unequivocally characterized. With the rapid shrinking in size in electronic devices, copper nanorods and nanowires may play an important role for connecting the future generation of electronic nanodevices and the shape selective catalyst for coupling phenols through 'C–C' bond formation.

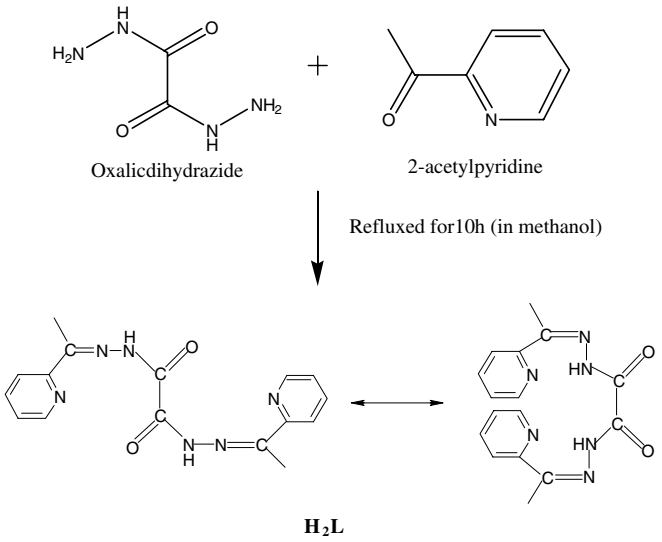

Scheme 1.

Thompson and co-workers [12] but behaves in a complete different fashion (vide infra).

In the present case, we employed copper(II) acetate and nickel(II) acetate, so that carboxylate might be able to connect the neighbouring dimeric subunits bridged by this flexidentate ligand and anticipated to get a polymeric or other architectures excluding molecular squares. From the molecular point of view, the nature of acetato bridging is magnetically very significant. For one atom acetate bridges between two paramagnetic transition metal centers, the magnetic interactions have been related to the magnitude of bridging angle (θ) and other structural features [13]. This has been especially studied for oxygen bridged metal atoms such as Cu–O–Cu. Small θ angles near 96° should lead to ferromagnetic interaction while larger value should make the interaction increasingly strongly antiferromagnetic [14,15].

Here, we use Cu(II) and Ni(II) as metal ions to observe the difference in coordination behavior of the ligand according to the geometrical preferences of the two metal centers. In case of Cu(II), we get a polymeric complex, where the ligand (**L**) in *trans* form binds two metal centers in exo fashion through the oxamido-type bridge in a bis-tridentate mode instead of the anticipated diazine bridging as observed for the ligand reported by Thompson and co-workers [12] and the dimeric subunits are connected by $\mu_{1,1}$-acetato bridges that lead to the formation of 1-D polymer. In the case of nickel(II) the ligand adopts a *cis*-conformation and binds in endo fashion as a tetradentate unit to lead to a four coordinated complex. The flexible ligand reorients itself in *trans*- and *cis*-forms by the unhindered rotation around C–C bond.

In this paper, we describe the synthesis, spectral characterization and crystal structures of two novel Cu(II) and Ni(II) complexes derived from the new flexible bistridentate ligand. The magnetic behavior for complex **1** was found to be driven by strong antiferromagnetic interactions.

2. Experimental

2.1. Materials

Oxalicdihydrazide, 2-acetylpyridine, copper(II) acetate monohydrate, nickel(II) acetate tetrahydrate were purchased from commercial sources and used as received.

2.2. Physical measurements

The infrared spectra were recorded on a Perkin–Elmer FT-IR spectrophotometer in KBr matrices. The electronic spectra were obtained as Nujol mulls as well as in acetonitrile solution on a Perkin–Elmer Lambda 40 (UV–Vis) spectrophotometer. Elemental analyses were carried out using a Perkin–Elmer 2400 II elemental analyser. Electrochemical studies were carried out with a CH600A cyclic voltammeter using tetrabutyl ammonium perchlorate as the supporting electrolyte.

Magnetic susceptibility measurement was carried out with a Quantum Design MPMS-5S SQUID magnetometer under an applied magnetic field of 5000 Oe. Diamagnetic correction was estimated from Pascal table and magnetic data were corrected for diamagnetic contribution of the sample holder. The temperature dependence of the molar magnetic susceptibility, χ_M, for the complex **1** was measured on polycrystalline sample in the temperature range 5–300 K.

2.3. Computational methodology

The computational methodology adopted in previous studies [16] on exchange-coupled dinuclear complexes has been used. For the evaluation of each coupling constant, two separate DFT calculations have been carried out, one for the highest spin state (triplet state in that case) and one for the broken symmetry state. The hybrid B3LYP functional [17] has been used as implemented in GAUSSIAN-98 [18]. For the Cu atoms a basis set of triple-ζ quality [19] was used for the valence orbitals supplemented with two p orbitals (''polarization functions''), whereas a double-ζ basis set [20] was used for C, H, N and O atoms. The J values are obtained by simply subtracting E_{HS} to E_{BS} ($J = E_{BS} - E_{HS}$) where E_{HS} and E_{BS} are the energies of high spin and broken symmetry states, respectively. Using this equation, we assume that the energy of the broken symmetry state is a good approximation of low spin state energy, following Ruiz et al. [21].

2.4. Synthesis of ligand and complexes

2.4.1. Ligand (H_2L)

Oxalic dihydrazide (1.18 g, 10 mmol) was added to a solution of 2-acetylpyridine (2.24ml, 20 mmol) in methanol (100 mL) and the mixture was refluxed for 10 h. A white solid formed which was filtered off, washed with methanol and vacuum dried (Yield: 70%). M.p. >270 °C. IR ν_{max}

cm^{-1} (KBr) 1685 (CO), 1579, 1568 (CN), 979 (pyr). *Anal* Calc. for $C_{16}H_{16}N_6O_2$: C, 59.3; H, 4.9; N, 24.9. Found: C, 59.2; H, 4.9; N, 24.8%.

2.4.2. $[\{Cu_2(L)(CH_3COO)_2\}\cdot 8H_2O]_n$ (1)

Ligand **H_2L** (0.324 g, 1 mmol) was added to a solution of $Cu(OAc)_2\cdot H_2O$ (0.398 g, 2 mmol) in 2-propanol/water (5:1) and the mixture was heated with stirring for 40 min. forming a green solution. The solution was filtered and kept in refrigerator. After five days dark green hexagonal shaped crystals suitable for X-ray diffraction were formed (Yield: 60%). IR ν_{max} cm^{-1} (KBr) 1563(CN), 455 (Cu–N), 379 (Cu–O). *Anal* Calc. for $C_{10}H_{18}N_3O_7Cu$: C, 33.7; H, 5.09; N, 11.8; Cu, 17.9. Found: C, 33.6; H, 4.9; N, 11.7; Cu, 17.7%.

2.4.3. $[Ni(L)]H_2O$ (2)

Compound **2** was prepared in a similar manner like complex **1** taking $Ni(OAc)_2\cdot 4H_2O$ instead of $Cu(OAc)_2\cdot H_2O$. After seven days red rectangular crystals suitable for X-ray diffraction were formed (Yield: 65%). IR ν_{max} cm^{-1} (KBr) 1673(CO), 1562(CN), 453 (Ni–N), 375 (Ni–O). *Anal* Calc. for $C_{16}H_{16}N_6O_3Ni$: C, 48.1; H, 4.0; N,21.0; Ni, 14.7. Found: C, 48.0; H, 3.9; N, 20.8; Ni, 14.3%.

2.5. X-ray crystallographic studies

Crystallographic data were collected on a Siemens P4 diffractometer with a Siemens SMART-CCD area detector with graphite monochromated Mo-Kα radiation ($\lambda = 0.71073$ Å) using oil-coated rapidly cooled single crystals [22]. Crystallographic parameters [23], details of data collection and refinement procedures are summarized in Table 1. The structures were solved by direct methods and refined with the software packages SHELXL-93 and SHELXL-97 [24,25]. Neutral scattering factors were taken from Cromer and Mann [26] and for the hydrogen atoms from Stewart et al. [27]. The non-hydrogen atoms were considered with a riding model under restriction of ideal symmetry at the corresponding carbon atoms.

3. Results and discussion

3.1. Description of the structures

3.1.1. $[\{Cu_2(L)(CH_3COO)_2\}\cdot 8H_2O]_n$ (1)

The molecular structure as well as the atom numbering scheme of $[\{Cu_2(L)(CH_3COO)\}\cdot 8H_2O]_n$ (**1**) illustrated in Fig. 1. Relevant bond lengths and angles are listed in Table 2. In the titled copper(II) complex **1**, one molecule of the deprotonated hexadentate ligand **L** binds two metal centers in *trans* orientation. The polynuclear complex involves distorted five coordinated copper(II) centers, each surrounded by NNO donor sets from hexadentate **L** and by two additional O-atoms from two acetate anions. For a pentacoordinated metal center, the distortion of structure from trigonal bipyramidal (TBP) to square pyramidal (SP) can be evaluated by the Addision distortion index τ [28]: $\tau = (\beta - \alpha)/60°$, α and β being the two largest angles around the central atom; values for τ are 1.0 for perfect TBP and 0.0 for perfect SP. In this complex the geometry of the Cu(II) centers are close to square pyramidal ($\tau = 0.016$) with short

Deviation (in Å) of the atoms for the complex **1** from the best plane calculated from O1, N3, O2, N1 and Cu1

Atoms	Deviation (Å)
Cu1	+0.246
O1	−0.033
N3	+0.034
O2	−0.033
N1	+0.034

equatorial contacts [1.993(3)–2.017(2) Å] by N_2O donor (N1, N3, O1 for Cu1) from the **L** and one acetato oxygen atom (O2 for Cu1) and a longer axial coordination [2.401(2) Å] by the oxygen atom (O2A for Cu1) of another acetate ligand. These bond lengths are comparable to the values obtained for the similar square pyramidal copper(II) systems [29]. Distortion from the square pyramidal geometry is evident from the deviation of the atoms forming the least square plane (Table 3). The two five-membered chelate rings formed by each **L** connecting two copper(II) centers are almost coplanar and make 5.229Å separation between these two centers. The diazine subunit present in the complex is tilted with respect to the mean square plane at an angle of 1.3° and the N–N diazine bond length [1.386(4) Å] is consistent with a N–N single bond [30]. The carbon–carbon bond distance (1.489(7) Å) in the coordinating ligand **L** is consistent with the C–C single bond [31]. Each of the two copper centers in one asymmetric unit is connected to neighbouring copper centers through double $\mu_{1,1}$-acetato bridges and forms an infinite polymeric network parallel to a-axis shown in Fig. 2. The non-bonding Cu–Cu separation in the double acetato bridging amounts to 3.449 Å. There are eight water molecules in the lattice for each dimeric subunit.

3.1.2. {[Ni(L)]H_2O} (**2**)

The ORTEP diagram of complex **2** with atom numbering scheme is illustrated in Fig. 3 and the relevant bond lengths and angles are listed in Table 4. Unlike **1** here, the deprotonated ligand **L** in *cis* form binds only one nickel center and forms a monomeric Ni(II) complex. The Ni(II) ion displays a distorted square planar coordination with a N_4 donor set from **L**. The square plane suffers a tetrahedral distortion as indicated by the deviation of the coordination sites from the mean plane calculated for the four N atoms

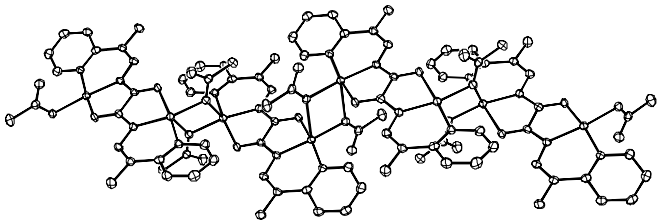

Fig. 2. Part of 1-D polymeric layer of complex **1** to show the arrangement of molecules.

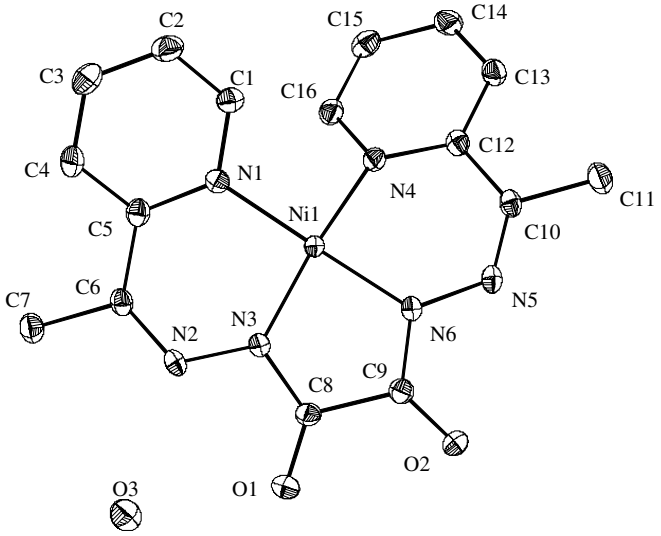

Fig. 3. ORTEP diagram of complex **2** (with water) with atom numbering scheme (thermal ellipsoids are drawn at 30% probability level). The H atoms are neglected for clarity reasons.

(N1, N3, N4 and N6) coordinated with the nickel(II) center (Table 5). This deviation from the planar arrangement of **L** is clearly seen from the torsion angle [N1–N3–N6–N4] of the coordinating Lewis bases with a value of −23.3°. The bite angles associated with six-membered rings [N1–Ni1–N3 = 91.79(8)°, N6–Ni1–N4 = 91.45(8)°] are within normal range [32]. In the title complex, the angle between the planes containing the two pyridine rings is 119.8°. The torsion angles for N1–C5–C6–N2 and N4–C12–C10–N5 with values of 20.9° and 12.4°, respectively, also show the twisting of the pyridine rings. The cause of all of these distortions (including the deviation from the planar environment of Ni1) is the steric strain induced by the hindrance of the hydrogen atoms at C1 and C16. Therefore, the pyridyl substituents are twisted away from each other thus destroying the planarity of the molecule. This fact leads to the formation of a chiral molecule, however, due to the crystallization of complex **2** in the centrosymmetric space group $P2_1/c$ the Δ and Λ isomers form a racemate in the solid state. One water molecule is present in the lattice.

The structural parameters of ligand **L** are comparable to those discussed for complex **1**. The electrical charge distribution of the ligand is symbolized by the mesomeric forms according to Fig. 4. The C8–C9 distance of 1.527(3) Å is a characteristic value for a C–C single bond [31]. This fact as well as the C5–C6 (1.480(3) Å) and C10–C12 (1.479(3) Å) bonds show that the π-systems of this ligand are well separated and a more extended delocalization of the anionic charge can clearly be excluded. The Ni1–N distances to the pyridyl groups are larger than those to the anionic nitrogen atoms N3 and N6 due to the additional electrostatic attraction of Ni1 to the latter ones. The C8–C9 single bond allows an unhindered rotation around this bond which offers the reorientation and adjustment to the copper and nickel cations.

N6	0.276
N4	0.276

3.2. Electronic spectra

Although the electronic spectra of the copper complexes with multidentate Schiff base ligands are not in general good indicators of geometry [33] but act as supporter of it. The solid-state Nujol mull absorption electronic spectrum for **1** appeared at 650, 340 and 244 nm. The broad absorption band at 650 nm is attributable to a copper ion in square pyradimal chromophore CuN_2O_3 [34]. This broad visible absorption band at 650 nm is shifted slightly to a lower energy (678 nm) in acetonitrile solution, consistent with square pyramidal geometry in solution phase. The complex displays two strong absorption bands at 340 and 244 nm in solid which are clearly charge transfer in origin and these two bands are shifted to 348 and 248 nm, respectively, in solution. The similarity in the spectrum of this complex in both solution phase and solid state indicates that the 1-D chain structure retains in the solution.

The absorption band in the solid-state Nujol mull electronic spectrum for **2** shows one band at 423 nm, which

is shifted to 432 nm in acetonitrile solution. This band corresponds to the d–d transition in square planar Ni(II) complex [35]. The solid state spectrum of this complex contains another more intense band at 310 nm, which is shifted to 316 nm in solution, is charge transfer in origin.

3.3. Electrochemical studies

The electrochemical study of the complexes **1** and **2** was performed using acetonitrile as solvent and tetrabutylammonium perchlorate as supporting electrolyte at a scan rate of 100 mV s^{-1}. Cyclic voltametry of the complex **1** shows two reductive responses on the negative side of SCE (at −0.55, −1.00 V), both of which are irreversible in nature. The observed potential gap (450 mV) between the two reductions is considerably large and is believed to be due to the effective communication between the two copper centers through the bridging ligands. One irreversible oxidation response is also observed on the positive side of SCE and which can be tentatively assigned to oxidation of the coordinated ligand.

The complex **2** exhibits an irreversible Ni(II)–Ni(III) oxidation at 1.26 V. This result suggests that Ni(III) species is unstable and undergoes rapid decomposition. One additional irreversible oxidation response is also observed on the positive side of SCE and can be tentatively assigned to oxidation of the coordinated ligand.

3.4. Magnetic studies

The magnetic behavior for complex **1** is given in Fig. 5 as χ_M versus T and $\chi_M T$ versus T, where χ_M is the magnetic susceptibility of a dinuclear unit. The rapid decrease of the $\chi_M T$ reaching very small values below 50 K and the rounded maximum exhibited by the χ_M curve around 250 K indicate that substantial antiferromagnetic interactions are operative between the Cu(II) ions. For this compound, the adjacent Cu(II) ions are linked alternatively by an oxamido-type ligand and two bridging O-atoms developing a 1-D supramolecular organization. However, considering the coordination sphere of these ions it appears that a bridging O-atom occupies an equatorial position on one Cu(II) whereas it is linked to the second center in apical position. The latter is characterized by a larger bond-length (2.399 versus 1.954 Å) due to the Jahn–Teller distortion along the z-direction. Taking into account that the unpaired electron of the Cu(II) is located in the $d_{x^2-y^2}$ orbital, no direct overlap exists between the magnetic orbitals of O-bridged Cu centers. Consequently, the exchange interaction mediated by this pathway should be weak. Conversely, it is well documented that the exchange interaction between two Cu(II) ions through the oxamido-bridge is strong [11]. A first attempt was made to analyze the experimental behavior with an alternating chain model derived from the spin Hamiltonian $\mathbf{H} = -J\sum_{i=1}^{n/2}[\mathbf{S}_{A2i}\cdot\mathbf{S}_{A2i-1} + \alpha\mathbf{S}_{A2i}\cdot\mathbf{S}_{A2i+1}]$ [11]. Best fit to the temperature dependence of $\chi_M T$ yielded $J = -330 \pm 2\ cm^{-1}$ and $\alpha J = -79\ cm^{-1}$ ($\alpha = 0.24 \pm 0.02$), $g = 2.14 \pm 0.01$, and a contribution of 0.01 mol of a $S = 1/2$ paramagnetic impurity with same molecular mass. However, the value obtained for the smallest exchange interaction, $-79\ cm^{-1}$, is not realistic if we consider it to correspond to the exchange occurring through the O-bridge. Therefore, we considered the observed magnetic behavior to result only from the strongest exchange interaction and the magnetic data have been analyzed with the Bleaney-Bowers equation [36] ($\mathbf{H} = -J\mathbf{S}_1\cdot\mathbf{S}_2$). The contribution of a paramagnetic $S = 1/2$ impurity was also taken into account. Best fit to the temperature dependence of $\chi_M T$ (Fig. 5) in the 5–310 K domain led to $J = -327 \pm 1\ cm^{-1}$, $g = 2.02$, and 0.02 mole of a paramagnetic impurity. Fitting to the variation of χ_M yielded $J = -307 \pm 2\ cm^{-1}$, $g = 1.95$. The exchange parameter found is well in the range of those reported for related oxamato- or oxalate-bridged Cu(II) ions [37,38].

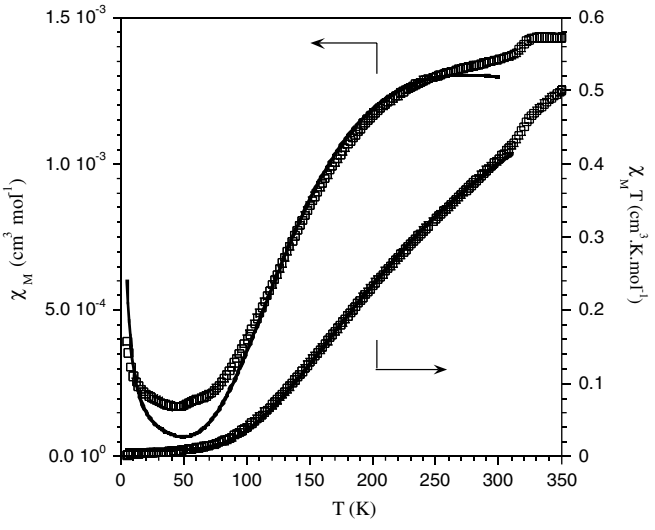

Fig. 5. Experimental (□) and calculated (——) temperature dependence of χ_M and $\chi_M T$ for complex **1**.

The magnetic behavior in the high-temperature domain deserves a short comment. Around 320 K both the $\chi_M T$ and χ_M curves exhibit a sudden slope break suggesting a modification of the magnetic behavior for the compound at this temperature. Such a disruption can be related to a structural modification occurring for a given temperature which does alter the magnetic behavior [39,40]. In the present case, the structural modification could be ascribed the water release.

3.5. DFT calculations of the exchange constants

In an effort to gain complementary information on compound **1** and in order to confirm our assumption, DFT calculations on the exchange interactions as function of the pathway were carried out. All calculations for high spin and broken symmetry states were done on dinuclear fragments with the X-ray coordinates, without any geometric optimization by theoretical methods. In order to evaluate the exchange coupling mediated by the oxamido bridge,

the calculation was done with the complete ligand set, i.e., the oxamido-ligand and the four acetates linked to the two Cu(II) centers. For the interaction through the acetate oxygen, another dinuclear cluster was extracted which contained two Cu(II) ions, two acetate ligands bridging the two copper atoms, and two shortened oxamido-ligands. These latter ligands have been shortened in the sense that the aromatic pyridine ring which is not involved in the coordination of the considered copper has been replaced by a methyl group. Both considered systems have a global charge of −2. The exchange coupling constants calculated are $J = -181$ and $+1.3\ cm^{-1}$ for oxamido- and oxygen-bridges, respectively. The main exchange interaction parameter calculated points to a somewhat smaller value than the one deduced from the experimental behavior ($J = -327\ cm^{-1}$) but the sign and the order of magnitude are correctly reproduced. More important, these calculations validate the analysis of the experimental data by a dimer model. Indeed, the computed interaction through the oxygen bridges is found to be ferromagnetic and very small compared to the antiferromagnetic interaction through the oxamido unit. In no way this weak ferromagnetic interaction can be revealed by the experimental behavior.

4. Conclusion

The design of polytopic ligand to prepare polymeric complexes is dependent on a number of factors, including the topological complexity of the ligand itself. The individual coordinating components in the ligand do not behave in a similar way for all metal ions. Here, in summary one 1-D polymeric copper(II) and one four coordinated monomeric nickel(II) complexes were assembled from copper(II) acetate and nickel(II) acetate with an easy to prepare flexible bistridentate ligand, in a rational fashion. The choice of different metal centers, in this case copper(II) or nickel(II), give rise to different products and is accomplished by the unhindered rotation of the C–C single bond, which offers the reorientation of the same ligand in *trans* and *cis*-form, respectively. This variation in the coordination behavior of the same ligand for copper(II) and nickel(II) occurred because Ni(II) has a better affinity for N-donor sites than for O ones.

5. Supplementary data

CCDC-265377 (**1**) and 265378 (**2**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk [or from Cambridge Crystallographic Data Center, 12, Union Road, Cambridge CB2 1EZ, UK; e-mail: deposit@ccdc.cam.ac.uk].

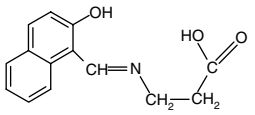
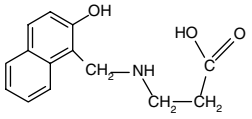
also for cobalt complexes with other types of ligands containing amino acid moieties [18].

The metal complexes with α-amino acid derivatives have been investigated extensively but less works are devoted to complexes with β-amino acid Schiff bases, particularly with β-alanine [21]. In our recent work, we have interested in the cobalt complexes of β-alanine Schiff base with 2-hydroxynaphthaldehyde and its reduced analogue. The new cobalt complexes of the Schiff base, binuclear cobalt (II) complex and trinuclear mixed-valence cobalt complex with *N*-(2-hydroxynapthalidene)-β-alanine, and cobalt complex of reduction product of the Schiff base have been synthesized; compositions and physicochemical properties of the complexes and possibilities to reduction with sodium borohydride have been studied. Crystal structure of trinuclear mixed-valence cobalt complex has been elucidated.



(Naphβala**H₂**) **(I)**

N-(2-Hydroxynapthalidene)-β-alanine



(RNaphβala**H₂**) **(II)**

N-(2-Hydroxynapthylmethyl)-β-alanine

2. Experimental

2.1. Physical and chemical measurements

UV–Vis. The electronic spectra were recorded on a Shimadzu UV–Vis 240 spectrophotometer using DMF and methanol as solvent. Kinetic measurements for reaction rates were also performed in termostated (±0.5 °C) quartz cuvettes. Optical densities were recorded at the maximum absorptivity wavelengths of the ligand (420 nm) and the complex $[Co_2(Nap\beta ala)_2 \cdot 2H_2O] \cdot H_2O$ (375 nm).

IR. Infrared spectra were recorded on a Hyper IR Shimadzu infrared spectrophotometer as KBr discs in the range of 4000–400 cm^{-1}.

Magnetic susceptibility measurements were carried out at room temperature on magnetic balance of Faraday type with $Hg[Co(SCN)_4]$ as standard.

NMR. ^1H NMR spectra of ligands were recorded on Mercury 300 BB spectrometer in DMF-d_6 solutions with TMS as internal standart at ambient temperature.

Elemental analyses. The elemental analyses were performed in the analytical laboratory, Tubitak, Ankara on LECO CHNS 932.

2.2. Synthesis of β-alanine Schiff bases with o-hydroxyaromatic aldehydes

2.2.1. Reagents

2-Hydroxynaphtaldehyde, β-alanine, sodium borohydride and the solvents used in the preparations and kinetic experiments were all Merk p.a. products.

2.2.2. N-(2-hydroxynaphtalidene)-β-alanine (NapβalaH₂) (I)

Since β-alanine is sparingly soluble in alcohols, the Schiff base formation takes long time even under the reflux conditions. To accelerate the reaction, following method was used:

The mixture of 2-hydroxynaphtaldehyde (20 mmol, 3.444 g) and β-alanine (20 mmol, 1.782 g) was milled in a porcelain mortar to obtain a homogenous mass until the release of water was observed. This mixture was added dropwise into the 200 ml of ethanol and refluxed for 1 h. The yellow crystalline compound **I** was precipitated after cooling (4.15 g, 85%). M.p.: 211–212 °C. IR (KBr, ν/cm^{-1}): 3433 (broad, OH), 3035, 3051 (broad, OH), 2476 (broad, CO*OH*), 1718 (s,C=O), 1644(C=N), 1547 (ν_{asym}(COO)), 1365 (ν_{sym}(COO)), 1268 (ν phenolic C–O). ^1H NMR (DMSO-d_6, δ): 8.96 (s, 1H, CH=N); 7.94 (d, 1H, arom. CH, $J = 7.5$ Hz); 7.65 (d, 1H, arom. CH, $J = 9.3$ Hz); 7.55 (d, 1H, arom. CH, $J = 7.5$ Hz); 7.35 (t, 1H, arom. CH, $J = 7.5$ Hz); 7.12 (t, 1H, arom. CH, $J = 7.5$ Hz); 6.63 (d, 1H, arom. CH, $J = 9.3$ Hz); 2.82 (t, 2H, CH_2, $J = 6.3$ Hz); 2.29 (t, 2H, CH_2, $J = 6.3$ Hz). *Anal*. Calc. for $C_{14}H_{13}NO_3$: C, 69.12; H, 5.39; N, 5.76. Found: C, 68.72; H, 5.34; N, 5.75%.

2.2.3. N-(2-hydroxynaphtylmethyl)-β-alanine (RNapβalaH₂) (II)

$Nap\beta alaH_2$ (10 mmol, 2.43 g) was suspended in 50 ml of ethanol and reduced by addition of excess sodium borohydride (10 mmol, 0.38 g). The solution was stirred until the yellow color of Schiff base disappeared, diluted with 8–10 times of water and the pH was adjusted to 6 by addition of 10% HCl. The white precipitate of **II** was purified by crystallization from DMF–ethanol mixture (1:1). M.p.: 198–199 °C. IR (KBr, ν/cm^{-1}): 3371 (broad, OH and NH); 2626–2700 (broad, CO*OH*), 1622 (s, C=C), 1518 (ν_{asym}(COO)), 1362 (ν_{sym}(COO)), 1273 (phenolic C–O). ^1H NMR (DMSO-d_6, δ): 7.03–7.97 (m, arom. CH); 2.83 (t, 2H, N–CH_2); 2.47 (s, 2H, Naph-CH_2) 2.29 (t, 2H, CH_2–COOH); 1.19 (s, 1H, NH). *Anal*. Calc. for $C_{14}H_{15}NO_3$: C, 68.56; H, 6.16; N, 5.71. Found: C, 68.26; H, 6.86; N, 5.70%.

2.2.4. $[Co_2(Nap\beta ala)_2 \cdot 2H_2O] \cdot H_2O$ (III)

This compound was always obtained along with trinuclear cobalt complex. It can be prepared in the yields more than 9% with water ratios higher than 9% in the solvent.

$Nap\beta alaH_2$(1 mmol, 0.243 g) was dissolved in 20 ml of hot ethanol and hot solution of cobalt acetate tetrahydrate (1 mmol, 0.249 g) in 10 ml of water was added to get

EtOH:water ratio of approximately 2:1. Immediate precipitation of fine violet-pink crystalline compound **III** was observed. The precipitate was filtered hot, washed with water, ethanol and dried in vacuo (0.22 g, 67% based on Co). M.p.: >300 °C; $\mu_{eff} = 4.87$ BM. TGA data (°C) (%) (calcd): 185 °C (5.60%) (5.70% calcd. for $-2H_2O$); 370 °C (21.0%) (21.7%, $-(3H_2O + 2CO_2)$). *Anal.* Calc. for $C_{28}H_{28}N_2O_9Co_2$: C, 51.39; H, 4.31; N, 4.28; Co, 18.01. Found: C, 51.56; H, 4.45; N, 4.55; Co, 17.18%.

2.2.5. $[Co_2(Nap\beta ala)_2 \cdot 2H_2O] \cdot H_2O$ (*III*) and $\{[Co(Nap\beta ala)_2]_2Co(H_2O)_4\} \cdot 4H_2O \cdot 2C_2H_5OH$ (*IV*)

NapβalaH$_2$(2 mmol, 0.486 g) was dissolved in 40 ml ethanol by heating and mixed with hot solution of cobalt acetate tetrahydrate (2 mmol, 0.498 g) in 4 ml water to get EtOH: water ratio of approximately 10:1. The warm solution was filtered from violet-pink fine powder (compound **III**) (0.06 g, 9% based on Co) and the filtrate was left for crystallization. The dark brown crystals (compound **IV**) were collected after 2–3 days standing (0.23 g, 25% based on Co). M.p.: >300 °C; $\mu_{eff} = 4.03$ BM; TGA Data (°C) (%) (calcd): 200 °C (17.0%) (17.1%, calcd. for $-(8H_2O + 2C_2H_5OH)$); 314 °C (23.0%) (23.5%, $-(8H_2O + 2C_2H_5OH + 2CO_2)$; 360 °C (29.0%) (29.9%, $-(8H_2O + 2C_2H_5OH + 4CO_2)$). *Anal.* Calc. for $C_{60}H_{72}N_4O_{22}Co_3$: C, 52.29; H, 5.23; N, 4.07; Co, 12.85. Found: C, 52.05; H, 5.16; N, 4.09; Co, 12.33%.

2.2.6. $Co(RNap\beta ala) \cdot 2H_2O$ (*V*)

RNapβalaH$_2$ (1 mmol, 0.245 g) in 10 ml of water containing 1 mmol NaOH was mixed with solution of cobalt acetate tetrahydrate (1 mmol, 0.249 g) in 10 ml of methanol. The deposited fine powder **V** was filtered, washed with water and ethanol and finally dried in air (0.22 g, 65% based on Co). M.p.: 335–336 °C; $\mu_{eff} = 3.67$ BM; TGA Data (°C) (%) (calcd): 111 °C (4.8%) (5.3%, calcd. for $-H_2O$); 216 °C (10.6%) (10.6%, $-2H_2O$); 310 °C (24.8%) (23.5%, $-(2H_2O + CO_2)$). *Anal.* Calc. for $C_{14}H_{17}NO_5Co$: C, 49.70; H, 5.03; N, 4.14; Co, 17.45. Found: C, 49.09; H, 4.79; N, 3.16; Co, 18.03%.

2.2.7. X-ray structural analysis

Dark brown single crystal suitable for data collection was mounted on a glass fiber and data collection was performed on a STOE IPDS 2 diffractometer with graphite monochromated Mo Kα radiation at 100 K. Details of crystal data, data collection and refinement are given in Table 1. The structure was solved by direct-methods using SHELXS-97 [30] and refined by full-matrix least-squares methods on F^2 using SHELXL-97 [34]. All non-hydrogen atoms were refined with anisotropic parameters. Hydrogen atoms bonded to carbon and ethanol hydrogens were placed in calculated positions (C–H 0.95–0.99 Å and alcohol 0.84 Å) and refined using riding model with $U = 1.2U$ of the parent atom for CH and CH$_2$ but $U = 1.5U$ for methyl and OH hydrogens). The hydrogens of the coordinated water were placed as methyl hydrogens with O–H 0.85 Å and then the one which was not involved in hydrogen bonds were deleted and refined using riding model with U 1.5 times that of attached oxygen atoms. Non-coordinated water hydrogens were found to be disordered over several positions and involved in very strong hydrogen bonding with neighboring oxygen atoms. The positions of the non-coordinated water hydrogens were not resolved. Molecular drawings were obtained using ORTEP-III [35] Geometric calculations were performed on PLATON [33]. Atomic coordinates and equivalent isotropic displacement parameters are listed in Table 2.

Table 1

3. Results and discussion

N-(2-hydroxynapthalidene)-β-alanine reacts with Co(II) acetate in aqueous ethanol (1:2; v/v) to give binuclear Co(II) complex **III**, $[Co_2(Nap\beta ala)_2 \cdot 2H_2O] \cdot H_2O$, in 67% yield.

$$2Co(H_2O)_6^{2+} + 2NapHbalaH_2 + 4CH_3COO^- \rightarrow [Co_2(Nap\beta ala)_2 \cdot 2H_2O] \cdot H_2O + 9H_2O + 4CH_3COOH$$

When the water content of solution is decreased, binuclear complex formation is diminished and in aqueous ethanolic solution of 1:10 (v/v), trinuclear complex **IV** is obtained in 25% yield along with the binuclear complex **III** (9%).

$$2\mathrm{NaphβalaH_2} + \mathrm{Co_2(Naphβala)_2 \cdot 2H_2O(aq)} + \mathrm{Co(H_2O)_6^{2+}} + \tfrac{1}{2}\mathrm{O_2} + \mathrm{H_2O} + 2\mathrm{C_2H_5OH} \rightarrow [\mathrm{Co(III)(Naphβala)_2–Co(H_2O)_4^{2+}–Co(III)} \times \mathrm{(Naphβala)_2}] \cdot 4\mathrm{H_2O} \cdot 2\mathrm{C_2H_5OH} + 2\mathrm{H_3O^+}$$

Trinuclear mixed-valence complex **IV** should be formed via the oxidation of Co(II) atoms in $[\mathrm{Co_2(Naphβala)_2 \cdot 2H_2O}] \cdot \mathrm{H_2O}$ complex which is followed by the reaction with hydrated Co(II) ion.

Reduction of Schiff base by $NaBH_4$ in ethanol gives the reduced Schiff base (RNaphβala) which reacts with Co(II) to give a stable mononuclear Co(II) complex Co(RNaphβala) · $2H_2O$ (**V**). Reduction of binuclear Schiff base complex also leads to same mononuclear Co(II) complex **V**.

$$[\mathrm{Co_2(Naphβala)_2 \cdot 2H_2O}] \cdot \mathrm{H_2O}\ (\mathbf{III}) + 4\mathrm{H} + \mathrm{H_2O} \rightarrow 2\mathrm{Co(RNaphβala)} \cdot 2\mathrm{H_2O}\ (\mathbf{V})$$

3.1. Crystal structure of $\{Co(H_2O)_4[Co(Napβala)_2]_2\} \cdot 4H_2O \cdot 2C_2H_5OH$ (*IV*)

The structure of $\{\mathrm{Co(H_2O)_4[Co(Napβala)_2]_2}\} \cdot 4\mathrm{H_2O} \cdot 2\mathrm{C_2H_5OH}$ complex consist of three cobalt centre (Fig. 1). Each outer Co (Co2 and Co3) atoms are coordinated by two tridentate Naphβala ligand; but the Co(1) coordination sphere is formed from four water oxygen atoms and two oxygen atoms of carboxylate groups of Naphβala ligands which bridge the terminal (Co2 and Co3) and central (Co1) cobalt ions. Co1 atom is bridged by one $\mu_{1,3}$-OCO to Co2 and one $\mu_{1,3}$-OCO to Co3. The didepronated Naphβala ligands act as a tridentate one to the Co2 and Co3; but monodentate one to Co1. The tridentate behaviour of the Naphβala ligand results in the formation of two six membered rings in each Co2 and Co3 coordination environment having Co2–N1, Co2–N2, Co3–N3 and Co3–N4 bonds. The coordination geometry around all three cobalt atoms could be described as weakly distorted octahedron.

The stoichiometry of four dideprotonated ligands per trinuclear cobalt complex suggests a Co^{III}–Co^{II}–Co^{III} distribution of oxidation states. This can be correlated by comparing the length of the Co–O bond: since the ionic radius of Co^{II} is larger than Co^{III}, Co1–O5 and Co1–O11 bond lengths (2.140(3) and 2.118(3) Å) are noticeably longer than the Co2–O1, Co2–O4, Co3–O7 and Co3–O10 (1.930(3), 1.941(3), 1.939(3) and 1.941(3) Å). While Co^{II}–O bond lengths is around 2.1 Å, Co^{III}–O bond lengths is ~1.94 Å [18,19,24,26,27]. The absence of characteristic IR absorptions around 1700 cm^{-1} expected for the vibration of protonated carboxyl groups (COOH) also indicates that all carboxyl groups are depronated. Co^{III}–N distances are slightly shorter than Co^{II}–N distances reported earlier [18,27] but similar to Co^{II}–N distances [19,25]. All IR, UV–Vis and magnetic data supports that complex molecule has Co^{III} and Co^{II}.

In both outer coordination sphere, Co^{III}–Naph O bond lengths (~1.85 Å) are noticeably shorter than that of Co^{III}–carboxyl oxygens. These bond lengths are in good agreement with those reported for Co^{III}–Naph oxygens [19,28,29]. The coordination around Co2 and Co3 which are 3+ oxidation states coincide with each other within error limits.The oxidation state of Co1 is 2+ and coordinated by four water oxygens and two carboxyl oxygens. The distances of Co1–water oxygens and Co1–carboxyl oxygens are in good agreement with those reported for Co^{II} ions [18,19,24,31,32].

All four naphthalenolates are essentially planer with a rms deviations of ~0.06 Å. Dihedral angles between the two naphthalenolates in Co2 and Co3 environments are 28.30(8)° and 29.74(8)°, respectively. Naphthalenolates are involved in π–π, C–H–π and C–H–O interactions (Table 3).

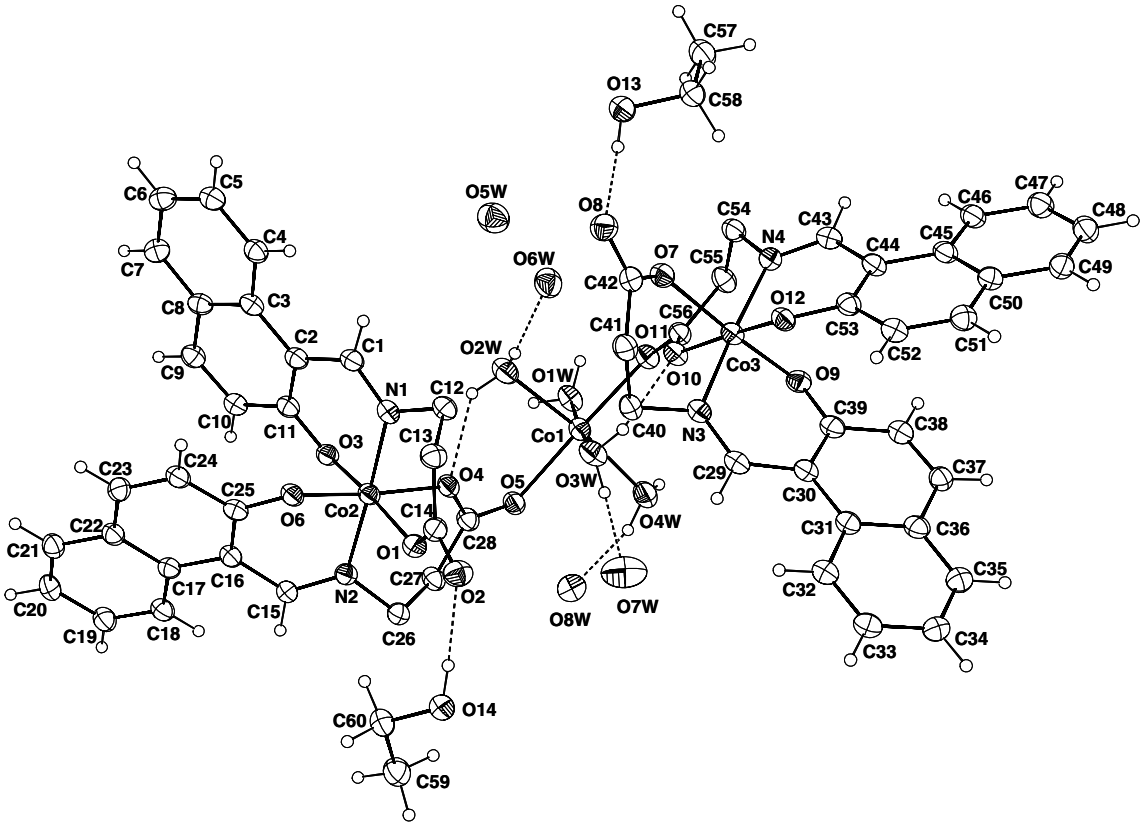

Fig. 1. A molecular view of the complex, water and ethanol solvates. The displacement ellipsoids are drawn at the 30% probability level and CH_2 hydrogens are removed for clarity.

In addition to neutral coordination sphere, structure contains four water and two ethanol solvate per complex. Waters coordinated to Co1(O1W, O2W, O3W and O4W), solvate waters(O5W, O6W, O7W and O8W) and oxygen of the ethanol solvates(O14 and O14) are all involved in very strong hydrogen bonds stabilizing the three dimensional crystal structure (Table 3). Further analysis by Platon reveals that unit cell contains no residual solvent accessible void [33].

3.2. Magnetic data

The magnetic moment of binuclear cobalt complex $[Co_2(Nap\beta ala)_2 \cdot 2H_2O] \cdot H_2O$ (**III**) measured at room temperature and calculated has the value of 4.87 BM which points the presence of high spin state Co(II) in the complex.

The magnetic moment of $\{[Co(Nap\beta ala)_2]_2Co(H_2O)_4\} \cdot 4H_2O \cdot 2C_2H_5OH$ (**IV**) is 4.03 BM. This value of magnetic moment and the X-data point out undoubtly that two cobalt ions in trinuclear complex are in oxidation state 3+ and one is in oxidation state 2+.

The magnetic moment of $Co(RNap\beta ala) \cdot 2H_2O$ (**V**) is 3.67 BM which confirms the presence of Co(II) in the complex.

3.3. Spectroscopic properties

In electronic spectrum of $[Co_2(Nap\beta ala)_2 \cdot 2H_2O] \cdot H_2O$ (**III**) complex in DMF solution are the absorption bands at

$v_1 = 9000\ cm^{-1}$, $v_2 = 16400\ cm^{-1}$, $v_3 = 18200\ cm^{-1}$ which can be referred to transition from $^4A_{1g}$ ground state in $^4B_{1g}$, ^4E_g and $^4A_{2g}$ excitated states of square pyramidal Co(II) complex. The v_2 and v_3 bands are observed as shoulders on the intensive absorbtion at $26500\ cm^{-1}$, which is the charge transfer band.

In trinuclear $\{[Co(Nap\beta ala)_2]_2 \cdot Co(H_2O)_4\}$, there can be to distinguish the absorbances of $Co(Nap\beta ala)_2^{2-}$ and $Co(H_2O)_4^{2+}$ units. The relative intensive absorbance at $14200\ cm^{-1}$ ($\varepsilon = 380\ l \cdot mol^{-1} \cdot cm^{-1}$) concerns to the spin allowed $^1A_{1g} \rightarrow {}^1T_{1g}$ transition, observed usually for octahedric Co(III) complexes. The low intensive bands at 19200 and $9100\ cm^{-1}$ connect with d–d transitions in octahedric hydrate $Co(H_2O)_4^{2+}$ units.

The infrared spectra of $\{[Co(Nap\beta ala)_2]_2 \cdot Co(H_2O)_4\} \cdot 4H_2O \cdot 2C_2H_5OH$ (**IV**) show very broad intensive band at $3343\ cm^{-1}$ of hydroxyl groups. Intramolecular hydrogen bond appears as a sharp band at $3632\ cm^{-1}$. The band of azomethine group at $1619\ cm^{-1}$ is appeared at lower frequence than the band of C=N stretching in noncoordinated ligand ($1644\ cm^{-1}$). The COOH band of the ligand at $1718\ cm^{-1}$ disappears and the $v_{asym}(COO)$ band of the ligand at $1547\ cm^{-1}$ splits into two peaks at 1545 and $1569\ cm^{-1}$, which are attributed to bidentate bridge and monodentate coordinated carboxylic groups, respectively. The v_{sym} of bridge carboxylic group is at $1392\ cm^{-1}$ and monodentate carboxylic group at $1360\ cm^{-1}$, which correspond the frequence stretching differences observed in similar coordinations.

In the infrared spectra of $[Co_2(Nap\beta ala)_2 \cdot 2H_2O] \cdot H_2O$ (**III**), the absorption of hydroxyl groups at $3360\ cm^{-1}$ considerable lower compared with the trinuclear complex. Intramolecular hydrogen bond appears as a sharp band at $3633\ cm^{-1}$. The $v_{asym}(COO)$ is splitted to give peaks at 1573 and $1542\ cm^{-1}$. The $v_{sym}(COO)$ band appear at 1394 and $1362\ cm^{-1}$. The separation between these bands with the Δv value is in agreement with the value observed for the bridge bidentate carboxylates. Elemental analyses, IR, UV–Vis and magnetochemical ($\mu_{eff} = 4.87$ BM) data can be pointed out on binuclear square pyramidal structure of complex **III**.

The presence of hydrated water have been confirmed by broad absorption bands between ca. 3350 and $3450\ cm^{-1}$ in complexes.

3.4. Hydrogenation by $NaBH_4$

The hydrogenation reactions of ligand and complexes were carried out with sodium borohydride in the water containing DMF solutions at room temperature.

$$\underset{N\text{-(2-hydroxynapthalidene)-}\beta\text{-alanine (I)}}{Ar\text{–}CH{=}NCH_2\text{–}CH_2\text{–}COOH} + 2H \rightarrow \underset{N\text{-(2-hydroxynapthylmethyl)-}\beta\text{-alanine (II)}}{Ar\text{–}CH_2\text{–}NH\text{–}CH_2\text{–}CH_2\text{–}COOH}$$

$NaBH_4$ does not decompose in DMF solution even in a long time. Spectrophotometric titration of Schiff base have shown that the stoichiometric quantity of borohydride solution was spent after 24 h to achieve full hydrogenation. Thus, water-containing DMF was used in hydrogenation.

Kinetic measurements of hydrogenation have been carried out by the observation of the absorbance change at

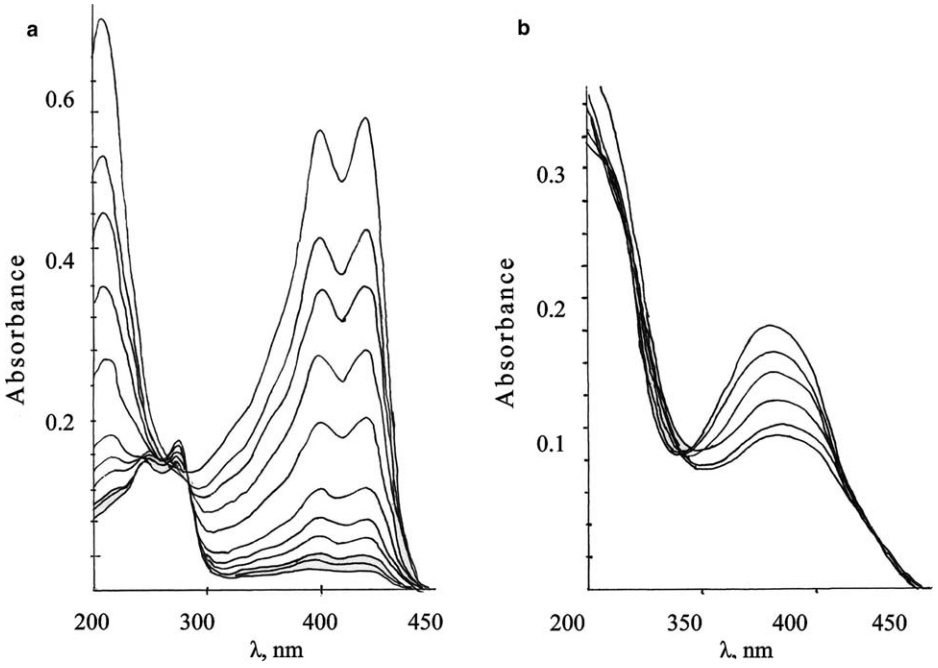

Fig. 2. (a) The absorbance change of $Nap\beta alaH_2$ (**I**) solution in DMF vs. time. Initial concentrations: $[Nap\beta alaH_2] = 10^{-4}\ mol\ L^{-1}$; $[NaBH_4] = 2 \times 10^{-3}\ mol\ L^{-1}$; $[H_2O] = 0.1\ mol\ L^{-1}$. (b) The absorbance change of $[Co_2(Nap\beta ala)_2 \cdot 2H_2O] \cdot H_2O$ (**III**) solution in DMF vs. time. Initial concentrations: $[Co_2(Nap\beta ala)_2 \cdot 2H_2O \cdot H_2O] = 9.7 \times 10^{-5}\ mol\ L^{-1}$; $[NaBH_4] = 2 \times 10^{-3}\ mol\ L^{-1}$; $[H_2O] = 0.1\ mol\ L^{-1}$.

418 nm for ligand ($NapβalaH_2$) and at 377 nm for complex **III** $[Co_2(Napβala)_2 \cdot 2H_2O] \cdot H_2O$ (Fig. 2).

Dependence of the reaction rate on the initial concentrations of ligand (or complex), sodium borohydride and water have been investigated. Reduction rates of Schiff base and the binuclear complex have been obtained by the kinetic investigations which were carried out by excess $NaBH_4$ and H_2O concentrations (about 100 times excess). In this case, the reaction can be considered as pseudo-first-order reaction

$$v = k_{\text{eff}}[\text{Sub}],$$

where k_{eff} is the reaction rate effective constant, including of initial concentrations of $NaBH_4$ and H_2O and possible intermediate active complexes formatting equilibria constants; [Sub] is the concentration of $NapβalaH_2$ or $[Co_2(Napβala)_2 \cdot 2H_2O] \cdot H_2O$.

The experimental values for k_{eff} of $NapβalaH_2$ and $[Co_2(Napβala)_2 \cdot 2H_2O] \cdot H_2O$ are 1.05×10^{-3} and 2.06×10^{-3} s^{-1} at initial concentrations of $[H_2O]_o$ and $[NaBH_4]_o$.

The obtained values

$$k'_{\text{eff}} = k_{\text{eff}}/[NaBH_4]_o[H_2O]_o,$$

are 2.0 and 3.9 l^2 mol^{-2} s^{-1} for $NapβalaH_2$ or $[Co_2(Napβala)_2 \cdot 2H_2O] \cdot H_2O$, respectively.

Trinuclear mixed-valence complex $\{[Co(Napβala)_2]_2 \cdot Co(H_2O)_4\} \cdot 4H_2O \cdot 2C_2H_5OH$ (**IV**) could not be reduced under similar conditions. Increases in sodium borohydride and water concentration did not give any results. High stability of this complex against sodium borohydride reduction can be connected with high energetic barrier reconstruction of the ligand environment around metal ion in the transition state. The presence of azomethine coordinated cobalt ions which have not contain water molecules in the coordination sphere can also be a reason for such stability against reduction.

4. Conclusions

Cobalt forms two types of complexes with *N*-(2-hydroxynaphtalidene)-β-alanine: binuclear $[Co_2(Napβala)_2 \cdot 2H_2O] \cdot H_2O$ and trinuclear mixed-valence $\{Co(H_2O)_4[Co(Napβala)_2]_2\} \cdot 4H_2O \cdot 2C_2H_5OH$. The X-ray and magnetochemical studies shows that trinuclear complex consist of two octahedrally coordinated outer cobalt ions with oxidation state 3+ and one is in oxidation state 2+. These kinds of complexations differ from the complexation with the Schiff base (LH_2) derived from 2-hydroxynaphtaldehyde and α-alanine which gives one kind of complex $Co(II)(LH)_2$ [15].

Schiff base, *N*-(2-hydroxynaphtalidene)-β-alanine, is easily reduced by $NaBH_4$ to a secondary amine which also acts as a ligand. An interesting point is observed that the binuclear complex $[Co_2(Napβala)_2 \cdot 2H_2O] \cdot H_2O$ could be reduced by sodium borohydride in water containing DMF solution into the complex **V** with hydrogenated ligand. However, according to kinetic measurements, the hydrogenation rate constant of free ligand is more noticable than the constant for complex.

It have been observed that the coordinating ligands in trinuclear complex could not be reduced under similar conditions. It connects probably with high activation energy, which is necessary for reconstruction of coordination sphere around Co^{3+} ions during the reduction reaction. Different behaviors of $[Co_2(Napβala)_2 \cdot 2H_2O] \cdot H_2O$ and $\{Co(H_2O)_4[Co(Napβala)_2]_2\} \cdot 4H_2O \cdot 2C_2H_5OH$ complexes against sodium borohydride action can be explained also by the simultaneous presence of azomethine group and water molecule in the coordination sphere of same cobalt ion, by which complex **III** is more succeptible to react with $NaBH_4$ reduction and cleaves simultaneously to give mononuclear complex of reduced ligand.

5. Supplementary material

Supplementary data are available from the Cambridge Crystallographic Data Center, CCDC, 12 Union Road, Cambridge CB2 1 EZ, UK on request quoting the deposition number 278124.

bis(L-alaninato)copper(II) with formaldehyde and acetamide, by electron impact (EI) mass spectroscopy, UV–Vis spectroscopy and magnetic susceptibility measurements. Compound **1** is soluble in water and its nucleolytic property is also described herein. The crystal structure of the insoluble compound **2**, with no lattice water molecule and slightly different from the previously synthesized compound which has one water molecule [1], has been determined.

2. Experimental

2.1. Synthesis of 1 and 2

The complexes **1** and **2** are identical or similar to those previously synthesized from the reactions of *trans*-[*bis*(L-alaninato)copper(II)], Cu(L-ala)$_2$, with formaldehyde and acetamide, as evidenced by their FTIR spectra [1]. For each reaction, a solid product crystallizes out of the reaction mixture containing Cu(L-ala)$_2$, aqueous formaldehyde and acetamide. After repeated attempts, one of the reactions finally yielded a suitable crystal of **2** for X-ray crystal structure analysis. Elemental analysis for (i) complex **1**, *Anal*. Calc. for $C_{12}H_{22}N_4O_6Cu \cdot 3H_2O$: C, 33.06; H, 6.47; N, 12.85. Found: C, 32.87; H, 6.10; N, 12.49% and (ii) complex **2**, *Anal*. Calc. for $C_{18}H_{32}N_6O_8Cu$: C, 41.26; H, 6.15; N, 16.04. Found: C, 40.74; H, 5.71; N, 15.70%.

2.2. Physical measurements

Elemental microanalysis was carried out with a Perkin–Elmer 2400. UV–Vis spectroscopic measurement was carried out on a Shimadzu UV-160 spectrophotometer on sample solutions of **1** dissolved in distilled water or dissolved in TN buffer pH 8.3 (TN = *Tris*–NaCl; *Tris* = *Tris*-(hydroxymethyl)aminomethane).

The EI mass spectra of **1** and **2** were collected on a HP 5989A mass spectrometer with a heating rate of 45 °C per minute and 70 eV electron beam. The temperature of the chamber for the insertion probe was programmed from 50 to 270 °C. Mass spectra were recorded when the ions were most abundant. The temperature range in which the mass spectra were recorded differs slightly for **1** and **2** but both are within the range 190–220 °C. The EI-MS of Cu(L-ala)$_2$ and L-alanine were similarly obtained for comparison. Infrared spectra of all compounds were recorded as KBr pellets using a Perkin–Elmer 1000 FTIR spectrometer in the frequency range 4000–600 cm^{-1}. The magnetic susceptibility measurements of **1** and **2** at room temperature were obtained with a Sherwood Magnetic Susceptibility Balance MSB Mk1 which was calibrated with Hg[Co(SCN)$_4$].

2.3. X-ray crystallography

A total of 7252 reflections for a crystal of **2** with a size of $0.48 \times 0.44 \times 0.04$ mm were collected at 293 K on a Bruker AXS area-detector diffractometer equipped with Mo Kα radiation ($\lambda = 0.71073$) using the ω-scan technique. The structure was solved by SHELXS-97 [8] and refined using SHELXL-97 [9]. The structure was refined on 2521 [$I > 2\sigma(I)$] of the 2883 reflections to $R_1 = 0.0366$ ($wR_2 = 0.0965$). Crystal data, selected bond lengths and angles and hydrogen bonding parameters are listed in Tables 1 and 2.

2.4. DNA cleavage experiments

A stock solution of complex **1** was prepared by dissolving it in Tris–NaCl buffer pH 8.3. This solution was used to react with supercoiled plasmid pBR322 DNA in the presence or absence of hydrogen peroxide. Each sample mixture was incubated with DNA (0.025 μg/μL) at 37 °C for 2 h, and then electrophoresed on 1% agarose gel. A digital

3. Results and discussion

3.1. Characterization of 1 and 2

The FTIR of compound **1** is identical to that of *bis*[*N*-(*N*′-methylacetamido)-L-alaninato]copper(II) trihydrate which was previously synthesized [1]. Therefore, mono-acetamidomethylation of each chelated amino acid in Cu(L-ala)$_2$ by acetamide and formaldehyde has occurred. Its magnetic moment is 1.85 B.M. This value is consistent with a copper(II) complex having an octahedral coordination geometry [10–12]. The fifth and sixth coordination sites are most likely to be the carbonyl oxygen atoms of the two *N*-methylacetamido pendants. In aqueous solution, **1** has a λ_{max} value of 619 nm ($\varepsilon = 46\ M^{-1}\ cm^{-1}$) in the visible region due to a d–d transition and a λ_{max} value of 244 nm ($\varepsilon = 5055\ M^{-1}\ cm^{-1}$) in the UV region due to a LMCT transition. In TN buffer pH 8.3, **1** has the corresponding λ_{max} values of 611 nm ($\varepsilon = 49\ M^{-1}\ cm^{-1}$) and 244 nm ($\varepsilon = 5522\ M^{-1}\ cm^{-1}$). Dissolving **1** in the buffer solution has practically not affected its λ_{max} values. Aqueous solutions of *bis*(aminoacidato)copper(II) typically show a λ_{max} value of ~620 nm when two nitrogen atoms are coordinated to the copper [13]. As these values are far from that of aqueous $CuCl_2$ at 819 nm, it is reasonable to assume that at least most of complex species of **1** are not dissociated in solution.

The crystal structure of compound **2** (Fig. 1) shows that each alaninate moiety in *trans*-Cu(L-ala)$_2$ has reacted with two formaldehyde and two acetamide molecules. The resultant Mannich reaction has yielded two *N*-methylacetamido substituents at the amino nitrogen atom. One of the two *N*-methylacetamido substituents at each amino acid moiety is coordinated at an axial position via its amide carbonyl oxygen atom while the other *N*-methylacetamido group is uncoordinated. Unlike **2**, the original *trans*-Cu(L-ala)$_2$ has its axial positions occupied by the carbonyl oxygen atoms of adjacent molecules [14]. The axial bonds in **2** are stronger as evidenced by the Cu–O bond length of 2.502 Å, compared to the average Cu–O bond length of 2.8 Å in *trans*-[Cu(L-ala)$_2$]. The alaninate amino nitrogen and carboxylate oxygen atoms occupy the equatorial positions in **2**. Therefore, the copper atom has an octahedral environment. However, the octahedron is tetragonally distorted. Interestingly, the copper atom lies on a centre-of-inversion in the crystal structure. The centric nature of **2** implies racemization has occurred as L-alanine has been used to prepare the *trans*-Cu(L-ala)$_2$. This seems consistent with a previous study which shows that Cu(II) and other metal(II) ions can enhance the rate of racemization of L-alanine [15].

The two *N*-methylacetamido substituents at each amino nitrogen atom can be further distinguished by intermolecular and intramolecular hydrogen bonding. N2 of the amido nitrogen of each coordinated *N*-methylacetamido pendant

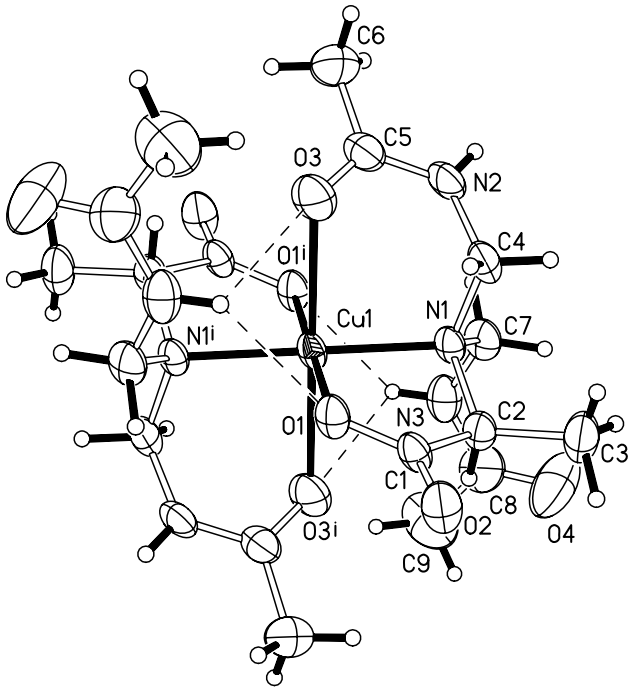

Fig. 1. ORTEP plot of **2** with the atom numbering scheme. The displacement ellipsoids are drawn at the 30% probability. Hydrogen bonding is shown by broken lines.

forms intermolecular hydrogen bonding with the amino acid carbonyl O2 of a neighbouring complex molecule. Each complex molecule thereby forms four such hydrogen bonds. On the other hand, the N3 proton of the amido nitrogen of the uncoordinated *N*-methylacetamido substituent of the *N*,*N*-di-(*N*′-methylacetamido)-L-alaninate ligand forms intramolecular hydrogen bonds with both O1 of the carboxylato oxygen atom and the amide O3 of a coordinated *N*-methylacetamido substituent of the other *N*,*N*-di-(*N*′-methylacetamido)-L-alaninate ligand (Fig. 1). Thus, four intramolecular hydrogen bonds bind together the two coordinated ligands, and this is akin to the hydrogen bonding that gives rise to the secondary structure in certain protein molecules. The prevalence of hydrogen bonding exhibited by **2** suggests a predisposition of the soluble neutral complex **1** towards hydrogen bonding as the predominant bonding mode of the complex towards DNA in the DNA grooves (see Fig. 2).

3.2. EI mass spectral analysis

The EI mass spectra of **1** and **2** show a very similar set of major fragments, viz *m*/*z* 15, 30, 41, 42, 43, 44, 59, 60, 73 and 87 (see Fig. 3 and supplementary information). Both mass spectra show close resemblance to the mass spectrum of acetamide (Wiley.1 ms library file no. 113824). In contrast, the EI-MS of Cu(L-ala)$_2$ and L-alanine (L-ala) show the absence of *m*/*z* peaks 45, 59, 60, 73 and 87. The peak at *m*/*z* 59 in both spectra of **1** and **2** can reasonably be ascribed to the molecular acetamide ion, M^+, which arises from the cleavage of the methylacetamido substituents.

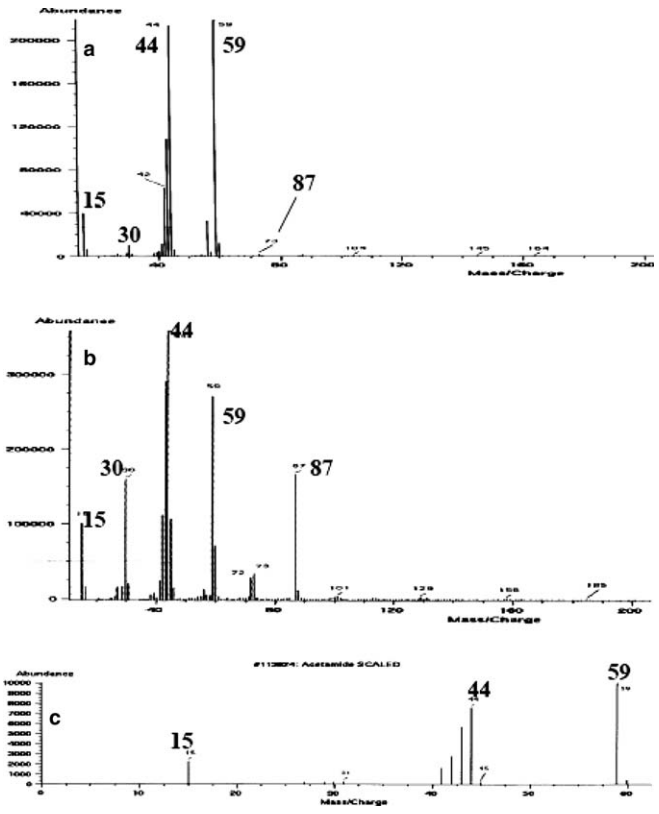

Fig. 2. Electron impact mass spectra of **1** (a), **2** (b) and acetamide (c).

The *m*/*z* 60 may be ascribed to the protonated acetamide ion while the *m*/*z* 87 is probably the immonium ion $+NH_2{=}CHNHCOCH_3$ which arises from simultaneous cleavage of the amino nitrogen from its amino acid moiety and cleavage of one of the attached acetamide moieties in **2**. Cleavage of the α-carbon – amino nitrogen bond in **2** can occur as similar cleavage has been postulated for the fragmentation of free L-alanine [16].

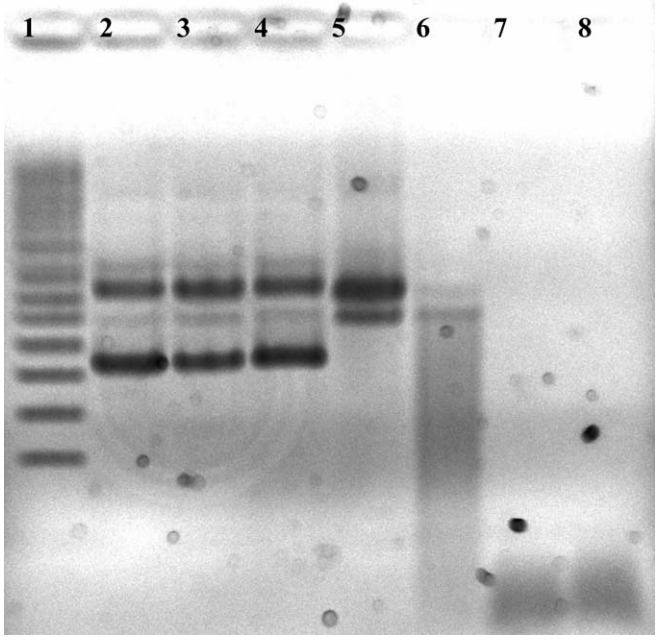

Fig. 3. Effect on the cleavage of pBR322 DNA (0.025 μg/μl) by **1** in the presence of H_2O_2 (4 mM). Lane 1, DNA marker (0.025 μg/μl), Lane 2, pBR322 alone, Lane 3, DNA + H_2O_2 (4 mM), Lane 4, DNA + **1** (6 mM), Lanes 5, 6, 7 and 8, DNA + **1** (25 μM), (50 μM), (3 mM), (6 mM) + H_2O_2, respectively.

3.3. DNA cleavage by *1*

The first set of gel electrophoresis results was obtained by reacting pBR322 DNA with an increasing complex concentration in the presence of hydrogen peroxide (4 mM). Neither incubating DNA with hydrogen peroxide alone nor DNA with 6 mM of complex alone results in any change in the DNA banding patterns (Fig. 3, lanes 3 and 4, respectively) compared to the control DNA lane (lane 2). Complex **1** (25 μM) in the presence of hydrogen peroxide caused cleavage of the DNA (Fig. 3, lane 5). Here, the entire supercoiled DNA has been converted to a more intense band of nicked DNA and a less intense band of linear DNA. The necessity of hydrogen peroxide for DNA cleavage suggests oxidative cleavage. Similar oxidative cleavage of DNA have been reported for various copper(II) complexes of other types of ligands [17,18]. At 50 μM complex concentration, all the nicked DNA has been cleaved and only a light band of linear DNA and a smear of degraded DNA are observed (Fig. 3, lane 6). Increasing the complex concentration further to 3 and 6 mM causes total degradation of the DNA. The above DNA cleavage mechanism by complex **1** is dissimilar to that of the copper(II)-L-histidine complex which is hydrolytic and where hydrogen peroxide is not needed [5].

The above electrophoresis experiment was repeated incubating a different batch of pBR322 DNA with increasing concentration of the complex in the range 15–60 μM with a lower concentration of hydrogen peroxide (2 mM; previously, the $[H_2O_2] = 4$ mM). A comparison is also made with Cu(L-ala)$_2$. Again complex **1** (60 μM) alone or hydrogen peroxide alone does not cause any change in banding patterns. This again implies that any cleavage of the DNA has to be oxidative. 15 and 35 μM of the complex are unable to cleave the DNA oxidatively (Fig. 4, lanes 5 and 6). At concentrations of 40 and 60 μM, the complex causes extensive degradation of the DNA in the presence of hydrogen peroxide via an oxidative mechanism. The precursor complex of **1** (60 μM), Cu(L-ala)$_2$, can also produce extensive oxidative cleavage of the DNA in the presence of hydrogen peroxide as a smear of DNA is observed (Fig. 4, lane 4). As lower density fragments are only present in the smear produced by 40 μM of **1** (Fig. 4, lane 7), it can be concluded that the nucleolytic ability of the complex **1** is higher than that of Cu(L-ala)$_2$. The complex **1** has an *N*-methylacetamido substituent group which has resulted from the reaction of **1** with formaldehyde and acetamide. The greater cleavage of **1** may be reasonably ascribed to the presence of these substituents.

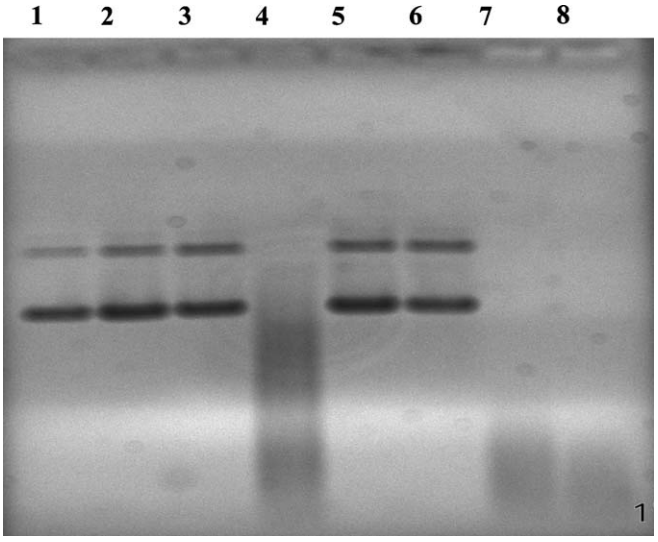

Fig. 4. Agarose (1%) gel electrophoresis banding patterns of pBR322 DNA (0.025 μg/μl) reacted with varying concentrations of **1** in the presence of H_2O_2 (2 mM). Lane 1, DNA alone, Lane 2, DNA + **1** (60 μM), Lane 3, DNA + H_2O_2, Lane 4, DNA + Cu(L-ala)$_2$ (60 μM), Lanes 5, 6, 7 and 8, DNA + **1** (15 μM), (25 μM), (40 μM) and (60 μM) + H_2O_2, respectively.

scale, and the crystal structure of newly prepared lithium bis(fluorosulfuryl)imide.

2. Results and discussion

2.1. Preparation of alkali metal bis(fluorosulfuryl)imides

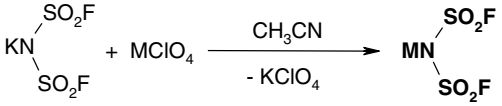
Attempts to prepare lithium bis(fluorosulfuryl)imide (**LISFI**) were made in our laboratory in last years. Unfortunately, no experiments led to a crystalline product [14]. This fact can be ascribed to the extreme solubility of **LISFI** in water and polar organic solvents. Therefore we looked for such approaches that could yield crystalline **LISFI**. For example, we tried to prepare lithium salt by the reaction of $HN(SO_2Cl)_2$ with anhydrous LiF or by the reaction of $LiClO_4$ with $KN(SO_2F)_2$ in oxygen-containing solvents (tetrahydrofuran, anisole, triglyme). The utilization of these solvents was based on the assumption that they can serve as ligands for lithium atom and the formation of complexes (or only solvates) thus can enable the crystallization of the lithium salt. Unfortunately, none of above mentioned ways led to a crystalline product.

At last, we were successful in the preparation of lithium and sodium salts according to Scheme 1.

The lithium salt obtained by this reaction was crystalline and thus its molecular and crystal structures could be determined by X-ray diffraction. The last traces of water coming from $LiClO_4$ were removed by action of thionyl dichloride.

The *sodium salt* was prepared in the same manner. Though this substance was also prepared in a crystalline state we were not able to grow appropriate monocrystals for X-ray structural determinations.

However, *rubidium and cesium* salts cannot be prepared by the above-mentioned way because of negligible solubility of $RbClO_4$ and $CsClO_4$ in polar organic solvents.



Scheme 1. Reaction of $KN(SO_2F)_2$ with $MClO_4$ (M = Li, Na) in acetonitrile.

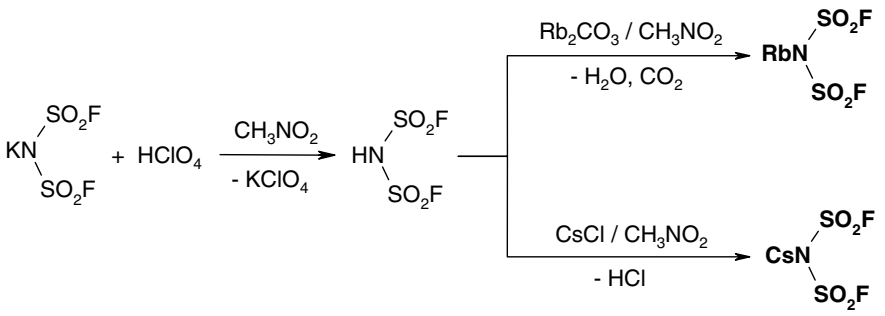
Therefore, we had to liberate free imido-bis(sulfuric acid) difluoride from its potassium salt in nitromethane by the action of conc. $HClO_4$. The solution of free imido-bis(sulfuric) acid difluoride was filtered off from precipitated $KClO_4$ and then was converted into a corresponding salt. Salts were precipitated from the solution by addition of dichloromethane. Scheme 2 shows the preparation of Rb and Cs salts.

The products of all synthetic reactions were followed by ^{19}F NMR spectroscopy. It was found that ^{19}F NMR spectra (in tetrahydrofuran) contain only one resonance signal (singlet) that can be ascribed to a corresponding bis(fluorosulfuryl) imide ion: $LiN(SO_2F)_2$ (54.80 ppm), $NaN(SO_2F)_2$ (51.40 ppm), $RbN(SO_2F)_2$ (51.45 ppm), $CsN(SO_2F)_2$ (51.69 ppm). Therefore, ^{19}F NMR spectroscopy confirms high fluorine purity of prepared salts.

2.2. Vibrational spectra

The wavenumbers and intensities of all bands observed in infrared spectra of prepared alkali metal bis(fluorosulfuryl)imides are given in Section 3. A comparison with infrared data of potassium, rubidium, and cesium salts recorded earlier [3,4,7] in the frequency range 700–2000 cm^{-1} shows a very good agreement. The recorded Raman spectra of alkali metal salts were complemented with the spectrum of $KN(SO_2F)_2$ which was obtained according to [7] and are shown in Fig. 1. The low intensity bands occurring in the Raman spectra of $LiN(SO_2F)_2$ and $NaN(SO_2F)_2$ at 940 and 941 cm^{-1}, respectively, were assigned to the ν_1 fundamental vibration of a perchlorate impurity that is present due to the used preparation method.

The Raman spectral data and band assignments of an $N(SO_2F)_2$ group have been reported for a number of the neutral and cationic Xe(II) derivatives of bis(fluorosulfuryl)imide, $FXeN(SO_2F)_2$ [15], $Xe[N(SO_2F)_2]_2$ [16], and $XeN(SO_2F)_2^+$ [17]. Since the vibrational spectra of the $N(SO_2F)_2^-$ anion in alkali metal salts were so far not studied in a greater detail, we attempted to assign its fundamental stretching modes at least. Because the absorption bands in infrared spectra are mostly broad and exhibit numerous shoulders, only the recorded Raman spectra with much better resolved sharp lines were taken into consideration.



Scheme 2. The preparation of $RbN(SO_2F)_2$ and $CsN(SO_2F)_2$.

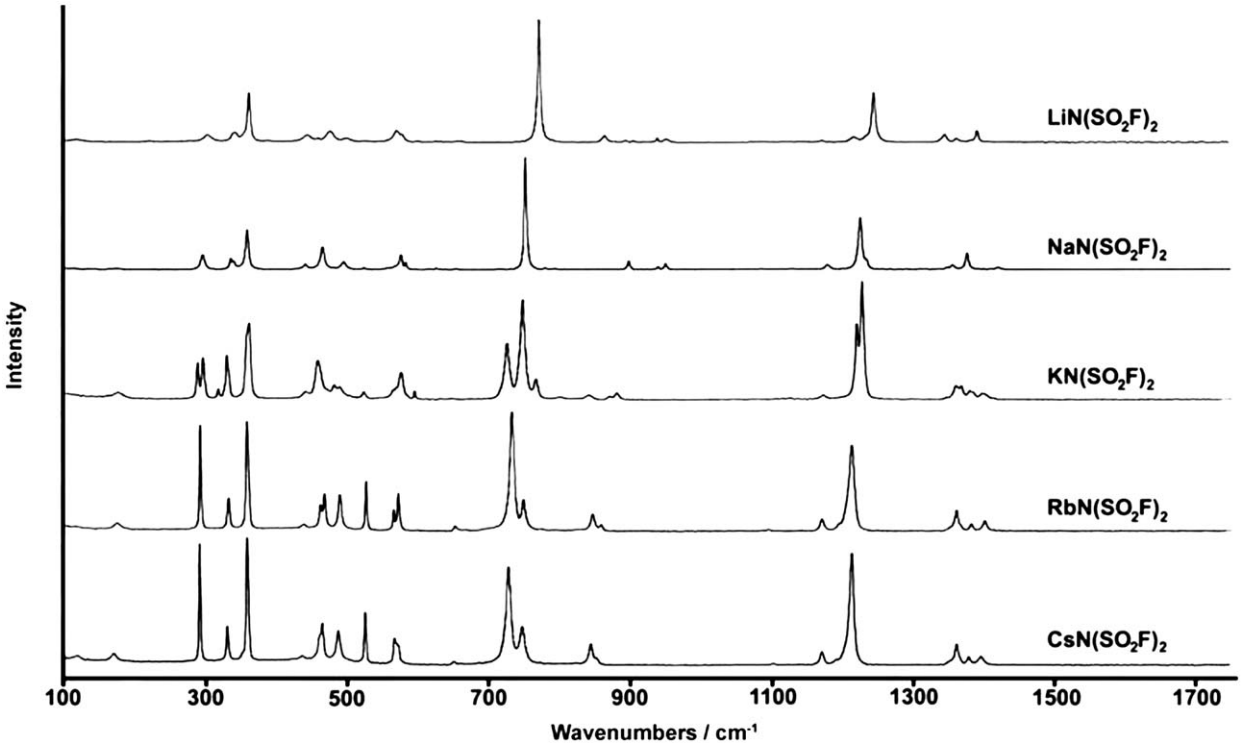


Fig. 1. Raman spectra of alkali metal bis(fluorosulfuryl)imides. K-salt was prepared according to [7].

Regardless of the actual molecular symmetry of the $N(SO_2F)_2^-$ anion in particular salts (approximately C_s for Li^+ and C_2 for Cs^+), there is eight normal stretching vibrations and all of them should be Raman and infrared active. Their tentative assignments are based mainly on previous assignments for related covalent derivatives of Xe(II) [15–17] and the isoelectronic molecule $O(SO_2F)_2$ [18], and are given in Table 1.

As follows from Fig. 1, there are four distinct groups of bands in the region of stretching vibrations above 700 cm^{-1}. Bands that occur between 1346–1421 and 1172–1246 cm^{-1} are assigned to the $\nu_{as}SO_2$ and ν_sSO_2 modes, respectively, and their average frequency is roughly invariable for the particular salts. The frequency of $\nu_{as}SO_2$ is about 100 cm^{-1} lower than for covalent compounds and indicates rather ionic character of an $N(SO_2F)_2$ group [19].

Table 1
Tentative assignments of normal stretching vibrations in Raman spectra of alkali metal bis(fluorosulfuryl)imides

Stretching mode[a]	$LiN(SO_2F)_2$	$NaN(SO_2F)_2$	$KN(SO_2F)_2$	$RbN(SO_2F)_2$	$CsN(SO_2F)_2$

	1392	1421	1381	1400	1396
		1409			

[a] Frequencies in cm^{-1}.
[b] ν In-phase motions; ν' out-of-phase motions of SO_2F groups.
[c] Values in parentheses denote infrared data.

On the other hand, the average frequencies of the two remaining band groups are not constant and exhibit a continual shift to higher wavenumbers when going from Cs^+ to Li^+ salt.

The high intensity lines in the 727–774 cm^{-1} range are assigned to the ν_s SNS mode and an increase of its average frequency from 738 cm^{-1} in $CsN(SO_2F)_2$ to 774 cm^{-1} in $LiN(SO_2F)_2$ corresponds well to the observed shortening of an average S–N bond length from 1.577(3) to 1.556(2) Å, respectively. However, the average S–N bond distances in $FXeN(SO_2F)_2$ (1.626(3) Å) [20] or $XeN(SO_2F)_2^+$ (1.69(1) Å) [17] are significantly longer than those found in alkali metal salts and, consequently, the ν_s SNS mode in these compounds should occur at lower frequency. Its reported assignment to the bands occuring in the range 797–830 cm^{-1} [16,17] therefore does not seem reasonable.

The low intensity lines, which are observed in the region 843–956 cm^{-1}, involve likely both νSF and ν_{as}SNS stretching modes. Earlier studies on the vibrational spectra of alkali metal fluorosulfates have indicated that the position of νSF in SO_3F^- is related to the polarizing power of the cation. Thus, going from the $CsSO_3F$ to $LiSO_3F$, the frequency of the νSF vibration changes quite significantly from 715 to 812 cm^{-1} [21]. Therefore, a similar set of gradually increasing Raman frequencies was chosen for the νSF stretching modes in $M^IN(SO_2F)_2$ and the remaining frequencies were attributed to the asymmetric stretch of the SNS bridge, ν_{as}SNS. Due to extremely low intensity of these bands, they were not observed in the Raman spectra of Na^+ and Rb^+ salts. For this reason, Table 1 was completed by the corresponding infrared data.

A marked increase of the frequency of ν SF and the moderate one of ν_sSNS and ν_{as}SNS in vibrational spectra of $LiN(SO_2F)_2$ and $NaN(SO_2F)_2$ is obviously related to their descending ionic character with respect to analogous salts of the heaviest alkali metals. A comparison of crystal structures of $CsN(SO_2F)_2$ [9], $KN(SO_2F)_2$ [8], and $LiN(SO_2F)_2$ indicates increasing cation–anion interactions in this order. A withdrawal of charge through the oxygen atoms of the anion by the cation therefore increases, resulting in increased pπ–dπ bonding between sulfur and fluorine and, to a smaller extent, between sulfur and nitrogen. Since a measure for the bond strengths are the internal stretching force constants, which in turn depend on vibrational frequencies, a strengthening of the S–F and S–N bonds results in a higher frequency of the corresponding stretching modes.

2.3. The crystal structure of LISFI

The basic crystal data and some details about the data collection and structure solution are given in Table 2, selected interatomic distances (Å) and angles (in degrees) in $LiN(SO_2F)_2$ and $HN(SO_2F)_2$, $KN(SO_2F)_2$, and $CsN(SO_2F)_2$ for comparison are collected in Table 3.

The structure is composed of cations and anions with strong cation–anion interactions. The asymmetric unit (Fig. 2) contains one anion in a general position and three non-equivalent Li^+ cations in special positions. Each anion is thus coordinated by three Li^+ cations and, in turn, each lithium cation is coordinated by six oxygen atoms. Li(1) is coordinated by three anions acting as

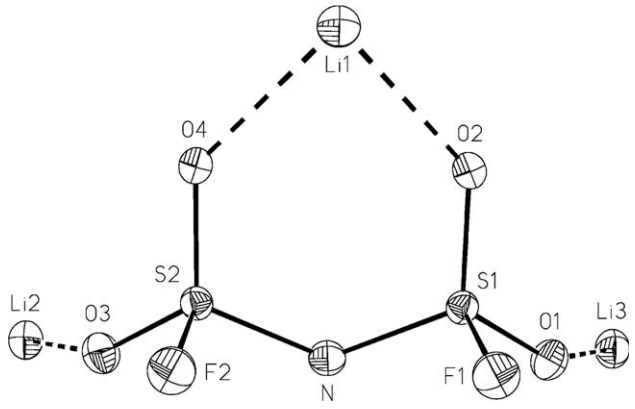

Fig. 2. Asymmetric unit of LISFI. Thermal ellipsoids are drawn on the 50% probability level.

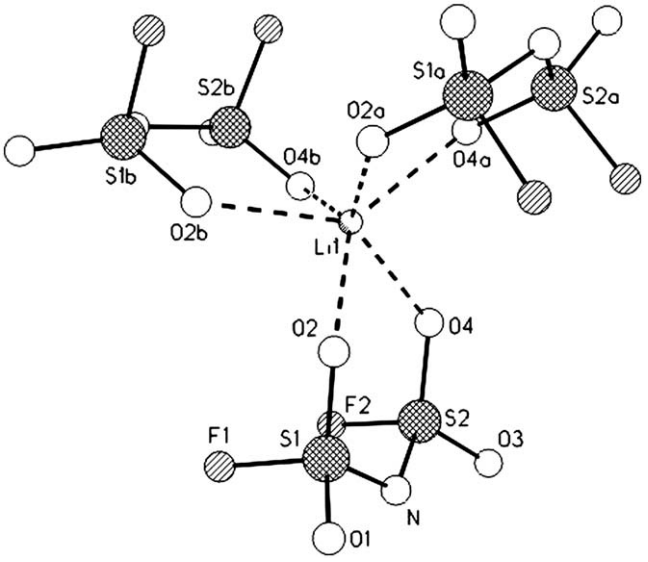

Fig. 3. Arrangement of $N(SO_2F)_2$ anions around Li1 (trigonal prismatic). Symmetry codes: O2a, O4a: $-x, 1+x-y, z$; O2b, O4b $-x+y-1, -x, z$.

bi-dentate ligands in regular trigonal prismatic arrangement (Fig. 3), while both Li(2) and Li(3) are coordinated identically by six mono-dentate anions forming distorted octahedrons (Fig. 4).

A brief search in the inorganic crystal structure database (ICSD) [22] revealed that most of Li salts of inorganic oxoacids possess tetragonal coordination of Li, e.g., carbonate, phosphate, selenate, sulfate, fluorosulfate, arsenate, etc. Octahedral coordination of Li is less common, e.g., in nitrate, perchlorate, trihydrogen bis(selenite), iodate(III). The coordination of Li in LISFI can be best compared with related compounds, $LiN(SO_2CF_3)_2$ [23] and $LiN(SO_2CF_3)_2 \cdot H_2O$ [24]. Tetrahedral coordination of Li in $LiN(SO_2CF_3)_2$ can be explained by a presence of bulky CF_3 groups which prevent anions to form chelate rings with Li and thus they serve only as bridging ligands. On the other hand, in $LiN(SO_2CF_3)_2 \cdot H_2O$ Li atoms are coordinated octahedrally by both chelating and bridging anions and water molecules.

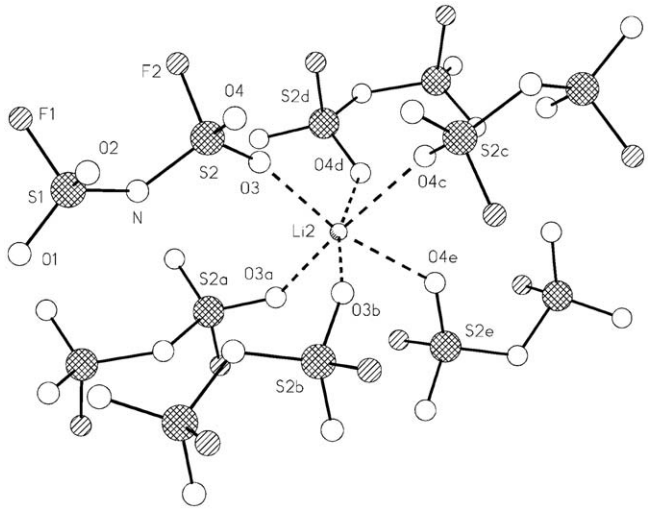

Fig. 4. Arrangement of $N(SO_2F)_2$ anions around Li2 and Li3, respectively (distorted octahedral). Symmetry codes: O3a: $1-x, 1+x-y, z$; O3b: $-x+y, 1-x, z$; O4c: $-x, 1-y, -z$; O4d: $y, -x+y, -z$; O4e: $1+x-y, 1+x, -z$.

Li–O distances in LISFI (2.020–2.201 Å) compare well with those observed in $LiN(SO_2CF_3)_2 \cdot H_2O$, 2.019–2.375 Å.

The anions in LISFI are in the "*cis*" positions having fluorine atoms on the same side of the plane defined by S–N–S bonds. This further supports previous observations that the actual configuration of $N(SO_2R)_2$ moieties depends on the character of intermolecular or cation–anion interactions [8].

A comparison of interatomic distances and angles of **LISFI** with those for free imide and K and Cs salts (Table 3) suggests that the free electron pair of the N atom is delocalized mainly in the S–N–S backbone. This fact is supported by identical bond lengths S1–N and S2–N (1.556(2) Å). Moreover, the bond order of both S–N bonds is significantly greater than 1 as compared with S–N single bond 1.775(3) in H_3NSO_3 [25].

3. Experimental

All reactions were performed under nitrogen in anhydrous conditions using conventional Schlenk techniques.

Solvents were dried by conventional methods prior to use [26]. Thionyl dichloride was supplied by Fluka and distilled with quinoline and linen oil before use [26]. Other chemicals were supplied by Lachema or Merck (p.a.).

^{19}F NMR spectra were recorded in THF using a Bruker AVANCE DRX 300 instrument.

IR and Raman spectra were recorded on a FT-IR Bruker EQUINOX IFS 55/S spectrometer with FRA 106/S equipment. IR spectra were measured as Nujol mulls between KBr windows, Raman spectra were excited by using Nd:YAG laser ($\lambda = 1064$ nm), maximal output 500 mW. Samples were measured in glass ampoules.

Intensity data were collected on a KUMA KM-4 κ-axis diffractometer equipped with CCD detector with graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at 120 K. The structure was solved by direct methods and refined anisotropically by full-matrix least-squares method. The software packages used were: Xcalibur CCD system [27] for the data collection/reduction, and SHELXTL V5.1 system [28] for the structure solution, refinement, and drawings (thermal ellipsoids are drawn at the 50% probability level).

3.1. Lithium bis(fluorosulfuryl) imide

2.5 g (23.6 mmol) dried $LiClO_4$ was dissolved in 20 ml acetonitrile in a Schlenk vessel and the solution of 5 g (22.8 mmol) $KN(SO_2F)_2$ in 5 ml acetonitrile was slowly dropwise added under stream of dry nitrogen. After the addition of the whole volume of $KN(SO_2F)_2$ solution, the reaction mixture was stirred for another 30 min. Precipitated $KClO_4$ was removed by vacuum filtration. Acetonitrile from the filtrate was then evaporated (2 kPa/40 °C) and the viscous almost colorless residue was then heated on the oil bad at 60 °C/650 Pa for 45 min. The content of the reaction vessel was left to crystallize at ambient temperature for next 24 h. The reaction mixture changed into crystalline mass containing small amount of the liquid. The desiccation of raw lithium salt was achieved by using of thionyl dichloride. The suspension of $LiN(SO_2F)_2$ in 5 ml thionyl dichloride was stirred 2.5 h at room temperature. The crystalline mass was filtered off under vacuum, washed three times by 5 ml portions of dichloromethane and dried in vacuum at 650 Pa. The product was placed into a tube and sealed. M.p. 124–128 °C. Yield: 3.8 g (88% of the theory). IR (cm^{-1}): 1378 vs, 1225 m, 1182 vs, 1121 m, 861 m, 789 m, 758 sh, 573 m.

3.2. Sodium bis(fluorosolfuryl) imide

3.5 g (28.6 mmol) dried $NaClO_4$ was dissolved in 20 ml acetonitrile in a Schlenk vessel and the solution of 6.2 g (28.3 mmol) $KN(SO_2F)_2$ in 10 ml acetonitrile was slowly dropwise added under stream of dry nitrogen. After 30 min of stirring the precipitated $KClO_4$ was filtered off under vacuum. Acetonitrile from the filtrate was evaporated (2 kPa/40 °C) and the viscous almost colorless residue was then heated on the oil bad at 50 °C/650 Pa for 60 min. The content of the vessel was left to crystallize at ambient temperature for next 24 h. The desiccation of raw sodium salt was done using thionyl dichloride. The suspension of $NaN(SO_2F)_2$ in 5 ml thionyl dichloride was stirred 1 h at room temperature. The crystalline mass was filtered off by vacuum, washed three times by 10 ml portions of dichloromethane and dried in vacuum at 650 Pa. The product was placed into a tube and sealed. M.p. 112–117 °C. Yield: 5.0 g (87% of the theory). IR (cm^{-1}): 1378 vs, 1364 s, 1229 m, 1178 m, 1124 m, 856 s, 777 m, 757 m, 654 vw, 573s, 496 w, 467 w, 442 vw.

3.3. Rubidium and cesium bis(fluorosulfuryl)imides

10.0 g (45.7 mmol) potassium bis(fluorosulfuryl) imide was dissolved in 20 ml nitromethane in a Schlenk vessel and 4.3 ml (49.9 mmol) 70% $HClO_4$ was dropwise added under cooling. The reaction mixture was stirred for 15 min. Precipitated $KClO_4$ was then filtered off under vacuum and the precipitate was twice washed by 5 ml portions of nitromethane. 6.0 g (26.0 mmol) anhydrous Rb_2CO_3 (during this reaction CO_2 is released) or 10.0 g (59.4 mmol) CsCl, respectively, was then added in small portions to combined filtrates of the $HN(SO_2F)_2$ solution under cooling. The reaction mixture was allowed to stand at room temperature for 30 min, solvent was evaporated under vacuum (ca. 2 kPa/50 °C). Crystalline raw product was pulverized and last traces of solvents were evaporated under vacuum. Rb and Cs salts were twice extracted by 20 ml portions of tetrahydrofuran, combined extracts were evaporated (2 kPa/40 °C) to 1/3 of the original volume and the isolation of solid salts was achieved by dropwise addition of dichloromethane. The IR spectra of Rb and Cs salts correspond to the published data [4]. Rb-salt: m.p. 92–96 °C, yield 10.6 g (87% of the theory), IR (cm^{-1}): 1376 vs, 1224 m, 1167 s, 1103 sh, 1092 m, 844 m, 823 sh, 768 s, 735 m, 581 m, 566 s, 491 w, 465 w, 440 w; Cs salt: m.p. 112–116 °C, yield 12.8 g (90% of the theory), IR (cm^{-1}): 1377 vs, 1221 m, 1172 s, 1100 s, 841 m, 818 sh, 764 s, 728 m, 581 m, 567 s, 489 w, 462 w, 437 w.

4. Supplementary material

Required for Ordering Data Sets, ICSD, Fachinformazionszentrum Karlsruhe.

For ordering, just send us an e-mail with the ICSD number (No. 415 618 for LISFI). It is urgently recommended to name at least the authors of the publication and the chemical formula of the compound, which will enable us to identify the record even if the CSD number was misspelled or transmitted incorrectly. The title of the deposited data set is not entirely reliable as it may be only a provisional title, and the publisher listed is the one to which the publication was to be sent at the date of deposition. E-mail: infodienste@fiz-karlsruhe.de.

azoimidazole system and the importance of a Cu(N,S) chromophore [19] has stimulated us to design thioether functionalized azoimidazole ligands and their copper complexes. In this first report, we summarize copper(II) complexes of 1-alkyl-2-{(*o*-thioalkyl)phenylazo}imidazoles and their mixed ligand complexes. The complexes are characterized by spectroscopic and electrochemical techniques. A structure of one of the complexes has been confirmed by X-ray diffraction study.

2. Results and discussion

2.1. 1-Alkyl-2-{(*o*-thioalkyl)phenylazo}imidazoles

Imidazolylazothioether belongs to tridentate N, N′, S donor system. They are synthesized (Scheme 1) by coupling *o*-(thioalkyl)phenyldiazonium ions (**1**) with imidazole in aqueous sodium carbonate and purified by solvent extraction and a chromatographic process.

The alkylation is carried out by adding alkyliodide (MeI, EtI) in dry THF solution to the corresponding 2-{*o*-(thioalkyl)phenylazo}imidazole in the presence of sodium hydride. The ligands are new. They are abbreviated as SRaaiNR′ (**3**, **4**). The donor centers are N(imidazole) (N), N(azo) (N′) and thioether (S). The atom numbering is shown in Scheme 1. Sharp intense single bands at 1420–1430 and 1580–1600 cm^{-1} correspond to ν(N=N) and ν(C=N) + ν(C=C), respectively. The ν(N–H) in **2** appears as a medium intense sharp stretch at 3010 cm^{-1} along with multiple peaks at 2800–2900 cm^{-1} corresponding to ν(C–H). The UV–Vis spectra in methanol show two strong absorptions ($\varepsilon \sim 10^4\ M^{-1}\ cm^{-1}$) at 350–355 and 250–265 nm along with two shoulders ($\varepsilon \sim 10^3\ M^{-1}\ cm^{-1}$) in longer wavelength region, 400–415 and 450–460 nm.

The structure has been established by ^{1}H NMR spectral data. The alkylation of imidazole is supported by the disappearance of δ (N–H) at ~10.30 ppm (of **2**) and the appearance of an alkyl signal at 1.5–4.5 ppm for **3** and **4**: The N(1)–Me appears as singlet at ca. 4.00 ppm; N–CH_2–CH_3 shows a quartet for –CH_2– at ca. 4.5 (10 Hz) and a triplet at ca. 1.5 (8.0 Hz) ppm. The imidazole 4- and 5-H appear as broad singlets at 7.2–7.3 and 7.0–7.1 ppm, respectively. Broadening may be due to rapid proton exchange between these imidazolic protons. The thioalkyl group S–R also exhibits a singlet signal at 2.4 ppm for S–Me of SMeaaiNR′ (**3**). SEtaaiNEt (**4b**) shows two quartets [4.46 (9.0 Hz) and 3.00 (8.0 Hz) ppm for –CH_2– protons of N–CH_2–(CH_3) and S–CH_2–(CH_3), respectively] and two triplets [at 1.48 (8.0 Hz) and 1.33 (8.0 Hz) ppm for –(N–CH_2)CH_3 and –(S–CH_2)CH_3, respectively]. The thiophenyl protons (8-H to 11-H) have been influenced by S–R substituents. Their assignment has been done by comparing with the spectra of thioalkylazobenzene [34]. The 11-H and 8-H appear as doublets at ca. 7.8 and 7.2 ppm, respectively. The closer proximity of the electron withdrawing –N=N– group may be the reason for the higher δ of 11-H.

2.2. Copper complexes. Cu(SRaaiNR′)Cl_2 (**5**, **6**)

Copper(II) complexes of these ligands were obtained by mixing equimolar concentrations of $CuCl_2 \cdot 2H_2O$ and SRaaiNR′ in methanol. All the complexes are soluble in common organic solvents. Microanalytical data and copper analyses have confirmed the composition of the complexes as Cu(RSaaiNR′)Cl_2 (**5**, **6**). Infrared spectra of the complexes exhibit ν(N=N) and ν(C=N) at 1420–1430 and 1575–1580 cm^{-1}, respectively, and these values are red shifted by 10 cm^{-1}. This supports coordination of azo-N(N′) and imidazole-N to Cu(II).

The electronic spectra (in MeOH) of the complexes exhibit multiple high intense transitions ($\varepsilon \sim 10^4\ M^{-1}\ cm^{-1}$) (Table 1) at 500–250 nm along with a weak transition at 680–720 nm ($\varepsilon \sim 200\ M^{-1}\ cm^{-1}$). The spectra are compared with free ligand data under identical conditions. Intraligand charge transfers n–π^* and π–π^* appear at 370–380 and 250–260 nm, respectively. Other transitions at 680–720, 440–450 and 445–455 nm are new and are only observed in the complexes (Table 1). Also, the thioalkylazoimidazoles ligands possess a thioalkyl (–SR) reducing center. Copper(II) complexes containing coordinated –SR group(s) exhibit strong S (thioether) → Cu^{II} LMCT bands.

Copper(II)–azoheterocycles [7,13,20,21] exhibit a strong MLCT transition involving d(Cu) → π*(arylazoheterocycle) because of efficient π-acidity of the ligands. On comparing with copper(II)-1-alkyl-2-(arylazo)imidazoles [23], pyridylthioazophenolates [35] and other pyridylthioether [19,36] based N, S donor ligands we may assign the 470–475 nm band as MLCT [d(Cu) → π*(azoimidazole)] and the 445–455 nm band as LMCT (S → Cu(II)) transitions. The very weak absorption at 680–720 nm ($\varepsilon \sim 200$ $M^{-1}\ cm^{-1}$) is undoubtedly a d–d transition [37].

2.3. Crystal structure of $Cu(SEtaaiNEt)Cl_2$

The X-ray structure of $Cu(SEtaaiNEt)Cl_2$ (**6b**) is shown in Fig. 1. The selected bond lengths and angles are listed in Table 2. The ligand serves as tridentate NN′S donor system. [N and N′ refer to N(imidazole) and N(azo) centers, respectively.] The bond parameters suggest a distorted square pyramidal geometry around the copper center. The basal plane is constituted by Cu(N,N′,S)Cl(1). One of the Cl ligands occupies an axial position (Cl(1)). The two Cu–Cl distances are different and the axial Cu–Cl(1) bond [2.4273(8) Å] is elongated by ~0.2 Å more than the Cu–Cl(2) bond [2.2296(8) Å]. There are two different N-donor centers N(imidazole)[N(1)] and N(azo) [N(4)]. The Cu–N distances do not vary significantly; Cu–N(azo) is slightly

Table 2
Bond distances and bond angles of [Cu(SEtaaiNEt)Cl_2] (**6b**)

Bond distances (Å)		Bond angles (°)	
Cu(1)–S(1)	2.3788(8)	S(1)–Cu(1)–Cl(1)	98.65(3)
Cu(1)–Cl(2)	2.2296(8)	S(1)–Cu(1)–Cl(2)	96.22(3)
Cu(1)–Cl(1)	2.4273(8)	S(1)–Cu(1)–N(1)	151.68(7)
Cu(1)–N(1)	2.014(2)	S(1)–Cu(1)–N(4)	80.93(6)
Cu(1)–N(4)	2.022(2)	Cl(1)–Cu(1)–Cl(2)	109.10(3)
N(3)–N(4)	1.272(3)	N(1)–Cu(1)–N(4)	77.88(9)
C(1)–N(4)	1.404(3)	N(1)–Cu(1)–Cl(1)	98.65(7)
C(8)–N(3)	1.374(3)	N(1)–Cu(1)–Cl(2)	99.07(7)
		N(4)–Cu(1)–Cl(1)	86.67(6)
		N(4)–Cu(1)–Cl(2)	164.23(6)

elongated (Cu(1)–N(4), 2.022(2) Å) compared to Cu–N(imidazole) (Cu(1)–N(1), 2.014(2) Å). This is contrary to the data previously reported for Cu(II)–azoimidazole complexes [23] in which N(imidazole) prefers Cu(II) to interact in stronger way than the N(azo) center. The presence of a third donor center, –SEt, may force N(azo) to chelate with Cu(II), which may be responsible for the squeezing of the Cu–N(azo) distance. The Cu–S bond distance [2.3788(8) Å] lies at the left side of the reported range of 2.3–2.8 Å [12,13,35,36]. There are two forces operating to make Cu–N(azo) a strong bond: the softening of Cu(II) on coordination to thioether–S and the structural demand of the tridentate N,N′,S system. Two chelate planes [Cu(1), S(1), C(1), C(2), N(4), deviation ⩽0.1 Å; Cu(1), N(1), C(8), N(3), N(4), mean deviation ⩽0.03 Å] are no longer planar and make a dihedral angle of 14.41(8)°. The azoimine chelated motif -Cu(-N=N-C=N-) forms a better plane than the thioazo chelating -Cu(-S -C=C -N-) unit. The large size of thioether–S may be the reason for the distortion.

2.4. Electrochemistry

The cyclic voltammogram shows a reductive response at ca. 0.2 V versus Ag/AgCl along with two couples at the negative side (Table 1 and Fig. 2). The free ligand does not show any oxidation but irreversible reductive responses appear at <−1.0 V. On comparing with the CV of Cu(RaaiR′)$_2X_2$ (X = N_3, NCS) [23], the quasireversible response at 0.2 V ($\Delta E_P > 100$ mV) may be ascribed to a Cu(II)/Cu(I) response. On traversing to the negative direction at a potential <−0.6 V, the scan reversal shows upsurge of current at av. −0.3 V followed by a Cu(II)/Cu(I) couple at av. 0.2 V. The desorption spike reflects deposition of Cu metal on the working electrode surface after reduction to copper(0). A clear Cu(I)/Cu(0) couple is not observed. To get a true picture the sweep of the CV has been started from 0.4 V in the negative direction up to −1.6 V. The reduction of Cu(II) → Cu(I) is observed at about 0.1 V and ligand reductions below −0.5 V. On scan reversal anodic peaks of the respective reductions appear at the usual positions in addition to a sharp anodic current upsurge at −0.3 V. The peak-to-peak separation of the redox couple is largely dependent on the scan rate and increases from 120 mV at 10 mV s^{-1} to 600 mV at 1000 mV s^{-1}. At slow scan rates (10–50 mV s^{-1}) ΔE_P remains almost constant as do the E_{Pa} and the E_{Pc} values. This observation suggests a low heterogeneous electron-transfer rate constant, which has been influenced by the applied potential [38]. Two quasireversible couples at −0.8 and −1.3 V are the description of [-N= N-] / [- N $\dot{-}\dot{-}$ N-] $^-$ and [-N $\dot{-}\dot{-}$ N-] $^-$ / [-N-N-] $^{=}$, respectively (Table 1).

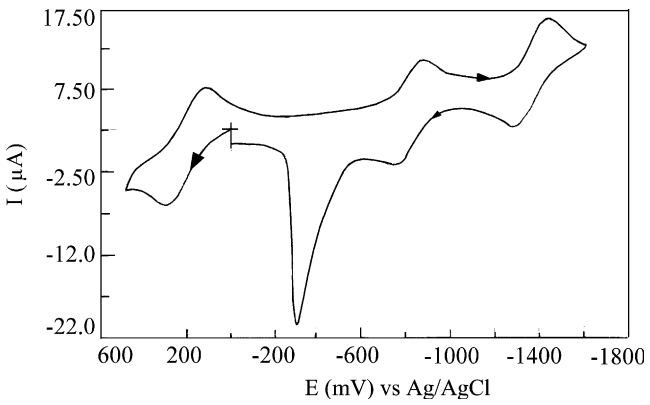

Fig. 2. Cyclic voltammogram of [Cu(SMeaaiNEt)Cl_2] in MeCN.

2.5. EPR studies

Polycrystalline spectra of Cu(SRaaiNR′)Cl_2 (**5**, **6**) at room temperature (298 K) are weakly resolved. The low resolution of the polycrystalline spectra is usual where copper centers are relatively close together, the hyperfine splitting is poor due to paramagnetic charge narrowing. However, the resolution is better in the solution, therefore the spectra (77 K) were used to determine the EPR parameters. The EPR spectra of Cu(II) complexes provide information about hyperfine and super-hyperfine structures which helps in defining the geometry and distortion of the complexes. The parallel region of the spectra is somewhat complicated compared to a single copper system and may be due to the presence of structurally different species. This means, at least in solution phase, Cu(II) may exist in geometrically different environments. The following possibilities may be considered: the existence of square pyramidal and trigonal bipyramidal geometries of Cu(NNS)Cl_2 or partial dissociation of Cl^- from the complex in MeOH forming solvento species. The conductance measurement in MeOH does not show any significant increment in molar conductivity (Λ_M = 7–9 Ω^{-1} mol^{-1}). Besides, trigonal bipyramidal Cu(II) centers give very characteristic 'inverse' EPR spectra, and no such inverse signal is present in Fig. 3. Therefore, the presence of a trigonal bipyramidal geometrical isomer of Cu(NNS)Cl_2 has been precluded. This contradiction may be explained by considering the presence of a solvated intimate ion-pair in the strongly interacting solvent MeOH, giving a mixture of different tetragonal Cu(II) species [Cu(NNS)Cl(MeOH)$^+ \cdot Cl^-$]. Mononuclear complexes show the usual four line (^{63}Cu, I = 3/2) EPR spectra and are anisotropic at higher magnetic field. The peaks of low

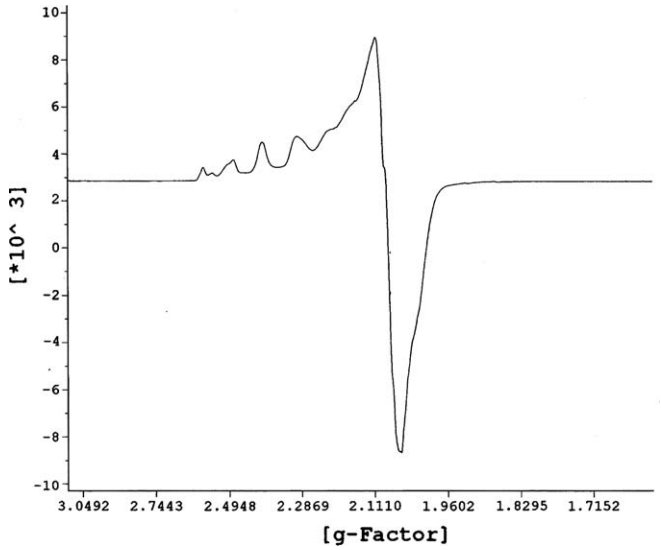

Fig. 3. EPR spectrum of Cu(SMeaaiNEt)Cl_2 (**5b**) in MeOH at 77 K.

intensity in the weaker field are considered to originate from the $g_{\|}$ component and $A_{\|}$ lies in the range 155–175 × 10^{-4} cm^{-1}. The calculated $g_{\|}$ and $g_{\perp}$ values for these complexes were 2.2–2.4 and 2.0–2.1, respectively. The relation $g_{\|} > g_{\perp} > 2.0023$ agrees with the ground state configuration of $d_{x^2-y^2}$. The super-hyperfine coupling constant $A_{\perp}$ averages to 16×10^{-4} cm^{-1} and is in the range for a Cu–N interaction [23]. For CuN_2 coordination there will be (2 × 2 + 1), 5 responses and they are observed, indeed (Fig. 3).

2.6. Ternary complexes: [Cu(NN′S)(NN/N,N′)](ClO$_4$)$_2$

To a CH_2Cl_2 solution of **5a** (**6b**) a methanolic solution of α-diimine (N,N; 2,2′-bipyridine (bpy) or 1,10-phenanthroline (phen)) was added and stirred for 2 h in air. An aqueous solution of $NaClO_4$ (saturated) was added to form a dark colored crystalline product of the composition [Cu(NN′S)(N,N)]$(ClO_4)_2$(N,N = bpy (**7**), phen (**8**))

$$Cu(NN'S)Cl_2 + N,N + 2NaClO_4 \Rightarrow [Cu(NN'S)(NN)](ClO_4)_2 + 2NaCl \quad (1)$$

Shining crystals were separated by slow diffusion of CH_2Cl_2 solution into hexane. However, these crystals were not of good enough quality to diffract X-rays for structural analysis. The characterization has been done by other physicochemical techniques. The complexes are 1:2 electrolytes in MeCN (Λ_M = 160–175 Ω^{-1} mol^{-1} cm^2). The bulk magnetic moment shows one electron paramagnetism (1.8–1.9 B.M.). The microanalytical data support the composition. Different isomers may be present and we could not separate them. The properties presented herein thus are referred to the isomer present in the compound.

Infrared spectra show a strong intense unstructured $\nu(ClO_4)$ at 1090 cm^{-1} along with a weak stretch at 625 cm^{-1}. The ν(N=N) and ν(C=N) appear at 1410–1420 and 1575–1590 cm^{-1}, respectively. The UV–Vis spectra of the complexes in CH_2Cl_2 exhibit high intense structured transitions within the wavelength range 600–250 nm along with a weak broad band >700 nm. The intraligand charge transfer transitions appear at 400–370, 300–310 and 260–270 nm, and are said to be associated with chelated diimine and azoimine functions. The intense band ($\varepsilon \sim 10^4$ mol^{-1} cm^{-1}) observed at 525–520 and 470–450 nm may be ascribed to d(Cu) → π* (azoimi/diimine), MLCT transition. The S(σ) → dπ(Cu), LMCT band has been significantly influenced by the coligands and is shifted to longer wavelength.

Cyclic voltammetry shows a reductive response at ca. 0.3 V versus Ag/AgCl along with three reductive responses at the negative side (Table 1). On comparing with the CV of Cu(NN′S)Cl_2 we may conclude that the couple is due to Cu(II)/Cu(I). Because of the better π-acidity of diimines (bpy/phen) than $2Cl^-$ the redox couple is shifted to the more positive side. Three quasireversible couples at −0.6, −0.9 and −1.3 V are the description of electron accommodation in the chelated ligands.

The complexes show four line (^{63}Cu, I = 3/2) EPR spectra and are anisotropic at higher magnetic field. The $g_{\|}$ and $g_{\perp}$ values for these complexes are 2.2–2.3 and 2.0–2.1, respectively. The relation $g_{\|} > g_{\perp} > 2.0023$ agrees with the ground state configuration of $d_{x^2-y^2}$. The $A_{\|}$ value lies in the range 160–175 × 10^{-4} cm^{-1}.

3. Experimental

3.1. Materials

$CuCl_2 \cdot 2H_2O$, *o*-(amino)thiophenol, methyl iodide (MeI), ethyl iodide (EtI), 2,2′-bipyridine (bpy), 1,10-phenanthroline (phen) were purchased from E. Marck. *o*-(Thioalkyl)-phenyldiazonium chloride was synthesized by the reported procedure [24]. Solvents were used after drying.

3.2. Measurements

Microanalyses (C, H, N) were performed using a Perkin–Elmer 2400 CHNO/S elemental analyzer. Spectroscopic measurements were carried out using the following instruments: UV–Vis spectra, reflectance spectra, JASCO UV–Vis/NIR model V-570; IR spectra (KBr disk, 4000–200 cm^{-1}), JASCO FT-IR model 420. Room temperature magnetic moments were measured using a vibrating sample 155 magnetometer at 298 K. Molar conductances (Λ_M) were measured in a Systronics conductivity meter 304 model using ca. 10^{-3} M solutions in MeCN. Electrochemical measurements were carried out with the use of a computer controlled EG&G PARC VersaStat model 250 Electrochemical instrument using a Pt-disk working electrode. The solution was IR compensated and the results were collected at 298 K. The reported results are referenced to Ag/AgCl in acetonitrile and are uncorrected for junction potential in the range +1.6 to −1.6 V. EPR spectra were measured in MeCN solution at room temperature

(298 K) and liquid nitrogen temperature (77 K) using a Bruker EPR spectrometer model EMX 10/12, X-band ER 4119 HS cylindrical resonator.

3.3. Synthesis of the ligands (SRaaiNR′)

The syntheses of the ligands were carried out following the common procedure of coupling different *o*-(thioalkyl)-phenyldiazonium ions (obtained by diazotization of *o*-(thioalkyl)aniline) with imidazole at pH 7. The procedure for the synthesis of 2-[*o*-(thiomethyl)phenylazo] (SMeaaiNH, **2a**) imidazole is as follows.

To a HCl solution (10 ml, 2 M) of *o*-(thiomethyl)aniline (1 g, 7.19 mmol), $NaNO_2$ solution (0.55 g, 7.97 mmol in 10 ml water) was added dropwise under cold conditions (cooling on an ice-salt bath, maintaining the temperature 0–5 °C). The yellow suspension thus formed was filtered through glass wool to remove tarry matter. Imidazole (0.6 g, 8.8 mmol) was dissolved in Na_2CO_3 (1.5 g in 20 ml water) solution and the diazotized solution was added in dropwise under cold conditions, and stirred with a glass rod. The initial red coloration was the indication of the diazocoupling reaction. The mixture was then kept in refrigerator for 1 h and neutralized with 2 M HCl, an orange-brown precipitate was separated. It was then filtered and dried under suction. The dry mass was redissolved in a minimum volume of 2 M HCl (volume not to exceed 20 ml) and filtered. The brown residue was rejected. The orange solution was then neutralized by adding pinch-wise finely powdered Na_2CO_3. The orange-red precipitate was filtered and dried. Yield: 0.58 g, 37%; m.p. 135 °C. UV–Vis (MeOH), λ nm (ε, $M^{-1}\,cm^{-1}$): 460 (4800) sh; 400 (7520) sh; 354 (14240); 263 (10380); 249 (9585). ^1H NMR ($CDCl_3$) (300 MHz) δ, ppm (*J*, Hz): 4-H, 7.28 bs; 5-H, 7.10 bs; 8-H, 7.25 (8.0) d; 9-H, 7.37 m; 10-H, 7.37 m; 11-H, 7.90 (8.0) d; N(1)-H, 10.30 bs; S-CH_3, 2.44.

SEtaaiNH (**2b**) was also prepared by a similar procedure with a yield of 44%; m.p. 139 °C. UV–Vis (MeOH), λ nm (ε, $M^{-1}\,cm^{-1}$): 461 (3768) sh; 403 (7976), 353 (14955); 263 (11606); 250 (10575). ^1H NMR ($CDCl_3$) (300 MHz) δ, ppm (*J*, Hz): 4-H, 7.27 bs; 5-H, 7.10 bs; 8-H, 7.23 (8.0) d; 9-H, 7.35 m; 10-H, 7.35 m; 11-H, 7.90 (8.0) d; N(1)-H, 10.30 bs; S-CH_2, 4.44 (9.0) q; (S-CH_2)-CH_3 1.54 (8.0) t [sh = shoulder; b = broad; bs = broad singlet; d = doublet; t = triplet; q = quartet; m = multiplet].

3.4. Alkylation of 2-[o-(thiomethyl)phenylazo]imidazole. Synthesis of 1-methyl-2-[o-(thiomethyl)phenylazo] imidazole (SMeaaiNMe) (**3a**)

To a dry THF solution (25 ml) of 2-[*o*-(thiomethyl) phenylazo]imidazole (0.8 g, 3.7 mmol) NaH (50% paraffin) (0.2 g) was added in small portions and stirred under cold conditions for 0.5 h. Methyl iodide (0.7 g, 4.9 mmol) was added slowly over a period of 30 min and then reaction mixture was warmed to 70 °C for an additional 1 h. The solution was evaporated, extracted with $CHCl_3$ (3 × 10 ml), washed with 15% NaOH (4 × 10 ml) and finally with distilled water (3 × 20 ml). It was chromatographed over silica gel prepared in petroleum ether (60–80 °C fraction) and the desired compound was eluted by toluene–acetonitrile (5:1 v/v). An orange-red gummy mass was separated by evaporation in vacuo (Yield: 0.35 g, 41%).

The other ligands were prepared by an identical procedure. The yield was 30–50%. The ligands are abbreviated SRaaiNR′: 1-methyl-2-[(*o*-thiomethyl)phenylazo]imidazole (SMeaaiNMe), **3a**, gum. UV–Vis (MeOH), λ nm (ε, $M^{-1}\,cm^{-1}$): 450 (3850) sh; 410 (7000) sh, 353 (12450); 260 (11150); 247 (10300). ^1H NMR ($CDCl_3$) (300 MHz) δ, ppm (*J*, Hz): 4-H, 7.25 bs; 5-H, 7.05 bs; 8-H, 7.22 (8.0) d; 9-H, 7.35 m; 10-H, 7.35 m; 11-H, 7.86 (8.0) d; 1-CH_3, 4.04 s; S-CH_3, 2.42; 1-ethyl-2-[(*o*-thiomethyl)phenylazo]imidazole (SMeaaiNEt), **3b**, gum. UV–Vis (MeOH), λ nm (ε, $M^{-1}\,cm^{-1}$): 454 (4050) sh; 405 (5565) sh, 350 (10400); 260 (9540); 250 (7500). ^1H NMR ($CDCl_3$) (300 MHz) δ, ppm (*J*, Hz): 4-H, 7.25 bs; 5-H, 7.08 bs; 8-H, 7.23 (8.0) d; 9-H, 7.40 m; 10-H, 7.40 m; 11-H, 7.85 (8.0) d; 1-CH_2, 4.50 (9.0), q; (1-CH_2)-CH_3, 1.53 (8.0) t; S-CH_3, 2.49; 1-methyl-2-[(*o*-thioethyl)phenylazo]imidazole (SEtaaiNMe), **4a**, gum. UV–Vis (MeOH), λ nm (ε, $M^{-1}\,cm^{-1}$): 455 (4205) sh; 400 (5840) sh, 350 (10580); 260 (9865); 250 (7525). ^1H NMR ($CDCl_3$) (300 MHz) δ, ppm (*J*, Hz): 4-H, 7.27 bs; 5-H, 7.07 bs; 8-H, 7.18 (8.0) d; 9-H, 7.33 m; 10-H, 7.33 m; 11-H, 7.81 (8.0) d; 1-CH_3, 4.01 s; S-CH_2, 2.97 (8.0) q, (S-CH_2)-CH_3, 1.36 (8.0), t; 1-ethyl-2-[(*o*-thioethyl)phenylazo]imidazole (SEtaaiNEt), **4b**, gum. UV–Vis (MeOH), λ nm (ε, $M^{-1}\,cm^{-1}$): 452 (4157) sh; 412 (5947) sh, 352 (11654); 263 (10188); 250 (8450). ^1H NMR ($CDCl_3$) (300 MHz) δ, ppm (*J*, Hz): 4-H, 7.29 bs; 5-H, 7.11 bs; 8-H, 7.18 (8.0) d; 9-H, 7.32 m; 10-H, 7.32 m; 11-H, 7.80 (8.0) d; 1-CH_2, 4.46 (9.0), q; (1-CH_2)-CH_3, 1.48 (8.0), t; S-CH_2, 3.00 (9.0), q; (S-CH_2)-CH_3, 1.33 (8.0), t [sh = shoulder; bs = broad singlet; d = doublet; t = triplet; m = multiplet; q = quartet; s = singlet].

3.5. Synthesis of the complexes

3.5.1. Cu(SMeaaiNMe)Cl_2 (**5a**)

1-Methyl-2-[*o*-(thiomethyl)phenylazo]imidazole (SMeaaiNMe) (0.2 g, 0.86 mmol) in methanol (10 ml) was added dropwise to a methanolic solution (10 ml) of $CuCl_2 \cdot 2H_2O$ (0.15 g, 0.88 mmol) at 298 K. The greenish brown solution was stirred for 10 min. It was then filtered and left undisturbed for a week. A dark brown crystalline compound separated. The crystals were filtered, washed with water, cold methanol and dried in vacuo. Yield was 0.21 g (66%).

All complexes were prepared by the same procedure. The yield varied from 60% to 75% and microanalytical data of the complexes are as follows: Cu(SMeaaiNMe)Cl_2 (**5a**), *Anal.* Calc. for $C_{11}H_{12}N_4SCl_2Cu$: C, 36.02; H, 3.27; N, 15.28; Cu, 17.32. Found: C, 35.94; H, 3.21; N, 15.22; Cu, 17.26%. Cu(SMeaaiNEt)Cl_2 (**5b**), *Anal.* Calc. for $C_{12}H_{14}N_4SCl_2Cu$: C, 37.80; H, 3.68; N, 14.72; Cu, 16.69. Found: C, 37.74; H, 3.62; N, 14.64; Cu, 16.58%. Cu(SEtaaiNMe)Cl_2 (**6a**), *Anal.*

Calc. for $C_{11}H_{12}N_4SCl_2Cu$: C, 37.80; H, 3.68; N, 14.72; Cu, 16.69. Found: C, 37.76; H, 3.62; N, 14.65; Cu, 16.60%. Cu(SEtaaiNEt)Cl_2 (**6b**), *Anal*. Calc. for $C_{13}H_{16}N_4SCl_2Cu$: C, 39.54; H, 4.06; N, 14.19; Cu, 16.09. Found: C, 39.48; H, 4.01; N, 14.08; Cu, 16.02%.

3.5.2. [Cu(SMeaaiNMe)(bpy)](ClO$_4$)$_2$ · H$_2$O (7)

To a CH_2Cl_2 solution (10 ml) of Cu(SMeaaiNMe)Cl_2 (0.15 g, 0.41 mmol) a methanolic solution (10 ml) of 2,2′-bipyridine (0.064 g, 0.41 mmol) was added and stirred for 3 h. The solution color turned from brown red to deep brown. It was then evaporated in air to reduce to its volume to 10 ml. A solution of $NaClO_4$ (2 ml saturated solution) was added to the methanolic suspension of the mixture and a deep brown mass immediately separated. It was filtered, washed with methanol and dried in vacuo. Slow diffusion of a CH_2Cl_2 solution of the dry mass into hexane separated shining crystals after a week. Yield was 0.198 (71%) and other yields varied from 70% to 75%. The microanalytical data of the complexes are as follows: [Cu(SMeaaiNMe)(bpy)](ClO$_4$)$_2$ · H$_2$O (**7**), *Anal*. Calc. for $C_{21}H_{22}N_6O_9SCl_2Cu$: C, 37.69; H, 3.29; N, 12.56; Cu, 9.49. Found: C, 37.58; H, 3.24; N, 12.47; Cu, 9.42%. [Cu(SMeaaiNMe)(phen)](ClO$_4$)$_2$ · H$_2$O (**8**), *Anal*. Calc. for $C_{23}H_{22}N_6O_9SCl_2Cu$: C, 39.85; H, 3.17; N, 12.13; Cu, 9.17. Found: C, 39.78; H, 3.09; N, 12.06; Cu, 9.11%. [Cu(SEtaaiNEt)(bpy)](ClO$_4$)$_2$ · H$_2$O (**9**), *Anal*. Calc. for $C_{23}H_{26}N_6O_9SCl_2Cu$: C, 39.63; H, 3.73; N, 12.06; Cu, 9.12. Found: C, 39.58; H, 3.68; N, 12.37; Cu, 9.24%. [Cu(SEtaaiNEt)(phen)](ClO$_4$)$_2$ · H$_2$O (**10**), *Anal*. Calc. for $C_{25}H_{26}N_6O_9SCl_2Cu$: C, 41.64; H, 3.33; N, 11.66; Cu, 8.81. Found: C, 41.57; H, 3.29; N, 11.75; Cu, 8.75%.

3.6. X-ray crystal structure analysis of [Cu(SEtaaiEt)Cl$_2$] (**6b**)

Data were collected with a Siemens SMART CCD diffractometer using graphite-monochromatized Mo Kα radiation ($\lambda = 0.71073$ Å) at 295(2) K. Unit cell parameters were determined from least-squares refinement of setting angles with 2θ in the range $3.8 \leqslant 2\theta \leqslant 56.6°$. Total data collected were 10661 out of which unique data were 3122. The hkl range was $-13 \leqslant h \leqslant 14$, $-19 \leqslant k \leqslant 17$, $-12 \leqslant l \leqslant 13$. A summary of the crystallographic data and structure refinement parameters are given in Table 3. Reflection data were recorded using the ω scan technique. Data were corrected for Lorentz polarization effects and for linear decay. Semi-empirical absorption corrections based on ψ-scans were applied. The structure was solved by heavy atom methods using SHELXS-97 and successive difference Fourier syntheses. All non-hydrogen atoms were refined anisotropically. The hydrogen atoms were fixed geometrically and refined using the riding model. In the final difference Fourier map the residual minima and maxima were [−0.27, 0.37 (e/Å^3) for] carried out using SHELXL-97.

Table 3
Summarized crystallographic data for [Cu(SEtaaiNEt)Cl_2] (**6b**)

	[Cu(SEtaaiNEt)Cl_2]
Empirical formula	$C_{13}H_{16}CuN_4SCl_2$
Formula weight	394.80
Temperature (K)	295(2)
Crystal system	monoclinic
Space group	$P2_1/c$
Crystal size (mm^3)	$0.15 \times 0.20 \times 0.22$
Unit cell dimensions	
a (Å)	10.7182(8)
b (Å)	14.4376(10)
c (Å)	10.7181(8)
β(°)	96.3(6)

MA

2. Experimental

2.1. General procedures

All manipulations were carried out under dry, oxygen-free nitrogen by using Schlenk techniques, unless otherwise noted. Solvents were dried and deoxygenated by refluxing over the appropriate reagents before use. Diethyl ether was purified by distillation from sodium/benzophenone, and methanol from Mg/I_2. The Visible absorption spectra were recorded on a Hitachi U-2000 spectrophotometer. IR spectra were obtained from a Jasco FT/IR-460 plus spectrometer. Elemental analyses were obtained from a PE 2400 series II CHNS/O analyzer.

2.2. Materials

The reagents $CuCl_2 \cdot 2H_2O$, $Cu(OAc)_2 \cdot H_2O$ and melamine were purchased from Aldrich Chemical Co.

2.3. Preparation of the $Cu_2Cl_2(\mu\text{-}Cl)(CH_3OH)_2(\mu\text{-}OCH_3)(MA)_2$ (1)

$CuCl_2 \cdot 2H_2O$ (0.34 g, 2.00 mmol) was added to a CH_3OH solution (10 ml) containing melamine (0.25 g, 1.98 mmol). The mixture was heated to reflux for 3 h until some green-yellow solid began to precipitate. The mixture was then allowed to stir for 1 h at room temperature *T*. The solid was filtered out, washed with diethyl ether (2×10 ml) and dried under vacuum to give a green-yellow powder. Yield: 0.41 g (73%). UV–Vis (MeOH): 385 nm. *Anal.* Calc. for $C_9H_{23}Cl_3Cu_2N_{12}O_3$ (MW = 580.81): C, 18.61; H, 3.99; N, 28.94. Found: C, 18.96; H, 4.11; N, 28.77%. IR (KBr disk): 3350(m), 3150(s), 2405(s), 1718(w), 1521(m), 1498(s), 1442(w), 1040(m), 792(m), 683(m), 562(w).

2.4. Preparation of $[Cu(\eta^1\text{-}OAc)(\mu\text{-}OCH_3)(MA)]_2$ (2)

$Cu(OAc)_2 \cdot H_2O$ (0.40 g, 2.00 mmol) was added to a MeOH solution (20 ml) containing melamine (0.25 g, 1.98 mmol). The mixture was refluxed for 3 h to afford a blue solution and a blue solid. The precipitate was filtered and washed by ether (3×10 ml) and then dried under reduced pressure to give a blue solid. Yield: 0.52 g (86%). UV–Vis (MeOH): 382 nm. *Anal.* Calc. for $C_{12}H_{24}Cu_2N_{12}O_6$ (MW = 559.49): C, 25.76; H, 4.32; N, 30.04. Found: C, 25.46; H, 3.99; N, 29.88%. IR (KBr disk): 3352(s),

3. X-ray crystallography

The diffraction data for complexes **1** and **2** were collected at 22 °C on a Bruker AXS P4 diffractometer, which was equipped with a graphite-monochromated Mo Kα ($\lambda_\alpha = 0.71073$ Å) radiation. Data reduction was carried by standard methods with use of well-established computational procedures [10]. A suitable crystal of **1** was mounted on the top of a glass fiber with epoxy cement. The hemisphere data collection method was used to scan the data points at $3.94 < 2\theta < 49.98°$. The structure factors were obtained after Lorentz and polarization correction. The positions of some of the heavier atoms, including the copper atom, were located by the direct method. The remaining atoms were found in a series of alternating difference Fourier maps and least-square refinements [11]. The crystallographic procedures for **2** were similar to those for **1**. The hydrogen atoms for **1** were added by using the HADD program in SHELXTL 5.10, while those for **2** were found in a series of alternating difference Fourier maps and least-square refinements. The final residuals of the final refinement were $R_1 = 0.0719$, $wR_2 = 0.1356$. Basic information pertaining to crystal parameters and structure refinement is summarized in Table 1.

4. Results and discussion

4.1. Synthesis

The complexes $Cu_2Cl_2(\mu\text{-}Cl)(CH_3OH)_2(\mu\text{-}OCH_3)\text{-}(MA)_2 \cdot 2Et_2O$ (MA = melamine), **1**, and [Cu(η¹-OAc)-

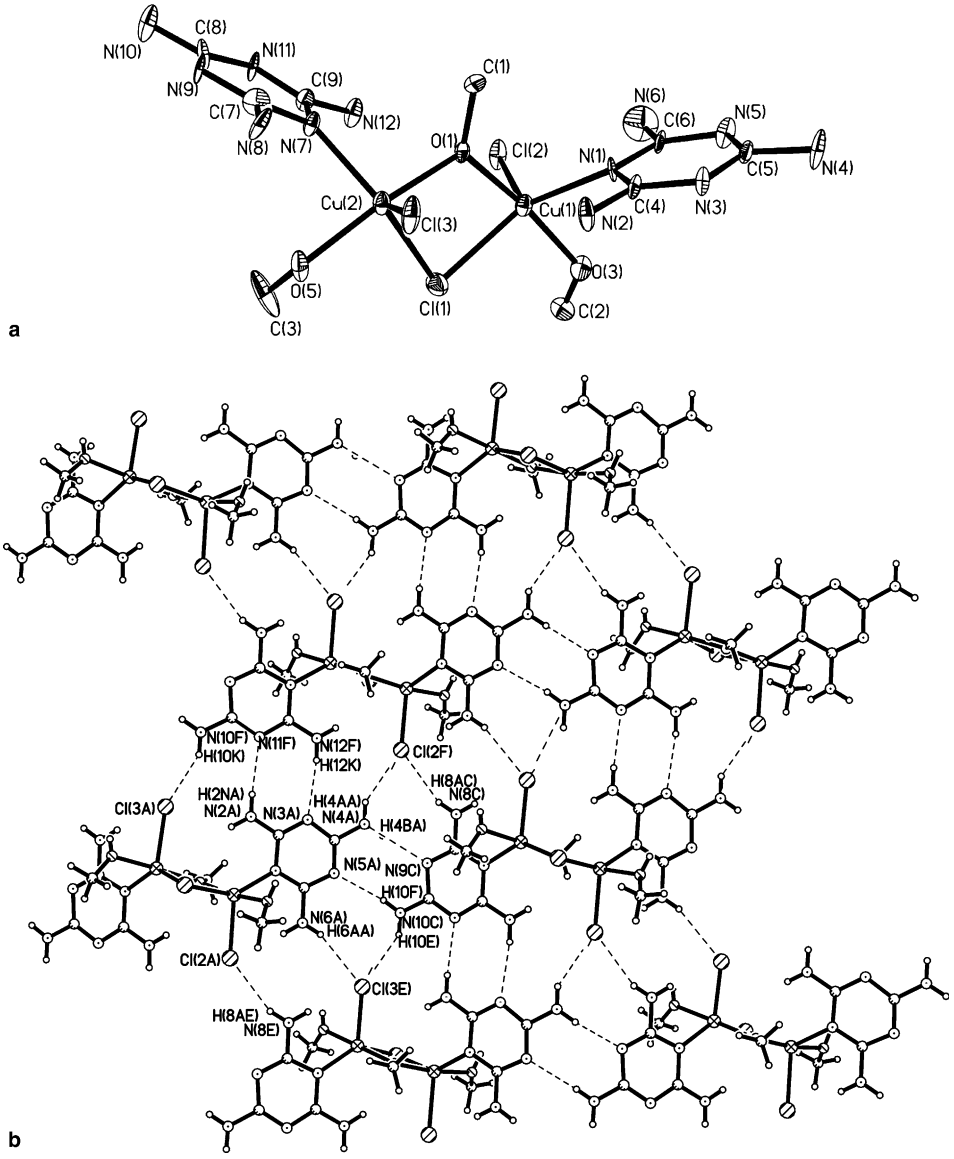

Fig. 1. (a) ORTEP drawing showing the coordination geometry of copper center of **1**. Ellipsoids are scaled to enclose 20% of the electron density. The hydrogen atoms are omitted for clarity. (b) Part of the 2-D hydrogen bonded layers of complexes present in the crystals of **1**, viewing down the *a*-axis.

(μ-OCH_3)(MA)]$_2 \cdot 0.33H_2O$, **2**, were prepared by reactions of $CuCl_2 \cdot 2H_2O$ and $Cu(OAc)_2 \cdot H_2O$, respectively, with MA in refluxing methanol. Crystals of **1** and **2** suitable for X-ray crystallography were obtained by slow diffusion of ether into a MeOH solution of **1** and **2**, respectively. Their structures have been determined by spectroscopic methods and by X-ray crystallography.

4.2. Structure of *1*

The structure of **1** was solved in the space group $Pna2_1$. Fig. 1(a) shows the local coordination of the two copper centers. Selected bond distances and angles are listed in Table 2. The copper metal center adopts slightly distorted square pyramidal coordination geometry with the bond angles significantly deviates from 90° or 180°. The basal plane comprises the bridging methoxide oxygen atom (Cu–O = 1.901(8), 1.913(7) Å), the bridging chloride atom (Cu–Cl = 2.344(3), 2.361(3)), a coordinated methanol oxygen atom (Cu–O = 1.959(9), 1.980(10) Å) and a ring nitrogen atom of a coordinated melamine ligand (Cu–N = 2.069(9), 2.077(10) Å), whereas the apical coordination site is occupied by a weakly coordinated monodentate chloride atoms (Cu–Cl = 2.447(3), 2.449(3) Å). The two copper atoms are bridged by one methoxide group and one chloride atom to form an edge-sharing bisquare pyramidal geometry and the non-bonded Cu···Cu separation in the Cu_2(μ-Cl)(μ-OCH_3) core is 3.171 Å. The dihedral angle between the two melamine planes is 44.5° and the planes of the melamine ligands are rotated by ca. 72.7° and 78.0° out of the basal coordinated planes.

The molecules of **1** are interlinked through two pairs of N–H···N self-complementary hydrogen bonds and N–H···Cl interactions (H···N = 2.15–2.34 Å, ∠N–H···N = 149.7–174.7°, H···Cl = 2.50–2.61 Å, ∠N–H···Cl = 145.4–159.0°), forming the 2-D sheets, Fig. 1(b). The diethyl ether solvents interact with the methanol groups of copper units through O–H···O hydrogen bonds (H···O = 1.84–2.61 Å, ∠O–H···O = 152.9–159.0°).

4.3. Structure of *2*

The structure of **2** was solved in the space group $R\bar{3}$. Fig. 2(a) shows the local coordination of the copper center in **2**. Selected bond distances and angles are listed in Table 2. The copper metal center adopts a slightly distorted square planar coordination geometry with the bond angles significantly deviates from 90° or 180° and the sum of the four angles about the Cu atoms is 362.37°. Complex **2** is an edge-sharing bisquare-planar complex of Cu(II) centers. The two copper centers are linked by two oxygen atoms of the methoxide groups with the non-bonded Cu···Cu separation in the Cu_2(μ-OCH_3)$_2$ core of 2.9757(9) Å. The Cu(II) atom is bonded to one nitrogen atom of the melamine ligand(Cu–N(1) = 1.986(3) Å), two *cis*-bridging methoxide oxygen atoms (Cu–O = 1.921(2)–1.924(2) Å) and one of the monodentate acetate group (Cu–O(2) = 1.938(3) Å). The dihedral angle between the two melamine planes is 0° and the planes of the melamine ligands are rotated by ca. 89.8° out of the square planar coordination planes. The molecules of **2** are interlinked through N–H···N

(d) A space-filling model representation for **2**. Only the Cu atoms and the melamine ligands are shown for clarity.

self-complementary hydrogen bonds and N–H···O interactions (H···N = 2.22–2.29 Å, ∠N–H···N = 155.8–177.7°, H···O = 2.02–2.29 Å, ∠N–H···O = 145.7–168.6°), Fig. 2(b), forming a 3-D porous structure with triangular and hexagonal pores, Fig. 2(c). Fig. 2(d) is a space-filling model representation for **2**, showing only metal atoms and MA ligands.

4.4. Structural comparisons for *1* and *2*

The structure of **1** is similar to the dinuclear complex $[Cu(MA)(\mu\text{-}OCH_3)(NO_3)(HOCH_3)]_2$ (Cu···Cu = 3.0016(8) Å), where the plane of the MA ligand is rotated by about 67° out of the basal coordination plane of the distorted square pyramidal geometry at the copper center, and the molecules are linked through N–H···O and N–H···N hydrogen bonds to form 2-D sheets [9]. In complex **2**, the Cu atoms adopt adopts a slightly distorted square planar coordination geometry and the planes of the melamine ligands are rotated by ca. 89.8° out of the square planar coordination planes, resulting in a 3-D porous structure with triangular and hexagonal pores. The edge length of the hexagonal pores is 5.48 Å defined as the distance between two Cu atoms of adjacent complex, while the edge length of the triangular pores is 6.98 Å defined as the distance between centers of the adjacent $Cu_2(\mu\text{-}OCH_3)_2$ cores. To our best knowledge, complex **2** shows a unique porous structure containing both hexagonal and triangular pores constrained by the N–H···N self-complementary hydrogen bonds.

4.5. Thermal properties

Complexes **1** and **2** are very stable in air at ambient temperature. Thermal gravimetric analyses (TGA) were carried out to examine the thermal stability of **1** and **2**. The samples were heated up in air at 1 atm pressure with the heating rate of 10 °C min^{-1}. The TGA curve shows that **1** is stable up to 96 °C. A total weight loss of 10.8% occurred

in the temperature range 96–295 °C, presumably due to the removal of the methanol ligands per formula unit (calcd. 11.0%). A weight loss of 43.8% occurred in the temperature range 295–372 °C, corresponding to the removal of two melamine ligands per formula unit (calcd. 43.4%). Another weight loss of 23.6% was found in the temperature range 375–420 °C, corresponding to the removal of the three chloride atoms and the bridging methoxide ligand (calcd. 23.7%). The TGA curve shows that **2** is stable up to 145 °C. A total weight loss of 56.0% occurred in the temperature range 145–310 °C, mainly corresponding to the removal of the two bridging methoxide ligands and two melamine molecules per formula unit (calcd. 56.2%). A appeasement weight loss of 21.6% occurred in the temperature range 340–410 °C, consistent with the removal of two monodentate acetate groups (calcd. 21.1%). The results indicate that a 3-D porous framework constrained by the N–H···N self-complementary hydrogen bonds is more stable than 2-D sheets.

5. Conclusions

The syntheses, structures and thermal properties of two new melamine complexes $Cu_2Cl_2(\mu\text{-}Cl)(CH_3OH)_2(\mu\text{-}OCH_3)(MA)_2 \cdot 2Et_2O$ (MA = melamine), **1**, and $[Cu(\eta^1\text{-}OAc)(\mu\text{-}OCH_3)(MA)]_2 \cdot 0.33H_2O$, **2** have been successfully accomplished. In addition to the N–H···N self-complementary hydrogen bonds, the dihedral angle between the melamine plane and the basal plane containing the metal atom of the complex may play an important role in linking the copper melamine complexes to form 2-D and 3-D architectures. The unique structure of complex **2** contains both hexagonal and triangular pores constrained by the N–H···N self-complementary hydrogen bonds.

6. Supplementary material

Crystallographic data (CIF files) for the structures **1** and **2** have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 280091–280092. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (Fax: +44 1223 336 033; e-mail: deposit@ccdc.cam.ac.uk or on the web www: http://www.ccdc.cam.ac.uk).

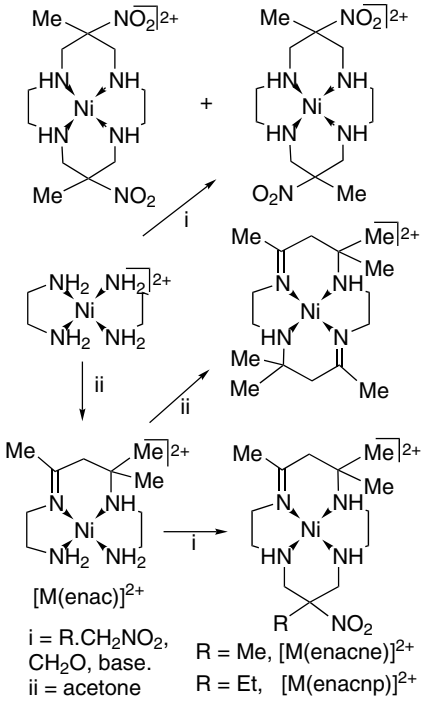

Scheme 1. Showing reactions of $[Ni(en)_2]^{2+}$ and $[Ni(enac)]^{2+}$ with methanal plus nitroethane or nitropropane: (i) [8] or with acetone (ii) [11–13].

In this communication the preparations of compounds of analogous nickel(II) cations, $[Ni(enacne)]^{2+}$ and $[Ni(enacnp)]^{2+}$, by reaction of (4,6,6-trimethyl-3,7-diazanon-3-ene-1,9-diamine)nickel(II), $[Ni(enac)]^{2+}$, with methanal and nitroethane or nitropropane are reported. The structure of $[Ni(enacne)][ZnCl_4]$ has been determined by X-ray diffractometry. An improved preparation of the $[Ni(enac)](ClO_4)_2$ starting material is reported.

2. Results

$[Ni(enac)]^{2+}$ reacts with methanal plus nitroethane (or nitropropane) in water, or methanol, plus base, to form nitro-substituted imine–triamine macrocyclic cations, see Scheme 1. These are very resistant to acid demetallation, as generally observed for azamacrocycle compounds of nickel(II), and in particular the hexamethyl-diimine–diamine azamacrocycle compounds formed by condensation of (ethane-1,2-diamine) nickel(II) compounds with acetone [12,13] and the dimethyl–dinitro cyclic tetraamine compounds formed by their condensation with methanal/nitroalkyl compounds [8]. The cations are, however, very slowly degraded in alkaline solution.

The nickel(II) cations form orange coloured singlet ground state square-planar salts with perchlorate and tetrachlorozincate anions, and blue–violet triplet ground state octahedral compounds with coordinating unidentate (NCS^- and NH_3) and bidentate $\{C_2O_4^{2-}$ (oxalato) and $C_3H_7O_2^-$ (pentan-2,4-dionato) and $NO_2^-\}$ ligands. The thiocyanato compounds show very strong singlet $\nu(C{\equiv}N)$ bands in the IR, at c. 2060 cm^{-1}, typical of *trans*-di-isothiocyanato-(tetraamine)nickel(II) compounds. The nitrite derivatives $[Ni(L)(NO_2)]ClO_4$ have properties indicative of chelate nitrito coordination, as observed for $[Ni(enac)(NO_2)]ClO_4$ [11]. The oxalato compounds $[\{Ni(L)\}_2(C_2O_4)](ClO_4)_2$ are analogous to many similar compounds in which the oxalate ion acts as a bridging bidentate ligand, coordinated with the macrocycle in a folded arrangement [14,15]. The formation of the oxalato compound is slow, and the perchlorate salt is slow to crystallise when a solution of this compound is acidified with perchloric acid. The slow interconversion between the perchlorate salt and oxalato compound suggests that a change in nitrogen configuration is occurring; as such changes are generally slow in acid. The stable configuration for the square-planar cation is 1*R*,8*R*,11*S*, as observed for the tetrachlorozincate salt (and for the copper(II) cation [9]) and folding would be expected to occur at the N1–Ni–N8 axis, for the least-strained 1*R*,8*R*,11*R*-configuration.

2.1. Structural study

The structure of $[Ni(enacne)][ZnCl_4]$ was determined by X-ray diffractometry, see Section 4.3 for details. The asymmetric unit of the compound is shown in Fig. 1. The nickel(II) ion is in square-planar coordination by the imine and three secondary amine nitrogen atoms of the 5,7,7,13-tetramethyl-13-nitro-1,4,8,11-tetraazacyclotetradec-4-ene azamacrocycle.

A persistent residual peak located axially with respect to C5 was modeled as resulting from disorder of the cation, with superposition of the 5,7,7,13-tetramethyl-4-ene and 5,5,7,13-tetramethyl-7-ene arrangements, obtained by reversal of the chelate ring –N4=C5(Me)–C6–C7(Me)$_2$–N8H– to –N4H–C5(Me)$_2$–C6–C7(Me)=N8–. The major

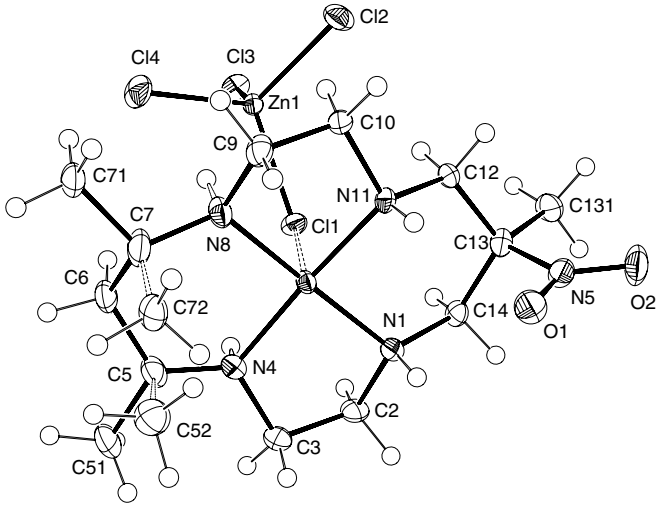

Fig. 1. The asymmetric unit of $[Ni(enacne)][ZnCl_4]$, drawn [17] with displacement ellipsoids at the 50% confidence level, with hydrogen atoms shown as circles of arbitrary radius. The site occupation factors of the C72 methyl group and H8 and of the C52 methyl group and H4 are 0.80(1) and 0.20(1), respectively.

Table 1
Selected geometric parameters for [Ni(enacne)][$ZnCl_4$][a]

Distance	Distance (Å)	Angle	Angle (°)
Ni–N1	1.934(3)	N1–Ni–N4	87.0(1)
Ni–N4	1.909(3)	N4–Ni–N8	95.0(1)
Ni–N8	1.932(3)	N8–Ni–N11	86.5(1)
Ni–N11	1.927(3)	N11–Ni–N1	91.2(1)
Ni–Cl1	2.9211(9)	N1–Ni–N8	175.8(1)
N4–C5	1.317(4)	N4–Ni–N11	174.6(1)
N8–C7	1.450(4)	N1–Ni–Cl1	86.0(1)
N5–O1	1.220(4)	N4–Ni–Cl1	88.0(1)
N5–O2	1.222(4)	N8–Ni–Cl1	97.8(1)
C13–N5	1.514(4)	N11–Ni–Cl1	97.0(1)
		O1–N5–O2	124.3(3)
		Ni–Cl1–Zn	115.9(3)

[a] Distances Zn–Cl range from 2.252(1) to 2.280(1) Å and angles Cl–Zn–Cl range from 105.87(3)° to 110.43(3)°.

component has the axial substituent on C7 (sof of $C72H_3$ and H8 = 0.80(1), 1*S*,5*S*,11*R* configuration) and the minor component has the axial substituent on C5 (sof of $C52H_3$ and H4 = 0.20(1), 1*S*,8*R*,11*R* configuration). The rest of the cation has approximate mirror symmetry.

The N_4 group is tetrahedrally twisted, with displacements of N atoms from the N_4 plane ±0.012(1) Å, with the Ni atom 0.074(1) Å from this plane {values for the copper(II) compounds [9,10] range from ±0.017(2) and 0.246(2) Å to ±0.067(2) and 0.088(2) Å}. Overall, the geometry of the cation is similar to those of the analogous copper(II) cations, but with the Ni–N distances c. 0.07 Å shorter than the corresponding Cu–N distances. The Ni–N distances (see Table 1) are similar to those of the (5,7,7,12,12,14-hexamethyl-1,4,8,11-tetraazacyclotetradeca-4,11-diene)nickel(II) perchlorate salts: for the *meso, rac*-isomers $Ni–N_{amine}$ = 1.938(2), 1.915(4); $Ni–N_{imine}$ = 1.907(2), 1.884(5) Å [16]. The six-membered diamine chelate ring including Ni,N1,N11 has a chair conformation with the nitro group axially oriented (on the same side of the NiN_4 plane as the axial methyl substituent), the five-membered chelate rings including Ni,N1,N4 and NiN8,N11 have unsymmetrical gauche conformations and the amine– imine chelate ring including Ni,N5,N8 has a twisted conformation (see Table 2 for displacements of atoms from NiN_2 planes for chelate rings). The distance N4–C5 and angles about these atoms reflect the predominant imine character of this bond.

For [Ni(enacne)][$ZnCl_4$] the nitro group is approximately aligned with C13···Ni, with O1 hydrogen-bonded to both N1–H1 and N11–H11 (see Table 3), whereas for the copper(II) compounds the nitro group is aligned approximately normal to this direction {for [Cu(enacnp)(H_2O)](ClO_4)$_2$ both these N–H groups hydrogen bond to perchlorate ion oxygen atoms [9] and for [Cu(enacnp)][$Ni(CN)_4$]·H_2O only one of these NH groups hydrogen bonds to a nitro group oxygen atom [10]}.

Table 3
Hydrogen bonding parameters (Å, °) for [Ni(enacne)][$ZnCl_4$]

Atoms	H···A	D···A	DH···A
N1–H1···O1	2.39	2.935(3)	117
N1–H1···Cl3[i]	2.58	3.348(3)	140
N4–H4···Cl1	2.72	3.432(3)	136
N8–H8···Cl4	2.74	3.658(3)	134
N11–H11···O1	2.27	2.885(4)	123
N11–H11···O1[ii]	2.22	3.100(4)	157

Symmetry operations: i, $-x+1/2$, $y+1/2$, $-z+1/2$; ii, $-x+1$, $-y+1$, $-z+1$.

The tetrachlorozincate ion is located on the side of the NiN_4 plane remote from the nitro and methyl groups, with one chloride ion located approximately axially with respect to the nickel(II) ion, with Ni1–Cl1 = 2.921(1) Å, which indicates a weak interaction. The closest axial approach on the other side of the plane is Ni···Cl3 ($-x+1$, $-y+1$, $-z+1$) = 3.598(1) Å. Intermolecular hydrogen bonds link partial occupancy N4–H4···Cl1 and N8–H8···Cl4 to the tetrachlorozincate ion, while intramolecular hydrogen bonds form a network, see Table 3.

3. Conclusions

The facile reaction of $[Ni(enac)]^{2+}$ with nitroalkyl compounds plus methanal to form the nitro-substituted imine–triamine macrocycles completes a set of azamacrocycle compounds formed by cyclization of the bis(ethane-1,2-diamine)nickel(II) cations by condensations with acetone (diimine macrocycles) or with methanal/nitroalkyls (dinitro–tetraamine macrocycles), shown in the Reaction Scheme 1. The cations have properties similar to those of the hexamethyl-diimine–diamine macrocycle cation formed with acetone [12,13] and the dimethyl–dinitro–tetraamine cations formed with methanal/nitroalkyl compounds [5]. However, the "mixed substituent" cations more readily form triplet ground state compounds, with both planar and folded-macrocycle, than either of the symmetrical cations, indicating less hindrance of the axial coordination

Table 2
Displacements of atoms from NiN_2 planes for chelate rings for [Ni(enacne)][$ZnCl_4$]

Atoms defining plane	Displacement (Å)
Ni,N1,N4	C2 −0.386(5); C3 0.204(5)
Ni,N8,N11	C9 0.425(5); C10 0.0.274(5)
Ni,N4,N8	C5 −0.010(5); C6 −0.326(6); C7 0.458(6); C51 −0.006(8); C71 0.298(8); C52 1.68(1); C72 1.996(6)
Ni,N8,N11	C12 −0.964(5); C13 −0.867(5); C14 −0.880(5); C131 −2.070(7); N5 0.423(7), O1 1.446(6); O2 0.370(8)
Ni,N4,N8	C5 0.082(4); C6 0.480(4); C7 −0.354(4); C51 −0.040(6); C71 −1.87(4); C72 −0.060(5)

sites by axial substituents. The cations are resistant to acid demetallation, but in base are slowly degraded by reversal of the Mannich reaction by which they are formed.

4. Experimental

4.1. Preparations of compounds

The perchlorate compounds described are potentially explosive and should be treated with caution, particularly the ethane-1,2-diamine starting materials. However, the enac, enacne and enacnp perchlorate compounds have shown no indication of shock sensitivity and decompose non-violently when strongly heated. The macrocyclic cations are resistant to acid demetallation (but are rapidly oxidized by nitric acid). They are slowly degraded in alkaline solution. The infrared spectra all show ν(NH) bands near 3200 cm^{-1}, and sharp peaks assigned to ν(N=C) near 1665 cm^{-1} and $\nu(NO_2)$ (more intense) near 1550 cm^{-1}.

4.1.1. (4,6,6-Trimethyl-3,7-diazanon-3-ene-1,9-diamine)nickel(II) perchlorate, [Ni(enac)](ClO4)2

Improvements have been made to the reported [11] preparation of $[Ni(enac)](ClO_4)_2$. $[Ni(en)_3](ClO_4)_2 \cdot H_2O$ (20 g) was added to a solution of $[Ni(H_2O)_6](ClO_4)_2$ (8.14 g) in methanol (100 cm^3), 2:1 mol ratio, producing a solution of "$[Ni(en)_2]^{2+}$". Acetone (100 cm^3) and 2-aminoethanol (2 g) were added and the solution was heated near boiling for 48 h. The solution was then rotary evaporated; the resulting orange gum dissolved in hot water (100 cm^3), treated with decolourising charcoal, filtered and again rotary evaporated to leave an orange gum. This was dissolved in ethanol (200 cm^3) by heating and stirring and the solution allowed to stand for 24 h. The orange product that slowly crystallised (nucleation with the preformed compound speeds this process) was filtered off, washed with ethanol and recrystallised from hot methanol, or by dissolving in hot acetone, adding an equal volume of ethanol and allowing the solution to evaporate. Yield 20 g, 75%.

4.1.2. (5,7,7,13-Tetramethyl-13-nitro-1,4,8,11-tetraazacyclotetradec-4-ene)nickel(II) perchlorate, [Ni(enacne)](ClO4)2

4.1.2.1. Preparation from [Ni(enac)](ClO4)2. $[Ni(enac)](ClO_4)_2$ (10 g) was dissolved in water (100 cm^3), nitroethane (1.8 g), paraformaldehyde (2.5 g) and $NaHCO_3$ (0.5 g) added and the solution heated at c. 75 °C. for 2 h. then filtered through charcoal while hot. Sodium oxalate (2 g) was added, and the solution heated near boiling for 2 h, then stood for 24 h. while blue violet $[\{Ni(enacne)\}_2(C_2O_4)](ClO_4)_2 \cdot 2H_2O$ crystallised. The solid was filtered off, washed well with hot water, then acetone (yield 8.6 g, 80%). This material was added to a hot aqueous solution of calcium perchlorate (prepared by dissolving 2 g of $CaCO_3$ in just sufficient perchloric acid in 50 cm^3 of water), adding "filter aid" or a further 1 g of $CaCO_3$ to facilitate later filtration and the suspension heated and stirred until the blue–violet starting material had all reacted to leave a white suspension in an orange solution. An equal volume of acetone was added and the solid filtered off and washed with hot 1:1 acetone water. The orange product crystallised as this solution evaporated.

The product was recrystallised from hot acetonitrile (in which it is extremely soluble)/propan-2-ol or from hot 10:1 acetone:water/ethanol. The compound tends to separate from water as an orange gum that only slowly crystallises. The orange *product* was filtered off and washed with ethanol. Yield c. 70%. *Anal.* Calc. for $C_{14}H_{29}Cl_2N_5NiO_{10}$: C, 30.2; H, 5.2; N, 12.6. Found: C, 29.9; H, 5.2; N, 12.5%. Visible spectrum in water {λ_{max}/nm (ε/dm^3 mol^{-1} cm^{-1}), 448 (76). IR spectrum (ν_{max}/cm^{-1}): ν(NH) 3236; ν(C=N) 1663; $\nu(NO_2)$ 1553.

4.1.2.2. Preparation from [Ni(enac)][ZnCl4]. [Ni(enac)]-$[ZnCl_4]$ [11] (10.1 g) was dissolved in water (100 cm^3) and $NaHCO_3$ (4.2 g) added. Effervescence occurred and $ZnCO_3$ precipitated. This was filtered off, nitroethane (1.8 g) and paraformaldehyde (2.5 g) added and the solution treated as for the previous preparation. Perchloric acid (4 g, 60%), sodium oxalate (2 g) then $NaHCO_3$ (2 g) (effervescence) were added, and the preparation continued as for the previous preparation, with similar yield of product.

4.1.3. (13-Ethyl-5,7,7-trimethyl-13-nitro-1,4,8,11-tetraazacyclotetradec-4-ene)nickel(II) Perchlorate, [Ni(enacnp)](ClO4)2

This orange compound was prepared and recrystallised as for the previous compound by using 1.9 g of nitropropane in place of the nitroethane, with similar yield of *product*. *Anal.* Calc. for $C_{15}H_{31}Cl_2N_5NiO_{10}$: C, 30.2; H, 5.2; N, 12.6. Found: C, 29.9; H, 5.2; N, 12.5%. Visible spectrum in water {λ_{max}/nm (ε/dm^3 mol^{-1} cm^{-1}) 447 (76). IR spectrum (ν_{max}/cm^{-1}): ν(NH) 3236; ν(C=N) 1663; $\nu(NO_2)$ 1553.

4.2. Other compounds

Compounds of $[Ni(enacne)]^{2+}$ and/or $[Ni(enacnp)]^{2+}$ were prepared from the perchlorate salts, with procedures for $[Ni(enacnp)]^{2+}$ compounds analogous to those described for the $[Ni(enacne)]^{2+}$ compound.

4.2.1. Ammine adducts

Sparingly soluble purple ammine adducts crystallised when the perchlorate salts were stirred under concd. aqueous ammonia. These slowly lost ammonia on exposure to the atmosphere, or when stirred with methanol, to reform the orange perchlorate salts.

4.2.2. trans-Dithiocyanato-(5,7,7,13-tetramethyl-13-nitro-1,4,8,11-tetraazacyclotetradec-4-ene)nickel(II), trans-[Ni(enacne)(NCS)2]

Sodium thiocyanate was added to a hot, concentrated aqueous solution of $[Ni(enacne)](ClO_4)_2$. Pale lavender coloured crystals of the *product* were filtered from the cold

solution and recrystallised from hot water. *Anal.* Calc. for $C_{16}H_{29}N_7NiO_2S_2$: C, 40.5; H, 6.2; N, 20.7. Found: C, 40.4; H, 6.0; N, 20.6%. IR spectrum (ν_{max}/cm^{-1}): ν(NH) 3302, 3217; ν(C≡N) 2066vs, ν(C=N) 1671; ν(NO_2) 1545.

4.2.3. trans-Dithiocyanato-(13-Ethyl-5,7,7-trimethyl-13-nitro-1,4,8,11-tetraazacyclotetradec-4-ene)nickel(II), trans-[Ni(enacnp)(NCS)$_2$]

Anal. Calc. for $C_{17}H_{31}N_7NiO_2S_2$: C, 42.1; H, 6.5; N, 20.2. Found: C, 41.8; H, 6.4; N, 20.1%. IR spectrum (ν_{max}/cm^{-1}): ν(NH) 3297, 3229; ν(C≡N) 2049vs; ν(C=N) 1671; ν(NO_2) 1543.

4.2.4. (5,7,7,13-Tetramethyl-13-nitro-1,4,8,11-tetraazacyclotetradec-4-ene)nickel(II) tetrachlorozincate, [Ni(enacne)][ZnCl$_4$]

Zinc chloride was added to a solution of [Ni(enacne)](ClO_4)$_2$ in acetonitrile, followed by propan-2-ol until turbid. The orange *product* was filtered off and recrystallised from hot methanol containing a few drops of concd. HCl. *Anal.* Calc. for $C_{14}H_{29}Cl_4N_5NiO_2Zn$: C, 29.7; H, 5.2; N, 12.4. Found: C, 29.9; H, 5.2; N, 12.2%. IR spectrum (ν_{max}/cm^{-1}): ν(NH) 3217, 3153; ν(C=N) 1650; ν(NO_2) 1550.

4.2.5. μ-Oxalato-bis{(5,7,7,13-Tetramethyl-13-nitro-1,4,8,11-tetraazacyclotetradec-4-ene)nickel(II)} perchlorate dihydrate, [{Ni(enacne)}$_2$(C$_2$O$_4$)](ClO$_4$)$_2$·2H$_2$O

Sodium oxalate was added to a hot aqueous solution of [Ni(enacne)](ClO_4)$_2$ and the solution heated for c. 30 min. The insoluble blue *product* was filtered from the cold solution and washed with water, then ethanol. *Anal.* Calc. for $C_{15}H_{33}ClN_5NiO_8$: C, 35.6; H, 6.6; N, 13.9. Found: C, 35.6, 35.8; H, 5.9, 5.7; N, 13.8, 13.9%. IR spectrum (ν_{max}/cm^{-1}): ν(NH) 3284, 3264; ν(C=N)+ν(C=O) 1650vs, complex; ν(NO_2) 1545.

4.2.6. (Pentane-2,4-dionato κ^2 O,O′)(5,7,7,13-tetramethyl-13-nitro-1,4,8,11-tetraazacyclotetradec-4-ene κ^4)nickel(II) perchlorate [Ni(enacne)(acac)]ClO$_4$

Pentane-2,4-dione (acetyl acetone, 0.5 g) was added to a hot aqueous solution of [Ni(enacne)](ClO_4)$_2$ (2 g), followed by dilute aqueous ammonia. The sparingly soluble blue *product* crystallised as the solution cooled. This was filtered off, washed with water then ethanol and was recrystallised from hot acetone/propan-2-ol. *Anal.* Calc. for $C_{19}H_{36}ClN_5NiO_8$: C, 41.0; H, 6.5; N, 12.6. Found: C, 41.2; H, 6.6; N, 12.6%. IR spectrum (ν_{max}/cm^{-1}): ν(NH) 3326, 3267; ν(C=N) 1656; ν(NO_2) 1549; (acac$^-$) 1600, 1520.

4.2.7. Nitrito κ^{2}O,O′(5,7,7,13-tetramethyl-13-nitro-1,4,8,11-tetraazacyclotetradec-4-ene κ^4)nickel(II) perchlorate, [Ni(enacne)(NO$_2$)]ClO$_4$

[Ni(enacne)](ClO_4)$_2$ was dissolved in a hot methanol solution containing a small excess of $NaNO_2$. The grey–green *product* that crystallised as the solution cooled was recrystallised from hot methanol/propan-2-ol. *Anal.* Calc. for $C_{14}H_{29}ClN_6NiO_8$: C, 33.4; H, 5.8; N, 16.7. Found: C, 33.9; H, 5.9; N, 16.6%. IR spectrum (ν_{max}/cm^{-1}): ν(NH) 3294, 3252; ν(C=N) 1658; ν(NO_2) 1540; ν_{as}(NO_2^-) 1203.

4.2.8. Nitrito κ^2 O,O′(13-ethyl-5,7,7-trimethyl-13-nitro-1,4,8,11-tetraazacyclotetradec-4-ene κ^4)nickel(II) perchlorate, [Ni(enacnp)(NO$_2$)]ClO$_4$

Anal. Calc. for $C_{15}H_{31}ClN_5NiO_4$: C, 33.4; H, 5.8; N, 16.6. Found: C, 33.6; H, 5.7; N, 16.6%. IR spectrum (ν_{max}/cm^{-1}): ν(NH) 3294, 3252; ν(C=N) 1658; ν(NO_2) 1540; ν_{as}(NO_2^-) 1203.

4.3. Crystallography

Diffraction data was collected for an orange plate ($0.80 \times 0.33 \times 0.03$ mm) grown from water of (5,7,7,13-tetramethyl-13-nitro-1,4,8,11-tetraazacyclotetradec-4-ene)-nickel(II) tetrachlorozincate, [Ni(enacne)][ZnCl$_4$], $C_{14}H_{29}Cl_4N_5NiO_2Zn$, $M_r = 565.3$.

The crystal was monoclinic, space group $P\,2_1/n$, a 9.3111(6), b 18.479(1), c 13.2900(8) Å, β 108.644(1)°. 7589 Reflections ($2.4 < \theta < 26.3°$) were used to determine cell parameters at 93(2) K.

Data was collected at 93(2) K, by using a SMART 1K CCD diffractometer [18] with fine focus sealed tube Mo Kα radiation (λ 0.71073 Å) using ω scans. Multi-scan absorption corrections [19] were applied, T_{min} 0.675. T_{max} 0.928. 17337 Reflections (avge. $R_{equiv} = 0.0322$) were collected ($-10 < h < 11$; $-22 < k < 22$; $-16 < l < 15$; $2.36 < \theta < 26.37°$) with 4341 unique reflections and 3475 reflections with $I > 2\sigma(I)$.

The structure was solved and refined on F^2 using SHELXTL [20], with H(C) and H(N) atoms in calculated positions and riding. A persistent residual peak near the axial substitution position on C5 was accommodated by assuming superposition of the 1*R*,8*R*,11*S* and 1*S*,8*S*,11*R* arrangements of the cation, effectively reversing the N4–N8 chelate ring, and thus shifting the position of the axial methyl substituent from site C72 to site C52. Independently refined sof of (methyl group C72 and H8) and of (methyl group C52 and H4) had a combined value close to 1. Refinement with the combined sof fixed at 1 gave values for sof (C72 methyl and H4) = 0.80(1) and for sof (C52 methyl and H8) = 0.20(1). The bond C5–C52 was restrained (1.56 Å, with default parameters), but remained long. Because of the low sof for C52 and the 1.68(1) Å C5–C52 distance, C52 was refined with isotropic parameters.

Final R_1 ($2\sigma(I)$) = 0.0352, R_1 (all) = 0.0503, R_w ($2\sigma(I)$) = 0.0848, R_w (all) = 0.0887; $(w = 1/[\sigma^2(F_o^2) + (0.0559P))^2]$, where $P = (F_o^2 + 2F_c^2)/3$.

5. Supplementary material

Crystallographic data has been deposited with the Cambridge Crystallographic Data Centre for this structure; CCDC 281480. Copies of this information may be obtained

GSK-3beta is a regulatory serine/threonine kinase that has many cellular targets. So, selecting small molecule inhibitors of GSK-3beta may have a variety of therapeutic uses including the treatment of neurodegenerative diseases, type II diabetes and cancer. This inhibition occurs on the edge of its ATP-binding-site [4].

Activation of the energy-sensing enzyme AMP-activated protein kinase (AMPK) has been shown to increase insulin-independent glucose transport in skeletal muscle in response to such stimuli as exercise and hypoxia. The concentration of malonyl CoA was increased and acetyl CoA carboxylase phosphorylation at serine 79 was decreased as the medium glucose was raised [5].

DNA damage can be induced by aminoacetone, a metabolite of threonine and glycine but this only occurs in the presence of Cu(II) [6].

Calcineurin is a serine/threonine phosphatase involved in cellular responses to calcium-mobilizing signals. Mutations of the antioxidant enzyme Cu, Zn superoxidismutase can be associated to calcineurin [7].

Since it is difficult to unravel all possible interactions in living systems due to the great number of existing potential ligands and metal ions involved in the biological processes, we have attempted to study the metals and ligands of interest in separate. The work here described intended to assess the interactions of a phosphorylated ligand, an amino acid containing an hydroxyl group and the metal ion Cu(II).

The present paper reports the results of aqueous solution equilibria and spectral studies of binary and ternary copper(II) ion complexes with ATP or PCr with the amino acids glycine, serine, tyrosine and threonine (Fig. 1). Although all these binary systems but Cu(II)–PCr were already studied, they were repeated in order to use the same conditions for the binary and ternary systems.

The phosphorylated ligands chosen were ATP and PCr. ATP is responsible for most of the energy-consuming activities in a cell. When the third phosphate group of ATP is removed by hydrolysis, resulting in the formation of ADP and Pi, free energy is released. PCr is an organic compound found in muscle tissue capable of storing and providing energy for muscular contraction. Creatine kinase, an enzyme present in muscle, brain, and other tissues of vertebrates, catalyses the reversible conversion of ADP and PCr into ATP and creatine [8].

The amino acids selected were serine, tyrosine, threonine and glycine. Glycine is the only amino acid of the four under study that does not have a hydroxyl group, and was used for comparison with the others in order to establish possible hydroxyl-phosphate interactions.

Glycine is a very important amino acid present in collagen and synthesized from serine [9]. Serine is involved in the synthesis of sphingol and therefore in the formation of sphingomyelins (phospholipids) in the brain. In the phosphoproteins, serine is present as phosphoserine [9]. It is part of the active center in the enzyme acetylcholinesterase. Acetylcholine synthesis is made through the choline–acetylase enzyme in the presence of ATP. PCr can replace ATP in this reaction [10]. Threonine's behavior and importance is similar to serine's. Tyrosine presents a third basic substituent in the aromatic ring, a hydroxy phenol group. This third group is not spatially favored for a direct complexation to a metal ion, but it is prone to participate in a complex of 5 or 6 linked rings [11]. Tyrosine is the precursor of the thyroid hormones and of melanin [8].

2. Experimental

2.1. Materials

ATP, PCr, Gly, Ser, Thr and Tyr were purchased from Sigma–Aldrich Chem. Co., USA and were used as received. Copper(II) sulfate pentahydrate, potassium nitrate, standard solutions of carbonate-free potassium hydroxide (Titrisol®) 0.1 mol/L, EDTA $c = 0.1$ mol/L and the buffer solutions of pH 4.0 and 7.0 were purchased from Merck (Germany), p.a. reagents. All other chemicals used were of analytical grade. All solutions and experiments were made with double distilled, deionized and carbonate-free water.

2.2. pH titrations

2.2.1. Reagents

A carbonate-free potassium hydroxide 0.1 mol/L solution was prepared from Titrisol ampoules. A copper(II) sulfate solution (0.01 mol/L) was prepared by dissolving copper(II) sulfate pentahydrate in deionized and bidistilled water and was standardized against a standard solution of EDTA $c = 0.1$ mol/L (Titriplex). All solutions were prepared with doubly distilled, deionized and carbonate-free water.

2.2.2. Apparatus

The titrimetric data were obtained using an E485 Methrom Herisau Multi-hand semiautomatic microburette, a B375 Micronal pH meter and a combined glass electrode. The glass electrode was calibrated before each titration with two Merck standard buffer solutions in a nitrate medium: first with the pH 7.0 solutions (the same in the bulb) followed by a pH 4.0 solution. All titrations were performed at 25.0 ± 0.1 °C by coupling the titration cell with a thermostatic bath set at this temperature.

2.2.3. Procedure

For the determination of the acid dissociation constants of all ligands (Gly, Ser, Thr, Tyr, ATP and PCr), aqueous solutions (1×10^{-3} mol/L) of the ligands were titrated with 0.1 mol/L KOH at 25.0 °C under ionic strength of 0.1 mol/L using a 1.2 mol/L solution of KNO_3. The amino acid solutions were protonated by the proper addition of strong acid. For the determination of the binary systems (one ligand and Cu(II)), solutions containing either the amino acids (aa), or PCr or ATP and Cu(II) ion were titrated at 1:1 metal to ligand ratios. For the ternary systems (Cu(II), one of the aa and either ATP or PCr), the

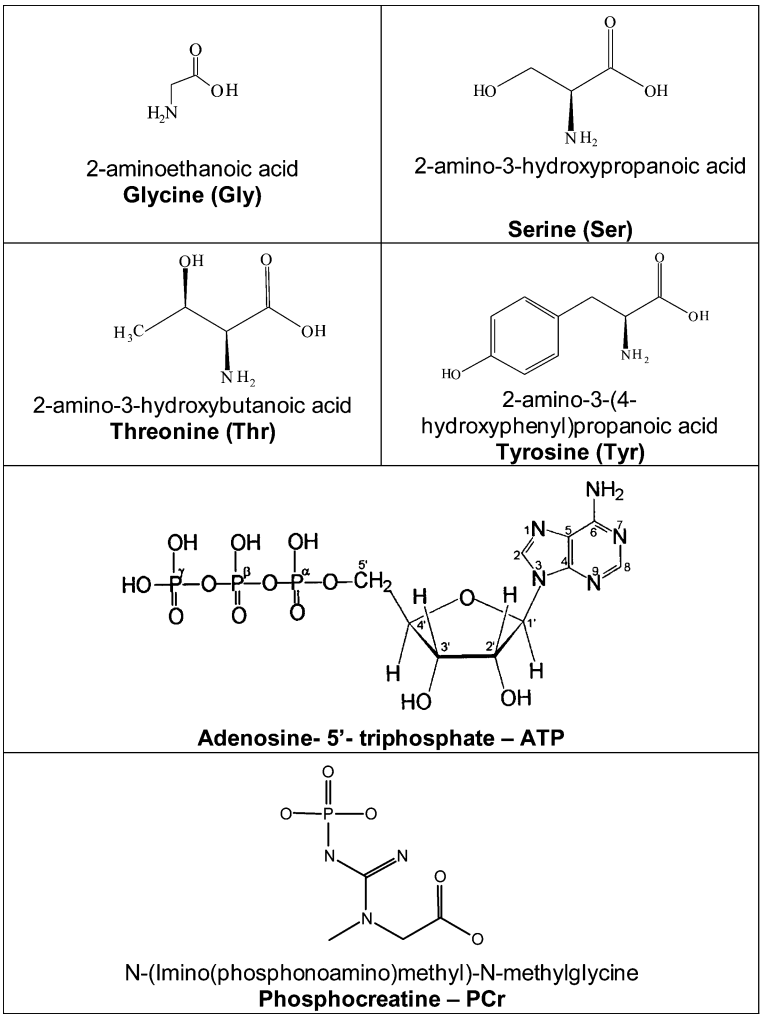

Fig. 1. Structures of ligands.

ratio used was 1:1:1 Cu(II):aa:ATP or PCr. The concentration of the stock solution of Cu(II) ion was 1×10^{-2} mol/L for all binary and ternary systems. The concentration of all studied ligands was always the same and equal to 1×10^{-3} mol/L. All binary and ternary systems were titrated with 0.1 mol/L KOH under the same experimental conditions mentioned above. Each set of titrations was performed at least thrice in order to check the repeatability of the data.

All the dissociation and the complex formation constants were determined using the HYPERQUAD program, and the speciation as a function of pH using the HYSS program [12].

The hydrolysis constants for the metal ion copper(II) were taken from the literature [13] and were fully employed in the calculations.

2.3. Spectral analysis

Cu(II) complexes were studied in aqueous solution at 25 °C by UV–Vis spectroscopy. These solutions were prepared in the same way as previously done for the potentiometry. The same metal:ligand ratio solutions were prepared and analyzed in a wide range of pH values, adjusted by adding small increments of 0.1 mol/L KOH solution in order to obtain the maximum absorbance of each predominant species, as was previously determined in the species distribution diagrams of all the binary and ternary systems. The ionic strength was 0.1 mol/L using a KNO_3 1.2 mol/L solution. A double-beam Perkin–Elmer Lambda 19 spectrophotometer was used with a quartz cell and 1 cm path length.

The solutions for EPR determinations were prepared by adding appropriate volumes of the ligand and the metal solutions in order to achieve a ratio of Cu(II):ligand 1:1 in the binary systems (where L = aa or ATP or PCr) and of Cu(II):aa:ATP or Cu(II):aa:PCr 1:1:1 in the ternary systems, in a previously acidified solution, pH < 2.0 (solution of HNO_3 0.1 mol/L). The pH was then adjusted with a solution of KOH (1.0 and 0.1 mol/L) according to the values in which the maximum percentage of one species was found in the species distribution diagrams and following the maximum absorbance values of the d–d transitions of the complexed species in the UV spectra, for each set of ligands and the copper(II) ion.

The EPR spectra of the aqueous solutions were obtained at room temperature (300 K) in a quartz flat cell. An ESP 300E EPR spectrometer (Bruker, Germany) was operated at a frequency of ≈9.7 GHz (X-band), with 100 kHz of modulation frequency, 10.145 G of modulation amplitude and approximately 20 mW microwave power.

It was not possible to obtain the spectrum of ATP and Cu(II) in solution because substantial insoluble products were formed in the pH where the 1:1 complex is formed.

3. Results and discussion

The stability of binary and ternary complexes may be evaluated by the following equilibria (charges were omitted for simplicity):

$$pM + qH + rA \text{ (or B)} \Longleftrightarrow M_pH_qA_r \text{ (or } B_r\text{)}, \quad \beta_{M_pH_qA_r} \text{ (or Br)}, \tag{1}$$

$$pM + qH + rA + sB \Longleftrightarrow M_pH_qA_rB_s, \quad \beta_{M_pH_qA_rB_s}, \tag{2}$$

where M is the metal ion, H is the proton, A is one of the aa and B is ATP or PCr.

The stability constant of the binary and ternary complexes may be represented by:

$$\log \beta_{pqr} = [M_pH_qA_r]/[M]^p[H]^q[A]^r, \tag{3}$$

$$\log \beta_{pqrs} = [M_pH_qA_rB_s]/[M]^p[H]^q[A]^r[B]^s. \tag{4}$$

It is also possible to define the stability constants of ternary complexes in relation to their corresponding binary ones [11], represented by the equilibria (5) and (6):

$$M + B \Longleftrightarrow MB, \quad K^M_{MB} = [MB]/[M][B], \tag{5}$$

$$MA + B \Longleftrightarrow MAB, \quad K^{MA}_{MAB} = [MAB]/[MA][B]. \tag{6}$$

The difference between the stability of the ternary and the two correspondent binary complexes shows the tendency of the formation of ternary species [14]. This is expressed by the following equation:

$$\Delta \log K = \log \beta_{MAB} - (\log \beta_{MA} + \log \beta_{MB}). \tag{7}$$

In order to verify the tendency of the formation of complexes with intramolecular interactions, the difference between the stability constants of the ternary and the binary complexes was calculated using Eq. (7).

3.1. Potentiometric studies

By using the potentiometric titration data, the protonation constants of the ligands and the complexation constants of the binary and ternary systems were refined using the HYPERQUAD program [12].

3.1.1. Dissociation constants of the ligands

Although data of all ligands can be found in the literature, all of them were refined in this study in order to obtain all values based on the same experimental conditions. The values found in this study (Table 1) are in good agree with the ones reported [15–17].

Table 1
Protonation constants ($\log\beta$) of Gly, Ser, Thr, Tyr, PCr and ATP at 25 °C, $I = 0.1$ mol/L (KNO_3) (the SDs are given in parenthesis)

Species	$\log\beta$ (this work)	$\log\beta$ [Ref.]
H_2Gly	12.44 (0.01)	11.70–12.29 [15]
HGly	9.62 (0.01)	9.30–9.80 [15]
H_2Ser	11.77 (0.01)	11.14–11.70 [15]
HSer	9.12 (0.01)	9.05–9.30 [15]
H_2Thr	11.69 (0.01)	11.13–11.27 [15]
HThr	8.98 (0.01)	8.93–9.52 [15]
H_2Tyr	11.73 (0.01)	10.91–11.32 [15]
HTyr	9.05 (0.01)	9.03–9.30 [15]
H_2ATP	11.05 (0.01)	10.75 [16]
HATP	6.81 (0.01)	6.50 [16]
H_2PCr	15.29 (0.01)	15.70 [17]
HPCr	11.04 (0.02)	11.20 [17]

PCr has four acidic groups: the first protonation constant refers to the guanidine group, the second to the hydroxyl group of the phosphoric group, the third to the carboxylic acid portion and the fourth to another hydroxyl group of the phosphoric terminal group. The obtained values refer to the guanidine group ($\log\beta_1$) and to the hydroxyl group of the phosphoric group ($\log\beta_2$) [17].

3.1.2. Cu(II):aa, Cu(II):ATP and Cu(II):PCR binary systems

The values of the formation constants of all binary species are listed in Table 2.

The only system for which no literature data could be found is Cu:PCr, but anyhow all systems were refined in this study so that all values would be based on the same experimental conditions.

It can be seen in Table 2 that the values for all Cu:aa systems studied are very similar. Since Gly does not have the hydroxyl group and behaves like the other aa, they are all

Table 2
Stability constants of binary systems Cu(II):aa (aa = Gly, Ser, Thr and Tyr), Cu(II):ATP and Cu(II):PCr at 25 °C, $I = 0.1$ mol/L (KNO_3) (the SDs are given in parenthesis)

Species	$\log\beta$ (this work)	$\log\beta$ [Ref.]
CuGly	8.23 (0.01)	8.23 [18]

$CuTyrH_{-2}$	−8.20 (0.01)	
CuATPH	10.36 (0.01)	10.24 [21]
CuATP	6.40 (0.01)	6.51 [21], 6.42 [22]
$CuATPH_{-1}$	−1.40 (0.01)	−1.21 [21]
$CuATPH_{-2}$	−10.52 (0.01)	
CuPCrH	14.41 (0.01)	
CuPCr	7.89 (0.01)	
$CuPCrH_{-1}$	1.97 (0.01)	

probably bound through the amino and the carboxylic groups, leaving the hydroxyl group free. The values here obtained were compared with the reported ones [18–20].

In all Cu:aa species distribution diagrams, ML species are formed early (pH around 3) due to the great affinity between Cu(II) and the amino group, which has its proton displaced in order to complexate. In Fig. 2 the species distribution diagram of Cu:Ser is shown as example.

The values of the formation constants of the Cu:ATP system are shown in Table 2 and compared with those already determined [21–23]. In Fig. 3, it can be seen that the Cu:ATP species is formed in higher pH than the Cu:aa species.

Although there is the possibility that PCr may act as a tridentate ligand, this hypothesis is not probable because the value of $\log \beta_{CuPCr}$ (7.89), Table 2, is much lower than the value for the correspondent complex with phosphoserine (9.38), where it acts as tridentate [24]. If the correspondent values of $\log \beta_{CuL}$ where L = diisopropylphosphorylguanidine (DPG), which does not have the carboxylate group, or creatine (Cr), which does not have the phosphate group ($\log \beta_{CuDPG} = 8.63$ [25] and $\log \beta_{CuCr} = 7.20$ [15]) are compared, it can be concluded that the value of $\log \beta_{CuPCr}$ can be either for the coordination through the oxygen atom of the phosphate group and through the nitrogen atom of the guanidine group, or through the oxygen atom of the carboxylate group and through the nitrogen atom of the guanidine group.

In Fig. 4, the species distribution can be seen as a function of pH for the species for which the constants were here determined, besides the hydrolysis constants of Cu(II) and the protonation constants of PCr. It can be observed that CuHPCr predominates until pH approximately 6, and afterwards, as the deprotonation begins to occur, the hydrolysis of the complex begins.

3.1.3. Cu:ATP:aa and Cu:PCr:aa ternary systems

The formation constants of the ternary systems (Cu:ATP or PCr:aa 1:1:1) involving Cu(II) and one of the aa and ATP or one of the aa and PCr are presented in Tables 3 and 4.

All ternary species in the systems Cu:ATP:aa have almost coincidental curves. This coincidental pH profile behavior explains the very similar stability constants calculated and presented in Table 3. The value of the formation constant of the CuATPTyr species was compared with an already determined value (12.86) [26].

The same occurs with the systems Cu:PCr:aa, as can be seen in Table 4.

From the species distribution diagram it can be concluded that the binary species prevail at acidic pH values for all Cu:ATP:aa systems and the ternary complexes only

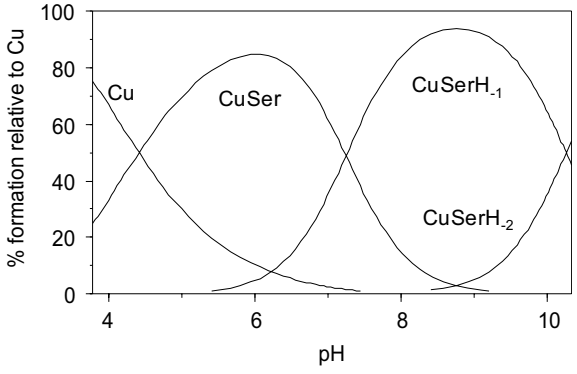

Fig. 2. Species distribution as a function of pH of 1:1 Cu:Ser.

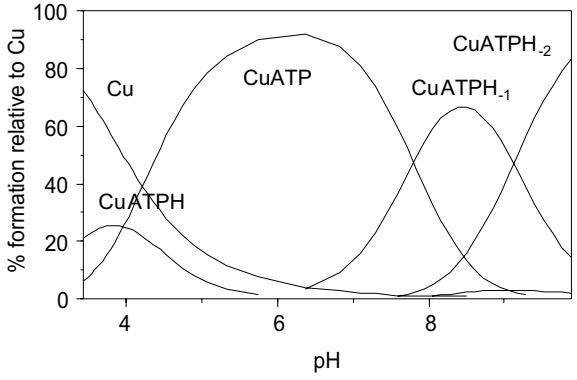

Fig. 3. Species distribution as a function of pH of 1:1 Cu:ATP.

at pH higher than 6. In Fig. 5, the species distribution diagram of Cu:ATP:Ser can be seen as an example.

As in the ternary systems where ATP was the second ligand, all profiles for the systems Cu:PCr:aa had coincidental behavior. The species distribution diagram of Cu:PCr:Ser is shown in Fig. 6. As the stability constants of the ternary systems are very similar, so are the species distribution diagrams. In these cases the ternary species predominate in all the pH range. In acidic pH values the protonated species prevail and after, pH 7, the species Cu:PCr:aa is the most abundant.

3.1.4. Intramolecular interactions in ternary systems

The possibility of intramolecular interactions between ATP or PCr and the aa in the ternary systems was investigated. These interactions can occur through hydrogen bonds between the OH group of the amino acid and the negatively charged oxygen atoms of the ATP's phosphate or the PCr's phosphate or carboxylate group. The evaluation of the possibility of intramolecular aa–ATP or aa–PCr interaction, shown in Table 5, was done by calculating the experimental values of $\log\beta$ with $\log K$ (Eq. (7)).

The values of $\Delta\log K$ for the ternary complexes formed with ATP do not indicate any additional stabilization of the complexes. If the Δ of the other complexes are compared with the glycinato one, the differences are −0.01, +0.08 and +0.2, therefore, interactions in CuATPTyr and CuATPThr complexes cannot be entirely rejected.

For the ternary complexes with PCr, the complexes Cu:PCr:Ser and Cu:PCr:Tyr show values of $\Delta\log K$ higher than zero, which can be justified by the presence of any kind of interaction between the ligands. As PCr acts as a bidentate ligand, there is one non-coordinated position (carboxylate or phosphate) and both Ser and Tyr have an OH group free. Since the possibility of interaction does not occur when the amino acid is Gly, which does not have an OH group, it may be assumed that the interaction in the ternary complexes of PCr with Ser and Tyr is between a phosphate or carboxylate of PCr and the OH group of the amino acids. In the case of Thr, this amino acid has an OH group in the β carbon, similarly to Ser, but it has an additional terminal methyl group that can make the interaction with PCr difficult. If the same comparison of Δ with the glycinato compound is done, the values obtained are +0.5, +0.31 and +0.6 which reinforce the probability of interactions.

3.2. Ultraviolet visible spectral analysis

In all systems studied, two distinct bands could be observed: a very intense band in the UV region that corresponds to LMTC and another one, less intense, in the visible region corresponding to a d–d transition band [27].

The wide band observed in the visible region, in all systems, is characteristic of the d^9 configuration of the copper(II) ion, which originates only one term of the free ion,

^{2}D, that has its energy levels shifted by the octahedral field. Both shifted levels belong to the same ^{2}D term and must have the same electronic repulsion [28].

In all the systems studied the donor atoms are either oxygen or nitrogen. For this reason, it is interesting to recognize when only oxygen or nitrogen is bonded to Cu(II). When oxygen atoms are replaced by nitrogen ones in a tetragonal geometry in a cupric ion, the maximum absorption wavelength value shifts to smaller values, indicating a formation of a stronger ligand field, and the molar absorptivity usually increases [28]. Generally speaking, when the maximum wavelength (λ_{max}) is greater than or equal to 720 nm, the chelating atom is oxygen; when λ_{max} is near 620 nm, the chelating atom is the nitrogen; and for values between 620 and 720 nm, both atoms are chelating the metal ion.

3.2.1. Binary systems

3.2.1.1. Cu:ATP system. This system was already studied by us [23]. As can be seen in Table 6, the maximum wavelengths of the d–d bands shift from 818.4 to 720.4 nm as the pH rises. These values suggest that Cu(II) is bound only to oxygen atoms, that is, to two phosphate groups.

3.2.1.2. Cu:PCr system. As can be seen in Table 6, the maximum wavelengths of the d–d bands in the Cu:PCr system shift from 754.0 to 692.4 nm. This indicates that the donor atoms are one oxygen (phosphate or carboxylate) and one nitrogen (guanidine group).

3.2.1.3. Cu:aa. For all aa, the maximum wavelength of the d–d bands shift from 802 nm at lower pHs to 620 nm at more basic pHs, as can be seen in Table 6 for the Cu:Ser system. This indicates that the amino acids bind first to Cu(II) through the oxygen of the carboxylate and, as the pH rises, the nitrogen atom of the amine group is also bound.

3.2.2. Ternary systems

3.2.2.1. Cu:ATP:aa systems. In all systems it can be observed that at low pHs all the maximum wavelengths are above 720 nm. This suggests that the predominating species is not bound to a nitrogen atom. This confirms that in the ternary systems with ATP, the Cu(II) ion binds firstly to ATP, then to the oxygen atom of the amino acid and only when the pH is higher than 7 the nitrogen is coordinated. At this moment the maximum wavelength is lower than 720 nm. The values for Cu:ATP:Ser can be seen in Table 6.

3.2.2.2. Cu:PCr:aa systems. For the ternary systems Cu:PCr:aa, it is also possible to make some generalizations (see Table 6). At lower pHs, the predominant species does not have a nitrogen atom of the aa bounded, which justifies the value of $\lambda_{max} > 720$ nm. As the pH rises the amino groups of the ligands begin to deprotonate and the λ_{max} shifts to smaller values, indicating the participation of nitrogen in the coordination.

Table 6
UV spectra data at different pH values of the binary systems Cu(II):ATP, Cu:PCr and Cu:aa in a 1:1 ratio and ternary systems Cu(II):ATP:aa and Cu(II):PCr:aa in a 1:1:1 ratio at 25 °C, $I = 0.1$ mol/L (KNO_3) (aa = Gly, Ser, Thr and Tyr)

	9.95	649.2	56.68

3.3. EPR spectral analysis

The EPR analysis was performed for the binary systems Cu:PCr and Cu:aa and for the ternary systems Cu:ATP:aa and Cu:PCr:aa. The isotropic EPR parameter A_0 of the corresponding species is shown in Table 7.

Table 7
Isotropic EPR parameter A_0 and the corresponding pH of the binary systems species Cu:aa and Cu:PCr in a 1:1 ratio and of the ternary systems Cu:ATP:aa and Cu:PCr:aa in a 1:1:1 ratio (aa = Gly, Ser, Thr and Tyr)

Predominant species	pH	A_0 ($\times 10^{-4}$), cm^{-1}
CuGly	5.82	57.5
CuSer	6.46	60.71
CuTyr	5.40	61.22
CuThr	6.23	61.5
CuATP	n.d.	n.d.
CuPCr	6.53	61.5
CuATPGly	8.21	64.0
CuATPSer	7.70	64.0
CuATPTyr	7.86	64.0
CuATPThr	7.89	64.0
CuPCrGly	9.47	64.0
CuPCrSer	8.80	64.0
CuPCrTyr	8.83	68.0
CuPCrThre	8.87	68.0

It can be observed that the A_0 parameter, which is associated to the ligand field, has lower values for the binary systems (57.5–61.5) and greater values for the ternary systems (64.0–68.0), indicating that more donor atoms are coordinated to Cu(II), which means that the ternary compounds were formed.

4. Conclusions

There are many possibilities regarding the bonding sites of ATP in Cu(II) complexes but from the values here obtained we can suggest that the donor atoms in the Cu:ATP complex are probably two oxygen atoms of phosphates [23].

The PCr molecule has three possible donor atoms: one oxygen of the phosphate group, the nitrogen atom of the guanidine group and the oxygen of the carboxylate group. Although there is the possibility of PCr acting as a tridentate ligand, this hypothesis is not probable because the value of $\log\beta_{\mathrm{CuPCr}}$ (7.89) is much lower than the value for the correspondent complex with phosphoserine (9.38) where it acts as tridentate [24]. If we compare the correspondent values of $\log\beta_{\mathrm{CuI}}$ where L = diisopropylphosphorylguanidine (DPG), which does not have the carboxylate group, or creatine (Cr), which does not have the phosphate group ($\log\beta_{\mathrm{CuDPG}} = 8.63$ [25] and $\log\beta_{\mathrm{CuCr}} = 7.20$ [15]), it can be concluded that the value of $\log\beta_{\mathrm{CuPCr}}$ can be either for coordination through the oxygen atom of the phosphate group and the nitrogen atom of the guanidine group, or through the oxygen atom of the carboxylate group and the nitrogen atom of the guanidine group. Since NMR analysis is very difficult for Cu(II) ion and far IR spectra cannot differentiate a M–O band corresponding to an oxygen of the phosphate and an oxygen of the carboxylate, we decided to study these complexes in the solid state. We synthesized a complex with Cu(II), PCr and Tyr and after its characterization we concluded that it was a complex Cu:Tyr:$PO_3H_2 \cdot H_2O$ [29] where PCr lost the creatine molecule. So it is more probable that the oxygen atom bound to Cu(II) in the Cu–PCr complex is that of the phosphate.

The values of the stability constants of the ternary Cu(II) complexes with the amino acid polyamines and ATP or PCr indicate that these are stable complexes. This behavior was confirmed by the increase of the maximum wavelength in the absorption spectra and the increase of the A_0 parameter of the EPR analyses when we compare them with the binary complexes. $\Delta\log K(\log\beta_{\mathrm{CuaaL}} - (\log\beta_{\mathrm{Cuaa}} + \log\beta_{\mathrm{CuLATP}}))$, aa = Gly, Ser, Tyr and Thr, and L = ATP or PCr, showed that in all cases but when aa = Ser or Tyr and L = PCr, the ternary complexes are less stable than the binary ones, suggesting that in most cases no interaction occurs between the ligands in the ternary complexes. This probably only occurs when L = PCr and aa = Ser or Tyr. Since PCr acts as a bidentate ligand, there is one non-coordinated position and both Ser and Tyr have an OH group free. Since the possibility of interaction does not occur when the amino acid is Gly, which does not have an OH group, it seems that the interaction in the ternary complexes of PCr with Ser and Tyr is between a phosphate or carboxylate (probably carboxylate) of PCr and the OH group of the amino acids. These results can help understand biological interactions among a phosphorylated ligand, an amino acid containing an hydroxyl group and the metal ion Cu(II).

Appendix A. Supplementary data

Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2005.09.016.

with a Nicolet Avatar 360 FT-IR spectrometer using the KBr pellet technique. Thermogravimetric analyses were conducted on a SDT Q600 Thermal Analyzer using a heating rate of 5 °C/min from room temperature to 900 °C.

2.2. Synthesis

2.2.1. [Zn(cca)(phen)]$_n$ (1)

A mixture of H_2cca (0.020 g, 0.1 mmol), $Zn(Ac)_2 \cdot 2H_2O$ (0.022 g, 0.1 mmol), phen · H_2O (0.020 g, 0.1 mmol), NaOH aqueous solution (0.3 ml, 0.65 mol l^{-1}) and deionized water (5 ml) was sealed in a Teflon-lined stainless vessel (25 ml), and heated at 140 °C for 72 h under autogenous pressure, then cooled slowly to room temperature. Colorless single crystals were obtained by filtration, washed with water and ethanol, and dried in air. Yield: 0.038 g (87.2%). *Anal*. Calc. for $C_{22}H_{14}N_2O_4Zn$: C, 60.59; H, 3.21; N. 6.43. Found: C, 60.34; H, 3.59; N, 6.38%. IR data (KBr pellet, cm^{-1}): 3442m, 1640m, 1625m, 1599s, 1555m, 1518m, 1428s, 1383s, 1355s, 1237w, 1142w, 1105w, 982w, 869w, 845w, 789m, 725s.

2.2.2. [Co(cca)$_{0.5}$(Hcca)(phen)(H_2O)] (2)

The synthesis of complex **2** followed the similar procedure as for complex **1**, but using $CoCl_2 \cdot 6H_2O$ and heated at 120 °C. Yield: 0.015 g (27.6%). *Anal*. Calc. for $C_{27}H_{20}N_2O_7Co$: C, 59.65; H, 3.68; N, 5.15. Found: C, 59.43; H, 3.39; N, 4.77%. IR data (KBr pellet, cm^{-1}): 3440s, 1689m, 1608m, 1427s, 1384s, 984w, 841w, 789m, 726m, 685w.

2.2.3. [Cu(cca)(phen)]$_n \cdot nH_2O$ (3)

The synthesis of complex **3** followed the similar procedure as for complex **1**, but using $CuCl_2 \cdot 2H_2O$. Yield: 0.036 g (79.7%). *Anal*. Calc. for $C_{22}H_{16}N_2O_5Cu$: C, 58.42; H, 3.54; N, 6.20. Found: C, 58.34; H, 3.29; N, 6.19%. IR data (KBr pellet, cm^{-1}): 3425s, 1640m, 1590s, 1551m, 1517m, 1425s, 1360s, 1235w, 1175w, 1106w, 1049w, 985w, 854m, 787m, 724s, 648w.

2.2.4. [Mn(cca)(phen)(H_2O)]$_n \cdot 0.25nH_2O$ (4)

The synthesis of complex **4** followed the similar procedure as for complex **1**, but using $Mn(Ac)_2 \cdot 2H_2O$. Yield: 0.02 g (44.7%). *Anal*. Calc. for $C_{22}H_{16.5}N_2O_{5.25}Mn$: C, 58.96; H, 3.68; N, 6.25. Found: C, 59.07; H, 3.52; N, 6.52%. IR data (KBr pellet, cm^{-1}): 3439s, 1650s, 1597m, 1553m, 1511w, 1425m, 1379s, 1345m, 1241w, 1098w, 1042w, 987w, 852w, 789w, 730w, 712w.

2.3. X-ray diffraction determination

Diffraction intensities for the four complexes were collected at 293 K on a Bruker SMART 1000 CCD area detector diffractometer employing graphite monochromatized Mo Kα radiation ($\lambda = 0.71073$ Å) in ϕ and ω scan modes. Semi-empirical absorption correction was applied on the four complexes using the SADABS program [25]. The structures were solved by direct methods [26] and refined by full-matrix least-squares method on F^2 using SHELXS 97 and SHELXL 97 programs, respectively [26,27]. Non-hydrogen atoms were refined anisotropically. Hydrogen atoms were placed in geometrically calculated positions. The crystallographic data for complexes **1**–**4** are listed in Table 1, selected bond lengths (Å) and bond angles (°) in Table 2.

3. Results and description

3.1. Description of the structures

In complexes **1**–**4**, the ligands derived from H_2cca proligand adopt three kinds of coordination modes, as shown in Scheme 1. The coordination mode Scheme 1a has been reported [24].

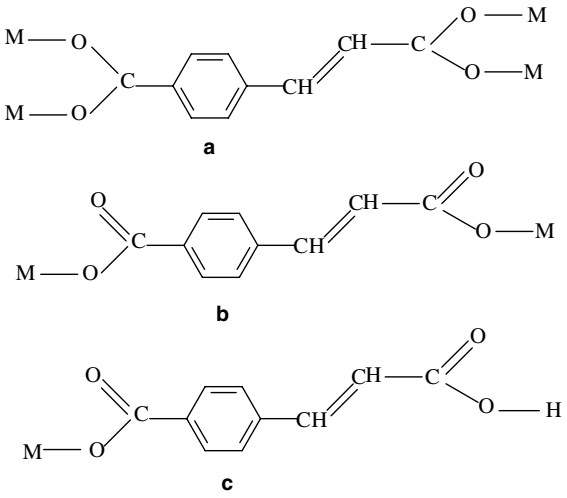

Scheme 1. The coordination modes of the ligands derived from H_2cca proligand in complexes **1**–**4**.

3.1.1. *[Zn(cca)(phen)]$_n$ (**1**)*

There is only one metal ion environment in complex **1**. As shown in Fig. 1, Zn(II) ion is placed in a distorted octahedron, which is completed by four oxygen atoms of four cca^{2-} anions and two nitrogen atoms of one phen ligand with the same Zn–N distance. In complex **1**, each cca^{2-} anion adopts a bis(bridging-bidentate) mode, bridging four Zn(II) ions (see Scheme 1a). All Zn(II) ions are linked by cca^{2-} anions into a three-dimensional MOF with channels of 12.388×13.381 Å (defined by the separation between two adjacent zinc atoms, see Fig. 2). Chelating phen ligand occupies the diagonal position, which greatly decreases the dimensions of the cavities. All phen rings in complex **1** are parallel to each other, and the nearest face-to-face distance is 3.29 Å, indicating the presence of π–π stacking interaction, which stabilizes the structure.

3.1.2. *[Co(cca)$_{0.5}$(Hcca)(phen)(H$_2$O)] (**2**)*

Complex **2** is a three-dimensional supramolecular structure constructed by coordination bonds, hydrogen bonds and π–π stacking interactions. Not all H_2cca ligands are completely deprotonated. Two types of coordination modes for anions of H_2cca ligands are present in the structure: (a) each carboxylate group of cca^{2-} anion adopts a monodentate mode, bridging two Co(II) ions (see Scheme 1b); (b) H_2cca ligand is partially deprotonated, forming $Hcca^-$ anion, which coordinates with Co(II) ions in monodentate mode (see Scheme 1c). The coordination environment of Co(II) ion is shown in Fig. 3. Each Co(II) ion is coordinated by two nitrogen atoms of one phen ligand and three oxygen atoms, one of which comes from a $Hcca^-$ anion, one from a cca^{2-} anion, and one from a water molecule. The coordination geometry of Co(II) ion can be described as trigonal bipyramid. Two Co(II) ions connected by a cca^{2-} anion constitute the basic building block, as shown in Fig. 3. Different kinds of hydrogen bonds are observed between the building blocks: (a) hydrogen bonds between the undeprotonated carboxylate groups and uncoordinated carboxylate oxygen atoms (O···O

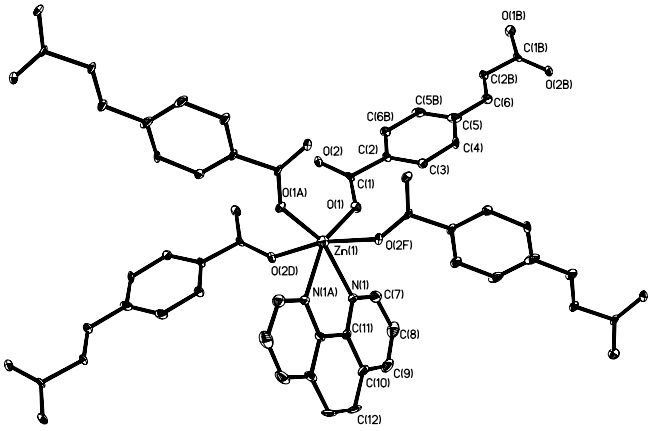

Fig. 1. The coordination environment of Zn(II) ion in complex **1** with 30% thermal ellipsoids, all hydrogen atoms are omitted for clarity.

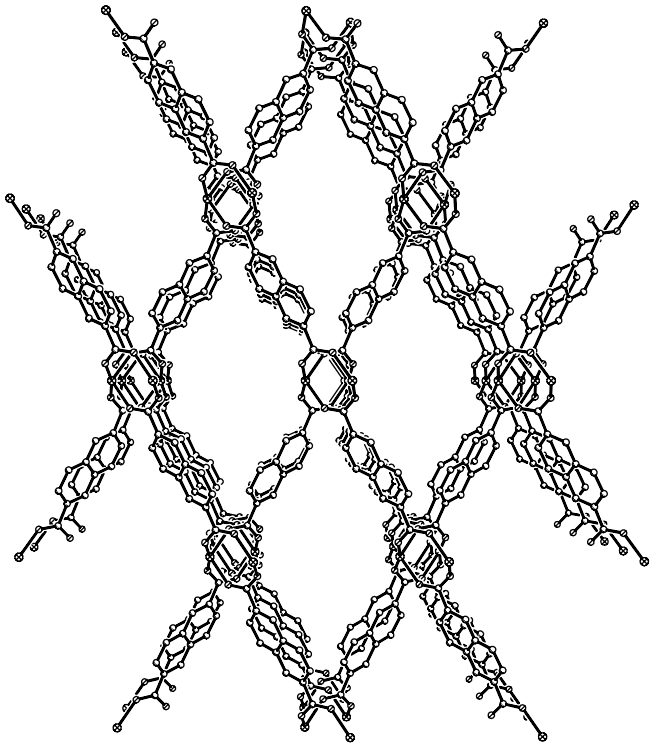

Fig. 2. The three-dimensional network of complex **1** viewed along the *c*-axis, phen molecules and all hydrogen atoms are omitted for clarity.

distance: 2.617 Å); (b) hydrogen bonds between the coordinated water molecules and uncoordinated carboxylate oxygen atoms (O···O distance: 2.713, 2.584 Å). These hydrogen bonds bring the building blocks into a layer structure with cavities of 13.626 × 15.861 Å (see Fig. 4). Chelating phen ligands lie at the diagonal lines, just the same as that in complex **1**. There are π–π stacking interactions between the phen rings (face-to-face distance: 3.29 Å), which causes the formation of a three-dimensional supramolecular network.

3.1.3. $[Cu(cca)(phen)]_n \cdot nH_2O$ (**3**)

The coordination environment of Cu(II) ion in complex **3** is shown in Fig. 5. Each Cu(II) ion is four-coordinated by two oxygen atoms of two cca^{2-} anions and two nitrogen atoms of one phen molecule with the same Cu–N bond length. The coordination geometry can be described as planar square. In complex **3**, cca^{2-} anions adopt bis(monodentate) mode (see Scheme 1b), linking Cu(II) ions into one-dimensional zigzag chains. There are hydrogen bonds between the crystal water molecules and the uncoordinated carboxylate oxygen atoms (O···O distance: 2.811 Å), which brings the chains into layers. All phen rings are parallel to each other and the nearest separation is 3.50 Å along the *a*-axis, showing the presence of π–π stacking interaction. It is the hydrogen bonds and the π–π stacking

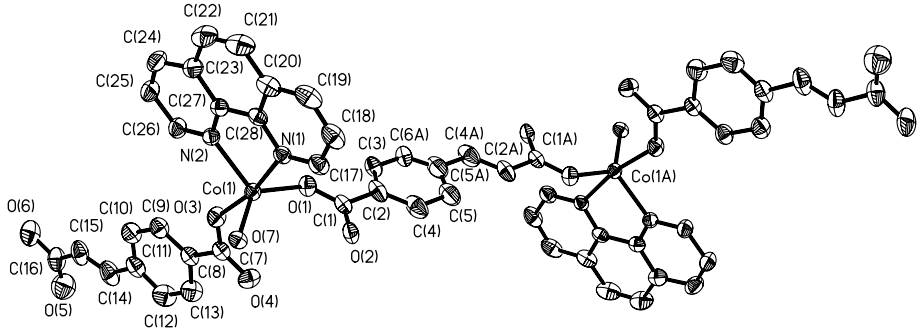

Fig. 3. The coordination environment of Co(II) ion in complex **2** with 30% thermal ellipsoids, all hydrogen atoms are omitted for clarity.

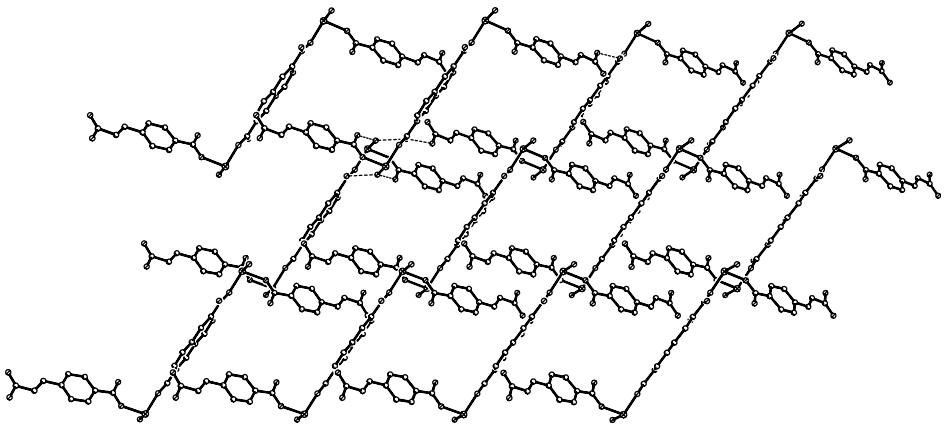

Fig. 4. Layer structure of complex **2** viewed along the *a*-axis, all phen molecules are omitted for clarity.

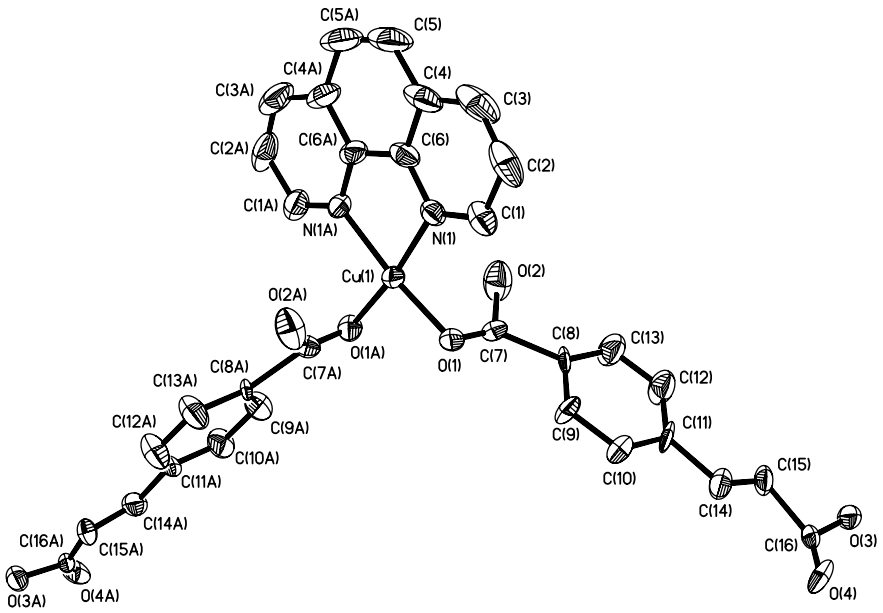

Fig. 5. The coordination environment of Co(II) ion in complex **3** with 30% thermal ellipsoids, all hydrogen atoms are omitted for clarity.

interactions that makes the formation of a three-dimensional supramolecular network, and crystal water molecules are enclosed, as shown in Fig. 6.

3.1.4. $[Mn(cca)(phen)(H_2O)]_n \cdot 0.25nH_2O$ (**4**)

There is only one type of metal ion environment in complex **4**. As shown in Fig. 7, each Mn(II) ion is placed in a distorted trigonal bipyramid, which is completed by two oxygen atoms of two cca^{2-} anions, one oxygen atom of one water molecule and two nitrogen atoms of one phen molecule. In complex **4**, each cca^{2-} anion adopts a bis(monodentate) mode (see Scheme 1b), bridging two Mn(II) ions. All Mn(II) ions are linked by cca^{2-} anions into one-dimensional zigzag chains, as shown in Fig. 8. There are hydrogen bonds between coordinated water molecules and uncoordinated carboxylate atoms (O···O distance: 2.922 Å) and π–π stacking interactions (face-to-face distance: 3.58 Å), which results in the formation of a three-dimensional structure.

From the above descriptions, it can be seen that although with same ligands H_2cca and phen, complexes **1**–**4** have different structures. In complex **1**, each cca^{2-} anion adopts a bis(bridging-bidentate) mode. Zn(II) ions are six-coordinated and linked by cca^{2-} anions into a three-dimensional structure; In complex **2**, each cca^{2-} anion adopts a bis(monodentate) mode and each $Hcca^{-}$ anion adopts a

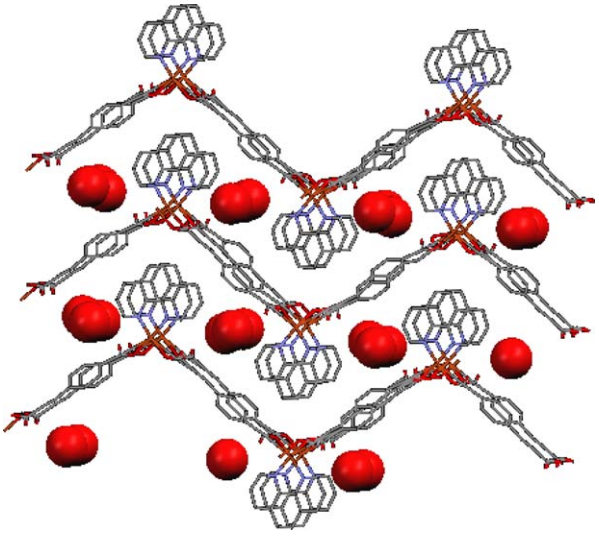

Fig. 6. Three-dimensional structure of complex **3** viewed along the *a*-axis, all hydrogen atoms are omitted for clarity, red balls represent the free water molecules.

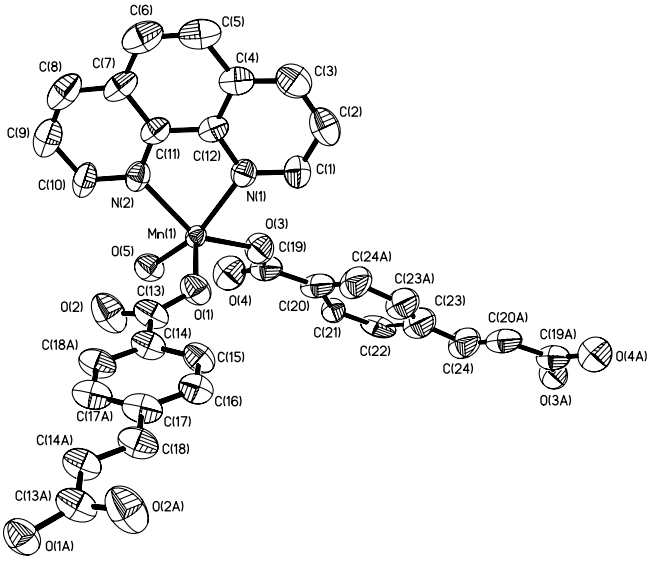

Fig. 7. The coordination environment of Mn(II) ion in complex **4** with 30% thermal ellipsoids, all hydrogen atoms are omitted for clarity.

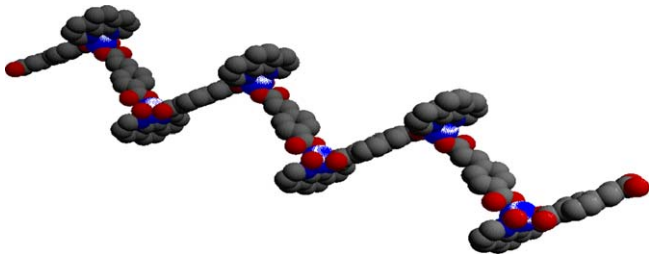

Fig. 8. The one-dimensional zigzag chain in complex **4** viewed along the *b*-axis.

monodentate mode. Co(II) ions are five-coordinated and constitute a dinuclear structure; In complexes **3** and **4**, each cca^{2-} anion adopts a bis(monodentate) mode. Metal(II) ions are all linked by cca^{2-} anions into one-dimensional zigzag chains. However, Cu(II) ions are four-coordinated, while Mn(II) ions are five-coordinated, in which one water molecule occupies the fifth coordination site. So we can conclude that the coordination number/or coordination geometry of the metal center, coordination modes of ligands, hydrogen bonds and π–π stacking interactions have profound influences on the supramolecular network.

3.2. Thermal analyses

Thermogravimetric analyses of complexes **2**–**4** were carried out to examine their water loss and thermal stabilities. For complex **2**, the first weight loss of 3.1% from 226 to 270 °C corresponds to the loss of coordinated water molecules (calc. 3.3%). Increasing temperature led to further decomposition above 370 °C. For complex **3**, the first weight loss of 3.7%, which occurred from 35 to 143 °C, corresponds to the loss of crystal water molecules (calc. 4.0%). The further decomposition of complex **3** occurred above 243 °C. While for complex **4**, it lost its crystal water molecules from 75 to 168 °C and further decomposed above 345 °C.

4. Supplementary data

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 278646–278649 for **1**–**4**, respectively. Copies of this information may be obtained free of charge from the CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax:+44 1223 336 033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

show only a singlet. δP values are −51.171, 67.665, and 13.640 ppm, respectively. $[Pd(L\text{-}L)(dppmS_2)](ClO_4)_2$ complexes were prepared by mixing of solution of $Pd(L\text{-}L)CI_2$ complexes in CH_2CI_2 and $dppmS_2$ ligand in $(CH_3)_2CO$ and in the presence of $NaClO_4 \cdot H_2O$ salt.

Analytical data of three yellow complexes are in accordance with the proposed formulation. Solid state IR spectra of the complexes **1**–**3** showed the characteristic absorption of P═S group at 585, 585 and 577 cm^{-1}, respectively. This bond in each complex is displaced towards lower frequencies as compared with the free ligand and corresponds to the coordinated P═S group. It clearly shows that $dppmS_2$ is coordinating to Pd(II) metal center via S donor atoms. ClO_4^- group vibrations give rise to two bands in 1100 and 620 cm^{-1} region. These values are consisted with the literature values [10].

In the case of $[Pd(dppe)(dppmS_2)](ClO_4)_2$ (**2**) and $[Pd(dppp)(dppmS_2)](ClO_4)_2$ (**3**), the resonances due to the dppe and dppp phosphorus atoms appear at 78.50 and 14.04 ppm, respectively. In the case of $[Pd(dppm)(dppmS_2)](ClO_4)_2$ (**1**), the chemical shift of dppm is −43.40 ppm. It has been seen that the signals of chelated diphosphine ligands are shifted to the down field relative to the starting complexes. Phosphorus chemical shifts of $dppmS_2$ are 40.50; 40.60 and 38.00 ppm in complexes **1**–**3**, respectively. These values have shown a small increase on coordination, relative to the free $dppmS_2$ ligand (34.5 ppm). In most of the present cases, the phosphorus of the P═S groups experiences a small increase in shielding on coordination. The range for $\Delta\delta$ is +2 to −11 ppm [11]. This might be expected since the metal is attached a site remote from the NMR active phosphorus nuclei (see Fig. 1).

Complex **1** was recrystalized from acetone–ether and includes one molecule acetone, and complex **3** was recrystalized from acetonitrile–ether for X-ray crystallography. The perspective views of complexes **1a** and **3** are given in Figs. 2 and 3, respectively. The selected bond distances and angles are listed in Table 1.

Both complexes adopt a monoclinic crystal system. $(CH_3)_2CO$ lies in the lattice as a non-bonded molecule in complex **1a**.

Palladium atoms in complex **1a** and **3** are distorted square planar environments (sum of the angles are 360.06 and 360.57) with from P(3)Pd(1)S(2) and P(4)Pd(1)S(1) angles of 93.80(5)° and 92.25(4)° for complex **1a**; P(4)Pd(1)S(2) and P(3)Pd(1)S(1) angles of 172.42(4)° and 173.43(4)° for complex **3**. There is a small difference in bite angles of diphosphine disulphide, [S(1)Pd(1)S(2); 102.05(4)° for complex **1a** and 97.19(4)° for complex **3**]. This difference should be related with the diphosphines bite angles [P(3)Pd(1)P(4); 71.96(5)° for complex **1a** and P(4)Pd(1)P(3); 88.97(4)° for complex **3**].

Pd–S bond lengths are slightly different from each other. Pd(1)–S(1) and Pd(1)–S(2) are 2.3850(12) and 2.4069(13) Å

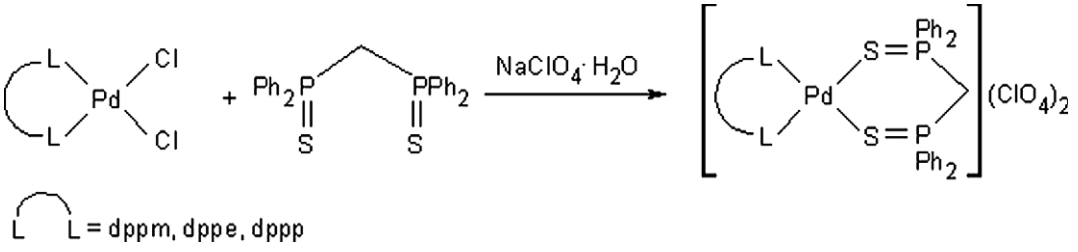

Fig. 1. Synthetic pathway of complexes $[Pd(L\text{-}L)(dppmS_2)]$ $(ClO_4)_2$.

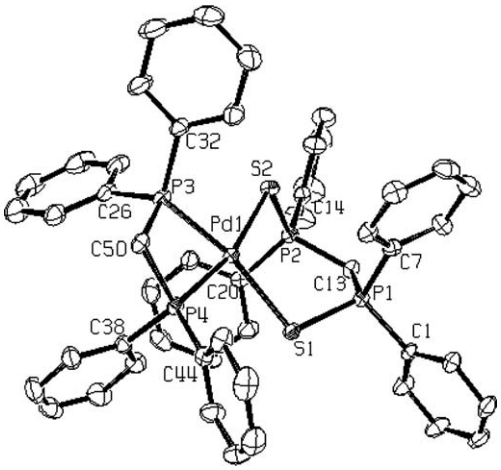

Fig. 2. The perspective view of **1a** (20% thermal probability). Hydrogen atoms, anions and solvent molecule are omitted for clarity.

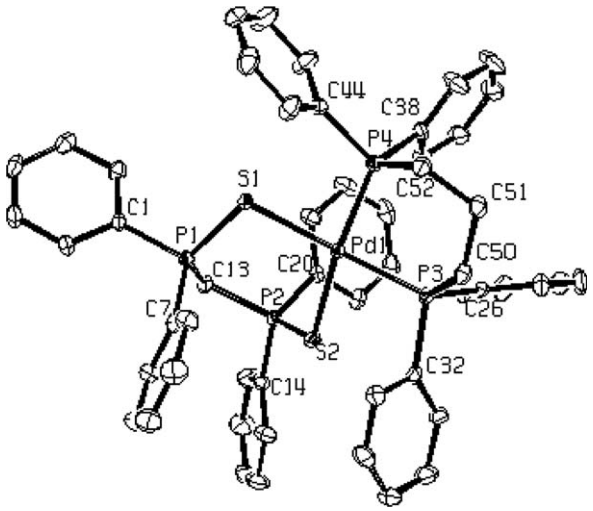

Fig. 3. The perspective views of **3** (20% thermal probability). Hydrogen atoms, anions are omitted for clarity.

Table 1
Selected bond angles (°) and distances (Å) for $[Pd(dppm)(dppmS_2)](ClO_4)_2 \cdot (CH_3)_2CO$ (**1a**) and $[Pd(dppp)(dppmS_2)](ClO_4)_2$ (**3**)

	1a	3
Bond distances		
Pd(1)–S(1)	2.3850(12)	2.3878(10)
Pd(1)–S(2)	2.4069(13)	2.3960(10)
P(1)–S(1)	2.0026(18)	1.9994(14)
P(2)–S(2)	2.0064(17)	1.9966(14)
Pd(1)–P(3)	2.2601(13)	2.2888(10)
Pd(1)–P(4)	2.2620(13)	2.2859(10)
Bond angles		
S(1)–Pd(1)–S(2)	102.05(4)	97.19(4)
P(4)–Pd(1)–S(2)	165.60(5)	172.42(4)
P(3)–Pd(1)–P(4)	71.96(5)	88.97(4)
P(3)–Pd(1)–S(1)	164.07(5)	173.43(4)
P(3)–Pd(1)–S(2)	93.80(5)	86.65(4)
P(4)–Pd(1)–S(1)	92.25(4)	87.76(4)

for complex **1a**. Pd(1)–S(1) and Pd(1)–S(2) are 2.3878(10) and 2.3960(10) Å for complex **3**. These are comparible with *cis*-$[Pd(\eta^1\text{–}S\text{–}C_5H_4NS)_2(dppe)]$ [12] and $Ni[N(SPPh_2)_2\text{–}SS^1]_2$ [13] complexes reported in the literatures.

In complex **3**, six membered dppp chelate ring has a chair conformation with Pd(1)–P(3)–C(50)–C(51) and Pd(1)–P(4)–C(52)–C(51) torsion angles of −59.4(4)° and 57.4(4)°, respectively, and with Pd(1) and C(51) atoms located 0.768 Å below and 0.818 Å above the plane defined by atoms P(3)–P(4)–C(50)–C(52). $dppmS_2$ rings are twist–boat and boat conformations in both complexes, respectively [14].

P–S bond lengths are 2.0026(18) and 2.0064(17) Å for complex **1a**; 1.9994(14) and 1.9966(14) Å for complex **3**. These values are agreement with $[Te_2(\mu\text{-}CI)_2\{(SPPh_2)_2N\}_2]$ complex reported in the literature [15].

Pd–P bond distances [2.2601(13) and 2.2620(13) for complex **1a**; 2.2859(10) and 2.2888(10) Å for **3**] are consisted with the mean Pd–P distance observed in the complex *cis*-$[Pt(\eta^1\text{–}S\text{–}C_5H_4NS)_2(dppe)]$ [12] but shorter than $[Pt(dppe)(PPh_3)(CHNMe_2)]^{2+}$ complex reported by Ferguson et al. [16].

3. Experimental

Solvents were dried according to the methods given in the literature and were purified under inert conditions [17]. All synthesis were carried using standard Schlenk tube techniques under inert atmosphere.

dppm, dppe, dppp, $NaClO_4 \cdot H_2O$ and acetone were purchased from Merck Chemical; dichloromethane, toluene, methanol, hexane and diethylether were purchased from Lab-Scan. The starting complexes, $[PdCl_2(COD)]$ (COD = 1,5-cyclooctadiene)[18], which is used for preparing the $[PdCI_2(L\text{-}L)]$ complexes [L-L = dppm ($Ph_2PCH_2PPh_2$), dppe ($Ph_2PCH_2CH_2PPh_2$), dppp ($Ph_2PCH_2CH_2CH_2PPh_2$)] [19], $dppmS_2$ ($Ph_2P(S)CH_2P(S)Ph_2$) [20] were synthesized according to the methods given in the literature.

$^{31}P\{^1H\}$ NMR spectra were recorded on Varian AS 400+Mercury instruments, chemical shifts, in ppm, related to external 85% H_3PO_4. Coupling constants are in Hz. IR spectra were recorded from 4000 to 400 cm^{-1} with a Perkin–Elmer 1600 FT-IR instrument. Melting points were determined by electrothermal melting point detection apparatus. Elemental analyses were performed by the Midwest Microlab in Indianapolis, USA.

3.1. $[Pd(dppm)(dppmS_2)](ClO_4)_2$ (1)

$PdCl_2(dppm)$ (0.18 mmol, 0.10 g) and $dppmS_2$ (0.18 mmol, 0.08 g) were placed in 30 mL CH_2Cl_2 and stirred. The solution of $NaClO_4 \cdot H_2O$ (0.71 mmol, 0.10 g) in 20 mL acetone was added dropwise to the stirring solution. Stirring was continued for 24 h at room temperature. After that, the solution was removed in vacuo and yellow solid was washed with water and diethyl ether. Complex **1** was recrystallized from acetone/diethyl ether (1:3 v/v) to give yellow crystals. (0.90 g, 80% yield). Data for **1**: $^{31}P\{^1H\}$ NMR (DMSO): −43.40 ppm (s), 40.50 ppm (s). Selected IR data (KBr): $\nu_{(P=S)}$ 585 cm^{-1}, 1100 (s) and 620 (m) cm^{-1} (ClO_4^-). *Anal.* Calc. for $C_{50}H_{44}Cl_2O_8P_4PdS_2$: C, 52.75; H, 3.90; S, 5.63. Found: C, 52.40; H, 4.10; S, 5.08%.

3.2. $[Pd(dppe)(dppmS_2)](ClO_4)_2$ (2)

$[PdCl_2(dppe)]$ (0.35 mmol, 0.20 g), $dppmS_2$ (0.35 mmol, 0.16 g) were placed together in 30 mL CH_2CI_2 and stirred. The solution of $NaClO_4 \cdot H_2O$ (1.40 mmol, 0.20 g) in 20 mL acetone was added dropwise to the stirring solution. The stirring was continued for 3 h and then solution was refluxed for 48 h. Then, the solution was removed in vacuo and yellow solid was washed with water and diethylether. Complex **2** was recrystallized from methanol/diethyl ether (1:3 v/v). (0.81 g, 71% yield). Data for **2**: $^{31}P\{^1H\}$ NMR (DMSO): 78.50 ppm (s), 40.60 ppm (s). Selected IR data (KBr): $\nu_{(P=S)}$ 585 cm^{-1}, 1100 (s) and 620 (m) cm^{-1} (ClO_4^-). *Anal.* Calc. for $C_{51}H_{46}Cl_2O_8P_4PdS_2$: C, 53.15; H, 4.02; S, 5.56. Found: C, 53.06; H, 4.44; S, 6.67%.

3.3. $[Pd(dppp)(dppmS_2)](ClO_4)_2$ (3)

A similar method was used for the preparation of $[Pd(dppm)(dppmS_2)](ClO_4)_2$ by using $[PdCl_2(dppp)]$ (0.33 mmol, 0.20 g), $dppmS_2$ (0.33 mmol, 0.15 g) and $NaClO_4 \cdot H_2O$ (1.30 mmol, 0.19 g). After 24 h, the yellow solution was removed in vacuo and the yellow solid was washed with water and diethylether. Complex **3** was recrystallized from acetonitrile/diethyl ether (1:3 v/v). (0.84 g, 72% yield). Data for **3**: $^{31}P\{^1H\}$ NMR (DMSO): 14.04 ppm (s), 38.00 ppm (s). Selected IR data (KBr): $\nu_{(P=S)}$ 577 cm^{-1}, 1100 (s) and 620 (m) cm^{-1} (ClO_4^-). *Anal.* Calc. for $C_{52}H_{48}Cl_2O_8P_4PdS_2$: C, 53.55; H, 4.15; S, 5.50. Found: C, 52.67; H, 4.17; S, 2.87%.

Table 2
Crystal data, data collection and structure-refinement parameters for complexes **1a** and **3**

	1a	**3**
Empirical Formula	$C_{50}H_{44}Cl_2O_8P_4PdS_2 \cdot (CH_3)_2CO$	$C_{52}H_{48}Cl_2O_8P_4PdS_2$

3.4. X-ray crystallographic study of *1a* and *3*

X-ray crystallographic data collection and processing was carried out using a Bruker AKS XMART APEX system; with graphite-monochromated Mo Kα radiation at 297 K. The structures were solved by direct methods SHELXTL [21]. The hydrogen atoms were placed in geometrically calculated positions using a riding model with U_{iso} constrained at 1.2 for non-methyl groups and 1.5 for methyl groups times U_{eq} of the carrier carbon atoms. Crystal data of **1a** and **3** are listed in Table 2.

4. Supplementary material

Crystallographic data for $C_{50}H_{44}Cl_2O_8P_4PdS_2 \cdot (CH_3)_2CO$ and $C_{52}H_{48}Cl_2O_8P_4PdS_2$ have been deposited with the Cambridge Crystallographic Data Center. Copies of available materials can be obtained, free of charge, on application to the Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (Fax: +44 1223 336-033 or E-mail: deposit@ccdc.cam.ac.uk). Deposition numbers are CCDC 279019 and CCDC 271253, respectively.

Acknowledgements

We thank the University of Babes Bolyai for X-ray crystallography support and the Research Foundation of Ege University (2002 FEN 072) for funding..

coordinated methanol molecules is sometimes critical for the catalytic activity of such compounds [7,12–15], while the *cis*-MoO_2^{2+} moiety can target to free methanol molecules and oxidize them to formaldehyde [16]. The presence of intramolecular C–H···O bond is important when referring to models proposed for C–H bond activation in the oxidation of methanol to formaldehyde [7,12].

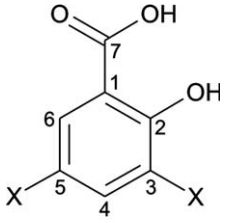
The bioinorganic consideration of DHBAs originates from their ability to act as non-toxic and effective chelating agents for ions with high charge to ionic radius ratio. DHBAs were used in the chelation therapy [17], are the basic neurotransmitter metabolites and take part in glucose metabolism [18] and in trace elements uptake by microorganisms [19]. Their redox multiplicity and antioxidant capability are of great interest for bioinorganic chemistry [20], particularly for modeling molybdenum hydroxylases [1]. They can easily coordinate as bidentate ligands with metals either through the two-hydroxyl oxygen atoms of the benzoic ring or through the hydroxyl oxygen atom of the carboxyl group [21–24]. The crystal structure of Zn(2,5-DHBA)$_2 \cdot 4H_2O$ suggests monodentate coordination, only through one carboxylic oxygen [25].

The ligands 2,3-DHBA and 2,5-DHBA (Scheme 1) are well known hydroxylation products of salicylic acid (they are indicators for the presence of hydroxyl radicals) and are used as models for organic compounds of larger molecular weight. They are found in plants, fruits and vegetables [26]. Their metal complexes can act as radical scavengers and are potential antiparalytic drugs [27]. Enzymes such as 2,3-dihydroxybenzoate dehydrogenase or ligase, catalyze the production or activation of 2,3-DHBA [28]. 2,3-DHBA can be found in the human body as an intermediate of many biological reactions [29,30], providing considerable antitumor and anti-inflammatory activity [31]. It is also used as a marker of in vivo oxidative stress [32]. 2,5-DHBA or gentisic acid is a well known second line metabolite of aspirin [33]. Gentisate 1,2-dioxygenase is the enzyme that catalyzes the degradation of gentisic acid [34]. The crystal form of this ligand is a necessary material in MALDI applications due to its ability to constrain peptides, carbohydrates or glycolipids via strong hydrogen bonds [35,36].

Although a molybdenum complex of 2,3-DHBA has been structurally characterized [29], no 2,5-DHBA complex with this metal has ever been referred. Zubieta et al. [7] have carried out extensive studies on polyoxomolybdate complexes including $(n\text{-}Bu_4N)_2 \cdot [Mo_4O_6(\mu\text{-}O)_4(\mu_3\text{-}OMe)_2(OC_6H_4O)_2]$, a structurally characterized tetrameric molybdenum complex of catechol. Complexes with the same metallic core $[Mo_4O_6(\mu\text{-}O)_4(\mu_3\text{-}OMe)_2]^{2+}$ and catechol derivatives (2,3-dihydroxynaphthalene [37] and phenanthraquinone [38]) have been structurally characterized. The core is structurally characterized even without an organic ligand, but with chloride ions as ligand [39]. A tetrameric complex with 3-hydroxy-picolinic acid having only oxo-bridges has also been structurally characterized [8]. For trinuclear oxomolybdenum complexes with catechol derivatives, there are no literature reports, while a trimetallic core has been investigated [40].

We have reported the isolation and characterization of a 2,3-DHBA complex with Fe(III) [41], the interaction of 2,3-DHBA with Mn(II) [42] or Ni(II) [21] and recently, the isolation from aqueous solution and characterization of Mo(VI) complexes with this ligand [22]. Moreover, we have worked on the synthesis and characterization of Mo(VI) complexes of 2,5-DHBA [23] or 3,4-DHBA [24] isolated from aqueous solution.

In the present study, we demonstrate two molybdenum complexes of 2,3- and 2,5-DHBA prepared by reaction with $(PPh_4)_4Mo_8O_{26}$ in the same solvent system, under aerobic conditions and at room temperature. The oligomeric tetra- and trinuclear molybdenum complexes were further investigated using IR and ESR in solid state, UV–Vis and NMR spectroscopy, as well as elemental, thermogravimetric analysis and cyclic voltammetry.



3-OH, 5-H: 2,3-DHBA
3-H, 5-OH: 2,5-DHBA

Scheme 1. 2,3- and 2,5-dihydroxybenzoic acids.

2. Experimental

2.1. Materials and methods

All chemicals were purchased from Aldrich and used without further purification. Elemental analyses were performed using a Perkin–Elmer 240B elemental analyzer. IR spectra were recorded using a KBr pellet on a Perkin–Elmer 880 IR spectrophotometer. Thermogravimetric and differential thermal analysis were carried out on a Mettler Toledo S R apparatus in N_2 atmosphere (temperature range: 40–1200 °C; heating rate: 20 °C/min). ESR spectra in solid state (298 and 10 K) were recorded on a Bruker ER-200D-SRC X-band spectrometer interfaced to a personal computer and equipped with an Oxford ESR 900 cryostat, an Anritsu MF76A frequency counter and a Bruker 035N NMR gaussmeter. UV–Vis spectra were recorded with 1-cm cuvette on a Hitachi U-2000 spectrophotometer. ^1H, ^{13}C and 2D (COSY, HSQC, HMQC) NMR spectra were recorded on a Varian UNITYplus operating at 300 MHz spectrometer or a Bruker Avance operating at 500 MHz, in CD_3OD solution with TMS as internal standard and DMSO-d_6 using the solvent peak as an internal reference (2.50 ppm). Cyclic voltammograms were recorded on an AFCBP1 Biopotentiostat (Pine Instrument Company) and a standard three-electrode assembly

(working: Pt disk, auxiliary: platinum wire, reference: SCE, scan rate: 100 mV s^{-1}).

2.2. Synthesis

2.2.1. Synthesis of $(PPh_4)_4Mo_8O_{26}$

An aqueous solution (15 ml) of PPh_4Br (209.7 mg, 0.5 mmol) was added to a solution of $(NH_4)_2MoO_4$ (98 mg, 0.5 mmol) in water (15 ml) and a white solid was produced. The solid was filtered and dried overnight in vacuum over $CaCl_2$, giving $(PPh_4)_4Mo_8O_{26}$ (solid **A**) as reported in analogous preparations [43,44].

2.2.2. Synthesis of $(PPh_4)_2 \cdot [Mo_4O_6(\mu\text{-}O)_4(\mu_3\text{-}OMe)_2\text{-}(2,3\text{-}DHBA)_2]$ (**1**)

2,3-DHBA (34.5 mg, 0.22 mmol) was added to 7 ml of an acetonitrile:methanol (7:3) stirred solution, and left until it was completely dissolved. Upon the addition of solid **A** (71.6 mg, 0.03 mmol), a deep red-brown solution was formed. After 5 h of stirring, the solution was filtrated and the filtrate was layered with Et_2O giving deep red-brown crystals. Yield: 82%. *Anal.* Calc. for $C_{64}H_{54}Mo_4O_{20}P_2$: C, 48.12; H, 3.41. Found: C, 48.42; H, 3.52%. UV–Vis (CH_3CN; λ_{max}, nm (ε, $cm^{-1}\,M^{-1}$)): 330 (20×10^3), 270 (27×10^3), 220 (185×10^3).

2.2.3. Synthesis of $(PPh_4)_2 \cdot [Mo_3O_6(\mu\text{-}O)_2\text{-}(2,5\text{-}DHBA)_2] \cdot CH_3CN$ (**2**)

2,5-DHBA (34.5 mg, 0.22 mmol) was added to 7 ml of an acetonitrile:methanol (7:3) stirred solution, and left until it was completely dissolved. After the addition of solid **A** (71.6 mg, 0.03 mmol), a yellow solution was formed. Without any further stirring, the layering with Et_2O produced orange crystals suitable for X-ray determination. Yield: 46%. *Anal.* Calc. for $C_{64}H_{51}Mo_3NO_{16}P_2$: C, 53.15; H, 3.56; N, 0.97. Found: C, 52.94; H, 3.51; N, 0.84%. UV–Vis (CH_3CN; λ_{max}, nm (ε, $cm^{-1}\,M^{-1}$)): 324 (13×10^3), 261 (24×10^3), 225 (131×10^3).

2.3. X-ray crystallography

The orange crystals of **1** and **2** were mounted in air. Diffraction measurements were made on a Crystal Logic dual goniometer diffractometer using graphite monochromated Mo Kα radiation. Unit cell dimensions were determined by the angular settings of 25 automatically centered reflections in the range $11° < 2\theta < 23°$ and they appear in Table 1. Three standard reflections monitored every 97 reflections showed less than 3% variation and no decay. Lorentz, polarization corrections were applied using Crystal Logic software. Further crystallographic details for **1**: $2\theta max = 50°$; scan speed 5°/min; scan range 1.6° plus $\alpha_1\alpha_2$ separation; reflections collected/unique/used, 5749/5512 ($R_{int} = 0.0136$)/5512; 514 parameters refined; $(\Delta/\rho)max = 0.002$; $(\Delta\rho)max/(\Delta\rho)min = 0.688/-0.572$ e/Å^3; R/R_w (all data) = 0.0350/0.0805. Further crystallographic details for **2**: $2\theta max = 50°$; scan speed 6°/min; scan range 1.6° plus $\alpha_1\alpha_2$ separation; reflections collected/unique/used, 9752/9344 ($R_{int} = 0.0138$)/9344; 960 parameters refined; $(\Delta/\rho)max = 0.008$; $(\Delta\rho)max/(\Delta\rho)min = 0.332/-0.284$ e/Å^3; R/R_w (all data) = 0.0220/0.0557.

The structures were solved by direct methods using SHELX-86 and refined in full-matrix least-squares procedure on F^2 with SHELX-97 [45]. All non-H atoms in the structures of **1** and **2** · MeCN were refined anisotropically. All hydrogen atoms in both structures were located by difference maps and were refined isotropically. The acetonitrile solvent molecule in **2** was found disordered over two positions and it was refined isotropically with occupation factors summing one (no H-atoms for the MeCN molecule were included in the refinement). Selected atomic distances and bond angles are presented in Tables 2 and 3.

3. Results and discussion

The general reactions of $(PPh_4)_4Mo_8O_{26}$ with the ligands are presented in Scheme 2. The ligand amount is in excess ($(PPh_4)_4Mo_8O_{26}/L = 1/8$), but the metal-to-ligand ratio is 1:1. It is notable that in the case of 2,5-DHBA, a long reaction under stirring leads to the formation of $(PPh_4)_2Mo_6O_{19}$ crystals. The crystals obtained were identified by X-ray crystallography with no further interest for presentation. Methanol seems to play an important role

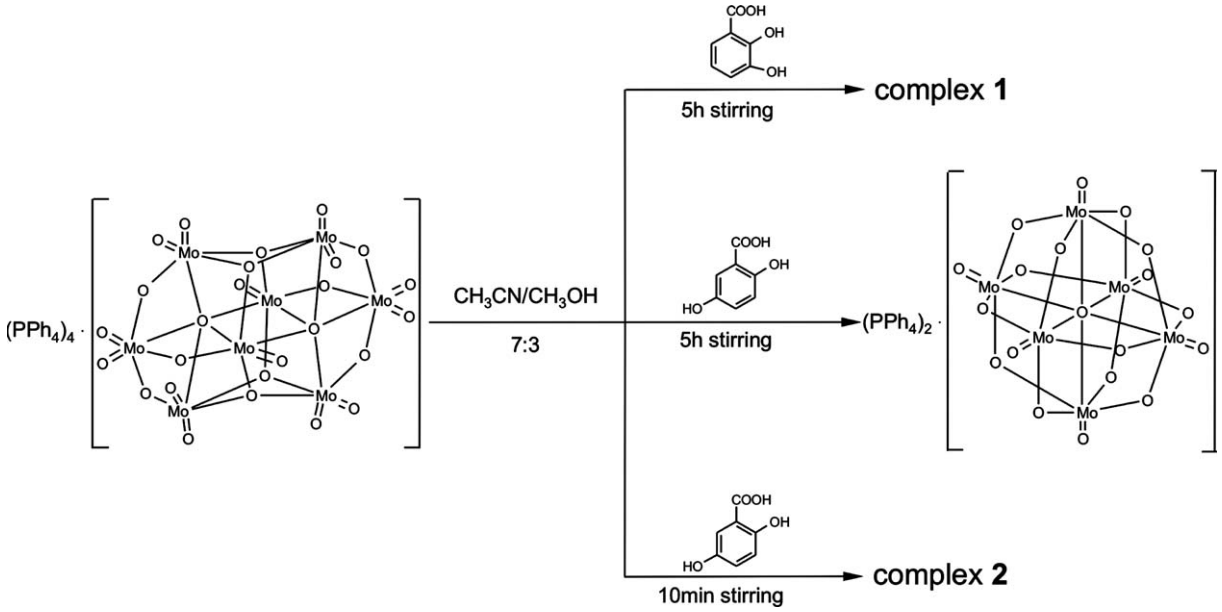
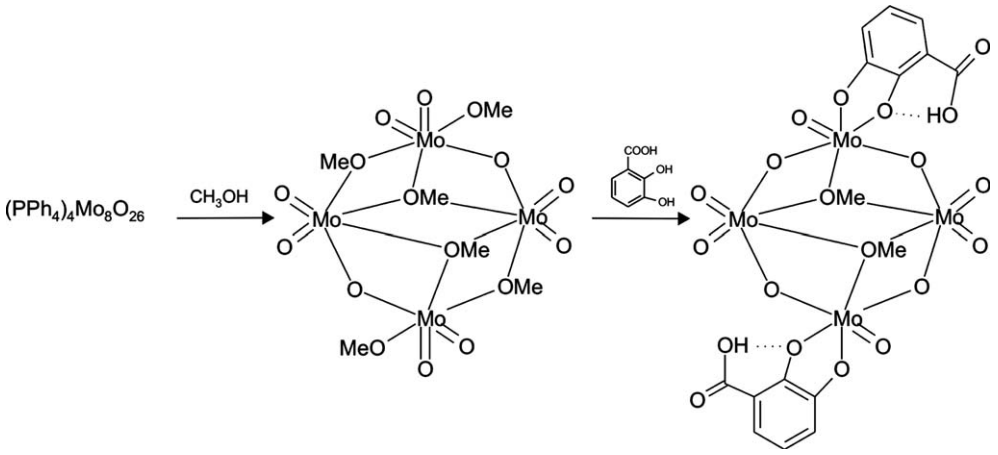
in the production of the tetranuclear complex of 2,3-DHBA, probably via an intermediate with bridged and terminal methanol molecules (Scheme 3).

The structure of complex **1** anion (Fig. 1) shows that 2,3-DHBA prefers, under these particular experimental conditions, the coordination to molybdenum via the two hydroxyl oxygen atoms rather than the participation of the carboxyl group. The structure consists of four distorted MoO_6 octahedra with two *cis*-MoO_2^{2+} units and two molybdenum atoms having each ligand coordinated and one terminal oxygen atom. There is a symmetry center in the molecule between the four molybdenum atoms. For the *cis*-MoO_2^{2+} unit, the Mo=O bond lengths (1.687(3) and 1.693(2) Å) as well as the O=Mo=O angles are in agreement with those mentioned in the literature [20,21]. The O4–Mo1–O3 angle (76.40(9)°) as well as the average O14–Mo1–O (101.43°) angle involving O3, O4, O11 and O12 atoms show this distortion. The two ligand molecules are in *trans* position to the metallic core, with strong hydrogen bonding between the carboxylic hydrogen and O3



Scheme 2. Reaction diagram of the complexes.



Scheme 3. The participation of methanol in the formation of complex **1**.

[HO2···O3 = 1.951 Å, O2···O3 = 2.618 Å, O2–HO2···O3 = 150.49°]. The hydrogen bond affects the C2–O3–Mo1 angle (115.75(18)°) relatively to the C3–O4–Mo1 one (119.18(19)°). The existence of the carboxyl-group does not dramatically change the metallic core configuration, as it is concluded from the comparison of our structure with the corresponding tetranuclear molybdenum complex of catechol [7].

The structure of complex **2** anion (Fig. 2) consists of three distorted MoO_6 octahedra. Each molybdenum atom has the *cis*-MoO_2^{2+} unit, with a Mo–O distance range of 1.693–1.726 Å and an average O=Mo=O angle of 104.37°. The structure of complex **2** is characterized as unusual, because of the rarity of trinuclear oxomolybdenum complexes and the fact that each of the two ligands coordinates with all three molybdenum atoms, due to a unique tridentating binding of gentisic acid that differs from the usual salicylate (bidentate) coordination type [46]. For each ligand, the hydroxyl-oxygen of the carboxylate group acts as a bridge between two molybdenum atoms, while the third molybdenum atom coordinates with the carbonyl-oxygen. The C–O (1.299(3) and 1.303(3) Å) and C=O (1.238(4) and 1.248(4) Å) bond lengths are obviously affected by the participation of the carboxylate group, in contrast to the respective bond lengths of a non-coordinated one, as for complex **1** (C–O 1.325(5), C=O 1.208(5) Å). The two hydroxyl non-bonded groups of the ligands are in *trans* position to the metallic core, and participate in hydrogen bonding interactions [HO4···O24′ $(2-x,-0.5+y,1-z)$ = 2.069 Å, O4···O24′ = 2.758 Å, O4–HO4···O24′ = 175.9°; HO14···O28″ $(1-x,-0.5+y,-z)$ = 2.142 Å, O14···O28″ = 2.717 Å, O14–HO14···O28″ = 162.4°] giving rise to a 2D polymeric network extended parallel to the [10−1] plane (Fig. 3).

The characteristic bands in the IR spectra of the complexes are presented in Table 4. For complex **1**, two medium sharp peaks at 2920 and 2818 cm^{-1} are indicative of the C–H stretch of methoxy groups [47] and the ν(C–O) vibration of the methoxo bridge is found at 1283 cm^{-1}.

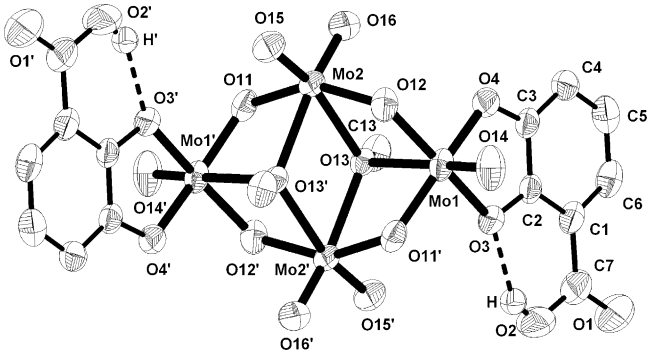


Fig. 1. The molecular structure of the complex **1** anion showing the atomic labeling (40% thermal probability ellipsoids). The intramolecular H-bonds are shown as dashed lines. Primed atoms are generated through the symmetry transformation $1-x$, $1-y$, $-z$.

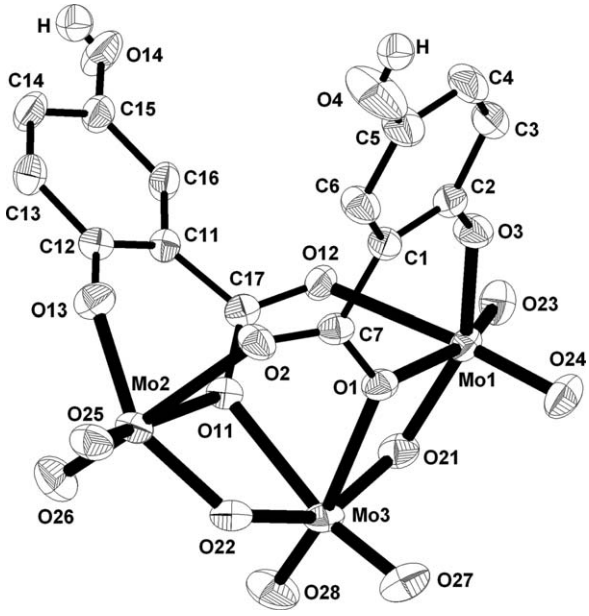

Fig. 2. The molecular structure of the complex **2** anion showing the atomic labeling (40% thermal probability ellipsoids).

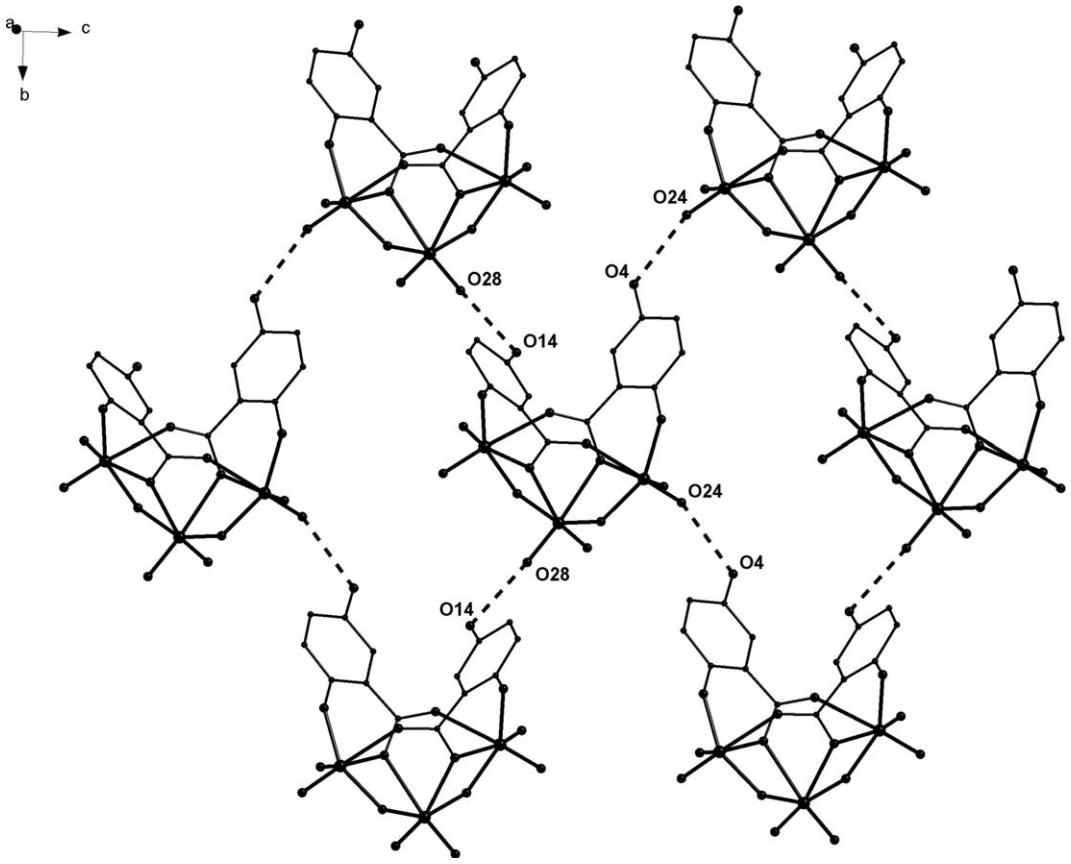

Fig. 3. The 2D polymeric network of complex **2** anion, extended in parallel to the [10−1] plane (H-bonds are shown as dashed lines).

The position of the carbonyl asymmetric stretching band at 1720 cm^{-1} and the broad symmetric one at 1379 cm^{-1} are indicative of the strong hydrogen bond in the carboxylic group. The intense characteristic doublet at 956 and 916 cm^{-1} is due to the *cis*-MoO_2^{2+} group and corresponds to the ν_{sym} and ν_{asym} of O=Mo=O bond, respectively. Approximately, the same vibration energy (936 cm^{-1}) is expected for the ν(Mo=O) stretch of the two molybdenum centers, connected with only one terminal oxygen. The bands appearing at 738, 662, 632 and 555 cm^{-1} are indicative of the Mo–O–Mo bridges, through oxygen or methanol. Moreover, the Mo–O bond types are attributed to the vibration observed at 337 cm^{-1} [7,8,24,46,48]. For complex **2**, the carbonyl asymmetric stretching band of the ligand's carboxylic group is observed at 1588 cm^{-1}, while two bands represent the symmetric one at 1379 and 1352 cm^{-1} showing two non-symmetric ligand molecules. The $\Delta\nu$ between the symmetric and asymmetric carboxylate vibration bands is equal to 218 cm^{-1}, in contrast to what is expected for such carboxylate coordination modes [49]. The two sets of bands for the vibration energy of the *cis*-MoO_2^{2+} group (940–881 and 908–854 cm^{-1}) indicate the geometrical differentiation of Mo(3) from the other two molybdenum atoms. The band attributed to the Mo–O–Mo bridges appears at 640 cm^{-1}, while the Mo–O bond vibration types at 337 cm^{-1}.

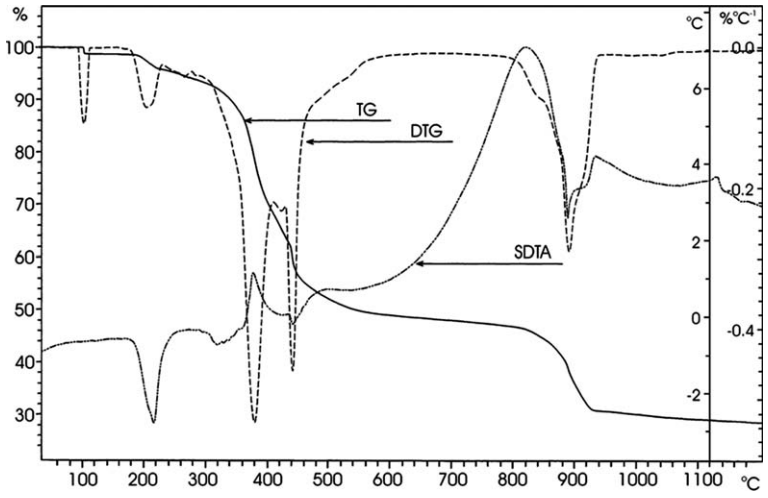

Fig. 4. TG, DTG and SDTA curves for complex **1** (the first peak observed in the DTG without any signal change in the energy flow corresponds to instrument noise).

Thermogravimetric data of complex **1** are summarized in Table 5. The extraction of the two methoxo triple-bridges (exp. 2.9%, calc. 2.9%) is observed with an endothermic reaction at the temperature of 217 °C (Fig. 4), producing $O(CH_3)_2$. In general, bridged methanol molecules are extracted in this temperature range, while terminal methanol molecules are extracted at lower temperatures [47]. The experimental organic loss (C, H from the ligand and the counter ion) occurred in the region between 300 and 500 °C having two main maximum values at 383 and 443 °C (DTG curve, Fig. 4). The weight loss at 383 °C involves an exothermic decomposition reaction of the complex, while the second involves an endothermic process (SDTA curve, Fig. 4). The organic loss is difficult to be confirmed by the corresponding theoretical value, because of the complicated reaction steps that take place [50], including partial structural fragmentation [51]. Experiments of combined TG analysis and IR identification confirm the tetraphenylphosphonium decomposition at temperatures of 350–400 °C, at metal complexes with this counter ion. The exothermic reaction can be related to the simultaneous strong reaction of phosphorus atom with oxygen, after the P–C bond breaking [52]. The ligand decomposition (443 °C) is an endothermic process that occurs at higher temperatures than that for the free ligand, because of its coordination with the metal [53]. A total mass loss of 46.9%, in this region, is required for the total carbon and hydrogen extraction (calc. 46.9%), while structural fragmentation also takes place. The next loss occurs at a much higher temperature value (891 °C) and corresponds to the extraction of P_2O_5 [54] and CO that are formed by the ligand decomposition (exp. 16.5%, calc. 16.0%) [24], while the metal oxides are formed [55]. So, the final residue at 1200 °C is free of phosphorus atoms and only consists of the dimeric molybdenum oxide, Mo_2O_5 (exp. 32.5%, calc. 34.2%).

The ESR spectra of both complexes in solid state at ambient temperature or at 10 K, did not give any signal characteristic of DHBAs in their semi-oxidized form (semiquinones) or Mo(V). A Mo(VI)-catecholate to Mo(V)-semiquinonate interconversion could be expected especially when a molybdenum atom does not contain a *cis*-MoO_2^{2+} moiety but only one terminal oxygen atom. The color of the crystal could also be an indication of an electronic transition for this interconversion.

The electronic absorptions of the complexes in CH_3CN showed no significant difference between the complexes in their absorption area but only in their ε values. The ligand-to-metal charge transfer band appears at 330 nm for **1** and 324 nm for **2**. The bands at 270 nm for **1** and 261 nm for **2** are characteristic of the $n \rightarrow \pi^*$ and $\pi \rightarrow \pi^*$ transition bands attributed to catechol [43]. The $Mo{=}O^{4+}$ chromophore band appears at 220 nm for **1** and 225 nm for **2** [24]. For each band, the molar coefficient of **1** is bigger than **2**, calculated per one molybdenum atom.

The ^1H NMR spectrum of complex **1** in CD_3OD (Fig. 5), demonstrates one group of ligand peaks with ppm values at 7.04 (doublet, correlated to H^6), 6.60

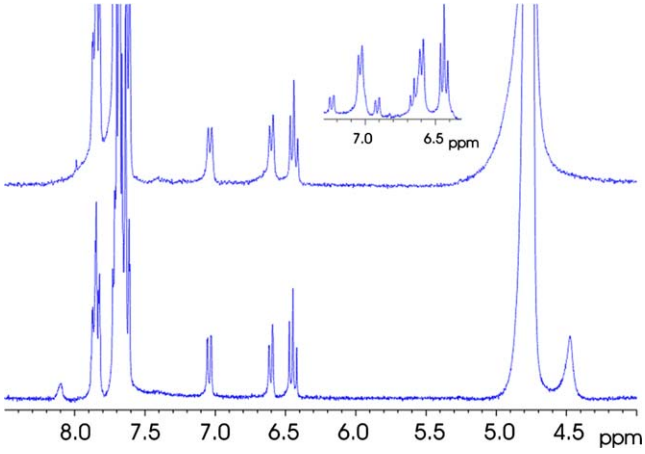

Fig. 5. ^1H NMR spectrum of complex **1** freshly diluted in CD_3OD (bottom), after 27 days (upper) and three months later (inset).

Table 6
^{1}H NMR data of complexes **1** and **2**

Solvent	Ligand protons (ppm)							
	1				**2**			
	H_{COOH} (s)	H^6 (d)	H^4 (d)	H^5 (tr)	$H_{OH\text{-}5}$ (s)	H^6 (s)	H^4 (d)	H^3 (d)
CD_3OD		7.04	6.60	6.45		6.77	6.54	6.67
		7.23[a]	6.92	6.65				
DMSO-d_6	13.08	7.00	6.84	6.76	8.94	6.85	6.49	6.69
	14.19[b]	6.91	6.55	6.38–6.35				

[a] Peaks due to degradation.
[b] Peaks due to isomerization.

(doublet, correlated to H^4) and 6.45 ppm (triplet, correlated to H^5). This only type of the ligand peaks and their infinitesimal splitting are indicative of its absolute intramolecular symmetry in the electronic environment of each atom, even when the complex is dissolved in this particular solvent. The integral quotient of the PPh_4^+ protons to the ligand ones equals to 1 (1.14), as expected. The methoxo triple-bridged protons appear with a single broad peak at 4.5 ppm, while the integral value confirms their 1:1 ratio with the ligand and the counter ion. Remarkable at the spectrum is the presence of a single broad peak at 8.1 ppm. This peak is lost after about one month (27 days) as well as the one at 4.5 ppm indicating a connection between them. Particularly, the methoxo groups seem to be displaced and the peak at 8.1 ppm represents an intermediate in this reaction. After approximately three months, a new group of peaks at 7.23 (doublet, H^6), 6.92 (doublet, H^4) and 6.65 ppm (triplet, H^5) appears. Since these peaks are in the same region, it is considered that the benzoic ring did not break (another metallic core or ligand oxidation state or decarboxylation). This conversion corresponds to 33%. The ^{1}H NMR spectrum of complex **2** in CD_3OD (Table 6) is more complicated giving no distinct peaks corresponding to the ligand peaks and this is due to the non-symmetrical conformation of the two ligand molecules.

In the ^{1}H NMR spectrum of complex **1** in DMSO-d_6 (Fig. 6) three groups of peaks are observed (also confirmed by the COSY experiment, Fig. 7) with the main peaks at 13.08 (–COO*H*), 7.00 (doublet, H^6), 6.84 (doublet, H^4) and 6.76 ppm (triplet, H^5). The corresponding proton shifts from the free ligand, show that H^6 (0.24 ppm downfield) and H^4 (0.16 ppm downfield) are more affected by the coordination. The secondary group exists in a 33% with peaks at 14.19 (–COO*H*), 6.91 (doublet, H^6), ~6.55 (two doublets, H^4) and 6.38–6.35 ppm (two triplets close, H^5). The peak partition of H^4 and especially H^5 indicates isomerization. For the third group, peaks at 13.59 (–COO*H*), 7.08 (doublet, H^6) and 6.43 ppm (triplet, H^5) are observed, in about 12% compared with the main group. So, in DMSO-d_6, complex **1** does not seem to be stable giving at 33% percentage a group of peaks having the same chemical shifts with the dimeric complex of molybdenum with 2,3-DHBA isolated from aqueous solution [22]. In the ^{13}C NMR spectrum of complex **1** in DMSO-d_6 (Table 7), the most characteristic shifts of the main group (as the secondary group carbons are not observed), compared with the free ligand, are focused on the carbons that are closer to the coordination area, while the only methoxo group peak at the area between 40 and 70 ppm appears at

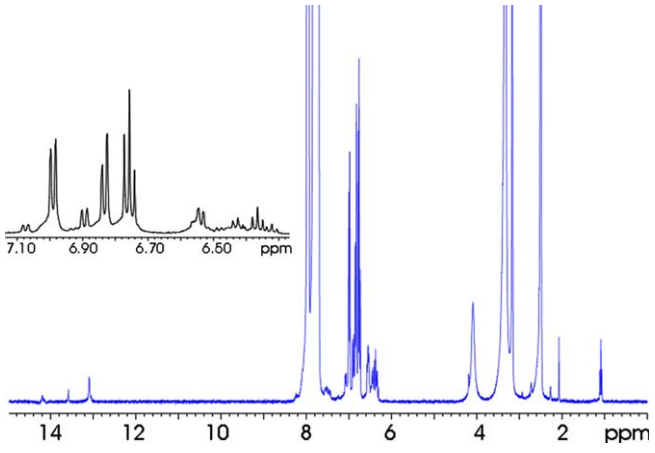

Fig. 6. ^{1}H NMR spectrum of complex **1** in DMSO-d_6.

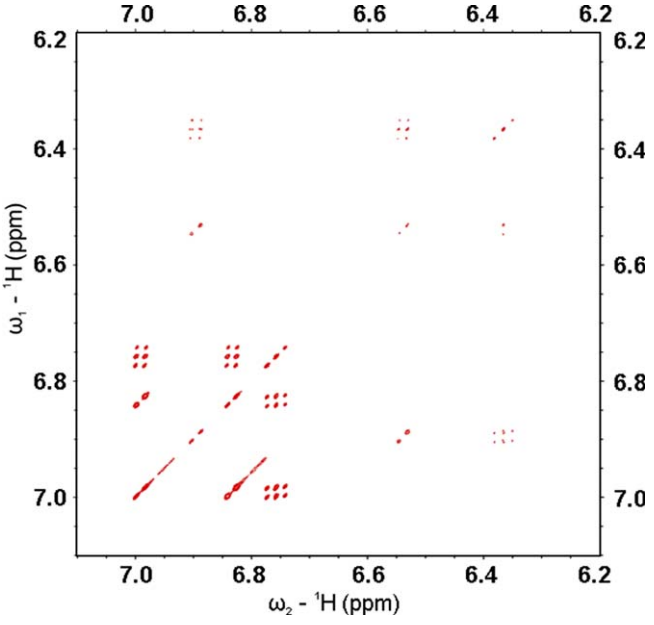

Fig. 7. COSY spectrum of complex **1** in DMSO-d_6.

Table 7
^{13}C NMR data (ppm) of complexes **1** and **2** in DMSO-d_6

	Ligand carbons							CH_3OH
	C^1	C^2	C^3	C^4	C^5	C^6	C^7	
1	120.06 (113.20)	156.10 (150.49)	153.65 (145.99)	118.38 (120.05)	116.36 (118.65)	120.67 (120.80)	165.49 (172.58)	48.56
2	123.55 (112.66)	155.74 (154.21)	119.34 (117.84)	119.96 (123.84)	149.23 (149.47)	113.81 (114.64)	173.10 (171.83)	

Free ligand corresponding shifts in parentheses.

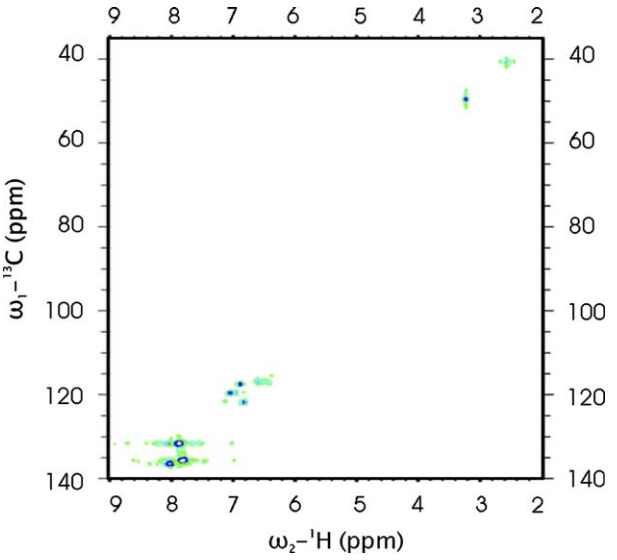

Fig. 8. HSQC spectrum of complex **1** in DMSO-d_6.

48.56 ppm (corresponding proton signal at 3.2 ppm), indicating that the bridged methanol molecules are extracted (Fig. 8). The ^1H NMR spectrum of complex **2** in DMSO-d_6 (Fig. 9), demonstrates one group of peaks at 8.94 (–O*H*), 6.84 (singlet, H^6), 6.69 (doublet, H^4) and 6.49 ppm (doublet, H^3). The integral ratio of the PPh_4^+ protons to the ligand ones equals to 1 (1.09), as expected. Comparing with the corresponding free ligand peaks, the peak of H^6 is more affected ($\Delta\delta = 0.33$ ppm) than those

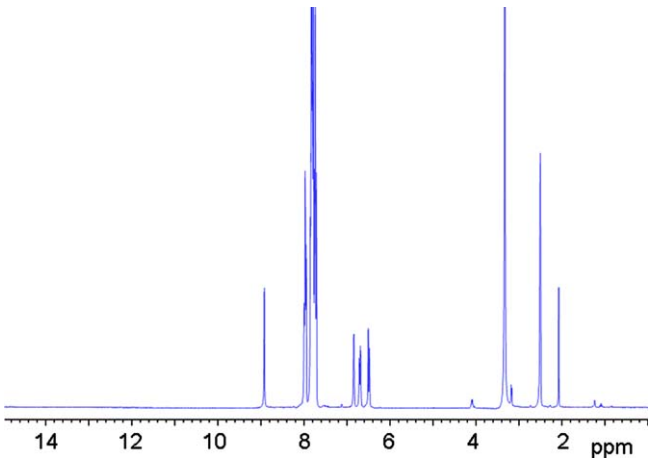

Fig. 9. ^1H NMR spectrum of complex **2** in DMSO-d_6.

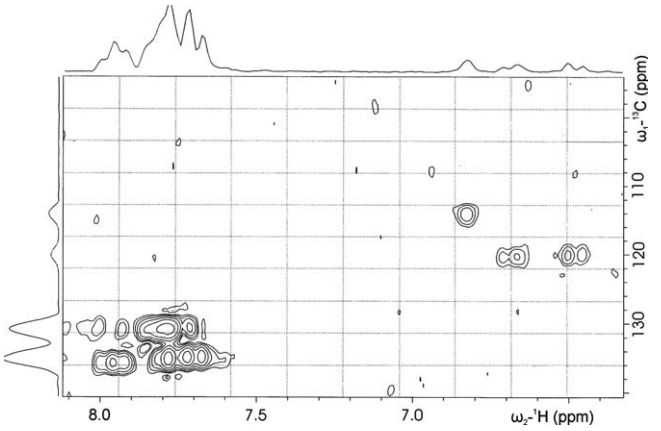

Fig. 10. HSQC spectrum of complex **2** in DMSO-d_6.

of H^4 ($\Delta\delta = 0.27$ ppm) or H^3 ($\Delta\delta = 0.29$ ppm). In the ^{13}C NMR spectrum of complex **2** in DMSO-d_6, the most affected by the coordination carbon atom is C^1 ($\Delta\delta = 11$ ppm), with a smaller shift for C^4 ($\Delta\delta = 4$ ppm) and surprisingly no important shift for C^2 (Fig. 10).

The cyclic voltammogram of complex **1** in CH_3CN, between −2 and +2 V vs. SCE, reveals the stabilization of the semi-oxidized form of the ligand when coordinated (Fig. 11). For the unbounded 2,3-DHBA, an oxidation at −0.67 V corresponds to the conversion of the reduced to the semi-oxidized form of the ligand (semiquinone), while one anodic peak at +0.53 V is due to the conversion of

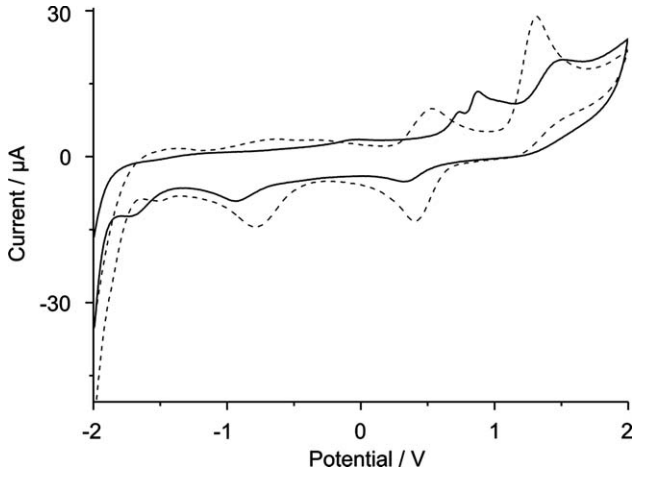

Fig. 11. Cyclic voltammograph of complex **1** (—) and 2,3-DHBA (-----), in CH_3CN. Supporting electrolyte: $TBNPF_6$; reference electrode: SCE.

the semi-oxidized to the fully oxidized form (quinone) [56]. The anodic peak at +1.30 V corresponds to the quinone polymerization [57]. For the complex, the first oxidation step of the catecholate to the semiquinonate form of the ligand occurs at −0.04 V and the second one that is due to the conversion to the quinonate form, at +0.74 V. In addition, a peak at +0.88 V corresponds to the decarboxylation of the ligand [58], while polymerization happens at 1.49 V [59,22].

4. Conclusions

In summary, the results reported in this paper are: (i) The reaction of the isomeric catechol derivatives 2,3- and 2,5-DHBA with an octanuclear molybdenum cluster in analogous conditions, lead to different polyooxomolybdate complexes. (ii) The tetranuclear molybdenum complex of 2,3-DHBA with two triple bridged methanol molecules was investigated for its reactivity by thermal decomposition studies yielding methyl ether, as happens in analogous complexes. The information collected by multinuclear NMR experiments in protolytic and complexing solvents indicates the degradation of the complex via the extraction of the methoxo bridges. The reductive form of the ligand was confirmed by solid state ESR and cyclic voltammetry. Further studies of a possible catalytic activity of complex **1** are in progress. (iii) To our knowledge the structure of the trinuclear molybdenum complex of 2,5-DHBA is the first example for polydentate coordination type of this ligand. Especially, the tridentate binding mode of gentisic acid differs from the usual salicylate with the participation of both carboxylate oxygen atoms. (iv) Complex **2** is less stable than **1** at the stirring time in their parent solutions, with ligand release and the formation of the polyoxometalate complex $(PPh_4)_2[Mo_6O_{19}]$.

5. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 282204 and 282205 for **1** and **2**, respectively. Copies of this information may be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44 1223 336 033; e-mail: deposit @ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

method. The recent calculations with the TD-DFT method for open- and closed-shell of 5d-metal complexes (including rhenium complexes) have supported the TD-DFT method to be applicable for such systems giving good assignment of experimental spectra [13–19].

2. Experimental

2.1. General procedure

The reactions were carried out under argon atmosphere. All solvents were of reagent grade and were used as received. Ammonium perrhenate, Ph_3P, pzH and pyz were purchased from Aldrich and used as received. $[ReCl_4(PPh_3)_2]$ was prepared according to the literature method [20].

IR spectra were recorded on a Nicolet Magna 560 spectrophotometer in the spectral range 4000–400 cm^{-1} with the samples in the form of KBr pellets. Electronic spectra were measured on a spectrophotometer Lab Alliance UV–VIS 8500 in the range 900–200 nm in deoxygenated dichloromethane solution. Elemental analyses (C H N) were performed on a Perkin–Elmer CHN-2400 analyzer.

2.2. Preparation of *[ReCl$_4$(pzH)(PPh$_3$)]* (*1*)

$[ReCl_4(PPh_3)_2]$ (1 g, 1.15 mmol) and pzH (0.30 g, 4.4 mmol) in chloroform (100 cm^3) were refluxed overnight. The colour of the reaction mixture changed slowly from dark red to brown. The volume was condensed to 10 cm^3 and orange microcrystalline solid was formed by an addition of 100 cm^3 of ethanol. The product was washed with EtOH and cold ether, and dried in vacuo. The crystals of **1** suitable for X-ray investigation were obtained by recrystallization from $CHCl_3$–EtOH. Yield 80%.

IR (KBr, cm^{-1}) 3342 (s), 3140 (m) 3062 (w), 1580 (w) 1517 (m) 1486 (s), 1444 (s), 1405 (m), 1350 (s), 1268 (m), 1150 (m), 1128 (s) 1093 (s), 1058 (s), 1008 (w), 778 (s), 755 (s), 700 (s), 582 (m), 531 (s), 494 (s).

Anal. Calc. for $C_9H_{15}N_6Cl_4ORe$: C, 38.31; H, 2.91; N, 4.25. Found: C, 38.53; H, 3.0; N, 4.30%.

2.3. Preparation of *[ReCl$_4$(pyz)(PPh$_3$)]* (*2*)

A procedure similar to that for **1** was used with $[ReCl_4(PPh_3)_2]$ (1 g, 1.15 mmol) and pyz (0.3 g, 3.7 mmol). An orange crystalline precipitate of **2** was collected in 80% yield.

IR (KBr, cm^{-1}) 3093 (w) 3059 (w), 1581 (w) 1512 (w) 1481 (s), 1434 (s), 1414 (m), 1339 (w), 1318 (w), 1188 (w), 1149 (s) 1120 (s), 1090 (s), 1053 (s), 1028 (w), 807 (s), 746 (s), 691 (vs), 524 (s), 502 (s), 465 (m), 450 (sh).

Anal. Calc. for $C_9H_{15}N_6Cl_4ORe$: C, 39.42; H, 2.86; N, 4.18. Found: C, 39.63; H, 2.92; N, 4.31%.

2.4. Crystal structures determination and refinement

The X-ray intensity data of **1** and **2** were collected on a KM-4-CCD automatic diffractometer equipped with CCD detector, 20 and 29 s exposure time was used receptively and all reflections of Ewald sphere was collected up to $2\theta = 50°$. The unit cell parameters were determined from least-squares refinement of the setting angles of 7903 and 12323 strongest reflections, respectively, for **1** and **2**. Details concerning crystal data and refinement are given in Table 1. Lorentz, polarization and numerical absorption corrections [21] were applied. The structure were solved by the Patterson method and subsequently completed by the difference Fourier recycling. All the non-hydrogen atoms were refined anisotropically using full-matrix, least-squares technique. The carbon bonded hydrogen atoms were founded on difference Fourier synthesis and they were refined as ''riding'' on their parent carbon atoms [d(C–H) = 0.96 Å] and assigned isotropic temperature factors equal 1.2 times the value of equivalent temperature

Table 1
Crystal data and structure refinement for **1** and **2**

factor of the parent carbon atom. SHELXS97 [22], SHELXL97 [23] and SHELXTL [24] programs were used for all the calculations. Atomic scattering factors were those incorporated in the computer programs.

2.5. Computational details

GAUSSIAN03 program [25] was used in the calculations. The geometry optimization was carried out with the DFT method with the use of B3LYP functional [26,27]. The electronic spectra were calculated with the TDDFT method [28]. The calculations were performed by using ECP basis set on the rhenium atom, the standard 6-31+g** basis for chlorine, oxygen and nitrogen, 6-31+g* for carbon and 6-31G basis for hydrogen atoms. The Xe core electrons of Re were replaced by an effective core potential and DZ quality Hay and Wadt Los Alamos ECP basis set (LANL2DZ) [29] was used for the valence electrons. Additional *d* function with exponent $\alpha = 0.3811$ and *f* function with exponent $\alpha = 2.033$ on the rhenium atom were added.

2.6. Magnetic measurement

The magnetic measurements of the powdered samples was measured over the temperature range 1.8–300 K using a Quantum Design SQUID – based MPMSXL – 5-type magnetometer. The superconducting magnet was generally operated at a field strength ranging from 0 to 5 T measurements. Measurements sample of compounds were made at magnetic field 0.5 T.

The SQUID magnetometer was calibrated with the palladium rod sample. Corrections are based on subtracting the sample – holder signal and contribution χ_D estimated from the Pascal constants [37] and equal -257×10^{-6} cm^3 mol^{-1} for complex [$ReCl_4(pzH)(PPh_3)$] (**1**) and -263×10^{-6} cm^3 mol^{-1} for complex [$ReCl_4(pyz)(PPh_3)$] (**2**). The t.i.p. per Re^{4+} center was assumed to be 70×10^{-6} cm^3 mol^{-1}. The effective magnetic moment was calculated from the equation, $\mu_{eff} = 2.83(\chi_M T)^{1/2}$(B.M.).

3. Results and discussion

The [$ReCl_4(pzH)(PPh_3)$] (**1**) and [$ReCl_4(pyz)(PPh_3)$] (**2**) complexes have been obtained in high yield in the reactions of [$ReCl_4(PPh_3)_2$] with pyrazole and pyrazine, respectively

$$[ReCl_4(PPh_3)_2] + pzH \rightarrow [ReCl_4(pzH)(PPh_3)] + PPh_3 \quad (R.1)$$

$$[ReCl_4(PPh_3)_2] + pyz \rightarrow [ReCl_4(pyz)(PPh_3)] + PPh_3 \quad (R.2)$$

The excess of pzH and pyz ensures the maximum yield of the products.

The elemental analysis of the complexes is in good agreement with their formulation. The presence of the strong band in the range assignable to N–H vibrations in the spectrum of **1** confirms the coordination of pyrazole in a neutral monodentate form. The absorption bands at ~1580 and ~1515 cm^{-1} are typical of mono-coordinated diaza ligands [30].

3.1. X-ray structures

Perspective drawings of **1** and **2** are given in Figs. 1 and 2, respectively. The rhenium atom of the both complexes is in a distorted octahedral environment with four chlorine

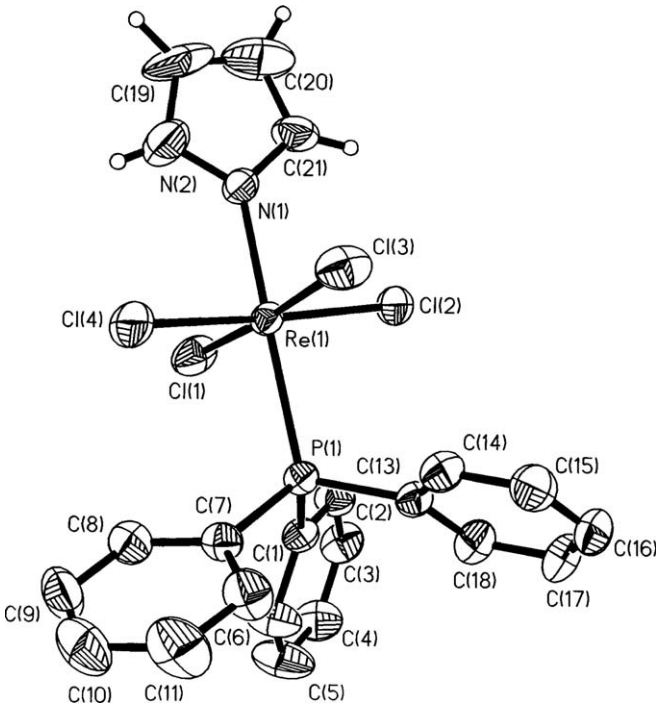

Fig. 1. The molecular structure of **1**. The hydrogen atoms of the phenyl rings are omitted for clarity.

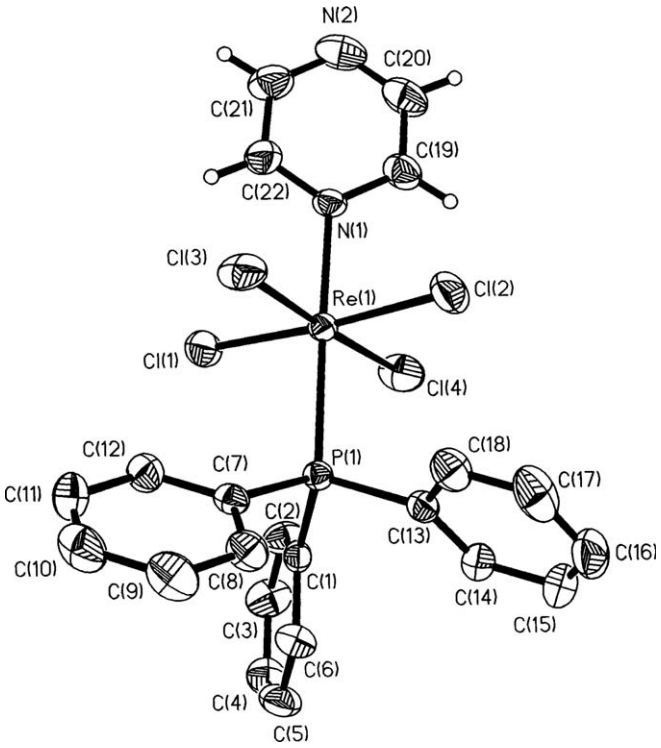

Fig. 2. The molecular structure of **2**. The hydrogen atoms of the phenyl rings are omitted for clarity.

ions in the equatorial plane, and N-donor ligand and PPh_3 molecule in axial positions. Table 1 presents crystal data and structural refinement for **1** and **2**. The most important experimental bond lengths and angles for **1** and **2** are reported in Tables 2 and 3, respectively. The Re–N, Re–Cl and Re–P bond lengths are unexceptional, they agree well with appropriate values found previously in similar rhenium compounds [7–12]. The weak C–H···Cl and medium strength N–H···Cl intra- and intermolecular hydrogen bonds [31,32] of **1** and **2** are presented in Table 4. Via these interactions a hydrogen bonded dimer (in **1**) and infinite hydrogen bonded chains along crystallographic *b* axis (in **2**) are created. The shortest Re···Re distance is 6.670 and 7.753 Å, respectively, for **1** and **2**.

The bond valences were computed as $v_{ij} = \exp[(R_{ij} - d_{ij})/b]$ [33–36], where R_{ij} is the bond-valence parameter (in the formal sense the R_{ij} parameter value can be considered as an idealized single-bond length between *i* and *j* atoms). The R_{Re-N}, R_{Re-P}, R_{Re-Cl} were taken as 2.06, 2.46 and 2.23 [35], respectively, and *b* was taken as 0.37 [33]. The computed bond valences of rhenium are $v_{Re-N} = 0.761$; $v_{Re-P} = 0.840$; $v_{Re-Cl} = 0.775$, 0.758, 0.730, 0.764 v.u. (valence units) for **1** and $_{Re-N} = 0.666$; $v_{Re-P} = 0.871$; $v_{Re-Cl} = 0.758$, 0.763, 0.784, 0.751 v.u. (valence units) for **2**. These means that the triphenylphosphine groups are strongest bonded substituents, the strength of Re–Cl bonds are comparable to the strength of $Re–N_{(pyrazole)}$ bond, and the pyrazine is the weakest bonded substituent (the bond is about 15% weaker in comparison to $Re–N_{(pyrazole)}$).

3.2. Optimized geometries

The geometries of **1** and **2** were optimized in quartet and doublet states using the DFT method with the B3LYP functional. The energies of the doublet states are of 15.8 and 16.3 kcal higher for **1** and **2**, respectively. The optimized geometric parameters of the quartet states are

gathered in Tables 2 and 3 for **1** and **2**, respectively. In general, the predicted bond lengths and angles are in good agreement with the values based upon the X-ray crystal structure data.

3.3. Charge distribution

Table 5 presents the atomic charges from the natural population analysis (NPA) for **1** and **2** complexes. The calculated charges on the rhenium atoms are considerable lower than the formal charge +4. It results from charge donation from the chloride ions and triphenylphosphine ligand. There is large positive charge on the P atom, and the charges on the chloride ions are significantly smaller than −1. The populations of the d_{xy}, d_{xz}, d_{yz}, $d_{x^2-y^2}$ and d_z^2 orbitals of the central atoms in **1** and **2** are following: complex **1** – 1.235, 1.239, 1.046, 1.130 and 1.228; complex **2** – 1.246, 1.233, 1.116, 1.124 and 1.186.

3.4. Molecular orbitals

The energies and characters of the selected MOs for **1** and **2** are presented in Tables 6 and 7, respectively. The rhenium atoms in **1** and **2** compounds possess $(d_{xz})^1(d_{yz})^1(d_{xy})^1$ configuration. For **1** and **2** complexes, the rhenium d_{xz}, d_{yz} and d_{xy} orbitals make main contributions into the HOMO − 2, HOMO − 1 and HOMO with α spin and HOMO, LUMO and LUMO + 1 with β spin. In all these molecular orbitals, the rhenium d_{xz}, d_{yz} and d_{xy} orbitals bear antibonding character towards the p_π orbitals of the chloride ligands. For complex **1**, the LUMO with α spin and the LUMO + 9 with β spin are of d_z^2-σ_{Cl}-σ_P character. The $d_{x^2-y^2}$ rhenium orbital has a significant contribution in the LUMO + 1 with α spin and the LUMO + 6 with β spin.

LUMO + 4	−1.147	π^*(Ph), σ^*(P–C)	−1.354	π^*(pyz)
LUMO + 5	−0.882	π^*(Ph), σ^*(P–C)	−1.264	d_{z^2}(Re)-σ(P)-σ(N), π^*(Ph)
LUMO + 6	−0.587	π^*(Ph), σ^*(P–C), d_{z^2}(Re)	−1.128	π^*(Ph), σ^*(P–C), d_{z^2}(Re)
LUMO + 7	−0.506	π^*(Ph)	−0.840	π^*(Ph), σ^*(P–C), d_{xz}(Re)
LUMO + 8	−0.298	π^*(Ph)	−0.757	$d_{x^2-y^2}$(Re)-σ(Cl)
LUMO + 9	−0.168	π^*(Ph)	−0.508	π^*(Ph)

For complex **2**, the LUMO orbital with α-spin has predominantly π* (pyz) character. The d_z^2 rhenium orbital has a significant contribution in the LUMO + 1 with α spin and the LUMO + 5 with β spin, whereas the LUMO + 2 with α spin and the LUMO + 8 with β have predominantly $d_{x^2-y^2}$-σ_{Cl} character. A contribution of σ* (P–C) phosphine orbitals is visible in several unoccupied molecular orbitals with α and β spins of **1** and **2** compounds. These orbitals are involved in the π-back bonding between metal center and phosphine ligand. In classical concepts empty phosphorous 3d orbitals are used for this purpose. Now, it is generally recognized that the d orbitals, which are very high in energy play only a minor role in the π_{M-PR3} bond formation [33].

3.5. Electronic spectrum from the TDDFT calculations

The electronic spectra of **1** and **2** exhibit two intense absorption bands below 300 nm and some weaker absorptions in the low energy range. The experimental and calculated electronic spectra of **1** and **2** are presented in Figs. 3 and 4, respectively. Each calculated transition was represented by a gaussian function with the height equal to the oscillator strength and width equal to 0.04.

Tables 8 and 9 show the energies and molar absorption coefficients of the experimental absorption bands and the spin-allowed quartet–quartet electronic transitions calculated with the TDDFT method for **1** and **2**, respectively. The assignment of the calculated transitions to the experimental absorption bands was based on the criterion of the energy and oscillator strength of the calculated transition.

The investigated complexes are of large size; the number of basis functions is equal 532 and 546 for **1** and **2**, respectively. Ninety electron transitions calculated by the TDDFT method do not comprise all the experimental absorption bands. The shortest wavelength experimental band of **2** is not assigned to the calculated transitions, and the assignment for the complex **1** is not complete. As the solution spectra of PPh_3, pyrazole and pyrazine exhibit intense absorption bands in 270–200 nm region, some additional intraligand and interligand transitions are expected to be found at higher energies in the calculations for **1** and **2**.

The longest wavelength weak experimental bands at 752 nm for **1** and 761 nm for **2** correspond to the spin-forbidden transitions $^4A_{1g} \rightarrow {}^2E_g$.

For **1** and **2** complexes, the experimental absorption bands between 500 and 250 nm result from d–d and ligand–metal charge transfer (LMCT) transitions. The last ones occur from chloride, phosphine and pyrazole or pyrazine ligand orbitals to the d rhenium orbitals. The d → d transitions calculated in this range have small oscillator strengths. Consequently, they do not contribute significantly to the overall shape of these bands.

3.6. Magnetic properties

The magnetic properties of $[ReCl_4(pzH)(PPh_3)]$ (**1**) complex under the form χ_M versus T and $\chi_M T$ versus T (χ_M being the molar magnetic susceptibilities) are shown in Fig. 5. The effective magnetic moment of 3.40 B.M. ($\chi_M T = 1.44\ cm^3\ mol^{-1}\ K$) at 300 K corresponding three

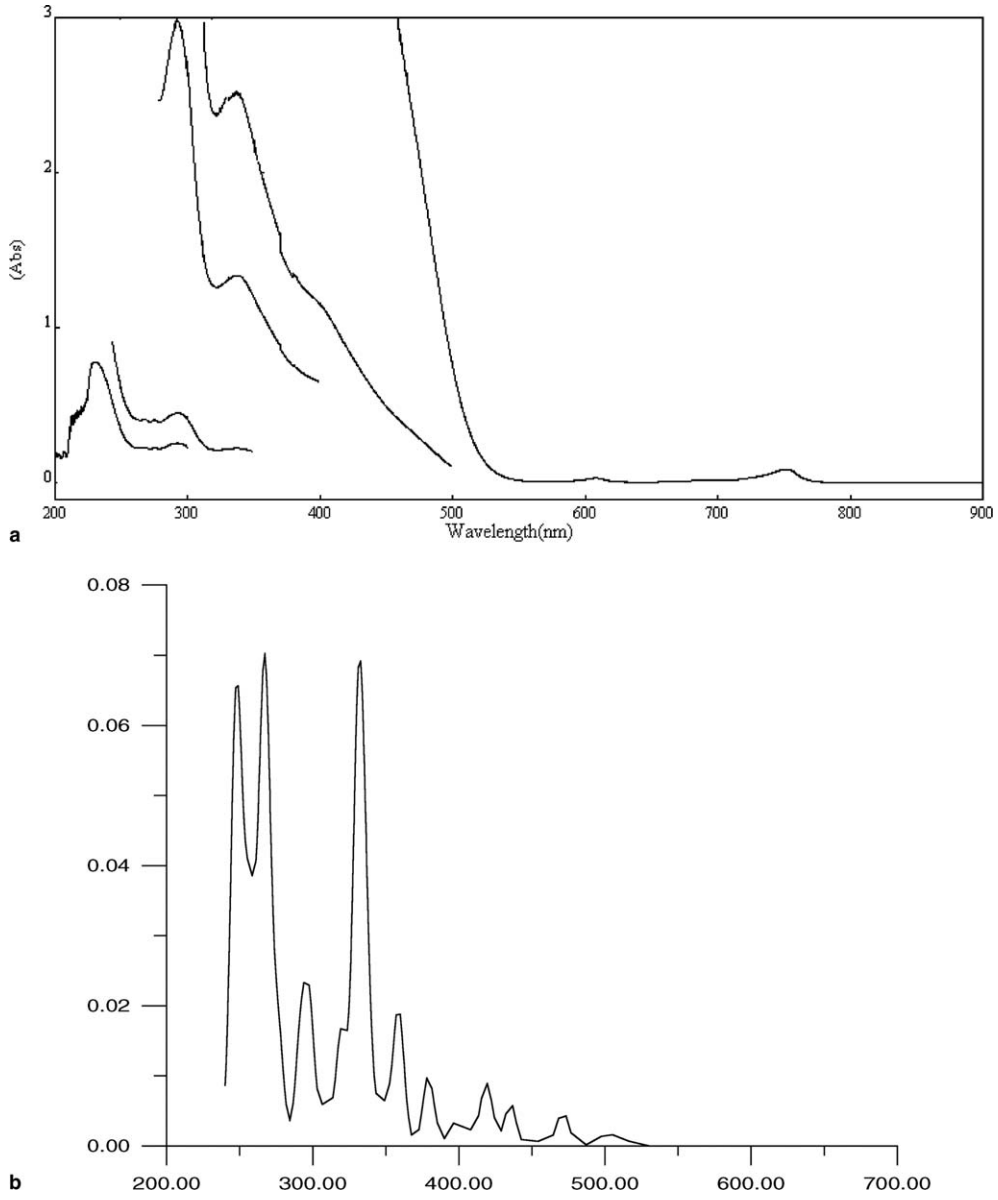

Fig. 3. The experimental (a) and calculated (b) electronic absorption spectrum of **1**.

unpaired electrons. The reduction of magnetic moments in comparison with the spin-only value (3.87 B.M.) can be explained on the basis of depopulation of spin–orbit coupled excited states and/or zero-field effects. The magnetic susceptibilities of other rhenium(IV) salts have been reported elsewhere [38–42]. The value of $\chi_M T$ product decreases only slightly with temperature lowering. In the low-temperature range (below 50 K), a more evident decrease of the value of $\chi_M T$ is observed with continuous decrease of the temperature to 0.04 $cm^3\ mol^{-1}$ K (0.57 B.M.) at 1.8 K.

The susceptibility curves exhibit the maximum at 8 K, indicating the presence the antiferromagnetic 3D ordering in the crystal lattice with the ratio of the Curie–Weiss Θ to the Neel's temperature $\Theta/T_N \approx 1$.

The values of the Curie and Weiss constants determined from the relation $1/\chi_M = f(T)$ over temperature range 80–300 K are equal to 1.50 $cm^3\ mol^{-1}$ and −10.1 K, respectively. A negative value of Weiss constant suggests the antiferromagnetic coupling of the rhenium(IV) centers in the crystal lattice.

To interpret quantitatively the susceptibility data, we used the approaches in which we considered that magnetic susceptibility of this complex might be described by the susceptibility of $^4A_{2g}$ term with the zero-field splitting [43].

Zero-field splitting and ligand field of symmetry lower than cubic lead to the anisotropy of magnetic properties of an ion. The relevant spin Hamiltonian is defined by the following equation:

$$H = D\left[S_z^2 - \frac{1}{3}S(S+1)\right] + g_{II}\beta H_z S_z + g_{\perp}\beta(H_x S_x + H_y S_y), \quad (1)$$

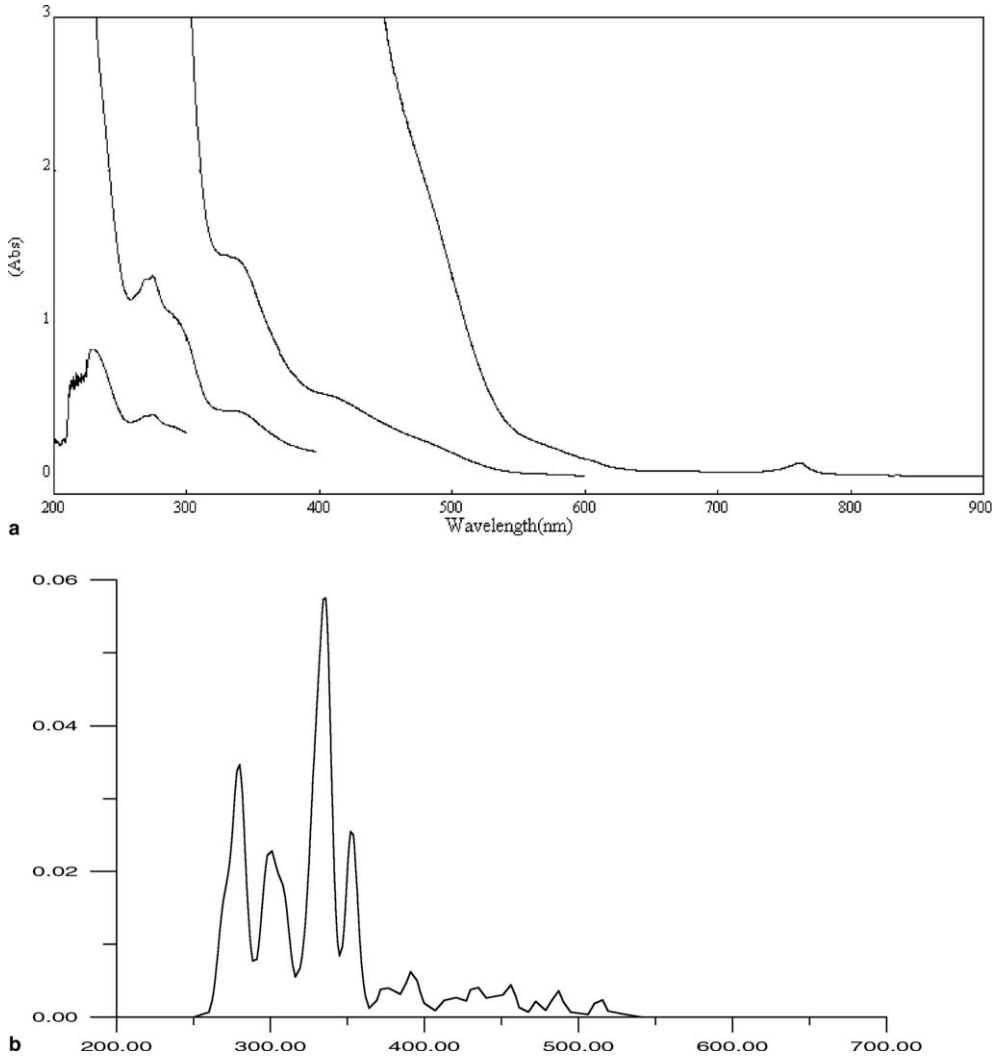

Fig. 4. The experimental (a) and calculated (b) electronic absorption spectrum of **2**.

where DS_z^2 represents the splitting into two Kramers doublets in the absence of magnetic field. The parallel and perpendicular zero field susceptibilities for $S = \frac{3}{2}$ (Eqs. (2) and (3)) were corrected by the factor predicted from the molecular field (Eq. (4)) [42,44]:

$$\chi_{\mathrm{II}} = \frac{N\beta^2 g_{\mathrm{ReII}}^2}{4kT} \cdot \frac{1 + 9\exp\left(-\frac{2D}{kT}\right)}{1 + \exp\left(-\frac{2D}{kT}\right)}, \tag{2}$$

$$\chi_{\perp} = \frac{N\beta^2 g_{\mathrm{Re}\perp}^2}{4kT} \cdot \frac{4 + 6\frac{kT}{2D}\left[1 - \exp\left(-\frac{2D}{kT}\right)\right]}{1 + \exp\left(-\frac{2D}{kT}\right)}, \tag{3}$$

where D is the zero-field splitting parameter, N is the Avogadro's number, g is the spectroscopic splitting factor, β is the Bohr magneton, k is the Boltzmann constant and T is the absolute temperature.

$$\chi_{\mathrm{av}} = \frac{\chi_{\mathrm{av}}}{1 - \left(\frac{2zJ'}{Ng_{\mathrm{av}}^2\beta^2}\right)\chi_{\mathrm{av}}}, \tag{4}$$

where zJ' is the exchange parameter and was applied to calculate magnetic exchange effect by means of a molecular field.

Since our data concern powdered sample, the average magnetic susceptibility is equal to $\chi_{\mathrm{av}} = 1/3\chi_{\mathrm{II}} + 2/3\chi_{\perp}$. The least-squares fit of the experimental data using this equation was limited to the 9–300 K range and leads to $D = 20.8\ \mathrm{cm}^{-1}$, $g_{\mathrm{II}} = 1.10$, $g_{\perp} = 2.03$ and $zJ' = -4.18\ \mathrm{cm}^{-1}$. The agreement factor R defined as $R = \Sigma_{i=1}^{n}\left(\chi_m^{\mathrm{exp}} - \chi_m^{\mathrm{calc}}\right)^2/\Sigma_{i=1}^{n}\left(\chi_m^{\mathrm{exp}}\right)^2$ is 2.93×10^{-5}.

The magnetic properties of $[ReCl_4(pyz)(PPh_3)]$ (**2**) complex under the form χ_M versus T and $\chi_M T$ versus T (χ_M being the molar magnetic susceptibilities) are plotted in Fig. 6. The effective magnetic moment of 3.35 B.M. ($\chi_M T = 1.40\ \mathrm{cm}^3\ \mathrm{mol}^{-1}\ \mathrm{K}$) at 300 K corresponding three unpaired electrons. The magnetic curve show that the $\chi_M T$ values remain nearly constant in a wide range and smoothly decrease at low temperatures. The slight decrease of $\chi_M T$ at low temperatures could be attributed to zero-field splitting effect [45].

Generally, the complex **2** shows linear χ_M^{-1} vs. T behavior in the 80–300 K interval, with $C = 1.44\ \mathrm{cm}^3\ \mathrm{mol}^{-1}$ and $\Theta = -7.9$ K.

The experimental magnetic data of complex **2** were fitted to the empirical relations proposed earlier [46]. The parallel and perpendicular zero field susceptibilities (Eqs. (5) and (6)) were corrected by the factor predicted from the molecular field (Eq. (4)) [42,44]:

$$\chi_{\mathrm{II}} = \frac{N\beta^2 g_{\mathrm{II}}^2}{4kT} \cdot \frac{1 + 9\exp\left(-\frac{2D}{kT}\right)\exp\left(\frac{J}{kT}\right)}{1 + \exp\left(-\frac{2D}{kT}\right)} \tag{5}$$

$$\chi_{\mathrm{I}\perp} = \left\{ \left[\frac{N\beta^2 g_{\perp}^2}{kT}\right]\left[1 + 9\exp\left(-\frac{2D}{kT}\right)\right]^{-1} + 3N\beta^2 g_{\perp}^2 \tanh\left(\frac{D}{kT}\right) \Big/ 4D \right\} \times \left\{ \left(\frac{kT}{J}\right)\tanh\left(\frac{J}{2kT}\right) + \left[\sec h^2\left(\frac{J}{2kT}\right)\right] \Big/ 2 \right\} \tag{6}$$

Since our data concern powdered sample, the experimental magnetic susceptibility is equal $\chi_{av} = 1/3\chi_{II} + 2/3\chi_{\perp}$. The least-squares fit of the experimental data using this equation was limited to the whole temperature range and leads to $D = -21.3\ cm^{-1}$, $J = -1.19\ cm^{-1}$, $zJ' = -0.58\ cm^{-1}$ and $g_{av} = 1.72$. The agreement factor R defined as $R = \Sigma_{i=1}^{n}(\chi_m^{exp} - \chi_m^{calc})^2/\Sigma_{i=1}^{n}(\chi_m^{exp})^2$ is 1.14×10^{-4}. A negative value of the exchange parameter suggests the presence of weak antiferromagnetic interactions between Re^{IV} ions at crystal lattice.

The occurrence of a bulky ligands result in the diamagnetic dilution due to increasing distance between the paramagnetic Re^{IV} centers, the magnetic interaction might be transmitted by hydrogen bonds.

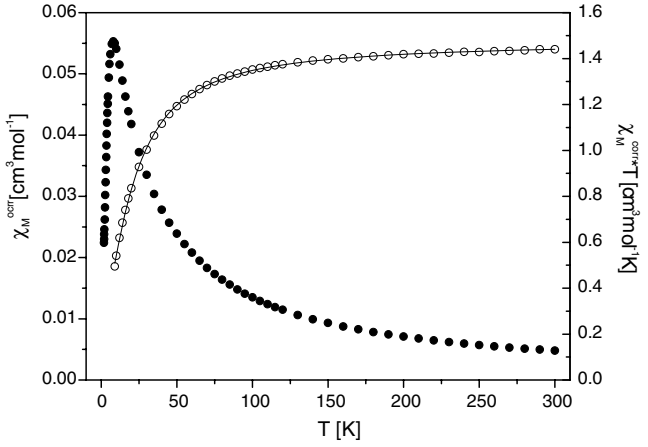

Fig. 5. Thermal dependence of χ_M (●) and $\chi_M T$ (○) for $[ReCl_4(pzH)(PPh_3)]$ (**1**) χ_M (●). The solid line is the calculated curve.

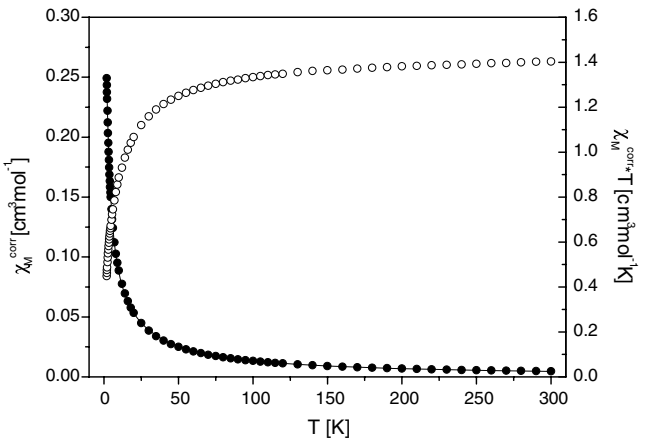

Fig. 6. Thermal dependence of χ_M (●) and $\chi_M T$ (○) for $[ReCl_4(pyz)(PPh_3)]$ (**2**). The solid line is the calculated curve.

4. Conclusions

Two novel Re(IV) compounds – $[ReCl_4(pzH)(PPh_3)]$ (**1**) and $[ReCl_4(pyz)(PPh_3)]$ (**2**) – have been prepared and structurally as well as spectroscopically characterized. The geometries of **1** and **2** were optimized in quartet and doublet states using the DFT method with the B3LYP functional. The energies of the doublet states of **1** and **2** complexes are higher, which is consistent with the results of magnetic measurements. The values of effective magnetic moments of **1** and **2** complexes at 300 K correspond to three unpaired electrons and confirm $(d_{xz})^1(d_{yz})^1(d_{xy})^1$ configuration of the rhenium atoms in **1** and **2**.

5. Supplementary data

Supplementary data for $C_{21}H_{19}Cl_4N_2PRe$ and $C_{22}H_{19}Cl_4N_2PRe$ are available from the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK on request, quoting the deposition numbers: 276935 for **1** and 276936 for **2**.

Acknowledgments

The GAUSSIAN03 calculations were carried out in the Wrocław Centre for Networking and Supercomputing, WCSS, Wrocław, Poland. Crystallographic part was financed by funds allocated by the Ministry of Scientific Research and Information Technology to the Institute of General and Ecological Chemistry, Technical University of Łódź.

possible coordination modes because the four carboxylate groups may be completely or partially deprotonated. These structural features render H_4BTEC an important ligand that yields various networks for coordination polymers [12]. The use of H_4BTEC in combination with the aromatic chelate ligand phen results in the formation of a 2-D uranyl-containing polymeric compound **2**.

2. Experimental

2.1. Synthesis

Compounds **1** and **2** were synthesized through a hydrothermal route. All reagents were of analytical grade and commercially available. The syntheses were carried out in 20 mL Telfon-lined stainless steel vessels under autogenous pressures with a filling capacity of approximately 70%.

2.1.1. $[(UO_2)_3O(OH)_3(NA)_2]^- \cdot H_3O^+$ (1)

A typical mixture of $UO_2(OAc)_2 \cdot 2H_2O$ (214 mg), H_2QA (120 mg), 2,2′-bipyridine (bipy, 168 mg) and water (10 mL) in a molar ratio of 1:2:2:1110 was stirred for 1 h in air, the final solution was transferred to and sealed in a Teflon-lined autoclave which was subsequently heated at 160 °C for 3 days. Pale-yellow block crystals of **1** were obtained after washing with water and drying in air, and the yield of the product was about 75% on the basis of U. Main IR features (KBr): $v = 3557$w, 3507w, 3120w, 3060w, 1634s, 1596s, 1558w, 1334s, 1147s, 1010m, 922s, 843m, 760s, 697s, 647s, 540s, 430s cm^{-1}.

2.1.2. $(UO_2)_2(phen)_2(BTEC)$ (2)

A mixture of $UO_2(Ac)_2 \cdot H_2O$ (220 mg), H_4BTEA (120 mg), phen (196 mg) and water (10 mL) in a molar ratio of 1:1:2:1100 was stirred for 1 h. The resulting solution was sealed in an autoclave and heated at 160 °C for 3 days under autogenous pressure. After cooling to room temperature, the yellow columnar crystals were washed several times with distilled water and dried in air at room temperature. The yield of the product was about 80% on the basis of U. Main IR features (KBr): $v = 3419$w, 3058w, 1627s, 1550s, 1501m, 1452m, 1400s, 1333s, 1215w, 1135m, 1097w, 933s, 840s, 771w, 712s, 663m, 544s, 440m cm^{-1}.

2.2. Physical measurements

The powder X-ray diffraction (XRD) patterns (Cu Kα radiation, $\lambda = 1.5418$ Å) were recorded on a Siemens D5005 diffractometer with a graphite monochromator at room temperature. The FT-IR spectra of the samples dispersed in KBr pellets were obtained on a Bruker IFS 66V/S FT-IR spectrometer. IR absorptions are described as follows: strong (s), medium (m) and weak (w). The thermogravimetric (TG) and the differential thermal analysis (DTA) were conducted on a Netzsch STA 449C thermal analyzer under a flow of dry air at a heating rate of 20 K min^{-1}. The solid state diffuse-reflectance UV–Vis spectra for powder samples were recorded on a Perkin–Elmer Lambda 20 UV–Vis spectrometer equipped with an integrating sphere, using $BaSO_4$ as white standard. The as-prepared powder samples were mounted on a Perkin–Elmer LS55 fluorescence spectrophotometer to measure the photoluminescent (PL) property.

2.3. X-ray crystal structure analyses

Single-crystal X-ray data for both **1** and **2** were collected at 293(2) K on a Bruker Smart-CCD diffractometer (Mo Kα, $\lambda = 0.71073$ Å). The structures were solved by direct methods (SHELXS-97), and refined with the full-matrix least-squares on F^2 method using the SHELXTL-97 program together with an empirical absorption correction. All non-hydrogen atoms were refined anisotropically and the aromatic hydrogen atoms were calculated ($d_{C-H} = 0.93$ Å) and fixed with thermal parameters based on the carbon atoms to which they are bonded. The H atoms attached to the oxygen atoms (Ow) of the lattice water and coordinating water molecules were not located. The experimental crystallographic data for **1** and **2** are listed in Table 1; selected bond lengths and angles of **1** and **2** are listed in Table 2.

3. Results and discussion

3.1. Syntheses

In the hydrothermal reaction process for compound **1**, H_2QA was transformed into HNA via decarboxylation. Decarboxylation of quinolinic acid is common under hydrothermal conditions [11a,11d,13a]. The electron-withdrawing effect of the N atom in the pyridine ring results in lower electron density on the *ortho*-C atom so

that the *ortho*-COOH group gets lost more easily than the *meta*-COOH. When we replaced H_2QA with HNA under the same synthetic conditions, a powder form of compound **1**, which was not suitable for single-crystal structure analysis, was also obtained and the product yield was lower. The crystallization temperature is also important for the hydrothermal synthesis of **1**. If the reaction temperature is below 160 °C (e.g. 150 or 140 °C), the decarboxylation of the ligand does not occur, and an unknown crystalline phase appears. At temperatures distinctly above 160 °C (e.g. 170 or 180 °C), the reactant is carbonized and no proper crystals of **1** are formed. The presence of bipy is critical for the growth of the crystals of **1** although this ligand is not incorporated in the structure of **1**. In the absence of bipy, no crystals of **1** are observed in the final product of the reaction system either. A pH value of about 7.0 (i.e., the reaction system is neutral) favors the formation of compound **1**, and it is believed that in the synthesis of **1**, bipy acts as both an auxiliary reagent and a pH adjuster.

In contrast, the single crystals of compound **2** are obtained easily. However, the reaction time affects the crystal size of **2**, and a crystallization time of 3 days is the best for the formation of high quality single crystals of **2** for structure analysis. If the reaction time is shorter than 3 days, the crystals are smaller, whereas a reaction time longer than 3 days leads to apparent defects on the crystals of **2**.

3.2. Thermal properties

The two compounds are stable in air and insoluble in water and common organic solvents such as ethanol, acetonitrile and acetone. Thermogravimetric curves have been obtained in air for crystalline samples of **1** and **2** in the temperature range of 37–800 °C. From the TG curves, the decomposition of **1** can be described as a two-step process. The first has an initial weight loss of about 4.7% from 37 to 300 °C, corresponding to the removal of the lattice water and hydroxyl groups (calculated value 4.6%) that accompanies a distinct endothermic effect at around 209 and 284 °C, respectively. For the second stage, the weight loss of 19.0% in the range of 300–500 °C is assigned to the removal of NA groups from the structure (calculated value 20.1%), as indicated by a strong exothermic effect at 460 °C. The total weight loss is 23.7%, in agreement with the calculated result based on the single-crystal structure (24.7%). Compound **2** is thermally stable up to approximately 450 °C on the basis of powder XRD patterns. The rapid decomposition of the compound starting at about 470 °C is followed by a distinct exothermic effect at around 570 °C. The total weight loss of **2** (56.1%), attributable to removal of the total organic component, is in agreement with the calculated value based on the single-crystal structure of **2** (53.7%).

3.3. Crystal structures

For both compounds **1** and **2**, the peak positions of the experimental powder X-ray diffraction patterns correspond well with those simulated on the basis of the single-crystal structures, confirming that the two compounds are single phases. The asymmetric units for **1** and **2** are depicted in Fig. 1.

3.3.1. $[(UO_2)_3O(OH)_3(NA)_2]^- \cdot H_3O^+$ (**1**)

Single-crystal X-ray diffraction analysis has revealed that the crystal structure of **1** consists of one-dimensional single-stranded helical ribbons with a composition of $[(UO_2)_3O(OH)_3]_n^{n+}$. The ribbons are coordinated with NA ligands at both sides. Compound **1** crystallizes in the monoclinic space group $P2_1/n$. In each independent crystallographic unit of **1**, there are two chelating NA ligands, one lattice water molecule and a $[(UO_2)_3O(OH)_3]^+$ species consisting of three interconnected uranyl sub-structures which join together through a common vertex (Fig. 1(a)). Each uranium center is seven-coordinated by two oxygen atoms in the axial positions and another five O atoms in the equatorial plane of the pentagonal bipyramid. The axial U=O bond distances range from 1.755(6) to 1.793(7) Å with an average value of 1.777(5) Å, whereas the equatorial U–O distances vary from 2.214(6) to 2.567(6) Å with an average value of 2.405(5) Å. These values are in accordance with

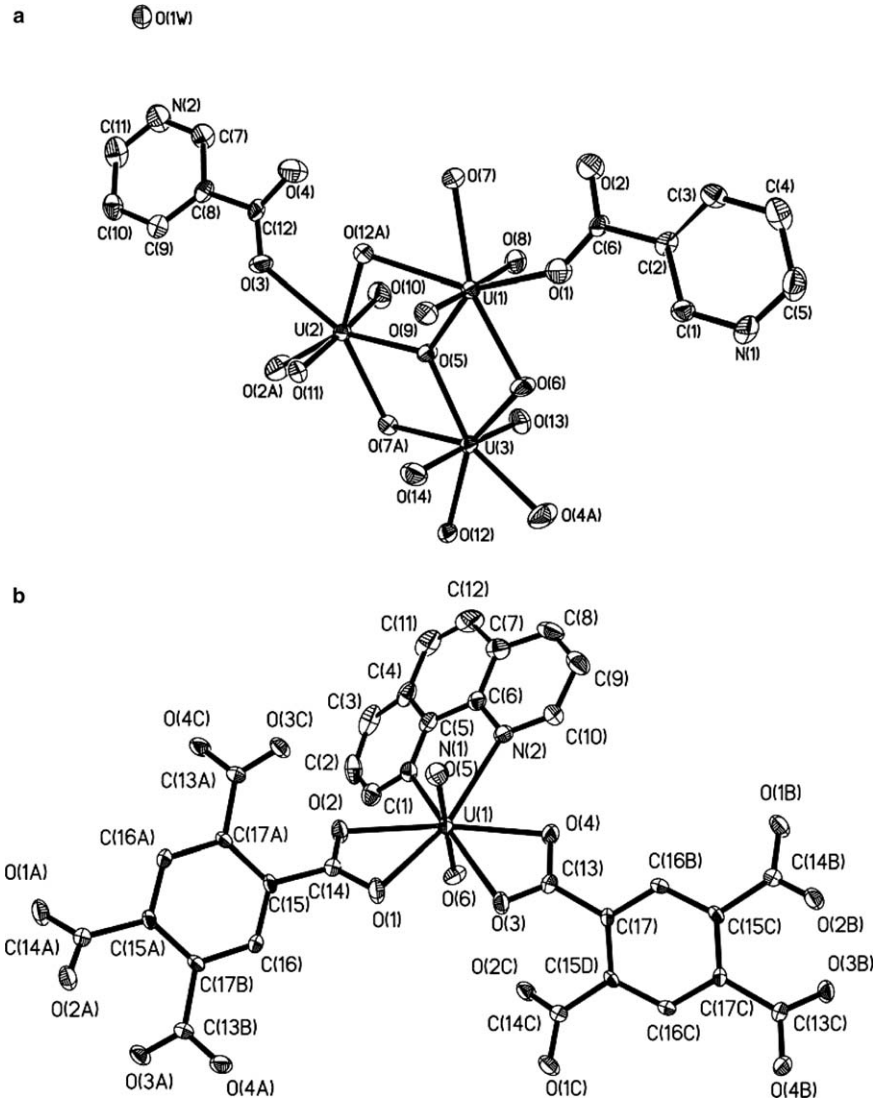

Fig. 1. (a) ORTEP drawing of the asymmetric unit of **1**. Thermal ellipsoids are shown at 50% probability. (b) ORTEP drawing of the asymmetric unit of **2**. Thermal ellipsoids are shown at 40% probability. All hydrogen atoms are omitted for clarity.

those observed for other uranium-containing compounds in the literature [3,7,11]. In addition, for the ribbons of **1**, there are three protons in each asymmetric unit, which are attached to O atoms to form hydroxyls. In total, there are four bridging O atoms in one asymmetric unit of **1** besides those from the NA ligands and from the axial O atoms of the U=O bonds. Among the four bridging O atoms, O(5) adopts a μ_3 binding mode in the center of the trinuclear-uranium unit, with the distance of U–O(5) for each UO_7 bipyramid being significantly shorter than those of other U–O bonds due to the stronger interactions in its environment. Bond-valence analysis [14a,14b] can be used to distinguish the O atoms and the OH groups. Bond valence sum calculations using the parameters derived by Burns et al. [14c] for seven-coordinate U(VI) give rise to a value of 2.13 for O(5). However, the bond valence sums for O(6), O(7) and O(12) are 1.06, 1.28 and 1.26, respectively, suggesting that these three O atoms have enough residual strength to seize protons. Therefore, it is reasonable that O(6), O(7) and O(12) are assigned as hydroxo O atoms. Similar calculation leads to bond valence sums of 5.92, 5.92 and 6.06 for U(1), U(2) and U(3), respectively. It is interesting to note that a trinuclear $[(UO_2)_3O(OH)_3]^+$ unit similar to that for our compound has also been observed previously by Åberg [13b].

The trinuclear $[(UO_2)_3O(OH)_3]^+$ units in **1** share edges to form infinite one-dimensional helical ribbons. A representation of the ribbon structure is depicted in Fig. 2(a). The central axis of each helical ribbon running along the *b*-axis is a twofold screw axis (Fig. 2(b)) and the ribbons are coordinated with NA ligands at both sides. The carboxyl groups of the NA ligands are deprotonated and adopt a bidentate bridging coordination fashion, establishing bridges between adjacent metal centers with distances of 3.894 Å for U(1)···U(2) and 3.873 Å for U(2)···U(3). The composition of the uranium oxide ribbon can be described as $[(UO_2)_3O(OH)_3]_n^{n+}$ which is in accord with the structural formula of the extensive polyhedral

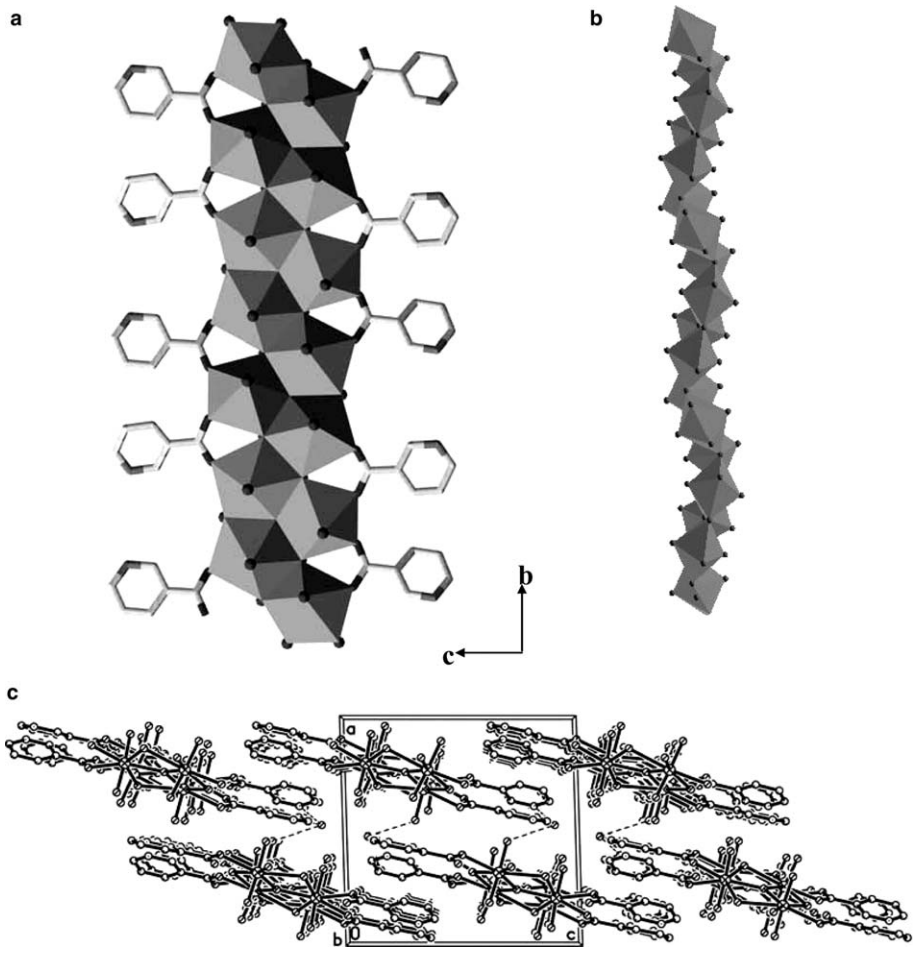

Fig. 2. (a) A polyhedral representation of the uranium ribbons built from edge-sharing pentagonal bipyramids along the *a*-axis; (b) the single-stranded helical ribbon with NA groups being omitted for clarity, and (c) view of the structure along the *b*-axis for **1**. The dotted lines show the Ow···N/O hydrogen bonding interactions.

$(UO_2)_kO_l(OH)_m$ chains or layers formed by uranyl units linked with oxo or hydroxo groups [15]. Burns et al. summarized the structural chemistry of uranyl oxides and systematically classified uranium minerals and inorganic phases based on the polymerization of uranyl polyhedra. The topological structure of the uranium oxide ribbon in **1** has not been observed in the uranyl compounds reported previously.

Taking into account of the attached NA ligands, the ribbons of $[(UO_2)_3O(OH)_3(NA)_2]_n^{n-}$ become negatively charged. The negative charges in the anionic NA-coordinated ribbons are compensated by H_3O^+ cations residing between adjacent ribbons. Although the H atoms of the water molecule could not be located from the difference Fourier map, the observed Ow···N/O contact distances (2.756/2.917 Å) in **1** suggest the presence of H-bondings involving the water molecules. In the crystal structure of **1**, each ribbon within the unit cell is surrounded by the nearest four ribbon neighbors. As illustrated in Fig. 2(c), the polyoxouranium ribbons in **1** are held together to form 2D layers in the *ab*-plane by packing forces of the H-bonds. These layers are further extended into a 3D architecture through offset face-to-face stacking interaction between the π-systems of the NA ligands from adjacent layers along the *a*-axis (the shortest C···C distance is about 3.45 Å) [16].

3.3.2. $(UO_2)_2(phen)_2(BTEC)$ (2)

The crystal structure of **2** comprises a layer with the composition of $UO_2(BTEC)_{0.5}$, which is coordinated by phen ligands above and below the layer plane. The uranium atom in **2** axially binds two oxygen atoms (Fig. 1(b)) to form a linear uranyl unit with an O=U=O angle of 179.3(2)° and U=O distances of 1.757(4) and 1.760(4) Å. Equatorially, each uranium atom is coordinated with four oxygen atoms from two chelating carboxylate groups of two different BTEC (mean U–O bond length 2.479(3) Å) ligands. These bond distances are typical of uranyl complexes [3,7,11]. On the other hand, the uranium atom is also coordinated by two nitrogen atoms of a single phen ligand, with U–N distances of 2.688(4) and 2.616(4) Å. The U–N distance of 2.688(4) Å is a little longer than those reported in the literature (2.371–2.633 Å) [4]. The phen ligand is twisted through the rotation of the whole molecule with a dihedral angle of 23° between the phen molecule and the equatorial plane, and as a result, the two coordinating N atoms are located above and below the uranyl equatorial plane,

respectively. The longer U–N bond distances and the tilt of the phen molecule minimize the repulsion between the phen group and the equatorial or axial O atoms, resulting in the location of the uranium atom in a distorted hexagonal bipyramid environment.

The connection of uranyl units with the BTEC ligands gives rise to a layer in which four uranyl and four BTEC units form a rectangular ring (Fig. 3(a)). All the carboxyl groups of each BTEC ligand, which is shared by four rings in the layer, are deprotonated and adopt a bidentate chelating mode. The phen units coordinate to the U atoms alternately from above and below the ring-containing layer. There exist edge-to-face π–π stacking interactions between the adjacent two phen rings with the shortest C···C

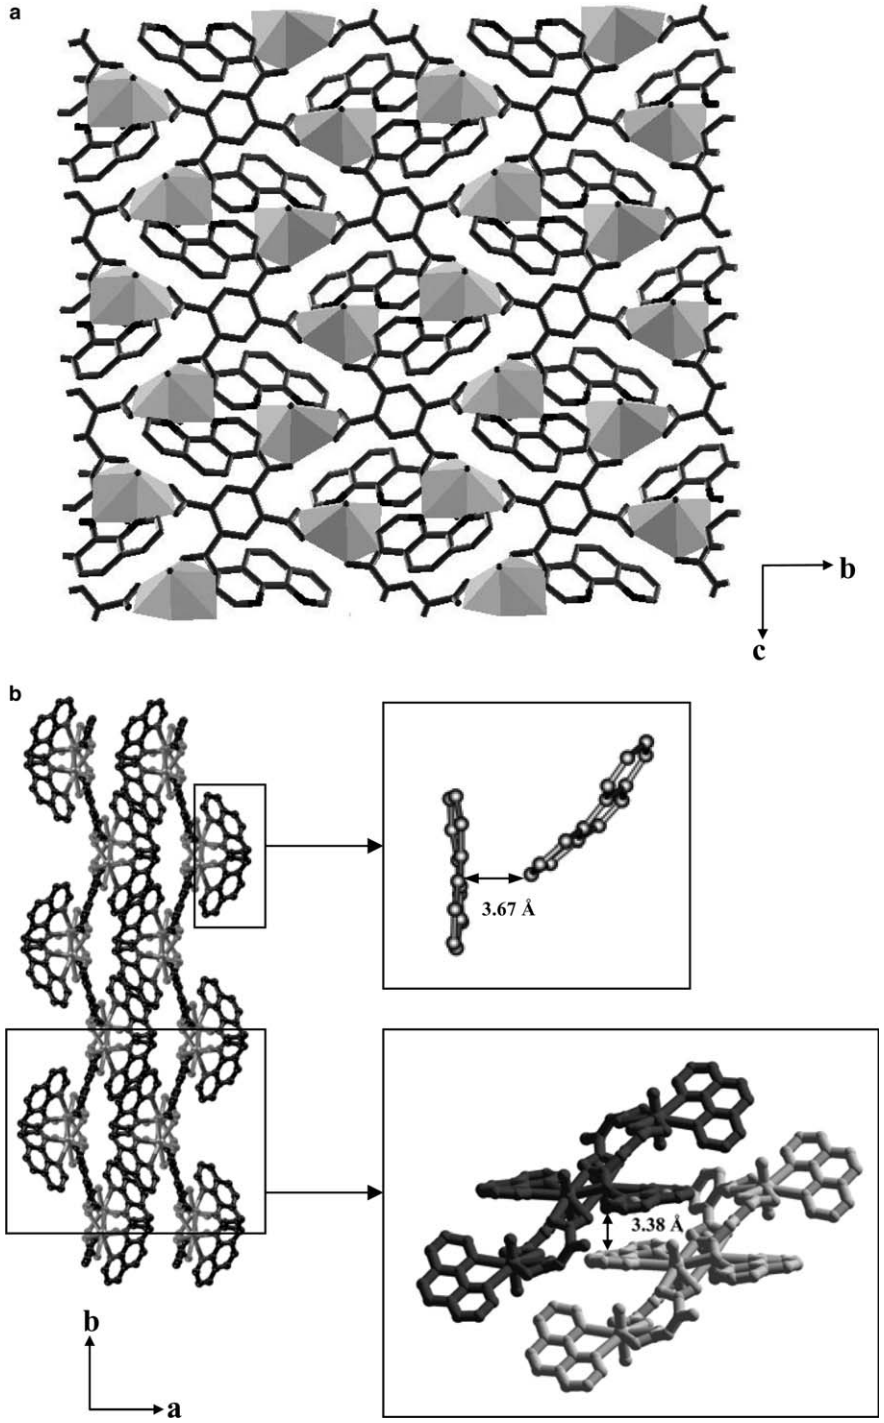

Fig. 3. (a) View of the connection of the BTEC ligand and uranyl ion along the *a*-axis and (b) the arrangement of the layers along the *a*-axis for **2.** Perspective views in the right part of (b) show the edge-to-face π–π interactions between adjacent phen rings of the same layers (top) and the π–π interactions between phen rings of adjacent layers (bottom).

distance being about 3.67 Å (Fig. 3(b)) [16]. Fig. 3(b) also displays the arrangement of the layers along the *a*-axis. The void space between two chelating phen groups on one side of the layer is filled with a phen group from the other side of an adjacent layer. There exists an offset face-to-face π–π stacking interaction between the interplanar phen rings, the shortest C···C distance being about 3.38 Å (Fig. 3(b)) [16]. Because of the two types of π–π interactions (edge-to-face and face-to-face), the crystals of **2** are insoluble in water.

3.4. Photoluminescent properties

Compounds **1** and **2** exhibit intense PL emissions in the solid state at room temperature. The emission spectrum of **1** is characterized by a broad band from 480 to 600 nm centered at 515 and 534 nm and two shoulders at 558 and 585 nm upon excitation at 434 nm. The solid-state emission spectrum of **2** under excitation at 341 nm appears somewhat different from that of **1** with the main emission peaks at 491, 511, 534 nm and two weak peaks at 560 and 586 nm. The PL spectra of **1** and **2** show typical emission features of uranyl compounds [8,7c,7d]. It is reasonable that the emission bands of **1** and **2** ranging from 500 to 600 nm are related to the transitions from the first excited electronic level to the symmetric and antisymmetric vibrational levels of the uranyl ion [17,18], and the relatively strong emission of **2** at 491 nm is attributable to uranyl ion emission from a triplet to a singlet state [18]. The excitation wavelengths (434 nm for **1** and 341 nm for **2**), under which the emission spectra were monitored, are much longer than the maximum absorption wavelengths of the ligands (283 nm for HNA, 322 nm for phen and 300 nm for H_4BTEC). This demonstrates that there is no intramolecular energy transfer from the ligand to uranium and the uranyl ion is excited directly.

The excitation spectra of **1** obtained by monitoring the emissions at 515 and 534 nm are rather similar and consist of several asymmetric broad bands ranging from 300 to 500 nm with the maximal excitation wavelengths being at 347, 434 and 476 nm. When the excitation wavelength is varied from 434 to 347 nm, the general feature of the emission spectra of **1** remains the same, but the emission intensities are slightly lower. When monitoring the emission at 511 nm for **2**, the excitation spectrum shows the most intense peak at 341 nm and contains fine structures with about 15-nm separations ranging from 300 to 500 nm. The fine structures correlate with the O=U=O symmetric stretching frequency in the excited state [19]. Obviously, the excitation behavior of **2** is different from that of **1**. This difference in excitation feature is coincident with the UV–Vis absorptions for **1** and **2** (Fig. 4(c)). For **2**, the broad UV–Vis absorption band in the 400–500 nm region contains fine structures with about 15-nm separations. In contrast, the absorption fine structures of **1** are not clear. The absorption bands from 400 to 500 nm arise from the electronic transitions from the bonding orbitals to the non-bonding orbitals. This transition is forbidden, and as a result, the absorption intensity in the visible region is lower than that of the absorption in the UV region arising from the transitions from the bonding orbitals to the anti-bonding orbitals [20].

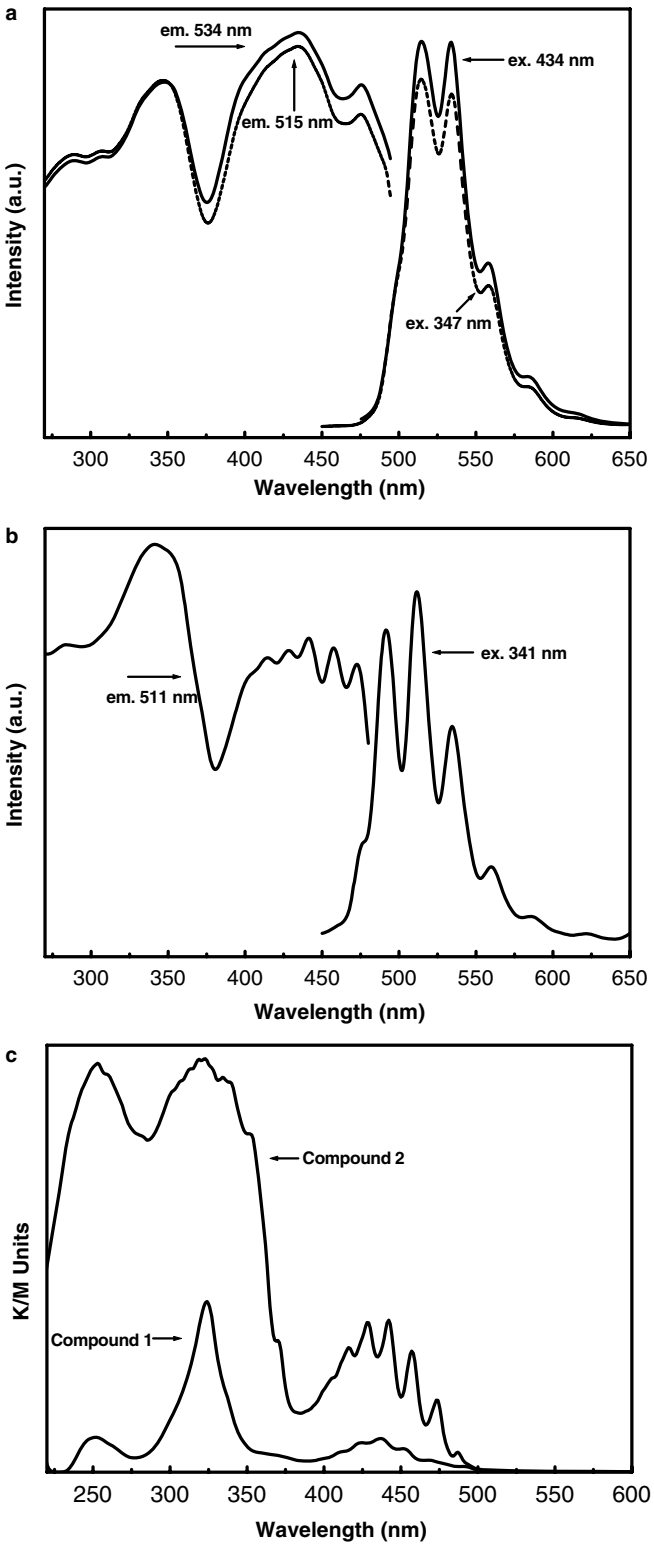

Fig. 4. Photoluminescent emission spectra of **1** with excitation at 354 and 434 nm, and excitation spectra of **1** with emission at 534 and 515 nm (a); emission spectrum of **2** with excitation at 341 nm, and excitation spectrum of **2** with emission at 511 nm (b); UV–Vis diffuse reflectance spectra of compounds **1** and **2** (c).

4. Conclusions

Two new uranium–organic compounds crystallize from hydrothermal reaction systems. Compound **1** is composed of unique one-dimensional helical chains $[(UO_2)_3O(OH)_3]_n^{n+}$ coordinated with nicotinate groups. The formation of **1** may prelude rich structures of uranyl ribbon in the presence of organic ligands. In the coordination polymer compound **2**, the O-donor (H_4BTEC) and N-donor ligands (phen) coordinate with the uranyl centers simultaneously. As a result, a layer is formed by the connection of uranyl units and BTEC ligands, with the chelating phen ligands decorating both sides of the layer. Both compounds emit intense yellow light under the excitation of UV rays.

2. Experimental

2.1. Materials

Crystals of $[Fe_2^{III}(\mu\text{-}O)(phen)_4(H_2O)_2](NO_3)_4 \cdot 5H_2O$ were prepared by a known method [24]. The prepared samples gave satisfactory electronic spectra [24] and elemental analyses (*Anal.* Calc. for $C_{48}H_{32}Fe_2O_{13}N_{12} \cdot 7H_2O$: C, 47.15; H, 3.8; Fe, 9.1; N, 13.75. Found: C, 47.1; H, 3.7; Fe, 9.0; N, 13.7%.). Stock solution of ascorbic acid was prepared by dissolving L-ascorbic acid (H_2A, G.R., E. Merck) in freshly boiled water and was stored in the dark. 1,10-Phenanthroline monohydrate (Sigma) was used as received. Solution of recrystallised $NaNO_3$ (G.R., E. Merck) was standardized by passing through a Dowex 50W 8-X strong cation exchange resin in the H^+ form and titrating the liberated acid with standard NaOH to a phenolphthalein end point. This solution of $NaNO_3$ was used for maintaining the ionic strength of the reaction mixtures. All other reagents used were of reagent grade. Doubly distilled freshly boiled water was used throughout. Reported kinetic data are in excess phenanthroline at 25.0 °C and $I = 1.0$ mol dm^{-3}.

2.2. Equilibrium measurements

Acid dissociation constants of **1** were determined by pH-metric titration of 15.0 ml of 1.0 mmol dm^{-3} solution of **1** with standard NaOH solution using a Metrohm (736 GP Titrino) autotitrator at 25.0 °C [30]. The ionic strength of the titrating medium was kept at 1.0 mol dm^{-3}. The built-in program of the autotitrator yielded two pK values.

2.3. Physical measurements and kinetics

Absorbance and electronic spectra were recorded with a Shimadzu (1601 PC) spectrophotometer using 1.00 cm quartz cells. Kinetics was monitored at 510 nm, the visible maximum of the reaction product $[Fe(phen)_3]^{2+}$ ($\varepsilon = 11\,100$ mol^{-1} dm^3 cm^{-1}) [25] in situ in the 'kinetic mode' of the instrument in the electrically controlled thermostated (25.0 ± 0.1 °C) cell housing (CPS-240A). At this wavelength only $[Fe(phen)_3]^{2+}$ absorbs appreciably. A large excess of C_{phen} (3.0 mmol dm^{-3}) over the complex (0.025 mmol dm^{-3}) was used. For all reactions, reagent solution (adjusted to desired pH by using dilute nitric acid and sodium hydroxide solutions) was directly injected into the spectrophotometer cell containing other components of the reaction mixture kept at same pH. Excess phenanthroline acted as buffer for the reaction mixtures. The pH of the experimental solutions was measured with a combined Ag/AgCl glass electrode of Metrohm (736 GP Titrino) autotitrator before and after the reaction. The linearity of measurements using the electrode was established using pH 4, 7 and 9 buffers. The electrode was calibrated to read $-\log[H^+]$ directly using a series of acid solutions at the ionic strength used for kinetic experiments. The $[H^+]$ in these solutions was determined by titration against NaOH solutions [26].

2.4. Stoichiometry and reaction products

Reaction stoichiometry was determined by spectrophotometric titration ($\lambda = 510$ nm) of a 0.05 mmol dm^{-3} solution of **1** with different amounts of reducing agent under the same condition at which kinetics were studied.

3. Results and discussion

3.1. Equilibrium studies

The built-in program of Metrohm 736 GP Titrino autotitrator yielded two pK_a values for the title complex (**1**) from the pH titration curve, $pK_{a1} = 3.71 \pm 0.11$ and $pK_{a2} = 5.28 \pm 0.10$, respectively. The difference ($pK_{a1} - pK_{a2}$) for the binuclear complex **1** is quite different from those for the dinuclear iron(III)-hydroxamic acid complexes ($pK_{a1} = 8.80 \pm 0.15$; $pK_{a2} = 9.40 \pm 0.18$) [27]. A prominent electronic interaction of the two M^{III} centers via the oxo-bridge in **1** is thus indicated and is indeed expected from the antiferromagnetic coupling well known in several μ-oxo bridged complexes of Fe^{III} [28].

In weakly acidic solution, viz. the pH interval chosen for our study, the oxo-bridge in **1** is stable. However, at pH < 2, **1** slowly cleaves to $[Fe(phen)_3]^{2+}$, identified spectrophotometrically.

We used excess 1,10-phenanthroline in all our kinetic measurements to suppress any possible phen releasing equilibrium and thereby minimized the number of kinetically active iron(III) species under investigation. Excess C_{phen} used in kinetic runs also buffers the reacting solution to within ±0.04 (but mostly within ±0.02) pH units. Use of excess C_{phen} was essential also to ensure quantitative formation of the tris(phenanthroline) complex $[Fe(phen)_3]^{2+}$.

3.2. Stoichiometry and reaction products

The break point in the absorbance versus total concentration of ascorbic acid (T_A) was observed at [complex]: $T_A = 1{:}1$ (Fig. 2; Table 1). The UV–Vis spectra of product solutions indicate quantitative formation of $[Fe(phen)_3]^{2+}$

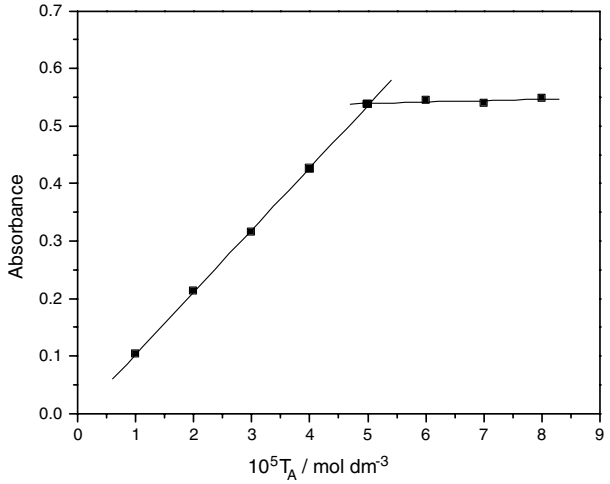

Fig. 2. Stoichiometry of the reaction between **1** and ascorbic acid. [**1**] = 0.050 mM, [Cl^-] = 1.0 M, I = 1.0 M, T = 25.0 °C, C_{phen} = 3.0 mM, pH 4.2, T_A = (0.010–0.080) mM, λ = 510 nm.

Table 1
Stoichiometry of reduction of **1**[a] by ascorbic acid

pH	$10^5 \times T_A$ (M)	Absorbance (λ = 510 nm)
4.2	1.0	0.104
	2.0	0.213
	3.0	0.315
	4.0	0.426
	5.0	0.538
	6.0	0.545
	7.0	0.540
	8.0	0.548

[a] Concentration of complex used = 0.050 mM, [Cl^-] = 1.0 M, I = 1.0 M, T = 25.0 °C, C_{phen} = 3.0 mM.

as the sole iron product. These results suggest the occurrence of reaction (1) in the entire redox process to produce $[Fe(phen)_3]^{2+}$ along with dehydroascorbic acid.

$$[Fe_2^{III}(\mu\text{-}O)(phen)_4(H_2O)_2]^{4+} + H_2A + 2phen \rightarrow 2[Fe(phen)_3]2^+ + 3H_2O + A \quad (1)$$

3.3. Kinetics and mechanism

In weakly acidic solutions, the oxo-bridge in **1** is thermodynamically stable. Unidentate ligands such as SCN^- rapidly substitute [17] the aqua ligands in **1**, thus indicating their labile nature [29]. Under the experimental conditions used, **1** and its H_2O acid dissociated derivatives **1a** and **2a** coexist in rapid equilibria (Eqs. (2) and (3)).

$$\mathbf{1} \overset{K_{a1}}{\rightleftharpoons} \underset{\mathbf{1a}}{[Fe_2^{III}(\mu\text{-}O)(phen)_4(H_2O)(OH)]^{3+}} + H^+ \quad (2)$$

$$\mathbf{1a} \overset{K_{a2}}{\rightleftharpoons} \underset{\mathbf{2a}}{[Fe_2^{III}(\mu\text{-}O)(phen)_4(OH)_2]^{2+}} + H^+ \quad (3)$$

In the experimental pH range, free ascorbic acid (H_2A) and its monodeprotonated conjugate base (HA^-) co-exist in solution. The dideprotonated form is negligible in the pH range of this study (pH 3.95–5.09), as expected from the pK_2 value [31,32]. In the presence of excess reducing agent, the reaction followed excellent first-order kinetics for at least 90% reaction. Fig. 3 shows the change in UV–Vis spectra of the complex solution and the reaction mixture after complete reaction. Fig. 4 demonstrates some first-order curves with different reagent concentrations. The final absorbance (A_{inf}) was in full agreement with the quantitative formation of $Fe(phen)_3^{2+}$. At a fixed pH, the first-order rate constant k_0 increases with increasing the total ascorbic acid concentration (T_A) (Table 2) and plot of k_0 versus T_A is an excellent straight line (r = 0.993) (Fig. 5) with no significant intercept. The observed linear dependence on T_A suggests that the reaction path involves one reagent molecule. At a fixed T_A, the observed

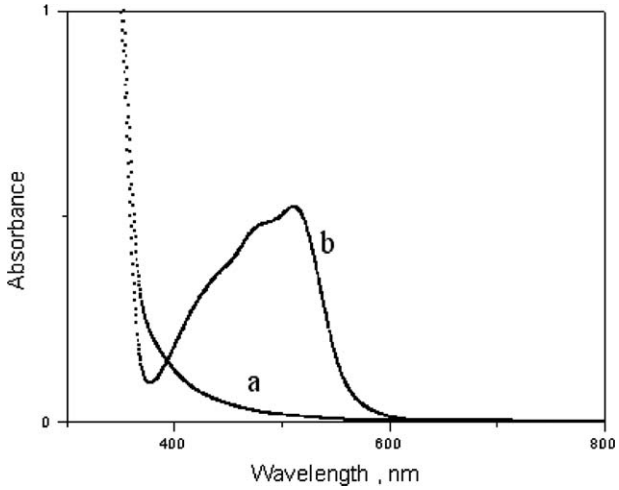

Fig. 3. Spectral changes observed by mixing **1** with ascorbic acid at: [**1**] = 0.025 mM, [Cl^-] = 1.0 M, pH 4.05, I = 1.0 M, T = 25.0 °C, C_{phen} = 3.0 M, T_A = 0.50 mM, Spectra noted at t = 0 s (a), t = 300 s (b).

[a] Concentration of complex used 0.025 mM. $C_{phen} = 3.0$ mM. Calculated k_0 are given in parentheses.

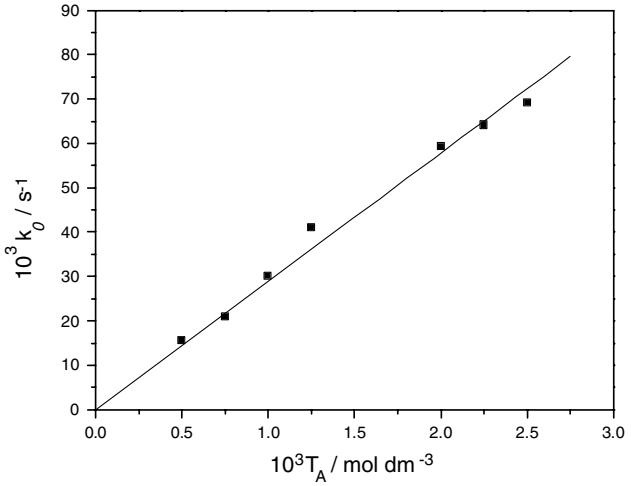

Fig. 5. Plot of $10^3 k_0$ vs. $10^3 \times T_A$. [**1**] = 0.025 mM, $[Cl^-] = 1.0$ M, $I = 1.0$ M, $T = 25.0$ °C, $C_{phen} = 3.0$ mM, $T_A = (0.50–2.5)$ mM. pH 4.05. The points indicate experimental data and the line indicates the best-fitting straight line.

pseudo-first-order rate constant increases with increasing pH (Table 2, Fig. 6), probably indicating kinetic inactivity of diprotonated form of the reducing agent, which is in accordance with some earlier studies [33]. The first-order rate constants show an inverse square dependence on the chloride ion concentration. Plot of $1/k_0$ versus $[Cl^-]^2$ is an excellent straight line (Fig. 7). No significant change in observed rate constant was noticed by varying C_{phen}. Varying C_{phen} in the range 3.0–10 mmol dm^{-3} at $T_A =$ 0.50 mmol dm^{-3}, $[Cl^-] = 1.0$ mol dm^{-3} and pH 4.05 yielded $k_0 = (1.6 \pm 0.1) \times 10^{-2}\ s^{-1}$. This observation

Scheme 1.

suggests that no phen-releasing equilibrium is important in the reaction media. Considering all these, Scheme 1 is proposed to account for the observed kinetics. We assume all the equilibria to be relatively rapid. Scheme 1 leads to the following equation:

$$k_0 = \frac{T_A K_a (k_1[H^+]^2 + k_2 K_{a1}[H^+] + k_3 K_{a1} K_{a2})}{([H^+] + K_a)(A + B[Cl] + C[Cl]^2)}, \quad (12)$$

where

$$A = [H^+]^2 + K_{a1}[H^+] + K_{a1}K_{a2}, \quad (13)$$

$$B = K_1[H^+]^2, \quad (14)$$

$$C = K_1 K_2 [H^+]^2. \quad (15)$$

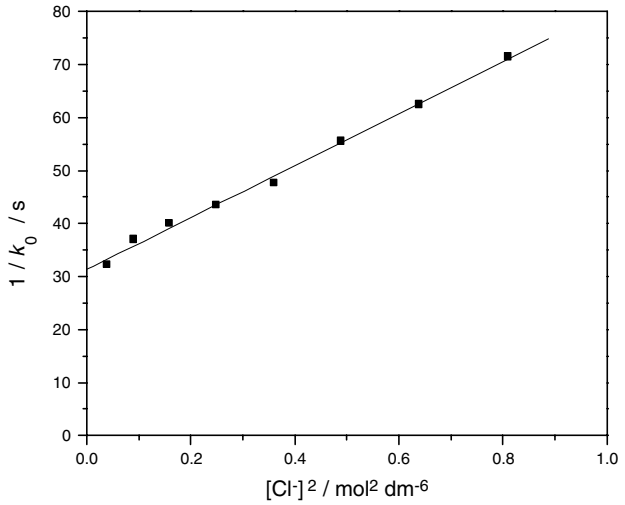

Fig. 7. Plot of $1/k_0$ vs. $[Cl^-]^2$. [**1**] = 0.025 mM, $[Cl^-] = (0.20–1.0)$ M, $I = 1.0$ M, $T = 25.0$ °C, $C_{phen} = 3.0$ mM, $T_A = 0.25$ mM, pH 4.2. The points indicate experimental data and the line indicates the best-fitting straight line.

As the plot of $1/k_0$ versus $[Cl]^2$ is an excellent straight line ($r = 0.995$) with an intercept, we neglect the terms which are first-order with respect to chloride ion concentration. Thus, Eq. (12) is transformed to the following equation:

$$k_0 = \frac{T_A K_a (k_1[H^+]^2 + k_2 K_{a1}[H^+] + k_3 K_{a1} K_{a2})}{([H^+] + K_a)(A + C[Cl]^2)}. \quad (16)$$

The straight line plot of $1/k_0$ versus $[Cl]^2$ at a fixed pH (=4.2) and fixed T_A (=0.25 m mol dm^{-3}) (Fig. 7) has slope = $([H^+] + K_a)C/(T_A K_a(k_1[H^+]^2 + k_2 K_{a1}[H^+] + k_3 K_{a1} K_{a2})) = (49 \pm 1)$ mol^{-1} dm^3 s and intercept $([H^+] + K_a) A/(T_A K_a(k_1[H^+]^2 + k_2 K_{a1}[H^+] + k_3 K_{a1} K_{a2})) = (31 \pm 1)$ mol dm^{-3} s. Hence, from intercept, $k_1[H^+]^2 + k_2 K_{a1}[H^+] + k_3 K_{a1} K_{a2} = 3.8 \times 10^{-6}$ s^{-1} at pH 4.2. Putting this value in the expression of slope, we get $K_1 K_2 = 7.0$ mol^{-2} dm^6 at 25.0 °C and $I = 1.0$ mol dm^{-3}. These calculations were done using the value of K_a ($pK_a = 4.03$) obtained from the literature [31]. Again, plot of k_0 versus T_A at fixed pH (=4.05) and fixed [Cl] (=1 mol dm^{-3}) is an excellent straight line with slope = $K_a(k_1[H^+]^2 + k_2 K_{a1}[H^+] + k_3 K_{a1} K_{a2})/(([H^+] + K_a)(A + C[Cl]^2)) = (29 \pm 1)$ mol^{-2} dm^6 s^{-1}. So, $k_1[H^+]^2 + k_2 K_{a1}[H^+] + k_3 K_{a1} K_{a2} = 5.1 \times 10^{-6}$ mol^{-1} dm^3 s^{-1} at pH 4.05. Plot of $k_0([H^+] + K_a)(A + C[Cl]^2)/T_A K_a$ versus $[H^+]$ is a good second-order polynomial fit ($r = 0.996$) (Fig. 6) which gives $k_1 = 2.5 \times 10^2$ mol^{-2} dm^6 s^{-1}, $k_2 = 1.8 \times 10^2$ mol^{-2} dm^6 s^{-1} and $k_3 = 33$ mol^{-2} dm^6 s^{-1}. Values of $(k_1[H^+]^2 + k_2 K_{a1}[H^+] + k_3 K_{a1} K_{a2})$ calculated for pH 4.2 and 4.05 using these values of k_1, k_2 and k_3 match well with the values obtained from the chloride plot and the reagent plot, respectively. The calculated first-order rate constants using Eq. (16) are in close proximity (10–15%) of the experimental values (Table 2).

The rate of the whole reaction is very much slowed down in presence of chloride ion. We have observed no rate saturation with increasing $[Cl^-]$. Eq. (16) explains the observed kinetics well and also implies that k_0 should tend to zero at very high chloride concentration. Hence, it seems reasonable to assume that an inner-sphere mechanism is operating. Ascorbate ion replaces the coordinated aquo or hydroxo moieties to form inner-sphere bond with Fe^{III} centers and then the electron transfers take place. The inhibition by chloride ions can be explained in terms of its competition with ascorbate to form the inner sphere bonds by replacing aquo or hydroxo ligands. Our experimental data show an inverse square dependence of k_0 on $[Cl^-]$ and thus allow us to neglect the terms which are first-order with respect to $[Cl^-]$. The implication is that incorporation of one chloride ion in the complex molecule does not inhibit the reaction. A possible explanation to this is that as long as there is one replaceable aquo or hydroxo group present in the complex molecule, reaction proceeds via its replacement by ascorbate ion. The presence of two chloride ions in the coordination sphere is necessary to block the reaction.

The order of magnitude $k_1 > k_2 > k_3$ indicates that the diaquo species is the most reactive form and the dihydroxo species is the least reactive. This is in accordance with the results found in the oxidation of hydrazine by **1** [30]. The diaquo species has the highest positive charge and interacts with the negative ascorbate ion more readily than the other two forms of the complex. The lowest activity of the dihydroxo form is due to its low charge. The order of activity can also be explained in terms of number of easily replaceable water molecules present in the coordination sphere. The diaquo has two water molecules, the monoaquo has one and the dihydroxo none and hence their order of reactivity. A similar trend of reactivity was found in the oxidation of thiosulfate ion by a dinuclear $Mn^{IV,IV}$ complex [34], where reactivity increased with increasing number of coordinated water molecules.

The steps (9)–(11) can occur either via an initial slow one-electron transfer followed by another rapid one-electron transfer, or by a two electron transfer mechanism, leading to $[Fe(phen)_3]^{2+}$ and dehydroascorbic acid. There are examples where formation of radical species HA$^{\cdot}$ have been proposed as a result of oxidation by iron(III) species [35–37]. In our case, the oxidant is a two electron acceptor and a two-electron transfer mechanism similar to the case of ferriporphyrin dimer [23] can also work. However, a choice between these two possibilities cannot be made from our results.

2. Results and discussion

2.1. Synthesis

The two complexes $Be[(Me_2N)_2P(O)F]_4(ClO_4)_2$ (**1**) and $Be[(Et_2N)_2P(O)F]_4(ClO_4)_2$ (**2**) were prepared by a method well-known in the literature [16]. They are soluble in nitromethane, acetonitrile and dichloromethane. The complexes prepared were characterised by elemental analysis and particularly by their NMR data and comparison with the corresponding data for the free ligands (see Table 1).

2.2. Spectroscopic studies

The infrared spectra show strong bands within the range 1295–1300 cm^{-1} attributed to $\nu_{P=O}$. The P=O stretching vibration is shifted towards lower wave numbers on coordination to the beryllium atom compared with its value for the free ligands. The coordination shift is about 20 cm^{-1} and is consistent with phosphoryl coordination to the beryllium atom. Absorption bands at 638 and 614 cm^{-1} were observed in the IR spectra of the two complexes and are assigned to metal–ligand stretching (Be–O bond), in agreement with literature results [17].

The NMR spectra of the two complexes prepared are quite similar and the data obtained from these spectra are summarised in Table 1. The ^{31}P and ^{19}F NMR resonances of bound ligands are shifted to higher field compared with those of the free ligands. The difference in the ^{31}P chemical shift between free and bound ligands is more important than that observed in ^{19}F NMR spectra, confirming coordination of the fluorophosphoramide ligand through the oxygen atom.

The $^{31}P\{^1H\}$ spectrum for the free ligand showed a doublet due to coupling with ^{19}F atom; a similar doublet shifted to higher field was observed for each of the two complexes prepared. In the latter, each signal of the doublet appears as a 1:1:1:1 quartet owing to coupling with ^9Be atom ($I = 3/2$) (Fig. 1). The coupling constants $^1J_{P-F}$ are larger for the bound ligand than for the free one (Table 1). The upfield shift of the bound ligand signals compared to that of the free ligand is indicative of disruption of the PO π interaction as a result of complex bond formation, in agreement with IR data [18]. This relatively small upfield shift (see Table 1) is perhaps demonstrative of a sizeable N → P inductive effect by means of π donation from the nitrogen centres of NMe_2 to compensate the loss of electron density around phosphorus following complexation. The same dichotomy has been observed with HMPA as ligand [19].

The ^9Be NMR spectrum of each of the two complexes prepared, at room temperature, consists of a 1:4:6:4:1 quintuplet (see Fig. 2) with $^2J_{P-Be}$ coupling constant of ~5 Hz comparable to that previously found for the HMPA derivative [10]. The sharpness of all the signals, which is consistent with a cubic symmetry around the quadrupolar metal centre, suggests, for the two complexes prepared, a tetrahedral geometry. The $^2J_{P-Be}$ coupling constant for complex **1** is 4.8 Hz versus 6 Hz for the complex $Be[HMPA]_4(ClO_4)_2$ [10]. The difference may be explained by the fact that the movement of the nitrogen lone pair towards phosphorus upon complex formation is more important in the case of HMPA than that of $(Me_2N)_2P(O)F$ due to a deficiency of a Me_2N group in the latter.

The two bonds spin coupling of beryllium with phosphorus is consistent with a 'covalent' Be–OP bond, similar to that observed for beryllium with the very hard fluoride anion [20]. In the absence of X-ray data, the use of theoretical calculations is particularly informative [21,22]. We have thus performed DFT calculations on complex **1**.

2.3. Theoretical calculations

The geometries of the $Be[(Me_2N)_2P(O)F]_4^{2+}$ cation of complex **1** and its ligand, $(Me_2N)_2P(O)F$, were optimised by means of the DFT B3LYP/6-31G* method. The optimised structure of complex **1** is shown in Fig. 3. The complex and its ligand have been identified as local minima on the singlet potential energy surfaces (PES). Optimised values of selected geometrical parameters are listed in Table 2. The ^{31}P, ^{19}F and ^9Be NMR chemical shifts calculated by the same method are collected in Table 3. The beryllium ion is considered to be coordinated by four ligand molecules. The tetrahedral geometry around the beryllium is shown with O–Be–O angles at the metal from 107° to 109°. The values of the Be–O distance, 1.620–1.635 Å, as well as the other bond distances and angles are in good agreement with the values reported for similar molecules using X-ray diffraction [23]. Interestingly, the P–O distance of 1.519 Å is very identical to that of 1.517 Å obtained by the crystal structure of the complex $[\{N(CH_2PPh_2O)_3\}Be(OH_2)](ClO_4)_2$ [12].

In complex **1**, the coordination mode is thus confirmed by a lengthening of the P=O bond of the complex compared to that of the free ligand (1.481 Å) calculated at the same level of theory. This lengthening is equal to 8.6% and is consistent with the low stretching frequency observed in the IR spectra and may also explain the differences observed in the ^{31}P NMR chemical shifts between the

Compound	δ_{31P} (ppm)	δ_{19F} (ppm)	δ_{9Be} (ppm)	$^1J_{P-F}$ (Hz)	$^2J_{P-Be}$ (Hz)
$(Me_2N)_2P(O)F$	17.3	79.1		948	
$(Et_2N)_2P(O)F$	16.3	79.7		949	
$Be[(Me_2N)_2P(O)F]_4(ClO_4)_2$ (**1**)	15.0	78.0	−5.07	952	4.8
$Be[(Et_2N)_2P(O)F]_4(ClO_4)_2$ (**2**)	15.6	78.3	−5.30	958	4.9

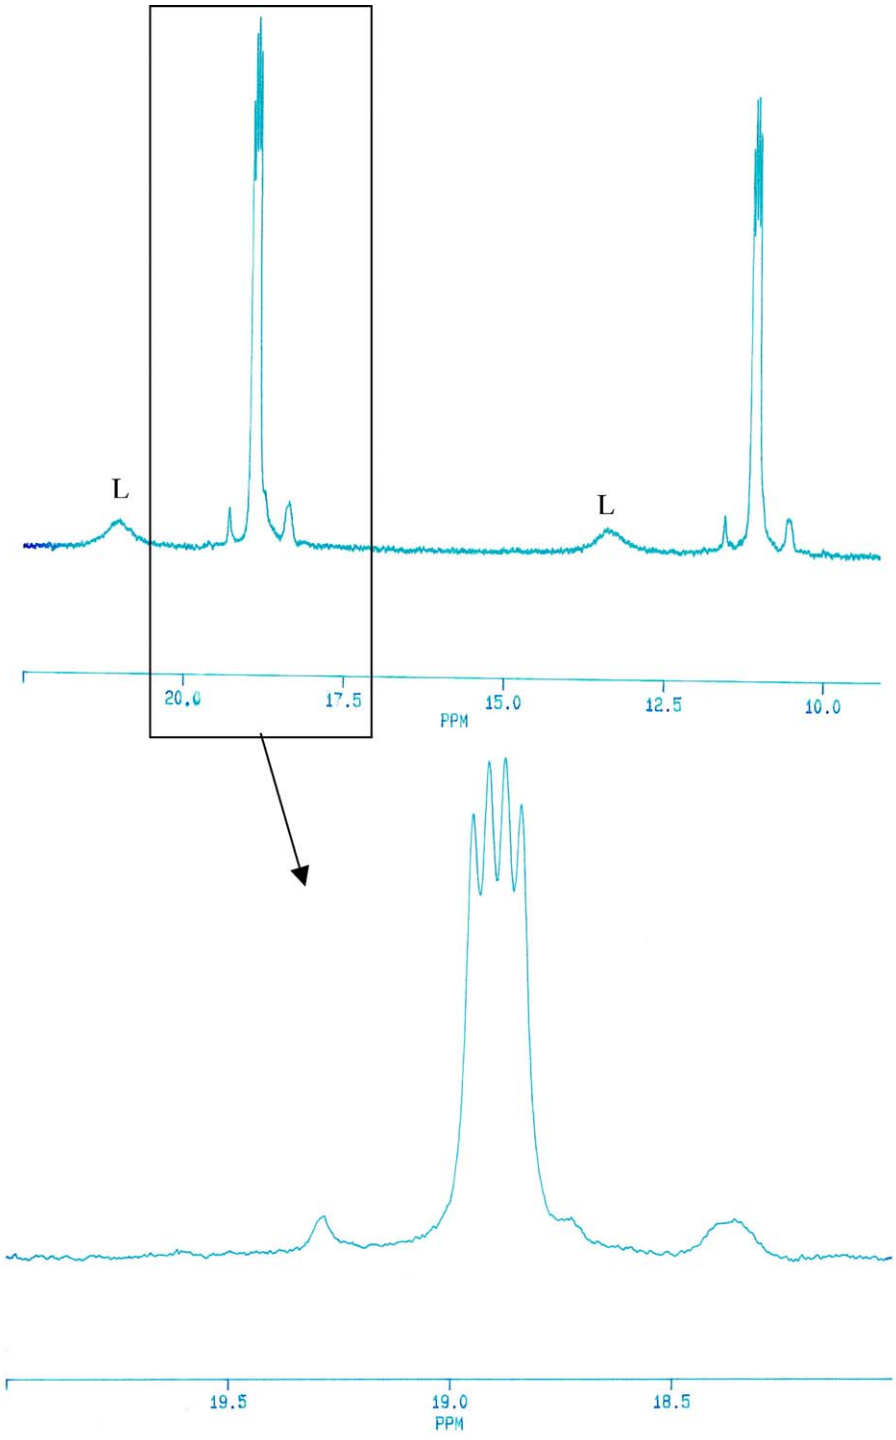

Fig. 1. $^{31}P\{^{1}H\}$ NMR spectrum of complex **1** at −35 °C in dichloromethane (L: dissociated ligand signals).

free and bound ligands in solution. The slight shortening of the P–F bond is in good agreement with the small increase of the $^{1}J_{P-F}$ coupling constant values found for the complexes compared with that of the free ligands in solution (see Table 1). The angle of the F–P–O in the free ligand (∼112°) is narrowed to ∼107° in the complex. This may be interpreted in terms of steric effects due to the coexistence of four ligand molecules around the beryllium atom in a tetrahedral geometry and may also explain the differences in $^{1}J_{P-F}$ coupling constants observed for the complex compared with the free ligand.

For complex **1** and its ligand, the overall agreement between theory and experiment is satisfactory. In particular, the small difference between the ^{31}P chemical shifts of bound and free ligands (Table 3) is in good agreement with that observed in solution. This small shift may be again explained by the N → P inductive effect compensating the loss of electron density around phosphorus following complexation.

It is satisfying to remark that the theoretical chemical shifts (Table 3) are in fair agreement with the experimental values. This leads further support to the structural characterisation discussed above.

In this context, it is also worth to note that the difference between the theoretical and experimental (solvent dependent) chemical shift values may be explained by the fact that no solvent effect was taken into account in the DFT calculations.

3. Experimental

3.1. Toxicity

Beryllium and its compounds are highly toxic [24,25] and should be handled with extreme care [26]. Experiments were conducted in a well ventilated fumehood. Spillages and especially ones of particular nature were washed down well with water. Transportation of samples outside the fumehood were minimised and NMR measurements were carried out with extreme caution.

3.2. Preparation

All preparations were carried out under a nitrogen atmosphere in solvents dried by standard techniques [27] and stored over molecular sieves. NMR spectra were recorded on a Bruker Ac-300 instrument in a mixture of CD_2Cl_2–CD_3NO_2; ^{31}P at 121 MHz (85% H_3PO_4), ^{19}F at 282 MHz ($CFCl_3$), and ^9Be at 42.17 MHz ($Be(H_2O)_4^{2+}$). IR spectra: Perkin–Elmer Paragon 1000 PC. The ligands $(R_2N)_2P(O)F$ were prepared according to methods described in the literature (R = Me [28]; R = Et [29]).

The two complexes **1** and **2** were prepared following a method described by Van Leeuwen et al. [16]. The hydrated beryllium(II) perchlorate (0.28 g, 1 mmol) was dissolved in ethanol and an appropriate amount of triethylorthoformate was added. After 2 h the ligand (4 mmol) was added, the solution was then concentrated by distilling off the solvent at reduced pressure. Addition of anhydrous ether led to the precipitation of the complex as a white solid. This was filtered washed with ether and dried in vacuum. ((**1**): 75% and (**2**): 80% yield). *Anal.* Calc. for complex $C_{16}H_{48}N_8O_{12}P_4F_4BeCl_2$ (**1**): C, 23.33; H, 5.83; N, 13.60. Found: C, 22.94; H, 6.13; N, 13.58%. *Anal.* Calc. for complex $C_{32}H_{80}N_8O_{12}P_4F_4BeCl_2$ (**2**): C, 36.67; H, 7.64; N, 10.69. Found: C, 36.45; H, 7.88; N, 10.62%.

3.3. Computational details

Density functional theory (DFT) calculations were carried out on the complex **1** using the suite of programs GAUSSIAN-03W [30], with the non-local hybrid functional denoted as B3LYP [31]. A double-ζ polarisation basis set 6-31G* [32–36] was employed for each atom. The geometries of both the complex **1** and the ligand were optimised using analytical gradient. The harmonic vibrational frequencies of the different stationary points of the PES have been calculated at the same level of theory in order to identify the local minima as well as to estimate the corresponding zero-point vibrational energy (ZPE).

The ^9Be, ^{31}P and ^{19}F NMR absolute shielding constants (δ values) were calculated at the B3LYP/DFT level with the Gauge-Independent Atomic Orbital (GIAO) method [37–41] using the same basis set. The calculated magnetic shieldings were converted into δ chemical shifts by noting that at the same level of theory the ^9Be (in $Be(H_2O)_4$), ^{31}P (in H_3PO_4) and ^{19}F (in $CFCl_3$) absolute shieldings are 114.24, 378.43 and 179.39, respectively.

4. Conclusions

We have shown that the ligands $(R_2N)_2P(O)F$ (R = Me or Et) form stable complexes with the beryllium(II) ion,

comparable to that obtained with HMPA. This indicates that the substitution of one NMe_2 group by a fluorine atom has little effect on the basicity (donor ability) of the ligands used. The results also show:

1. The remarkable affinity of the beryllium(II) ion toward the PO functionalities.
2. That the ^{9}Be NMR spectroscopy is a potential technique for the study of phosphoryl-containing beryllium complexes.
3. That the DFT calculations are a useful supporting tool for such a study since a combination of empirical and theoretical studies can, in favourable cases, overcome the limitations of each.

Acknowledgements

The authors wish to thank Professor A. Baklouti of the Department of Chemistry, Faculty of Sciences of Tunis, University of Tunis El Manar for his valuable help and discussions of this work.

occurrence and mechanical separation is often needed. In this case, conglomerate crystallization arising from a racemizing solution (molten state) or mechanical stirring can be used to give high enantiomeric excess [10].

In this paper, we describe the preparations and single-crystal structures of two enantiomerically pure crystals, formulated as $[Ru(phen)(bpy)_2](PF_6)_2$ (**1** for Δ-enantiomer and **2** for Λ-enantiomer), crystallizing in the chiral $P4_1$ and $P4_3$ space groups, which means that some spontaneous resolution process takes place. To the best of our knowledge, this work is the first example of conglomerate crystallization for Ru(II) complexes. Additionally, three similar hexa-coordinate Ru(II) complexes, i.e., $[Ru(phen)(bpy)_2](BF_4)_2$ (**3**), $[Ru(phen)_2(bpy)](PF_6)_2$ (**4**) and $[Ru(bpy)_2(dmbpy)](PF_6)_2$ (**5**) with different bidentate chelating ligands and counterions, which pack into the centrosymmetric space groups, are also involved by contrast.

2. Experimental

2.1. Materials and measurements

All reagents and solvents were of analytical grade and used without further purification. UV/Vis spectra were recorded with a Shimadzu UV-3150 double-beam spectrophotometer. Infrared spectra (IR, 4000–400 cm^{-1}) were determined in a Horiba FT-700 spectrophotometer. Analyses for carbon, hydrogen and nitrogen were performed on a Perkin–Elmer 1400C analyzer. ^1H NMR spectra were collected on a Varian Unit 500 MHz spectrometer and a JEOL GSX 270 MHz spectrometer. Fast atom bombing mass spectra (FAB-MS) were measured with a JEOL JMS-777V spectrometer.

2.2. Syntheses of bis(2,2′-bipyridine)(1,10-phenanthroline)ruthenium(II) hexafluorophosphorate (*1* and *2*) and bis(2,2′-bipyridine)(1,10-phenanthroline)-ruthenium(II) tetrafluoroborate (*3*)

A solution of 1,10-phenanthroline monohydrate (0.180 g, 1.0 mmol) in methanol (20 mL) was added to a solution of *cis*-bis(2,2′-bipyridine) dichlororuthenium(II) hydrate (0.484 g, 1.0 mmol) in 100 mL methanol. This mixture was refluxed for 1 h, and then divided into two halves after cooled to room temperature. Excess saturated aqueous NH_4PF_6 and $NaBF_4$ solutions were added, respectively. The resulting two mixtures were concentrated to ca. 10 mL by a rotatory evaporator and the red precipitates were filtered, washed by water and dried in vacuo. Racemic mixture of **1** and **2**; Yield: ~60%. Main IR (KBr pellets, cm^{-1}): 3434s, 2925m, 2855w, 1637s, 1467m, 1447m, 1428m, 1067m, 840vs, 763m, 558m. ^1H NMR (500 MHz, CD_3COCD_3, ppm, TMS): 8.86 (d, 2H, $J = 8.05$ Hz, H_7), 8.83 (d, 2H, $J = 7.88$ Hz, H_3), 8.81 (d, 2H, $J = 7.67$ Hz, H_{13}), 8.45 (d, 2H, $J = 5.15$ Hz, H_{11}), 8.41 (s, 2H, H_{14}), 8.26–8.25 (m, 2H, H_8), 8.18 (d, 2H, $J = 5.85$ Hz, H_{10}), 8.14–8.13 (m, 2H, H_4), 7.95–7.92 (d, d, 2H, H_{12}), 7.89 (d, 2H, $J = 5.05$ Hz, H_6), 7.64–7.63 (m, 2H, H_9), 7.39–7.38 (m, 2H, H_5). *Anal.* Calc. for $RuC_{32}H_{24}N_6P_2F_{12} \cdot C_2H_5OH$: C, 43.93; H, 3.25; N, 9.04. Found: C, 43.84; H, 3.31; N, 8.89%. FAB-MS: 739 $[Ru(bpy)_2(phen)(PF_6)]^+$. UV–Vis ($\lambda_{max}$, methanol, nm): 449.0 (MLCT), 286.0 ($\pi \rightarrow \pi^*$), 264.5 (MLCT). **3**; Yield: 76%. Main IR (KBr pellets, cm^{-1}): 3065w, 1635m, 1618m, 1600m, 1544m, 1064vs, 848s, 773s and 719m. *Anal.* Calc. for $RuC_{32}H_{24}N_6B_2F_8$: C, 50.09; H, 3.15; N, 10.95. Found: C, 50.01; H, 3.30; N, 10.87%. FAB-MS: 680 $[Ru(bpy)_2(phen)(BF_4)]^+$.

2.3. Synthesis of bis(1,10-phenanthroline)(2,2′-bipyridine) ruthenium(II) hexafluorophosphorate (*4*)

The synthesis of **4** is similar to **1** and **2** except that 0.360 g (2.0 mmol) 1,10-phenanthroline monohydrate was added and refluxed for 12 h. Yield: 67%. Main IR: 3406b, 2923m, 2853w, 1605m, 1467m, 1447m, 1428m, 838vs, 759m, 557s. ^1H NMR: 8.90 (d, 2H, $J = 8.95$ Hz, bpy), 8.85 (d, 2H, $J = 4.65$ Hz, phen), 8.83 (d, 2H, $J = 3.90$ Hz, phen), 8.46 (d, 2H, $J = 5.15$ Hz, phen), 8.42 (d, 2H, $J = 2.85$ Hz, phen), 8.28 (d, 2H, $J = 6.55$ Hz, phen), 8.20 (d, 2H, $J = 5.20$ Hz, phen), 8.16–8.14 (m, 2H, bpy), 7.96 (d, 2H, $J = 2.85$ Hz, bpy), 7.91–7.89 (m, 2H, phen), 7.67–7.64 (m, 2H, phen), 7.42–7.39 (d, d, 2H, bpy). *Anal.* Calc. for $RuC_{34}H_{24}N_6P_2F_{12}$: C, 44.99; H, 2.67; N, 9.26. Found: C, 44.93; H, 2.81; N, 9.22%. FAB-MS: 763 $[Ru(bpy)(phen)_2(PF_6)]^+$. UV–Vis ($\lambda_{max}$, methanol, nm): 449.0 (MLCT), 286.0 ($\pi \rightarrow \pi^*$), 264.5 (MLCT).

2.4. Synthesis of bis(2,2′-bipyridine)(4,4′-dimethyl-2,2′-bipyridine) ruthenium(II) hexafluorophosphorate (*5*)

The synthetic method of **5** is similar to that of **1** and **2** except that 4,4′-dimethyl-2,2′-bipyridine (0.184 g, 1.0 mmol) was added instead of 1,10-phenanthroline monohydrate. Yield: 82%. Main IR (KBr pellets, cm^{-1}): 3397b, 2923w, 1620s, 1604w, 1466s, 1447s, 1424m, 844vs, 763s, 557s. ^1H NMR: 8.82 (d, 2H, $J = 3.10$ Hz, bpy), 8.80 (d, 2H, $J = 3.40$ Hz, bpy), 8.69 (s, 2H, dmbpy), 8.21–8.18 (m, 4H, bpy) 8.06 (m, 4H, bpy), 8.03 (m, 2H, dmbpy) 7.59–7.54 (m, 4H, bpy), 7.41 (d, $J = 5.65$ Hz, 2H, dmbpy), 2.56 (s, 6H, Me). *Anal.* Calc. for $RuC_{32}H_{28}N_6P_2F_{12} \cdot 2C_2H_5OH$: C, 44.13; H, 4.12; N, 8.58. Found: C, 44.22; H, 4.29; N, 8.47%. FAB-MS: 743 $[Ru(bpy)_2(dmbpy)(PF_6)]^+$.

2.5. X-ray data collection and solution

X-ray single-crystal diffraction data of complexes **1**–**5** were collected on a Rigaku Mercury CCD area-detector at 293(2) K using graphite mono-chromated Mo Kα radiation ($\lambda = 0.71073$ Å). All the diffraction data were reduced by the program CRYSTALCLEAR [11] and empirical absorption corrections were done [12]. The original data files generated by CRYSTALCLEAR were transformed to SHELXTL97 format by TEXSAN program [13], and then all five structures

were solved by direct methods and refined by least-squares method on F^2_{obs}. All non-H atoms were anisotropically refined and all hydrogen atoms were inserted in the calculated positions assigned fixed isotropic thermal parameters and allowed to ride on their respective parent atoms. All calculations and molecular graphics were carried out with the SHELXTL PC program package on a PC computer [14]. The summary of the crystal data, experimental details and refinement results for complexes **1**–**5** is listed in Table 1.

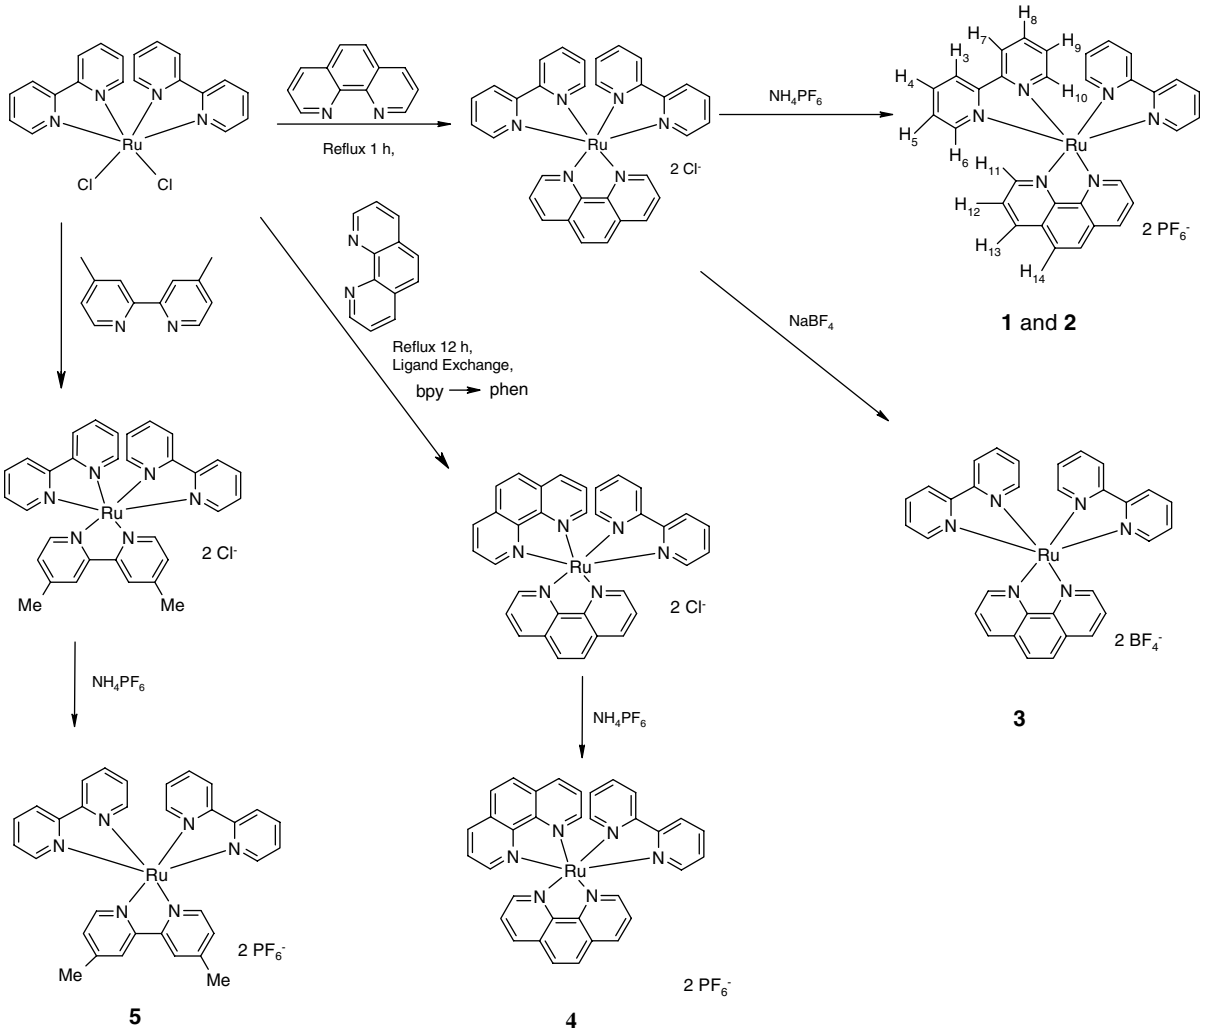
3. Results and discussion

3.1. Preparation and characterization

All the complexes reported in this paper were synthesized by refluxing stoichiometric amounts of *cis*-bis(2, 2′-bipyridine)dichlororuthenium(II) hydrate and phen monohydrate for **1**–**4** and dmbpy for **5**, respectively, in methanol, and then treated in situ anion exchange by adding excess NH_4PF_6 or $NaBF_4$ in order to precipitate the complexes from their mother solutions (Scheme 1). They all have satisfactory analytic results of IR, EA, UV–Vis and MS, and their single-crystal samples suitable for X-ray diffraction determination were grown from the mixtures of methanol/water or ethanol/water by slow evaporation in air at room temperature. Three sets of data for **1** and **2** were recorded and solved, respectively, to verify the repeatability of conglomerate crystallization, however, only the best ones were reported herein.

3.2. Structural description of Ru(II) complexes

According to the X-ray single-crystal diffraction analysis, **1** and **2** crystallize in the tetragonal system of chiral space groups $P4_1$ and $P4_3$, while **3**, **4** and **5** crystallize in the monoclinic centrosymmetric space groups $P2_1/c$ (**3**) and $C2/c$ (**4** and **5**). Each asymmetric unit of **3** contains two crystallographically unequivalent molecules (a pair of Δ and Λ enantiomers), and there is half of the crystallographically unique molecule in the asymmetric units of **4** and **5**. For complex **4**, a reduced unit cell [$a = 17.205(3)$, $b = 10.691(2)$, $c = 18.438(4)$ Å, $\beta = 91.10(3)°$] with smaller



Scheme 1. Schematic illustration for the preparation of Ru(II) complexes **1**–**5**.

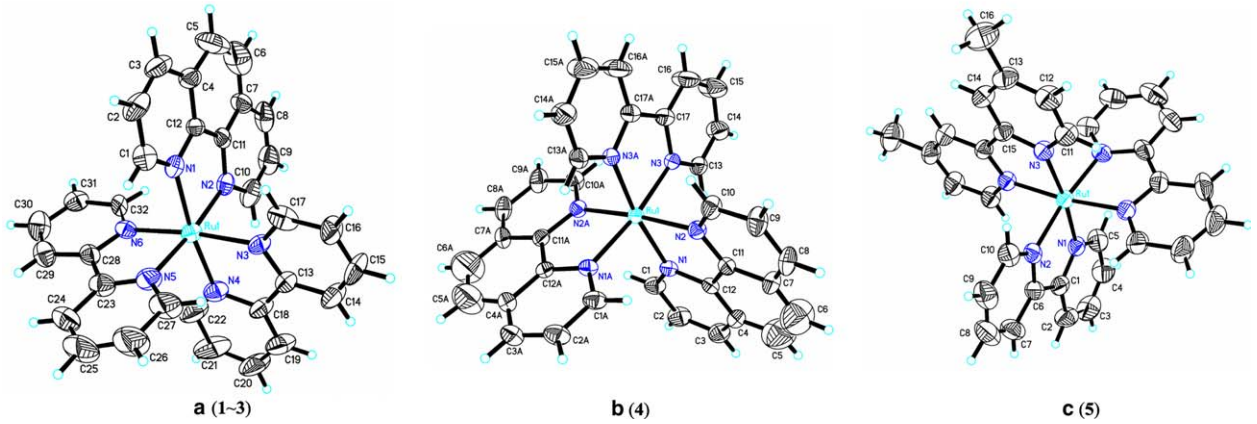


Fig. 1. ORTEP views of molecular structures of **1**–**5** with the atom-numbering scheme. Displacement ellipsoids are drawn at the 30% probability level and anions are omitted for clarity.

β angle and $I2/a$ space group can be obtained by performing the unit cell transformation (the matrix used is 0 0 1, 0 1 0, −1 0 −1). In view of the non-standard setting of space group $C2/c$ generated in this case, the initial unit cell is retained.

As illustrated in Fig. 1, all of five ruthenium(II) centers are coordinated by six nitrogen atoms from three bidentate phen, bpy or dmbpy ligand, adopting distorted octahedron configurations. The geometries (bond lengths, bond angles and dihedral angles) around all the Ru(II) centers are in the normal range, and some of PF_6^- and BF_4^- counterions are found to be disordered over two positions with different site occupancy factors.

Typical π–π stacking interactions are found between phen ligands of adjacent units in the packing structures of **1**, **2** and **3** with the separations of 3.52(1) Å for **1** and **2**, and 3.62(1) Å for **3** because phen has better delocalized π-system in comparison with bpy. π–π Stacking interactions are also observed in **4** between two neighboring phen molecules with the distance at 3.56(1) Å. Offset π–π stacking interactions are found in **5** between two vicinal bpy ligands with the shortest separation of 3.65(2) Å as well as the ones between two contiguous dmbpy ligands with the shortest separation of 3.68(2) Å. In **1** and **2**, it is worthwhile to mention that the phen rings are perpendicular to the screw c-axis in their crystal structures (Fig. 2), which may contribute to the formation of chiral packing.

The absolute configuration of crystals can be verified by the Flack parameters [15] of their single-crystal structures. In our case, the Flack absolute structure parameter of **1** has a value of 0.02(5), while the inverted stereochemistry gives a high value of 0.96(6). As for **2**, the value is 0.01(5) for right space group but 0.97(5) for the inverted one. The low Flack parameters indicate that the absolute configurations of **1** and **2** are correct. In fact, spontaneous resolution is a well-documented phenomenon. However, it is not the case for the system where six-coordinate metal complexes with three bidentate ligands are involved. There have been many crystallographic reports about similar complexes, but most of them crystallize in the centrosymmetric space groups [16]. To the best of our knowledge, this is the first report on the spontaneous resolution for Ru(II) complexes that may be interesting on the research for obtaining enantiomerically pure coordination complexes [17].

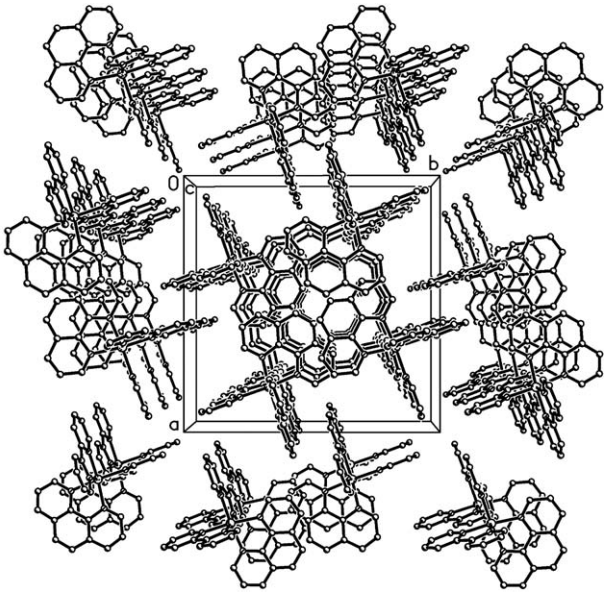

Fig. 2. Perspective view of packing structure of **2** down the 4-fold screw c-axis, hydrogen atoms and PF_6^- anions are omitted for simplicity.

In our experiment, single-crystal sample of **2** is obtained first, however, we do not know it crystallizes in a chiral space group ($P4_3$) until the structure is successfully solved. At that time we think the result is uncommon because no obvious symmetry breakage is present and no related report for this Ru(II) complex. If it is true, there should be another crystal packed into the other enantiomorphic space group ($P4_1$) with the same unit cell within the experimental errors. After repeating the experiment many times, we do obtain the expected crystal of **1** but racemic crystal has never been found. Further studies hint that both of the needle-like

crystals can be controlled by seeding with preformed chiral crystals. In their absence, the chirality of crystals is sometimes $P4_1$ and sometimes $P4_3$ but almost equiprobable. This is also true when the same beaker and the same mother liquid are used for repeated crystallization. Actually, **1** and **2** grow radially as a single colony from the first-appearing nucleus, which makes the mechanical separation of them possible. This could be the reason why a single chirality is preserved during the whole crystal growth. In this way, **1** and **2** can afford enantiomerically pure chiral coordination complexes simply upon self-resolution crystallization. Thus, it is concluded that the chirality is essentially governed by the chirality that happens to the first-separating nucleus acting as the seed for subsequent crystal growth.

Kondepudi et al. [18] have discussed the kinetics of symmetry breakage in the process of seeding or in the presence of chiral autocatalysis and competition for solute (direct or indirect) between the two enantiomers. However, it is still difficult for us to specify why only either Δ or Λ configuration can be obtained (Fig. 3). It is believed that PF_6^- anions and hydrogen bonding interactions found in the solid-state play key role in the process of crystal growth, because experimental results tell us that neither BF_4^- nor ClO_4^- with the same cationic structure can crystallize in the chiral space group under the same condition [19].

A ligand exchange reaction is found between bpy and phen ligands when 2-fold 1,10-phenanthroline monohydrate was treated with *cis*-bis(2,2′-bipyridine)dichlororuthenium(II) hydrate by refluxing for 12 h. Crystalline solids **4** can be obtained in a moderate yield, other than $[Ru(phen)_3][PF_6]_2$, $[Ru(bpy)_3][PF_6]_2$ or starting $[Ru(bpy)_2(phen)][PF_6]_2$, but only in the racemic form. It is suggested that the symmetry breaking process may be destroyed when both Δ and Λ enantiomers undergo the ligand exchange reaction. Hesek et al. [20] reported the crystal structure of the Δ-enantiomer for **5** using a stereoretentive synthesis from the predetermined Δ-$[Ru(bpy)_2(Me_2SO)Cl]Cl$, which crystallizes in the orthorhombic space group $P2_12_12_1$ with obviously different unit cell: $a = 13.731(11)$, $b = 20.496(9)$, $c = 13.521(8)$ Å, $V = 3805$ Å^3. In our case, only racemic complex can be crystallized because of the lack of symmetric breakage, which is supposed to be normal for general Ru(II) complexes.

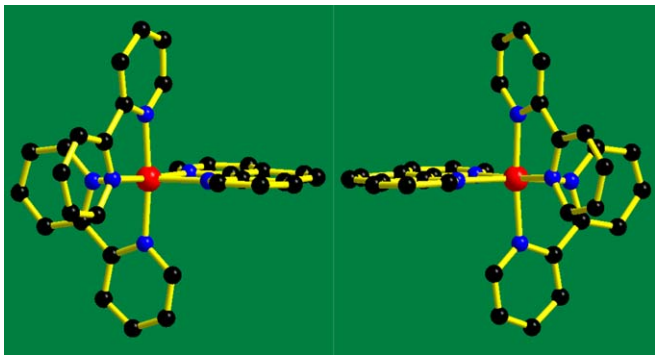

Fig. 3. Ball-and-stick view of the enantiomeric pair of **1** (Δ-enantiomer, left) and **2** (Λ-enantiomer, right) with mirror symmetry (sphere colors: black – C; blue – N; red – Ru). Hydrogen atoms and PF_6^- anions are omitted for clarity.

4. Conclusion

In summary, we reported herein a pair of chiral ruthenium(II) complexes crystallizing in $P4_1$ and $P4_3$ space groups, which were obtained by crystallization-induced single-colony crystal growth from the racemic alcohol–water solution under ambient condition. Their absolute configurations were verified by the Flack parameters and interactions at the supramolecular level may dominate the spontaneous resolution process. A ligand exchange between phen and bpy was found if long time refluxing was performed but only the racemic product **4** could be yielded. To extend our study, another counterion (BF_4^-) and ligand (dmbpy) were selected to prepare similar hexa-coordinate Ru(II) complexes. However, the X-ray single-crystal diffraction studies demonstrated that racemic crystals could only be obtained in these experiments, which could be in agreement with the results in most cases.

5. Supplementary material

CCDC Nos. 271355–271359 (complexes **1**–**5**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; fax: (internat.) +44 1223 336 033; e-mail: deposit@ccdc.cam.ac.uk].

of (μ-Se)[CpFe(CO)$_2$]$_2$ with alkyl or aryl chloroformates [31].

Based on our previous reactions of the iron selenide with electrophiles [29–31] this paper describes its reaction with chlorothionoformates (ROC(S)Cl). This reaction was found to give the expected selenothiocarbonates, CpFe(CO)$_2$SeC(S)OR. These complexes can be converted to the chelated complexes CpFe(CO)(κ^2*Se*,*S*-SeC(S)OR) upon photolysis.

2. Experimental

All manipulations were performed under an inert atmosphere of nitrogen using standard Schlenk line techniques. Diethyl ether, hexane and benzene were distilled from sodium/benzophenone ketyl under nitrogen. Dichloromethane was refluxed over P_2O_5 and distilled under nitrogen. The complex (μ-Se)[CpFe(CO)$_2$]$_2$ was prepared by literature method [23]. The reagents: chlorothionoformates, iron dimer [CpFe(CO)$_2$]$_2$, and selenium were obtained from Acros and were used as received.

Nuclear magnetic resonance (NMR) spectra were recorded on a Bruker 200 MHz spectrometer. Chemical shifts are in ppm relative to TMS at 0 ppm. Infrared (IR) spectra were recorded on a Nicolat Nexus FT-IR spectrometer using NaCl solvent cells. Elemental analyses were done in Laboratoire d'Analyse Elémentaire, Université de Montréal, Montréal, Que., Canada. Melting points were reported on a Staurt Melting point apparatus (SMP3) and are uncorrected. The photolytic reactions were carried out in a medium pressure mercury lamp (150 W) with a quartz immersion cell.

2.1. General procedure for the preparation of CpFe(CO)$_2$SeC(S)OR (**1**)

The complex (μ-Se)[CpFe(CO)$_2$]$_2$ (0.22 g, 0.50 mmol) dissolved in diethyl ether (70 mL) was stirred under N_2 and chlorothionoformate (0.55 mmol) was added. After stirring overnight, the volatiles were removed under reduced pressure and the resulting solid was redissolved in a minimum amount of CH_2Cl_2 and introduced to a silica gel column made up in hexane. Elution with hexane removes the unreacted chlorothionoformates. Elution with hexane/dichloromethane solution (1:1 v:v ratio) gave a red-brown band which was collected and identified as CpFe(CO)$_2$SeC(S)OR, followed by a red band which was also collected and identified as CpFe(CO)$_2$Cl. The CpFe(CO)$_2$SeC(S)OR were recrystallized from dichloromethane/hexane.

2.1.1. [CpFe(CO)$_2$SeC(S)OC$_6$H$_5$] (**1a**)

Yield: 72%. m.p. 159–160 °C. ^{1}H NMR ($CDCl_3$) δ 4.95 (s, 5H, C_5H_5); 7.41 (m, 5H, C_6H_5). IR (CH_2Cl_2, cm^{-1}) ν_{CO} 2035s, 1985s. Calc. for $C_{14}H_{10}FeO_3SSe$: C, 42.78; H, 2.56; S, 8.16. Found: C, 42.70; H, 2.44; S, 7.88%.

2.1.2. [CpFe(CO)$_2$SeC(S)O-4-C$_6$H$_4$Cl] (**1b**)

Yield: 82%. m.p. 99–100 °C. ^{1}H NMR ($CDCl_3$) δ 5.06 (s, 5H, C_5H_5); 7.02 (d, 2H, C_6H_4); 7.37 (d, 2H, C_6H_4). IR (CH_2Cl_2, cm^{-1}) ν_{CO} 2037s, 1992s. Calc. for $C_{14}H_9ClFeO_3SSe$: C, 39.33; H, 2.12; S, 7.50. Found: C, 39.02; H, 1.96; S, 7.00%.

2.1.3. [CpFe(CO)$_2$SeC(S)O-4-C$_6$H$_4$F] (**1c**)

Yield: 80%. m.p. 136–137 °C. ^{1}H NMR ($CDCl_3$) δ 5.06 (s, 5H, C_5H_5); 7.06 (d, 2H, C_6H_4); 7.20 (d, 2H, C_6H_4). IR (CH_2Cl_2, cm^{-1}) ν_{CO} 2036s, 1991s. Calc. for $C_{14}H_9FFeO_3SSe$: C, 40.90; H, 2.21; S, 7.80. Found: C, 39.98; H, 2.18; S, 7.11%.

2.1.4. [CpFe(CO)$_2$SeC(S)OC$_6$F$_5$] (**1d**)

Yield: 87%. m.p. 133–134 °C. ^{1}H NMR ($CDCl_3$) δ 5.08 (s, H's, C_5H_5). IR (CH_2Cl_2, cm^{-1}) ν_{CO} 2041s, 1997s. Calc. for $C_{14}H_5F_5FeO_3SSe$: C, 34.81; H, 1.04; S 6.64. Found: C, 34.34; H, 1.08; S, 5.98%.

2.1.5. [CpFe(CO)$_2$SeC(S)O-4-C$_6$H$_4$Me] (**1e**)

Yield: 89%. m.p. 148–149 °C. ^{1}H NMR ($CDCl_3$) δ 2.33 (s, 3H, CH_3); 5.03 (s, 5H, C_5H_5); 6.93 (d, 2H, C_6H_4); 7.22 (d, 2H, C_6H_4). IR (CH_2Cl_2, cm^{-1}) ν_{CO} 2036s, 1991s. Calc. for $C_{15}H_{12}FeO_3SSe$: C, 44.25; H, 2.97; S, 7.88. Found: C, 44.46; H, 2.77; S, 7.50%.

2.2. General procedure for the preparation of CpFe(CO)(κ^2Se,S-SeC(S)OR) (**2**)

A THF solution (30 mL) of CpFe(CO)$_2$SeC(S)OR (0.25 mmol) was irradiated under a stream of N_2 for 30 min. The volatiles were removed by vacuum and the resulting solid was dissolved in a minimum amount of dichloromethane and transferred to a silica gel column. The column was eluted with CH_2Cl_2/hexane (1:2 v:v ratio) to separate the products as an orange-brown band which were recrystallized from hexane.

2.2.1. [CpFe(CO)(κ^2Se,S-SeC(S)OC$_6$H$_5$)] (**2a**)

Yield: 85%. m.p. 102–103 °C. ^{1}H NMR ($CDCl_3$) δ 4.65 (s, 5H, C_5H_5); 7.10 (m, 5H, C_6H_5). IR (CH_2Cl_2, cm^{-1}) ν_{CO} 1954s. Calc. for $C_{13}H_{10}FeO_2SSe$: C, 42.77; H, 2.76; S 8.78. Found: C, 42.54; H, 2.66; S, 8.47%.

2.2.2. [CpFe(CO)(κ^2Se,S-SeC(S)O-4-C$_6$H$_4$Cl)] (**2b**)

Yield: 90%. m.p. 79–80 °C. ^{1}H NMR ($CDCl_3$) δ 4.65 (s, 5H, C_5H_5); 7.07 (d, 2H, C_6H_4); 7.35 (d, 2H, C_6H_4). IR (CH_2Cl_2, cm^{-1}) ν_{CO} 1947s. Calc. for $C_{13}H_9ClFeO_2SSe$: C, 39.08; H, 2.27; S, 8.03. Found: C, 39.60; H, 2.47; S, 7.38%.

2.2.3. [CpFe(CO)(κ^2Se,S-SeC(S)O-4-C$_6$H$_4$F)] (**2c**)

Yield: 78%. m.p. 95–96 °C. ^{1}H NMR ($CDCl_3$) δ 4.65 (s, 5H, C_5H_5); 7.11 (d, 2H, C_6H_4); 7.25 (d, 2H, C_6H_4). IR (CH_2Cl_2, cm^{-1}) ν_{CO} 1952s. Calc. for $C_{13}H_9FFeO_2SSe$: C, 40.77; H, 2.37; S, 8.37. Found: C, 40.34; H, 2.09; S, 7.95%.

2.2.4. [CpFe(CO)(κ^2Se,S-SeC(S)OC$_6$F$_5$)] (**2d**)

Yield: 65%. m.p. 72–73 °C. ^{1}H NMR ($CDCl_3$) δ 4.69 (s, H's, C_5H_5). IR (CH_2Cl_2, cm^{-1}) ν_{CO} 1959s. Calc. for

2.3. X-ray structure analysis

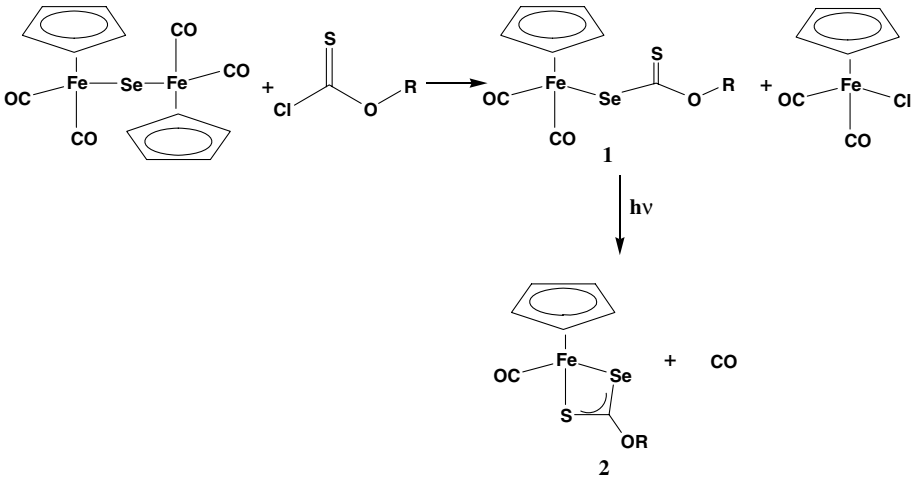
Single crystal of **1b** was obtained from CH_2Cl_2/hexane mixture. Intensity data were collected on a KappaCCD diffractometer with graphite monochromated Mo Kα radiation at 173 K. The crystallographic data are shown in Table 1. The cell parameters were determined from 5095 reflections collected in the range $1.96 \leqslant \theta \leqslant 30.04°$. There were 4473 independent reflections with 3717 observed reflections ($>2\sigma(I)$). The structure was solved by direct method using SHELXS-97 [32] and DIFMAP synthesis using SHELXTL-96 [33].

3. Results and discussion

3.1. Synthesis and characterization of *1*

The selenothiocarbonate complexes $CpFe(CO)_2SeC(S)OR$ [R = Ph (**1a**), 4-C_6H_4Cl (**1b**), 4-C_6H_4F (**1c**), C_6F_5 (**1d**), 4-C_6H_4Me (**1e**)] were readily synthesized by stirring a diethylether solution of chlorothionoformates and (μ-Se)$[CpFe(CO)_2]_2$ (Scheme 1) at room temperature.

To the best of my knowledge, complexes **1** are the first selenothiocarbonate of iron to be reported. The analogues ethyl-dithiocarbonate complexes, $Cp'Fe(CO)_2SC(S)OEt$ ($Cp' = C_5H_5$, C_5Me_5) are reported by the reaction of $[Cp'Fe(CO)_2]_2$ and $[EtOC(S)S]_2$. Substitution reactions of these dicarbonyl complexes with phosphine or phosphite ligands gave $Cp'Fe(CO)(L)SC(S)OEt$ ($L = PPh_3$, PBu_3, $P(OEt)_3$, $P(OPh)_3$) [34,35]. Complexes **1** are air stable as solids and in solutions. They are soluble in most common organic solvents such as THF, CH_2Cl_2 but sparingly soluble in hydrocarbons. These complexes were isolated as red-brown solids and characterized by elemental analysis, IR and ^{1}H NMR spectroscopy. The solution IR spectra of **1** (in CH_2Cl_2) exhibited two strong absorbances in the carbonyl region at 2035–2041 and 1985–1997 cm^{-1}. These ν_{CO} stretches are comparable to those of $CpFe(CO)_2SeSO_2R$ (2038–2043 and 1993–1999 cm^{-1}) [29] and of $CpFe(CO)_2SeCO_2R$ (2036–2043 and 1988–1993 cm^{-1}) [31] but higher than those of selenocarboxylates, $CpFe(CO)_2SeCOR$



R= Ph (**a**), 4-C_6H_4Cl (**b**), 4-C_6H_4F (**c**), C_6F_5 (**d**), 4-C_6H_4Me (**e**)

Scheme 1.

(2030–2035 and 1965–1973 cm^{-1}) [23]. These results show that the ligands: selenosulfonates, selenocarbonates and selenothiocarbonates are of comparable basicity, and they all have higher basicity than the selenocarbxylate ligands.

The ^1H NMR spectra for complexes **1** are in accordance with their formulation. Their spectra display a singlet in the range 4.95–5.08 ppm for their cyclopentadienyl ring protons. This peak falls within the same range observed for selenocarbonates $CpFe(CO)_2SeCO_2R$ (4.98–5.09 ppm) [12]. However, this peak is lower than that observed for selenosulfonate, $CpFe(CO)_2SeSO_2R$ (5.19–5.24 ppm) [29] and of selenocarboxylate complexes, $CpFe(CO)_2SeCOR$ (5.08–5.11 ppm) [23]. The resonances for the protons of the R-groups are observed in the expected values and multiplicity.

3.2. Synthesis and characterization of 2

Photolytic reaction of a THF solution of complexes **1** in the absence of added ligand leads to the generation of the chelate complexes $CpFe(CO)(\kappa^2 Se,S\text{-}SeC(S)OR)$ (**2**). The selenocarbonate ligands in **2** are bonded to the metal through both the sulfur and the selenium atoms. These dark red complexes are soluble in most organic solvents including hydrocarbons. Solutions of **2** are quite air sensitive even under inert atmosphere. Upon exposure to air, they decompose within few minutes.

Complexes **2** are characterised by IR, ^1H NMR spectroscopy as well as elemental analysis. The IR spectra of **2** show the characteristic ν_{CO} absorption in the range 1947–1959 cm^{-1}. This absorption is similar to those of $CpFe(CO)(EPh_3)SeCOR$ (1941–1957 cm^{-1}) and are lower than those of the starting complexes **1**. These differences might be attributed to the weak π-acid character of the chelate selenothiocarbonate ligand compared to that of carbonyl ligand. The ^1H NMR spectra of **2** show the Cp-peak in the range 4.65–4.69 ppm. This peak is lower than that of the corresponding Cp-peak of complexes **1** and within the same range observed for $CpFe(CO)(EPh_3)$-SeCOR (4.61–4.77 ppm).

3.3. Crystal structure

The structure of $CpFe(CO)_2SeC(S)O\text{-}4\text{-}C_6H_4Cl$ (**1b**) was determined crystallographically and is shown in Fig. 1. The relevant bond parameters are listed in Table 2. The complex adopts the geometry of a three-legged pianostool, with Cp as the base and the two carbonyls and the Se-coordinated selenothiocarbonate ligand as the legs. The Cp ligand is bound to the metal in an η^5-fashion with Fe–C bond distances ranging between 2.081(3) and 2.112(3) Å. The Fe–C bond distances (of carbonyl ligands) of 1.785(3) and 1.769(3) Å are in normal range for $CpFe(CO)_2X$ complexes. The Fe–Se bond length of 2.3958(5) Å is close to the range of Fe–Se bond lengths found in related iron complexes such as $CpFe(CO)_2SeSO_2C_6H_5$ [29] and $CpFe(CO)_2$-$SeCO_2C_2H_5$ [30]. The C=S bond distance of 1.633(3) Å is similar to that observed for $(PPh_3)_2Pt(CS_3)$ and $(dppe)PtCS_3$ [36].

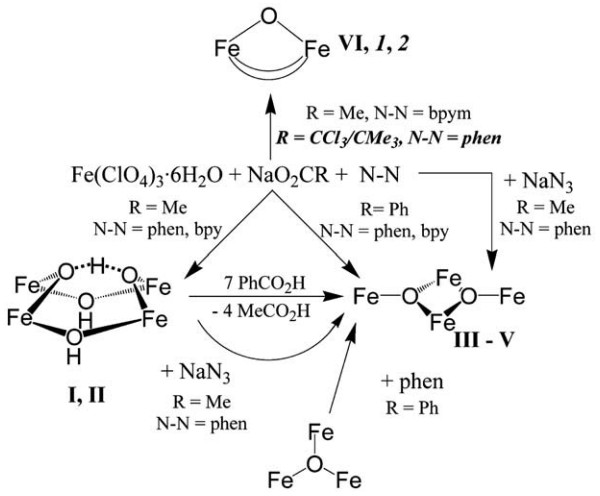

Scheme 1. The various preparations/transformations and the cores of the isolated clusters resulting from our synthetic efforts in the $Fe^{III}/RCO_2^-/N–N$ chemistry. The results described in this work are presented in bold italics.

and $[Fe_4(OHO)(OH)_2(O_2CMe)_4(bpy)_4](ClO_4)_3$ (**II**) were synthesized [7]. It was then found that when R = Ph and N–N = phen, we invariably obtained the tetranuclear butterfly-shaped complex $[Fe_4O_2(O_2CPh)_7(phen)_2](ClO_4)$ (**III**). This metal core persisted even when perchlorates were eliminated from the reaction mixture by reacting basic iron(III) benzoate with phen in MeCN, leading to complex $[Fe_4O_2(O_2CPh)_8(phen)_2]$ (**IV**) [8]. When R = Me, N–N = phen and NaN_3 was added to the reaction mixture, the butterfly tetranuclear cluster $[Fe_4O_2(O_2CMe)_6(N_3)_2(phen)_2]$ (**V**) was obtained, instead of the rectangular core [9]. Finally, when R = Me, N–N = bpym, intermolecular hydrogen-bonds between coordinated bipyrimidine with aquo ligands of adjacent molecules influenced the structure of the final product leading to hydrogen-bonded chains of $[Fe_2O(O_2CMe)_2(bpym)_2(H_2O)_2](ClO_4)_2$ (**VI**) [10]. All these reactions and transformations are summarized in Scheme 1.

A key observation is that the R group has the most important influence upon the identity of the final product when N–N is either phen or bpy. Being intrigued by this observation, we decided to further explore the parameter space of this reaction system with respect to that particular degree of freedom, the R group. We herein report the syntheses, structural and physical studies of complexes $[Fe_2O(O_2CR_3)_2(phen)_2(H_2O)_2](ClO_4)_2$ (**1**: R = CCl_3, **2**: R = CMe_3).

2. Experimental

2.1. Materials

All reagents and solvents were of analytical grade and used as received, except for sodium carboxylates, which were synthesized from reaction of their respective acids with sodium hydrogen carbonate at a 1:1 ratio. The syntheses were carried out under aerobic conditions. *Warning*: Although no such tendency was observed during the present work, perchlorate salts are potentially explosive and should be handled with caution in small quantities.

2.2. Syntheses

2.2.1. $[Fe_2O(O_2CCCl_3)_2(phen)_2(H_2O)_2](ClO_4)_2 \cdot 0.5MeCN \cdot 1.5H_2O$ (**1** · 0.5MeCN · 1.5H_2O)

A solution of phen · H_2O (0.238 g, 1.20 mmol) in MeCN (5 mL) was added to a solution of $Fe(ClO_4)_3 \cdot 9H_2O$ (0.620 g, 1.20 mmol) and NaO_2CCCl_3 (0.389 g, 4.10 mmol) in MeCN (5 mL). Upon addition the color of the solution turned from deep red to very dark green-brown. Parallelepiped green-brown crystals formed after ca. 5 days. These were collected by filtration, washed with a small amount of MeCN and dried in vacuo over silica gel (Yield: 0.35 g, ~46%). The dried sample analysed as solvent-free. *Anal*. Calc. for $C_{28}H_{16}Cl_8Fe_2N_4O_{13}$: C, 32.24; H, 1.59; N, 5.54. Found: C, 32.15; H, 1.68; N, 5.43%.

2.2.2. $[Fe_2O(O_2CCMe_3)_2(phen)_2(H_2O)_2](ClO_4)_2 \cdot MeCN$ (**2** · MeCN)

A solution of phen · H_2O (0.397 g, 2.00 mmol) in MeCN (8 mL) was added to a solution of $Fe(ClO_4)_3 \cdot 9H_2O$ (1.033 g, 2.00 mmol) and NaO_2CCMe_3 (0.435 g, 3.50 mmol) in MeCN (7 mL). Upon addition the color of the solution turned from deep red to very dark green-brown. The solution was allowed to slowly evaporate until its volume had reached ~3 mL. Then the solution was capped, and parallelepiped green crystals formed after ca. 5 days. These were collected by filtration, washed with a small amount of chilled MeCN and dried in vacuo over silica gel (Yield: 0.23 g, ~31%). The dried sample analysed as solvent-free. *Anal*. Calc. for $C_{34}H_{34}Cl_2Fe_2N_4O_{13}$: C, 45.92; H, 3.85; N, 6.30. Found: C, 45.79; H, 3.97; N, 6.21%.

2.3. Physical measurements

Elemental analysis for carbon, hydrogen, and nitrogen was performed on a Perkin–Elmer 2400/*II* automatic analyzer. Infrared spectra were recorded as KBr pellets in the 4000–400 cm^{-1} range on a Bruker Equinox 55/S FT-IR spectrophotometer. Variable-temperature (4.2–300 K) Mössbauer spectra were collected with a constant acceleration spectrometer using a ^{57}Co (Rh) source and a variable temperature Oxford cryostat. Home-written routines were used to fit the Mössbauer parameters and determine their standard deviations of statistical origin (given in parentheses). Isomer shift values (δ) are reported relative to iron foil at 300 K. Variable-temperature magnetic susceptibility measurements were carried out on a polycrystalline sample of **1** over the 5–300 K temperature range using a Quantum Design MPMS SQUID susceptometer under a magnetic field of 1 T. Diamagnetic corrections for the complex were estimated from Pascal's constants. The magnetic susceptibility has been computed by analytical calculation of the energy levels associated with the spin Hamiltonian.

Least-squares fittings were accomplished with an adapted version of the function-minimization program MINUIT [11]. The error factor R is defined as $R = \sum \frac{(x_{exp}-x_{calc})^2}{Nx_{exp}^2}$, where N is the number of experimental points. X-band EPR spectra at liquid helium temperatures were recorded with an ER200D Bruker spectrometer equipped with an Oxford ESR-900 cryostat and an Anritsu frequency counter.

2.4. X-ray crystallography

A green-brown prismatic crystal of **1** ($0.18 \times 0.38 \times 0.78$ mm) was mounted on a glass fiber and covered with epoxy glue, and a green prismatic crystal of **2** ($0.06 \times 0.30 \times 0.30$ mm) was mounted in capillary with drops of mother liquid. Diffraction measurements were made on a Crystal Logic Dual Goniometer diffractometer using graphite monochromated Mo radiation. Important crystal data and parameters for data collection for **1** and **2** are reported in Table 1. Unit cell dimensions were determined and refined by using the angular settings of 25 automatically centered reflections in the range $11° < 2\theta < 23°$. Intensity data were recorded using a θ–2θ scan. Three standard reflections, monitored every 97 reflections showed less than 3% intensity fluctuation and no decay. Lorentz polarization and psi-scan absorption corrections (only for **1**) were applied using Crystal Logic software. The structures were solved by direct methods using SHELXS-97 [12] and refined by full-matrix least-squares on F_o^2 with SHELXL-97 [13]. Further experimental crystallographic details for **1**: $2\theta_{max} = 50°$, scan speed 5.0 °/min; scan range $1.6 + \alpha_1\alpha_2$ separation; reflections collected/unique/used, 7459/7150 [$R_{int} = 0.0190$]/7150; 643 parameters refined; $(\Delta/\sigma)_{max} = 0.000$; $(\Delta\rho)_{max}/(\Delta\rho)_{min} = 0.850/-0.774$ e Å^{-3}; R/R_w (for all data), 0.0611/0.1253. All hydrogen atoms were located by difference maps and were refined isotropically, except those of the MeCN and partially occupied H_2O solvent molecules which were not included in the refinement. All non-hydrogen atoms were refined anisotropically. Further experimental crystallographic details for **2**: $2\theta_{max} = 48°$, scan speed 1.5°/min; scan range $1.6 + \alpha_1\alpha_2$ separation; reflections collected/unique/used, 7114/6794 [$R_{int} = 0.0364$]/6794; 631 parameters refined; $(\Delta/\sigma)_{max} = 0.000$; $(\Delta\rho)_{max}/(\Delta\rho)_{min} = 0.777/-0.496$ e Å^{-3}; R/R_w (for all data), 0.1074/0.1991. All hydrogen atoms were located by difference maps and were refined isotropically, except those of the methyl groups, which were introduced at calculated positions as riding on bonded atoms. All non-hydrogen atoms were refined anisotropically.

3. Results and discussion

3.1. Synthesis

The syntheses of the complexes were based upon the syntheses of other complexes of the $Fe^{III}/RCO_2^-/N$–N reaction system. Previous investigations involved the variations of carboxylates (R = Me or Ph), aromatic N-donor ligands (phen, bpy, bpym), or anions (elimination of perchlorates, or the inclusion of azides). In all previous studies, R groups were electron donating and no investigations had been carried out with electron withdrawing groups. We therefore decided to carry out a comparative study between two different carboxylates, one with electron withdrawing substituents and one with electron donating ones. For purposes of comparison, we have chosen two substituents with comparable steric hindrances, $R = CCl_3$ (trichloroacetates) and CMe_3 (pivalates).

Similar to previous investigations, an effort was made to minimize the degrees of freedom, by keeping the $Fe^{III}/RCO_2^-/N$–N stoichiometry constant to 1:1.75:1, respectively, and by carrying out the reactions in MeCN, without the use of solvent mixtures to induce crystallization. The reactions that led to **1** and **2** can be summarized by the following reaction:

$$2Fe(ClO_4)_3 \cdot 6H_2O + NaO_2CR + 2phen \cdot H_2O \xrightarrow[20\ °C]{MeCN} \underset{\mathbf{1}:R=CCl_3;\ \mathbf{2}:R=CMe_3}{[Fe_2O(O_2CR)_2(phen)_2(H_2O)_2](ClO_4)_2} + 2NaClO_4 + 2HClO_4 + 11H_2O \quad (1)$$

The close resemblance of the two structures, despite the very different acidities of the RCO_2^- ligands, leads us to assume that this is not a factor noticeably affecting the product of the reaction. It may rather be the steric hindrances of the R groups, similar for both carboxylates, which regulate the product identity. Of course, we should note that in solution a variety of species may be present, of which the least soluble will precipitate. Therefore, it would be more precise to state that the bulkiness of the ligand has a simultaneous effect both on the relative stabilities of the species

in solution *and* their relative solubilities. It is those two parameters together that define the final product, with solubility possibly being preponderate, without us being able to distinguish their individual contributions. This has been beautifully illustrated by Caneschi et al. [14], who have managed to isolate and characterize three different complexes from the same reaction mixture.

One final synthetic detail concerns the high propensity of **1** and **2** to form supersaturated solutions. Indeed, very concentrated solutions were employed for precipitation to occur, and despite the rapid colour changes, indicative of product formation, no crystallization occurred until after several days. In the case of **2** in particular, slow evaporation of the reaction solution had to be additionally employed to induce crystallization. Once crystallization was initiated however, important yields of both complexes precipitated very rapidly, as is the case for supersaturated solutions.

3.2. Description of the structures

Complex **1** crystallizes in the monoclinic $C2/c$ space group. A partially labelled ORTEP plot is shown in Fig. 1. It consists of $[Fe_2O(O_2CCCl_3)_2(phen)_2(H_2O)_2]^{2+}$ cations containing the typical $\{Fe_2(\mu_2\text{-}O)(\mu_2\text{-}O_2CCCl_3)_2\}^{2+}$ metal core.

The coordination environment around the Fe atoms is octahedral, with O_4N_2 donor atom sets. The cation of the complex is similar in structure with the cation of complex **VI** previously reported [10], with a difference being that whereas in **1** the two aqua ligands are in *cis* positions with respect to the Fe–O–Fe plane, in **VI** they are in *trans* positions with respect to that plane (see Table 2).

Complex **2** crystallizes in the triclinic $P\bar{1}$ space group. Its overall structure is very similar to that of **1**, with the two iron atoms forming a $\{Fe_2(\mu_2\text{-}O)(\mu_2\text{-}O_2CCMe_3)_2\}^{2+}$ metal core. A partially labelled ORTEP plot is shown in Fig. 2. The main difference of the two structures is that in **2** the aqua ligands are in *trans* positions with respect to the Fe–O–Fe plane, similar to complex **VI** (see Table 3).

Hydrogen bonding interactions between the coordinated water molecules, the perchlorate counterions and the solvent molecules lead to the formation of polymeric networks in the crystal structures of **1** and **2** stabilizing the lattice structures of both compounds (Table 4).

3.3. IR spectroscopy

In the $\nu(OH)_{water}$ region, the spectra of dried **1** and **2** show medium, broad bands at 3355 and 3386 cm^{-1}, respectively, assignable to coordinated water [15]. The spectrum of **1** presents two strong bands at 1626 and 1361 cm^{-1},

attributed to the antisymmetric and symmetric stretching vibrations of the carboxylate group, respectively [16,17]. The respective bands for the pivalato ligands in **2** appear at 1536 and 1427 cm^{-1}. The differences $\Delta = \nu_{as}(COO) - \nu_s(COO)$ between the asymmetric and symmetric stretching vibration frequencies are equal to 265 cm^{-1} for **1** and 109 cm^{-1} for **2**, lower than that of NaO_2CCl_3 ($1675 - 1354 = 321\ cm^{-1}$) and NaO_2CMe_3 ($1552 - 1413 = 139\ cm^{-1}$), as expected for the crystallographically established bidentate bridging mode of the trichloroacetate and pivalate ligation, respectively [17].

Of the ν(C=C) and ν(C=N) stretching vibrations of free 1,10′-phenanthroline between 1200 and 1600 cm^{-1}, all are known to shift to slightly higher frequencies upon complexation, except the one at 1586 cm^{-1}, which is virtually unaffected [18]. However, due to overlaps with the carboxylate asymmetric and symmetric stretching vibrations some of those are unobserved. Thus, in the spectrum of **1** we can identify some of those bands having shifted to 1585, 1519, 1427 and 1226 cm^{-1} and in the spectrum of **2** to 1625, 1583, 1484, 1520, 1226 cm^{-1}. A band at 1627 cm^{-1} in **1** is masked by the asymmetric stretching of the trichloroacetates, whereas a band at 1427 cm^{-1} in **2** is masked by the symmetric stretch of the pivalates. Bands of free phen in the 1050–700 cm^{-1} region shift to lower frequencies in the spectra of the complexes with splitting to the strong bands at ca. 730 cm^{-1} (only for **1**) and 850 cm^{-1} (only for **2**) [19].

The Fe–O–Fe antisymmetric and symmetric stretching vibrations [20] occur at 727 (**1**)/728 cm^{-1} (**2**) and 527 (**1**)/539 cm^{-1} (**2**), respectively. Finally, the strong and broad band around 1100 cm^{-1} and the medium band at 625 cm^{-1} are attributed to the $\nu_3(F_2)$ and $\nu_4(F_2)$ modes of the uncoordinated T_d perchlorate anions [16]. The broad character and signs of splitting of the band at ~1100 cm^{-1} both indicate the involvement of the ClO_4^- ions in hydrogen bonding [21].

3.4. Mössbauer spectroscopy

Mössbauer spectra from powder samples of **1** and **2** were collected between 4.2 and 300 K. Representative spectra of both complexes recorded at 78 K are shown in Fig. 3. These consist of symmetric quadrupole-split doublets, over the whole temperature regime, as predicted by the crystal structures, which reveal the existence of two iron sites in each complex with similar coordination spheres and geometries. Mössbauer parameters are presented in Table 5.

An increase of the isomer shifts of **1** and **2** upon cooling from 300 to 78 K is attributed to a second-order Doppler effect [22]. The quadrupole splitting does not exhibit significant temperature dependences, as is expected for high-spin iron(III). The lines are quite narrow and perfectly symmetric, indicating on the one hand, samples of high purity and on the other hand, iron sites of very similar Mössbauer parameters in both complexes. Thus, the different

orientations of the aqua ligands (see Section 3.2) do not have any significant effect from the view of Mössbauer spectroscopy. The quadrupole splitting for both compounds is relatively large for ferric species, as found in other ferric sites of spin-coupled diiron oxo-bridged complexes encountered in proteins and model compounds [23]. A similar large quadrupole splitting has been observed for the ferric site of a (μ-oxo)-bis(carboxylato) Fe^{III}–Cr^{III} heterometallic complex [24]. This large value has been considered to arise from two sources. First, a large EFG arises from the asymmetry of the charge of the ligand sphere which is enhanced by the short Fe–O_{oxo} distance, and second, from covalency effects, that perturb the valence electron configuration of Fe^{III}.

Both complexes exhibit almost identical isomer shifts over the entire temperature range, which is in line with their similar donor atom sets (O_4N_2 for both complexes) and coordination geometries. However, there exists an interesting difference in their quadrupole splitting; complex **1** shows a quadrupole splitting of ~1.8 mm s^{-1}, significantly larger than that exhibited by **2** (~1.6 mm s^{-1}). All ferric sites exhibit O_4N_2 donor atom sets so these differences should not arise from varying inhomogeneities in the coordination spheres. A close inspection of the two structures reveals that bond length dispersions for all iron atoms fall in almost identical limits [**1**: Fe(1), 1.791–2.196; Fe(2), 1.787–2.173; **2**: Fe(1), 1.798–2.216; Fe(2), 1.791–2.205]. Thus, geometrical deviations from ideal octahedral geometries may as well be excluded from influencing the quadrupole splitting, since these deviations are remarkably similar for both complexes. Thus, the only other factor that can be held responsible for the observed differences are the different carboxylate ligands in **1** and **2**. Specifically, we observe that whereas trichloroacetates contain an electron withdrawing Cl_3C group, pivalates contain an electron donating Me_3C group attached to the carboxyl function. This correlates with the differences in the pK_a values of the respective acids (0.70 for Cl_3CCO_2H and 5.03 for Me_3CCO_2H). Comparisons with strictly similar complexes are difficult, since there are no examples of $[Fe_2O(O_2CR)_2(phen)_2(H_2O)_2]^{2+}$ complexes characterized by Mössbauer spectroscopy. However, a similar complex, $[Fe_2O(O_2CCH_2Cl)_2(bpy)_2(H_2O)_2](NO_3)_2$ was reported [25] to exhibit an isomer shift of 0.52 mm s^{-1} and a quadrupole splitting of 1.89 mm s^{-1} at 4.2 K. This high quadrupole splitting coincides with the presence of a ligand with an electron-withdrawing side group (–CH_2Cl). However, more examples would be required in order to make a valid correlation between those factors. We also conclude from the above that such simple systems are ideally suited for the study of physical phenomena at a fundamental level, without the complications encountered on larger systems.

3.5. Magnetic properties

Variable-temperature magnetic susceptibility data (5–300 K) for **1** are shown in Fig. 4.

The $\chi_M T$ product at 300 K is 1.66×10^{-3} cm^3 mol^{-1} K, much lower than the spin-only value expected for two

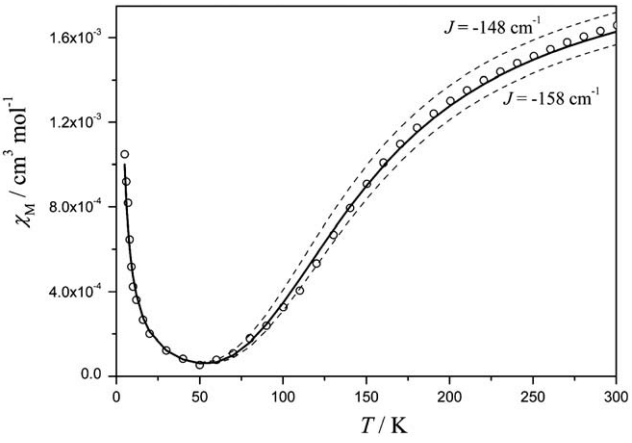

Fig. 4. χ_M vs. T plot for complex **1**. The solid line represents the best fit to the experimental data (open circles) according to the respective Hamiltonian. The dashed lines represent simulations with J values fixed to ± 5 cm^{-1} with respect to the best-fit value.

non-interacting $S = 5/2$ ions ($8.76\ cm^3\ mol^{-1}\ K$), and decreases rapidly upon cooling, indicating strong antiferromagnetic interactions (Fig. S1). This is corroborated by the constant drop of the magnetic susceptibility upon cooling, down to a minimum of $5.39 \times 10^{-5}\ cm^3\ mol^{-1}$ at ~50 K, indicating a diamagnetic ground state. An increase of χ_M below that temperature is attributed to a small fraction of high-spin ferric paramagnetic impurities. The presence of such impurities is also evident in X-band EPR spectra recorded at 4.2 K (Fig. S2) giving rise to characteristic derivative signal at $g \sim 4.3$ and weaker absorption peaks for $g \leqslant 9.0$. The overall magnetic behaviour of the complex is typical of oxo-bridged diferric complexes. The spin Hamiltonian describing the coupling within the system is

$$\hat{H} = -2J\hat{S}_1\hat{S}_2 \quad (2)$$

with $S_1 = S_2 = 5/2$.

Fitting the experimental data with the above-mentioned model and allowing for a small fraction ρ of ferric impurities yields best-fit parameters $J = -153\ cm^{-1}$, $g = 2.0$ (fixed), $\rho = 0.3\%$ with $R = 4.2 \times 10^{-3}$. The J value is well defined within a narrow range, as can be seen by simulations carried out with theoretical values differing by $\pm 5\ cm^{-1}$ (~±3%) from the best-fit value. The coupling strength falls beyond the upper limit (more negative value) of the range previously reported for (μ-oxo)bis(μ-carboxylato) bridged [23,26] diferric complexes, which is $-140\ cm^{-1}$ in $[Fe_2O(O_2CMe)_2(metpen)_2](ClO_4)_4$ (where metpen = *N*-methyl-*N*,*N*,*N*′,*N*′-tetrakis(2-pyridylmethyl)-1,2-ethanediamine) [27]. Taking into account the structural parameters of **1**, the empirical relation proposed by Gorun and Lippard [28] yields a calculated value of $-127\ cm^{-1}$, whereas the semiempirical one proposed by Weihe and Güdel [29] yields a J value of $-118\ cm^{-1}$ (using the $-2J$ Hamiltonian formalism), both of which are lower than the experimentally derived value. More recent theoretical studies, employing density functional theory, have correctly predicted the order of magnitude of the exchange interaction in μ-oxo and μ-hydroxo bis(acetato) complexes and have elucidated the 10-fold decrease of the coupling upon protonation of the oxo bridge [30,31]. In the Fe^{III}–O–Fe^{III} dimers the dominant pathway dictating the magnitude of the exchange coupling was found to be through the oxo bridge. A pathway mediated by the bridging acetates was also found [30] albeit of lesser importance. As in the case of quadrupole splitting (see above) this may suggest that the nature of the bridging carboxylates may be responsible for the variations of the exchange couplings [23] in the various (μ-oxo)bis(carboxylato) diferric complexes.

4. Conclusions

The use of two bulky carboxylates in the well-studied Fe^{III}/RCO_2^-/phen system has yielded two new dinuclear complexes containing the $\{Fe_2O(O_2CR)_2\}^{2+}$ metal core. The important differences in the electron withdrawing (or donating) strengths of the alkyl groups of the carboxylate ligands were not found to greatly influence the structures of the final products, both of which are dinuclear and contain the same metal core; it was rather concluded that it is the steric hindrances of the RCO_2^- ligands that mostly affect the identities of the final products. On the other hand, however, despite the close structural resemblance of the two complexes, their Mössbauer spectra exhibit important differences in their quadrupole splitting. This has been attributed to the different electron withdrawing potentials of the R substituents. The magnetic behaviour of **1** is typical of oxo-bridged diferric complexes, and the antiferromagnetic coupling is the strongest reported for complexes containing the $\{Fe_2O(O_2CR)_2\}^{2+}$ core.

can mimic the active site of those metalloenzymes which are known to contain imidazole groups from histidine, bound to the metal centre in the active site [18]. This is the case of hydrotris(pyrazolyl)borates, that have been employed to modelize metalloproteins thanks to their ability to mimic the multiple coordination of histidine to metal ions [19].

Taking into account the afore-mentioned, during last years we have carried out a systematic investigation on the coordination chemistry of thiazoline derivatives with transition metal ions [20–27]. As a continuation of this research, we have recently initiated a study about the coordination behaviour of thiazoline derivatives that contain the pyrazole ring in their structure. In this paper, results are reported on the structural characterization of 2-(pyrazol-1-yl)-2-thiazoline (PyTn), as well as a study through elemental analysis, IR, UV–Vis–NIR diffuse reflectance, X-ray diffraction, and magnetic susceptibility of the solid phases obtained by reaction of PyTn with Co(II) and Cu(II), as well as electronic paramagnetic resonance (EPR) of the latter.

2. Experimental

2.1. Preparation of 2-(pyrazol-1-yl)-2-thiazoline (PyTn)

The preparation of PyTn has been carried out as it is described by Haugwitz et al. [28]. The resulting oil was crystallized from 1:2 diethyl ether–petroleum ether mixture. *Anal*. Calc. for $C_6H_7N_3S$: C, 47.04; H, 4.61; N, 27.43; S, 20.93. Found: C, 46.82; H, 4.73; N, 27.08; S, 20.54%. UV–Vis (EtOH): λ_{max}, nm (ε, L mol^{-1} cm^{-1}) 242 (32364), 268 (7409). ^{1}H NMR (deuteriochloroform): δ 8.21 (d, $J = 2.6$ Hz, 1H, C(5)H), 7.68 (s, 1H, C(6)H), 6.42 (s, 1H, C(4)H), 4.34 (t, $J = 8.2$, 2H, CH_2–N), 3.50 ppm (t, $J = 8.2$, 2H, CH_2–S); ^{13}C NMR (deuteriochloroform): δ 158.68 C(1), 142.60 C(4), 128.07 C(6), 108.72 C(5), 61.18 C(3), 34.05 ppm C(2).

2.2. Preparation of $[CoCl_2(PyTn)_2]\cdot 2H_2O$ (1)

This complex was isolated from a freshly prepared 96% ethanol solution (2.5 mL) of $CoCl_2\cdot 6H_2O$ (77.6 mg, 0.3 mmol) that was added to a 96% ethanol solution (5 mL) of PyTn (100 mg, 0.6 mmol). The resulting solution was allowed to evaporate slowly at room temperature. After a few days, red crystals were isolated from the solution (99.4 mg, 67%). Crystals were separated by filtration, washed with cold ether and air-dried. *Anal*. Calc. for $C_{12}H_{18}Cl_2CoN_6O_2S_2$: C, 30.52; H, 3.84; N, 17.79; S, 13.58. Found: C, 30.51; H, 3.73; N, 17.61; S, 13.59%.

2.3. Preparation of $[\{CuCl(PyTn)\}_2(\mu\text{-}Cl)_2]$ (2)

This complex was prepared by reacting a 96% ethanol solution (2.5 mL) of $CuCl_2\cdot 2H_2O$ (111.3 mg, 0.6 mmol) with a 96% ethanol solution (5 mL) of PyTn (100 mg, 0.6 mmol), being obtained a green powder that was filtered and crystallized from distilled water (165.1 mg, 88%). Crystals were filtered and washed with cold ether and air-dried. *Anal*. Calc. for $C_6H_7Cl_2CuN_3S$: C, 25.05; H, 2.45; N, 14.61; S, 11.15. Found: C, 25.00; H, 2.49; N, 14.45; S, 11.18%.

2.4. Instrumental procedures

Chemical analyses of carbon, hydrogen, nitrogen and sulphur were performed by microanalytical methods using a FISONS EA-1108 microanalyser. IR spectra were recorded on a Perkin–Elmer FT-IR 1720 spectrophotometer, from KBr pellets in the 4000–370 cm^{-1} range and on a Perkin–Elmer FT-IR 1700X spectrophotometer, from polyethylene pellets in the 500–150 cm^{-1} range. Electronic spectra of the ligand in ethanol solution and the copper(II) complex in DMSO solution were measured on a Shimadzu UV-3101 PC using a 10 mm quartz cell. UV–Vis–NIR reflectance spectra for complexes in the 200–2500 nm range were obtained from pellets of the samples, using a Shimadzu UV-3101 PC spectrophotometer and $BaSO_4$ as a reference. Magnetic susceptibility measurements were performed on polycrystalline samples using a magnetometer with pendulum MANICS DSM8, equipped with helium continuous-flow cryostat and a electromagnetometer DRUSCH EAF 16 UE. Data were corrected for temperature independent paramagnetism and diamagnetic contributions, which were estimated from the Pascal constants. The EPR spectrum was recorded at room temperature on a BRUKER ESP-300E spectrometer using the X band of microwave. ^{1}H and ^{13}C NMR spectra were obtained with a Bruker AM 400 instrument at 400 and 100 MHz, respectively, in $CDCl_3$ using Me_4Si as internal standard.

2.5. Crystal structures determination

Crystal data, data collection and refinement details for PyTn, **1** and **2** are given in Table 1. X-ray diffraction measurements were performed using a Bruker SMART CCD diffractometer. The first 50 frames were recollected at the end of data collection to monitor for decay. All data were corrected for Lorentz and polarization effects, while absorption corrections were performed by means of SADABS program [29]. The structures of PyTn and **2** were solved by direct methods and subsequent Fourier differences, while **1** structure was solved using Patterson method and subsequent Fourier differences. For these structure solutions, the WinGX package [30] was employed, and all the structures were refined by full-matrix least-squares. The H atoms attached to C atoms were positioned geometrically, with U_{iso} values derived from U_{eq} values of the corresponding C atom. The hydrogen atoms from water molecules were directly located from successive Fourier differences syntheses and included in the calculation with estimated isotropic displacement parameters without refinement, with the O–H and H···H distances restrained (DFIX) to 0.957(3) and 1.513(3) Å, respectively, in order

to ensure a chemically reasonable geometry for these molecules.

3. Results and discussion

3.1. Description of the structures

3.1.1. PyTn

The X-ray study of PyTn reveals that crystals are made of monoclinic unit cells, each one containing four PyTn molecules. A diagram of the molecular structure and the atom numbering system used are shown in Fig. 1. Selected bond lengths and angles are given in Table 2.

In the S–C(1)–N(1)–C(2)–C(3) ring, the short C(1)–N(1) bond [1.257(2) Å], together with a high S–C(1)–N(1) bond angle [120.8(1)°] and a relatively long S–C(1) bond distance [1.750(2) Å], indicates that it deals with a thiazoline ring [31].

Regarding to pyrazole ring, bond distances and angles are the normal ones for a ring of this nature [32].

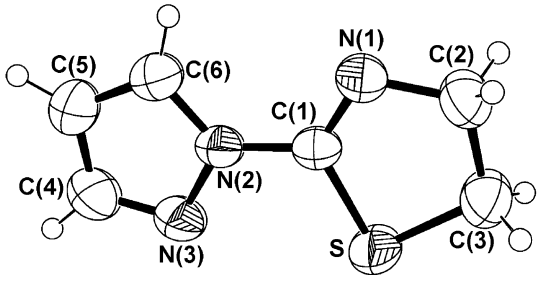

Fig. 1. Crystal structure of PyTn, showing the atom-numbering scheme. The thermal ellipsoids are drawn at a 50% level.

From the examination of the least squares planes, it is deduced that both heterocyclic rings are plane, with a maximum deviation with respect to the rings mean plane of 0.004(2) Å for C(3) from thiazoline ring and 0.006(2) Å for C(6) from pyrazole ring. The dihedral angle between thiazoline and pyrazole rings [2.9(0)°] indicates that both heterocycles are nearly coplanar.

3.1.2. $[CoCl_2(PyTn)_2]\cdot 2H_2O$ (1)

The X-ray diffraction study of $[CoCl_2(PyTn)_2]\cdot 2H_2O$ shows that crystals are made up of triclinic unit cells, each one containing one complex molecule and two crystallization water molecules. A diagram of the molecular structure is shown in Fig. 2, while selected bond lengths, angles and hydrogen-bond parameters are given in Table 3.

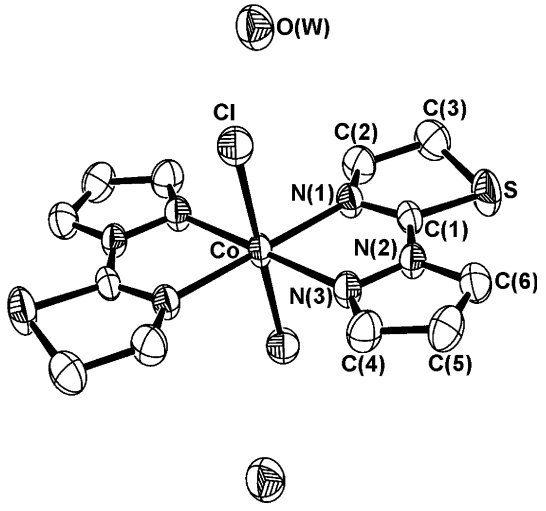

Fig. 2. Molecular structure of the $[CoCl_2(PyTn)_2]\cdot 2H_2O$ molecule, showing the atom-numbering scheme. The ellipsoids are drawn at a 50% level.

The cobalt(II) atom is hexa-coordinate, showing a distorted octahedral environment with the ligand–metal–ligand bite angles being comprised within 77.2(1)° [N(1)–Co–N(3)] and 102.8(1)° [N(1)–Co–N(3a)]. It is linked to two thiazoline N atoms and two pyrazole N atoms from two PyTn ligands that behave as didentate, constituting the equatorial plane, as well as to two chloride ions in the axial positions.

The Co–Cl distances [Co–Cl = 2.472(1) Å] are in accordance with the calculated average value [2.308(143) Å] for 129 hexa-coordinate cobalt(II) complexes with a chromophore group CoN_4Cl_2 obtained from the Cambridge Structural Database (CSD) [33] using CONQUEST software [34]. Likewise, the Co–N distances [Co–N(1) = 2.097(2) Å, Co–N(3) = 2.157(2) Å] are similar and comparable to the mean value [2.004(155) Å] calculated for 129 cobalt(II) complexes in which the metal ion is hexa-coordinate and has such chromophore group, found in a survey using CSD.

The two five-membered chelate rings are essentially planar, with a maximum deviation in relation to the corresponding mean plane of 0.039 Å for C(1).

In the case of PyTn ligands, the 2-thiazoline heterocycles lose their planar conformation, adopting a conformation near to envelope with the apex at C(3), deviating 0.339 Å from the plane formed by S, C(1), N(1) and C(2) [maximum mean-plane deviation for C(1) = 0.013 Å], which is in accord with their puckering parameters [$q = 0.217$ Å, $\phi = 140.1°$] [35].

Meanwhile, pyrazole ring remains planar, as was to be expected for an aromatic ring, with a maximum deviation with respect to the mean plane of 0.004 Å for C(6).

As it can be seen in Fig. 2, the thiazoline ring rotates around C(1)–N(2) bond in such a way that pyrazole and 2-thiazoline rings arrange their N atoms [N(1) and N(3)] to the same side in order to coordinate. Thus, the torsion angle N(1)–C(1)–N(2)–N(3) possesses a value of 7.3(3)° in the cobalt(II) complex, while in the free ligand, is 176.4(2)°.

The crystal structure is stabilized by a hydrogen-bond network, in which chlorine atoms act as acceptors of hydrogen and water molecules act as donors of hydrogen. A diagram showing this network is given in Fig. 3.

Table 3
Selected bond lengths (Å), angles (°) and hydrogen-bond parameters for $[CoCl_2(PyTn)_2]\cdot 2H_2O$ (**1**)

Co–Cl	2.472(1)	Co–N(1)	2.097(2)

3.1.3. [{CuCl(PyTn)}$_2$(μ-Cl)$_2$] (2)

The molecular structure of the copper(II) complex is shown in Fig. 4. Selected interatomic distances and angles are listed in Table 4.

The structure consists of centrosymmetric dimeric $[\{CuCl(PyTn)\}_2(\mu\text{-}Cl)_2]$ units, in which two chloro ligands bridge the copper atoms forming a four-membered ring; a terminal chloro ligand and a didentate chelating molecule of PyTn completing five-coordination at each metal. The bridging Cu_2Cl_2 unit is strictly planar by the presence of the crystallographic inversion centre in the middle of the dimer.

The five donor atoms do not define a regular polyhedron around copper. The approach of Reedijk et al. [36] has been used to assign a specific coordination geometry. Analysis of the shape determining angles, α and β (the two largest angles around the central atom) yields a value for the trigonality index, τ [$\tau = (\alpha - \beta)/60$], of 0.05. According to it ($\tau = 0$ and 1 for perfect square pyramidal and trigonal bipyramidal geometries, respectively), the geometry around copper can be described as a slightly distorted tetragonal pyramid. In this structure, the basal plane is made up of one thiazoline nitrogen atom N(1), one pyrazole nitrogen atom N(3), the bridging chloro ligand Cl(2) and the terminal chloro ligand Cl(1), while the apical site is occupied by the other bridging chloro ligand Cl(2a). The Cl(2a)–metal–basal ligand angles differ from the ideal value for a square pyramid (90°), ranging between 106.1(1)° [for Cl(1)–Cu–Cl(2a)] and 83.3(1)° [N(1)–Cu–Cl(2a)]. Likewise, the basal ligand–metal–basal ligand angles differ from the ideal value of 90°, ranging between 96.2(1)° [Cl(1)–Cu–Cl(2)] and 78.9(1)° [N(3)–Cu–N(1)].

Table 4
Selected bond lengths (Å) and angles (°) for $[\{CuCl(PyTn)\}_2(\mu\text{-}Cl)_2]$ (2)

Cu–Cl(2)	2.217(1)	Cu–Cl(1)	2.254(1)
Cu–N(1)	2.012(2)	Cu–N(3)	1.995(2)
Cu–Cl(2a)	2.906(1)	C(1)–N(1)	1.260(3)
C(1)–N(2)	1.373(3)	N(3)–N(2)	1.374(3)
C(2)–N(1)	1.442(3)	C(1)–S	1.743(2)
C(6)–N(2)	1.366(3)	C(4)–N(3)	1.306(3)
Cl(1)–Cu–Cl(2)	96.2(1)	N(3)–Cu–Cl(2)	170.4(1)
N(3)–Cu–N(1)	78.9(1)	N(1)–Cu–Cl(1)	167.5(1)
N(1)–Cu–Cl(1)	91.5(1)	N(3)–Cu–Cl(1)	93.0(1)
Cl(2)–Cu–Cl(2a)	91.4(1)	Cl(1)–Cu–Cl(2a)	106.1(1)
N(1)–Cu–Cl(2a)	83.3(1)	N(3)–Cu–Cl(2a)	88.6(1)

The terminal Cu–Cl(1) distance [Cu–Cl(1) = 2.254(1) Å] is slightly shorter than the calculated average value [2.268(35) Å] for 90 copper(II) complexes with a chromophore group $CuCl_3N_2$ and short Cu–$Cl_{terminal}$ bond distances (<2.4 Å) according to Orpen et al. [37]. These bond distances have been obtained by means of CONQUEST software [34] from the CSD [33]. Likewise, the bridging Cu–Cl(2) distance [Cu–Cl(2) = 2.217(1) Å] is comparable

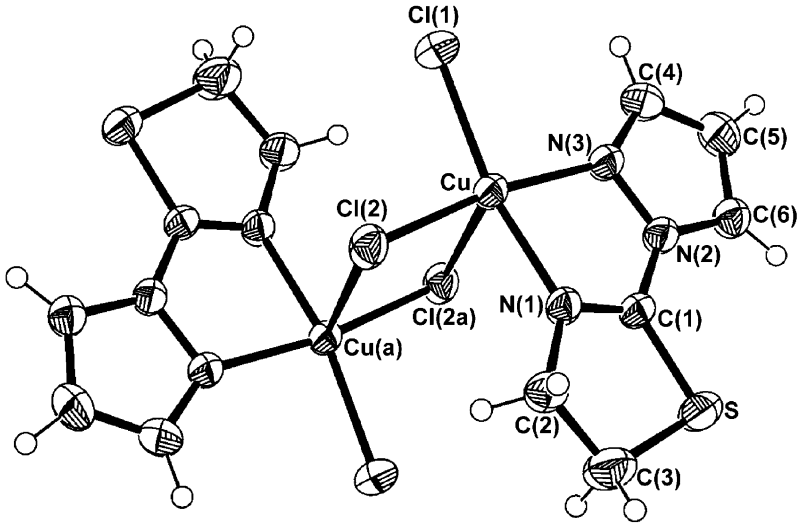

Fig. 4. Molecular structure of $[\{CuCl(PyTn)\}_2(\mu\text{-}Cl)_2]$, showing the atom-numbering scheme. The ellipsoids are drawn at a 50% level.

to the calculated average value [2.309(53) Å] for short Cu–$Cl_{bridging}$ bond distances (<2.43 Å) [37] of 56 five-coordinated copper(II) complexes collected in CSD [33]. On the other hand, the Cu–Cl(2a) distance [Cu–Cl(2a) = 2.906(1) Å] is considerably larger than the calculated average value [2.554(100) Å] for 11 copper(II) complexes with Cu–$Cl_{bridging}$ bond distances considered long (>2.50 Å) [37]. The Jahn–Teller distortion, often seen in Cu(II) complexes, causes the substantial elongation of Cu–Cl(2a) bond compared with in-plane bonds. The angle Cu–Cl(2)–Cu(a) [88.6(1)°] is slightly shorter than the average 89.40(5)° in CSD. Likewise, the Cu–Cu distance [3.612(1) Å] is larger than the average value found for 188 dinuclear copper(II) complexes containing two chloro bridging ligands [3.499(133) Å] in CSD. Likewise, the Cu–$N_{pyrazole}$ bond distance [Cu–N(3) = 1.995(2) Å] is in good agreement with the calculated average value [1.987(16) Å] found for [$CuCl_2(pdmp)_2$] [pdmp = 1-phenyl-3,5-dimethylpyrazole] [38,39], [$CuCl_2(DPEP)_2$] [DPEP = P,P-diphenyl-2-(3,5-dimethylpyrazol-1-yl)ethylphosphinate-N] [40], *trans*-bis(4-bromopyrazole-N)-dichloro-copper (II) [41] and [$CuCl_2(Pz_2CPh_2)$] [Pz_2CPh_2 = diphenyl dipyrazolylmethane-*N*,*N*′] [42]. Finally, the Cu–$N_{thiazoline}$ bond distance [Cu–N(1) = 2.012(2) Å] is comparable to the calculated mean value [1.952(38) Å] for 12 copper(II) complexes collected in CSD, and to the Cu–$N_{thiazoline}$ bond length in [$CuCl_2$(TzHy)] [Cu–N(1) = 1.969(3) Å] [TzHy = (4,5-dihydro-1,3-thiazol-2-yl)hydrazine] [27].

The five-membered chelate ring Cu–N(1)–C(1)–N(2)–N(3) shows a conformation near to envelope with the apex at Cu. This atom is 0.263 Å out of the plane formed by N(1), C(1), N(2) and N(3) [maximum mean-plane deviation for C(1) = 0.014 Å]. This geometry is proved by the puckering parameters $q = 0.128$ Å and $\phi = 350.5°$ [35].

As was to be expected, the pyrazole ring N(2)–N(3)–C(4)–C(5)–C(6) is essentially planar with maximum mean-plane deviation for C(4) [0.004 Å]. Nevertheless, the puckering parameters calculated for the thiazoline ring S–C(1)–N(1)–C(2)–C(3) [$q = 0.187$ Å; $\phi = 138.8°$], according to Cremer and Pople [35], indicate a conformation between half-chair and envelope with the C(2) and C(3) atoms deviating above (0.107 Å) and below (0.181 Å), respectively, from the plane formed by S, C(1) and N(1).

As it happens in the case of **1**, the thiazoline ring rotates around C(1)–N(2) bond, disposing N(1) and N(3) atoms to the same side with the aim of coordinating, which leads to a torsion angle N(1)–C(1)–N(2)–N(3) of 2.7(3)°, much lower compared with the value for PyTn [176.4(2)°].

3.2. Magnetic susceptibility measurements

The observed molar magnetic susceptibility for **1** was corrected for diamagnetism and temperature-independent paramagnetism to provide the fully corrected magnetic moment at room temperature, 4.61 BM. The value of the fully corrected magnetic moment obtained for complex **1** can be considered in the range 4.7–5.2 BM characteristic of complexes with the octahedral environment around cobalt(II) [43].

Variable temperature (7.5–300 K) magnetic susceptibility data were collected for polycrystalline sample of the complex **2**. Susceptibility values per mole of dimer as a function of the temperature have been plotted in Fig. 5. This behaviour is typical for ferromagnetic interaction between the two Cu(II) centres of the dimer. The experimental data were fitted using the following Bleaney–Bowers equation [44] for a binuclear compound with a total spin $S = 1$ containing the J' term

$$\chi_M = \frac{2N\beta^2 g^2}{kT - (6J' + \exp(-J/kT))}[3 + \exp(-J/kT)]^{-1}.$$

In this expression, χ_M represents the susceptibility per mole of dimer, corrected for diamagnetism and temperature independent paramagnetism, J is the exchange coupling constant, J' is the interdimers exchange coupling constant and the other symbols have their usual meaning. The average value got from EPR spectrum (2.148) has been taken as g value. The parameters J and J' were determined as adjustable parameters, in a least-squares fitting procedure that led to the values $J = 13.73\ cm^{-1}$ and $J' = -6.04\ cm^{-1}$.

The agreement factor R, defined as $\sum(\chi_{exp} - \chi_{calc})^2/(\chi_{exp})^2$ is then equal to 7.91×10^{-6}.

The positive J parameter implies intradimer ferromagnetic interaction.

Dinuclear copper(II) complexes with a Cu(μ-Cl)$_2$Cu motif containing chloro bridging ligands have been studied in order to draw meaningful magneto-structural correlations. In these complexes, the local geometry around the metal centre is usually a square pyramid with a different degree of distortion towards a trigonal bipyramid. The global arrangement of the two square pyramids gives rise to three types of geometries: square pyramids sharing one base-to-apex edge with the two bases nearly perpendicular to one another (type I), square pyramids sharing one base-to-apex

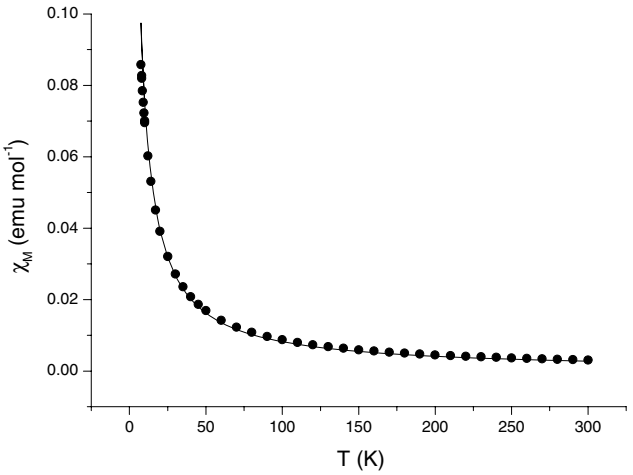

Fig. 5. Variation of the susceptibility as a function of the absolute temperature for [{CuCl(PyTn)}$_2$(μ-Cl)$_2$].

edge but with parallel basal planes (type II) and square pyramids sharing a basal edge with coplanar basal planes (type III). The extended Hückel calculations performed by Rodríguez et al. [45,46] show that the super exchange pathway with the metal centres will take place mainly through a π* type interaction between the $d_{x^2-y^2}$ orbitals of Cu(II) ions and the p orbitals of chloro bridging ligands for type II complexes, as it is the case of $[\{CuCl(PyTn)\}_2(\mu\text{-}Cl)_2]$. For an ideal geometry with a square core, the overlap integral between the former orbitals would be zero, and therefore, there would not be any magnetic coupling between the copper centres. As above, these type II complexes present very small J values, which are due to structural deviations from the ideal square Cu_2Cl_2 core. The small calculated J value for $[\{CuCl(PyTn)\}_2(\mu\text{-}Cl)_2]$ is therefore consistent with the calculations performed by the aforementioned authors.

3.3. Spectroscopic studies

The cobalt(II) complex exhibits a typical spectrum for octahedral species in the solid state [47]. Two multicomponent absorptions are observed in the 6800–11 000 and 15 000–21 000 cm^{-1} ranges, which are assigned to the $^4T_{1g}(F) \rightarrow {}^4T_{2g}(F)$ and $^4T_{1g}(F) \rightarrow {}^4T_{1g}(P)$ transitions, respectively.

The ν_3 and ν_1 bands are splitted into two components of almost equal intensities, that together with the lower magnetic moment value, can be due to the presence of a low symmetry of the crystal field, C_i.

Moreover, the spectrum shows one intense band at 34 020 cm^{-1} which is assigned to the $\pi \rightarrow \pi^*$ transition of the organic ligand.

Ligand field parameters, $10Dq$ and B, were calculated on the basis of octahedral geometry from the averaged values of the ν_1 and ν_3 bands taking the centre of gravity of the total intensity by using the Konig's equations [48]

$$\nu_1 = 1/2(10Dq - 15B) + 1/2[(10Dq + 15B)^2 - 12B \cdot 10Dq]^{1/2},$$
$$\nu_3 = [(10Dq + 15B)^2 - 12B \cdot 10Dq]^{1/2}.$$

The calculated values of the ligand field parameters $10Dq = 9500\ cm^{-1}$ and $B = 740\ cm^{-1}$ are in good agreement with the predicted values for octahedral complexes and are consistent with the presence of a chromophore group $[CoCl_2N_4]$.

The electronic reflectance spectrum of the copper(II) complex displays two strong bands at 34 250 and 27 860 cm^{-1} which can be assigned to organic ligand → Cu and Cl → Cu charge transfer transitions, respectively.

Furthermore, this spectrum consists of a broad d–d asymmetric band centred at about 14 000 cm^{-1} (12 870 cm^{-1} in DMSO solution). Presumably, all four d–d transitions ($^2A[(d_{x^2-y^2})^1] \rightarrow {}^2A[(d_{z^2})^1]$, $^2A[(d_{xy})^1]$, $^2A[(d_{xz})^1]$, $^2A[(d_{yz})^1]$) of the square-pyramidal geometry [49] are responsible to this band.

The EPR spectra of a polycrystalline sample at 298 K (Fig. 6) and at 77 K in DMSO solution (Fig. 7) of complex **2** were recorded in the X-band, using the 100 kHz field modulation.

The EPR parameters of copper(II) complex are presented in Table 5.

The spectrum of **2** at 298 K is typically axial with well-defined $g_\parallel$ and $g_\perp$ values. The geometric parameter $G = (g_\parallel - 2)/(g_\perp - 2)$ value is found to be in the range 3.5–5.0 and $g_\parallel > g_\perp > 2.0023$, which is consistent with a $d_{x^2-y^2}$ ground state having a negligible exchange coupling [49,50].

With regard to the EPR spectrum in frozen DMSO (77 K), it shows four hyperfine lines, characteristic of monomeric copper(II) complexes.

Kivelson and Neiman have shown that $g_\parallel$ is a moderately sensitive function for indicating covalency;

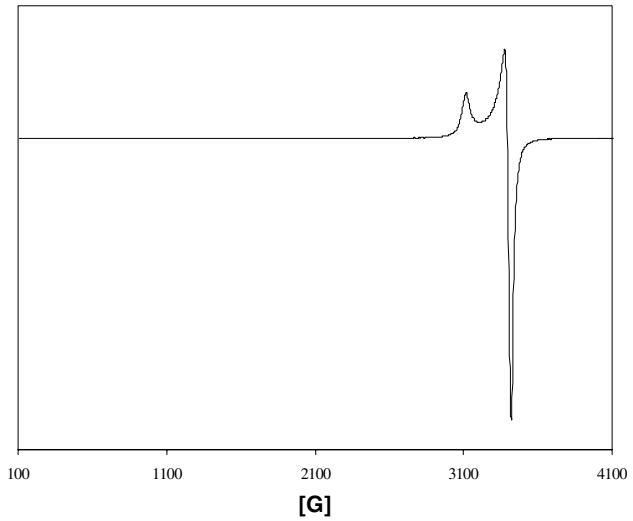

Fig. 6. EPR spectrum of $[\{CuCl(PyTn)\}_2(\mu\text{-}Cl)_2]$ in the polycrystalline state at 298 K.

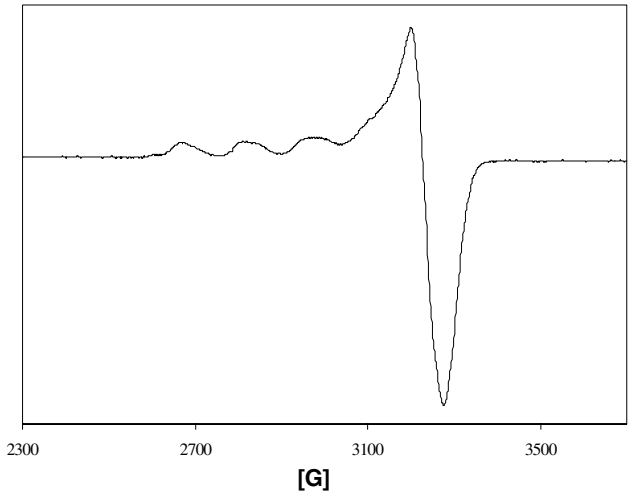

Fig. 7. EPR spectrum of $[\{CuCl(PyTn)\}_2(\mu\text{-}Cl)_2]$ in DMSO solution at 77 K.

Table 5
EPR parameters of $[\{CuCl(PyTn)\}_2(\mu\text{-}Cl)_2]$ (**2**)

Compound	Solid (298 K)		DMSO (77 K)			
	$g_\parallel$	$g_\perp$	$g_\parallel$	$g_\perp$	$A_\parallel$[a]	G
$[CuCl_2(PyTn)]$	2.2437	2.0483	2.2422	2.0499	143.49	4.85

[a] Units: $\times 10^{-4}$ cm^{-1}.

Table 6
Bonding parameters and orbital reduction parameters of $[\{CuCl(PyTn)\}_2(\mu\text{-}Cl)_2]$ (**2**)

Compound	α^2	β^2	γ^2	$K_\parallel$	$K_\perp$
$[\{CuCl(PyTn)\}_2(\mu\text{-}Cl)_2]$	0.6990	0.9768	0.8709	0.6828	0.6088

for an ionic environment, $g_\parallel$ is normally greater than 2.3 and for covalent environment, it is less than 2.3. The $g_\parallel$ value of this compound is found to be less than 2.3, which indicates covalent character of M–L bond [51].

The EPR parameters $g_\parallel$, $g_\perp$, $A_\parallel$ and the energy of the d–d transition band were used to evaluate the bonding parameters α^2, β^2 and γ^2, which may be regarded as measures of the in-plane σ bonds, in-plane π bonds and out-of-plane π bond covalency, respectively (Table 6) [52].

The value of the in-plane σ bonding parameter α^2 was calculated using the following expression [51,53]:

$$\alpha^2 = -A_\parallel/0.036 + (g_\parallel - 2.0023) + 3/7(g_\perp - 2.0023) + 0.04.$$

The orbital reduction factors, $K_\parallel = \alpha^2\beta^2$ and $K_\perp = \alpha^2\gamma^2$ were calculated using the following expressions:

$$K_\parallel^2 = (g_\parallel - 2.0023)E_{d\text{–}d}/8\lambda_0,$$
$$K_\perp^2 = (g_\perp - 2.0023)E_{d\text{–}d}/2\lambda_0,$$

where λ_0 is the spin–orbit coupling constant, with a value of -828 cm^{-1} for a copper(II) system.

According to Hathaway [49], for pure σ bonding, $K_\parallel \approx K_\perp \approx 0.77$, and for in-plane π bonding, $K_\parallel < K_\perp$, while for out-of-plane π bonding, $K_\perp < K_\parallel$. In this complex, it is observed that $K_\parallel > K_\perp$ which indicates the presence of significant out-of-plane π bonding. This is further confirmed by the bonding parameters α^2, β^2 and γ^2, which are less than 1.0, expected for pure ionic character of the bonds, and decrease with increasing covalent nature of the bonding.

Therefore, the evaluated α^2, β^2 and γ^2 values are consistent with both in-plane σ and out-of-plane π bonding.

The IR spectrum of PyTn in the 4000–370 cm^{-1} range presents bands attributable to thiazoline ring vibrations at 1641 (W_1), 991 (W_2), 904 (W_3), 773 (W_4), 677 (W_5), 649 (W_6), 615 (W_8), 575 (W_7) and 428 cm^{-1} (Γ_1) [54,20–27].

Moreover, characteristic bands of pyrazole ring vibrations are detected at 1514 (ν_6), 1392 (ν_{10}), 1350 (ν_{11}), 991 (ν_{17}), 914 (ν_{18}), 674 (ν_{19}) and 649 cm^{-1} (ν_{27}), and likewise, a typical band of N-substituted pyrazoles is found at 1263 cm^{-1} (ν_{12}) [55–57].

Table 7
Infrared bands (cm^{-1}) due to thiazoline and pyrazole rings vibrations of PyTn, $[CoCl_2(PyTn)_2]\cdot 2H_2O$ (**1**) and $[\{CuCl(PyTn)\}_2(\mu\text{-}Cl)_2]$ (**2**)

The IR spectra of $[CoCl_2(PyTn)_2]\cdot 2H_2O$ (**1**) and $[\{CuCl(PyTn)\}_2(\mu\text{-}Cl)_2]$ (**2**) in the 4000–370 cm^{-1} region show the presence of bands due to organic moiety rings vibrations, as it is shown in Table 7.

Other relevant bands in the spectrum of **1** are the ones assignable to symmetric and antisymmetric H_2O stretchings at 3495 and 3423 cm^{-1} [23,58]. Moreover, the librational mode of water molecules, due to rotational oscillations, is observed at 553 and 508 cm^{-1} [59], whereas the band attributable to HOH bending and a third librational mode band are hindered by the bands due to W_1 and Γ_1 vibrations.

In the low frequency (500–150 cm^{-1}) region, the C_i symmetry of the cobalt(II) complex predicts the appearance of three bands assignable to metal–ligand stretching vibrations. Thus, the far-infrared spectrum of this complex shows three bands due to this type of vibrations at 303, 283 and 210 cm^{-1}. From these, the band at 303 cm^{-1} could be assigned to ν(Co–Cl) [22,60], the band at 283 cm^{-1} may correspond to $\nu(Co\text{–}N_{Pyrazole})$, according to the literature data [60], while the band at 210 cm^{-1} can be tentatively attributed to ν $(Co\text{–}N_{Thiazoline})$ [21,25].

In the case of the dimer **2**, the appearance of four bands is observed, from which the one at 388 cm^{-1} may be attributed to $\nu(Cu\text{–}N_{Pyrazole})$ vibration [61], whereas the band at 319 cm^{-1} could be assigned to $\nu(Cu\text{–}Cl_{terminal})$ [27,59,62–64]. The band at 295 cm^{-1} may comprise the two $\nu(Cu\text{–}Cl_{bridging})$ vibrations [27,59,62–64], and finally, $\nu(Cu\text{–}N_{Thiazoline})$ vibration is found at 249 cm^{-1} [24].

4. Supplementary material

CCDC Nos. 259316, 272078 and 259315 corresponding to PyTn, $[CoCl_2(PyTn)_2]\cdot 2H_2O$ and $[\{CuCl(PyTn)\}_2(\mu\text{-}Cl)_2]$ contain the supplementary crystallographic data

for this paper. These data can be obtained free of charge via www.ccdc.cam.ac.uk/conts/retrieving.html (or from the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK; fax: +44 1223 336 033; e-mail: deposit@ccdc.cam.ac.uk).

2 mmol) in chloroform. The reaction mixture was refluxed for 20 min and cooled. Deep brown shining microcrystals of compound **1** separated out, which were filtered, washed thoroughly with ether and dried over P_4O_{10} in vacuo. X-ray quality single crystals were grown from a solution of chloroform in 6 days.

*2.2.2. Synthesis of [Mn(BpychTsc)$_2$] · H_2O (**2**)*

Manganese acetate (0.2449 g, 1 mmol) dissolved in 20 ml ethanol and HBpychTsc (0.676 g, 2 mmol) dissolved in 30 ml hot ethanol were mixed and stirred for 3 h. The yellow colored solid, which separated on cooling, were filtered, washed with hot ethanol and ether and dried over P_4O_{10} in vacuo.

*2.2.3. Synthesis of [Mn(BpyphTsc)$_2$] (**3**)*

Manganese sulphate (0.169 g, 1 mmol) dissolved in a mixture of hot water and methanol and HBpyphTsc (0.664 g, 2 mmol) dissolved in 30 ml hot methanol were mixed and stirred for 3 h. The yellow colored solids, which separated, were filtered, washed with hot ethanol and ether and dried over P_4O_{10} in vacuo.

2.3. Physical measurements

Elemental analyses were carried out using a Heraeus elemental analyzer at CDRI, Lucknow, India. Molar conductance measurements of the complexes of the solutions in dimethylformamide (10^{-3} M) at room temperature were measured using a digital conductivity meter. The magnetic susceptibility measurements were carried out at Indian Institute of Technology, Roorkee, India, at room temperature in the polycrystalline state on a PAR model 155 vibrating sample magnetometer at 5 K Oersted field strength.

The IR spectra were recorded on a Shimadzu DR 8001 series FTIR instrument using KBr pellets. The solid-state reflectance spectra of the ligand and the complexes were recorded on Ocean Optics, Inc. SD2000 Fibre Optic Spectrometer. The EPR spectra of the complexes were recorded in a Varian E-112 Spectrometer using TCNE as the standard at SAIF, IIT, Bombay, India.

2.4. X-ray crystallography

Single crystals of compound **1** for X-ray analysis were grown by slow evaporation of the complex in chloroform/methanol mixture. A deep brown shining crystal of compound **1** was mounted on a glass fiber with epoxy cement. The crystallographic data and structure refinement parameters for the compound are given in Table 1. The data were collected using a Bruker Smart Apex CCD diffractometer equipped with graphite monochromated Mo Kα ($\lambda = 0.71073$ Å) radiation at temperature 293 K. The trial structure was solved using SHELXS-97 and refinement was carried out by full-matrix least squares on F^2 (SHELXTL) [7]. Molecular graphics employed was ORTEP-III and PLATON [8].

3. Results and discussion

3.1. Synthesis of complexes

Colors, elemental analyses and stoichiometries of the three Mn(II) complexes are presented in Table 2. All the

[1] Molar conductivity of 10^{-3} M solution, in ohm^{-1} cm^2 mol^{-2}.

compounds are soluble in polar organic solvents like chloroform, DMF, DMSO, etc. The three complexes synthesized using the three ligands have the same stoichiometry $[ML_2]$, i.e. a structure in which two anionic ligands are coordinated to the Mn(II) ion.

Conductivity measurements of the three complexes in DMF (10^{-3} M) indicate that all complexes are nonelectrolytes in DMF. The magnetic moments of the three Mn(II) complexes were calculated from the magnetic susceptibility measurements and using the diamagnetic corrections. The magnetic moments of the three complexes $[Mn(BpypTsc)_2]$, $[Mn(BpychTsc)_2]\cdot H_2O$, and $[Mn(BpyphTsc)_2]$ are 6.01, 5.94 and 5.79 B.M., respectively, indicating the presence of five unpaired electrons and hence these are high spin complexes [9,10].

3.2. Crystal structure of $[Mn(BpypTsc)_2]$

The single crystal X-ray diffraction studies indicate a distorted octahedral geometry for the compound. A list of selected bond parameters of the Mn complex (1) is presented in Table 3. The Mn(II) center is coordinated in an N_4S_2 meridional manner by two monodeprotonated ligand moieties using pairs of *cis* pyridyl-*N*, *trans* azomethine-*N* and *cis* thiolate-*S* atoms and form four five membered chelate rings. Of these, sulfur involving rings are somewhat planar and slightly puckered, while the other two are almost planar. From the bond angles, it is observed that the coordination geometry is quite far from a perfect octahedron. The dihedral angle formed by the mean planes of the bicyclic chelate systems of each of the ligands is 86.36°. The planes containing Mn1, S1, N5, N1, S2 and Mn1, N2, N5, N6, S2 are deviated from the mean plane by −0.7280(1) Å (N5) and −0.2915(1) Å (N6), respectively, whereas Mn1, S1, N2, N1, N6 plane deviated from the mean plane by 0.1392(1) Å (Mn1). However, the N5–Mn1–S2 angle is only 148.0(1) Å. Fig. 2 shows the molecular structure of the compound along with atom numbering scheme.

On coordination to the metal ion, the ligand undergoes structural reorientation as the configuration about the N2–C6 changes from Z to E. This suggests that a possible rotation about the azomethine double bond occurs on coordination and pyridyl nitrogen is now in a position to coordinate as NNS manner. The two thiolate sulfur atoms are observed to be deviated farthest from the central Mn(II) atom, at distances of 2.523(2) Å {Mn1–S1} and 2.499(2) Å {Mn1–S2}, while the Mn–N bonds are observed

Table 3
Selected bond lengths and angles of the compound **1**

Bond lengths (Å)		Bond angles (°)	
Mn(1)–N(2)	2.227(6)	N(2)–Mn(1)–N(6)	155.5(2)
Mn(1)–N(1)	2.307(6)	N(2)–Mn(1)–N(5)	95.2(2)

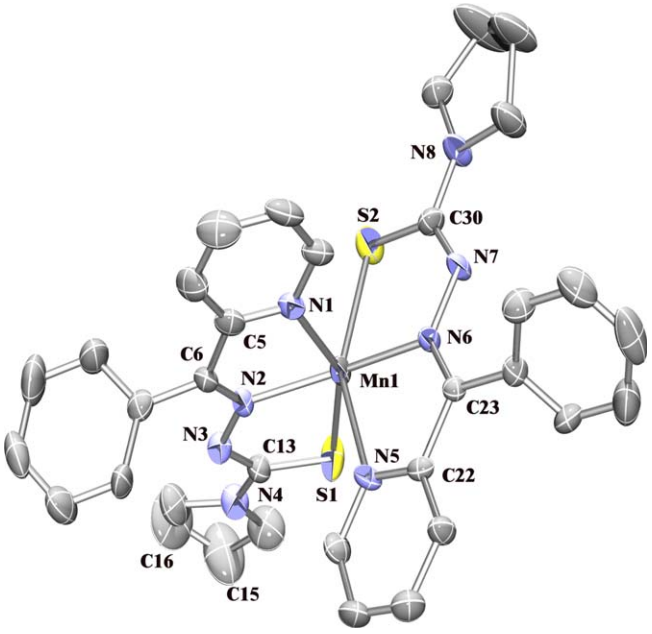

Fig. 2. ORTEP diagram for the compound $Mn(BpypTsc)_2$ (**1**) in 50% probability ellipsoids. Hydrogen atoms are omitted for clarity.

at an average distance of 2.3 Å. The Mn–$N_{azomethine}$, Mn–N_{py}, and Mn–S bond lengths are comparable with the previously reported manganese complexes [11,12]. These comparatively larger bond lengths are indicative of weak bonding of the ligand to the metal. The C13–N3–N2 bond angle reduced from 121.1(2)° of metal free ligand to 113.1(6)° in the complex as a consequence of bonding. Coordination lengthens the thiosemicarbazone moiety's C13–S1 bond length by 0.024(8) Å and C30–S2 by 0.046(8) Å. The decrease in bond length of N3–C13 and N7–C30 by 0.024(10) and 0.019(10) Å, respectively, on coordination confirms the deprotonation after enolization. Ring puckering analysis shows that the N4 containing pyrrolydine ring is closest to a twist form on C15 and C16, and N8 containing ring is in a half chair form [13]. Interestingly, there are no classic hydrogen bonds seen in crystal structure. However, some weak hydrogen bonding and C–H...π interactions including that between metal containing chelate rings Cg(1) and Cg(2) with pyridyl ring protons (Table 4) are seen in the crystal lattice. The orientation in the close packing (Fig. 3) is in such a way that the symmetry related molecules are reinforced by very weak π...π interactions involving phenyl and pyridyl rings (Table 4).

3.3. Infrared spectra

The infrared spectral assignments (cm^{-1}) of ligands HBpypTsc, HBpychTsc and HBpyphTsc and their Mn(II) complexes are presented in Table 5. The bonding sites of the thiosemicarbazones to the metal ion have been deduced by comparing the spectra of the complexes with the spectra of the ligands.

The *ν*(C=N) bands of thiosemicarbazones are found to be shifted to higher frequencies in **2** and **3** and to lower frequency in **1** indicating the coordination via the azomethine nitrogen [14–16]. The involvement of this nitrogen in bonding is also supported by a shift in *ν*(N–N) to higher frequencies. The appearance of a new band at 1450 cm^{-1} in the IR spectra of compound **1** and bands at ≈1510 cm^{-1} in compounds **2** and **3** due to the newly formed *ν*(N=C) support the above observation. The bands observed at ca. 1370 and 830 cm^{-1}, which are assigned to *ν*(C=S) and *δ*(C=S) vibrations in the free ligands are shifted to lower wavenumbers in the complexes suggesting the change of bond order and strong electron-delocalization. This large negative shift of the *ν*(C=S) band indicates the coordination of the ligand via the thiolate sulfur to the manganese atom. The coordination of the nitrogen atom of the pyridine ring to the Mn(II) ion in the complexes is indicated by the shifting of the pyridine ring vibrations of the ligands to higher frequencies in their manganese complexes [17–19]. In the far IR spectra of the complexes, the bands at ca. 470, 424 and 310 cm^{-1} are assigned to the *ν*(Mn–$N_{azomethine}$), *ν*(Mn–S) and *ν*(Mn–N_{py}) modes [20] respectively.

3.4. Electronic spectra

The diffuse reflectance spectra of the three Mn(II) complexes were recorded in MgO matrix and the spectral data are given in Table 6. The ground state of the high spin octahedrally coordinated Mn^{2+} ion is $^6A_{1g}$. Since there are no other terms of sextet spin multiplicity, all the d–d transitions in high spin d^5 complexes are not only Laporte forbidden but also spin forbidden [21]. The d^5 configuration gives rise to the ^4G, ^4D and ^4P excited states. The diffuse reflectance spectra of the Mn(II) complexes exhibit weak absorption bands at ca. 18 000, 23 000 and 25 974 cm^{-1}. The three lowest energy bands are assigned to $^6A_{1g} \rightarrow {}^4T_{1g}(G)$, $^6A_{1g} \rightarrow {}^4T_{2g}(G)$ and $^6A_{1g} \rightarrow {}^4Eg(G)$, $^4A_{1g}(G)$ transitions. The pair of transitions $^6A_{1g} \rightarrow {}^4Eg(G)$, $^4A_{1g}(G)$, are degenerate in octahedral symmetry whose energies are given by $10B + 5C$. These assignments are obtained by fitting the observed spectrum to the Tanabe Sugano diagram [22]. The energies corresponding to the above transitions and the values of Racah parameters *B* and *C* and *D*q calculated are given in Table 6. The extent of covalence in the metal–ligand bond may be evaluated from the electronic spectrum by estimating $\beta = B/B_0$. The value of B_0 for Mn^{2+} is 860 cm^{-1} [23]. The absorption bands observed for $n \rightarrow \pi^*$ and $\pi \rightarrow \pi^*$ transitions of the ligands are slightly shifted in the complexes.

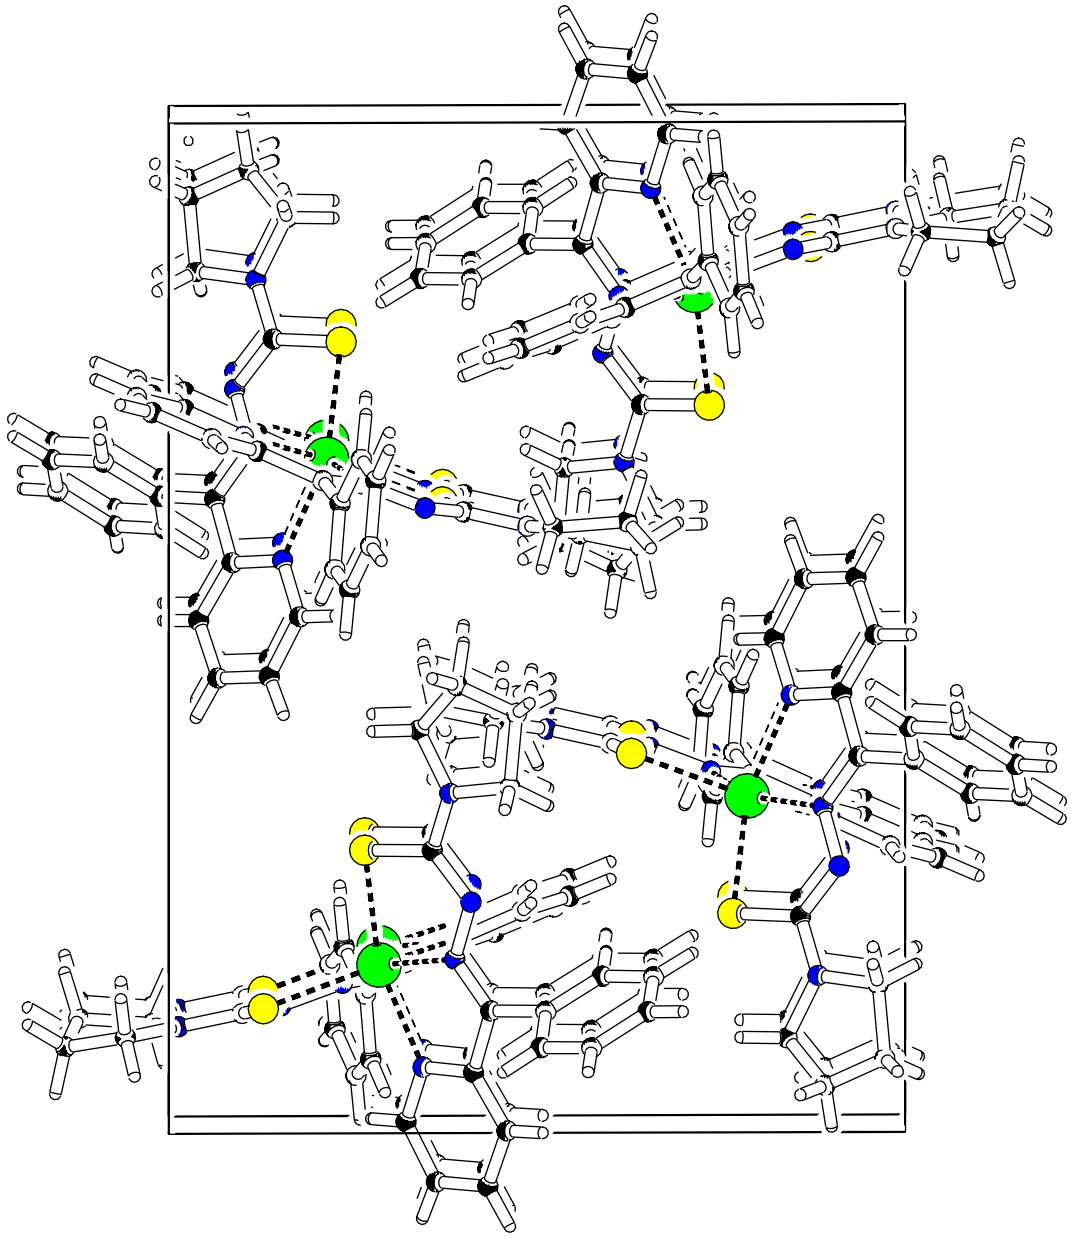

Fig. 3. Packing diagram of compound **(1)** viewing along the '*a*'-axis.

3.5. Electron paramagnetic resonance spectra

The spin Hamiltonian used to represent the EPR spectra of Mn(II) is given by $\mathscr{H} = g\beta Hs + D[S_z^2 - S(S+1)/3] + E(S_x^2 - S_y^2)$, where H is the magnetic field vector, g is the spectroscopic splitting factor, β the Bohr magneton, D is the axial zero field splitting term, E is rhombic zero field splitting parameter and S is the electron spin vector [24]. If D and E are very small compared to $g\beta Hs$, five EPR transitions are expected viz., $|+5/2> \leftrightarrow |+3/2>$, $|+3/2> \leftrightarrow |+1/2>$, $|+1/2> \leftrightarrow |-1/2>$, $|-1/2> \leftrightarrow |-3/2>$ and $|-3/2> \leftrightarrow |-5/2>$.

In the X band, CW-EPR spectra of the polycrystalline samples of the three manganese(II) complexes, a broad signal is observed with g value ~2.19. In polycrystalline samples, at room temperature, Mn(II) complexes give very broad signals, which are due to dipolar interactions and enhanced spin lattice relaxation [25].

The EPR spectra of the three compounds in DMF solution at 298 K are almost similar exhibiting a six line manganese hyperfine pattern centered at $g = 2.015$, 1.993 and 2.008, respectively. A sextet is observed in the spectra of the compound **2** and **3** in solution at room temperature due to electron spin nuclear spin coupling. This hyperfine spectrum of six lines corresponds to $m_I = \pm 5/2$, $\pm 3/2$, $\pm 1/2$, resulting from allowed transitions ($\Delta m_s = \pm 1$, $\Delta m_I = 0$). These hyperfine lines are not clearly resolved in the spectrum of compound **1**, due to poor glass formation.

In addition to this a pair of low intensity forbidden lines lying between each of the two main hyperfine lines is

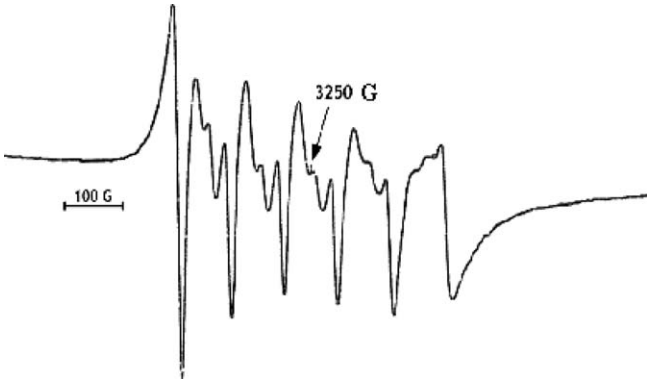

Fig. 4. EPR spectrum of compound **2** in DMF at 77 K.

observed in the frozen solution spectra of the complexes **2** (Fig. 4) and **3** in DMF at 77 K. The forbidden lines in the spectrum arise due to the mixing of the nuclear hyperfine levels by the zero-field splitting factor of the Hamiltonian [26,27]. The ^{55}Mn hyperfine coupling constant for the complexes are estimated to be approximately $A = 270$, 253 and 247 MHz, respectively. The average separation of the forbidden hyperfine lines in the spectrum is approximately 70 MHz.

The observed g values are very close to the free electron spin value of 2.0023 indicating the absence of spin–orbit coupling in the ground state, $^6A_1$. It is seen that the A values are somewhat lower than those of the pure ionic compounds. The A_{iso} values are consistent with the octahedral coordination [28]. Based on the spectral studies an octahedral structure can be assigned to the Mn(II) complexes.

4. Supplementary information

Crystallographic data for the structural analysis has been deposited with the Cambridge Crystallographic Data center, CCDC 222664 for compound Mn(BpypTsc)$_2$ (**1**). The data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html (or from Cambridge Crystallographic Data Centre (CCDC), 12 Union Road, Cambridge CB2 1EZ, UK; fax: +44 0 1223-336033; e-mail: deposit@ccdc.cam.ac.uk).

IR spectra were recorded on a Pye Unicam SP3-300 spectrophotometer over the spectral range 4000–200 cm^{-1} in the solid state using KBr/CsI Pellets. ^{1}H, ^{19}F and ^{13}C NMR spectra were recorded on Jeol JNM-400 NMR spectrometer using TMS, CF_3COOH and $CDCl_3$ as references, respectively. Antimony was determined according to a literature method [11]. Molecular weights were determined cryoscopically in nitrobenzene using a Beckman thermometer of ±0.01 accuracy. The molar conductance of 10^{-3} M solution of the compounds was determined at 25 °C with a Khera DC610 Digital conductivity meter in methanol.

The FAB mass spectra were recorded on Jeol SX 102 mass spectrometer using DA-6000 data analysis system. Argon was used as bombarding gas at 6 kV, 10 mA. The accelerating voltage was kept at 10 kV. *m*-nitrobenzyl alcohol (NBA) was used as matrix.

2.2. Representative synthetic procedures

2.2.1. Synthesis of $(C_6F_5)_2SbCH_3$

A solution of iodomethane (2.839 g, 0.02 mol) in dry diethyl ether was added drop wise to magnesium turnings (0.486 g, 0.02 mol) embedded in diethyl ether under nitrogen atmosphere at 0 °C. The resulting Grignard solution was cooled upto −10 °C and a solution of $(C_6F_5)_2SbCl$ (9.826 g, 0.02 mol) in dry diethyl ether was slowly added with constant stirring. The mixture was stirred for an additional 1 h at room temperature and subsequently refluxed for 1 h more. The mixture was then cooled to 0 °C and treated with ice water containing NH_4Cl and subsequently followed by the addition of 4 N HCl (1 ml) and stirred to make the solution acidic. The ether layer was separated and the aqueous brownish layer was further extracted with chloroform. The organic layers were then mixed and kept over anhydrous Na_2SO_4 overnight. The organic layer was filtered and the filtrate was distilled on an oil-bath to remove the solvent. The residue was crystallized by petroleum–ether (40–60 °C) to afford pale yellow crystals of $(C_6F_5)_2Sb(CH_3)$ (**1**), yield 6.87 g (73%), m.p. 98–99 °C.

2.2.2. Synthesis of $(C_6F_5)_2Sb(C_6H_4CH_3$-*p*)

p-Bromotoluene (3.421 g, 0.02 mol), dissolved in dry diethyl ether was added drop wise to magnesium turnings (0.486 g, 0.02 mol) embedded in diethyl ether under nitrogen atmosphere at 0 °C. This Grignard solution was cooled upto −10 °C and a solution of $(C_6F_5)_2SbCl$ (9.826 g, 0.02 mol) in dry diethyl ether was slowly added with constant stirring. The mixture was stirred for 2 h at room temperature and subsequently refluxed for 1 h more. The mixture was then cooled to 0 °C and treated with ice water containing NH_4Cl and subsequently followed by the addition of 4 N HCl (1 ml) and stirred to make the solution acidic. The ether layer was separated and the aqueous brownish layer was further extracted with chloroform. The organic layers were then mixed and kept over anhydrous Na_2SO_4 overnight. The organic layer was filtered and the filtrate was distilled on an oil-bath to remove the solvent. The residue was crystallized by petroleum–ether (40–60 °C) to afford $(C_6F_5)_2Sb(C_6H_4CH_3$-*p*) (**2**), yield 7.548 g (69%), m.p. 93 °C.

2.2.3. Synthesis of $(C_6F_5)_2Sb(C_6H_5)$

A solution of bromobenzene (3.140 g, 0.02 mol) in dry diethyl ether was added drop wise to magnesium turnings (0.486 g, 0.02 mol) embedded in diethyl ether under nitrogen atmosphere at 0 °C. The resulting Grignard solution was cooled upto −10 °C and a solution of $(C_6F_5)_2SbCl$ (9.826 g, 0.02 mol) in dry diethyl ether was slowly added with constant stirring. The mixture was stirred for an additional 1 h at room temperature and subsequently refluxed for 1 h more. The mixture was then cooled to 0 °C and treated with ice water containing NH_4Cl and subsequently followed by the addition of 4 N HCl (1 ml) and stirred to make the solution acidic. The ether layer was separated and the aqueous brownish layer was further extracted with chloroform. The organic layers were then mixed and kept over anhydrous Na_2SO_4 overnight. The organic layer was filtered and the filtrate was distilled on an oil-bath to remove the solvent. The residue was crystallized by petroleum–ether (40–60 °C) to afford $(C_6F_5)_2Sb(C_6H_5)$ (**3**), yield 7.035 g (66%), m.p. 89–90 °C.

Similarly the $(C_6F_5)Sb(C_6H_5)_2$ (**4**) was prepared by using Grignard reagent (C_6H_5MgBr) and $(C_6F_5)SbCl_2$.

$(C_6F_5)_2Sb(C_6H_5)$ and $(C_6F_5)Sb(C_6H_5)_2$ were also prepared by the reaction of C_6F_5MgBr with $C_6H_5SbCl_2$ and $(C_6H_5)_2SbCl$, respectively, and the yields were 47% and 26%, respectively. These compounds were synthesized in the same reaction conditions as described earlier for other compounds.

2.2.4. Reaction of $(C_6F_5)_2Sb(C_6H_5)$ and Cl_2 gas

Dry chlorine gas (generated by reaction of $KMnO_4$ and conc. HCl) was bubbled in a solution of $(C_6F_5)_2Sb(C_6H_5)$ (5.33 g, 10 mmol) in petroleum–ether (60–80 °C) at 0 °C under moisture free and nitrogen atmosphere with constant stirring. White precipitate was started to settle down and the bubbling of Cl_2 gas was stopped as soon as pale yellow colour in the solution persist and the reaction mixture was further stirred for 30 min at room temperature, afterwards the solvent was filtered off. The precipitate was washed thrice with petroleum–ether (60–80 °C) to remove unreacted $(C_6F_5)_2Sb(C_6H_5)$. The precipitate was characterized as $(C_6F_5)_2(C_6H_5)SbCl_2$ (**9**), m.p. 207 °C, yield 4.89 g (81%).

Similarly the dichlorides of $(C_6F_5)_2Sb(CH_3)$, $(C_6F_5)_2Sb(C_6H_4CH_3$-*p*) and $(C_6F_5)Sb(C_6H_5)_2$ were obtained.

2.2.5. Reaction of $(C_6F_5)_2Sb(C_6H_5)$ and liquid Br_2

Solution of liquid bromine (1.6 g, 10 mmol) in petroleum–ether (60–80 °C) was added drop wise into a precooled (0 °C) solution of $(C_6F_5)_2Sb(C_6H_5)$ (5.3 g, 10 mmol) in petroleum–ether (60–80 °C) (100 ml) under nitrogen atmosphere with constant stirring. After each drop of addition of liquid bromine, yellow colour disappeared, as soon as the colour of bromine persists, the addition was stopped.

After allowing the temperature to rise slowly to room temperature the petroleum–ether was distilled (50 ml) and solution was cooled overnight to obtain a solid mass. The solid mass was washed thrice with petroleum–ether (60–80 °C) to remove unreacted $(C_6F_5)_2Sb(C_6H_5)$. The residue was characterized as $(C_6F_5)_2(C_6H_5)SbBr_2$ (**10**), m.p. 193–194 °C, yield 5.27 g (76%).

Similarly the dibromides of $(C_6F_5)_2Sb(CH_3)$, $(C_6F_5)_2$-$Sb(C_6H_4CH_3$-*p*) and $(C_6F_5)Sb(C_6H_5)_2$ were obtained.

3. Results and discussion

In our previous publications, we have reported the synthesis of mono- and bis(pentafluorophenyl)antimony(III) chlorides and their oxidative-addition and displacement reactions [5]. So, continuing our interest in the synthesis, reactions and spectroscopic studies of pentafluorophenylantimony derivatives, in the present investigation some new mixed triorganoantimony(III) compounds bearing pentafluorophenyl and hydrocarbon based organic groups, i.e., methyl and aryl, were synthesized by Grignard reaction using methyl- or arylmagnesium halide and pentafluorophenyl antimony(III) chloride in diethylether as shown below (Scheme 1).

Compounds **3** and **4** were also synthesized alternatively by the reaction of pentafluorophenylmagnesium bromide and arylantimony halide (Scheme 2).

It has been observed that earlier method (Scheme 1) is more satisfactory and the yields of the products were high and also the reactions proceeded more smoothly.

The oxidative-addition reactions of these mixed triorganoantimony(III) compounds were also studied and it has been observed that the dihalides could be formed very easily like other triorganoantimony(III) compounds by passing dry chlorine gas or adding a solution of liquid Br_2 in petroleum–ether to a solution of mixed triorganoantimony(III) compounds in petroleum–ether, respectively (Scheme 3).

The molar conductance values of the compounds were evaluated in methanol (10^{-3} M solution), which were in the range of 15–45 Ω^{-1} mol^{-1} cm^2, showing their non-conducting behaviour in solution [12]. The molecular weights and thus van't Hoff factor '*i*' (0.98–1.02) determined cryoscopically in nitrobenzene showed their monomeric nature.

$$nRMgX + (C_6F_5)_{3-n}SbCl_n \longrightarrow (C_6F_5)_{3-n}SbR_n$$

n = 1, X = I, R = CH_3 **1**, X = Br, R = $C_6H_4CH_3$-*p* **2**, C_6H_5 **3**

Scheme 3.

The elemental analysis were also found satisfactory and within permissible limits (Table 1).

3.1. Infrared spectra

IR spectra of the compounds **1**–**12** were recorded in solid state using KBr/CsI pellets in the range of 4000–200 cm^{-1}. Some of the characteristic absorption bands of the synthesized mixed pentafluorophenylantimony(III and V) compound are given in Table 2.

In all derivatives characteristic ν(C–C) bands of C_6F_5 group were appeared at ~1640 (s), 1515 (vs) and 1480 (vs) cm^{-1} as well as ν(C–F) absorption band at ~1380 (s), 1275 (m), 1080 (vs) and 980 (vs) cm^{-1} and comparable to reported values [13].

In compounds **1**, **2** and **5**–**8** aliphatic ν(C–H) stretching vibrations for CH_3 group appeared at ~2900 cm^{-1} and δ(C–H) bending vibrations at 1415–1390 cm^{-1}.

The C_6H_5 group in compounds **2**–**4** and **7**–**12** showed aromatic ν(C–H) stretching vibrations at ~3040-3000 cm^{-1} and ring stretching vibrations ν(C–C) at ~1440 (m) cm^{-1}. In these derivative ring stretching vibrations due to C_6H_5 (except at ~1440 cm^{-1}) [14] and C_6F_5 (except at ~1645 cm^{-1}) [13] groups overlapped at ~1520–1470 cm^{-1} due to close proximities of these absorption bands, hence could not be separately assignable. Further the characteristic out of plane (C–H) bending vibrations δ(C–H) appeared at ~735 (m) cm^{-1}, gave an additional information for the formation of these compounds.

The spectra of all the chlorides show a band at 332 ± 7 cm^{-1} and the spectra of all the bromides show a strong band at 232 ± 5 cm^{-1}, which may be assigned to antimony-chlorine and -bromine stretching vibrations, respectively.

3.2. ^1H NMR spectra

The ^{1}H NMR spectra of compounds **1**–**12** were recorded in $CDCl_3$ using TMS as the reference at 400 MHz instrument. The chemical shift values are tabulated in Table 3.

The signals for CH_3 protons in compound **1**, **5** and **6** appeared at δ 2.65 ± 0.08 ppm as singlet and in compounds **2**, **7** and **8** appeared at δ 2.31 ± 0.04 ppm as singlet. The aryl protons of the compounds **2**–**4** and **7**–**12** appeared at δ 7.15–7.80 ppm as multiplet and do not allow any clear interpretation.

12	$(C_6F_5)(C_6H_5)_2SbBr_2$	3040, 3015	1632 (s), 1515 (vs), 1488 (vs), 1430 (m)	766 (m), 731 (w)	1391 (m), 1286 (s), 1092 (vs), 994 (vs)	608 (m)	237

In these mixed triorganoantimony(V) halides **5**–**12**, due to halogens no significant shifting was observed in proton NMR signals compared to parent compounds as only one signal due to methyl protons is observed which indicates that organyl functionalities are present in one plane and halogens acquire apical position. Thus, it may be assigned that these compounds bear trigonal bipyramidal structure.

3.3. ^{19F}NMR spectra

All these compounds showed invariably the signals due to $F_{2,6}$, F_4 and $F_{3,5}$ at δ −121.00 to −129.91 ppm, −147.21 to −150.20 ppm and −157.63 to −160.90 ppm, respectively. The resonance of F_4 was easily recognizable in each spectrum being half of the intensity compared to $F_{2,6}$ and $F_{3,5}$. The F_4 signal appeared as triplet due to $F_{3,5}$ coupling. The $F_{2,6}$ signals appeared as doublet in all these derivatives and the $F_{3,5}$ signals as triplet. The $F_{3,5}$ signals appeared at higher field as compared to the $F_{2,6}$ and F_4 chemical shift, indicating that the electron density has been withdrawn from these centers ($F_{2,6}$ and F_4) to antimony and attached halogens, which may be attributed to a combined effect of electron donor abilities of pentafluorophenyl ring [15] as well as electrophilic nature of the antimony in these compounds. This observation is in accordance to previous studies that the C_1 carbon of perfluorinated benzene ring feels high electron density due to diminished inductive effect of fluorine atom and donation of electron density from the unshared p electron of fluorine to the π system of the ring (p–π interaction) [7,16]. A marginal yet distinct

Table 3

6		2.68 (s)		−157.63 (t) [19.53]	−128.80 (d) [20.53]	−147.64 (t)
7	7.16–7.60 (m)	2.27 (s)		−159.91 (t) [19.53]	−123.22 (d) [20.54]	−149.81 (t)
8	7.15–7.56 (m)	2.30 (s)		−159.71 (t) [19.53]	−122.71 (d) [20.53]	−149.61 (t)
9	7.28–7.60 (m)			−159.22 (t) [19.54]	−125.90 (d) [20.55]	−149.82 (t)
10	7.30–7.65 (m)			−159.12 (t) [19.54]	−124.78 (d) [20.54]	−149.63 (t)
11	7.25–7.80 (m)			−159.13 (t) [19.53]	−123.82 (d) [20.53]	−148.91 (t)
12	7.30–7.75 (m)			−158.82 (t) [19.53]	−122.91 (d) [20.53]	−149.73 (t)

effect on chemical shift has been noticed due to electronegativity difference of halogens (Cl, Br) attached to antimony. The additive effects of halogens and pentafluorophenyl rings seem to be negligible.

3.4. ^{13}C NMR spectra

In compounds **1** and **2**, ^{13}C signals for CH_3 appeared at δ 27.6 and 21.47 ppm, respectively. Chemical shifts for C_6F_5 group in compound **1**, appeared as very weak signals at δ 140.4 (C_1), 153 ($C_{2,6}$), 143.7 ($C_{3,5}$) and 149 (C_4) ppm, which indicate that C_1 position is more shielded than $C_{3,5}$, $C_{2,6}$ or C_4 centers and the order of chemical shift is $C_1 > C_{3,5} > C_4 > C_{2,6}$.

In compound **2**–**4** the ^{13}C signals due to C_6F_5 group were not prominent thus could not be assigned and only signals for C_6H_5 group were assigned which appeared at δ 129.1–146.6 ppm.

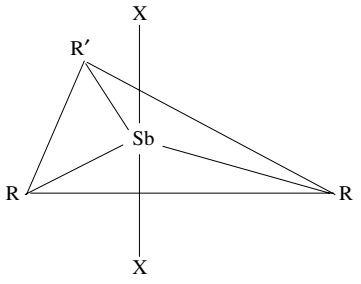
3.5. Mass spectrometry

The FAB mass spectra have been measured for two compounds $(C_6F_5)_2Sb(C_6H_4CH_3\text{-}p)$ (**2**) and $(C_6F_5)_2Sb(C_6H_5)$ (**3**). The FAB mass spectrum of compound **2** showed parent ion peak at m/z 546 (19.1%) for $[(C_6F_5)_2Sb(C_6H_4CH_3)]^+$, but the highest mass fragment was $[(C_6F_5)Sb(C_6H_4CH_3)]^+$ at m/z 379 (100%). Other important peaks at m/z 455 (18.7%), 288 (42.3%) and 212 (32.6%) corresponds to $[(C_6F_5)_2Sb]^+$, $[(C_6F_5)Sb]^+$ and $[(C_6H_4CH_3)Sb]^+$, respectively.

The parent ion peak in the FAB spectrum of compound **3** was $[(C_6F_5)_2Sb(C_6H_5)]^+$ at m/z 532 (36.1%). Two other important peaks for $[(C_6F_5)Sb(C_6H_5)]^+$ at m/z 365 (22.3%) and $[(C_6F_5)Sb]^+$ m/z 288 (53.4%) were also appeared in the spectrum.

4. Conclusion

Hydrocarbon based Grignard reagent found more favourable for the synthesis of such mixed triorganoantimony(III) derivatives and the reactions of these derivatives with halogens took place in similar manner as in case of other triorganoantimony(III) derivatives (Fig. 1).



$R \neq R' = C_6F_5$, CH_3, $C_6H_4CH_3\text{-}p$, C_6H_5 and X = Cl or Br

Fig. 1. Configuration of mixed triorganoantimony(V) halides.

Spectroscopic studies revealed that the pentavalent compounds **5**–**12** bear trigonal bipyramidal structure having organyl functionalities in one plane.

Acknowledgements

One of the authors (SKS) is thankful to DRDO, New Delhi for the award of Senior Research Fellowship. Thanks are also due to Mr. N. Ahmed of IIT, Kanpur for extending NMR facilities and RSIC, Lucknow for providing Mass spectra.

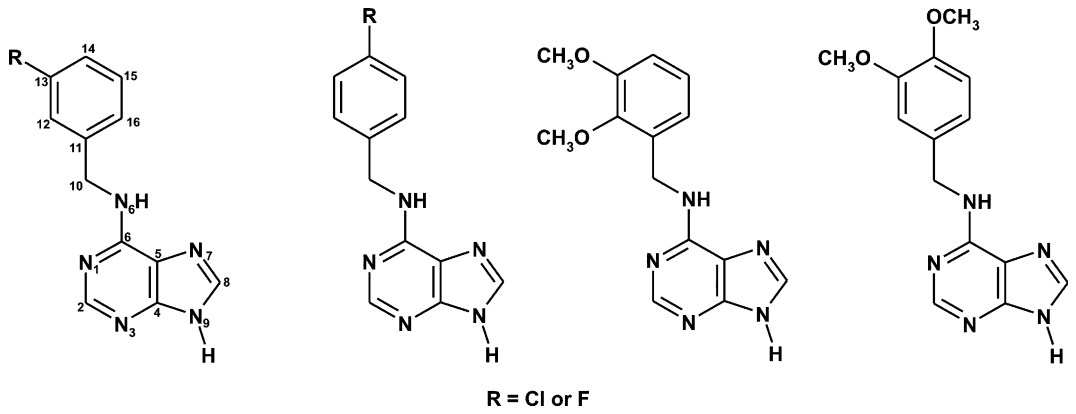

Scheme 1.

be increased by coordination of cytokinin-derived compounds to a suitable transition metal. Recently, we have focused our interest on the preparation of Pt(II), Pd(II), Cu(II), Ni(II) and Co(II) complexes with the above-mentioned organic derivatives [4–8].

To date, only a few of cobalt complexes with purine and adenine derivatives as ligands have been structurally characterized and deposited at Cambridge Crystallographic Data Centre (CCDC) [9]. The coordination variability both the purine and adenine moieties, relating to their four or five nitrogen-donor atoms, can be shown, among others, on the following examples. In 1D-polymeric chain octahedral cobalt complexes of formulae $[Co^{II}(\mu\text{-ox})(H_2O)(purH\text{-}N9)]_n$, $[Co^{II}(\mu\text{-ox})(H_2O)(purH\text{-}N9)_{0.76}(adeH\text{-}N9)_{0.24}]_n$ (ox = oxalate(2−), purH = purine, adeH = adenine), purine and/or adenine are coordinated to cobalt through the *N*9 atom of an imidazole ring [10]. The same manner of the ligand coordination was found in monomeric complexes *cis*-$[Co^{III}(ade\text{-}N9)Cl(en)_2]Br \cdot H_2O$ (en = 1,2-diaminoethane) [11] and $(adeH^+)_2[Co^{II}(H_2O)_4(adeH\text{-}N9)_2](SO_4)_2 \cdot 6H_2O$ [12]. On the other hand, the adenine can be also bound via *N*3 as determined in $\{[Co^{II}(\mu\text{-ox})(H_2O)(adeH\text{-}N3)] \cdot 2(adeH) \cdot (H_2O)\}_n$ [10]. From general point of view, other nitrogen atoms of purine (i.e., *N*1 and *N*7) and adenine (i.e., *N*1, *N*6 and *N*7) derivatives can be also used for coordination to cobalt. This was found in some Co(III) complexes which X-ray structures were determined. For example, the coordination through *N*7 was found in $[Co(acac)_2(NO_2)(tca\text{-}N7)] \cdot H_2O \cdot DMF$ (acacH = acetylacetone, tca = tricanthine) [13], $[Co(acac)_2(NO_2)(1,9\text{-dimethyl-ade}H^+\text{-}N7)][Co(acac)_2(NO_2)_2]$ [14] and $[Co(3\text{-benzyl-ade-}N7)(dmg)_2(dmp)] \cdot H_2O \cdot EtOH$ (dmg = dimethylglyoximate, dmp = dimethylphosphonate) [15]. Moreover, in the tetrahedral $[Co^{II}(ade\text{-}N6,N7)Cl(H_2O)] \cdot H_2O$ complex, adenine acts probably as a bidentate ligand through *N*6 and *N*7 atoms [16]. Unfortunately, the conclusion relating to a mode of coordination in the latter complex is not supported by results following from a single crystal X-ray analysis and was deduced from IR data only.

In our previous work, we have published the first preparation and biological activity of mononuclear tetrahedral high-spin Co(II) complexes bearing the cytokinin-derived compounds as ligands [8]. Herein, we describe the preparation, characterization and cytotoxicity of the Co(II) complexes with 6-(3-chlorobenzylamino)purine (HL_1), 6-(4-chlorobenzylamino)purine (HL_2), 6-(2,3-dimethoxybenzylamino)purine (HL_3), 6-(3,4-dimethoxybenzylamino)purine (HL_4), 6-(3-fluorobenzylamino)purine (HL_5) and 6-(4-fluorobenzylamino)purine (HL_6) (see Scheme 1).

2. Experimental

2.1. Materials

$CoCl_2 \cdot 6H_2O$, 6-chloropurine, 3-chlorobenzylamine, 4-chlorobenzylamine, 2,3-dimethoxybenzylamine, 3,4-dimethoxybenzylamine, 3-fluorobenzylamine, 4-fluorobenzylamine and the solvents {dimethyl sulfoxide (DMSO), *N*,*N*-dimethylformamide (DMF), etc.} were purchased from Aldrich Co. and were used as received.

2.2. Syntheses

2.2.1. 6-(3-Chlorobenzylamino)purine (HL_1), 6-(4-chlorobenzylamino)purine (HL_2), 6-(2,3-dimethoxybenzylamino)purine (HL_3), 6-(3,4-dimethoxybenzylamino)purine (HL_4), 6-(3-fluorobenzylamino)purine (HL_5), 6-(4-fluorobenzyl amino)purine (HL_6) and $[H^{2+}L_2](ClO_4)_2 \cdot 2H_2O$

Compounds HL_1–HL_6 were prepared by the reaction of 6-chloropurine with an appropriate benzylamine in *n*-butanol with the addition of triethylamine by the procedure similar to that as described previously [17]. Yields ranged from 65% to 70%. The purity and composition of the compounds were proved by elemental analyses, ^1H and ^{13}C NMR spectra, thin-layer chromatography using a Silica gel 60 F_{254} (Merck) precoated aluminum plates with $CHCl_3$:CH_3OH:conc. NH_4OH (8:2:0.2, v/v/v) as a mobile phase, and melting points (data shown in Doležal et al., Bioorg. Med. Chem. 2005, submitted). Crystals of $[H^{2+}L_2](ClO_4)_2 \cdot 2H_2O$ were obtained by recrystallization of HL_2 from 2 M $HClO_4$.

2.2.2. $[Co(L_1)Cl(H_2O)_2]\cdot H_2O$ (1), $[Co(L_2)Cl(H_2O)_2]\cdot 2H_2O$ (2), $[Co(L_3)Cl(H_2O)_2]\cdot H_2O$ (3), $[Co(L_4)Cl(H_2O)_2]\cdot H_2O$ (4), $[Co(L_5)Cl(H_2O)_2]\cdot H_2O$ (5), $[Co(L_6)Cl(H_2O)_2]\cdot H_2O$ (6) and $[Co_6(\mu\text{-}L_6)_4Cl_8(DMSO)_{10}]\cdot 4DMSO$ (7)

Co(II) complexes **1**–**6** were synthesized by the following general method: a solution of an appropriate organic ligand (1 mmol) in EtOH (15 cm^3) and triethylamine (0.14 cm^3) were mixed with stirring. Then, a solution of $CoCl_2\cdot 6H_2O$ (0.24 g, 1 mmol) was added. The pale blue precipitate formed immediately. This reaction mixture was refluxed at 70 °C and stirred for 5 h. All the synthetic steps proceeded under nitrogen atmosphere. Then, the precipitate was filtered off, washed with EtOH (3×10 cm^3), Et_2O (2×10 cm^3) and dried under an infrared lamp at 40 °C. Yields ranged from 60% to 75%.

Crystals of $[Co_6(\mu\text{-}L_6)_4Cl_8(DMSO)_{10}]\cdot 4DMSO$ (**7**) suitable for single crystal X-ray analysis were obtained by recrystallization of the complex **6** from DMSO. In more details, complex **6** was dissolved in DMSO and dark green crystals were obtained by slow evaporation of the solvent after several months.

2.3. Physical measurements

All compounds were characterized by elemental analyses (C, H, N) using a ThermoFinnigan Flash EA-1121 Elemental Analyser. The cobalt content was determined by a chelatometric (EDTA) titration on murexide as an indicator. IR spectra of all compounds were recorded on a ThermoNicolet Nexus 670 FT-IR spectrometer as KBr pellets (400–4000 cm^{-1}) and using Nujol (150–500 cm^{-1}) and DRIFT (4000–10 000 cm^{-1}) techniques (only in case of the complexes). ^{1}H and ^{13}C NMR data of the ligands and Co(II) complexes in DMF-d_7 were collected on a Bruker 300 MHz NMR spectrometer Avance 600 with tetramethylsilane as an internal standard. Electronic absorption spectra of DMF solutions of the complexes were obtained on a Perkin–Elmer Lambda40 spectrometer in the 11 000–25 000 cm^{-1} range. Diffuse-reflectance spectra were recorded using a Perkin–Elmer Lambda35 spectrometer in the same range. Magnetic susceptibilities were measured by the Faraday method at room temperature using $Hg[Co(SCN)_4]$ as a calibrant, corrections for diamagnetism were calculated from Pascal's constants [18]. ES+ mass spectra of the ligands and complexes were recorded on a Waters ZMD 2000 mass spectrometer using a flow injection mode in mass monitoring interval 30–900 *m/z*. The spectra were collected using 3.0 s cyclical scans with cone voltage 20 and 40 V, at the source block temperature 80 °C, desolvation temperature 150 °C and desolvation gas flow rate 200 l/h. Conductances of 10^{-3} M solutions of the complexes in DMF were measured using a WTW Cond340i/SET conductometer at 25 °C. Thermogravimetric (TG) measurements were made in the temperature range of 20–1000 °C using a THASS TGA XP-10 thermal analyser. Melting points of the ligands used were determined on a Büchi Melting point B-540 apparatus and were uncorrected.

2.4. X-ray structure determinations

Diffraction data for $[H^{2+}L_2](ClO_4)_2\cdot 2H_2O$ and $[Co_6(\mu\text{-}L_6)_4Cl_8(DMSO)_{10}]\cdot 4DMSO$ (**7**) were collected on an Oxford Diffraction Xcalibur2 diffractometer equipped with Sapphire2 CCD detector at 100 K. The CRYSALIS software package (Version 1.171.24) was used for data collection and reduction. Both structures were solved by the SIR97 program [19] incorporated in the WINGX system (Version 1.70.00) [20]. All non-hydrogen atoms were refined anisotropically by the full-matrix least-squares procedure SHELXL-97 [21] on F^2 with weight: $w = 1/[\sigma^2(F_o)^2 + (0.0869P)^2 + 1.9024P]$ for $[H^{2+}L_2](ClO_4)_2\cdot 2H_2O$ and $w = 1/[\sigma^2(F_o)^2 + (0.1875P)^2 + 8.3404P]$ for **7**, where $P = (F_o^2 + 2F_c^2)/3$. In $[H^{2+}L_2](ClO_4)_2\cdot 2H_2O$, H-atoms attached to C and N atoms were found from difference Fourier maps and refined using a 'riding' model with C–H distances of 0.95 and 0.99 Å, the N–H distances of 0.88 Å with U_{iso} values derived from U_{eq} of the corresponding C and N atoms, respectively. $U_{iso}(H) = 1.2U_{eq}$ (CH, CH_2 and NH). The H-atoms of water molecules were refined freely. The largest peak and hole on the final difference map were 0.632 [0.90 Å from O(4)] and −0.606 [0.87 Å from Cl(2)] e Å^{-3}, respectively. In **7**, H-atoms belonging to all ligands, except for those of disordered DMSO molecules, were positioned theoretically and H-atoms of solvated DMSO were not included into calculation. In connection with overall bad crystal data quality [$R_{int} = 0.1333$], statistical data relating to this structure are not satisfactory. Nevertheless, the molecular structure of **7** was determined unambiguously from chemical point of view. The crystal data and structure refinements for $[H^{2+}L_2](ClO_4)_2\cdot 2H_2O$ and **7** are given in Table 1.

Table 1
Crystal data and structure refinements for $[H^{2+}L_2](ClO_4)_2 \cdot 2H_2O$ and $[Co_6(\mu\text{-}L_6)_4Cl_8(DMSO)_{10}] \cdot 4DMSO$ (**7**)

2.5. Cytotoxicity testing

Cytotoxicity of the starting compounds (i.e., HL_1–HL_6 and $CoCl_2 \cdot 6H_2O$) and complexes **1**–**6** was assessed by a Calcein AM assay. The following human tumour cell lines were used: malignant melanoma (*G361*), chronic myelogenous erythroleukemia (*K562*), osteogenic sarcoma (*HOS*) and breast adenocarcinoma (*MCF7*). IC_{50} values, i.e., the drug concentration lethal to 50% of the tumour cells, were estimated. Our experimental setup relating to the cytotoxicity testing was described previously in greater details [7].

3. Results and discussion

3.1. Magnetic, conductivity data, electronic spectra

Magnetic, conductivity and electronic spectral data of the prepared complexes are given in Table 2. The effective magnetic moment values vary from 4.4 to 4.7 μ_{eff}/μ_B, which correspond with the values expected for tetrahedral high-spin (d^7) Co(II) complexes [22–25] (see Scheme 2). The molar conductivity values of the complexes (10^{-3} M in DMF) at 25 °C range from 11.0 to 18.7 S cm^2 mol^{-1} and show on their non-ionic character [26].

Both absorption (DMF solutions) and diffuse-reflectance (solid state) electronic spectra of all the complexes are similar and exhibit three maxima at ca. 15 700, 16 100 and 18 700 cm^{-1}, and 15 600, 16 000 and 18 100 cm^{-1}. The electronic spectra of compound **2** are shown in Fig. 1. As it is generally known, regular tetrahedral Co(II) complexes should have only one d–d transition in the visible region. In the case of described complexes, a band centered at ca. 16 000 cm^{-1} is splitted into two peaks what is probably due to the interaction with the doublet state through spin–orbit coupling and may be attributed to the ν_3 transition, i.e., $^4A_2 \rightarrow {}^4T_1(P)$ [27–31]. The calculated values of molar absorption coefficients range from 103 to 527 M^{-1} cm^{-1} and correspond to d–d transitions [32]. Additionally, the next two d–d transitions were observed in the NIR region. The broadbands at ca. 7560 cm^{-1} can be attributed to the spin allowed transition $^4A_2 \rightarrow {}^4T_1(F)$ (ν_2) [33], while weak peaks near 4450 cm^{-1} were assigned to the ν_1 transition, i.e. $^4A_2 \rightarrow {}^4T_2(F)$. The curve shapes and maxima positions both in the solution and solid-state spectra are almost identical, and so, it can be expected that the prepared complexes are sufficiently chemically inert and do not change their coordination spheres in the solvent used. The ligand field parameters *10Dq* and the Racah parameters *B* were calculated from Tanabe–Sugano matrices described in the literature [34,35]. To calculate *10Dq* and *B* values, the maximal intensity of the relevant ν_2 and ν_3 bands were used. Calculated values for degree of covalent binding of ligands β (≈ 0.69) and ligand field strength *10Dq* (4420–4430 cm^{-1}) as well as Racah parameters *B* (668–671 cm^{-1}) are comparable for all the complexes. However, these values differ to those described for some tetrahedral complexes in the literature, e.g., [Co(Th4DM)(OH)(H$_2$O)] (*10Dq* = 4110 cm^{-1}, *B* = 709 cm^{-1} and $\beta = 0.73$), where HTh4DM = 4-acetamidobenzaldehyde-N(4)-dimethyl-thiosemicarbazone [36], and [$CoCl_2$(TdTn)] (*10Dq* = 4861 cm^{-1}, *B* = 754 cm^{-1} and $\beta = 0.78$), where TdTn = 2-(3,4-dichlorophenyl)imino-*N*-

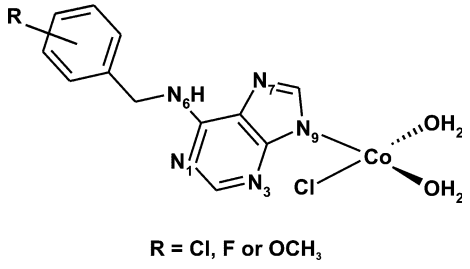
[a] Measured in 10^{-3} M DMF solutions.



Scheme 2.

(2-thiazolin-2-yl)thiazolidine [37]. The difference of spectral parameters is caused by dissimilarity of chromophores, i.e. $CoNClO_2$ versus $CoNSO_2$ or CoN_2Cl_2. Thus, the results following from electronic spectral data are in agreement with the conclusions from magnetic measurements.

3.2. NMR measurements

The ^{1}H and ^{13}C NMR spectra of the free cytokinin derivatives as well as the complexes were measured in DMF-d_7 and the chemical shifts are summarized in Section 2.2. Differences between NMR spectra of the complexes and free ligands provide circumstantial evidence on a complex formation. The largest coordination shifts $\Delta\delta$ ($\Delta\delta = \delta_{complex} - \delta_{ligand}$) were observed in ^{1}H NMR spectra for the H8 protons, which were shifted downfield by 0.38–0.59 ppm. The largest coordination shifts were also found for C8 and C4 signals in ^{13}C NMR spectra. The C8 signals were shifted downfield by ca. 6.29 ppm, while the C4 signals were shifted upfield by ca. 4.09 ppm. On the basis of this fact, we can conclude that the ligands are deprotonated at the *N*9 position of an imidazole ring and moreover, the coordination of the cytokinin derivatives to cobalt proceeds

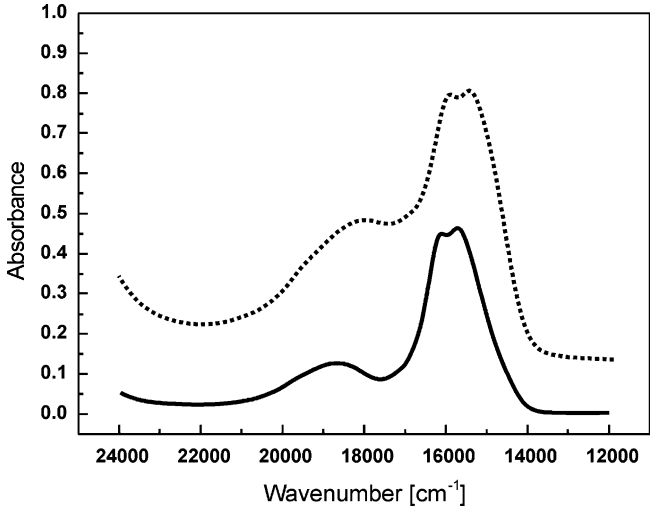


Fig. 1. Absorption electronic solution (—) and diffuse-reflectance spectra (···) of complex **2**.

via the same atom in all the complexes (see Scheme 2). The similar conclusion can be made in case of the measurement in methanol-d_4. However, the interpretation of the spectra is somewhat complicated due to limited solubility of the complexes as well as free ligands in methanol-d_4. We have also measured NMR spectra in DMSO-d_7 and acetone-d_6. Unfortunately, reproducible NMR data in DMSO-d_7 and acetone-d_6 have not been obtained, probably in connection with the decomposition of the complexes in these solvents. This conclusion was proved in the case of **6** by a single crystal X-ray analysis, where the recrystallization of the complex from DMSO led to formation of complex **7** (see Section 3.8).

3.3. Computational analysis

Theoretical calculations using the DFT (B3LYP) approach were performed with the aim to suggest a possible coordination mode of the studied 6-benzylaminopurine derivatives to the cobalt(II) ion. This approach partially substitutes the absence of crystallographic data of any of the studied Co(II) complexes. All calculations were done using the GAUSSIAN03 program [38]. As a model system, complex **2** was chosen. Preliminary optimized data were prepared on the HF/6-31* level of the theory. Then, the obtained geometries were fully optimized at the B3LYP level with 6-311++G** (for ligands) and 6-311+G* (for complexes) basis sets. Harmonic-frequency analysis was used to verify the nature of found stationary points as the minima as well as for the calculation of zero-point vibrational energies. Calculated infrared frequencies of the ligands, as shown in Table 3, were not scaled. Natural-bond orbital analysis (NBO) was used for investigation of the electron distribution in the studied complexes [39].

From general point of view, each of the 6-benzylaminopurine derivatives used in this study offers several possible binding sites for the cobalt complex formation, e.g., *N*1, *N*3, *N*7 or *N*9 for the monodentate binding, *N*6–*N*7 for bidentate one, and *N*7–*N*9 or *N*3–*N*9 for bridging coordination [9,16]. The *N*1 binding site is strongly sterically hindered by the methylene hydrogens of the benzylamino group, and complex **2** is not probably formed by this way. The optimized geometries of complex **2** with the possible monodentate coordination modes of the 6-(4-chlorobenzylamino)purine ligand are shown in Fig. 2. Similar to the *N*1 coordination, the benzyl functional group partially hinders the bidentate coordination to cobalt(II) ion via the *N*6 and *N*7 donor atoms. Mutual orientation of purine ring and benzylamino group leads to the different spatial orientation of the lone electron pairs of *N*6 and *N*7 atoms. This arrangement makes impossible effective a bidentate binding of the organic ligand to cobalt(II) ion. On the other hand, the *N*3 and *N*9 positions are in essence equivalent from both the geometrical and sterical perspectives, and moreover, both donor atoms are well uncovered for the coordination with the cobalt ion.

The electron distribution within the purine skeleton of anion L_2^- gives preference rather to the coordination via the *N*7 atom with highest negative partial charge. The remaining three nitrogen atoms (i.e., *N*1, *N*3 and *N*9) have comparable charges. On the other hand, the greatest changes in the charge distribution have been observed in case of the coordination via the *N*9 atom (for details, see Table 3).

Bond distances between the corresponding nitrogen and cobalt atoms are nearly identical in all three studied systems (Table 4). All three suggested models also offer the strong hydrogen bond interaction between one water molecule coordinated to the cobalt(II) ion and the corresponding adjacent nitrogen atom, i.e., *N*3 for the *N*9-coordinated complex, *N*9 for the *N*3-coordinated complex and *N*6 for the *N*7-coordinated complex (see Fig. 2). Selected calculated hydrogen bond parameters are also summarized in Table 3.

Difference between ΔSCF energies of the *N*3 and *N*9 coordinated complexes is 1.01 kcal mol^{-1} in favour of the *N*9 coordination. The energy of the *N*7 complex is higher by 15.7 kcal mol^{-1}, also in comparison with the *N*9 complex. It is supposable that the L_2^- anion is coordinated to cobalt via *N*9 or *N*3 atom in complex **2**, and some dynamic equilibrium should be expected in the solution.

Table 3
Selected calculated partial charges and geometrical parameters of the complex **2**

3.4. IR spectra

In the IR spectra of all the ligands as well as the complexes, the maxima belonging to the ν(C=N) vibration appeared in the 1620–1630 cm^{-1} region, while the bands at 1465–1491 and 1510–1568 cm^{-1} belong to ν(C=C) vibration. The broadbands between 3339 and 3447 cm^{-1} are associated with the ν(N–H) vibration. The characteristic bands of the C_{ar}–Cl, C_{ar}–F and C_{ar}–O groups are observed in the 1155–1174, 1250–1272, and 1255–1275 cm^{-1} regions, respectively. All the bands discussed above confirm the presence of the ligands in complexes **1**–**6** [40]. The far-IR spectra of the complexes revealed absorptions in the 430–449 and 314–324 cm^{-1} ranges, which may be assigned to the ν(Co–N), and ν(Co–O) stretching bands, respectively. The bands between 303 and 310 cm^{-1} can be attributed to the ν(Co–Cl) stretching vibration [41–45].

The comparison of measured frequencies with calculated values is given in Table 4. Because of the fact that calculations were carried out in vacuum, and thus interactions among molecules were ignored, differences between experimental and theoretical values appeared. In spite of this, values correspond sufficiently.

3.5. Mass spectroscopy

The ES+ mass spectra of complexes **1** and **2** showed a peak at 260 *m*/*z* identifying the presence of HL_1 and HL_2 molecule in these complexes. The presence of HL_3 and HL_4 in compounds **3** and **4** is obvious from the maximum at 286 *m*/*z*. The maxima observed at 244 *m*/*z* confirmed the presence of the ligands HL_5 and HL_6 in compounds **5** and **6**. The peaks observed at 136 and 121 *m*/*z* correspond to the fragments of adenine and purine, respectively. The peaks for fragments $[Co(L_1)Cl(H_2O)_2]^+$ and $[Co(L_2)Cl(H_2O)_2]^+$ appeared at 391 *m*/*z*, while peaks observed at 414 *m*/*z* belong to fragments $[Co(L_3)Cl(H_2O)_2]^+$ and $[Co(L_4)Cl(H_2O)_2]^+$. The peaks observed at 354 *m*/*z* for compounds **1** and **2** are associated with fragments $[Co(L_1)Cl]^+$ and $[Co(L_2)Cl]^+$, respectively. The peaks

appeared at 379 *m/z* correspond with fragments $[Co(L_3)Cl]^+$ and $[Co(L_4)Cl]^+$. In case of the complexes **5** and **6**, the maxima appeared at 337 *m/z* agree with the fragments $[Co(L_5)Cl]^+$ and $[Co(L_6)Cl]^+$.

3.6. Thermal analyses

Thermal decomposition of all complexes is very similar. TG curves showed that compounds **1** and **3**–**6** are monohydrates while the complex **2** exists as a dihydrate. The curves of thermal degradation of compounds **2** and **4** are shown in Fig. 3. In the case of **2**, the first weight loss is apparent between 40 and 138 °C and can be attributed to the loss of one crystal water molecule (found/calc. 4.1/4.2%) and the existence of the compound having formula of $[Co(L_2)Cl(H_2O)_2]\cdot H_2O$, which is stable between 138 and 196 °C. The weight loss connected with the elimination of the second crystal water molecule can be observed between 196 and 280 °C. A plateau occurs on the TG curve in the 280–305 °C temperature interval and it can be associated with formation of an anhydrous complex $[Co(L_2)Cl(H_2O)_2]$ (found/calc. 8.7/8.5%). It is evident from the TG curves of **1** and **3**–**6** that the weight loss between ca. 35 and 140 °C is connected with the release of one crystal water molecule. Thermal decomposition of all complexes is finished at ca. 960 °C, giving Co_3O_4/CoO mixture in ratio 4:1 which was determined by means of X-ray powder diffraction analysis and PDF2 database [46] in the case of **3** and **6**.

3.7. X-ray structure of 6-(4-chlorobenzylamino)purin-di-ium diperchlorate dihydrate, $[H^{2+}L_2](ClO_4)_2\cdot 2H_2O$

The crystal structure of 6-(4-chlorobenzylamino)purin-di-ium diperchlorate dihydrate is composed of 6-(4-chlorobenzylamino)purin-di-ium cation, two perchlorate anions and two water molecules of crystallization. The molecular structure together with the atom numbering scheme is shown in Fig. 4. The cation is clearly protonated at the *N*7 and *N*9 positions, and a combination of *N*1 and *N*3

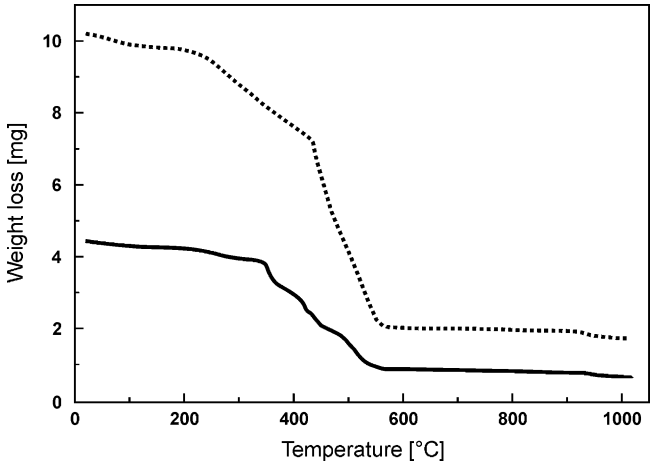

Fig. 3. Thermogravimetric curves of the complexes **2** (—) and **4** (···).

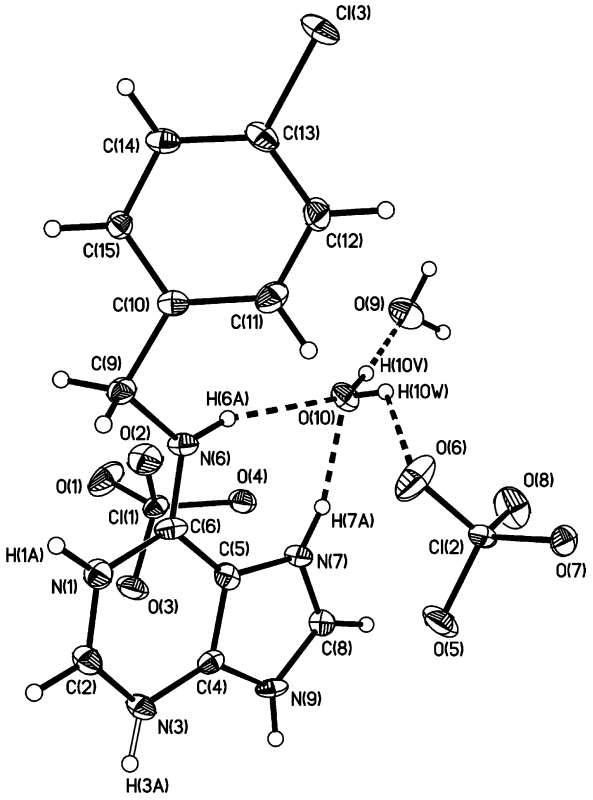

Fig. 4. The molecular structure of $[H^{2+}L_2](ClO_4)_2\cdot 2H_2O$ with the atom labelling scheme. The non-H atoms are drawn as displacement ellipsoids at the 50% probability level and H atoms are shown as small spheres at arbitrary radii. Dashed lines indicate possible hydrogen bonds. The H1A and H3A positions belong to the identical hydrogen atom, which is disordered over two positions with the probability of 34% for the H1A position and 66% for the H3A one.

ones. However, the positions of the latter proton are statistically disordered over two positions with probability of 34% (for N(1)–H), and 66% (for N(3)–H), respectively. The position of the hydrogen atoms differs from free bases, where the protonation occurs only at the *N*9 position. The molecular structure of $[H^{2+}L_2](ClO_4)_2\cdot 2H_2O$ represents the (*N*1, *N*3), *N*9-protonated *N*7 tautomer. There are significant deviations from planarity in both purine and phenyl rings [47]. Maximum deviation from the LSQ-plane is 0.0119(3) Å for C2 of the purine ring and 0.0077(3) Å for C14 of the phenyl ring. The dihedral angle between the above-mentioned rings is equal to 53.45(1)°. It is significantly lower in comparison to that found for 6-(2-chlorobenzylamino)purine dihydrate [79.5(2)°] [5], 6-(4-chlorobenzylamino)purinium perchlorate [86.19(1)°] [6] and 6-(4-methoxybenzylamino)purin-3-ium chloride [77.46(5)°] [48]. Selected bond lengths and angles are given in Table 5, while hydrogen bond parameters are summarized in Table 6. The C2–N3–C4, C8–N7–C5 and C8–N9–C4 bond angles in a purine skeleton of $[H^{2+}L_2](ClO_4)_2\cdot 2H_2O$ are 116.1(3)°, 108.3(3)° and 107.5(3)° and are slightly different from the values obtained for the above-mentioned compounds. All the above-discussed differences are probably caused by a degree of

protonation and substitution of the whole 6-benzylaminopurine moiety. The $C_g1\cdots C_g2$, $C_g1\cdots C_g3$ and $C_g2\cdots C_g3$ distances are 6.311(2), 7.0208(21) and 2.1086(7) Å, respectively, where C_g1, C_g2 and C_g3 are the centroids of benzene, purine and imidazole rings. Torsion angles of C9–N6–C6–C5, C6–N6–C9–C10 and N6–C9–C10–C15 are 178.8(3)°, 157.6(3)°, and 138.7(3)°, respectively.

3.8. X-ray structure of $[Co_6(\mu\text{-}L_6)_4Cl_8(DMSO)_{10}] \cdot 4DMSO$ (7)

The interatomic and geometrical parameters of complex **7** are not discussed in detail in connection with the overall bad crystal data quality and consequently with the low quality of the refinement. Thus, the discussion regarding to the molecular structure of **7** is focused on the description of the stereochemistry in the vicinity of the central Co(II) ions and on the manner of coordination of organic ligands only. The molecular structure of the centrosymmetric hexanuclear complex $[Co_6(\mu\text{-}L_6)_4Cl_8(DMSO)_{10}] \cdot 4DMSO$ is depicted in Fig. 5. Four of the six central atoms, Co(1), Co(1A), Co(2) and Co(2A), are surrounded by six atoms in a distorted octahedral arrangement, while the geometry around Co(3) and Co(3A) atoms is tetrahedral. Thus, HL_6, i.e., 6-(4-fluorobenzylamino)purine, acts as a tridentate bridging ligand in this complex. There is a direct metal–metal interaction between Co(1) and Co(1A) atoms with the bond length of 2.667(2) Å. Furthermore, these two cobalt atoms are connected with four bridging organic ligands HL_6, which are coordinated via *N*3 and *N*9 donor atoms. One chlorine atom is bonded to Co(2) and Co(2A), respec-

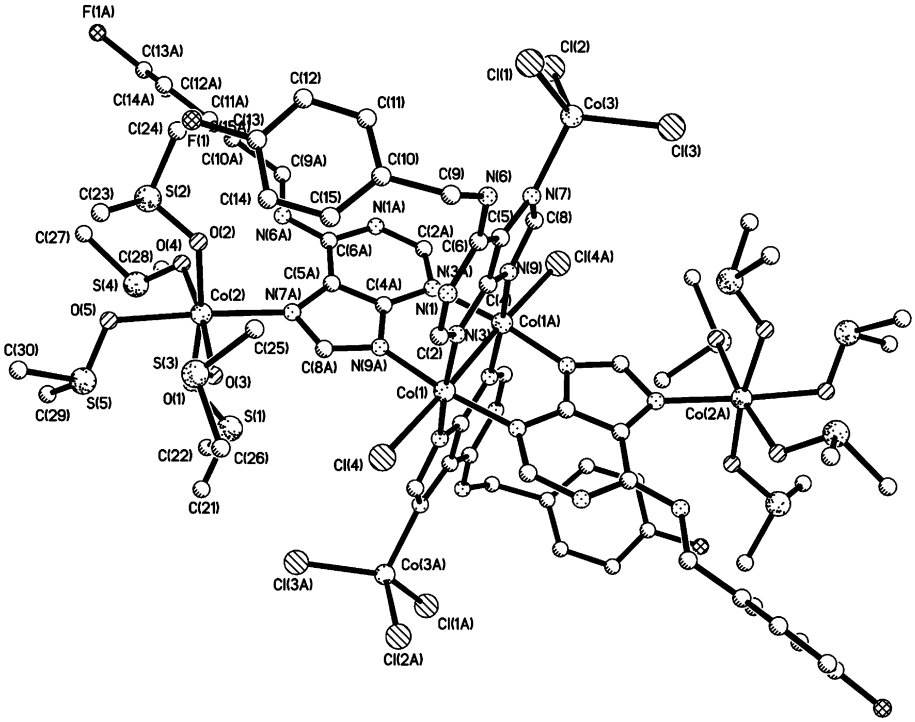

Fig. 5. The molecular structure of $[Co_6(\mu\text{-}L_6)_4Cl_8(DMSO)_{10}] \cdot 4DMSO$ (**7**). Hydrogen atoms and solvated DMSO molecules were omitted for clarity.

Co(3)–Cl(3)	2.237(3)		

Symmetry transformations used to generate equivalent atoms: (i) $-x+1$, $-y+1$, $-z+2$.

tively, and it appears as a terminal ligand. Each of the Co(2) and Co(2A) atoms are coordinated by five oxygen atoms of DMSO and the *N*7 atom of the purine moiety. Coordination spheres of Co(3) and Co(3A) are formed by three chlorine atoms and the *N*7 atom originating from 6-(4-fluorobenzylamino)purine. Selected bond lengths and angles are given in Table 7. It is evident, that the octahedral surrounding of Co(1) atom is slightly deformed as can be obvious from angle values in the vicinity of the central atom, i.e., N(9A)–Co(1)–N(3A), N(3)–Co(1)–N(9) and Cl(4)–Co(1)–Co(1A), which were found to be 172.2(3)°, 172.6(3)° and 175.45(9)°, respectively. As for the Co(2) atom, the O(2)–Co(2)–O(1), O(4)–Co(2)–O(3) and N(7A)–Co(2)–O(5) bond angles are 171.7(3)°, 172.3(3)° and 176.9(3)°, respectively. A tetrahedral surrounding of the Co(3) atom is slightly deformed which can be seen from the bond angle values N(7)–Co(3)–Cl(3) [110.6(2)°], N(7)–Co(3)–Cl(1) [111.4(2)°], Cl(3)–Co(3)–Cl(1) [112.56(15)°], N(7)–Co(3)–Cl(2) [103.9(2)°], Cl(3)–Co(3)–Cl(2) [110.07(15)°] and Cl(1)–Co(3)–Cl(2) [107.93(14)°].

3.9. Testing for cytotoxicity

The cytotoxicity of the prepared complexes as well as the starting compounds, i.e., $CoCl_2\cdot 6H_2O$ and ligands HL_1–HL_6, was tested against malignant melanoma (*G361*), chronic myelogenous erythroleukemia (*K562*), osteogenic sarcoma (*HOS*) and breast adenocarcinoma (*MCF7*) human cancer cell lines. As can be seen from Table 8, *G361*, *K562* and *MCF7* cell lines were insensitive to all the assayed compounds in tested concentrations. *HOS* cell line was insensitive to starting compounds and **2**, whereas complexes **1** and **3**–**6** showed increased cytotoxic activity against this cell line. IC_{50} values of these compounds range from 7 to 28 μM and are close to that for similar Co(II) complexes we had described previously [8]. Moreover,

Table 8
The cytotoxicity of the studied compounds, expressed as IC_{50} values (μM) assessed by a Calcein AM assay

Compound	Cell line[a]			
	G361	*HOS*	*K562*	*MCF7*
HL_1	>50	>50	>50	>50
HL_2	>50	>50	>50	>50
HL_3	>50	>50	>50	>50
HL_4	>50	>50	>50	>50
HL_5	>50	>50	>50	>50
HL_6	>50	>50	>50	>50
1	>50	28	>50	>50
2	>50	>50	>50	>50
3	>50	27	>50	>50
4	>50	22	>50	>50
5	42	10	>50	>50
6	>50	7	>50	>50
$CoCl_2\cdot 6H_2O$	>50	>50	>50	>50

[a] *G361* – human malignant melanoma, *K562* – human chronic myelogenous erythroleukemia, *HOS* – human osteogenic sarcoma, *MCF7* – human breast adenocarcinoma.

these values are comparable and even better than those obtained for Roscovitine (CYC202) (20 μM) [7], a cytokinin-derived compound, currently undergoing Phase IIb clinical trials for lung cancer and cancer from a group of B-cell hematological malignancies [49]. The obtained IC_{50} values in the case of all complexes, except for **2**, in connection with the HOS cell line show that higher cytotoxicity of the Co(II) complexes as compared to free cytokinins is probably caused by the complex formation.

4. Supplementary material

Crystallographic data of the structural analysis have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication numbers CCDC: 269650 {for $[H^{2+}L_2](ClO_4)_2\cdot 2H_2O$} and 269651 {for **7**}. Copies of this information may be obtained free of charge from The director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44 1223-336-033; e-mail: deposit @ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk).

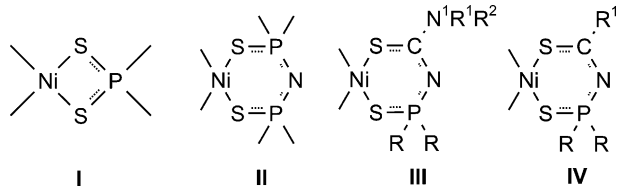

Scheme 1. Ni(II) complexes with thiophosphorus ligands containing NiS_4 core.

The complexes III and IV – with thiophosphoryl thioureas and thioamides – are the most suitable for investigation owing to convenient methods of synthesis of the ligands available in the literature [18–20] and the ease of variation of the substituents at phosphorus, carbon, and exocyclic nitrogen N^1 for alteration of steric environment around the nickel atom. Thus *bis*-bidentate ureas $[(i\text{-PrO})_2P(S)NHC(S)]_2Z$ with Z equal to open-chain substituents $[NH(CH_2)_2NH$, $NH(CH_2)_7NH$, $NH(CH_2)_2O(CH_2)_2NH$, $NH(CH_2)_2O(CH_2)_2O(CH_2)_2NH]$, crown (diaza-18-crown-6), or piperazine fragment are known [2,21,22].

To date complexes of type III have been described for $R = Ph$, $R^1 = H$, $R^2 = H$ [23,24], $R = Ph$, $R^1 = H$, $R^2 = Me$ **6** [23,25,26], $R = Ph$, $R^1 = H$, $R^2 = Ph$ [1,24,26], $R = Ph$, $R^1 = H$, $R^2 = C_6H_4Me$-3 [1], $R = Ph$, $R^1 = H$, $R^2 =$ Napht-1 [1], $R = Ph$, $R^1 = H$, $R^2 =$ Napht-2 **7** [1], $R = Ph$, $R^1 = H$, $R^2 = C_6H_4(OMe)$-4 [27]; $R = Ph$, $R^1 = R^2 = Me$ [23], $R = Ph$, $R^1 = R^2 = Et$ [24,26]; $R = Ph$, $R^1 = R^2 =$ Bu **8** [24]; $R = Ph$, $N^1R^1R^2 =$ Piperidine **9** [1]; $R = OPr^i$, $R^1 = H$, $R^2 = Ph$ **10** [28]; $R = OPh$, $R^1 = R^2 = Pr^i$ **11** [29]; $R = OPr^i$, $N^1R^1R^2 =$ Monoaza-18-crown-6 **12** [30]. The only complex of the type IV is known for $R = OPr^i$, $R^1 = Ph$ **13** [31,32].

We report here the structure of the complex $[Ni\{PhNHC(S)NP(S)(OPr^i)_2\text{-}S,S\}_2]$ **10** determined by X-ray single crystal diffraction and its behavior in dichloromethane solution investigated by NMR ^{31}P spectroscopy.

2. Results and discussion

X-ray structural analysis of the title molecule shows that the nickel atom is positioned in the symmetry center of a distorted square-planar arrangement with *trans*-disposition of the ligands; the S(2)Ni(1)S(1) and S(1)Ni(1)S(2)$(2 - x; 1 - y; 1 - z)$ angles are equal to 98.13(3) and 81.87(3)°, respectively (Fig. 1).

The six-membered cycle Ni(1)S(1)P(1)N(1)C(1)S(2) has a form of the asymmetric boat; the P(1)N(1)C(1)S(2) fragment is essentially planar within the limits of 0.011(4) Å while the S(1) and Ni(1) atoms deviate by 0.2039 and 1.1232(9) Å, respectively, from the plane. The exocyclic N(2) atom is located practically in the base plane of the heterocycle [the N(2) atom deviation is 0.012(4) Å]. No any strong inter- or intramolecular hydrogen bonding has been found in the solid state.

The geometry of the thiourea N(1)C(1)N(2) fragment indicates sp^2 hybridization of the N(2) atom with the valence angles sum being equal to 360°. The lone electron pair on N(2) is in a conjugation with the endocyclic N(1)=C(1) bond; the torsion angle N(1)C(1)N(2)C(3) is 5.1(6)°. The bond lengths distribution in the planar N(1)C(1)N(2) fragment supports the existence of such conjugation. Actually, the C(1)–N(1) bond length [1.291(4) Å] is somewhat elongated in comparison with the average C=N distance in Schiff bases of 1.27 Å [33] and the standard C=N bond length measures 1.279 Å [34]. On the other hand, the C(1)–N(2) bond [1.357(4) Å] is intermediate between double and ordinary bonds (the C–N distance in amines is 1.469 Å [34] and the standard N–C(sp^2) bond length is 1.452 Å [35]). The Ni(1)–S(1) and Ni(1)–S(2) distances of 2.2174(9) and 2.2073(9) Å, respectively, are close, suggesting electron density delocalization between the S(1) and S(2) atoms of the ligand. The C(1)–S(2) bond length [1.740(3) Å] indicates also such delocalization; this distance

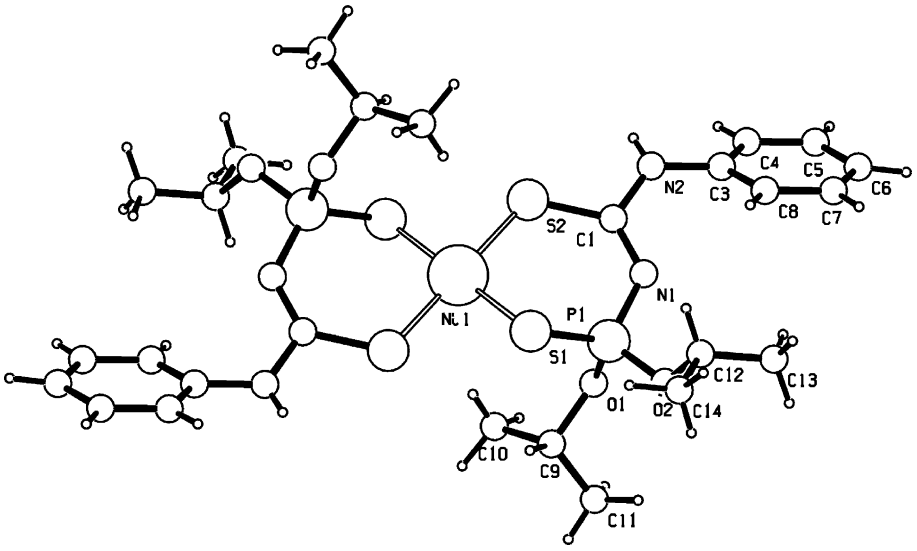

Fig. 1. Molecular structure of the $[Ni\{PhNHC(S)NP(S)(OPr^i)_2\text{-}S,S\}_2]$ complex.

differs significantly from the C=S bond length in thioureas (1.681 Å) and C–S bond length in sulfides (1.819 Å) [34]. The C(1)–S(2) and P(1)–S(1) distances in **10** are close to those in **6** [25], **11** [29], and **12** [30]. The basic geometrical parameters of these compounds are compared in Table 1. As it is evident from the data in this Table 1, the close similarity of the bond parameters between the compounds indicate that they are not influenced by the different nature of substituents attached to the phosphorus (Ph, OPr^i, or OPh) and exocyclic nitrogen N(2) atoms (H and Me, H and Ph, or Alk and Alk). Conformations of the complexes **10**, **11**, **12**, and **6** are also essentially identical.

2.1. Behavior of the [Ni{PhNHC(S)NP(S)(OPr^i)$_2$-S,S}$_2$] complex in dichloromethane solution

Aside from compounds **7** and **9** almost all the rest complexes above mentioned are diamagnetic both in the solid state and in solution, consistent with a square-planar environment. The complexes **7** and **9** are reported [1] to possess square-planar coordination geometry only in solution but in the solid state there are present both square-planar and tetrahedral forms. The authors [29] note an upfield ^{31}P NMR shift for the complex **11** in comparison with the free ligand: −11 and 53.3 ppm, respectively. Unfortunately, the absence of information about the conditions of the spectra recording (concentrations, solvent, etc.), makes the interpretation of this fact difficult. However in our opinion it is the tetrahedral distortion of the nickel environment of the complex in solution that gives rise to this considerable shift.

These results made us investigate the behavior of the complex **10** in solution. Solid state MAS NMR data (^{31}P and ^{13}C) of complex **10** reveal the only diamagnetic form which was found to be *trans*-square-planar isomer with C_i symmetry. NMR ^{31}P and UV–Vis spectroscopy data for solutions show the following picture.

In the electronic absorption spectra of complex **10** (Fig. 2) two bands at ~640 and ~530 nm, two "shoulders"

Table 1
Selected interatomic distances (Å) and angles (°) for **10**, **6** [25], **11** [29], and **12** [30]

	10	6	11	12
Ni(1)–S(1)	2.2174(9)	2.216	2.226	2.219

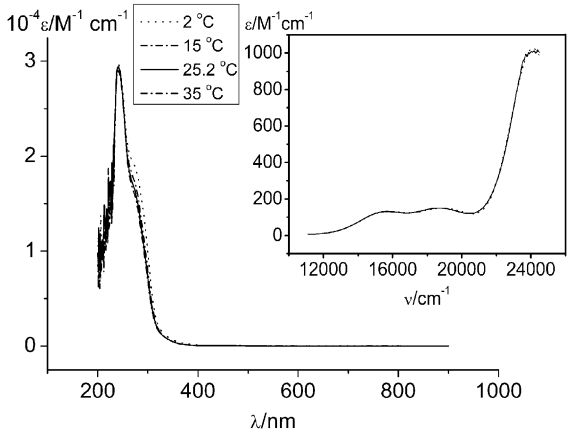

Fig. 2. Electronic absorption spectra of complex **10** in dichloromethane solutions at 2, 15, 25.2, and 35 °C ($c_{Ni(II)} = 1.0 \times 10^{-4}$ M); in the right insert the long-wave part of experimental spectrum at 25.2 °C ($c_{Ni(II)} = 3.49 \times 10^{-3}$ M) (solid line) and that reconstructed on Gaussian components (dot line) are shown.

at ~410 and ~275 nm, as well as band at 242 nm are observed at 298 K. The spectra exhibit weak temperature dependence. The latest high-energy intensive transitions ($\nu_{sh} = 36400$ cm^{-1}, $\varepsilon_{sh} = 16000$ mol dm^{-3} cm^{-1} and $\nu_{max} = 41332$ cm^{-1}, $\varepsilon_{max} = 29500$ mol dm^{-3} cm^{-1}) fall obviously into ligand–ligand and ligand-to-metal transitions [36]. From the long-wave spectrum part three Gaussian components were reconstructed (see Fig. 2) with the spectral parameters $\nu_{max} = 15411$ cm^{-1} ($\varepsilon_{max} = 130$ mol dm^{-3} cm^{-1}), $\nu_{max} = 19078$ cm^{-1} ($\varepsilon_{max} = 160$ mol dm^{-3} cm^{-1}), and $\nu_{max} = 24132$ cm^{-1} ($\varepsilon_{max} = 1190$ mol dm^{-3} cm^{-1}).

The three bands reported for the absorption spectra of the square-planar species Ni[S_2CNEt$_2$-*S,S*]$_2$ (at 15900, 19000, and 21000 cm^{-1}) [37] and **13** Ni[PhC(S)NP(S)(OPr^i)$_2$-*S,S*]$_2$ (at 16530, 18920, and 21960 cm^{-1}) [32] were assigned, respectively, to the d–d transitions $^1A_{1g} \rightarrow {}^1B_{1g}$ ($d_{x^2-y^2} \rightarrow d_{xy}$), $^1A_{1g} \rightarrow {}^1B_{3g}$ ($d_{xz} \rightarrow d_{xy}$), and $^1A_{1g} \rightarrow {}^1B_{1g}$ ($d_{z^2} \rightarrow d_{xy}$) at the local D_{2h} symmetry. Thus the bands at 15411 and 19078 cm^{-1} for compound **10** can be assigned to the corresponding $^1A_{1g} \rightarrow {}^1B_{1g}$ and $^1A_{1g} \rightarrow {}^1B_{3g}$ transitions respectively with the same D_{2h} symmetry of square-planar isomers. The reconstructed band at 24132 cm^{-1} may be assigned to the remaining $^1A_{1g} \rightarrow {}^1B_{1g}$ transition with its high intensity deriving from activation by the ligand-to-metal transition [32,37]. Bands in the range of 700–800 nm, which are inherent features of tetrahedral or pseudo-tetrahedral complexes with the $Ni^{II}S_4$ core [13,38], were not observed in the electronic spectra of complex **10** (Fig. 2), indicating negligible contribution for pseudo-tetrahedral isomers in the solutions.

In dichloromethane solutions of the compound **10** four signals which were denoted by A_1, A_2, B, and C have been detected by ^{31}P–{^{1}H} NMR method (Fig. 3). The dominant C signal refers to the monocrystal *trans*-isomer **C** (with anti-disposition of two ligands in boat conformations) because its ^{31}P chemical shift in solution at −80 °C (55.41 ppm) coincides very closely with that in the MAS

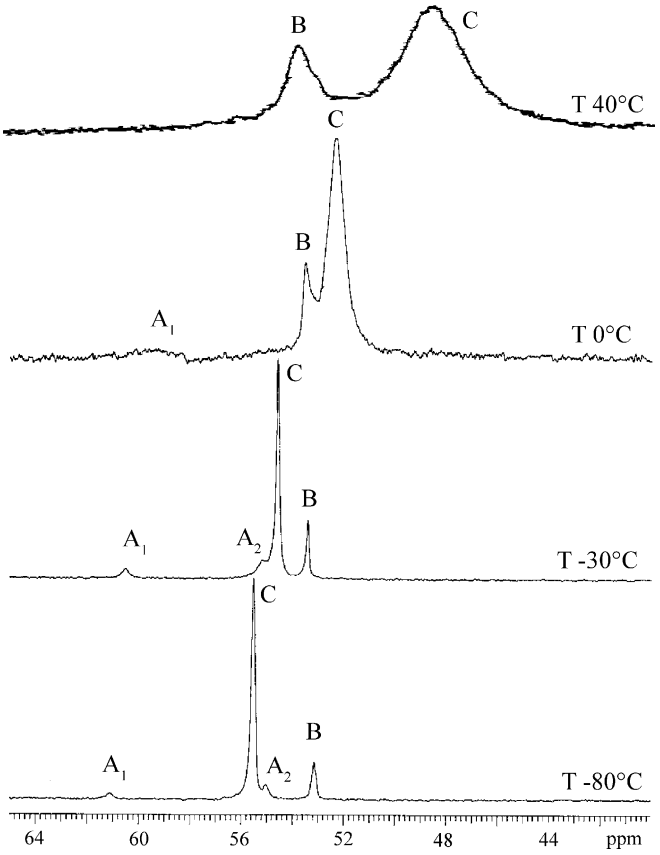

Fig. 3. The NMR $^{31}P–\{^1H\}$ spectrum of the complex **10** solutions in dichloromethane at different temperatures ($c_{Ni(II)} = 2.5 \times 10^{-2}$ M) and 121.4 MHz.

NMR $^{31}P–\{^1H\}$ spectrum of the polycrystals (56.2 ppm). As can be seen from the 2D-NMR $^{31}P–\{^1H\}$ spectra (Fig. 4), the cross-peaks are evidence for exchange between signals – A_1–C, A_2–C, and B–C. The absence of exchange between A_1 and A_2 implies, in view of alike intensity and line-width of the A_1 and A_2 signals, that they are diastereotopic and assigned to nonequivalent ligand conformations (boat and chair) of the same complex isomer (**A**). A rather small displacement of the B signal (53.03 ppm at −80 °C) from the C signal suggests to the same ligand conformations in the isomers (boat) but with different disposition (*cis*- instead of *trans*-) in the plane of the NiS_4 core. In accordance with this the A_1 signal at 54.93 ppm (−80 °C) relates to the boat ligand conformation whereas the A_2 signal at 61.02 ppm (−80 °C) belongs to the chair one of the complex form (**A**). Taking into account that in all studied crystals of related complexes, **6**, **10**, **11**, and **12**, two ligands are in anti-orientation about the NiS_4 core plane (see above) and based on reported electronic and NMR spectra, the three signal groups ($A_1 + A_2$, B, and C) can be related respectively to the three following diamagnetic square-planar isomers with different dispositions and conformations of two ligands in anti-orientation: *trans*-chair–boat (**A**) [39], *cis*-boat–boat (**B**), and *trans*-boat–boat (**C**) in equilibrium (Fig. 5).

One more possible conformation isomer **D** (*cis*-chair–boat) is instable and consequently may be unobserved considering that for steric reasons the *cis*-disposition of the ligands should be energy unfavorable and chair-conformation is not realized in the crystal. However the signals of all of four possible isomers (**A**, **B**, **C**, and **D**), including two weak diastereotopic phosphorus signals D_1 and D_2, are observed in the ^{31}P NMR spectra of the allied complex [Ni{*t*-BuNHC(S)NP(S)(OPr^i)$_2$-*S*,*S*}$_2$] [40] (**14**) (Fig. 6). This is not surprising, since line-widths of all the ^{31}P NMR signals for **14** are several times narrower than those for **10** in the whole temperature range studied. In keeping with the above assignment, the lack of visible exchange between A_1 or A_2 and B signals (Fig. 4) is due to the low probability of simultaneous change of the ligand conformation and disposition at the **A**–**B** interconversion and the latter process is carried out in two stages through slow *cis*–*trans*-isomerisation with **C** (see below).

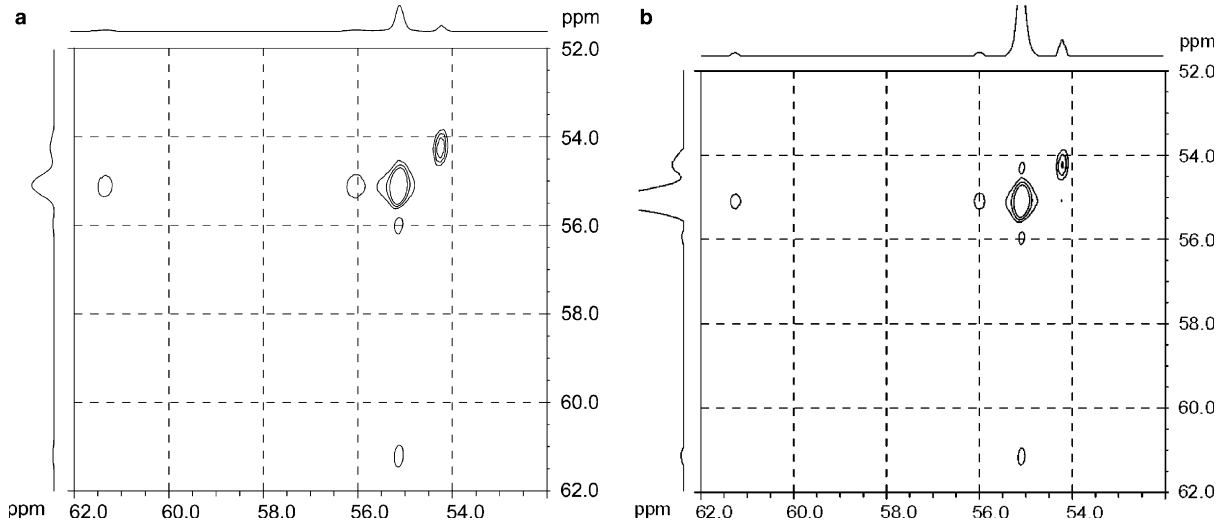

Fig. 4. The 2D-NMR NOESY $^{31}P–\{^1H\}$ spectra of the complex **10** solution in dichloromethane-d_2 at −20 °C and 161.9 MHz with mixing time 130 ms (a) and 500 ms (b).

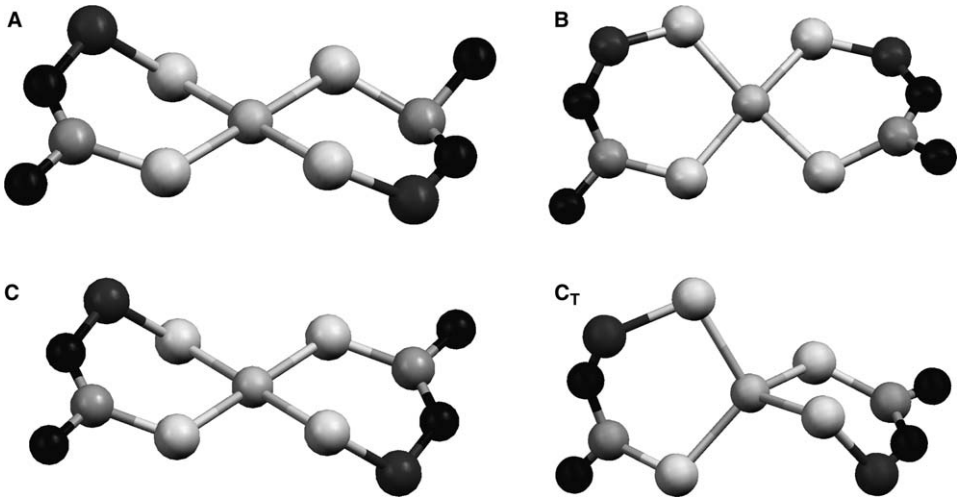

Fig. 5. Proposed structures of isomers of the **10** complex in dichloromethane solutions: **A** (*trans*-chair–boat), **B** (*cis*-boat–boat), **C** (*trans*-boat–boat), and, as an example, $\mathbf{C_T}$ (pseudo-tetrahedral). In all square-planar forms two ligands are in anti-orientation about the NiS_4 core. Only chelate backbones shown.

From the relative integral intensities of signal C to $A_1 + A_2$, the equilibrium constant $K_{AC} = [\mathbf{C}]/[\mathbf{A}]$ values were calculated for the temperature range from −80 to 0 °C. Likewise the equilibrium constant $K_{BC} = [\mathbf{C}]/[\mathbf{B}]$ values were determined at different temperatures (from −80 to 40 °C). Then from the $\log K_{AC(BC)} - 1/T$ dependences (Fig. 7) the enthalpy (ΔH) and entropy (ΔS) of corresponding equilibria were calculated by:

$$2.303R \log K = \Delta S/R - (\Delta H/R) \cdot 1/T, \quad (1)$$

with $\Delta H_{AC} = -6.3 \pm 0.4$ kJ mol^{-1} and $\Delta S_{AC} = -12.5 \pm 1.9$ J K^{-1} mol^{-1} (whence it follows $K_{AC} = 2.83$ at 25 °C), $\Delta H_{BC} = -6.0 \pm 0.4$ kJ mol^{-1} and $\Delta S_{BC} = -14.2 \pm 1.7$ J K^{-1} mol^{-1} ($K_{BC} = 2.07$ at 25 °C). With regard to the above K_{AC} and K_{BC} values the magnitude of the K_{AB} constant (Scheme 2) can be estimated as $K_{AB} = K_{AC}/K_{BC}$ (for example, $K_{AB} = 1.37$ at 25 °C).

It should be particularly emphasized that in the 2D-NMR ^{31}P–{^1H} spectra (Fig. 4) cross-peaks between $A_{1(2)}$ and C signals have rather high intensity at both mixing time, 130 and 500 ms, intensity of cross-peaks between B and C signals is detectable only at mixing time 500 ms and negligible (minor) at 130 ms, while cross-peaks between $A_{1(2)}$ and B signals are completely absent. From the dependence of integral intensities of the exchange cross-peaks on mixing time in NOESY ^{31}P–{^1H} spectra (Fig. 4), the rate constants for the **A**–**C** exchange can be only roughly estimated [41] at about several s^{-1} whereas those for the **B**–**C** exchange are many times smaller. Low rates of the **B**–**C** exchange and unobserved **A**–**B** exchange confirm above-made assignment of **B** form to *cis*-isomer with slow *cis*–*trans*-isomerisation rate. In any case the roughly estimated rate constant values for any exchange processes between **A**, **B**, and **C** forms are too small to

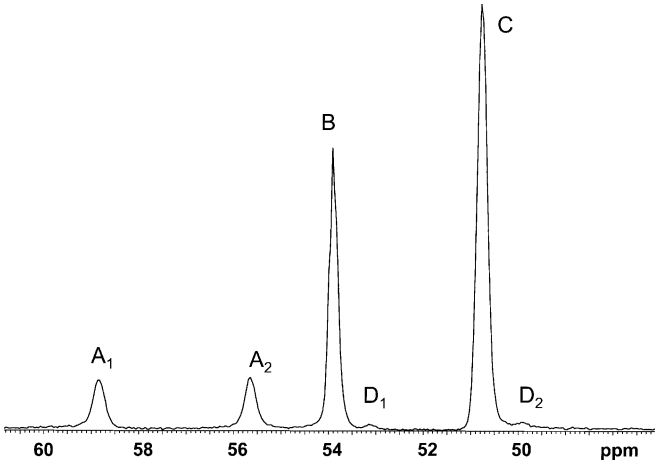

Fig. 6. The NMR ^{31}P–{^1H} spectrum of the complex [Ni{*t*BuNHC(S)-NP(S)(OPr^i)$_2$-*S*,*S*}$_2$] solution in dichloromethane-d_2 at 25 °C and 121.4 MHz [40].

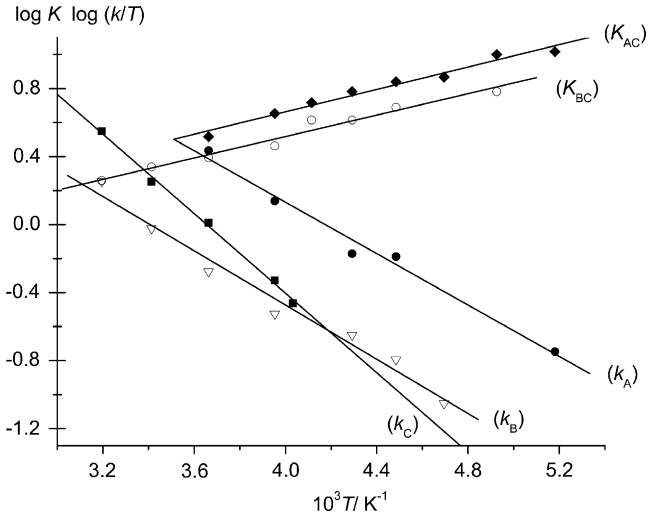

Fig. 7. Dependences of $\log K_{AC}$, $\log K_{BC}$, $\log(k_A/T)$, $\log(k_B/T)$, and $\log(k_C/T)$ on $1/T$ for the complex **10** solutions in dichloromethane.

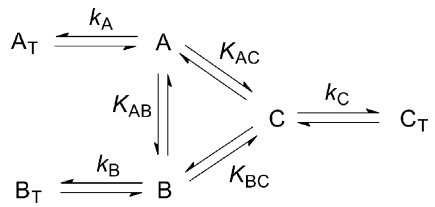

Scheme 2. Conformation equilibria realized in the complex **10** solutions in dichloromethane.

explain the observed line-width spreading of all signals when temperature is increased (Fig. 3). The increasing of the line-width at half height ($\Delta\nu_{1/2}$) with increasing temperature for diamagnetic species **A**, **B**, and **C** (Fig. 3) is explicable only through acceleration of "slow" chemical exchange between them and respective minor (unobserved) pseudo-tetrahedral forms of D_{2d} symmetry ($\mathbf{A_T}$, $\mathbf{B_T}$, and $\mathbf{C_T}$). According to well-known relations [41] such exchange provides also an explanation for marked upfield shift of the A_1, A_2, and C signals with increased temperature (Fig. 3). Indeed, on the one hand, the equilibrium square-planar-pseudo-tetrahedral isomers for nickel(II) complexes are commonly shifted with temperature to the latter [13,38,42,43]. On the other hand, large upfield ^{31}P NMR shift is typical for paramagnetic nickel(II) species [13,29,32]. As an example, the upfield ^{31}P NMR shifts are −86 and −424 ppm (at 298 K), respectively, for mono-adduct and bis-adduct of [Ni{PhC(S)NP(S)(OPr^i)$_2$-*S*,*S*}$_2$] with pyridine [32] and ∼−500 ppm for [Ni{(SPPh$_2$)$_2$N-*S*,*S*}$_2$] in organic solvents [13]. (The very slight temperature dependence of the B signal shift (Fig. 3) will be explained below). Hence the equilibria realized in studied solutions can be presented by Scheme 2.

In the "slow-exchange" limit Eq. (2) [41] applies to the line-width ($\Delta\nu_{1/2}$) or spin-spin relaxation rate (T_2^{-1}) of the **A** or **B** or **C** form.

$$\pi\Delta\nu_{1/2} = T_2^{-1} = T_{2A(B,C)}^{-1} + \tau_{A(B,C)}^{-1}. \quad (2)$$

In this expression $T_{2A(B,C)}^{-1}$ is the spin–spin relaxation rate of the **A**(**B**,**C**) form in the absence of chemical exchange and $\tau_{A(B,C)}$ is the life time of this form associated with the pseudo-first-order rate constants for transitions $\mathbf{A} \rightarrow \mathbf{A_T}$, $\mathbf{B} \rightarrow \mathbf{B_T}$, and $\mathbf{C} \rightarrow \mathbf{C_T}$, respectively, $\tau_{A(B,C)}^{-1} = k_{A(B,C)}$, see Scheme 2. In such a manner the k_A, k_B, and k_C values at different temperatures were estimated by Eq. (2) including the $T_{2A(B,C)}^{-1} = \pi \cdot 8$ Hz contribution and then the activation enthalpy ($\Delta H_A^{\neq}$, $\Delta H_B^{\neq}$, and $\Delta H_C^{\neq}$) and entropy ($\Delta S_A^{\neq}$, $\Delta S_B^{\neq}$, and $\Delta S_C^{\neq}$) of the $\mathbf{A} \rightarrow \mathbf{A_T}$, $\mathbf{B} \rightarrow \mathbf{B_T}$, and $\mathbf{C} \rightarrow \mathbf{C_T}$ reactions were evaluated from the $\log(k_{A(B,C)}/T) - 1/T$ dependencies (Fig. 7) using the Eyring equation (3).

$$k = (k_B T)/h \cdot \exp(\Delta S^{\neq}/R)\exp(-\Delta H^{\neq}/RT). \quad (3)$$

The results obtained are $\Delta H_A^{\neq} = 14.5 \pm 1.1$ kJ mol^{-1} and $\Delta S_A^{\neq} = -137.2 \pm 4.6$ J K^{-1} mol^{-1} (with $k_A = 1.2 \times 10^3$ s^{-1} at 25 °C), $\Delta H_B^{\neq} = 15.3 \pm 1.1$ kJ mol^{-1} and $\Delta S_B^{\neq} = -145.6 \pm 4.2$ J K^{-1} mol^{-1} (with $k_B = 3.3 \times 10^2$ s^{-1} at 25 °C), and $\Delta H_C^{\neq} = 22.5 \pm 0.9$ kJ mol^{-1} and $\Delta S_C^{\neq} = -115.4 \pm 3.3$ J K^{-1} mol^{-1} (with $k_C = 6.7 \times 10^2$ s^{-1} at 25 °C).

Above-mentioned absence of high-field shift with increasing temperature for the B signal in comparison with A and C signals can be then explained by slower $\mathbf{A} \rightarrow \mathbf{A_T}$ exchange relative to the $\mathbf{B} \rightarrow \mathbf{B_T}$ and $\mathbf{C} \rightarrow \mathbf{C_T}$ exchange, $k_A < k_B$, k_C (see [41]). In this case the slight temperature upfield shift of the B signal that is responsible for exchange may be canceled by own downfield temperature shift of the B_T signal due to Fermi-contact interaction (cf. [32]).

The above-mentioned low rates of the exchange processes between square-planar **A** and **B** or **B** and **C** forms are due to need of *cis–trans*-isomerisation. The latter can be only slow because it calls for conversion of pseudo-tetrahedral D_{2d} isomers ($\mathbf{A_T}$ and $\mathbf{B_T}$) to high-energy tetrahedral T_d transition state. It is necessary to note small accumulation fractions of the pseudotetrahedral isomers and the higher rates of their interconversion with the square-planar forms for the compound **10** in reference to the nickel(II) complexes with Schiff bases [42–44]. The minor accumulation of the pseudotetrahedral forms can be explained by a high degree of covalency of the Ni–S bonds (similar to the Cu–S σ and π bonds [45]) providing higher crystal field stabilization energy (CFSE) for the square-planar isomers with low-spin d^8 configuration in comparison with high-spin D_{2d} isomers.

3. Experimental

3.1. General procedures

Infrared spectrum was recorded in Nujol in the range 250–4000 cm^{-1} on a Bruker-Vector 22 Fourier-transform spectrometer. Electronic absorption spectra of solutions were recorded in the range 200–900 nm on a Perkin–Elmer Lambda 35 spectrophotometer. The NMR ^{31}P–{^{1}H} spectra were obtained at 121.4 MHz using a Varian Unity-300 NMR spectrometer with a standard VTC 4 variable temperature unit. Spectra were recorded with complete ^{1}H noise decoupling. Normal conditions were as follows: sweep width 400 ppm; pulse consisting 7 μs (45°), number of accumulations 250–7000 and a repetition rate of 1–5 s. The 2D-NMR NOESY ^{31}P–{^{1}H} spectra were obtained on the Bruker AVANCE-400 NMR spectrometer (9.4 T) at 161.9 MHz for ^{31}P with mixing time 10–500 msec. NOESY spectra were acquired in the phase sensitive TPPI mode, with 1 K × 64 complex FIDs, spectral width of 2500 Hz, recycling delay of 2 s, 64 scans, at −20 °C. The high-resolution solid-state NMR experiments were acquired using a Bruker DSX-400 spectrometer (9.4 T) and 4 mm Bruker probe head. Room temperature ^{31}P MAS spectra were acquired using single-pulse consisting of 0.5 μs (π/12) pulse widths of 300 kHz, and pulse delays of 5 s, with collection of 256 transients and spinning rate of 10 kHz. The ^{31}P chemical shifts are referenced to 85% phosphoric acid (0 ppm). Transverse relaxation times (T_2)

were evaluated from the NMR $^{31}P–\{^1H\}$ line-widths ($\Delta\nu_{1/2}$) by relation $T_2^{-1} = \pi(\Delta\nu_{1/2})$ with an accuracy of 3–5%. ^{13}C chemical shifts were measured relative to adamantane as external standard. Spinning rate was 12 kHz. The electronic spectra reconstruction and thermodynamic and kinetic parameters computations were carried out by means of Microcal Origin 6.1 programs. Electrospray mass spectrum was obtained on a Micromass Q-TOF Ultima3 instrument.

3.2. *[Ni{PhNHC(S)NP(S)(OPr^i)$_2$-S,S}$_2$] (**10**)*

This complex was prepared according to the established literature method [28]. M.p. 127–129 °C (*Anal.* Calc. for $C_{26}H_{40}N_4NiO_4P_2S_4$: C, 43.29; H, 5.52; Ni, 8.14; P, 8.60. Found: C, 43.65; H, 5.53; Ni, 8.01; P, 8.45%.). IR ν/cm^{-1} (Nujol mull) 3403m [ν(NH)], 1590m [δ(Ph)], 1523s [ν(SPNCS)], 1033s, 1001s, 979s [ν(POC)], 573m [ν(P=S)] and 403w, 370w [ν(Ni–S)]. {Lit.: ν/cm^{-1} (CCl_4, $c = 0.10$ mol dm^{-3}) 3400 (NH), 1525 (S–C=N), 1005 (P–N), 1030, 980 (POC), 575 (P=S); $^{31}P–\{H\}$ NMR: δ 52 (s) [28]}. ESI-MS ($CHCl_3$) {*m*/*z* (%) [assignment]}: 743 (41) $[NiL_2 + Na]^+$, 1111 (100) $[2Ni + 3L]^+$, 1465 (88) $[2(NiL_2) + Na]^+$, 1831 (8) $[3Ni + 5L]^+$. MAS NMR $^{31}P–\{^1H\}$, 56.2 ppm. MAS NMR $^{13}C–\{^1H\}$, ppm: 177.0 (CS), 135.8, 129.4, and 125.6 (all 3 peaks – Ph), 73.1 and 71.8 (OCH_2), 25.8 and 24.6 (CH_3).

3.3. *X-ray crystallography*

Crystal data for **10**: $C_{26}H_{40}N_4NiO_4P_2S_4$, monoclinic, space group $P2_1/c$, $Z = 2$ (molecule in a special position), $a = 8.4637(2)$, $b = 21.3625(2)$, $c = 9.3263(3)$ Å, $\beta = 100.68(2)°$, $V = 1691.2(5)$ Å^3 (at 20 °C), $D_{calc} = 1.42$ g cm^{-3}. Data were collected on an Enraf-Nonius CAD-4 diffractometer in the $\omega/2\theta$-scan mode, $\theta \leqslant 26.9°$, using graphite monochromated MoKα radiation. An empirical absorption correction based on ψ-scans was applied (μMo 9.41 cm^{-1}). The structure was solved by direct method using the SIR [46] program and refined by the full-matrix least-squares using SHELXL97 [47] program. All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were located from a subsequent difference map and refined isotropically in the final cycles. The final residuals were $R(F_o^2) = 0.036, R_w(F_o^2) = 0.073$. All calculations were performed on PC using WINGX [48] program. Cell parameters, data collection and data reduction were performed on Alpha Station 200 computer using MOLEN [49] program. All figures were made using the program PLATON [50].

CCDC-262044 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif. X-ray crystallographic file, in CIF format, for [Ni{PhNHC(S)NP(S)(OPr^i)$_2$-S,S}$_2$] **10**. This material is available free of charge via the Internet at http://pubs.acs.org.

2. Results and discussion

In search of new group 6 metal catalysts, we endeavor to prepare carbonyl complexes of tungsten with a silyl anion such as Ph_3Si^-, Ph_2SiH^-, Et_3Si^-, and Et_2SiH^- in their coordination sphere. We envisage a viable route to such complexes from $W(CO)_6$, whose carbonyl ligands could be replaced by the desired anion in photochemical oxidative addition reaction with the corresponding hydrosilanes. The activation of the Si—H bond by tungsten(0) carbonyls and the formation of a W—H bond can be followed by ^1H NMR spectroscopy due to the appearance of a high-field signal with the corresponding satellite signals caused by the coupling with the ^{183}W atom (14% ^{183}W abundance; $I = 1/2$).

2.1. Activation of the Si—H bond of diphenylsilane

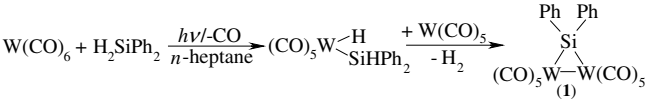
In a previous paper, we showed that the photochemical reaction of $W(CO)_6$ with H_2SiPh_2 leads to the formation of the μ-diphenylsilylene complex $[(\mu\text{-}SiPh_2)\{W(CO)_5\}_2]$ (**1**) [28]. This reaction probably occurs via the formation of an intermediate silyl complex containing a W—H bond, e.g., $[WH(SiHPh_2)(CO)_5]$ (Scheme 1).

However, the pentacarbonyl tungsten(II) compound is very unstable, making direct observation difficult. To utilize the activation of the Si—H bond of diphenylsilane by tungsten carbonyls, the reaction of H_2SiPh_2 with $W(CO)_6$ in the presence of ketones was investigated (Scheme 2).

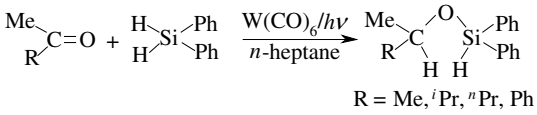
2.1.1. Photochemical reaction of $W(CO)_6$ with H_2SiPh_2 in the presence of $Me_2C{=}O$ and ^iPrOH in the NMR tube

The photochemical reaction of $W(CO)_6$ with H_2SiPh_2 and acetone (6:6:1 molar ratio) in cyclohexane-d_{12} occurs very smoothly to give alkoxysilane, $Ph_2SiH(O^iPr)$ (**I**), as a major product (Scheme 3). The formation of compound **I** is revealed by the characteristic proton signals in the ^1H NMR spectrum, i.e., a singlet at δ_H 5.48 (Si—H, $^1J_{Si-H} = 210$ Hz), a heptet at δ_H 4.12 (CH), and a doublet at δ 1.19 (2Me), in the intensity ratio 1:1:6, respectively (Fig. 1(b)–(d)).

Several small portions of acetone were consumed and transformed almost completely to **I**. The very low-intensity proton signal observed at δ_H 5.64 (Si—H, $^1J_{Si-H} = 220$ Hz) is due to disiloxane, $Ph_2HSiOSiHPh_2$ (**II**) [6b,22,27] identified by GC–MS analysis ($M_r = 382.60$) in the post-reaction mixture. Disiloxane **II** is formed in reaction of H_2SiPh_2 with water, which initially gives a silanol, Ph_2HSiOH (δ_H 5.60, $^1J_{Si-H} = 220$ Hz), which can then react as an alcohol, producing the dehydrosilylation product **II**. The dehydrocondensation of siloxane **I** and diphenylsilanol gives $Ph_2SiHOSiPh_2(O^iPr)$ (**III**), whose Si—H bond was observed by ^1H NMR at δ_H 5.71 ($^1J_{Si-H} = 218$ Hz) (Fig. 1). An alternative route to **III**, which cannot be excluded, is the hydrosilylation of acetone by disiloxane **II**. The formation of compound **III** was also established by GC–MS analysis ($M_r = 440.68$). In order to determine whether the photochemically generated catalyst is also capable of effecting dehydrosilylation after the decay of acetone, 2-propanol was added to the same NMR tube (Fig. 1(d)). Irradiation led to the alcoholysis of H_2SiPh_2, and monoalkoxysilane (**I**) as well as dialkoxysilane $Ph_2Si(O^iPr)_2$ (**IV**) [22,24,25,29] were produced (Fig. 1(e)). The formation of compound **IV** is manifested by characteristic proton signals in the ^1H NMR spectrum, i.e., a heptet at δ_H 4.18 (CH) and a doublet at δ_H 1.18 (Me), in the intensity ratio 1:6. Furthermore, the formation of compound **IV** was proved by GC–MS analysis ($M_r = 300.47$). These spectral results suggest a mechanism for the activation of the Si—H bond of silane in which the coordinatively unsaturated tungsten(0) carbonyl compound activates the silane for backside nucleophilic attack at the silicon by the oxygen atom of ketone, alcohol, or water resulting in the formation of a silicon–oxygen bond. Subsequent reductive elimination of the hydrosilylation or dehydrosilylation product releases the coordinatively unsaturated tungsten(0) carbonyl compound able to activate the Si—H bond of silane.



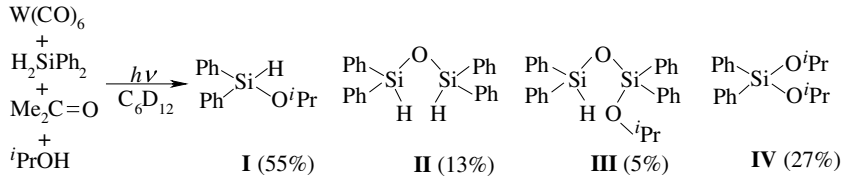
Scheme 1. Photochemical reaction of H_2SiPh_2 with $W(CO)_6$.



Scheme 2. Hydrosilylation of ketones by H_2SiPh_2.

2.1.2. Hydrosilylation of acetone with H_2SiPh_2 in the presence of catalytic amounts of $W(CO)_6$

Irradiation of $W(CO)_6$, H_2SiPh_2, and an excess of acetone (1:50:150 molar ratio) in *n*-heptane gives hydrosilylation product **I** (42%), and disiloxane (**II**) (7.5%) and **III** (1%) (Table 1). However, under these photochemical conditions, acetone can be transformed to 4-hydroxo-4-methyl-2-pentanone, $Me_2C(OH)CH_2COMe$, which undergoes dehydrosilylation by H_2SiPh_2 to give $Ph_2SiH(OCMe_2CH_2COMe)$ as the intermediate dehydrosilylation product and next the cyclization product, 4,6-trimethyl-2,2-diphenyl-1,3-dioxa-2-silacyclohexane $Ph_2Si(OCMe_2CH_2CHMeO)$ (**V**) (13.5%) ($M_r = 298.45$). In the ^1H NMR spectrum of the above reaction mixture, the methine proton of **V** was detected at δ 4.45 as a pseudo sextet, i.e. a quartet of triplets with an average $^3J_{H-H}$ value of 5.2 Hz. Similar dioxasilacycloalkanes have been reported by Bedard and Corey [22] from the reaction of secondary silanes with diols. Although conversion of acetone reached ca. 70% after 10 min of photolysis, in the post-reaction mixture unchanged H_2SiPh_2 was detected by GC–MS in ca. 36% (Table 1).



Scheme 3. Results of GC–MS analysis of silicon compounds formed as a result of H_2SiPh_2 transformation by acetone, 2-propanol, and water in the presence of photochemically activated $W(CO)_6$ in cyclohexane-d_{12} solution.

2.1.3. Dehydrogenative silylation of ^{i}PrOH with H_2SiPh_2 in the presence of $W(CO)_6$

After 2.5 h photolysis of *n*-heptane solution of $W(CO)_6$, H_2SiPh_2, and ^{i}PrOH (1:50:50 molar ratio) the conversion of 2-propanol reached 25% and the formation of silicon compounds **I** (35%), **II** (14%), **III** (10%), and **IV** (7%) was observed by GC–MS analysis (Table 1). Unchanged H_2SiPh_2 was present in 34%, and the formation of biphenyl (<1%) was also detected. This experiment proved that the activation of hydridosilanes by the tungsten atom also plays a key role in alcoholysis of H_2SiPh_2 by 2-propanol.

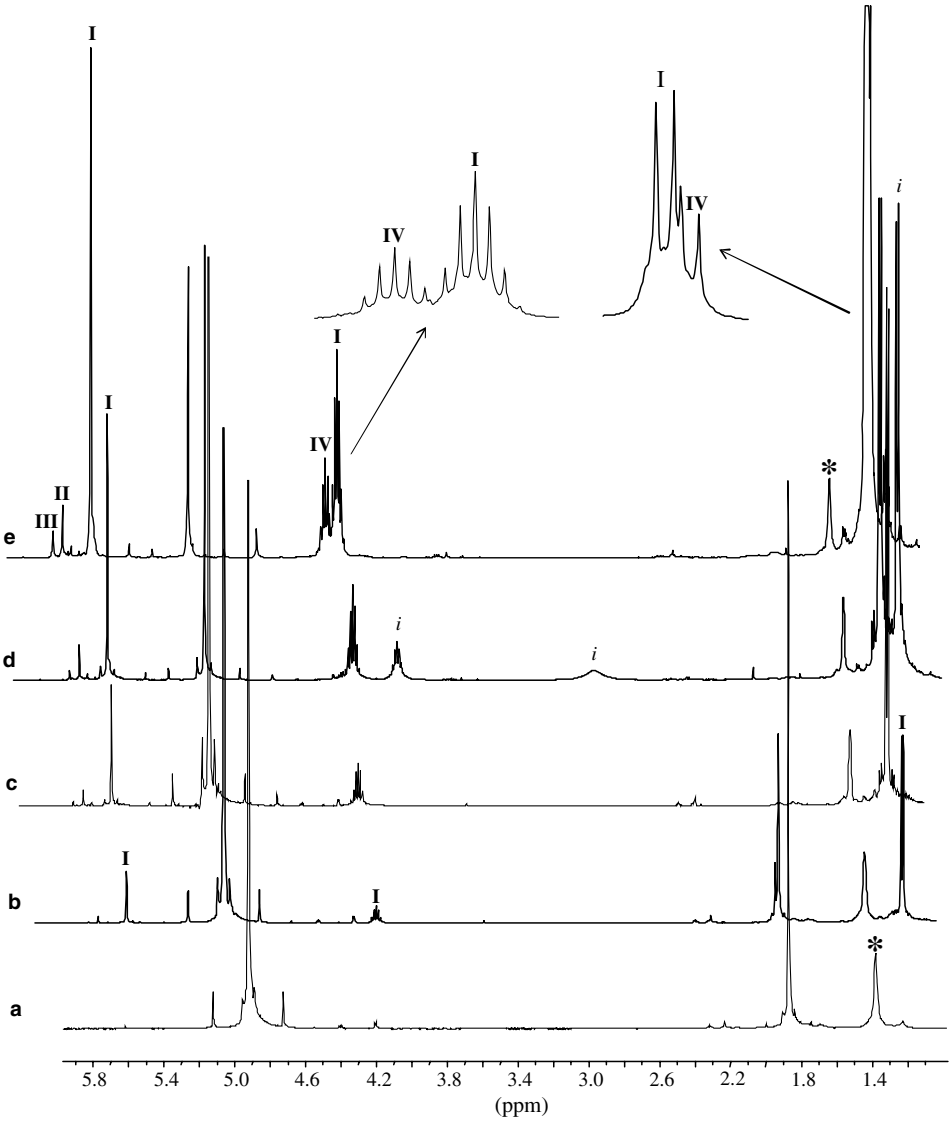


Fig. 1. ^{1}H NMR spectral changes during photolysis of $W(CO)_6$, acetone, and H_2SiPh_2 in cyclohexane-d_{12} (*): (a) prior to photolysis; (b)–(c) after continued photolysis; (d) after addition of ^{i}PrOH (*i*); (e) after photolysis. The peaks at 1.89 and 1.12 ppm represent methyl resonances for acetone and $Ph_2SiH(O^iPr)$ (**I**), respectively. The peaks at 5.48 and 4.94 ppm are due to Si—H proton resonances for **I** and H_2SiPh_2, respectively. Two heptets at 4.18 and 4.12 ppm are due to the methine proton resonances of $Ph_2Si(O^iPr)_2$ (**IV**) and **I**, respectively.

Table 1
Organosilicon compounds detected by GC–MS analysis of the post-reaction mixture obtained from photochemical reaction of $W(CO)_6$, H_2SiPh_2, ketones RMeC=O, R = Me, ^{i}Pr, ^{n}Pr, Ph and/or ^{i}PrOH

[c] Photochemical reaction (2.5 h) of ^{i}PrOH without of ketone.

2.1.4. Hydrosilylation of ^{i}PrMeC=O with H_2SiPh_2 in the presence of $W(CO)_6$

In photochemical reaction (1 h) of $W(CO)_6$, H_2SiPh_2, and ^{i}PrMeC=O (1:50:150 molar ratio) in *n*-heptane the formation of the hydrosilylation product $Ph_2SiH(OCHMe^iPr)$ (**VI**) ($M_r = 270.44$) was observed by GC–MS (Table 1). However, tetraphenyldisiloxane (**II**) was also produced. Some times, the further products of hydrolysis such as $Ph_4Si_4O_3$ (**IIa**) ($M_r = 468.05$) were also detected in small amounts (ca. 1%). The conversion of ^{i}PrMeC=O reached only ca. 20%, but unchanged H_2SiPh_2 was present in 58% in the residue obtained after evaporation of volatile substances.

2.1.5. Hydrosilylation of ^{n}PrMeC=O with H_2SiPh_2 in the presence of $W(CO)_6$

In photochemical reaction (1 h) of $W(CO)_6$, H_2SiPh_2, and ^{n}PrMeC=O (1:50:150 molar ratio) in *n*-heptane the conversion of ^{i}PrMeC=O reached only ca. 30%. The formation of the hydrosilylation product $Ph_2SiH(OCHMe^nPr)$ (**VII**) ($M_r = 270.44$) was observed by GC–MS with 29% yield (Table 1).

2.1.6. Hydrosilylation of acetophenone with H_2SiPh_2 in the presence of $W(CO)_6$

Photochemical reaction (1 h) of $W(CO)_6$, H_2SiPh_2, and MePhC=O (1:50:150 molar ratio) in *n*-heptane leads to the low (ca. 10%) conversion of acetophenone. In the post-reaction mixture, the hydrosilylation product $Ph_2SiH(OCHMePh)$ (**VIII**) ($M_r = 304.46$) was present in 61% and disiloxane **II** in 20% (Table 1).

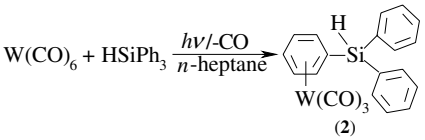
2.1.7. Photochemical reaction of $W(CO)_6$ with H_2SiPh_2 in the presence of water

The photochemical reaction (3.5 h) of $W(CO)_6$, H_2SiPh_2, and water (1:50:50 molar ratio) in *n*-heptane selectively provided disiloxane **II** [6b,22,27], probably through the intermediate formation of diphenylsilanol. In spite of the fact that the formation of $HOSiHPh_2$ was observed (δ_H 5.60, $^1J_{Si-H} = 220$ Hz) in all reactions monitored by ^{1}H NMR, its high reactivity precluded its isolation and full characterization. This experiment proved very well that the reaction of H_2SiPh_2 with water is concurrent to the hydrosilylation of ketones or dehydrogenative silylation of alcohols.

2.2. Photochemical reaction of $W(CO)_6$ with $HSiPh_3$

During the photochemical reaction of $W(CO)_6$ and $HSiPh_3$ in *n*-heptane solution, the η^6-coordination of the phenyl ring of triphenylsilane to the tungsten atom and the formation of the compound $[W(CO)_3(\eta^6\text{-}PhSiHPh_2)]$ (**2**) as the major product and no oxidative addition of the Si—H bond to the tungsten atom was observed (Scheme 4) [30].

In an attempt to reveal the reactivity of compound **2** we treated its cyclohexane-d_{12} solution with acetone. Proton NMR analysis showed the immediate decay of the proton signal characteristic for the Si—H bond of **2** and the appearance of new proton signals at 3.47 and 1.17 ppm in an intensity ratio of 1:6. Such results suggested a strong interaction between the C=O linkage of acetone and the Si—H bond of **2**. However, the evaporation of acetone returned the chemical shift values for compound **2** to their original position in the absence of acetone. In an attempt to activate compound **2** for further reaction, we irradiated its solution in C_6D_{12} containing $HSiPh_3$ and ca. 15 equiv. of acetone. ^{1}H NMR monitoring of proton signals indicates that acetone could not be hydrosilylated by $HSiPh_3$ in the presence of **2**. The appearance of a proton signal at 2.34 ppm indicates rather the coordination of an acetone molecule to the tungsten atom in place of the CO ligand, lost during the irradiation. The η^6-coordination of silane to the tungsten atom does not activate the Si—H bond of **2** for the 1,2 addition of the carbonyl group of acetone.



Scheme 4. η^6-arene compound **2** formed in photochemical reaction of $HSiPh_3$ with $W(CO)_6$ in *n*-heptane solution.

2.3. Photochemical reaction of $W(CO)_6$ with $HSiEt_3$

Upon irradiation of $W(CO)_6$ and $HSiEt_3$ in cyclohexane-d_{12} the η^2-coordination of the Si—H bond to the tungsten atom was detected by ^1H NMR spectroscopy due to a high-field shift for the hydrogen bound to silicon from δ_H 3.71 (heptet, $^3J_{H-H} = 3.2$ Hz, $^1J_{Si-H} = 179$ Hz) to $\delta_H - 8.58$ (heptet, $^3J_{H-H} = 1.6$ Hz, $^1J_{W-H} = 35$ Hz, $^1J_{Si-H} = 89$ Hz) (Fig. 2). Although the value of the tungsten–hydrogen coupling constant is typical for the W—H bond, the magnitude of the silicon–hydrogen coupling constant indicates substantial retention of the Si—H bond and the formation of an η^2–silane complex. A similar $^1J_{Si-H}$ value of ca. 80 Hz was earlier observed for chromium compounds formed in photochemical reaction of [$Cr(CO)_3(\eta^6$-arene)] and H_2SiPh_2 [6a]. These NMR data support the existence of a three-centre, two-electron Si—H···W bond (Scheme 5).

Such agostic interactions between C—H bonds and transition metal centres have been detected in numerous electronically unsaturated transition metal alkyl and alkylidene complexes and have been shown to play a key role in many catalytic processes involving the C—H bond activation [31–36]. As was shown by a ^1H NMR experiment, the addition of acetone to the NMR tube containing the Si—H bond of $HSiEt_3$ activated by η^2-coordination to the tungsten atom leads to the formation of the hydrosilylation product $Et_3Si(O^iPr)$ (**IX**) [24]. The formation of compound **IX** is indicated by the characteristic proton signals, i.e., a heptet at δ_H 3.99 (CH) and a doublet at δ_H 1.13 (2Me) in an intensity ratio of 1:6, respectively. The proton signals of the ethyl groups of compound **IX** are very close to those of free silane and are observed at δ_H 0.97 (t, Me) and 0.57 (q, CH_2).

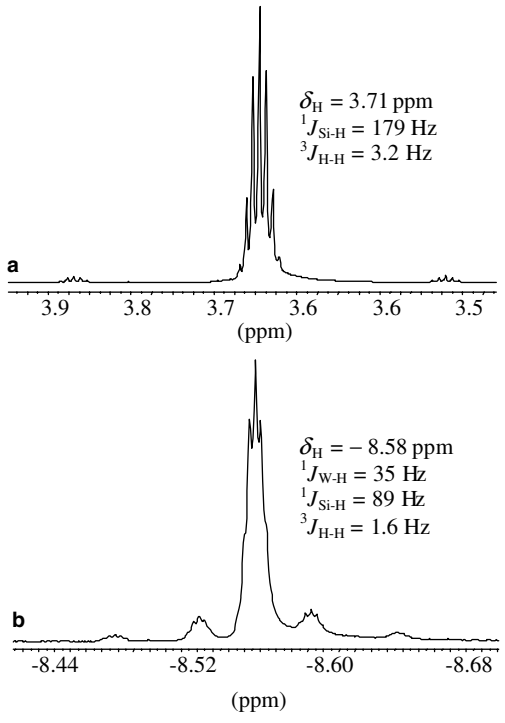


Fig. 2. (a) The Si—H region of the ^1H NMR spectrum of $HSiEt_3$ in C_6D_{12}. (b) Proton signal at δ_H −8.58 generated during the photolysis of $HSiEt_3$ in the presence of $W(CO)_6$ at 279 K showing the η^2-interaction of the Si—H bond with the tungsten atom.

$$W(CO)_6 + HSiEt_3 \xrightarrow[C_6D_{12}]{h\nu/-CO} (CO)_5W \leftarrow \begin{matrix} H \\ | \\ SiEt_3 \end{matrix}$$

Scheme 5. Activation of Si—H bond of $HSiEt_3$.

The monitoring of photochemical reaction between $W(CO)_6$ and $HSiEt_3$ in *n*-heptane solution by IR spectroscopy revealed the decay of the ν(CO) frequency due to $W(CO)_6$ and the appearance of three ν(CO) bands characteristic for a pentacarbonyltungsten moiety with a local C_{4v} symmetry at 2083 (vw), 1951 (vs), and 1938 (s) cm^{-1}. A week band simultaneously observed at 1914 cm^1 may be due to a ν(CO) frequency of a subsequently formed $W(CO)_4$ moiety. However, isolation of the pure reaction product failed. Evaporation of the solvent gave a compound whose IR spectrum in the carbonyl region (2098 (vw), 2069 (w), 2006 (s), 1912 (vs)) was rather similar to the binuclear compound **1** [28].

2.4. Photochemical reaction of $W(CO)_6$ with H_2SiEt_2

The photochemical reaction between $W(CO)_6$ and H_2SiEt_2 in *n*-heptane solution was monitored by IR spectroscopy, which showed the decay of the ν(CO) frequency due to $W(CO)_6$ and the appearance of three ν(CO) bands characteristic for the pentacarbonyltungsten moiety at 2086 (w), 1958 (vs), and 1944 (s) cm^{-1}. A very weak band observed at 2098 cm^{-1} may be due to the ν(CO) frequency of a simultaneously formed binuclear compound. However, isolation of the pure reaction product failed. Evaporation of the solvent gave a mixture of compounds whose IR spectrum in the carbonyl region (ν(CO): 2098 (vvw), 2070 (w), 2010 (s), 1959 (vs), and 1944 (vs)) is rather similar to the binuclear compound **1** with ν(CO) bands at 2098 (s), 2056 (vs), 2032 (s), 2020 (w), 2007 (s), 1975 (vs), and 1956 (vs) [28] and [{W(μ-SiI_2)$(CO)_5$}$_2$] obtained by Schmid and Boese (ν(CO): 2065, 1995, 1935) [37]. The ^1H NMR spectrum (toluene-d_8, 243 K) of this crude product revealed three hydride resonances at δ_H −8.98 ($^1J_{W-H} = 40$ Hz), −9.32 ($^1J_{W-H} = 37$ Hz), and −10.18 ($^1J_{W-H} = 44$ Hz) in an intensity ratio of 1:10:1, respectively. The hydride signal at −9.32 ppm has comparable intensity to proton signal at 4.80 ppm, on which 29-silicon satellites are observed (Fig. 3). This NMR spectrum indicates the presence of a H—W—$SiHEt_2$ unit. The IR and NMR data suggest the formation of a mixture of pentacarbonyl and tetracarbonyl hydride compounds also containing a binuclear compound such as [{W(μ-$SiEt_2$)H$(CO)_4$}$_2$] characterized by the X-ray diffraction study by Bennett and Simpson [38]; however, none was isolated from the reaction mixture in a pure state.

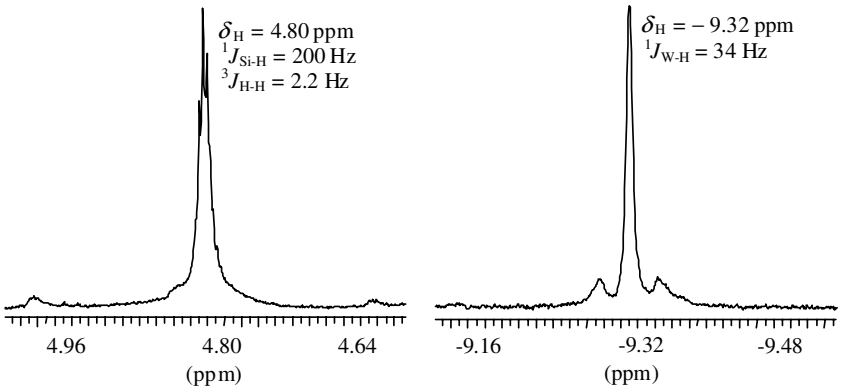

Fig. 3. The Si—H and W—H region of the ^{1}H NMR spectrum (C_7D_8, 500 MHz), showing the formation of a H—W—SiHEt$_2$ unit in photochemical reaction of W(CO)$_6$ with H_2SiEt_2.

3. Conclusions

Photochemical reactions of W(CO)$_6$ create a coordinatively unsaturated d^6 species which interacts with the Si—H bond of hydridosilanes such as H_2SiPh_2, H_2SiEt_2, and $HSiEt_3$. The η^2-interaction of the Si—H bond with the tungsten atom and the existence of a three-centre, two-electron Si—H···W bond was detected by ^{1}H NMR during the photochemical reaction of W(CO)$_6$ with $HSiEt_3$ in cyclohexane-d_{12} ($\delta_H - 8.58$, heptet, $^3J_{H-H} = 1.6$ Hz, $^1J_{W-H} = 35$ Hz, $^1J_{Si-H} = 89$ Hz). This spectral result is consistent with a mechanism where a tungsten(0) compound activates the Si—H bond of silane for backside nucleophilic attack by the oxygen atom of ketone, alcohol, or water at the silicon atom, resulting in the formation of a silicon–oxygen bond.

The photochemical activation of W(CO)$_6$ has been found effective for both the hydrosilylation of ketones as well as the dehydrosilylation of 2-propanol and water by H_2SiPh_2. In reaction with water H_2SiPh_2 transforms very easily to silanol and next to disiloxane. The reaction of H_2SiPh_2 with water is concurrent to the hydrosilylation of ketones or dehydrosilylation of alcohols.

It must be noted that the activation of Si—H bond by tungsten(0) carbonyls can be observed only in non-coordinating solvents such as alkanes, which proves that silanes are activated by the coordinatively unsaturated complex of tungsten(0). We continue to investigate the scope and mechanistic details of these tungsten-catalyzed processes.

Further efforts to explore the photochemical reaction of W(CO)$_6$ with hydrosilanes in catalytic hydrosilylation of C=C bonds of cyclic olefins (norbornene and norbornadiene) are currently in progress.

4. Experimental

4.1. General information

The synthesis and manipulation of all chemicals was carried out under an atmosphere of nitrogen using the standard Schlenk technique. Solvents and liquid reagents were predried with CaH_2 and vacuum-transferred into small storage flasks prior to use. Other chemicals (W(CO)$_6$, H_2SiPh_2, $HSiPh_3$, H_2SiEt_2, and $HSiEt_3$) were obtained from commercial suppliers and used as received. IR spectra were measured with a Nicolet-400 FT-IR instrument. NMR spectra were obtained on a Bruker AMX 500 MHz spectrometer (^{1}H NMR, 500.13 MHz; ^{13}C{^{1}H} NMR, 125.76 MHz; ^{29}Si{^{1}H} 99.36 MHz). The chemical shifts for ^{1}H NMR spectra were referenced to the residual protons in $CDCl_3$ at δ_H 7.24 and in cyclohexane-d_{12} at δ_H 1.40 or to the proton signal of the Si—H bond of H_2SiPh_2 at δ_H 4.93. ^{13}C NMR spectra were calibrated to the natural abundance of ^{13}C in $CDCl_3$ at δ_C 77.00 and in cyclohexane-d_{12} at δ_C 27.8. ^{29}Si{^{1}H} NMR spectra were calibrated to $SiMe_4$ or to the signal of H_2SiPh_2 at δ_{Si} −37.08. The photolysis source was an HBO 200 W high-pressure Hg lamp. The analysis of the organic products was carried out on a Hewlett–Packard GC–MS system.

4.2. Photochemical reaction of W(CO)$_6$ with silanes

A solution of W(CO)$_6$ (0.1 g, 0.28 mmol) and silanes (H_2SiPh_2 [28], $HSiPh_3$ [30], H_2SiEt_2, $HSiEt_3$) (ca. 0.28 mmol) in freshly distilled *n*-heptane (60 cm^3) was irradiated through quartz at 283 K or at room temperature (H_2SiPh_2 and $HSiPh_3$). Generally, the color of the solution changed from yellow to brown during the course of the reaction, which was monitored by IR measurements in solution. Photolysis was stopped when the IR band of W(CO)$_6$ reached its minimum intensity (ca. 1–4 h). The volatile materials were then stripped from the reaction mixture under reduced pressure at room temperature. The residue was analyzed by IR and NMR spectroscopy. In reaction of H_2SiPh_2 and $HSiPh_3$ analytically pure compounds **1** [28] and **2** [30] were isolated, but in other cases isolation of pure compounds was not possible due to substantial decomposition even in strictly anhydrous conditions.

4.3. Reactions in a NMR tube

A solution of W(CO)$_6$ (0.01 g, 0.028 mmol) and silane in cyclohexane-d_{12} or toluene-d_8 (0.7 cm^3) was irradiated in a

NMR tube at 283 K or 243 K and periodically analyzed by ^{1}H NMR at an appropriate temperature. Reactions with acetone and 2-propanol subsequently added via syringe to the NMR tube were carried out under the same conditions.

4.4. Procedure for testing the catalytic activity of $W(CO)_6$ and characterization of silicon compounds

Hydrosilylation experiments were carried out in a photoreactor containing *n*-heptane solution (10 cm^3) of $W(CO)_6$ (0.01 g, 0.028 mmol), H_2SiPh_2 (0.26 cm^3, 1.4 mmol), ketone (4.2 mmol), and cyclopentane, hexane, or undecane as the internal chromatographic standard. In reaction of 2-propanol and water, the molar ratio of H_2SiPh_2 and the reagents was 1:1. The reaction mixture was irradiated (1 h) through quartz at room temperature, and the conversion was monitored by gas chromatography. The solvent was then removed under reduced pressure at room temperature, and the residue was analyzed by GC–MS and NMR spectroscopy.

4.5. Identification of silicon compounds detected during the hydrosilylation and dehydrogenative silylation reactions

$Ph_2SiH(O^iPr)$ (**I**) ($C_{15}H_{18}OSi$, $M_r = 242.39$). GC–MS: *m*/*z* (relative intensity): 242 (M^+, 4), 199 (24), 183 (50), 164 (100), 122 (96), 105 (38), 78 (50). ^{1}H NMR ($CDCl_3$, 298 K): δ_H 7.6–7.2, (m, 10H, Ph), 5.48 (s, $^1J_{Si-H} = 210$ Hz, 1H, Si—H), 4.14 (heptet, $^3J_{H-H} = 6$ Hz, 1H, CH), 1.20 (d, $^3J_{H-H} = 6$ Hz, 6H, Me). $^{13}C\{^1H\}$ NMR ($CDCl_3$, 298 K): δ_C 67.25 (1C, CH), 25.11 (2C, Me). $^{29}Si\{^1H\}$ NMR (cyclohexane-d_{12}, 298 K): δ_{Si} − 18.56.

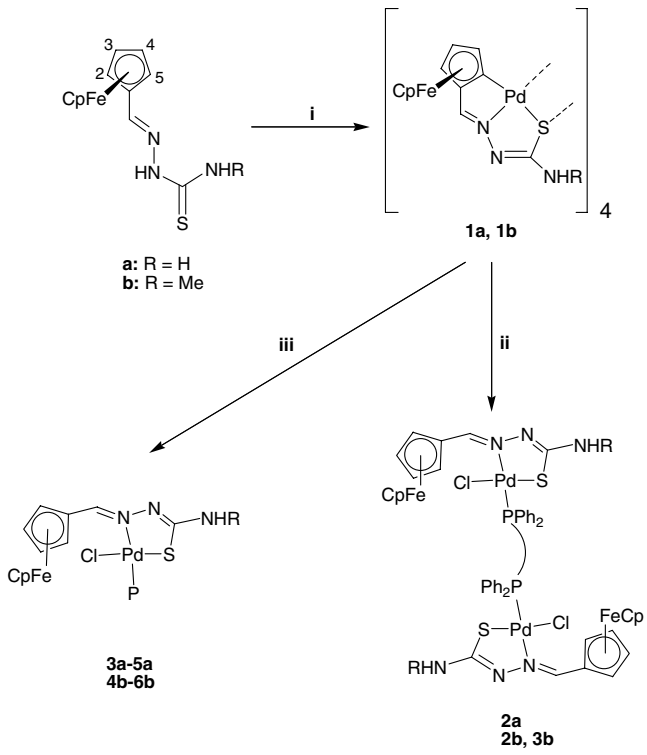
[C(sp^2/aryl or sp^3), N, X] terdentate ligands are well known and many examples have been reported with X = N [14], S [15], O [16], mainly due to the potential hemilability of the Pd–X bond in these systems, which plays an important role in homogeneous catalysis. Nevertheless all the examples reported for those complexes containing terdentate [C(sp^2/ferrocene), N, X] ligands are scarce, and to the best of our knowledge only compounds with X = N [17] and S [17b,17d,18] have been described, and recently ferrocene-based pincer complexes of palladium have been reported, bearing a terdentate [P, C, P] ligand [19]. Ferrocene-based cyclometallated complexes with [C, N, S] ligands are mainly with thioethers, and the unique examples derived from thiosemicarbazones have been recently reported by us [20]. As a continuation of our studies related to ferrocenylthiosemicarbazone ligands, herein we report the synthesis and characterization of new polynuclear organometallic and coordination compounds, the latter being generated after unusual σPd–C bond cleavage in the starting material.

2. Results and discussion

2.1. Synthesis and characterization

The thiosemicarbazones (η^5-C_5H_5)Fe(η^5-C_5H_4)C(H)=NN(H)C(=S)NHR (R = H, **a**; R = Me, **b**) were obtained by reaction of ferrocenecarboxaldehyde with thiosemicarbazide or with 4-methylthiosemicarbazide, respectively, in H_2O in the presence of HCl at room temperature. The NH_2 protons gave rise to two characteristic resonances at 6.33 and 7.10 ppm in the ^{1}H NMR spectrum of ligand **a** which were attributed to the restricted rotation of the NH_2 group about the C(=S)NH_2 axis. The NH protons showed resonances at 9.79 (**a**), 7.34 (N*H*Me, **b**) and 9.41 ppm (N*H*, **b**). A singlet ca. 7.80 ppm was assigned to the HC=N proton, and two apparent triplets ca. 4.50 ppm were ascribed to the H2/H5 and H3/H4 protons of the substituted ferrocenyl ring, as a simplification of the expected 20 lines of the theoretical spectrum for an AA′XX′ spin system. The C_5H_5 resonance appeared as a singlet at 4.20 ppm. The resulting new complexes derived from **a** and **b** are shown in Scheme 1. Preparative details, characterising microanalytical, IR, ^{1}H and ^{31}P–{^{1}H} NMR data are in Section 4.

Thus, treatment of a suspension of K_2PdCl_4 in EtOH/H_2O with the corresponding thiosemicarbazone afforded the cyclometallated complexes [Pd{(η^5-C_5H_5)Fe(η^5-C_5H_3)C(H)=NN=C(S)NHR}]$_4$ (R = H, **1a**; R = Me, **1b**), with the ligand in the *E*/*Z* configuration for which an octanuclear structure is proposed following the trend for these and other related compounds of tridentate [C, N, S] ligands [21]; the FAB mass spectra of **1a** and **1b** showed clusters of peaks, centred at 1566 and 1622 amu, which correspond to $[M]^+$, supporting the proposed formulation. The sulfur atom of each cyclometallated moiety displaying two different coordination modes: chelating, as part of the Pd*N*NC(NHR)*S* coordination ring, and bridging, linking two cyclometallated moieties through the metal atoms.



Scheme 1. (i) K_2PdCl_4, ethanol/water; (ii) $Ph_2P(CH_2)_nPPh_2$ (*n* = 1, **2b**; *n* = 4, **2a**, **3b**) 1:2 molar ratio, acetone, CH_2Cl_2/hexane; (iii) $P(PPh_3$, **3a**, **4b**; PPh_2Et, **4a**, **5b**; $P(C_6D_5)_3$, **5a**, **6b**) 1:4 molar ratio, acetone, CH_2Cl_2/hexane.

The absence of the signal for the NH group in the ^{1}H NMR spectra was in agreement with deprotonation [22]. The NH_2 (**1a**) and N*H*Me (**1b**) resonances appeared as a singlet (5.34 ppm) and a broad signal (5.37 ppm), respectively, shifted to lower frequency with respect to the spectra of the free ligands. Metallation of the ligand was clear from the absence of the AA′XX′system of the C_5H_4 ring; three proton resonances were assigned to the new C_5H_3 ring (see Section 4). In the IR spectra, the presence of the *ν*(N–H) band ca. 3420 cm^{-1} indicated the NHR group was not coordinated, and absence of the *ν*(N–H) band for the NNH group confirmed deprotonation of the latter [23]. The *ν*(C=N) band was shifted to lower wavenumbers upon complex formation [24] in an opposite trend to that observed in other thiosemicarbazones complexes [23], which can be attributed to the C,N moiety being part of the five-membered metallacycle [25]. The band assigned to the *ν*(C=S) stretching vibration ca. 870 cm^{-1} in the free ligands disappeared in the spectra of the complexes, in accordance with loss of the C=S double bond character upon deprotonation of the NH group.

Treatment of complexes **1a** and **1b** with tertiary diphosphines (1:2 molar ratio) or monophosphines (1:4 molar ratio) in acetone at room temperature and ulterior recrystallization from CH_2Cl_2/*n*-C_6H_{14} gave rise to tetranuclear or dinuclear complexes, respectively, with loss of the metallated ring upon cleavage of the σPd–C bond, as opposed to the case of similar complexes with ferrocenylthiosemicarbazones obtained by us earlier [21b], where

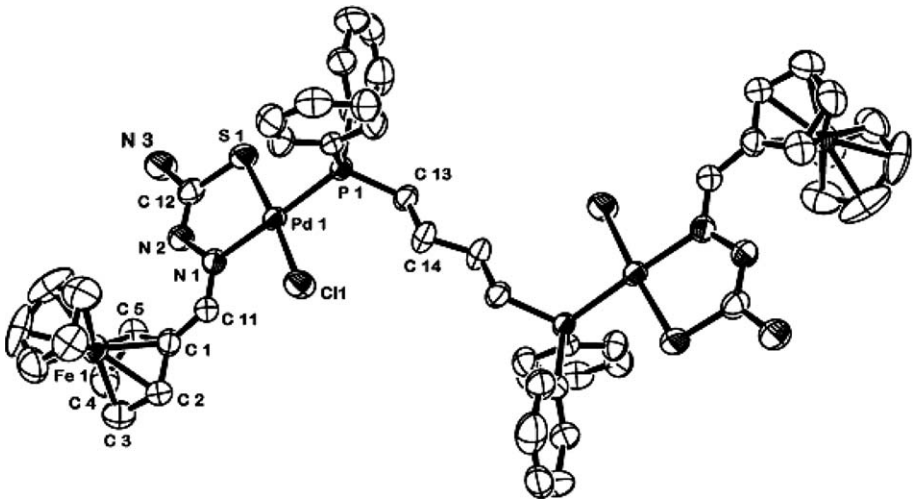


Fig. 1. Molecular structure of [{Pd[(η^5-C_5H_5)Fe(η^5-C_5H_4)C(H)=NN=C(S)NH_2](Cl)}$_2${μ-$Ph_2P(CH_2)_4PPh_2$}] (**2a**), with labelling scheme. Hydrogen atoms have been omitted for clarity.

the metal–carbon bond was retained. These results, together with our most recent findings[1], allow us to anticipate possible reasons for the behaviour of these complexes: (a) the absence of the MeC=N methyl group in the present complexes seems to favour demetallation of the cyclopentadienyl ring; (b) under the reaction conditions employed the source of chlorine should be either dichloromethane, which would put forward the non-spectator character of this solvent, or possibly traces of acid in the solvent; (c) it is also noteworthy to point out that the latter could account for the proton source and act as catalyst in the process [26]. Thus, reaction of **1a** and **1b** with tertiary diphosphines ($Ph_2PCH_2PPh_2$, $Ph_2P(CH_2)_4PPh_2$, 1:2 molar ratio) or with tertiary monophosphines (PPh_3, PPh_2Et, $P(C_6D_5)_3$, 1:4 molar ratio) gave the tetranuclear complexes [{Pd[(η^5-C_5H_5)Fe(η^5-C_5H_4)C(H)=NN=C(S)NHR]-(Cl)}$_2$(μ-PP)] (**2a**, **3b**: PP = $Ph_2P(CH_2)_4PPh_2$; **2b**, PP = $Ph_2PCH_2PPh_2$; see Scheme 1) and the dinuclear complexes [Pd{(η^5-C_5H_5)Fe(η^5-C_5H_4)C(H)=NN=C(S)-NHR}(Cl)(P)] (**3a**, **4b**: P = PPh_3; **4a**, **5b**: P = PPh_2Et; **5a**, **6b**, P = $P(C_6D_5)_3$; see Scheme 1), respectively; with the diphosphine acting as a bridging ligand between the two palladium atoms in the former case. In the IR spectra, the absence of the *ν*(C=S) stretching vibration and of the *ν*(N–H) band for the NNH group, as well as the shift to lower wavenumbers of the *ν*(C=N) band was in accordance with [N,S] coordination of the deprotonated ferrocenylthiosemicarbazone ligands to the palladium atom. A band ca. 310 cm^{-1} was assigned to the *ν*(Pd–Cl) vibration, in accordance with the now present terminal Pd–Cl bonding. In the ^{1}H NMR spectra, two apparent triplets assigned to the H2/H5 and H3/H4 protons (AA′XX′ system) confirmed the regeneration of the substituted ferrocene ring, whilst absence of the –NH resonance suggested the hydrazynic nitrogen atom remained deprotonated. The *H*C=N resonance ca. *δ* 8.30 ppm appeared as a doublet due to coupling with the ^{31}P nucleus [^4J(PHi) ca. 4.0 Hz], thereby indicating a phosphorus *trans* to nitrogen geometry, within the terms of the "transphobic effect" [27]; in the case of complexes **2a**, **2b**, **3b**, the ^{1}H NMR spectra showed only one set of signals putting forward the symmetric nature of these complexes. The ^{31}P–{^{1}H} NMR spectra showed a singlet, shifted to higher frequency from the spectrum of the free phosphine, in agreement with phosphorus coordination to metal center; for complexes **2a**, **2b**, **3b**, this showed that the two phosphorus nuclei were equivalent [28] as might be expected from the ^{1}H NMR data (vide supra).

2.2. Molecular structures of compounds *2a* and *2b*

Suitable crystals of **2a** and **2b** were grown by slowly evaporating CH_2Cl_2/*n*-C_6H_{14} solutions. The molecular structure of each neutral compound with the numbering scheme is illustrated in Figs. 1 and 2, respectively. Selected bond lengths and angles are listed in Table 1. The structures consist in discrete molecules separated by van der Waals distances (Table 2).

The crystal structures comprise a half molecule per asymmetric unit, and exhibit C_2 symmetry about the PCH_2CH_2–CH_2CH_2P bond (**2a**) or the central PCH_2P group (**2b**). The four-coordinated palladium(II) atoms are bonded to an iminic nitrogen atom and a thioamide sulphur atom of the deprotonated thiosemicarbazone ligand, and to a chlorine atom (*trans* to S). A phosphorus atom from the diphosphine ligand, which bridges the two palladium atoms, completes the metal coordination sphere. The sum of angles about palladium are 360.28° (**2a**) and 360.05°

[1] Recently, we have found that related ligands with five-membered rings, such as pyrrol, furane and thiophene thiosemicarbazones, are difficult to metallate or they do not undergo cyclometallation at all when the imine carbon, C=N, is bonded to hydrogen (for pyrrol derivatives see J.M. Vila et al., Z. Anorg. Allg. Chem., 635 (2005) 2197); however, ligands with alkyl substituted C=N groups readily undergo cyclometallation (A. Amoedo, Ph.D. Dissertation, Universidad de Santiago de Compostela, Santiago).

(**2b**), with the distortion most noticeable in the somewhat reduced "bite" angle of the thiosemicarbazone moiety consequent upon chelation (83.37(15)° for **2a**, 83.1(3)° for **2b**). The geometry around the palladium atom is slightly distorted square-planar, the mean deviation from the least squares plane (plane 1: Pd(1), N(1), S(1), P(1), Cl(1) are 0.0783 (**2a**) and 0.0731 (**2b**)). The metallated rings (plane 2: Pd(1), S(1), C(12), N(1), N(2), r.m.s. 0.0261 (**2a**), 0.0433 (**2b**)) are also planar and coplanar with the palladium coordination plane (angles between planes: 1/2 3.83(0.12)° (**2a**), 4.56(0.10)° (**2b**)).

The palladium–nitrogen bond lengths (2.107(5) Å, **2a**; 2.079(9) Å, **2b**) are longer than the predicted single bond value of 2.011 Å, based on the sum of covalent radii for nitrogen(sp^2) and palladium, 0.701 and 1.31 Å, respectively [29] and reflects the *trans* influence of the phosphorus atom

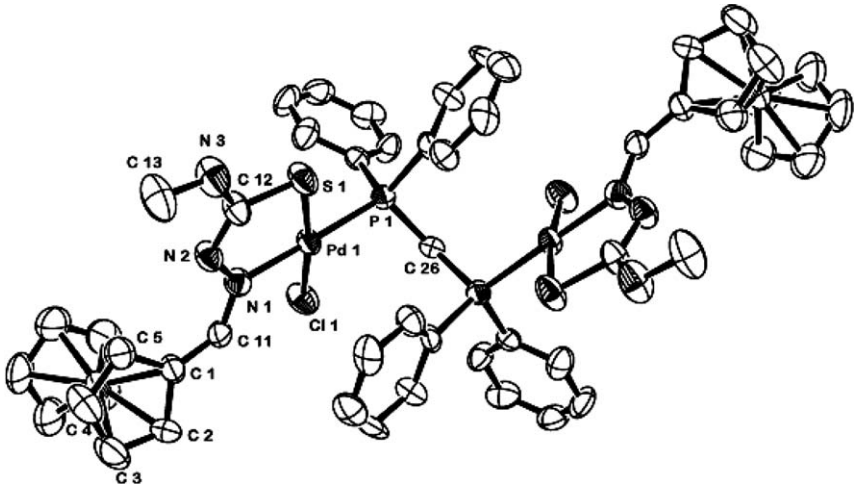

Fig. 2. Molecular structure of [{Pd[(η^5-C_5H_5)Fe(η^5-C_5H_4)C(H)=NN=C(S)NHMe](Cl)}$_2$(μ-$Ph_2PCH_2PPh_2$)] (**2b**), with labelling scheme. Hydrogen atoms have been omitted for clarity.

[30,31]. The palladium–sulfur bond lengths, (2.2436(17) Å, **2a**; 2.242(3) Å, **2b**) are shorter than the expected value of 2.33 Å (based on the sum of the covalent radii for sulfur and palladium, 1.02 and 1.31 Å, respectively). The Pd–P bond distances, 2.2543(16) (**2a**) and 2.257(3) (**2b**) are shorter than the sum of the single bond radii for palladium and phosphorus (2.41 Å), whilst the Pd–Cl bond lengths, 2.3397(16) (**2a**) and 2.350(3) Å (**2b**), are slightly longer than the sum of the covalent radii (2.30 Å). The S–C and C–N bond lengths in the chelate ring [S(1)–C(12), 1.776(6), N(2)–C(12), 1.280(7) Å, **2a**; S(2)–C(39), 1.773(11), N(5)–C(39), 1.296(13) Å, **2b**] are consistent with increased single and double bond character, respectively.

3. Conclusions

The results reported in the present paper show that ferrocenyl thiosemicarbazones are readily metallated to give the corresponding cyclopalladated octanuclear complexes. However, reaction of the latter with tertiary mono- and diphosphines yields products with cleavage of the Pd–C bond, protonation of the cyclopentadienyl ring, and Pd–Cl bond formation. These results, together with very recent findings from our laboratory, allow us to point out several factors responsible for this behaviour such as are the absence of an alkyl group on the imine carbon atom, the presence of traces of acid in CH_2Cl_2, and the not so negligible reactivity of this solvent. We are currently undertaking the research of related chemistry aimed at providing further proof for our proposal, which shall be communicated in the near future.

4. Experimental

Solvents were purified by standard methods [32], chemicals were reagent grade. Microanalyses were carried out at the Servicio de Análisis Elemental at the University of Santiago using a Carlo Erba Elemental Analyzer, Model 1108. IR spectra were recorded on a Perkin–Elmer 1330 and on a Mattson spectrophotometer. NMR spectra were obtained as $CDCl_3$ solutions and referenced to $SiMe_4$ (^1H) or 85% H_3PO_4 (^{31}P–{^1H}) and were recorded on Bruker WM250 and AMX-300 spectrometers (only selected data is presented for compounds containing phosphine). All chemical shifts are reported downfield from standards. The FAB mass spectra were recorded with a Fisons Quatro mass spectrometer with a Cs ion gun; 3-nitrobenzyl alcohol was used as the matrix.

4.1. (η^5-C_5H_5)Fe(η^5-C_5H_4)C(H)=NN(H)C(=S)NH_2 (**a**)

To a stirred suspension of thiosemicarbazide (0.213 g, 2.336 mmol) in water (40 cm^3) a few drops of HCl 36% and ferrocenecarboxaldehyde (0.5 g, 2.336 mmol) were added. The resulting mixture was stirred for 4 h at r.t., filtered off, washed with water and dried in vacuo to yield an orange solid.

Yield: 91.4%. *Anal*. Calc. for $C_{12}H_{13}N_3FeS$: C, 50.2; H, 4.6; N, 14.7; S, 11.2. Found: C, 49.7; H, 4.4; N, 14.2; S, 11.1%. IR: ν(N–H) 3431m, 3151w, ν(C=N) 1592m, ν(C=S) 876 cm^{-1}. ^1H NMR (δ ppm, J Hz): 4.20 (s, 5H, C_5H_5), 4.32 (t, 2H, H3/H4, $N = 3.4$), 4.58 (t, 2H, H2/H5, $N = 3.4$), 6.33, 7.10 (s, 2H, NH_2), 7.80 (s, 1H, *H*C=N), 9.79 (s, 1H, N*H*).

Ligand **b** was prepared as an orange air-stable solid following a similar procedure.

4.2. (η^5-C_5H_5)Fe(η^5-C_5H_4)C(H)=NN(H)C(=S)NHMe (**b**)

Yield: 93.5%. *Anal*. Calc. for $C_{13}H_{15}N_3FeS$: C, 51.8; H, 5.0; N, 14.0; S, 10.6. Found: C, 51.5; H, 5.0; N, 13.5; S, 10.1%. IR: ν(N–H) 3430m, 3143w, ν(C=N) 1609m, ν(C=S) 873 cm^{-1}. ^1H NMR (δ ppm, J Hz): 3.24 (d, 3H, NH*Me*, ^3J(HMe) = 4.8 Hz), 4.20 (s, 5H, C_5H_5), 4.40 (at, 2H, H3/H4, $N = 3.8$), 4.57 (at, 2H, H2/H5, $N = 3.8$), 7.34 (b, 1H, N*H*Me), 7.69 (s, 1H, *H*C=N), 9.41 (s, 1H, N*H*).

4.3. [Pd{(η^5-C_5H_5)Fe(η^5-C_5H_3)C(H)=NN=C(S)-NH_2}]$_4$ (**1a**)

To a stirred solution of K_2PdCl_4 (200 mg, 0.613 mmol) in EtOH (40 cm^3) and H_2O (6 cm^3), (η^5-C_5H_5)Fe(η^5-C_5H_4)C(H)=NN(H)C(=S)NH_2 (**a**) (193 mg, 0.674 mmol) were added. The mixture was stirred for 24 h at r.t. and the resulting precipitate filtered off, washed with cold ethanol and dried in vacuo.

Yield: 53.3%. *Anal.* Calc. for $C_{48}H_{44}Fe_4N_{12}Pd_4S_4$: C, 36.8; H, 2.8; N, 10.7; S, 8.2. Found: C, 36.3; H, 2.8; N, 10.3; S, 8.3%. 4.13. [Pd{(η^5-C_5H_5)Fe(η^5-C_5H_3)C(H)=NN=C(S)NHMe}(Cl){$P(C_6D_5)_3$}] (**6b**)

Yield: 57.4%. *Anal*. Calc. for $C_{31}H_{14}D_{15}ClFeN_3PPdS$: C, 51.8; H, 6.2; N, 5.8; S, 4.5. Found: C, 51.8; H, 5.9; N, 5.6; S, 3.9%. IR: ν(N–H) 3428s, ν(C=N) 1593m, ν(Pd–Cl) 278w cm^{-1}. ^1H NMR (δ ppm, J Hz): 2.85 (d, 3H, NH*Me*, ^3J(HMe) = 5.1), 4.21 (s, 5H, C_5H_5), 4.31 (t, 2H, H3/H4, $N = 3.8$), 4.53 (t, 2H, H2/H5, $N = 3.8$), 5.02 (b, 1H, N*H*Me), 8.78 (d, 1H, *H*C=N, ^4J(PH) = 2.2). ^{31}P–{^1H} NMR (δ ppm) 25.7s.

4.14. X-ray crystallographic study[2]

Three-dimensional, room temperature X-ray data were collected in the range $1.86 < \theta < 26.43°$ (**2a**), $1.33 < \theta < 26.44°$ (**2b**) on a Bruker CCD diffractometer by the omega scan method. Reflections were measured from a hemisphere of data collected of frames each covering 0.3 degrees in omega. The 13790 (**2a**), 16756 (**2b**) reflections measured were corrected for Lorentz and polarisation effects and for absorption using a semi-empirical correction based on symmetry-equivalent and repeated reflections. The structure was solved by direct methods and refined by full matrix least unique data, 307 (**2a**) 339 (**2b**) parameters, with allowance for the thermal anisotropy of all non hydrogen atoms. Hydrogen atoms were included in calculated positions and refined in riding mode. The refinement was carried out taking into account the minor components of the disorder. Minimum and maximum final electron density 0.748 and −0.502 (**2a**), 0.635 and −0.686 (**2b**) e $Å^{-3}$. The structure solution and refinement were carried out using the program package SHELX-97 [33].

totpy = 4′-(4-tolyl)-2,2′:6′,2″-terpyridine); their spectral, electrochemical and catalytic properties were studied. The ability of the complexes to act as catalysts for electrooxidations of benzyl alcohol, cyclohexanol, cyclohexene, ethylbenzene, 1,2-butanediol and 1,4-butanediol were studied in homogeneous solution and with the complexes immobilized in carbon paste electrodes and within Nafion® films on electrodes.

2. Experimental

2.1. Materials

Water was doubly distilled from alkaline potassium permanganate. $RuCl_3 \cdot xH_2O$, 1,2-bis(dichlorophosphine)-ethane and 1,2-bis(dimethylphosphine) ethane were purchased from Aldrich Chemical Co. Methylene chloride and acetonitrile were kept in an alumina column before use. All other reagents and solvents were of reagent quality and were used without further purification.

2.2. Instrumentation and measurements

Routine UV–Vis spectra were obtained in 1-cm quartz cells by using a Hewlett–Packard 8453 spectrophotometer. Electrochemical experiments were conducted by using a PAR Model 273A Potentiostat/Galvanostat. Cyclic voltammetric and differential pulse voltammetric experiments were performed in a one-compartment cell using a carbon working electrode, a platinum wire auxiliary electrode and a saturated calomel (SCE) or a Ag/AgCl reference electrode. The $E_{1/2}$ values for reversible couples were calculated from half the difference between E_p values for the cathodic and anodic waves. The catalytic tests were performed at 25 ± 1 °C. The pH values of aqueous solutions were buffered at an ionic strength of 0.25 mol L^{-1} by HNO_3 and $NaNO_3$ (pH 2.0), potassium hydrogen phthalate, HNO_3 and $NaNO_3$ (pH 3.0), potassium hydrogen phthalate, NaOH and $NaNO_3$ (pH 4.0–5.5), Na_2HPO_4 and NaH_2PO_4 (pH 6.0–8.0), $Na_2B_4O_7 \cdot 10H_2O$ and $NaNO_3$ (pH 9.0) and $Na_2B_4O_7 \cdot 10H_2O$ and NaOH (pH 10.0–10.8). Elemental analyses were performed using a CHNS-O CE Instruments Model EA 1110 elemental analyzer. Ruthenium analyses were performed with a Model V-85 B Braun ICP-AES-atomic emission spectrometer. EPR spectra of the solid complexes were recorded at room temperature on a Bruker EP 200D spectrometer. ^{1}H NMR spectra were obtained with a Bruker AC-80 spectrometer. Mass spectra were obtained with a Hewlett–Packard gas chromatograph/MS system 5988A.

2.3. Preparation of the ligand 4′-(4-tolyl)-2,2′:6′,2″-terpyridine (totpy)

The 4′-(4-tolyl)-2,2′:6′,2″-terpyridine ligand was prepared analogously to the literature procedure [24,25]; a 2:1 ratio of 2-acetylpyridine:*p*-tolualdehyde was used. The solid was recrystallized from ethanol to obtain 1.01 g (54%) of light green crystals, identified as 4′-(4-tolyl)-2,2′:6′,2″-terpyridine (totpy) (Fig. 1). ^{1}H NMR: m, 8.65–8.85 ($H_{3,3''}$; $H_{6,6''}$; $H_{3',5'}$); m, 7.80–8.00 ($2H_o$; $H_{4,4''}$); m, 7.35–7.45 ($2H_m$; $H_{5,5''}$); s, 2.47 ($-CH_3$). ESI MS: *m*/*z* 323.20. *Anal.* Calc. for $C_{22}H_{17}N_3$: C, 81.71; H, 5.30; N, 12.99. Found: C, 82.09; H, 5.28; N, 13.38%.

2.4. Preparation of the complexes

$[RuCl_3(totpy)]$ was prepared according to the literature procedure [1,2]. Yield: 85%. *Anal.* Calc. for $C_{22}H_{17}N_3Cl_3Ru$: C, 49.78; H, 3.23; N, 7.92. Found: C, 48.95; H, 3.28; N, 7.67%.

2.4.1. [Ru(L)(totpy)Cl](PF$_6$) (L = 1,2-bis(dimethylphosphino)ethane)

A mixture of $[RuCl_3(totpy)]$ (0.38 g, 0.71 mmol) and 1,2-bis(dimethylphosphino)ethane (0.15 g, 1.00 mmol) were heated to reflux, under a N_2 atmosphere, in 115 mL of 3:2 ethylene glycol:water in the presence of NEt_3 (0.5 mL) and LiCl (0.15 g, 3.55 mmol) for 2.5 h. The hot solution was filtered and 2.0 mL of a saturated aqueous solution of NH_4PF_6 was added to the filtrate. The resulting red-brown crystals were washed with cold water and dried under vacuum. The product was recrystallized by dissolution in acetone and precipitated by adding diethyl ether. Yield: 0.32 g (60%). The complex is pure enough to be used in the synthesis of the aqua complex described in Section 2.4.3.

2.4.2. [Ru(L′)(totpy)Cl](PF$_6$) (L′ = 1,2-bis(dichlorophosphino)ethane)

The complex was prepared analogously to that described in the above section, except that a 4:1 ratio of acetonitrile:water and *N*-ethylmorpholine (30 drops) were used. Yield: 0.40 g (68%). The complex is pure enough to be used in the synthesis of the aqua complex described in Section 2.4.4.

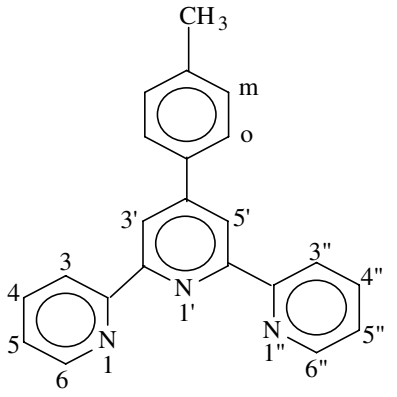

Fig. 1. 4′-(4-Tolyl)-2,2′:6′,2″-terpyridine (totpy).

2.4.3. [Ru(L)(totpy)(OH$_2$)](PF$_6$)$_2$ (L = 1,2-bis(dimethylphosphino)ethane) (**1**)

One hundred and seventy milligrams (0.23 mmol) of [Ru(L)(totpy)Cl](PF$_6$) and 0.07 g (0.27 mmol) of silver *p*-toluenesulfonate were heated to reflux in 46 mL of 1:1 acetone:water under a N_2 atmosphere for 1 h; the hot solution was filtered and 3.0 mL of a saturated aqueous solution of NH_4PF_6 was added to the filtrate. The volume was reduced to 20 mL in a rotatory evaporator. The brown crystals were collected by filtration, washed twice with cold water and dried under vacuum. The complex was reprecipitated twice from acetone–diethyl ether. Yield: 0.14 g (69%). *Anal.* Calc. for $C_{28}H_{35}N_3OP_4F_{12}Ru$: C, 39.11; H, 4.00; Ru, 11.47. Found: C, 39.44; H, 4.29; Ru, 11.46%.

2.4.4. [Ru(L′)(totpy)(OH$_2$)](PF$_6$)$_2$ (L′ = 1,2-bis(dichlorophosphino)ethane) (**2**)

The complex was prepared analogously to **1**, except that a 1:2 ratio of acetone:water was used. Yield: 0.10 g (43%). *Anal.* Calc. for $C_{24}H_{23}ON_3Cl_4P_4F_{12}Ru$: C, 29.90; H, 2.40; Cl, 14.7; Ru, 10.48. Found: C, 31.40; H, 2.39; Cl, 14.2; Ru, 10.27%.

2.5. Modified electrodes

2.5.1. Carbon paste electrodes

Carbon paste electrodes [7,20] containing 3:2 by weight of carbon powder: mineral oil were used for cyclic voltammetric studies. The modified electrodes contained 3:22 by weight of complex:paste. The carbon paste holder was constructed of a thick-walled Teflon tube with 0.3 cm i.d. A copper sleeve equipped with a copper wire plunger was mounted at the top of the Teflon tube. By rotating the sleeve, the plunger could be made to extrude a used paste layer which was sliced off to form a fresh paste surface.

2.5.2. Nafion® transparent ITO modified electrode [21–23]

Sixty microliters of Nafion® ethanolic solution (2.5%) was cast on the ITO electrode surface (effective area = 1.0 cm^2); the solvent was air evaporated at room temperature; the coated electrode was dipped in pure water for 1 h and then soaked in an aqueous solution of the complex (2.0 mmol L^{-1}) for 30 min.

3. Results and discussion

3.1. Spectroscopic and redox properties of the aqua complexes in solution

Fig. 2 shows the absorption spectrum of **1** in methylene chloride. Cyclic and differential pulse voltammograms of **2** in methylene chloride are shown in Fig. 3. Table 1 shows spectroscopic and redox data for the complexes. The aqua complexes have similar spectra. Both aqua complexes exhibit several very intense bands in the UV region, assignable to polypyridyl ligand $\pi \rightarrow \pi^*$ excitations; in the visible region the bands at $\lambda_{max} = 490$ nm ($\varepsilon =$

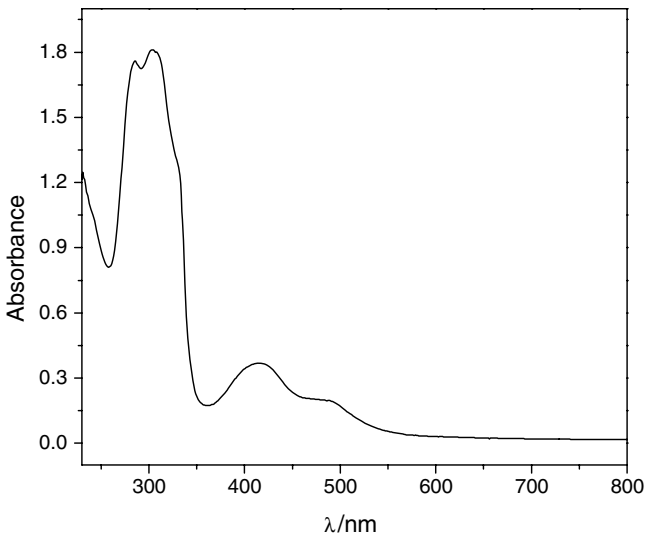

Fig. 2. UV–Vis spectrum of 1.0×10^{-4} mol L^{-1} [Ru(L)(totpy)(H$_2$O)](PF$_6$)$_2$ (**1**) (L = 1,2-bis(dimethylphosphino)ethane) in CH_2Cl_2.

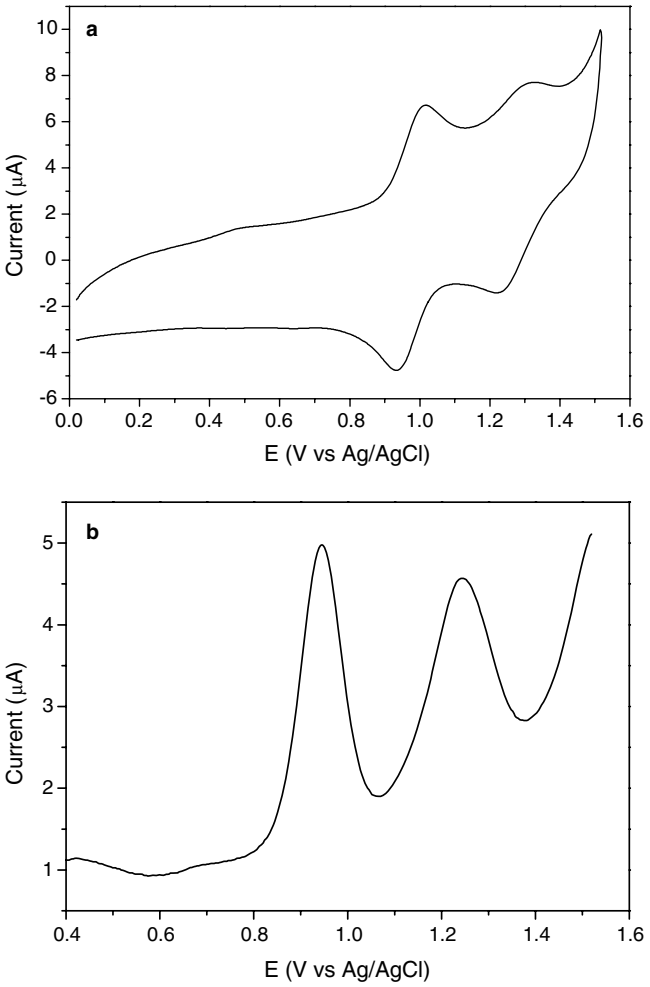

Fig. 3. (a) Cyclic voltammogram and (b) differential pulse voltammogram of 1.0×10^{-3}mol L^{-1} [Ru(L′)(totpy)(H$_2$O)](PF$_6$)$_2$ (**2**) (L′ = 1,2-bis(dichlorophosphino) ethane) in CH_2Cl_2 + 0.1 mol L^{-1} TBAP, glassy carbon working electrode; (a) $v = 100$ mV s^{-1}; (b) 10 mV s^{-1}.

[c] CH_2Cl_2 + 0.1 mol L^{-1}; glassy carbon working electrode; $v = 100$ mV s^{-1}.
[d] In 7:3 phosphate buffer ($\mu = 0.20$ mol L^{-1}): *tert*-butyl alcohol solution, pH 6.8.
[e] CH_2Cl_2.

1.9×10^3 mol L^{-1} cm^{-1}) and 475 nm ($\varepsilon = 7.9 \times 10^3$ mol L^{-1} cm^{-1}) for **1** and **2**, respectively, can be attributed to metal-to-ligand $d\pi(Ru) \rightarrow \pi^*$ (diphosphine) transitions. One additional band is observed for **1** at 414 nm ($\varepsilon = 3.7 \times 10^3$ mol L^{-1} cm^{-1}) and can be attributed to metal-to-ligand $d\pi(Ru) \rightarrow \pi^*$ (polypyridyl) transitions [26]. For **1**, the MLCT band appears at higher wavelength; this reflects the electron-donation effect of the methyl substituents on the phosphine ligand, which destabilize the $d\pi(Ru)$ electrons, causing the $d\pi(Ru) \rightarrow \pi^*$ (diphosphine) transitions to occur at lower energy. On the other hand, for **2**, the MLCT band appears at higher energy, due to the electron-withdrawing effect of the chloro substituents on the phosphine ligand; similar effects were observed for a substituted bipyridine ligand [10]. It can be observed that the MLCT bands are shifted to higher energies upon substitution of the anionic chloride ligand for the neutral aqua ligand.

The cyclic voltammograms for both **1** and **2** in methylene chloride exhibit two reversible redox waves corresponding to the $Ru^{III/II}$ and $Ru^{IV/III}$ couples (0.85/1.02 and 0.96/1.26 V versus Ag/AgCl, respectively). The oxo-aqua ligands allow rapid proton transfer to be concomitant with electron transfer, permitting the accessibility of several oxidation states via gain or loss of protons (Scheme 1). The redox potentials of **1** are less positive, reflecting the electron-donation effect of the methyl substituents on the phosphine ligand. The observed potentials in methylene chloride are more positive than those obtained in aqueous solution (Table 1); for **2**, the separation between the two couples (mV) is larger than in water. This behavior can be due to a very slow deprotonation of the first oxidized species; the deprotonation of the aqua ligand to form Ru^{III}–OH is facilitated in aqueous solution but not in methylene chloride (low protic and polar solvent).

EPR spectra of ruthenium(III) complexes show *g* tensor values [27] that can be used to derive ground states. The

$$[\overset{II}{Ru}\text{-}OH_2]^{2+} \underset{+e,\,+H^+}{\overset{-e,\,-H^+}{\rightleftharpoons}} [\overset{III}{Ru}\text{-}OH]^{2+} \underset{+e,\,+H^+}{\overset{-e,\,-H^+}{\rightleftharpoons}} [\overset{IV}{Ru}{=}O]^{2+}$$

Scheme 1.

1 and **2** aqua complexes show no EPR signals, indicating the oxidation state Ru(II).

3.2. $E_{1/2}$ versus pH of the aqua complexes

The potentials of the $Ru^{IV/III}$ couple of **1** and the potentials of the $Ru^{III/II}$ couple of **2** vary with the pH of the solution, resulting in the $E_{1/2}$ versus pH variations shown in Fig. 4 for **2**. Within the $8.3 > pH > 2.0$ region, the plot for **1** is a straight line, with slope −0.062; for **2**, within the $9.6 > pH > 2.0$ region, the straight line has slope −0.059; the slopes are very close and coincident with the Nernstian prediction of −0.059 V/pH unit, indicative of one-electron oxidation accompanied by the dissociation of one proton [7,28] (Schemes 2 and 3).

For **1**, the potentials become pH independent at $pH > 8.3$, indicating that, in this region, $[Ru^{III}(L)(totpy)(O)]^+$ is the dominant species (Scheme 4).

The same behavior is shown for **2** at $pH > 9.6$; in this case $[Ru^{II}(L')(totpy)(OH)]^+$ is the dominant species (Scheme 5):

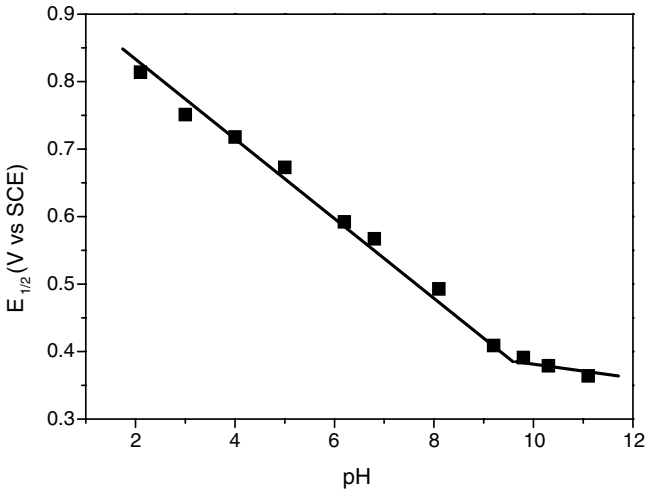

Fig. 4. Plot of $E_{1/2}$ vs. pH for the $Ru^{III/II}$ redox couple of $[Ru(L')(totpy)(H_2O)](PF_6)_2$ (**2**) (L′ = 1,2-bis(dichlorophosphino)ethane); glassy carbon working electrode.

$$[Ru^{III}(L)(totpy)(OH)]^{2+} \underset{+e^-,+H^+}{\overset{-e^-,-H^+}{\rightleftharpoons}} [Ru^{IV}(L)(totpy)(O)]^{2+}$$

Scheme 2.

3.3. Electrocatalytic oxidations of organic substrates in homogeneous solution

The catalytic activities of **1** and **2** for the oxidation of organic substrates were investigated by cyclic voltammetric experiments in 7:3 phosphate buffer (pH 6.8):*tert*-butyl alcohol solutions. Mixed solvent systems have been used by other groups for similar experiments with no adverse effects [12]. In the presence of a 50-fold excess of substrate, the cyclic voltammograms of **1** and **2** show an enhancement of the oxidation peaks and a decrease of the reduction peaks upon reversal potential scan. This is indicative of catalytic activity [7].

Catalytic tests can give the reactivity order for the electrooxidations: for **1**, benzyl alcohol > 1,4-butanediol > cyclohexanol > cyclohexene > ethylbenzene > 1,2-butanediol; for **2**, 1,4-butanediol > benzyl alcohol > cyclohexanol > cyclohexene > 1,2-butanediol > ethylbenzene. The oxidation products were identified in bulk electrolyses experiments using polypyridyl and phosphine ruthenium complexes described previously [6–10]: benzyl alcohol was oxidized to benzaldehyde and benzoic acid, 1-4 butanediol to δ-butyrolactone, 1-2-butanediol to 1-hydroxy-2-butanone, cyclohexanol to cyclohexanone, cyclohexene → 2-cyclohexen-1-one, and ethylbenzene to acetophenone. The proposed mechanism for oxidations using ruthenium oxo complexes suggests the formation, in the transition state, of an electron-deficient carbon [29]. A substituent can decrease the activation energy, inducing delocalization of the positive charge by hyperconjugation, inductive or resonance effects. In this way, the benzyl alcohol has a higher reactivity than cyclohexene: the resonance effect in the benzyl alcohol aromatic ring is responsible by positive charge delocalization; in cyclohexene, the allylic carbocation formed at C-3 before the water molecule attack (S_N2 reaction) induces a stabilization by resonance with a conjugated unsaturation at the carbon ring. Nevertheless, as cyclohexene has fewer canonic structures than benzyl alcohol, the lower positive charge delocalization decreases the reactivity. The higher reactivity of a primary alcohol compared to a secondary one was also observed in homogeneous catalysis by using $[Ru(tpy)(bpy)(H_2O)]^{2+}$ [8].

A generalization can be made: benzyl alcohol and 1,4-butanediol are more reactive than cyclohexanol; cyclohexene has an intermediate reactivity; ethylbenzene and 1,2-butanediol have the lowest reactivities.

$$[Ru^{II}(L')(totpy)(OH)]^{+} \underset{+e^-}{\overset{-e^-}{\rightleftharpoons}} [Ru^{III}(L')(totpy)(OH)]^{2+}$$

Scheme 5.

3.4. Electrocatalytic oxidation of organic substrates at a carbon paste electrode (CPE) containing *1* and *2*

The cyclic voltammetric behavior of the CPE containing **1** and **2** in 7:3 phosphate buffer (pH 6.8):*tert*-butyl alcohol solutions, in the presence of benzyl alcohol, cyclohexanol, 1,4-butanediol, 1,2-butanediol and ethylbenzene shows pronounced enhancement of the anodic currents. The observed reactivity order for **1** is benzyl alcohol > cyclohexanol > 1,4-butanediol > 1,2-butanediol > cyclohexene > ethylbenzene and for **2** is benzyl alcohol > ethylbenzene > cyclohexanol > 1,4-butanediol cyclohexene > 1,2-butanediol. The reactivities of CPE containing **1** and **2** were somewhat different from those of homogeneous catalysis; surprisingly, high reactivity in the oxidation of ethylbenzene by **2** was observed. Higher reactivity of the primary alcohol was also observed in homogeneous catalysis by using **1** and **2**. The high reactivity of benzyl alcohol can be due to its higher permeability into the active surface of the carbon paste electrode.

For quantitative evaluation of the electrocatalysis surface, the dependence of the peak height on the benzyl alcohol concentration and on the potential scan rate was studied [30]. The peak height was linearly dependent (Fig. 5) (correlation coefficient 0.998, with plot intercept near zero) on the concentration of benzyl alcohol, indicating that the electrocatalysis is *pseudo-first-oder* in this

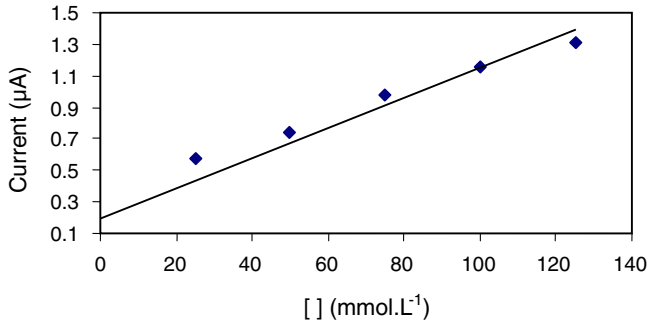

Fig. 5. Plot of the oxidation peak currents of the CPE containing $[Ru(L)(totpy)(H_2O)](PF_6)_2$ (**1**) (L = 1,2-bis(dimethylphosphino)ethane) against benzyl alcohol concentrations; in 7:3 phosphate buffer (pH 6.8):*tert*-butyl alcohol solution, $v = 100\ mV\ s^{-1}$.

benzyl alcohol concentration range. The anodic peak currents change linearly with the square root of the scan rate; this is characteristic of surface electrocatalysis with the catalyst confined to the electrode surface under diffusion control of the substrates.

3.5. Electrocatalytic oxidation of organic substrates at a ITO/Nafion®/complex electrode

The cyclic voltammogram of **1** in the ITO/Nafion® transparent electrode shows the $Ru^{IV/III}$ redox couple only ($E_{1/2} = +0.74$ V versus SCE). This is probably due to the sluggishness of the $Ru^{III/II}$ couple observed in modified electrodes [18b].

The reactivity of $Ru^{IV}{=}O^{2+}$ complexes has been explored with ITO electrodes [31]. The cyclic voltammogram in the presence of 50 mmol L^{-1} of benzyl alcohol shows a decrease of the anodic current, as a consequence of the dissolution of the aqua complex adsorbed in the Nafion® polymer film. The dissolution of the aqua complex is clearly noticed when the solution changes from colorless to yellow. Therefore, benzyl alcohol being a polar substrate can dissolve the Nafion® film. When the substrate is cyclohexene, that which has a low polarity, the catalytic activity is noticed by the significant increase of the anodic current and the decrease of the cathodic current (Fig. 6).

The dependence of the anodic peak current with scan rate was studied from 50 to 500 mV s^{-1}, in the presence cyclohexene (Fig. 7(a)). The plot of I_{pa} versus $v^{1/2}$ (Fig. 7(b)) shows that the anodic peak current varies linearly with the square root of the scan rate (correlation coefficient 0.998), indicating that the reaction is also controlled by diffusion of the substrate [7].

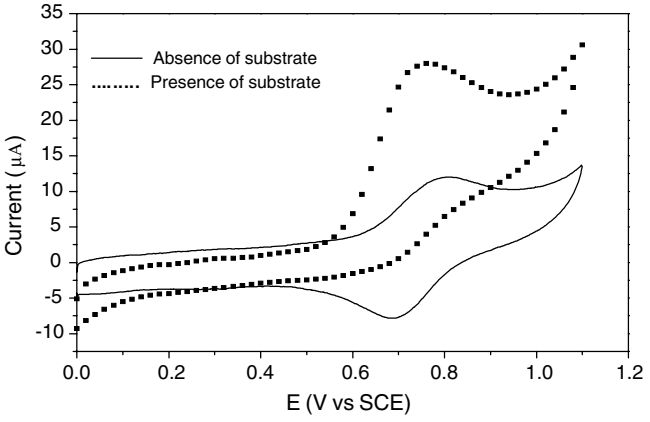

Fig. 6. Cyclic voltammograms of ITO electrode, modified by Nafion® containing $[Ru(L)(totpy)(H_2O)](PF_6)_2$ (**1**) (L = 1,2-bis(dimethylphosphino)ethane) in 4:1 $HNO_3/NaNO_3$ buffer (pH 2.3):*tert*-butyl alcohol solution (——), and in the presence of 50 mmol L^{-1} of cyclohexene (■■■), $v = 100$ mV s^{-1}.

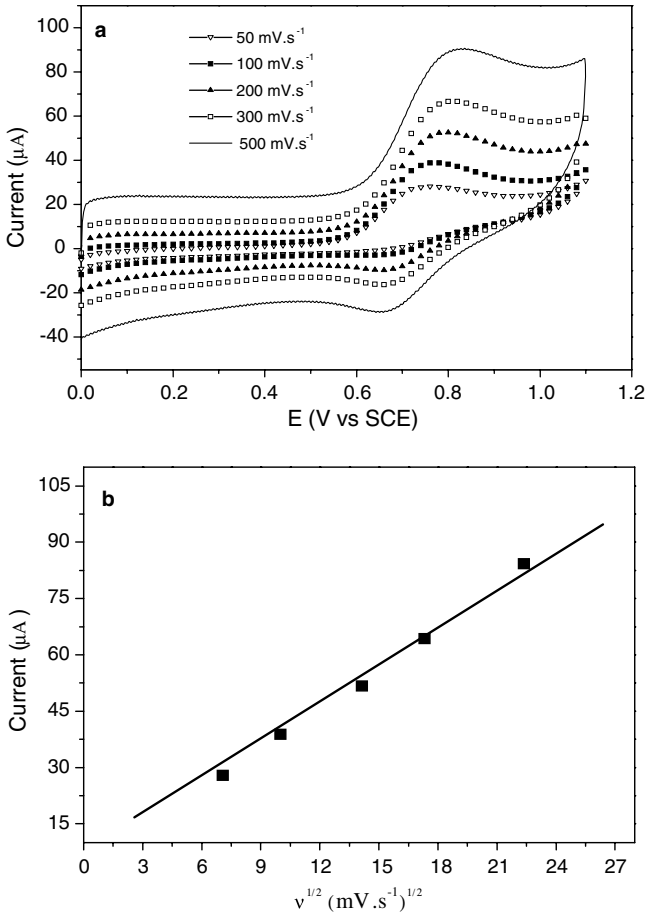

Fig. 7. (a) Cyclic voltammograms of ITO electrode, modified by Nafion® containing $[Ru(L)(totpy)(OH_2)](PF_6)_2$ (**1**) (L = 1,2-bis(dimethylphosphino)ethane), in 4:1 $HNO_3/NaNO_3$ buffer (pH 2.3):*tert*-butyl alcohol solution, in the presence of 50 mmol L^{-1} of cyclohexene, several scan rates. (b) Plot I_{pa} vs. $v^{1/2}$.

4. Conclusions

The results obtained in this work show that the complexes $[Ru(L)(totpy)(OH_2)](PF_6)_2$ (L = 1,2-bis(dimethylphosphino)ethane) (**1**) and $[Ru(L')(totpy)(OH_2)](PF_6)_2$ (L′ = 1,2-bis(dichlorophosphino)ethane) (**2**) can be used in electrooxidations of organic substrates containing different functional groups. The phosphine–ruthenium(IV)-oxo complexes have the advantage of being mild oxidants, since more powerful oxidants usually cause undesirable side reactions.

The preparations of carbon paste and ITO/Nafion® electrodes are simple and straightforward and the characteristics of the mediators are preserved upon transfer from solution to the immobilized state.

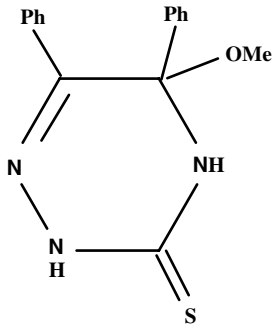

Scheme 1. Drawing of LH_2OCH_3.

particular ligand can show different coordination behaviour, as we have established in previous works [14]. In fact, we have characterized complexes of the title ligand acting as bidentate NS giving monomeric complexes with some organotin (IV) derivatives [15], as well as with nickel and cobalt salts. With other metals, as cadmium, acts also as bidentate bridging via the sulphur atom, giving dinuclear structures [16].

The most usual type of coordination in compounds of Hg(II) is a distorted octahedron with two bonds much shorter than the other four. In extreme, this results in a linear-2 coordination in which case bonds are largely covalent. This situation usually takes place with S-donor ligands. The complexes [Hg(5-CF_3-pyS_2)] and [Hg(5-CF_3-MepyS_2)] are examples of this type of coordination, where the Hg(II) ion is bonded to two ligands via the sulphur atoms, giving a linear SS disposition [17,18].

The aim of this work is the synthesis and characterization of mercury complexes derived of 5-methoxy-5,6-diphenyl-4,5-dihydro-2H-[1,2,4]triazine-3-thione LH_2OCH_3 (Scheme 1), in order to get new complexes and to explore their potential capability as modifiers of a carbon paste electrode for mercury determination and kinetic speciation in water samples. In this paper, we report the synthesis and structural characterisation of two mercury compounds with this cyclic ligand. In both complexes, and induced by the metal structural preferences, the triazine acts as monodentate through the sulphur atom, behaviour that has not been observed previously.

2. Experimental

2.1. Physical measurements

IR spectra in the 4000–400 cm^{-1} range were recorded as KBr pellets on a Jasco FT/IR-410 spectrophotometer. ^1H and ^{13}C NMR spectra were recorded on a spectrophotometer Bruker AMX-300 using $CDCl_3$ and DMSO-d_6 as solvents and TMS as reference. Fast atom bombardment (FAB) mass spectra were recorded on a VG Auto Spec instrument using Cs as the fast atom and *m*-nitrobenzilalcohol (*m*NBA) as the matrix. Conductivity data were measured using freshly prepared DMF solutions (ca. 10^{-3} M) at 25 °C with a Metrohm Herisau model E-518 instrument. Electrochemical measurements were performed with a BAS CV 27 voltammograph and a BAS A-4 XY register using a glassy carbon (∅ 5 mm) as working electrode, a platinum wire as auxiliary, and a double junction, with porous ceramic wick, Ag/AgCl as reference electrode, standardized for the redox couple ferricinium/ferrocene ($E_{1/2} = +0.400$ V, $\Delta E_p = 60$ mV). Cyclic voltammetry studies of LH_2OCH_3 and complexes were carried out on 0.01 M solutions in dimethylformamide containing 0.1 M [NBu_4][PF_6] as supporting electrolyte. The range of potential studied was between +1.0 and −2.2 V. All solutions were purged with nitrogen steam for 5 min before measurement and the working electrode was polished before each experiment with diamond paste. The procedure was performed at room temperature and nitrogen atmosphere was maintained over the solution during the measurements.

2.2. Crystallography

Crystals were mounted on a glass fibre and transferred to a Bruker SMART 6K CCD area-detector three-circle diffractometer with a MAC Science Co., Ltd. Rotating Anode (Cu Kα radiation, $\lambda = 1.54178$ Å) generator equipped with Goebel mirrors at settings of 50 kV and 110 mA. X-ray data were collected with a combination of six runs at different φ and 2θ angles, 3600 frames. The data were collected using 0.3° wide ω scans and crystal-to-detector distance of 4.0 cm. Empirical absorption corrections (SADABS) [19] were applied using multiple measurements of symmetry-equivalent reflections (ratio of minimum to maximum apparent transmission: 0.373482 for complex **1** and 0.556564 for complex **2**). The unit cell parameters were obtained by full-matrix least-squares refinements of 5528 and 7730 reflections for complexes **1** and **2**, respectively. The raw intensity data frames were integrated with the SAINT [20] program, which also applied corrections for Lorentz and polarization effects. The software package SHELXTL [21] version 6.10 was used for space group determination, structure solution and refinement. The space group determination was based on a check of the Laue symmetry and systematic absences and was confirmed using the structure solution. The structure was solved by direct methods (SHELXS-97) [22], completed with difference Fourier syntheses, and refined with full-matrix least squares using SHELXL-97 [23] minimizing $\omega(F_o^2 - F_c^2)^2$. Weighted R factors (R_w) and all goodness of fit (S) are based on F^2; conventional R factors (R) are based on F. All non-hydrogen atoms were refined with anisotropic displacement parameters. All scattering factors and anomalous dispersions factors are contained in the SHELXTL [24] 6.10 program library. H atoms were found in a difference map, but were then positioned geometrically and included as riding, with C–H = 0.95 and 0.99 Å, and $U_{iso}(H) = 1.2\,U_{eq}(C)$. The coordinates were refined as riding on the parent atom and the occupancy and U_{ij} were fixed.

2.3. Syntheses

All reagents and other solvents were obtained from standard commercial sources and were used as received.

2.4. 5-Methoxy-5,6-diphenyl-4,5-dihydro-2H-[1,2,4]triazine-3-thione, LH_2OCH_3

The characterisation of the ligand LH_2OCH_3 was previously published [24], although it was synthesised according to a modified procedure [25].

Selected spectroscopic data: IR (KBr, cm^{-1}): 3184s and 3131s (NH), 1608w (C=N), 1550s (NCS), 846w (CS). ^1H NMR (300 MHz, $CDCl_3$, 25 °C): 3.4 (s, 3H, OCH_3), 6.9 (d, 1H, NH), 7.1–7.3 (m, 6H, Ph), 7.4 (m, 2H, Ph), 7.6 (m, 2H, Ph), 9.5 (d, 1H, NH), ^{13}C NMR (300 MHz, $CDCl_3$, 25 °C): 169.7 (CS), 142.4 (CN), 141.7, 133.7, 129.3, 126.5, (Ph), 83.2 (CR_4), 50.7 (CH_3O).

2.5. [HgL_2] (**1**)

This complex was prepared as previously reported [26].

M.p. 218 °C (D). Λ_M (DMF, $\Omega^{-1}\,cm^2\,ml^{-1}$): 25. *m/z* ($FAB^+$): 731 ($[HgL_2+1]^+$, 30%). Selected spectroscopic data: IR (KBr, cm^{-1}): 1601w, 1581w (C=N), 1491s (NCS), 815w (CS). ^1H NMR (300 MHz, DMSO, 25 °C): 7.4–7.1 (m, Ph). ^{13}C NMR (300 MHz, DMSO-d_6, 25 °C): 174.7 (CS), 154.3, 153.2 (CN), 135.2, 134.4, 130.9, 129.5, 129.4, 129.0, 128.6, 128.1 (Ph). Single crystals of complex **1** suitable for X-ray analysis, were grown by slow evaporation of a solution of the complex in acetonitrile.

2.6. [HgMeL] (**2**)

Over a solution of LH_2OCH_3 (0.32 g, 1.1 mmol) and $LiOH\cdot H_2O$ (0.05 g, 1.1 mmol) in 50 ml of methanol was drop wise added a solution of HgMeCl (0.27 g, 1.1 mmol) in the same solvent. The solution was stirred at room temperature for 6 h. Then it was evaporated until a yellow solid appeared, which was filtered off and vacuum dried. Yield 73%. m.p 140 °C. Λ_M (DMF, $\Omega^{-1}\,cm^2\,ml^{-1}$): 9. *m/z* (FAB+): 482.0 ($[HgMeL+1]^+$, 100%). 696.0 ($[Hg_2MeL+1]^+$, 30%), 945 ($[Hg_2Me_2L_2]^+$, 4%), 961.1 ($[Hg_2Me_2L_2]^+$, 2%). IR (KBr, cm^{-1}): 1598w, 1578w (C=N), 1483s (NCS), 816w (CS). ^1H NMR (300 MHz, DMSO-d_6, 25 °C): 7.3–7.5 (m, 10H, Ph), 0.89 (s, 3H, CH_3, $J^2(^{199}Hg–^1H) = 186$ Hz). ^{13}C NMR (300 MHz, DMSO-d_6, 25 °C): 176.5 (CS), 154.6, 153.1 (CN), 135.6, 135.4, 130.7, 129.6, 129.2, 129.1, 128.6, 128.5 (Ph), 9.4 (CH_3). Single crystals suitable for X-ray analysis were obtained by slow evaporation of a solution of the complex in DMF.

3. Results and discussion

In the synthesis of both complexes takes place the loss of the methoxy group as a methanol molecule, probably due to acid–base reaction with the relatively high acidic N–H bond, yielding LH, according to a mechanism previously published. Reaction with mercury nitrate does not need the presence of lithium hydroxide, which is necessary in the reactions studied with other metal salts [15,16].

Conductivity measurements in DMF indicate the presence of non-ionic species in this solvent [27]. The mass spectrometry indicates the different mercury/ligand ratio. Mass spectrum of complex **1** shows a peak corresponding to $[HgL_2+1]^+$, which indicates the presence of a specie containing one mercury ion and two deprotonated ligands. However, mass spectrum of complex **2** shows a peak at 482.0 amu, which is attributed to $[HgMeL+1]^+$ and corresponds to the molecular ion. The other peaks observed are probably due to molecular associations produced during the experiment.

The X-ray analysis shows that the crystal structure of complex **1** is made up of discrete centrosymmetric molecules of [HgL_2] (Fig. 1), which agrees with the spectroscopic data, but rules out the structure previously proposed for this complex [26]. The mercury atom is bonded to two sulphur atoms of two thiosemicarbazone ligands in a linear disposition (S–Hg–S = 180.0°). Complex **2** consists of [HgMeL] entities (Fig. 2), where the mercury is also in a linear disposition, bonded to the sulphur atom of a triazine ligand and the methyl group (S–Hg–C = 175.7°). Crystallographic data and selected bond distances and angles are given in Tables 1–3.

In both complexes, the triazine rings can be considered planar with a maximum deviation of 0.0498 Å for C(3) in complex **1** and 0.0571 Å for C(1) in complex **2**. The sulphur atom is 0.260 Å above this plane in complex **1** and 0.3385 Å under in complex **2**. The mercury atom is 0.5938 Å above this plane and 0.2791 Å under in complexes **1** and **2**, respectively. The aromatic rings form with respect to this plane dihedral angles of 44.9° for C(10)–C(15) and 36.95° for C(4)–C(9) in complex **1** and 47.22° and 31.92°, respectively, in complex **2**. An important change is observed with respect to LH_2OCH_3, where the dihedral angles are 95.07° and 36.94°, respectively, [24]. This change in one of the phenyl rings could be explained by the loss of the methoxy group, although it also could be attributed to crystal packing. Owing to deprotonation, there is a considerable electronic delocalisation through the thiosemicarbazone backbone, which is slightly larger in complex **2**. As a consequence all the C–N bonds have almost the same length, which does not occur in LH_2OCH_3 (1.28–1.459 Å). In the complexes, the thione bonds distances (1.755 and 1.763 Å for complexes **1** and **2**) are longer than in the precursor ligand (1.628 Å) and they are closer to the value expected for a single bond (1.82 Å) [28]. In addition the N(3)–C(2)–C(3) angles are close to 120°, as would be expected for sp^2 hybridisation, while in LH_2OCH_3 is 108°, corresponding to sp^3 hybridisation.

Although there is no covalent bond between the mercury atom and N(1) in complex **1** and N(3) in complex **2**, there is some interaction, because N–Hg distances are

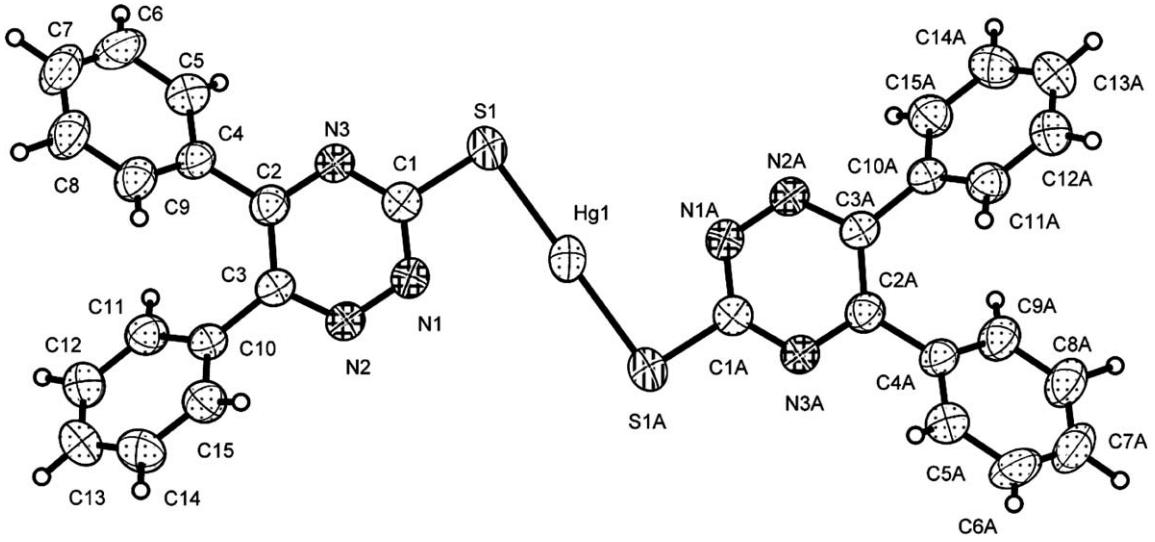

Fig. 1. Molecular structure of complex [HgL_2] **1**. Thermal ellipsoids are shown at 50% probability.

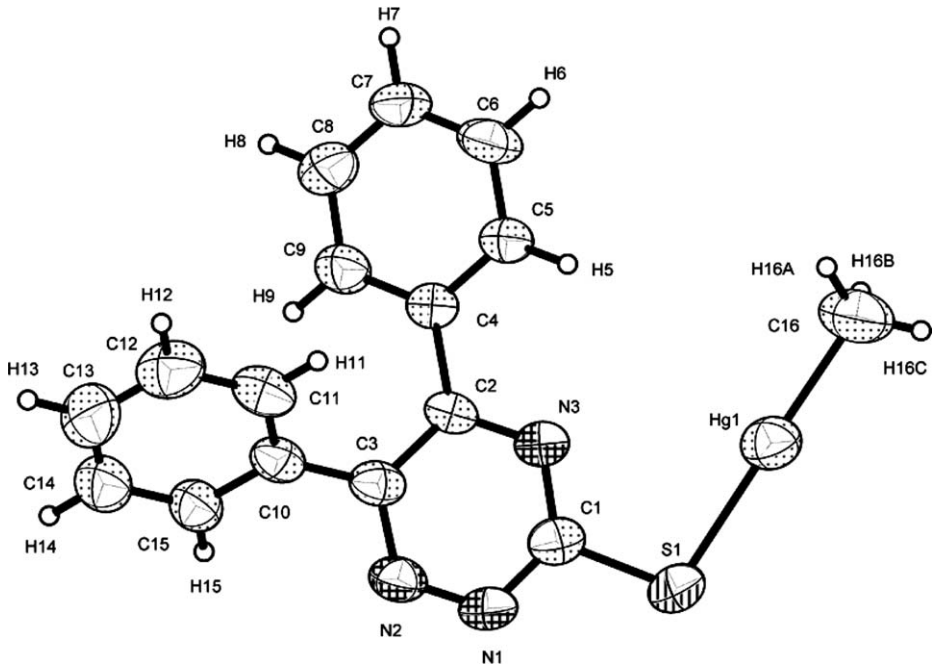

Fig. 2. Molecular structure of complex [HgMeL] **2**. Thermal ellipsoids are shown at 50% probability.

2.806 and 3.146 Å, respectively, which are larger than the sum of the covalent radii (2.25 Å), but shorter than the sum of the Van der Waals radii (3.23 Å). Some authors assume that if the Hg–N distance is lower than the sum of the Van der Waals radii there is covalent bond [29]. The non-existence of a Hg–N bond in both complexes is supported by the S–Hg–S angle, which is perfectly linear. If the mercury ion would have to accommodate an additional bond with the nitrogen atom, there must be a change in the sp hybridisation, which will be reflected in a deviation of the angle [13].

There are π–π interactions between the phenyl rings, with a distance of 3.817 Å in complex **1** and 3.846 Å in complex **2**.

The crystal structure of complex **1** belongs to the monoclinic system. In the crystal packing the mercury atoms are placed in the eight corners and in the middle of a cube, giving a body-centred cubic packing.

The absence of any band in the 2600-cm^{-1} region in the IR spectra of both complexes suggests the absence of any thiol tautomer [30]. In the spectra, there are no bands in the 3000–3300-cm^{-1} region, which indicates the absence of N–H bonds. Moreover bands attributable to the nitrate group in complex **1** are not observed [31]. The absence of these bands confirms that the ligand acts as a monoanion L in this complex. The band corresponding to the CS moiety is shifted to lower frequencies, indicating coordination of the sulphur to the metal ion. The presence of two bands

attributable to C=N bonds could indicate the formation of a new imine group, due to the loss of the methoxy group of the ligand LH_2OCH_3, although the great electronic delocalisation in the ring probably leads to there being only one C=N band and the new band could be due to the hydrazinic CN. These imine nitrogen atoms are non-coordinate to the metal ion.

The ^{1}H NMR spectra of both complexes show a multiplet in the aromatic region, corresponding to the phenyl rings of the ligand. In complex **2** a signal at 0.89 ppm, corresponding to the CH_3 group, can also be observed. The absence of any signal corresponding to amine protons supports the ligand deprotonation. The absence of the singlet attributable to the methoxy group at 3.4 ppm confirms the loss of the inserted methoxy group. In the spectrum of complex **2**, the singlet corresponding to the methyl group shows the satellites corresponding to the coupling with the mercury ion with $J^2 = 186$ Hz.

In the ^{13}C NMR spectra the signals corresponding to the methoxy group (50.7 ppm) and the tetrasubstituted carbon atom (83.2 ppm) of LH_2OCH_3 have disappeared and a new signal corresponding to an imine group is observed. The imine groups are not bonded to the metal ion, as the X-ray diffraction has established for complexes **1** and **2**. In addition the signal corresponding to the thione group is deshielded, suggesting the presence of metal–sulphur bonds. In complex **2**, the signal of the methyl group bonded to the mercury atom appears at 9.4 ppm.

Cyclic voltammetry of the ligand LH_2OCH_3 and complex **1** have been previously published [26]. Complex **1** shows a reversible redox couple at $E_{1/2} = -0.492$ V. On scanning from +1.0 to −2.2 V cyclic voltammogram of complex **2** shows a redox couple at $E_{1/2} = -0.275$ V, corresponding to a Hg(II)/Hg(I) process (Fig. 3) and two irreversible cathodic peaks corresponding to ligand reduction processes at −1.325 and −1.825 V. Analysis of the redox couple in the interval 25–800 mV s^{-1} shows a lineal variation of i_{pc} versus

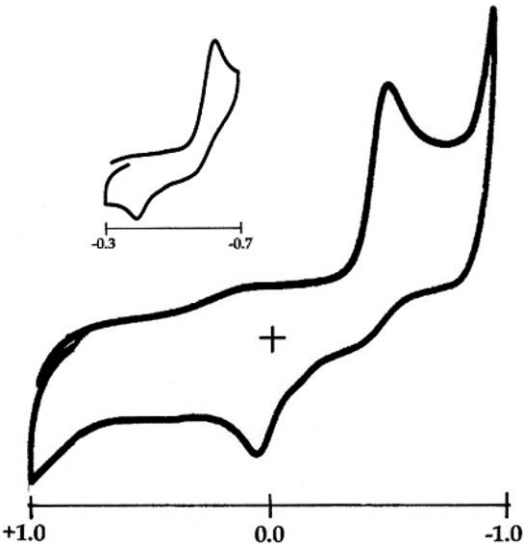

Fig. 3. Cyclic voltammogram of complex [HgMeL] **2** in DMF; $v = 100$ mV/s. Inset the redox couple.

$v^{1/2}$. Small dependence of the potential peak with the scan rate is observed, and the i_{pa}/i_{pc} ratio is close to the unity. These results suggest a diffusion controlled quasirreversible process [32]. The reduction process Hg(II)/Hg(I) is more difficult in complex **1**, where the mercury atom is bonded to two sulphur atoms due to the fact that electronic density over the metal ion is bigger than when the environment is formed by one sulphur and one carbon atom, as occurs in complex **2**.

4. Conclusions

Reactions of the ligand LH_2OCH_3 with two mercury salts lead to the formation of the corresponding coordination compounds, where the ligand has lost the methoxy group and acts as a monoanion. The methylmercury derivative is only obtained in the presence of basic medium.

In both complexes the ligand acts as monodentate and binds to the mercury ion through the sulphur atom, giving a linear disposition around the metal. This coordination mode is usually observed in mercury complexes, although coordination only via the sulphur atom is not frequent in triazines and it is observed for the first time in this particular ligand.

The results obtained confer good prospects for compound **2** to be used to prepare new sensors for the highly toxic $HgMe^+$ ion. Development of these sensors is very important due to alkyl mercury derivatives are great environmental pollutants and could affect food and soils (some compounds are used as pesticides in the treatment of seeds and can be introduced in natural waters).

5. Supplementary material

CCDC 256950 for complex **1** and 269350 for complex **2** contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge, CB2 1EZ, UK, fax: +44 1223 366 033, e-mail: deposit@ccdc.ac.uk or on the web www: http://www.ccdc.cam.ac.uk.

suitable matrix [1e–g]. One potentially interesting approach is to encapsulate the complexes in cyclodextrins (CDs) [6]. In these host–guest systems, the CDs are acting as second-sphere ligands non-covalently attached to the first-sphere ligands [7]. As well as modifying the mechanical and thermal stabilities of the guest, the inclusion in CDs can also affect the photophysical behavior. Thus, the encapsulation of the complex $Eu(NTA)_3 \cdot 2H_2O$ in β-CD induces emission from the singlet excited state of the ligands, with the corresponding inefficiency of the ligand-to-metal energy transfer step [6b]. In contrast, encapsulation of the same complex in γ-CD, which has a cavity diameter of 7.9 Å compared with 6.2 Å for β-CD, actually induces a more efficient ligand-to-metal ion energy transfer pathway [6c].

The presence of coordinated water molecules in complexes with the general formulae $Eu(\beta\text{-diket})_3 \cdot 2H_2O$ is usually a disadvantage because the luminescence can be quenched by the nonradiative dissipation of energy on the high-energy O–H vibrations. As a result, many complexes of the type $Eu(\beta\text{-diket})_3 \cdot L$ have been prepared in which the solvent molecules are replaced by a Lewis base organic ligand. $Eu(NTA)_3$ complexes are now known with L = bipy [4f], phen [4j,8], 1,4-diaza-1,3-butadienes [9] and pyrazolylpyridine [10]. Binuclear complexes $[Ln(NTA)_3]_2 \cdot bpym$ (Ln = Eu, Gd; bpym = 2,2′-bipyrimidine) have also been obtained [8]. The photoluminescence properties of these complexes, such as the $^5D_0$ quantum efficiency, vary considerably according to the nature of the adducting molecule. In the present work, we report on the encapsulation of the complex $Eu(NTA)_3 \cdot bipy$ in β-CD. The photoluminescence properties of the resultant inclusion compound have been studied and compared with those of the "free" complex. We also describe the single-crystal X-ray structure of the solvated compound $Eu(NTA)_3 \cdot bipy \cdot 0.44CHCl_3$.

2. Experimental

2.1. Materials and methods

Microanalyses were performed at the Instituto de Tecnologia Química e Biológica (ITQB), Lisbon. Thermogravimetric analysis (TGA) studies were performed using a Shimadzu TGA-50 system at a heating rate of 5 K min^{-1} under air. IR spectra were obtained as KBr pellets using a FT-IR Mattson-7000 infrared spectrophotometer. Raman spectra were recorded on a Bruker RFS100/S FT instrument (Nd:YAG laser, 1064 nm excitation, InGaAs detector). ^{13}C solid-state NMR spectra were recorded at 100.62 MHz on a Bruker Avance 400 P spectrometer. ^{13}C CP MAS NMR spectra were acquired with a 3.5 μs 90° proton pulse and 2 ms contact time with spinning rates of 7–8.5 kHz and 4 s recycle delays. The photoluminescence measurements were recorded between 10 and 300 K on a modular double grating excitation spectrofluorimeter with a TRIAX 320 emission monochromator (Fluorolog-3, Jobin Yvon-Spex) coupled to a R928 Hamamatsu photomultiplier, using the front face acquisition mode. All of the photoluminescence spectra were corrected for optical and detection spectral response.

The complex $Eu(NTA)_3 \cdot 2H_2O$ was prepared using the literature method [11]. β-CD was kindly donated by La Roquette (France) and used as received.

2.2. $Eu(NTA)_3 \cdot bipy$ (**1**)

A solution of 2,2′-bipyridine (0.055 g, 0.35 mmol) in $CHCl_3$ (5 mL) was added to a solution of $Eu(NTA)_3 \cdot 2H_2O$ (0.344 g, 0.35 mmol) in $CHCl_3$ (15 mL) at room temperature, and the reaction mixture was stirred for 3 h at room temperature. The solvent was then removed and the resulting solid washed with *n*-hexane. After drying in vacuum, a light orange powder was obtained (0.31 g, 80%). *Anal.* Calc. for $EuC_{52}H_{32}F_9N_2O_6$ (1103.8): C, 56.58; H, 2.92; N, 2.54. Found: C, 56.50; H, 2.59; N, 3.10%. IR (ν_{max}/cm^{-1}): 2977w, 2911w, 1640s, 1621s, 1614vs, 1568s, 1530s, 1509s, 1472m, 1463m, 1384m, 1299vs, 1198s, 1189s, 1135s, 1123s, 793s, 763m, 684m, 568m. Raman (ν_{max}/cm^{-1}): 3059m, 2990m, 1622s, 1595s, 1570w, 1466s, 1430w, 1386vs, 1356w, 1312m, 1292m, 1218m, 1201m, 1015m, 771m, 517m, 346w, 228w. ^1H NMR (300 MHz, $CDCl_3$): $\delta = 12.95$ (br, 2H, bipy), 10.43 (d, $J = 7$ Hz, 2H, bipy), 9.74 (br, 2H, bipy), 8.52 (d, $J = 8$ Hz, 2H, bipy), 7.91 (d, $J = 8$ Hz, 3H, naphth), 7.79, 7.76 (s + d, 9H, naphth), 7.55 (d, $J = 8$ Hz, 6H, naphth), 7.42 (d, $J = 8$ Hz, 3H, naphth), 3.45 (s, 3H, COC*H*CO).

2.3. β-CD:$Eu(NTA)_3 \cdot bipy$

A solution of β-CD (245 mg, 0.181 mmol) in water (10 mL) and ethyl acetate (2.5 mL) was treated with a solution of $Eu(NTA)_3 \cdot bipy$ (**1**) (200 mg, 0.181 mmol) in ethyl acetate (1.0 mL), and the mixture was stirred at 65 °C for 4 h. The resulting pale yellow precipitate was isolated by centrifugation and dried in air at room temperature (53 mg). *Anal.* Calc. for $C_{42}H_{70}O_{35} \cdot 0.5(C_{52}H_{32}F_9N_2O_6Eu) \cdot 8H_2O$ (1831.0): C, 44.61; H, 5.62; N, 0.76. Found: C, 44.46; H, 5.00; N, 0.86%. TGA up to 150 °C revealed a sample weight loss of 8.1% (calcd: for loss of $8H_2O$, 7.9%). IR (ν_{max}/cm^{-1}): 3383s, 2934m, 1675w, 1631sh, 1611m, 1595m, 1570m, 1532m, 1509m, 1461m, 1438w, 1385w, 1368w, 1355w, 1335w, 1301s, 1254w, 1199s, 1185sh, 1156s, 1134sh, 1099sh, 1079s, 1053sh, 1033vs, 1004sh, 947m, 937m, 863w, 845sh, 794m, 761m, 738w, 707w, 684m, 644w, 608m, 579m, 530w, 523sh, 474w, 453vw, 411vw. ^{13}C CP MAS NMR: $\delta = 194.0$–184.1 (very broad, guest CO), 136.6–114.6 (very broad, guest bipy/naphth), 102.4 (β-CD C-1), 84.0, 81.0, 78.3 (β-CD C-4), 73.1 (β-CD C-2,3,5), 63.7, 59.5 (β-CD, C-6).

2.4. Crystal structure determination of **1** (chloroform solvate)

Crystals suitable for X-ray diffraction were obtained by slow diffusion of diethyl ether into a solution of the crude

product in chloroform. The structure was determined at 120 K using graphite monochromatized radiation. Data were collected on a Siemens SMART diffractometer and corrected for Lorentz-polarization effects and for absorption [12]. Crystal data and experimental parameters are presented in Table 1. The structure was solved by direct methods using SIR-97 [13] and refined by least-squares techniques using programs from the KRYSTAL package [14]. Hydrogen atoms were kept fixed in calculated positions with C–H = 0.95 Å and with isotropic displacement factors 20% larger than U_{eq} for the atoms to which they were bonded. The europium chelate complex crystallized together with chloroform molecules, which were constrained to have threefold symmetry [15]. The chloroform site was not fully occupied. The CF_3 groups at C40 and C60 were both orientationally disordered over two sites; all C–F distances were constrained to be equal. Atomic scattering factors were taken from elsewhere [16]. Selected bond distances and angles are listed in Table 2.

3. Results and discussion

The compound $Eu(NTA)_3 \cdot bipy$ (**1**) was prepared by the reaction of $Eu(NTA)_3 \cdot 2H_2O$ with 2,2′-bipyridine in a 1:1 ratio in chloroform. The ^1H NMR spectrum of **1** (recrystallized) in $CDCl_3$ was in accordance with a NTA:bipy ratio of 3:1. Only one set of signals was observed for the protons of the bipy ligand between 8.5 and 13.0 ppm (two doublets and two broad peaks), considerably downfield shifted with respect to the analogous signals in the spectra of the free ligand (7.2–8.7 ppm [17]). The observed shifts are comparable with those measured for other 1:1 adducts of bipy with tris(β-diketonate)europium(III) complexes [17,18]. No evidence was found for the dissociation of the complex in solution. The NMR signals of the NTA groups appear as a sharp singlet at 3.45 ppm for the methine protons and several sharp peaks between 7.4 and 7.9 ppm for the aromatic protons. Single crystals suitable for X-ray diffraction analysis were obtained by slow diffusion of diethyl ether into a solution of the crude product in chloroform. The molecular structure is shown in Fig. 1. The molecule crystallized together with chloroform. $Eu(NTA)_3 \cdot bipy \cdot 0.44CHCl_3$ is monomeric, with the Eu ion being coordinated to the nitrogen atoms of the bipyridine group (Eu–N = 2.57 Å) and the oxygen atoms of the three NTA groups (Eu–O = 2.315–2.437 Å, Table 2). These distances are similar to those for unsolvated $Eu(NTA)_3 \cdot bipy$ [4f], $Eu(NTA)_3 \cdot bipy \cdot 0.5CH_3CH(OH)CH_3$ [4f], and the corre-

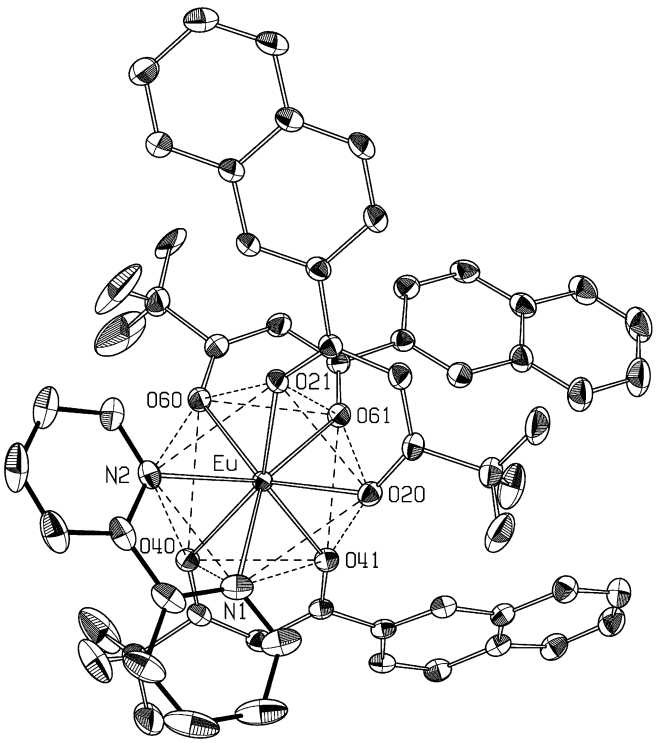

Fig. 1. Molecular structure of $Eu(NTA)_3 \cdot bipy$ in $Eu(NTA)_3 \cdot bipy \cdot 0.44CHCl_3$ with atom numbering scheme. Thermal ellipsoids are drawn at the 50% probability level and hydrogen atoms have been omitted for clarity.

sponding 1,10-phenanthroline and 2,2′-bipyrimidine adducts [8]. The coordination polyhedron is a distorted square antiprism, with the bidentate ligands spanning opposite sides of the 'square' faces. These faces are defined by N1,N2,O20,O21 and by O40,O41,O60,O61. In the ideal square antiprism, these would be planar but here the faces are creased about the diagonals N1···O21 and O40···O61 with angles of 9.0(1)° and 3.3(1)° (cf. 0°, 0° for a square antiprism, 0°, 21.8° for a bicapped trigonal prism and 29.5°, 29.5° for a dodecahedron [19]). In the unsolvated complex $Eu(NTA)_3 \cdot bipy$, there are two crystallographically independent molecules both having coordination polyhedra which are well-defined square antiprisms, whereas in the isopropanol solvate the polyhedron is a distorted bicapped trigonal prism [4f].

Addition of a solution of **1** in ethyl acetate to a solution of β-CD in water and ethyl acetate gave a pale yellow precipitate which was isolated by centrifugation and air-dried at ambient temperature. The product, designated as β-CD:$Eu(NTA)_3 \cdot bipy$, was characterized by elemental analysis, powder XRD, TGA, ^{13}C CP MAS NMR, FT-IR and photoluminescence spectroscopy. Although a 1:1 molar ratio of β-CD and complex **1** was used, elemental analysis of the product (together with TGA – see below) was more consistent with a final stoichiometry of about 2:1. Powder XRD analysis of the product showed the formation of a new poorly crystalline phase (not shown), different from either of the starting components β-CD or complex **1**. This was an initial indication for the isolation of a true inclusion compound.

Fig. 2 shows the TGA results for β-CD:$Eu(NTA)_3 \cdot bipy$ compared with those for the pure components β-CD hydrate and complex **1**, and also a physical mixture of β-CD and **1** in a 2:1 molar ratio. TGA of β-CD shows loss

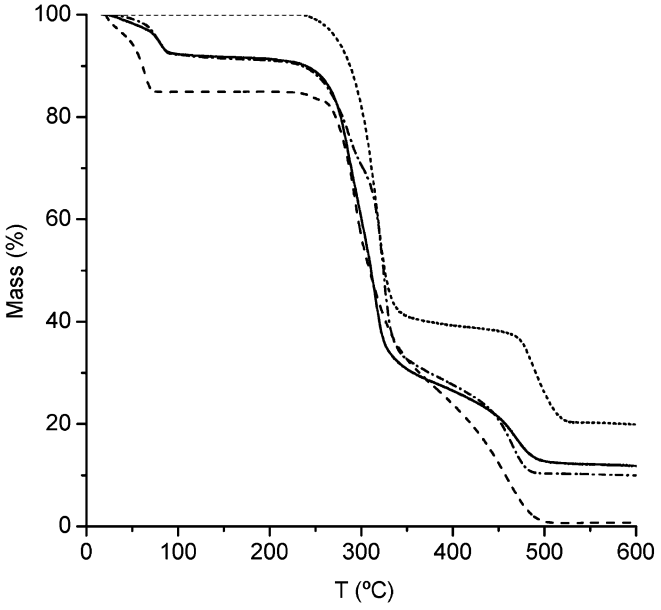

Fig. 2. TGA traces for β-CD (– – –), $Eu(NTA)_3 \cdot bipy$ (**1**) (· · · · · ·), a 2:1 physical mixture of β-CD and **1** (– · –), and the compound β-CD:$Eu(NTA)_3 \cdot bipy$ (——).

of hydrated water up to 80 °C (15%, 10 water molecules per β-CD molecule). There is no further change until about 230 °C when the compound starts to melt and decompose. At 500 °C, 100% mass loss is complete. The europium chelate **1** is devoid of hydration waters since the thermogram does not show any weight loss up to 250 °C. The compound then decomposes in two steps up to 530 °C, leaving a residual mass of 20%. Even though β-CD and complex **1** start decomposing at nearly the same temperature, we can clearly distinguish the two overlapping processes in the TG curve for the physical mixture, which demonstrates that the two components behave independently. In contrast, compound β-CD:$Eu(NTA)_3 \cdot bipy$ starts decomposing at about the same point as β-CD (230 °C), but there is no overlapping step towards slightly higher temperature for the degradation of the europium chelate **1**. The fact that the decomposition of the two components cannot be distinguished is an additional support for the successful isolation of a true inclusion compound, because it suggests that the $Eu(NTA)_3 \cdot bipy$ molecules are isolated from one another by complexation with the host β-CD molecules.

^{13}C MAS NMR spectroscopy is often useful for the recognition of inclusion complex formation between organic or metallo-organic guests and cyclodextrins [6b,20]. The spectrum of pristine β-CD hydrate exhibits multiple resonances for each type of carbon atom [21]. This has been mainly correlated with different torsion angles about the (1 → 4) linkages for C-1 and C-4 [21a,21b], and with torsion angles describing the orientation of the hydroxyl groups [21c]. The different carbon resonances are assigned to C-1 (101–104 ppm), C-4 (78–84 ppm), C-2,3,5 (71–76 ppm), and C-6 (57–65 ppm). In the spectrum of the compound β-CD:$Eu(NTA)_3 \cdot bipy$ (not shown), the β-CD resonances are broader, becoming almost single peaks for C-1 and C-2,3,5. The broadening of the peaks could be induced by the paramagnetic Eu^{3+} ions of encapsulated guest molecules. However, it is more likely that conformational changes of the β-CD macrocycle are responsible. Thus, the inclusion of bulky guest molecules in β-CD compels the ring to adopt a more symmetrical conformation, with each glucose unit in a more similar environment [20]. By comparison with previous experimental and theoretical studies on the interaction of the complex $Eu(NTA)_3 \cdot 2H_2O$ with β-CD and γ-CD [6b,6c], and also crystallographic studies of inclusion compounds of naphthalene or naphthalene derivatives in CDs [22], we propose that the host–guest interaction in the compound β-CD:$Eu(NTA)_3 \cdot bipy$ involves the partial inclusion of the naphthoyl moieties of the guest within the β-CD cavities. The ^{13}C CP MAS NMR spectrum of the compound β-CD:$Eu(NTA)_3 \cdot bipy$ also contained resonances due to the europium chelate molecule, but these were broad and weak. The presence of structurally intact $Eu(NTA)_3 \cdot bipy$ molecules was confirmed by the IR spectrum, which contained strong peaks due to the europium complex (e.g., 1614, 1299 and 793 cm^{-1}) and β-CD (e.g., 1157, 1079 and 1029 cm^{-1}). These bands were essentially unshifted

and with equal relative intensities compared with the corresponding bands for the pure components (complex **1** and pristine β-CD hydrate).

Fig. 3 compares the excitation spectrum of the complex **1** with that of the inclusion compound β-CD:Eu(NTA)$_3$ · bipy, monitored around the $^5D_0 \rightarrow {}^7F_2$ lines. The spectrum of the complex shows a large broad band ascribed to the triplet levels of the ligands and a series of lines corresponding to intra-4f^6 lines. The inclusion of the complex into β-CD induces an enlargement of the ligands excited levels, suggesting an effective interaction between β-CD and the NTA ligands of the complex, and a decrease of the intensity of the Eu^{3+} lines with respect to that of the large broad band. This intensity decrease of the intra-4f^6 lines indicates an enhancement of the Eu^{3+} sensitized process due to encapsulation of the Eu(NTA)$_3$ · bipy molecules. Moreover, the sensitized spectral region of the inclusion compound covers a larger UV-A-B range, compared with that for non-included **1**.

Fig. 4 shows the emission of Eu(NTA)$_3$ · bipy (**1**) and the inclusion compound β-CD:Eu(NTA)$_3$ · bipy for the excitation wavelengths that maximize the Eu^{3+} emission intensities. The spectra consist of the typical Eu^{3+} emission lines ascribed to the intra-4f^6 $^5D_0 \rightarrow {}^7F_{0-4}$ transitions. For both compounds only one line is observed for the non-degenerate $^5D_0 \rightarrow {}^7F_0$ transition and no changes are detected in the emission spectra upon variation of the excitation wavelength, suggesting, therefore, that the Eu^{3+} ions occupy the same average local environment within each compound. However, changes are observed in the energy and number of Stark components due to the encapsulation of the complex. In particular, a higher ligand field splitting is evident for the $^5D_0 \rightarrow {}^7F_{1,2}$ transitions: 2 and 3 Stark components for bulk **1**, and 3 and 4 Stark components for the inclusion compound. The increase in the number

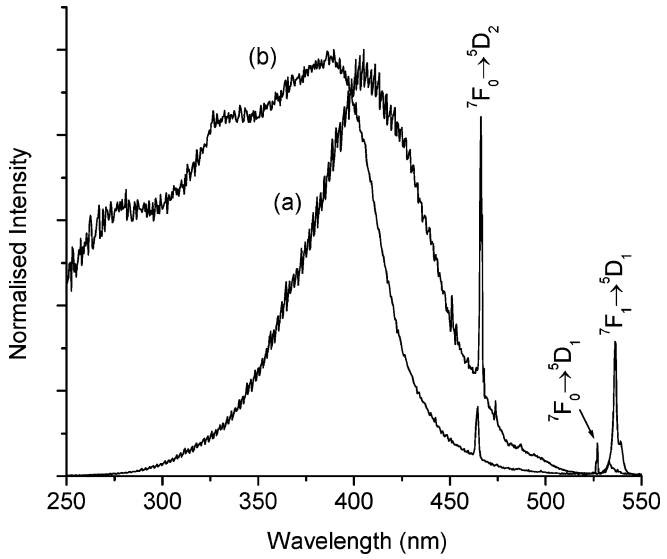

Fig. 3. Room-temperature excitation spectra for: (a) the complex Eu(NTA)$_3$ · bipy (**1**) and (b) the inclusion compound β-CD:Eu(NTA)$_3$ · bipy, monitored around 613 and 615 nm, respectively.

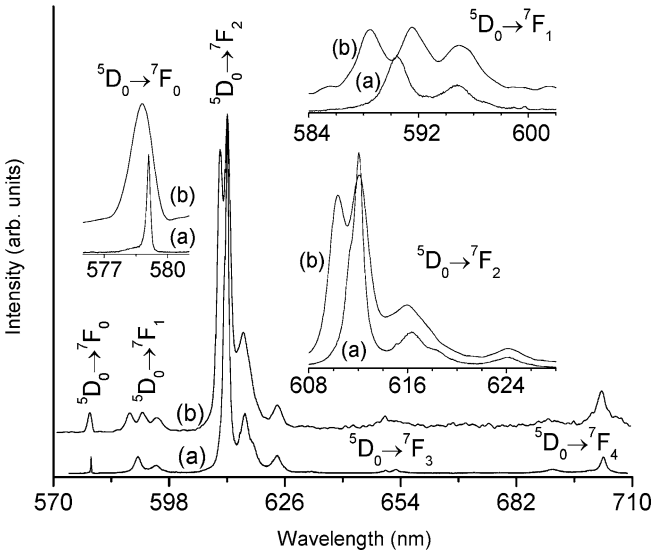

Fig. 4. Room-temperature emission spectra for: (a) the complex Eu(NTA)$_3$ · bipy (**1**) and (b) the inclusion compound β-CD:Eu(NTA)$_3$ · bipy, excited around 405 and 398 nm, respectively.

of Stark components indicates a decrease in the Eu^{3+}-local symmetry. We may speculate that the change in the Eu^{3+} coordination polyhedron makes the NTA ligands more geometrically accessible for inclusion in the host cavities. For both the complex **1** and the inclusion compound, no emission from the ligands triplet states could be observed, suggesting an efficient energy transfer between them and the Eu^{3+} levels. The non-observation of excited states of the ligands in the inclusion compound suggests a better accommodation of the luminescent complex within the cyclodextrin cavity, as has been reported for the 1:1 inclusion compound comprising β-cyclodextrin and Eu(NTA)$_3$ · 2H$_2$O [6b].

4. Conclusions

Powder XRD, TGA, ^{13}C CP MAS NMR and photoluminescence spectroscopy indicate that an inclusion compound comprising β-cyclodextrin and the adduct Eu(NTA)$_3$ · bipy can be prepared by co-precipitation from a solvent mixture. The photophysical properties of the europium complex are modified by the introduction of the second-sphere ligand (β-CD) non-covalently attached to the first-sphere ligands (NTA and bipy). This may be due, in part, to a change in the Eu^{3+} coordination polyhedron. The reorganization of the ligands may be necessary for the formation of an inclusion complex with a 2:1 (host:guest) stoichiometry, in which the naphthoyl moieties of the guest species are partially encapsulated within the β-CD cavities. Such a change would not be surprising since we now know that at least three different polyhedra are possible for the adduct Eu(NTA)$_3$ · bipy simply by recrystallizing the compound from different solvents. Thompson et al. [4f] already showed that two of these crystalline forms have different luminescence spectra.

5. Supplementary data

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 279710. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (internat.) +44 1223 336 033; e-mail: deposit@ccdc.cam.ac.uk].

Acknowledgements

The authors are grateful to FCT, POCTI and FEDER for financial support (Project POCTI/CTM/46780/2002). We also thank the University of Aveiro (J.A.F.) and the FCT (J.A.F., S.S.B) for research grants. A.H. is indebted to the Carlsberg Foundation for the diffractometer. We are grateful to Prof. João Rocha for access to research facilities and Paula Esculcas for assistance in the NMR experiments.

like tetrahedral, square pyramidal or trigonal-bipyramidal of comparable stability and this often leads to significant differences in the metal–ligand geometry and overall molecular shape. This metal ion also finds significant use in bioinorganic chemistry [7] and magnetism [8]. Using $[Cd(NCS)_6]^{4-}$ as a building block in conjunction with $[Cu(tren)(OH_2)]^{2+}$, results in a bimetallic trinuclear complex of the type $[Cu_2Cd(tren)_2(NCS)_6]$ (**1**) with *trans*-$[Cd(NCS)_4(SCN)_2]^{4-}$ instead of covalently bonded polymeric $[Cu_2Cd(tren)_2(NCS)_6]_n$ with *cis*/*trans*-$[Cd(NCS)_2(SCN)_4]^{4-}$ as molecular ions. X-ray crystallography study shows the presence of hydrogen bonded trinuclear entities to form a 3D supramolecular continuum. Although the magnetic behaviour of this complex is less important, its structure establishes the fact that the coordination nature of the metal ions plays a vital role in structure determination as well as on the coordination matrix of the molecular ion. The details of synthesis, structure and properties are described below.

2. Experimental

2.1. Materials

High purity tris(2-aminoethyl)amine (Fluka, Germany), copper nitrate trihydrate (E. Merck, India), cadmium nitrate tetrahydrate (E. Merck, India) and ammonium thiocyanate (E. Merck, India) were purchased from the respective concerns and used as received. All other chemicals and solvents were AR grade and were used as received.

2.2. Physical measurements

Elemental analyses (carbon, hydrogen and nitrogen) were performed on a Perkin–Elmer 2400 CHNS/O elemental analyzer. IR spectra (KBr discs, 4000–300 cm^{-1}) were recorded using a Perkin–Elmer model RX 1 spectrometer. Molar conductance was measured using a Systronics conductivity meter where the cell constant was calibrated with 0.01 M KCl solution and dry MeOH was used as the solvent. Ground state absorption measurements were made with a Jasco model V-530 UV–Vis spectrophotometer. Magnetic susceptibilities at room temperature were measured with a PAR 155 vibrating sample magnetometer with $Hg[Co(SCN)_4]$ as the reference. Measurements on powdered samples were performed in the temperature range 2–300 K using a Quantum Design MPMS-7 SQUID magnetometer in a magnetic field of 0.1 T. The experimental susceptibilities were corrected for the diamagnetism of the constituent atoms (Pascal tables).

2.3. Preparation of the complex

The trinuclear complex **1** was prepared as a bluish green crystalline product through three different methods. These are described below.

2.3.1. Method A

An aqueous solution (5 cm^3) of NH_4NCS (0.457 g, 6 mmol) was added to a solution of $Cd(NO_3)_2 \cdot 4H_2O$ (0.311 g, 1 mmol) in the same solvent (10 cm^3) giving rise to a colourless solution. In another container $Cu(NO_3)_2 \cdot 3H_2O$ (0.483 g, 2 mmol) and tren (0.293 g, 2 mmol) were mixed together in an aqueous solution (10 cm^3) producing a bluish green solution. This bluish green solution was slowly added to the above colourless solution. During addition a colour change was not distinct but the intensity of the bluish green colour increased indicating complexation. The final mixture was filtered and left for slow evaporation in air. Bluish green rectangular crystals suitable for X-ray diffraction formed after a week. Yield, 0.69 g (75%). *Anal*. Calc. for $C_{18}H_{36}N_{14}S_6CdCu_2$ (**1**): C, 24.56; H, 4.12; N, 22.27. Found: C, 24.59; H, 4.09; N, 22.29%. IR (KBr, cm^{-1}): *v* (NCS) 2129, 2064. Λ_M (DMF, $ohm^{-1}\,cm^2\,mol^{-1}$): 10. UV–Vis (λ, nm): 885, 670, 260.

2.3.2. Method B

$Cd(NO_3)_2 \cdot 4H_2O$ (0.311 g, 1 mmol), $Cu(NO_3)_2 \cdot 3H_2O$ (0.483 g, 2 mmol), tren (0.293 g, 2 mmol) and NH_4NCS (0.457 g, 6 mmol) were mixed in water (20 cm^3) in a container resulting in a bluish green solution. The mixture was filtered and left for slow evaporation. Bluish green crystals were formed after few days. Yield, 0.55 g (60%).

2.3.3. Method C

An NH_4NCS (0.457 g, 6 mmol) solution in water (10 cm^3) was added to a solution of $Cu(NO_3)_2 \cdot 3H_2O$ (0.242 g, 1 mmol) in a container resulting in a brown mixture. $Cd(NO_3)_2 \cdot 4H_2O$ (0.622 g, 2 mmol) in water (10 cm^3) was mixed with tren (0.293 g, 2 mmol) in a separate container producing a colourless solution. The brown solution was added dropwise to the colourless solution giving a bluish green coloration. This was filtered and left for slow evaporation in air. Bluish green rectangular crystals were formed after two weeks. Yield, 0.36 g (40%).

2.4. X-ray crystallography

Single crystals were obtained by slow evaporation of an aqueous solution of the reaction mixture. The crystal data and data collection parameters are listed in Table 1. Bluish green crystals suitable for X-ray crystallographic analyses were selected following examination under a microscope. Diffraction data were collected on a Bruker-AXS SMART APEX/CCD diffractometer using Mo Kα radiation, and were corrected for Lorentz and polarization effects and for absorption using the SADABS program [9]. The structure was solved by direct methods and the structure solution and refinement were based on $|F|^2$. All non-hydrogen atoms were refined with anisotropic displacement parameters whereas hydrogen atoms were placed in calculated positions when possible and given isotropic *U* values 1.2 times that of the atom to which they are bonded. The

crystallographic calculations were conducted with the SHELXTL v.6.1 program package [10].

3. Results and discussion

3.1. Synthesis and formulation

The trinuclear $[Cu_2Cd(tren)_2(NCS)_6]$ (**1**) compound was prepared using three different routes (Methods A–C; see Section 2). In Method A, the building units $[Cu(tren)(OH_2)]^{2+}$ and $[Cd(NCS)_6]^{4-}$ were generated in solutions separately. The molecular ion, $[Cd(NCS)_6]^{4-}$, was obtained by addition of six moles of ammonium thiocyanate to one mole of cadmium(II) nitrate tetrahydrate (Eq. (1)). The complementary unit $[Cu(tren)(OH_2)]^{2+}$ was prepared by dropwise addition of two moles of tren to a two molar copper(II) nitrate trihydrate in a separate container (Eq. (2)). The trinuclear **1** resulted through union of *trans*-$[Cd(NCS)_4(SCN)_2]^{4-}$ and $[Cu(tren)(OH_2)]^{2+}$ in a 1:1 ratio of these building blocks (Eq. (3)).

$$Cd(NO_3)_2 \cdot 4H_2O + 6NH_4NCS \rightarrow (NH_4)_4[Cd(NCS)_6] + 2NH_4NO_3 + 4H_2O \quad (1)$$

$$2Cu(NO_3)_2 \cdot 3H_2O + 2tren \rightarrow 2[Cu(tren)(OH_2)](NO_3)_2 + 4H_2O \quad (2)$$

$$(NH_4)_4[Cd(NCS)_6] + 2[Cu(tren)(OH_2)](NO_3)_2 \rightarrow [Cu_2Cd(tren)_2(NCS)_6] + 4NH_4NO_3 + 2H_2O \quad (3)$$

The principle involved is the union of two complementary units $[Cd(NCS)_6]^{4-}$ and $[Cu(tren)(OH_2)]^{2+}$, which results in the trinuclear compound instead of the polymers of the type **2** and **3** [4]. **1** was also achieved in good yield by a single-pot [11] reaction (Method B, see Section 2) using a 1:2:2:6 molar ratio of $Cd(NO_3)_2 \cdot 4H_2O$, $Cu(NO_3)_2 \cdot 3H_2O$, tren and NH_4NCS. A 1:2 molar ratio of alternate building units $[Cu(NCS)_6]^{4-}$ and $[Cd(tren)(OH_2)_2]^{2+}$ leads to the same trinuclear complex showing a inherent tendency towards its formation (Method C, see Section 2). A change in metal ion arouses a change in the coordination matrix of the molecular ion as well as in the dimensionality compared to that of **2** and **3** [4].

The complex was characterised by elemental (C, H and N) analyses, solution electrical conductivity and magnetic susceptibility measurements and spectroscopic (IR and UV–Vis) properties and X-ray results. It is moderately soluble in common organic solvents like, methanol, ethanol, acetonitrile, dimethylformamide and dimethylsulfoxide. In methanol it behaves as a non-electrolyte as is evident from its low conductivity value [12]. The trinuclear complex, $[Cu_2Cd(tren)_2(NCS)_6]$ (**1**) shows bands at 3355 and 3265 cm^{-1} due to N–H stretching of the NH_2 group and bands at 2890 cm^{-1} can be assigned to the aliphatic C–H stretching vibration. Two well resolved peaks at 2129 and 2064 cm^{-1} attributed to the ν(NCS) stretching mode of thiocyanate [13] are distinctly seen. Presence of more than one band confirm both *N*- and *S*-coordination of thiocyanates in a bridging motif as well as terminals. The band corresponding to the stretching frequency ν(CS) appears at 770 cm^{-1}. The complex displays multiple absorption bands and shoulders in the 200–1000 nm range in MeOH solution. A band at 885 nm is assignable to a d–d transition ($d_{x^2-y^2}$, $d_{xy} \rightarrow d_{z^2}$) of copper(II) moieties in a trigonal bipyramidal (tbp) geometry [14]. A higher energy shoulder is observed at 670 nm which is typical of copper(II) complexes with tbp geometry. An absorption at 260 nm may be assigned to a ligand based transition. The solid state reflectance spectrum shows a good correspondence to the solution spectrum indicating similar gross geometric and electronic structure in the solid state and in solution.

3.2. Structure

The structural analysis shows that trinuclear **1** consists of 3D supramolecular continuum by multiple weak intra- and intermolecular N–H···S hydrogen bondings. An ORTEP diagram of the trinuclear unit and perspective view of the hydrogen bonded 3D network structure are shown in Figs. 1 and 2, respectively. Selected interatomic bond distances and bond angles relevant to the cadmium(II) and copper(II) coordination spheres are given in Table 2. The significant hydrogen bonding parameters are set in Table 3.

Each *trans*-$[Cd(NCS)_4(SCN)_2]^{4-}$ is connected to two $[Cu(tren)]^{2+}$ units through 1,3-thiocyanate bridges leading to a trinuclear unit and the cadmium atom is at the inversion centre. The geometry around the 4d ion, Cd(1), is a distorted octahedron with a relatively hard *trans*-CdN_4S_2 instead of the relatively soft *cis*/*trans*-CdN_2S_4 matrix

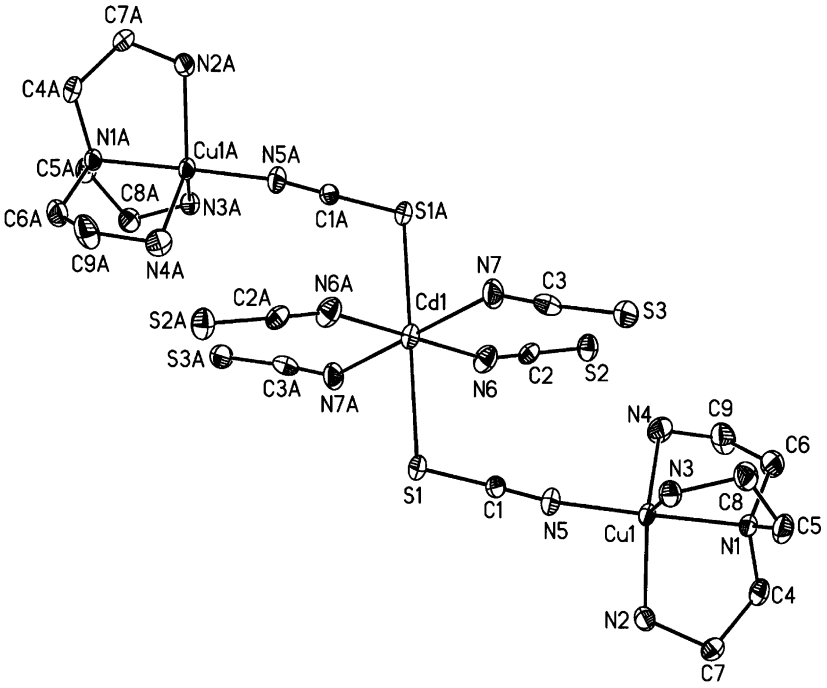

Fig. 1. ORTEP representation of $[Cu_2Cd(tren)_2(NCS)_6]$ (**1**).

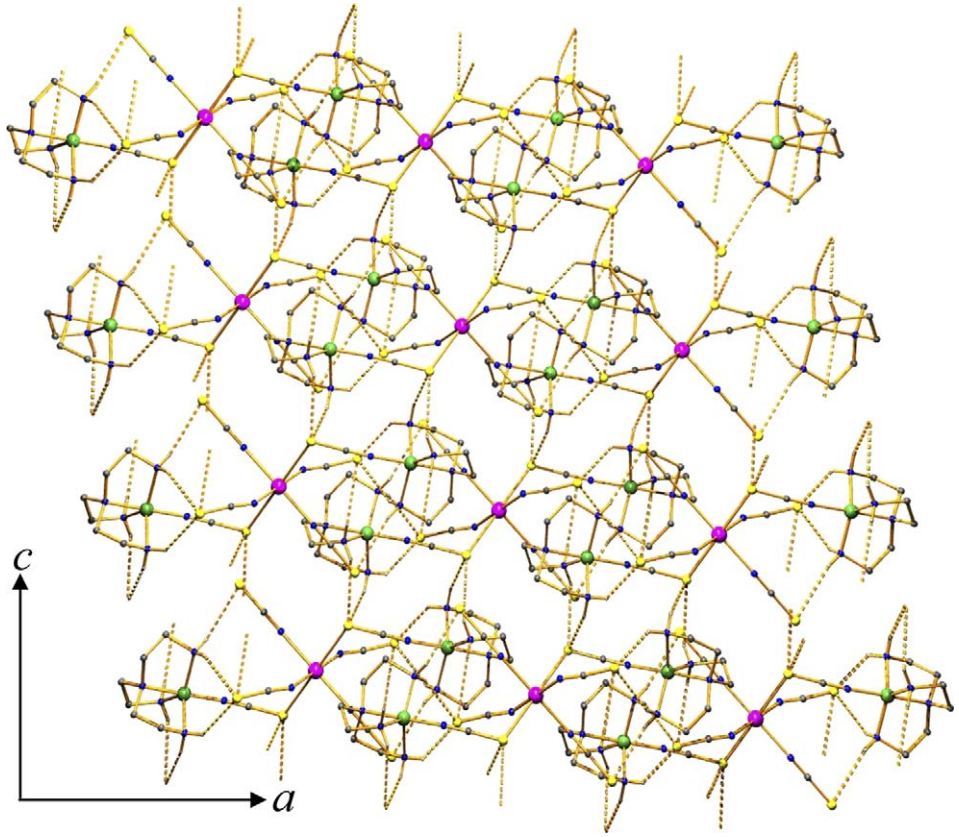

Fig. 2. 3D network in **1** formed by N–H···S hydrogen bondings.

present in **2** and **3** [4]. The *trans*-CdN_4S_2 chromophore is formed by two S atoms of two different bridging NCS^- and four N atoms of the four terminal pseudohalides. Cu(1) of $[Cu(tren)]^{2+}$ is in a distorted trigonal bipyramidal environment with a hard CuN_5 chromophore produced through attachment of four N atoms of the tripodal amine

Table 2
Selected bond distances (Å) and angles (°) for **1**

Bond distances			
Cu(1)–N(1)	2.047(2)	Cd(1)–N(6A)	2.273(3)
Cu(1)–N(2)	2.057(3)	Cd(1)–N(7)	2.373(3)

C(9)–H(9A)···S(3)[a]	0.9900	2.8400	3.636(5)	138.00

Symmetry code: [a] $1/2 - x$, $1/2 + y$, $1/2 - z$; [b] $1 - x$, y, $1/2 - z$.

and one N atom of a bridging NCS^-. The sequence in the bridge is represented as Cu(1A)–N(5A)–C(1A)–S(1A)–Cd(1)–S(1)–C(1)–N(5)–Cu(1) (Fig. 1).

The equatorial plane of Cd(1) consists by four terminal N-coordinated thiocyanates [N(6), N(6A), N(7), N(7A)] and the two S atoms of the bridging pseudohalide [S(1), S(1A)] lie in the axial positions. The Cd(1)–S bond length [2.7805(8) Å] is much longer than the Cd(1)–N lengths which lie within the range 2.273(3)–2.373(3) Å. Ranges of *cisoid* angles [85.64(8)°–94.36(8)°] reflect the deviation of the chromophore from an ideal octahedron. *Transoid* angles on the other hand are 180.00°. Two bridging thiocyanate nitrogens [N(5), N(5A)] of *trans*-$[Cd(NCS)_4(SCN)_2]^{4-}$ coordinate to the adjacent $[Cu(tren)]^{2+}$ forming the trinuclear unit. The three primary amine nitrogens [N(2), N(3), N(4)] of the tripod form the equatorial plane around copper(II) with the tertiary amine [N(1)] and thiocyanate nitrogen [N(5)] placed at the axial sites. Cu–N distances within the equatorial plane lie within a close range [2.047(3)–2.115(3) Å] while the axial distances show a significant difference [Cu(1)–N(1), 2.047(3) Å; Cu(1)–N(5), 1.960(3) Å]. Angles of the equatorial plane [N(2)–Cu(1)–N(3), 115.07(11)°; N(2)–Cu(1)–N(4), 129.55(12)°; N(3)–Cu(1)–N(4), 112.31(12)°] show deviation from the ideal 120° whereas the *trans* axial angle N(1)–Cu(1)–N(5), 178.73(12)° is close to the ideal 180°. The mean deviation of the copper(II) atom from the basal plane is 0.209 Å. Cu···Cd and Cu···Cu distances within the same unit are 5.975 and 11.949 Å, respectively and the Cu···Cu distance between two adjacent layers is 9.714 Å. All the Cd–S/N and Cu–N/S bond lengths and angles are similar to the reported ones [15,16].

An interesting feature of **1** is the interionic hydrogen bonds which play an important role in the crystal packing and the stability of the trinuclear complex. Adjacent trinuclear units are cross-linked by three intramolecular and three intermolecular N–H···S hydrogen bondings [17] with involvement of all the S atoms of the pseudohalides. The range of the donor–acceptor distances lie within a range of 3.40–3.64 Å and this is slightly greater than the usual 3.35 Å as reported in several works [18,19]. Trinuclear entities are so placed that a copper(II) coordination moiety of one unit lies very close to another copper(II) moiety of the adjacent trimer. One terminal sulfur [S(3)] of CdN_2S_4 is engaged in trifurcated N–H···S hydrogen bonding. Of them, two are intramolecular with the H's of the two amine nitrogens [N(2), N(3)] of tren from the same unit (Table 3) and the other one is an intermolecular hydrogen bonding between the amine nitrogen [N(4)] of tren belonging to the adjacent unit. The other terminal sulfur atom [S(2)] participates in intramolecular hydrogen bonding with the remaining amine nitrogen [N(4)] of tren bound to copper(II) of the same unit. Presence of four such types of N–H···S bondings (three-intra and one-inter) leads to the formation of supramolecular layers of the trinuclear units. The bound S(1) of cadmium(II) participates in intermolecular bifurcated hydrogen bonding with amine nitrogens [N(2), N(3)] of the adjacent layers leading to an extended three-dimensional network (Fig. 2).

3.3. Magnetism

Variable-temperature magnetic susceptibility measurements have been performed in the range 2–300 K. The thermal variation of molar susceptibility χ_M together with a plot of $\chi_M T$ versus T of complex **1** is shown in Fig. 3. The magnetic moment (μ_{eff}) per copper(II) centre is the same as that expected for an isolated paramagnetic system with $S = 1/2$ ($\mu_{eff} = 1.732$ BM) for copper(II) [20]. **1** consists of two copper(II) ions as its basic unit. For each copper(II), $\chi_M T$ is, as indicated, close to 0.4 $cm^3\,mol^{-1}\,K$ – thus a total of 0.8 $cm^3\,mol^{-1}\,K$ is the result. The experimental value of 0.82 $cm^3\,mol^{-1}\,K$ is almost constant throughout the temperature range (Fig. 3). This shows coupling between the paramagnetic centres is negligible. Each magnetic centre behaves as a discrete unit which implies that the long –NCS–Cd–SCN– bridge inhibits magnetic exchange.

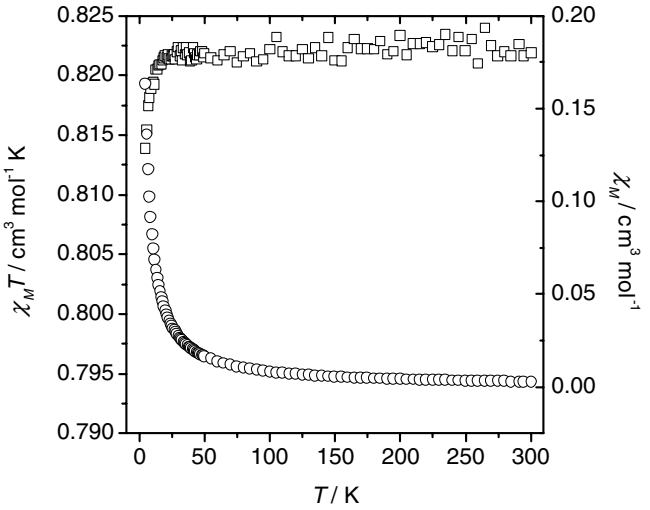

Fig. 3. Plots of $\chi_M T$ vs. T and χ_M vs. T in **1**.

4. Conclusion

A new trinuclear based supramer is synthesised through reactions of the building components $[Cu(tren)(OH_2)]^{2+}$ and $[Cd(NCS)_{6-n}(SCN)_n]^{4-}$ with a preassigned ratio. Use of copper(II) with lower coordination affords the heterotrinuclear ensemble $[Cu_2Cd(tren)_2(NCS)_6]$ instead of polymeric $[Cu_2Cd(tren)_2(NCS)_6]_n$ like that of **2** and **3** [4]. Presence of the diamagnetic $[Cd(NCS)_{6-n}(SCN)_n]^{4-}$ molecular ion hinders magnetic coupling between the paramagnetic centres in this complex. This prompts us to extend our work with a paramagnetic ion based molecular ion to find its effect on magnetic interactions in different complexes.

5. Supplementary data

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 211745 (**1**). Copies of this information can be obtained free of charge from the Director, CCDC, 12 Union Road, Cambridge, CB2 IEZ, UK (Fax: +44 1223 336033; e-mail: deposit@ccdc.cam.ac.uk or www.ccdc.cam.ac.uk).

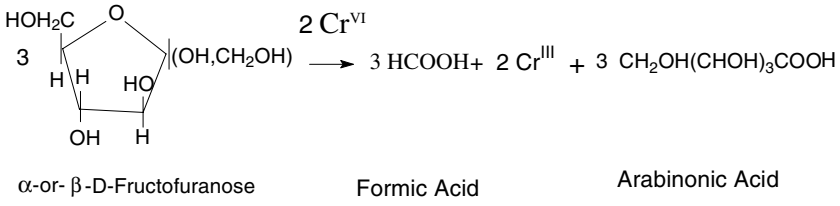

Scheme 1.

to occur in most oligo- and polysaccharides, probably because of the greater stability of this form of the sugar as compared with its pyranose form [14]. The mechanism of oxidation of ketohexoses by transition-metal ions in acid media has been little studied [15–18]. Being D-Fru present at animal and vegetal level, the chromic interaction of this ketose was considered of great importance to be studied, in order to compare its reactivity with aldoses, deoxyaldoses, aminoaldoses, aldonic acids and the respective lactones. In this paper, results on the chromic oxidation of D-Fru (Scheme 1) and structural evidences of the intermediate Cr^{V} complexes formed in acid and neutral aqueous solutions are described.

2. Experimental

2.1. Materials

D-Fructose, potassium dichromate, acrylonitrile, perchloric acid, and sulfuric acid were commercial products of highest available purity. Aqueous solutions were prepared in double-destilled, deionized, water. For experiments performed in the pH range 1–7, the pH of the solutions was adjusted by addition of 0.5 M $HClO_4$ and NaOH 0.5 M. In experiments performed at constant ionic strength ($I = 1.0$ M) and different $[H^+]$, mixtures of $NaClO_4$ and $HClO_4$ solutions were prepared. The concentration of stock solutions of $HClO_4$ was determined by titration by standard analytical methods [19].

The stability of the organic substrate under conditions used in the kinetic studies was tested by paper chromatography (PC) at a given $[H^+]$ and by HPLC.

2.2. Spectrophotometry

Spectrophotometric measurements were made by monitoring absorbance changes at 350 and 570 nm on a Jasco-V-530-UV/Vis spectrophotometer with fully thermostated cell compartments (±0.2 °C). Each kinetic run was performed under pseudo-first-order conditions using excess of [D-Fru] over $[Cr^{VI}]$. A mixture containing appropriate amounts of all reactants (except oxidant) was thermally equilibrated at the desired temperature and this was rapidly added to a measured amount of the oxidant solution (pre-equilibrated at the same temperature). The reaction was followed until at least 80% conversion. Experiments were performed at 33° unless otherwise mentioned and mixtures of sodium perchlorate were used to maintain a constant ionic strength (I) of a 1.00 M.

The Cr^{VI} consumption was followed spectrophotometrically at 350 nm. In all experiments, the concentration of Cr^{VI} was kept constant at 8.0×10^{-4} M while ketose concentration was varied from 0.02 to 0.1 M. The observed pseudo-first-order rate constants (k_{obs}), determined from the slopes of the linear part of plots of $\ln(Abs_{350})$ versus time, were deduced from multiple determinations and were within ±5% of each other.

The formation of Cr^{III} was monitored at 570 nm, $[Cr^{VI}] = 6.0 \times 10^{-3}$ M in the presence of excess ketose and $[HClO_4] = 1.0$ M.

Chromate esters were investigated by UV/Vis spectrophotometry in the 300–500 nm region in which these esters show characteristic absorption bands. An excess of organic substrate maximized ester formation while minimizing successive oxidation steps. Reactions were performed at pH 4.0, to ensure that ester formation was not rate limiting; at higher pH the overall reduction of Cr^{VI} is much slower than at pH 1.0. The instrument was zeroed to an arrangement of the reference and sample beams passing through matched cuvettes, both containing Cr^{VI} in H_2O at pH 4.0. The solution in the sample cell was replaced with the reaction solution containing 6×10^{-4} M Cr^{VI} and 0.06–0.33 M ketose at pH 4.0, $I = 1.0$ M and $T = 33$ °C.

The formation of CrO_2^{2+} was examined by periodic scanning of O_2-saturated solutions containing 0.125 M Fru and 0.045 mM Cr^{VI} in $HClO_4$.

2.3. Product analysis

2.3.1. General

HPLC was employed to detect the reaction products under the conditions used in the kinetic measurements (excess of ketose over Cr^{VI}). The chromatograms were obtained on a KNK-500 A chromatograph provided with a 7125 HPLC pump. The separation was carried out on a supelcogel C-610 H HPLC column (300.0 × 7.8 mm, Bio-Rad Laboratories), using 0.1% v/v H_3PO_4 as eluent, and a flow rate of 0.5 ml/min, at 30 °C. The samples were filtered through at 0.2-μm membrane prior to the injection into the chromatographic system. The effluent was monitored with refractive index (ERC-7522, ERMA INC) and 115 UV Gilson ($\lambda = 220$ nm) detectors.

Standard solutions of the D-Fru, D-arabinonic acid, D-formic acid were prepared individually in 0.2 M $HClO_4$

and chromatographed separately to determine the retention time (t_R) of each sample.

2.4. EPR measurements

All of the EPR experiments were carried out at room temperature with a Bruker ESP-300 E spectrometer. The microwave frequency was generated with a Bruker 04-ER (9–10 GHz) and measured with a Racal-Dana frequency meter. The magnetic field was measured with a Bruker NMR-probe gaussmeter. All the EPR experiments were carried out at 20 °C. EPR spectra were simulated by means of the program PEST WinSIM [20] with 100% Lorentzian lineshapes. The spectral parameters for each Cr^V species were consistent within all simulations.

2.5. Free-radicals test

Upon addition of 0.5 ml acrylonitrile (0.20 M in 0.20 M $HClO_4$) to a reaction mixture: 2.5×10^{-2} M $K_2Cr_2O_7$ and 5.0×10^{-2} M D-Fru in 2 ml of 0.20 M $HClO_4$, at 33 °C. After 10 min, a white precipitate of a polymer appeared slowly. Blank experiments with either Cr^{VI} or D-Fru gave no detectable white precipitates. The possible reaction of Cr^V or Cr^{IV} with acrylonitrile was excluded based on the absence of a precipitate one day after mixing [Cr^VO-(ehba)]K [21] or [Cr^{IV}O(ehba)]K [22] (ehba = 2-ethyl-2-hydroxybutanoic acid) and acrylonitrile under the same reaction conditions than before.

3. Results and discussion

3.1. Rate studies

The absorbance versus times curves at 350 nm exhibit a monotonic decrease of absorbance which cannot be described by a single exponential decay.

Under the present experimental conditions, no induction period was detected as Kabir-ud-Din et al. [18] observed in their study of Influence of sodium dodecil sulfate/Triton X-100 micelles on the oxidation of the D-fructose by chromic acid in presence of perchloric acid.

At this wavelength, kinetics traces show an initial deviation from first-order decay over short time periods. These kinetics profiles could be adequately described by the set consecutive first-order reactions of Scheme 2.

It is known that Cr^V species absorb strongly at 350 nm and may superimpose Cr^{VI} absorbance yielding the wrong interpretation of spectrophotometric absorbance decay values [23] . Thus considering the Cr^V absorption superimposition, the absorbance at 350 nm, at any time during the reaction, is given by:

$$Abs_{350} = \varepsilon^{VI}[Cr^{VI}] + \varepsilon^{V}[Cr^{V}]. \quad (1)$$

Combining Eq. (1) with rate expressions [24] derived from Scheme 2 yields:

$$S + Cr^{VI} \xrightarrow{k_6} I^o \xrightarrow{k_5} Cr^V \rightarrow Cr^{III}$$

$$+ \quad S$$

$$Cr^{III}$$

S= organic substrate I^o = intermediate

Scheme 2.

$$Abs_{350} = Abs_0\, e^{-2k_6 t} + k_6 \varepsilon^V [Cr^{VI}]_0 (e^{-k_5 t} - e^{-2k_6 t})/(2k_6 - k_5). \quad (2)$$

In this equation, ε^V refers to the molar absorptivity of Cr^V at 350 nm. Values of ε^V depend of pH and were assumed to be the same as for the complex $[Cr^V(O)(ehba)_2]^-$ [21] in the same [H^+] range (ε^V 900–1000 $M^{-1}\,cm^{-1}$). Parameters k_6 and k_5 refer to the rate of disappearance of Cr^{VI} and Cr^V, respectively, and were evaluated from a non-linear iterative computer fit of Eq. (2). It must be noted that in Eq. (2), k_6 appears in the numerator of the pre-exponential term and $2k_6$ appears in the denominator and in the exponential terms because, according to the proposed reaction scheme, only half of the Cr^{VI} reaches Cr^{III} throughout a Cr^V intermediate.

Unlike that observed for the chromic oxidation of D-gluconic acid [25], in the present case, Cr^V was not detected spectrophotometrically at 750 nm under conditions used in the EPR kinetic experiments. Fortunately, it could be easily detected by EPR measurements.

The reaction of D-Fru and Cr^{VI} was performed at [H^+] lower than used in the kinetic measurements in order to obtain information of the structure of Cr^V species formed as intermediates in the reduction of Cr^{VI} to Cr^{III}.

In 0.2 M $HClO_4$, the EPR spectra consist of the one signal at $g_{iso} = 1.9791$. At this [H^+], the superhyperfine (shf) pattern of the EPR signal (the ^1H shift splitting (a_H) for Cr^V-alcoholato species is usually < 1 G) could not be resolved.

When the pH > 1, the redox reaction becomes slow and Cr^V species remain in solution for a long time and the distribution and structure of these intermediates may be analyzed from the EPR spectral features.

In the 3–7 pH range and D-Fru:Cr^{VI} ratio 19/1 at 25 °C, the EPR spectrum is composed (signals were deconvoluted by fitting the spectra by lorentzian derivatives) of two triplet at $g_{iso1} = 1.9800$ ($a_H = 0.79 \times 10^{-4}\,cm^{-1}$), $g_{iso2} = 1.9797$ ($a_H = 0.71 \times 10^{-4}\,cm^{-1}$) and one doublet at $g_{iso3} = 1.9792$ ($a_H = 0.58 \times 10^{-4}\,cm^{-1}$), each with the four weak ^{53}Cr (9.55% abundance, $I = 3/2$) hyperfine peaks at 17.7 G spacing, typical of five-coordinate oxochromate (V) complexes (see Fig. 1) [26,27].

In order to rule out the possibility to assign one of the three Cr^V species to chelates formed with the oxidation products; a reaction of chromate with glutatione (1:1 ratio) in the presence of a 20 times excess of D-Fru was performed

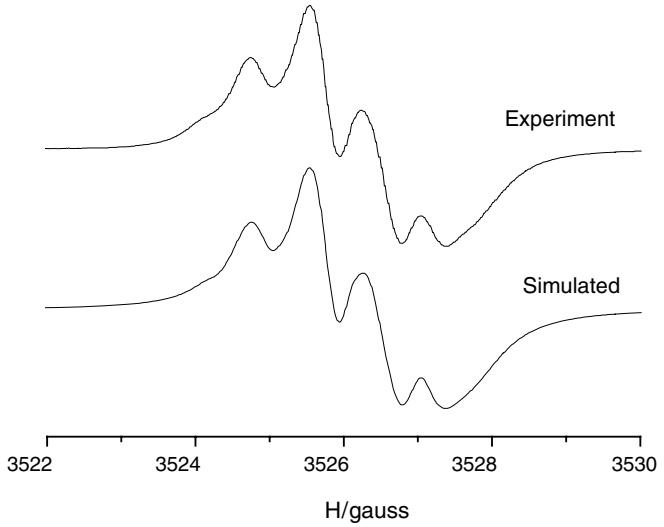

Fig. 1. Experimental and simulated X-band EPR spectra of mixtures of $[Cr^{VI}] = 0.015$ M, [D-Fru] = 0.28 M, $T = 24$ °C, $I = 1$ M, pH 5, $t = 24$ h, frequency ≈ 9.7 GHz, mod. amp. = 0.4 G.

and afforded Cr^{V} EPR spectra identical to those obtained by direct reaction of D-Fru with Cr^{VI}.

The different shf coupling constants of the two triplets indicate that they may correspond to the two geometric isomers of the Cr^{V} bischelate ($[Cr(O)(O^{2(4)}, O^{3(5)}$-β-D-fructopyranose$)_2]^-$).

The doublet at g_{iso3} indicates that, in this oxo-Cr^{V}-D-Fru species, only one carbinolic proton is coupled to the electronic spin and can be assigned to the Cr^{V} bischelate $[Cr(O)(O^{ring},O_2$-β-D-fructofuranose$)$ $(O^{2(4)},O^{3(5)}$-β-D-fructopyranose$)]^-$ with one D-Fru molecule acting as bidentate through the α-hydroxodiolate moiety of the piranosic form and the second D-Fru molecule bound to Cr^{V} at the α-hydroxodiolate group, and the ring oxygen atom of the furanosic form (see Scheme 3).

Fig. 2 shows a curve for peak-to-peak heights of Cr^{V} EPR signals versus time obtained on a reacting solution. Values of the rates of disappearance of Cr^{VI} (k_6) and Cr^{V} (k_5), respectively, may be calculated by Eq. (3) [25,28] which fits well the experimentally observed Cr^{V} intermediate growth and decay curve in Fig. 2

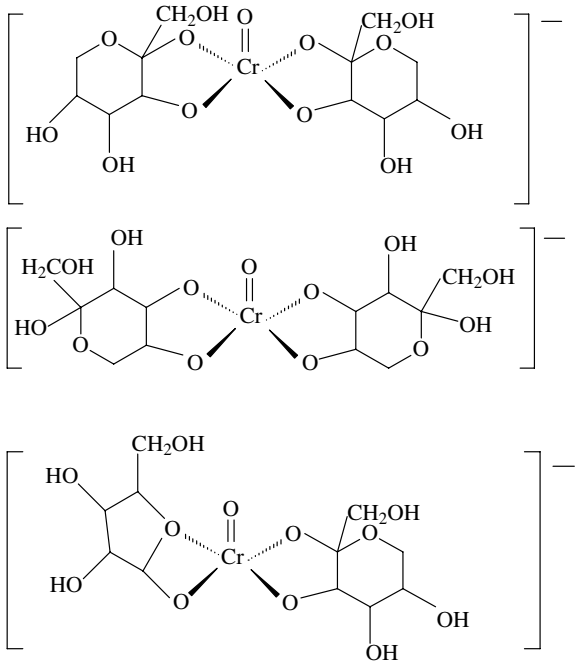
$$h = Ak_6\{\exp(-k_5t) - \exp(-2k_6t)\}/(2k_6 - k_5). \quad (3)$$

In Eq. (3), h is the peak-to-peak height and A depends on the spectrometer settings and is adjusted by the fitting program [29].

For conditions stated in Fig. 2, the values of k_6 and k_5 were: $k_6 = 1.4 \times 10^{-4}$ s^{-1}, $k_5 = 1.37 \times 10^{-3}$ s^{-1} and the time of maximum Cr^{V} concentration, $T_{max} \approx 17$ min.

To verity if this assignment of the rate constant values was correct, k_{obs} ($2k_6$) was evaluated spectrophotometrically at 25 °C under conditions used in the EPR experiments and the k_{obs} ($2k_6$) value was reproduced.

For several runs at different D-fructose/chromium(VI) ratios, k_5 values were at least six times larger than k_6 values [27].



Scheme 3.

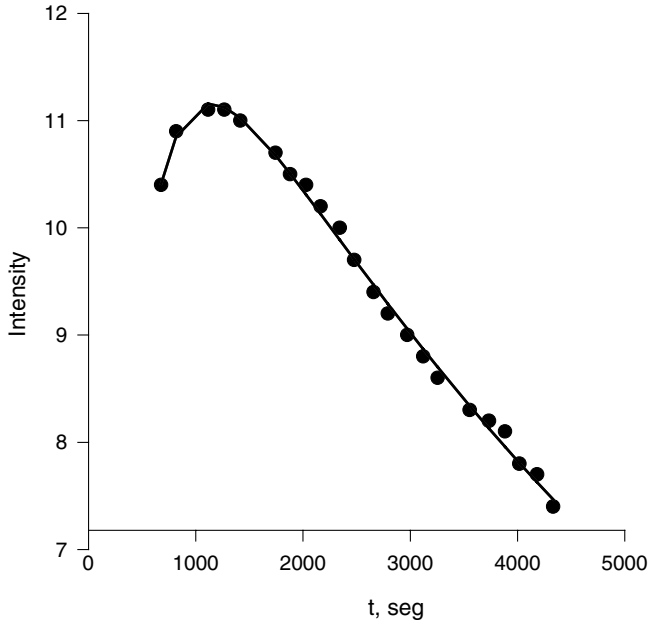


Fig. 2. Peak-to-peak heights of Cr^{V} EPR signals vs. time. $[Cr^{VI}] = 0.44$ M, [D-Fru] = 0.83 M, $[HClO_4] = 0.2$ M, $T = 24$ °C, $I = 1$ M.

The reactions were carried out at various fixed [oxidant] keeping other variables, viz. [D-Fru], $[H^+]$, I and temperature constant. Pseudo-first-order rate constants obtained from Eq. (2) ($2k_6$) were coincident with values obtained from the slope of the linear part of the ln absorbance versus time curves, therefore, most of the k_{obs} were calculated through the last approach.

The independence of k_{obs} over a range of $[Cr^{VI}]_0$ (Table 1) was in agreement with a first-order dependence on $[Cr^{VI}]_T$. The rate law was, therefore, given as:

Table 1
Observed first-order rate constant for different $[Cr^{VI}]_0$, [D-Fru] = 0.025 M, $[H^+]$ = 1 M, I = 1 M, T = 33 °C, λ = 350 nm

$10^4[Cr^{VI}]_0$ (M)	4.0	5.0	6.0	7.0	8.0	10.0
$10^4\ k_{obs}$ (s^{-1})	4.50 ± 0.01	4.90 ± 0.01	5.20 ± 0.01	5.10 ± 0.01	5.20 ± 0.01	5.00 ± 0.02

$$-d[Cr^{VI}]/dt = k_{obs}[Cr^{VI}].$$

The observed rate constants were calculated from the absorbance data obtained at 350 nm.

The first-order-dependence of the rate upon $[Cr^{VI}]$ was verified, and k_{obs} was obtained following the Cr^{III} growth at 570 nm. Initial reaction rates were obtained by fitting the absorbance at 570 nm/time data to a polynomial expression [30] and calculating the slope of the tangent at time zero (r_i). First-order rate constants were obtained from these initial rates by means of the equation $-r_i/(A_0 - A_t)$ and were coincident with those obtained at 350 nm.

This is consistent with the observation of the isosbestic point at 527 nm (Fig. 3). At the end of the reaction, the two d–d bands ascribed to Cr^{III} were observed at $\lambda_{max} = 411$ nm ($\varepsilon = 17.5\ mol^{-1}\ cm^{-1}$) and $\lambda_{max} = 570$ nm ($\varepsilon = 15.2\ mol^{-1}\ cm^{-1}$). We found no shift toward shorter wavelength with those observed to the $^4A_{2g} \rightarrow {}^4T_{1g}$ and $^4A_{2g} \rightarrow {}^4T_{2g}$ transitions of $[Cr(OH_2)_6]^{3+}$ ion [31] at the same $[H^+]$.

Thus, it was confirmed that chromium(III) aqua ion was the product under the present experimental conditions.

Table 2 summarizes values of k_{obs} for various concentrations of D-Fru at fixed concentrations of perchloric acids. Plots of k_{obs} versus [D-Fru] (Fig. 4) gave good straight lines with a positive intercept from which values of k_1 and k_2 were determined (Table 3).

Dependence of k_1 and k_2 with $[HClO_4]$ are shown in Figs. 5 and 6 and may be expressed by the following equation:

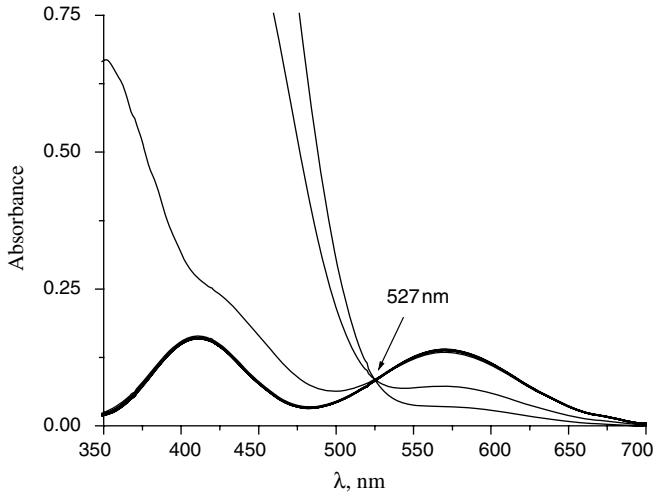

Fig. 3. Time evolution of the UV/Vis spectrum of a mixture of $[Cr^{VI}] = 9.00 \times 10^{-3}$ M, [D-Fru] = 0.20 M, $[HClO_4]$ = 1.00 M, T = 33 °C, I = 1 M over a period of ca. 240 min.

$$k_{obs} = k_1 + k_2\ [S],$$
$$k_1 = a\ [H^+]^2, \quad (4)$$
$$k_2 = b\ [H^+]^2,$$

where $a = 1.66 \times 10^{-4} \pm 3.56 \times 10^{-6}\ M^{-2}\ s^{-1}$ and $b = 1.79 \times 10^{-2} \pm 5.63 \times 10^{-4}\ M^{-3}\ s^{-1}$.

The complete rate law is then given by:

$$-d[Cr^{VI}]/dt = (a + b[\text{D-Fru}])[H^+]^2[Cr^{VI}]_T, \quad (5)$$

where $[Cr^{VI}]_T$ represents the total chromium(VI) concentration.

The oxidation of D-Fru by Cr^{VI} should occur through two parallel slow steps leading to the redox products.

3.2. Detection of the intermediate Cr^{VI} ester

Differential UV–Vis spectra obtained within 5 min after mixing revealed a distinctive absorption at 374 nm (Fig. 7) consistent with that ascribed to Cr^{VI}-oxy-esters [32,33]. Fig. 7 showed that the absorbance at 374 nm increased with increasing the concentration of D-Fru, probably as a result of a shift toward the ester in the esterification equilibrium.

The formation of Cr^{IV} is consistent with the observation of CrO_2^{2+}, the product of the reaction of Cr^{II} with O_2, which is taken as an indirect evidence of Cr^{IV} formation [34].

The band at 350 nm decreased in intensity over a period of 4 h, while new peaks at 293 and 248 nm grew in and then decreased (Fig. 8). The observed peaks were those of CrO_2^{2+}[35], formed as a long-lived intermediate. The CrO_2^{2+} absorbance at 249 nm ($Abs_{249}(CrO_2^{2+})$) was estimated by subtracting the $Abs_{249}(Cr^{VI})$ – the contribution of Cr^{VI} species to the absorbance at 249 nm, which concentrations could be calculated at 350 nm – from the total Abs_{249}, and the rate constant for the formation of $Abs_{249}(CrO_2^{2+})$ versus time curve (inset in Fig. 8).

Under all experimental conditions (large to moderate excess of D-ketose over Cr^{VI}), CO_2 was never observed as a reaction product, but the presence of HCOOH acid was detected through the $HgCl_2$ reaction [36], indicating that degradation to the lower homologues occurred. Formic acid was also detected by HPLC.

A reaction mixture obtained from 9.6×10^{-3} M Cr^{VI} and 0.24 M ketose in 0.2 M $HClO_4$ acid was submitted to HPLC: two products appearing at t_r 13.32 and 17.01 min were detected besides the peak corresponding to the starting D-Fru at t_r = 15.52 min. The retention time of the reaction products was coincident with of the standard solution of D-arabinonic acid and formic acid, respectively. The

Table 2
Observed pseudo-first-order rate constant for different concentrations of $HClO_4$ and D-Fru. $T = 33$ °C; $[Cr^{VI}]_0 = 8.00 \times 10^{-4}$ M, $I = 1$ M

[S] (M)	$[HClO_4] = 0.10$ M $10^6 k_{obs}$ (s^{-1})	$[HClO_4] = 0.20$ M $10^5 k_{obs}$ (s^{-1})	$[HClO_4] = 0.50$ M $10^5 k_{obs}$ (s^{-1})	$[HClO_4] = 0.75$ M $10^4 k_{obs}$ (s^{-1})	$[HClO_4] = 1.00$ M $10^4 k_{obs}$ (s^{-1})
0.02	9.00 ± 0.01	3.00 ± 0.01	14.50 ± 0.0	2.55 ± 0.01	4.30 ± 0.01

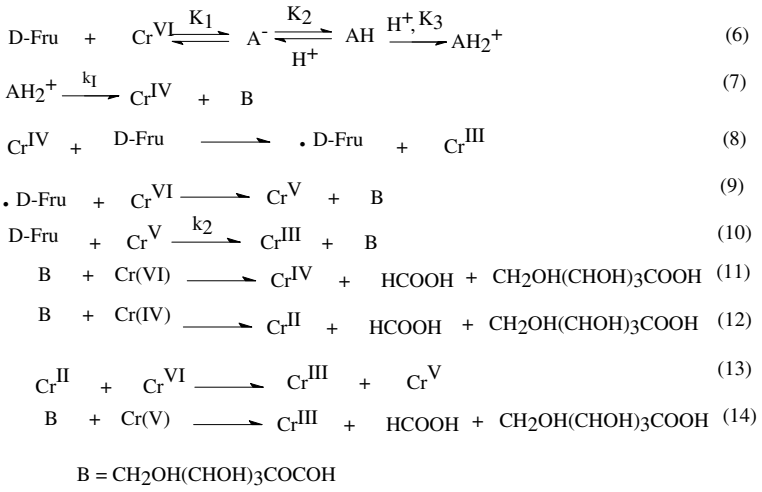
0.10	40.00 ± 0.06	12.50 ± 0.06	58.50 ± 0.10	10.40 ± 0.02	18.50 ± 0.05



Scheme 4.

presence of D-arabinonic acid as the reaction product was further confirmed by paper chromatography using BuOH/AcOH/H_2O (4:1:5) as eluent. Paper chromatogram was visualized by two kinds of development reagents: a three stage dip of silver nitrate, sodium hydroxide and sodium thiosulfate [37] an *p*-anisidine reagent [38].

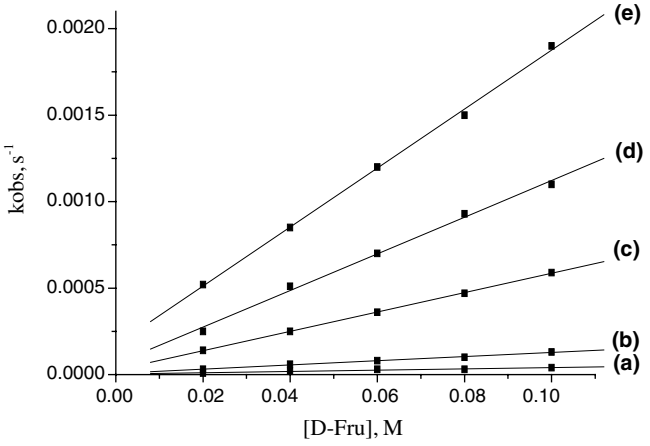


Fig. 4. Effect of [D-Fru] on k_{obs} at 33 °C, $I = 1$ M and [$HClO_4$] (M) = (a) 0.10 M, (b) 0.20 M, (c) 0.50 M, (d) 0.75 M and (e) 1.00 M.

In Scheme 4, a complex multistep mechanism that takes into account all the previous results detailed above (a) kinetic results, (b) polymerization of acrylonitrile added to the reaction mixture, (c) detection of an intermediate Cr^{VI} ester and oxocromate(V) species, (d) observation of CrO_2^{2+} and (e) identification of oxidation and reduction products is being proposed.

According to the above mechanism, the full rate law for the oxidation of D-Fru by Cr(VI), under the kinetic measurements, can be written as:

$$-d[Cr^{VI}]/Dt = (k_I + k_{II}[D\text{-Fru}])K_1K_2K_3[D\text{-Fru}] \times [H^+]^2\,[Cr^{VI}]. \quad (15)$$

Since

$$[Cr^{VI}]_T = [Cr^{VI}](1 + K_1[D\text{-Fru}] + K_1K_2[D\text{-Fru}][H^+] + K_1K_2K_3[D\text{-Fru}][H^+]^2). \quad (16)$$

Table 3
Values of k_1 and k_2 for different [$HClO_4$]

[$HClO_4$] (M)	0.100	0.200	0.500	0.750	1.000
$10^4 k_1$ (s^{-1})	0.024 ± 0.005	0.067 ± 0.009	0.40 ± 0.05	0.90 ± 0.09	1.7 ± 0.3
$10^4 k_2$ (M^{-1} s^{-1})	3.7 ± 0.4	11.0 ± 0.5	55.0 ± 0.7	106.2 ± 4.0	174.0 ± 4.0

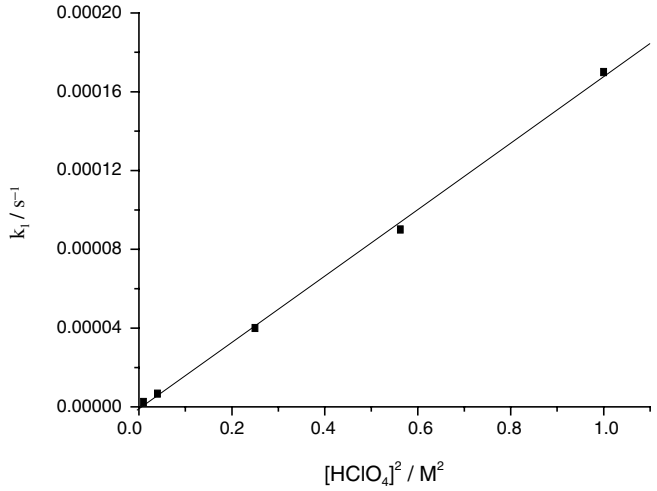

Fig. 5. Effect of acidity on k_1.

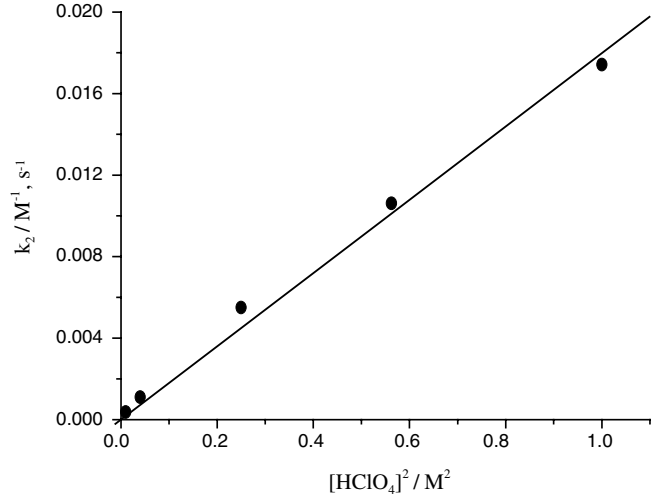

Fig. 6. Effect of acidity on k_2.

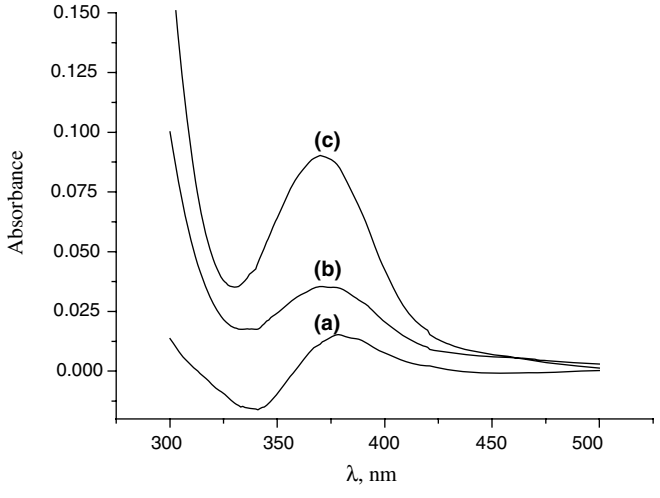

Fig. 7. UV–Vis difference spectra of Cr^{VI}/D-Fru solutions at pH 4.00, showing the increasing band at 374 nm with increasing [D-Fru] = (a) 0.06 M, (b) 0.18 M, (c) = 0.33 M; $[Cr^{VI}] = 6.00 \times 10^{-4}$ M, $T = 33$ °C, $I = 1$ M. Spectra taken after 5 min.

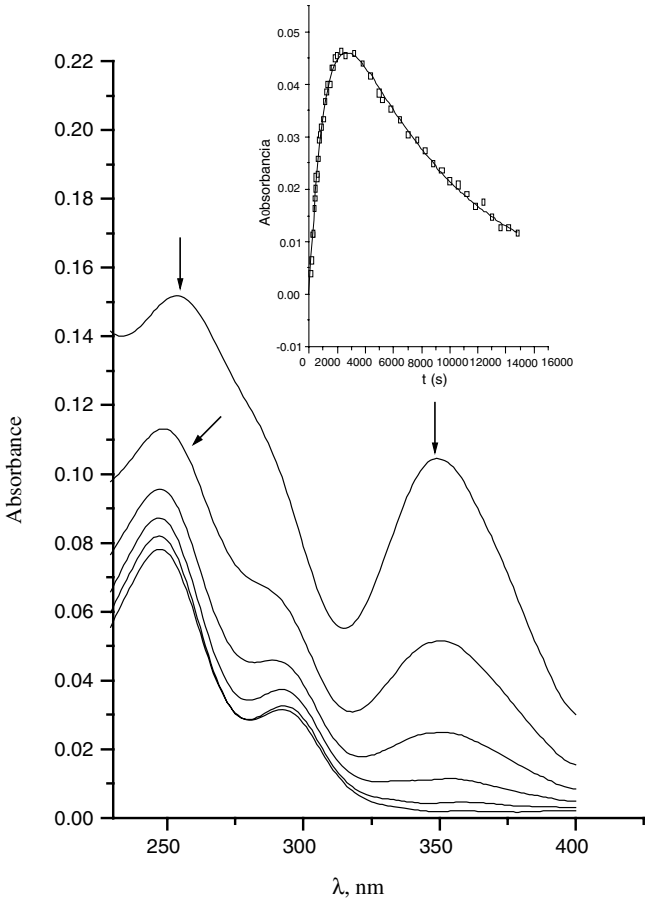

Fig. 8. Formation of CrO_2^{2+} ($\lambda_{max} = 293, 248$ nm) from the reaction between 0.125 M D-Fru, 1.26 mM O_2 and 4.5×10^{-2} mM Cr^{VI} in 1 M $HClO_4$. Inset: Experimental (□) and simulated (—) curves for the variation of the CrO_2^{2+} absorbance with time.

Replacing $[Cr^{VI}]$ in Eq. (15)

$$-\mathrm{d}[Cr^{VI}]/\mathrm{d}t = \frac{(k_I + k_{II}[\text{D-Fru}])K_1K_2K_3[\text{D-Fru}][H^+]^2[Cr^{VI}]_T}{1 + K_1[\text{D-Fru}] + K_1K_2[\text{D-Fru}][H^+] + K_1K_2K_3[\text{D-Fru}][H^+]^2}. \quad (17)$$

Thus, if K_1 [D-Fru] is the largest term in the denominator, Eq. (17) will be simplified to the experimentally observed form (see Eq. (5)).

Since

$$a = k_I K_2 K_3,$$
$$b = k_{II} K_2 K_3.$$

In this mechanism, we have assumed that the β-D-fructopyranose form is the reactive form of the organic substrate because this form is the most plentiful in aqueous solutions, with the two furanose forms also being present in quantifiable amounts. The remaining two tautomers are present only in trace amounts [39]. This assumption is based on the detection of HCOOH and D-arabinonic acid in the reaction mixture, which implies that the chromic ester is produced between the hemiacetal hydroxyl group

and the hydroxyl in *cis* position as has been observed for chromic oxidation of D-aldoses [40] with the concomitant C_1–C_2 breaking bond. In any case, a possible mechanism involving the open chain or the furanose forms may not be discarded.

Acknowledgments

We thank the National Research Council of Argentina (CONICET), the Third World Academy of Sciences (TWAS), the National University of Rosario (UNR), the International Foundation for Science (IFS), the National Agency for Science Promotion, the ALFA Program (CRO-CON Network, Project 7-0064-9), ANTORCHAS Foundation for financial support, the SEPCYT- Hungarian conmimment Grant HU/A98-EVI/07. Our thank is extensively to Dr. Sandra Signorella for revising the present manuscrit and to Miss Ana Tioni for helpful technical assistance.

2. Experimental

2.1. Chemicals and reagents

The metal salts were obtained from Aldrich and used as received. All other chemicals were procured from S.D. Fine Chemicals, India. The solvents were purified prior to use by standard procedure. All hydrothermal syntheses were performed at 180 °C for 48 h in Teflon-lined stainless steel autoclaves under autogenous pressure.

2.1.1. Synthesis of the ligand $ptaH_3$

The synthesis and characterization of the podand was achieved as described earlier [12].

2.1.2. $\{[La(ptaH)(NO_3)]\cdot 4H_2O\}_n$ (**1**)

A mixture of the tripodal ligand $ptaH_3$ (0.13 g; 0.25 mmol) and $La(NO_3)_3\cdot 6H_2O$ (0.16 g; 0.37 mmol) taken in 4 ml of water, was placed in a Teflon-lined stainless steel autoclave. The vessel was sealed and heated to 180 °C for 48 h and then cooled to room temperature at a rate of 1 °C per min. Colorless rectangular parallelepiped crystals were collected in ~50% yield from the reaction mixture. *Anal.* Calc. for $C_{27}H_{33}N_2O_{16}La$: C, 41.55; H, 4.26; N, 3.59. Found: C, 41.44; H, 4.47; N, 3.49%.

Crystals of **1** were heated in an oven for 3 h at 150 °C to obtain **1′**.

2.1.3. $\{[Pr(ptaH)(NO_3)]\cdot 3H_2O\}_n$ (**2**)

Compound **2** was prepared following a similar procedure as above, by treating $ptaH_3$ with $Pr(NO_3)_3\cdot 6H_2O$ in 1:1.5 molar ratio. Faintly purple crystals in the form of rectangular parallelepiped were collected from the reaction mixture in ~45% yield. *Anal.* Calc. for $C_{27}H_{31}N_2O_{15}Pr$: C, 42.42; H, 4.08; N, 3.66. Found: C, 42.33; H, 4.16; N, 3.39%.

2.1.4. $\{[Ce(ptaH)(NO_3)]\cdot 3H_2O\}_n$ (**3**)

This was synthesized as above treating $ptaH_3$ with $Ce(NO_3)_3\cdot 6H_2O$ in 1:1.5 molar ratio. Colorless rectangular crystals were isolated from the reaction mixture in

~39% yield. *Anal.* Calc. for $C_{27}H_{31}N_2O_{15}Ce$: C, 42.46; H, 4.09; N, 3.66. Found: C, 42.31; H, 4.14; N, 3.78%.

2.2. Physical measurements

Spectroscopic data were collected as follows: IR (KBr disk, 400–4000 cm^{-1}) Perkin–Elmer Model 1320; X-ray powder pattern (CuK_α radiation at a scan rate of 3°/min, 293 K) Siefert ISODEBYEFLEX-2002 X-ray generator; thermogravimetric analysis (heating rate of 5 °C/min) Perkin–Elmer Pyris 6. Microanalyses for the compounds were obtained from the Central Drug Research Institute, Lucknow, India.

2.3. X-ray crystallography

Single crystal X-ray data at 100 K were collected on a Bruker SMART APEX CCD diffractometer using graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). Data reduction, structure solution and structure refinement were carried out as described earlier [12]. The crystal and refinement data are collected in Table 1 while selected bond distances and angles are given in Table 2. The H-bonding distances and angles pertaining to the water clusters are listed in Table 3.

3. Results and discussion

All the compounds are stable in air and insoluble in common organic solvents. Each shows strong infrared absorption bands between 1350 and 1550 cm^{-1} that are diagnostic [13] of coordinated carboxylates.

The structure (Fig. 1) of **1** consists of La(III) ions, partially deprotonated $ptaH^{2-}$ ligand, nitrate anions and water molecules. Each metal is bonded to four carboxylates from four different ligand units. One carboxylate donates both its O atoms, two carboxylates donate one O atom each (the other O atom in each case is

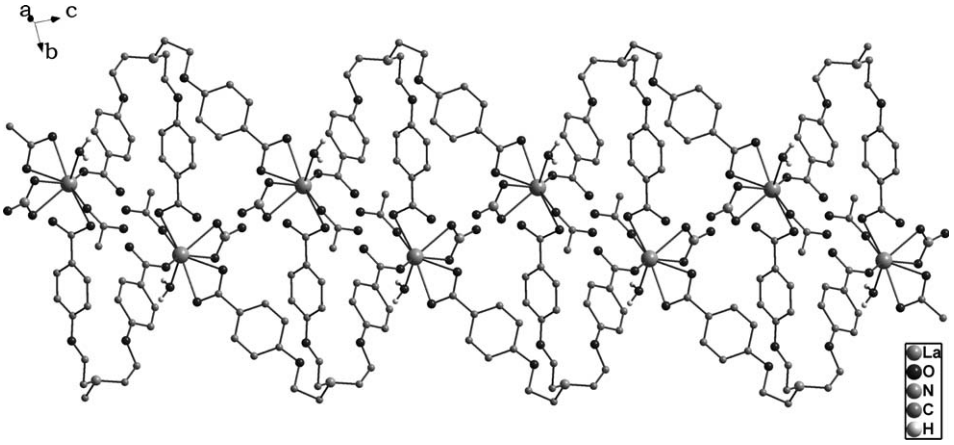

Fig. 1. A perspective view of the metallomacrocycle in **1**. For clarity, only metal bound water H atoms are shown.

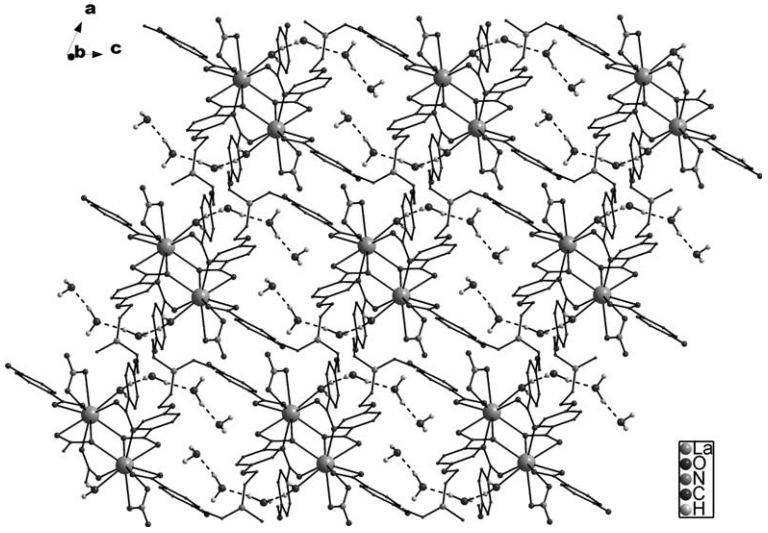

Fig. 2. A view showing water tetramers occupying the voids of the interlinked metallocycles along crystallographic *c*-axis in **1**.

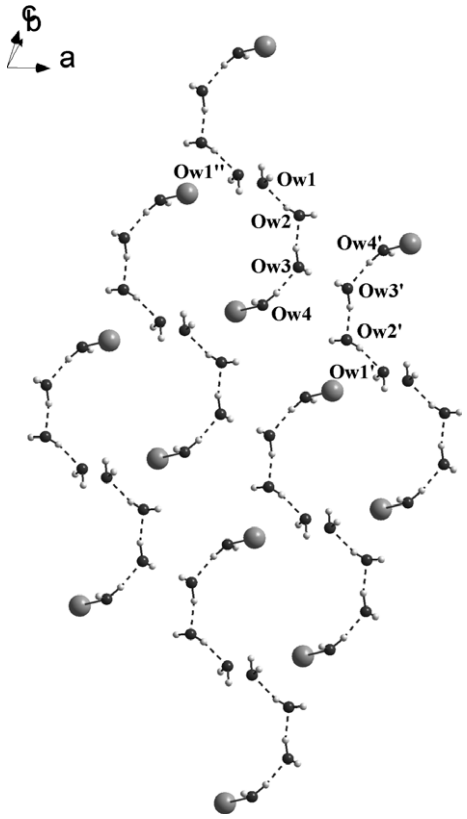

Fig. 3. A close view of the water tetramer present in **1** showing the atom numbering scheme.

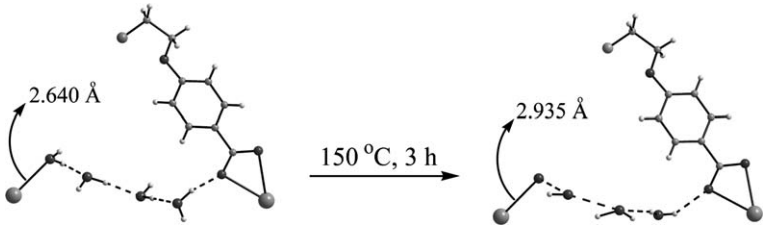
donated to a different La(III)) while the fourth carboxylate is protonated and donates a single O atom. Each metal ion is also bound to two O atoms of the nitrate anion and one water molecule (Ow4) showing eight coordination. The overall structure looks like (Fig. 1) an array of metallocycles joined via the bridgehead N atom of the podand extending along the crystallographic *c*-axis. In the metallocyclic units, the two La(III) ions show a distance of either 9.24 or 10.78 Å while the distance between the bridgehead N atoms is 17.42 Å forming an oval-shaped cavity. The bond distances and bond angles involving the metal ions (Table 2) are within normal [10,12] statistical errors.

An interesting feature of **1** is that the La(III)-bound water (Ow4) is H-bonded to three more water molecules forming an acyclic tetramer (Fig. 2). These tetramers extend to the middle of the void spaces of the metallocycles. The four water O atoms in the cluster are coplanar to within ±0.03 Å. Both theoretical and experimental studies of tetrameric water clusters indicated [14–17] a quasi-planar cyclic minimum energy structure with an S_4 symmetry where each water molecule forms two hydrogen bonds. Thus, the existence of high energy acyclic tetramer in **1** is a consequence of the MOF structure which does not have enough room to accommodate a cyclic structure. The average O···O distance in the cyclic structure was estimated to be 2.79 Å in the gas phase while those found in crystal lattices [16,17] show a wide ranging O···O distances (2.77–3.00 Å). In **1**, the water molecules are quite strongly bonded to each other as evident from the O···O distances (range 2.681(4)–2.789(6) Å) and O···H–O angles (range 166.24(3)–169.44(4)°). The atom Ow1 is close to Ow1″ (2.923(4) Å) although the positions of hydrogen atoms are such that Ow1 is not hydrogen-bonded to Ow1″ (Fig. 3). Instead, Ow1 is hydrogen-bonded to a nearby carboxylate O atom. Other water molecules of the cluster act as H-bond donors to available carboxylate O or nitrate anions with an O···O distance in the range 2.714–2.861 Å further reinforcing the structure.

The robustness of the framework is reflected in the thermogravimetric analysis of **1** which shows negligible weight loss till about 150 °C and the loss of 9.3% corresponding to all of the water (calculated 9.22%) takes place above 260 °C. However, complete breakdown of the complex takes place at ~270 °C. The macroscopic crystal shape and color of **1** remain unchanged after heating the crystals at 150 ± 1 °C for 3 h at atmospheric pressure. A new X-ray data are collected every hour after the heat treatment. The X-ray crystal structure of **1**′ reveal that the porous framework is retained with slight changes in La(III)-carboxylate bonding (Table 2). However, the metal-bound water tetramer slowly moves away from the metal (Scheme 2) showing La–Ow4 bond distance of 2.935(13) Å from the original 2.640(6) Å. This experiment shows that each La(III) ion is strongly bonded to the carboxylate. Also, supramolecular interactions between the water molecules and between the water molecules and the MOF are strong enough to resist escape of water. To the best of our knowledge, it is the first example where the movement of a water cluster is monitored after applying heat and the passage of time in the crystalline state.



Scheme 2. A shematic view illustrating the movement of metal bound water cluster away from the La(III) atom upon heating in **1**.

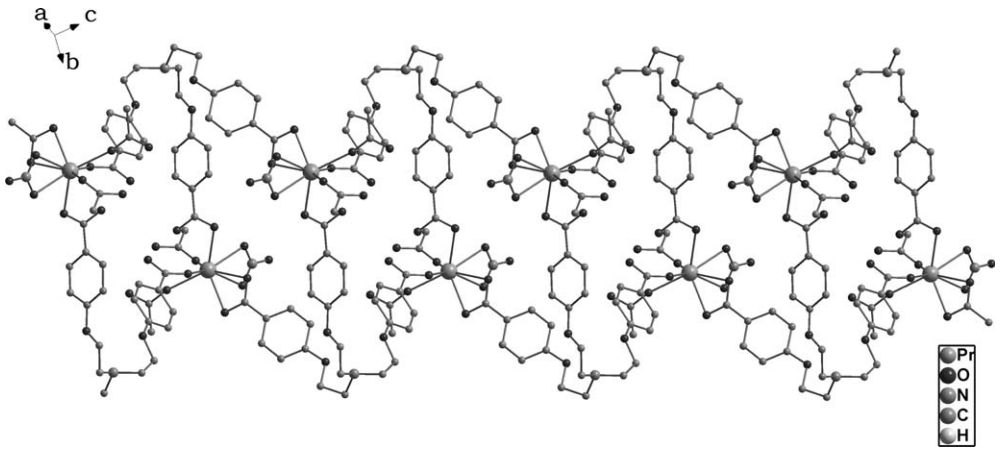


Fig. 4. A perspective view of the metallomacrocycle in **2**. All H atoms are omitted for clarity.

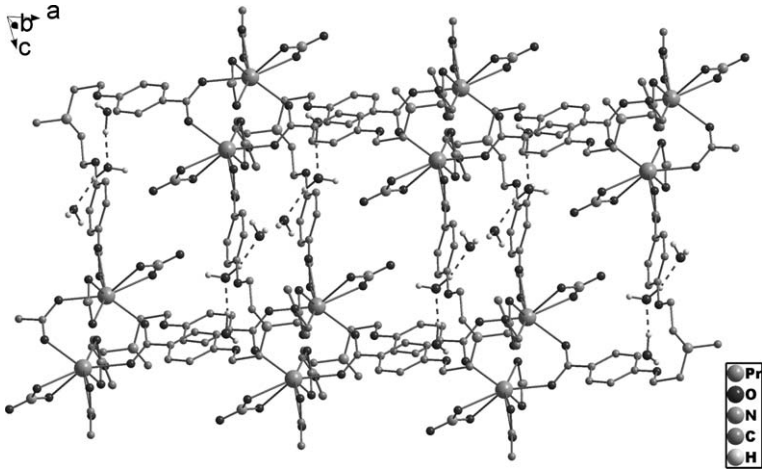

Fig. 5. View of the metal-organic framework structure along *a* crystallographic axis in **2** containing water trimer in the metallocyclic cavity.

As **2** and **3** have the identical structure, the structure of **2** is only described here. The structure consists of a partially deprotonated $ptaH^{2-}$ ligand, nitrate anion, one Pr(III) ion and three water molecules in the asymmetric unit. Each metal is bonded to five carboxylates from five different ligand units (Fig. 4) where one carboxylate donates both its O atoms, three carboxylates donate one O atom each (the other O atom in each case is donated to a different Pr(III)) while the fifth carboxylate is protonated and donates a single O atom. Each metal ion is also bonded to two O atoms of a nitrate anion assuming overall eight coordination. The bridging carboxylates propagate the MOF as an array of metallocycles extending along the crystallographic *c*-axis. In the metallocycles, the two Pr(III) ions show a distance of either 9.43 or 10.03 Å while the distance between the bridgehead N atoms is 17.58 Å. The bond distances and angles involving the metal ion (Table 2) are similar to the ones found in the carboxylate complexes of the metals [10,12]. The three water molecules form a bent $(H_2O)_3$ cluster (Fig. 5) occupying the voids in the metallocycles. Theoretical studies [18] on water trimers predicted the existence of several cyclic and two acyclic structures. However, to the best of our knowledge, only one acyclic water trimer has been found [19,20] in a crystal host till date. The water molecules in **2** are quite strongly bonded to each other (Table 3) as evident from the O···O distances (range 2.719–2.773 Å) and O···H–O angles (range 151.60–163.92°). These water molecules act as H-bond donors to the available carboxylate or nitrate O atoms with the O···O distances in the range 2.816–2.884 Å maintaining strong water–MOF interactions.

Thermogravimetric analyses show that in **2** or **3**, weight-loss occurs in stages beginning above 70 °C and the loss of 7.1% corresponding to all of the water (calculated 7.07%) takes place above 250 °C. The FTIR spectra of **1**–**3** show a broad band centered around 3420 cm^{-1} attributable [13] to the O–H stretching frequency pertaining to the water cluster. This broad band significantly reduces on heating the compounds under vacuum (0.1 mm) at 260 °C for 3 h suggesting escape

of the water molecules from the lattice. The IR spectrum of ice shows the O–H stretching at 3220 cm^{-1} while this stretching vibration in liquid water [21] appears at 3490 and 3280 cm^{-1}. Thus, the water clusters in **1**, **2** and **3** shows O–H stretching vibration similar to that of liquid water. Once water is expelled from the lattice by heating, no re-absorption is observed upon deliberate exposure to water vapor for 3 days as monitored by FTIR spectroscopy. Powder X-ray diffraction patterns corroborate the thermal behavior of **1**, **2** and **3** showing major changes in peak positions as well as their intensities before and after water expulsion.

4. Conclusion

In conclusion, we have characterized La(III)-bound acyclic water tetramer in **1** and bent acyclic water trimer in **2** and **3** in the porous coordination polymers of lanthanide ions with the podand. The water clusters gains stability from strong hydrogen-bonding interactions with the available carboxylate O atoms as well with metal bound nitrate anion. The metal bound water cluster in **1** slowly moves away upon heating. The MOFs are quite robust and maintain their crystallinity on heating at ~150 °C in normal atmosphere up to 4 h. We are presently engaged in building porous framework structures using this ligand with different metal ions including lanthanides with guests other than water.

Acknowledgments

We gratefully acknowledge the financial support received from the Department of Science and Technology, New Delhi, India (to P.K.B.) and a SRF (from the CSIR) to S.N. We thank Prof. V. Chandrasekhar for the TGA data.

Appendix A. Supplementary data

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. for **1**, **1′**, **2** and **3** are 238353, 247658, 273126 and 273127, respectively. These data can be obtained online free of charge via www.ccdc.cam.ac.uk/conts/retrieving.html (or from Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB21EZ, UK, fax: +44 1223 336 033; or e-mail: deposit@ccdc.cam.ac.uk). IR, TGA, and X-ray powder diffraction patterns of complexes **1**–**3**. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2005.08.003.

in which $[Mn(\eta^5\text{-}C_5H_5)_2]$ was reacted with carbon monoxide at elevated temperatures and pressures [4,8]. Reactions analogous to those used for the preparations of $[Mn(\eta^5\text{-}C_5Me_5)(CO)_3]$ and $[Mn(\eta^5\text{-}C_5Bz_5)(CO)_3]$ were also not suitable due to the very low solubility of C_5Ph_5H [9–12]. For instance, the purple radical, $C_5Ph_5^{\bullet}$, generated from the mixture of C_5Ph_5Br, zinc dust and $Mn_2(CO)_{10}$ in refluxing tetrahydrofuran, was not sufficiently reactive to cleave the Mn–Mn bond even though the reaction was continued for four days. In most reactions involving $Mn_2(CO)_{10}$ as a precursor, metal–metal bond cleavage has been shown to be the initial step [13]. $[Mn(CO)_3Br]$, $[Mn(CO)_3(CH_3CN)_3]Br$ and $[Mn(CO)_3(CH_3CN)_2Br]$ are readily prepared and are the most commonly used precursors for substitution reactions as a consequence of the lability of the CH_3CN and Br^- ligands.

Both (**1**) and (**3**) are air stable in solid and in solution. Their inertness parallels that of other substituted cyclopentadienyl complexes. The kinetic inertness of $[Mn(\eta^5\text{-}C_5RH_4)(CO)_3]$ (R = H, Me) is well known; no carbonyl exchange with ^{14}CO occurs in toluene at 32 °C over several weeks, no reaction occurs between PPh_3 and $[Mn(\eta^5\text{-}C_5H_5)(CO)_3]$ even in refluxing decalin and substitution of CO is only possible either by ultraviolet irradiation or by using Me_3NO to actively remove CO [13].

Similarly, $[Mn(\eta^5\text{-}C_5Me_5)(CO)_3]$ undergoes monosubstitution either under ultraviolet irradiation or by oxidative substitution [12,14]. There are many reports of cyclopentadienyl manganese derivatives with one or more ligands substituted for CO [13,15]. Recently, a study on the monosubstitution of $[Mn(\eta^5\text{-}C_5R_5)(CO)_3]$ (R = H, Me or Et) in *n*-heptane solution under ultraviolet irradiation showed that the bulkier ligand, C_5Et_5, better stabilised the formation of the solvated intermediate, $[Mn(\eta^5\text{-}C_5R_5)(CO)_2(n\text{-heptane})]$ than did the other two ligands [16]. Substitution of one CO in $[Mn(\eta^5\text{-}C_5Ph_5)(CO)_3]$ (**1**) by PMe_2Ph was readily achieved by refluxing a THF solution in the presence of Me_3NO to give $[Mn(\eta^5\text{-}C_5Ph_5)(CO)_2(PMe_2Ph)]$ (**2**). Using an analogous procedure, it was possible to introduce a range of other substituents (including phosphines and isonitriles).

$[Mn(\eta^5\text{-}C_5Ph_5)(CO)_3]$ (**1**) is not oxidised by reactants such as Br_2, I_2 or $NOBF_4$, even in the presence of CH_3CN. Recently, it has been found that monosubstitution of a carbonyl ligand proceeded smoothly when $[Ru(\eta^5\text{-}C_5Ph_5)(CO)_2Br]$ or $[Os(\eta^5\text{-}C_5Ph_5)(CO)_2Br]$ were reacted with other ligands in the presence of Me_3NO [17,18].

However, compounds (**1**) and (**3**) each undergo a reversible, one-electron cyclic voltametric oxidation in CH_2Cl_2 at 0.98 V for (**1**) and 0.89 V for (**3**) (both versus $Fc^{+/0}$).

$$[Mn(\eta^5\text{-}C_5Ar_5)(CO)_3] \rightleftharpoons [Mn(\eta^5\text{-}C_5Ar_5)(CO)_3]^+ + e^-$$

The reversibility of these oxidations confirms that complexes of the penta-*p*-tolylcyclopentadienyl ligand, $C_5(p\text{-tol})_5^-$, are easier to oxidise than are those of the $C_5Ph_5^-$ ligand. These oxidation potentials are much higher than that for $[Mn(\eta^5\text{-}C_5H_5)(CO)_3]$ which undergoes a reversible oxidation at ca. 0.29 V [19]. In general, the value of the redox couple for a pentaphenylcyclopentadienyl complex is shifted 0.25–0.30 V more positively than that of its cyclopentadienyl analogue [20,21].

In addition, $[Mn(\eta^5\text{-}C_5H_5)(CO)_3]$ exhibits a second irreversible oxidation at 1.48 V detected in CF_3CO_2H at a platinum electrode [19], an electrochemically reversible reduction, coupled to a follow-up chemical reaction at −2.46 V [22] and a second irreversible reduction at −3.32 V observed in tetrahydrofuran at a platinum electrode [23]. The first reduction has been shown by preparative electrolysis to generate red $[Mn(\eta^5\text{-}C_5H_5)(CO)_3]^-$. However, chemical reduction of $[Mn(\eta^5\text{-}C_5H_5)(CO)_3]$ in HMPA yields predominantly first $[Mn(CO)_5]^-$ and then $[Mn(CO)_4]^{3-}$ by poorly defined ligand redistribution reactions [24]. We have observed no additional oxidations, nor corresponding reductions of $[Mn(\eta^5\text{-}C_5Ar_5)(CO)_3]$.

Table 1
Selected average interatomic distances and angles in $[Mn(\eta^5\text{-}C_5Ph_5)(CO)_3]$ (**1**)

Atoms	Average dimension
Mn–C (C_5)	2.16(1) Å
Mn–CO	1.78(1) Å
C–O	1.17(1) Å
C–C (C_5 ring)	1.42(2) Å
C(C_5)–*ipso*-C (C_6)	1.50(2) Å
CO–Mn–CO	90.3(5)°
Mn–C–O	175(1)°
C–C–C (C_5 ring)	107.7(1)°

2.1. Crystal structure determinations

2.1.1. $[Mn(\eta^5\text{-}C_5Ph_5)(CO)_3]$ (1)

An air-stable crystal of $[Mn(\eta^5\text{-}C_5Ph_5)(CO)_3]$ (**1**) was grown by slow vapour diffusion of pentane into a dichloromethane solution of (**1**) and the crystal structure was determined at room temperature. A single crystal X-ray diffraction study of (**1**) was undertaken for comparison with that of (**2**). Compound (**1**) crystallises in the monoclinic space group $P2_1/n$ (#14). The crystal structure of (**1**) consists of discrete molecules in the solid state and no intermolecular contacts of significance were observed in the solid. The closest intermolecular contact is 3.46 Å between C(33) on molecule (x, y, z) and C(34) on molecule $(-x, -y, -z)$. The closest intermolecular non-bonding approaches to manganese are greater than 4 Å. Final atomic positional coordinates, with estimated standard deviations, bond lengths and angles and anisotropic thermal parameters are deposited.[1] Selected interatomic bond distances and angles, with standard

[1] The atomic coordinates and thermal parameters have been submitted as supplementary material for deposition at the Cambridge Crystallographic Data Centre with deposition number CCDC 284608 (see Deposition of crystallographic data).

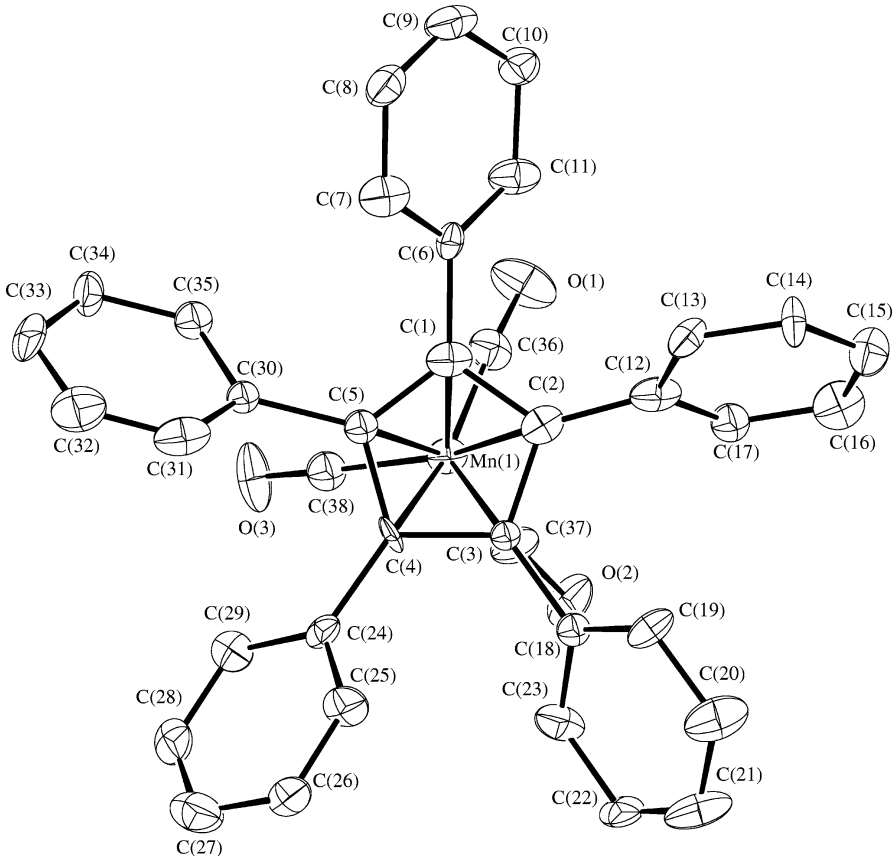

Fig. 1. ORTEP [39] illustration of $[Mn(\eta^5\text{-}C_5Ph_5)(CO)_3]$ (**1**), viewed perpendicular to the C_5 ligand plane, showing the atom numbering scheme.

deviations derived from the refinement, are given in Table 1. The atomic nomenclature is defined in Fig. 1. Figs. 1 and 2 illustrate the molecular geometry viewed along, and perpendicular to, the normal to the C_5 plane of the $C_5Ph_5^-$ ligand, respectively.

2.1.2. The $[Mn(\eta^5\text{-}C_5Ph_5)(CO)_3]$ molecule

Coordination by the η^5-pentaphenylcyclopentadienyl group and the three carbonyl groups creates a "three-legged piano stool" environment about the manganese atom. The Mn–(C_5 centroid) distance is 1.784 Å and the average Mn–C distance of 2.16 Å may be compared with the mean of nearly 147 structures of $[Mn(C_5R_5)(CO)_3]$ compounds of 1.775(1) and 2.142(2) Å. The Mn–CO distances (1.74(1), 1.77(1) and 1.83(1) Å) are indistinguishable and may be compared, for example, with the mean bond length of 1.784(2) in the $[Mn(C_5R_5)(CO)_3]$ compounds. The C=O bond lengths in (**1**) are the same within experimental error. The Mn–(C_5 centroid) distance is relatively long; there being only 42 compounds with Mn–(C_5 centroid) distances of 1.785 Å or longer. There appears to be no simple correlation between Mn–(C_5 centroid) distance and other parameters – whilst many of these 42 compounds do have bulky cyclopentadienyl ligands and the longest Mn–(ring centroid) distance reported to date is the exceptionally long (at $R = 0.0979$) 1.912 Å of $[\{Os_3(\mu\text{-}H)(CO)_8(PPh_3)_2\}(\mu\text{-}O_2C\text{-}\{(\eta^5\text{-}C_5H_4)Mn(CO)_3\}]$[2]) [25], that of $[Mn(\eta^5\text{-}C_5H_5)(CO)_3]$ is 1.794 Å.

The C_5 nucleus of the pentaphenylcyclopentadienyl ligand is planar to within 0.014 Å. The C–C bond lengths of the C_5 ring range from 1.39(2) to 1.46(1) Å, the average C–C bond length being 1.42 Å, which is consistent with C_5Ph_5 rings in other metal complexes. The *ipso*-carbon atoms of each of the phenyl rings are displaced slightly from the C_5 plane by between 0.09 and 0.20 Å, with the average distance being 0.16 Å. The *ipso*-carbon atoms of all phenyl rings are on the opposite side of the C_5 plane to the manganese atom. The phenyl rings are all also planar to within a mean deviation from the plane of 0.02 Å and are canted at between 46.2° and 61.9° (average 51.6°) to the C_5 ring in a paddle wheel arrangement. The average angle between the planes of adjacent phenyl rings of the $C_5Ph_5^-$ ligand is 54.9°.

2.1.3. $[Mn(\eta^5\text{-}C_5Ph_5)(CO)_2(PMe_2Ph)]$ (**2**)

$[Mn(\eta^5\text{-}C_5Ph_5)(CO)_2(PMe_2Ph)]$(**2**) also crystallises in the monoclinic space group $P2_1/n$ (#14). The crystal structure of (**2**) consists of discrete molecules in the solid state and no

[2] This distance is a considerable outlier in Mn–(C_5 centroid) distances, d, of $[Mn(\eta^5\text{-}C_5R_5)(CO)_3]$ compounds – the next 7 longest distances are in the range $1.812 \leqslant d \leqslant 1.823$ Å.

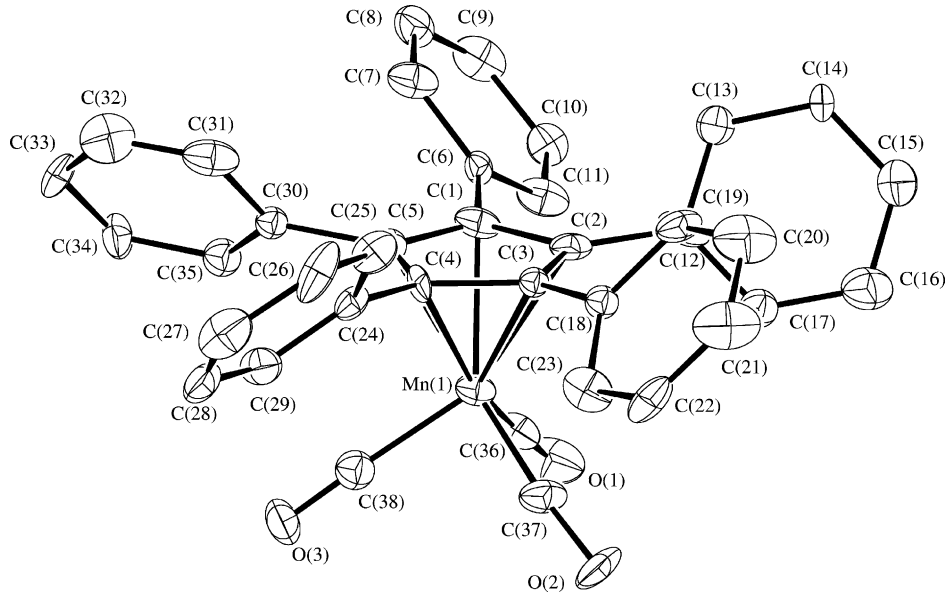

Fig. 2. ORTEP [39] illustration of $[Mn(\eta^5\text{-}C_5Ph_5)(CO)_3]$ (**1**), viewed parallel to the C_5 ligand plane, showing the atom numbering scheme.

intermolecular contacts of significance were observed in the solid. The closest intermolecular contact is 3.332(5) Å between O(1) on molecule (x, y, z) and C(41) on molecule $(1/2 - x, 1/2 + y, 1/2 - z)$. The closest intermolecular non-bonding approaches to manganese are greater than 4 Å. Final atomic positional coordinates, with estimated standard deviations, bond lengths and angles and anisotropic thermal parameters are deposited.[3] Selected interatomic bond distances and angles, with standard deviations derived from the refinement, are given in Table 2. The atomic nomenclature is defined in Fig. 3. Figs. 3 and 4 illustrate the molecular geometry viewed along, and perpendicular to, the normal to the C_5 plane of the $C_5Ph_5^-$ ligand, respectively.

The Mn–(C_5 centroid) distance is 1.809 Å and the average Mn–C(C_5) distance of 2.178(4) Å are both slightly longer than those of (**1**). The Mn–(C_5 centroid) distance is at the upper end of such distances in $[Mn(C_5R_5)(CO)_3]$ compounds, with only 8 compounds with longer Mn–(C_5 centroid) distances. It is easily the longest such distance in $[Mn(\eta^5\text{-}C_5R_5)(CO)_2(PX_3)]$ ($X \neq M$, P) compounds, as are, therefore, the Mn–C(C_5) distances.[4] That is, *on average*, the Mn–cyclopentadienyl distance of $[Mn(C_5R_5)(CO)_3]$ compounds *contracts* on phosphine substitution, but has increased in this case. The Mn–CO distances (1.757(4), 1.773(4) Å) are indistinguishable and similar to those in (**1**), but relatively long

Table 2
Selected average interatomic distances and angles in $[Mn(\eta^5\text{-}C_5Ph_5)(CO)_2PMe_2Ph]$ (**2**)

Atoms	Average dimension
Mn–C (C_5)	2.178(4) Å
Mn–P	2.264(1) Å
Mn–CO	1.765(4) Å
C–O	1.158(4) Å
C–C (C_5 ring)	1.427(5) Å
C(C_5)–*ipso*-C (C_6)	1.492(5) Å
CO–Mn–CO	91.2(2)°
Mn–C–O	178.9(3)°
C–C–C (C_5 ring)	108.0(3)°

for $[Mn(\eta^5\text{–}C_5R_5)(CO)_2(PX_3)]$ ($X \neq M$, P) compounds. As in (**1**), the C=O bond lengths in (**2**) are the same within experimental error. The Mn–P distance of 2.264(1) Å is again easily the longest in the 31 $[Mn(\eta^5\text{-}C_5R_5)(CO)_2(PX_3)]$ ($X \neq M$, P) compounds reported to date (range $2.126 \leqslant d \leqslant 2.359$, mean 2.215 Å). These distances easily exceed those of the $[Mn(\eta^5\text{-}C_5R_5)(CO)_2(PX_3)]^+$ ($X \neq M$, P) cations, which are included in the above analyses.

The C_5 nucleus of the pentaphenylcyclopentadienyl ligand is planar to within 0.006 Å. The C–C bond lengths of the C_5 ring range from 1.415(5) to 1.432(5) Å, the average C–C bond length being 1.427(5) Å, which is consistent with C_5Ph_5 rings in other metal complexes. The *ipso*-carbon atoms of each of the phenyl rings are displaced slightly from the C_5 plane by between 0.158 and 0.268 Å, with the average distance being 0.202 Å. This is a greater displacement than in $[Mn(\eta^5\text{-}C_5Ph_5)(CO)_3]$ (mean 0.161 Å). The *ipso*-carbon atoms of all phenyl rings are on the opposite side of the C_5 plane to the manganese atom. The phenyl rings are all also planar to within a mean deviation from the plane of

[3] The atomic coordinates and thermal parameters have been submitted as supplementary material for deposition at the Cambridge Crystallographic Data Centre with deposition number CCDC 284609 (see Deposition of crystallographic data).

[4] 41 observables from 31 compounds, ranges: Mn–(C_5 centroid) $1.744 \leqslant d \leqslant 1.791$, mean 1.774 Å; Mn–C($C_5$) $2.113 \leqslant d \leqslant 2.211$, mean 2.140 Å.

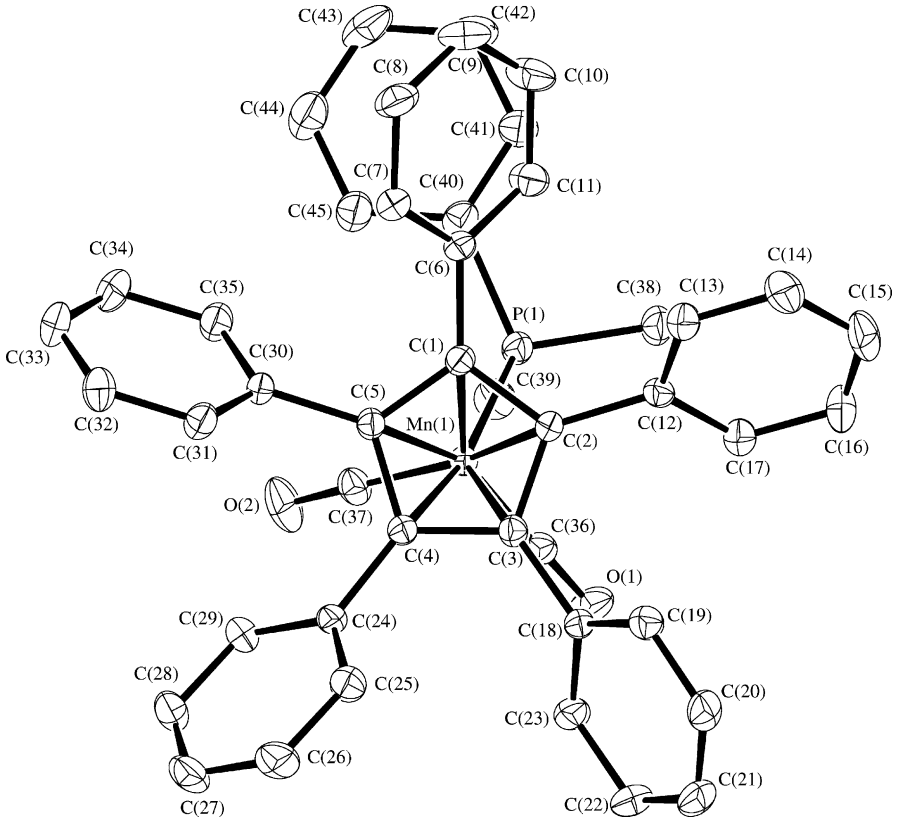

Fig. 3. ORTEP [39] illustration of $[Mn(\eta^5\text{-}C_5Ph_5)(CO)_2PMe_2Ph]$ (**2**), viewed perpendicular to the C_5 ligand plane, showing the atom numbering scheme.

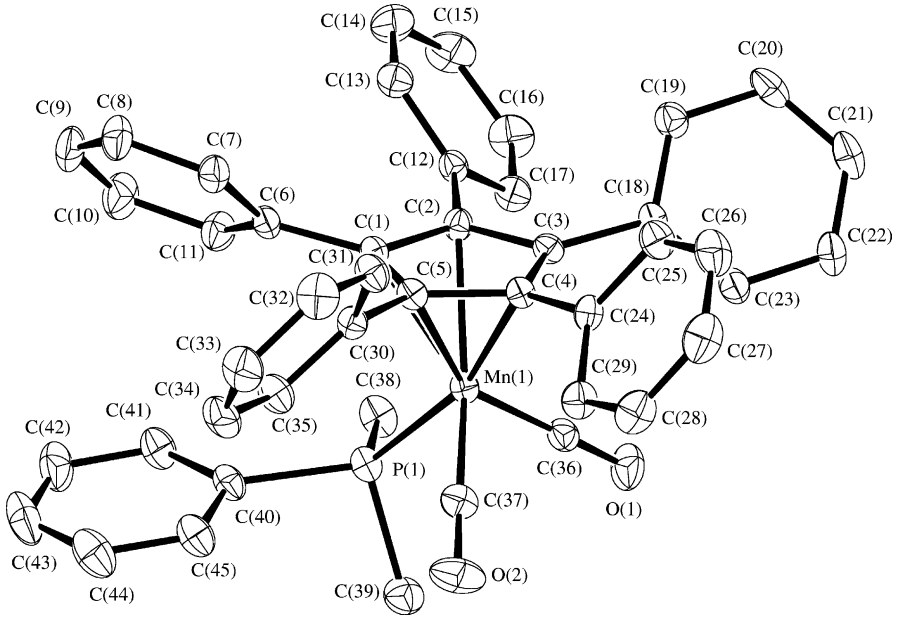

Fig. 4. ORTEP [39] illustration of $[Mn(\eta^5\text{-}C_5Ph_5)(CO)_2PMe_2Ph]$ (**2**), viewed parallel to the C_5 ligand plane, showing the atom numbering scheme.

0.012 Å and are canted at between 47.06° and 56.87° (average 51.5°) to the C_5 ring in a paddle wheel, or propeller, arrangement. The average angle between the planes of adjacent phenyl rings of the $C_5Ph_5^-$ ligand is 52.6°.

2.1.4. The $[Mn(\eta^5\text{-}C_5Ph_5)(CO)_2(PMe_2Ph)]$ molecule

A similar "three-legged piano stool" environment about the manganese atom results from coordination by the η^5-pentaphenylcyclopentadienyl group, the two carbonyl groups and the phosphine.

The most remarkable feature of the structure is the near parallel orientations of the C_5 and the PMe_2Ph phenyl planes. The angle between the phosphine phenyl and C_5 planes is only 7.55°, a consequence of the need to minimise intramolecular interferences between the phosphine methyl and cyclopentadienyl phenyl substituents. This steric pressure is also reflected in the slightly longer Mn-(C_5 centroid) distance in (**2**) by comparison with (**1**), and the considerably longer dimensions than in all $[Mn(\eta^5\text{-}C_5R_5)(CO)_2(PX_3)]$ ($X \neq M$, P) compounds reported to date.

With the chiral $C_5Ph_5^-$ phenyl propeller, and the chirality at the manganese atom, molecule (**2**) is diastereotopic in the solid state. However, the phenyl propellers and the phosphine substituents appear to rotate freely on the NMR time-scale at room temperature in solution, as there are no unexpected multiplicities in the ^1H, ^{13}C or ^{31}P NMR spectra, and, unlike $[Ru(\eta^5\text{-}C_5Ph_5)(CO)_2(PPh_3)Br]$ [26], the diastereomers are not resolved in solution.

3. Conclusions

Manganese derivatives of $C_5Ar_5^-$ ligands are readily accessible in high yield from easily available starting materials. The compounds $[Mn(\eta^5\text{-}C_5Ar_5)(CO)_3]$ undergo reversible one-electron oxidations at potentials more positive than the cyclopentadienyl analogue. Substitution of one of the CO ligands by P- and C-donor ligands is conveniently effected via the intermediacy of Me_3NO. The Mn-(C_5 centroid) distances of $[Mn(\eta^5\text{-}C_5Ph_5)(CO)_3]$ and $[Mn(\eta^5\text{-}C_5Ph_5)(CO)_2(PMe_2Ph)]$ are relatively long for compounds of these types. In particular, the Mn-ligand distances in $[Mn(\eta^5\text{-}C_5Ph_5)(CO)_2(PMe_2Ph)]$ are considerably longer than those reported for $[Mn(\eta^5\text{-}C_5R_5)(CO)_2(PX_3)]$ ($X \neq M$, P) compounds to date. Although the phosphine and cyclopentadienyl phenyl substituents of $[Mn(\eta^5\text{-}C_5Ph_5)(CO)_2(PMe_2Ph)]$ adopt configurations minimising steric interferences in the solid state, these substituents appear to be freely rotating (on the NMR time-scale) in solution at room temperature.

4. Experimental

All manipulations were performed at atmospheric pressure under an atmosphere of dinitrogen by using conventional Schlenk techniques. Chlorobenzene (Merck) was dried, distilled and stored over calcium hydride. Tetrahydrofuran (thf) (Merck) was pre-dried over sodium wire and distilled from sodium benzophenone ketyl. *n*-Hexane (BDH) was distilled from sodium wire. Dichloromethane (Ajax) was distilled from calcium hydride. C_5Ph_5Br [27], and $C_5(p\text{-}MeC_6H_4)_5Br$ [28] were prepared as described previously. $Mn_2(CO)_{10}$ (Aldrich), PMe_2Ph (Fluka) and ^tBuNC (Aldrich) were used as received. $[Mn(CO)_5Br]$, $[Mn(CO)_3(CH_3CN)Br]_2$ and $[Mn(CO)_3(CH_3CN)_3]Br$ were prepared according to literature procedures [29–31]. Trimethylamine *N*-oxide dihydrate (Aldrich) was dehydrated by sublimation prior to use. Flash silica (240–400 mesh) was obtained from Merck. Melting points were recorded on a Reichert hot platform in air and are uncorrected. ^1H and ^{13}C NMR spectra were recorded on Bruker AC200F (^1H NMR 200.13 MHz, ^{13}C NMR 50.33 MHz) or Bruker AMX400 (^1H NMR 400.21 MHz) spectrometers. The spectra were referenced internally to TMS or to residual solvent resonances (CD_2Cl_3, ^1H δ 5.30 ppm, ^{13}C δ 53.8 ppm). ^{31}P NMR spectra were recorded on a Bruker AMX400 spectrometer operating at 162.0 MHz and were referenced to external neat trimethylphosphite (taken to be δ 140.85 ppm from 85% H_3PO_4). Electron impact mass spectra were obtained using a Kratos MS 9 geometry mass spectrometer with a direct insertion probe, a 280 °C source temperature, 70 eV ionisation voltage and 4 kV acceleration voltage.

Melting points were determined using a Gallenkamp melting point apparatus in air and are uncorrected.

Elemental analyses were carried out by one of the following departments: the Australian Microanalytical Service in Melbourne, the Microanalytical Service at the Australian National University or at the JEAF in The University of Sydney.

Infrared spectra were recorded on a Digilab FTS-40 infrared spectrophotometer either as a solution or as a suspension in a potassium bromide matrix. The resolution used was 4 cm^{-1} and the number of scans was 16.

Electrochemical experiments were performed using a BAS 100W Electrochemical Analyser. The sample cell was fitted with a plastic top that could be sealed almost air-tight. A three-electrode configuration was used. The working electrode was a BAS glassy carbon disc (3 mm diameter) which was polished with an alumina (0.25 mm grade) suspension on a velvet polishing cloth, then rinsed with distilled water and acetone, and then dipped in the solvent of use for one minute before each cyclic voltammogram was recorded. The auxiliary electrode was a platinum wire (0.5 mm diameter, 4 cm length) which did not need cleaning between voltammograms but was cleaned by rinsing with 5 M aqueous HNO_3, distilled water and the solvent used prior to each set of experiments. The reference electrode was a BAS Ag/AgCl/NaCl (3 M) electrode with a vycor frit. All samples were thoroughly degassed with high purity argon (CIG) which was passed through a scrubber and a drying tower to remove any traces of oxygen and water, respectively. All potentials are quoted relative to the ferrocenium/ferrocene redox couple, which was observed at ca. 500 mV against the reference electrode [Ag/AgCl/NaCl (3 M)]. Samples were prepared as approximately 1 mM solutions with tetra(*n*-butyl)ammonium tetrafluoroborate (TBATFB ca. 0.1 M) as the supporting electrolyte. TBATFB was prepared either from aqueous HBF_4 (35% v/v, Merck) and $(n\text{-}C_4H_9)NOH$ (40% w/w, Aldrich) or by recrystallisation of TBATFB (Aldrich) three times from ethyl acetate/diethyl ether in air, then drying in vacuo. Full *iR* (100%) compensation was employed in each scan. Except as otherwise stated, all measurements were carried out in dichloromethane

solution with 0.1 M TBATFB as the supporting electrolyte and a scan rate of 100 mV s^{-1}.

4.1. Preparation of [$Mn(\eta^5$-$C_5Ph_5)(CO)_3$] (1)

4.1.1. Method A: reaction of [$Mn(CO)_3(CH_3CN)_3$]Br with LiC_5Ph_5

A solution of LiC_5Ph_5 (1.0 mmol) in tetrahydrofuran (10 mL) was added to a solution of $[Mn(CO)_3(CH_3CN)_3]Br$ (0.34 g, 1.0 mmol) in tetrahydrofuran (10 mL). The solution was refluxed with stirring for 16 h, then the solvent was removed under reduced pressure. The orange/yellow solid was extracted into CH_2Cl_2, and chromatographed on a hexane/alumina column under N_2. Elution with CH_2Cl_2/hexane (1:3) gave a light yellow band which was collected. The solvent was removed under vacuum to yield [$Mn(\eta^5$-$C_5Ph_5)(CO)_3$] (**1**) as a pale yellow solid (0.40 g, 68%).

4.1.2. Method B: reaction of [$Mn(CO)_5Br$] with LiC_5Ph_5

A solution of LiC_5Ph_5 (1.0 mmol) in tetrahydrofuran (10 mL) was added to a solution of $[Mn(CO)_5Br]$ (0.27 g, 1.0 mmol) in tetrahydrofuran (10 mL) and the resultant solution was refluxed with stirring for 16 h. The product was purified chromatographically as in Method A (0.22 g, 38%).

4.1.3. Method C: reaction of [$Mn(CO)_3(CH_3CN)_2Br$] with C_5Ph_5Br and Zn

A mixture of $[Mn(CO)_3(CH_3CN)_2Br]$ (0.15 g, 0.50 mmol), C_5Ph_5Br (0.26 g, 0.50 mmol) and zinc dust (0.033 g, 0.50 mmol) in tetrahydrofuran (15 mL) was refluxed with stirring for 16 h. The product was purified chromatographically as in Method A (0.17 g, 59%). M.p. 287–289 °C. *Anal*. Calc. for $C_{38}H_{25}MnO_3$: C, 78.08; H, 4.31. Found: C, 78.0; H, 4.3%. ^{1}H NMR (ppm, 200 MHz, CD_2Cl_2): δ 7.06 (br, m, 25 H, Ar-*H*). IR ν_{max} (cm^{-1}, KBr): 3060 w, 2007 vs, 1934 vs, 1923 vs, 1503 w, 1445 w, 746 w, 739 w, 699 m sh, 665 m, 636 m, 559 w, ν_{max} (CO) (cm^{-1}, CH_2Cl_2): 2015 s, 1934 s. MS (EI) (*m*/*z*%): 584 (M^+, 12), 528 ($M^+ - 2CO$, 17), 500 ($M^+ - 3CO$, 100), 446 ($C_5Ph_5H^+$, 33).

4.2. Preparation of [$Mn(\eta^5$-$C_5Ph_5)(CO)_2(PMe_2Ph)$] (2)

$PPhMe_2$ (0.22 mL, 0.70 mmol) and trimethylamine oxide (0.045 g, 0.60 mmol) were added to a solution of $[Mn(C_5Ph_5)(CO)_3]$ (0.295 g, 0.51 mmol) in tetrahydrofuran (30 mL) and the resulting reaction mixture was heated at reflux for 16 h. The solvent was removed in vacuo to afford an orange oil and the crude product was purified by column chromatography on alumina eluting with CH_2Cl_2/hexane (20/80 *v*/*v*). The product was recrystallised from CH_2Cl_2/hexane to give [$Mn(\eta^5$-$C_5Ph_5)(CO)_2(PMe_2Ph)$] (**2**) as an orange crystalline solid (0.285 g, 81%). M.p. 287–289 °C. *Anal*. Calc. for $C_{45}H_{36}MnOP$: C, 77.80; H, 5.22. Found: C, 77.4; H, 4.9%. ^{1}H NMR ($CDCl_3$): δ 7.55–6.75 (br m, 30H, (C_6H_5)C_5 and P(C_6H_5)), 1.59 (br s, 6H, $2 \times PCH_3$) ppm. $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ 45.86 (s) ppm. I.R. (KBr): *v* 1850 (vs), 1918 (vs) cm^{-1}.

4.3. Preparation of [$Mn(\eta^5$-$C_5(p\text{-}tol)_5)(CO)_3$] (3)

4.3.1. Method A: reaction of [$Mn(CO)_3(CH_3CN)_3$]Br with $LiC_5(p\text{-}tol)_5$

A solution of $LiC_5(p\text{-tol})_5$ (0.87 mmol) in tetrahydrofuran (10 mL) was added to a solution of $[Mn(CO)_3(CH_3CN)_3]Br$ (0.30 g, 0.86 mmol) in tetrahydrofuran (10 mL). The resultant solution was refluxed with stirring for 16 h, then the solvent was removed under reduced pressure. The orange/yellow solid was extracted into CH_2Cl_2, and chromatographed on a hexane/alumina column under N_2. Elution with CH_2Cl_2/hexane (1:5) gave a light yellow band which was collected. The solvent was then removed to yield [$Mn(\eta^5$-$C_5(p\text{-tol})_5)(CO)_3$] (**3**) as a pale yellow solid (0.19 g, 34%).

4.3.2. Method B: reaction of [$Mn(CO)_3(CH_3CN)_3$]Br with $C_5(p\text{-tol})_5Br$ and Zn

Tetrahydrofuran (15 mL) was added to a solid mixture of $[Mn(CO)_3(CH_3CN)_3]Br$ (0.34 g, 1.0 mmol), $C_5(p\text{-tol})_5Br$ (0.59 g, 1.0 mmol) and zinc dust (0.075 g, 1.1 mmol). The resultant solution was refluxed with stirring for 16 h. The product was purified chromatographically as in Method A (0.45 g, 69%).

M.p. 255–257 °C. *Anal*. Calc. for $C_{43}H_{35}MnO_3$: C, 78.89; H, 5.39. Found: C, 78.1; H, 5.2%. ^{1}H NMR (ppm, 200 MHz, CD_2Cl_2): δ 7.09–6.83 (m, 20H, Ar-*H*) 2.26–2.17 (m, 15H, CH_3). IR ν_{max} (cm^{-1}, KBr): 3020 w, 2922 w, 2008 vs, 1932 vs, 1926 vs, 1520 m, 1187 w, 1020 w, 838 w, 820 w, 805 w, 728 w, 666 m, 630 m, 538 m sh. MS (EI) (*m*/*z*%): 654 (M^+, 4.4), 598 ($M^+ - 2CO$, 2), 570 ($M^+ - 3CO$, 100), 526 ($C_5Ph_5H^+$, 34).

4.4. Structure determinations

[$Mn(\eta^5$-$C_5Ph_5)(CO)_3$] (**1**): a yellow blade like crystal having approximate dimensions of $0.47 \times 0.20 \times 0.12$ mm was attached to a thin glass fibre, and mounted on an Enraf-Nonius CAD4 diffractometer employing graphite monochromated Mo Kα radiation. Primitive monoclinic cell constants were obtained from a least-squares refinement using the setting angles of 25 reflections in the range $16.02 < 2\theta < 24.24°$. Diffraction data were collected at a temperature of 21 ± 1 °C using ω scans to a maximum 2θ value of 49.9°. The intensities of three representative reflections measured every 60 min, decreased by 53.2% and a polynomial correction factor was accordingly applied to the data. An analytical absorption correction was applied and the data were also corrected for Lorentz and polarisation effects.

All calculations were undertaken with the TEXSAN [32] crystallographic software package. Neutral atom scattering factors were taken from Cromer and Waber [33]. Anomalous dispersion effects were included in Fcalc [34] and the

values for $\Delta f'$ and $\Delta f''$ were those of Creagh and McAuley [35]. The values for the mass attenuation coefficients were those of Creagh and Hubbell [36]. The structure was solved in the space group $P2_1/n$ (#14) by heavy-atom Patterson methods [37] and expanded using Fourier techniques [38]. In general non-hydrogen atoms were modelled anisotropically, however C(3), C(5), C(17), C(18), C(30) and C(35) were refined with isotropic thermal parameters. Hydrogen atoms were included in the model at calculated positions with group thermal parameters. ORTEP projections of the molecule are provided in Figs. 2 and 3 [39].

4.5. Crystal data for $[Mn(\eta^5\text{-}C_5Ph_5)(CO)_3]$ (1)

Formula $C_{38}H_{25}MnO_3$, M 584.52, monoclinic, space group $P2_1/n$ (#14), a 16.929(4), b 8.928(2), c 20.054(4) Å, β 106.04(2), V 2913.0(11) Å^3, D_c 1.333 g cm^{-3}, Z 4, crystal size 0.47 by 0.20 by 0.12 mm, colour yellow, habit blade, temperature 294(2) K, λ(Mo Kα) 0.71073 Å, μ(Mo Kα) 0.4900 mm^{-1}, T (Analytical)$_{min,max}$ 0.8984, 0.9489, $2\theta_{max}$ 49.98, hkl range −20 19, −1 10, −1 10, N 4061, N_{ind} 3167-(R_{merge} 0.0738), N_{obs} 2058($I > 2\sigma(I)$), N_{var} 344, residuals[5] $R_1(F)$ 0.0967, $wR_2(F^2)$ 0.2971, GoF(all) 1.274, $\Delta\rho_{min,max}$ −1.516, 1.455 e$^-$ Å^{-3}.

[Mn(η^5-C_5Ph_5)(CO)$_2$(PMe_2Ph)] (**2**): a yellow blade like crystal having approximate dimensions of $0.28 \times 0.25 \times 0.11$ mm was attached to a thin glass fibre, and mounted on a Rigaku AFC7R diffractometer employing graphite monochromated Cu Kα radiation from a rotating anode generator. Primitive monoclinic cell constants were obtained from a least-squares refinement using the setting angles of 21 reflections in the range $68.01 < 2\theta < 91.99°$. Diffraction data were collected at a temperature of 21 ± 1 °C using ω–2θ scans to a maximum 2θ value of 130.2°. Omega scans of several intense reflections made prior to data collection, had an average width at half-height of 0.18°, and scans of $(1.73 + 0.35 \tan\theta)°$ were made at a speed of 16.0°/min (in omega). The weak reflections ($I < 15.0\sigma(I)$) were rescanned up to 10 times. Stationary background counts were recorded on each side of the reflection, with a 2:1 ratio of peak to background counting time. The intensities of three representative reflections measured every 150 reflections, did not change significantly during the data collection. An analytical absorption correction was applied and the data were also corrected for Lorentz and polarisation effects.

All calculations were undertaken with the TEXSAN [32] crystallographic software package. Neutral atom scattering factors were taken from Cromer and Waber [33]. Anomalous dispersion effects were included in Fcalc [34] and the values for $\Delta f'$ and $\Delta f''$ were those of Creagh and McAuley [35]. The values for the mass attenuation coefficients were those of Creagh and Hubbell [36]. The structure was solved in the space group $P2_1/n$ (#14) by direct methods [40] and expanded using Fourier techniques [38]. Non-hydrogen atoms were modeled with anisotropic thermal parameters and hydrogen atoms were included in the model at calculated positions with group thermal parameters. ORTEP projections of the molecule are provided in Figs. 1 and 2 [39].

4.6. Crystal data for $[Mn(\eta^5\text{-}C_5Ph_5)(CO)_2(PMe_2Ph)]$ (2)

Formula $C_{45}H_{33}MnO_2P$, M 691.62, monoclinic, space group $P2_1/n$(#14), a 15.251(4), b 13.804(3), c 17.682(4) Å, β 106.39(2), V 3571.2(15) Å^3, D_c 1.286 g cm^{-3}, Z 4, crystal size 0.28 by 0.25 by 0.11 mm, colour yellow, habit blade, temperature 294(2) K, λ(Cu Kα) 1.5418 Å, μ(Cu Kα) 3.714 mm^{-1}, T(Analytical)$_{min,max}$ 0.420, 0.698, $2\theta_{max}$ 130.20, hkl range 0 17, 0 16, −20 19, N 6028, N_{ind} 6027 (R_{merge} 0.05469), N_{obs} 4016($I > 2\sigma(I)$), N_{var} 443, residuals[6] $R_1(F)$ 0.0472, $wR_2(F^2)$ 0.1356, GoF(all) 1.189, $\Delta\rho_{min,max}$ −0.383, 0.495 e$^-$ Å^{-3}.

many nucleophilic and electrophilic reactions [16,17], so it was reasonable to examine metallosurfactants in this content. It is argued that the high charge and size of the head group of complexes having long paraffin tails, detergent-like characteristics are able to penetrate biological membranes and destabilize the exterior membrane of the organism [18]. Moreover, transition metal ions complexes with lipophilic ligands in micellar or vesicular aggregates have attracted considerable attention as catalysts for the cleavage of esters and amides and as biomimetic models of hydrolytic metalloenzymes [19,20]. Recently, there has been increasing interest in the use of these organized media to study the fundamental photochemical reactions of metal complexes with relevance to the conversion of solar energy into other useful forms of energy through photochemical reactions [21,22]. As a part of our studies on transition metal-based surfactants [3,4] in this paper we report the synthesis, characterization and determination of critical micelle concentration values of some more novel cobalt(III) surfactant complexes.

2. Experimental

2.1. Chemicals and reagents

All the reagents were of analytical grade (Aldrich and Merck). Ultra pure water, obtained by deionising distilled water using a Milli-Q Reagent Grade water system, was used for preparative work and to make up solutions for all physical measurements.

2.2. Synthesis of metallosurfactants of cobalt(III) complexes

The surfactant cobalt(III) complexes synthesized here were prepared by a similar method to those complexes reported in the literature [23], by replacing the lower amine groups by long-chain amine ligands as follows.

2.2.1. *cis*-$[Co(en)_2(C_{12}H_{25}NH_2)Cl](ClO_4)_2$ and *cis*-$[Co(en)_2(C_{16}H_{33}NH_2)Cl](ClO_4)_2$

trans-$[Co(en)_2Cl_2]Cl$ [24], (3.0 g, 10.5 mmol) was dissolved in water (20 mL). To this solution slightly more than the calculated amount of dodecylamine (3 mL), where the amine used was not sufficiently miscible with (soluble in) water, was first mixed with ethanol (2 mL) and then added drop by drop over a period of 30 min. The green solution gradually became red during the reaction. The mixture was set aside at 313 K for 2 days until no further change was observed. Afterwards a saturated solution of sodium perchlorate in very dilute perchloric acid was added. Slowly a pasty solid mass separated out and it was filtered off, washed with small amounts of alcohol followed by acetone, and then it was dried over air. The semi-dried solid was further dried in a drying pistol over fused calcium chloride and stored in a vacuum desiccator. For the complex *cis*-$[Co(en)_2(C_{16}H_{33}NH_2)Cl](ClO_4)_2$ cetylamine was used instead in the place of dodecylamine.

2.2.2. *cis*-$[Co(en)_2(C_{12}H_{25}NH_2)Br](ClO_4)_2$ and *cis*-$[Co(en)_2(C_{16}H_{33}NH_2)Br](ClO_4)_2$

This complex was synthesized by adopting the same method as described for the synthesis of the complex *cis*-$[Co(en)_2(C_{16}H_{33}NH_2)Cl](ClO_4)_2$ except that in place of *trans*-$[Co(en)_2Cl_2]Cl$, *trans*-$[Co(en)_2Br_2]Br$ [23] (3.0 g, 7.16 mmol) was used. The same procedure was followed for the complex *cis*-$[Co(en)_2(C_{16}H_{33}NH_2)Br](ClO_4)_2$, but in the place of dodecylamine, cetylamine was used.

Complexes *cis*-$[Co(en)_2(C_{12}H_{25}NH_2)NO_2](NO_3)_2$, *cis*-$[Co(en)_2(C_{16}H_{33}NH_2)NO_2](NO_3)_2$, *cis*-α-$[Co(trien)(C_{12}H_{25}NH_2)NO_2](NO_3)_2$ and *cis*-α-$[Co(trien)(C_{16}H_{33}NH_2)NO_2](NO_3)_2$ were prepared by the ligand substitution method by replacing the chloride ion with dodecylamine/cetylamine from the corresponding *cis*-$[Co(en)_2(NO_2)Cl](NO_3)_2$ [25] and *cis*-α-$[Co(trien)(NO_2)Cl](NO_3)_2$ [26].

Complexes *cis*-α-$[Co(trien)(C_{12}H_{25}NH_2)Cl]^{2+}$ and *cis*-α-$[Co(trien)(C_{12}H_{25}NH_2)Br]^{2+}$ were prepared as reported in the literature [4], the same procedure was followed for complexes *cis*-α-$[Co(trien)(C_{16}H_{33}NH_2)Cl]^{2+}$ and *cis*-α-$[Co(trien)(C_{16}H_{33}NH_2)Br]^{2+}$, but in the place of dodecylamine, cetylamine was used as a coordinating ligand.

Safety note! Perchlorate salts of metal complexes with organic ligands are potentially explosive. Only small amounts of materials should be prepared, and these should be handled with caution.

2.3. Instrumentation

Infrared (IR) spectra were recorded on a Jasco 460 plus spectrometer using the potassium bromide discs method. ^1H NMR spectra were recorded in the appropriate deuteriated solvents using a Bruker AC 300F (300 MHz) spectrometer with TMS as internal reference. Electronic absorption spectra were taken in 10^{-3} M perchloric acid medium recorded on a Varian Cary 500 Scan UV–Vis–NIR spectrophotometer. C, H and N were estimated using a Perkin–Elmer 2400 CHN instrument. Conductivity studies were done in aqueous solutions of the complexes with an Elico conductivity bridge type CM 82 and a dip-type cell with a cell constant of 1.0.

2.4. Determination of CMC

The critical micelle concentration values of these complexes were determined conductometrically using a specific conductivity meter (Elico CM 82). The conductivity cell (dip-type with a cell constant of 1.0) was calibrated with KCl solutions in the appropriate concentration range. The cell constant was calculated using molar conductivity data for KCl published by Shedlovsky [27] and Chambers [28]. Various concentrations of cobalt(III)-surfactant complexes were prepared in the range 10^{-5}–10^{-1} mol dm^{-3} in aqueous solution. The conductivity of these solutions was measured at 303, 308 and 313 K. The temperature of the thermostat was maintained constant to within ±0.01 K. At least a set of 50 specific conductance readings for 50

different concentrations of complex was noted in order to get the critical micelle concentration values for each system.

3. Results and discussion

The cobalt(III)-surfactant complexes synthesized in the present study were characterized by UV–Vis, IR and NMR spectra and checked by comparing the spectra with those for the corresponding ordinary complexes where one of the ligands is butylamine instead of dodecylamine/cetylamine, reported earlier [3,4,29–34]. The purity of the complexes was checked by cobalt [35], elemental and halide analyses, which were found to be in good agreement with those of the calculated ones (Table 1).

The uniqueness of the cobalt(III)-surfactant coordination complexes lies in the fact that the bond between the head group and the tail part of the surfactant-cobalt(III) complex is a coordinate bond and the surfactant contains a higher charge on the head group unlike common surfactants (sodium dodecyl sulfate). At the same time like the common surfactants, these cobalt(III)-surfactant coordination compounds form foam in aqueous solution when mechanically disturbed like shaking, and these complexes dissolve slowly in water, though sometimes we have to sonicate the solution to get a homogeneous solution (see Fig. 1).

3.1. Spectroscopic characterization

Several attempts have been made to relate differences in infrared spectra to the structure of the geometrical configuration of complexes [29–34]. The IR spectra of a number of Co(III) complexes were determined and were recorded in Tables 2 and 3. For the assignment of a geometrical configuration to these complexes, infrared spectroscopy was used. Various workers have employed [29–34] the NH_2 deformation mode in the 1700–1500 cm^{-1} region, CH_2 rocking mode in the 900–850 cm^{-1} region and Co–N stretching mode in the 610–500 cm^{-1} region to distinguish between the *cis* and *trans* isomers of cobalt(III)-ethylenediamine complexes. Baldwin [31] suggested that the most consistent variations between the spectra of *cis* and *trans* isomers were found in the CH_2 rocking region (900–850 cm^{-1}). The *cis* isomers always show two peaks, whereas the *trans* isomers usually have only one. Hughes and McWhinnie [30] studied the infrared absorption spectra of several bis(ethylenediamine)cobalt(III) complexes and obtained a satisfactory correlation in the 610–500 cm^{-1} region, where Co–N stretching modes of the chelate ring occur. Here, no *trans* isomers had more than three strong bands, while all *cis* isomers had at least four, sometimes occurring as shoulders. The bands for the *trans* isomers were generally evenly distributed, while those for *cis* complexes occurred in two groups with a wide separation between them. The data in Tables 2 and 3, indicate that generally the complexes studied followed the previous trends. Because of lower symmetry in the present study (Fig. 2), the *cis* isomers show two bands for the NH_2 deformation, two bands for the NH_2 wagging modes, two bands for the CH_2 rocking mode and four bands occurring as groups of two with a wide separation for the Co–N stretching mode. The complex of the type *cis*-α-[Co(trien)XCl]$^{n+}$ of the present study shows two bands for the NH_2 deformation in the region 1630–1580 cm^{-1}, two bands for the

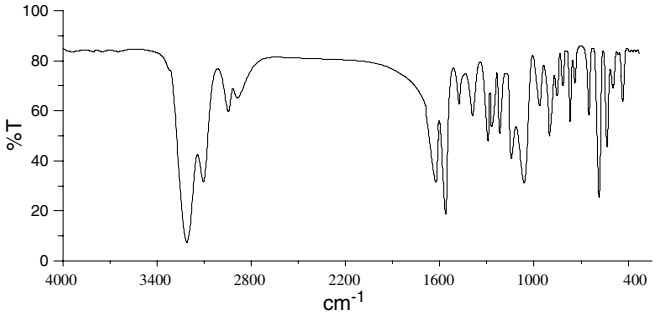

Fig. 2. Infrared spectra of *cis*-$[Co(en)_2(C_{16}H_{33}NH_2)Cl](ClO_4)_2$.

CH_2 or NH_2 twist mode in the region 1150–980 cm^{-1}, and the CH_2 rock mode in the region 940–860 cm^{-1} appeared as two bands. The spectroscopic data collected in Tables 2 and 3, therefore clearly indicate a *cis* configuration for the cobalt(III)-ethylenediamine and *cis*-α configuration for the cobalt(III)-triethylenetetramine type of surfactant complexes.

The ^1H NMR spectrum offers conclusive proof of the configuration of the isomers in solution. The *cis* and *trans* isomers of $[Co(en)_2X_2]^+$ ions have different symmetry properties, and this factor appears to govern the difference in their NMR spectra. The *cis* isomers possess C_2-symmetry with the twofold axis in the plane of the cobalt and the two X groups, and this makes the $–CH_2CH_2–$ groups

equivalent provided that the cobalt–ethylenediamine rings have the same conformation. Moreover, in complexes of the type *cis*-$[Co(en)_2X_2]^{n+}$ there are four pairs of equivalent nitrogen protons, but in complexes of the type *cis*-$[Co(en)_2XY]^{n+}$, although some protons are similarly orientated, no two protons are in identical situations. In complexes of the type *trans*-$[Co(en)_2X_2]^{n+}$ all the protons are equivalent, but in complexes of the type *trans*-$[Co(en)_2XY]^{n+}$ the protons on one side of the plane of the ethylenediamine ring all will experience a different field from those on the other side. It is possible that if the ligands X and Y differed greatly in size, inversion of the chelate ring would be hindered or even inhibited. In the case of *trans* complexes, two separate proton resonances of equal area would be observed if inversion was inhibited, while with *cis* complexes a most complex pattern would result. In *trans* isomers, however, with D_{2h} symmetry, the amine protons and methylene protons of ethylenediamine appear as a singlet at 3 ppm. In the present study, for the *cis* complexes (Fig. 3), due to the lower symmetry, the methylene protons of ethylenediamine show a more complex absorption around 2.8–2.7 ppm. The methylene protons of the long chain moieties (dodecylamine/cetylamine) give rise to a multiplet usually at 1.25–1.8 ppm, whereas the terminal methyl group of the hydrocarbon chain substituent gives a triplet at 0.84 ppm. The ^{1}H NMR spectral data for the cobalt(III)-triethylenetetramine complexes exhibit signals in the region 2.6–3.0 ppm attributable to the $-CH_2$ group of the triethylenetetramine chelate ring, thus confirming the *cis* structure of the complex.

The wavelength of the first absorption maximum in aqueous perchlorate medium for each complex is given in Table 1. It has been observed that the absorption spectra [33,34] of the *cis* and *trans* forms of $[Co(en)_2(NH_3)Y]^{n+}$ cations (Y = Cl or H_2O) showed some differences in the longest-wavelength absorption band (d–d transition). The *trans* form showed a lower intensity band ($\varepsilon < 50\ M^{-1}\ cm^{-1}$) whereas the *cis* form showed a higher intensity band ($\varepsilon > 70\ M^{-1}\ cm^{-1}$). This observation can be used to determine the geometrical configuration of the present cations, whose longest-wavelength absorption maxima are shown in Table 1. By comparing the spectra of the corresponding butylamine complexes [23], it reveals that both the ordinary and the surfactant complexes have the same structure and the replacement of lower aliphatic amine ligands by long chain aliphatic amine ligands does not affect the symmetry of the surfactant complexes (Fig. 1).

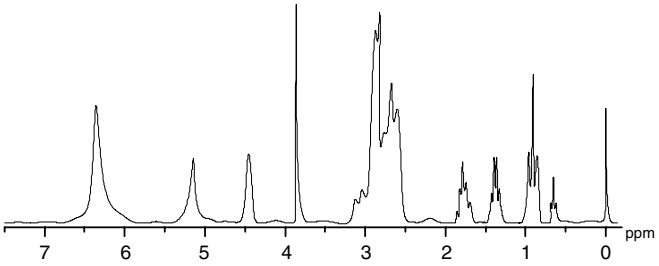

Fig. 3. ^{1}H NMR spectrum of *cis*-$[Co(en)_2(C_{16}H_{33}NH_2)Cl](ClO_4)_2$.

3.2. Critical micelle concentration values (CMC)

The CMC values were computed from the slope of [Co(III)] versus specific conductance data. The complex concentration at which the micellization starts was evident from the change in the slope of the plot and that particular concentration is the CMC under the experimental conditions. The CMC values were determined at three different temperatures (303, 308 and 313 K). At all temperatures a break in the conductance versus concentration plots, characteristic of micelle formation was observed. The CMC values were determined by fitting the data points above and below the break to two equations of the form $y = mx + c$ and solving the two equations simultaneously to obtain the point of intersection. Least-squares analysis was employed and correlation coefficients were greater than 0.98 in all the cases. The conductivity measurements at three different temperatures have been repeated three times and the accuracy of the CMC values was found with in ±3% error. Fig. 4 illustrates the plot for the complex *cis*-$[Co(en)_2(C_{12}H_{25}NH_2)Cl](ClO_4)_2$; similar plots (not shown) were obtained for all the remaining complexes. Tables 4 and 5 show the values of the CMCs of cobalt(III)-ethylenediamine surfactant and Cobalt(III)-triethylenetetramine surfactant respectively, as a function of temperature. It was found that CMC values increase on increasing the temperature for a given system. This behavior may be related to two competitive effects. Firstly, a temperature increase causes a decrease in hydration in the hydrophilic group, which favors micellization. Secondly, a temperature increase also causes a disruption of the water surrounding the hydrophobic group, and this retards micellization. The relative magnitude of these two opposing effects will determine the CMC behavior. It is observed that by changing

the ion from Cl^- to Br^-, the CMC decreases. It may be due to the increase in the size of the ion in the coordination sphere, which makes it more weakly hydrated. Weakly hydrated ions can be adsorbed more readily in the micellar surface which decreases the charge repulsion between the polar groups and thus facilitates the micellization. Further with an increase in the alkyl chain on the polar head group, the CMC again shows a decrease. This may be due to an increase in hydrophobic character of the molecule in the coordination sphere with that of dodecyl/cetylamine.

3.3. Thermodynamics of micellization

The change in the CMC with temperature is generally analyzed in terms of the phase separation or the equilibrium model for micelle formation [36–38]. According to these models, the standard Gibbs free energy of micelle formation per mole of monomer, ΔG^0_m, is given by

$$\Delta G^0_m = RT(2-\alpha_{ave})\ln \mathrm{CMC}, \quad (1)$$

where R, T and α_{ave} are gas constant, absolute temperature and average degree of micellar ionization, respectively.

The enthalpy of micelle formation can be obtained by applying the Gibbs–Helmholtz equation to Eq. (1)

$$\Delta H^0_m = -RT^2(2-\alpha_{ave})\mathrm{d}\ln \mathrm{CMC}/\mathrm{d}T. \quad (2)$$

Once the Gibbs free energy and the enthalpy of micelle formation are obtained, obviously, the entropy of micelle formation can be determined by

$$\Delta S^0_m = (\Delta H^0_m - \Delta G^0_m)/T. \quad (3)$$

The thermodynamic parameters of micellization for the cationic surfactant with variable head group polarity were compiled in Tables 4 and 5. The observed more negative Gibbs free energy of micellization for the surfactants with increasing head polarity indicates more favored micellization. Moreover, since the changes of CMC with temperature are small, the value of ΔH^0_m and ΔS^0_m must be rather inaccurate and should be considered as only approximate. Negative values of enthalpy (ΔH^0_m) of micellization indicate an exothermic nature of the micellization process. Nuselder and Engberts [39] have suggested that for the negative ΔH^0_m the London-dispersion forces play major role in the micelle formation. The positive values of ΔS^0_m clearly indicate that the micellization of the studied surfactants in aqueous solution is governed mainly by hydrophobic interactions between the surfactant cations resulting in the breakdown of the structured water surrounding the hydrophobic groups, and indicates that the cationic surfactants are entropy driven. The observed increase in the entropy values indicates that increasing the head group polarity favors the micellization process.

4. Conclusion

As mentioned in our previous reports [3,4], the critical micelle concentration values of cobalt(III)-surfactant coordination complexes in the present study are also very low compared to that of the simple organic surfactant, dodecylammonium chloride (CMC = 1.5×10^{-2} mol dm^{-3}). Thus, it is concluded that these metal surfactant complexes have more capacity to associate themselves, forming aggregates, compared to those of ordinary synthetic organic surfactants. This suggests that the introduction of a metal complex to the hydrophilic part of the amphiphile can remarkably enhance the ability of aggregation.

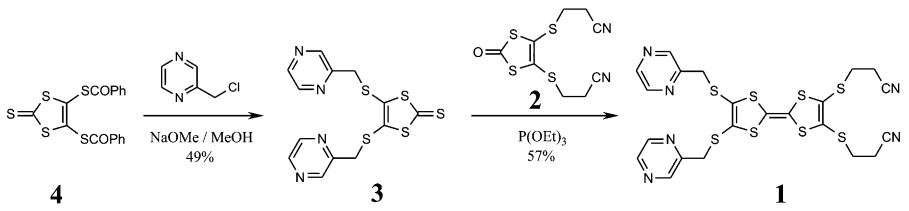

Scheme 1. Synthetic pathway to the target compound **1** via the triethylphosphite mediated coupling reaction.

2. Experimental

2.1. Materials

The compounds 4,5-bis(cyanoethylthio)-1,3-dithiole-2-one (**2**) [13], 4,5-bis(benzoylsulfanyl)-1,3-dithiole-2-thione (**4**) [13] and 2-chloromethylpyrazine [14] were prepared according to the literature procedures. All other chemicals and solvents were purchased from commercial sources and were used without further purification.

2.2. Preparation of *3*

Compound **4** (4.27 g, 10.5 mmol) was suspended in 25 ml of dry MeOH under Ar. Na (0.63 g, 27.4 mmol) was dissolved in 52 ml of dry MeOH. The NaOMe solution was then added dropwise over a period of 15 min to the suspension of **4**. The resulting dark red solution was stirred for another 30 min. Freshly prepared 2-chloromethylpyrazine (2.70 g, 21.0 mmol) was added at once and the resulting brownish yellow mixture was stirred overnight. The reaction mixture was then extracted twice with $CHCl_3$ and CH_2Cl_2. The organic phases were collected, dried over $MgSO_4$ and the filtrate was evaporated under reduced pressure. Purification of the brownish oil by column chromatography eluting with a gradient of 0–100% EtOAc in CH_2Cl_2 yielded compound **3** as brownish oil. Yield: 0.85 g (49%). *Anal.* Calc. for $C_{13}H_{10}N_4S_5$: C, 40.81; H, 2.63; N, 14.64. Found: C, 40.67; H, 2.54; N, 15.42%. ^{1}H NMR (ppm): δ 4.12 (s, 4H), 8.53 (m, 6H). ^{13}C NMR (ppm): δ 39.6, 137.0, 143.9, 144.3, 144.5, 151.8, 210.4. Selected IR data (cm^{-1}, KBr pellet): 3038, 3006, 2974, 1665, 1577, 1527, 1473, 1401, 1308, 1217, 1186, 1115, 1065, 1018, 887, 837, 763, 516. Mass spectrum (FAB) *m*/*z*: 383 $(\mathbf{3})^+$.

2.3. Preparation of *1*

Compound **1** was synthesized according to the literature procedure for the preparation of the pyridyl analogue [15].

Compounds **3** (0.99 g, 2.6 mmol) and **2** (1.31 g, 5.1 mmol) were refluxed for 2 h in 25 ml of $P(OEt)_3$ at 110 °C under Ar. The mixture was then cooled to 0 °C and the orange precipitate was filtrated off and washed with cold MeOH. The precipitate was dried over P_4O_{10} under vacuum and purified by column chromatography eluting with a gradient of 0–100% EtOAc in CH_2Cl_2. Yield: 0.92 g (57%). *Anal.* Calc. for $C_{22}H_{18}N_6S_8$: C, 42.42; H, 2.91; N, 13.49. Found: C, 42.39; H, 2.96; N, 13.04%. ^{1}H NMR (ppm): δ 2.75 (t, $J = 7$ Hz, 4H), 3.09 (t, $J = 7$ Hz, 4H), 4.04 (s, 4H), 8.50 (m, 6H). ^{13}C NMR (ppm): δ 18.9, 31.3, 39.5, 109.2, 113.0, 117.4, 128.1, 129.3, 143.5, 144.4, 144.6, 152.3. Selected IR data (cm^{-1}, KBr pellet): 2925, 2855, 2250 (CN), 1731, 1668, 1527, 1474, 1401, 1307, 1282, 1216, 161, 1113, 1056, 1018, 888, 838, 772. Mass spectrum (ESI) *m*/*z*: 621.94 $(\mathbf{1})^+$, 528.83 (**1**-methylpyrazyl)$^+$.

2.4. Preparation of the CT compound $(\mathbf{1}_2)^{2+}[(I_2)_{3/2}I^-]_2 \cdot 2CH_2Cl_2$

The black crystals of the charge-transfer salt of **1** with I_2 were obtained by layer diffusion. 5 ml of a 2 mM clear solution of **1** in CH_2Cl_2 were successively superposed by layers of 2 ml of pure CH_2Cl_2, 2 ml of pure hexane and 5 ml of a 4 mM solution of I_2 in hexane. Crystals were grown within 2 days at 5 °C. *Anal.* Calc. for $C_{22}H_{18}I_4N_6S_8 \cdot CH_2Cl_2$: C, 22.73; H, 1.66; N, 6.91. Found: C, 22.38; H, 1.53; N, 6.75%.

2.5. Physical measurements

All ^{1}H NMR and ^{13}C NMR spectra were measured in $CDCl_3$ at 300 and 75.5 MHz, respectively. FT-IR data were collected on a Perkin–Elmer Spectrum One spectrometer at a resolution of 1 cm^{-1}. Elemental analyses were performed on an EA 1110 Elemental Analyzer CHN Carlo Erba Instruments. Cyclic voltammetric measurements were conducted on a Metrohm VA-Stand 663 electrochemical analyser. Conductivity measurements were made with the standard four-probe technique. Mass spectra were recorded on a Micromass AutoSpec spectrometer using FAB or ESI. Magnetic susceptibility data of the polycrystalline sample were collected with a Quantum Design SQUID magnetometer (XL5S) equipped with a 50 kG magnet and operating in the temperature range 1.8–300 K. Pascal's constants were used for the diamagnetic correction.

2.6. X-ray structural analyses

A single crystal ($0.36 \times 0.80 \times 0.04$ mm) of the title compound $(\mathbf{1}_2)^{2+}[(I_2)_{3/2}I^-]_2 \cdot 2CH_2Cl_2$ was mounted on a Nonius four circle diffractometer equipped with a CCD camera and a graphite monochromated Mo Kα radiation source

($\lambda = 0.71073$ Å). Effective absorption correction was performed (SCALEPACK) [16]. The structure was solved with direct method using SHELXS-97 and refined with full-matrix least-squares method on F^2 using SHELX-97 programs [17]. Crystallographic data: Triclinic, space group $P\bar{1}$, $a = 10.9642(3)$ Å, $b = 11.6722(4)$ Å, $c = 16.4413(8)$ Å, $\alpha = 91.690(1)°$, $\beta = 98.031(1)°$, $\gamma = 113.591(3)°$, $V = 1900.9(1)$ Å^3, $Z = 2$, $T = 293(2)$ K, μ(Mo Kα) = 3.816 mm^{-1}, $D_{calc} = 2.10$ g cm^{-3}, 12426 reflections measured of which 6302 unique ($R_{int} = 0.0319$), $R(F^2) = 0.0604$ [4467 data with $I > 2\,\sigma(I)$], $wR(F^2) = 0.1784$. Complete crystal structure results as CIF files including bond lengths, bond angles and atomic coordinates are deposited as Supplementary materials.

3. Results and discussion

3.1. Synthesis and characterization

For the synthesis of the asymmetrically functionalized donor ligand **1**, the generally adopted strategy via the triethylphosphite mediated coupling of two appropriate chalcogenone precursors was used, as depicted in Scheme 1. The precursor **3** was prepared according to the procedure for the preparation of 4,5-bis(2-pyridylmethylsulfanyl)-1,3-dithiole-2-thione [18]. Compared to the pyridyl analogue, the slightly lower yield of **3** is mainly due to the thermal instability of 2-chloromethylpyrazine which slowly decomposes at room temperature [14] and thus should be freshly prepared prior to use. Although the coupling reaction frequently suffers from disadvantages such as low yield or tedious separations [19], the target compound **1** could be prepared from its corresponding precursors in reasonable yield comparable to other typical phosphite mediated coupling reactions [15,20]. All compounds have been characterized by ^{1}H NMR, ^{13}C NMR, elemental analysis and mass spectrometry and are in agreement with the proposed structures (Scheme 1). In the IR spectrum of **1** the intense absorption band at 2250 cm^{-1}, corresponding to CN vibrations, is clearly visible. Due to the good solubility in chloroform even the quaternary C atoms of the inner (109.2 and 113.0 ppm) and outer double bonds (128.1 and 129.3 ppm) of the TTF core could be detected in the ^{13}C NMR spectrum.

Although the neutral donor is very soluble in common organic solvents, no single crystals of X-ray quality have been obtained yet. Nevertheless, compound **1** can readily be oxidized by iodine, affording the CT complex $(\mathbf{1}_2)^{2+}$-$[(I_2)_{3/2}I^-]_2 \cdot 2CH_2Cl_2$ which crystallizes as black rod-like crystals.

3.2. Electrochemical measurements

The solution redox properties of the new donor ligand **1** were investigated in dichloromethane by cyclic voltammetry (CV). The CV data are presented in Table 1 together with those of bis(ethylenedithio)tetrathiafulvalene (ET) [21] and 4,5-bis(cyanoethylthio)-4′,5′-(ethylenedithio)tetrathiafulvalene (BCET-ET) [20] for comparison. In each case the two typical reversible single-electron redox couples are observed, corresponding to the sequential formation of the stable TTF radical cation and the dication. Compared to ET and BCET-ET, attachment of the cyanoethyl protection groups and the pyrazine units in compound **1** increases mainly the first redox potential due to the electron-withdrawing effect of these groups [21]. The second potential remains almost unaffected.

Table 1
Cyclic voltammetric data[a]

Compound	$E_1^{1/2}$ (V)	$E_2^{1/2}$ (V)	ΔE (mV)
ET	0.52	0.94	420
BCET-ET	0.60	0.98	380
1	0.69	0.97	280

[a] All oxidation potentials were determined under N_2 in CH_2Cl_2 vs. Ag/AgCl at room temperature. Measurements have been done at a scan rate of 100 mV s^{-1} using 0.1 M Bu_4NPF_6 as electrolyte and Pt as working electrode.

3.3. Crystal structure

The ORTEP drawing of the asymetric unit of compound $(\mathbf{1}_2)^{2+}[(I_2)_{3/2}I^-]_2 \cdot 2CH_2Cl_2$, which crystallizes in the triclinic space group $P\bar{1}$, is shown in Fig. 1(a). The asymmetric unit

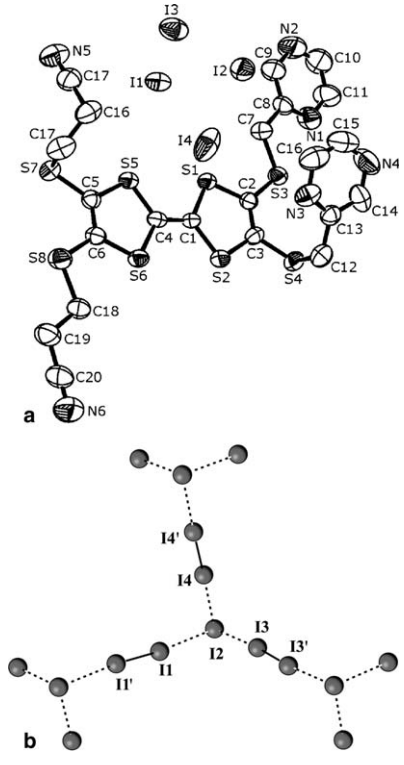

Fig. 1. (a) ORTEP representation of the asymmetric unit of $(\mathbf{1}_2)^{2+}$-$[(I_2)_{3/2}I^-]_2 \cdot 2CH_2Cl_2$, ellipsoids are drawn at 50% probability; C1–C4 1.37(1), C1–S1 1.726(8), C1–S2 1.721(8), C2–S1 1.750(9), C3–S2 1.740(9), C4–S6 1.743(8), C4–S5 1.710(9), C5–S5 1.732(9), C6–S6 1.725(9), C2–C3 1.33(1), C5–C6 1.34(1) Å; (b) iodine connectivity, I2–I1 3.427(1), I2–I3 3.448(1), I2–I4 3.467(2), I1–I1′ 2.768(1), I3–I3′ 2.789(2), I4–I4′ 2.830(3) Å. Hydrogen atoms and solvent molecules are omitted for clarity.

contains one donor molecule $\mathbf{1}^{\cdot+}$, 3/2 molecules I_2, one I^- and one solvent molecule. The donor molecule exhibits no unusual structural parameters (for selected bond distances see Fig. 1(a)). Nevertheless, it is worth mentioning that the central C=C bond length (1.37(1) Å) of the TTF unit is slightly larger than that of the neutral pyridyl analogue (1.34(1) Å) [15] which, however, is in accordance with its oxidized state.

The crystal structure is built up by layers of head-to-tail dimers of $\mathbf{1}^{\cdot+}$ which are embedded in a 2D polyiodide network, as illustrated in Fig. 2. Disordered solvent molecules (dichloromethane) are located inbetween the layers.

The 2D polyiodide network exhibits an interesting topology. Four crystallographically independent iodine atoms form a trigonal pyramid with I2 as vertex and I1, I3, I4 as the triangular base. The distances between the vertex (I2) and the other three atoms (I1, I3, I4) are in the range of 3.42–3.47 Å (Fig. 1(b)). These trigonal pyramids are connected through the iodine atoms of the bases to form a 2D grid of 18-membered hexagonal rings in chair conformation parallel to the *ab*-plane (Fig. 2). The I–I distances between two adjacent pyramids range from 2.77 to 2.83 Å (Fig. 1(b)). This particular iodine arrangement can also be described as aggregates consisting of I_2 units (I1–I1′, I3–I3′ and I4–I4′) and iodide $(I2)^-$. Consequently, per formula unit, the overall iodine/iodide stoichiometry can be given as $[(I_2)_{3/2}I^-]_2$ and regarded as a special case of an octaiodide I_8^{2-} which usually consists of two I_3^- units connected through an I_2 molecule [22]. Indeed, the structure looks very similar to the one found in $[Co(urea)_6]I_8$ where distinguishable Z-shaped octaiodides with contact distances of 3.75 and 3.93 Å build up an analogous hexagonal honeycomb structure [23]. However, in the present case all contact distances are in the range of secondary I···I bonds (3.4–3.7 Å) [22] and are symmetrically arranged so that specific I_8^{2-} units cannot be recognized and the overall structure is best described as an infinite two-dimensional polyiodide network [11].

The dimers of $\mathbf{1}^{\cdot+}$ are located inside the hexagonal meshs (Fig. 3(a)). The S–S contacts between the donor molecules of a dimer (3.41–3.55 Å) are shorter than the sum of the van der Waals radii (3.60 Å) [24], reflecting the formation of spin-paired π-dimers [25] (Fig. 3(b)). This is confirmed by a magnetic measurement of the CT compound which shows only a diamagnetic behaviour corresponding to a total $S = 0$ spin state. Finally, a conductivity measurement revealed that the resistivity was too high (>1.5 GΩ cm) to be measured by the specific instrumental set-up. This is in a good agreement with the large distances (more than 7 Å) between neighbouring dimers as determined by X-ray structure analysis.

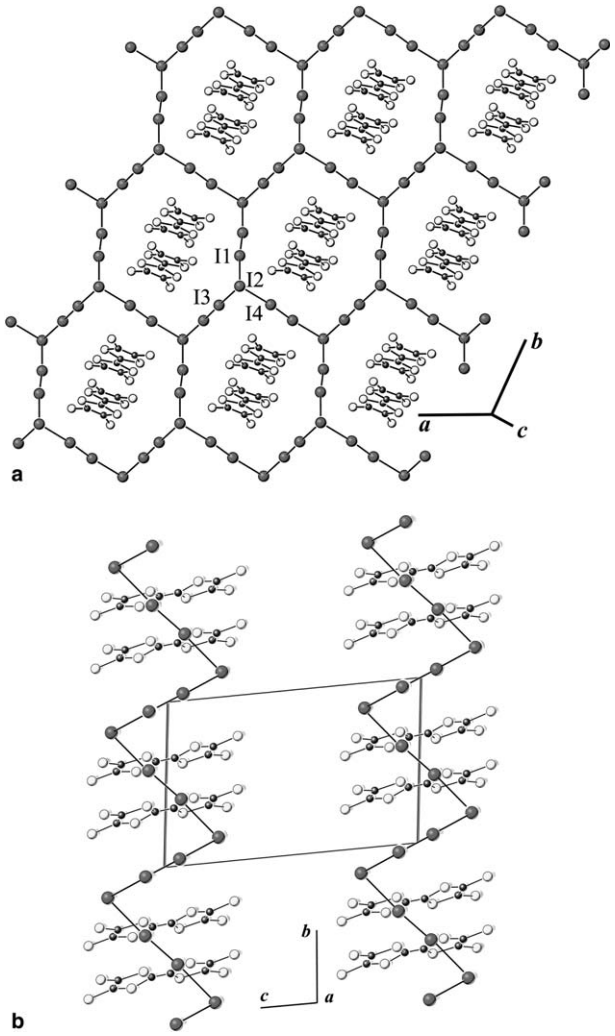

Fig. 2. (a) 2D iodide grid with embedded dimers of oxidized compound $\mathbf{1}^{\cdot+}$; (b) crystal packing of $(\mathbf{1}_2)^{2+}[(I_2)_{3/2}I^-]_2 \cdot 2CH_2Cl_2$. Hydrogen atoms, solvent molecules, methylpyrazine and $-(CH_2)_2CN$ groups are omitted for clarity.

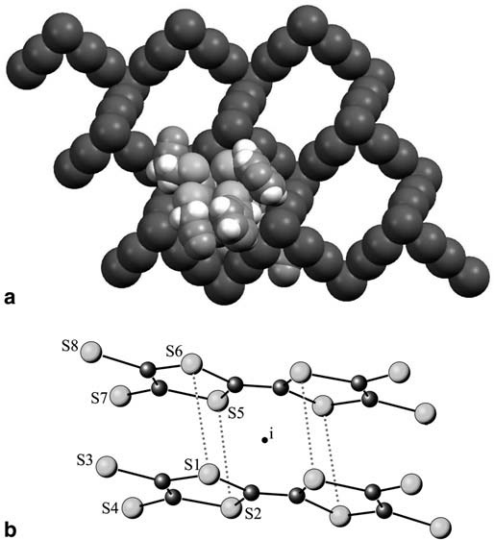

Fig. 3. (a) Space filling representation of the hexagonal polyiodide meshs with embedded dimer of $\mathbf{1}^{\cdot+}$; (b) intradimer S···S contacts: S1–S6 3.542(3), S2–S5 3.412(3) Å.

4. Conclusion

The oxidation of the new donor ligand **1** with iodine resulted in the formation of a CT-compound where the radical cations of **1** form spin-paired π-dimers. The embedding of these dimers in layers of regular 2D honeycomb like grids formed by the unique $[(I_2)_{3/2}I^-]$ units is responsible for the insulating property of this compound.

The ability to bind transition metal ions and the formation of charge transfer complexes and radical salts of this new donor **1** are currently under investigation in our laboratory.

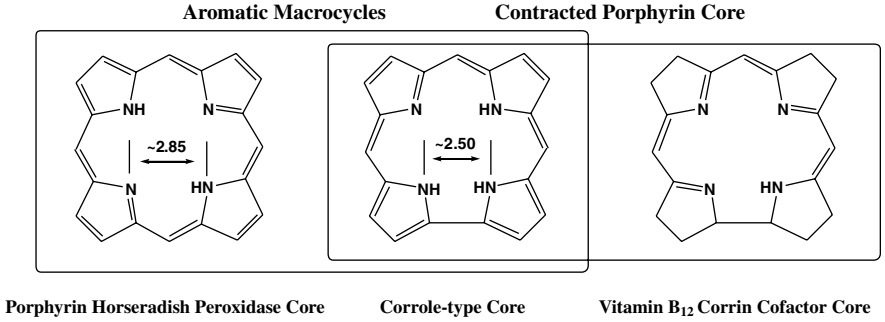

Fig. 1. A comparison of porphyrin derivative metal binding cores.

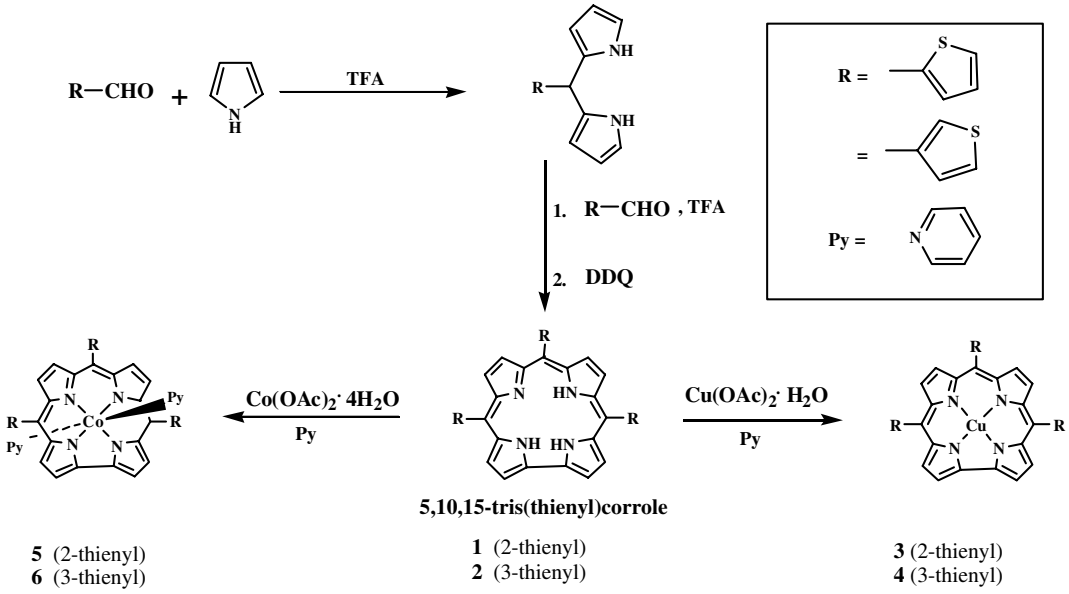
pentafluorophenyl group substitution at the *meso* positions of the corrole. Metalloporphyrins bearing thienyl substituents on all *meso* groups (tetrathienyl-substituted) have been reported in which the metal is copper [30,31] or cobalt [32]. Thus, studying metallocorroles with thienyl substitution allows us to probe the steric and electronic effects at the metal site [28,33]. Presence of peripheral sulfur groups may furthermore open the possibility for subsequent metal ion binding and allow for supramolecular assemblies.

Thienyl group substituents are comparable to phenyl substitution and are far removed from the electron withdrawing capacity of the pentafluorophenyl group. However, this can be evaluated by electrochemical studies and a consideration of Hammett parameters. We have recently reported the synthesis and crystallographic structures of both 5-(thienyl)dipyrromethane isomers [34]. Thus, herein we describe the synthesis and full characterization of new 5,10,15-tris(thienyl)metallocorroles by techniques that include single-crystal X-ray diffraction, spectroscopy, mass spectrometry, and cyclic voltammetry. Importantly, the molecular structures of 2-thienyl metallocorrole complexes of copper and cobalt, and the 3-thienyl cobalt corrole have been obtained (see Scheme 1).

2. Results and discussion

2.1. Synthesis

Both free base thienyl corroles were prepared from the respective dipyrromethanes and aldehydes using general conditions previously developed for sterically unhindered dipyrromethanes [35]. In particular, the reaction between 5-(2-thienyl)dipyrromethane or 5-(3-thienyl)dipyrromethane [34] and thiophene carboxyaldehyde occurs with the addition of a catalytic amount of TFA; subsequent addition of DDQ gives the green fluorescent 5,10,15-tris(2-thienyl)corrole and 5,10,15-tris(3-thienyl)corrole, respectively (Scheme 1). Both copper complexes **3** and **4** were obtained by the reaction of the corresponding 5,10,15-tris(thienyl)corrole with excess $Cu(OAc)_2 \cdot H_2O$ in pyridine solution at room temperature. This synthetic step is very low yielding in the overall scheme providing ca. 3%



Scheme 1. Preparation of 5,10,15-tris(thienyl)corroles and their corresponding copper complexes and cobalt bis-pyridine complexes.

of free base. The direct synthesis of such corroles from aldehydes and pyrrole was not achievable in our hands.

Metallation occurs rapidly and accompanied by a visible color change. The corresponding reddish-brown copper complexes were obtained within 20 min with yields of ca. 90%. Both cobalt complexes **5** and **6** were obtained by the reaction of the corresponding 5,10,15-tris(thienyl)corrole with excess $Co(OAc)_2 \cdot 4H_2O$ in a refluxing pyridine solution for an overall yield of ca. 90%.

The stability of complexes **3**–**6** are notable in contrast to some related copper and cobalt systems with the electron withdrawing $-C_6F_5$ groups at the three *meso* positions [8,11]. For the copper species, there is no green component in the reaction mixture as in the tris-pentafluorophenyl-substituted corrole reported by Gross and coworkers [8]. The solution containing the copper complexes remains reddish-brown after one week at RT and in the absence of light. This points to an enhanced stability towards C–C coupling compared to the trispentafluorophenyl corroles and has furthered our interest in these derivatives [8,11]. Thus, CV data and diffraction studies have been obtained and are presented and discussed below to attempt to understand the unique properties of thienyl substitution.

2.2. Structural studies

We have conducted single-crystal X-ray diffraction studies of Cu(T2TC) (**3**), Co(T2TC)$(Py)_2$ (**5**) and Co(T2TC)$(Py)_2$ (**6**) (Tables 1 and 2). Complex **3** was found to crystallize in the monoclinic space group $C2/c$ with the cell parameters: $a = 10.374(13)$ Å, $b = 23.21(3)$ Å, $c = 20.625(17)$ Å, $\beta = 95.53(5)°$, $V = 4942(9)$ Å^3, and contained no solvent of crystallization. The cell parameters for the analogous tris-substituted 3-thienyl derivatives **5** and **6** are as follows: (**5**), triclinic, $P\bar{1}$, $a = 11.6509(13)$ Å, $b = 12.4878(14)$ Å, $c = 15.4676(18)$ Å, $\alpha = 98.237(2)°$, $\beta = 105.613(2)°$, $\gamma = 106.376(2)°$, $V = 2020.1(4)$ Å^3; (**6**) triclinic, $P\bar{1}$, $a = 9.705(4)$ Å, $b = 11.745(5)$ Å, $c = 16.401(6)$ Å, $\alpha = 101.298(7)°$, $\beta = 95.059(7)°$, $\gamma = 112.872(7)°$ and $V = 1661.0(11)$ Å^3, $Z = 2$. The solution for **5** and **6** contained two axial pyridine ligands and a benzene solvent of crystallization in the case of **5**. The molecular structures and packing diagrams for compound **3** are provided in Figs. 2 and 3; these diagrams for compounds **5** and **6** are found in Figs. 5–8. The crystallographic data for **3**, **5** and **6** is summarized in Table 3.

The *meso* aryl groups are often found approximately normal to the corrole plane. For the thienyl groups, there is a wide range of $C_{pyrrolyl}$–C_{meso}–C_{ipso}–$C_{thienyl}$ dihedral values. For the copper compound, the angles were ca. 26°, 43° and 53° showing great flexibility of the thienyl moiety. Additionally, these angles for the cobalt complex **5** were ca. 52°, 86° and 87° and for **6** were ca. 55°, 60° and 80°, showing that the thienyl group may contribute partially to corrole core conjugation. Rotational fluxionality is further supported by NMR studies provided below.

The measurements of copper corrole cores of those structurally characterized to date are compared in Fig. 4. All examples lack axial substituents, in contrast to the cobalt complexes presented hereafter.

As illustrated in Fig. 4, copper corrole core measurements are similar, irrespective of peripheral substitution and define a Cu sitting between the four nitrogens that are in a distorted square with all Cu–N bonds 1.87–1.89 Å. The short N···N distance in the distorted square is 2.46 Å and the opposing side is 2.83 Å – a difference of ca. 0.4 Å that is accommodated by the sides of ca. 2.70 Å. These geometric similarities suggest differences that lead to dinuclear products as in the *meso*-5,10,15-trispentafluorophenylcorrole may be mainly electronic in nature.

Molecular structures of cobalt corrole compounds number 14 to date in which almost all of these structures have been characterized as a complex containing a central cobalt of formal oxidation state III. There are structural examples in which the cobalt oxidation state has been assigned as IV

and V [36,37]. Interestingly, the axial pyridine groups in Figs. 5 and 7 are nearly orthogonal to each other. Structures in which orthogonality and near coplanarity have been previously reported [11,38,39].

2.3. NMR spectroscopy

To probe the dynamics of our systems, variable temperature NMR spectra have been obtained for complexes **3** and **4**. Variable temperature stack plotted ^{1}H NMR data are provided below, obtained between the temperatures of −50 and 60 °C (Figs. 9 and 10). Noteworthy is the difference in spectral signal broadening over this range. This is thought to be due exclusively to the different rotational conformations in the metallocorroles of the thienyl groups whose rotations are on the time scale of NMR at the temperature of the studies, not due to the change in electronics of the Cu core [6]. ^{1}H NMR spectra, below room temperature feature broad signals. This same shifting is apparent in the free corrole base. Upon complexation, there is a slight degree of up-field shifting with respect to metal free corroles. High temperature ^{1}H NMR spectra of the Cu complexes appear more resolved [40]. These data indicate that the diamagnetic square planar d^8 complexes with low spin Cu(III) ions coordinated by closed-shell corroles. Our studies in $CDCl_3$ solvent precluded examining beyond these minimum and maximum temperatures.

In the cobalt complex, the proton signals of the *trans* axial pyridines in a 2:4:4 ratio are all up-field shifted perhaps due to the formation of diamagnetic current-effect of the corroles in the complexes [11]. With the common $-C_6F_5$ substituent, there is greater bulk and greater symmetry which does give rise to broadening, but the proton spectrum of the species is simplified.

In addition to these obtaining NMR, all compounds were characterized by UV–vis spectra. Porphyrinoids and corresponding metal complexes give rise to a Soret band, the strong ligand based π–π^* electron transition. These bands for compounds **1**–**6** appear in Table 4. The sulfur atom that is changed from the α-(2-thienyl) to the β-(3-thi-

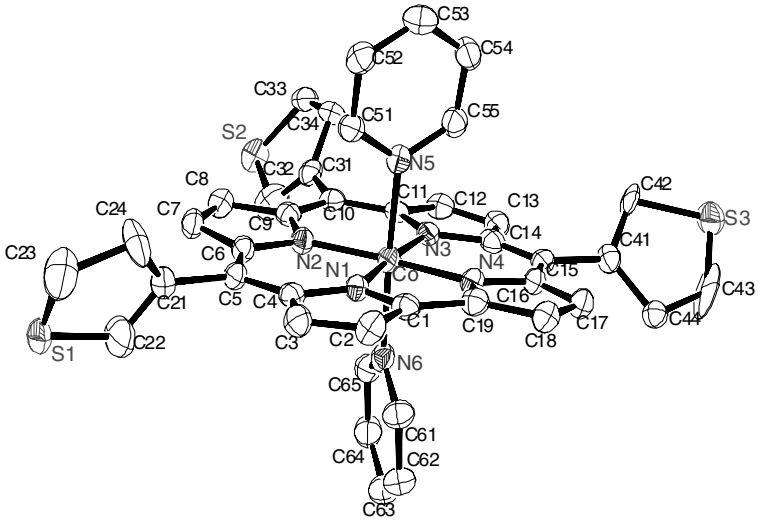

Fig. 7. Molecular structure of Co(T3TC)(Py)$_2$ (**6**). Thermal ellipsoids are shown at the 50% level. Hydrogen atoms have been removed for clarity.

The values for the porphyrins exhibit the same trend at H_2(T2TP): 426 (5.59) and H_2(T3TP) 421 (5.76) [30]. Upon copper complexation, the bands are red shifted keeping an isomeric separation of 21 nm; the corresponding porphyrin system yields a separation of 3 nm [30]. The cobalt metallocorrole isomeric difference is 8 nm.

2.4. Mass spectrometry

Further data have been obtained to support the enhanced stability of metallocorrole compounds **3**, **4**, **5** and **6** towards C–C coupling, as compared to the $–C_6F_5$ substituted systems. The mass spectra of the copper isomer complexes **3** and **4** show no degree of C–C dinuclear coupling, and the isolated material for the Co isomers shows small observable peaks by high resolution mass spectrometry (see mass spectra provided in the Supporting Information). The monomers seem markedly more stable at room temperature than the corresponding $–C_6F_5$ systems. The [$(\mathbf{3})_2$-2H] products that these signals suggest were not isolated, but only characterized by mass spectrometry but thought to be the same C–C coupling species as those seen by Gross and coworkers [8]. Compared to the $–C_6F_5$ substituted systems, coordinating solvents for these systems were not required. The cobalt compound was further purified by preparative TLC before performing the cyclic voltammetry studies provided below. Material for these studies was made possible through the recrystallization of cobalt crystals with a DCM and *n*-heptane mixture.

2.5. Electrochemistry

The cyclic voltammograms (CVs) of the 5,10,15-tris(thienyl)corrole ligands (**1** and **2**) and their corresponding complexes (**3**, **4**, **5** and **6**) have been obtained and are presented below. Their redox potentials are also provided (Fig. 11).

The reversible half-wave potentials ($E_{1/2}$) for Cu(T2TC) are −0.57 and 0.27 V. The potential at 0.27 V, compares to the oxidation potential of metal-free corrole [$E_{1/2} = 0.15$ V] and has been assigned to corrole-centered oxidation, while the reduction potential at −0.57 V has been assigned to the metal center. The difference in this redox couple ($E_{1/2(ox)} - E_{1/2(red)}$; 0.84 V) also indicates that the two different centers are involved for reduction and oxidation processes (see Table 5).

$$(T2TC)Cu^{II} \underset{-e^-}{\overset{+e^-}{\rightleftharpoons}} (T2TC)Cu^{III} \underset{+e^-}{\overset{-e^-}{\rightleftharpoons}} (T2TC^{\bullet+})Cu^{III} \quad (1)$$

The one-electron oxidation of the 5,10,15-tris(2-thienyl)corrole ligands (**1**) is similar to that of the 5,10,15-tris(3-thienyl)corrole ligands (**2**). The 5,10,15-tris(2-thienyl)corrole ligand (**1**) and its metal complexes (**3** and **5**) have more positive redox potentials than those of the corresponding 3-thienyl ligand (**2**) and its metal complexes (**4** and **6**) because of the greater electron-withdrawing power of 5,10,15-tris(2-thienyl)corrole ligands. This is further supported by a consideration of Hammett and Modified Swain-Lupton Constants (Table 6). Sulfur oxidation has not fully been ruled out in this case. Lastly, these systems are not directly analogous to the corresponding tetrathienyl porphyrin derivatives in that the porphyrin systems undergo two oxidations and two reductions each [30].

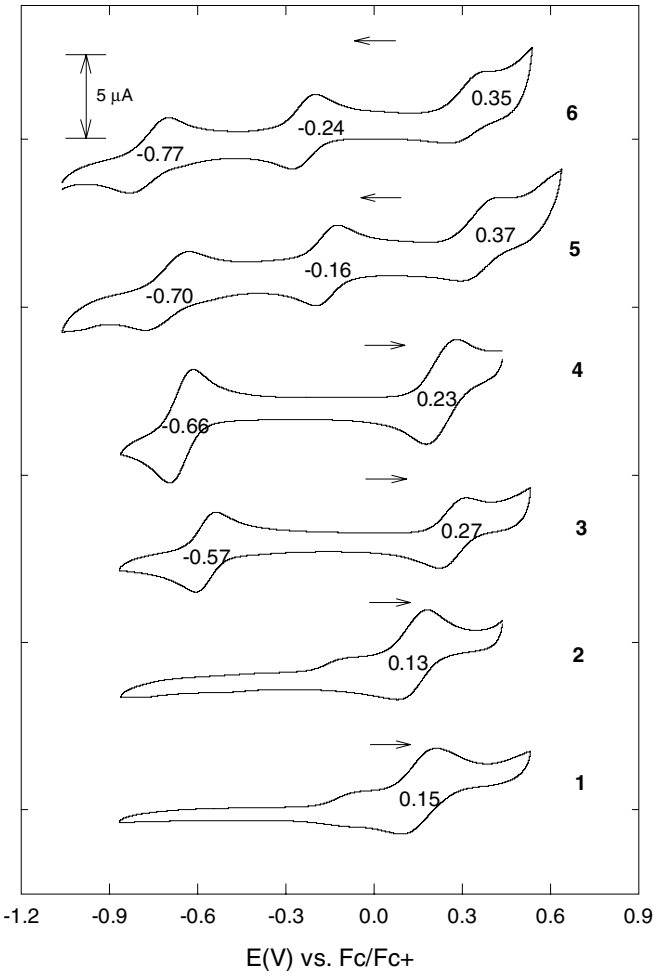

Fig. 11. The cyclic voltammograms of 1 mM 5,10,15-tris(thienyl)corrole ligands (**1** and **2**), 1 mM copper(III) 5,10,15-tris(thienyl)corrole (**3** and **4**), and 1 mM cobalt(III) 5,10,15-tris(thienyl)corrole (**5** and **6**) in benzonitrile solution, 0.1 M TBAP at a scan rate of 100 mV/s (second scans are provided only). $E_{1/2}$ (V) values are provided for each species.

As compared with the copper corroles, the species Co(T2TC)$(py)_2$ (**5**) and Co(T3TC)$(py)_2$ (**6**) have two reduction steps (Fig. 11). This is in contrast to the previously reported Co(tpfc)PPh_3 derivative which exhibits an irreversible reduction process [11]. Co(tpfc)PPh_3 loses a PPh_3 group during the reduction process and then changes to a bis-pyridine coordinated complex. In the case of **5** and **6**, there is an absence of phosphine, and there is excess pyridine; thus, the pyridines present at the outset of the

voltammetric measurement are believed to be retained throughout the course of the experiment. As compared with the copper corrole complexes (**3** and **4**), the cobalt corrole complexes (**5** and **6**) have a more positive oxidation and more negative metal-centered reduction. That means corrole-centered oxidation and metal-centered reduction of cobalt corrole complexes is more difficult than their corresponding copper corrole complexes.

Firstly, *meso* substituents in metallocorroles exert a strong influence on the half-wave potential for one-electron oxidation and this potential is shifted from 820 mV to ca. 270 mV, when the *meso* substituents vary from pentafluorophenyl to thienyl groups. This large decrease in potential shift ca. 550 mV suggests that the removal of an electron is from the corrole "HOMO" [28]. It is easier for thienyl-substituted corroles to be oxidized than the pentaflurophenylphenyl analogs (Table 5) [28].

C–C bond coupling of metallocorroles through the β-carbon in solution has been considered an electronic effect when comparing like tris-*meso*-substituted metallocorroles. Again we see less evidence for corrole oxidation in these thienyl-substituted systems than for tris-pentafluoro derivatives. Thus, Hammett parameters for the various substituents can be discussed. The values for both 2- and 3-thienyl systems are quite similar and can be discussed in connection to electrochemical differences. The Hammett constants (σ) for pentafluorophenyl (pfp)/pentachlorophenyl (pcp) groups are higher than that of 2-thienyl/3-thienyl groups in terms of the ionizations of benzoic acid and *meta*-substituted benzoic acid. Furthermore the electronic effects, i.e. field effects (F) and resonance effects (R) of pfp and pcp substituents are higher than those of both thienyl substituents. By comparing electronic effects with metallocorrole, pfp/pcp groups at the 3-position are more electron withdrawing than the thienyl groups. The 2,6-dichlorophenyl group, though of greater bulk than the thienyl groups, has a greater electron withdrawing effect. C–C coupling is prominent for electron withdrawing substituents at the *meso* positions of metallocorroles but is not necessarily due to the bulkiness of the groups.

3. Conclusions

We have reported novel *meso*-substituted thienyl corroles and the respective metallocorroles for copper and

cobalt. These new derivatives allow for the investigation of compounds electrochemically for coordination and thiophene–thiophene coupling to form macromolecular arrays. Cu(T2TC), Co(T2TC)$(Py)_2$ and Co(T3TC)$(Py)_2$ have been structurally characterized. Dimerization of metallocorroles in solution depends on the electronic effects of the substituents at *meso* positions which are revealed through cyclic voltammetry, NMR and UV–vis spectroscopic data. More electron withdrawing groups tend to give coupling through β-carbons. The bulkiness of the aromatic group is thought to be important. But the thienyl groups are less electron withdrawing than the commonly studied pentafluorophenyl substitutions. Our cyclic voltammetric data support a single oxidation/reduction, devoid of C–C coupling dinuclear products. UV data allow for Soret bands for all ligands and complexes to be measured and indicate red shifting upon metal complexation. One of our strong research motivations involves exploring peroxidase reactivity in related iron systems.

4. Experimental

4.1. General considerations

All solvents and chemicals used in the following synthetic steps were of analytical grade and were used as received: i.e., 2-thiophene carboxyaldehyde, 3-thiophene carboxyaldehyde, pyrrole, $Cu(OAc)_2 \cdot H_2O$, $Co(OAc)_2 \cdot 4H_2O$, pyridine, and C_6H_5CN (Aldrich), dichloromethane, hexane, $MgSO_4$, EtOAc (Merck) and TBAP (Fluka). TBAP was dried overnight under vacuum at 70 °C prior to use. All solvents used for NMR spectral analysis were purchased commercially and were of spectroscopic grade. Infrared spectra were recorded with a Bruker Equinox 55 spectrophotometer and UV–vis spectra were with JASCO V-503 UV–vis spectrometer. A Vario EL III CHNS elemental analyzer was used for microanalysis. High-resolution MALDI mass spectrometry was performed by the staff of the research supporting team at KAIST on a VG AUTOSPEC ULTIMA with a trisector double focusing magnetic sector analyzer at a resolution of 80 000.

^1H spectra were measured in $CDCl_3$ with Bruker Avance 300 and Bruker Avance 400 spectrometers. Variable temperature ^1H NMR spectra were performed in $CDCl_3$ at temperatures between and including −50 and 60 °C. At each temperature, thermal equilibration time was monitored automatically. Spectral signals were calibrated by the protio impurity of the $CDCl_3$ solvent. The synthetic details for the preparation of 5(2-thienyl)dipyrromethane and 5(3-thienyl)dipyrromethane have been reported previously [34,42].

4.2. Physical methods

Cyclic voltammetry was carried out with a BAS 100B (Bioanalytical Systems, Inc.). A three-electrode system was used and consisted of a gold disk working electrode, a platinum wire counter electrode, and a Ag/Ag^+ electrode (MF-2062 kit, Bioanalytical Systems, Inc.) as the reference electrode. The Ag/Ag^+ contained 0.1 M tetrabutylammonium perchlorate (TBAP) and 0.01 M $AgNO_3$ in benzonitrile. In 0.1 M TBAP, the $E_{1/2}$ of the ferrocene/ferrocenium ion couple was taken to be 0.067 V vs. Ag/Ag^+ in benzonitrile. The values in electrochemical experiments are reported versus the ferrocene/ferrocenium ion redox couple.

4.3. X-ray crystallography of Cu(T2TC), Co(T2TC)$(Py)_2$ and Co(T3TC)$(Py)_2$

Crystals of **3**, **5** and **6** suitable for diffraction were grown by slow evaporation of dichloromethane (**3**) and benzene solution, (**5**, **6**), at room temperature. The single-crystal sizes **3**, **5** and **6** were $0.30 \times 0.03 \times 0.20\ mm^3$, $0.50 \times 0.40 \times 0.30\ mm^3$, and $0.3 \times 0.2 \times 0.2\ mm^3$, respectively. Reflection data for **3**, **5**, and **6** were collected on a Bruker 1 K SMART CCD-based diffractometer with graphite-monochromated Mo Kα radiation ($\lambda = 0.7107$ Å). The hemisphere of reflection data was collected as ω scan frames with 0.3°/frame and an exposure time of 5 s/frame under room temperature conditions. Cell parameters were determined and refined by the SMART program [43]. Data reduction was performed using SAINT software [44]. The data were corrected for Lorentz and polarization effects. An empirical absorption correction was applied using the SADABS program [45]. The structures of the compounds were solved by direct methods and refined by full matrix least-squares methods using the SHELXTL program package with anisotropic thermal parameters for all non-hydrogen atoms. Early into the crystallographic solution it was established that each of the three thienyl moieties in compounds **3** and **6** were disordered by ca. 180° rotation about the C_{meso}–$C_{thienyl}$ vector as evidenced by distortions in the atomic thermal parameters upon least-squares refinement. Thiophene fluxionality was evident from VT NMR data provided below, and thus crystallographic disorder was anticipated and has been observed also in the structural solutions for the dipyrromethane precursors [34]. To obtain the molecular structures of **3** and **6** satisfactorily, modeling of this disorder was undertaken and involved creating atomic coordinates for a second thienyl group; both parts were refined to nearly half occupancy. Additionally, the carbon atoms in the benzene solvent molecule of crystallization (in the crystallographic solution for **4**) were refined with the ISOR command in which a given standard deviation is assigned and allows the atomic thermal parameters to approximate isotropic behavior.

4.4. Preparation of 5,10,15-tris(2-thienyl)corrole [H_3(T2TC)]

A sample of 5(2-thienyl)dipyrromethane (1.00 g; 4.38 mmol) and 2-thiophene carboxyaldehyde (0.245 g; 2.19 mmol) were added to 150 mL of a dichloromethane solution of TFA (0.13 mM). The reaction mixture was

standing for 6 h at room temperature. The colour of the solution changed from yellow to pink-red. DDQ (1.0 g, 4.4 mmol) in 50 mL toluene was added during a 10 min period with vigorous stirring. Stirring was continued for an additional 15 min. The reaction mixture was then concentrated and filtered twice through a pad of silica gel using CH_2Cl_2 as the eluent, followed by preparative TLC separation (CH_2Cl_2/hexane 1:1). A broad dark green band was collected as pure corrole (71 mg, 3.0%). *m/z* ($M + H^+$): 545.08 Calc. 545.11 Obs. IR (KBr; cm^{-1}): 3436; 3361 [ν_{N-H}]. ^1H NMR (δ; $CDCl_3$): 9.10 [br, 2H], 8.87 [br, 2H], 8.72 [br, 4H], 7.96 [br, 2H], 7.83 [br, 4H], 7.54 [br, 3H] at 25 °C. 9.10 [br, 2H], 8.73 [br, 2H], 8.46 [br, 4H], 7.91 [br, 4H], 7.86 [br, 1H], 7.81 [br, 1H], 7.58 [br, 2H], 7.52 [br, 1H] at −50 °C. UV–vis: λ_{max} ($\log\varepsilon/(M^{-1}\,cm^{-1})$) 627 nm (4.25); 588 nm (4.29); 425 nm (5.17) [Soret band]; 286 nm (4.43).

4.5. Preparation of 5,10,15-tris(3-thienyl)corrole [H_3(T3TC)]

The synthetic procedure of H_3(T3TC) is similar to that of H_3(T2TC) using 5(3-thienyl)dipyrromethane and 3-thiophene carboxyaldehyde as a replacement of 5(2-thienyl)dipyrromethane and 2-thiophene carboxyaldehyde, respectively. The yield was 83.5 mg (3.5%). *m/z* (M^+): 544.08 (calc); 544.19 (obs). IR (KBr; cm^{-1}): 3436; 3373 (ν_{N-H}). ^1H NMR (δ; $CDCl_3$): 8.95 [br, 2H], 8.82 [br, 2H], 8.64 [br, 2H], 8.48 [br, 2H], 8.20 [br, 2H], 8.17 [br, 2H], 8.09 [br, 2H], 7.82 [br, 2H], 7.76 [s, 1H] at 25 °C. λ_{max} ($\log\varepsilon/(M^{-1}\,cm^{-1})$) 622 nm (3.84); 581 nm (3.82); 416 nm (4.78) [Soret band]; 281 nm (4.18).

4.6. Preparation of Cu(T2TC)

Copper(II) acetate monohydrate (excess) was added to a 5 mL pyridine solution of H_3(T2TC) (**1**) (33 mg, 0.63 mmol). The reaction mixture was stirred for 30 min at room temperature during which the colour of the solution changed from green to reddish-brown. The volatiles were then removed by reduced pressure using a vacuum line. The crude product was then dissolved in a minimum volume of dichloromethane and purified by silica gel column chromatography. A reddish-brown fraction containing Cu(T2TC) was collected by using a dichloromethane–hexane (1:1 v/v) eluant. Yield 33.4 mg. (91%). *m/z* ($M + H^+$): 605.00 (calc); 605.97 (obs). ^1H NMR (δ; $CDCl_3$): 7.95 [br; 2H], 7.88 [d; 2H; $J = 3.7$ Hz], 7.72 [br, 2H]; 7.58 [d; H; $J = 5.1$ Hz]; 7.55 [d; 2H; $J = 4.6$ Hz], 7.50 [d; 4H; $J = 4.2$ Hz], 7.42 [br, H], 7.22–7.17 [m; 3H] at 60 °C. λ_{max} ($\log\varepsilon/(M^{-1}\,cm^{-1})$) 521 nm (3.80); 442 nm (4.82) [Soret band]; 312 nm (3.91); 270 nm (4.20).

4.7. Preparation of Cu(T3TC)

The synthetic procedure reported above for Cu(T2TC) was used to generate Cu(T3TC), in which H_3(T3TC) was used in place of H_3(T2TC). Yield 33 mg. (90%). *m/z* (M^+): 604.00 (calc); 604.09 (obs). ^1H NMR (δ; $CDCl_3$): 8.06 [br; 2H], 7.71 [d; 2H; $J = 3.71$ Hz]; 7.67 [br; 2H], 7.57 [br, 2H], 7.47 [m, 4H], 7.40 [d, $J = 4.7$ Hz, 2H], 7.35 [d, $J = 4.2$ Hz, 2H]; 7.32 [d, $J = 4.3$ Hz, H] at 60 °C. λ_{max} ($\log\varepsilon/(M^{-1}\,cm^{-1})$) 565 nm (3.71); 539 nm (3.98); 421 nm (5.05) [Soret band]; 268 nm (4.53).

4.8. Preparation of Co(T2TC)(Py)$_2$

An approximate threefold excess of $Co(OAc)_2 \cdot 4H_2O$ was added to a hot pyridine solution of H_2(T2TC) (33 mg; 0.06 mmol) and this reaction mixture was refluxed for 1 h. After this time, the reaction mixture was cooled to room temperature and the solvent and volatiles were removed by rotary evaporation. The green crude product was dissolved in a minimum volume of dichloromethane and then isolated by vacuum-filtration. A large volume of diethyl ether was added to the filtrate and a brown precipitate formed after a 30-min period which was then separated by vacuum filtration. The green filtrate was collected and pure crystalline Co(T2TC)$(Py)_2$ was obtained slow diffusion of dichloromethane into *n*-heptane solvent. Yield 40.05 mg. (87%). *m/z* ($M^+ - 2Py$): 599.99 (calc.); 600.98 (obs). ^1H NMR (δ; $CDCl_3$): 9.21 [d, $J = 4.7$ Hz, 2H] 9.1 [d, $J = 4.3$ Hz, 2H], 8.94 [br, 1H], 8.89 [br, 2H], 7.92 [br, 2H], 7.79 [d, $J = 4.7$ Hz, 2H], 7.74 [br, 1H], 7.70 [d, $J = 4.7$ Hz, 2H], 7.49–7.52 [m, 2H], 7.40–7.43 [m, 1H], 6.08 [t, 2H; *para*-H of pyridine], 5.28 [br, 4H; *meta*-H of pyridine], 2.13 [b, 4H; *ortho*-H of pyridine]. λ_{max} ($\log\varepsilon/(M^{-1}\,cm^{-1})$) 629 nm (4.48); 588 nm (4.20); 549 nm (4.04); 446 nm (4.96) [Soret band]; 418 nm (4.72); 314 nm (4.43) (in the presence of excess Py).

4.9. Preparation of Co(T3TC)(Py)$_2$

The synthetic procedure of Co(T3TC) $\cdot$ $(Py)_2$ is similar to that of Co(T2TC)$(Py)_2$ using H_3(T3TC) as a replacement of H_3(T2TC). A yield of 42 mg (91%) was obtained. *m/z* ($M^+ - 2Py$): 599.99 (calc); 600.09 (obs). ^1H NMR (δ, $CDCl_3$ RT): 9.32 [2H]; 9.22 [2H]; 9.11 [2H]; 9.07 [2H]; 8.09 [2H]; 7.92 [3H]; 7.82 [1H]; 7.21–7.27 [m, 3H]; 4.81 [b, 2H; *para*-H of pyridine], 4.39 [b, 4H; *meta*-H of pyridine], 2.54 [b, 4H; *ortho*-H of pyridine]. λ_{max} ($\log\varepsilon/(M^{-1}\,cm^{-1})$) 629 nm (4.49); 584 nm (4.04); 543 nm (3.87); 455 nm (4.78); 438 nm (4.85) [Soret band]; 400 nm (4.57); 309 nm (4.33) (in the presence of excess Py).

5. Supporting information

(i) Cif files of the crystallographic determinations of **3**, **5** and **6**: files CCDC-273811, CCDC-273812, and CCDC-277370 are included. These data are available without cost at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data center (CCDC), 12 Union Road, Cambridge CB2 IEZ, United Kingdom; fax +44(0)1223 336033; e-mail: deposit@ccdc.cam.ac.kr.

(ii) Mass spectrometric data. (iii) Photo of a preparative TLC plate prior to isolation of the purified H3(T3TC) material.

2.1. Preparation of the complexes

2.1.1. $[Co(2,3\text{-}L)_2(N_3)_2][Na_3(H_2O)_{10}]$ (1)

A mixture of cobalt(II) chloride pentahydrate (0.73 g, 3 mmol) in 15 cm^3 water and NaN_3 (0.78 g, 7 mmol) in 5 cm^3 water. To this mixture an aqueous/ethanolic solution of 20 cm^3 of 2,3-H_2L (1.0 g, 6 mmol) was added, followed by addition of 150 cm^3 acetone, the final mixture was stirred for about 2 h, and filtered. The filtrate was allowed to stand in an open beaker over several days to deposit deep green crystal of the complex. Good quality complexes were obtained by mixing cobalt(II) chloride pentahydrate in acetone, NaN_3 in water and 2,3-H_2L in water/ethanol in the above molar ratio. To this mixture, an excess amount of solid $K_2S_2O_8$ was added with vigorous stirring for about 2 h. The final mixture was filtered and the filtrate allowed to stand over several days, to produce 60% yield. *Anal.* Calc. for $C_{14}H_{26}CoN_8Na_3O_{18}$: C, 23.3; H, 3.6; N, 15.5; Co, 8.4. Found: C, 23.27; H, 3.32; N, 15.47; Co, 8.4%.

2.1.2. $[Co(2,5\text{-}L)_2(N_3)_2][Na_3(H_2O)_8](H_2O)_2$ (2)

This complex was prepared by the procedures given for **1**, except that 2,5-pyridine dicarboxylic acid used instead of 2,3-H_2L. Good quality dark green crystals of **2**, were obtained upon using a large excess solid $K_2S_2O_8$ yield 45%. *Anal.* Calc. for $C_{14}H_{26}CoN_8Na_3O_{18}$: C, 23.3; H, 3.6; N, 15.5; Co, 8.4. Found: C, 23.22; H, 3.32; N, 15.55; Co, 8.5%.

2.2. Physical measurements

Elemental analyses were carried out using a Perkin–Elmer analyzer. Infrared spectra were recorded in a Bruker IFS-125 model FT-IR spectrophotometer as Nujol mulls. Electronic spectra were obtained using Shimadzu UV-3101 PC Scanning spectrophotometer. The experimental procedures and instruments used for other measurements are as described previously [7].

Caution. Metal azide complexes are potential explosives. Only a small amount of material should be prepared and handled with caution.

2.3. X-ray crystallography

Single crystal X-ray data were measured at 99(2) K on a modified STOE four circle diffractometer using graphite crystal-monochromatized Mo Kα radiation ($\lambda = 0.71069$ Å). The intensities were corrected for Lorentz-polarization effects, intensity decay and for absorption. Crystallographic data and processing parameters are given in Table 1. The structures were solved by direct methods and subsequent Fourier analyses. Anisotropic displacement parameters were applied to non-hydrogen atoms in full-matrix least-squares refinements based on F^2. The hydrogen atoms were located from difference Fourier maps, assigned with isotropic displacement factors and included in the final refinement cycles on calculated positions. Analytical expressions of neutral-atom scattering factors were employed, and anomalous dispersion corrections were incorporated. Occupancy of 0.5 was assigned for atoms Na(2) in case of **1**; for Na(2) and the hydrogen atoms bonded to O(6) and O(7) atoms in case of **2**, respectively. The SHELXTL/PC program package [8] and program DIFABS [9] were used for computations. Selected bond parameters are given in Tables 2 and 3, for complexes **1** and **2**, respectively.

3. Results and discussion

Despite the many trials for preparation of cobalt(III) azido complexes of 2,3-, 2,4-, 2,5-, 2,6-, 3,4- and 3,5-pyridine dicarboxylic acids ligands, we isolated only solid complexes for 2,3 and 2,5-pyridine dicarboxylic acids. In the case of other acids, we could not isolate the solid complexes although green colors were obtained upon addition of $K_2S_2O_8$ to an aqueous/acetone solutions of the contents. The electronic spectra (vide infra) of these solutions are similar to those of the isolated solid complexes dissolved in water, suggesting the formation of respective complexes in solutions. In fact the change of the red to green colored solution takes place only if the ratio of acetone to water exceeds 6:1. In aqueous solution, no such change to green whatever the amount of $K_2S_2O_8$ added to the mixture. That we isolated solid cobalt(III) azido complexes of 2,3- and 2,5-pyridine dicarboxylic acids only but not with other acids, is in contrast with the result of similar reactions with dimethyl pyridine, also known as lutidines. In case of these latter ligands, cobalt(III) azido complexes have been isolated for 3,4-, and 3,5-dimethyl pyridines only whereas

2,*x*-dimethyl pyridines form cobalt(III) azido complexes in solution only. This difference is definitely due to the different nature of the di-substituents in both cases. For dimethyl pyridines, the presence of a methyl group in the 2-position in the pyridine ring which is not interacting with cobalt atom, causes a steric hindrances and prevents the formation of such complexes. In case of dicarboxylic acid, the carbonyl group in position 2 in the pyridine ring takes part in the coordination of cobalt center thus forming solid cobalt(II) azido complexes whereas the carbonylate groups in 3,4- or 3,5- are far from the hetero N atom and could not form N, O chelate rings with the metal center. For 2,4-pyridine dicarboxylic acid, it may be an electronic reason that prevents the formation of solid cobalt(III) azido complex.

3.1. Structures

Perspective views of compounds **1** which is formulated as $[Co(2,3\text{-}L)_2(N_3)_2][Na_3(H_2O)_{10}]$ and **2** as $[Co(2,5\text{-}L)_2(N_3)_2][Na_3(H_2O)_8](H_2O)_2$ are given in Figs. 1 and 2 and selected bond parameters are summarized in Tables 2 and 3, respectively. Both complexes **1** and **2** are similar and crystallize in the triclinic space group $P\bar{1}$ with $Z=1$. The trivalent Co(1), located at the inversion center, is six-coordinated with *trans*-octahedral geometry. The CoN_4O_2 chromophore is formed by N(1) and O(1) in **1** and N(1) and O(1A) in **2**, respectively, donor atoms of two chelating 2,3- or 2,5-pyridine dicarboxylato anions, two (N11) atoms of mono dentate azido ligands [Co(1)–N(1) = 1.927(2), Co(1)–O(1) = 1.893(2) and Co(1)–N(11) = 1.966(2) Å for **1** and Co(1)–N(1) = 1.905(2), Co(1)–O(1A) = 1.898(2) and Co(1)–N(11) = 1.958 (2) Å for **2**]. In both complexes the chelating –COO group in position 2 is asymmetric [Δ(C–O) = 0.069(3) Å for **1** and Δ(C–O) = 0.059(3) Å for **2**], and coplanar to central pyridine ring [torsion angle N(1)–C(1)–C(6)–O(1) = 1.6(3)° (**1**) and N(1)–C(1)–C(6A)–O(1A) = 5.5(4)° (**2**)]. The non-chelating –COO groups in position 3 in complex **1** has symmetric C–O bonds and is almost perpendicular to the aromatic ring [torsion angle C(1)–C(2)–C(7)–O(3) = −89.4(3)°] whereas for that in

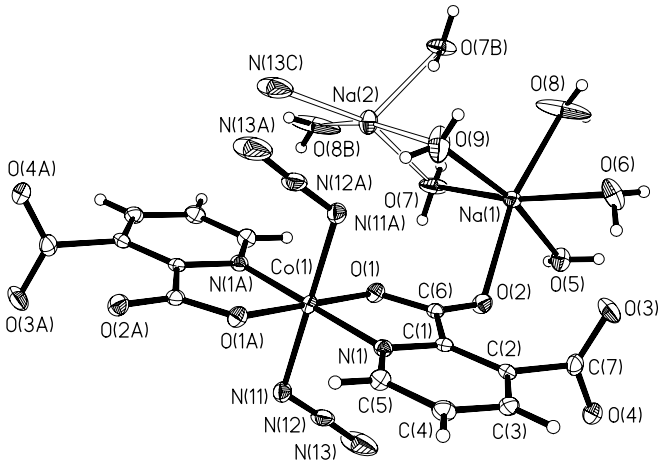

Fig. 1. Perspective view and atom labeling scheme of (**1**). Na(2) has occupancy of 0.5.

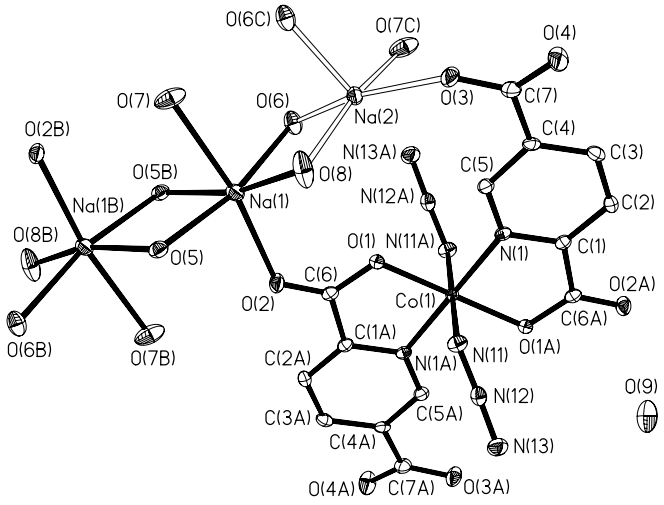

Fig. 2. Perspective view and atom labeling scheme of (**2**). Na(2) has occupancy of 0.5.

position 5 in **2** which has also symmetric C–O bonds the torsion angle C(3)–(C4)–C(7)–O(3) is −10.4(4)°. The bond parameters of the asymmetric mono-dentate azido ligand [N(11)–N(12) = 1.200(3), N(12)–N(13) = 1.146(4) Å; N(11)–N(12)–N(13) = 177.7(3)°, Co(1)–N(11)–N(12) = 116.4(2)°] in **1**, are comparable with corresponding parameters in **2** [N(11)–N(12) = 1.203(3), N(12)–N(13) = 1.154(4) Å; N(11)–N(12)–N(13) = 177.3(3)°, Co(1)–N(11)–N(2) = 116.0(2)°] and in good agreement with values reported for *mer*-[$Co(L_3)(N_3)_3$] (L = py or 4-picolinic) [10], (L = 3,4-lutidine or 3,5-lutidine) [11] or bis(ethylenediamines)cobalt(III) complexes [12]. The Co···Co separation of the monomeric $[Co(2,3\text{-}L)_2(N_3)_2]^{3-}$ complex anion is 6.879(3) Å and that of the monomeric $[Co(2,5\text{-}L)_2(N3)_2]^{3-}$ is 7.522(3) Å, Na(1), and Na(2) with occupancy 0.5, act as counter ions in both complexes. Na(1) is octahedrally coordinated by O(2) of chelating –COO groups and O atoms of five water molecules with Na(1)–O distances from 2.339(3) to 2.439(3) Å in **1** and from 2.184(3) to 2.415(3) Å in **2**. In complex **1**, the distorted tetragonal pyramids of the Na(2) are formed by N(13C) of azide group and O atoms of four water molecules with Na(2)–N(13C) = 2.421(4) Å, Na(2)–O from 2.037(4) to 2.502(3) Å. In contrast to **1**, the tetragonal pyramids of Na(2) in **2** are formed by five O atoms, O(3) of non-chelating COO^- group and O atoms of four water molecules [Na(2)–O distances from 2.184(3) to 2.425(3) Å] and two centro symmetrically related octahedra of Na(1) have a common edge [O(5) and O(5B)], thus O(9) is not coordinated to Na and acts as a lattice water molecule. Hydrogen bonds of the types O–H–O and O–H···N (Tables 2 and 3) connected the complex anions, the Na polyhedra for **1** and additionally lattice water for **2** to form supramolecular network structures.

3.2. Electronic spectra

The electronic spectra of the solid complex **1** and **2** in Nujol mull exhibited two split bands as given in Table 4. These spectra are similar to those of six-coordinate *mer*-$[CoL_3(N_3)_3]$ complexes [10,11]. The band in the range 28 000–25 000 cm^{-1} is due to $^1A_{1g} \rightarrow {}^1T_{2g}$ in a low spin octahedral cobalt(III) complexes which is not affected by lowering of the symmetry. Owing to the high intensity of this band it may be mixed with a change transfer transition. The low energy absorption band $^1A_{1g} \rightarrow {}^1T_{1g}$ in an octahedron is expected to be less intense and split to a very much greater extent in the spectra of *trans*-$[CoL_4X_2]$ than in the *cis*-isomers. The spectrum of $Co(en)_2(H_2O)$ complex shows two components for the $^1T_{1g}$ state (in O_h) [13]. Similar split is observed here with the band around 17 000–16 000 cm^{-1} due to $^1A_{1g} \rightarrow {}^1A_{2g}$ [14]. The spectra of aqueous solution of **1** and **2** exhibit also two split bands (Table 4), which are more or less similar to those of solid complexes suggesting that they retain their identity in aqueous solutions. The electronic spectra of aqueous solution of **1** and **2** are similar to that of a green filtrate obtained from the reaction

Table 4
Electronic spectral data[a]

Complex	λ_{max} (ξ)	
	NM[b]	H_2O
1	28 570vs[c,f]	28 650vbr[c,d] (14 559)

2	26 316vs	28 500 (14 000)
		24 875 (1300)
	17 301	17 206 (230)
	15 106	14 970 (120)

[a] In cm^{-1}.
[b] Nujol mull.
[c] v = very.
[d] br = broad.
[e] sh = shoulder.
[f] s = strong.

mixture of cobalt(II) in azide ions and 3,4-pyridine dicarboxylic acid in water–acetone (2:12) solution to which a sufficient amount of solid $K_2S_2O_8$ was added and the final mixture allowed to stand one day. This observation suggests that the cobalt(III) azide complex is also formed in case of other pyridine dicarboxylic acids in acetone solutions.

3.3. IR spectra

The IR spectra (Table 5) of free acid ligands show several bands in the range 3400–1900 cm^{-1}, very similar to those observed in spectra of free pyridine mono carboxylic acids [15]. No carbonyl stretch bands are observed around 1700 cm^{-1} suggesting that the two –COOH groups are involved in strong inter- and intra-hydrogen bonds. Several ν_{as} COO^- bands in the range 1680–1600 cm^{-1} in free ligands are shifted to lower frequencies (1645–1600 cm^{-1}) in complexes confirming the coordination of the least one of the two carboxylate groups. The shift of the lower frequency bands related to pyridine nucleus evidences that the nitrogen atoms are involved in complexation of both ligands in **1** and **2**. The $\nu_{as}N_3$ appears as a very strong sharp band at 2031 and 2038 cm^{-1} for **1** and **2**, respectively. The position of this band is consistent with terminal azides in other cobalt(III) complexes [16], and the appearance for the asymmetric nature of the terminal azido ligands in **1** and **2**.

3.4. Thermal analysis

First step of decomposition of **1** from 20 to 100 °C is due to emission of H_2O, followed by a second step with further emission of H_2O up to 235 °C (3 or more superimposed peaks in MS and DTA signal). At 250 °C rapid, exothermic decomposition of sample occurs with emission of N_2 and CO_2 (step 3). An undetermined amount of solid sample was last during deflagration. For complex **2**, heating to $T > 225$ °C was avoided in order to prevent deflagration of azide (contamination of furnace and sample holder). First step is due to emission of H_2O up to 116 °C (several superimposed peaks in MS and DTA signal), followed by further emission of H_2O up to 225 °C. MS signal shows no significant emission of N_2 up to 225 °C.

4. Conclusion

Of six pyridine dicarboxylic acids; 2,3-, 2,4-, 2,5-, 2,6-, 3,4-, and 3,5-H_2L, we isolated only two solid cobalt(III) azido complexes of 2,3- and 2,5-H_2L. Although the other acids form cobalt(III) complexes in acetone solutions it is still questionable why no solid complex of any stoichiometry has been isolated, particularly for 2,4- and 2,6-H_2L acids. Both complexes **1** and **2** are found to contain sodium ion. Although the Na ions in **1** and **2** are surrounded by aqua molecules, there is a link between Na and one or more oxygen atoms of the carboxylato groups of H_2L acids, thus, the two metal centers are connected via the organic ligand while the azide ligand bridges only the cobalt(III) centers. Thus, alkali metal and transition metal atoms can be connected via an azido ligand or organic ligand or both azido and organic ligand. Investigations with other pseudo halides as well as other metals are in progress.

5. Supplementary material

Crystallographic data in CIF format have been deposited with the Cambridge Crystallographic Data Centre as CCDC-278125 and CCDC-278126 for **1** and **2**, respectively. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44 1233 336033; e-mail: deposit@ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk).

H_4L^1 H_4L^2

Scheme 1. The Schiff bases H_4L^1 and H_4L^2.

We report herein the crystal structure of two new examples of polynuclear complexes in the first category, obtained with the ligands *N*,*N*′-bis(3-hydroxysalicylidene)-2-methyl-1,2-propanediamine] (H_4L^1) and *N*,*N*′-bis(3-hydroxysalicylidene)-2,2-dimethyl-1,3-propanediamine (H_4L^2), represented in Scheme 1.

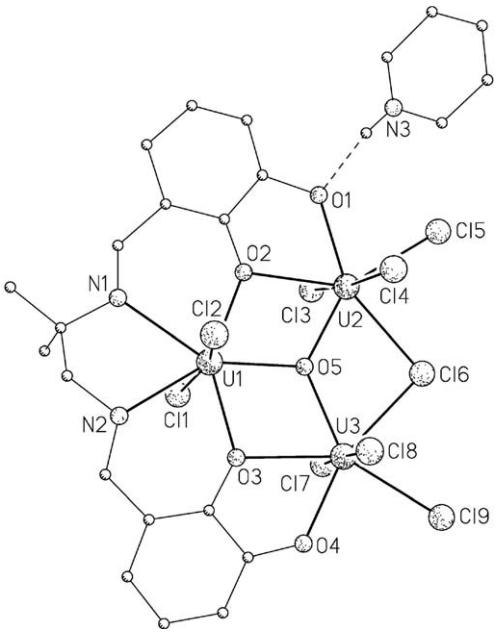

Fig. 1. View of the dianionic $\{[Hpy][U_3L^1Cl_9O]\}^{2-}$ complex in **1**. Other counter-ions, solvent molecules and hydrogen atoms are omitted for clarity. Atoms are represented as spheres, the carbon ones being arbitrarily reduced. The hydrogen bond is shown as a dashed line.

2. Results and discussion

The trinuclear compound $[Hpy]_3[U_3L^1Cl_9O] \cdot HpyCl \cdot 2py$ crystallizes in the monoclinic space group $P2_1/n$, with one complete molecule in the asymmetric unit (Fig. 1). The complex is trianionic and its charge is compensated by three pyridinium ions (a fourth pyridinium being associated with a non-coordinated chlorine atom). The atom U1 is bound to the two oxygen atoms O2 and O3 [mean value 2.292(4) Å] and the two nitrogen atoms N1 and N2 [mean value 2.53(5) Å] defining the inner site of the Schiff base. Two chlorine atoms [mean U–Cl bond length 2.653(2) Å] and the μ_3-oxo atom O5 complete the environment of U1 (Table 1). The resulting uranium hepta-coordinated environment is pentagonal bipyramidal with the two chlorine atoms Cl1 and Cl2 in apical positions. U1 is located at 0.019(8) Å from the mean plane defined by the five atoms O2, O3, O5, N1, N2 [maximum deviation 0.11(1) Å]. Atoms U2 and U3 are also hepta-coordinated, in pentagonal bipyramidal environments; both atoms are linked to two oxygen atoms of the outer site of the Schiff base (O1 and O2 for U2, O3 and O4 for U3) and they are positioned at −0.12(2) and 0.07(2) Å, respectively, from the mean plane defined by these four oxygen atoms [maximum deviation 0.139(9) Å]. Three terminal chlorine atoms (Cl3, Cl4, Cl5 for U2; Cl7, Cl8 and Cl9 for U3), the μ_2-chloro atom Cl6 [U2–Cl6–U3 90.75(18)°] and the μ_3-oxo atom O5 complete their coordination spheres. The mean planes defined by the five donor atoms in the pentagonal environment of the three uranium atoms [maximum deviation 0.15(1) Å for U2 and 0.25(1) Å for U3; displacement of the metal atom 0.001(6) Å for U2 and 0.025(6) Å for U3] define dihedral angles in the range 1.7(6)–7.5(6)°. The whole assembly, including the three uranium atoms, the N_2O_4 donor set of the Schiff base, the μ_3-oxo ion and the Cl5, Cl6 and Cl9 chlorine atoms is thus not far from planarity, as can be seen in Fig. 2 [maximum deviation 0.265(8) Å for Cl9]. The Schiff base conformation is of the *stepped* type with the two aromatic rings defining a very small dihedral angle of 9(1)° with each other and being nearly coplanar with the mean N_2O_2 inner site plane [dihedral angles 6(1)° and 14.1(9)°]. The core of the complex is made of a nearly equilateral triangle of U^{4+} ions around the central O^{2-} ion [U1···U2 3.7954(12), U1···U3 3.8119(11), U2···U3 4.0198(12) Å, U1–O5–U2 117.1(6)°, U1–O5–U3 115.0(7)°, U2–O5–U3 127.8(7)°]. A search of the Cambridge Structural Database [6] gives a mean value of 2.24(7) Å for U–O bond lengths involving μ_3-oxo groups, which is in agreement with the present value of 2.24(4) Å. One pyridinium ion is involved in a hydrogen bond with the oxygen atom O1 of the ligand [N3···O1 2.74(3), N3–H 0.86, H···O1 1.89 Å, N3–H···O1 167°] and two other ones with pyridine molecules [N4···N5 2.82(3), N4–H 0.86, H···N5 1.97 Å, N4–H···N5 171°; N7···N8 2.82(3), N7–H 0.86, H···N8 1.98 Å, N7–H···N8 167°]. A fourth pyridinium ion, associated with a chlorine atom, is also present as an independent group [N6···Cl 10 3.00(3), N6–H 0.86, H···Cl 10 2.14 Å, N6–H···Cl 10 176°].

The compound $[U_4(L^2)_2(H_2L^2)_2(py)_2O][CF_3SO_3]_2$ (**2**) crystallizes in the monoclinic space group $C2/c$, with only half a molecule in the asymmetric unit, the other half being

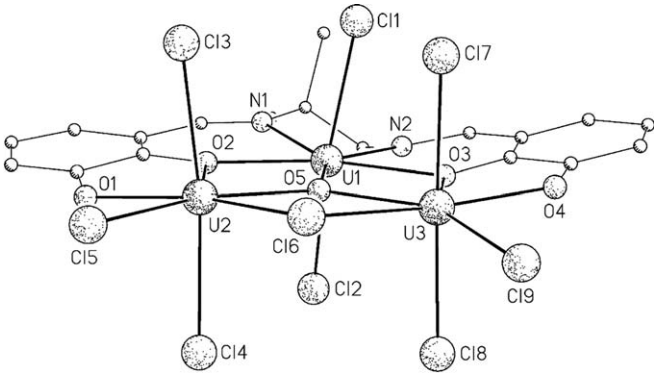

Fig. 2. View along the plane of the Schiff base of the trianionic $[U_3L^1Cl_9O]^{3-}$ moiety in **1**. Counter-ions, solvent molecules and hydrogen atoms are omitted for clarity. Atoms are represented as spheres, the carbon ones being arbitrarily reduced.

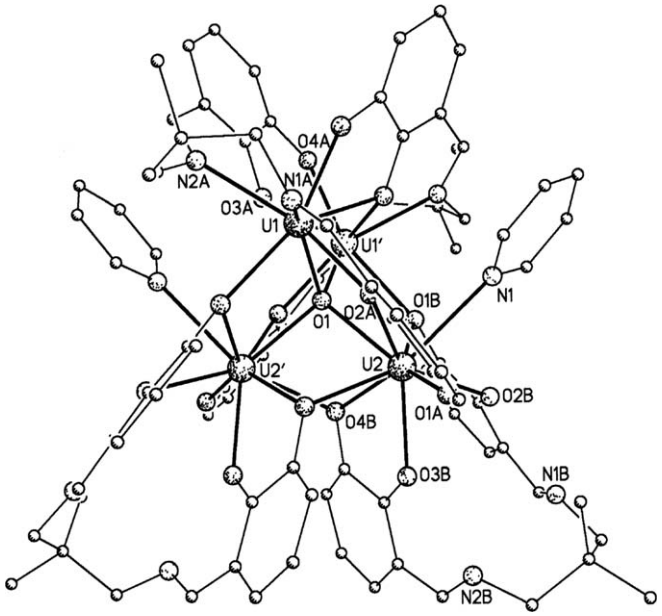

Fig. 3. View of the dicationic $[U_4(L^2)_2(H_2L^2)_2(py)_2O]^{2+}$ complex in **2**. Hydrogen atoms and counter-ions are omitted for clarity. Atoms are represented as spheres, the carbon ones being arbitrarily reduced. Symmetry code: $' = -x, y, 0.5 - z$.

generated by the binary axis (Fig. 3). The complex itself is dicationic, which, considering the presence of a central μ_4-oxo ion, implies that four protons are still attached to the Schiff bases. The two independent uranium atoms are in different environments, as shown in Fig. 4. The atom U1 is bound to the two oxygen atoms O2A and O3A and two nitrogen atoms N1A and N2A defining the inner site of the Schiff base labelled A, whereas the atom U2 is bound to the four oxygen atoms O1B–O4B defining the outer site of the second Schiff base, labelled B. The Schiff base A and the symmetry related molecule A′ ensure the assembly of U1 and U1′ through the bridging oxygen atoms O3A and O3A′ and the terminal hydroxy groups O4A and O4A′ which are linked to U1′ and U1, respectively. The uranium atoms U2 and U2′ are associated by the Schiff bases B and B′ via the bridging oxygen atoms O4B and O4B′. Both Schiff bases A and B are involved in the association of U1, U1′, U2 and U2′, with the bridging oxygen atoms

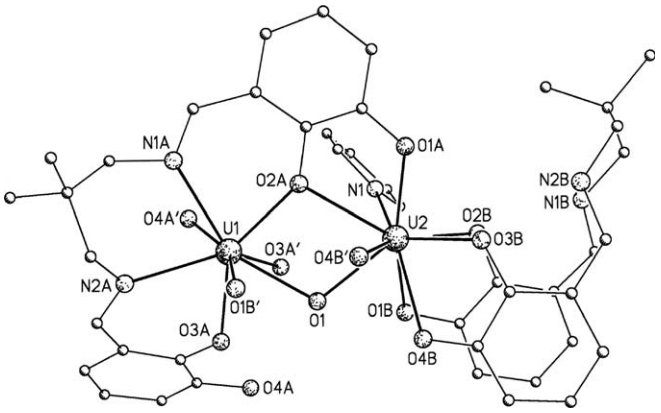

Fig. 4. View of the environment of the uranium atoms in the asymmetric unit in **2**. Atoms are represented as spheres, the carbon ones being arbitrarily reduced. Symmetry code: $' = -x, y, 0.5 - z$.

O2A and O1B, the terminal hydroxy group O1A and their symmetry equivalents. Finally, the four uranium atoms are linked by the μ_4-oxo atom O1. The eight-coordinate U1 atom adopts a dodecahedral configuration [7] defined by the two nearly orthogonal trapezia O2A, N1A, N2A, O3A and O4A′, O3A′, O1, O1B′ [dihedral angle 88.3(2)°]. Because of the coordination of an extra pyridine molecule, U2 is nine-coordinate and its environment can be described as a capped square antiprism with the two sets of atoms O1B, O2B, O3B, O4B and O1A, N1, O1, O4B′ defining the bases [dihedral angle 5.6(7)°] and O2A in capping position [7]. The mean U1–N and the U2–N1 (pyridine) bond lengths, 2.54(2) and 2.732(14) Å respectively, are unexceptional. The U1–O4A′ and U2–O1A bond lengths, which involve non-bridging oxygens, are typically short [mean value 2.199(15) Å] while U2–O2B and U2–O3B [2.367(10) Å] are significantly longer, indicating that the remaining protons are likely to be located on these two oxygen atoms. The bridging oxygen atoms are all involved in dissymmetric bonds, one of them shorter than the other, with the corresponding ranges 2.291(9)–2.404(10) and 2.502(10)–2.619(10) Å; such differences have been observed in some of the structures reported previously [2b,2c]. Finally, the bond lengths involving the μ_4-oxo atom O1 [mean value 2.35(2) Å] are similar to those of the other two reported cases [2.40(9) and 2.36(10) Å] [2a,4c] while the U–O1–U angles span the range 102.7(5)–113.67(2)°. It may be noted that a μ_6-oxo group is present in the U(V) hexanuclear isopolyoxometalate complex reported by Duval et al. with a mean U–O bond length of 2.6(1) Å [4b].

The two Schiff bases in **2** present very different conformations. Molecule A does not match exactly the usual *boat* (*umbrella*) or *stepped* conformations [8] since the mean plane defined by the aromatic ring bearing O1A and O2A is close to the N_2O_2 mean plane defined by the four donor atoms of the inner site [maximum deviation 0.237(7) Å] with a dihedral angle of 13.4(7)°, while the other aromatic ring, bearing O3A and O4A, is more tilted, with a dihedral angle of 39.8(6)°. However, this conformation is not far from that generally observed when the inner site-coordinated uranium atom is close to the N_2O_2 mean plane [out-of-plane displacement 0.113(6) Å in **2**], the distorsions being likely due to the distinct attachment of the four oxygen atoms O1–O4 to the metal centres. The second ligand presents a more unusual conformation which is a borderline case of the *umbrella* shape, in which the two aromatic rings are facing each other, with a dihedral angle of 24.8(6)°. The Schiff base, which roughly admits a pseudo-mirror plane, thus appears as if folded around its middle line. As a result, the four oxygen atoms of the outer site define a mean plane with a maximum deviation of 0.138(5) Å. but, at variance with U1 and ligand A, atom U2 is expelled at a distance of 1.561(5) Å from this plane; the two nitrogen atoms of this molecule are the only ones among all the donor atoms of both ligands to be un-coordinated. The centroids of the two aromatic rings facing each other are separated by 3.89 Å, which could indicate the presence of a weak π–π interaction. The Cambridge Structural Database [6] gives several examples of such conformations, with different kinds of folding around the diimino bridge, leading to inter-centroid distances lower than 4 Å, some of them for triatomic diimino bridges comparable to that in **2** [9], but the largest number for longer bridges [10]. As a further difference between molecules A and B, it may be noted that the non-bridging oxygens are the external ones in A and the internal ones (protonated) in B. The four uranium centres are arranged so as to form a slightly distorted tetrahedron encompassing the central μ_4-oxo atom (Fig. 5), with U···U distances and U···U···U angles in the range 3.6465(14)–3.9373(9) Å and 55.44(2)–62.774(16)°, respectively. The edges of the tetrahedron cor-

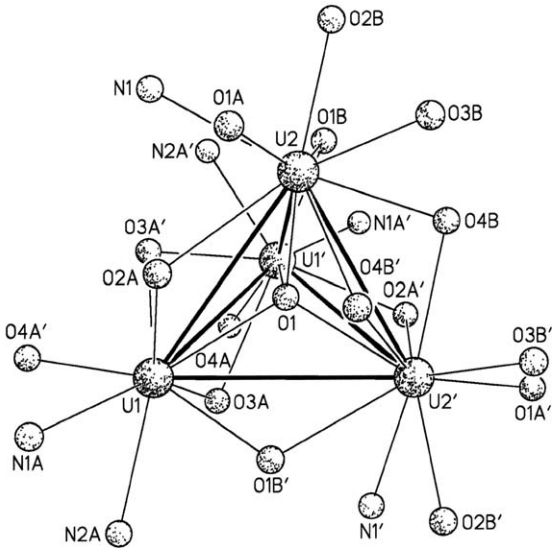

Fig. 5. View of the uranium atoms and their environment in **2**. The μ_4-oxo-centered U_4 tetrahedron is highlighted. Symmetry code: $' = -x, y, 0.5 - z$.

respond either to double (U1···U1′ and U2···U2′) or simple (all other edges) oxygen bridging.

In contrast with the symmetric or pseudo-symmetric elongated tetra- or hexanuclear complexes which are built from di- or trinuclear subunits [2b,2c], respectively, the more compact arrangement associated with convergent Schiff bases leads to more tightly packed uranium assemblages with unusual geometries, since a cubane-type U_4O_4 motif was present in the octa-nuclear complex aforementioned (in which the eight uranium centres were arranged as four edge-sharing, oxo-centered tetrahedra) [2a] whereas a single triangle or tetrahedron is observed in the present cases. It is to be noted that, in these cases and in contrast with the elongated assemblages, these globular polyuranium assemblies are held by μ_3-oxo or μ_4-oxo groups resulting from adventitious traces of water and/or oxygen present during the synthesis, which are effective in promoting these architectures containing tightly packed uranium assemblages.

3. Experimental

3.1. Synthesis

[Hpy]$_3$[U$_3$L^{1}Cl$_9$O] · HpyCl · 2py (***1***). UCl_4 was synthesized as reported in the literature [11]. H_4L^1 was mixed in a 1:1 ratio with UCl_4 in pyridine. Adventitious traces of oxygen and/or water probably entered the reaction flask during prolonged heating at 110 °C, which resulted in the formation of yellow crystals of the trinuclear U^{IV} compound $[Hpy]_3[U_3L^1Cl_9O] \cdot HpyCl \cdot 2py$ (**1**).

[U$_4$(L^2)$_2$(H$_2$L^2)$_2$(py)$_2$O][CF$_3$SO$_3$]$_2$ (***2***). $U(OTf)_3$, where OTf is trifluoromethanesulfonate, was synthesized as reported in the literature [12]. The copper complex CuH_2L^2 was synthesized by reaction of H_4L^2 with 1 mol equiv. of $Cu(acac)_2$ in tetrahydrofuran. This mononuclear metal complex was mixed in a 1:1 ratio with $U(OTf)_3$ in pyridine. Adventitious traces of oxygen and/or water probably entered the reaction flask during prolonged heating at 80 °C, which resulted in the formation of red crystals of the tetranuclear U^{IV} compound $[U_4(L^2)_2(H_2L^2)_2(py)_2O][CF_3SO_3]_2$ (**2**) following the substitution of Cu for U. Attempts to prepare this complex in a controlled way, by introducing measured quantities of water into the reaction mixture, were unsuccessful.

3.2. Crystallography

Data were collected at 100(2) K on a Nonius Kappa-CCD area detector diffractometer [13] using graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) and processed with DENZO-SMN [14]. The structures were solved by direct methods with SHELXS-97 and refined by full-matrix least-squares on F^2 with SHELXL-97 [15]. Absorption effects were empirically corrected with the program DELABS from PLATON [16]. All non-hydrogen atoms were refined with anisotropic displacement parameters.

Due to the rather low quality of the crystals, and hence the data, for compound **1**, some restraints on displacement parameters had to be applied for several badly behaving atoms, particularly in the pyridinium ions and pyridine solvent molecules. Some restraints on displacement parameters were also applied for the O, C and F atoms of the CF_3SO_3 moiety in compound **2**. The hydrogen atoms were introduced at calculated positions (except the phenolic ones in compound **2**, which were not found on Fourier-difference maps) and were treated as riding atoms with an isotropic displacement parameter equal to 1.2 (CH, CH_2) or 1.5 (CH_3) times that of the parent atom. The molecular plots were drawn with SHELXTL [17]. Crystal data and structure refinement details are given in Table 2.

4. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 285357 and 285358. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44 1223 336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

for the difference in affinity of ruthenium for hydrogen sulfide and dimethyl sulfide ligands, this effect has been elegantly applied to explain some unusual features of sulfur based metal complexes including the questions related to the competitive catalysts for metal sulfur enzymes [10].

The 1,4-dithiane (1,4-dt) ligand can bind to a metal center via a variety of bonding modes. This versatility of 1,4-dt is attributed to the presence of two S atoms and its proximity. The large size of the S atom makes it easier to adopt different angles at this atom in complexes, which is necessary for different geometries. The 1,4-dithiane can function as a chelating ligand for a single metal center, as a monodentate or yet as bridged ligand in binuclear species [11]. The literature reports that the chair conformation of the 1,4-dt species is preferred [12,13]. Probably, this is the reason why a very few X-ray structures of compounds containing the 1,4-dt molecule as a bidentate ligand are noticed [14–17].

In this work, we present the first example of a metal center system that form complexes with the 1,4-dithiane acting as bidentate, monodentate and bridged ligand. The electrochemical, spectroscopic and crystallographic data of such complexes highlights the conformational versatility of this ligand towards the coordination chemistry.

2. Experimental

2.1. Materials

All manipulations were carried out under argon atmosphere using Schlenk techniques. The solvents were purified according to standard procedures [18]. The water used throughout was purified by a Milli-Q system (Millipore Co.). The *mer*-[$Ru^{III}Cl_3$(dppb)H_2O] and [$Ru^{II}Cl_2$(dppb)-PPh_3] (dppb = 1,4-bis(diphenylphosphino)butane, PPh_3 = triphenylphosphine) complexes were prepared according to the literature [19,20]. Tetrabutylammonium perchlorate (TBAP) was purchased from Fluka, recrystallized twice from absolute ethanol solution, filtered and dried under vacuum. All other chemicals of reagent grade were used as received.

2.1.1. *trans*-[$RuCl_2$(dppb)(1,4-dt)]

trans-[$RuCl_2$(dppb)(1,4-dt)] complex was synthesized from the [$RuCl_2$(dppb)PPh_3] (0.100 g, 0.12 mmol) and 1,4-dt (0.014 g, 0.12 mmol) at room temperature in 5 mL of dichloromethane. The mixture was stirred under argon during 30 min and the resulting solution was reduced to near 1 mL volume. The product was precipitated by the addition of diethyl ether, separated by filtration, washed with diethyl ether and dried under vacuum. Yield: 40.0 mg, 80%. *Anal.* Calc. for $C_{32}H_{36}Cl_2P_2S_2Ru$, fw.: 718.69; C, 53.48; H, 5.05; S, 8.92. Found: C, 53.27; H, 5.06; S, 8.87%.

Recrystallization of *trans*-[$RuCl_2$(dppb)(1,4-dt)] from dichloromethane/diethyl ether solution yielded yellow crystals suitable for single crystal X-ray analysis. Crystal data and structure refinement for this complex are summarized in Table 1.

Table 1
Crystal data and structure refinement for the *trans*-[$RuCl_2$(dppb)(1,4-dt)] complex

Empirical formula	$C_{32}H_{36}Cl_2P_2S_2Ru$
Formula weight	718.69
Temperature (K)	120(2)
Wavelength (Å)	0.71073
Crystal system	monoclinic
Space group	$P2_1/c$
Unit cell dimensions	
a (Å)	10.7020(1)
b (Å)	12.0660(1)
c (Å)	26.5840(3)
β (°)	99.57(1)
Volume (Å^3)	3385.06(6)
Z	2
D_c (Mg m^{-3})	1.577
Absorption coefficient (mm^{-1})	1.021
F(000)	1640
Crystal size (mm^3)	$0.20 \times 0.04 \times 0.04$
θ Range for data collection (°)	1.55–25.00
Index ranges	$-12 \leqslant h \leqslant 12$, $-14 \leqslant k \leqslant 14$, $-31 \leqslant l \leqslant 31$
Reflections collected	11 543
Independent reflections [R_{int}]	5957 [0.0215]
Completeness to $\theta = 25.00°$	100.0%
Maximum and minimum transmission	0.9603 and 0.8219
Refinement method	full-matrix least-squares on F^2
Data/parameters	5957/406
Goodness-of-fit on F^2	1.171
Final R indices [$I > 2\sigma(I)$]	$R_1 = 0.0373$, $wR_2 = 0.1077$
R indices (all data)	$R_1 = 0.0581$, $wR_2 = 0.1534$
Largest difference peak and hole (e Å^{-3})	1.104 and −2.421

2.1.2. *mer*-[$RuCl_3$(dppb)(1,4-dt)]

mer-[$RuCl_3$(dppb)(1,4-dt)] complex was prepared from *mer*-[$RuCl_3$(dppb)H_2O] (0.100 g, 0.15 mmol) and 1,4-dt (0.039 g, 0.32 mmol) dissolved in CH_2Cl_2 (10 mL) with stirring for 12 h, at room temperature. The resulting red dark solution was reduced to near 1 mL volume, by rotary evaporation. A red solid was obtained by the addition of diethyl ether, which was separated by filtration, washed with diethyl ether, and dried and stored under vacuum. Yield: 98.0 mg, 85%. *Anal.* Calc. for $C_{32}H_{36}Cl_3P_2RuS_2$, fw. 754.16; C, 50.96; H, 4.81; S, 8.50. Found: C, 50.85; H, 4.86; S, 8.54%.

2.1.3. [{$RuCl_3$(dppb)}$_2$(μ-(1,4-dt))]

The [{$RuCl_3$(dppb)}$_2$(μ-(1,4-dt))] binuclear complex was obtained from stoichiometric amounts (1:1) of *mer*-[$RuCl_3$(dppb)H_2O] (0.100 g, 0.15 mmol) and *mer*-[$RuCl_3$-(dppb)(1,4-dt)] (0.115 g, 0.15 mmol) dissolved in CH_2Cl_2 (10 mL), with stirring for 12 h, at room temperature. The solution was then reduced to near 3 mL volume, followed by the addition of diethyl ether (10 mL) to form of a red-violet precipitate that was collected, washed with diethyl ether, dried and stored under vacuum in the absence of light. Yield: 190.0 mg, 89%. *Anal.* Calc. for $C_{60}H_{64}Cl_6P_4$-Ru2S_2, fw. 1388.08; C, 51.92; H, 4.65; S: 4.62. Found: C, 51.89; H, 4.68; S, 4.59%.

2.2. Apparatus

Single crystals were used for data collection and cell parameter determination on an Enraf–Nonius Kappa-CCD diffractometer, using Mo Kα radiation ($\lambda = 0.71073$ Å). Data collection was made by using the COLLECT program [21]; integration and scaling of the reflections were performed with the HKL Denzo-Scalepack system of programs [22]. Absorption corrections were carried out by using the multi-scan method [23]. The structure was solved by direct methods with SHELXS-97 [24]. The models were refined by full-matrix least-squares on F^2 with SHELXL-97 [25]. All the hydrogen atoms were stereochemically positioned and refined with the riding model [26]. The NMR spectra were obtained in a T BRUKER DRX400 spectrometer at 298 K, using H_3PO_4 85% as external reference for $^{31}P\{^1H\}$ (161 MHz). Elemental analyses were performed on a Fison equipment, EA 1108 model. The electrochemical experiments were carried out at room temperature in freshly distilled dichloromethane containing 0.1 mol L^{-1} TBAP under argon atmosphere. These measurements were performed by using an electrochemical analyzer from Bioanalytical Systems Inc. (BAS), model 100BW, at 25 ± 0.2 °C. A conventional electrochemical glass cell of one compartment containing three electrodes and two gas inlets was used in these experiments. A platinum foil and a pseudo-reference Ag/AgCl electrode prepared at the working day, 1 h before the experiments beginning, were used as working and auxiliary electrodes, respectively. The electrochemical potentials reported in this study were all converted to the normal hydrogen electrode (NHE), based on the ferrocene/ferrocenium ($Fc^{+/0}$) redox couple in CH_2Cl_2, as reported by Koelle et al. [27]. The transmission infrared spectra of the isolated species dispersed in CsI were obtained by using a BOMEM MICHELSON instrument, model 102. The electronic spectra, acquired on a HP8452A spectrophotometer, were obtained in CH_2Cl_2 solutions.

3. Results and discussion

The characterization of the *trans*-[$RuCl_2$(dppb)(1,4-dt)], *mer*-[$RuCl_3$(dppb)(1,4-dt)] and [{$RuCl_3$(dppb)}$_2$(μ-(1,4-dt))] complexes was carried out by cyclic voltammetry, electronic, infrared, NMR and EPR spectroscopies and X-ray diffraction when it was possible.

The very intense infrared absorption of the free 1,4-dt molecule at 664 cm^{-1}, which is assigned to the C–S stretching mode [12], shifts to lower frequency (650 cm^{-1}) and dramatically decreases in intensity in the spectra of the *trans*-[$RuCl_2$(dppb)(1,4-dt)] and [{$RuCl_3$(dppb)}$_2$(μ-(1,4-dt))] complexes. Similar behavior was observed for some similar systems [28,29]. These downshifts would suggest that in these complexes the 1,4-dithiane ligand is coordinated through both sulfur atoms to the metal center. On the other hand, the IR spectrum of the *mer*-[$RuCl_3$(dppb)-(1,4-dt)] complex shows two bands at 668 and 655 cm^{-1} assigned to the C–S stretching modes of the 1,4-dt non-coordinated and coordinated to the Ru(III) ion, respectively [12]. Based on similar systems, these observations suggest that the 1,4-dt is coordinated through only one sulfur atom to the ruthenium in the *mer*-[$RuCl_3$(dppb)(1,4-dt)] complex [28]. For the *trans*-[$RuCl_2$(dppb)(1,4-dt)] complex, the Ru–Cl stretching frequency (*ν*Ru–Cl) is observed at 260 cm^{-1}. The presence of only one *ν*Ru–Cl band suggests the *trans* configuration for this complex. Conversely, two *ν*Ru–Cl bands would be expected for the *cis* configuration [30].

The X-ray structure of the *trans*-[$RuCl_2$(dppb)(1,4-dt)] complex clearly shows that the 1,4-dt ligand is coordinated in a bidentate mode to the ruthenium atom, in a distorted octahedron with the metal on a twofold axis with a *trans* configuration of the Cl atoms with the sulfur atoms necessarily *trans* to the phosphorous atoms (Fig. 1). The 1,4-dt molecule normally exists in a C_{2h} conformation similar to the chair form of cyclohexane [13]. The D_2 form of this molecule, similar to a boat, has not been detected in any appreciable amount of complexes since it has a relative unstable energy level, 5 kcal mol^{-1} higher than the C_{2h} form [12]. Despite the energy difference between the C_{2h} and D_2 configurations, the crystallographic data point for the 1,4-dt D_2 conformer in the *trans*-[$RuCl_2$(dppb)(1,4-dt)] complex, where 1,4-dt acts as a bidentate ligand. The relevant interatomic bond lengths and angles are listed in Table 2.

As expected for a relatively soft Ru (II) center, the Ru–P distances (2.297(1) and 2.317(1) Å) are shorter than the Ru–S distances (2.404(1) and 2.444(1) Å). The Ru–S, Ru–P and Ru–Cl bond lengths (Table 2) are within the well established range for Ru(II) complexes [31,32]. The S–C distances (ca. 1.824 Å) of the coordinated ligand are slightly elongated compared with the free 1,4-dt molecule (ca. 1.811 Å) [12]. The C–C bonds of the coordinated

1,4-dt (average value of 1.54 Å) are elongated comparatively with the free species, 1.490(18) Å [12].

The angles of the bonds involving the ruthenium atom indicate that the chloride atoms are in the *trans* configuration (see Table 2). The observation that the C–S–C angles of the 1,4-dt change from ca. 99.0° (6) in the free molecule to 95.42° (19) in the coordinated ligand [13], strongly suggests that electronic density of the sulfur atoms was withdrawn upon coordination. The S–M–S angle is smaller for the ruthenium complex, 74.80(3)°, comparatively to the [PtI_2(1,4-dt)] compound, 79.74 (8)° [15]. This result is attributed to the size difference between these atoms, i.e. 134 pm for ruthenium and 138 pm for platinum [33].

The $^{31}P\{^1H\}$ spectrum of the *trans*-[$RuCl_2$(dppb)(1,4-dt)] complex showed one single signal, at δ 33.0 ppm, indicating that the symmetrical arrangement of the two phosphorous atoms is maintained in solution [30]. This signal presents a downshift in comparison with similar complexes in which the metal centers are bonded to a nitrogen atoms where the $^{31}P\{^1H\}$ NMR chemical shifts are close to 42 ppm [30].

The electronic absorption spectrum data are shown in the Table 3. Apart from the transitions involving the phosphine ligands, observed at 240 nm [34], the UV/Vis spectrum of the *trans*-[$RuCl_2$(dppb)(1,4-dt)] complex, presents one band at 452 nm ($\varepsilon = 290$ L mol^{-1} cm^{-1}), in CH_2Cl_2 solution. This absorption band is sensitive toward solvent changes (425 nm in *N*,*N*′-dimethylformamide) and was assigned to the metal-to-ligand charge transfer transition, (1,4-dt) $\pi \leftarrow d\pi$ (Ru). Charge transfer transitions of low extinction coefficients were also observed for the $[Ru(NH_3)_5L]^{2+}$ type complexes, where L = dithioether ligands (see Table 3) [4].

Table 3
Electronic absorptions data, λ (nm), ε (L mol^{-1} cm^{-1}), and $Ru^{III/II}$ half-wave formal potential, $E_{1/2}$ (*V* vs. NHE), for some ruthenium complexes

Complex	λ	$\varepsilon \times (10^{-3})$	$E_{1/2}$	Reference
mer-[$RuCl_3$(dppb)(1,4-dt)]	530	2.0	0.45	this work
	420	1.6		
	347	2.2		
[{$RuCl_3$(dppb)}$_2$(μ-(1,4-dt))]	530	3.8	0.45	this work
	420	3.2		
	347	4.2		
mer-[$RuCl_3$(dppb)H_2O]	533	1.6	0.34	[19]
	420	1.3		
	350	1.7		

For the *mer*-[$RuCl_3$(dppb)(1,4-dt)] complex, the absorption at 530 nm is observed with higher intensity ($\varepsilon = 2.0 \times 10^3$ L mol^{-1} cm^{-1}) when compared with the band at 533 nm for the *mer*-[$RuCl_3$(dppb)H_2O] complex ($\varepsilon = 1.6 \times 10^3$ L mol^{-1} cm^{-1}), in the same experimental conditions [19]. The band at 533 nm in the spectrum of *mer*-[$RuCl_3$-(dppb)H_2O] complex has been assigned as a ligand-to-metal charge transfer (LMCT), (Ru^{III}) $d\pi \leftarrow p\pi$ (Cl) [12]. For the *mer*-[$RuCl_3$(dppb)(1,4-dt)] and [{$RuCl_3$(dppb)}$_2$-(μ-(1,4-dt))] complexes, the absorption bands at 530 nm occur with higher intensity than that of *mer*-[$RuCl_3$-(dppb)H_2O] complex probably due to the contribution of the (Ru^{III}) $d\pi \leftarrow p\pi$ (S) LMCT [26]. As expected, for the [{$RuCl_3$-(dppb)}$_2$(μ-(1,4-dt))] binuclear complex the extinction coefficient of the band at 530 nm is almost two times more intense ($\varepsilon = 3.8 \times 10^3$ L mol^{-1} cm^{-1}) than that observed for the *mer*-[$RuCl_3$(dppb)(1,4-dt)] mononuclear complex.

The EPR spectrum of the *mer*-[$RuCl_3$(dppb)(1,4-dt)] complex, in CH_2Cl_2, differently of that acquired for the aqua-complex that presents zero field signals [14], shows three *g*-values in 2.87, 2.15 and 1.73. This result is typical of Ru(III) species with rhombic distortions [35], suggesting that the 1,4-dt is coordinated in a monodentate mode.

The EPR spectrum of the binuclear [{$RuCl_3$(dppb)}$_2$(μ-(1,4-dt))] complex, in CH_2Cl_2, shows a large signal ($g =$ 2,31) which is characteristic of complexes with exchange interaction between the ruthenium atoms [36].

The cyclic voltammograms obtained for the *trans*-[$RuCl_2$(dppb)(1,4-dt)] complex in CH_2Cl_2 evidenced a redox process with half-wave formal potential, $E_{1/2} =$ 0.77 V. This value was observed to be independent of the sweep rate from 0.05 to 0.5 V s^{-1}. In addition, it was observed that the ratio between the anodic and cathodic currents is almost unit, the difference between the anodic and cathodic potentials, ΔE, is approximately equals to 0.07 V, and plots of ip versus $v^{1/2}$ are linear. These results indicate that the Ru^{III}/Ru^{II} redox process of this complex is reversible, involving one-electron transfer and diffusion-controlled [37]. The $E_{1/2}$ value observed for this complex is 0.11 V higher than that observed for the *trans*-[$RuCl_2$-(dppb)(bipy)], $E_{1/2} = 0.66$ V, where bipy = 2,2′-bipyridine, in the same experimental conditions [30]. This difference reflects the stronger π-acid property of the 1,4-dt compared

Table 4
$E_{1/2}$ values (in V vs. NHE) for Ruthenium complexes.

System	L	$E_{1/2}$	Reference

$[Ru(NH_3)_5(L)]^{2+}$	Pyridine	0.30	[38]
	4,4′-Dithiodipyridine	0.40	[39]
	Dimethyl sulfide	0.50	[40]
	1,4-Dithiane	0.52	[4]
	1,3-Dithiane	0.55	[4]
	1,2-Dithiane	0.66	[4]

[a] $[RuCl_2(dppb)(NH_3)_2]$.
[b] $[RuCl_2(dppb)(py)_2]$, where py = pyridine.

with bipy ligand, when bonded to Ru(II) in the *trans*-$[RuCl_2(dppb)(LL)]$ type complexes. For comparison, the electrochemical data for a series of $[Ru(NH_3)_5(L)]^{2+}$ and *trans*-$[RuCl_2(dppb)(LL)]$ type complexes are displayed in Table 4.

For both type of complexes, the $E_{1/2}$ values show the stability enhancement of the reduced Ru(II) state when the metal center is coordinated through sulfur instead of nitrogen pyridine ring atom [41,42]. This data reflect the pronounced π-acid effect of the sulfur atom, especially for the dithiane isomers (see Table 4). In these cases, the higher values are assigned to the extra interaction between the coordinated and noncoordinated sulfur atoms which decreases as the S–S distance increases [4].

4. Conclusion

The data collected in this work for the *trans*-$[RuCl_2$-(dppb)(1,4-dt)], *mer*-$[RuCl_3(dppb)(1,4\text{-dt})]$ and $[\{RuCl_3$-$(dppb)\}_2(\mu\text{-}(1,4\text{-dt}))]$ complexes where the 1,4-dithiane ligand acts as bidentate, monodentate and ambidentate forms, respectively, exemplify the conformational versatility of this ligand towards the coordination chemistry. The *trans*-$[RuCl_2(dppb)(1,4\text{-dt})]$ complex consists in the first example of an hexacoordinated ruthenium complex with 1,4-dithiane as a bidentate ligand, in a D_2 conformation.

5. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Center, CCDC No. 279648. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44 1223 336033; e-mail: deposit@ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk).

of the electronic and steric properties of the triarylphosphines on the synthesis, spectroscopical properties and structure of mononuclear Rh(I)–chloride complexes.

2. Experimental

2.1. Chemicals and physical measurements

Phosphines PR_3 with $R = 4\text{-}(OCH_3)C_6H_4$, $3\text{-}(OCH_3)C_6H_4$, $2\text{-}(OCH_3)C_6H_4$, $4\text{-}(CH_3)C_6H_4$, $3\text{-}(CH_3)C_6H_4$, $2\text{-}(CH_3)C_6H_4$, $4\text{-}ClC_6H_4$, $3\text{-}ClC_6H_4$, $4\text{-}FC_6H_4$, $4\text{-}(CF_3)C_6H_4$, C_6H_5, and $R_3 = (C_6H_5)_2(C_6F_5)$, $(C_6H_5)(C_6F_5)_2$ and $(C_6F_5)_3$ and $RhCl_3 \cdot 3H_2O$ were purchased from Strem Chemicals and used as received. The complex $[\{Rh(\mu\text{-}Cl)(\eta^4\text{-}COD)\}_2]$ was prepared as previously reported [11]. Solvents were dried and degassed prior to use. All manipulations were carried out under dry nitrogen atmospheres using Schlenk techniques. Thin layer chromatography (Merck, 5×7.5 cm^2 Kiesegel 60 F_{254}) was used to monitor the progress of the reactions. Elemental analyses were determined by Galbraith Labs. Inc., USA. NMR spectra were recorded by Spectral Data Services (IL, USA) on a SDS-360 spectrometer working at 360 MHz (^{1}H), 282 MHz (^{19}F) and 202 MHz (^{31}P) in $CDCl_3$ solutions at ambient temperature. Chemical shifts are given in ppm relative to TMS (^{1}H, $\delta = 0$), H_3PO_4 (^{31}P, $\delta = 0$) and $CFCl_3$ (^{19}F, $\delta = 0$). Since all reactions were conducted similarly, only a general procedure is described.

2.2. General procedure

To a solution of the complex $[\{Rh(\mu\text{-}Cl)(\eta^4\text{-}COD)\}_2]$ (200 mg, 0.406 mmol) in acetone (10 cm^3) were added two equivalents of the corresponding phosphine. The color of the solution quickly changed from orange to yellow. The mixture was stirred at room temperature and checked for completion by TLC. After that the solvent was removed in vacuo. All complexes were isolated as crystalline solids.

2.3. Compounds characterization

2.3.1. $[RhCl(\eta^4\text{-}COD)(P(4\text{-}OCH_3C_6H_4)_3)]$ (**1**)

Yield 89%; orange-yellow. *Anal.* Calc. for $C_{29}H_{33}ClO_3PRh$: C, 58.16; H, 5.55. Found: C, 58.06; H, 5.17%. ^{1}H NMR, $CDCl_3$ δ (ppm); 7.64 (m, 6H, C*H*-phosphine) 6.89 (m, 6H, C*H*-phosphine), 5.53 (m, 2H, COD-C*H trans*-P), 3.81 (s, 9H, phosphine-OCH_3), 3.12 (m, 2H, COD-C*H trans*-Cl), 2.20 (m, 4H, COD-CH_2), 2.10–1.90 (m, 4H, COD-CH_2). ^{31}P NMR, $CDCl_3$ $\delta = 27.7$ ppm, d, $^1J_{Rh-P} = 148.7$ Hz.

2.3.2. $[RhCl(\eta^4\text{-}COD)\{P(4\text{-}CH_3C_6H_4)_3\}]$ (**2**)

Yield 99%; yellow. *Anal.* Calc. for $C_{29}H_{33}ClPRh$: C, 63.23; H, 6.04. Found: C, 64.00; H, 6.07%. ^{1}H NMR, $CDCl_3$ δ (ppm); 7.71 (m, 6H, C*H*-phosphine), 7.53 (m, 6H, C*H*-phosphine), 5.54 (m, 2H, COD-C*H trans*-P), 3.13 (m, 2H, COD-C*H trans*-Cl), 2.40 (m, 4H, COD-CH_2), 2.35 (s, 9H, phosphine-CH_3), 2.10–1.90 (m, 4H, COD-CH_2). ^{31}P NMR, $CDCl_3$ $\delta = 29.3$ ppm, d, $^1J_{Rh-P} = 149.3$ Hz.

2.3.3. $[RhCl(\eta^4\text{-}COD)\{P(C_6H_5)_3\}]$ (**3**)

Yield 94%; yellow. *Anal.* Calc. for $C_{26}H_{27}ClPRh$: C, 61.41; H, 5.36. Found: C, 61.74; H, 5.33%. ^{1}H NMR, $CDCl_3$ δ (ppm); 7.75 (m, 6H, C*H*-phosphine), 7.40 (m, 9H, C*H*-phosphine), 5.58 (m, 2H, COD-C*H trans*-P), 3.15 (m, 2H, COD-C*H trans*-Cl), 2.40 (m, 4H, COD-CH_2), 2.15–1.85 (m, 4H, COD-CH_2). ^{31}P NMR, $CDCl_3$ $\delta = 31.3$ ppm, d, $^1J_{Rh-P} = 150.1$ Hz.

2.3.4. $[RhCl(\eta^4\text{-}COD)\{P(4\text{-}FC_6H_4)_3\}]$ (**4**)

Yield 93%; yellow. *Anal.* Calc. for $C_{26}H_{24}ClF_3PRh$: C, 55.49; H, 4.30. Found: C, 55.84; H, 4.29%. ^{1}H NMR, $CDCl_3$ δ (ppm); 7.70 (m, 6H, C*H*-phosphine), 7.10 (m, 6H, C*H*-phosphine), 5.60 (m, 2H, COD-C*H trans*-P), 3.08 (m, 2H, COD-C*H trans*-Cl), 2.45 (m, 4H, COD-CH_2), 2.20–1.90 (m, 4H, COD-CH_2). ^{31}P NMR, $CDCl_3$ $\delta = 29.5$ ppm, d, $^1J_{Rh-P} = 152.6$ Hz. ^{19}F NMR, $CDCl_3$, $\delta = -109.4$ ppm.

2.3.5. $[RhCl(\eta^4\text{-}COD)\{P(4\text{-}CF_3C_6H_4)_3\}]$ (**5**)

Yield 97%; yellow. *Anal.* Calc. for, $C_{29}H_{24}ClF_9PRh$: C, 48.86; H, 3.39. Found: C, 48.56; H, 3.08%. ^{1}H NMR, $CDCl_3$ δ (ppm); 7.84 (m, 6H, C*H*-phosphine), 7.68 (m, 6H, C*H*-phosphine), 5.69 (m, 2H, COD-C*H trans*-P), 3.11 (m, 2H, COD-C*H trans*-Cl), 2.44 (m, 4H, COD-CH_2), 2.20–1.95 (m, 4H, COD-CH_2). ^{31}P NMR, $CDCl_3$ $\delta = 32.2$ ppm, d, $^1J_{Rh-P} = 154.1$ Hz. ^{19}F NMR, $CDCl_3$, 4-CF_3C$_6$H$_4$, $\delta = -63.6$ ppm, s.

2.3.6. $[RhCl(\eta^4\text{-}COD)\{P(4\text{-}ClC_6H_4)_3\}]$ (**6**)

Yield 82%; yellow. *Anal.* Calc. for $C_{26}H_{24}Cl_4PRh$: C, 51.01; H, 3.95. Found: C, 51.62; H, 4.06%. ^{1}H NMR, $CDCl_3$ δ (ppm); 7.65 (m, 6H, C*H*-phosphine), 7.38 (m, 6H, C*H*-phosphine), 5.61 (m, 2H, COD-C*H trans*-P), 3.07 (m, 2H, COD-C*H trans*-Cl), 2.42 (m, 4H, COD-CH_2), 2.20–1.90 (m, 4H, COD-CH_2). ^{31}P NMR, $CDCl_3$ $\delta = 30.3$ ppm, d, $^1J_{Rh-P} = 152.8$ Hz.

2.3.7. $[RhCl(\eta^4\text{-}COD)\{P(3\text{-}OCH_3C_6H_4)_3\}]$ (**7**)

Yield 87%; orange-yellow. *Anal.* Calc. for $C_{29}H_{33}ClO_3PRh$: C, 58.16; H, 5.55. Found: C, 58.66; H, 5.57%. ^{1}H NMR, $CDCl_3$ δ (ppm); 7.40 (m, 3H, C*H*-phosphine), 7.25 (m, 6H, C*H*-phosphine), 6.70 (m, 3H, C*H*-phosphine), 5.57 (m, 2H, COD-C*H trans*-P), 3.77 (s, 9H, phosphine-OCH_3), 3.21 (m, 2H, COD-C*H trans*-Cl), 2.40 (m, 4H, COD-CH_2), 2.15–1.85 (m, 4H, COD-CH_2). ^{31}P NMR, $CDCl_3$ $\delta = 32.8$ ppm, d, $^1J_{Rh-P} = 149.9$ Hz.

2.3.8. $[RhCl(\eta^4\text{-}COD)\{P(3\text{-}CH_3C_6H_4)_3\}]$ (**8**)

Yield 90%; orange-yellow. *Anal.* Calc. for $C_{29}H_{33}ClPRh$: C, 63.23; H, 6.04. Found: C, 62.90; H, 5.95%. ^{1}H NMR, $CDCl_3$ δ (ppm); 7.54 (m, 6H, C*H*-phosphine), 7.25 (m, 6H, C*H*-phosphine), 5.56 (m, 2H, COD-C*H trans*-P), 3.14

(m, 2H, COD-C*H trans*-Cl), 2.40 (m, 4H, COD-CH_2), 2.35 (s, 9H, phosphine-CH_3), 2.15–1.85 (m, 4H, COD-CH_2). ^{31}P NMR, $CDCl_3$ $\delta = 30.8$ ppm, d, $^1J_{Rh-P} = 149.4$ Hz.

*2.3.9. [RhCl(η⁴-COD){P(3-ClC₆H₄)₃}] (**9**)*

Yield 83%; yellow. *Anal.* Calc. for $C_{26}H_{24}Cl_4PRh$: C, 51.01; H, 3.95. Found: C, 50.65; H, 4.02%. ^{1}H NMR, $CDCl_3$ δ (ppm); 7.63 (m, 6H, C*H*-phosphine), 7.40 (m, 6H, C*H*-phosphine), 5.66 (m, 2H, COD-C*H trans*-P), 3.11 (m, 2H, COD-C*H trans-Cl*), 2.45 (m, 4H, COD-CH_2), 2.20–1.95 (m, 4H, COD-CH_2). ^{31}P NMR, $CDCl_3$ $\delta = 32.4$ ppm, d, $^1J_{Rh-P} = 153.2$ Hz.

*2.3.10. [RhCl(η⁴-COD){P(2-OCH₃C₆H₄)₃}] (**10**)*

Yield 87%; yellow. *Anal.* Calc. for, $C_{29}H_{33}ClO_3PRh$: C, 58.16; H, 5.55. Found: C, 57.89; H, 5.48%. ^{1}H NMR, $CDCl_3$ δ (ppm); 7.38 (m, 3H, C*H*-phosphine), 7.20 (m, 3H, C*H*-phosphine), 6.90 (m, 3H, C*H*-phosphine), 6.81 (m, 3H, C*H*-phosphine), 5.23 (m, 2H, COD-C*H trans*-P), 3.84 (m, 2H, COD-C*H trans*-Cl), 3.52 (s, 9H, phosphine-OCH_3), 2.35 (m, 4H, COD-CH_2), 1.98 (m, 4H, COD-C**H**$_2$). ^{31}P NMR, $CDCl_3$ $\delta = 16.6$ ppm, d, $^1J_{Rh-P} = 147.2$ Hz.

*2.3.11. [RhCl(η⁴-COD){P(2-CH₃C₆H₄)₃}] (**11**)*

Yield 95%; yellow. *Anal.* Calc. for $C_{29}H_{33}ClPRh$: C, 63.23; H, 6.04. Found: C, 63.41; H, 5.92%. ^{1}H and ^{31}P NMR, not observed in solution, see text.

*2.3.12. [RhCl(η⁴-COD){P(C₆H₅)₂(C₆F₅)}] (**12**)*

Yield 64%; yellow. *Anal.* Calc. for $C_{26}H_{22}ClF_5PRh$: C, 52.15; H, 3.70. Found: C, 52.97; H, 3.72%. ^{1}H NMR, $CDCl_3$ δ (ppm); 7.75 (m, 4H, C*H*-phosphine), 7.45 (m, 6H, C*H*-phosphine), 5.55 (m, 2H, COD-C*H trans*-P), 3.38 (m, 2H, COD-C*H trans*-Cl), 2.40 (m, 4H, COD-CH_2), 2.15–1.80 (m, 4H, COD-CH_2). ^{31}P NMR, $CDCl_3$ $\delta = 22.5$ ppm, d, $^1J_{Rh-P} = 151.9$ Hz. ^{19}F NMR, $CDCl_3$, $\delta = -124.9$ (m, 2F, *ortho*), −149.4 (dd, 1F, *para*), −160.3 (m, 2F, *meta*).

2.4. X-ray crystallography

Single crystals of **11** were obtained by slow evaporation of a saturated acetone solution. X-ray diffraction data were measured at 298 K on a Siemens P4 diffractometer using common procedures [12] and were corrected for absorption effect by means of ψ-scans data. The structure was solved and refined using standard procedures [13] without restraints or constraints. H atoms were placed on idealised positions and refined using a riding model with fixed isotropic U. Crystal data are collected in Table 1.

Table 1
Crystal data for [RhCl(η⁴-COD){P(2-CH₃C₆H₄)₃}] (**11**)

Empirical formula	$C_{29}H_{33}ClPRh$
Formula weight	550.88
Color, habit	yellow regular prism
Crystal size (mm)	$0.5 \times 0.2 \times 0.1$
Space group	$P2_1/n$
a (Å)	8.2231(11)
b (Å)	17.575(3)
c (Å)	17.058(2)
β (Å)	91.334(11)
V (Å^3)	2464.5(6)
Z	4
Absorption coefficient (mm^{-1})	0.882
Radiation	Mo Kα ($\lambda = 0.71073$ Å)
2θ Range (°)	4.64–45.98
Reflections collected	4650
Independent reflections[a]	3417 ($R_{int} = 3.01\%$)
Transmission factors (minimum, maximum)	0.804, 0.917
Final R indices [2610 $I > 2\sigma(I)$] (%)[a]	$R_1 = 4.09$, $wR_2 = 8.47$
Final R indices [all data] (%)[a]	$R_1 = 6.49$, $wR_2 = 9.43$
Goodness-of-fit, S[a]	1.026
Data-to-parameters ratio	3417/289

[a] R_{int}, R_1, wR_2 and S are defined as follows:

$$R_{int} = \frac{\sum |F_o^2 - \langle F_o^2 \rangle|}{\sum F_o^2},\quad R_1 = \frac{\sum ||F_o| - |F_c||}{\sum |F_o|},\quad wR_2 = \sqrt{\frac{\sum w(F_o^2 - F_c^2)^2}{\sum w(F_o^2)^2}},$$

$$S = \sqrt{\frac{w(F_o^2 - F_c^2)^2}{m - n}}.$$

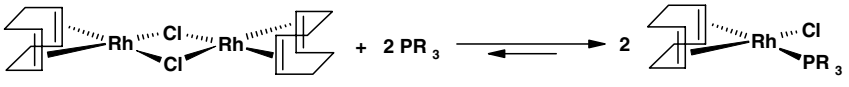
3. Results and discussion

3.1. Synthesis and characterization

The reactions of the chloro-bridged complex [{Rh(μ-Cl)(η⁴-COD)}$_2$] with 12 different triarylphosphines in acetone solutions afforded the mononuclear complexes [RhCl(η⁴-COD)(PR$_3$)], with R = 4-(OCH$_3$)C$_6$H$_4$ (**1**), 4-(CH$_3$)C$_6$H$_4$ (**2**), C$_6$H$_5$ (**3**), 4-FC$_6$H$_4$ (**4**), 4-(CF$_3$)C$_6$H$_4$ (**5**), 4-ClC$_6$H$_4$ (**6**), 3-(OCH$_3$)C$_6$H$_4$ (**7**), 3-(CH$_3$)C$_6$H$_4$ (**8**), 3-ClC$_6$H$_4$ (**9**), 2-(OCH$_3$)C$_6$H$_4$ (**10**), 2-(CH$_3$)C$_6$H$_4$ (**11**) and R$_3$ = (C$_6$H$_5$)$_2$(C$_6$F$_5$) (**12**) (Scheme 1).

An equilibrium between mononuclear and dinuclear species is rapidly achieved, with the mononuclear complex existing as the predominant species [14].

Compounds **1**–**12** are yellow or orange-yellow, stable crystalline solids which are soluble in common solvents – acetone, chloroform and dichloromethane. Analytical data and NMR parameters are consistent with the given formulae. IR spectra show absorptions characteristic of the 1,5-cyclooctadiene and the substituted triarylphosphines although they are not significant to the following discussion. A summary of spectroscopic data for complexes **1**–**12** is presented in Table 2.



Scheme 1. Reaction between [{Rh(μ-Cl)(η⁴-COD)}$_2$] and PR$_3$.

Table 2
Summary of spectroscopic data for complexes **1**–**12**

Complex	Phosphine	^{1}H δ (ppm) CH	^{31}P δ (ppm)	$^1J_{Rh-P}$ (Hz)
1	P(4-$OCH_3C_6H_4$)$_3$	5.53, 3.12	27.7	148.7
2	P(4-$CH_3C_6H_4$)$_3$	5.54, 3.13	29.3	149.3
3	P(C_6H_5)$_3$	5.58, 3.15	31.3	150.1
4	P(4-FC_6H_4)$_3$	5.60, 3.08	29.5	152.6
5	P(4-$CF_3C_6H_4$)$_3$	5.69, 3.11	32.2	154.1
6	P(4-ClC_6H_4)$_3$	5.61, 3.07	30.3	152.8
7	P(3-$OCH_3C_6H_4$)$_3$	5.57, 3.21	32.8	149.9
8	P(3-$CH_3C_6H_4$)$_3$	5.56, 3.14	30.8	149.4
9	P(3-ClC_6H_4)$_3$	5.66, 3.11	32.4	153.2
10	P(2-$OCH_3C_6H_4$)$_3$	5.23, 3.84	16.6	147.2
11	P(2-$CH_3C_6H_4$)$_3$	[a]	[a]	[a]
12	P(C_6H_5)$_2$(C_6F_5)	5.55, 3.38	22.5	151.9

[a] Not observed in solution.

Equivalent experiments using P(C_6H_5)(C_6F_5)$_2$ or P(C_6F_5)$_3$ failed to react, even when a reflux or excess of phosphine were used, probably reflecting a considerable reduction of the basicity of the phosphorous atom impairing its ability to act as a base (see Table 3).

Proton NMR spectra of compounds **1**–**12** show the expected different resonances for methine (CH) and methylene (CH_2) protons of the cyclooctadiene ring, the aromatic protons and, for complexes **1**, **2**, **7**, **8** and **10**, the methyl protons of the phosphine.

Two different sets for the CH protons of the cyclooctadiene were observed, arising from two different *trans* substituents at the metallic centre [15]. The overall range for complexes **1**–**12** is $\Delta\delta = 3.84$–3.07 ppm for the *trans*-Cl CH absorptions and $\Delta\delta = 5.69$–5.23 ppm for the *trans*-P. However, these resonances are rather insensitive to the nature of the phosphine in *trans* position.

Fluorine NMR spectra of compounds **4** (P(4-FC_6H_4)$_3$ with a AA′BB′X magnetic system), and **5** (P(4-$CF_3C_6H_4$)) exhibit single absorptions. ^{19}F NMR spectrum of [RhCl(η^4-COD)(P(C_6H_5)$_2$(C_6F_5))] (**12**), show three signals of a AA′BB′C magnetic system corresponding to *ortho*, *meta* and *para* fluorine nuclei of the PC_6F_5 moiety.

Table 3
Summary of electronic and steric parameters for the triphenylphosphines employed in this study [6]

Phosphine	χ	θ (°)
P(4-$OCH_3C_6H_4$)$_3$	10.5	145
P(4-$CH_3C_6H_4$)$_3$	11.5	145
P(C_6H_5)$_3$	13.3	145
P(4-FC_6H_4)$_3$	15.7	145
P(4-$CF_3C_6H_4$)$_3$	20.5	145
P(4-ClC_6H_4)$_3$	16.8	145
P(3-$OCH_3C_6H_4$)$_3$	[a]	[a]
P(3-$CH_3C_6H_4$)$_3$	11.3	148
P(3-ClC_6H_4)$_3$	19.6	148
P(2-$OCH_3C_6H_4$)$_3$	[a]	[a]
P(2-$CH_3C_6H_4$)$_3$	10.7	178
P(C_6H_5)$_2$(C_6F_5)	20.4	158
P(C_6H_5)(C_6F_5)$_2$	27.6	171
P(C_6F_5)$_3$	34.8	184

[a] Data not available.

^{31}P NMR spectra of compounds **1**–**12** exhibit signals with chemical shifts spanning over ca. 5 ppm from 27.7 to 32.8 ppm except for compounds **10** ($\delta = 16.63$ ppm) and **12** ($\delta = 22.50$ ppm). Each signal is a doublet due to ^{103}Rh–^{31}P coupling with $^1J_{Rh-P}$ between 147.7 and 154.05 Hz.
