In this work the synthesis, crystal structure and the vibrational spectra of coordination polymers with BPP and squarate ion ligands and first transition metal ions (M = Mn^{2+}, Co^{2+}, Ni^{2+}, Cu^{2+} and Zn^{2+}) are described. The correlation between crystal data and vibrational spectra is also investigated, with the aim of identifying the intermolecular interactions present in the solid state, as well as their influence on the crystal packing of such structures.

2. Experimental

2.1. Synthesis

$C_{13}H_{14}N_2$ (BPP) (50 mg, 0.25 mmol) and $H_2C_4O_4$ (29 mg, 0.25 mmol) were dissolved in water and mixed. Aqueous solution of metal chloride hydrate (0.25 mmol in 10.0 mL of water) was layered on to the previous solution, and after slow diffusion for a few days, suitable single crystals were obtained and analyzed by vibrational spectroscopy, thermogravimetric analysis and X-ray diffraction techniques. Elemental *Anal.* Calc. for $[C_{13}H_{16}N_2]^{2+}$-$[Mn(C_4O_4)_2(H_2O)_2]^{2-}$ (light yellow, yield = 47%): C, 48.94; N, 5.44; H, 3.88. Found: C, 47.23; N, 4.76; H, 3.82%; *Anal.* Calc. for $[C_{13}H_{16}N_2]^{2+}[Co(C_4O_4)_2(H_2O)_2]^{2-}$ (light pink, yield = 55%): C, 48.56; N, 5.39; H 3.85. Found: C, 48.29; N, 5.26; H, 3.89%; *Anal.* Calc. for $[C_{13}H_{16}N_2]^{2+}$-$[Ni(C_4O_4)_2(H_2O)_2]^{2-}$ (light green, yield = 51%): C, 48.58; N, 5.39; H, 3.86. Found: C, 48.15; N, 5.25; H 4.06%; *Anal.* Calc. for $[C_{13}H_{16}N_2]^{2+}[Cu(C_4O_4)_2(H_2O)_2]^{2-}$ (golden, yield = 50%): C, 48.14; N, 5.35; H, 3.82. Found: C, 46.79; N, 4.70; H 3.91%; *Anal.* Calc. for $[C_{13}H_{16}N_2]^{2+}$-$[Zn(C_4O_4)_2(H_2O)_2]^{2-}$ (colourless, yield = 47%): C, 47.96; N, 5.33; H, 3.81. Found: C, 47.82; N, 5.33; H, 3.85%.

2.2. X-ray diffraction

Single crystal X-ray data were collected in a Nonius Kappa CCD diffractometer with Mo Kα ($\lambda = 0.71073$ Å) at room temperature. Data collection and reduction, and cell refinement were performed by DENZO and SCALEPACK programs [21]. The structures were solved and refined using SHELXL-97 [22]. An empirical isotropic extinction parameter x was refined, according to the method described by Larson [23]. Analytical absorption, Lorentz and polarization effects were corrected. The structures were drawn by ORTEP-3 for Windows [24]. Hydrogen atoms were located from Fourier difference maps. Anisotropic displacement parameters were refined to all non-hydrogen atoms.

2.3. Raman spectra

Fourier-transform Raman spectroscopy was carried out using a Bruker RFS 100 instrument, Nd^{3+}/YAG laser operating at 1064 nm in the near infrared and CCD detector cooled with liquid N_2. Good signal-to-noise ratios were obtained from 2000 scans accumulated over a period of about 30 min, using 4 cm^{-1} as spectral resolution. All spectra were obtained at least twice to show the reproducibility, and no changes in band positions and intensities were observed.

2.4. Infrared spectra

Infrared spectra were obtained in a Bomem MB-102 spectrometer fitted with CsI beam splitter, using KBr disks and spectral resolution of 4 cm^{-1}. Good signal-to-noise ratio was obtained from the accumulation of 128 scans.

2.5. Thermogravimmetric analysis

Thermogravimmetric data were obtained in a Mettler STARe TG50 thermobalance; the samples were heated at

10 °C/min from room temperature to 800 °C in dynamic air flow.

3. Results and discussion

Transition metal complexes of general formulae $\{(H_2BPP)^{2+}[M(C_4O_4)_2(H_2O)_2]^{2-}\}$, where $M = Mn^{2+}$, Co^{2+}, Ni^{2+}, Cu^{2+} and Zn^{2+}, were obtained by slow diffusion of metal chloride aqueous solutions into an aqueous solution containing squaric acid and BPP. In all cases, analytical data suggest the formation of compounds with (1:1:2)/(M^{2+}:BPP:$C_4O_4^{2-}$) stoichiometric ratio. Thermogravimetric curves, which are deposited as Supplementary material, show that Mn^{2+}, Cu^{2+} and Zn^{2+} complexes are stable up to 170 °C, whereas Co^{2+} and Ni^{2+} ones, up to 200 °C. Above these temperatures it can be observed the first weight loss corresponding to two water molecules. The dehydration process occurs at high temperatures indicating the presence of coordination water molecules probably involved in hydrogen bonding. Afterwards, the curves show at least two other weight loss steps attributed to compounds thermodecomposition.

The polymeric nature of compounds was revealed by X-ray single crystal structure analysis. Tables 1 and 2 exhibit crystal data and main geometrical parameters of all transition metal complexes and comparing the listed crystallographic parameters it can be noticed that all compounds are isostructural. Fig. 1 shows the first M^{2+} coordination sphere in a distorted octahedral geometry. Surprisingly, BPP ligands are not coordinated to the metal centers and appear in the cationic form (H_2BPP^{2+}) due to the protonation of pyridyl nitrogen atoms. The formation of H_2BPP^{2+} cation can be explained by the acid-base reaction between squaric acid and BPP.

The metal ions are located in the unit cell inversion center and are surrounded by six oxygen atoms from two squarate ions and two water molecules with average of M–O bond distance of 2.106(2) Å and O–M–O bond angles varying from 83.5° to 96.5°. In the manganese compound it can be observed the longest M–O bond distance to squarate ion, as well as to water molecules (2.174(2) and 2.194(2) Å respectively). However, the shortest M–O bond distances are observed in different complexes: M–O (average of 2.078(2) Å) in nickel and M–O_w (1.980(2) Å) in copper complexes. The average of M–O and M–O_w bond distances are respectively 2.127(2) and 2.085(2) Å. In all compounds the M–O bond distances (M–O2) of one squarate ligand and M–O_w (M–O5) are close to each other when compared to M–O of two squarate ligands (M–O2 and M–O4). Additionally, the two coordination water molecules are involved in medium hydrogen bonds with the non-coordinated oxygen atoms of squarate ligands, as indicated by thermal analysis results, and the average of O···O distance is 2.679(3) Å.

Each squarate ion adopts the 1,3-bis(monodentate) coordination mode and bridges two metal centers giving rise to a two-dimensional (2D) grid with (4,4) topology, as can be seen in Fig. 2. The four-membered rings, formed by metals and squarate ligands, are slightly distorted due to different M–M separations with averages of smaller and larger distances of 8.024 and 8.111 Å, respectively. Squarate rings of four-member topology are almost planar with mean deviation range between 0.011 and 0.016 Å. These rings are not perpendicular to each other, forming an angle around 82° between them. Electronic delocalization is observed in oxocarbon rings since the average of the largest difference in C–C and C–O bond distances is short (respectively 0.006 and 0.018 Å). The oxocarbon rings are within a

long distance each other and consequently it is not observed π-stacking interaction between them. The supramolecular arrangements are based on single layers, which are not superimposed, showing parallel arrangement of squarate rings along crystallographic *a* axis and ring planes are shifted *ca.* 0.5 Å. Along *b* axis, the squarate rings of adjacent layers are not parallel presenting a rotationz of around 15°.

BPP cationic species are placed inside the four-member ring cavities in two different orientations, inverted to each other, as shown in Fig. 2. In the middle of BPP molecule (C11) is located the twofold axis symmetry. The phenyl rings atoms give rise to planes where the average of deviation of the best plane is 0.004 Å, whereas the range of the angle between phenyl rings is between 76.2° and 78.2°. The smallest angle of phenyl rings is observed for copper

complex and the biggest for manganese. These molecules adopt the TT conformation with N-to-N separation range for all compounds between 9.32 and 9.36 Å. These values are in agreement to other compounds containing BPP ligand in TT conformation structurally characterized [18h,18i,25]. Analysis of topological parameters of π-stacking [1] shows that phenyl rings of adjacent H_2BPP^{2+} layers present centroid–centroid and interplanar distances shorter than 4.0 Å (average of 3.92 and 3.53 Å, respectively), and small horizontal shift (average of 1.19 Å), strongly suggesting π-stacking interaction in these structures. In addition, according to the geometrical parameters of H_2BPP^{2+} displayed in Table 2, BPP cation forms two types of hydrogen bond interactions between layers of four-member rings: N–H···O medium and C–H···O very weak interactions. The presence of all these interactions between two adjacent 2D grids leads to the establishment of a three-dimensional supramolecular array as can be seen in Fig. 3.

Vibrational spectra of these compounds are very similar, and are in agreement with crystal data. The main vibrational modes are listed in Table 3 and Fig. 4 shows the Raman spectra of all compounds. Infrared spectra are deposited as Supplementary materials. In the infrared spectra it can be observed characteristic bands of squarate units around 1500 cm^{-1}, which are related to CC and CO stretching modes, whereas the M–O bond stretching mode is observed at 505 cm^{-1}. Ring breathing of pyridyl group has been assigned to the bands at 995 and 579 cm^{-1} [26,27]. The spectral region between 1600 and 1650 cm^{-1}, where CC and CN stretching modes are expected, is very important in the BPP ligand coordination analysis [17a]. This band shows up at 1605 cm^{-1} for the free ligand and at higher wavenumbers (around 1620 cm^{-1}) when BPP is coordinated to the metal ion. In all investigated compounds infrared spectra it can be seen a medium band at 1640 cm^{-1}, which can be tentatively assigned to the in

[a] SQ = squarate and Py = pyridyl.

plane deformation mode of NH bond, indicating the formation of BPP cationic species, in a very good agreement with the X-ray diffraction data.

Raman spectra of all compounds are also very similar. Ring bending and ring breathing of squarate unit have been observed at 645 and 730 cm^{-1}, respectively. Raman features of pyridyl group at 1220 and 1020 cm^{-1} can also be assigned as described above. An interesting comparison of Raman spectra can be done within squarate alkaline salts [28]. Ring bending and ring breathing modes occur in the same region, indicating that the coordination to metal ions does not affect these specific ring modes. In the Raman spectra of the alkaline salts it can be observed a weak band around 1800 cm^{-1}, assigned to CO bond stretching mode [28]. Similar band is observed around 1790 cm^{-1} in the spectra of all complexes, indicating the presence of non-coordinated CO species in the solid state, which is in agreement with crystal structure where O1 and O3 (Fig. 1) are not bonded to metal site. Previous Raman spectra investigation of transition metal squarates [6d] shows the appearance of two distinct CO stretching modes, observed around 1600–1800 cm^{-1} region. Crystal structures of these squarate complexes [12] show that squarate ion is coordinated to metal sites in a 1,3-bis(monodentate) fashion giving rise to a 1D chain. Those complexes, likewise the ones studied in this work, present both free and coordinated CO groups, which show two different CO stretching wavenumber values. Comparing these data, the band observed around 1600 cm^{-1} can be tentatively assigned to the coordinated CO stretching mode. The CC stretching mode is assigned to a medium band around 1110 cm^{-1} which, in the case of Mn(II), Co(II) and Zn(II) complexes spectra, presents a shoulder at 1120 cm^{-1}; the Ni(II) complex presents a very asymmetric band, and Cu(II) complex do not show any splitting. Previous studies in alkaline squarate salts [29,30] have shown that the bands between 1100 and 1200 cm^{-1} can be used to infer about electronic delocalization in oxocarbon ring. The presence of a single band in the spectra indicates that the squarate ring is very symmetric, with a high degree of electronic delocalization, as observed in the case of rubidium and ammonium salts. On the other hand, in lithium, sodium and potassium squarate, which present small electronic delocalization, the band separation is between 86 and 37 cm^{-1}. In the compounds investigated here, besides the appearance of a shoulder in the high spectral region, the wavenumber separation is not so pronounced when compared within the alkaline squarate compounds, so suggesting an emphasized degree of electronic delocalization in oxocarbon rings. This result is confirmed by X-ray structure data, where the largest C–C bond difference between all squarate ions is very small, around 0.011 Å (Table 2). Similar to the infrared spectra, the CC and CN bond stretching of H_2BPP^{2+} species (*ca.* 1510 cm^{-1}) is observed in low wavenumber values when compared to free (*ca.* 1605 cm^{-1}) and coordinated BPP (*ca.* 1620 cm^{-1}).

4. Conclusion

The new structures involving first transition metal ions ($M = Mn^{2+}$, Co^{2+}, Ni^{2+}, Cu^{2+} and Zn^{2+}), squarate ion and 1,3-bis(4-pyridyl)propane (BPP) are described by means of X-ray diffraction, thermogravimetric and vibrational techniques. All compounds are isostructural and the metal sites are coordinated to squarate ligand in a 1,3-bis(monodentate) fashion and water molecules forming a slightly distorted octahedral geometry. The two water molecules are involved in medium hydrogen bonds with squarate ligands, with O···O distance around 2.680 Å. Crystal structures of these compounds show that the arrangement of metal sites and squarate ligands is in 2D sheets with (4,4) topology. Inside of four-member ring topology are located the cationic BPP molecules, which present two orientations in the same 2D layer, one is inverted related to the other. H_2BPP^{2+} cation forms two types of hydrogen bond interactions with the 2D layers, where one is medium (N–H···O) and another is very weak (C–H···O), in a three dimensional arrangement. Vibrational spectra of these compounds are very similar, in agreement to crystal data. In all infrared spectra a medium band at 1640 cm^{-1} has been observed, assigned to the NH in plane deformation mode, indicative of the formation of H_2BPP^{2+} cation. These metal complexes present free and coordinated CO groups, which show two different CO stretching wavenumbers: one observed at *ca.* 1600 cm^{-1}, assigned to coordinated carbonyl stretching, and another observed at *ca.* 1800 cm^{-1} attributed to the free CO group. The formation of H_2BPP^{2+} cation is probably due to the acid-base reaction between squaric acid and BPP. At last, a very important achievement of this investigation refers to the coordination geometries of all the investigated compounds, which are governed only by the ligands, independently of the different electronic properties of the metal ions.

Scheme 1. Structures of substrates and products for the electrooxidations using poly-[*cis*-aquadimethylbipyridyltriphenylphophineruthenium II diphenol anion].

Modified electrodes are useful because they can be applied to several electrochemical systems without modification of their characteristic or efficiency, thus enabling their reuse. Electrodes coated with polymeric films containing reactive groups can be connected to a cell so that they function as working electrodes, leading to the desired organic substrate transformations.

Several modified electrodes containing films bonded to ruthenium complexes from Viologen [14], bipyridyl carbonyl [15,16], bipyridyl ethylamine [17] and other ligands [18,19] were studied and can be used in electrocatalytic oxidations.

In our laboratories we synthesized the allyl ether of *p*-substituted benzenes and we carried out their polymerization so as to obtain chemically and mechanically stable modified electrodes with anionic or cationic ion exchange properties, depending on the nature of the *p*-benzene group [20–22]. Crystallites of noble metals were dispersed in the film which led to the electrocatalytic hydrogenation of unsaturated organic substrates via reduction of H^+ from a mineral acid solution [23,24].

The introduction of a covalent azo bond in the *p*-position of the benzene ring bonded to quinolin-8-ol group, a well known reagent for metal complexation, allows to the preparation of a modified electrode that can be used as metal sensor in the field of the electroanalytical chemistry [25]. Polymerization of this monomer can be accomplished by carrying out anodic scans in a less positive range than that where the redox discharge of the remainder quinoline group occurs. This is possible because the allyl moiety of the monomer polymerizes chemically after electrooxidation at a less positive potential, thus avoiding modification in the structure of the quinoline ligand group. In addition, a large potential window is left untouched in a range corresponding to the reduction potential of transition metals after their complexation with quinoline.

The strategy described above allows the performance of specific electrochemical transformation when these reactions occur at higher potentials in electrocatalytic procedures. Therefore, anchored molecules containing several electrochemical active sites can react with high specificity.

Phenol polymerizes via anodic oxidation, giving a stable film that contains free hydroxyl groups. The electrochemical range of this oxidation is +0.2 to +0.8 V, which is less positive than the potentials for the redox discharges of the ruthenium catalysts [26,27]. Therefore, the above-mentioned strategy can be applied to polyphenol films.

This work presents the transformation of the synthesized *cis*-aquadimethylbipyridyltriphenylphosphineruthenium II perchlorate into its diphenol anion derivative, followed by its electropolymerization to a stable film. We used this film to coat a glassy carbon or a porous carbon felt electrode, and we performed essays to demonstrate the untouched redox activity of this new modified electrode with respect to the aqua and oxo ruthenium group. We also report the use of this modified electrode in the electrocatalytic oxidation of two substrates previously studied in our laboratories (results not yet published).

2. Experimental

2.1. Equipments

Voltammetric measurements were performed using an EG&G PAR 273A potentiostat, connected to an Electrochemical Analysis software model 270. Cyclic voltammetry was carried out in a cylindrical cell (20 mL) using an Ag/AgCl electrode as reference. Glassy carbon (3 mm diameter) was employed as the working electrode, and a platinum wire was used as the auxiliary electrode.

For the electrocatalytic oxidation of the organic substrates, we used a porous carbon felt plate with a surface of 4.7 cm^2 covered with the polymeric film as the working electrode. This electrode was sustained by a platinum wire.

2.2. Reagents

All chemicals used were of analytical grade and were purified when necessary. All solutions were prepared with deionized water (Milli-Q, Millipore Inc., >18 MΩ).

2.3. Analysis

FTIR spectra were recorded in a Perkin Elmer spectrometer model RX series using either liquid film or KBr. Proton nuclear magnetic resonance (^{1}H NMR) spectra were obtained using a Bruker spectrometer model Advance DRX 400 (400 MHz). UV–Vis absorption spectra were recorded on an 8452A HP spectrophotometer 8453 coupled to an 89090A model accessory, at 25 °C. Elemental Analysis measurements were performed on a FISIONS EA1108 model.

2.4. Preparation of cis-aquadimethylbipyridyltriphenylphosphineruthenium II diphenol anion derivative

The complex *cis*-[RuCl(dmbpy)$_2$(PPh$_3$)](PF$_6$) was prepared according to the procedure described in the literature [10], with a global yield of 73%. Then, this material (0.523 g; 0.57 mmol) was dissolved in water (150 mL)/ethanol (150 mL) and an aqueous solution of *p*-silver toluenesulfonate (0.214 g; 0.44 mmol; 100 mL) was added. This mixture was refluxed for 3 h under N_2, the precipitated AgCl was filtered and the volume of the solution was reduced to 1/3 by evaporation. A solution (100 mL) containing phenol (0.269 g; 2.87 mmol) and NaOH (0.114 g; 2.87 mmol) was added slowly, leading to precipitation of the diphenol anion derivative. The dark brown crystalline monomer *cis*-[Ru(dmbpy)$_2$(PPh$_3$)(OH$_2$)](OPh)$_2$ was filtered and washed with cold water and ethyl ether, yielding 0.389 g (0.40 mmol) 70% yield of the product.

^{1}H NMR δ_H (ppm, 400 MHz, CDCl$_3$): 8.8–7.8 (12 H, m, pyridyl hydrogen); 7.3–7.2 (15 H, m, aromatic hydrogen from PPh$_3$); 6.9–7.0 (12 H, m, aromatic hydrogen from phenol) and 2.5 (12 H, methyl).

FTIR (neat, cm^{-1}): 3410 (H$_2$O); 3058 (CH$_3$); 2922 and 2852 (pyridyl and phenyl CH); 1620 and 1436 (C=C and C=N); 1240 and 1092 (PPh$_3$), 728 (pyridyl out of plane CH absorption).

UV–Vis (λ_{max}, nm): 228 (PhO$^-$); 230 (pyridine); 279 (PhO$^-$); 290 (PPh$_3$); 449 (Ru–O).

Elemental *Anal.* Calc. for $C_{54}H_{39}N_4RuPO_3$: C, 70.20; H, 4.03; N, 4.75. Found: C, 77.83; H, 6.06; H, 4.22%.

This monomer was also characterized by cyclic voltammetry with scan ranging from 0.0 to +0.2 V.

2.5. Preparation and characterization of the polymeric film

The monomer (0.053 g; 3.84×10^{-3} mol L^{-1}) was dissolved in a 20 mL cell containing a glassy carbon working electrode and a PTAB/CH_2Cl_2 solution (0.1 mol L^{-1}; 15 mL). Scans from 0.0 to 1.0 V at 25 mV s^{-1} was carried out. To characterize the film scan from 0.0 to +0.9 V was carried out.

The porous carbon felt electrode was prepared in the same way and scans were carried out at 25 mV s^{-1} in the 0.0 to +0.9 V potential range. Characterization was done by comparing the voltammograms obtained here with those described in literature [26,27].

2.6. Electrocatalytic oxidation of safrol (5-allyl-benzo[1,3]dioxole) and isosafrol (5-propenyl-benzo[1,3]dioxole)

A controlled potential of +1.6 V was applied to a 100 mL cell containing the porous carbon felt working electrode coated with the film and a solution (80 mL) of safrol or isosafrol (0.1 mol; 1.6 g) Na_2HPO_4/H_2O 0.05 mol L^{-1} pH 7.

After the current had fallen to low and constant values, the products were extracted with CH_2Cl_2 and dried. Safrol was converted to *piperonal* (5-propenyl-benzo[1,3]dioxole) with 61% yield and isosafrol to 3-benzo[1,3]dioxol-5-yl-propenal with 54% yield. Piperonal: ^{1}H NMR δ_H (ppm, 400 MHz, CDCl$_3$): 9.90 (s, 1H), 7.35–7.10 (m, 3H) and 6.05 (s, 2H).

3-Benzo[1,3]dioxol-5-yl-propenal: ^{1}H NMR δ_H (ppm, 400 MHz, CDCl$_3$): 9.80 (s, 1H), 7.60 (d, 1H), 7.25 (s, 1H), 7.20–6.90 (m, 2H), 6.70 (dd, 1H) and 6.15 (s, 2H).

2.7. Kinetic determinations

From the same experimental conditions described above for the oxidation of the substrates, a new set of experiments was carried out without product extraction. Aliquots were analyzed by UV/Vis spectroscopy until $2 \times t_{1/2}$: the decay observed for the maximum absorbance at 286 nm, in the case of safrol, and at 304 nm, in the case of isosafrol, was converted into concentration values and plotted versus time. Then, the apparent speed constants were calculated (Table 1). The absorbance was converted into concentration taking into account the extinction coefficient ξ for each substrate calculated for the correspondent $\lambda_{max.}$ values. The mass of the substrate that was electrooxidized during the $2 \times t_{1/2}$ experiments was calculated (converted mass, Table 1) from the graphic of the kinetic data, whose abscissas give mass directly.

The mass of ruthenium in the film (2.37×10^{-5} g) prepared over the porous carbon felt electrode was calculated by coulometry (45.18 mC) considering the two electrons for the oxidation peaks showed by voltammetry. The turnover (Table 1) of the ruthenium complex was calculated using the ruthenium equivalent (two electrons = 2.34×10^{-7} eq.) and substrate equivalents (four electrons necessary for the overall transformation, giving the above-indicated products isosafrol = 6.23×10^{-3} eq. and safrol = 5.24×10^{-3} eq.).

3. Results and discussion

The glassy carbon modified electrode coated with the film consisting of poly-[*cis*-aquadimethylbipyridyltriphenylphophineruthenium II diphenol anion] was prepared by scanning the potential range (0.0–1.0 V) corresponding to the phenol anion discharge (0.2–0.75 V), according to the mechanism studied in the literature [26,27].

Fig. 1 A shows that after eight scans the voltammogram remains unchanged, so we assumed that the film formation

Table 1
Kinetic and catalytic parameters for the substrates electrooxidations

Substrates	k for 2 t1/2 (min^{-1})	Coulombs (C)	Turnover	Converted mass (g)
Isosafrol	1.21×10^{-2}	2406 ± 0.25[a]	26623	1.010
Safrol	3.25×10^{-2}	2022 ± 0.22	22393	0.849

[a] Differential theory was used for error calculation.

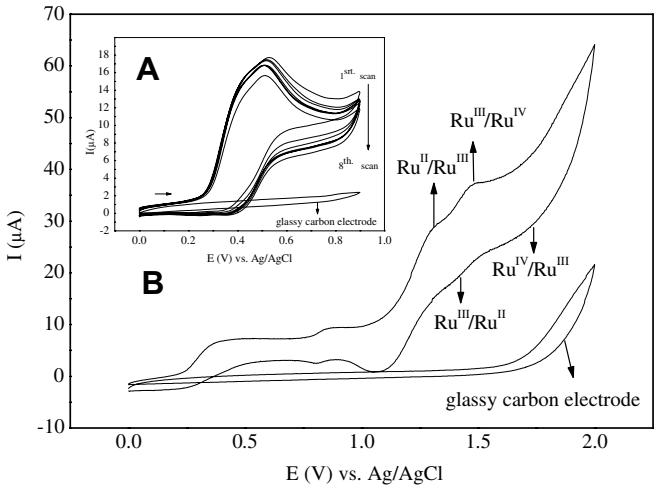

Fig. 1. Cyclic voltammograms of (A) *cis*-aquadimethylbipyridyltriphenylphophineruthenium II diphenolate (polymerization of the film in glassy carbon electrode), scan range from 0.0 to 1.0 V at 25 mV cm^{-1} and (B) characterization of the film, scan range from 0.0 to 1.9 V at 25 mV cm^{-1}.

was completed by them. It was possible to notice the formation of a yellow film on the surface of the electrode. Scanning of the film in the potential range 0.0–2.0 V shows that the discharges of the ruthenium complex (1.0–1.75 V) were not affected by the lower potential range used to polymerization of the phenol anion moiety. Fig. 1B shows that do not occur dissociation in the medium of the positive ruthenium complex associated to the polyphenol anion. This probably is due to the great volume of the complex that remains retained in the lattice of the polymeric chain. This modified electrode was able to catalyze electrooxidation of organic substrates.

The modified carbon felt electrode was prepared in the same way and dedicated in two sets of experiments: electrolysis, from where the reaction products were extracted and analyzed and for the calculation of kinetic and catalytic parameters. Fig. 2 shows the ruthenium complex discharges after the range for phenol oxidation. The voltammogram displays less defined peaks in accordance with the larger surface coated by the film in this electrode.

From the kinetic experiments one can assume that the reactions are pseudo-first order due to the great excess of substrate and the use of a catalytic electrooxidation process. Using the extinction coefficient of the two substrates and the absorbance values obtained by UV/Vis spectroscopy, it was possible to calculate the substrate concentration at various reaction times and plot it versus time, which enable calculation of the apparent speed constants (Table 1), as shown in Fig. 3, with adequate correlation coefficients.

After extraction and analysis of the electrocatalytic oxidation products, the 3-benzo[1,3]dioxol-5-yl-propenal and piperonal obtained from isosafrol and safrol respectively, gives evidence of the occurrence of a 4 electron oxidation. They are interesting from a synthetic point-of-view and are obtained with good yields. The reactions are fast (10^{-2} min^{-1}, Fig. 3). The more stable isosafrol (conjugation between the double bond and aromatic ring: lower speed) had its methyl group oxidized to aldehyde. Safrol (higher speed) underwent a typical organic oxidation of arenes where the $–CH_2$-group close to the aromatic ring was cleaved giving piperonal. In both cases, the selective oxidation to aldehydes and not to the expected carboxylic acids was observed here, as opposed to what occurs in conventional organic oxidation.

The number of Coulombs calculated from the current versus time exponential curve corresponding to $2 \times t_{1/2}$ for safrol and isosafrol for the electrocatalytic oxidation is shown in Table 1 and they are quite similar because these substrates are isomers and their reactions involve four electrons each.

The mass of ruthenium in the film was calculated taking into account the number of Coulombs related to the two-electrons oxidation shown in the voltammogram of Fig. 2.

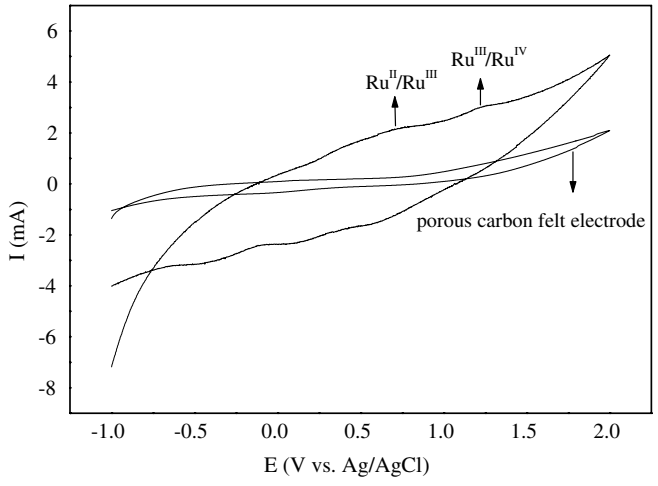

Fig. 2. Characterization of the film that coats the porous carbon felt electrode by cyclic voltammetry, scan range from −1.0 to 1.9 V at 25 mV cm^{-1}.

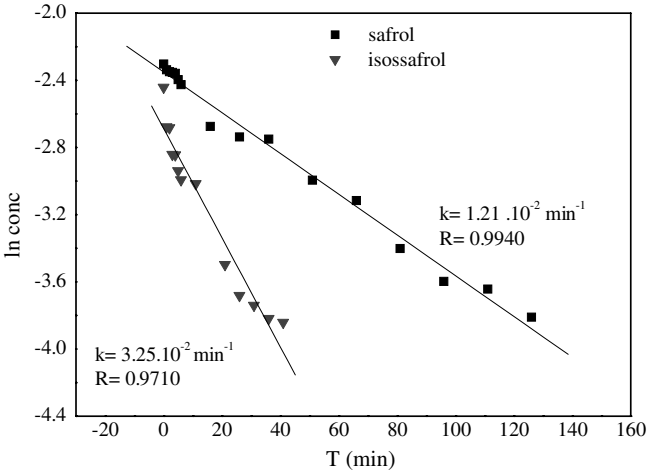

Fig. 3. Linear regression of safrol and isosafrol of the kinetic data analyzed by UV/Vis spectroscopy.

The turnover values calculated from the number of equivalents of substrates and ruthenium (Table 1) are also quite similar and in accordance with the number of Coulombs.

After use this modified electrode presented the same voltammetric properties.

4. Conclusion

The new modified electrode containing ruthenium complex bonded to stable polyphenol film catalyses the rapid electrooxidation of organic substrates, giving products of synthetic interest in good yields. Its preparation can be carried out using a lower potential for oxidation of the phenol moiety, thus avoiding modifications in the electroactive and functional bonded ruthenium complex. Product isolation is very simple and the electrode can be reused. With good turnover, this modified electrode seems to be very convenient for potentially useful electrocatalytic oxidations of organic compounds.

retain their structural integrity upon desolvation–solvation cycles [9].

With these precedents in mind, we undertook hydrothermal synthetic explorations with divalent nickel precursors in the presence of both nicotinic acid and organoimines, which has afforded the 3-D hydrated nickel(II)nicotinate, $[Ni_4(\mu\text{-}H_2O)_2(nic)_8 \cdot 2H_2O]$ (**1**), along with the pillared 3-D material $[Ni_2(H_2O)_2(nic)_4(4,4'\text{-bpy})]$ (**2**). **1** represents a new nickel (II) nicotinate polymorph, contrasting markedly from Lin's previously reported 3-D tetragonal phase $[Ni_2(\mu\text{-}H_2O)(nic)_4] \cdot CH_3CH_2OH \cdot H_2O$ (**3**) [10a], and subtly different from its dehydrated centrosymmetric analog $[Ni_2(\mu\text{-}H_2O)(nic)_4]$ (**4**) [10b]. Herein, we report the syntheses, crystal structures, and thermal properties of these two 3-D coordination polymers along with a magnetochemical investigation of **1**.

2. Experimental

2.1. General considerations

All starting materials were obtained commercially from Aldrich, with the exception of 1,3-di-4-pyridylpropane (TCI America) and 4,4′-dipyridylamine (prepared via literature procedure) [11]. Water was deionized above 3 MΩ in-house. Thermogravimetric analysis was performed on a TA Instruments TGA 2050 Thermogravimetric Analyzer with a heating rate of 5 °C/min up to 900 °C. Elemental analysis was carried out using a Perkin Elmer 2400 Series II CHNS/O Analyzer. IR spectra were recorded on a Mattson Galaxy FTIR Series 3000 using KBr pellets. Variable temperature magnetic susceptibility data (2–300 K) was collected on a Quantum Design MPMS SQUID magnetometer at an applied field of 0.1 T. After each temperature change the sample was kept at the new temperature for 5 min before magnetization measurement to ensure thermal equilibrium. The susceptibility data were corrected for diamagnetism using Pascal's constants [12]. A correction for the diamagnetism of the sample holder was also applied.

2.2. Preparation of $[Ni_4(\mu\text{-}H_2O)_2(nic)_8 \cdot 2H_2O]$ (1)

$NiCl_2 \cdot 6H_2O$ (66 mg, 0.28 mmol), nicotinic acid (68 mg, 0.55 mmol), pyridine (45 μL, 0.56 mmol), and NaOH (1.0 M, 0.42 mL, 0.42 mmol) were mixed into 10 mL distilled H_2O in a 23 mL Teflon-lined Parr acid digestion bomb, which was then sealed and heated at 150 °C for 5 days. The reaction vessel was cooled slowly to 25 °C. Light blue blocks of **1** (60 mg, 68% yield based on Ni) were isolated as a single phase after washing with distilled water and drying in air. As ascertained by unit cell determinations performed on single crystals, **1** could also be prepared by utilizing 1,2-di-4-pyridylethane, 1,3-di-4-pyridylpropane, or 4,4′-dipyridylamine instead of pyridine. However, in all of these cases an insoluble white powder was also produced, which hindered separation of bulk quantities of pure **1**. Single crystals of **1** do not form in the absence of an organoimine. *Anal.* Calc. for $C_{48}H_{40}N_8Ni_4O_{20}$ **1**: C, 44.91; H, 3.14; N, 8.73. Found: C, 44.68; H, 2.98; N, 8.57%. IR (KBr, cm^{-1}): 3445(m), 3143(w), 3085(w), 1638(vs), 1599(m), 1586(m), 1547(w), 1400(vs), 1319(w), 1194(s), 1158(w), 1094(w), 1049(w), 1037(m), 823(m), 765(m), 700(m), 647(w), 575(w), 462(m).

2.3. Preparation of $[Ni_2(H_2O)_2(nicotinate)_4(4,4'\text{-bpy})]$ (2)

$NiCl_2 \cdot 6H_2O$ (66 mg, 0.28 mmol), nicotinic acid (68 mg, 0.55 mmol), 4,4′-bipyridine (87 mg, 0.56 mmol), and NaOH (0.56 mL, 1.0 M, 0.56 mmol) were mixed into 10 mL distilled H_2O in a 23 mL Teflon-lined Parr acid digestion bomb, which was then sealed and heated at 120 °C for 5 days. The reaction vessel was cooled slowly to 25 °C. Large blue blocks of **2** (85 mg, 76% yield based on Ni) were isolated after washing with distilled water and acetone and drying in air. *Anal.* Calc. for $C_{17}H_{14}N_3NiO_5$ **2**: C, 51.17; H, 3.54; N, 10.53. Found: C, 50.24; H, 3.43; N, 10.26%. Carbon analyses were slightly low on several samples, presumably due to incomplete combustion. IR (KBr, cm^{-1}): 3641(w), 2925(m, br), 1615(vs), 1596(m), 1573(m), 1560(m), 1541(w), 1491(w), 1414(s), 1386(vs), 1221(w), 1217(w), 1186(w), 1161(w), 1098(w), 1082(w), 1052(w), 949(w), 834(m), 769(m), 704(m), 635(w), 564(w), 428(w).

3. X-ray crystallography

A blue block crystal of **1** with dimensions 0.52 mm × 0.34 mm × 0.24 mm and a dark blue block crystal of **2** with dimensions 0.70 mm × 0.20 mm × 0.20 mm were subjected to single crystal X-ray diffraction at 173 K using a Bruker-AXS SMART 1k CCD instrument. Reflection data were acquired using graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). The data were integrated via SAINT [13]. Lorentz and polarization effect and empirical absorption corrections were applied with SADABS [14]. The structures were solved using direct methods and refined on F^2 using SHELXTL [15]. All non-hydrogen atoms were refined anisotropically. Hydrogen atoms bound to carbon atoms were placed in calculated positions and refined isotropically with a riding model. The hydrogen atoms belonging to all water molecules in **1** and **2** were found via Fourier difference maps, then restrained at fixed positions and refined isotropically. The PLATON ADDSYM [16] subroutine indicated the possibility of the centrosymmetric space group $P2_1/m$ for **1**, however, attempts to refine the structure in this higher symmetry space group were unsuccessful (Ni–Ni distances <1 Å). Successful solution and refinement of the crystal structure of **1** was only possible in $P2_1$ using appropriate routines for racemic twinning (TWIN/BASF). This twinning was evident on several crystals of **1** prepared in different batches in the presence of various organoimines (*vide infra*). Relevant crystallographic data for **1** and **2** is listed in Table 1.

4. Results and discussion

4.1. Syntheses and spectral characterization

Hydrothermal treatment of an aqueous mixture of nickel(II) chloride, nicotinic acid, sodium hydroxide, and pyridine in a 1:2:2:1.5 mole ratio at 150 °C afforded a high yield of **1** as single phase large blue crystals. Eschewing pyridine for 4,4′-bipyridine in the above synthesis resulted in formation of blue blocks of **2** in high yield as a single-phase product. Attempts to prepare other nickel nicotinate/organoimine coordination polymers were subsequently undertaken using 4,4′-dipyridylamine, 1,2-di-4-pyridylethane, and 1,3-di-4-pyridylpropane. In all of these cases, large blue crystals were garnered in addition to variable amounts of an insoluble amorphous white solid. Unit cell determinations via matrix frame collection indicated that in all of these cases **1** was the only single crystalline product. An organoimine was required to successfully prepare single crystals of **1**; only a sea green powder was obtained if the organoimine was omitted. This is consistent with reports where successful hydrothermal synthesis of a desired product requires a reactant that is not incorporated into the final structure, instead serving as a mineralizer or a structure-directing templating agent [17]. The infrared spectra of **1** and **2** show broad, intense O–C–O stretching bands at 1638 cm^{-1} and 1400 cm^{-1}, and 1615 cm^{-1} and 1386 cm^{-1}, respectively, without any bands due to unligated carboxylic acids at ~1710 cm^{-1}. This observation is fully consistent with the presence of only metal-bound carboxylate moieties [18]. Sharper and weaker bands within the

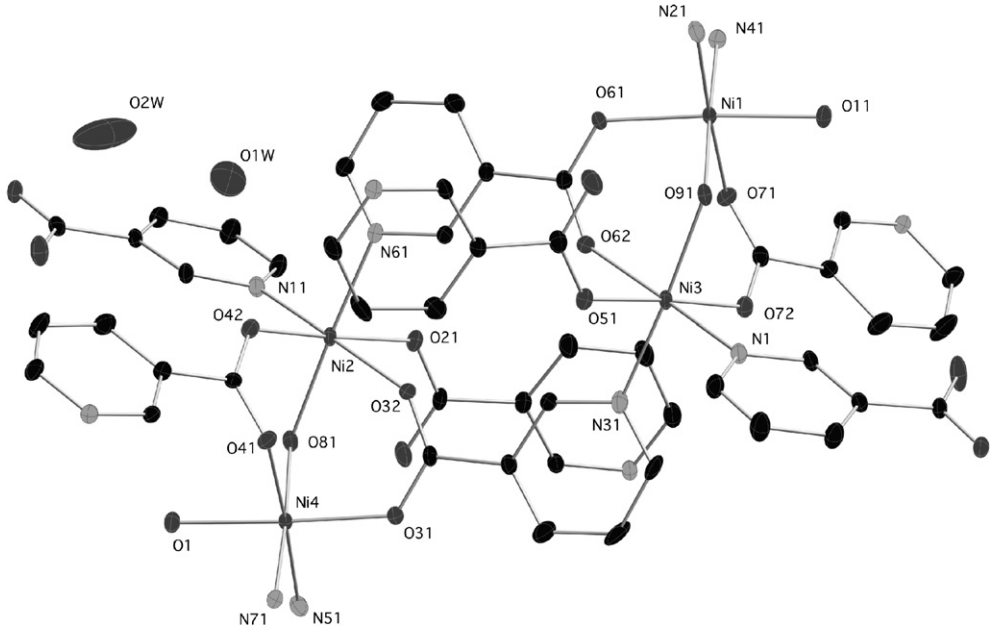

Fig. 1. Thermal ellipsoid plot (50% probability) of the asymmetric unit of **1** with partial atomic number scheme. Hydrogen atoms have been omitted for clarity.

1300–1600 cm^{-1} region correspond to pyridyl ring bending modes [19]. Spectral features between 3000 cm^{-1} and 3400 cm^{-1} in both cases reflect the presence of bound and/or unligated water molecules.

4.2. Crystal structure of $[Ni_4(\mu\text{-}H_2O)_2(nic)_8 \cdot 2H_2O]$ (1)

1 crystallizes in the acentric monoclinic space group $P2_1$, with a large asymmetric unit consisting of four nickel atoms, eight deprotonated nicotinic acid moieties, two μ_2-bridging water molecules, and two water molecules of crystallization (Fig. 1). Each of the four crystallographically distinct Ni atoms displays slightly distorted octahedral $[NiN_2O_4]$ coordination, with standard bond lengths and angles (Table 2). The arrangement of donor atoms about each of the four nickel atoms is identical, albeit with subtly altered bond distances and angles. The two nitrogen donors, one belonging to an exobidentate μ_2-nic ligand and the other to an exotridentate μ_3-nic ligand, are disposed *cis* relative to each other. Oxygen atoms belonging to two different μ_3-nic ligands are also situated in a *cis* orientation. The remaining two coordination sites occupied by oxygen atoms from a μ_2-nic ligand and a μ_2-water molecule, again in a *cis* disposition. The μ_3-nic pyridyl nitrogen donor is arranged *trans* to the μ_2-water molecule that bridge each pair of Ni atoms (Ni–O–Ni angles = 114.2(2)°, 114.9(2)°) into binuclear $[Ni(\mu\text{-}H_2O)(\mu_3\text{-}nic)_2Ni]^{2+}$ units with a Ni–Ni through-space distance of 3.56 Å. Within the two types of binuclear units, the Ni centers are bridged by both carboxylates in a distorted *syn–syn* orientation, with the four sets of Ni–O–O–Ni torsion angles ranging from 28.5° to 41.8° (0° for an idealized *syn–syn* disposition).

Each binuclear unit is turn connected to its neighbors through μ_3-nic ligands to form 1-D $[Ni_2(H_2O)(\mu_3\text{-}nic)_2]$ helical chains that run down the *c* crystal axis. The structure of **1** also contains rippled 2-D cationic $[Ni_4(H_2O)_2(\mu_2\text{-}nic)_4]$ layers coincident with the *bc* crystal plane, built from the junction of the two types of $[Ni_2(\mu_2\text{-}H_2O)]^{4+}$ subunits through all of the μ_2-nic ligands (Fig. 2). This 2-D layer stands in contrast to the $[Co_2(\mu\text{-}H_2O)(\mu_2\text{-}nic)_2]$ 1-D double chain staircase motif observed in the 3-D open framework coordination polymer $[Co_2(\mu\text{-}H_2O)(\mu_2\text{-}nic)_4]$, which contains similar binuclear units [9]. The 2-D cationic layers in **1** are then stitched into the full 3-D crystal structure through the aforementioned helical 1-D $[Ni_2(H_2O)(\mu_3\text{-}nic)_2]$ chains (Fig. 3).

Viewing the 3-D structure down the *c* crystal axis (Fig. 4) of the **1** reveals ~10 Å × ~13 Å "bird-shaped" voids delineated by the nicotinate ligands. The "heads", "tails", and the front parts of the "wings" of the "birds" are demarcated by μ_2-nic moieties, while the rear parts of the "wings" are constructed by the μ_3-nic ligands. As calculated by the PLATON program [16], the void space within the structure occupies 15.1% of its overall volume. Within these incipient void spaces lie dimers of co-crystallized water molecules (O1W···O2W distance = 2.81 Å) which are anchored to the coordination polymer framework via hydrogen bonding from O1W to unligated μ_2-nic carboxylate oxygen atoms (O2 and O62), and from O2W to the ligated μ_3-nic oxygen atom O12. All unligated μ_2-nic oxygen atoms also engage in hydrogen bonding acceptance from the metal-bridging water molecules. Hydrogen bonding distances and angles within **1** are listed in Table 3.

The 3-D framework structure of **1** is very similar to that displayed in the dehydrated phase $[Ni_2(nic)_4(H_2O)]$ (**4**) reported by Lu in 2003 [10b]. However, **1** possesses a slightly smaller unit cell, larger Ni–O–Ni angles, and a wider range of Ni–O–O–Ni torsion angles within its binuclear units, presumably due to the effect of hydrogen

remarkably different channel morphology. It is therefore instructive to highlight both the significant similarities and differences between these two phases. The coordination geometry and $[NiN_2O_4]$ arrangement of the donors about the nickel centers are extremely similar in both **1** and **3**, with only minor variations in metrical parameters and torsion angles. Both compounds display triply bridged binuclear $[Ni(\mu\text{-}H_2O)(\mu_3\text{-nic})_2Ni]^{2+}$ subunits, which further conjoin into 1-D helices via μ_3-nic ligands (as seen in Fig. 2 for **1**). However, in **3**, the μ_2-nic ligands bind neighboring binuclear units into tubular 1-D barrels, while this type of ligand propagates a rippled 2-D layered structural motif in **1** (Fig. 3a). The 1-D barrel substructures in **3** are connected into 3-D by μ_3-nic ligands, resulting in a markedly different channel architecture that exhibits "cross-shaped" and "circle-shaped" cavities within the structure (Fig. 5). In **3**, the cross-shaped cavities were found to contain disordered ethanol solvent molecules, while the circular cavities enclathrated water molecules of crystallization.

A comparison of Figs. 4 and 5 shows that neighboring 1-D helical chains in a single plane in **1** (along *bc*, left to right in the figures) spiral in the same direction, while in **3**, the helical chains within a single plane alternate their orientations. Thus, a change in the orientation of the μ_3-nic based helical chains running down the *c*-axis could convert each "cross" and "circle" cavity pair in **3** into two "bird"-type cavities in **1**, or vice versa. It is postulated that the ethanol used in the synthesis of **3** is required as a template for formation of the larger "cross" shaped cavities, which forces the 1-D helical subunits into their necessary orientations during self-assembly. This proposal is corroborated by the structural retention of **1** after refluxing in ethanol for 24 h, as determined by powder XRD.

4.3. Crystal structure of $[Ni_2(H_2O)_2(nicotinate)_4(4,4'\text{-bpy})]$ (2)

The asymmetric unit of **2** (Fig. 6) consists of one nickel atom, one bound aquo ligand, one-half of a 4,4′-bipyridine molecule, and two nicotinate ligands. One of the nicotinate

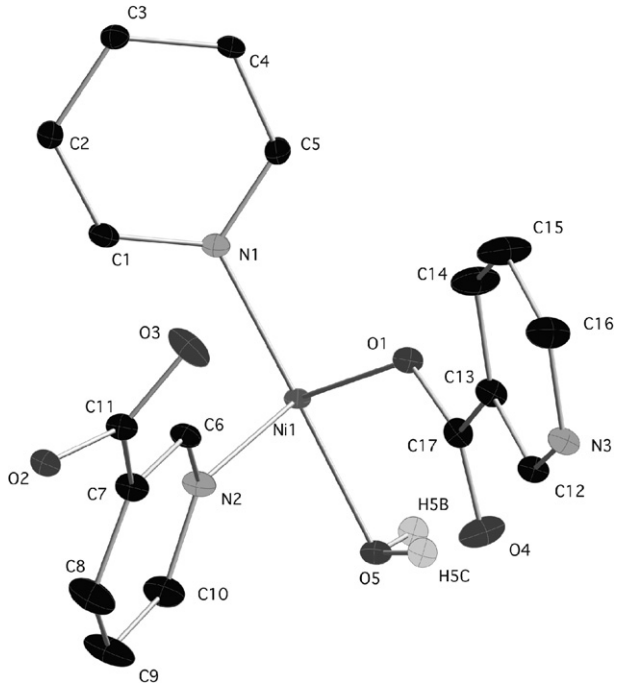

Fig. 6. Asymmetric unit of **2** shown with thermal ellipsoids (50% probability) and atomic numbering scheme. Hydrogen atoms have been omitted for clarity.

anions in the asymmetric unit is bound to Ni through its pyridyl nitrogen atom, while the other is bound in a monodentate manner via a carboxylate oxygen atom. Bond lengths and angles within **2** are typical for $[NiN_3O_3]$ coordination octahedra and are listed in Table 4. At each Ni site, the two *cis*-disposed nicotinate nitrogen donors both are situated *trans* to the two *cis*-oriented monodentate carboxylate oxygen atom donors. The coordination sphere is completed by an aquo ligand and one 4,4′-bpy nitrogen terminus, situated *trans* to each other, and *cis* to the donor atoms from four different μ_2-nic ligands. Thus all three nitrogen donors, and all three oxygen donors, are arranged in a *fac* fashion about the octahedral coordination sphere. Each nickel atom is connected to four others via μ_2-nic ligands, forming a 2-D neutral $[Ni(\mu_2\text{-nic})_2]$ (4,4)-net layer

with ~14.6 Å × 7.9 Å 24-membered rectangular-shaped rings (Fig. 7).

The nickel-bound water molecules engage in intralayer hydrogen bonding to two neighboring unligated carboxylate oxygen atoms with H···O distances of 1.81 Å and 1.84 Å (Hydrogen bonding data for **2** is given in Table 3). In order to maximize these hydrogen bonding interactions, the carboxylate subunits of the nicotinate ligands twist to varying degrees (5.15° and 22.0° torsion angles with respect to the pyridyl rings). It is possible that the *cis*-disposition of carboxylate oxygen donors, and therefore the *fac*-type donor arrangement, at each $[NiN_3O_3]$ coordination octahedron may be provoked by the favorability of this hydrogen bonding pattern.

Aided by the conformational twist of the nicotinate ligands, the coordination octahedra about adjacent Ni centers within the same layer are tilted nearly 100° with respect to each other. Each nearly flat 4,4′-bpy tether (1.52° inter-ring torsion angle) points approximately 50° away from the layer plane, connecting each 2-D $[Ni(nic)_2]$ layer to identical layers above and below, thus fostering the full 3-D structure of **2** (Fig. 8). As a result of this rather acute angle, the Ni–Ni contacts through the 4,4′-bpy tether (11.7 Å) are significantly longer than the through-space distances

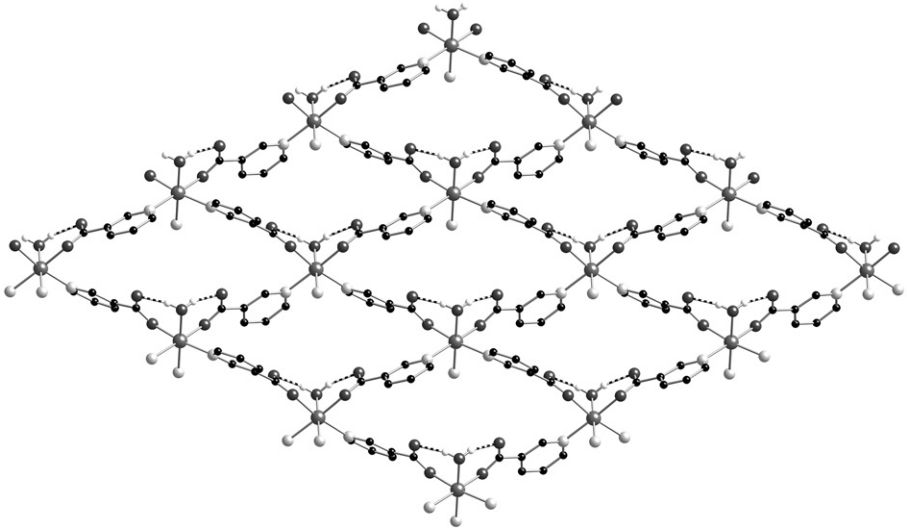

Fig. 7. View of a single 2-D Ni(nicotinate)$_2$ (4,4) layer down *b* in **2**. Bipyridine carbon atoms and most hydrogen atoms have been omitted for clarity. Intralayer hydrogen bonding contacts between aquo ligands and unligated μ_2-nicotinate oxygen atoms are indicated with dashed lines.

between directly overlaid Ni atoms in different layers (6.6 Å, 8.2 Å). As can be seen in Fig. 8, the 4,4′-bpy tethers do not link Ni atoms positioned directly above each other in each pair of layers.

4.4. Thermal properties

Thermogravimetric analysis of **1** (Fig. S1) showed a slight mass loss beginning at room temperature and ending at approximately 75 °C, consistent with unligated water loss (3.0% observed, 2.8% calculated). The mass then remained virtually unchanged until ~330 °C whereupon rapid decomposition commenced. The high thermal stability of **1** can be rationalized by its covalent 3-D network structure, augmented by significant hydrogen bonding. Between 330 °C and 425 °C, a 65.8% mass loss was observed, corresponding to the removal of the bridging water molecules, four nic ligands, and four pyridyl substituents (65.4% calculated). A subsequent mass loss of 11.9% occurred during heating to 650 °C, presumably due to decarboxylation of $NiCO_3$. The final mass loss of 77.7% at 900 °C is consistent with the deposition of NiO (76.7% calculated).

A similar analysis performed on a sample of **2** showed that its 3-D structure is somewhat less thermally robust than that of **1**, with a decomposition onset temperature of ~230 °C. Three distinct degradation steps were seen (Fig. S2). The 21.0% mass loss by 300 °C was consistent with the loss of bound water molecules and 4,4′-bipyridine ligands (24.1% calculated). A further mass loss step of 53.1%, roughly corresponding to the removal of two equivalents of nic ligands and two pyridyl groups (50.4% predicted), was complete by 425 °C. From this point, a slow mass decrease (8.1%) continued until 900 °C, likely marking the expulsion of CO_2 from $NiCO_3$. The total weight loss of 82.2% is in agreement with a remnant of NiO (81.3% calculated).

4.5. Magnetic properties of $[Ni_4(\mu\text{-}H_2O)_2(nic)_8 \cdot 2H_2O]$ (**1**)

Variable temperature magnetochemical investigations were carried out to probe possible spin communication across the triply bridged Ni^{2+} binuclear motifs in **1**. As seen in Fig. 9, a plot of $1/\chi_m$ vs. T (30–300 K) for **1** shows that its variable temperature magnetic susceptibility follows the Curie–Weiss Law ($\chi_m = C/T - \Theta$), with $C = 1.240$ cm^3–K/mol Ni, corresponding to a g value of 2.227 ($g^2 = C/0.125S(S+1)$, with $S = 1$), consistent with published values for pseudo-octahedral Ni^{2+} [20]. The Weiss constant Θ is −1.26 K, which gives a J exchange coupling constant of −0.65 cm^{-1} (via $J = 3\Theta k_B/2S(S+1)$), indicating possible weak antiferromagnetic coupling between the divalent nickel centers in the water-bridged and doubly *syn–syn* carboxylate-bridged binuclear units in **1** (assuming any magnetic interactions through the μ_2-nic or μ_3-nic ligands are very weak). $[M(\mu\text{-}H_2O)M]^{4+}$ units whose M–O–M angles exceed 90°, as is present in **1**, and divalent metal ions bridged by *syn–syn* carboxylate moieties have both previously been shown to promote antiferromagnetic coupling [21,22]. The weakness of the antiferromagnetic coupling in the present case could arise from the deviation of the carboxylate bridges from an idealized *syn–syn* conformation, resulting in poorer interaction between the magnetic e_g-type orbitals of each Ni ion. In addition, the carboxylate bridges in **1** are oriented ~100° apart from each other. It has been previously noted that orthogonality of the bridging groups mitigates antiferromagnetic exchange in a

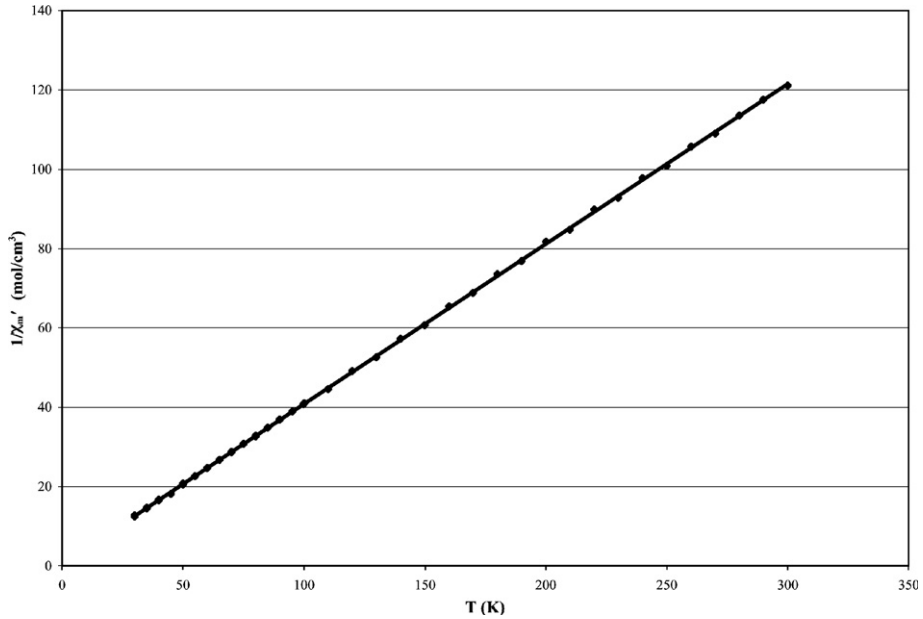

Fig. 9. Curie–Weiss plot for **1** (χ_m^{-1} vs. T)

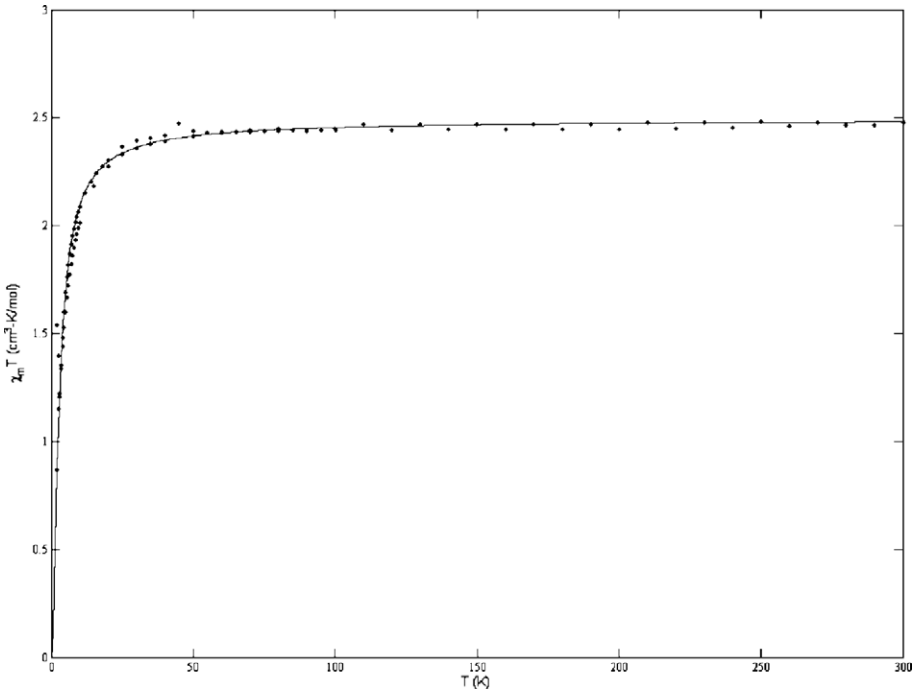

Fig. 10. Plot of $\chi_m T$ vs. T for **1**. Observed data are shown as points. The solid line represents the calculated curve from Eq. (2).

carboxylate- and phenoxo-bridged binuclear nickel complex [23].

A plot of $\chi_m T$ (cm^3–K/mol Ni_2 binuclear units) vs. T for **1** is depicted in Fig. 10. The product $\chi_m T$ at 300 K is 2.49 cm^3–K/mol, almost midway between the calculated values for an uncoupled (1.99 cm^3–K/mol) and coupled (2.99 cm^3–K/mol) pair of Ni^{2+} ions, potentially indicating the presence of antiferromagnetic coupling. This is corroborated by the diminution in the $\chi_m T$ value below 30 K. The Heisenberg Hamiltonian for an isotropically interacting pair of $S = 1$ ions (Eq. (1)) affords the expression for the magnetic susceptibility shown in Eq. (2). Even though there are two crystallographically distinct binuclear units in **1**, the close similarity of their metrical parameters safely allows the two possible intradimer J exchange parameters to be considered equal for ease of treatment.

$$\boldsymbol{H} = -J\boldsymbol{S}_{\mathrm{A}} \cdot \boldsymbol{S}_{\mathrm{B}} \quad (1)$$

$$\chi_m = (2N\beta^2 g^2/kT)(e^x + 5e^{3x}/1 + 3e^x + 5e^{3x})(x = J/kT) \quad (2)$$

The variable temperature susceptibility data were fit to Eq. (2) with the MAGMUN 4.0 software program [24], resulting in the following values: $g = 2.233(2)$, $J = -1.61(2)$ cm^{-1}, and $R = 0.00943$.[1] For *pseudo*-octahedrally coordinated Ni^{2+} ions, a low temperature decrease of $\chi_m T$ due to the single-ion zero-field-splitting parameter D cannot be excluded from consideration. Therefore the reported value of J for **1** should be considered an upper limit.

The magnetochemical behavior of **1** stands in marked contrast to that of its dehydrated structural analog **4** [10b], which displays apparent ferromagnetic coupling ($J = 26.82$ cm^{-1}) between the nickel ions in its binuclear units, with weak antiferromagnetic interactions ($J' = -0.89$ cm^{-1}) through the bridging nic ligands that span the individual binuclear units. Unfortunately no satisfactory empirical correlation exists for bridging ligand geometry and magnetic behavior in Ni^{2+} dimeric systems, as can be made for binuclear Cu^{2+} complexes [25]. It is possible that the observed differences in magnetic behavior between **1** and **4** arise from the slight variances in the Ni–O–Ni bond angles across the bridging water molecule and Ni–O–O–Ni torsion angles through the distorted *syn–syn* carboxylate bridging moieties. Alternatively, it is noted that crystalline samples of **4** were garnered only via manual separation of a multiphase mixture. It is therefore also plausible that the true nature of its susceptibility was masked by the presence of a small amount of ferromagnetic impurity.

5. Conclusion

In summary, hydrothermal treatment of nickel(II) chloride and nicotinic acid in the presence of organoimines has afforded two 3-D nickel(II) nicotinate coordination polymers that exhibit different nicotinate binding modes, highlighting the structural diversity accessible with pyridylcarboxylate ligands. Compound **1** possesses binuclear subunits containing divalent nickel ions bridged by water molecules and *syn–syn* carboxylate groups, further linked by μ_2- and μ_3-nic ligands to form "bird-shaped" cavities. On the other hand **2** displays a pillared 3-D structure

[1] $R = \sum\{[(\chi^2_{\mathrm{obs}} - \chi^2_{\mathrm{calc}})^2]/\sum[\chi^2_{\mathrm{obs}}]^2\}^{1/2}$.

constructed from μ_2-nic based layered motifs connected through 4,4′-bpy tethers. In both compounds, synergistic interactions between carboxylate binding modes and hydrogen bonding patterns serve to provide necessary structure-directing information during nucleation and crystal growth. Both **1** (after dehydration) and **2** display high thermal stability, consistent with their 3-D covalent network structures. In contrast to its previously reported dehydrated analog, **1** manifests possible weak antiferromagnetic coupling across its binuclear subunits. It is certain that further efforts exploring the versatility of carboxylate and dicarboxylate anionic ligands and neutral organoimines will continue to uncover functional coordination polymers with novel structural motifs and intriguing physico-chemical properties.

H_2L $[Cu(HL)]^+$ $[Cu(L)(BF_2)]^+$

In our earlier report, we have been able to extend the coordination number of copper(II) under a sterically congested N_4 donor macrocyclic environment [6]. In an extension to such efforts, here, we have considered a comparatively reluctant $[Cu(HL)]^+$ chromophore to investigate its axial interaction with the tetracyanonickelate ion.

Again, the chemistry of cyano-bridged coordination complexes of transitional metal ions is of contemporary interest due to remarkable diversity in their structural topologies and indeed, it is a popular approach for designing the construction of different supramolecular architectures with unusual and interesting properties [7]. Among various cyanometalates, the tetracyanonickelate anion $[Ni(CN)_4]^{2-}$ exhibits bridging character involving either one, two, three or four of the cyano groups and all four possibilities have been found [7]. Although a few copper(II) complexes with tetracyanonickelate bridged 1D [8], 2D [9] and even 3D [9b] structures have been reported recently, the number of structural studies on discrete molecules is surprisingly low [10] and such complexes are prepared mainly by utilizing various N_1, N_2 or N_3 donor ligands. Moreover, there is only a few reports on structural studies of such discrete tetracyanonickelate bridged copper(II) complexes under an N_4 donor ligand environment [11] and to the best of our knowledge this is the first report on an oxime–imine like N_4 donor pseudo-macrocyclic precursor.

On the other hand, from the chemical redox point of view, periodate is thought to be a typical inner-sphere oxidant often featuring diverse mechanistic behavior [12]. Though, there are reports on the oxidation of some inorganic species with a few copper(III) oxime–imine complexes [13], corresponding kinetic studies on the oxidation of copper(II) complexes by inorganic oxidant have not yet been reported. So a kinetic study on the oxidation of the cyano-bridged complex, $[Cu(HL)]_2[Ni(CN)_4]\cdot 4H_2O$ (**2**) along with the parent complex, $[Cu(HL)]ClO_4\cdot 2H_2O$ (**1**) by periodate would be valuable and interesting mechanistically. In this article we report synthesis, crystal structure, electrochemical and kinetic studies on the periodate oxidation on a cyano-bridged Cu(II)–Ni(II)–Cu(II) heterotrinuclear complex **2**. A parallel electrochemical and kinetic studies on the parent complex **1** reveals that there is a distinct difference in behavior of **2** over **1** due to the presence of $[Ni(CN)_4]^-$ in **2**.

2. Results and discussion

2.1. Description of structure of $[Cu(HL)]_2[Ni(CN)_4]\cdot 4H_2O$ (2)

Complex **2** crystallizes in the monoclinic space group *C*2/*c* and exhibits crystallographic C_2 symmetry. The asymmetric unit contains half of the formula unit along with three water molecules. The molecular structure of the complex **2** consists of a discrete hetero-trinuclear species (Cu–Ni–Cu) with the copper–copper separation of 9.778 Å by severely bent cyano bridging [C(8)–N(5)–Cu, 143.7(4)°] of $[Ni(CN)_4]^{2-}$ ion in di-*trans* fashion; along with four water molecules. The bonding arrangement of this trinuclear unit is shown in Fig. 1 and selected bond distances and angles in Table 1. Such type of cyano bridging of $[Ni(CN)_4]^{2-}$, leaves two other *trans* CN groups as terminal, and is comparable to $[Cu(bappz)]_2[Ni(CN)_4]\cdot(ClO_4)_2$ [11a] [bappz = 1,4-bis(3-aminopropyl)piperazine]. The coordination geometry about the copper atom is best described by a square pyramid with the geometrical factor $\tau = 0.01$ [14]. The four nitrogen atoms of the H_2L ligand construct the basal plane and the nitrogen atom of the bridging cyanide occupies the apical position. The copper atom is situated 0.302 Å above the plane towards the apical direction. This makes the basal angles N(1)–Cu–N(3), 161.81(2)° and N(2)–Cu–N(4), 162.64° to deviate significantly from 180° and the four N(5)–Cu–N(*x*) [*x* = 1, 2, 3 and 4] angles are larger than 90° (avg. 98.82(2)^0) indicating that the coordination geometry around each copper(II) atom is a distorted square pyramid. The average Cu–N bond length (1.964(4) Å) at the basal plane is comparable with the complex $[Cu(HL)]ClO_4\cdot 1/2CH_3OH$ [15]. However, in that complex each copper atom of monomeric $[Cu(HL)]ClO_4\cdot 1/2CH_3OH$ unit is further very weakly coordinated to an oxime oxygen (average Cu–O distances of 2.492 (4) Å) of the adjacent equivalent unit to form a singly bridged zigzag chain, whereas, a discrete trinuclear structure is prevailing for complex **2** with no possibility of formation of such oxime oxygen bridged Cu–O bonds.

From the charge balance considerations, it is evident that out of two *cis* oxime groups of each asymmetric unit, one is deprotonated during complex formation and makes intramolecular H-bonding with the remaining –N–OH group. The O(1)–O(2) distance (2.520 Å) is similar to the H-bonded oxygen–oxygen distance observed in other copper–oxime complexes and supports this proposition [15,16]. The Cu–N(5) apical bond length (2.155(4) Å) is comparatively longer than the Cu–N (bridging cyanide)$_{basal}$ (2.040(7) Å) found in $[Cu(Me_6Cy)][Ni(CN)_4]$ [6]. In contrast, Cu–N axial bond lengths for several such cyano bridged copper(II) complexes fall in the range 2.147–2.677 [11a,11b] which are comparable to the Cu–N(5) axial bond length in **2** and indicate the inclination of Cu atom towards the axial site (*vide infra*).

The C-end of the cyano ligand produces a strong field effect, while the N-end behaves as medium ligand with a ligand field lower than that of NH_3. Generally, C–N dis-

N(5)–C(8)–Ni(1)	178.3(5)
N(6)–C(9)–Ni(1)	177.8(5)

tances fall in the range 1.12–1.16 and no difference is found whether it is a terminal or bridging ligand [7]. In complex **2**, the C–N distances for the bridging and terminal cyanide groups are 1.134 (6) Å and 1.152(7) Å respectively and conform to the above proposition.

The Ni–C bond distances in $[Ni(CN)_4]^{2-}$ fall in the range 1.856(5)–1.859(5) Å for both bridging and terminal cyano groups and are very close to the ideal value of 1.86 [17]. The $[Ni(CN)_4]^{2-}$ moiety in **2** effectively retains its original square planar geometry and this is evidenced by the fact that all the Ni–C–N bond angles fall in the narrow range of 177.8(5)–178.3(5)°. Such rigidity of the square planer structure is generally seen for $[Ni(CN)_4]^{2-}$ in various bridging structures regardless of different modes of bridging [7].

As it is already known to us that lattice water molecules present in the crystal play a unique and ubiquitous role, not only to impart stability of the complex but simultaneously help to build up the supramolecular as well as the biological architectures. The arrangement of lattice water molecules in the present complex is highly ordered and produces a water column viewed down the *b* axis (Fig. 2).

2.2. IR study

The positions of the relevant IR bands were listed in the experimental section. For cyano complexes the absorption bands due to ν_{CN} stretching vibrations are very characteristic. In the free tetracyanonickelate anion this absorption band appears at 2128 cm^{-1} [17]. On bridging via N atom this band shifts to higher wave number. Here two ν_{CN} IR

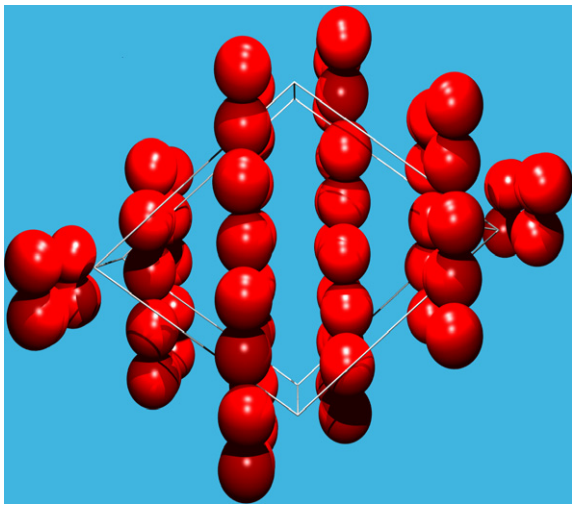

Fig. 2. Water column of the lattice water molecules (viewed down the *b* axis).

bands appeared at 2118(vs) and 2135(s) cm^{-1} for **2** can be assigned to the terminal and bridging cyanides respectively [6]. The broad ν_{O-H} band at 3389 cm^{-1} can assure the presence of O–H···O hydrogen bonded oxime proton [16] as well as the hydrogen bonded lattice water molecules. All the other bands appear more or less at their usual positions.

2.3. Thermal analyses

Thermal decomposition of complex **2** starts at *ca.* 41 °C and consequently, the complex eliminates its uncoordinated four water molecules and the process continues up to *ca.* 58 °C (found/calcd.: 6.45/6.43% with respect to loss of wt%). This is accompanied by a small *endo*-effect on the DTA curve at *ca.* 54 °C. The anhydrous complex $[Cu(HL)]_2[Ni(CN)_4]$ maintains its thermal stability upto *ca.* 171 °C, after which it undergoes an immediate exothermal decomposition with a DTA curve maxima at *ca.* 201 °C. The decomposition of the complex is complete at *ca.* 200 °C, giving CuO and NiO as the final products (found/calcd.: 81.65/81.64% with respect to loss of wt%).

2.4. Magnetic property

The room temperature (298 K) effective magnetic moment per monomer of complex **2** is 1.78μ_B and is comparable with the spin only value (1.73μ_B) for ideally monomeric copper(II) complexes. The large Cu···Cu separation (9.778 Å) in between two monomeric units *via* diamagnetic tetracyanonickelate bridging, weakens the chance of magnetic interactions in the complex.

2.5. EPR studies

Room temperature solid state EPR of the polycrystalline sample of the complex **2** is typical for mononuclear copper(II) complexes with axial distortion and the elongation of axis is characterized by $g_\parallel = 2.134 \pm 0.005$ and $g_\perp = 2.022 \pm 0.002$. Simulation of this signal using the Lorentzian function [18] of the individual EPR line gives: $g_\parallel = 2.13$, $g_\perp = 2.02$, $A_\parallel = 40$ Oe, $A_\perp = 5$ Oe with $\Delta H =$ 40 Oe at $\nu = 9.517$ GHz. The observed values ($g_\parallel > g_\perp$) confirm that the unpaired electron resides in the $d_{x^2-y^2}$ orbital.

2.6. Electrochemical studies

The electrochemical properties of the parent complex $[Cu(HL)]ClO_4 \cdot 2H_2O$ (**1**) and that of complex $[Cu(HL)]_2[Ni(CN)_4] \cdot 4H_2O$ (**2**) were investigated using the cyclic voltammetric technique in aqueous and MeCN solutions. Tetrabutyl ammonium perchlorate (TBAP, 0.1 mol L^{-1}) was used as the supporting electrolyte in MeCN solution, while 0.1 M $NaClO_4$ was used in aqueous solution. For comparison of the data obtained in aqueous solution, cyclic voltammetry of the free ligand (H_2L) was also carried out under similar conditions. All the electrochemical data are summarized in Table 2.

Fig. 3a shows the cyclic voltammogram for complex **2** in MeCN (1.0×10^{-3} mol L^{-1}) with a well defined cathodic wave for copper(II) to copper(I) reduction at a potential *ca.* −0.60 V, for which the reverse scan gave an anodic wave at *ca.* −0.50 V and the corresponding $E_{1/2}$ was estimated as −0.55 V *versus* Ag/AgCl. The peak potentials were invariant of scan rates and i_{pc} *versus* $\nu^{1/2}$ were linear passing through origin, where i_{pc} is the cathodic peak current and ν is the scan rate in V s^{-1}. Though the ΔEp value was slightly higher than that for the Nernstian behavior it may be assumed as a reversible process with a i_{pa}/i_{pc} value approximated to unity. When the scan was continued further to more negative potential, it gave an irreversible reduction peak at potential *ca.* −1.75 V *versus* Ag/AgCl (not shown in the figure). However, this reduction process has not been investigated further. In the anodic potential region, a quasi-reversible one electron oxidation of copper(II) to copper(III) was observed with $\Delta Ep = 0.16$ V and $E_{1/2} = 1.23$ V *versus* Ag/AgCl. It is important to note that the both anodic and cathodic peak positions were invariant with scan rates in the range of 0.05–0.8 V s^{-1}. The diffusion co-efficient [19] value of the complex **2** was determined and shown in Table 2.

Electrochemical reduction and oxidation behavior of the parent complex **1** was found behave similarly in MeCN. Fig. 3b shows a typical voltammogram for the cyclic voltammetry of the parent complex in MeCN with glassy carbon working electrode. The quasi-reversible reduction process appeared at a slightly more positive potential than that in complex **2** under the similar condition and also the voltammetric peak current was consistent with a slightly greater diffusion co-efficient as shown in Table 2. It is important to note that the intensity of the anodic peak for the oxidation of copper(I) to copper(II) in the reverse scan was greatly reduced with the formation of a desorption peak at *ca.* −0.20 V. Here also the second reduction peak, which was again irreversible, was not investigated further.

Cyclic voltammetric studies in MeCN indicate that the complex **2** is reduced at more negative potential (Fig. 3a)

Table 2
Electrochemical parameters[a] of the compounds

Compound	Solvent	Supporting electrolyte (0.1 M)	Ep_c (V)	Ep_a (V)	ΔEp (V)	$E_{1/2}$ (V)	D ($cm^2\ s^{-1}$)

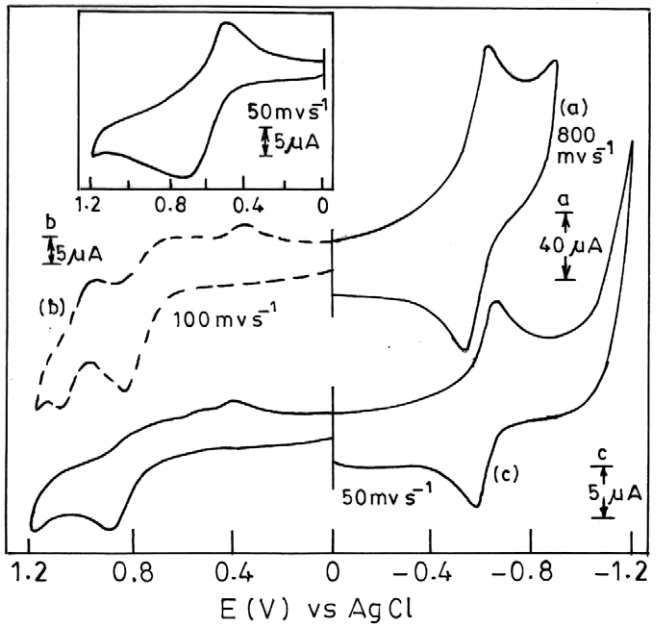

Fig. 4. Cyclic voltammograms of complex **1** (c) and **2** (a and b) in water using a glossy carbon electrode and $NaClO_4$ (0.10 M) as supporting electrolyte at different scan rates. Inset is the cyclic voltammogram of H_2L under the same conditions.

in comparison to that of the parent complex and this is attributed due to the axial ligation of $[Ni(CN)_4]^{2-}$ to $[Cu(HL)]^+$ precursor through nitrogen end (*vide supra*).

In aqueous solution the cyclic voltammetry of the complex **2** (Fig. 4a and b) showed a reduction behavior very similar to that observed in MeCN with a quasi-reversible reduction of Cu^{II}/Cu^{I} at a $E_{1/2}$ of −0.58 V *versus* Ag/AgCl. But in contrast, the oxidation behavior in MeCN was completely different from that in aqueous solution. Oxidation of copper(II) takes place at a $E_{1/2}$ of 1.04 V *versus* Ag/AgCl which was shifted to a lower potential in comparison to that observed in MeCN. Oxidation of copper(II) or reduction of copper(III) involves a fast proton transfer which is facilitated in aqueous solution, and as a result the redox potential is shifted to a lower region. This is a kind of proton-coupled electron transfer reaction and very common for many nickel(II) and iron(II) complexes of analogous ligands [2]. Further, in addition to the oxidation of copper(II) to copper(III) another anodic wave was noticed at $Ep_a = 0.84$ V having a reduction wave in the cathodic scan at *ca.* 0.36 V with $E_{1/2} = 0.60$ V *versus* Ag/AgCl and was assigned to a quasi-reversible oxidation of the copper-bound ligand. It is worth-mentioning here that when the free ligand H_2L was scanned under the similar condition (Fig. 4 inset), an almost identical oxidation of the ligand at $E_{1/2} \sim 0.61$ V was observed. Thus it may be suggested that this quasi-reversible oxidation process is due to oxidation of the copper-bound ligand.

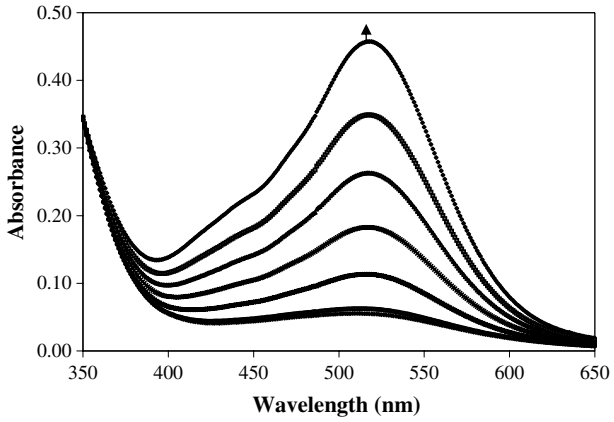
The electrochemical behavior of **1** (Fig. 4c) was also studied in aqueous solution under the similar condition.

It showed a quasi-reversible reduction of copper(II) to copper(I) with a $E_{1/2}$ at around −0.61 V *versus* Ag/AgCl. It also showed an oxidation process having $E_{1/2} \sim 0.63$ V which is assigned to the quasi-reversible oxidation of the metal bound ligand. It is however surprising that we could not get any wave for the oxidation of copper(II) to copper(III) in the potential range up to 1.2 V *versus* Ag/AgCl.

The chemical and electrochemical oxidation of the parent complex is highly pH sensitive and those were studied in detail by Sulfab et al. [3]. They claimed that the $E_{1/2}$ values for the oxidation of copper(II) to copper(III) of the parent complex are 0.955 V, 0.933 V and 0.895 V *versus* SCE at the pH 3.63, 4.00 and 4.59 respectively [3b]. This is in agreement with the decrease of electrode potential with increasing pH. Such consistency holds good over the pH range 1.2–5.0 [13]. However at higher pH the situation seems peculiar. Our cyclovoltammetric study of the parent complex **1** was carried out at pH 6.58 and under such condition the ligand is very likely to undergo fast internal oxidation and consequently destabilize the copper(III) complex. Such ligand oxidation may be the prime reason for the absence of finding any oxidation peak for copper(II) to copper(III) oxidation at ca 1.20 V. However, in complex **2** at pH 6.32, the presence of axial σ-donation from $[Ni(CN)_4]^{2-}$ through N atom may be responsible for stabilization of copper(III) complex under an oxidized ligand environment. Interestingly, at pH < 5.0, no ligand oxidation for both **1** and **2** was observed and this resembles the earlier trend [3b]. And finally, it is noteworthy to mention here that such ligand oxidation in the anodic part dose not arise in complex **1** as well as in **2** in MeCN, and hence the previous claim of ligand oxidation at 1.05 V *versus* SCE by Addison et al. in the same solvent seems surprising [5].

2.7. Kinetic study

The kinetics of oxidation of the complexes **1** and **2** by periodate, I^{VII}, was carried out in the range $[H^+] = (1.0–50.0) \times 10^{-3}$ mol L^{-1}, $[I^{VII}]_t = (0.1–10.0) \times 10^{-3}$ mol L^{-1} (t represents total) at $\mu = 0.50$ mol L^{-1} (Na_2SO_4) and at temperature 25 °C. Kinetics were followed under pseudo-first-order conditions taking complexes as the minor component (2×10^{-4} mol L^{-1}) and by monitoring the increase in absorbance due to the formation of copper(III) complexes at the wavelengths of maximum absorption (515 nm). Fig. 5 represents the time-resolved spectra generated from a kinetic trace. The reactions were clean for more than four half lives, after which kinetic traces become irregular, maybe due to decomposition or for some other reactions. As we are interested to note the chemical redox behavior of these complexes towards periodate as an oxidant, we looked into the initial oxidation process. Pseudo-first-order rate constants (k_{obs}/s^{-1}) were obtained by fitting the kinetic curves with the help of a suitable single exponential computer-fit program and the results obtained in more than two determinations fall in the error limit ± 5%.



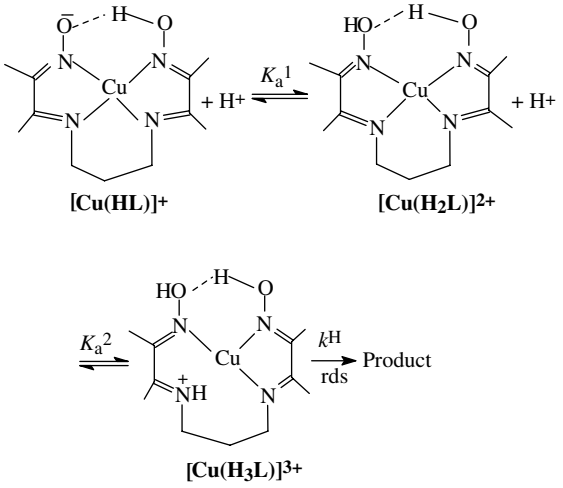


Fig. 5. Spectral scan showing the conversion of copper(II) to copper(III) of the complex **2** under kinetic conditions. First spectrum was for the complex and second was taken immediately after mixing with $[I^{VII}] = 0.0007$ M at $[H^+] = 0.01$ M. Successive spectra were taken in an arbitrary time scale.

2.7.1. Acid catalyzed decomposition of parent complex (*1*) and complex (*2*)

It was observed that both the complexes **1** and **2** undergo acid catalyzed decomposition. So an attempt was taken to study the kinetics of acid catalyzed decomposition these complexes. For this purpose, $[H^+]$ variation experiments were conducted in the range 0.01–0.20 mol L^{-1} at $\mu = 0.50$ mol L^{-1} (Na_2SO_4) and 25 °C, where single exponential decay curves manifests a first-order dependence on the complex. It is interesting to note that this decomposition rate constant (k_{obs}/s^{-1}) is second-order in H^+ and can best be described as the rapid protonation of oximato-oxygen and then second protonation on one of the two imine nitrogen followed by decomposition of the protonated species in a rate determining step and has been described in Eq. (1). Corresponding data have been listed in Table 3. Such protonation weaken both the Cu–N(R)(OH) and Cu–$N(R^1)(R^2)$ bonds and causes the decomposition of the complexes.

(1)

Plots of k_{obs} *versus* $[H^+]$ give non-linear curves (Fig. 6) with increasing slope which were solved by using suitable com-

Table 3
Summary of pseudo-first-order rate constants for the acid catalyzed decomposition of complexes **1** and **2** at $\mu = 0.50$ mol L^{-1} (Na_2SO_4) and 25 °C

$[H^+]$/M	$10^4 \times k_{obs}$ (**1**)/s^{-1}	$10^4 \times k_{obs}$ (**2**)/s^{-1}
0.01	1.46	3.60
0.05	3. 12	9.01
0.10	9.10	21.6
0.15	25.7	52.1
0.20	41.6	90.0

puter-fit program to Eq. (1a) to get $k^H = 0.098 \pm 0.03$ L^2 mol^{-2} s^{-1} and $n = 1.95 \pm 0.17$ for **1** and $k^H = 0.20 \pm 0.05$ L^2 mol^{-2} s^{-1} and $n = 1.93 \pm 0.13$ for **2**

$$k_{obs} = k^H[H^+]^n \quad (1a)$$

The acid catalyzed decomposition rate constant, k^H, for **2** is found to be ~2 times higher than that of complex **1** and can be attributed to the axial coordination of $[Ni(CN)_4]^{2-}$ to the copper(II) center which probably destabilizes the system and facilitates this process.

2.7.2. Oxidation of *1*

The dependence of rate on $[I^{VII}]_t$ was carried out at $[H^+] = 0.01$ mol L^{-1} and a plot of k_{obs} *versus* $[I^{VII}]_t$ shows an initial rapid increase in rate with $[I^{VII}]_t$ followed by slower increase and then becomes almost independent on $[I^{VII}]_t$ (Fig. 7). Such a dependence of rate is best described by Eq. (2). The factor 2 comes from the stoichiometry of the reactions

$$k_{obs} = 2\frac{kQ[I^{VII}]}{1 + Q[I^{VII}]} \quad (2)$$

A non-linear least-square computer-fit program provides $k = (1.37 \pm 0.06) \times 10^{-2}$ s^{-1} and $Q = (1002 \pm 166)$ L mol^{-1}. The dependence of k_{obs} on $[H^+]$ in the range 0.001–0.01 mol L^{-1} at $[I^{VII}]_t = 0.0007$ mol L^{-1}, where a strict first-order dependence on $[I^{VII}]_t$ holds, is shown in

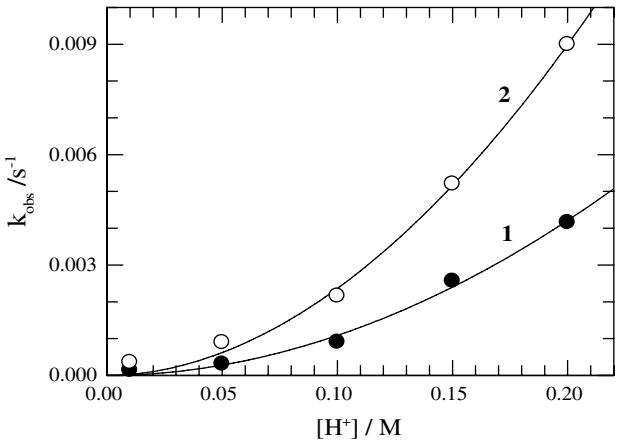

Fig. 6. Plot of pseudo-first-order rate constants (k_{obs}/s^{-1}) *vs.* $[H^+]$ for the acid catalyzed decomposition of complexes **1** and **2** at $\mu = 0.50$ M (Na_2SO_4) and 25 °C.

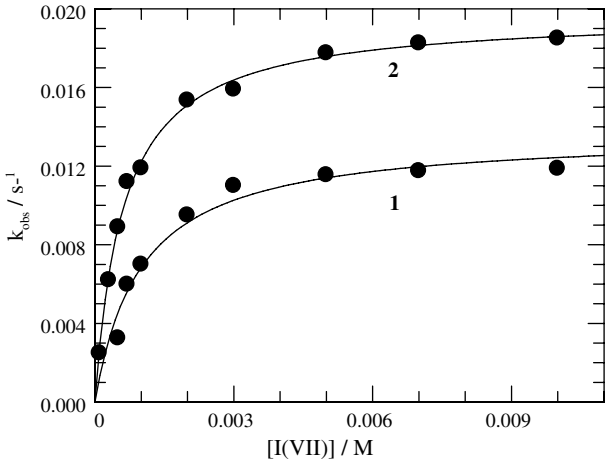

Fig. 7. Plots of k_{obs} *vs.* $[I^{VII}]$ for the oxidation of complexes **1** and **2** at $[H^+] = 0.01$ M.

Fig. 8. The presence of measurable intercept on the rate axis indicates that both protonated (HIO_4) and deprotonated (IO_4^-) species are reactive towards **1**. The following reaction sequence could be framed to explain the above observation:

$$[Cu(HL)]^+ + HIO_4 \overset{Q_1}{\rightleftharpoons} \{[Cu(HL)]^+, HIO_4\} \xrightarrow{k_1} [Cu(L)]^+ + 2H^+ + IO_4^{\cdot -} \quad (3)$$

$$[Cu(HL)]^+ + IO_4^- \overset{Q_2}{\rightleftharpoons} \{[Cu(HL)]^+, IO_4^-\} \xrightarrow{k_2} [Cu(L)]^+ + H^+ + IO_4^{\cdot -} \quad (4)$$

The radical thus generated reacts in a fast step with another copper(II) complex to give $[Cu(L)]^+$ and IO_3^- as the final products (Eq. (5)) to account for an overall 2:1 stoichiometry of the reaction with respect to the complex, which is common to the most of reactions involving periodate as oxidant in acid medium [12]. The fast decomposition of the copper(III) complex generated thereby precludes the

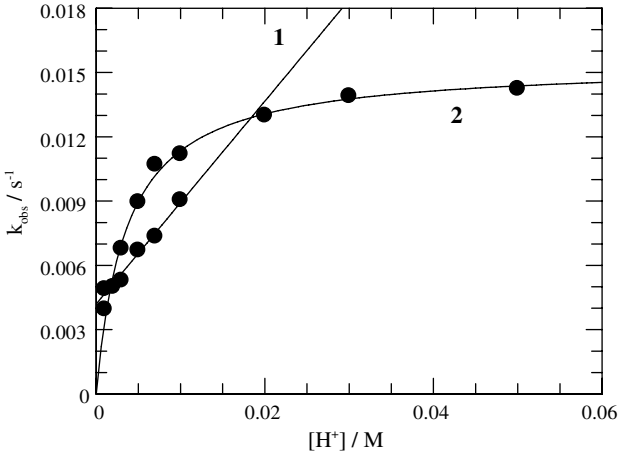

Fig. 8. Plots of k_{obs} *vs.* $[H^+]$ for the oxidation of complexes **1** and **2** at $[I^{VII}] = 0.0007$ M.

determination of the stoichiometry of the reaction under the kinetic conditions

$$[Cu(HL)]^+ + IO_4^{\cdot -} + H^+ \xrightarrow{fast} [Cu(L)]^+ + IO_3^- + H_2O \quad (5)$$

The rate law derived is shown in Eq. (6)

$$k_{obs} = 2\frac{k_1Q_1[H^+] + k_2Q_2K_a}{\{K_a + [H^+]\}}[I^{VII}]_t \quad (6)$$

As, HIO_4 is a strong acid, it is imperative that K_a (0.023) [20] > $[H^+]$ and Eq. (6) where, $k = k_{obs}/2[I^{VII}]_t$, turns to Eq. (7) and easily explains the observed dependence of rate on $[H^+]$,

$$k = (k_1Q_1/K_a)[H^+] + k_2Q_2 \quad (7)$$

The linear fit of data to $[H^+]$ gives parameters as: $k_1Q_1/K_a = (6.75 \pm 0.54) \times 10^2\ s^{-1}$, $k_1Q_1 = 15.5\ L\ mol^{-1}\ s^{-1}$ and $k_2Q_2 = (6.00 \times 0.33)\ L\ mol^{-1}\ s^{-1}$.

2.7.3. Oxidation of **2**

The dependence of rate on $[I^{VII}]_t$ was carried out at $[H^+] = 0.01$ M and a plot of k_{obs} *versus* $[I^{VII}]_t$ shows an initial rapid increase in rate with $[I^{VII}]_t$ followed by slower increase and then becomes almost independent on $[I^{VII}]_t$ (Fig. 7) and best represented by rate law (2). The effect of $[H^+]$ on the oxidation rate was investigated in the range $[H^+] = 0.001$–$0.05\ mol\ L^{-1}$ at $[I^{VII}]_t = 0.0007\ mol\ L^{-1}$, where a strict first-order dependence on it holds good. The rate increases initially rapidly with increasing $[H^+]$, then slowly and finally becomes almost independent of $[H^+]$ resulting in a plateau with a negligibly small or no intercept on the rate axis (Fig. 8). Such a dependence of rate on $[H^+]$ indicates that anionic forms of periodic acid ($H_4IO_6^-$ or IO_4^-) are un-reactive towards the complex leaving H_5IO_6 or $HIO_4 \cdot 2H_2O$ (H_2A) as the sole oxidant. The proton association of periodate anion, which can exist as $H_4IO_6^-$ and IO_4^- and $[HA^-]_t = [IO_4^-] + [H_4IO_6^-]$, can be described by Eq. (8) [12d]

$$HA^- + H^+ \overset{K}{\rightleftharpoons} H_2A \quad (8)$$

thus, K actually represents the apparent proton association constant reported to have value in the range 43–61 $L\ mol^{-1}$ at 25 °C [12d,21]. Considering the foregoing discussion, a reasonable reaction sequence may be proposed to account for the oxidation of $[Cu(HL)]_2[Ni(CN)_4]$ by periodic acid

$$[Cu(HL)]^* + H_5IO_6 \overset{Q}{\rightleftharpoons} \{[Cu(HL)]^*, H_5IO_6\} \quad (9)$$

$$\{[Cu(HL)]^*, H_5IO_6\} \xrightarrow{k} [Cu(L)]^+ + H_3IO_5^{\cdot -} + H_3O^+ \quad (10)$$

Here $[Cu(HL)]^*$ represents the modified species of $[Cu(HL)]_2[Ni(CN)_4]$ where $[Ni(CN)_4]^{2-}$ may be weakly coordinated to a copper center in solution. The radical thus generated reacts with another molecule of the complex in a rapid step to yield $H_3IO_5^{2-}$ as the final reduction product of periodate, which is common to the most of reactions involving periodate as oxidant in acid medium and corresponds to a 2:1 stoichiometric reactions [12]. Here also the fast decomposition of the copper(III) complex precludes the determination of the stoichiometry of the reaction under the kinetic conditions

$$-d[C]/dt = 2\frac{kQ[H_5IO_6]}{1 + Q[H_5IO_6]}[C] \quad (11)$$

Here, $C = [Cu(HL)]_2[Ni(CN)_4]$. While expressing H_5IO_6 in terms of total periodate concentration Eq. (11) turns to Eq. (12).

$$k_{obs} = 2\frac{kQK[H^+][I^{VII}]_t}{1 + \{K[H^+](1 + Q[I^{VII}]_t)\}} \quad (12)$$

Eq. (12) was solved for k and K by fitting k_{obs} as a function of $[I^{VII}]_t$ keeping Q fixed at 100, and the evaluated parameters are: $k = (1.97 \pm 0.03) \times 10^{-2}\ s^{-1}$ and $Q = 3263 \pm 170\ L\ mol^{-1}$. Again fitting k_{obs} as a function of $[H^+]$ with $Q = 3263$ as a fixed parameter gives parameters: $k = (2.21 \pm 0.05) \times 10^{-2}\ s^{-1}$ and $K = (85 \pm 7)\ L\ mol^{-1}$. It is to be mentioned here that very good fitting of two separate sets of data for $[H^+]$ and $[I^{VII}]_t$ indicates the self-consistency of the proposed mechanism. The evaluated proton association equilibrium constant ($K = 85$) for $H_4IO_6^-$ is in reasonable agreement with the literature value of $K = 61$ [12d]. The very large association constant also consistent with an inner-sphere mechanism which may occur either through hydrogen bonding between the hydrogen atom on H_5IO_6 and O^- of the oxime–imine ligand or the oxygen atom of H_5IO_6 and the undissociated H on the oxime–imine ligand. Another possibility is that H_5IO_6 may directly coordinate to the metal center. The main objection of this proposition is the absence of the reactivity of IO_4^- or $H_4IO_6^-$, which may be a better coordinating ligand than H_5IO_6.

It is to be mentioned here that the acidity of reaction media were so chosen for both the reactions that the acid catalyzed decomposition of the complexes is negligible compare to the electron transfer process. The complex $[Cu(HL)]_2[Ni(CN)_4]$ may undergo dissociation to give individual ions $[Cu(HL)]^+$ and $[Ni(CN)_4]^{2-}$; $[Cu(HL)]_2[Ni(CN)_4]$ should then behave identically to that of parent compound prepared separately. As the dependences of rate (k_{obs}/s^{-1}) on $[I^{VII}]_t$ and $[H^+]$ for the reaction with $[Cu(HL)]_2[Ni(CN)_4]$–I^{VII} differ from that of $[Cu(HL)]^+$–I^{VII} reaction, this may arise due to the presence of $[Ni(CN)_4]^{2-}$ ions in the former which may form an ion pair with $[Cu(HL)]^+$ or may be coordinated to the metal center causing this difference. To establish this proposition we checked the dependence of k_{obs} on $[H^+]$ in presence of $[Ni(CN)_4]^{2-}$ in the mole ratio 1:2 = $[Ni(CN)_4]^{2-}$:$[Cu(HL)]^+$ and it was observed that this dependence was almost identical to that observed for $[Cu(HL)]_2[Ni(CN)_4]$–I^{VII} reaction and support our proposition. As the acid catalyzed decomposition of complex **2** is ~2 times higher than complex **1**, it manifests the coordination of $[Ni(CN)_4]^{2-}$ moiety to the copper center destabilizes the system. It indirectly supports the coordination of $[Ni(CN)_4]^{2-}$ moiety to the copper center over the formation of ion pair which rather will stabilize the system.

It is generally accepted that periodate reacts via inner-sphere mechanism and supported by its failure to oxidize $[Fe(Phen)_3]^{2+}$ (phen = phenanthroline), which requires an inner-sphere route [12c]. The oxidation of $[Cr(H_2O)_6]^{3+}$, an inert complex, was proposed to proceed by inner-sphere route assuming $[Cr(H_2O)_5(OH)]^{2+}$ as the reacting species, where the ligated OH^- increases the lability of the metal center [12c]. The substantially high formation constant ($Q = 3263 \pm 170$ L mol^{-1}) suggests that the reaction proceeds through the pre-equilibrium formation of a precursor complex, an inner-sphere adduct, followed by electron transfer. Similar proposition was also advocated in the oxidation of dodecatungstocobaltate(II), a robust outer-sphere reactant, by periodate, where also HIO_4 was the sole reacting species [12d].

3. Conclusion

(1) A cyano-bridged hetero-trinuclear complex, $[Cu(HL)]_2[Ni(CN)_4]\cdot 4H_2O$ (**2**) has been synthesized and characterized by single crystal X-ray structure determination. The square planar $[Cu(HL)]^+$ cation, assumes a square pyramidal geometry through axial ligation by a cyano group of $[Ni(CN)_4]^{2-}$ ion.

(2) The arrangement of lattice water molecules in $[Cu(HL)]_2[Ni(CN)_4]\cdot 4H_2O$ is highly ordered producing water columns viewed down the *b* axis.

(3) Both the complexes **1** and **2** electrochemically behaves very similarly in MeCN as well as in water showing well defined quasi-reversible redox couples for $Cu^{II/I}$ and $Cu^{III/II}$ conversions, with the exception that the latter conversion does not arise in **1** in aqueous medium.

(4) The copper(II) bound ligand oxidation occurs at $E_{1/2} = 0.63$ and 0.60 V *versus* Ag/AgCl for the complexes **1** and **2** respectively only in aqueous solution. The absence of such process in MeCN may be attributed to the fact that it is a proton-coupled electron transfer process, which is only feasible in aqueous medium. Assignment of such a process to the coordinated ligand oxidation was confirmed by carrying out parallel study with the free ligand which showed similar redox process with $E_{1/2} =$ 0.61 V *versus* Ag/AgCl.

(5) Both the complexes **1** and **2** undergo H^+ catalyzed decomposition with a rate second-order in H^+ and can best be described as the rapid protonation of oximato-oxygen and then second protonation on one of the two imine nitrogen followed by decomposition of the protonated species in a rate determining step. Such protonations weaken both the Cu–N(R)(OH) and Cu–N(R^1)(R^2) bonds and causes the decomposition of the complexes.

(6) Periodate oxidation of **1** and **2** reveals that both HIO_4 and IO_4^- are the reacting species for **1** while HIO_4 is the sole reacting species for **2**.

(7) The slightly higher reactivity of **2** over **1** may arise due to the destabilization of complex **2** through axial ligation by $[Ni(CN)_4]^{2-}$. This is in line with the electrochemical behavior in aqueous solution.

4. Experimental

4.1. Materials and methods

All the starting materials like $Cu(CH_3COO)_2\cdot H_2O$, $CuCO_3$, KOH, KCl, CH_3COONa, $NaClO_4$, $HClO_4$, HCl, H_2SO_4, MeOH, diisopropyl ether, *N*,*N*-dimethylformamide, standard buffer solutions (ACROS ORGANICS, USA) of pH 4.0 and 7.0 *etc*. were of reagent grade and used as received. 1,3-Propanediamine (E-Merck, India) was distilled by refluxing over Na metal for about an hour before use. Analytical grade diacetyl monooxime (Merck Germany), KIO_4 (Aldrich) and Na_2SO_4 (Merck Germany) were used after recrystallization. All the experimental solutions of the complexes for electrochemical and kinetic studies were prepared freshly by doubly distilled water.

Elemental analyses were carried out using a Perkin–Elmer 240 elemental analyzer. Infrared spectra (400–4000 cm^{-1}) were recorded from KBr pellets on a Nicolet Magna IR 750 series-II FTIR spectrophotometer. EPR spectra of polycrystalline samples were recorded using a Varian Century Series X-band EPR spectrophotometer (model E 109) with 100 kHz magnetic field modulation. Room temperature magnetic susceptibilities were recorded on a PAR vibrating sample magnetometer using $Hg[Co(NCS)_4]$ as the calibrant. Diamagnetic corrections were estimated from Pascal's constants. TGA and DTA curves were recorded simultaneously on a Perkin–Elmer, Model PyrisDimond TG/DTA in static dry nitrogen at the heating rate of 5 °C min^{-1}. Electrochemical measurements were carried out using a computer controlled PAR model 263A VERSASTAT electrochemical instrument with a glassy carbon disk (4 mm diameter, EG&G) as the working electrode. All the results were collected at 25 ± 0.5 °C with reference to the Ag/AgCl electrode. All the solutions were purged with pure argon gas for at least ten minutes prior to each experiment. Junction potentials are not corrected. Electronic spectra and kinetic experiments were recorded on an Agilent 8453 UV–Vis diode array spectrophotometer with Peltier thermostatic temperature control facility at 25 ± 0.10 °C. The pH (± 0.01) measurements were carried out with a Systronics (model 335, India) digital pH-meter at 25 °C.

4.2. Syntheses

Caution! *Since the perchlorate salts are potentially explosive, only small amounts of the materials should be handled with care.*

$Cu(ClO_4)_2\cdot 6H_2O$ was prepared from $CuCO_3$ and 50% $HClO_4$ by the standard method. $Na_2[Ni(CN)_4]\cdot 3H_2O$ was prepared according to standard literature procedure

[22] taking NaCN instead of KCN, and further characterized by CHN analysis. The ligand H_2L [23] and the parent complex $[Cu(HL)]ClO_4 \cdot 2H_2O$ [5] (**1**) were prepared by using the literature methods and the purity was also checked by CHN analysis.

4.2.1. $[Cu(HL)]_2[Ni(CN)_4] \cdot 4H_2O$ (2)

To a methanolic solution of $[Cu(HL)]^+$ (1.0 mmol, in 40 mL MeOH, generated *in situ* by mixing equimolar quantities of $Cu(ClO_4)_2 \cdot 6H_2O$ and H_2L) $Na_2[Ni(CN)_4] \cdot 3H_2O$ (0.158 g, 0.6 mmol) dissolved in a minimum volume of water, was added drop-wise with constant stirring for 5 min. The precipitate that appeared initially was filtered off and the dark brown filtrate was allowed to undergo slow evaporation at ambient temperature whereupon shiny dark brown crystals suitable for X-ray study were obtained after two weeks. Yield: 52% based on Cu. *Anal.* Calc. for $C_{26}H_{46}N_{12}O_8Cu_2Ni$: C, 37.16; H, 5.52; N, 20.00. Found: C, 37.26; H, 5.51; N, 19.79%.

Selected IR in cm^{-1} (KBr): 3389 (br), 2930 (w), 2135 (s), 2118 (vs), 1630 (m), 1541 (br, m), 1500 (w), 1431 (m), 1379 (m), 1358 (m), 1323 (m),1275 (m),1225 (m), 1115 (br), 1089 (w), 1014 (w), 692 (w), 627 (w). μ_{eff} (per monomer): 1.78μ_B at 25 °C.

4.3. Crystal data collection and refinement

Intensity data for **2** was collected at 293(2) K on a Siemens P4 defractometer using graphite monochromatized Mo Kα radiation ($\lambda = 0.71073$ Å.) and the ω–2θ scan mode in the range $2.06 \leqslant \theta \leqslant 27.51°$. The intensities were corrected for Lorentz-polarization effects and for absorption using ψ-scans. The minimum and maximum transmission factors were 0.154 and 0.235. The structure was solved by direct methods and all non-hydrogen atoms refined anisotropically by full matrix least squares on F^2 using the SHELXTL PLUS-PC version [24] and hydrogen atoms were included geometrically and refined isotropically except the oxime proton and those of water hydrogens of which the former is randomly disordered over its two possible ligand sites in the unit cell. Other additional information concerning the data collection and refinement of the structure is compiled in Table 4.

Table 4
Crystal data and structure refinement for complexes **2**

Empirical formula	$C_{26}H_{46}Cu_2N_{12}NiO_8$
fw	840.25

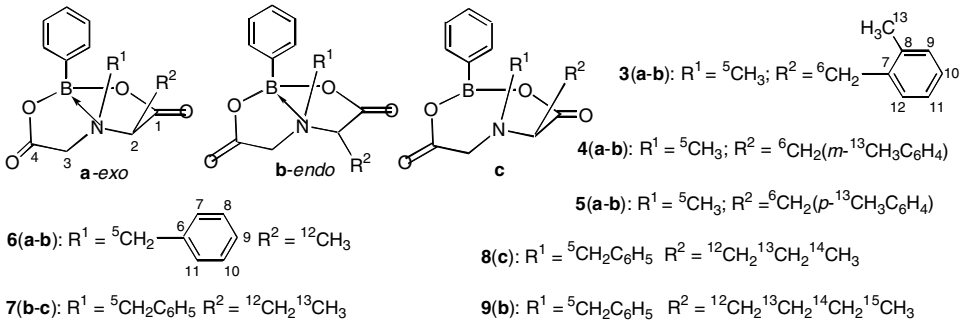
Fig. 1. Synthesis of boron heterocycles **3**–**9**.

by ^1H, ^{13}C and ^{11}B NMR, COSY, HETCOR and homonuclear proton decoupling experiments, therefore compounds **8**(**c**) and **9**(**b**) by mass spectrometry and infrared spectroscopy.



2. Results and discussion

Reactions of (N→B) phenyl[*N*-methyliminodiacetate-*O*,*O*′,*N*]borane **1** with *n*-BuLi and 2-methylbenzyl bromide **a**, 3-methylbenzyl bromide **b**, 4-methylbenzyl bromide **c**, lead to a pair of diasteromers of bicyclic structure **3**–**5**(**a**–**b**), the same is observed under same reaction conditions for (N→B) phenyl[*N*-benzyliminodiacetate-*O*,*O*′,*N*]borane **2** using iodomethane **d**, was obtained the bicyclic structures **6**(**a**–**b**), but in different proportion. However, with iodoethane **e**, lead to the bicyclic structure **7**(**b**) and **7**(**c**), which does not display the intramolecular N→B coordination bond. Whereas compound **8**(**c**) was obtained from the reaction of compound 2 with iodopropane **f**, while **9**(**b**) was obtained with iodobutane **g**.

^1H NMR data of the compounds **3**–**6**(**a**–**b**), **7**(**b**–**c**), **9**(**b**) and **8**(**c**) are summarized in Table 1. The ^1H NMR spectra in $CDCl_3$ of compounds **3**–**5**(**a**–**b**) show two single signals between 2.04 and 2.41 ppm characteristic of *N*-CH_3, indicating the presence of two diasteromers in a ratio 79/21, 76/24 and 82/18, respectively. This in according to the generation of three chiral centers: boron, nitrogen and carbon atoms, four pairs of enantiomers may be expected, but, two of them are eliminated owing to the *cis*-fusion of the ring. In this context the substitute at C2 can be in the *exo* or *endo* position. These spectra exhibit a complex pattern between 3.36 and 4.0 ppm due to the coupling between H2 and H6 showing an ABX system, as well as AB systems of the H-3 protons, showing the presence of two diasteromers. The complete assignment was achieved for the more abundant isomers (*exo*) due to the signals of H-3 and H-6 of the minor isomer are overlapped with those of the more abundant. Structural analysis was achieved by comparison with analogous boron heterocycles [9], where the AB system of H3 of the more abundant isomers appears at lower field than H-3 of the minor isomers. The $\delta(^{11}B)$ values (Table 1) confirm the tetrahedral environment of the ^{11}B nucleus, since they lie in the range reported previously for analogous boron heterocylces [9–11,14–16,18–20].

^1H NMR analyses of the reaction products of compound **2** with iodomethane **d** showed a more complex pattern than compounds **3**–**5**(**a**–**b**). Its spectrum shows two series of signals in a ratio 86/14, where the more abundant isomer has the CH_3 group in the *endo* position, this can be attributed to a steric hindrance of the *N*-benzyl group. The assignment was achieved by homonuclear proton decoupling experiment ^1H $\{^1H\}$, decoupling each quartet signal of H2 at 4.76 and 3.43 ppm, these reduced the doublet signal at 0.98 (CH_3-12 group at *endo* position) and 1.18 ppm, (CH_3-12 group at *exo* position) to a singlet, respectively. The fact that the H2 at *exo* position appears at lower field than H2 at *endo* position can be due to the deshielding of the electronic density of the ring and this effect can be observed for CH_3-12 group at *exo* position, which appears at lower field than CH_3-12 group at *endo* position. Also the spectrum displays two AB systems for H3 at and 4.39 and 3.89 ppm (minor isomer) and 4.21 and 3.96 ppm (more abundant), by comparison of their chemical shift values to those found for compounds **3**–**5** and their analogous [9], the isomer more abundant was assigned to **6**(**b**), where the substituent at 2 is at *endo* position. Furthermore, it was expected that H6 protons of **6**(**b**) showed an AB system; however they exhibited a triplet signal at 4.01, showing a very similar chemical shifts; the (^1H–^1H) COSY spectrum shows correlation between H6 at 4.01 ppm and H_{3A}, which indicates that the H6 protons are close to H_{3A}. This result gives evidence of the steric effect of the *N*-benzyl group obtaining the kinetic diasteromer in mayor proportion. Moreover, a variable temperature experiment in the ^1H NMR of **6**(**a**–**b**) shows coalescence of the AB system at δ 4.21 and 3.96 at 383 K. This is interpreted by a dissociation-inversion mechanism observed bicyclic boron compounds derived from diethanolamines [20,21] and iminodiacetic acids of similar structure [11]. Application of the coalescence temperature was used to calculated the $\Delta G^{\neq}_{coal} = 81.09$ kJ/mol, which is lower in comparison with the corresponding $\Delta G^{\neq}_{coal}$ obtained for a boron heterocycle

$\delta(^{1}H)$ relative to $Si(CH_3)_4$; solvent $CDCl_3$.
[a] Solvent DMSO-d_6.
[b] The signals of the B–Ph group and those of the benzyl group are overlapped, exhibiting an unresolved pattern between 6.9 and 8 ppm. d: double; dd: doublet of doublets; m: unresolved pattern; q: quartet; s: singlet; t: triplet and |j| Hz.

derivate of *N*-alkyliminodiacetic acid (98.4 kJ/mol) [11]. The ^{1}H NMR spectrum at 413 K displays the doublet signals of CH_3-12 groups in a ratio 1/1, suggesting the conversion of the kinetic to the thermodynamic diasteromer. ^{1}H NMR analyses of the reaction products of compound **2** with iodoethane **e** showed two complex pattern for H12 at δ 1.69 and 1.59, and two triplet signals for H13 at δ 1.05 and 0.85 characteristic of ethyl group, respectively in a ratio 50/50. The assignment was achieved by homonuclear proton decoupling experiment ^{1}H $\{^{1}H\}$, decoupling the complex patterns signal at δ 1.69 and 1.59, these reduced the triplet signals at δ 1.05 and 0.85 to a singlet signals, respectively. In addition, the spectrum display the signals for H2, which were assigned by (^{1}H–^{1}H) COSY and confirmed by HETCOR experiment, the triplet signal at δ 4.13 correlates with the complex pattern of H12 at δ 1.59, while the signal at δ 3.72, which is overlapped with a singlet signal, correlated with the complex pattern of H12 at δ 1.69. Additionally the spectrum exhibits two AB systems at δ 4.04 and 3.53, and 3.93 and 3.57 assigned to H3, the first one assigned to compound **7**(**b**) by comparison the chemical shift values of compound **6**(**b**). The spectrum also exhibit two signals for H5 protons, a singlet at δ 3.60 assigned to compound **7**(**b**), giving evidence of a similar electronic environment, and an AB system at δ 3.75 and 3.56 with chemical shift values very close, assigned to **7**(**c**), where the R^2 can give different electronic environment to H5, as well as increase the steric effect to avoid the formation of N→B coordination bond. It is known that N→B bond strength depends strongly on steric effect; bulky substituents at boro or nitrogen tend to weaken the N→B bond [20,21]. ^{11}B NMR spectrum confirm both structures with the signal at δ +11.4 for **7**(**b**) and +29.60 for **7**(**c**) which is characteristic for boron atom tricoordinated [20]. ^{1}H NMR of compound **8**(**c**) clearly showed the triplet signal and two complex pattern for the H14, H13 and H12, respectively, of the propyl group at 2 position, as well as the triple signal characteristic of H2 at δ 3.98. Protons H3 and H5 display a singlet, suggesting that the boron atom is tricoordinated, this is confirmed by its ^{11}B NMR, which exhibits a signal at δ +28.30. ^{1}H NMR spectrum of compound **9**(**b**) clearly shows the signals due to the butyl group at 2 position, a triplet signal at δ 4.0, protons H5 present an AB system and H5 a singlet, these data give

Table 2
^{13}C NMR data for compounds **3**–**6**(**a**–**b**), **7**, **9**(**b**) and **7**–**9**(**c**)

[b] C_i, 140.1 ppm.

evidence of the formation of intramolecular N→B coordination bond and the butyl group is at *endo* position keeping away from bulky substitute on nitrogen atom. Its ^{11}B NMR shows a signal a δ +11.50 demonstrating the tetrahedral environment of boron atom.

Table 2 shows that compounds **3**–**6**(**a**–**b**), **7**(**b**–**c**), **8**(**c**) and **9**(**b**) exhibit the expected ^{13}C NMR spectra. Structural analysis of the compounds was based on 2D HETCOR NMR data, compounds **6**(**a**–**b**) by COSY NMR data, whereas, by comparison with the chemical shifts of bicyclic analogous [9,16,19].

The 70 eV EI mass spectra of compounds **8**(**c**) and **9**(**b**) do not exhibit the molecular ion. The following important fragment ions are observed, the base peak is at $m/z = 321$ $[C_6H_5CH_2NH_2CH_2C(O)OB(C_6H_5)OCOCH_3]^+$, which correspond to the loss of CHR^2 and rearrangement of the alkyl group, $m/z = 208$ $[C_6H_5CHNNCHC_6H_5]^+$, with relative abundance of 15% and 16%, respectively, the fragment ion at $m/z = 164$ $[C_6H_5CH_2NH(CH_3)CH_2COH]^+$, with relative abundance of 77% and 73%, respectively, and $m/z = 131$ $[C_6H_6CHNCHCH_6]^+$, with relative abundance of 13% and 16%, respectively. The IR spectrum of compound **8**(**c**) exhibits the $\nu_{(CO)}$ carbonyl oxygen band in 1712 and 1600 cm^{-1}, a band due to B–O in 1262 cm^{-1}, as well as the bands due to the $\nu_{C-H\,arom.}$ in 3058 cm^{-1} and $\nu_{C-H\,aliph.}$ in 2920 cm^{-1}. The IR spectrum of compound **9**(**b**) shows the $\nu_{(CO)}$ bands in 1736 and 1602 cm^{-1}, a band attributable to B–O in 1254 cm^{-1}, the bands due to the $\nu_{C-H\,arom.}$ in 3058 cm^{-1} and $\nu_{C-H\,aliph.}$ in 2926 cm^{-1}, also the band due to N→B in 1024 cm^{-1}.

3. Conclusion

The new (N→B) phenyl[*N*-alky-*N*(2-alkyl)aminodiacetate-*O*,*O*′,*N*]boranes **3**–**6**(**a**–**b**), **7**(**b**) and **9**(**b**) and phenyl-[*N*-alkyl-*N*-2-alkyl)aminodiacetate-*O*,*O*′,*N*]boranes **7**(**c**) and **8**(**c**) isomers were characterized by spectroscopic methods, where the compounds **3**–**6**(**a**–**b**), **7**(**b**) and **9**(**b**) exhibit a bicyclic structure due to the presence of an intramolecular N→B coordination bond. Therefore, these compounds show that the substituent can be in *exo* or *endo* position. The existence of steric effects; between the *N*-substituent and the alkyl group at 2 position was indicated by ^1H ^{13}C and ^{11}B NMR data. Moreover, compounds **7**(**c**) and **8**(**c**) do not display intramolecular N→B coordination bond. The study of the intramolecular N→B coordination by dynamic NMR afforded a $\Delta G^{\ddagger}$ value of 81.09 kJ/mol for compound **6**(**b**).

4. Experimental

4.1. General procedure and measurements

The reagents were purchased from Aldrich Co., Boron heterocycles **1** and **2** were prepared according to the literature [14]. ^1H, ^{13}C and ^{11}B NMR spectra were recorded on Jeol GLX-270, Jeol Eclipse-400 and Bruker Avance 300-DPX spectrometers, $CDCl_3$ and DMSO-d_6 were used as solvent. Mass spectra were obtained on a Hewlett-Packard 59940-A spectrometer at 70 eV electron impact. The IR spectra were recorded as KBr pellets on a Perkin–Elmer 16F Pc FT-IR spectrometer. Melting points were measured in open capillary tubes on a Gallemkamp MFB-595 apparatus and have not been corrected.

4.2. Preparation of compounds

The procedure outlined below is general for the preparation of compounds **3**–**6**(**a**–**b**), **7**(**b**–**c**), **8**(**c**) and **9**(**b**).

4.2.1. Synthesis of (N→B) phenyl[N-methyl-N-{2(2-methylbenzyl)}aminodiacetate-O,O′,N]boranes 3(a–b)

A solution of 0.5 g (2.1 mmol) of (N→B) phenyl[*N*-methyliminodiacetate-*O*,*O*′,*N*]borane **1** in 50 ml of THF was cooled to −80 °C and 2.47 ml (2.1 mmol) of *n*-BuLi (0.87 M) in hexane were added dropwise. The reaction mixture was stirred 30 min at −80 °C and 1:30 h at room temperature. After the reaction mixture was cooled with a dry ice acetone bath to −80 °C, 0.28 ml (2.1 mmol) of 2-methylbenzyl bromide **a**, were added. After being warmed at room temperature and stirred 24 h, the solvent was evaporated under vacuum. The solid was treated with a mixture of methylenchloride/petroleum ether to give 0.58 g (80%) of a mixture of **3**(**a**) and **3**(**b**) compounds in a ratio 79/21.

4.2.2. Synthesis of (N→B) phenyl[N-methyl-N-{2(3-methylbenzyl)}aminodiacetate-O,O′,N]boranes 4(a–b)

0.5 g (2.1 mmol) of compound **1**, 2.47 ml (0.87 M) of *n*-BuLi and 0.29 ml (2.1 mmol) of 3-methylbenzyl bromide **b**, gave 0.62 g (85%) of a mixture of **4**(**a**) and **4**(**b**) compounds in a ratio 76/24.

4.2.3. Synthesis of (N→B) phenyl[N-methyl-N-2{(4-methylbenzyl)}aminodiacetate-O,O′,N]boranes 5(a–b)

0.5 g (2.1 mmol) of compound **1**, 2.47 ml (0.87 M) of *n*-BuLi and 0.29 ml (2.1 mmol) and a solution of 0.3 g (2.1 mmol) of 4-methylbenzyl bromide **c** in 2 ml of THF, gave 0.61 g (83%) of a mixture of compounds **5**(**a**) and **5**(**b**) in a ratio 82/18.

4.2.4. Synthesis of (N→B) phenyl[N-benzyl-N-2(methyl)aminodiacetate-O,O′,N] boranes 6(a–b)

0.5 g (1.61 mmol) of (N→B) phenyl[*N*-benzyliminodiacetate-*O*,*O*′,*N*]borane **2** in 25 ml of THF, 1.65 ml (1.61 mmol) 1.01 M of *n*-BuLi and 0.10 ml (1.61 mmol) of iodomethane **d**, gave 0.41 g (75%) of a solid of a mixture of **6**(**a**) and (**6b**) compounds in a ratio 14/86.

4.2.5. Synthesis of (N→B) phenyl[N-benzyl-N-2(ethyl)aminodiacetate-O,O′,N] borane 7(b) and phenyl-[N-benzyl-N-2(ethyl)aminodiacetate-O,O′,N]borane 7(c)

0.5 g (1.61 mmol) of boron heterocycle **2** in 25 ml of THF, 1.60 ml of *n*-BuLi 1.01 M and 0.13 ml (1.61 mmol)

of iodoethane **e**, gave 0.28 g (41%) of a yellow solid of a mixture of **7**(**b**) and **7**(**c**) compounds in a ratio 50/50.

*4.2.6. Synthesis of phenyl[N-benzyl-N-2(propyl)aminodiacetate-O,O′,N]borane **8**(**c**)*

0.5 g (1.61 mmol) of boron heterocycle **2** in 25 ml of THF, 1.60 ml of *n*-BuLi 1.01 M and 0.16 ml (1.61 mmol) of iodopropane **f**, to yield 0.37 g (63%) of compound **8**(**c**) as beige solid with m.p. 189–191 °C.

*4.2.7. Synthesis of (N→B) phenyl[N-benzyl-N-2(butyl)aminodiacetate-O,O′,N] borane **9**(**b**)*

0.5 g (1.61 mmol) of boron heterocycle **2** in 25 ml of THF, 1.60 ml of *n*-BuLi 1.01 M and 0.16 ml (1.61 mmol) of iodobutane **g**, to yield 0.58 g (95%) of compound **9**(**b**) as a solid with m.p. 203–205 °C.

representative compounds are presented, as well as the NMR studies of these paramagnetic nickel(II) complexes.

2. Experimental

2.1. General methods

C, H, and N analyses were carried out with a microanalyzer Carlo Erba model EA 1108. Infrared spectra were recorded on a Perkin–Emer 16F PC FT-IR spectrophotometer using Nujol mulls between polyethylene sheets. The UV–Vis spectra (in acetone) were recorded on a Hitachi 2000V spectrophotometer for 300–700 nm range. The ^{1}H and ^{19}F NMR spectra (in acetone) were recorded on a Bruker AC 200E, Bruker AC 300E or Bruker AV-400 spectrometer. Chemical shifts (in ppm) are reported with respect to the residual solvent signal or $CFCl_3$ (as standard), respectively. The ^{1}H COSY spectrum was obtained at 20 °C for **4** with 256 data points in the F1 dimension and 2048 data points in the F2 dimension with a delay time of 150 or 20 ms. An unshifted sine-bell-squared weighting function was applied prior to Fourier transformation followed by baseline correction in both dimensions and symmetrization. Fast atom bombardment (FAB) mass spectra were run on a Fisons VG Autospec spectrometer operating in the FAB^+ mode. All chemicals were purchased from Aldrich and were used without further purification. Solvents were dried and distilled by general methods before use. The complexes $[Ni(mcN_3)(\mu\text{-}OH)]_2(PF_6)_2$ (mcN_3 = 2,4,4-trimethyl-1,5,9-triazacyclododec-1-ene (Me_3-mcN_3) and its 9-methyl derivative (Me_4-mcN_3)) were prepared by procedures previously described [10,11].

2.2. Syntheses

2.2.1. *[Ni(mcN$_3$)(Bz)](PF$_6$) (mcN$_3$ = Me$_3$-mcN$_3$, Bz = 2-NH$_2$Bz (**1**), 2-NO$_2$Bz (**2**), 4-NH$_2$Bz (**3**); mcN$_3$ = Me$_4$-mcN$_3$, Bz = 2-NH$_2$Bz (**4**), 2-NO$_2$Bz (**5**), 4-NH$_2$Bz (**6**))*

These complexes were prepared by reaction of $[Ni_2(mcN_3)_2(\mu\text{-}OH)_2](PF_6)_2$ (0.12 mmol) with the corresponding carboxylic acid (0.24 mmol) in acetone (25 mL). After stirring for 12 h the solution was concentrated under reduced pressure and the addition of diethyl ether caused the precipitation of a green solid, which was collected by filtration, washed with diethyl ether and air-dried.

2.2.2. *[Ni(mcN$_3$)(Bz)(H$_2$O)](PF$_6$) (mcN$_3$ = Me$_3$-mcN$_3$, Bz = 4-NO$_2$Bz (**7**), 2,3,4,5,6-F$_5$Bz (**8**); mcN$_3$ = Me$_4$-mcN$_3$, Bz = 4-NO$_2$Bz (**9**), 2,3,4,5,6-F$_5$Bz (**10**))*

Complexes **7**–**10** were prepared by allowing $[Ni_2(mcN_3)_2(\mu\text{-}OH)_2](PF_6)_2$ (0.12 mmol) to react with the corresponding benzoic acid (0.24 mmol) in acetone (25 mL). After stirring for 12 h the solvent was removed under reduced pressure and the addition of diethyl ether caused the precipitation of a green solid, which was collected by filtration, washed with diethyl ether and air-dried.

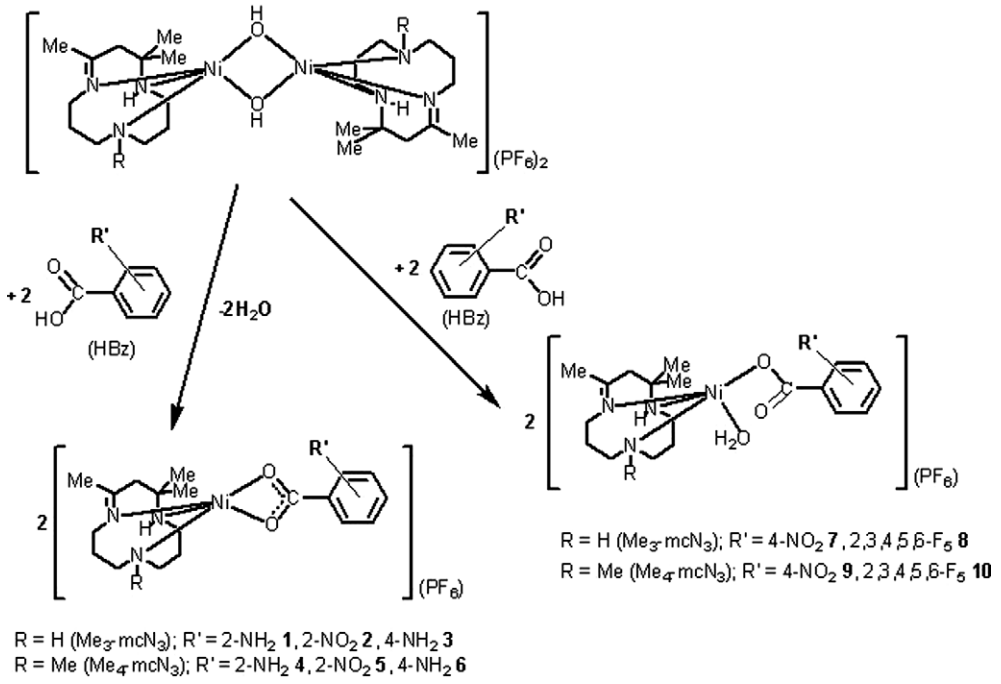
2.3. X-ray data collection and structure determination

Data collection was performed on a Bruker Smart CCD diffractometer with a nominal crystal to detector distance of 4.5 cm. Diffraction data were collected based on a ω scan run. A total of 1371 (complexes **2** and **3**) and 2524 (complexes **4** and **7**) frames were collected at 0.3° intervals and 10 s per frame. The diffraction frames were integrated using the SAINT package [12] and corrected for absorption with SADABS [13]. Data collection for **10** was performed on a Siemens P4 diffractometer. The crystallographic data are shown in Table 1. The structure were solved by direct methods [14] and refined anisotropically on F^2 [13]. Hydrogen atoms were introduced in calculated positions.

3. Results and discussion

3.1. Synthesis

The hydroxo complexes [Ni(mcN_3)(μ-OH)]$_2$(PF_6)$_2$ (mcN_3 = 2,4,4-trimethyl-1,5,9-triazacyclododec-1-ene (Me_3-mcN_3) and its 9-methyl derivative (Me_4-mcN_3)) have been used as starting materials for the preparation of several five-coordinate nickel(II) complexes [15]. When [Ni(mcN_3)(μ-OH)]$_2$(PF_6)$_2$ was treated with substituted benzoic acids HBz-2-NH_2, HBz-2-NO_2, HBz-4-NH_2, HBz-4-NO_2 or HBz-2,3,4,5,6-F_5 in acetone, complexes **1**–**10** were obtained in moderate high yields (Scheme 1). The acid-base reaction occurs at room temperature in acetone with the concomitant liberation of water for **1**–**6** complexes. In contrast, the benzoic acids HBz-4-NO_2 and HBz-2,3,4,5,6-F_5, under the same reaction conditions gave aquo-complexes [Ni(mcN_3)(Bz)(H_2O)](PF_6). Complexes **1**–**10** are all blue-green air-stable solids and they have been characterized by partial elemental analyses, FAB$^+$ mass spectrometry and spectroscopic (IR and NMR) methods.



3.2. Infrared and electronic spectra

The IR spectra of complexes **1**–**10** show characteristic absorptions for the mcN_3 ligands [16]: 3297–3244 cm^{-1} ν(N–H), ~1660 cm^{-1} ν(C=N), and two strong bands due to the presence of the PF_6^- ion at 840 and 560 cm^{-1} are also observed. The benzoate ligand in compounds **1**–**6** exhibits κ^2-coordination mode to the nickel atom that is suggested by the IR spectra. The separation between the components of ν(OCO) is in the range 126–164 cm^{-1} and this is consistent with a symmetrical bidentate coordination [17,18]. For complexes **7**–**10** where the carboxylate acts as monodentate ligand, the Δ value is larger (*ca.* 200 cm^{-1}). These coordination modes in **2**, **3**, **4**, **7** and **10** were authenticated by an X-ray crystal structure determination (vide infra). A broad band in the spectra of **7**–**10** in the range 3600–3500 cm^{-1} can be assigned to coordinated water vibrations.

The electronic spectra of the complexes in acetone solution are all similar and show bands in the 620 and 380 nm regions which could be assigned to $^3B_1(F) \rightarrow {}^3E(F)$ and $^3B_1(F) \rightarrow {}^3A_2$, $^3E(P)$ transitions, respectively. The λ_{max} values and molar absorptivities are consistent with a pentacoordinate environment around nickel(II) [15].

Scheme 1. Reaction schemes for substituted-benzoate complexes of nickel(II).

3.3. NMR spectroscopy

All of the complexes exhibit relatively sharp hyperfine-shifted ^{1}H NMR signals in acetone solution spanning from 350 to −35 ppm. The ^{1}H NMR spectra of complexes **1**–**10** have been assigned on the basis of our previous studies of paramagnetic nickel(II) macrocyclic complexes [19]. The spectra show (Tables 2 and 3) the expected resonance line pattern because of a dominant spin-polarisation mechanism [20]. The eight α-methylene protons shift downfield whereas the six β-methylene protons shift upfield with regard to the diamagnetic position [21]. The equatorial protons are expected to experience larger contact shifts than the axial protons and therefore the most downfield resonances are due to α-CHeq and the most upfield ones to β-CHeq [22]. The isotropically shifted ^{1}H NMR signals observed for the methyl groups (2-Me, 4-Me(a, b) and 9-Me–N) in Table 2 and phenyl groups of benzoates can be initially assigned by inspection of their peak areas. All the resonances of the phenyl rings (Table 3) are downfield to TMS in accordance with a dominant σ-delocalization pattern of spin density consistent with the ground state

5		10.6 (3-H)	6.1	6.3 (5-H + 6-H)		
6	9.3 (2-H + 6-H)	7.9 (3-H + 5-H)	5.5 (NH_2)			
7	9.4 (2-H + 6-H)	9.9 (3-H + 5-H)				4.7 (H_2O)
8						8.7 (H_2O)
9	9.9 (2-H + 6-H)	10.1 (3-H + 5-H)				5.6 (H_2O)
10						9.8 (H_2O)

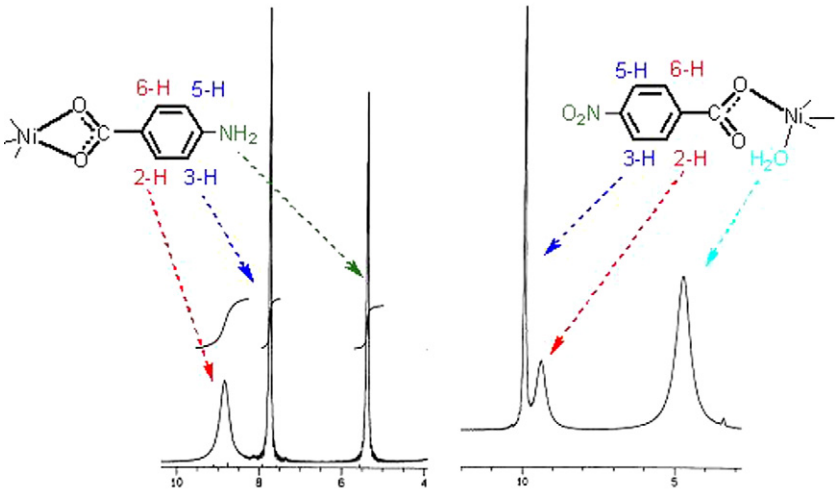

Fig. 1. ^{1}H NMR spectra (in d_6-acetone solution at room temperature) of **3** (left) and **7** (right). Only the phenyl resonances region is shown.

of nickel(II) although the unpaired electrons could polarise the net spin density in the dπ orbitals. A similar behaviour has been observed elsewhere [7]. In spectra of the 4-NH_2 (**3**, **6**) and 4-NO_2 (**7**, **9**) derivatives two resonances for the phenyl protons have been observed (Fig. 1). The broad signal can be assigned to the 2-H and 6-H protons of the aromatic rings nearer to the nickel atom; moreover for the 4-NO_2 derivatives (**7**, **9**) the 3-H and 5-H resonance is more downfield shifted (9.9 and 10.1 ppm) than for 4-NH_2 derivatives (**3**, **6**) (7.8 and 7.9 ppm). Substitution at the position two breaks the ring symmetry so that four phenyl resonances of equal intensity were observed for **1** and **4**. The complete assignment of these isotropically shifted signals required an application of two-dimensional ^{1}H NMR techniques. A magnitude COSY spectrum of **4** (Fig. 2), recorded at 20 °C, clearly shows cross signals between the resonances at 11.2, 8.1 and 6.1 ppm and also between resonances at 10.3 and 8.1 ppm. These signals can be assigned to the phenyl 3-H (11.2), 6-H (10.3), 5-H (8.1), and 4-H (6.1) protons, respectively, of the benzoate ligand. The spectra of 2-NO_2 derivatives (**2**, **5**) show two resonances of intensity corresponding to one and three protons that can be assigned to 3-H and 4,5,6-H (not well-resolved) respectively. Therefore, on the basis of the X-ray structure of **2** and **4** (see below) the distortion in the square pyramidal arrangement of the nickel atom due to the small bite angle of the chelated carboxylate moiety and the substitution on 2-position of the ring result in a larger magnetic anisotropy that in turn induces a larger isotropic shift of the 3-H proton. The ^{19}F NMR spectra of complexes **8** and **10** show the presence of $C_6F_5(OCO)^-$ ring giving three resonances with relative intensities of 2:1:2 due to the *ortho*-, *para*-, and *meta*-F atoms, respectively.

3.4. Solid state structures of the complexes

The single-crystal X-ray diffraction study on [Ni(Me_3-mcN$_3$)(Bz-2-NO_2)](PF_6) (**2**), [Ni(Me_3-mcN$_3$)(Bz-4-NH_2)](PF_6) (**3**) and [Ni(Me_4-mcN$_3$)(Bz-2-NH_2)](PF_6) (**4**) confirms that benzoate formed by deprotonation of the corresponding benzoic acid, is bonded to the nickel atom as a bidentate ligand. The structures of compounds **2**, **3** and **4** are similar. Selected distances angles for these complexes are given in Table 4, and Figs. 3–5 show the thermal ellipsoid diagrams. In these compounds, nickel atoms have distorted square-pyramidal geometry around the metal ion. The Reedijk parameter [23] τ shows values of 0.240, 0.059 and 0.024 for complexes **2**, **3** and **4**, respectively. The three

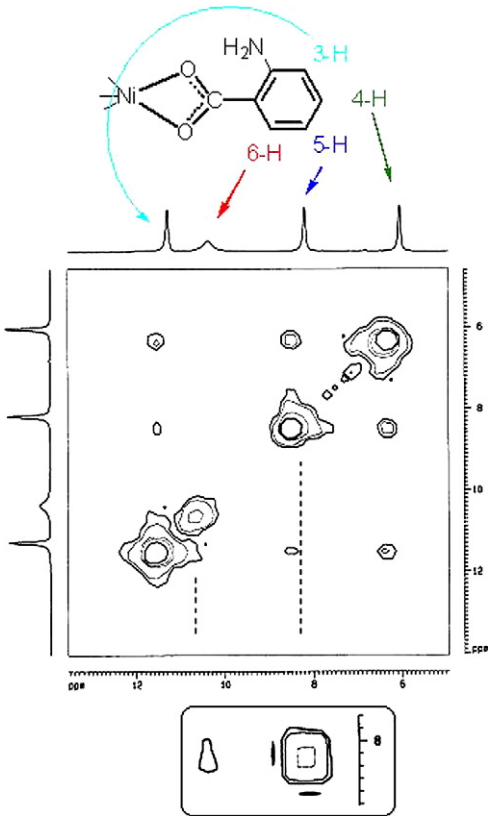

Fig. 2. Magnitude ^{1}H COSY spectrum of complex **4** at 400 MHz at 20 °C in d_6-acetone solution recorded with a delay time of 150 ms. Only the region relevant to the assignment of phenyl resonances is shown in the top trace. The inset on the bottom shows an enlargement of the 5-H–6-H cross-peak area obtained with a delay time of 20 ms.

nitrogen atoms of the macrocyclic ligand constitute a trigonal face of the pyramid. The two oxygen atoms from the benzoate and two nitrogens of the macrocycle form the basal plane. The nickel ion lies above this plane and is displaced 0.288(1), 0.374(1) and 0.310(1) Å for complexes **2**, **3** and **4**, respectively, towards the N(3) nitrogen, which constitutes the axial donor. The Ni–N distances lie within the range reported in complexes containing the {Ni(mcN$_3$)}

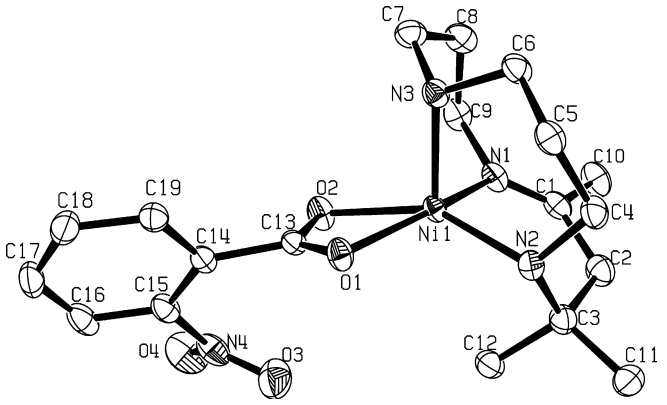

Fig. 3. ORTEP drawing of complex **2** showing the atom numbering scheme. Displacement ellipsoids are drawn at the 50% probability level. For clarity hydrogen atoms of macrocycle are omitted.

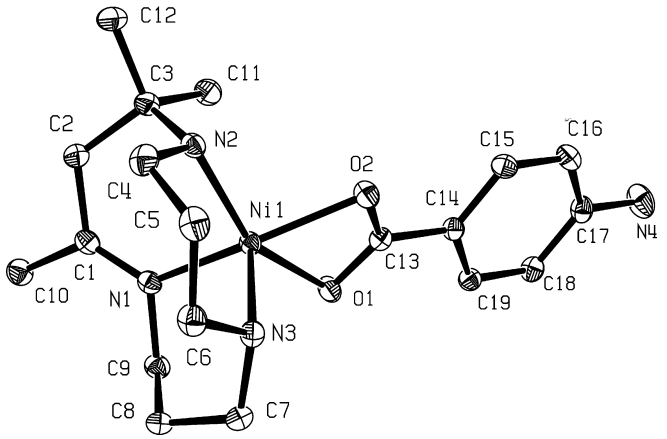

Fig. 4. ORTEP drawing of complex **3** showing the atom numbering scheme. Displacement ellipsoids are drawn at the 50% probability level. For clarity hydrogen atoms of macrocycle are omitted.

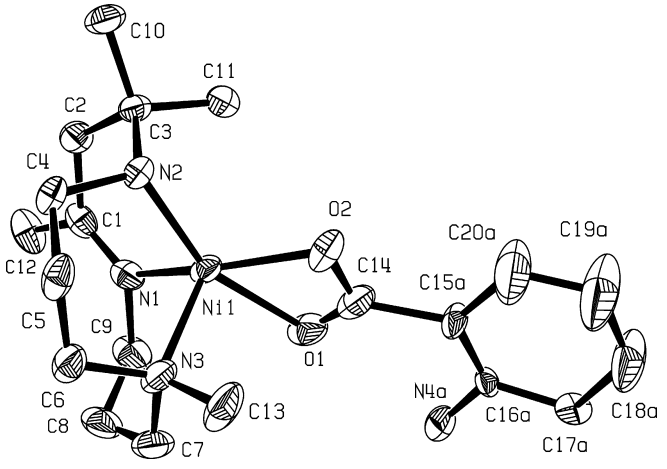

Fig. 5. ORTEP drawing of complex **4** showing the atom numbering scheme. Displacement ellipsoids are drawn at the 50% probability level. For clarity hydrogen atoms of macrocycle are omitted.

moiety [13,15]. The Ni–O bond distances are close to each other (2.0802(15) and 2.1198(17) Å (**2**), 2.0622(12) and 2.1034(12) Å (**3**) and 2.078(2) and 2.1103(18) Å (**4**)) thus the benzoate ligand is bonded in a symmetric (or almost) chelating mode with {[Ni–O(1)]–[Ni–O(2)]} = ΔO values of 0.0396, 0.0412 and 0.0323 Å for **2**, **3** and **4**, respectively. These bond distances are comparable to those reported for other crystallographically characterized nickel-carboxylate complexes with a distorted square pyramidal [24] or octahedral [25,26] geometry. The bite angle of the chelating carboxylate anion shows values of 62.84(6)° **2**, 63.52(5)° **3** and 62.51(8)° **4**, respectively. The torsion angle between the aromatic ring and the nickel-bounded carboxylate group is 57.3 (3) and −8.5 (3)° for complexes **2** and **3**. In addition, there are some interconnections by hydrogen bonds in compound **3** the NH_2 groups in the packing are oriented towards PF_6^- anions with the shortest N···F distances of N4···F3^{i}: 2.937(2) Å and N4···F3^{ii}: 3.084(2) Å (i: $x-1$, $-y+3/2$, $z+1/2$; ii: $-x$, $y+1/2$, $-z+3/2$). In complex **4** the aromatic ring is disordered over two positions with an occupation factor close to 50%. In both positions there is an intramolecular hydrogen bond with a mean O···N distance of 2.682 Å. The molecular structures, with the atom-numbering schemes, of compounds **7** and **10** are shown in Figs. 6 and 7, respectively. Selected bond lengths and angles of complexes **7** and **10** are listed in Table 5. The nickel centre is bonded to a N_3-macrocyclic ligand, a monodentate benzoate and a water molecule in a distorted trigonal bipyramidal geometry for **7** and distorted square-pyramidal geometry for **10**. The τ parameter shows values of 0.593, and 0.175 for complexes **7** and **10**, respectively. The Ni–N (macrocycle) bond distances in **7** and **10** are very similar to those observed in **2**, **3** and **4**. The carboxylate anion acts as a monodentate ligand through the deprotonated hydroxyl oxygen. The Ni–O (benzoate) bond distances are close to each other 2.0472(13) Å for **7** and 2.048(4) Å for **10** and the Ni–O (water) distances are also similar (2.0429(15) Å (**7**) and 2.041(5) Å (**10**)). The nickel atom in **10** is 0.304(2) Å out of de basal plane defined by N1, N2, O1 and O3. The rmsd of this plane is 0.087 Å. The dihedral angle between the carboxylate group and the aromatic ring is 22.6(3)° for **7** and 51.0(5)° for **10**. In compound **7** there is an intramolecular strong hydrogen bond between the water molecule and the carboxylate group with an O5···O2 distance of 2.559(2) Å. In the crystal packing, the complexes appear grouped by pairs (Fig. 8) with a N2···O3^{i} distance (i: $-x+1$, $-y+1$, $-z$) of

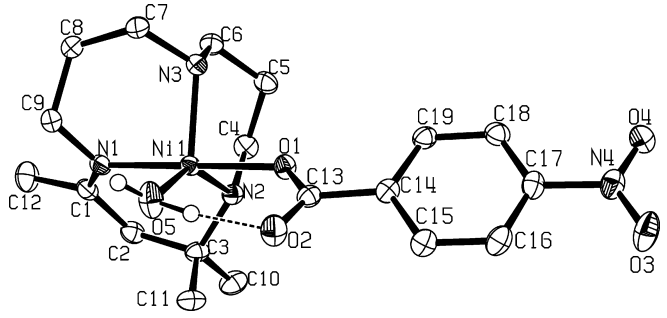

Fig. 6. ORTEP drawing of complex **7** showing the atom numbering scheme. Displacement ellipsoids are drawn at the 50% probability level. For clarity hydrogen atoms of macrocycle are omitted.

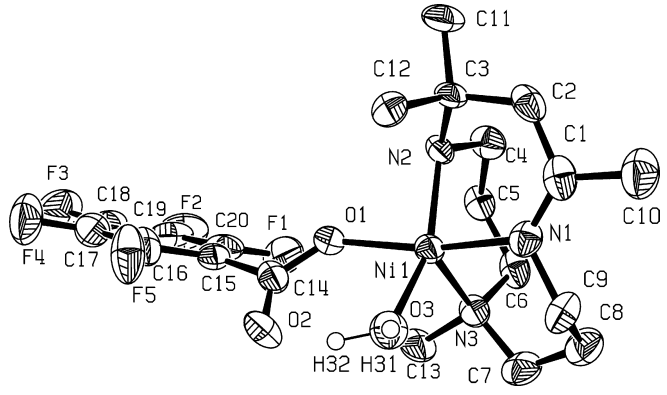

Fig. 7. ORTEP drawing of complex **10** showing the atom numbering scheme. Displacement ellipsoids are drawn at the 50% probability level. For clarity hydrogen atoms of macrocycle are omitted.

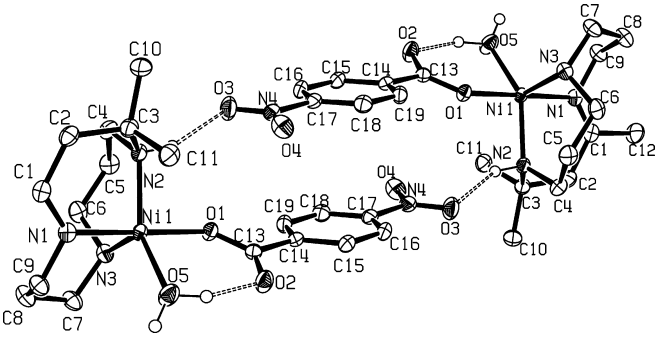

Fig. 8. Molecular grouping in the solid state of complex **7**. Hydrogen atoms of the macrocycle are omitted.

3.054(2) Å and the aromatic rings adopt a parallel orientation having a distance between centroids of 3.741 Å and an angle between the ring normal and the centroid vector of 26.5°. In a similar manner, in **10** there is a strong intramolecular hydrogen bond between the water molecule and the carboxylate group with an O3···O2 distance of 2.580(7) Å. In this case, the O3···F9^{i} distance, 2.720(8) Å, also suggests the existence of a hydrogen bond to the PF_6^- anion (i: $x+1$, y, z). In these complexes Ni atom and N atoms from the macrocycle form three six-membered rings. The conformations adopted for those rings have been used to characterize the conformation of complexes containing these macrocycles [27]. In all the structures reported in this paper the six-membered rings that do not contain the C=N bond have chair-like conformations; this is the most frequent conformation in this kind of complexes [27].

Acknowledgements

We wish to thank Dr. Donaire for his valuable suggestions and to Dr. de Godos for recording the NMR spectra. We thank also the Fundación Séneca de la Región de Murcia (00484/PI/04 and 03010/PI/05) for financial support and the Ministerio de Educación y Ciencia for partial financial support (CTQ2005-09231-C02-01).

Appendix A. Supplementary material

CCDC 613433, 613434, 613435, 613436 and 613437 contain the supplementary crystallographic data for **2**, **3**, **4**, **7** and **10**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2006.09.068.

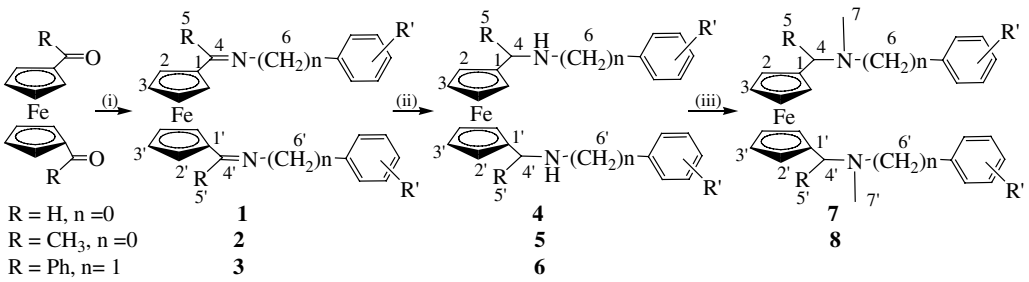
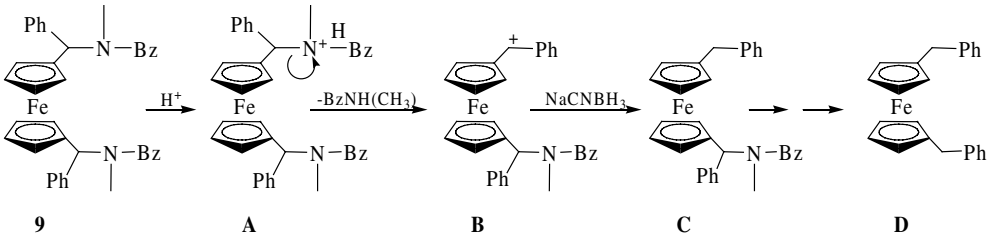
Heck reaction [9]. Encouraged by our earlier results and in order to explore new types of 1,1′-diaminoferrocenes, in this paper, we report the synthesis and characterization of 1,1′-bis[(*N*-methyl-*N*-phenyl)aminomethyl(ethyl)]ferrocenes starting from diacylferrocenes (acyl = formyl, acetyl) and anilines. Additionally, the debenzylation phenomenon observed in the synthesis of 1,1′-bis[{(*N*-methyl-*N*-benzyl)-amino}benzyl]ferrocenes, starting from dibenzoylferrocene and benzylamines, will be also discussed.

2. Results and discussion



2.1. Synthesis of 1,1′-bis[(N-methyl-N-phenyl)-aminomethyl(ethyl)]ferrocenes 7(8)

The synthetic pathway for 1,1′-bis[(*N*-methyl-*N*-phenyl)aminomethyl(ethyl)]ferrocenes **7**(**8**) is outlined in Scheme 1. Diimine complexes **1** are obtained directly by condensation of diformyl ferrocene and anilines at room temperature in methanol whereas **2**(**3**) are synthesized by condensation of diacetylferrocene (dibenzoylferrocene) and anilines (benzylamines) in toluene using titanium tetrachloride as the catalyst. Although active aluminum oxide as the catalyst in these reactions is also applicable [10], the titanium catalyzed method shows some advantages such as time savings and affording moderate yields of the products, *etc.* Reduction of **1** with sodium borohydride produce quantitatively the 1,1′-bis[(*N*-phenylamino)-methyl]ferrocenes (**4**). However, it is difficult to isolated **5** and **6** due to the incomplete reduction of **2** and **3** with sodium borohydride. Thus, a catalytic reductive system *i.e.*, lithium aluminum hydride–aluminum chloride is chosen to catalyze their reduction, and **5**, **6** are obtained in good yields. Reductive methylation of **4** and **5** with sodium cyanoborohydride and aqueous formaldehyde in the presence of acetic acid [11] yield **7**, **8**, respectively, in moderate yields. Surprisingly, *N*-methylation of **6** with the conditions as mentioned above does not afford the corresponding complexes **9**, in contrast, a sole product, 1,1′-dibenzyl ferrocene [12], is isolated. The same product is also obtained in the *N*-methylation reaction of 1,1′-bis[(*N*-phenylamino)benzyl]ferrocene.



We are puzzled by the above observations. Comparison of the structures of **7**(**8**) and **9** and consideration of the acidic medium in our reactions, it is easily understood that **9** are indeed produced in these reactions. The unsuccessful isolation of **9** is probably attributed to the unique structure of the benzylferrocenyl moiety, causing their debenzylation (Scheme 2), and this result is consistent with Baltzly's observation [13]. As illustrated in Schemes 1 and 2, **7**(**8**) and **9** are in fact *tert*-amines and are easily protonated by acetic acid, particularly for **9**, to give ammonium salts **A**, which is followed by elimination of a neutral benzylamine to afford cations **B**, the latter are better stabilized by both ferrocenyl and phenyl groups. Nucleophilic attack of hydride on **B** will generate **C**. Similarly, the elimination of a second benzylamine, yielding 1,1′-dibenzylferrocene (**D**), is in the same manner as that for the first one (**A** → **C**). Since **9** bear a 1,1′-bis[(*N*-methyl-*N*-benzyl)amino-benzyl] group, the possible elimination of two benzylamines at the same time to generate **D** is also not excluded.

2.2. Spectra characterization of 7(8)

Compounds **1**, **3**–**8** are characterized by elemental analysis, IR and ^{1}H NMR. The elemental analyses are in good agreement with the proposed formula. In the IR spectra, **4** and **6** all display a weak or medium absorption approximate at ν 3340 cm^{-1}, indicating that a N–H group is present in these molecules and this assignment is further confirmed by their ^{1}H NMR where a singlet appears at $\delta \sim 3.90$ ppm in **5** and δ 2.30 ppm in **6** (the peak for **a** N–H group in **4** is missing). In addition, a peak $\delta \sim 4.25$ ppm in **4** is assigned to H4 (H4=H4′=H5=H5′). The satellites correspond to H4 and H5 (H4=H4′, H5=H5′) in **5** (a multiplet $\delta \sim 3.15$ ppm, a doublet $\delta \sim 1.44$ ppm) and **6** (a singlet $\delta \sim 4.37$ ppm, H4=H4′, H5=H5′=0). All of these confirm that diimines **1**–**3** are converted into diamines **4**–**6**, respectively. In the IR spectra of **7**, the absorptions at ν 3340 cm^{-1} observed in **4**, **5** disappear, meanwhile the absorptions at ν 2960, 2870, 1460, 1380 cm^{-1} are present, implying that a N–H group is replaced by N–CH$_3$ in **4** and **5**, and this assignment is consistent with their ^{1}H NMR where H7(7′) display a singlet $\delta \sim 2.80$ ppm in **7** and $\delta \sim 2.45$ ppm in **8**, and these δ values are comparable to those of [(*N*-methyl-*N*-phenyl)aminomethyl]ferrocenes ($\delta \sim 2.70$ ppm) [7]. In addition, the protons in *para*-substituted phenyl rings in **1**, **3**–**8** all display their corresponding splitting patterns.

Scheme 1. Condition: (i) R′C$_6$H$_4$(CH$_2$)$_n$NH$_2$/TiCl$_4$, toluene, reflux for acetyl- and benzoylferrocenes; (ii) LiAlH$_4$–AlCl$_3$/THF; (iii) NaCNBH$_3$, 37%HCHO, AcOH, CH$_3$CN. $n = 0$, R′ = 4-CH$_3$O (a), 4-CH$_3$ (b), C$_6$H$_5$ (c), 3-Cl (d), 4-Cl (e); $n = 1$, R′ = 4-CH$_3$ (f), H (g).

Scheme 2. The possible mechanism for the decomposition of **9**.

2.3. X-ray analysis for the crystal structures of *3g* and *7a*

In order to better understand the structures of the **7**(**8**), complexes, the structures of **3g** and **7a** were determined by X-ray single crystal diffraction. The crystal structures of **3g** and **7a** are presented in Figs. 1 and 2, respectively. Crystallographic data for **3g** and **7a** are given in Table 1, selected bond lengths and angles are listed in Table 2.

Fig. 1 demonstrates that the crystal of **3g** consists of $[Fe\{(\eta^5\text{-}C_5H_4)\text{–}C(C_6H_5)\text{=}NCH_2C_6H_5\}_2]$. However, the crystal of **7a** (Fig. 2) consists of two molecular units $[Fe\{(\eta^5\text{-}C_5H_4)\text{–}CH_2N(CH_3)C_6H_4OCH_3\text{-}4\}_2]$, each being located at a crystallographic center of symmetry. In Fig. 1, the bond lengths of N1–C11 (1.273(3) Å) and N2–C25 (1.278(3) Å) of **3g** correspond to C=N double bonds and are all in the normal range. The phenyl rings attached directly to C11 and C25 are not coplanar with the C=N planes due to the steric hindrance between the phenyl rings and hydrogen atoms of the cyclopentadienyl (Cp) rings. The related dihedral angles between the phenyl planes and the corresponding Cp rings are 63.7° and 102.4°, respectively. In Fig. 2, the bond lengths of N1–C6 (1.502(7) Å) and N2–C20 (1.498(7) Å) in the two molecular units of **7a** are nearly the same. The phenyl plane defined by C8-C13 in one molecular unit is situated above the same side Cp ring, and the dihedral angle between them is 78.5°. A similar location of the phenyl ring and the dihedral angle (with Cp ring, 77.1°) in the other molecular unit is also observed. All of these data are nearly the same as those of [(*N*-methyl-*N*-phenyl)aminomethyl]ferrocenes [14]. The average C–C bond length of the Cp rings in **3g** (1.417 Å) and **7a** (1.453 Å) are similar to the values reported for other ferrocene derivatives [15]. The Fe–C(ring) bond distances range from 2.036 to 2.050 Å in **3g** and from 2.079 to 2.098 Å in **7a**. The two Cp rings of the ferrocenyl fragment in **3g** and **7a** are planar and nearly parallel (interplanar angle 1.7° in **3g**).

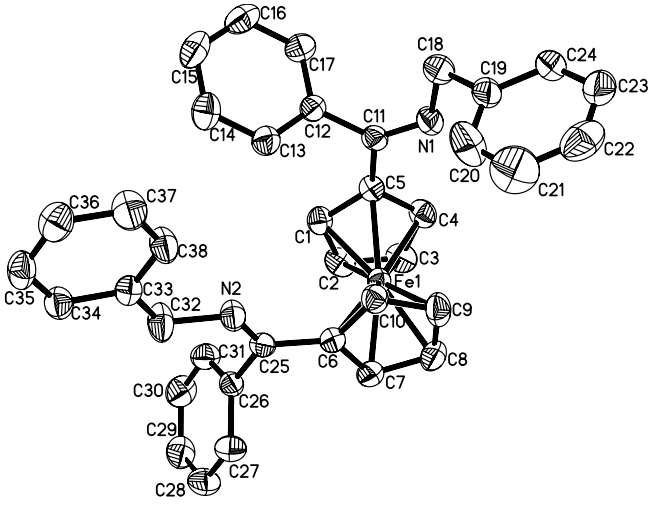


Fig. 1. Perspective view of the independent molecule of **3g** with the atomic numbering scheme (H atoms are omitted for clarity).

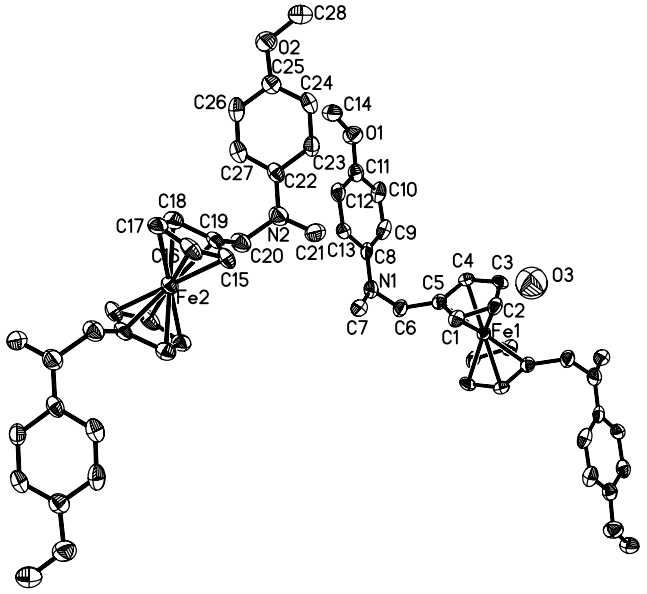

Fig. 2. Perspective view of the independent molecules of **7a** with the atomic numbering scheme (H atoms are omitted for clarity).

3. Experimental

3.1. Materials and instruments

Diformylferrocene [16], diacetylferrocene and dibenzoylferrocene [17] were prepared according to the literature methods. Sodium borohydride, sodium cyanoborohydride were used as received, anilines, titanium tetrachloride, formaldehyde, acetic acid, lithium aluminum hydride, and aluminum chloride were obtained commercially. All of the solvents were purified according standard methods prior to use. Melting points were obtained from a Yanaco micro

melting point apparatus and were uncorrected. Elemental analyses were obtained from a Carlo Erba 1106 Elemental analyzer. ^{1}H NMR spectra were measured with a Bruker AV-400 spectrometer by using $CDCl_3$ as a solvent and TMS as internal standard. IR spectra were taken on a BIO-RAD 3000 spectrophotometer.

3.2. Preparation of *7a*, *7b*, *7d* from diformylferrocene (*I*)

3.2.1. Preparation of dialdimines *1a–b*, *1d* from *I*

General procedure: the synthetic procedure for **1a**–**b**, **1d** was the same as described previously [7].

*3.2.1.1. [Fe{(η^5-C_5H_4)–CH=N–$C_6H_4OCH_3$-4}$_2$] (**1a**).* Dark-red solid. M.p. 134–136 °C; Yield 85%. *Anal.* Calc. for $C_{26}H_{24}FeN_2O_2$: C, 69.04; H, 5.35; N, 6.19. Found: C, 68.87; H, 5.33; N, 6.18%. Yield 81%. ^{1}H NMR ($CDCl_3$) δ: 3.81(s, 6H, OCH_3), 4.08(s, 4H, H3, H3′), 4.19(s, 4H, H2, H2′), 6.83(q, 8H, PhH), 8.01(s, 2H, H4, H4′) ppm. IR(KBr) v: 3075(w), 2991(w), 2931(w) 2833(m), 1622(s), 1598(m), 1511(s), 1458(s), 1240(s), 1176(s), 1164(m), 1038(s), 819(vs), 691(w) cm^{-1}.

*3.2.1.2. [Fe{(η^5-C_5H_4)–CH=N–$C_6H_4CH_3$-4}$_2$] (**1b**).* Dark-red solid. M.p. 98–100 °C; Yield 81%. *Anal.* Calc. for $C_{26}H_{24}FeN_2$: C, 74.29; H, 5.76; N, 6.66. Found: C, 74.07; H, 5.73; N, 6.64%. ^{1} H NMR ($CDCl_3$) δ: 1.99(s, 6H, Ar–CH_3), 4.07(s, 4H, H3, H3′), 4.18(s, 4H, H2, H2′), 6.85(q, 8H, PhH), 8.01(s, 2H, H4, H4′) ppm. IR(KBr) v: 3077(w), 3021(w), 2919(w), 2860(w), 1623(vs), 1596(s), 1506(s), 1467(m), 1367(w), 1217(m), 1187(w), 1039(m), 819(s), 778(m) cm^{-1}.

*3.2.1.3. [Fe{(η^5-C_5H_4)–CH=N–C_6H_4Cl-3}$_2$] (**1d**).* Dark-red solid. M.p. 80–82 °C; Yield 83%. *Anal.* Calc. for $C_{24}H_{18}Cl_2FeN_2$: C, 62.51; H, 3.93; N, 6.07. Found: C, 62.43; H, 3.91; N, 6.06%. ^{1} H NMR ($CDCl_3$) δ: 4.08(s, 4H, H3,H3′), 4.21(s, 4H, H2, H2′), 6.88(m, 8H, phH), 8.02(s, 2H, H4, H4′) ppm. IR(KBr) v: 3083(w), 2937(w), 2891(w), 2811(w), 1625(s), 1596(vs), 1498(s), 1361(m), 1251(m), 1094(m), 985(s), 920(w), 761(s), 682(m) cm^{-1}.

3.2.2. Preparation of *4a–b*, *4d* from *1a–b*, *1d*

General procedure: the synthetic procedure for **4a**–**b**, **4d** was the same as described previously [7].

*3.2.2.1. [Fe{(η^5-C_5H_4)–CH_2NH–$C_6H_4OCH_3$-4}$_2$] (**4a**).* Yellow liquid. Yield 90%. *Anal.* Calc. for $C_{26}H_{28}FeN_2O_2$: C, 68.43; H, 6.18; N, 6.14. Found: C, 68.19; H, 6.16; N, 6.13%. IR(KBr) v: 3386(m), 3076(w), 2992(w), 2933(w) 2830(m), 1616(w), 1518(s), 1463(s), 1241(s), 1179(s), 1163(m), 1035(s), 818(vs), 692(w) cm^{-1}. ^{1}H NMR ($CDCl_3$)

δ: 3.75(s, 6H, OCH_3), 4.01(s, 4H, H2, H2′), 4.11(s, 4H, H3, H3′), 4.24(s, 4H, H4, H4′), 6.77(q, 8H, PhH) ppm.

*3.2.2.2. [Fe{(η⁵-C_5H_4)–CH_2NH–$C_6H_4CH_3$-4}$_2$] (**4b**).* Yellow solid. Yield 89%; m.p. 70–72 °C. *Anal.* Calc. for $C_{26}H_{28}FeN_2$: C, 73.59; H, 6.65; N, 6.60. Found: C, 73.41; H, 6.62; N, 6.59%. IR(KBr) *v*: 3401(m), 3089(w), 2912(w), 2857(w), 1613(m), 1517(vs), 1461(w), 1315(m), 1246(m), 1183(w), 1032(w), 805(s) cm^{-1}. ^1H NMR ($CDCl_3$) δ: 2.26(s, 6H, Ar–CH_3), 3.96(s, 4H, H4, H4′), 4.16(s, 4H, H2, H2′), 4.24(s, 4H, H3, H3′), 6.80 (q, 8H, PhH) ppm.

*3.2.2.3. [Fe{(η⁵-C_5H_4)–CH_2NH–C_6H_4Cl-3}$_2$] (**4d**).* Yellow solid. Yield 85%; m.p. 46–48 °C. *Anal.* Calc. for $C_{24}H_{22}Cl_2FeN_2$: C, 61.96; H, 4.77; N, 6.02. Found: C, 61.78; H, 4.71; N, 6.00%. IR(KBr) *v*: 3421(m), 3088(w), 2939(w), 2893(w), 2811(w), 1594(vs), 1557(m), 1495(s), 1362(m), 1251(m), 1098(m), 987(s) 920(w), 831(m), 760(s), 681(m) cm^{-1}. ^1H NMR ($CDCl_3$) δ: 4.10(s, 4H, H2, H2′), 4.14(s, 4H, H3, H3′), 4.25(s, 4H, H4, H4′), 6.62–7.15(m, 8H, PhH) ppm.

3.2.3. Preparation of 7a–b, 7d from 4–b, 4d

General procedure: the synthetic procedure for **7a**–**b**, **7d** was the same as described previously [7].

*3.2.3.1. [Fe{(η⁵-C_5H_4)–$CH_2N(CH_3)$–$C_6H_4OCH_3$-4}$_2$] (**7a**).* Yellow solid. Yield 85%; m.p. 78–80 °C. *Anal.* Calc. for $C_{28}H_{32}FeN_2O_2$: C, 69.42; H, 6.66; N, 5.78. Found: C, 69.31; H, 6.60; N, 5.77%. IR(KBr) *v*: 2980(w), 2939(w), 2893(w), 1509(s), 1456(w), 1332(w), 1243(vs), 1183(m), 1039(m), 917(w), 810(s), 697(m) cm^{-1}. ^1H NMR ($CDCl_3$) δ: 2.73(s, 6H, H7, H7′), 3.76(s, 6H, OCH_3), 4.04(s, 4H, H2, H2′), 4.06(s, 4H, H3, H3′), 4.15(s, 4H, H4, H4′), 6.79(q, 8H, PhH) ppm.

*3.2.3.2. [Fe{(η⁵-C_5H_4)–$CH_2N(CH_3)$–$C_6H_4CH_3$-4}$_2$] (**7b**).* Yellow solid. Yield 78%; m.p. 84–86 °C. *Anal.* Calc. for $C_{28}H_{32}FeN_2$: C, 74.33; H, 7.13; N, 6.19. Found: C, 74.17; H, 7.12; N, 6.18%. IR(KBr) *v*: 3067(w), 3009(w), 2911(w), 2853(w), 1619(m), 1522(s), 1373(m), 1332(m), 1253(m), 1189(m), 1101(w), 830(m), 802(s) cm^{-1}. ^1H NMR ($CDCl_3$) δ: 2.25(s, 6H, Ar–CH_3), 2.80(s, 6H, H7, H7′), 4.05(s, 4H, H2, H2′), 4.09(s, 4H, H3, H3′), 4.22(s, 4H, H4, H4′), 6.72(q, 8H, PhH) ppm.

*3.2.3.3. [Fe{(η⁵-C_5H_4)–$CH_2N(CH_3)$–C_6H_4Cl-3}$_2$] (**7d**).* Yellow liquid. Yield 72%. *Anal.* Calc. for $C_{26}H_{26}Cl_2FeN_2$: C, 63.31; H, 5.31; N, 5.68. Found: C, 63.11; H, 5.29; N, 5.64%. IR (KBr) *v*: 3078(w), 2924(w), 2888(w), 1593(s), 1558(s), 1491(s), 1355(m), 1230(m), 1099(s), 986(s), 827(m), 756(m), 684(m) cm^{-1}. ^1H NMR ($CDCl_3$) δ: 2.89(s, 3H, H7), 2.96(s, 3H, H7, H7′), 4.13(s, 4H, H2, H2′), 4.18(s, 4H, H3, H3′), 4.28(s, 4H, H4, H4′), 6.67-7.19(m, 8H, PhH) ppm.

3.3. Preparation of 8a–c, 8e from diacetylferrocene (II)

3.3.1. Preparation of diketimines 2a–c, 2e from II

General procedure: to the stirred mixtures of diacetylferrocene in toluene and titanium tetrachloride (3% mol), were added 4 equivalents of anilines. The mixtures were refluxed for 6–8 h under argon. After the reactions completed, the mixtures were washed with water three times (3 × 100 ml). The organic phase was dried over anhydrous sodium sulfate and filtered. The solvent was removed under reduced pressure, and the residues were purified by flash chromatography (silica gel, ethyl acetate/hexane = 1:5) to give **2a**–**c**, **2e**.

*3.3.1.1. [Fe{(η⁵-C_5H_4)–$C(CH_3)$=N–$C_6H_4OCH_3$-4}$_2$] (**2a**).* Dark-red solid. Yield 65%; m.p. 182–184 °C (dec.) (lit. [18], >184 °C). IR(KBr) *v*: 3097(w), 2963(w), 2856(w), 1622(vs), 1504(vs), 1465(m), 1361(m), 1236(vs), 1197(m), 1032(m), 850(m), 833(m) cm^{-1}.

*3.3.1.2. [Fe{(η⁵-C_5H_4)–$C(CH_3)$=N–$C_6H_4CH_3$-4}$_2$] (**2b**).* Dark-red solid. Yield 65%; m.p. 144–146°C (lit. [18], 147–147.5 °C). IR(KBr) *v*: 3015(w), 2965(w), 2857(w), 1624(vs), 1504(m), 1460(m), 1287(m), 1117(m), 1036(w), 809(s) cm^{-1}.

*3.3.1.3. [Fe{(η⁵-C_5H_4)–$C(CH_3)$=N–C_6H_5}$_2$] (**2c**).* Dark-red solid. Yield 62%; m.p. 138–140 °C (lit. [18], 141.5–142.5 °C). IR(KBr) *v*: 3021(w), 2968(w), 2858(w), 1623(vs), 1502(m), 1458(m), 1285(m), 1117(m), 1035(w), 809(s) cm^{-1}.

*3.3.1.4. [Fe{(η⁵-C_5H_4)–$C(CH_3)$=N–C_6H_4Cl-4}$_2$] (**2e**).* Dark-red solid. Yield 58%, m.p. 183–185 °C (lit. [18], 184.5–185.5 °C). IR(KBr) *v*: 3023(m), 2969(w), 2861(w), 1623(s), 1494(vs), 1454(w), 1278(m), 1234(w), 1091(m), 825(m) cm^{-1}.

3.3.2. Preparation of 5a–c, 5e from 2a–c, 2e

General procedure: to the stirred solutions of **2a**–**c** and **2e** (10 mmol) in anhydrous THF (50 ml) was added aluminum chloride (3% mmol) and the resulted mixtures were continuously stirred for 30 min at room temperature. Then 20 mmol of lithium aluminum hydride was added in one portion and the mixtures were refluxed for 1 h under argon. The solvent was evaporated under reduced pressure to dryness, dichloromethane (120 ml) was then added and stirred for 1 h. The extraction phase was dried over sodium sulfate and filtered. Removal of solvent yielded residues which were purified by column chromatography (silica gel, ethyl acetate/hexane = 1:3) to yield **5a**–**c**, **5e**.

*3.3.2.1. [Fe{(η⁵-C_5H_4)–$CH(CH_3)NH$–$C_6H_4OCH_3$-4}$_2$] (**5a**).* Yellow liquid. Yield 86%. *Anal.* Calc. for $C_{28}H_{32}FeN_2O_2$: C, 69.42; H, 6.66; N, 5.78. Found: C, 69.31; H, 6.65; N, 5.78 %. IR(KBr) *v*: 3380(w), 3088(w), 2970(m), 2929(m), 2832(m), 1510(vs), 1469(m), 1408(w), 1232(s), 1182(m),

1126(m), 1037(s), 819(s) cm^{-1}. ^1H NMR ($CDCl_3$) δ: 1.43(d, 6H, H5, H5′), 3.75(s, 6H, OCH_3), 3.11(m, 2H, H4, H4′), 3.88(s, 2H, NH), 4.04(s, 4H, H2, H2′), 4.16(s, 4H, H3, H3′), 6.71(q, 8H, PhH) ppm.

*3.3.2.2. [Fe{(η^5-C_5H_4)–CH(CH_3)NH–$C_6H_4CH_3$-4}$_2$] (**5b**).* Yellow liquid. Yield 80%. *Anal.* Calc. for $C_{28}H_{32}FeN_2$: C, 74.33; H, 7.13; N, 6.19. Found: C, 74.19; H, 7.12; N, 6.16%. IR(KBr) *v*: 3404(m), 3094(w), 3023(w), 2961(m), 2913(m), 1616(s), 1517(vs), 1449(m), 1298(m), 1241(m), 1134(m), 1024(w), 807(s) cm^{-1}. ^1H NMR ($CDCl_3$) δ: 1.44(d, 6H, H5, H5′), 2.23(s, 6H, Ar–CH_3), 3.15(m, 2H, H4, H4′), 3.89(s, 2H, NH), 4.06(s, 4H, H2, H2′), 4.20(s, 4H, H3, H3′), 6.90(q, 8H, PhH) ppm.

*3.3.2.3. [Fe{(η^5-C_5H_4)–CH(CH_3)NH–C_6H_5}$_2$] (**5c**).* Yellow liquid. Yield 50%. *Anal.* Calc. for $C_{26}H_{28}FeN_2$: C, 73.59; H, 6.65; N, 6.60. Found: C, 73.40; H, 6.62; N, 6.58%. IR (KBr) *v*: 3405(m), 3083(w), 3047(w), 2970(m), 2924(w), 2863(w), 1601(vs), 1502(vs), 1424(m), 1367(m), 1313(s), 1249(m), 1129(m), 1029(m), 748(s), 691(s) cm^{-1}. ^1H NMR ($CDCl_3$) δ: 1.45(s, 6H, H5, H5′), 3.21(m, 2H, H4, H4′), 3.90(s, 2H, NH), 4.05(s, 4H, H2, H2′), 4.13(s, 4H, H3, H3′), 6.92(m, 10H, PhH) ppm.

*3.3.2.4. [Fe{(η^5-C_5H_4)–CH(CH_3)NH–C_6H_4Cl-4}$_2$] (**5e**).* Yellow liquid. Yield 89%. *Anal.* Calc. for $C_{26}H_{26}Cl_2FeN_2$: C, 63.31; H, 5.31; N, 5.68. Found: C, 63.17; H, 5.29; N, 5.66%. 3.5. Crystal structure determination for 3g and 7a

The prismatic single crystals of **3g** and **7a** suitable for X-ray analysis were obtained by slow evaporation of the mixture of ethyl acetate and hexane at room temperature over a period of 1 week. The single crystals of **3g** and **7a** were mounted on a Bruker SMART CCD diffractometer equipped with graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at ambient temperature ($T = 293$ K for **3g** and 294 K for **7a**) using the ω-2θ multi-scans technique with the range of $2.05° \leqslant \theta \leqslant 25.03°$ (**3g**), $2.16° \leqslant \theta \leqslant 25.02°$ (**7a**) for data collection. Semi-empirical absorption corrections were applied using the SABABS program [19]. The structures were solved by direct methods and refined by the full-matrix least-squares procedure on F^2 using the SHELX suite of programs [20]. The values of R_1 were given based on F_o with a typical threshold of $F^2 \geqslant 2\sigma(F^2)$. The weighted *R*-factors *wR* were based on F^2 with $w = 1/[\sigma^2(F_o^2) + (0.0376P)^2 + 0.2035P]$ where $P = (F_o^2 + 2F_c^2)/3$ for **3g**, $w = 1/[\sigma^2(F_o^2) + (0.0587P)^2 + 2.9596P]$ where $P = (F_o^2 + 2F_c^2)/3$ for **7a**. Crystallographic data for **3g** and **7a** are summarized in Table 1. Selected bond lengths and angles for **3g** and **7a** are presented in Table 2.

Supplementary material

CCDC 614253 and 613898 contain the supplementary crystallographic data for **3g** and **7a**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Scheme 1.

manganese and copper [9,10]. In $[CdX(picOH)(HpicOH)(H_2O)]_2$ ($X = Cl^-$, Br^-) we established two modes of HpicOH binding: *N*,*O*-chelating and *O*-monodenate with the pyridine nitrogen atom protonated [11].

Our former investigations pointed out that the mercury(II) ion is capable of forming various binding coordination modes with *N*,*O*-donor atoms when provided by suitable ligands [12–16]. Our present interest on mercury(II) coordination complexes has been directed towards the understanding of the competition between halide ions and ligands containing *N*,*O*-donors for coordination sites of the mercury(II) ion. So far, we found that the tendency of mercury to achieve effective coordination by spatial arrangement of donor atoms of different types of acids, leads to various, mostly highly irregular, coordination polyhedra of mercury. Mono- and dicarboxylic acids containing a pyridine ring, or their hydroxy derivatives, are good ligand systems with *N*,*O*-donor atoms at appropriate sites for modelling various mercury coordination polyhedra in discrete or polymeric complexes of the formulas HgXL, HgX_2L or HgX(L)(LH) (LH and L stand for the protonated and deprotonated form of the ligand, respectively, $X = Cl^-$, Br^-, I^-, SCN^-).

Our wider interest includes investigation of toxicity effects of various metal complexes of the 12th group of elements on microbial communities. For such a study well characterized complexes are needed. This paper describes new mercury(II) complexes with 3-hydroxypicolinic acid. They were synthesized, identified by chemical analysis, characterized by the appropriate spectroscopic methods, both in solution and in the solid state, and two crystal structures were determined by the X-ray diffraction method.

2. Experimental

2.1. Materials and physical measurements

All reagents were supplied by Aldrich Chemical Co. and were used as received without further purification. The CHN-microanalyses were measured by the Central Analytical Service of the Ruđer Bošković Institute, Zagreb. The mercury content in the complexes was determined by complexometric titration with sodium diethyldithiocarbamate of the solution obtained after decomposition of the specimen in *aqua regia* [17].

Pressed KBr pellets were used for IR measurements within the range 4000–400 cm^{-1} with a Perkin–Elmer FT-IR spectrometer 1600 Series.

The one- and two-dimensional homo- and heteronuclear ^1H and ^{13}C NMR spectra were recorded with a Bruker AV 600 spectrometer, operating at 600.133 MHz for the ^1H nucleus and 150.917 MHz for the ^{13}C nucleus. Samples were measured from DMSO-d_6 solutions at 22 °C (295 K) in 5 mm NMR tubes. Chemical shifts, in ppm, are referred to TMS as internal standard. FID resolution in ^1H NMR and ^{13}C NMR spectra was 0.29 and 0.54 Hz per point, respectively. The following measurement techniques were used: standard ^1H, ^{13}C gated proton decoupling, APT, COSY, HMQC and HMBC. The 2D NMR spectra were measured in the pulsed field gradient mode (*z*-gradient).

X-ray and NMR data are given in Tables 1 and 2, respectively.

[a] $R = \sum||F_o| - |F_c|/\sum|F_o|$.

[b] $wR = \left[\sum(F_o^2 - F_c^2)^2/\sum w(F_o^2)^2\right]^{1/2}$.

[c] $w = 1/[\sigma^2(F_o^2)] + [g_1P + g_2P]$ where $P = (F_o^2 + 2F_c^2)/3$.

[d] $S = \sum[w(F_o^2 - F_c^2)^2/(N_{obs} - N_{param})]^{1/2}$.

[e] The maximum electron density in the last difference Fourier map is near Hg.

2.2. HgCl(picOH) (1)

To an aqueous solution of mercury(II) chloride (0.30 g; 1.1 mmol in 15 ml H_2O) an aqueous solution of 3-hydroxypicolinic acid was added dropwise (0.16 g; 1.15 mmol in 15 ml H_2O). The reaction mixture was allowed to stand for a few days at room temperature to crystallize. The crystalline product was filtered off, washed with cold water and dried in a desiccator. Yield: 0.31 g (75.6%). *Anal.* Calc. for $C_6H_4ClHgNO_3$ (mol. wt. 374.14): C, 19.26; H, 1.08; N, 3.74; Hg, 53.61. Found: C, 19.38; H, 1.18; N, 3.67; Hg, 53.81%. IR max. (cm^{-1}): 3087w, 1621vs, 1601s, 1570s, 1527m, 1476s, 1456vs, 1375vs, 1312vs, 1249s, 1229s, 1149m, 1064w, 893m, 872m-w, 829s, 805m-s, 692s, 578m.

When the same reaction is performed in ethanol **1** is also obtained, however the yield is better from aqueous solution.

2.3. $HgBr_2$(HpicOH) (2)

To an ethanolic solution of mercury(II) bromide (0.3 g; 0.83 mmol in 15 ml of EtOH) an ethanolic solution of 3-hydroxypicolinic acid was added dropwise (0.12 g; 0.86 mmol in 25 ml EtOH). The reaction mixture was left to stand for a few days. The crystalline product was filtered off, washed with cold ethanol and dried. Yield: 0.37 g (90.5%). *Anal.* Calc. for $C_6H_5Br_2HgNO_3$ (mol. wt. 499.52): C, 14.43; H, 1.01; N, 2.80; Hg, 40.16. Found: C, 14.13; H, 1.07; N, 3.15; Hg, 40.07%. IR max. (cm^{-1}): 3585m, sharp, 3526m, sharp, 3065m-w, 2856w, br, 1655s, 1613s, 1534s, 1470s, 1412s, 1377m, 1335s, 1283s, 1252m, 1214m, 1152m, 1120m-w, 1048m-w, 874s, 816vs, 802s, 682s, 667vs, 576w, 549w, 446m.

The same reaction performed in an aqueous solution also results in **2**, but with traces of unreacted $HgBr_2$ which is less soluble in water than ethanol.

2.4. Hg(picOH)$_2$ (3) and Hg(picOH)$_2 \cdot H_2O$ (3a)

To an aqueous solution of mercury(II) acetate (0.3 g; 0.94 mmol in 15 ml H_2O with a few drops of 2 M acetic acid) an aqueous solution of 3-hydroxypicolinic acid was added (0.3 g; 2.15 mmol in 15 ml H_2O). The yellowish product was filtered off, washed with water and dried. Yield (**3**): 0.40 g (88.9%). From the reaction of 3-hydroxypicolinic acid (0.24 g; 1.72 mmol in 15 ml H_2O) and mercury(II) nitrate monohydrate (0.3 g; 0.86 mmol in 15 ml H_2O with a few drops of 20% nitric acid) the 1/1 solvate of $Hg(picOH)_2$ with water was obtained. Yield (**3a**): 0.38 g (87.8%). *Anal.* Calc. for $C_{12}H_8HgN_2O_6$ (mol. wt.

Table 2

2.5. X-ray crystallographic structure determination of *1* and *2*

The general and crystal data, and summary of intensity data collection and structure refinement for compounds **1** and **2** are given in Table 1.

The data collection for both structures was carried out on an Oxford Diffraction Xcalibur four-circle kappa geometry single-crystal diffractometer with Sapphire 3 CCD detector, by applying the CrysAlis Software system [18]. A crystal-detector distance of 60 mm and ω scan type was used for both structures. Data reduction, including absorption correction, was done by the CrysAlis RED application of the CrysAlis Software system [18]. Coordinates of the non-hydrogen atoms were determined by direct methods using the SHELXS program [19]. The coordinates and anisotropic thermal displacement parameters for all non-hydrogen atoms were refined by the least-squares methods based on F^2 using the SHELXL97 program [20]. The coordinates of the hydrogen atom belonging to the nitrogen atom in **2** were found by examination of the electron-density Fourier map at the final stages of refinement and were refined freely [the bond distance is 0.8(1) Å]. The other hydrogen atoms which belong to the pyridine carbon atoms, as well as the hydroxyl hydrogen atom, were generated at ideal geometrical positions [Csp^2–H 0.93 Å, $U_{iso}(H) = 1.2\ U_{eq}(C)$; O–H 0.82 Å; $U_{iso}(H) = 1.5\ U_{eq}(O)$], and were refined applying the riding model. The molecular graphics were created by means of the PLATON98 program [21].

3. Results and discussion

3.1. Preparation

Compound **1** HgCl(picOH) was obtained from the reaction of 3-hydroxypicolinic acid (HpicOH) with mercury(II) chloride in an aqueous solution. Similarly, reaction with $HgBr_2$ in ethanolic solution gave $HgBr_2$(HpicOH) (**2**). In both cases the reaction products were not influenced by the molar ratio of reactants (1:1 or 2:1). Both mercury(II) acetate and nitrate monohydrate react with HpicOH in aqueous media giving typical metal carboxylates i.e. $Hg(picOH)_2$ (**3**) and $Hg(picOH)_2 \cdot H_2O$ (**3a**), respectively. All the isolated compounds are soluble in solvents with pronounced coordination properties such as dimethyl sulfoxide (DMSO), *N*,*N*-dimethyl formamide (DMF) or pyridine. Crystals suitable for X-ray diffraction studies were obtained from the mother liquor for compounds **1** and **2**, but all our attempts to prepare crystals of compounds **3** and **3a** failed.

3.2. Structural description of *1* and *2*

In **1** the shortest bonds to Hg are from nitrogen and chlorine atoms (Hg–N 2.143(4) and Hg–Cl 2.298(1) Å) giving a

slightly distorted characteristic linear coordination, N–Hg–Cl 172.7(1)° [22,23]. These bonds are slightly longer than the sum of the covalent radii of the corresponding atoms because of the additional Hg···O contacts. Both carboxylate oxygen atoms of the deprotonated picolinic acid are involved in coordination to two neighboring mercury atoms (Hg···O1 2.460(3) and Hg···O2 (x, $0.5 - y$, $z - 0.5$) 2.609(3) Å) thus bridging them and forming infinite zigzag chains along the b axis, Fig. 1. Relevant bond distances and bond angles are shown in Tables 3 and 4. Besides the two already mentioned, there are two more long Hg···O contacts (Hg···O2 ($1 - x$, $1 - y$, $2 - z$) 2.888(3) Å and Hg···O1 ($1 - x$, $0.5 + y$, $1.5 - z$) 2.904(3) Å), still shorter than the sum of van der Waals radii (r_{VDW}(Hg) = 1.55–1.65 Å; r_{VDW}(O) = 1.40–1.52 Å) [22–25]. All contacts fulfill the effective coordination sphere of mercury, which is therefore 2 + 4. This behavior is in agreement with Grdenić's classification of a characteristic and effective coordination sphere of mercury in crystal structures [22,23]. Through these contacts (Fig. 2), infinite two-dimensional layers are formed. There is an intramolecular hydrogen bond connecting the hydroxyl and carboxylic group, O3–H···O2 of 2.542(5) Å. The intermolecular hydrogen bonds are very weak (Table 5). A similar coordination, yet with slightly longer covalent Hg–N and Hg–Cl bonds than in **1**, is found in the structure of (pyda · H)$_2$[Hg(pydc)Cl$_2$ · 2H$_2$O] (pyda = 2,6-pyridinediamine; pydc = 2,6-pyridinedicarboxylic acid). In this structure the distances amount to 2.198(6)

N–H···O2^{iii}	2.737(12)	133(14)
C3–H···Br2^{iv}	3.495(12)	140

Symmetry transformations used to generate equivalent atoms: (i) $-x$, $1/2+y$, $3/2-z$; (ii) $1-x$, $1-y$, $1-z$; (iii) $-1-x$, $-y$, $-z$; (iv) $-x$, $1-y$, $-z$.

and 2.310(2) Å, respectively [26]. The greater elongation is caused by four Hg···O contacts that are in the range 2.488(5)–2.659(5) Å.

Structure of **2** consists of polymeric chains (Fig. 3). There are two covalent bonds, Hg–Br1 2.277(1) and Hg–Br2 2.366(1) Å forming the linear characteristic coordination, Br1–Hg–Br2 168.22(4)° (Table 4). The effective coordination sphere of mercury can be described as irregular 2 + 3, consisting of three weak additional contacts, two with bromine atoms from adjacent molecules (Hg–Br1 (x, $1+y$, z) 3.309(1) and Hg–Br2 (x, $-1+y$, z) 3.247(1) Å), and one with the carboxylic oxygen of HpicOH in the zwitterionic form (Hg–O1 2.602(7) Å). Interestingly, both covalent Hg–Br bonds are shorter than the sum of the covalent radii for Hg(digonal) and Br atoms (1.30 and 1.14 Å, respectively) [22–25] and also shorter than in the brucite structural type of $HgBr_2$ (Hg–Br of 2.444(7) and 2.445(7) Å, $2\times$Hg···Br of 3.240(5) and $2\times$Hg···Br 3.243(5) Å) [27]. The two bridging mercury to bromine contacts as well as the mercury to oxygen contact are longer than the covalent bond, but shorter than the van der Waals interactions (r_{VDW}(Br) = 1.85–1.95 Å) [22–25]. The coordination polyhedron is best described as very deformed square-pyramidal with an O atom at the apex. The Hg to Br distance at the sixth coordination site of 3.8475(11) Å is too long to be considered as a contact. Analysis of all structures deposited with the Cambridge Crystallographic Data Centre [28] that contain a mercury to bromine bond, showed that the short Hg–Br1 bond in **2** is similar to the shortest one found so far in κ-(d_8-ET)$_4$[$HgBr_2\cdot Hg_2Br_6$] (d_8-ET = wholly deuterated bis(ethylenediothio)tetrathiafulvalene) where Hg–Br is 2.28(2) Å and Br–Hg–Br is 169.7(7)°. There are two additional contacts of 3.41(2) Å at one side of this linear bond, yet the Hg–Br distance of 3.77(2) Å at the other side points to an absence of any additional interactions to Hg [29].

A similar polymeric structural motif to that of **2** was found in the structure of $HgCl_2$(tolnapH), (tolnapH = *N*-*p*-tolyl-2-oxo-1-napthylideneamine) [30]. In the structure of the polymeric HgBr(nic) (nic^- = nicotinate anion, pyridine-3-carboxylate) [15] the effective Hg coordination is a 3 + 2 irregular polyhedron with Hg–Br bond distances of 2.6528(9) and 2.6468(9) Å, which are longer than in **2** and slightly longer than the tetrahedral Hg–Br covalent bond of 2.62 Å [22,23,25].

As in **1**, the O3 hydroxyl atom forms an intramolecular hydrogen bond O3–H···O1 of 2.334(11) Å, yet there is another one involving the protonated nitrogen (N–H···O2

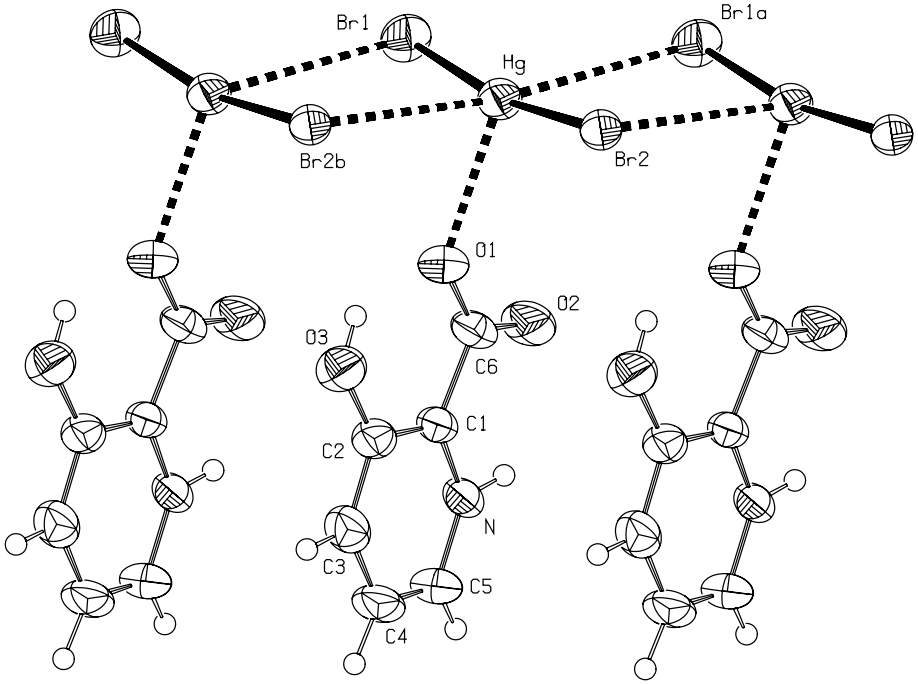

Fig. 3. Drawing of $HgBr_2$(HpicOH) (**2**) with the atom labelling scheme. The thermal ellipsoids are at the 50% probability level. Dashed lines represent Hg···Br and Hg···O contacts. Symmetry operations: $a = x, y-1, z$; $b = x, 1+y, z$.

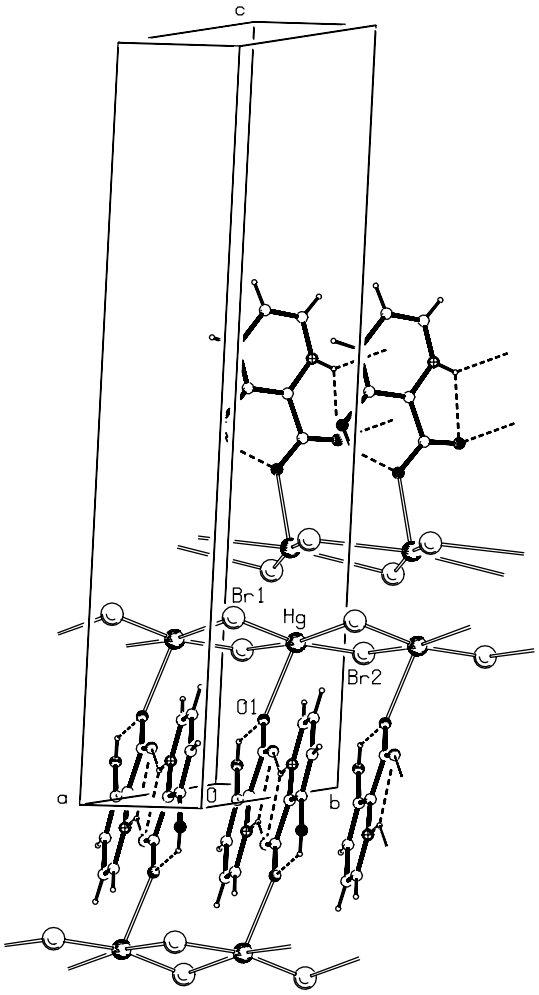
2.662(10) Å). Two polymeric chains are mutually connected by centrosymmetric pairs via intermolecular hydrogen bonds N–H···O2 ($-1-x$, $-y$, $-z$) of 2.737(12) Å (Fig. 4, Table 5). In such a manner three-center hydrogen bonds are formed and the N–H group is distributed between two proton acceptors.

3.3. Spectral analysis

The infrared spectra of the complexes proved that 3-hydroxypicolinic acid is bound to the mercury(II) ion in the deprotonated form in all the isolated compounds (see ν_a(COO) in the experimental data), however different modes of ligand coordination in **1** and **2** were unambigously confirmed by X-ray structure analysis. Unfortunately, due to overlaping of maxima and vibrational coupling, the observed shifts of absorption bands sensitive to metal coordination relatively to those of the free ligands could not be unambigously assigned.

^{1}H and ^{13}C NMR data of 3-hydroxypicolinic acid and its mercury(II) compounds are given in Table 2 while Scheme 2 shows the labelling of the atoms. The NMR spectra of **1**, **2** and **3** in DMSO solution revealed narrow signals and a lack of long range couplings, which is characteristic of the monomeric form of the molecules. This is not unexpected since in solution the polymers almost certainly break up into monomeric units. On the other hand, the NMR data showed that the ligand is bound as in the solid state with a deprotonated N and O in **1** and **3**, while a neutral O in **2**. The obtained ^{1}H spectra of **1**, **2** and **3** display four groups of signals. The assignments of the protons were supported by COSY spectra. In the ^{1}H NMR spectra, the greatest shifts ($\Delta\delta$) after complexation are observed for OH-protons which are five or six bonds remote from mercury. Interestingly, the OH-proton of compounds **1** and **3** is found to be deshielded, in comparison to the one in **2** which is a shielded proton. Such behavior arises from the different mode of mercury coordination. In all ^{1}H spectra the multiplicity of the signals is alike. The mercury binding does not influence significantly the other protons in the molecules of both compounds **1** and **2**. A small shielding effect is observed on the H-4 atom in complexes **1** and **2**, however deshielding effects are observed on H-5 and H-6 atoms in all three complexes.



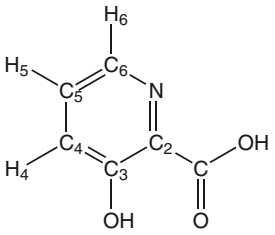


Fig. 4. Packing of $HgBr_2$(HpicOH) (**2**) molecules into polymeric layers. The deformed square pyramidal geometry around Hg is shown by double lines. Hydrogen bonds are shown by dashed lines.

Scheme 2.

The assignments of all the carbon atoms are confirmed by HMQC and HMBC measurements. In the ^{13}C NMR spectra, the greatest change upon complexation with mercury was observed for the chemical shifts of the C-6 atom. In **1** and **3**, C-6 is more deshielded than in **2**, since in complexes **1** and **3** the mercury atom is bonded to the nitrogen atom and the carboxyl group, while in **2** only to the carboxyl group. In all three compounds, carboxyl carbon atom was found to be not so deshielded as the C-6 atom. Shielding effects are observed on C-3 and C-4 atoms (-0.30 and -0.19 ppm, respectively) in complex **2**, and on the C-4 atom in **1** and **3** (-1.94 and -1.88 ppm, respectively). The carbon atom C-2 is deshielded in all three complexes (0.13–1.79 ppm) as expected, since it is close to the mercury binding site. The mercury binding induces electronic redistribution throughout the molecule which makes all the carbon atoms sensitive to mercury binding even if they are distant from mercury.

4. Conclusion

The competition reaction of halide ($X = Cl^-$, Br^-) with the 3-hydroxypyridine-2-carboxylate ligand ($picOH^-$) toward the mercury(II) ion was investigated. It was established that the molar ratio of the reactants did not influence

the type of reaction product, and polymeric $\{HgCl(picOH)\}_n$ or $\{HgBr_2(HpicOH)\}_n$ was always obtained. X-ray crystal structural analysis of these polymeric compounds showed interesting $2+4$ and $2+3$ coordination polyhedra around the mercury atom, and confirmed two different coordination modes of HpicOH. The NMR spectra of all the isolated mercury compounds in DMSO solutions revealed that they exist in the monomeric form.

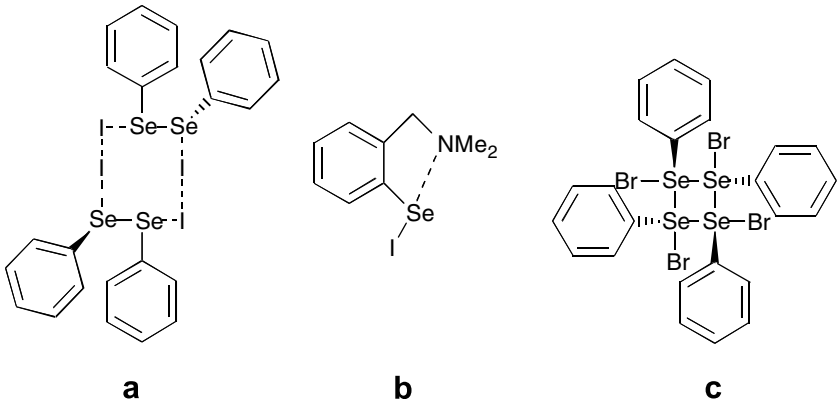

Fig. 1. Examples of different structural motifs observed for ArSeX compounds.

2-(Me_2NCH_2)C_6H_4SeI (Fig. 1(b)) [15]. These compounds feature a linear N···Se–I motif with the selenium atom in a T-shaped geometry. The strong Se···N interactions vary between 2.01(4) and 2.242(5) Å, close to the sum of the covalent radii of selenium and nitrogen (1.80 Å). The Se–I bond lengths in these systems range between 2.7419(9) and 2.8935(8) Å, and are significantly elongated compared with the monomeric RSeI iodoselanes, consistent with a linear N···Se–I system permitting interaction between the lone pair on nitrogen and the σ^* orbital of the Se–I bond.

There are few reported structures of arylselenium bromides or chlorides. The majority of those reported feature structures which are stabilised by non-bonded N···Se–X [10–19], or O···Se–X interactions [20–23], or by hypervalent coordination from either non-bonded halide ions [24] or halogen-substituted groups on the aryl ring [25,26]. Crystallographic reports of unstabilised systems are rarer, and until recently there were no crystallographic reports on PhSeX (X = Cl, Br), although gas-phase electron diffraction data on PhSeBr has appeared [27].

We have recently reported the solid-state structure of PhSeBr [28], which adopts a "square" motif, $Ph_4Se_4Br_4$ (Fig. 1(c)) where four "PhSeBr" units are held together by long Se–Se bonds [Se–Se: 3.004(2) to 3.051(2) Å]. The extended structure is further linked through long Br···Br contacts [Br–Br: 3.693(2) to 3.798(2) Å] to form planar sheets of selenium and bromine atoms. This type of square motif has also been reported for the related tellurium compound, $Ph_4Te_4I_4$ [29], and interestingly, contrasts with the CT structure exhibited by $(Ph_2Se_2I_2)_2$ [9].

There are far fewer structural reports concerning arylselenium pseudohalides. Most of the known examples involve systems where the pseudohalide is cyanide, with structural data reported for RSeCN, where R = C_6F_5 [30], 3-C_5H_4N [31], and 2,4,6-$R_3C_6H_2$ (R = Me, CF_3) [32]. Additionally, the structure of the diselenocyanate *p*-$C_6H_4(SeCN)_2$ [33], has been reported. Other structurally characterised arylselenium pseudohalides include 2,4,6-$(CF_3)_3C_6H_2SeNSO$ [34], the thiocarbamate derivatives $(Me_2NCH_2)C_6H_4SeSC(=S)CNR_2$ (R = Me, Et) [16], and the first stable selenium(II) azide, 2-(Me_2NCH_2)$C_6H_4SeN_3$ [15], which was also stabilised through intramolecular coordination of the NMe_2 group.

With little structural data available for ArSeX compounds which do not feature stabilisation by non-bonded Y···Se–X interactions (Y = N, O, halogen), and in view of the different structural motifs already observed for PhSeX (X = Br, I) [9,28], we have now undertaken a structural study of PhSeCl, and related PhSeX compounds containing pseudohalogens, such as PhSeCN and PhSeSCN, in order to further understand the factors affecting the solid-state structures of such systems.

2. Results and discussion

2.1. Structure of $Ph_4Se_4Cl_4$

PhSeCl is available commercially but may also be synthesised by the 1:1 reaction of diphenyldiselenide with sulfuryl chloride (SO_2Cl_2) in anhydrous diethyl ether. Care should be taken to avoid an excess of SO_2Cl_2 as oxidation readily occurs to the trichloride, $PhSeCl_3$ [35]. The orange solid obtained was characterised by multinuclear NMR spectroscopy, IR spectroscopy and elemental analysis (see Section 3), and the data obtained is consistent with previous literature reports [36]. Crystals of PhSeCl were obtained from a refluxing Et_2O/CH_2Cl_2 (1:1) solution of the compound which was then cooled to form suitable crystals after several days. PhSeCl crystallises in the orthorhombic space group $P2_12_12_1$, and was revealed to adopt a loosely held tetrameric "square" structure, $Ph_4Se_4Cl_4$, see Fig. 2a.

The square motif adopted by $Ph_4Se_4Cl_4$ is analogous to the solid-state structure of $Ph_4Se_4Br_4$ [28], and displays similar structural features. Four "PhSeCl" units are linked by weak selenium-selenium bonds to form an Se_4 square, with the Se–Cl bonds lying in the plane of the square, two phenyl rings located above the plane, and two below. The selenium atoms are thus in a "see-saw" geometry. Some asymmetry is observed for the Se–Se bonds, (as seen for $Ph_4Se_4Br_4$), as there are two shorter bonds, Se(1)–Se(2): 3.002(3) Å/Se(4)–Se(1): 2.993(3) Å, and two longer bonds,

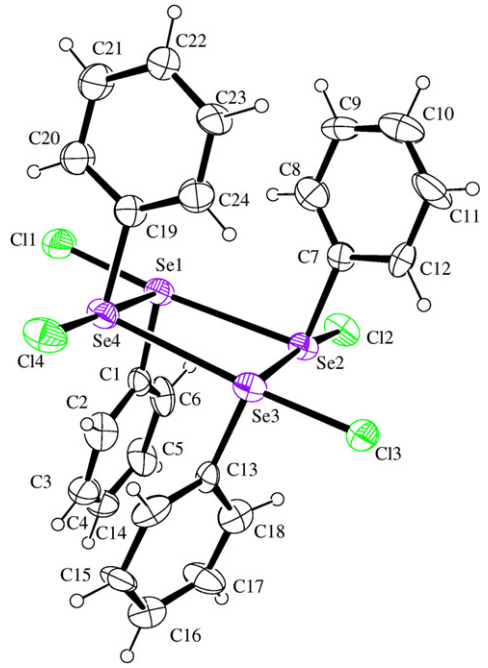

Fig. 2a. Molecular structure of $Ph_4Se_4Cl_4$. Thermal ellipsoids are shown at the 30% probability level. Selected bond lengths (Å) and angles (°): Se(1)–Se(2): 3.002(3), Se(2)–Se(3): 3.035(3), Se(3)–Se(4): 3.031(3), Se(4)–Se(1): 2.993(3), Se(1)–Cl(1): 2.242(5), Se(2)–Cl(2): 2.265(6), Se(3)–Cl(3): 2.251(5), Se(4)–Cl(4): 2.262(6), Se(1)–C(1): 1.929(15), Se(2)–C(7): 1.929(18), Se(3)–C(13): 1.881(18), Se(4)–C(19): 1.944(15), C(1)–Se(1)–Cl(1): 95.2(5), C(7)–Se(2)–Cl(2): 94.7(6), C(13)–Se(3)–Cl(3): 96.9(5), C(19)–Se(4)–Cl(4): 95.7(6), Cl(1)–Se(1)–Se(2): 174.79(16), Cl(1)–Se(1)–Se(4): 92.78(16), C(1)–Se(1)–Se(2): 88.3(5), C(1)–Se(1)–Se(4): 99.8(5), Se(1)–Se(2)–Se(3): 89.86(7), Se(2)–Se(3)–Se(4): 89.08(7), Se(3)–Se(4)–Se(1): 90.11(7), Se(4)–Se(1)–Se(2): 90.42(7).

Se(2)–Se(3): 3.035(3) Å/Se(3)–Se(4): 3.031(3) Å. These Se–Se bonds are well within the sum of the van der Waals radii for two selenium atoms (3.80 Å), and are slightly shorter than those reported for $Ph_4Se_4Br_4$, which vary between 3.004(2) and 3.051(2) Å [28], yet they are considerably longer than the Se–Se bonds in Ph_2Se_2 [Se–Se: 2.29(1) Å] [37], and $(Ph_2Se_2I_2)_2$ [Se–Se: 2.347 Å] [9]. The Se–Se–Se angles in $Ph_4Se_4Cl_4$ vary between 89.08(7) and 90.42(7)°, and are thus very close to the anticipated 90° for a square motif. Similar Se–Se linkages have been reported for 1,2-$C_6H_4(SeCl)_2$ [38], which dimerises, with weak Se–Se bonds of 3.025(1) and 3.039(2) Å between the two 1,2-$C_6H_4(SeCl)_2$ units.

The Se–Cl bonds in $Ph_4Se_4Cl_4$ range in distance between 2.242(5) and 2.265(6) Å, slightly longer than observed for 2,4,6-$R_3C_6H_2SeCl$ [R = Me (Se–Cl: 2.184(1)/2.187(1) Å); R = CF_3 (Se–Cl: 2.177(2) Å)] [32], or 1,2-$C_6H_4(SeCl)_2$ [Se–Cl: 2.185(3)–2.230(3) Å] [38]. These distances are considerably shorter than the Se–Cl bonds observed in ArSeCl compounds with N···Se–Cl interactions present, where distances vary between 2.429(2) and 2.482(8) Å [12,14–16]. Unusually, the Se–C bonds to the phenyl rings in $Ph_4Se_4Cl_4$ show considerable asymmetry, ranging between 1.881(18) and 1.944(15) Å.

The extended structure of $Ph_4Se_4Cl_4$ is similar to $Ph_4Se_4Br_4$ in that the Se_4 squares are further linked by weak chlorine–chlorine contacts (Fig. 2b) to form a planar network of Se_4 and larger Cl_4 squares. However, the Cl···Cl contacts [3.737(7)–3.881(7) Å] are longer than the sum of the van der Waals radii for two chlorine atoms (3.60 Å), but the presence of this extended structural motif might explain the elongation of the Se–Cl bonds compared with 2,4,6-$R_3C_6H_2SeCl$ (R = Me, CF_3), where such contacts are not present [32].

The $^{77}Se\{^1H\}$ NMR spectrum of a solution of the crystals in $CDCl_3$ reveals a single peak at 1045 ppm, in good agreement with previous reports for phenylselenenyl chloride [15], which is suggestive that the aggregation of PhSeCl into an Se_4 square is a solid-state phenomenon, and that the compound is monomeric in solution.

2.2. Structure of PhSeCN

Whilst no PhSeX compounds containing pseudohalogen groups have been structurally characterised, a large number of arylselenocyanates, ArSeCN, are known. The structure of PhSeCN is likely to be of interest as it is a commercially available reagent which has found significant use in organic reactions [1–3] and since the Cl^- and CN^- anions display similar electronegativities, a comparison with the structure of $Ph_4Se_4Cl_4$ would be interesting. PhSeCN is a liquid at room temperature, although crystals suitable for X-ray analysis were obtained in situ by cooling the liquid in capillary tubes at 150(2) K. PhSeCN crystallises in the monoclinic space group $P2_1/n$, with two independent molecules in the unit cell, as shown in Fig. 3a below.

The solid-state structure of PhSeCN is quite different to $Ph_4Se_4Cl_4$, as no aggregation of "PhSeX" units into an Se_4 square is observed. PhSeCN is essentially monomeric, with two independent molecules in the unit cell. The two molecules are loosely linked by Se···N contacts; Se(1)–N(12): 3.329(4) Å, Se(2)–N(11): 3.444(4) Å, both slightly shorter than the sum of the van der Waals radii for selenium and nitrogen (3.45 Å). The Se–C bonds to the cyanide groups [Se–C: 1.849(4)/1.845(4) Å] are considerably shorter than the Se–C bonds to the phenyl rings [Se–C: 1.925(4)/1.936(4) Å], reflecting the increased double bond character in the Se–C bond to the sp hybridised cyanide carbon, compared with the sp^2 hybridised ring carbon. The Se–CN distances are similar to other reported arylselenocyanates [30–33], selenium cyanides such as $Se(CN)_2$ [39], $Se_2(CN)_2$, $Se_3(CN)_2$ [40] and the $[SeCNBr_2]^-$ and $[(SeCN)_2Br]^-$ anions [41]. The C≡N bond lengths [C(11)–N(11): 1.142(5) Å, C(12)–N(12): 1.138(5) Å] are typical for selenocyanates, with Se–C–N angles close to linear, Se(1)–C(11)–N(11): 177.4(4)/Se(2)–C(12)–N(12): 178.7(4)°. The SeCN group is non-planar with respect to the phenyl ring, with torsion angles, C(11)–Se(1)–C(21)–C(31): –35.7(3)° and C(12)–Se(2)–C(22)–C(32): –34.4(3)°.

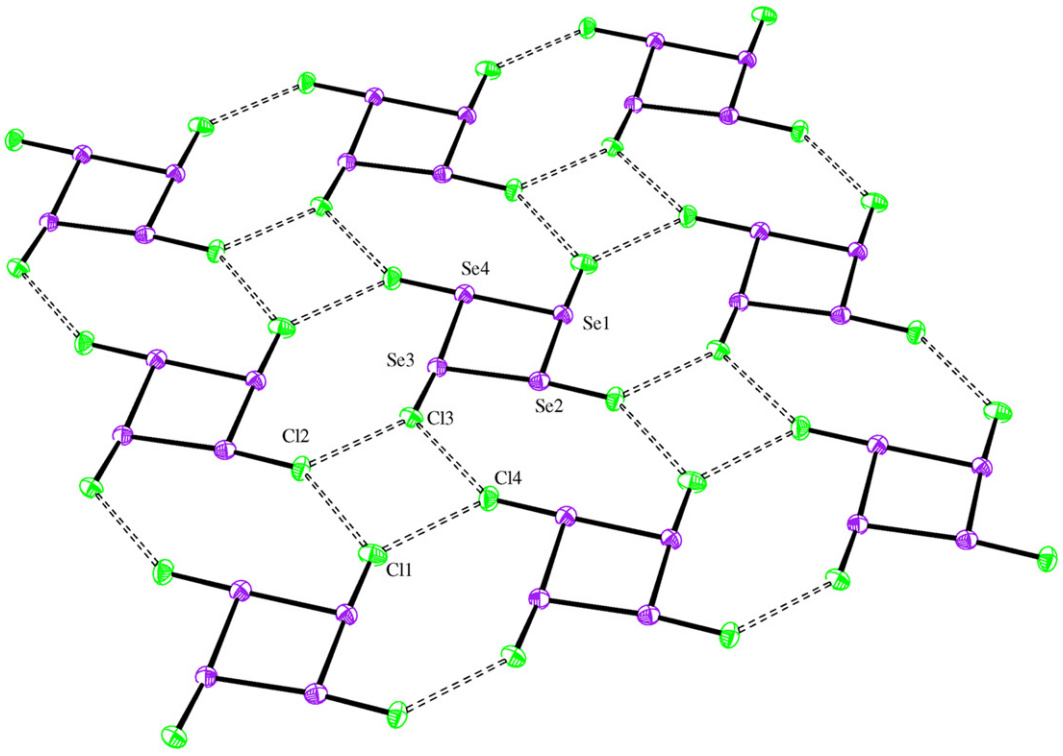

Fig. 2b. Extended solid-state structure of $Ph_4Se_4Cl_4$, showing Se–Se and Cl–Cl contacts. Phenyl rings are omitted for clarity. Contact distances (Å): Cl(1)···Cl(2): 3.791(7), Cl(2)···Cl(3): 3.737(7), Cl(3)···Cl(4): 3.793(7), Cl(4)···Cl(1): 3.881(7).

The loose dimeric structure observed for PhSeCN contrasts with that of the perfluorinated analogue C_6F_5SeCN [30], where the two independent molecules in the unit cell are not linked by any weak Se···N interactions, although a similar dimeric linkage is observed for 3-C_5H_4NSeCN [Se···N: 3.387(6) Å] [31] and 1,4-$C_6H_4(SeCN)_2$ [Se···N: 3.32 Å] [33]. In the extended structure (Fig. 3b) the molecules form infinite one-dimensional chains along the a axis, linked by short Se···N interactions, [Se(1)–N(11_1): 3.023(3) Å, Se(2)–N(12_1): 3.065(4) Å], with C≡N···Se angles close to linear, the deviation being greater in one chain than the other; [C(11)–N(11)···Se(1_2): 172.94(13)°, C(12)–N(12)···Se(2_2): 166.07(14)°]. The Se···N interactions along the chain are thus appreciably shorter than those between the two chains. Additionally, very weak Se···Se contacts of 3.789(7) Å are observed between the chains, just within the sum of the van der Waals radii for two selenium atoms (3.80 Å).

2.3. Structure of PhSeSCN

For comparative purposes we decided to structurally characterise a further PhSeX pseudohalogen system, PhSeSCN. Examples of arylselenium thiocyanates are rare in the literature, but may be prepared by metathesis from RSeX (X = Cl, Br) with alkali metal thiocyanates or Me_3SiNCS [42–47]. PhSeSCN was prepared by the literature method from PhSeCl and Me_3SiNCS in anhydrous

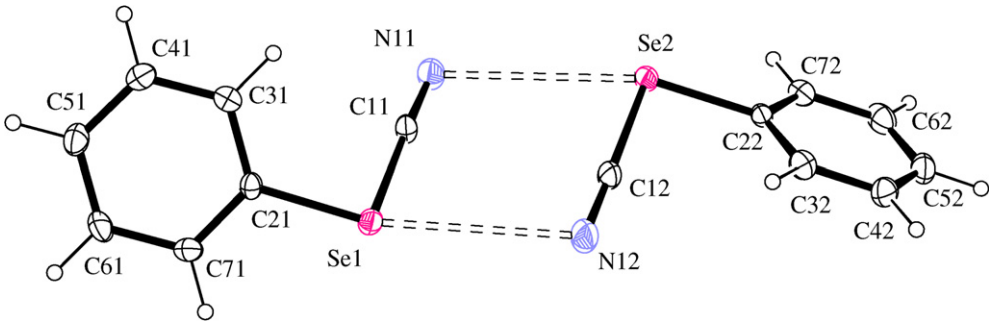

Fig. 3a. Molecular structure of PhSeCN. Thermal ellipsoids are shown at the 30% probability level. Selected bond lengths (Å) and angles (°): Se(1)–C(11): 1.849(4), Se(1)–C(21): 1.925(4), Se(2)–C(12): 1.845(4), Se(2)–C(22): 1.936(4), C(11)–N(11): 1.142(5), C(12)–N(12): 1.138(5), C(21)–Se(1)–C(11): 94.92(15), C(22)–Se(2)–C(12): 95.15(16), Se(1)–C(11)–N(11): 177.4(4), Se(2)–C(12)–N(12): 178.7(4).

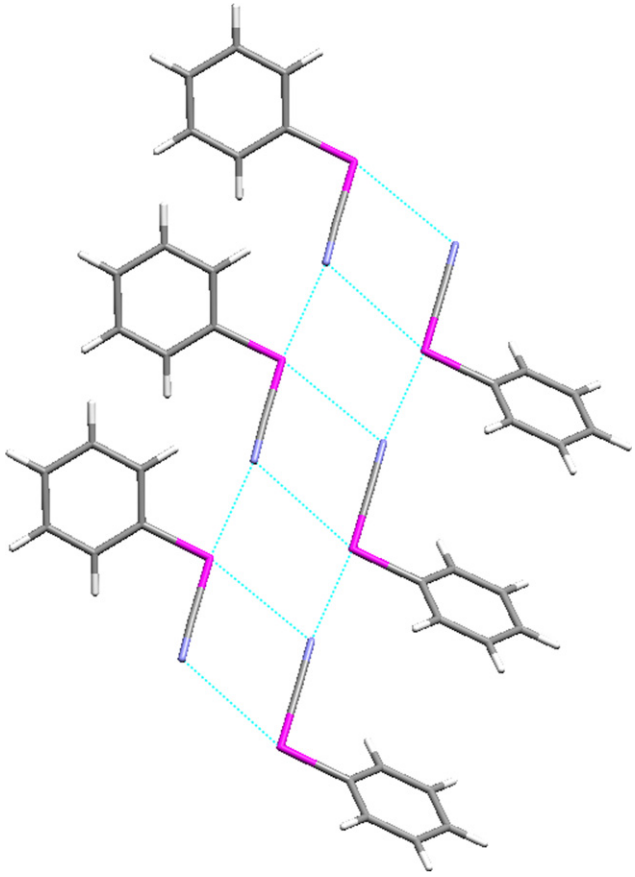

Fig. 3b. Extended structure of PhSeCN, showing Se···N interactions. Selected contact lengths (Å): Se(1)···N(12): 3.329(4), Se(2)···N(11): 3.444(4), Se(1)···N(11_1): 3.023(3), Se(2)···N(12_1): 3.065(4).

dichloromethane [46]. Crystals were obtained by refluxing a Et_2O/CH_2Cl_2 (1:1) solution of the compound, followed by cooling to room temperature, which produced a large crop of orange crystals. PhSeSCN crystallises in the monoclinic space group $P2_1/c$, and the molecular structure is shown in Fig. 4a.

PhSeSCN is, to the best of our knowledge, the first crystallographically characterised selenium-thiocyanate compound, although space-group determinations of 2-RC_6H_4SeSCN (R = NO_2, $COCH_3$) have been reported [43]. The thiocyanato group is coordinated to the selenium through the sulfur atom, and it would appear that the soft selenium centre prefers to bind with sulfur, rather than the harder nitrogen atom. Selenium does bind to nitrogen in the absence of a "softer option", as in 2,4,6-$(CF_3)_3C_6H_2SeNSO$ [34], but clearly the thiocyanato coordination mode is preferred over the isothiocyanato in PhSeSCN, as confirmed in solution by $^{13}C\{^1H\}$ NMR studies, where the SCN carbon resonance is observed at 111.9 ppm (cf. δSCN: 109.6 for C_6F_5SeSCN) [47]. No resonance for the NCS isomer was observed [$^{13}C\{^1H\}$ NMR shifts for NCS groups are typically found at 130–140 ppm] [48]. Additionally, the ν(SCN) band is observed at 2150 cm^{-1} in the IR spectrum, consistent with other reported RSeSCN compounds [46,47].

The Se–S bond in PhSeSCN is 2.2211(11) Å, close to the reported mean for covalent Se–S bonds, 2.193 Å [49], but is slightly shorter than the Se–S bond in the thiocarbamate derivatives 2-$(Me_2NCH_2)C_6H_4SeSC(=S)CNR_2$ [R = Me, Se–S 2.2659(7) Å; R = Et, Se–S: 2.247(1) Å] [16]. The geometry of the SCN group is near linear, S(1)–C(1)–N(1): 176.5(4)°, with S–C and C≡N bond lengths similar to those observed for the free SCN^- ion in KSCN [50]. The bent geometry at both the selenium and sulfur atoms reflects the presence of lone pairs on both atoms with angles S(1)–Se(1)–C(2): 99.30(12)° and Se(1)–S(1)–C(1): 100.49(14)°.

In the extended structure of PhSeSCN individual molecules stack such that a weak interaction, Se(1)···N(1) of 3.348(4) Å is set up, see Fig. 4b. Unlike in PhSeCN, the Se···NC contact angles are non-linear, Se(1)···N(1)–C(1): 102.7(3)°. The shortest Se···N interaction between

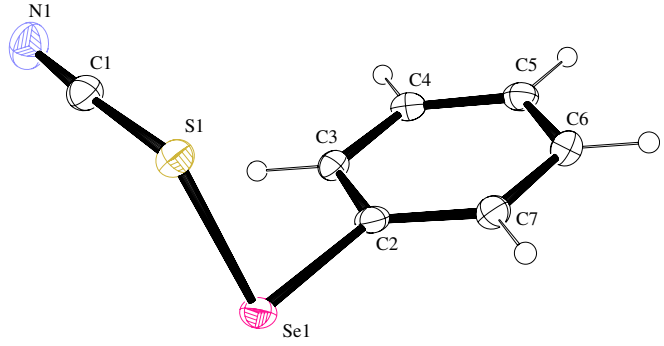

Fig. 4a. Molecular structure of PhSeSCN. Thermal ellipsoids are shown at the 30% probability level. Selected bond lengths (Å) and angles (°): Se(1)–S(1): 2.2211(11), Se(1)–C(2): 1.925(4), S(1)–C(1): 1.696(4), C(1)–N(1): 1.157(6), C(2)–Se(1)–S(1): 99.30(12), Se(1)–S(1)–C(1): 100.49(14), S(1)–C(1)–N(1): 176.5(4).

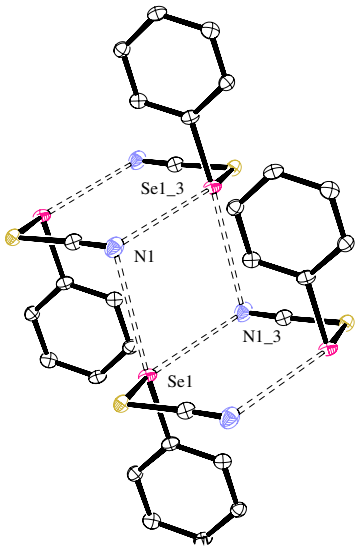

Fig. 4b. Extended structure of PhSeSCN. Thermal ellipsoids are shown at the 30% probability level, and H atoms have been omitted for clarity. Selected contact distances (Å) and angles (°): Se(1)···N(1): 3.348(4) Å, Se(1)···N(1_3): 3.567(4), C(1)–N(1)···Se(1): 102.7(3), C(2)–Se(1)···N(1): 172.10(13), S(1)–Se(1)···N(1): 88.50(7).

adjacent stacks, Se(1)···N(1_3): 3.567(4) Å, is slightly longer than the sum of the van der Waals radii for selenium and nitrogen (3.45 Å).

2.4. Conclusion

The factors influencing the solid-state structures of arylselenium halides are clearly quite subtle, with the structural motif observed being sensitive to both the nature of the R groups bound to selenium, and the identity of the halogen or pseudohalogen in the system. In the absence of bulky aryl groups, monomeric ArSeX structures are seldom observed, and the majority of previously reported structures display intramolecular stabilisation from groups present on the aryl rings. In the phenyl series of compounds, PhSeX, there are no groups present to participate in such interactions, and the solid-state structures of ''PhSeBr'' and ''PhSeI'' are quite different from each other, (square versus centrosymmetric dimer). The results reported herein further illustrate the structural diversity exhibited by ''PhSeX'' compounds. When X = Cl a square motif, $Ph_4Se_4Cl_4$, is observed, analogous to $Ph_4Se_4Br_4$. Both of these compounds consist of a weakly held network of Se_4 squares and larger X_4 (X = Cl or Br) squares. This extended motif is adopted in the absence of any stronger packing forces. The analogous pseudohalogen compounds PhSeCN and PhSeSCN do not exhibit a square motif, but are essentially monomeric, and are linked into chains by Se···N contacts, which are notably shorter in PhSeCN than in PhSeSCN. In the former the Se···NC contact angles are close to linear, whilst for the SCN compound the Se···N interaction is longer, and the Se···NC contact angle non-linear. Such Se···N contacts appear to be the dominant packing force in these compounds, and are strong enough to preclude any formation of the weak lattice of Se_4 squares favoured by $Ph_4Se_4Cl_4$ and $Ph_4Se_4Br_4$.

3. Experimental

3.1. Reagents and physical measurements

$Ph_4Se_4Cl_4$ and PhSeSCN are moisture sensitive, therefore their synthesis was performed under strict anhydrous conditions. Diethyl ether and *n*-hexane (BDH) were distilled over sodium/benzophenone ketyl before use. Anhydrous dichloromethane (Aldrich), diphenyl diselenide (Aldrich), sulfuryl chloride (Aldrich), phenylselenocyanate (Acros) and trimethylsilylisothiocyanate (Aldrich) were all purchased commercially and used as received. ^1H and $^{13}C\{^1H\}$ NMR spectra were recorded on a Bruker DPX400 machine operating at 399.9 and 100.6 MHz, respectively. $^{77}Se\{^1H\}$ NMR spectra were recorded on a Bruker DPX200 machine operating at 38.2 MHz. Peak positions are quoted relative to external TMS $\{^1H/^{13}C\}$ and Me_2Se $\{^{77}Se\}$, using the high frequency positive convention throughout. All spectra were recorded at 300 K. Infrared spectra were recorded on a Nicolet–Nexus combined FT-IR/FT-Raman spectrometer, with the samples for IR prepared as Nujol mulls held between KBr plates ($Ph_4Se_4Cl_4$/PhSeSCN) or as a liquid film (PhSeCN). Melting points were recorded on a Bibby SMP10 melting point apparatus and elemental analyses were performed by the University of Manchester, School of Chemistry Microanalytical Service.

3.2. Crystallographic details

Details of the structural analyses for $Ph_4Se_4Cl_4$, PhSeCN and PhSeSCN are summarised in Table 1. Crystals of $Ph_4Se_4Cl_4$ were twinned by a fourfold rotation about the *c* axis (*a* and *b* axes are almost the same length) and also display racemic twinning. Diffraction data for $Ph_4Se_4Cl_4$ and PhSeSCN were recorded on a Nonius κ-CCD four circle diffractometer at 223(2) and 150(2) K, respectively, and data for PhSeCN on a Bruker Smart APEX CCD diffractometer equipped with an Oxford Cryosystems low-temperature device operating at 150(2) K. Graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) was used in all cases. The structural data for all the compounds was solved by direct methods (SHELXS97) and refined by full-matrix least squares against F^2 using all data (SHELXL97) [51]. Absorption corrections were carried out with the multiscan method, and were applied either with the SORTAV program [52] (for $Ph_4Se_4Cl_4$ and PhSeSCN), or SADABS [53] (for PhSeCN). Non-hydrogen atoms were refined with anisotropic thermal parameters. Hydrogen atoms for $Ph_4Se_4Cl_4$ and PhSeSCN were refined isotropically. Figures were generated using ORTEP-3 for Windows [54].

3.3. Synthesis of $Ph_4Se_4Cl_4$

1.561 g (5 mmol) of diphenyl diselenide was dissolved in 50 cm^3 of freshly distilled diethyl ether under a nitrogen atmosphere. Sulfuryl chloride (0.480 cm^3, 5 mmol) was added dropwise over several minutes, and the solution turned orange in colour. The reaction was allowed to stir for 24 h, after which time the volume of the solvent was reduced to ca. 20 cm^3 with gradual precipitation of a yellow-orange solid which was isolated using standard Schlenk techniques. Yield = 1.747 g (91 %), mp 63-66°C. Calc. for $C_{24}H_{20}Cl_4Se_4$: C, 37.63; H, 2.64; Cl, 18.51. Found: C, 38.03; H, 2.64; Cl, 18.50%. ^1H NMR ($CDCl_3$): δ 7.36–7.46 [m, 3H], 7.74–7.86 [m, 2H]. $^{13}C\{^1H\}$ NMR ($CDCl_3$): δ 130.0 [s, C_m], 131.0 [s, C_p], 132.1 [s, C_i], 134.8 [s, C_o]. $^{77}Se\{^1H\}$ NMR ($CDCl_3$): δ 1045 [s]. IR (cm^{-1}): 1720, 1578, 1302, 1155, 1022, 687.

3.4. Spectroscopic data for PhSeCN

^1H NMR ($CDCl_3$): δ 7.34–7.49 [m, 3H], 7.61–7.75 [m, 2H]. $^{13}C\{^1H\}$ NMR ($CDCl_3$): δ 102.1 [s, CN], 122.3 [s, C_i], 129.8 [s, C_p], 130.7 [s, C_m], 133.2 [s, C_o]. $^{77}Se\{^1H\}$

3.5. Synthesis of PhSeSCN

PhSeCl (1.915 g, 10 mmol) was dissolved in 50 cm^3 of anhydrous dichloromethane under a nitrogen atmosphere. Me_3SiNCS (1.41 cm^3, 10 mmol) was added dropwise over several minutes with formation of an orange coloured solution. The reaction was stirred overnight, after which time the solvent and volatile by-products (Me_3SiCl) were removed in vacuo. The resultant orange oil was washed with 30 cm^3 of freshly distilled hexane and left at 0 °C overnight to yield an orange solid which was filtered off using standard Schlenk techniques. Yield = 0.913 g (43%), mp 38–39 °C. Calc. for C_7H_5NSSe: C, 39.62; H, 2.36; N, 6.54; S, 14.97. Found: C, 39.20; H, 2.28; N, 6.47; S, 14.45%. ^1H NMR ($CDCl_3$): δ 7.46–7.53 [m, 3H], 7.82–7.89 [m, 2H]. $^{13}C\{^1H\}$ NMR ($CDCl_3$): δ 111.9 [s, SCN], 130.0 [s, C_i], 130.4 [s, C_m], 131.4 [s, C_p], 135.2 [s, C_o]. $^{77}Se\{^1H\}$ NMR ($CDCl_3$): δ 651 [s]. IR (cm^{-1}): 2150, 739, 686.

4. Supplementary material

CCDC 603331, 603332 and 603333 contain the supplementary crystallographic data for $Ph_4Se_4Cl_4$, PhSeCN and PhSeSCN. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Acknowledgement

The authors would like to thank EPSRC for a research studentship (RTAH), and also for the UMIST FT IR/Raman facility (Grant No: GR/M30135), NMR facility (Grant No: GR/L52246), and X-ray facility (Research Initiative Grant), and also the University of Edinburgh for facilities to grow crystals of PhSeCN at low temperature. The authors would also like to thank Dr. Alan Brisdon for helpful discussions.

wires and ion conducting channels [15]. Several Pcs of these types have been designed in order to investigate the complexation behaviour and potential for electronic and ionoelectronic applications [16].

Adam et al. reported that a discotic liquid crystal of triphenylene substituted by alkylthio groups exhibits considerably higher charge carrier mobility in the discotic mesophase, compared with conventional organic semiconductors [17a]. It can be inferred from this example that the sulfur atoms may significantly influence the conductivity of the mesophase. Eichorn and Wöhrle reported the first example of columnar mesomorphism of octakis(octylthio)-substituted Pc zinc and copper complexes [17b]. Ohta et al. reported the synthesis of a series of octakis-(alkylthio)-phthalocyanines [abbreviated as $(C_nS)_8PcH_2$, $n = 8$, 10, 12, 16] and their copper complexes and investigated their mesomorphism. They discussed the influence of sulfur atoms and chain length on the mesomorphism and unique aggregated dimer structures in the columnar mesophase [18]. Although Pcs with methylene bridges showing mesogenic properties which contain O-donors are rather few number [7a,19], there is only one with thioether moieties [20].

There are a large number of different peripherally substituted phthalocyanines and normally they are formed in a single-step reaction from available derivatives of phthalic acid, phthalic anhydride, phthalimide, 2-cyanobenzamide, phthalonitrile, diiminoisoindoline, 1,2-dibromobenzene, or 1,2-dibromo-4,5-dimethylbenzene [1,21]. 1,2-Dibromo-4,5-dimethyl-benzene undergoes the Rosenmund–von Braun reaction effectively and the methyl groups can be brominated using *N*-bromosuccinimide (NBS) to yield 4,5-di(bromomethyl) phthalonitrile [22]. This compound is a valuable starting material for other 4,5-disubstituted phthalonitriles including phthalonitriles appended to thiol [22a], phosphanates [22b], and glycoluril [23]. The particular advantage of performing the Rosenmund–von Braun reaction before the addition of the desired functional groups is that it allows addition of more labile functional groups to the phthalonitrile molecule by avoiding their presence during the harsh cyanodehalogenation reaction. In the bromination reaction of the methyl groups of 4,5-dimethylphthalonitrile, we obtained two products: 4,5-di(bromomethyl) phthalonitrile (**1**) and 4-bromomethyl-5-methylphthalonitrile (**2**). Up until now, the synthesis of 4,5-di(bromomethyl) phthalonitrile (**1**) has been mentioned once in the literature [22a] and in one patent [22b], but 4-bromomethyl-5-methylphthalonitrile (**2**) is not given as a precursor of phthalocyanine. In the literature, Howard and co-workers obtained only compound **1** under reaction conditions similar to ours, but we obtained two products (**1** and **2**). They purified compound **1** with a chromatographic technique using dichloromethane as the eluent. Dichloromethane is very polar solvent for these compounds as an eluent. We separated **1** and **2** on a TLC (silica gel) card using hexane/dichloromethane: 5/2 as the eluent. According to Howard and co-workers, the melting point of compound **1** was between 110 and 122 °C. This is different from our result. The patent concerning compound **1** includes only NMR and IR data and the melting point was not reported. Compound **1** was obtained by crystallization in MeOH after column chromatography [22a]. However, according to our experiences, phthalonitrile derivatives **1** and **2** are crystallized in MeOH as a mixture. We separated the dinitrile derivatives (**1** and **2**) by dissolving in $EtOH/CH_2Cl_2$ (25:1) and then fractional crystallization. It must be emphasized that 4,5-di(bromomethyl) phthalonitrile (**1**) and 4-bromomethyl-5-methylphthalonitrile (**2**) were isolated and characterized clearly for the first time by our group.

In the following, we report the synthesis of new sterically hindered methyl-bridged tetra- and octa-(13,17-dioxa nonacosane-15 sulfanyl)-substituted Pcs using dinitrile derivatives **1** and **2**. The influence of the presence of methylene-bridges in the phthalocyanine core on the mesomorphic properties were determined.

2. Experimental

2.1. Materials

All solvents were purified as described in Perrin and Armarego [24]. 15-Thiol-13,17-dioxa nonacosane [21b] and 4,5-dimethyl phthalonitrile [21a] were prepared according to the reported procedures. All other reagents and solvents were reagent grade quality and were obtained from commercial suppliers.

2.2. Measurements

Elemental analyses were obtained from a Carlo Erba 1106 Instrument. Infrared spectra in KBr pellets were recorded on a Bio-Rad FTS 175C FT-IR spectrophotometer. Optical spectra in the UV–visible region were recorded with a Shimadzu 2001 UV Pc spectrophotometer using 1 cm pathlength cuvettes at room temperature. Electrospray full scan spectra, in the range m/z 50–2000 amu or m/z 2000–3000 amu, were obtained by infusion through fused silica tubing at 2–10 μL min^{-1}. The solutions were analyzed in the positive mode. The LCQ calibration (m/z 50–2000) was achieved according to the standard calibration procedure from the manufacturer (mixture of caffeine, MRFA and Ultramark 1621). An ES-Tuning Mix solution (Agilent) was used to calibrate the spectrometer between 2000 and 3000 amu. The temperature of the heated capillary of the LCQ was set to the range 180–200 °C, the ion spray voltage was in the range 1–7 kV with an injection time of 5–200 ms. Electron ionisation (EI) full scan spectra were obtained from an LCQ-ion trap (Thermofinnigan, San Jose, CA, USA). ^1H and ^{13}C NMR spectra were recorded in $CDCl_3$ solutions on a Varian 500 MHz spectrometer. Transition temperatures were determined at scan rates of 10 °C min^{-1} using Mettler Toledo Star Thermal Analysis System/DSC 822 System differential scanning

calorimeter calibrated with indium under a nitrogen atmosphere. The phase transition behaviours of these compounds were observed with a polarizing microscope, Leitz Wetzler Orthoplan-pol, equipped with the hot stage Linkam TMS 93 and temperature-controller Linkam LNP. X-ray measurements were performed with Cu Kα radiation using a Rigaku Kristalloflex diffractometer (Dmax 2200).

2.3. Synthesis

2.3.1. 4,5-Di(bromomethyl) phthalonitrile (1) and 4-(bromomethyl)-5-methyl phthalonitrile (2)

4,5-Dimethyl phthalonitrile (4.9 g, 31 mmol), NBS (11.2 g, 63 mmol)and benzoyl peroxide (ca. 200 mg) were mixed in carbontetrachloride (50 ml) and the mixture was stirred vigorously, heated under reflux and UV light for 6 h until all the NBS was converted to the succinimide, which floated on the surface of the solution. The solution was cooled to room temperature then filtered and the filtrate was evaporated to dryness. The yellow oily residue was dissolved in methanol, cooled to 5 °C and white solids formed. The solids were filtered. These solids are mixture of the two products. These compounds were detected by thin-layer chromatography [$R_f = 0.24$ (**1**) and $R_f = 0.28$ (**2**)] using dichloromethane:*n*-hexane/2:5 as the mobile phase and separated with the ethanol:dichloromethane 25:1 solvent system using the fractional crystallization technique.

Compound **1** consists of white crystals. Yield: 4 g (41%). m.p. 156 °C. (*Anal.* Calc. for $C_{10}H_6Br_2N_2$ (314) requires: C, 38.25; H, 1.93; N, 8.92. Found: C, 38.13; H, 1.85; N 8.80%.) 2.3.2. 1,2-Di(13,17-dioxa nonacosane-15-sulfanylmethyl) phthalonitrile (3)

4,5-Di(bromomethyl) phthalonitrile (**1**) (1.57 g, 5 mmol) was dissolved in anhydrous dimethyl sulfoxide (9 ml) under argon and an excess of 15-thiol-13,17-dioxa nonacosane (6.67 g, 15 mmol) was added. After stirring for 15 min at room temperature, dry and finely powdered potassium carbonate (2.50 g, 18 mmol) was added portion wise over 0.5 h with efficient stirring. The reaction mixture was stirred under argon at 50 °C for 48 h. After cooling, the reddish-brown mixture was filtered off and the solvent was evaporated under reduced pressure. The product was purified by column chromatography on silica gel using dichloromethane:*n*-hexane/5:2 as the eluent. Yield: 2.08 g (40%). mp. 26 °C. (*Anal.* Calc. for $C_{64}H_{116}N_2O_4S_2$ (1040) requires :C, 73.60; H, 11.10; N, 2.70. Found: C, 73.79; H, 11.22; N, 2.69%.) 3. Results and discussion

Generally, substituted Pcs are prepared by cyclotetramerization of substituted 1,2-dicyanobenzenes or 1,3-diimino-1*H*-isoindoles [1]. The same route in the literature [21a,25] was applied to prepare the di-substituted dinitrile derivative (**3**) from an excess amount of 15-thiol-13,17-dioxa nonacosane and 4,5-di(bromomethyl) phthalonitrile (**1**). Similarly, the reaction of compound **2** under the same conditions with 15-thiol-13,17-dioxa nonacosane resulted in the expected compound **4** by using the thiol derivative. Starting from 4,5-dimethyl phthalonitrile, the synthetic

Scheme 1. (i) NBS, CCl_4, 6 h reflux under UV light and in an argon atmosphere; (ii) DMSO, K_2CO_3, 50 °C, 48 h.

route is outlined in Scheme 1. The synthesis of methylene-bridged octa-alkylthia substituted phthalocyanine derivatives was reported by Cho and Lim [20]. In their work, 1,2-dibromo-4,5-di(bromomethyl)benzene was substituted with alkylthio chains and then the dibromo derivative was converted into a dinitrile by a Rosenmund–von Braun reaction. However, all efforts to accomplish these reactions failed in the nitrilation step, no dinitriles could be observed, according to our experience on the synthesis of alkylthio substituted dinitrile derivatives [26]. In order to overcome this problem, we used 4,5-di(bromomethyl) phthalonitrile (**1**) and 4-(bromomethyl)-5-methyl phthalonitrile (**2**) as starting compounds for the preparation of alkylthia-substituted phthalonitrile derivatives **3** and **4** respectively, by a nucleophilic displacement reaction.

The preparation of Pc derivatives from the aromatic nitriles occurs under different reaction conditions [1]. A convenient high-yield synthesis requires further consideration. For various substituted dinitriles, the reaction in the presence of strong not nucleophilic bases 1,8-diazabicyclo[5.4.0]undec-7-ene(DBU) or 1,5-diazabicyclo[4.3.0]non-5-ene(DBN), either in 1-pentanol or in bulk, with yields of phthalocyanines of up to 90% is most efficient in comparison to other methods [27]. In addition, these reactions are easy to perform, take place under relatively mild conditions and they yield more pure Pcs. Therefore, metal-free Pc derivatives **3b** and **4b** were obtained directly from the reaction of the dicyano compounds **3** and **4** in 1-pentanol at reflux temperature in the presence of a strong organic base such as DBU (Scheme 1). Also, cyclotetramerization of dinitrile derivatives **3** and **4** in the presence of anhydrous $NiCl_2$ and DBU in 1-pentanol gave the octasubstituted nickel (II) Pc **3a** and **4a**, respectively. The chemical structure of tetra- and octa-substituted phthalocyanine derivatives are given in Fig. 1. We expect that **4a**–**b** were prepared as a statistical mixture of four regioisomers owing to the various possible positions of the alkylthia side chains relative to one another. The four possible isomers can be obtained. By their molecular symmetry as D_{4h}, C_{4h}, C_{2v} and C_s, each isomer would be prepared in a relative yield of 1:1:2:4 respectively [28]. No attempt was made to separate the isomers of **4a**–**b**.

Compound	R_1	R_2	M
3a	$SCH[(CH_2O(C_{12}H_{25})]_2$	$SCH[(CH_2O(C_{12}H_{25})]_2$	Ni
3b	$SCH[(CH_2O(C_{12}H_{25})]_2$	$SCH[(CH_2O(C_{12}H_{25})]_2$	2H
4a	$SCH[(CH_2O(C_{12}H_{25})]_2$	H	Ni
4b	$SCH[(CH_2O(C_{12}H_{25})]_2$	H	2H

Fig. 1. Chemical structure of tetra- and octa-substituted phthalocyanine derivatives.

The methylene-bridged tetra- and octa-Pcs (**3a**–**b**, **4a**–**b**) substituted with the branched thioether were purified in each case by column chromatography (silica gel) and then preparative thin-layer chromatography (TLC) using a mixed solvent system of dichloromethane/*n*-hexane and *n*-hexane/ethylacetate as the eluent respectively. The intense blue waxy products are very soluble in a polar and apolar solvents, such as chloroform, benzene, carbon-tetrachloride and tetrahydrofuran. They were characterized by ^1H and ^{13}C NMR. In addition to elemental analysis results, the mass spectra of the new organic intermediate compounds and Pcs obtained by the ES and EI techniques show relatively intense molecular ion peaks. NMR investigation of all compounds have provided the characteristic chemical shifts for the structures as expected. However, the NH peak was observed in the ^1H NMR spectrum of compound **3b**, but there was no peak belong to NH at the high field for **4b**. A common feature of the ^1H NMR spectra of Pcs (**4a**–**b**) is the broad absorptions when compared with that of octa-substituted Pc derivatives, probably caused by the aggregation of the Pc which is frequently encountered at the concentrations used for NMR measurements. Due to steric hindrance, the octa-substituted Pcs show a lower aggregation tendency than the tetra-substituted Pcs. Also the NH protons of **4b** could not be observed due to this phenomena.

For substances **3a**–**b** and **4a**–**b**, typical absorption spectra of Pcs were observed [29] showing absorption bands in

Compound	λ_{max}/nm (ε/10^4 dm^3 mol^{-1} cm^{-1})	
	Soret band region	Q band region
3a	336.5 (4.79) 462.5 (0.23)	611.5 (3.38) 651[a] (3.54) 679.5 (21.65)
3b	348.5 (7.49)	620.5 (2.85) 653.5[a] (4.62) 673 (13.84) 708.5 (16.56)
4a	334.5 (5.38)	609.5[a] (3.68) 648 (3.98) 676.5 (21.54)
4b	345.5 (14.77)	618.0 (5.44) 650.5[a] (9.09) 669.5 (25.60) 705.5 (29.00)

[a] Shoulder.

the Soret-band region 300–400 nm and Q band transitions at 600–700 nm (Table 1). The metal-free Pcs **3b** and **4b** give a doublet Q band as a result of the D_{2h} symmetry (Fig. 2B for **4b**). The nickel (II) Pcs **3a** and **4a** exhibit intense Q bands around 680 nm with a relatively sharp absorption peak and almost no shoulder on the higher energy side, which correspond to aggregated species. Q bands of the tetra-substituted Pcs (**4a** and **4b**) are at lower wavelengths than those of the octa-substituted Pcs (**3a** and **3b**) as expected (Table 1). For all the phthalocyanines, the effect of thia-substitution was observed as a shift of these intense Q bands to higher wavelengths when compared with unsubstituted, alkyl- or alkoxy-substituted derivatives.

For Pcs, the aggregation behaviour in solution is a good indication of interactions between the aromatic macrocycles. Aggregation is easily detected from optical absorption studies. Any increase in concentration results in aggregation of Pc molecules which is accompanied by a blue shift of the Q band with some decrease in intensity [19a,21b]. It has been concluded that aggregation is enhanced by solvent polarity and the presence of aliphatic side chains [16a,16b,16d,30]. This has indeed been observed with the tetra-substituted derivatives (Fig. 2A for **4a**).

The optical absorption spectra of compounds **3a**–**b** and **4a**–**b** depend on the solvent type. Although, aggregation is not detectable in tetrahydrofuran, chloroform, benzene or pyridine, broad Q bands were observed in the methanol/chloroform (1/1) solvent system. The tendency to form aggregates increases in the order: tetrahydrofuran < chloroform < benzene < pyridine < methanol/chloroform system for tetra-substituted Ni(II) Pc (**4a**) (Fig. 2A). Similar spectra have been obtained in the case of both octa- and tetra-substituted Pc derivatives. The position of the Q band in UV/Vis absorption spectra of the Pc compounds in the methanol/chloroform (1/1) solvent system showing an intermolecular interaction of the Pc core is more prevalent than in other solvents because of the polar solvent system.

3.1. Characterization of the mesophase

The phase transition temperatures were determined by DSC. Table 2 lists the phase transition temperatures established by DSC and polarizing microscopic observations for the octa- and tetra-substituted Pc derivatives (**3a**–**b** and **4a**–**b**). All the thermograms of the Pcs recorded with increasing temperature showed clearly two endothermic peaks. We assume that the first peaks are related to the transitions from the crystal phases to discotic mesophases, and the second ones to the transitions from discotic mesophases to isotropic liquid phases. In addition, the DSC diagrams of the tetra-substituted compounds **4a**–**b** depict a weak peak at about 153 °C (**4a**) and 144 °C (**4b**) in the heating cycle that belongs to the clearing point, and that enthalpy is much smaller than the melting enthalpy, which is due to the fact that for the mesophase to isotropic transition the structural rearrangement of the molecules is far more relevant than for solid to mesophase (Table 2). Similar behaviour was observed in the literature [21a,31]. These investigations indicate that the compounds exhibit a thermotropic liquid crystalline phase between the melting and clearing point (Table 2). The textures observed by polarizing optical microscopy for the compounds studied are very

Compound	Heating		Cooling	
	C → Col_h → I		I → CoI_h → C	
3a	−7.56 (84.76)	28.87 (122.50)	19.07 (74.79)	−15.61 (41.45)
3b	−9.39 (65.41)	23.55 (105.10)	4.24 (54.36)	−15.11 (32.81)
4a	5.02 (127.53)	180.00 (28.88)	179.00 (62.81)	−3.11 (18.64)
4b	8.42 (110.20)	153.10 (3.69)	143.69 (3.11)	1.43 (94.31)

C: solid phase, Col_h: hexagonal discotic columnar mesophase, I: isotropic phase.

similar to those described in Refs. [10,21a]. Excellent textures of samples, preferably fan like textures (Fig. 3) of mesophases were obtained by slowly cooling from the isotropic melt.

The mesophases were identified by microscopic observation and X-ray diffraction measurements at 20 °C. The X-ray data are summarized in Table 3. Powder diffraction patterns of **3a**–**b** and **4a**–**b** contain the typical reflections of a columnar mesophase of substituted Pcs [5]. The Pcs gave five sharp peaks whose spacings are in the ratio of $1{:}\sqrt{3}{:}\sqrt{4}{:}\sqrt{7}\ldots$ in the low angle region, so that each of the mesophases could be established as a discotic hexagonal columnar (Col_h) mesophase. These results suggest a two-dimensional hexagonal lattice with disk-like molecules stacked in columns in the hexagonal arrangement. In the wide angle regions the compounds **3a**–**b** and **4a**–**4b** show a diffuse halo around 4.5 Å which corresponds to the melting of alkyl chains [25c]. An additional reflection at around 3.4 Å is observed which may be assigned to the packing of the macrocyclic subunits in the columns for the compounds

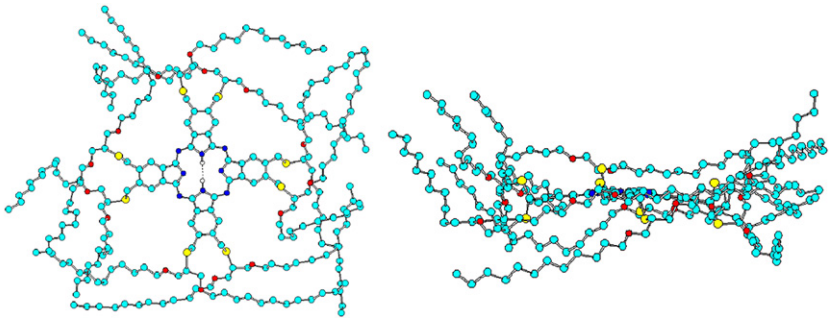

Fig. 4. Molecular structure of metal-free pc **3b**.

3a and **3b**. The sharpness of this reflection suggests good order within the columns and is consistent with the strong intermolecular periodicity associated with the discotic hexagonal ordered Col_h-mesophase [32]. No reflections corresponding to the interdisc distance were observed for **4a–4b**.

The influence of the side chains's nature upon the mesomorphic properties was compared with mesophases of the methylene-bridged octa-alkoxy chain substituted Pc derivatives and their analogues without methylene-bridged derivatives. According to the literature, the mesophase transition temperature of the methylene-bridged alkoxy substituted free Pc was 78 °C, and 83 °C for its without a methylene-bridge derivative [7a,33]. Also, when compared with their octa-substituted branched thioether derivatives, the same behaviour was observed. While the phase transfer temperature of the **3b** analogue without a methylene-bridge was around 0 °C [21a], it was around −9 °C for **3b**. It could be seen that addition of a methylene-bridge to the phthalocyanine core decreases the liquid crystal phase transition temperatures. In addition, comparing the mesophases of the branched thioether Pcs derivatives and their analogous oxoether derivatives, a Col_h mesophase could be seen over a wide temperature region for the thioether Pc derivatives.

Quantum chemical calculations have been applied to predict the electronic and excited states properties of metal free and metallophthalocyanines in recent years [34]. The geometrical data produced from the calculations are usually in good agreement with the data from X-ray analysis. Computer modelling was used to calculate the diameter of the Pc derivatives. The metal free phthalocyanine (**3b**) was subjected to semi-empirical AM1 calculations. Semi-empirical AM1 geometry optimisation calculations were performed in vacuum to obtain the structure with the minimum energy. The conformational changes in the peripheral substituents group, that is methylene-bridged alkylthia, were predicted with molecular dynamics (MD) simulations in vacuum. The starting conformation in molecular dynamics simulations was taken from a geometry optimization with AM1. Twenty picoseconds of MD simulations were run at 300 K constant temperature with 0.001 ps step size, 0.1 ps bath relaxation time and using a molecular mechanics (MM+) force field. At the end of the MD simulations, the diameter of the metal-free Pc was found to be 45 Å. The experimental diameter result from X-ray analysis data is 5 Å less than the calculated one. As shown in Fig. 4, it may be explained that, according to the X-ray diffraction analysis data (Table 3), the alkyl chains do not prefer a straight form but a frizzed form. The geometry optimization with the AM1 method was performed for core the Pc molecule. This was carried out to see the effect of peripheral substituent groups with sulfur atoms on the diameter of the Pc molecule. The diameter of the Pc core is 20 Å. Molecular modelling calculations were performed using HyperChem 7.0 for Windows (Hypercube, FL, USA).

4. Conclusions

Recently we have essentially focused on the synthesis of new Pcs exhibiting gas sensor [35] and liquid crystal properties at room temperature [10d,14d,21b,25c,28b]. Films of the Pcs showing mesomorphic properties at room temperature have been proven to be used as photoconductors and gas sensors in molecular electronic devices and ordered pc films are more sensitive than disordered pc films [35c,36]. In this work, the Pc precursors, 4,5-di(bromomethyl) phthalonitrile (**1**) and 4-bromomethyl-5-methylphthalonitrile (**2**), were isolated and clearly characterized. By using these nitrile derivatives, new methylene-bridged octa- and tetra-branched thioether substituted Pcs Ni(II) and metal-free Pcs were synthesized. These products are soluble in most solvents (carbon tetrachloride, THF, ethylacetate), thermally stable over a wide temperature range and exhibit a hexagonal columnar (Col_h) structure.

The influence of the nature of the side chains upon the mesomorphic properties was compared between mesophases of the Pcs substituted by a methylene-bridged octa-alkoxy chain and their analogues without methylene-bridged derivatives. It could be seen that addition of a methylene-bridge to the phthalocyanine core decreased the liquid crystal phase transition temperatures. In addition, comparing the mesophases of the branched thioether Pcs derivatives and their analogous oxoether derivatives, a Col_h mesophase could be seen over a wide temperature region for the thioether Pc derivatives.

The experimental results of the mesogenic product by X-ray powder analysis were justified by comparison with a computational technique.

phthalocyanines; the change in symmetry caused by these moieties on periphery is also important. Generally, tetra substituted phthalocyanines are more soluble than symmetrically octasubstituted ones due to the formation of four positional isomers in the case of tetra substituted analogues [13,19,20,26,27]. Thus, a mixture of similar positional isomers may practically be preferred than a single less soluble isomer [28].

Metal phthalocyanine derivatives are known to exhibit high electron transfer properties. The electron transfer properties of phthalocyanines depend on the kind and number of the substituents and are due to the interaction between the phthalocyanine ring and the metal center which is influenced by the conjugated 18π electrons of the phthalocyanine ring [27,29–32]. An electrochemical reaction involves not only electron charge transfer, but also ensues various processes, for instance mass transfer, adsorptions of electroactive species on the electrode, and contribution of coupled chemical reactions. Especially very precise electrochemical analyses are required in the development of functional materials. In this paper, we describe the synthesis and electrochemical properties of soluble biphenyl-malonic ester substituted phthalocyanines. The new compounds were characterized by elemental analyses, ^{1}H NMR, ^{13}C NMR, UV–Vis, and FT-IR spectroscopy, as well as by MASS spectrometry.

2. Experimental

IR spectra were recorded on a Perkin–Elmer Spectrum One FT-IR (ATR sampling accessory) spectrophotometer, electronic spectra on a Unicam UV2 UV–Vis spectrophotometer. Elemental analyses were performed by the Instrumental Analysis Laboratory of the TUBİTAK Marmara Research Centre. ^{1}H NMR and ^{13}C NMR spectra were recorded on a Bruker 250 MHz spectrometer using TMS as internal reference. Mass spectra were measured on a VG Zabspec GC–MS. All reagents and solvents were of reagent grade quality and were obtained from commercial suppliers. The homogeneity of the products was tested in each step by TLC (SiO_2). 4-Nitrophthalonitrile [33], diethyl-3,4-dicyanophenylmalonate [34], potassium salt of diethyl-3,4-dicyanophenylmalonate [34] were synthesized according to the published procedures.

All electrochemical techniques were carried out with a Princeton Applied Research potentiostat/galvanostat controlled by an external PC using the computer program HEADSTRT and utilizing a three-electrode configuration at 25 °C. A Pt wire served as the counter electrode. A saturated calomel electrode (SCE) was employed as the reference electrode and separated from the bulk of the solution by a double bridge containing saturated KCl adjacent to SCE and solvent and carrier adjacent to the solution. Ferrocene/ferrocenium was used as universal reference. The working electrode was a Pt plate with an area of 0.10 cm^2. The surface of the working electrode was polished with a H_2O suspension of Al_2O_3 before each run. The last polishing was done with a particle size of 50 nm. Electrochemical grade tetrabutylammoniumperchlorate (TBAP) in extra pure DCM was employed as the supporting electrolyte at a concentration of 0.1 mol dm^{-3}. High purity N_2 was used for deaeration and to maintain a nitrogen blanket for at least 15 min prior to each run.

2.1. 4-(1,1-Dicarbethoxy-2-(4-biphenyl)-ethyl)-phthalonitrile (1)

To the potassium salt of diethyl-3,4-dicyanophenylmalonate (0.995 g, 3 mmol) in 2:1 acetone:acetonitrile (150 ml) was added 4-(chloromethyl)biphenyl (0.709 g, 3.5 mmol). The mixture was boiled for 20 h under N_2 and then filtered. The solvent was evaporated under reduced pressure to give an oily residue which was washed with water until the product was free of KCl and finally crystallized from diethylether. This compound was soluble in acetone, chloroform, THF, and dichloromethane. Yield: 0.986 g, 71%. Mp 135 °C. IR (KBr), ν (cm^{-1}): 3119 (CH, aromatic), 3059–3032 (CH, aromatic), 2982–2937 (CH, aliphatic), 2237 (C≡N), 1734 (C=O), 1178 (C–O–C); ^{1}H NMR ($CDCl_3$) δ: 7.69–7.32 (m, 10H, aromatic H), 6.84–6.80 (d, 2H, aromatic H), 4.37–4.19 (m, 4H, CH_2), 3.61 (s, 2H, CH_2), 1.28–1.23 (t, 6H, CH_3); ^{13}C NMR ($CDCl_3$) δ: 168.52 (C=O), 142.93, 140.57, 140.23, 133.89, 133.28, 133.14, 132.69, 130.52, 128.79, 127.47, 127.01, 126.96, 115.29 (C–C≡N), 115.16 (C≡N), 115.09 (C≡N), 114.71 (C–C≡N), 63.98 (C–C=O), 62.64 (CH_2–CH_3), 42.56 (C–CH_2–Ph), 13.88 (CH_3); CI-MS (m/z): 453 [M$^+$]; *Anal.* Calc. for $C_{28}H_{24}N_2O_4$: C, 74.32; H, 5.34; N, 6.19. Found: C, 73.98; H, 5.29; N, 6.23%.

2.2. General procedures for phthalocyanine derivatives (2–4)

A mixture of **1** (0.1 g, 0.22 mmol) and the metal salt (0.055 mmol; 0.007 g $CoCl_2$, 0.007 g $CuCl_2$ or 0.009 g $PdCl_2$) was fused in a glass tube (10 × 75 mm) and sealed under N_2. The mixture was heated to 180 °C and stirred for 24 h in an oil bath. After it was cooled to room temperature, the tube was opened and a dark blue solid was obtained. Finally, pure phthalocyanine derivatives were obtained by chromatography on silica gel (first with methanol, then with THF as eluents).

2.2.1. 2,9,17,23-Tetra-(1,1-(dicarbethoxy)-2-(4-biphenyl)-ethyl)phthalocyaninatocobalt (2)

Yield: 0.063 g, 63%. IR (KBr), ν (cm^{-1}): 3027 (CH, aromatic), 2978 (CH, aliphatic), 1724 (C=O), 1165 (C–O–C); UV–Vis λ_{max} (nm) in chloroform: 671, 330; *Anal.* Calc. for $C_{112}H_{96}N_8O_{16}Co$: C, 71.97; H, 5.17; N, 5.99. Found: C, 71.85; H, 5.08; N, 6.10%.

2.2.2. 2,9,17,23-Tetra-(1,1-(dicarbethoxy)-2-(4-biphenyl)-ethyl)phthalocyaninatocopper (3)

Yield: 0.069 g, 71%. IR (KBr), ν (cm^{-1}): 3027 (CH, aromatic), 2978 (CH, aliphatic), 1726 (C=O), 1166 (C–O–C);

UV–Vis λ_{max} (nm) in chloroform: 681, 344; *Anal*. Calc. for $C_{112}H_{96}N_8O_{16}Cu$: C, 71.80; H, 5.16; N, 5.98. Found: C, 71.79; H, 5.12; N, 6.01%.

*2.2.3. 2,9,17,23-Tetra-(1,1-(dicarbethoxy)-2-(4-biphenyl)-ethyl)phthalocyaninatopalladium (**4**)*

Yield: 0.059 g, 61%. IR (KBr), ν (cm^{-1}): 3027 (CH, aromatic), 2920 (CH, aliphatic), 1724 (C═O), 1169 (C–O–C); ^1H NMR ($CDCl_3$) δ: 9.50–9.32 (br, 8H, aromatic H), 8.12–6.98 (m, 40H, aromatic H), 4.46–4.11 (m, 16H, CH_2), 3.66 (s, 8H, CH_2), 1.42–1.23 (q, 24H, CH_3); UV–Vis λ_{max} (nm) in chloroform: 662, 333; MALDI TOF-MS (*m*/*z*): 1916.9 [M^+]; *Anal*. Calc. for $C_{112}H_{96}N_8O_{16}Pd$: C, 70.17; H, 5.04; N, 5.84. Found: C, 70.12; H, 5.01; N, 5.86%.

3. Results and discussion

3.1. Synthesis and characterization

The phthalonitrile derivative **1** was obtained through displacement reaction of 4-nitrophthalonitrile first with diethylmalonate and then in a further reaction with 4-(chloromethyl)biphenyl. Conversion of phthalonitrile derivative **1** into corresponding metallophthalocyanines **2**–**4** was accomplished by reaction with anhydrous salts in fused state [13]. The reaction was complete to give a relatively high yield under these conditions without any need to use ammonium molybdate as the catalyst [27,35]. The yields of the products were 61–71% range which was in accordance with the reported phthalocyanine compounds

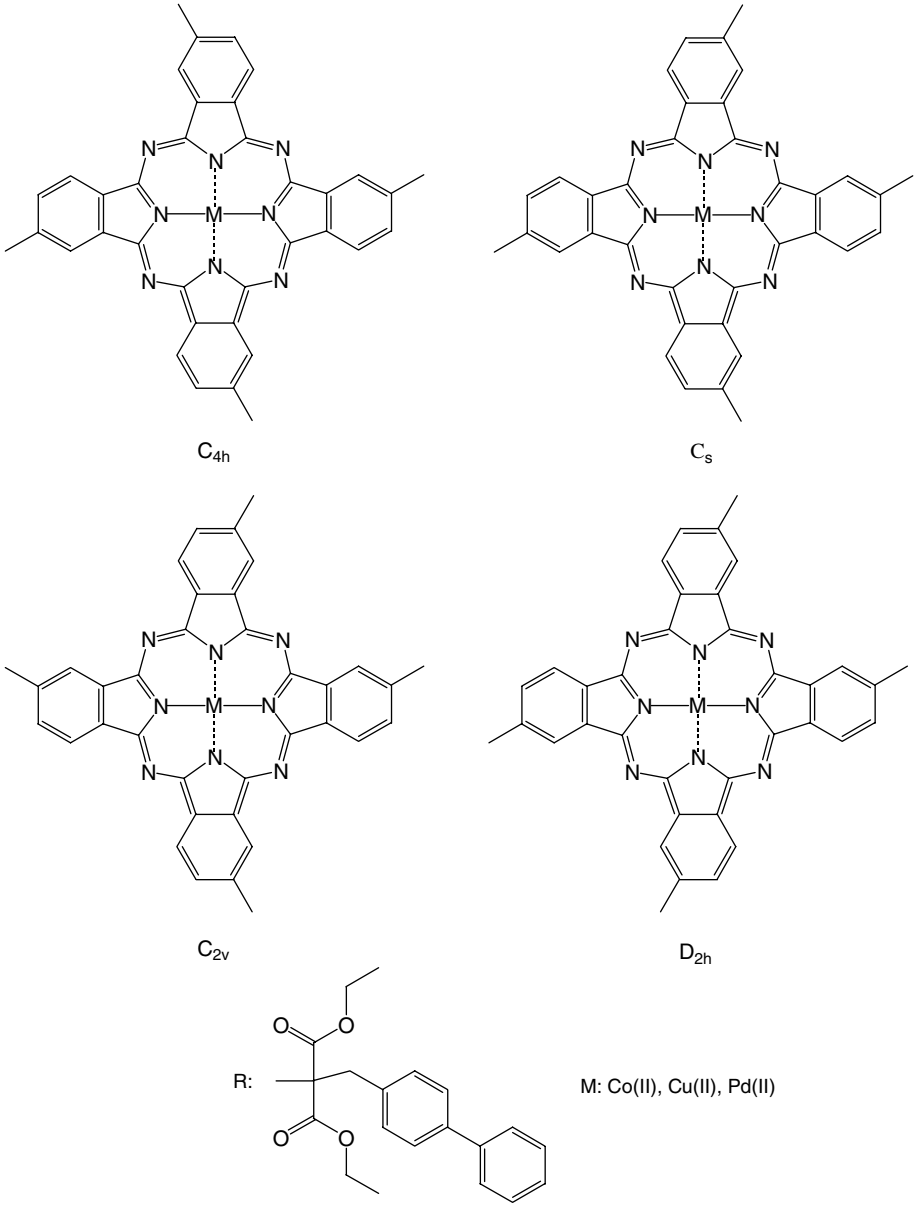

Fig. 1. Isomers of metallophthalocyanines (**2**–**4**).

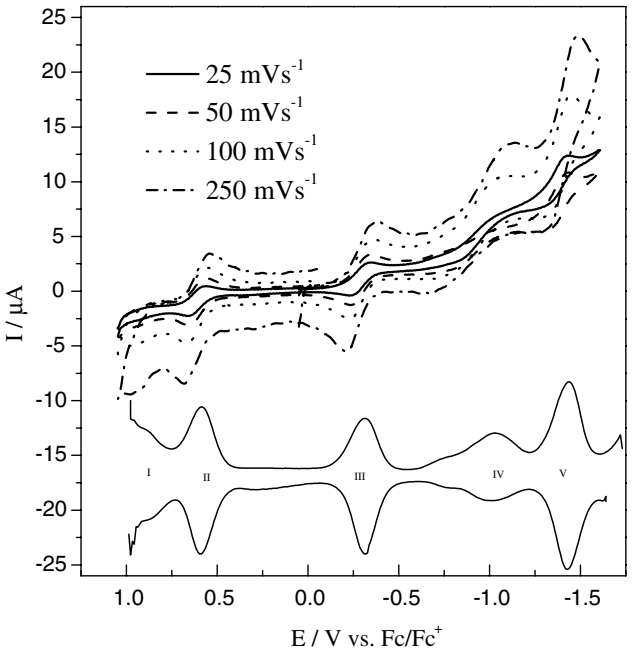

Fig. 2. Cyclic and differential pulse voltammograms of CoPc (**2**) in 0.1 mol dm^{-3} TBAP/DCM electrolyte system at different scan rates.

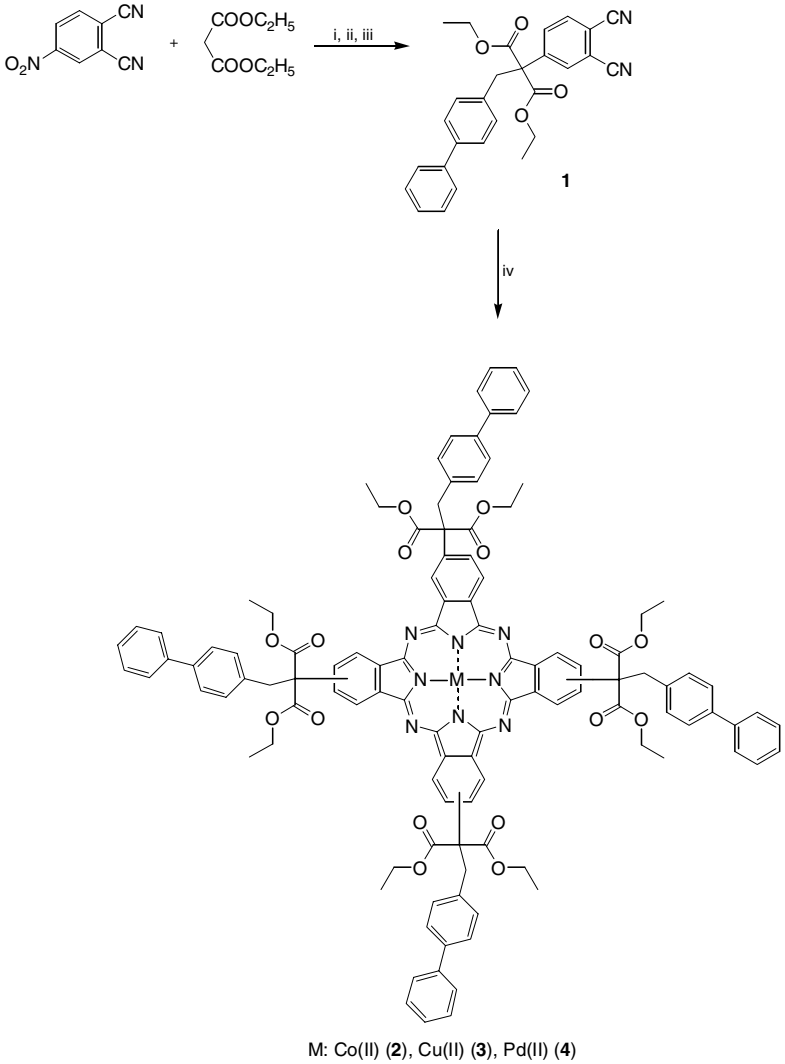
synthesized directly from the phthalonitrile derivatives and the metal salts without any solvent [36–38]. The phthalocyanines **2**–**4** were purified by column chromatography using silica gel as the stationary phase and methanol, THF as eluents. As a natural consequence of the single substituent on each benzo group, the phthalocyanines **2**–**4** are all a mixture of four constitutional isomers (D_{2h}:C_s:C_{2v}:C_{4h}) (Fig. 1). To the best of our knowledge, there is no literature presently available that reports the successful separation of these four isomers with ordinary column chromatography. Our attempts to separate these isomers by column chromatography are not successful. The blue products are easily soluble in number of solvents such as chloroform, dichloromethane, THF, acetone, DMF, and DMSO.

All of these new compounds were characterized by elemental analyses together with FT-IR, ^{1}H NMR, ^{13}C NMR, UV–Vis, and MASS spectroscopic techniques. Elemental analyses correspond closely with the values calculated for **1**–**4**. In compound **1**, stretching vibrations of C≡N (2237 cm^{-1}), C=O (1734 cm^{-1}), C–O–C (1178 cm^{-1}) appeared at expected frequencies. At the same time, aliphatic CH stretching vibrations are observed at 2982–2937 cm^{-1} and aromatic CH stretching vibrations are observed at 3119–3032 cm^{-1}. The IR spectrum of **1** and those of **2**–**4** were similar, the only difference being the disappearance of C≡N vibration in the latter group.

In the ^{1}H NMR spectrum of **1**, the aromatic protons appear as multiplets and doublet at 7.69–7.32 ppm and 6.84–6.80 ppm. CH_2 protons are observed around 4.37–4.19 ppm as multiplets and singlet at 3.61 ppm. CH_3 protons are observed at 1.28–1.23 ppm as a triplet. The ^{13}C NMR data of **1** confirm the result of the ^{1}H NMR spectrum. In the CI-MS spectrum of **1**, the molecular ion peak appeared at *m*/*z* 453. ^{1}H NMR investigations of compound **4** provided the characteristic chemical shifts for the structures expected. The aromatic protons are observed around 9.50–9.32 ppm as a broad band and 8.12–6.98 ppm as multiplets. CH_2 protons appear at 4.46–3.66 ppm and CH_3 protons appear at 1.37–1.23 ppm. In the MALDI TOF-MS spectrum, we observed a molecular ion peak at *m*/*z* 1916.9 for **4**.

The phthalocyanines display typical electronic spectra with two strong absorption regions, one of them in the UV region at about 300–350 nm (B band) and the other one in the visible region at 600–700 nm (Q band). UV–Vis spectra of all metallophthalocyanines **2**–**4** in chloroform exhibit intense Q bands around 662–681 nm and the B bands in the near UV region, around 330–344 nm, both correlated to π–π* transitions. Because of the bulky substituents on the periphery of phthalocyanines **2**–**4**, Q bands are observed as a sharp absorption peak and almost no shoulder on the higher energy side, which would correspond to aggregated species [39].

3.2. Electrochemical measurements



The cyclic voltammograms (CV) of **2** recorded at different scan rates are shown in Fig. 2. The voltammograms of **2** display three reduction couples at −0.29, −0.88, and −1.38 V and two oxidation couples at 0.61 and 0.92 V versus Fc/Fc^+ at 0.100 V s^{-1} scan rate within the available potential range of TBAP/DCM solvent system. Differential pulse voltammetry of the complex confirms the recorded redox processes clearly. The reduction and oxidation behavior of metal-phthalocyanine derivatives is due to the interaction between the phthalocyanine ring and the central metal. The redox properties of metal Pc have been studied by many authors [40–47]. First-row transition metals Pc differ from those of the main-group metals Pc due to the fact that metal "d" orbitals may be positioned between HOMO and LUMO of the phthalocyanine (Pc^{-2}) ligand. This has been well established by several papers published by Lever et al. [27,30–32]. According to this studies, while the first oxidation and first reduction processes occur on the metal center in the metal Pc only for Mn, Fe, and Co derivatives in polar solvent such as DMF and DMSO, the first oxidation process occur on the ring in nonpolar solvent such as DCM and THF. According to Lever et al., for Ni, Cu, and Zn phthalocyanines, redox processes take place on the Pc ring. These studies indicate that first reduction and second oxidation processes of **2** recorded at −0.29 and 0.92 V could be attributed easily to the Co^{II}/Co^{I} and Co^{II}/Co^{III} redox couple, respectively, and the remaining processes to the phthalocyanine ring. All predicted redox processes are given in Eq. 1:

$$[\mathrm{Co(II)Pc}(-1)]^{+} \underset{[\mathrm{Co(III)Pc}(-1)]^{2+}}{\overset{e^{-}\Updownarrow 0.92\ \mathrm{V}}{}} \Longleftrightarrow \overset{e^{-}}{\underset{0.61\ \mathrm{V}}{\Longleftrightarrow}} [\mathrm{Co(II)Pc}(-2)] \overset{e^{-}}{\underset{-0.29\ \mathrm{V}}{\Longleftrightarrow}} [\mathrm{Co(I)Pc}(-2)]^{1-} \overset{e^{-}}{\underset{-0.88\ \mathrm{V}}{\Longleftrightarrow}} [\mathrm{Co(I)Pc}(-3)]^{2-} \underset{[\mathrm{Co(I)Pc}(-4)]^{3-}}{\overset{e^{-}\Updownarrow -1.38\ \mathrm{V}}{}} \quad (1)$$

The separation between the first reduction and first oxidation processes (~0.907 V), which related with the HOMO–LUMO gap of the complex is comparable with the reported CoPc papers [27]. While all redox processes display reversible peak characters only the second reduction process is quasi reversible with a ΔE_p of 0.320 V at 0.100 V s^{-1} scan rate eventhough it has a unity I_{pc}/I_{pa} ratio constant values of $I_p/v^{1/2}$ for all processes suggest diffusion-controlled electron transfer mechanism of redox processes of **2**. For each redox process of **2**, I_{pc}/I_{pa} is almost unity and not changed considerably with the increasing scan rates (Scheme 1).

The voltammograms of **3** (Fig. 3) display three redox processes, assigning to the phthalocyanine ring reduction and oxidation reactions. Scanning the potential to the negative side, two reduction processes at −0.910 and −1.270 V versus Fc/Fc^{+} at 0.1 V s^{-1} scan rate were recorded. Up on scanning anodically an oxidation reaction just at the end of the solvent window (at ~0.560 V) was obtained. All redox processes have quasi reversible peak character with respect to their ΔE_p variation with the scan rate. The separation of the firs reduction and the first oxidation processes (~1.5 V) reflects the HOMO–LUMO gap of the complex. Variation of I_p as a function of $v^{1/2}$ and I_{pc}/I_{pa} ratio suggest diffusion-controlled electron transfer reactions for all redox processes.

Fig. 4 shows the cyclic voltammograms of **4**. Within the available potential range of the solution system, **4** gives only two reversible reduction reactions at −0.895 and −1.280 versus Fc/Fc^{+} at 0.100 V s^{-1} scan rate, respectively. All of these processes are attributed to the phthalocyanine ring electron transfer reactions.

Scheme 1. Synthesis of Pcs. (i) K_2CO_3, DMF, 50 °C; (ii) KOH, ethanol; (iii) acetone/acetonitrile, 4-(chloromethyl)biphenyl, 20 h reflux; (iv) metal salts, 24 h.

In conclusion, we have described the synthesis and electrochemical characterization of new metallophthalocyanines. Electrochemical studies show that these compounds have multi-electroned reversible/quasi-reversible redox processes, which are the main requirement for the technological usage of these compounds. The distinctive property of these compounds is that they have a good solubility in polar organic solvents.

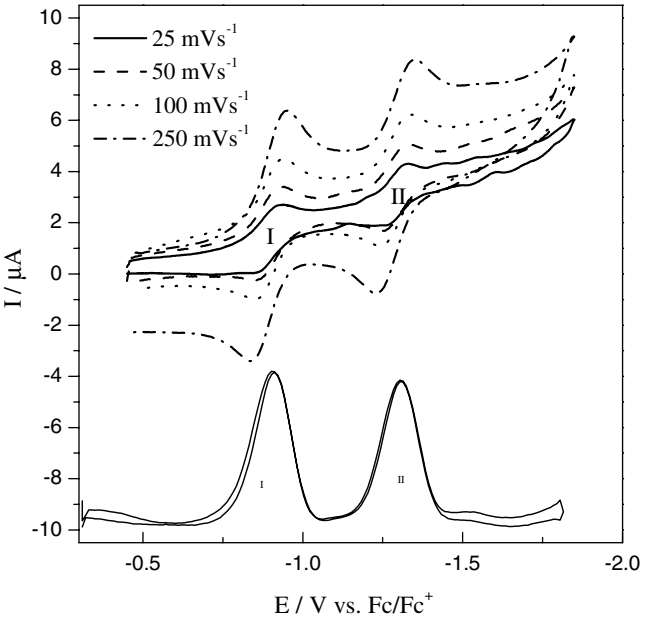

Fig. 4. Cyclic and differential pulse voltammograms of PdPc (**4**) in 0.1 mol dm^{-3} TBAP/DCM electrolyte system at different scan rates.

however, there is a competition between two different ligands for coordination bonds to the same metal, the formation of mixed-ligand coordination compounds gives new and interesting properties [9]. It is known that bipy forms cationic octahedral complexes with divalent transition metal ions, e.g. $[Co(bipy)_3]^{2+}$ [10], while salicylaldehyde ligands form neutral square-planar chelates, e.g. $[Zn(salo)_2]$ and $[Zn(5\text{-Br-salo})_2]$ [11,12].

The Lewis acidity of $[Co^{II}(salo)_2]$ chelates, renders them susceptible to nucleoplilic attack and addition compounds can be obtained. While unidentate nitrogen donor ligands, such as pyridine, may impose tetragonal distortion by occupying *trans* positions $[Co(salo)_2(py)_2]$ [13], structural requirements of the bidentate Lewis base, bipy, dictate occupancy of *cis* positions. Although there are mentioned complexes of Co(II) with 3,5-dichloro-salicylaldehyde and the Lewis base dipyridylamine (dpamH) [14], it has not been reported in the literature any mixed-ligand cobalt(II) compound with 2-hydroxyarylaldehydes and bipyridine, characterized by X-ray diffraction analysis.

For a better understanding of the bonds and structure of mixed-ligand compounds with bipy and substituted salicylaldehydes, we report here the synthesis of a series of new cobalt(II) addition compounds under the formula $[Co^{II}(X\text{-salo})_2bipy]$, where X = 3-$OCH_3$ (**1**), 5-CH_3 (**2**), 5-Cl (**3**) and 5-NO_2 (**4**). The resultant octahedral compounds were characterized by physico-chemical methods and spectroscopic (IR, UV–Vis) studies. Correlation between theoretical results and electronic excitation data were undertaken and the results are presented and discussed. Their structure was verified by X-ray diffraction analysis of a representative compound, the solvated 2,2′-bipyridine-bis(2-hydroxy-5-methoxy-benzaldehydato)cobalt(II), $[Co^{II}(3\text{-}OCH_3\text{-salo})_2\text{-bipy}]\cdot CH_3OH$ (**1**). A cyclic voltammetry (CV) study was employed to investigate their electrochemical behavior, while the thermal behavior for one compound was investigated by simultaneous thermogravimetric-differential thermal analysis (TG-DTA) technique, under nitrogen and oxygen atmosphere. Furthermore, during the synthesis of the titled addition compounds, a side-product was isolated and verified by X-ray analysis as $[Co^{II}(bipy)_3]Br_2\cdot 0.5\text{-(5-chloro-salicylaldehydeH)}\cdot 1.5CH_3OH$ (**5**).

2. Experimental

2.1. Materials

The ligands, substituted 2-OH-benzaldehydes (substituted salicylaldehydes, X-salo), where X = 3-OCH_3, 5-CH_3, 5-Cl or 5-NO_2, the 2,2′-bipyridine (bipy) and the metal salt $CoBr_2\cdot 6H_2O$ were obtained as reagent grade from Aldrich and used as received. The precursor compound $Co(bipy)_2Br_2$ was prepared according to the literature [15]. Solvents for preparation and physical measurements of "extra pure" were obtained from Fluka without further purification.

2.2. Instrumentation/analytical procedures

Microanalyses were obtained using a Perkin–Elmer 240 B CHN microanalyzer. Infrared spectra were recorded on a Perkin–Elmer 1600 FT-IR spectrometer in KBr discs at room temperature and are reported in cm^{-1}. Electronic absorption spectra in solutions were obtained on a Shimatzu 160 A spectrometer. The solid-state electronic spectra were obtained from Nujol mulls. Molar conductivities were measured in CH_3OH, CH_3CN and DMF solutions, employing a WTW conductivity bridge and a calibrated dip type cell. Magnetic susceptibility measurements on powdered samples were performed at 25 °C employing the Faraday method on a home-build balance calibrated against $Hg[Co(SCN)_4]$.

Cyclic voltammetry technique (CV) was used for the electrochemical measurements on a μ-AUTOLAB Potentio-Galvanostat (ECO CHEMIE, Netherlands). A saturated calomel electrode was used as a reference electrode and graphite one as an auxiliary electrode for all measurements. As a working electrode a platinum wire was used. The tests in CH_3CN solution were carried out in the potential region −1900 to +2200 mV at ambient temperature. Recrystallized TEA perchlorate 0.1 M was used as the electrolyte at a scan rate of 100 mV/s. All scans were recorded in degassed solvent and under current of moisture free argon over the solution surface. The thermal behavior of the titled compounds was studied using the simultaneous TG/DTG-DTA technique, over the temperature range ambient-to-1000 °C, using a Setaram Model Setsys-1200 thermogravimetric analyzer. The samples, with mass about 12 mg under nitrogen and 7 mg in oxygen, were heated in platinum crucible, at a heating rate 10 °C/min. Computational techniques: All calculations have been performed using the GAUSSIAN-03 package from Gaussian, Inc. Carnegie Office Park, Building 6 Carnegie, PA 15106, USA. Energy and orbitals calculations were performed using the B3LYP Density Functional Theory approximation (DFT). The basis set used was the LANL2DZ for all atoms. The prediction of the spectrum was calculated using ZINDO option.

2.2.1. Preparation of $[Co^{II}(3\text{-}OCH_3\text{-salo})_2(bipy)]\cdot CH_3OH$ (1)

A solution of 3-methoxy-2-hydroxybenzaldehyde (3-OCH_3-salo), (*o*-vanillin) (152 mg, 1 mmol) and CH_3ONa (54 mg, 1 mmol) in MeOH (25 mL), was added drop-wise to a solution of $Co(bipy)_2Br_2$ (0.266 g, 0.5 mmol) in H_2O (15 mL) at room temperature, under aerobic or inert, under argon, conditions. The solution was stirred for 2 h and then turned darker and an orange-brown solid was formed. The solid was filtered, washed with water and dried under vacuo (0.17 g, 63% yield). The crystalline compound analyzed as *Anal.* Calc. for $C_{27}H_{26}N_2O_7Co$ (MW 549): C, 59.00; H, 4.70; N, 5.10. Found: C, 58.82; H, 4.55; N, 5.08%.

The magnetic value ($\mu_{eff} = 4.26\ \mu_B$) gives the bivalent character of the cobalt ion. The conductivity in freshly

prepared CH_3OH and CH_3CN solutions was found equal to 20 and 27 μS/cm, respectively, denoting the neutral character of the compound, while in DMF equals to 164 μS/cm denoting 2:1 electrolyte. IR spectrum (KBr): selected peaks in cm^{-1}: 3460 m, 1634 and 1616 s (double), 1596 vs, 1093 s, 855 m, 770 and 755 s (double), 729 s, 555 m, 420 m.

2.2.2. Preparation of $[Co^{II}(5\text{-}CH_3\text{-}salo)_2(bipy)] \cdot CH_3OH$ (2)

A solution of 5-methyl-2-hydroxybenzaldehyde (5-CH_3-salo), (136 mg, 1 mmol) and CH_3ONa (54 mg, 1 mmol) in MeOH (25 mL), was added drop-wise to a solution of $Co(bipy)_2Br_2$ (0.266 g, 0.5 mmol) in H_2O (15 mL) at room temperature, under aerobic or inert, under argon, conditions. The solution was stirred for 2 h and then turned darker and an orange-brown solid was formed. The solid was filtered, washed with water and dried under vacuo (0.16 g, 61% yield). The crystalline compound analyzed as *Anal.* Calc. for $C_{27}H_{26}N_2O_5Co$ (MW 517): C, 62.66; H, 5.02; N, 5.41. Found: C, 62.57; H, 4.89; N, 5.25%.

Magnetic value, $\mu_{eff} = 1\,4.10\ \mu_B$, conductivity in CH_3OH and CH_3CN 12 and 15 μS/cm, respectively, while in DMF 167 μS/cm. IR spectrum (KBr): selected peaks in cm^{-1}: 3400 m, 1633 s, 1597 vs, 1148 s, 835 m, 770 s, 547 m, 414 m.

2.2.3. Preparation of $[Co^{II}(5\text{-}Cl\text{-}salo)_2(bipy)] \cdot CH_3OH$ (3)

A solution of 3-chloro-2-hydroxybenzaldehyde (5-Cl-salo), (160 mg, 1 mmol) and CH_3ONa (54 mg, 1 mmol) in MeOH (25 mL), was added drop-wise to a solution of $Co(bipy)_2Br_2$ (0.266 g, 0.5 mmol) in H_2O (15 mL) at room temperature, under aerobic or inert, under argon, conditions. The solution was stirred for 2 h and then turned darker and an orange-brown solid was formed. The solid was filtered, washed with water and dried under vacuo (0.14 g, 52% yield). The crystalline compound analyzed as *Anal.* Calc. for $C_{25}H_{20}N_2O_5Cl_2Co$ (MW 558): C, 52.76; H, 3.58; N, 5.01. Found: C, 52.78; H, 3.53; N, 4.92%.

Magnetic value, $\mu_{eff} = 4.12\ \mu_B$, conductivity in CH_3OH and CH_3CN 15 and 18 μS/cm, respectively, while in DMF 160 μS/cm. IR spectrum (KBr): selected peaks in cm^{-1}: 3401 m, 1638 and 1621 s (double), 1598 vs, 1102 s, 783 and 737 s, 729 s, 544 m, 418 m.

2.2.4. Preparation of $[Co^{II}(5\text{-}NO_2\text{-}salo)_2(bipy)] \cdot H_2O$ (4)

A solution of 5-nitro-2-hydroxybenzaldehyde (5-NO_2-salo), (167 mg, 1 mmol) and CH_3ONa (54 mg, 1 mmol) in MeOH (25 mL), was added drop-wise to a solution of $Co(bipy)_2Br_2$ (0.266 g, 0.5 mmol) in H_2O (15 mL) at room temperature, under aerobic or inert, under argon, conditions. The solution was stirred for 2 h and then turned darker and an orange-brown solid was formed. The solid was filtered, washed with water and dried under vacuo (0.155 g, 55% yield). The crystalline compound analyzed as *Anal.* Calc. for $C_{24}H_{18}N_4O_9Co$ (MW 565): C, 50.97; H, 3.18; N, 9.91. Found: C, 50.47; H, 3.25; N, 9.64%.

Magnetic value, $\mu_{eff} = 4.19\ \mu_B$, conductivity in CH_3OH and CH_3CN 21 and 25 μS/cm, respectively, while in DMF 163 μS/cm. IR spectrum (KBr): selected peaks in cm^{-1}: 3436 m, 1634 s, 1596 vs, 1093 s, 840 m, 764 m, 720 m, 545 w, 495 m, 416 m.

2.2.5. Preparation of $[Co^{II}(bipy)_3]Br_2 \cdot 0.5(5\text{-chloro-salicylaldehydeH}) \cdot 1.5CH_3OH$ (5)

A solution of the ligand 5-chloro-salicylaldehyde (160 mg, 1 mmol) and CH_3ONa (54 mg, 1 mmol) in MeOH (25 mL) was added drop-wise to a solution of $Co(bipy)_2Br_2$ (0.30 g, 0.56 mmol) in H_2O (15 mL) at room temperature. The solution was stirred for 2 h and the orange-brown solid was formed as the main product (compound **3**). In the filtration the deep-brown crystals were isolated upon slow evaporation as the side product (compound **5**). This compound is stable in air, soluble in water, but insoluble in ether and analyzed as *Anal.* Calc. for $C_{35}H_{32.\ 5}N_6O_{2.5}Cl_{0.5}$-$CoBr_2$: C 51.66; H, 3.99; N, 10.33. Found: C, 53.11; H, 3.57; N, 10.45%. The conductivity in CH_3CN equals to 260 μS/cm, denoting 1:2 electrolyte. IR spectrum (KBr): selected peaks in cm^{-1}: 3410 m, 1680 and 1660 vs, 1596 vs, 1470 s, 1276 s, 783 and 737 s, 418 m.

2.3. X-ray crystal structure determinations

Crystals of compounds **1** and **5** were mounted on a Phillips-STOE diffractometer employing Mo Kα radiation. All data were collected at 295 K using the ω–2θ technique. The first matrix was obtained from 25 high theta reflections and leaded to the pronounced space groups. After the centering of the reflections and the definition of the space groups the followed data collection included all reflections with 2θ up to at least 25°. Crystallographic data and other pertinent information are given in Table 1. The data were corrected for Lorentzian polarization effects as usual. For both crystals the first solution came out using the SIR-92 method [16]. Subsequent calculations and data refinement were performed using CRYSTALS version 12.1 [17]. Final unit cell parameters were determined by least-squares method using all observed reflections and finally all data were corrected using DIFABS method [18]. Concerning the compound $[Co(3\text{-}OCH_3\text{-}salo)_2(bipy)] \cdot CH_3OH$ (**1**), all non-hydrogen atoms were refined anisotropically, together with those coming from the solvent molecule. Hydrogen atoms were located in difference Fourrier maps. After refining their positions using fixed thermal parameter values to 0.07 and soft restraints on the bond lengths and angles to regularize their geometry (C···H to 0.98, O···H to 0.82) their positions were finally refined with riding constraints.

For the compound $[Co(bipy)_3]Br_2 \cdot 0.5$(5-chloro-salo-H) $\cdot 1.5CH_3OH$ (**5**), SIR-92 revealed the positions of the atoms forming the moiety $Co(bipy)_3Br_2$, while successive Fourier synthesis revealed the positions of all the rest non-hydrogen atoms and their disordered distribution.

Table 1
Crystal data for compounds **1** and **5**

Compound	**1**	**5**
Empirical formula	$C_{26}H_{22}CoN_2O_6 \cdot CH_4O$	$2(C_{35}H_{32.5}N_6O_{2.5}Cl_{0.5}CoBr_2)$

Especially for the 5-chloro, salicylaldehyde molecule it was found disordered over three positions as rotating around a C_3 axis passing from the center of the phenyl ring. The carbonyl carbon atom was never located, as it was masked from the chlorine atom as well as all hydrogen atoms due to the disorder rotation. The rest of the hydrogen atoms were positioned geometrically and their positions were finally refined with riding constraints. Soft constraints were also introduced on the bond lengths and angles to regularize geometry of 5-chloro-salicylaldehyde molecule. All disordered atoms coming from the 5-Cl-saloH were refined isotropically. The rest non-hydrogen, non-disordered atoms, were refined anisotropically.

Selected interatomic distances and bond angles are given in Tables 2 and 3, respectively. The figures of the clinographic projections were produced with the CAMERON program [19] and are given in Figs. 1 and 2.

3. Results and discussion

3.1. Synthesis and characterization

The reaction of [Co(II)(bipy)$_2$Br]Br with the anions of the substituted salicylaldehydes (X-salo) and 2,2′-bipyridine (bipy), under proper aerobic or inert conditions, leaded to the formation of the crystalline orange-brownish products. They are stable in air, soluble in almost all the organic solvents but insoluble in water. Their elemental analyses and the absence of electrical conductivity in CH_3CN and CH_3OH solutions indicated neutral compounds, with general formula [Co(II)(X-salo)$_2$(bipy)], while their magnetic moments ($\mu_{eff} = \sim 4.2\ \mu_B$) corroborate with high-spin octahedral coordination of the cobalt(II) ion.

The coordination mode of the ligands in the addition compounds was studied using spectroscopic methods. The X-ray diffraction study of [Co(II)(3-OCH$_3$-salo)$_2$-(bipy)] · CH_3OH, provided evidence regarding the geometry around cobalt(II) ion and the configuration of the ligands.

The successful isolation of these compounds depends on the concentration of the ligand and the precursor compound. When the precursor compound is in excess, a second deep-brown product is always present having the general formula [Co(II)(bipy)$_3$]Br$_2$ · X-saloH. The structure of the latter compounds was elucidated for the compound [Co(II)(bipy)$_3$]Br$_2$ · 0.5(5-chloro-saloH) · 1.5CH_3OH (**5**) by X-ray diffraction study.

3.2. Description of the structure [Co^{II}(3-methoxy-salicylaldehyde)$_2$(bipy)] · CH_3OH (**1**) and [Co^{II}(bipy)$_3$]Br_2 · 0.5(5-chloro-saloH) · 1.5CH_3OH (**5**)

In both compounds the cobalt atom is coordinated to the ligands in a distorted octahedron. In the case of compound [Co(3-OCH$_3$-salo)$_2$(bipy)] (**1**), the most axial vector is this passing through O(4), Co and N(2). If O(4) and N(2) would be considered to occupy the axial positions, then O(5), O(2), N(1) and O(1) would be on the equatorial plane and the geometry could be better described as axially elongated distorted octahedral. All distances and angles are similar with those reported in analogous complexes

Table 2

[13,20]. The atoms forming the equatorial plane present a maximum deviation 0.163(14) Å from it (for O(2)), while the Co(II) cation was found to be 0.015(15) Å lower of the plane with a deviation equal with the error. The bipyridine and the two *o*-vanillin ligands were found to be practically planar with deviations smaller than the error. The dihydral angles formed were 60.86° and 77.73° between the bipy and the two *o*-vanillin moieties, while the angle between the two *o*-vanillins was 54.34°. The bipyridine ligand was found to be nearly perpendicular to the equatorial plane with a formed angle of 85.56°. The two *o*-vanilins form angles of 25.83° and 63.51° with the equatorial plane. No interaction between the complex and the methanol molecule was observed.

In the case of compound, $[Co(bipy)_3]^{2+}2Br^- \cdot 0.5(5\text{-chloro-salicylaldehyde}) \cdot 1.5CH_3OH$ (**5**), the geometry around Co(II) is distorted octahedral due to symmetry reasons. All distances and angles (Tables 2 and 3) are typical as compared with similar complexes previously reported [10,21]. The Br^- anions present no interactions with the complex moiety. In the cell can also be found three disordered methanol molecules, as well as one molecule of 5-chloro-salicylaldehydeH, (badly disordered as previously described) on the symmetry plane $z = 1/4$. The neutral ligand 5-Cl-saloH is completely planar due to symmetry reasons and has no interaction with the cobalt complex (Fig. 2).

3.3. Theoretical calculations and electronic excitation study

Theoretical calculations were performed for structure optimization and assignment of the experimentally observed electronic excitation spectrum for the compound **1**. Specifically, in the crystal structure description, it was

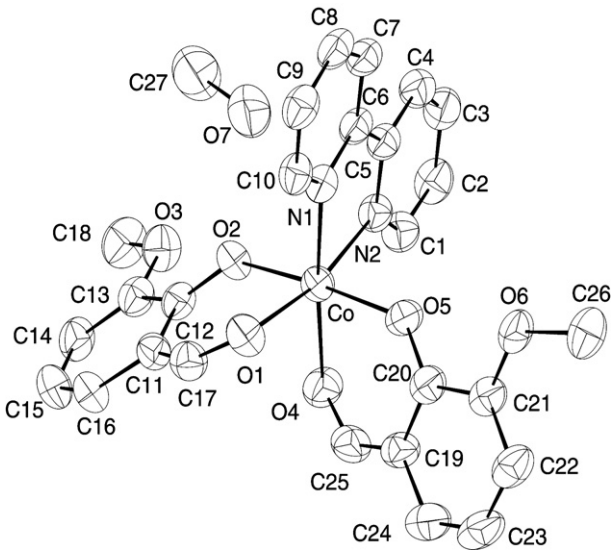

Fig. 1. Molecular structure of $[Co^{II}(3\text{-}OCH_3\text{-}salo)_2(bipy)] \cdot CH_3OH$ (**1**).

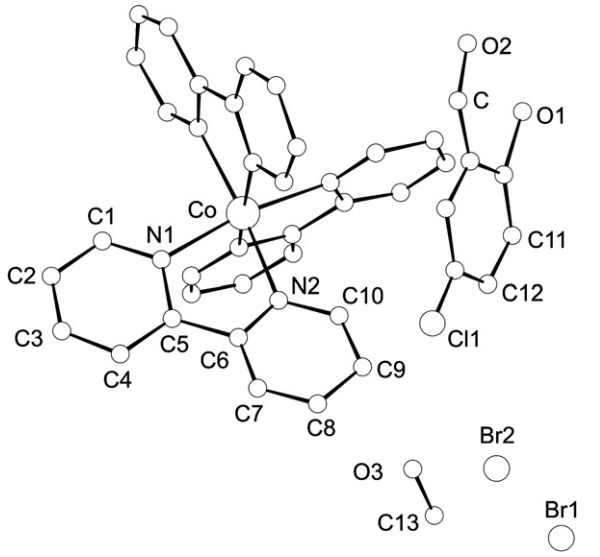

Fig. 2. Molecular structure of $[Co^{II}(bipy)_3]Br_2 \cdot 0.5(5\text{-Cl-saloH}) \cdot 1.5\text{-}CH_3OH$ (**5**).

considered that the complex possessed a coordination sphere with a compressed distorted octahedral arrangement. This resulted considering that the most axial vector was the one passing through N(2), Co and O(4) having an angle of 173.8°. If the vector passing through O(5), Co and O(2), having an angle of 172.0°, would be considered as the most axial, then the geometry could be better described as compressed distorted octahedral. The comparison between the optimized and the "frozen" geometry theoretical spectra, greatly helps to the better assignment of the observed electronic excitation spectra of the compounds recorded in solvents with different dielectric constants, as well as in Nujol mulls.

The experimental UV–Vis spectra of the compound $[Co^{II}(o\text{-vanillin})_2(bipy)]$ (**1**) in the solid state as Nujol mull presented six dominant bands in the region 300–1100 nm (Fig. 3). The two intense bands in the UV region, present at wavelengths 300 and 360 nm (bands I and II, respectively) were assigned to intra-ligand $\pi^* \leftarrow \pi$ or $\pi^* \leftarrow$ n transitions, evidence arising from the position and intensity, as well as from the comparison with the spectra of the corresponding ligands bipy and *o*-vanillin. In the visible region, the three bands at 440, 550 (sh) and 990 nm (bands IV, V, and VI, respectively), are due to the metal suggesting an octahedral arrangement of the ligands around Co(II) [22]. Accordingly, these bands could be assigned to the spin-allowed excitations from the $^4T_{1g}(F)$ ground state to the electronic levels $^4T_{1g}(P)$; $^4A_{2g}$; and $^4T_{2g}$. The band at 396 nm (band III) is the more doubtful to be assigned. It can be either a CT or a d–d transition and its character will be clarified by the theoretical calculations (see below).

As it can be figured out from the electronic spectra of the compound **1** in several solvents (Fig. 3), there is evidence of a solvent effect affording changes in stereochemistry of the cobalt(II) environment. The existence of the octahedral configuration was also concluded for CH_3CN solutions, although the bands II and IV are masked under the single broad band centered at 396 nm (band III). The band at 550 nm (band V) is apparent only in concentrated solutions, while the band at 990 nm (band VI) is clearly seen.

In the cases of DMF and CH_3OH solutions, however, changes either in stereochemistry or in chromophore can be assumed. One new band around 610 nm appears, while the band at 990 nm completely disappears. Changes in the coordination sphere may be accomplished with or without changes in stereochemistry, depending on whether it takes place a nucleophilic substitution or an elimination reaction. Thus, in the case of CH_3OH solution, *possibly* upon oxidation to Co(III), one protonated *o*-vanillin ligand passes in the solution, while a peroxide (O_2^{2-}) group takes its place according to the following equation [23, and references therein]:

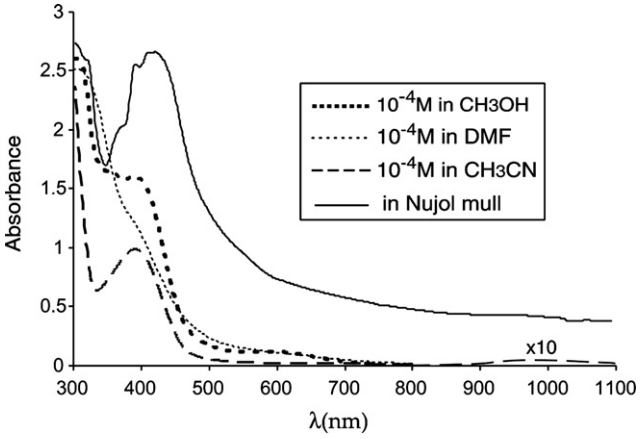

Fig. 3. Electronic excitation (UV–Vis) spectra for $[Co^{II}(3\text{-}OCH_3\text{-salo})_2\text{-}(bipy)] \cdot CH_3OH$ (**1**) in various solvents and in Nujol mull.

$$[Co^{II}(o\text{-vanillin})_2(bipy)] \rightarrow [Co^{III}(o\text{-vanillin})(bipy)(O_2^{2-})] + o\text{-vanillinH}$$

In the case of DMF solutions most possibly upon oxidation to Co (III), an *o*-vanillin ligand was dissociated according to the following equation [24]:

$$[Co^{II}(o\text{-vanillin})_2(bipy)] \rightarrow [Co^{III}(o\text{-vanillin})(bipy)(DMF)]^{2+} + o\text{-vanillinH} + 2X \text{ (or } o\text{-vanillin} + X$$

where X is probably CH_3O)

The two new resulting complexes in solution most probably adopt tetragonal pyramidal geometry of the chromophore. In the case of the more polar DMF molecules a change in configuration is more favorable attributable to the dissociation effect of a ligand. This is also in coincidence to the conductivity measurements especially in the case of DMF, where the transformation seems to be very fast. In the case of CH_3OH the change seems to be slow and the final product occurs from well aerated solutions after a few hours.

In order to find out the influence of the substituents in the benzene ring of the salicylaldehyde ligands, on the electronic spectra of the investigated addition compounds, we recorded them in CH_3CN solutions (Fig. 4). The position of the absorption bands, along with their extinction coefficients (ε values) are given in Table 4. It can be seen that the band VI is present at the same wavelength, around 990 nm for all compounds, while the position and intensity of the band III around 390 nm depends on the substituents of the salicylaldehyde ligand. The bands IV and V found in Nujol spectrum at 440 and 550 nm, respectively, are not clearly observed in CH_3CN solutions with concentration 10^{-4} M.

Theoretical calculations on the crystal structure fixed geometry resulted that the coordination geometry was elongated distorted octahedral. This arises from the d-orbitals arrangement pattern, which was the typical for this

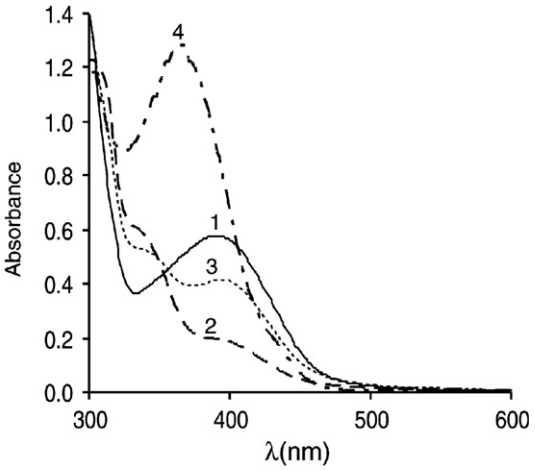

Fig. 4. Electronic excitation (UV–Vis) spectra for the compounds $[Co^{II}(X\text{-salo})_2(bipy)]$, 10^{-4} M in CH_3CN (X = 3-OCH_3 (**1**); 5-CH_3 (**2**); 5-Cl (**3**); 5-NO_2 (**4**)).

Table 4
Electronic excitation (UV–Vis) data for the compounds $[Co^{II}(X\text{-salo})_2(bipy)_2]$ in CH_3CN

Compound	Band I λ (nm), ε	Band II λ (nm), ε	Band III λ (nm), ε	Band VI λ (nm), ε
1	300, 14000	masked	394, 5900	990, 100
2	306, 12100	340, 6100	389, 2180	989, 95
3	301, 13000	330, 5800	390, 4250	989, 95
4	300, 12000	masked	375, 12300	988, 100

geometry. When leaving the complex free to optimize, the final predicted structure was nearly identical with the one observed from the crystal structure with maximum bonds and angles deviations of 0.6 Å and 2°, respectively. The optimized structure had again the same coordination geometry. The d-orbitals arrangement was exactly the same, as the previously observed, with slight differences to the energy calculated values.

The predicted excitation spectrum for the complex **1**, revealed from the coordinates of the optimized structure using the ZINDO approximation, presents six dominant excitation bands in the visible region of the spectrum. These bands were calculated to be at the following excitation maxima: 986.87 nm, 574.77 nm, 507.56 nm, 478.56 nm, 402.70 nm, 399.34 nm. It is resulted that the bands at 987 nm and 478 nm are virtually of d–d character, while the one at around 400 nm is virtually of MLCT character. This is in accordance with the results from the experimental spectrum in the solid state and clarifies the bands character, as one molecular orbital, symmetrically spread over the two vanillin ligands, was found to be located between the e_g and the t_{2g} metal orbitals.

3.4. IR spectra

For all the studied compounds, a plethora of discrete bands appears in their IR spectra, which can be classified as those emanating from crystal water or methanol, from the bipy molecule, from the substituted salicylaldehyde, and those due to the coordination bonds. Thus, the band at 3460–3400 cm^{-1} is indicative of the vibration ν(OH), which is due to the non-coordinated water or methanol. The intense bands at 1596 cm^{-1}, attributable to the stretching vibration of C=N (aromatic bond) are present in all complexes. The intense band at 750 ± 20 cm^{-1}, ascribed to the rocking vibrations of the pyridyl C–H bonds and the band at 870 ± 15 cm^{-1}, attributable to the deformation vibrations of the pyridyl C–H bonds, disclosed the occurrence of the nitrogenous bases in the studied addition compounds. Upon coordination the intense bands stemming from the stretching and bending vibrational modes of the phenolic OH disappear indicating the removal of a hydrogen atom, while the band at ~1640 cm^{-1}attributable to C=O is shifted to lower frequencies indicative of their coordination mode. The bands originating from the C–O stretching vibrations at ~1070 cm^{-1} exhibit small positive shifts, while their intensity is enhanced appreciably. The

medium intensity bands at about 550 and 416 cm^{-1} are attributed to the coordination bonds [25].

3.5. Electrochemical studies

All the studied compounds exhibit the same behavior during the cyclic voltammetry experiments. A typical CV diagram of the compound **1** is, representatively, depicted in Fig. 5, while the experimental data for the studied compounds are presented in Table 5. The CV in the region from −1900 mV to 2200 mV revealed the reversible waves of the couples Co(II)–Co(III) around 400 mV and Co(I)–Co(II) around −850 mV. Both couples present a single electron wave, as compared with the waves generated by equimolar amount of ferrocene solution. These values are very close to them found from the CV of similar compounds [26,27].

The oxidation of the phenolic oxygen is presented with a wave around 1400 mV, while the reduction of the same group takes place at ca. −1800 mV. Both are two electron waves and this suggests that the ligands in the complex are equivalent as expected. The remaining peak in the anodic region at around 1700 mV can be attributed to the oxidation of the bipyridine group. All the results are in accordance with the voltage values of the waves present in the cyclic voltamograms of the free ligands.

In the case of [Co(5-nitro-salicylaldehyde)$_2$bipy] · H_2O (**4**), the CV diagrams in both the free ligand and the complex (Fig. 6), were presented one more reversible wave at −1350 mV, which can be attributed to the oxidation and reduction of the nitro group connected to the phenyl ring of the ligand. This wave is present in the CV of the free ligand with the same pattern.

3.6. Thermal studies

The thermal behaviour of the compound **1** was studied in nitrogen and oxygen atmosphere, over the temperature range ambient to 980 °C by using the simultaneous TG/DTG-DTA technique. As it can be seen from the thermoanalytical curves in nitrogen (Fig. 7), though this compound is very stable at ambient temperature, it is unstable upon heating, decomposing in four successive endothermic stages. The first stage at 25–120 °C is attributed to the elimination of the methanol molecule from the crystal lattice. The second and third decomposition stages possess sharp intense endothermic effects, due to the melting (210 °C) and successive decomposition (270 °C) accompanied by sudden mass loss, about 47%. The decomposition proceeds with the rupture of bonds inside the salicylaldehyde ligands, along with the dissociation of the coordinated bonds.

The small endotherm on the DTA curve at 400 °C, without mass loss, is indicative of possible phase or structural change of the intermediate compound formed at 350 °C. This is probably consisted of the {CoO(bipy)} moiety, as inferred from TG/DTG curves and verified from the IR peaks (760 and 730 cm^{-1}, attributable to the ν(=C–H) of the pyridine molecule).

The gradually elimination of the bipy ligand was followed, leading to the isolation of pure CoO at 500 °C in oxygen atmosphere, verified by IR spectra, while the residue at 980 °C in nitrogen atmosphere was found to be CoO mixed with small amount of carbon. This decomposition mode is in accordance with other analogous nickel(II) addition compounds with bipy and 2-hydroxyaryloximes [28] or cobalt addition compounds with phen and salicylato ligands [29].

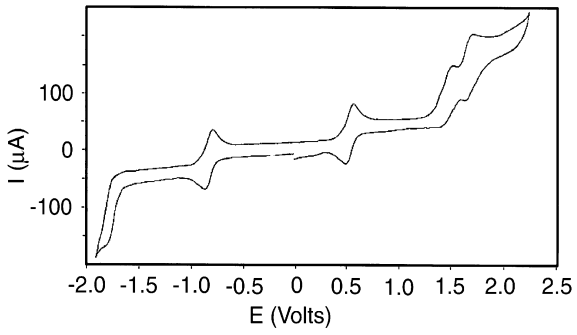

Fig. 5. Cyclic voltammogram of [Co^{II}(3-OCH_3-salo)$_2$(bipy)] (**1**), in CH_3CN with 0.1 M TEAP (scan rate 100 mV/s).

4	−0.82	−0.78	−0.80	0.40	0.46	0.44	1.40	1.46	1.43	1.63	−1.82	−1.43	−1.38	−1.41

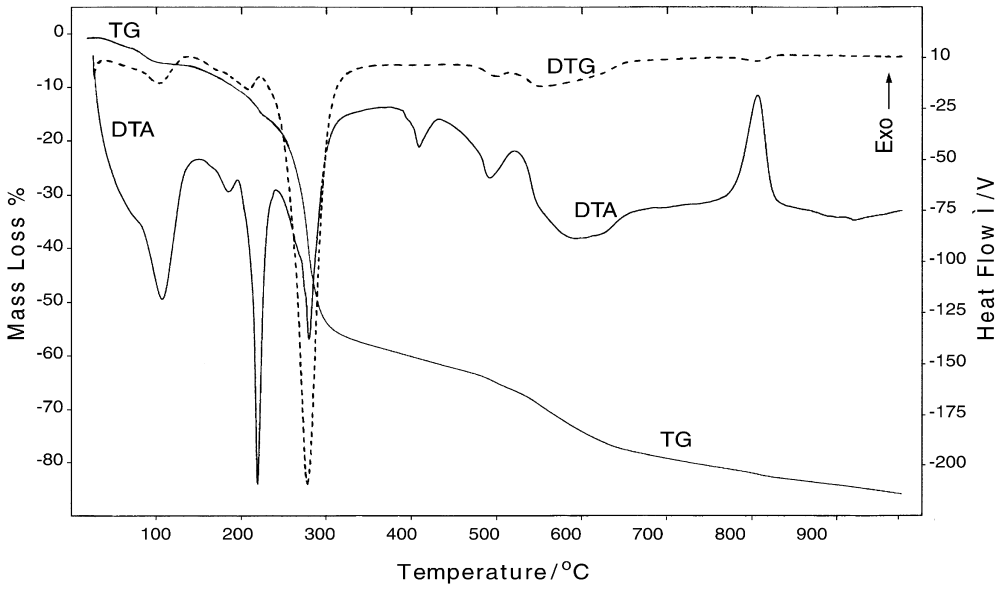

Fig. 7. Thermoanalytical curves (TG/DTG-DTA) of $[Co^{II}(3\text{-}OCH_3\text{-}salo)_2(bipy)] \cdot CH_3OH$ (**1**) in N_2 (heating rate 10 °C/min).

The sharp exothermic peak at 780 °C, accompanied by small mass loss, cannot be assigned with certainty, since in nitrogen atmosphere an exothermic peak maybe due to a sudden decomposition like an explosion or to crystallization.

4. Conclusions

The prepared noval octahedral compounds $[Co^{II}(X\text{-}salo)_2\text{-}(bipy)]$ are stable in air in the solid state and in CH_3CN solutions, while in CH_3OH and DMF solutions are gradually oxidized to Co(III). The theoretical ZINDO investigation with GAUSSIAN-03 for the prediction of the electronic spectrum, gave good correlation with the experimental spectrum in the solid state for the compound **1**. The cyclic voltammogram gave all the expected waves for the redox processes of the metal Co(II) and the ligands bipy and salicylaldehydes. X-ray studies of compounds **1** and **5** verified the existence of two octahedral Co(II) compounds coming from the same reaction. The compound **1** is very stable at ambient temperature, but unstable upon heating, decomposing to CoO at 980 °C in nitrogen, but at 500 °C in oxygen atmosphere.

Acknowledgment

We thank X. Sidiropoulos, Chemistry Department of Aristotle University of Thessaloniki for running the TG-DTA experiments.

Appendix A. Supplementary material

CCDC 267680 and 606952 contain the supplementary crystallographic data for **1** and **5**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2006.09.084.

applications in design of new biologically active metal–biomolecule compounds on the other hand. The importance of the effects of metal ions in stabilizing particular conformations in peptides has been shown for the copper(II) and zinc(II) complexes with *N*-phthaloylglycylglycine, in which the *N*-protected dipeptide adopted β-pleated conformations in the solid state [9]. While the zinc(II) complex was monomeric, the copper(II) complex had a polymeric structure formed by bridging carboxylates [9].

The steric van der Waals interactions between the aliphatic groups in the copper(II) chelates with *N*,*N*-dimethylated L-isoleucine, L-valine and L-leucine were suggested to be the cause for different EPR parameters measured for these complexes dissolved in hydrogen-bond making solvents [10–12]. The steric intramolecular and crystal lattice effects rather than electronic effects were attributed to cause the geometry differences found between the experimental crystalline molecular structures and the vacuum molecular structures (calculated applying the hybrid density functional method B3LYP [13–16]; the electronic properties were calculated using the natural population analysis (NPA) method [17]) for a series of anhydrous and aqua copper(II) complexes with amino acids [18,19]. These effects can be studied and modeled with the molecular mechanics method [18–20].

There have been a number of reported experimental crystal structures of bis-copper(II) complexes with glycine and *N*-alkylated glycine derivatives. These are: *cis* bis-(glycinato)copper(II) hydrate [21], *trans* diaquabis-(sarcosinato)copper(II) [22], *trans* aquabis(*N*,*N*-dimethylglycinato)copper(II) dihydrate [23], *trans* aquabis(*N*-*tert*-butyl-*N*-methylglycinato)copper(II) [24], *cis* and *trans* bis-(glycinato)copper(II) [25], *trans* bis(glycinato)copper(II) hydrate [25], and *trans* bis(*N*-*tert*-butyl-*N*-benzylglycinato)copper(II) [26]. The structural and electronic properties of the first four listed complexes were investigated [19], as well as of (di- and more) hydrated copper(II) chelates with glycine [27,28] by using the quantum chemical B3LYP [13–16] and NPA [17] methods. The mechanism of the *cis* to *trans* isomerism of bis(glycinato)copper(II) was theoretically studied in the gas phase [29] and related with the observed solid state *cis* to *trans* bis(glycinato)copper(II) geometry rearrangements [29,30].

The UV–Vis and IR characterizations of *trans* bis-(*N*,*N*-diethylglycinato)copper(II), $Cu(Et_2Gly)_2$, and *trans* bis(*N*,*N*-dibutylglycinato)copper(II) were reported by Nash and Scheafer [31]. They noticed that these two complexes as well as *trans* bis(D,L-*N*,*N*-diethylalaninato)-copper(II) formed red solutions when dissolved in benzene or ethylene chloride solutions. While bis(D,L-*N*,*N*-diethylalaninato)copper(II) retained the red color in the crystalline state, the two glycinato complexes changed the color from red to bluish upon cooling the solution and crystallization. Nash and Sheaffer concluded that the red color would mean truly four-coordinate complex, while blue color indicated the copper(II) coordination number greater than four [31]. Indeed the X-ray determination and refinement of the crystal structure of *trans* $Cu(Et_2Gly)_2$ presented for the first time in this Article revealed that the coordination about the copper atom was a distorted pyramid with carbonyl oxygen atom from neighboring molecule occupying the fifth copper(II) coordination position at a relatively short distance of 2.312 Å. To our best knowledge, such type of the copper(II) coordination geometry has not yet been observed for anhydrous *trans* bis copper(II) amino acid complexes in the crystalline state. It may be obvious that the copper(II) coordination geometry changed from four-coordinate to five-coordinate upon crystallization. Similar pyramidal coordination pattern with axially placed carbonyl oxygen was found in the crystal structures of *cis* bis(D-alaninato)copper(II) [32], *cis* bis(L-alaninato)copper(II) [33], and *cis* bis(glycinato)copper(II) [25] in which the carbonyl oxygen was 2.37 Å away from the copper(II). In the solid state structures of earlier reported *trans* bis copper(II) chelates with *N*,*N*-dialkylated amino acids, the copper(II) was either truly four-coordinate or with a water molecule at the fifth coordination position [19]. Conversely, in anhydrous *trans* bis copper(II) complexes with *N*-unsubstituted aliphatic amino acids the copper(II) coordination geometry was either an irregular square-planar or a distorted planar, with two carbonyl oxygen atoms from adjacent molecules in the crystal lattice completing an elongated octahedron [19].

This paper examines the ability of recently reported molecular mechanics (MM) force field FFW [19,20] developed for modeling anhydrous and aqua copper(II) amino acid complexes in simulated crystalline surroundings and in vacuo to reproduce the unit cell dimensions and molecular conformation of the novel crystal structure of $Cu(Et_2Gly)_2$. The study has been aimed at investigating the effects of steric interactions caused by the replacement of amino hydrogen atoms with flexible ethyl substitutents on the structural properties of the copper(II) glycinato complex in the solid state and vacuum. The conformational analysis of $Cu(Et_2Gly)_2$ showed that the experimentally obtained conformer was not the most stable in vacuo. The result has motivated us to study the intermolecular interactions of different conformers in the crystal state to elucidate the processes that governed the appearance of experimentally observed conformer in the real crystal structure.

2. Experimental

2.1. Syntheses and crystal structure determination

The *N*,*N*-diethylglycine ligand was prepared by condensation of glycine with acetaldehyde. The catalytic hydrogenation was carried out over three days at room temperature and 1.5 bar in ethanol/water (1:1) solution following the procedure of Bowman and Stroud [34]. After removing the catalyst, the product was recrystallized from ethanol/ether solution giving *N*,*N*-diethylglycine (m.p. 131–132 °C). The elemental analysis confirmed the composition

of the ligand. The $Cu(Et_2Gly)_2$ complex was prepared according to the modified procedure of Nash and Schaefer [31], i.e., by reaction of copper(II) acetate monohydrate with the sodium salt of *N*,*N*-diethylglycine in dichloromethane. The blue anhydrous crystals appeared upon slow evaporation from red-violet methylene chloride solution. Single blue crystals of polymeric $Cu(Et_2Gly)_2$ were obtained by recrystallization from water solution by slow evaporation at room temperature. The cell and refinement data were collected at room temperature using diffractometer with serial detector. The F^2 reflection data were prepared by standard data reduction procedure including the absorption correction.

The crystal structure of *catena*-poly[(*N*,*N*-diethylglycinato-κ*O*,κ*N*)copper(II)-μ-[*N*,*N*-diethylglycinato-κO^1,κ*N*:O^2]] was solved in the classical way using the heavy-atom method. Non-hydrogen atoms were allowed for anisotropic thermal motion. The hydrogen atom positions were calculated as riding atoms at default effective non-H-to-H atom distances according to corresponding sterteochemical requests. All calculations were performed and the figures were drawn using WinGX suite of programs [35].

Crystal data. $C_{12}H_{24}CuN_2O_4$, $M = 323.87$, monoclinic, $a = 9.9151(8)$ Å, $b = 7.4321(8)$ Å, $c = 21.2665(19)$ Å, $\beta = 103.122(7)°$, $V = 1526.2(2)$ Å^3, $T = 293(2)$ K, space group $P2_1/c$ (No. 14), $Z = 4$, μ(Mo Kα) = 1.44 mm^{-1}, 3693 reflections measured, 3331 unique reflections ($R_{int} = 0.017$). The final $R_1 = 0.0369$ (based on 2333 reflections with $I \geqslant 2\sigma I$), and 0.0704 (all data), $wR_2 = 0.1102$.

2.2. Molecular mechanics calculations

The conformational (strain) potential energy of the molecule was calculated from the following basic formula:

$$V_{\text{strain}} = \sum_{\text{bonds}} D_e(e^{-2\alpha(b-b_0)} - 2e^{-\alpha(b-b_0)}) + \frac{1}{2}\sum_{\text{valence angles}} k_\theta(\theta-\theta_0)^2 + \frac{1}{2}\sum_{\text{torsion angles}} V_\varphi(1 \pm \cos n\varphi) + \frac{1}{2}\sum_{\text{out-of-plane angles}} k_\chi\chi^2 + \sum_{i<j}\left(A_iA_jr_{ij}^{-12} - B_iB_jr_{ij}^{-6}\right) + \sum_{l<m} q_lq_mr_{lm}^{-1}$$

Here b, θ, φ, χ and r are bond lengths, valence, torsion, and out-of-plane angles, and nonbonded distances. D_e, α and b_0 are empirical parameters for bond stretching (a Morse function), k_θ and θ_0 for valence-angle bending, and k_χ for the out-of-plane deformational potential for the carboxyl group. Torsional interactions are specified with V_φ and n (height and multiplicity of the torsional barrier, respectively). One torsion per bond was calculated. A and B are one-atom empirical parameters for the van der Waals interactions (a Lennard-Jones 12-6 function). The q is a charge parameter. Intramolecular interactions separated by three and more bonds were considered nonbonded and calculated with the Lennard-Jones and electrostatic potentials. The interactions inside the copper(II) coordination sphere were modeled using the Morse potential between the copper and ligand donor atoms (two nitrogens and two oxygens), the repulsive electrostatic potential between the four donor atoms, and a torsion-like potential dependent on the "torsion" angle O–N–N–O, with two minima at 0° and 180° that correspond to the *cis*- and the *trans*-planar CuN_2O_2 configurations, respectively. It is a model without any explicit valence-angle bending potential for the angles around copper.

All MM calculations were performed using the modified [36] Lyngby version of the CFF program for conformational analysis [37–39], and with the force field FFW [19,20] suited for modeling anhydrous and aqua copper(II) complexes with aliphatic amino acids with *trans*- or *cis*-CuN_2O_2 coordination polyhedron.

In the Lyngby-CFF program [37–39], the input charge parameters are used for an assignment of fractional atomic charges. The assignment is done by a special charge redistribution algorithm, which keeps the total charge of the molecules neutral and distributes the charge values in a manner supposed to mimic ab initio results [36,39]. For the copper(II) amino acid complexes the charge redistribution algorithm has been adapted to yield the assigned fractional charges close to the charges resulting from NPA calculated for the bis-copper(II) complexes with L-*N*,*N*-dimethylvaline, L-alanine, L-leucine [18], as well as with glycine, sarcosine, *N*,*N*-dimethylglycine, and *N*-*tert*-butyl-*N*-benzylglycine [19].

A detailed description of the FFW's development as well as of the discussion on the efficacy of the force field in simulation and prediction of experimental crystal and molecular structures and quantum-chemically calculated vacuum structures can be found in our earlier paper [19]. Specifically, the modeling included experimental molecular and crystal structures of 13 anhydrous and 10 aqua copper(II) complexes with aliphatic amino acids and their alkyl derivatives. The efficacy of the force field expressed by means of the root-mean-square (rms) deviations between the experimental and theoretical crystal values of 23 copper(II) amino acid complexes were 0.018 Å in the bond lengths, 2.2° in the valence angles, 5.5° in the torsion angles (the hydrogen atoms were omitted in the internal coordinates' comparisons), 0.395 Å in the unit cell lengths, and the unit cell volumes were reproduced in the range from −8.1% to 9.6% [19].

The conformational potential energy was minimized for an isolated molecular system (in vacuo or a gas-phase approximation), and for a molecule surrounded with other molecules in the crystal lattice (a condensed-phase approximation). During the energy minimization of a crystal, all degrees of freedom (i.e., six lattice constants and 3N position coordinates of the N atoms in the asymmetric unit) were allowed to vary, except α and γ unit cell angles and all three unit cell angles in the cases of a monoclinic and an orthorhombic crystal, respectively. The chosen lattice constants were kept unchanged to preserve the presumed symmetry of the crystals. The other asymmetric units in the simulated crystalline environment were generated from

the original asymmetric unit by symmetry operations of a specific space group assigned to the crystal lattice. The intermolecular atom–atom interactions between the atoms of the original asymmetric unit of $Cu(Et_2Gly)_2$, and the atoms of surrounding asymmetric units, $V_{intermolecular}$, were calculated using the same functional forms (Lennard-Jones 12-6 function and coulombic potential) and empirical parameters as for the intramolecular nonbonded interactions. The crystal simulations were carried out by using the Williams variant of the Ewald lattice summation method [40,41] with a spherical and abrupt cut-off limit of 14 Å, and convergence constants of 0.2 $Å^{-1}$, 0.2 $Å^{-1}$, and 0.0 for Coulomb, dispersion, and repulsion lattice summation terms. A detailed description of the crystal simulations is given elsewhere [41]. The potential energy of the $Cu(Et_2Gly)_2$ molecule in the simulated crystal surroundings, $V_{crystal}$, was calculated as a sum of the intramolecular strain potential energy, V_{strain}, and the intermolecular van der Waals and electrostatic contribution (lattice energy), $V_{intermolecular}$, i.e., $V_{crystal} = V_{strain} + V_{intermolecular}$.

3. Results and discussion

3.1. The X-ray molecular and crystal structure

The asymmetric unit contains the copper atom coordinated in distorted square-planar fashion with two glycine ligands' oxygen and nitrogen atoms, respectively, attached to the metal center in *trans* position (Fig. 1). Selected bond distances and angles in polymeric $Cu(Et_2Gly)_2$ are listed in Table 1.

The displacement of copper from calculated best plane through the donor O and N atoms may be considered significant being 0.1749(4) Å. The deviation of the O(11)–Cu–O(21) and N(1)–Cu–N(2) from linearity is considerable (Table 1). Five-membered chelate rings have the conformation of an open envelope with different ring atoms on the flap. Nitrogen atom N(1) is moved out of the plane calculated through the Cu, O(11), C(11), and C(12), respectively, for 0.724(2) Å, while methylene carbon atom C(22) is shifted for 0.429(3) Å out of the best plane through the Cu, O(21), N(2), and C(21), respectively. The copper atom is coordinatively unsaturated. Oxygen atom $O(22^i)$ [(i): $1-x$, $y-1/2$, $-z+1/2$] from the neighboring molecule increases the Cu coordination number to 5 turning its coordination sphere from square-planar to distorted square-pyramidal. The chelate bidentate ligand containing O(22) serves as the bridging moiety between neighboring copper atoms developing the discrete endless coordination polymer chains spreading along the *y*-axis (Figs. 2 and 3). Neighboring parallel polymeric chains are held together by standard van der Waals interatomic interactions and through very weak C–H···O(12) and C–H···O(22) hydrogen bonding (i.e., close carbon to carbonyl oxygen atoms' intermolecular contacts are from 3.152 to 3.657 Å).

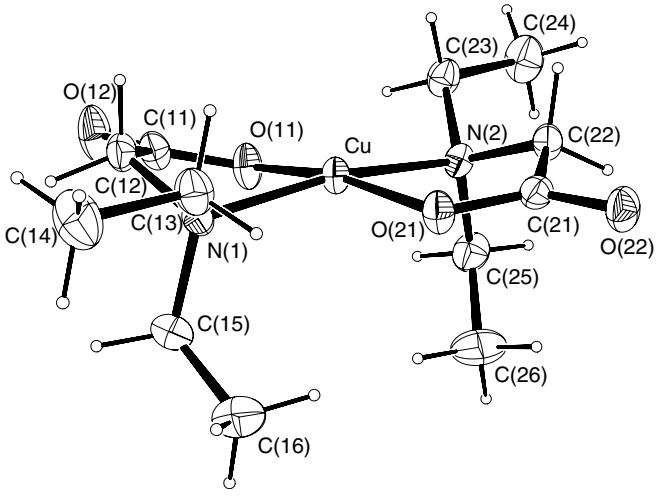

Fig. 1. An ORTEP-3 figure of the asymmetric unit with thermal ellipsoids drawn at 30% probability level.

The apical Cu–$O(22^i)$ bond distance is significantly longer than the basal Cu–O(11) and Cu–O(21) bond lengths (Table 1) and represents an average bond distance found in corresponding aqua copper(II) complexes with *N*-alkylated amino acids having water molecule placed in the apex of a square pyramid (bordering values from 2.206 to 2.464 Å) [23,24,42–46]. As expected, the copper atom is shifted out of the basal plane to the square-pyramid vertex. There are no significant discrepancies from standard non-hydrogen atoms bond lengths and bond angles values [20,22,24,31,42–46]. The intermolecular copper-to-oxygen linkage effects to the spatial orientation of the nitrogen atoms ethyl substituents (Fig. 3).

3.2. The MM simulation of the experimental molecular and crystal structure

The experimental atomic coordinates and the unit cell lengths and angles were taken as the starting point for geometry optimization using the crystal simulator of the Lyngby-CFF program [38,41]. All degrees of freedom were allowed to relax during the geometry optimization except the α and γ unit cell angles were kept equal to 90° to preserve required $P2_1/c$ unit cell symmetry.

According to the FFW input charge parameters given elsewhere [20], the fractional charges assigned to the atoms of $Cu(Et_2Gly)_2$ by the charge redistribution algorithm of the Lyngby-CFF program (see Section 2.2) are as follows: 1.31044 e (Cu), −0.61612 e [N(1) and N(2)], −0.85348 e [O(11) and O(21)], −0.65548 e [O(12) and O(22)], −0.26148 e [C(12), C(13), C(15), C(22), C(23), and C(25)], −0.57328 e [C(14), C(16), C(24), and C(26)], 0.86262 e [C(11) and C(21)], and 0.21152 e to the hydrogen atoms.

The FFW force field reproduces well the X-ray crystal data as it may be seen from the fit between the experimental and theoretical molecular and crystal structures depicted in Figs. 4 and 5. Table 1 lists selected theoretical internal coordinates of the simulated FFW(crystal) structure (we named it also as the 1-3 conformer) in line with their experimental values.

Table 1
Selected experimental bond distances (Å) and angles (°) in polymeric $Cu(Et_2Gly)_2$ and their corresponding theoretical FFW(crystal) and FFW(vacuum) values for two conformers named 1-3 (observed experimentally) and 12-12

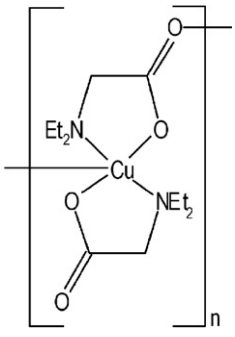

Fig. 2. Two-dimensional sketch showing the way the monomeric $Cu(Et_2Gly)_2$ units link together via Cu–O intermolecular bonding producing the polymeric chains.

As mentioned in Section 1, the short distance of 2.312 Å between the copper(II) and carbonyl oxygen atom of the neighboring complex has not been so far observed for the anhydrous *trans* bis-copper(II) amino acid complexes. The FFW force field yields the distance to be 2.599 Å. This value is in accord with the mean value of experimental intermolecular distances $Cu\cdots O_{carbonyl} = 2.79 \pm 0.23$ Å observed in 8 copper(II) complexes with aliphatic amino acids included in the modeling and parametrization of the FFW force field (FFW yielded the corresponding mean of Cu to carbonyl oxygen distances to be 2.72 ± 0.11 Å) [19]. The equilibrium Cu to O(22^i) distance yielded by FFW is the result of the interplay of intramolecular and intermolecular forces during the energy minimization. Generally, the intermolecular distances are reproduced with lower accuracy than the intramolecular bond lengths. The longer than observed Cu to O(22^i) distance and consequently less pronounced influence of the axially placed carbonyl oxygen on the distortion of the copper(II) coordination polyhedron are most probably the cause that the copper(II) coordination geometry is less distorted in FFW(crystal) than in the experimental crystal structure (Fig. 4, Table 1).

The shortage in the reproduction of the Cu to O(22^i) distance as well as of the extent of copper(II) coordination polyhedron distortion did not influence correct reproduction of the molecules' packing in the unit cell (Fig. 5).

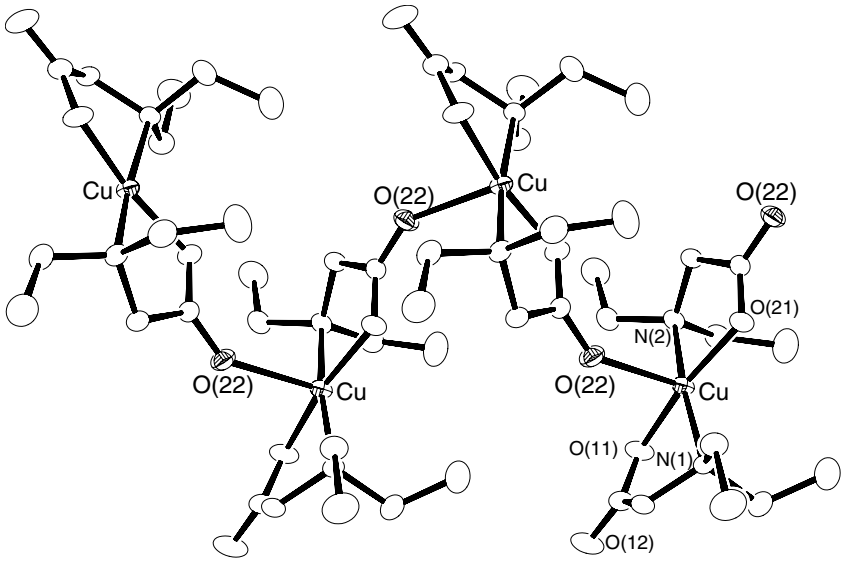

Fig. 3. An ORTEP-3 presentation of the discrete chain of the coordination polymer of *catena*-poly[(*N*,*N*-diethylglycinato-κ*O*,κ*N*)copper(II)-μ-[*N*,*N*-diethylglycinato-κO^1,κ*N*:O^2]] spreading along the *y*-axis. The hydrogen atoms are excluded because of clarity.

Fig. 4. The fit between the experimental X-ray crystal (in white) and theoretical FFW(crystal) (in black) molecular structures. Depicted in grey is the FFW(vacuum) structure calculated without the influence of the intermolecular forces. The molecule orientation is as in Fig. 1.

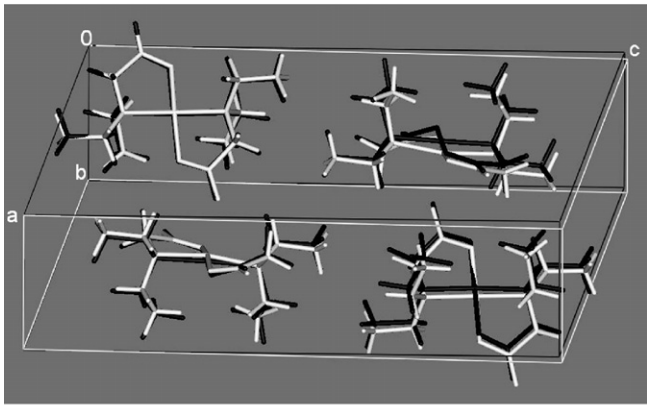

Fig. 5. The match of the unit cell dimensions and molecules' packing between the experimental X-ray crystal data (in white) and theoretical FFW(crystal) results (in black, $a = 9.8774$ Å, $b = 7.5125$ Å, $c = 21.1378$ Å, $\beta = 104.147°$, $V = 1520.9$ Å^3).

The relative error in reproducing the unit cell volume is 0.3%, showing that FFW models well the intermolecular aliphatic–aliphatic interactions between the ethyl groups, and the C–H···O(12) and C–H···O(22) hydrogen bonding. Namely, the differences between the experimental and theoretical close intermolecular contacts between the carbon atoms and carbonyl oxygen atoms are in the range from −0.057 Å up to 0.096 Å.

The rms deviations and maximum errors between the X-ray experimental and FFW(crystal) bond lengths, *b*, valence angles, *θ*, and torsion angles, *φ* (hydrogen atoms were not taken into account) are as follows: rms(Δ*b*) = 0.019 Å, $\Delta b_{max} = -0.053$ Å [for the C(13)–C(14) bond length], rms(Δ*θ*) = 2.9°, $\Delta\theta_{max} = -8.3°$ [for the O(11)–Cu–O(21) angle], and rms(Δ*φ*) = 3.2°, $\Delta\varphi_{max} = 5.7°$ [for the C(16)–C(15)–N(1)–Cu torsion]. These values are within the range of the maximum errors obtained for previously studied copper(II) amino acid complexes [19]. Specifically, the maximum differences calculated between the experimental and FFW internal coordinates for previously studied 13 anhydrous copper(II) chelates were −0.073 Å for the bond lengths, −8.3° for the valence angles, and −11.7° for the torsion angles [19]. By including $Cu(Et_2Gly)_2$ to the set of 23 anhydrous and aqua copper(II) amino acid complexes on which the FFW force field has earlier been examined [19], the total rms errors in the reproduction of experimental crystal data of currently 24 copper(II) chelates are 0.018 Å in the bond lengths, 2.3° in the valence

[a] Torsion angles are in °, and strain energies are in kcal mol^{-1}. Zero strain energy: −4221.69 kcal mol^{-1}.

angles, and 5.4° in the torsion angles. The presented results in reproducing the molecular and crystal structure of $Cu(Et_2Gly)_2$ additionally prove that the FFW force field is well suited for modeling bis-copper(II) complexes with aliphatic amino acids.

The impact of the crystal packing forces on the molecule geometry may be examined from the fit between the FFW(vacuum) and crystalline molecular structures (Fig. 4), and credited to be the most noticeable for the ethyl chain geometry (Table 1), i.e., for the groups that took part in the aliphatic–aliphatic interactions in the crystal lattice, and to more strained (i.e., more non-planar) five-atom chelate ring geometry in crystal than in vacuo.

3.3. Conformational analysis in vacuo

FFW was also used to study the strain energy distribution among the conformers of $Cu(Et_2Gly)_2$ in vacuo without the influence of the intermolecular interactions. From theoretical sterochemical considerations, it can be proposed that each chelate ring has 18 possible conformations; that is, two possible conformations of the five-atom chelate ring (characterized by the torsion angle $C'–C^{\alpha}–N–Cu \approx \pm 30°$) and nine combinations of the ethyl group orientations (as each ethyl group can adopt any of three possible orientations that correspond to the C–C–N–Cu torsion angle values close to 180°, 60°, or −60°). Table 2 lists the minimum strain energy values of the conformers having the same conformations of the two chelate rings, the minima's torsion angle values characterizing these conformers, and the number-names we assigned to the conformers. The conformation found in the experimental crystal structure (Figs. 1 and 4) corresponds to the conformation mixed between the 1-1 and 3-3 conformers (Table 2), and accordingly we called it as the 1-3 conformer (Fig. 6).

In the gas phase the 1-3 conformer is predicted to have the strain energy, V_{strain}, greater than the most stable conformer 12-12 (Table 2, Fig. 6) by 9.21 kcal mol^{-1}. In vacuo the most stable conformers 12-12 and 9-9 (Table 2) have the ethyl groups oriented perpendicularly to the chelate ring planes, shielding the copper coordination site for axial bonding (Fig. 6). As we initially supposed four-coordinate complex in the red-violet solution, the forming of close intramolecular van der Waals aliphatic–aliphatic contacts between the C–H

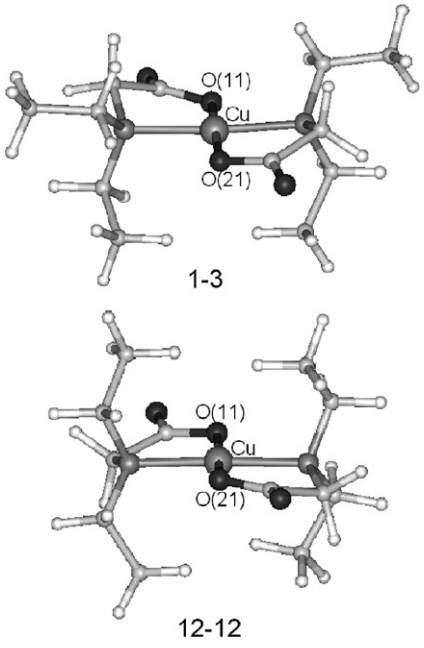

Fig. 6. FFW(vacuum) minimum structures of the 1-3 and 12-12 conformers (selected internal coordinates are given in Table 1).

groups, and the inaccessibility of the fifth copper(II) coordination site make these conformers stereochemically and energetically suited to be prevailing conformers in solution too. Conversely, the 1-3 conformer has the ethyl groups oriented to make possible bonding of the carbonyl oxygen atom to the copper(II) as well as forming intermolecular aliphatic–aliphatic interactions between the ethyl groups in the crystal lattice (Figs. 3, 5 and 6). Therefore, we supposed that not only the change in the copper(II) coordination geometry but also in the molecular conformation occurred upon crystallization.

3.4. Unit cell packings and intermolecular interactions of different conformers

To verify the supposition that a conformer having the ethyl group orientations so as to make the fifth copper(II) coordination site accessible for axial bonding (i.e., the conformer with at least one ethyl group torsion angle C–C–N–Cu ≈ 180°) is better suited for crystal packing than the vacuum most stable conformers 12-12 and 9-9, we extended the conformational analysis to the calculations of crystal lattice packings of selected conformers (mostly of

[a] Thicken line marks the conformers with the lowest energies calculated.
[b] Zero $V_{crystal}$ value corresponds to −4258.44 kcal mol^{-1}.

the conformers having lower in vacuo strain energy, Table 2). The energy minimizations were started from equilibrium vacuum Cartesian coordinates for a series of conformers, and from the same unit cell dimensions, $P2_1/c$ space group symmetry operations, and molecule's orientation as in the experimental structure. For instance, the 12-1 conformer had the initial orientation such that its chelate ring conformations 12 and 1 (defined in Table 2) were in place of experimental chelate ring conformations 1 and 3, respectively. The in-crystal energy values for the obtained minima are given in Table 3. The geometry optimizations for the conformers with the same combination of the chelate ring conformations were started from their two possible orientations (e.g., 1-12 and 12-1) and usually led to different minima (Table 3), revealing the dependence of the energy minimization result on the initial orientation. For some conformers, a conformational change occurred during energy minimization, e.g., the 9-12 conformer transformed into the 12-12 conformer (the minimum denoted as 12-12 (min 2) in Table 3). Table 4 lists the unit cell dimensions of 9 minima having lowest V_{cystal} energies obtained (the unit cell dimensions of the 1-3 minimum are given in Fig. 5).

It seems reasonable to assume that during the process of crystallization from solution the $Cu(Et_2Gly)_2$ molecules tended to arrange themselves in the solid state so as to form as many aliphatic–aliphatic close contacts between the C–H groups, the C–H···O hydrogen bonds as well as the axial coordinative bonds between the copper(II) and carbonyl oxygen atoms as possible. Indeed systematically the lowest $V_{\text{intermolecular}}$ energy values were yielded by FFW for the conformers that could form close axial Cu to O(22) intermolecular bonding (Tables 3 and 4). The energy differences between the V_{cystal} values obtained for most of the conformers having the same combination of the chelate ring conformations are up to 3–4 kcal mol^{-1} (Table 3). Larger energy differences were obtained only for the conformers having the chelate ring conformation 15, and for the 7-12 and 12-7 conformers (Table 3). One more $P2_1/c$ minimum of 12-12 (denoted as 12-12 (min 3) in Table 4; relative V_{crystal} = 1.50 kcal mol^{-1}, $V_{\text{intermolecular}}$ = −37.02 kcal mol^{-1}), and two predicted crystal packing minima of the 12-12 conformer in space group $P2_12_12_1$ (for which the molecule orientation and the unit cell lengths of the $P2_1/c$ 12-12 and 12-12 (min 3) minima (Table 4), respectively, were taken as the input data prior to energy minimization) are also within the energy difference range of 3 kcal mol^{-1}. Namely, V_{cystal} of one $P2_12_12_1$ minimum differed by −0.79 kcal mol^{-1} ($V_{\text{intermolecular}}$ = −38.53 kcal mol^{-1}; a = 6.799 Å, b = 15.830 Å, c = 13.955 Å, V = 1502.1 Å^3) and of the second one differed by 0.77 kcal mol^{-1} ($V_{\text{intermolecular}}$ = −37.03 kcal mol^{-1}; a = 10.760 Å, b = 7.826 Å, c = 18.541 Å, V = 1561.3 Å^3) from the lowest energy 12-12 minimum calculated in space group $P2_1/c$ (Tables 3 and 4) and illustrated in Fig. 7.

For some conformers other space group symmetry operations and differently chosen initial conditions prior to energy minimization may lead to more energetically favorable minimum. However, on the basis of the achieved in-crystal results for the conformers of $Cu(Et_2Gly)_2$ and within the MM calculation approximations applied, we expect that if there is any energetically more favored crystal packing than already found for the 12-12 and 9-9 conformers, its $V_{\text{intermolecular}}$ is unlikely to overcome the intermolecular potential energy difference of about 7–9 kcal mol^{-1} between the in-crystal minima of 12-12 and 9-9 on one side

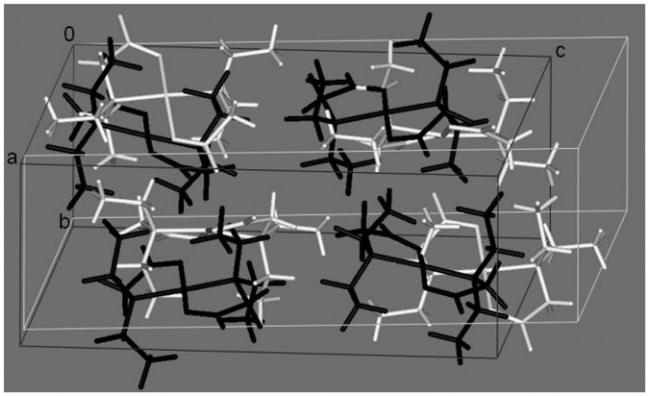

Fig. 7. The predicted unit cell packing of the 12-12 conformer in space group $P2_1/c$ (denoted in black; unit cell dimensions are given in Table 4) compared with the experimental X-ray crystal unit cell (denoted in white).

Table 4

9-9	10.639	7.790	18.339	98.09	1504.7	4.272, 4.350

[a] Vacuum strain energy values for the conformers not listed in Table 2 are as follows (relative to −4221.69 kcal mol^{-1}): 9.21 kcal mol^{-1} for 3-1; 5.47 kcal mol^{-1} for 9-1; 4.37 kcal mol^{-1} for 1-12; 3.43 kcal mol^{-1} for 15-12; 6.38 kcal mol^{-1} for 15-3.

and the conformers having the ethyl groups' orientation that allows close axial coordinative bonding to the copper(II) on the other side (Tables 3 and 4).

The 14-14 conformer had the most favorable intermolecular interactions (-47.06 kcal mol^{-1}, Table 3) but too large intramolecular strain (Table 2) to allow the possibility of its crystallization in the real case. The next conformer with the lowest intermolecular interaction energy is the 1-3 conformer (Fig. 5), followed by the 3-3 conformer (Tables 3 and 4). The theoretical results confirmed what we would expect, that both intramolecular stability and crystal lattice close packing affect the occurrence of specific conformer in the solid state. As the 1-3 conformer has been observed in the real crystal structure, and FFW predicts its V_{crystal} as well as $V_{\text{intermolecular}}$ among the most favorable ones (Table 3), we choose the 1-3 minimum (Fig. 5, Table 1) to discuss its crystal packing in relation to the 12-12 minimum (Fig. 7, Table 1). Hence, the 1-3 and 12-12 conformers are selected to represent the conformers that can have and cannot have the axial Cu to carbonyl oxygen atom coordinative bonding in the solid state, respectively.

The energy difference between the 1-3 and 12-12 theoretical structures dropped from 9.21 kcal mol^{-1} in the vacuum to 1.43 kcal mol^{-1} in the simulated crystal surroundings. The energy drop is due to the intermolecular potential energy contribution, $V_{\text{intermolecular}}$, as the difference between the 1-3 and 12-12 intramolecular V_{strain} energy contributions to V_{crystal} amounts 10.52 kcal mol^{-1}. Therefore, the possibility of the 1-3 conformer to form both the aliphatic–aliphatic interactions and the Cu to axial O coordinative bonding lowered the in-crystal potential energy difference relative to the 12-12 conformer. As already mentioned, FFW overestimated the Cu to carbonyl oxygen distance in the simulated crystal structure of the 1-3 conformer (Table 1), and thus most probably underestimated the energy contribution of the interaction between Cu(II) and axially placed O(22^{i}) that might have decreased (or even increased in favor to 1-3) the difference between the potential energy of this particular conformer and other conformers in the crystal lattice. Whether further reparametrization of the FFW force field (which might be a rather complicated task [19]) may offer more definite answer on the energetic problem of this particular interaction remains to be examined in forthcoming studies. However, the difference between the intermolecular energy contributions of 12-12 and 1-3 equals 9.09 kcal mol^{-1} (8.40 kcal mol^{-1} for the $P2_12_12_1$ 12-12 minimum) and gives a quantitative proof that the crystal packing forces favor the 1-3 conformation over the 12-12 one.

4. Conclusions

The X-ray diffraction measurements of the crystal structure of *catena*-poly[(*N*,*N*-diethylglycinato-κ*O*,κ*N*)copper(II)-μ-[*N*,*N*-diethylglycinato-κO^1,κ*N*:O^2]] reveal that five-coordinate copper(II) coordination geometry and coordination polymer chain formation can occur in the crystal structures of anhydrous *trans* bis-copper(II) amino acid complexes. Good match between the experimental and simulated crystal structures of the title compound confirms the reliability of the FFW force field for modeling steric aliphatic–aliphatic interactions in the copper(II) amino acid complexes. The MM results suggest that intermolecular aliphatic–aliphatic interactions between flexible ethyl groups replacing the amino hydrogen atoms in glycine affected the changes in the molecular conformation and consequently in the copper(II) coordination sphere upon crystallization of $Cu(Et_2Gly)_2$. The MM force field applied for the conformational analysis in vacuo and in crystal yielded the results to assist in understanding the crystallization process from solution.

Recently, our group has paid attention to the study of new tin sulfur-based compounds with oxygen or other ligands [9]. We have reported the first octanuclear tin oxy-sulfide clusters $[Sn_8S_{12}O_4(SPh)_6]^{6-}$ [9a], and subsequently developed a simple route to prepare $[Sn_8S_{12}(\mu_4\text{-}O)_2(\mu_2\text{-}OH)_2Cl_6]^{6-}$ and $[Sn_{10}S_{16}(\mu_4\text{-}O)_4Cl_4]^{4-}$ [9b]. During our investigation on the reaction behavior of $(Bu_4N)_2[Sn_3S_4(edt)_3]$, two novel trinuclear tin(IV) oxy-sulfide complexes of $(Bu_4N)[Sn_3(\mu_3\text{-}OH)S_3(edt)_3]\cdot DMF$ (**1**) and $(Bu_4N)[Sn_3(\mu_3\text{-}OH)S_3(edt)_3]\cdot H_2O$ (**2**) were unexpectedly obtained. Herein, the syntheses, structures and characterizations of complexes **1** and **2** are reported.

2. Experimental

2.1. Materials and instrumentation

All synthetic operations were performed in air. $(Bu_4N)_2[Sn_3S_4(edt)_3]$ [10], $Zn(SCN)_2$ [11] and $Cd(SCN)_2$ [12] were synthesized according to the literature. The other chemicals and reagents were of reagent grade and were used as received without further purification. Carbon, hydrogen and nitrogen analyses were performed on a Vario EL III Elemental Analyzer. The infrared and far-infrared spectra were recorded on a Nicolet Magna 750 FT-IR spectrometer using pressed KBr and CsI pellets, respectively. The samples for Raman spectra were diluted with KBr powder and placed in an NMR tube. The Raman spectra were taken on a Nicolet Magna 950 Raman spectrometer. Mass spectra (ES-MS) were measured on a Finngan LCQ mass spectrometer using CH_2Cl_2 as solvent. ^1H NMR spectra were obtained on a Unity 500 MHz NMR spectrometer.

2.2. Synthesis of $(Bu_4N)[Sn_3(\mu_3\text{-}OH)S_3(edt)_3]\cdot DMF$ (1)

2.2.1. Method 1

To the colorless solution of $(Bu_4N)_2[Sn_3S_4(edt)_3]$ (0.125 g, 0.1 mmol) in 10 ml of CH_3CN, a 1 ml solution of DMF containing CuI (0.019 g, 0.1 mmol) and KI (0.017 g, 0.1 mmol) were rapidly added while stirring. The resulting mixture was stirred for 1 h, followed by filtration to remove brown deposits. The pink filtrate was allowed to crystallize in air. Three weeks later, a lot of colorless prismatic crystals were obtained, washed with *i*-propanol and dried in air. Yield: 0.032 g (30% based on $(Bu_4N)_2[Sn_3S_4(edt)_3]$) Elemental *Anal.* Calc. for $C_{25}H_{56}N_2O_2S_9Sn_3$: C, 28.29; H, 5.32; N, 2.64. Found: C, 28.93; H, 5.48; N, 2.76%. IR (KBr pellet) and far-IR (CsI pellet) spectra: (cm^{-1}): 3563w, 3374w, 2958s, 2906s, 2872s, 1641m, 1467m, 1413m, 1382m, 1284m, 1247w, 1160w, 921m, 845m, 737w, 640w, 440m, 357s, 306m, 255w, 222w, 198w. Raman spectrum (cm^{-1}): 2991s, 1117m, 557w. ^1H NMR (Unity 500, $CDCl_3$, $-NCH_2^dCH_2^cCH_2^bCH_3^a$): δ 1.041–1.070 (12H, $^3J(^1H\text{–}^1H) = 15$ Hz, $-CH_3^a$), 1.520–1.564 (8H, $^3J(^1H\text{–}^1H) = 15$ Hz, $-CH_2^b$), 1.693–1.707 (8H, $-CH_2^c$), 2.888, 2.963 (6H, $-NCH_3$), 3.009–3.164 (12H, $^3J(^1H\text{–}^1H) = 77.5$ Hz, $1SCH_2$), 3.219 (1H, –OH), 3.284–3.317 (8H, $^3J(^1H\text{–}^1H) = 16.5$ Hz, $-CH_3^d$), 8.022 (1H, –COH).

2.2.2. Method 2

$(Bu_4N)_2[Sn_3S_4(edt)_3]$ (0.125 g, 0.1 mmol) and $CuCl_2$ (0.013 g, 0.1 mmol) were dissolved in 5 ml of DMF to give a red solution. This red solution was allowed to stand in air for one day, resulting in a brown precipitate. The precipitate was removed by filtration. The colorless filtrate was placed on a surface utensil to crystallize in air. Three days later, lots of colorless crystals were obtained, washed with ether and dried in air. Yield: 0.010 g (9.4% based on $(Bu_4N)_2[Sn_3S_4(edt)_3]$).

2.3. Synthesis of $(Bu_4N)[Sn_3(\mu_3\text{-}OH)S_3(edt)_3]\cdot H_2O$ (2)

2.3.1. Method 1

$Zn(SCN)_2$ (0.020 g, 0.11 mmol) and 1,10-phen · $2H_2O$ (0.020 g, 0.1 mmol) were dissolved in 10 ml of CH_3CN/CH_2Cl_2 (1:1) and stirred for 3 h. $(Bu_4N)_2[Sn_3S_4(edt)_3]$ (0.125 g, 0.1 mmol) was added into the solution, resulting in a white turbid solution. The mixture was stirred for 2 h and then filtered. The colorless filtrate was allowed to crystallize in air. Three weeks later, lots of colorless block crystals were obtained and washed with *i*-propanol and dried in air. Yield: 0.036 g (35.4% based on $(Bu_4N)_2[Sn_3S_4(edt)_3]$). Element *Anal.* Calc. for $C_{22}H_{51}NO_2S_9Sn_3$: C, 26.26; H, 5.11; N, 1.39. Found: C, 26.59; H, 5.05; N, 1.60%. IR (KBr pellet) and far-IR (CsI pellet) spectra (cm^{-1}): 3629m, 3561m, 3403m, 3162w, 2958s, 2904s, 2871s, 1477m, 1467m, 1416w, 1379m, 1288w, 1250w, 1180w, 922w, 891w, 735w, 669w, 640w, 441m, 357s, 307w, 251w, 199m; Raman spectrum (cm^{-1}): 2991m, 1120s, 561m; ^1H NMR (Unity 500, $CDCl_3$, $-NCH_2^dCH_2^cCH_2^bCH_3^a$): δ 1.041–1.069 (12H, $^3J(^1H\text{–}^1H) = 14$ Hz, $-CH_3^a$), 1.550 (8H, $-CH_2^b$), 1.707 (8H, $-CH_2^c$), 3.010–3.168 (12H, $^3J(^1H\text{–}^1H) = 79$ Hz, $-SCH_2$), 3.221 (1H, –OH), 3.284–3.312 (8H, $^3J(^1H\text{–}^1H) = 14$ Hz, $-CH_3^d$).

2.3.2. Method 2

$Cd(SCN)_2$ (0.020 g, 0.09 mmol) and 1,10-phen · $2H_2O$ (0.020 g, 0.1 mmol) were added into 20 ml of CH_3CN/CH_2Cl_2 (1:1). The mixture was stirred for 3 h. To the mixture $(Bu_4N)_2[Sn_3S_4(edt)_3]$ (0.125 g, 0.1 mmol) was added. The mixture was stirred for another 2 h and then filtered. The colorless filtrate was left in air. Three weeks later, lots of colorless block crystals were obtained. The crystals were filtered and washed with *i*-propanol and dried in air. Yield: 0.016 g (16.0% based on $(Bu_4N)_2[Sn_3S_4(edt)_3]$).

2.4. X-ray crystallography

Crystal data for compound **1** was collected at 130.15 K on a Rigaku RAXIS IIc Smart/CCD diffractometer with Mo Kα radiation ($\lambda = 0.71073$ Å). Data reduction, cell

refinements and absorption correction were performed with CrystalClear software (Rigaku Corp., 2000). Crystal data for compound **2** was collected at 293(2) K on a Siemens Smart/CCD diffractometer with Mo Kα radiation ($\lambda = 0.71073$ Å). Data reduction and cell refinements were performed with Smart-CCD software. An absorption correction was applied by using SADABS software [13].

In the two compounds, all non-hydrogen atoms and the hydrogen atoms of OH were located through direct methods. All non-hydrogen atoms, except disordered atoms, were refined anisotropically by full-matrix least-squares methods. All hydrogen atoms, except the hydrogen atom of OH, were generated geometrically. All calculations were performed by SHELXL-97 [14]. Final $R = \sum\|F_o| - |F_c\|/\sum|F_o|$ and $Rw = [\sum[w(F_o^2 - F_c^2)^2]/\sum w(F_o^2)^2]^{1/2}$ with $w = 1/[\sigma^2(F_o^2) + (aP)^2 + bP]$ (where $P = (F_o^2 + 2F_c^2)/3$). A summary of crystal data and structure refinement for the two compounds is provided in Table 1. Selected bond lengths and angles for **1** and **2** are summarized in Table 2. H-bond data of the two compounds are listed in Table 3.

3. Results and discussion

3.1. Syntheses

As shown in Scheme 1, compound **1** was obtained through the reaction of $[Sn_3S_4(edt)_3]^{2-}$ with $CuCl_2$ or $KCuI_2$ in the presence of DMF, while compound **2** was formed by the reaction of $[Sn_3S_4(edt)_3]^{2-}$ with Zn(1,10-phen)$(SCN)_2$ or Cd(1,10-phen)$(SCN)_2$ in CH_3CN/CH_2Cl_2 (1:1). Our original aim was to prepare cubane-like clusters through the addition reaction of $[Sn_3S_4(edt)_3]^{2-}$ with metal blocks. However, two new compounds containing the same

Scheme 1. Replacement of μ_3-S by μ_3-OH in the anion cluster of $[Sn_3S_4(edt)_3]^{2-}$ in the presence of proper desulfurizing agents.

incomplete cubane-like anion clusters of $[Sn_3(\mu_3\text{-}OH)S_3(edt)_3]^-$ capped by μ_3-OH and with different H-bond acceptors were unexpectedly obtained. This may because Zn^{2+}, Cu^{2+} or Cd^{2+} play the role of sulfide scavengers in the reactions. A similar phenomenon has been reported previously in the literature [15]. The mechanism may be that the looser μ_3-S–Sn bond was first cleft by Zn^{2+} (Cu^{2+} or Cd^{2+}), and then OH^- was incorporated into the three tin atoms to form $[Sn_3(\mu_3\text{-}OH)S_3(edt)_3]^-$. The bridging OH^- in the two compounds might come from trace water in the solvents.

3.2. Description of the crystal structures of complexes *1* and *2*

As shown in Fig. 1, there are two crystallographically independent but chemically equivalent DMF molecules, two anions and two cations in the asymmetric unit. ORTEP drawing of anions A and B are shown in Fig. 2. In anion A three tin atoms are connected by a central μ_3–OH and three μ_2-S atoms, affording an incomplete cubane-like skeleton. The skeleton is similar to that of $[Sn_3S_4(edt)_3]^{2-}$ [10] except that the central μ_3-S is replaced by μ_3-OH. The average Sn···Sn separation (Sn(1)···Sn(2) 3.533 Å, Sn(1)···Sn(3) 3.559 Å, Sn(2)···Sn(3) 3.563 Å) is 3.552 Å, and is shorter than that of $(Et_4N)_{2n}[Sn_3S_7]_n$ (3.6053 Å) [3d], but is longer than that of $\{[(c\text{-}C_5H_9)_7Si_7O_{12}Sn]_3(OH)_4\}^-$ (3.512 Å) [17]. All tin atoms are five-coordinated by two sulfur atoms of $SC_2H_4S^{2-}$, two μ_2-S and one μ_3-OH in a trigonal bipyramidal geometry. The sum of the equatorial angles are 356.96° (S(2)–Sn(1)–S(9) 120.85(6)°, S(2)–Sn(1)–S(7) 120.12(6)°, S(7)–Sn(1)–S(9) 115.99(5)°) for Sn(1), 356.29° (S(7)–Sn(2)–S(3) 123.36(6)°, S(7)–Sn(2)–S(8) 113.89(6)°, S(3)–Sn(2)–S(8) 119.04(5)°) for Sn(2) and 355.39° (S(8)–Sn(3)–S(5) 119.02(5)°, S(8)–Sn(3)–S(9) 113.97(6)°, S(9)–Sn(3)–S(5) 122.40(5)°) for Sn(3). They are all less than 360°, indicating that all the Sn atoms are slightly deviated from the corresponding equatorial plane. All the axial angles of O(1)–Sn(1)–S(1) (179.54(11)°), O(1)–Sn(2)–S(4) (177.03(11)°) and O(1)–Sn(3)–S(6) (177.18(10)°) are also slightly deviated from 180°. Thus the coordination geometry of each tin atom can be described as a distorted trigonal bipyramid.

The average axial Sn–S bond length (2.4507(15) Å) is obviously longer than that of equatorial Sn–S

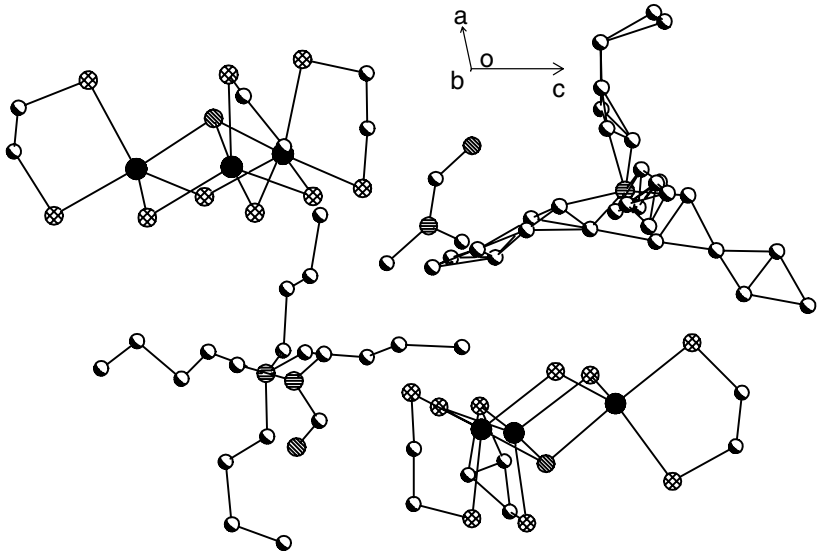

Fig. 1. Perspective view of complex **1** showing two crystallographically independent but chemically equivalent anions, two cations and two DMF molecules in the asymmetric unit.

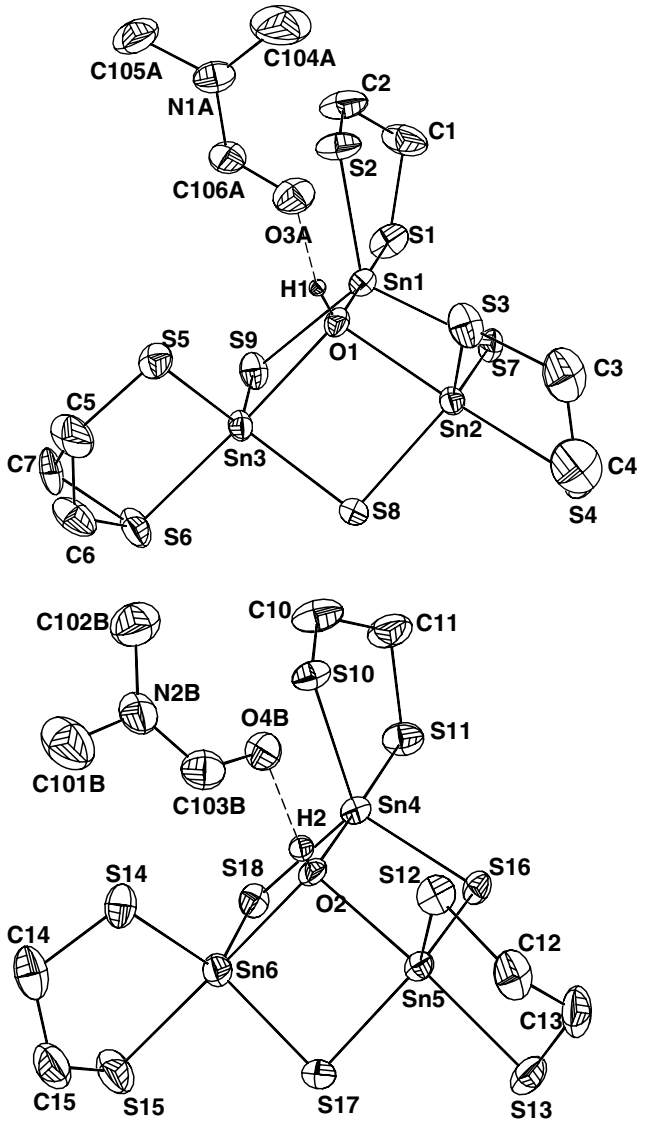

Fig. 2. ORTEP diagrams of anion A (top) and anion B (bottom) in the asymmetric unit of complex **1** with the atom numbering scheme (all non-hydrogen atoms are represented by ellipsoids at 50% probability). Symmetry code: A: $x-1$, y, z; B: $x+1$, y, z.

(2.4040(15) Å). The Sn–O bond lengths fall in the range of 2.287(4)–2.346(4) Å, and their average bond length (2.310 Å) is longer than that of $\{[(c\text{-}C_5H_9)_7Si_7O_{12}Sn]_3(OH)_4\}^-$ (2.276 Å) [17]. The separation of O(1)–O(3A) is 2.739(5) Å, suggesting the presence of an intermolecular H-bond between the cluster of $[Sn_3(\mu_3\text{-}OH)S_3(edt)_3]^-$ and the neighboring DMF molecule.

As shown in Fig. 2, anion B also possesses an incomplete cubane-like metal skeleton. The average Sn···Sn separation is 3.55 Å, and the average bond lengths of Sn–O(2), $Sn–S_{axial}$ and $Sn–S_{equatorial}$ are 2.313, 2.4543 and 2.406 Å, respectively. They are all comparable with those in anion A. The separation of O(2)–O(4B) of 2.774(5) Å is slightly longer than that in anion A.

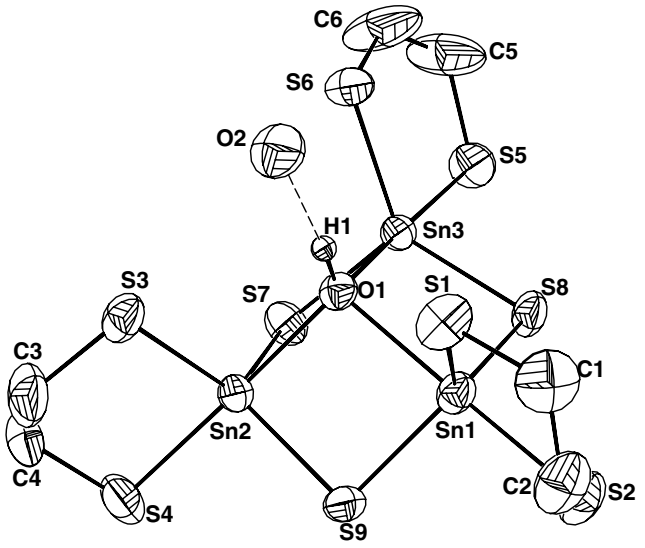

Fig. 3. ORTEP diagram of the anion of complex **2** with the atom numbering scheme (all non-hydrogen atoms are represented by ellipsoids at 40% probability).

Different from anion B, disorder (C6) exists in anion A. In addition, serious disorders are present in one cation of Bu_4N^+ (the details can be seen in Supplemental CIF file).

The anion structure of complex **2**, as shown in Fig. 3, is similar to that of **1** except that the hydrogen acceptor is the water molecule. The H-bond data for complexes **1** and **2** are summarized in Table 3.

3.3. Spectrum

The broad band around 3400 cm^{-1} in the IR spectra of the two compounds suggests the presence of the OH group. For complex **1**, the characteristic stretching vibration of C=O, occurring about 1640 cm^{-1}, is shifted to lower frequency by 35 cm^{-1} with respect to the standard IR spectrum of DMF film, owing to the formation of an intermolecular H-bond. The band around 198 cm^{-1} in the spectra of the two compounds could be attributed to νSn–O [8b]. The medium absorption bands in the region of 300–450 cm^{-1} should be ascribed to the Sn–S stretching vibrations [8b,16].

In the Raman spectra of **1** and **2**, an obvious medium peak for νC–S is found at 557 and 561 cm^{-1}, respectively. The peak around 1120 cm^{-1} could be attributed to the stretching vibration of νC–N.

It can be seen from Table 4 that the ^1H NMR chemical shift (δ) of Sn–OH varies greatly in the range of 1.60–8.90 ppm depending on their various chemical and physical environments [17–24]. The ^1H NMR chemical shift (δ) of Sn–OH for complexes **1** and **2** was found at 3.219 and 3.221 ppm, respectively.

The ES-MS spectra for the two compounds show the molecular ion peak of $[Sn_3(\mu_3\text{-}OH)S_3(edt)_3]^-$ at around 744.6 (m/z).

[{$C_2S_3N_2(PhCH_2)_2$Sn}$_2$O$(PhCH_2)_2$Sn(OH)(OEt)]	5.15	$CDCl_3/D_2O$ 300 MHz	[24]

4. Conclusion

In summary, two new incomplete cubane-like trinuclear tin (IV) oxy-sulfide clusters $(Bu_4N)[Sn_3(\mu_3\text{-}OH)S_3(edt)_3]\cdot DMF$ (**1**) and $(Bu_4N)[Sn_3(\mu_3\text{-}OH)S_3(edt)_3]\cdot H_2O$ (**2**) were prepared by a cluster-skeleton substitution reaction based on the precursor $(Bu_4N)_2[Sn_3S_4(edt)_3]$. The two compounds differ only in controlling the nature of the solvate molecule which is hydrogen bonded to the cluster in the resulting solid. $CuCl_2$, $KCuI_2$, Cd(1,10-phen)$(SCN)_2$ or Zn(1,10-phen)$(SCN)_2$ were found to act as a mild desulfurizing agent under the appropriate conditions. This may provide a convenient method for preparing new tin oxy-sulfides.

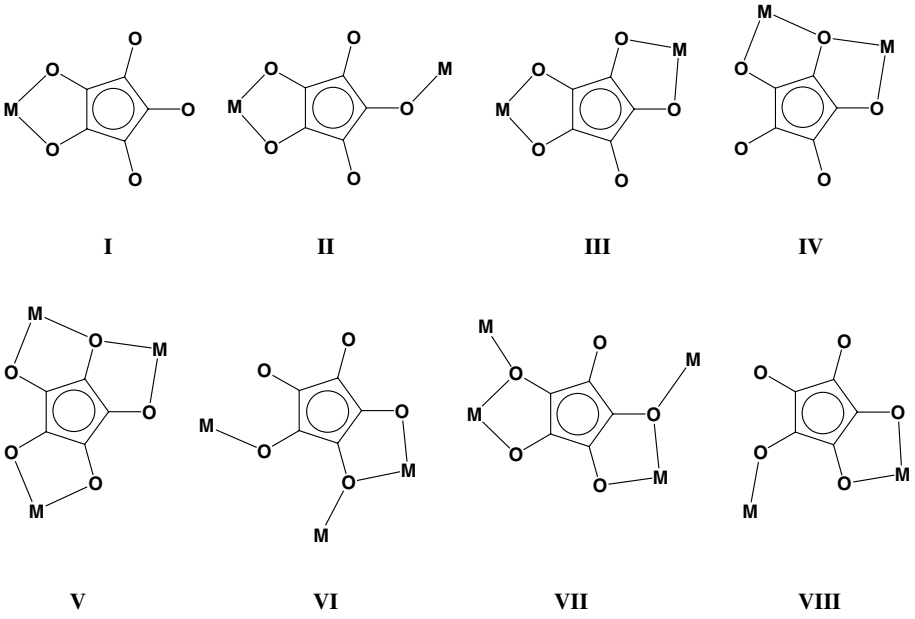
the use of squarate afforded notable works through versatile bridging modes [6]. On the contrary, the number of reports relating to the coordination chemistry of the croconate dianion is limited. A few structures of first row transition metal-croconate systems, $[M(II)(C_5O_5)(H_2O)_3]$ [M = Cu, Zn, Mn, Fe and Co] [7] and of some croconate complexes associated with co-ligands such as imidazole [8], histamine [9], 2,2′-bipyridine [10], 4,4′-bipyridine, [11] bis(2-pyridylcarbonyl)amido anion, [12], etc. are reported. A literature survey reveals different binding modes (Scheme 1) of croconate: bidentate chelate (**I**) [5f,7a,8–10,13], bridging bidentate/monodentate (**II**) [7a,7b,7c], bridging bis-bidentate ligand through either four (**III**) [12,14] or three adjacent (**IV**) [14,15] croconate oxygen atoms and bidentate chelate/bridging bis-bidentate chelate (μ_5) (**V**) [11]. Recently our group reported three new different bridging modes of croconate, acting as a tridentate (**VI**) and tetradentate ligand (**VII**) [5a,16] in Cd(II)- and Ag(I)–Na(I) complexes, respectively, and bridging bidentate chelate/monodentate (**VIII**) [17] in a Cu(II) complex where C–H···O interactions contribute to control the coordination bond formation in the metal-organic framework (MOF). Moreover we have also reported the croconate dianion sitting as a lattice moiety in the solid state architecture, which stabilizes the MOF through H-bonding occurring between its oxygens and coordinated water molecules [18]. The present contribution reports the synthesis, crystal structure and thermal behavior of $\{[Co(4,4'\text{-bipy})(H_2O)_4]\cdot(C_5O_5)\cdot(H_2O)_2\}_n$ (**1**), $\{[Fe(4,4'\text{-bipy})(H_2O)_4]\cdot(C_5O_5)\cdot(H_2O)_2\}_n$ (**2**) and $\{[Co_2(bpds)_2(C_5O_5)_2(H_2O)_4]\cdot(H_2O)_3\}_n$ (**3**) networks [4,4′-bipy = 4,4′-bipyridyl, bpds = 4,4′-bipyridyl disulfide, $C_5O_5^{2-}$ = croconate dianion], all having a 3D supramolecular architecture.

2. Experimental

2.1. Materials

High purity 4,4′-bipyridyl (98%), 4,4′-bipyridyl disulfide (aldrithiol-4; 98%) and the disodium salt of croconic acid were purchased from the Aldrich Chemical Co. Inc. and were used as received. All other chemicals were of AR grade.



2.2. Physical measurements

Elemental analyses (carbon, hydrogen and nitrogen) were performed using a Perkin–Elmer 240C elemental analyzer. IR spectra were measured using KBr pellets on a Nicolet 520 FTIR spectrometer. The magnetic susceptibility was measured at 27 °C using an EG and G PAR-155 vibrating sample magnetometer, using $Hg[Co(SCN)_4]$ as reference material; a diamagnetic correction was made by using Pascal's constants. The UV–Vis reflectance spectra were recorded between 200 and 1400 nm on a Perkin–Elmer Lambda 950 spectrophotometer at room temperature in the solid state. Thermogravimetric analyses were carried out on a Mettler Toledo Star system.

2.3. Synthesis

2.3.1. $\{[Co(4,4'\text{-bipy})(H_2O)_4]\cdot(C_5O_5)\cdot(H_2O)_2\}_n$ (1)

The complex was synthesized by slow diffusion of a mixture of a methanolic solution (10 ml) of 4,4′-bipyridyl (1 mmol, 0.156 g) and the disodium salt of croconic acid (1 mmol, 0.186 g, dissolved in a minimum amount of water) over an aqueous solution (10 ml) of $Co(NO_3)_2\cdot 6H_2O$ (1 mmol, 0.291 g). Single crystals suitable for X-ray

Scheme 1.

analysis were obtained at the junction of the layers after a few days. Yield: 70%. *Anal.* Calc. for $C_{15}H_{20}CoN_2O_{11}$ (463.26): C, 38.85; H, 4.31; N, 6.04. Found: C, 38.84; H, 4.33; N, 6.05%. μ_{eff} at 300 K = 5.05 BM.

*2.3.2. $\{[Fe(4,4'\text{-bipy})(H_2O)_4]\cdot(C_5O_5)\cdot(H_2O)_2\}_n$ (**2**)*

A methanolic solution (10 ml) of 4,4′-bipy (1 mmol, 0.156 g) was gently poured into an aqueous solution (5 ml) of the disodium salt of croconic acid (1 mmol, 0.186 g). Ferrous ammonium sulfate hexahydrate (1 mmol, 0.393 g) in water (5 ml) was added to this solution dropwise with constant stirring. A deep red complex separated out. Single crystals suitable for X-ray analysis were obtained by diffusing the aqueous solution (5 ml) of ferrous ammonium sulfate hexahydrate on a water–methanol (1:2) layer (15 ml) of the disodium salt of croconic acid and 4,4′-bipy (1:1) in a corked tube. The red colored single crystals were deposited at the junction of the two solutions after a few weeks. Yield: 70%. *Anal.* Calc. for $C_{15}H_{20}FeN_2O_{11}$ (460.18): C, 39.14; H, 4.35; N, 6.09. Found: C, 39.09; H, 4.31; N, 6.05%. μ_{eff} at 300 K = 5.52 BM.

*2.3.3. Complex $\{[Co_2(bpds)_2(C_5O_5)_2(H_2O)_4]\cdot(H_2O)_3\}_n$ (**3**)*

A methanolic solution (5 ml) of $Co(NO_3)_2\cdot 6H_2O$) (1 mmol, 0.291 g) was added to a methanolic solution (5 ml) of bpds (1 mmol, 0.220 g) dropwise with constant stirring. To this reaction mixture an aqueous solution (10 ml) of the disodium salt of croconic acid (1 mmol, 0.186 g) was added and stirred for 30 min. It was filtered and deep brown single crystals suitable for X-ray analysis were obtained from the filtrate kept in a $CaCl_2$ desiccator after a few days. Yield: 75%. *Anal.* Calc. for $C_{30}H_{30}Co_2N_4S_4O_{17}$ (964.68): C, 37.32; H, 3.11; N, 5.81. Found: C, 36.66; H, 3.24; N, 5.71%. μ_{eff} at 300 K = 5.00 BM.

2.4. Crystallographic data collection and refinement

Crystal data and details of data collection and refinement for the structures reported are summarized in Table 1. The data collections were carried out using Mo Kα radiation ($\lambda = 0.71073$ Å) at 293(3) K on a Nonius DIP-1030H system (complexes **1** and **2**) and at 100(3) K on a Bruker SMART (complex **3**) equipped with a CCD area detector. Cell refinement, indexing and scaling of the data sets were performed using the program MOSFLM [19]. All the structures were solved by the Patterson method and Fourier analyses and refined by the full-matrix least-squares method based on F^2 with all observed reflections [20]. The calculations were performed using the WinGx System, Ver 1.64.05 [21].

3. Results and discussion

3.1. IR spectroscopy

The IR spectra of complexes **1** and **2** in the 1400–1800 cm^{-1} region, where characteristic bands for the different binding modes of the croconate dianion are observed,

Table 1

Residuals (e Å^{-3})	0.696, −0.381	0.293, −0.227	1.241, −0.625

[a] $R_1 = \sum||F_o|-|F_c||/\sum|F_o|$, $wR_2 = [\sum w(F_o^2 - F_c^2)^2/\sum w(F_o^2)^2]^{1/2}$.

[b] Goodness-of-fit $= \{\sum[w(F_o^2 - F_c^2)^2]/(n-p)\}^{1/2}$.

exhibit a very strong and broad band (ca. 1500 cm^{-1} for **1**; 1502 cm^{-1} for **2**) and one sharp band (1662 cm^{-1} for **1**; 1660 cm^{-1} for **2**). The former band is assigned to a mixture of ν(C–C) and ν(C–O) stretching vibrations and the latter to ν(C=O) of croconate [8], which hints that the oxocarbon species function as a counter anion rather than being involved in the coordination sphere. IR spectra of complex **3** in the same region possess some different bands: a very strong band at 1514 cm^{-1} and three strong bands at 1540, 1591 and 1485 cm^{-1}. The broad band (3500–3200 cm^{-1}) in all the complexes confirms the presence of water molecules. The IR spectra also show bands corresponding to ρ_r (H_2O) [735, 731 and 725 cm^{-1} for **1**, **2** and **3**, respectively] and $\rho_w(H_2O)$ [636, 636 and 625 cm^{-1} for **1**, **2** and **3**, respectively] which indicate the presence of coordinated water molecules.

3.2. Description of the structures

3.2.1. $\{[Co(4,4'\text{-bipy})(H_2O)_4]\cdot(C_5O_5)\cdot(H_2O)_2\}_n$ (**1**) and $\{[Fe(4,4'\text{-bipy})(H_2O)_4]\cdot(C_5O_5)\cdot(H_2O)_2\}_n$ (**2**)

The crystal structures having the same stoichiometry are described together in order to compare the subtle details that differentiate their geometry. The iron derivative (complex **2**) is isomorphous to that containing manganese(II), reported by this laboratory a couple of years ago [18]. A drawing of the packing with the atom labelling scheme is shown in Figs. 1 and 2, and a selection of bond lengths and angles is given in Tables 2 and 3. The present complexes reveal Co$(H_2O)_4^{2+}$ and Fe$(H_2O)_4^{2+}$ units bridged by 4,4′-bipy ligands with the occurrence of 1D coordination polymeric chains (Figs. 1 and 2). Four water molecules (O(1w), O(2w) and the symmetry related ones) form the equatorial plane and the 4,4′-bipy nitrogen atoms N1 and N2 occupy the *trans* axial positions. The metal and 4,4′-bipy nitrogen donors are positioned on a mirror plane in complex **1** and on a twofold axis in **2**. This different symmetry site leads to a N–Co–N bond angle of 177.90(12)°, while the N–Fe–N fragment is collinear. The Fe–N distances (Table 3) are slightly shorter than the values of 2.237 Å found in the mononuclear complex, $[Fe(H_2O)_4(bipy)_2]$(disaccharinate) [22].

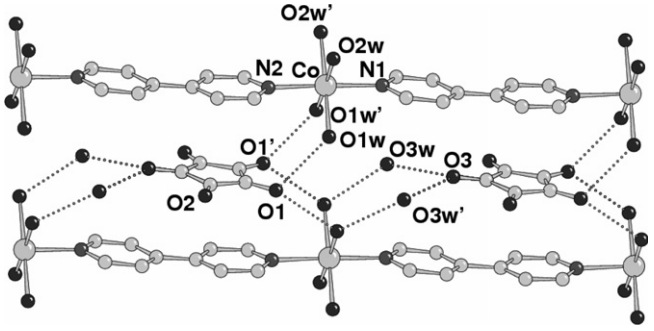

Fig. 1. Coordination polymer in complex **1** developed along the *c*-axis with the encapsulated croconate dianion (dotted lines indicate H-bonds).

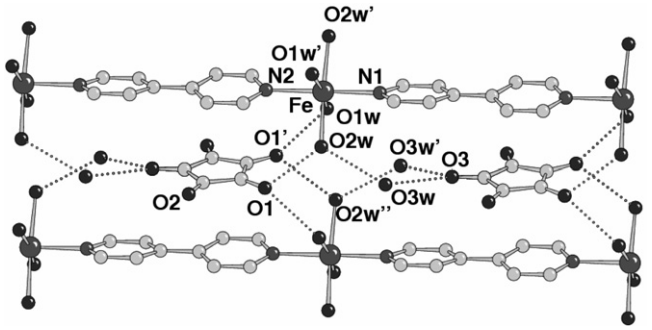

Fig. 2. Coordination polymer in complex **2** running along the *b* axis with the encapsulated croconate dianion (dotted lines indicate H-bonds).

		N(1)–Fe–N(2″)	180.0

Symmetry operations: (′) $-x+1$, y, $-z+3/2$; (″) x, $y-1$, z.

The water oxygens of the equatorial plane are coplanar in complex **1** and exhibit a slight distortion in complex **2** (±0.104 Å), with the metal ion displaced from this mean plane by 0.031(2) Å (Co) and 0.035(1) Å (Fe) towards N(1). From a careful analysis of Tables 2 and 3 it is worth noting in both cases there are differences between the M–O bond distances for the two independent H_2O ligands (~30σ) and between the two M–N distances (~10σ). We do not have an explanation for this feature, the packing and the environment of the cited atoms not being indicative for these apparent discrepancies. The rings of the 4,4′-bipy ligand are almost coplanar in complex **1**, but rather tilted by about 12° in the iron derivative (**2**).

The intermetallic distances connected by the 4,4′-bipy ligand are 11.325(3) Å (Co–Co) and 11.437(3) Å (Fe–Fe), which are to be compared with the value found in the Mn derivative of 11.531(4) Å; these values follow the increasing ionic radius of the metal(II).

The croconate dianions, encapsulated between contiguous polymeric chains at a distance of about 3.4 Å from

the N(2) pyridine rings of 4,4′-bipy, give rise to a H-bonding scheme involving coordinated and lattice water molecules (Figs. 1 and 2). However, the H-bonding pattern leading to the supramolecular architecture in the two crystals is slightly different. H-bonds are formed between the croconate O(1) and coordinated water molecules, while croconate oxygen O(3) is connected to the lattice water molecules O(3w), but in such a way that the latter interact with water molecules of the same chain in complex **1**, but with aqua ligands of different polymers in complex **2**. The three dimensional structure is achieved through O(2) of an adjacent croconate that behaves as a H-bond acceptor with respect to O(1w) and O(3w). The latter interactions are not shown in Figs. 1 and 2.

3.2.2. $\{[Co_2(bpds)_2(C_5O_5)_2(H_2O)_4]\cdot(H_2O)_3\}_n$ (**3**)

The structural determination evidences two crystallographic independent metal ions in a severely distorted octahedral coordination with O_4N_2 chromophore (Fig. 3), embracing a chelating croconate dianion, two water molecules and two nitrogens, all arranged in *cis* positions. The octahedral coordination spheres are highly distorted with deviations of up to 10° from ideal angles (Table 4). It is worth noting that the pyridine rings present an unsymmetrical coordination, as evident from Fig. 3, with a Co–N···S angle that varies from 168.62° to 174.02°, the pyridine ring N(4) being the most bent. The Co–OH_2 bond lengths, falling in the range 2.051(4)–2.093(4) Å, are about 0.05–0.10 Å shorter than the Co–N [2.106(4)–2.150(5) Å] and the Co–O(croconate) ones [2.133(4)–2.196(4) Å]. The involvement of oxygen atoms in H-bonding (*vide supra*) may account for these differences.

Table 4
Selected bond lengths (Å) and angles (°) for complex **3**

Co(1)–O(1w)	2.091(4)	Co(2)–O(3w)	2.093(4)

Symmetry operation: (′) $x-1, y-1, z$.

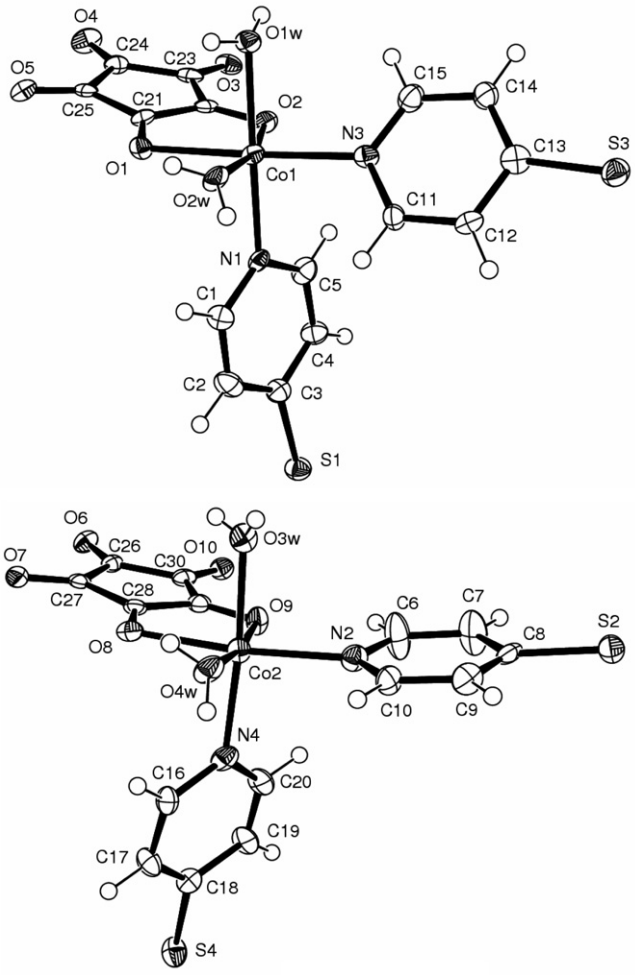

Fig. 3. ORTEP view of the metal coordination sphere of the two independent cobalt ions in complex **3** (ellipsoid at the 40% probability level).

The crystal structure comprises of a 1D undulating polymeric chain of $[Co(H_2O)_2(C_5O_5)]$ neutral units linked by bpds spacers (Fig. 4). Along the –Co–(bpds)–Co– array the metal ions are alternatively separated by 11.598(2) and 10.999(2) Å, with a Co–Co–Co angle of 147.32(1)°. The different Co–Co distance is caused by the slightly dissimilar conformation of the two bpds ligands. These present a C–S–S–C torsion bond angle of 91.8(3)° and 101.7(3)°, leading to a slightly different N–N bridging distance, 7.840, and 8.452 Å, respectively.

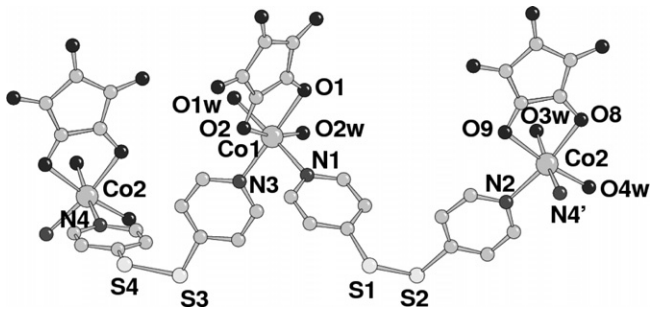

Fig. 4. Coordination polymer of complex **3**.

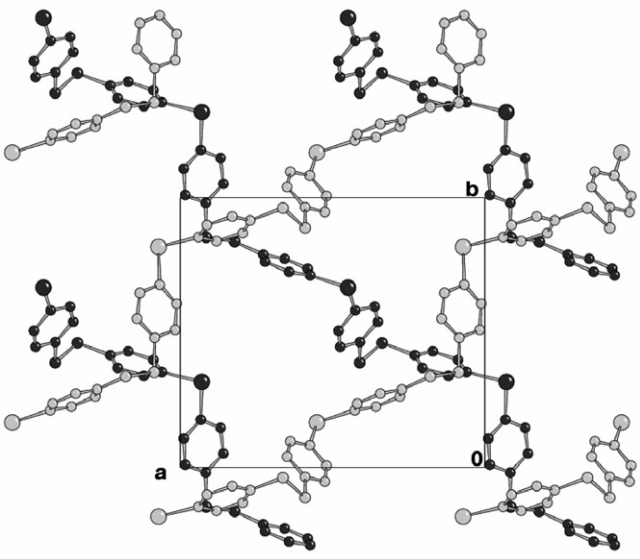

Fig. 5. Packing diagram of Co(dpds) polymers in complex **3** projected down the *c* axis (water molecules and croconate not shown for the sake of clarity).

The torsion angles of bpds linkers are well within or slightly above the range of values [83.8(6)–95.5(8)°] reported for a series of metal complexes [23], where the authors stated that bpds is "a rather conformationally rigid linker".

Series of coordination polymers running in different directions are piled parallel to the [0 0 1] plane and a different conformation of the bpds ligands may be caused in order to favor the crystal packing (Fig. 5). Finally, a H-bonding interaction occurring among coordinated and lattice water molecules as well as croconate oxygens (Table 5) leads to a 3D supramolecular architecture. It is interesting to note that in the crystal the shortest intermetallic distance between different polymers is 6.851 Å [Co(1) and Co(2) at $-x$, $1/2 + y$, $1/2 - z$].

3.3. Thermal analysis

Thermogravimetric analysis of complex **1** shows desolvation in the temperature range 100–156 °C. The TG profile (Fig. 6) hints loss of two lattice and four coordinated water molecules (Fig. 1) taking place simultaneously (mass loss: experimental, 23.31% and calculated, 23.32%) without showing any intermediate step. The deaquation temperature range corroborates the involvement of H-bonding among the coordinated/lattice water molecules and the croconate dianion (Fig. 1). The deaquated species (**1a**, blue) is stable up to 270 °C. The IR spectral bands of the

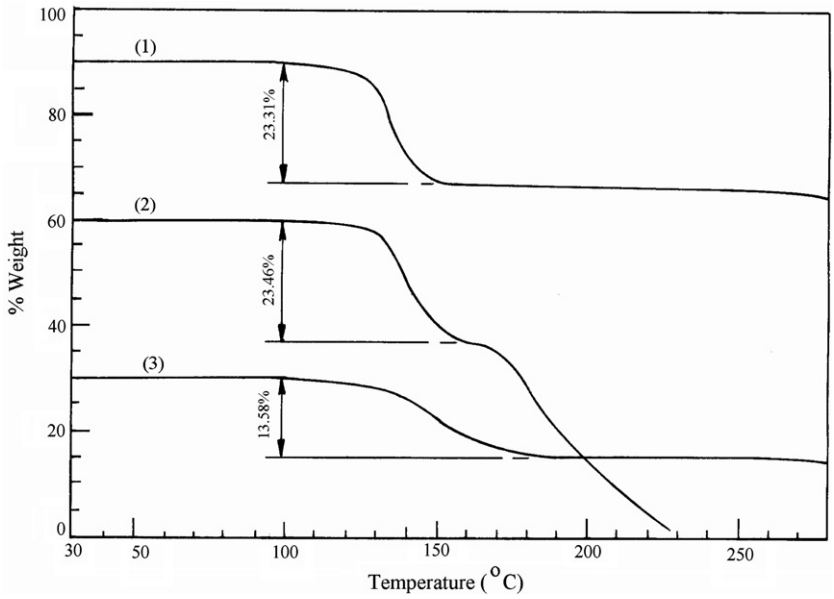

Fig. 6. Thermogravimetric curves for complexes **1**, **2** and **3**.

dehydrated complex, assigned to ν(C–C) and ν(C–O) stretch vibrations of the croconate moiety, shift towards lower wavenumber, splitting at 1481 and 1413 cm^{-1}. The band corresponding to ν(C=O) weakens and shifts to 1637 cm^{-1}. One additional band at 1604 cm^{-1}, assigned to ν(C=C), is obtained. These facts indicate linkage of the croconate dianion with the cobalt(II) center. It is interesting to note that **1a** looks transparent when observed under an optical microscope with a polarizer, but X-ray powder diffraction analysis indicates an amorphous material. Moreover, the croconate dianion may function as a bridging ligand to satisfy the tetrahedral coordination geometry of Co(II) in **1a** [solid state electronic spectra (19445, ~16646 and 8495 cm^{-1} for **1**) and (19275, 17970, 13990–15475 and 8798 cm^{-1} for **1a**) and room temperature magnetic measurements (μ_{eff} for **1** 5.05 BM and for **1a** 4.81 BM (at 300 K)]. On exposure to humid atmosphere (RH ~ 80%) **1a** reverts at ambient temperature showing thermochromism due to octahedral ⇌ tetrahedral geometrical transformation. X-ray powder diffraction analysis also corroborates the above facts.

Complex **2** is thermally stable up to 130 °C and shows deaquation beyond this temperature and gets deaquated (mass loss: experimental, 23.46%; calculated, 23.47%) at 160 °C. The deaquated species collapses immediately upon further heating as the iron(II) centers fail to attain the required geometry after removal of water molecules.

Upon heating complex **3** up to 100 °C there is no mass change, then upon further heating coordinated and lattice water molecules are released in two steps, overlapping each other, in the temperature range ~100 to ~185 °C, yielding blue species, **3a** (mass loss: experimental, 13.58%; calculated, 13.07%). The deaquation temperature range corroborates the structural results which evidence the existence of H-bonding among the coordinated/lattice water molecules and croconate dianion. The species **3a** is stable up to 300 °C and does not revert on exposure to humid atmosphere (RH ~ 80%) at ambient temperature. Room temperature magnetic susceptibility measurement of **3a** was carried out but the difference of magnetic moment between **3** and **3a** is negligible. There is difference in the electronic mull spectral bands, though, which indicate a tetrahedral geometry around Co(II) in **3a**. It is to note that the color change upon deaquation is not prominent like **1**.

4. Conclusion

Three supramolecular architectures using the croconate dianion and bipyridyl spacers have been investigated. The presence of oxocarbons dianions as lattice species or as metal ligands leads to 1D coordination polymeric chains of different topology. Structure determination of complexes **1** and **2** shows $Co(H_2O)_4$ and $Fe(H_2O)_4$ units connected by bridging 4,4′-bipy. The adjacent chains undergo H-bonding with the lattice croconate dianion and water molecules to form a 3D supramolecular architecture. In contrast, the polymer of complex **3** is built of bridging bpds, with metals coordinated by chelating croconate and two water molecules. The resulting chains undergo H-bonding with the lattice water molecules resulting in a 3D supramolecular network in the solid state. Thermal study shows octahedral–tetrahedral transformations taking place in complexes **1** and **3** in the solid state.

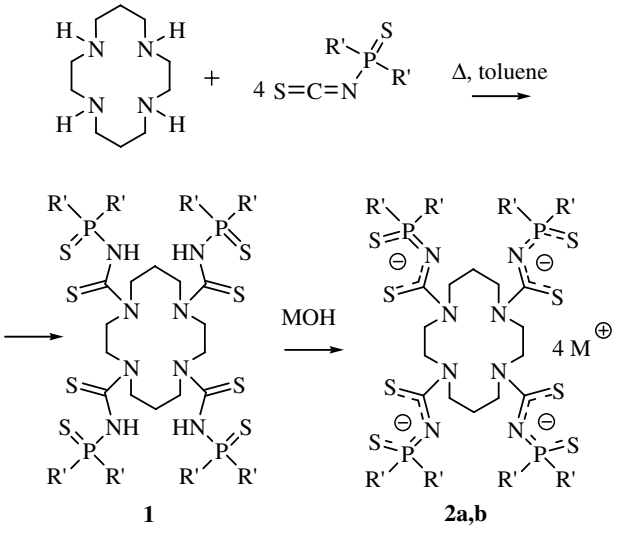
Surprisingly, urea derivatives of 1,4,7,10-tetraazacyclododecane (cyclen) and 1,4,8,11-tetraazacyclotetradecane (cyclam) have, to the best of our knowledge, been reported in the literature by a unique example [13]. Although the introduction of carbamoyl groups at the nitrogen atoms reduces their basicity and binding ability irreversibly, the clean and high-yielding reaction is useful for receptor synthesis [13].

Herein we present the synthesis and structure determination of novel tetrafunctional *N*-thiophosphorylated thiourea, based on a cyclam backbone. The syntheses and studying of its salts with sodium and potassium ions, and the complex with the $[Cu(PPh_3)_2]^+$ cation is also reported.



2. Results and discussion

2.1. Synthesis

Thiourea **1** was prepared by the reaction of cyclam with the isothiocyanate of diisopropyl-thiophosphoric acid in toluene (Scheme 1). The compound was obtained as a crystalline solid, soluble in most polar solvents. Its composition has been confirmed by elemental analysis.

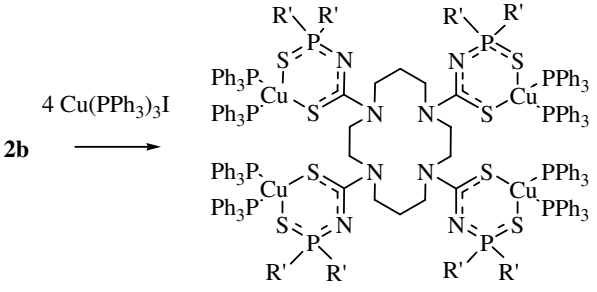
IR, ^{31}P and ^{1}H NMR spectroscopy data have shown that thiourea **1** partially decomposes in solution with elimination of isothiocyanate $(i\text{PrO})_2\text{P(S)NCS}$ molecules, while the four-substituted product **1** has been isolated in the solid state.

Addition of acceptor groups to the cyclam nitrogen atoms results in the substantial decrease of the donor abilities of the cyclic nitrogens [13] and the macrocyclic cavity loses its efficacy to coordinate metal ions. In our case, hydrogens of cyclam NH groups are substituted by acylamidophosphate.

R' = O*i*Pr M = Na+ (**2a**), K+(**2b**)

Scheme 1.

It was found that deprotonation of the exocyclic functions prevents the dissociation of the $(i\text{PrO})_2\text{P(S)NCS}$ moiety, as is the case in the sodium and potassium M_4L salts **2a**,**b**. Salts **2a**,**b** were prepared by the reaction of the hydroxide of the corresponding metal in aqueous ethanol (Scheme 1). The compounds obtained are polycrystalline solids soluble in water and acetone. The salt **2b** has been used for copper(I) complex synthesis by the reaction with $Cu(PPh_3)_3I$ in aqueous ethanol–dichloromethane solution (Scheme 2).



Chelating C(S)NP(S) units are coordinated with the copper(I) cation with a {*S*,*S*′}-bidentate donor set of thiocarbonyl and thiophosphoryl groups. Compound **3** is a stable polycrystalline solid, soluble in dichloromethane, chloroform, acetone and DMF.

2.2. IR and NMR spectroscopy

The IR spectrum of **1** in Nujol contains the unique absorption band of the NH group at 3110 cm^{-1}. There are two absorption bands at 1496 and 1518 cm^{-1} corresponding to the S=C–N group. The absorption band assigned to the P=S group is displayed in the characteristic area at 660 cm^{-1}. The wide absorption band of the ester POC unit of **1** at 1000 cm^{-1} unequivocally confirms the presence of the substituted thiophosphoryl moiety.

The IR spectrum in Nujol does not exhibit any band in the 1980–2200 m^{-1} range. In a CCl_4 solution of **1** there is a band at 1988 cm^{-1}, corresponding to the absorption of the S=C=N group. It may indicate that thiourea **1** partially dissociates in solution with elimination of isothiocyanate $(i\text{PrO})_2\text{P(S)NCS}$ molecules. ^{31}P and ^{1}H NMR spectroscopy data confirm this suggestion. There are two singlet signals at $\delta = 59.7$ and 43.1 ppm in the $^{31}P\{^1H\}$ NMR spectrum of **1**. The major signal at $\delta = 59.7$ ppm is in the region that is characteristic for *N*-thiophosphorylated thioamides and thioureas [9], whereas the second one corresponds to the isothiocyanate $(i\text{PrO})_2\text{P(S)NCS}$ [14].

The ^{1}H NMR spectrum of **1** contains a double set of signals assigned to $(i\text{PrO})_2\text{P(S)}$ protons. The signals of CH_3 and OCH protons of acylamidophosphate fragments are at $\delta = 1.37$ ppm with $^3J_{H,H} = 6.0$ Hz and 4.86 ppm with

3, R' = O*i*Pr

Scheme 2.

$^3J_{H,H} = 6.2$ Hz and $^3J_{POCH} = 12.4$ Hz. The signals of CH_3 and OCH protons of $(i\text{PrO})_2\text{P(S)NCS}$ are broad singlets at $\delta = 1.56$ and 4.93 ppm, respectively. The set of multiplets corresponding to CH_2 protons at $\delta = 1.78$–4.43 ppm, derives from the cyclam moiety.

The broadened signal corresponding to the NHP(S) proton of thiourea **1** is observed at 6.99 ppm. The broad peak of the $NHCH_2$ proton is also observed, supporting the presence of an unsubstituted nitrogen in the cyclam moiety.

The IR spectrum of **2a** in Nujol is similar to that of **2b**. The absorption bands of the P=S group of the anionic forms of thiourea **1** in salts **2a**,**b** are shifted by approximately 35 cm^{-1} to lower frequencies relative to the band of the parent ligand **1**. This confirms the deprotonation of the exocyclic fragments [9]. The NH band is not seen in the IR spectra of the **2a** and **2b** salts. There are intensive absorption bands of the deprotonated thioamide groups around 1532 (**2a**) and 1538 (**2b**) cm^{-1} [9]. These bands and those observed for POC at 991 (**2a**) and 998 (**2b**) cm^{-1} indicate the preservation of the ligand structure.

The $^{31}P\{^1H\}$ NMR signals of both **2a**,**b** salts appear at $\delta = 62.0$ and 62.1 ppm, respectively, showing a downfield shift when compared to the free ligand **1**.

The ^1H NMR spectra contain a single set of signals for the CH_3 protons at $\delta = 1.32$ (**2a**) and 1.34 (**2b**) ppm. The signals of OCH protons are overlapped by the solvent signal. The CH_2 band, corresponding to the cyclam fragment, appears at $\delta = 1.60$–4.46 ppm. The signal for the NHP(S) proton was not observed. The integrated intensities of the signals of CH_3 and CH_2 protons with a ratio of 48:20 support the tetra-N-substituted cyclam ligand. No bands were observed for the proton corresponding to the mono-, di- or tri-N-substituted cyclam moiety.

The IR bands of P=S in **3** are shifted by 43 and 11 cm^{-1} to lower frequencies relatively to the parent ligand **1** and the salt **2b**, respectively. This confirms the chelate formation with Cu^I. The intensive absorption band of the conjugated thioamide group in the spectrum of **3** is observed at 1508 cm^{-1} and it is shifted to lower frequencies when compared to **2b**.

The ^{31}P NMR spectrum of **3** contains two singlet signals at $\delta = -1.1$ and 52.0 ppm. The broad resonance band at 52.0 ppm corresponds to the phosphorus of the thiophosphoryl group and is in the characteristic region for similar complexes [10]. The signal at −1.1 ppm corresponds to the triphenylphosphine and it is downfield compared to free PPh_3.

The exchange between free and bound triphenylphosphine in solutions of the studied complex **3** results in the phosphine signal broadening in the ^{31}P NMR spectrum, as was observed for Cu(I) thioether complexes (see [15] and references therein). The ratio of the integral intensity in the ^1H NMR spectrum reveals the composition of the complex **3**. The ratio of OCH protons (OPri) signal intensity to phenyl protons of PPh_3 is 1:15 while the intensities of OCH protons correlates to the total intensity of the NCH_2 multiplet as 1:2.

2.3. EI and ES mass spectrometry

The electron impact mass spectrum (EI-MS) of **1** contains the $[\text{cyclam}]^+$ (100%) and $[(i\text{PrO})_2\text{P(S)NCS}]^+$ (36%) structure ion peaks. The molecular ion of **1** is unstable under the measurement conditions.

ES-MS (electrospray method) of **1** shows peaks for the following ions: $[\text{cyclam}+H]^+$ (24%) и $[(i\text{PrO})_2\text{P(S)NCS}+H]^+$ (17%), $[M-3(i\text{PrO})_2\text{P(S)NCS}+H]^+$ (100%), $[M-2(i\text{PrO})_2\text{P(S)NCS}+K]^+$ (9%), $[M-(i\text{PrO})_2\text{P(S)NCS}+K]^+$ (11%) and $[M+CH_3OH+K]^+$ (8%). Positive ions with a greater weight in the ES-MS of **1** were absent.

There is a peak for the molecular ion of **2a** $[M+H_2O+Na]^+$ with an intensity of 18%. The molecular ion peak of **2b** is absent in the ES-MS. Their electrospray spectra contain all ions characteristic of the mono-, di- and tri-N-substituted derivatives of cyclam: $[M-3(i\text{PrO})_2\text{P(S)NCS}-2Me+3H]^+$ (37%, Me = Na, **2a**; 100%, Me = K, **2b**), $[M-2(i\text{PrO})_2\text{P(S)NCS}-Me+2H]^+$ (100% **2a**, Me = Na; 46%, Me = K, **2b**) and $[M-(i\text{PrO})_2\text{P(S)NCS}+H]^+$ (14%) (**2b**).

The ES spectrum of complex **3** contains rather intensive peaks of mono- and di-N-substituted derivatives: $[M-3(i\text{PrO})_2\text{P(S)NCS}-3Cu(PPh_3)_2+4H]^+$ (32%) and $[M-2(i\text{PrO})_2\text{P(S)NCS}-2Cu(PPh_3)_2+K+2H]^+$ (58%). The are also peaks of cations of the composition $[\text{cyclam}]^+$ (100%) and $[(i\text{PrO})_2\text{P(S)NCS}+H]^+$ (23%). The ES-MS does not show any peak for the molecular ion of **3**.

3. Experimental

3.1. Physical measurements

Infrared spectra (Nujol) were recorded with a Specord M-80 spectrometer in the range 400–3600 cm^{-1}. NMR spectra were obtained on a Varian Unity-300 NMR spectrometer at 25 °C. ^1H and $^{31}P\{^1H\}$ spectra were recorded at 299.948 and 75.429 MHz, respectively. Chemical shifts are reported with reference to Me_4Si (^1H) and H_3PO_4 ($^{31}P\{^1H\}$). The electron ionisation mass spectrum of thiourea **1** was measured on a TRACE MS Finnigan MAT instrument. The ionisation energy was 70 eV. The substance was injected directly into the ion source at 150 °C. Heating was carried out in a programmed mode from 35 to 200 °C at a rate of 35 °C/min. Electrospray ionisation mass spectra were measured with a Finnigan-Mat TCQ 700 mass spectrometer on a 10^{-6} M solution in CH_3OH. The speed of sample submission was 2 μL/min. The ionisation energy was 4.5 kV. The capillary temperature was 200 °C. Elemental analyses were performed on a Perkin–Elmer 2400 CHN microanalyser.

3.2. Synthesis of *1*

A suspension of cyclam (100 mg, 0.5 mmol) in toluene (10 cm^3) was mixed with a toluene solution of the isothiocyanate of *O*,*O*′-diisopropylthiophosphoric acid (525.8 mg,

2.2 mmol). The mixture was boiled for 10 min. The solvent was then removed in vacuo. A colourless precipitate of **1** (520.0 mg, 90%) was isolated from dichloromethane by *n*-hexane (Found: C, 39.48; H, 7.03; N, 9.66. $C_{38}H_{80}N_8O_8P_4S_8$ requires C, 39.43; H, 6.97; N, 9.68%); mp 66 °C (from CH_2Cl_2/*n*-C_6H_{14}); IR ν_{max}(Nujol)/cm^{-1} 660 (P═S), 1000 (POC), 1496, 1518 (S═C–N) and 3110 (NH); ν_{max} (CCl_4)/cm^{-1} 656 (P═S), 998 (POC), 1480 (S═C–N), 1988 (S═C═N) and 2870–3000 (NH); NMR δ_H ($CDCl_3$/ppm, *J* in Hz) 1.37 (36H, t, $^3J_{H,H}$ 6.0, CH_3), 1.56 (12H, br s, CH_3, (*i*PrO)$_2$P(S)NCS), 1.78–4.43 (20H, m, CH_2), 4.86 (6H, d sept, $^3J_{POCH}$ 12.4, $^3J_{H,H}$ 6.2, OCH), 4.93 (2H, br s, OCH, (*i*PrO)$_2$P(S)NCS), 6.99 (3H, br s, P(S)NH) and 8.18 (1H, s, NH); δ_P($CDCl_3$/ppm) 43.1 (s, (*i*PrO)$_2$P(S)NCS) and 59.7 (br s, P(S)NH); *m*/*z* (EI) 200 (cyclam, 100%)$^+$ and 239 [(*i*PrO)$_2$P(S)NCS, 36]$^+$; *m*/*z* (ES) 201.5 (cyclam+H, 24%)$^+$, 240.6 [(*i*PrO)$_2$P(S)NCS+H, 17]$^+$, 441.2 (M−3(*i*PrO)$_2$P(S)NCS+H, 100)$^+$, 718.2 (M−2(*i*PrO)$_2$P(S)NCS+K, 9)$^+$, 957.8 (M−(*i*PrO)$_2$P(S)-NCS+K, 11)$^+$ and 1229.1 (M+CH_3OH+K, 8)$^+$.

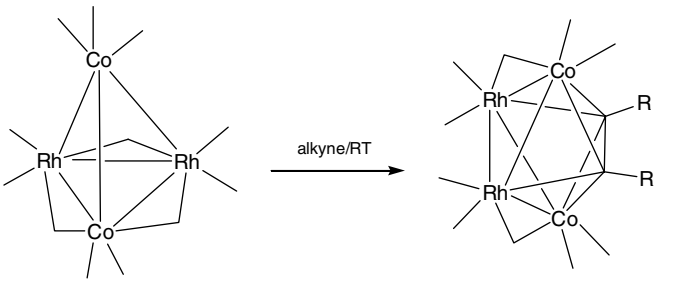
3.3. Synthesis of *2a,b*

A suspension of **1** (115.6 mg, 0.1 mmol) in aqueous ethanol (10 cm^3) was mixed with an ethanol solution of sodium (17.6 mg, 0.44 mmol) or potassium hydroxide (24.6 mg, 0.44 mmol). The mixture was stirred at room temperature for 30 min. The solvent was then removed in vacuo.

A colourless precipitate of **2a** (113.2 mg, 91%) was isolated from aqueous ethanol by *n*-hexane (Found: C, 36.73; H, 6.10; N, 8.86. $C_{38}H_{76}N_8Na_4O_8P_4S_8$ requires C, 36.65; H, 6.15; N, 9.00%); mp 195 °C (from EtOH/*n*-C_6H_{14}); IR ν_{max}/cm^{-1} 623 (P═S), 991 (POC) and 1532 (S···C···N); NMR δ_H (D_2O/ppm) 1.32 (48H, br s, CH_3) and 1.60–4.41 (20H, m, CH_2); δ_P(D_2O/ppm) 62.0; *m*/*z* (ES) 485.1 (M−3(*i*PrO)$_2$P(S)NCS−2Na+3H, 37%)$^+$, 746.2 (M−2(*i*PrO)$_2$P(S)NCS−Na+2H, 100)$^+$ and 1286.6 (M+H_2O+Na, 18)$^+$.

A colourless precipitate of **2b** (107.3 mg, 82%) was isolated from aqueous ethanol by *n*-hexane (Found: C, 34.89; H, 5.79; N, 8.61. $C_{38}H_{76}N_8K_4O_8P_4S_8$ requires C, 34.84; H, 5.85; N, 8.55%); mp 183 °C (from EtOH/*n*-C_6H_{14}); IR ν_{max}/cm^{-1} 628 (P═S), 998 (POC) and 1538 (S···C···N); NMR δ_H (D_2O/ppm) 1.34 (48H, br s, CH_3) and 1.67–4.46 (20H, m, CH_2); δ_P(D_2O/ppm) 62.1; *m*/*z* (ES) 517.1 (M−3(*i*PrO)$_2$P(S)NCS−2K+3H, 100%)$^+$, 794.3 (M−2(*i*PrO)$_2$P(S)NCS−K+2H, 46)$^+$ and 1071.7 (M−(*i*PrO)$_2$P(S)NCS+H, 14)$^+$.

3.4. Synthesis of *3*



A suspension of **2b** (105 mg, 0.08 mmol) in aqueous ethanol (10 cm^3) was mixed with a dichloromethane solution of Cu(PPh_3)$_3$I (312.6 mg, 0.32 mmol). The mixture was stirred at room temperature for 4 h. The solvent was then removed in vacuo. A colourless precipitate of **3** (874.6 mg, 78%) was isolated from dichloromethane by *n*-hexane (Found: C, 62.23; H, 5.69; N, 3.36. $C_{182}H_{196}Cu_4N_8O_8P_{12}S_8$ requires C, 62.35; H, 5.63; N, 3.30%); mp 148 °C (from CH_2Cl_2/*n*-C_6H_{14}); IR ν_{max}/cm^{-1} 617 (P═S), 1002 (POC) and 1508 (S═C–N); NMR δ_H ($CDCl_3$/ppm) 1.27 (48H, br s, CH_3), 1.46–4.38 (20H, m, CH_2) and 4.71 (8H, br s, OCH) and 7.28–7.49 (120H, m, PPh_3); δ_P($CDCl_3$) −1.1 (br s, PPh_3) and 52.0 (s, P(S)N); *m*/*z* (ES) 201.2 (cyclam+H, 100%)$^+$, 240.4 [(*i*PrO)$_2$P(S)NCS+H, 23]$^+$, 1027.3 (M−3(*i*PrO)$_2$P(S)NCS− 3Cu(PPh_3)$_2$+4H, 32)$^+$ and 1891.2 (M−2(*i*PrO)$_2$P(S)NCS−2Cu(PPh_3)$_2$+K+2H, 58)$^+$.

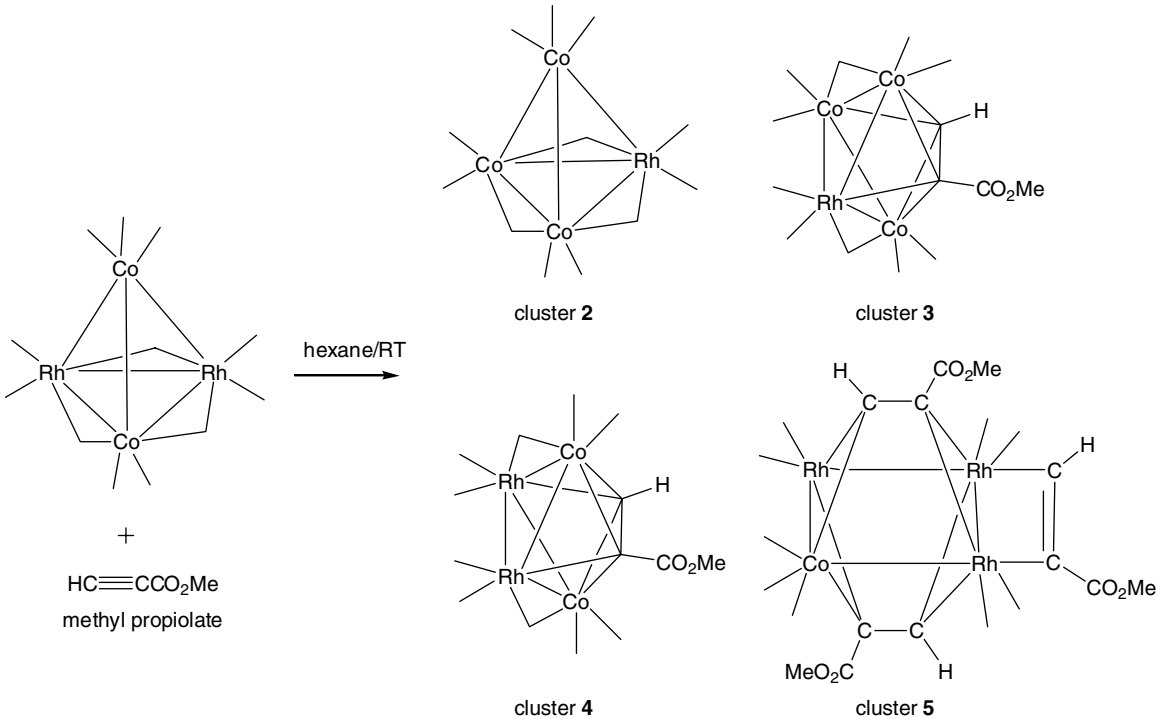
(1)

The reaction depicted in Eq. (1) initially captured our attention because, with the exception of bis(pentafluorophenyl)acetylene [7a], all of the alkyne ligands studied for their reactivity with cluster **1** have possessed electron-donating substituents. Accordingly, this prompted our earlier study on the reaction of **1** with the electron-poor alkyne dimethyl acetylenedicarboxylate (dmad), where facile cluster fragmentation and specific metal redistribution to give $Co_3Rh(CO)_{10}(\mu\text{-dmad})$ and $CoRh_3(CO)_9(\mu\text{-dmad})_3$ were demonstrated [8]. Interestingly no evidence for the expected butterfly cluster $Co_2Rh_2(CO)_{10}(\mu\text{-dmad})$ was observed, suggesting that once formed $Co_2Rh_2(CO)_{10}(\mu\text{-dmad})$ is unstable and fragments in solution to give $Co_3Rh(CO)_{10}(\mu\text{-dmad})$ and $CoRh_3(CO)_9(\mu\text{-dmad})_3$. If the electronic character of the alkyne is important in controlling the stability of the initially formed butterfly cluster $Co_2Rh_2(CO)_{10}(\mu\text{-alkyne})$, the use of an alkyne ligand that is not as electron deficient as dmad might allow us to trap and/or observe $Co_2Rh_2(CO)_{10}(\mu\text{-alkyne})$ before any fragmentation of the $Co_2Rh_2(\mu\text{-alkyne})$ cluster. Herein we report our results on the reaction between cluster **1** and methyl propiolate, which gives $Co_3Rh(CO)_{12}$ (**2**), $Co_3Rh(CO)_{10}(\mu\text{-HCCCO}_2\text{Me})$ (**3**), $Co_2Rh_2(CO)_{10}(\mu\text{-HCCCO}_2\text{Me})$ (**4**), and $CoRh_3(CO)_9(\mu\text{-HCCCO}_2\text{Me})_3$ (**5**) as the principal products. These products have been characterized by a combination of methods including comparison to independently prepared samples, spectroscopic methods, and FAB mass spectrometry. The solid-state structure of $Co_2Rh_2(CO)_{10}(\mu\text{-HCCCO}_2\text{Me})$ (**4**) and the regiospecific insertion of the methyl propiolate ligand into the Co–Co bond of **1** was established by X-ray crystallography.

2. Experimental

2.1. General

The mixed-metal cluster $Co_2Rh_2(CO)_{12}$ was prepared from $Co_2(CO)_8$ and $Rh_2(CO)_4Cl_2$ [9], with the latter chemical synthesized by carbonylation of hydrated $RhCl_3$ [10]. Thermolysis of $Co_2Rh_2(CO)_{12}$ in hexane gave the sample of pure $Co_3Rh(CO)_{12}$ that was used as a standard for cluster **2** and in the independent synthesis of cluster **3** [9]. The chemicals $Co_2(CO)_8$ and methyl propiolate were purchased from Strem Chemical Co. and Aldrich Chemical Co., respectively, and were used as received. All reaction and NMR solvents were distilled from an appropriate drying agent using Schlenk techniques and stored under argon in storage vessels equipped with a high-vacuum Teflon stopcock [11].



The IR spectral data were recorded on a Nicolet 20 SXB FT-IR spectrometer in sealed 0.1 mm NaCl cells, while the ^1H spectral data were recorded at 200 MHz on a Varian Gemini-200 spectrometer. The ESI-APCI mass spectrum of cluster **5** was recorded at the UC San Diego Mass Spectrometry Center in the positive ionization mode.

2.2. Reaction of $Co_2Rh_2(CO)_{12}$ with methyl propiolate

To a small Schlenk vessel containing 0.13 g (0.21 mmol) of $Co_2Rh_2(CO)_{12}$ in 40 mL of hexane was added 36 mg (0.43 mmol) of methyl propiolate under argon flush. The vessel was capped and stirred for 3.0 h at room temperature, during which time some precipitate corresponding to $CoRh_3(CO)_9(\mu\text{-HCCCO}_2\text{Me})_3$ was observed. TLC examination of the reaction solution at this point revealed the presence of three spots ($R_f = 0.95$ for cluster **2**; $R_f = 0.80$ for clusters **3** and **4**; $R_f = 0.10$ for cluster **5**) using CH_2Cl_2 as the mobile phase. The hexane was removed in vacuo and the residue dissolved in a minimum amount of CH_2Cl_2, followed by chromatographic separation over silica gel. Cluster **2** was eluted using hexane, followed by clusters **3** and **4** as overlapping bands using a mixture of hexane/CH_2Cl_2 (1:2), after which cluster **5** was obtained by changing the eluent to ethyl acetate/CH_2Cl_2 (1:9). The IR data spectrum for the isolated $Co_3Rh(CO)_{12}$ exactly matched that of the independently prepared sample of cluster **2**, as did the TLC properties. The amount of **2** isolated from the column was ca. 15 mg. The cluster mixture composed of $Co_3Rh(CO)_{10}(\mu\text{-HCCCO}_2\text{Me})$ and $Co_2Rh_2(CO)_{10}(\mu\text{-HCCCO}_2\text{Me})$ was isolated as a brown-purple colored solid (47 mg). IR (hexane): ν(CO) 2102 (m), 2072 (vs), 2056 (vs), 2047 (vs), 2030 (m), 2005 (m), 1897 (m), 1878 (sh, m), 1716 (w, ester) cm^{-1}. ^1H NMR ($CDCl_3$): δ 3.68 (s, Me), 8.72 (s, alkyne CH, cluster **3**), 9.20 (s, alkyne CH, cluster **4**). $CoRh_3(CO)_9(\mu\text{-HCCCO}_2\text{Me})_3$ was isolated as a dark red solid (50 mg). IR (CH_2Cl_2): ν(CO) 2095 (m), 2061 (vs), 2022 (s), 1911 (b, w), 1729 (s, ester) cm^{-1}. ^1H NMR ($CDCl_3$): δ 3.93 (s, 9H, CO_2Me), 7.74 (d, 1H, $J = 7.74$ Hz), 8.19 (d, 1 H, $J = 7.74$ Hz), 8.42 (s, 1H). ESI-APCI MS (m/z): 894.71 $[\mathbf{5}+Na]^+$.

2.3. X-ray diffraction structure for $Co_2Rh_2(CO)_{10}(\mu\text{-HCCCO}_2\text{Me})$

Single crystals of $Co_2Rh_2(CO)_{10}(\mu\text{-HCCCO}_2\text{Me})$ were grown from a hexane solution containing $Co_3Rh(CO)_{10}(\mu\text{-HCCCO}_2\text{Me})$ and $Co_2Rh_2(CO)_{10}(\mu\text{-HCCCO}_2\text{Me})$ at 0 °C. The reported X-ray data were collected on a Bruker SMART™ 1000 CCD-based diffractometer at 213 K. The frames were integrated with the available SAINT software package using a narrow-frame algorithm [12], and the structure was solved and refined using the SHELXTL program package [13]. The molecular structure

Scheme 1.

was checked by using PLATON [14], and solved by direct methods with all nonhydrogen atoms refined anisotropically. All carbon-bound hydrogen atoms were assigned calculated positions and allowed to ride on the attached heavy atom, unless otherwise noted. Refinement for $Co_2Rh_2(CO)_{10}(\mu\text{-}HCCCO_2Me)$ converged at $R = 0.0511$ and $R_w = 0.1497$ for 2742 independent reflections with $I > 2\sigma(I)$.

3. Results and discussion

3.1. Reaction of $Co_2Rh_2(CO)_{12}$ with methyl propiolate and spectroscopic characterization of clusters 2–5

The reaction between the cluster compound $Co_2Rh_2(CO)_{12}$ and methyl propiolate proceeds rapidly at room temperature in hexane. The brown color of cluster **1** changes to that of red-purple with the accompanying formation with a red precipitate of cluster **5**, which is relatively insoluble in hexane. TLC examination of the reaction solution revealed the presence of four new spots belonging to clusters **2**–**5**. Of these products, clusters **3** and **4** not exhibit distinct separation on silica gel or alumina chromatographic supports and were consequently isolated together as an inseparable mixture. This chromatographic behavior mirrors that reported by Tunik et al. for the closely related alkyne clusters $Co_3Rh(CO)_{10}(\mu\text{-}PhCCPh)$ and $Co_2Rh_2(CO)_{10}(\mu\text{-}PhCCPh)$ that could not be separated by column chromatography [15]. The products were subsequently isolated by chromatography using silica gel as described in the experiment section. Scheme 1 outlines this reaction and the nature of the resulting products.

The identity of cluster **3** was ascertained by its independent synthesis [9], with the TLC and IR spectral data perfectly matching that of the cluster isolated from the reaction. The observed fragmentation of cluster **1**, along with the formation of cluster **2**, has been documented by us in our earlier study involving the reaction of cluster **1** with the alkyne dmad [8]. The mixture composed of clusters **3** and **4** was characterized in solution by IR and ^1H NMR spectroscopies. While the IR spectral data are of little help in the characterization of these two closed related compounds, the ^1H NMR data do allow us to comment on the unequivocal composition of the mixture. Despite the appearance of a single methyl resonance at δ 3.68 for both products, the two down-field alkyne resonances at δ 8.72 (cluster **3**) and 9.20 (cluster **4**) are consistent with the proposed products [7b,16]. These assignments were further strengthened by the independent synthesis of cluster **3** starting from $Co_3Rh(CO)_{12}$ (**2**) and methyl propiolate. The expected alkyne-substituted cluster **3** was indeed produced and its ^1H NMR spectrum was in excellent agreement with those data obtained from the cluster mixture containing **3** and **4**. The presence of **4** in the mixture was confirmed by X-ray diffraction analysis (*vide infra*). Based on the area associated with the terminal alkyne hydrogens in the mixture of **3** and **4**, the major product was determined to be cluster **4** (ca. 70%).

The lability of clusters **3** and **4** towards added methyl propiolate was next probed. Treatment of a hexane solution containing **3** and **4** with excess methyl propiolate led

to the slow consumption of both **3** and **4** (ca. 50%) and concomitant formation of cluster **5** and material decomposition, as assessed by TLC. The metal redistribution observed here is in keeping with our premise of enhanced metal scrambling and alkyne activation reactivity in this genre of cluster in the presence of electron-deficient alkynes.[1] The reactivity of clusters **1**, **3**, and **4** with different alkyne ligands is currently under study by groups.

The 64e-cluster $CoRh_3(CO)_9$(μ-$HCCCO_2Me)_3$, which is analogous to the dmad-substituted cluster $CoRh_3(CO)_9$-(μ-dmad)$_3$ prepared by us, was characterized in solution (IR and NMR) and by mass spectrometry. The IR spectrum exhibits terminal carbonyl stretching bands from 2095 to 1911 cm^{-1}, with the ester carbomethoxy groups displaying a strong ν(CO) band at 1729 cm^{-1}. The ^{1}H NMR spectrum provides valuable information concerning the coordination of the three methyl propiolate ligands to the planar metallic frame. The observation of three distinct alkyne hydrogen resonances at δ 7.74, 8.19, and 8.42, each of which integrates for a single hydrogen, immediately rules out the below cluster isomers. These particular isomers possess equivalent face-capping μ_4-alkyne groups that would display two ^{1}H resonances in a 2:1 ratio for the alkyne hydrogens instead of the three CH moieties spectroscopically found. The two face-capping alkyne ligands must be bound to the cluster in a head-to-tail fashion, as depicted in Scheme 1. Cluster **5** was also examined by ESI mass spectrometry in order to unequivocally establish the $CoRh_3$ metallic composition of the cluster. The mass spectrum exhibited a strong m/z peak at 894.71 that is consistent with the formation of the singly charged sodium adduct of cluster **5**, $[CoRh_3(CO)_9(\mu\text{-}HCCCO_2Me)_3{+}Na]^+$.

[a] Numbers in parentheses are estimated standard deviations in the least significant digit.

[1] The reaction of cluster **1** with excess dmad (ca. 12 mol equiv.) in hexane leads to complete cluster fragmentation and coupling of three alkyne molecules to furnish the dirhodium flyover compound $Rh_2(CO)_4$-[μ-C(CO_2Me)C(CO_2Me)C(CO_2Me)C(CO_2Me)C(CO_2Me)C(CO_2Me)]. Unpublished results.

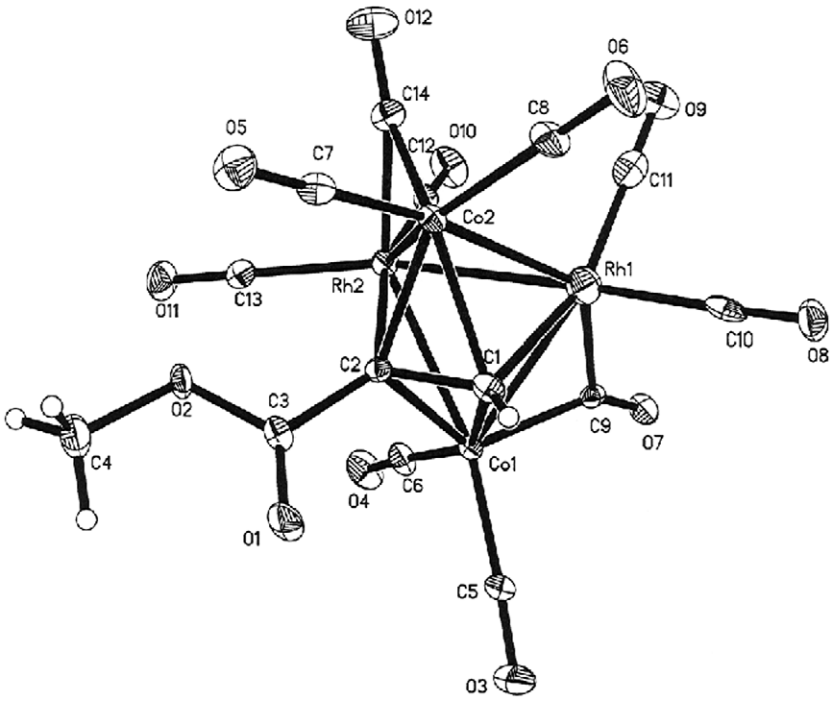

Fig. 1. Thermal ellipsoid plot of $Co_2Rh_2(CO)_{10}(\mu\text{-}HCCCO_2Me)$ showing the thermal ellipsoids at the 50% probability level.

3.2. X-diffraction structure of $Co_2Rh_2(CO)_{10}(\mu\text{-}HCCCO_2Me)$

The solid-state structure of $Co_2Rh_2(CO)_{10}(\mu\text{-}HCCCO_2Me)$ was established by X-ray crystallography. Single crystals of $Co_2Rh_2(CO)_{10}(\mu\text{-}HCCCO_2Me)$ were found to exist as discrete molecules in the unit cell with no unusually short inter- or intramolecular contacts. Tables 1 and 2 report the X-ray data collection and processing parameters and selected bond distances and angles, respectively.

The thermal ellipsoid plot of $Co_2Rh_2(CO)_{10}(\mu\text{-}HCCCO_2Me)$ is shown in Fig. 1, where the polyhedral expansion or opening of the original cluster tetrahedron and the formal insertion of the methyl propiolate ligand into the Co–Co bond of the cluster **1** are confirmed. This 60e-cluster may be viewed as either a butterfly or *arachno* cluster derived from the regiospecific opening of the original Co–Co bond in **1** or as a *closo* six-vertex based on a $Co_2Rh_2C(alkyne)_2$ core [17]. The two rhodium atoms are situated parallel to the 4e-methyl propiolate donor ligand, as found in the $Co_2Rh_2(CO)_{10}(\mu\text{-alkyne})$ clusters that have been structurally characterized [7]. The Rh(1)–Rh(2) bond length of 2.645(2) Å is slightly longer in comparison to the mean distance of 2.546 Å exhibited by the four Co–Rh bonds in cluster **4**. The experimentally determined metal–metal bond distances in **4** are in good agreement with those distances found in other mixed-metal Co_xRh_n containing clusters [7,8,15,18]. The six metal–C(alkyne) bond distances range from 2.02(1) Å [Co(2)–C(2) and Co(1)–C(1)] to 2.12(1) Å [Co(1)–C(2)] and display an average length of 2.06 Å. The C(1)–C(2) distance of 1.39(2) Å is longer than the corresponding C–C bond distance of 1.202 Å associated with the analogous distance of a free alkyne ligand [19]. Of the ten ancillary CO ligands, the C(9)O(7) and C(14)O(12) groups function as bridging groups and span the Co(1)–Rh(1) and Co(2)–Rh(2) vectors, respectively. The distances and angles exhibited by the two bridging CO groups and the remaining eight linear CO groups are unremarkable and require no comment.

4. Conclusions

The mixed-metal cluster $Co_2Rh_2(CO)_{12}$ reacts with methyl propiolate to give the clusters $Co_3Rh(CO)_{12}$ (**2**), $Co_3Rh(CO)_{10}(\mu\text{-}HCCCO_2Me)$ (**3**), $Co_2Rh_2(CO)_{10}(\mu\text{-}HCCCO_2Me)$ (**4**), and $CoRh_3(CO)_9(\mu\text{-}HCCCO_2Me)_3$ (**5**) as the principal products. The solid-state structure of **4** unequivocally was established by X-ray crystallography, and with it the first structurally characterized $Co_2Rh_2(alkyne)$ butterfly cluster containing an electron-withdrawing alkyne ligand.

V-shaped building block [Cu(dbsf)]. Using these V-shaped building blocks, with the help of different auxiliary ligands, we have successfully obtained five new copper coordination compounds: $[Cu(dbsf)(H_2O)]_n \cdot 0.5n(i\text{-}C_3H_7OH)$ (**1**), $[Cu(dbsf)(4,4'\text{-bpy})_{0.5}]_n \cdot nH_2O$ (**2**), $[Cu(dbsf)(2,2'\text{-bpy})(H_2O)]_2 \cdot (n\text{-}C_3H_7OH) \cdot 0.5H_2O$ (**3**), $[Cu(dbsf)(phen)(H_2O)]_2 \cdot 1.5H_2O$ (**4**) and $[Cu(dbsf)(2,2'\text{-bpy})(H_2O)]_n \cdot n(i\text{-}C_3H_7OH)$ (**5**).

2. Experimental

2.1. Materials and apparatus

All reagents were used as received without further purification (H_2dbsf from TCL). The C, H, N microanalyses were carried out with a Vario EL elemental analyzer. The IR spectra were recorded with a Nicolet Avatar 360 FT-IR spectrometer using the KBr pellet technique. The thermal analyses were performed on a ZRY-2P thermal analyzer using a heating rate of 20 °C/min from room temperature to 900 °C.

2.2. Synthesis

2.2.1. Synthesis of $[Cu(dbsf)(H_2O)]_n \cdot 0.5n(i\text{-}C_3H_7OH)$ (*1*)

A mixture of $CuCl_2 \cdot 6H_2O$ (0.017 g, 0.1 mmol), H_2dbsf (0.030 g, 0.1 mmol), NaOH aqueous solution (0.05 mL, 0.65 M), HCl aqueous solution (0.05 mL, 1.20 M), distilled water (5 mL), isopropanol (5 mL) and *N*,*N*-dimethyl formamide (0.1 mL) was sealed in a Teflon-lined stainless vessel (25 mL) and heated at 180 °C for 72 h under autogenous pressure. The vessel was then cooled slowly to room temperature. Blue strip crystals were obtained by filtration, washed with distilled water and isopropanol, and dried in air. Yield: 0.002 g (4.8%). Additionally a lot of blue polycrystals were also obtained (~50%. Found: C, 42.09; H, 4.11%). *Anal.* Calc. for $C_{15.5}H_{14}CuO_{7.5}S$ (415.87): C, 44.77; H, 3.39. Found: C, 44.70; H, 3.64%. IR data (KBr pellet, cm^{-1}): 3441s, 1633s, 1409s, 1169m, 1140w, 1100w, 742m, 727w, 523w.

2.2.2. Synthesis of $[Cu(dbsf)(4,4'\text{-bpy})_{0.5}]_n \cdot nH_2O$ (*2*)

A mixture of $CuCl_2 \cdot 6H_2O$ (0.017 g, 0.1 mmol), H_2dbsf (0.030 g, 0.1 mmol), 4,4′-bpy · $2H_2O$ (0.019 g, 0.1 mmol), NaOH aqueous solution (0.05 mL, 0.65 M), HCl aqueous solution (0.05 mL, 1.20 M), distilled water (5 mL) and *N*,*N*-dimethyl formamide (0.1 mL) was sealed in a Teflon-lined stainless vessel (25 mL) and heated at 180 °C for 72 h under autogenous pressure. The vessel was then cooled slowly to room temperature. Green strip crystals were obtained by filtration, washed with distilled water and dried in air. Yield: 0.015 g (32.3%). *Anal.* Calc. for $C_{19}H_{14}CuNO_7S$ (463.91): C, 49.19; H, 3.04; N, 3.02. Found: C, 49.48; H, 3.18; N, 3.05%. IR data (KBr pellet, cm^{-1}): 3439s, 1644s, 1608m, 1570m, 1408s, 1326w, 1302w, 1169m, 1100m, 1015w, 739s, 726w, 620w, 520m.

2.2.3. Synthesis of $[Cu(dbsf)(2,2'\text{-bpy})(H_2O)]_2 \cdot (n\text{-}C_3H_7OH) \cdot 0.5H_2O$ (*3*)

The synthesis of complex **3** was the same as that for complex **2** but substituting 2,2′-bpy (0.016 g, 0.1 mmol) for 4,4′-bpy · $2H_2O$, and *n*-propanol (5 mL) was also added to the reaction mixture. Blue block crystals were obtained by filtration, washed with distilled water and *n*-propanol, and dried in air. Yield: 0.020 g (34.7%). *Anal.* Calc. for $C_{25.5}H_{22.5}CuN_2O_{7.75}S$ (576.55): C, 53.13; H, 3.92; N, 4.86. Found: C, 53.56; H, 4.34; N, 4.53%. IR data (KBr

2.2.4. Synthesis of [Cu(dbsf)(phen)(H_2O)]$_2$ · 1.5H_2O (4)

The synthesis of complex **4** followed a similar process as for complex **2** except that 4,4′-bpy · 2H_2O was replaced by phen·H_2O (0.020 g, 0.1 mmol), and isopropanol (5 mL) was added to the reaction mixture. Blue strip crystals were obtained by filtration, washed with distilled water and isopropanol, and dried in air. Yield: 0.031 g (53.5%). *Anal.* Calc. for $C_{26}H_{19.5}CuN_2O_{7.75}S$ (579.54): C, 53.89; H, 3.39; N, 4.83. Found: C, 53.53; H, 3.76; N, 4.74%. IR data (KBr pellet, cm^{-1}): 3423s, 1604s, 1563s, 1518w, 1426m, 1398s, 1380s, 1344m, 1298m, 1161s, 1102m, 856w, 746s, 724s, 624m, 585w.

2.2.5. Synthesis of [Cu(dbsf)(2,2′-bpy)(H_2O)]$_n$ · n(i-C_3H_7OH) (5)

The synthesis of complex **5** followed the same procedure as that for complex **2** except using 2,2′-bpy (0.016 g, 0.1 mmol) instead of 4,4′-bpy · 2H_2O, and isopropanol (5 mL) was added to the reaction mixture. Blue board crystals were obtained by filtration, washed with distilled water and isopropanol, and dried in air. Yield: 0.051 g (84.7%). *Anal.* Calc. for $C_{27}H_{26}CuN_2O_8S$ (602.10): C, 49.69; H, 3.07; N, 3.05. Found: C, 49.72; H, 3.11; N, 3.01%. IR data (KBr pellet, cm^{-1}): 3418s, 1600s, 1560s, 1475w, 1447m, 1399s, 1298m, 1163s, 1133m, 1101m, 744m, 731w, 623w.

In the syntheses of the complexes **1**–**5**, HCl and NaOH solutions were added to adjust the pH of the reaction system. Propanol and DMF were added to enhance the solubility of the H_2dbsf ligand. Complexes **1**, **4** and **5** were synthesized in the mixed solvent of water, isopropanol and DMF, and **2** was formed in the mixed solvent of water and DMF, while complex **3** was obtained in the mixed solvent of water, *n*-propanol and DMF, showing that selectivity of the solvent plays an important role in the formation of the complexes.

2.3. X-ray diffraction determination

Diffraction data for complexes **1**–**5** were collected at 294 K on a Bruker SMART 1000 CCD diffractometer with a graphite-monochromatized Mo Kα radiation (λ = 0.71073 Å), using the ω and φ scan technique. A semi-empirical absorption correction was applied with the SADABS program. The structures were solved by direct methods and refined by full-matrix least-squares on F^2 using the SHELXS-97 and SHELXL-97 programs [12–14], respectively. All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were placed in geometrically calculated positions. Crystallographic data for complexes **1**–**5** are summarized in Table 1, and selected bond lengths (Å) and bond angles (°) are listed in Table 2 while selected hydrogen bond lengths (Å) and bond angles (°) are presented in Table 3.

3. Results and discussion

3.1. Description of the structures

In complexes **1**–**5**, the dbsf^{2-} ligands are completely deprotonated and are largely bent at the sulfone-sulfur sites (C–S–C = 103.0(2)–106.5(3)°, O–S–O = 119.1(2)–120.2(3)°). Each of them displays a V-shaped configuration, and assembles with the Cu(II) ion to form the V-shaped building block [Cu(dbsf)]. The coordination

Scheme 1. The coordination modes of the $dbsf^{2-}$ ligand in complexes **1**–**5**.

modes of the $dbsf^{2-}$ ligand in complexes **1**–**5** are represented in Scheme 1.

3.1.1. [Cu(dbsf)(H$_2$O)]$_n$ · 0.5n(i-C$_3$H$_7$OH) (**1**)

In complex **1**, each Cu(II) ion is coordinated to five oxygen atoms, four oxygen atoms from four $dbsf^{2-}$ ligands and one oxygen atom from a water molecule, as shown in Fig. 1a. O(1), O(1C), O(3B) and O(3C) atoms form an equatorial plane and one oxygen atom (O(4)) occupies the axial position, giving a slightly distorted square-pyramidal geometry. In complex **1**, each $dbsf^{2-}$ ligand adopts a bis(bridging-bidentate) mode (Scheme 1a) to coordinate to four Cu(II) ions. V-Shaped building blocks [Cu(dbsf)] are joined to form 1D double-chains, as shown in Fig. 1b. The single 1D double-chain possesses rhombic voids with dimensions of about 8 × 8 Å. All these double-chains are parallel to each other. Along the *c*-axis, these double-chains are arranged in an ABAB fashion and there is a displacement between the adjacent chains, which leads to the formation of small 1D channels (Fig. 1c). Hydrogen bonds are observed between the coordinated water molecules and the carboxylate oxygen atoms of $dbsf^{2-}$ ligands among the adjacent chains along the *c*-axis (Table 3), and there are π–π stacking interactions in the *ab*-plane, with a distance of 3.507 Å between the phenyl rings of $dbsf^{2-}$ ligands. Hydrogen bonds and π–π stacking interactions result in the formation of the porous supramolecular network of complex **1**. Isopropanol molecules are accommodated in the channels (see Fig. 1c). There are hydrogen bonds between the oxygen atom (O(5w)) of isopropanol molecules and coordinated water molecules of the chains (Table 3).

3.1.2. [Cu(dbsf)(4,4′-bpy)$_{0.5}$]$_n$ · nH$_2$O (**2**)

In complex **2**, there are two kinds of crystallographically independent Cu(II) ions, as shown in Fig. 2a. Both Cu(1) and Cu(2) are five-coordinated, and their coordination environments are similar but the bond lengths and bond angles around Cu(1) and Cu(2) are different. Each Cu(II) ion is coordinated to four oxygen atoms of four different $dbsf^{2-}$ ligands and one nitrogen atom of one 4,4′-bpy molecule. In complex **2**, the $dbsf^{2-}$ ligands adopt a bis(bridging-bidentate) mode (Scheme 1a), linking the Cu(II) ions into a 1D double-chain structure along the *a*-axis, which is similar to that in complex **1**. However, because of the introduction of 4,4′-bpy molecules, these 1D [Cu(dbsf)]$_n$ double-chains are pillared to generate 2D square-grids (Fig. 2b). Unexpectedly, two such grids interpenetrate each

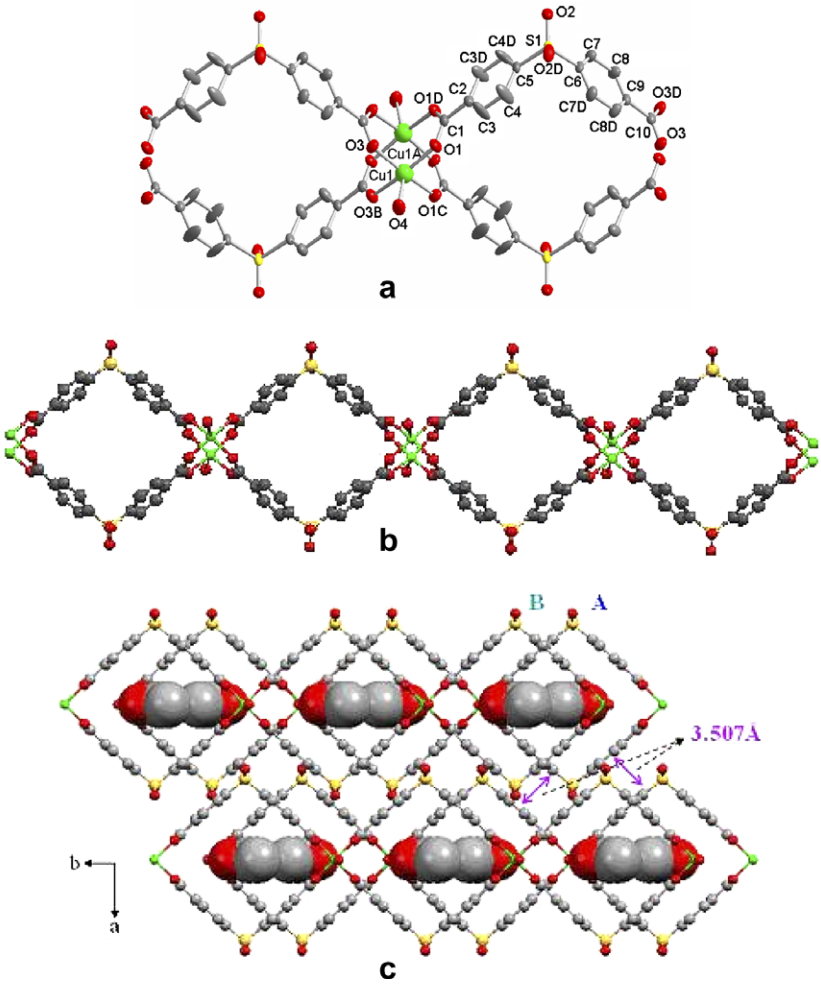

Fig. 1. (a) The coordination environment of the Cu(II) ion in complex **1** with 30% thermal ellipsoids, all hydrogen atoms are omitted for clarity. (b) The 1D double-chain structure with rhombic voids. (c) View of the supramolecular network of complex **1** along the *c*-direction (space-filling model represents isopropanol molecules).

other to generate a novel catenane-like 2D layer (Fig. 2c). Such catenane-like layers are unusual [15]. These catenane-like 2D structures stack in an ABAB fashion along the *c*-axis with some displacement between A and B, resulting in the formation of a 3D supramolecular network. There are lattice water molecules accommodated between the layers.

3.1.3. *[Cu(dbsf)(2,2′-bpy)(H$_2$O)]$_2$ · (n-C$_3$H$_7$OH) · 0.5H$_2$O* (**3**) *and [Cu(dbsf)(phen)(H$_2$O)]$_2$ · 1.5H$_2$O* (**4**)

X-ray diffraction analysis reveals that complexes **3** and **4** possess similar structures, except that the 2,2′-bpy ligand in complex **3** is replaced by a phen ligand in complex **4**, and the guest molecules are different in the two complexes (*n*-C_3H_7OH and H_2O for **3**, H_2O for **4**). So only the structure of complex **3** will be described here. The coordination environment of the Cu(II) ion in complex **3** is shown in Fig. 3a. The Cu(II) ion is five-coordinated, with two oxygen atoms from two $dbsf^{2-}$ ligands, two nitrogen atoms from one 2,2′-bpy ligand and one oxygen atom from a coordinated water molecule. The coordination geometry of the Cu(II) ion can be described as a distorted square-pyramid. The Cu–N bond lengths are 2.014(4) and 2.020(4) Å, and the Cu–O bond lengths are in the range of 1.941(4)–2.353 (4) Å (the Cu–N bond lengths are 1.992(5) and 1.996(5) Å, and the Cu–O bond lengths are in the range of 1.924(4)–2.303 (4) Å for complex **4**). In complex **3**, every $dbsf^{2-}$ ligand adopts a bis(monodentate) mode (Scheme 1b), so that two V-shaped building blocks encircle to form a macrocyclic dimer unit (Fig. 3a). All the dimer units are parallel, and plenty of hydrogen bonds exist between them. Along the *a*-axis, there exists O–H···O hydrogen bonds [O(7)–H(7B)···O(6)] between the coordinated water molecule and the oxygen atom of the uncoordinated carboxyl group. In addition, three kinds of C–H···O hydrogen bonds, such as C(13)–H(13)···O(4), C(22)–H(22)···O(3) and C(21)–H(21)···O(6) exist in the adjacent dimers in the *bc*-plane. Moreover, a π–π stacking interaction exists between 2,2′-bpy ligands (the face-to-face distance is 3.639 Å). These hydrogen bonds and π–π stacking interactions lead to the

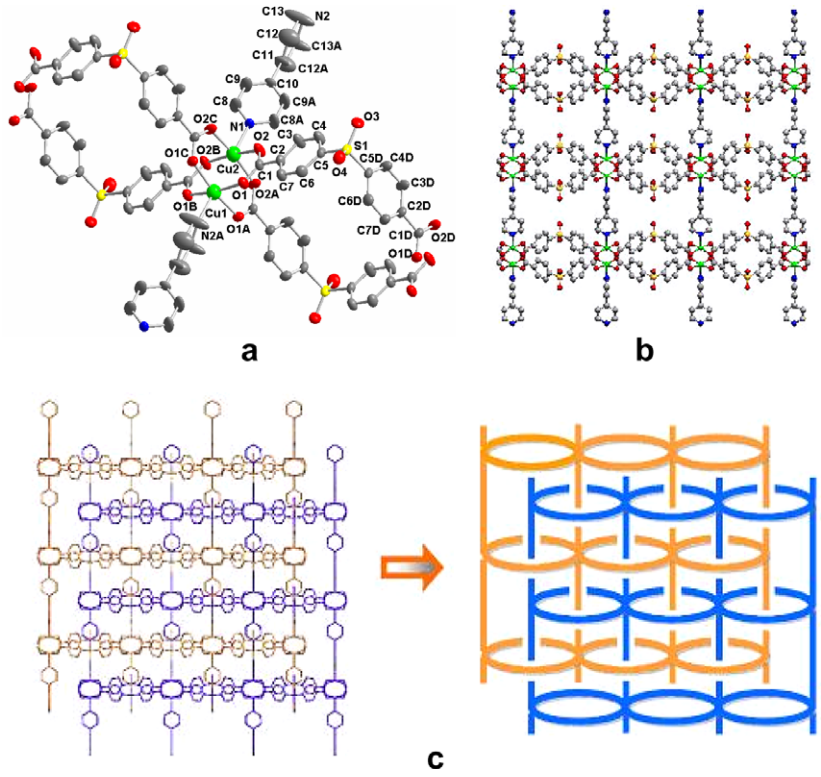

Fig. 2. (a) The coordination environments of the Cu(II) ions in complex **2** with 30% thermal ellipsoids, all hydrogen atoms are omitted for clarity. (b) The 2D layer framework of complex **2**. (c) Interpenetrated catenane-like 2D layers and its schematic view.

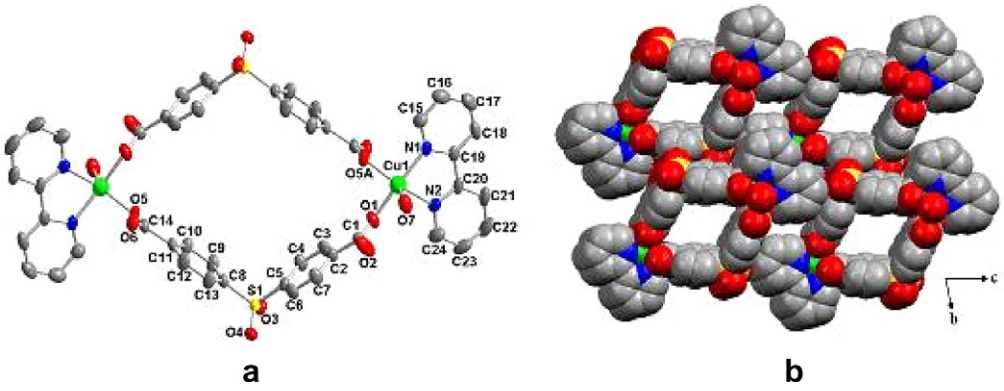

Fig. 3. (a) The coordination environment of the Cu(II) ion in complex **3** with 30% thermal ellipsoids, all hydrogen atoms are omitted for clarity. (b) View of the 3D porous supramolecular structure along the *a*-axis, all the atoms except hydrogen atoms are shown as a space-filling model.

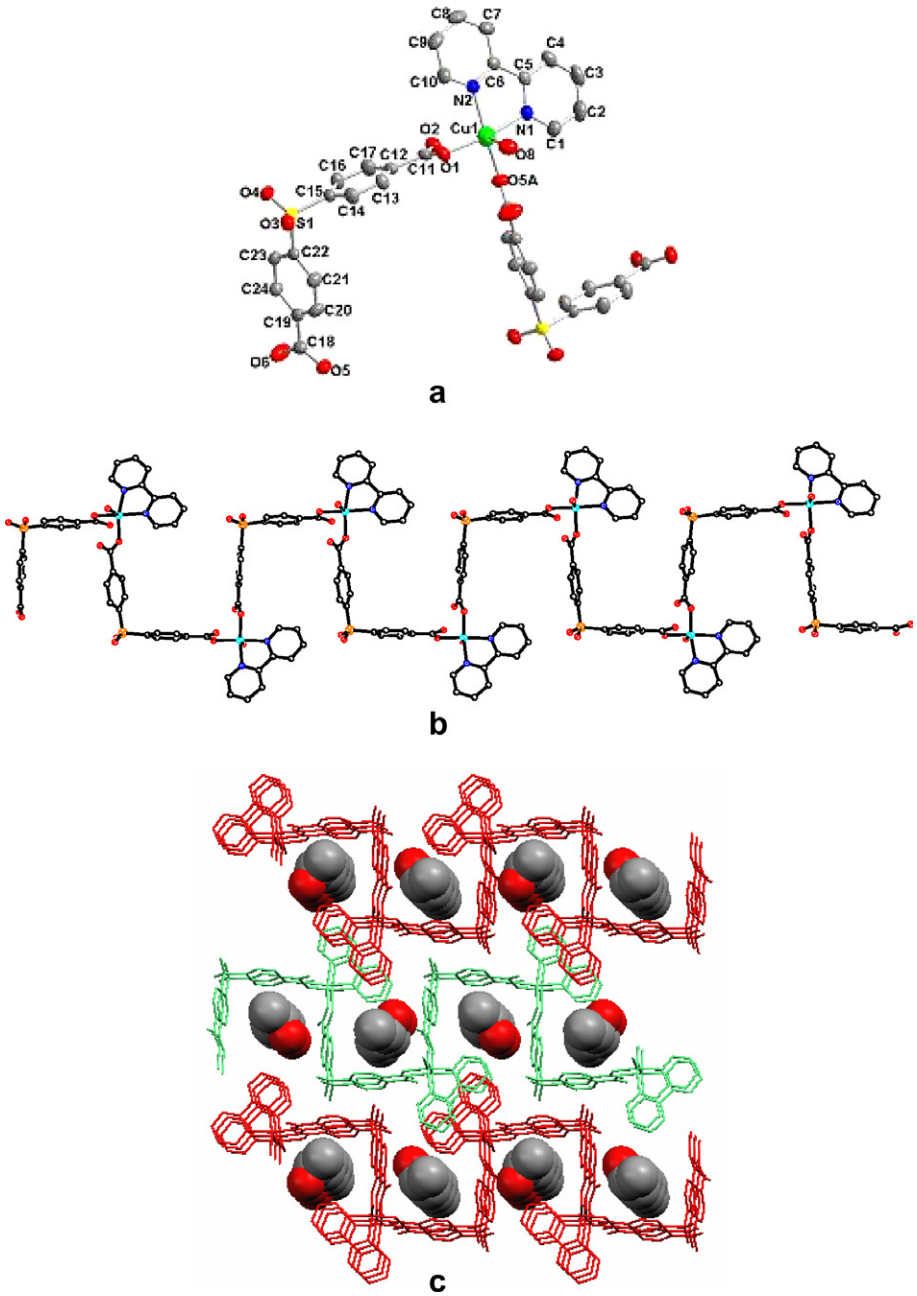
formation of a 3D porous supramolecular architecture [16], as shown in Fig. 3b. Water molecules and *n*-propanol molecules alternately occupy the 1D channels along the *a*-axis. But they are so far away from the dimers that no hydrogen bonds are formed between the guest molecules and the dimers.

3.1.4. $[Cu(dbsf)(2,2'\text{-bpy})(H_2O)]_n \cdot n(i\text{-}C_3H_7OH)$ (**5**)

The X-ray crystallographic analysis shows that complex **5** possesses 1D tooth-like chains. There is one crystallographically independent Cu(II) center in the crystal structure. As shown in Fig. 4a, the Cu(II) ion is five-coordinated and displays a distorted square-pyramidal geometry, which is completed by two nitrogen atoms from one chelating 2,2′-bpy ligand, two oxygen atoms from two $dbsf^{2-}$ ligands, and one oxygen atom from one coordinated water molecule. In complex **5**, the $dbsf^{2-}$ ligands adopt a bis(monodentate) mode (Scheme 1b), the same as that in complex **3**, but they connect the Cu(II) ions into a completely different structure. V-Shaped building blocks are joined head-to-tail to form infinite tooth-like chains (Fig. 4b). Among these chains, there are plenty of hydro-



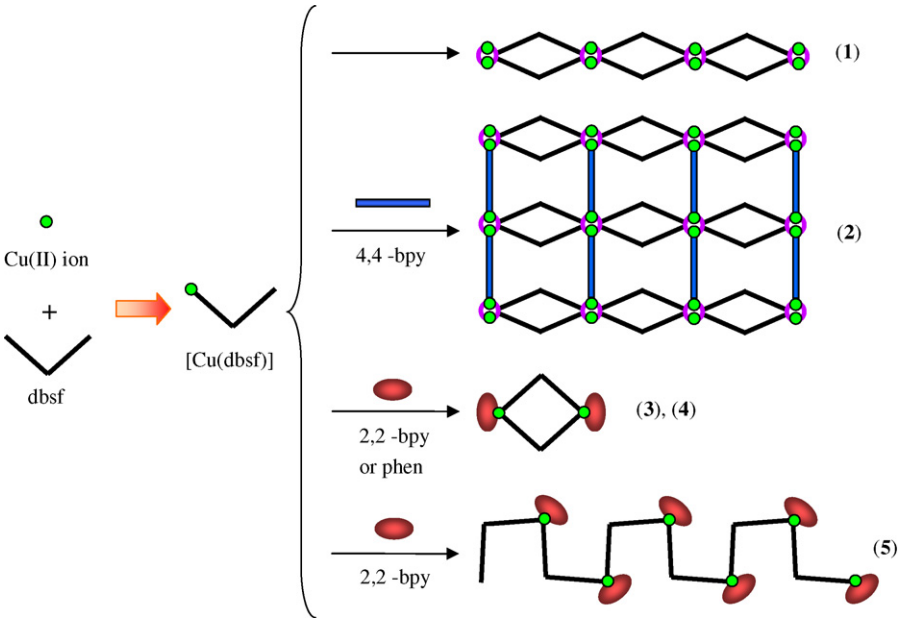


Fig. 4. (a) The coordination environment of the Cu(II) ion in complex **5** with 30% thermal ellipsoids, all hydrogen atoms are omitted for clarity. (b) The infinite 1D chain structure formed by V-shaped building blocks of [Cu(dbsf)]. (c) View of the 3D supramolecular structure along *a*-axis (space-filling model represents solvent molecules).

gen bonds. O–H···O hydrogen bonds are observed between the uncoordinated oxygen atoms (O(6)) and coordinated water molecules of the adjacent chains. Additionally, C–H···O hydrogen bonds are observed between C···H (H(4)) of the 2,2′-bpy molecule and the other uncoordinated carboxylate oxygen atoms (O(2)) of the adjacent chain (Table 3). The 2,2′-bpy molecules also participate in face-to-face π–π stacking interactions with a separation at the closest contact of 3.267 Å, and the pyridyl planes of the 2,2′-bpy ligands are parallel to ones in the adjacent chains. Thus a 3D supramolecular structure is formed via hydrogen bonds and π–π stacking interactions. In the 1D channels along the *a*-axis, isopropanol molecules are accommodated (Fig. 4c). They form O–H···O hydrogen bonds with the non-coordinated oxygen atoms (O(6)) of the $dbsf^{2-}$ ligands. The formation of these hydrogen bonds prevents the $dbsf^{2-}$ ligands encircling to form a dimer fragment. Besides, isopropanol molecules occupy the voids of the tooth-like chains, functioning as important supports to the shape of the chains.

3.1.5. Comparison of the structures of complexes *1*–*5*

By self-assembly from V-shaped building blocks [Cu(dbsf)], we obtained five new complexes with structure described as

Scheme 2. The simplified representation of the structures of the five complexes.

0D metallocyclic, 1D chain and 2D catenane-like layer. From the above descriptions, it is obvious that the introducing of different auxiliary ligands has a crucial effect on the assembly of the [Cu(dbsf)] building block and the formation of the final structures. The simplified structures of these five complexes are represented in Scheme 2. In complexes **1**–**5**, the $dbsf^{2-}$ ligand shows two coordination modes (Scheme 1). It adopts a bis(bridging-bidentate) mode (Scheme 1a) in complexes **1** and **2**, and the bis(monodentate) mode (Scheme 1b) in complexes **3**–**5**. In complex **1**, V-shaped building blocks [Cu(dbsf)] are joined to form 1D double-chains. While in complex **2**, when the bridging auxiliary ligand 4,4′-bpy is introduced, these 1D double-chains are pillared into 2D layers. When terminal auxiliary ligands phen/2,2′-bpy were introduced into the Cu/dbsf system, 0D dimeric complexes **3** and **4** were obtained, in which every two V-shaped building blocks [Cu(dbsf)] encircle to form metallocyclic units in which the terminal ligands phen/2,2′-bpy prevent the structures extending to a higher dimension.

In addition, solvent molecules impact the structure too. It is worth noting that complexes **3** and **5** were obtained from the same reactants in different solvents, they possess very different structures [17]. Complex **3** is composed of dimetal macrocyclic molecules with two V-shaped building blocks of [Cu(dbsf)], while in complex **5**, V-shaped building blocks of [Cu(dbsf)] are linked in a head-to-tail model, and 1D tooth-like chains are organized. This may be attributed to the dissimilar solvent molecules included. In complex **5**, the free isopropanol molecules form hydrogen bonds with the main chain so as to prevent the $dbsf^{2-}$ ligands encircling to form dimer fragments (see Fig. 4c), occupying the voids of the tooth-like chains, and acting as important supports to the shape of the chains.

3.2. Thermal analyses

Thermogravimetric analyses of the complexes **2**–**5** were carried out to examine their thermal stabilities. The observed TG curve reveals that complex **2** looses its lattice water molecules at the first weight loss of 3.0% (calc. 3.8%) from 64 °C to 172 °C. For complex **3**, the TG curve shows that the uncoordinated solvent molecules and coordinated water molecules are lost at the first weight loss, 9.0% (calc. 9.1%) from 109 °C to 201 °C. While for complex **4**, the uncoordinated and coordinated water molecules are lost from 73 °C to 112 °C at the first weight loss of 6.2% (calc. 5.4%). In complex **5**, the first weight loss of 9.9% from 169 °C to 206 °C corresponds to the loss of uncoordinated isopropanol molecules (calc. 9.9%).

The TG curves of the complexes **3** and **5** show that further decomposition starts when the solvent was removed, indicating that the host framework collapses when the solvent is absent.

4. Conclusions

In summary, a series of Cu/dbsf complexes were prepared under hydro/solvothermal conditions. The crystal structures of the title complexes are the first report on metal complexes of 4,4′-dicarboxybiphenyl sulfone. Different structures of complexes **1**–**5** indicate that the V-shaped dicarboxylate ligand $dbsf^{2-}$ has the ability of adjusting its coordination configuration in different reaction systems

intelligently. Complexes **1**–**5** are all built up from V-shaped building blocks [Cu(dbsf)] with diverse auxiliary ligands. Our studies show that the configuration of the building blocks of [Cu(dbsf)] together with the help of auxiliary ligands has a crucial effect on the topology and configuration of the final structures of the Cu(II) complexes. Additionally, the solvent molecule acting as a guest is another notable factor for the arrangement of the 3D supramolecular networks.

5. Supplementary material

CCDC 611527, 611528, 611529, 611530 and 611531 contain the supplementary crystallographic data for **1**, **2**, **3**, **4** and **5**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

structural novelty has resulted in the synthesis of a series of compounds with NiP_nX (X = halogens or N or C or S) chromophores. Dithiocarbamates have proven to be versatile metal chelates and in particular nickel(II) dithiocarbamates with a planar NiS_4 chromophore are found to show interesting variations in reactivity towards soft Lewis bases such as phosphines and hard bases such as nitrogenous ligands. As a continuation of our interest [5,6] in exploring the synthetic and structural chemistry of transition metal dithiocarbamates and to understand the influence of phosphines and nitrogenous ligands on the NiS_2PX (X = C or N or P) chromophore and on the S_2–C N< bond we investigated the following compounds: [Ni(4-mpzdtc)-(PPh_3)(NCS)] (**1**), [Ni(4-mpzdtc)(PPh_3)(CN)] (**2**), [Ni-(4-mpzdtc)(PPh_3)$_2$]$ClO_4 \cdot H_2O$ (**3**) and [Ni(4-mpzdtc)-(dppe)]ClO_4 (**4**), where 4-mpzdtc = 4-methylpiperazinecarbodithioato anion, PPh_3 = triphenylphosphine and dppe = 1,2-bis((diphenylphosphino)ethane). In this paper, we report the synthesis, spectral and electrochemical properties of the compounds **1**–**4** along with the single crystal X-ray structures of **1** and **3** which crystallized out as single crystals.

2. Experimental

All the reagents and solvents employed were commercially available analytical grade materials and were used as supplied, without further purification. IR spectra were recorded on an ABB Bomem MB 104 spectrophotometer (range 4000–400 cm^{-1}) as KBr pellets. The UV–Vis spectra were recorded in CH_2Cl_2 on a HITACHI U-2001 spectrophotometer. Cyclic voltammetric studies were carried out using an ECDA-001, Basic Electrochemistry system. A three-electrode configuration was used, comprising of glassy carbon as the working electrode, a platinum wire as the counter electrode and Ag|AgCl as the reference electrode. Experiments were carried out at room temperature using 0.01 M tetrabutylammonium perchlorate as the supporting electrolyte under a nitrogen atmosphere. NMR spectra were recorded on a Bruker 400 MHz spectrometer at room temperature, using $CDCl_3$ as solvent. ^{13}C NMR spectra were recorded in the proton decoupled mode.

2.1. Preparation of the complexes

2.1.1. Bis(4-methylpiperazinecarbodithioato) nickel(II)

2.1.1.1. [Ni(4-mpzdtc)$_2$]. A mixture of 1-methylpiperazine (100 mg, 1 mmol) and CS_2 (76 mg, 1 mmol) in ethanol (50 mL) was kept under ice cold conditions (−5 °C) for 10 min and to this pale yellow solution $NiCl_2 \cdot 6H_2O$ (120 mg, 0.5 mmol) in water (25 mL) was added slowly with vigorous stirring. The dark green precipitate obtained was filtered, washed with ether and water. It was kept for evaporation and dried over anhydrous calcium chloride (Yield: 95%, dec.: >250 °C).

2.1.2. (4-Methylpiperazinecarbodithioato)(thiocyanato-N)-(triphenylphosphine) nickel(II)

*2.1.2.1. [Ni(4-mpzdtc)(PPh_3)(NCS)] (**1**).* A mixture of Ni(4-mpzdtc)$_2$ (205 mg, 0.5 mmol), PPh_3 (260 mg, 1 mmol), $NiCl_2 \cdot 6H_2O$ (120 mg, 0.5 mmol) and NH_4SCN (75 mg, 1 mmol) was refluxed for 3 h in an acetonitrile–methanol solvent mixture (2:1, 75 cm^3) and was then concentrated to ca. 25 cm^3. The dark purple-red solution obtained was filtered and was kept for evaporation. After 2 days, a solid separated out, was filtered, and then dried over anhydrous calcium chloride. Single crystals suitable for X-ray analysis were obtained by recrystallization from the same solvent mixture (Yield: 75%, dec.: 189 °C). *Anal.* Calc. for $C_{25}H_{26}N_3NiPS_3$: C, 54.16; H, 4.72; N, 7.58. Found: C, 54.01; H, 4.59; N, 7.44%.

2.1.3. (Cyano)(4-methylpiperazinecarbodithioato)-(triphenylphosphine) nickel(II)

*2.1.3.1. [Ni(4-mpzdtc)(PPh_3)(CN)] (**2**).* A mixture of Ni(4-mpzdtc)$_2$ (205 mg, 0.5 mmol), PPh_3 (260 mg, 1 mmol), $NiCl_2 \cdot 6H_2O$ (120 mg, 0.5 mmol) and KCN (65 mg, 1 mmol) was refluxed for 3 h in an acetonitrile–methanol solvent mixture (2:1, 75 cm^3) and then concentrated to ca. 25 cm^3. The pale orange-red solution obtained was filtered and kept for evaporation. After 2 days, an orange-red solid separated out. It was dried over anhydrous calcium chloride and recrystallized from the same solvent mixture (Yield: 65%, dec.: 180 °C). *Anal.* Calc. for $C_{25}H_{26}N_3NiPS_2$: C, 57.49; H, 5.01; N, 8.04. Found: C, 57.38; H, 4.90; N, 7.94%.

2.1.4. Bis(triphenylphosphine)(4-methylpiperazine-carbodithioato)nickel(II) perchlorate monohydrate

*2.1.4.1. [Ni(4-mpzdtc)(PPh_3)$_2$]$ClO_4 \cdot H_2O$ (**3**).* A mixture of Ni(4-mpzdtc)$_2$ (205 mg, 0.5 mmo1), PPh_3 (520 mg, 2 mmol), $NiCl_2 \cdot 6H_2O$ (120 mg, 0.5 mmol) and NH_4ClO_4 (115 mg, 1 mmol) was refluxed for about 2 h in a methanol–dichloromethane solvent mixture (1:1, 50 cm^3), and then concentrated to ca. 25 cm^3. The purple-red solution obtained was filtered and left for evaporation. The separated solid was filtered and dried, and single crystals suitable for X-ray analysis were obtained by repeated recrystallization from the same solvent mixture (Yield: 65%, dec.: 183 °C). *Anal.* Calc. for $C_{42}H_{43}ClN_2NiO_5P_2S_2$: C, 57.58; H, 4.94; N, 3.19. Found: C, 57.42; H, 4.84; N, 3.10%.

2.1.5. 1,2-Bis((diphenylphosphino)ethane)(4-methyl-piperazinecarbodithioato) nickel(II) perchlorate

*2.1.5.1. [Ni(4-mpzdtc)(dppe)]ClO_4 (**4**).* A mixture of Ni(4-mpzdtc)$_2$ (410 mg, 1 mmol), dppe (790 mg, 2 mmol), $NiCl_2 \cdot 6H_2O$ (240 mg, 1 mmol) and NH_4ClO_4 (230 mg, 2 mmol) was refluxed for about 4 h in a methanol-dichloromethane solvent mixture (1:1, 50 cm^3). The solution was then concentrated to ca. 25 cm^3. The purple-red solution obtained was filtered and kept for evaporation. After 2 days, a purple-red solid separated out and it was recrystallized from the same solvent mixture (Yield: 65%,

2.2. X-ray crystallography

Details of the crystal data, data collection and refinement parameters for **1** and **3** are summarized in Table 1. Intensity data were collected at ambient temperature (295 K) on Bruker AXS (with CCD) (for **1**) [7] and Philips PW 1100 (for **3**) diffractometers [8], using graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å and 0.71069 Å for **1** and **3**, respectively). All the non-hydrogen atoms were refined anisotropically and all the hydrogen atoms were refined isotropically. The absorption corrections were performed with the method in SHELXTL-NT V5.1 [7] for **1** and with the North, Phillips and Mathews method for **3** [9]. The ORTEP diagram was drawn with the ORTEP-3 program [10]. Selected bond distances and bond angles are given in Table 2.

3. Results and discussion

3.1. Electronic spectra

The d–d transition bands are observed at 483, 465, 483 and 467 nm for complexes **1**, **2**, **3** and **4**, respectively. The

bands are assigned to $d_{z^2}/d_{xy} \rightarrow d_{x^2-y^2}$ transitions [11]. The cyanide ion exerts a larger LFSE and hence the lowest λ_{max} value is associated with **2**. The observed red shift in **2** when compared to similar complexes with a NiS_2PN chromophore [6] is significant.

3.2. IR spectral studies

For complexes **1**, **2**, **3** and **4**, the ν_{C-N} (S_2–C=N<) bands are observed at 1547, 1529, 1534 and 1519 cm^{-1}, respectively. The increase in wavenumber for the mixed ligand complexes compared to that observed for the parent complex [Ni(4-mpzdtc)$_2$] (1503 cm^{-1}) is attributed to the mesomeric drift of electron density towards the nickel atom through the S_2–C=N< bond from the dithiocarbamate. The ν_{C-S} stretching vibrations are observed around 1000 cm^{-1} (**1**–**4**) without any splitting, supporting the bidentate coordination of the dithiocarbamate ligand. The observed stretching frequencies at 2093 cm^{-1} for complex **1** and at 2115 cm^{-1} for complex **2** are attributed to the 'N'-coordinated thiocyanate and 'C'-coordinated cyanide anions, respectively. The intense signals observed in the fingerprint region for complexes **3** and **4** [1095 cm^{-1} for **3** and 1089 cm^{-1} for **4**] are due to the presence of $\nu_{ClO_4^-}$ stretching in both cases.

3.3. Cyclic voltammetric studies

The reduction potential for the parent [Ni(4-mpzdtc)$_2$] complex is observed at −1548 mV. All the mixed ligand complexes showed lower one electron reduction potentials. (−1189, −972 and −754 mV for complexes **1**, **2** and **3** respectively). For the chelating phosphine complex **4**, quasi-reversible reduction potentials are observed at $-998(E_p^c)/-790(E_p^a)$ mV and it is due to the chelating nature of the phosphine, which is not completely delinked from the Ni^I-species formed as a result of the electrochemical reduction. Lower reduction potentials observed for complexes **1**–**3** indicate the ease of electron addition in the mixed ligand complexes and this is because of the presence of PPh_3, NCS^- and CN^- around the nickel atom [5].

3.4. NMR spectral studies

NMR chemical shifts of the synthesized complexes are summarized in Table 3.

3.4.1. ^1H NMR

For all the four mixed ligand complexes (**1**–**4**), the aromatic protons resonate in the region 7.31–7.91 ppm. The α(methylene) protons are greatly deshielded and are observed in the downfield region due to complexation. However, the β-CH_2 and N–CH_3 proton signals are observed closely and the assignments are made on the basis of proton integral values obtained for the corresponding signals. For complex **4**, the signal due to the methylene protons of the chelating phosphine appears at 2.67 ppm.

3.4.2. ^{13}C NMR

For all the four complexes, the N–CH_3 carbon signal is observed around 45.0 ppm and this deshielding is due to the minor deshielding effect of the nearby electronegative nitrogen. The β-CH_2 carbon signals are observed around 53.0 ppm with a small upfield shift of about 3 ppm compared to that of the corresponding carbon signal in *N*-methylpiperazine [56.4 ppm]. Signals due to α-carbons are only slightly deshielded. Aromatic carbon signals are observed in the downfield region of 126.9–137.3 ppm for all the four synthesized complexes. The N–$^{13}CS^-$ and $^{13}CN^-$ carbon signals are observed at 143.9 and ~131 ppm for complexes **1** and **2**, respectively (for complex **2**, the $^{13}CN^-$ signal at 131 ppm, is merged with the aromatic carbon signals). For complex **4**, the methylene carbon present in the chelating phosphine is observed at

Table 3
NMR chemical shifts of the complexes (in ppm)

Compound	NMR	α-CH_2[a]	β-CH_2[a]	δ-CH_3	PPh_x[b]	>N $^{13}CS_2$	S–^{13}C–N^-	$^{13}CN^-$

[a] Chemical shifts due to a, e protons.
[b] Where $x = 3$ for **1**, **2** and **3** and 2 for **4**.
[c] The (>P–CH_2–)$_2$ signal is observed at 2.67 ppm.
[d] The (>P–$^{13}CH_2$–)$_2$ signal is observed at 26.4 ppm.

26.4 ppm. Finally, the most important ^{13}C NMR signals of the $S_2-^{13}C{=}N<$ carbons are observed at 202.8, 204.2, 199.2 and 201.7 ppm for complexes **1**, **2**, **3** and **4**, respectively with a very weak intensity characteristic of the quaternary carbon signals. The mesomeric shift of electron density from the dithiocarbamate moiety towards the metal centre contributes to the upfield shift from the normal chemical shift values of $Ni(dtc)_2$ complexes (206–210 ppm) [12]. The $S_2-^{13}C{=}N<$ chemical shifts of the three complexes with PPh_3 follow the order: **3** < **1** < **2**, indicating the influence of PPh_3, NCS and CN, respectively on the mesomeric drift of electron density towards nickel.

3.4.3. ^{31}P NMR

^{31}P chemical shifts are observed at 20.5, 22.1, 30.9 and 61.8 ppm for complexes **1**, **2**, **3** and **4**, respectively. A good extent of deshielding of about 75 ppm is observed for the ^{31}P signal of complex **4**, compared to the free chelating dppe ^{31}P signal observed at −13 ppm [13]. In the case of complexes **1**, **2** and **3** signals are also observed in the deshielded region compared to the free PPh_3 signal at −5 ppm [14]. A very high deshielding of signals observed in all the cases is attributed to the movement of electron density from the phosphorus towards the nickel atom on complexation. The PPh_3 complexes show the following order of increasing ^{31}P chemical shifts: **3** (30.9 ppm) > **2** (22.1 ppm) > **1** (20.5 ppm). The observed order clearly establishes the ease with which the back bonding interaction takes place. The back bonding electron donation is the best in the case of **3**, containing the NiP_2 chromophore.

3.5. Structural analysis

The single crystal X-ray structure of **1** contains four discrete molecules per unit cell. The ORTEP diagram of the molecule is shown in Fig. 1. The observed distortion of the square planar coordination around nickel is attributed to the small bite angle of 78.86(8)°. The planarity is supported by the observed diamagnetism of the complex. Delocalization of π electron density over the S_2CN moiety leads to a decrease in the C–N [S_2–C=N<] distance [1.316(8) Å] and also an increase in the S–C–N angles [125.3(6)° and 125.4(6)°] over the S–C–S angle [109.3(4)°]. The observed difference in Ni–S distances [2.213(4) and 2.1809(19) Å] is attributed to the difference in the *trans* influencing properties of PPh_3 and NCS^-. PPh_3 being a good π acceptor has a greater *trans* influence and hence the Ni–S bond *trans* to PPh_3 is longer than the other Ni–S bond.

The Ni–N distance [1.859(6) Å] is quite short, showing the effective bonding between the nickel atom and the thiocyanate-*N*. The C–N bond distance in N–C–S [1.152(7) Å] is significantly shorter than the S_2–C=N< N–C bond distance of 1.316(8) Å. The C–S bond length in N–C–S is 1.619(7) Å, which is similar to the C=S distance of 1.69 Å. The N–C–S bond is [179.5(9)°] and is almost linear. In the dithiocarbamate part, the piperazine ring is in a sterically favoured chair conformation with the normal C–C and C–N bond lengths. The *N*-methyl group in the terminal position is equatorially oriented to avoid the 1,3-diaxial steric interactions with the axial hydrogens. Phenyl groups in triphenylphosphine show normal bond parameters.

$[Ni(4\text{-mpzdtc})(PPh_3)_2]ClO_4 \cdot H_2O$ is discrete and monomeric. One molecule of water is co-crystallized with the complex. Eight formula units are present in the unit cell. Each asymmetric unit has two molecules and the bond parameters of one molecule are listed. The ORTEP diagram of **3** is shown in Fig. 2. Distortions with respect to the idealized geometry are observed in the coordination angles: the P–Ni–P angle is very large [99.82(6)°] due to steric interactions between two PPh_3 groups, while the S–Ni–S bite angle is low, 78.44(5)° as observed in similar compounds [6]. The observed shortening of the >N–CS_2 C–N distance is in line with the bond parameters observed for $[Ni(dtc)(PPh_3)_2]^+$ (where, dtc = dmdtc or dedtc or pipdtc) complexes [6]. Among the mixed ligand complexes, those

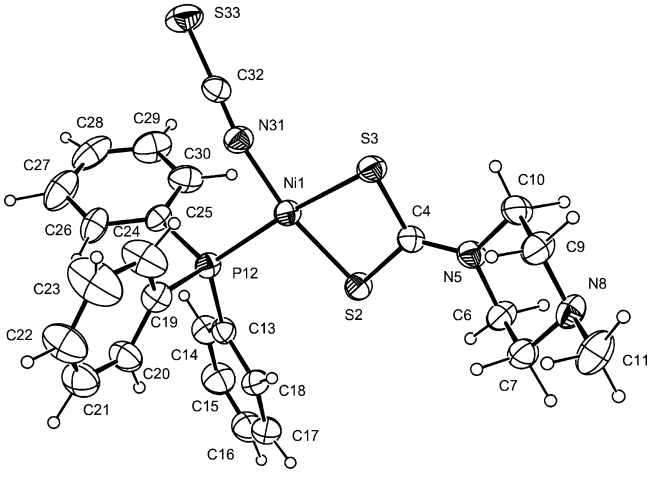

Fig. 1. Thermal ellipsoid plot of $[Ni(4\text{-mpzdtc})(PPh_3)(NCS)]$ (30% probability).

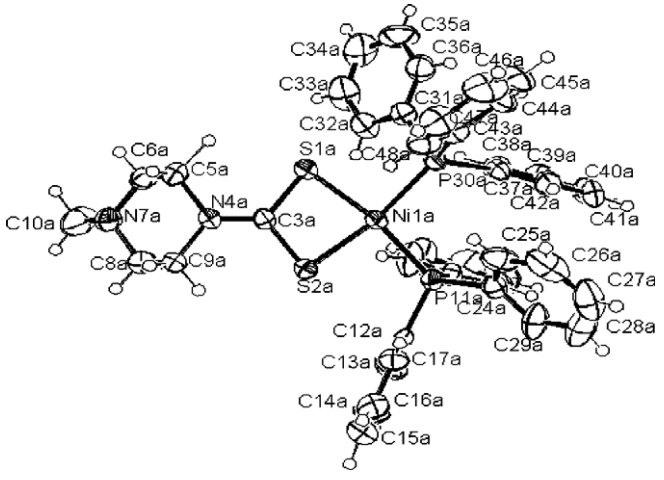

Fig. 2. Thermal ellipsoid plot of $[Ni(4\text{-mpzdtc})(PPh_3)_2]ClO_4 \cdot H_2O$ (30% probability) (H_2O and the ClO_4^- ion are omitted for clarity).

of the NiS_2P_2([Ni(dtc)$(PPh_3)_2]^+$) chromophore show very short S_2–C---N< distances due to the π-acidic nature of the triphenylphosphine. The two S–C–N angles [123.7(4)° and 126.5(4)°] are observed to be larger than the S–C–S angle [109.8(3)°]. Ni–P distances are very similar [2.2333(16) and 2.2149(16) Å]. The two Ni–S and S–C distances are comparable, showing that the negative charge of the bidentate ligand is equally distributed over the two donor atoms. The perchlorate ion shows thermal disorder as reported earlier [5]. The disordered perchlorate ion shows extensive short contacts ranging from 2.5 to 2.9 Å with H atoms of the piperazine ring and similarly with the oxygen atom of the water molecule O1W in the same range. Two hydrogen atoms of the water molecule attached to O2W could not be located in the Fourier map. Also, the disorder associated with ClO_4^- has been modelled such that each oxygen atom is positioned at two coordinate positions of 50% site occupancy at distances of 0.552, 0.336, 0.465, 0.391 Å (for molecule A) and 0.912, 0.815, 0.778, 1.223 Å. (for molecule B). Probable contacts indicating H-bonded interactions in the distance range of 2.4–2.8 Å are observed. Approximately 32 such interactions were noted [15,16]. The very large number of short contacts observed is a result of the modelled oxygen atoms of the perchlorate ion (eight oxygens of 50% site occupancy for every perchlorate ion). The triphenylphosphine and piperazine ring in the dithiocarbamate ligand show normal bond parameters. As observed in complex **1**, the methyl group in the terminal position prefers the equatorial orientation.

Comparison of bond parameters of **1** and **3** indicates a similarity in shortening of the N–CS_2 (N–C) distance for both complexes. The Ni–P distance in the NiS_2PN chromophore [2.207(3) for **1**] is slightly shorter than that of the NiS_2P_2 chromophore [the mean value is 2.2241(16) Å for **3**]. The observed decrease in P–Ni–N angle of about 8° for **1** [92.15(19) versus 99.82(6)] compared to that of the P–Ni–P angle in **3** is due to the decrease in steric crowding around metal centre by the replacement of bulky PPh_3 with NCS^-. The S–C–S and S–Ni–S angles are however similar.

Appendix A. Supplementary material

CCDC 263874 and 263875 contain the supplementary crystallographic data for **1** and **3**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2006.10.006.

macrocyclic cavity and periphery can be chosen independently, thus giving rise to physical properties not seen in the phthalocyanine or metal fragment alone. Using these strategies, so far many novel substituted phthalocyanines have been synthesized [18–22]. The family of reactive phthalocyanine molecules has been an interesting target for the development of further chemical reactions with the phthalocyanine complexes [11,23]. Designed peripheral moieties on the phthalocyanines bearing heteroatoms (N, O, S) are used to bind an exocyclic metal ion, design desired geometries and confer solubility [7,11,13,14,17]. These functionally designed phthalocyanines/porphyrazines perturb pc optical transitions by shifting the absorption from the visible to near-IR or UV-region. For example, phthalocyanines bearing the thia functionality show optical changes when they bind transition metal ions, while phthalocyanines bearing a crown ether are well suited to binding alkaline and alkaline-earth metal ions [11–14,24].

In our previous studies, we have synthesized and characterized octasubstituted ionophore metallophthalocyanines bearing reactive propane 1,2-diolsulfanyl and water-soluble metalloporphyrazines with peripherally functionalized bis [thioethoxy (ethoxy)ethanol] moieties. To increase the solubility in polar solvents and the polarity to bind a metal ion peripherally, in this paper we report the preparation, optical, electrochemical and specific cation binding properties of the functional receptor phthalocyanines having a peripheral thiohexylalcohol functionality, $\{M[Pc(S–C_6H_{13}OH)_4]\}$ (M = Zn(II), Cu(II), Co(II)). To extend the application of the complexes we have also investigated the electrochemical properties of the designed complexes.

2. Experimental

2.1. Materials and equipment

$Zn(O_2CMe)_2$, $CuCl_2$ and $CoCl_2$ were purchased from Aldrich and Alfa Aesar and were used as received. 4-Nitro phthalonitrile was prepared according to the literature procedure [25]. All other reagents were obtained from Merck, Aldrich, Fluka, and Alfa Aesar, Chemical Co. and were used without purification. All reactions were carried out under a dry nitrogen atmosphere. ^1H NMR and ^{13}C NMR spectra were recorded on Bruker 300 spectrometer instruments. Multiplities are given as s (singlet), d (doublet), t (triplet) and m (multiplet). FTIR (Thin Solution Film) were recorded on anATI UNICOM-Mattson 1000 Spectrophotometer. Elemental analysis (C, H, N and S) was performed at the Instrumental Analysis Laboratory of Marmara University. Routine UV–Vis spectra were obtained in a quartz cuvette on a Unicom UV-2 spectrometer. Chromatography was performed with silica gel (Merck grade 60 and sephadex) from Aldrich. The homogenities of the products were tested in each step by TLC (SiO_2, $CHCl_3$ and MeOH).

2.2. Electrochemical method

The cyclic voltammetry (CV), differential pulse voltammetry (DPV) and controlled potential chronocoulometry (CPC) measurements were carried out with a Princeton Applied Research Model VersaStat II potentiostat/galvanostat controlled by an external PC and utilizing a three-electrode configuration at 25 °C. The working electrode was a Pt plate with a surface area of 0.10 cm^2. The surface of the working electrode was polished with a H_2O suspension of Al_2O_3 before each run. The last polishing was done with a particle size of 50 nm. A Pt wire served as the counter electrode. A saturated calomel electrode (SCE) was employed as the reference electrode and separated from the bulk of the solution by a double bridge. Ferrocene was used as an internal reference. Electrochemical grade tetrabutylammonium perchlorate (TBAP) in extra pure dimethylsulfoxide (DMSO) was employed as the supporting electrolyte at a concentration of 0.10 mol dm^{-3}. High purity N_2 was used for deaeration for at least 15 min prior to each run and to maintain a nitrogen blanket during the measurements. During voltammetric measurements, the reference electrode tip was moved as close as possible to the working electrode so that uncompensated resistance of the solution was a smaller fraction of the total resistance, and therefore the potential control error was low. IR compensation was also applied to the CV scans to further minimize the potential control error.

For controlled potential chronocoulometric (CPC) studies, a Pt gauze working electrode (10.5 cm^2 surface area), a Pt wire counter electrode separated by a glass bridge and a SCE reference electrode separated by a glass bridge were used.

2.3. MALDI sample preparation and MALDI mass spectrometry

3-Indole acrylic acid (IAA) (20 mg/mL in acetonitrile) and α-cyano-4-hydroxy cinnamic acid (ACCA) (15 mg/mL 1:1 water–acetonitrile) MALDI matrices for **2**, **3** and **4** were prepared. MALDI samples were prepared by mixing complexes (2 mg/mL in acetonitrile) with the matrix solution (1:10 v/v) in a 0.5 mL eppendorf® micro tube. Finally, 1 μL of this mixture was deposited on the sample plate, dried at room temperature and then analyzed. Mass spectra were acquired on a Voyager-DE™ PRO MALDI-TOF mass spectrometer (Applied Biosystems, USA) equipped with a nitrogen UV-Laser operating at 337 nm. Spectra were recorded in the reflectron mode with average of 50 shots.

2.4. Synthesis

2.4.1. 4′-(6-Hydroxyhexylsulfanyl)-1,2-dicyanobenzene (*1*)

6-Mercapto-1-hexanol (0.77 g, 5.78 mmol) and 4-nitrophthalonitrile (1.00 g, 5.78 mmol) were dissolved in dry DMF and heated at 40 °C in N_2 atmosphere for 1 h.

Then finely ground anhydrous potassium carbonate (~1.20 g, 8.67 mmol) was added portionwise to the mixture over 0.5 h. The reaction mixture was stirred efficiently under nitrogen at 40–45 °C for 3 days. After the reaction mixture was cooled to room temperature it was poured into ca. 200 cm^3 ice-water. The creamy precipitate thus formed was filtered and washed with water until the washings became neutral. The crude product was dissolved in chloroform and washed with 5% $NaHCO_3$ to remove starting unreacted compounds. The creamy solution was then dried with anhydrous Na_2SO_4, and filtered. The solvent, chloroform, was removed under reduced pressure giving a creamy powder. It was chromatographed over a silica gel column using a mixture of $CHCl_3$:MeOH (10/1) as eluent, giving a hydroscopic solid, 4′-(6-hydroxyhexylsulfanyl)-1,2-dicyanobenzene (**1**). Finally, the pure powder was dried in a vacuum. Yield: 0.93 g (61.89%); m.p.: 74 °C, IR (thin film) ν/cm^{-1}: 2233 (–CN), 3342 (CH_2–OH), 3104, 3023 (Ar–H), 2929, 2888, 2859 (Aliph-CH_2) 1710 (H–O···H, weak), 1581 (st), 1544, 1473, 1390, 1286, 1191, 1128, 1072, 983, 873, 831, 719, 572; ^{1}H NMR ([d_6]-DMSO) J/Hz, δ/ppm: 7.78 (dd, $^3J = 7.5$, 1H, *ortho* to SR, phenyl H5) 7.67 (1H, *ortho* to CN and SR, phenyl H3), 7.60 (dd, $^3J = 7.0$, 1H, *ortho* to SR and Ar–H, phenyl H6), 4.19 (t, q, –CH_2–OH, D_2O exchangeable), 3.57 (t, 2H, –CH_2OH), 3.00 (CH_2–CH_2–S–), 1.65 (m, 2H, CH_2–S–Ar), 1.50 (m, 2H, $CH_2CH_2CH_2$–OH), 1.40 (m, 2$x$$CH_2CH_2CH_2$); ^{13}C NMR ([300 MHz, d_6]-DMSO + $CDCl_3$) δ/ppm: 147.81, 133.73, 130.43, 130.35, 116.20, 116.20, 115.95, 115.75, 110.30, 78.23 ($CDCl_3$), 61.68 (–CH_2OH), 40.44 (DMSO), 32.77 (S–CH_2), 31.63 (CH_2CH_2OH), 28.72 (SCH_2CH_2), 28.30 ($SCH_2CH_2CH_2$), 25.57 ($CH_2CH_2CH_2CH_2$OH). *Anal.* Calc. for $C_{14}H_{16}N_2OS$ (%): C, 64.62; H, 6.15; N, 10.77. Found: C, 64.04; H, 6.05; N, 10.28%. MS (ESI-MS): m/z: 261.1 $[M+H]^+$ (45%), 278.1 $[M+H_2O]^+$ (10%), 284.1 $[M+Na]^+$ (20%).

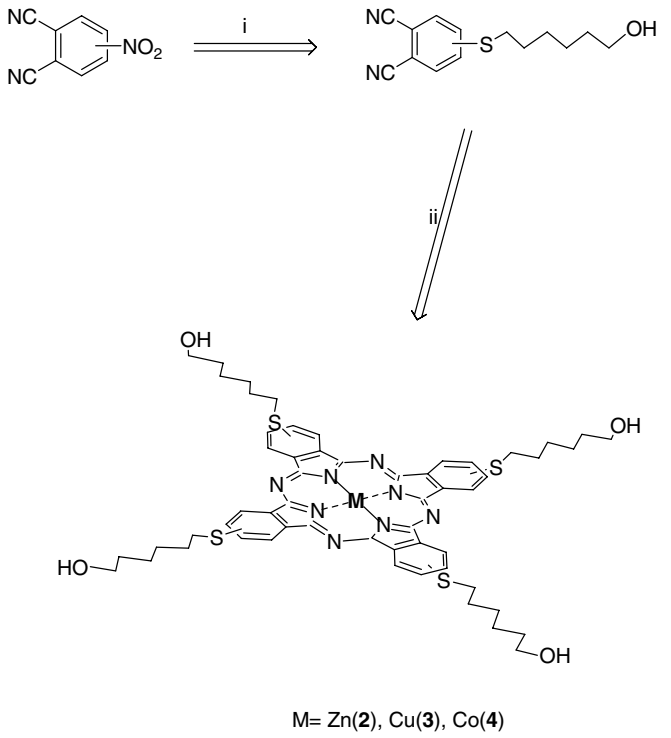
2.4.2. 2,9,16,23-Tetrakis(6-hydroxyhexylsulfanyl)phthalocyaninatozinc(II) (**2**)

A mixture of **1** (0.25 g, 0.96 mmol), anhydrous $Zn(O_2CMe)_2$ (0.04 g, 0.24 mmol) and DBU (0.05 cm^3) in a sealed tube was pulverized and transferred to a sealed tube and heated with efficient stirring at 170 °C for 8 h under a nitrogen atmosphere. The deep green-blue product was cooled to room temperature, and solid was washed successively with CH_3CN, *i*-PrOH, and HAc, to remove any inorganic and organic impurities, until the filtrate was clear. The green-blue product was isolated by silica gel column chromatography with THF–MeOH (50/1 v/v) as eluent. Pure **2** was obtained as a viscous yellow oil following column chromatography over sephadex (1/20 (v/v) $CH_3OH/CHCl_3$, eluent) and then dried in a vacuum. Complex **2** is soluble in THF, MeOH, DMF, DMSO, DMAA and pyridine. Yield: 0.087 g (32.80%). *Anal.* Calc. for $C_{56}H_{64}N_8O_4S_4Zn$ (1105 g/mol): C, 60.81; H, 5.79; N, 10.14. Found: C, 60.08; H, 5.80; N, 9.77%. IR (thin film) ν/cm^{-1}: 3640 (free OH, w), 3287 (br, H-bonded), 2927, 2855, 1737 (H–O···H, weak), 1612 (w), 1597, 1484, 1433, 1365, 1303, 1229, 1217, 1138, 1069, 1034, 909, 814,759,742. ^{1}H NMR ([d_6]-DMSO) J/Hz δ/ppm: 7.83 (broad, 1H, *ortho* to SR, $^3J = 7.0$, phenyl H5) 7.82 (s, isomer, 1H, *ortho* to CN and SR, $^3J = 7.2$, phenyl H3), 7.61(dd, 1H, *ortho* to SR and Ar–H, $^3J = 7.0$, phenyl H6), 4.22 (s, t, br, –CH_2–OH, D_2O exchangable), 3.59 (t, 2H, –CH_2OH), 3.01 (CH_2–S–), 1.65 (m, 2H, CH_2–S–Ar), 1.47 (m, 2H, $CH_2CH_2CH_2$–OH), 1.40 (m, 2$x$$CH_2$-$CH_2CH_2$). UV–Vis (THF), λ_{max}/nm: 681 (6.00), 615 (1.22), 582 (sh, 0.57), 345 (5.7); MS (Maldi-TOF, α-cyano-4-hydroxy cinnamic acid (CHCA) as matrix): m/z (100%): 1105.20 $[M+H]^+$, 1149.20 $[M-H+2Na]^+$, 1189.20 $[M-2H+3Na+H_2O]^+$, 1151.20 $[M+2Na]^+$, 1192 $[M+3Na+H_2O]^+$, 1129.20 $[M-3H+4Na+2H_2O]^+$.

2.4.3. 2,9,16,23-Tetrakis(6-hydroxyhexylsulfanyl)phthalocyaninatocopper(II) (**3**)

4′-(6-Hydroxyhexylsulfanyl)-1,2-dicyanobenzene (**1**) (0.25 g, 0.96 mmol), anhydrous copper (II) chloride (0.03 g, 0.24 mmol) and dbu (0.05 cm^3) in 1-hexanol (~1 cm^3) were heated to reflux in a sealed tube under N_2 for 8 h. The green-blue mixture was cooled to room temperature after which the mixture was diluted with petroleum ether. The crude precipitate was washed several times successively with first *i*-PrOH, CH_3CN and then HAc to remove any organic and inorganic impurities. Finally, the product was redissolved in $MeOH/CHCl_3$ and further purified by silica gel chromatography (eluent: $MeOH/CHCl_3$ (10/100)) and sephadex (10/100 $MeOH/CHCl_3$). After washing the resulting oily product with copious amounts of hexane, diethylether and finally *i*-PrOH, it was then dried in a vacuum. This product is moderately soluble in MeOH and THF, and soluble in DMF, DMSO and pyridine. Yield: 0.06 g (24.16%). *Anal.* Calc. for $C_{56}H_{64}N_8O_4S_4Cu$ (1103.5 g/mol): C, 60.90; H, 5.80; N, 10.15. Found: C, 60.69; H, 5.77; N, 9.58%. IR (thin film) ν/cm^{-1}: 3638 (free OH, w), 3250 (H-bonded, OH), 3010, 2973, 2951, 2856, 1732 (H–O···H, weak), 1657 (w), 1598, 1433 (w), 1364 (st), 1364, 1310, 1229, 1217, 1137, 1118, 1034, 910, 887, 873, 811, 742, 687; UV–Vis (THF), λ_{max}/nm: 684 (15.70), 622 (3.76), 582 (1.18), 351 (9.80); MS (Maldi-TOF, CHCA as matrix): m/z (100%): 1103.20 $[M+H]^+$, 1187 $[M-2H+3Na+H_2O]^+$, 1227 $[M-3H+4Na+2H_2O]^+$, 1267 $[M-4H+5Na+3H_2O]^+$.

2.4.4. 2,9,16,23-Tetrakis(6-hydroxyhexylsulfanyl)phthalocyaninatocobalt(II) (**4**)



Compound **1** (0.25 g, 0.96 mmol), anhydrous $CoCl_2$ (left overnight in an oven at 110 °C) (0.03 g, 0.24 mmol) and DBU (0.05 cm^3) were pulverized and transferred to a tube and sealed under nitrogen atmosphere. The temperature of the reaction mixture was raised to 150–160 °C and kept at this value for 12 h. After cooling to room temperature and diluting with *i*-PrOH, the reaction mixture was filtered. The dark green-blue crude product

formed during the reaction was treated with *i*-PrOH several times and filtered off. It was then successively washed with H_2O, acetonitrile and dried. It was further purified by column chromatography (flash column) with silica gel ($CHCl_3$/MeOH as eluent, (5/100)) and dried in a vacuum. Blue star phthalocyanine (**4**) is slightly soluble in 2-propanol and acetonitrile, and well soluble in THF, MeOH, EtOH, DMF and DMSO. Yield: 0.07 g (27.30%). *Anal.* Calc. for $C_{56}H_{64}N_8O_4S_4Co$ (1099 g/mol): C, 61.15; H, 5.82; N, 10.19. Found: C, 60.56; H, 5.56; N, 9.59%. IR (KBr thin film) ν/cm^{-1}: 3639 (free OH), 3243 (H-bonded, OH), 3017, 2976, 2927, 2856, 1727 (H–O···H, weak), 1603 (w), 1505, 1432 (w), 1364 (st), 1314, 1229, 1216, 1141, 1105, 1040, 931, 873, 781, 750, 740, 690. 3. Result and discussion

3.1. Synthesis and characterization

The synthesis of the metallophthalocyanines (**2**–**4**) required the preparation of the key phthalonitrile precursor (**1**) (Scheme 1). We used nucleophilic aromatic displacement of the nitro group of 4-nitrophthalonitrile [25] with the –SH functional site of 6-mercapto-hexanol, which is more preferable than –OH nucleophiles, to afford compound **1**, 4′-(6-hydroxyhexylsulfanyl)-1,2-dicyanobenzene,

Scheme 1. Synthetic route of 2,9,16,23-tetrakis(6-hydroxyhexylsulfanyl)-phthalocyanine M[Pc(S–$C_6H_{13}OH)_4$] (M = Zn(II), Cu(II), Co(II)). (i) K_2CO_3, 6-mercapto-1-hexanol, DMF, 40 °C, 3 days. (ii) anhydrous $Zn(O_2CMe)_2$, $CuCl_2$, $CoCl_2$, DBU.

in good yield at reflux temperature in THF in the presence of K_2CO_3. Receptor metallophthalocyanines M[Pc-(S–$C_6H_{13}OH)_4$] (M = Zn^{II}, Cu^{II}, Co^{II}) (**2**–**4**) in the present work were obtained from the cyclotetramerization reaction of **1** with the corresponding appropriate anhydrous metal salt in the presence of hexanol and 1,8-diazabicyclo [5.4.0] undec-7-ene (DBU) as a strong base (Scheme 1), followed by chromatographic purification on silica gel and size exclusion columns. The green-blue cyclotetramerization products (**2**–**4**), were isolated as a mixture of isomers and purified by column chromatography in workable yields (32.80% for **2**, 24.16% for **3**, and 27.30% for **4**). Purification steps were tedious because of peripheral polar reactive end-groups. The peripheral OH– and sulfur donor atom have a profound influence on physical and chemical properties of the phthalocyanine macrocycle. The four polar peripheral groups confer good solubility on these macromolecules in polar media such as MeOH, THF, DMF, DMSO and DMAE.

3.2. Spectroscopic characterization

The characterization of each phthalocyanine was carried out by FTIR, ^{1}H NMR (except **3** and **4**), UV–Vis and MALDI-MS spectroscopic methods, as well as by elemental analysis. All the analytical and spectral data are consistent with the predicted structures.

In the IR spectra of **2**, **3** and **4**, the major strong –CN band at 2233 cm^{-1} belonging to **1** disappeared after conversion to the metallophthalocyanines (**2**–**4**). A very weak band in all phthalocyanines above 3000 cm^{-1} is due to the aromatic C–H stretchings. In the IR spectra of all the phthalocyanines, the most intense bands of the spectra are the absorption at ca. 2930 and 2855–2860 cm^{-1} due to the C–H stretching vibrations of the $-CH_2$ groups for the 1-hydroxyhexyl moieties. Primary aliphatic –OH peaks at around 3240 and 3640 cm^{-1} (free (w) and H-bonded OH) and the rest of the spectra are closely similar to that of former one's and are diagnosed easily. The most instinctive indicators for **1** are the signals belonging to the aromatic protons *ortho* to the cyano group in the lower field region of the ^{1}H NMR (DMSO-d_6) and six different aromatic carbon atoms between 110 and 148 ppm in the ^{13}C APT spectrum. As the ^{1}H NMR spectrum of compound **1** was recorded in $CDCl_3$, it showed only broad signals for the substituents, while the aromatic proton signals were not observed. However, in the presence of DMSO-d_6, the aromatic proton signals emerged as relatively broad signals in the downfield region of the spectrum. In compound **1**, bearing substituents in the four-positions, the aromatic protons *ortho* to the cyano group appeared at 7.67 ppm as one slightly broad singlet in the downfield region of the ^{1}H NMR spectrum, in addition to a doublet of doublets at 7.78 and 7.60, while broad deuterium exchangeable –OH protons came out at 3.57 ppm. The ^{1}H NMR spectrum of **2** was almost identical to the starting compound **1** except for small shifts and slight broadening. The broad

signals in **2** are probably due to the chemical exchange associated with aggregation–disaggregation equilibria which occur at the high concentrations used in the NMR measurements or because of it being an isomeric mixture [1]. The substitution of **2**–**4** with 6-mercaptohexanol results in the formation of positional isomers, which causes the splitting of the signals for the peripheral aromatic protons in the downfield of the aromatic region. Slightly broad signals for primary aliphatic –OH exchangeable protons of the phthalocyanines at 3.57 ppm disappeared after addition of D_2O.

UV–Vis spectra of the phthalocyanine complexes (**2**–**4**) exhibited characteristic absorptions in the Q-band region at around 650–700 nm, attributed to the π–π^* transition from the HOMO (highest occupied molecular orbital) to the LUMO (lowest unoccupied molecular orbital) of the Pc^{2-} ring, and in the B band region (UV region) at around 300–400 nm, arising from the deeper π–π^* transitions. In the UV–Vis absorption spectra of all phthalocyanines, the Q-band absorptions were observed as a single band of high intensity at 686, 686 and 674 nm, respectively. There was also a shoulder at the slightly higher energy side of the Q band for each phthalocyanine. In the phthalocyanines bearing sulfanyl substituted moieties on the periphery, the Q band absorption was shifted to the lower energy side as a result of the electron-donating thioether substituents compared to that of phthalocyanines bearing oxa substituted moieties, whereas the position of the soret-like π–π^* bands of all the phthalocyanines was only slightly shifted. Any increase in the concentration results in the aggregation of the phthalocyanine molecules, which is accompanied by a blue shift of the Q-band with a decrease in intensity (ε_{max}). The extent of aggregation is slightly stronger for the phthalocyanines bearing tetrasubstituents on the periphery than that for the octasubstituted ones [13,20,26].

3.3. MALDI-MS spectra

The mass spectra of **2**, **3** and **4** confirmed the proposed structures. The protonated molecular ion peaks were easily identified at *m*/*z*: 1105.20 $[M+H]^+$ for **2**, and *m*/*z*: 1103.20 $[M+H]^+$ for **3**. The protonated molecular ion peak for **4** was observed at 1099 Da which exactly overlapped with the mass of the cobalt complex calculated theoretically from the elemental composition of the complex (Fig. 1). Beside the protonated molecular ion peak of the complex, additional peaks were observed at 1100, 1101, 1102, 1103 and 1104 in the high mass range, representing the isotopic distribution of the metal and carbon. Following the protonated molecular ion peak, a peak group was observed at 18 Da mass higher than the protonated molecular ion peak group, with almost the same pattern. This peak is the result of a water adduct with the protonated ion peak of complex **4**. The MALDI spectra of **2** and **3** showed very clear and low fragmentations in the MALDI-MS.

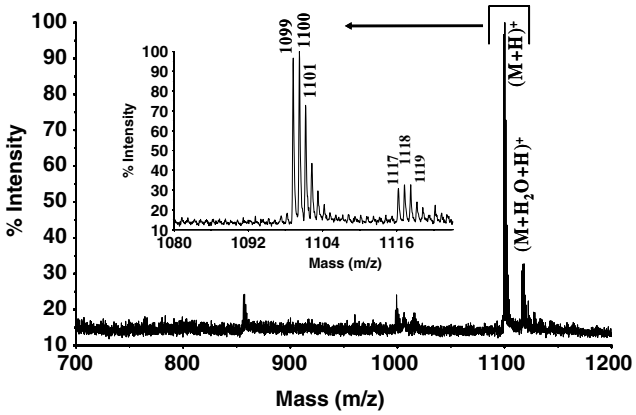

Fig. 1. Positive ion and reflectron mode MALDI-MS spectrum of **4** was obtained in 3-indoleacrylic acid MALDI matrix using nitrogen laser accumulating 50 laser shots. Inset spectrum shows the expanded molecular mass region of the complex.

3.4. Spectroscopic metal ion binding titrations

The sulfur groups on the periphery of the metallophthalocyanine complexes (MPc's) are optically sensitive to soft metal ions, such as Ag^I and Pd^{II}. Therefore, we have employed UV–Vis spectroscopic titrations to monitor the capability of our MPc's for sensing/coordinating transition metal ions of different size. Each titration experiment was carried out using a MeOH/THF solution of MPc's (10/90, v/v) to ensure complete dissolution of the analyte salts, $AgNO_3$, Na_2PdCl_4, $Cd(O_2CMe)_2$ and $Hg(NO_3)_2$ dissolved in MeOH. Here, the concentration of each MPc and the metal salt was ca 10^{-5} and 10^{-3} mol dm^{-3}, respectively. The reason for the higher concentration of the metal salt was to produce negligible changes by dilution after its addition to the phthalocyanine solution. Sulfur donor atoms of 1-hydroxyhexylsulfanyl moieties of **2**–**4** coordinate Ag^I and Pd^{II}, exhibiting optical changes. However, no optical changed were observed when the complexes were titrated with Cd^{II} and Hg^{II}.

The titration of **2**–**4** with Pd^{II} showed similar optical changes, as shown in Fig. 2. The room temperature gradual addition (μl) of Pd^{II} to the solution of **2**–**4** caused a gradual color change, from blue-green to intractable dark-green, suggesting the complex formation of the complexes with Pd^{II}. As shown in Fig. 2, Pd^{II} binding to the donor atoms of the complexes results in pronounced effects in the Q and B-bands, and in the n–π^* transitions (attributed to the non-bonding sulfur electron (n) to the π^* phthalocyanine orbital) [14]. While addition of small increments of Pd^{II} to **2**–**4** leads to a gradual disappearance of the monomeric species, which show absorptions at 686, 686 and 674 nm, simultaneously enhancing the intensity of the oligomeric aggregated species with absorptions around 654, 655 and 640 nm, respectively. B-bands of all the complexes shift to the higher energy side by about 15–20 nm, without change in intensity. As in Fig. 2, the titration shows clear isobestic points at 345, 384, 487, 607, 624, 662 and

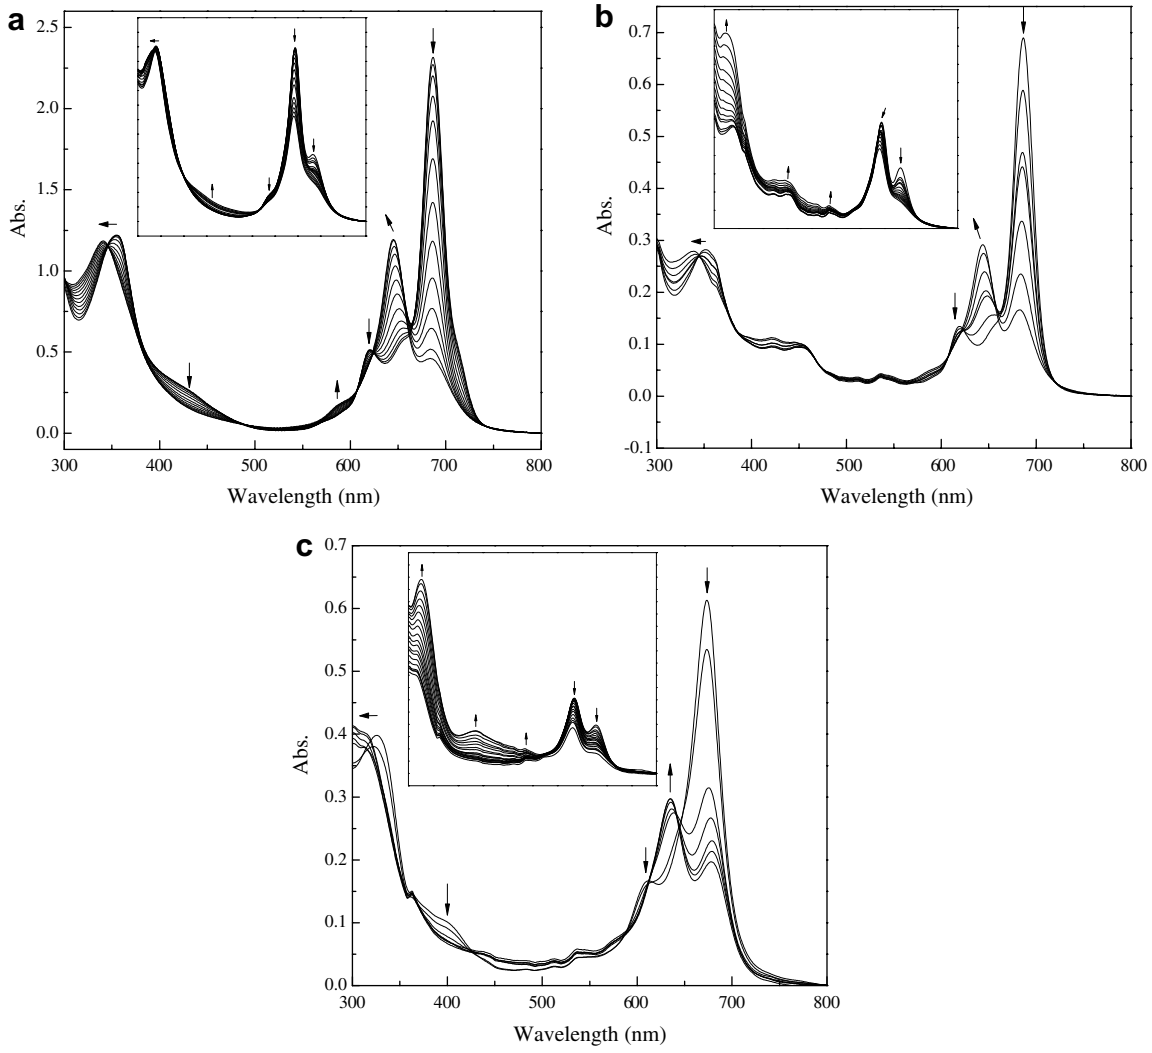

Fig. 2. UV–Vis spectra of **2** (a), **3** (b) and **4** (c) in THF/MeOH during titration by Pd^{2+} (in MeOH).

740 nm for **2**, 345, 377, 467, 607, 623, 661 and 720 nm for **3** and 315, 363, 425, 590, 612 and 645 nm for **4**. This type of spectroscopic behavior probably results from the complexation of Pd^{II} with the phthalocyanine complexes and the aggregation-disaggregation equilibrium of the Pd^{II}–Pc complexes. This observation is in harmony with previously reported studies [14,17,23,26]. However, further addition of Pd^{II} indicates very distinct spectroscopic changes as shown in the inset of Fig. 2. While the intensities of the Q-bands of monomeric and oligomeric aggregated species start to decrease, the intensity of B-bands and the n–π^* transition-bands (attributed to the non-bonding sulfur electron (n) to the π^* phthalocyanine orbital) at around 400–500 nm increase. These uncommon spectroscopic changes indicate that the overall complexation behavior of the complexes likely to be more complex. These uncommon changes may be the result of the formation of a Pd^{II}–Pc complex exhibiting a different geometry, the decomposition of the aggregates and the formation of square planar complexes (inset figures in Fig. 2a–c).

Fig. 3 shows the initial and end points of the titration of **2** and **3** with Ag^{I}, representing the optical changes of the complexes with Ag^{I}. The addition (μl) of Ag^{I} to a solution of **2**–**4** caused a gradual color change, from blue-green to intractable dark-blue, suggesting complex formation of the complexes with Ag^{I}. As shown in Fig. 3, addition of Ag^{I} to the solution of the complexes leads to a gradual disappearance of the monomeric species, simultaneously enhancing the intensity of the oligomeric aggregated species observed at the higher energy side of the Q-band of the monomeric species. A blue shift of about 15–20 nm without change in intensity for the B-bands of the all complexes was also recorded. The titration shows clear isobestic points at 330, 478, 607, 655 and 715 nm for **2**, 335, 387, 486, 615, 656 and 715 nm for **3** and 335, 380, 470, 620, 656 and 716 nm for **4**. These spectroscopic changes indicate the coordination of Ag^{I} by the donor atoms of the phthalocyanines and the formation of network type polymer units due to the aggregation of complexes. Further addition of Ag^{I} did not change the spectra. The results of the titration

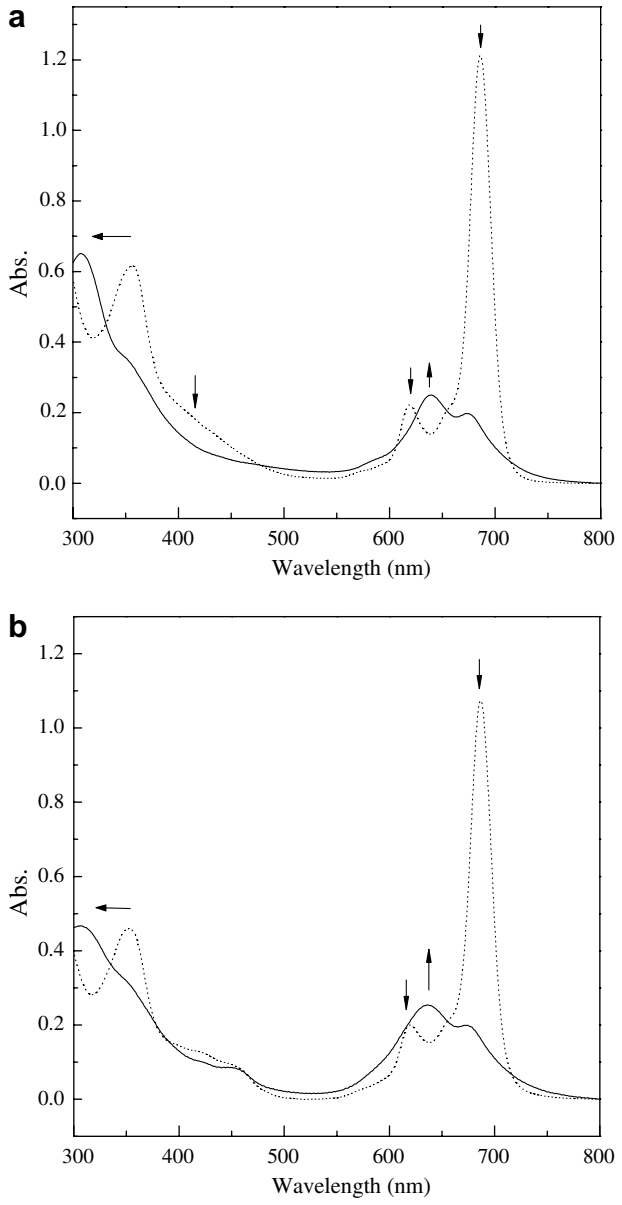

Fig. 3. UV–Vis spectra of **2** (a) and **3** (b) in THF/MeOH during titration by Ag^{+} (in MeOH).

with Ag^{I} ion closely followed those obtained in previous works [14,17,23,26].

3.5. Electrochemical measurements

The electrochemical behavior of all of the phthalocyanines was investigated by cyclic voltammetry (CV) and differential pulse voltammetry (DPV) on a platinum working electrode in DMSO. The half-wave redox potential values ($E_{1/2}$) versus SCE are summarized in Table 1. Fig. 4 shows the cyclic voltammograms and differential pulse voltammograms of **3** and **4**, as typical representatives of the compounds.

Within the electrochemical window of TBAP/DMSO, compound **4** undergoes a quasi-reversible one-electron

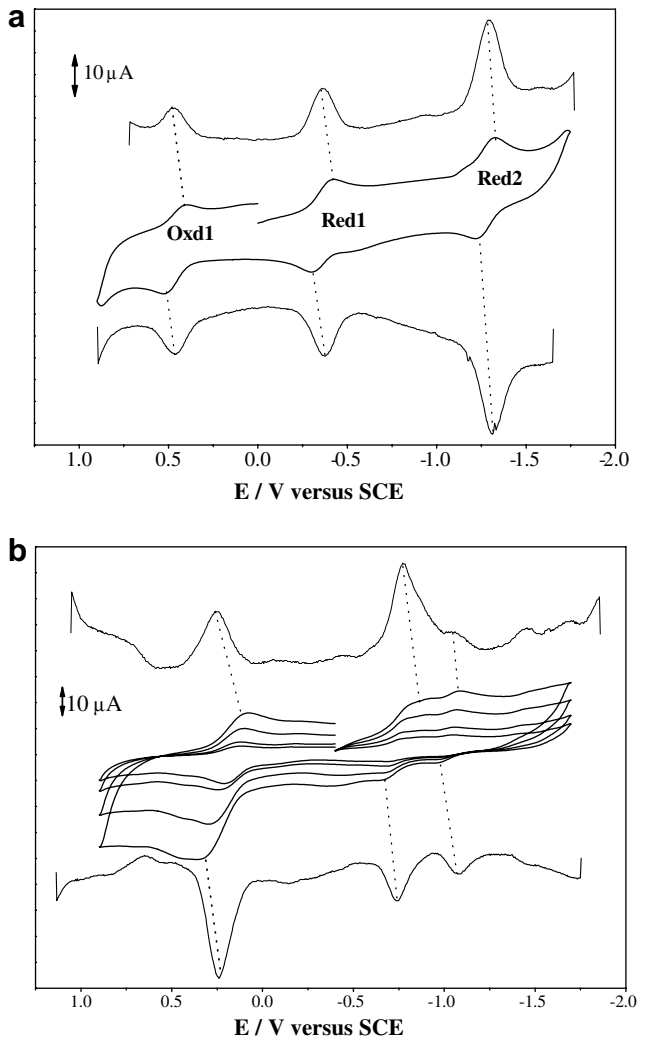

Fig. 4. Cyclic and differential pulse voltammograms of **4** (a) and **3** (b) at various scan rates on Pt in DMSO/TBAP.

oxidation and two quasireversible one-electron reductions at 0.47, −0.36 and −1.27 V versus SCE at a 0.100 V s^{-1} scan rate, respectively. Differential pulse voltammetry of the complex confirms the recorded redox processes clearly. Reversibility is illustrated by the similarity in the forward and reverse DPV scans (inset in Fig. 4) [27]. First-row transition metal Pcs differ from the main-group metal Pcs due to the fact that metal "d" orbitals may be positioned between the HOMO and LUMO of the phthalocyanine (Pc^{-2}) ligand. The first oxidation and first reduction processes occur on the metal center in the metal Pc only for Mn, Fe and Co derivatives in polar solvents such as DMF and DMSO. For Ni, Cu and Zn phthalocyanines, redox processes take place on the Pc ring [27,28]. This study indicates that the first reduction and first oxidation processes of **4**, recorded at 0.465 and −0.360 V, could easily be assigned to the Co^{II}/ Co^{I} and Co^{II}/ Co^{III} redox couples, respectively, and the remaining processes to the phthalocyanine ring. All predicted redox processes are given in Eq. (1). Furthermore, both the first oxidation and the first reduction of **4** are recorded at almost the same potentials relative to those of the reported CoPc with a slight shift as a result of the electron-donating substituents, with the separation between the metal center reduction and oxidation processes also remaining unchanged (Table 1). The separation between the metal center reduction and oxidation processes (∼0.825 V) is comparable with the CoPc papers [28–32]. As shown in Table 1, the redox processes are shifted towards a positive potential as a result of the electron releasing ability of the tetra –(6-mercapto 1-hexanol) substituents with respect to the tetra-(propanediolsulfanyl) tetrachloro substituted CoPc characterized in our previous study [17].

$$[\mathrm{Co(III)Pc}(-2)]^{+} \underset{0.47\ \mathrm{V}}{\overset{e^-}{\Longleftrightarrow}} [\mathrm{Co(II)Pc}(-2)] \Longleftrightarrow \overset{e^-}{\underset{-0.36\ \mathrm{V}}{}}[\mathrm{Co(I)Pc}(-2)]^{1-} \underset{-1.27\ \mathrm{V}}{\overset{e^-}{\Longleftrightarrow}} [\mathrm{Co(I)Pc}(-3)]^{2-} \quad (1)$$

Within the electrochemical window of TBAP/DMSO, **2** and **3** undergo a one-electron oxidation and three one-electron reductions. Because of the electro-inactive metal center of the complexes, all of these processes are attributed to successive removal of electrons from, or addition of electrons to, the macrocycle orbitals. Differential pulse voltammetry of the complex confirms the recorded redox processes clearly. Moreover the oxidation process of **3** has adsorption character due to the very intense anodic current and the linear variation of the anodic peak current with scan rate. Copper macrocycles generally showed adsorption behavior in our previous studies [33,34]. As a result of the adsorption of the complexes on the electrode surface, the oxidation couple of the complexes shift to a less positive potential with respect to common copper phthalocyanine studied in the literature. Adsorption of the complexes results in a significantly decreased potential difference between the first reduction and first oxidation redox processes, i.e., a decreased HOMO–LUMO gap (0.910 V) of the compounds. However, the HOMO–LUMO gap (∼1.470 V) of **2** is comparable with those of common metallophthalocyanines (∼1.300–1.700 V). A positive potential shift of the redox processes for **2** and **3** with respect to tetra-propanediolsulfanyl tetra-chloro substituted CuPc, characterized in our previous study [17], was also observed.

4. Conclusions

We have synthesized novel phthalocyanine derivatives bearing peripheral tetrakis(6-hydroxyhexylsulfanyl) substituents which are soluble in a range of especially polar organic solvents. The peripherally modified phthalocyanines have been fully characterized with various spectroscopic and electrochemical methods in this work, representing a unique class of selective metal–ion chelators that absorb in the visible region. The thio donors as a soft-base, which are distributed on benzene moieties of the phthalocyanine, are coordinated with metal ions,

such as Ag^{I} and Pd^{II}, so resulting in a polymeric assembly. The thio groups on the periphery provide good donor capabilities for soft metal ions, resulting in the red shift of the Q-band. Thus, the ease of altering of the chemical and spectroscopic properties of these phthalocyanines through peripheral variation allows continuing studies to focus on the development of the next generation of sensor complexes for the targeting of particular metal cations. Peripheral and center metal variation of the complexes also affect the redox properties in solution. Electrochemical studies establish that the phthalocyanine derivatives undergo up to four quasi-reversible one-electron diffusion controlled metal and/or ligand-based oxidation/reduction electron transfer reactions, differing with potential shift as a result of the electron withdrawing/releasing effect of the substituents and the metal–ligand interactions.

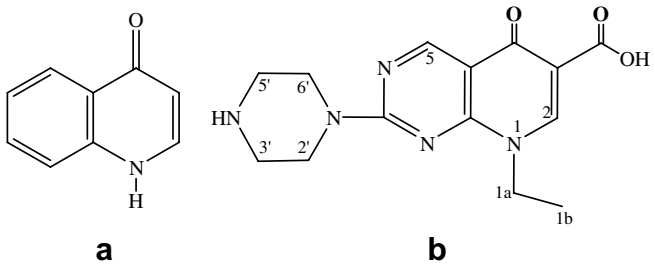

Fig. 1. (a) The 4-oxo-1,4-dihydroquinoline skeleton. (b) Pipedimic acid (8-ethyl-5,8-dihydro-5-oxo-2-(1-piperazinyl)pyrido(2,3-d)pyrimidine-6-carboxylic acid = HPPA) and atom labelling.

rofloxacin complexes as polyoxometalates have been characterized [25], while no quinolone complexes of $Mo(VI)O_2^{2+}$ and $U(VI)O_2^{2+}$ have been reported yet, although their role as bioelements is well established [26–29].

Pipemidic acid, HPPA (Fig. 1b), a 4-quinolone product, is an antibacterial agent used to treat gram-negative urinary tract infections [30] and severely damages DNA in the absence of an exogenous metabolizing system [31]. Pipemidic acid can act as a bidentate ligand through the quinolone oxygen and one carboxylate oxygen atom. In the literature, complexes of protonated pipemidic acid are reported with Ca^{2+}, Sr^{2+}, Ba^{2+}, Sn(IV) [32] and with the lanthanides La(III), Ce(III), Pr(III), Nd(III), Sm(III), Tb(III), Dy(III) and Y(III) [33] as well as of the deprotonated pipemidic acid with pentacoordinate Cu(II) and Mn(II) [34]. The reported results suggest that metal ion coordination might be involved in the antibacterial activity of HPPA [35].

We have initiated the study of the structure, spectroscopic and biological properties of transition metal complexes of diverse quinolone antibacterial drugs [36–39]. In this context we have studied the interaction of deprotonated pipemidic acid with the transition metal ions $V^{IV}O^{2+}$, Mn(II), Fe(III), Co(II), Ni(II), Zn(II),Cd(II), $Mo^{VI}O_2^{2+}$ and $U^{VI}O_2^{2+}$ in an attempt to examine the mode of binding and possible synergetic effects. The resulting mononuclear complexes have been characterized with elemental analysis and diverse spectroscopic techniques (IR, UV–Vis, NMR and EPR spectroscopy). Molecular modelling techniques have been employed so as to propose a low energy model for the most favorable isomer of the VO^{2+}, Fe^{3+} and MoO_2^{2+} complexes based on molecular mechanics calculations in the gas phase. The interaction of complexes with calf-thymus (CT) DNA has been studied with UV and circular dichroism (CD) spectroscopy. The antibacterial activity of the complexes has been also investigated against three microorganisms.

2. Experimental

2.1. Materials

All the chemicals for the synthesis of the compounds were used as purchased. DMF was distilled from calcium hydride (CaH_2) and CH_3OH from Mg, and stored over 3 Å molecular sieves. Diethyl ether, anhydrous grade and absolute ethanol were used without any further purification. Pipemidic acid and CT DNA were purchased from Sigma and $VOSO_4 \cdot 5H_2O$, $CoCl_2 \cdot 6H_2O$, $MnCl_2 \cdot 4H_2O$, $FeCl_3 \cdot 3H_2O$, $NiCl_2 \cdot 6H_2O$, $ZnCl_2$, $CdCl_2 \cdot 2.5H_2O$, $UO_2(NO_3)_2 \cdot 6H_2O$, $MoO_2(acac)_2$, KOH and all the solvents were purchased from Aldrich Co. Agarose was purchased from BRL. Tryptone and yeast extract were purchased from Oxoid (Unipath, Hampshire, UK). All chemicals and solvents were reagent grade.

DNA stock solutions (5 mM) were prepared by dilution of CT DNA with buffer (containing 150 mM NaCl and 15 mM trisodium citrate at pH 7.0) followed by exhaustive stirring at 4 °C for three days [40] and the solutions were kept at 4 °C for no longer than a week. The nucleotide concentrations were determined by their absorption at 260 nm using $\varepsilon = 6600\ M^{-1}\ cm^{-1}$ (expressed as phosphate).

2.2. Synthesis of the complexes

2.2.1. $VO(PPA)_2(H_2O)$ (1)

A warm methanolic solution (15 mL) of deprotonated pipemidic acid (0.4 mmol, 121 mg) was added to a methanolic solution (10 mL) of $VOSO_4 \cdot 5H_2O$ (0.2 mmol, 51 mg) and the reaction mixture was refluxed for 2 h. The solution was filtered and left for slow evaporation. After a few days a brown-green microcrystalline product was deposited, collected with filtration, washed with methanol and dried. Yield: 104 mg, ~75%. *Anal.* Calc. for $VO(PPA)_2(H_2O)$ ($C_{28}H_{34}N_{10}O_8V$) (MW = 689.58): C, 48.77; H, 4.97; N, 20.31. Found: C, 49.05; H, 5.03; N, 20.10%. The complex is soluble in DMSO and DMF and is a non-electrolyte.

In a similar way complexes **2**–**9** were prepared with the use of the corresponding metal salt.

2.2.2. $Mn(PPA)_2(H_2O)_2$ (2)

$MnCl_2 \cdot 4H_2O$ (0.2 mmol, 40 mg) was used. A yellow microcrystalline product was collected. Yield: 97 mg, ~70%. *Anal.* Calc. for $Mn(PPA)_2(H_2O)_2$ ($C_{28}H_{36}N_{10}O_8Mn$) (MW = 695.59): C, 48.35; H, 5.22; N, 20.13. Found: C, 48.62; H, 5.30; N, 19.89%. The complex is soluble in DMSO, DMF, CH_3CN and acetone and is a non-electrolyte.

2.2.3. $Fe(PPA)_3$ (3)

$FeCl_3 \cdot 3H_2O$ (0.2 mmol, 44 mg) and pipemidic acid (0.6 mmol, 192 mg) were used. An orange microcrystalline product was collected. Yield: 140 mg, ~67%. *Anal.* Calc. for $Fe(PPA)_3$ ($C_{42}H_{48}N_{15}O_9Fe$) (MW = 962.79): C, 52.39; H, 5.03; N, 21.82. Found: C, 51.93; H, 4.91; N, 22.03%. The complex is soluble in DMSO, DMF and H_2O and is a non-electrolyte.

2.2.4. $Co(PPA)_2(H_2O)_2$ (4)

$CoCl_2 \cdot 6H_2O$ (0.2 mmol, 48 mg) was used. An orange-yellow microcrystalline product was collected. Yield: 90 mg, ~65%. *Anal.* Calc. for $Co(PPA)_2(H_2O)_2$

($C_{28}H_{36}N_{10}O_8Co$) (MW = 699.59): C, 48.07; H, 5.18; N, 20.02. Found: C, 47.76; H, 5.37; N, 19.65%. The complex is soluble in DMSO and DMF and is a non-electrolyte.

2.2.5. $Ni(PPA)_2(H_2O)_2$ (5)

$NiCl_2 \cdot 6H_2O$ (0.2 mmol, 48 mg) was used. A light green microcrystalline product was collected. Yield: 98 mg, ~70%. *Anal.* Calc. for $Ni(PPA)_2(H_2O)_2$-($C_{28}H_{36}N_{10}O_8Ni$) (MW = 699.37): C, 48.09; H, 5.19; N, 20.03. Found: C, 48.41; H, 5.01; N, 20.17%. The complex is soluble in DMSO, DMF, ethanol and H_2O and is a non-electrolyte.

2.2.6. $Zn(PPA)_2(H_2O)_2$ (6)

$ZnCl_2$ (0.2 mmol, 28 mg) was used. A pale yellow microcrystalline product was collected. Yield: 105 mg, ~75%. *Anal.* Calc. for $Zn(PPA)_2(H_2O)_2$ ($C_{28}H_{36}N_{10}O_8Zn$) (MW = 706.04): C, 47.63; H, 5.14; N, 19.84. Found: C, 47.75; H, 5.21; N, 19.98%. The complex is soluble in DMSO, CH_3CN, acetone and H_2O and is a non-electrolyte.

2.2.7. $MoO_2(PPA)_2$ (7)

$MoO_2(acac)_2$ (0.2 mmol, 66 mg) was used. A pale yellow microcrystalline product was collected. Yield: 100 mg, ~69%. *Anal.* Calc. for $MoO_2(PPA)_2$ ($C_{28}H_{32}N_{10}O_8Mo$) (MW = 732.56): C, 45.91; H, 4.40; N, 19.12. Found: C, 46.19; H, 4.62; N, 19.00%. The complex is soluble in DMSO and DMF and is a non-electrolyte.

2.2.8. $Cd(PPA)_2(H_2O)_2$ (8)

$CdCl_2 \cdot 2.5H_2O$ (0.2 mmol, 46 mg) was used. A yellow microcrystalline product was collected. Yield: 100 mg, ~66%. *Anal.* Calc. for $Cd(PPA)_2(H_2O)_2$ ($C_{28}H_{36}N_{10}O_8Cd$) (MW = 753.07): C, 44.66; H, 4.82; N, 18.60. Found: C, 45.07; H, 4.75; N, 18.45%. The complex is soluble in DMSO, DMF, H_2O, $CHCl_3$ and acetone and is a non-electrolyte.

2.2.9. $UO_2(PPA)_2$ (9)

$UO_2(NO_3)_2 \cdot 6H_2O$ (0.2 mmol, 100 mg) was used. A pale yellow microcrystalline product was collected. Yield: 125 mg, ~70%. *Anal.* Calc. for $UO_2(PPA)_2$ ($C_{28}H_{32}$-$N_{10}O_8U$) (MW = 874.65): C, 38.45; H, 3.69; N, 16.01. Found: C, 38.88; H, 3.80; N, 15.87%. The complex is soluble in DMSO, DMF, CH_3CN, acetone and H_2O and is a non-electrolyte.

2.3. Physical measurements

IR spectra (400–4000 cm^{-1}) were recorded on a Nicolet Magna-IR 550 with samples prepared as KBr pellets. UV–Vis spectra were recorded on a Thermo Electron Corporation Helios α dual beam spectrophotometer. C, H, and N elemental analysis were performed on a Perkin–Elmer 240B elemental analyzer. Electric conductance measurements were carried out with a WTW model LF 530 conductivity outfit and a type C cell, which had a cell constant of 0.996. This represents a mean value calibrated at 25 °C with potassium chloride. NMR spectra were recorded with a Bruker Avance 500 MHz instrument and were processed by X-WIN NMR 2.6 (Bruker Analytik GmbH). X-band EPR spectra at liquid helium temperatures were recorded on a Bruker ER 200D EPR spectrometer equipped with an Oxford Instruments ESR900 cryostat and an Anritsu microwave frequency counter. Simulations of EPR spectra were carried out with a computer program written by Prof. Michael P. Hendrich, Department of Chemistry, Carnegie Mellon University, Pittsburgh, USA [41,42].

All CD spectra were recorded on a Jasco J-700 spectropolarimeter using a 1.0 cm path quartz cell and the following acquisition parameters: $\lambda = 190$–400 nm, scan speed 50 nm min^{-1}, resolution step 0.2 nm, sensitivity 50 mdeg, response 1 s, bandwidth 1.0 nm, accumulations 10. In some cases, the spectra were averaged over an appropriate number of scans. All CD spectra were recorded at 25 °C after the complexes had been incubated with CT DNA for 24 h at 37 °C.

2.4. Molecular modelling

With the aim to present a molecular model for each new complex that is unbiased by the starting structure, we have used Langevin dynamics with a simulated annealing protocol. Using this method, the mean total energy of an ensemble of structures guides the selection of the most favorable configuration for each complex. The starting structures were constructed using the program HyperChem and the MM+ force field that is based on the Allinger's MM2 force field [43]. For all the metal ions we used a default parameter set with $R^* = 2.20$ Å and $e^* = 0.02$ kcal mol^{-1}, since their van der Waals interactions are not expected to play a major role in such bonded representations as in octahedral complexes. Metal–ligand bond lengths were corrected in the final models using harmonic restraints with equilibrium values that were extracted from crystallographic data of similar compounds [44–56] (Tables S1, S3, and S5). Non-bonded interactions were calculated in vacuo with no cutoff and the electrostatic energy term was treated using bond dipoles. Initial energy minimizations were carried out by a conjugate gradient method with rms gradient <0.01 as convergence criterion.

Each model (Schemes S1–S3) was subjected to 20 individual rounds of simulated annealing setting a different value to the seed for the assignment of the starting velocities. To integrate the Langevin equation [57] the step size was set to 1fs and the collision frequency to 1 ps^{-1}. The annealing calculation comprised three phases: (i) raising the temperature of the system from 10 to 1000 K over 2 ps, (ii) keeping the system at 1000 K for 3 ps, and (iii) cooling the system down to 0 K over 15 ps. A tight coupling of the system with temperature (0.1 ps) was used for the heating and equilibration

phases. During the cooling phase the bath relaxation time was gradually decreased from 5.0 ps (7000 steps), 2.0 ps (3000 steps), 1.0 ps (2000 steps), 0.5 ps (2000 steps) to 0.05 ps (1000 steps). At the final step all structures had rms gradient < 0.01 and their total energy was recorded (Tables S2, S4, and S6). The models presented herein were selected from among the lowest energy structures that were generated for each starting geometry. A final minimization of their energy was performed as above, but having applied the metal–ligand distance restraints.

2.5. Antibacterial activity – minimum inhibitory concentration

The antibacterial activity of the compounds (ligands, metal salts and complexes) was studied against *S. aureus*, *E. coli* and *P. aeruginosa*. The microorganisms were maintained in the laboratory of "Inorganic Materials and Biomolecules" of NCSR "Demokritos". Screening was performed by determining the minimum inhibitory concentration (MIC). Two different media [Luria broth medium (=LB, containing 1% w/v tryptone, 0.5% w/v NaCl and 0.5% w/v yeast extract) and minimal medium salts broth (=MMS, containing 1.5% w/v glucose, 0.5% w/v NH_4Cl, 0.5% w/v K_2HPO_4, 0.1% w/v NaCl, 0.01% w/v $MgSO_4 \cdot 7H_2O$ and 0.1% w/v yeast extract)] were used. The compounds were dissolved in distilled water with twofold serial dilutions from 128 to 4 $\mu g\,mL^{-1}$. All cultures were incubated at 37 °C. Control tests with no active ingredients were also performed.

The MIC was determined using twofold serial dilutions in liquid media containing 4–128 $\mu g\,mL^{-1}$ of the compound being tested. The solvent used was water where the solubility of the compound permits and DMSO in the remaining cases. The activity of DMSO has been also investigated and no activity at the quantities used in this work has been found. A preculture of bacteria was grown in LB overnight at the optimal temperature of each species. Two milliliters of MMS were inoculated with 20 mL of this preculture. This culture was used as a control to examine if the growth of the bacteria tested is normal. In a similar second culture, 20 μL of the bacteria as well as the tested compound at the desired concentration were added. A third sample containing 2 mL MMS supplemented with the same compound concentration was used as a second control to check the effect of the compound on MMS. All samples were in duplicate. We monitored bacterial growth by measuring the turbidity of the culture after 12 and 24 h. If a certain concentration of a compound inhibited bacterial growth, half the concentration of the compound was tested. This procedure was carried on to a concentration that bacteria grow normally. The lowest concentration that inhibited bacterial growth was determined as the MIC value. All equipment and culture media were sterile.

3. Results and discussion

3.1. Synthesis of the complexes

All the complexes have been prepared at high yield (65–75%) via the addition of a methanolic solution of deprotonated pipemidic acid to a methanolic solution of the metal ion at a ratio 3:1 for Fe^{3+} and 2:1 for the remaining divalent metal ions according to the reaction:

$$M^{n+} + n\mathrm{PPA} \rightarrow M(\mathrm{PPA})_n(H_2O)_x$$

where $M^{n+} = VO^{2+}$, Mn^{2+}, Co^{2+}, Ni^{2+}, Zn^{2+}, MoO_2^{2+}, Cd^{2+}, UO_2^{2+} ($n = 2$) and Fe^{3+} ($n = 3$), $x = 0$, 1 or 2. All complexes were collected as microcrystalline products. Although diverse crystallization techniques were employed, we did not manage to obtain crystals suitable for determination of structures with X-ray crystallography.

3.2. Infrared spectroscopy

In Table 1 the characteristic absorptions of the IR spectra of all the complexes are listed. In the IR spectra of complexes **1**–**9** the band at 1723 cm^{-1} in the HPPA spectrum attributed to the absorption of $\nu(C{=}O)_{carb}$ has disappeared and has been replaced by two very strong characteristic bands in the ranges 1600–1615 cm^{-1} and 1370–1360 cm^{-1}, that can be assigned as asymmetric, $\nu(CO_2)_{asym}$, and symmetric, $\nu(CO_2)_{sym}$, stretching ν(O–C–O) vibrations. The difference $\Delta = \nu_{asym}(CO_2) - \nu_{sym}(CO_2)$ is a useful characteristic for determining the coordination mode of the ligands. The Δ values fall in the range 238–252 cm^{-1}, indicating a monodentate coordination mode of the carboxylato group [58–60]. Finally, the pyridone stretch $\nu(C{=}O)_p$ is shifted from 1617 to 1634 cm^{-1} upon bonding. These changes of the IR spectra suggest that PPA is coordinated to the metal via the pyridone oxygen and one carboxylate oxygen atom [5].

The existence and the number of the $\nu(M{=}O)$ absorptions is a useful diagnostic tool of complex characterization. The appearance of the V=O stretching frequency in complex **1** at ~954 cm^{-1} suggests that a monoanionic ligand lies in a *trans* position to O_v ($O_{vanadyl}$) [61]. This acceptance is indicative of the arrangement of one O_{carb} ($O_{carboxylate}$) or O_{pyr} ($O_{pyridone}$) atom in the axial position of the octahedron around the V atom and excludes the O_w (O_{water}) atom. The existence of two $\nu(M{=}O)$ absorptions for MoO_2^{2+} and UO_2^{2+} complexes are indicative of a *cis* arrangement of two oxygen atoms around Mo and U atoms, respectively [26]. The band at ~3400–3420 cm^{-1} in the IR spectra of the complexes **1**, **2**, **4**, **5**, **6** and **8** can be attributed to the ν(O–H) vibration of one or two coordinated water molecules [59].

3.3. Electronic spectroscopy

The UV–Vis spectra of the complexes have been recorded as nujol mulls and in solution. The solvent has

Table 1
Characteristic absorptions (in cm^{-1}) of the IR spectra of the complexes

	$\nu(C{=}O)_p$	$\nu(CO_2)_{asym}$	$\nu(CO_2)_{sym}$	Δ[a]	$\nu(M=O)$

$UO_2(PPA)_2$	1634	1614	1365	249	910, 870

[a] $\Delta = \nu(CO_2)_{asym} - \nu(CO_2)_{sym}$.
[b] As ν(COOH).

been chosen based on the solubility of each complex. Practically, the spectra in solution are identical with those in nujol with the exception of a few nm shifts in some cases. In Table 2, the UV–Vis spectral data of all the complexes in the different solvents are given.

The UV spectra of the complexes are practically identical with that of the pipemidato ligand but slightly shifted, indicative of coordination through the pyridone and one carboxylate oxygen atom.

In the visible spectra, there are characteristic bands attributed to d-d transitions only for VO^{2+}, Fe^{3+}, Co^{2+} and Ni^{2+} complexes. For the $V^{IV}O^{2+}$ complex three low-intensity bands at ~802 (band I), 600 (band II) and 495 (band III) nm attributed to d–d transitions are observed. Band I at $\lambda = 802$ nm ($\varepsilon = 12\ M^{-1}\ cm^{-1}$) can be attributed to a $b_2(d_{xy}) \rightarrow e^*_\pi(d_{xz}, d_{yz})$ transition of the $V^{IV}O^{2+}$ and band II at $\lambda = 600$ nm ($\varepsilon = 20\ M^{-1}\ cm^{-1}$) to a $b_2(d_{xy}) \rightarrow b_1^*(d_{x^2-y^2})$ transition [62]. Band III at $\lambda = 495$ nm ($\varepsilon = 26\ M^{-1}\ cm^{-1}$) is also observed and can be attributed to a $d_{xy} \rightarrow d_{z^2}$ transition, although it usually lies under the much stronger ligand-to-metal charge-transfer (=LMCT) transition at $\lambda = 425$ nm ($\varepsilon = 100\ M^{-1}\ cm^{-1}$) and can be difficult to distinguish [63,64]. These bands are typical for distorted octahedral VO^{2+} complexes [46,48,61].

The spectrum of $Fe(PPA)_3$ exhibits two bands that can be attributed to d–d transitions: one weak band (as a shoulder) at ~600 nm ($\varepsilon = 30\ M^{-1}\ cm^{-1}$) which can be assigned as a $^6A_{1g} \rightarrow {}^5T_{1g}$ transition and an intense one at $\lambda = 500$ nm ($\varepsilon = 95\ M^{-1}\ cm^{-1}$) assigned as a $^6A_{1g} \rightarrow T_{2g}(G)$ transition [65,66]. These bands are typical for distorted octahedral Fe^{3+} complexes [49–51]. Additionally, a band at $\lambda = 436$ nm ($\varepsilon = 135\ M^{-1}\ cm^{-1}$), observed as a shoulder, can be attributed to a LMCT transition.

In the visible spectra of $Co(PPA)_2(H_2O)_2$ and $Ni(PPA)_2(H_2O)_2$ one band at ~555 ($\varepsilon = 40\ M^{-1}\ cm^{-1}$) and ~625 nm ($\varepsilon = 45\ M^{-1}\ cm^{-1}$), respectively, attributed to a d–d transition has been found as expected for octahedral Co^{2+} [67] and Ni^{2+} [68] high-spin complexes. Similar behavior has been observed for the octahedral high-spin Co^{2+} [12] and Ni^{2+} [11] cinoxacin complexes.

All the complexes also exhibit an absorption band at ~425–435 nm which can be assigned to the LMCT transition for the quinolone ligand [36–39].

3.4. NMR spectroscopy

^1H NMR spectra of HPPA, $Zn(PPA)_2(H_2O)_2$ and $UO_2(PPA)_2$ have been recorded in d_6-DMSO. The assignment of every signal has been achieved by comparing the

Table 2
Characteristic bands λ_{max} (nm) (ε, $M^{-1}\ cm^{-1}$) in the UV–Vis spectra of the complexes in different solvents

^{1}H NMR spectra of the complexes to that of the ligand and spectra reported in the literature [69]. The results are shown in Table 3.

Comparison of the ^{1}H NMR spectra of $Zn(PPA)_2(H_2O)_2$ and $UO_2(PPA)_2$ with that of HPPA shows a significant perturbation of the chemical shift (up to 0.7 ppm) of the aromatic protons H2 and H5, indicating that H2 and H5 are close to the coordination site of the ligand. The signals for the aliphatic and piperazine protons are practically unchanged since they lie far from the binding site of the ligand.

The overall changes of the NMR spectra of the complexes are indicative of coordination of the pipemidato ligand to the metal via the pyridone and carboxylate oxygen atoms.

3.5. EPR spectroscopy

The EPR spectrum of $VO(PPA)_2(H_2O)$ in DMSO at 12 K is shown in Fig. 2. The spectrum is typical for a mononuclear VO^{2+} complex. We have simulated the spectrum assuming an $S = 1/2$ species interacting with a nucleic spin of $I = 7/2$ through the usual spin Hamiltonian:

$$H = \beta \mathbf{SgB} + \mathbf{IAS}$$

where β is the Bohr magneton and **A** is the tensor of the hyperfine interaction. The spectrum is well reproduced with axial **g**- and **A**-tensors with the values $g_{\|}$=1.942(2), $g_{\perp} = 1.976(2)$, $g_{iso} = (2g_{\perp} + g_{\|})/3 = 1.965$, $A_{\|} = 170(1) \times 10^{-4}$ cm^{-1}, $A_{\perp} = 59.7(1) \times 10^{-4}$ cm^{-1} and $A_{iso} = (2A_{\perp} + A_{\|})/3 = 96.5 \times 10^{-4}$ cm^{-1}. The experimentally deduced pair of values ($g_{\|} = 1.942(2)$ and $A_{\|} = 170(1) \times 10^{-4}$ cm^{-1}) support an O_4 basal plane of the octahedron [60].

The value of $A_{\|}$ is helpful in predicting the nature of the equatorial ligands of the VO^{2+} moiety through the "additivity principle" [70–72]. In the present case, the ligands involved are two O_{carb} and two O_{pyr} atoms of PPA ligands and one O_w atom. From the literature we obtained $A_{\|}(O_{pyr}) = 38.6 \times 10^{-4}$ cm^{-1}, $A_{\|}(O_{carb}) = 42.7 \times 10^{-4}$ cm^{-1} and $A_{\|}(O_w) = 45.7 \times 10^{-4}$ cm^{-1} [71,72]. By making use of these values, the three possible configurations and the respective $A_{\|}$ values are: (i) two O_{carb} and two O_{pyr} atoms of PPA with O_w at the axial position and $A_{\|} = 162.6 \times 10^{-4}$ cm^{-1}, (ii) two O_{pyr}, one O_{carb} atoms of PPA and one O_w with the other O_{carb} at the axial position and $A_{\|} = 165.6 \times 10^{-4}$ cm^{-1} and (iii) two O_{carb}, one O_{pyr} atoms of PPA and one O_w with the other O_{pyr} at the axial position and $A_{\|} = 169.7 \times 10^{-4}$ cm^{-1}. We observe that the configuration with an axial O_w gives rise to a relatively low $A_{\|}$ value in comparison to the experimental value of $A_{\|} = 170(1) \times 10^{-4}$ cm^{-1}, suggesting that O_w occupies an equatorial position, lying *cis* to O_v. Among the other two configurations, the conformation with O_{pyr} at the axial position is more consistent with the EPR parameters and in agreement with that observed in the crystal structure of the complex VO(ciprofloxacinato)$_2$(H_2O) [45] where $A_{\|} = 173 \times 10^{-4}$ cm^{-1}, leading us to the conclusion that the equatorial sites of the octahedron around V are occupied by two O_{carb} and one O_{pyr} atoms of PPA ligands and one O_w, with the second O_{pyr} at the axial position *trans* to O_v.

The EPR spectrum of $Fe(PPA)_3$ in DMSO at 12 K shows a signal at $g \sim 4.3$, characteristic for a high-spin Fe^{3+} ion in an almost rhombic environment. The EPR spectrum of $Mn(PPA)_2(H_2O)_2$ in DMSO consists of a six line pattern at $g \sim 2.0$, typical for a mononuclear Mn^{2+} ($S = 5/2$) complex. The EPR spectrum of $Co(PPA)_2(H_2O)_2$ in DMF at 10 K is rather complicated; it exhibits multiple signals, has a maximum at $g \sim 5.7$ and is consistent for a mononuclear octahedral high-spin Co^{2+} ($S = 3/2$) complex.

Table 3
Chemical shifts (ppm) in ^{1}H NMR spectra of HPPA, $Zn(PPA)_2(H_2O)_2$ and $UO_2(PPA)_2$ in d_6-DMSO

	HPPA	$Zn(PPA)_2(H_2O)_2$	$UO_2(PPA)_2$
H2 and H5	8.90 (2H)	8.16 (2H)	8.16 (2H)
H1a	4.39 (2H)	4.39 (2H)	4.40 (2H)
H1b	1.36 (3H)	1.35 (3H)	1.35 (3H)
H2′, H6′ or	3.14–3.25 (4H)	3.15–3.23 (4H)	3.15–3.26 (4H)
H3′, H5′	3.86(4H)	3.81(4H)	3.70 (4H)
H4′	9.19 (1H)	8.91 (1H)	8.91 (1H)

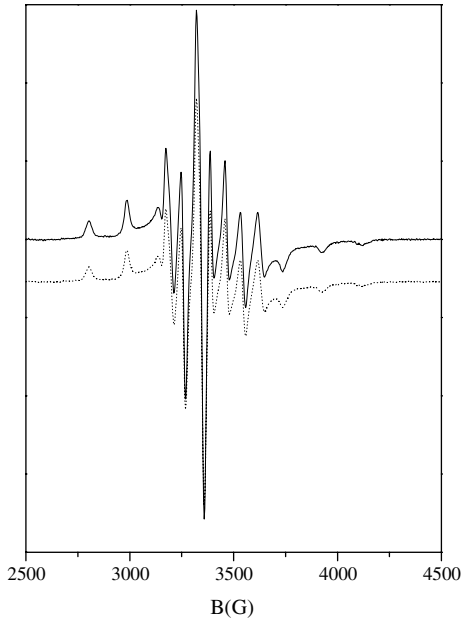

Fig. 2. Experimental (——) and theoretical (·····) EPR spectrum for complex $VO(PPA)_2(H_2O)$ in DMSO. EPR conditions: $T = 12$ K; microwave power = 0.13 mW; modulation amplitude = 5 Gpp; microwave frequency = 9.42 GHz.

3.6. Molecular dynamics

3.6.1. $Fe(PPA)_3$

In order to present a model for the complex we have constructed the two *fac*- and the two *mer*-$Fe(PPA)_3$

enantiomers (Scheme S1). The average energy of each set of enantiomers is almost equal, as is expected from such molecular mechanics calculations. However, the final structures of *mer*-[Fe(PPA)$_3$] exhibit lower energies by less than 0.3 kcal mol^{-1} in comparison to the energies of the *fac* isomers. For the *mer* models we have applied a set of harmonic restraints at the metal–ligand bonds during an additional minimization phase (Table S1) [49–52]. Based on these results we present the lowest energy model of one *mer*-[Fe(PPA)$_3$] enantiomer as the favorable configuration of the complex (Fig. S1). However, we can neither exclude the formation of any of the other isomers, nor unambiguously distinguish between the favorable enantiomers.

3.6.2. VO(PPA)$_2$(H$_2$O)

Using the same approach as above, 8 diastereoisomers of the VO(PPA)$_2$(H$_2$O) complex have been constructed (Scheme S2). In all these models the water molecule occupies a *cis* position with respect to V = O, in accordance with our EPR results and just as in similar vanadyl complexes [45–48]. Again, the resultant models of all VO(PPA)$_2$(H$_2$O) isomers exhibit comparable average total energy with the two *transOc* enantiomers (as are arbitrarily designated in Scheme S2) being more stable by more than 2 kcal mol^{-1} (Table S4). After application of the distance restraints to the M–L bonds (Table S3) and their geometry correction by minimizing the energy of the complex, the structure of the predicted most stable isomer is obtained (Fig. 3).

3.6.3. MoO$_2$(PPA)$_2$

Three pairs of enantiomers have been constructed as starting models of MoO$_2$(PPA)$_2$ (Scheme S3). After the Langevin dynamics simulated annealing calculations, we obtained the total energy results of 20 different conformations for each starting model, which guide us to select the *transOc* isomers as the more favorable. Their average energy is almost equal, as expected, and is lower than the other four isomers by more than 3 kcal mol^{-1} (Table S6). The lowest energy model structure found is illustrated in Fig. S3.

3.7. Antimicrobial activity

The efficiencies of the complexes have been tested against two Gram(−), *Escherichia coli* (*E. coli*) and *Pseudomonas aeruginosa* (*P. aeruginosa*), and one Gram(+), *Staphylococcus aureus* (*S. aureus*), microorganisms. The results are presented in Table 4.

It is evident (Table 4) that the ligand and the complexes have inhibitory action against all microorganisms tested and the coordination of HPPA (MIC = 16–64 μg mL^{-1}) with transition metal ions results in diverse biological activity (MIC for the complexes = 8–64 μg mL^{-1}). The activity of complexes VO(PPA)$_2$(H$_2$O), Mn(PPA)$_2$(H$_2$O)$_2$, MoO$_2$(PPA)$_2$ and Cd(PPA)$_2$(H$_2$O)$_2$ is equal to that of HPPA against all microorganisms tested. Complexes Fe(PPA)$_3$

Table 4
MIC in μg mL^{-1}

	E. coli	*P. aeruginosa*	*S. aureus*
HPPA	64	64	16
VO(PPA)$_2$(H$_2$O)	64	64	16
Mn(PPA)$_2$(H$_2$O)$_2$	64	64	16
Fe(PPA)$_3$	64	64	32
Co(PPA)$_2$(H$_2$O)$_2$	64	64	32
Ni(PPA)$_2$(H$_2$O)$_2$	64	32	32
Zn(PPA)$_2$(H$_2$O)$_2$	32	32	32
MoO$_2$(PPA)$_2$	64	64	16
Cd(PPA)$_2$(H$_2$O)$_2$	64	64	16
UO$_2$(PPA)$_2$	8	8	8

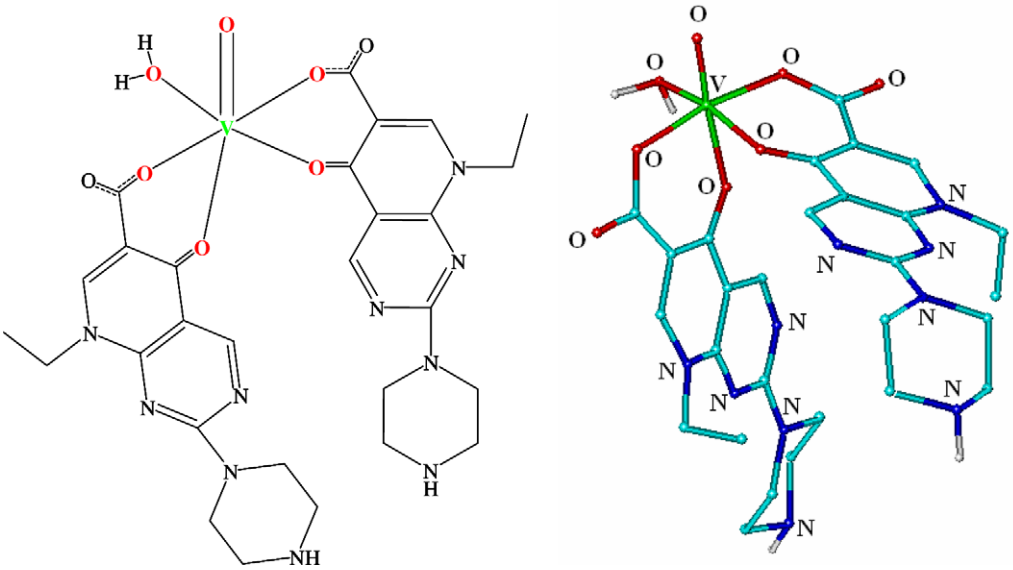

Fig. 3. Lowest energy model of VO(PPA)$_2$(H$_2$O).

and $Co(PPA)_2(H_2O)_2$ have antibacterial activity against *E. coli* and *P. aeruginosa* similar to that of HPPA (MIC = 64 μg mL^{-1}), but they are twice less active against *S. aureus* (MIC = 32 μg mL^{-1}). The antibacterial activity of $Ni(PPA)_2(H_2O)_2$ against *E. coli* is equal to that of HPPA. $Ni(PPA)_2(H_2O)_2$ is twice more active than HPPA against *P. aeruginosa* and twice less active against *S. aureus*. $Zn(PPA)_2(H_2O)_2$ is twice more active than HPPA against two Gram(−) microorganisms but twice less active against *S. aureus*. Finally, $UO_2(PPA)_2$ is four and two times more active than HPPA against two Gram(−) microorganisms and *S. aureus*, respectively.

The antimicrobial activity of the metal salts has also been investigated. It has been found that the metal salts do not exhibit antimicrobial activity at the concentration range used to assay the activity of the complexes in this work. When the antimicrobial activity of the metal complexes is investigated, the following principal factors [73,74] should be considered: (i) the chelate effect of the ligands; (ii) the nature of the *N*-donor ligands; (iii) the total charge of the complex; (iv) the existence and the nature of the ion neutralizing the ionic complex; (v) the nuclearity of the metal center in the complex. For complexes **1**–**9**, only the first of these factors is present, i.e. the chelate effect of the ligand. This is probably one of the main reasons for the diverse antibacterial activity shown by the complexes while the nature of the metal ion coordinated to PPA may have a significant role in this diversity. The significant improvement of the activity of PPA when coordinated to the uranyl complex is simply an evidence of the role of the coordinated metal ion [45]. On the other hand, further biological experiments in order to clarify the possible mechanism of action of the complexes are under investigation.

In conclusion, the best inhibition of the complexes is provided by $UO_2(PPA)_2$ (MIC = 8 μg mL^{-1}) against the three microorganisms tested.

3.8. Interaction of the complexes with CT DNA

DNA can provide three distinctive binding sites for the quinolone complexes; namely, groove binding, binding to phosphate group and intercalation [75]. This behavior is of great importance with regard to the relevant biological role of fluoroquinolone antibiotics in the human body [76,77].

3.8.1. Study of the complexes – CT DNA interaction with UV spectroscopy

The absorption spectra of the interaction of the complexes with CT DNA have been recorded for a constant CT DNA concentration (3.125×10^{-4} M) in different mixing ratios. Representative UV spectra of the complexes **1**, **2** and **9** with CT DNA derived for diverse complex:CT DNA mixing ratios (*r*) are shown in Fig. 4 while UV spectra of all the complexes with CT DNA are shown in Fig. S4. The changes observed in the absorption spectra

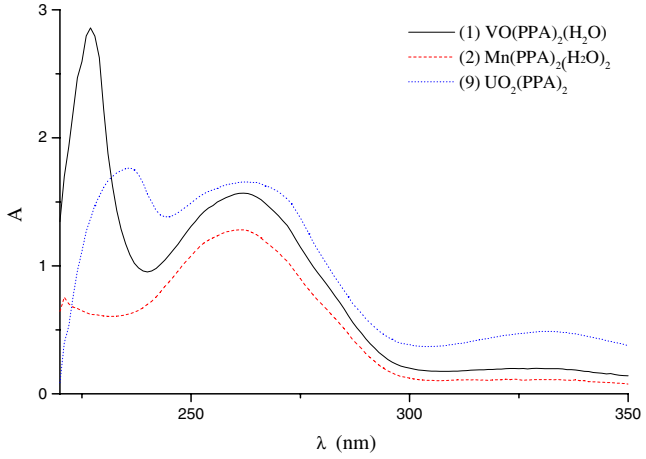

Fig. 4. Absorption spectra of complexes **1**, **2** and **9** in the presence of CT DNA. The *r* value is 1:200. The spectra were recorded at 25 °C after complexes had been incubated with CT DNA for 24 h at 37 °C.

of the complexes after mixing with CT DNA indicate that the interaction of the complexes with CT DNA takes place by a direct formation of a new complex with double-helical CT DNA [78].

3.8.2. Study of the complexes – CT DNA interaction with CD spectroscopy

The CD spectra of the complexes with double-stranded CT DNA for different *r* values can provide us with useful information concerning the complex–nucleotide interaction. The CD spectra of the interaction of the free ligand with CT DNA do not show any transitions because there is not any asymmetry or chirality in the molecules [78].

The CD spectrum of free CT DNA is conservative and consists of a negative band at 245 nm and a positive one at 275 nm, characteristic of the B-form of DNA [79]. The CD spectra of CT DNA in the presence of complex **1** are shown in Fig. 5a. They consist of a positive band I at 275 nm and a strong negative one II at 246 nm. When *r* increases, the λ_{max} of band I is shifted from 275 nm to higher wavelengths (up to 282 nm) followed by a decrease of the intensity, indicating that the DNA-form changes from the B- to A-form (B → A transition). This change (CD Cotton effect) is characteristic of reduced DNA helicity which is attributed to complex interstrand crosslinking to the DNA pairs [80]. Quite similar behavior is observed in the CD spectra of CT DNA in the presence of complex $MoO_2(PPA)_2$.

The CD spectra of CT DNA in the presence of complex **2** are shown in Fig. 5b. The increase of *r* leads to a raise in the intensity of band I at 275 nm and a shift of the λ_{max} from 280 nm to lower wavelengths (up to 274 nm) while the negative band at 246 nm remains practically unchanged. The overall changes in the CD spectra indicate the existence of a B → A CT DNA transition that can be attributed to intrastrand linking of adjacent

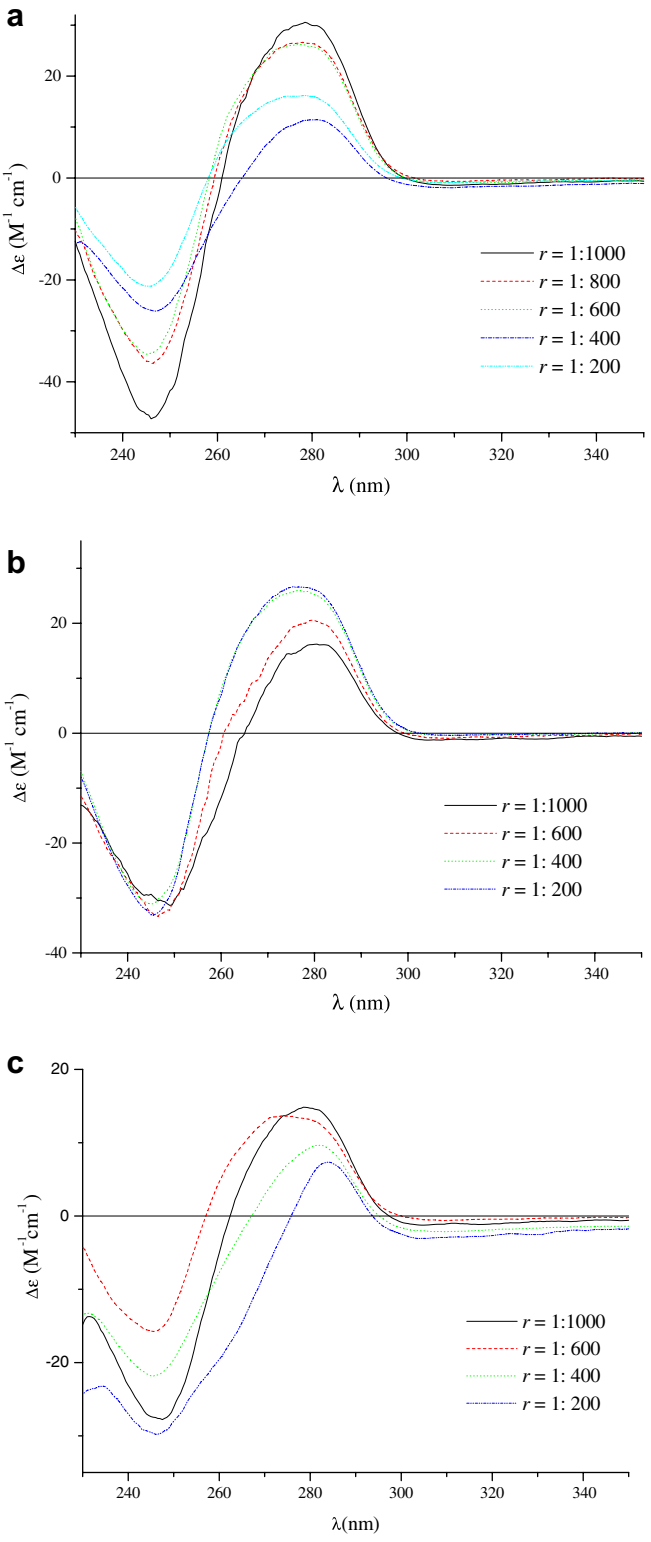

Fig. 5. CD spectra of CT DNA in 5 mM buffer (containing 150 mM NaCl and 15 mM trisodium citrate at pH 7.0) in the presence of: (a) complex $VO(PPA)_2(H_2O)$ (**1**), (b) complex $Mn(PPA)_2(H_2O)_2$ (**2**) and (c) complex $UO_2(PPA)_2$ (**9**), with different r values. The spectra were recorded at 25 °C after samples had been incubated with CT DNA for 24 h at 37 °C.

guanines so that the DNA conformation is modified and destacking of the adjacent bases occurs [81–83]. Similar behavior is observed in the CD spectra of CT DNA in the presence of complexes $Fe(PPA)_3$, $Co(PPA)_2(H_2O)_2$, $Ni(PPA)_2(H_2O)_2$, $Zn(PPA)_2(H_2O)_2$ and $Cd(PPA)_2(H_2O)_2$.

The CD spectra of CT DNA in the presence of complex $UO_2(PPA)_2$ (**9**) are shown in Fig. 5c. The λ_{max} of positive band I is shifted from 275 nm to higher wavelengths (up to 285 nm) followed by a decrease in the intensity upon increase of r, while the intensity of the negative band II at 246 nm increases indicating that the DNA-form changes from the B- to A-form (B → A transition) [81].

4. Conclusions

The synthesis and characterization of nine mononuclear complexes of the first-generation quinolone antibacterial drug pipemidic acid with the ions VO^{2+}, Mn^{2+}, Fe^{3+}, Co^{2+}, Ni^{2+}, Zn^{2+}, MoO_2^{2+}, Cd^{2+} and UO_2^{2+} has been realized with physicochemical and spectroscopic methods. In all the complexes, the pipemidato ligand is bound to the metal via the pyridone oxygen and one carboxylate oxygen atom. Each metal is six-coordinate and its environment could be described as a distorted octahedron. With the use of molecular modelling, we have proposed a low energy model for the structures of $Fe(PPA)_3$, $VO(PPA)_2(H_2O)$ and $MoO_2(PPA)_2$. The antimicrobial activity of the complexes has been tested on three different microorganisms. The complexes show diverse biological activity in comparison to the free pipemidic acid. The best inhibition of the complexes is provided by $UO_2(PPA)_2$ ($MIC = 8\ \mu g\ mL^{-1}$) against the three microorganisms tested. The investigation of the interaction of the complexes with CT DNA has been performed with diverse spectroscopic techniques and showed that the complexes can be bound to CT DNA. For all the complexes, a B → A CT DNA transition has been observed.

Acknowledgements

The authors are grateful to E.L.K.E (70/4/6495) and the "Excellence in the Research Institutes" Program (Action 3.3.1 co-funded by the Greek Ministry of Development and E.U.) for financial support. We thank Prof. M.P. Hendrich, Department of Chemistry, Carnegie Melon University, Pittsburgh, USA for providing us with the EPR simulation program and Dr. I. Eskioglou, Department of Medical Laboratories, Technological and Educational Institution of Larissa, Larissa, Greece for the supply of the microorganisms.

Appendix A. Supplementary material

IR and UV–Vis spectral data for HPPA and all the complexes and ^1H NMR chemical shifts for HPPA, $MoO_2(PPA)_2$ and $UO_2(PPA)_2$. Three schemes (Schemes S1–S3) for the diastereoisomers of $Fe(PPA)_3$, $VO(PPA)_2(H_2O)$ and $MoO_2(PPA)_2$ employed in the simulated annealing calculations. Three Tables (Table S1, S3, and S5)

for the metal–ligand distance restraints applied during the energy minimization phase in order to adjust the geometry of $Fe(PPA)_3$, $VO(PPA)_2(H_2O)$ and $MoO_2(PPA)_2$ models. Three Tables (Table S2, S4, and S6) for the energy statistics from the simulated annealing results of $Fe(PPA)_3$, $VO(PPA)_2(H_2O)$ and $MoO_2(PPA)_2$ diastereoisomers, respectively. Three figures (Figs. S1–S3) for the lowest energy models of $[Fe(PPA)_3]$, $VO(PPA)_2(H_2O)$ and $MoO_2(PPA)_2$ enantiomers. One figure (Fig. S4) for representative UV spectra of all the complexes with CT DNA. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2006.10.017.

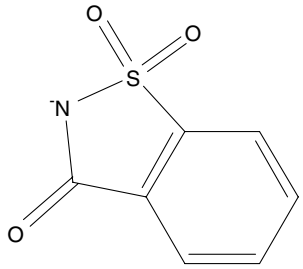

Fig. 1. The structure of the saccharinate anion.

A suggestion has been made that the importance of saccharin complexes lies in the potential use of saccharin as an antidote for metal poisoning [11,13]. Metal complexes of saccharin could also play a role in understanding human metabolic processes [6].

Since very little information has been reported on mixed-ligand complexes containing saccharin and tridentate sulfur–nitrogen chelating agents as co-ligands, we report herein the synthesis, characterization and bioactivity of mixed-ligand copper (II) complexes of three HNNS ligands formed between *S*-benzyldithiocarbazate with 2-acetylpyridine, 2-benzoylpyridine and 6-methyl pyridine-2-aldehyde (Fig. 2) with saccharinate anion as a co-ligand.

2. Experimental

All chemicals and solvents were of analytical grade and were used as received. The *S*-benzyldithiocarbazate (SBDTC), its Schiff bases (HNNS′, HNNS″ and HNNS‴ and $[Cu(sac)_2(H_2O)_4]\cdot 2H_2O$ were prepared by the following literature methods [6,14–16].

2.1. General method of synthesis of the complexes

$[Cu(sac)_2(H_2O)_4]\cdot 2H_2O$ [6] (0.536 g, 0.001 mol) dissolved in boiling water (25 ml) was mixed with a solution of the appropriate Schiff base (0.001 mol) in ethanol (40 ml), and the resulting mixture was heated on a water bath for 30 min. On standing overnight, the mixture yielded crystalline complexes which were filtered, washed with ethanol and dried in a desiccator over silica gel for 24 h. Yield: (ca. 75%). Crystals of [Cu(NNS′)(sac)] (where NNS′ = *S*-benzyl-β-*N*-(2-acetylpyrid-2-yl)methylenedithiocarbazate) suitable for X-ray diffraction analysis were obtained from an acetonitrile solution.

2.2. Physical measurements

Microanalyses for carbon, hydrogen, nitrogen and sulphur were carried out using a LECO CHNS-932 instrument. The IR spectra as KBr pellets were recorded using a Perkin–Elmer FT IR 1750X spectrophotometer (4000–400 cm^{-1}). The molar conductance of 10^{-3} M solutions of the metal complexes in DMSO were measured at 29 °C using a Jenway 4310 conductivity meter and a dip-type cell with a platinized electrode. Magnetic susceptibilities at room temperature were measured using a Sherwood Scientific MSB-AUTO magnetic susceptibility balance. The UV–Vis spectra were run on a Shimadzu UV-2501 PC Recording Spectrophotometer (900–200 nm).

2.3. X-ray structure determination of [Cu(S-benzyl-β-N-(2-acetylpyrid-2-yl)methylenedithiocarbazate)(sac)]

Beautiful green-brown crystals of the metal complex were formed after the acetonitrile solution was allowed to slowly evaporate for a few weeks. A selected crystal was mounted on a glass fibre using perfluoropolyether oil and cooled rapidly to 150 K in a stream of cold N_2 using an Oxford Cyrosystems CYROSTREAM unit. Diffraction data were measured using an Enraf-Nonius Kappa CCD diffractometer (graphite-monochromated Mo Kα radiation, $\lambda = 0.71073$ Å). Intensity data were processed using the DENZO-SMN package [17]. The structures were solved using the direct-methods program [18] to locate all non-hydrogen atoms. Subsequent full-matrix least-squares refinement on *F* was carried out using CRYSTALS Program Suite [19]. Coordinates and anisotropic thermal parameters of all non-hydrogen atoms were refined. Hydrogen atoms were positioned geometrically after each cycle of refinement. A five-term Chebychev polynomial weighting scheme

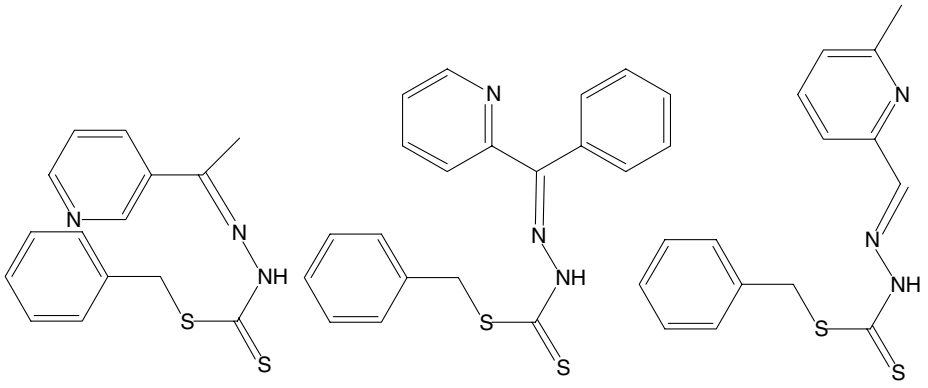

Fig. 2. Structure of HNNS′, HNNS″ and HNNS‴ ligands, respectively (in thione form).

was applied. Refinement converged satisfactorily to give $R = 0.0301$ and $R_w = 0.0360$ with residual electron density minimum and maximum of −0.49 and 0.44 e Å^{-3}. Further crystallographic and refinement details are shown in Table 3.

2.4. Bioactivity

2.4.1. Target microorganisms

Eight pathogenic microbials were used to test the biological potential of the complexes. They were *Methicillin resistant staphylococcus* (MRSA), *Bacillus subtilis* wild type (B29), *Subtilis mutant* (mutant defective DNA repair-B28), *Pseudomonas aeruginosa* (60690), *Candida albicans* (CA), *Aspergillus ochraceous* (398), *Saccaromyces ceciricaee* (20341) and *Candida lypolytica* (2075). The source of microbes and culture maintenance were as previously described [20].

2.4.2. Qualitative antimicrobial assay

Antimicrobial activity of each sample was qualitatively determined by a modified disc diffusion method [21] as previously detailed [22]. A lawn of microorganisms was prepared by pipetting and evenly spreading inoculum (10^{-4} cm^3, adjusted turbidometrically to 10^5–10^6 cfu cm^{-3} (cfu: colony forming units) on to agar set in Petri dishes, using Nutrient agar (NA) for the bacteria and potato dextrose agar (PDA) for fungi. Whatman No. 1 filter paper discs of 6 mm diameter were impregnated with stock solution of the compound (100 mg cm^{-3}) and dried under sterile conditions. The dried discs were then placed on the previously inoculated agar surface. The plates were inverted and incubated for 24 h at 30 °C for bacteria and 37 °C for fungi. Antimicrobial activity was indicated by the presence of clear inhibition zones around the discs. Commercially available streptomycin (Sigma, USA) was used for the antibacterial control while nystatin (Sigma, USA) was used as the antifungal control.

2.4.3. Quantitative antimicrobial assay

Compounds that showed positive (>15 mm) anti-microbial inhibition with the disc diffusion assay were subjected to the broth dilution method for the quantitative measurement of microbiostatic (inhibitory) activity as described by Hufford and Clark [23]. The lowest concentration that completely inhibited visible microbial growth was recorded as the minimum inhibitory concentration (MIC, μg cm^{-3}). Streptomycin and nystatin were used as positive controls for bacteria and fungi, respectively.

2.4.4. Cytotoxic assay

The HL-60 (Human T-lymphoblastic leukemia) and MCF-7 cell lines were obtained from the National Cancer Institute, USA. The cells were cultured in RPMI-1640 (Sigma) medium supplemented with 10% fetal calf serum. Cytotoxicity was determined using the microtitration of 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay (Sigma, USA) as reported by Mosmann [20]. Controls that contained only cells were included for each sample. Cytotoxicity was expressed as CD_{50}, i.e. the concentration that reduced the absorbance of treated cells by 50% with reference to the control (untreated cells). Doxorubicin, Tamoxifen and Cisplatin were used as standard cytotoxins.

3. Results and discussion

The reaction of $[Cu(sac)_2(H_2O)_4]$ with the Schiff bases in boiling ethanol afforded crystalline complexes containing one Schiff base and one saccharinate ligand. The physicochemical properties of the complexes together with their analytical data are shown in Table 1. The analytical data support the proposed formulations for the complexes. The complexes are sparingly soluble in most organic solvents but dissolve readily in donor solvents such as DMSO and DMF. They appear to be stable in air.

3.1. Magnetic and conductivity data

The complexes exhibit room temperature magnetic moments in the 1.8–1.87 BM range (Table 1), which is normal for a $3d^9$ metal ion in a magnetically dilute environment [8]. Their molar conductance values in DMSO (Table 1) fall in the range of 9.31–27.4 ohm^{-1} cm^2 mol^{-1} indicating that, although some dissociation of these complexes seems to occur in this solvent, the conductance values are much lower than that expected for a 1:1 electrolyte [24]. The con-

Table 1

[d] Calculated values are given in parentheses.

ductivity data, therefore, support that both the saccharinate anion and the Schiff base are coordinated to the central copper (II) ion as uninegatively charged ligands [25].

3.2. Electronic and infrared spectra

The IR spectra of the ligands exhibit the ν(C=N), ν(N–N) and ν(CSS) bands at ca. 1580, 1050–1100 and 800–900 cm^{-1} (Table 2), respectively, which are shifted in the spectra of the metal complexes indicating coordination of the ligands to the copper (II) ions via the pyridyl nitrogen, the azomethine nitrogen and the thiolate sulphur atom. The coordination of the azomethine nitrogen to the metal is indicated by the shift of the ν(C=N) band and the ν(N=N) band to higher frequencies (Table 2). Generally, evidence of coordination of thiosemicarbazone and dithiocarbazate ligands to metal ions via the azomethine nitrogen has been based on the shifting of the azomethine C=N band of the free ligand from higher to lower wavenumbers in the spectra of the metal complexes [26]. However, shifting of this band to both higher and lower frequencies has been reported [27]. The ν(N=N) bands of all the free ligands were shifted to higher wavenumbers on complexation as a result of a reduction in the repulsion between the lone pairs of electrons on the nitrogen atoms due to coordination via the azomethine nitrogen atom [28]. The lowering of the ν(CSS) band in the spectra of the copper (II) complexes as compared to the frequencies for the free ligands indicates coordination through one of the sulphur atoms. The pyridine ring deformation mode at ca. 600 cm^{-1} in the spectra of the free ligands is shifted to higher wavenumbers in the spectra of the complexes indicating coordination of the pyridine ring nitrogen atom to the copper (II) ion. The spectra of the complexes do not exhibit the ν(NH) bands of the free ligands supporting the fact that deprotonation of the ligands occurs during their coordination to the copper (II) ion. In addition to showing the characteristic bands due to the Schiff bases, the IR spectra of the present copper (II) complexes also show the $\nu(SO_2)_{sym}$, $\nu(SO_2)_{assym}$ and ν(C=O) bands for the saccharinate ion at ca. 1150, 1290 and 1640 cm^{-1}, respectively [11,29–31]. An X-ray crystallographic structural analysis of [Cu(*S*-benzyl-β-*N*-(2-acetylpyrid-2-yl)methylenedithiocarbazate)(sac)] agrees with the interpretation of the above IR spectral data.

The electronic spectra of the copper (II) complexes (Table 2) exhibit intra-ligand bands attributable to $n \rightarrow \pi^*$ transition in the range 328–354 nm, $S \rightarrow Cu(II)$ charge transfer band in the 422–400 nm and a d–d band in the 700–640 nm range. The presence of the $S \rightarrow Cu(II)$

[a] NNS′ = *S*-benzyl-β-*N*-(2-acetylpyrid-2-yl)methylenedithiocarbazate, NNS″ = *S*-benzyl-β-*N*-(2-benzoylpyrid-2-yl)methylenedithiocarbazate and NNS‴ = *S*-benzyl-β-*N*-(6-methylpyrid-2-yl)methylenedithiocarbazate.
[b] $\log\varepsilon$ (L mol^{-1} cm^{-1}) are given in parentheses.

LMCT band at ca. 420 nm in all these spectra is indicative of the coordination of the Schiff base to the copper (II) ion via the thiolate sulphur atom [32]. Such LMCT bands are common in the electronic spectra of copper (II) complexes of related tridentate NNS thiosemicarbazone ligands [33]. The presence of a d–d band in the 690–640 nm range agrees well with the position of the d–d band in the electronic spectra of other square-planar copper (II) complexes that contain the CuN_3S chromophore, some structures of which have been established by X-ray diffraction [2,10,22,34,35].

4. The structure of the [Cu(*S*-benzyl-β-*N*-(2-acetylpyrid-2-yl)methylenedithiocarbazate)(sac)] complex

The thermal ellipsoid drawing of the [Cu(NNS′)(sac)] molecule with the atom numbering scheme is shown in Fig. 3. The bond lengths and bond angles are given in Table 4. The complex crystallizes as a monomeric species. As implied by the physicochemical results, the copper (II) ion is of distorted four-coordinate geometry with the donor atoms of the Schiff base being the pyridine nitrogen atom, the azomethine nitrogen atom and the mercapto-sulphur atom. The nitrogen of the saccharinate anion occupies the fourth coordination position. The Schiff base is coordinated to the copper (II) ion in its iminothiolate form. Tautomerism of the dithiocarbazate ligand to its iminothiolate form is expected to convert the C=S bond to a single C–S bond, but the length of the C–S bond in the present complex falls between a C–S single bond and C=S double bond, indicating extensive delocalization over the C–N–N–C–S chain. This is also evident in the interatomic bond distances, C(7)–N(8) [1.295(2) Å], N(8)–N(9)[1.389(2) Å], and C(10)–N(9) [1.301(3) Å]. The C(10)–S(11) bond [1.739(19) Å] retains its partial double bond character with the length between that of a C–S single bond [1.82 Å] and a C=S double bond [1.62 Å]. It is longer than that found in

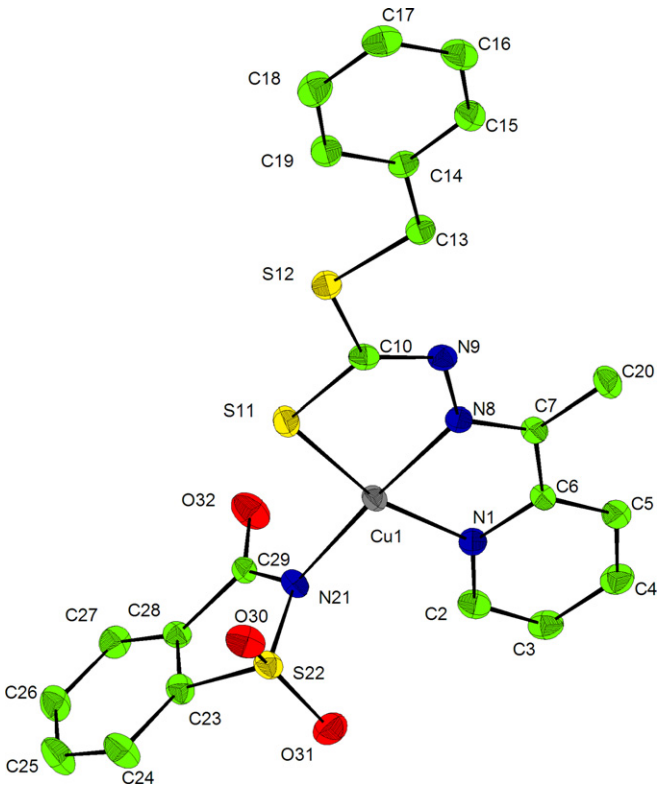

Fig. 3. ORTEP diagram of $C_{22}H_{18}CuN_4O_3S_3$ (with 50% probability displacement ellipsoids) with atomic numbering scheme.

Table 4
Selected bond lengths (Å) and bond angles for [Cu(NNS′)(sac)]

trans-$[Cu(sac)_2(NH_3)_4]$	2.508(12)		2.07(12)			[37]
			2.042(12)			
$[Cu(sac)_2(H_2O)_4]\cdot 2H_2O$	2.061(2)					[2]

[a] pytsc = pyridine-2-aldehydethiosemicarbazone, pysme = pyridine-2-aldehyde SMDTC, 6mpsme = 6-methylpyridine-2-aldehyde SMDTC, mpy = 2-pyridylmethanol.

the free methylpyruvate Schiff base of SMDTC [1.652(6) Å] [25] and pyridine-2-carboxaldehydethiosemicarbazone [1.698(3) Å] [28]. The Cu–S [2.243(5) Å], Cu–$N_{azomethine}$ [1.958(16) Å} and Cu–N_{py} [2.016(16) Å] bond lengths compare well with other copper (II)-saccharinate complexes regardless of the geometry around the central Cu(II) ion, as shown in Table 5.

An examination of the bond angle data in Table 4 shows that the [Cu(NNS′)(sac)] complex does not have ideal square-planar geometry. The angles N(21)–Cu(1)–S(11), N(8)–Cu(1)–S(11), N(21)–Cu(1)–N(1) and N(8)–Cu(1)–N(1) deviate substantially from that expected for an ideal square-planar structure. This distortion could be due to the restricted bite size of the deprotonated tridentate Schiff base ligand.

5. Biological activities

5.1. Antimicrobial activities

These copper (II) complexes have been assayed against several selected pathogens to evaluate their antibacterial and antifungal properties. The results collected in Table 6 indicate that the complexes are weakly active against all the bacteria and fungi chosen (inhibitory zones < 15 mm). The values are lower than those found for both SBDTC and SMDTC [28,36]. The [Cu(NNS‴)(sac)(H_2O)] complex is completely inactive against the bacteria and fungi assayed whereas the [Cu(NNS″)(sac)] complex is completely inactive towards the bacterial strains and weakly active against the fungal strains. This is in contrast with the antimicrobial activities of the complexes of SMDTC that have been shown to exhibit moderate to strong activities against the bacteria and fungi assayed [34]. It appears that the coordination of the saccharinate anion to the copper (II) in the complexes of the present tridentate Schiff base ligands diminishes the antibacterial and antifungal activities of the Schiff bases which were previously found to be active against several bacteria and fungi [34].

5.2. Cytotoxic activities

The measure of cytoxicity used in this work, CD_{50}, is the concentration required to reduce growth of cancer cells by 50%. CD_{50} values <5.0 μg cm^{-3} indicate that the complex is strongly active; CD_{50} values of 5.0–10.0 μg cm^{-3} indicate that the complex is moderately active, values of 10.0–25.0 μg cm^{-3} indicate that the complex is weakly active and values above 25 μg cm^{-3} indicate that the complex is inactive. The complexes, [Cu(NNS″)(sac)] and [Cu(NNS‴)(sac)] exhibit marked activity against the HL-60 cell line (Human Myeloid leukemic cells) with CD_{50}(μg cm^{-3}) values of 0.25 and 0.5, respectively, whereas the complex [Cu(NNS′)(sac)] is inactive. *S*-benzyldithiocarbazate from which the Schiff bases are derived [34] and the simple $CuCl_2 \cdot 2H_2O$ salt are both inactive. Since complexes with bulkier ligands are expected to be thermodynamically less stable, it is possible that the saccharinate ligand from [Cu(NNS″)(sac)] and [Cu(NNS‴)(sac)] are more easily displaced in solution making available a site through which coordination can occur with a suitable donor atom in the cancer cells. All of the Cu(II) complexes reported herein are inactive against the MCF-7 cell line (human breast carcinoma with positive estrogen receptor). The values for the standards, Doxorubicin, Tamoxifen and cisplatin are 0.8, 1.8 and 1.00 μg cm^{-3}, respectively (see Table 7).

Table 7
Cytotoxic activities of the copper (II)-saccharinate complexes

Compound[a]	HL-60	MCF-7	Caov-3
[Cu(NNS′)(sac)]	–	–	0.40
[Cu(NNS″)(sac)]	0.25	–	40.0
[Cu(NNS‴)(sac)]	0.50	–	13.5
Doxorubicin (standard)	0.80		
Tamoxifen (standard)		1.80	
Cisplatin (standard)			1.00

HL-60 = Human Myeloid Leukemic Cells, MCF-7 = Human Breast Carcinoma Cells with Positive Estrogen Receptor, Caov-3 = Human Ovarian Papillary Adenocarcinoma Cancer Cells, – ,inactive.

[a] CD_{50} < 5.0 μg cm^{-3} – strongly active, CD_{50} 5.0 < 10.0 μg cm^{-3} – moderately active, CD_{50} 10.0 < 25.0 μg cm^{-3} – weakly active, CD_{50} > 25.0 μg cm^{-3} – not active. CD_{50} (μg cm^{-3}) = Cytotoxic dose at 50%, i.e. the concentration to reduce growth of cancer cells by 50%.

6. Conclusion

The reaction of $[Cu(sac)_2(H_2O)_4] \cdot 2H_2O$ with the tridentate Schiff bases derived from *S*-benzyldithiocarbazate and heterocyclic ketones in a methanol–water mixture produces crystalline green complexes in high yields which are mixed-

ligand binary copper (II) complexes containing the saccharinate anion and the tridentate NNS^- Schiff bases. An X-ray crystal structure determination of [Cu(NNS′)(sac)] shows that it has a distorted square-planar geometry. In view of the similarity of the IR and electronic spectra of the [Cu(NNS″)(sac)] and [Cu(NNS‴)(sac)] complexes with that of the [Cu(NNS′)(sac)], it is proposed that the former complexes also have a distorted square-planar geometry.

Of the three mixed-ligand complexes, the ones with methyl and phenyl groups in the ligands exhibit marked anticancer activity against the leukemic HL-60 cell lines, the activities being higher than the standard anticancer drug, Doxorubicin. The high selectivity towards this cell line is of particular interest and is worthy of further investigation.

7. Supplementary data

Crytallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 262373 A copy of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, Cb2 1EZ, UK (fax: +44 1223 336 033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.ac.uk).

Acknowledgements

We thank the Department of Chemistry and Laboratory of Molecular and Cell Biology, Institute of Biosciences, Universiti Putra Malaysia, for the provision of laboratory facilities and the University of Oxford for providing X-ray crystallographic services. We also thank Md. Uwaisulqarni Osman for technical assistance. The research was funded by a grant from the Ministry of Science and Environment, Malaysia, under the Intensification of Research in Priority Areas Scheme (IRPA Grant Nos. 09-02-04-0296 and 09-02-04-0755-EA001).

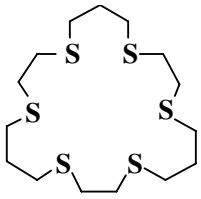

Fig. 1. [21]aneS$_6$.

1,4,7,10,13,16-hexathiacyclohexadecane ([18]aneS$_6$) have shown that these ligands may be capable of producing transition metal complexes with some unique properties [12a]. It is also well documented that the low-spin states of Co(II) and Fe(II) as well as some unusual oxidation states such as Pd(III), Pt(III) and Rh(II) are stabilized by S_6 ligand sphere [12a]. However, macrocyclic six-coordinate copper hexathiaether complexes have not been explored extensively except, for some work by Cooper and coworkers [7], Schroder et al. [9c], de Groot and Leob [12a], Desper and Gellman [13j], and Rogers and Nunez [14].

In this paper, we wish to present our work on copper(II/I) complexes with a new hexathiaether ligand 1,4,8,11,15,18-hexathiacyclo-henicosane ([21]aneS$_6$) (Fig. 1). Herein, we describe the stability constant and electrochemical potential data obtained for Cu([21]aneS$_6$)$^{2+}$, Cu([21]aneS$_6$)$^{+}$ complexes and the crystal structure of the latter complex, and compare the data with that of similar homoleptic copper complexes reported to date. Interestingly, this is the first report of synthesis and characterization of a metal coordinated [21]aneS$_6$ complex.

2. Experimental

Ultraviolet and visible spectra were obtained using a Hewlett-Packard 8452A diode array spectrophotometer. Stability constant measurements were determined using a Cary model 17D dual-beam spectrophotometer equipped with a thermostated (at 25 ± 0.2 °C) cell holder. Cyclic voltammetric studies were determined by using a BAS 100 electrochemical work station (Bioanalytical Systems, Lafayette, IN) operated at ambient temperature, by means of slow scan cyclic voltammetry ($v = 10$–$100\ \mathrm{mV\ s^{-1}}$). A three-electrode electrochemical cell was used and consisted of a 3-mm glassy carbon disk working electrode, a Pt wire electrode, and a Ag/AgCl (3 M NaCl) reference electrode (Bioanalytical Systems; $E^f = 0.228$ V versus SHE). A standard solution of ferroin (Fe(phen)$_3 \cdot 3ClO_4$ in 0.05 M KCl) was used as an external reference. The potential of ferroin has been accurately determined as $E^f = 1.117$ V versus SHE [15]. Nuclear magnetic resonance spectra were recorded on a Varian U 500 (500 MHz) FT-NMR Spectrometer. All NMR spectra for copper(II/I) complexes were obtained in D_2O at room temperature and the chemical shifts are reported in δ values (ppm) relative to TMS.

Ligand [21]aneS$_6$ was synthesized by Dr. Leo Ocrymowycz as reported previously [16]. Copper(II)perchlorate hexahydrate was synthesized as reported earlier [17]. (*Warning! Metal perchlorate salts are potentially explosive; the isolated salts should never be dried and should not be subjected to shock!*). Solutions of copper([21]aneS$_6$)$^{2+}$ were prepared as reported prevoiusly [18,8d]. Ionic strength of solutions was maintained at 0.1 M by adding $HClO_4$. On formation of the Cu([21]aneS$_6$)$^{2+}$ complex, the solution turned dark green and a new peak appeared in the ultraviolet and visible spectra at 410 nm confirming the formation of the copper([21]aneS$_6$)$^{2+}$ complex. All spectral observations were made at 410 nm. ^{1}H NMR (D_2O): δ 2.96 (s, 12H), 2.90 (t, 12H), 2.21 (p, 6H): ^{13}C NMR (D_2O): δ 33.01, 31.43, 30.36. A crystal of Cu([21]aneS$_6$)$^{+}$ was grown by preparing a stoichiometric solution of Cu([21]aneS$_6$)$^{2+}$ by mixing Cu(ClO_4)$_2$ and [21]aneS$_6$ in 1:1 ratio, and reducing the solution of Cu([21]aneS$_6$)$^{2+}$ under argon using copper shot, followed by slow evaporation of the solvent. The crystals appeared as colorless needles. Crystal structure data have been deposited at the Cambridge Crystallographic Data Center by Dr. Mary Jane Heeg [19], and allocated the deposition number CCDC 268931.

3. Results and discussion

Copper combines with ligands according to the following general equation (Eq. (1)). L designates the ligand, and the Cu^{II}L designates the Copper–ligand complex

$$Cu^{2+} + L \rightleftarrows Cu(II)L \tag{1}$$

$$K_{Cu^{II}L} = [Cu^{II}L]/([Cu^{2+}][L]) \tag{2}$$

In general, copper(II) thiaether complexes exhibit strong S-to-Cu charge transfer bands in the vicinity of 390 nm, which facilitate monitoring of the Cu(II)complex concentration in solution. In aqueous media, Cu([21]aneS$_6$)$^{2+}$ showed a strong absorbance peak at 410 nm and this peak was used to obtain absorbance data for stability constant determinations. Cu([21]aneS$_6$)$^{2+}$ forms a weak complex in aqueous solution. Therefore, we used the method of McConnell and Davidson [20] to determine the molar absorptivity (ε) and stability constant ($K_{Cu^{II}L}$) of the complex (Eq. (2)). This method allows convenient, simultaneous determination of both molar absorptivity and stability constant for a given weak metal–ligand complex. The applicable relationship, as derived from mass balance expressions and Beer's law, may be written in the form (Eq. (3)),

$$\frac{bC_L}{A} = \frac{1}{\varepsilon_{ML}} + \frac{1}{\varepsilon_{ML} K_{ML} C'_M} \tag{3}$$

where b represents the path length of the spectrophotometric cell; C_L is the total concentration of ligand added; M represents the metal of interest, which is Cu in this case, and ML represents the metal–ligand complex; ε_{ML} is the molar absorptivity of the Cu^{II}L complex; A is the measured absorbance corrected for any contribution from uncomplexed Cu(II); K_{ML} is the stability constant of the

metal–ligand complex; C_M is the concentration of the free metal ion (uncomplexed) in solution. The value of C_M (in Eq. (3)), which is equivalent to $C_{Cu^{II}} - [Cu^{II}L]$ (in Eq. (4)), was calculated by using a computer software program [21]. A more appropriate equation for the current copper–ligand complex could be written as (4) as derived from Eq. (3)

$$\frac{bC_L}{A} = \frac{1}{\varepsilon_{Cu^{II}L}} + \frac{1}{\varepsilon_{Cu^{II}L} K_{Cu^{II}L'}(C_{Cu^{II}} - [Cu^{II}L'])} \quad (4)$$

In the above eqution, the primed quantity ($Cu^{II}L'$) indicates any anion complexes that may form in 0.10 M $HClO_4$. By plotting bC_L/A against $1/(C_{Cu^{II}} - [Cu^{II}L'])$ yields ε_{CuL} as the reciprocal intercept and $K_{Cu^{II}L}$ as the intercept/slope ratio. By employing this method, molar absorptivity of Cu([21]aneS$_6$)$^{2+}$ was determined to be 6000 $M^{-1}\,cm^{-1}$ and the stability constant of Cu([21]aneS$_6$)$^{2+}$ was found to be 1.26×10^1 M^{-1} (Table 1). This indicates that Cu^{2+} forms a weak complex with [21]aneS$_6$ in aqueous medium. Our earlier studies with a similar homoleptic macrocycle namely, [18]aneS$_6$, gave a stability constant value of 2.5×10^3 M^{-1} for Cu([18]aneS$_6$)$^{2+}$ [22], which agrees well with the value reported ($\sim 5 \times 10^3$ M^{-1}) in a recent study [8b].

Cyclic voltammetry of Cu([21]aneS$_6$)$^{2+/+}$ at scan rates between 50 and 100 mV/s generated cyclic voltammograms where ΔE_{pp} was 64 mV indicating the reversible nature of the copper complex. Similar reversible electrochemical behavior has been reported for Cu([18]aneS$_6$)$^{2+/+}$ in aqueous solution [8b] and nitromethane [7]. Reversible behavior requires that electron transfer process determines the rate of the redox process [7]. The formal potential of Cu([21]aneS$_6$)$^{2+/+}$ complex was found to be 0.89 V (versus SHE). This is the highest potential reported to date for a macrocyclic $Cu^{2+/+}$ complex in aqueous solution. High potential values of 0.79 V (versus SHE) and 0.72 V (versus SCE) have been reported for Cu([18]aneS$_6$)$^{2+/+}$ in aqueous [8b] and non-aqueous media [7]. Similar high potentials (as high as 0.83 V versus SHE) have been reported for acyclic ligands bearing thiaether donor atoms [22,23], and a series of acyclic pentadentate N_2S_3 donor atom system [24].

The stability constant of Cu([21]aneS$_6$)$^{+}$ was calculated by using the Nernst equation in the form (Eq. (5)) by employing the formal potential value for the $Cu^{2+/+}$ complex and the stability constant obtained for Cu([21]aneS$_6$)$^{2+}$

$$E^f_{Cu^{II/I}L} = E^f_{Cu^{II/I}solv} - \frac{2.303RT}{F} \log \frac{K_{Cu^{II}L'}}{K_{Cu^{I}L'}} \quad (5)$$

In the above equation, $E^f_{Cu^{II}L}$ represents the formal potential of the $Cu^{II/I}L$ complex (assumed to be identical with the half-wave potential) [8b], $E^f_{Cu^{II/I}solv}$ represents the potential for the solvated Cu(II/I) redox couple which was determined to be 0.13 V (relative to SHE) in water in the presence of 0.1 M $HClO_4$ [18]. $KCu^{II}L'$ and $KCu^{I}L'$ are the conditional stability constants for the oxidized and reduced species, respectively. The calculated value for the stability constant of Cu([21]aneS$_6$)$^{+}$ was 7.9×10^{13} M^{-1}. A similar high value of 6×10^{14} M^{-1} has been reported for the stability constant of Cu([18]aneS$_6$)$^{+}$ in aqueous solution [8b]. Furthermore, high stability constant values in the order of $\sim 10^{15}$ for Cu(I) complexes have been determined for various acyclic and macrocyclic ligands containing both sulfur and amine nitrogen donor atoms [25].

High formal potentials indicate a significant difference in stability of the $Cu^{2+/+}$ complexes. Such high potentials reflect thermodynamic stabilization of Cu(I) over Cu(II) by either electronic or stereochemical properties of the ligands and result, for example, when a ligand forces Cu(II) to assume a geometry (e.g., tetrahedral) more appropriate to Cu(I) [26]. Hartman and Cooper [7], as well as Chaka et al. [8b], obtained high redox potentials for $Cu^{2+/+}$ [18]aneS$_6$ system. According to Hartman and Cooper [7], the very high redox potentials are attributed to the π acidity of the sulfur donor atoms. Interestingly, according to Rorabacher [6a,8b], Cu(II/I) redox potentials are primarily a function of the stability of the Cu(II) complex. This has been clearly demonstrated in a study which involved measuring potentials and stability constants of Cu(II/I) complexes for a wide variety of copper complexes involving thiaether sulfurs as well as imine and amine nitrogen donor atoms [25]. Accordingly, for about 35 different uncharged terdentate, quadridentate and quindentate ligands, the stability constants of Cu(I)L complexes remained in the narrow range of 10^{12}–10^{16}, with few exceptions, regardless of large differences in coordination geometry and donor strength. For these same 35 ligands, the Cu(II)L stability constants spanned 26 orders of magnitude. Thus the study revealed that the Cu(II/I) potentials, which covered a range of 1.5 V, were inversely related to the logarithmic values of the Cu(II)L stability constants for a wide range of ligand types. Since Cu(II) complexes where $K_{Cu^{II}L} < 10$ cannot be forced to form completely under reasonable solution conditions, the practical upper limit for formal potentials of Cu(II/I)L systems maybe very close to the potential obtained for Cu([21]aneS$_6$)$^{2+/+}$ (0.89 V versus SHE) [25]. This can be shown clearly by using the Nernst equation, Eq. (5) [25].

By comparing stability constant and electrochemical potential data obtained for similar homoleptic $Cu^{2+/+}$ systems such as [14]aneS$_4$ and related 12-13-15-16-membered S$_4$ macrocycles, Rorabacher [6a,8b] points out clearly that the larger 18-membered macrocycle has more flexibility to

accommodate the tetrahedral geometry commonly encountered by Cu(I) complexes than do the smaller macrocycles (stability constants and redox potentials of some of these systems are listed in Table 2 for comparison). Similarly, the large stability constant of Cu([21]aneS$_6$)$^+$ implies that the larger 21-membered ring, [21]aneS$_6$, favors the Cu(I) tetrahedral geometry to a greater extent than its smaller macrocyclic counterparts (Table 2). This can be demonstrated by comparing the difference in magnitude of stability constants for a given Cu(II/I) macrocyclic system. For the large [21]aneS$_6$ macrocycle, the stability constant of the Cu(I) complex (7.9×10^{13} M^{-1}) is 12 orders of magnitude greater than that of the Cu(II) complex (1.3×10^{1} M^{-1}). Similarly for the large [18]aneS$_6$ system, the stability constant of the Cu(I) complex (6×10^{14} M^{-1}) is 11 orders of magnitude greater than that of the Cu(II) complex (5×10^{3} M^{-1}). For a smaller macrocycle such as [14]aneS$_4$, this difference between the Cu(II/I) complexes is much less and eight orders of magnitude. This shows clearly that as the size of the macrocycle increases the strength of the Cu(I) complex increases favoring its easy formation in solution (Table 2). This is ample evidence to show that larger macrocycles have more flexibility to accommodate the tetrahedral geometry commonly encountered for Cu(I) complexes than do the smaller macrocycles.

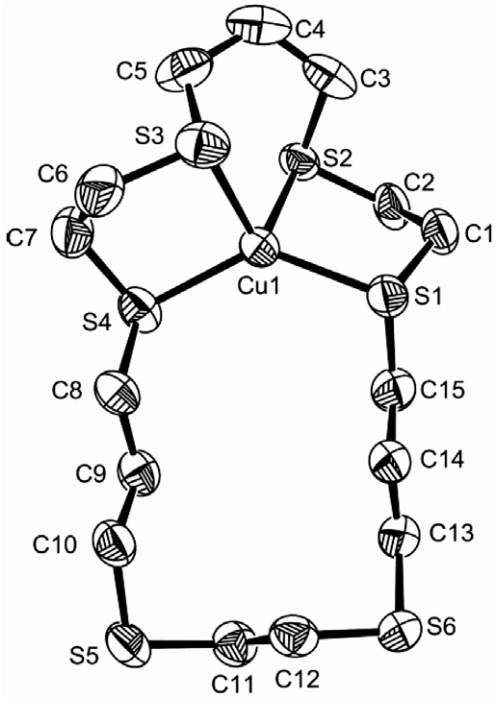

Fig. 2. ORTEP drawing of the cationic unit of Cu^I([21]aneS$_6$)ClO$_4$ showing the labeling scheme for atoms at 50% probability (hydrogen atoms removed for clarity).

The crystal structure of Cu([21]aneS$_6$)$^+$ (Fig. 2) shows that four sulfur atoms adjacent to one another are coordinated to the Cu$^+$ ion in this complex. The Cu$^+$ ion is encapsulated by [21]aneS$_6$ ligand bonding directly to S1, S2, S3 and S4 at distances of 2.2756 (8), 2.3522 (8), 2.3576 (9) and 2.2773 (8) Å, respectively (Table 3). The copper ion is not coordinated to the remaining two sulfur atoms. Bond distances and angles calculated for the crystal (Table 3) show that it is a distorted tetrahedron, which is a common geometry encountered by Cu(I)L complexes. A similar structure has been reported for Cu([18]aneS$_6$)$^+$ [7], while a slightly different crystal structure has been reported for Cu([16]aneS$_6$)$^+$ [12a]. Crystal structures of many other copper(I) complexes we studied earlier showed Cu(I) complex adopting a distorted tetrahedron [6a,6g,8a,8e,22]. Similar distorted tetrahedral structures of copper(I) have been well documented [6a].

In general, as a d^9 system, Cu(II) tends to adopt a six-coordinate tetragonal (distorted octahedral) geometry or a five-coordinate (square pyramidal or trigonal bipyramidal) geometry, whereas Cu(I), as a d^{10} system, is found to be four-coordinate (tetrahedral) [6a].

Copper(I) structures are known to be strongly influenced by the nature of coordinating groups [6a]. The first crystal structure of a macrocyclic Cu(I) complex, 1,4,8,11-tetrathiacyclotetra-decancopper(I) (Cu([14]-aneS$_4$)$^+$), was reported by Rorabacher et al. in 1977 [27]. Accordingly, copper(I) complex attained an irregular tetrahedron where Cu(I) was coordinated to three sulfur donor atoms from one ligand molecule and another sulfur donor atom from an adjacent ligand molecule. This has been attributed

Table 3
Selected bond lengths (Å) and angles (°) for [Cu^I([21]aneS$_6$)ClO$_4$

Cu(1)–S(1)	2.2756(8)
Cu(1)–S(4)	2.2773(8)
Cu(1)–S(2)	2.3522(8)
Cu(1)–S(3)	2.3576(9)
S(1)–Cu(1)–S(4)	131.80(3)
S(1)–Cu(1)–S(2)	93.18(3)
S(4)–Cu(1)–S(2)	115.84(3)
S(1)–Cu(1)–S(3)	121.03(3)
S(4)–Cu(1)–S(3)	94.33(3)
S(2)–Cu(1)–S(3)	96.51(3)

to the inability of [14]aneS$_4$ ligand to distort sufficiently to accommodate a tetrahedral geometry [27]. Rogers et al. reported a tercoordinate polymeric crystal structure for copper(I)complex of [18]aneS$_6$ ligand, where one copper atom was bound to two sulfur atoms of one ligand and one sulfur atom of the other [14]. We obtained similar crystal structures of 1:2 (copper:ligand), and polymers for copper(I) complexes of dibz-[14]aneS$_4$, bz-cis-cyhx-[14]aneS$_4$ and bz-trans-cyhx-[14]aneS$_4$ [22] (dibz = dibenzo, cyhx = cyclohexyl). Polymeric structures involving Copper(I) are not uncommon [22,28].

Hartman and Cooper [7] determined the crystal structures of both Cu(II) and Cu(I) complexes of [18]aneS$_6$. In the Cu([18]aneS$_6$)$^{2+}$ complex, all six sulfur donor atoms were coordinated to the copper atom and it crystallized as a centrosymmetric meso isomer, in which each triad of adjacent sulfur atoms coordinates to a trigonal face of the coordination octahedron. This arrangement is known to maximize the number of gauche placements at the C–S bonds, a marked tendency of macrocyclic thiaethers [29]. Cu([18]aneS$_6$)$^{2+}$ was a tetragonally-distorted octahedron with four short and two long Cu–S bonds where the axial elongation was due to Jahn–Teller distortion [7].

The Cu([18]aneS$_6$)$^{+}$ adopted a severely distorted tetrahedral geometry [7]. This was reminiscent of that found for the Cu([14]aneS$_4$)$^{+}$ [27] and Cu([15]aneS$_5$)$^{+}$ [8g]. In Cu([18]aneS$_6$)$^{+}$, four adjacent sulfur atoms were bonded to the copper atom indicating that the other two adjacent Cu–S bonds have been ruptured upon reduction. The crystal structure of Cu([21]aneS$_6$)$^{+}$ shows a similar conformation as described for Cu([18]aneS$_6$)$^{+}$, where four adjacent sulfurs are coordinated to the copper(I) atom. In fact, the bond distances and bond angles around the copper ion in Cu([21]aneS$_6$)$^{+}$ (Table 3) match very well with those of Cu([18]aneS$_6$)$^{+}$ [7]. The crystal structure reported for a Cu(I) complex of a similar homoleptic hexathiaether ligand, Cu([16]aneS$_6$)$^{+}$ [12a], is different to both Cu([21]aneS$_6$)$^{+}$ and Cu([18]aneS$_6$)$^{+}$ [7]. In Cu([16]aneS$_6$)$^{+}$, four sulfur donor atoms are bonded to the copper atom but the two non-bonded sulfur atoms do not lie adjacent to each other. They are separated from each other by two pairs of bonded sulfur atoms. This forms a symmetric crystal structure, which consists of two identical components. However, the Cu–S bond distances reported for the Cu([16]aneS$_6$)$^{+}$ crystal match very well with those of Cu([21]aneS$_6$)$^{+}$ and Cu([18]aneS$_6$)$^{+}$.

In Cu([18]aneS$_6$)$^{2+}$octahedral complex, two adjacent Cu–S bonds break upon reduction to yield the tetrahedral Cu([18]aneS$_6$)$^{+}$ [7]. Considering the similarity of the structures between [18]aneS$_6$ and [21]aneS$_6$ ligands as well as their Cu(I) complexes, in the absence of a crystal structure for Cu([21]aneS$_6$)$^{2+}$, we can speculate a similar analogy for breaking of Cu–S bonds during reduction of Cu([21]-aneS$_6$)$^{2+}$ to Cu([21]aneS$_6$)$^{+}$. It implies that Cu([21]aneS$_6$)$^{2+}$ may also form a six-coordinate complex, where all six sulfur atoms are bonded to the copper atom, which could undergo a similar Cu–S bond rupture in adjacent Cu–S bonds upon reduction to give a four-coordinate Cu([21]-aneS$_6$)$^{+}$.

As noted earlier, blue copper proteins are known to display high redox potentials [1]. Considering type 1 ''blue'' copper proteins structurally characterized to date, rusticyanin bears the highest redox potential (0.68 V), while stellacyanin bears the lowest redox potential (0.18 V) [30]. The significant difference in redox potential of these ''blue'' copper proteins is attributed to the type of axial ligand, which is bonded to the copper atom [30]. It has also been suggested earlier that the reason for this variation is that the protein constrain the distance between the copper ion and the axial ligands to different values, and its unusual cupric geometry [30]. The role of the axial ligand has been extensively debated in terms of its function in the fine-tuning of the redox potential and spectroscopic properties of type1 'blue' copper proteins [30]. Studies carried out during the last decade [31], and more recent studies [32], however, challenge the earlier speculation. It maybe interesting to investigate whether the significant difference in redox potential of these ''blue'' copper proteins bears any relationship to the degree of stabilization created by their surrounding ligands for Cu(I) geometry over Cu(II) by a similar phenomenon as discussed herein.

In summary, we present the first synthesis and characterization of a metal coordinated [21]aneS$_6$ complex. The Cu([21]aneS$_6$)$^{2+/+}$ system shows a formal potential of 0.89 V (vs. SHE), which is the highest reported to date for a Cu(II/I) system in aqueous media. By employing the Nernst equation we can infer that the practical upper limit for formal potential of Cu(II/I)L systems maybe close to this high value. The stability constant obtained for Cu([21]aneS$_6$)$^{+}$ is 12 orders of magnitude greater than that of Cu([21]aneS$_6$)$^{2+}$ indicating the flexibility of this large macrocyclic ligand to accommodate the tetrahedral geometry commonly encountered for Cu(I) complexes more favorably, than Cu(II) complexes. Recent studies carried out on a Cu(II/I) system in aqueous media with a similar homoleptic ligand, [18]aneS$_6$, reported a comparable trend with a high formal potential value (0.79 V versus SHE) and large difference in stability constants where Cu(I) has been favored 11 orders of magnitude greater than that of Cu(II) [8b]. The results of the current study further support the conclusions drawn earlier by Rorabacher [6a,8b,25] that the Cu(II/I) redox potentials are primarily a function of the stability of the Cu(II) complex, and that the larger macrocyclic ligands have more flexibility to accommodate the tetrahedral geometry commonly encountered for Cu(I) complexes than do the smaller macrocycles.

Acknowledgments

I thank Dr. Leo Ochrmowycz for preparing the ligand [21]aneS$_6$, and Dr. Mary Jane Heeg for resolving the crystal structure of Cu([21]aneS$_6$)$^{+}$. I also thank Dr. Mark A. Whitener for the ORTEP diagram, and Dr. David J. Szalda for assistance with structural parameters of the crystal.

The valuable comments and suggestions of the reviewers are gratefully acknowledged.

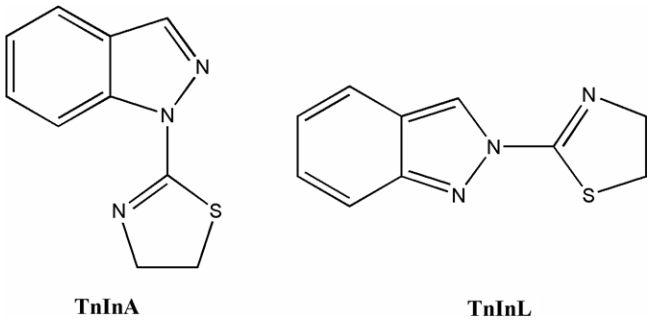

Fig. 1. Structure of TnInA and TnInL.

and were recrystallized from ethanol 96% (3.63 g, 35%) and acetone (2.54 g, 25%), respectively.

2.2. Preparation of $[Cu(NO_3)(TnInA)_2(H_2O)](NO_3)\cdot(H_2O)$ (1)

$Cu(NO_3)_2\cdot 3H_2O$ (121 mg, 0.5 mmol) dissolved in an ethanol–water was added to an ethanol–water solution of TnInA (100 mg, 0.5 mmol). The resulting solution was allowed to evaporate slowly at room temperature. After a few days, green crystals were isolated from the solution (122 mg, 38.7%). The crystals were first separated by filtration, then washed with cold ether and finally air-dried. *Anal*. Calc. for $C_{20}H_{22}CuN_8O_8S_2$: C, 38.12; H, 3.52; N, 17.79; S, 10.18. Found: C, 38.03; H, 3.33; N, 17.61; S, 10.12%.

2.3. Preparation of $[Cu(NO_3)_2(TnInL)(H_2O)]$ (2)

This complex was prepared by reacting an ethanol–water solution of $Cu(NO_3)_2\cdot 3H_2O$ (121 mg, 0.5 mmol) with an ethanol–water solution of TnInL (100 mg, 0.5 mmol), giving green crystals after a slow evaporation of the solution at room temperature (117.3 mg, 57.4%). The crystals were filtered and washed with cold ether and air-dried. *Anal*. Calc. for $C_{10}H_{11}CuN_5O_7S$: C, 29.38; H, 2.71; N, 17.13; S, 7.83. Found: C, 29.23; H, 2.67; N, 16.80; S, 7.80%.

2.4. Instrumental procedures

Chemical analyses of carbon, hydrogen, nitrogen and sulphur were performed by microanalytical methods using a Leco CHNS-932 microanalyser. IR spectra were recorded on a Perkin–Elmer FT-IR 1720 spectrophotometer, from KBr pellets in the 4000–370 cm^{-1} range and on a Perkin–Elmer FT-IR 1700X spectrophotometer, from polyethylene pellets in the 500–150 cm^{-1} range. UV–Vis–NIR reflectance spectra for complexes in the 200–1500 nm range were obtained from pellets of the samples, using a Shimadzu UV-3101 PC spectrophotometer and $BaSO_4$ as a reference. Magnetic susceptibility measurements were performed on polycrystalline samples using a magnetometer with pendulum MANICS DSM8, equipped with helium continuous-flow cryostat and an electromagnetometer DRUSCH EAF 16 UE. Data were corrected for temperature independent paramagnetism and diamagnetic contributions, which were estimated from the Pascal constants. The EPR spectra were recorded at room temperature in solid state and at 77 K in DMSO solution employing a BRUKER ESP-300E spectrometer using the X band of microwave.

2.5. Crystal structure determinations

Experimental details of crystal structure determinations including crystal data, data collection, structure determinations and refinement parameters for **1** and **2** are listed in Table 1. X-ray diffraction measurements were performed using a Bruker SMART CCD diffractometer equipped with graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) using the ϕ–ω scan technique for **1** and an Enraf–Nonius CAD4 diffractometer equipped with graphite-monochromated Cu Kα radiation ($\lambda = 1.5418$ Å) using the ω–2θ scan technique for **2**. Empirical absorption

corrections were applied using the SADABS [8] program for **1** whereas semiempirical absorption corrections were made based on psi-scan application using the WINGX [9] package for **2**. The structure of **1** was solved by Patterson methods and subsequent Fourier differences, whereas the structure of **2** was solved by direct methods and subsequent Fourier differences using, in all cases, the WINGX package [9] and refined by full-matrix least-squares on F^2. All non-hydrogen atoms were refined with anisotropic displacement parameters. Hydrogen atoms attached to carbon and nitrogen atoms were positioned geometrically, with U_{iso} values derived from U_{eq} values of the corresponding carbon and nitrogen atoms. However, hydrogen atoms of the water molecules were detected by Fourier differences and were refined with isotropic displacement parameters.

3. Results and discussion

3.1. Crystal structures

Complex **1** crystallizes into monoclinic unit cells, each one containing two $[Cu(NO_3)(TnInA)_2(H_2O)]^+$ cations, two nitrate anions and two water molecules held by a three-dimensional hydrogen bonds network. The overall view and labelling of the atoms of complex cation are displayed in Fig. 2. Table 2 lists the selected bond lengths, angles and hydrogen-bond parameters.

The environment around the copper(II) atom may be described as a distorted octahedral geometry with the ligand–metal–ligand bite angles varying between 80.6(1)° [N(1)–Cu–N(3)] and 99.8(1)° [N(1)–Cu–N(6)]. The metallic atom is coordinated by two thiazoline nitrogen atoms [av. Cu–N = 1.981 Å], two indazole nitrogen atoms [av. Cu–N = 2.054 Å], one oxygen atom from a monodentate nitrate group [Cu–O(1) = 2.446(2) Å] and one oxygen atom from a water molecule [Cu–O(1W) = 2.333(1) Å].

The $Cu–O_{water}$ bond distance is shorter to the calculated mean value [2.47(19) Å] calculated using the data of 130 six-coordinate copper(II) complexes with an N_4O_2 environment, obtained with the CONQUEST software [10] from the Cambridge Structural Database (CSD) [11] and likewise, the $Cu–O_{nitrate}$ bond length is similar to the average value [2.51(16) Å] calculated from the data of 67 complexes. The $Cu–N_{thiazoline}$ bond lengths are in good agreement with the mean value [1.96(4) Å] found for 15 copper(II) complexes with this type of bond in the CSD. Finally, the $Cu–N_{indazole}$ bond lengths are slightly shorter to those found in bis(Hydrogen tris(indazol-1-yl)borato)-copper(II)-chloroform solvate [2.132 Å] [12] and bis(Hydrogen–tris(indazol-1-yl)borato)-copper(II)-tetrahydrofuran solvate [2.127 Å] [12].

The chelate ring Cu–N(1)–C(1)–N(2)–N(3) is essentially planar with maximum mean plane deviation for N(3) (0.058 Å). However, the chelate ring Cu–N(4)–C(11)–N(5)–N(6) shows a conformation near to envelope with the apex at N(6), deviating 0.198 Å from the mean plane formed by Cu, N(4), C(11) and N(5). This geometry is

Table 3
Criteria for assigning nitrate coordination modes [14]

	Monodentate	Anisobidentate	Bidentate
l_2–l_1 (Å)	>0.6	0.3–0.6	<0.3
A_1–A_2 (°)	>28	14–28	<14
l_3–l_2 (Å)	<0.1	0.1–0.2	>0.2
A_3 (°)	<162	162–168	>168

proved by the puckering parameters $q = 0.127$ Å and $\phi = 142.7°$ calculated according to Cremer and Pople [13].

The thiazoline rings S(1)–C(1)–N(1)–C(2)–C(3) [$q = 0.256$ Å; $\phi = -44.3°$] [13] and S(2)–C(11)–N(4)–C(12)–C(13) [$q = 0.165$ Å; $\phi = -49.9°$] [13] show an intermediate conformation between envelope and half-chair. In the first thiazoline ring, C(2) and C(3) are deviating −0.133 and 0.285 Å, respectively, from the plane formed by S(1), N(1) and C(1). Likewise, in the second thiazoline ring, C(12) and C(13) are deviating −0.133 and 0.136 Å, respectively, from the plane formed by S(2), C(11) and N(4).

According to the criteria for the assignment for nitrate binding modes introduced by Kleywegt et al. [14] (see also Fig. 3, Tables 3 and 4), the nitrate binding mode in **1** has been classified as monodentate.

The crystal structure presents a three-dimensional hydrogen-bond network in which oxygen atoms O(2), O(3) and O(4) from nitrate groups act as acceptors of hydrogen, whereas water molecules act as donors. A diagram showing this network is given in Fig. 4.

The crystal structure of **2** is built up of neutral $[Cu(NO_3)_2(TnInL)(H_2O)]$ entities linked through hydrogen bonds involving water molecules and nitrate groups. The structure of the complex is shown in Fig. 5, together with the atomic numbering scheme. Selected bond lengths, angles and hydrogen-bond parameters are given in Table 5.

The stereochemistry of the complex centre is basically five coordinate, but with the second oxygen of the nitrate group occupying the sixth coordination position at a potentially bonding distance of 2.685 Å, to give a $(4 + 1 + 1^*)$ type coordination [15,16]. The ligand geometry around copper(II) centre is best described as distorted square

Table 4
Parameters for complexes

Complex	Nitrate group	l_2–l_1 (Å)	A_1–A_2 (°)	l_3–l_2 (Å)	A_3 (°)	Classification
1	N(7), O(1), O(2), O(3)	0.990	50.0	−0.139	150.4	monodentate
2	N(4), O(1), O(2), O(3)	0.723	32.9	0.024	160.4	monodentate
	N(5), O(4), O(5), O(6)	0.961	49.0	−0.104	157.7	monodentate

pyramidal with a τ value of 0.26, indicating a geometry closer to a regular square pyramid ($\tau = 0$) than a regular trigonal bipyramid ($\tau = 1$) [17]. The equatorial positions are occupied by one water molecule [Cu–O(1W) = 1.964(2) Å], one nitrate oxygen atom [Cu–O(1) = 1.962(2) Å], one thiazolinic nitrogen atom [Cu–N(1) = 1.996(2) Å] and one indazolic nitrogen atom [Cu–N(2) = 2.034(2) Å]. The axial position is occupied by one nitrate oxygen atom at a distance of 2.342(2) Å from copper atom. The O(4)–metal–basal ligand angles vary from the ideal value for a square pyramid (90°) and they are comprised between 106.7(1)° [O(4)–Cu–O(1W)] and 83.1(1)° [O(4)–Cu–O(1)]. Likewise, the basal ligand–metal–basal ligand angles differ from the ideal value of 90°, varying between 95.1(1)° [O(1W)–Cu–N(1)] and 80.3(1)° [N(1)–Cu–N(2)].

The Cu–$O_{nitrate}$ basal bond distance is similar to the average value [1.99(4) Å] calculated for 29 square pyramidal copper(II) complexes with an N_2O_3 environment in CSD. In the same way, the Cu–$O_{nitrate}$ axial bond distance is in good agreement with the mean value 2.35(11) Å obtained for 53 complexes and the Cu–O_{water} distance is comparable to the mean values 1.97(2) Å found for 68 complexes. Finally, the Cu–$N_{thiazoline}$ and Cu–$N_{indazole}$ bond lengths are similar to those found in **1**.

Table 5

N(1)–Cu–O(4)	95.1(1)	N(2)–Cu–O(4)	95.1(1)

Bond A···H–D	Position of A	A···D (Å)	A···H–D (°)
O(6)···H(1W)–O(1W)	$x-1, y, z$	2.756(3)	168.4(2)
O(6)···H(2W)–O(1W)	$x-1/2, -y+1/2, z+1/2$	2.832(4)	166.5(2)

The five-membered chelate ring Cu–N(1)–C(1)–N(3)–N(2) is essentially planar with maximum mean plane deviation for C(1) (0.030 Å). For the thiazoline ring, the puckering parameters $q = 0.308$ Å and $\phi = 137.6°$ [13] indicate a conformation near to envelope with the C(3) atom deviating 0.478 Å above the mean plane formed by S, C(1), N(1) and C(2).

The nitrate binding mode has been classified in a similar form to **1**. Thus, the results showed in Table 4 indicate that the nitrate group N(5), O(4), O(5), O(6) acts undoubtedly as monodentate, whereas nitrate group N(4), O(1), O(2), O(3) exhibits values of monodentate but close to anisobidentate.

In fact, focusing our attention on the N(4)–O(1)–Cu angle, we see that its values differs significantly from linearity, amounting to 110.7(2)°. Likewise, the mean plane formed by the atoms O(1), O(2), O(3) and N(4) of monodentate nitrate ligand forms an angle of 83.4° with the plane constituted by O(1W)–Cu–N(2). Both facts may possibly be explained in terms of crystal packaging effects, but as they facilitate the approach from O(2) to the central ion, it cannot be excluded that they are conditioned by the existence of a O(2)–Cu weak interaction [2.685(3) Å].

It should be pointed out that the main difference in both complexes with respect to the structure of free ligands TnInA and TnInL is due to the different degree of rotation of the thiazoline ring around the C(1)–N(2) [or C(11)–N(5)] and C(1)–N(3) bond, respectively, which permits the coordination through N(1) [torsion angle N(1)–C(1)–N(2)–N(3) = −2.6° and N(4)–C(11)–N(5)–N(6) = −11° in **1**; −176.9° in TnInA free; torsion angle N(1)–C(1)–N(3)–N(2) = 8.7° in **2**; 178.8° in TnInL free].

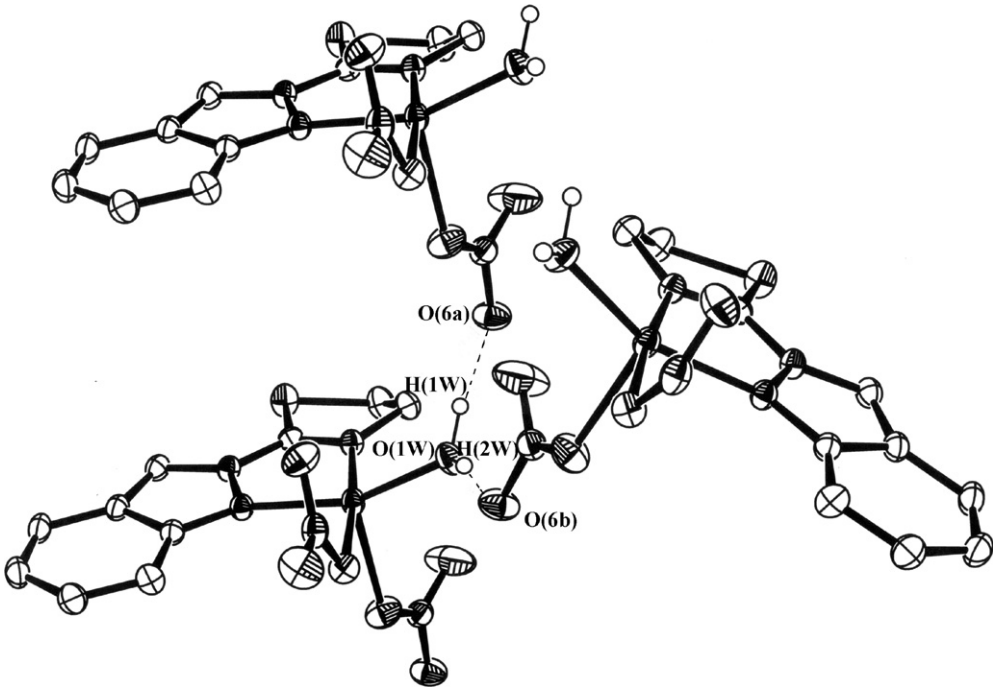

Fig. 6. View of the hydrogen bonds of **2**.

Finally, the crystal structure is stabilized by a two-dimensional hydrogen-bond system perpendicular to the b direction in which the water molecule is involved in two intermolecular hydrogen bonds, each of them linking to a nitrate group belonging to two different neighbouring $[Cu(NO_3)_2(TnInL)(H_2O)]$ entities. A diagram showing this network is given in Fig. 6.

3.2. Spectroscopic properties

The reflectance spectrum of **1** exhibits one broad asymmetric band centred at $\sim$14 250 cm^{-1} with a low energy shoulder assigned to the $^2T_{2g}(D) \leftarrow {}^2E_g(D)$ transition in agreement with the octahedral stereochemistry [18–20]. Moreover, the spectrum shows other strong band at $\sim$30 490 cm^{-1} what is assigned to a charge-transfer band [21]. The reflectance spectrum of **2** consists of a very broad d-d asymmetric band centred at $\sim$13 330 cm^{-1} with a shoulder at $\sim$10 800 cm^{-1} assigned to the $^2B_1[(d_{x^2-y^2})^1] \rightarrow {}^2A_1[(d_{z^2})^1]$ and $^2B_1[(d_{x^2-y^2})^1] \rightarrow {}^2B_2[(d_{xy})^1]$, $^2E[(d_{xz})^1]$, $^2E[(d_{yz})^1]$ transitions, respectively. This spectral pattern is typical of the square-pyramidal stereochemistry [21]. Likewise, the spectrum shows a strong absorption at $\sim$27 170 cm^{-1} with a shoulder at $\sim$35 460 cm^{-1} which may be associated with a charge-transfer band and with the $\pi \rightarrow \pi^*$ transitions of the organic ligand, respectively.

The EPR spectra of polycrystalline samples at 298 K (Fig. 7 for **1** and Fig. 8 for **2**) and at 77 K in DMSO solution (Fig. 9 for **1** and Fig. 10 for **2**) of complexes were recorded in the X-band, using the 100 kHz field modulation.

In the solid state, complex **1** exhibits a typically axial spectrum ($g_\parallel = 2.28$ and $g_\perp = 2.09$). The geometric parameter $G = (g_\parallel - 2)/(g_\perp - 2)$ value is found to be in the range 3.5–5.0 and $g_\parallel > g_\perp > 2.0023$, which is consistent with a $d_{x^2-y^2}$ ground state having a negligible exchange coupling [21,22]. In frozen solution the spectrum ($g_\parallel = 2.32$ and $g_\perp = 2.08$) cannot be simulated by only one species. An other species should be formed directly when the solution of DMSO is prepared and this species may involve DMSO in the coordination sphere. One of these signals affords g

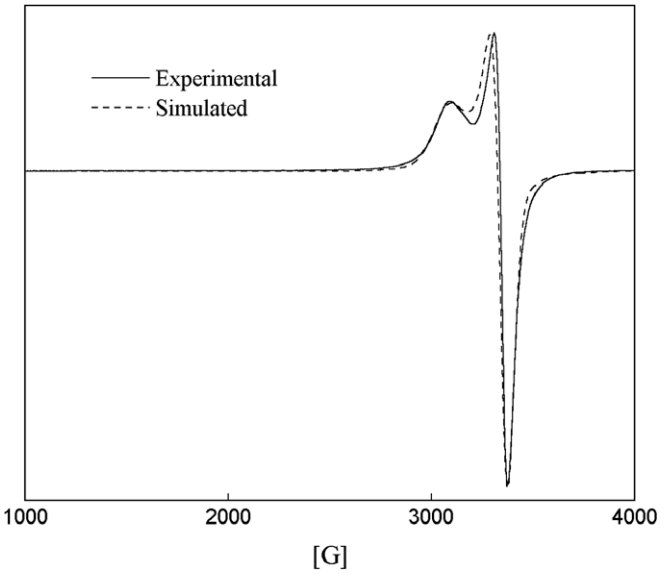

Fig. 7. EPR spectrum of **1** in the polycrystalline state at 298 K.

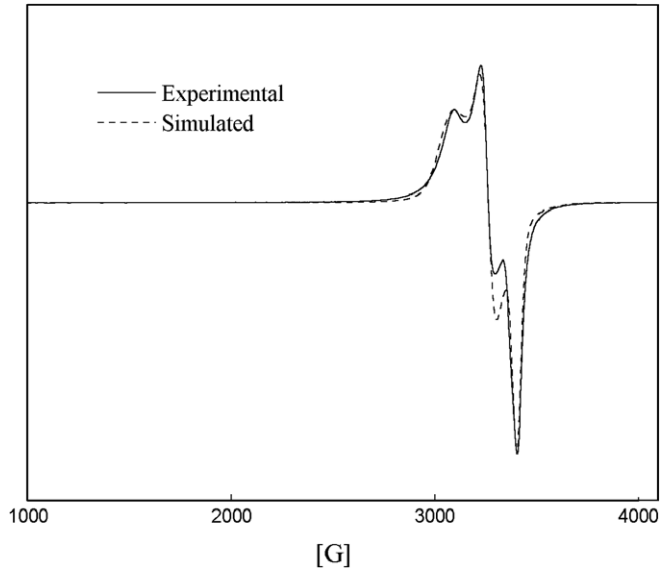

Fig. 8. EPR spectrum of **2** in the polycrystalline state at 298 K.

values that resemble those of **1** in the powder which shows that this complex have a static structure in the solid, and that their molecular and electronic structures in the solid state and in solution are the same. The other signal of spectrum cannot be well simulated.

The spectrum of **2** in the solid state at 298 K is typically rhombic ($g_1 = 2.06$, $g_2 = 2.15$ and $g_3 = 2.28$). The geometric parameter $R = (g_2 - g_1)/(g_3 - g_2)$ value is 0.69, which is consistent with a square-pyramidal or octahedral geometry with a $d_{x^2-y^2}$ ground state [15,21,23,24]. The spectrum in DMSO solution of this complex at 77 K changes to an axially elongated form with $g_{\|} = 2.33$ and $g_{\perp} = 2.08$, indicating a square pyramidal geometry and showing four hyperfine lines corresponding to monomeric copper(II) species (no superhyperfine structure is observed). The g values that resemble those of **1** in the powder which shows that this complex have a static structure in the solid, and that their molecular and electronic structures in the solid state and in solution are the same. The other signal of spectrum cannot be well simulated.

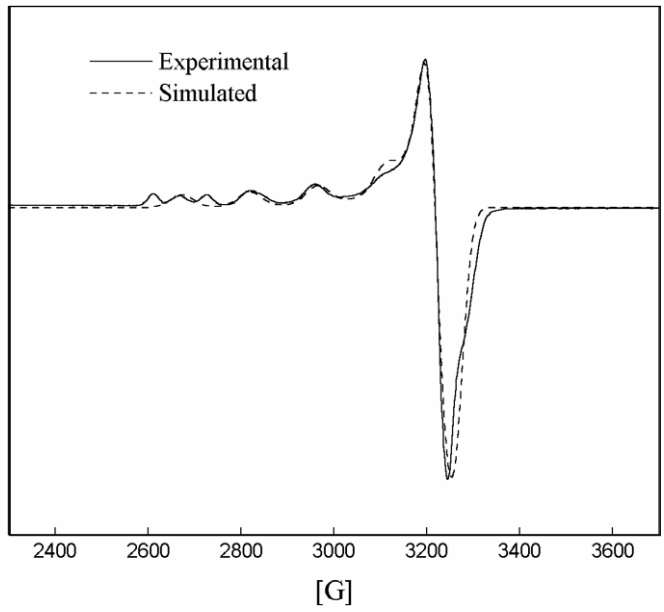

Fig. 9. EPR spectrum of **1** in DMSO solution at 77 K.

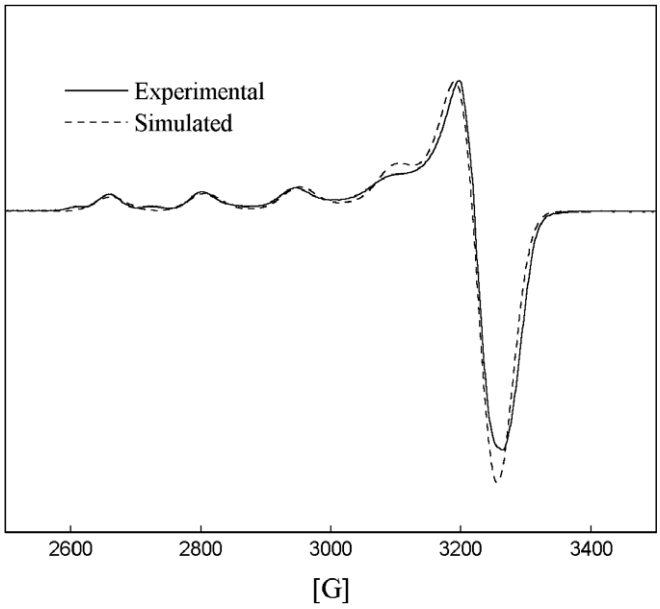

Fig. 10. EPR spectrum of **2** in DMSO solution at 77 K.

ues in the solid state at room temperature and in frozen solution are not much different from each other, hence the geometry around the copper ion is unaffected on cooling the solution to liquid nitrogen temperature, which gives no information indicative to a fluxional behaviour.

The IR spectra of **1** and **2** in the 4000–370 cm^{-1} region show the presence of bands due to the organic moiety. In both complexes the bands assigned to ν(C=N) skeletal vibration of the indazole ring (1598 cm^{-1} for **1** and 1622 cm^{-1} for **2**) and ν(C=N) skeletal vibration of the thiazoline ring (W_1) (1615 cm^{-1} for **1** and 1633 cm^{-1} for **2**), undergoes a negative shift when compare with that for the uncoordinated respective ligand (TnInA: ν(C=N) = 1614 cm^{-1}, $W_1 = 1632$ cm^{-1}; TnInL: ν(C=N) = 1637 cm^{-1}, $W_1 = 1641$ cm^{-1}). From all this can be deduced a coordination via these nitrogen atoms of the ligands [25–28].

In addition, the IR spectra of the complexes were investigated to obtain evidence for ionic or coordinated nitrate ions. This question has been the subject of considerable study. The most commonly used for determining coordination of the nitrate ion is the method based on the ($\nu_1 + \nu_4$) combination bands [29–32]. In this way, the bands registered at 1763, 1717 and 1707 cm^{-1} for **1** are assigned to ($\nu_1 + \nu_4$) combination bands. The first one is assignable to combination band of group nitrate ionic [30]. The value of the splitting ($\Delta = 10$ cm^{-1}) for the last two bands reveals the presence of one monodentate nitrate group in agreement with Lever's criteria [30]. For **2** the ($\nu_1 + \nu_4$) region shows bands at 1763 and 1752 cm^{-1} and at 1735 and 1716 cm^{-1} with the separation of 11 cm^{-1} and of 19 cm^{-1}. These bands can be assigned to one monodentate nitrate group and one anisobidentate nitrate group, respectively [30]. These results are in good accord with the X-ray structural determination data.

Table 6
Far IR bands (cm^{-1}) with tentative assignments

Compound	ν(Cu–O_{water})	ν(Cu–$N_{indazole}$)	ν(Cu–$N_{thiazoline}$)	ν(Cu–ONO_2)
$[Cu(NO_3)(TnInA)_2(H_2O)](NO_3)\cdot(H_2O)$ (**1**)	341	306	249 235	323
$[Cu(NO_3)_2(TnInL)(H_2O)]$ (**2**)	326	291	249	254

Besides, other bands due to monodentate nitrate ligands are registered at 707 and 697 cm^{-1} (ν_4), 1395 cm^{-1} (ν_3), 840 cm^{-1} (ν_2) and 1015 cm^{-1} (ν_1) for **1** and at 730 and 707 cm^{-1} (ν_4), 1435 and 1299 cm^{-1} (ν_3), 820 cm^{-1} (ν_2) and 1034 cm^{-1} (ν_1) for **2** [30]. Bands at 1387, 1056 and 826 cm^{-1} can be assigned to the nitrate ion group for the complex **1** and the bands at 719 and 690 cm^{-1} (ν_4) can be attributed to anisobidentate nitrate group for complex **2**.

The far IR spectra of these complexes show the appearance of bands due to metal–ligand stretching vibrations. Tentative assignments are listed in Table 6. The strong bands in the region 325–340 cm^{-1} are assigned to ν(Cu–O_{water}) vibration [33,34], whereas new bands at 305–290 cm^{-1} can be tentatively attributed to ν(Cu–$N_{indazole}$) vibration [35]. Likewise, bands due to ν(Cu–$N_{thiazoline}$) vibration [33,36,37] are found in the 250–235 cm^{-1} range. Finally, ν(Cu–ONO_2) vibrations [38–42] are registered in spectra at 325–255 cm^{-1}.

3.3. Magnetic measurements

The observed molar magnetic susceptibility for Cu(II) complexes was corrected for diamagnetism and temperature-independent paramagnetism to provide the fully corrected magnetic moment at room temperature ($\mu = 2.46$ BM for **1**; $\mu = 1.91$ BM for **2**). These values are slightly over or in the range 1.75–2.2 BM, which allows to exclude metal–metal interactions, supporting a monomeric structural formulation for these compounds [43].

4. Conclusion

For Cu(II)/TnInA and Cu(II)/TnInL systems, both with a 1:1 ligand/metal ratio, it was obtained complexes with six and five coordination numbers, respectively. Thus, $[Cu(NO_3)(TnInA)_2(H_2O)](NO_3)(H_2O)$ (**1**) shows an environment around the copper atom that may be described as distorted octahedral geometry with two organic ligands coordinated to metal centre. However, in $[Cu(NO_3)_2(TnInL)(H_2O)]$ (**2**) the geometry around the metal atom is adequately described as a square pyramid with only one organic ligand linked to ion copper.

From these results, we can conclude that the linear arrangement of heterocycles in TnInL ligand generate a greater steric impediment on the coordination sphere than the angular one in TnInA ligand. This fact hinder the access of a second organic ligand in complex **2**.

Likewise, these results are in good agreement with the cadmium(II) complexes preliminary reported [1], where complexes exhibited similar triangulated dodecahedral geometry that was more distorted in complex $[Cd(NO_3)_2(TnInL)_2]$ than in complex $[Cd(NO_3)_2(TnInA)_2]$, which was attributed to packing effects. The difference stoichiometry in copper complexes can be explained because of the presence of a smaller metal ion that intensifies the structural difference between TnInA and TnInL ligands.

Appendix A. Supplementary material

CCDC 619126 and 619127 contain the supplementary crystallographic data for $[Cu(NO_3)_2(TnInL)(H_2O)]$ and $[Cu(NO_3)(TnInA)_2(H_2O)](NO_3)(H_2O)$. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2006.10.001.

donation from O to Mo, as indicated by the short Mo–O bond length. Results of electrochemical studies show that the complexes of the type $[\{M(NO)(Tp^{Me2})X\}_n(QH_{2-n})]$ undergo one-electron reduction when $n = 1$ thereby generating 17*e* species, or two distinct one-electron reduction processes when $n = 2$. These redox processes may be reversible, depending on X [13].

Many bimetallic complexes $[\{M(NO)(Tp^{Me2})X\}_2(Q)]$ (M = Mo or W, X = halide, Q = bifunctionalised hydrocarbons or related aromatic ring systems) have been reported. Examples include species where Q = 1,*x*-O_2C_n-H_{2n-2} ($n = 6$, $x = 2$–4; $n = 5$, $x = 3$) [14]; Q = *para*- or *meta*-OC_6H_4O; $OC_6H_4YC_6H_4O$ (Y = none, O, S, SO_2, CO, $COC_6H_4C_6H_4CO$) [15]; Q = $OC_6H_4(C_6H_4)_nC_6H_4O$ ($n = 1$ or 2), $OC_6H_4CR{=}CRC_6H_4O$ (R = H or Et), and $OC_6H_4CH{=}CHC_6H_4CH{=}CHC_6H_4O$ [16]; Q = 4,4′-bipyridines [17]; Q = α,ω-bis(4-pyridyl)polyenes [18]; Q = $OC_6H_4(CH_2)_nO$ ($n = 1$–3) or $NHC_6H_4(CH_2)_nO$ ($n = 2$, 3) [19]; Q = $(NHCH_2)_2Z$ (Z = none, CH_2 or $\{CH_2OCH_2\}_2$) [20]; Q = *ortho*-, *meta*- and *para*-$[C_6H_4(NH)_2]^{2-}$ [21–23]; Q = NHC_6H_4O [15]; Q = 4-(imidazol-1-yl)phenol [24]; Q = pyrazine [25]. Dinuclear complexes incorporating short bridge O^{2-} have also been reported [26]. However, little work has been presented on species containing short saturated hydrocarbyl ligand systems, for example ethane-1,2-diol. Earlier synthetic and spectroscopic characterization of bimetallic Mo complexes was carried out some time ago [13f] but most of the results were not published because of difficulties with separation of diastereoisomers and determination of the crystal structure of a doubly bridged complex.

In order to further develop our studies of the dinuclear nitrosyl complexes of Mo and W with the bridge coordinated to metals by oxygen donor we have returned to our research involving ethane-1,2-diol. We have now been able to separate singly bridged diastereoisomers and have determined the crystal structure of *anti*-$[\{Mo(NO)(Tp^{Me2})(OCH_2CH_2O)\}_2]\cdot 4CHCl_3$. Additionally, we prepared $[\{M(NO)(Tp^{Me2})X\}_n(OCH_2CH_2OH_{2-n})]$ (M = Mo, X = Br, $n = 1$ or 2; M = W, X = Cl, $n = 1$ or 2) complexes. All compounds were characterized electrochemically using cyclic voltammetry (CV) and differential pulse voltammetry (DPV).

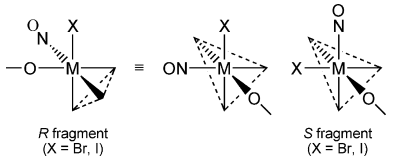
2. Results and discussion

2.1. Syntheses

The bimetallic species $[\{M(NO)(Tp^{Me2})X\}_2(OCH_2CH_2O)]$ (M = Mo, X = Cl, Br, I; M = W, X = Cl) were obtained by two different routes: (i) reaction between $[M(NO)(Tp^{Me2})X_2]$ and $HOCH_2CH_2OH$ in dichloromethane or diethyl ether in the presence of silver acetate or hexamethylenetetramine, and (ii) by direct reaction between the main reagents. The first route afforded a mixture of diastereoisomers of $[\{Mo(NO)(Tp^{Me2})X\}_2(OCH_2CH_2O)]$ (each metal centre is chiral, possible types are *R*–*R*/*S*–*S* and *R*–*S*/*S*–*R*)[1] which are difficult to separate chromatographically. Diastereoisomer I could be separated by taking advantage of its better stability at higher temperatures. Thus, refluxing a mixture of diastereoisomers in toluene allowed isolation of pure diastereoisomer I. Analogously, it was also possible to obtain one diastereoisomer of $[\{Mo(NO)(Tp^{Me2})I\}_2(OCH_2CH_2O)]$ by directly reacting $[Mo(NO)(Tp^{Me2})I_2]$ with $HOCH_2CH_2OH$ in refluxing benzene. This method gave the highest yield. Also a single diastereoisomer has been obtained from the direct reaction between $[W(NO)(Tp^{Me2})Cl_2]$ with $HOCH_2CH_2OH$ in refluxing toluene. In the separation of tungsten bimetallic isomers we have taken advantage of the fact that one isomer is much more soluble in CH_2Cl_2 than the other.

Substitution of both iodides in $[Mo(NO)(Tp^{Me2})I_2]$ by $HOCH_2CH_2OH$ in the presence of NEt_3 provided the doubly-bridged bimetallic complex, whose structure was established by X-ray crystallographic study to be the *anti*-isomer.

The monometallic species $[Mo(NO)(Tp^{Me2})X(OCH_2CH_2OH)]$ (X = Cl, I), which were described previously [13f,27] and for X = Br, may be also obtained from the reaction between $[Mo(NO)(Tp^{Me2})X_2]$ and $HOCH_2CH_2OH$ in dichloromethane in the presence of silver acetate. These complexes, eluted as the second fractions in chromatographic separation, have spectroscopic data identical with those published before. The monometallic $[Mo(NO)(Tp^{Me2})(OCH_2CH_2OH)_2]$ [27] was prepared by substitution of ethoxy groups in $[Mo(NO)(Tp^{Me2})(OEt)_2]$ by the more acidic ethane-1,2-diol in boiling toluene.



The analytical data for the new bimetallic complexes are given in Table 1.

2.2. Spectroscopic studies

IR spectra of the mono- and dinuclear compounds exhibit absorptions which are characteristic for the $[HB(3,5\text{-}Me_2pz)_3]^-$ ligand: ν(BH) at ca. 2550 cm^{-1} and ν(C–Me) in the range 1365–1451 cm^{-1}. Molybdenum monometallics and singly-bridged complexes show one ν(NO) in the range 1672–1675 cm^{-1}, that of the tungsten dinuclear complex at 1630 cm^{-1} and of the molybdenum doubly bridged complex at 1642 cm^{-1} (Table 1). These values are consistent with trends observed earlier [13f].

The mass spectra (Table 1) of the compounds contain ion clusters which span a wide mass range due to the presence of a large number of possible isotope combinations.

[1] According to the Cahn–Ingold–Prelog rules, the relative configurations of the metal fragments are assigned as shown:

when X = Cl then the assignment of the configuration is opposite.

								2.24 (6s)	
								2.22 (6s)	

[a] {Mo} or {W} = Mo(NO)(Tp^{Me2}) or W(NO)(Tp^{Me2}); Q = OCH_2CH_2O.

[b] Calculated values in parentheses; complexes may be isolated containing n moles of C_6H_{14} or $CHCl_3$ (which was also seen in the ^{1}H NMR spectrum) as determined for $\{MoBr\}_2(Q) \cdot 1/3C_6H_{14}$ and $\{Mo(Q)\}_2 \cdot 4CHCl_3$.

[c] The results of elemental analysis of freshly prepared sample. Results of the repeated elemental analysis after few weeks: $C_{34}H_{52}B_2Mo_2N_{14}O_6 \cdot 2/5CHCl_3$ requires: C, 34.66; H, 4.34; N, 15.50; found: C, 34.18; H, 4.08; N, 15.12% indicate, along with the presence of diffuse streaks in the diffraction pattern, that the crystals were losing solvent slowly.

[d] Recorded from KBr discs.

[e] Most intense peak of clusters; values in parentheses based on isotopic distribution calculated by ChemCalc [28].

[f] MALDI spectrum.

[g] ESI spectrum.

[h] Spectra were recorded at 300 MHz in $CDCl_3$; s = singlet, m = multiplet.

[i] Diastereoisomer I is thermodynamically more stable.

The most intense peak of the cluster does not always correspond exactly to the value based on most abundant isotopes. The spectra provide parent molecular ions (or alkali metal adducts) in addition to fragment ions consistent with the loss of halide and/or NO.

The ^{1}H NMR spectra (Table 1) are consistent with the formulations of the complexes and contain two groups of signals characteristic for the $[HB(3,5\text{-}Me_2pz)_3]^-$ ligand. In the spectra of the diastereoisomers (I and II) of $[\{M(NO)(Tp^{Me2})X\}_2(OCH_2CH_2O)]$ [M = Mo, X = Cl, Br or I; M = W, X = Cl] the pyrazolyl proton resonances occur in the range δ 5.86–5.41 (Mo) and 5.86–5.62 (W) as three signals of relative intensity 2:2:2, whilst the 3,5-methyl protons appear as five or six resonances of relative area 6:6:6:6:6:6 or 6:6:12:6:6 in the range δ 2.50–1.75 (Mo) and 2.57–2.18 (W). This behaviour is consistent with the absence of a plane of symmetry through {Mo(NO)-(Tp^{Me2})} centre. These spectra suggest the presence of the same centre of symmetry as found in $[\{Mo(NO)(Tp^{Me2})\text{-}Cl\}_2(NHCH_2CH_2NH)]$, i.e. antiperiplanar arrangement with respect to the bridge [20].

The spectrum of *anti*-$[\{Mo(NO)(Tp^{Me2})(OCH_2\text{-}CH_2O)\}_2]$ is exceptional and contains *one* resonance (δ 5.81) due to protons attached to C^4 atom of the pyrazolyl rings (probably by a reason of accidental degeneracy; normally, for related bis-alkoxides [13f] two singlets 2:1 are expected), and four signals of relative area 6:12:6:12 in the range δ 2.94–2.92, due to the twelve 3,5-methyl groups. This indicates that the complex contains a plane of symmetry. It shows, along with the crystal structure, that the metal centres are equivalent.

As had been observed previously [13f], the diastereotopic protons attached to the α-carbon atom in all the complexes resonate at low field with respect to free α,ω-diol. This effect is due to the strong electronegativity of the {M(NO)-(Tp^{Me2})X} centre (M = Mo or W, X = halide or none).

2.3. Electrochemical studies

The electrochemical properties of the bimetallic compounds and related monometallic species were investigated by CV and DPV in dichloromethane (Table 2). The monometallic complexes $[M(NO)(Tp^{Me2})X(OCH_2CH_2OH)]$ exhibit a single one-electron quasi-reversible reduction wave at potentials within the range of -1.05 to -1.11 V (M = Mo, X = Cl, Br or I) and -1.63 V (M = W, X = Cl) versus ferrocene–ferrocenium. The $E_{1/2}$-values, for mono- and bimetallic complexes, become more negative in the sequence I < Br < Cl, due to p(π) → d(π) donation from X to Mo, consistently with electronegativity effects. The bis-alkoxide $[Mo(NO)(Tp^{Me2})(OCH_2CH_2OH)_2]$ is reduced at -1.62 V which is consistent with the lower value of ν(NO) which, in turn, reflects electron density at the metal centre. As a result of p(π) → d(π) donation from O to Mo the LUMO orbital is destabilised and shifts the $E_{1/2}$ of the complex to more cathodic value [29]. All the species reveal $E_{1/2}$-values in the regions expected for related mono-alkoxides [30] and bis-alkoxides [31].

The bimetallic complexes $[\{M(NO)(Tp^{Me2})X\}_2(OCH_2\text{-}CH_2O)]$ [M = Mo, X = Cl, Br or I; M = W, X = Cl] exhibit two one-electron reductions waves, with separations ΔE_{dpv} of the order of 300 mV. The comproportionation constants[2] (in the range 10^4–10^5) for formation of mixed-oxidation-state complexes [12] indicate substantial interactions between the two metal-based redox centres. These

[2] Comproportionation constant calculated from $K_c = \exp(F\Delta E_{1/2}/RT)$.

[a] Formal potentials versus the ferrocene–ferrocenium couple measured in CH_2Cl_2 with a scan rate of 0.1 V s^{-1}; ca. 10^{-3} mol dm^{-3} in complex.
[b] Difference between anodic and cathodic peak potentials (for Fc/Fc^+ couple $\Delta E_p = 60$–80 mV).
[c] Separation between the two one-electron reduction potentials, determined by cyclic voltammetry.
[d] Difference between first and second reduction potentials determined by differential pulse voltammetry; pulse amplitude 50 mV.
[e] Practically irreversible ($i_c > i_a$).
[f] A new anodic wave is observed at −0.85 V.

interactions are dependent on the nature of M, and that in tungsten complex being smaller than its molybdenum analogue. The $E_{1/2}$-values of the *first* and second reduction processes are more *cathodic* (the first ca. 30–60 mV) than the $E_{1/2}$-value for the reduction of the corresponding monometallic species. The reduction processes for the chloro and bromo complexes are chemically reversible, whereas those in iodo species were practically irreversible as a result of dissociation of I^-. The large values of ΔE_p indicate that electron transfer processes are kinetically slow. The significant metal–metal interactions detected electrochemically in the bimetallic complexes incorporating the saturated bridging ligand could arise from through-σ-bond inductive effects and coulombic through-space interactions [14]. For the bimetallic iodo-complex the absolute magnitude of ΔE_{dpv} should be treated with caution because of the irreversible nature of the reduction processes. The tungsten complexes are reduced at potentials ca. 500 mV more *cathodic* than their Mo analogues. It was checked in the case of isolated diastereoisomers that they showed identical electrochemical behaviour.

The complex *anti*-$[\{Mo(NO)(Tp^{Me2})(OCH_2CH_2O)\}_2]$ was insoluble in solvents other than chloroform, which is unsuitable for electrochemical studies.

2.4. Crystal structure of anti-$[\{Mo(NO)(Tp^{Me2})(OCH_2CH_2O)\}_2]\cdot 4CHCl_3$

In the crystal structure of *anti*-$[\{Mo(NO)(Tp^{Me2})(OCH_2CH_2O)\}_2]\cdot 4CHCl_3$ two nonequivalent dinuclear molecules were found, with identical Mo centres and chloroform solvates (2 Mo atoms:4 solvent molecules) held together by weak van der Waals forces. The complex is constructed from two $\{Mo(NO)(Tp^{Me2})\}$ distorted octahedral units linked by two (OCH_2CH_2O) bridges (Fig. 1). The short Mo–O bond lengths (1.86, 1.91 Å) as well as Mo–O–C angles (136.3°, 137.0°), which suggest a significant degree of $p(\pi) \rightarrow d(\pi)$ donation from O to Mo, are comparable with those found in the related alkoxide complexes $[Mo(NO)(Tp^{Me2})X(Y)]$ [$X = OPr^i$, $Y = OPr^i$ or OEt; $X = I$, $Y = O(CH_2)_3Br$] [32]. The molybdenum-nitrosyl system is slightly bent from linearity (175.0°). The nitrosyl substituents are oriented *antiperiplanar* with respect to each other. Simplified representation of the metal first coordination sphere is shown in Fig. 2. The asymmetric unit contains two tetrahedral fragments of complex and two independent molecules of $CHCl_3$ (typical geometry and no short contact to the complex). The small crystal size and the presence of disordered solvent molecules in crystal (diffuse streaks in the diffraction pattern are observed) resulted in relatively poor refinement ($R = 10.89\%$). However the atoms positions in the main part of elementary cell (see Fig. 3) were found with a good precision. That is why the bonds length and the values of angles (Table 3) are comparable with values which were obtained for similar structures.

The point group of molecule $2/m$ (C_{2h}) confirms the presence of a plane of symmetry which is reflected in ^1H NMR spectra.

3. Experimental

3.1. Materials and instrumentation

Precursors $[M(NO)(Tp^{Me2})X_2]$ (M = Mo, X = Cl, Br, I or OEt; M = W, X = Cl) [33] and monometallic species $[M(NO)(Tp^{Me2})X(OCH_2CH_2OH)]$ (M = Mo or W; X = Cl, I) [13f,27] were prepared according to previously described methods. All reactions were carried out under pure argon (BOC, N5.0) using Schlenk techniques. Commercial solvents and triethylamine were purified by distillation under argon; dichloromethane from CaH_2, toluene and benzene from sodium-benzophenone and triethylamine from sodium. Anhydrous, 99.8% ethane-1,2-diol was supplied from Aldrich and used directly. Column

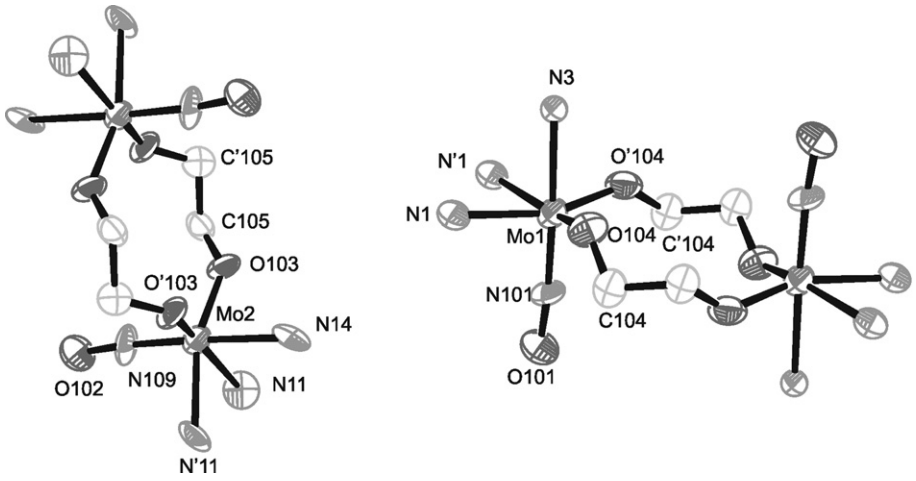

Fig. 2. Illustration of the dinuclear core in the structure of *anti*-[{Mo(NO)(Tp^{Me2})(OCH_2CH_2O)}$_2$] · 4$CHCl_3$.

chromatography was carried out in glass columns with Merck silica gel 60 (70-230 mesh) as the stationary phase. The reaction's progress and purity of compounds were monitored by TLC analysis using Merck silica gel (60) F_{254} plates. Elemental analyses were performed by the Microanalytical Laboratory of the Faculty of Chemistry at Jagiellonian University.

IR spectra were recorded using a Bio-Rad FTS 175C spectrophotometer in KBr discs and ^{1}H NMR spectra using a Varian Mercury-Vx 300 MHz spectrometer. Mass spectra were collected on a Bruker-Daltonics Esquire 3000 (ESI) and Reflex IV (MALDI). Cyclic and differential pulse voltammetry measurements were carried out using a BAS 100B/W electrochemical workstation (BioAnalytical Systems), under argon in 10^{-3} M solution of complex in dry dichloromethane, containing 0.1 M [NBu^n_4][PF_6] as base electrolyte. A standard three-electrode cell was used, with a platinum-bead working electrode, a platinum wire secondary electrode, and a Ag/AgCl electrode as the reference. Ferrocene was added at the end of each experiment as an

internal standard; all potentials are quoted versus the ferrocene–ferrocenium couple. The number of electrons in each transfer was estimated by comparison with [{Mo(NO)(Tp^{Me2})Cl}$_2$O], for which a one electron process has been shown [26a].

3.2. Synthetic procedures

3.2.1. Synthesis of [{Mo(NO)(Tp^{Me2})Cl}$_2$(OCH_2CH_2O)]

To a solution of [Mo(NO)(Tp^{Me2})Cl_2] (0.50 g, 1.0 mmol) in dry dichloromethane (80 cm^3) AgOCOMe (0.20 g, 1.2 mmol) and ethane-1,2-diol (0.26 g, 4.2 mmol) were added. The mixture was stirred and refluxed overnight affording a deep blue solution. The precipitate of inorganic salts was filtered off and the filtrate evaporated in vacuo. The residue was dissolved in the minimum volume of dichloromethane and chromatographed on silica gel using dichloromethane as eluant. Two blue bands were observed on the column (bi- and monometallic species). The first major fraction was collected, the solvent was partially evaporated in vacuo and *n*-hexane was added. The volume of the mixture was further reduced in vacuo until precipitation began. The resulting blue product was filtered off, washed with *n*-hexane, dried at ca. 80 °C for 1 h and then in vacuo for 12 h (mixture of diastereoisomers, 0.13 g, 26%).

3.2.2. Synthesis of [{Mo(NO)(Tp^{Me2})Br}$_2$(OCH_2CH_2O)] and [Mo(NO)(Tp^{Me2})Br(OCH_2CH_2OH)]

Method 1. These compounds were prepared as blue-green powders as described above using [Mo(NO)(Tp^{Me2})Br_2] (0.50 g, 0.86 mmol), ethane-1,2-diol (0.22 g, 3.5 mmol) and AgOCOMe (0.15 g, 0.90 mmol) in dichloromethane (60 cm^3), but heating was finished after 8 h. The first and the second blue fractions were collected and precipitated from CH_2Cl_2/*n*-hexane (0.12 g, 27%, mixture of bimetallic diastereoisomers; 0.05 g, 10%, monometallic).

Method 2. [Mo(NO)(Tp^{Me2})Br_2] (0.50 g, 0.86 mmol) together with ethane-1,2-diol (1.1 g, 18 mmol) and hexamethylenetetramine (0.12 g, 0.86 mmol) in diethyl ether–dichloromethane mixture (50 cm^3; 5:1 v/v) was stirred and refluxed for 2 h. The resulting blue solution was decanted from an oily deposit, filtered and cooled to −10 °C overnight. The mixture was decanted again and the supernatant liquid evaporated to dryness. The residue was chromatographed on silica gel using dichloromethane as eluant (0.08 g, 18%, mixture of bimetallic diastereoisomers; 0.07 g, 14%, monometallic).

3.2.3. Synthesis of [{Mo(NO)(Tp^{Me2})I}$_2$(OCH_2CH_2O)]

Method 1. This compound was prepared as a green powder according to the procedure described above using [Mo(NO)(Tp^{Me2})I_2] (0.50 g, 0.74 mmol), ethane-1,2-diol (0.22 g, 3.5 mmol) and AgOCOMe (0.13 g, 0.78 mmol) in

dichloromethane (60 cm^3), but heating was finished after 4 h (mixture of diastereoisomers, 0.07 g, 16%).

Method 2. A mixture of [Mo(NO)(Tp^{Me2})I_2] (0.50 g, 0.74 mmol) and ethane-1,2-diol (0.55 g, 8.9 mmol) was stirred and refluxed in benzene (50 cm^3) for 10 h and then stirred overnight at RT. The resulting green solution was decanted and filtered and an oily deposit was discarded. The filtrate was reduced in volume and left to crystallise diastereoisomer I (0.22 g, 51%).

Method 3. A mixture of [Mo(NO)(Tp^{Me2})I_2] (0.50 g, 0.74 mmol) and ethane-1,2-diol (2.2 g, 35 mmol) was stirred and refluxed in diethyl ether (50 cm^3) for 2 h. The resulting green solution was decanted from an oily deposit, filtered and cooled to −10 °C overnight. The mixture was decanted again and the supernatant liquid evaporated to dryness. The residue was chromatographed on silica gel using dichloromethane as eluant. The first green fraction was collected and precipitated from CH_2Cl_2/*n*-hexane as a green powder (mixture of diastereoisomers, 0.06 g, 14%).

3.2.4. Synthesis of [{Mo(NO)(Tp^{Me2})(OCH_2CH_2O)}$_2$]

A mixture of [Mo(NO)(Tp^{Me2})I_2] (1.0 g, 1.5 mmol) and ethane-1,2-diol (0.11 g, 1.8 mmol) in dry toluene (100 cm^3) was brought to reflux and then triethylamine (3.5 ml) was added. After 1 h ethane-1,2-diol (0.066 g, 1.1 mmol) was added affording a red-brown solution, and a precipitate was formed. Then, refluxing was continued for 30 min. The mixture was then cooled to −10 °C and the pink precipitate which formed was filtered off and washed with *n*-hexane, dichloromethane and dried at ca. 80 °C for 1 h and then in vacuo for 12 h (*anti* isomer, 0.16 g, 23%). The complex was recrystallised from chloroform as a red crystals.

3.2.5. Synthesis of [Mo(NO)(Tp^{Me2})(OCH_2CH_2OH)$_2$]

To a solution of [Mo(NO)(Tp^{Me2})($OEt)_2$] (0.10 g, 0.20 mmol) in dry toluene (30 cm^3) ethane-1,2-diol (0.11 g, 1.8 mmol) was added. The mixture was stirred and refluxed for 6 h, the solution was cooled and evaporated in vacuo to one third of its volume. The mixture was cooled to −10 °C overnight and the pink crystals which formed were filtered off, washed with dichloromethane, *n*-hexane, dried at ca. 80 °C for 1 h and then in vacuo for 12 h (0.047 g, 44%).

3.2.6. Synthesis of [{W(NO)(Tp^{Me2})Cl}$_2$(OCH_2CH_2O)]

A mixture of [W(NO)(Tp^{Me2})Cl_2] (0.5 g, 0.86 mmol) and ethane-1,2-diol (1.1 g, 18 mmol) in dry toluene (100 cm^3) was stirred and refluxed for 6 h. The resulting purple solution was decanted from an oily deposit, filtered, and cooled to −10 °C overnight. The mixture was decanted again and the supernatant liquid evaporated to dryness. The residue was redissolved in CH_2Cl_2 and the purple precipitate which formed was filtered off (diastereoisomer I, 0.04 g, 8%) and the filtrate evaporated in vacuo to low volume and chromatographed using dichloromethane as eluant. The first fraction was collected and precipitated from CH_2Cl_2/*n*-hexane as a purple powder (diastereoisomer II, 0.05 g, 10%).

3.2.7. Crystal structure determination of anti-[{Mo(NO)(Tp^{Me2})(OCH_2CH_2O)}$_2$]

The red crystals were grown by slow evaporation of a solvent from concentrated solution of the complex in $CHCl_3$. Selected crystal had dimensions $0.2 \times 0.15 \times 0.1$ mm^3. X-ray data were collected on a Nonius Kappa CCD with graphite monochromated Mo Kα radiation ($\lambda = 0.71070$ Å). 2651 reflections were measured ($2\theta_{max} = 40°$) at 20 °C. Corrections for Lorentz and polarization were applied. The structure was solved by direct methods and refined by the full-matrix least-squares method on all F^2 data using the SHELXL-97 suite of programs. The model, accepted as the 'correct' structure, gave final R $[=\sum(F_o - F_c)/\sum(F_o)]$ and wR $[=\sum\{w(F_o^2 - F_c^2)^2\}/\sum\{w(F_o^2)^2\}]^{1/2}$ values of 0.1875 and 0.2425, respectively, for 377 parameters and all 2651 data. The corresponding R values for 1579 data with $I > 2\sigma(I)$ were 0.1089 and 0.2153. Weighting scheme, $w = 1/[\sigma^2(F_o^2) + (0.0512P)^2 + 113.8839P]$, where $P = (F_o^2 + 2F_c^2)/3$. All non-hydrogen atoms were refined with anisotropic thermal parameters; hydrogen atoms were included in calculated positions and refined isotropically.

Crystal data. $C_{34}H_{52}B_2Mo_2N_{14}O_6 \cdot 4CHCl_3$, $M = 1443.89$, tetragonal, space group $P4_2/m$, $a = b = 17.1770(4)$ Å, $c = 20.8570(7)$ Å, $V = 6153.84(3)$ $Å^3$, $Z = 2$, $D_c = 1.562$ g cm^{-3}, $F(000) = 2924$, μ(Mo Kα) = 0.981 mm^{-1}.

4. Conclusion

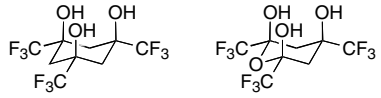
The characterization of dinuclear complexes derived from the {M(NO)(Tp^{Me2})X}$^+$ (M = Mo or W; X = halide) moiety and ethane-1,2-diol is difficult because of isomeric forms which may be present. It is possible to obtain the thermodynamically more stable isomer I by using benzene as the solvent in the synthesis of the bimetallic iodo-complex or by prolonged boiling of the isomeric mixture in toluene. In the separation of tungsten bimetallic isomers we have taken advantage of the fact that one isomer is much more soluble in CH_2Cl_2 than the other.

Results of cyclic voltammetry studies of the bimetallic complexes have revealed $\Delta E_{1/2}$ ca. 300 mV (M = Mo, X = Cl or Br), which reflects the extent of interactions between metal centres comparable with that obtained from analogous complexes containing cyclohexane-1,2-diol as the bridge.

The doubly bridged complex, [{Mo(NO)(Tp^{Me2})(OCH_2-CH_2O)}$_2$], should exist as the *syn* and *anti* isomers, but as yet, only *anti* isomer has been obtained and its molecular structure has been determined.

Acknowledgements

We are grateful to the Chemical Company Dwory S.A. for the partial support of this work and thank the Joint X-Ray Laboratory, Faculty of Chemistry and ŚLAFiBS, Jagiellonian University for making the Nonius KappaCCD



diffractometer available. One of us (A.W.) is especially grateful to Professor J.A. McCleverty for providing the opportunity to advance the work on this topic and a very long lasting and very fruitful scientific collaboration.

Scheme 1. Ligands H_3TTFTCH (**1**) and H_3TTPT (**2**).

The tetranuclear structure of **6** is largely similar in structure to that observed for the reported structure **4** with the exception that now four copper ions constitute the tetranuclear core. The coordination pattern of the ligand **2** is identical to the one found in **4**. Its formation is accomplished by reaction of copper-hexafluoroacetylacetonate with 3-methyl-1*H*-pyrazole (=3-Hmpz). For both complexes **4** and **6** no attempt as to the isolation of the free ligands **1** and **2**, respectively, has been reported and thus no proof was provided for their stability in their fully protonated forms. While **1** displays a C_{3v} symmetry, **2** belongs to the point group C_s.

We present here a greatly simplified synthetic access to **3** avoiding the electrolytic pathway (Scheme 2) [10], full characterisation of the neutral, isolated form of **2**, and unequivocal evidence for the presence of **2**, rather than **1**, in the tetranuclear complex (**4** → **5**), thus in fact contesting the structural interpretation of the diffraction data obtained for this complex, as given in Ref. [4].

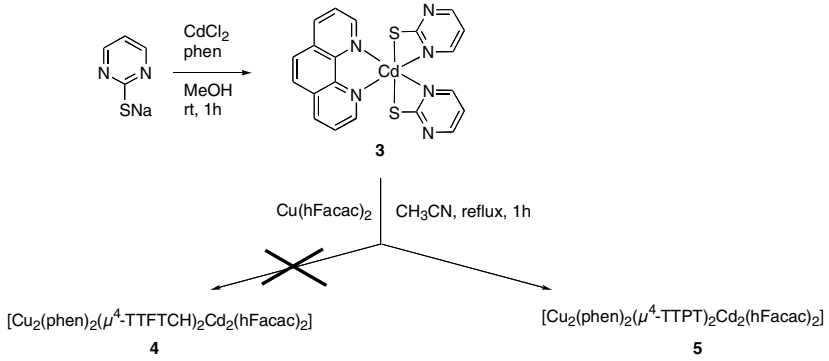
2. Experimental

2.1. General

Reagents were purchased from commercial suppliers and used without further purification. All solvents except tetrahydrofuran (THF) were used without purification. THF was distilled from sodium-benzophenone and, when mentioned, degassed thoroughly by freeze–thaw–vacuum cycles. NMR spectra were recorded on a Bruker Avance 200 (operating at 200.13 MHz for ^{1}H, 50.32 MHz for ^{13}C and 188.31 MHz for ^{19}F). For ^{1}H and ^{13}C, chemical shifts (δ) are reported in parts per million relative to TMS, using the solvent line as secondary internal reference. For ^{19}F spectra, chemical shifts are reported in parts per million (δ) relative to $CFCl_3$, using $CFCl_3$ in $CDCl_3$ as external reference. The IR spectra were recorded on a Mattson 3000 FT-IR spectrometer between 3500 and 500 cm^{-1} using KBr disks (w: weak, m: medium, s: strong, vs: very strong, sh: shoulder). The UV–Vis spectra were recorded on a Jasco V-550 spectrometer.

2.2. Synthesis

2.2.1. 1,10-Phenanthroline-bis(pyrimidine-2-thionato)-cadmium(II) (3)



$CdCl_2$ (2.0 g, 10.80 mmol) and 204 mL of methanol were placed into a 500 mL round-bottom flask. The mixture was heated to reflux until all the cadmium chloride was dissolved (*ca.* 2 h). Separately, a freshly prepared MeONa solution (0.24 M, 595 mg Na, 106 mL MeOH) in a 250 mL round-bottom flask was treated with 2-mercaptopyrimidine (2.86 g, 25.0 mmol) and 1,10-phenanthroline monohydrate (0.89 g, 4.48 mmol) was added successively. The resulting yellow thiolate solution was added dropwise to the $CdCl_2$ solution at room temperature. An off-white solid immediately precipitated. After stirring for one additional hour, the reaction mixture was filtered, the precipitate was successively washed with 30 mL of methanol, 30 mL of water and 10 mL of methanol and then dried *in vacuo* to afford 4.78 g of a white powder (9.28 mmol, 85%). The crude material was recrystallised in boiling acetonitrile (*ca.* 2.5 L), and 3.56 g of **3** were isolated as yellow crystals (6.91 mmol, 64%).

Anal. Calc. for $C_{20}H_{14}CdN_6S_2$: C, 46.65; H, 2.74; N, 16.32; S, 12.45. Found: C, 46.91; H, 2.94; N, 16.28; S, 12.53%.

^{1}H NMR (DMSO-d_6, 200 MHz) δ 9.26 (1H, d, $^3J = 4.5$ Hz) 8.86 (1H, d, $^3J = 8.0$ Hz); 8.26 (2H, d, $^3J = 5.0$ H) 8.24 (1H, s) 8.11 (1H, dd, $^3J = 8.0$, 4.5 Hz) 6.90 (1H, t, $^3J = 5.0$ Hz); ^{13}C NMR ($CDCl_3$, 50 MHz) δ 115.0, 126.5, 128.5, 130.2, 140.4, 142.1, 151.2, 157.8.

2.2.2. [Cu$_2$(phen)$_2$(μ^4-TTPT)$_2$Cd$_2$(hFacac)$_2$]CH$_3$CN (5)

Into a 6 L round-bottom flask were introduced complex **3** (1.49 g, 2.89 mmol), Cu(hFacac)$_2 \cdot x$H$_2$O (2.98 g, 6 mmol) and 4.7 L of acetonitrile. The green reaction mixture was

Scheme 2. Synthetic procedure for tetranuclear complex **5**.

refluxed for 1 h in order to dissolve **3**. After hot filtration, the resulting orange solution was allowed to slowly evaporate at room temperature over one month which resulted in a loss of approx. 1.5 L. 740 mg of dark blue, X-ray quality crystals were collected (0.39 mmol, 27% based on **3**) (see Figs. 1 and 2).

Anal. Calc. for $C_{50}H_{26}Cd_2Cu_2F_6N_4O_{12}CH_3CN$: C, 33.99; H, 1.59; N, 3.81. Found: C, 33.93; H, 1.73; N, 3.93%. IR (KBr): 3098 w, 2971 w, 2265 w, 1655 s, 1607 w, 1589 m, 1551 m, 1522 s, 1501 s, 1462 m, 1431 m, 1343 w, 1260 vs, 1191 sh, 1182 vs, 1147 vs, 1133 sh, 1092 m, 1060 m, 1024 w, 968 m, 927 w, 890 w, 845 m, 791 m, 737 w, 724 m, 665 m, 609 w, 580 w, 552 w cm^{-1}. UV–Vis (THF): $\lambda_1 = 296$ nm ($\varepsilon = 22{,}300$ L^{-1} mol cm^{-1}); $\lambda_2 = 273$ nm ($\varepsilon = 35{,}400$ L^{-1} mol cm^{-1}); $\lambda_3 = 225$ nm ($\varepsilon = 34{,}100$ L^{-1} mol cm^{-1}); $\lambda_4 = 208$ nm ($\varepsilon = 35{,}100$ L^{-1} mol cm^{-1}).

2.2.3. 2,4,6-tris(trifluoromethyl)tetrahydropyran-cis,cis-2,4,6-triol (2)

In a 25 mL round-bottomed flask, **5** (280 mg, 0.149 mmol) was treated with Et_2O (5 mL) and 3 N H_2SO_{4aq} (5 mL). The reaction mixture was vigourously stirred at room temperature until complete disappearance of the blue crystals (*ca.* 1 h). The aqueous phase was extracted two times with Et_2O, and the combined organic phases were dried over anhydrous Na_2SO_4, filtered, and concentrated *in vacuo*. Purification by silica gel column chromatography (ethyl acetate/hexane = 1:50–1:2, R_F (1:2) = 0.3, stains colourless (!) with $KMnO_4$) gave 95 mg of **2** as colorless crystals (0.281 mmol, 94%). Recrystallisation in hot hexane afforded diffraction quality crystals (see Fig. 2b).

2.2.4. General procedures for decomplexation and ligand isolation

2.2.4.1. Typical aqueous conditions. A 50 mL Schlenk tube charged with 45 mg of **5** (0.024 mmol) was vacuum-purged several times with Ar (or H_2). Then, Et_2O (10 mL) and distilled water (5 mL) containing the reagent (HCl, NH_4Cl or Na_2EDTA) were added. The reaction mixture, monitored by TLC, was stirred at room temperature for the prescribed time stated in Table 1. The aqueous phase was extracted two times with Et_2O, the combined organic phases dried over anhydrous Na_2SO_4, filtered, and concentrated *in vacuo*. The crude organic residue was analysed by ^{1}H and ^{19}F NMR spectroscopy.

2.2.4.2. Typical anhydrous conditions. **5** (45 mg, 0.024 mmol) was placed in a 15 mL flame-dried Schlenk tube which was subsequently vacuum-purged several times with Ar. The addition of degassed THF and stirring for a short period of time (*ca.* 15 min) at room temperature led to complete dissolution of **5**. The resulting blue solution was then treated by several means with the gaseous reagent: direct bubbling into the solution, dropwise addition in

gas-saturated THF or streaming on the liquid surface. The reaction mixture was allowed to react until total disappearance of the blue colour. After purging the system with Ar for 15 min, the crude reaction mixture was filtered in order to remove all metal precipitates ($CdCl_2$, $CuCl_2$, CuS or CdS, respectively). The solvent was evaporated, and the resulting residue in solution in $CDCl_3$ was subjected to NMR analysis.

2.3. Mass spectrometry

Mass spectra were acquired on a ThermoFinnigan LCQ Advantage ion trap instrument, detecting positive ions (+) or negative ions (−) in the ESI mode. Samples (in methanol:dichloromethane:water, 45:40:15, v/v/v) were infused directly into the source (5 μL/min) using a syringe pump. As a control experiment, **2** (respectively **4/5**) was dissolved in acetonitrile (respectively in THF) and introduced into the ESI source at a flow rate of 5 μL/min: no major modification of the spectra could be observed. The following source parameters were applied: spray voltage 3.0–3.5 kV, nitrogen sheath gas flow 5–20 arbitrary units. The heated capillary was held at 200 °C. A high-resolution mass spectrum (HR-MS) of compound **2** was obtained using a ThermoFinnigan MAT95XL double-focusing mass spectrometer equipped with a ESI III source.

2.4. X-ray crystallography

Suitable crystals were mounted on a Nonius Kappa CCD diffractometer using Mo Kα radiation ($\lambda = 0.71073$ Å) and equipped with a CCD area detector. Intensities for **2** and **4/5** were collected at room temperature by means of the program COLLECT [11]. Cell-refinement and data reduction were carried out with the EVALCCD [12] program. An analytical absorption correction was achieved by modeling the crystal faces [13] through the WINGX gui [14]. The resulting set of *hkl* was used for structure solution with SIR97 [15]. All non-hydrogen atoms were refined anisotropically with the program CRYSTALS [16]. Hydrogen atoms were placed geometrically and then refined using riding constraints. Crystallographic data details on data collection and structure refinement are listed in Table 2.

3. Results and discussion

Castro et al. proposed that, while conducting the reaction between the two starting materials (Scheme 2), **1** was generated in a metal-assisted mechanism starting from

hexafluoroacetylacetonate (hFacac). As a consequence of our interest in **1**, we have opted for a "quick" access to a sample of it by resynthesizing $[Cu_2(phen)_2(\mu^4\text{-TTFTCH})_2\text{-}Cd_2(hFacac)_2]$ (**4**), rather than conducting new metal-free experiments with unknown outcome. Simple hydrolysis of **4** would then afford the desired H_3TTFTCH (**1**).

Initially, we needed to make 1,10-phenanthroline-bis(pyrimidine-2-thionato)cadmium(II) (**3**), precursor for the tetranuclear complex **4/5** (Scheme 2). Rather than pursuing the published electrochemical approach [17] using Cd plate as the anode, we developed a simpler and more high-yielding (85%) procedure based on $CdCl_2$ and the thiol in its fully deprotonated form. With [Cd(pymt)$_2$phen] (**3**) in hand, we reproduced on a larger scale the exact experimental conditions proposed by Castro et al. for the formation of **4/5** allowing **3** and bis(hexafluoroacetylacetonato)Cu(II) to react in refluxing acetonitrile. It is imperative to use recrystallised **3** (in hot acetonitrile) in order to observe the formation of **4/5**. Furthermore, optimisation of the speed of solvent evaporation during the crystallisation period of **4/5** turned out to be crucial: an elevated evaporation rate only led to an unknown green precipitate. Once the solubility limit of **4/5** was reached, further evaporation caused the formation of an undesired yellow precipitate. Under optimal conditions, **4/5** could be obtained as deep blue crystals in 27% yield (calculation based on **3**). Mono-crystals were subjected to a routine X-ray diffraction analysis and the presence of **1** was confirmed in the resulting tetranuclear complex structure (Fig. 1a).

The deep blue crystals of **4/5** were subsequently destroyed in a biphasic mixture of 3 N H_2SO_4 and diethyl ether. Column chromatography of the organic residue isolated from the ethereal phase afforded partially hydrated hexafluoroacetylacetone and a colorless crystalline solid. Surprisingly, all NMR data (1H, 13C, and 19F) for the latter compound supported a C_2-symmetry incompatible with the C_{3v} space group of **1** (Scheme 1). Additional characterisation by ESI-MS, and HR-MS supported a tetrahydropyran structure rather than a cyclohexyl moiety. A subsequent X-ray analysis of the isolated ligand (Fig. 2b) confirmed the tetrahydropyran structure **2**. Remarkably, treatment with 3 N H_2SO_4 did not lead to the formation of a mixture of an entirely *cis*-configured acetal and its *cis–trans*-configured counterpart by thermodynamic equilibration : the stereoconfiguration found in the crystals of **4/5** was retained.

Although no usual mechanistic pathway could explain a possible *in situ* transformation of **1** into **2** (two C–C bonds broken and two C–O bonds formed under reasonably mild conditions), the high yield of **2** (94% based on **4/5**) led us to explore the possibility that TTFTCH (**1**) was getting quantitatively oxidized during hydrolysis. We thus decided to

[a] Estimated standard deviations in the least significant digits are given in brackets.

perform a series of rigorous experiments to liberate the ligand using reagents as various as HCl_{gas}, H_2S_{gas}, or EDTA, while partially or entirely excluding oxygen and water as possible oxygen sources (Table 1). The resulting highly insoluble compounds with copper and cadmium ($CdCl_2$, $CuCl_2$, CuS and CdS) provided a powerful driving force for TTFTCH liberation. Under inert and reductive atmosphere, the biphasic system HCl_{aq}/Et_2O led to the "oxidised" compound **2**. The softer reagent NH_4Cl was found to be inert toward **4/5**. Tetrahydrofuran turned out to be an excellent solvent to dissolve **4/5** which greatly aided in tests with various reagents. Use of hydrogen sulfide (reaction time: 3 min) was particularly powerful in cleaving the complex while ensuring perfectly reductive conditions. In all these attempts, only the acetal **2** was obtained despite rigorous exclusion of oxygen. These results made any oxidation of **1**–**2** increasingly unlikely. Two subsequent liberation attempts with orthogonal conditions were carried out, one using a Grignard reagent, the other EDTA, the former leading to exclusive formation of **2**, the latter having no impact on crystalline **4/5** in the absence of THF.

Keeping in mind the very unusual way how **1** was formed and the reported X-ray structure of a similar complex containing **2** in place of **1**, we started to doubt the original X-ray diffraction assignment corresponding to

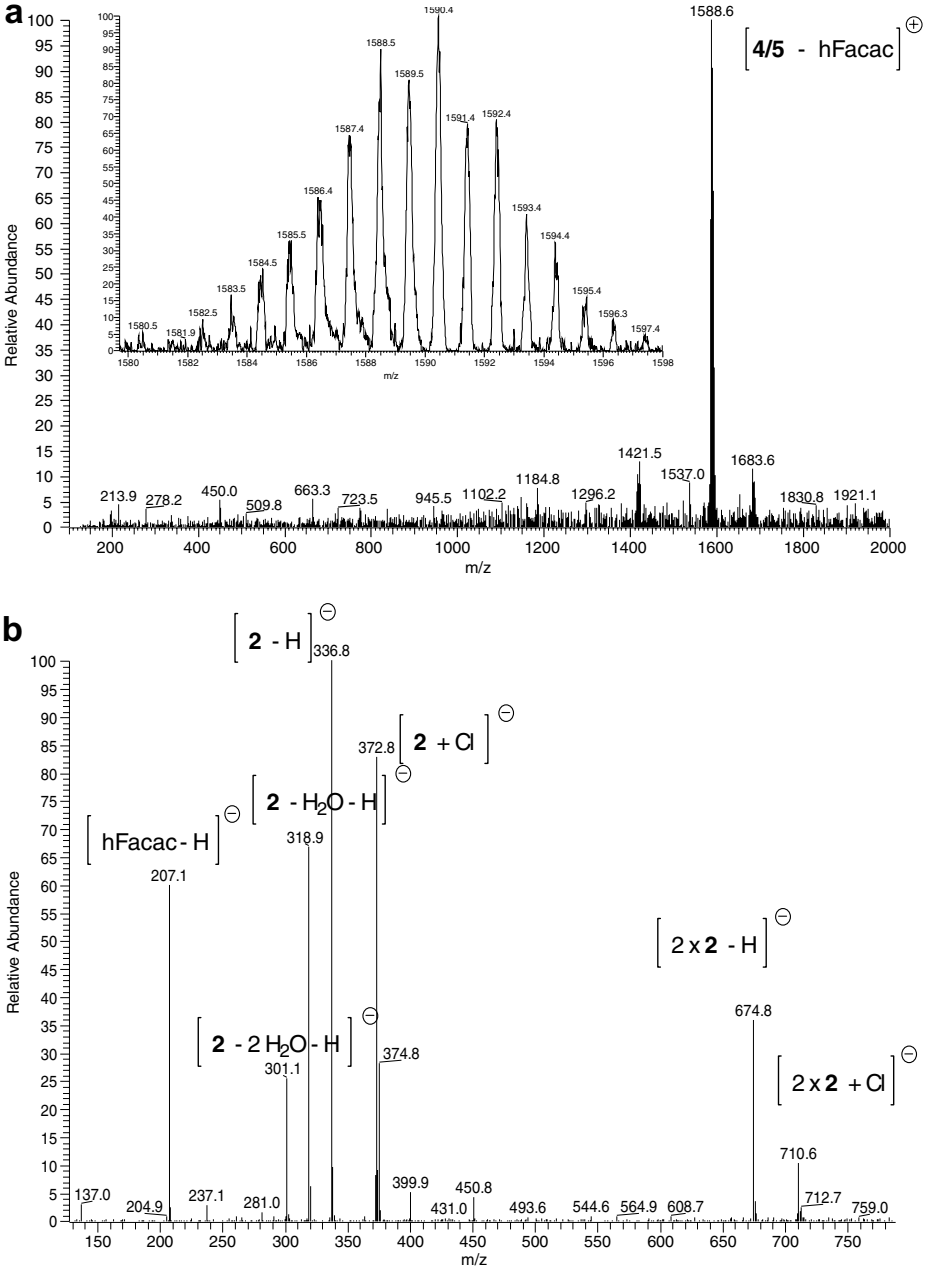

Fig. 3. ESI-MS of cpd. **4/5** dissolved in THF: (a) positive mode (inlet: expansion of peak [**4/5**-hFacac]$^+$), (b) negative mode.

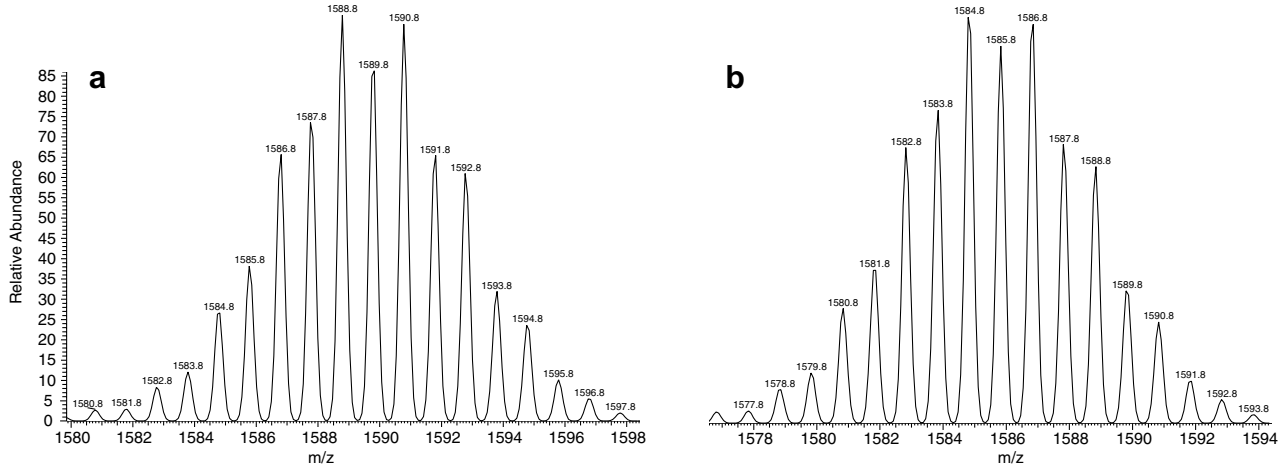

Fig. 4. Expansion of the peak [**4**/**5**-hFacac]$^+$: (a) calculated isotopic distribution for [**5**-hFacac]$^+$ and (b) calculated isotopic distribution for [**4**-hFacac]$^+$.

structure **4**, reported by Castro et al. and redetermined by us. Newly collected crystallographic data (space group, cell volume, cell parameters) from crystals of **4**/**5** were in full agreement with Ref. [4]. The data collected for **4**/**5** were used to reinvestigate the identity of the atoms constituting the presumed cyclohexane ring of ligand **1**. We explored the effect of interchanging one methylene group with an oxygen. Refinement as an oxygen atom led to a similar *R* factor but the equivalent displacement parameter was slightly high ($U_{eq} = 0.059$) compared to those of the atoms forming the 6-membered ring ($U_{eq} \sim 0.030$). Consequently, the structure containing a located oxygen on the cycle as reported for the tetra-copper complex **6** was discarded. Another refinement was achieved by modelling an oxygen atom delocalised over the three available positions (Figs. 1 and 2a) using soft restraints on bond length. This procedure led to a slight improvement of the *R* factor (4.3%) compared to the one obtained using a cyclohexane structure (4.5%). Thus, the refinement results tend to show that the oxygen atom is present and delocalised on three positions revealing a statistical disorder. This is confirmed by the fact that a low temperature measurement (150 K) did not allow to localise the oxygen atom on a given position. Relevant bonding distances and angles for structure **4** (with previous reported values), **5** and **2**, as well as crystal parameters and basic information pertaining to data collection are given in Section 2 (see Table 3).

Elemental analysis of **4**/**5** turned out to be very different from the one published (C, 33.93; H, 1.73; N, 3.93 versus C, 36.0; H, 1.8; N, 4.3) and tends to validate structure **5** with one molecule of solvent as found in the crystal lattice. Nevertheless, we looked for additional analytical methods to support our assumptions: liquid and solid NMR spectroscopy had to be ruled out due to the paramagnetic character of copper(II). IR spectroscopy did not furnish clear evidence for a tetrahydropyran ring: the characteristic C–O–C stretching band of such a structure being possibly masked by the very broad C–OH and C–F stretching bands around 1150 cm^{-1}. Since **4**/**5** was soluble enough in THF, we thus turned to mass analysis for independent data.

It is worthy to note that cadmium as well as copper present several abundant isotopes which lead to unambiguous peak patterns aiding in structure assignment [18]. Ionisation of **4**/**5** dissolved in THF was achieved using the soft electrospray-ionisation technique. Although no molecular ion peak could be detected, relevant fragmentation ions were identified, especially [**4**/**5**-hFacac]$^+$ (Fig. 3a). A "zoom" scan in the region of *m*/*z* 1589 was compared to the calculated isotopic mass distribution for [Cu_2(phen)$_2$-(μ^4-TTFTCH)$_2$$Cd_2$(hFacac)]$^+$ (**4**) and [Cu_2(phen)$_2$-(μ^4-TTPT)$_2$$Cd_2$(hFacac)]$^+$ (**5**) (Fig. 4): the experimental set of peaks perfectly corresponded to the simulated spectrum of **5**, thus rendering the presence of ligand **2** indisputable. The unique loss of one hexafluoroacetylacetonate unit from the molecular ion rules out any rearrangement or oxidation process during ionisation. Importantly, detection in negative mode only gave rise to derivatives of **2** and hexafluoroacetylacetonate [hFacac]$^-$ without traces of **1** (Fig. 3b). The ESI-MS spectrum of free tetrahydropyran **2** (not shown) was in full agreement with this fragmentation pattern.

4. Conclusions

An improved large-scale synthesis of [Cu_2(phen)$_2$-(μ^4-TTPT)$_2$$Cd_2$(hFacac)$_2$] in the form of deep-blue crystals (**5**) and the isolation and characterisation of the free ligand, *cis*,*cis*-2,4,6-tris(trifluoromethyl)tetrahydropyran-2,4,6-triol (**2**) is presented.[1] Structure **4** was previously attributed to the crystals by an X-ray structure determination. A newly conducted X-ray analysis does not provide sufficient data to assign structure **4** or **5** to these same blue crystals.

[1] The coordinating properties of compound **2** are currently under investigation.

However, three sets of independent data (elemental analysis, chemical reactivity and mass spectral analysis) unequivocally establish their identity as being structure **5** rather than **4**, thus proving this study a case where diffraction data interpretation meets its limits.

5. Supplementary material

CCDC 618989 and 616292 contain the supplementary crystallographic data for **2** and **5**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Acknowledgements

This work was supported by the CNRS and the French Research Ministry. We thank Laurence Arzel for help with the mass spectral analysis.

2.2. Physical measurements

FT-IR spectra in the 400–4000 cm^{-1} range were recorded on a Perkin–Elmer FT-IR spectrometer using KBr pellets. Optical diffuse-reflectance spectra were measured on a Perkin–Elmer instrument Lambda 900 UV/Vis spectrometer equipped with an integrating sphere at 293 K, and the $BaSO_4$ plate was used as the reference. The C, H and N analyses were carried out on an Elemental Vario EL III analyzer. Room-temperature fluorescence spectra were measured on a FLS920P spectrometer with a laser at 397 nm as the excitation light. Thermogravimetric analyses were carried out on a NETZSCH STA 449C unit at a heating rate of 15 °C min^{-1} under a nitrogen atmosphere.

2.3. Preparation of 1–3

2.3.1. $[Et_4N]_2[WOS_3Cu(dppe)]_2 \cdot H_2O$ (1)

A mixture of $[Et_4N]_2[WOS_3CuCN]$ (0.20 mmol, 129.20 mg) and dppe (0.20 mmol, 79.60 mg) in DMF (4 mL) was stirred for 20 min and then filtered. By slow diffusion of *i*-PrOH into the filtrate gave air stable yellow crystals of **1**. Yield: 42%. *Anal*. Calc. for $C_{68}H_{90}Cu_2N_2O_3P_4S_6W_2$: C, 45.51; H, 5.05; N, 1.56. Found: C, 45.44; H, 5.13; N, 1.63%. IR (KBr pellet, cm^{-1}): 1629 w, 1482 s, 1457 w, 1434 s, 1394 w, 1171 w, 1099 w, 1000 w, 892 vs, 880 sh, 746 m, 721 m, 696 s, 514 s, 482 m, 471 s, 438 s, 414 sh.

2.3.2. $[WS_4Cu_2(dppe)_2]_n$ (2)

A mixture of **1** (0.02 mmol, 35.89 mg) and AgI (0.04 mmol, 9.39 mg) was placed in a glass tube and 2 mL of DMF was added. The tube was sealed after evacuation and heated to 120 °C for 1 day. Upon slowly cooling to room temperature over 2 days, yellow crystals of **2** were obtained in 17% yield (based on W). *Anal*. Calc. for $C_{52}H_{48}Cu_2P_4S_4W$: C, 50.53; H, 3.91. Found: C, 50.49; H, 3.98%. IR (KBr pellet, cm^{-1}): 1482 m, 1433 s, 1165 w, 1098 m, 1026 w, 999 w, 882 w, 740 m, 718 m, 692 vs, 514 m, 481 m, 455 s, 447 sh.

2.3.3. $[Et_4N]_2[WEE'S_2Ag(dppe)]_2 \cdot CH_3CN$ (3)

The synthetic procedure was similar to that of **1** with $[Et_4N]_2[WOS_3AgCN]$ (0.20 mmol, 138.10 mg) instead of $[Et_4N]_2[WOS_3CuCN]$. Yield: 35%. *Anal*. Calc. for $C_{70}H_{91}Ag_2N_3O_{1.89}P_4S_{6.11}W_2$: C, 44.07; H, 4.81; N, 2.20. Found: C, 43.96; H, 4.86; N, 2.12%. IR (KBr pellet, cm^{-1}): 1662 m, 1482 m, 1457 w, 1433 vs, 1393 w, 1170w, 1095 m, 900 s, 884 sh, 755 m, 735 m, 719 m, 696 s, 510 m, 473 s, 442 s, 431 s.

2.4. X-ray crystallography

The data for **1**–**3** were collected on a RIGAKU MERCURY CCD area-detector diffractometer with graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). The structures were solved by direct methods and refined on F^2 by full-matrix least-squares procedures using the SHELXTL software suite [31]. All non-hydrogen atoms were refined anisotropically except for those with disordered positions of the $[Et_4N]^+$ and CH_3CN in **3**. The positions of H atoms were generated geometrically (C–H bond fixed at 0.96 Å), assigned isotropic thermal parameters, and allowed to ride on their parent carbon atoms before the final cycle of refinement. Hydrogen atoms have not been included in the disordered part of the model. The hydrogen atoms of the water molecule in **1** could not be located theoretically and were not located. The occupancies of the disordered S and O atoms in **3** were refined freely with the sum of occupancies being 1.000 at each site of E or E′. The occupancies of the disordered components of the $[Et_4N]^+$ and CH_3CN in **3** were assumed to be 0.50 for each disordered atom. A summary of the crystallographic data of **1**–**3** is presented in Table 1.

3. Results and discussion

3.1. Syntheses

Treatment of $[Et_4N]_2[WOS_3MCN]$ (M = Cu or Ag) with one equiv. of dppe in DMF produced **1** and **3**. Crystals of **1** and **3** could be obtained via slow diffusion of *i*-PrOH into their DMF solutions. In addition, reactions using MCN or MSCN (M = Cu or Ag) with $[Et_4N]_2[WOS_3]$ in the presence of dppe also led to the same results. Compound **2** was isolated in the attempt to make W/Cu/Ag clusters by the reaction of **1** and AgI in DMF under vacumm. It is possible that an equilibrium $2WOS_3^{2-} \rightleftharpoons WO_2S_2^{2-} + WS_4^{2-}$ exists in solution and it will be reasonable for the transformation from WOS_3^{2-} to WS_4^{2-}. The reaction of **1** with AgI also produced a large amount of Ag_2S and some unidentified precipitate, which resulted in the decrease of the yield of **2**. The measurements of the ^1H and ^{31}P NMR spectra of **1**–**3** were not done due to their poor solubility in solvents.

3.2. Crystal structures of 1–3

The molecular structure of **1** was confirmed by a single-crystal X-ray diffraction study. The structure of the anion of **1** is shown in Fig. 1 and selected bond lengths and angles are listed in Table 2. The molecule is situated on an inversion center. In the asymmetric unit of **1**, the WOS_3^{2-} dianion acts as a bidentate ligand to coordinate one Cu atom through two bridging S atoms leaving the other S and O atoms uncoordinated. The W=O bond length [1.756(2) Å] is slightly greater than those observed for $[W_2O_2S_6Cu_4(PPh_3)_4]$ [1.696(1) Å] [32] and $[WOS_3Cu_3(PPh_3)_2(SC_4H_9)]_2$ [1.695(5) Å] [33]. The W=S_t bond length is characteristic of a typical double bond. The two W–S_{br} bond lengths are within the normal range of the W–μ-S bonds observed in other W/Cu/S clusters and are considered to be single bonds. The W···Cu distance [2.779(1) Å], which is comparable to those found for $[WOS_3Cu_3(S_2COEt)(PPh)_3]$ [2.752(2) Å] (av) [33] and $[W_2O_2S_6Cu_4(PPh_3)_4]$ [2.780(1) Å] (av) [32], suggests the

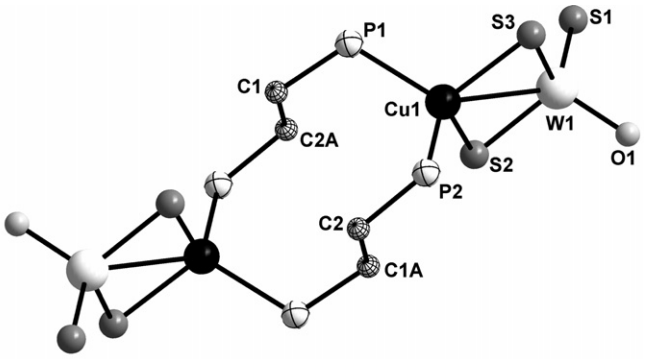

Fig. 1. Structure and labeling of the $[WOS_3Cu(dppe)]_2^{2-}$ anion of **1**. Hydrogen atoms and the phenyl rings bound to phosphorous atoms are omitted for clarity. Symmetry code: #A $-x, -y+1, -z$.

Symmetry transformations used to generate equivalent atoms: [a]For **1**: #1 $-x, -y+1, -z$. [b]For **2**: #1 $-x+1, -y+1, -z+1$; #2 $-x, -y, -z$. [c]For **3**: #1 $-x+2, y, -z+3/2$; #2 $-x+3/2, -y+5/2, -z+1$; #3 $-x+1, -y+2, -z+1$.

existence of metal–metal interaction. Two cluster cores (WOS_3Cu), orientated in opposite direction, are linked via two dppe bridging ligands to form a 10-membered ring [–Cu–P–C–C–P–]$_2$. The distance between the two Cu atoms of the ring is 5.929(1) Å. The flexible dppe adopts a twisted chair conformation. The P1–C1–C2A and P2–C2–C1A angles are 110.2(2)° and 111.1(2)°, respectively. There is a H_2O molecule around the O atom of the [WOS_3] unit. The O1···O2 distance is 2.854(3) Å, suggesting the existence of O–H···O interaction. Thus, as shown in Fig. 2, a helical chain forms through the O–H···O interaction. The pitch (length per turn) of the helical chain is 29.2 Å.

Fig. 3 shows the structure of **2** and selected bond lengths and angles are listed in Table 2. The crystallographic structure of **2** extends in a one-dimensional way as a neutral chain. The WS_4^{2-} dianion coordinates two Cu atoms and acts as a bridging block in the polymeric chain. The W–μ-S bond distances [2.209(1) Å] (av) are typical for W–S single bonds. The W···Cu distance [2.779(1) Å] (av) is a little longer than those observed for [$WS_4Cu_4(dppm)_4$][PF_6]$_2$ [2.760(1) Å] [23] and [$WS_4Cu_2(PPh_3)_3$]·0.8CH_2Cl_2 [2.740(1) Å] (av) [28]. The Cu–P bond [2.285(1) Å] (av) and the Cu–S bond [2.322(1) Å] (av) are comparable to those in other W/S/Cu compounds. The [$CuWS_4Cu$] units are bridged by the dppe ligands to give repeating 10-membered [–Cu–P–C–C–P–]$_2$ rings. The dppe ligand also adopts a twisted chair conformation as observed in **1**, with the P1–C1–C2A, P2–C2–C1A, P3–C3–C4B and P4–C4–C3B angles being 113.3(3)°, 109.6(3)°, 110.2(3)° and 113.1(3)°, respectively. As shown in Fig. 4, the tungsten and copper atoms of **2** form a helical chain with the Cu atoms acting as the turning points. The pitch (length per turn) of the helical chain is 20.5 Å.

The crystal structure of **3** was determined by a single-crystal X-ray diffraction study. The structure of the anion of **3** is shown in Fig. 5. Selected bond lengths and angles are listed in Table 2. The terminal S and O atoms of the [$WEE'S_2Ag$] unit are disorderd with different occupancies at the site of E or E′ (E = 0.636S + 0.364O, E′ = 0.581O + 0.419S), which are in consistent with the bond lengths of W=E [2.082(2) Å] and W=E′ [1.969(3) Å]. The W=E bond length is a little shorter than that of a normal W=S_t double bond, while the W=E′ bond length is somewhat longer than that of a standard W=O bond. The

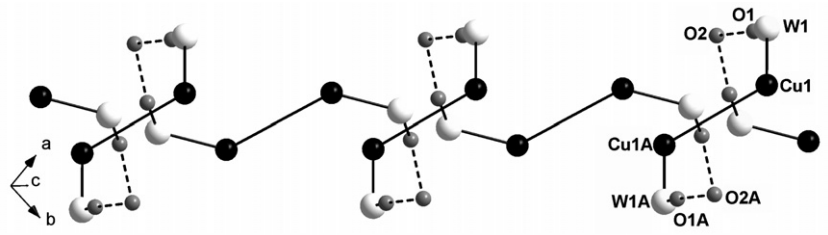

Fig. 2. Simplified diagram of the helical chain of **1** formed through the O–H···O interaction. For clarity, only tungsten, copper and oxygen atoms which form the chain are displayed. Symmetry code: #A $-x$, $-y+1$, $-z$.

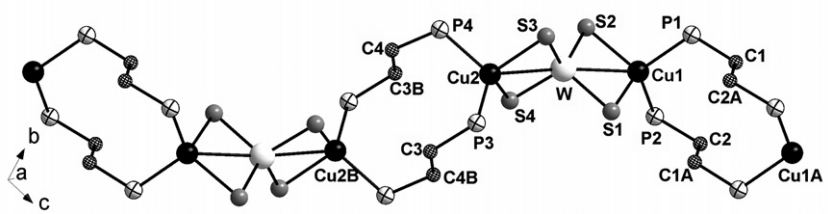

Fig. 3. Structure and labeling of the polymeric chain of **2**. Hydrogen atoms and the phenyl rings bound to phosphorous atoms are omitted for clarity. Symmetry code: #A $-x+1$, $-y+1$, $-z+1$; #B $-x$, $-y$, $-z$.

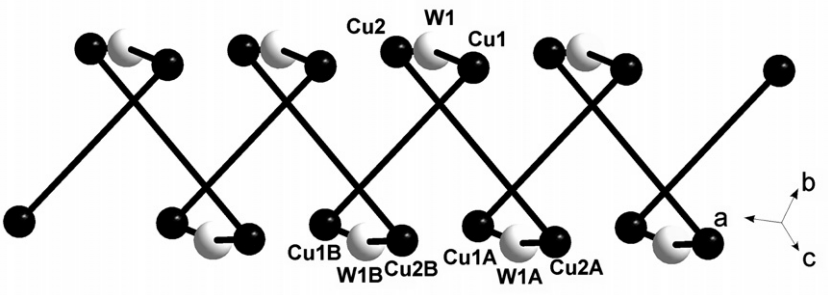

Fig. 4. Simplified diagram of the helical chain of **2**. For clarity, only tungsten and copper atoms which form the chain are displayed. Symmetry code: #A $-x+1$, $-y+1$, $-z+1$; #B $-x$, $-y$, $-z$.

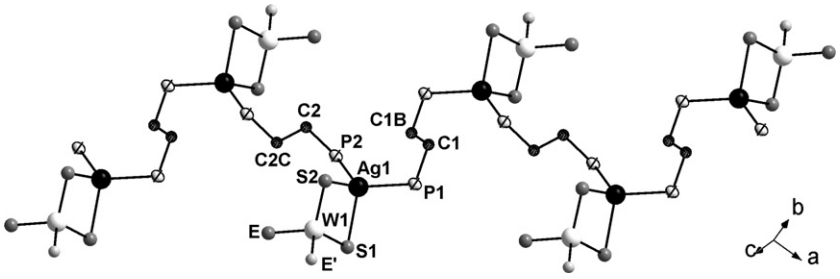

Fig. 5. Structure and labeling of the polymeric anionic chain of **3**. Hydrogen atoms and the phenyl rings bound to phosphorous atoms are omitted for clarity. Symmetry code: #A $-x+2$, y, $-z+3/2$; #B $-x+3/2$, $-y+5/2$, $-z+1$; #C $-x+1$, $-y+2$, $-z+1$.

W···Ag distance [3.062(1) Å] is slightly longer than those found for $[(WS_4)_2Ag_4(PPh_3)_4]$ [2.977(1) Å] [34] and $[W_2S_8Ag_2(dppm)_3](CH_2Cl_2)$ [2.947(1) Å] [25]. The Ag–S bond lengths [2.613(1) Å] (av) and Ag–P bond lengths [2.494(1) Å] (av) are comparable to those found for other W/S/Ag compounds. The [WEE′S_2Ag] units are bridged by bidentate dppe ligands to form a zig-zag chain. The bidentate dppe also adopts a twisted chair conformation with the P1–C1–C1B and P2–C2–C2C angles being 109.4(3)° and 112.2(2)°, respectively.

3.3. Infrared spectra and optical absorption spectra

The infrared spectra of these complexes show typical absorptions around 515 cm^{-1} due to the Cu–P bonds and around 510 cm^{-1} due to the Ag–P bonds. Other bands at ca. 500 cm^{-1} can be assigned to the vibrations ν(M═S) according to the literature data and those at lower frequencies are attributed to the bridging sulfur atoms [35]. As expected, the vibrations ν(W═O) are observed at ca. 900 cm^{-1}.

Optical absorption spectra of compounds **1**–**3** (Fig. 6) have been measured by diffuse-reflectance experiments. The UV–Vis absorption data were calculated from the reflectance data using the Kubelka–Munk function [36,37]: $\alpha/S = (1-R)^2/2R$, where R is the experimentally observed reflectance, α the absorption coefficient and S the scattering coefficient. The absorption edges for **1**–**3** are about 2.46, 2.33 and 2.54 eV, respectively, determined as the intersection point by $(\alpha/S)^2 = 0$ in a $(\alpha/S)^2$ versus E plot [38]. These results show that the present compounds may be classed as semiconductors.

3.4. Luminescent properties and TGA study

Fig. 7 depicts the luminescent emission spectra of compounds **1**–**3** in the solid state at 298 K. With excitation of laser at 397 nm, the emissions observed for **1**–**3** are 578, 574 and 652 nm, respectively, which are much higher than that of free ligand dppe (434 nm), but near to those of $[Cu_3(dppm)_3WS_4](ClO_4)$ (615 nm) [22] and $[Cu_4(dcpm)_4WS_4](ClO_4)_2$ (619 nm) [24] in the solid state. With reference to $[Cu_3(dppm)_3WS_4](ClO_4)$ [22] and $[Cu_4(dcpm)_4WS_4](ClO_4)_2$ [24], the origin of the emission may be assigned as $^3[\psi(M,P)^1\sigma^*(W\text{–}S)^1]$ (M = Cu, Ag) triplet MMCT excited states. The red shift of emission from compound **1** (or **2**) to **3** is consistent with the higher energy of the 4d (Ag) orbital than that of the 3d (Cu) orbital.

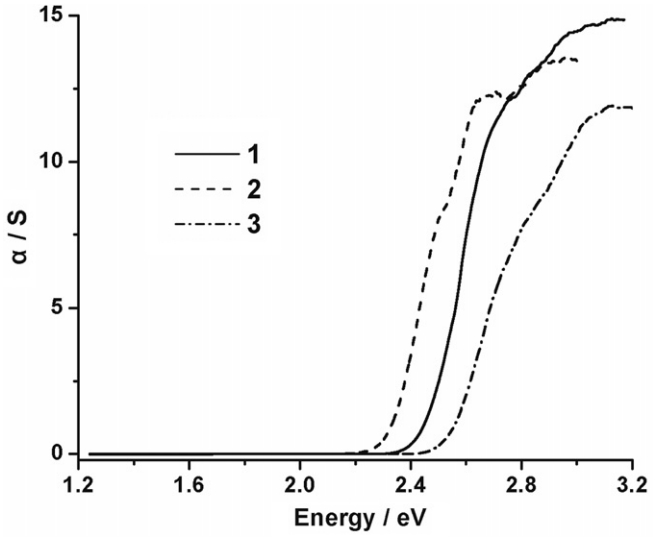

Fig. 6. Optical absorption spectra for **1**–**3**.

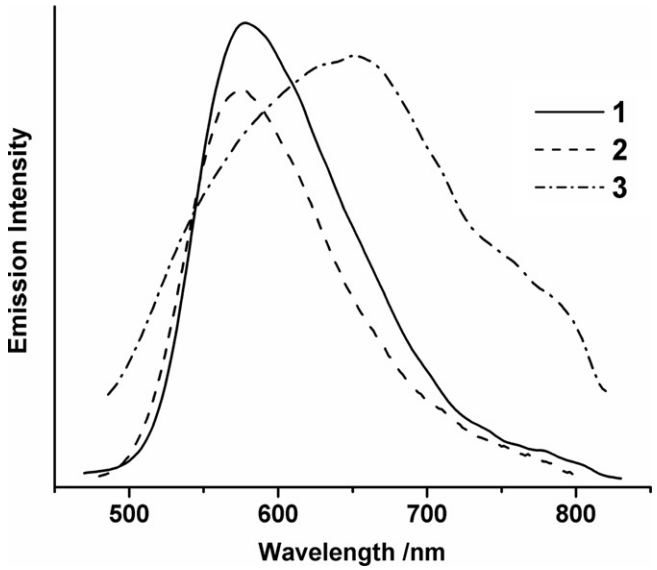

Fig. 7. Solid-state emission spectra of **1**–**3** at 298 K.

The thermogravimetric analysis (TGA) study shows that compounds **1**–**3** are stable up to 216 °C, 291 °C, and 215 °C, respectively.

4. Conclusion

Three W/Cu(Ag)/S complexes containing bridging diphosphine ligands, varying from tetranuclear cluster **1** to one-dimentional polymeric clusters **2** and **3**, have been prepared. To the best of our knowledge, **2** and **3** are the first two examples of polymers containing bridging diphosphine ligands for the W/Cu(Ag)/S system. The optical absorption spectra show that compounds **1**–**3** may be classed as semiconductors. With excitation of laser at 397 nm, complexes **1**–**3** are luminescent at room temperature in the solid state.

with the general formula [VO_2(phsalR)]. In the following account, we have described the synthesis, characterization and physical properties of these complexes. The molecular structure of a representative complex has been determined by X-ray crystallography.

Hphsal (R = H)
HphsalOMe (R = OCH_3)
HphsalCl (R = Cl)
HphsalBr (R = Br)
HphsalNO_2 (R = NO_2)

2. Experimental

2.1. Materials

The Schiff bases (HphsalR) were prepared in 70–80% yield by condensation reactions of 2-hydrazinopyridine with the corresponding 5-substituted salicylaldehyde in methanolic media [15–17]. All other chemicals and solvents used in this work were of analytical grade available commercially and were used without further purification.

2.2. Physical measurements

Microanalytical (C, H, N) data were obtained with a Thermo Finnigon Flash EA1112 series elemental analyzer. Infrared spectra were collected by using KBr pellets on a Jasco-5300 FT-IR spectrophotometer. A Sherwood Scientific balance was used for magnetic susceptibility measurements. A Shimadzu 3101-PC UV/Vis/NIR spectrophotometer was used to record the electronic spectra. The ^1H ($Si(CH_3)_4$ as internal standard) and ^{51}V ($VOCl_3$ as external standard) NMR spectra were recorded with the help of a Bruker 400 MHz NMR spectrometer. A Jeol JES-FA200 spectrometer was used for EPR experiments. Solution electrical conductivities were measured with a Digisun DI-909 conductivity meter.

2.3. Synthesis of [VO_2(phsal)] (1)

An aqueous solution (15 ml) of $VOSO_4 \cdot 5H_2O$ (100 mg, 0.4 mmol) was added to an acetonitrile solution (20 ml) of Hphsal (85 mg, 0.4 mmol) and $N(C_2H_5)_3$ (0.07 ml, 51 mg, 0.5 mmol). The mixture was refluxed for 1 h. The resulting brown solution was kept in air at room temperature for slow evaporation. Dark brown crystalline material separated in about 2 days was collected by filtration, washed with acetonitrile and finally dried in air. Yield: 60 mg (51%).

The other four complexes [VO_2(phsalOMe)] (**2**), [VO_2-(phsalCl)] (**3**), [VO_2(phsalBr)] (**4**) and [VO_2(phsalNO_2)] (**5**) reported in this work were synthesized by using one mole equivalent each of $VOSO_4 \cdot 5H_2O$, $N(C_2H_5)_3$ and the corresponding Schiff base in 50–60% yields by following the same procedure as described above.

2.4. X-ray crystallography

Single crystal of [VO_2(phsal)] (**1**) was collected directly from the product precipitated in the synthetic reaction mixture. The unit cell parameters and the intensity data were obtained on a Bruker-Nonius SMART APEX CCD single crystal diffractometer, equipped with a graphite monochromator and a Mo Kα fine-focus sealed tube ($\lambda = 0.71073$ Å) operated at 2.0 kW. The detector was placed at a distance of 6.0 cm from the crystal. Data were collected at 298 K with a scan width of 0.3° in ω and an exposure time of 5 s/frame. The SMART software was used for data acquisition and the SAINT-Plus software was used for data extraction [18]. The SADABS program [19] was used for the absorption correction. The complex crystallizes in the space group $P\bar{1}$. The structure was solved by direct method and refined on F^2 by full-matrix least-squares procedures. All non-hydrogen atoms were refined anisotropically. The hydrogen atom of the NH group in the hydrazine fragment of the ligand was located on a difference map and refined with $U_{iso}(H) = 1.2U_{eq}(N)$. The other hydrogen atoms were added at idealized positions by using a riding model. The SHELX-97 programs [20] were used for structure solution and refinement. The ORTEX6a [21] and PLATON [22] packages were used for molecular graphics. Selected crystallographic data for **1** are listed in Table 1.

Table 1
Crystallographic data for [VO_2(phsal)] (**1**)

3. Results and discussion

3.1. Synthesis and some properties

The complexes were synthesized in moderate yields by reacting equimolar amounts of $VOSO_4 \cdot 5H_2O$, HphsalR and $N(C_2H_5)_3$ in water–acetonitrile mixture under aerobic conditions. The elemental analysis data are consistent with the general molecular formula $[VO_2(phsalR)]$ (Table 2). The complexes are insoluble in common organic solvents except dimethylsulphoxide and dimethylformamide. In solutions, they are electrically non-conducting. The EPR silence and the room temperature magnetic susceptibilities indicate the diamagnetic character of these complexes. Thus the metal ion in each of the five complexes is in +5 oxidation state. Most likely during the formation of these complexes from oxovanadium(IV) starting material, the aerial oxygen acts as the oxidizing agent.

It is interesting to note that our previously reported ternary oxovanadium(IV) complexes, [VO(phsalR)(acac)], were also synthesized under aerobic conditions from equimolar amounts of $[VO(acac)_2]$ and HphsalR in acetonitrile [15]. Thus the synthetic procedures for $[VO_2(phsalR)]$ and [VO(phsalR)(acac)] differ in (i) the oxovanadium(IV) starting material, (ii) use of base $N(C_2H_5)_3$, and (iii) the reaction medium. Perhaps the chelated acetylacetonate instead of the non-coordinating or weakly coordinating sulphate in the oxovanadium(IV) starting material used for the synthesis of [VO(phsalR)(acac)] stabilizes the +4 oxidation state of the metal centre by forming the mixed-ligand species.

3.2. Spectroscopic characteristics

The infrared spectra of **1**–**5** display a broad band centred at ~3400 cm^{-1}. This band is possibly due to the N–H stretch of the hydrazine fragment of the ligand [23]. The strong band observed in the range 1632–1636 cm^{-1} is most likely associated with the C=N stretch of the tridentate Schiff base ligand [10–15,24]. The complexes of dioxovanadium(V) with tridentate ligands display two strong to medium bands in the ranges 930–970 and 900–940 cm^{-1} [12–14,25–28]. The higher energy band is assigned to the ν_{as} stretch and the lower energy band is assigned to the ν_s stretch of the *cis*-VO_2^+ moiety. The coordination geometry of the metal ion in these complexes varies between trigonal-bipryamidal and distorted octahedral. The latter is due to either coordination of an additional monodentate ligand or formation of weakly associated di(μ-oxo) bridged dimeric species from two square-pyramidal molecules. The present series of complexes **1**–**5** also displays a strong and sharp band at ~942 cm^{-1}. This band is attributed to the ν_{as} stretch of the *cis*-VO_2^+ moiety. All the spectra show a very strong band at ~890 cm^{-1} with a shoulder at ~910 cm^{-1}. Perhaps the ν_s stretch of the *cis*-VO_2^+ unit is the origin of this shoulder.

Electronic spectra were recorded using dimethylformamide solutions of **1**–**5**. The spectral profiles of all the complexes are very similar. A representative spectrum is shown in Fig. 1. The complexes display several absorptions in the wavelength range 512–270 nm (Table 2). The absorptions in the range 512–350 nm are possibly due to the ligand-to-metal charge transfer transitions [10–14,25–28]. The highest energy absorption observed in the range 280–270 nm is most likely due to a ligand centred transition [15].

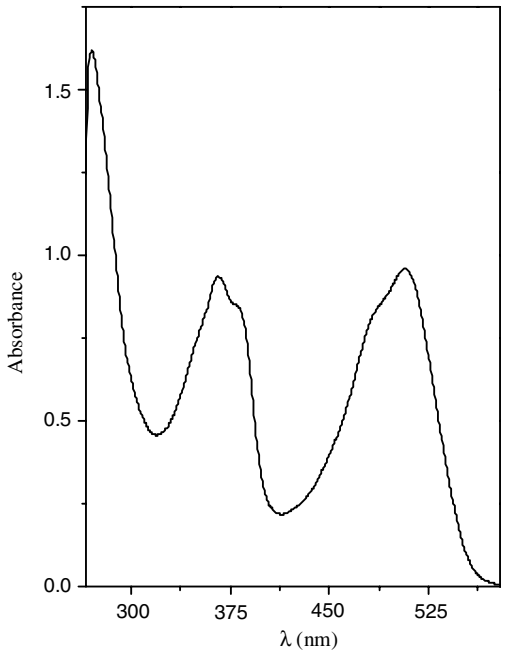

Fig. 1. Electronic spectrum of $[VO_2(phsalCl)]$ (**3**) in dimethylformamide solution.

The dimethylsulphoxide-d_6 solutions of **1**–**5** were used to record the proton NMR spectra. The aromatic protons appear as multiplets in the range δ 8.5–6.8 ppm. The protons of the methyl group of the methoxy substituent in $[VO_2(phsalOMe)]$ (**2**) resonate as a singlet at δ 3.74 ppm. The –NH– proton of the hydrazine fragment in all the complexes appears as a broad singlet within δ 12.65–12.87 ppm. The azomethine (–CH=N–) proton is observed as a singlet in the range δ 8.55–8.59 ppm. We have also recorded the ^{51}V NMR spectra of **1**–**5** in dimethylsulphoxide-d_6. All the complexes show a resonance between δ −549 and −555 ppm. These chemical shifts are comparable with those reported for similar dioxovanadium(V) complexes [25,27–29].

3.3. Structure of $[VO_2(phsal)]$ (*1*)

Dioxovanadium(V) complexes with planar tridentate ligands can have either trigonal-bipyramidal or square-pyramidal geometry [12–14,25–27,29–31]. In the solid state, trigonal-bipyramidal complexes remain mononuclear while square-pyramidal complexes can dimerise and form di(μ-oxo) bridged dinuclear species. Examples of such di(μ-oxo) bridged species are rare [12,25,29–31]. Complex **1** belongs to this category of dioxovanadium(V) complexes. The structure of **1** is depicted in Fig. 2. The bond parameters associated with the metal ion are listed in Table 3. The metal ion is in a square-pyramidal N_2O_3 coordination sphere. One of the two oxo groups and the pyridine-N, the imine-N and the phenolate-O donor $phsal^-$ form the N_2O_2 basal plane (mean deviation 0.07 Å). The second oxo group satisfies the apical coordination site. As commonly observed for square-pyramidal complexes [10–12,25,29–33], the metal centre in **1** is displaced by 0.367(1) Å from the N_2O_2 basal plane toward the apical oxo group. The distortion of a square-pyramidal geometry toward a trigonal-bipyramidal geometry can be indicated by the value of τ which is defined as $(\beta - \alpha)/60$, where α is the smaller and β is the larger *trans* bond angles in the basal plane [33]. For a perfect square-pyramidal geometry the value of τ is zero and for an ideal trigonal-bipyramidal geometry the value of τ is unity. In the case of **1**, the τ is found to be 0.02. Thus the N_2O_3 coordination sphere in **1** is very close to an ideal square-pyramidal shape. As expected the V–O(phenolate) (1.8797(18) Å) and V–N (pyridine) (2.112(2) Å) bond lengths in **1** (Table 3) are shorter than these bond lengths (1.935(2) and 2.121(4) Å) observed in the previously reported ternary oxovanadium(IV) complex with $phsal^-$ [15]. However, the V–N(imine) bond length (2.1706(19) Å) in **1** is longer than that (2.066(2) Å) in [VO(phsal)(acac)] [15]. This difference is possibly due to the greater *trans* effect of the oxo group in **1** compared to that of the acetylacetonate-O in [VO(phsal)(acac)]. In general, the V–O(phenolate), the V–N(pyridine) and the V–N(imine) bond lengths in **1** are comparable with the bond lengths observed in VO^{3+} and VO_2^+ complexes containing the same coordinating atoms [10–14,25–31]. In **1**, the V=O bond length (1.6736(17) Å) in the basal plane is significantly longer than the apical V=O bond length (1.600(2) Å). This is due to the formation of a centrosymmetric dimeric species via sharing of the basal plane oxo groups by the metal centres of two molecules of **1** (Fig. 3). In $[VO_2(phsal)]_2$, the $\{V_2(\mu\text{-}O)_2\}$ unit is planar and unsymmetrical with respect to the V–O distances (V–O(2), 1.6736(17) Å and V–O(2a), 2.5193(19) Å). Such unsymmetrical $\{V_2(\mu\text{-}O)_2\}$ unit is common in dinuclear species formed by similar square-pyramidal dioxovanadium(V) complexes with tridentate ligands [12,25,29–31]. The V–O(2)–V(a) and the O(2)–V–O(2a) angles are 103.08(8)° and 76.92(8)°, respectively. The metal···metal

Symmetry transformation used to generate the equivalent atoms: $-x$, $-y$, $-z+1$.

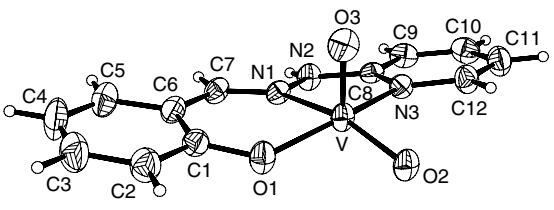

Fig. 2. Structure of $[VO_2(phsal)]$ (**1**) with the atom labeling scheme. All non-hydrogen atoms are represented by their 40% probability thermal ellipsoids.

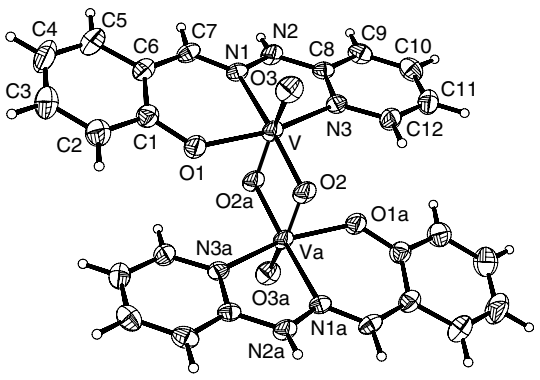

Fig. 3. Centrosymmetric dimer of $[VO_2(phsal)]$ (**1**). All non-hydrogen atoms are represented by their 40% probability thermal ellipsoids.

distance is 3.325(1) Å. The long V–O(2a) distance suggests weak coordination at the *trans* position to the apical oxo group. Thus the metal centres are in distorted octahedral N_2O_4 coordination spheres in $[VO_2(phsal)]_2$ and the dimeric species resembles two edge-shared octahedra.

3.4. Intermolecular hydrogen bonding and self-assembly

The complexes **1**–**5** described in this work possess an acceptor as well as a donor group for conventional hydrogen bonding interaction. These are the metal coordinated oxo group and the N–H group of the hydrazine fragment of phsal$^-$. The vanadium(IV/V) bound oxo group is fairly strong basic centre and is known to participate in intermolecular conventional as well as non-conventional hydrogen bonding interactions [14,15,34]. It has been observed before that the acidity of the N–H proton increases significantly in aryl- or aroylhydrazine based Schiff bases when the adjacent imine-N is coordinated to a metal ion [35,36]. It may be noted that for the ternary oxovanadium(IV) complex of phsal$^-$, [VO(phsal)(acac)], the strong intermolecular N–H···O=V hydrogen bonding interaction plays the decisive role in providing the infinite one-dimensional supramolecular structure [15]. The same self-assembly pattern via intermolecular N–H···O=V hydrogen bonding interaction is also observed in the crystal lattice of **1** (Fig. 4). The dimeric species $[VO_2(phsal)]_2$ forms a one-dimensional chain structure due to the involvement of the N–H group of phsal$^-$ and the metal bound oxo group at the basal plane of the square-pyramidal monomeric unit in intermolecular N–H···O=V hydrogen bonding interaction. The N(2)–H, H···O(2) and N(2)···O(2) distances and the N(2)–H···O(2) angle are 0.82(3), 1.94(3) and 2.745(3) Å and 168(3)°, respectively. There is no other significant non-covalent interaction between the parallel one-dimensional structures.

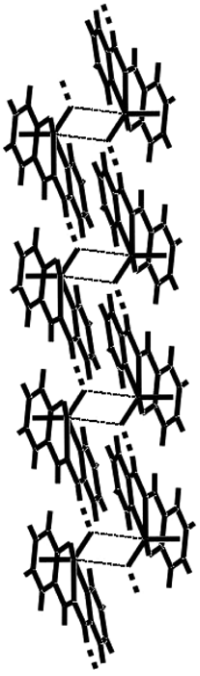

Fig. 4. One-dimensional ordering of the dimers of $[VO_2(phsal)]$ (**1**) via intermolecular N–H···O=V hydrogen bonds in the crystal lattice.

4. Conclusion

A new series of dioxovanadium(V) complexes of general formula $[VO_2(phsalR)]$ (HphsalR = 4-R-2-(pyridin-2-yl-hydrazonomethyl)-phenols) has been synthesized. The complexes have been characterized with the help of microanalytical, magnetic susceptibility, various spectroscopic and X-ray crystallographic measurements. All the complexes are diamagnetic and NMR active. The electronic spectra of the complexes display several bands due to ligand-to-metal charge transfer and ligand centred transitions. The crystal structure of $[VO_2(phsal)]$ (R = H) reveals that the metal centre is in an essentially perfect square-pyramidal N_2O_3 coordination sphere assembled by the pyridine-N, the imine-N and the phenolate-O donor planar phsal$^-$ and two oxo groups. Dimerisation of $[VO_2(phsal)]$ leads to the formation of a di(μ-oxo)-bridged species in which the metal centres are in two edge-shared distorted octahedral N_2O_4 coordination spheres. In the crystal lattice, these dimers form an intermolecular N–H···O=V hydrogen bond assisted one-dimensional supramolecular assembly.

5. Supplementary material

CCDC 618872 contains the supplementary crystallographic data for $[VO_2(phsal)]$ (**1**). These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Acknowledgements

Financial assistance received from the Council of Scientific and Industrial Research (CSIR) (Grant No. 01(1880)/03/EMR-II) is gratefully acknowledged. Ms. A. Sarkar thanks the CSIR for a research fellowship. X-ray structure determination was performed at the National Single Crystal Diffractometer Facility, School of Chemistry, University of Hyderabad (established by the Department of Science and Technology). We thank the University Grants Commission for the facilities provided under the UPE and CAS programs.

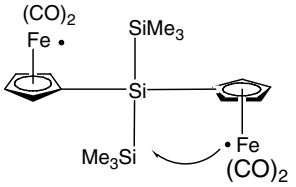

Fig. 1. Iron-centered free radicals from Fe–Fe bond homolysis of **1**.

bonds attached to the Cp rings [16,17], which furnished strong evidence to rule out the stepwise pathway of the free radical mechanism [24]. To further examine the regiospecific feature, a study on systems containing non-bridging Si–Si bonds attached to other positions, such as at the bridge, is desirable. In this aspect, we have in a recent study [25] occasionally isolated the silicon-bridged complex $[\eta^5,\eta^5\text{-}C_5H_4\text{–}Si(Me)(SiMePh_2)\text{–}C_5H_4]Fe_2(CO)_2(\mu\text{-}CO)_2$ that contains a non-bridging exocyclic Si–Si bond at the silicon bridge. Unfortunately, the complex has been obtained as a by-product in a too small amount to study its chemistry.

In this paper, we report the first designed synthesis of such complexes by choosing the 1,1,1,3,3,3-hexamethyltrisilanylene-bridged complex $[\eta^5,\eta^5\text{-}C_5H_4\text{–}Si(SiMe_3)_2\text{–}C_5H_4]Fe_2(CO)_2(\mu\text{-}CO)_2$ (**1**) and its CO ligand substitution derivatives $[\eta^5,\eta^5\text{-}C_5H_4\text{–}Si(SiMe_3)_2\text{–}C_5H_4]Fe_2(CO)L(\mu\text{-}CO)_2$ [L = $P(OPh)_3$ (**2**), $P(OMe)_3$ (**3**), PPh_3 (**4**), PMe_3 (**5**)] that contain two exocyclic Si–Si bonds at the silicon bridge as the target molecules. Examination of the chemical properties of these complexes under various conditions demonstrated that these Si–Si bonds could not be cleaved by the intramolecular iron centers, providing further evidence to rule out the possibility of activation of Si–Si bonds by the iron-centered free radicals from homolysis of the Fe–Fe bond (Fig. 1). On the contrary, the inertness of the Si–Si bonds towards the metal centers could be rationally explained in terms of the oxidative addition mechanism of activation of Si–Si bonds [26,27].

2. Experimental

2.1. General

All the reactions were carried out under a nitrogen or argon atmosphere by using vacuum line and Schlenk techniques. THF, *p*-xylene and hexane were dried and distilled from sodium/benzophenone. IR spectra were recorded with a Bio-Rad FTS 135 spectrometer. ^1H and ^{13}C NMR spectra were recorded with a Varian UNITY Plus-400 or a Bruker AC-P200 spectrometer. Elemental analysis was performed using an Elementar Vario EL instrument. $(Me_3Si)_2SiCl_2$ was prepared according to the literature procedures [28].

2.2. Synthesis of complex *1*

To a flask containing 1.9 g (29 mmol) of cyclopentadiene and 50 ml of THF was added 14 ml (1.77 M in hexane, 25 mmol) of *n*-butyllithium at −78 °C. The mixture was stirred at room temperature for 1 h, then, 3.0 g (12 mmol) of $Me_3SiSiCl_2SiMe_3$ was added dropwise at −78 °C. The mixture was allowed to warm to room temperature, stirred at this temperature overnight and then refluxed for 2 h. After cooling to room temperature, the mixture was hydrolyzed with a saturated solution of NH_4Cl, extracted with ether, washed with water and dried over anhydrous magnesium sulfate. Evaporation of the solvent under reduced pressure gave $Me_3SiSi(C_5H_5)_2SiMe_3$ as an oil, which was used directly, without further purification, for the next step of reaction.

To a flask containing the oil product obtained above and 50 ml of *p*-xylene was added 4.9 g of $Fe(CO)_5$ (25 mmol). The mixture was refluxed with stirring overnight. The solvent was removed under reduced pressure (unreacted $Fe(CO)_5$ should be collected in a liquid nitrogen trap) to give a solid residue, which was separated through a neutral alumina column. Elution with petroleum ether/dichloromethane (4:1) gave a red band, from which 1.2 g of **1** (28% yield) was obtained as a dark-red crystalline solid, m.p. 220 °C (dec). *Anal.* Calc. for $C_{20}H_{26}O_4Fe_2Si_3$: C, 45.63; H, 4.94. Found: C, 45.64; H, 5.00%. ^1H NMR ($CDCl_3$): δ 0.26 (s, 9H, SiMe), 4.99 (t, $J = 2.1$ Hz, 2H, Cp), 5.46 (t, $J = 2.1$ Hz, 2H, Cp). ^{13}C NMR ($CDCl_3$): δ 0.64 (SiMe), 86.45, 86.83, 101.38 (Cp), 209.83 (terminal CO), 272.65 (bridging CO). 2.3. Synthesis of complexes *2*–*5*

2.3.1. Thermal reactions of *1* with $P(OPh)_3$ and $P(OMe)_3$

To a flask charged with 100 mg (0.19 mmol) of **1** and 10 ml of *p*-xylene was added 92 mg (0.74 mmol) of $P(OPh)_3$. The mixture was refluxed for 16 h with magnetic stirring. The solvent was removed under reduced pressure. The residue was separated through a neutral alumina column. Elution with petroleum ether/dichloromethane (4:1) developed a green band, from which 46 mg (36% yield) of **2** was afforded as black crystals. In a similar fashion, **3** was prepared (32% yield) from **1** and $P(OMe)_3$ after refluxing for 24 h.

For **2**: m.p. 210 °C (dec). *Anal.* Calc. for $C_{37}H_{41}O_6Fe_2PSi_3$: C, 54.95; H, 5.07. *2.3.2. Photochemical reactions of **1** with PPh_3 and PMe_3*

A solution containing 100 mg (0.19 mmol) of **1**, 199 mg (0.76 mmol) of PPh_3 and 20 ml benzene in a Pyrex tube was irradiated with a high-pressure mercury lamp (500 W) for 10 h at room temperature. The solvent was removed under reduced pressure and the residue was separated through a column (neutral alumina, petroleum ether/ether, 10:1). Collection of the dark green band gave black crystals of **4** (90 mg, 62% yield). In a similar fashion, **5** was obtained by using PMe_3 in place of PPh_3 as grey crystals in 53% yield.

For **4**: m.p. 220 °C (dec). *Anal.* Calc. for $C_{37}H_{41}Fe_2O_3PSi_3$: C, 58.42; H, 5.43. *2.4. X-ray molecular structure determination of **1** and **2***

Single crystals of **1** and **2** suitable for X-ray diffraction analyses were obtained from *n*-hexane/dichloromethane solutions. Data collections were performed on a BRUKER SMART 1000 diffractometer at room temperature using $2\theta/\omega$ scan techniques with Mo Kα radiation ($\lambda = 0.71073$ Å). The structures were solved by direct methods using the SHELX-90 program and refined by least square methods on F^2. All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were added theoretically and included in the refinement processes in an isotropic manner. Crystal data and selected experimental information have been listed in Table 1.

3. Results and discussion

3.1. Synthesis of complexes

Synthesis of complex **1** was accomplished through the reaction of $(Me_3Si)_2Si(C_5H_5)_2$, prepared from $(Me_3Si)_2SiCl_2$ and two equivalents of C_5H_5Li in THF, with $Fe(CO)_5$ in refluxing *p*-xylene in a total yield of 28% (Scheme 1).

When **1** was heated in refluxing *p*-xylene in the presence of $P(OPh)_3$ or $P(OMe)_3$, CO-substituted derivatives **2** and **3** were obtained, respectively. The CO substitution reaction with PPh_3, which did not occur under thermal conditions

Scheme 1. Synthesis of the complexes.

due to steric hindrance, could be carried out under photochemical conditions, to provide complex **4**. The same kind of reaction of **1** with PMe_3, which is too volatile to be used at high temperatures, could be effected photochemically at room temperature to afford complex **5** (Scheme 1).

Complexes **1**–**5** were characterized by elemental analyses and spectroscopic methods. The ^1H NMR spectrum of **1** showed a singlet at 0.26 ppm for the SiMe protons and two sets of pseudotriplets at 4.99 and 5.46 ppm for protons of the Cp groups. After substitution of CO by a phosphite or phosphine ligand, the singlet due to the SiMe groups remained little changed, whereas the signals due to the Cp protons split into four sets, demonstrating successful substitution of CO by a phosphorus ligand. Signals due to PR_3 were also observed. The ^{13}C NMR spectrum of **1** exhibited one signal at 0.64 ppm for the SiMe carbons, three signals at 86.45, 86.83 and 101.38 ppm for Cp carbons, and two signals at 209.83 and 272.65 ppm for terminal and bridging CO carbons, respectively. The spectra of the PR_3-substituted derivatives showed generally one signal for SiMe carbons, six signals due to Cp carbons, a singlet and a doublet for terminal and bridging CO, respectively, along with those attributable to the PR_3 ligands. The doublet signal for the bridging CO was due to coupling with the adjacent phosphorus nucleus. IR spectra of these complexes showed absorption bands for both terminal and bridging CO groups, just as expected.

3.2. Stability of the Si–Si bonds

It was found that the Si–Si bonds of **1** were stable under the conditions of refluxing in *p*-xylene. This is in sharp contrast to the case of the $–Me_2SiSiMe_2–$ bridged complexes [11,12], in which the bridging Si–Si bond could be readily broken under the same conditions. Moreover, the Si–Si bonds of **1** were also stable under UV irradiation. The stability of the Si–Si bonds has allowed the CO substitution reactions of **1** to be operated under either thermal or photochemical conditions. The Si–Si bonds in the ligand substituted derivatives **2**–**5** were also found to be stable under both thermal and photochemical conditions. Since it has been well established that the phosphorus ligands can considerably accelerate the Si–Si bond activation in the Si–Si bond-bridged systems [12], the present results could further strengthen the conclusion that these exocyclic Si–Si bonds could not be activated by the intramolecular transition metal centers.

Since iron-centered free radicals could easily be produced under the thermal and photochemical conditions [29,30], the stableness of the Si–Si bonds means that these radicals are not able to activate the Si–Si bonds. Also formed under these conditions could be the coordinatively unsaturated iron species from dissociation of the appropriate ligands [30–32]. Although these species are believed to be responsible for activation of the bridging Si–Si bond as concluded in the previous paper [15], they are apparently not able to cleave the non-bridging exocyclic Si–Si bonds in the present systems. This should be attributed to the fact that these Si–Si bonds are located in a position such that they could not be approached by the intramolecular iron center, due to restriction of the cyclic structure. Such spatial restriction, however, does not exist in the structure of the iron-centered free radical (Fig. 1), because the cyclic structure has been opened after breaking the Fe–Fe bond.

3.3. Molecular structures

The molecular structures of **1** and **2** have been determined by X-ray diffraction methods. The molecule of **1** (Fig. 2) contains a disordered Me_3Si group that has two rotational positions (each at 50% occupancy). The overall molecule has C_s symmetry. The symmetrical plane goes through three silicon atoms and the center of the Fe–Fe

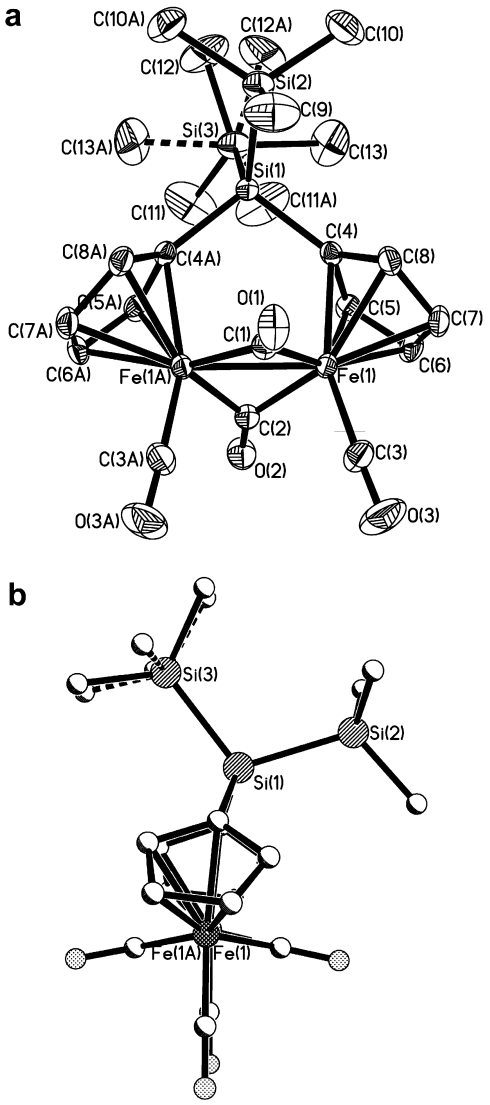

Fig. 2. (a) ORTEP drawing of $[\eta^5,\eta^5\text{-}C_5H_4–Si(Me_3Si)_2–C_5H_4]Fe_2(\mu\text{-}CO)_2(CO)_2$ (**1**). Thermal ellipsoids are at the 30% probability level. Hydrogen atoms are omitted for clarity. (b) Side view of **1**.

bond. The bridging silicon atom, however, is not located on the top of the molecule but moves away from the plane defined by two iron and two bridged-head Cp carbon atoms by a distance of 0.58 Å (see Fig. 2b). This results

in the five-membered ring composed of the bridging silicon, two iron and two the bridged-head Cp carbon atoms taking an envelope-like conformation. This type of conformation has previously been observed in other silicon- and carbon-bridged complexes [2,7,8]. Interestingly, in complex **2** the bridging silicon atom has moved onto the top of the molecule (Fig. 3). Thus, the molecule has C_1 symmetry in the crystalline state. The five-membered cyclic skeleton is basically planar, with a mean deviation of only 0.011 Å (Fig. 3b). This is, to our knowledge, the first example of a silicon-bridged complexes to have such a conformation.

The shift of the bridge onto the top of the molecule is likely caused by the steric effect of the $P(OPh)_3$ ligand. Meanwhile, the bulkiness of $P(OPh)_3$ makes the Fe–Fe bond slightly lengthened from 2.5227 Å for **1** to 2.5311 Å for **2**. The Cp–Si–Cp angle is also increased from 103.7° for **1** to 105.3° for **2**. Interestingly, the bridging Si–Cp bonds have been slightly shortened from 1.886 Å for **1** to 1.870/1.880 Å for **2**, implying that the original strain that may exist in the five-membered cyclic structure may have been released to some extent. The lengths of the Si–Si bonds are 2.362/2.361 Å for **1** and 2.355/2.351 Å for **2**, which are rather close to one another. Other selected bond lengths and angles for **1** and **2** have been listed in Tables 2 and 3, respectively.

4. Summary

According to the results observed above, it seems that an appropriate position of the Si–Si bonds with respect to the transition metal centers should be an important factor that may control the intramolecular Si–Si bond

activation. Without such a position that is approachable by the intramolecular coordinatively unsaturated transition metal centers, the Si–Si bond would remain stable, although Si–Si bonds should be highly susceptible towards oxidative addition to intramolecular transition metal centers [33,34].

a *N*,*N*′-chelating system like bpy (2,2′-bipyridine), phen (1,10-phenanthroline) have been reported [11,20]. The scarcity of the rhenium nitrosyl core with the azoimine function has created profound interest in studying the reactivity of the $Re(NO)^{3+}$ moiety towards arylazoheterocycles.

In order to explore the rhenium–nitrosyl chemistry of RaaiR′ we have used the reductive nitrosylation process. In an aqueous alkaline medium ReO_4^- undergoes reductive nitrosylation by $NH_2OH \cdot HCl$, furnishing the $Re(NO)^{3+}$ moiety in solution. The moiety is isolable as $M[Re(NO)(OH)_4]$ (M = Ph_4P or Ph_4As) salts or as $[Re(NO)(OH)_3(L\text{-}L')]$ (L-L = diimine ligand like bpy or phen) [11]. Addition of RaaiR′ to this solution has separated a brown red solid complex of the composition $[Re(NO)(OH)_3(N,N')]$ (*N*,*N*′) = azoimine ligand, RaaiR′ where R = H; R′ = H (Pai-H; 2-(phenylazo)imidazole, **1a**), Me (Pai-Me; 1-methyl-2-(phenylazo)imidazole, **1b**), Et (Pai-Et; 1-ethyl-2-(phenylazo)imidazole, **1c**): R = Me; R′ = H (Tai-H; 2-(*p*-tolylazo)imidazole, **2a**), Me (Tai-Me; 1-methyl-2-(*p*-tolylazo)imidazole, **2b**), Et (Tai-Et; 1-ethyl-2-(*p*-tolylazo)imidazole, **2c**)]. The spectroscopic characterisation and reactivity of the compounds are reported in this work.

2. Experimental

2.1. Materials

The starting material, $K[ReO_4]$, was of extra-pure quality and obtained from Aldrich. The AR grade solvents used for physicochemical studies were further purified by a literature method [21]. Water of high purity was obtained by distilling deionized water from $K[MnO_4]$. The ligands, 2-(arylazo)imidazoles (RaaiH) and 1-alkyl-2-(arylazo)imidazoles (RaaiR′) were prepared by the reported procedure [15].

2.2. Physical measurements

UV–Vis spectra were recorded on a Lambda 25, Perkin–Elmer UV–Vis spectrophotometer. IR spectra (KBr disk) were recorded on RX-1 Perkin–Elmer FT-IR (4000–450 cm^{-1}) and JASCO Model 420 FT-IR (4000–200 cm^{-1}) spectrophotometers. Electrical conductivity in a MeCN solution was measured with a Systronics 304 digital conductivity meter with a solution concentration of ca. 10^{-3} mol dm^{-3}. Magnetic susceptibilities were obtained from a vibrating sample magnetometer PAR 155 model. Microanalytical (C, H, N) data were collected on a Perkin–Elmer 2400C elemental analyzer. ESR spectra were measured in MeCN solution at 298 K using a Bruker ESR spectrophotometer model EMX 10/12, X-band ER 4119 MS cylindrical resonator. All pH measurements were made with an E.C. (India) digital pH meter (model 5651). Electrochemical measurements were carried out with the use of a computer controlled EG&G PARC VersaStat model 250 Electrochemical instrument using a Pt-disk working electrode and Pt-wire auxiliary electrode. The solution was IR compensated and the results were collected at 298 K. The reported results are referenced to SCE in MeCN and are uncorrected for junction potentials. $[n\text{-}Bu_4N][ClO_4]$ was used as the supporting electrolyte.

2.2.1. Preparation of tri-hydroxo-nitrosyl-{*N*(1)-methyl-2-(phenylazo)-imidazole}rhenium(II) hydrate, $[Re(NO)(OH)_3(Pai\text{-}Me)] \cdot H_2O$, (*1b*) generation of the $Re(NO)^{3+}$ moiety

A mixture of $K[ReO_4]$ (0.11 g, 0.38 mmol) and $NH_2OH \cdot HCl$ (0.36 g, 5.25 mmol) was dissolved in 25 ml water. The solution was heated to ca. 80 °C for 10 min with constant stirring. Solid NaOH beads were gradually added to the stirred solution until it turned red and the pH increased to ca. 10.5. The red solution was stirred at 80 °C for half an hour and cooled.

$$ReO_4^-(aq) \xrightarrow[\text{Excess } OH^-]{NH_2OH \cdot HCl} Re(NO)^{3+} \quad (1)$$

2.2.2. Preparation of $[Re(NO)(OH)_3(Pai\text{-}Me)]$

The pH of the red solution was lowered to ca. 5–6 by adding 1:1 HCl. To an ethanolic solution of 1-methyl-2-(phenylazo)imidazole (Pai-Me) (0.13 g, 0.70 mmol) the red solution was added dropwise whilst stirring. Immediately a buff coloured precipitate appeared. The solution was stirred for ca. 10 min and the precipitate was filtered, washed with water, ethanol and diethyl ether, and finally dried over fused $CaCl_2$ under vacuum. The yield was 0.12 g (67%). All the other complexes were prepared by the same procedure and yield varied from 60% to 70%.

$$Re(NO)^{3+}(aq) + \text{Pai-Me} \rightarrow [Re(NO)(OH)_3(\text{Pai-Me})] \quad (2)$$

3. Results and discussion

3.1. Synthesis

An aqueous solution of $K[ReO_4]$ was treated with $NH_2OH \cdot HCl$ and NaOH to prepare a red solution of the $Re(NO)^{3+}$ moiety (Solution-A). An ethanolic solution of 1-alkyl-2-(arylazo)imidazole (RaaiR′) was added dropwise to Solution-A whilst stirring at room temperature. Brown red complexes of the composition $[Re(NO)(OH)_3(RaaiR')]$, namely $[Re(NO)(OH)_3(Pai\text{-}H)] \cdot H_2O$ (**1a**), $[Re(NO)(OH)_3(Pai\text{-}Me)] \cdot H_2O$ (**1b**), $\{Re(NO)(OH)_3(Pai\text{-}Et)] \cdot H_2O$ (**1c**), $[Re(NO)(OH)_3(Tai\text{-}H)] \cdot H_2O$ (**2a**), $[Re(NO)(OH)_3(Tai\text{-}Me)] \cdot H_2O$ (**2b**) and $[Re(NO)(OH)_3(Tai\text{-}Et)] \cdot H_2O$ (**2c**), were separated.

[Re(NO)(OH)$_3$(Pai-R′)] [Re(NO)(OH)$_3$(Tai-R′)]

Pai-R′ = Pai-H (**1a**), Pai-Me (**1b**), Pai-Et (**1c**); Tai-R′ = Tai-H (**2a**), Tai-Me (**2b**), Tai-Et (**2c**)

The complexes were filtered, washed and recrystallised from a 2-methoxy-ethanol-EtOH mixture. The composition and molecularity of the complexes have been supported by microanalytical data. Molar conductance measurements in MeCN suggest non-conductivity of the complexes. Thermogravimetric (TG and DTA) analyses of the compounds reveal that one water molecule in each case is very loosely held, and this is released at 80–85 °C. Although three different isomers are possible, with $[Re(NO)(OH)_3(RaaiR')]$ having an unsymmetrical *N*,*N*′ chelating ligand, we have not been able to separate them.

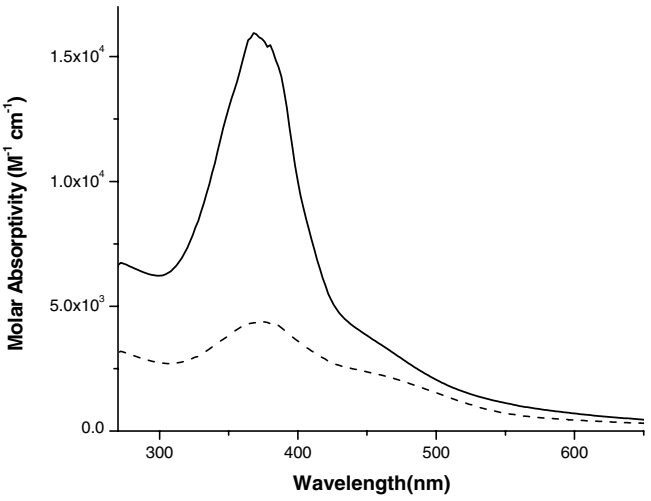
3.2. IR and electronic spectra

The isolated complexes are all monomeric as is evident from the microanalytical data. The hydroxo group and lattice held water molecules together show a single and slightly broad υ(OH) IR band at ca. 3400 cm^{-1}, but the $\partial(H_2O)$ band is apparently occluded in the low energy tail of the υ(NO) vibrational band. All the complexes exhibit a sharp and symmetrical υ(NO) vibrational band at ca. 1700 cm^{-1}. The υ(NO) stretch suffers a blue shift by 10–15 cm^{-1} relative to the corresponding bpy and phen complexes [11,20]. The complexes exhibit a moderately intense band at 1435–1445 cm^{-1} which may be ascribed to υ(N=N) vibrations. The said frequency is also blue shifted by 40–65 cm^{-1} in the complexes relative to the free ligand values. The chelated azoimine function receives electrons by $d\pi(M) \rightarrow \pi^*(azo)$ means which usually lowers the υ(N=N) stretch [17–19,22]. In the present series of complexes two π-acidic groups, NO^+ and N=N, are competing for same $d\pi$(Re(II)) electrons. The stronger π-acidic NO^+ accepts π-electrons more efficiently than the azoimine grouping and probably weakens the π back donation that raises the υ(N=N) stretching frequency. Other bands at 790, 775, 700–600 cm^{-1} corresponding to the imidazole moiety are observed.

The solution electronic spectra of the complexes were recorded in the range 900–200 nm in MeCN. The complexes show absorption bands in the ranges 320–330, 365–385 and 440–450 nm (Fig. 1). The transitions below 400 nm are of high intensity and are ascribed to intraligand charge-transfer, $\pi \rightarrow \pi^*$ and $n \rightarrow \pi^*$ transitions [15,16] of the chelated ligand (RaaiR′). The longer wavelength transition may correspond to the combination of MLCT ($d\pi(Re) \rightarrow \pi^*$(azoimine)) and $b_2 \rightarrow e$ transitions [23]. The said bands also appear in the complexes but are blue shifted by ca. 55 and 35 nm, respectively.

3.3. Magnetic properties and e.s.r data

The complexes exhibit a μ_{eff} value of ca. 1.8 BM at 298 K. A slightly higher value than the spin-only value expected for a single electron [Re(II), d^5, low-spin octahedral case] may be due to the negative value of the spin–orbit coupling constant and orbital non-degeneracy of the singly occupied molecular orbital (s.o.m.o) involved.



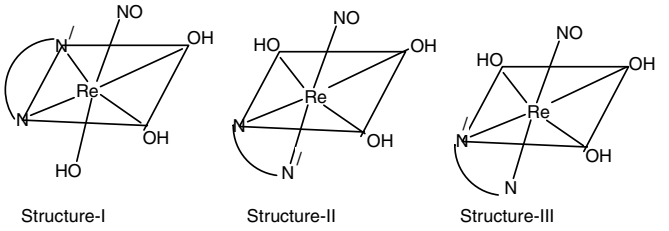


Fig. 1. Electronic spectra of $[Re(NO)(OH)_3(Pai\text{-}H)]$ (····) and $[Re(NO)(OH)_3(Pai\text{-}Et)]$ (—) in MeCN solution.

The e.s.r spectra (Fig. 2) are difficult to explain in terms of molecular symmetry. There may be three (**I**–**III**) structures; of them, structure-**I** is asymmetric and **II**, **III** posses C_s symmetry. The axial e.s.r. spectra may be more appropriately described by structure **II** or **III** than that of **I**. A well defined sextet is observed which arises from hyperfine coupling with the spin-active ^{185}Re and ^{187}Re nuclei [both have $I = 5/2$, Fig. 2] [24].

3.4. Electrochemical studies

Cyclic voltammetry was carried out in a MeCN solution using a Pt-working electrode in the potential range 1.8 V to −1.8 V in the presence of $[NBu_4][ClO_4]$ as the supporting electrolyte. The cyclic voltammogram shows quasireversible to irreversible responses at 0.7–0.8 (couple I), 0.2–0.3 (couple II), −0.1 to −0.2 (couple III), −0.5 to −0.6 (couple IV) and −1.3 to −1.4 V (couple V) (Table 1, Fig. 3). The couples I and II do not have a well defined cathodic peak on scan reversal from positive to negative. Separate voltammetric drawings at variable scan rates for couples I and II exhibit similar behaviour. This suggests that the redox performances are independent of scan speed or asking potential. At slow scan rates (10–50 mV s^{-1})ΔE_P remains almost constant, as do the E_{Pa} and the E_{Pc} values. However, the peak-to-peak separation of the redox couples III–V is largely dependent on the scan rate and increases from 120 mV at 10 mV s^{-1} to 600 mV at 1000 mV s^{-1}. This observation suggests a low heterogeneous electron-transfer rate constant which has been influenced by the applied potential. The arylazoimidazoles (RaaiR′) do not show any oxidation but irreversible reductive responses, in general two quasireversible couples at −0.8 and −1.3 V are ascribed to [—N═N—]/[—N⁻—N—]$^-$ and [—N⁻—N—]/[—N⁻—N⁻—]$^=$, respectively [22]. Thus, couples IV and V are reductive responses of the chelated azoimine ligand. The anodic shift of these two couples (IV and V) compared to the free ligand values may be due to electron drifting to Re(II) from the coordinated ligand. The first three couples (couples I, II and III) may be assigned to [Re(NO)] centred redox responses. Couple I is assigned to $[Re(NO)(OH)_3(RaaiR')]^+/[Re(NO)(OH)_3(RaaiR')]$ [11]. Couples II and III are assigned to successive one electron reductions of the coordinated NO^+ unit; $[Re–NO]^+ \rightarrow [Re–NO]$ (couple II), $[Re–NO] \rightarrow [Re–NO]^-$ (couple III). These three couples are irreversible in nature indicating the instability of the reduced species.

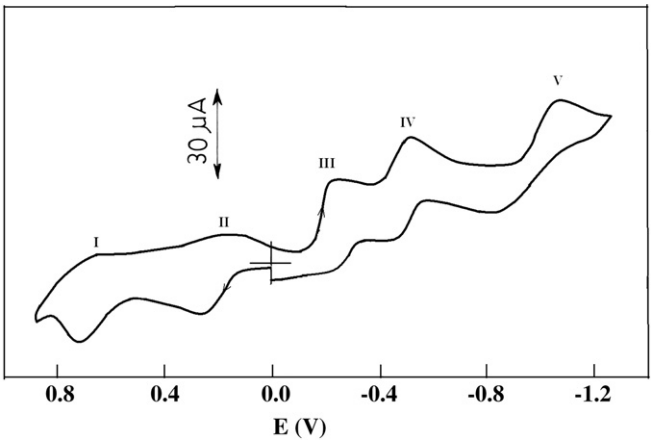
[b] g_s represents the g value of the derivative curve in the polycrystalline state.
[c] For spin paired d^5 system $g_\perp > g_\parallel$ and $g_\parallel < 2$.
[d] $g_{av} = (2g_\perp + g_\parallel)/3$.



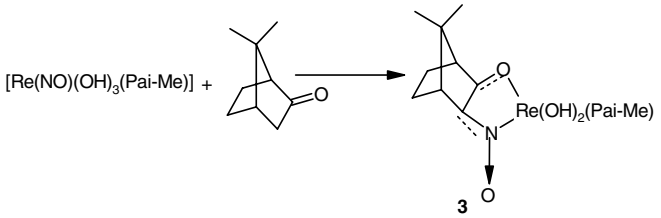


Fig. 3. Cyclic voltammogram of $[Re(NO)(OH)_3(Tai\text{-}Et)]$ (**2c**) in MeCN using a Pt-working electrode, SCE reference and a Pt-wire auxiliary electrode in the presence of $[n\text{-}Bu_4N][ClO_4]$ as the supporting electrolyte.

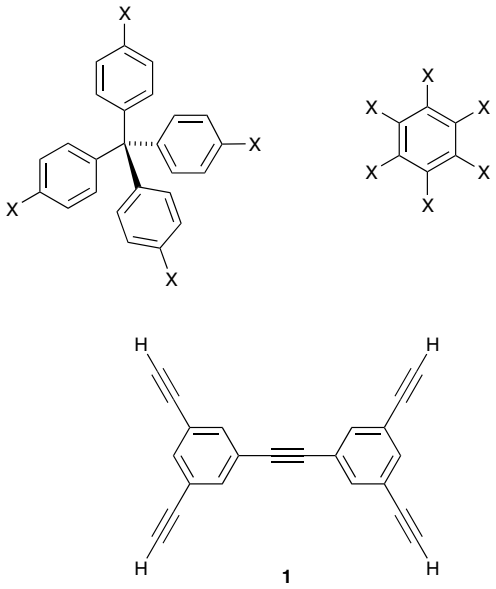
4. Reactivity of [Re(NO)(OH)$_3$(Tai-Me)]

The nitrosyl complexes exhibit a high degree of electrophilic character [25] of the coordinated NO ligand. The electrophilic behaviour of these new complexes has been investigated by reacting with camphor (cmp), a compound having an active methylene group. An acetonitrile solution of [Re(NO)(OH)$_3$(Tai-Me)] reacted smoothly with camphor in the presence of NaOMe, and the solution colour changed from brown-red to red-violet. The progress of the reaction was followed by monitoring ν(NO), which decreased steadily from 1700 cm^{-1}, and the composition of the reaction mixture was followed by thin-layer chromatography, collecting portions of the reaction solution from time-to-time. The product analyses are in accordance with reaction (3). The reaction involves electrophilic addition of the coordinated NO to the activated

(3)

–CH$_2$– group, forming a bound oxime (camphorquinone monoxime). Deprotonation of the active methylene (–CH$_2$–) leads to the generation of a carbanion which subsequently attacks the electrophilic NO$^+$, with the synthesis of camphorquinone monoxime. The disappearance of ν(NO) (1700 cm^{-1}) and the growth of ν(N → O) at 1220 cm^{-1} strongly support the reaction. Microanalytical, spectroscopic and electrochemical results of the camphorquinone monoxime complex (**3**) suggest a structure of the complex which supports this coupling reaction of the coordinated NO. The compound shows a very complex pattern of proton signals in the aliphatic region, 0.8–1.0, 1.28–1.40, 2.20, 2.40 and 4.00 ppm. Camphor –CH$_2$– and –CH– may be assigned to 0.8–1.0 and 1.28–1.40 ppm. 9-Me and 1-Me of the coordinated Tai-Me appear at 2.35 and 4.11 ppm, respectively. In the aromatic region (6.00–9.00 ppm) imidazole protons 4-H and 5-H appear as broad singlets at ca. 7.18 and 6.92 ppm, respectively. Broadening of the signals may be due to rapid proton exchange with solvent ($CHCl_3$ from $CDCl_3$). *p*-Tolyl protons (7-H to 11-H) appear at 8.32 ($J = 7.5$ Hz, 7, 11-H, doublet) and 7.44 ppm ($J = 7.5$ Hz, 8, 10-H, doublet). The cyclic voltammogram shows a peak, E_{Pa}, at 0.62 V, which suggests a Re(III)/Re(II) couple, and ligand reductions at −0.73 ($\Delta E_p = 140$ mV) and −1.3 V ($\Delta E_p = 220$ mV).

5. Conclusion



Rhenium–nitrosyl complexes of arylazoimidazoles are synthesized by reductive nitrosylation of ReO_4^- in aqueous alkaline medium by $NH_2OH \cdot HCl$. The ligands are bidentate *N*,*N*′ chelating type. The complexes exhibit υ(NO) at ca. 1700 cm^{-1}, which upon reaction with camphor in alkaline medium vanishes with appearance of a new impression at 1220 cm^{-1}. This and other spectroscopic properties suggest a C–N coupling reaction of the coordinated NO and formation of a camphoroxime complex. The precursors [Re(NO)(OH)$_3$(azoimidazole)] are magnetically active and show $\langle g_{av} \rangle \approx 2.0$. Cyclic voltammetry exhibits irreversible metal oxidation, and NO$^+$ and azo reductions.

Scheme 1. Central cores for four- or six-armed stars and dendrimers.

3,5-Dibromonitrobenzene [23], 3,5-diiodonitrobenzene [24] and compound **1** [22] were made by published routes or slight modifications thereof.

2.2. Compound 2

Compound **2** was prepared as previously reported [27], except that a catalytic amount of CuI was added before the addition of KI. Spectroscopic data were in accord with those published [27].

2.3. Compound 3

Compound **2** (345 mg, 1.15 mmol), CuCl (4.10 mg, 0.0414 mmol) and $[Pd(PPh_3)_2Cl_2]$ (28.8 mg, 0.0410 mmol) were dissolved in Et_3N (25 ml). Compound **1** (75.0 mg, 0.273 mmol) was then added and the reaction mixture heated to 60 °C and stirred at this temperature for 24 h. After cooling to room temperature, solvent was removed under reduced pressure and the residue was purified by column chromatography (alumina, hexanes: CH_2Cl_2 1:0 changing to 3:1 during elution). Compound **3** was isolated as a brown solid (81.5 mg, 0.0846 mmol, 32.4%). ^{1}H NMR (400 MHz, $CDCl_3$) δ/ppm 7.63 (s, 6H, H^B), 7.47 (s, 16H, H^A),0.28 (s, 36H, C^{Me}). ^{13}C NMR (100 MHz, $CDCl_3$) δ/ppm 134.3, 134.2, 131.9, 131.5, 123.9, 123.5, 123.3, 122.7, 104.5 ($C^{C\equiv CTMS}$), 96.6 ($C^{C\equiv CTMS}$), 90.3 ($C^{C\equiv C}$), 89.5 ($C^{C\equiv C}$), 88.9 ($C^{C\equiv C}$), −0.1 (C^{Me}). FAB-MS *m/z* 963 $[M]^+$, 766 $[M–C_2C_6H_4C_2TMS]^+$, 73 $[TMS]^+$ (base peak). IR (ν, cm^{-1}) 2955w, 2153m, 1581s, 1505m, 1404w, 1246s, 1102w, 1018w, 859vs, 832vs, 757s, 677s.

2.4. Compound 4

The method used differs from that published [25] but gave a similar yield of **4**; more recently, another modification has been published [26]. 3,5-Dibromonitrobenzene (1.00 g, 3.56 mmol) was dissolved in Et_3N (50 ml) with CuCl (53.5 mg, 0.540 mmol) and $[Pd(PPh_3)_2Cl_2]$ (379 mg, 0.540 mmol). After the addition of TMSC≡CH (1.52 ml, 10.8 mmol), the mixture was heated to 60 °C and was stirred at this temperature for 20 h. After cooling to room temperature, solvent was removed under reduced pressure and the residue was extracted with a solution of 10% CH_2Cl_2 in hexanes (150 ml). The crude material was purified by column chromatography (alumina, hexanes: CH_2Cl_2 1:0 gradually changing to 10:1). Compound **4** was isolated as a light brown solid (613 mg, 1.94 mmol, 54.6%). ^{1}H NMR (400 MHz, $CDCl_3$) δ/ppm 8.21 (s, 2H, H^2), 7.82 (s, 1H, H^4), 0.28 (s, 18H, H^{Me}). ^{13}C NMR (100 MHz, $CDCl_3$) δ/ppm 148.2 (C^1), 140.6 (C^4), 126.3 (C^2), 125.4 (C^3), 101.6 ($C^{C\equiv C}$), 98.4 ($C^{C\equiv C}$), −0.2 (C^{Me}). FAB-MS *m/z* 315 $[M]^+$, 300 $[M–CH_3]^+$ (base peak). IR (ν, cm^{-1}) 2959m, 2160m, 1537vs, 1410w, 1352vs, 1250s, 843vs, 746vs, 775s, 760s, 669s. Previously reported spectroscopic data [25] are for an acetone solution of **4**.

2.5. Compound 5

Compound **5** was prepared by a modification of that reported [25]. 3,5-Diiodoaniline (1.15 g, 3.33 mmol) was dissolved in Et_3N (50 ml) with CuCl (49.5 mg, 0.500 mmol) and $[Pd(PPh_3)_2Cl_2]$ (351 mg, 0.500 mmol). TMSC≡CH (1.18 ml, 8.38 mmol) was then added and the mixture was heated to 60 °C and was stirred at this temperature for 20 h. After cooling to room temperature, solvent was removed under reduced pressure and the crude residue was purified by column chromatography (alumina, hexanes: CH_2Cl_2 1:0 changing to 3:1). Compound **5** was isolated as a light brown solid (891 mg, 3.12 mmol, 93.7%). ^{1}H NMR (400 MHz, $CDCl_3$) δ/ppm 7.00 (t, *J* 1.6 Hz, 1H, H^4), 6.71 (d, *J* 1.6 Hz, 2H, H^2), 3.52 (br, NH_2), 0.23 (s, 18H, C^{Me}). ^{13}C NMR (100 MHz, $CDCl_3$) δ/ppm 146.4 (C^1), 126.5 (C^4), 124.3 (C^2), 118.8 (C^3), 104.8 ($C^{C\equiv C}$), 94.5 ($C^{C\equiv C}$), 0.4 (C^{Me}). FAB-MS *m/z* 285 $[M]^+$, 270 $[M–CH_3]^+$ (base peak). IR (ν, cm^{-1}) 3381m, 2959m, 2899m, 2152m, 1587s, 1553m, 1429m, 1410m, 1248s, 839vs, 756s, 648s. Previously reported spectroscopic data [25] are for an acetone solution of **5**.

2.6. Compound 6

Compound **5** (70.0 mg, 0.245 mmol) was suspended in water (25 ml), concentrated HCl (5 ml) was added and the brown solution was cooled to 0 °C. A solution of $NaNO_2$ (17.3 mg, 0.251 mmol) in water (10 ml) was added to the reaction mixture and this was stirred at 0 °C for 1 h. A catalytic amount of CuI (10 mg) was added, followed by KI (105 mg, 0.633 mmol). The reaction mixture was stirred at 0 °C for 6 h, during which time THF (total 30 ml) was added in small amounts to increase the solubility of the reactants. After warming to room temperature, water and Et_2O (1:2, 75 ml) were

added to the vigorously stirred reaction mixture. Two layers were allowed to separate, and the aqueous layer was extracted with Et_2O (100 ml), and the organic layer was collected, washed with brine, and dried over $MgSO_4$. After removal of solvent under reduced pressure, the crude residue was purified by column chromatography (alumina, hexanes: CH_2Cl_2 1:0 changing to 10:1). Compound **6** was isolated as a yellow solid (72.8 mg, 0.184 mmol, 75.1%). ^{1}H NMR (400 MHz, $CDCl_3$) δ/ppm 7.74 (d, J 1.6 Hz, 2H, H^2), 7.52 (t, J 1.6 Hz, 1H, H^4),0.23 (s, 18H, C^{Me}). ^{13}C NMR (100 MHz, $CDCl_3$) δ/ppm 140.2 (C^2), 134.4 (C^4), 125.0 (C^3), 102.2 ($C^{C\equiv C}$), 96.6 ($C^{C\equiv C}$), 92.8 (C^1), −0.2 (C^{Me}). FAB-MS m/z 396 $[M]^+$, 381 $[M–CH_3]^+$ (base peak). IR (ν, cm^{-1}) 3086w, 2955m, 2924m, 2854w, 2214w, 2160w, 1898m, 1774m, 1574s, 1481s, 1411s, 1396m, 1272m, 1250m, 1072m, 1011m, 864s, 817vs, 756s, 679s.

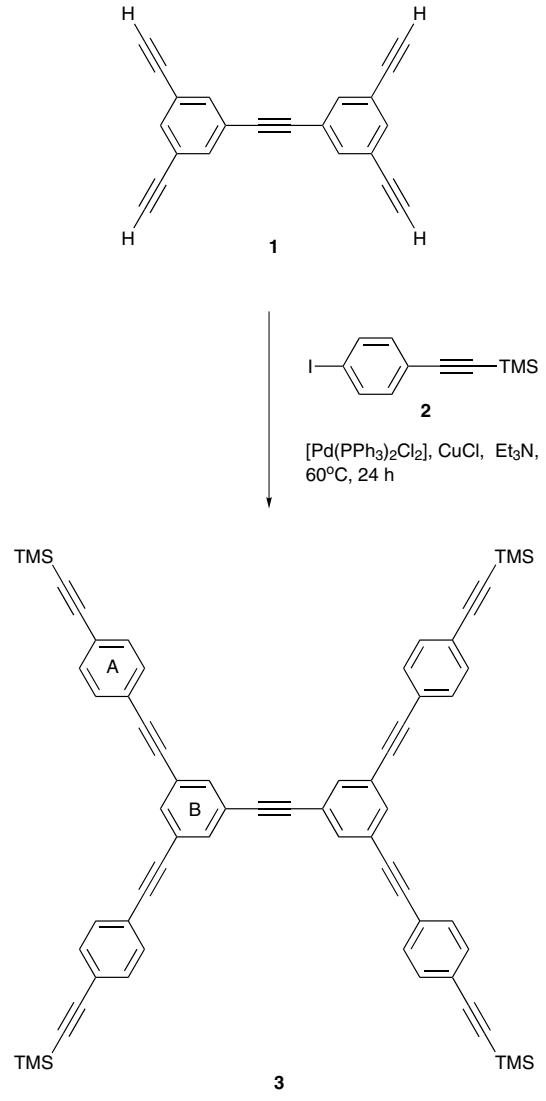
2.7. Compound 7

Compound **6** (325 mg, 0.821 mmol), CuCl (3.0 mg, 0.030 mmol) and $[Pd(PPh_3)_2Cl_2]$ (21.1 mg, 0.0301 mmol) were dissolved in Et_3N (25 ml). Compound **1** (55.0 mg, 0.201 mmol) was then added. The reaction mixture was heated at 60 °C for 18 h. After cooling to room temperature, solvent was removed and the residue was purified by column chromatography (alumina, hexanes: CH_2Cl_2 1:0 changing to 5:1). Compound **7** was isolated as a brown solid (71.4 mg, 0.0523 mmol, 26.0%). ^{1}H NMR (400 MHz, $CDCl_3$) δ/ppm 7.57 (m, 18H, $H^{A,B}$), 0.25 (s, 72H, C^{Me}). ^{13}C NMR (100 MHz, $CDCl_3$) δ/ppm 135.2, 135.1, 134.6, 134.4, 123.9 (overlapping signals), 123.1, 122.9, 103.0 ($C^{C\equiv CTMS}$), 95.9 ($C^{C\equiv CTMS}$), 89.1 ($C^{C\equiv C}$), 88.9 ($C^{C\equiv C}$), 88.5 ($C^{C\equiv C}$), −0.1 (C^{Me}). MALDI-MS m/z 1346 $[M]^+$, 1331 $[M–CH_3]^+$ (base peak). IR (ν, cm^{-1}) 2958w, 2152w, 1740w, 1558w, 1473m, 1404w, 1377w, 1248s, 1191m, 945w, 873sh, 839vs, 760s, 702w, 644m.

2.8. Compound 8

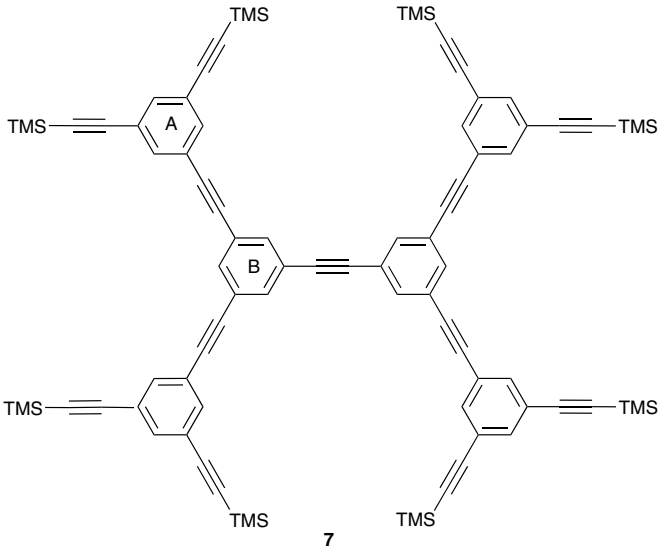
Compound **3** (20.0 mg, 0.0208 mmol) was dissolved in CH_2Cl_2 (35 ml), and $Co_2(CO)_8$ (142 mg, 0.415 mmol) was added to the solution. The reaction mixture was stirred at room temperature for 3 h. Solvent was then removed under reduced pressure, and the crude product was purified by column chromatography (silica, hexanes) to yield **8** as a red solid (67.5 mg, 0.0191 mmol, 91.8%). ^{1}H NMR (400 MHz, $CDCl_3$) δ/ppm 7.50 (m, 22H, $H^{A,B}$), 0.42 (s, 36H, C^{Me}). ^{13}C NMR (100 MHz, $CDCl_3$) δ/ppm 199.8 (C^{CO}), 198.6 (C^{CO}), 198.4 (C^{CO}), 140.2, 140.1, 138.2, 137.7, 130.5, 129.6, 129.5, 128.0, 104.4 ($C^{C\equiv CTMS}$), 94.2 ($C^{C\equiv CTMS}$), 91.1 ($C^{C\equiv C}$), 90.4 ($C^{C\equiv C}$), 79.8 ($C^{C\equiv C}$), 0.8 (C^{Me}). MALDI-MS m/z 987 $[M–18Co–54CO + Na]^+$. IR (ν, cm^{-1}) 2085s, 2046s, 1988vs, 1730w, 1573m, 1481m, 1402m, 1247s, 1109m, 885m, 833vs, 758w, 687w.

2.9. Compound 9



Compound **7** (35.0 mg, 0.0257 mmol) was dissolved in CH_2Cl_2 (50 ml), and $Co_2(CO)_8$ (253 mg, 0.740 mmol) was added to the solution. The reaction mixture was stirred at room temperature for 3 h. Solvent was removed, and the crude product was purified by column chromatography (silica, hexanes: CH_2Cl_2 1:0 changing to 10:1 during elution) to yield **9** as a red solid (101 mg, 0.0199 mmol, 77.3%). ^{1}H NMR (400 MHz, $CDCl_3$) δ/ppm 7.39 (m, 18H, $H^{A,B}$), 0.25 (s, 72H, C^{Me}). ^{13}C NMR (100 MHz, $CDCl_3$) δ/ppm 199.6 (C^{CO}), 199.0 (C^{CO}), 198.5 (C^{CO}), 140.5, 140.0, 139.9, 139.8, 133.4, 131.7, 131.5, 129.6, 103.8 ($C^{C\equiv CTMS}$), 93.3 ($C^{C\equiv CTMS}$), 93.0 ($C^{C\equiv C}$), 88.2 ($C^{C\equiv C}$), 80.3 ($C^{C\equiv C}$), 0.9 (C^{Me}). MALDI-MS see text. IR (ν, cm^{-1}) 2091s, 2044s, 1998vs, 1767w, 1573m, 1497w, 1404m, 1250s, 1011w, 833vs, 756m, 679m.

2.10. Crystal structure determination of 4



Data were collected on an Enraf Nonius Kappa CCD instrument; data reduction, solution and refinement used the programs COLLECT [28], SIR92 [29] and CRYSTALS [30]. Crystal data for **4**: $C_{16}H_{21}NO_2Si_2$, $M = 315.52$, monoclinic, space group $C2$, $a = 30.8355(3)$, $b = 8.4122(1)$, $c = 17.9490(2)$ Å, $\beta = 99.1107(7)°$; $U = 4597.13(9)$ Å^3, $Z = 10$, $D_c = 1.140$ g cm^{-3}, μ(Mo Kα) = 0.196 mm^{-1}, $T = 173$ K, 19 002 reflections collected, 5616 unique reflections. Refinement of 477 parameters against F^2 using all data converged to a final $R_1 = 0.0515$ ($I > 2.0\sigma$, 0.0619 all data), $wR_2 = 0.1711$ ($I > 2.0\sigma$, 0.1740 all data), Goodness-of-fit = 0.9827.

3. Results and discussion

We have previously reported the preparation and characterization of compound **1** (Scheme 1) as part of a study of small polyalkyne frameworks and their cobalt cluster-decorated derivatives [22]. We now report the use of **1** as an alkyne-centred core for the construction of a first generation star and dendrimer. Each terminal alkyne in **1** is easily coupled to the linear, protected alkyne **2** by Sonogashira methodology [31,32] (Scheme 2). We observed that coupling occurred more effectively using the iodo-derivative **2** rather than the analogous bromo-compound. A slight excess over the stoichiometrically required four equivalents of **2** was needed to optimize the yield of product **3**. Compound **3** was characterized by spectroscopic and mass spectrometric methods. The highest mass peak in the FAB mass spectrum of **3** at m/z 963 corresponded to the parent ion, although facile loss of the TMS protecting group led to a base peak at m/z 73. The ^{1}H NMR spectrum confirmed the expected symmetry of the product, with singlets at δ 7.63 and 7.47 ppm assigned on the basis of relative integrals to protons H^B and H^A, respectively. Four equivalent TMS groups gave rise to a singlet at δ 0.28 ppm. The ^{13}C NMR spectrum was also consistent with the expected

Scheme 2. Synthetic route to compound **3** (first generation star), and ring labelling for the NMR spectroscopic assignments.

Scheme 3. Compound **7** (first generation dendrimer), and ring labelling for the NMR spectroscopic assignments.

symmetry of **3**, with the appearance of five signals in the region for the alkyne carbon atoms. Following from our earlier observations for related systems [22], we assign the carbons for the outermost alkyne groups to the signals of highest frequency (δ 104.5 and 96.6 ppm) with the innermost alkyne carbons coming at δ 90.3, 89.5 and 88.9 ppm.

For the formation of the first generation dendrimer **7** shown in Scheme 3, the most desirable unit to react with **1** was iodo-derivative **6**. The first strategy that we adopted for the synthesis of **6** was the conversion of 3,5-dibromonitrobenzene to the bis(alkyne) derivative **4**, followed by reduction to amine **5**, and final conversion to **6**. The initial Sonogashira coupling was successful, and produced **4** in 54.6% yield. Although this compound has been reported previously [25,26], its solid state structure has not been determined. X-ray quality crystals of **4** were grown from CH_2Cl_2 solution. Interestingly, although achiral, **4** crystallizes in the chiral space group *C*2 [33,34]. There are three independent molecules in the unit cell, one of which (molecule A) is located on a special position and thus contains a 2-fold axis. The independent molecules B and C and half of molecule A together form a chiral building block that assembles into a chiral structure. The three molecules are structurally similar, and one molecule (type B) is shown in Fig. 1. Selected bond lengths and angles are given in the figure caption and are unexceptional. For the two molecules (molecules B and C) that do not lie on special positions, the nitro group is twisted with respect to the aryl ring (angles between the least squares planes of NO_2 and C_6 ring are 13.5(7)° (molecule B, Fig. 1) and 4.6(6)° (molecule C). These angles compare with a range of 5.6–17.0° in other 1-NO_2-3,5-(RC≡C)$_2$C$_4$H$_3$-type compounds [26,35,36] found in a search of the Cambridge Structural Database

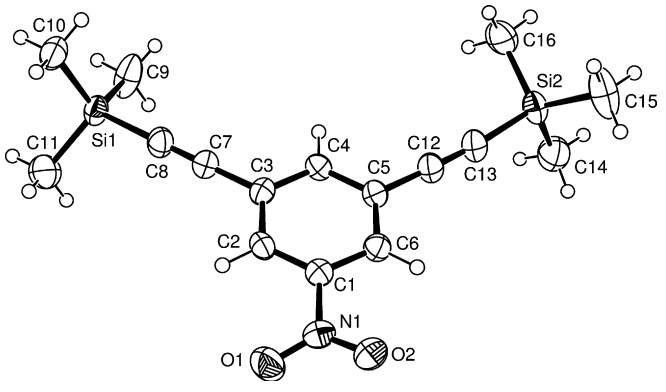


Fig. 1. The molecular structure of one of three crystallographically independent (but structurally similar) molecules of **4**. Selected bond parameters: O1–N1 = 1.223(6), O2–N1 = 1.212(6), N1–C1 = 1.480(7), C3–C7 = 1.447(7), C5–C12 = 1.445(7), C7–C8 = 1.193(7), C12–C13 = 1.196(7), Si–C range 1.846(6)–1.863(8) Å; O1–N1–O2 = 123.5(5), O1–N1–C1 = 118.2(5), O2–N1–C1 = 118.3(5), C3–C7–C8 = 177.8(5), Si1–C8–C7 = 174.1(5), C5–C12–C13 = 178.1(6), Si2–C13–C12 = 174.0(5)°.

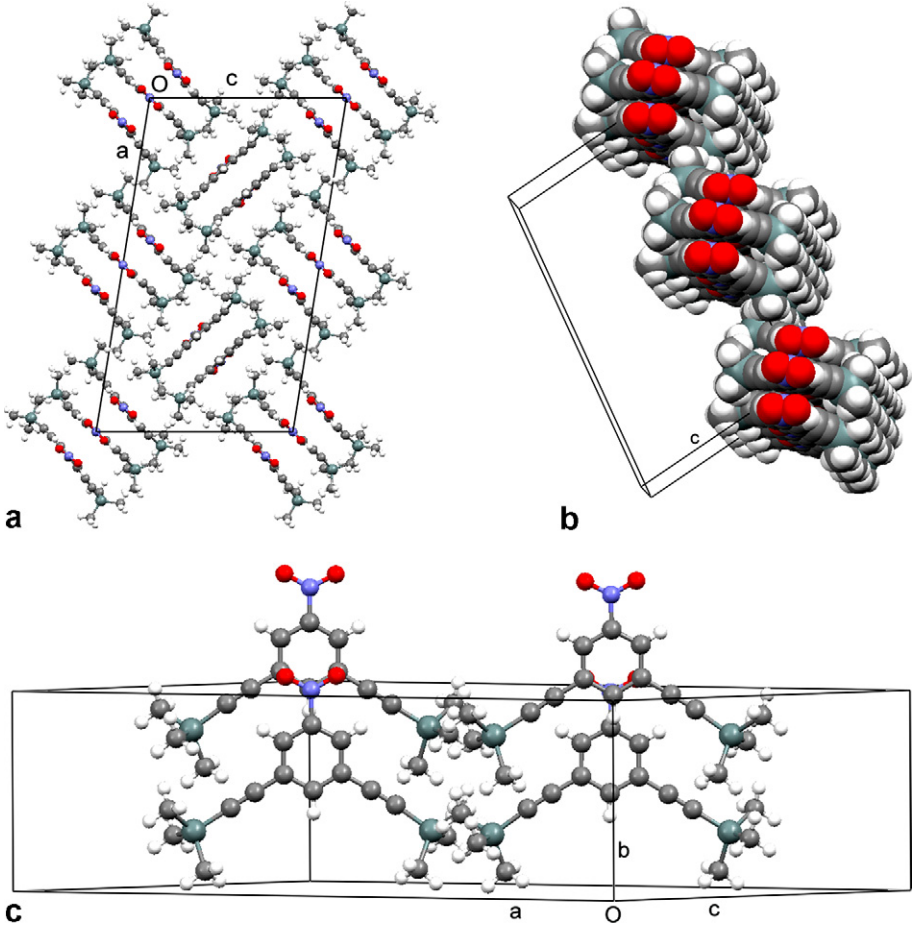
[37,38]. The packing of the molecules in the solid state deserves a mention. Fig. 2a views the unit cell down the crystallographic *b*-axis. Each molecule lying on a special position is the central member of a group of three (BAB) molecules, while molecules C are arranged in pairs. Extension of these motifs generates triple or double layers of molecules, respectively. This is shown for the triple layers in Fig. 2b. All molecules within one type of layer are oriented in the same direction (Fig. 2b and c), whereas molecules in triple and double layers are oriented in opposite directions (Fig. 2a). Within each layer, the principal intermolecular interactions arise from the fact that each NO_2 group lies directly over an aromatic ring (Fig. 2c). In the double layers, the C···N distance is 3.23 Å, and the C···O distances are 3.36 and 3.19 Å. In the triple layers, the stacking of molecules leads to alternating NO_2···aryl···NO_2 (C···N = 3.34 Å) and aryl···NO_2···aryl (C···N = 3.32 Å) sandwiches.

Attempts to reduce compound **4** to amine **5** were unsuccessful, and this strategy to building block **6** was therefore abandoned. Our second approach was to start with an amino precursor, but required the use of the more reactive iodo- rather than bromo-derivative for reaction with TMSC≡CH. Compound **5** was obtained in almost quantitative yield by the Sonogashira coupling of 3,5-diiodoaniline with two equivalents of TMSC≡CH. Conversion of **5** to **6** (Scheme 4) was carried out using Sandmeyer conditions, and **6** was obtained in 75.1% yield. In its FAB mass spectrum, the highest mass peak at *m*/*z* 396 was assigned to the parent ion, with the base peak (*m*/*z* 381) arising from loss of a methyl group. ^{1}H and ^{13}C NMR spectroscopic data were fully in accord with the symmetry of **6**, confirming the introduction of two alkyne functionalities. With an efficient route to **6** established, we were able to proceed to the assembly of the first generation dendrimer **7** (Scheme 3). Reaction of **1** with just over four equivalents of **6** under Sonogashira conditions gave, after workup, polyyne **7** in 26.0% yield. The highest mass peak (*m*/*z* 1346) in the MALDI mass spectrum of the product was assigned to the parent ion, but as with other protected alkynes reported here, facile loss of a methyl group generated the base peak (*m*/*z* 1331). The ^{1}H NMR spectrum was simple, exhibiting only two signals at δ 7.57 and 0.25 ppm, consistent with complete functionalization of the dendrimer core **1**, and



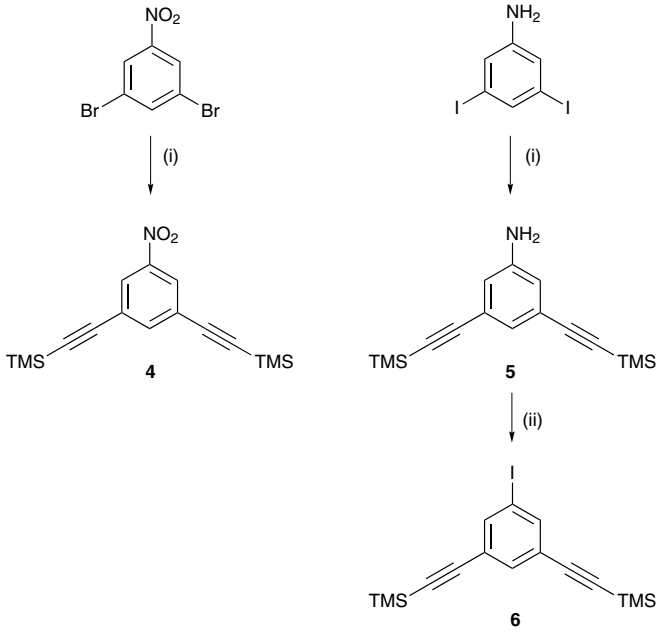


Fig. 2. Packing of molecules of **4**: (a) the unit cell viewed along the *b*-axis; (b) triple layers of molecules running parallel to the *b*-axis; (c) double layers are formed by stacking of molecules C.

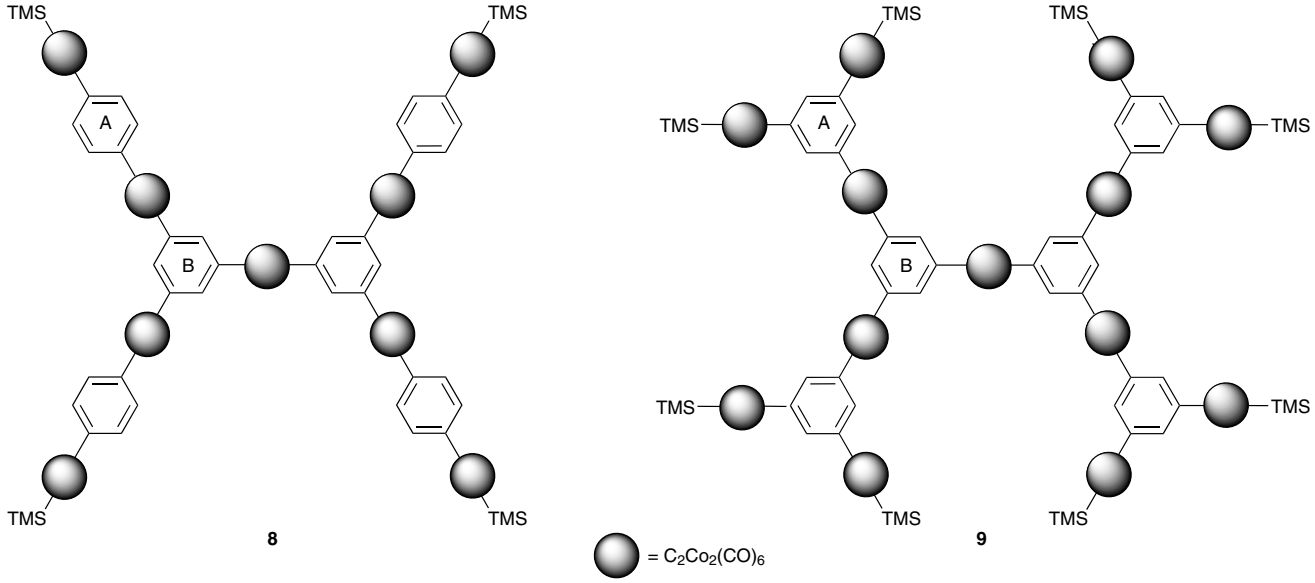

Scheme 4. Synthetic conditions for the formation of **4** and **6**: (i) $[Pd(PPh_3)_2Cl_2]$, CuCl, TMSC≡CH, Et_3N, 60 °C, 20 h; (ii) $NaNO_2$, HCl, CuI, KI, 0 °C, 6 h.

the formation of a monodispersed product. The ^{13}C NMR spectrum was also in accord with the degree of molecular symmetry expected for **7**.

Each of polyynes **3** and **7** reacted with $Co_2(CO)_8$ in CH_2Cl_2 solution at room temperature. A significant excess of $Co_2(CO)_8$ was needed in order to achieve complete functionalization of the alkyne domains (ratio **3**: $Co_2(CO)_8 \approx 1{:}20$, and **7**: $Co_2(CO)_8 \approx 1{:}29$). Chromatographic workup resulted in **8** and **9** (Scheme 5) being isolated in high yield, but all attempts to grow X-ray quality crystals led to decomposition of the materials, and good elemental analytical data could not be obtained. Characterization of the compounds therefore relied on spectroscopic techniques.

The IR spectra of **8** and **9** showed the characteristic signature of a $C_2Co_2(CO)_6$ unit in the carbonyl region. The ^1H NMR spectrum of **9** exhibited a multiplet at δ 7.39 ppm and a singlet at δ 0.25 ppm; the presence of one TMS environment was consistent with a symmetrical product. A well-resolved ^{13}C NMR spectrum of **9** was particularly informative. The ^{13}C NMR spectra of asymmetrical clusters of type $Co_2(CO)_6C_2RR'$ typically exhibit only one signal for the six carbonyl ^{13}C nuclei [39]. For **9**, the ^{13}C NMR spectrum revealed three CO environments (δ 199.6, 199.0 and 198.5 ppm with approximate relative integrals of 8:1:4). These data support the presence of three cluster environments and the symmetry of the structure for **9** shown in Scheme 5. The ^1H NMR spectrum of **8** exhibited a multiplet at δ 7.50 ppm and singlet at δ 0.42 ppm, but the latter signal had a shoulder at δ 0.44 ppm. The relative integrals of these signals were approximately 10:1. Examination of the spectrum revealed a low intensity signal at δ 6.4 ppm [22] that was assigned to a C≡CH proton, indicating that a degree of deprotection had occurred. This, together with the relative integrals of the aryl: TMS signals (≈24:38) suggested the presence of compound **8** and approximately 10% of a derivative of **8** in which one C≡CTMS group had been converted to C≡CH, or smaller amounts of derivatives with more than one deprotected terminal alkyne. Further support for this came from the carbonyl region of the ^{13}C NMR spectrum which exhibited signals at δ 199.8, 198.6 and 198.4 ppm with relative integrals 4:4:1, with additional low intensity signals at δ 198.9 and 198.2 ppm. A clean sample of **9** could not be obtained. On going from **3** to **8**, and from **7** to **9**, five ^{13}C NMR resonances are retained in the alkyne region for

Scheme 5. Cobalt carbonyl derivatives **8** (star) and **9** (first generation dendrimer), with ring labelling for the NMR spectroscopic assignments.

each compound. Signals in the ^{13}C NMR spectrum of **8** for the deprotected derivative could not be resolved. Although the addition of the $Co_2(CO)_6$ unit to the alkyne functionality causes only a small shift in the associated ^{13}C signals, it is sufficient to indicate that Co_2C_2-cluster formation has occurred [22].

We have previously observed that either FAB-MS or MALDI-TOF mass spectrometry is suited to the characterization of cobalt-cluster functionalized polyynes, depending on the size of the molecule [22]. The highest mass peak in the MALDI-TOF of **8** was observed at *m*/*z* 987 and could be assigned to $[M–18Co–54CO + Na]^+$, i.e. total loss of the nine $Co_2(CO)_6$ units appears to be facile under laser irradiation conditions. For compound **9**, we did not observe a well-resolved MALDI-TOF spectrum, although a low intensity peak corresponding to the polyyne framework (*m*/*z* 1349) was detected; attempts with and without matrix were made. We conclude that we have reached the upper limits of the usefulness of MALDI-TOF mass spectrometry for the characterization of compounds of this family.

4. Conclusions

We have reported synthetic strategies for the construction of alkyne-centred first generation star and dendritic polyynes, and their reactions with $Co_2(CO)_8$ to produce fully decorated cobalt-cluster containing species. Characterization of the latter is not trivial. Crystal growth tends to lead to decomposition, and MALDI-TOF mass spectrometry (which has proven invaluable for related, but smaller, molecules) fails to give definitive information. The most useful technique for characterization of the compounds is ^{13}C NMR spectroscopy. In particular, well-resolved spectra allow one to distinguish between the core, inner and peripheral cluster domains, adding to the correlation data that we have previously reported [22].

Arguably the most extensively studied luminescent lanthanide complexes are those with β-diketonate ligands [6]. When three β-diketonate ligands coordinate a trivalent lanthanide ion, an electrically neutral complex is produced. Unless a sterically encumbering β-diketonate ligand is used, additional ligands such as water and other Lewis bases are necessary in order to fulfill the high coordination requirement of these large metal ions. For practical applications, non-aqua neutral ligands are typically used, as high phonon energy OH oscillators can bridge off at very high rates the energy of the excited states of a lanthanide ion, leading to low quantum efficiency of light emission [7].

The property of the Lewis base adduct of a lanthanide β-diketonate depends on not only the diketonate but also the accompanying neutral ligand(s). Specifically, while the wavelength of light emission is inherently metal-dependent, its quantum efficiency is heavily dependent on how well the energetic levels of the ligand singlet, triplet, and the lanthanide emissive states are matched, a direct consequence of the ligand-assisted transfer of excitation energy [3,4,8]. Other properties such as thermal stability, solubility, and film-forming characteristics (for the fabrication of light-emitting devices) are also strongly dependent on the nature of the ligands.

We have been interested in the design and synthesis of lanthanide β-diketonates for applications as light-emitting materials in organic electroluminescent devices, as they offer a number of advantages over the much studied conducting polymers and other non-lanthanide materials [9]. Specifically, we have been looking at ligand design as a fundamental means of enhancing the thermal stability of a complex and improving its charge-carrier transporting ability in a working device [10]. For example, a terbium complex with acetylacetonate ligand modified with an electron-withdrawing oxadiazolyl group has been shown to possess higher thermal stability than its unmodified counterpart. More importantly, significantly improved electroluminescence device performance was also achieved [10]. In comparison, the unmodified complex barely produced any green emission using an otherwise identically configured device. Work by others has also validated this ligand design approach for producing improved electroluminescent lanthanide materials [11].

The neutral ligands are equally important in modifying the properties of luminescent lanthanide β-diketonates. Just like the negatively charged ligands, neutral ligands contribute to the overall stability of the resulting complex. They may also serve to promote energy transfer for light emission. Based on such considerations, we have recently started the quest for adducts of lanthanide β-diketonates with unique neutral ligands [12]. One of the ligands of interest is 2,4,6-tri(2-pyridyl)-1,3,5-triazine (TPTZ), a bulky aromatic compound featuring three 2-pyridyl rings fixed on a central 1,3,5-triazine platform [13]. This ligand has been studied previously for its application in actinide–lanthanide group separations in a synergistic extraction system [14]. There also exist a few structurally characterized lanthanide complexes in which TPTZ acts as a tridentate ligand [15,16]. However, TPTZ adducts of lanthanide β-diketonates are unknown prior to our work. In addition to the novelty of such complexes, the bulky ligand, by offering three coordinating atoms, helps protect the lanthanide ion from interacting with solvent molecules, and therefore, suppressing solvent-based vibrational coupling and luminescence quenching [17]. Furthermore, the remaining nitrogen atoms allow for further coordination to other metals, transition metals in particular. Thus, structurally sophisticated heterometallic complexes may be envisioned, for which novel magnetic as well as luminescence properties can be expected [18,19].

As a first step to many of the research opportunities elaborated above, we have prepared the TPTZ adducts of several lanthanide β-diketonates, wherein the lanthanide ion is Eu^{3+}, Tb^{3+}, or Er^{3+}, and the β-diketone is dibenzoylmethane (DBM), 1-benzoylacetone (BA), thenoyltrifluoroacetone (TTA), or 4,4,4-trifluoro-1-phenyl-1,3-butanedione (BTFA). The Eu^{3+} and Tb^{3+} complexes are synthesized as potential red- and green-emitting materials, respectively, while their Er^{3+} cognate is potentially useful in developing integrated lasers or fiber amplifiers due to its near infrared emission [20,21]. In this report, we describe in detail the synthesis, structural characterization by single-crystal diffraction, and photoluminescence studies of these new members of the lanthanide β-diketonate family.

2. Experimental

Reagents were of commercial origin (Aldrich) and were used as received. The recently reported procedure [12] for the synthesis of $Eu(DBM)_3TPTZ$ was adopted with modifications where necessary. Elemental analysis (CHN) was performed by Desert Analytics Laboratory, Tucson, Arizona.

2.1. Synthesis of $Tb(DBM)_3TPTZ$

A mixture of TPTZ (0.312 g, 1.00 mmol) and $TbCl_3 \cdot 6H_2O$ (0.265 g, 1.00 mmol) in 15 mL of absolute ethanol was stirred under reflux for 30 min to afford a clear solution. To this mixture was added over 10 min a solution of $KOBu^t$ (0.800 g, 7.130 mmol) and DBM (0.672 g, 3.00 mmol) in 20 mL of absolute ethanol, and the resulting mixture was stirred at 50 °C for 1 h, and then at room temperature for an additional 30 min. Ethanol was removed under vacuum, and the residue was washed with copious de-ionized water. The crude product thus obtained was dissolved in a minimum amount of chloroform, and the solution was dried over anhydrous $MgSO_4$. The filtrate was collected, from which a yellow solid was obtained upon removal of the solvent. Upon recrystallization from ethanol/chloroform (v/v 2:1), analytically pure product was obtained as a yellow crystalline solid (0.73 g, 64.0%). *Anal.* Calc. for $C_{63}H_{45}N_6O_6Tb$: C, 66.32; H, 3.98; N, 7.36. Found: C, 66.44; H, 3.96; N, 7.08%.

2.2. Synthesis of Er(DBM)$_3$TPTZ

This compound was prepared by starting with $ErCl_3 \cdot 6H_2O$ (0.382 g, 1.00 mmol) and adopting otherwise identical preparative and purification procedures to those for Tb(DBM)$_3$TPTZ. The product was obtained as a pale yellow crystalline solid (1.02 g, 88.8%). *Anal.* Calc. for $C_{63}H_{46}N_6O_{6.5}Er$: C, 65.32; H, 4.00; N, 7.25. Found: C, 65.45; H, 4.33; N, 7.28%.

2.3. Synthesis of Eu(BA)$_3$TPTZ

A mixture of TPTZ (0.312 g, 1.00 mmol) and $EuCl_3 \cdot 6H_2O$ (0.366 g, 1.00 mmol) in 20 mL of absolute ethanol was stirred at 50 °C for 10 min to afford a clear solution. To this mixture was added with stirring a solution of $KOBu^t$ (0.600 g, 5.347 mmol) and BA (0.487 g, 3.00 mmol) in 15 mL of absolute ethanol. The resulting mixture was stirred at 60 °C for 0.5 h, and then at room temperature under nitrogen for an additional 1.5 h. Purification of the reaction mixture followed the procedures detailed above for Tb(DBM)$_3$TPTZ. Analytically pure product was obtained as a pale yellow crystalline solid (0.57 g, 60.0%) upon recrystallizing the crude product from ethanol: chloroform:hexane (v/v/v 2:1:1). *Anal.* Calc. for $C_{48}H_{40}N_6O_{6.5}Eu$: C, 60.25; H, 4.11; N, 8.80. Found: C, 60.25; H, 4.34; N, 9.01%.

2.4. Synthesis of Eu(BTFA)$_3$TPTZ

$EuCl_3 \cdot 6H_2O$ was allowed to react with TPTZ as described above. To this mixture was added with stirring a solution of $KOBu^t$ (0.336 g, 3.00 mmol) and BTFA (0.648 g, 3.00 mmol) in 20 mL of absolute ethanol. The resulting mixture was stirred at 60 °C for 30 min, and then at room temperature under nitrogen for an additional 3 h. The mixture was filtered and the solid was washed with copious de-ionized water to remove KCl byproduct. The crude product thus obtained was washed with hexane (3 mL), dissolved in acetone (50 ml), and the solution was dried over anhydrous $MgSO_4$. The filtrate was collected, from which a pale yellow solid was obtained upon removal of the solvent. Recrystallization from ethanol:acetone (v/v 1:1) afforded analytically pure product as a pale yellow crystalline solid (0.63 g, 57.0%). *Anal.* Calc. for $C_{48}H_{30}N_6O_6F_9Eu$: C, 51.95; H, 2.72; N, 7.57. Found: C, 51.56; H, 2.54; N, 7.37%.

2.5. Synthesis of Eu(TTA)$_3$TPTZ

Starting with $EuCl_36H_2O$ (0.366 g, 1.00 mmol) and adopting otherwise identical preparative and purification procedures described for Eu(BTFA)$_3$TPTZ, the product was obtained as a pale yellow crystalline solid (1.00 g, 78.0%). *Anal.* Calc. for $C_{42}H_{24}N_6O_6F_9S_3Eu$: C, 44.72; H, 2.14; N, 7.45. Found: C, 44.38; H, 2.20; N, 7.45%.

2.6. X-ray structure determinations

Single crystals of Tb(DBM)$_3$TPTZ and Er(DBM)$_3$-TPTZ suitable for X-ray diffraction studies were obtained by directly layering their respective saturated chloroform solutions with diethyl ether at room temperature. Single crystals of Eu(BTFA)$_3$TPTZ and Eu(TTA)$_3$TPTZ were produced by slow evaporation of their respective solutions in ethanol:acetone (v/v 1:1), while single crystals of Eu(BA)$_3$TPTZ were obtained from its solution in ethanol:chloroform:hexane (v/v/v 2:1:1).

The crystals were mounted on a glass fiber in a random orientation. Examination of the crystal was carried out on a Bruker SMART 1000 CCD detector X-ray diffractometer at 170(2) K and a power setting of 50 kV, 40 mA. Data were collected on the SMART1000 system using graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). The frames were integrated using the Bruker SAINT [22] software package's narrow frame algorithm, and empirical absorption and decay corrections were applied using the program SADABS [23]. The structures were solved using SHELXS in the Bruker SHELXTL (Version 5.0) software package [22]. Refinements were performed using SHELXL and illustrations were made using XP.

Solution was achieved by using direct methods followed by Fourier synthesis. Hydrogen atoms were added at idealized positions, constrained to ride on the atom to which they are bonded and given thermal parameters equal to 1.2 or 1.5 times U_{iso} of that bonded atom. Details on data collection and structure refinements are given in Table 1.

2.7. Photophysical studies

Electronic absorption spectra in the solid state and chloroform solutions were recorded on a Perkin–Elmer Lambda 10 spectrophotometer. Photoluminescence studies were carried out with a Fluorolog-3 fluorometer. The measured solid-state and solution-phase luminescence for the Tb^{3+} and Eu^{3+} complexes was excited by the light from a Xe-Arc lamp and detected using a photo multiplier tube at an angle of 90° with respect to the incident beam. Near infrared emission spectrum of Er(DBM)$_3$TPTZ was obtained at room temperature by excitation using a 980-nm laser diode (ADC Telecommunications), a grating monochromator, and an InGaAs detector (Thorlabs). A chopper and a lock-in amplifier were used for signal amplification.

Photoluminescence quantum yields were measured and calculated using cresyl violet perchlorate (quantum yield $\varphi = 0.54$ in methanol [24]) and rhodamin 6G ($\varphi = 0.95$ in ethanol [25]) as the standards. Corrections were made for the instrumental parameters and differing refractive indices of the solvents used [26,27]. The relative quantum yields were calculated using the following established equation where Abs, A, and n denote the absorbance at the excitation wavelength, integrated area of the corrected emission

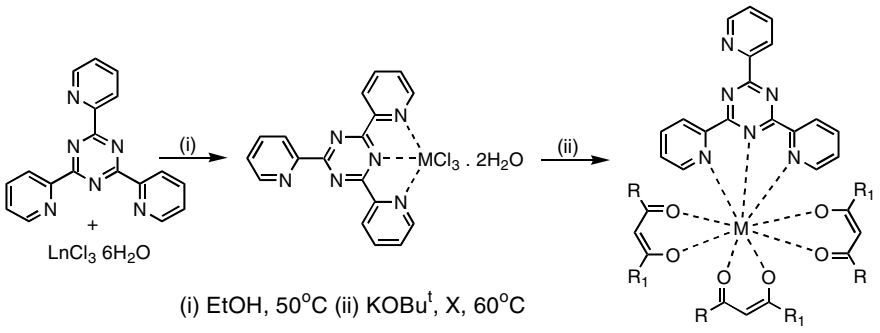
spectrum, and refractive index of the solvent, respectively. Subscript R and S refer to the reference and the unknown sample, respectively [28,29]. The experiments were performed using chloroform solutions ($1–5 \times 10^{-5}$ M) of the title complexes whose absorbance values are less than 0.2. The experimental uncertainty for the quantum efficiency calculations was found to be 10%.

$$\varphi_S = \varphi_R(\mathrm{Abs}_R/\mathrm{Abs}_S)(A_S/A_R)(n_S^2/n_R^2)$$

The stoichiometry of each of the title complexes in the solution phase was evaluated by titration of the specific lanthanide chloride solution ($1–5 \times 10^{-5}$ M) with TPTZ and the corresponding β-diketone. A stock solution of the ligand was freshly prepared by deprotonation of the β-diketone using a stoichiometric amount of $KOBu^t$. Following each addition of the ligand (both TPTZ and β-diketonate) solution, the integrated emission intensities of the $^5D_0 \rightarrow {}^7F_2$ (for Eu^{3+} at 614 nm) and $^5D_4 \rightarrow {}^7F_5$ (for Tb^{3+} at 544 nm) transitions were monitored. Details of the experiments can be found in Supporting Information. The lanthanide (Eu^{3+} or Tb^{3+}):TPTZ ratio was found to be 1:1, while the ratio of Eu^{3+}:diketonate (BTFA, TTA, or BA) were found to be 1:3. However, the sensitization of Tb^{3+} luminescence by DBM is too weak to allow a reliable determination of the Tb^{3+}:DBM ratio. This finding is consistent with the results, presented below, of the spectroscopic and luminescence studies of $Tb(DBM)_3TPTZ$ in chloroform.



3. Results and discussion

3.1. Synthesis and structural characterization

As noted in our previous work, the Lewis base ligand (TPTZ) is introduced prior to the coordination of DBM, BA, TTA, or BTFA ligands (Scheme 1) to avoid possible adventitious hydrolysis which has been shown to produce unexpected polynuclear oxo/hydro complexes [30]. The pre-occupation of part of the coordination sphere by the rather bulky TPTZ ligand also helps prevent more than three β-diketonate ligands from being incorporated [31]. Thus, electrically neutral and coordinatively saturated complexes were obtained. All compounds were produced in good to excellent yields. They are readily soluble in solvents such as acetone, chloroform, and dichloromethane, but sparingly soluble in alcohols. Product purification by recrystallization from alcohol and one of these solubilizing solvents proved to be facile. Satisfactory microanalysis results (CHN) were obtained for all complexes.

The crystal structures of all five complexes have been established by single crystal X-ray diffraction, and are shown in Figs. 1–5, respectively. Selected metric values of bond distances and angles are summarized in Table 2.

In each of these complexes, the lanthanide ion is situated in a coordination sphere composed of six oxygen atoms of the β-diketonate ligands and three nitrogen atoms of the TPTZ ligand. The coordination polyhedron can be best

described as a distorted square antiprism monocapped by the central coordinating nitrogen atom. The rather crowded coordination environment effectively protects the lanthanide center from any substantial interactions with potentially luminescence-quenching solvent molecules.

The aromatic rings of the TPTZ ligand are nearly coplanar in each of the five complexes. Within the same complex, the Ln–N bond to the central coordinating N is the shortest (indicated in bold face in Table 2), in agreement with our previous observation [12,32] and those made by

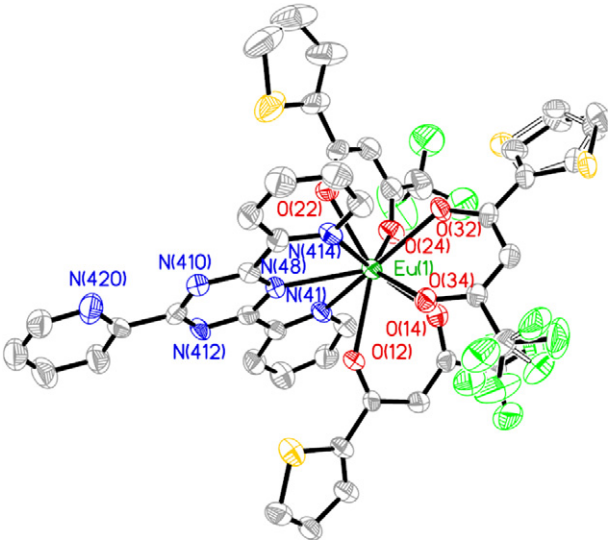

Fig. 3. An ORTEP view of the crystal structure of $Eu(TTA)_3(TPTZ)$ with partial atomic labeling. Thermal ellipsoids are drawn at the 50% probability level.

others [14–16,33]. It is also of interest to note that the Eu–N(central) bonds [2.6757(16) Å for $Eu(DBM)_3TPTZ$; 2.618(11) Å for $Eu(BA)_3TPTZ$; 2.580(7) Å for $Eu(TTA)_3$-TPTZ; 2.607(3) Å for $Eu(BTFA)_3TPTZ$] are all noticeably longer than that of $[Eu(TPTZ)Cl_3(MeOH)_2]$ [2.555(4) Å], the only other Eu–TPTZ complex [14]; the TPTZ ligand is understandably forced further away from the metal center by the bulkier diketonate ligands than if it is in a less coordinatively congested environment. By a similar argument, the presence of a bulky TPTZ ligand causes noticeably longer Eu–O distance (average) in the present adducts than those of closely related complexes with smaller neutral ligands. For example, the average Eu–O distance of $Eu(DBM)_3(TPTZ)$ is 2.384 Å versus 2.348 Å of $Eu(DBM)_3L$ [L = 2-(4′-dimethylaminophenyl)imidazo-[4,5-f]1,10-phenanthroline] [34]; the corresponding value for $Eu(BTFA)_3TPTZ$ is 2.405 Å versus 2.360 Å for $Eu(BTFA)_3(2,2'$-dipyridyl) [35].

The non-coordinating "arm" of the TPTZ ligand in $Eu(BA)_3TPTZ$ and $Eu(BTFA)_3TPTZ$ is close in space to a corresponding arm of a second molecule. As such, π-dimers are formed, with a separation between two TPTZ ligands of 3.155 and 3.285 Å, shown in Figs. 4 and 5, respectively. The formation of such π-dimers raises an interesting question of whether excimers can form in the solid state, a point inviting further investigation.

3.2. Electronic spectroscopic and photoluminescence studies

Electronic spectroscopic and photoluminescence studies have been carried out for the title complexes in both chloroform solutions and the solid state, from which very similar results have been obtained. In addition, luminescence titration experiments utilizing solutions with concentrations comparable to those for the luminescence quantum

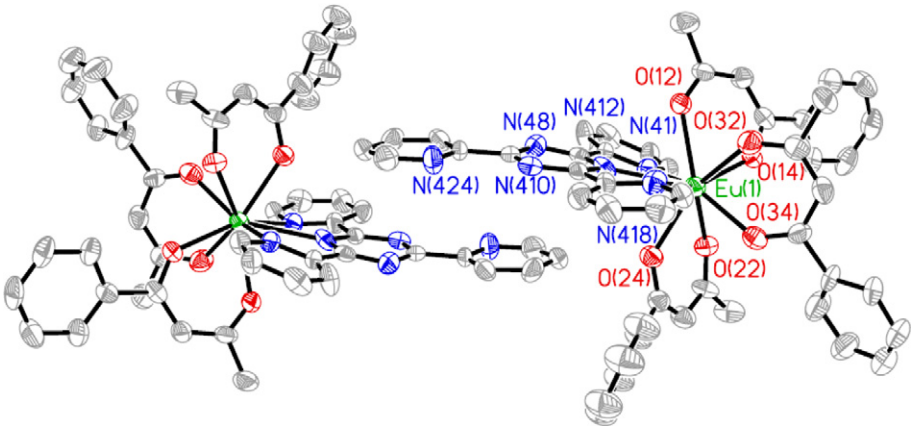

Fig. 4. The TPTZ ligands stack to form a centrosymmetric "dimer" in the crystal structure of $Eu(BA)_3TPTZ$. The closest contact between the TPTZ ligands is 3.155 Å.

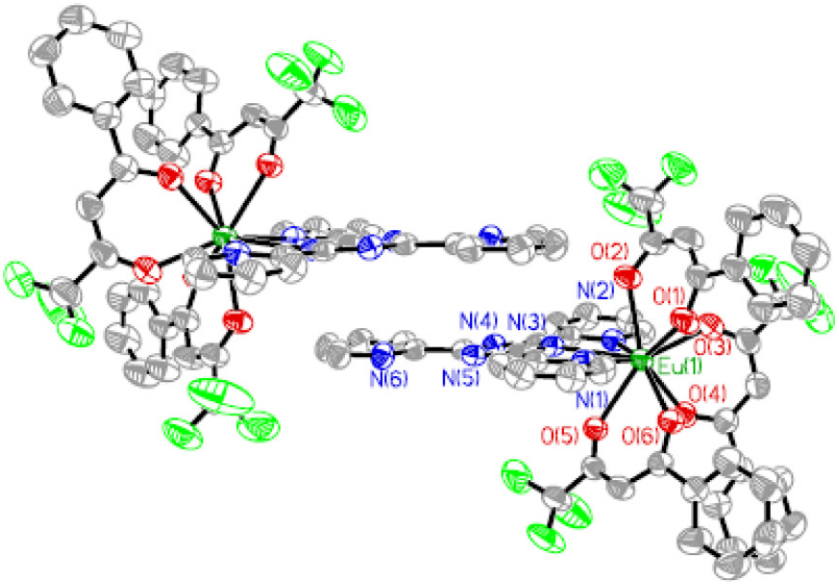

Fig. 5. The TPTZ ligands stack to form a centrosymmetric "dimer" in the crystal structure of $Eu(BTFA)_3TPTZ$. The closest contact between the TPTZ ligands is 3.285 Å.

yield measurements were also conducted. The observed ratio of 1:1:3 (TPTZ:Ln^{3+}:diketonate) is consistent with the molecular and crystal structures of the title complexes. In other words, the complexes remained un-dissociated in solution, even at the relatively low concentrations utilized.

The electronic absorption spectra of $Er(DBM)_3TPTZ$ and $Tb(DBM)_3TPTZ$ in chloroform each show three maxima at 250, 285, and 353 nm, independent of the central lanthanide metal. This observation is consistent with ligand-based absorptions [DBM (250 and 352 nm) and TPTZ (250 and 285 nm)] of these complexes. Complexes $Eu(BA)_3TPTZ$, $Eu(TTA)_3TPTZ$, and $Eu(BTFA)_3TPTZ$ also show ligand-based absorption in the range of 230–385 nm (Supporting Information).

The electronic excitation and photoluminescence of $Tb(DBM)_3TPTZ$, $Eu(BA)_3TPTZ$, $Eu(TTA)_3TPTZ$, and $Eu(BTFA)_3TPTZ$ were also studied in chloroform solutions.

It is clear that the excitation of these complexes is mostly ligand based. The maximum emission of the terbium complex was observed when the complex was excited at 290 nm, suggesting that ligand-to-Tb^{3+} energy transfer is mainly mediated by the TPTZ ligand (Fig. 6). In contrast, the strongest emissions of $Eu(BA)_3TPTZ$, $Eu(TTA)_3TPTZ$, and $Eu(BTFA)_3TPTZ$ were observed when the complexes were excited at 345, 355, and 342 nm, respectively. These excitation wavelengths match the absorption spectra of the corresponding β-diketonate ligands [12] (Supporting Information), suggesting that energy transfer originates from the β-diketonate ligands to Eu^{3+} ion. Only the excitation and emission spectra of $Eu(BA)_3TPTZ$ are shown in Fig. 7 as representatives. Those for $Eu(TTA)_3TPTZ$ and $Eu(BTFA)_3TPTZ$ are deposited in Supporting Information. These observations are in line with the commonly accepted notion of "antenna effect" for lanthanide luminescence [36,37].

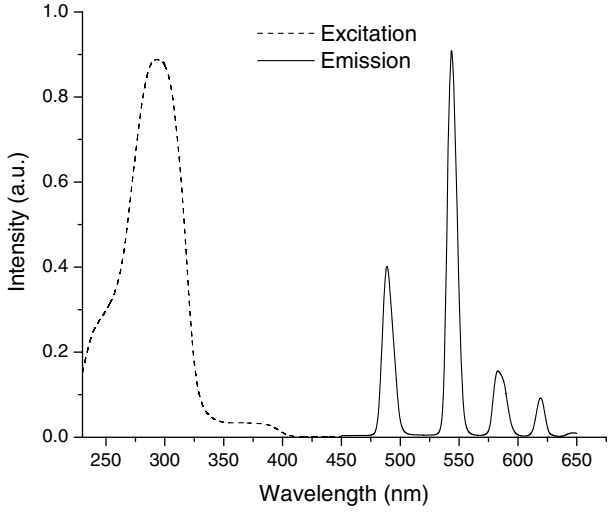

Fig. 6. The excitation (---) and emission (—) spectra of $Tb(DBM)_3TPTZ$ in $CHCl_3$.

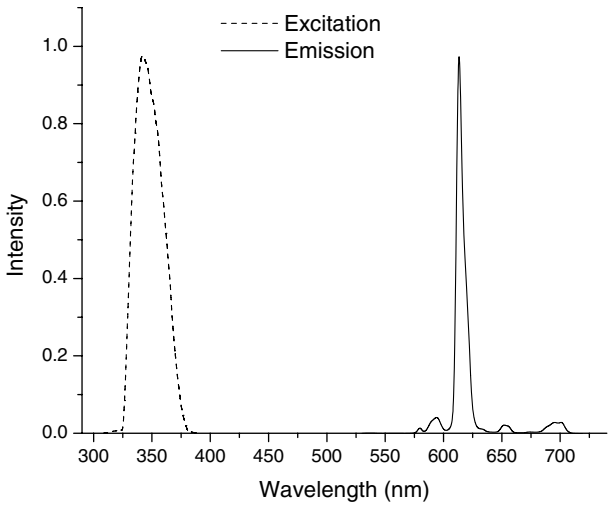

Fig. 7. The excitation (---) and emission (—) spectra of $Eu(BA)_3TPTZ$ in $CHCl_3$.

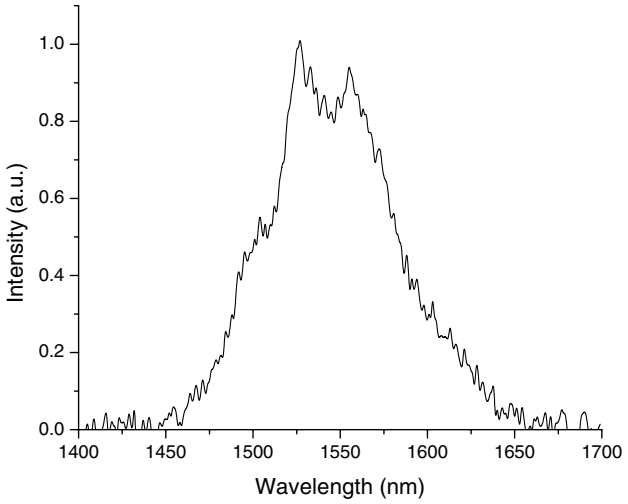

Fig. 8. The emission spectrum of $Er(DBM)_3TPTZ$ in $CHCl_3$.

The photoluminescence quantum yields of $Tb(DBM)_3$-TPTZ, $Eu(DBM)_3TPTZ$, $Eu(BA)_3TPTZ$, $Eu(TTA)_3TPTZ$, and $Eu(BTFA)_3TPTZ$ were found to be 3.4%, 17.4%, 15.5%, 40.2%, and 69.7% respectively. As expected, these lanthanide β-diketonate adducts with TPTZ display higher emission quantum yields than their aqua analogs [17,38]. In terms of photoluminescence quantum yield, $Eu(BTFA)_3$-TPTZ is among the most efficient Eu^{3+} complexes that are without substitution of H for D.

When the chloroform solution of $Er(DBM)_3TPTZ$ was excited by a 980-nm pump laser, near infrared emission, shown in Fig. 8, was observed. The maximum intensity peak is located at 1527 nm, assigned to $^4I_{13/2} \rightarrow {}^4I_{15/2}$, with a full width at half-maximum (FWHM) of about 81 nm. The value is greater than those of erbium-doped phosphate glass (55 nm) [39] and an erbium complex doped in epoxy resin polymers (47 nm) [40], but comparable to those of erbium polydentate cage complexes (70 nm) in organic solutions [41] and erbium tris(8-hydroxy)quinoline (73 nm) doped in sol–gels [20]. A broad spectrum enables a wide gain bandwidth for optical amplification in telecommunication systems.

4. Conclusion

Several new lanthanide β-diketonate adducts with the neutral ligand TPTZ were synthesized and their structures were established using single crystal X-ray diffraction. In each case, the lanthanide center is coordinatively saturated with three β-diketonate ligands and a TPTZ ligand. π–π interactions involving TPTZ ligands were observed with the formation of dimers of both $Eu(BA)_3TPTZ$ and $Eu(BTFA)_3TPTZ$. Photoluminescence studies confirmed that excitation of the complexes is originated from the ligand absorption of photons, and the emission is characteristic of the lanthanide ion of the complex. It is likely that the bulky TPTZ ligand enhances the luminescence efficiency of the title complexes over their aqua species by effectively shielding the lanthanide ions from interacting with luminescence-quenching solvent molecules.

Furthermore, the use of volatile and/or toxic organic solvents is considered to be undesirable from the green chemistry point of view. Thus, solvent-free reactions or reactions carried out in innocuous solvents are thought to provide an environmentally friendly route to chemical synthesis. From this standpoint it will be highly desirable to find ways in which water can be used as a reaction medium. Herein, we describe the preparation and characterization of a tetrameric cubane complex of cobalt(III), viz. $Co_4^{III}(\mu_3\text{-}O)_4(\mu\text{-}O_2CCH_3)_4(4\text{-}CNpy)_4$ (**I**) which homogeneously catalyses the oxidation of *p*-xylene under mild conditions with molecular oxygen as the oxidant in aqueous media.

2. Experimental

2.1. Materials and methods

All materials used in this work were obtained from commercial sources and used without further purification. $Co(NO_3)_2 \cdot 6H_2O$, sodium acetate and hydrogen peroxide were obtained from E. Merck (India), 4-cyanopyridine was purchased from Aldrich (USA) and *p*-xylene was purchased from SRL (India). Methanol used was of reagent grade. C, H, N analysis was performed using a Perkin–Elmer 2400 CHNS/O Analyser, while the determination of the cobalt content was done by standard gravimetric procedure. UV–Vis spectrum was recorded on a Hitachi U-3210 spectrophotometer. Infrared spectra of the complex in the mid-IR region (4000–450 cm^{-1}) were recorded using a Perkin–Elmer RX1 FT-IR spectrophotometer for KBr pellets. The ^1H NMR spectrum of compound **I** was recorded using a Bruker 400 MHz instrument. Tetramethylsilane (TMS) was used as an internal standard. Chemical shifts reported are in parts per million (ppm) taking the TMS signal as 0.00. A Bruker Daltonics Esquire 300 Plus ESI instrument was used to obtain the mass spectrum.

Cyclic and differential pulse voltammetric measurements were performed using an EG&G PAR model 253 VersaStat potentiostat/galvanostat (with electrochemical analysis software 270) having a three-electrode setup consisting of a glassy carbon working, platinum wire auxiliary and a saturated calomel reference electrode (SCE). All electrochemical studies were carried out at room temperature using TBAP as the supporting electrolyte dissolved in dichloromethane at a concentration 50 times higher than that of complex **I**. The sample solutions were purged with and kept under an atmosphere of N_2. The $E_{1/2}$ values quoted for the CV experiments correspond to the midpoints of the forward (anodic, E_{pa}) and reverse (cathodic, E_{pc}) peak potentials [$E_{1/2} = (E_{pc} + E_{pa})/2$]. The reversibility of the redox couples was determined from peak-to-peak separations [$\Delta E_p = E_{pa} - E_{pc}$] observed and by estimating the ratio of the cathodic peak current (i_{pc}) and anodic peak current (i_{pa}) at various scan rates (v). The stoichiometry of the electron transfer processes was determined from the peak current measurements and by comparing the results with data obtained for related systems using ferrocene as a standard [9].

2.2. Preparation of $Co_4^{III}(\mu_3\text{-}O)_4(\mu\text{-}O_2CCH_3)_4(4\text{-}CNpy)_4$ (**I**)

$Co(NO_3)_2 \cdot 6H_2O$ (2.91 g, 10 mM) and sodium acetate (2.72 g, 20 mM) are stirred in methanol (30 mL) and then 4-cyanopyridine (1.04 g, 10 mM) is added to the solution. The stirred reaction mixture is then heated to boiling and 30% hydrogen peroxide (2 mL, 20 mM diluted with MeOH to 10 mL) is slowly added drop wise into it. Stirring under reflux is continued for 4 h. The cooled reaction mixture is filtered and concentrated to ca. 15 mL. CH_2Cl_2 (30 mL) is added to the concentrated solution whereupon a light pink aqueous layer separates out on top. The green dichloromethane layer is separated and petroleum ether (60–80° fraction) is added into it to obtain an olive green product. The product is dried in a vacuum desiccator over fused calcium chloride. Yield: 1.24 g (~52%). Analysis for $C_{32}H_{28}N_8O_{12}Co_4$, *Anal.* Calc.: C, 40.36; H, 2.96; N, 11.77, Co, 24.75. Found: C, 40.73; H, 3.03; N, 11.92; Co, 24.46%. Electronic spectra [λ_{max} (CH_2Cl_2), nm (ε, $M^{-1}\,cm^{-1}$)]: 634 (sh), 445 (8017), 362 (sh), 259 (22 500). IR spectral data [ν_{max}/cm^{-1}, (KBr)]: –C≡N stretch: 2250; ν_{asym} (COO^-), 1533; ν_{sym} (COO^-), 1411; pyridyl ring stretches, 1611, 1492; μ_3-oxo-bridge, 634. ^1H NMR data [δ/ppm (DMSO-D_6)]: 8.56 (d, $J = 6.2$ Hz, 8H), 7.69 (d, $J = 6.1$ Hz, 8H), 1.93 (s, 12H). ESI-MS data (m/z): 953 (M^+), 849 ('M^+−4-CNpy', most intense peak).

2.3. Conversion of p-xylene to p-toluic acid

All reactions were carried out in a medium pressure batch reactor supplied by BERGHOF GmbH, Germany with reaction vessel capacities ranging from 75 to 250 mL. It is electronically controlled with an external heating system and has internally stirring magnetic devices. The experimental temperature is also maintained electronically.

A mixture of *p*-xylene, water and the catalyst were taken in a PTFE container. This was then put into the reactor. The reactor was closed and then oxygen was purged through it. Desired O_2 pressure was applied from an O_2-cylinder and the temperature of the reaction mixture was raised to 130 °C. The reaction was carried out for 4 h at this temperature. The reaction mixture was stirred continuously during the course of the reaction. When the reaction time was over, (time period counts from the moment the reactor reaching 130 °C to the moment the heating was switched off) the reactor was allowed to cool down to room temperature without any help of cooling device.

After completion of the reaction, the reaction mixture was taken out from the reactor. It was extracted out with diethyl ether and water. The product *p*-toluic acid contained in the organic layer was separated and the solvent

was removed by rotary vacuum evaporation and finally by using a high vacuum pump to remove the last traces of volatile liquids. The product so obtained was weighed to determine the percentage yield on the basis of moles of *p*-xylene used and *p*-toluic acid obtained. Formation of terephthalic was detected and estimated by isolating and analysing the solid residue left in the PTFE container after solvent extraction.

3. Results and discussion

3.1. Synthesis and characterization of $Co_4^{III}(\mu_3\text{-}O)_4(\mu\text{-}O_2CCH_3)_4(4\text{-}CNpy)_4$ (I)

The tetrameric cobalt(III) complex has been prepared by oxidizing cobalt(II) ions in the presence of the nitrogen base ligand 4-cyanopyridine and acetate ion.

$$Co^{2+} + CH_3CO_2^- + 4\text{-CNpy} \xrightarrow[MeOH]{H_2O_2} Co_4^{III}(\mu_3\text{-O})_4(\mu\text{-O}_2CCH_3)_4(4\text{-CNpy}_4)$$

The substituted pyridine ligand stabilises the higher oxidation state of the metal. Although a dark olive green complex can be isolated from the concentrated reaction mixture, the isolated yield of the product is relatively low due to its high solubility in the solvent system used. However, isolation of complex **I** via precipitation by adding petroleum ether to a CH_2Cl_2 extract of the reaction mixture leads to a much higher yield without affecting the purity of the product.

The complex has been studied by infrared and UV–Vis spectroscopy. In the KBr phase IR spectrum of complex **I** it is possible to identify bands due to the bridging acetate anions as well as for the pyridyl N-bound 4-cyanopyridine ligands. The asymmetric –COO stretching (ν_{asym}) and symmetric –COO stretching (ν_{sym}) bands appear at 1531 cm^{-1} and 1411 cm^{-1}, respectively. The separation of the asymmetric and symmetric stretching vibrations ($\nu_{asym} - \nu_{sym} = \Delta\nu = 120\ cm^{-1}$) of the carboxyl group is consistent with this ligand bonding in a bridging fashion. A weak but sharp band at 2250 cm^{-1} indicates the presence of 4-cyanopyridine ligand in the complex.

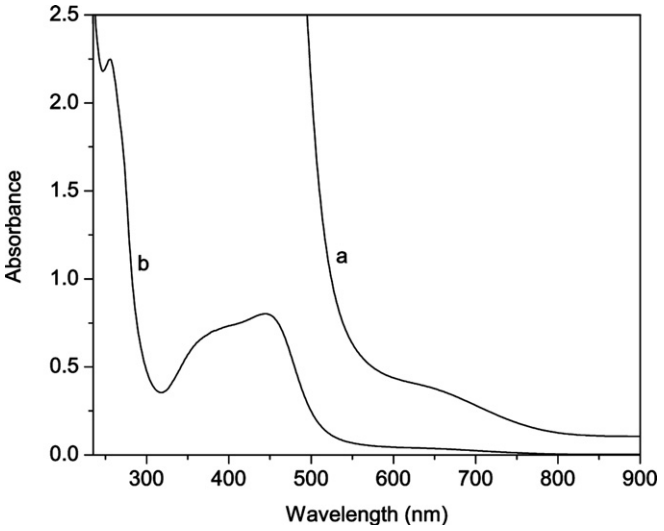

Fig. 1. UV–Vis spectrum recorded for $Co_4^{III}(\mu_3\text{-O})_4(\mu\text{-O}_2CCH_3)_4(4\text{-CNpy})_4$ (**I**) at two different concentrations in CH_2Cl_2: (a) 10^{-3} M; (b) 10^{-4} M.

The UV–Vis spectrum of complex **I** is shown in Fig. 1. The spectral band at 634 nm is likely to be due to a spin allowed d–d transition, while the stronger absorption at

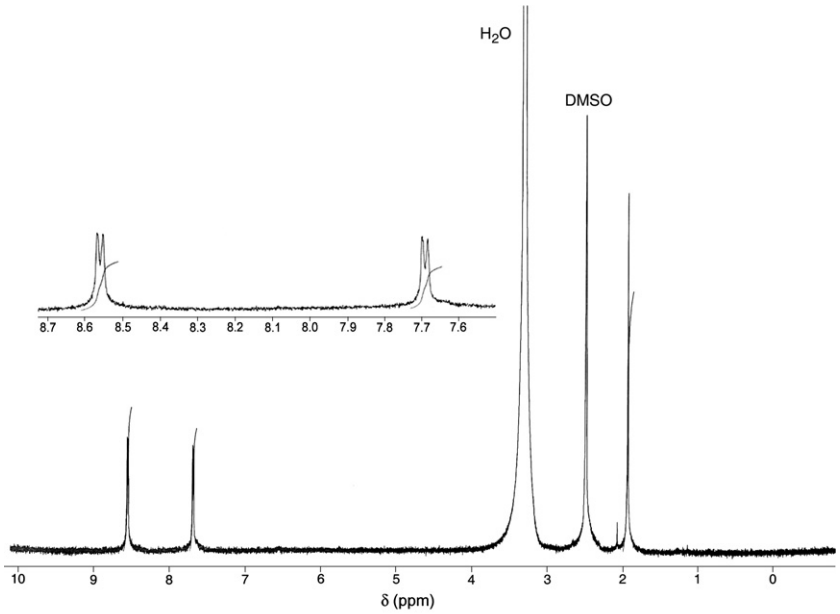

Fig. 2. ^1H NMR spectrum recorded for $Co_4^{III}(\mu_3\text{-O})_4(\mu\text{-O}_2CCH_3)_4(4\text{-CNpy})_4$ (**I**) in DMSO-D_6.

445 nm having a shoulder at 362 nm is likely to have its origin in charge transfer transitions of the MLCT type. Based on X-ray crystallographic studies on related complexes prepared under similar conditions in this laboratory [9,10] it appears likely that complex **I** has four cobalt atoms along with four oxygen atoms occupying the alternate corners of an approximate cube and thus this complex belongs to the class of compounds commonly referred to as 'cubane clusters' [11]. All four cobalt atoms are in the +3 oxidation state to result in a diamagnetic compound for the d^6-Co^{3+} system. The diamagnetic nature is shown up in the ^{1}H NMR spectrum recorded for complex **I** dissolved in DMSO-D_6 (Fig. 2). Apart from the signals due to the residual DMSO and water admixed with it, there is one sharp singlet at 1.93 ppm due to the methyl group of the acetato ligand and in addition, a pair of sharp doublets centred at 8.56 and 7.69 ppm are observed as expected for the pyridyl ring of 4-cyanopyridine. This suggests that complex **I** also has a similar molecular structure with $[Co_4(\mu_3\text{-}O)_4(\mu\text{-}O_2CR)_4(py)_4]$ with R = CH_3 and C_6H_5 [9]. This formula is also supported by elemental analysis. Conclusive evidence regarding the tetrameric formula of complex **I** comes from the appearance of an intense peak corresponding to the *m*/*z* value 953 in the electrospray ionization mass spectrum (ESI-MS). This peak is assigned to the molecular ion peak for complex **I**. Based on experimental evidences given above, we believe that the molecular structure of $[Co_4(\mu_3\text{-}O)_4(\mu\text{-}O_2CCH_3)_4(4\text{-}CNpy)_4]$ is as shown in Fig. 3.

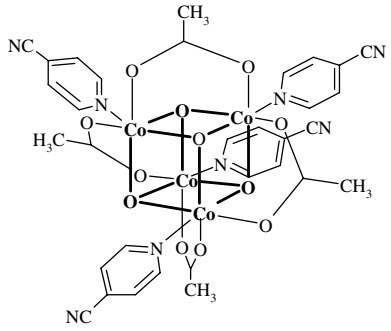

Fig. 3. Proposed molecular structure of $Co_4^{III}(\mu_3\text{-}O)_4(\mu\text{-}O_2CCH_3)_4(4\text{-}CNpy)_4$ (**I**).

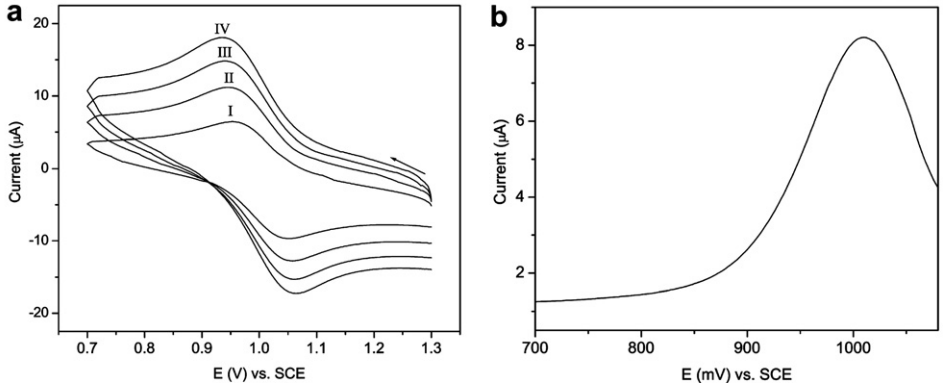
Electrochemical properties of the tetrameric oxo-bridged complex **I** have been studied by cyclic and differential pulse voltammetric techniques using a three electrode assembly. The results are shown in Fig. 4.

Electrochemical studies on $Co_4^{III}(\mu_3\text{-}O)_4(\mu\text{-}O_2CCH_3)_4(4\text{-}CNpy)_4$ (**I**) show a one-electron oxidation process with $E_{1/2} = 1.003$ V and $\Delta E_p = 90$ mV versus SCE at 5 mV s^{-1}. No other notable electrochemical response was observed in the potential range −1.3 to +1.3 V. The electron transfer process is quasireversible in nature as judged from the high ΔE_p values as well as from the dependence of the peak-to-peak potential separation on scan rate ($\Delta E_p = 128$ mV at 20 mV s^{-1}). The differential pulse voltammetric study also shows a single redox response with a peak potential of 1.02 V, which is close to the value obtained with cyclic voltammetry. Based on results published [12] for related systems, it is believed that the following couple involving the tetrameric Co_4O_4 core in complex **I** gives rise to the redox activity

$$[Co_4^{III}(\mu_3\text{-}O)_4]^{4+} \overset{-e}{\underset{+e}{\rightleftharpoons}} [Co_3^{III}Co^{IV}(\mu_3\text{-}O)_4]^{5+}.$$

3.2. Catalytic oxidation of p-xylene

Production of terephthalic acid from homogeneous liquid phase oxidation of *p*-xylene is an industrially important reaction. A large number of investigations have been carried out to refine the process as well as to understand the kinetics and mechanism of the important industrial reaction. Cobalt salts or their combinations with activators and/or co-catalysts are commonly used as catalysts. Almost all the commercial processes use acetic acid as solvent for the oxidation of methyl substituted benzene. One of the problems of current manufacturing processes for terephthalic acid is the corrosive medium (acetic acid, Co, Mn and Br) in which the reaction takes place [4]. In view



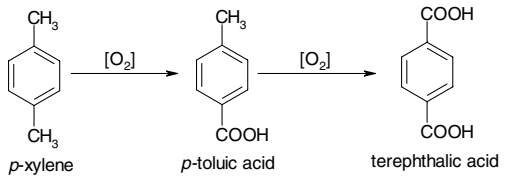


Fig. 4. Cyclic voltammograms for $Co_4^{III}(\mu_3\text{-}O)_4(\mu\text{-}O_2CCH_3)_4(4\text{-}CNpy)_4$ (**I**) in CH_2Cl_2–0.2 M TBAP: (a) at scan rates [I] 5, [II] 10, [III] 15, [IV] 20 mV s^{-1}; (b) Differential pulse voltammogram of **I** at 5 mV s^{-1}.

of various environmental issues, research on the development of catalysts for such processes is still live and relevant.

In absence of a promoter cobalt-catalysed autoxidation of *p*-xylene is a sluggish process because the methyl groups in the intermediate, i.e., *p*-methylbenzoic (*p*-toluic) acid are deactivated by the electron withdrawing nature of the carboxyl group and thus the remaining methyl group is particularly resistant to further oxidation. Even in presence of bromide ion promoter which significantly affects the kinetics of the reaction, faster rates are observed only at high temperatures (typically at ~200 °C). Cobalt(II) acetate alone in catalytic concentrations is a poor catalyst for one-step oxidation of *p*-xylene to terephthalic acid in most solvents. It is also relevant to note here that an inordinately long induction period is often observed in the catalytic conversion of *p*-xylene to terephthalic acid because the Co(II) to Co(III) oxidation is a slow process.

In view of the above facts, it is important to investigate if a cobalt(III) catalyst such as complex **I** can be used as a catalyst for the oxidation of *p*-xylene. We studied the effect of pressure and catalyst concentration on *p*-xylene oxidation using water as a solvent to find that *p*-toluic is the principal product with terephthalic acid forming only in traces (~1%). Our results on the homogeneous catalysis of the oxidation of *p*-xylene by dioxygen are presented below under two separate headings.

3.3. Effect of pressure

The effect of pressure was studied at applied pressures of 10, 15, 20 and 25 bar, the actual pressure during the reaction being ~5 bar higher than the initially applied pressure in each case. The data are presented in Fig. 5. It is found that the formation of *p*-toluic acid form terephthalic acid is linearly dependent on applied pressure. The amount of *p*-toluic acid increases with increase of pressure (Fig. 4).

3.4. Effect of catalyst concentration

Effect of catalyst concentration was investigated at 130 °C under the reaction pressure of 20 bar. Highest yield of the product, *p*-toluic acid is obtained at the maximum catalyst concentration. As evidenced by the linear increase of product yield with increasing catalyst concentration (Fig. 6), the reaction is likely to follow first order kinetics with respect to catalyst concentration.

Although the formation of terephthalic acid could be observed only in very low yield, keeping in view the fact that the reaction is carried out without addition of any promoter, it is still a significant result from the fact that at least the first oxidation step is occurring in a selective manner. Our results are also interesting in view of the fact that the reactions are carried out in the environmentally benign solvent water.

Effect of added water on the rate of *p*-xylene oxidation by cobalt(II) and manganese(II) catalysts has been addressed by other authors [13]. On the other hand, Higashijima [14] reported a ruthenium-substituted heteropolyanion $[SiW_{11}O_{39}Ru^{III}(H_2O)]^{5-}$, which is very active as a water soluble catalyst for the oxidation of *p*-xylene to terephthalic acid at 200 °C. This reaction was also found to

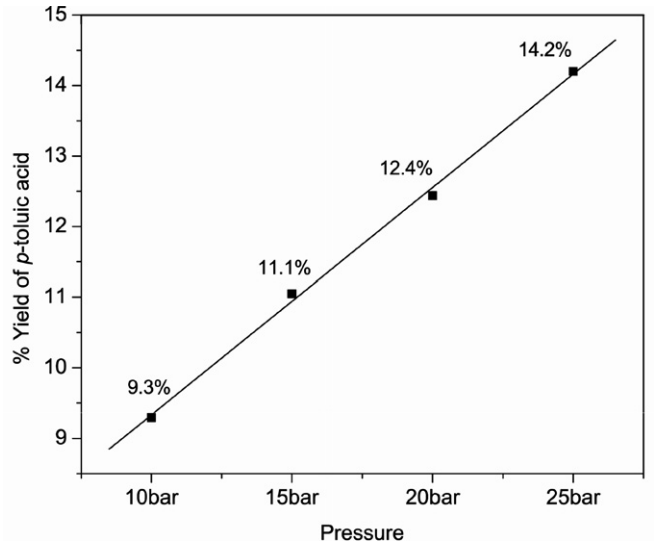

Fig. 5. Effect of pressure on *p*-toluic acid formation catalysed by $Co_4^{III}(\mu_3\text{-}O)_4(\mu\text{-}O_2CCH_3)_4(4\text{-}CNpy)_4$ (**I**) in water. [*Conditions*: *p*-xylene = 2 mL (16 mmol); H_2O = 48 mL; amount of catalyst = 0.05 g; oxidant, O_2; T = 130 °C; reaction time = 4 h.]

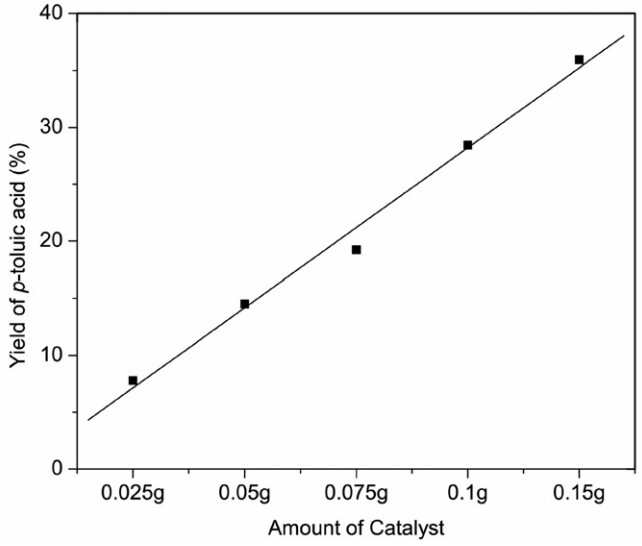

Fig. 6. Effect of catalyst concentration on toluic acid formation catalysed by $Co_4^{III}(\mu_3\text{-}O)_4(\mu\text{-}O_2CCH_3)_4(4\text{-}CNpy)_4$ (**I**) in water. [*Conditions*: *p*-xylene = 2 mL (16 mmol); H_2O = 48 mL; pO_2 = 20 bar; oxidant, O_2; T = 130 °C; reaction time = 4 .]

give *p*-toluic acid as a co-product. Water has also been suggested as a viable medium for terephthalic acid synthesis at 300 °C by Dunn et al. [15]. At the same time, it also has been the subject of patent literature [16]. Comparing our observations with results described in the published literature, we are led to believe that if complex **I** remains intact at higher temperatures, it may be possible to improve the *p*-toluic acid yield beyond what is being reported here. Formation of terephthalic acid is also likely to become more significant under such conditions.

4. Conclusion

The present work has shown that carboxylate bridged cobalt(III) oxo clusters can be generated by H_2O_2 oxidation of Co(II) in presence of pyridine based ligands. Effectiveness of a cobalt(III) system for homogeneously catalysed oxidation of *p*-xylene by O_2 in aqueous media has been demonstrated. Because the catalyst is appreciably soluble in both water as well as *p*-xylene, it may be assumed that the conversion of the substrate to *p*-toluic acid occurs in the rapidly stirred liquid medium. Electrochemical results described in this paper also suggests that both cobalt(III) and cobalt(IV) may be involved in the catalytic cycle leading to the selective oxidation of *p*-xylene to form *p*-toluic acid as the principal product.

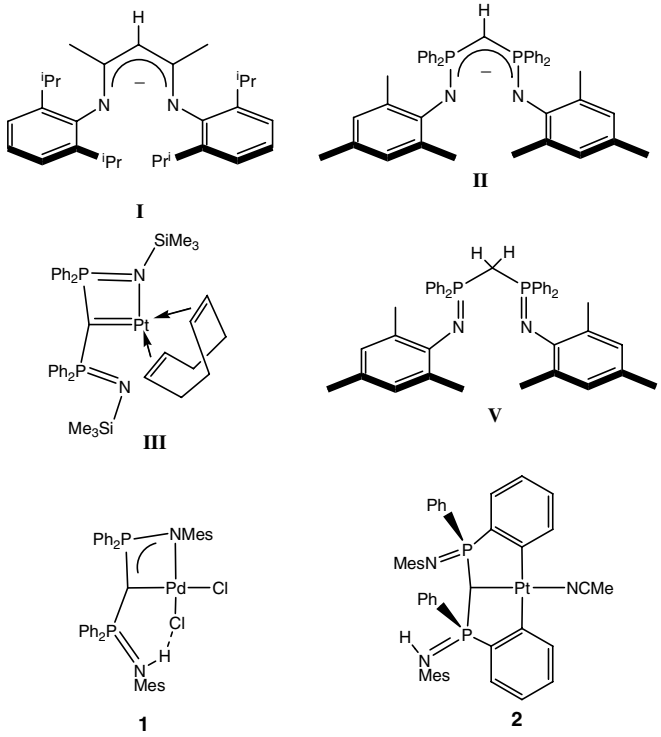

Chart 1.

formation of the singly metallated complex [Pd(**II**)Cl]. The solution spectroscopic data were not however consistent with this, likely, square planar and symmetrical configuration. The ^{1}H NMR spectrum revealed two singlet resonances for each of the *ortho*- and *para*-methyls as well as the *meta*-methine centres of two inequivalent *N*-mesityl substituents. The *P*-phenyl region of the spectrum was also considerably more complex than anticipated. The $^{31}P\{^{1}H\}$ NMR spectrum indicated an unsymmetrical disposition of the bis(phosphinimino)methanide ligand and appeared as an AX pair of doublet signals centred at 39.9 and 27.6 ppm [$^{2}J_{PP} = 15.4$ Hz].

This inference was confirmed by a single crystal X-ray diffraction analysis, which revealed that, although deprotonation of the ligand precursor had occurred under these mild conditions, compound **1** also contained the HCl liberated during the deprotonation process and may be best described as a dichloropalladate(II). The molecular structure of **1** is illustrated in Fig. 1. Details of the X-ray analysis are provided in Table 1, while selected bond lengths and angles are provided in Tables 2 and 3, respectively. Coordination around the palladium centre is approximately square planar. Two of the coordination sites about Pd are occupied by the three-membered chelate provided by the methanide carbon (C1) centre and one of the phosphinimino substituents of the κ-C,κ-N bis(phosphinimo)methanide ligand. The chlorides occupy the two remaining sites. Despite the restricted bite angle of the three-membered N(1)–P(1)–C(1) chelate [N(1)–Pd–C(1),

75.74(8)°], the remaining angles provided by the *cis*-disposed ligands are close to 90°. The Pd–Cl bond distances [Pd–Cl(1) 2.3257(6), Pd–Cl(2) 2.3177(6) Å] are similar despite the increased coordination number of the Cl(2) centre which displays an additional hydrogen bonded interaction to the N(2) proton of the 'free' P(2)–N(2) arm of the chelated ligand. Any effect is probably offset by the relative *trans* influences of the C(1) and N(1) donors.

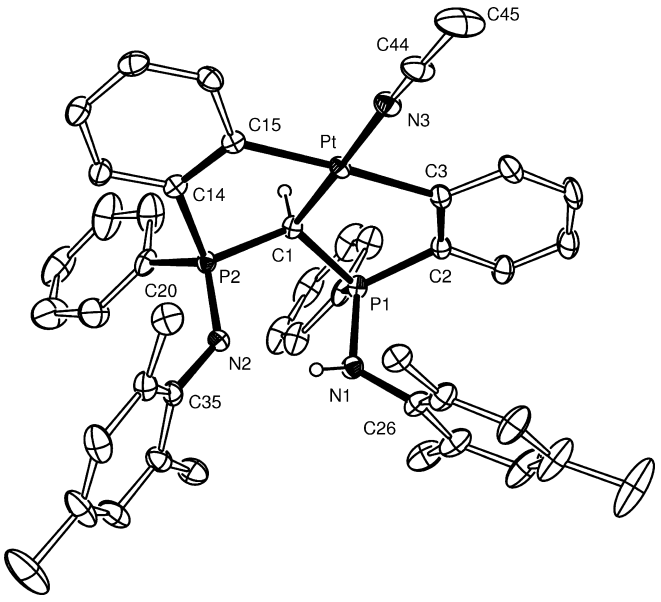
It did not prove possible to enforce any further deprotonation of the C(1) centre within compound **1**, to produce palladium carbenoid species analogous to **III**, either by heating (100 °C) or by addition of an external base (DBU, Et_3N). Monitoring of these reactions by $^{31}P\{^1H\}$ NMRin d_8-toluene indicated either decomposition to complex mixtures of products or no apparent reaction respectively.

Although the directly analogous reaction of **V** and $[PtCl_2(NCMe)_2]$ has not yet yielded identifiable products, reaction of $[Pt(PPh_2Me)Cl(\mu\text{-}Cl)]_2$ and a closely related *N*-tolyl-substituted bis(phosphinimino)methane has been reported by Elsevier and co-workers to produce the similarly *N*,*C*-coordinated complex $[PtCl(PPh_2Me)\{CH(Ph_2PNC_6H_4\text{-}4\text{-}Me)(Ph_2P{=}N(H)C_6H_4\text{-}4\text{-}Me)\}]^+Cl$ [7]. This cation was also formed irrespective of added base and, for this reason, we attempted the alternative methane-elimination route to the platinum carbenoid species illustrated in Scheme 1. Extended heating and NMR (^1H, $^{31}P\{^1H\}$) monitoring of an NMR-scale reaction of $[PtMe_2(COD)]$ and **V** in C_6D_6 indicated that no reaction had occurred. In contrast, a similar reaction performed in d_3-MeCN resulted in the complete disappearance of Pt–Me resonance at 0.63 ppm in the ^1H NMR spectrum after 18 h at 100 °C. These conditions also resulted in the loss of the characteristic methylene triplet of **V** centred at 4.01 ppm and the appearance of a series of resonances consistent with the formation of unligated COD. Attempted ^{31}P NMR monitoring of this reaction at regular intervals over a 7 day period was not informative and revealed only the resonances due to the starting material and several unidentifiable resonances, which, once apparent, did not alter in relative intensity. Upon slow cooling, however, colourless crystals of compound **2** deposited within the NMR tube, and we assume that plausible intermediates (vide infra) are either short-lived or present in too low concentration as to be observable, while the ultimate product, compound **2**, deposits and is depleted from solution as the reaction proceeds and is thus not observed. The crystalline material would not redissolve in d_3-MeCN, but proved to be highly soluble in $CDCl_3$ enabling the full spectroscopic characterisation of compound **2**. Although the $^{31}P\{^1H\}$ NMR spectrum consisted of a single resonance at 46.0 ppm, indicative of symmetrical coordination of the deprotonated ligand, it was apparent that the desired

Scheme 1.

synthesis of a carbenoid species had again been unsuccessful. Compound **2** did not contain coordinated COD and it was clear that the PCH_2P methylene of **V** had not been doubly deprotonated as evidenced by a triplet resonance (1H by integration) at 3.26 ppm ($^2J_{PP} = 9.2$ Hz) in the ^1H NMR spectrum. Attempts to acquire ^{195}Pt NMR data were unsuccessful, most likely due to the anisotropic magnetic environment of the metal centre.

The origin of these solution data was made clear by a single crystal X-ray analysis performed on crystals of compound **2**. The results of this study, illustrated in Fig. 2, were consistent with the solution data and revealed that **V** had undergone a triple C–H activation reaction. Details of the X-ray analysis are provided in Table 1, while selected bond lengths and angles are provided in Tables 2 and 3 respectively. Three coordination sites about the square planar platinum centre are provided by the deprotonated C(1) methanide carbon and two bonds to sp^2 carbon atoms which have been formed by *ortho*-metallation of two of the P-bound phenyl rings. A coordinated molecule of acetonitrile, *trans* to the methanide carbon centre, occupies the remaining coordination site. Charge balance is maintained by protonation of one of the non-coordinated phosphinimine (N1) nitrogen atoms. The resulting chemical inequivalence of the phosphorus nuclei was not, however, apparent in the NMR spectra most likely due to rapid exchange of the proton between the two phosphinimino nitrogen centres and the development of apparent C_2 symmetry. Although the bond lengths and angles within the structure itself are entirely normal and consistent with previously reported Pt(II) alkyl and aryl derivatives [8], and such intramolecular aromatic substitution by late transition metal complexes has been known to occur for over 40 years [9], a transformation of a neutral bis(phosphinimino)methane into a formally trianionic chelate is unique. It is interesting to note that Cavell has reported that **III** underwent thermally initiated *ortho*-metallation of a single *P*-phenyl with concomitant protononation of the carbenoid C=Pt bond [6a]. This latter process occurred diastereoselectively to generate P and C stereocentres with fixed relative absolute configurations and it was speculated that metallation involved the intermediacy of an undetectable platinum(IV) hydride intermediate. The formation of compound **2** occurred with similar diastereoselectivity and, although we have not yet definitively identified any intermediates and a number of viable alternative pathways may be envisaged, it is plausible that **2** results from a similar mechanism (Scheme 2) and the intermediacy of a carbenoid species similar to that depicted in Scheme 1.



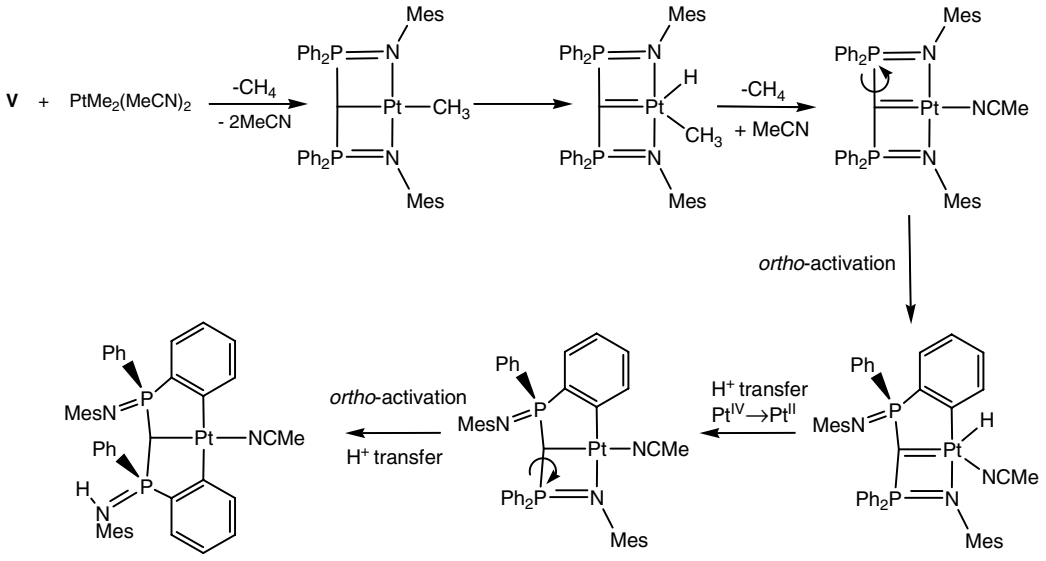


Fig. 2. ORTEP drawing (30% ellipsoids) of compound **2**. Hydrogen atoms except those attached to C1 and N1 removed for clarity.

Scheme 2. Proposed 'carbenoid' pathway to compound **2**.

We are continuing to investigate this hypothesis and will report the outcome of these studies in a future publication.

3. Experimental section

All manipulations were carried out using standard Schlenk and glovebox techniques under an inert atmosphere of either nitrogen or argon. All solvents were distilled under nitrogen and dried with conventional drying agents. NMR spectra were recorded at 270 or 500 (^{1}H), 125.8 (^{13}C) and 202.5 (^{31}P) MHz from samples in either C_6D_6 or d_8-toluene or $CDCl_3$; chemical shifts are given relative to $SiMe_4$. Mass spectra were recorded under fast atom bombardment (FAB) on samples in a matrix of nitrobenzyl alcohol. In spectral assignments Mes = 2,4,6-trimethylphenyl. The ligand precursor **V** was synthesised by a literature procedure [4g].

3.1. Preparation of compound *1*

A solution of **V** (0.25 g, 3.8 mmol), in CH_2Cl_2 (10 cm^3) was added at room temperature to a CH_2Cl_2 (10 cm^3) solution of $[PdCl_2(NCMe)_2]$ (0.1 g, 3.8 mmol), resulting in an immediate colour change from yellow to orange/red. This solution was stirred for 14 h before complete removal of volatiles. The red solid was crystallised from hexane at room temperature to yield **1** as dark red crystals (0.25 g, 79%). Anal. Calc. for $C_{43}H_{44}Cl_2N_2P_2Pd$: C, 62.38; H, 5.31; N, 3.38. Found: C, 62.55; H, 5.50; N, 3.23%. ^{1}H NMR ($CDCl_3$); δ 1.39 (s, 3H, *p-Me*, mesN), 1.54 (s, 3H, *p-Me*, mesN=P), 1.96 (s, 6H, *o-Me*, mesN), 1.99 (s, 6H, *p-Me*, mesN=P), 2.78 (dd, 1H, $^{2}J_{PH} = 14.8$, 1.6 Hz, PC*H*P), 5.25 (s, 1H, N*H*), 6.39 (s, 2H, *m*-C*H*, mesN), 6.39 (s, 2H, *m*-C*H*, mesN=P), 6.80–8.20 (m, 20H, *Ph*–P). ^{13}C NMR ($CDCl_3$): δ −15.5 (dd, $^{1}J_{PP} = 79.2$, 75.5 Hz, P*C*P), 20.4 (*o*-Me), 20.7 (*o*-Me), 20.8 (*p*-Me), 122.1 (d, $^{1}J_{PP} = 93.1$ Hz, *i*–CP), 125.2 (Ar), 125.4 (d, $^{1}J_{PP} = 106.9$ Hz, *i*–CP), 127.9 (d, $J_{PP} = 12.5$ Hz, PhP), 128.1 (Ar), 128.4 (d, $J_{PP} = 11.3$ Hz, PhP), 128.4, 128,7, 128.8 (Ar), 129.5 (d, $J_{PP} = 11.3$ Hz, PhP), 131.8 (d, $J_{PP} = 23.9$ Hz, PhP), 131.8 (Ar), 132.6 (Ar), 132.9 (d, $J_{PP} = 12.0$ Hz, PhP), 133.4 (d, $J_{PP} = 16.3$ Hz), 133.8 (Ar), 134.4 (d, $J_{PP} = 11.0$ Hz, PhP), 135.9 (Ar), 136.3, 136.4 (Ar), 136.7 (d, $J_{PP} = 8.9$ Hz, PhP), 137.8 (Ar). ^{31}P{^{1}H} NMR ($CDCl_3$): δ 27.6 (d, $^{2}J_{PP} = 15.4$ Hz), 39.9 (d, $^{2}J_{PP} = 15.4$ Hz). MS (FAB: *m*/*z*): 792 [2, M^+−HCl], 756 [5, M^+−HCl−Cl], 651 [5], 440 [100], 330 [40], 183 [35], 147 [55].

4. Preparation of compound 2

A mixture and $[PtMe_2(COD)]$ (0.035 g, 0.11 mmol) and **V** (0.070 g, 0.11 mmol) were dissolved in d_3-MeCN and transferred to an NMR tube equipped with a Youngs tap. Initial NMR analysis of the pale yellow solution indicated that no reaction had occurred. The NMR tube was then heated to 100 °C for 18 hours, after which time the Pt–Me signal (0.62 ppm) in the ^{1}H spectrum and the ^{31}P NMR (−17 ppm) signal for V had completely disappeared. Upon standing at room temperature overnight colourless crystals of compound **2** deposited and were isolated by filtration (0.07 g, 70%). A sample for analysis was prepared by grinding and exposure to a dynamic vacuum. Anal. Calc. for $C_{43}H_{43}D_3N_3P_2Pt$: C 60.86, H 4.78, N 4.73. Found: C 60.65, H 4.65, N 4.80. ^{1}H NMR ($CDCl_3$); δ 2.11 (s, 6H, *p-Me*), 2.14 (s, 12H, *o-Me*), 3.26 (t, 1H, $^{2}J_{HP} = 9.2$ Hz, $^{2}J_{HPt} = 54$ Hz, PC*H*P), 6.60 (s, 4H, *m*-C*H,mes*), 6.82 (4, 6H, *o*-C*H*,PhP), 7.16–7.51 (m, 18H, *Ph*–P). ^{13}C NMR ($CDCl_3$): δ 19.9 (*p*-Me), 20.9 (*o*-Me), 30.9 (CHP) 122.3 (Ar), 127.9 (Ar), 128.4 (Ar), 130.8 (Ar), 131.8 (Ar), 136.5. ^{31}P{^{1}H} NMR ($CDCl_3$): δ 46.0. MS (FAB: *m*/*z*): 888 [30, M^+], 844 [10, M^+−d_3-MeCN], 650 [5], 277 [100], 57 [70].

5. Crystal structure determinations

Data for **1** and **2** were collected at 173 K on a Nonius KappaCCD diffractomer, λ(Mo-Kα) = 0.71073 Å. An absorption correction (MULTISCAN) was applied. The structures were solved by direct methods (SHELXS-97) [10] and refined by full matrix least squares (SHELXL-97) [11] with non-H atoms anisotropic and H atoms included in riding mode except for the H atoms on C1 and N1 of compound **1**, and C1 and N1 of compound **2** which were refined.

Our interest is continuation of investigating coordinating properties of Cu(II) with pyridine-2-carboxylate ligand. Until now, aside from the violet form of the formula Cu(2-pca)$_2$ obtained by us earlier [4a], only a few 1:1 mononuclear adducts of bis(pyridine-2-carboxylate)copper(II) [6] have been reported for which structural data are available.

In this work, we present a synthesis, the spectral and magnetic properties, and the X-ray single-crystal analysis of a blue-violet form of Cu(2-pic)$_2$, where 2-pic = pyridine-2-carboxylate. We would like to emphasize that the compound studied is another new complex of copper(II) with pyridine-2-carboxylate structurally and magnetically characterized by us. The anhydrous Cu(pyridine-2-carboxylate)$_2$ prepared directly from picolinic acid was previously obtained by others [7] and the square-planar environment was proposed, but the crystal structure was not determined. This compound was obtained by us using a procedure slightly modified with respect to those described in the literature.

In view of the structural data, it should be expected that exchange interactions between copper(II) ions occur through double out-of-plane carboxylate bridges. Hence, the object of our interest was an investigation of the magnetic properties of this compound and an estimation of the value of the exchange interaction.

Here, we describe the results of spectroscopic and magnetic studies of blue-violet form of Cu(pyridine-2-carboxylate)$_2$ in the light of structure description.

2. Experimental

2.1. Reagents and physical measurements

Starting materials and solvents for the synthesis were obtained commercially and used as received. Metal content was determined using a Carl-Zeiss-Jena atomic absorption spectrophotometer. Elemental analyses were carried out using a Perkin–Elmer elemental analyzer 2400CHN.

Infrared spectra (100–4000 cm^{-1}) were recorded on a Bruker IFS 113v spectrophotometer using KBr pellets, and solid-state electronic spectra (28 000–4000 cm^{-1}) were performed on a Cary 500 spectrophotometer.

The EPR spectra of powder samples were recorded (at 295 and 77 K) on a Bruker ESP 300E spectrometer operating at X-band and equipped with a Bruker NMR gaussmeter ER 035 M and a Hewlett–Packard microwave frequency counter HP 5350B. The EPR parameters were calculated by computer simulation of the experimental spectra of the powder samples using Bruker's WIN-EPR SimFonia Version 1.25.

Magnetic measurements of polycrystalline sample were carried out with a Quantum Design SQUID magnetometer (MPMSXL-5 type). Measurements were recorded at magnetic field of 0.5 T over the temperature range 1.8–300 K. The correction for diamagnetism of the experimental susceptibility was based on subtracting the sample-holder signal and estimating the contribution χ_D from Pascal constants [8]. The effective magnetic moments were calculated from $\mu_{eff} = 2.83(\chi_M T)^{1/2}$ using temperature-independent paramagnetism of 60×10^{-6} cm^3 mol^{-1} for Cu(II).

2.2. X-ray crystallography

All measurements of crystal were performed on a Kuma KM4CCD κ-axis diffractometer [9a] with graphite-monochromated Mo Kα radiation. The crystal was positioned at 65 mm from the KM4CCD camera. Frames (612) were measured at 0.75° intervals with a counting time of 45 s. No absorption correction was applied. Data reduction and analysis were carried out with KUMA DIFFRACTION (Wrocław) programs. The structure was solved by direct methods (program SHELXS97 [9b]) and refined by the full-matrix least-squares method on all F^2 data using the SHELXL97 [9c] programs. Non-hydrogen atoms were refined with anisotropic displacement parameters; hydrogen atoms were included from geometry and were fixed.

2.3. Synthesis

This compound was obtained by us with a procedure similar to those described in literature [7] but modified by us. Copper(II) acetate monohydrate (1 mmol) was dissolved in DMF (40 cm^3) and tetrahydrofuran (THF, 5 cm^3) was added to a solution of picolinic acid (2 mmol) in DMF (20 cm^3). After ca. 30 min of stirring the blue solution was filtered. Single blue crystals suitable for X-ray analysis were obtained by slow evaporation of the solvent.

Anal. Calc. for [$C_{12}H_8N_2O_4Cu$]: C, 46.84; H, 2.62; N, 9.10; Cu 20.65. Found: C, 46.32; H, 2.58; N, 8.95; Cu, 20.79%.

3. Results and discussion

3.1. Description of the structure

Crystallographic parameters are summarized in Table 1 and selected bond distances and angles are listed in Table 2.

The structure of the Cu(2-pic)$_2$ compound with crystallographic numbering is depicted in Fig. 1.

The Cu(2-pic)$_2$ molecule, as a whole, is nearly planar and forms obliquely stacked planes. The copper(II) ion has nearly square-planar coordination with *trans* positioned oxygen and nitrogen donor atoms of two N,O-chelating picolinate ligands (2-pic = pyridine-2-carboxylate) to form a complex involving a five-membered stable chelate ring. The copper(II) ion is slightly deviating from the basal plane (0.02 Å). No unusual bond angles and bond lengths are observed for the coordinated picolinate anion. Both axial and planar Cu–O bond lengths are identical within experimental error (3σ). The Cu–O and Cu–N distances in the basal plane agree well with those found in other square-planar copper(II) complexes [10]. Additionally, there are weak axial interactions between copper

atoms of one plane and carboxylic oxygens of neighboring planes ($Cu\cdots O(2A) = 2.745(8)$, $Cu\cdots O(12B) = 2.770(8)$ Å). Because axial bonding interactions to the copper(II) ion are reported up to 3.3 Å [11] and the angle between the Cu–O(2A) vector and the normal to the equatorial plane, which is the measure of overlap of metal–ligand orbitals, is 0°, the axial interaction must be considered as bonding [12], though the interaction is assumed to be very weak. The spectroscopic evidence supports the axial bonding (see Section 3.2). Therefore, the polyhedron can be described as a tetragonally distorted ($CuN_2O_2O'_2$ chromophore) octahedron, elongated along in the axial direction with a long Cu–O distance, as is expected for apical bond lengths in six-coordinated, strongly tetragonally distorted copper(II) complexes [13]. The most important features of the structure result from the fact that the copper(II) ions

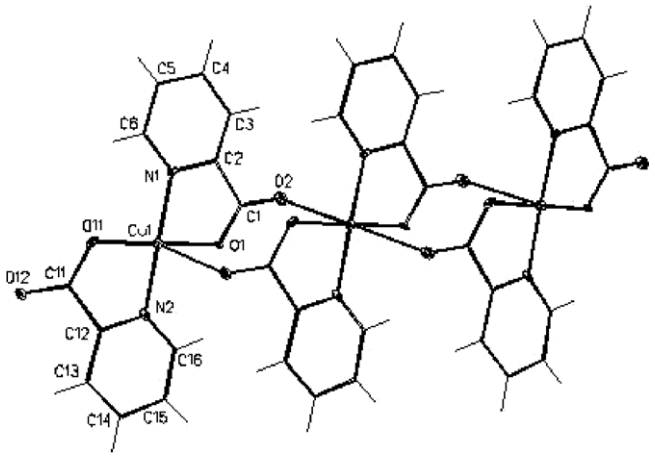

Fig. 1. One-dimensional structure of $Cu(2\text{-pic})_2$ with crystallographic numbering. Cu···Cu distances are 5.163 Å.

are sequentially doubly bridged by carboxylate groups to form an infinite linear one-dimensional polymeric chain extended along the crystallographic x-axis (Fig. 1). The crystal packing is shown in Fig. 2.

Each polymeric chain is linked to other ones by very weak hydrogen bonds C(3)–H(3)···O(2) $(2-x, 1-y, -z)$ [C(3)···O(2) 3.277(13) Å; H(3)···O(2) 2.49 Å; ∠C(3)–H(3)···O(2) 140°] and C(15)–H(15)···O(12) $(1+x, 1/2-y, -1/2+z)$ [C(15)···O(12) 3.162(13) Å; H(15)···O(12) 2.40 Å; ∠C(15)–H(15)···O–(12) 137°]. These bonds

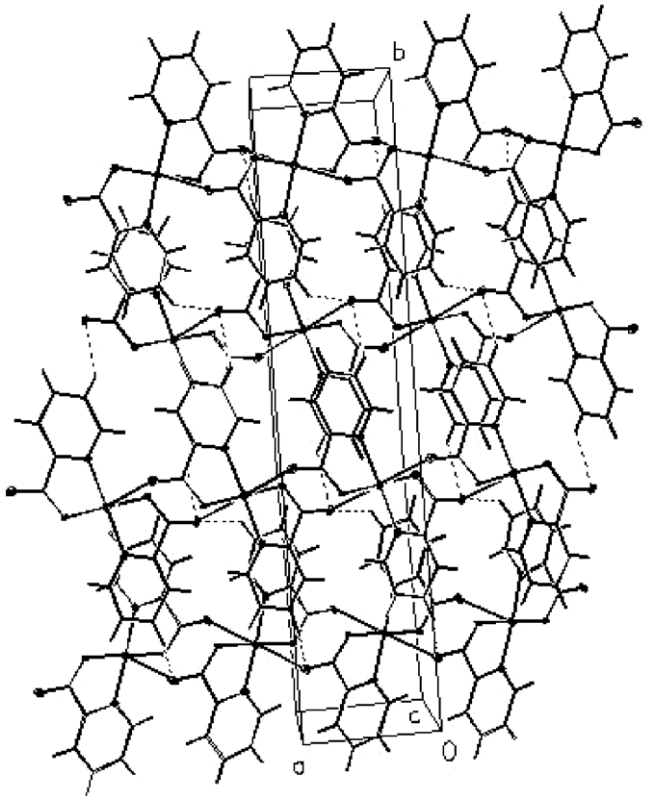

Fig. 2. Crystal packing of $Cu(2\text{-pic})_2$ showing hydrogen bonds (dashed lines).

arise from interaction of a CH from pyridine and an O atom from the carboxylate group. These hydrogen bond interactions, linked in a zigzag chain arrangement, lead to the formation of a 2D sheet structure (Fig. 3a,b). The shortest interchain Cu···Cu separations are 7.43 and 8.09 Å.

As previously noted, each carboxylate group bridges two copper(II) ions through the O(2A) and O(12B) oxygen atoms of the equatorial and the axial position on the copper(II) coordination polyhedron, respectively. This coordination behavior causes the non-planarity of the Cu–O–C–O–Cu′ fragment and gives rise to the formation of a chair-like eight-membered ring Cu–O–C–O–Cu′–O–C–O–Cu with the Cu·Cu distance of 5.163 Å. This distance is near the range of reported values of ca. 5 Å observed for polyatomic bridges [14]. The bridging pathway Cu–O–C–O–Cu′ is asymmetric not only in its conformation but also with respect to Cu–O bond lengths. The intermolecular Cu···Cu distance (5.163 Å) suggests magnetic interactions between the copper(II) centers (see Section 3.3).

3.2. Spectroscopic properties

The IR spectrum of the $Cu(2\text{-pic})_2$ compound shows asymmetric and symmetric stretching vibrations of the coordinated carboxylate groups, $\nu_{as}(COO)$ and $\nu_s(COO)$, at 1649 and 1351 cm^{-1}, respectively. The difference between the two bands, $\Delta\nu$, which gives information on the bonding mode of the carboxylate group [15], is equal for the complex to 298 cm^{-1}, and may suggest a monodentate coordination. Owing to the non-symmetric bonding mode of the carboxylate group, a large splitting ($\Delta\nu$) of the COO stretching frequencies should be expected [15a]. In other words, large $\Delta\nu$ values (>200 cm^{-1}) indicate highly asymmetrical bridging, i.e. a "pseudo-monodentate" coordination, which may be approaching a monodentate coordination. So, the large $\Delta\nu$ value observed in our compound can be viewed as a pseudo-monodentate coordination, which is consistent with the structure. Generally, the number, shape and position of the corresponding absorption bands are strongly affected by some hydrogen bonding interactions of the carboxyl group of pyridine-carboxylate [16]. So, the shoulder observed on the broad band of $\nu_{as}(COO)$ stretch about 1650 cm^{-1}, overlapping with the stretching vibration of $\nu(C{=}N)$ of the pyridine ring, may be responsible for the presence of hydrogen bonding as confirmed by the crystal structure (Fig. 3).

The characteristic band attributed to the out-of-plane ring deformation vibration of the pyridine ring $\delta(C{=}N)$, which occurs for a free ligand at 407 cm^{-1}, is shifted in the complex to a higher frequency (419 cm^{-1}), indicating bond formation between the copper ion and the nitrogen atom of the heterocyclic ring. The bands associated with Cu–N and Cu–O vibrations at 257 and 340 cm^{-1}, respectively, were tentatively assigned on the basis of previous studies of pyridines as N-donor ligands, carboxylate compounds and by comparison with free ligands [17]. For $Cu(2\text{-pic})_2$, where CuN_2O_2 chromophore has *trans* square-planar geometry, only a single band corresponding to Cu–O and Cu–N stretches is observed. However, for the *cis*-isomer two absorption bands would be expected. This is consistent with the criteria published by Herlinger et al. [18] and with the reported crystal structure.

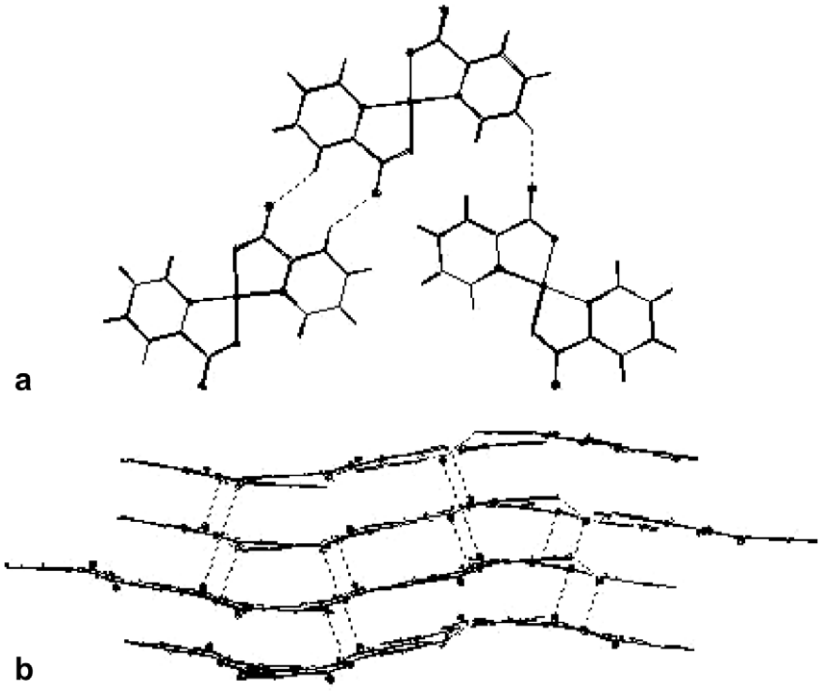

Fig. 3. (a, b) Two views of the 2D sheet structure of $Cu(2\text{-pic})B_2$ showing the sites of hydrogen bonding between the molecules (dashed lines).

The X-band EPR spectrum of a polycrystalline sample of Cu(2-pic)$_2$ (**1**) is of axial type with no hyperfine structure. As a result of a computer simulation procedure (powder spectrum simulation) the following values of the spectroscopic splitting factors were obtained: $g_{\|} = 2.22_8$, $g_{\perp} = 2.05_2$ (Fig. 4). The spectra are independent of temperature. The g-values obtained from the simulations indicate basically a d($x^2 - y^2$) ground state for Cu(II) as observed for other copper–aminoacid complexes [19].

The hyperfine structure expected for Cu(II) ions is not observed, suggesting the existence of exchange interactions coupling the paramagnetic ions [20]. The $g_{\|}$ value is in agreement with that observed for CuN_2O_2 chromophores with strong planar and weaker axial bonds [21].

The ligand-field spectrum shows one broad asymmetric band centered at 16 670 cm^{-1}, characteristic of a tetragonally distorted octahedral with a $CuN_2O_2O'_2$ chromophore [22], consistent with the structural analysis.

3.3. Magnetic properties

Because the results of structural determination of Cu-(2-pic)$_2$ clearly indicate that in this complex there are carboxylate bridging groups through which an exchange interaction may be mediated, we performed a magnetic study of them. In general, the ability of the carboxylate group to propagate exchange interactions between two copper(II) ions separated by more than 5 Å has been well demonstrated [23]. Additionally, because the interchain Cu···Cu separations of 7.43 and 8.09 Å are in the range, up to 11 Å, in which magnetic exchange has been observed [24], a weak exchange interaction mediated by an H-bond system is also expected.

The magnetic properties of the Cu(2-pic)$_2$ were investigated in the temperature range of 1.8–300 K. The magnetic susceptibility results for polycrystalline sample obey the Curie–Weiss law between 25 and 300 K, $\chi = C/(T - \theta)$, where χ is the magnetic susceptibility per copper atom, the Curie constant $C = Ng^2\beta^2S(S+1)/3k$ and $S = 1/2$. The best fit values of the Curie (C) and Weiss (θ) constants are equal to 0.42 cm^3 K mol^{-1} and −1.9 K, respectively. Negative Weiss constant value suggests a weak antiferromagnetic interaction between the copper(II) ions. The temperature variation of χT is depicted in Fig. 5.

The magnetic moment at room temperature (1.83 μ_B) is typical of the normal value for an uncoupled copper(II) system and might suggest the absence of spin exchange, but the χT value decreases slowly with temperature, lowering from 0.418 cm^3 K mol^{-1} at 300 K to 0.291 cm^3 K mol^{-1} at 1.8 K. This suggests the existence of a weak antiferromagnetic exchange between the copper(II) ions at low temperatures.

Taking into account the crystal structure of the compound, the magnetic properties could be explained by the Heisenberg linear-chain model of magnetic interaction arising from the isotropic model $S = 1/2$ described by the Hamiltonian $H = -2J\sum_{i=1}^{n} S_i \cdot S_{i+1}$. The magnetic data were analyzed using the Bonner–Fisher expression [25a], assuming a first-order molecular-field correction to account for the interchain interaction, Eq. (1) [25b]:

$$\chi_{Cu}^{coor} = \frac{\chi_{Cu}}{1 - \frac{2zJ'}{N\beta^2 g^2}\chi_{Cu}} \quad (1)$$

where χ_{Cu} is the susceptibility of copper(II) centers in an isolated Heisenberg chain, $J'$is the interchain exchange, and z is the number of nearest neighbors chains. In the frame of this model, the best-fit parameters obtained by the least-squares fit are the following: $J = -0.73$ cm^{-1}, $zJ' = -0.06$ cm^{-1}, $g = 2.08$ with the value of R=3.93 × 10^{-5}, where R is the agreement factor defined as $R = \sqrt{\sum \frac{1}{(\chi_i^{exp})^2}(\chi_i^{exp} - \chi_i^{calc})^2 / \sum \frac{1}{(\chi_i^{exp})^2}}$

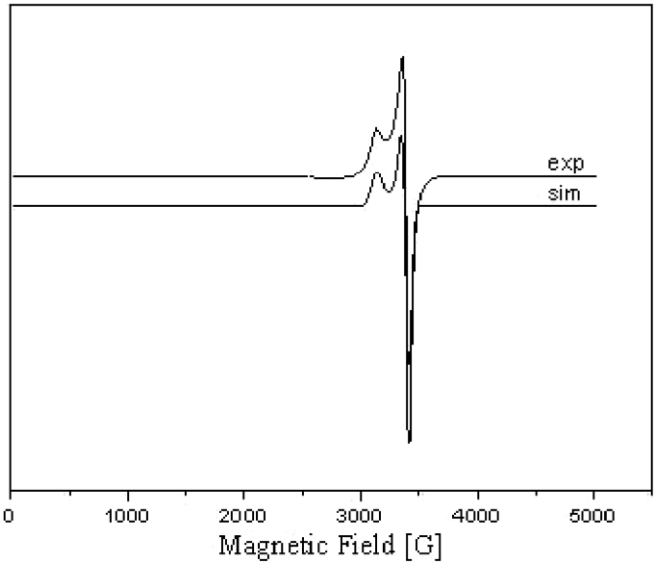

Fig. 4. The experimental EPR powder spectrum of Cu(2-pic)$_2$ obtained at 9.5 GHz (exp) and computer simulation (sim).

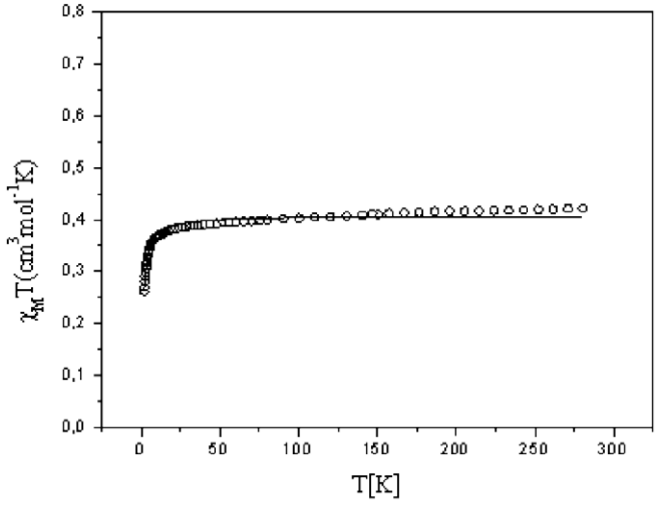

Fig. 5. Plot of $\chi_{Cu}T$ (O) *vs.* T for Cu(2-pic)$_2$. The solid line represents the best fit of the experimental data to the Bonner–Fisher chain model with the parameters reported in the text.

The temperature variation of experimental and calculated values of $\chi_M T$ of the Cu(2-pic)$_2$ is shown in Fig. 5.

3.4. Magneto-structural correlations

Different coordination modes of carboxylato groups lead to the formation of mononuclear and polynuclear structures. From the magnetic point of view, the range of magnetic behaviour as a function of different coordination modes was pointed out, from strongly coupled to moderate or weak antiferromagnetic compounds and even ferromagnetic ones.

For copper(II) complexes, the *syn–syn* conformation mediates strong antiferromagnetic interactions (singlet–triplet separation value $\sim -300\ cm^{-1}$). Weak antiferro- or ferromagnetic interactions are observed in carboxylato-bridged copper(II) complexes in which the carboxylate group adopts the *syn–anti* conformation [4b]. In an *anti–anti* carboxylate bridge, a weak to moderate antiferromagnetic coupling is observed [26].

It is worth noticing that a large number of dinuclear and polynuclear copper(II) geometries, planar or parallel planar, especially those bridged by hydroxide [27] and chloride [28] ions, have been reported. These compounds are often divided into two types (Fig. 6): (i) parallel plane bridging in which the bridging ligands are equatorially bound to both metal ion and (ii) perpendicular plane bridging in which the bridging ligands are axially bound to one metal ion and equatorially bound to the other, characteristic for hydroxo- and chloro-bridged systems, respectively. The carboxylato-bridged compound studied in this work belong to (ii) type, i.e. with a double out-of-plane bridging framework and parallel planar geometry of copper(II) ion.

Generally, magnetic coupling for all known out-of-plane polynuclear compounds is relatively weak, because of the near-orthogonality of magnetic orbitals, as it has been shown for chloro- [28d,29], carbonato- [30] and oximato- [31] bridged compounds. In the case of interactions in apical-equatorial bond modes, the orthogonality of magnetic orbitals leads to a coupling which must be very weakly antiferromagnetic, zero or weakly ferromagnetic.

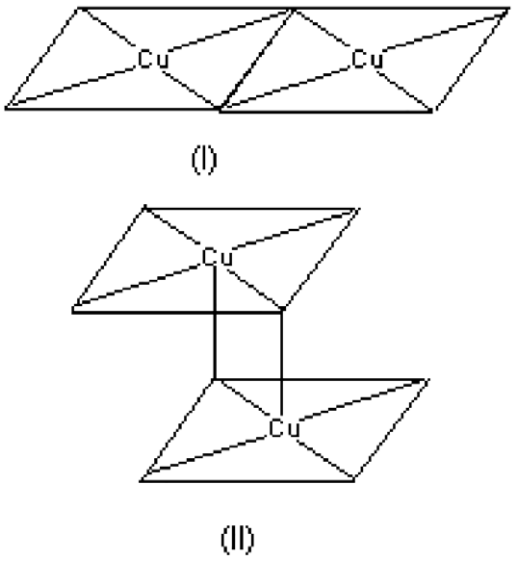

Fig. 6. Relative orientation of the coordination planes in the copper(II) compounds of in the plane (I) and out-of-plane (II) bridging modes type.

It is worthy of note that the weak interaction between copper(II) centers has been previously observed for some carboxylato-bridged complexes (J from ~ 0.5 to ~ -1 cm^{-1}) in which the carboxylate group bridges from the basal to the axial position with a long Cu–O distance (2.28–2.68 Å) [5b]. The value of J is small as expected for this kind of compounds exhibiting an out-of-plane bridging framework.

In the case of the Cu(2-pic)$_2$, the very weak antiferromagnetic coupling observed between the copper atoms is expected in the light of the following electronic and structural features: (i) relatively long Cu–O axial distance, (ii) non planarity of the Cu–O–C–O–Cu′ fragment (an out-of-phase exchange pathway), and (iii) each carboxylate bridge involves an axial position on a copper(II) ion, where the spin density of the unpaired electron is very small, in square-based geometry the unpaired electron is in $d(x^2 - y^2)$. In other words, the bridge links the axial-equatorial coordination sites of the square-planar neighboring Cu(II) centers via both superexchange pathways, and the delocalization of unpaired electron density along the axial coordination site should be very poor, and magnetic orbitals are almost orthogonal. All these features are unfavorable to the propagation of strong interactions.

The magnitude of the interaction in Cu(2-pic)$_2$ is much less than in the di-chlorobridged series [28d,29], because of the greater distance through which exchange effects have to be transmitted in the carboxylate group. The results indicate that the carboxylate group is less effective in allowing for electron spin delocalization than the pathways between ligands and Cu(II) ions involving a chloro-bridge.

In summary, a comparison between the values of J for Cu(2-pic)$_2$ analyzed here and those for out-of-plane single carboxylato-bridged compounds [5b] reveals that the monocarboxylato-bridged series exhibit weaker antiferromagnetic coupling. This is consistent with the simple orbital model proposed by Kahn et al. [32], in which magnetic coupling is proportional to the square of the overlapping integral. So, for mono-out-of-plane bridged copper(II) compounds, the values of coupling constant are smaller due to a decreasing number of the bridging groups.

Finally, although the distance between the donor and the acceptor of C–H···O hydrogen bonds is relatively short, only very weak antiferromagnetic interactions are possible due to large Cu···Cu separations. It is worth of mentioning, that despite large axial Cu–O bond distances, a covalent carboxylate bridge is more effective in allowing for electron spin delocalization than pathways involving non-covalent hydrogen bonds. These results are important in view of the fact that those chemical pathways are present in most metalloproteins.

4. Concluding remarks

In summary, a new example of copper(II) compound (blue-violet form) with the pyridine-2-carboxylate ligand of the formula $Cu(2\text{-pic})_2$ is reported in this paper. We would like to emphasize that the compound here studied and a violet form of $Cu(2\text{-pca})_2$ obtained by us earlier [4a] are the polymorphic forms of Cu(pyridine-2-carboxylate)$_2$.

Two key factors control the crystal structure of $Cu(2\text{-pic})_2$ and provide superexchange paths for magnetic interactions between the copper ions, the bridging coordination and the interchain hydrogen bonds. The hydrogen bonds generate a supramolecular structure and governing stability of the complexes, and have an important role in the magnetism by a further increase in the dimensionality of the overall structure.

Finally, it was interesting to design a new polynuclear copper(II) compound with parallel planar geometry and with an out-of-plane framework of carboxylate bridges.

investigation and the density functional theory (DFT) calculations for the complex [{$ReOBr_4$}(μ-O){$ReO(3,5\text{-}Me_2pzH)_4$}]. The UV–Vis spectrum of the dirhenium complex has been discussed on the basis of the spin-allowed electronic transitions calculated for [{$ReOBr_4$}(μ-O){$ReO(3,5\text{-}Me_2pzH)_4$}] with the time-dependent DFT (TDDFT) method.

Recent calculations with the TDDFT method for open- and closed-shell 5d-metal complexes (including rhenium complexes) have supported the TDDFT method to be applicable for such systems, giving a good assignment of experimental spectra [9–14].

Gancheff and co-workers [15] have performed extended tests of the ability of the B3LYP method in the LANL2DZ basis set for rhenium oxo complexes in a geometry optimization and calculation of spectral properties. Although this is not a very extended basis set, its use with the DFT has shown it to be sufficient for geometry optimization and calculation of spectral properties. It gives good agreement with the experimental data and its use is especially justified in the case of large molecules.

2. Experimental

2.1. General procedure

All the reagents used in the synthesis were commercially available and were used without further purification. The complex [$ReOBr_3(PPh_3)_2$] and 3,5-Me_2pzH were prepared according to the literature methods [16,17].

The IR spectrum was recorded on a Nicolet Magna 560 spectrophotometer in the spectral range 4000–400 cm^{-1} with the sample in the form of KBr pellets. The electronic spectrum was measured on a spectrophotometer Lab Alliance UV–VIS/8500 in the range 800–200 nm in deoxygenated dichloromethane solution. The ^1H NMR spectrum was obtained in $CDCl_3$ using an Inova 300 spectrometer. Elemental analyses (CHN) were performed on a Perkin–Elmer CHN-2400 analyzer.

2.2. Preparation of [{$ReOBr_4$}(μ-O){$ReO(3,5\text{-}Me_2pzH)_4$}]

[$ReOBr_3(PPh_3)_2$] (1 g, 1.03 mmol) was suspended in acetone (30 ml), acidified by four drops of concentrated HBr and then 3,5-Me_2pzH (0.5 g, 5.2 mmol) in acetone (5 ml) was added dropwise to the stirred suspension. The mixture was stirred for 24 h at room temperature. The reaction solution was concentrated to ~10 ml and diethyl ether (30 ml) was added. Blue crystals of [{$ReOBr_4$}(μ-O){$ReO(3,5\text{-}Me_2pzH)_4$}], suitable for X-ray structure determination, were obtained by slow recrystallization from acetonitrile. Yield 55%.

Anal. Calc. for $C_{20}H_{32}Br_4N_8O_3Re_2$: C, 21.36; H, 2.87; N, 9.96. Found: C, 21.54; H, 3.00; N, 9.86%. IR (KBr, cm^{-1}) 3186 (s), 3137 (s), 3035 (w), 2970 (w), 1574 (s), 1479 (m), 1406 (m), 1368 (w), 1259 (m), 1221 (w), 1186 (m), 1148 (m), 1094 (w), 1064 (m), 1029 (w), 969 (m), 812 (s), 778 (s), 752 (m), 698 (vs), 614 (m), 445 (w).

^1H NMR (20 °C, $CDCl_3$, ppm): $\delta = 1.91$ (s, 12H, CH_3), 2.68 (s, 12H, CH_3), 6.04 (s, 4H, CH), 11.58 (s, 4H, NH).

2.3. Crystal structure determination and refinement

A blue crystal of [{$ReOBr_4$}(μ-O){$ReO(3,5\text{-}Me_2pzH)_4$}] was mounted on a KM-4-CCD automatic diffractometer equipped with a CCD detector, and used for data collection. X-ray intensity data were collected with graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at a temperature of 293.0(2) K, with the ω scan mode. Exposure time (34 s) was used and all the Ewald sphere reflections were collected up to $2\theta = 50.2°$. The unit cell parameters were determined from least-squares refinement of the setting angles of the 4248 strongest reflections. Details concerning crystal data and refinement are given in Table 1. Lorentz, polarization and numerical absorption corrections [18] were applied. The structure was solved by means of the Patterson method and subsequently completed by difference Fourier recycling. All the non-hydrogen atoms were refined anisotropically using the full-matrix, least-squares technique. All the hydrogen atoms were found from difference Fourier synthesis after four cycles of anisotropic refinement, and refined as "riding" on the adjacent carbon atom with an individual isotropic temperature factor equal to 1.2 times the value of the equivalent temperature factor of the endocyclic parent atom and equal to 1.5 times the value of the equivalent temperature factor of the methyl parent carbon atom. During refinement the methyl groups were allowed to rotate about their local threefold axis. SHELXS97 [19], SHELXL97 [20] and SHELXTL [21] programs were used for all the calculations. Atomic scattering factors were those incorporated in the computer programs.

2.4. Magnetic measurements

The magnetic measurements of the powdered samples were measured over the temperature range 1.8–300 K using a Quantum Design SQUID-based MPMSXL-5-type magnetometer. The superconducting magnet was generally operated at a field strength ranging from 0 to 0.5 T. Measurements of a sample of the compound were made at a magnetic field of 0.5 T.

The SQUID magnetometer was calibrated with a palladium rod sample. Corrections are based on subtracting the sample-holder signal.

2.5. Computational details

The GAUSSIAN03 program [22] was used in the calculations. The geometry of [{$ReOBr_4$}(μ-O){$ReO(3,5\text{-}Me_2pzH)_4$}] was optimized in a singlet state using the DFT method with the B3LYP functional [23,24]. The electronic spectrum was calculated with the TDDFT method [25].

Table 1
Crystal data and structure refinement for the complex [{$ReOBr_4$}(μ-O){$ReO(3,5\text{-}Me_2pzH)_4$}]

Empirical formula	$C_{20}H_{32}Br_4N_8O_3Re_2$
Formula weight	1124.58
Temperature (K)	293.0(2)
Wavelength (Å)	0.71073
Crystal system	tetragonal
Space group	*I*4
Unit cell dimensions	
a (Å)	10.3282(9)
b (Å)	10.3282(9)
c (Å)	15.1065(17)
Volume (Å^3)	1611.4(3)

Reflections collected	8571
Independent reflections (R_{int})	1453 (0.0752)
Completeness to $2\theta = 50°$ (including systematically absent reflections)	100%
Maximum and minimum transmission	0.2292 and 0.0883
Data/restraints/parameters	1453/1/91
Goodness-of-fit on F^2	1.146
Final *R* indices [$I > 2\sigma(I)$]	$R_1 = 0.0322$ $wR_2 = 0.0796$
R indices (all data)	$R_1 = 0.0327$ $wR_2 = 0.0799$
Absolute structure parameter	0.00(3)
Largest difference in peak and hole (e Å^{-3})	1.283 and −0.986

The calculations were performed using an ECP basis set on the rhenium atom and the standard 6-31G basis set for the other atoms. For bromine, oxygen, nitrogen and carbon atoms, diffuse and polarization functions were added. The Xe core electrons of Re were replaced by an effective core potential and a DZ quality Hay and Wadt Los Alamos ECP basis set (LANL2DZ) [26] was used for the valence electrons. An additional *d* function with exponent $\alpha = 0.3811$ and *f* function with exponent $\alpha = 2.033$ on the rhenium atom were added.

3. Results and discussion

3.1. Preparation

The compound [{$ReOBr_4$}(μ-O){$ReO(3,5\text{-}Me_2pzH)_4$}] has been isolated in the reaction of [$ReOBr_3(PPh_3)_2$] with 3,5-dimethylpyrazole in acidified acetone at room temperature. The reaction was carried out in a system open to the atmosphere, and water is the source of the bridging oxo group.

3.2. Infrared data

The elemental analysis of the complex is in good agreement with its formulation. The infrared spectrum confirms the presence of terminal and bridging oxo ligands and 3,5-Me_2pzH in the coordination sphere. A sharp band at 969 cm^{-1} is assignable to the symmetric Re═O stretch, and a strong multicomponent band at 698 cm^{-1} with the same shape as that illustrated in the article of Cotton et al. [27] results from overlapping of the antisymmetric Re–O–Re stretching modes with the aromatic ring out-of-plane deformation vibrations. The ν(Re═O) and ν_{as}(Re–O–Re) observed for [{$ReOBr_4$}(μ-O){$ReO(3,5\text{-}Me_2pzH)_4$}] agree well with the appropriate values found previously in similar dirhenium oxocompounds. The electron-withdrawing effect of the terminal Re═O group in complexes with an O═Re─O─Re═O framework results in a relative weakening of the bridging Re–O_b bonds and leads to the reduction in the frequency of the ν(Re–O–Re) stretching mode in comparison with $[Re_2OCl_{10}]^{4-}$. The antisymmetric ν(Re–O–Re) stretching mode of the last compound occurs as a strong band at 850–855 cm^{-1} [28]. The strong bands in the range 3200–3100 cm^{-1}, assignable to N–H vibrations, indicate the coordination of the pyrazole ligands in the neutral monodentate form [29]. Such coordination of the 3,5-dimethylpyrazole molecules is also supported by ^{1}H NMR studies; the singlet at 11.58 ppm corresponds to NH protons.

3.3. Magnetic properties

The magnetic data of the [{$ReOBr_4$}(μ-O){$ReO(3,5\text{-}Me_2pzH)_4$}] complex under the form χ_g versus *T* (χ_g being the experimental gram magnetic susceptibility) are shown in Fig. 1. The relation of χ_g versus *T* indicates

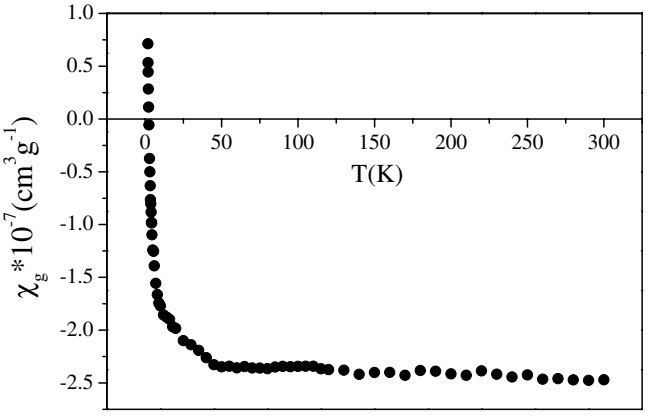

Fig. 1. Plot of the experimental magnetic data χ_g (●) vs. T for complex [{$ReOBr_4$}(μ-O){$ReO(3,5\text{-}Me_2pzH)_4$}].

diamagnetism of the complex in the temperature range ⩾2.5–300 K and very high purity of the sample.

The magnetic properties of the complex evidence coupling electrons in the O═Re—O—Re═O core and confirm the $5d^2$ electronic configuration of both rhenium (V) centers.

3.4. Crystal structure

A definite proof for the structure is provided by the X-ray diffraction results. A perspective drawing of [{$ReOBr_4$}-(μ-O){$ReO(3,5\text{-}Me_2pzH)_4$}] is given in Fig. 2, and the most important bond lengths and angles are reported in Table 2. The [{$ReOBr_4$}(μ-O){$ReO(3,5\text{-}Me_2pzH)_4$}] complex takes a dinuclear structure in which two rhenium atoms are bridged by the oxo ligand. The rhenium and oxygen (terminal and bridging) atoms occupy special positions *a* of *I*4 (No.79) space group at 0, 0, *z* [30]. This forces the molecule

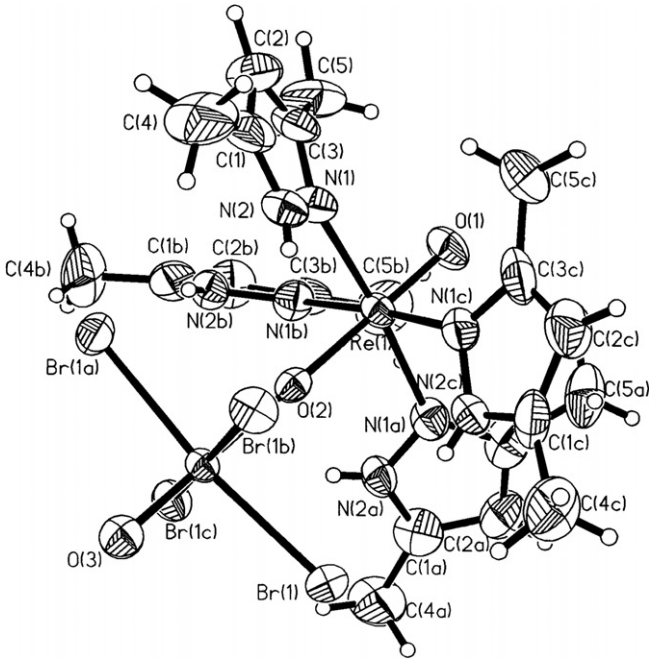

Fig. 2. The molecular structure of [{$ReOBr_4$}(μ-O){$ReO(3,5\text{-}Me_2pzH)_4$}].

to occupy four asymmetric units. The molecules are linked *via* two intermolecular hydrogen bonds: medium strength N(2)–H(2N)···Br(1)#(−*y*, *x*, *z*) (D···A distance 3.366(8) Å and D–H···A angle 164.2°) and weak C(2)–H(2)···O(3)#(*x* − 0.5, *y* − 0.5, *z* − 0.5) (D···A distance 3.496(13) Å and D–H···A angle 163.6°) [31,32]. The intramolecular hydrogen bond linkage C(5)–H(5)···O(1) (D···A distance 3.207(16) Å and D–H···A angle 126.1°) provides additional stabilisation of the [{$ReOBr_4$}(μ-O){$ReO(3,5\text{-}Me_2pzH)_4$}] molecule [31,32].

Each rhenium ion of [{$ReOBr_4$}(μ-O){$ReO(3,5\text{-}Me_2pzH)_4$}] is in a distorted octahedral geometry. The equatorial plane of the Re(1) center is occupied by four 3,5-Me_2pzH molecules, whereas the equatorial plane of the Re(2) atom consists of four bromide ligands. The axial positions of Re(1) and Re(2) centers are occupied by terminal (O_t) and bridging (O_b) oxo ligands. Because of the crystallographic symmetry, the O═Re—O—Re═O core is perfect linear.

The Re(1)–O_t bond is shorter (by 0.037 Å) in comparison with the Re(2)–O_t distance, and the Re(1)–O_b is shorter (by 0.06 Å) than the Re(2)–O_b distance. Both Re–O_t bond lengths fall in the range 1.639–1.76 Å [33], typical of mononuclear complexes of rhenium(V) having a $[ReO]^{3+}$ core, and suggest a considerable degree of triple bond character due to $O_t \rightarrow Re_\pi$ bonding. On the other hand, the Re–O_b bond distances in the dirhenium complex are shorter than a single Re–O length. An ideal single Re–O bond distance, predicted by the use of Pauling's oxygen covalent radius and Cotton and Lippard's value for the Re(V) octahedral covalent radius, should be *ca.* 2.04 Å [34]. It indicates some redistribution of the d_π–p_π interaction along the O_t–Re–O_b unit in the discussed dinuclear rhenium complexes.

The Re–N and Re–Br and bond lengths of [{$ReOBr_4$}-(μ-O){$ReO(3,5\text{-}Me_2pzH)_4$}] are unexceptional, they agree well with appropriate values found previously in similar rhenium compounds [8,35].

A mixed oxidation state formulation involving Re(III) and Re(VII) centers could be proposed for the unsymmetrical [{$ReOBr_4$}(μ-O){$ReO(3,5\text{-}Me_2pzH)_4$}] complex. However, Re(VII) is generally found in complexes including a {ReO_3} moiety and Re(III) coordination compounds are not normally associated with a terminal oxo ligand [36]. A mixed oxidation state formulation involving Re(III) and Re(VII) centers is also inconsistent with the magnetic susceptibility measurements. It seems that the diamagnetic [{$ReOBr_4$}(μ-O){$ReO(3,5\text{-}Me_2pzH)_4$}] complex can be best formulated as the $[Re^VOBr_4][Re^VO_2(3,5\text{-}Me_2pzH)_4]$ adduct. Such a formulation is supported by general features of rhenium coordination compounds and is in accordance with the magnetic studies and DFT calculations for [{$ReOBr_4$}(μ-O){$ReO(3,5\text{-}Me_2pzH)_4$}].

3.5. Optimised geometry

The geometry of [{$ReOBr_4$}(μ-O){$ReO(3,5\text{-}Me_2pzH)_4$}] was optimized in a singlet state using the DFT method

Table 2
The experimental and optimized bond lengths (Å) and angles (°) for [{$ReOBr_4$}(μ-O){$ReO(3,5\text{-}Me_2pzH)_4$}]

	Bond lengths			Bond angles

#1 $-x, -y, z$; #2 $y, -x, z$; #3 $-y, x, z$.

with the B3LYP functional. The optimized geometric parameters are gathered in Table 2. Considerable differences between experimental and calculated values can be noticed for the Re–O_t and Re–O_b bond lengths. To some extent the differences are ascribed to the crystallographic symmetry of [{$ReOBr_4$}(μ-O){$ReO(3,5\text{-}Me_2pzH)_4$}]. The optimized geometry seems to represent the chemically reasonable structure [$Re^{V}OBr_4$][$Re^{V}O_2(3,5\text{-}Me_2pzH)_4$] for the title complex. The calculated Re(1)–O(1) and Re(1)–O(2) bonds are similar to those observed in $[ReO_2L_4]^+$ complexes and the Re(2)–O_b bond is considerable weaker in comparison with the Re(1)–O_b one.

3.6. Charge distribution

Table 3 presents the atomic charges from the Natural Population Analysis (NPA) for [{$ReOBr_4$}(μ-O){$ReO(3,5\text{-}Me_2pzH)_4$}]. The calculated charges on the rhenium atoms are considerable lower than the formal charge of +5. The populations of the $5d_{xy}$, $5d_{xz}$, $5d_{yz}$, $5d_{x^2-y^2}$ and $5d_z^2$ orbitals of the central atoms in [{$ReOBr_4$}(μ-O){$ReO(3,5\text{-}Me_2pzH)_4$}] are as follows: Re(1): 0.862, 0.862, 0.916, 1.061 and 1.532; Re(2): 0.814, 0.814, 1.492, 1.048 and 1.394. This is a result of significant charge donation from the oxo ligands, bromine ions and N-heterocyle molecules. The Re(2) center, with the bromide ions in the equatorial plane, is less positive in comparison with the Re(1) ion. Considerable differences in the values of charges are

Table 3
Atomic charges from the natural population analysis (NPA) for [{$ReOBr_4$}(μ-O){$ReO(3,5\text{-}Me_2pzH)_4$}]

Atom	Atomic charge
Re(1)	1.424
Re(2)	0.944
O(1)	−0.566
O(2)	−0.830
O(3)	−0.353
Br(1)	−0.407
Br(2)	−0.404
Br(3)	−0.405
Br(4)	−0.405
N(1)	−0.347
N(2)	−0.354
N(3)	−0.347
N(4)	−0.354
N(5)	−0.347
N(6)	−0.354
N(7)	−0.347
N(8)	−0.354

observed for the terminal and bridging oxo ligands – less negative terminal oxo ligands indicates higher electron density delocalization from the terminal ligands towards the rhenium centers and corresponds to differences in the Re–O_t and Re–O_b bonds lengths. Some differences are also visible in the values of the charges of the terminal oxo ligands – the oxo ligand coordinated to the Re(2) atom is less negative. It corresponds to populations of the 2s, $2p_x$, $2p_y$ and $2p_z$ orbitals of the oxo ligands: O(1): 1.839, 1.769, 1.473 and 1.473; O(3): 1.831, 1.705, 1.399 and 1.399; O(2): 1.780, 1.767, 1.632 and 1.633. An increase in the p orbital population is observed for the bridging oxo ligand.

Table 4
The occupancies and hybridization of the calculated Re–O natural bond orbitals (NBOs) for [{$ReOBr_4$}(μ-O){$ReO(3,5\text{-}Me_2pzH)_4$}]

BD	Occupancy	Hybridization of NBO
Re(1)–O(1)	1.961 (0.304)	$0.437(sd^{2.82})_{Re(1)} + 0.899(sp^{1.53})_{O(1)}$

Re(1)–O(1)	1.986 (0.350)	$0.559(d)_{Re(1)} + 0.829(p)_{O(1)}$
Re(2)–O(3)	1.967 (0.263)	$0.877(sp^{1.92})_{O(3)} + 0.480(sd^{4.42})_{Re(2)}$
Re(2)–O(3)	1.988 (0.225)	$0.817(p)_{O(3)} + 0.576(d)_{Re(2)}$
Re(2)–O(3)	1.992 (0.227)	$0.816(p)_{O(3)} + 0.578(d)_{Re(2)}$

3.7. NBO analysis

Each natural bond orbital (NBO) σ_{AB} can be written in terms of two directed valence hybrids (HHOs) h_A i h_B on atoms A and B:

$$\sigma_{AB} = c_A h_A + c_B h_B$$

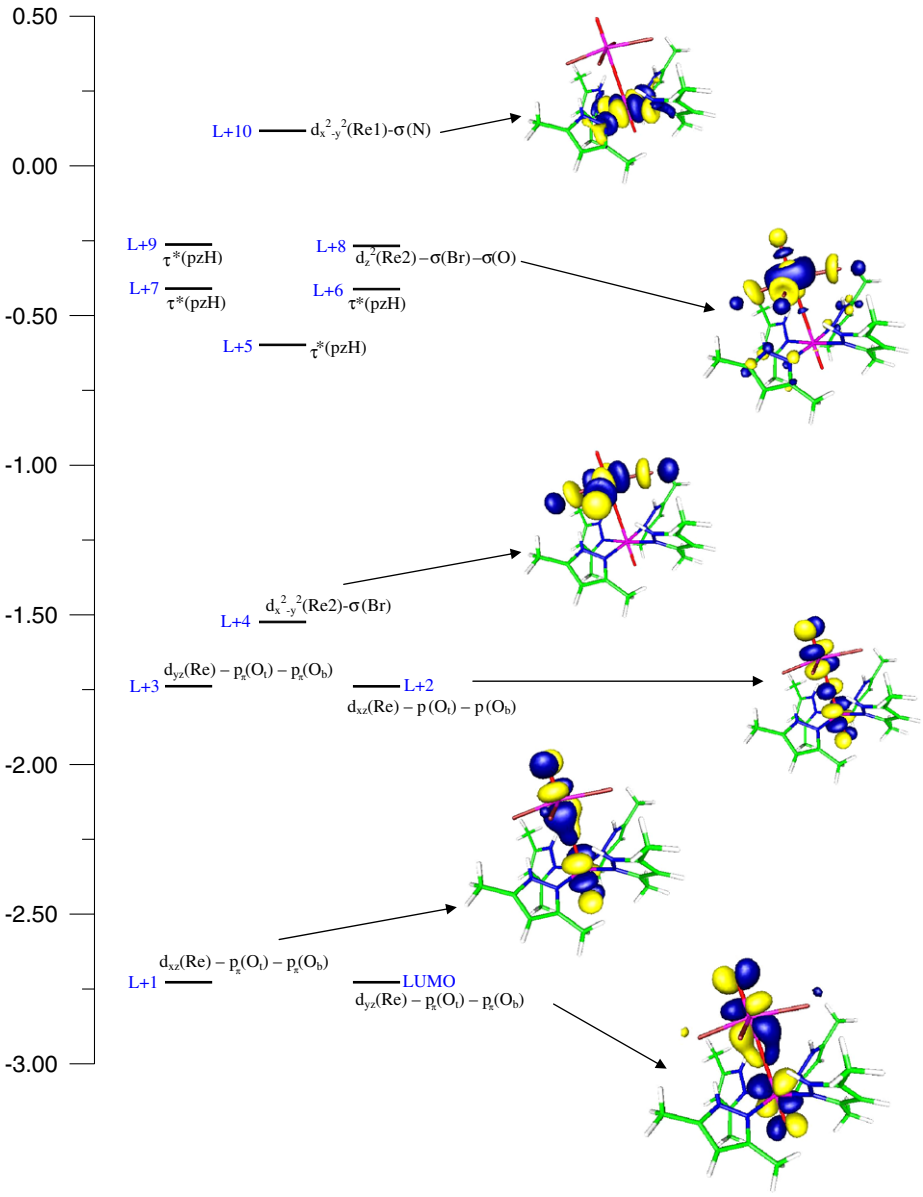

Fig. 3a. The energy (eV), character and contours of the selected unoccupied molecular orbitals of [{$ReOBr_4$}(μ-O){$ReO(3,5\text{-}Me_2pzH)_4$}].

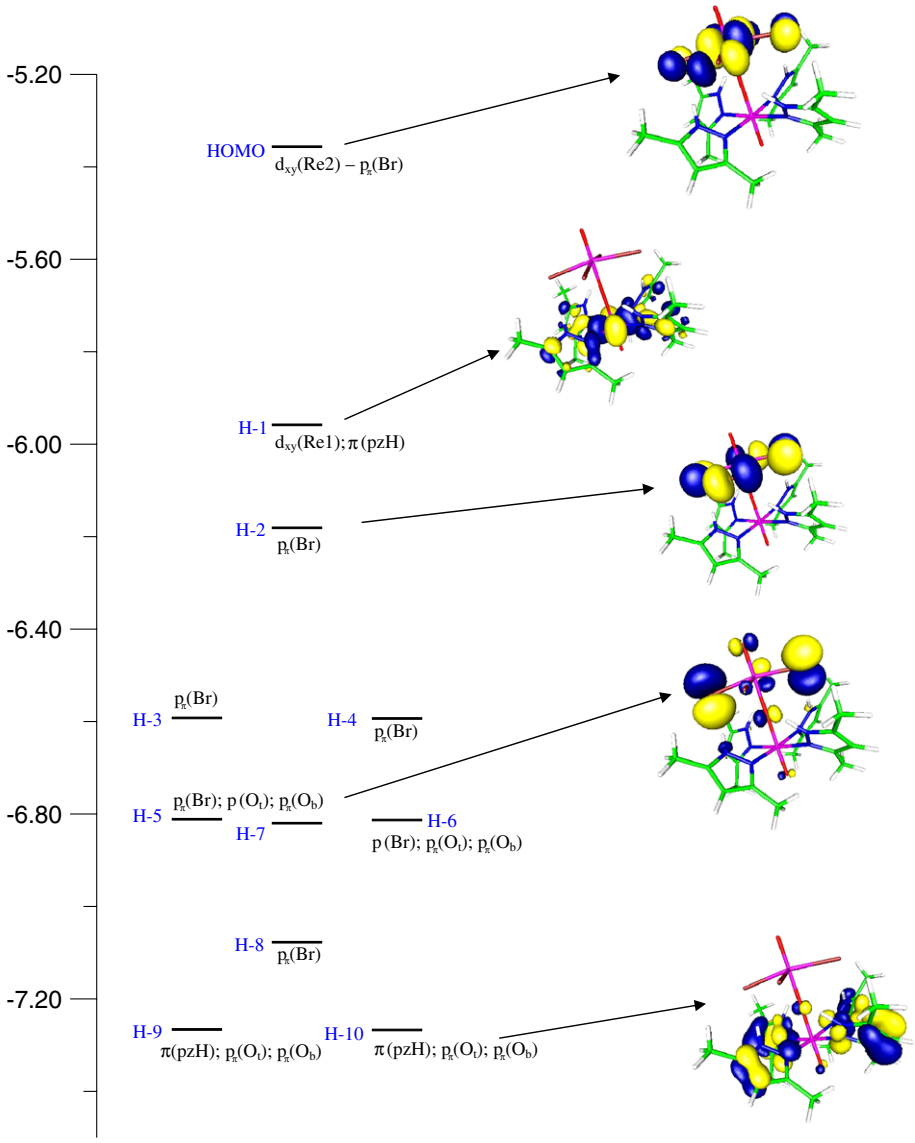

Fig. 3b. The energy (eV), character and contours of the selected occupied molecular orbitals of [{$ReOBr_4$}(μ-O){$ReO(3,5\text{-}Me_2pzH)_4$}].

where c_A i c_B are polarization coefficients. Each valence bonding NBO must in turn be paired with a corresponding valence *anti*-bonding NBO:

$$\sigma^*_{AB} = c_B h_A - c_A h_B$$

to complete the span of the valence space. The Lewis-type (donor) NBOs are thereby complemented by the non-Lewis-type (acceptor) NBOs that are formally empty in an idealized Lewis picture. The interactions between 'filled' Lewis-type NBOs and 'empty' non-Lewis NBOs lead to a loss of occupancy from the localized NBOs of the idealized Lewis structure into the empty non-Lewis orbitals, and they are referred to as 'delocalization' corrections to the zeroth-order natural Lewis structure. The stabilization energy ΔE_{ij} (kcal/mol) associated with the delocalization is estimated by the second-order perturbative as

$$\Delta E_{ij} = q_i(F(i,j)^2)/(\varepsilon_j - \varepsilon_i)$$

where q_i is the donor orbital occupancy, ε_i, ε_j are diagonal elements (orbital energies) and $F(i,j)$ is the off-diagonal NBO Fock or Kohn–Sham matrix element [37].

In the case of the complex [{$ReOBr_4$}(μ-O){$ReO(3,5\text{-}Me_2pzH)_4$}], three Re–$O_t$ natural bond orbitals were detected for each Re atom. The occupancies and hybridization of the calculated Re–O_t natural bond orbitals (NBOs) are given in Table 4. The Re–O_t bonds are all strongly polarized towards the oxygen atom. The *s* and *p* oxygen orbitals and s and d rhenium orbitals take part in the $\sigma_{Re\text{–}Ot}$ bond formation, whereas the $\pi_{Re\text{–}Ot}$ bond orbitals result from overlapping of the empty d_{xz} and d_{yz} rhenium orbitals with the occupied p_x and p_y orbitals of the terminal oxygen ligands. Each terminal oxo ligand of [{$ReOBr_4$}-(μ-O){$ReO(3,5\text{-}Me_2pzH)_4$}] has one lone pair with an occupancy close to 2. The Re–O_b bonds were not detected, indicating predominantly Coulomb-type interactions between the central ion and the bridging oxo ligand [38].

Table 5 presents the occupancies and atomic orbital compositions of the lone pairs (LP) orbitals detected on the bridging oxygen atom, as well as the character of the acceptor orbital and stabilization energies (ΔE_{ij}) for the corresponding donor–acceptor interactions. The O_b ligand has four lone pairs orbitals (LP) and electron density from LP orbitals of the bridging oxygen is mainly delocalized into the antibonding Re(1)–O(1) bond orbitals (Table 5). It explains the considerable differences in the calculated Re(1)–O(2) and Re(2)–O(2) bond lengths and supports the formulation of the title complex as Re(V) species.

3.8. Electronic structure

The energies, characters and contours of selected unoccupied and occupied molecular orbitals of the investigated complex are presented in Figs. 3a and 3b, respectively. The z axis goes along the O═Re—O—Re═O linkage, and the local symmetry of the rhenium centers is considered in the discussion.

The two highest MOs of [{$ReOBr_4$}(μ-O){$ReO(3,5\text{-}Me_2pzH)_4$}] are predominantly localized on the d_{xy} orbitals of the Re(1) and Re(2) atoms, and the remaining eight d-type orbitals of the rhenium ions are found among unoccupied MOs. The LUMO, LUMO + 1, LUMO + 2 and LUMO + 3 can be ascribed as π-antibonding rhenium–oxygen molecular orbitals.

Each rhenium atom uses six valence orbitals, $5d^{2^2}_{x-y}$, $5d^2_z$, 6s, $6p_x$, $6p_y$ and $6p_z$, to form σ-bonds with the six ligands, the occupied $5d_{xy}$ orbitals of both rhenium ions remains non-bonding, and the empty $5d_{yz}$ and $5d_{xz}$ orbitals interact with the filled $2p_x$ and $2p_y$ orbitals of the terminal and bridging oxo ligands to give four π-bonding, two π-non-bonding and four π-antibonding molecular orbitals. In total, there are four σ and four π bonding orbitals describing the Re_2O_3 unit.

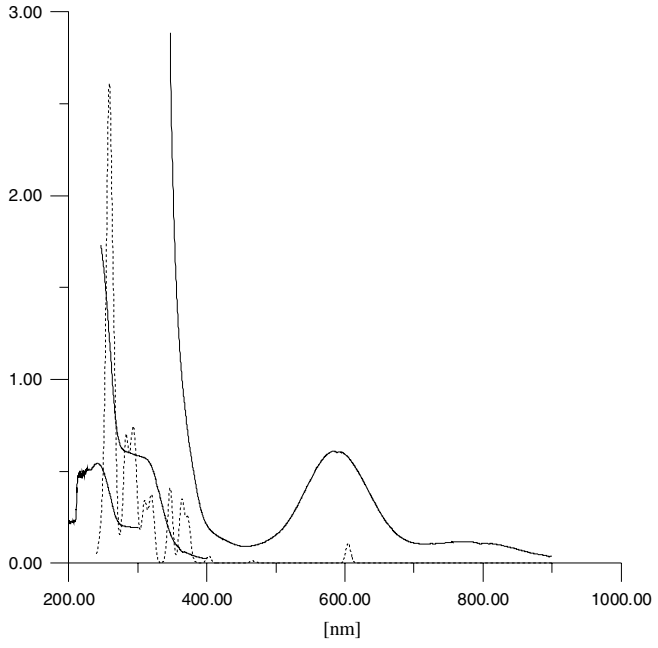

Fig. 4. The experimental (——) and calculated (- - - -) electronic absorption spectra of [{$ReOBr_4$}(μ-O){$Re(O)(3,5\text{-}Me_2pzH)_4$}].

3.9. Electronic spectrum

The experimental and calculated electronic spectra of [{$ReOBr_4$}(μ-O){$ReO(3,5\text{-}Me_2pzH)_4$}] are presented in Fig. 4. Each calculated transition is represented by a gaussian function $y = ce^{-bx^2}$ with the height (c) equal to the oscillator strength and b equal to 0.04 nm^{-2}.

Table 6 shows the spin-allowed singlet–singlet electronic transitions calculated with the TDDFT method for [{$ReOBr_4$}(μ-O){$ReO(3,5\text{-}Me_2pzH)_4$}]. For the high energy part of the spectrum, only transitions with oscillator strengths larger than 0.050 are listed in Table 6.

The investigated complex is of large size, and a hundred electron transitions calculated by the TDDFT method do not comprise all the experimental absorption bands. The UV–Vis spectrum of [{$ReOBr_4$}(μ-O){$ReO(3,5\text{-}Me_2pzH)_4$}] was calculated to 240 nm, so the shortest wavelength experimental band cannot be assigned completely to the calculated transitions. Some additional mainly intraligand and interligand transitions are expected to be found at higher energies in the calculation for [{$ReOBr_4$}-(μ-O){$ReO(3,5\text{-}Me_2pzH)_4$}].

The assignment of the calculated transitions to the experimental bands is based on the criterion of the energy and oscillator strength of the calculated transitions. Only the main components of the molecular orbital are taken into consideration for the description of the electronic transitions.

The two longest wavelength experimental bands are attributed to the transitions of d → d character with small oscillator strengths.

Table 5
The occupancies and atomic orbital compositions of the lone pairs (LP) detected on the bridging oxygen atom and the character of the acceptor orbital, as well as stabilization energies (ΔE_{ij}) for the corresponding donor–acceptor interactions

The broad and intense experimental band with a maximum at 306.8 nm can be assigned to the *LMCT* transitions occurring from the bromine and oxo ligands to the *d* orbitals of the rhenium centers. In this range, the calculated d → d transitions are significantly weaker in comparison with the *LMCT* transitions, which means they are hidden by the latter transitions.

The experimental band at 239.6 nm can mainly be attributed to transitions of *MLCT* character occurring from the rhenium centers to the π-antibonding orbitals of the pyrazole ligands. However, contribution of the *LMCT* transitions into this band is also confirmed by the calculations.

4. Conclusions

A novel dinuclear oxo complex, [{$ReOBr_4$}(μ-O){$ReO(3,5\text{-}Me_2pzH)_4$}], has been prepared and structurally as well as spectroscopically and magnetically characterized. X-ray studies confirm a distorted octahedral geometry of the rhenium centers and the presence of a prefect linear O═Re—O—Re═O core. The diamagnetic [{$ReOBr_4$}(μ-O){$ReO(3,5\text{-}Me_2pzH)_4$}] complex can be best formulated as the [$Re^{V}OBr_4$][$Re^{V}O_2(3,5\text{-}Me_2pzH)_4$] adduct. Such a formulation is supported by general features of coordination rhenium compounds and is in accordance with the DFT calculations for [{$ReOBr_4$}(μ-O){$ReO(3,5\text{-}Me_2pzH)_4$}].

5. Supplementary material

CCDC 622582 contains the supplementary crystallographic data for $C_{38}H_{47}Cl_4N_8O_2PRe_2$. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Acknowledgements

The GAUSSIAN03 calculations were carried out in the Wrocław Centre for Networking and Supercomputing, WCSS, Wrocław, Poland Under Calculational Grant No51/96.

The crystallographic part was financed by funds allocated by the Ministry of Scientific Research and Information Technology to the Institute of General and Ecological Chemistry, Technical University of Łódź.

synthetic therapeutics [6,7], or, not infrequently, by a combination therapy. There is therefore a need for research efforts to seek effective active drugs that mimic or enhance the properties of insulin.

Vanadium and organovanadium complexes have been proposed as adjuncts in the treatment of diabetes mellitus and the efficacy of vanadium as an insulin-mimicking transition metal has been reported [8,9]. Several clinical studies have been performed with organovanadium complexes using low doses of vanadium (2 mg/kg/day) in order to improve the insulinomimetic efficacy of vanadium without increasing its toxicity in diabetic patients [9,10].

Insulin mimetic VO compounds are described in the literature and several of them are sugar-derived substances [11–15]. Different types of coordination involving the vanadyl ion have also been investigated [16,17]. However, poor absorption from the gastrointestinal tract into the bloodstream and the optimal effectiveness in vivo are current limitations to administering vanadate to diabetic patients. Some vanadium complexes have been shown to increase potency over inorganic vanadium in induced-diabetic rats [18]. One example is bis(maltolato)oxovanadium(IV) which offers significant water solubility, neutral charge, and lipophilicity and may therefore enhance gastrointestinal tract absorption [19,20].

Saccharides belong to an interesting class of chemical compounds that plays an important role in various forms of living systems by being present as small integral parts of diverse biological molecules, including nucleic acids, polysaccharides, antibiotics, glycoproteins, glycolipids and aminosugars. Saccharide molecules posses several functional hydroxyl groups that may play key roles in complexing with transition metal ions to produce a variety of metal–saccharide complexes differing in their nature and utility [21–23].

In this approach we characterized the species of sugar chelated with vanadium in the VO–HGlu system, at physiological pH, in order to study its anti-diabetic effect in an acute treatment of hyperglycemic rats by intraperitoneal injection or oral gavage. The aim of this study was to investigate the use of sugars as a chelating agent in a vanadium complex with the aim of presenting an insulin mimetic compound, which would be expected to have a low toxicity.

2. Experimental

2.1. Materials

The monossaccharides D-Gluconic acid (potassium salt), D-ribose, D-ribono-1,4-lactone, D-galactone-1,4-lactone and 2-deoxy-D-glucose and the metallic salts of analytic grade ($VOSO_4$) were purchased from commercial sources (Sigma and Aldrich) and used without further purification. The stock solution of VO(IV) (1×10^{-2} mol L^{-1}) was standardized by titration with a standard solution of $KMnO_4$ (potassium permanganate) through the oxi-reduction method [24]. The exact amount of the acid added to prevent the cation precipitation was calculated using Gran's Plot [25]. Purity of all the ligands was established by potentiometric titration. Carbonate-free solutions of 0.100 mol L^{-1} KOH were prepared from Baker Dilut-It ampoles and were standardized by titration with potassium acid phthalate purchased from Sigma.

2.2. Animals

Male Wistar rats (160–190 g) were used. They were bred in our animal facility and housed in an air-conditioned room (approximately 22 °C) with controlled lighting 12:12 h light/dark cycle (lights on from 06:00 to 18:00 h). The animals were maintained with food pellets (Nuvital, Nuvilab CR1, Curitiba, PR, Brazil), while tap water was available ad libitum. Fasted animals were deprived of food for at least 16 h but allowed free access to water. All the animals were carefully monitored and maintained in accordance with ethical recommendations of the Brazilian Veterinary-Medicine Council (CMV) and the Brazilian College of Animal Experimentation (COBEA). Rats fasted for 16 h received 70 mg/kg body weight of alloxan (Sigma, St. Louis, MO, USA) by a single intravenous injection. The diabetic state was assessed, by measuring serum glucose levels 3 days later [26]. Rats that died during the experiment (around 8%) were excluded from the analysis.

2.3. Synthesis of the VO–HGlu complex

The VO–HGlu complex was synthesized following a modified procedure describe in the literature [27]. The solids were prepared by mixing concentrated solutions of $VOSO_4$ and D-Gluconic acid (potassium salt) in aqueous media at neutral pH value and the solvent was evaporated until a solid was formed. The solid was purified after successive recrystallizations.

2.4. Potentiometric titrations

The potentiometric titrations were carried out in a sealed thermostated vessel at 25 °C, under inert atmosphere (Ar) with continuous magnetic stirring. The pH meter (Corning) with glass and reference electrodes (Ingold) was calibrated with standard HCl and KOH solutions to directly read $-\log[H^+]$, designated as pH. The experimental solutions, adjusted to 0.1000 mol L^{-1} ionic strength by addition of KCl, were titrated with 0.100 mol L^{-1} standard CO_2-free KOH solution. Equilibrium measurements of sugars were carried out in the presence and absence of VO^{2+}. The problem solutions contained 0.100 mmol of saccharides and the metal system had a molar ratio of 1:1 and 1:2 (metal:ligand) with 0.1000 mmol of VO^{2+}. All the potentiometric studies were

carried out with 40.00 mL of experimental solution and each system was titrated at least three times. The pH range for accurate measurements was considered to be 2.5–11.0.

All equilibrium constants were calculated using the program BEST7 [28a]. Mole and millimole units were used to express the quantities of reagents, and the hydrolysis constants in water for the metal ion were obtained from the literature [28b] and were fully employed in all calculations. The species distribution curves were drawn with the SPE and SPEPLOT programs [28a].

2.5. EPR

EPR spectra were obtained at 298 K and 77 K for the metal–ligand complex solution at pH 3.6, 7.25 and 10.6, on a Bruker ESP300E instrument operating at 9.5 GHz (X-band) with 100 kHz field modulation.

2.6. TGA–DSC

Thermal analysis was carried out using a Shimadzu system (DSC – 50 and TGA – 50) at a heating rate of 10 °C min^{-1} and under N_2 atmosphere (50 mL min^{-1}). The sample mass used was 6.730 mg. Standard indium (156.6 °C) and hydrate calcium oxalate were used for DSC and TGA calibration, respectively.

2.7. Time-course of VO–HGlu complex effects on hyperglycemia in alloxan-induced diabetic rats

Animals for which the development of hyperglycemia was confirmed (around 98%) 72 h after the alloxan injection were randomized into four groups of six rats: Group I, normal rats that received a saline solution by oral gavages (0.5 mL); Group II, diabetic rats that received VO(IV) (0.0607 mol/L; 0.5 mL) intraperitoneally; Group III, diabetic rats that received 0.5 mL of VO–HGlu at 100 mg/kg intraperitoneally and Group IV, diabetic rats that received 0.5 mL of VO–HGlu at 100 mg/kg by oral gavages. The VO–HGlu complex was prepared immediately prior to its use and was kept in a physiological pH solution to be administered to the animals. The serum glucose was measured before the animals received the complex solution and at 1, 2 and 3 h subsequent to the treatment [29].

2.8. Determination of serum glucose concentration

Blood samples were collected from the cannula previously implanted in the jugular vein as described by [30], and centrifuged. Serum glucose levels were determined by the oxidase method [31]. The absorbencies were measured with a Pharmacia LKB-Ultrospec III spectrophotometer (Pharmacia LKB Biotechnology, Inc., Uppsala, Sweden) at 505 nm. A serum glucose range of 480–570 mg/dL was used for the experiment.

2.9. Statistical analysis

Data were expressed as mean ± SEM. One-way analysis of variance (ANOVA) followed by the Bonferroni post-test, with the aid of the INSTAT program (version 1.121) was carried out. Differences were considered to be significant at $p \leqslant 0.05$.

3. Results and discussion

3.1. Equilibrium of the D-gluconic acid and the vanadyl cation VO^{2+}

The potentiometric titration profile of HGlu in the presence and absence of VO^{2+} in the 1:1 (metal:ligand) ratio, is given in Fig. 1. Complexation began around pH 3, requiring almost three moles of protons per mole of sugar to reach the break point. The buffer region above pH 7 shows the consumption of over one addition mole of titrant (totally 4.5) per mole of the ligand (sugar). Only this system presented a solubility feature up to pH 11, while the other systems studied precipitated. The negative values in the abscissa represent the neutralization of the acid excess in the metallic solution.

The equilibria in the VO–Hglu system are represented by Eqs. (1)–(7) where HL and L^- are the protonated and deprotonated species of the D-Gluconic acid, respectively;

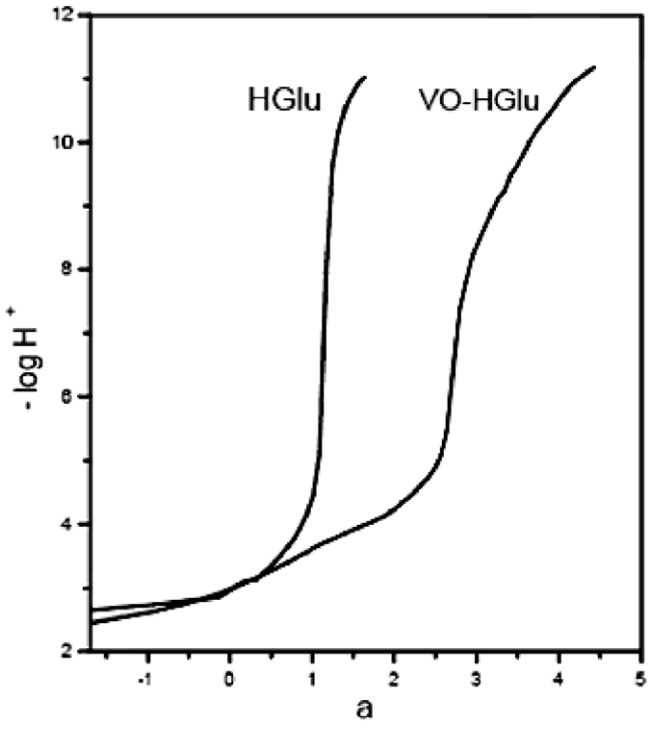

Fig. 1. Potentiometric pH profiles of D-gluconic acid (HGlu) in the presence and absence of VO^{2+}, in the metal to ligand ratio of 1:1 (M:L), at 25.0 °C and $I = 0.100$ mol/L (KCl). Negative values in the abscissa represent the neutralization of mineral acid added to the system. In the abscissa **a** stands for number of moles of KOH per number of moles of ligand.

VO^{2+} is the aqueous oxovanadium and VOL^{+}, $VOH_{-1}L$, $VOH_{-2}L^{-}$, $VOH_{-3}L^{2-}$ and $VOH_{-4}L^{3-}$ are the mononuclear species formed with none, one, two, three and four hydroxyl groups from the D-gluconic acid, which were deprotonated in the complexation by the metal ion. The values for the equilibrium constants defined by Eqs. (1)–(7) are presented in Table 1.

$$L^{-} + H^{+} \rightleftharpoons HL \quad (1)$$

$$VO^{2+} + L^{-} \rightleftharpoons VOL^{+} \quad (2)$$

$$VOL^{+} \rightleftharpoons VOH_{-1}L + H^{+} \quad (3)$$

$$VOH_{-1}L \rightleftharpoons VOH_{-2}L^{-} + H^{+} \quad (4)$$

$$VOH_{-2}L^{-} \rightleftharpoons VOH_{-3}L^{-2} + H^{+} \quad (5)$$

$$VOH_{-3}L^{2-} \rightleftharpoons VOH_{-4}L^{-3} + H^{+} \quad (6)$$

$$2VOH_{-2}L \rightleftharpoons (VO)_2H_{-5}L_2 + H^{+} \quad (7)$$

The potentiometric pH profile of D-galactone-1,4-lactone (Galac) in the presence of VO^{2+}, in the 1:1 (metal ligand) ratio is given in Fig. 2. The curves for Riblac and dGlu in the presence of the VO^{2+} ion are similar to that shown in Fig. 2 and they are not shown here. The titration curves for Galac, Riblac and dGlu in the presence of the VO^{2+} ion were interrupted around pH 4.6 due to the precipitation of the metal ion hydrolysis products.

The logarithms of the constants defined by Eqs. (8) and (9) are displayed in Table 2 and they refer to the sugars: Galac, Riblac, and dGlu in the presence of the VO^{2+} ion.

$$VO^{2+} + L^{-} \rightleftharpoons VOH_{-1}L + H^{+} \quad (8)$$

$$VOH_{-1}L \rightleftharpoons VOH_{2-}L + H^{+} \quad (9)$$

It can be seen from the values in Table 2 that the closed chain sugars do not chelate well to the metal ion studied, although there is the formation of insoluble hydrolysis products of the metal species. Since the cyclic sugars complex the vanadyl ion weakly, the other analytical assays were performed only with the HGlu sugar molecule.

The species distribution diagram of the HGlu and VO^{2+} system is given in Fig. 3. For this sugar, more species are formed than in the case of the others, because this is an open chain sugar and its hydroxyl groups are in appropriate positions to complex with the metal ion yielding five-member rings, thus, inhibiting its hydrolysis and precipitation. We did not detect in solution complexes in a molar ratio of 1:2 metal:ligand, as reported in the literature in solid state and characterized by IR and UV–Vis spectroscopies [32]. In that publication the authors detected the presence of a deprotonated carboxylate molecule and also a deprotonated hydroxyl group coordinated to the metal ion given rise to the $[OV(gluconate)_2]^{2-}$ ion complex. The formation of the 1:2 metal:ligand complex in the solid state, is most probably due to some packing effects which are contributing to the formation of this species and thus the authors were able to isolate this compound in the solid state when they used an excess of ligand.

The formation of 48% VOL species at pH 2.8 and 42% $VOH_{-1}L$ species at pH 3.8 can be seen in Fig. 3. Formation of the $VOH_{-2}L$ predominates above pH 4.0 until pH

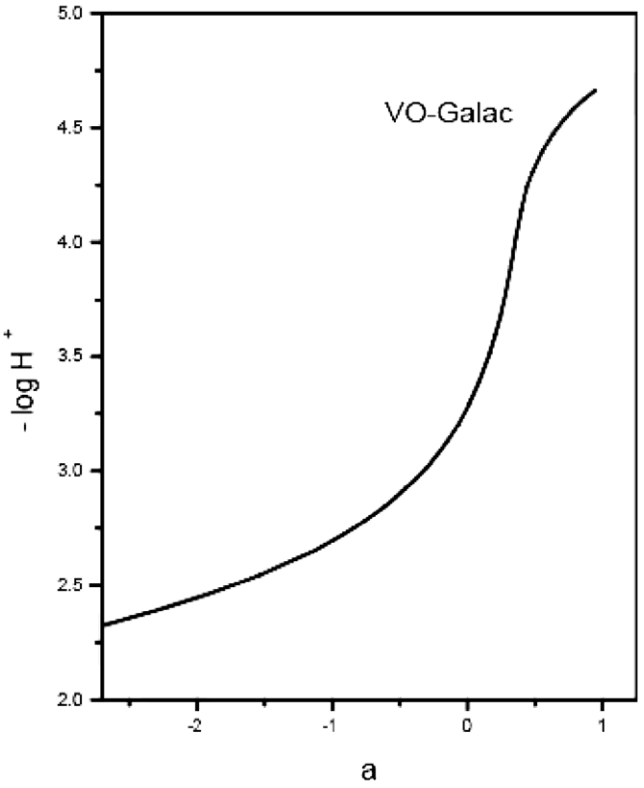

Fig. 2. Potentiometric pH profiles of D galactone-1,4-lactone (Galac) and VO^{2+}, in the metal to ligand ratio of 1:1 (M:L), at 25.0 °C and $I = 0.100$ mol/L (KCl). Negative values in the abscissa represent the neutralization of mineral acid added to the system. In the abscissa **a** stands for number of moles of KOH per number of moles of ligand.

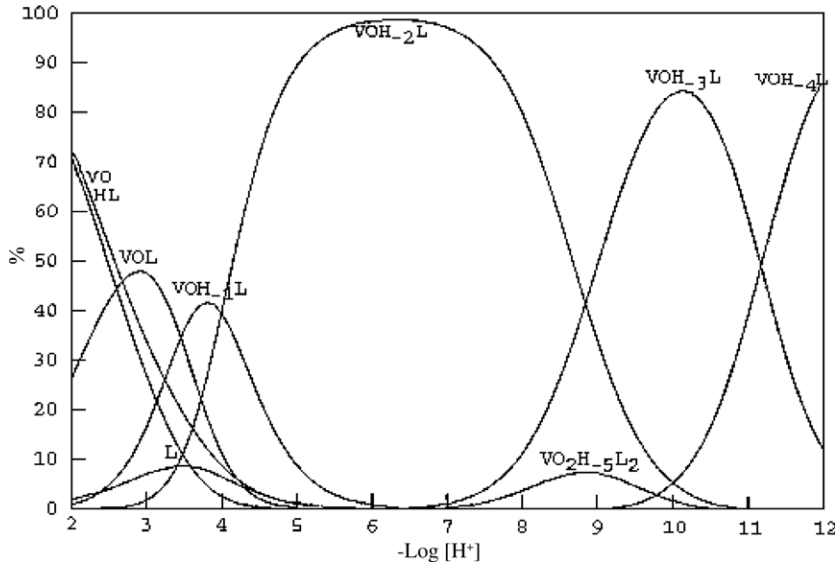
Table 1
Logarithms of stability constants ($\log K$) for the acid–base and complex equilibriums for HGlu and the metal ion VO(IV)

Species	$\log K$[a]
$[HL]/[H^{+}]\,[L^{-}]$	3.60 (3) (3.46)[b]
$[VOL^{+}]/[VO^{2+}]\,[L^{-}]$	3.90 (3)
$[VOH_{-1}L]\,[H^{+}]/[VOL^{+}]$	−3.46 (5)
$[VOH_{2-}L^{-}]\,[H^{+}]/[VOH_{-1}L]$	−4.00 (5)
$[VOH_{-3}L^{2-}]\,[H^{+}]/[VOH_{-2}L^{-}]$	−8.84 (5)
$[VOH_{-4}L^{3-}]\,[H^{+}]/[VOH_{-3}L^{2-}]$	−11.18 (6)
$[(VO)_2H_{-5}L_2]\,[H^{+}]/[VOH_{-2}L]^2$	−6.60 (5)

$T = 25.0$ °C, and $\mu = 0.100$ mol/L (KCl).
[a] The numbers in parenthesis represent the absolute error of the last digit of the value.
[b] Ref. [27].

Table 2
Values for the logarithms of the formation constants for the ligands Galac, Riblac, dGlu with VO^{2+}; 25.0 °C and $I = 0.100$ mol/L

Species	$\log K$		
	Galac	Riblac	dGlu
$[VOH_{-1}\,L]\,[H^{+}]/[VO^{2+}][L]$	−0.78 (6)	−0.64 (6)	−0.88 (6)
$[VOH_{2-}\,L]\,[H^{+}]/[VOH_{-1}L]$	−4.92 (6)	−4.93 (6)	−5.32 (6)



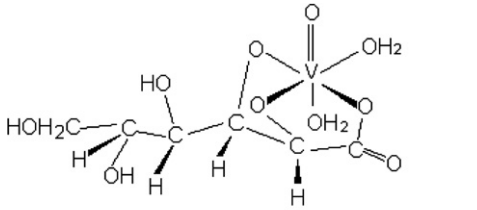


Fig. 3. Species distribution diagram for the species formed in the HGlu–VO system, in the ligand to metal ratio of 1:1 according to pH variation. VO is the free concentration of the oxocation, HL is the fully protonated sugar molecule and VOL is the complex in 1:1 stoichiometry, $VOH_{-1}L$, $VOH_{-2}L$, $VOH_{-3}L$ and $VOH_{-4}L$ are the mono-, di-, tri- and tetra- hydroxyl deprotonated species and $VO_2H_{-5}L_2$ represents the dinuclear $(VO)_2H_{-5}L_2$ species. The ligand concentration is 2.5×10^{-3} mol/L, $T = 25.0$ °C and $I = 0.100$ mol/L (KCl).

values close to 9. This species has two deprotonated OH groups complexed to the metal ion. This is the major species present at physiological pH (7.4). In this species the ligand does not occupy all the coordination sites of the metal ion, leaving two positions where water molecules can be coordinated to the octahedral vanadium(IV) ion (Fig. 4). At pH values above 7.0 there is the formation of a small amount of the dinuclear complex species presenting a hydroxo bridge linking two metal ions. Above a pH value of 8.8 $VOH_{-3}L$ and $VOH_{-4}L$ species predominate, as three and four alcohol groups of the sugar molecule are deprotonated, respectively.

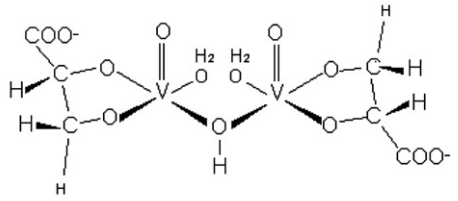

Fig. 4. Proposed structure for the species represented as $VOH_{-2}L$ and $(VO)_2H_{-5}L_2$, between the HGlu ligand and vanadyl ion.

3.2. EPR spectra

The Hglu–VO complexes are EPR-active in liquid (300 K) or in frozen (77 K) water solution. Experimental spectra of the frozen water solutions of the complexes at pH 3.6, 7.25 and 10.6 are shown in Fig. 5. The g values and hyperfine splitting constants of the Hglu–VO complexes were obtained from computer simulation (Simfonia®, Bruker). According to the species distribution diagram (Fig. 3) at pH 3.6 there are two main types of complexes, VOL and VOH_{-1} L. The best g and hyperfine splitting constant values for the two complexes are: $g\| = 1.9405$,

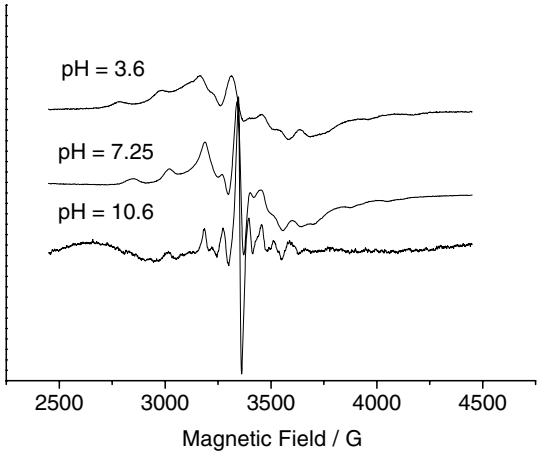

Fig. 5. EPR spectra at X-band ($\nu \approx 9.5$ GHz) of the frozen water solution of the Hglu–VO complexes at pH 3.6, 7.25 and 10.6. Instrument settings for the experimental spectra: power, 20 mW; modulation 100 kHz; sweep centre, 3450 G; sweep width, 2000 G.

$g\perp = 1.9827$, $A\| = 180 \times 10^{-4}\ cm^{-1}$, $A\perp = 70 \times 10^{-4}\ cm^{-1}$. The orders ($g\| < g\perp$ and $A\| \gg A\perp$) are consistent with the oxovanadium(IV) site of C_{4v} symmetry with a $^2B_2$ ground state (unpaired electron on a d_{xy} vanadium orbital). The magnitude of the EPR parameters $g\|$ and $A\|$ are consistent with four oxygen atoms as equatorial ligands. These could be one from the Hglu carboxylate group and three from water molecules or, alternatively, two from water molecules and two from the Hglu molecule. $VO(acac)_2$ has been previously study and it was found that this compound has four oxygen atoms as equatorial ligands, $g\| = 1.944$ and $A\| = 174 \times 10^{-4}\ cm^{-1}$ [33a]. This result is consistent with those for the VOL and $VOH_{-1}L$ complexes. The EPR parameters for the Hglu–VO complexes at pH 7.25 and 10.6 are analogous ($g\| = 1.9495$, $g\perp = 1.9810$, $A\| = 156 \times 10^{-4}\ cm^{-1}$, $A\perp = 58 \times 10^{-4}\ cm^{-1}$) and support a different set of equatorial donor atoms for the VO^{2+} group, with a stronger coordination ligand field than those for the complexes formed at pH 3.6, using two or three hydroxyl groups of the Hglu ligand as donor atoms ($VOH_{-2}L$ and $VOH_{-3}L$) and perhaps with a little distortion of the C_{4v} symmetry around the vanadyl centre [33b]. The different degree of distortion for the two complexes could bring the EPR parameters for the two complexes to the same values.

Fig. 6 represents the DSC curve for the VO–HGlu complex isolated at neutral pH showing one endothermic transition at 118.82 °C, corresponding to 12.5% of a molecular weight of 296 g mol^{-1}, corresponding to two water molecules coordinated to the metal ion in the complex as shown in Fig. 4. The two water molecules can be replaced during the association of the complex with a receptor site of the insulin. In other words, it has two free positions for coordination. The second endothermic transition (at 345.77 °C) is assigned to a break in the sugar chain [34,35].

3.3. Biological assays

Taking into account our previous results performed with this experimental approach [36,37] we chose the optimal time-course procedure to investigate the short-term action of this new complex. Table 3 shows the glycemia profiles for normal animals (control group) and diabetic animals treated with VO(IV) solution (0.0607 mol/L) intraperitoneally or a single dose of VO–HGlu complex (100 mg/kg) intraperitoneally or by oral gavage, over time (from zero to 3 h). This dose of VO–HGlu complex showed a significant hypoglycemic effect from 0 to 3 h when compared to the respective zero time when the animals were treated intraperitoneally, but after oral administration of the complex only a slight lowering in glucose serum levels was observed.

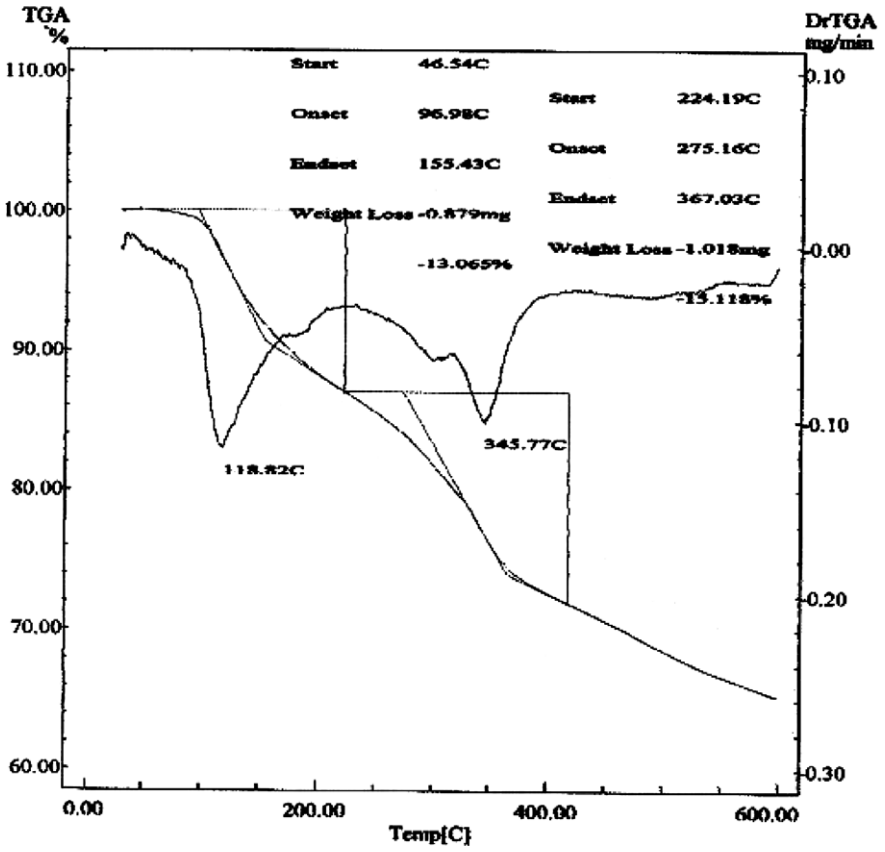

Fig. 6. TGA–DSC of HGlu–VO complex showing one endothermic transition at 118.82 °C, with a 12.5% water weight loss (2 mol) and another endothermic transition at 345.77 °C, corresponding to the decomposition of the complex.

Table 3
Time-course for the effect of VO–HGlu on glycemia in diabetic rats[a]

Time (h)	Group I	Group II	Group III	Group IV
	Normal + saline solution (oral gavage)	Diabetic + VO(IV) (0.0607 mol/L) (intraperitoneal)	Diabetic + VO–Hglu (100 mg/kg) (intraperitoneal)	Diabetic + VO–Hglu (100 mg/kg) (oral gavage)
0	130 ± 2	505 ± 3	516 ± 8	502 ± 24
1	117 ± 2	434 ± 32[b]	459 ± 8[b]	410 ± 12[b]
2	115 ± 6	418 ± 16 [b]	413 ± 9[b]	497 ± 6
3	130 ± 4	430 ± 10[b]	397 ± 12[b]	487 ± 20

[a] Values are expressed as mean ± SEM; $n = 6$ in duplicate for each group.
[b] Statistically significant difference in relation to the corresponding zero time value; $p \leqslant 0.05$.

According to the literature, results from glycemia studies in diabetic animals, using acute screening trials of the complexes bis(maltolato)oxovanadium(IV); (BMOV), bis(maltolato)-zinc(II) dihydrate, *cis*-bis(maltolato)dioxomolybdenum(IV), tris(maltolato)chromium(III) monohydrate, bis(maltolato)copper(II) and bis(maltolato)cobalt (II), indicate that only vanadyl maltol, when administered by oral gavage, lower plasma glucose levels compared to untreated diabetic animals (zero time) [38]. BMOV has been experimentally used as a representative standard in several biological studies due to its approval for clinical experiments [18]. However, a pharmacologically beneficial dose of BMOV is associated with some toxicity and hence attempts are underway to evolve vanadium complexes with fewer side effects while retaining their enhanced therapeutic activities [39]. Additionally, besides the BMOV complex, many vanadium complexes have been reported to be more effective when introduced by intraperitoneal administration than by oral gavage treatment [40].

Vanadium alone, in the form of vanadyl, was effective in lowering glucose levels in a similar concentration (0.0607 mol/L) to that used to prepare the sugar complex (0.0788 mol/L). The maximum percentage reduction in the case of simultaneous administration, HGlu–VO complex, at a dose of 100 mg/kg administered intraperitoneally in diabetic animals was 23%. As demonstrated in this preliminary study the HGlu–VO(IV) complex has a pharmacological potential to be efficient as an organically chelated vanadium complex. One of the advantages of this sugar complex is that, unlike the cyclic sugar complexes, it keeps the metal ion in solution at physiological pH at the concentrations used in the potentiometric studies. There is no metal ion hydrolysis and undesirable precipitates are therefore not formed. Increasing the vanadium or HGlu doses with the aim of observing synergy is unlikely to be advantageous due to the potential toxicity of high doses of vanadium. However, studies on the efficiency of this new complex toward hyperglycemia, as well as investigations into its toxicity, are in progress, using the chronic treatment approach in diabetic animals.

Hg(II) halide complexes of a BPMO ligand 1,2-bis(diphenylphosphino)ethane monoxide (dppeO).

2. Experimental

All reactions were carried out under an atmosphere of dry nitrogen. Reactants and reagents were obtained from Aldrich Chemical Company and used without further purification. The solvents were dried and distilled using standard methods [13].

2.1. Instrumentation

The ^{1}H and ^{31}P–$\{^{1}H\}$NMR spectra were recorded in $CDCl_3$ solution on a Bruker DPX400 spectrometer at 400.13 and 161.98 MHz, referenced relative to residual $CHCl_3$ and external 85% H_3PO_4, respectively. The IR spectra in the interval of 4000–400 cm^{-1} were recorded on a Perkin–Elmer 1720X FT-IR spectrometer using KBr pellets. Elemental analyses were performed at the Ecole d'ingénieurs de Fribourg, Switzerland.

2.2. Synthesis of compounds

2.2.1. 1,2-Bis(diphenylphosphino)ethane monoxide (dppeO)

The phosphonium salt obtained by the reaction of 1,2-bis(diphenylphosphino)ethane (dppe) with benzyl bromide in dry toluene, was hydrolysed with aqueous sodium hydroxide to yield the ligand, as reported previously [14]. IR (cm^{-1}): 3052, 1937, 2903, 1588, 1480, 1435, 1182, 1122, 1106, 1069, 1025, 997, 881, 783, 727, 692, 712, 536, 513, 504, 474. ^{1}H NMR : 2.28 (br, 4H), 7.29–7.71 (m, 20H). ^{31}P NMR : −11.68 (d, $^{3}J_{P-P} = 48.4$), 33.18 (d, $^{3}J_{P-P} = 48.4$).

2.2.2. $[HgCl_2(dppeO)]_n$ (1)

To a methanolic solution of mercury(II) chloride (0.13 g, 0.48 mmol), solid dppeO (0.2 g, 0.48 mmol) was added in portions and allowed to stir overnight. The white precipitate obtained was filtered, washed with cold methanol and recrystallized from acetonitrile. Yield: 0.27 g, 83%; m.p.: 253–255 °C. *Anal.* Calc. for $C_{26}H_{24}Cl_2HgOP_2$: C, 45.53; H, 3.53. Found. C, 45.93; H, 3.51%. IR (cm^{-1}): 3054, 2913, 1589, 1436, 1160, 1121, 1103, 997, 741, 725, 690, 540, 516, 506, 476. ^{1}H NMR : 2.87–2.97 (m, 2H), 3.08–3.13 (m, 2H), 7.40–7.91 (m, 20H). ^{31}P NMR : 33.40 (d, $^{3}J_{P-P} = 58.9$), 37.12 (d, $^{3}J_{P-P} = 58.9$, $^{1}J_{Hg-P} = 7449$).

2.2.3. $[HgBr_2(dppeO)]_n$ (2)

The reaction was carried out as for **1** using mercury(II) bromide (0.17 g, 0.48 mmol). The product obtained was recrystallized by slow evaporation of a chloroform solution. Yield: 0.32 g, 87%; m.p.: 225–227 °C. *Anal.* Calc. for $C_{26}H_{24}Br_2HgOP_2$: C, 40.30; H, 3.12. Found. C, 40.21; H, 3.08%. IR (cm^{-1}): 3054, 2907, 1589, 1483, 1435, 1409, 1164, 1121, 1101, 1069, 1026, 997, 739, 726, 690, 540, 515, 476. ^{1}H NMR : 2.89 (br, 2H), 3.06 (br, 2H), 7.42–7.89 (m, 20H). ^{31}P NMR : 29.46 (d, $^{3}J_{P-P} = 57.5$), 33.38 (d, $^{3}J_{P-P} = 57.5$, $^{1}J_{Hg-P} = 6422$).

2.2.4. $[HgI_2(dppeO)]_n$ (3)

Complex **3** was obtained in the same way as **1** using mercury(II) iodide (0.22 g, 0.48 mmol) and dppeO (0.2 g, 0.48 mmol). The product obtained was recrystallized by slow evaporation of a chloroform solution. Yield: 0.35 g, 83%; m.p.: 212–214 °C. *Anal.* Calc. for $C_{26}H_{24}Hg\ I_2OP_2$: C, 35.94; H, 2.78. Found. C, 35.87; H, 2.75%. IR (cm^{-1}): 3053, 2906, 1588, 1484, 1436, 1411, 1156, 1120, 1098, 998, 739, 726, 691, 538, 507, 494, 474. ^{1}H NMR: 2.75 (br, 2H), 2.92 (br, 2H), 7.45–7.86 (m, 20H). ^{31}P NMR: 6.34 (br, $^{1}J_{Hg-P} = 4366$), 32.93 (d, $^{3}J_{P-P} = 54.9$).

2.2.5. $[HgCl_2(dppeO)_2]$ (4)

A solution of mercury(II) chloride (0.098 g, 0.36 mmol) in methanol was added dropwise to a solution of dppeO (0.3 g, 0.72 mmol) in dichloromethane. The mixture was stirred for 3 h. White feathery crystals obtained after slow evaporation of the solvent were washed with cold methanol and dried *in vacuo*. Yield: 0.29 g, 75%; m.p.: 250 °C. *Anal.* Calc. for $C_{52}H_{48}Cl_2HgO_2P_4$: C, 56.76; H, 4.40. Found. C, 56.47; H, 4.35%. IR (cm^{-1}): 3051, 2912, 1573, 1484, 1436, 1188, 1121, 1104, 997, 738, 728, 693, 540, 517, 506, 479. ^{1}H NMR: 2.90 (br, 8H), 7.27–7.91 (m, 40H). ^{31}P NMR: 28.75 (br, $^{1}J_{Hg-P} = 4654$), 34.08 (br).

2.2.6. $[HgBr_2(dppeO)_2]$ (5)

Complex **5** was prepared in the same way as for **4** using mercury(II) bromide (0.13 g, 0.36 mmol). Yield: 0.29 g, 70%. m.p.: 216–218 °C. *Anal.* Calc. for $C_{52}H_{48}Br_2HgO_2P_4$: C, 52.52; H, 4.07. Found. C, 51.92; H, 4.06%. IR (cm^{-1}): 3429, 3051, 2910, 1573, 1484, 1436, 1190, 1121, 1103, 996, 737, 727, 693, 539, 516, 507, 478. ^{1}H NMR: 2.88 (br, 8H), 7.45–7.93 (m, 40H). ^{31}P NMR: 21.19 (br, $^{1}J_{Hg-P} =$ 3874), 33.21 (br).

2.2.7. $[HgI_2(dppeO)_2]$ (6) · $CHCl_3$

Complex **6** was prepared in the same way as for **4** using mercury(II) iodide (0.16 g, 0.36 mmol). The product was crystallized in chloroform. Yield: 0.35 g, 75%; m.p.: 196–198 °C. *Anal.* Calc. for $C_{53}H_{49}Cl_3HgI_2O_2P_4$: C, 45.38; H, 3.52. Found. C, 45.82; H, 3.53%. IR (cm^{-1}): 3052, 2942, 1589, 1483, 1436, 1184, 1120, 1103, 997, 736, 692, 538, 508, 478. ^{1}H NMR: 2.70–2.83 (m, 8H), 7.27–7.88 (m, 40H). ^{31}P NMR: 4.32 (br, $^{1}J_{Hg-P} = 3042$), 33.14 (br).

2.3. X-ray crystallography

Single crystals of **2** and **3** were obtained by slow evaporation of a chloroform solution. Well formed crystals of **4** were obtained as a DMSO solvate by mixing two equivalents of dppeO, 1 equiv. of $HgCl_2$ and one equivalent of dimethyltin dichloride, in DMSO and allowed to stand. Crystals of **5** were grown from a dichloromethane solution by vapour diffusion of hexane. The intensity data were

collected at 173 K (−100 °C) on a Stoe Mark II-Image Plate Diffraction System [15] equipped with a two-circle goniometer using Mo Kα graphite monochromated radiation. The structures were solved by Direct methods using the programme SHELXS-97 [16]. The refinement and all further calculations were carried out using SHELXL-97 [17]. The H-atoms were included in calculated positions and treated as riding atoms using SHELXL default parameters. The non-H atoms were refined anisotropically, using weighted full-matrix least-squares on F^2. In complex **2**, disorder was noted in one of the ligand molecules in the atoms C53, C54, P6, O3 and the phenyl rings C67–C72 and C73–C78; two sets of positions were refined for the above atoms (occupancies 0.47(A) and 0.53(B)). The phenyl ring atoms C42, C43, C45 and C46 were also found to be disordered over two positions and refined with occupancies 0.5 for both the positions (A and B). In the co-crystallised chloroform molecule, the chlorine atoms were found to be disordered over two positions (occupancies 0.566 (A) and 0.434 (B)), the C–Cl distances were constrained to their theoretical values and the thermal parameters made equal. All the phenyl rings, except ring C21–C26, have been constrained to have thermal parameters equal to that of their respective *ipso* carbon atom. Complex **3** crystallized in the non-centrosymmetric triclinic space group $P\bar{1}$ and was refined as an inversion twin (final BASF value =0.418(13)). In complexes **3** and **4**, the phenyl rings were constrained to have thermal parameters equal to that of their respective *ipso* carbon atom. Disorder was also found in the phenyl rings and in atoms P2 and O1 of complex **5**. Two sets of positions (A and B) were refined with occupancies of 0.5,

and the bond distances have been constrained to their theoretical values. Semi-empirical absorption corrections were applied using MULscanABS (PLATON) for **2** ($T_{min}/T_{max} = 0.080/0.178$) and **5** ($T_{min}/T_{max} = 0.621/0.895$). Empirical absorption corrections were applied using DELrefABS (PLATON) for **3** ($T_{min}/T_{max} = 0.167/0.639$) and **4** ($T_{min}/T_{max} = 0.401/0.796$). Further crystallographic data are given in Table 1 and selected bond distances and angles are given in Tables 2 and 3. The molecular structure and crystallographic numbering schemes are illustrated in ORTEP III [18] and PLATON [19] drawings, Figs. 1–5.

3. Results and discussion

The reaction of 1,2-bis(diphenylphosphino)ethane monoxide (dppeO) with various mercury(II) halides has been carried out. Different coordination modes have been observed with different metal to ligand stoichiometry. The reactions are represented in Scheme 1.

3.1. Hg(II)–dppeO 1:1 complexes

The reaction of HgX_2 (X = Cl, Br, I) and dppeO in equimolar ratio in methanol yielded white precipitates immediately. The IR spectra of the products show strong

Scheme 1. Reaction of dppeO with Hg(II) halides.

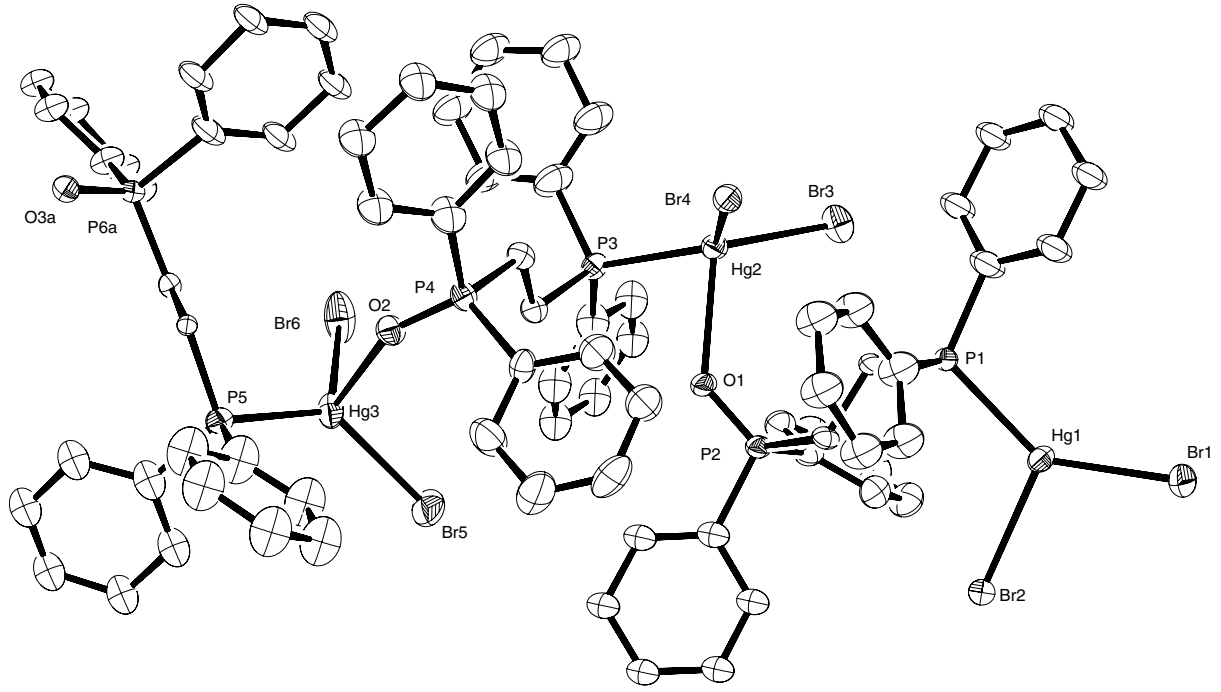

Fig. 1. Asymmetric unit of **2** at 30% probability ellipsoids. The hydrogen atoms, the disordered components and the solvent molecule of $CHCl_3$ have been omitted for clarity.

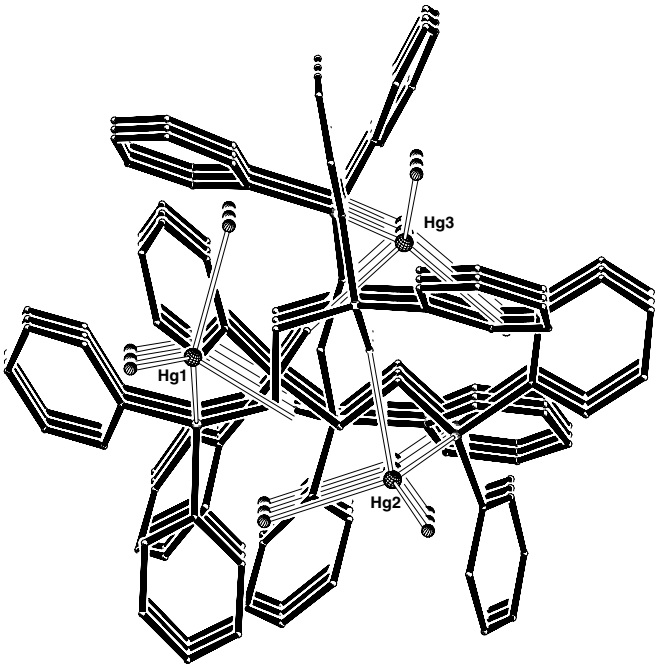

Fig. 2. A view of complex **2** along crystallographic *b*-axis. The figure shows the pseudo three-fold screw axis leading to an helical arrangement.

bands at 1160, 1164 and 1156 cm^{-1} for **1**, **2** and **3**, respectively, attributed to the coordinated (P = O) group. The ^{1}H NMR spectra exhibit two broad multiplets for two magnetically non-equivalent methylene protons in the ligand. Of the two signals in the ^{31}P NMR spectra, the ones exhibiting satellite signals due to ^{199}Hg (16.4% natural abundance, $I = 1/2$), are assigned to the coordinated 'PPh_2'. The chemical shifts and the coupling constants decrease going from chloride to iodide (see Table 4) as observed previously for $[HgX_2(PPh_3)_n]$ (X = Cl, Br,I) ($n = 1, 2$) [20,21]. The ^{31}P NMR signals due to '$Ph_2P = O$' are not shifted much from the corresponding free ligand resonance (+33.18 ppm), suggesting the dissociation of the Hg–O bond in solution.

3.2. Hg(II)–dppeO 1:2 complexes

When 1 equiv. of HgX_2 (X = Cl, Br, I) was added dropwise to two equivalents of dppeO, the 1:2 complexes were obtained in which the ligand coordinates exclusively with the phosphine moiety. The IR and ^{31}P NMR spectra are in accordance with the observed coordination mode. Interestingly, the coordination chemical shifts ($\Delta\delta = \delta_{complex} - \delta_{ligand}$) and the Hg–P coupling constants are lower for the 1:2 complexes (Table 4). The difference in the spectral parameters for the 1:1 and 1:2 complexes is most probably dominated by the steric interactions [20] due to the proximity of bulky phenyl groups to the metal center in the latter. Indeed, complex **6** with bulky iodide ligands appears very labile in solution. Repeated attempts to obtain single crystals of complex **6** lead to the formation

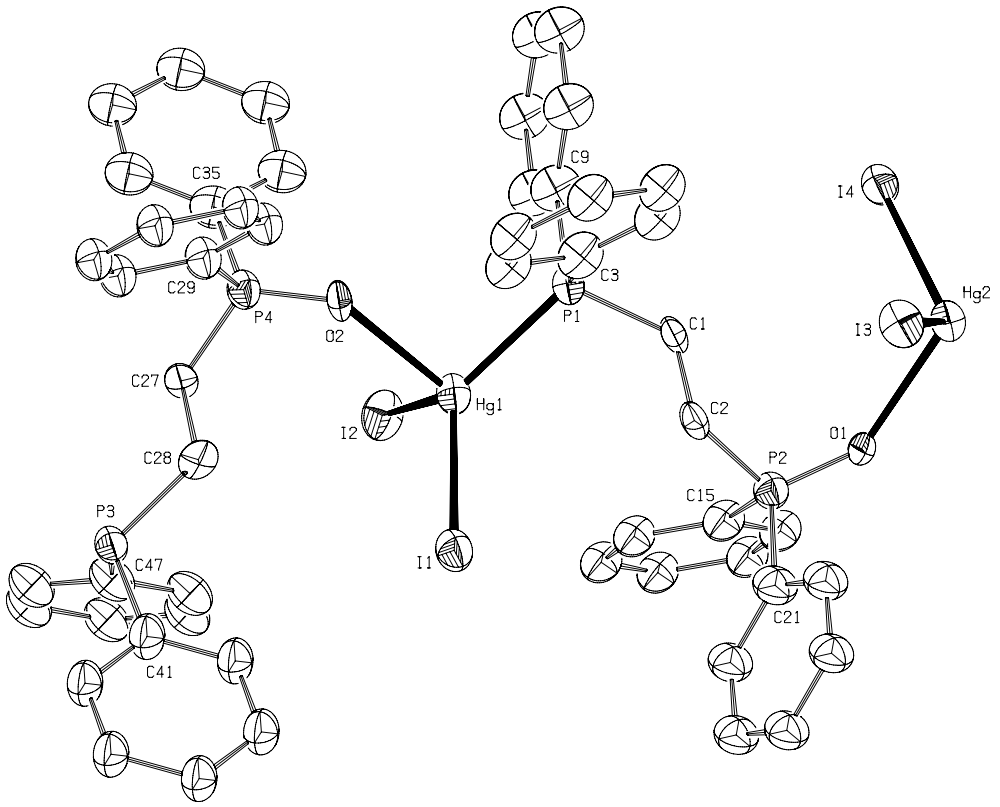

Fig. 3. Asymmetric unit of **3** at 30% probability ellipsoids. The hydrogen atoms have been omitted for clarity.

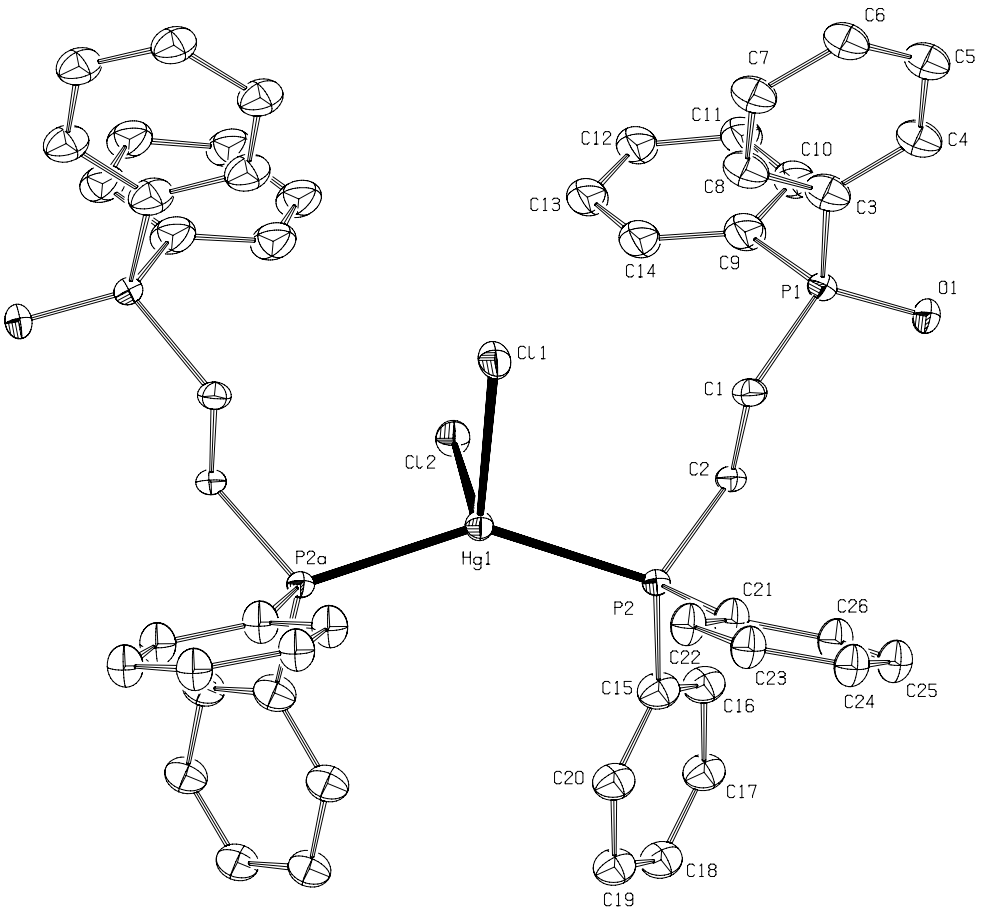

Fig. 4. Molecular structure of **4** at 30% probability ellipsoids. Atoms Hg1, Cl1 and Cl2 lie in the mirror plane. The hydrogen atoms and the DMSO solvent molecule have been omitted for clarity.

of complex **3**, as confirmed by the unit cell parameters derived from the preliminary X-ray diffraction data. In the ^{1}H NMR spectra, the methylene protons of the dppeO framework appear as a single peak for complexes **4** and **5**, while the same protons show two broad resonances for complex **6**.

A noteworthy feature of the ^{31}P NMR spectra is the increased intensity of the phosphine oxide signal which seems to have merged peaks. This may be attributed to the presence of $Ph_2P(O)CH_2CH_2P(O)Ph_2$ (dppeO_2) in solution, formed due to the oxidation of dissociated dppeO by Hg^{2+}. Catalytic oxidation of bis(diphenylphosphino)methane (dppm) by Hg^{2+} to dppmO and dppmO_2 has been noted previously [22].

3.3. Molecular structures of the 1:1 complexes *2* and *3*

The molecular structures of complexes **2** and **3** are shown in Figs. 1 and 3, respectively, and selected bond distances and angles are given in Table 2. The asymmetric unit of **2** is composed of three $HgBr_2$ units bridged by three dppeO ligands and a molecule of chloroform solvent. The X-ray analysis reveals the coordination of both 'P' and 'O' atoms of the ligand to mercury thereby forming an infinite one dimensional polymeric chain. The chain contains a pseudo three-fold screw axis which propagates along the crystallographic *b*-axis, thus exhibiting a pseudo-helical arrangement (Fig. 2).

The geometries around the three Hg centers are highly distorted tetrahedral. The bond angles range from 88.2(5)° to 134.95(6)°, 81.42(14)° to 134.13(6)° and 86.67(16)° to 127.62(7)° for Hg(1), Hg(2) and Hg(3), respectively. Similar range has been observed in $[Hg\{Ph_2P(S)CH_2PPh_2\}I_2]$ [10]. The geometry around Hg in the above complex was considered as flattened tetrahedral, since the metal deviates by only 0.3823(8) Å from the least-squares plane defined by the two I atoms and one P atom in the direction of the capping S atom. In the present case the Hg atom deviations from the best least-squares plane defined by the two Br atoms and one P atom are 0.244, 0.234, 0.229 Å for Hg(1), Hg(2) and Hg(3), respectively, from the direction of the capping O atom. Such type of flattening from the tetrahedral geometry could be the result of several factors including the steric interactions. While the Hg–P distances (2.395(2)–2.411(2) Å) are comparable to the same distance in the P,O-chelate complex *trans*-$[Hg\{Ph_2PNP(O)Ph_2\text{–}P,O\}_2]$ [7], the Hg–O bonds (mean distance 2.55(9) Å) are longer than the *normal*

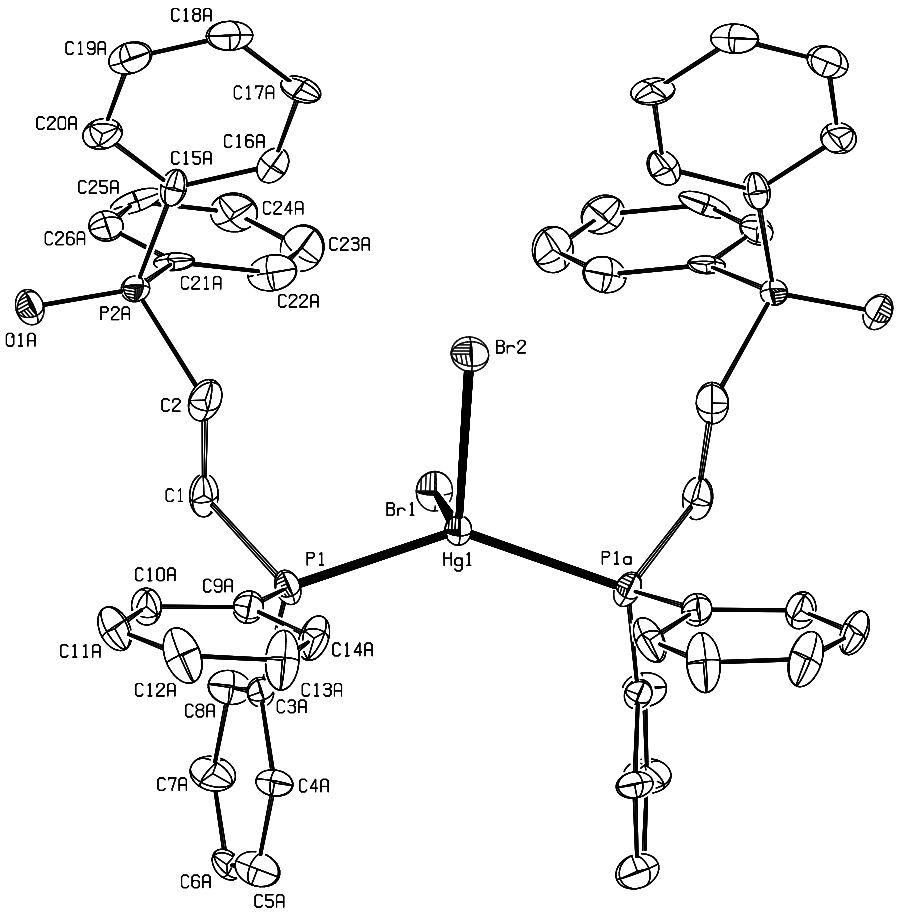

Fig. 5. Molecular structure of complex **5** at 30% probability ellipsoids. Atoms Hg1, Br1 and Br2 lie in the mirror plane. The hydrogen atoms and the disordered components have been omitted for clarity.

Hg–O covalent bond (ca. 2.1 Å), thus accounting for its dissociation in solution as noted in the ^{31}P NMR spectra.

Complex **3** crystallizes in the non-centrosymmetric triclinic space group $P\bar{1}$. The asymmetric unit consists of two HgI_2 units bridged by two dppeO molecules, resulting in the formation of a linear zig-zag polymeric chain. A similar distorted arrangement is observed as that of **2**. However, compared to **2,** the deviations of the Hg(1) and Hg(2) atoms from the least-squares plane described by two I atoms and one P atom are high being equal to 0.406 and 0.367 Å, respectively. The average Hg–P distance of 2.472(7) Å is longer than the values observed in **2**, while the average Hg–O distance of 2.485(2) Å is shorter.

It is interesting to note that although the precursor ligand, dppe and its fully oxidized form $dppeO_2$ have the pronounced tendency to act as a bridging ligands, the bridging tendency of dppeO has not been, to the best of our knowledge, previously confirmed [23] crystallographically with any metal. Hence, complexes **2** and **3** represent the first examples of structurally characterized polymeric complexes where dppeO acts as a bridging bidentate ligand.

Table 4
IR and ^{31}P NMR spectral parameters [ν (cm^{-1}), δ (ppm), J (Hz)]

[a] ($\Delta\delta = \delta_{complex} - \delta_{ligand}$).

3.4. Molecular structures of 1:2 complexes **4** and **5**

The molecular structures of the 1:2 complexes **4** and **5** are shown in Figs. 4 and 5, respectively. Table 3 contains selected bond distances and angles. The mercury atom is coordinated to two halogens and two phosphorus atoms. The P = O groups in both complexes remain free and no significant interaction with the metal has been observed. The mercury and the two halogen atoms lie in the mirror plane. Complex **4** crystallizes as a DMSO solvate. The geometry around mercury is distorted tetrahedral. The Hg–P distances of 2.453(2) and 2.456(2) Å in **4** and **5**, respectively, are in the range of 2.39(1)–2.574(3) Å reported previously for 1:2 mercuric halide–phosphine complexes [24,25]. The P–Hg–P angles 143.93(8)° and 142.34(10)° in **4** and **5**, respectively, are significantly higher than the tetrahedral angle. Such a trend was observed in the complexes $[HgCl_2(PPh_3)_2]$ [24] and $[HgCl_2(PEt_3)_2]$ [26], where the P–Hg–P angles are 134° and 158°, respectively. These were interpreted in terms of strong Hg–P bonding and weaker Hg–Cl interactions. It seems reasonable to include steric effects as well as the tendency of Hg(II) to acquire primary coordination of valency of two, to account for the higher P–Hg–P angles.

In summary, we have prepared and characterized mercury(II)–dppeO complexes with different molecular structures and geometries. The P, O-coordinated infinite one- dimensional polymers were obtained when 1:1 molar ratio of metal to ligand was used. Complexes **2** and **3** represent the first crystallographically characterized examples containing dppeO ligand in bridging bidentate coordination mode. The Hg(II) center is located in a highly distorted tetrahedral environment. The change in the halogen from bromide to iodide has a marked influence in the structure of the polymeric chain from pseudo helical to a zig-zag arrangement. On the other hand exclusively P, P-coordinated complexes were obtained when two equivalents of ligand were added to one equivalent of the metal salt . The complexes were discretely monomeric containing uncoordinated phosphine oxide group. The results suggest that the interaction of Hg(II) with different phosphines remain an active field of research leading to complexes with unusual structures.

2. Experimental

2.1. Materials and physical methods

The complexes $[M(CO)_4L_2]$ and $Ph_4P[MCl(CO)_3L_2]$ were freshly prepared by the published method [7], and all other chemicals were purchased from commercial sources and used without further purification. Experiments were carried out under an N_2 atmosphere. Infrared spectra were recorded on a Perkin–Elmer 781 spectrometer using samples prepared as nujol mulls on sodium chloride discs. The ^1H NMR spectra were obtained for solutions in dimethylsulfoxide-d_6 and were referenced to the solvent as internal standard.

2.2. Synthesis of $[MoCl(CO)_2(\eta^3\text{-}CH_2C(COCl)C{=}CH_2)L_2]$ (L_2 = bipy **4a**, L_2 = phen **4b**)

A mixture of $[Mo(CO)_4L_2]$ (2.0 mmol), Ph_4PCl (824 mg, 2.2 mmol) and excess 1,4-dichloro-2-butyne (**3**) (0.2 ml) was refluxed in CH_2Cl_2 (10 ml) for 6 h, cooled to room temperature and then stored at 5 °C for 3 days. The orange product was filtered from solution and dried *in vacuo*. Yields = 69% **4a**, 73% **4b**.

2.3. Synthesis of $[WCl(CO)_2(\eta^3\text{-}CH_2C(COCl)C{=}CH_2)(2,9\text{-}Me_2phen)]$ (**4c**)

A mixture of $[W(CO)_4(2,9\text{-}Me_2phen)]$ (504 mg, 1.0 mmol) and Ph_4PCl (400 mg, 1.07 mmol) in 1,2-$C_2H_4Cl_2$ (25 ml) was refluxed for 6 h with an excess of **3** (0.1 ml). Reduction of the solvent volume under reduced pressure followed by storage at 5 °C for 3 days gave the orange title product. This was filtered from solution and dried *in vacuo*. Yield = 76%.

2.4. Attempted preparation of **4a**

$Mo(CO)_6$ (264 mg, 1.0 mmol), phen (180 mg, 1.0 mmol), Ph_4PCl (400 mg, 1.1 mmol) and **3** (0.1 ml) were refluxed in CH_2Cl_2, $CHCl_3$ or CH_2Br_2 (25 ml) and monitored by IR spectroscopy for 3–72 h.

2.5. Thermal study of **4a**

Method a: Mixtures of $[Mo(CO)_4(phen)]$ (**1a**) (50 mg, 0.13 mmol) and Ph_4PCl (60 mg, 0.16 mmol) were refluxed with **3** (0.1 ml) in CH_2Cl_2, $CHCl_3$, 1,1,1-$C_2H_3Cl_3$, 1,2-$C_2H_4Cl_2$, CH_2Br_2 or C_6H_5Cl (25 ml) for 3–6 h. *Method b:* The reaction was carried out as *a*, but **1a** and Ph_4PCl were replaced by **4a** (60 mg, 0.12 mmol). For both methods, the complex $[MoCl_2(CO)(\eta^2\text{-}ClCH_2C{\equiv}CCH_2Cl)(phen)]$ (**5**) was obtained from those solvents boiling in the range 61–96 °C. For **5**: ^1H NMR in DMSO-d_6, 5.41 (brs, 4H), 8.05–9.35 (m, 8H); IR (Nujol) 1956 cm^{-1}; elemental *Anal.* Calc. for ($\cdot 0.5CH_2Cl_2$): C, 38.85; H, 2.40; N 5.18. Found: C, 39.70; H, 2.34; N 5.43.

2.6. Synthesis of $[MoCl(CO)_2(\eta^3\text{-}CH_2C(COBr)C{=}CH_2)(phen)]$

A suspension of **4a** (365 mg, 0.5 mmol) and potassium bromide (595 mg, 5.0 mmol) in refluxing acetone (50 ml) was stirred for 18 h. The resulting mixture was poured into water (20 ml), and then extracted twice with dichloromethane (25 ml). The separated organic layer was dried over $MgSO_4$, and removal of solvent in vacuo gave the orange-red product. Yield = 45%.

2.7. Synthesis of $[MoCl(CO)_2(\eta^3\text{-}CH_2C(COX)C{=}CH_2)L_2]$ ($X = NHCH_2CH{=}CH_2$, L_2=bipy **6** or phen **7**; $X = NC_5H_{10}$, L_2 = bipy **8**; $X = NHCH_2C{\equiv}CH$, L_2 = bipy **9**)

Method a: A mixture of $[Mo(CO)_4L_2]$ (1.0 mmol) and Ph_4PCl (393 mg, 1.05 mmol) was stirred in CH_2Cl_2 (10 ml) with an excess of allyl amine, piperidine or propargyl amine (0.25 ml), and to this was added **3** (0.1 ml). The mixture darkened on addition, and after refluxing for 7 h, the volume was reduced by half using a flow of N_2. Storage overnight at low temperature gave the product as orange-red microcrystals. These were filtered from solution, and recrystallized from methanol or CH_2Cl_2–petrol mixtures. *Method b*: The acyl chloride complex was prepared as given in Section 2.2, and to this was added the amine. After a further 1 h reaction under reflux, the product was isolated as described above. *Method c*: The reaction was carried out as described in *a*, but $[Mo(CO)_4L_2]$ and Ph_4PCl were replaced by $Ph_4P[MoCl(CO)_3L_2]$ (1.0 mmol). Yields of each complex obtained by methods *a–c* were similar, and in the range 42–68%.

2.8. Synthesis of $[WCl(CO)_2(\eta^3\text{-}CH_2C(COX))C{=}CH_2\text{-}(2,9\text{-}Me_2phen)]$ ($X = N(CH_2CH{=}CH_2)_2$ **10** or $NHCH(Ph)CO_2Me$ **11**)

The synthesis was carried out as described in Section 2.7 method *a*, but using 1,2-$C_2H_4Cl_2$ and the appropriate amine. Yields = 49% **10**, 54% **11**.

2.9. Synthesis of $MoCl(CO)_2(\eta^3\text{-}CH_2C(CO_2CH_2C{\equiv}CH)C{=}CH_2)(phen)]$ (**12**) and $[MoCl(CO)_2(\eta^3\text{-}CH_2C(COS(CH_2)_2SH)C{=}CH_2)(phen)]$ (**13**)

The reaction was carried out as described in Section 2.7 method *a*, with the amine replaced by propargyl alcohol or 1,2-ethanedithiol (0.5 ml) and triethylamine (0.1 ml). Yields = 54% **12**, 47% **13**.

2.10. X-ray crystallography

A single orange crystal of **9** ($0.50 \times 0.20 \times 0.12$ mm) was grown from a CH_2Cl_2–petrol mixture and mounted on a glass fibre in paratone oil. Data were collected at 120 K on an Nonius KappaCCD area detector diffractometer located at the window of a Nonius FR591 rotating anode

X-ray generator, equipped with a molybdenum target (λ Mo Kα = 0.71073 Å). The structure was solved and refined using the SHELX-97 suite of programs and data were corrected for absorption effects by means of comparison of equivalent reflections using the program SADABS [8,9]. Non-hydrogen atoms were refined anisotropically, whilst hydrogen atoms were fixed in idealised positions with their thermal parameters riding on the values of their parent atoms. Positional disorder (180° rotation) was found to be present in the propargyl chain (C18–C20) with an occupancy ratio of 66:34, and only one orientation of this chain is shown in Fig. 1 for clarity. $C_{20}H_{16}ClMoN_3O_3$, monoclinic, $P2_1/c$, $a = 7.4910(1)$, $b = 16.9292(3)$, $c = 15.2343(2)$ Å, $\beta = 93.9620(10)°$, volume = 1927.35(5) Å^3, $Z = 4$, $D_c = 1.646$ Mg/m^3, $\mu = 0.846$ mm^{-1}, 29 518 measured, 4422 unique ($R_{int} = 0.0358$) and 3827 ($F_o > 4\sigma(F_o)$) reflections, R_1 (obs) = 0.0287 and wR_2 (all data) = 0.0732 $\rho_{max}/\rho_{min} = 0.650/-0.933$ e Å^{-3}.

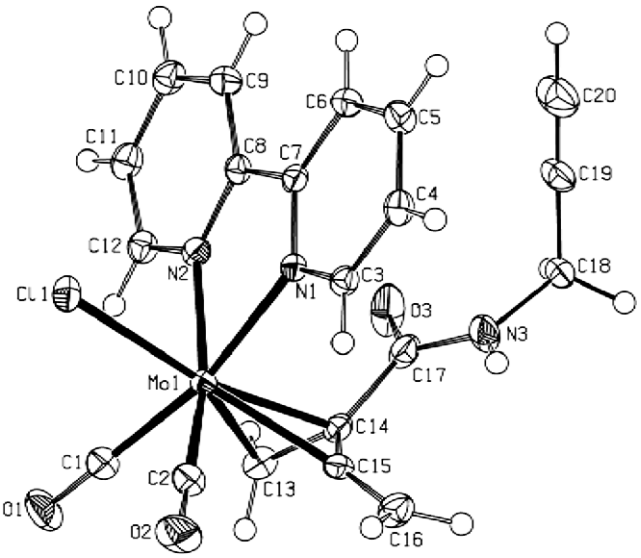

Fig. 1. The crystal structure of [MoCl(CO)$_2$(η^3-CH$_2$C(CONHCH$_2$C≡CH)C=CH$_2$)(2,2′-bipyridine)] (**9**), with the second component of the disordered propargyl chain (C18′–C20′) omitted for clarity.

3. Results and discussion

3.1. Synthesis of substituted butadienyl complexes

A mixture of [Mo(CO)$_4$L$_2$] (L$_2$ = phen, **1a**, bipy **1b**), Ph$_4$PCl and 1,4-dichloro-2-butyne (**3**) was refluxed in CH$_2$Cl$_2$, and the product was monitored by IR and NMR spectroscopy over time. After 3 h approximately equal quantities of unreacted **1** and [MoCl(CO)$_2$-(η^3-CH$_2$C(COCl)C=CH$_2$)L$_2$] (**4a**,**4b**) were obtained, and complete conversion of **1** to **4** was achieved after a further 3 h (Eq. (1), Scheme 1). During this period the orange reaction mixture showed no signs of darkening due to formation of purple Ph$_4$P[MoCl(CO)$_3$L$_2$] (**2a**,**2b**), nor was there evidence of this compound in the spectra. This was not unexpected, since **2** reacted rapidly with **3** at 20 °C, and at elevated temperatures would be consumed on formation. Whilst yields of **4** were similar to the previous two stage process (Eqs. (2) and (3)), the new reaction time exceeds the latter by 3 h. A mixture of [W(CO)$_4$(2,9-Me$_2$phen)] (**1c**), Ph$_4$PCl and **3** heated in CH$_2$Cl$_2$, CHCl$_3$ or 1,1,1-C$_2$H$_3$Cl$_3$ (40–72 °C) over the same 6 h period showed no spectroscopic change. However increasing the temperature to 81 °C (1,2-C$_2$H$_4$Cl$_2$) afforded the acyl chloride (**4c**) in good yield, and this new reaction time compares favourably with the previous two stage total of 18 h (Eqs. (2) and (3)). The practical and environmental advantages of transferring to the one pot method are therefore, (i) isolation of products in good yield using minimum glassware and cleaning solvents, (ii) complete elimination of MeCN (Eq. (2)), (iii) reduction of solvent temperatures by 60–70 °C (previously 110 °C Mo and 140 °C W, Eq. (2))

$$\underset{\mathbf{1}}{M(CO)_4L_2} + Ph_4PCl + \underset{\mathbf{3}}{ClCH_2C{\equiv}CCH_2Cl} \rightarrow \underset{\mathbf{4}}{[MCl(CO)_2(\eta^3\text{-}CH_2C(COCl)C{=}CH_2)L_2]} \quad \text{(eqn. 1)}$$

$$\mathbf{1} + Ph_4PCl \rightarrow \underset{\mathbf{2}}{Ph_4P[MCl(CO)_3L_2]} \quad \text{(eqn. 2)}$$

$$\mathbf{2} + \mathbf{3} \rightarrow \mathbf{4} \quad \text{(eqn. 3)}$$

$$\mathbf{1} + Ph_4PCl + \mathbf{3} \rightarrow \underset{\mathbf{5}}{[MCl_2(CO)(\eta^2\text{-}ClCH_2C{\equiv}CCH_2Cl)L_2]} \quad \text{(eqn. 4)}$$

$$\mathbf{4} + \mathbf{3} \rightarrow \mathbf{5} \quad \text{(eqn. 5)}$$

$$\mathbf{1} + Ph_4PCl + \mathbf{3} + XH \rightarrow \underset{\mathbf{6\text{-}13}}{[MCl(CO)_2(\eta^3\text{-}CH_2C(COX)C{=}CH_2)L_2]} \quad \text{(eqn. 6)}$$

Scheme 1. Conditions: Eq. (1) Δ CH$_2$Cl$_2$ (Mo, 6 h) or 1,2-C$_2$H$_4$Cl$_2$ (W, 6 h), Eq. (2) Δ toluene (Mo, 1 h) or xylene (W, 16 h) and MeCN, Eq. (3) RT CH$_2$Cl$_2$2 h, Eqs. 94) and (5) Δ CHCl$_3$6 h, Eq. (6) Δ CH$_2$Cl$_2$ (Mo, 7 h) or 1,2-C$_2$H$_4$Cl$_2$ (W, 7 h).

and (iv) reaction time for tungsten complexes reduced by 12 h.

In an effort to decrease the time required to convert $[Mo(CO)_4L_2]$ to **4**, reactions of **1a**, Ph_4PCl and **3** were carried out in higher boiling point solvents. Coordinating solvents were avoided in view of their potential reaction with **1** to form solvated compounds of the type $[M(CO)_3(L_2)(S)]$ [10], and chlorinated solvents were selected for their ability to dissolve reactants and products. After 4 h in $CHCl_3$ (61 °C), peaks due to carbonyl stretching in **1a** had been replaced by those of **4a** and an additional peak of almost equal intensity at 1956 cm^{-1}. The latter predominated on raising the temperature to 96 °C (CH_2Br_2), and the complex $[MoCl_2(CO)(\eta^2\text{-}ClCH_2C{\equiv}CCH_2Cl)(phen)]$ (**5**) was isolated from solution. This product was also obtained on refluxing a mixture of **4a** and excess 1,4-dichloro-2-butyne in this solvent (Eqs. (4) and (5), Scheme 1), and one pot production of **5** occurred in solvents of higher boiling point until onset of decomposition of intermediate **2** occurred at 129 °C (C_6H_5Cl). Dichloroalkyne **3** is not expected to undergo rearrangement within this temperature range [11], and therefore the additional chlorine in **5** originates from decomposition of **4a**. On refluxing **4a** in acetone containing bromide ions, the derivative $[MoCl(CO)_2(\eta^3\text{-}CH_2C(COBr)C{=}CH_2)(phen)]$ was obtained,[1] and thus both **4a** and its acyl bromide analogue were stable at 56 °C. Isolation of **5** from one pot reactions of **1a**, Ph_4PCl and **3** in solvents boiling within the range 61–129 °C was therefore attributable to destabilization at these higher temperatures.

Attempts to prepare **4a** or **4b** by a one pot method using $[Mo(CO)_6]$, L_2, Ph_4PCl and **3** in refluxing CH_2Cl_2 over several days were less successful. Loss of CO from the hexacarbonyl was found to be slow at this temperature, and 12 h were required to form uncontaminated **1**. The diimine ligands bipy and phen, being weaker pi acceptors than CO, labilize $[M(CO)_4L_2]$ complexes towards dissociative ligand loss from the position *cis* to them. This *cis* labilization results in reaction substitution rates several orders of magnitude larger for these chelate complexes than for $Mo(CO)_6$. After 24 h the IR solution spectrum showed carbonyl stretching absorptions due to **1** and acyl chloride complex **4** of approximately equal intensity. However continued reaction times resulted in decreasing strength of these bands, suggesting the acyl chloride was thermally unstable over extended periods. A good yield of **4** could not be obtained via this method after 48 h (21%), and little remained in solution after refluxing for 72 h. Increasing the reaction temperature by use of $CHCl_3$ or CH_2Br_2 was found to accelerate formation of **1** and **4**, but also resulted in more rapid decomposition of the latter.

[1] For $[MoCl(CO)_2(\eta^3\text{-}CH_2C(COBr)C{=}CH_2)phen]$: ^1H NMR in DMSO-d_6 1.91 (s, H), 3.79 (s, H), 5.67 (d, 1.38H), 6.19 (d, 1.38H), 7.99 (m, 2H), 8.18 (s, 2H), 8.82 (m, 2H), 9.13 (d, 4.42H), 9.29 (d, 4.66H); IR (Nujol), cm^{-1}. 1989, 1912, 1650.

Addition of primary or secondary amines XH to the one pot reaction mixture of **1**, Ph_4PCl and **3** in CH_2Cl_2 afforded substituted complexes of the type $[MCl(CO)_2(\eta^3\text{-}CH_2C(COX)C{=}CH_2)L_2]$ (**6**–**11**), and in the presence of triethylamine and alcohol or thiol, the corresponding ester and thioester complexes could also be achieved (X = $OCH_2C{\equiv}CH$ **12**, $S(CH_2)_2SH$ **13**). These were characterized by their IR and NMR spectra (Tables 1 and 2), and the stereochemistry of **9** was investigated by a single crystal X-ray analysis. In some cases, where complexes were only soluble in DMSO, reproducible elemental analyses could not be obtained since oxidation to $[Mo_2Cl_2O_4(L_2)_2]$ occurred readily on recrystallization [12]. Complete replacement of CH_2Cl_2 by water in this one pot method was not possible due to insolubility of **1**. However **4** and **6**–**9** could be achieved from a two phase CH_2Cl_2/H_2O system, and where small volumes of the former were used, water assisted mixing and filtration. For example, similar yields of **4a** and **6** were obtained when 10 ml CH_2Cl_2 was replaced by 10 ml water and 0.5 ml CH_2Cl_2 in Sections 2.2 and 2.7, respectively. The tungsten complexes however proved more sensitive to water, and on heating **1c**, Ph_4PCl and **3** to 80 °C in an equivolume mixture of 1,2-$C_2H_4Cl_2$ and water (2.3), a mixture of **4c** and the known complex $[WCl_2(CO)_3(2,9\text{-}Me_2phen)]$ was obtained.

3.2. Characterization of complexes

3.2.1. Spectroscopic data

All the η^3-butadienyl complexes exhibited a pair of strong absorptions in their IR spectra between 1982 and 1894 cm^{-1} due to the metal *cis*-dicarbonyl fragment. A band of medium intensity near 1710 cm^{-1} arising from ν(C=O) of the acyl chloride **4** was shifted to lower wavenumber in **6**–**13**, and weak peaks near 3400 or 3250 cm^{-1} were assigned to ν(NH) or ν(C≡CH), respectively. The ^1H NMR spectra showed two singlets near 1.8 and 3.7 ppm due to the methylene terminus of the η^3-bonded butadienyl, and a pair of doublets arising from the double bond of this unit appeared near 5.7 and 6.2 ppm, with coupling constants of 2.2 Hz. Amide complexes containing NH gave rise to a triplet between 6.1 and 6.6 ppm, and a further triplet at 2.84 ppm was attributable to the terminal propargyl proton of **9**. Other signals due to aliphatic substituents of the butadienyl and aromatic protons of the L_2 ligand were unexceptional. As a result of their low solubilities, the ^{13}C NMR spectra of **6**–**13** were not recorded.

3.2.2. Crystal structure determination of 9

A solid-state crystal structure determination of $[MoCl(CO)_2(\eta^3\text{-}CH_2C(CONHCH_2C{\equiv}CH)C{=}CH_2)(2,2'\text{-bipyridine})]$ was carried out to determine the stereochemistry of the substituted η^3-butadienyl fragment. Fig. 1 shows a view of the molecule and the atomic labeling scheme used, and selected bond lengths and angles for **9** are given in Table 3. The coordination geometry about the Mo centre may be considered to be that of a slightly distorted octahedron

[a] Spectra recorded in DMSO-d_6. Data reported in ppm, multiplicity, coupling constant (Hz), number of protons.

if the central atom of the butadienyl based ligand (C14) is considered to be the point of attachment. The central molybdenum atom is bonded to two carbonyl groups [Mo1–C1 1.980(2) Å; Mo1–C2 1.976(2) Å], two nitrogens of 2,2′-bipyridine [Mo1–N1 2.2309(17) Å; Mo1–N2 2.2246(16) Å], a chlorine atom [Mo1–Cl1 2.4997(5) Å] and a 2-substituted butadienyl unit, C_8H_8NO. The metal–CO and carbonyl bond lengths [C1–O1 1.150(3) Å; C2–O2 1.147(3) Å] and angles [Mo1–C1–O1 179.3(2)°; Mo1–C2–O2 178.5(2)°], and the C1–Mo1–C2 bond angle [82.22(9)°], are all typical of a pair of mutually *cis* carbonyl groups. The rings of the bipyridine unit are approximately planar within experimental error, and their bond lengths and angles are similar to values found for related molybdenum η^3-allyl and η^3-pentadienyl bipyridyl complexes [13–15].

Within the butadienyl moiety, the C13–C14–C15 angle of 113.27(19)°, the C13–C14 and C14–C15 bond lengths

C13–Mo1–C11	147.83(6)		

of 1.423(3) and 1.414(3) Å respectively, and the Mo1–C13 and Mo1–C14 separations of 2.300(9) and 2.228(8) Å are all similar to 1- and 2-substituted η^3-allyl complexes of molybdenum [16–18]. However the shorter Mo1–C15 distance of 2.208(9) Å may reflect an intermediate bond order between **1** and **2** that is not expected within an η^3-allyl system. (Compare [Mo(CO)$_2$(η^3-1-RC$_3$H$_4$)(phen)(O$_2$CCF$_3$)] R = H 2.316(5) Å, R = Me 2.411(13) Å.) Although the C15–C16 bond length of 1.317(3) Å is slightly longer than that observed for the related selenoester 2-substituted complex [1.242(13) Å], this value is consistent with related dienyl complexes of the type [Mo(CO)$_2$(η^3-CH$_2$CHC=CR^{1}R^2)L$_3$] (L$_3$ = Cp, Tp; R^1, R^2 = H, Me) [4,5,19]. A non-planar arrangement of hydrogen atoms at terminal atoms C13 and C16 suggests the double bond C15–C16 is not conjugated with respect to the C13–C14–C15 unit, and this should be reflected in the chemical reactivity. The amide group of the butadienyl fragment is approximately planar, with the carbonyl orientated away from the C=CH$_2$ terminus, and the propargyl substituent extends over the bipy ring system. The C18–C19–C20 angle of 178.9(4)° and the C19–C20 bond length of 1.180(6) Å are both in accord with this linear chain.

Asymmetry at the metal centre may occur in related complexes of the type [Mo(CO)$_2$(η^3-allyl)L$_2$Y] due to a non-dissociative trigonal twist rearrangement of L$_2$Y against the M(CO)$_2$(allyl) unit, and this may give rise to dynamic NMR spectra. For example, an asymmetric arrangement of L$_2$Y at the metal has been found in solution and solid states for bipy and phen complexes [Mo(CO)$_2$(η^3-RC$_3$H$_4$)L$_2$Y] (R = H, 1-Me) [13,16]. In contrast, solid state structures of **9** and its phen thioester (M = W, X = SBu) and selenoester (M = Mo, X = SePh) analogues all exhibit a symmetrical arrangement of the M(CO)$_2$L$_2$Cl unit [20,21] and their NMR solution spectra are non-complex and invariant over the temperature range −50 to 20 °C. Whilst allyl complexes [W(CO)$_2$(η^3-CH$_2$CRCH$_2$)L$_3$]$^+$ (L$_3$ = bis(2-methylpyridyl)amine) exhibit dynamic behaviour in solution at room temperature for both R = H and Me, and an asymmetric arrangement of the tridentate ligand has been shown in the solid state [22], fluxionality has not been reported for either [Mo(CO)$_2$(η^3-CH$_2$CHC=CH$_2$)Cp] or [Mo(CO)$_2$(η^3-CH$_2$CMeC=CH$_2$)Tp] [4,5]. A more detailed molecular orbital description of bonding in metal η^3-butadienyl complexes is required to explain these differences.

4. Conclusions

Complexes containing the η^3-CH$_2$C(COCl)C=CH$_2$ moiety can be synthesized from 1,4-dichloro-2-butyne by a one pot reaction with [M(CO)$_4$L$_2$] and Ph$_4$PCl. Chlorinated solvents with boiling points in the range 40–60 °C (M = Mo) or 83–96 °C (M = W) are required for this conversion, and at elevated temperatures destabilization of the butadienyl complex can occur to afford [MCl$_2$(CO)(η^2-ClCH$_2$C≡CCH$_2$Cl)L$_2$]. Preparation of the η^3-dienyl complex from one pot reactions involving [M(CO)$_6$] are hindered by this temperature requirement. Loss of CO below 60 °C (Mo) or 96 °C (W) is relatively slow and rate determining, and over the necessarily extended periods, increasing decomposition of dienyl product occurs. In contrast, conversion of the tetracarbonyl to [MCl(CO)$_3$L$_2$]$^-$ occurs more rapidly, and reaction in situ with the dichloroalkyne is fast. Thus under conditions for successful one pot production of the acyl chloride, addition of alcohols, amines or thiols generates the analogous ester, amide and thioester complexes, and in general these are found to have greater thermal stability below 120 °C. Both Mo and W complexes can also be obtained in the presence of water, however for the latter, formation of [WCl$_2$(CO)$_3$L$_2$] as a co-product reduces final yields. Comparison of the structure of propargyl amide **9** with related selenoester and thioester reveals a common arrangement of the acyl substituent and non-coordinated double bond. Isomers of these forms have not been observed in solution or solid states, and a combination of steric and electrostatic factors may explain the preferred orientation. Crystallographic data of all three complexes suggest pi-delocalization within the metal bound C1C2C3 unit is unconjugated with respect to C3=C4, and whilst these complexes may undergo similar reactions to substituted η^3-allyl analogues, the unusually short M–C3 bond length suggests direct parallels can't be assumed. Their behaviour with nucleophilic and electrophilic reagents is under investigation.

Appendix A. Supplementary material

CCDC 612555 contains the supplementary crystallographic data for the crystal structure reported in this paper. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2006.10.040.

complexes with X-ray studies, $[M(ox)_2]$, for some divalent metals (Cu, Ni, Pd), reveal the bidentate monoanion mode of the ligand, resulting in a slightly distorted trans square-planar configuration for the chromophore MN_2O_2. Strong intramolecular hydrogen bonds between the phenolic oxygen and the hydrogen of the oximic hydroxyl were observed in all the cases [12–15]. In the case of cobalt, however, 2-hydroxy-aryloximato complexes were not reported systematically and crystal structures are limited to the square pyramidal complexes of the type $[Co(saox)_2NO]$ [16], and to the octahedral adducts with dimethylsulfoxide $[Co(saox)_2(dmso)_2]$ [17]. An analogous structure had been reported previously by us, for Ni adducts with phenanthroline $[Ni(saox)_2phen]$ [18].

Moreover, cobalt plays an important role among biologically active ions [3]. It has been found that the $[Co(III)(saox)_2(CH_3COO)]$ [19], inhibits 50% of leukemic cell proliferation, binds DNA strongly and also inhibits the relaxation activity to topoisomerase II. The biological activities of cobalt can be increased when mixed-ligand complexes with heterocyclic bases, such as bipy are involved. For example, the complex $[Co(III)(bipy)_2L]^{2+}$, where L = benzoylhydrazone derivative, a ligand with N and O donor atoms, shows DNA binding and antitumor activity [20].

Based on the above-mentioned applications and in order to fill the gap on structurally characterized cobalt 2-hydroxy-aryloximates, we report here the synthesis and structural study of 12 new mixed-ligand cobalt(III) complexes, under the general formula $[Co(oxime)(enR)_2]Br$, where oxime is the dianion of a 2-hydroxy-aryloxime (H_2oxime) and enR an α-diimine (bipy or phen). It is known that H_2saox usually behaves as bidentate monoanion [15] or as bridging dianion ligand between two metal centers in polynuclear complexes [21–24]. To the best of our knowledge, this is the second example of mononuclear 2-hydroxy-aryloximato complexes, where the ligand H_2saox acts as dianion (saox). The first example was reported for the complex [Co(III)(saox)triethyl tetramine]-Cl [25].

The new cationic Co(III) compounds were characterized by physicochemical and spectroscopic methods. The octahedral environment with CoN_5O chromophore was confirmed by X-ray diffraction analysis of the compound $[Co(saox)(bipy)_2]Br$ (**1**). Correlation between theoretical results and electronic excitation data were undertaken for the compound **1** and the results are presented and discussed. Cyclic voltammetry (CV) study was employed to investigate the electrochemical behavior of the prepared complexes.

The ligands 2-OH-aryloximes (H_2oxime) used in this work are: 2-OH, $C_6H_4CR{=}NOH$ [R = H (salicylaldoxime, H_2saox); R = CH_3 (acetophenonoxime, H_2apox); R = C_2H_5 (propiophenonoxime, H_2ppox); R = C_6H_5 (benzophenonoxime, H_2bpox)] or 2-OH, 3-MeO, $C_6H_3CH{=}NOH$ (3-methoxy-salicylaldoxime or *o*-vanillinoxime (H_2vanox)) and 2-OH, 5-Me, $C_6H_3C(CH_3){=}NOH$ (5-methyl-acetophenonoxime, H_2mpox) The crystal structure of one of the investigated oxime ligand, the 2-hydroxy-benzophenonoxime (H_2bpox) was also determined by X-ray analysis, verifying the strong intra-and intermolecular hydrogen bonds.

2. Experimental

2.1. Materials

The ligand 2-OH-benzaldoxime (salicylaldoxime, H_2saox), the 2,2′-bipyridine (bipy), the 1,10′-phenanthroline (phen) and the metal salt $CoBr_2 \cdot 6H_2O$ were obtained as reagent grade from Aldrich and used as received. The other 2-OH-aryloxime ligands (H_2oxime) and the precursor compounds $Co(bipy)_2Br_2$ and $Co(phen)_2Br_2$ were prepared according to the literature methods [26,27]. Solvents for preparation and physical measurements of "extra pure" were obtained from Fluka without further purification.

2.2. Instrumentation/analytical procedures

Microanalyses were obtained using a Perkin–Elmer 240 B CHN microanalyzer. Infrared spectra were recorded on a Perkin–Elmer 1600 FT-IR spectrometer in KBr discs at room temperature and are reported in cm^{-1}. Electronic absorption spectra in solutions were obtained on a Shimatzu 160 A spectrometer. The solid-state electronic spectrum was obtained from Nujol mull. The H NMR spectrum was recorded on a Bruker AM 300 (300 MHz) in $CDCl_3$ solution with TMS as internal standard. Molar conductivity was measured in DMF solution employing a WTW conductivity bridge and a calibrated dip type cell. Magnetic susceptibility measurement on powdered sample was performed at 25 °C employing the Faraday method on a home-build balance calibrated against $Hg[Co(SCN)_4]$. CV was used for the electrochemical measurements on a μ-AUTOLAB Potentio-Galvanostat (ECO CHEMIE, Netherlands). A saturated calomel electrode was used as a reference electrode and graphite one as an auxiliary electrode for all measurements. As a working electrode a platinum wire one was used. The tests in CH_3CN solution were carried out in the potential region −1800 to +2200 mV at ambient temperature. Recrystallized TEA perchlorate 0.1 M was used as the electrolyte at a scan rate of 100 mV/s. All scans were recorded in degassed solvent and under current of moisture free argon over the solution surface.

Computational techniques. All calculations have been performed using the GAUSSIAN-98 revision A11 package from Gaussian, Inc. Carnegie Office Park, Building 6 Carnegie, PA 15106, USA. Energy and orbitals calculation were performed using the B3LYP Density Functional Theory approximation. The basis set used was the LANL2DZ for all atoms. The prediction of the spectrum was calculated using CIS and ZINDO options.

2.3. Preparation of the complexes $[Co(oxime)(enR)_2]Br \cdot 2H_2O$

2.3.1. $[Co(saox)(bipy)_2]Br \cdot 2H_2O$

A solution of H_2saox (68.5 mg, 0.5 mmol) and CH_3ONa (54 mg, 1 mmol) in MeOH (20 mL), was added drop-wise to a solution of $Co(bipy)_2Br_2$ (0.266 g, 0.5 mmol) in H_2O (20 mL) at room temperature, under air. The brown solution (pH 8) was stirred for 2 h and then turned darker and a dark green solid was formed. The solid was filtered and washed with diethyl ether and dried under vacuum (0.22 g, 65% yield). The resulting powder analyzed as solvent free and bipyridine free. *Anal.* Calc. for $C_{27}H_{21}N_5O_2CoBr \cdot 2H_2O$ (MW 622): C, 52.09; H, 4.02; N, 11.25. Found: C, 51.82; H, 4.13; N, 10.80%. Conductivity in DMF = 65 μS/cm, $\mu_{eff} = 0$. IR (KBr): selected peaks in cm^{-1}: 3407 m, ν(OH crystal water); 1604 s and 1604 and 1590 s, ν(C=N); 1325 s, ν(–C–O); 1033 m and 916 m, ν(=N–O); 756, 773 s (double) and 729 s (pyridine molecules); 524 m, ν(Co–O); 474 m, ν(Co–N).

The newly prepared microcrystalline Co(III) compound is stable in air, soluble in almost all the organic solvents and in water, but insoluble in diethyl ether. Single crystals suitable for X-ray analysis were separated from the mother liquid by slow evaporation and characterized as $[Co^{III}(saox)(bipy)_2]Br \cdot 0.166bipy \cdot 0.15CH_3OH \cdot 1.75H_2O$.

2.3.2. $[Co(vanox)(bipy)_2]Br \cdot 2H_2O$

A solution of H_2vanox (83.5 mg, 0.5 mmol) and CH_3ONa (54 mg, 1 mmol) in MeOH (20 mL), was added drop-wise to a solution of $Co(bipy)_2Br_2$ (0.266 g, 0.5 mmol) in H_2O (20 mL) at room temperature, under air. The brown solution (pH 7.8) was stirred for 2 h and then turned darker and a dark green solid was formed. The solid was filtered and washed with diethyl ether and dried under vacuum (0.19 g, 58% yield). *Anal.* Calc. for $C_{28}H_{23}N_5O_3CoBr \cdot 2H_2O$ (MW 652): C, 51.53; H, 4.14; N, 10.73. Found: C, 52.31; H, 4.34; N, 10.40%. Conductivity in DMF = 68 μS/cm, $\mu_{eff} = 0$. IR (KBr): selected peaks in cm^{-1}: 3395 m, ν(OH crystal water); 1605 s and 1605 and 1596 s, ν(C=N); 1322 s, ν(–C–O); 1035 m and 896 m, ν(=N–O); 738, 767 s (double) and 730 s (pyridine molecules); 541 m, ν(Co–O); 446 m, ν(Co–N).

2.3.3. $[Co(apox)(bipy)_2]Br \cdot 2H_2O$

A solution of H_2apox (75.5 mg, 0.5 mmol) and CH_3ONa (54 mg, 1 mmol) in MeOH (20 mL), was added drop-wise to a solution of $Co(bipy)_2Br_2$ (0.266 g, 0.5 mmol) in H_2O (20 mL) at room temperature, under air. The brown solution (pH 7.8) was stirred for 2 h and then turned darker and a dark green solid was formed. The solid was filtered and washed with diethyl ether and dried under vacuum (0.24 g, 73% yield). *Anal.* Calc. for $C_{28}H_{23}N_5O_2CoBr \cdot 2H_2O$ (MW 636): C, 52.83; H, 4.24; N, 11.00. Found: C, 53.80; H, 4.20; N, 10.52%. Conductivity in DMF = 73 μS/cm, $\mu_{eff} = 0$. IR (KBr): selected peaks in cm^{-1}: 3401 m, ν(OH crystal water); 1605 s and 1605 and 1590 s, ν(C=N); 1315 s, ν(–C–O); 1018 m and 896 m, ν(=N–O); 738, 767 s (double) and 730 s (pyridine molecules); 513 m, ν(Co–O); 422 m, ν(Co–N).

2.3.4. $[Co(ppox)(bipy)_2]Br \cdot 2H_2O$

A solution of H_2ppox (82.5 mg, 0.5 mmol) and CH_3ONa (54 mg, 1 mmol) in MeOH (20 mL), was added drop-wise to a solution of $Co(bipy)_2Br_2$ (0.266 g, 0.5 mmol) in H_2O (20 mL) at room temperature, under air. The brown solution (pH 8) was stirred for 2 h and then turned darker and a dark green solid was formed. The solid was filtered and washed with diethyl ether and dried under vacuum (0.17 g, 52% yield). *Anal.* Calc. for $C_{29}H_{25}N_5O_2CoBr \cdot 2H_2O$ (MW 650): C, 53.53; H 4.46; N, 10.76. Found: C, 54.20; H, 4.52; N, 10.80%. Conductivity in DMF = 67 μS/cm, $\mu_{eff} = 0$. IR (KBr): selected peaks in cm^{-1}: 3400 m, ν(OH crystal water); 1604 s and 1604 and 1592 s, ν(C=N); 1319 s, ν(–C–O); 1020 m and 922 m, ν(=N–O); 742, 759 s (double) and 735 s (pyridine molecules); 530 m, ν(Co–O); 460 m, ν(Co–N).

2.3.5. $[Co(bpox)(bipy)_2]Br \cdot 2H_2O$

A solution of H_2bpox (106.5 mg, 0.5 mmol) and CH_3ONa (54 mg, 1 mmol) in MeOH (20 mL), was added drop-wise to a solution of $Co(bipy)_2Br_2$ (0.266 g, 0.5 mmol) in H_2O (20 mL) at room temperature, under air. The brown solution (pH 7.5) was stirred for 2 h and then turned darker and a dark green solid was formed. The solid was filtered and washed with diethyl ether and dried under vacuum (0.19 g, 54% yield). *Anal.* Calc. for $C_{33}H_{29}N_5O_2CoBr \cdot 2H_2O$ (MW 698): C, 56.73; H, 4.15; N, 10.02. Found: C, 57.78; H, 4.17; N, 10.08%. Conductivity in DMF = 78 μS/cm, $\mu_{eff} = 0$. IR (KBr): selected peaks in cm^{-1}: 3395 m, ν(OH crystal water); 1603 s and 1603 and 1585 s, ν(C=N); 1321 s, ν(–C–O); 1034 m and 951 m, ν(=N–O); 763, 781 s (double) and 736 s (pyridine molecules); 550 m, ν(Co–O); 498 m, ν(Co–N).

2.3.6. $[Co(mpox)(bipy)_2]Br \cdot 2H_2O$

A solution of H_2mpox (82.5 mg, 0.5 mmol) and CH_3ONa (54 mg, 1 mmol) in MeOH (20 mL), was added drop-wise to a solution of $Co(bipy)_2Br_2$ (0.266 g, 0.5 mmol) in H_2O (20 mL) at room temperature, under air. The brown solution (pH 7.6) was stirred for 2 h and then turned darker and a dark green solid was formed. The solid was filtered and washed with diethyl ether and dried under vacuum (0.21 g, 64% yield). *Anal.* Calc. for $C_{29}H_{25}N_5O_2CoBr \cdot 2H_2O$ (MW 650): C, 53.54; H, 4.46; N, 10.765. Found: C 54.43; H, 4.66; N, 10.76%. Conductivity in DMF = 67 μS/cm, $\mu_{eff} = 0$. IR (KBr): selected peaks in cm^{-1}: 3403 m, ν(OH crystal water); 1604 s and 1604 and 1576 s, ν(C=N); 1323 s, ν(–C–O); 1018 m and 892 m, ν(=N–O); 762, 780 s (double) and 736 s (pyridine molecules); 526 m, ν(Co–O); 497 m, ν(Co–N).

2.3.7. [Co(saox)(phen)$_2$]Br · 2H$_2$O

A solution of H$_2$saox (68.5 mg, 0.5 mmol) and CH$_3$ONa (54 mg, 1 mmol) in MeOH (20 mL), was added drop-wise to a solution of Co(phen)$_2$Br$_2$ (0.289 g, 0.5 mmol) in H$_2$O (20 mL) at room temperature, under air. The brown solution (pH 8) was stirred for 2 h and then turned darker and a dark green solid was formed. The solid was filtered and washed with diethyl ether and dried under vacuum (0.27 g, 80% yield). *Anal.* Calc. for $C_{31}H_{21}N_5O_2CoBr \cdot 2H_2O$ (MW 670): C, 55.52; H, 3.73; N, 10.44. Found: C, 56.18; H, 3.94; N, 10.03%. Conductivity in DMF = 69 μS/cm, $\mu_{eff} = 0$. IR (KBr): selected peaks in cm^{-1}: 3420 m, *ν*(OH crystal water); 1604 s and 1615 and 1589 s, *ν*(C=N); 1320 s, *ν*(–C–O); 1034 m and 913 m, *ν*(=N–O); 756, 842 s (double) and 719 s (pyridine molecules); 535 m, *ν*(Co–O); 473 m, *ν*(Co–N).

2.3.8. [Co(vanox)(phen)$_2$]Br · 2H$_2$O

A solution of H$_2$vanox (83.5 mg, 0.5 mmol) and CH$_3$ONa (54 mg, 1 mmol) in MeOH (20 mL), was added drop-wise to a solution of Co(phen)$_2$Br$_2$ (0.289 g, 0.5 mmol) in H$_2$O (20 mL) at room temperature, under air. The brown solution (pH 7.8) was stirred for 2 h and then turned darker and a dark green solid was formed. The solid was filtered and washed with diethyl ether and dried under vacuum (0.19 g, 54% yield). *Anal.* Calc. for $C_{32}H_{23}N_5O_2CoBr \cdot 2H_2O$ (MW 700): C, 54.85; H, 3.85; N, 10.00. Found: C, 54.07; H, 4.06; N, 10.72%. Conductivity in DMF = 70 μS/cm, $\mu_{eff} = 0$. IR (KBr): selected peaks in cm^{-1}: 3405 m, *ν*(OH crystal water); 1610 s and 1610 and 1587 s, *ν*(C=N); 1330 s, *ν*(–C–O); 1077 m and 966 m, *ν*(=N–O); 775, 844 s (double) and 719 s (pyridine molecules); 535 m, *ν*(Co–O); 433 m, *ν*(Co–N).

2.3.9. [Co(apox)(phen)$_2$]Br · 2H$_2$O

A solution of H$_2$apox (75.5 mg, 0.5 mmol) and CH$_3$ONa (54 mg, 1 mmol) in MeOH (20 mL), was added drop-wise to a solution of Co(phen)$_2$Br$_2$ (0.289 g, 0.5 mmol) in H$_2$O (20 mL) at room temperature, under air. The brown solution (pH 7.9) was stirred for 2 h and then turned darker and a dark green solid was formed. The solid was filtered and washed with diethyl ether and dried under vacuum (0.17 g, 49% yield). *Anal.* Calc. for $C_{32}H_{23}N_5O_2CoBr \cdot 2H_2O$ (MW 684): C, 56.14; H, 3.95; N, 10.23. Found: C, 56.13; H, 4.07; N, 10.86%. Conductivity in DMF = 78 μS/cm, $\mu_{eff} = 0$. IR (KBr): selected peaks in cm^{-1}: 3417 m, *ν*(OH crystal water); 1610 s and 1610 and 1590 s, *ν*(C=N); 1365 s, *ν*(–C–O); 1017 m and 940 m, *ν*(=N–O); 753, 841 s (double) and 720 s (pyridine molecules); 507 m, *ν*(Co–O); 449 m, *ν*(Co–N).

2.3.10. [Co(ppox)(phen)$_2$]Br · 2H$_2$O

A solution of H$_2$ppox (82.5 mg, 0.5 mmol) and CH$_3$ONa (54 mg, 1 mmol) in MeOH (20 mL), was added drop-wise to a solution of Co(phen)$_2$Br$_2$ (0.289 g, 0.5 mmol) in H$_2$O (20 mL) at room temperature, under air. The brown solution (pH 7.5) was stirred for 2 h and then turned darker and a dark green solid was formed. The solid was filtered and washed with diethyl ether and dried under vacuum (0.21 g, 60% yield). *Anal.* Calc. for $C_{33}H_{25}N_5O_2CoBr \cdot 2H_2O$ (MW 698): C, 56.73; H, 4.15; N, 10.02. Found: C, 56.63; H, 4.07; N, 9.70%. Conductivity in DMF = 73 μS/cm, $\mu_{eff} = 0$. IR (KBr): selected peaks in cm^{-1}: 3410 m, *ν*(OH crystal water); 1607 s and 1607 and 1580 s, *ν*(C=N); 1315 s, *ν*(–C–O); 1018 m and 920 m, *ν*(=N–O); 754, 846 s (double) and 719 s (pyridine molecules); 520 m, *ν*(Co–O); 476 m, *ν*(Co–N).

2.3.11. [Co(bpox)(phen)$_2$]Br · 2H$_2$O

A solution of H$_2$bpox (106.5 mg, 0.5 mmol) and CH$_3$ONa (54 mg, 1 mmol) in MeOH (20 mL), was added drop-wise to a solution of Co(phen)$_2$Br$_2$ (0.289 g, 0.5 mmol) in H$_2$O (20 mL) at room temperature, under air. The brown solution (pH 7.3) was stirred for 2 h and then turned darker and a dark green solid was formed. The solid was filtered and washed with diethyl ether and dried under vacuum (0.28 g, 75% yield). *Anal.* Calc. for $C_{37}H_{25}N_5O_2CoBr \cdot 2H_2O$ (MW 746): C, 59.51; H, 3.88; N, 9.38. Found: C, 59.84; H, 4.02; N, 8.88%. Conductivity in DMF = 75 μS/cm, $\mu_{eff} = 0$. IR (KBr): selected peaks in cm^{-1}: 3415 m, *ν*(OH crystal water); 1610 s and 1610 and 1585 s, *ν*(C=N); 1318 s, *ν*(–C–O); 1035 m and 950 m, *ν*(=N–O); 754, 841 s (double) and 729 s (pyridine molecules); 525 m, *ν*(Co–O); 458 m, *ν*(Co–N).

2.3.12. [Co(mpox)(phen)$_2$]Br · 2H$_2$O

A solution of H$_2$mpox (82.5 mg, 0.5 mmol) and CH$_3$ONa (54 mg, 1 mmol) in MeOH (20 mL), was added drop-wise to a solution of Co(phen)$_2$Br$_2$ (0.289 g, 0.5 mmol) in H$_2$O (20 mL) at room temperature, under air. The brown solution (pH 7.4) was stirred for 2 h and then turned darker and a dark green solid was formed. The solid was filtered and washed with diethyl ether and dried under vacuum (0.23 g, 66% yield). *Anal.* Calc. for $C_{33}H_{25}N_5O_2CoBr \cdot 2H_2O$ (MW 698): C, 56.73; H, 4.15; N, 10.02. Found: C, 57.08; H, 4.24; N, 9.76%. Conductivity in DMF = 70 μS/cm, $\mu_{eff} = 0$. IR (KBr): selected peaks in cm^{-1}: 3427 m, *ν*(OH crystal water); 1604 s and 1604 and 1592 s, *ν*(C=N); 1364 s, *ν*(–C–O); 1032 m and 900 m, *ν*(=N–O); 778, 843 s (double) and 720 s (pyridine molecules); 512 m, *ν*(Co–O); 455 m, *ν*(Co–N).

2.4. X-ray crystallography

Data for single crystals of titled compounds [Co(saox)(bipy)$_2$]Br · 0.166bipy · 0.15CH$_3$OH · 1.75H$_2$O and H$_2$bpox (Table 1) were collected with a Bruker SMART APEX CCD system with Mo Kα radiation ($\lambda = 0.7107$ Å) and corrected for absorption by semi-empirical methods (multi-scan). Both structures were solved by direct methods.

For the [Co(saox)(bipy)$_2$]Br structure the assignment of non-hydrogen atoms was immediate except for those present in the crystallographic mirror plane at $y = 1/4$. Many peaks appear at this plane in the ΔFmaps, the assignment

of which was not obvious, indicating considerable disorder of the structure at this plane. The two most intense peaks were assigned to bromine atoms with partial occupancy: after some trial and error, occupancies were fixed to optimize the refinement while keeping electrical neutrality of the compound. After this, a set of 12 weak peaks which roughly formed two hexagons were assigned as a non-coordinated bipyridine molecule with partial occupancy, which was introduced with fixed bond distances. Other weak peaks in this plane were assigned as partial occupancy water or methanol molecules (the latter introduced with constrained C–O distance). All full-occupancy non-hydrogen atoms were refined anisotropically as well as partial occupancy bromine atoms. Other partial occupancy atoms were refined isotropically. Hydrogen atoms of the organic moieties at general positions were placed at ideal positions as well as those of the bipy molecule at the mirror plane. Those belonging to water and methanol molecules were found by ΔFmaps and refined using soft constraints. Finally, all hydrogen positions were refined using riding constraints. The refinement on F^2 was performed using CRYSTALS version 12 [28] under a Chebyshev weighting scheme.[1]

All non-hydrogen atoms of the H_2bpox structure were refined anisotropically and all hydrogen atoms were found by ΔFmaps at their expected positions. The oximic and the phenoxy hydrogen atoms were refined using soft constraints to regularize their geometries. Finally, all hydrogen atoms were positioned at their ideal positions and refined using riding constraints. The refinement on F^2 was performed using SHELX-97 [29].

3. Results and discussion

3.1. Synthesis and characterization

The reaction of $[Co^{II}(enR)_2Br]Br$ with 2-hydroxy-aryloximes (H_2oxime) and nitrogenous bases enR, such as 2,2′-bipyridine (bipy) or 1,10′-phenanthroline (phen) under proper aerobic conditions lead to the formation of the green cobalt compounds. The elemental analyses, the electrical conductivity and the absence of magnetic moment (diamagnetic), indicated 1:1 electrolyte of the type $[Co^{III}(oxime)(enR)_2]Br \cdot 2H_2O$. The rare dianionic nature of the oximes, such as salicylaldoxime ($saox^{-2}$) in mononuclear complexes, is inferred from the absence of the stretching mode of the oximino hydroxyl group in the IR spectrum and the absence of the oximic proton signal, in the H NMR spectrum in $CDCl_3$, while for the free ligand is observed at ~3380 cm^{-1} and ~10.44 ppm, respectively [10]. This is further verified from the X-ray analysis discussed later.

3.2. Theoretical calculations and electronic excitation study

The excitation spectra of all the complexes presented five dominant bands in the region 200–900 nm in a series of solvents with different dielectric constant and as Nujol spreads. Two of them at the higher energies with high ε values (established at the region around 255 nm and 300 nm depending on the solvent) were attributed to intraligand $\pi^* \leftarrow \pi$ or $\pi^* \leftarrow n$ excitations and will not be further discussed. The three remaining bands around 340 nm, 400 nm and 670 nm can be attributed as follows: for the first as presenting an MLCT character (see below) and as d ← d transitions of Co(III) for the latest two. Table 2 presents the excitation bands (in wave lengths) together with the ε values for all the studied complexes. Table 3 presents the excitation and ε values in all the studied solvents for the complex $[Co(saox)(bipy)_2]Br$.

When recording the spectrum in organic solvents the arrangement effects of the dissolution, change the positions of the observed bands presenting a solvatochromic effect. The shape of the electronic spectra in the visible region even in solution or as a spread, as well as the low extinction coefficients, are suggestive of an octahedral configuration around the cobalt(III) ion. The positions of the absorption bands in the visible are in good agreement with other octahedral coordination compounds of Co(III) [20,30,31]. The bands II and III show a red shift due to the solvent polarity according to the solvent order Nujol > $CHCl_3$ > CH_3OH > CH_3CN > DMF as it can be seen in Fig. 1. The above d–d excitations in the visible can be attributed to the transition terms $^3T_{2g} \leftarrow {}^1A_{1g}$, and $^1T_{2g} \leftarrow {}^1A_{1g}$, respectively. The position of the Band I (MLCT), which is observed as shoulder at 340 nm is stable and does not depend on the solvent.

The main objective of the theoretical calculations was to explain the electronic excitation spectrum of the complexes using the geometry of the X-ray molecular structure determination of $[Co(saox)(bipy)_2]Br$, as well as the geometry of a slightly modified model in order to obtain a C_{4v} symmetry of the coordination sphere.

The predicted spectrum of the two slightly different complexes of $[Co(saox)(bipy)_2]Br$ in the asymmetric unit of the molecular structure, presents three dominant excitation bands in the visible region of the spectrum using the CIS theoretical approximation. For the one of the complexes in the asymmetric unit (see Section 3.3) these bands were calculated to be at 403 nm, 473 nm and 670 nm. For the second complex the three bands were predicted at 412 nm, 465 nm and 695 nm. All the above bands became of singlet excitations and their symmetry was undetermined. These transitions found all to have main participation from cobalt(III) d orbitals. Especially the orbitals involved are the $d_{xy} \leftarrow d_{z^2}$ for the transition at 670–695 nm, $d_{x^2-y^2} \leftarrow d_{z^2}$ for the one at 465–473 nm and

[1] Method, part 1, Chebychev polynomial (Watkin, 1994, Prince, 1982) $[weight] = 1.0/[A \sim 0 \sim {}^*T \sim 0 \sim (x) + A \sim 1 \sim {}^*T \sim 1 \sim (x) + \cdots + A \sim n-1 \sim]^*T \sim n-1 \sim (x)$ where $A \sim i \sim$ are the Chebychev coefficients listed below and $x = F_{calc}/F_{max}$. Method = Robust Weighting (Prince, 1982) $A \sim i \sim$ are: 9.68, 13.3, 4.23.

Table 3
Electronic excitation data for the [Co(saox)(bipy)$_2$]Br in various solvents

Solvent	Band I, sh		Band II		Band III	
	λ (nm)	logε	λ (nm)	logε	λ (nm)	logε
$CHCl_3$	340	4.10	386	3.80	646	2.47
CH_3OH	340	3.31	400	2.92	653	2.30
CH_3CN	340	3.81	407	2.90	674	2.32
DMF	340	3.81	412	2.97	680	2.35

$d_{x^2-y^2} \leftarrow d_{yz}$ for the one at 403–415 nm. The two of the three doubly occupied obritals of Co(III), the HOMO − 1 (d_{yz}) and the HOMO − 2 (d_{xz}), were calculated to have nearly the same energy, while the energy of the HOMO (d_{z^2}) was considerably higher. As LUMO in both cases were found π^* orbitals from the ligands and further higher were found the d_{xy} and the $d_{x^2-y^2}$ orbitals. In this case it is clear that the equatorial plane contains the following four nitrogen atoms N1, N2, N3, N4. The axial positions were occupied from the rest bipy nitrogen, N5 and the phenolic oxygen from the oxime, O1. The final geometry of the model could be better described as compressed distorted octahedral.

Better results have been obtained when calculating the transition energies using the ZINDO approximation through GAUSSIAN-98. The calculated excitations in the visible were established at 594 nm (singlet-no symmetry), 442 nm (singlet-no symmetry) and 408 nm (triplet-no symmetry) while the orbitals were involved as follows: $d_{z^2} \leftarrow d_{xy}$ for the transition at 594 nm, $d_{x^2-y^2} \leftarrow d_{xy}$ for the one at 442 nm and $d_{x^2-y^2} \leftarrow d_{yz}$ for the one at 408 nm. The two cationic cobalt(III) complexes in this case were calculated to have excitation maxima difference less than 1 nm. The two of the three doubly occupied orbitals of Co(III), the HOMO − 1 (d_{yz}) and the HOMO − 2 (d_{xz}), were calculated to have nearly the same energy with values considerably lower than the energy value of the HOMO (d_{xy}). As LUMO and NLUMO π^* orbitals from the ligands were found, while the d_{z^2} and the $d_{x^2-y^2}$ orbitals lied at higher energies. The geometry in this case was assumed to be elongated distorted octahedral. The nitrogen atoms N1 and N3 are placed on the axial positions while the equatorial plane is formed from the atoms N2, O1, N4 and N5 with respect to the crystal molecular structure numbering. The orbitals arrangement also suggests that

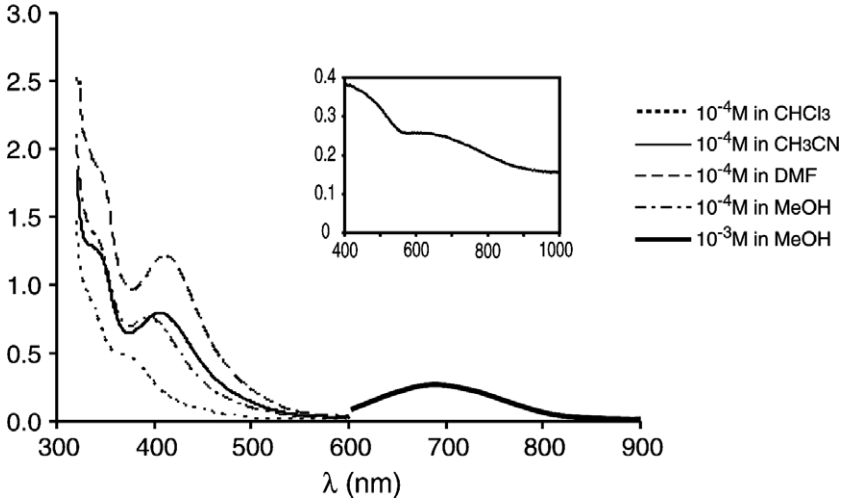

Fig. 1. Electronic excitation (UV/Vis) spectra for [Co(saox)(bipy)$_2$]Br in various solvents and in Nujol mull (in the window).

the bands present around 350 nm are mainly of MLCT character and this is in fairly agreement with the results found in analogous Co(III) complex with the Schiff-base salen (390 nm) [32].

The excitation energies especially from the ZINDO calculations were very close to those found from the experimental visible excitation spectrum of the complex in Nujol. The only difference is that the band around 442 nm was not clearly recorded as it was probably masked from the one around 408 nm which was much more intense. This is why the suggested complex geometry was elongated distorted octahedral as described previously.

In the case of a theoretical model, a mean distance of 1.94 Å from Co(III) for all nitrogen and oxygen atoms has been used. The symmetry of the coordination sphere was C_{4v}. After performing a ZINDO calculation the arrangement of the d orbitals of cobalt(III) differs from the one found from the crystal structure, obtaining the typical octahedral form and the excitations calculated were the following: 470 nm (singlet-B1) representing the $d_{x^2-y^2} \leftarrow d_{xy}$ transition and two nearly equal excitations around 400 nm both singlets with E symmetry representing the $d_{z^2} \leftarrow d_{xz}$ and the $d_{z^2} \leftarrow d_{yz}$ transitions. The energy difference between the HOMO (d_{xy}) and HOMO − 2 (d_{xz}) orbitals in this case was 0.001 eV while HOM − 1 (d_{yz}) and HOMO − 2 had equal energies. Both d_{z^2} and $d_{x^2-y^2}$ orbitals were found at higher positions (compared to the LUMO orbital which was a ligand antibonding orbital) with practically equal calculated energy values.

3.3. Description of the structures

The asymmetric unit of $[Co(saox)(bipy)_2]Br \cdot 0.166bipy \cdot 0.15CH_3OH \cdot 1.75H_2O$ contains two unicationic mononuclear Co(III) complexes with similar geometries. Each Co(III) is coordinated to one bis deprotonated dianionic oxime ligand and two bipy ligands in an octahedral arrangement of the coordination sphere. All distances and angles (Table 4) around cobalt have typical values for Co(III)–nitrogen and Co(III)–oxygen bonds and bonding angles [16a,33,34]. The charge of the complex cations is balanced by bromide anions, two of them placed at general positions with full and 0.2 occupancy, respectively, and the others disordered on three positions with occupancies 0.35, 0.30 and 0.15 on the mirror plane at $y = 1/4$; this adds up to two bromides per asymmetric unit (one per complex cation). The structure is completed by interstitial full occupancy water molecules at general positions and by disordered methanol and non-coordinated bipyridine molecule, both of them with partial occupancy on the mirror plane at $y = 1/4$. A strong hydrogen bonding net is present through all the water molecules hydrogen atoms and the bromine anions.

Concerning the two cobalt(III) complexes the geometry around the metal can be described as distorted octahedral. The nitrogen atoms N1 and N3 (Fig. 2) are placed on the axial positions. The equatorial plane is formed from the atoms N2, O1, N4 and N5. The cobalt(III) ion is placed on this plane with a deviation smaller than the error, while the maximum deviation is coming from the N(1) atom being 0.073(7) Å. The coordination sphere can then be described as elongated distorted octahedral. The two coordinated bipy molecules are planar as expected forming a dihedral angle of 93.86(12)° between them.

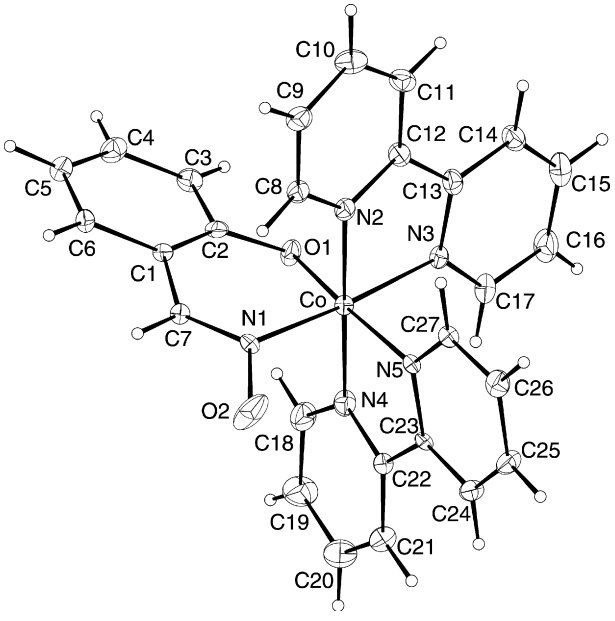

Fig. 2. Molecular structure of one of the cationic complexes $[Co(saox)(bipy)_2]^+$ in the asymmetric unit.

The bond distances between N1 and O2 as well as those between all atoms forming the oximic chelate ring are not equal to those found in two structures of similar compounds presented previously [25,35]. In our case they all have an intermediate value between the normal double and single bond. This fact lead to the conclusion that the oximic chelate ring in both complexes can be better described as an extended delocalized π system. This bis deprotonated oxime ligand is not quite planar presenting a maximum deviation from the mean plane of 0.238(7) Å for the oximic oxygen. The formed dihedral angles of the oxime mean plane with the two bipy ligands have values of 111.30(13)° and 85.15(12)°. Analogous plane distances and angles were obtained when studying the second Co(III) complex in the asymmetric unit.

The unit cell of the neutral ligand H_2bpox consists of eight molecules. All distances and angles (Table 5) are similar to those found in other oxime molecules in the literature. The phenoximic group (excluding the phenyl substitution) is planar with maximum deviation of 0.080(2) Å coming from C(7). The phenyl group is completely planar with deviations from the mean plane equal or smaller than the error and the formed angle between the planes was found to be 63.96(2)°. Strong intra-molecular hydrogen bond is formed between H(1) and N(1) with a distance between O(1) and N(1) of 2.558(2) Å. Inter-molecular hydrogen bond was also found between H(2) and O'(1) with symmetry operator $(1/2 + x,\ 1/2 - y,\ 1 - z)$. The distance O(2) to O′(1) was found to be 2.779(1) Å. These hydrogen bondings is keeping close pairs of molecules in the cell, forming four pairs in each cell, while each pair connected to its neighboring one, is finally forming a zig-zag chain of paired molecules along the a axis of the crystal (Fig. 3).

3.4. Electrochemical study

Cyclic voltammetry experiments were performed with pre-purified crystalline fine powder solutions of the compounds (crystals treated with diethyl ether in order to get the compound free from the crystalline bipy or phen and solvent). A typical voltavogram gave primarily three well separated reversible anodic waves close to 0.39 V, 0.73 V and 1.07 V (Fig. 4). Two more irreversible waves

were present at ca 1.50 V and at −1.75. Finally, the last reversible wave was in the cathodic region at ca −0.89 V as shown in Table 6, which contains the full experimental data of the electrochemical behavior of the studied compounds.

The waves at −0.89 V and 0.39 V are corresponding to the couples Co(I/II) and Co(II/III), respectively. These values are very close to them found from the cyclic voltammetry of similar compounds [36–38]. The rest of the reversible waves at 0.72 V and 1.06 V are assigned to the oxidation of the bipyridine rings, while the phenanthroline rings seemed to be oxidized a little higher at ca 0.74 V and 1.09 V. The oxidation of the oxime ligands could be attributed to the waves at ca 1.50 V up to 1.80 V, while the reductions appear at ca −1.4 V down to −1.8 V depending on the oxime ligand. The latest is in accordance with the waves found when studying the electrochemical behavior of the free oxime ligands under the same experimental conditions. The oxidation waves in the cases of [Co(saox)(bipy)$_2$]Br and [Co(ppox)(phen)$_2$]Br were found at 1.58 V and 1.74 V, respectively, while the reduction waves were found to be at −1.77 V and −1.55 V (Figs. 4 and 5).

The waves assigned to the redox potentials of the free oxime ligands, as well as of the oxime ligands in the complexes, represent two-electron fermentations for ppox, apox, mpox and bpox. For vanox and saox, however, we observe one-electron oxidation waves and two-electron reduction waves. It is possible that the second oxidation wave is outside the studied voltage region. It is worthy to be mentioned that in the voltamograms of H_2ppox and H_2apox free ligands, two well separated oxidation waves were observed, each one representing one-electron, while in the cases of H_2bpox and H_2mpox one wave representing two electrons. All the rest waves on the voltavograms of the complexes represent one-electron transformations, as compared with the waves generated by equimolar amount of ferrocene solution.

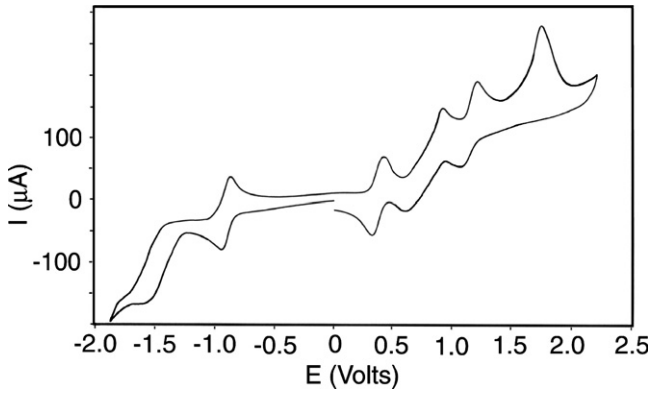

Fig. 5. Cyclic voltammogram of [Co(ppox)(phen)$_2$]Br in CH_3CN with 0.1 M TEAP (scan rate 100 mV/s.).

4. Conclusions

In the novel complexes [Co(oxime)(enR)$_2$]Br · 2H_2O, with octahedral arrangement of the chromophore CoN_5O, the rare for mononuclear Co(III) complexes, bidentate dianion character of the oxime ligand is established. The theoretical investigation with GAUSSIAN-98 for the prediction of the electronic spectrum and especially the ZINDO calculations, gave good correlation with the experimental spectrum in the solid state of the complex [Co(saox)(bipy)$_2$]Br. The cyclic voltammetry study gave all the expected waves for the redox processes of the metal Co(III) and the oxime ligands, as well as for the α-diimines bipy and phen.

Appendix A. Supplementary material

CCDC 292952 and 622386 contain the supplementary crystallographic data for this paper. ing Q^- and a tridentate Schiff-base, interesting chemistry was observed. When $Ti(O^iPr)_4$ reacted with (2-hydroxyphenyl)salicylideneimine in the presence of a large excess of 8-hydroxyquinoline, only Ti(IV)-Schiff-base complex precipitate was obtained initially. However, another Ti(IV) complex containing both Schiff-base and 8-hydroxyquinolinate was obtained only after standing for a long period of time. The mechanism of the delayed formation of the mixed-ligand complex was investigated and the results are reported herein. Though Schiff-bases are well known as versatile ligands [9], the literature on their complexes with Ti(IV) are limited, more specifically there are only few Ti(IV) complexes with tridentate Schiff-base being reported so far [10].

2. Experimental

2.1. Physical measurement

^1H NMR spectra were recorded on a Bruker AC-400 spectrometer. ^{13}C NMR spectra were measured on a Bruker Avence 600 NMR spectrometer. Elemental analyses were carried out in a Heraeus CHN Rapid Analyzer. Mass spectrum was recorded on a JOEL JMS-SX 102 high resolution mass spectrometer.

2.2. Synthesis of *N*-(2-hydroxyphenyl)salicylideneimine$_2$ Sap [11]

In a round bottom flask, 2-aminophenol 5.45 g (50 mmol) was dissolved in 90 mL dried THF at elevated temperature under nitrogen atmosphere. Salicylaldehyde 6.11 g (50 mmol) in THF was added drop-wise to this THF solution. The reaction mixture was heated under refluxing condition. Orange precipitates were observed within 10 min. Reaction was continued for 1 h. Filtering, washing the precipitate with toluene, and drying in a vacuum oven at 60 °C, orange crystal (9.34 g, 89%) was obtained. M.p. 110 °C. Elemental *Anal.* Calc. for $C_{13}H_{11}NO_2$: C, 73.23; H, 5.20; N, 6.57. Found: C, 73.28; H, 5.33; N, 6.61%. The ^1H NMR data are consistent with the literature values.

2.3. Synthesis of bis[*N*-(2-oxophenyl)-salicylideneiminato]titanium(IV), Ti(Sap)$_2$

Under nitrogen atmosphere, $Ti(O^iPr)_4$ 0.16 mL (0.50 mmol) was transferred to a 90 mL dried methanol solution containing *N*-(2-hydroxyphenyl)salicylideneimine (H_2Sap) 0.21 g (1.0 mmol). Red solid suspension formed immediately. Reaction was continued for 1.5 h. Filtering, washing with methanol, and drying in a vacuum oven at 80 °C, red solid product 0.21 g (0.45 mmol) was obtained. Yield: 90%. Decomposition temperature: 375 °C. δ_H (400 MHz, CD_3OD:CD_2Cl_2 (3:1), Me_4Si) 6.395 (2H, d, Ar), 6.634 (2H, d, Ar), 6.825 (2H, t, Ar), 6.980 (2H, t, Ar), 7.066 (2H, t, Ar), 7.465 (2H, m, Ar), 7.534 (2H, d, Ar), 7.705 (2H, d, Ar), 9.136 (2H, s, CH=N). δ_C (150 MHz, DMSO-d_6, Me_4Si) 113.81, 115.83, 116.12, 119.49, 120.21, 121.94, 130.08, 135.08, 136.99, 138.43, 159.05, 160.92, 162.78. Elemental *Anal.* Calc. for $TiC_{26}H_{18}N_2O_4$: C, 66.40; H, 3.86; N, 5.96. Found: C, 66.30; H, 3.86; N, 5.86%. HRMS. M^+: 470.0740 (calc. 470.0746).

2.4. Synthesis of *N*-(2-oxophenyl)salicylideneiminato-8-hydroxyquinolinato methoxotitanium(IV), Ti(Sap)Q(OMe)

2.4.1. Method I

Under a nitrogen atmosphere, a 5 mL dried methanol solution containing $Ti(O^iPr)_4$ 0.18 mL (0.58 mmol) was added to a 5 mL dried methanol solution containing 8-hydroxyquinoline 0.15 g (1.03 mmol). Then a 90 mL dried methanol solution containing *N*-(2-hydroxyphenyl)salicylideneimine (H_2Sap) 0.11 g (0.52 mmol) was added to the reaction mixture. The solution became cloudy immediately with red solid suspension, which then precipitated. After stirring for additional 1.5 h, the solution was left standing overnight. Fine red crystals grew on the wall of the reaction vessel. These crystals were collected, washed with methanol and dried in air. The single crystals were subjected to X-ray diffraction studies.

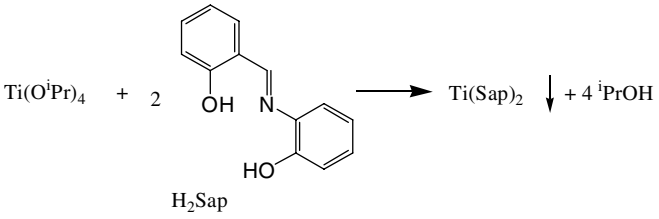
2.4.2. Method II

$Ti(O^iPr)_4$ 0.10 mL (0.31 mmol) was added to a 80 mL methanol solution containing *N*-(2-hydroxyphenyl)salicylideneimine (H_2Sap) 57 mg (0.27 mmol). The solution became turbid with red solid suspension, then became clear after heating to 60 °C for 10 min. A 5 mL methanol solution containing HQ 0.39 g (2.69 mmol) was added to this clear solution. The resulting clear red solution was maintained at 60 °C under stirring for 30 min. The solution was then chilled down rapidly to 10 °C by immersing in cold water. The resulting small amount of precipitates identified by ^1H NMR to be Ti(Sap)$_2$ were removed by filtering. The volume of the filtrate was then reduced to 30 mL, solid product Ti(Sap)Q(OMe) 0.043 g (0.10 mmol) was then obtained by filtration and drying in a vacuum oven. Yield: 32% based on Ti. δ_H 400 MHz, (400 MHz, CD_3OD:CD_2Cl_2 (3:1), Me_4Si) 6.343 (1H, d, Ar), 6.488 (1H, d, Ar), 6.784 (1H, t, Ar), 6.863 (1H, t, Ar), 6.972 (1H, d, Ar), 7.023 (1H, t, Ar), 7.310–7.368 (3H, m, Ar), 7.557 (1H, t, Ar), 7.588 (2H, d, Ar), 8.232 (1H, d, Ar), 8.293 (1H, d, Ar), 9.109 (1H, s, CH=N). δ_C (150 MHz, CD_3OD:CD_2Cl_2 (3:1), Me_4Si) 53, 111.36; 111.41; 115.04; 115.35; 115.63; 117.13; 117.32; 119.27; 119.68; 121.76; 121.95; 129.37; 129.80; 129.99; 130.54; 134.76; 136.66; 138.61; 138.82; 145.66; 146.04; 158.08. Elemental *Anal.* Calc. for $TiC_{23}H_{18}N_2O_4$: C, 63.61; H, 4.18; N, 6.45. Found: C, 64.55; H, 4.03; N: 6.42%.

2.5. Preparation of (μ-oxo)-bis[N-(2-oxophenyl)-salicylideneiminato-8-hydroxyquinolinatotitanium(IV)]

Under nitrogen atmosphere, a 5.0 mL dried methanol solution containing $Ti(O^iPr)_4$ 0.018 mL (0.058 mmol) was added to a 5 mL dried methanol solution containing 8-hydroxyquinoline 0.075 g (0.50 mmol) in a round bottom flask. Then a 90 mL methanol dried solution containing *N*-(2-hydroxyphenyl)salicylideneimine 0.011 g (0.052 mmol) was added to the round bottom flask. Red suspension of $Ti(Sap)_2$ was formed immediately. The reaction mixture was stirred for additional 1.5 h. To this mixture, 100 mL of acetonitrile (not going through rigorous drying procedure) was added. After standing for two days, few pieces of red single crystals were formed on the wall of the round bottom flask. These single crystals were characterized by X-ray diffraction method to be $[Ti(Sap)Q]_2(\mu\text{-}O)$. δ_H (400 MHz, CD_3OD:CD_2Cl_2 (3:1), Me_4Si) 6.339 (2H), 6.475 (2H), 6.954 ~ 7.043 (6H), 7.074 (2H), 7.271 (2H), 7.343 (2H), 7.576 (2H), 7.639 (2H), 7.661 (2H), 7.706 (2H), 8.362 (2H), 8.522 (2H), 9.193 (2H).

2.6. X-ray crystallography



The red prism single crystal ($0.58 \times 0.62 \times 0.80$ mm) of Ti(Sap)Q(OMe) was obtained directly from its preparative solution of method I. Red plate single crystal ($0.20 \times 0.40 \times 0.60$ mm) of $[Ti(Sap)Q]_2(\mu\text{-}O)$ were also obtained directly from its preparative solution. Both crystals of Ti(Sap)Q(OMe) and $[Ti(Sap)Q]_2(\mu\text{-}O)$ were sealed in glass capillaries. Diffraction data measurements were recorded on Rigaku AFC7S diffractometer with graphite monochromated Mo Kα radiation for both Ti(Sap)Q(OMe) and $[Ti(Sap)Q]_2(\mu\text{-}O)$. Empirical absorption corrections were made. The structures were solved by direct method [12], and expanded using Fourier techniques. All non-hydrogen atoms were refined anisotropically. The imine moieties of the Sap^{2-} ligands in both structures were disordered. They were refined with fixed s.o.f's (0.65/0.35 for Ti(Sap)-Q(OMe) and 0.5/0.5 and 0.65/0.35 for the two Sap^{2-} ligands in $[Ti(Sap)Q]_2(\mu\text{-}O)$, respectively). All hydrogen atoms (including those on disordered imine moieties) assumed their calculated positions with riding model. The crystal data, important information on the diffraction data collections and refinements of structural data are presented in Table 1.

3. Results and discussion

The reaction between $Ti(O^iPr)_4$ and *N*-(2-hydroxyphenyl)salicylideneimine (H_2Sap), a tridentate Schiff-base ligand, in a stoichiometric ratio in dried methanol solution, produced a red solid product with high yield 90%. The product was identified by ^1H NMR, $^{13}C\{1H\}$ NMR, high resolution mass spectrometry and elemental analysis to be consistent with $Ti(Sap)_2$. This reaction can be summarized by

H_2Sap

(1)

Attempt to prepare titanium complexes containing both Sap^{2-} and Q^- (8-hydroxyquinolinate) failed when the amounts of the reactants were in the stoichiometric ratio of $Ti(O^iPr)_4$:H_2Sap:HQ = 1:1:1. Only a red precipitate, identified by ^1H NMR to be $Ti(Sap)_2$, was obtained. When the amount of HQ was increased up to 10 equiv. reaching a reactant molar ratio of $Ti(O^iPr)_4$:H_2Sap:HQ = 1:1:10, again only red precipitates $Ti(Sap)_2$ were obtained. We tried several combinations of the ratios of reactants, even with less than stoichiometric H_2Sap, $Ti(Sap)_2$ precipitate was always obtained as the only initial product. However, when the reaction mixture with 2 equiv. HQ was left in the reaction vessel overnight, some small red single crystals formed on the wall of reaction vessel. These single crystals were identified by X-ray diffraction study to be Ti(Sap)Q(OMe). The methoxide group in this compound originated from solvent. If wet acetonitrile was added to a reaction mixture with 10-fold excess of HQ before standing for two days, then different red single crystals, identified by X-ray diffraction study to be $Ti[(Sap)Q]_2(\mu\text{-}O)$, were grown on the wall of reaction vessel.

The color of Ti(Sap)Q(OMe) is red which is different from the orange color of $TiQ_2(O^iPr)_2$. Therefore, introducing the Schiff-base ligand into the coordination sphere of Ti(IV) do change its color as expected. The problem is how to prepare Ti(Sap)Q(OMe) in large quantity. This can be accomplished only after the mechanism of the reaction of $Ti(OR)_4$ with HQ and H_2Sap is understood.

One approach to obtain Ti complex containing both Sap^{2-} and Q^- as major product is to use $TiQ_2(O^iPr)_2$ as a starting reactant. This approach would work if the reason for failing to obtain Ti(Sap)Q(OR) from a mixture of $Ti(O^iPr)_4$, H_2Sap and HQ in methanol was because H_2Sap had a high reaction rate in coordinating to Ti(IV) center to precipitate out as $Ti(Sap)_2$ before HQ can coordinate to Ti(IV), i.e., the rate of reaction of H_2Sap to Ti(IV) is much faster than that of HQ. When Ti(IV) is pre-coordinated with two Q^- ligands, then the rate of the reaction of HQ with Ti(IV) played no role in forming Ti(IV) complex with both Sap^{2-} and Q^-. Therefore, if the ratio of reactants $TiQ_2(O^iPr)_2$:H_2Sap is 1:1, one would expect to see a mixed ligand complex Ti(Sap)Q(OMe) as a major product. Experimentally, the direct reaction between $TiQ_2(O^iPr)_2$ and H_2Sap yielded $Ti(Sap)_2$ as the initial precipitate even in the presence of excess $TiQ_2(O^iPr)_2$ up to 10-fold excess.

To understand the unusual behavior of the reaction between $TiQ_2(OR)_2$ and H_2Sap, it was monitored by ^1H NMR spectra. The ^1H NMR spectrum of a solution of $TiQ_2(O^iPr)_2$ in CD_3OD:CD_2Cl_2 (3:1) mixed solvent, recorded three minutes after the addition of H_2Sap with a molar ratio of 1 to 1 showed the presence of $Ti(Sap)_2$ together with HQ and unreacted $TiQ_2(OR)_2$ (OR is most likely OCD_3 due to rapid exchange with solvent) and H_2Sap. Red solid suspension of $Ti(Sap)_2$ could be seen in the reaction mixture. However, there was no sign of the formation of Ti(Sap)Q(OR). After 10 min of reaction, the ^1H NMR spectrum indicated that the reaction of H_2Sap with $TiQ_2(OR)_2$ proceeded continuously, signals of HQ increased, H_2Sap decreased and a set of small new signals corresponding to Ti(Sap)Q(OR) was detected. After 30 min of reaction, the ^1H NMR spectrum was similar to that obtained at 10 min reaction time except the relative intensities corresponding to H_2Sap and $TiQ_2(OR)_2$ were decreasing, while those for HQ and Ti(Sap)Q(OR) were increasing and those for $Ti(Sap)_2$ remained unchanged. After 1 h reaction time, the ^1H NMR signals became steady. At this stage, three drops of deuterated water was added to the NMR tube. The signals of $Ti(Sap)_2$ and Ti(Sap)Q(OR) disappeared. After standing for additional hour, signals attributed to $[Ti(Sap)Q]_2(\mu\text{-}O)$ and $[TiQ_2(\mu\text{-}O)]_4$ were observed.

These ^1H NMR results provided insight into the mechanistic pathways for the formation of the products obtained in our experiment. One interesting finding in the ^1H NMR spectral monitoring of the reaction between H_2Sap and $TiQ_2(OR)_2$ was that no trace of Ti(Sap)Q(OR) was detected initially. One expects that formation of $Ti(Sap)_2$ from the reaction between $TiQ_2(OR)_2$ and H_2Sap should be a stepwise process, as depicted in Eqs. (2) and (3), instead of simultaneous reaction of two molecules of H_2Sap with $TiQ_2(OR)_2$

$$TiQ_2(OR)_2 + H_2Sap \rightleftharpoons Ti(Sap)Q(OR) + HQ + ROH \quad (2)$$

$$Ti(Sap)Q(OR) + H_2Sap \rightleftharpoons Ti(Sap)_2 + HQ + ROH \quad (3)$$

To be consistent with the observation of the initial absence of Ti(Sap)Q(OR), this compound must be formed and reacted immediately with H_2Sap. In other word, the rate of reaction of H_2Sap toward Ti(Sap)Q(OR) is much higher than that toward $TiQ_2(OR)_2$. In this initial stage, most Ti(Sap)Q(OR) formed reacts immediately with H_2Sap leading to the absence of its ^1H NMR signal. As the reaction proceeds to completion, the concentration of H_2Sap decreases leading to reduced forward rates for both Eqs. (2) and (3). In the mean time, the concentration of HQ increases resulting in increased reverse rates. If the reverse rate of Eq. (3) is fast, then one expect to see the build-up of Ti(Sap)Q(OR) at sufficient low concentration of H_2Sap and sufficient high concentration of HQ.

To investigate the reversibility of the reaction in Eq. (3), the ^1H NMR spectra of a saturated solution of $Ti(Sap)_2$ in CD_3OD:CD_2Cl_2 (3:1) were examined in the presence of large amount of HQ with a molar ratio greater than 5. Immediately after the addition of HQ to the $Ti(Sap)_2$ solution, signals due to $Ti(Sap)Q(OCD_3)$ and H_2Sap appeared besides those of saturated $Ti(Sap)_2$. In addition, the integrated intensities of signals indicated that $Ti(Sap)Q(OCD_3)$ and H_2Sap were formed with equal concentrations. The ^1H NMR spectrum remained unchanged after the initial measurement. It indicated that the equilibrium in Eq. (3) was reached within the time scale of sample preparation for NMR measurement. From the integrated intensities of the four species in solution, the apparent equilibrium constant K_3 in Eq. (3) is calculated to be 60 M. This experiment demonstrated unequivocally that the reaction in Eq. (3) is reversible. In this experiment, $TiQ_2(OR)_2$ was not observed within experimental limit, it implies that the apparent equilibrium constant K_2 for Eq. (2) is in favor of products under these experimental conditions. To estimate K_2, the ^1H NMR spectra used to monitor the reaction of excess $TiQ_2(OR)_2$ with H_2Sap were examined. The integrated intensities of non-overlapping signals for $TiQ_2(OR)_2$, Ti(Sap)Q(OR), HQ and H_2Sap at equilibrium in CD_3OD (18 M)/CD_2Cl_2 (3/1) allowed us to determine the apparent equilibrium constants $K_2 = 10$ M. Based on the concentration-calibrated ^1H NMR integrated signal intensities of the above two ^1H NMR experiments, the apparent solubilities of $Ti(Sap)_2$ and $Ti(Sap)Q(OCD_3)$ are 5.0×10^{-3} M and 1.4×10^{-2} M, respectively. Obviously, the solubilitiy of $Ti(Sap)_2$ is about three times lower than that Ti(Sap)Q(OR). When D_2O is added to the reaction mixture of $TiQ_2(O^iPr)_2$ and H_2Sap, the ^1H NMR spectra showed the disappearance of $Ti(Sap)_2$ and Ti(Sap)Q(OR) and appearance of $[Ti(Sap)Q]_2(\mu\text{-}O)$ and $[TiQ_2(\mu\text{-}O)]_4$.

The disappearance of $Ti(Sap)_2$ was due to its reduced solubility in the presence of water. The disappearance of Ti(Sap)Q(OR) was due to its reaction with water to form $[Ti(Sap)Q]_2(\mu\text{-O})$ as depicted in:

$$2Ti(Sap)Q(OR) + D_2O \rightarrow [Ti(Sap)Q]_2(\mu\text{-O}) + 2ROD \quad (4)$$

This equation can be used to account for the formation of the red single crystals of $[Ti(Sap)Q]_2(\mu\text{-O})$ when wet acetonitrile was added to the reaction mixture of $Ti(O^iPr)_4$, H_2Sap and HQ. The formation of $[TiQ_2(\mu\text{-O})]_4$ is due to the known reaction between $TiQ_2(OR)_2$ with water as depicted in [7]:

$$4TiQ_2(OR)_2 + 4H_2O \rightarrow [TiQ_2(\mu\text{-O})]_4 + 8ROH \quad (5)$$

Therefore, the formation of $Ti(Sap)_2$, Ti(Sap)Q(OMe) and $[Ti(Sap)Q]_2(\mu\text{-O})$ from the reaction of $Ti(O^iPr)_4$ and H_2Sap and HQ can be satisfactorily accounted for by Eqs. (2)–(4). To isolate large amount of Ti(Sap)Q(OMe), we tried to overcome the formation of precipitate of $Ti(Sap)_2$ by elevating the reaction temperature to 60 °C. When H_2Sap (0.27 mmol) was added to 80 mL methanol solution of $Ti(O^iPr)_4$ (0.31 mmol), the precipitates of $Ti(Sap)_2$ were formed immediately. When the solution temperature was raised to 60 °C, the precipitate dissolved. At this temperature, a clear red solution was obtained when large excess of HQ (2.69 mmol) was added. After the resulting mixture was cooled down to 10 °C, some initial precipitate, identified to be $Ti(Sap)_2$, was removed by filtration. When the volume was reduced to 30 mL, precipitates of Ti(Sap)Q(OMe) were obtained at 32% yield based on Ti. Thus we have found a procedure to prepare large amount of the Ti(IV) complex coordinated simultaneously by tridentate, bidentate and monodentate ligands.

The structure of Ti(Sap)Q(OMe) and its atomic numbering are shown in Fig. 1. Some relevant bond distances and bond angles are collected in Table 2. The Ti atom is octahedrally coordinated by one nitrogen atom and one oxygen atom of 8-hydroxyquinolinate ligand, one nitrogen atom and two oxygen atoms of *N*-(2-oxophenyl)salicylideneiminate ligand, and one oxygen atom of methoxide ligand. The two oxygen atoms of Sap^{2-} are *trans* to each other, as expected from the planar structure of this ligand. Indeed, all atoms on the Sap^{2-} ligand are essentially co-planar with mean deviation of 0.08 Å. However, the O2–Ti1–O3 angle of 157.6° is far from the ideal 180; presumably because Ti atom is too large to fit into the linear position. This may be one of the main reason why Sap^{2-} is labile when coordinated to Ti(IV). Both nitrogen atoms are trans to oxygen atoms; ∠O1–Ti1–N2 (161.4) and ∠O4–Ti1–N1 (169.6) are closer to 180 than ∠O2–Ti1–O3. N1–Ti1–O4 is particularly close to linear because the methoxide ligand can adjust its position without constraint. The bite angle of Q^- is 75°. This is quite close to the O3–N2 bite angle of Sap^{2-}. On the other hand, the bite angle of O2–N2 with Ti atom is 86° which is substantially larger than those for the five-member rings.

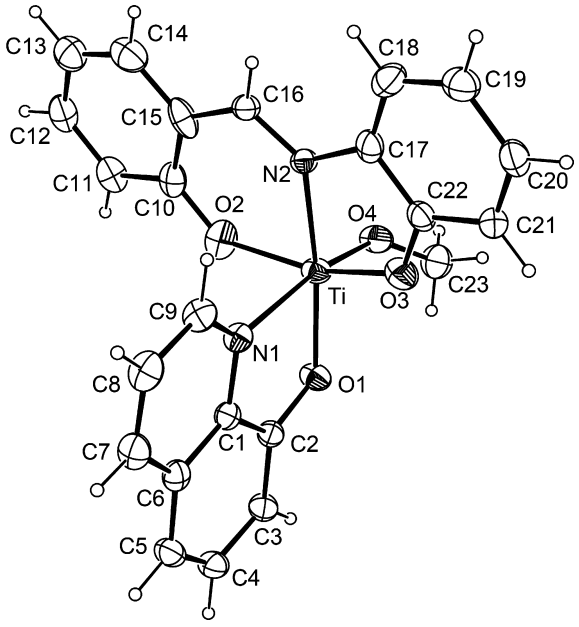

Fig. 1. Molecular plot of Ti(Sap)Q(OMe). Thermal ellipsoids represent 30% probability.

The Ti–O distances are at least 0.3 Å shorter than any Ti–N distance. This is due to the formation of partial double Ti–O bond by the donation of oxygen lone-paired electrons into the empty π-orbitals on Ti(IV). Ti1–O4 is particularly short because the methoxide can be positioned to maximize the formation of partial double bond. The detailed comparison of Ti–N distances is somewhat unreliable due to the fact that the imine group is disordered. The bond angles between O4–Ti1 and the four *cis* atoms are all larger than 90° (O1: 94.2°; O2: 96.1°; N2: 103.6°/N2A: 105.5°; O3: 95.1°), indicating that Ti is situated above the O1–O2–N2–O3 plane toward O4. Indeed Ti is 0.24(8) Å above the least square plane O1–O2–N2–O3 whose maximum planar deviation is within 0.09 Å.

The disorder in the Ti(Sap)Q(OMe) complex resulted from the 180° flip-over of the Sap^{2-} ligand. Their occupancies (s.o.f's) for the two orientations are fixed to 0.65 for N2/C16/H16 and 0.35 for N2A/C16A/H16A, respectively.

The structure of $[Ti(Sap)Q]_2(\mu\text{-O})$ and its atomic numbering are shown in Fig. 2. Some relevant bond distances and bond angles are collected in Table 1. Both Ti1 and Ti2 are octahedrally coordinated by one oxygen atom and one nitrogen atom of Q^- ligand, two oxygen atoms and one nitrogen atom of Sap^{2-} ligand, and one oxygen atom of the bridging oxide ligand. The bond distances and bond angles around the two Ti(IV) centers are remarkably similar to the corresponding ones in Ti(Sap)Q(OMe) when the bridging oxide ligand is viewed as taking the place of methoxide ligand. The similarities around each Ti center, taking Ti1 as an example, include: (a) N1–Ti1–O4 is the one that is closest to the linear arrangement comparing to other *trans* atom1–Ti1–atom2 arrangements; (b) the bite angles for five-member rings are all very similar; (c) the

[a] Averaged value of two disordered parts.

Ti1–O4 bond distance is particularly short; (d) the Ti1–N2 distance is noticeably shorter than that of Ti1–N1; (e) the Ti1 is above the O1–O2–N2–O3 plane toward the O4 atom. The Ti1–O4–Ti2 angle is 154.0° indicating the Sap^{2-} ligands are not parallel to each other; a dihedral angle 7.2° exists between these two ligands.Similar flip-over disorders in Sap^{2-} were found in the $[Ti(Sap)Q]_2(\mu\text{-}O)$ complex. The two Sap^{2-} ligands were assigned with different ratio of occupancies (s.o.f's): 0.5/0.5 (N2/C16/H16 vs. N2A/C16A/H16A) for one ligand, 0.65/0.35 (N4/C38/H38 versus N4A/C38A/H38A) for another.

The bonding parameters of some known structures of titanium(IV) complexes containing 8-hydroxyquinolinate ligand [7,8,13–17] fall in the narrow ranges: Ti–O(Q): 1.87–1.96 Å; Ti–N(Q): 2.20–2.29 Å; and bite angle: 75–77°. The structural parameters between Ti and Q^- of

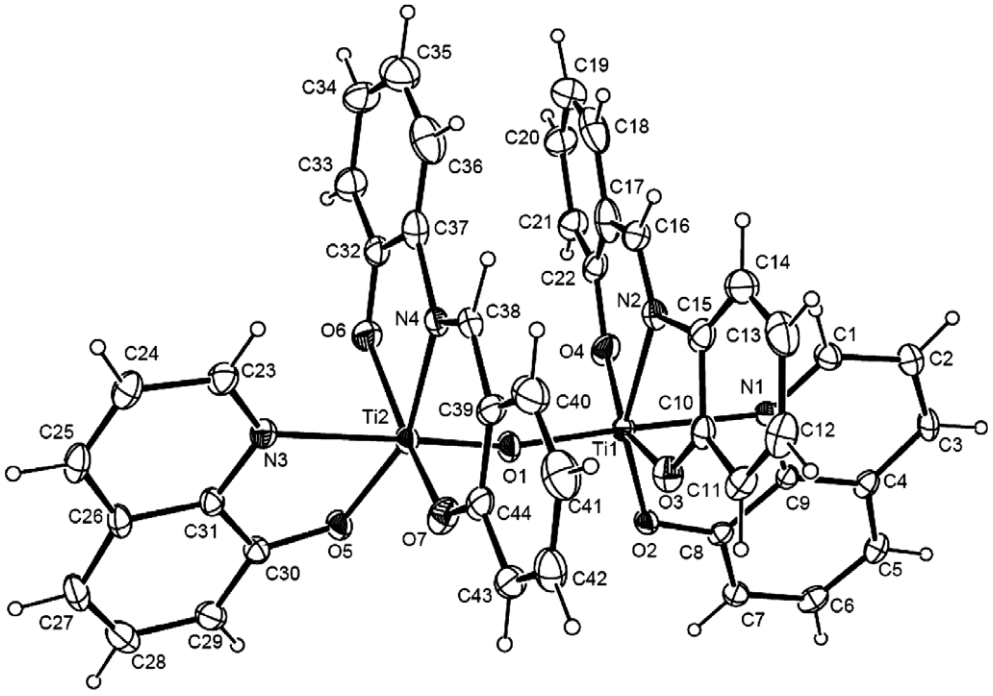

Fig. 2. Molecular plot of $[Ti(Sap)Q]_2(\mu\text{-}O)$. Thermal ellipsoids represent 30% probability.

the two compounds reported in this work are also in these narrow ranges. The bonding parameters between Ti(IV) and the Sap^{2-} ligand in both Ti(Sap)Q(OMe) and $[Ti(Sap)Q]_2(\mu\text{-}O)$ are comparable to those reported in $Ti[4,6\text{-}^tBu\text{-}2\text{-}\{CH{=}N(2\text{-}C_6H_4O)\}C_6H_3O]_2$ [9a]. However, large biting angles for the six member rings (86° versus 81°) and small biting angles (ca. 70° versus 76°) for the five-member rings are observed in this work in comparison with those in the work of Owiny et al. [10a].

It has been shown by Bickley and Serpone [18] that $TiQ_2(OR)_2$ is fluxional via a Ti–N bond rupture mechanism. We have further established that both Q^- in $TiQ_2(OR)_2$ can be substituted by Sap^{2-} and the Sap^{2-} ligand in $Ti(Sap)_2$ can be substituted by Q^- in a time scale of minutes. Therefore, in Ti(IV) complexes both Q^- and Sap^{2-} are substitutional labile in spite of being multidentate chelating ligands. While $TiQ_2(OR)_2$ and Ti(Sap)Q(OR) are air stable, the substitutional lability of Q^- and Sap^{2-} is a desirable feature for their potential application as precursors for metal oxide based materials via sol–gel process.

4. Conclusion

The reaction of $Ti(O^iPr)_4$ in the simultaneous presence of tridentate Schiff-base H_2Sap and 8-hydroxyquinoline HQ in methanol at room temperature, is not a viable method for the preparation of Ti(Sap)Q(OMe) because $Ti(Sap)_2$ precipitate can be formed immediately. Then small amount of the desired product can be formed only slowly through a set of equilibrating reactions. These reactions were established and their equilibrium constants were evaluated. However, when the reaction was carried out at 60 °C, at which the $Ti(Sap)_2$ precipitate was soluble, Ti(Sap)Q(OMe) was obtained conveniently after rapid chilling to 10 °C and following workup procedure.

In the course of our ongoing exploration of the use of hydrothermal techniques to prepare mixed-valence polyoxovanadates, we have isolated a series of discrete hexadecavanadates by introducing bigger N-containing chelate ligands (such as 1,10′-phenanthroline and 2,2′-bipyridine) to the reaction system [14b,22]. While the hydrothermal synthesis, as an extremely convenient method, has been proven to be well suited for the preparation of metastable mixed-valence polyoxometalates, the reactive mechanism has not been understood yet [23]. Herein, we report the hydrothermal synthesis, single crystal investigation and chemical and physical characterization of a new "hexadecavanadate" from the stoichiometric point of view, that can be formulated as $[Ni(phen)_3]_2\{[V_{15}O_{36}(Cl)]_{0.5}[V_{17}O_{40}(Cl)]_{0.5}\}\cdot H_2O$ (**1**), in which two kinds of architectures $\{V_{17}O_{40}(Cl)\}$ and $\{V_{15}O_{36}(Cl)\}$ coexist. One of these two clusters, $\{V_{17}O_{40}(Cl)\}$, has never been previously observed in polyoxovanadate chemistry.

2. Experimental

2.1. Materials, instruments and analytical methods

All the chemicals purchased were of reagent grade and were used as received. The hydrothermal synthesis was carried out in a polytetrafluoroethylene lined stainless steel container under autogeneous pressure. The oxalic acid used in the reaction system acts as the reducing agent that generates V(IV) from the V(V) used in the synthesis. The reaction vessel was filled to approximately 60% of its volume capacity. Distilled water was used in the reactions.

Elemental analyses (C, H and N) were performed on a Perkin–Elmer 2400 CHN Elemental Analyzer. V and Ni were determined by a Leaman inductively coupled plasma (ICP) spectrometer. The IR spectrum was recorded in the range 400–4000 cm^{-1} on an Alpha Centaurt FT/IR spectrophotometer using KBr pellets. The XPS spectrum was recorded on an ESAY ESCA spectrometer with a Mg Kα achromatic X-ray source. TG analysis was performed on a Thermal Analyzer DT-30B instrument in an air atmosphere at a heating rate of 10 °C min^{-1}. Variable temperature susceptibility measurements were carried out in the temperature range 2–300 K at an applied magnetic field of 0.1 T on polycrystalline samples with a Quantum Design MPMS-XL-5 SQUID magnetometer. The susceptibility data were corrected for the sample holder, previously measured using the same conditions, and for the diamagnetic contributions of the salt as deduced using Pascal's constant tables (-1318.8×10^{-6} emu mol^{-1} per $\{V_{16}\}$ cluster). Q-band ESR spectra were recorded on a polycrystalline sample with a Bruker E-500 ELEXSYS spectrometer in the temperature range 300–4.2 K.

2.2. Syntheses

$[Ni(phen)_3]_2\{[V_{15}O_{36}(Cl)]_{0.5}[V_{17}O_{40}(Cl)]_{0.5}\}\cdot H_2O$ (**1**). A mixture of V_2O_5 (0.90 g, 5.0 mmol), $Ni(NO_3)_2\cdot 6H_2O$ (0.30 g, 1.0 mmol), phen (0.60 g, 3.3 mmol), $H_2C_2O_4\cdot 2H_2O$ (0.20 g, 2.2 mmol), CH_3COONa (0.60 g, 7.3 mmol), Tris (Tris = Trishydroxymethylaminomethane) (0.36 g, 3.0 mmol) and H_2O (10 mL, 555 mmol) in the presence of HCl (4 M) in a molar ratio of 5:1:3:2:7:3:555 was sealed in a 20 mL Teflon-lined autoclave and heated at 165 °C for 36 h. The initial pH was around 4.0 and the final pH was close to 4.3. After slow cooling to room temperature, black prismatic crystals of the title compound were filtered and washed with distilled water (55% yield based on V). *Anal.* Calc. (%): C, 32.25; H, 1.80; N, 6.27; Ni, 4.39; V, 30.49. Found (%): C, 31.85; H, 1.79; N, 6.22; Ni, 4.30; V, 30.48%. IR (solid KBr pellet/cm^{-1}): 3440.3 (s), 1603.9 (m), 1519.2 (s), 1458.2 (s), 1420.5 (s), 994.1 (s), 845.2 (s), 717.4 (w), 637.6 (m).

2.3. X-ray crystallography

Black single crystals of **1**, with dimensions $0.37\times0.25\times0.18$ mm, were selected and mounted on a Rigaku RAXIS RAPID IP diffractometer equipped with a graphite-monochromated Mo Kα (λ = 0.71073 Å) radiation source at 293 K. A total of 8045 independent reflections were collected among which 4993 reflections with $I > 2\sigma(I)$ were considered observed. The structure was solved by direct methods and refined on F^2 by full-matrix least squares methods using SHELXTL 97 [24,25]. V8, V9 and V10 atoms in this compound are disordered and all have 50% occupancy. Anisotropic refinements were employed for the non-hydrogen atoms. A summary of the crystallographic data is listed in Table 1. Atomic coordinates and equivalent isotropic displacement parameters as well as selected bond lengths and angles for compound **1** are listed in the tables of supplementary material.

3. Results and discussion

3.1. Description of the structure

The single-crystal X-ray diffraction analysis reveals that compound **1** (Fig. 1) is composed of one stoichiometric $[V_{16}O_{38}Cl]^{4-}$ anion, two $[Ni(phen)_3]^{2+}$ cations and one lattice water molecule. The $[Ni(phen)_3]^{2+}$ cation exhibits the typical tris-chelated structure where the Ni(II) ion is surrounded by three bidentate phen ligands. All the Ni–N distances are very similar (2.073(5)–2.109(6) Å) and the N–Ni–N angles are close to 180° for the *trans* positions (172.0(2)°–173.2(2)°) and close to 90° for the *cis* positions (90.1(2)°–97.5(2)°), except for the three chelate angles, which are smaller and identical within experimental error (79.8(2)°, 79.9(2)° and 80.2(2)°). These distances and angles are very similar to those found for this complex in other salts [26].

The polyanion exhibits a host shell structure containing one Cl^- ion in its center with approximate C_{2v} symmetry. The atoms V8, V9 and V10 (and those in the symmetry-related positions) in the cluster present a positional disorder, having 50% occupancy. This positional disorder means that in every two POM units one must have the V8 (and V8A) and V9 (and V9A) atoms whereas the other must have the V10 (and V10A) atom, leading to the presence of a $\{V_{15}\}$ and a $\{V_{17}\}$ cluster coexisting in the structure. This assumption means that both architectures coexist in the crystal (co-crystallize) probably as a result of a coexistence of both species in similar concentrations in the solution under the hydrothermal conditions. Note that any other possible combination where V10 (and V10A) coexist with V8 (and V8A) or V9 (and V9A) atoms is not realistic since the V8–V10 and V9–V10 distances (1.94 and 1.47 Å, respectively) are much shorter than the average V–V distance in the cluster (ca. 3.0 Å), and than the V8–V9 distance (3.26 Å). Note also that the possibility of a rotational disorder of only one $\{V_{16}\}$ cluster could also explain the presence of the disorder in the V8, V9 and V10 positions by a rotation around the C_2 axis. This $\{V_{16}\}$ polyoxovanadate should have the three V atoms present simultaneously on different sides of the cluster (i. e., V8 and V9 on one side and V10 on the other side) since the presence of the three V atoms on the same side of the cluster is unrealistic given the short V8–V10 and V9–V10 distances (see above). Albeit in this hypothetical $\{V_{16}\}$ cluster, the C_2 axis would be removed. Finally, as a consequence of the described disorder, the oxygen atom O21, which is very close to the C_2 axis, appears in two very close positions at a distance of 0.96 Å with an occupancy factor of 50% each. This O21 atom is bonded to the V9 atoms and, therefore it presents a similar positional disorder to that of the V9 atom.

Note that this disorder is similar to that found for the V1 atom in the related compound $H_2[C(CH_2OH)_3NH_3]_{0.5}$-$[Cd(phen)_3]\{[Cd(H_2O)(phen)_2]_2(V_{16}O_{38}Cl)\}_{0.5}\{[Cd(H_2O)$-$(phen)_2]_2(V_{16}O_{39}Cl)\}_{0.5} \cdot 2H_2O$ [22b].

In summary, the only remaining possible distribution implies that the crystal structure must contain two different kinds of POM fragments: $\{V_{15}\}$ and $\{V_{17}\}$. Since these two clusters differ only in the presence or absence of three kinds of V atoms (V8, V9 and V10), this means that the two clusters have a common portion of $\{V_{13}\}$ (Fig. 2a). The $\{V_{13}\}$ fragment also has a crystallographic twofold symmetry (C_{2v}) with the C_2 axis aligned along the V7–Cl1 axis. Obviously there are two big cavities on each side of the $\{V_{13}\}$ fragment, thus it can accommodate two more V–O groups {V10–O18} to form the $\{V_{15}\}$ cluster (Fig. 2b) or four more V–O groups ({V8–O20} and {V9–O19}), leading to the$\{V_{17}\}$ cluster (Fig. 2c). Therefore, compound **1** can be considered as a fused product of architectures $\{V_{15}\}$ and $\{V_{17}\}$.

The $\{V_{15}\}$ cluster is similar to the classical $[V_{15}O_{36}]^{5-}$ [12] anion and is formed by fifteen $\{VO_5\}$ square pyramids, encapsulating a Cl^- anion, sharing edges and corners via three μ_2- and eighteen μ_3-oxygen atoms, respectively. Remarkably, owing to the disorder of the V10 group, the observed distance between V10 and O18 is unusually short (1.415(6) Å) for the expected vanadyl bond (V=O). Besides the terminal oxygen atom O18, the square pyramid $\{V(10)O_5\}$ configuration is accomplished by other four μ_3-oxygen atoms O16, O12, O17 and O14 with two long (V10–O16 = 2.162(7) Å and V10–O12 = 2.167(7) Å) and two short (V10–O17 = 1.971(6) Å and V10–O14 = 1.997(5) Å) bond distances.

As depicted in Fig. 2c, the $\{V_{17}\}$ cluster is built up from seventeen $\{VO_5\}$ square pyramids encapsulating a central Cl^- ion. The seventeen $\{VO_5\}$ square pyramids share edges and corners through two μ_2- and twenty-one μ_3-oxygen atoms, respectively, giving rise to a cage-like cluster. To the best of our knowledge, the topology of this $\{V_{17}\}$ cluster is unprecedented in polyoxovanadate chemistry.

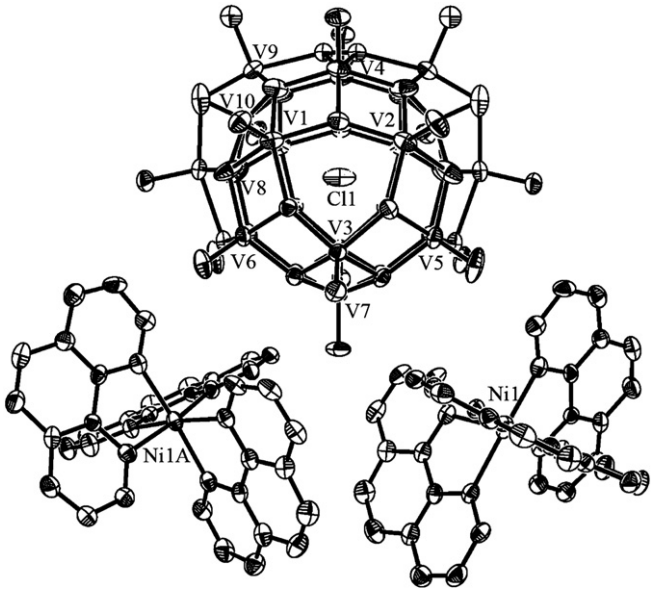

Fig. 1. ORTEP plot of compound **1** with thermal ellipsoids at 30% probability. The crystal lattice waters are omitted for clarity.

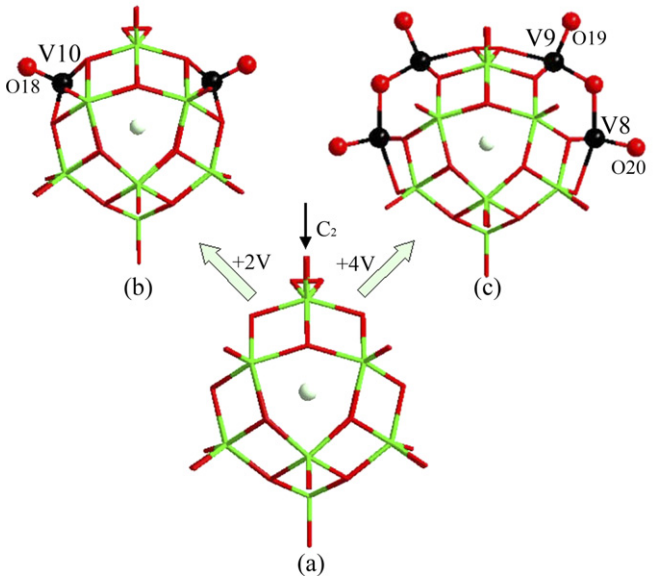

Fig. 2. The scheme of the transformation of architectures $\{V_{15}O_{36}(Cl)\}$ (b) and $\{V_{17}O_{40}(Cl)\}$ (c) from the common portion of $\{V_{13}\}$ (a).

Fig. 3 shows the topology comparison of these two clusters, in which the skeletons are built up via short V–V contacts of ca. 3.0 Å. Although they have the common portion of $\{V_{13}\}$, their geometrical features are quite different. In the $\{V_{15}\}$ cluster (Fig. 3a), the added V10 atoms enhance the whole symmetry from C_{2v} to D_{3h}. This cluster exhibits two kinds of vanadium atom nodes: the 3-connected (V1, V2 and V3) one and the 2-connected (V4, V5, V6, V7 and V10) one. While in the $\{V_{17}\}$ cluster (Fig. 3b), the added V8 and V9 atoms just retain the original C_{2v} symmetry. Three kinds of vanadium atom nodes are present in it, that is the 4-connected (V4) nodes, the 3-connected (V3, V5 and V6) nodes and the 2-connected (V1, V2, V7, V8 and V9) nodes. This framework differs from all other known polyoxovanadate structures in that it has one quadrangle, three octagons and four hexagons [14c].

Based on the type of bonded oxygen atoms in the $\{V_{17}\}$ framework, the coordination environments around the V atoms may be classified into two types of square pyramids (as shown in Fig. 2c): (i) those formed by a terminal, three μ_3- and one μ_2-oxygen atom: $\{(O{=})V(\mu_3\text{-}O)_3(\mu_2\text{-}O)\}$ such as V8 and V9 and (ii) those formed by one terminal oxygen atom and four μ_3-oxygen atoms:$\{(O{=})V(\mu_3\text{-}O)_4\}$, as observed in all the other V atoms. In the first type of square pyramid, the bond distances are 1.581(9)–1.645(2) Å, 1.769(5)–2.201(6) Å and 1.729(6)–2.022(8) Å for the terminal, μ_3- and μ_2-oxygen atoms, respectively. The second type of pyramid presents distances of 1.584(5)–1.598(5) Å and 1.846(4)–2.018(5) Å for the terminal and μ_3- oxygen atoms, respectively.

In this cluster, the mean distance from the central Cl^- anion to the bridging oxygen atoms of the periphery is 3.556 Å and to the vanadium atoms is 3.609 Å. The template effect of the encapsulated Cl^- ion in an anionic

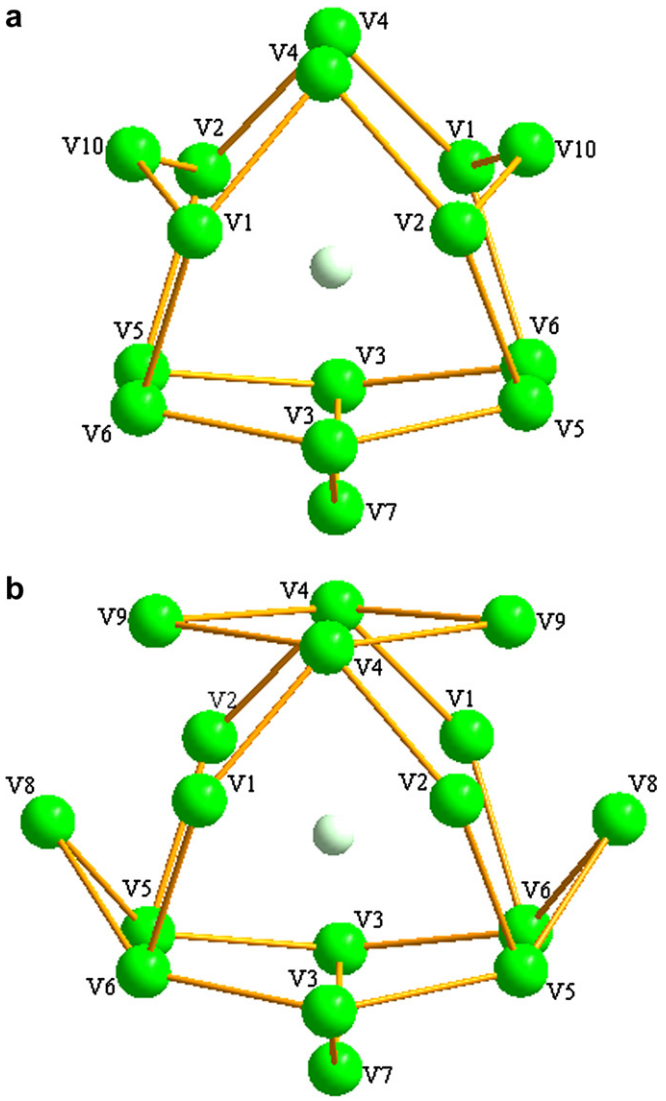

Fig. 3. The representations of the metal frameworks of $\{V_{15}O_{36}(Cl)\}$ (a) and $\{V_{17}O_{40}(Cl)\}$ (b) built up via V–V close contacts of ca. 3.0 Å. Short contacts between vanadium atoms: in (a), V1–V4 2.890(2) Å, V1–V6 2.958(2) Å, V1–V10 2.988(3) Å, V2–V4 2.931(2) Å, V2–V5 2.983(2) Å, V2–V10 2.999(4) Å, V3–V5 2.915(2) Å, V3–V6 2.866(2) Å, V3–V7 3.016(2) Å; in (b), V1–V4 2.890(2) Å, V1–V6 2.958(2) Å, V2–V4 2.931(2) Å, V2–V5 2.983(2) Å, V3–V5 2.915(2) Å, V3–V6 2.866(2) Å, V3–V7 3.016(2) Å, V4–V9 3.074(3) Å, V5–V8 2.891(3) Å,V6–V8 2.880(3) Å, V9–V4, 3.045(3) Å.

molecular oxide host has previously been discussed in many polyoxovanadate clusters with hollow structures [27].

Examination of the intermolecular contacts between the clusters reveals an unusual one-dimensional zigzag chain along the *c*-axis which is constructed by hydrogen-bonding interactions between terminal oxygen atoms O20 in adjacent clusters [O20···O20 = 2.967 Å] (see Fig. S1). Between the polyoxoanions and the Ni complexes, there exist extensive C···O short contacts ranging from 3.008 to 3.215 Å.

The assignment of the oxidation state of the V atoms can be done according to their coordination geometries and bond valence sum calculations. With this method we can estimate a global charge of −2.8 for the $[V_{17}O_{40}Cl]^{n-}$

cluster and of −4.4 for the $[V_{15}O_{36}Cl]^{n-}$ cluster. Consequently, the whole cluster can be approximately formulated as $\{[V_{15}O_{36}(Cl)]_{0.5}[V_{17}O_{40}(Cl)]_{0.5}\}^{3.6-}$. Note that due to the above-mentioned disorder problems this method may not be adequate in calculating the charge on those V atoms presenting disorder, but when it is applied to the whole cluster the relative errors are diluted and minimized and we can assume that the obtained results are acceptable. In fact the estimated value of −3.6 is in agreement with the expected charge of −4, calculated by taking into account that there are two Ni^{2+} cations per cluster. Thus, the "average" polyanion can be formulated as $[V_{16}O_{38}Cl]^{4-}$, indicating the presence of seven reduced V(IV) atoms: $[V_7^{IV}V_9^{V}O_{38}Cl]^{4-}$. The manganometric titration of the reduced vanadium indicates the presence of seven V^{IV} sites per formula unit in agreement with the estimations of the bond valence sum calculation analysis and the cationic charges in the structure. The XPS spectrum (see Fig. S2) of **1** gives two overlapped peaks at 515.51 and 516.95 eV, attributed to V^{IV} and V^{V}, respectively [28], confirming the presence of reduced V(IV) atoms.

3.2. Thermal stability of compound *1*

Thermogravimetric analysis of **1** was carried out in air atmosphere with a heating rate of 10 °C min^{-1} in the temperature range 50–1000 °C. It shows two distinct weight loss stages on the TGA curve (Fig. 4). The first weight loss of 31.2% takes place in the range 50–483 °C. This is attributed to the loss of one lattice water and five phen molecules (calc. 34.12%). The second weight loss of 8.3% at 483–570 °C is in good agreement with the loss of one phen molecule and one Cl^- (calc. 7.9%). Since the TG analysis was carried out in air atmosphere, the V(IV) ions must be oxidized to V_2O_5. Therefore, assuming the residue corresponds to V_2O_5 and NiO, the observed residue (60.36%) is in good agreement with the calculated value (59.97%). Exact elemental analysis of the residue after the calcination of **1** at 1000 °C shows a V:Ni molar ratio of 8.18 (close to the expected value of 8.0), confirming the formula of **1**. As the DTA curve shows, between 400 and 550 °C there are two strong exothermic peaks which correspond to the decomposition of the water molecule, phen molecules and Cl^-. An endothermal peak at 646 °C is attributed to the melting point peak of vanadium pentoxide.

3.3. FT-IR spectrum for compound *1*

The IR spectrum (Fig. S3) of **1** exhibits intense bands at 845.2, 717.4 and 637.6 cm^{-1} that can be ascribed to the ν(V–O–V) vibrations. The strong bands at 994.1 cm^{-1} can be assigned to the stretching vibrations of ν(V=O) bonds, which are consistent with that of some known polyoxovanadates [17,22c,29]. The bands appearing in the 1603–1104 cm^{-1} region can be attributed to the characteristic vibrations of phen molecules. Finally, the broad band at 3440 cm^{-1} is characteristic of the water molecules.

3.4. Magnetic properties

The thermal variation of the product of the molar magnetic susceptibility times the temperature, $\chi_M T$, per $[V_{16}O_{38}Cl]^{4-}$ cluster shows at room temperature a value of 3.67 emu K mol^{-1} which decreases almost linearly with decreasing temperature to reach a plateau of ca. 2.8 emu K mol^{-1} between ca. 10 and 5 K. Below ca. 5 K the $\chi_M T$ product shows a more abrupt decrease to reach a value of ca. 1.5 emu K mol^{-1} at 2 K (Fig. 5). Since the title compound presents two Ni(II) ions per $[V_{16}O_{38}Cl]^{4-}$ cluster, its magnetic moment is expected to be the sum of the magnetic contribution from the two Ni(II) ions plus that of the $[V_{16}O_{38}Cl]^{4-}$ cluster. If we assume that the two Ni(II) complexes are paramagnetic and, therefore, their expected contribution is ca. 2.2 emu K mol^{-1} (expected value for two $S = 1$ ions with a g value of ca. 2.1), then the magnetic contribution of the $[V_{16}O_{38}Cl]^{4-}$ cluster is estimated to be ca. 1.5 emu K mol^{-1} at room temperature and ca. 0.8 emu K mol^{-1} at low temperature.

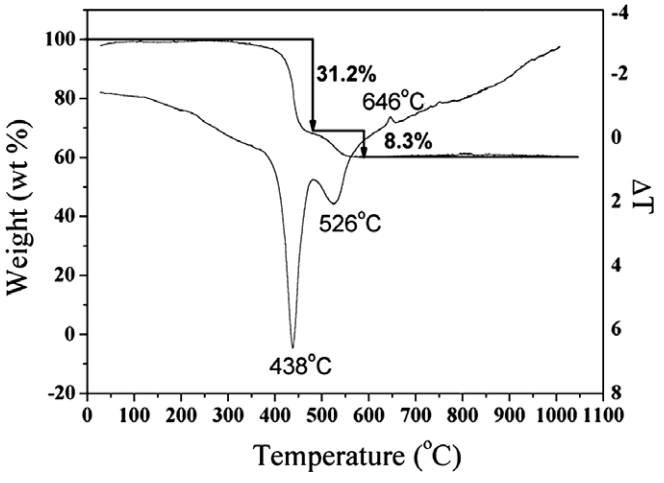

Fig. 4. Thermogravimetric analysis for compound **1**.

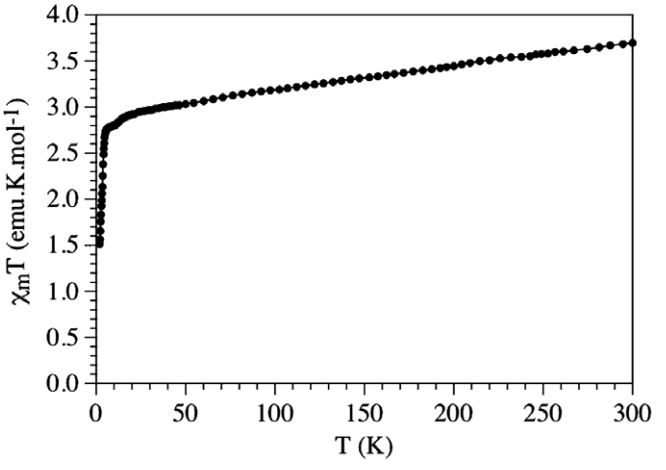

Fig. 5. Thermal variation of the product of the magnetic susceptibility and temperature per $[V_{16}O_{38}Cl]^{4-}$ cluster.

Note that the abrupt decrease observed at low temperatures, typical of Ni(II) complexes with zero field splitting (ZFS), precludes the exact determination of the contribution from the POM at low temperatures. The behavior deduced for the POM is very close to that observed in many other reduced polyoxovanadates [27a,30], where the room temperature magnetic moment is well below the expected value (in the title compound the expected value for seven independent unpaired electrons with $g = 2$, coming from the seven reduced V(IV) centers, is $7*0.375 = 2.625$ emu K mol^{-1}). This lower value of the magnetic moment is attributed to the strong antiferromagnetic coupling due to a large degree of delocalization. As in many other reduced vanadates, the magnetic moment of the title compound shows an almost linear decrease when decreasing the temperature, indicating the presence of the population of thermally accessible excited spin states at high temperature. The sharp decrease observed below ca. 5 K can be attributed to the presence of a zero field splitting (ZFS) in the two Ni(II) ions and/or to the presence of antiferromagnetic coupling between the reduced V(IV) in the POM. Due to the complexity of the possible exchange pathways there is no magnetic model available to date to fit the magnetic behavior of the reduced polyoxovanadate cluster.

The Q-band ESR spectrum of the title compound at room temperature shows only one wide signal with a line width, ΔH, of ca. 550 G (55 mT), centered at ca. 12360 G (1.236 T) ($g = 1.959$) that can be attributed to the presence of the delocalized electrons of the reduced polyoxovanadate (Fig. 6), since the Ni(II) ion is ESR silent in octahedral complexes due to the ZFS. The intensity of the ESR signal increases with decreasing temperature in a similar way to that found in the SQUID measurements. At low temperatures, the product of the spin susceptibility times the temperature ($\chi_{spin}T$, χ_{spin} being the area of the ESR signal) shows a sharp decrease starting at ca. 30 K that can be attributed to the presence of antiferromagnetic exchange interactions appearing at this temperature due to a progressive localization of the delocalized electrons of the POM. This progressive localization is also observed in the thermal variation of the line width (ΔH) and the g factor. Thus, ΔH linearly increases with decreasing temperature from a room temperature value of ca. 55 mT down to ca. 25 K where ΔH is ca. 80 mT (slope of ca. 0.1 mT K^{-1}) and then sharply increases, also linearly, below ca. 25 K to reach a value of ca. 112 mT at 4.2 K (slope of ca. 1.5 mT K^{-1}) (Fig. 7). The g value remains constant from room temperature down to ca. 25 K and below this temperature it sharply increases to reach a value of 1.980 at 4.2 K (inset in Fig. 7). These changes in the thermal variations of the g value and in ΔH below ca. 25 K suggest that the added electrons in the reduced polyoxovanadate remain delocalized over the V atoms in the polyoxovanadate clusters in the temperature range 300–25 K and that at low temperatures they start a progressive localization process. This localization process should lead to an axial signal with two components

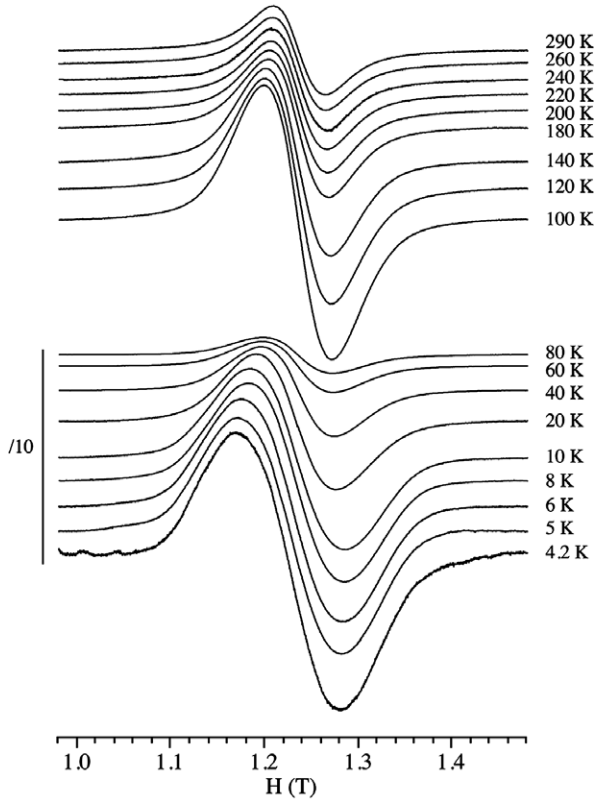

Fig. 6. Thermal variation of the Q-band ESR signal of the title compound.

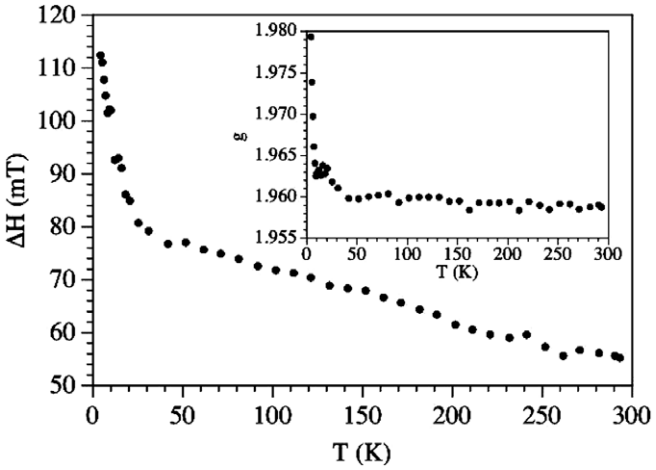

Fig. 7. Thermal variation of the ΔH value of the Q-band ESR signal of the title compound. **Inset:** thermal variation of the g value of the Q-band ESR signal of the title compound.

($g_{\parallel}$ and $g_{\perp}$) splitting into eight signals each due to the hyperfine coupling with the ^{51}V nucleus ($I = 7/2$, natural abundance 99.75%). Since there are several crystallographically different V atoms in the clusters, this localization process should give rise to several groups of eight signals each overlapping in the $g = 2$ region. The observed signal would be, therefore, the sum of all these signals. Three facts support this idea: (i) the signal becomes asymmetric below ca. 25 K (as expected, since $g_{\parallel} \neq g_{\perp}$), (ii) the line width at low

temperatures (ca. 112 mT) corresponds to the range where the two groups of eight signals expand in other V(IV) ions in a similar coordination environment [31] and (iii) the spectrum at 4.2 K shows weak features at both sides of the central signal that can be attributed to the extreme signals of one of the several groups of eight signals expected.

4. Conclusions

In summary, we have discovered a new polyoxovanadate which contains two different architectures: $\{V_{17}O_{40}(Cl)\}$ and $\{V_{15}O_{36}(Cl)\}$. The $\{V_{17}O_{40}(Cl)\}$ cluster represents a new vanadium oxide framework in polyoxometalate chemistry. The magnetic behavior of **1** indicates that the extra seven electrons of the reduced polyoxovanadate skeleton are delocalized at room temperature and are progressively localized at low temperature.

either as KBr pellets or as a solution in a cell provided with a KBr window, using a Perkin–Elmer Spectra GX 2000 spectrometer. ^{1}H NMR spectra were recorded on a Bruker 200 MHz FT NMR (model: Avance-DPX 200) using $CDCl_3$ as the solvent and tetramethylsilane (TMS) as an internal standard. Electronic spectra were recorded with a Shimadzu UV-3101 PC or a Cary 500 Scan UV–Vis-NIR spectrometer; while room temperature luminescence spectra were recorded with a Perkin–Elmer LS 50B luminescence spectrofluorimeter. Electrochemical experiments were performed on a CH-660A (USA) electrochemical instrument with a conventional three-electrode cell assembly. Saturated Ag/AgCl as a reference and platinum as a working electrode were used for all measurements. Ferrocene was added at the end of each experiment as an internal standard and all potentials are quoted versus the ferrocene/ferrocenium (Fc/Fc^+) couple. X-ray single crystal data for $\mathbf{L}_2$ was collected using Mo Kα ($\lambda = 0.7107$ Å) radiation on a SMART APEX diffractometer equipped with a CCD area detector. Data collection, data reduction [10] and structure solution/refinement [11,12] were carried out using the software package of SMART APEX. The structure was solved by direct methods and refined in a routine manner. All hydrogen atoms were geometrically fixed at their idealized position. Graphics were generated using Mercury 1.4.1 [13].

2.3. Synthesis

2.3.1. 1-Hydroxy-2-methoxy-anthraquinone ($\mathbf{L}_1$)

1.0 g (4.16 mM) of 1,2-dihydroxy-9,10-anthraquinone was dissolved in 30 ml of acetone. To this, 1.6 g of anhydrous K_2CO_3 was added and the mixture was stirred at room temperature for a few minutes. Then 1.049 g dimethyl sulfate (8.33 mM) dissolved in 5 ml of acetone was added from a dropping funnel over 30 min. The resulting solution was then refluxed for 4 h. Then acetone was partially removed under reduced pressure (~5 ml). To this about 25 ml of diethylether was added and the undesired compounds were discarded in the water layer by solvent extraction. The ether solution was then dried over anhydrous $MgSO_4$ and ether was removed to yield the crude product. Purification of the desired product was achieved by gravity chromatography using SiO_2 as the stationary phase and *n*-hexane–$CHCl_3$ (3:7; v/v) as the eluent. Yield: 0.25 g (23%). ^{1}H NMR (200 MHz, $CDCl_3$): 13.05 (s, 1H, –OH), 8.25–8.2 (m, 2H, H^5, H^8), 8.078 (d, 1H, $J = 8.4$ Hz, H^4), 7.89–7.83 (m, 2H, H^6, H^7), 7.24 (1H, d, $J = 8.4$ Hz, H^3), 3.94 (s, 3H, $-OCH_3$). FT-IR (KBr; cm^{-1}): 3329 (NH), 3272 (NH), 1651 (–C=O). ESI MS [*m*/*z* (positive ion mode)]: 278 (M^++Na^+, 20%), 255 (M^+, 38%). Elemental analysis for $C_{15}H_{10}O_4$: *Anal.* Calc.: C, 70.86; H, 3.96. Found: C, 70.7; H, 4.0%. UV–Vis spectra (DMF, λ_{max} nm (ε M^{-1} cm^{-1})): 278 (1.10×10^5), 369 (4.44×10^4).

2.3.2. 1,2-Dimethoxy-anthraquinone ($\mathbf{L}_2$)

2 g (34 mM) of 1,2-dihydroxy-9,10-anthraquinone and 12.4 g anhydrous K_2CO_3 were mixed in 40 ml of acetone and then stirred at room temperature for a few minutes. To this resulting mixture, 14 ml dimethyl sulfate (150 mM) dissolved in 20 ml of acetone was added from a dropping funnel over 30 min. The resulting solution was then refluxed for 4 h. Then acetone was partially removed under reduced pressure (~15 ml) and about 50 ml of diethyl ether was added. The starting compound and any $\mathbf{L}_1$ formed due to partial conversion were removed in the water layer, whose pH was maintained at 9.5. The ether was dried under reduced pressure to recover the crude product. This was further purified by chromatography using a SiO_2 column and *n*-hexane–$CHCl_3$ (1:1; v/v) as eluent. Yield: 0.7 g (39%). ^{1}H NMR (200 MHz, $CDCl_3$): 8.28–8.23 (m, 2H, H^5, H^8), 8.174 (d, 1H, $J = 8.6$ Hz, H^4), 8.78–8.74 (m, 2H, H^6, H^7), 7.28 (1H, d, $J = 8.6$ Hz, H^3), 4.0 (s, 3H, $-[OCH_3]^1$), 3.03 (s, 3H, $-[OCH_3]^2$) . FT-IR (KBr; cm^{-1}): 1336, 1270 (O–CH_3), 1670 (–C=O). ESI MS [*m*/*z* (positive ion mode)]: 291 (M+Na^+, 50%); 269 (M+H^+; 90%); Elemental analysis for $C_{15}H_{10}O_4$: *Anal.* Calc.: C, 71.64; H, 4.52. Found: C, 72.0; H, 4.5%. UV–Vis spectra (DMF, λ_{max} nm (ε M^{-1} cm^{-1})): 279 (1.59×10^4), 328 (7.6×10^3), 425 (9.20×10^3). The structure for $\mathbf{L}_2$ was further established by single crystal X-ray studies.

2.4. Spectrophotometer titrations

A 1.0×10^{-3} M solution of the receptor $\mathbf{L}_1$ and a 1.0×10^{-3} M solution of the receptor $\mathbf{L}_2$ in DMF were prepared and stored in the dark. These solutions were used for all spectroscopic studies after the appropriate dilution. 1.0×10^{-3} M solutions of $MClO_4$ (M is an alkali metal ion) or $M'(ClO_4)_2$ (M′ is an alkaline earth metal ion) were prepared in dried and distilled DMF, and were stored under an inert atmosphere. All titration experiments were performed using 1.0×10^{-4} M solutions of receptor $\mathbf{L}_1$ and 1.35×10^{-5} M solutions of receptor $\mathbf{L}_2$ in DMF and various concentrations of the cations (5.0×10^{-6} to 5.0×10^{-4} M) in DMF. Affinity constants were evaluated after calculating the concentrations of the respective species, like free $\mathbf{L}_1$, $\mathbf{L}_2$, $\mathbf{M}^{2+}$ and the associated complexes, e.g. $\mathbf{L}_1 \cdot \mathbf{M}^{2+}/\mathbf{L}_2 \cdot \mathbf{M}^{2+}$. The effect of the ionic strength on the affinity constant value was also examined by repeating the studies at various 0–0.1 M [(^{t}Bu$_4$N)ClO_4] supporting electrolyte concentrations. The affinity constant values were evaluated from the absorbance data of the titration curve using 519 nm as the probe wavelength.

2.5. Luminescence titration

The standard solutions mentioned above were also used for luminescence titration studies. For all measurements, λ_{ext} used was 517 nm ($\mathbf{L}_1$)/514 nm ($\mathbf{L}_2$) with an excitation and emission slit width of 5 nm. All titration experiments were performed using 2.5×10^{-5} M solutions of receptors $\mathbf{L}_1$ and $\mathbf{L}_2$ in DMF (thoroughly degassed before measurement with IOLAR grade dinitrogen gas) and solutions of various cations (3.0×10^{-5} to 5.0×10^{-4} M) in DMF.

2.6. Computational details

All calculated geometries were fully optimized at the RHF/6-31G* level of theory using the JAGUAR program [14,15]. These structures were a true minimum at this level of theory and were characterized by harmonic vibrational frequencies.

3. Results and discussion

$\mathbf{L}_1$ and $\mathbf{L}_2$ were synthesized following standard reaction procedures. Both these receptors were characterized by standard analytical and spectroscopic techniques. The structure of $\mathbf{L}_2$ was further confirmed by single crystal X-ray diffraction (Fig. 1) studies. X-ray quality crystals were obtained by the slow evaporation of $\mathbf{L}_2$ from a CH_3CN solution at room temperature. Single crystal X-ray analysis revealed that $\mathbf{L}_2$ belongs to a non-centrosymmetric monoclinic space group $P2_1$. The asymmetric unit comprises of one molecule of $\mathbf{L}_2$, and the methyl C-atom of one of the methoxy groups is oriented above the plane containing the anthraquinone moiety and the other methoxy group. In the crystal structure the oxygen atoms of the anthraquinone moiety of $\mathbf{L}_2$ display non-bonded interactions with the neighboring molecule through C–H···O interactions thereby forming a helical chain parallel to the *c*-axis (Fig. 1b). The helical nature of $\mathbf{L}_2$ is due to the inclined packing of the adjacent molecules at an angle of 52.1° parallel to the *c*-axis. Such helical chains are further packed parallel to the *a*-axis via various C–H···O non-bonded interactions.

Receptor $\mathbf{L}_1$ shows a strong absorption band at 278 nm and a shoulder at 328 nm; while for $\mathbf{L}_2$ this shoulder is barely detectable in this region (Figs. 2 and 3). In the visible region, for $\mathbf{L}_1$ a well defined absorption band at 427 nm was observed, however, for $\mathbf{L}_2$ a shoulder at 369 nm was observed. This absorption band in the visible region was due to charge transfer from the donor –OH/–OCH_3 unit to the acceptor quinone units [16]. On addition of Mg^{2+} a set of new absorption bands appeared in the range 500–575 nm for both receptors and, consequently, a visual color change from yellow to red was noticed (Figs. 2 and 3).

However, the changes were more prominent for $\mathbf{L}_1$ as compared to $\mathbf{L}_2$. Similar experiments were performed for all the metal ions of the groups IA and IIA. Group IA metal ions do not show any color change upon addition to receptor solutions (SI Figure 1). Other group IIA metal ions show a mild color change with receptors $\mathbf{L}_1$ and $\mathbf{L}_2$ (SI Figure 2). Luminescence spectra for $\mathbf{L}_1$ and $\mathbf{L}_2$ were also recorded. Both were found to be weakly emitting on excitation at their respective charge transfer spectral band ($\lambda_{ext} = 369$ nm for $\mathbf{L}_1$ and 425 nm for $\mathbf{L}_2$; Figs. 2 and 3). The weak emission property was due to photoinduced

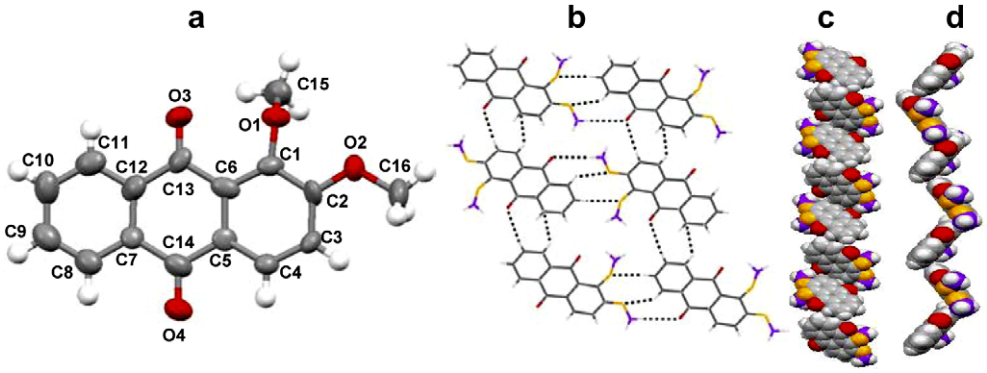

Fig. 1. (a) ORTEP diagram of $\mathbf{L}_2$ (50% probability); (b) illustration of various non-bonded interactions between the C–H of $\mathbf{L}_2$ and oxygen atoms; (c) helical arrangement of $\mathbf{L}_2$ along the *c*-axis; (d) packing of the helical network, view down the *a*-axis. Color code: Oxygen atom of the methoxy group (orange), C-atoms of the methoxy group (purple) and oxygen atom of the anthraquinone (red). (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

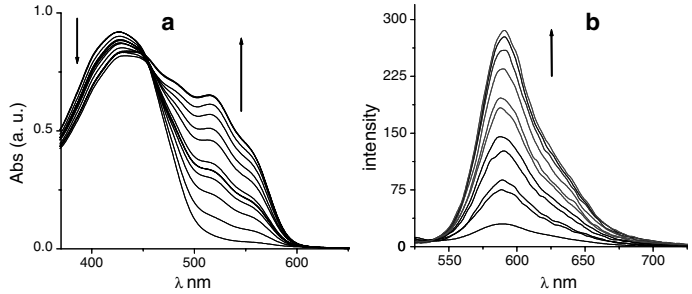

Fig. 2. Spectral changes for $\mathbf{L}_1$ at varying [Mg^{2+}] in DMF at 25 °C: (a) Absorption spectral changes $\mathbf{L}_1$ (1.0×10^{-4} M) with [Mg^{2+}] (5.0×10^{-6} to 5.0×10^{-4} M); (b) fluorescence spectral changes ($\lambda_{ext} = 517$ nm) of $\mathbf{L}_1$ (2.5×10^{-4} M) with [Mg^{2+}] (3.0×10^{-6} to 5.0×10^{-4} M).

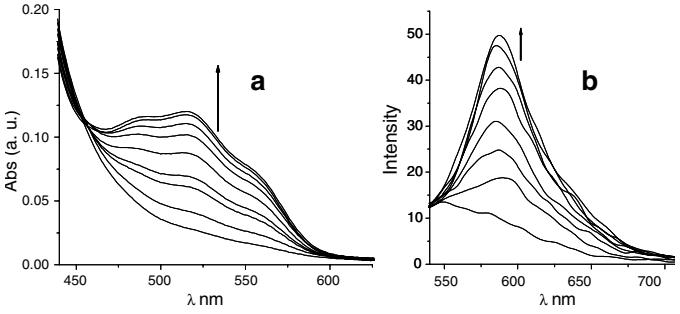

Fig. 3. Spectral changes for $\mathbf{L}_2$ at varying [Mg^{2+}] in DMF at 25 °C: (a) Absorption spectral changes $\mathbf{L}_2$ (1.35×10^{-5} M) with [Mg^{2+}] (5.0×10^{-6} to 3.75×10^{-4} M); (b) fluorescence spectral changes ($\lambda_{ext} = 515$ nm) of $\mathbf{L}_2$ (2.5×10^{-4} M) with [Mg^{2+}] (3.0×10^{-5} to 5.0×10^{-4} M).

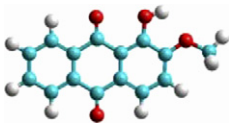
electron transfer between the donor (–OH/–OCH_3) and acceptor (quinone) centers [16,17]. For, $\mathbf{L}_1$, the possibility of intra- and inter-molecular excited state proton transfer may cause a highly efficient radiationless deactivation of the excited states to the ground state and this might also have contributed to the observed low steady state emission quantum yield for $\mathbf{L}_1$ [17]. However, for both these receptors an appreciable increase in emission intensity was observed on addition of excess alkaline earth metal ions – especially Mg^{2+}, when excited at their respective new absorption maximum (517 nm for $\mathbf{L}_1$ and 515 nm for $\mathbf{L}_2$). The excitation spectra of the complexes matched well with the respective absorption spectra. This result suggests that the observed fluorescence was due to the formation of new complexes, $\mathbf{L}_1\cdot\mathbf{Mg}^{2+}$ and $\mathbf{L}_2\cdot\mathbf{Mg}^{2+}$. Thus changes in electronic and emission spectra suggest a binding of the alkaline earth metal ions to the receptor molecules. Significant spectral changes on addition of Mg^{2+} ions suggest a stronger binding to $\mathbf{L}_1$ and $\mathbf{L}_2$. The association constants for the respective group IIA metal ions, towards $\mathbf{L}_1$ and $\mathbf{L}_2$, were obtained from systematic spectrophotometric titrations (Table 1). Representative spectrophotometric titration profiles for Mg^{2+} with $\mathbf{L}_1$ and $\mathbf{L}_2$ are shown in Figs. 2 and 3. Association constants for the metal ions, evaluated from spectrophotometric titrations, for the specific receptors ($\mathbf{L}_1$ and $\mathbf{L}_2$) are presented in Table 1.

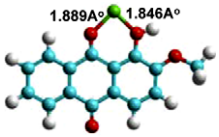
Table 1
Constants[a] of the complex formation equilibrium

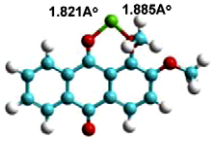
M^{n+}	K_1 (10^3 M^{-1})	K_2 (10^3 M^{-1})
Mg^{2+}	102 (4)	20.0 (1)
	139 (5)[b]	24.0 (1)[b]
Ca^{2+}	13.6 (0.4)	7.8 (0.4)
Sr^{2+}	12.0 (0.4)	6.0 (0.3)
Ba^{2+}	1.30 (0.2)	0.6 (0.1)

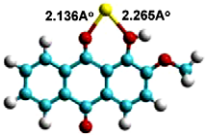
Perchlorate salts of the respective metal ions were used for the studies.

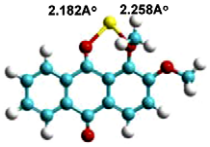
[a] K value reported (K_1 and K_2 values are for receptors $\mathbf{L}_1$ and $\mathbf{L}_2$, respectively) is the average of five independent data evaluated from each individual UV–Vis titration data for the respective receptor and cation.

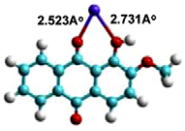


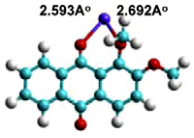


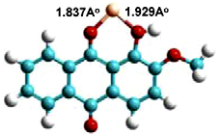


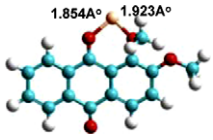


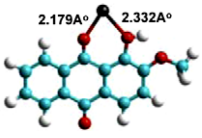


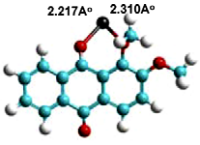






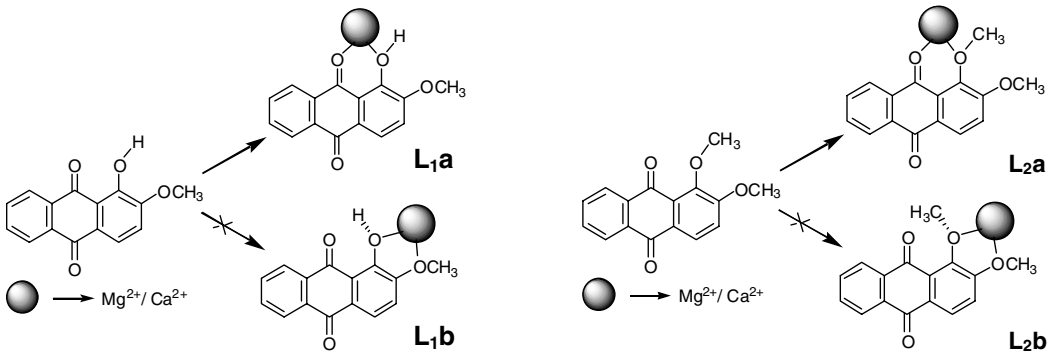






[b] Values obtained from the fluorescence titration data. The value provided in the parentheses is the uncertainty.

The job plot for each titration signified the stoichiometry for the binding of the respective metal ion to each receptor and in all cases a 1:1 complex formation was observed (SI Figure 3). The association constant for the Mg^{2+} ion to each receptor was also evaluated from the emission titration data (Figs. 2b and 3b). The values obtained thus were found to match well with the spectrophotometric titration data and are shown in Table 1. Stability constant values showed the following order for the group IIA metal ions: $K_{Mg^{2+}} \gg K_{Ca^{2+}} > K_{Sr^{2+}} \gg K_{Ba^{2+}}$. Data presented in Table 1 also revealed that $\mathbf{L}_1$ binds these ions more strongly as compared to $\mathbf{L}_2$.



Electrochemical studies revealed that binding of the Mg^{2+} ion to $\mathbf{L}_1$ and $\mathbf{L}_2$ also caused a change in the reduction potential for the quinone fragment of the receptor units. The anthraquinone moiety is known to undergo a reversible two electron reduction process to generate 9,10-dihydroxy anthracene in the presence of protic solvents – as this redox process involves a simultaneous 2e-$2H^+$ transfer reaction [18]. Thus, as expected, $\mathbf{L}_1$ and $\mathbf{L}_2$ showed an irreversible redox process in aprotic solvent (DMF) at −0.07 and −0.20 V (versus Fc/Fc^+ couple), respectively. The potential values were evaluated from differential pulse voltammetric (DPV) studies. In the presence of the Mg^{2+} ion, these respective potential values shifted to −0.01 and −0.16 V (versus Fc/Fc^+ couple), respectively. Comparison of the potential data before and after addition of the Mg^{2+} ion revealed that reduction of the quinone fragment became more facile on binding the metal ion to the receptor units. The change in potential data for $\mathbf{L}_1\cdot\mathbf{Mg}^{2+}$ (60 mV), as compared to that for $\mathbf{L}_2\cdot\mathbf{Mg}^{2+}$ (40 mV), clearly indicates that the binding of the Mg^{2+} ion to $\mathbf{L}_1$ is stronger than that to $\mathbf{L}_2$. Thus, the data obtained from the electrochemical studies also corroborate our observation of the spectrometric titration experiments. Further, lower reduction potential data also signified the lowering of the LUMO energy level for the anthraquinone fragment, which presumably accounts for the observed red shift of the charge transfer absorption band in $\mathbf{L}_1\cdot\mathbf{Mg}^{2+}$ and $\mathbf{L}_2\cdot\mathbf{Mg}^{2+}$ as compared to $\mathbf{L}_1$ and $\mathbf{L}_2$, respectively. The observed increase in emission intensity for $\mathbf{L}_1$ and $\mathbf{L}_2$ on addition of an increasing amount of Mg^{2+} suggests that metal ion complexation suppresses the intramolecular photoinduced electron transfer from the non-bonding orbitals of the donor fragment to the LUMO of the acceptor fragment [16,17].

The calculated results for the complexation of the metal ions with the receptors $\mathbf{L}_1$ and $\mathbf{L}_2$ are shown in Table 2. The complexation study has been performed with the following metal ions, i.e., Li^+, Na^+, K^+, Mg^{2+} and Ca^{2+}. Alkali metal ions show relatively poor binding affinity towards the receptors $\mathbf{L}_1$ and $\mathbf{L}_2$ compared to that of Mg^{2+} and Ca^{2+} ions (Table 2). The calculated parent geometry of $\mathbf{L}_2$ has been found to be in good agreement with the observed X-ray structure. The orientation of the methoxy groups of $\mathbf{L}_2$, shown in Table 2, has a good match with the orientations obtained in the X-ray structure (Fig. 1).

Table 2
RHF/6-31G* calculated structures for L_1 and L_2 and their corresponding metal complexes with Li^+, Na^+, K^+, Mg^{2+} and Ca^{2+}

L_1	Energy	L_2	Energy
	(0.26881)		(0.27569)
	−71.69 (0.34903)		−71.862 (0.34827)
	−53.04 (0.33214)		−50.29 (0.33602)
	−31.11 (0.32777)		−35.18 (0.33362)
	−192.19 (0.24833)		−191.16 (0.24949)
	−128.08 (0.26515)		−126.297 (0.26716)

Binding energies are in kcal/mol and the HOMO–LUMO energy gaps in eV are shown in parentheses.
Color code used is as follows: green: Li^+; yellow: Na^+; violet: K^+; orange: Mg^{2+}; black: Ca^{2+}.
For interpretation of the references to color in this table legend, the reader is referred to the web version of this article.

Scheme 1. Schematic presentation of the binding of Mg^{2+} and Ca^{2+} ions to L_1 and L_2.

Calculations further show that this geometry is a minimum on the potential energy surface. In the calculated structures, metal ions prefer to bind with one of the carbonyl oxygen atoms and the OH/OMe groups (Table 2). A shift of the stretching frequency to lower energy for the carbonyl functionality in the FTIR spectra, recorded for $\mathbf{L}_1$ and $\mathbf{L}_2$ in the absence and presence of Mg^{2+} in DMF solution, confirmed the binding of the C=O unit to the Mg^{2+} ion. It is known in the literature that Mg^{2+} binds to the oxygen of a carbonyl functionality in a chelating ligand. For coumarin an appreciable bathochromic shift in the absorption spectra was observed on binding to the Mg^{2+} ion [19,20].

Further, support to the presumption of the coordination by the carbonyl oxygen and adjacent OH/OCH_3 functionalities came from the energy optimized structures for $\mathbf{L}_1 \cdot \mathbf{Mg}^{2+}$ and $\mathbf{L}_2 \cdot \mathbf{Mg}^{2+}$. The possibility of two binding modes for Mg^{2+} and Ca^{2+} towards $\mathbf{L}_2$ was examined theoretically. The calculated binding energy values revealed that the binding modes shown in Scheme 1: (L_1b & L_2b) are less favored than those of Scheme 1: (L_1a & L_2a). The RHF/6-31G* calculated results show that the resultant binding of Mg^{2+} in $\mathbf{L}_2\mathbf{a}$ is preferred by 24.32 kcal/mol than $\mathbf{L}_2\mathbf{b}$ and Ca^{2+} shows the same preferential binding by 15.59 kcal/mol. Additional calculations performed with $\mathbf{L}_1$ also showed a similar trend of interaction energies with Mg^{2+} and Ca^{2+} ions. $\mathbf{L}_1\mathbf{a}$ has been found to be preferred by 6.7 kcal/mol for Mg^{2+} and 20.8 kcal/mol for Ca^{2+} (Supporting information). Importantly, in the case of the Mg^{2+} ion, interaction with –OH and –OMe groups of $\mathbf{L}_1$ leads to the transfer of the hydroxyl proton to the carbonyl oxygen atom (Supporting information). However, this optimized geometry has been found to be a minimum on the potential energy surface. The binding energy for the alkaline earth metal ions with receptor $\mathbf{L}_1$ has been found to be slightly higher than that of $\mathbf{L}_2$ and this result qualitatively corroborates the experimental observation that the stability constants for the binding of alkaline earth metal ions are higher with receptor $\mathbf{L}_1$. It can be assumed that electron correlated calculations could lead to a better prediction for the relative interaction of $\mathbf{L}_1$ with the metal ions compared to that of $\mathbf{L}_2$, this, however, would be expensive for this size of system and hence it has not been calculated in this study. Further, the HOMO–LUMO energy gap calculated at the RHF/6-31G* level of theory suggests that the preferential binding of alkaline earth metal ions reduces this energy gap compared to the corresponding parent geometries and supports the observation of visual color change in the case of these metal ions (Table 2).

4. Conclusions

Two chromogenic receptors, $\mathbf{L}_1$ and $\mathbf{L}_2$, bind with alkaline earth metal ions with a subsequent change in the electronic and luminescence spectral patterns. Binding of different group IIA metal ions follows the order $K_{Mg(II)} \gg K_{Ca(II)} > K_{Sr(II)} \gg K_{Ba(II)}$. A binding induced change in color could be detected for group IIA metal ions; while it was more prominent for Mg^{2+}. Relative affinities of the metal ions towards $\mathbf{L}_1$ and $\mathbf{L}_2$ were rationalized by ab initio calculations. X-ray study reveals an interesting helical structure for $\mathbf{L}_2$.

The scaffold we have employed integrates an anthraquinone lumophore with a receptor that incorporates an intraannular carbonyl oxygen. Complexation by a metal cation of sufficiently high charge binds with the carbonyl oxygen and results in inversion of the non-radiative n–π* and radiative π–π* transitions, resulting in luminescence turn-on. Recent examples that utilize the PCT photodynamic mechanism include: the detection of alkaline earth metals by a xanthone macrocycle that also contains an intraannular carbonyl oxygen [31,32]; the detection of Ca^{2+} and alkali metals by a tetranaphthylcalixarene [29,30]; and the detection of Hg^{2+} by a 8-hydroxybenzoate [33]. A novel fluorogenic probe that senses reaction chemistry by inversion of n–π* and π–π* states has also been described [34]. Already we have demonstrated selective detection of Pb(II) by **1**, the complete oxygen-containing analog [35]. With relative synthetic ease, we have achieved both the selective detection of Cd(II) and the selective detection of Hg(II) using different thia-substituted macrocycles **2** and **3**. Crystallographic results are presented, including an unusual Hg_2^{2+} crown ether dimer complex which forms upon mercury(II) reduction by the solvent DMF.

2. Experimental

2.1. Materials and instrumentation

The metal salts cadmium(II) perchlorate monohydrate (Sigma–Aldrich), mercury(II) perchlorate trihydrate (Alfa-Aesar) and magnesium perchlorate hexahydrate (Sigma–Aldrich), were used as purchased. 1,8-oxybis(ethyleneoxyethyleneoxy)anthracene-9,10-dione (**1**), 1,8-oxybis(ethylenethioethyleneoxy)anthracene-9,10-dione (**2**), and 1,8-thiobis(ethylenethioethyleneoxy)anthracene-9,10-dione (**3**) were synthesized using previously reported procedures [36]. Elemental analyses for carbon and hydrogen were conducted using an Exeter CE-440 Elemental Analyzer. Microanalyses for sulfur were conducted by MHW Laboratories of Phoenix, AZ. All samples were previously dried at 100 ° C under vacuum before elemental analyses to remove solvates. LC-ESI-MS was conducted using a Micromass (Manchester, UK) mass spectrometer. Spectroscopic data including fitting routines for binding constants were conducted according to Ref. [35]. Ref. [37] describes determination of quantum yields. Absorbance data was collected using a HP 8452A diode array spectrophotometer and luminescence titrations conducted using a SPEX Fluoromax fluorimeter. *Caution*. Although we have experienced no difficulties with the perchlorate salts, these should be regarded as potentially explosive and handled with care.

2.2. Synthesis of $[Cd \cdot \mathbf{2}](ClO_4)_2$ (**4**)

0.2 g (0.47 mmol) of **2** was dissolved in 20 mL of dichloromethane, and cadmium (II) perchlorate monohydrate (0.15 g, 0.47 mmol), dissolved in 15 mL of acetonitrile, was added drop wise and stirred for 2 h. All the solvents were evaporated under reduced pressure and the residue dissolved in 20 mL of CH_2Cl_2–methanol (8:2) mixture and layered with diethyl ether. Bright yellow crystals were obtained. Yield ~0.29 g (72%). Melting point 190–194 °C (dec). Elemental *Anal.* Calc. for $C_{22}H_{22}O_{13}S_2CdCl_2$: C, 35.63; H, 2.97; S, 8.65. Found: C, 35.53; H, 3.29; S, 8.74%. ^{1}H NMR (CD_3CN, 22 °C): δ 3.24 (*t*, 4H, CH_2–O, $J = 5.5$ Hz); 3.42 (*t*, 4H, CH_2–O, $J = 5.5$ Hz); 3.89 (*t*, 4 H, CH_2–O, $J = 5.5$ Hz); 4.39 (*t*, 4H, CH_2–O, $J = 5.5$ Hz); 7.35 (*t*, 2H, Ar–H, $J = 5$); 7.69–7.78 (*m*, 4H, Ar–H). ^{13}C NMR (CD_3CN, 25 °C): δ 38.2, 33.9, 67.4, 68.3, 120.4, 120.6, 122.8, 135.4, 131.4, 159.7, 183.4, 185.6. ESI-S *m*/*z*: Found 642.88 (M^+, 100%); Calc. 642.4.

2.3. Synthesis of $[Hg \cdot \mathbf{2}](ClO_4)_2$ (**5**)

0.2 g (0.47 mmol) of **2** was dissolved in 20 mL of dichloromethane and mercury (II) perchlorate trihydrate (0.21 g, 0.47 mmol), in 15 mL of acetonitrile, was added drop wise stirred for 2 h. All the solvents were evaporated under reduced pressure. The residue was dissolved in 5 mL of acetonitrile and mixed with excess diethyl ether (40 mL). A yellow colored precipitate was obtained which was dissolved in 25 mL of acetonitrile and layered with diethyl ether. Yellow colored fibrous crystals were obtained. Yield ~0.19 g (48%). Melting point: 228–230 °C (dec). Elemental *Anal.* Calc. for $C_{22}H_{22}O_{13}S_2HgCl_2$: C, 31.84; H, 2.65; S, 7.73. Found: C, 31.86; H, 2.69; S, 8.04%. ^{1}H NMR (d^6-DMSO, 22 °C): δ 3.51–3.59 (*bm*, 4H, CH_2–O); 3.94–4.01 (*bm*, 8H, CH_2–O); 4.58–4.63 (*bm*, 4H, CH_2–O); 7.62 (*d*, 2H, Ar–H, $J = 7.8$); 7.77–7.89 (*bm*, 4H, Ar–H). ^{13}C NMR (CD_3CN, 25 °C): δ 35.8, 37.3, 64.1, 65.9, 119.4, 119.7, 123.5, 133.7, 135.2, 157.3, 182.6, 185.5. ESI-S *m*/*z*: Found 730.93 (M^+, 100%); Calc. 730.6.

2.4. Synthesis of $[Cd \cdot \mathbf{3}](ClO_4)_2$ (**6**)

0.2 g (0.45 mmol) of **3** was dissolved in 25 mL of dichloromethane and cadmium (II) perchlorate monohydrate (0.14 g, 0.45 mmol), dissolved in 15 mL of acetonitrile,

was added drop wise and stirred for 2 h. All the solvents were evaporated under reduced pressure and the residue dissolved in 20 mL of acetonitrile and layered with diethyl ether. A yellow solid was obtained. Yield ~0.20 g (60%). Melting point: 222–224 °C (dec). Elemental *Anal.* Calc. for $C_{22}H_{22}O_{12}S_3CdCl_2$: C, 34.87; H, 2.91; S, 12.69. Found: C, 35.02; H, 3.23; S, 13.57%. ^{1}H NMR (d^6-DMSO, 22 °C): δ 2.93 (*t*, 4H, CH_2–O, $J = 5$ Hz); 3.03 (*t*, 4H, CH_2–O, $J = 5$ Hz); 3.12 (*t*, 4H, CH_2–O, $J = 5$ Hz); 4.31 (*t*, 4H, CH_2–O, $J = 5$ Hz); 7.5–7.54 (*d*, 2H, Ar–H, $J = 9.8$ Hz); 7.66–7.76 (*bm*, 4H, Ar–H). ^{13}C NMR (DMSO-d_6, 25 °C): δ 30.4, 32.4, 32.7, 71.8, 118.7, 120.4, 123.4, 134.2, 134.4, 158.1, 180.9, 183.3. ESI-MS *m*/*z*: Found 658.82 (M^+, 100%); Calc. 658.5.

2.5. Synthesis of [Hg · 3](ClO$_4$)$_2$ (7)

0.2 g (0.45 mmol) of **3** was dissolved in 20 mL of dichloromethane and mercury (II) perchlorate trihydrate (0.2 g, 0.45 mmol), in 15 mL of acetonitrile, was added dropwise and stirred for 2 h. The precipitate that formed was dissolved again in 25 mL of 617 acetonitrile–methanol (8:2) and layered with diethyl ether. A flaky, yellow solid was obtained. Yield ~0.25 g (65%). Melting point: 165–68 °C (dec). Elemental *Anal.* Calc. for $C_{22}H_{22}O_{12}S_3HgCl_2$: C, 31.24; H, 2.60; S, 11.37. Found: C, 31.36; H, 2.96; S, 11.86%. ^{1}H NMR (d^6-DMSO, 22 °C): δ 3.30–3.54 (*bm*, 12H, CH_2–O,); 4.38–4.49 (*bm*, 4H, CH_2–O); 7.5–7.54 (*d*, 2H, Ar–H, $J = 9.4$ Hz); 7.66–7.79 (*bm*, 4H, Ar–H). ^{13}C NMR (d^6-DMSO, 25 °C): δ 30.8, 31.9, 32.3, 68.4, 119.1, 120.1, 123.3, 133.9, 134.9, 157.4, 180.1, 182.7. ESI-MS *m*/*z*: Found 746.65 (M^+, 100%); Calc. 746.6.

2.6. Synthesis of [Hg$_2$ · (3)$_2$](ClO$_4$)$_2$ (8)

0.1 g (0.12 mmol) of **7** was dissolved in 5 mL of dimethylformamide. Over time, yellow crystals were obtained along with elemental mercury. Yield ~0.25 g (65%). Melting point 195–198 °C (dec). Elemental *Anal.* Calc. for $C_{44}H_{44}O_{16}S_6Hg_2Cl_2$: C, 35.40; H, 2.95; S, 12.89. Found: C, 35.31; H, 3.35; S, 12.80%. Due to poor solubility, no NMR spectra were obtained. ESI-MS *m*/*z*: Found 1393.15 (M^+, 100%); Calc. 1393.8.

2.7. Synthesis of [Mg · 1](ClO$_4$)$_2$ (9)

0.15 g (0.37 mmol) of **1** was dissolved in 15 mL of acetonitrile and a solution of 0.125 g (0.37 mmol) of magnesium (II) perchlorate hexahydrate in 10 mL of acetonitrile was slowly added. The mixture was stirred for 2 h and the solvent evaporated under reduced pressure. The residue was dissolved in 10 mL of acetonitrile and layered with diethyl ether which produced a yellow crystalline solid. Yield: 55%. Melting point >300 °C. Elemental *Anal.* Calc. for [Mg · **1** · (H_2O)](ClO$_4$)$_2$: $C_{22}H_{24}O_{16}MgCl_2$: C, 41.32; H, 3.75. 2.8. X-ray crystallography

A crystal of compound **4**, grown by vapor diffusion of diethyl ether in methanol, was mounted on a Bruker SMART CCD diffractometer for data collection at 173(2) K using Mo Kα radiation. Final cell constants were calculated from the *xyz* centroids of 2947 reflections from the data collection after integration [38]. Structures were solved by direct methods using SIR92 [39] or SHELXS-97 [40] and refined using SHELXL-97 [41]. There is a compositional disorder in one coordination site around the Cd atom. The site is occupied 71% of the time by a methanol molecule and 29% of the time by a water molecule, hydrogen bonded to another water molecule. The perchlorate (Cl2–O14) was modeled as disordered over two positions (57:43). The dichloromethane was modeled as disordered over two positions (69:31). Crystallographic data for compound **8** and **9** were collected at 295 K, using Mo Kα radiation on a Nonius CAD4 diffractometer. Psi-scan data collection was used for absorption corrections. Refinement was completed using the WINGX suite of crystallographic software [41,42]. Compound **9** has one perchlorate, Cl(2), disordered over two positions in a 62:38 ratio. Table 1 lists additional crystal and refinement information.

3. Results

3.1. Synthesis and crystallography

Addition of equal molar amounts of macrocycles **2** and **3** to cadmium and mercury perchlorate salts yield 1:1 adducts as confirmed by NMR, elemental analyses and ESI-MS. Characterization of compound **4** by single-crystal X-ray crystallography also confirms that Cd^{2+} is encapsulated by macrocycle **2** (Fig. 1). The metal center has octahedral geometry that includes bonds to the three ring heteroatoms, the intraannular carbonyl, a perchlorate anion, and either a methanol or water solvent molecule in compositional disorder (71:29%). The dihedral angle formed between the two aromatic rings of the anthraquinone is 0.0°, requiring a planar anthraquinone that also participates in π-stacking (~3.5 Å) within the unit cell. Important bond distances and angles of **4** are listed in Table 2.

Both compound **3** and its mercury(II) adduct have poor solubility in most organic solvents. For this reason, crystals were grown in the polar solvent DMF. Upon slow evaporation of the solvent, yellow crystals of **8** formed in addition to very fine droplets of elemental mercury. Subsequent structural analysis revealed that **3** does not contain the Hg(II) cation, but surprisingly ligates Hg_2^{2+}

instead, bridged by two molecules of **3** (Fig. 2). The ring structure is significantly bent to accommodate a trigonal arrangement of sulfur atoms that bind to a Hg(I) atom within each macrocycle. The anthraquinone also adopts a slightly bent conformation where the two aromatic rings are related by a dihedral angle of 10.7°. The Hg–Hg bond in this structure is 2.550(1) Å, on the same order as that found in $Hg_2(NO_3)_2$ (2.508(2) Å) [43]. The Hg_2^{2+} unit has previous been found bridging oxygen-containing crown ethers [44] and has also been found bridging nitrogen-containing phenanthroline [45] and selenaaza complexes [46]. Only two sulfur-containing Hg_2^{2+} complexes have been reported [47,48]. Poor solubility of **8** restricted study by NMR spectroscopy, and luminescence of the Hg_2^{2+}-containing complex was not observed.

The crystal structure of the magnesium(II) perchlorate complex **9** is shown in Fig. 3. Compound **1** has been distorted to accommodate a pseudo pentagonal bipyramidal geometry around the central magnesium(II) ion. While the Mg–O4 bond distance is longer (2.716(3) Å) than the bonds to the ether or carbonyl oxygens (Table 2), this bond is significantly shorter than the bond to the second phenolic type oxygen (Mg–O3 = 3.767(4) Å). Although crystals were grown by vapor diffusion of diethyl ether into acetonitrile, the oxophilic magnesium remains capped by two water molecules, present as hydrates from the metal salt or other water present in the solvent. The planarity of the anthraquinone in this structure is midway between the previous two structures with a dihedral angle of 4.7°.

3.2. Spectroscopy

A shift to longer wavelength occurs in the optical absorption spectrum upon titration of **2** with $Cd(ClO_4)_2$ in acetonitrile (Fig. 4). Concomitant with the shift in the absorbance maximum of **2** is the corresponding increase in fluorescence at 506 nm. We observe a clean isosbestic point in the titration of Cd(II) with **2**, that produces a $\log K_{binding}$ of 4.1(2), representing: $\mathbf{2} + Cd^{2+} \leftrightarrow [Cd \cdot \mathbf{2}]^{2+}$ (Table 3 and fitting plot provided in the Supplemental material). Fluorescence enhancement ($\lambda_{max} = 522$ nm) is also observed when Hg^{2+} ion is combined with **3** (Supplemental material); however the binding properties could not be determined in this case since isosbestic behavior was not observed. We attribute initial Hg^{2+} complex formation to a 1:2 metal:ligand sandwich complex, $[Hg \cdot \mathbf{3}_2]^{2+}$, before conversion into the 1:1 $[Hg \cdot \mathbf{3}]^{2+}$ product at higher Hg^{2+} concentration. Fig. 5 shows the luminescence changes exhibited by **2** and **3** in the presence of two equivalents of metal perchlorate salts in acetonitrile and compared to changes previously observed for **1** [13]. While **1** has good selectivity for Pb(II), **2** and **3** are almost exclusively selec-

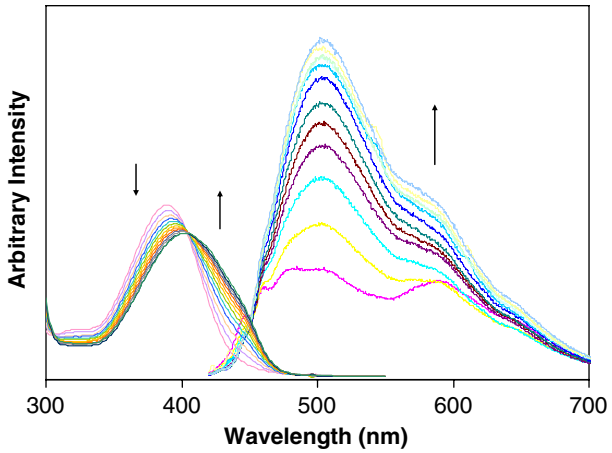

Fig. 4. UV/Vis and fluorescence titration of **2** with $Cd(ClO_4)_2$ in acetonitrile. Each addition equals 0.2 equiv. of Cd^{2+}. Excitation at 404 nm ($\varepsilon_{404} = 7100\ M^{-1}\ cm^{-1}$). $\mathbf{2} = 1.0 \times 10^{-4}$ M.

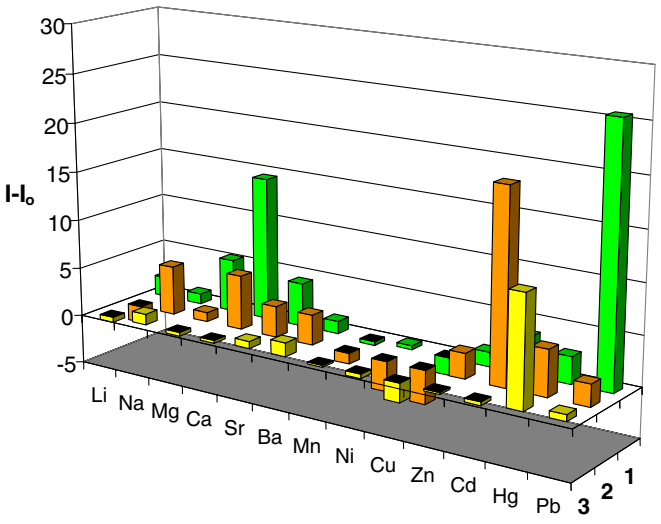

Fig. 5. Fluorescence changes of **1**–**3** after addition of two equivalents of metal perchlorate salts. Excitation wavelength was 420 nm and the emission intensity changes were calculated λ_{max} at 515 nm (Pb^{2+}), 510 nm (Cd^{2+}) and 520 nm (Hg^{2+}). **1**–**3** $= 1.0 \times 10^{-4}$ M; $M^{n+} = 2.0 \times 10^{-4}$ M. Data for **1** are from Ref. [35]. A digital picture showing luminescence is part of the TOC graphic.

tive for Cd(II) and Hg(II), respectively. A photograph for comparison is provided in the TOC graphic and the Supplemental material.

4. Discussion

Addition of **2** and **3** to cadmium(II) and mercury(II) perchlorate salts in acetonitrile produces selective luminescence that is different from that previously observed for **1** in the presence of lead(II) [35]. Each macrocycle has unique emission properties that are cation dependent. We have also observed that interference from alkaline earth metals decrease with increasing number of sulfur atoms in the lumophore. This is quite apparent in Fig. 5 which shows the change in luminescence going across each series and supports previous knowledge that alkaline earth metals tend to be more oxophilic, and supported by the coordination of two water molecules in the Mg^{2+} complex (Fig. 3). Results are consistent with the soft mercuric ion showing preference for the macrocycle with the greatest number of soft sulfur atoms. Also, transition metals with partially filled d-orbitals always quench luminescence in these cases. Metal ions such as Mn^{2+}, Ni^{2+} and Cu^{2+} show complete quenching in fact, where luminescence is even less than the macrocycle alone in acetonitrile solvent. This quenching mechanism using available d–d transitions has previously been observed in other luminescence systems [49].

X-ray crystallography of these complexes reveals that a variety of coordination geometries can exist for the central metal in the solid-state. Previous work with Pb(II) has two perchlorates coordinated to the metal center, one above and one below macrocycle **1**, and the Zn and Mn structures of **1** reveal that both a water molecule and an acetonitrile molecule cap the metal above and below the plane of the same encapsulating macrocycle [35]. Two different cases are presented here; (A) where one perchlorate anion and one solvent molecule are coordinated in the case of Cd^{2+} (Fig. 1), and (B) a second case where two water molecules coordinate to Mg^{2+} (Fig. 3). In the case of magnesium, this structure is essentially isostructural to that found for Zn and Mn where an acetonitrile has been replaced by either methanol or water (71:29% compositional disorder). The space group and cell parameters are quite similar in these two structure types, and suggest the magnesium metal center prefers the harder oxygen-containing ligands.

Previous work has demonstrated that Hg_2^{2+} extraction can be accomplished using thiacarbamoyl substituted calix[4]arenes [50]. The Hg_2^{2+} adduct formed in this case however, **8** (Fig. 2), does not result from the addition of

Table 3

mercurous ion, but certainly via reduction of added mercuric ion by the solvent DMF. This has previously been observed in the formation of silver nanocrystals by the reduction of Ag^{+} ion in DMF [51]. The presence of **3** is also not necessary for reduction since Hg^{0} is still formed when Hg^{2+} is the only species added to DMF. Reduction by DMF is also observed for other Hg(II) salts. Formation of Hg^{0} is postulated based upon the known mercurous ion disproportionation reaction: $Hg_2^{2+} \leftrightarrow Hg^{0} + Hg^{2+}$. This also does not occur in other polar solvents such as CH_3CN or DMSO, which do not contain an aldehyde group available for oxidation as is the case with DMF. Reduction of Hg^{2+} has also been observed in the structural characterization of a Hg_2^{2+} complex containing a tripodal nitrogen ligand [52]. The authors concluded that oxidation of the ligand by Hg^{2+} happens in this case, where the production of Hg^{0} was not observed and isolation of the Hg_2^{2+} complex occurs in low yield. Using DMF as the media in this case, production of Hg_2^{2+} and the resulting sulfur-mercury(I) adduct occur in high yield.

5. Conclusions

Photoinduced charge transfer (PCT) sensors of this type provide a means of imparting cation selectivity. Whereas other systems typically incorporate standard size macrocycles (i.e. 18-crown-6, 15-crown-5, and their heteroatom-substituted analogs), the intraannular carbonyl in this system changes the receptor size and alters binding properties of potential guests, distinctive from previously studied macrocycles. With relative ease of synthesis as well, we have been able to tailor the PCT macrocycle and fine tune selectivity with excellent control using rings of the same size that contain different combinations of heteroatoms. The charge-to-size ratio of the metal cation in combination with receptor composition results in variation in emission properties, specific for Cd^{2+}, Hg^{2+} and Pb^{2+} in these examples. We are currently investigating new receptors that will further refine selectivity and solubility for this family of luminescence sensors.

Acknowledgments

The authors thank the National Science Foundation (0082978) and the South Dakota 2010 Initiative for financial support. We also thank the University of South Dakota and NSF-EPSCOR (9720642 and 0091948) for the purchase and upgrade of a Nonius CAD4 X-ray diffractometer. Benjamin Kucera at the University of Minnesota X-ray Diffraction Laboratory completed the structure determination of $[Cd \cdot \mathbf{2} \cdot H_2O \cdot ClO_4]ClO_4 \cdot CH_2Cl_2$ (**4**). The elemental analyzer was purchased using NSF-URC funding (CHE-0532242).

Appendix A. Supplementary material

Hg(II) absorbance and luminescence spectra are available as supplementary data. CCDC 296855, 296853, and 296854 contain the supplementary crystallographic data for **4**, **8** and **9**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2006.10.046.

On the other hand, the design of transition-metal clusters with novel magnetic properties is considerable interest from the standpoint of material chemistry and condensed matter physics [27–30]. Although a great effort has been made to study magnetic properties of dinuclear Cu(II) complexes, there has been comparatively little work reported on higher nuclearity isolated compounds, especially for these with more than four metal ions. Structural and magnetic data have been reported for pentanuclear Cu(II) complex, in which four metal centers are arranged in a square Cu_4O_4 alkoxide bridged grid and one external Cu(5) ion is connected via diazine N–N group to Cu(2) [31]. Antiferromagnetic intramolecular interactions between external Cu(II) and Cu(2) ions are predominant, whilst those between Cu(1)–Cu(4) and Cu(4)–Cu(3) within the triangular grouping of coppers are weak ferromagnetic ($J_1 = 1.9$ and $J_2 = -90$).

A chiral hexanuclear complex having a propeller structure has been studied [32]. Its core structure consists of six Cu(II) ions and five oxygen atoms and resembles a cryptand, and has a proton trapped inside. Magnetic susceptibility measurements show the complex has antiferromagnetically coupled ground state. Similarly, hexanuclear compound $[Cu_6(tmen)_6(\mu\text{-}N_3)_2(\mu\text{-}C_2O_4)_3(H_2O)_2][ClO_4]_4$ with *N*,*N*,*N*′,*N*′-tetramethylethane-1,2-diamine [33] and sulfato-bridged hexanuclear dimer show significant antiferromagnetic coupling [34]. On the contrary, the six copper(II) ions in the core of the hexanuclear cluster – $[PhSiO_2Cu_6(O_2SiPh)_6]\cdot 6EtOH$ are ferromagnetically coupled with $J = 42\ cm^{-1}$ [35]. Antiferromagnetic exchange between copper(II) ions has been also observed in octanuclear macrocyclic complexes [36]. The structural and magnetic studies for the dodecanulcear macrocyclic complex $[Cu_6L(\mu_2\text{-}OH)_3](ClO_4)_3\cdot 4H_2O$ have been reported [37]. The structure of the dimeric cation consists of two almost flat, hexagonal macrocyclic rings, each involving an array of six Cu(II) centers. Two macrocyclic rings are connected by four hydroxide groups. The magnetic behavior and calculated exchange integrals indicate significant antiferromagnetic interactions.

This paper deals with the structural, spectroscopic and magnetic studies of new decanuclear copper(II), in which two pentanuclear subunits are linked through chloride bridges.

2. Experimental

2.1. Synthesis

The complex of the formula $[Cu_5(\beta\text{-alaha})_4Cl_2]_2\cdot 2HCl\cdot 15H_2O$ was synthesized in reaction of $CuCl_2$ (0.1 M) and β-alaninehydroxamate hydrochloride $C_3H_8N_2O_2\cdot HCl$ (0.1 M) in water solution. The deep blue solution was adjusted to pH ≈ 5.5. The solution kept at stable temperature provided dark green single crystals suitable for X-ray analysis. The size of the crystals was appropriate for absorption spectra measurements.

2.2. X-ray structure determination

The structure of the title compound was determined by single-crystals X-ray diffraction. Crystal data are given in Table 1, together with the refinement details. All X-ray measurements of the crystal were performed at low temperature using an Oxford Cryosystem device on a Kuma KM4CCD κ-axis diffractometer with graphite-monochromated MoKα radiation. The crystal was positioned at 65 mm from the CCD camera. 612 frames were measured at 0.75° intervals with a counting time of 15 s. Accurate cell parameters were determined and refined by least-squares fit of 4200 the strongest reflections. The data were corrected for Lorentz and polarization effects. Analytical absorption correction was applied. Data reduction and analysis were carried out with the Oxford Diffraction (Poland) Sp. z o.o (formerly Kuma Diffraction Wrocław, Poland) programs. The structure was solved by direct methods (program SHELXS97 [38]) and refined by the full-matrix least-squares method on all F^2 data using the SHELXL97 [39] programs. Non-hydrogen atoms were refined with anisotropic displacement parameters; all hydrogen atoms from the $>CH_2$ and $>NH_2$ groups were included from geometry of molecules and four hydrogen atoms only from the water molecules were identified in $\Delta\rho$ maps. During refinement all hydrogen atoms parameters, including isotropic displacement factors, were fixed.

2.3. Magnetic and spectroscopic measurements

The magnetic susceptibility of solid sample was recorded using a SQUID MPMS5 magnetometer in the temperature range 1.8–300 K at external field of 0.5 T and 200 G. All data were corrected for diamagnetism estimated from Pascal's constants.

Absorption spectra were measured at 293 and 4 K on a Carry-Varian 500 Scan spectrophotometer equipped with a helium flow cryostat (OXFORD CF 1204).

3. Results and discussion

The crystal structure of the title compound consists of discrete decanuclear molecules of complex: $[Cu_5(\beta\text{-alaha})_4Cl_2]_2$ composed of two pentanuclear clusters bridged by chloride ions, chloride anions and non-coordinated water molecules. Coordination of copper(II) ions in pentanuclear subunit as well as the atom labeling are given in Fig. 1. Table 2 contains the selected bond distances and angles relevant to the metal coordination sphere. All nitrogen and oxygen atoms of four β-alaninehydroxamate ligands are involved in coordination of five copper(II) ions. The pentanuclear cluster with symmetry close to C_{4v} is formed by four copper(II) ions (Cu(2)–Cu(4)) in the basal plane (±0.0368 Å) and a Cu(1) ion in apex, situated 0.54 Å above this plane. The center-to-center distances are in the range 3.2805–6.5262 Å. The distances between the central and peripheral copper(II) ions vary from 3.2805 (Cu1–Cu2) to

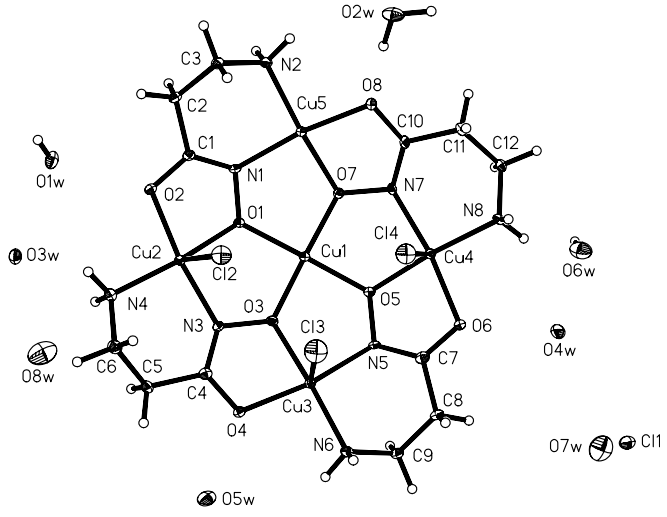

Fig. 1. X-ray crystal structure of the pentameric subunit of complex $[Cu_5(\beta\text{-alaha})_4Cl_2]_2 \cdot 2HCl \cdot 15H_2O$.

3.3335 Å (Cu1–Cu3), while those between peripheral copper(II) ions are longer and vary from 4.5731 (Cu3–Cu4) to 4.610 Å (Cu4–Cu5). All peripheral Cu(II) ions are coordinated in the similar manner. The two nitrogen donors of β-alaninehydroxamate ligand are bound to Cu(II) ion while the two oxygen atoms chelate the adjacent metal ion. In this way tetrameric unit comprising four six-membered as well as five-membered chelate rings is created. In the center of the tetrameric unit, the fifth Cu1 ion is centered, which is bridged to peripheral Cu(II) ions (Cu2–Cu5) by four oxygen atoms of the hydroxamic groups (–NHOH). It causes formation of next four five-membered rings in pentanuclear species. The central metal ion adopts a nearly square planar environment, what can be confirmed by the fact that a sum of the valence angles (O–Cu1–O) is 360.06°. The Cu2, Cu3, Cu4, Cu5 ions are additionally linked to chloride atoms acting as bridges coupling the metal ions from two pentameric subunits. Fig. 2 shows the view of decanuclear complex with four chloride bridges. The average Cu···Cl distance equals to 2.708 Å, thus it is much longer then Cu···O and Cu···N distances, which are equal to 1.942 and 1.988 Å, respectively. The distances between two metal centers coupled by chloride bridges are as follows: Cu2–Cu2′ = 4.8596 Å, Cu3–Cu5′ = 5.1275 Å, Cu4–Cu4′ = 5.0982 Å and Cu5–Cu3′ = 5.1275 Å. The position of two hydrogen cations was not localized by

Symmetry transformations used to generate equivalent atoms: #1 $-x$, y, $-z + 1/2$.

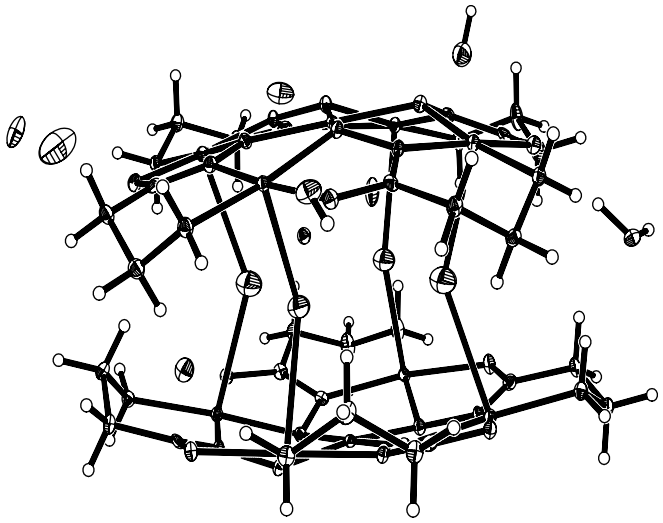

Fig. 2. X-ray crystal structure of the complex $[Cu_5(\beta\text{-alaha})_4Cl_2]_2 \cdot 2HCl \cdot 15H_2O$.

X-ray refinement. In our opinion the Cl^- ion and water molecules could be occupied by both hydrogen atoms.

The hydrogen-bonding system in this structure is complex due to the presence of water molecules. Non-coordinated water molecules and chloride anions participate in hydrogen-bonds with nitrogen atoms from amine groups, carboxyl oxygen atoms and other water molecules (see Table 3).

The structure of the pentanuclear cluster unit shows some common features with another cooper(II) compound, published by Kurzak et al. [26]. In earlier reported structure of a general formula $[Cu_5(\beta\text{-alaha})_4](ClO_4)_2 \cdot 5H_2O$, pentameric subunits are also created and the same coordination mode of β-alaninehydroxamate anions is observed. All copper(II) ions are additionally connected to fifth oxygen atom of water molecule, perchlorate anion or alaninehydroxamate ligand (distances vary from 2.363 to 2.675 Å). Moreover, the central metal ion (Cu5) exhibits a long interactions with oxygen atom $O(5^{II})$, which also interacts with one of the peripheral copper(II) ion (Cu4) leading to an increase of the coordination number of the latter to CN = 6. Contrary to our system with chloride bridges, the perchlorate bridges between cooper(II) ions from two different pentameric subunits are not present. In this case two pentanuclear clusters are joined only by one hydroxamic oxygen atom. It is worth to notice that the structure of our system is more ordered in comparison to that reported by Kurzak et al. [26]. It is probably caused by the presence of chloride bridges playing important role in stabilization of the crystal structure. Deformation of the pentameric cluster from C_{4v} symmetry is stronger in the earlier published complex what is manifested mainly in larger deviation from basal plane of four peripheral Cu(II) ions (±0.10 [26] and 0.039 for our compound). It was also observed in now investigated compound that the central copper(II) ion is situated higher above the plane formed by four peripheral metal ions (0.54 Å) then in $[Cu_5(\beta\text{-alaha})_4](ClO_4)_2 \cdot 5H_2O$ (0.4 Å) [26].

Fig. 3 shows the absorption spectra of $[Cu_5(\beta\text{-alaha})_4Cl_2]_2 \cdot 2HCl \cdot 15H_2O$ single crystal obtained at room and liquid-helium temperature. The electronic spectra consist of overlapped d–d absorption bands of Cu(II) ions with different symmetry sites and the charge-transfer band (L → M). The broad band centered at UV region, with some shoulders indicating unresolved bands (15 848 cm^{-1}, 16 886 cm^{-1}, 18 188 cm^{-1}), consists of the bands of four slightly different copper(II) optical centers with very low symmetry (peripheral metal ions) and the bands of cooper(II) ion with a symmetry close to D_{4h} (central metal ion). As the result of splitting of energy levels for a d^9 metal ion with D_{4h} symmetry the d–d hole transitions: $x^2 - y^2 \rightarrow xy$, $x^2 - y^2 \rightarrow z^2$, $x^2 - y^2 \rightarrow (xz, yz)$ may be expected, but in C_1 the transitions depend on magnitude of energy levels' splitting. In fact, appropriate transitions should be observed for pentagonal coordination of Cu^{2+} ion: $x^2 - y^2 \rightarrow z^2$, $x^2 - y^2 \rightarrow xy$, $x^2 - y^2 \rightarrow (xz, yz)$. Overlapping of these transitions for four non-equivalent five-coordinated Cu(II) centers (Cu2–Cu5) and four-coordinated Cu(II) (Cu1) center leads to a complex, unresolved absorption spectrum, which does not became

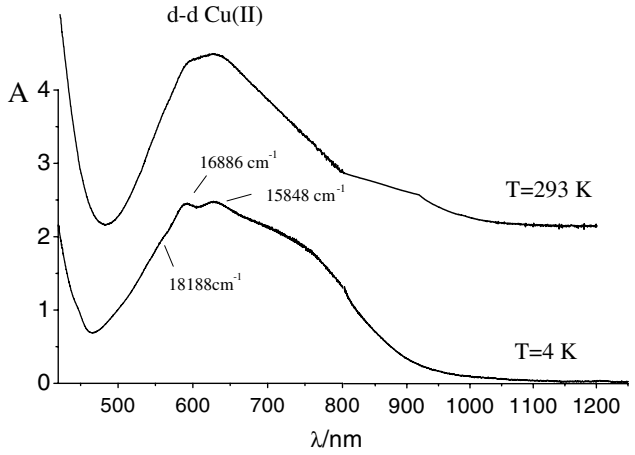

Fig. 3. The absorption spectra of single crystal of $[Cu_5(\beta\text{-alaha})_4Cl_2]_2 \cdot 2HCl \cdot 15H_2O$ at 298 and 4 K.

resolved even at liquid-helium temperature. Moreover, stronger electron–phonon coupling than in f-electron systems can lead to a broadening of the optical lines, too.

The EPR spectra of title compound at room as well as at nitrogen liquid temperature show broad copper(II) signals having $g = 2.01$ (298 K) and 2.17 (77 K), and no resolution of g_{II} and $g_{\perp}$ is observed.

The molar magnetic susceptibilities χ_M of $[Cu_5(\beta\text{-alaha})_4Cl_2]_2 \cdot 2HCl \cdot 15H_2O$ are measured on a powdered sample in the temperature range 1.9–300.5 K under the applied magnetic field of 0.5 T, and the results are shown in Fig. 4 in the form of $\chi_M T$ versus T. The inset in this figure presents the temperature dependence of $\chi_M T$ (1.9–50 K) registered under the applied magnetic field of 200 G. The value of $\chi_M T$ at 300.5 K is 1.09 $cm^3\,mol^{-1}$ K, which is lower than the spin only value of five uncoupled Cu(II) ions (1.875 $cm^3\,mol^{-1}$ K for $g = 2$), thus indicating the presence of strong antiferromagnetic interaction. As the temperature is lowered the $\chi_M T$ decreases gradually, reaching a value of 0.42 $cm^3\,mol^{-1}$ K at 38 K (as expected for five Cu(II) ions AF coupled, the value for one copper(II) ($S = 1/2$) with g different from 2) (Fig. 4). On further cooling it decreases very slowly to reach a plateau below 18 K at about 0.39 $cm^3\,mol^{-1}$ K (Fig. 4). Below 5 K a further decrease of $\chi_M T$ is observed (0.30 $cm^3\,mol^{-1}$ K at 1.9 K), which can be attributed to interactions between two pentanuclear units ($S = 1/2$) in complex $[Cu_5(\beta\text{-alaha})_4Cl_2]_2 \cdot 2HCl \cdot 15H_2O$. The profile of the curve indicates predominant antiferromagnetic interactions between the Cu(II) centers within the pentameric Cu_5 core and weaker antiferromagnetic interactions between Cu(II) ions from two pentanuclear Cu_5 units bridged by chloride anions. The temperature dependence of reciprocal susceptibilities χ_M^{-1} is also indicative on the antiferromagnetic interactions (Fig. 5). It is almost linear in the temperature range of 50–300.5 K, the Curie constant (C) is 1.47 $cm^3\,mol^{-1}$ K and the Curie-Weiss temperature is −111.71 K. Similar magnetic behavior has been reported for a sulfato-bridged hexanuclear dimer $[Cu_3(MeImds)(SO_4)(H_2O)_3]_2$, where MeImds stands for bis(salicylaldehyde)methylimino-diacetylhydrazone [34]. The decrease of $\chi_M T$ on lowering the temperature indicates quite strong antiferromagnetic coupling within trinuclear unit. Below 40 K, the curve reaches plateau at $\chi_M T = 0.42$ $cm^3\,mol^{-1}$.The further decrease at lower temperature was attributed to a weak antiferromagnetic interactions between the trimetallic units mediated by sulfate bridges. For another trinuclear complex with bis(2-hydroxybenzyl)-1,3diamnopropane the second decrease of $\chi_M T$ at temperature below 10 K was attributed to intermolecular interactions between $S = 1/2$ trimeric units [40].

Considering that there are not significant differences between Cu(1) and peripheral Cu ions distances, and also between neighboring peripheral Cu ions laying in almost planar square, we assumed the four exchange integrals for interactions between central Cu(1) ion and Cu(2), Cu(3), Cu(4), Cu(5) as the same one (J). Similarly, we

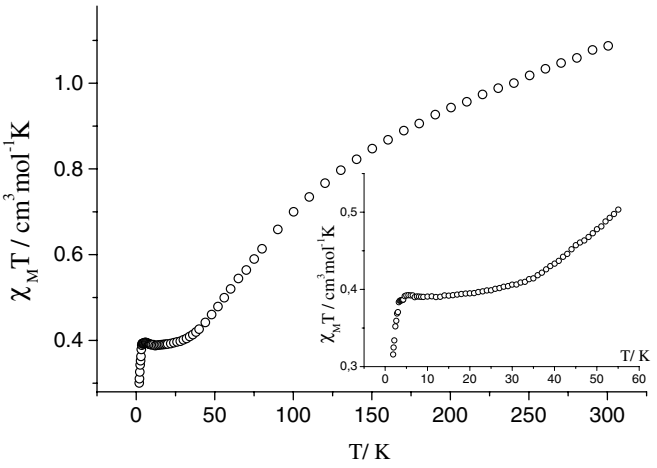

Fig. 4. Experimental magnetic data plotted as $\chi_M \cdot T$ vs. T calculated per molecule of complex $[Cu_5(\beta\text{-alaha})_4Cl_2] \cdot HCl \cdot 7.5H_2O$; from measurements performed at 0.5 T. The inset shows $\chi_M \cdot T$ vs. T from measurements performed at 200 G.

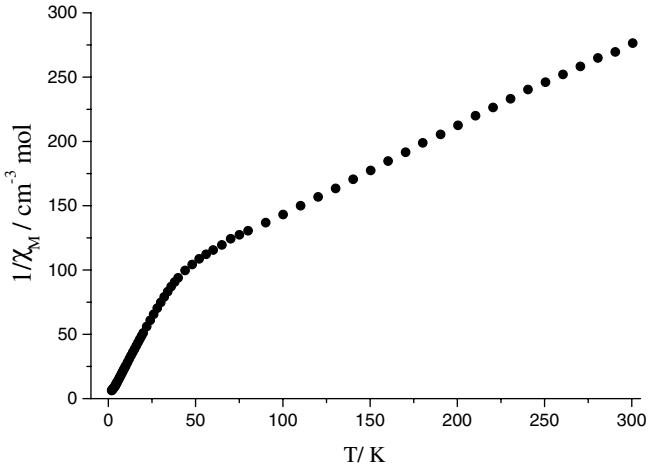

Fig. 5. Experimental magnetic data plotted as χ_M^{-1} vs. T for $[Cu_5(\beta\text{-alaha})_4Cl_2] \cdot HCl \cdot 7.5H_2O$.

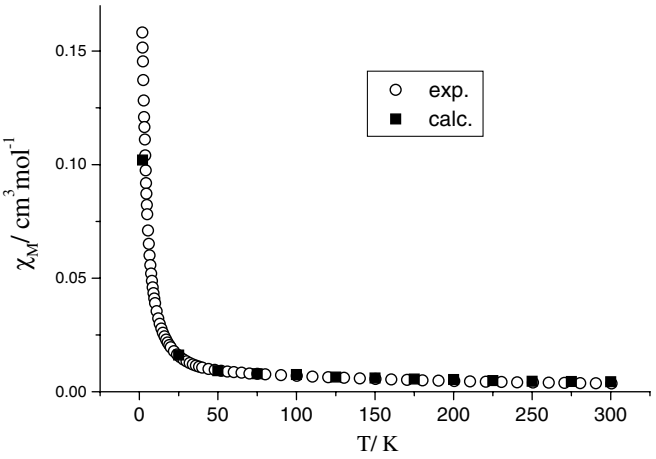

Fig. 6. Experimental and calculated magnetic susceptibility χ_M for $[Cu_5(\beta\text{-alaha})_4Cl_2]\cdot HCl\cdot 7.5H_2O$.

assumed one exchange integral (J′) for interactions between peripheral copper ions. Calculations of the dependence of magnetic susceptibility versus temperature were undertaken using the following expression:

$$\chi_M = N\frac{\mu_B^2 g^2}{kT}\left\{\frac{30\exp(2y-11x)+6\exp(-2y-11x)+6\exp(-11x)+6\exp(-15x)}{5\exp(2y-11x)+3\exp(-2y-11x)+3\exp(-11x)+4\exp(-15x)+\exp(-2y-15x)}\right\},$$

where J describes interactions between Cu1 ion and remaining Cu(II) ions (2, 3, 4, 5) (Fig. 1) and J' describes interactions between four peripheral Cu(II) ions (2, 3, 4, 5) creating a square (Fig. 1)

$$x = J'/2kT, \quad y = J/kT.$$

This equation relates to the system of five interacting copper(II) ions (pentanuclear cluster) with C_{4v} symmetry. The interactions between peripheral Cu(II) ions of two pentanuclear cluster joined by chloride bridges were not taken into account. The best fit was obtained for the following parameters set: $H = 5000$ G, $g = 2.15$, $J = 25\ cm^{-1}$ and $J' = -55\ cm^{-1}$. The calculated data do not fit very well to experimental results (see Fig. 6), what shows that the interaction of two clusters Cu_5 through chloride bridges influences the magnetic properties of the investigated system. These super-exchange interactions seem to be antiferromagnetic in character and they are displayed at very low temperatures (1.8–5 K). It is worth to mention that interactions between neighboring clusters can be mostly ferromagnetic or antiferromagnetic as it was reported earlier by Cukerblat [41]. More precise explanation of the magnetic behavior of our complex compound requires further, more detailed theoretical investigations.

4. Supplementary material

ligands with functional groups have been comparatively little synthesized and investigated. In contrast to the coordination polymers with flexible imidazole ligands, the coordination polymers containing rigid π-conjugated imidazole ligands have potential applications in the fields of electrooptical devices [3c]. Therefore, more efforts should be focused on the design and synthesis of rigid imidazole ligand by functional group modifications.

In addition, in construction of the infinite supramolecular networks, multidentate ligand thiocyanate is usually employed to bridge between metal centers to form polymeric structures. Thiocyanate is a highly versatile ambidentate ligand with a polarizable π system and two different donor atoms, which can coordinate to metals through either the nitrogen or the sulfur atoms, or both [15]. The various bridging modes of the thiocyanate ligand not only generate new types of network structures but also offer the opportunity for forming hetero-metallic complexes involving various combinations of metal ion node points. Such combinations could lead to the formation of materials with useful properties deriving from the presence of the hetero-metallic arrays [16,17].

We have rationally designed and synthesized a functional imidazole ligand with good electron donor and acceptor through a conjugated bridge [18]. Based on the bridging potential of the hard and soft coordination centers of the ambidentate thiocyanate ligand, we obtained a series of organic-inorganic hybridized supramolecular polymers containing functional rigid imidazole ligands, which is original and different from the other reported imidazole-containing coordination polymers [19]. The combination of inorganic and functional organic moieties leads to both new structural architectures and excellent properties. In this article, we report the synthesis, structures and photoluminescence of three new supramolecular coordination polymers $[Cd(SCN)_2L_2]_n$ (**1**), $[CdHg(SCN)_4L_2]_n$ (**2**) and $[MnHg(SCN)_4L_2]_n$ (**3**).

2. Experimental

2.1. General

All commercially available chemicals are of analytical grade and used without further purification. The solvents were purified by conventional methods before use. *trans*-4-Imidazolyl-4′-(*N*,*N*-diethylamino)stilbene (L) was synthesized according to the methods reported [18]. IR spectra were recorded on a Nicolet FT-IR instrument by using KBr discs in the 4000–400 cm^{-1} range. Elemental analyses were carried out on Perkin–Elmer 240 analyzer. UV–Vis spectra were recorded with a UV-265 spectrophotometer. Luminescence spectra were recorded on a Perkin–Elmer LS55B fluorescence spectrophotometer at room temperature. Thermal stability studies from room temperature to 600 °C in nitrogen atmosphere with a heating rate of 10 °C min^{-1} were executed on a Perkin–Elmer pyres-1 DMDA-V1 instrument.

2.2. Synthesis

2.2.1. Preparation of $[Cd(SCN)_2L_2]_n$ (*1*)

The complex was synthesized by layering method at room temperature. A clear methanol solution (15 mL) of $Cd(NO_3)_2 \cdot 4H_2O$ (30.8 mg, 0.1 mmol) and NaSCN (16.4 mg, 0.2 mmol) was carefully layered onto a solution of L (73.4 mg, 0.2 mmol) in chloroform (15 mL). Yellow needle-shaped crystals suitable for X-ray diffraction were obtained by slow interlayer diffusion. Yield: 67.3 mg (70%). *Anal.* Calc. for $[CdC_{44}H_{46}N_8S_2]_n$: C, 61.21; H, 5.37; N, 12.98. Found: C, 61.18; H, 5.39; N, 12.94%. IR (KBr, cm^{-1}): 3421 m, 2088 s, 1598 s, 1523 s, 1468 w.

2.2.2. Preparation of $[CdHg(SCN)_4L_2]_n$ (*2*)

Methanol solution of $CdHg(SCN)_4$ was prepared by reaction of $Cd(NO_3)_2 \cdot 6H_2O$ (34.2 mg, 0.1 mmol), $Hg(NO_3)_2 \cdot H_2O$ (34.3 mg, 0.1 mmol) and NaSCN (32.8 mg, 0.4 mmol) in 20 mL of methanol. The white precipitate of KNO_3 was removed by filtration. The methanol solution of $CdHg(SCN)_4$ was carefully layered onto a solution of L (73.4 mg, 0.2 mmol) in chloroform (15 mL). Yellow sheet-like crystals suitable for X-ray diffraction were obtained by slow interlayer diffusion. Yield: 83.1 mg (65%). *Anal.* Calc. for $[CdHgC_{46}H_{46}N_{10}S_4]_n$: C, 46.81; H, 3.93; N, 11.78. Found: C, 46.85; H, 3.97; N, 11.82%. IR (KBr, cm^{-1}): 3438 m, 2119 s, 1620 s, 1591 s, 1426 w.

2.2.3. Preparation of $[MnHg(SCN)_4L_2]_n$ (*3*)

The same synthetic procedure as for **2** was used except that $Cd(NO_3)_2 \cdot 4H_2O$ was replaced by $Mn(NO_3)_2 \cdot 6H_2O$ and a 1:2 metal-to-ligand molar ratio was adopted, giving yellow rhomboid single crystals. Yield: 70.9 g (60%). *Anal.* Calc. for $[MnHgC_{46}H_{46}N_{10}S_4]_n$: C, 49.21; H, 4.13; N, 12.48. Found: C, 49.19; H, 4.15; N, 12.53 (%). IR (KBr, cm^{-1}): 3421 m, 2119 s, 1620 s, 1591 m, 1426 w.

2.3. X-ray crystallography

The X-ray diffraction measurements were performed on a Bruker SMART CCD area detector using graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at 298(2) K. Intensity data were collected in the variable ω-scan mode. The structures were solved by direct methods and difference Fourier syntheses. All non-hydrogen atoms were refined anisotropically and hydrogen atoms were introduced geometrically. Calculations were performed with the SHELXTL-97 program package [20]. All crystallographic data for complexes **1**, **2** and **3** are summarized in Table 1. Selected bond lengths and bond angles are listed in Table 2.

3. Results and discussion

3.1. Spectroscopic characterization

The organic ligand, *trans*-4-imidazolyl-4′-(*N*,*N*-diethylamino)stilbene (L) is the first reported imidazole derivative

with π-conjugated system and functional group [19]. The IR spectrum of free ligand shows absorption at 1480 cm^{-1}, attributing to the vibration of the C=N of imidazole [18a]. Compared with the double peaks 1496, 1436 cm^{-1}, 1490, 1427 cm^{-1} and 1492, 1426 cm^{-1} assigned to the C=N of imidazole in complexes **1**, **2** and **3**, respectively, the shifts and splits of the band suggest coordination of the imidazole groups in the complexes [21]. The C–N stretching vibrations of SCN^- at 2126 and 2128 cm^{-1} for **2** and **3**, suggest bridging modes of SCN^- ligands [22]. The absorption peak at lower wave numbers (2088 cm^{-1}) was for ν(C–N) of the thiocyanate in complex **1**, implying a different binding mode in accordance with the results of X-ray analysis. The electronic absorption spectra of all compounds were measured in DMF solutions (10^{-5} mol L^{-1}). The free L ligand displays strong absorption peak at 369 nm, which is assigned as K band absorption arising from $\pi \rightarrow \pi^*$ transitions within the extended π-conjugated system. The large molar absorption coefficient ($\log\varepsilon = 4.29$) is indicative of highly π-conjugated system [18a]. Complexes **1**, **2** and **3** display absorption peaks at 368 ($\log\varepsilon = 4.65$), 363 ($\log\varepsilon = 4.65$) and 365 ($\log\varepsilon = 4.65$) nm, also arising from $\pi \rightarrow \pi^*$ transitions of L ligands.

3.2. Thermal stability

Thermal stabilities for the title compounds were determined by TG technique. The TG curves exhibited that $[Cd(SCN)_2L_2]_n$ (**1**), $[CdHg(SCN)_4L_2]_n$ (**2**) and $[MnHg(SCN)_4L_2]_n$ (**3**) were stable up to their decomposition temperatures of 327.9, 316.6 and 326.8 °C, respectively, without showing any melting process, indicating the high stabilities of them. The decomposition temperatures of coordination polymers are much higher than that of the free ligand (289.3 °C). Therefore, coordination of the ligand to the metal ion results in greater thermal stability. The higher thermal stabilities indicate the potential applications of complexes **1**, **2** and **3**.

3.3. Crystal structures

3.3.1. Crystal structure of $[Cd(SCN)_2L_2]_n$ (1)

Complex **1** was obtained as yellow needle crystals by layering methanol solution of $Cd(NO_3)_2 \cdot 4H_2O$ and NaSCN onto L in chloroform. The structural unit and the one-dimensional chain for complex **1** are shown in Fig. 1a and b. Cd^{II} ion, being in between soft and hard acid, exhibits both (S and N) bonding modes [15,23]. Each Cd^{II} ion lies at a center of symmetry surrounded by six related atoms. The equatorial positions are occupied by two nitrogen atoms and two sulfur atoms from four thiocyanate anions (the Cd–N bond lengths are 2.291(7) Å, the Cd–S bond lengths are 2.750(2) Å), and two nitrogen atoms of imidazole groups from two different ligands occupy the axial positions with Cd–N bond lengths of 2.304(5) Å, therefore, the polyhedron can be described as a distorted octahedron. From Table 2, it can be seen that the S–C–N bond angles are 179.3(7)°, that is, the SCN^- group is almost perfectly linear. The S–C and C–N distances of 1.622(8) and 1.150(9) Å in SCN^- indicate a π-delocalization along the metal–thiocyanate chains [15]. This observation is consistent with the fact that the SCN^- ligand is easily polarizable ($^-$S–C≡N ↔ S=C=N$^-$).

Equivalent atoms generated by complex **1**: #1 $-x+2$, $-y+2$, $-z+2$; #2 $x-1$, y, z; #3 $-x+3$, $-y+2$, $-z+2$; #4 $x+1$, y, z. By complex **2**: #1 $-x+1$, $-y+1$, $-z$; #2 $-x+1$, $-y+1$, $-z+1$; #3 $x-1$, y, z; #4 $x+1$, y, z. By complex **3**: #1 $-x+1$, $-y+1$, $-z$; #2 $-x+2$, $-y$, $-z+1$; #3 $-x+2$, $y+1/2$, $-z+1/2$.

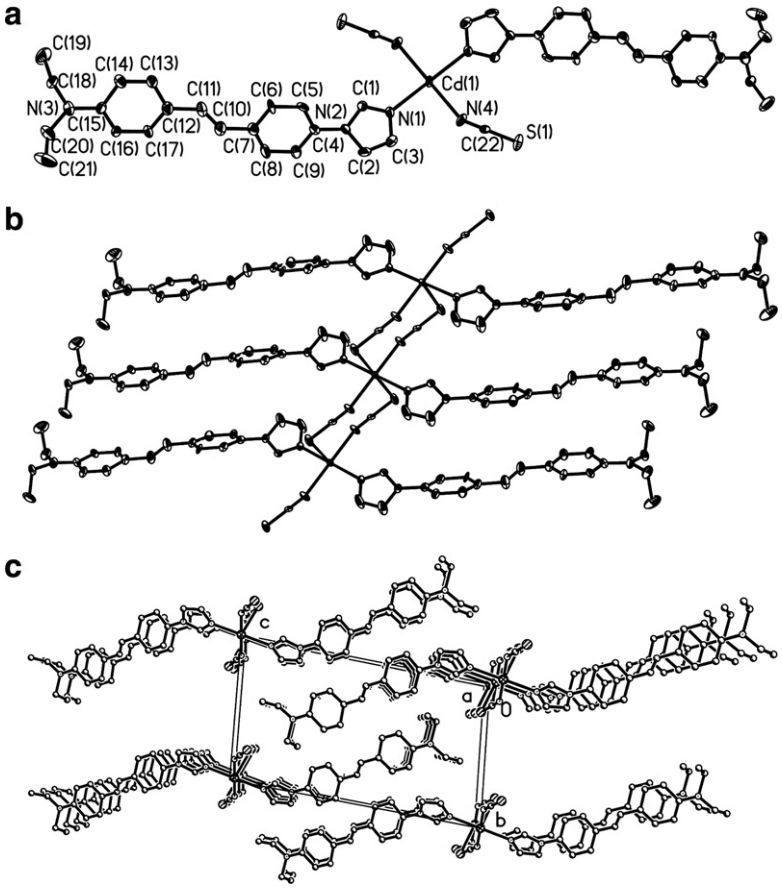

Fig. 1. (a) The structural unit of complex **1**. (b) One-dimensional zigzag chain fragment of complex **1**. (c) Perspective view of molecular packing of complex **1** (hydrogen atoms are omitted for clarity).

Adjacent Cd^{II} ions are linked by two bridging SCN^- ligands with the Cd···Cd distance of 5.785 Å, creating a one-dimensional polymeric chain structure along the *a*-axis comprising eight-membered $(N–C–S–Cd)_2$ rings, which have been well documented in Cd–NCS systems [24]. The molecular packing is shown in Fig. 1c.

In this complex, the molecular structure of L is almost planar, least-square plane calculations show that the dihedral angle between the two benzene rings is 8.3°, indicating they are nearly coplanar. The geometry around N(3) is planar. The bond lengths of N(3)–C(18) (1.57(2) Å) and N(3)–C(20) (1.41(2) Å) are longer than that of N(3)–C(15) (1.362(9) Å), indicating π conjugation from the lone pair of N(3) to the adjacent phenyl ring [25]. The C–C bond lengths are located between the normal C–C single-bond distance of 1.54 Å and double-bond distance of 1.34 Å, which also show that L has a highly delocalized π-electron system in the molecule.

3.3.2. Crystal structure of $[CdHg(SCN)_4L_2]_n$ (**2**)

To extend metal–thiocyanate coordination chains into higher dimensional architectures, Hg^{II} ions were added. By layering methanol solution of $Cd(NO_3)_2 \cdot 4H_2O$, $Hg(NO_3)_2 \cdot H_2O$ and NaSCN onto L in chloroform, yellow sheet-like crystals were obtained. The structure of complex **2** is two-dimensional hetero-metallic framework sheet. The coordination modes in the structure can be rationalized in terms of the hard–soft acid–base (HSAB) concept [24]. Hg^{II} ion, being a soft acid, is preferentially coordinated by the soft base (S) terminus of the SCN^- ligand [15,23]. As shown in Fig. 2a, each Cd^{II} ion is placed in a distorted octahedral environment, being coordinated by six N atoms, two N atoms from two L and other four N atoms from four NCS^- ligands. The Cd–N bond lengths are in the range between 2.23(1) and 2.44(2) Å. The Cd–N–C angles are range between 171(2)° and 141(1)°, respectively. Each Hg^{II} ion is in a distorted tetrahedral geometry, being coordinated by four thiocyanate sulfur atoms. The Hg–S bond lengths are in the range between 2.566(7) and 2.508(5) Å. The Hg–S–C angles are in the range between 101.1(6)° and 92.4(6)°. The SCN^- ligands are virtually linear with average S–C and N–C bond lengths of 1.64(2) and 1.16(2) Å, respectively, indicating a π-delocalization in the metal–thiocyanate frameworks.

Cd^{II} and Hg^{II} ions are bridged by NCS^- groups to form two-dimensional sheets in the *ac*-plane, containing

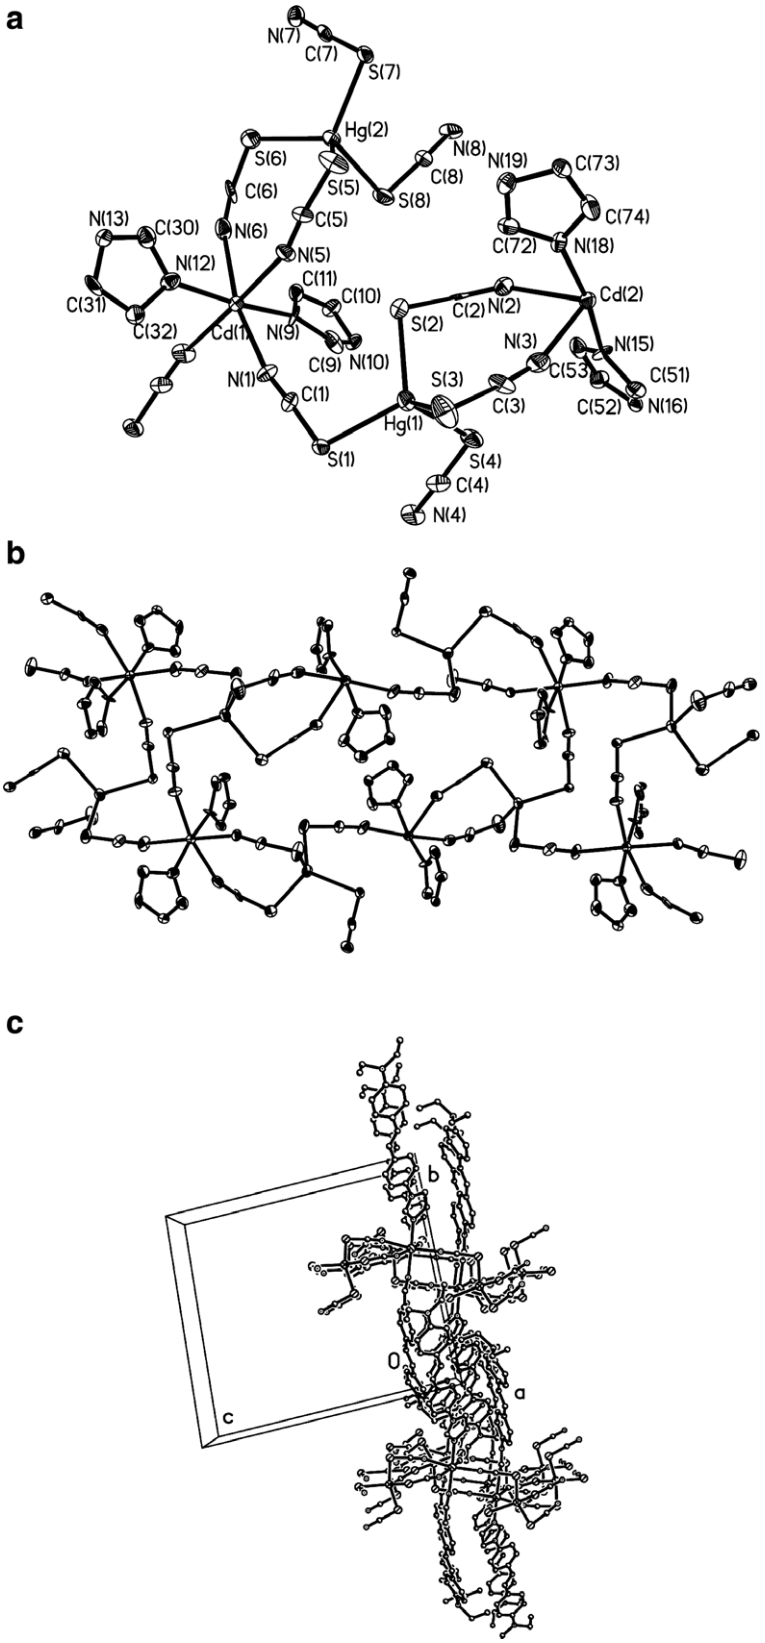

Fig. 2. (a) The coordination environment of Cd^{II} and Hg^{II} in complex **2**. (b) The polymeric sheet of complex **2** (hydrogen atoms and *trans*-4-(4-diethylamino styryl)phenyl are omitted for clarity). (c) Perspective view of molecular packing of complex **2** (hydrogen atoms are omitted for clarity).

16-membered $[Cd_2Hg_2(SCN)_4]$ and 32-membered $[Cd_4Hg_4(SCN)_8]$ cycles as subunits, which adopt pseudo-chair conformations, as shown in Fig. 2b. To our knowledge, such arrangements of the subunits have not been reported in Cd–SCN–Hg system. The molecular packing is shown in Fig. 2c.

The C–C bond lengths of the imidazole ligands in complex **2** are located between the normal C–C single-bond dis-

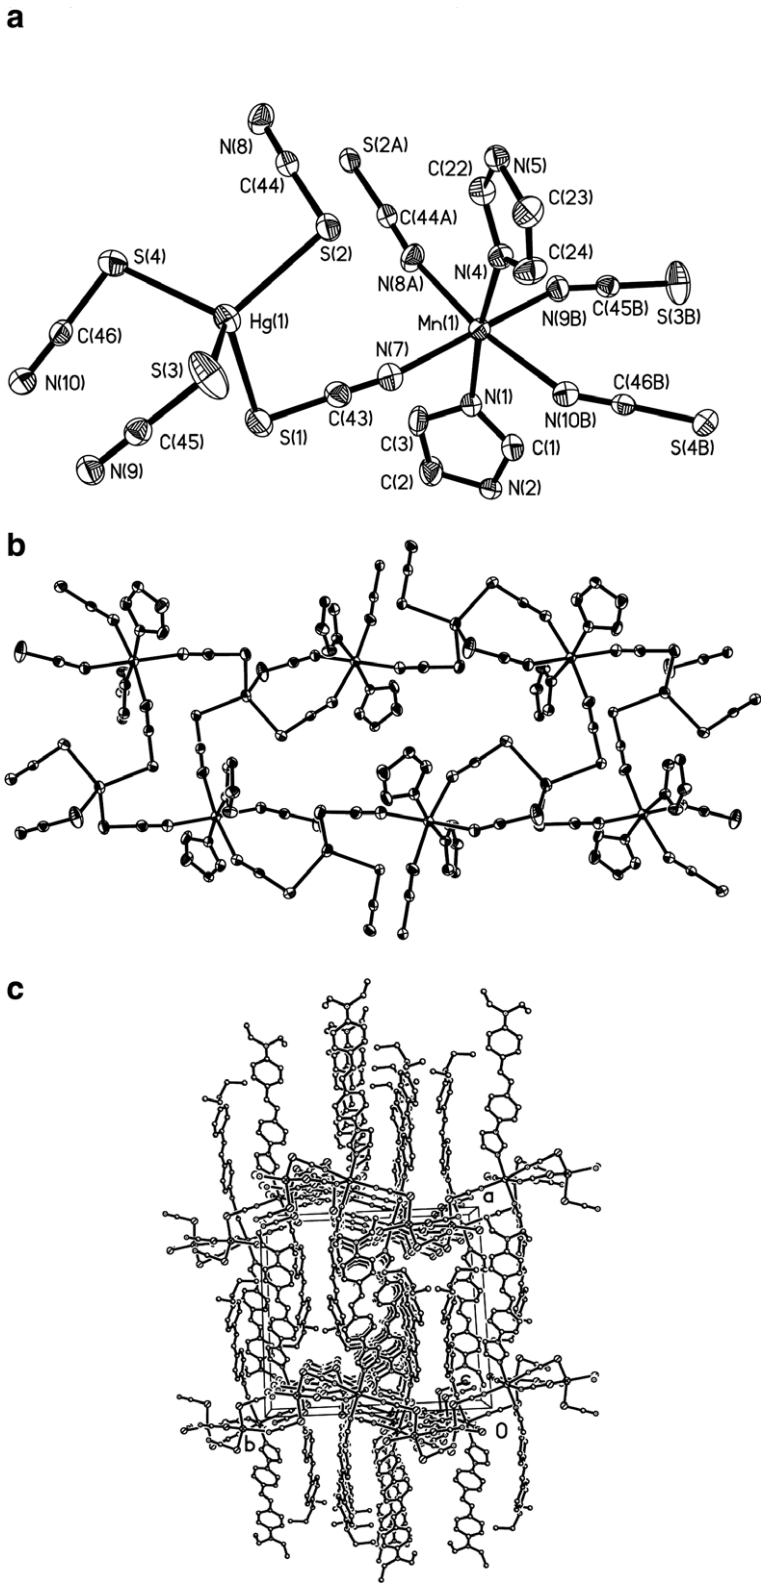

Fig. 3. (a) The coordination environment of Mn^{II} and Hg^{II} in complex **3**. (b) The 2D polymeric sheet of complex **3** (hydrogen atoms and *trans*-4-(4-diethylamino styryl)phenyl are omitted for clarity). (c) Perspective view of molecular packing of complex **3** (hydrogen atoms are omitted for clarity).

tance and double-bond distance, which show that they have delocalized π-electron systems.

3.3.3. Crystal structure of $[MnHg(SCN)_4L_2]_n$ (3)

The yellow rhomboid single crystals of complex **3** were obtained using the same synthetic procedure as for **2** except that Cd^{II} ions were replaced by Mn^{II} ions. The structure of **3** is two-dimensional hetero-metallic framework sheet. The coordination modes in the structure can be rationalized in terms of the hard–soft acid–base (HSAB) concept. Mn^{II}, being a metal in the first transition series, exhibits only N-coordination. As shown in Fig. 3a, each Mn^{II} ion is in a N_6 distorted octahedral geometry, being coordinated by two nitrogen atoms from two imidazole ligands and four thiocyanate nitrogen atoms. The Mn–N bond lengths are in the range between 2.218(8) and 2.301(9) Å. Each Hg^{II} ion is in a S_4 distorted tetrahedral geometry, being coordinated by four thiocyanate sulfur atoms. The Hg–S bond lengths are in the range between 2.492(3) and 2.557(3) Å. The dihedral angle between the two benzene rings of the two ligands (L) in the complex is 10.8° and 13.7°, respectively. As shown in Fig. 3b, the Mn^{II} and Hg^{II} ions are linked by bridging NCS^- groups to form two-dimensional sheets in the *bc*-plane, containing 16-membered $[Mn_2Hg_2(SCN)_4]$ and 32-membered $[Mn_4Hg_4(SCN)_8]$ cycles to adopt pseudo-chair conformation as subunits. The molecular packing is shown in Fig. 3c.

Comparing the three structures, we have observed the difference in dimensions and geometries with variation of the center metals. The thiocyanate links the center metals in various fashions to form different polymeric constructions. The conjugated systems of ligands (L) are also different in the three structures.

3.4. Photoluminescene

The photoluminescence properties of compounds have been studied in the solid state at room temperature. The measurements were carried out under the same experimental conditions and the results are shown in Fig. 4. The maxima emissions observed in complexes **1**, **2** and **3** are assigned to the $\pi \rightarrow \pi^*$ transitions of the L ligands due to their close resemblance to that of the free ligand [26]. Compared with that of the free ligand, the maximum wavelength of **1** is red-shifted by 2 nm from 475 to 477 nm upon excitation over the range of 300–450 nm, accompanied by a decreased luminescent intensity. However, the maxima emission wavelengths of **2** and **3** are red-shifted by 8 and 9 nm from 475 to 483 and 484 nm, respectively, relative to that of the free ligand, accompanied by the increased luminescent intensity. The results indicate that photoluminescence properties of complexes can been controlled by the frameworks and coordination of different center metals.

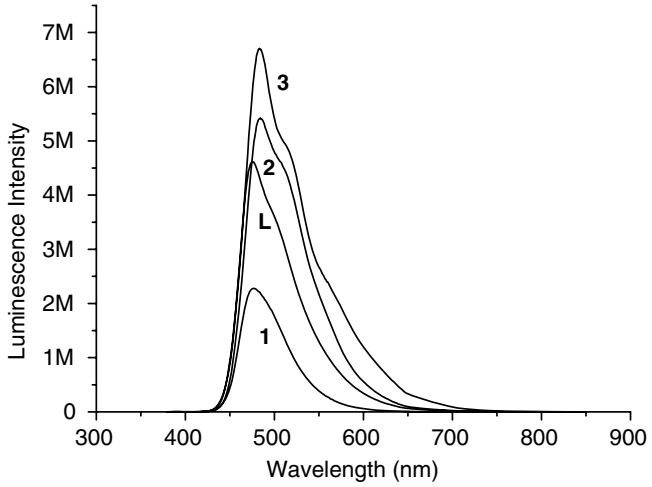

Fig. 4. Solid-state emission spectra of the compounds.

4. Conclusions

Three new coordination polymers containing functional rigid imidazole ligand with one- and two-dimensional frameworks have been obtained. The study shows that rational design metal-organic frameworks constructed from metals and functional π-conjugated ligands have prepared supramolecular polymers with both new structural architectures and unusual properties. By supramolecular self-assembly of different metals with the same ligands, different types of frameworks can be obtained. In $[Cd(SCN)_2L_2]_n$ (**1**), Cd^{II} ions are linked by bridging SCN^- ligands to form a one-dimensional polymeric chain structure. In $[CdHg(SCN)_4L_2]_n$ (**2**) and $[MnHg(SCN)_4L_2]_n$ (**3**), hetero-metals are linked by SCN^- ligands to form 2D coordination polymers, which show that the choice of metal ions is critical in determining the architecture of the complex. The title crystals posses better stabilities and do not show any decomposition and hygroscopic at room temperature. Their high thermal stabilities and excellent optical properties make them suitable to be used as potential optical materials. Further studies on related properties and synthesis of other functional rigid imidazole ligands with metals are under way.

5. Supplementary material

CCDC 257858, 255806 and 257859 contain the supplementary crystallographic data for **1**, **2** and **3**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

toluene, methanol and acetonitrile were distilled and used. The X-ray diffraction data were collected at 296 K with Mo Kα radiation ($\lambda = 0.71073$ Å) using a Bruker Nonius SMART CCD diffractometer equipped with graphite monochromator. The SMART software was used for data collection and also for indexing the reflections and determining the unit cell parameters; the collected data were integrated using SAINT software. The structures were solved by direct methods and refined by full-matrix least-squares calculations using SHELXTL software. All the non-H atoms were refined in the anisotropic approximation against F^2 of all reflections. The H-atoms, except those attached to N, O, and F were placed at their calculated positions and refined in the isotropic approximation; those attached to heteroatoms (N and O) were located in the difference Fourier maps, and refined with isotropic displacement coefficients. In case of complex **1a**, the included benzene molecule was solved in the isotropic approximation. Moreover, in the case of compound **2**, only one of the hydrogen atoms of the hydrogen bonded water molecule could be located in the difference Fourier (for crystal data see Table 1).

2.2. Synthesis of the complexes

2.2.1. Synthesis of $[Co_2(\mu\text{-}H_2O)(\mu\text{-}OBz)_2(OBz)_2(Py)_4]\cdot(C_6H_6)(BzOH)$ (**1a**)

In a typical experiment, benzoic acid (0.24gm, 2 mmol), sodium hydroxide (0.08gm, 2 mmol) and cobalt (II) chloride hexahydrate (0.238gm, 1 mmol) were finely ground in mortar and heated at 100 °C for 15 min, the pink colour turns blue. The solid mixture was cooled to room temperature transferred into a round bottom flask and benzene (20 ml) was added to it and the heterogeneous mixture was stirred at room temp for 5 min followed by the addition of pyridine (0.158 g, 2 mmol). The blue supernatant liquid turned pink

Magnetic moment: 6.54BM at 25 °C; UV–Vis: λ_{max} (MeOH) 519 nm, $\varepsilon = 40.10\ M^{-1}\ cm^{-1}$.

2.2.2. Synthesis of $[Co_2(\mu\text{-}H_2O)(\mu\text{-}OBz)_2(OBz)_2(Py)_4]\cdot 1.5(C_6H_6)$ (**1b**)

Sodium benzoate (0.29 g, 2 mmol) and cobalt (II) chloride hexahydrate (0.238 g, 1 mmol) were finely ground in the mortar and heated at 100 °C for 15 min, during which the pink colour became blue. The mixture was cooled to room temperature and transferred into a round bottom flask. To this mass, benzene (20 ml) was added and the heterogeneous mixture was stirred at room temp for 5 min followed by the addition of pyridine (0.158 g, 2 mmol). The blue supernatant liquid turned pink in colour. The residue was filtered off and the pink filtrate was left undisturbed. Pink crystals were obtained after 3 days that were collected and dried in air. Yield: 23%. *Anal.* Calc. for $C_{57}H_{51}Co_2N_4O_9$: C, 64.90; H, 4.83. Found: C, 64.98, H, 4.94%. IR (KBr, cm^{-1}): 3446(b), 3066(bs), 2361(b), 1627(s), 1601(s), 1573(s), 1537(m), 1485(m), 1393(s), 1068(m), 1038(m), 812(ms), 757(ms), 716(s), 701(s), 677(m). Magnetic moment: 6.52 BM at 25 °C; UV–Vis: λ_{max}(MeOH) 519 nm, $\varepsilon = 40.32\ M^{-1}\ cm^{-1}$.

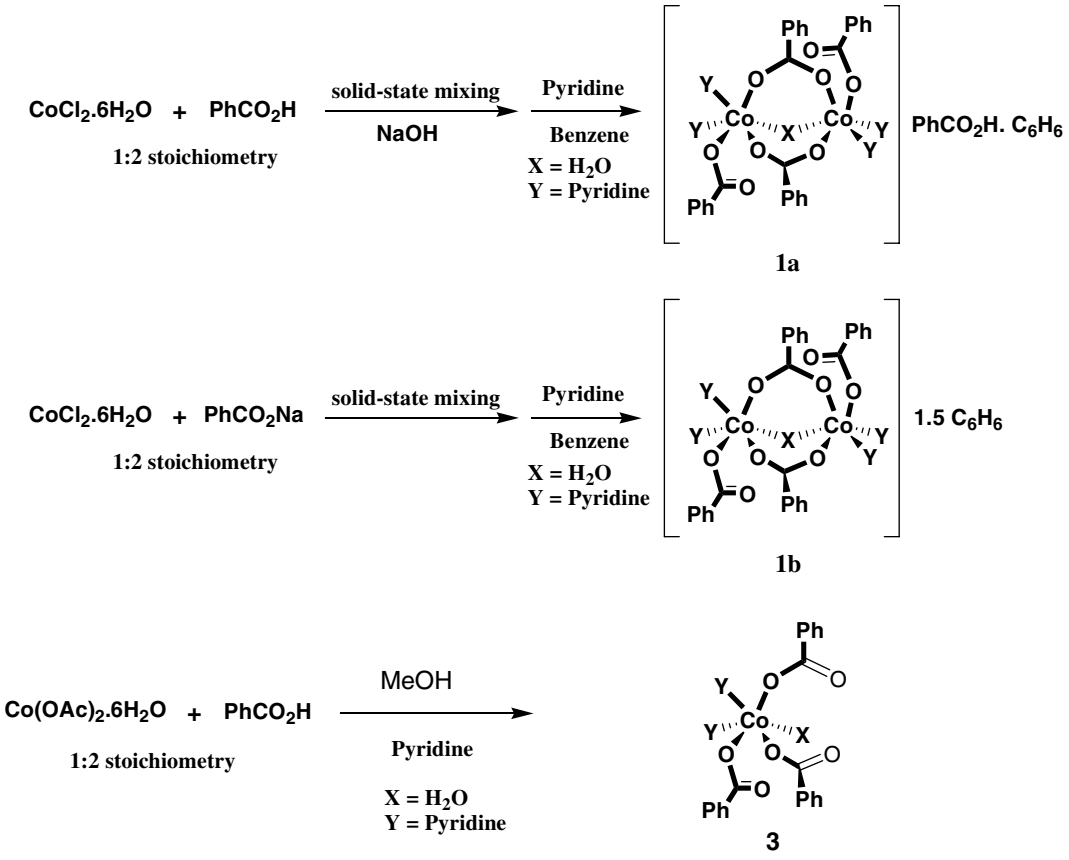
2.2.3. Compound $[Co_2(\mu\text{-}H_2O)(\mu\text{-}p\text{-}Cl\text{-}OBz)_2(p\text{-}Cl\text{-}OBz)_2(Py)_4]$ (**1c**) (where p-Cl-OBz = para-chlorobenzoate)

It was prepared in a similar procedure as adopted for **1a**. Yield 39%. *Anal.* Calc. for $C_{48}H_{38}Cl_4Co_2N_4O_9$: C, 53.58; H, 3.53. Found: C, 54.52; H, 3.50%. IR (KBr, cm^{-1}): 3069(bs), 1608(s), 1561(s), 1486(ms), 1446(ms), 1403(s), 1219(m), 1169(m), 1091(ms), 1014(ms), 856(m), 772(s), 699(s), 537(s). Magnetic moment: 5.93 BM at 25 °C; UV–Vis: λ_{max}(MeOH) 518 nm, $\varepsilon = 37.06\ M^{-1}\ cm^{-1}$.

2.2.4. Synthesis of complex $Co_4O_4(Py)_4(O_2CPh)_4\cdot 4CH_3CN\cdot 4H_2O$ (**2**)

Complex **1a** (0.114 g, 0.1 mmol) was dissolved in acetonitrile (10 ml) and H_2O_2 (0.4 ml; 30% v/v) was added dropwise. On addition of hydrogen peroxide the pink solution became dark green. The solution was filtered to remove undissolved material (if any) and the filtrate was left undisturbed for 2 days. Dark green crystals were obtained after 2 days, which were found suitable for single crystal X-ray diffraction studies. Yield: 52%; IR (KBr, cm^{-1}): 3412(b), 3060(b), 2368(ms), 1602(bs), 1527(s), 1448(ms), 1384(s), 1212(ms), 1070(ms), 1026(ms), 757(ms), 718(s), 691(s). ^1H NMR ($CDCl_3$, 400 MHz) 8.73 (8H, d, $J = 6.0$ Hz), 8.02 (8H, d, $J = 8.0$ Hz), 7.46 (4H, t, $J = 7.2$ Hz), 7.32 (4H, t, $J = 7.2$ Hz), 7.22 (8H, m), 6.97 (8H, t, $J = 7.2$ Hz).

2.2.5. Synthesis of $[Co(H_2O)(Py)_2(OBz)_2]$ (**3**)



To a well-stirred solution of benzoic acid (0.24 g, 2 mmol) in methanol (20 ml) cobalt (II) acetate tetrahydrate (0.25 g, 1 mmol) was added and stirred for 12 h at room temperature. After that pyridine (0.158 g, 2 mmol) was added and at room temperature for half an hour. On standing pink crystals were precipitated after 6 days. The crystals were dried in air. Crystalline yield: 42% (based on Co). *Anal.* Calc. for $C_{24}H_{22}N_2O_5Co$: C, 60.37; H, 4.61. Found: C, 60.29; H, 4.62%. 3. Result and discussion

We have found that the reaction of cobalt (II) chloride hexahydrate, benzoic acid and sodium hydroxide in the solid-state (Scheme 1) followed by addition of pyridine (in 1:2:2 stoichiometry) gave the cobalt (II) benzoate complex, $[Co_2(\mu\text{-}H_2O)(\mu\text{-}OBz)_2(OBz)_2(Py)_4]\cdot(C_6H_6)(BzOH)$ (**1a**). The complex is soluble in chloroform, benzene or toluene and could subsequently be crystallised from benzene as pink plates in the $P2_1/c$ space group.

Crystal structure of **1a** shows this complex to be a binuclear cobalt (II) assembly (Fig. 2), where each of the cobalt centres have octahedral geometries, such that Co(1)···Co(2) distance is 3.597(3) Å. The binuclear structure of the cobalt (II) complex is stabilised by two μ-benzoate molecules, which are present in the bridging mode along with a bridging water molecule. In this regard it may be pointed out that these binuclear cobalt complexes having two bridging carboxylate groups and the aqua bridge have close structural similarities to the biological relevant system aminopetidase [3a]. Each cobalt (II) centre in complex **1a** is coordinated to two pyridine molecules and a monodentate benzoate group thereby completing the 6-coordination environment about the metal ion.

The monodentate benzoate groups are intramolecularly hydrogen bonded to the water molecule through O9–H···O8 (2.583 Å, 169.4°) and O9–H···O6 (2.546 Å, 163.9°) interactions. The Co1–$O9_{aqua}$ and Co2–$O9_{aqua}$ bond distances in this complex are 2.135(3) and 2.129(3) Å while the corresponding the Co1–O_{aqua}–Co2 bond angle is 115.03(12)°. The important bond distances and bond angles for this complex are given in Table 2. Solid state FT-IR spectra of the complex **1a** shows a sharp absorption at 3063 cm^{-1} due to O–H stretching and is an indication of the strong hydrogen bonding interactions involving the bridging aqua ligand. In methanol, the

Scheme 1.

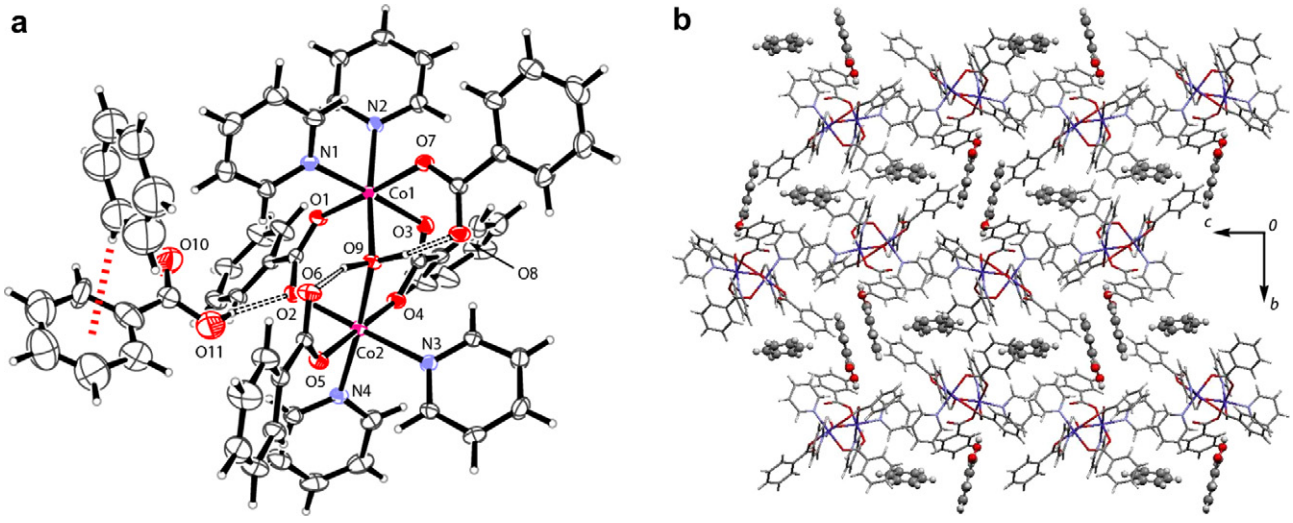

Fig. 2. (a) Crystal structure of **1a** (thermal ellipsoids drawn to 30% probability) and (b) inclusion of benzoic acid and benzene molecules.

UV–Vis spectrum of **1a** shows a weak absorption band at 512 nm that is assigned to the $^4T_1(F) \rightarrow {}^4A_2(F)$ transition [3a]. The absorption spectra have a shoulder at 414 nm, which is attributed to the $^4T_1(F) \rightarrow {}^4T_1(P)$.

This aqua-bridged binuclear cobalt (II) benzoate complex **1a** leads to the inclusion of free benzoic acid molecules as well as benzene molecules in the crystal lattice via self-assembly. This is because *in situ* preparation of sodium benzoate by reacting benzoic acid and sodium hydroxide in the solid phase possibly leaves unreacted neutral benzoic acid molecules. These benzoic acid molecules readily dissolve in benzene and are held in the lattice through intermolecular O10–H···O2 (2.722 Å, 164.9°) hydrogen bonding interactions to one of the bridging benzoate ligand of the complex. Weak aromatic C–H···π interactions ($d_C \cdots \pi$ 3.87 Å) involving the C60–H of the benzene

molecule as donor and the aromatic ring of the benzoic acid molecule as acceptor stabilises the solid-state assembly of **1a**.

Addition of pyridine to a mixture of cobalt (II) chloride hexahydrate and preformed sodium benzoate in the solid phase in 2:1:2 stoichiometries gave a pink solid, which was dissolved in benzene. The benzene soluble component was found to be the corresponding aqua-bridged binuclear complex, $[Co_2(\mu\text{-}H_2O)(\mu\text{-}OBz)_2(OBz)_2(Py)_4]\cdot 1.5C_6H_6$. Subsequent crystallisation of the complex from benzene gave the benzene inclusion compound as shown in Fig. 3, which also crystallises in $P2_1/c$ space group.

Crystal structure of the complex **1b** shows that the two cobalt (II) centres are bridged by one water molecule and two benzoates. The coordination environment of **1b** is similar to that of complex **1a** wherein each cobalt (II) centre is coordinated to a monodentate benzoate and two N-donor pyridine ligands. The bridging aqua group in **1b** is hydrogen bonded to the carboxyl group of the monodentate benzoate ligand through intramolecular O9–H9A⋯O8 (2.571 Å, 172.2°) and O9–H9B⋯O8 (2.579 Å, 166.9°) interactions as shown in Fig. 3. The Co1–$O9_{aqua}$ and Co2–$O9_{aqua}$ bond distances are 2.139(2) and 2.143(2) Å while the corresponding Co1–$O9_{aqua}$–Co2 bond angle is 111.87(11)°. Although the Co1–$O9_{aqua}$ and Co2–$O9_{aqua}$ bond distances in **1b** are only slightly longer than **1a**, (∼0.05 Å) the Co1–$O9_{aqua}$–Co2 bond angle is smaller by ∼4°. Important bond angles and bond distances for structure of complex **1b** is shown in Table 3. The observed parameters of the Co–O_{aqua}–Co motif in **1a** and **1b** are comparable with structural analogs reported elsewhere [7d,7e,7f,7g,7h].

It is noteworthy that solid state self-assembly of the binuclear complex **1a** leads to the inclusion of both benzoic acid and benzene molecules in the lattice while in **1b** inclusion of benzene is observed. The absence of benzoic acid in the lattice of **1b** may be rationalised by the fact that sodium benzoate, which has poor solubility in benzene, was used as the benzoate source. In this case, the self-assembly of binuclear cobalt (II) benzoate complex leads to the inclusion of two benzene molecules in the crystal lattice that are stabilised by weak intermolecular C–H···π interactions. The magnetic moments of complexes **1a** and **1b** at room temperature are found to be 6.54 and 6.52BM, respectively, which corresponds to octahedral geometry about the cobalt (II) centre and the presence of orbital contribution to the spin-only value for a Co^{2+} ion [8].

Mild oxidation of **1a** with H_2O_2 in acetonitrile under neutral conditions gave dark green complex **2**, which could be crystallised from acetonitrile. Crystallographic studies of the **2** shows the structure is derived from a composition $Co_4O_4(Py)_4(O_2CPh)_4 \cdot 4CH_3CN \cdot 4H_2O$ as shown in Fig. 5a. The complex has a core comprising of Co_4O_4 cluster in which the Co···Co distances are 2.7093(5), 2.7111(5) and 2.8191(5) Å as shown in Fig. 5b. The corresponding Co–O bond distances are found to be 1.9539(14), 1.9600(14) and 1.8661(13) Å, which indicates that the Co_4O_4 cluster has a cubic geometry. Each of the cobalt centres is attached to a pyridine ligand and μ-benzoate group bridges each two alternate cobalt centres. The tetranuclear cobalt (III)–benzoate complex **2** are held in the lattice through intermolecular O4–H···O3 (2.756 Å, 175.1°) hydrogen bonding interactions involving the included water molecule and the bridging oxo-groups of the Co_4O_4 units of **2**. This results in the formation three-dimensional networks in which the acetonitrile molecules are included as guests in the lattice. The complex is diamagnetic and shows broad absorptions at 639 nm in the visible spectrum, which is assigned to $^1A_1 \rightarrow {}^1T_1$ transition. It may be mentioned that the tetrameric cobalt (III) complexes are reported in the literature [9] and have interesting catalytic oxidative properties [9d].

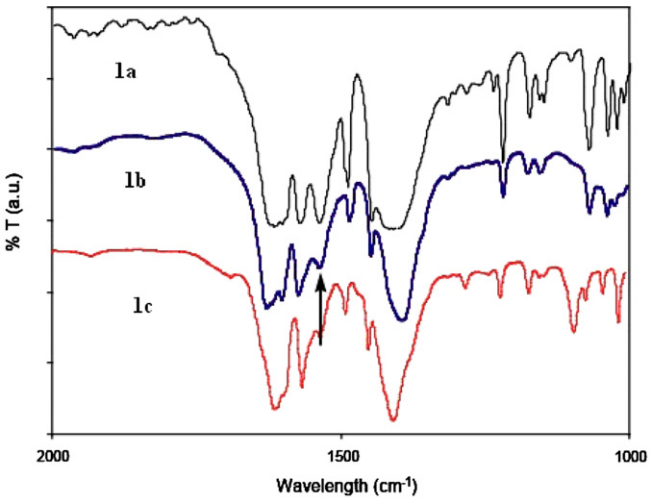

Fig. 4. FT-IR spectra of **1a**, **1b** and **1c** (solid-state) showing the absorption bands (1538 cm^{-1}) due to inclusion of aromatic guest molecules in the lattice.

To understand the effect of substituents on the benzoic acid molecule on the formation of binuclear cobalt (II) complexes, similar reactions were performed with *o*-nitrobenzoic acid and *p*-chlorobenzoic acid.

The complex $[Co_2(\mu\text{-}H_2O)(\mu\text{-}p\text{-Cl–OBz})_2(p\text{-Cl–OBz})_2(Py)_4]$ (**1c**) was prepared by reacting cobalt (II) chloride hexahydrate with *p*-chlorobenzoic acid in the presence of sodium hydroxide, and subsequent addition of pyridine (Fig. 6). The complex obtained was a pink solid, which could be crystallised from toluene. It may be mentioned that although the complex dissolves in benzene, diffraction quality crystals containing benzene could not be isolated. The structure of this aqua-bridged binuclear complex, **1c** is similar to **1a**–**b**, wherein, the two cobalt (II) centres are bridged by two bidentate benzoate groups and an aqua bridge. There is slight variation in the Co1–O_{aqua}–Co2

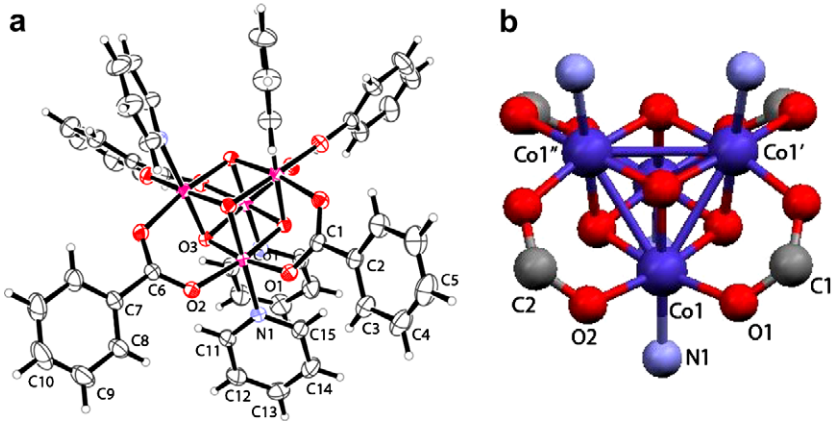

Fig. 5. (a) Crystal structure of **2** (thermal ellipsoids drawn to 30% probability) and (b) the Co_4O_4 core, where Co1···Co1′ 2.7093(5) Å, Co1···Co1″ 2.7111(5) Å, and Co1′···Co1″ 2.8191(5) Å. Solvent molecules are not shown for clarity. Symmetry equivalence $^{\#1}-x+1/4, -y+1/4, z$; $^{\#2}x, -y+1/4, -z+1/4$; $^{\#3}-x+1/4, y, -z+1/4$.

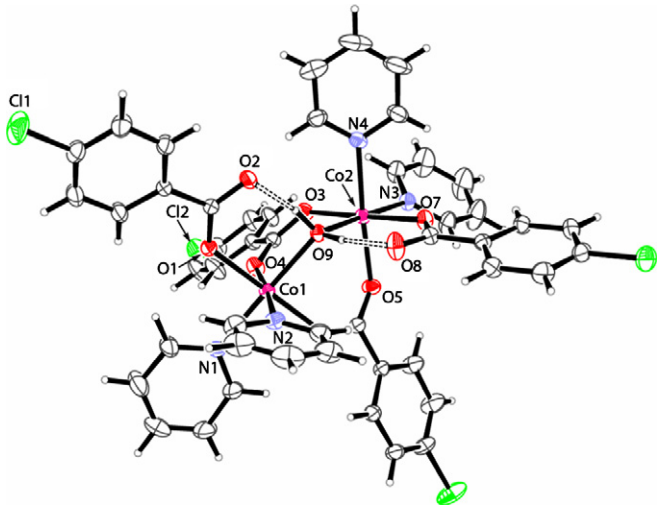

Fig. 6. Crystal structure of **1c** (thermal ellipsoids drawn to 30% probability).

separation due to electronic effect (see Table 4) and due to the different environment created by guest molecule but the observed distances are within the expected bond distances of systems that are reported [5a,7e]. Aqua-bridged Co–O–Co frame having pyridine as axial ligands with trifluoroacetate and stearate are reported in the literature and have similar co-ordination features to the one reported in this study [7o,7p].

Absence of aromatic guest molecules in the crystal lattice is also apparent in the solid state IR spectra as shown in Fig. 4. The presence of aromatic guests such as benzoic acid and benzene in the lattice of **1a** and **1b** give rise to a strong absorption band at 1538 cm^{-1}. This absorption band is absent in the solid state FT-IR spectrum of **1c**.

The bond distances and bond angles for the Co1–O_{aqua}–Co2 motif in the complexes, **1a**–**1c**, shows slight variation

in the distances and angles (Table 5). This happens due to subtle electronic factors, while the supramolecular assembly as in the case of **1a** and **1b** controls the inclusion properties.

When similar reaction of cobalt (II) acetate tetrahydrate in methanolic solution were carried out in the presence of benzoic acid and pyridine a mononuclear cobalt complex $[Co(H_2O)(Py)_2(OBz)_2]$ (**3**) is formed. The crystal structure of the complex is shown in Fig. 7. The compound remains as dimeric units through hydrogen bonding interaction between the O–H···O interaction between the C=O of carboxylate with a water molecule. The magnetic moment and the visible spectral features support the structure.

4. Conclusions

We have described a solid-state synthetic route to a few binuclear cobalt (II) complexes, and method of synthesis leads to either acid inclusion or inclusion of aromatic solvent. The aqua bridge in these binuclear structures is stabilised by intramolecular O–H···O hydrogen bonding interactions between the bridging aqua group and the monodentate benzoate/substituted benzoate groups. The solution state synthesis of similar complexes led to the formation of mononuclear cobalt (II) complex.

5. Supplementary material

CCDC 608661, 608662, 608663, 608664 and 620811 contain the supplementary crystallographic data for **1a**, **1b**, **1c**, **2** and **3**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

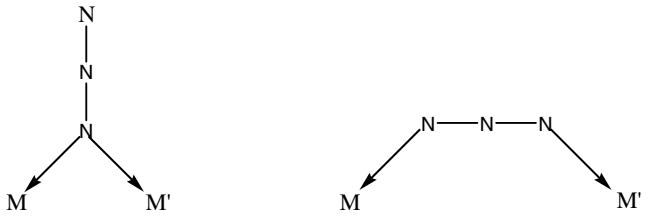

Fig. 1. The different kind of bridging mode of the azide ligand.

The main rationale for such studies stems from the understanding of the magneto-structural correlations in molecular systems and developing new functional molecule-based materials [8].

We report here the synthesis of an asymmetric μ-1,3-EE doubly azido bridged copper(II) complex incorporating a new tridentate Schiff base ligand. It is noteworthy that only a very few cases of the end-to-end azido bridged polynuclear copper(II) complexes reported so far have shown ferromagnetic coupling. The complex has been completely characterized with micro-analytical techniques, FT-IR, UV–Vis, EPR spectra and structure with single crystal X-ray diffraction analysis. Cryomagnetic susceptibility measurement (2–300 K) shows a ferromagnetic interaction with $J = 13.6\ cm^{-1}$.

2. Experimental

2.1. Materials

Analytical reagent grade $Cu(ClO_4)_2 \cdot 6H_2O$, 2-dimethylaminoethylamine and 1,1,1-trifluoropentane-2,5-dione were purchased from Aldrich Chemical Co. and used as received without further purification. All the solvents used were of reagent grade and super dried before use.

2.2. Syntheses

Caution! Perchlorate salts of metal complexes in the presence of organic ligands are potentially explosive. Though no problem has been encountered during the synthesis of the reported materials, they should be prepared in small quantities and must be handled with proper care.

2.2.1. Synthesis of the Schiff base ligand LH

The ligand LH was synthesized by refluxing a mixture of a 25 ml dry methanolic solution of 3 mmol 1,1,1-trifluoropentane-2,5-dione with a 25 ml methanolic solution of 3 mmol 2-dimethylaminoethylamine for 50 min. The resulting yellow solution containing the Schiff base ligand (LH) was cooled and used without further purification.

2.2.2. Synthesis of $[CuL(\mu_{1,3}\text{-}N_3)]_2$ (1)

To a 30 ml, 1.11 g stirred methanolic solution of $Cu(ClO_4)_2 \cdot 6H_2O$, the liquid Schiff base solution was slowly added, followed by a sodium azide (5 mmol) solution prepared with a minimum volume of water in methanol. The resulting mixture was stirred for an additional 35 min, and the final filtrate was kept undisturbed at room temperature. Deep green block shaped crystals of **1** were obtained after three days. Suitable X-ray diffraction quality single crystals were mechanically isolated from the bulk materials. Yield: 86% with respect to the metal substrate. *Anal.* Calc. for $C_{18}H_{28}Cu_2F_6N_{10}O_2$: C, 32.88; H, 4.29; N, 21.30; Cu, 19.33. Found: C, 32.82; H, 4.25; N, 21.20; Cu, 19.53%.

2.3. Physical measurements

Elemental analyses (carbon, hydrogen and nitrogen) were performed on a Perkin–Elmer 2400 CHN Elemental Analyser. Copper has been estimated quantitatively by a standard iodometric procedure. The Fourier Transform infrared spectrum was recorded on a Perkin–Elmer RX I FT-IR spectrophotometer in the range 4000–400 cm^{-1} as a solid KBr disc and the electronic spectrum on a Perkin–Elmer $\lambda - 40$ UV–Vis spectrometer at 300 K in 1 cm quartz cuvettes using HPLC grade acetonitrile as the solvent. Magnetic susceptibility measurements for **1** were carried out on polycrystalline samples at the Servei de Magnetoquímica of the Universitat de Barcelona, with a Quantum Design SQUID MPMS-XL susceptometer apparatus working in the range 2–300 K under a magnetic field of approximately 500G (2–30 K) and 1000 G (35–300 K). Diamagnetic corrections were estimated from Pascal's tables. The EPR spectrum has been recorded on an X-band Bruker Spectrometer (ESR 300E), working with an Oxford helium liquid cryostat for variable temperature.

2.4. X-ray crystallography

A good quality dark green air stable single crystal with dimensions $0.01 \times 0.02 \times 0.03$ mm was mounted on a Nonius Kappa CCD Diffractometer equipped with a graphite monochromated focused X-ray tube bearing a molybdenum target ($\lambda_{MoK\alpha} = 0.71069$ Å). Intensity data were collected at 293 K. A total of 5346 reflections (unique reflections, 3060; $R_{int} = 0.03$) were measured and 2097 data were observed [$I/\sigma(I) > 3$] for **1**. The crystal showed almost no decomposition under X-ray exposure during data collection. Preliminary orientation matrices and unit cell parameters were obtained from the peaks of the first 10 frames and refined using the whole data set. Frames were integrated and corrected for Lorentz and polarization effects using DENZO. The scaling as well as the global refinement of the crystal parameters was performed by SCALEPACK. Reflections that were partly measured on previous and following frames were used to scale the frames on each. Whole data processing was performed using the Kappa CCD analysis software [9a]. The lattice constants were refined by least-square refinement using 2646 reflections ($1.00° < \theta < 27.48°$). No absorption correction was applied

[b] $R = \sum(|F_o - F_c|)/\sum|F_o|$.
[c] $Rw = \{\sum[w(|F_o - F_c|)^2]/\sum[w|F_o|^2]\}^{1/2}$.

to the data sets. According to the observed systematic extinctions, the structure has been solved in the monoclinic system with the H–M space group $P2_1/n$. The structure has been solved by direct methods with the SIR 97 program [9b], combined with Fourier difference syntheses and refined against F using reflections with [$I/\sigma(I) > 3$] using the CRYSTALS program [9c]. All non-hydrogen atoms were successfully refined with anisotropic thermal parameters. The hydrogen atoms were placed geometrically and refined with isotropic thermal parameters. All calculations and graphical works have been done using WinGX [9d], ORTEP [9e] and PLATON [9f] programs. Selected crystallographic data, experimental conditions and some features of the structural refinements are summarized in Table 1.

3. Results and discussion

3.1. Infrared spectrum

The solid state Fourier Transform infrared spectrum of the complex was recorded on a FT-IR spectrophotometer for the range 4000–400 cm^{-1} and is fully consistent with the structure confirmed from single crystal X-ray diffraction studies. The sample was studied as powder dispersed in a KBr pellet. The metal bonded ν_{str}(CH=N) frequency was observed as intense bands at 1597 and 1625 cm^{-1} [10a]. Sharp transitions for the ν_{str}(C–O) frequency appeared at 1275 and 1285 cm^{-1} [10b]. Schiff base ligand coordination to the Cu(II) metal center is substantiated by two bands at 425 and 400 cm^{-1} corresponding to ν_{str}(Cu–N) and ν_{str}(Cu–O) respectively [10c]. $\nu_{sym}(CF_3)$ and $\nu_{asym}(CF_3)$ frequencies were supported by well resolved peaks at 1140 and 1200 cm^{-1} respectively [10a]. The broad bands observed in the range 3520 and 1600 cm^{-1} are attributable to the ν_{str}(O–H) and δ(O–H) frequencies for the adhered water. The IR spectrum of **1** shows the most intense absorption band at 2070 cm^{-1} corresponding to the N_3^- ligand. The $\delta(N_3^-)$ vibration is splitted (635–610 cm^{-1}), indicating the existence of a bridged group in it [10a], though it cannot be used to ascertain the exact nature of the bridging mode of the azide anion.

3.2. UV–Vis spectrum

Although the electronic spectra of copper(II) complexes with multidentate Schiff base ligands are not in general good indicators of geometry, they can help to support it. The electronic spectrum of complex **1** in acetonitrile solution shows two strong absorption bands in the region 211 and 275 nm. These bands are clearly charge transfer in origin [11a]. The bands in the region 460–330 nm are assigned to the n–π^* transition of the azomethine group. In the spectrum of the complex, the bands of the azomethine chromophore n–π^* transition are shifted to lower frequencies indicating that the imine nitrogen atom is involved in coordination to the metal ion [11a]. The UV absorption band observed at 380 nm can be attributed to the ligand to Cu(II) charge transfer transition (LMCT) [11b,11c]. The visible spectrum of the azido complex displays a single broad band between 530 and 630 nm. These spectral features are consistent with the five-coordinate geometry of the Cu(II) complex. In general typical Cu(II) complexes of SP or distorted SP geometries exhibit a band in the range 550–660 nm, whereas the corresponding TBP complexes usually show a maximum at $\lambda > 800$ nm with a higher energy shoulder [12]. This indicates that the solution spectrum of the complex ion is adequately explained by a d–d transition for the Cu(II) ion in a distorted SP geometry where the absorption maximum band observed in the visible region results from a $^2E \rightarrow {}^2B_1$ transition.

3.3. X-ray crystal structure of $[CuL(\mu_{1,3}\text{-}N_3)]_2$ (**1**)

The crystal structure of complex **1** has been determined. The most relevant features of the structure with the asymmetric unit and symmetry related fragments, has been shown as an ORTEP diagram with atom numbering scheme in Fig. 2. A few selected bonding parameters also have been included in Table 2.

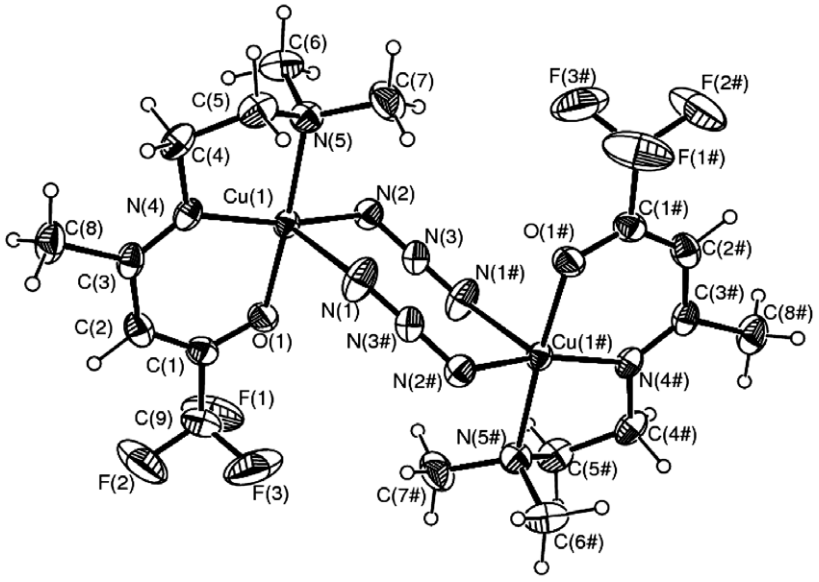

Fig. 2. ORTEP view of the dimeric unit (non-hydrogen atoms shown with 40% ellipsoid probability).

Table 2
Selected bond lengths and bond angles of **1**

Bond lengths	(Å)	Bond angles	(°)
Cu(1)–O(1)	1.924(2)	O(1)–Cu(1)–N(1)	94.21(14)
Cu(1)–N(1)	2.394(3)	O(1)–Cu(1)–N(2)	89.08(12)
Cu(1)–N(2)	1.992(3)	O(1)–Cu(1)–N(4)	93.73(12)
Cu(1)–N(4)	1.958(3)	O(1)–Cu(1)–N(5)	174.89(12)
Cu(1)–N(5)	2.040(3)	N(1)–Cu(1)–N(2)	97.22(12)
		N(1)–Cu(1)–N(4)	98.65(13)
		N(1)–Cu(1)–N(5)	90.87(14)
		N(4)–Cu(1)–N(5)	85.01(15)
		N(3)–N(1)–Cu(1)	129.6(3)
		N(3)–N(2)–Cu(1)	118.2(2)
		N(2)–N(3)–N(1)	176.5(3)

The structure determination reveals that the complex is a centrosymmetric dimer in which the metal atoms are five-coordinated, being bonded to three coordinating donor sites from the corresponding tridentate Schiff base ligand, *L*, and two bridging azide anions as shown in Fig. 2. As can be seen, each azide ion bridges the metal centers in an end-to-end (EE) fashion making an intra-metal Cu–Cu distance of 5.096(4) Å within the dimeric part, with an inversion center placed midway between them. It is the most striking structural feature of the reported dimer due to the fact that despite being an EE-doubly azido bridged copper(II) complex it shows a significant ferromagnetic interaction, which is not very common. The Cu atoms [Cu(1) and Cu(2)] adopt a distorted square pyramidal geometry with a CuN_4O chromophore furnished by three ligating atoms N(4), N(5) and O(1) of the corresponding tridentate Schiff base ligand and a nitrogen atom, N(1), forming the basal plane [Cu(1)–N(4) = 1.958(3), Cu(1)–N(5) = 2.040(3), Cu(1)–O(1) = 1.924(2), Cu(1)–N(1) = 2.394(3) Å] and the elongated apical position is occupied by the nitrogen atom N(2) from the other centrosymmetrically related EE azide bridge [Cu(1)–N(2) = 1.992(3) Å]. The longer Cu(1)–N(2) bond length is clearly associated with the pseudo Jahn-Teller effect on the Cu(II) ion [13,14]. The Cu atom is displaced by an amount of 0.181(2) Å from the basal plane towards the apical atom N(2). The distortions of the coordination polyhedron from square pyramidal to trigonal bipyramidal is expressed as τ, an index of the degree of trigonality; τ is defined as $(\beta - \alpha)/60$ where β and α are the two *trans*-basal angles. For a perfectly square pyramidal geometry the value is equal to 0, while it becomes 1 for a perfect trigonal bipyramidal geometry. The τ value calculated for the reported complex is 0.19, which supports well the geometry of the Cu atoms in the dimeric entity. In the diazo bridged Cu(II) dimeric complex two adjacent Cu centers are interconnected via two azide anions in an end-to-end bridging fashion. The EE bridging azide is quasilinear with a N–N–N bond angle of 176.52° and the N–N bond lengths in the azide anion are 1.154(5) and 1.185(4) Å with Cu–N_{axial}–N, 129.6(3)° and Cu–N_{eq}–N, 118.2(2)° respectively. The μ-(1,3)-azido ligand is almost linear [N–N–N angle: 176.5(3)°]. The EE azide bridges form a closed and puckered eight membered ring in very stable chair form incorporating Cu(1)–N(1)–N(3)–N(2)–Cu(1*)–N(1*)–N(3*)–N(2*) atoms. The packing diagram of the complex shows no significant intramolecular covalent or hydrogen bonding interactions present in the complex.

3.4. Magneto-structural correlation

End-on (EO) dibridged azido complexes are well known in the literature and magneto-structural correlations have determined that the coupling is ferromagnetic for bridging Cu–N–Cu angles <108° [15]. In end-to-end (EE) dibridged azido complexes with Cu(II) exhibiting its common

elongated octahedral or square pyramidal coordination geometry in its 6 or 5 coordination environment, the EE linkage can occur via two different routes: in the equatorial–equatorial configuration (*equatorial–equatorial*), where the azido group coordinates via the equatorial bonds to both the copper atoms, strong antiferromagnetic coupling can occur since the σ orbitals on the azido group couple directly with the unpaired electron density in the $d_{x^2-y^2}$ orbitals [16]. In contrast, if the bridging conformation involves an equatorial linkage to one of the Cu ions and an axial linkage to the second (*equatorial–axial*), the coupling is expected to be a weak one, since there is a little overlap of the azido σ and π orbitals with the magnetic $d_{x^2-y^2}$ orbital via the axial interaction.

The magnetic behaviour of the complex is shown in Fig. 3, as a $\chi_M T$ versus T plot. At room temperature the $\chi_M T$ value is 0.860 cm^3 K mol^{-1}, which is close to the expected value for two uncoupled copper(II) ions, with $g = 2.12$. $\chi_M T$ increases slightly with lowering of temperature and reaches a maximum of 1.034 cm^3 K mol^{-1} at *ca.* 9.5 K. Below this temperature $\chi_M T$ decreases to a value of 0.851 cm^3 K mol^{-1} at 2 K. The shape of this curve indicates dominant ferromagnetic coupling until 9.5 K, which results from the interaction of the copper(II) ions through the double end-to-end azide bridge. The decrease in $\chi_M T$ observed at low temperature may be due to an intradimer antiferromagnetic exchange and/or the presence of a zero field splitting of the $S = 1$ ground state. To determine the exchange parameters *via* the double (μ-1,3) azide bridge, $\chi_M T$ was fit to the Bleaney–Bowers expression for an isotropically coupled pair of $S = 1/2$ ions, [17] [Eq. (1)] in conjunction with an additional mean-field correction term, χ_{MF}, [Eq. (2)] where N is Avogadro's number, μ_B is the Bohr magneton, k_B is the Boltzmann constant and z is the number of nearest neighbours [18]. The best fit parameters for reproducing satisfactorily the experimental data, as shown in Fig. 4, are $J_1 = +13.6$ cm^{-1}, $zJ' = -0.52$ cm^{-1}

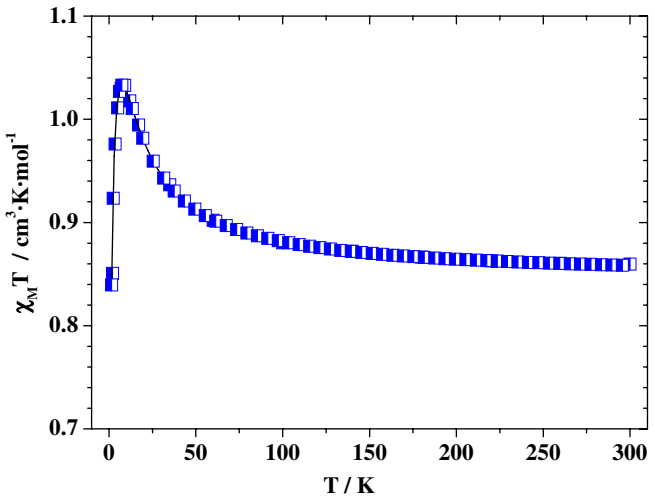

Fig. 3. Plot of $\chi_M T$ vs. T for complex **1** (per Cu–Cu) (solid line shows the best fit of the data).

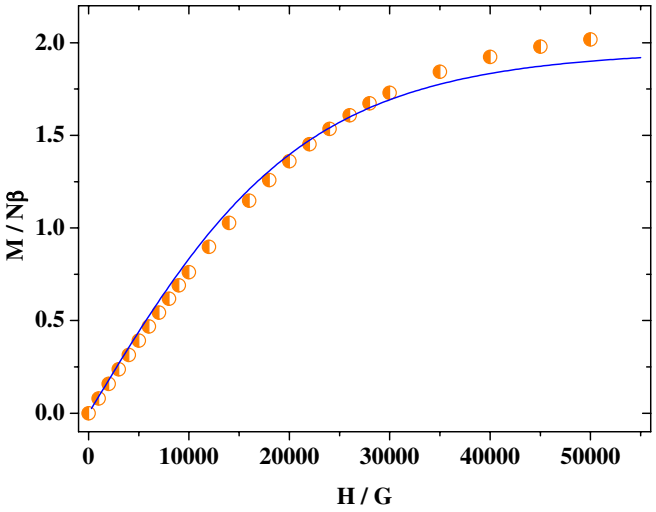

Fig. 4. The field dependence of the magnetization at 2 K for complex **1** (per Cu–Cu) (solid line shows the best fit of the data).

and $g = 2.12$ with $R = 3.4 \times 10^{-5}$ ($R = \sum_i (\chi T_{icalc} - \chi T_{iexp})^2 / (\chi T_{iexp})^2$). During the regression analysis the temperature independent paramagnetism was fixed as $2 \times 30 \times 10^{-6}$.

$$\chi_M = \frac{Ng^2\mu_B^2}{k_B T} \frac{2\exp(J/k_B)}{1 + 3\exp(J/k_B)} \quad (1)$$

$$\chi_{MF} = \frac{\chi_M}{1 - \chi_M(zJ'/Ng^2\mu_B^2)} \quad (2)$$

The weak ferromagnetic coupling found in the complex can be compared to that previously reported by Xie et al. [19a] for an analogous double asymmetric $\mu_{1,3}$-(N_3) bridged dimeric copper(II) system $[Cu_2(bben)_2(N_3)_4]_n$. EE azido bridges are well known to mediate antiferromagnetic interactions. However, ferromagnetic interactions are favored for complexes with very large M–$\mu_{1,3}(N_3)$–M bond and torsion angles, according to theoretical calculations [19b,19c,20]. Escuer et al. have recently elaborated in a nice way the topic of ferromagnetism in these kinds of doubly azido bridged copper(II) complexes with all relevant current references [5a].

The field dependence of magnetization (0–5.5 T) measured at 2 K is shown in Fig. 4, in the form of M/Nβ (per Cu_2 unit) versus H. The magnetization reaches a value of 1.92 Nβ at 5.5 T which is close to the expected $S = 1$ value of 2 Nβ for the Cu_2 system, indicating the presence of a ferromagnetic interaction between the nearest copper(II) ions.

3.5. EPR spectrum

The room temperature X-band EPR spectrum of complex **1** shows the typical axial pattern for distorted copper(II) species with $d_{x^2-y^2}$ ground state ($g_\parallel > g_\perp > 2.0$) (Fig. 5) in agreement with crystal data. Two bands are observed at $g_\parallel = 2.16$ and $g_\perp = 2.07$ (3205.2 and 3373.3 Gauss for $\nu = 9.7878$ GHz), corresponding to the transi-

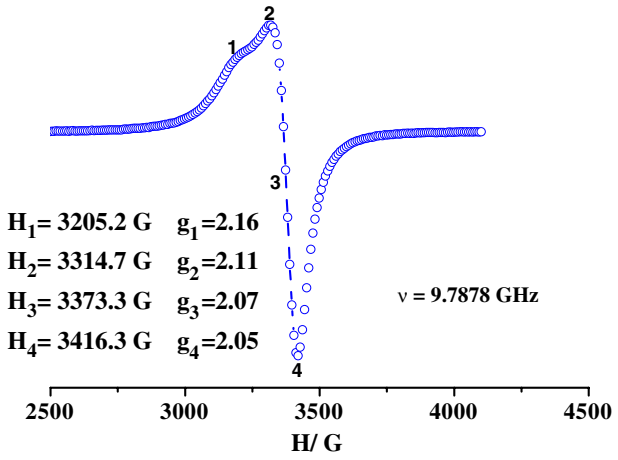

Fig. 5. EPR spectrum recorded at room temperature for complex **1**.

tion $\Delta M_S = \pm 1$ [4c,14]. The possible half-field transition $\Delta M_S = \pm 2$, rather frequent in copper(II) dimers, is not observed.

4. Conclusion

In conclusion, the results of the X-ray structure determination for the complex **1** are consistent with dinuclear doubly bridged azido groups in an end-to-end bonding fashion. The copper centers are penta-coordinated with a slight distortion from SP geometry, which was also confirmed through the UV studies in solution. The experimental observations suggest that the stretching frequencies of the azide group alone cannot be used to make a diagnosis of their exact bonding coordination modes in the complex. Cryomagnetic susceptibility measurements reveals a ferromagnetic interaction of $J = 13.6\ cm^{-1}$ is operating via the double azido bridges between the paramagnetic centers.

2.1.2. Preparation of $[Cu(dipicH_2)(OH_2)_3][Ce(dipic)_3]\cdot 3H_2O$ (2)

This compound was prepared by similar method to that of **1**, with $(NH_4)_2Ce(NO_3)_6$ (0.552 g, 1.01 mmol), $Cu(NO_3)_2\cdot 3H_2O$ (0.241 g, 0.998 mmol) and dipicH_2 (0.670 g, 4.01 mmol). Pale blue blocks were formed in 4–5 days (0.740 g, 76%). During the preparation a small amount of blue coloured crystals, identified as Cu(dipic)-(dipicH_2)$\cdot 3H_2O$ was also formed. The pale blue blocks of **2** were separated and recrystallized from hot water. *Anal.* Calc. for $C_{28}H_{26}CeCuN_4O_{22}$: C, 34.52; H, 2.69; N, 5.75. Found: C, 34.56; H, 2.50; N, 5.76%. ν_{max}(KBr)/cm^{-1} 3084, 1645, 1477, 1431, 1361, 1273, 1176, 1072, 1022, 923, 765 and 733. Magnetic moment at 298 K, 1.94 B.M.

2.1.3. Preparation of $[Zn(dipicH_2)(OH_2)_3][Ce(dipic)_3]\cdot 3H_2O$ (3)

The preparation was similar to that of **1** and **2** with $(NH_4)_2Ce(NO_3)_6$ (0.550 g, 1.00 mmol), $Zn(NO_3)_2\cdot 6H_2O$ (0.310 g, 1.04 mmol) and dipicH_2 (0.672 g, 4.02 mmol). Pale yellow blocks were formed in 4–5 days (0.770 g, 78%). These blocks were recrystallized from hot water. *Anal.* Calc. for $C_{28}H_{26}CeN_4O_{22}Zn$: C, 34.45; H, 2.68; N, 5.74. Found: C, 34.14; H, 2.41; N, 5.02%. ν_{max}(KBr)/cm^{-1} 3406, 1647, 1427, 1383, 1178, 1078, 1024, 916 and 729.

2.2. X-ray crystallography

X-ray data were collected for compounds **1** and **2** on an Enraf Nonius CAD-4 diffractometer and for **3** on a Bruker SMART APEX CCD X-ray diffractometer, using graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). Data of **1** and **2** were reduced using XCAD4 [3] and psi-scan [4] absorption corrections were applied. For **3** the data was reduced using SAINTPLUS [5] and a multiscan absorption correction using SADABS [6] was performed. The structure was solved using SHELXS-97 and refined using SHELXL-97 [7]. All ring hydrogens were assigned on the basis of geometrical considerations and were allowed to ride upon the respective carbon atoms. Drawings were made using ORTEP3 for Windows [8] and Mercury [9]. In compound **3**, one lattice water molecule was disordered in two positions. The crystal data for the three compounds are presented in Table 1 and selected bond lengths and angles in Tables 2–4.

Powder diffractograms were measured using a PW3710 model Philips Analytical X-ray diffractometer.

2.3. Physical measurements

EPR spectra were measured on a JEOL JES – FA 200 spectrometer. Powder simulations were done using a previously described computer program [10]. Electronic Reflectance spectra were measured by using a Shimadzu UV-3100 spectrometer equipped with an ISR-3100 integrating sphere attachment. Thermogravimetric analysis was per-

formed using a NETZSCH STA 409 PC/PG instrument. Room temperature magnetic susceptibilities of the powdered samples were measured using a Sherwood Scientific magnetic susceptibility balance.

2.4. Computational details

DFT along with geometry optimizations and time dependent DFT (TDDFT) have been performed using the B3LYP exchange correlation functional [11] as implemented in the Gaussian-03 [12]. The spin-unrestricted version was employed for open shell ions. For both types of calculations, triple-ζ basis sets [13] were used for Ni, Cu and Zn atoms and double-ζ basis sets [14] were used for all other atoms. Other basis sets in the Gaussian-03 suite were also used for comparison.

Ligand field theory calculations based on the angular overlap model (AOM) [15] were done using the AOMX program [16].

EPR g and A tensors were calculated using the program package ORCA [17] at the B3LYP level of DFT. A triple-ζ basis set [13] was used for all atoms.

3. Results and discussion

3.1. Synthesis

All three compounds are obtained in good yield by mixing the reagents in the appropriate molar ratio. The initial crystalline blocks obtained from aqueous methanolic solution and the crystals formed from hot water were found to be identical by comparing their X-ray powder patterns. The powder patterns also matched with those calculated based on the crystal structure.

$DipicH_2$ can coordinate in the neutral form as well as in monoanionic ($dipcH^-$) and dianionic ($dipic^{2-}$) forms. The following complex species have been previously reported: $M(dipicH)_2$ M = Ni, Zn [18], $M(dipic)_2^{2-}$ M = Ni, Cu, Zn [19], $Cu(dipic)(dipicH_2)$ [18b,20], $Cu(dipic)(OH_2)_2$ [21] and $Cu(dipic)(OH_2)_3$ [21b,22]. In the preparation of **2**, a small amount of $Cu(dipic)(dipicH_2)\cdot 3H_2O$ was formed along with the main compound. Besides this, no other side products were formed in the present synthesis. The presence of $Ce(dipic)_3^{2-}$ appears to ensure the crystallization of cationic complexes containing the neutral form of the ligand in all cases.

3.2. Structures

All the three compounds **1**–**3** are obtained as isomorphous ionic crystals containing $[M(dipicH_2)(OH_2)_3]^{2+}$ and $[Ce(dipic)_3]^{2-}$ ions (Figs. 1–3). The tri-capped trigonal prismatic Ce(IV) chelate has also been observed in Ce(IV)-alkaline earth-dipic complexes [2]. However, in all these cases some of the free oxygen atoms of the chelate coordinate to M(II) ions forming chains and networks. In the present cases there is no coordination link between the anions and cations. Instead, the free oxygen atoms form H-bonds with carboxylic groups and coordinated water molecules of the cation.

All the three cations, $[M(dipicH_2)(OH_2)_3]^{2+}$, have very similar 4+2 coordination polyhedra. The equatorial plane contains the nitrogen atom of $dipicH_2$ and the O atoms of the three water molecules, while the axial positions are occupied by the carbonyl oxygen atoms of $dipicH_2$. The major difference is that the axial elongation is significantly more in the case of the copper complex. The average equatorial and axial distances (Å) are 2.026(3), 2.175(3) (Ni); 1.984(2), 2.344(2) (Cu); 2.057(1), 2.236(1) (Zn). It would

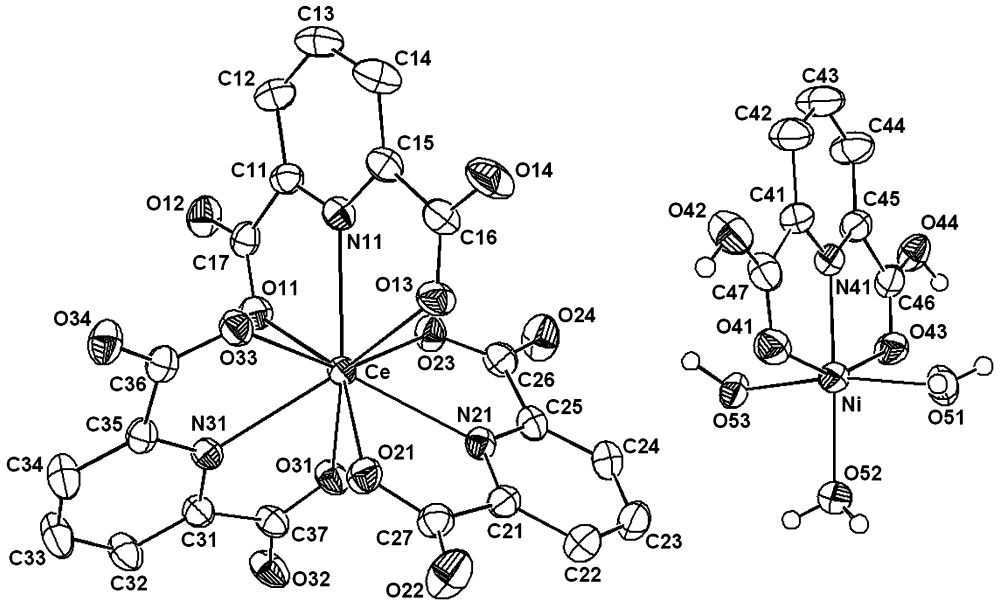

Fig. 1. ORTEP view of compound **1** showing the atom labeling. Thermal ellipsoids are drawn at the 50% probability level and ring hydrogen atoms and lattice water molecules have been omitted for clarity.

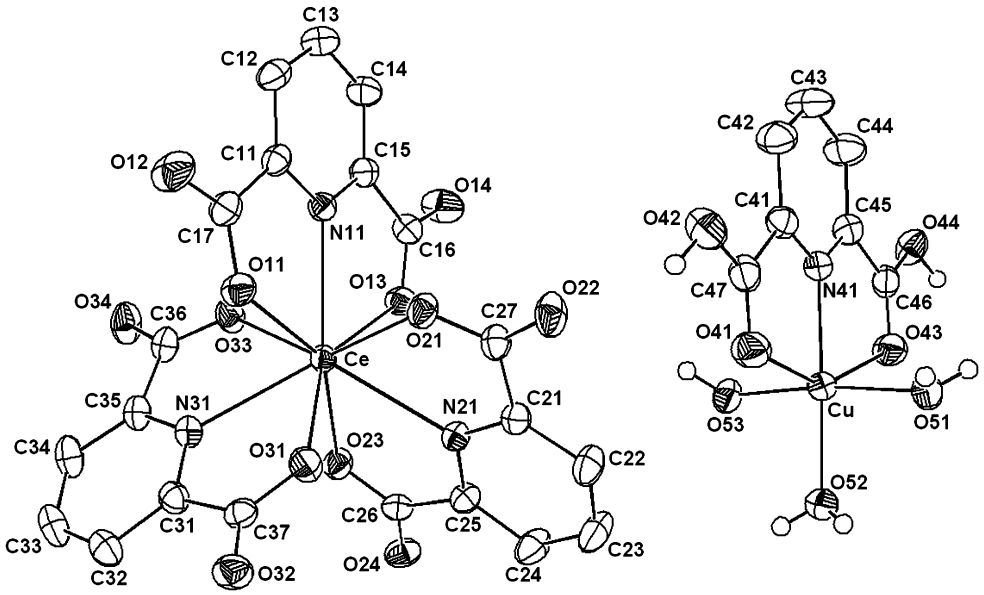

Fig. 2. ORTEP view of compound **2**, showing the atom labeling. Thermal ellipsoids are drawn at the 50% probability level and ring hydrogen atoms and lattice water molecules have been omitted for clarity.

appear that the expected vibronic effects are superimposed on the steric requirements of the ligand to produce the observed static structure in the case of the copper complex. The average off-axis deviation (°) of the axial ligand atoms are 13.5 (Ni) and 15.1 (Cu, Zn). The equatorial atoms including the metal atoms are very nearly coplanar in all cases with a largest deviation of the atoms (Å) from the mean plane 0.038(3) (Ni), 0.062(2) (Cu) and 0.111(2) (Zn). The deviations amount to a very slight tetrahedral distortion with the following inter planar angles (°): 3.3(2) (Ni); 4.6(1) (Cu); 8.2(1) (Zn).

Hydrogen bonding interactions between cations and anions generate a one-dimensional chain in all three crystals (Fig. 4). Further H-bonding involving lattice water molecules generates a three-dimensional network.

3.3. Electronic spectra

Assuming a tetragonal symmetry for the d^8 complex ion, the broad features in the solid state spectrum of **1** in the range 8000–20 000 cm^{-1} may be assigned to transitions arising from the ground state ($^3A_2$) to the split components

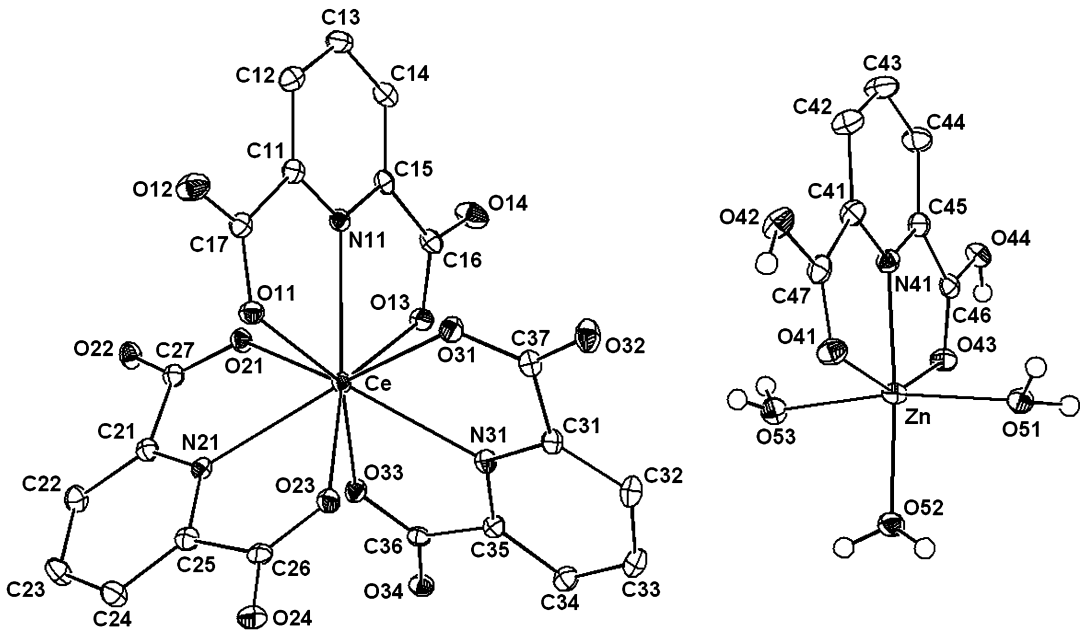

Fig. 3. ORTEP view of compound **3** showing the atom labeling. Thermal ellipsoids are drawn at the 50% probability level and ring hydrogen atoms and lattice water molecules have been omitted for clarity.

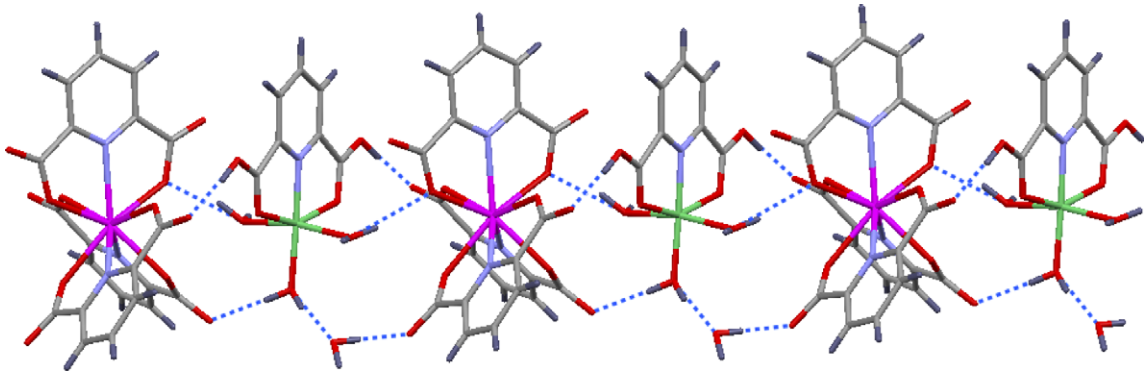

Fig. 4. 1D chain formed by H-bond interactions of cation and anion units.

of $^3T_2$ and $^3T_1$. The band positions and assignments are shown in Table 5. In the case of the copper complex **2**, two broad bands are seen which are assigned to excitations from d_z^2 and d_{xy} to $d_{x^2-y^2}$. Higher energy transitions could not be measured for these compounds due to the presence of strongly absorbing $[Ce(dipic)_3]^{2-}$ ions. The assignments are in general agreement with the calculations based on the AOM model as well as TDDFT theory. As indicated in Table 5, the axial perturbation in the case of the Cu(II) complex is only about one-fourth of the corresponding interaction in the Ni(II) complex. The excitation energies obtained from TDDFT calculations for the Cu(II) complex are in satisfactory agreement with the AOM calculations. The agreement is less than satisfactory in the case of the Ni(II) complex. It has been reported that transitions involving double excitations are not well represented in the TDDFT model [23]. In a low-symmetry six-coordinate d^8 complex, transitions to the split components of $^3T_2$ and $^3T_1(F)$ are essentially single electron excitations. The six lowest energy excitations quoted in Table 5 correspond to these. It is seen that the energies are overestimated by about 2000–3000 cm^{-1}. All the eight different basis sets used gave similar results.

3.4. EPR Spectrum of 2

The packing of the Cu(II) complex cations alternating with the bulky diamagnetic anions in the crystals lead to magnetic dilution. The EPR spectrum of the polycrystalline sample is shown in Fig. 5, in which the hyperfine splitting is fully resolved in the parallel region. The EPR parameters derived by computer simulation of the experimental spectra are given in Table 6. The parameters are consistent with the tetragonally distorted Cu(II) complex. Included in the table are the EPR parameters derived using DFT calculations with the experimental geometry. The calculated *g*-values

Table 5
Electronic spectral data

[a] A-values in units of 10^{-4} cm^{-1} (sign of A not determined).
[b] Spin–orbit parameters (λ) = −828 cm^{-1}, $\langle r^{-3}\rangle = 7.64$ a.u. See text for covalency factors.

are within 1% (g_x, g_y) and 6% (g_z) of the experimental value. The parallel component (g_z) is the one most influenced by spin–orbit perturbation. To a first approximation, its deviation from the free spin value is directly proportional to the square of the coefficient of the metal d-orbital in the SOMO and inversely proportional to the energy gap between the molecular orbitals based on $d_{x^2-y^2}$ (SOMO) and d_{xy}. Simple ligand field analysis [24] assuming axial symmetry and using the proposed electronic spectral assignments (*vide infra*) leads to the following values for the d-orbital coefficients in the molecular orbitals: 0.98 ($d_{x^2-y^2}$), 0.94 (d_{xy}) and 0.89 (d_{xz}, d_{yz}). The values of the different contributions to the metal hyperfine splitting *viz.* Fermi contact (A_F), Spin dipolar (A_z^D, A_x^D, A_y^D) and spin–orbit ($A_z^{so}, A_x^{so}, A_y^{so}$) based on this analysis are included in Table 6. It is seen that the agreement of the hyperfine splitting components calculated by DFT with the ligand field

analysis is poor. The deviations in the calculated values are as much as 200% for the in-plane component and 13% for the axial component. It is seen that the better agreement in the case of the axial component in mainly due to the cancellation of errors in A_F and A_z^D having a negative sign and A_z^{so}, which makes a positive contribution. A similar observation has been made earlier with regard to hyperfine splitting calculations using the program ORCA [25]. In spite of the poor agreement of the magnitude of the calculated hyperfine tensor components with the experiment, the orientation of the *g*- and *A*-tensor are collinear with each other (within 1°) and the in-plane components are along the Cu–N and Cu–O bonds (within 3°). While this orientation is reasonable for the observed structure (all in plane bond angles being $90 \pm 2°$), the powder spectrum does not afford the orientation of the *g* and *A* principal directions.

3.5. Thermal analysis

The thermogravimetric analyses of all compounds show the same trend. The weight loss begins at 50 °C and the loss of five water molecules is complete at 160 °C (wt. loss calculated 9.28%, found 9.39% for **1**; 9.23% and 9.59% for **2**; 9.22% and 10.28% for **3**). The loss of the last coordinated water takes place gradually and the structures were found to completely break down above 270 °C. This indicates that the four-coordinate structures are thermally stable relative to the six-coordinate ones at temperatures higher than about 160 °C.

3.6. Geometry optimization

The geometry of the cationic part of **1**, **2** and **3** were optimized without any constraints. The optimized structures of the isolated cations are superimposed on the crystallographic structures in Fig. 6. The bond distances in the optimized geometry are within 0.06 Å of the crystallographic values in all cases. It is noteworthy that the DFT calculation captures the essential feature of the static Jahn–Teller distortion in the case of the Cu(II) complex, *viz.*, elongation of the axial bonds [26]. In this context, it is worth investigating the structural changes associated with the deprotonation of $dipicH_2$ in these complexes. The results are shown in Fig. 7, wherein the calculated minimum energy structures of $M(dipic)(OH_2)_3$ are superimposed on the corresponding $[M(dipicH_2)(OH_2)_3]^{2+}$ structures. In the case of Ni(II), there was only a small

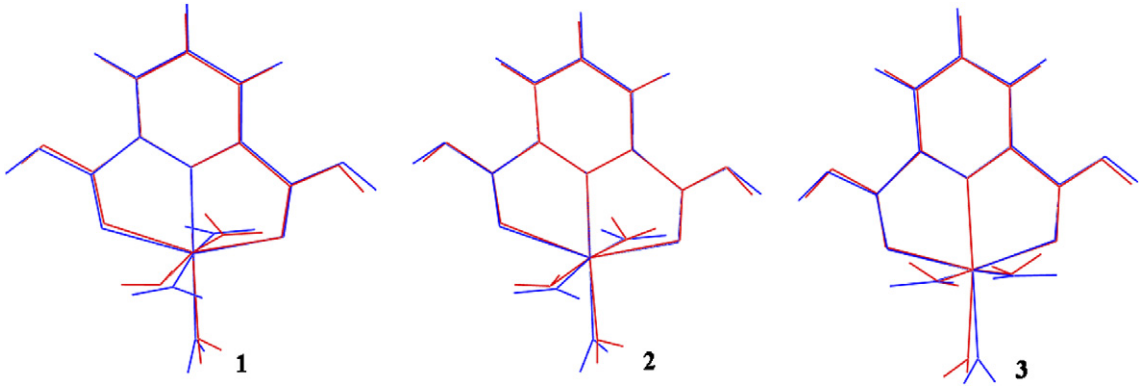

Fig. 6. Optimized structures of the isolated cations, superimposed on the crystallographic structures.

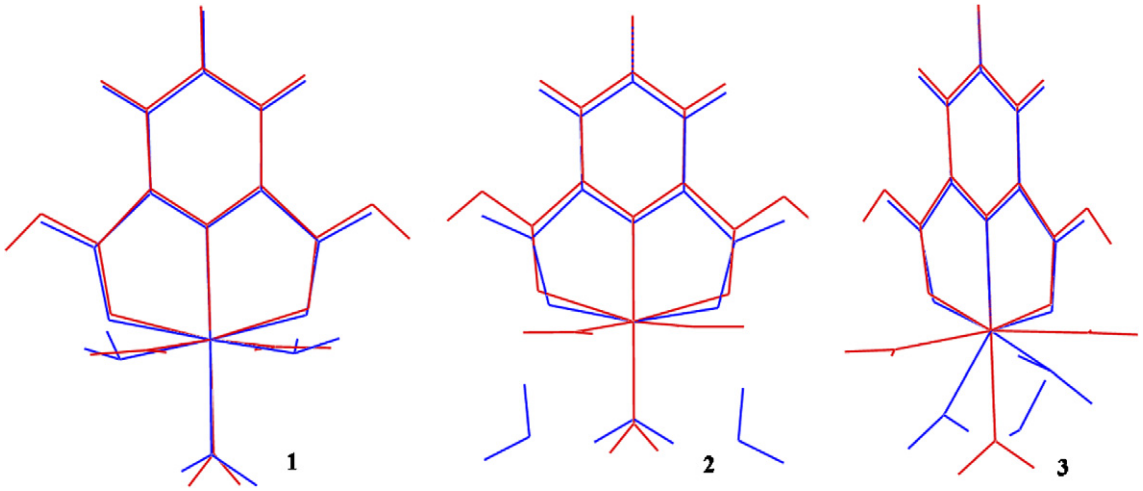

Fig. 7. Optimized structures of $M(dipic)(OH_2)_3$ and $[M(dipicH_2)(OH_2)_3]^{2+}$ (see text for description).

reduction in the two axial bond distances, by 0.05 and 0.1 Å. In the case of Cu(II), there is a switch of the elongation axis. The carboxylate oxygen atoms close in on copper with a simultaneous weakening of the two *trans* bonds to water molecules. The final structure is square planar, the two water molecules which are no longer in the coordination sphere of Cu(II) are involved in H-bonding on the periphery of the complex. The $Cu–O_{carboxylate}$ bonds are shortened by 0.3 Å. The crystal structure of Cu(dipic)-$(OH_2)_3$ [22] differs from the computed gas phase structure. It consists of six-coordinated molecules with weak axial bonds to water molecules. Nevertheless, the present result shows that the calculation is able to model the switch of the Jahn–Teller axis accompanying the deprotonation of the ligand. The Zn(II) complex transforms to a five-coordinate structure upon deprotonation in which the $Zn–O_{carboxylate}$ bonds are shortened by 0.2 Å.

4. Conclusion

The cations $[M(dipicH_2)(OH_2)_3]^{2+}$, containing strongly acidic hydrogen atoms, are stabilized in crystals by bulky $[Ce(dipic)_3]^{2-}$ anions. Even though the three crystals with M = Ni, Cu, Zn are isomorphous, the cations maintain the structural features characteristic of their electronic configurations. This is especially prominent for the Cu(II) complex in which a vibronic distortion is superimposed on the steric distortion. This complex also affords well-resolved EPR spectra due to magnetic isolation of the cations provided by the bulky anions. It is shown that TDDFT calculations are able to reproduce the electronic transition energies with reasonable accuracy for the d^9 complex. The agreement is not satisfactory for the d^8 complex. Geometry optimizations using DFT are able to model static Jahn–Teller elongation of the Cu(II) complex ion as well as changes accompanying the deprotonation of the coordinated $dipicH_2$. While DFT is able to model the structure, electronic transition and *g*-anisotropy of the d^9 complex, the agreement of the hyperfine splitting constants is poor. Various contributions to hyperfine coupling are not satisfactorily modelled at the present level of theory.

Acknowledgements

The X-ray data were collected at the diffractometer facility at the University of Hyderabad, established by the Department of Science and Technology, Government of India. Computations were performed at CMSD. Infrastructure support from UGC (UPE program) is also acknowledged. This work was supported by CSIR, India. T.K.P. thanks the CSIR for the award of a research fellowship.

[26] (a) As a check on this procedure, we optimized the structure of $[Cu(OH_2)_6]^{2+}$ starting with a regular octahedral geometry having a bond distance 2.12 Å. The water molecules were constrained with O–H = 0.96 Å and H–O–H = 105°. The optimized structure is of tetragonal symmetry with axial and equatorial distances of 2.20 and 1.99 Å, respectively. The structure is stabilized to the extent of 23.4 kJ mol^{-1} with respect to the regular octahedral structure. Similar optimizations in the case of $[Ni(OH_2)_6]^{2+}$ and $[Zn(OH_2)_6]^{2+}$ results in regular octahedral geometries with bond distances 2.04 Å (Ni^{2+}) and 2.07 Å (Zn^{2+}). The optimized structure of $[Cu(OH_2)_6]^{2+}$ compares well with the previous ab initio SCF calculations [26b]: bond distances, 2.24 Å (axial), 2.06 Å (equatorial), stabilization energy = 7.0 kJ mol^{-1};

to bring about apoptosis in lymphocyte cell cultures [36]. The (salen)chromium(III)/DMAP catalyst system is used in the fixation of CO_2 with epoxides to form carbonates [37].

As part of the ongoing investigations [38] by our group of metal–salen catalyzed oxidations and of insulin-mimetic complexes [39] we prepared complexes of chromium–salen. In this paper we describe chromium(III) complexes of the tetradentate Schiff bases, *N*,*N*′-bis(salicylidene) ethylene-diamine, H_2L^1; *N*,*N*′-bis(5-bromosalicylidene) ethylenediamine, H_2L^2; *N*,*N*′-bis(5-chlorosalicylidene)ethylenediamine, H_2L^3; *N*,*N*′-bis(5-methoxysalicylidene)ethylenediamine, H_2L^4; *N*,*N*′-bis(5-nitrosalicylidene)ethylenediamine, H_2L^5; *N*,*N*′-bis(3,5-diclorosalicylidene)ethylenediamine, H_2L^6; *N*,*N*′-bis(3,5-dibromo-salicylidene)ethylenediamine, H_2L^7; and *N*,*N*′-bis(3,5-diiodosalicylidene)ethylenediamine, H_2L^8. A structural representation of the ligands, their abbreviations, and numbering system of the carbons for ^{13}C NMR are given in Fig. 1.

2. Experimental

2.1. Reagents

Ethylenediamine, 99%; salicylaldehyde, 98%; 5-bromosalicylaldehyde, 98%; 5-chlorosalicylaldehyde, 98%; 5-methoxyosalicylaldehyde, 98%; 5-nitrosalicylaldehyde, 99%; 3,5-dibromosalicylaldehyde, 98%; 3,5-dichlorosalicylaldehyde, 99%; 3,5-diiodosalicylaldehyde, 97%; (methyl sulfoxide)-d_6, 99.9 atom% D, DMSO-d_6; chloroform-*d* 99.8 atom% D, $CDCl_3$ (Aldrich Chemical Co.) and $CrCl_3 \cdot 6H_2O$ (Riedel-de-Haën Inc.) were used as received. All other solvents and reagents were obtained commercially and were used without further purification.

2.2. Preparation of the Schiff bases

The Schiff bases were prepared in a similar manner [40] by the following procedure: to a stirred solution of 4.0 mmol of the appropriate substituted salicylaldehyde in ethanol (50 ml) was added dropwise an ethanolic solution (10 ml) of 2.0 mmol ethylenediamine. This mixture was then heated for 2 h. Afterwards the mixture was cooled to room temperature, then cooled for 24 h at 5 °C. The solid was filtered and washed with cold ethanol (5 ml at 5 °C) and dried over silica. The ligands were used without further purification.

2.2.1. Ligand H_2L^1

Brilliant yellow flakes. Yield: 0.498 g, 92.8%. m.p.: 125–126 °C (uncorrected). *Anal*. Calc. for $C_{16}H_{16}N_2O_2$: C, 71.6; H, 6.0; N, 10.4. Found: C, 71.7; H, 6.0; N, 10.4%. Selected IR bands (KBr, cm^{-1}): 1634s, $\nu_{C=N}$; 1576m, $\nu_{C=C}$; 1371m, ν_{C-N}; 1283m, ν_{C-O}. UV–Vis spectrum in DMSO [λ_{max} (nm), ε (M^{-1} cm^{-1})]: 317 (8420), 402 (465). Mass spectrum, ESI/MS in DMSO [*m*/*z*(%)]: 267(18), 245(19), 227(51), 172(73), 157(39), 141(100).

2.2.2. Ligand H_2L^2

Light yellow crystals. Yield: 0.794 g, 93.2%. m.p.: 171–173 °C (uncorrected). *Anal*. Calc. for $C_{16}H_{14}N_2O_2Br_2$: C, 45.1; H, 3.3; N, 6.6. Found: C, 45.5; H, 3.3; N, 6.7%. Selected IR bands (KBr, cm^{-1}): 1632s, $\nu_{C=N}$; 1565m, $\nu_{C=C}$; 1360m, ν_{C-N}; 1274s, ν_{C-O}; 1072m, ν_{C-Br}. UV–Vis spectrum in DMSO [λ_{max} (nm), ε (dm^3 cm^{-1} mol^{-1})]: 329 (7050), 421 (735). Mass spectrum, ESI/MS, in DMSO [*m*/*z*(%)]: 425(43), 385(6), 339(25), 325(37), 249(46), 201(100).

2.2.3. Ligand H_2L^3

Light yellow crystals. Yield: 0.560 g, 83.0%. m.p.: 155–157 °C (uncorrected). *Anal*. Calc. for $C_{16}H_{14}N_2O_2Cl_2$: C, 57.0; H, 4.2; N, 8.3. Found: C, 57.0; H, 4.2; N, 8.4%. Selected IR bands (KBr, cm^{-1}): 1633s, $\nu_{C=N}$; 1570m, $\nu_{C=C}$; 1362m, ν_{C-N}; 1275m, ν_{C-O}; 1092m ν_{C-Cl}. UV–Vis spectrum in DMSO [λ_{max} (nm), ε (dm^3 cm^{-1} mol^{-1})]: 328 (7510), 423 (670). Mass spectrum, ESI/MS, in DMSO [*m*/*z*(%)]: 338(4), 254(36), 215(30), 179(100).

2.2.4. Ligand H_2L^4

Yellow powder. Yield: 0.560 g, 85.4%. m.p.: 150–152 °C (uncorrected). *Anal*. Calc. for $C_{18}H_{20}N_2O_4$: C, 65.8; H, 6.1; N, 8.5. Found: C, 66.1; H, 6.0; N, 8.4%. Selected IR bands (KBr, cm^{-1}): 1638s, $\nu_{C=N}$; 1587m, $\nu_{C=C}$; 1357m, ν_{C-N}; 1274m, ν_{C-O}; 1228m, ν_{C-O-C}. UV–Vis spectrum in DMSO [λ_{max} (nm), ε (dm^3 cm^{-1} mol^{-1})]: 346 (8630), 430 (140).

2.2.5. Ligand H_2L^5

Yellow powder. Yield: 0.580 g, 81.0%. m.p.: 261–263 °C (uncorrected). *Anal*. Calc. for $C_{16}H_{14}N_4O_6$: C, 53.6; H, 3.9; N, 15.6. Found: C, 53.3; H, 3.8; N, 15.8%. Selected IR bands (KBr, cm^{-1}): 1646s, $\nu_{C=N}$; 1614s, $\nu_{C=C}$; 1542m, ν_{NO_2}; 1353m, ν_{C-N}; 1324s ν_{NO_2}. UV–Vis spectrum in DMSO [λ_{max} (nm), ε (dm^3 cm^{-1} mol^{-1})]: 365 (15100), 420 (17400). Mass spectrum, ESI/MS, in DMSO [*m*/*z*(%)]: 359(11), 259(6), 228(10), 179(58), 157(100).

2.2.6. Ligand H_2L^6

Yellow powder. Yield: 1.036 g, 88.7%. m.p.: 238–241 °C (uncorrected). *Anal.* Calc. for $C_{16}H_{12}N_2O_2Br_4$: C, 32.9; H, 2.1; N, 4.8. Found: C, 33.1; H, 2.2; N, 4.9%. Selected IR bands (KBr, cm^{-1}): 1636s, $\nu_{C=N}$; 1592m, $\nu_{C=C}$; 1356w, ν_{C-N}; 1287w, ν_{C-O}. UV–Vis spectrum in DMSO [λ_{max} (nm), ε ($dm^3\,cm^{-1}\,mol^{-1}$)]: 289 (6180), 335 (4340), 431 (6340).

2.2.7. Ligand H_2L^7

Yellow powder. Yield: 0.696 g, 85.7%. m.p.: 208–210 °C (uncorrected). *Anal.* Calc. for $C_{16}H_{12}N_2O_2Cl_4$: C, 47.3; H, 3.0; N, 6.9. Found: C, 47.0; H, 2.7; N, 6.7%. Selected IR bands (KBr, cm^{-1}): 1639s, $\nu_{C=N}$; 1552w, $\nu_{C=C}$; 1369w, ν_{C-N}; 1289w, ν_{C-O}. UV–Vis spectrum in DMSO [λ_{max} (nm), ε ($dm^3\,cm^{-1}\,mol^{-1}$)]: 286 (5600), 334 (4570), 431 (5610).

2.2.8. Ligand H_2L^8

Yellow powder. Yield: 0.854 g, 55.0%. m.p.: 240–242 °C (uncorrected). *Anal.* Calc. for $C_{16}H_{12}N_2O_2I_4$: C, 24.9; H, 1.6; N, 3.6. Found: C, 24.6; H, 1.6; N, 3.3%. Selected IR bands (KBr, cm^{-1}): 1630s, $\nu_{C=N}$; 1580m, $\nu_{C=C}$; 1353m, ν_{C-N}; 1281m, ν_{C-O}. UV–Vis spectrum in DMSO [λ_{max} (nm), ε ($dm^3\,cm^{-1}\,mol^{-1}$)]: 296 (5800), 344 (5000), 438 (6520).

2.3. Preparation of the chromium(III) complexes

The chromium(III) complexes were prepared essentially as described [41]. The following procedure was used: ethylenediamine (0.12 g, 2.0 mmol) and the appropriate salicylaldehyde (4.0 mmol) were added to a solution of chromium(III) chloride hexahydrate (0.53 g, 2.0 mmol) in ethylene glycol–water–methanol (1:1:3, 50 ml). After the mixture was refluxed for 30 min, potassium carbonate (0.21 g, 1.5 mmol) was gradually added to the solution, then refluxing the solution for about 3–4 h. The precipitate was filtered, washed with cold water (5 ml) and cold ethanol (5 ml) and dried over silica. The complex was recrystallized from 95% ethanol and dried over silica in a desiccator at room temperature.

2.3.1. Preparation of $[Cr(L^1)(OH)(H_2O)]$

Brown powder. Yield: 0.253 g, 35.8%. m.p.: 245–250 °C decomposition (uncorrected). *Anal.* Calc. for $C_{16}H_{17}N_2O_4Cr$: C, 54.4; H, 4.9; N, 7.9. Found: C, 54.7; H, 5.2; N, 7.95%. Selected IR bands (KBr, cm^{-1}): 1638s, $\nu_{C=N}$; 1540m, $\nu_{C=C}$; 1372m, ν_{C-N}; 1295m, ν_{C-O}; 538w, ν_{Cr-O}; 375w, ν_{Cr-N}. UV–Vis spectrum in DMSO [λ_{max} (nm), ε ($dm^3\,cm^{-1}\,mol^{-1}$)]: 277 (14000), 334 (3420), 393 (3700). Mass spectrum, ESI/MS, in DMSO [m/z(%)]: 474(60), 428(17), 319(20), 241(22), 215(20), 179(100), 153(88). μ_{eff}(298 K): 3.92 BM.

2.3.2. Preparation of $[Cr(L^2)(OH)(H_2O)]$

Brown powder. Yield: 0.358 g, 35.0%. m.p.: >360 °C. *Anal.* Calc. for $C_{16}H_{15}N_2O_4Br_2Cr$: C, 37.6; H, 2.95; N, 5.5. Found: C, 37.8; H, 2.6; N, 5.3%. Selected IR bands (KBr, cm^{-1}): 1627s, $\nu_{C=N}$; 1592m, $\nu_{C=C}$; 1377m, ν_{C-N}; 1300m, ν_{C-O}; 582w, ν_{Cr-O}; 378w, ν_{Cr-N}. UV–Vis spectrum in DMSO [λ_{max} (nm), ε ($dm^3\,cm^{-1}\,mol^{-1}$)]: 284 (12400), 341 (1294), 407 (980). Mass spectrum, ESI/MS, in DMSO [m/z(%)]: 633(10), 521(16), 470(9), 339(52), 325(54), 311(42), 283(51), 249(100). μ_{eff}(298 K): 4.13 BM.

2.3.3. Preparation of $[Cr(L^3)(OH)(H_2O)]$

Brown powder. Yield 0.372 g, 44.0%. m.p.: >360 °C. *Anal.* Calc. for $C_{16}H_{15}N_2O_4Cl_2Cr$: C, 45.5; H, 3.6; N, 6.6. Found: C, 45.1; H, 3.2; N, 6.4%. Selected IR bands (KBr, cm^{-1}): 1629s, $\nu_{C=N}$; 1599m, $\nu_{C=C}$; 1379m, ν_{C-N}; 1302m, ν_{C-O}; 584w, ν_{Cr-O}; 376w, ν_{Cr-N}. UV–Vis spectrum in DMSO [λ_{max} (nm), ε ($dm^3\,cm^{-1}\,mol^{-1}$)]: 344 (2000), 413 (1570). Mass spectrum, ESI/MS, in DMSO [m/z(%)]: 543(8), 319(10), 257(10), 215(10), 184(27), 179(100), 153(63), 145(19). μ_{eff}(298 K): 3.92 BM.

2.3.4. Preparation of $[Cr(L^4)(OH)(H_2O)]$

Brown powder. Yield: 0.445 g, 53.8%. m.p.: >360 °C. *Anal.* Calc. for $C_{18}H_{21}N_2O_6Cr$: C, 52.3; H, 4.8; N, 6.8. Found: C, 52.2; H, 5.1; N, 6.6%. Selected IR bands (KBr, cm^{-1}): 1628s, $\nu_{C=N}$; 1563m, $\nu_{C=C}$; 1388m, ν_{C-N}; 1305m, ν_{C-O};. 5 69w, ν_{Cr-O}; 380w, ν_{Cr-N}. UV–Vis spectrum in DMSO [λ_{max} (nm), ε ($dm^3\,cm^{-1}\,mol^{-1}$)]: 357 (2010), 430 (1380). μ_{eff}(298 K): 4.00 BM.

2.3.5. Preparation of $[Cr(L^5)(H_2O)_2]Cl$

Brown powder. Yield: 0.409 g, 46.0%. m.p.: >360 °C. *Anal.* Calc. for $C_{16}H_{16}N_4O_8ClCr$: C, 40.1; H, 3.4; N, 11.7. Found: C, 40.6; H, 3.3; N, 12.0%. Selected IR bands (KBr, cm^{-1}): 1638s, $\nu_{C=N}$; 1580m, $\nu_{C=C}$; 1390m, ν_{C-N}; 1304m, ν_{C-O}; 569w, ν_{Cr-O}; 375w, ν_{Cr-N}. UV–Vis spectrum in DMSO [λ_{max} (nm), ε ($dm^3\,cm^{-1}\,mol^{-1}$)]: 375 (19200). Mass spectrum, ESI/MS, in DMSO solutions [m/z(%)]: 564(12), 476(13), 359(32), 305(56), 275(52), 259(68), 227(100), 215(21). μ_{eff}(298 K): 3.51 BM.

2.3.6. Preparation of $[Cr(L^6)(H_2O)_2]Cl$

Brown powder. Yield: 0.363 g, 25.7%. m.p.: >360 °C. *Anal.* Calc. for $C_{16}H_{14}N_2O_4ClBr_4Cr$: C, 27.2; H, 2.0; N, 4.0. Found: C, 27.5; H, 1.8; N, 3.7%. Selected IR bands (KBr, cm^{-1}): 1634s, $\nu_{C=N}$; 1578m, $\nu_{C=C}$; 1358w, ν_{C-N}; 1298w, ν_{C-O}; 575w, ν_{Cr-O}; 370w, ν_{Cr-N}. UV–Vis spectrum in DMSO [λ_{max} (nm), ε ($dm^3\,cm^{-1}\,mol^{-1}$)]: 286 (16400), 336 (4570), 410 (4180). μ_{eff}(298 K): 4.19 BM.

2.3.7. Preparation of $[Cr(L^7)(H_2O)_2]Cl$

Brown powder. Yield: 0.522 g, 53.0%. m.p.: >360 °C. *Anal.* Calc. for $C_{16}H_{14}N_2O_4Cl_5Cr$: C, 36.4; H, 2.7; N, 5.3. Found: C, 36.2; H, 2.7; N, 5.5%. Selected IR bands (KBr, cm^{-1}): 1628s, $\nu_{C=N}$; 1519w, $\nu_{C=C}$; 1376w, ν_{C-N}; 1290w, ν_{C-O}; 580w, ν_{Cr-O}; 357w, ν_{Cr-N}. UV–Vis spectrum in DMSO [λ_{max} (nm), ε ($dm^3\,cm^{-1}\,mol^{-1}$)]: 319 (4060), 415 (2370). μ_{eff}(298 K): 4.05 BM.

2.3.8. Preparation of $[Cr(L^8)(H_2O)_2]Cl \cdot H_2O$

Brown powder. Yield: 0.245 g, 13.4%. m.p.: >360 °C. *Anal.* Calc. for $C_{16}H_{164}N_2O_5ClI_4Cr$: C, 21.1; H, 1.8; N, 3.1. Found: C, 21.0; H, 2.0; N, 3.2%. Selected IR bands (KBr cm^{-1}): 1637s, $\nu_{C=N}$; 1566w, $\nu_{C=C}$; 1372w, ν_{C-N}; 1391m, ν_{C-O}; 569w, ν_{Cr-O}; 375w, ν_{Cr-N}. UV–Vis spectrum in DMSO [λ_{max} (nm), ε ($dm^3\ cm^{-1}\ mol^{-1}$)]: 292 (9940), 346 (3410), 415 (2370). μ_{eff}(298 K): 4.03 BM.

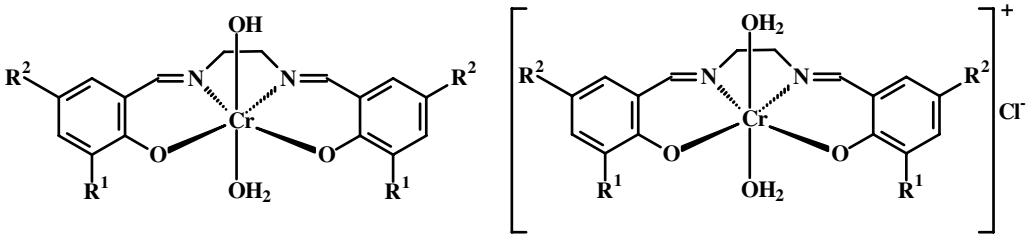
2.4. Physical measurements

Elemental microanalyses (C, H, N) were performed by the Microanalytical Laboratory of the Departamento de Química of the Universidade Federal de São Carlos, with a Faison EA 1108 CHNS-O instrument. Melting points were determined using a Mel-Temp II Laboratory Devices USA. The molar conductance was determined with a Cole-Parmer Model 1481-90 conductivity meter. IR spectra were recorded in KBr pressed discs (1% by weight) with a Bomem Michelson 102 FT-IR instrument. The ^1H and ^{13}C NMR spectra of the free ligand in $CDCl_3$ and DMSO-d_6, with tetramethylsilane as an internal standard, were obtained using a Bruker ARX 400 MHz 9.4 T spectrophotometer. All chemical shifts (^1H and ^{13}C) are given in ppm versus tetramethylsilane (TMS). Magnetic susceptibility measurements were made on a powered sample at 298 K using a Johnson–Matthey Magnetic Susceptibility Balance model Mark II using the magnetic susceptibility standard $HgCo(NCS)_4$.

All the mass spectra were performed by the mass spectrometry Laboratory of the Departamento de Química of the Universidade Federal de São Carlos using a QuattroLC triple-quadrupole mass spectrometer (Micromass, Manchester, UK) coupled with an liquid chromatograph; the data were acquired using Masslynx software (version 3.2). The electrospray ionization capillary voltage was maintained between 4 and 4.2 kV, and the cone voltage was kept at 30 V unless otherwise stated. Nitrogen was used as the desolvation and nebulization gas. The source and desolvation temperatures were kept at 100 °C. The ESI mass spectra were recorded by scanning MS1. The mass spectra of these compounds were performed on 15 ng dm^{-3} DMSO solutions.

Electronic spectra were recorded in the 260–800 nm range using a Shimadzu MultSpec-1501 instrument. These spectra of the DMSO solutions were obtained at room temperature using matched 1.0 cm quartz cells. The electronic spectra were resolved by deconvolution using the Voigt function, amplitude, Gaussian/Lorentzian widths, of the Jandel Scientific Software PeakFit™ program [42]. In this version of the Voigt function, the Gaussian and Lorentzian widths were calculated as well as the amplitude and center of each peak. The width and area of each peak were allowed to vary without using a background function. A reliability factor, defined as $R = \sum|y_{obs.,i} - y_{calc.,i}|/\sum y_{obs.,i}$, was used to determine the goodness of fit between the measured and the calculated spectra. A degree of freedom adjusted coefficient of determination of the Jandel Scientific Software PeakFit™ program [42] was also used in the determination of the goodness of fit [43].

3. Results and discussion



The complexes of chromium(III) are stable in air, both in solution and in the crystalline state. The solids are various shades of brown. The yields of the purified complexes varied from 13.7% to 53.7%. The variation is due to differences in the solubility of the starting ligands and the final complexes. The complexes showed magnetic moment in the range of 3.5–4.2 BM which corresponds to three unpaired electrons [44].

The molar conductance of the complexes was an aid for proposing their formulas. For pure DMSO the measured conductivity was 15.1 S $cm^2\ mol^{-1}$, for a 1:1 electrolyte, KCl, 1.00×10^{-3} mol L^{-1} in DMSO, the molar conductivity was 46.0 S $cm^2\ mol^{-1}$ and 126.5 S $cm^2\ mol^{-1}$ for the 2:1 electrolyte, $MgCl_2$, 1.00×10^{-3} mol L^{-1} in DMSO. The molar conductances in DMSO solutions, at 25 °C, with a concentration of 1×10^{-3} mol L^{-1}, are: $[Cr(L^5)(H_2O)_2]Cl$, 54 S $cm^2\ mol^{-1}$; $[Cr(L^6)(H_2O)_2]Cl$, 39 S $cm^2\ mol^{-1}$; $[Cr(L^7)(H_2O)_2]Cl$, 45 S $cm^2\ mol^{-1}$ and $[Cr(L^8)(H_2O)_2]Cl$, 50 S $cm^2\ mol^{-1}$. These data are, as expected, for a 1:1 electrolyte. The complexes, $[Cr(L^1)(OH)(H_2O)]$, 14 S $cm^2\ mol^{-1}$; $[Cr(L^2)(OH)(H_2O)]$, 13 S $cm^2\ mol^{-1}$; $[Cr(L^3)(OH)(H_2O)]$, 26 S $cm^2\ mol^{-1}$ and $[Cr(L^4)(OH)(H_2O)]$, 18 S $cm^2\ mol^{-1}$, are neutral electrolytes. Solutions of the complexes were also tested with $AgNO_3$ for free chloride íon with the results confirming the proposed structures. The proposed structural representations of the complexes and their abbreviations are given in Fig. 2.

The results of the microanalyses, the molar conductance and tests with $AgNO_3$ indicate that two series of complexes are formed by the same synthetic procedure [41]. The first series of complexes $[Cr(L^n)(H_2O)_2]Cl$, is the expected product of the synthesis. The second series, $[Cr(L^m)(OH)(H_2O)]$, is related to the first series by the deprotonation of a coordinated water forming a neutral complex. A slow addition rate results in the expected $[Cr(L^n)(H_2O)_2]Cl$ product. However, either if the potassium carbonate is added too fast or if amount is larger than the value calculated, the product is $[Cr(L^n)(OH)(H_2O)]$. The potassium carbonate is used in the synthesis to deprotonate the Schiff base H_2L^n.

3.1. IR spectra

The IR spectra of the free ligands and the complexes exhibit various bands in the 250–4000 cm^{-1} region. A typical spectrum of the free ligand and the corresponding chromium(III) are shown in Fig. 3. The O–H stretching frequency of the ligand is expected in the 3300–3800 cm^{-1} region, however, this frequency is generally displaced to the 2840–2960 cm^{-1} region due to the internal hydrogen bridge OH···N=C [45,46]. As the hydrogen bond becomes stronger, the bandwidth increases, and this band sometimes is not detected. Hydrogen bonds in these Schiff bases are

R^1	R^2	L	Complexes
H	H	OH	$[Cr(L^1)(OH)(H_2O)]$
H	Br	OH	$[Cr(L^2)(OH)(H_2O)]$
H	Cl	OH	$[Cr(L^3)(OH)(H_2O)]$
H	MeO	OH	$[Cr(L^4)(OH)(H_2O)]$

R^1	R^2	L	Complexes
H	NO_2	H_2O	$[Cr(L^5)(H_2O)_2]Cl$
Br	Br	H_2O	$[Cr(L^6)(H_2O)_2]Cl$
Cl	Cl	H_2O	$[Cr(L^7)(H_2O)_2]Cl$
I	I	H_2O	$[Cr(L^8)(H_2O)_2]Cl$

Fig. 2. Complexes prepared in this study.

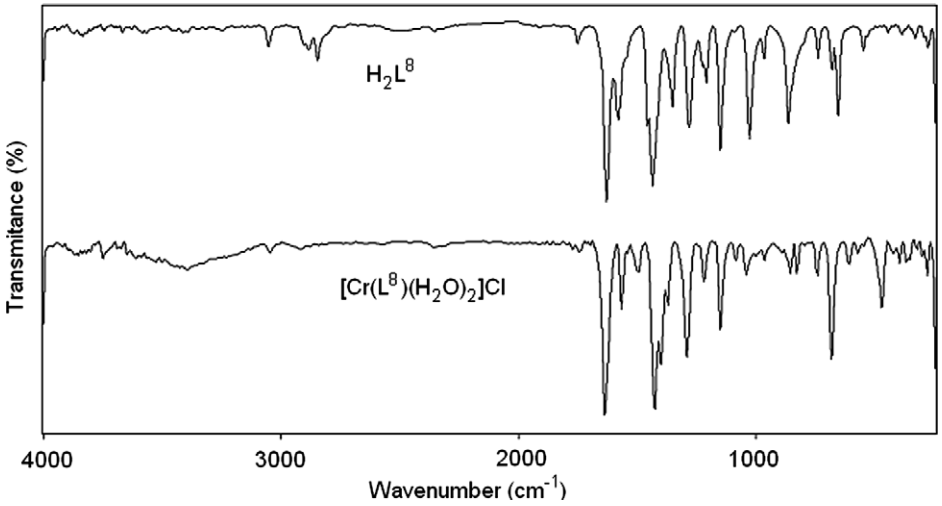


Fig. 3. IR spectra (250–4000 cm^{-1}) of H_2L^8 and $[Cr(L^8)(H_2O)_2]Cl$.

usually very strong. The ligands are relatively planar with adequate intramolecular distance that favors intramolecular hydrogen bond formation [47]. Electron-donating groups on the phenolic ring increase the electron density on the hydroxyl oxygen making the H–O bond stronger, the absorption usually appears as a broad band in the IR spectrum. For the chromium(III) complexes, the disappearance of this band is expected due to the substitution of hydrogen for the metal on the complex formation.

The C=N stretching frequencies are in the 1592–1640 cm^{-1} region as reported for similar ligands [48,49]. The ligands exhibit the characteristic C=N band in 1630–1646 cm^{-1} region, while the complexes the C=N were observed in the 1628–1638 cm^{-1} region. The C=N stretching frequency is generally shifted to a lower frequency, indicating a decrease in the C=N bond order due to the coordinate bond of the metal with the imine nitrogen lone pair [50,51].

In the 1500–1600 cm^{-1} region, the observed bands were attributed to aromatic C=C vibrations. On coordination these bands shift to lower frequencies for the chromium complexes of ligands H_2L^1, H_2L^7 and H_2L^8 and to higher frequencies for H_2L^2, H_2L^3, H_2L^4 and H_2L^6 [52].

The C–N stretching frequency has been reported [52–54] in the 1350–1410 cm^{-1} region. For the free ligands, the band occurs in the 1290–1310 cm^{-1}region and for the complexes, 1350–1390 cm^{-1} region. The C–O stretching frequency appears as a weak band within the 1290–1340 cm^{-1} range as reported for similar ligands [45,46,55]. This band occurs in the 1280–1300 cm^{-1} region for the free ligands and in the 1290–1310 cm^{-1} region for the complexes. The C–O stretching frequency is generally shifted to a higher frequency, indicating the formation of bond oxygen of phenolic group with the metal ion [50,51].

Evidence regarding the bonding of the chromium with the nitrogen and/or oxygen atom of the Schiff base is provided by the appearance of bands in the 250–600 cm^{-1} region. The band at 570–590 cm^{-1} is assigned to ν(Cr–O),

while band at 260–390 cm^{-1} is assigned to ν(Cr–N). These bands are observed as new peaks for the complexes and are not present in the spectrum of the free ligand. As pointed out by Percy and Thornton [55], the metal–oxygen and metal–nitrogen frequency assignments are at times very difficult.

3.2. Nuclear magnetic resonance spectra

The ^{1}H NMR spectra of the free ligands were recorded in $CDCl_3$ and DMSO-d_6. The chemical shifts, expressed in ppm downfield form tetramethylsilane, are given in Table 1. ^{1}H NMR spectra of similar Schiff base ligands have been reported [40,52,56–58]. The free ligands exhibit a broad peak between 14 and 12.5 ppm, which is due to hydrogen-bonded phenolic protons. This peak is due to hydrogen bonded phenolic protons [56,59–61] and the integration is generally less than 2.0 due to this intramolecular hydrogen bonding [40,61,45]. Signals for the methine protons of the azomethine group, –N=C(H)– were observed between 8.4 and 8.2 ppm. In the region of 7.6–6.8 ppm were assigned chemical shifts for hydrogen of the aromatic ring. The alkyl protons =N–CH_2–CH_2–N= were observed between 4.2 and 3.9 ppm. For H_2L^4, the signal for the –OCH_3 group was observed at 3.75 ppm.

The ^{13}C NMR spectra of the free ligands were recorded in $CDCl_3$ or DMSO-d_6. The chemical shifts, expressed in ppm downfield form tetramethylsilane, are given in Table 2. Our numbering system follows that of Fig. 1. The ^{13}C spectra allow an assignment of the peaks based on ^{13}C shifts in μ-oxobis(disalicyldeneiminato) complexes [40,62] and in similar tetradentate Schiff base ligands and their complexes [40,52]. The chemical shifts for carbon C(8) of =N–CH_2CH_2-N=, were recorded between 59.7 and 54.2 ppm. The signals for carbon C(7) from imine group –N=C(H)– were observed between 166.8 and 165.2 ppm with no noticeable influence of the substituent groups. The signal for C(OCH_3) of ligand H_2L^4 is 55.8 ppm.

[a] $CDCl_3$.
[b] DMSO-d_6.

Other chemical shifts are for the aromatic carbons and depend on the substituent group when compared to ligand H_2L^1 with hydrogens on C(3), C(4), C(5), and C(6). The signal for C(1) bonded to the imine group is observed between 118.3 and 122.0. This signal is the least affected by the substituent groups. The largest shift is only 3.4 ppm due the nitro group. The chemical shifts for the carbon C(2) bonded to the oxygen of the phenolic group were observed between 167.2 and 155 ppm. The methoxy group causes the greatest upfield shift of 6.0 ppm and the nitro group, the greatest downfield shift of 6.2 ppm when compared to hydrogen as the substituent. This is reasonable since methoxy is an electron donating group and nitro an electron withdrawing group and both being *para* to C(2).

The signal for C(3) varies between 92.6 and 121.2 ppm. The greatest effect occurs when iodine is bonded to this carbon. The nitro group, which is *meta* to this position, has the next largest effect. The presence of the substituent groups on C(3) and C(5) has a variable effect on the signal of C(4), which occurs between 119.4 and 149.0. When C (4) is *ortho* to methoxy, the signal suffers an upfield shift of 12.9 ppm and a downfield shift of 16.7 when *ortho* to two iodides in positions 3 and 5. The chemical shifts for the carbon C(5) also suffer a wide variation, from 109.4 for Br to 151.9 for MeO. All the substituents affect this signal. The signal of C(6) is most affected by the methoxy group *ortho* to this carbon.

All the substituents affect the chemical shifts of the aromatic carbons. For the mono-substituted ligands, the methoxy and nitro groups present the greatest influence. The methoxy group on C(5) causes a upfield shift of the signals of C(2), C(4), and C(6) and a downfield shift for C(5) in comparison with the ^{13}C spectrum of H_2L^1. The nitro group on C(5) causes a downfield shift of the signals of C(1), C(2), C(3) and C(5) and an upfield shift for C(4) and C(6). For the di-substituted ligands, the order of influence is I > Br > Cl.

3.3. Electronic spectra

The electronic spectra of the DMSO solutions of the free ligands, recorded in the 250–800 region, exhibit one or two bands. Bands due to the $n \rightarrow \pi^*$ transition of the C=C and C=N chromophores normally occur between 270 and 300 nm [63]. These bands shift to the red when the chromophores are in a conjugated system. These are observed as a shoulder only for H_2L^6, 289 nm; H_2L^7, 286 nm; and H_2L^8, 296 nm. The strong intramolecular hydrogen bond occurring in the Schiff base ligands may also account in part for the shift of these bands that occurs between 400 and 440 nm [64]. Molecular orbital calculations indicate that this band in the 400–440 nm region is an $n \rightarrow \pi^*$ transition type, involving the promotion of an electron of the free electron pair on the nitrogen to an antibonding π-orbital of imine group [64]. Another factor to be considered in the assignment of this transition is its absence in spectra of the corresponding complex as shown in Figs. 4 and 5.

The isolated benzene ring exhibits three characteristic absorptions at 184, 204 and 256 nm; all assigned to $\pi \rightarrow \pi^*$-type transitions [63]. Substitutions on the ring, by auxochromes and chromophores, shift this band to the red. The ligand band between 317 and 370 nm is assigned as a $\pi \rightarrow \pi^*$ transition involving molecular orbitals of C=N chromophore and the benzene ring [65]. Electron-donating

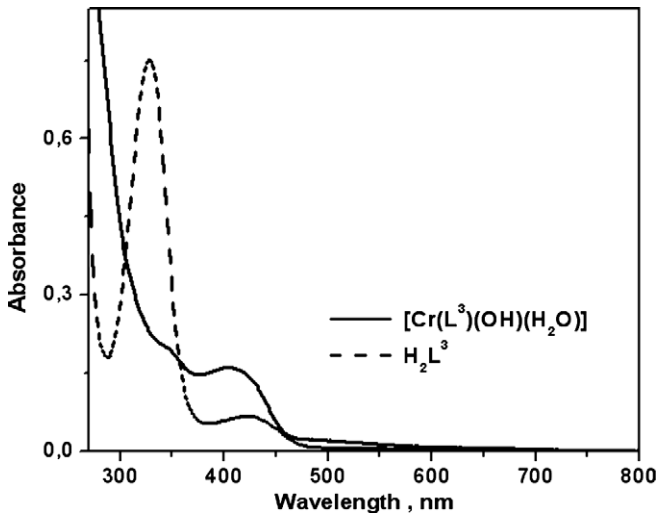

Fig. 4. Electronic spectra (260–800 nm) of H_2L^3 and $[Cr(L^3)(OH)(H_2O)]$ in DMSO.

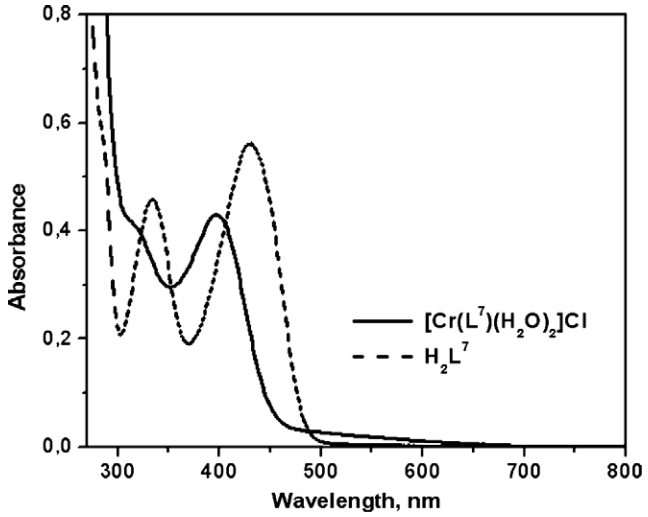

Fig. 5. Electronic spectra (260–800 nm) of H_2L^7 and $[Cr(L^7)(H_2O)_2]Cl$ in DMSO.

groups on the aromatic ring generally result in a bathochromic shift in all observed bands. The $\pi \rightarrow \pi^*$-type transition due to the C=N chromophore shifts to lower energies on complexation. In general, the $\pi \rightarrow \pi^*$-type transition due to the aromatic ring undergoes a similar smaller shift.

Another difference observed in the electronic spectra of the chromium(III) complexes, compared to the spectra of the corresponding free ligand, is associated with the appearance of a broad low intensity band at ca. 500 nm. This band is attributed to the d–d transitions of the chromium ion. These bands are of low molar absorptivity, ε, being Laporte 'forbidden' transitions. Another important characteristic is the absence of the $n \rightarrow \pi^*$ band. The formation of the metal–nitrogen bond stabilizes the electron pair on the nitrogen atom [64]. The appearance of a strong band between 390 and 430 nm is attributed to ligand-to-metal charge-transfer bands. These charge-transfer transitions probably occur form the π-orbitals of the Schiff bases to the d-orbitals of chromium.

The Gaussian/Lorentzian analysis of the visible portion, 11 760–25 000 cm^{-1} of the optical absorption spectrum yields three peaks, due to a symmetry that is less than octahedral in a six-coordinate complex. Each of the triply degenerate T terms is split into two new terms, an E and an A or B, with the result that six transitions are now expected instead of three [66,67]. For the chromium(III) complexes with C_{2v} symmetry six transitions I: $^4B_{1g} \rightarrow {}^4E_g(^4T_{2g})$; II: $^4B_{1g} \rightarrow {}^4B_{2g}(^4T_{2g})$; III: $^4B_{1g} \rightarrow {}^4E_g(^4T_{1g})$; IV: $^4B_{1g} \rightarrow {}^4A_{2g}(^4T_{1g})$; V: $^4B_{1g} \rightarrow {}^4A_{2g}(^4T_{1g}(P))$; VI: $^4B_{1g} \rightarrow {}^4E_g(^4T_{1g}(P))$ were proposed. The three transitions appear at higher energies and are covered by ligand-to-metal charge-transfer bands. Thus, only the three first transitions are calculated as shown in Fig. 6. The calculated values for the absorption maximum, the molar absorptivity, and the oscillator strength [68] for each peak are given in Table 3.

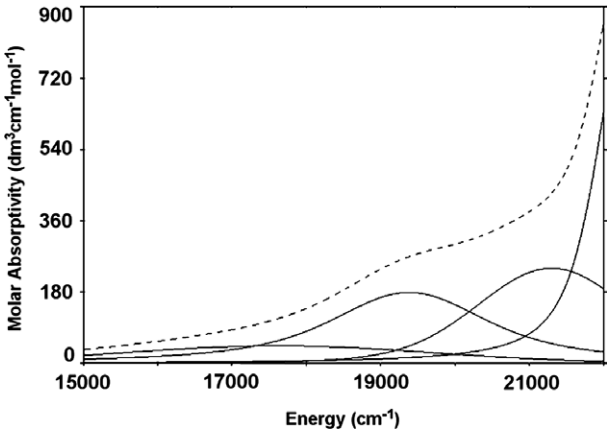

Fig. 6. Gaussian/Loretzian analysis of $[Cr(L^2)(OH)(H_2O)]$ for the DMSO electronic spectrum.

A consistent treatment for the bands is to assign the band near 15 600–17 600 cm^{-1} as the $^4B_{1g} \rightarrow {}^4E_g(^4T_{2g})$ transition; the band at ca. 18 400–20 400 cm^{-1} as the $^4B_{1g} \rightarrow$

Table 3
Gaussian/Loretzian band components for the visible spectra of the chromium(III) complexes in DMSO

Complexes	Band[a]	$\lambda_{max} \times 10^3$ (cm^{-1})	ε_{max} (dm^3 mol^{-1} cm^{-1})	Oscillator strength[b]

	III	22.52	204.3	5.27×10^{-3}

[a] Assignments I, $^4B_{1g} \rightarrow {}^4E_g(^4T_{2g})$; II, $^4B_{1g} \rightarrow {}^4B_{2g}(^4T_{2g})$; III, $^4B_{1g} \rightarrow {}^4E_g(^4T_{1g})$.
[b] Ref. [70].

$4B_{2g}(^4T_{2g})$ transition and that 20000–23100 cm^{-1} as the $^4B_{1g} \rightarrow {}^4E_g(^4T_{1g})$ transition.

3.4. Mass spectra

A preliminary study of ESI mass spectra of the free ligands and their corresponding complexes gave promising results. The negative ion ESI mass spectrum of the H_2L^1 ligand in DMSO showed the ion $[M-H]^-$ at 267 *m/z* and for H_2L^2 the ion $[M-H]^-$ at 425 *m/z*. The positive ion ESI mass spectrum of the H_2L^3 ligand in DMSO presented the ion $[M+H]^+$ at 338 *m/z* and for H_2L^5 the ion $[M+H]^+$ at 359 *m/z*. For both types of complexes, $[Cr(L)(OH)(H_2O)]$ or $[Cr(L)(H_2O)_2]$ Cl, the results indicated the presence of the $[Cr(L^n)(DMSO)_2]^+$ ion in DMSO solution. The positive ion ESI mass spectrum of the $[Cr(L^1)]^+$ complex showed an ion at 474 *m/z* corresponding to $[Cr(L^1)(DMSO)_2]^+$; for $[Cr(L^2)]^+$, an ion at 633 *m/z*, $[Cr(L^2)(DMSO)_2]^+$; for $[Cr(L^3)]^+$, an ion at 543 *m/z*, $[Cr(L^3)(DMSO)_2]^+$ and for $[Cr(L^5)]^+$, an ion at 564 *m/z*, $[Cr(L^5)(DMSO)_2]^+$. Such coordination of solvent molecules to the central metal atom in the ESI process has been reported [69,70]. A detailed study of the complexes including a study of the daughter ions of $[Cr(L^n)(DMSO)_2]^+$ complex will be undertaken to determine the behavior of fragmentations of these compounds.

4. Conclusions

A series of symmetrical tetradentate Schiff bases containing the N_2O_2 donor set and their corresponding chromium(III) complexes have been synthesized and spectrally characterized. The same synthetic procedure gives two series of complexes depending on the amount and rate of addition of potassium carbonate used to deprotonate the Schiff base. The initial mass spectra study indicates that for the two series of complexes in DMSO that the same species, $[Cr(L^n)(DMSO)_2]^+$ is present.

Acknowledgements

Financial support from the Conselho Nacional de Desenvolvimento Cientifico e Tecnológico, CNPq, and the Fundação de Amparo à Pesquisa do Estado de São Paulo, FAPESP, is gratefully acknowledged. We thank FAPESP for providing an undergraduate scholarship to P.E.A. and the CNPq for graduate scholarships to M.P. dos S. and S.R. We thank Prof. Alzir A. Batista for the use of the magnetic susceptibility balance and Dr. Gustavo Von Poelhsitz for his help with these measurements.

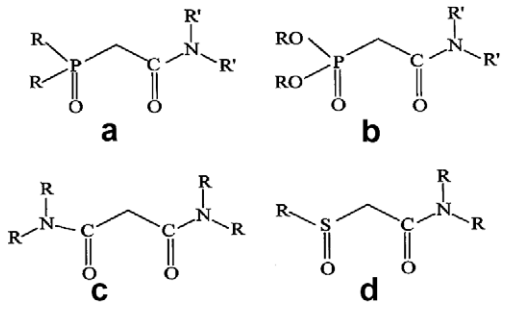

Fig. 1. Different bi-functional ligands: (a) CMPO; (b) CMP; (c) malanonamide and (d) CMSO.

[28a] and $[UO_2(DBM)_2 \cdot 2H_2O]$ [28b] (DBM = $C_6H_5COCHCOC_6H_5$) were prepared according to the reported methods. FTIR spectra were recorded on a JASCO-610 spectrometer and the samples were mounted as nujol mulls. The ^1H NMR spectra were recorder on Brucker AC-300 or 500 MHz spectrometers and the peaks were calibrated with respect to an internal $CHCl_3$ peak. The Analytical Chemistry Division of Bhabha Atomic Research Center, Mumbai, performed the elemental analysis.

2.1. Synthesis of $[UO_2(DBM)_2C_6H_5CH_2SOCH_2CONHC_6H_5]$ (1)

To a solution of $[UO_2(DBM)_2 \cdot 2H_2O]$ (300 mg, 0.408 mmol) in chloroform, $C_6H_5CH_2SOCH_2CONHC_6H_5$ was added (111.6 mg, 0.408 mmol) and refluxed for 5 h. The solution was filtered, layered with dodecane and allowed to evaporate slowly overnight. The orange colored product obtained was filtered, washed with hexane and dried. Yield: 370 mg (91.5%). Elemental *Anal.* Calc. (%) for $[UO_2(DBM)_2C_6H_5CH_2SOCH_2CONHC_6H_5]$; $C_{45}H_{37}O_8SNU$: C, 54.6: H, 3.7; N, 1.4. Found: C, 54.4; H, 3.8; N, 1.2%. IR (KBr, ν cm^{-1}): 3350 (NH), 1674 (CO of CMSO), 1590 (CO of DBM), 1007 (SO), 904 (O=U=O); ^1H NMR ($CDCl_3$, δ ppm): 3.58 (d, 14 Hz, 1H, OS–CH_2–CO), 4.08 (d, 14 Hz, 1H, OS–CH_2–CO), 4.66 (br, 2H, –CH_2–SO–), 7.09–8.43 (m, 33H, C_6H_5 + CH + NH).

2.2. Synthesis of $[UO_2(DBM)_2C_6H_5SOCH_2CON^iPr_2]$ (2)

This was prepared similar to **1** by taking $UO_2(DBM)_2 \cdot 2H_2O$] and $C_6H_5SOCH_2CON^iPr_2$in a 1:1 ratio and the final orange colored product was recrystallized from a $CHCl_3$/iso-octane mixture as an orange colored powder. Yield: 91%. Elemental *Anal.* Calc. (%) for $[UO_2(DBM)_2C_6H_5SOCH_2CON^iPr_2]$; $C_{44}H_{43}O_8SNU$: C, 53.7; H, 4.4; N, 1.4. Found: C, 54.0; H, 4.1; N, 1.0%. IR (KBr, ν cm^{-1}): 1640 (CO of CMSO), 1590 (CO of DBM), 990 (SO), 906 (O=U=O); ^1H NMR ($CDCl_3$, δ ppm): 0.87 (d, 6 Hz, 3H, CH_3), 1.26 (d, 6 Hz, 3H, CH_3), 1.67 (m, 6H, CH_3), 3.48 (m, 2H, CH), 4.29 (d, 14 Hz, 1H, OS–CH_2–CO), 4.87 (d, 14 Hz, 1H, OS–CH_2–CO), 7.23 (s, CH, 2H, DBM), 7.43–8.48 (br, m, 25H, C_6H_5).

2.3. Synthesis of $[\{UO_2(DBM)_2\}_2C_6H_5CH_2SOCH_2CONHC_6H_5]$ (3)

This was prepared by taking 2 equiv. of $[UO_2(DBM)_2 \cdot 2H_2O]$ (300 mg, 0.408 mmol) and 1 equiv. of $C_6H_5CH_2SOCH_2CONHC_6H_5$ (55.8 mg, 0.204 mmol). The final orange colored product was recrystallized from $CHCl_3$/iso-octane as a red-orange crystalline solid. Yield: 315 mg (90.4%). Elemental *Anal.* Calc. (%) for $[\{UO_2(DBM)_2\}_2C_6H_5CH_2SOCH_2CONHC_6H_5]$; $C_{75}H_{59}O_{14}SNU_2$: C, 52.7; H, 3.5; N, 0.8. Found: C, 52.4; H, 3.7; N, 0.9%. IR (KBr, ν cm^{-1}): 3255 (NH), 1638 (CO of CMSO), 1590 (CO of DBM), 999 (SO), 914 (O=U=O); ^1H NMR ($CDCl_3$, δ ppm): 3.81 (d, 12 Hz, 1H, OS–CH_2–CO), 4.31 (d, 12 Hz, 1H, OS–CH_2–CO), 4.64 (br, 2H, –CH_2–SO), 6.98–8.42 (m, 55H, C_6H_5 + CH + NH).

2.4. Synthesis of $[\{UO_2(DBM)_2\}_2C_6H_5SOCH_2CON^iPr_2]$ (4)

This was prepared similarly to **3** by taking 2 equiv. of $[UO_2(DBM)_2 \cdot 2H_2O]$ and 1 equiv. of $C_6H_5SOCH_2CON^iPr_2$, and the final product was recrystallized from a $CHCl_3$/iso-octane mixture as an orange colored powder. Yield: 87%. Elemental *Anal.* Calc. (%) for $[\{UO_2(DBM)_2\}_2C_6H_5SOCH_2CON^iPr_2]$; $C_{74}H_{65}O_{14}SNU_2$: C, 52.2; H, 3.8; N, 0.8. Found: C, 52.0; H, 4.0; N, 0.7%. IR (KBr, ν cm^{-1}): 1600 (CO of CMSO), 1590 (CO of DBM), 990 (SO), 905 (O=U=O); ^1H NMR ($CDCl_3$, δ ppm): 1.07 (d, 6 Hz, 3H, CH_3), 1.27 (d, 6 Hz, 3H, CH_3), 1.92 (m, 6H, CH_3), 3.55 (m, 2H, CH), 4.61 (d, 13 Hz, 1H, OS–CH_2–CO), 5.02 (d, 12 Hz, 1H, OS–CH_2–CO), 7.20 (s, 4H, CH, DBM) 7.5–8.41 (br, m, 45H, C_6H_5).

2.5. Solvent extraction studies

Distribution studies were performed by using a pre-equilibrated solution of HTTA (thenoyl trifluoroacetone), CMSO ($C_6H_5SOCH_2CONBu_2$) and a HTTA + CMSO mixture in toluene (pre-equilibrated with 1 M HNO_3) with the required aqueous phase (0.02 M HNO_3 + 0.1 M $NaNO_3$) spiked with a ^{233}U tracer in a thermostated water bath for 1 h at 25 ± 0.1 °C. Assays of organic and aqueous phases were done in duplicate by alpha counting using a dioxane based liquid scintillator. The distribution ratio (D) is defined as the ratio of the concentration of uranium in the organic phase to that of the aqueous phase.

2.6. X-ray diffraction studies of 3

The X-ray diffraction data for compound **3** were collected on a Siemens SMART CCD diffractometer fitted with graphite monochromated Mo Kα radiation (λ = 0.71073 Å) at 297(2)°. Data collection, indexing and initial cell refinement were handled using SMART software [33]. Frame integration and final cell refinement were carried out using SAINT software [34]. The SADABS software

$w = 1/[\sigma_2(F_o^2) + (0.0513P)^2 + 5.3717P]$; $P = (F_o^2 + 2F_c^2)/3$ for **3**.

[35] package was used to perform the absorption corrections. The structures were solved by direct methods, completed by subsequent difference Fourier syntheses and refined by full-matrix least-squares procedures on F^2 using SHELXTL [36] version 5.1. The non-hydrogen atoms were refined anisotropically. The hydrogen atoms were refined with geometrical constraints with ideal bond lengths and angles, and were treated as riding atoms. All computations were carried out on a PC using the SHELXTL-PC program package. Selected crystallographic and refinement details are given in Table 1.

3. Results and discussion

3.1. Complexation study of $C_6H_5CH_2SOCH_2CONHC_6H_5$ and $C_6H_5SOCH_2CON^iPr_2$ with uranyl bis(β-diketonate) (1:1 compounds)

The reaction of $C_6H_5CH_2SOCH_2CONHC_6H_5$ or $C_6H_5SOCH_2CON^iPr_2$ with uranyl bis(β-diketonate) in a 1:1 ratio yielded **1** or **2**. IR spectra of the compounds show that the ligand is bonded only through the sulfoxo oxygen atom to the uranyl group ($\Delta\nu_{co}$ is close to zero, $\Delta\nu_{co} = \nu_{\text{free ligand}} - \Delta\nu_{\text{complex}}$, see Supplementary material) and acts as a monodentate ligand. The observed frequency differences for the sulfoxo groups ($\Delta\nu_{SO} = 11\ cm^{-1}$ and 48 cm^{-1} for **1** and **2** respectively) agree well with the supposition that the sulfoxo group is bonded to the uranyl group directly [28,37,38] in the reported compounds. ^{1}H NMR spectra of **1** and **2** also support the IR spectral observations by showing downfield shifts (ca $\Delta\delta = 0.45$ ppm for $C_6H_5CH_2$ of **1** and 0.27–0.35 and 0.59–0.84 ppm for $SOCH_2CO$ of **1** and **2** respectively, $\Delta\delta = \delta_{\text{free ligand}} - \delta_{\text{complex}}$) for the CH_2 protons adjacent to the sulfoxo group. We could not get suitable crystals for **1** and **2** to confirm our spectroscopic observations.

3.2. Complexation study of $C_6H_5CH_2SOCH_2CONHC_6H_5$ and $C_6H_5SOCH_2CON^iPr_2$ with uranyl bis(β-diketonate) (1:2 compounds)

The 1:2 reaction of $C_6H_5CH_2SOCH_2CONHC_6H_5$ or $C_6H_5SOCH_2CON^iPr_2$ with uranyl bis(β-diketonate) yielded **3** or **4**. IR spectra of the compounds show that the CMSO ligand is bonded through both the sulfoxo and carbamoyl oxygen atoms to the uranyl group. The observed frequency differences for the sulfoxo ($\Delta\nu_{SO} = 19\ cm^{-1}$ for **3** and 48 cm^{-1} for **4**) [28,37,38] and carbamoyl ($\Delta\nu_{CO} = 36\ cm^{-1}$ for **3** and 42 cm^{-1} for **4**) [14–28] groups agree well with the supposition that the sulfoxo and carbamoyl groups are bonded to the uranyl group directly in the reported compounds. The ^{1}H NMR spectra of **3** and **4** also support the coordination of both the sulfoxo and carbamoyl oxygen atoms to the uranyl group by showing downfield shifts for the CH_2 protons adjacent to the donor groups SO and CO ($C_6H_5CH_2SO$ and $SOCH_2CO$). It is interesting to note that the coordination chemical shifts ($\Delta\delta = \delta_{\text{free ligand}} - \delta_{\text{compound}}$) for the CH_2 protons of the $C_6H_5CH_2SO$ group in **1** and **3** are almost same (0.45 and 0.43 ppm respectively) and those of the $SOCH_2CO$ group are different (0.27–0.35 and 0.50–0.58 ppm respectively, see Supplementary material). The compounds **2** and **4** (0.59–0.84 and 0.91–1.01 ppm respectively for **2** and **4**) also show similar results for the $SOCH_2CO$ protons. The structure for compound **3** was determined by single crystal X-ray diffraction methods and shows a bridging bidentate mode of bonding for the CMSO ligand.

3.3. Molecular structure of 3

The molecular structure of **3** is given in Fig. 2 (there is a solvent molecule in the crystal lattice which is not shown in the figure for clarity) and selected interatomic bond distances and angles are given in Table 2. The structure shows that the CMSO ligand $C_6H_5CH_2SOCH_2CONHC_6H_5$ is bonded through both sulfoxo and carbamoyl oxygen atoms to two different uranyl bis(β-dibenzoyl methanate) units and acts as a bridging bidentate ligand. The observed uranium to sulfoxo oxygen distance [U–O(S), 2.402(5) Å] is slightly longer compared to those observed in $[UO_2(DBM)_2PhCH_2SOCH_3]$ (2.375(6) Å) [39] and $[UO_2(NO_3)_2(^iPrO)_2POCH_2SO(p\text{-}MeC_6H_4)]$ (2.36(2) Å) [20] and shorter compared to those observed in $[UO_2(NO_3)_2C_6H_5SOCH_2CONBu_2]$ (2.442(9) Å) [28] and $[UO_2(DBM)_2PhSOPh]$ (2.427(6) Å) [40]. The U–O (amide) distance (2.492(5) Å) is longer in magnitude compared to those observed in $[UO_2(NO_3)_2Ph(EtO)POCH_2CONEt_2]$ (2.426(8) Å), $[UO_2(NO_3)_2Ph_2POCH_2CONEt_2]$ (2.404(5) Å) [17], $[UO_2(NO_3)_2{}^iPr_2NCOCH_2CON^iPr_2]$ (2.41(2) Å) [27] and $[UO_2(NO_3)_2C_6H_5SOCH_2CONBu_2]$ (2.408(9) Å) [28] and comparable with

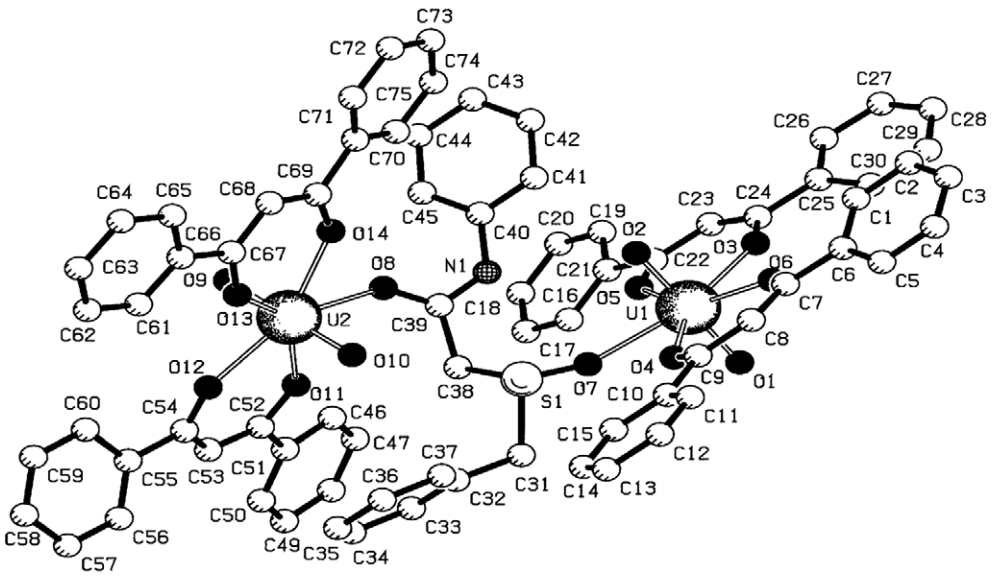

Fig. 2. Molecular structure of $[\{UO_2(DBM)_2\}_2C_6H_5CH_2SOCH_2CONHC_6H_5]$.

Table 2
Selected interatomic bond distances (Å) and angles (°) for **3**

U1–O1	1.783(5)	U1–O2	1.766(5)	U1–O3	2.296(5)
U1–O4	2.368(5)	U1–O5	2.398(5)	U1–O6	2.336(5)
U1–O7	2.402(5)	U2–O8	2.492(5)	U2–O9	1.774(6)
U2–O10	1.778(6)	U2–O11	2.350(6)	U2–O12	2.324(6)
U2–O13	2.340(6)	U2–O14	2.325(5)		
O1–U1–O2	178.1(2)		O3–U1–O4		71.25(18)
O4–U1–O7	74.57(17)		O7–U1–O5		70.23(16)

O12–U2–O13	74.3(2)		O13–U2–O14		71.0(2)
O14–U2–O8	71.8(2)		O8–U2–O11		72.5(2)

those observed in $[\{UO_2(DBM)_2\}_2C_6H_5NHCOCH_2CONHC_6H_5]$ (2.495(7) Å) [41]. The average bond distances for U–O (β-diketonate) [2.349(5) Å for U1 and 2.334(6) Å for U2] [39–41] and U=O (uranyl) [1.774(5) Å for U1 and 1.776(6) Å for U2] [14–28,39–41] are normal. The whole molecule is stabilized in the solid state by various intra [N1–H1···O5, 3.084(7) Å, 155.67°; N1–H1···O7, 3.175(8) Å, 126.78°] and inter [C11–H11···O10, 3.374(10) Å, 154.26°; C59–H59···O9, 3.501(10) Å, 169.38°; C73–H73···O2, 3.386(10) Å, 143.91°] molecular hydrogen bonding interactions to give a polymeric arrangement in the solid state.

3.4. Extraction studies on U(VI) with HTTA and $C_6H_5SOCH_2CONBu_2$

Extraction studies for the uranyl ion in the tracer level by using a mixture of HTTA (thenoyl trifluoroacetone) and CMSO ($C_6H_5SOCH_2CONBu_2$) were carried out to explore the possibility of separation from nitric acid medium. The distribution ratio data for the uranyl ion from nitric acid medium with various concentrations of CMSO at a constant HTTA concentration of 0.1 F is shown in Fig. 3. This shows clearly that CMSO or HTTA alone did not show any appreciable extraction for the uranyl ion (D_U for 0.1 F HTTA is 0.062 and for 0.01 F CMSO is negligible) under the conditions studied. However, it shows an appreciable extraction when a mixture was employed ($D_U = 3.2$ when a mixture of 0.1 F HTTA + 0.01 F CMSO was used).

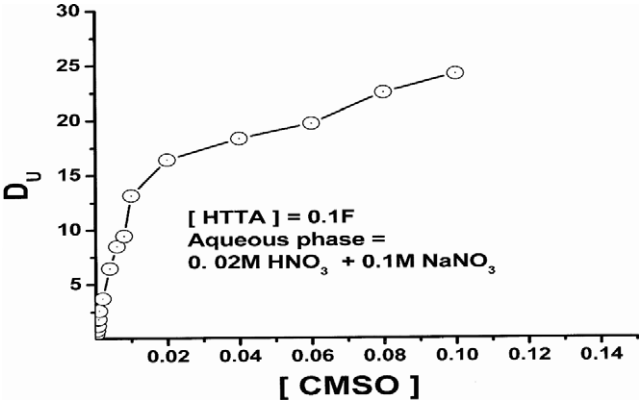

Fig. 3. Variation of D_U with [CMSO] at constant [HTTA].

In order to establish the nature of the species extracted during the solvent extraction process, the distribution ratios were measured as a function of CMSO and HTTA at constant HTTA and CMSO respectively in the linear region of the curve. The plots of $\log D_U$ versus log[HTTA] at constant [CMSO] and $\log D_U$ versus log[CMSO] at constant [HTTA] are given in Figs. 4 and 5 respectively (see Supplementary material). These plots show that the slopes of the straight lines obtained were found to be closer to **2** and **1** respectively for HTTA and CMSO. These results suggest that the species extracted under the conditions studied has the composition $[UO_2(TTA)_2 \cdot CMSO]$ in the

organic phase, which is in agreement with the reported studies [42,43].

4. Conclusions

Complexation studies of CMSO with uranyl bis(β-diketonate) show that it acts as a monodentate ligand in 1:1 compounds and bonds through the sulfoxo oxygen atom to the uranyl group. It shows further that CMSO acts as a bridging bidentate ligand in 1:2 compounds and bonds through both the sulfoxo and carbamoyl oxygen atoms to two different uranyl bis(β-diketonate) units. Extraction studies show that there is an enhancement in the extraction of the uranyl ion from nitric acid medium when a mixture of CMSO and HTTA are used.

Acknowledgements

We wish to thank the Head, Analytical Chemistry Division, BARC for carbon, hydrogen and nitrogen analysis, the Head, National NMR facilities, TIFR, Mumbai for NMR spectra and the Head, Fuel Chemistry Division, BARC for his support. H.K.F would like to thank the Malaysian Government and Universiti Sains Malaysia for research grant R&D No. 305/pfizik/610961. A.U. thanks the Universiti Sains Malaysia for a visiting Post-Doctoral Fellowship.

Appendix A. Supplementary material

CCDC 205003 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge via htpp://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2006.11.019.

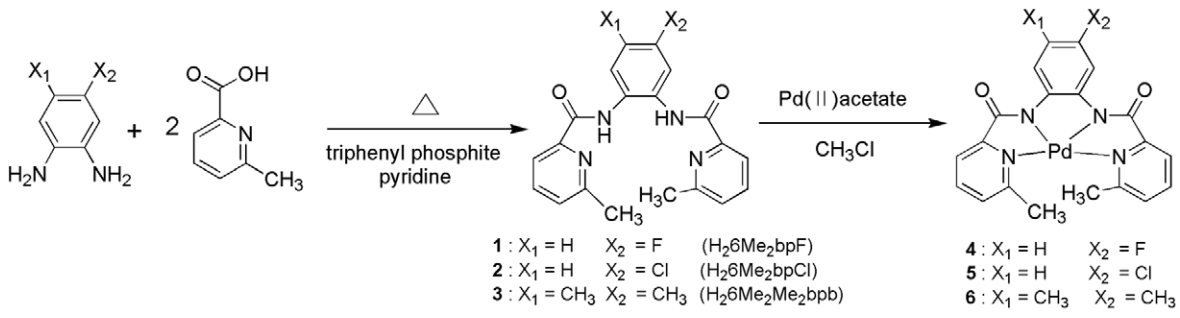
rigid and N4-tetradentate ligand, shows unprecedented reactivity towards Suzuki–Miyaura cross-coupling reactions under mild conditions, whilst N4-type saturated Pd complexes have never been used for C–C coupling reactions.



2. Experimental

2.1. General

Elemental analysis for carbon, nitrogen and hydrogen was carried out using an EA1108 (Carlo Erba Instrument, Italy) in the Organic Chemistry Research Center of Sogang University, Korea. Product analyses for the Suzuki–Miyaura cross-coupling reaction were performed on either a Hewlett–Packard 5890 II Plus gas chromatograph interfaced with Hewlett–Packard Model 5989B mass spectrometer or a Donam Systems 6200 gas chromatograph equipped with a FID detector using a 30-m capillary column (Hewlett–Packard, HP-1, HP-5 and Ultra 2). Diamines, 6-methyl-2-picolinic acid, and triphenylphosphite were purchased from Aldrich and were used as received.

2.2. Syntheses of ligands *1*, *2* and *3* and of complexes *4*, *5* and *6*

Ligands **1** ($6Me_2bpF$) and **2** ($6Me_2bpCl$) were prepared by the reactions of the appropriate diamines (10 mmol) with 6-methyl-2-picolinic acid (20 mmol) in pyridine in the presence of triphenylphosphite (20 mmol), according to the literature method [5]. For **1**, ^{1}H NMR ($CDCl_3$, 300 MHz) δ: 2.42 (s, 3H, CH_3), 2.62 (s, 3H, CH_3), 6.88–8.22 (m, 9H, aromatic-H), 10.08 (s, 1H, N–H), 10.58 (s, 1H, N–H). IR (KBr): ν(N–H) 3299 and ν(C=O) 1686 cm^{-1}. *Anal.* Calc. for $C_{20}H_{17}FN_4O_2$ (364.36): C, 65.92; H, 4.71; N, 15.38. Found: C, 66.03; H, 4.55; N, 15.12%. For **2**, ^{1}H NMR ($CDCl_3$, 300 MHz) δ: 2.46 (s, 6H, $2CH_3$), 6.32–8.11 (m, 8H, aromatic-H), 10.34 (s, 2H, 2N–H). IR (KBr): ν(N–H) 3274 and ν(C=O) 1688 cm^{-1}. *Anal.* Calc. for $C_{20}H_{17}ClN_4O_2$ (380.83): C, 63.07; H, 4.51; N, 14.72. Found: C, 63.25; H, 4.32; N, 14.73%. Ligand **3** ($6Me_2Me_2bpb$) was obtained as in the previous study [5]. Complexes **4**–**6** were obtained from the reaction of each ligand (0.5 mmol) with palladium(II) acetate (0.11g, 0.5 mmol) in CH_3Cl (20 mL) in good yields. Crystals of

Scheme 1. Syntheses of the ligands and their Pd complexes.

the complexes **4**–**6** were grown by slowly evaporating their solutions in CH_3CN/ether. For **4** (Pd(6Me$_2$bpF)), ^{1}H NMR (DMSO-d_6, 300 MHz) δ: 2.52 (s, 6H, 2CH_3), 6.71–8.18 (m, 9H, aromatic-H). IR (KBr): ν(C=O) 1630 cm^{-1}. *Anal*. Calc. for $C_{22}H_{20}N_4O_2Pd$ (478.82): C, 55.18; H, 4.22; N, 11.70. Found: C, 54.98; H, 4.00; N, 11.91%. For **5** (Pd(6Me$_2$bpCl)), IR (KBr): ν(C=O) 1635 cm^{-1}. *Anal*. Calc. for $C_{22}H_{20}N_4O_2Pd$ (478.82): C, 55.18; H, 4.22; N, 11.70. Found: C, 54.97; H, 4.20; N, 11.64%. For **6** (Pd(6Me$_2$Me$_2$bpb)), ^{1}H NMR (DMSO-d_6, 300 MHz) δ: 2.13 (s, 6H, 2CH_3), 7.64–8.13 (m, 8H, aromatic-H). IR (KBr): ν(C=O) 1623 cm^{-1}. *Anal*. Calc. for $C_{22}H_{20}N_4O_2Pd$ (478.82): C, 55.18; H, 4.22; N, 11.70. Found: C, 55.16; H, 4.33; N, 11.75%.

2.3. Catalytic activity of compound 5

Catalytic reaction conditions: Under air atmosphere, aryl halide (25 mM, 0.1 mmol) was added to a mixture of aryl boronic acid (50 mM, 0.2 mmol), catalyst **5** (0.1 mM, 4×10^{-4} mmol) and K_3PO_4 (50 mM, 0.2 mmol) in ethanol at room temperature. The reaction mixture was agitated in a shaking incubator at 50 °C. Conversions and yields were determined by GC/Mass analysis of 20 μL aliquots

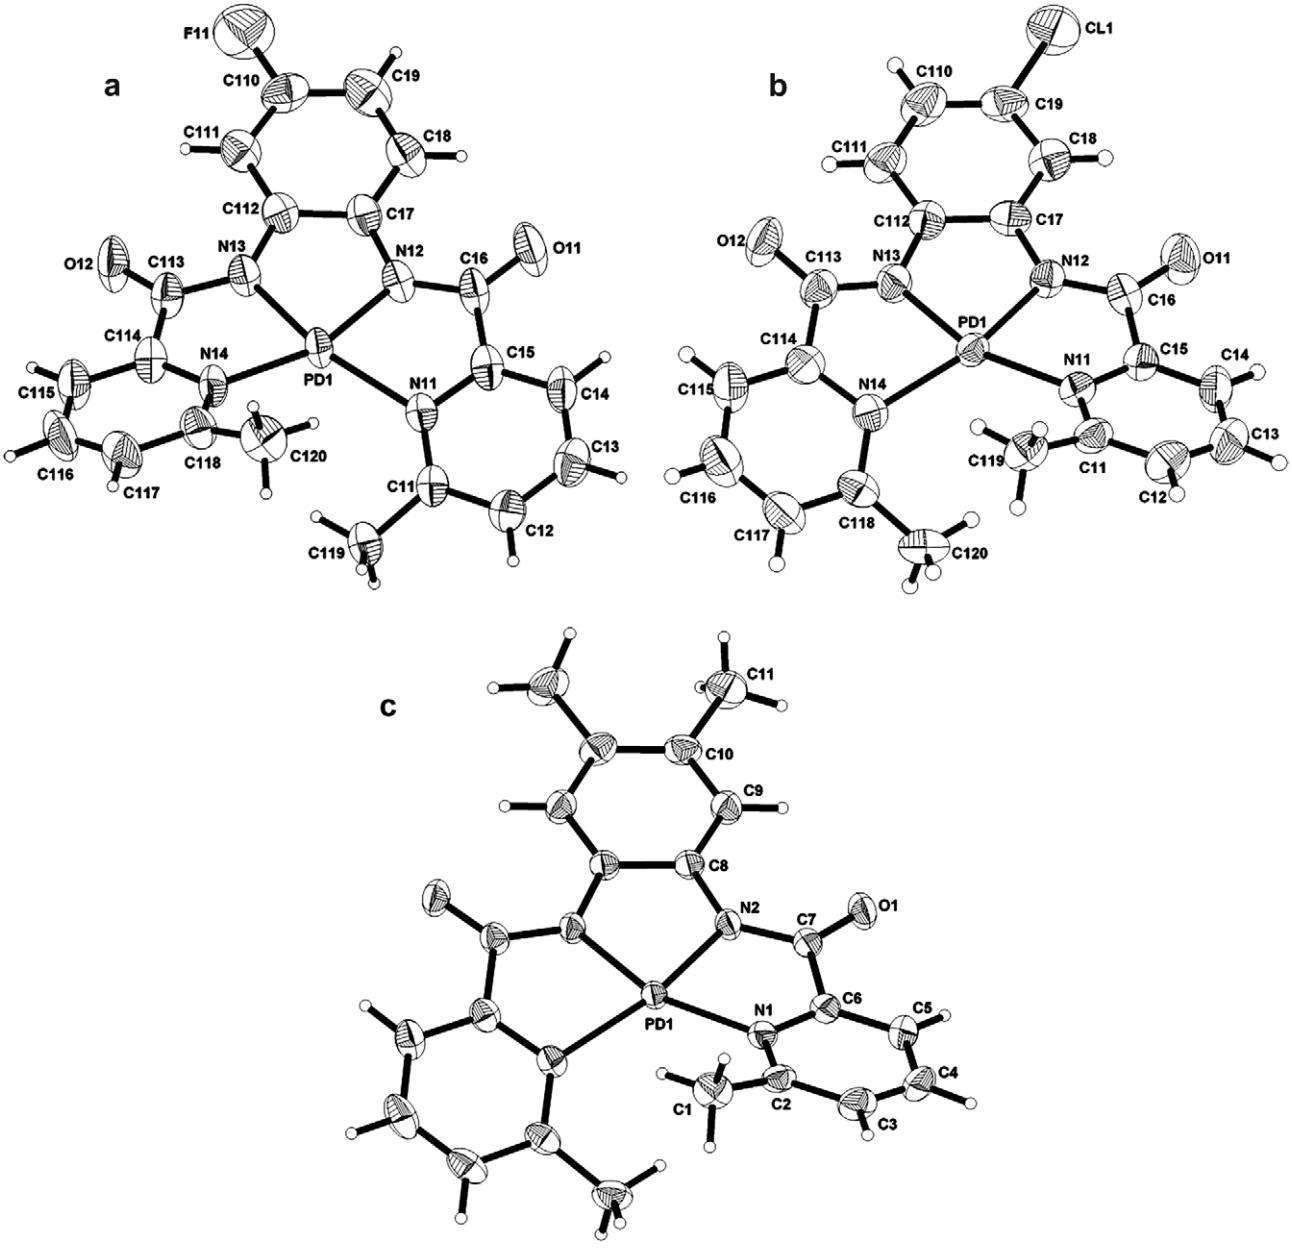


Fig. 1. Building blocks for compounds **4** (a), **5** (b) and **6** (c). Only one unit for each compound is present, but there are four independent Pd complex units in compound **4** and three independent Pd complex units in compound **5**.

withdrawn periodically from the reaction mixture, using an internal standard (dodecane). Control reactions carried out in the absence of the catalysts showed trace amounts of conversion of the reactant to the corresponding product in the same time period.

2.4. X-ray crystallography

The X-ray diffraction data for all three compounds were collected on a Bruker SMART APX diffractometer equipped with a monochromater in the Mo Kα ($\lambda = 0.71073$ Å) incident beam. Each crystal was mounted on a glass fiber. The CCD data were integrated and scaled using the Bruker-SAINT software package, and the structures were solved and refined using SHEXTL V6.12 [6]. All hydrogen atoms were placed in calculated positions. The crystallographic data for compounds **4**, **5** and **6** are listed in Table 1.

3. Results and discussion

Ligands **1**–**3** were prepared in good yields (40–60%) by the reactions between the appropriate diamines with 6-methyl-2-picolinic acid in pyridine (Scheme 1) according to the literature method [5] or its modified method. Complexes **4** and **5** were obtained from the reactions of ligands **1** and **2**, respectively, with palladium(II) acetate in CH_3Cl in excellent yields and their structures were determined by X-ray crystallography. We also prepared a Pd(II) complex **6** containing the non-halogen and dimethyl-substituted

ligand ($6Me_2Me_2bpb$) for comparison to compounds **4** and **5**.

All three compounds **4**, **5** and **6** contain simple building blocks that are four-coordinated Pd(II) complex units (Fig. 1). The four nitrogen atoms of the ligands coordinate to the Pd(II) ions to form mononuclear complex building blocks, and selected bond distances and angles are listed in Tables 2–4 for compounds **4**, **5** and **6**, respectively. The molecules are much distorted from square planar because of steric hindrance of the methyl groups of the pyridyl rings. The torsion angles of C11–N11–Pd1–N14, C21–N21–Pd2–N24, C31–N31–Pd3–N34 and C41–N41–Pd4–N44 for compound **4** are −17.5(5)°, −26.3(5)°, 34.0(6)° and −33.8(6)°, respectively. The torsion angles of C11–N11–Pd1–N14, C21–N21–Pd2–N24 and C31–N31–Pd3–N34 for compound **5** are −17.6(5)°, 24.2(5)° and −31.0(5)°, respectively. The torsion angle of C2–N1–Pd1–N1#1 for compound **6** is −23.57 (17)°. In compound **4**,

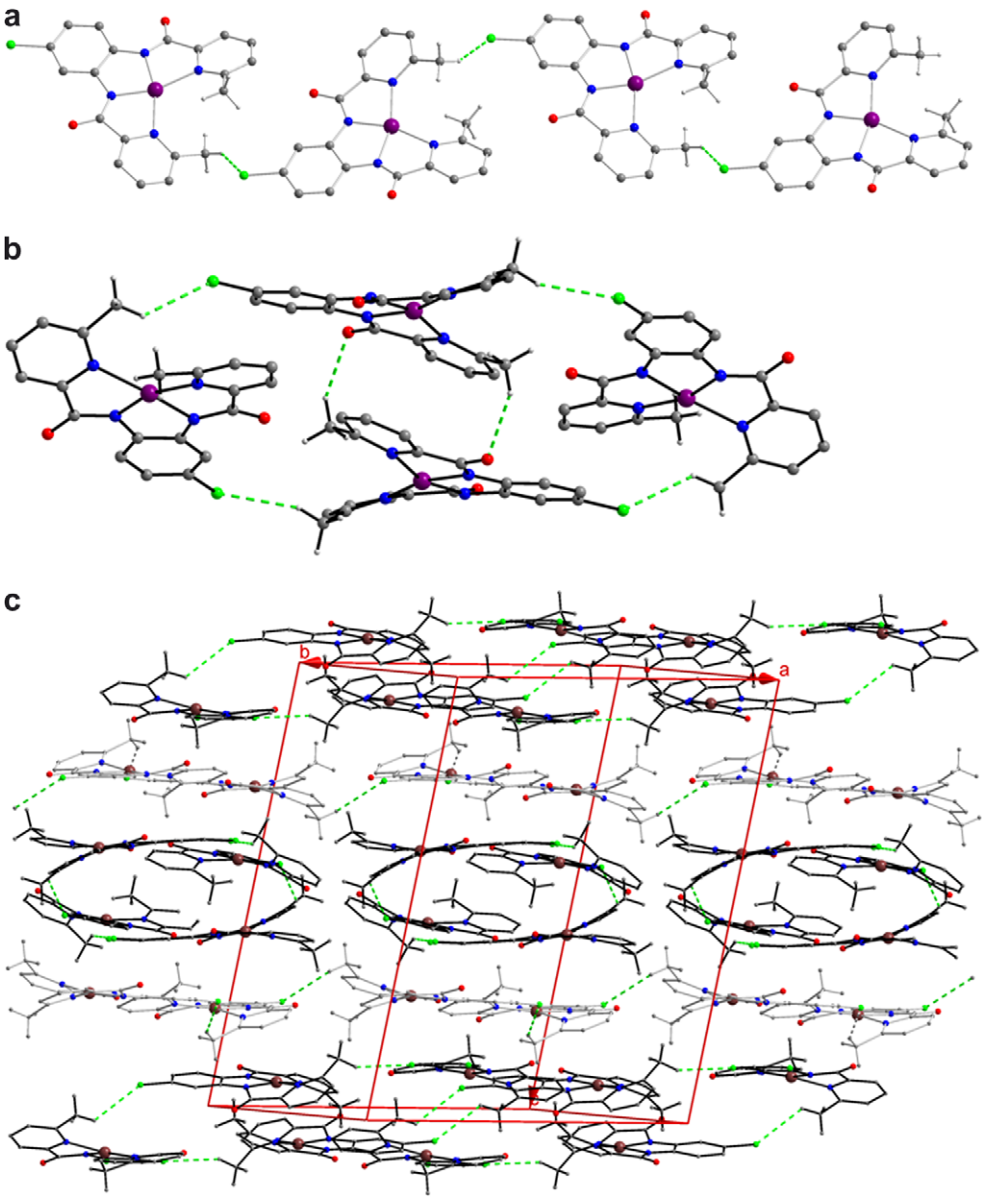
there are four independent Pd(II) complex building units, and Pd(1) and Pd(2) complex units are connected altenatively by C(methyl)–H···F–C intermolecular interactions to form one-dimensional chains, and Pd(3) and Pd(4) complex units are also connected by C(methyl or pyridyl)–H···F–C intermolecular interactions to produce two-dimensional zigzag sheets. These Pd(1)–Pd(2) chains and Pd(3)–Pd(4) zigzag sheets are stacked by weak C–H···F–C interactions as shown in Fig. 2 (Tables 2 and 5). Only C(methyl)–H···F–C interactions contribute to the construction of compound **4** even though C=O acceptor groups coexist. In compound **5** there are three independent Pd(II) complex building units, and Pd(1) complex units are connected by weak C(methyl)–H···Cl–C interactions to form a one-dimensional chain. Pd(2) and Pd(3) complex units are connected by both C–H···Cl–C and C(methyl)–H···O=C interactions to form Pd(2)–Pd(3)–Pd(2)–Pd(3) tetranuclear rings. These Pd(1) chains and Pd(2)–Pd(3)–Pd(2)–Pd(3) rings are stacked alternatively as shown in Fig. 3 (Tables 3 and 5). The C–Cl sites do compete with C=O groups, and both C–H···Cl–C and C–H···O=C interactions do contribute to the crystal structure in compound **5**. In compound **6**, there is no halogen atom for intermolecular C–H···X–C interactions, and instead there is C(pyridyl)–H···O=C hydrogen bonding. The carbonyl oxygen atoms interact with a methyl hydrogen atom and with a pyridyl hydrogen atom of the neighbouring molecule to form a two-dimensional compound as shown in Fig. 4 (Tables 4 and 5).

Usually, it is well known that the ''organic fluorine'', C–F groups cannot form hydrogen bonds if there coexist O and N atom acceptors in the molecule, in spite of the high electronegativity of the F atom [4]. As we have shown above, however, C–H···F–C interactions contribute exclusively to the crystal structure of Pd(II) compound **4** in the presence of stronger C=O hydrogen acceptor groups, suggesting that the F atom does not act like ''organic fluorine'' in our Pd complex. In addition, in the case of compound **5**, both C–H···O=C and C–H···Cl–C interactions were observed in construction of the crystal structure. This phenomenon might stem from the similar electronegativity of Cl and O atoms. Pd(II) complex **6** containing a non-halogen and dimethyl-substituted ligand produces a two-dimensional network through intermolecular C–H···O interactions as one can expect. All these results indicate that weak intermolecuar C–H···X–C interactions can contribute to the crystal packing and stabilize the multi-dimensional structures, and the C–X (X = F, Cl) sites can form hydrogen bonds although stronger C=O acceptor groups coexist, in particular in these Pd(II) complexes.

3.1. Catalytic activity

The Suzuki–Miyaura cross-coupling reaction represents one of the most widely used processes for the synthesis of biaryls, that are versatile intermediates in organic synthesis and a recurring functional group in many natural products and bioactive compounds [7]. Therefore, considerable effort has been directed towards the development of efficient and selective methods for the synthesis of biaryls. Phosphine ligands are generally used to complex and activate the palladium species, and excellent results have been reported for the palladium-catalyzed Suzuki–Miyaura cross-coupling reaction [8]. However, certain phosphine-complexed palladium catalysts are air- and moisture-sensitive, and the reactions have to be handled under an inert atmosphere [9].



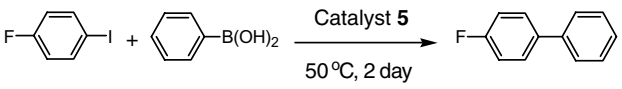


Fig. 3. (a) One-dimensional chain containing the Pd1 complex unit coloured in grey. (b) A tetranuclear ring containing Pd2 and Pd3 complex units coloured in black. (c) Packing diagram of compound **5** showing both C(methyl)–H···Cl–C and C(methyl)–H···O=C interactions. H atoms not involved in intermolecular interactions have been omitted for clarity. Green dotted lines represent C(methyl)–H···Cl–C and C(methyl)–H···O=C interactions. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

Therefore, the development of phosphine-free palladium catalysts, which are insensitive to air, would be significant. Very recently, nitrogen ligands such as diazabutadiene, oxime, *N*-acylamidine and di-2-pyridylmethylamine have emerged as efficient partners for the Suzuki reaction in order to circumvent the problems associated with tertiary phosphine derivatives [10]. These facts inspired us to test complexes **4**–**6** in the Suzuki reaction under aerobic conditions in consideration of their beneficial air- and moisture-stability properties, whilst N4-type saturated Pd complexes have never been used for C–C coupling reactions.

We first tested the catalytic activity of all complexes in the Suzuki–Miyaura reaction between 4-fluoroiodobenzene (25 mM) and phenylboronic acid (50 mM) with K_3PO_4 (50 mM) as a base in EtOH (5 mL) *at low temperature* (50 °C; bath temperature) (Eq. (1)).

(1)

Complex **5** catalyzed almost quantitatively the C–C coupling reaction with a 2 day reaction time (entry 1 of Table 6), whilst **4** did not show any catalytic activity and **6** only catalyzed the C–C coupling reaction slowly (25 days).

Based on these results, next we tested the catalytic efficacy of catalyst **5** in the Suzuki reaction using 4-substituted aryl iodides as the substrate and 4-substituted aryl boronic

Table 6
5-catalyzed cross-coupling reactions of aryl iodides with arylboronic acids at 50 °C[a]

Entry	Ar-I	$ArB(OH)_2$	Time (days)	Conversion[b] (%)	Yield[c] (%)
1	4-flooroiodobenzene	phenylboronic acid	2	96.2	95.0
2	iodobenzene	phenylboronic acid	4	94.4	94.0
3	4-methyliodobenzene	phenylboronic acid	6	83.7	81.3
4	4-flooroidobenzene	4-flooroPhenylboronic acid	4	90.0	89.5
5	iodobenzene	4-flooroPhenylboronic acid	6	90.8	90.0
6	4-methyliodobenzene	4-flooroPhenylboronic acid	6	83.8	78.0
7	4-flooroiodobenzene	4-methylphenyiboronic acid	4	92.3	92.0
8	iodobenzene	4-methylphenyiboronic acid	4	90.3	85.0
9	4-methyliodobenzene	4-methylphenyiboronic acid	6	89.8	86.2

[a] Unless otherwise indicated, the reaction conditions were as follows: aryl iodide (25 mM, 0.1 mmol), aryl boronic acid (50 mM, 0.2 mmol), catalyst **5** (0.1 mM, 4×10^{-4} mmol) and K_3PO_4 (50 mM, 0.2 mmol) in ethanol at 50 °C. Control reactions carried out in the absence of the catalysts showed trace amounts of conversion of the reactant to the corresponding product in the same time period.
[b] Conversion was determined by GC using an internal standard (dodecane).
[c] Yield was determined by GC using an internal standard (dodecane).

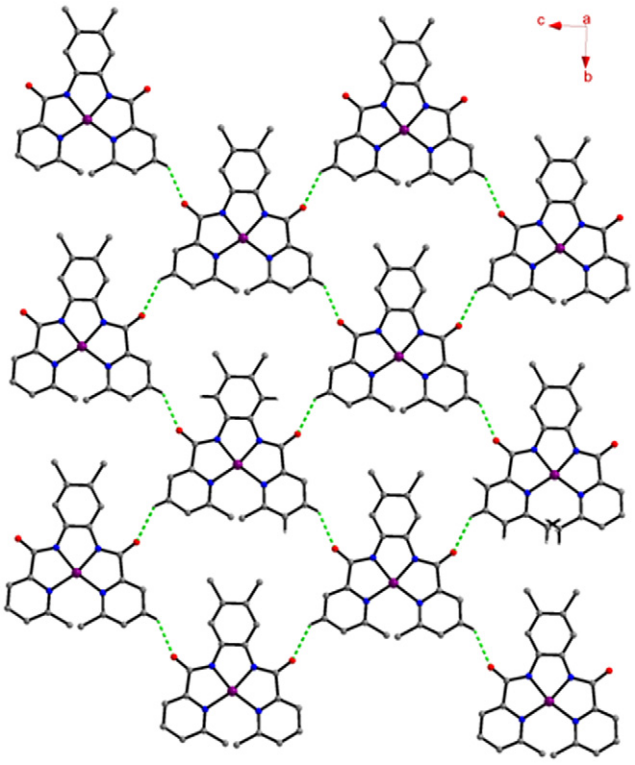

Fig. 4. Two-dimensional structure of compound **6** showing intermolecular C–H···O=C interactions. H atoms not involved in intermolecular interactions have been omitted for clarity. Green dotted lines represent C(pyridyl)–H···O=C interactions. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

acids under aerobic conditions, and the coupling results are listed in Table 6. As illustrated in Table 6, various aryl iodides, including both electron-poor and -rich aryl iodides, were readily converted to the corresponding coupled products in excellent yields within 2–6 days. It is worth noting that this reaction was performed without the protection of inert gas. In particular, electron-poor 4-fluoroiodobenzene underwent the fastest C–C coupling reaction (entries 1, 4 and 7 of Table 6), whilst electron-rich 4-methyliodobenzene was the most slow to be converted to the corresponding biaryls (entries 3, 6 and 9 of Table 6). In addition, catalyst **5** was found to be thermally stable in subsequent catalytic runs, not sensitive to air or moisture, and easily accessible from inexpensive starting materials. Further detailed studies regarding the C–C coupling mechanism by new N4-type Pd systems,[2] as well as the influence of the steric and electronic factors of the ligands are ongoing.

4. Conclusion

In summary, we have reported the synthesis and characterization of new palladium polymeric compounds containing novel tetradentate ligands, 1,2-bis(6-methylpyridine-2-carboxamide)-4,5-substituted-benzene, and in the cases of the halogen-substituted compounds **4** and **5**, non-classical C(methyl or pyridyl)–H···X–C interactions play important roles for the construction of crystal structures in the presence of stronger C=O hydrogen acceptor groups in the molecule. In case of the non-halogen and methyl-substituted compound **6**, C(pyridyl)–H···O=C interactions can generate a two-dimensional structure. We have also reported that the novel catalyst **5** was used to carry out Suzuki coupling reactions with aryl iodides and aryl boronic acids *at low temperature* (50 °C), whilst **4** showed no catalytic activity and **6** only catalyzed the C–C coupling reaction slowly. This novel catalyst **5** is air- and moisture-stable, and the reaction can be readily conducted under aerobic conditions. In addition, the use of the catalyst **5** for the Suzuki–Miyaura cross-coupling

[2] At this stage, we do not know the exact reaction mechanism for the C–C coupling reaction. However, based on the olefin polymerization mechanism proposed with N4-type Zr complexes (J. Chem. Soc., Dalton Trans. (1997) 2487–2484), we assume that the 6-methylpyridyl moiety of catalyst **5** could dissociate to produce one or two labile sites during the catalytic reaction, and then the C–C coupling reaction may go through a reductive elimination step.

reaction represents an interesting alternative to existing catalytic systems based on the use of tertiary phosphine ligands. Moreover, this system shows unprecedented reactivity for a N4-type ligand system with regard to reactivity with the C–C coupling reaction. Furthermore, the fact that the catalyst can be synthesized from inexpensive and readily available starting materials using a straightforward procedure makes these complexes very promising catalysts.

Scheme 1. Structure of L-carnitine zwitterion.

copper ions with biologically interesting ligands have been investigated in detail. Copper is involved in the activation and hydroxylation of various substrates via free radical reactions [31,32]. Copper(II) complexes with diverse drugs and their synergetic activity have been the subject of a large number of research studies [33–36]. We have recently reported the synthesis, the structure characterization and the biological activity of copper(II) complexes with coumarin and quinolone derivatives [37–39].

In a recent work, Chang et al. reported that oxidative stress elicited from copper accumulation, increases the amount of free fatty acids, thereby inducing mitochondrial dysfunction. L-carnitine treatment can inhibit this mitochondrial injury [40]. Therefore the investigation of copper and L-carnitine interaction is biologically important.

In the present study, two copper complexes with L-carnitine were isolated and characterized using several spectroscopic techniques. One of the complexes was also characterized using X-ray crystallography. To our knowledge this is the first example of crystal structure characterization of a metal complex containing L-carnitine.

2. Experimental

2.1. Materials and methods

All reagents were purchased from Aldrich without any further purification. Deuterated solvents for use in the NMR (D_2O and DMSO-d_6) were purchased from Merck. ESMS spectra were recorder on a Fisons Instruments VG BIO-Q quadrupole mass spectrometer, with the solution injected via a Rheodyne injector valve directly through the 10 μL loop in the OCP-V4.06 QUATT 4000 spectrometer. Nitrogen was the nebulizing and drying gas. Focus voltage was set to 10 V, the capillary voltage at 3.00 kV and HV Lens Voltage at 0.46 kV. 20–50 spectra combination was required for acceptable S/N ratio. Sample flow rate was 3 μL/min, with CH_3CN or CH_3OH used as mobile phase, while the electrostatic ion source operated at atmospheric pressure. ^1H and ^{13}C NMR spectra were recorded on a Varian UNITYplus operating at 300 MHz spectrometer in D_2O solution with TSP as internal standard and DMSO-d_6 using the solvent peak as an internal reference (2.50 ppm). Thermogravimetric and differential thermal analysis were carried out on a Mettler Toledo S R apparatus in N_2 atmosphere (temperature range: 40–1000 °C; heating rate: 20 °C/min). IR spectra were recorded in a KBr pellet on a Perkin-Elmer 880 IR spectrophotometer. High-frequency Raman spectra were recorded with a Perkin-Elmer GX Fourier transform spectrometer with a diode pumped Nd:YAG laser at 1064 nm as the excitation source. EPR spectra in solid state (298 and 40 K) or aqueous solution (298 and 11 K) were recorded on a Bruker ER-200D-SRC X-band spectrometer interfaced to a personal computer and equipped with an Oxford EPR 900 cryostat, an Anritsu MF76A frequency counter and a Bruker 035N NMR gaussmeter. UV–Vis spectra were recorded with 1-cm cuvette on a Hitachi U-2000 spectrophotometer. Elemental analysis (C, H, N) was carried out at the Organic Chemistry Laboratory of the National Technical University of Athens, Greece while Cu was determined by atomic absorption.

2.2. Synthesis

2.2.1. Synthesis of $[Cu_2(L\text{-carnitine})_2Cl_2(H_2O)_2]Cl_2$ (1)

L-Carnitine (0.16 g, 1 mmol) was dissolved in ethanol (20 ml) and was added to an ethanol (20 ml) solution of $CuCl_2 \cdot 2H_2O$ (0.18 g, 1 mmol), under stirring. After the mixing, a green product was precipitated. It was filtered off and dried over $CaCl_2$ (yield: 0.16 g, 45%). *Anal.* Calc. for $Cu_2C_{14}H_{34}N_2Cl_4O_8$: C, 26.92; H, 5.49; N, 4.49; Cu, 20.0. Found: C, 27.22; H, 5.88; N, 4.20; Cu, 19.6%. IR (KBr): 3418 (*v* O–H), 3021, 2955, 2918 (*v* C–H), 1619 (v_{as} COO^-), 1421 (v_{sym} COO^-), 561, 431 (Cu–O) cm^{-1}. ^1H NMR (300 MHz, D_2O, 25 °C): 1.29 (–CH_2–COO^-), 3.24 [$(CH_3)_3N^+$], 3.87 (–CH–OH) ppm. ^{13}C NMR (300 MHz, D_2O, 25 °C): 19.55 (C2), 56.62 (C5), 59.81 (C4), 81.73 (C3) ppm. UV–Vis (H_2O): $\lambda = 240$, 400, 790 nm ($\varepsilon = 30.7\ M^{-1}\ cm^{-1}$).

2.2.2. Synthesis of $[Cu_2(L\text{-carnitine})_4(H_2O)_2] \cdot (ClO_4)_4 \cdot H_2O \cdot CH_2Cl_2$ (2)

L-carnitine (0.31 g, 2 mmol) was added to an aqueous (10 ml) solution of $Cu(ClO_4)_2 \cdot 6H_2O$ (0.37 g, 1 mmol), under stirring and a blue-green solution was resulted. Slow evaporation of the solvent resulted a blue-green precipitate, which after dilution to a 10 ml acetonitrile/dichloromethane (1:1) solution and layering with 10 ml ether gave a small quantity of blue-green crystals, suitable for X-ray determination. *Anal.* Calc. for $Cu_2C_{29}H_{68}N_4Cl_6O_{31}$: C, 26.62; H, 5.24; N, 4.28. Found: C, 26.77; H, 5.38; N, 4.40%. IR (KBr): 3432 (*v* O–H), 3019, 2948, 2921 (*v* C–H), 1620 (v_{as} COO^-), 1420 (v_{sym} COO^-), 1148, 1096 (*v* Cl–O), 626 (Cu–O) cm^{-1}. ^1H NMR (300 MHz, DMSO, 25 °C): −51, −5, −2, 28 ppm.

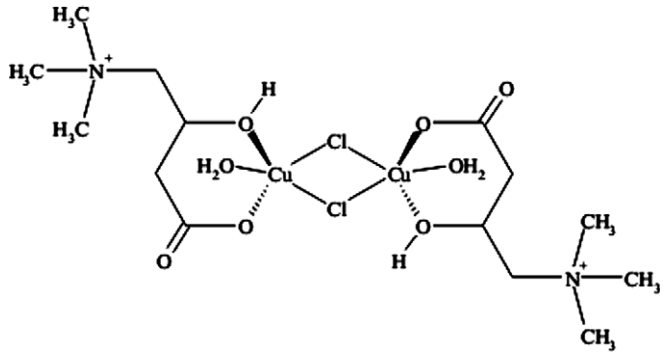
2.3. X-ray crystallography

The complex **2** crystals were mounted in air at the temperature of 150 K. Diffraction measurements were made on a Bruker SMART diffractometer using graphite monochromated Mo Kα radiation. Unit cell dimensions were determined by the angular settings of 9352 reflections in

the range $3 < 2\theta < 28°$. The structure was solved by direct methods and refined in full-matrix least-squares procedure on F^2 with DIRDIF-96 [41]. Hydrogen atoms placed geometrically after each cycle and were not placed on the OH side-groups of the carnitine ligands or the ligated water molecules. The Me_3N^+ group of carnitine molecule #1 is disordered. The two sets of methyl positions were refined in the occupancy ratio 0.7:0.3. The part weight atoms were refined with a common overall isotropic displacement parameter. Similarity restraints were applied to the distances, angles and displacement parameters in the carnitine ligands. The Me_3N^+ groups were additionally restrained to have local 3-fold symmetry. The ClO_4^- anions were badly disordered, and these and the solvents of crystallisation (CH_2Cl_2 and H_2O) were treated by the SQUEEZE procedure.

3. Results and discussion

Complex **1** was prepared in ethanol by mixing equimolar amounts of L-carnitine and $CuCl_2 \cdot 2H_2O$, while complex **2** was prepared in aqueous solution by mixing L-carnitine and $Cu(ClO_4)_2 \cdot 6H_2O$ in a molar ratio of 2:1. The resulted precipitate was dissolved in an acetonitrile/dichloromethane solution which was layered with ether.



The proposed structure of complex **1** cation is presented in Scheme 2. The two metal ions are connected through two chloro-bridges. The ligand is coordinated with the carboxyl oxygen atom monodentately and the hydroxyl group of carbon atom 3, forming a six membered chelate ring. An analogue coordination mode of L-carnitine has been proposed for a zinc complex [28].

In the solid state IR spectrum of the complex, the replacement of the valence stretching carboxylic vibration $\nu(C{=}O)_{carb}$ of L-carnitine zwitterion at 1600 cm^{-1} by the asymmetric, $\nu(CO_2)_{asym}$, at 1619 cm^{-1} and the symmetric stretching ν(O–C–O) vibration, $\nu(CO_2)_{sym}$, at 1421 cm^{-1} as well as the Δ value of 198 cm^{-1} ($\Delta = \nu(CO_2)_{asym} - \nu(CO_2)_{sym}$) are indicative of the monodentate coordination mode of the carboxylato group. This is not a large Δ value for such coordination mode and probably the acetate oxygen is hydrogen bonded to water or a hydroxyl group of another ligand molecule, giving what may be regarded as a ''pseudo-bridging'' arrangement [42]. Peaks due to the C–H vibration of the methyl- and methylene-groups appear in the region 2900–3100 cm^{-1}. The Cu–O stretching frequencies are observed at 431 and 561 cm^{-1} [43]. It is noteworthy that no band in the region of 320–350 cm^{-1} appears, indicating the absence of a $Cu–Cl_{terminal}$ bond. The ν(Cu–Cl–Cu) band which corresponds to the bridging character of the Cu–Cl bond could not be observed as it appears at higher energies and out of the spectrometer scan limit. However, using Raman spectroscopy in the range of 10–3500 cm^{-1} a peak was observed at 166 cm^{-1} that can be connected to the chloro-bridge symmetric vibration.

The TG and DTG analysis curves of the complex were carried out in the temperature range of 40–1000 °C (Supplementary material). The first weight loss (8.6%) at the temperature range of 50–180 °C is attributed to the evaluation of the two coordinated water molecules and one probably to moisture (theor.: 8.6). The second major weight loss (52.2%) occurs between 180 and 390 °C and corresponds to the extraction of the two ligand molecules (theor.: 51.4%). The final residue (21.9%) at 1000 °C consists of the two remaining copper atoms (theor.: 20.2%) [31,44].

The solid state EPR spectrum of complex **1** (Fig. 1) did not give any signal at room temperature, while at lower temperature (40 K) comprised a broad weak signal with $g = 2.13$ with no hyperfine interactions even at 10 K and higher power. The absence of hyperfine structure in the powder spectra points to a significant inter-dimer interaction of the two copper(II) ions via the chloro-bridge.

The complex dissolved in water was also EPR silent at room temperature. At lower temperatures (11 K) the spectrum reveals two signals at $g \sim 2$, around 3100 G, and at $g \sim 4$, around 1500 G. The first one is an unsaturated signal without hyperfine interactions, which decreases upon increase of temperature following the Curie law (Fig. 2). The appearance of an additional very weak signal at lower field (near half-field) is characteristic of binuclear copper complexes [45] due to a singlet–triplet transition of

Scheme 2. The proposed structure of complex **1**.

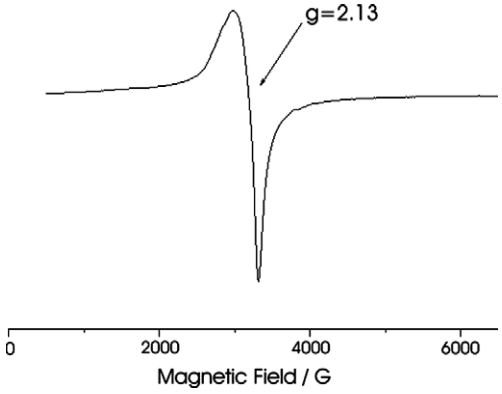


Fig. 1. EPR spectrum of complex **1** in solid state.

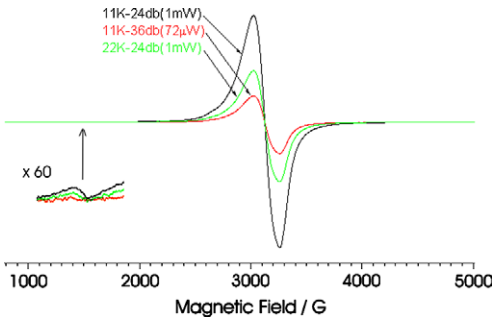

Fig. 2. EPR spectra of complex **1** in aqueous solution ($T = 11$ and 22 K) and different energy parameters. The appearance of a half-field transition is also presented (inset).

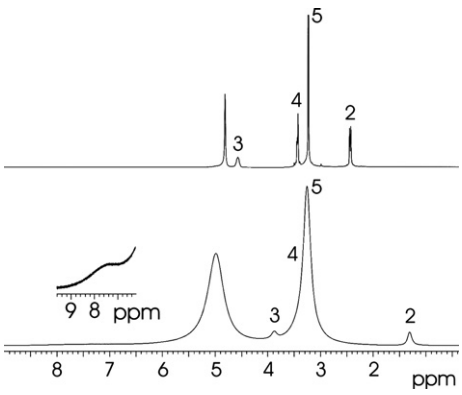

Fig. 3. ^{1}H NMR spectra of complex **1** (bottom) and L-carnitine (upper), in D_2O solution.

$\Delta M_s = 2$ (Fig. 2, inset) and implies that the binuclear complex is not totally dissociated in aqueous solution.

The NMR experiments confirmed the coordination mode of the ligand and therefore the proposed structure. The NMR data are presented in Table 1. The ^{1}H NMR spectrum of the complex in D_2O was compared to that of free L-carnitine (Fig. 3). The spectrum shows a weak paramagnetic effect that can happen after the degradation of even a small part of the complex to monomeric copper(II) complex (represented by a wide peak at 7.5 ppm). The H2 and H3 protons are expected to be the most affected since they are nearest to the Cu–O coordination points (Table 1). The two protons (H2) of the methylene group attached to the carboxylic group are shifted upfield ($\Delta\delta = 1.15$ ppm) as well as the H3 proton ($\Delta\delta = 0.7$ ppm). The H4 protons are less affected and overlapped in the spectrum by the methyl-group protons (H5) that are not shifted. The ^{13}C NMR spectrum of the complex and free L-carnitine were also obtained with analogous results for the carbon shifts where C1 and C3 are affected most, since they participate in the six-membered chelation ring.

In DMSO-d_6 solution, the ^{1}H NMR spectrum is paramagnetic with a characteristic broad peak at 18 ppm. This spectrum suggests that the dimeric complex has been degraded due to DMSO that can coordinate to copper(II) leading to dissociation of dimers.

The electronic spectrum of the complex has been recorded in aqueous solution. A shoulder at 240 nm is attributed to $\pi \rightarrow \pi^*$ transitions within the ligands, while at 300 nm to a ligand-to-metal charge transfer band corresponding to the $Cl \rightarrow Cu(II)$ transition [45]. The complex exhibits also a d–d transition weak and very broad band in the region 650–900 nm which is typical for a distorted square pyramidal geometry in an equilibrium towards a trigonal bipyramid [46,47].

The ESMS of complex **1** (cationic and anionic mode) was obtained in aqueous solution and the identified fragments are presented in Table 2. For both modes the parent ion could not be observed indicating that the complex was dissociated in the experimental conditions and therefore gave rise to low mass fragments with high relative abundance. In the cationic mode (Fig. 4), the peak of L-carn^{+} (m/z 162) is observed. The main fragment (m/z 145) is due to the loss of a hydroxyl group from L-carnitine. The fragment with many isotopes at m/z 267 is due to $[Cu_2Cl_2(H_2O)_2(OOH^-)]^+$, a hydroperoxo dimeric copper(II) complex without the ligand. The similarity of the theoretical and experimental isotopic allocation patterns is obvious for this fragment, which maintains the binuclear form of the complex. The hydroperoxo group is produced under the electrospray experimental conditions. From the spectrum the simultaneous release and degradation of the ligand are shown. The most of the observed fragments are the same with those referred in bibliography for the ESMS spectrum of L-carnitine in aqueous solution [48]. Fragments resulting from the degradation of L-carnitine are observed at m/z 118, 103, 85 and 60 due to glycine betaine, the loss of trimethyl-amine from L-carnitine, the sequential dehydrogenation and trimethyl-amine, respectively. In the anionic mode (Fig. 5), the main fragment appears at m/z 170 due to $[CuCl_3]^-$ and its theoretical pattern is schematized (Fig. 5, inset). The ESMS, under these

experimental conditions and although it did not provide the parent complex ion, was indicative of the binuclear form with chloro-bridges from the fragment $[Cu_2Cl_2(H_2O)(OOH)]^+$. It was also informative of the $Cu_2Cl_2^{2+}$ core stability and the degradation path of the carnitine ligand.

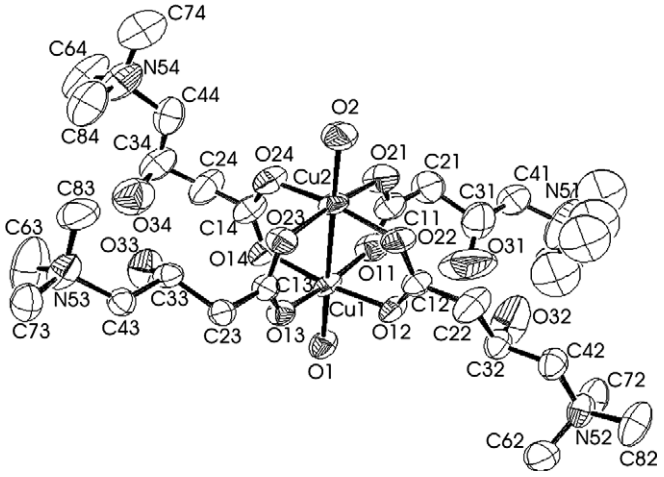

Fig. 6. The structure of complex **2** cation as it was identified from X-ray analysis showing the atomic labeling (50% thermal probability ellipsoids).

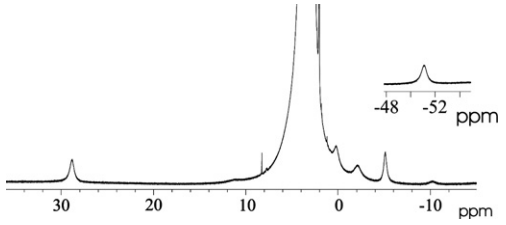

Fig. 7. ^1H NMR spectrum of complex **2** in DMSO-d_6 solution.

Efforts to obtain crystals of complex **1** had no satisfactory results using copper(II) chloride. When copper(II) perchlorate was used in aqueous solution, crystals were isolated and the X-ray analysis demonstrated the binuclear complex cation presented in Fig. 7. The small quantity of the crystals prevented further experiments as in complex **1** except for IR and NMR spectroscopy. The IR spectrum (Supplementary material) shows a broad band of medium intensity around 3700–3100 cm^{-1}, due to the symmetric and asymmetric O–H stretching vibrations. The stretching frequencies for C–H bonds in the aliphatic CH, CH_2 and CH_3 groups of the ligand are observed at 2900–3100 cm^{-1}, while bands attributed to aliphatic CH bending

[d] F^2 and all data.

are verified in the region of 990–920 cm^{-1}. The asymmetrical carboxylate C–O vibration for complex **2** appears at 1620 cm^{-1} with the symmetric one observed at 1472 cm^{-1}. Additional bands at 1096 and 626 cm^{-1} are characteristic of perchlorate anions. The ^{1}H NMR spectrum of the complex in DMSO-d_6 (Fig. 7) reveals strong paramagnetism since broad peaks are observed at +28, −2, −5 and −51 ppm, indicating that the dimer is dissociated to a mononuclear complex.

The crystallographic details of complex **2** blue-green crystal are presented in Table 3. The structure of complex **2** cation (Fig. 6) consists of dinuclear *paddle-wheel* units in which four carnitine ligands are bridging the two copper atoms in a *syn–syn* disposition (the hydrogen atoms have been omitted for clarity). The copper(II) ions are close enough with a Cu...Cu distance value of 2.5957(8) Å. Each ligand is connected to both metal ions via its carboxylate group making a bridge, while a water molecule occupies the axial position of each copper atom. Each copper atom lies in a square-planar pyramidal coordination with the four oxygen atoms in the basal plane and the water oxygen atom at the apex [Cu1–O1, 2.160(4) Å; Cu2–O2, 2.160(5) Å]. As expected, the axial bonds are the longest. Cu(1) lies 0.182 Å and Cu(2) lies 0.175 Å out of their respective least-squares basal planes towards O(1) and O(2), respectively. A number of *paddle-wheel* complexes have been reported in the literature. This structural type is associated with metal–metal interactions that vary from no interactions, weak or moderate spin-pairing in the copper(II) carboxylates, various orders of metal–metal bonding, to "super-short" metal–metal bonds. For Cu...Cu distances that have been reported, this distance in complex **2** is at the lower limit [49]. Some selected bond lengths and angles are listed in Table 4.

4. Conclusions

Two binuclear copper(II) complexes of L-carnitine were synthesized and characterized. The X-ray structural characterization of a L-carnitine metal complex is the first to be reported. The knowledge of L-carnitine's coordination mode with copper(II) as well as the spectroscopic study of the thermodynamic and kinetic stability in aqueous solution of these complexes are important for the biological activity of L-carnitine with copper(II) in mitochondria.

stereoelectronic effects that reduce the exothermicity of the reaction, inhibit the approach of another enR molecule and may render the $[Cu(enR)_2]^{2+}$ entity unattainable [9], while the approach of different molecules or ions with compatible spatial requirements, such as the anions of β-diketonates, is not impeded and in many instances is actually favored leading to the formation of mixed ligand chelates. The mixed-ligand entity $[Cu(enR)\beta]^{2+}$ has attracted appreciable attention because of solvatochromism influenced by the species that effect electrical neutrality either forming covalent bond or acting as counteranions, while in the $[Cu(enR)\beta_2]$ addition compounds, the structure of several of which has been elucidated by crystallographic methods, coordination saturation of copper(II) is achieved [10,11].

Previous studies revealed that addition of 1,2-diaminoethane, en, and its *N*-substituted derivatives, enR (such as the *N*,*N*-dimethyl-1,2-diaminoethane, Me_2en), to bis(β-diketonato)copper(II) chelates cleaves the oxygen–copper(II) bonds and coordination of the 1,2-diamine predominates resulting in the formation of the distorted octahedral CuN_4O_2 chromophore [5,12,13]. Total cleavage of the oxygen–copper(II) bonds also takes place [14] when Me_2en reacts with bis(3-cyano-2,4-pentanedionato)copper(II), $Cu(NC–acac)_2$, and the $CuN_4N'_2$ chromophore prevails with the anion $NC–acac^-$ interacting through the cyano nitrogen and attaining the $S(E,Z)$ conformation instead of the commonly encountered $U(Z,Z)$.

The variable coordination mode and conformation of the substituted 2,4-pentanedionato anions prompted the present investigation in order to get acquainted with the factors influencing the mode of interaction and the conformation of anions β-diketonates in the presence of copper(II) and 1,2-diamines and related nitrogenous bases. Density functional calculations were carried out as an elegant means to probe the consequences of substitution within the 2,4-pentanedionato moiety as regards their likely bonding sites and conformation. Further, the bis(pentane-2,4-dionato)copper(II), $Cu(acac)_2$, and its substituted derivatives ($Cu(NC–acac)_2$ $Cu(O_2N\text{-}acac)_2$, and $Cu(tfac)_2$) were reacted with 1,2-ethanediamine, en, several of its *N*-alkyl derivatives, enR, and 1,2-propanediamine, pn, and the resulting chelates were studied in order to obtain information regarding: (a) the reactivity of the $Cu\beta_2$ chelates towards 1,2-diamines, enR, (b) the influence of substituents within the β-diketonates on the interactions with enR, (c) the occurrence and the role of hydrogen bonding, (d) the effect of functional groups on the interactions and the conformation of the anion of the β-ketoenol, and (e) the changes in the electronic excitation energies as a result of substituent effects and the ensuing changes in group vibrations. Additionally, the crystal structure of $[Cu(MeenMe)_2(NC–acac)_2]\cdot 2H_2O$ was elucidated and is reported.

2. Results and discussion

The reaction of *N*-substituted 1,2-ethanediamines, enR, and 1,2- propanediamine, pn, with the resonance-stabilized bis(β-diketonato)copper(II) chelates, $Cu\beta_2$ (β = acacH, O_2N–acacH, NC–acacH, tfacH) leads to addition compounds, the structure and composition of which depends on the nature and the concentration of the reactants [11,12]. The preference for the formation of the $[Cu\beta_2(enR)_2]$ addition compounds is exemplified in the case of $Cu(NC–acac)_2$. The 1:2 adducts $[Cu(NC–acac)_2(enR)_2]$ were obtained even when the concentration of the sterically unhindered enR was below the required amount for the formation of the 1:1 adduct. The existence of unreacted $Cu(NC–acac)_2$ species in the reaction sediment was revealed by the intense absorption band (due to the cyano group) at 2196 cm^{-1} while in $[Cu(NC–acac)_2(enR)_2]$ this band is split. It transpires that in dilute solutions equilibrium involving the $[Cu(NC–acac)_2enR]$ species pertains and implies that disproportionation takes place upon loss of solvent.

There are distinct differences in the physicochemical properties between the present series of compounds corresponding to the general composition $[Cu(enR)_2\beta_2]$ and the $[Cu(enR)\beta_2]$ adducts. The molar conductivity values Λ_M, of the 1:2 addition compounds, $[Cu(enR)_2\beta_2]$, in nitromethane are in the range 15–60 S cm^2 M^{-1} and in water span a rather wide range indicating that the extent and the nature of interactions of the bifunctional anions of the β-diketonates, β^-, are altered and suggest that fission of copper–oxygen bonds has apparently taken place. As has been reported [5,11,14] and the infrared spectra suggest, the β-diketonato chelate rings no longer exist and the anions β^-, that essentially counterbalance the charge of the evolving $[Cu(enR)_2]^{2+}$ species, do not necessarily retain their $U(Z,Z)$ conformation.

2.1. Infrared spectra

The extensive investigations on the infrared spectra of the $Cu\beta_2$ chelates and the species resulting from covalent interactions of copper(II) cations with 1,2-diamines [15] facilitate the assessment of the structural changes incurred upon addition of enR to $Cu\beta_2$ and their effect on group vibrations. Regarding the partially substituted 1,2-diamines, the absence of bands at frequencies above 3300 cm^{-1} in the infrared spectra of $[Cu(enR)_2\beta_2]$ and suggests that the enR species coordinate as bidentate ligands (Table 1). The bands due to the 1,2-diamines in the 900–750 cm^{-1} region are regarded as indicative of the spatial disposition of the 1,2-diamine. The pattern of these bands in the compounds under investigation suggests chelation and *gauche* conformation since it is closely related to the pattern observed in the spectra of the $[Cu(enR)_2]^{2+}$ entity as well as in 1,2-diamine addition compounds of $Cu\beta_2$ for which the structure has been elucidated by X-ray diffraction.

Coordination of the 1,2-diamine also induces changes in absorptions associated with the anion of the β-diketonate. In the compounds $[Cu(enR)_2\beta_2]$ the frequency of the bands emanating from certain groups within the β-diketonato moiety is of particular importance. For instance, the band

Table 1
Band maxima ($\tilde{\nu}/cm^{-1}$) of the main absorptions in the IR spectra of addition compounds resulting from the reaction of some bis(β-diketonato) copper(II) chelates with 1,2-diamines

due to the asymmetric vibration of the C–C–C segment is shifted to lower frequency while the absorption associated with the perturbed C⇢O and the conjugated C⇢C bonds is shifted to higher frequency relative to that of the parent compounds $Cu\beta_2$ (Table 1). The large shifts in such adducts were understood [16] as indicative of hydrogen bonded β-ketoenolato-anions and unidentate coordination through one of the carbonyl oxygens. Apparently, upon ligation of the diamine a weakening of the copper–oxygen bond and even cleavage takes place, as the conductivity results imply. Shifts in the absorptions associated with skeletal vibrations of the carbon chain were rather difficult to interpret and are attributed to changes in the conformation suggesting that the skeletal carbon atoms of the β-diketonato-moiety are not coplanar.

Groups such as the –CN and the $–NO_2$ that are also capable of covalent interactions with the metal center and are attached to the β-diketonato anion make the IR spectra more interesting. In the case of $[Cu(MeenMe)_2(NC–acac)_2]$ the band emanating from the stretching vibration of the cyano group peaks at 2173 cm^{-1} compared to 2196 cm^{-1} in $Cu(NC–acac)_2$. This diminution of frequency is attributed to bonding interactions of the terminal nitrogen atom with the metal ion. In the case of $[Cu(Me_2en)_2(O_2N–acac)_2]$ and $[Cu(MeenMe)_2(O_2N–acac)_2]$ the interactions of β-diketonato anion with copper(II) apparently do not involve the oxygens of the $–NO_2$ group since the band at 1525 cm^{-1}, assigned to the asymmetric stretching vibration (ν_{as}) of the $–NO_2$ group, as well as the bands at 1395 cm^{-1} and 826 cm^{-1} attributed to the symmetric stretching vibrations (ν_s) and the scissoring deformation of the $–NO_2$ group, respectively, are present in virtually the same position as those in the spectra of the parent compound.

2.2. Electronic excitation spectra

The diffuse reflectance spectra of the $[Cu(enR)_2\beta_2]$ addition compounds are different from those of the $[Cu\beta_2(enR)]$ compounds and the $[Cu\beta_2]$ chelates and are characterized by a broad structureless envelope in the visible having width at half-height ~3.8 μm^{-1} under which all of the ligand field transitions in the copper chelates are congregated. The Jahn–Teller theorem requires any non-linear system with a degenerate ground state to undergo such a distortion as will remove the degeneracy. The d^9 configuration of the copper(II) ion precludes regular octahedral structures since the single unpaired electron would reside in the doubly degenerate e_g orbital manifold. Tetragonal distortions that remove the orbital degeneracy are very common, especially with σ-bonding ligands such as the 1,2-diamines and the extremum of the envelope in the region 1.74–1.87 μm^{-1} compares favorably with the wavenumber of maximum absorption occurring in the cationic species $[Cu(enR)_2]^{2+}$. Previous studies of $[Cu(enR)_2\beta_2]$ compounds revealed the presence of the CuN_4 entity in either D_{2h} or D_{4h} microsymmetry depending on the substitution of the 1,2-diamine, and for the sake of brevity, a D_{4h} symmetry of the CuN_4 chromophore with $^2B_{1g}$ ground state was assumed for the compounds under consideration. Under these circumstances the energy required for the transition $^2A_{1g} \leftarrow {}^2B_{1g}$ reflects the degree of tetragonal distortion. The distortion involves elongation of the axial bonds, a measure of which is the ratio $T = R_S/R_L$, where R_S is the mean in-plane copper–ligand bond length and R_L is the mean out-of plane (axial) bond length. The tetragonal distortion T resulting from crystallographic data on a large number of copper(II) chelates is not dependent on the ligands present and in tetragonally distorted octahedral copper(II) compounds involving unidentate ligands diminishes below 0.6, when the axial ligands are merely positioned by lattice packing factors. The T value is about 0.8 whenever the axial ligands are weakly bonded, and the term ''semi-coordination'' has been introduced to describe this structural situation. In order to gain additional information an unsuccessful attempt was made to analyze the room temperature low-energy envelope into

three components attributed to transitions $^2A_{1g} \leftarrow {}^2B_{1g}$, $^2B_{2g} \leftarrow {}^2B_{1g}$, $^2E_g \leftarrow {}^2B_{1g}$ and to obtain a reasonable fit and a consistent sequence of band intensities. While a number of alternative sets of bands with reasonable fit were obtained, no consistency of intensities was realized.

A plausible alternative for explaining the observed ligand field excitation energy seems to be the existence of a $CuN_4N'_2$ chromophore in $[Cu(MeenMe)_2(NC–acac)_2]$ as in $[Cu(Me_2en)_2(NC–acac)_2]$ that result from the coordination of $NC–acac^-$ through the cyano nitrogen. Irrefutable proof that this rarely occurring mode of coordination actually occurs was obtained by elucidating the crystal structure of $[Cu(Me_2en)_2(NC–acac)_2]$ and was reaffirmed by resolving the structure of $[Cu(MeenMe)_2(NC–acac)_2]$ reported here.

2.3. Description of the Structure of $[Cu(MeenMe)_2(NC–acac)_2]\cdot 2H_2O$

The experimental results are in accord with the existence of an $[Cu(enR)_2]^{2+}$ entity that interacts with two β-ketoenolato anions to achieve electrical neutrality. Consideration of the interatomic distances in $[Cu(MeenMe)_2(NC–acac)_2]\cdot 2H_2O$ reveals that the copper ion is surrounded by nitrogen donor atoms (Table 2). The distances between the diamine nitrogens and the copper atom are slightly unequal being 2.028(2) and 2.049(2) Å. The CuN_4 chromophore exists in a plane (the basal plane) that is expressed by the equation $8.323x - 4.405y - 8.705z = 1.718$. The apical positions are occupied by the cyano nitrogens of the $NC–acac^-$ anion at a distance of 2.617(2) Å from the copper ion. Covalent interactions through the nitrogen of the cyano group are rare and have only been observed before in [16] and [17]. The interatomic distances and bond angles within the β-diketonato moiety indicate extensive electron delocalization. The lengthy separation of the carbonyl oxygens signifies change of conformation to the rarely encountered $S(E,Z)$ one.

The nearest oxygen atom to the metal center is that of a water molecule at a distance of 4.137(3) Å that precludes any direct covalent interactions with copper. Further away at a distance of 5.485(3) Å is the oxygen of a carbonyl group that also abstains from covalent interactions with copper. The absence of interactions of the carbonyl oxygen with the copper atom is in contrast to numerous $[Cu(enR)\beta_2]$ addition compounds and two of the $[Cu(enR)_2\beta_2]$ species in which carbonyl oxygens occupy the apical positions in a tetragonally distorted octahedral arrangement about copper (see Fig. 1).

The disposition of the donor atoms stipulates that the central metal ion exists in a tetragonally distorted octahedral arrangement and microsymmetry approaching D_{2h}. The tetragonal distortion, T, is appreciable ($T = 0.78$) and is more pronounced than that in $[Cu(Me_2en)_2(NC–acac)_2]$ in which $T = 0.82$. However the R_L distance of 2.617(2) Å is appreciably shorter than the values found out in $[Cu(en)_2(acac)_2]\cdot 2H_2O$ and in $[Cu(Me_2en)_2(hfac)_2]$ where the β^- anions retaining the $U(Z,Z)$ conformation interact with the copper center through only one of the carbonyl oxygens at a distance of ~2.79 Å. These are in accord with the notion that the copper ion has a prolate ellipsoidal shape the eccentricity of which is continuously variable, but does not support suggestions that the elongation of the axial bonds is accompanied by simultaneous contraction of the in-plane ones [7].

Hydrogen bonds have been observed in $[Cu(Me_2en)_2(hfac)_2]$ and reexamination of the crystallographic data for $[Cu(Me_2en)_2(NC–acac)_2]$ indicates the occurrence of intramolecular hydrogen bonds involving the hydrogens of the amino group and one of the carbonyl oxygens. In the

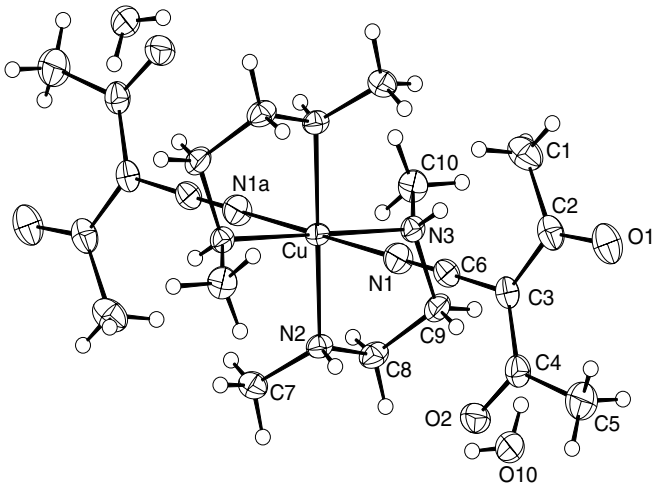

Fig. 1. ORTEP diagram of $[Cu(MeenMe)_2(NC–acac)_2]\cdot 2H_2O$.

compound under consideration the orientation of the NC–acac$^-$ anion does not bring any of the carbonyl oxygens in the environs of the diamine nitrogens that are bonded to the same metal center. However intermolecular hydrogen bonds are observed between the remote carbonyl oxygens of the [Cu(MeenMe)$_2$(NC–acac)$_2$] entity and the diamine nitrogens bonded to other copper centers . Additionally, the second carbonyl oxygen and the second diamine nitrogen are also implicated in intermolecular hydrogen bonding albeit in a different manner involving the water molecules. In fact a network of hydrogen bonding interlinks all the entities in the unit cell and brings about a supramolecular structure. The network of hydrogen bonds in the unit cell is portrayed in Fig. 2.

2.4. Theoretical considerations

Study of the β-*diketonato ligands*. The β-diketonates and their anions have been known to exhibit multiple active sites and attain various conformations. Since diffraction data are not always available nor easily obtainable, we undertook quantum chemical calculations in order to further understand their chemistry. Thus, the series of symmetrically and non-symmetrically substituted β-diketonates and the conformers of their anions, β$^-$, listed in Scheme 1, were fully optimized without imposing any constraint. Frequency calculations were performed on the optimized structures in order to determine the nature of the stationary point found. $W(E,E)$ conformers of the β-diketonato anions have not been observed in [Cuβ$_2$(enR)$_2$] compounds, therefore only the results of the S and U conformers are presented here. The results reaffirm that the $U(Z,Z)$ conformer of the free β-diketonates has enhanced stability due to the strong intramolecular hydrogen bond. Removal of the labile hydrogen enhances the keto form and in most cases β$^-$ adopts the lower energy $S(E,Z)$ conformation with the two oxygen atoms being placed on either side of the carbon chain. The calculated electronic energy E, the relative energy ΔE, the corrected zero-point vibrational energy (ZPVE) denoted E_{corr}, and the free energy, G, of the conformers are listed in Table 3. For instance, the energy of the $U(Z,Z)$ conformer of the NC–acac$^-$ anion exceeds the energy of the $S(E,Z)$ conformer by 18.98 kJ/mol, while the energy of the $U(Z,Z)$ conformer of the acac$^-$ anion exceeds the energy of the $S(E,Z)$ conformer by 26.02 kJ/mol. The ZPVE corrected energy, as well as the free energy, shows the same relative energy order. In the case of the hfac$^-$ anion its $U(Z,Z)$ conformer is more stable by 5 kJ/mol, because in this manner close contacts between the electronegative fluorine and oxygen atoms are avoided.

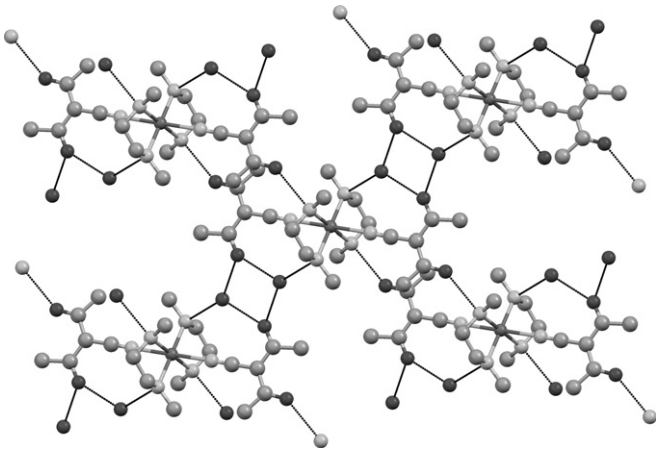

Fig. 2. Network of hydrogen bonds in the unit cell of [Cu(MeenMe)$_2$(NC–acac)$_2$] · 2H$_2$O.

The reactions described here took place in ethanol solutions and for this reason the solvent effect was studied in the frame of the COSMO model. The relative energy order is preserved even though the $U(Z,Z)$ and $S(E,Z)$ conformers lay closer in energy with the $U(Z,Z)$ conformers exhibiting lower solvation energies (ΔG_{solv}) and thus acquiring additional stabilization. In the case of the acac$^-$ anion, the present calculations suggest that while the energy difference between the $U(Z,Z)$ and $S(E,Z)$ conformers in the gas phase is substantial (26.02 kJ/mol), it diminishes to only 2.91 kJ/mol in solution.

The condensed Fukui function value, f_k^-, was advantageously employed to assess the relative reactivity of different sites in the ligands. In the case of the hfac$^-$ anion, the condensed Fukui functions for all the fluorine atoms of the U conformer were calculated. Although the fluorine atom that lies on the carbon plane is predicted to have higher charge with respect to the other fluorine atoms (−0.385 versus −0.377), the f_k^- are equal for all these atoms. Selected atomic charges (NPA) and f_k^- values for the $S(E,Z)$ and $U(Z,Z)$ conformers of the β-diketonato anions are presented in Table 4. The f_k^- values point to the oxygen atoms as the most favorable reactive sites whenever the NC–acac$^-$ anion achieves its U conformation. However, upon change of conformation to $S(E,Z)$ there is a steep increase in the f_k^- value of the nitrogen atom whereas an unsymmetrical sharp drop is observed in the f_k^- values of the carbonyl oxygen atoms. These findings are corroborated from the experimental data of the crystal structures of the [Cu(Me$_2$en)$_2$(NC–acac)$_2$] and [Cu(MeenMe)$_2$(NC–acac)$_2$] · 2(H$_2$O)$_2$ chelates that are in accord with the adoption by NC–acac$^-$ of the $S(E,Z)$ conformation and the interaction through the cyano nitrogen atom.

Study of the [Cuβ$_2$(*enR*)$_2$]. Further, we probed certain [Cu(enR)$_2$β$_2$] systems for which reliable crystallographic data exist. The systems [Cu(MeenMe)$_2$(NC–acac)$_2$] (**S1**) and [Cu(Me$_2$en)$_2$(NC–acac)$_2$] (**S2**) were surveyed in which the anion NC–acac$^-$ was allowed to adopt the $S(E,Z)$ conformation. In the calculations for [Cu(Me$_2$en)$_2$(hfac)$_2$] (**U$_F$**) the conformation of the hfac$^-$ anion was settled to $U(Z,Z)$ as experimentally observed. While the B3LYP/LanL2MB calculations predict rather elongated Cu–ligand bonds, the structures obtained from the B3LYP/LanL2DZ model chemistry are in better agreement with solid state X-ray crystal structures. Therefore, the focus will be on the results

[2]: O(b) oxygen atom of the –NO_2 group.
[3]: N atom of the –NC group.
[4]: Cl atom.
[5]: O oxygen atom of the $CH_3C(O)$-group.

obtained from the latter DFT calculations (i.e. B3LYP/LanL2DZ). Selected optimized structural parameters of **S1**, **S2** and $\mathbf{U_F}$ are presented in Table 5 together with the experimental ones. Our calculations further predict intramolecular hydrogen bonding for all complexes involving amino hydrogen H(N2-1) and one carbonyl oxygen, O2. Upon formation of the $[Cu(enR)_2]^{2+}$ entity the β-diketonato ligand is oriented in such a way so as to enhance its interactions with the metal atom and to maximize hydrogen bonding. The NC–acac$^-$ anion approaches the $[Cu(enR)_2]^{2+}$ entity and assumes the $S(E,Z)$ conformation enabling the cyano nitrogen (N1) to be in the neighborhood of the metal center and as the Cu–N1 distance diminishes weak interactions prevail. Simultaneously, the carbonyl oxygens are involved in hydrogen bonding. The results of the DFT calculations for $[Cu(Me_2en)_2(NC–acac)_2]$ (**S2**) are in harmony with the findings of the X-ray crystallographic data and the outcome of the DFT calculations for $[Cu(MeenMe)_2(NC–acac)_2]$ in the (**S1**) conformation deviate only imperceptibly from the X-ray structure favoring a shorter distance of the axially positioned cyano nitrogen. Shorter distances of the axially positioned carbonyl oxygens are also envisaged for $[Cu(Me_2en)_2(hfac)_2]$ ($\mathbf{U_F}$) in discord with the X-ray crystallographic data. These discrepancies may be attributed to the fact that the theoretical results refer to the isolated molecule in the gas phase while the experimental data refer to the solid state. Additionally, since the water molecules in $[Cu(MeenMe)_2(NC–acac)_2]\cdot 2H_2O$ induce charge redistribution and bring about multiple hydrogen bonding, the disagreement between theoretical and experimental results could be attributed to the exclusion of the water molecules from the calculations.

In order to probe the influence of conformation of the β-diketonato ligands on the energetics of the $[Cu(MeenMe)_2(NC–acac)_2]$ and $[Cu(Me_2en)_2(NC–acac)_2]$ systems, the $Cu(MeenMe)_2(NC–acac)_2$ (**U1**) and $[Cu(Me_2en)_2(NC–acac)_2]$ (**U2**) compounds were also studied with the NC–acac$^-$ anion constrained to $U(Z,Z)$ conformation. Selected geometric, energetic and electronic parameters for **S1**, **U1**, **S2**, and **U2** are compiled in Table 6. It was revealed that the **U1** and **U2** appear to be slightly more stable (by 0.3 and 1.5 kcal/mol, respectively) forming stronger intramolecular hydrogen bonds between the NC–acac$^-$ and the $[Cu(enR)_2]^{2+}$ entity. When the β-diketonato ligand assumes the $U(E,Z)$ conformation, it comes closer to the equatorial plane of the $[Cu(enR)_2]^{2+}$ entity. The distance between the copper ion and the carbonyl oxygen atoms (O1) occupying the apical positions is 2.497 for **U1** and 2.445 for **U2**. Stronger intramolecular bonding is observed relative to **S1** and **S2**, implicating the second carbonyl oxygen (O2) and the hydrogens of the amino group.

The association of the two β-diketonato ligands with the $[Cu(enR)_2]^{2+}$ entity to afford the $[Cu\beta_2(enR)_2]$ compounds implicates a rather strong interaction. The computed association energies ΔE_1 amount to 118.6–143.9 kcal/mol, and are higher for the **U1** and **U2** compounds. Further, the net charges on the Cu atoms calculated by NPA are +1.364, +1.378, +1.327 and 1.341 for the **U1**, **U2**, **S1** and the **S2** structures, respectively. The smaller net charge on the Cu atom of the latter complexes implies enhanced electron density transfer from all ligands to the copper atom, i.e. enhanced sigma bonding when they coordinate through the cyano nitrogen. This electron transfer is located mainly in the 4s orbital of the Cu atoms as shown by the natural electron configuration in Table 6.

Regarding the elongated axial Cu–N distance and the consequences on the nature of interaction of the NC–acac$^-$ with the metal center, the molecular orbital (MO) composition of the systems under investigation was considered. The MO composition reveals that the highest occupied molecular orbital (HOMO) of the (**S1**), (**S2**) structures comes mainly from an orbital of the β$^-$ diketonato anion

with negligible contributions from the atomic orbitals (AO) of the Cu atom and orbitals from the nitrogen donor atoms of the diamine ligand. On the other hand, the main contribution to the lowest unoccupied molecular orbital (LUMO) comes mainly from the Cu atom and the nitrogen atoms of the diamine ligand and essentially no contribution from the β^- diketonato anion. These findings suggest a small degree of covalency (see Fig. 3).

3. Conclusions

The reaction of bis(2,4-pentadionato)copper(II) and cognate compounds with ethanediamine and some of its *N*-derivatives, enR, culminates in the dissolution of the copper–oxygen bond and subsequent formation of copper-nitrogen bonds with the anions of the β-diketonates interacting through atoms placed in apical positions of the square planar $[Cu(enR)_2]^{2+}$ entity. Substituents within the β-diketonate anion affect its mode of interaction and conformation. DFT calculations suggest that when the β-diketonato anion acts as a monodentate ligand, it binds through one of the carbonyl oxygens, while in the case of the NC–acac$^-$ anion binding is envisaged through the nitrogen atom of the cyano group. Further the results indicate that the conformation of the β-diketonato ligand is affected by the formation of hydrogen bonds. The presence of solvent molecules, especially when the solvent is capable of hydrogen bonding, may influence appreciably the conformation of the β-diketonate anion. Water exemplifies this case by participating in extensive hydrogen bonding. The present elucidation of the crystal structure of $[Cu(Me\text{-}en)_2(NC\text{-}acac)_2]\cdot 2H_2O$ supports the results of the DFT calculations. The NC–acac$^-$ anion interacts through the terminal nitrogen atom and attains the $S(E,Z)$ conformation. Extensive intermolecular hydrogen bonding involving the hydrogen atoms of the amino groups and the water molecules present culminates in supramolecular structure.

4. Experimental

4.1. Reagents

1,2-diaminoethane (ethylenediamine, en) and its *N*-alkyl substituted derivatives *N*,*N*-dimethyl-1,2-diaminoethane, Me_2en, its symmetric isomer *N*,*N*′-dimethyl-1,2-diaminoethane, MeenMe, and 1,2-diaminopropane, pn, were purchased from Aldrich and Alfa Aesar. The β-ketoenols (β), 2,4-pentanedione (acetylacetone acacH) and trifluoroacetylacetone (1,1,1-trifluoro-2,4-pentanedione, tfacH), were purchased from Lancaster Synthesis and Aldrich.

4.2. Physical measurements and determinations

Details on the methods and the instruments employed for elemental analyses are given elsewhere [12,16]. Melting points were determined on a Reichert heated plate apparatus and are uncorrected. Molar conductivities were measured on a Metrohm 660 conductivity bridge employing a calibrated dip type cell. The measurements were performed in a series of solutions of analytical grade nitrobenzene and nitromethane and concentrations ranging from 10^{-4} M to 10^{-2} M were employed in order to examine the likelihood of concentration dependence. Molecular mass determinations were accomplished on a Knauer apparatus. Magnetic susceptibility measurements in powdered samples were performed at 25 °C employing the Faraday method on a home-build balance calibrated against $Hg[Co(SCN)_4]$. Diamagnetic corrections were estimated employing the experimental values obtained for Me_2en, MeenMe, $(CH_3COCHCOCH'_3)$Na, and $(CH_3COCCNCOCH'_3)$Na, and from Pascal's constants. The effective magnetic moments, $\mu_{eff}(m_B)$, were calculated using the expression

$\mu_{eff} = 49(\chi_M^{corr})^{1/2}$ $(T = 298\ K)$.

Electronic spectra in solution were measured on a Shimatzu 160A spectrophotometer using 10 mm teflon stoppered quartz cells. The solid state electronic spectra were obtained from nujol mulls. Infrared spectra were obtained by the KBr disc technique and were recorded on a Perkin–Elmer 1430IR spectrophotometer with a range 4000–200 cm^{-1} calibrated against polystyrene.

4.3. Synthesis

The synthesis of 3-cyano-2,4-pentanedione (Traube's acetylacetone, CN-acacH) was performed by reacting acetylacetone with cyanogen employing the procedure described by Fackler [1] while the 3-nitro-2,4-pentanedione (NO_2–acacH) was prepared by Collman's procedure [12]. The homoleptic bis(ß-diketonato)copper(II) chelates, $Cuß_2$, and 1:2 addition compounds, $[Cuß_2(enR)_2]$, were prepared as described in the literature [14,17,18]. The $[Cu(enR)_2(NC–acac)_2]$ compounds are obtained as colored crystals while the $[Cu(enR)_2(tfac)_2]$ and the $[Cu(enR)_2(O_2N–acac)_2]$ compounds are separated as amorphous solids.

[Cu(en)$_2$(acac)$_2$](H$_2$O)$_2$. Yield: 82%. Colour: purple. M.p.: 164–166 °C. *Anal.* Calc. for $C_{14}CuN_4O_6H_{34}$: C, 43.67; N, 14.51; H, 8.88. Found: C, 43.43; H, 8.90; N, 14.30%. 4.4. X-ray crystallographic measurements of [Cu(MeenMe)$_2$(NC–acac)$_2$] · 2H$_2$O

The dark blue crystal selected for lattice constant determination and intensity data collection was a rectangular prism with dimensions $0.22 \times 0.35 \times 0.42$ mm. The crystal was mounted in an arbitrary orientation on a Enraf-Nonius CAD4 four cycles automatic diffractometer using graphite monochromator and Mo Kα radiation. The lattice parameters were calculated by least squares refinement of 25 strong reflections ($17 < \theta < 19°$) which were specifically measured for this purpose. The collection of 3448 reflections as accomplished by operating the diffractometer in the $\omega/2\theta$ scan mode between $2 < \omega < 28°$. Three reference reflections did not show any intensity fluctuations during the measurements. Systematic absences led to space group $P2_1/c$.

All heavy atoms were readily found from a three-dimensional synthesis map using the SIR-92 program [19]. After least-squares refinements with the non-hydrogen atoms, the hydrogen atom were also located in the difference Fourier map. The coordinates for all hydrogen atoms were refined using slack constraints to regularize their geometry, while all non-hydrogen atoms have been refined anisotropically. All calculations were performed employing the CRYSTALS program [20]. Refinement was carried out by full-matrix least-squares on F^2. Details of crystal analysis, data collection and structure refinement are given in Table 7, together with the final values for the unit cell. The figures of the clinographic projections were produced with the program ORTEPII [21].

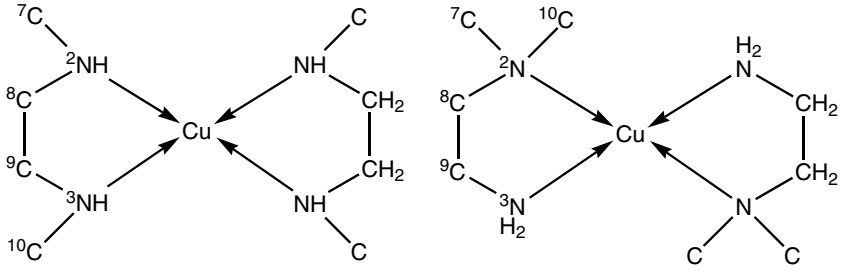
Scheme 1. $S(E,Z)$, $U(Z,Z)$ and $W(E,E)$ conformers of the anions β^-.

4.5. Computational procedure

All quantum chemical calculations were performed using the GAUSSIAN 98W Rev. A.11 program [22].

4.5.1. Study of the β-diketonato ligands



Full geometry optimizations and harmonic frequency calculations for certain β-diketonates and the *S*, *U*, and *W* conformers of their anions, β^-, have been performed in the framework of density functional theory with Becke's three-parameter hybrid functional and the correlation functional of Lee, Yang and Parr B3LYP [23,24] (Scheme 1). The medium sized split valence 6–31G(d,p) basis set, improved with one diffuse function, was implemented. This combination of method and basis set is considered sufficient for an estimate of conformational energy difference [25]. To analyze the nature of bonding the natural population analysis of Weinhold and Carpenter [26] was employed. To study the effect of the solvent (ethanol) on the stability of the anions, the conductor-like screening solvation model (COSMO) was applied using the CPCM keyword [27]. The condensed Fukui functions were employed to predict the most probable reactive sites of the systems under consideration. These reactivity descriptors are derived from the density functional theory as function of the electron density. In the case of electrophilic attack, the Fukui function f_k^- of an atom k in a molecule is expressed by the equation[28]: $f_k^- = q_k(N) - q_k(N-1)$ where $q_k(N)$, $q_k(N-1)$ are atomic charges for atom k in the N and $(N-1)$ electron systems, respectively. These atomic charges were computed from single point calculations at the optimized geometries for the N and $(N-1)$ electron systems.

4.5.2. Study of the $[Cu\beta_2(enR)_2]$

Full geometry optimizations have also been performed for the following chemical entities: $[Cu(MeenMe)_2]^{2+}$ (denoted **M**), $Cu(MeenMe)_2(NC–acac)_2$ (**S1**), $Cu(Me_2en)_2(NC–acac)_2$ (**S2**) in which the NC–acac$^-$ adopts the $S(E,Z)$ conformation, and $Cu(Me_2en)_2(hfac)_2$ ($\mathbf{U_F}$) in which the hfac$^-$ anion is constrained to the $U(Z,Z)$ conformation (see Scheme 2). Furthermore, the compounds $Cu(MeenMe)_2(NC–acac)_2$ (**U1**) and $[Cu(Me_2en)_2(NC–acac)_2]$ (**U2**) were also studied with the conformation of the NC–acac$^-$ anion constrained to $U(Z,Z)$. The B3LYP scheme was employed, since it has been shown to provide accurate results for many transition metal containing systems. Two different basis sets were considered: LanL2MB and LanL2DZ. The LanL2MB basis set specifies the STO-3G basis set [29] for first-row atoms and the Los Alamos effective core potential (ECP) [30] plus MBS on Na–Bi. The LanL2DZ basis set specifies the D95 basis set [31] for first-row atoms and the Los Alamos effective core potential (ECP) plus DZ on Na–Bi. When available, initial geometries were obtained from X-ray structures. The stationary points found from the B3LYP/LanL2MB optimization have been characterized by frequency analysis. No frequency analysis of the optimized points found from the B3LYP/LanL2DZ was attempted due the considerable computational effort required to calculate second derivatives. In order to get an understanding of the main features of the Cu–ligand bonding in this family of compounds the Natural Population Analysis was implemented.

Appendix A. Supplementary material

CCDC 267832 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax:

Scheme 1. Formulae of thyroxine and two model compounds of it: *o*-iodohippuric acid and *o*-iodobenzoylglycilglycine.

the new results obtained and the previously reported by us, in three binary and four ternary complexes involving *ortho*-iodohippuric acid derivatives and acyclovir (acv) or 1,10-phenanthroline (phen).

2. Experimental

Elemental microanalyses were carried out using a Thermo Finnigan model Flash 1112 microanalyzer. IR spectra in the solid state (KBr pellets) were measured in the 4000–400 cm^{-1} range on a Bruker IFS 66 spectrometer. ^1H NMR spectra were recorded at room temperature on a Bruker AMX 300 (300 MHz). Proton chemical shifts in deuterated dimethylsulfoxide ([D_6] DMSO) were referenced to [D_6] DMSO (δ[D_6] DMSO: 2.47 ppm).

Reagents were used as received from Sigma, Merck or Aldrich. *o*-Iodohippuric acid (*o*-iodobenzoylglicine) was prepared according to the literature procedure [20,21] or supplied by Aldrich. *o*-Iodobenzoylglycilglycine (B^IGG) was also synthesized according to the general procedure for hippuric acid [20,21] (see below).

Synthesis of binary complexes, $[Zn(I\text{-}hip)_2(OH_2)_2]_2 \cdot 3H_2O$ (**1**) [17], $[Ag(I\text{-}hip)] \cdot 1.25H_2O$ (**2**) [18] and $[Cu(I\text{-}hip)_2(OH_2)_3] \cdot 2H_2O$ (**3**) [19] are reported previously. Moreover, we have tried to form some ternary complexes between these compounds and others ligands: [(Co, Ni or Zn)$(I\text{-}hip)_2(acv)(OH_2)_3$] (**4**) [17], $[Cu(I\text{-}hip)(phen)_2]^+$-$(I\text{-}hip^-) \cdot 7H_2O$ (**5**) [19], $[Cu(I\text{-}hip)(bpy)_2]^+(I^-) \cdot 1.5H_2O$ (**6**) and $[Cu(B^IGG)(bpy)_2]^+(I^-) \cdot 4H_2O$ (**7**).

2.1. Synthesis of o-iodobenzoilglycilglycinate sodium salt (B^IGG)

Sodium bicarbonate (42 mmol) was added to a solution of glycilglycine (20 mmol) in water (35 ml). The mixture was stirred for 1 h until complete solution and *o*-iodobenzoyl chloride (20 mmol) was added together with acetone (5 ml) (in order to increase the solubility and reactivity of the *o*-iodobenzoil chloride). The reaction was slightly heated at 50 °C and stirred for 4 h. Subsequently, the reaction mixture was neutralized with HCl of 1 N, stirred for 15 min, and the resulting precipitate was filtered off and washed with cold water. The neutralization-washing process was repeated three times and finally the crude *o*-iodobenzoylglycilglycinate sodium salt were washed with diethyl ether, filtered off and dry at room temperature (yield: 65%).

The isolated product, white powder, was the monohydrated sodium salt: sodium *o*-iodobenzoylglycilglycinate (B^IGG) monohydrate. *Anal.* Calc. for $C_{11}H_{12}IN_2NaO_5$: C, 32.86; H, 3.01; N, 6.97. Found: C, 32.73; H, 3.12; N, 6.95%. IR (cm^{-1}): 414vw, 433vw, 546m, 586m, 611m, 637m, 680m, 728w, 749m, 775w, 872w, 914vw, 943vw, 985m, 999s, 1015m, 1041w, 1093m (br), 1239s, 1263m, 1293m, 1347m, 1432s, 1443s, 1463m, 1535s, 1587m, 1620vs, 1664s, 1711s, 2043m, 3343vs. ^1H NMR ([D_6] DMSO): δ 12.03 [bs, 1H, C(2)OO(1)-H], 8.61 [t, 1H, N(7)-H, $J = 5.7$ Hz], 8.08 [t, 1H, N(4)-H, $J = 5.4$ Hz], 7.85 [d, 1H, H(14), $J = 7.8$ Hz], 7.42 [s(br), 2H, H(11 and 12)], 7.15 [m, 1H, H(13)], 3.85 [d, 2H, C(6)-H_2, $J =$ 5.7 Hz], 3.76 [d, 2H, C(3)-H_2, $J = 5.4$ Hz].

2.2. $[Cu(I\text{-}hip)(bpy)_2]^+(I^-) \cdot 1.5H_2O$ (6)

Basic copper carbonate $[CuCO_3 \cdot Cu(OH)_2]$ (1 mmol) and I-hipH (3 mmol) in water (100 ml) were refluxed for 2 h, then the excess of insoluble reactants were filtered off, followed by the addition of solid bpy (3 mmol) and subsequently the mixture was refluxed for two more hours. Finally, sodium iodide (1.5 mmol) was added to the solution to assist the crystallization. This synthesis is similar to that previously reported to prepare acyclovir ternary compounds [17]. Green crystals of $[Cu(I\text{-}hip)(bpy)_2]^+(I^-) \cdot 1.5H_2O$ (**6**) suitable for X-ray diffraction studies were obtained after 4–5 days from the parental solution and has been separated one-to-one of others brown crystals corresponding to the non-desired reaction by-product $[Cu(I)(bpy)_2]^+ \cdot I^-$ [22]. The ternary complex obtained decomposes on air by lose of water molecules (yield: ca. 30%). Repetitions of this synthesis without sodium iodide addition yield a mixture of two types of crystals corresponding to $[Cu(I\text{-}hip)(bpy)_2]^+(I\text{-}hip^-) \cdot 4H_2O$ and a certain quantity of the previously described ternary complex

$[Cu(I\text{-}hip)(bpy)_2]^+(I^-)\cdot 1.5H_2O$ where the origin of the iodide counter ion is not clear (an impurity or a decomposition of I-hip).

$[Cu(I\text{-}hip)(bpy)_2]^+(I\text{-}hip^-)\cdot 4H_2O$: Blue crystals. *Anal*. Calc. for $C_{38}H_{38}CuI_2N_6O_{10}$: C, 43.22; H, 3.63; N, 7.96. Found: C, 42.50; H, 3.54; N, 7.96%. IR (cm^{-1}): 416vw, 440vw, 456vw, 532w, 579w, 624w, 636w, 652w, 663w, 672w, 715w, 732m, 762m, 772m, 867vw, 955vw, 1013m, 1031vw, 1062vw, 1086vw, 1106vw, 1158vw, 1175w, 1232w, 1253m, 1261m, 1311m, 1398vs, 1448m, 1457m, 1470m, 1506s, 1582s, 1600s, 1634s, 1652vs, 3061w, 3313m, 3394m, 3486m.

2.3. $[Cu(B^IGG)(bpy)_2]^+(I^-)\cdot 4H_2O$ (7)

Basic copper carbonate (1 mmol) and B^IGG sodium salt (3 mmol) in water (100 ml) were refluxed for 2 h, then the excess of insoluble reactants were filtered off, followed by the addition of solid bpy (3 mmol) and subsequently the mixture was refluxed for two more hours. An oily complex material was obtained in all attempts. Only one crystal suitable for X-ray diffraction studies could be obtained.

2.4. X-ray crystallographic study

Suitable crystals of **6** and **7** were selected for X-ray single crystal diffraction experiments and mounted at the tip of glass fibres on an Enraf-Nonius CAD4 diffractometer producing graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). In each case, after the random search of 25 reflections, the indexation procedure gave rise to the cell parameters (see Table 1 for a summary of the crystal data). Data were collected in the ω-2θ scan mode. Absorption correction for **6** was performed following the empirical DIFABS method. The structural resolution procedure was made using the WinGX package [23]. Solving for structure factor phases was performed by SHELXS-97 [24] for **6** and SIR-2004 [25] for **7**, and the full matrix refinement by SHELXL-97 [26]. Non-H atoms were refined anisotropically and H-atoms were introduced in calculated positions and refined riding on their parents atoms. A summary of refinements parameters can also be seen in Table 1. H-atoms of water molecules could not be located in any

case. Largest diffraction peaks and holes were located close to heavy atoms in Fourier difference map. The ORTEP [27] representations of the two complexes were made at 50% probability.

The software used to generate the figures and to calculate the distances and angles values are MERCURY 1.4.1 [28], which can be obtained free of charge from CCDC, and Accelrys DS Viewer Pro 5.0 [29], which a 30-days trial version can also be obtained free of charge.

D_{pln}, D_{Atn} and D_{lim} distances as well as θ, φ and ω angles in C–I···π interactions are calculated as defined by Prasanna and Guru-Row [30].

In order to measure the distortions of the coordination polyhedron from the square pyramid to the trigonal bipyramid (CN = 5), the Addison parameter (τ) has been calculated according to the literature procedures [31], as an indication of the degree of trigonality. τ is defined as $(\beta - \alpha)/60$, where β and α are the two *trans*-basal angles. For a perfectly square pyramidal geometry τ is equal to zero, while it becomes unity for a perfectly trigonal-bipyramidal geometry.

3. Results and discussion

3.1. Crystal structure of $[Cu(I\text{-}hip)(bpy)_2]^+(I^-)\cdot 1.5H_2O$ (6)

In X-ray crystal structure of $[Cu(I\text{-}hip)(bpy)_2]^+(I^-)\cdot 1.5H_2O$ (**6**) (Fig. 1), we detect, in a first approach, that the coordination environment is coincident with that for compound $[Cu(I\text{-}hip)(phen)_2]^+(I\text{-}hip^-)\cdot 7H_2O$ (**5**). Two complex units are present in the asymmetrical unit where the two copper(II) ions present distorted octahedral coordinations. These ions are linked to two oxygen atoms of the carboxylate anion of I-hip by means of a strong and an ancillary bonds [Cu–O distances: O(9), 2.100(8) and O(10), 2.71 Å for Cu(1); O(43), 2.217(9) and O(44), 2.47 Å for Cu(2)] and to the four nitrogen atoms from two bpy molecules [Cu–N distances: N(11), 1.972(8); N(22), 2.064(7); N(23), 2.164(8) and N(34), 1.975(7) Å for Cu(1); N(45), 2.131(8); N(56), 1.990(7); N(57), 1.982(7) and N(68), 2.089(8) Å for Cu(2)]. The positive charges of complex units are compensated by the presence of iodide atoms (one per formula unit). The structure is completed by three water molecules per asymmetrical unit.

In this compound, the Addison parameter (τ) presents a value of $\tau = 0.41$. It means that, considering a coordination number CN = 5, the real coordination polyhedron is about halfway between a square pyramidal and a trigonal bipyramidal coordinations.

The 3D structure of this compound is formed by bidimensional layers coincident with the *a*–*c*-plane.

There is not present any intramolecular interaction, but the crystal unit is built by means of a lot of intermolecular interactions among complex units and also with the water molecules. The more relevant interactions should be:

(a) Stacking [32] between bipyridyl rings in the couple of complexes in the asymmetrical unit [distance C(27)···C(50) or C(29)···C(52), ca. 3.34 Å; torsion, 179°] strengthened by $C_{aromatic}$–H···π interactions

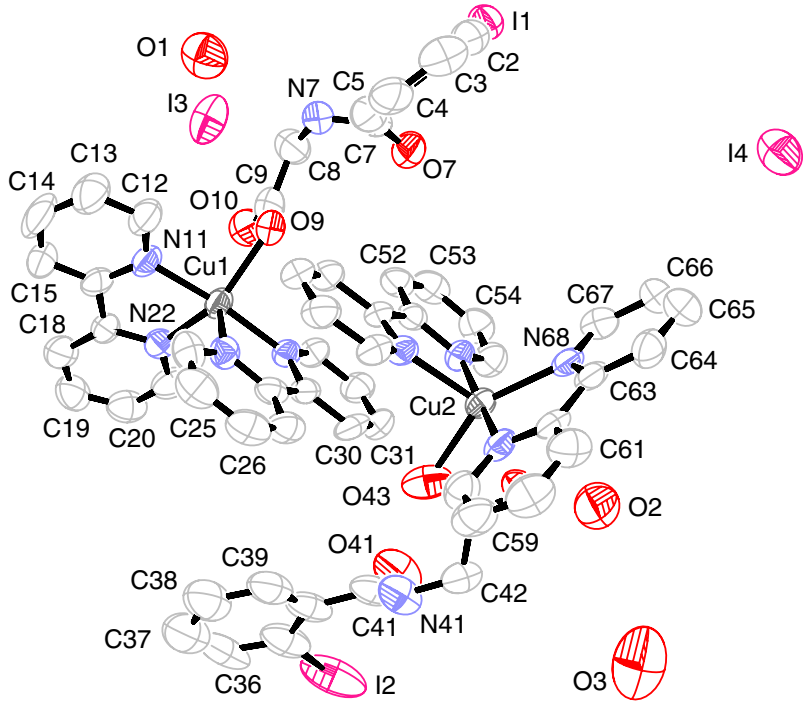

Fig. 1. ORTEP representation (50% probability) of the asymmetrical unit in $[Cu(I\text{-}hip)(bpy)_2]^+(I^-)\cdot 1.5H_2O$ (**6**). Numeration of several atoms has been omitted for clarity.

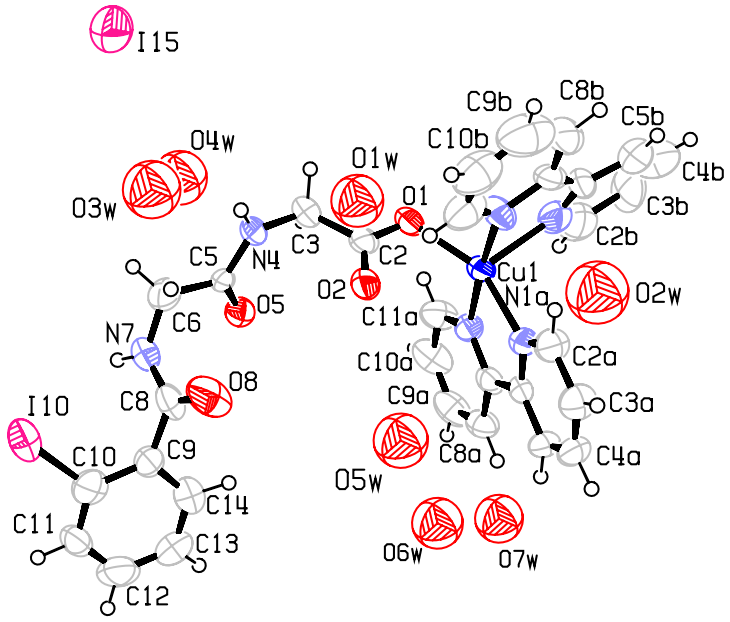

Fig. 2. ORTEP representation (50% probability) of the complex $[Cu(B^{I}GG)(bpy)_2]^{+}(I^{-}) \cdot 4H_2O$ (**7**).

for each bipyridyl [distance H(2)···C(28), H(36)···C(50) and H(36)···C(51); 2.79, 2.70 and 2.87 Å], which yields a more extended and complex C–H···π···π···H–C interaction.

(b) An extended stacking, normal to the described C–H···π···π···H–C units, between four aromatic rings, two *o*-iodobenzoyl rings, which are part of the C–H···π contact, at the inside [distance C(2)···C(38) or C(4)···C(36), ca. 3.36 Å; torsion, 175°], and two bipyridyl ligands which do not participate in that interaction at the outside of the group [distance C(2)···C(21) or C(3)···C(21), ca. 3.25 Å and torsion, 158°; distance C(67)···C(36), ca. 3.31 Å and torsion, 157°]. This π-cluster unit, is extended along the *a* direction, like a wire, assisted by the formation of another stacking between the winger bipyridyl rings [distance C(16)···C(64), ca. 3.49 Å and torsion 173°] and strengthened by contacts between O(44)···H(18) and O(10)···H(64) (see below). These infinite stacking chains are intertwined by orthogonal C–H···π···π···H–C clusters which grow from the two central *o*-iodobenzoyl rings to right and left sides. These crisscrossed strings form 2D networks which are piled in the *b* direction related, for instance, by the iodine anions and water molecules (for more information see Section 3.3.1.5).

(c) An interesting $C_{aromatic}$–H···O hydrogen bonds[1] between carboxylate or carboxamide from I-hip ligand and bipyridyl [distance and angle: C(27)–H(27)···O(43), 3.34 Å and 153°; C(52)–H(52)···O(9), 3.41 Å and 144°; C(47)–H(47)···O(7), 3.22 Å and 127°;C(32)–H(32)···O(41), 3.39 Å and 146°; C(18)–H(18)···O(44), 3.33 and 143°; and C(64)–H(64)···O(10), 3.46 Å and 158°].

(d) And finally, iodine atoms interact with their environment: thus, iodine from *o*-iodobenzoyl rings, shows an intramolecular contact between this halogen and the oxygen atom from amide bond [distances I(1)···O(7) and I(2)···O(41), 3.42 and 3.26 Å]. Although the contact angle is not very adequate [angle C=O···I, 80°], we observe a decrease in the torsion between the aryl ring and the peptidic bond of the I-hip ligand, with regard to the binary I-hip complexes, which could be explained by the presence of this interaction. And finally, the iodide anions interact with I–$C_{aromatic}$ [distance I(4)···I(1), 3.89 Å] and H–$C_{aromatic}$ moieties [distance I(4)···H(41), 2.83; I(4)···H(58), 3.08; I(3)···H(14), 3.07; and I(3)···H(48), 3.10 Å]. All these contacts are shorter than the corresponding van der Waals values [I···I, 3.96; I···O, 3.50; and I···H, 3.18 Å] calculated by Bondi [33].

3.2. Crystal structure of $[Cu(B^{I}GG)(bpy)_2]^{+}(I^{-}) \cdot 4H_2O$ (7)

In this X-ray structure, the copper(II) ion present a distorted octahedral coordination (see Fig. 2), being linked to the two O atoms of the carboxylate in I-hip [Cu(1)–O distances: O(1), 2.012(7) and O(2), 2.74 Å] and to the four N atoms from two bpy molecules [Cu(1)–N distances: N(1A), 2.041(8); N(12A), 1.993(9); N(1B), 2.175(10) and N(12B), 2.016(9) Å]. The coordination environment is again coincident with the

[1] All hydrogen bond distances are given between the donor and the acceptor atoms; angles of interaction correspond to D–H···A.

corresponding to compounds **5** and **6** and the complex unit is positively charged and compensated by the presence of one iodide atom. The presence of seven water molecules completes the structure (water molecules O1W and O2W have complete occupancy (100%); but O3W, O4W and O5W have only 40%; O6W, 30%; and O7W, 50% occupancy). The 3D structure of this compound is also formed by bi-dimensional layers in the *a*–*b*-plane.

The Addison parameter (τ) relating to this compound presents a value of $\tau = 0.33$. In this compound, the geometry is a little nearer to a square pyramid than those for compound **6**, but anyway it is also faraway from any of the two perfect geometries.

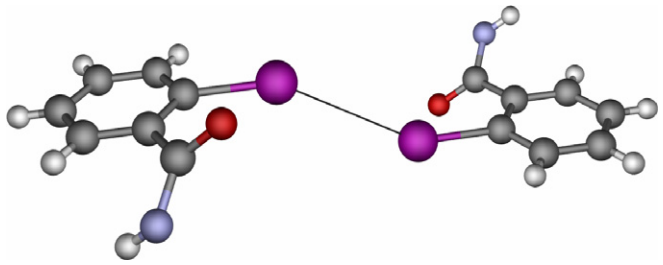

Fig. 3. Iodine–iodine interaction in compound $[Cu(I\text{-}hip)_2(OH_2)_3]\cdot 2H_2O$ (**3**). In order to centre this short contact with a value of 3.78 Å, only the nearness of iodine atoms has been represented (more structural information in Ref. [19]).

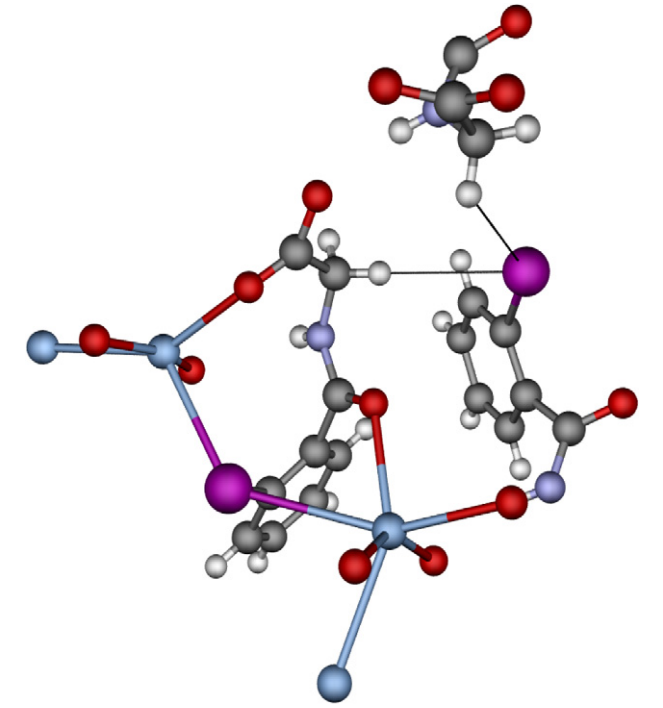

Fig. 4. Iodine–hydrogen interaction (depicted with black lines) and iodine–metal bond (depicted as a standard bond) in compound **2** [18]. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

Every cationic complex recognizes another one (head to tail) by means of a tandem of hydrogen bonds between peptide moieties [distance and angle O(5)···H(7)–N(7), 2.94 Å and 167°] and each of these couples interacts with another one via water molecules and iodide atoms. In order to form the molecular planes within the crystal structure, each bipiridyl ring of one couple interacts with the corresponding one of other couple by means of stacking interactions [distance C(10A)···C(4A) and C(4A)···C(10A), 3.35 Å; distance C(6A)···C(8A) and C(8A)···C(6A), 3.43 Å; torsion 170°] [distance C(6B)···C(9B) and C(9B)···C(6B), 3.33 Å; distance C(7B)···C(8B) and C(8B)···C(7B), 3.36 Å; torsion 171°].

With regard to iodine interactions, one short contact between iodine moiety and iodide anion are present [distance I(10)···I(15), 3.81 Å], shorter than the corresponding van der Waals distance must be mentioned and the iodide anion also interacts with H–$C_{aromatic}$, as in compound **6** [distance I(15)···H(9B), 3.09 Å].

Finally, two $C_{aromatic}$–H···O hydrogen bonds are also present between O atoms from carboxylato/peptide and bipyridyl (type A) moieties [distance and angle: C(4A)–H(4A)···O(5), 2.98 Å and 119.9°; C(5A)–H(5A)···O(2), 3.52 Å and 166.1°; and C(8A)–H(8A)···O(2), 3.46 Å and 163.5°].

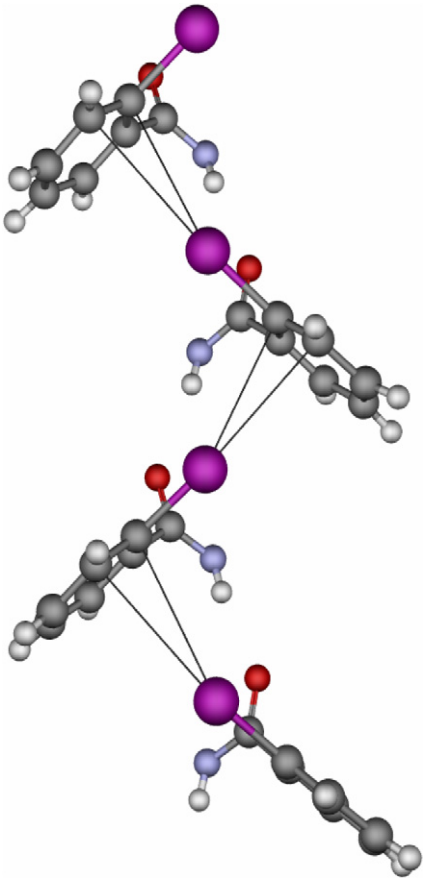

Fig. 5. C–I···π interaction in compound $[Zn(I\text{-}hip)_2(OH_2)_2]_2\cdot 3H_2O$ (**1**) [17]. The I···$C_{aromatic}$ distance values are 3.56 and 3.74 Å alternatively.

3.3. Iodine interactions present in these compounds

Different levels of interactions and self-assemblies involving iodine atoms have been detected in the seven compounds previously described.

3.3.1. A simple type of recognition patterns

3.3.1.1. Iodine–iodine interaction (I···I). $[Cu(I\text{-}hip)_2(OH_2)_3]\cdot 2H_2O$ (**3**) presents a short contact between two iodine atoms in I-hip rings (Fig. 3). The bond distance is about 0.2 Å shorter than de van der Waals value and the final 3D structure is generated by means those reported iodine contacts which yields different planes in the *c* direction.

Similar type of interaction is also present in compound $[(Co, Ni \text{ or } Zn})(I\text{-}hip)_2(acv)(OH_2)_3]$ (**4**). Likewise, an equivalent contact Ph-I···I^- appears in compounds $[Cu(I\text{-}hip)(bpy)_2]^+(I^-)\cdot 1.5H_2O$ (**6**) and $[Cu(B^IGG)(bpy)_2]^+(I^-)\cdot 4H_2O$ (**7**). In all cases, these iodide interactions are very important to maintain the 3D crystal structure.

3.3.1.2. Iodine–hydrogen interaction (I···H–C). Another type of interaction is present between iodine and hydrogen(-C) atoms as, for instance, in complex $[Ag(I\text{-}hip)]\cdot 1.25H_2O$ (**2**), where iodine moiety is closed to two hydrogen atoms from glycine moieties (Fig. 4). These distances are approximately 3.10 Å whereas the calculated van der Waals distance is 3.18 Å.

In the other compounds, as in $[(Co, Ni \text{ or } Zn})(I\text{-}hip)_2(acv)(OH_2)_3]$ (**4**), $[Cu(I\text{-}hip)(bpy)_2]^+(I^-)\cdot 1.5H_2O$ (**6**) and $[Cu(B^IGG)(bpy)_2]^+(I^-)\cdot 4H_2O$ (**7**), is also detected this kind of interaction, where the hydrogen atoms belong to aromatic rings instead of aliphatic chains.

3.3.1.3. Iodine–metal bond (I–Ag). Complex $[Ag(I\text{-}hip)]\cdot 1.25H_2O$ (**2**) also presents direct bonds between iodine (I-hip) and two silver atoms at 3.15 and 3.36 Å (Fig. 4). These contacts are in the levels described in the literature for Ag–I short contact or large bond. Iodine bonded to metals is only present in silver complexes.

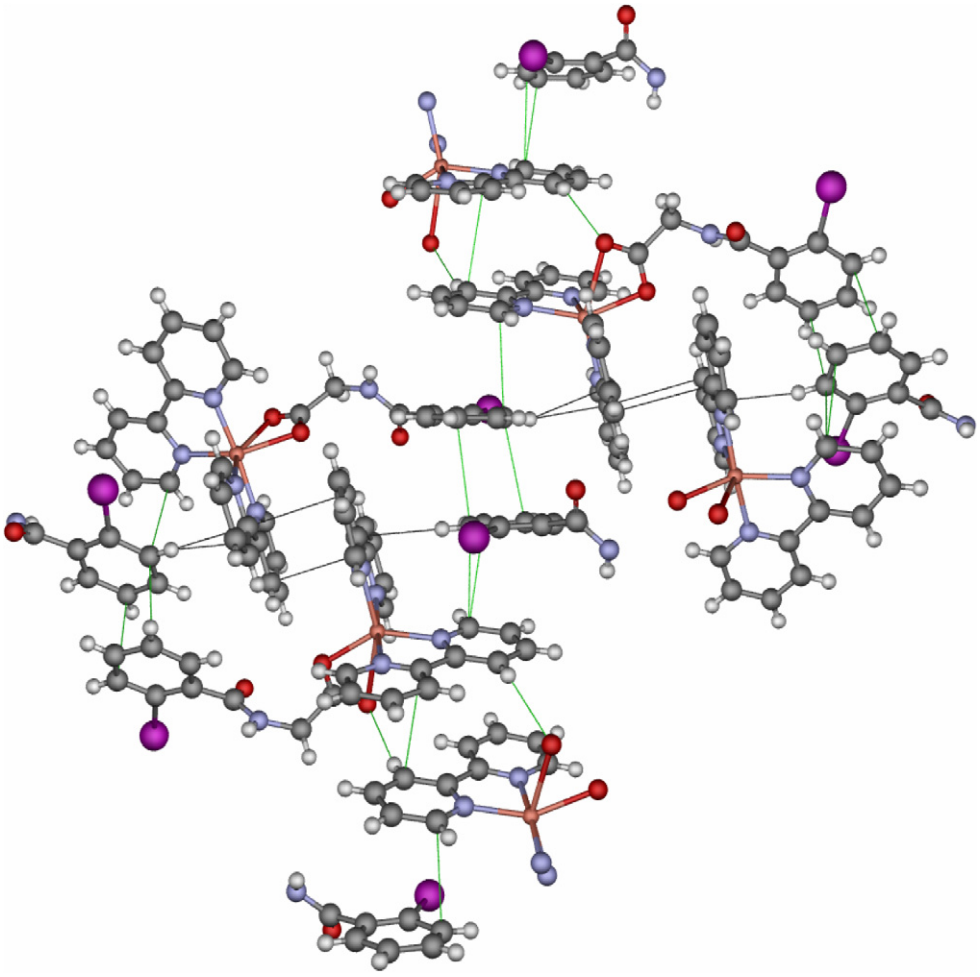

Fig. 6. Two types of connected interactions which direct the formation of a planar structure in compound $[Cu(I\text{-}hip)(bpy)_2]^+(I^-)\cdot 1.5H_2O$ (**6**). The stacking piled along the *a* direction extended to all the crystal is depicted with green lines (vertical in the center of the figure) and the C–H···π···π···H–C patterns which are observed in horizontal and indicated with black lines (one on the left side and another one on the right side). (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

3.3.1.4. Iodine–π system interaction (C–I···π). Binary derivative $[Zn(I\text{-hip})_2(OH_2)_2]_2 \cdot 3H_2O$ (**1**) holds, in its crystal structure, a close contact between iodine atoms and aromatic rings which remember us a C–H···π interaction. In these complex an extended C–I···π interaction (Fig. 5) where one iodine moiety of I-hip contacts closely with the aromatic ring of another I-hip molecule is present. The interaction occurs in the neighbourhood of the iodine moieties (see Fig. 5). This fact tells us than the iodine atom is important in the interaction not only to bond another ring, but also to active the aromatic ring in order to be bonded.

A recent publication [30] has been defined various parameters (three distances and three angles) in order to explore and compare this interaction type. In compound **1**, the six parameter values are (for shorter/longer interactions): D_{pln}, 3.577/3.778 Å; D_{Atn}, 3.559/3.739 Å; D_{lim}, 3.493/3.709 Å; θ, 78.13–78.02°/80.70–77.93°; φ, 79.70–79.40°/78.33–81.16° and ω, 84.10°/84.22°. In the cited paper, is also defined de maximum distance at which a iodine–aromatic ring contact can be considered as interaction: D_{max}, identified as sum of the van der Waals radii of iodine and half-thickness of aromatic ring with an added tolerance of 5% of this sum in order to address electrostatic contributions to the interaction, has a value of 3.86 Å. Our results, confirm the directional preference of the C–I···π interactions.

3.3.1.5. Interactions promoted by iodine atoms which do not directly participate in them. Iodine substitution in aromatic rings improves the capability of interaction between these aromatic rings. Thus, in $[Cu(I\text{-hip})(bpy)_2]^+(I^-) \cdot 1.5H_2O$ (**6**) is not possible to detect any important iodine interaction, but there are very important stacking self-assemblies. In Fig. 6 are depicted the 2D plane formed by these interactions. In green colour represent the stacking along the *a* direction, which crosses all the crystal, whereas in black colour two C–H···π···π···H–C cluster patterns are shown. Detailed distances of these interactions have been reported in Section 3.1.

There are other examples in which the presence of a iodine substitution in the aromatic rings helps to stabilize the formation or reinforcement of stacking interactions. For instance, in compound $[(Co, Ni \text{ or } Zn)(I\text{-hip})_2(acv)(OH_2)_3]$ (**4**), it is possible to detect a stacking interaction between acyclovir and I-hip which enforce the formation of two enantiomeric structures.

3.3.2. A complex pattern of recognition factors

3.3.2.1. Iodine–iodine (I···I) plus iodine–hydrogen (I···H–C) interactions. $[(Co, Ni \text{ or } Zn)(I\text{-hip})_2(acv)(OH_2)_3]$ (**4**) show two types of described single recognition patterns involving iodine atoms (Fig. 7). Thus, the resulting iodine network is formed by iodine–hydrogen(aromatic) contacts at 3.15 Å [van der Waals value, 3.18 Å] and iodine–iodine bonds at 3.80 Å [van der Waals value, 3.96 Å]. In the picture, the first ones are indicated in green thin lines, and the second ones are indicated in black thin lines.

3.3.2.2. C–I···π···π···I–C. Another interesting way of interaction between iodine atoms is by means a long

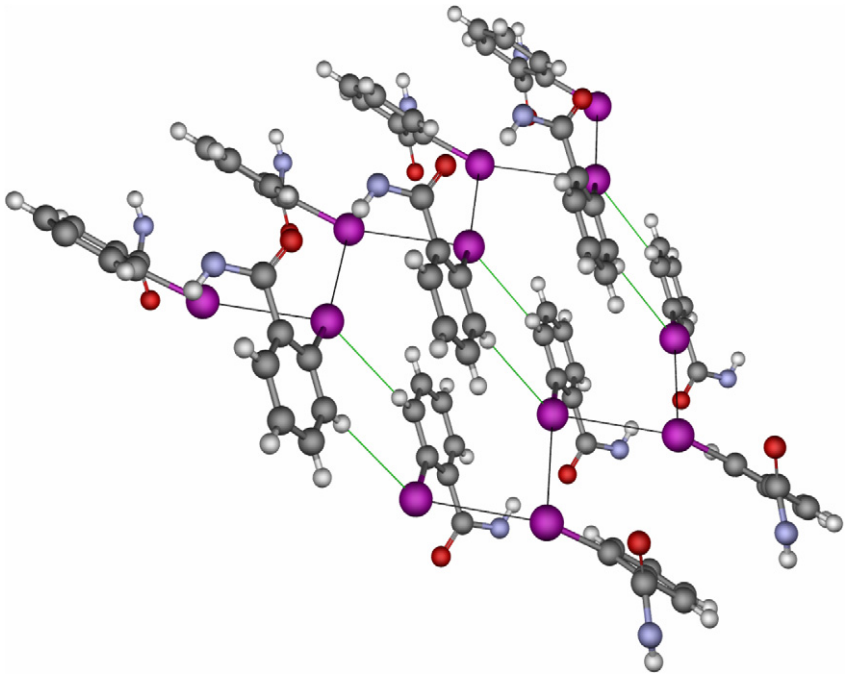

Fig. 7. Network of interactions in complex $[(Co, Ni \text{ or } Zn)(I\text{-hip})_2(acv)(OH_2)_3]$ (**4**) [17]. There are hydrogen–iodine interactions depicted with green lines and iodine–iodine contacts indicated with black lines. These two types of recognitions form to chains of iodine atoms which are related to each other by means of tandems of C–H···I interactions. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

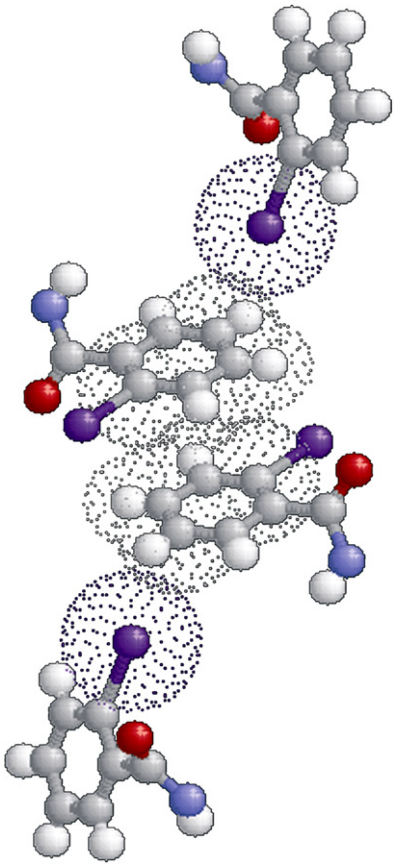

Fig. 8. New C–I···π···π···I–C cluster pattern presents in complex [Cu-(I-hip)(phen)$_2$]$^+$(I-hip$^-$) · 7H$_2$O (**5**) [19]. As it is the most complex iodine interactions observed in the family of compounds presented in this work, we have represented the implied atoms as boundary surfaces in order to well understand the composition of recognition patterns.

distance C–I···π···π···I–C as can be observed in [Cu(I-hip)-(phen)$_2$]$^+$(I-hip$^-$) · 7H$_2$O (**5**). Fig. 8 illustrates these ideas and show this new pattern of molecular recognition: an stacking interaction between two aryl rings from I-hip [distance, 3.39 Å; torsion, 180°] reinforced by two interesting C–I···C(ring) interactions [distance, 3.60 and 3.55 Å], similar to a C–H···π one, on each stacked ring. We can also understand this cluster as two C–I···π interactions locked by a stacking between two other *o*-iodobenzoyl rings (four iodophenyl moieties are implied in these kind of interaction).

The six distance parameters for compound **5** are: D_{pln}, 4.158 Å; D_{Atn}, 3.551–3.602 Å; D_{lim}, 3.509 Å; θ, 54.90–57.26°; φ, 106.64–103.88° and ω, 115.04°. These results are also in agreement with the discussion about this type of interaction, made for compound **1**.

4. Conclusion

Different and interesting patterns of molecular recognition involving iodine atoms are shown in this paper. Among these interactions it is possible to include: I···I, I···H–C(aromatic or aliphatic), I···M(metal ion), I···π (like C–H···π) and aromatic self-assemblies assisted by iodine atoms. These interactions could be similar to their formed between thyroxine and its binding molecules because of the similarity between thyroxine and the different iodohippurate compounds studied in the present work.

Acknowledgments

Scheme 1.

(BDH) were used without further purification. All solvents obtained commercially were distilled before use.

2.2. Synthesis of the ligand and its metal complexes

The semicarbazone was synthesized as per the earlier reported method [5]. The structural formula of the ligand (H_2L) is depicted in Scheme 1.

The mixed ligand complexes CuLphen and CuLpy [where L is the dianion of 2-hydroxyacetophenone-*N*(4)-phenyl semicarbazone, phen is 1,10-phenanthroline and py is pyridine] were synthesized by the following method. A hot solution of H_2L (0.540 g, 2 mmol) in methanol (20 cm^3) was mixed with 2 mmol of the appropriate heterocyclic base in methanol. To this a hot filtered solution of $Cu(OAc)_2 \cdot H_2O$ (0.398 g, 2 mmol) in methanol was added with constant stirring. The mixture was then stirred for 3 h. The complexes, separated as microcrystals, were filtered and thoroughly washed with water, methanol and ether and finally dried over P_4O_{10} *in vacuo*.

Complexes Cu(HL)Cl and $Cu_2(HL)_2SO_4$ were synthesized by the direct reaction of the copper salt with the ligand. A solution of the appropriate copper salt (1 mmol) in methanol was added to a hot methanolic solution of the ligand, H_2L (1 mmol) and the mixture was then stirred for 3 h. The resulting microcrystals were filtered and thoroughly washed with water, methanol and then ether and finally dried over P_4O_{10} *in vacuo.*

The compound Cu_2L_2 was obtained when a hot solution of H_2L (0.540 g, 2 mmol) in methanol (20 cm^3) was mixed with a hot filtered solution of $Cu(OAc)_2 \cdot H_2O$ (0.398 g, 2 mmol) in methanol with constant stirring. The mixture was then stirred for 3 h. The complexes, separated as microcrystals, were filtered and thoroughly washed with water, methanol and ether and finally dried over P_4O_{10} *in vacuo*.

Single crystals of CuLphen suitable for X-ray diffraction were obtained by the slow evaporation of its solution in a mixture of acetonitrile and methanol.

2.3. Physical methods

Elemental analyses were carried out using a Vario EL III CHNS analyzer at SAIF, Kochi, India. IR spectra were recorded on a Thermo Nicolet AVATAR 370 DTGS model FT-IR Spectrophotometer with KBr pellets and the ATR technique at SAIF, Kochi, India. Electronic spectra were recorded on a Cary 5000, version 1.09 UV–Vis-NIR Spectrophotometer from solutions in DMSO. Magnetic moment measurements were carried out in the polycrystalline state on a Vibrating Sample Magnetometer at 5 kOe field strength. EPR spectra were recorded in a Varian E-112 X-band EPR spectrometer using TCNE as a standard at SAIF, IIT, Bombay, India.

2.4. X-ray crystallography

Single crystals of the compound CuLphen suitable for X-ray diffraction studies were grown from its solution in a mixture of acetonitrile and methanol (1:1) by slow evaporation in air. A single crystal of dimension $0.45 \times 0.30 \times 0.20$ mm was selected and mounted on a Bruker SMART APEX diffractometer, equipped with a graphite crystal incident-beam monochromator and a fine focus sealed tube Mo Kα ($\lambda = 0.71073$ Å) X-ray source. The crystallographic data along with details of structure solution refinements are given in Table 1. The unit cell

Largest difference peak and hole (e Å^{-3})	0.485 and −0.400

dimensions were measured and the data collection was performed at 173 K. Bruker SMART software was used for data acquisition and Bruker SAINT software for data integration [6]. Absorption corrections were carried out using SADABS based on Laue symmetry using equivalent reflections [7]. The structure was solved by direct methods and refined by full-matrix least-squares calculations with the SHELXTL-PLUS software package (version 5.1) [8]. The graphics used was diamond version 3.0 [9]. All non-hydrogen atoms were refined anisotropically, and all hydrogen atoms were located from the difference Fourier map and refined isotropically.

3. Result and discussion

The principal ligand H_2L was synthesized by the direct condensation of 2-hydroxyacetophenone with *N*(4)-phenyl semicarbazide. The elemental analysis data obtained is in good agreement with the stoichometry of 2-hydroxyacetophenone-*N*(4)-phenyl semicarbazone. H_2L can exist in the keto or enol form or an equilibrium mixture of the two since it has an amide –NH–C═(O) function. However, the IR spectrum of H_2L indicates that in the solid state it remains in the keto form. The IR spectra of complexes, however, do not show any intense absorption band at 1696 cm^{-1} due to the carbonyl stretching of the semicarbazone moiety. This shows that in solution, it converts to the enol form and coordinates to the metal in the enolate form.

The complexes CuLphen and CuLpy were readily formed by the reaction of the ligand and heterocyclic base with copper acetate. The complexes Cu(HL)Cl and $Cu_2(HL)_2SO_4$ were formed by the reaction of the ligand with copper chloride and copper sulfate, respectively.

The principal ligand H_2L undergoes double deprotonation to L^{2-} and acts as a tridentate ligand in CuLphen, whilst 1,10-phenanthroline acts as a bidentate ligand and occupies the fourth and fifth coordination positions of copper. In the case of CuLpy, L acts as a tridentate ligand thus occupying three positions and pyridine completes the fourth coordination position. In Cu(HL)Cl and $Cu_2(HL)_2SO_4$, the principal ligand acts as a monoanionic tridentate ligand.

The colours, elemental analyses, stoichiometries of H_2L and its complexes are presented in Table 2. The complexes are insoluble in most polar and non-polar solvents. They are soluble in DMF, acetonitrile and DMSO. The conductivity measurements were made in DMSO solutions and all the complexes were found to be non-electrolytes [10].

The room temperature magnetic susceptibilities of the complexes in the polycrystalline state fall in the range 1.80–2.00 BM, which are very close to the spin-only value of 1.73 BM for a d^9 copper system.

3.1. Electronic and IR spectra

The significant electronic absorption bands in the spectra of the ligand and all the complexes recorded in DMSO solution are presented in Table 3.

The semicarbazone and copper(II) complexes have two bands; one centered around 40 000 cm^{-1} and another around 28 000 cm^{-1}. These bands are assigned to $\pi \rightarrow \pi^*$ and $n \rightarrow \pi^*$ transitions of the phenyl rings and semicarbazide moiety, respectively [11]. The charge transfer bands are observed around 25 000 cm^{-1}, and their broadness can be explained as being due to the combination of $O \rightarrow Cu$ and $N \rightarrow Cu$ LMCT transitions [12]. For the Cu(II) complexes there are three spin allowed transitions, $B_{1g} \rightarrow A_{1g}$, $B_{1g} \rightarrow B_{2g}$ and $B_{1g} \rightarrow E_g$, but it is very difficult to resolve them into separate bands due to the very low energy difference between these bands.

The band $n \rightarrow \pi^*$, which is found at 27 770 cm^{-1} in the spectrum of the uncomplexed semicarbazone, was slightly shifted on complexation. This is an indication of the enolization followed by the deprotonation of the ligand during complexation. All the complexes gave d–d bands in the 15 000–16 000 cm^{-1} range [13,14]. In the chloro complex,

Table 3
Electronic spectral assignments, λ (cm^{-1}) for H_2L and its copper(II) complexes

a shoulder observed at 31 446 cm^{-1} is assigned as a Cl → Cu charge–transfer transition [15].

The tentative assignments for the IR spectral bands, useful for determining the ligand's mode of coordination, are listed in Table 4. A sharp band at 1621 cm^{-1} in the semicarbazone can be attributed to the characteristic >C=N group. This band shifts slightly (20–40 cm^{-1}) towards lower frequencies in the copper(II) complexes [16,17] indicating the coordination of azomethine nitrogen to copper. It is further supported by the appearance of new bands at 421–450 cm^{-1}, assignable to ν(Cu–N) for these complexes [18].

The increase in the ν(N–N) value in the spectra of the complexes is due to the increase in double bond character, off-setting the loss of electron density via donation to the metal and it is a confirmation of the coordination of the ligand through the azomethine nitrogen. The appearance of bands in the 1496–1546 cm^{-1} range in the complexes is due to the asymmetric stretching vibration of the newly formed N=C bond as a result of the enolization of the principal ligand. The ν(N–H) band of the semicarbazone disappears in the complexes, except in Cu(HL)Cl and $Cu_2(HL)_2SO_4$, also indicating the enolization and deprotonation of H_2L followed by coordination of the enolate to Cu. This is further supported by the appearance of a new peak in the range 365–375 cm^{-1} indicating ν(Cu–O).

A broad absorption band observed in the 3500–3050 cm^{-1} region for H_2L is due to the phenolic OH. This band, however, disappears in the complexes, thereby indicating the coordination of the phenolic oxygen to the copper atom. Bands in the region 950–550 cm^{-1} are due to the substituted benzene ring. These bands correspond to out-of-plane bending of C–H ring protons and C–C bonds of the aromatic rings.

Thus it is seen that the principal ligand H_2L acts as a dianionic tridentate ligand in the complexes CuLphen, Cu_2L_2 and CuLpy. In complexes Cu(HL)Cl and $Cu_2(HL)_2SO_4$, it is acting as a monoanionic tridentate ligand.

The fourth (and fifth) coordination sites in complexes CuLphen and CuLpy are occupied by N atom(s) of the heterocyclic base and these bands are assignable in the 243–336 cm^{-1} region of the spectra. The IR spectra of the complexes CuLphen and CuLpy display bands characteristic of coordinated heterocyclic bases [19].

In the spectrum of the complex Cu(HL)Cl, a peak at 331 cm^{-1} indicates the terminal nature of the chlorine atom. The sulfato complex $Cu_2(HL)_2SO_4$ has bands at 997, 1039 and at 1119 cm^{-1}, indicating the presence of bidentate bridging sulfato group [20].

3.2. EPR spectra

The EPR spectra of polycrystalline samples at 298 K, DMF solution at 298 and 77 K were recorded in the X-band, using 100-kHz modulation; g factors were quoted relative to the standard marker TCNE ($g = 2.00277$). The EPR parameters of the copper(II) complexes are presented in Table 5.

The EPR spectra of the complexes recorded in the polycrystalline state at room temperature provide information about the coordination environment around copper(II) in these complexes.

The EPR spectra of CuLphen and Cu_2L_2 in the polycrystalline state at 298 K show only one broad signal at $g_{iso} = 2.099$ and 2.096, respectively. Such isotropic spectra, consisting of only one broad signal and hence only one g value (g_{iso}), arises from extensive exchange coupling through misalignment of the local molecular axes between different molecules in the unit cell (dipolar broadening) and enhanced spin lattice relaxation. This type of spectra unfortunately give no information on the electronic ground state of the copper(II) ions present in the complexes. For Cu_2L_2 we got a half field signal at $g = 4.192$, indicating dimeric species [21]. The spectra of CuLpy and $Cu_2(HL)_2SO_4$ showed axial spectra with well defined $g_{\|}$ and $g_{\perp}$ features. The variation in the $g_{\|}$ and $g_{\perp}$ values indicate that the

geometry of the compounds in the solid state are affected by the nature of the coordinating gegenions.

For the complex CuLpy, the $g_\parallel > g_\perp > 2$ and a G value falling within the range 2.1–3.8 are consistent with a $d_{x^2-y^2}$ ground state.

The geometric parameter G, which is a measure of the exchange interaction between copper centers in the polycrystalline compound, is calculated using the equation, $G = (g_\parallel - 2)/(g_\perp - 2)$. G values < 4.4, are consistent with a $d_{x^2-y^2}$ ground state having a small exchange coupling [22]. If $G > 4$, the exchange interaction is negligible [23].

The EPR spectrum of the complex Cu_2L_2 in DMF solution at 298 K (Fig. 1) is isotropic with hyperfine splitting into four lines. In addition, the high field signal ($M_I = -3/2$) is split into three lines by the bonding of the azomethine nitrogen atom with copper. The g_{iso} value is found to be 2.115 and A_N is found to be 20.4×10^{-4} cm^{-1}. However, the spectrum of this compound in DMF solution at 77 K shows typical rhombic features with three g values g_1, g_2 and g_3 (Fig. 2). All the parallel hyperfine lines split into three with a superhyperfine coupling constant, $A_N = 15.3 \times 10^{-4}$ cm^{-1}. These indicate the involvement of the azomethine nitrogen in coordination. The presence of a weak line, lower in the field, is due to the less abundant ^{65}Cu isotope [24].

In the EPR spectrum of the five coordinate copper(II) complex, CuLphen in frozen DMF, the expected superhyperfine lines of three N atoms (one azomethine nitrogen and two nitrogens from phenanthroline) are not observed but shows four fairly resolved hyperfine lines [^{63,65}Cu, $I = 3/2$] corresponding to $-3/2$, $-1/2$, 1/2 and 3/2 transi-

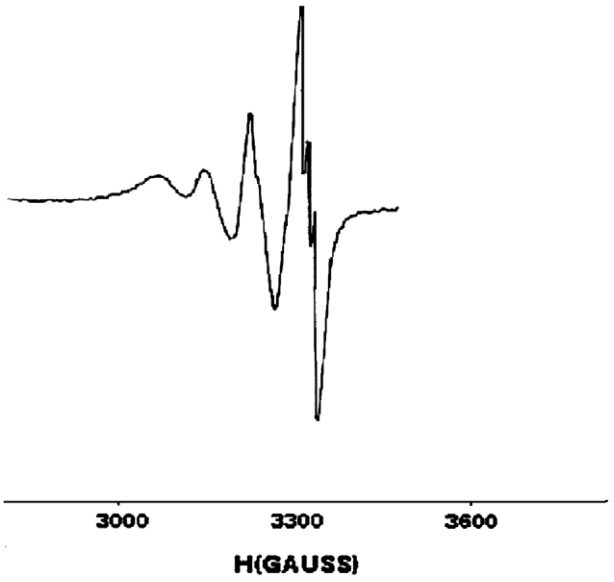

Fig. 1. EPR spectrum of Cu_2L_2 in DMF at 298 K.

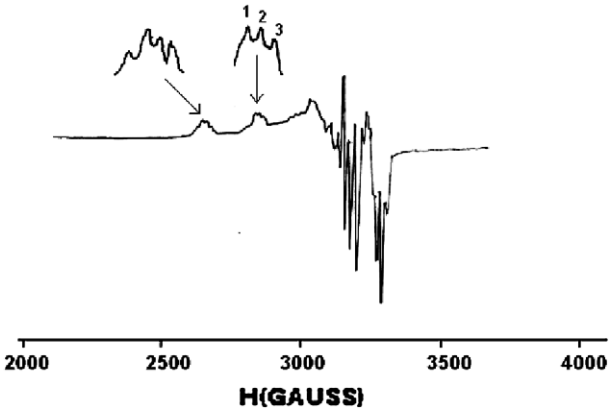

Fig. 2. EPR spectrum of Cu_2L_2 in DMF at 77 K. The $M_I = +3/2$ and $+1/2$ are expanded.

tions. The $g_\parallel > g_\perp$ value suggest a distorted square pyramidal structure and rules out the possibility of a trigonal bipyramidal structure which would be expected to have $g_\perp > g_\parallel$. Thus the coordination polyhedron comprises of one phenanthroline nitrogen, an azomethine nitrogen, an enolate oxygen and a phenolate oxygen of the semicarbazone which forms the base of the pyramid and the remaining phenanthroline nitrogen occupies the axial position, as the results obtained from the crystal study.

The EPR spectra of the four coordinate copper(II) complexes, CuLpy, Cu(HL)Cl and $Cu_2(HL)_2SO_4$, in DMF at 77 K show resolved four copper hyperfine lines. The expected superhyperfine splitting of nitrogen atoms are also not observed here. The $g_\parallel > g_\perp$ suggests a square planar geometry for these complexes. The EPR spectrum of the compound Cu(HL)Cl in DMF solution at 77 K is given in Fig. 3.

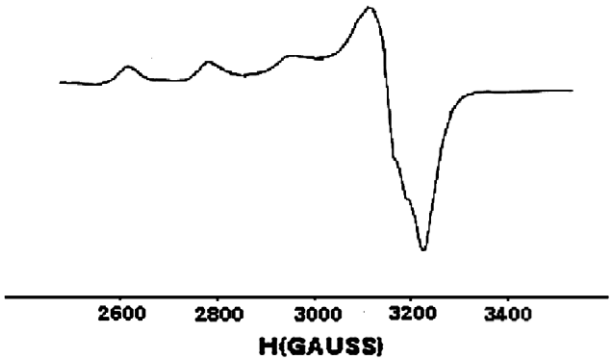

Fig. 3. EPR spectrum of Cu(HL)Cl in DMF at 77 K.

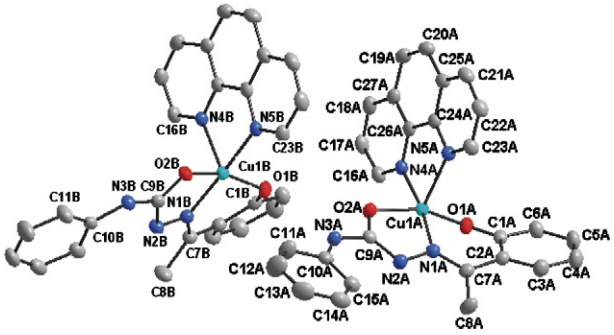

Fig. 4. The molecular structure of CuLphen along with the atom numbering scheme. The hydrogen atoms are omitted for clarity.

The $g_{\|}$ values are nearly the same for all the complexes indicating that the bonding is dominated by the semicarbazone moiety. In all the complexes, $g_{\|} > g_{\perp} > 2.00$. The fact that $g_{\|}$ values are less than 2.3 is an indication of significant covalent character to the M–L bond [25,26].

The EPR parameters $g_{\|}$, $g_{\perp}$, $A_{\|}$(Cu) and the energies of d–d transitions were used to evaluate the bonding parameters α^2, β^2 and γ^2 which may be regarded as measures of the covalency in the in-plane σ-bonds, in-plane π-bonds and out-of-plane π-bonds. The value of the in-plane σ-bonding parameter α^2 is estimated from the expression:

$$\alpha^2 = -A_{\|}/0.036 + (g_{\|} - 2.00277) + 3/7(g_{\perp} - 2.00277) + 0.04 \text{ [27,28]}.$$

The following simplified parameters were used to evaluate the bonding parameters [29],

$$K_{\|}^2 = (g_{\|} - 2.00277)E_{\text{d–d}}/8\lambda_o$$

$$K_{\perp}^2 = (g_{\perp} - 2.00277)E_{\text{d–d}}/2\lambda_o$$

Where $K_{\|}^2 = \alpha^2\beta^2$ and $K_{\perp}^2 = \alpha^2\gamma^2$, $K_{\|}$ and $K_{\perp}$ are orbital reduction factors and λ_o represents the one electron spin orbit coupling constant which equals $-828\ \text{cm}^{-1}$.

Hathaway [30] has pointed out that for pure sigma bonding, $K_{\|} \approx K_{\perp} \approx 0.77$ and for in plane π-bonding, $K_{\|} < K_{\perp}$, while for out-of-plane π-bonding $K_{\perp} < K_{\|}$. In all the complexes, it is observed that $K_{\|} < K_{\perp}$ which indicates the presence of significant in-plane π bonding. Furthermore α^2, β^2 and γ^2 have values less than 1.0, which is expected for 100% ionic character of the bonds, and become smaller with increasing covalent character. Therefore, the evaluated values α^2, β^2 and γ^2 of the complexes are consistent with both strong in-plane σ- and in-plane π-bonding.

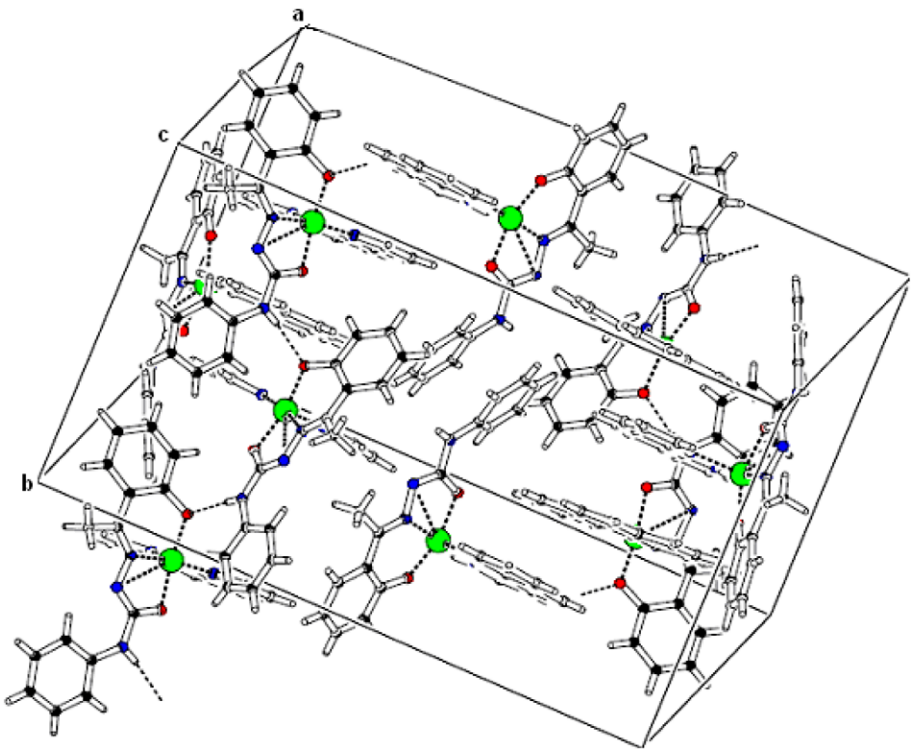

Fig. 5. Packing diagram of CuLphen showing intermolecular hydrogen bonding.

bond lengths and bond angles are summarized in Table 6. The compound crystallizes in a monoclinic lattice with space group $P2_1/c$. The asymmetric unit contains two molecules. The two discrete molecules differ from each other in the orientation of the *N*-phenyl rings – the molecular unit with an A residue has a *transoidal* orientation while that with B residue has a *cisoidal* orientation. The unit cell contains eight molecules. The copper in the mononuclear complex is five coordinate and has a distorted square pyramidal geometry in both the molecules. The basal coordination positions are occupied by the phenolate oxygen O(1), azomethine nitrogen N(1), enolate oxygen O(2) of the semicarbazone and the phen nitrogen, N(4). The apical position is occupied by the second nitrogen of phen, N(5)A, at a larger distance (2.2216 Å) compared to N(4)A (2.0321 Å). In molecule B, these distances are 2.2874 and 2.0302 Å, respectively. The four base atoms are coplanar, showing a significant distortion from a square geometry as indicated by the O(1)A–Cu(1)A–O(2)A bond angle of 159.53°. The corresponding angle for the second molecule is slightly less at 157.24°. The deviation of the central copper atom from the basal plane in the direction of the axial nitrogen is evident from the bond angles of N(1)A–Cu(1)A–N(4)A (170.90°) and O(1)A–Cu(1)A–N(1)A (92.42°). The corresponding angles in molecule B are 175.54° and 92.57°, respectively. Most of the angles involving the central copper atoms are widely different, from 90° and 180°, indicating significant distortion from the square pyramidal geometry. One of the reasons for the deviation from an ideal stereochemistry is the restricted bite angle imposed both by the H_2L and phen ligands. The trigonality index τ is calculated using the equation $\tau = (\beta - \alpha)/60$ [31] (for perfect square pyramidal and triogonal bipyramidal geometries the values of τ are zero and unity, respectively). The value of τ for molecules A and B are 0.19 and 0.30, respectively. This shows that both have distorted square pyramidal geometries and molecule B has more distortion than molecule A.

The variation in Cu–N the bond distances, Cu(1)A–N(1)A (1.9514 Å), Cu(1)A–N(4)A (2.0321 Å), Cu(1)A–N(5)A (2.2215 Å), Cu(1)B–N(1)B (1.9424 Å), Cu(1)B–N(4)B (2.0302 Å) and Cu(1)B–N(5)B (2.2874 Å), indicate the differences in the strength of the bonds formed by each of the coordinating N atoms. The difference in the bond lengths can be attributed to the difference in the π back bonding between the phen and the semicarbazone moieties. However, the large bond distances at the axial Cu(1)A–N(4)A position supports the lack of significant out-of-plane π-bonding. This fact is in accordance with the absence of superhyperfine splitting due to N(4) in the EPR spectrum of the compound.

All the phenanthroline rings are arranged parallel to each other within the unit cell (Fig. 5). The phenanthroline rings Cg [5] and Cg [15] are involved in π–π interactions with a distance of 3.4277 Å in CuLphen. The *cisoid*al *N*-phenyl rings Cg [18] and Cg [18] of the neighboring molecules in the unit cell are also involved in π–π interactions with a distance of 3.8825 Å. In addition to the π–π stacking, C–H···π interactions of the phen hydrogen with the

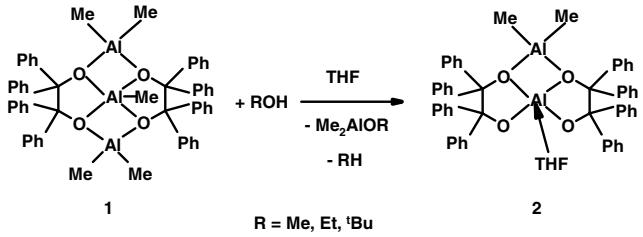
groups. An ionic $[MeAl(OR)_2AlMe_2]^+(MeAlCl_3)^-$ complex and monomeric organoaluminum complexes $R'Al(OR)_2$ and R'_2AlOR (where OR = (*S*)-α,α-diphenyl-2-pyrrolidinyl-methoxide as a ligand possessing a "magic" group, R′ = Me, Et, 1-Nor, ^{t}Bu) were obtained in reactions of (*S*)-α,α-diphenyl-2-pyrrolidinyl-methanol with Me_2AlCl and R'_3Al, respectively [7]. The reaction of a cyclopropene analog of aluminum $LAl[\eta^2\text{-}C_2(SiMe_3)_2]$ (L = HC[(CMe)-(NAr)]$_2$, Ar = 2,6-*i*-$Pr_2C_6H_3$) with Ph_2CO yielded the complex $LAl[OC(Ph)_2C_2(SiMe_3)_2]$ possessing the "magic" group. The complex was the result of an insertion of the carbonyl into an Al–C (vinyl) bond [8]. Treatment of the bridging hydride complex $(\mu,\eta^1\text{:}\eta^1\text{-}Ph_2pz)(Al^iBu_2)_2(\mu\text{-}H)$ with diphenylmethanol or benzophenone afforded the diphenylmethoxide compound $(\mu,\eta^1\text{:}\eta^1\text{-}Ph_2pz)(Al^iBu_2)_2(\mu\text{-}OCHPh_2)$ [9]. Aluminum macrocyclic structures with the Ph_2CO group were synthesised in reactions of diphenylglycolic acid with Me_3Al [10]. Among the diphenylmethoxo aluminum complexes, the four-coordinated monomeric complex (EDBP)Al(OCHPh$_2$)(THF) (EDBP-H_2 = 2,2′-ethylidene-bis(4,6-di-*tert*-butylphenol)) is the only example to possess efficient catalytic activity in the ROP of lactones [11].



Considering the ability of the Ph_2CO group to enhance the catalytic activities of organometallic complexes and our last results involving the catalytic activity of dinuclear alkylaluminum benzopinacolates in the ROP of ε-caprolactone, we found it imperative to study group 13 complexes with diphenylmethoxo ligands. In this work we present the reactions of ^{t}Bu$_3$M (M = Al, Ga, In), Me_3Ga and Me_3In with benzopinacol. We report the unusual structure of a methylmethoxo indium benzopinacolate and the results of alcoholysis reactions of group 13 benzopinacolates.

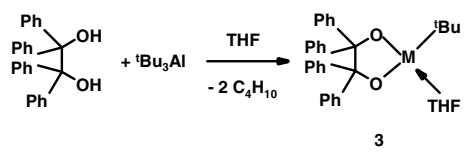
2. Results and discussion

2.1. Reactions of $Me_5Al_3[OC(C_6H_5)_2C(C_6H_5)_2O]_2$ (1) with alcohols

As described in Section 1, the partial hydrolysis reaction of compound **1** led to the formation of the dinuclear complex $Me_2Al_2[OC(C_6H_5)_2C(C_6H_5)_2O]_2(C_4H_8O)$ (**2**). In this study, we showed that the reaction of the compound **1** with 1 equiv. of alcohol ROH (R = Me, Et, ^{t}Bu) resulted with the formation of the same product **2** in 80–90% yield (Scheme 1).[1]

Compound **2** was isolated from the post reaction mixture as a precipitate after addition of *n*-hexane. The presence of signals at −1.85 (AlCH_3), −1.06 (AlCH_3), 1.45 (THF) and 3.52 (THF) ppm and aromatic proton signals in the ^{1}H NMR spectrum indicated that the structure of compound **2** was the same as that of the earlier reported

Scheme 1.



partial hydrolysis product [4]. Similarly to water, the alcohols played the role of the factor formally eliminating a Me_3Al molecule (in a form of a methylaluminum alkoxide) from the trinuclear compound **1**.

2.2. Reactions of benzopinacol with ^{t}Bu$_3$M (M = Al, Ga, In)

^{t}Bu$_3$Al reacted with an equimolar amount of benzopinacol to form the complex ^{t}BuAl[OC(C$_6$H$_5$)$_2$C(C$_6$H$_5$)$_2$O]-(C$_4$H$_8$O) (**3**) (Scheme 2).

In contrast to the trinuclear methyl- and ethylaluminum benzopinacolates $R_5Al_3[OC(C_6H_5)_2C(C_6H_5)_2O]_2$ (R = Me (**1**), Et) [4], the *tert*-butyl compound **3** was monomeric. The molecular structure of **3** has been determined by X-ray crystallography and it is shown in Fig. 1. Data collection and structure analysis are presented in Table 1. The molecule of **3** consists of a diolate unit, ^{t}Bu group bonded to the aluminum atom and a THF molecule coordinated to the Al atom. The aluminum atom is in a four coordinate highly distorted tetrahedral environment. The Al–O(3)$_{THF}$ bond [1.889(2) Å] is much longer than the Al–O(2) [1.745(2) Å] and Al–O(1) [1.724(2) Å] bonds. Fundamental studies have recently produced a number of trimetallic diolates [3], however compound **3** is the first mononuclear product of the reaction of aliphatic diols with alkylalanes. Several monomeric alane aromatic diolates were prepared by Lin [12] and Okuda [13]. Recently Lewiński [14] has reported a monomeric methylaluminum(bisphenoxide)-ε-caprolactone complex.

In contrast to the dimeric aluminum benzopinacolates $R_2Al_2[OC(C_6H_5)_2C(C_6H_5)_2O]_2(C_4H_8O)$ [R = Me (**2**), Et] [4], the monomeric compound **3** demonstrated very low activity in the polymerisation of ε-caprolactone. An attempt to activate **3** by replacing the ^{t}Bu with an alkoxyl group failed. Reactions of compound **3** with *iso*-propyl- and benzyl alcohols resulted in the formation of a mixture of *tert*-butylaluminum alkoxides and benzopinacol. In the presence of dioxygen, compound **3** underwent transformation into a complicated mixture of products instead of the expected *tert*-butoxoaluminum benzopinacolate.

Scheme 2.

[1] Alcohols are more soluble in organic solvents than water. Therefore, the cost of the synthesis of complexes $\{R_2Al_2[OC(C_6H_5)_2C(C_6H_5)_2O]_2(B)\}$ (R = alkyl group, B = Lewis base) in reactions of compounds $\{R_5Al_3[OC(C_6H_5)_2C(C_6H_5)_2O]_2\}$ with alcohols, is lower due to the small amount of solvents needed for the process.

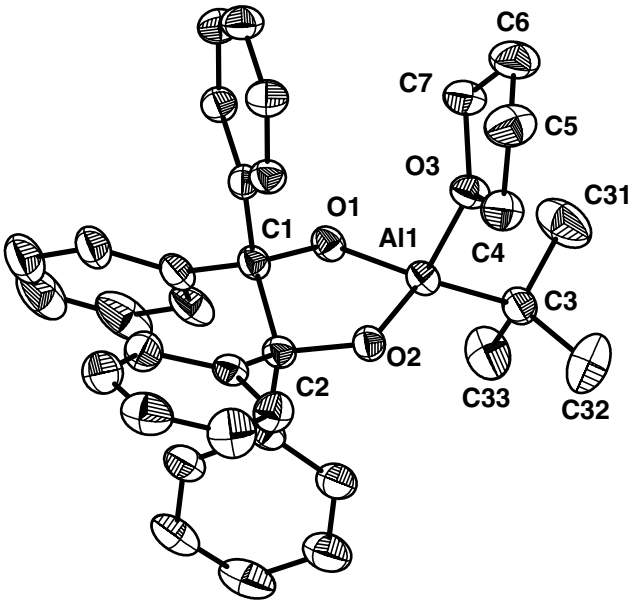


Fig. 1. Molecular structure of ^{t}BuAl[OC(C$_6$H$_5$)$_2$C(C$_6$H$_5$)$_2$O](C$_4$H$_8$O) (**3**). Thermal ellipsoids are shown at the 30% level. Hydrogen atoms are omitted for clarity. Selected bond lengths (Å) and bond angles (°): Al–O(2) 1.745(2), Al–O(1) 1.724(2), Al–O(3) 1.889(2), Al–C(3) 1.961(2), O(1)–C(1) 1.431(2), O(2)–C(2) 1.423(3), C(1)–C(2) 1.645(3); O(2)–Al–O(1) 93.9(1), O(2)–Al–O(3) 100.9(1), O(1)–Al–O(3) 111.6(1), O(2)–Al–C(3) 130.2(1), O(1)–Al–C(3) 115.7(1), O(3)–Al–C(3) 103.6(1).

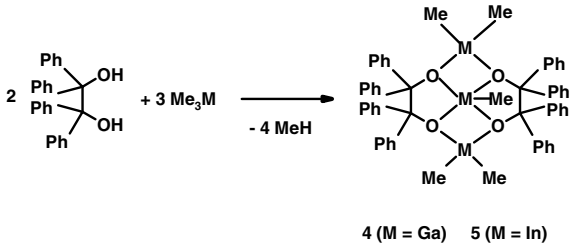
Reactions of benzopinacol with ^{t}Bu$_3$Ga and ^{t}Bu$_3$In were carried over 3 h upon refluxing in toluene. We found that benzopinacol did not react with ^{t}Bu$_3$Ga, which was in agreement with our earlier observation of less reactivity of ^{t}Bu$_3$Ga and ^{t}Bu$_3$In in comparison with ^{t}Bu$_3$Al [15,16]. The ^{1}H NMR spectrum of the post reaction mixture revealed the signals of unreacted benzopinacol and ^{t}Bu$_3$Ga only. On the other hand, the reaction of ^{t}Bu$_3$In with benzopinacol resulted in the precipitation of indium and oxygenation of benzopinacol to benzophenone. The presence of benzophenone in the post reaction mixture was confirmed on the basis of the *C*O carbon signal at 77.21 ppm in the ^{13}C NMR spectrum.



2.3. Methylgallium- and methylindium benzopinacolates

Independently of the molar ratio of the reagents, reactions of Me$_3$M (M = Ga, In) with benzopinacol afforded trinuclear complexes Me$_5$M$_3$[OC(C$_6$H$_5$)$_2$C(C$_6$H$_5$)$_2$O]$_2$ [**4** (M = Ga), **5** (M = In)], containing two diolate units (Scheme 3).

Compound **4** was crystallised from a post reaction mixture in 90% yield. The molecular structure of **4** was determined on the basis of a X-ray diffraction study and it is shown in Fig. 2. Data collection and structure analysis

Scheme 3.

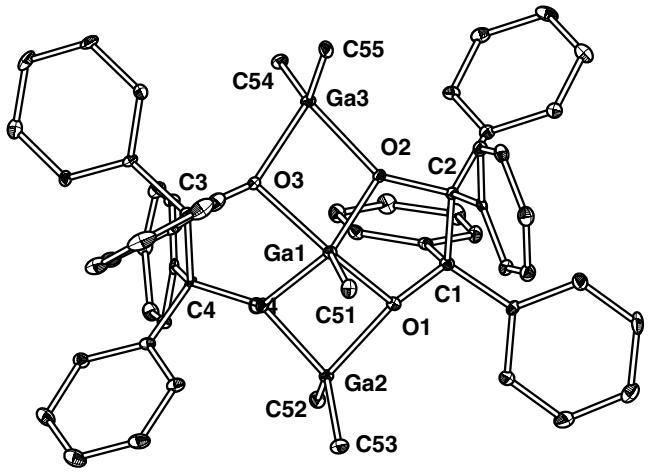

Fig. 2. Molecular structure of $Me_5Ga_3[OC(C_6H_5)_2C(C_6H_5)_2O]_2 \cdot 2CH_2Cl_2$ ($\mathbf{4} \cdot 2CH_2Cl_2$). Thermal ellipsoids are shown at the 20% level. Hydrogen atoms and molecules of CH_2Cl_2 are omitted for clarity. Selected bond lengths (Å) and bond angles (°): Ga(1)–O(4) 1.924(3), Ga(1)–O(2) 1.932(3), Ga(1)–C(51) 1.951(5), Ga(1)–O(3) 1.986(3), Ga(1)–O(1) 2.013(3), Ga(2)–O(1) 1.964(3), Ga(2)–O(4) 1.992(3), Ga(3)–O(3) 1.978(3), Ga(3)–O(2) 1.994(3); O(4)–Ga(1)–O(2) 122.0(1), O(4)–Ga(1)–O(3) 79.6(1), O(2)–Ga(1)–O(3) 79.4(1), O(4)–Ga(1)–O(1) 80.6(1), O(2)–Ga(1)–O(1) 79.5(1), O(3)–Ga(1)–O(1) 137.2(1), O(4)–Ga(1)–C(51) 113.6(2), O(2)–Ga(1)–C(51) 124.2(2), C(51)–Ga(1)–O(3) 116.4(2), C(51)–Ga(1)–O(1) 106.3(2).

are presented in Table 1. Two molecules of CH_2Cl_2 are present in the formula unit of **4**. The molecule of **4** consists of a tetracyclic structure formed from two Ga_2O_2 four-membered rings and two GaO_2C_2 five-membered rings. A central Ga(1) atom is five-coordinate, residing in the distorted square pyramidal geometry with the basal plane consisting of four oxygen atoms of the diol units and the methyl group residing in an apical position. The coordination sphere geometry of the central metal atom is closer to a square pyramidal structure [i.e., O(3)–Ga(1)–O(1) 137.2(1)°, O(4)–Ga(1)–O(2) 122.0(1)°] than to a trigonal bipyramidal geometry. The same geometry around the central metal atom was observed for related trinuclear aluminum complexes [4,17–20]. The sums of the angles about the oxygen atoms {$\sum$[O(1)] 350.3°; $\sum$[O(2)] 358.9°; $\sum$[O(3)] 358.8°; $\sum$[O(4)] 359.9°} were slightly less than 360°, which indicates a small steric strain in the molecule.

The ^{1}H NMR spectrum of **4** revealed three singlets of CH_3Ga group protons (at −0.15, −0.67 and −0.71 ppm) and multiplet of aromatic protons at 7.33–7.01 ppm with the integration ratio of 6:6:3:40, which were in agreement with the measured structure. The signal of *C*O carbons at 91.29 ppm in the ^{13}C NMR spectrum was situated in the region of the *C*O signals (ppm) of alkylaluminum benzopinacolates {**1** (93.31); $Et_5Al_3[OC(C_6H_5)_2C(C_6H_5)_2O]_2$ (93.30); **2** (92.81, 87.73); $Et_2Al_2[OC(C_6H_5)_2C(C_6H_5)_2O]_2$(THF) (92.62, 87.78)} [4]. In comparison with *C*O signals of alkylalane-[2] and alkygallane aliphatic diolates (ppm), ^{t}Bu$_4$Ga$_2$(OCH$_2$C$_6$H$_4$CH$_2$OH)$_2$ (67.49); ^{t}Bu$_5$Ga$_3$(OCH$_2$C$_6$H$_4$CH$_2$O)$_2$ (68.30); ^{t}Bu$_4$MeGa$_3$(OCH$_2$C$_6$H$_4$CH$_2$O)$_2$ (67.58); ^{t}Bu$_2$Me$_3$Ga$_3$(OCH$_2$C$_6$H$_4$CH$_2$O)$_2$ (67.44, 65.63) [15]; $Me_5Ga_3[OC(CH_3)_2CH_2C(CH_3)_2O]_2$ (74.86) [21]; ^{t}Bu$_5$Ga$_3$[OCH$_2$C(CH$_3$)$_2$CH$_2$O]$_2$ (78.4) [20], the *C*O carbon signal of **4** is dramatically shifted downfield, which is caused by the electron withdrawing effect of the aromatic rings.

The methylindium benzopinacolate **5** was not isolated as a pure compound. The ^{1}H NMR spectrum of a white solid crystallised in the post reaction mixture, besides signals of compound **5**, exhibited several small singlets in the region from 0.0 to −1.0 ppm. It indicated the presence of indium methyls, which crystallised together with **5**. Attempts to isolate the pure compound **5** failed, because it underwent easy decomposition and became dark. The elemental analysis, molecular weight and melting point were not measured due to the impurity and the instability of compound **5**. The structure of **5** was proposed on the basis of ^{1}H and ^{13}C NMR spectra. Similarly to the spectra of compounds **1** [4] and **4**, the ^{1}H NMR spectrum of **5** revealed three singlets at −0.21, −0.47 and −0.72 ppm with a 2:2:1 integration ratio, assigned to the protons of five methyl groups bonded to indium atoms. The signal of *C*O carbons (at 89.94 ppm) in the ^{13}C NMR spectrum was situated in the same region as those of aluminum- and gallium benzopinacolates. The presence of one signal of *C*O carbons in the spectrum indicated the equivalence of the CO groups, which was in agreement with the proposed structure of **5**. The analogy of the spectra of compounds **1**, **4** and **5** showed that **5** was isostructural to the compounds **1** and **4**.

Attempts to synthesise the dinuclear complexes $Me_2M_2[OC(C_6H_5)_2C(C_6H_5)_2O]_2(C_4H_8O)$ (M = Ga, In), isostructural to the aluminum derivative **2**, failed. In contrast to the partial hydrolysis and alcoholysis reactions of the aluminum benzopinacolate **1**, reactions of the methylgallium- and methylindium benzopinacolates (**4** and **5**) with water and alcohols resulted in the decomposition of the compounds to benzopinacol and metalloxanes or a mixture of alkoxides, respectively. The ^{1}H NMR spectra of the post reaction mixtures revealed a singlet of O*H* group protons at 3.04 ppm and a multiplet of aromatic protons (7.37–7.21 ppm) characteristic for benzopinacol. The reaction carried out under milder reaction conditions (at 0 °C in a diluted solution) resulted in the same products. In our opinion, the digallium complex $Me_2Ga_2[OC(C_6H_5)_2C(C_6H_5)_2O]_2(C_4H_8O)$ was formed as a very unstable inter-

[2] For chemical shift of CO signals of alkylalane aliphatic diolates see Ref. [4], p. 2933.

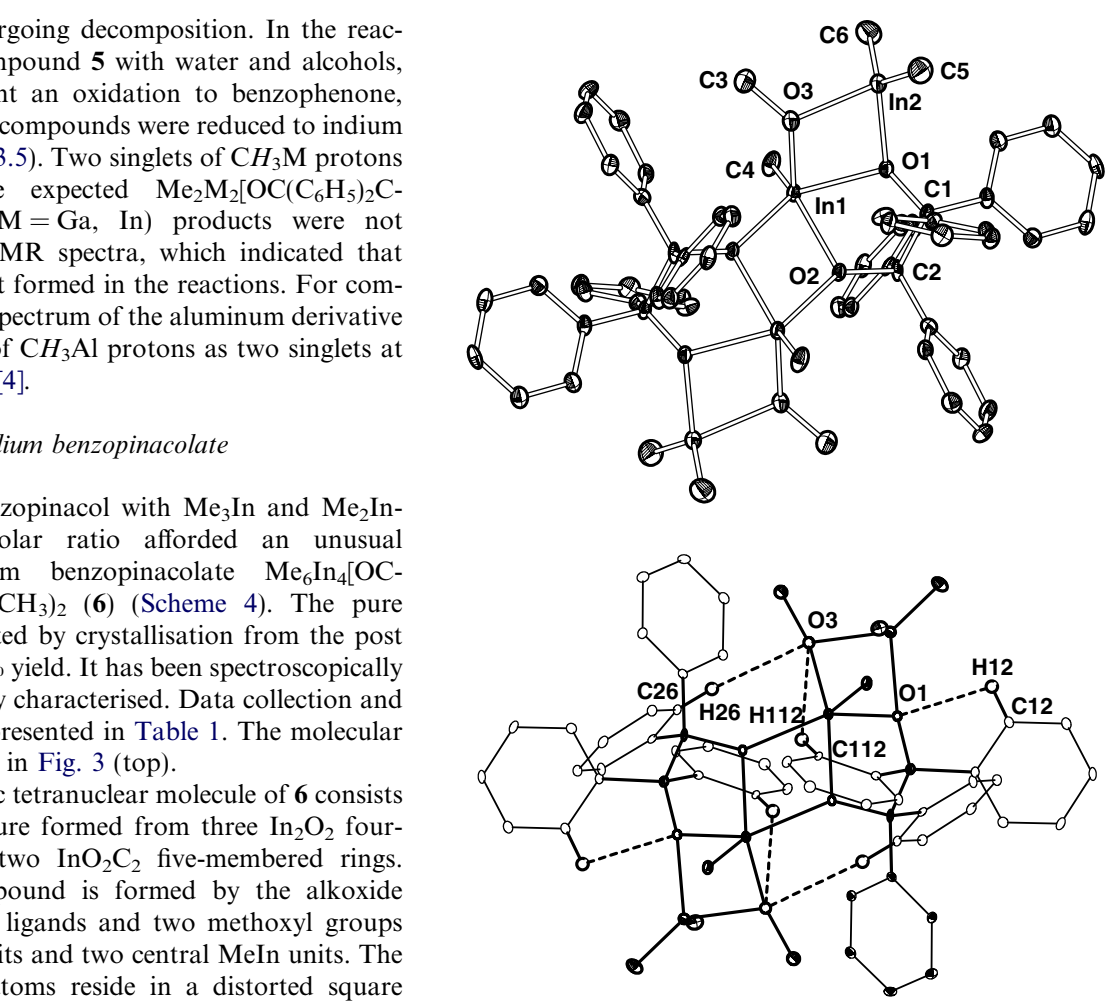
mediate product, undergoing decomposition. In the reaction of the indium compound **5** with water and alcohols, benzopinacol underwent an oxidation to benzophenone, whereas organoindium compounds were reduced to indium (for details see Section 3.5). Two singlets of CH_3M protons characteristic for the expected $Me_2M_2[OC(C_6H_5)_2C(C_6H_5)_2O]_2(C_4H_8O)$ (M = Ga, In) products were not observed in the ^1H NMR spectra, which indicated that these products were not formed in the reactions. For comparison, the ^1H NMR spectrum of the aluminum derivative **2** revealed the signals of CH_3Al protons as two singlets at −1.06 and −1.85 ppm [4].

2.4. Methylmethoxo indium benzopinacolate

The reaction of benzopinacol with Me_3In and Me_2InOMe in a 1:1:1 molar ratio afforded an unusual methylmethoxo indium benzopinacolate $Me_6In_4[OC(C_6H_5)_2C(C_6H_5)_2O]_2(OCH_3)_2$ (**6**) (Scheme 4). The pure compound **6** was isolated by crystallisation from the post reaction mixture in 35% yield. It has been spectroscopically and crystallographically characterised. Data collection and structure analysis are presented in Table 1. The molecular structure of **6** is shown in Fig. 3 (top).

The centrosymmetric tetranuclear molecule of **6** consists of a pentacyclic structure formed from three In_2O_2 four-membered rings and two InO_2C_2 five-membered rings. The tetranuclear compound is formed by the alkoxide termini of two diolate ligands and two methoxyl groups bridging two Me_2In units and two central MeIn units. The five-coordinate In(1) atoms reside in a distorted square pyramidal geometry with the basal plane consisting of three oxygen atoms of the diolate units and one atom of the OMe group. The Me group is situated in an apical position. The angles $O(2)^{\#1}$–In(1)–O(1) 135.4(1)° and O(2)–In(1)–O(3) 121.1(1)° indicate that the coordination geometry of the In(1) atoms is closer to a square pyramidal structure than to a trigonal bipyramidal geometry.

It is worthy of note, that the two terminal In_2O_2 rings deviate highly from a plane tetragon {sums of the angles about the oxygen atoms $\sum$[O(1)]: 349.8° and $\sum$[O(3)]: 342.8°; torsion angle O(3)–In(1)–O(1)–In(2): −16.8(1)°}.



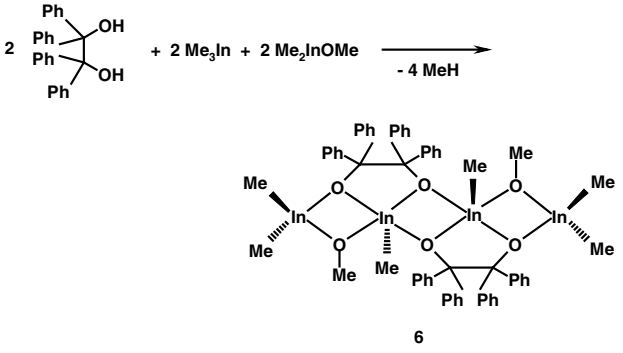


Fig. 3. Molecular structure of $Me_6In_4[OC(C_6H_5)_2C(C_6H_5)_2O]_2(OCH_3)_2 \cdot 2CH_2Cl_2$ (**6** · $2CH_2Cl_2$). (Top) Thermal ellipsoids are shown at the 40% level. Hydrogen atoms and molecules of CH_2Cl_2 are omitted for clarity. Selected bond lengths (Å) and bond angles (°): In(1)–O(1) 2.217(3), In(1)–O(2) 2.156(3), In(1)–O(3) 2.176(3), In(1)–$O(2)^{\#1}$ 2.182(3), C(4)–In(1) 2.138(5), C(5)–In(2) 2.131(6), C(6)–In(2) 2.148(6), In(2)–O(1) 2.157(3), In(2)–O(3) 2.193(3); $O(2)^{\#1}$–In(1)–O(1) 135.4(1), O(2)–In(1)–O(3) 121.1(1), C(4)–In(1)–$O(2)^{\#1}$ 116.3(2), C(4)–In(1)–O(1) 106.8(2), C(4)–In(1)–O(2) 125.8(2), C(4)–In(1)–O(3) 110.5(2), C(5)–In(2)–C(6) 134.8(2), C(5)–In(2)–O(1) 116.5(2), C(6)–In(2)–O(1) 99.2(2), C(5)–In(2)–O(3) 112.7(2), C(6)–In(2)–O(3) 101.5(2), O(1)–In(2)–O(3) 76.3(1). (Bottom) A view of the intramolecular hydrogen bonds in the molecule of **6** · $2CH_2Cl_2$. Hydrogen atoms are omitted excluding those involved in the H-bond formation. The dashed lines represent C–H···O hydrogen bonds.

Scheme 4.

A detailed examination of the structural data showed that very probably the deviation is the result of intramolecular interactions of *ortho*-positioned hydrogens with O(1) and O(3) oxygen atoms [(O(1)–H(12): 2.40 Å, C(12)–H(12)···O(1): 102°, O(3)–H(26): 2.55 Å, C(26)–H(26)···O(3): 174°, O(3)–H(112): 2.64 Å, C(112)–H(112)···O(3): 138°) (Fig. 3 bottom). The hydrogen atoms were placed in calculated positions, however short distances between the confirmed *ortho*-positioned carbons and O(1) and O(3) oxygen atoms [C(26)–O(3): 3.499(6) Å, C(112)–O(3): 3.406(7) Å, C(12)–O(1): 2.760(5) Å] indicated the possibility of involving the hydrogen atoms H(12), H(26) and

H(112) in hydrogen bond interactions with the oxygen atoms O(1) and O(3). Intermolecular hydrogen interactions in the crystal structure were not found. Moreover long-distances donor–acceptor interactions were absent in the supramolecular structure. Recently Lewinski has presented the substantial role of non-covalent interactions ($C–H_{aryl}\cdots O$, $C–H_{aliph}\cdots O$ and $C–H\cdots\pi$ hydrogen bonds) in molecular assembly and the structure of metal complexes [22].

Compound **6** was more stable than the compound **5**. It demonstrated very low solubility in solvents. The ^1H NMR spectrum of **6** revealed one singlet at 2.17 ppm of OCH_3 protons and three singlets (at −0.14, −0.81 and −1.05 ppm) of $InCH_3$ protons with a 1:1:1:1 integration ratio, which is in agreement with the measured structure of the compound. The presence of two signals of *C*O carbons (at 87.22 and 82.98 ppm) in the ^{13}C NMR spectrum indicate the inequivalence of the CO groups. In comparison with the *C*O signals of group 13 metal benzopinacolates: **1** (93.31 ppm), **2** (92.81 and 87.73 ppm), **3** (88.85 ppm), **4** (91.29 ppm) and **5** (89.94 ppm), the *C*O signal of **6** at 82.98 ppm is shifted upfield. It is the result of weakening of the electron withdrawing effect of the aromatic rings by a donating effect of the methoxyl groups.

Group 13 alkylalkoxides incorporating diolate ligands are rare. Earlier Chisholm and Lin [23] reported one dimeric methylalkoxo aluminum biphenolate (μ-biphenolate)AlMe(μ)–OCH(^{i}Pr)$_2$AlMe$_2$, prepared from the reaction of biphenolate-H_2 with 2 mol equiv. of Me_3Al in the presence of 1 mol equiv. of 2,4-dimethyl-3-pentanol. The compound demonstrates a catalytic activity in ROP of *rac*-lactide.

In conclusion, trinuclear alkylaluminum benzopinacolates react with alcohols to yield binuclear complexes $R_2Al_2[OC(C_6H_5)_2C(C_6H_5)_2O]_2(C_4H_8O)$. Alcohols, as well as water, play the role of a factor formally eliminating a R_3Al molecule (as an alkylaluminum alkoxide) from the trinuclear benzopinacolates. The compounds **4** and **5** were studied as starting materials for the syntheses of dinuclear complexes $Me_2M_2[OC(C_6H_5)_2C(C_6H_5)_2O]_2(C_4H_8O)$ (M = Ga, In), a potential ROP of cyclic esters. Unfortunately, in the presence of water and alcohols compounds **4** and **5** underwent a decomposition reaction to benzopinacol and mixtures of metalloxanes and alkoxides. Contrary to the stable aluminum compound **2**, presumably the gallium and indium derivatives $Me_2M_2[OC(C_6H_5)_2C(C_6H_5)_2O]_2$-$(C_4H_8O)$ were formed as unstable intermediate products. Further attempts with substituted benzopinacols will be undertaken to obtain stable dinuclear complexes.

We found that the reaction of benzopinacol with Me_3In and Me_2InOMe in a 1:1:1 molar ratio afforded the unusual tetranuclear methylmethoxo indium benzopinacolate **6**. The reaction of diols with a mixture of group 13 trialkyl metals and dialkyl metal alkoxides can be regarded as the general method of synthesis of alkylalkoxo group 13 metal diolates. Diolate alkylmetal complexes supported by additional alkoxide ligands are potential useful reagents in organic transformations and polymerisation. Further studies on the syntheses and characteristics of alkylalkoxo group 13 metal diolates will be continued.

3. Experimental

All manipulations were carried out using standard Schlenk techniques under an inert gas atmosphere. The solvents were distilled over a blue benzophenone-K complex. Prof. K.B. Starowieyski (Warsaw University of Technology) kindly supported us with Me_3Ga and Me_3In. Compound **1**, benzopinacol and $^tBu_3Al$ were synthesised as described in the literature [4,24,25]. ^1H and ^{13}C NMR spectra were run on Mercury-400BB spectrometer. ^1H NMR spectra were recorded at 400.09 MHz. Chemical shifts were referenced to the residual proton signals of $CDCl_3$ (7.26 ppm). ^{13}C NMR spectra were run at 100.60 MHz (standard: chloroform $^{13}CDCl_3$, 77.20 ppm). Elemental analysis of **6** was obtained on a Perkin–Elmer 2400 analyser.

3.1. Reactions of $Me_5Al_3[OC(C_6H_5)_2C(C_6H_5)_2O]_2 \cdot 2CH_2Cl_2$ (**1** · $2CH_2Cl_2$) with alcohols

A solution of MeOH (0.016 g, 0.5 mmol) in THF (4 cm^3) was added to solid compound **1** · $2CH_2Cl_2$ (0.528 g, 0.5 mmol). The mixture was set aside for ca. 24 h. Volatiles were removed in vacuo. A resulting glassy solid consisting of **2** and Me_2AlOMe was washed with *n*-C_6H_{14} (5 cm^3) two times, then dried in vacuo furnishing a white solid of **2** · THF (0.421 g, 88%). The ^1H NMR spectrum of products washed away from **2** · THF and soluble in *n*-C_6H_{14} revealed signals of Me_2AlOMe. ^1H NMR ($CDCl_3$): δ 3.63 [3H, s, $(CH_3)_2AlOCH_3$], −0.95 [6H, s, $(CH_3)_2AlOCH_3$] ppm. The spectrum of Me_2AlOMe obtained in the reaction of **1** · $2CH_2Cl_2$ with MeOH was similar to that published elsewhere [26].

Similarly, from of EtOH (0.023 g, 0.5 mmol) and **1** · $2CH_2Cl_2$ (0.528 g, 0.5 mmol) the white solid of **2** · THF (0.392 g, 82%) was obtained. The ^1H NMR spectrum of products washed away from **2** · THF and soluble in *n*-C_6H_{14} revealed signals of Me_2AlOEt. ^1H NMR ($CDCl_3$): δ 3.94 [2H, q, $(CH_3)_2AlOCH_2CH_3$], 1.39 [3H, t, $(CH_3)_2AlOCH_2CH_3$], −0.86 [6H, s, $(CH_3)_2AlOCH_2CH_3$] ppm. The spectrum of Me_2AlOEt obtained in the reaction of **1** · $2CH_2Cl_2$ with EtOH was similar to that published elsewhere [27].

The reaction of ^tBuOH (0.037 g, 0.5 mmol) with **1** · $2CH_2Cl_2$ (0.528 g, 0.5 mmol) afforded **2** · THF (0.430 g, 90%). The ^1H NMR spectrum of products washed away from **2** · THF and soluble in *n*-C_6H_{14} revealed signals of Me_2AlO^tBu. ^1H NMR ($CDCl_3$): δ 1.27 [9H, s, $(CH_3)_2AlOC(CH_3)_3$], −0.51 [6H, s, $(CH_3)_2AlOC(CH_3)_3$] ppm. The spectrum of Me_2AlO^tBu obtained in the reaction of **1** · $2CH_2Cl_2$ with ^tBuOH was similar to that published elsewhere [28].

The ^1H NMR spectrum of **2** obtained in the above reactions was the same as described earlier [4].

3.2. Synthesis of $^tBuAl[OC(C_6H_5)_2C(C_6H_5)_2O](C_4H_8O)$ (3)

A solution of $^tBu_3Al \cdot OEt_2$ (0.544 g, 2 mmol) in THF (10 cm^3) was added to a stirred solution of benzopinacol (0.732 g, 2.0 mmol) in THF (30 cm^3) at 0 °C. The reaction mixture was allowed to warm to room temperature and refluxed (1 h). Volatiles were removed in vacuo, then a white colourless solid of **3** (0.718 g, 69%) was sublimed off in vacuo. A solution of **3** in *n*-C_6H_{14} upon cooling at −25 °C furnished X-ray quality crystals. M.p.: 171 °C.

^{1}H NMR ($CDCl_3$): δ 7.64–7.00 (20H, m, H aromat), 3.71 [broadened, 4H, m, CH_2O (THF)], 1.15 (9H, s, (CH_3)$_3$C), 1.76 [broadened, 4H, m, CH_2 (THF)] ppm. ^{13}C NMR ($CDCl_3$): δ 150.31, 148.22, 129.37, 129.33, 126.78, 126.00, 125.49, 125.21 (*C* aromat), 88.85 (*C*O), 65.80 [*C*H$_2$O (THF)], 30.41 [(*C*H$_3$)$_3$C], 24.94 [*C*H$_2$ (THF)], 15.25 [(CH$_3$)$_3$*C*] ppm.

Molecular weight: found: 504, calc.: 520. Elemental *Anal.* Calc.: Al, 5.19; ^{t}Bu, 10.96 wt%. Found: Al, 5.30; hydrolysable *tert*-butyl groups, 10.62.

3.3. Synthesis of $Me_5Ga_3[OC(C_6H_5)_2C(C_6H_5)_2O]_2 \cdot 2CH_2Cl_2$ ($4 \cdot 2CH_2Cl_2$)

A solution of benzopinacol (1.098 g, 3 mmol) in CH_2Cl_2 (30 cm^3) was added to a stirred solution of Me_3Ga (0.541 g, 4.7 mmol) in Et_2O (20 cm^3) at −78 °C. The reaction mixture was allowed to warm to room temperature (2 h). The post reaction mixture was stored at −5 °C, yielding colourless crystals of $4 \cdot 2CH_2Cl_2$ (1.860 g, 1.35 mmol, 90%). m.p.: 186–189 °C.

^{1}H NMR ($CDCl_3$): δ 7.33–7.01 (40H, m, H aromat), −0.15 (6H, s, GaCH_3), −0.67 (6H, s, GaCH_3), −0.71 (3H, s, GaCH_3). ^{13}C NMR ($CDCl_3$): δ 145.28, 144.92, 130.63, 130.59, 128.56, 127.28, 126.93, 126.52, 126.46,126.40 (*C* aromat) 91.29 (*C*O), −0.14, −0.31 (Ga*C*H$_3$) ppm. Anal. Calc. for $C_{59}H_{59}Ga_3O_4Cl_4$: C, 59.85; H, 4.99%. C, 59.40; H, 5.30%.

3.4. Synthesis of $Me_5In_3[OC(C_6H_5)_2C(C_6H_5)_2O]_2$ (5)

A solution of benzopinacol (0.732 g, 2 mmol) in CH_2Cl_2 (20 cm^3) was added to a stirred solution of Me_3In (0.525 g, 3.3 mmol) in Et_2O (20 cm^3) at −78 °C. The reaction mixture was allowed to warm to room temperature (2 h). The post reaction mixture was stored at −25 °C (one week), yielding a white solid (0.340 g) sensitive to light and higher temperature. The solid undergoes a slow decomposition and becomes dark. NMR spectra revealed the signals of **5** (main product) and a mixture of methylindium compounds. An attempt to isolate the pure compound **5** by recrystallisation failed.

^{1}H NMR (**5**) ($CDCl_3$): δ 7.85–7.04 (40H, m, H aromat), −0.21 (6H, s, InCH_3), −0.47 (6H, s, GInCH_3), −0.72 (3H, s, InCH_3). ^{13}C NMR (**5**) ($CDCl_3$): δ 147.78, 130.61, 130.52, 127.17, 126.80, 126.32 (*C* aromat), 89.94 (*C*O), 0.98, 0.49 (In*C*H$_3$) ppm.

3.5. Reactions of compounds 4 and 5 with water and alcohols

The reaction of compound **4** with water was carried out as described in Section 3.1. using 0.592 g (0.5 mmol) of $4 \cdot 2CH_2Cl_2$ and 0.0045 g (0.25 mmol) of water. After removal of THF from the post reaction mixture, *n*-C_6H_{14} (10 cm^3) was added to the reaction products. A white solid precipitated. The solution was filtered to separate the solid. The solvent was removed from the filtrate under reduced pressure and products, soluble in *n*-C_6H_{14}, were obtained. The products soluble in *n*-C_6H_{14} and the solid were studied by NMR spectroscopy. ^{1}H NMR (reaction product of **4** with water, soluble in *n*-C_6H_{14}) ($CDCl_3$): δ 7.5–6.9 (H aromat, m), 3.04 (O*H*, s, benzopinacol), 0.0 to −1.0 (CH_3, m, broad, galloxanes) ppm. ^{1}H NMR (white solid insoluble in *n*-C_6H_{14}) ($CDCl_3$): δ 7.37–7.21 (20H, m, H aromat, benzopinacol), 3.04 (2H, s, OH, benzopinacol) ppm.

Reactions of compound **5** with water and workup of the products were carried out as described above for **4**, using 0.574 g (0.5 mmol) of **5** and 0.0045 g (0.25 mmol) of water at 0 and −40 °C. The reaction mixtures were allowed to warm to room temperature. After addition of *n*-C_6H_{14} to the post reaction mixture, a grey solid precipitated. ^{1}H NMR (reaction product of **5** with water, soluble in *n*-C_6H_{14}) ($CDCl_3$): δ 7.45–7.82 (H aromat, m, benzophenone, benzopinacol) 3.04 (O*H*, s, benzopinacol) ppm. ^{13}C NMR (reaction product of **5** with water, soluble in *n*-C_6H_{14}) ($CDCl_3$): δ 77.21 (*C*═O, benzophenone) ppm. The grey solid insoluble in *n*-C_6H_{14}, probably containing indium, was a complicated mixture of products. The products of the reactions carried out at 0 and −40 °C were the same.

Reactions of **4** with alcohols were carried out as described in Section 3.1 using 0.592 g (0.5 mmol) of $4 \cdot 2CH_2Cl_2$ and 0.5 mmol of alcohol (0.023 g of EtOH, 0.016 g of MeOH). After addition of *n*-C_6H_{14} to the post reaction mixture, a white solid appeared. The solution was filtered to separate the solid. The solvent was removed from the filtrate under vacuum and products soluble in *n*-C_6H_{14} were obtained. The products soluble in *n*-C_6H_{14} and the solid were studied by NMR spectroscopy.

^{1}H NMR (reaction product of **4** with EtOH, soluble in *n*-C_6H_{14}) ($CDCl_3$): δ 7.17–7.81 (H aromat, m), 3.87 (OCH_2CH$_3$, m), 1.26 (OCH$_2$CH_3, m), −0.2 to −0.5 (CH_3Ga, broad, m, oligomeric methylgallium compounds), 3.04 (O*H*, s, benzopinacol), −0.15, −0.67 and −0.71 (CH_3Ga, three singlets, unreacted compound **4**) ppm. ^{1}H NMR (white solid, insoluble in *n*-C_6H_{14}) ($CDCl_3$): δ 7.37–7.21 (20H, m, H aromat, benzopinocol), 3.04 (2H, s, OH, benzopinacol) ppm. Similarly, from **4** and MeOH, products soluble in *n*-C_6H_{14} and a white solid were obtained. ^{1}H NMR (reaction product of **4** with MeOH, soluble in *n*-C_6H_{14}) ($CDCl_3$): δ 7.02–7.32 (H aromat, m), 3.58 (OCH_3, m), −0.2 to −0.6 (CH_3Ga, broad, m, oligomeric methylgallium compounds), 3.04 (O*H*, s, benzopinacol), −0.15, −0.67

and −0.71 (CH_3Ga, three singlets, unreacted compound **4**) ppm. ^1H NMR (white solid, insoluble in n-C_6H_{14}) ($CDCl_3$): δ 7.37–7.21 (20H, m, H aromat, benzopinacol), 3.04 (2H, s, OH, benzopinacol) ppm.

The spectra indicated that the post reaction mixtures of **4** with EtOH and MeOH consisted of benzopinacol, methylgallium alkoxides and unreacted compound **4**.

The reaction of compound **5** with MeOH was carried out as described above using 0.574 g (0.5 mmol) of **5** and 0.016 g (0.5 mmol) of MeOH. A grey solid of indium precipitated from the post reaction mixture of **5** with MeOH in THF. After filtration the grey solid was removed. THF was distilled off from the filtrate and reaction products were studied by ^1H NMR spectroscopy. ^1H NMR ($CDCl_3$): δ 7.48–7.83 (H aromat, m, benzophenone, benzopinacol), 3.69, 3.51 (OCH_3, m, broad), −0.07, −0.35 ($InCH_3$, m, broad, methylindium methoxides), −0.21, −0.47 −0.72 ($InCH_3$, s, unreacted compound **5**) ppm. Similarly to the partial hydrolysis products of **5**, the post reaction mixture of **5** with MeOH contained indium, benzophenone, benzopinacol and unreacted **5**.

3.6. Synthesis of $Me_6In_4[OC(C_6H_5)_2C(C_6H_5)_2O]_2(OCH_3)_2 \cdot 2CH_2Cl_2$ ($\mathbf{6} \cdot 2CH_2Cl_2$)

A solution of methanol (0.096 g, 3 mmol) in Et_2O (2 cm^3) was added to a solution of Me_3In (0.960 g, 6 mmol) in Et_2O (10 cm^3) at −78 °C. A reaction mixture was allowed to warm to room temperature (1 h), then cooled to −78 °C. A solution of benzopinacol (1.098 g, 3 mmol) in CH_2Cl_2 (20 cm^3) was added dropwise to the mixture. A reaction mixture was allowed to warm to room temperature (2 h). Colourless, X-ray quality crystals of $\mathbf{6} \cdot 2CH_2Cl_2$ (0.790 g, 0.53 mmol) were obtained after crystallisation from the post reaction mixture at 5 °C (yield 35%). The compound undergoes decomposition at 163 °C without melting.

^1H NMR ($CDCl_3$): δ 7.00–7.40 (m, H aromat), 2.17 (6H, s, OCH_3), −0.14 (6H, s, $InCH_3$), −0.81 (6H, s, $InCH_3$), −1.05 (6H, s, $InCH_3$). ^{13}C NMR ($CDCl_3$): δ 144.11, 130.84, 128.58, 127.29 (C aromat), 87.22, 82.98 (CO), 52.80 (OCH_3), −4.26, −4.51 ($InCH_3$) ppm. *Anal.* Calc. for $C_{62}H_{68}In_4O_6Cl_4$: C, 49.77; H, 4.50. Found: C, 49.02; H, 4.76%.

3.7. X-ray crystal structure analyses

Crystals of compounds **3**, **4** and **6** were mounted in inert oil and sealed in glass capillaries under argon. Determination of the crystal structures of **3**, **4** and **6** was performed on a KUMA KM4CCD κ-axis diffractometer with graphite-monochromated Mo Kα radiation. The crystals of **3**, **4** and **6** were positioned 65 mm from the KM4CCD camera. For compound **3** 1000 frames were measured in 0.6° intervals with a counting time of 10 s. For compound **4** 600 frames were measured in 1.0° intervals with a counting time of 25 s. For compound **6** 1000 frames were measured in 1.2° intervals with a counting time of 25 s. All of the data were corrected for Lorentz and polarisation effects. No absorption correction was applied. Data reduction and analysis were carried out using the KUMA Diffraction (Wrocław) programs. The structures of the investigated crystals were solved by direct methods [29] and refined using the SHELXS/SHELXL computer programs [30]. All hydrogen atoms were placed in calculated positions and their thermal parameters were refined isotropically. Scattering factors were taken from the literature [31, Tables 6.1.1.4 and 4.2.4.2].

Absorption corrections were not made for compounds **4** and **6** because, following our experience, for such values of absorption coefficients, the corrections do not lead to a significant improvement of the final results. According to [32], for $0 < \mu < 25$ cm^{-1} ($0 < \mu < 2.5$ mm^{-1}) an absorption correction is not usually necessary unless a crystal with a very unfavorable shape is used, since if applied the absorption corrections will not significantly improve in accuracy of the results. In our case the crystals were rather small with no big differences in the three dimensions.

The X-ray structures were measured in the Crystallography Unit of the Physical Chemistry Laboratory at the Chemistry Department of the University of Warsaw.

dinitrogen and freeze–pump–thaw degassed immediately prior to use. The ^{1}H, $^{13}C\{1H\}$, $^{31}P\{^{1}H\}$ NMR spectra were recorded at 300, 75.4 and 121.4 MHz, respectively, at 295 K, using a Bruker Avance DRX 300 MHz NMR spectrometer. ^{1}H NMR and $^{13}C\{^{1}H\}$ NMR chemical shifts are reported in ppm downfield from TMS. ^{1}H NMR chemical shifts are referenced to the residual hydrogen signal of the deuterated solvents and in $^{13}C\{^{1}H\}$ NMR the ^{13}C signal of the deuterated solvents was used as a reference. $^{31}P\{^{1}H\}$ NMR chemical shifts are reported in ppm downfield from H_3PO_4 and referenced to the high frequency of 85% H_3PO_4. GC analyses were carried out in a Shimadzu GCMS-QP5000 Electron Ionization (EI) system. Elemental analyses were determined on a Heraeus CHN-O-RAPID elemental analyzer. The starting materials 1,3-benzenedimethanol, chlorodiisopropylphosphine, 4-(dimethylamino)pyridine (DMAP), $PdCl_2$, $CDCl_3$ were purchased from Aldrich Chemical Co. and used without further purification. The complex $[PdCl_2(COD)]$ was synthesized according to the published procedure [5].

2.2. Preparation and procedure

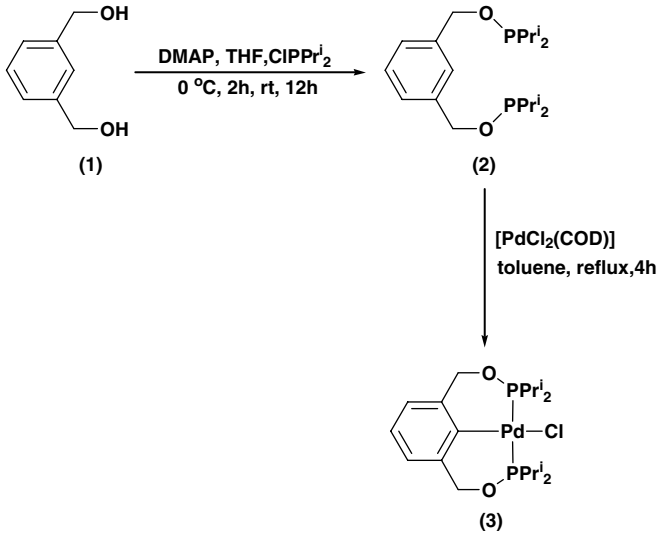
The synthesis and characterization of the pincer ligand 1,3-bis[(di-isopropylphosphinite)methyl]benzene$\{C_6H_4(CH_2\text{-}OPPr^{i})_2\text{-}1,3\}$ (**2**), its palladium derivative **3** and catalytic experiments were done as follows.

2.2.1. Synthesis and characterization of $\{C_6H_4(CH_2OPPr^{i})_2\text{-}1,3\}$ (2)

To a stirred solution of 1,3-benzenedimethanol (0.4145 g, 3 mmol) and DMAP (0.7451 g, 6.1 mmol) in THF (60 mL) was added $ClPPr^{i}_2$ (0.95 mL, 6 mmol) *via* a syringe at 0 °C. After the addition was completed the cooling bath was removed and stirring was continued at room temperature overnight. The solvent was then evaporated and the crude product dissolved in toluene and passed through a short path of silica gel. Toluene was evaporated under vacuum to afford a colorless oil of **3** (1.056 g, 2.85 mmol, 95%). This compound was used in the next step without further purification. ^{1}H NMR (299.847 MHz, $CDCl_3$): $\delta = 0.72$ (dd, $^{3}J_{HP} = 15.3$ Hz, $^{3}J_{CHCH_3} = 7.2$ Hz, 12H, $CH(CH_3)_2$), 0.84 (dd, $^{3}J_{HP} = 10.2$ Hz, $^{3}J_{CHCH_3} =$ 6.9 Hz, 12H, $CH(CH_3)_2$), 1.40 (m, 4H, $CH(CH_3)_2$), 4.47 (d, $J_{HP} = 8.40$ Hz, 4H, CH_2O), 6.73–7.13 (m, 4H, ArH). $^{31}P\{^{1}H\}$ NMR (121.379 MHz, $CDCl_3$): $\delta = 155.23$ (s). $^{13}C\{^{1}H\}$ NMR (75.404 MHz, $CDCl_3$): $\delta = 17.22$ (d, $J = 8.6$ Hz, $CH(CH_3)_2$), 18.13 (d, $J = 20.1$ Hz, $CH(CH_3)_2$), 28.43 (d, $J = 17.7$ Hz, $CH(CH_3)_2$), 74.52 (d, $J =$ 21.2 Hz, CH_2O), 126.80, 128.43, 129.27, 140.11 (d, $J = 7.4$ Hz), Ar.

2.2.2. Synthesis and characterization of $[PdCl\{C_6H_3(CH_2OPPr^{i}_2)\text{-}2,6\}]$ (3)

A solution of **2** (1.056 g, 2.85 mmol) in toluene (20 mL) was added dropwise to a suspension of $[PdCl_2(COD)]$ (0.815 g, 2.85 mmol) in toluene (30 mL) and set up for reflux for 5 h. The solution was filtered over a short pad of silica gel, washed with diethyl ether and pumped off to dryness. The resulting solid was extracted with diethyl ether and then the solvent was removed under vacuum. Recrystallization of the crude product in CH_2Cl_2/hexane resulted in the formation of a colorless crystalline solid, (1.026 g, 2 mmol, 70%). ^{1}H NMR (299.847 MHz, $CDCl_3$): $\delta = 1.11$ (dd, $^{3}J_{HP} = 14.40$ Hz, $^{3}J_{CHCH_3} = 6.70$ Hz, 12H, $CH(CH_3)_2$), 1.40 (dd, $^{3}J_{HP} = 17.40$ Hz, $^{3}J_{CHCH_3} =$ 6.70 Hz, 12H, $CH(CH_3)_2$), 2.40 (m, 4H, $CH(CH_3)_2$), 4.77 (d, $J_{HP} = 19.2$ Hz, 2H, CH_2O), 6.82–7.21 (m, 3H, Ar). $^{31}P\{^{1}H\}$ NMR (121.392 MHz, $CDCl_3$): $\delta = 144.88$ (s). $^{13}C\{^{1}H\}$ NMR (75.404 MHz, $CDCl_3$): $\delta = 15.02$ (brs, CH_3), 16.50 (brs, CH_3), 18.28 (brs, CH_3), 26.78 (brs, CH), 80.55 (CH_2O), 124.56, 127.74, 139.72 (vt, $J = 6.33$ Hz), 145.86. *Anal.* Calc. for $C_{20}H_{35}Cl_1O_2P_2Pd_1$ ($M_r = 511.311$): C, 46.98; H, 6.90. Found: C, 47.05; H, 6.93%.



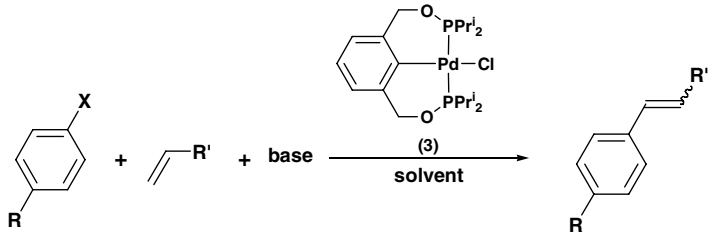
2.2.3. General procedure for heck coupling reactions

A solution (solvent, 3–5 ml) of 5.0 mmol of halobenzene, 6.0 mmol of alkene, and the prescribed amount of **3** as catalyst was introduced into a Schlenk tube. The tube was charged with a magnetic stir bar and 1.1 equiv. of base, sealed, and fully immersed in a 180 °C silicon oil bath. After the prescribed reaction time, the mixture was cooled to room temperature and the organic phase was analyzed by gas chromatography.

3. Results and discussion

The overwhelming majority of the reported PCP pincer complexes are based on the same structural principle, namely a bis-chelating metallacycle incorporating an aromatic carbon formed by C–H activating a 1,3-di(phosphinomethyl)benzene moiety. Except $[MBr\{C_6H_3(CH_2\text{-}CH_2PPh_2)_2\text{-}2,6\}]$ (M = Pd, Pt) [6], which is the only reported example of a PCP bis(phosphino)pincer complex with two six-membered metallacycles by Venanzi and coworkers, so far all other reported PCP pincer complexes are mainly five-membered metallocycles. To the best of our knowledge there are no reports on the synthesis and usage of bis(phosphinite) PCP pincer complexes with two six-membered metallocycles. We have previously reported on the synthesis of a new class of unsymmetric PCP′ pincer complexes which are useful for the Heck coupling reaction of aryl iodides [7]. Herein, we report the synthesis and catalytic activity of the first bis(phosphinite) PCP pincer complex with two six-membered metallacycles, showing that complex **3** has excellent catalytic activity in the Heck coupling reaction of halo-benzenes, including aryl chlorides.

The synthesis of the ligand 1,3-bis[(di-isopropylphosphinite)methyl]benzene (**2**) is outlined in Scheme 1. Thus 1,3-benzenedimethanol **1** is converted into **2** by using $ClPPr^{i}_2$ in THF in the presence of DMAP as a base. The $^{31}P\{^{1}H\}$ NMR spectrum of this compound shows a sharp singlet at 155.23 ppm. Refluxing **2** with $[PdCl_2(COD)]$ in



Scheme 1. Synthesis of the two six-membered Pd complex **3**.

toluene for 5 h affords the palladium complex [PdCl{C_6H_3-($CH_2OPPr^i_2$)-2, 6}] (**3**) in 85% yield. The $^{31}P\{^1H\}$ NMR spectrum of this complex shows a singlet at 144.88 ppm. The palladium complex **3** is thermally stable up to 180 °C and in the open air (oxygen and moisture).

Reaction conditions were found where complex **3** exhibited very good catalytic activity with excellent results on the Heck coupling of iodobenzene with styrene. Hence, we decided to extend the study to other substrates, in order to determine whether our catalyst could be operative in the C–C coupling of less reactive C–Br and C–Cl bonds. The results obtained are presented in Table 1. In general, complex **3** exhibits higher activity than the previously reported bis(phosphine) PCP pincer complexes [PdCl-{C_6H_3-2, 6-($CH_2PPr^i_2$)$_2$}] (**4**) and bis(phosphinito) PCP pincer complex [PdCl{C_6H_3-2, 6-($OPPr^i_2$)$_2$}] (**5**) (Scheme 2) [8,9]. In these cases, compound **4** is not effective at all with arylchlorides while complex **5** only showed TON's (Turn Over Numbers) 100 times lower with aryl chlorides when compared to complex **3**. Thus, while both complexes **4** and **5** have two five-membered palladacycle rings, complex **3** differs not only with respect to the phosphorous donor atoms but also to the size of the chelate rings. Based on the results shown in Table 1, complex **3**, with two phosphinite groups and two six-membered palladacycle rings (in principle more flexible), has higher activity than either complex **4** or **5**. Although complex **3** has the higher ring size of the three compounds, the fact that the phosphorous donor atoms in complex **3** are $OPPr^i_2$ makes it electronically different from complex **4** with $CH_2PPr^i_2$ donating groups.

There has been a considerable debate in the literature about the oxidation states of the species involved in the catalytic cycle, with Pd(IV)/Pd(II) and Pd(II)/Pd(0) both being proposed at various times [4,8]. Another feasible proposal for the present case is that it might be possible that

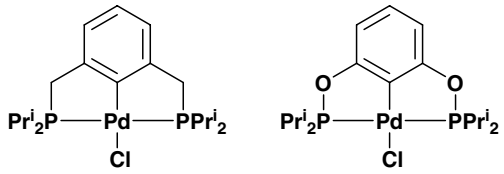


Table 1
Heck couplings of halobenzenes with different olefins using the complex [PdCl{$C_6H_3(CH_2OPPr^i)_2$-2,6}] (**3**) as a catalyst

Entry	Aryl halide	Olefin R′	Base	Catalyst (mol %)	Solvent	Yield (%)[a]	TON
1	PhCl	Ph	Na_2CO_3	0.01	NMP	94	9400

9	PhI	*n*-butyl methacrylate	Na_2CO_3	0.006	NMP	100[b]	16667
10	PhI	*n*-butyl methacrylate	Na_2CO_3	0.006	DMF	99[b]	16500
11	PhBr	*n*-butyl methacrylate	Na_2CO_3	0.006	NMP	100[b]	16667
12	PhBr	*n*-butyl methacrylate	Na_2CO_3	0.006	DMF	97[b]	16167

[a] Yields obtained at 180 °C by GC analysis are based on aryl halide and product. In all experiments with styrene only the *trans* configured product was detected.

[b] Using *n*-butylmethacrylate the product is a mixture of *n*-butyl-2-benzylacrylate, *n*-butyl-(E)-2-methylcinnamate and *n*-butyl (Z)-2-methylcinnamate. The yields reported are total.

Scheme 2. Five-membered Pd(II) PCP pincer complexes.

one or both arms may delicate at some stage enabling the compound to catalyze the reaction, thus behaving as a hemilabile ligand [10]. However, as it has been shown recently it is possible that complex **3** would not be the true catalyst but merely a catalyst precursor able to generate nanoparticles in the media [11]. Thus, although the precise mechanism of the catalytic reaction using complex **3** remains to be elucidated, efforts aimed at shedding some further light regarding this are currently under progress in our laboratories.

In summary, so far the catalyst described here is among the most active yet reported in Heck coupling reactions. This complex is ideal to catalyze the coupling of deactivated and sterically hindered aryl bromides and chlorides as they are comparatively inexpensive, very easily synthesized and can be used to give high conversion at low concentrations of catalyst. By comparing catalysts **3**, **4** and **5** it is clear that increasing the ring size from five to six-membered and also using phosphinite instead of phosphine groups both lead to the more active catalyst **3**.

2. Experimental

2.1. Apparatus

Melting points were measured with a Mettler FP90 equipment. Partial elemental analyses were performed on a Perkin Elmer CHN 2400 analyzer. Electronic spectra were recorded on a Hewlett Packard 8453 spectrometer using dimethylformamide (DMF) solutions and 1 cm cells. Infrared spectra were recorded on a Perkin Elmer FT-IR Spectrum GX spectrometer using nujol mulls between CsI plates as support. An YSI model 31 conductivity bridge was employed for molar conductivity measurements.

^{1}H and ^{13}C NMR spectra in solution were recorded on a Bruker DRX 400 ADVANCE spectrometer using tetramethylsilane (TMS) as internal standard. The samples (15 mg) were dissolved in $CDCl_3$ or DMSO-d_6 (~0.5 mL). Chemical shifts are given in ppm (δ units).

Solid-state NMR spectra were recorded on a Bruker AMX 400 wide-bore NMR spectrometer using a commercial triple resonance MAS 4 mm probe. Proton-decoupled ^{13}C MAS NMR spectra were acquired using cross polarization [10]. Typical acquisition parameters were the following: spin lock time 2.0 ms, recycle delay 3 s, ^{1}H B1 field 91 kHz, 3072 data points, 25000 acquisitions, and spectral width of 50 kHz. The spectra were acquired at 298 K with a spinning speed of 10 kHz. Adamantane was used as reference (high field signal at 29.5 ppm).

Solid-state MAS NMR spectra were recorded at different temperatures on a Bruker AMX 500 wide-bore NMR spectrometer using commercial triple resonance MAS probes (3.2 mm for ^{13}C and 2.5 mm for ^{1}H experiments). Proton-decoupled ^{13}C MAS NMR spectra were acquired using cross polarization [10]. Typical acquisition parameters were the following: spin lock time 3.0 ms, recycle delay 3 s, ^{1}H B1 field 83 kHz, 10240 data points, 5000 acquisitions, and spectral width of 66 kHz. The ^{13}C NMR spectra were acquired at 323 and 343 K with a spinning speed of 20 kHz. ^{1}H MAS NMR spectra were acquired at 298 K with a spinning speed of 30 kHz. Typical acquisition parameters were the following: recycle delay 5 s, ^{1}H B1 field 114 kHz, 4096 data points, 32 acquisitions, and spectral width of 20 kHz.

The crystal structures of H4NO$_2$Ac4M (**1**) and its nickel(II) complex (**2**) were investigated. Data for **1** were obtained using the XSCANS software [11] and for **2** with the Collect package [12]. Crystal data and refinement for **1** and **2** are shown in Table 1. Cell dimensions of the

crystals of **1** and **2** were found by least-squares fit of 27 and 20387 accurate centred reflections respectively, with 2θ values ranging from 10 to 25 (**1**) and from 7.3 to 53.0 (**2**). Three standard reflections measured periodically for **1** showed no decrease in intensity during data collection. Data were corrected for Lorentz and polarization effects, but not for absorption. The structures were solved by direct methods and refined on F^2 by full-matrix least-squares using the SHELX97 [13] program in a WinGX system [14]. Although some of the hydrogen atoms could be identified in a Fourier difference map, in the final model they were geometrically positioned and refined using a riding model. All non-H atoms were anisotropically refined.

2.2. Synthesis of *N*(4)-methyl-4-nitroacetophenone thiosemicarbazone (*1*) and its nickel(II) complex (*2*)

N(4)-Methyl thiosemicarbazide and 4-nitroacetophenone have been purchased from Aldrich Chem. Co. and used without further purification. The thiosemicarbazone **1** was obtained by mixing equimolar amounts (6.6 mmol) of 4-nitroacetophenone and *N*(4)-methyl thiosemicarbazide in absolute ethanol (40 mL) with addition of two drops of concentrated sulfuric acid as catalyst. The reaction mixture was kept under reflux for 7 h. The resulting solids were filtered at room temperature and then washed with ethanol followed by diethyl ether and dried under reduced pressure.

N(4)-Methyl-4-nitroacetophenone thiosemicarbazone (**1**): Yellow solid. Mp: 216.3–217.6 °C; *Anal.* Calc. for $C_{10}H_{12}N_4O_2S$: C, 47.61; H, 4.79; N, 22.21. Found: C, 47.55; H, 4.69; N, 22.26%. UV–Vis λ_{max} (cm^{-1}): 36900, 27400. IR (nujol mulls, cm^{-1}): 3342 ν_{ass}(NH), 3182 ν_s(NH), 1590 ν(C=N), 1538 $\nu_{ass}(NO_2)$, 1330 $\nu_s(NO_2)$, 819 ν(C=S). ^{1}H and ^{13}C NMR data are shown in Tables 4 and 5, respectively.

Complex **2** was obtained by reacting of **1** (2.0 mmol in 15 mL of ethanol) with nickel(II) acetate (1.0 mmol in 15 mL of ethanol). The reaction mixture was kept under reflux for 3 h. The resulting solid was filtered at room temperature and then washed with ethanol followed by diethyl ether.

N(4)-Methyl-4-nitroacetophenone thiosemicarbazonatonickel(II) (**2**): Brown solid. 257.0–258.4 °C (dec); *Anal.* Calc. for $C_{20}H_{22}N_8NiO_4S_2$: C, 42.80; H, 3.95; N, 19.96. Found: C, 42.77; H, 3.97; N, 19.78%. UV–Vis λ_{max} (cm^{-1}): 32050, 27100, 24070, 17600. IR (nujol mulls, cm^{-1}): 1578 ν(C=N), 1532 $\nu_{ass}(NO_2)$, 1332 $\nu_s(NO_2)$, 768 ν(C–S), 460 ν(M–N), 390 ν(M–S). Molar conductivity (1×10^{-3} mol L^{-1} DMF): 0.96 Ω^{-1} cm^2 mol^{-1}; ^{1}H and ^{13}C NMR data of **2** in DMSO-d_6 are shown in Tables 6 and 7 respectively.

2.3. Theoretical methodology

Theoretical studies were carried out using the GAUSSIAN03W software package [15]. HF and DFT geometry optimizations were performed using the geometries previously obtained by the PM3 semi-empirical method [16]. BLYP and B3LYP functionals with the standard Pople's split valence 6-31G* basis set [17] were used in the DFT calculations. The optimized geometries were characterized as true minima on the potential energy surface (PES) with all harmonic frequencies being real. The electronic-nuclear energies (E) were calculated by means of the HF and DFT methods. Solvent effects ($CHCl_3$, $\varepsilon = 6.66$, and DMSO, $\varepsilon = 46.7$) in the geometry optimizations were taken into consideration using the Polarizable Continuum Model (PCM) [17a,17b,18] as implemented in the HF/6-31G* and DFT/B3LYP/6-31G* GAUSSIAN03 software package.

DFT/BLYP/6-31G* optimized geometries of **1** were used for the hydrogen ($^{Calc}\delta_H$) and carbon ($^{Calc}\delta_C$) chemical shift calculations. Hydrogen and carbon calculated chemical shifts of **1** were obtained in relation to the correspondent DFT/BLYP/6-31G* calculated values for tetramethylsilane ($^{Calc}\delta_H$ 32.44 and $^{Calc}\delta_C$ 190.90). For **2** the HF/6-31G* method has been used. In this case, the values for tetramethylsilane are $^{Calc}\delta_H$ 32.09 and $^{Calc}\delta_C$ 201.19.

3. Results and discussion

Microanalyses of the nickel(II) complex (see Section 2) suggest the formation of $[Ni(4NO_2Ac4M)_2]$ (**2**) in which two anionic ligands coordinate to the metal. The molar conductivity data indicate that the complex is a non-electrolyte, in accordance with the proposed formulation.

The π–π^* absorption at ca. 37000 cm^{-1} in the electronic spectrum of **1** was not significantly modified upon complexation. The n–π^* transitions attributed to the azomethine and thioamide groups overlap at 27400 cm^{-1} in the electronic spectrum of **1**, but were found separately at 32050 and 27100 cm^{-1} in the spectrum of **2**. The N–Ni(II) and S–Ni(II) ligand-to-metal charge transfer transitions occur probably under the same envelope at ca. 24070 cm^{-1}. Ligand field transitions were observed at 17600 cm^{-1} [19,20].

The ν(C=N) stretching vibration at 1590 cm^{-1} in the infrared spectrum of **1** shifts to 1578 cm^{-1} in the spectrum of **2**, indicating coordination of the imine nitrogen. The absorption at 819 cm^{-1} attributed to ν(C=S) in the spectrum of **1** shifts to 768 cm^{-1} in that of **2**, indicating complexation through a thiolate sulfur. Absorptions at 390 cm^{-1} and at 460 cm^{-1} in the spectrum of **2** were attributed to the ν(Ni–S) and ν(Ni–N) vibrations respectively. Hence the infrared spectra indicate coordination of the thiosemicarbazones through the N–S chelating system [19,20].

3.1. Structural characterization of *1* and *2*

ORTEP3 views [21] of the structures of $H4NO_2Ac4M$ (**1**) and $[Ni(4NO_2Ac4M)_2]$ (**2**) can be seen in Figs. 1 and 2 respectively. Table 2 shows selected bond distances (Å) and angles (°). Both compounds form hydrogen bonds and the geometry parameters are presented in Table 3.

Table 2
Selected bond lengths (Å) and angles (°) for $H4NO_2Ac4M$ (**1**) and $[Ni(4NO_2Ac4M)_2]$ (**2**)

Bond lengths (Å)			Angle (°)		
Atoms	$H4NO_2Ac4M$	$[Ni(4NO_2Ac4M)_2]$	Atoms	$H4NO_2Ac4M$	$[Ni(4NO_2Ac4M)_2]$

N1–O2	1.209(4)	1.223(5)	N2–Ni–N2[a]		100.8(2)
Ni–N2		1.937(3)	N2–Ni–S[a]		164.2(1)
Ni–S		2.156(1)	N2–Ni–S		85.8(1)
			S–Ni–S[a]		91.5(1)

[a] Symmetry operation $-x+1, y, -z+1/2$.

Table 3
Hydrogen bonding geometry, H···A $\langle r(A) + 2.000$ A and $\angle DHA \rangle$ 110, for $H4NO_2Ac4M$ (**1**) and $[Ni(4NO_2Ac4M)_2]$ (**2**)

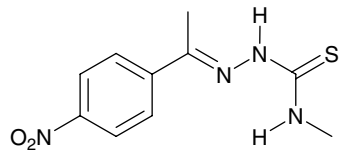
Compound	D–H···A	d(D–H)	d(H···A)	d(D–H···A)	∠D–H···A
$H4NO_2Ac4M$	N3–H–S$^{\#}$	0.86	2.70	3.533(3)	163.5
	N4–H–O1*	0.86	2.45	3.141(4)	138.2
$[Ni(4NO_2Ac4M)_2]$	N4–H4···O1′	0.86	2.34	3.067(6)	142.7

Symmetry operation: (#1) $-x+1, -y+1, -z+1$; (*) $-x+1, -y-1, -z+2$ and (′) $x, -y, z+1/2$.

Compound **1** crystallizes in the *EE* configuration in relation to the C7–N2 and N3–C8 bonds, respectively. Compound **2** crystallizes in the *EZ* configuration, in which a twisting of approximately 180° in the N3–C8 bond occurs, to match the steric requirements of bidentate coordination through the N2–S system.

In **1** the hydrogen at N4 forms an intermolecular hydrogen bond with O1, and the hydrogen at N3 forms an intermolecular hydrogen bond with the sulfur of a second molecule. The N4–H···O1 hydrogen bond observed in the crystal structure of **1** remains in the structure of **2**, forming a polymeric chain.

In the complex the sulfurs are approximately in *cis* positions to each other. The Ni atom lies on a twofold axis (1y 1/4). Different angles were found between the metal and the atoms in the two ligands: N2–Ni–N2* = 100.8(2)°, N2–Ni–S = 85.8(1)°, N2–Ni–S* 164.2(1)°, S–Ni–S* 91.5(1)° (* symmetry operation $-x+1, y, -z+1/2$), indicating that the geometry around the metal centre is distorted quadratic or distorted tetrahedral.



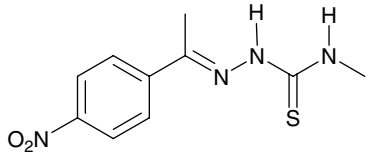
In the complex the two thiosemicarbazone molecules present the same bond distances and angles. The C8–S bond distance goes from 1.682(3) Å in the free thiosemicarbazone to 1.755(4) Å in the complex, in accordance with the C–S bond changing from mainly double in **1** to predominantly single in **2**. The C8–N3 bond varies from 1.364(5) Å in **1** to 1.298(5) Å in **2**, indicating the formation of a new predominantly double bond, in agreement with deprotonation at N3. The N2–N3 bond goes from 1.377(4) Å in **1** to 1.394(4) Å in **2**; C7–N2 goes from 1.275(4) in **1** to 1.296(5) Å in **2**; C7–C1 goes from 1.494(4) Å in **1** to 1.475(6) Å in **2**.

The angles in the thiosemicarbazone moiety undergo significant changes on coordination (see Table 2). The N4–C8–S angle goes from 123.5(3)° in **1** to 117.4(3)° in **2**, the N3–C8–S angle goes from 119.7(3)° in **1** to 123.4(3)° in **2**; the N3–N2–C7 angle goes from 119.6(3)° in **1** to 114.6(3)° in **2** and the N2–N3–C8 angle from 118.3(3)° in **1** to 112.0(3)° in **2**. The angle between the aromatic ring and the thiosemicarbazone chain goes from 24.7(2)° in the free thiosemicarbazone to 30.4(1)° in the complex.

3.2. Experimental and theoretical NMR studies of *1*

DFT/BLYP/6-31G* and DFT/B3LYP/6-31G* calculations were used for geometry optimizations of **1** in the gas phase as well as with consideration of solvent ($CHCl_3$ and DMSO) effects. Fig. 3 shows the differences in the electronic-nuclear energies (E) between the various geometries of **1**. DFT/BLYP/6-31G* calculations indicate that the **1-*E*,*E*** isomer presents the lowest energy as compared to **1-*Z*,*E***, **1-*E*,*Z*** and **1-*Z*,*Z***, with $\Delta E = 3.16$, 10.58 and 13.74 kcal/mol, respectively. DFT/B3LYP/6-31G* calculations revealed the same order of energy for these geometries, with differences of $\Delta E = 2.81$, 10.67 and 13.60 kcal/mol, of **1-*E*,*E*** in relation to **1-*Z*,*E***, **1-*E*,*Z*** and **1-*Z*,*Z*** respectively.

DFT/BLYP/6-31G*/$CHCl_3$ calculations considering the effect of $CHCl_3$ show that **1-*E*,*E*** is still the geometry of lowest energy, with differences in energy of $\Delta E = 1.98$, 6.55 and 9.10 kcal/mol, respectively in relation to **1-*Z*,*E***, **1-*E*,*Z*** and **1-*Z*,*Z***. A lower difference in energy was found between the optimized geometries (DFT/BLYP/6-31G*/DMSO) considering the effect of DMSO with $\Delta E = 1.91$,



1-*E*,*E*

Fig. 3. Electronic-nuclear energy (*E*) of the DFT/BLYP/6-31G* and DFT/B3LYP/6-31G* optimized geometries of **1** in the gas phase and considering solvent ($CHCl_3$ and DMSO) effects (PCM).

4.12 and 9.10 kcal/mol, respectively. The results indicate a decrease in energy of the optimized geometries in the order DFT/BLYP/6-31G*, DFT/B3LYP/6-31G*, DFT/BLYP/6-31G*/$CHCl_3$ and DFT/B3LYP/6-31G*/DMSO. However, all theoretical calculations suggest a lower relative energy for the **1-*E*,*E*** isomer. The theoretical calculations did not indicate stabilization effects of $CHCl_3$ on any of the studied geometries.

Fig. 4 shows partial ^{1}H NMR spectra of **1** in DMSO-d_6 and $CDCl_3$. The NMR signals were attributed based on 1D (^{1}H, ^{13}C and DEPT 135) and 2D (COSY, NOESY, HSQC and HMBC) experiments. The spectrum in DMSO-d_6 (Fig. 4a) exhibits only one signal (singlet) in the aromatic region (δ_H 8.20). This signal integrates for four hydrogens and shows HSQC correlation with signals of the methine carbons at δ_C 127.74 (C2/C6) and 123.39 (C3/C5). The singlet observed at δ_H 10.46 (integration for one hydrogen) does not correlate with any carbon in the HSQC contour map. This signal shows HMBC correlations with the signals at δ_C 145.13 (C7) and 178.87 (C8). Therefore, the signal at δ_H 10.46 can be assigned to H–N3. In the HSQC contour map the singlet at δ_H 2.34 (integration for three hydrogens) shows a correlation with the signal for at δ_C 14.02 (C9). In the HMBC contour map this signal correlates with only a carbon signal at δ_C 145.13 (C7), via $^2J_{H,C}$. The NOESY contour map shows correlations between the signals at δ_H 10.46 (H–N3) and 2.34 (H–C9). These long range interactions are spatially permitted only for the *E*-configuration in relation to the imino group and for the *E*- and *Z*-configurations in relation to the thioamide group, i.e. for isomers **1-*E*,*E*** and **1-*E*,*Z***, respectively (Fig. 3).

Fig. 4b shows the ^{1}H NMR spectrum of **1** in $CDCl_3$. The aromatic hydrogens are observed at δ_H 8.26 (H–C3/H–C5) and 7.87 (H–C2/H–C6). The NOESY contour map of **1** did not allow the determination of its stereochemistry. However, the existence of two signals assigned to the aromatic hydrogens in the ^{1}H NMR spectrum of **1** could indicate a different geometry from that observed in DMSO-d_6, since in the latter only one signal was noticed (Fig. 4a).

Table 4 shows the experimental ^{1}H NMR chemical shifts ($^{Exp}\delta_H$) for **1** in $CDCl_3$ and DMSO-d_6, as well as the DFT/BLYP/6-31G* calculated ^{1}H NMR chemical shifts ($^{Calc}\delta_H$) for the **1-*E*,*E***, **1-*Z*,*E***, **1-*E*,*Z*** and **1-*Z*,*Z*** optimized geometries at the same theoretical level. The experimental chemical shifts of H–C2, H–C6, H–N3 and H–N4 in DMSO-d_6 are found at higher frequencies than in $CDCl_3$. Similarly, the calculated chemical shifts of the same hydrogens ($^{Calc}\delta_H$) were obtained at higher frequencies for **1-*E*,*E*** and **1-*E*,*Z*** than for **1-*Z*,*E*** and **1-*Z*,*Z***. In addition, the experimental chemical shifts for H–C3/H–C5 in DMSO-d_6 were found at lower frequency than in $CDCl_3$. Similarly, the calculated chemical shifts of these hydrogens in **1-*E*,*E*** and **1-*E*,*Z*** were found at lower frequencies than the

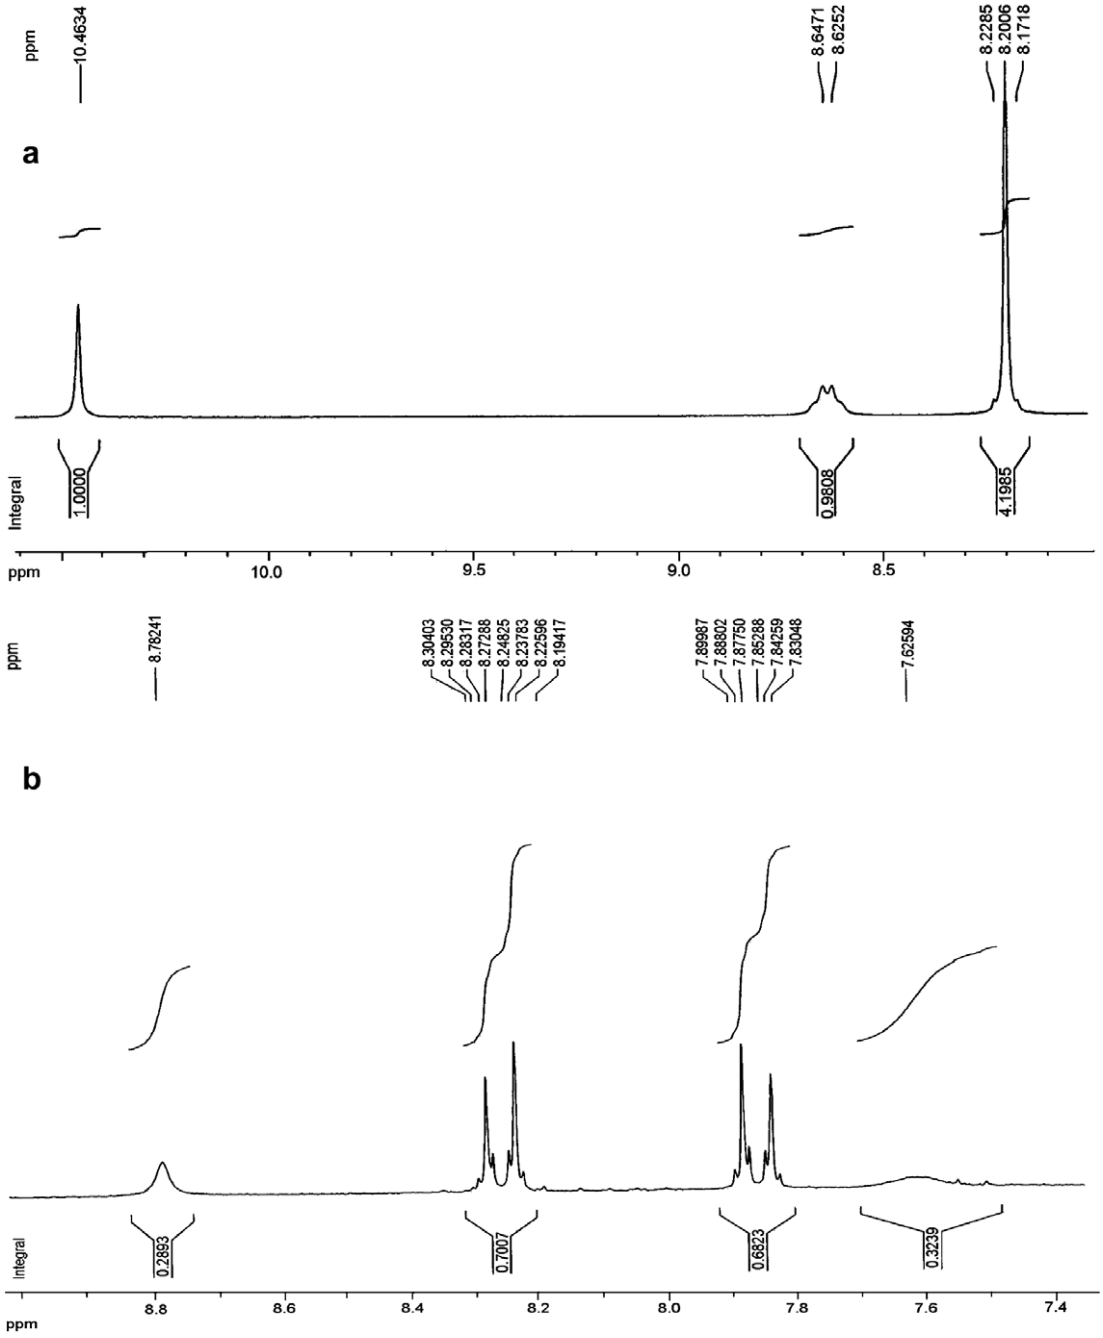

Fig. 4. Partial ^{1}H NMR spectra (400 MHz, TMS) of **1** in (a) DMSO-d_6 and (b) $CDCl_3$.

corresponding values in **1**-*Z*,*E* e **1**-*Z*,*Z*. Therefore the calculated chemical shifts are closer to the experimental values for **1**-*E*,*E* and **1**-*E*,*Z* in DMSO-d_6 and for **1**-*Z*,*E* and **1**-*Z*,*Z* in $CDCl_3$.

Table 5 shows the experimental ^{13}C NMR chemical shifts ($^{Exp}\delta_C$) for **1** in $CDCl_3$ and DMSO-d_6, as well as DFT/BLYP/6-31G* calculated ^{13}C NMR chemical shifts ($^{Calc}\delta_C$) for the carbons of the **1**-*E*,*E*, **1**-*Z*,*E*, **1**-*E*,*Z* and **1**-*Z*,*Z* optimized geometries at the same theoretical level. The C1, C2, C4, C6 and C7 chemical shifts in DMSO-d_6 were observed at higher frequencies than the corresponding values in $CDCl_3$. Similarly, the calculated chemical shifts for the same carbons of the **1**-*E*,*E* and **1**-*E*,*Z* isomers were found at higher frequencies than the corresponding carbons of **1**-*Z*,*E* and **1**-*Z*,*Z*. In addition, the C3, C5, C8 and C10 chemical shifts in DMSO-d_6 were found at lower frequencies than the shifts of the corresponding carbons in $CDCl_3$. The calculated shifts of these carbons were found at lower frequencies for the **1**-*E*,*E* and **1**-*E*,*Z* isomers than for **1**-*Z*,*E* and **1**-*Z*,*Z*. Hence the calculated values ($^{Calc}\delta_C$) for **1**-*E*,*E* and **1**-*E*,*Z* are closer to the experimental data ($^{Exp}\delta_C$) in DMSO-d_6. In $CDCl_3$ the calculated values of carbon chemical shifts were closer to the experimental data for **1**-*Z*,*E* and **1**-*Z*,*Z*.

Table 4
^{1}H NMR chemical shifts ($^{Exp}\delta_H$) of **1** in $CDCl_3$ and DMSO-d_6 (400 MHz, TMS) and DFT/BLYP/6-31G* calculated ^{1}H NMR chemical shifts ($^{Calc}\delta_H$[a]) for the optimized geometries of **1** given in Fig. 3

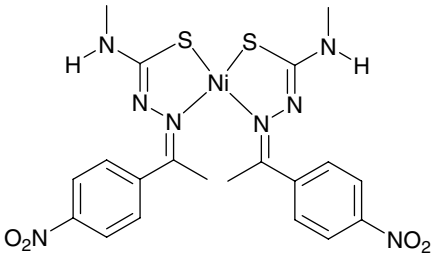
[a] Values obtained relative to the calculated chemical shift of the carbons of TMS (δ_C 190.90) using DFT/BLYP/6-31G*.

As already mentioned, the lowest energy isomer is **1-*E*,*E*** and the energy difference between **1-*E*,*E*** and **1-*E*,*Z*** is of 4.12 Kcal/mol in DMSO-d_6, suggesting that in this solvent the **1-*E*,*E*** isomer is the most plausible. In $CDCl_3$ the energy difference between **1-*E*,*E*** and **1-*Z*,*E*** is small (1.98 kcal/mol). Since the NMR spectra in the two solvents are not the same, the **1-*Z*,*E*** isomer is probably present in $CDCl_3$. The presence of **1-*Z*,*Z*** in $CDCl_3$ seems improbable considering the significant energy difference between **1-*E*,*E*** and **1-*Z*,*Z*** (9.10 kcal/mol).

3.3. Experimental and theoretical NMR studies of (2)

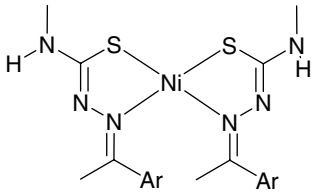


HF/3-21G* and HF/6-31G* theoretical calculations were employed for the geometry optimization of **2** in the gas phase as well as considering the effect of DMSO. Fig. 5 shows the electronic-nuclear energies of the different geometries of **2**. In all geometries of **2** the thiosemicarbazone must adopt the *Z*-configuration in relation to the N3–C8 bond to match the steric requirements of bidentate coordination. Hence only the configuration in relation to the C7–N2 bond is considered hereafter. The HF/3-21G* optimized geometry for **2-*cis*(*E*-Ni-*E*)** presents lower energy in relation to **2-*cis*(*Z*-Ni-*Z*)**, **2-*cis*(*E*-Ni-*Z*)**, **2-*trans*(*E*-Ni-*E*)**, **2-*trans*** (***E*-Ni-*Z***) and **2-*trans*** (***Z*-Ni-*Z***), with $\Delta E = 7.59$, 4.22, 2.01, 9.37 and 4.01 kcal/mol, respectively. HF/6-31G* calculations of the differences in energy between the optimized geometry for **2-*cis*(*E*-Ni-*E*)** in relation to **2-*cis*(*Z*-Ni-*Z*)**, **2-*cis*(*E*-Ni-*Z*)**, **2-*trans*(*E*-Ni-*E*)**, **2-*trans*** (***E*-Ni-*Z***) and **2-*trans*** (***Z*-Ni-*Z***)gave $\Delta E = 5.45$, 2.91, −1.83, 9.27 and −2.23 kcal/mol, respectively.

Table 6 shows the ^{1}H NMR data for **2** in DMSO-d_6 (**2** was insoluble in $CDCl_3$). The NMR signals were attributed based on 1D (^{1}H, ^{13}C and DEPT 135) and 2D (COSY, NOESY, HSQC and HMBC) experiments. NOESY correlations may occur either between the hydrogens of one of the ligands or between hydrogens located in the two ligands. The observed NOESY correlations between H–C2/H–C6, H-C9 and H–C10 could be attributed to all isomeric forms of **2**. However, the ^{1}H and ^{13}C NMR data (Tables 6 and 7) indicate that the chemical shifts for the atoms of the two ligands are equal. In this case, both ligands in **2** should adopt the same configuration, which cannot be attributed to **2-*trans*(*Z*-Ni-*E*)** and **2-cis** (***Z*-Ni-*E***). Therefore the NMR data of **2** can only be assigned to **2-*cis*(*E*-Ni-*E*)**, **2-*cis*(*Z*-Ni-*Z*)**, **2-*trans*(*Z*-Ni-*Z*)**, or **2-*trans*(*E*-Ni-*E*)**.

Table 6 also shows the HF/6-31G* hydrogen calculated chemical shifts for the geometries of **2** optimized at the same theoretical level. Since both thiosemicarbazones adopt the same configuration in the complex only one value of the calculated chemical shifts is reported. The calculated ^{1}H chemical shifts for **2-*cis*(*E*-Ni-*E*)** and **2-*trans*-(*E*-Ni-*E*)** deviate too much from the experimental shifts in DMSO-d_6 (mean deviations between the experimental and calculated shifts, $\Delta\delta_H$, are 12.49 and 11.66 respectively). The mean deviation of each hydrogen is smaller for the **2-*trans*** (***Z*-Ni-*Z***) ($\Delta\delta_H = 2.52$) and **2-*cis*(*Z*-Ni-*Z*)** ($\Delta\delta_H = 4.10$).

Table 7 shows ^{13}C NMR experimental data of **2**, along with HF/6-31G* calculated ^{13}C NMR chemical shifts ($^{Calc}\delta_C$) of the geometries of **2** optimized at the same theoretical level. Since both thiosemicarbazones adopt the same configuration in the complex only one value of the calculated chemical shifts is reported. The calculated ^{13}C chemical shifts for **2-*cis*(*E*-Ni-*E*)** and **2-*trans*(*E*-Ni-*E*)** deviate too much from the experimental shifts in DMSO-d_6. (mean deviations between the experimental and calculated shifts, $\Delta\delta_c$, are 7.99 and 13.50 respectively). The mean difference between the experimental and calculated chemical shifts of each carbon is smaller for the **2-*trans*** (***Z*-Ni-*Z***) ($\Delta\delta_C = 5.08$) and **2-*cis*** (***Z*-Ni-*Z***) ($\Delta\delta_C = 5.05$).



The solid-state ^{1}H MAS NMR does not provide information on the stereochemistry of **2**. Fig. 6 shows the solid-state ^{13}C MAS NMR of **2** at different temperatures. At room temperature the spectrum of the powder is similar to that obtained in DMSO-d_6, indicating the possible presence of the same isomer in both media. However, in the

powder two signals were observed for C2/C6, suggesting that the non-equivalency of these two carbons is probably due to the more rigid arrangement in the solid. As mentioned before, the crystal structure of **2** shows that the complex adopts the **2-*cis*(*E*-Ni-*E*)**-configuration. Since the crystal has been obtained from a solution made from the

powder dissolved in DMF, we suggest that in the powder a *cis* isomer is probably present, which would be **2-*cis*(*Z*-Ni-*Z*)**,considering that the theoretical and experimental chemical shifts for this isomer were in good agreement. Therefore **2-*cis*(*Z*-Ni-*Z*)** → **2-*cis*(*E*-Ni-*E*)** conversion probably occurs during crystallization, since **2-*trans*(*Z*-Ni-*Z*)** → **2-*cis*(*E*-Ni-*E*)** conversion would require coordination of the solvent to the metal centre with displacement of one

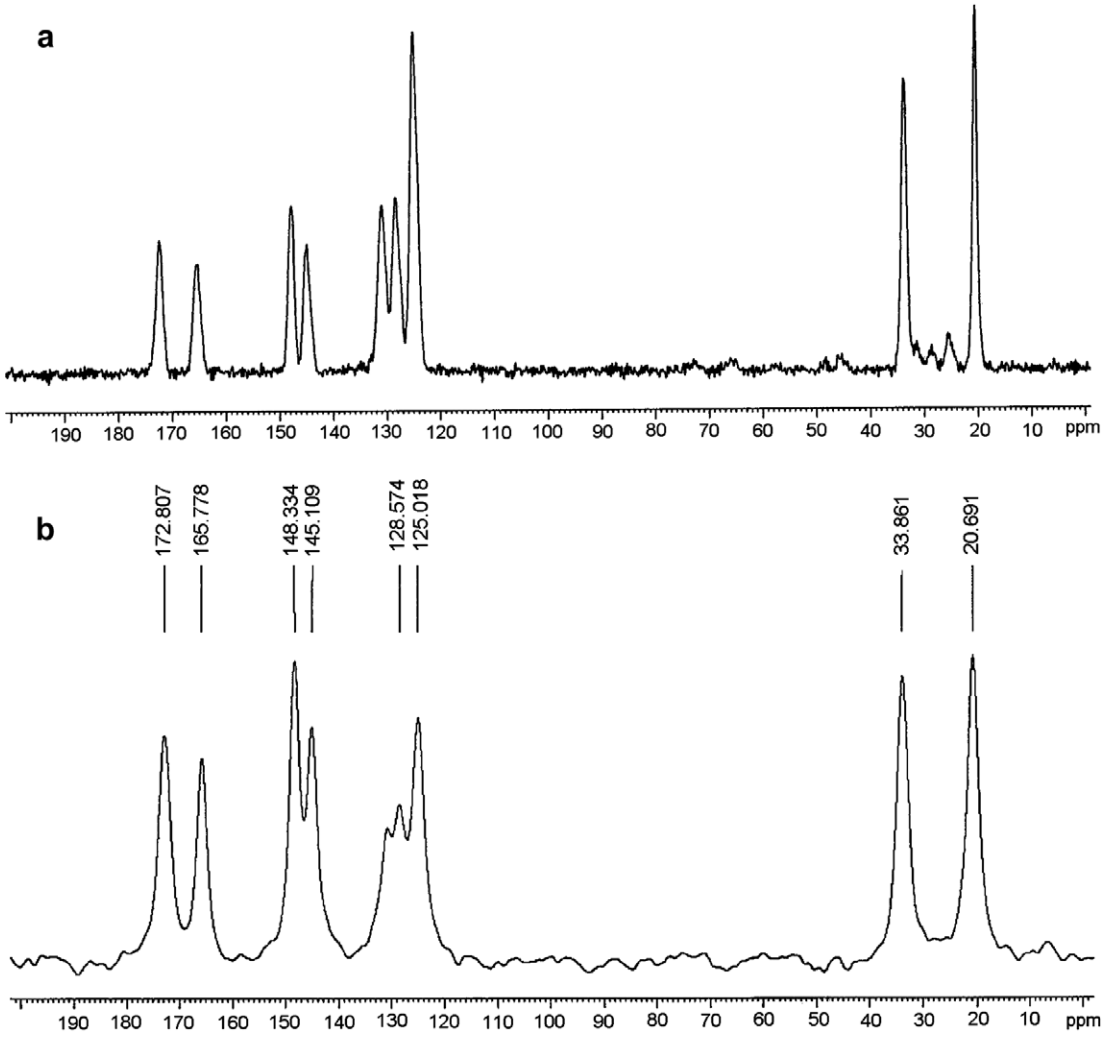

Fig. 6. Solid-state ^{13}C MAS NMR of **2** at: (a) 323 K (100 MHz; adamantane) and (b) 343 K (125 MHz; adamantane).

of the ligands, followed by re-coordination of the thiosemicarbazone in a different configuration.

Fig. 6b shows the solid-state ^{13}C MAS NMR spectrum of **2** at 343 K. When the temperature goes from 323 to 343 K the signal at ca. δ_C 131.0 decreases in intensity whereas the intensity of the signal at δ_C 128.6 increases, probably due to the motion of the aromatic rings through rotation along the C7–C1 bond. As a consequence, coalescence of the signals of C2 and C6 occurs because of the similar chemical ambiance of these two carbons. The PM3 calculated rotational barrier of C7–C1 for **2-*cis*(*E*-Ni-*E*)** is $\Delta E = 24.47$ kcal/mol which is too high to allow rotation to occur, corroborating that this configuration is not present in the powder. For the other configurations this barrier is ca. 10 kcal/mol, which is small enough to allow rotation to occur, with coalescence of the C2 and C6 signals with rising the temperature. Hence **2-*cis*(*Z*-Ni-*Z*)** is the most probable configuration in the powder.

4. Conclusion

X-ray structural studies of *N*(4)-methyl-4-nitroacetophenone thiosemicarbazone, $H4NO_2Ac4M$ (**1**) and its nickel(II) complex, $[Ni(4NO_2Ac4M)_2]$ (**2**) revealed that the **1-*E*,*E*** isomer of the thiosemicarbazone and the **2-*cis*** (**E-Ni-*E***) isomer of the complex are formed in the crystal. Analyses of experimental NMR data along with HF and DFT theoretical calculations of energies and of ^1H and ^{13}C NMR chemical shifts for the optimized geometries of **1** suggest that the **1-*E*,*E*** isomer probably exists in DMSO-d_6, and the **1-*Z*,*E*** isomer in $CDCl_3$. Analyses of solid state (powder) as well as solution (DMSO-d_6) NMR data along with HF and DFT calculations of chemical shifts for the optimized geometries of **2** indicate the presence of **2-*cis*(*Z*-Ni-*Z*)** in DMSO-d_6 as well as in the powder, indicating that **2-*cis*(*Z*-Ni-*Z*)** → **2-*cis*(*E*-Ni-*E*)** conversion probably occurs during crystallization.

5. Supplementary material

CCDC 622046 and 622047 contain the supplementary crystallographic data for **1** and **2**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

$[Cu(en)_3]^{2+}$ (en = 1,2-ethanediamine), $[Cu(OMPA)_3]^{2+}$ (OMPA = octamethylpyrophosphoramide), $[Cu(bpy)_3]^{2+}$ (bpy = 2,2′-bipyridyl) and $[Cu(phen)_3]^{2+}$ (phen = 1,10-phenanthroline). Within the copper chromophore, complexes containing three equivalent didentate chelate ligands, $[Cu(en)_3]SO_4$ [5] and $[Cu(OMPA)_3](ClO_4)_2$ [6], have been found to involve D_3 site symmetry with six apparently equivalent bonds as a consequence of the dynamic Jahn-Teller effect [8–12] and show partially statically and dynamically distorted CuN_6 octahedra for the lower symmetry C_2 or C_1 complexes. The most likely form of the vibronically induced distortion or dynamic Jahn-Teller distortion consistent with C_2 symmetry is the elongated tetragonal distortion [13], producing the most common type of static stereochemistry of the copper(II) ion, namely elongated rhombic or tetragonal octahedral.

In cases of copper(II) complexes with two equivalent didentate chelate ligands and some sulfur oxoanions including those of the ClO_4^-, BF_4^- and PF_6^- anions, the structures displayed four-, five- or six-coordinated chromophores with the monodentate, chelate, didentate polymeric bridge (along the anion) or non-coordinating natures of these anions depending on the nature of the chelate ligands. The examples are $[Cu(dpyam)_2](ClO_4)_2$ [14], $[Cu(dpyam)_2](BF_4)_2$ [15], $[Cu(dpyam)_2](PF_6)_2$ [present work], $[Cu(bpy)_2(OH_2)](S_2O_6)$ [16], $[Cu(dpyam)_2(OH_2)](S_4O_6)$ [17], $[Cu(bpy)_2(O_2ClO_2)](ClO_4)$ [18], $[Cu(bpy)_2(F_2BF_2)](BF_4)$ [18,19], [Cu(bpy or phen)$_2$(OS_4O_5)] [20], $[Cu(bpy)_2(S_3O_6)]$ [20,21] and $[Cu(bpy)_2(OS_2O_7)]H_2O$ [16]. In order to continue the investigation on the coordination properties and the correlation of the stereochemistry and electronic properties of the tris and bis-chelate copper(II) complexes with these anions, the structures and electronic properties of two new tris-chelate complexes, $[Cu(phen)_3](S_4O_6)(S_8)$ (**1**) and $[Cu(phen)_3](BF_4)_2$ (**2**), and two new bis-chelate complexes, $[Cu(phen)_2(OS_2O_7)]$ (**3**) and $[Cu(phen)_2(FBF_3)](BF_4)$ (**4**), are now reported and discussed in comparison with other relevant complexes. The latter two complexes display some differences in Cu(II) environment and binding modes of $S_2O_8^{2-}$ and BF_4^- anions.

2. Experimental

2.1. General

The ligand 1,10-phenanthroline and all reagents are commercial grade materials and were used without further purification. Elemental analyses (C, H, N) were determined on a Perkin-Elmer PE 2400 CHNS Analyzer.

IR spectra were recorded on a Perkin-Elmer Spectrum One FT-IR spectrophotometer as KBr discs in the 4000–450 cm^{-1} spectral range. Solid-state (diffuse reflectance) electronic spectra were measured as polycrystalline samples on a Perkin-Elmer Lambda2S spectrophotometer, within the range 8000–18 000 cm^{-1}. ESR spectra were recorded using a Bruker ESR-300 X-band instrument operating at room temperature with DPPH ($g = 2.0036$) as a reference.

2.2. Syntheses of the compounds

2.2.1. $[Cu(phen)_3](S_4O_6)(S_8)$ (1)

A hot DMF solution (10 ml) of phen (0.198 g, 1.0 mmol) was added to a warm aqueous solution (10 ml) of $Cu(NO_3)_2 \cdot 3H_2O$ (0.241 g, 1.0 mmol). Then an aqueous solution (10 ml) of $Na_2S_2O_3 \cdot 5H_2O$ (0.248 g, 1.0 mmol) was added to the mixture, yielding a brown solution. After a month, blue polygon-shaped crystals of compound **1** were obtained which were filtered off, washed with the mother liquid and air-dried. Yield ca. 60%. $C_{36}H_{24}CuN_6O_6S_8$: *Anal.* Calc. C, 45.20; H, 2.53; N, 8.79. Found: C, 45.50; H, 2.61; N, 8.84%.

2.2.2. $[Cu(phen)_3](BF_4)_2$ (2)

This compound was prepared by adding a hot ethanol solution (10 ml) of phen (0.198 g, 1.0 mmol), to a warm aqueous solution (5 ml) of $Cu(BF_4)_2 \cdot nH_2O$ (0.118 g, 0.5 mmol). The resulting blue solution was allowed to evaporate at room temperature. After two weeks, needle blue crystals of compound **2** were obtained which were filtered off, washed with the mother liquid and air-dried. Yield ca. 85%. $C_{36}H_{24}CuF_8N_6B_2$: *Anal*. Calc. C, 55.59; H, 3.11; N, 10.81. Found: C, 55.62; H, 3.25; N, 10.67%.

2.2.3. $[Cu(phen)_2(OS_2O_7)]$ (3)

Compound **3** was prepared by adding an aqueous solution (10 ml) of $Cu(CH_3COO)_2 \cdot nH_2O$ (0.091 g, 0.5 mmol) to a solution of phen (0.198 g, 1.0 mmol) in acetonitrile (20 ml), then an aqueous solution (5 ml) of $K_2S_2O_8$ (0.109 g, 1.0 mmol) was added, yielding a blue solution. The solution was allowed to evaporate at room temperature. After a week, bluish green rod crystals of compound **3** were formed. They were filtered off, washed with the mother liquid and air-dried. Yield ca. 92%. $C_{24}H_{16}S_2CuN_4O_8$: *Anal.* Calc. C, 46.79; H, 2.61; N, 9.10. Found: C, 46.45; H, 2.54; N, 9.14%.

2.2.4. $[Cu(phen)_2(FBF_3)](BF_4)$ (4)

Compound **4** was prepared by adding an aqueous solution (20 ml) of $Cu(BF_4)_2 \cdot nH_2O$ (0.236 g, 1.0 mmol) to a solution of phen (0.346 g, 2.5 mmol) in ethanol (20 ml), yielding a blue solution. The solution was allowed to evaporate at room temperature. After a week, bluish green crystals of compound **4** were formed. They were filtered off, washed with the mother liquid and air-dried. Yield ca. 74%. $C_{24}H_{16}B_2CuN_4F_8$: *Anal*. Calc. C, 48.25; H, 2.70; N, 9.38. Found: C, 48.18; H, 2.61, N, 9.45%.

2.3. Crystallography

The X-ray single-crystal data were collected at 293 K for compounds **1**–**4** on a 4K Bruker SMART APEX CCD area-detector diffractometer (rotating anode, graphite-monochromated Mo Kα radiation, $\lambda = 0.71073$ Å) using the SMART program [22]. Raw data frame integration was performed with SAINT [23], which also applied correction

for Lorentz and polarization effects. An empirical absorption correction using the SADABS [24] program was applied, which resulted in transmission coefficients ranging from 1.000 to 0.733 for **1**, 1.000 to 0.739 for **2**, 1.000 to 0.768 for **3** and 1.000 to 0.740 for **4**.

The structures were solved by direct methods and refined by the full matrix least-squares method on $(F_{obs})^2$ with anisotropic thermal parameters for all non-hydrogen atoms, except disordered *F* atoms of the BF_4^- groups in **2**, using the SHELXTL-PC V 6.12 software package. For the structure determination of compound **1**, the sulfur atoms of the S_8 group showed disorder; the occupancies of the disordered positions were initially refined and later fixed at 0.50 and 0.50. The two F atoms of each BF_4^- group in **2** showed disorder, with occupancies of 0.5. All hydrogen atoms of the phen ligand in **1** were fixed and allowed to ride on the attached atoms, while those of compounds **2**–**4** were located geometrically and refined isotropically. The molecular structure pictures were created by using the SHELXTL-PC package [25]. The crystal and refinement details for compounds **1**–**4** are listed in Table 1.

3. Results and discussion

3.1. Description of $[Cu(phen)_3](S_4O_6)(S_8)$ (1) and $[Cu(phen)_3](BF_4)_2$ (2)

The asymmetric unit of complexes **1** and **2** involves $[Cu(phen)_3]^{2+}$ cations and $S_4O_6^{2-}$ and BF_4^- anions, respectively. In addition, **1** has S_8 molecules in the lattice. The ORTEP views of the asymmetric units of **1** and **2** are shown in Fig. 1, together with the numbering scheme. Selected bond distances and angles are listed in Table 2. The cationic species $[Cu(phen)_3]^{2+}$ in **1** and **2** are similar in stereochemistry, in which the copper(II) ion is six-coordinated by six nitrogen atoms from three phenanthroline ligands. The coordination geometry around the copper ion can be described as elongated rhombic octahedral with four equatorial Cu–N bond distances being markedly different in the case of **1** (2.026(3) to 2.115(3) Å, $\Delta N_{in} = 0.089(3)$ Å) as compared to those of **2** (2.031(3) to 2.054(3) Å, $\Delta N_{in} = 0.023(3)$ Å), with the remaining two nitrogens occupying the apical sites at significantly larger distances (2.295(4) and 2.328(4) Å for **1**; 2.269(3) and 2.346(4) Å for **2**). This leads to a slight difference in tetragonalities (*T*), 0.892 for **1** and 0.886 for **2** (*T* = the average four-in-plane distance/the axial out-of-plane distance [26]), the tetragonality increasing with increasing in-plane bond distances. Compound **1** has a high ΔN_{in} value of 0.089 Å, corresponding to a high in-plane rhombic distortion, and there is very little in-plane rhombic distortion in **2**, attributed to a low ΔN_{in} value of 0.023 Å. The basal CuN_4 planes of both compounds are slightly twisted, with dihedral angles (CuN_2/CuN_2) of 20.4(1)° for **1** and 19.3(1)° for **2**. The phenanthroline moieties do not display any unusual features with regard to bond lengths and angles in either of the two compounds studied compared with the free molecule [27]. However, they do exhibit meaningful deviations from

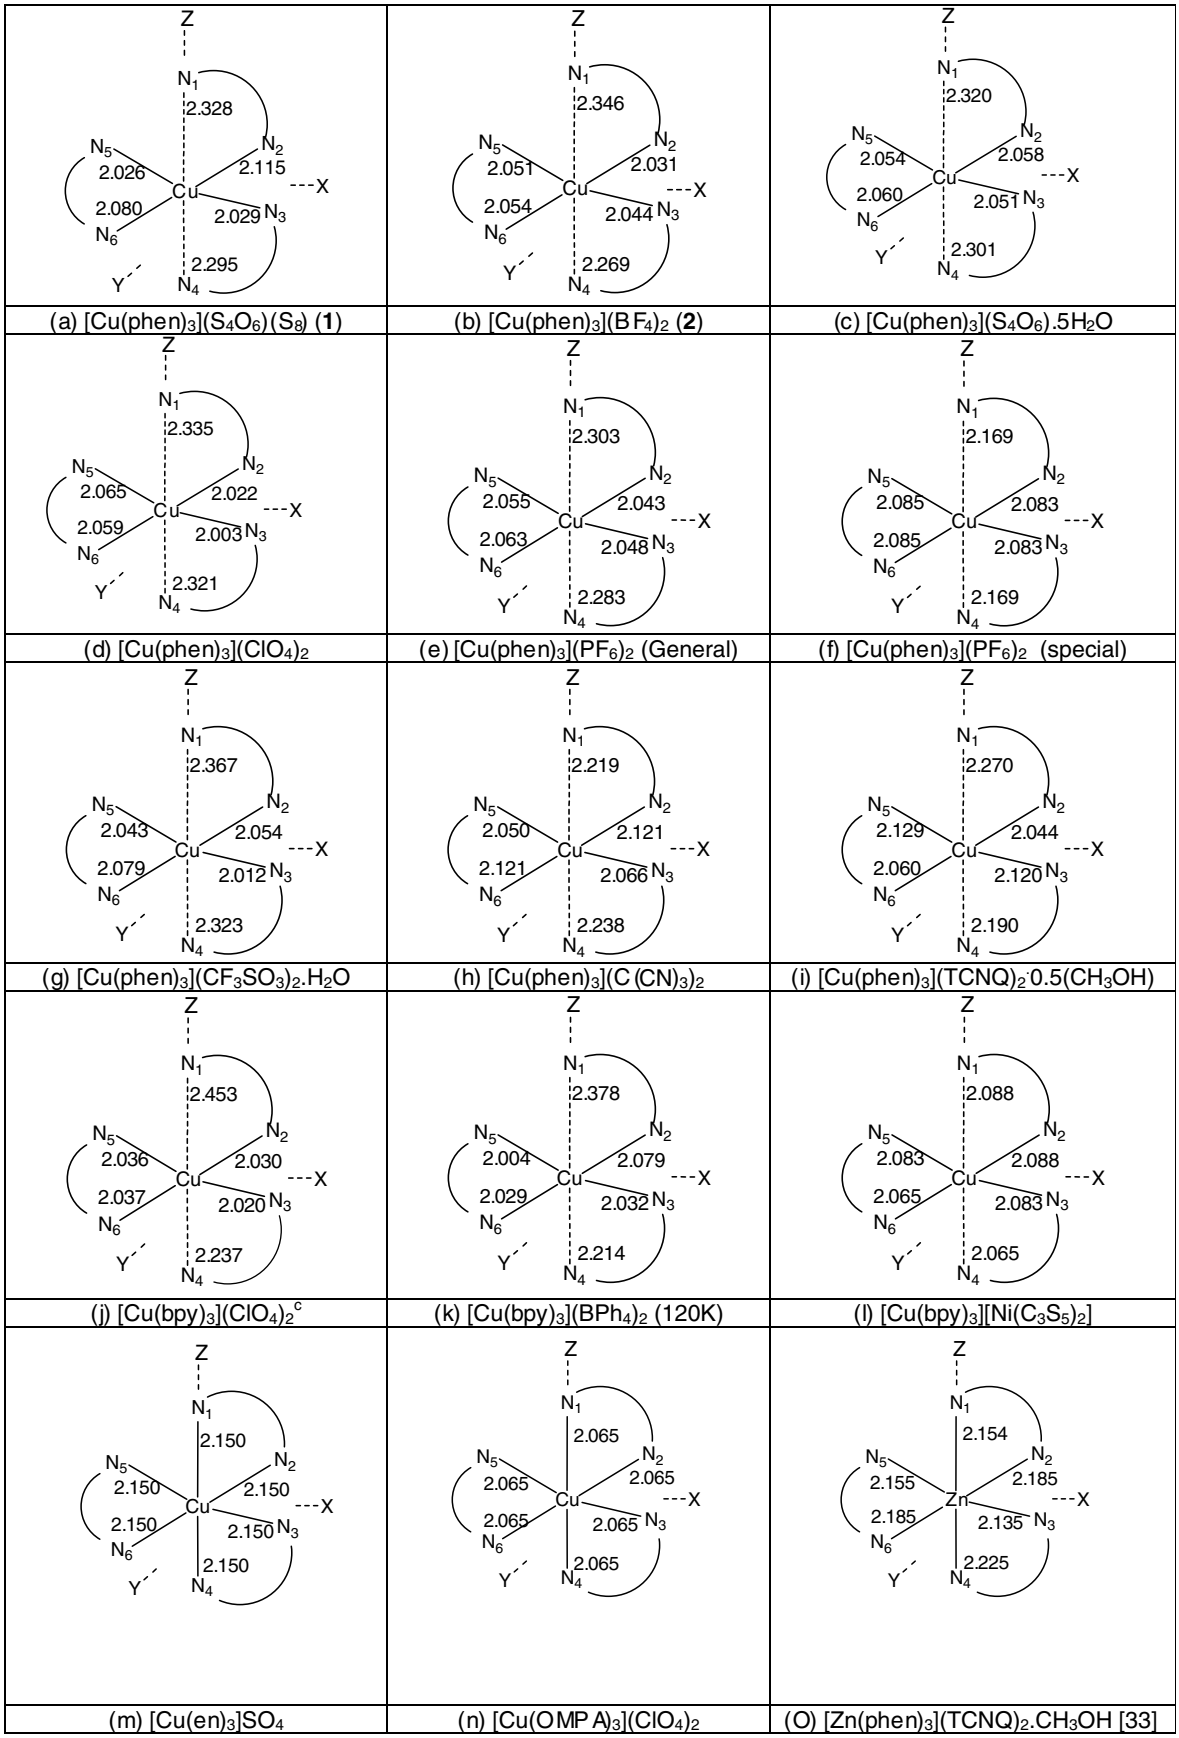

Fig. 2. Comparison of $[M(phen)_3]^{2+}$ coordination geometries.

planarity, as measured by the dihedral angle between opposite pyridine groups [2.3(1)°, 3.0(1)° and 3.8(1)° for **1** and 2.4(1)°, 3.9(1)° and 1.3(1)° for **2**]. The angles between the least-square phenanthroline planes are [phen(N(1)–N(2))]–[phen(N(3)–N(4))] = 85.9(1)°, [phen(N(1)–N(2))]–[phen(N(5)–N(6))] = 82.3(1)° and [phen(N(3)–N(4))]–[phen(N(5)–N(6))] = 68.4(1)° for **1** and [phen(N(1)–N(2))]–[phen(N(3)–N(4))] = 87.3(1)°, [phen(N(1)–N(2))]–[phen(N(5)–N(6))] = 75.1(1)° and [phen(N(3)–N(4))]–[phen(N(5)–N(6))] = 81.4(1)° for **2** (See Table 3).

Complexes **1** and **2** are the most common type of tris-chelate copper(II) complexes with three equivalent ligands. The appearance of regular CuN_6 or CuO_6 are rare and are found in few complexes: $[Cu(en)_3](SO_4)$ [5], $K_2Pb[Cu(NO_2)_6]$ [28] and $[Cu(OMPA)_3](ClO_4)_2$ [6] in which their Cu(II) chromophore has either D_3 or T_d site symmetries, in apparent violation of the Jahn-Teller theorem due to the dynamic Jahn-Teller effect. Complexes **1** and **2** exhibit lower symmetry of C_1, distorted from the parent dynamic Jahn-Teller complex D_3 symmetry, and produce the most common type of static stereochemistry ($T < 0.9$) [26], an elongated rhombic octahedron. The elongated octahedral CuN_6 chromophores in **1** and **2** are somewhat different; **1** is much more rhombic and only a few examples have been observed with this feature, Fig. 2h and i. This can rationalized using the approximate forms of the Q_ε and Q_θ components of the JT active e vibration of a trigonal tris-chelate $[Cu(chelate)_3]^{2+}$ chromophore with D_3 symmetry and a ^2E electronic ground state and a_{2u} [12], as shown in Fig. 3. For both compounds a linear combination of the separate Q_ε and Q_θ components of the JT active e vibration is in operation for which the Q_ε component in **1** is big when compared to that of **2**. The Q_ε component can introduce a rhombic distortion of the CuN_6 chromophore, although the component itself is small as compared to Q_θ. A distortion along the Q_θ component results in a tetragonally distorted CuN_6 octahedron for both compounds. In addition, the molecule of both compounds distorts along the a_{2u} coordinate, resulting in the unequivalent Cu–N_{ax} bond distances. The most relevant complexes to **1** and **2** are found in the elongated rhombic octahedral complexes $[Cu(phen)_3]X_2$ where $X = (S_4O_6^{2-})_{0.5} \cdot 5H_2O$ [2], $C(CN)_3^-$ [29], ClO_4^- [30], $CF_3SO_3^- \cdot H_2O$ [31], PF_6^- [32] and $TCNQ^- \cdot (CH_3OH)_{0.5}$ [33]; $[Cu(bipy)_3](ClO_4)_2$ [34–36], $[Cu(bipy)_3](BPh_4)_2$ [3], $[Cu(bpy)_3][Ni(C_3S_5)_2]$ [37] and $\{C_{14}H_{19}N_2\}[Cu(hfacac)_3]$ [38]; the copper(II) chromophores are compared in Table 4 and Fig. 2.

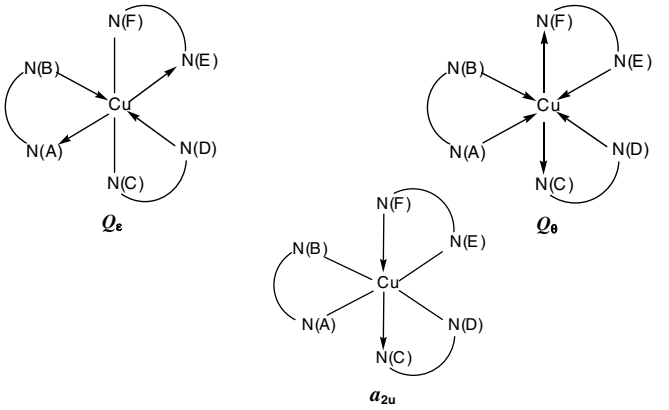

Fig. 3. The approximate forms of Q_ε and Q_θ components of the active JT e vibration of the trigonal tris-chelate $[Cu(chelate)_3]^{2+}$ chromophore. D_3 symmetry: chelate = (N–N) or (O–O), and a_{2u}.

The lattice of compound **1** is stabilized by hydrogen bonding between the amine-C and $O(S_4O_6^{2-})$ (C...O distances 3.030(1)–3.367(2) Å). For compound **2**, the lattice is stabilized by hydrogen bonding between the amine-C and $F(BF_4^-)$ (C...F distances 3.094(1)–3.321(2) Å).

3.2. Description of $[Cu(phen)_2(OS_2O_7)]$ (3) and $[Cu(phen)_2(FBF_3)](BF_4)$ (4)

The structures of **3** and **4** consist of chains of $[Cu(phen)_2(OS_2O_7)]$ and $[Cu(phen)_2(FBF_3)]^+$ units, parallel to an axis, respectively with uncoordinated, disordered BF_4^- anions for **4.** The copper(II) ions are linked into infinite chains by the asymmetrically bridging peroxodisulfato groups (Cu–O 2.353(2), Cu–O′ 3.182(2) Å) in **3** across the anion, and the asymmetrically bridging tetrafluoroborate groups (Cu–F 2.184(2), Cu–F′ 3.110(2) Å) in **4**. However, the sixth axial coordination sites of the bridging $S_2O_8^{2-}$ in **3** and BF_4^- in **4** are too long to be considered even as semi-coordination to the Cu(II) ion, 3.182(2) and 3.110(2) Å for **3** and **4**, respectively. Consequently, the local molecular structure of both compounds, Figs. 4 and 5, involves five-coordinate CuN_4O and CuN_4F chromophores, which can be best described as having a distorted square pyramidal geometry with $\tau = 0.31$ for **3** and a distorted trigonal bipyramidal geometry with $\tau = 0.66$ for **4** ($\tau = (\beta - \alpha)/60$, $\tau = 0$ for square pyramid and $\tau = 1$ for trigonal bipyramidal) [39]. In **3** the equatorial Cu–N distances are not significantly different, ranging from 1.985(2) to 2.034(3) Å. The axial position is occupied by an O atom of the peroxodisulfate at 2.353(2) Å. The CuN_4 chromophore is non-planar with a marked tetrahedral twist of 36.0(1)°. The Cu atom lies above the basal CuN_4 plane, 0.162(1) Å toward the O atom of peroxodisulfate. The Cu ... Cu distance is 7.540(3) Å. The bonding parameters for the S_2O_8 ligand are very close to those found for a previously reported coordinated peroxodisulfate group [18]. The bond lengths in the terminal SO_3 groups are 1.415(3)–1.440(3) Å, the longest, S(1)–O(1) = 1.440(3) Å, is significantly longer than the rest, consistent with the involvement of O(1) in semi-coordination to the Cu(II) atom at 2.353(2) Å [40]. The lattice of compound **3** is stabilized by hydrogen bonding between the amine-C and $OS_2O_8^{2-}$ (C...O distances 3.137(1)–3.444(2) Å) and a very weak interaction between the Cu atom and O′ atom of the neighbouring $S_2O_8^{2-}$ group (Cu–O′, 3.182(2) Å).

In the case of **4**, the local molecular structure involves a five-coordinate CuN_4F chromophore with a distorted trigonal bipyramidal geometry, $\tau = 0.66$, Fig. 5. The out of trigonal plane Cu–N(2) and Cu–N(4) distances are only just

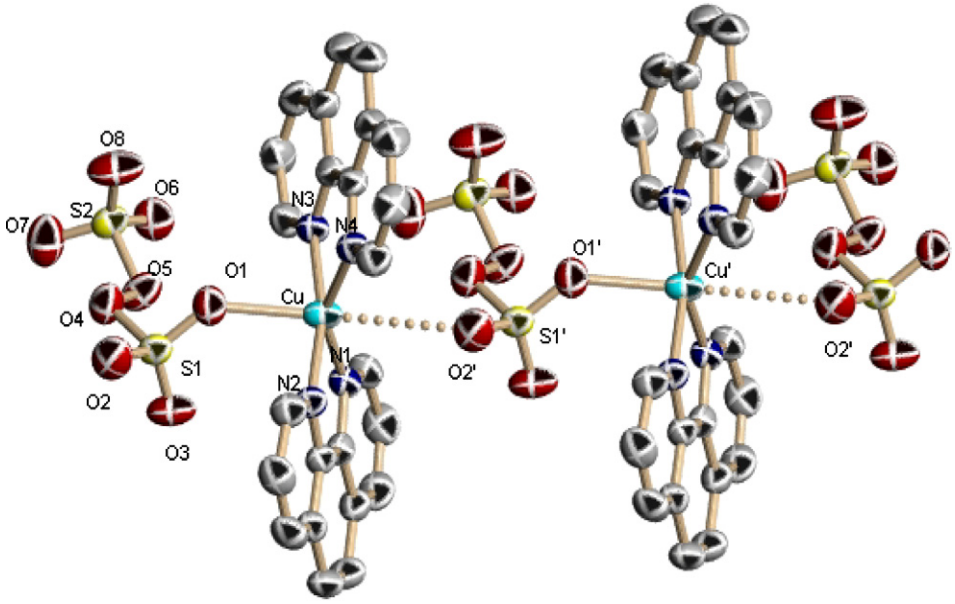

Fig. 4. Thermal ellipsoid (50% probability) plot of $[Cu(phen)_2(OS_2O_7)](S_2O_8)$ (**3**). Hydrogen atoms are omitted for clarity.

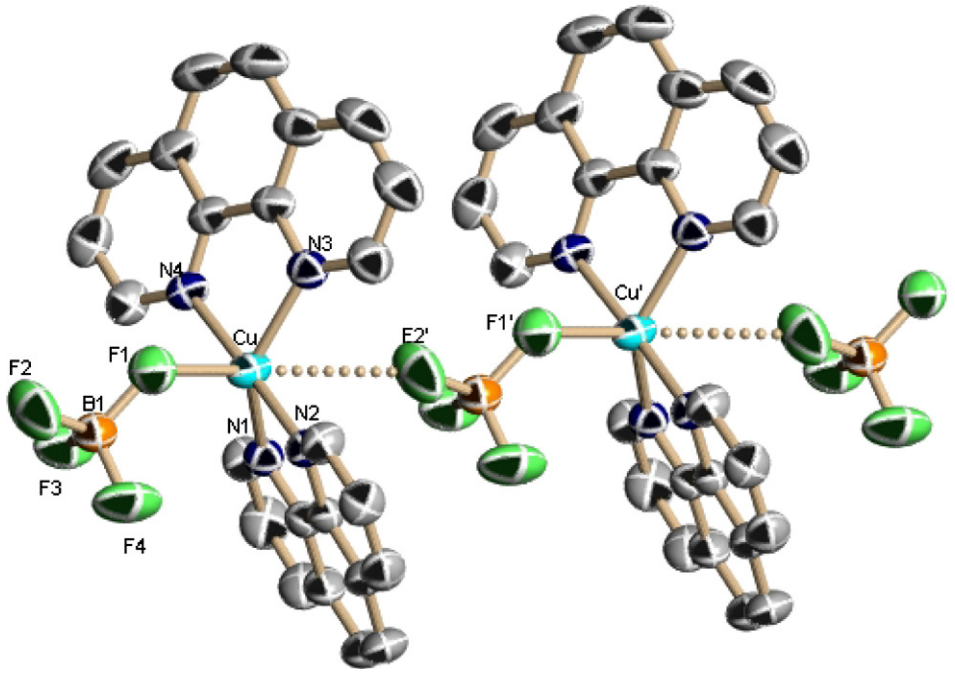

Fig. 5. Thermal ellipsoid (50% probability) plot of $[Cu(phen)_2(FBF_3)](BF_4)$ (**4**). Hydrogen atoms and uncoordinating BF_4^- are omitted for clarity.

significantly different (2.019(2) and 1.999(2) Å) and are almost linear, with N(2)–Cu–N(4) = 177.0(1)°. The three in-plane Cu–N distances are significantly different (2.060(2), 2.078(2) and 2.184(2) Å) and longer than the out of plane Cu–N distances by 0.060 Å, only slightly less than the difference of 0.1 Å previously observed in trigonal-bipyramidal Cu(II) complexes [41]. The much shorter in-plane Cu–F(1) distance of 2.184(2) Å suggests the non-involvement in axial sites of the typical elongated octahedral geometry as compared with the elongated, previously observed, Cu–F distance of 2.560(2) Å in $[Cu(bpy)_2(F_2BF_2)](BF_4)$ [19]. The octahedral units in this analogous compound are linked into infinite chains by the bridging didentate tetrafluoroborate group. For compound **4**, the lattice is stabilized by hydrogen bonding between the amine-C and $F(BF_4^-)$ (C…F distances 3.107(4)–3.345(1) Å) and a very weak interaction between Cu atoms and F′ atoms of the neighbouring BF_4^- groups (Cu–F′, 3.110(2) Å).

The coordination geometries of the corresponding $Cu(chelate)_2X_2$ or, $Cu(chelate)_2Y$, where chelate = phen [42–44], dpyam [16,44,45] or bpy [13,20]; X = BF_4^-,

ClO_4^- and PF_6^- and $Y = S_4O_6^{2-}$, $S_2O_6^{2-}$, $S_3O_6^{2-}$ and $S_2O_8^{2-}$, are compared with those of the title complexes as in Table 5. The binding behaviour of the anions and the geometries are different depending on types of the chelate ligands.

3.3. Spectral characterization

The IR spectra of compounds **1**–**4** show broad and intense bands of the ionic $S_4O_6^{2-}$ (1249 and 1215 cm^{-1} for **1**), $S_2O_8^{2-}$ (1285 cm^{-1} for **3**) and BF_4^- anions (1059 cm^{-1} for **2** and 1066 cm^{-1} for **4**). The electronic reflectance spectra of compounds **1** and **2** show two well-resolved bands with nearly equal intensity at approximately 14570 and 8630 cm^{-1} for **1**; 14860 and 8620 cm^{-1} for **2**, which are assigned as the $d_{z^2} \rightarrow d_{xy}$ and $d_{xz} \approx d_{yz} \approx d_{x^2-y^2} \rightarrow d_{xy}$ transitions, respectively, corresponding to an elongated octahedral geometry with high tetragonalities of ca. 0.89. This yields a tentative one-electron orbital sequence of $d_{xy} > d_{z^2} > d_{xz} \approx d_{yz} \approx d_{x^2-y^2}$, an order which is comparable to that previously deduced for the elongated octahedral complexes [38,46]. The electronic reflectance spectrum of **3** consists of a single broad peak at 13820 cm^{-1}. This spectral character of the compound is consistent with the distorted square pyramidal geometry ($\tau = 0.31$), but with a slightly lower energy than expected due to a high tetrahedral twist of the square base (36.0°) [15]. The one-electron ground state configuration is $d_{x^2-y^2} > d_{z^2} > d_{xy} > d_{xz} \approx d_{yz}$. The transition may be assigned as $d_{xy}, d_{xz}, d_{yz}, d_{z^2} \rightarrow d_{x^2-y^2}$. Complex **4** with $\tau = 0.66$ displays a single $d \rightarrow d$ transition at 12820 cm^{-1}, with some evidence for a possible low-energy shoulder at 10700 cm^{-1}, consistent with a distorted TBP stereochemistry [46]. The one-electron ground-state configuration is $d_{z^2} > d_{xy} \approx d_{x^2-y^2} > d_{xz} \approx d_{yz}$ and the principal absorption may be assigned as a $d_{xz} \approx d_{yz} \rightarrow d_{z^2}$ transition, with the low-energy shoulder assigned as a $d_{xy} \approx d_{x^2-y^2} \rightarrow d_{z^2}$ transition.

The polycrystalline ESR spectrum of **3** is axial with $g_\parallel \gg g_\perp > 2.0 = 2.210 \gg 2.062 > 2.0$, consistent with a $d_{x^2-y^2}$ ground state for the distorted square-based pyramidal geometry of the CuN_4O' chromophore [46]. However, X-band EPR measured on polycrystalline samples of **1**, **2** and **4** at RT showed a broad isotropic signal with a g_{iso} at around 2.108, 2.098 and 2.180, respectively which give no information regarding to the electronic ground state.

4. Supplementary material

CCDC 616539, 616540, 616541 and 616542 contain the supplementary crystallographic data for **1**, **2**, **3** and **4**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

and anions [4–11]. BPP is a flexible ligand that can adopt different conformations with respect to relative orientations of CH_2 groups, such as TT, TG, GG and GG' (where T = trans and G = gauche) [7b,9a,11a]. A wide variety of network topologies and structural motifs, including one-dimensional (1-D) chains [9c–11a] two-dimensional (2-D) open-framed, interpenatrated or interdigitated sheets [5a,5b–9a,9b,10a,10b,11] and three-dimensional (3-D) arrays [5a,5c,9b,9d,10b,10c] can be obtained using BPP ligand due to its flexibility.

In addition, several investigations have shown the potencial application of oxocarbon species, in particular squarate ($C_4O_4^{2-}$) and croconate ($C_5O_5^{2-}$) ions, as building blocks in crystal engineering to the construction of desired arrangements using supramolecular structures self-assembly [11c,12]. On the other hand, 3,5-bis(dicyanomethylene)-cyclopentane-1,2,4-trionate dianion, namely Croconate Violet (CV^{2-}), an interesting member of the so-called pseudo-oxocarbon family [13], has received much less attention in coordination chemistry studies. CV^{2-} species shows extended π electron delocalization, strong absorption in the visible region, reversible electrochemical behavior as well as electrical conductivity typical of semiconductors materials [14]. It has been observed that CV^{2-} dianion exhibits basically two different coordination modes; through the vicinal oxygen atoms in a chelating fashion [15] or through nitrogen atoms of dicyanomethylene groups in a bridging mode [16].

From this point of view, in this work, the synthesis, spectroscopic properties and crystal structure of a novel Zn(II) two-dimensional coordination polymer containing both versatile structural components BPP and Croconate Violet dianion, are reported.

2. Experimental

2.1. Materials and physical measurements

1,3-Bis(4-pyridyl)propane was purchased from Aldrich Chemical Co. and used without further purification. $(NBu_4)_2CV$ was prepared according to the published method [15c]. Elemental analyses for C, H and N were carried out on a Perkin–Elmer 2400 analyzer. Zinc was measured with an atomic absorption spectrophotometer Hitachi Z-8200. Thermogravimetric analysis (TG/DTG) was obtained on a TG-50 Mettler STARe. Sample was heated at 10 °C/min from room temperature to 800 °C in a dynamic nitrogen atmosphere (flow rate = 200 mL/min). Infrared spectra were recorded on a FT-IR Bomem MB102 spectrometer in the wavenumber range 4000–400 cm^{-1} using KBr pellets. Raman spectra were obtained in the solid state in a Bruker RFS 100 instrument equipped with Nd^{3+}/YAG laser operating at 1064 nm in the near infrared and CCD detector cooled with liquid N_2 with an average of 1000 scans and 4 cm^{-1} of spectral resolution.

2.2. Synthesis of $\{[Zn(\mu\text{-}BPP)(BPP)(CV)(H_2O)]\cdot H_2O\}_n$ (1)

To 30 mL of a methanolic solution containing 106 mg (0.356 mmol) of $Zn(NO_3)_2\cdot 6H_2O$ at 65 °C, 256 mg (0.356 mmol) of $(NBu_4)_2CV$ dissolved in 20 mL of methanol were added. After 15 min, 20 mL of a methanolic solution containing 140 mg (0.712 mmol) of BPP were added. The resulting solution was kept under stirring at 65 °C for 1 h and after this time, 10 mL of water were added. The solution was set aside and a week later the formation of dark green crystals and a small amount of golden crystals was observed. The crystals were recovered by filtration and the golden ones were identified as $(NBu_4)_4[Zn(CV)_3]$ already described in the literature [15c]. The crystals were washed several times with methanol, dichloromethane and acetone to eliminate $(NBu_4)_4[Zn(CV)_3]$ and the prismatic dark green single crystals of $\{[Zn(\mu\text{-}BPP)(BPP)(CV)(H_2O)]\cdot H_2O\}_n$ were isolated and used in the X-ray diffraction data collection. Yield: 50%. m.p. = 180 °C (d). *Anal.* Calc. for $C_{37}H_{32}N_8O_5Zn$: C, 60.54; H, 4.39; N, 15.27; Zn, 8.90. Found: C, 60.39; H, 4.42; N, 16.03; Zn, 8.71%. 2.3. X-ray data collection and structure determination

Single-crystal X-ray diffraction measurement of complex **1** was carried out on an Enraf-Nonius *CAD*-4 diffractometer with a graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at 295(2) K. The structure was solved by direct methods with SHELXS97 [17] and refined by full-matrix least-square procedure based on F^2 using SHELXL97 program [18]. Crystal data and structure refinement parameters are summarized in Table 1.

3. Results and discussion

3.1. Synthesis and general characterization

Reaction of $Zn(NO_3)_2 \cdot 6H_2O$, $(NBu_4)_2CV$ and BPP ligand in methanolic media has afforded $\{[Zn(\mu\text{-BPP})(BPP)(CV)(H_2O)] \cdot H_2O\}_n$ (**1**). Recently, it has been reported the synthesis of a Zn(II) complex with the dianion CV^{2-} namely $K_2[Zn(CV)_2(H_2O)_2] \cdot 2H_2O$ containing the core $[Zn(CV)_2]^{2-}$ that can be used as a building block for coordination polymers construction [15d]. In the present work, the original idea was the replacement of coordinated water molecules in $[Zn(CV)_2(H_2O)_2]^{2-}$ by the nitrogen ligand BPP to generate an anionic coordination polymer. In this sense, the precursor $(NBu_4)_2CV$ was used to afford a great cation (NBu_4^+) that could stabilize the anionic polymeric chain. However, the analytical data have indicated the formation of a neutral compound with (1:1:2)/(Zn^{2+}:CV^{2-}:BPP) molar ratio in which tetrabutylammonium cations are not present.

The results of thermogravimetric analysis show two weight losses at 80 and 110 °C, indicating the presence of two distinct water molecules in the structure (Obs., 5.1% and Calc., 4.9%) corresponding to coordination and lattice water molecules. Above 180 °C, the complete thermodecomposition takes place and at 800 °C there is a residue consistent with metallic zinc in association with a black amorphous material.

The IR and Raman spectra of compound **1** are shown in Fig. 1. It can be verified that the stretching modes at 2210 and 2200 cm^{-1} assigned to ν(CN) vibrations are little affected in comparison to free CV^{2-} dianion [15c], indicating that dicyanomethylene groups do not participate in the coordination to Zn(II) centers. On the other hand, ν(CO) mode originally at 1635 cm^{-1} in the $(NBu_4)_2CV$ spectrum [15c], is absent in the spectrum of **1**, although it can be observed the presence of a low intensity band at 1688 cm^{-1}. These results suggest the pseudo-oxocarbon coordination to the metal center through the vicinal oxygen atoms O1 and O2, in a bidentate fashion, as observed for

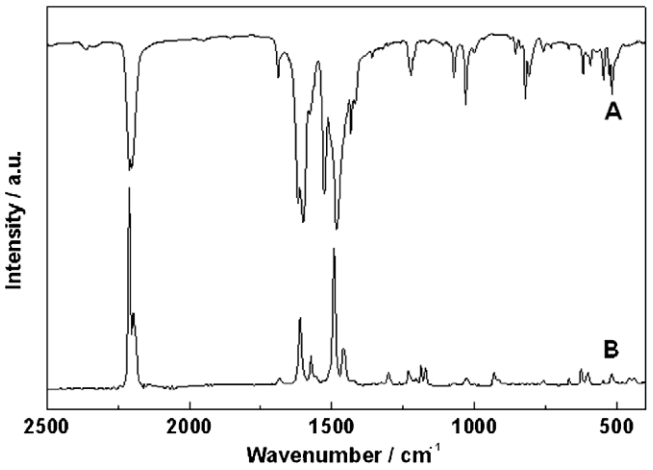

Fig. 1. Infrared (A) and Raman (B) spectra of $\{[Zn(\mu\text{-BPP})(BPP)(CV)(H_2O)] \cdot H_2O\}_n$ (**1**).

other complexes with CV^{2-} dianion coordinated in a O,O-bonding mode, described in the literature [15]. It should be noticed that in **1**, the pyridine ring vibrational band shifts from 1605 cm^{-1} in free BPP to 1619 cm^{-1}. In fact, the presence of ν(CC/CN) in higher wavenumber is indicative of metal coordination [19] to BPP pyridine nitrogen atoms, as observed for previous structurally characterized compounds [9a,20].

3.2. Description of the crystal structure of *1*

The asymmetric unit of **1**, shown in Fig. 2, is constituted by a Zn(II) ion coordinated to three pyridine nitrogen atoms (N21, N41 and N51) from two different BPP ligands as well as to two oxygen atoms (O1 and O2) from one CV^{2-} dianion and one *aqua* ligand (OW1). Additionally, there is one lattice water molecule in the structure as was indicated by thermal analysis. The donor atoms are arranged around the metal center in a distorted octahedral geometry with a *facial* local isomery (ZnN_3O_3). As was suggested by spectroscopic data, the pseudo-oxocarbon CV^{2-} is coordinated to the Zn(II) center in a O,O-bonding bidentate fashion with no participation of the dicyanomethylene ($-C(CN)_2$) groups. Selected bond distances and angles are presented in Table 2.

It can be noticed that Zn–O bond distances are not equivalent, corresponding to an asymmetrical bidentate coordination mode. The Zn–O2 bond distance (2.0772(15) Å) is much shorter than Zn–O1 (2.3510(15) Å) and the latter one is longer than Zn–OW1 bond distance (2.2067(16) Å). This asymmetrical bidentate coordination mode has been already observed for other complexes containing the CV^{2-} dianion described in the literature [15a,15b,15d]. In addition, the coordination promotes great perturbations in Croconate Violet C–O bonds. In fact, all C–O bonds are equivalent in the free CV^{2-} with mean distances of 1.244(6) Å for $K_2CV \cdot 2H_2O$ [13b] and 1.239(2) Å for $(NBu_4)_2CV$ [15c], characterizing a delocalized electronic system. On the other hand, in **1**, C2A–O2

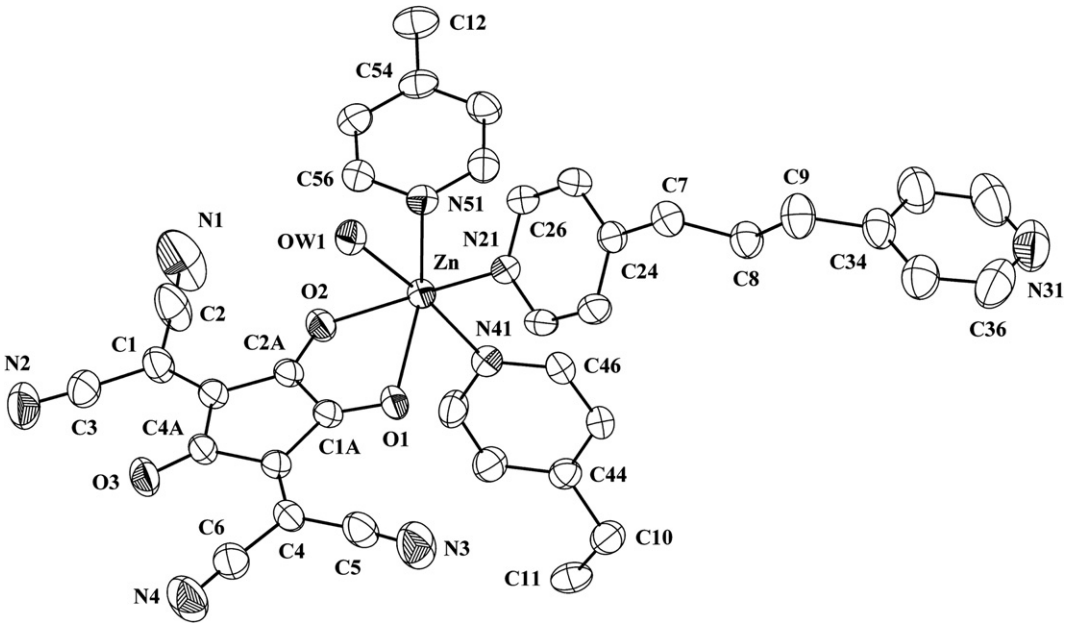

Fig. 2. Projection of the asymmetric unit of **1** with the atomic numbering scheme [21]. Displacement ellipsoids drawn at the 50% probability level. Hydrogen atoms and lattice water molecule oxygen atom (OW2) were omitted for clarity.

bond distance, in which the oxygen atom is more strongly bonded to Zn(II), is longer than C1A–O1, assuming the values of 1.264(3) and 1.246(3) Å, respectively. However, C4A–O3 bond length (1.221(3) Å), which oxygen atom is not involved in the coordination to the metal center, is much shorter than C2A–O2 and C1A–O1 and even than those observed in the free ligand, indicating a great carbonyl character for C4A–O3 bond. In this sense, it can be concluded that the pseudo-oxocarbon exhibits a partial localization of the π electrons upon complexation. This fact can be responsible for the low intensity stretching bands in 1688 and 1684 cm^{-1}, assigned to ν(CO), observed in IR and Raman spectra respectively.

The one-dimensional (1-D) polymeric nature of $\{[Zn(\mu\text{-BPP})(BPP)(CV)(H_2O)]\cdot H_2O\}_n$, shown in Fig. 3, was revealed through the connection of asymmetric units metallic centers by BPP ligands. It must be pointed out that there are two kinds of BPP ligands in the structure. The BPP ligands, which contain N41 and N51 pyridine nitrogen atoms, act in a bridging coordination mode toward the Zn(II) centers and are responsible for the 1-D polymeric chain formation along the crystallographic *a* axis. On the other hand, the BPP ligands, which contain N21 and N31 nitrogen atoms, are pendants and coordinate the metal ions through N21 atom in a monodentate fashion, with no participation of N31.

Table 2
Selected bond distances (Å) and angles (°) for compound **1**

Zn–O1	2.3510(15)	C1A–O1	1.246(3)
Zn–O2	2.0772(15)	C2A–O2	1.264(3)
Zn–OW1	2.2067(16)	C4A–O3	1.221(3)
Zn–N21	2.0841(18)	C2–N1	1.146(3)
Zn–N41	2.1542(19)	C3–N2	1.134(3)
Zn–N51	2.1215(18)	C5–N3	1.141(3)
		C6–N4	1.141(3)
O1–Zn–O2	77.37(6)	N21–Zn–OW1	83.77(7)
O1–Zn–OW1	86.27(6)	N21–Zn–N41	96.50(7)
O1–Zn–N21	90.31(6)	N21–Zn–N51	102.29(7)
O1–Zn–N41	86.43(6)	N41–Zn–OW1	172.69(6)
O1–Zn–N51	167.00(6)	N41–Zn–N51	95.18(7)
O2–Zn–OW1	83.41(6)		
O2–Zn–N21	162.75(6)		
O2–Zn–N41	94.76(7)		
O2–Zn–N51	89.63(7)		

The BPP ligands that act in a bridging coordination mode adopt a TG (*trans–gauche*) conformation along the 1-D polymeric chain exhibiting a N41-to-N51′ separation of 8.73(3) Å (symmetry code (′) $1 + x$, y, z). On the other hand, it can be noticed that the pendant BPP ligands assume the TT (*trans–trans*) conformation which is associated to a maximum separation between the pyridine nitrogen atoms (d(N21···N31) = 10.023(4) Å). These values are in accordance to other metal compounds containing BPP ligand structurally characterized [7b]. Additionally, the intra-chain distance between two adjacent metallic centers is equivalent to the crystallographic *a* axis length corresponding to 11.8730(6) Å.

Among the several known coordination polymers constructed through the interaction of metal cations with the flexible ligand BPP [4–11] there is a Mn(II) complex namely $[\{Mn(bpp)_3Cl_2\}(H_2O)_2]_n$ reported in the literature [9d] which has bridging and pendant BPP ligands. However, in contrast to **1** structure, in the manganese complex the bridging BPP molecules adopt a TT conformation (d(N···N) = 9.962 Å) and, the pendant ones assume a TG conformation (d(N···N) = 8.985 Å).

The most prominent structural feature of **1** is that, besides the metal–ligand (Zn–N) interaction, responsible for the 1-D chain formation along the crystallographic *a*

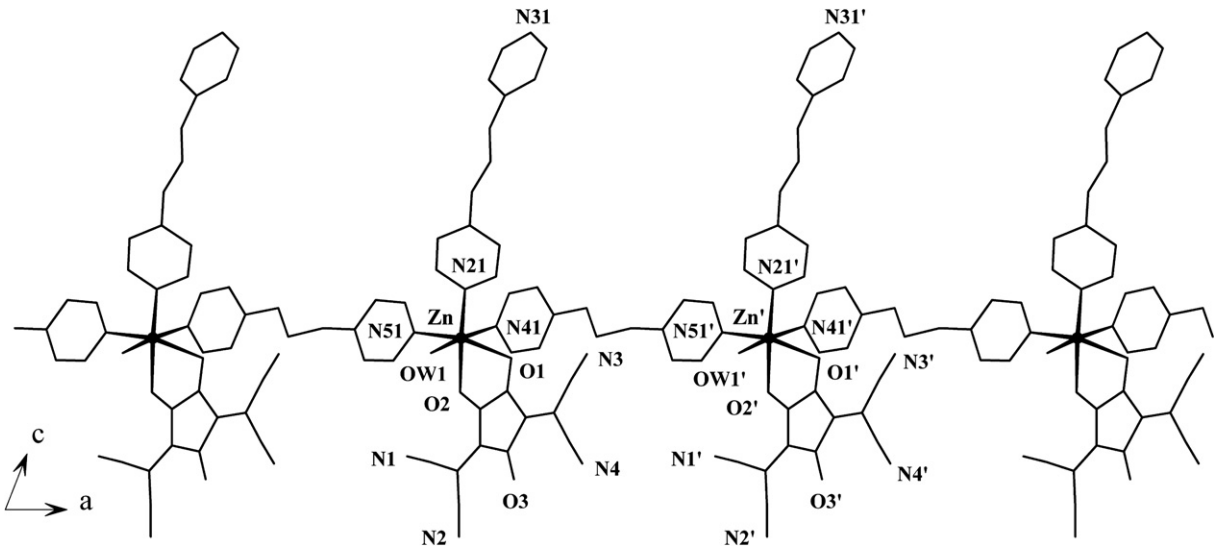

Fig. 3. One-dimensional (1-D) polymeric chain of $\{[Zn(\mu\text{-BPP})(BPP)(CV)(H_2O)]\cdot H_2O\}_n$ extended along the crystallographic *a* axis. Hydrogen atoms and lattice water molecule oxygen atom (OW2) were omitted for clarity. Symmetry transformations used to generate equivalent atoms: (′) $1+x, y, z$.

axis, it can be noticed other interactions like hydrogen bonding. Normally, these interactions are weaker than those of coordination, however, as in the present case, they play an essential role in the establishment of multi-dimensional networks in the solid state. In this sense, as can be seen in Fig. 4, the 1-D polymeric chains are connected through cooperative hydrogen bonding involving N31, OW2 and OW1 atoms giving rise to a two-dimensional (2-D) supramolecular array along the crystallographic *c* axis. In fact, each N31 atom, which is not coordinated to metal ion, from terminal BPP ligands, forms hydrogen bonding with the non-coordinated water molecules present in the crystalline lattice. In this hydrogen bond (OW2$\cdots$N31″ = 2.841(3) Å, OW2–H3 = 0.935(2) Å, H3$\cdots$N31″ = 1.909(3) Å, OW2–H3$\cdots$N31″ = 174.6(2)°, symmetry code (″) $x, y, 1-z$) the separation between nitrogen and oxygen atoms is much shorter than the van der Waals radii sum (3.07 Å). In addition, the non-coordinated water molecules are involved in stronger hydrogen bonds with the coordination water molecules (OW1$\cdots$OW2 = 2.725(3) Å, OW1–H1 = 0.932(2) Å, H1$\cdots$OW2 = 1.794(2) Å, OW1–H1$\cdots$OW2 = 177.1(1)°).

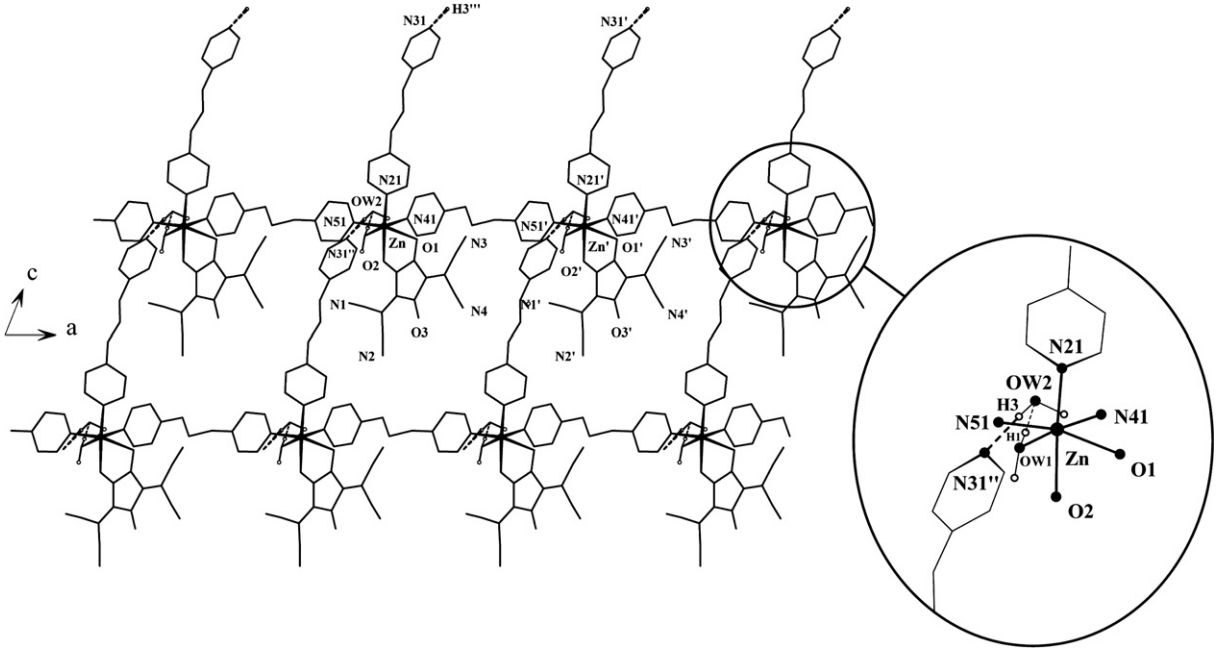

Fig. 4. Two-dimensional (2-D) supramolecular network of $\{[Zn(\mu\text{-BPP})(BPP)(CV)(H_2O)]\cdot H_2O\}_n$, **1**, extended through cooperative hydrogen bonding involving N31, OW2 and OW1 atoms. Symmetry transformations used to generate equivalent atoms: (′) $1+x, y, z$; (″) $x, y, -1+z$; (‴) $x, y, 1+z$.

The separation between two inter-chain Zn(II) centers, along the terminal BPP ligands, is equivalent to the crystallographic *c* axis, leading to a 2-D network extended by hydrogen bonding with (4,4) type structural topology, similar to a distorted square grid. The lowest closed path represents a parallelogram of $a \times c$ (11.8730(6) × 13.845(2) Å) dimensions.

In addition, an interesting interdigitation phenomenon can be observed in the compound **1** structure. Since the BPP ligands in TT and TG conformations are oriented to opposite sides in the network lowest closed path, the parallelogram exhibits two concave sides and two convex ones, resulting in an extremely undulated rhombohedral grid. Two complementary grids fit each other, without being interpenetrated, giving rise to a bilayer supramolecular structure. π–π interactions between Croconate Violet rings of adjacent sheets with an interplanar distance of 3.618(4) Å, as well as, hydrogen bonds between CV^{2-} non-coordinated oxygen atoms (O3) and coordinated water molecules (OW1···O3$''''$ = 3.018(2) Å, OW1–H2 = 0.982(2) Å, H2···O3$''''$ = 2.272(2) Å, OW1–H2···O3$''''$ = 131.9(1)°, symmetry code ($''''$) $-1+x, -y, -z+1$), can be identified. Although these interactions are much weaker than those discussed before, they seem to be very important in the (4,4) networks interdigitation to maintain the bilayer supramolecular structure.

It must be pointed out that there is only one example of a coordination polymer containing Croconate Violet dianion reported in the literature [16], namely $\{[Fe(\mu\text{-CV})(H_2O)_2]\cdot 2H_2O\}_n$, and therefore $\{[Zn(\mu\text{-BPP})(BPP)(CV)(H_2O)]\cdot H_2O\}_n$, described in this work, is the first 2-D coordination polymer involving Zn(II), the CV^{2-} ion and an ancillary nitrogen ligand.

4. Conclusion

In summary, the present study provides an interesting example of Zn(II) coordination polymer constructed from the flexible nitrogen ligand BPP and Croconate Violet dianion namely $\{[Zn(\mu\text{-BPP})(BPP)(CV)(H_2O)]\cdot H_2O\}_n$ (**1**). Thermogravimetric results have shown the presence of coordination and lattice water molecules in the complex structure. According to vibrational spectroscopic data, the Croconate Violet dianion is coordinated to Zn(II) center through the vicinal oxygen atoms O1 and O2 in a chelating fashion with no involvement of CN moieties. All these facts were confirmed by single crystal X-ray diffraction analysis. The asymmetric unit consists on a Zn(II) center surrounded by three nitrogen atoms from two different BPP ligands, two oxygen atoms from one Croconate Violet dianion and one *aqua* ligand, adopting a distorted octahedral geometry in a *facial* arrangement (ZnN_3O_3). The one-dimensional (1-D) polymeric nature of **1** was revealed through the connection of asymmetric units metallic centers by BPP ligands, which adopt a TG conformation. The 1-D polymeric chains are connected through cooperative hydrogen bonding, giving rise to a two-dimensional (2-D) supramolecular array with (4,4) structural topology. Two complementary 2-D sheets fit each other exhibiting an interdigitation phenomenon, affording a bilayer supramolecular structure.

5. Supplementary material

CCDC 615919 contains the supplementary crystallographic data for $\{[Zn(\mu\text{-BPP})(BPP)(CV)(H_2O)]\cdot H_2O\}_n$ (**1**). These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

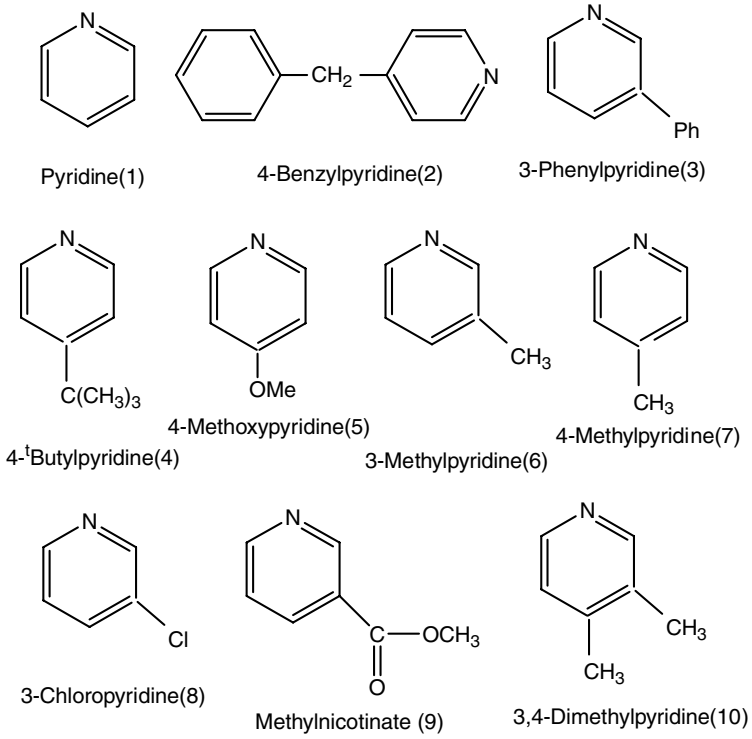
Tertiary amine ligands offer considerable flexibility in the reactivity of the OsO_4/ligand mixture. In using OsO_4, as an effective reagent, in *cis*-hydroxylation of alkenes as well as in a variety of catalytic systems, the critical step depends on the formation of an osmium(VI) cycloadduct which is promoted by bases such as pyridine [10–12].

On the other hand, nitrogen ligands are important chemicals in chemistry [13]. The pyridines' substituted derivatives are also a family of donors commonly used in coordination chemistry. The 2- and 2,6-substituted derivatives invariably have steric problems with Lewis acids. Derivatives of pyridine in the *meta* and *para* positions provide a set of ligands with a constant steric requirement toward bulky Lewis acids. Since steric problems are often encountered in transition metal ion chemistry, the pyridine family is often used to determine electronic influences on the chemistry.

Despite the importance of OsO_4 in catalytic processes, a field where the Lewis acidity of OsO_4 plays an important role, it is surprising that no quantitative information exists on the acidity strength of this important compound in the literature. A particular question that this study attempts to address is to find the Lewis acidity of osmium tetroxide using three simple and straightforward scales, pK_a of N-donors, the Hammett reaction constant and the ECW model. This article concerns the reaction (1), the formation of an $OsO_4 \cdot L$ complex. We have measured the relative coordination ability of different N-donor ligands (shown in Scheme 1) toward OsO_4. We have also measured the enthalpies of the adduct formation in CCl_4. Carbon tetrachloride is an excellent solvent in the present study, as it has a very poor solvating effect and the compounds have good solubility in this solvent. The Drago's E_A and C_A parameters for OsO_4 are also obtained. This is particularly significant because of the importance of OsO_4 in inorganic, organometallic, and catalytic chemistry. These parameters also allow the chemists to predict and correlate quantitatively the enthalpies of $OsO_4 \cdot$ Lewis base interactions.

2. Experimental



Caution: Osmium tetroxide presents an especial hazard to the eyes. Appropriate care should be taken in handling this compound.

2.1. Materials

Osmium tetroxide was obtained from Merck. Pyridine and its substituted derivatives were purchased from commercial sources and used without further purification. CCl_4 (Merck; quality for spectroscopy) was used as a solvent throughout this study.

2.2. Instruments

Equilibrium measurements were performed with conventional UV–vis spectrophotometer (Perkin–Elmer Lambda 25). Quartz cuvettes with 1 cm optical path lengths were used. Equilibrium measurements were carried out at different temperatures, maintained by a circulating water thermostatic system (EYELA NCB-3100 constant-temperature bath).

Scheme 1. Structural formulas of pyridine and its derivatives.

2.3. Measurements

The stepwise titration of the OsO_4 with 10 ring-substituted pyridines in CCl_4 according to Eq. (1) was followed spectrophotometrically at corresponding wavelength. Eqs. (3) and (4) were fitted to data of equilibrium absorbances to give the equilibrium constants and the enthalpies [14,15].

$$\mathrm{Abs}_{eq} = \left\{\frac{\varepsilon_{OsO_4} + \varepsilon_{OsO_4\cdot L}K_{eq}[L]}{1 + K_{eq}[L]}\right\}[Os]_T \quad (3)$$

Here, Abs_{eq} is the absorbance of a solution at equilibrium; ε_{OsO_4} and $\varepsilon_{OsO_4\cdot L}$ are molar absorptivities for OsO_4 and $OsO_4 \cdot L$ species, respectively at corresponding wavelength; $[Os]_T$ is the total concentration of OsO_4 and $OsO_4 \cdot L$ in the solution, and [L] represents the equilibrium ligand concentration. Such solutions contained L at a known concentration because $[L]_T \cong [L]_{eq} \gg [Os]_T$.

$$\ln K_{eq} = \frac{-\Delta H}{RT} + \frac{\Delta S}{R} \quad (4)$$

3. Results and discussion

We have previously reported that methyltrioxorhenium (MTO) forms only 1:1 complexes in solution with a variety of substituted pyridines [14,15]. The equilibrium constants for the MTO reactions show both $\log K_{eq}$ versus pK_a and Hammett-type correlations. We now report equilibrium constants for the formation of the corresponding OsO_4 complexes [Eq. (1)] and try to find the Lewis acidity of OsO_4 using three scales.

3.1. Scale 1: Acidity order based on pK_a of N-donors

In a similar manner, as shown previously [14,15] for MTO, OsO_4 forms only 1:1 pyridine adducts, in agreement with other studies [11,12]. Table 1 gives the equilibrium constants, for reaction (1) in CCl_4 solvent. The non-linear least square analysis was used to determine K_{eq} by fitting of absorbance–concentration data to Eq. (3).

The acidity of OsO_4 has been compared with MTO and Zn(TPP). Equilibrium data for MTO and Zn(TPP) are reported in the literature [15,19]. The excellent linear relationship was observed between the equilibrium constants and the pK_a values of the ligands. Fig. 1 shows the linear relationship of $\log K_{eq}$ for three acids, OsO_4 (in CCl_4), MTO (in CCl_4) and Zn(TPP) (in toluene) with the pK_a of the base, which is of the form $\log K_{eq} = m(pK_a) + b$. For OsO_4, MTO and Zn(TPP), $m = 0.33$, 0.43 and 0.65, respectively. This equation has been widely used as an empirical representation of equilibrium constant data [14,15,20,21].

It has been suggested that m is related to the σ-polarizing power of a cation [21], which we find to be $Zn^{II} > Re^{VII} > Os^{VIII}$. From Fig. 1, an extrapolation shows that the Zn(TPP) adducts will become more stable than OsO_4 or MTO as ligand basicity increases. The higher ligand basicities place more electron density on the pyridine nitrogen making it more polarizable. This increased polarizability has more effect for the more polarizing metal ion, i.e., $Zn^{II} > Re^{VII} > Os^{VIII}$, or in the order of increasing m values.

3.2. Scale 2: The Hammett reaction constant (ρ)

The Hammett σ values of substituted pyridines are shown in Table 1. Fig. 2 shows that the equilibrium data fit a Hammett correlation of the form shown in Eq. (5).

$$\log \frac{K_{eq}}{K_0} = \rho\sigma \quad (5)$$

In this equation K_0 is for $OsO_4 \cdot$ pyridine, K_{eq} is for $OsO_4 \cdot$ substituted pyridines, and σ is the Hammett substituent constant. The ρ constant values for different acids and the corresponding R^2 (correlation coefficient) values are collected in Table 2.

Gasperini and Ragaini have recently reported [24], for the first time, that ρ can be considered as a measure of

Table 1
Equilibrium constants[a] and ΔH values for the complex formation reactions [Eq. (1)] between OsO_4 and pyridines (shown in Scheme 1) in CCl_4

$[Cu(PhMePh)_2]$	−1.7	0.998	$CHCl_3$	[18]
Zn(OEP)	−2.0	0.987	toluene	[19]
Zn(TPP)	−2.7	0.992	toluene	[19]
H^+	−5.6	0.996	water	[22]
C_{60}-fullerene	−2.9	0.997	CCl_4	[23]

[a] MTO = Methyltrioxorhenium, *o*-Chloranil = 3,4,5,6-tetrachloro-1,2-benzoquinone, PhMePh = 1-hydroxy-3-phenyl-4,5-dimethylpyrazole 2-oxide, OEP = octaethylporphyrin, TPP = tetraphenylporphyrin.

the Lewis acidity of the metal complexes bearing completely different ligands and having metals with different oxidation states. They have also reported that there is very little experimental quantitative information on the Lewis acidity of transition metal complexes, in the literature. In this section, we attempt to make a comparison between the ρ constants of different acids including OsO_4 (see Table 2). The data in Table 2 can be used to give an experimental answer to an important question i.e., acidity of OsO_4.

3.2.1. The sign of ρ

A negative reaction constant ($\rho < 0$) means that the reaction center is more positive and the reaction is favored by electron-donating substituents or ligand to metal σ-bonding influences, while vice versa a positive reaction constant ($\rho > 0$) indicates the development of a negative charge at reaction center. The data reported in Table 2 show that ρ is negative for the pyridine equilibria with acids and it shows that a positive charge expands on the pyridine nitrogen in the complex as compared with the free ligand. The metal center, so, acts as an electron acceptor and attracts electrons upon coordination.

3.2.2. The magnitude of ρ

The magnitude of the reaction constant (ρ) is also essentially a measure of the susceptibility of a reaction to the polar effect of substituents in the adjacent benzene ring – the larger the value of ρ, the greater the susceptibility of the reaction. The important point that is obvious from the data in Table 2, is that the values of ρ constants are greatly variable and range from −1.0 to −5.6. In general terms, the ρ values show the OsO_4 reactions to be less sensitive to substituent effects than those of MTO or Zn(TPP). The more negative ρ values of MTO and Zn(TPP) compared to OsO_4 indicates that in the complex the pyridine nitrogen on MTO (or Zn(TPP)) has a higher formal positive charge than that on the nitrogen in the OsO_4 complex. Thus a given electron-donating group on pyridine will have more effect (greater sensitivity) in stabilizing the higher positive charge on the nitrogen adjacent to MTO than in the corresponding OsO_4 species. The higher positive charge on the pyridine nitrogen in MTO results from the Re^{VII} accepting relatively more of the electron pair from nitrogen than did Os^{VIII}. In other words, the Re^{VII} is a better σ polarizer than Os^{VIII}, a conclusion reached earlier on the basis of the *m* values.

In a similar method, to compare the Lewis acidity of OsO_4, the Hammett correlation for other acids has been used and shown in Table 2. Obviously, the acid strength order on the basis of data collected in Table 2 is as follow:

$$H^+ > \text{o-Chloranil} > C_{60}\text{-fullerene} > \text{Zn(TPP)} > \text{MTO} > \text{Zn(OEP)} > OsO_4 > [Cu(PhMePh)_2] > \text{Phenol}$$

3.3. Scale 3: The ECW model

The third scale that has been used to make an acidity scale for OsO_4 is the ECW model. We have measured values of the enthalpy change from the temperature dependency of the equilibrium constant for reaction shown in

Eq. (1). The enthalpy values were evaluated from the corresponding temperature data by applying a linear $\ln K_{eq}$ least squares analysis according to van't Hoff equation [Eq. (4) and Fig. 3] and listed in Table 1.

Drago et. al. have introduced [25] an empirical four-parameter equation to describe and predict the enthalpy change accompanying the reaction of neutral acids with neutral bases in poorly solvating solvents (e.g. CCl_4) or in the gas phase. This equation takes the form

$$-\Delta H = E_A E_B + C_A C_B \quad (6)$$

where E_A and C_A are parameters for the acid (arbitrarily set as $E_A = 0.50$ and $C_A = 2.00$ for I_2) and where E_B and C_B are parameters for the base (E_B for dimethylacetamide (DMA) was set at 2.35 and C_B for $(C_2H_5)_2S$ was set at 3.92). It is felt that the $E_A E_B$ term reflects the electrostatic part of the acid-base interaction and that the $C_A C_B$ term reflects the covalent part. The beauty of the Drago equation lies in its minimum of constraints, which in turn allows the best possible fitting of the enthalpy data by an equation of its form [26].

In this section, we try to obtain the values for E_A and C_A parameters of OsO_4 and establish another scale for acidity of OsO_4. Cramer and Bopp [27] have reported a graphical representation of the E and C equation that can result for OsO_4 when the base is varied. Thus, factoring Eq. (6) and extracting $(C_B + E_B)$ gives Eq. (7).

$$\frac{-\Delta H}{C_B + E_B} = \left(\frac{C_A + E_A}{2}\right) + \left(\frac{C_A - E_A}{2}\right) R_B \quad \text{where}$$

$$R_B = \left(\frac{C_B - E_B}{C_B + E_B}\right) \quad (7)$$

Note that this is the equation for a straight line, $y = ax + b$. Using the values of $-\Delta H$ (in kcal/mol) for Lewis bases (shown in Scheme 1) from Table 1, $-\Delta H/(C_B + E_B)$ is calculated and plotted versus the value of R_B calculated for N-donor ligands from their parameters in Table 3 (see Fig. 4). Fitting of the data to Eq. (7) gives values of $E_A = 2.01$ (kcal/mol)$^{1/2}$ and $C_A = 0.25$ (kcal/mol)$^{1/2}$ for OsO_4. The results are basically important because they create an acidity scale for OsO_4. Another very important use of these parameters is the calculation of enthalpy of OsO_4 interactions for hundreds of systems which have not been examined experimentally.

To put the acidity of OsO_4 on an external scale, it is better to compare OsO_4 with other famous acids. For this comparison, I_2, H_2O, BMe_3, BF_3, C_6H_5OH, $AlMe_3$, Me_3SnCl, CoPPIXDME {cobalt^{II} protoporphyrin IX dimethyl ester}, MTO {methyltrioxorhenium}, Zn(TPP) {zinc^{II} tetraphenylporphyrin}, $Cu(HFacac)_2$ {HFacac = hexafluoroacetylacetonato}, $VO(acac)_2$ {vanadyl acetyl-

acetonate} and $Mo_2(PFB)_4$ {molybdenium(II) perfluorobutyrate} were chosen. E_A and C_A parameters of these acids are listed in Table 3. Using parameters from Table 3 and Eq. (7), $-\Delta H$ (in kcal/mol) is calculated for a given acid, (e.g. BF_3) interacting with a base (e.g. pyridine). This value of $-\Delta H$ (in kcal/mol) divided by $(C_B + E_B)$ for pyridine {i.e. $-\Delta H/(C_B + E_B)$} is plotted versus the value of R_B calculated for pyridine from its parameters in Table 3, according to Eq. (7). Next, $-\Delta H$ is calculated for BF_3 interacting with methylnicotinate using Eq. (6). Dividing $-\Delta H$ by $(C_B + E_B)$ and calculating R_B for methylnicotinate give a second point on the BF_3 line. More points can be obtained using parameters for other bases listed in Table 3. A straight-line characteristic of the acid results by connecting the two or more plotted points. The line for BF_3 is shown in Fig. 5, along with those obtained in a similar fashion for a series of different acids (listed in Table 3) including OsO_4. Bases can range from a covalent base, ($R_B = 1.0$ for $E_B = 0$) to an electrostatic base ($R_B = -1.0$ for $C_B = 0$). The acceptor order toward any base whose E_B and C_B values are known can be determined from the corresponding plot. The value of R_B is calculated for the base, and a line parallel to the vertical axis is drawn. Listing the acceptors' intersection with this parallel line in order of decreasing $-\Delta H/(C_B + E_B)$ produces the acceptor order. For an electrostatic base with $R_B = -1.0$, $AlMe_3$ is the strongest acceptor and the acceptor order toward this electrostatic base is read off the graph in decreasing order as

$$AlMe_3 > BF_3 > Mo_2(PFB)_4 > BMe_3 > Me_3SnCl > Zn(TPP) > MTO > CoPPIXDME > C_6H_5OH > OsO_4 > Cu(HFacac)_2 > VO(acac)_2 > H_2O > I_2$$

For a covalent base with $R_B = 1.0$, the order is as follow:

$$AlMe_3 > BMe_3 > BF_3 > Cu(HFacac)_2 > I_2 > VO(acac)_2 > Zn(TPP) > CoPPIXDME > MTO > C_6H_5OH > Mo_2(PFB)_4 > H_2O > Me_3SnCl > OsO_4$$

For different amount of covalency in the base, the R_B value varies and different acceptor order results. Toward a base like pyridine ($C_B = 3.54$, $E_B = 1.78$ and $R_B = 0.33$) the acid strength order is

$$AlMe_3 > BF_3 > BMe_3 > Cu(HFacac)_2 > Zn(TPP) > VO(acac)_2 > Mo_2(PFB)_4 > CoPPIXDME > MTO > I_2 > C_6H_5OH > Me_3SnCl > H_2O > OsO_4$$

and for a base like C_5H_5NO ($C_B = 2.33$, $E_B = 2.29$ and $R_B = 0.01$) the order is

$$AlMe_3 > BF_3 > BMe_3 > Cu(HFacac)_2 > Mo_2(PFB)_4 > Zn(TPP) > CoPPIXDME > VO(acac)_2 > Me_3SnCl > MTO > C_6H_5OH > I_2 > OsO_4 > H_2O$$

and toward C_6H_5CN ($C_B = 0.75$, $E_B = 1.65$ and $R_B = -0.38$) the acceptor order is

$$AlMe_3 > BF_3 > BMe_3 > Mo_2(PFB)_4 > Zn(TPP) > Me_3SnCl > Cu(HFacac)_2 > CoPPIXDME > MTO > C_6H_5OH > VO(acac)_2 > OsO_4 > H_2O > I_2$$

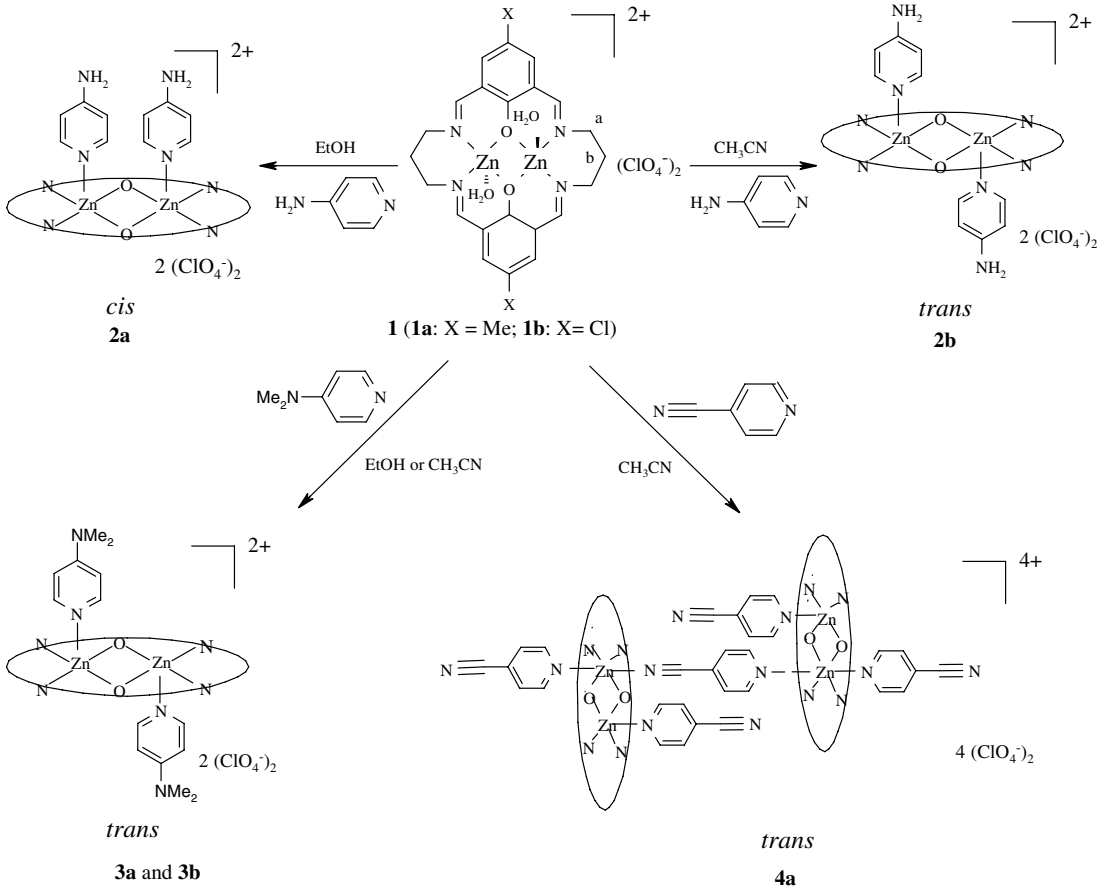
When the acceptor lines for two different acids cross, the acceptor order changes towards bases on opposite sides of the intersection. If the lines do not cross over the range of R_B from -1 to $+1$ (e.g. OsO_4 and BF_3 in Fig. 5), the acceptor order for these two acids will never change for a σ-bonding interaction as the base varies (e.g. BF_3 is always a stronger σ acceptor than OsO_4). Generally, ECW model has provided an acidity scale that accommodates a multitude of acceptor orders towards different kinds of bases.

4. Conclusion

The results presented here clarify the acidity of osmium tetroxide using three simple and straightforward scales.

(i) Donor ability of N-donors: The excellent linear relationship was observed between the equilibrium constants and the pK_a values of the ligands as $\log K_{eq} = m(pK_a) + b$. The m values are related to the σ-polarizing power of metal ion and so the acidity order is $Zn(TPP) > MTO > OsO_4$.

(ii) The Hammett reaction constant: A linear correlation between the relative coordination strength and the Hammett σ constant of the substituents on the pyridine ring was also found. This allowed one to measure the Lewis acidity of OsO_4 using reaction constant, ρ. Obviously OsO_4 is a weaker acid than MTO and Zn(TPP) toward substituted pyridines.



(iii) The ECW model: Comparing E_A and C_A parameters of OsO_4 with parameters for other well-known acids, the following results can be obtained: (1) Since both E_A and C_A values are greater for BMe_3, MTO, BF_3 and Zn(TPP) as compared to those for OsO_4, they are the stronger acids toward all bases. (2) In the case of OsO_4, $Cu(HFacac)_2$, $VO(acac)_2$, H_2O and I_2, the situation is ambiguous. Thus OsO_4 is more acidic than I_2 toward bases with $E_B \gg C_B$, but is a weaker acid for bases where $C_B \gg E_B$.

Scheme 1. Schematic illustration for the preparation of the macrocyclic complexes.

For the dinuclear Zn(II) centers $[Zn_2L(H_2O)_2](ClO_4)_2$ (**1**) (Scheme 1), prepared from the [2+2] sodium template condensation of 1,3-diaminopropane and 2,6-diformyl-4-substitutedphenol, both penta-coordinate and hexa-coordinate modes are common, depending on the ligands used [5]. Weakly coordinated water molecules at each side of the macrocyclic framework [6] can be replaced by an additive ligand bearing strong coordination atoms. If small or linear ligands such as CH_3COO^- [7a] and N_3^- [7b] anions are applied to react with **1**, the *trans* positional isomers will be the dominant products in order to minimize the spatial hindrance, since the two zinc(II) ions are positioned in a distance less than 3.3 Å. Nevertheless, if ligands containing aromatic rings are involved, *cis* and *trans* conformations, with respect to the rigid macrocylic skeletons, are accessible upon interaction at the supramolecular level. Compared to conventional means, X-ray single-crystal diffraction is the most powerful tool to characterize these two possible isomers. In our previous reports, we have described two *cis* molecular ladder elements by using 4-aminopyridine and 4-pyridinecarboxylate [8] as well as two infinite coordinative bond driven 1D ladders in which macrocyclic platforms are connected by 4,4-bipyridine [9]. All of these complexes are further stabilized by complementary hydrogen binding and face-to-face π–π interactions.

Recently, there have been a few reports on 1D chains of this type of macrocycle with mono μ_2-bridging ligands, such as formate bridged dinuclear Zn(II) [10], 1,3-diaminopropane bridged dinuclear Ni(II) [11], acetylenedicarboxylate [12] and 7,7,8,8-tetracyanoquinodimethane bridged dinuclear Cu(II) complexes [13]. Moreover, several sandwich-like dimacrocyclic complexes with double μ_2-oxygen bridges like tetranuclear Zn(II) [14] and tetranuclear Fe(III) [15] complexes have also been documented. Additionally, we have reported two coordinative bond free donor-acceptor hydrogen-bond-supported layer complexes bearing 2-methylquinoline [14a] and 8-methylquinoline [16]. However, the motif of a molecular stair, where two aromatic rings adopt a *trans* conformation with respect to the macrocyclic plane, is a relatively new topology that is rarely reported to date [17]. Moreover, the study of regulating the *cis* and *trans* macrocyclic subunits has not been mentioned. In this paper, we report the self-assembly study of macrocyclic complexes having pendant 4-aminopyridine (4-ampy), 4-dimethylaminopyridine (4-dmampy) and isonicotinonitrile (4-cnpy) groups, in which these pyridine rings are *trans* relative to the rigid macrocyclic plane. Controlled synthesis of the *cis* and *trans* isomers can be achieved for the 4-ampy subunits and the experimental result is supported by DFT calculations.

2. Experimental

2.1. Materials and general methods

All solvents and chemicals were of analytical grade and were used without further purification. 4-Ampy, 4-dmampy and 4-cnpy were purchased as commercial chemicals from Aldrich. 4-Methyl-2,6-diformylphenol was prepared in high yield by an improved oxidation method using active manganese(IV) dioxide [6b]. Dinuclear macrocyclic zinc complexes **1** were synthesized via a sodium template method described previously [6a]. Elemental analyses for carbon, hydrogen and nitrogen were performed on a Perkin–Elmer 1400C analyzer. Infrared spectra (4000–400 cm^{-1} and 600–100 cm^{-1}) were recorded on a Nicolet FTIR 170X spectrophotometer at 298 K using KBr plates. UV–visible (UV–vis) spectra were recorded with a Shimadzu UV-3150 double-beam spectrophotometer using a Pyrex cell with a path length of 10 mm. ^1H NMR spectra were obtained on a Bruker 500 MHz NMR spectrometer. Electrospray ionization mass spectra (ESI-MS) were recorded on a Finnigan MAT SSQ 710 mass spectrometer in the scan range of 100–1200 amu.

All the Density Function Theory computations were carried out with the Gaussian 03, Revision C.02 programs [18]. The fixed atom coordinates given by their CIFs were used in these cases where the number, type of atoms and the charge of molecules were kept the same. The B3LYP method and the LanL2DZ basis set were used for the zinc(II) macrocyclic *cis* and *trans* isomers, i.e. two monocations ([**2a**-ClO_4]$^+$ and [**2b**-ClO_4]$^+$) as well as two dications ([**2a**-2ClO_4]$^{2+}$ and [**2b**-2ClO_4]$^{2+}$), in order to compare the total energy differences of these isomers.

Caution: Although no problem was encountered in all our experiments, transition metal perchlorates are potentially explosive and should be handled in small quantities.

2.2. Synthesis of complex *2b*

An acetonitrile solution (10 cm^3) of 4-ampy (0.094 g, 1 mmol) was added to a stirred solution of polycrystalline **1b** [$Zn_2L_b(H_2O)_2$](ClO_4)$_2$ (0.405 g, 0.5 mmol) in hot acetonitrile (40 cm^3, 50 °C). The mixture was heated under reflux for 1 h, after which it was cooled to room temperature and filtered. The filtrate was slowly evaporated in air to near 5 cm^3, and then yellow single crystals, suitable for X-ray diffraction measurements, were collected in a yield of 87% (0.418 g). *Anal.* Calc. for [($Zn_2C_{22}H_{20}N_4O_2Cl_2$)-($C_5H_6N_2$)$_2$] · ($ClO_4$)$_2$: C, 39.98; H, 3.36; N, 11.66. Found: C, 40.02; H, 3.32; N, 11.57%. Main FT-IR (KBr disk, cm^{-1}): 3458 and 3365 (NH_2), 1641 (C=N), 1095, 1081 and 625 cm^{-1} (ClO_4^-), 408 and 242 cm^{-1} (Zn-py). ^1H NMR (500 MHz, DMSO-d^6, 298 K, TMS): $\delta = 8.52$ (s, 4H, HC=N), 7.82 (d, 8H, py-H), 7.79 (s, 4H, phenyl), 6.48 (s, 4H, NH_2), 3.86 (t, 8H, $^aCH_2$), 1.98 (m, 4H, $^bCH_2$). UV–vis: (λ_{max} in MeOH), 371, 246, 212 nm (**1b**: 365, 245, 216 nm). ESI-MS: *m*/*z* 671 [$Zn_2L_bClO_4$]$^+$, 286 [Zn_2L_b]$^{2+}$/2.

2.3. Synthesis of complex *3a*

A 10 cm^3 methanol solution of 4-dmampy (0.122 g, 1.0 mmol) was added to a stirred solution of **1a** [Zn_2L_a(H_2O)$_2$](ClO_4)$_2$ (0.384 g, 0.5 mmol) dissolved in 40 cm^3 methanol. The mixture was heated under reflux for 2 h, after which it was cooled to room temperature and filtered. The filtrate was slowly evaporated in air to near 10 cm^3, and yellow crystalline solids, suitable for X-ray diffraction measurements, were obtained in a yield of 86% (0.420 g). *Anal.* Calc. for [($Zn_2C_{24}H_{26}N_4O_2$)($C_7H_{10}N_2$)$_2$] · (ClO_4)$_2$: C, 46.74; H, 4.75; N, 11.47. Found: C, 46.71; H, 4.91; N, 11.39%. Main FT-IR (KBr disk, cm^{-1}): 3011 (C–H), 2925 and 2859 (alkyl), 1639 (C=N), 1561 and 1541 (C=C), 1415 (alkyl), 1093, 1084 and 623 cm^{-1} (ClO_4^-), 408 and 243 cm^{-1} (Zn-py). ^1H NMR (500 MHz, CD_3OD, 298 K, TMS): $\delta = 8.44$ (s, 4H, HC=N), 8.02 (d, 4H, py-H), 7.46 (s, 4H, phenyl), 6.71 (d, 4H, py-H), 4.02 (t, 8H, $^aCH_2$), 3.07 (s, 12H, py-NMe_2), 2.32 (m, 6H, PhMe), 2.07 (m, 4H, $^bCH_2$). UV–vis: (λ_{max} in MeOH), 366, 252, 203 nm (**1a**: 362, 251, 208 nm). ESI-MS: *m*/*z* 633 [Zn_2L_a-ClO_4]$^+$, 266 [Zn_2L_a]$^{2+}$/2.

2.4. Synthesis of complex *3b*

The procedure is similar to **3a** except that **1b** [$Zn_2L_b(H_2O)_2$](ClO_4)$_2$ (0.405 g, 0.5 mmol) was used and the yield is 88% (0.450 g). In our reference experiments, single crystals having the same structures as **3a** and **3b** can also be obtained from their acetonitrile solutions. *Anal.* Calc. for [($Zn_2C_{22}H_{20}N_4O_2Cl_2$)($C_7H_{10}N_2$)$_2$] · ($ClO_4$)$_2$: C, 42.50; H, 3.96; N, 11.01. Found: C, 42.51; H, 3.99; N, 11.08%. Main FT-IR (KBr disk, cm^{-1}): 2929 (alkyl), 1641 (C=N), 1625, 1583, 1559 and 1542 (C=C), 1442 and 1412 (alkyl), 1094, 1079 and 623 cm^{-1} (ClO_4^-), 407 and 242 cm^{-1} (Zn-py).^1H NMR (500 MHz, CD_3OD, 298 K, TMS): $\delta = 8.43$ (s, 4H, HC=N), 8.02 (d, 4H, py-H), 7.66 (s, 4H, phenyl), 7.00 (d, 4H, py-H), 4.03 (t, 8H, $^aCH_2$), 3.07 (s, 12H, py-NMe_2), 2.15 (m, 4H, $^bCH_2$). UV–vis: (λ_{max} in MeOH), 370, 245, 213 nm. ESI-MS: *m*/*z* 671 [$Zn_2L_bClO_4$]$^+$, 286 [Zn_2L_b]$^{2+}$/2.

2.5. Synthesis of complex *4a*

The procedure is similar to **2b**. A 10 cm^3 methanol solution of 4-cnpy (0.104 g, 1.0 mmol) was added to a stirred solution of **1a** [$Zn_2L_a(H_2O)_2$](ClO_4)$_2$ (0.384 g, 0.5 mmol) in 40 cm^3 methanol, and finally yellow crystalline solids, suitable for X-ray diffraction measurements, were obtained in a yield of 84% (0.473 g). *Anal.* Calc. for [($Zn_2C_{24}H_{26}$-N_4O_2)($C_6H_4N_2$)$_3$] · (ClO_4)$_2$ · (CH_3CN)$_2$: C, 49.04; H, 3.94; N, 14.92. Found: C, 49.01; H, 3.99; N, 14.78%. Main FT-IR (KBr disk, cm^{-1}): 3029 (C–H), 2914 and 2853 (alkyl), 2131 (C≡N), 1642 (C=N), 1593 and 1559

(C=C), 1412 (alkyl), 1097, 1085 and 627 cm^{-1} (ClO_4^-), 409 and 244 cm^{-1} (Zn-py). ^1H NMR (500 MHz, CD_3OD, 298 K, TMS): $\delta = 8.79$ (d, 6H, py-H), 8.47 (s, 4H, HC=N), 7.75 (d, 6H, py-H), 7.49 (d, 4H, phenyl), 4.05 (t, 8H, $^aCH_2$), 2.33 (s, 6H, PhMe), 2.19 (s, 6H, CH_3CN), 2.03 (m, 4H, $^bCH_2$). UV–vis: (λ_{max} in MeOH), 365, 252, 202 nm. ESI-MS: m/z 633 $[Zn_2L_aClO_4]^+$, 266 $[Zn_2L_a]^{2+}/2$.

2.6. X-ray data collection and solution

Single-crystal samples of **2b**, **3a**, **3b** and **4a** were glue-covered and mounted on glass fibers and then used for data collection. Crystallographic data of **2b** were collected at 291(2) K on a Bruker SMART 1 K CCD diffractometer, while those of **3a**, **3b** and **4a** were collected at 120(2) K on a Rigaku Mercury CCD area-detector, using graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). In the case of the Rigaku system, the original data files generated by Crystalclear were transformed to SHELXTL97 format by the TEXSAN program [19]. The crystal systems were determined by laue symmetry and the space groups were assigned on the basis of systematic absences using XPREP. Absorption corrections were performed to all data and the structures were solved by direct methods and refined by full-matrix least-squares method on F^2_{obs} by using the SHELXTL-PC software package [20]. All non-H atoms were anisotropically refined and all hydrogen atoms were inserted in calculated positions, assigned fixed isotropic thermal parameters and allowed to ride on their respective parent atoms. The middle carbon atom of the 1,3-diaminopropane unit (C9) in **3a** and atoms O3 and O4 of the perchlorate anions in **4a** are found to be disordered over two positions with different site occupancy factors. A summary of crystal data, experimental details and refinement results for macrocyclic complexes **2b**, **3a**, **3b** and **4a** is listed in Table 1, while selected bond distances and bond angles around every zinc(II) center are given in Table 2.

3. Results and discussion

3.1. Synthesis and general characterization

All the macrocyclic complexes described herein are facilely synthesized in high yields under mild conditions (Scheme 1) and are fully characterized. In comparison with the starting materials, several nanometer red shifts are

observed for all the complexes in their electronic spectra, indicative of axial complexation with pyridine-based ligands. ^{1}H NMR, IR spectra and C H N elemental analyses are consistent with their structures. ESI-MS spectral studies of **2b**, **3a**, **3b** and **4a** in methanol show that only mono and doubly charged peaks corresponding to the production of macrocyclic units of **1a** and **1b** are found. In addition, the ESI-MS peaks have been calculated and verified by using the numbers and natural isotopic abundance of the atoms [21].

The syntheses of **2a** and **2b** are reproducible in our experiments. In view of the difficulties of distinguishing the *cis* and *trans* isomers by IR, EA and UV–vis methods, X-ray single-crystal diffraction was used as the main approach to check the stereo configurations. We found that controlled synthesis of the *cis* or *trans* isomers **2a** or **2b**, where the same rigid macrocyclic platform and counterion are used, can be achieved merely by the substitution of a protonic solvent (ethanol) for a non-protonic solvent (acetonitrile). When the hydrogen atoms of the amino group are substituted by methyl groups, i.e. in the case of 4-dmampy, only the *trans* isomers (**3a** and **3b**) can be isolated no matter what solvent is used (protonic or non-protonic) because there is no strong H-bond donor present in the 4-dmampy molecule. In other words, this reference experiment demonstrates the importance of the participancy of the H-bond in our case. Furthermore, when a 4-cnpy molecule, which has a stronger coordination ability and may act as a bidentate bridging ligand, is used, an infinite 1D macrocycle-based stair **4b** is generated via compensatory coordinative bonds as well as hydrogen bonding and face-to-face π–π stacking interactions. One can see that subtle change of the 4-substitution group of pyridine-based ligands yields different molecular arrays and packing fashions.

3.2. Single-crystal structures of *2b*, *3a*, *3b* and *4a*

The X-ray determination results of **2b** reveal that each asymmetric unit contains half of the molecule and each zinc(II) center displays a five-coordinate pyramidal configuration consisting of four macrocyclic donors and an apical nitrogen atom from 4-ampy. As illustrated in Fig. 1a, two 4-ampy molecules in a *trans* mode are perpendicular to the macrocyclic platform. The bond lengths and bond angles of **2b** are analogous to those of **2a**. It is of much interest to note that the amino group of 4-ampy is uncoordinatedly naked, which makes the compound look like a molecular stair element. Effective N–H...O hydrogen contacts (Fig. 2) are found between the oxygen atoms of one perchlorate anion and two adjacent 4-ampy molecules (Table 3), which are obviously different from those in the *cis* isomer where a 12-membered N–H...O hydrogen-bonded ring stands on the top of macrocyclic plane [9]. Moreover, weak C–H...O type H-bonds are observed in **2b** between the imino H atom of the macrocyclic unit and one perchlorate oxygen atom. In addition, weak offset π–π stacking interactions are present between the vicinal phenyl rings of the macrocycles in a head-to-tail fashion. The shortest intermolecular contact distance between them is 3.851 Å.

X-ray diffraction analyses for **3a** and **3b** reveals that they have the same molecular symmetry as **2b**, as can be seen in Fig. 1b and Fig. 1c. They are isomorphous structures although **3a** and **3b** have different substituted groups (Me or Cl) in their macrocyclic backbones. Both central zinc(II) ions display five-coordinate pyramidal configurations consisting of four macrocyclic donors and an axial nitrogen atom of 4-dmampy. The macrocyclic dications are countered by two perchlorate ions and no solvent molecule is present in their crystal structures. The bond lengths and bond angles related to one central zinc(II) ion in **3a** are as follows: Zn1–O1, 2.049(2), Zn1–O1A $[-x, 2-y, -z]$, 2.092(2), Zn1–N1, 2.071(2), Zn1–N2, 2.056(3), Zn1–N3, 2.046(2) Å; N3–Zn1–O1, 103.17(9), N3–Zn1–O1A, 76.07(8), N3–Zn1–N1, 103.43(9), N3–Zn1–N2, 106.64(10)°. In contrast, those in **3b** are listed as follows: Zn1–O1, 2.098(3), Zn1–O1A $[1-x, 1-y, 1-z]$, 2.059(3), Zn1–N1, 2.066(4), Zn1–N2, 2.077(3), Zn1–N3, 2.030(5) Å; N3–Zn1–O1, 100.99(14), N3–Zn1–O1A, 103.64(14), N3–Zn1–N1, 104.63(14), N3–Zn1–N2, 103.24(14)°. 4-Dmampy

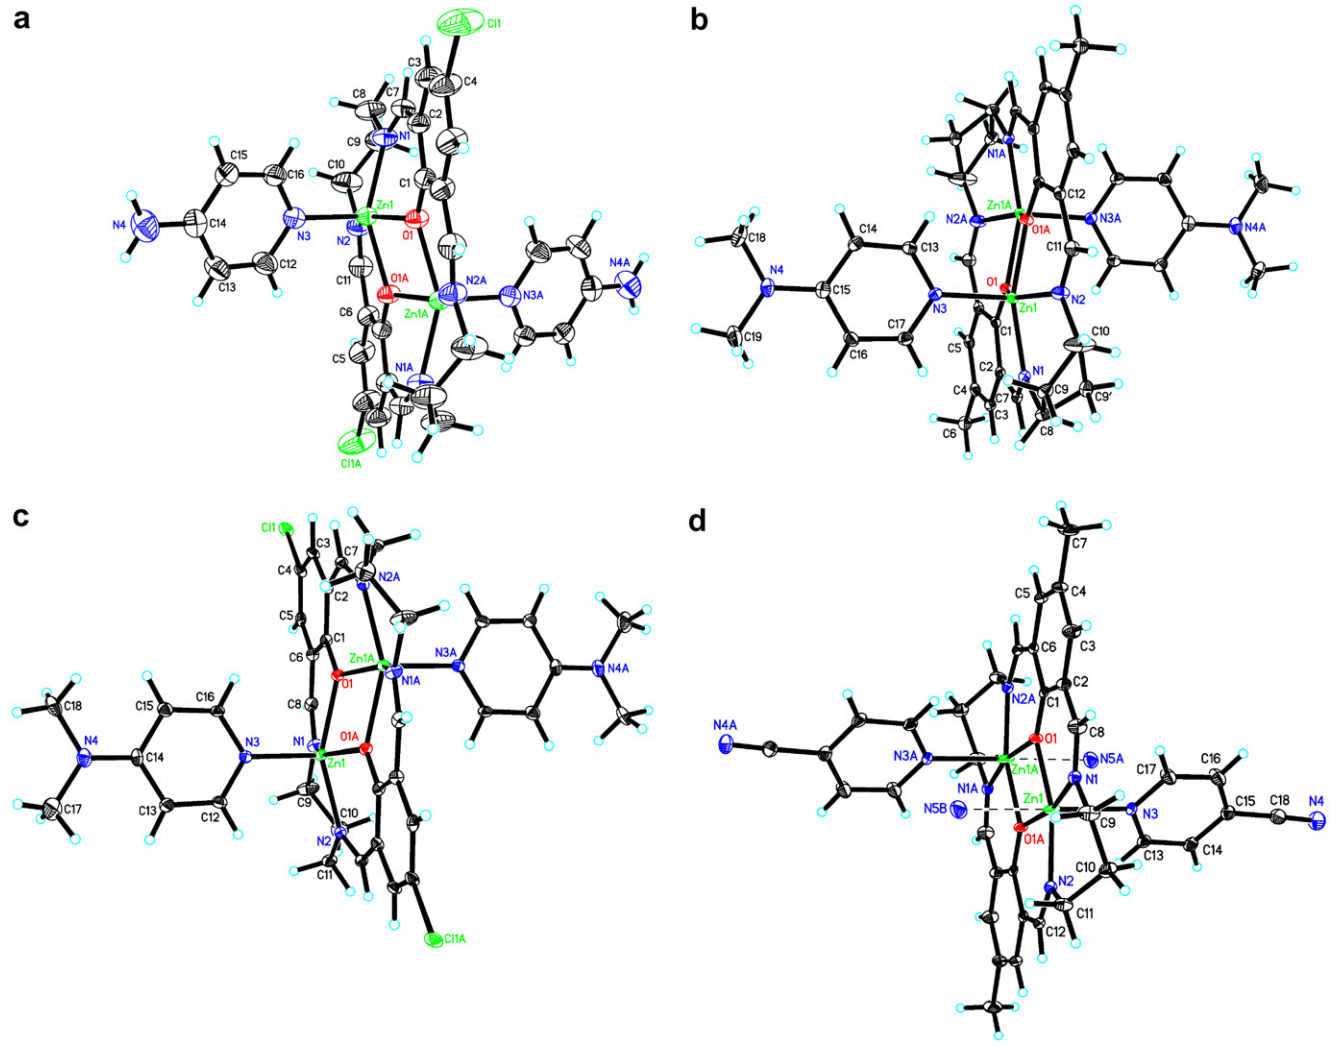

Fig. 1. ORTEP diagrams (30% thermal probability level) of the molecular structures of **2b** (a), **3a** (b), **3b** (c) cations and the polymeric unit of **4a** (d) cation with a partial atom-numbering scheme. The perchlorate anions and solvent molecules are omitted for simplicity.

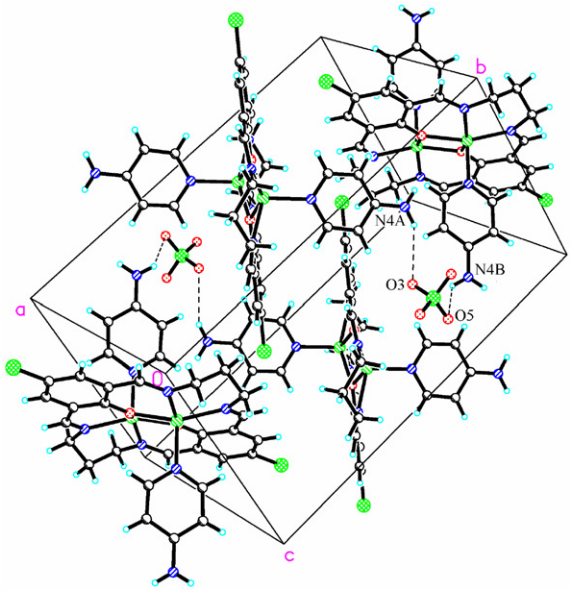

Fig. 2. A perspective view of the π–π stacking and hydrogen bonding interactions in **2b** with the unit cell.

molecules in **3a** and **3b** serve as monodentate ligands at each side of the macrocyclic plane and similar macrocycle-based molecular stair elements are formed.

The crystal packing structures of **3a** and **3b** are also very similar. Nevertheless, different from **2a** and **2b**, only weak C–H...O hydrogen bonds are found between the neighboring molecules in **3a** and **3b** after the H atoms of amino group are substituted by two methyl groups (Table 3). The lack of strong hydrogen bonds present in **2b** that fix the contiguous 4-ampy molecules to a certain degree makes the axial Zn–N σ-bond rotate to a parallel mode so as to minimize the spatial repulsion between the neighboring macrocyclic units. Accordingly, adjacent pyridine rings are parallel via the offset π–π stacking interactions with intermolecular separations of 3.652 Å in **3a** and 3.714 Å in **3b**. Thus similar quasi 1D molecular stairs based mainly on π–π stacking interactions are formed, as can be seen in Fig. 3.

From the outcome of the X-ray single-crystal diffraction study, complex **4a** crystallizes in the triclinic space group $P\bar{1}$. Like **2b**, **3a** and **3b**, each asymmetric unit of **4a** contains half

of the macrocyclic platform and two 4-cnpy molecules are situated at each side of the macrocyclic plane. There is another 4-cnpy molecule that lies across a crystallographic inversion center positioned at the phenyl carbon atom bonded to the cyano group, which results in the same separation with two contiguous macrocycles. Two six-coordinate zinc(II) ions are located essentially on the coordination plane (mean deviation from the basal plane is 0.126 Å), which is different from those pyramids in **1a**, **1b**, **2b**, **3a** and **3b** but analogous to the macrocyclic ladders [6]. The change of the coordination geometry makes the separation between the two metal centers shorter (3.174 Å) than those in **2b** (3.285 Å), **3a** (3.261 Å) and **3b** (3.275 Å). Each 4-cnpy plane is perpendicular to the macrocyclic plane to minimize steric crowding (Fig. 1d). It should be mentioned that two apical coordinative bonds connecting zinc(II) ions are obviously different, generating asymmetric and elongated octahedron configurations. However, both of the axial Zn–N bonds are longer than those in the three above-mentioned structures (2.022–2.046 Å).

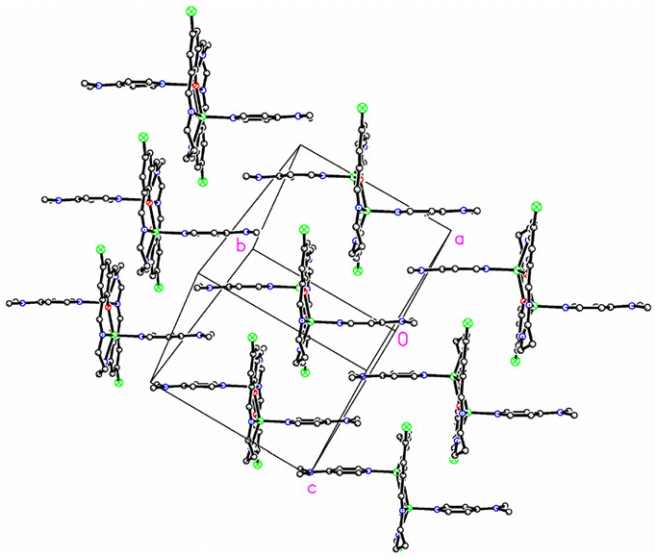

Fig. 3. A perspective view of the π–π packing structure in **3b** with the unit cell. The perchlorate anions and the hydrogen atoms are omitted for clarity.

It is noteworthy that two 4-cnpy moieties on one side of a macrocycle have different coordination modes, one serves as a bridge to connect two neighboring macrocyclic metal centers by using its head and tail nitrogen atoms, while the other is only mono-coordinated to a metal ion via its pyridyl nitrogen atom, leaving the cyanic group uncoordinated. As a significant result, an infinite 1D polymeric stair is constituted (Fig. 4), where all 4-cnpy planes are nearly parallel one another. 4-Cnpy molecules bend a little bit to the opposite side with a dihedral angle of 9.4° between two pyridine rings, and their centroid–centroid separation is 3.555 Å, exhibiting typical π–π stacking interactions. As shown in Fig. 5, the molecular stairs are further stabilized by intermolecular C–H...O and C–H...N hydrogen bonds, where oxygen atoms of perchlorate anions, macrocyclic nitrogen atoms and cyanic groups of 4-cnpy serve as acceptors while hydrogen atoms of 1,3-diaminopropane units and 4-cnpy act as donors (see also Table 3).

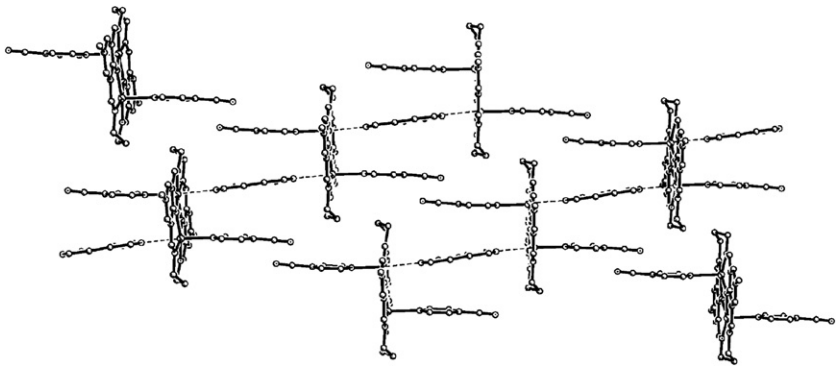

Fig. 4. A perspective view of the 1D molecular stairs in **4a** where the perchlorate anions and the solvent acetonitrile molecules are left out for simplicity.

3.3. Density function theory (DFT) calculations

Now that our experiments hint that it is possible to regulate the orientation (*cis* or *trans*) of the organic subunits by controlling the reaction conditions, namely the alteration of the solvent used can lead to the different topologies of **2a** and **2b**, we have tried to seek some other support by performing theoretical computations. Firstly, DFT calculations were carried out to get the total "Energy" of the isolated *cis* and *trans* isomers with fixed atom coordinates given by their CIFs, where substituted groups of the phenyl rings were replaced by hydrogen atoms to keep the same amount of atoms, and only the dications were retained. When the B3LYP method and the LanL2DZ basis set were used, the program gave the close total energies of −1228940.68 and −1228903.03 Kcal/mol for $[\mathbf{2a}\text{-}2ClO_4]^{2+}$ and $[\mathbf{2b}\text{-}2ClO_4]^{2+}$, respectively, which indicated that the *cis* dicationic species is somewhat more thermally stable than the *trans* one. However, the energy difference (37.65 Kcal/mol) is not so large, which means that both of them are accessible isomers. Furthermore, when the perchlorate anion was introduced for the same calculation in order to investigate the contribution of hydrogen bonding and face-to-face π–π stacking interactions, the resulting total energy gap (219.63 Kcal/mol) became larger, also in favor of the *cis* isomer, (−1426756.94 Kcal/mol for $[\mathbf{2a}\text{-}ClO_4]^{+}$ and −1426537.31 Kcal/mol for $[\mathbf{2b}\text{-}ClO_4]^{+}$). Thus it can be concluded that the presence of the 12-membered N–H...O hydrogen-bonded ring between the perchlorate anions and 4-ampy as well as the face-to-face π–π stacking interactions in **2a**, probably induced by the protonic ethanol molecules encapsulated in the crystal and causing such a big energy difference, have contributed significantly to the formation of the *cis* isomer in the solid state.

Secondly, in order to compare the differences between the energy-minimized and crystal structures, optimized structures for the above-mentioned dications and monocations were carried out. The energy-minimized structures show a very small energy difference of 1.13 Kcal/mol for dications $[\mathbf{2a}\text{-}2ClO_4]^{2+}$ (−1229347.10 Kcal/mol) and $[\mathbf{2b}\text{-}2ClO_4]^{2+}$ (−1229345.97 Kcal/mol), and 7.77 Kcal/mol for monocations $[\mathbf{2a}\text{-}ClO_4]^{+}$ (−1427359.08 Kcal/mol) and (−1427351.31 Kcal/mol) $[\mathbf{2b}\text{-}ClO_4]^{+}$, also favoring the formation of the *cis* isomer. However, compared with the energy generated from the structural parameters determined by the X-ray diffraction method, the larger ΔE values from the dications (405.29 and 444.07 Kcal/mol) to the monocations (602.14 and 814.00 Kcal/mol) also show clearly the contribution of hydrogen bonding and π–π stacking interactions in **2a** and **2b**.

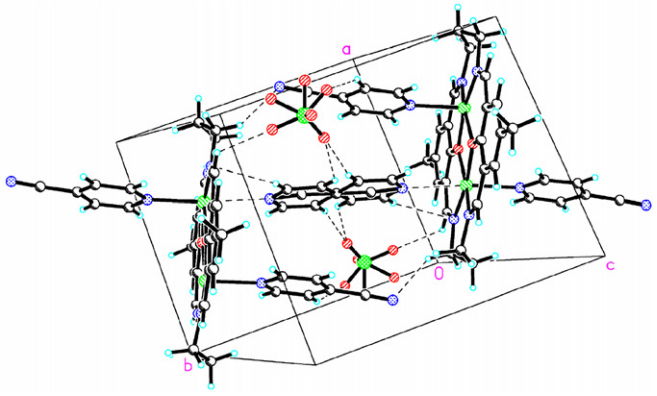

Fig. 5. A perspective view of the self-complementary π–π stacking and hydrogen bonding interactions in **4a**.

4. Conclusions

In summary, self-assembly of dinuclear zinc(II) macrocyclic species with three different linear 4-substituted pyridyl ligands (4-ampy, 4-dmampy and 4-cnpy) results in three *trans* molecular stair elements and one 1D molecular stair. The self-assembly study of these *trans* macrocyclic staircases is novel, and the driving forces in the formation of these molecular aggregations are synergistic interactions of metal–ligand bonding, hydrogen bonding and π–π stacking interactions in the solid state. Controlled synthesis of the *cis* or *trans* isomers (**2a** or **2b**), where the same rigid macrocyclic platform and counterion are used, can be achieved merely by the substitution of a protonic solvent for a non-protonic solvent since hydrogen bonding and π–π stacking interactions play a significant role here. This

is further verified by theoretical calculations and subsequent comparison between the energy-minimized and crystal structures for different monocations or dications.

Furthermore, when the two hydrogen atoms of the amino group are replaced by methyl groups in order to block the formation of effective hydrogen bonds, only the *trans* isomer can be obtained either in protonic or non-protonic solvents. Additionally, weak offset π–π stacking interactions are observed in the packing structures of **2b**, **3a** and **3b**. In contrast, strong face-to-face π–π stacking interactions are found in the packing structure of 1D stair **4a** because of the confinement of coordinative bonds to a small separation (<3.3 Å) between two zinc(II) centers. Compared with the starting materials, complexes **2b**, **3a** and **3b** retain the five-coordinate pyramidal configurations, while **4a** undergoes a configuration transformation to a six-coordinate elongated octahedron. The outcome demonstrates that the subtle change of the 4-substitution group of the pyridine-based ligand yields different molecular arrays and packing fashions, and that hydrogen bonding and π–π stacking interactions play an important role in the formation of the resultant complexes. Further studies are in progress for the preparation and the physical properties of Schiff-base macrocyclic complexes having different backbones, sizes and nuclearities.

tubing inserted inside a furnace. Pt–Rh thermocouples and eurotherm heat controllers monitored the temperatures of all gas inlet lines. Tungsten hexachloride (99.9%-W) was purchased from Strem Chemicals, Inc. and ethanol (denatured) was purchased from Aldrich. WCl_6 and the ethanol were placed into separate heated stainless steel bubblers and the vapours generated introduced into the gas streams by passing hot nitrogen gas through the bubblers. Gas flows were adjusted using suitable regulators and flow controllers. The exhaust from the reactor was vented directly into the extraction system of a fume cupboard. All of the apparatus was baked out with nitrogen at 150 °C for 60 min before deposition. Deposition experiments were conducted by heating the horizontal-bed reactor and the bubblers to the required temperatures before diverting the nitrogen line through the bubblers and hence to the reactor. At the end of the deposition the bubbler-lines were closed and only nitrogen passed over the sensor. The sensor was allowed to cool with the graphite block to ca. 150 °C before it was removed. Coated sensors were handled and stored in air. The samples were analysed using X-ray Photoelectron Spectroscopy (XPS), Scanning Electron Microscopy (SEM), Raman spectroscopy and X-ray Diffraction (XRD).

X-ray powder diffraction patterns were measured on a Siemens D8 diffractometer using monochromated Cu Kα1 radiation (Cu Kα1 = 1.5406 Å) utilising a large angle detector. The diffractometer was used in low incident geometry (5°). Data manipulation were performed using Bruker EVA software and samples were indexed using Unit Cell and compared to database standards. SEM were obtained on a Jeol 6301F (accelerating voltage 20 kV) using Oxford Instruments ISIS software. Raman spectra were acquired on a Renishaw Raman System 1000 using a helium–neon laser of wavelength 632.8 nm. The Raman system was calibrated against the emission lines of neon. X-ray photoelectron spectra were recorded with a VG ESCALAB 220i XL instrument using focused (300 μm spot) monochromatic Al Kα radiation at a pass energy of 20 eV. Scans were acquired with steps of 50 meV. A flood gun was used to control charging and the binding energies were referenced to an adventitious C 1s peak at 284.8 eV. Depth profile measurements were obtained using argon beam sputtering (etch voltage 5 kV). Electrical conductivity was determined by 4-probe measurement on glass substrates.

Gas-sensing measurements were carried out using an apparatus of in house design, comprising a glass flow-through cell to which three heated devices could be connected and sealed. Gases were applied using computer operated mass flow controllers (Tylan General) through two separate lines. The first carried pre-mixed gases in air of known concentration (100 ppm EtOH, 500 ppm NO_2), purchased directly from source (BOC Special Gases). The remaining line carried dry air ('zero grade' compressed air purchased directly from BOC). In this way the gas concentration of the air supplied to the sensors could be controlled (EtOH 1–100 ppm). Gas-sensing experiments were performed at sensor temperatures of 300, 400, 500 and 600 °C, with the total resistance of the WO_3 film being measured using a digital multimeter (Keithley 175A).

3. Results and discussion

The APCVD reaction of WCl_6 with ethanol was examined. It was found that the use of ethanol as the co-reactant in a molar ratio of 1:10 (W:ethanol) at a substrate temperature of 625 °C with a total N_2 carrier flow of 15 l/min caused the deposition of blue films on the sensor substrates. The films were adherent to the substrate and passed the 'Scotch tape test'. The deposition time was 30 s.

SEM was used to examine the film microstructures. The films deposited using ethanol as the co-reactant (Fig. 1) appeared as a 'mat' of discrete needles orientated parallel to the substrate.

These morphologies are unlike those seen in the literature for films deposited from tungsten hexaphenoxide via aerosol-assisted (AA-) CVD on glass substrates, from tungsten(VI) ethoxide via sol–gel on silicon substrates, from tungsten hexacarbonyl via LPCVD on silicon or from tungsten hexaphenoxide deposited onto a sensor substrate under the application of an electric field [3,10–12]. The change in film morphology with different co-reactants is an exciting avenue for developing gas sensors because the sensor morphology plays a critical role in the response characteristics.

The films deposited at 625 °C were analysed using glancing-angle XRD. The films deposited from ethanol ($a = 7.36(9)$, $b = 7.42(9)$, $c = 3.87(9)$ Å) indexed as monoclinic WO_3 ($a = 7.285$, $b = 7.517$, $c = 3.835$ Å) but showed striking preferred orientation with the $\langle 0\,2\,0\rangle$ and $\langle 0\,4\,0\rangle$ diffraction peaks greatly enhanced (Fig. 2) [13].

Further analysis was performed using Raman spectroscopy (Fig. 3). The films deposited using ethanol had the

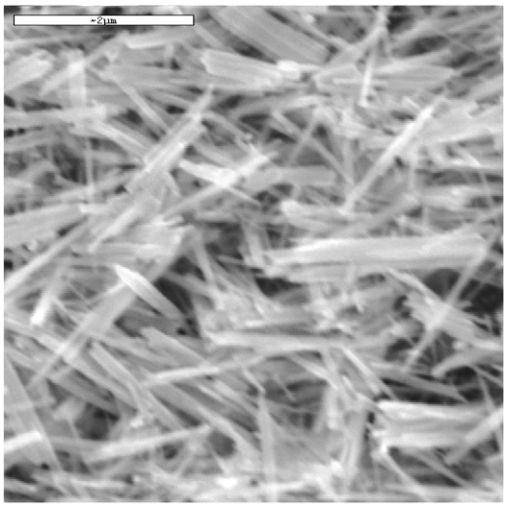

Fig. 1. Micrograph of film deposited using ethanol.

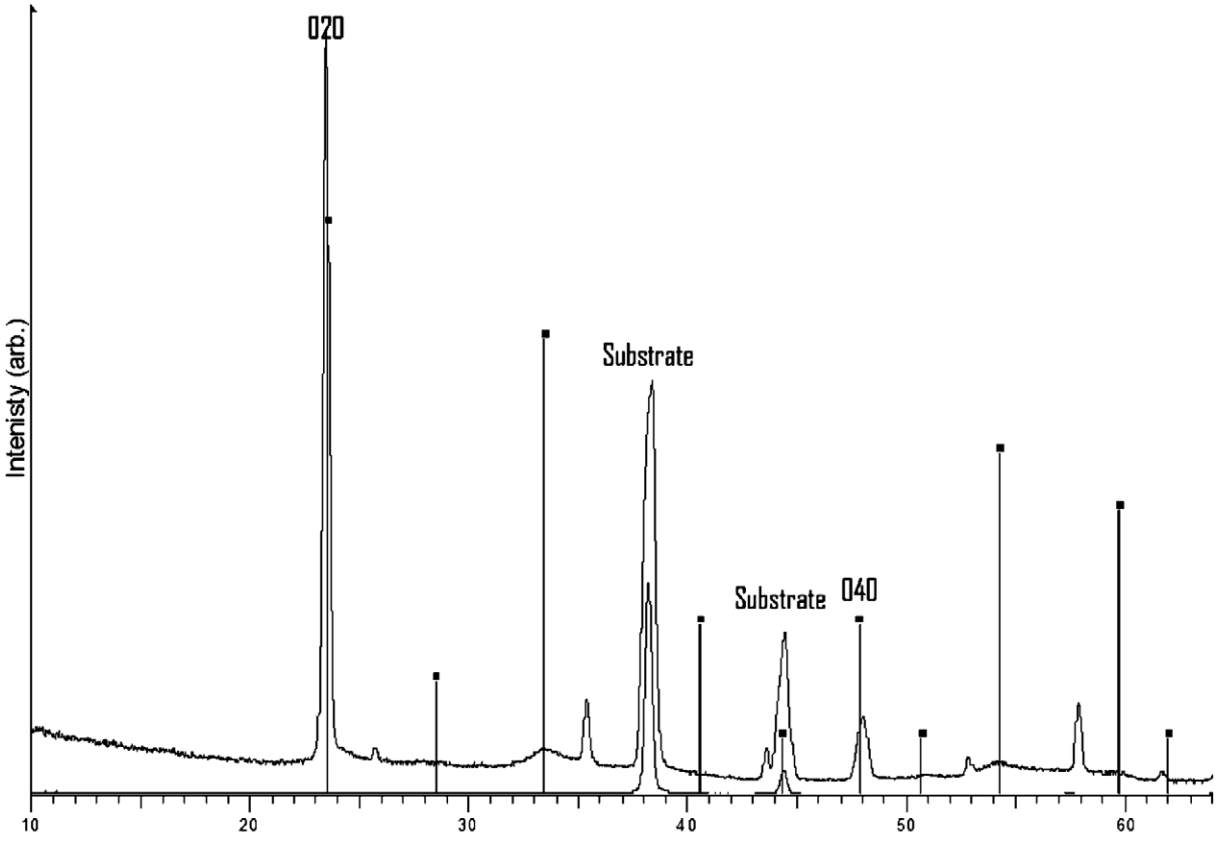

Fig. 2. X-ray diffraction pattern of film deposited using ethanol (substrate pattern also shown).

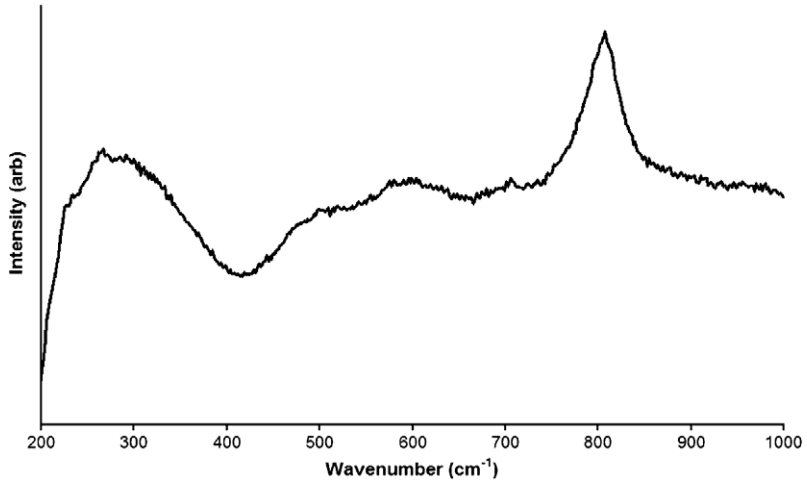

Fig. 3. Raman spectrum of film deposited using ethanol.

approximate form of crystalline WO_3 but with an amorphous appearance, with broad poorly defined peaks [14,15]. The films had a significantly different spectrum in the region 200–400 cm^{-1}. This region has been identified as containing W^{4+}–O and W^{5+}–O vibrations in amorphous WO_{3-x} tungsten oxides and may suggest the presence of reduced species in this film [16].

XPS was used to analyse the surface of the as-deposited films. The films were exposed to air after deposition and prior to XPS analysis. The film deposited from WCl_6 and ethanol had a very poor peak shape in the W4f region, being very broad and asymmetric. Deconvolution of the peak, using FWHM and peak area constraint, revealed 3 $W4f_{7/2}$ peaks. The peak fitting did not precisely model the experimental data, with slight deviation at the high energy side, but it was clear that there was a W^{6+} environment (35.5 eV), a W^{5+} environment (34.4 eV) and a W^{4+} (33.3 eV) environment in an approximate ratio of 3:2:1 [17]. The presence of such a large relative amount of reduced tungsten species would explain the very deep blue

colour observed in this film. No chlorine contamination was detected in the deposited films but carbon contamination was significant at the surface (~15–20%). An exact determination of the bulk carbon contamination was not made, however, it was shown that the carbon was graphitic rather than carbide and was reduced even after short etch periods, indicating that the film bulk probably had low levels of carbon contamination.

The gas-sensing properties of the deposited films were examined. The sensors were not annealed or treated prior to measurements on their response to repeated treatments of 20 ppm ethanol in flowing air (Fig. 4). It can be seen that after an initial 'burn-in' period (up to 200 min, effectively annealing the sensor) that the sensor behaves as a typical n-type sensor on exposure to the reducing gas ethanol at an operating temperature of 400 °C. In gas-sensing experiments conducted at operating temperatures of 300, 500 and 600 °C no response was observed. The sensor reaches its maximum response within 60 s of exposure. The magnitude of response remains stable during the exposure and returns to 50% of the initial resistance value within 60 s of the exposure ending. The response of the sensor to 20 ppm ethanol (defined as R/R_0, the maximum resistance on exposure to test gas/baseline resistance) was $R/R_0 = 1.84$. Some baseline drift was observed over the 30 h analysis period, although the baseline stabilised towards the end of the experiment. The response was found to be consistent and reproducible.

The response of the sensor to exposure to different concentrations of ethanol was examined (Fig. 5). It can be seen

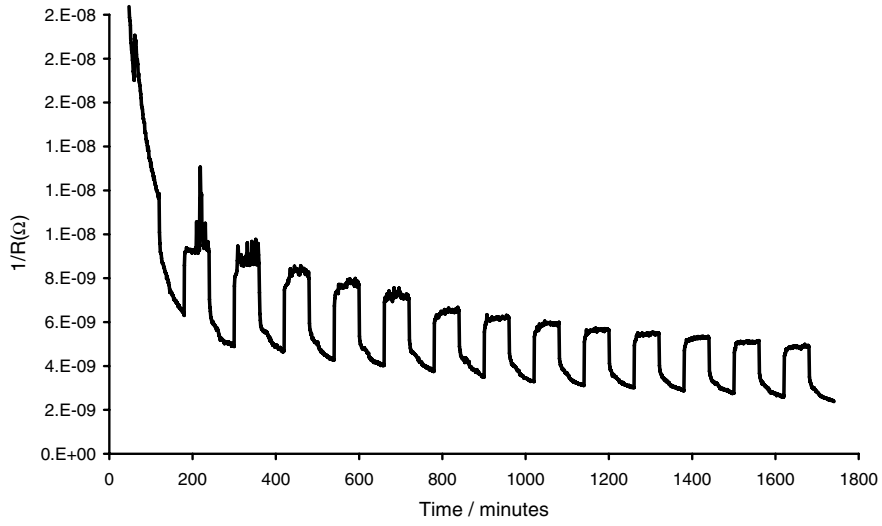

Fig. 4. CVD sensor response upon repeated exposure to 20 ppm ethanol vapour at an operating temperature of 400 °C.

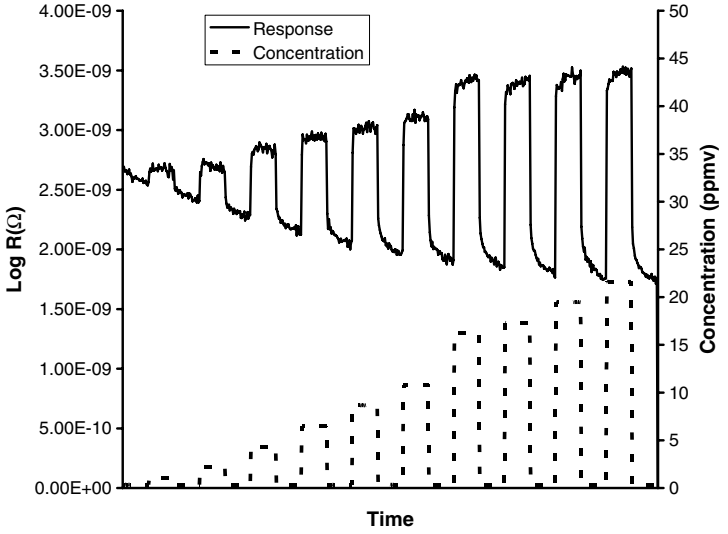

Fig. 5. The change in CVD prepared sensor resistance upon exposure to varying concentrations of ethanol vapour at an operating temperature of 400 °C.

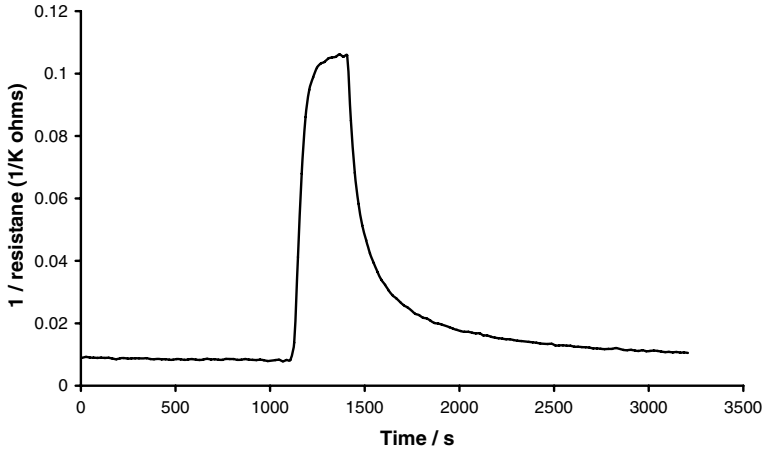

Fig. 6. Commercially produced screen-printed sensor response upon exposure to 100 ppm ethanol vapour at an operating temperature of 400 °C.

that the sensor response increases upon increasing ethanol concentration. Indeed it was found that the sensor response increases linearly over the concentration range examined (1–25 ppm) of ethanol.

In all cases the peak response was square and similar to the response produced by other sensors produced via CVD routes [18]. In all cases the response is fairly "clean" and free from noise. The response shape indicates that some of the resistivity change is a result of contributions from the bulk of the material; dense films, such as those produced by CVD, have relatively fewer absorption sites than porous films, such as those produced by screen-printing; hence they tend to saturate much more quickly in line with the network resistor model [19] (see Fig. 6).

Indeed, direct comparison to a commercially produced screen-printed WO_3 sensor, tested on the same experimental set up, indicates some key differences. The response is an order of magnitude larger, 10.32 versus 1.84 for the CVD produced centre though it should be noted the concentration of test gas is higher. Also the screen-printed sensor does not saturate as quickly and has a more familiar "shark fin" response shape this is because screen-printed sensors have a generally porous and open microstructure that leads to a greater number of potential surface absorption sites. The CVD produced sensor had a faster response time; this is likely to be because the ratio of surface sites to test gas molecules is lower.

All the tests show that production of a gas sensor using the newly developed CVD technique for the deposition of tungsten oxide show great promise. The future challenges will be to tailor film thickness and microstructure to optimise the gas response to a particular scenario and to stabilise the resistance baseline.

4. Conclusions

The gas-sensing characteristics of a particular material are governed by a great number of factors, such as stoichiometry, density/porosity, grain size and thickness. CVD gives direct control over these properties from the deposition conditions allowing a material to be deposited for specific sensing roles. These results demonstrate that a gas sensor made from CVD tungsten oxide is sensitive and gives a linear response to a reducing vapour (ethanol).

Acknowledgement

The EPSRC is thanked for providing the grant for this work. Pilkington Glass is thanked for the supply of substrates, Mr. Kevin Reeves of UCL Archaeology, and Mr. Robert Palgrave of UCL Chemistry are thanked for assistance with SEM and XPS techniques, respectively. I.P.P. thanks the Royal Society/Wolfson Trust for a merit award.

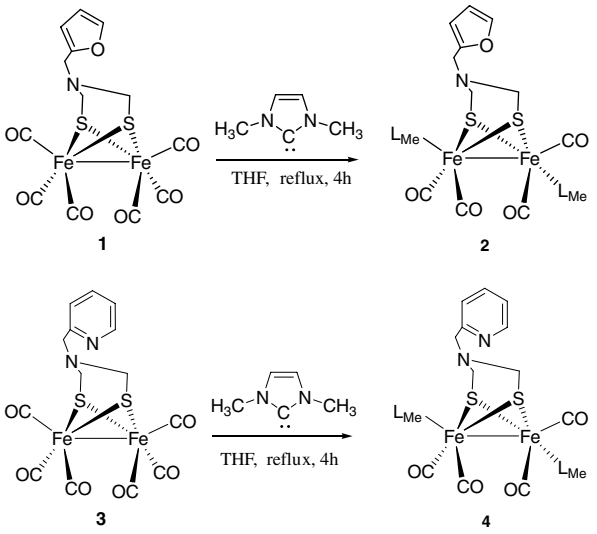
Recently, the use of NHC ligands has emerged as replacements for organophosphanes in organometallic catalysts [9] and PDT (propanedithiolates) hydrogenase models [10,11]. NHCs are superior to a "phosphane mimic", as they often show a greater electron-donating power than phosphine ligand. Unlike other carbenes, the electronic and steric effects of the *N*-substituents make these compounds stable.



On the other hand, numerous possibilities of nitrogen functionalization induce a great structural versatility. We have previously described the furan-containing Fe_2S_2 complex [12]. Owing to its electron-rich property, this complex exhibited electrochemically favorable positive potential under acid ambient. We would like to know the behavior of pyridine analogues, with the electronic property contrary to that of furan. Our interest in pyridine stems also from the idea that the protonation of pyridine *N* atom would be a convenient route to increase the water-solubility of the corresponding metal complexes, with the ultimate objective being the homogeneous catalytic H_2 production. To the best of our knowledge, the use of NHC's as powerful ligands for the design of new diiron systems relevant to the furan- and pyridine-containing azadithiolate active site of the Fe-only hydrogenase has not been reported. We describe here our results concerning the novel NHC disubstituted diiron azadithiolate complexes $[\{(\mu\text{-}SCH_2)_2NCH_2(2\text{-}C_4H_3O)\}Fe_2(CO)_4(L_{Me})_2]$ (**2**) and $[\{(\mu\text{-}SCH_2)_2NCH_2(2\text{-}C_5H_4N)\}Fe_2(CO)_4(L_{Me})_2]$ (**4**) (L_{Me} = 1,3-dimethyl imidazol-2-ylidene).

2. Results and discussion

2.1. Synthesis and spectroscopy

The reaction of the diiron azadithiolate precursor $[\{(\mu\text{-}SCH_2)_2NCH_2(2\text{-}C_4H_3O)\}Fe_2(CO)_6]$ (**1**) [12] with excess of 1,3-dimethylimidazol-2-ylidene [13] (L_{Me}) (8 equiv.) smoothly afforded $[\{(\mu\text{-}SCH_2)_2NCH_2(2\text{-}C_4H_3O)\}Fe_2(CO)_4(L_{Me})_2]$ (**2**) (Scheme 1). The pyridine-containing carbene ligands substituted complex $[\{(\mu\text{-}SCH_2)_2NCH_2(2\text{-}C_5H_4N)\}Fe_2(CO)_4(L_{Me})_2]$ (**4**) was obtained in a similar manner from complex **3**, which was prepared from *C*-pyridin-2-yl-methylamine and $[(\mu\text{-}S_2)Fe_2(CO)_6]$ according to the literature [12]. These two products must be purified scrupulously by neutral Al_2O_3 column chromatography, and were characterized by ^1H NMR, IR spectra and X-ray diffraction method.

The IR spectra of the NHC disubstituted derivatives **2** and **4** displayed, respectively, three strong bands in the carbonyl region (1964, 1919, 1886 cm^{-1} and 1963, 1918, 1886 cm^{-1}) in a frequency ranging lower than those of the trimethylphosphine disubstituted PDT (propanedithiolate) (1979–1898 cm^{-1}) [14], the same ligand substituted PDT (1967–1888 cm^{-1}) [10], and very close to those of the bis-cyanide compound $[Fe_2(\mu\text{-}S(CH_2)_3S)(CN)_2(CO)_4]_2$ (ν(CO) 1965–1884 cm^{-1}) [15,16]. Overall, these IR spectra data confirmed the expected greater electron-donating

Scheme 1. Preparation of complexes **2** and **4**.

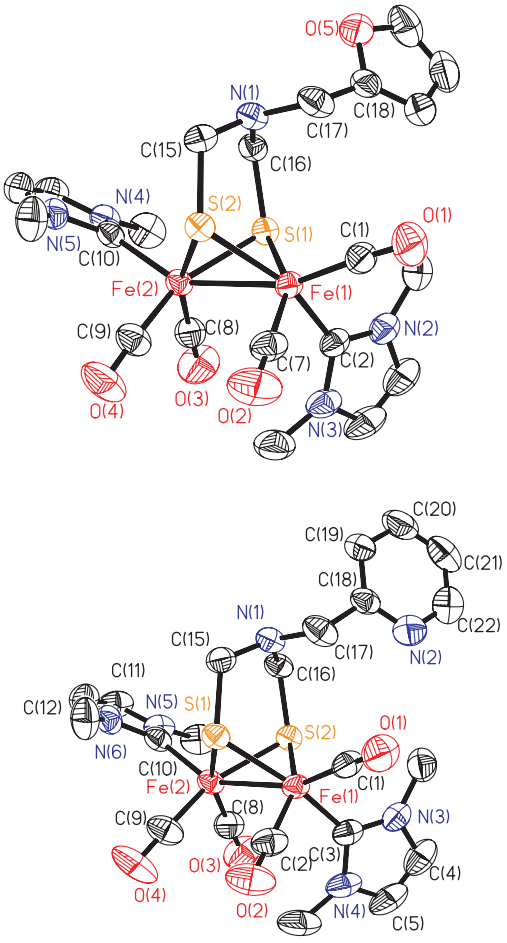


Fig. 1. ORTEP view (ellipsoids at 30% probability level) of **2** (upper) and **4** (lower). Selected bond distances (Å) and angles (°): complex **2**: Fe1–Fe2, 2.5314(6), Fe–S, 2.2828(6)–2.3037(8), Fe–C, 1.747(3)–1.985(3), Fe1–S1–Fe2, 67.28(2), Fe1–S2–C15, 115.85(9), Fe2–S2–C15, 109.16(10), Fe1–S2–Fe2, 66.88(2), C15–N1–C16, 113.4(2), C15–N1–C17, 114.7(2), C16–N1–C17, 118.6(2); complex **4**: Fe1–Fe2, 2.5341(8), Fe–S, 2.2822 (10)–2.2964(9), Fe–C, 1.751(4)–1.992(3), Fe2–S2–Fe1, 67.13(3), C15–N1–C16, 112.7(2), C15–N1–C17, 115.2(2), C16–N1–C17, 117.4(2).

ability of the NHC ligand (L_{Me}) was superior to that of the trimethylphosphine ligand and almost the same to the cyanide ligand.

2.2. Molecular structure

Fig. 1 shows the crystal structures of **2** and **4** with selected bond lengths and angles. The Fe_2S_2 skeletons of **2** and **4** are the well known butterfly structures found in related diiron complexes [17,18]. Each iron center displays approximately the square-pyramidal coordination geometry. The Fe–Fe distances in **2** (2.5314(6) Å) and **4** (2.5341(8) Å) are very close to those of other diiron dithiolate analogues. It is worth noting that the Fe–Fe distances are notably lengthened in the disubstituted species than those of complex **1** and **3** by ca. 0.02 Å [12]. One of the NHC group in **2** and **4** lies in the apical position, and the other in the basal positions (*cis* to the Fe–Fe axis) as expected, due to the spatial effect. The Fe–C (carbene L_{Me}) distances in **2** and **4** (1.981(3), 1.985(3), 1.979(3) and 1.992(3) Å) are longer than others. The sum of C–N–C angles around the *N*-bridged atom is respectively 346.7° and 345.3°, 10° larger than **1** (334.5°) and **3** (331.29°). The N(1)–C(17)–C(18) locates in the same side with the basal NHC, since such arrangement ensures that the furan and the basal NHC adopt the sterically less demanding position.

2.3. Eletrochemistry and protonation

Cyclic voltammetry (CV) experiments in MeCN–Bu_4NPF_6 indicated a totally irreversible one-electron reduction of **2** ($E_{red} = -2.53$ V versus Fc/Fc^+) (Fig. 2). In comparison to the parent hexacarbonyl complex **1** ($E_{red} = -1.55$ V versus Fc/Fc^+), the replacement of the two CO for two 1,3-dimethylimidazol-2-ylidenes resulted in a negative shift of the reduction potential by 980 mV. Similarly, the irreversible one-electron reduction of **4** ($E_{red} = -2.49$ V versus Fc/Fc^+) (Fig. 2) had the 950 mV shift comparison to that of **3**. The shifts were significantly larger by contrast with the reductive potentials of the disubstituted PMe_3 (410 mV) [19] and disubstituted PTA (1,3,5-triaza-7-phosphaadamantane) of PDT (440 mV) [16c], and even larger than that of the same disubstituted *N*-heterocyclic carbene ligands of PDT (810 mV) [9]. Attributing to the strong electron-donating ligand L_{Me},

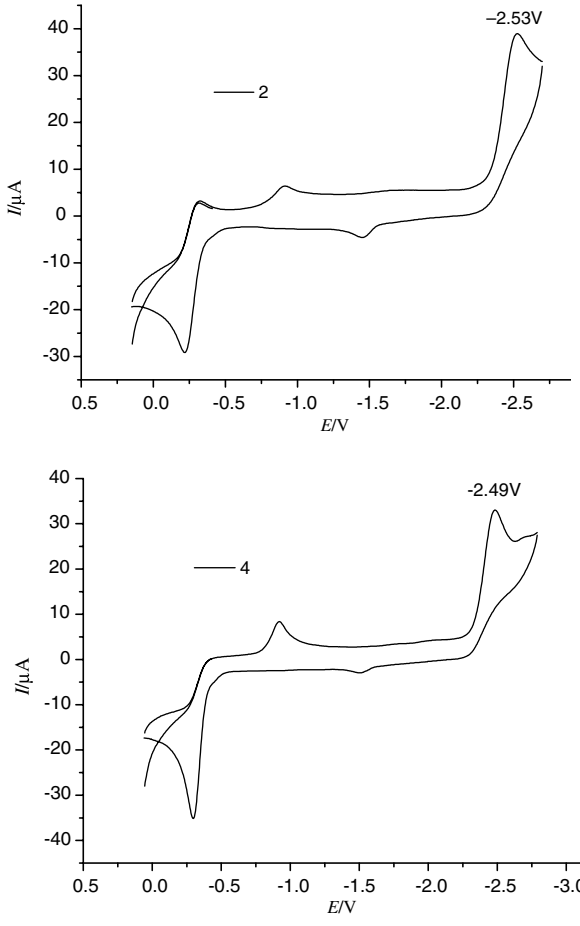

Fig. 2. Cyclic voltammograms of **2** and **4**: 1.0 mmol in 0.05 M *n*-Bu_4NPF_6/CH_3CN at a scan rate of 100 mV s^{-1}. All potentials given are vs. Fc/Fc^+.

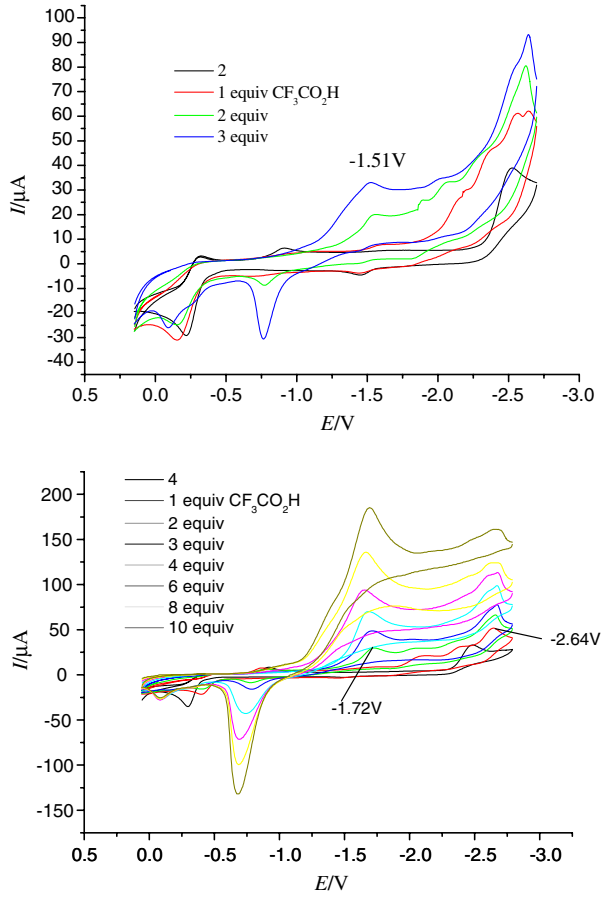

Fig. 3. Cyclic voltammograms of **2** and **4** in the presence of CF_3CO_2H in different concentrations, and sample concentration is 1.0 mmol in 0.05 M *n*-Bu_4NPF_6/CH_3CN, scan rate = 100 mV s^{-1}, working electrode: glassy carbon. All potentials are given vs. Fc/Fc^+.

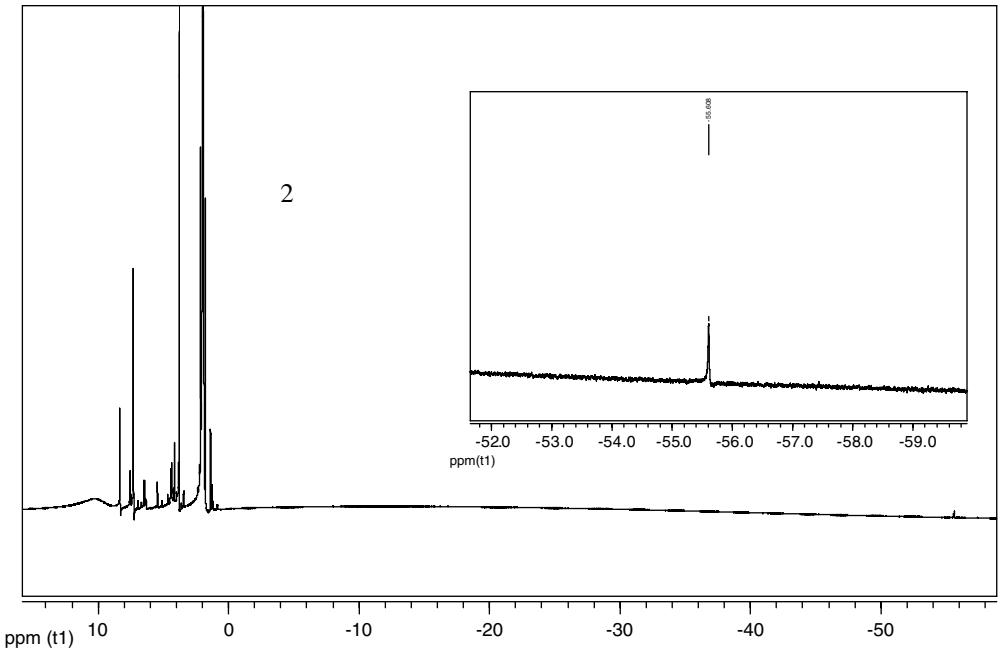

Fig. 4. The ^{1}H NMR of **2** in the presence of CF_3CO_2H.

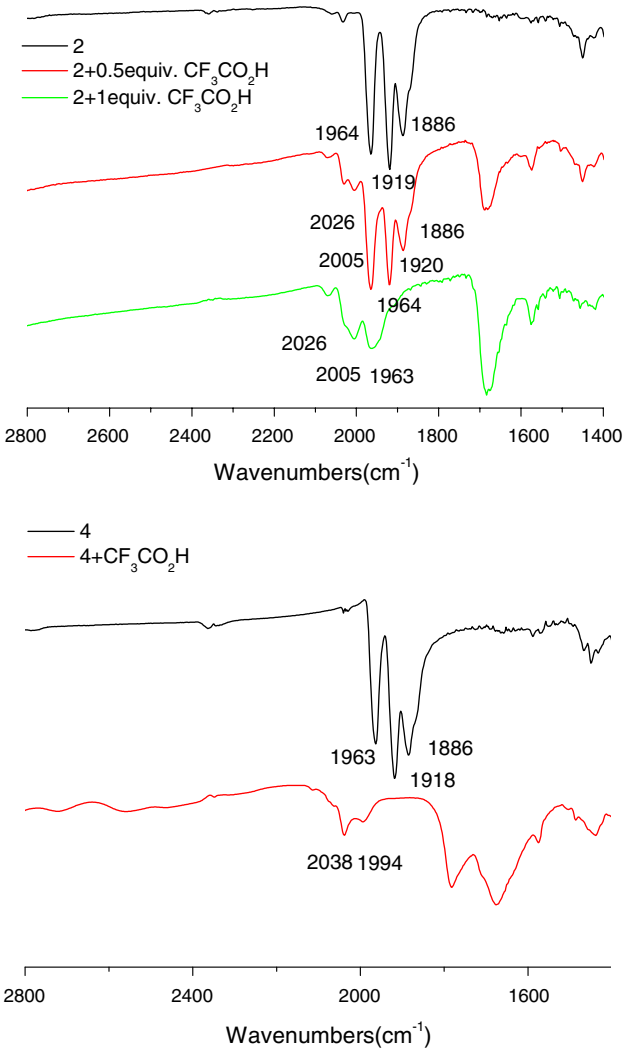

Fig. 5. The IR spectra of **2** and **4** in the presence of CF_3CO_2H.

the more negative potential was expected thanks to the changed electron density of diiron atoms. Moreover, it seemed that the results were also related to furan and pyridine heterocycles. Therefore, IR spectra data and electrochemical data clearly indicated that the Fe–Fe bonds in **2** and **4** were rendered sufficiently rich electron density to catch proton and produce hydrogen further.

The electrochemical performance was further investigated in the presence of CF_3CO_2H. Upon addition of one equivalent acid to **2** and **4**, the new reduction peaks were observed at $E_{red} = -1.51$ V and $E_{red} = -1.72$ V in the CV graphs (Fig. 3), with 1.02 V and 0.77 V less negative by comparison to those before the ligands exchanged. The new electrochemical events were assigned to the reduction of $\mathbf{2H}^+$ and $\mathbf{4H}^+$. The current intensity of the new peak enhanced gradually with the increment of the acid, suggesting the electrochemically catalytic proton reduction. The new peaks indicated the formation of Fe–H–Fe bond, which could be detected for the negative H signal at −55 ppm and −27 ppm respectively in ^{1}H NMR (Fig. 4, taking **2** as an example), and the hydride signal showed the rich electron density of diiron nuclear. In addition, the detected shifts of IR spectra data for **2** (from 1964, 1919, 1886 to 2026, 2005, 1963 cm^{-1}) and **4** (from 1963, 1918, 1886 to 2038, 1994 cm^{-1}) also indicated the formation of Fe–H–Fe bond according to the shift wavenumbers after protonation between Fe–Fe reported (Fig. 5).

3. Experimental

3.1. Reagents and instruments

The reactions and operations related to organometallic complexes were carried out under a dry, oxygen-free

nitrogen atmosphere. THF was dried and distilled by standard methods. Commercially available reagents, *N*-methylimidazole and CH_3I were used without further purification. The reagent potassium *tert*-butoxide was purchased from Aldrich. [{(μ-SCH_2)$_2$$NCH_2$(2-$C_4H_3O$)}$Fe_2$-$(CO)_6$] was prepared according to the described method [12]. IR spectra were recorded on a JASCO FT/IR 430 spectrophotometer. ^{1}H NMR spectra were collected with a Varian INOVA 400 NMR spectrometer. Elemental analyses were performed on a CARLO ERBA MOD-1106 elemental analyzer. Diffraction measurements were made on a Siemens SMART CCD diffractometer using graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å).

3.2. Synthesis of [{(μ-SCH_2)$_2$$NCH_2$(2-$C_4H_3O$)}-$Fe_2(CO)_4(L_{Me})_2$] (**2**) ($L_{Me}$ = 1,3-dimethyl imidazol-2-ylidene)

A Schlenk flask was charged with 1-methylimidazole (0.58 mL, 7.25 mmol). The solution was cooled and maintained at 0 °C while CH_3I (0.45 mL, 7.25 mmol) was added dropwise. After stirring for 20 min at room temperature, the imidazolium iodide salt was yielded. Potassium *tert*-butoxide (1.2 g, 10.6 mmol) in THF (40 mL) was added to give a light yellow solution and turned to pink 3 h later. The reaction solution was filtered through Celite and eluted with THF. After the combined filtrates were concentrated to ca. 40 mL and transferred into Schlenk flask, **1** (0.47 g, 1 mmol) was added. After refluxing for 5 h, it gave a dark red solution. After evaporation of the solvent, the crude product was purified by column chromatography with neutral Al_2O_3 by using hexane/CH_2Cl_2 (3:1) as eluent to give complex **2** as a red solid (0.37 g, 80%). Recrystallization in the mixture solvent of hexane and CH_2Cl_2 (1:1) afforded crystals suitable for X-ray crystallography study. ^{1}H NMR ($CDCl_3$) δ (ppm): 7.25 (s, 1H), 6.21 (s, 1H), 5.97 (s, 1H), 6.96 (s, 4H), 4.01 (s, 12H), 3.5 (s, 2H), 3.2 (s, 4H); ESI-MS: *m*/*z*: 604.4 $[M + H]^+$, IR (cm^{-1}): *ν*(CO) 1964, 1919, 1886 cm^{-1}; *Anal.* Calc. for $C_{21}H_{25}Fe_2N_5O_5S_2$: C, 41.81; H, 4.18; N, 11.61. Found: C, 41.67; H, 4.20; N, 11.72%.

3.3. Synthesis of [{(μ-SCH_2)$_2$$NCH_2$(2-$C_5H_4N$)}-$Fe_2(CO)_6$] (**3**)

The hydroxylation product (1.68 g, 10 mmol), prepared from 2-pyridinemethylamine (1.08 g, 10 mmol) and HCHO/H_2O (2 mL, 20 mmol) in THF (20 mL), was added to a THF solution (20 mL) of [(μ-Li_2S_2)$Fe_2(CO)_6$], freshly derived from [(μ-S)$_2$$Fe_2(CO)_6$] (0.344 g, 1.0 mmol), and $LiEt_3BH$ (1 M in THF, 1.0 mL, 1.0 mmol) at −78 °C. The mixture was stirred for 1 h at −78 °C, then 2 h at room temperature. During the course of the reaction, the color of the solution turned dark red. After evaporation of the solvent, the crude product was purified by column chromatography with silica gel by using CH_2Cl_2 as eluent to give complex **3** as a red solid (0.22 g, 45%). Recrystallization in hexane afforded crystals of **3** suitable for X-ray crystallography study. ^{1}H NMR ($CDCl_3$) δ 8.60 (s, 1H), 7.64 (s, 1H), 7.25 (s, 2H), 3.95 (s, 2H), 3.52 (s, 4H); ^{13}C NMR ($CDCl_3$) δ 207.9, 160.0, 156.7, 149.4, 137.0, 123.0, 77.5, 77.2, 76.9, 63.5, 52.8; ESI-MS: *m*/*z*: 478.9 $[M + H]^+$; IR (cm^{-1}): *ν*(CO) 2070, 2014, 1993; *Anal.* Calc. for $C_{14}H_{10}N_2O_6S_2Fe_2$: C, 35.17; H, 2.11; N, 5.86. Found: C, 35.39; H, 2.13; N, 5.91%.

3.4. Synthesis of [{(μ-SCH_2)$_2$$NCH_2$(2-$C_5H_4N$)}-$Fe_2(CO)_4(L_{Me})_2$] (**4**)

This complex was prepared from **3** (0.38 g, 8 mmol) in a similar manner as complex **2** to give complex **4** as a red solid (0.40 g, 82%). Recrystallization in hexane and CH_2Cl_2 afforded crystals suitable for X-ray crystallography study. ^{1}H NMR ($CDCl_3$) δ (ppm): 8.43 (s, 1H), 7.54 (s, 1H), 7.08 (s, 1H), 6.68 (s, 1H), 6.96 (s, 4H), 4.06 (s, 12H), 3.60 (s, 2H), 3.09 (s, 4H); ESI-MS: *m*/*z*: 615.4 $[M + H]^+$, IR (cm^{-1}): *ν*(CO) 1963, 1918, 1886 cm^{-1}; *Anal.* Calc. for $C_{22}H_{26}Fe_2N_6O_4S_2$: C, 43.01; H, 4.27; N, 13.68. Found: C, 42.67; H, 4.40; N, 13.72%.

4. Conclusion

In summary, the combined use of furan and NHC has led to the preparation of complex **2**, which shows a very low reduction potential at −2.53 V. Pyridine analogue **4** is also obtained in a similar manner with a reduction potential at −2.49 V. Our preliminary studies have shown that this two model complexes exhibited some desirable properties with the strong electron-donating capability. The ^{1}H NMR, IR spectra and electrochemical data clearly show that the *N*-heterocyclic carbene ligands possess electron-donating properties, even superior to those of phosphane ligands and very close to the cyanide ligands. Thanks to the versatility of the *N*-heterocyclic carbene ligands, these carbene disubstituted furan- and pyridine-containing Fe-only azathiolate hydrogense models represent a new class of hydrogenase active site mimics with desirable catalytic reduction properties.

5. Supplementary material

CCDC 276212, 272295 and 604776 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

constant [15] of the corresponding phosphorus(V) selenide, [16,17] prepared by the oxidation of the phosphine with elemental selenium, where phosphorus(V) selenides incorporating electron-withdrawing groups exhibit larger coupling constants that those for phosphorus(V) selenides incorporating electron-donating groups. Here, we report data for a comprehensive series of phosphorus(V) selenides, which offer a clearer insight into the effect of perfluoroalkyl groups on the electronic properties of phosphines used in fluorous catalysis.

2. Experimental

Proton, ^{19}F and ^{31}P NMR spectroscopies were carried out on a Bruker ARX250 spectrometer at 250.13, 235.34 and 101.26 MHz or a Bruker DPX300 spectrometer at 300.14, 282.41 and 121.50 MHz, respectively, and were referenced to external $SiMe_4$ (^1H), external $CFCl_3$ (^{19}F) and to external H_3PO_4 (^{31}P) using the high frequency positive convention. Abbreviations for NMR spectral multiplicities are as follows: s = singlet, d = doublet, t = triplet, q = quartet, m = multiplet. Elemental analyses were performed by the Elemental Analysis Service at the University of North London. Mass spectra were recorded on a Kratos Concept 1H mass spectrometer.

$P(4\text{-}C_6H_4R)_3$ (R = H, F, Cl, Me, OMe and NMe_2) and BINAP were commercial samples and used as received, whilst *cis*-$[PtCl_2(MeCN)_2]$ was prepared by the literature route [18].

2.1. General procedure for the preparation of phosphines

n-BuLi (2.0 mmol, 1.6 M solution in hexane) was added dropwise over 1 h to a solution of the required bromobenzene (2.0 mmol) in diethyl ether at −78 °C. This solution was then stirred at −78 °C for 3 h. The requisite chlorophosphine (2.0 mmol for diphenylchlorophosphines, 1.0 mmol for dichlorophenylphosphines or 0.66 mmol for PCl_3) was then added dropwise in a solution of diethyl ether over 1 h and the solution allowed to warm to room temperature overnight. The solution was then washed well with water, the organic layer separated, dried and the solvent removed in vacuo. The resulting phosphine was purified by column chromatography using petroleum ether as the eluent. Uniquely, **1f** was prepared by a modification of the literature route for **3f**, [6b] by the reaction of the chlorosilane with the lithiate formed from the reaction of $Ph_2P(C_6H_4\text{-}4\text{-}Br)$ with BuLi at low temperature in diethylether. Many of the phosphines prepared in this work have been described previously (**1b**, [7]; **2b**, [7]; **3a**, [15]; **3b**, [7]; **3d**, [8b]; **3e**, [11]; **3f**, [6b]; **3g**, [9a]; **3h**, [9b]; **3j**, [19]; **3k**, [20]; **3l**, [21]; **4b**, [14]; **5b**, [14]; **6b**, [22]; **7a**, [23]; **7b**, [24]; **7c**, [24]; **8a**, [24]; **8b**, [24]; **9a**, [22,23]; **10a**, [24]; **10b**, [24]; **11b**, [25]; **11d**, [25]), and here we just report data for new ligands and additional data for established species where appropriate.

2.1.1. 4-(Trifluoromethylphenyl)diphenylphosphine (*1a*)

M.p. = 53–54 °C (Lit. 51–53 °C) [26]. *m/z* (FAB) 330 (M^+). ^1H NMR ($CDCl_3$) 7.50 (2H, d, $^3J_{HH}$ 10.0, ArH), 7.30 (2H, d, $^3J_{HH}$ 10.0, ArH), 7.28 (10H, m, ArH). $^{19}F\{^1H\}$ NMR ($CDCl_3$) −63.20 (s). $^{31}P\{^1H\}$ NMR ($CDCl_3$) −5.4 (s).

2.1.2. 4-(Heptadecafluoro-n-octylphenyl)diphenylphosphine (*1c*)

M.p. = 89–91 °C. *Anal.* Calc. for $C_{26}H_{14}F_{17}P$: C, 45.88; H, 2.06. −122.90 (6F, m, CF_2) −126.29 (6F, m, CF_2). $^{31}P\{^1H\}$ NMR ($CDCl_3$) −6.9 (s).

2.2. General procedure for the preparation of phosphorus(V) selenides

The phosphine (0.20 g) was dissolved in chloroform (10 ml) and selenium powder added (0.30 g, 3.8 mmol). The mixture was heated to 70 °C overnight. After cooling, the excess selenium was removed by filtration through a cotton wool plug and the solvent removed in vacuo to give the phosphorus(V) selenide in a 64–89% yield. A few of the phosphorus(V) selenides used in this study have been reported previously; tris(4-*N*,*N*-dimethylaminophenyl) phosphine selenide, [28] tris(4-methoxyphenyl)phosphine selenide, tris(4-methylphenyl)phosphine selenide, trisphenylphosphine selenide, tris(4-fluorophenyl)phosphine selenide, tris(4-trifluoromethylphenyl)phosphine selenide, tris (3-trifluoromethylphenyl)phosphine selenide and tris(3,5-trifluoromethylphenyl)phosphine selenide, [15] and tris(4-chlorophenyl)phosphine [29]. Table 1 summarises all the analytical and NMR spectroscopic data for the new phosphorus(V) selenides prepared in this work.

2.3. General procedure for the preparation of $[PtCl_2L_2]$ complexes

The phosphine (0.1 mmol) and $[PtCl_2(CH_3CN)_2]$ (0.05 mmol) were dissolved in dichloromethane (10 ml) and heated to reflux for 2 h. After cooling, the solvent was removed and the resulting solid washed well with petroleum ether to give a pale yellow solid in 84–91% yield.

2.3.1. cis- and trans-$[PtCl_2\{Ph_2P(C_6H_4\text{-}4\text{-}CF_3)\}_2]$

Anal. Calc. for $C_{38}H_{28}Cl_2F_6P_2Pt$: C, 49.30; H, 3.03. 3. Results and discussion

Measuring $^1J_{PtP}$ for *cis*-[$PtCl_2L_2$] (L = triarylphosphine) is a very useful tool for the characterisation of platinum complexes, with the magnitude of the coupling constant being a predictive function of the triarylphosphine ligand, and Pringle et al. have shown that these values correlate very well with the Hammett σ_p parameter of the substituent

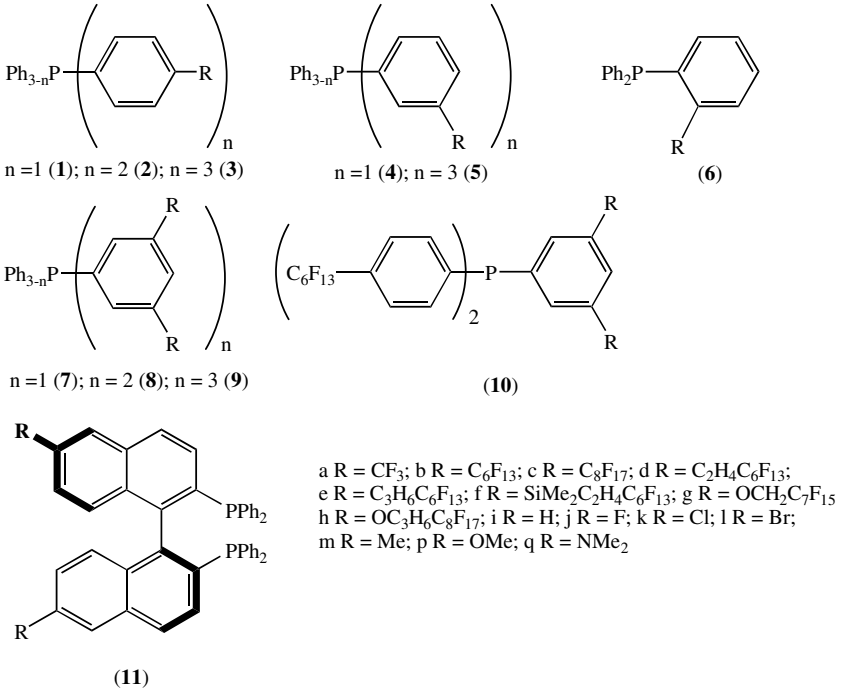

Fig. 1. Phosphines used in this study.

on the aryl ring [30]. We have previously used this technique to probe the effect of perfluoroalkylation on the donor properties of triarylphosphines [13]. However, systematic comparison of the electronic impact of the perfluoroalkyl-substituent is not always possible since, as a consequence of steric constraints, some *cis*-$[PtCl_2L_2]$ complexes are not available. Furthermore, even where the complexes can be formed, it is difficult to be certain that the effect being probed is entirely electronic. For example, the $^1J_{PtP}$ values for the *cis*-$[PtCl_2L_2]$ complexes derived from $Ph_2P(C_6H_4\text{-}4\text{-}C_6F_{13})$ and $Ph_2P(C_6H_4\text{-}3\text{-}C_6F_{13})$ are 3653 Hz [13] and 3635 Hz [14], respectively, although it

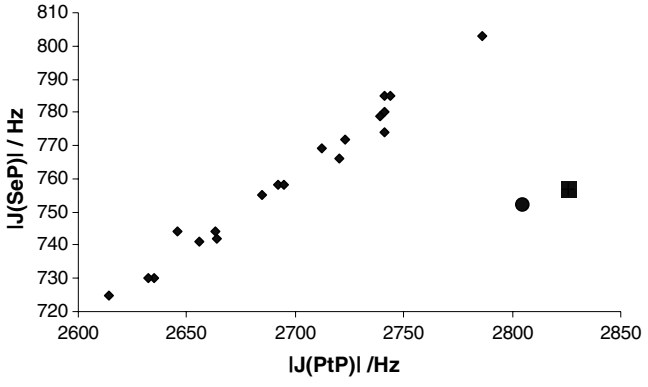
would be anticipated that placing the perfluoroalkyl group in the *para*- or *meta*-position would have little effect on the electronic properties of the phosphine and, indeed, Howell et al. report that the electron-withdrawing effect of the purely inductive CF_3 is felt almost equally at the *ortho*-, *meta*- and *para*-positions [16].

In order to fully understand the electronic influence of perfluoroalkyl substituents on the donor properties of triarylphosphines, we have prepared a comprehensive series of phosphorus(V) selenides from a range of triaryl phosphines (Fig. 1). NMR spectroscopic data for these compounds, alongside those for the *cis*-$[PtCl_2L_2]$ complexes and selected values from the literature, are presented in Table 2. The NMR data, in particular the $|^1J_{SeP}|$ coupling constants, [15] are solvent dependent and this must be borne in mind in any comparison. Unfortunately, not all the phosphorus(V) selenides are soluble in either $CDCl_3$ or diethyl ether so, in order to offer a comprehensive analysis, data for many of the compounds are reported for both solvents; the correlations discussed below apply equally well to both sets of data.

These data reveal a number of significant facts. Firstly, as reported previously for the CF_3-derivatised aryl phosphines, [16] the $|^1J_{SeP}|$ values for the C_6F_{13} derivatised phosphorus(V) selenides are cumulative. So, ΔJ_{PSe} (relative to $Se=PPh_3$) for the selenide derived from $P(C_6H_4\text{-}4\text{-}C_6F_{13})_3$, **3b**, is three times that for the selenide derived from $Ph_2P(C_6H_4\text{-}4\text{-}C_6F_{13})$, **1b**. Similarly, that from **8b** gives a value four times greater than that from **1b**. Secondly, despite various anecdotal, spectroscopic and catalytic evidence to the contrary, the lengths of the perfluoroalkyl substituents have no impact upon the electronic environment at phosphorus since ΔJ_{SeP} for related series (phosphines = **1a**, **1b** and **1c**; **3a**, **3b** and **3c**; **4a**, **4b** and **4c**; **5a**, **5b** and **5c**; **6a** and **6b**; **7a**, **7b** and **7c**) are virtually identical. Finally, since the values from the *meta*- and *para*-substituted phosphines (**1a**, **1b** and **1c**; **4a**, **4b** and **4c**) are very similar and those from **10b** and **8b** give identical results, the electron-withdrawing effect of the perfluoroalkyl groups on the phosphorus centre is independent of their position in these phosphines. As indicated above, this effect is not apparent from the $^1J_{PtP}$ values for pairs of *cis*-$[PtCl_2L_2]$ complexes, particularly since all attempts at forming *cis*-$[PtCl_2L_2]$ for phosphine **8b** failed, presumably due to steric congestion. However, in direct contrast to the observations of Howell et al., [16] this cannot be extended to the *ortho*-substituted phosphines, **6a** and **6b**, where $|^1J_{SeP}|$ for their selenides are substantially different to those for the selenides of **1a**, **4a**, **1b** and **4b**. This type of effect has, for the *ortho*-methylated triarylphosphine selenides, been attributed to the steric impact of the substituents, [17] and this could equally apply to our fluoroalkylated phosphine selenides. An alternative explanation arises from through space interactions between the phosphorus and fluorine atoms [34]. This is clearly evident in the free phosphines ($R=C_6F_{13}$, $^4J_{PF}=99$ Hz; $R=CF_3$, $^4J_{PF}=53$ Hz) and, although the magnitude of the interaction is reduced in the phosphine selenides ($R=C_6F_{13}$, $^4J_{PF}=10$ Hz; $R=CF_3$, $^4J_{PF}=3$ Hz), its presence is likely to seriously alter the electronic properties of the phosphorus atoms and hence the P–Se interaction.



As expected, since both parameters are affected by the electronic environment of the phosphine, there is a linear relationship between $|^1J_{SeP}|$ and $|^1J_{PtP}|$ for both the *cis*-, Fig. 2, and *trans*-$[PtCl_2L_2]$ complexes, Fig. 3. The only data point which does not show the linear correlation in Fig. 2 is that for the *cis*-$[PtCl_2(\mathbf{9a})_2]$ quoted by Alt et al. [22]. However, although ΔJ_{SeP} for the selenide of **9a** is entirely consistent with the presence of six CF_3 groups, we were unable to prepare the *cis*-platinum metal complex to confirm the magnitude of this $^1J_{PtP}$ coupling constant. In contrast, in Fig. 3, the data for *trans*-$[PtCl_2(\mathbf{9a})_2]$ is consistent with the linear correlation. In Fig. 3, the data points associated with phosphines **6a** and **6b** do not follow the linear correlation, which is accounted for by the additional steric and electronic interactions in both their selenides and platinum metal complexes [34].

Many attempts have been made to minimise the electronic effect of fluoroalkyl groups on the donor properties of the

phosphines, which has been achieved by the introduction of spacer groups between the perfluoroalkyl group and the aromatic ring. By examining the $^1J_{SeP}$ data it is possible to determine the efficiency of these groups at insulating the phosphorus centre from the perfluoroalkyl groups and illustrative data are collected in Table 3. It can be seen that, using these different perfluoroalkyl groups, it is possible to generate a range of different electronic environments at the phosphorus atoms. For these triarylphosphines, additional CH_2 spacer units can provide insulation of the phosphorus atom from the perfluoroalkyl groups, but at least two are required for complete insulation. Finally, by using spacer groups incorporating an oxygen atom, it is possible to generate phosphines for use in a perfluorocarbon solvent that are actually electron rich, as illustrated by the data for the $OCH_2CH_2CH_2$ (**3h**) spacer group substituted phosphine that gives the same $^1J_{SeP}$ as tris(4-tolyl)phosphine selenide (**3m**).

4. Conclusions

The $^1J_{SeP}$ coupling constants of a series of trisarylphosphines derivatised with a variety of different perfluoroalkyl groups have been measured, which allow the direct comparison between phosphine ligands that is not possible via other spectroscopic probes. The values have been used to compare a range of different fluorinated groups and to determine the efficiency of a variety of spacer groups at insulating the phosphorus centre from the electron-withdrawing effect of the perfluoroalkyl group. This data illustrates that it is possible to generate phosphines for use in fluorous catalysis that are either electron rich, electron neutral or electron poor with respect to triphenylphosphine.

($X = Cl^-$, Br^- and CO_3) [11], $[V_{16}O_{38}(X)]$ ($X = Cl^-$, H_2O) [12,8d], $[V_{22}O_{54}(X)]$ $X = (ClO_4^-$, SCN^- and CH_3COO^-) [13] and $[V_{18}O_{42}(X)]$ ($X = H_2O$, Cl^-, Br^-, I^-, SO_4 and VO_4) [14] clusters. The central guest species in the shell exert templating effects on the electronic and framework structures of the host metal-oxide shells [15]. (2) The important family of magnetic polyoxometallates involves the mixed valence $V^{IV/V}$ oxometallates [16]. Magnetic studies performed on the mixed valence vanadium (IV/V) clusters arising from the full or partial deloclization of single 3d electrons of the V^{IV} ions over both V^{IV} and V^{V} have shown antiferromagnetic coupling and a few ferromagnetic coupling [17,14a]. (3) The mixed-valence vanadium oxide clusters have luminescence properties. This class of compounds could be active in photo-oxidation reactions and a potential photocatalyst, which is worth further investigating [9].

Owing to the synergistic interaction between the metal–organic and inorganic components, this class of compounds reveals some remarkable properties. We are currently exploring to design and develop organic–inorganic hybrid materials by the amalgamation of cage-like mixed-valence vanadium clusters with metal–organic complexes. The mixed-valence vanadium clusters that fuse paramagnetic transition metal complexes might be of interest in molecular magnetism [18,8d]. During this ongoing effort, different paramagnetic metal ions have been introduced into the reaction system, such as manganese (II), cobalt (II) and nickel (II). As a result, magnetic materials are obtained through combining paramagnetic metal ions and $[V_7^{IV}V_9^{V}O_{38}X]^{4-}$ clusters. In addition, the significant role of organic components in controlling the inorganic oxide microstructure was investigated by using different organic ligands. In this paper, we describe the synthesis and characterization of hybrid materials **1**–**5**. The magnetic properties of compounds **3**, **4** and **5** are reported as well.

2. Experimental

2.1. General remarks

All reagents were readily available from commercial sources and were used as received without further purification. The IR spectra in KBr pellets were recorded in the range 400–4000 cm^{-1} with an Alpha Centaurt FT/IR Spectrophotometer. Elemental Analyses (C, H and N) were performed with a Perkin–Elmer 2400 CHN Elemental Analyzer. M and V were determined with a PLASMA-SPEC (I) ICP atomic emission spectrometer. X-ray photoelectron spectrometry (XPS) spectra were measured on an ESCALAB spectrometer. Thermogravimetric analyses were carried out using a Pyris Diamond TG/DTA instrument, with a heating rate of 10 °C/min, under a nitrogen atmosphere. Magnetic susceptibility and magnetization data were collected over the temperature range 1.8–300 K in an applied field up to 50 kOe on a Quantum Design MPMS-5 SQUID magnetometer.

2.2. Preparation

2.2.1. Synthesis of $[Ni(4,4'\text{-}bpy)_2]_2[V_7^{IV}V_9^{V}O_{38}F]\cdot(4,4'\text{-}bpy)_{1.5}(H_2O)_3$ (**1**)

A mixture of $NaVO_3$ (122 mg, 1 mmol), Na_2TeO_3 (222 mg, 1 mmol), $Ni(CH_3COO)_2$ (177 mg, 1 mmol), 4,4′-bipyridine (50 mg, 0.38 mmol), HF (40%, 0.2 mL), CH_3CH_2OH (2 mL) and H_2O (5 mL) was stirred for ca. 1 h in air until it was homogeneous, and adjusted by CH_3COOH to pH 4.6, and then transferred and sealed in a 16 mL Teflon-lined stainless steel container. After heated to 170 °C under autogenously pressure for 4d, the bomb was cooled down to room temperature. Black octahedron block crystals of **1** along with an amorphous grey impurity were filtered from the colorless mother liquor, washed by distilled water and air-dried at room temperature. The crystals were mechanically separated from the powdery grey impurity to give a yield of 61% (based on V), and were stable in air and insoluble in water and common organic solvents. IR (KBr, cm^{-1}): $\tilde{\nu} = 3446$ (m), 1601 (m), 1559 (m), 1530 (m), 1487 (m), 1408 (m), 1066 (m), 983 (m), 813 (m), 733 (m), 670 (m), 657 (m), 631 (m), 507 (m), 459 (m), 418 (m), 403 (m). Elemental *Anal.* Calc. for $Ni_2C_{55}H_{50}N_{11}O_{41}V_{16}F$: C, 26.72; H, 2.04; N, 6.23; Ni, 4.75; V, 32.97. Found: C, 27.01; H, 2.27; N, 6.54; Ni, 4.27; V, 32.79%.

2.2.2. Synthesis of $[Ni(4,4'\text{-}bpy)_2]_2[V_7^{IV}V_9^{V}O_{38}Br]\cdot(4,4'\text{-}bpy)_{1.5}(H_2O)_{3.5}$ (**2**)

The reaction was carried out in the same way as for **1** except that HBr (0.25 mL) was used instead of HCl. Yield: 62% based on V. IR (KBr, cm^{-1}): $\tilde{\nu} = 3442$ (m), 1600 (m), 1548 (m), 1516 (m), 1479 (m), 1412 (m), 990 (m), 946 (m), 731 (m), 669 (m), 656 (m), 631 (m), 472 (w), 417 (m). Elemental *Anal.* Calc. for $Ni_2C_{55}H_{51}N_{11}O_{41.5}V_{16}Br$: C, 25.98; H, 2.02; N, 6.06; Ni, 4.62; V, 32.06. Found: C, 26.21; H, 2.19; N, 6.35; Ni, 4.34; V, 29.87%.

2.2.3. Synthesis of $[Co(4,4'\text{-}bpy)_2]_2[V_7^{IV}V_9^{V}O_{38}Cl]\cdot(4,4'\text{-}bpy)_{1.5}(H_2O)_2$ (**3**)

The preparation of **3** was similar to that of **1** except that $Co(CH_3COO)_2$ (177 mg, 1 mmol) was used in place of $Ni(CH_3COO)_2$. Yield: 59% based on V; IR (KBr, cm^{-1}): $\tilde{\nu} = 3680$ (w), 3446 (w), 2360 (m), 1743 (m), 1692 (m), 1646 (m), 1546 m, 1531 (m), 1515 (m), 1482 (m), 1411 (m), 985 (m), 816 (w), 677 (m), 575 (w), 455 (w). Elemental *Anal.* Calc. for $Co_2C_{55}H_{48}N_{11}O_{40}V_{16}Cl$: C, 26.73; H, 1.96; N, 6.23; Co, 4.77; V, 32.98. Found: C, 27.03; H, 2.31; N, 6.44; Co, 4.59; V, 32.65%.

2.2.4. Synthesis of $[Mn(4,4'\text{-}bpy)_2]_2[V_7^{IV}V_9^{V}O_{38}Cl]\cdot(4,4'\text{-}bpy)(H_2O)_{2.5}$ (**4**)

The reaction was carried out in the same way as for **1** except that $MnSO_4$ (151 mg, 1 mmol) was used instead of $Ni(CH_3COO)_2$. Yield: 65% based on V; IR (KBr, cm^{-1}): $\tilde{\nu} = 3740$ (m), 3681 (m), 3416 (w), 2358 (m), 1743 (m), 1688 (m), 1609 (m), 1525 (m), 1514 (m), 1462 (m), 1406

2.2.5. Synthesis of $[Ni(2,2'\text{-bpy})_3]_3[V_8^{IV}V_7^{V}O_{36}Cl]\cdot(H_2O)_3$ (**5**)

A mixture of $NaVO_3$ (183 mg, 1.5 mmol), Na_2TeO_3 (220 mg, 1 mmol), $Ni(CH_3COO)_2$ (177 mg, 1 mmol), 2,2′-bipyridine (50 mg, 0.38 mmol), HCl (0.1 mL), CH_3CH_2OH (2 mL) and H_2O (5 mL) was stirred for ca. 45 min in air until it was homogeneous, and adjusted by CH_3COOH to pH 5.5, and then transferred and sealed in a 16 mL Teflon-lined stainless steel container. After heated to 170 °C under autogenously pressure for 4 days, the bomb was cooled down to room temperature. Black block crystals of **5** along with an amorphous grey impurity were filtered from the colorless mother liquor, washed by distilled water and dried at ambient temperature. The crystals were mechanically separated from the grey impurity to give a yield of 51% (based on V), and were stable in air and insoluble in water and common organic solvents. IR (KBr, cm^{-1}): $\tilde{\nu}$ = 3441 (m), 1835 (w), 1741 (m), 1692 (m), 1646 (m), 1565 (m), 1548 (m), 1532 (m), 1516 (m), 1444 (m), 1314 (m), 1162 (m), 980 (m), 767 (m), 664 (m), 477 (m), 429 (m). 2.3. Crystal structure determination

Black crystals of **1**–**5** were glued on to glass fibers. Data were collected at 298(2) K on a Rigaku R-AXIS RAPID IP diffractometer with Mo Kα monochromated radiation (λ = 0.71073 Å). The structures were solved by direct methods and refined by full-matrix least-squares methods on F^2 with the SHELXTL software package. An empirical absorption correction was applied. All non-hydrogen atoms were refined anisotropically and hydrogen atoms were included at idealized positions and refined by use of the riding model. A summary of the crystallographic data of complexes **1**–**5** is presented in Table 1.

3. Results and discussion

3.1. Synthesis

The syntheses of the compounds **1**, **1′** [19], **2**, **3**, **4** and the spherical mixed-valence host–guest V15 cluster **5** are summarized in Scheme 1. The $\{V_{16}O_{38}\}$ core has been observed in some well characterized compounds containing the same numbers of reduced vanadium (IV) sites [11,8d]. The basic $\{V_{16}O_{38}\}$ shell in all these compounds is built up from 16 VO_5 distorted square pyramids that share edges and corners through two μ_2- and 20 μ_3-oxygen atoms, respectively. The shell could encapsulate Cl^- ions and H_2O molecules that exert templating effects on the electronic and framework structures of the host metal-oxide shells. However,

Scheme 1. Synthetic routes to the isolated compounds **1**–**5**.

we have successfully obtained **1** and **2** with a suitable fluoride and bromide ion source (HF and HBr) in the reaction. Compound **1** is the first example of hybrid materials that contain a $[V_{16}O_{38}F]^{4-}$ cluster and **2** is the first example of hybrid materials that contain a $[V_{16}O_{38}Br]^{4-}$ cluster. Furthermore, the $[V_{16}O_{38}F]^{4-}$ and $[V_{16}O_{38}Br]^{4-}$ clusters present different numbers of reduced vanadium (IV) sites compared to the reported $\{V_{16}O_{38}\}$ core.

Thinking about the comparability of the first-row transition metals, different paramagnetic metal ions Co(II), Ni(II) and Mn(II) were introduced into the reaction system. Compounds **3** and **4** were prepared under similar conditions. In order to study the effect of the organic ligands on the inorganic oxide microstructure, we intended to replace 4,4′-bpy with other organic ligands containing nitrogen (i.e., 2,2′-bpy and en). Based on this thought, compound **5** was obtained by reaction of 2,2′-bpy with $NaVO_3$, Na_2TeO_3 and HCl in acidic aqueous solution (pH 5.5). Though ethanol is not necessary for the formation of compounds **1**–**5**, a large number of parallel experiments indicate that the presence of a small quantity of ethanol could improve the yield and purity of these compounds.

Significantly, the presence of Na_2TeO_3 is necessary for the formation of compounds **1**–**5**. When the reactions were performed in the absence of Na_2TeO_3, nothing could be obtained except for some yellow precipitation, likely corresponding to complexes of V^V. Consequently, it appears that Na_2TeO_3 exerts the role of reducer for V^V. Taking into account the characteristic comparability of identical group elements, we replaced Na_2TeO_3 with an equal amount of Na_2SO_3 or Na_2SeO_3 in the reaction system. When Na_2SO_3 was used, compounds **1**–**5** cannot be obtained. However, compounds **1**–**5** could be obtained when Na_2SeO_3 was used instead of Na_2TeO_3, but at a cost of the yield and crystal quality of these compounds. It can be concluded that the reductive ability of Na_2TeO_3 and Na_2SeO_3 are comparative and both are weaker than that of Na_2SO_3, which indicates that weak reducer is propitious to the formation of **1**–**5**.

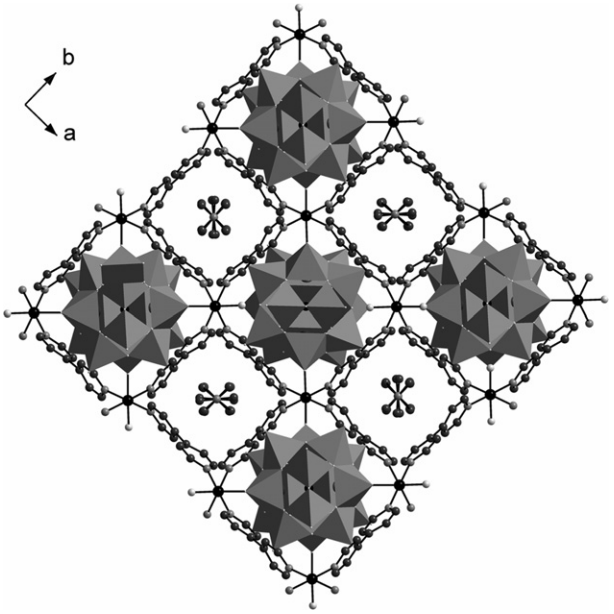

Fig. 1. Simplified schematic representation of the structure of a single crystal of **1**. Color code: $\{V_{16}O_{38}(F)\}^{4-}$ clusters, medium grey; Ni atoms, black; N atoms, medium grey; C atoms, dark grey; O atoms, light grey. All H atoms are omitted for clarity.

During our experiments, we also found that **1**–**5** cannot be obtained when some other common reducers such as oxalic acid, ethylenediamine and hydrazinium sulfate were used instead of Na_2TeO_3.

3.2. Description of the crystal structure

Single crystal X-ray diffraction analysis reveals that compounds **1**–**4** are isomorphous. They have similar molecular formulas and crystal structures, hence only the structure of **1** will be discussed in detail. The crystal structure of **1** can be described as a three-dimensional framework constructed from helical metal–organic coordination polymers $[\{Nibpy\}^{2+}]_n$ cations, $[V_{16}O_{38}(F)]^{4-}$ cluster

anions, guest 4,4′-bpy and water molecules (Fig. 1). The $[V_{16}O_{38}F]^{4-}$ cluster, with S_4 symmetry, is composed of a $\{V_{16}O_{38}\}$ shell with an encapsulated F^- ion in the center. The 16 V atoms are arranged at the surface of the shell with radius of 3.57 ± 0.21 Å from the central haloid ion. The host $\{V_{16}O_{38}\}$ shell consists of 16 VO5 square pyramids by sharing edges and corners with 20 μ_3-O atoms and 2 μ_2-O atoms. The other 16 oxygen atoms are terminal in the polar positions of the 16 VO5 square pyramids. The geometry around vanadium (V1) in the 4 VO5 units is defined by four basal μ_3-O groups and an apical μ-oxygen which in turn is linearly bonded to the Ni(II) center and then {V1–O–Ni–O–V1} bonds, which link $[V_{16}O_{38}F]^{4-}$ clusters, are formed. The square pyramidal geometry around vanadium (V2 and V3) in eight of the 16 VO5 groups is defined by a terminal oxo group and four μ_3-O atoms of the shell. The geometry around vanadium (V4) in the remaining 4 VO5 units is defined by three μ_3-O groups, one μ_2-O group and one terminal oxygen atom.

In the metal–organic coordination polymers, each Ni atom is 6-coordinate and shows a "4+2" distorted octahedron geometry. The equatorial plane is defined by four nitrogen donors of four 4,4′-bpy ligands (Ni–N: 2.141–2.144 Å). The axial positions are occupied by two bridging oxygen atoms coming from two different $[V_{16}O_{38}(F)]^{4-}$ clusters (Ni–O: 2.034 Å). An unusual feature of **1** is that the transition-metal Ni^{2+} and organic 4,4′-bpy are joined by N atoms to generate rectangular left and right-handed helical channels alternately, with N–Ni–N bond angles ranging from 89.38° to 91.2°, and these channels can be seen in a view along the [0 0 1] direction (Fig. 2b). Furthermore, large chiral channels that are suitable for incorporating organic guest molecules exist between the helices, in which disordered 4,4′-bpy as guest molecules reside. Interestingly, each chiral channel is formed by a double-stranded helical chain intertwined by homochiral polymeric chains (Fig. 2a).

In the structure of **1**, the $[V_{16}O_{38}(F)]^{4-}$ cluster acts as a tetradentate ligand coordinating to four Ni^{2+} ions through

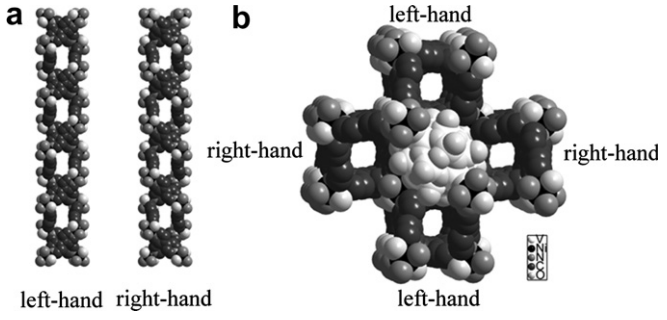

Fig. 2. (a) A space-filling view of the double-stranded left and right-handed helical chains along b exhibited by **1**. (b) The framework viewed along the [0 0 1] direction, showing two types of helical channels and achiral channels which are alternately arranged. All H atoms are omitted for clarity.

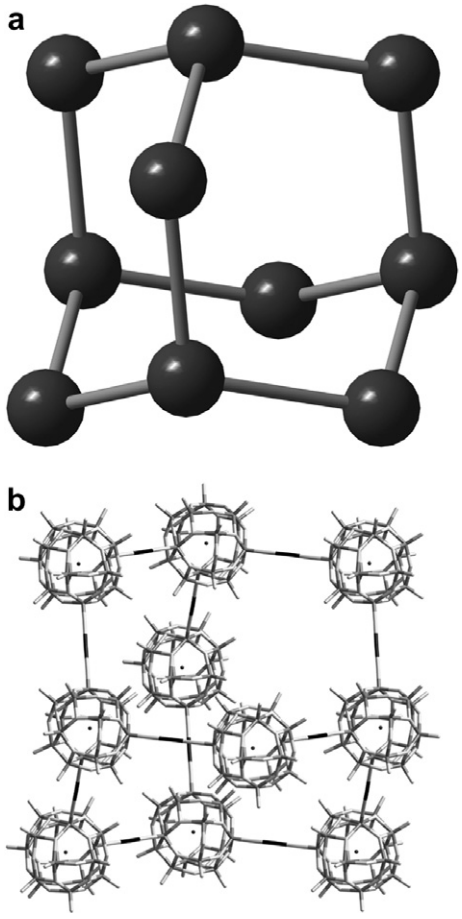

Fig. 3. Schematic illustration presenting the structural analogy recognized between diamond and compound **1**. (a) diamond, (b) compound **1**. Color code: V atoms, medium grey; Ni atoms, black; F atoms, dark grey; O atoms, light grey. All 4,4′-bpy molecules are omitted for clarity.

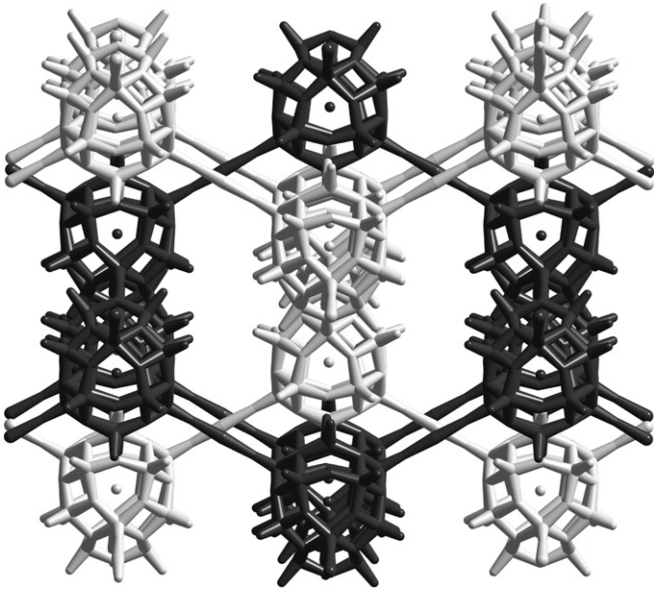

Fig. 4. Simplified schematic representation of the twofold interpenetrating network of **1**. All 4,4′-bpy molecules are omitted for clarity.

the terminal oxo groups of vanadium sites with Ni–O distances ranging from 2.034 to 2.132 Å. The linkage of Ni atoms and $[V_{16}O_{38}(F)]^{4-}$ clusters form a diamond framework by replacing each C in diamond with a $[V_{16}O_{38}(F)]^{4-}$ cluster and each C–C with a Ni(II) center (Fig. 3). This connectivity behavior may enhance the stability of the framework of **1**. Additionally, the metal–organic coordination polymer cations $[\{Nibpy\}^{2+}]_n$ connect with $[V_{16}O_{38}(F)]^{4-}$ clusters to form a twofold interpenetrating three-dimensional structure through the terminal oxo groups of vanadium sites (Fig. 4). Unlike many other solids with interpenetrating networks, the extent of interpenetration in **1** does not fill all the available voids but leaves a significant portion in the form of rectangular extended channels that are occupied by disordered 4,4′-bpy molecules. To the best of our knowledge, the occurrence of this interpenetrating net, composed of large polyoxoanion clusters and a metal–organic coordination polymer, is unprecedented. It shows that the incorporation of large polyoxoanion clusters could provide efficient cation–anion packing to prevent interpenetration of the cationic polymers.

The structure of the $[V_{16}O_{38}Br]^{4-}$ cluster in compound **2** is similar to the $[V_{16}O_{38}F]^{4-}$ cluster, but the bond lengths and bond angles are different, see Figs. S1 and S2. In the case of compounds **1**, **2** and **3**, the polyoxovanadate clusters are composed of a $[V_{16}O_{38}]$ shell with an encapsulated F^-, Br^- or Cl^- ion in the center, respectively. This is confirmed by XPS measurements in the F_{1s}, Br_{3d} and Cl_{2p} energy region, respectively. The XPS spectra of compounds **1**, **2** and **3** show peaks at 684 eV, 70 eV and 198 eV, respectively, attributable to F^-, Br^- and Cl^- (Fig. S3). The host shells are formed by using the template function of the anionic guest and are dependent on its shape and size. The van der Waals radii of the guests must of course be smaller than those of the cavities [20a]. The nearest distance from the center of the $[V_{16}O_{38}F]^{4-}$, $[V_{16}O_{38}Br]^{4-}$ and $[V_{16}O_{38}Cl]^{4-}$ clusters to the O atoms of the periphery is 3.318 Å, 3.358 Å and 3.341Å, and to the 16 V atoms at the surface of the shell is 3.396 Å, 3.397 Å and 3.390 Å, respectively. It is possible that the V16 cluster encapsulates negatively charged halide ions with significant different radii ($F^- = 1.33$ Å, $Br^- = 1.96$ Å, $Cl^- = 1.81$ Å and $O^{2-} = 1.32$ Å). When HCl was replaced with HI, however, the expected product was not obtained. Because the effective ionic radius of the I^- ion (2.20 Å) is larger, the I^- ion cannot be encapsulated by the shell of $[V_{16}O_{38}]$. Also, we have tried to replace halide ions with SO_4^{2-}, CO_3^{2-}, NO_3^- and ClO_4^- in order to study the templating effects of the central ions, but failed. It is due to that the assembly of the host cage is probably determined by the shape and symmetry of the small guest molecule. Additionally the host cage tends to adapt not only to the shape of the guest system, but also to its molecular electrostatic potentials distribution [20b]. So in compounds **1**, **2** and **3**, global halide ions with high symmetry and suited shape, size and molecular electrostatic potential distributions are propitious to form the $\{V_{16}O_{38}\}$ shell.

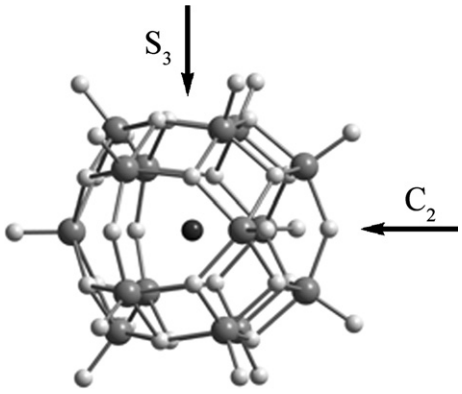

Fig. 5. The structure of $[V_{15}O_{36}Cl]^{6-}$ cluster in **5**. Color code: V atoms, medium grey; Cl atoms, dark grey; O atoms, light grey.

The assignment of the oxidation states of the vanadium atoms in compounds **1**–**4** is based on bond valence sum calculations, which reveal the average value of the V atoms is 4.551 for **1**, 4.555 for **2**, 4.566 for **3** and 4.563 for **4**, very close to the value of 4.562 for $V_7^{IV}V_9^{V}$ [21]. This conclusion and the result of the manganometric titration of V^{IV} sites correspond to the stated formulations of **1**–**4**.

When 2,2′-bpy was used instead of 4,4′-bpy, compound **5** was obtained. Compound **5** is constructed from $[V_{15}O_{36}Cl]^{6-}$ anions and $[Ni(2,2'\text{-bpy})_3]^{2+}$ cations via electrostatic and aryl–aryl interactions (Fig. S4). Each C atom of three 2,2′-bpy coordinating to the Ni(3) atom is disordered over two positions, and the best refinement has been obtained with occupancy factors of about 0.5 and 0.5 (Fig. S5). The spherical cluster $[V_{15}O_{36}Cl]^{6-}$ formally contains 15 V centers arranged on the surface of a sphere at a distance of 3.42 ± 0.11 Å from the center of the cluster in which the Cl^- resides (Fig. 5). For**5**, bond valence sums calculations reveal that the $[V_{15}O_{36}Cl]$ clusters have six negative charges. The average value calculated for the oxidation state of V is 4.423, very close to the value of 4.467 for $V_8^{IV}V_7^{V}$. This conclusion and the result of the manganometric titration of V^{IV} sites correspond to the stated formulation of **5**.

If 4,4′-bpy was substituted by en, compound $[Ni(en)_2][V_6O_{14}]$ was synthesized in our reaction system. The mixed-valence vanadium oxide $[V_6O_{14}]^{2-}$ layers contain infinite zigzag chains composed of edge-sharing VO_5 square pyramids. Adjacent chains are connected through corner-shared VO_4 tetrahedra to form a layer structure. Compound $[Ni(en)_2][V_6O_{14}]$ has been synthesized in our reaction system, though it can be obtained under other conditions [16b]. Several different polyoxovanadate clusters, such as $[V_{16}O_{38}X]^{4-}$, $[V_{15}O_{36}Cl]^{6-}$ and $[V_6O_{14}]^{2-}$, have been obtained by using organic ligands with different functionalities, which indicate that the organic components could modify the inorganic oxide microstructure. So under similar conditions, hybrid materials containing different polyoxometallate clusters are prepared by selecting different organic ligands.

3.3. Thermogravimetric analysis

Thermogravimetric analysis of **1**–**4** reveals a continuous weight loss (36.7% for **1**, 35.5% for **2**, 36.1% for **3** and 35.8% for **4**) until 429 °C, 421 °C, 431 °C and 428 °C, respectively, corresponding to the removal of water molecules, the guest 4,4′-bpy molecule and four coordinated 4,4′-bpy molecules (calc.36.1% for **1**, 36.2% for **2**, 36.9% for **3** and 36.3% for **4**). In compound **5**, the TG curve shows four weight loss steps, which suggests a multiple-stage decomposition process. Heating from about 25 to 130 °C leads to the loss (weight loss of ca. 2.03%) of three crystal H_2O molecules per formula unit (calc. 1.79%). The next three weight loss steps (45.23%), occurring between 180 and 596 °C, correspond to the loss of three 2,2′-bpy molecules per formula unit (calc. 46.68%).

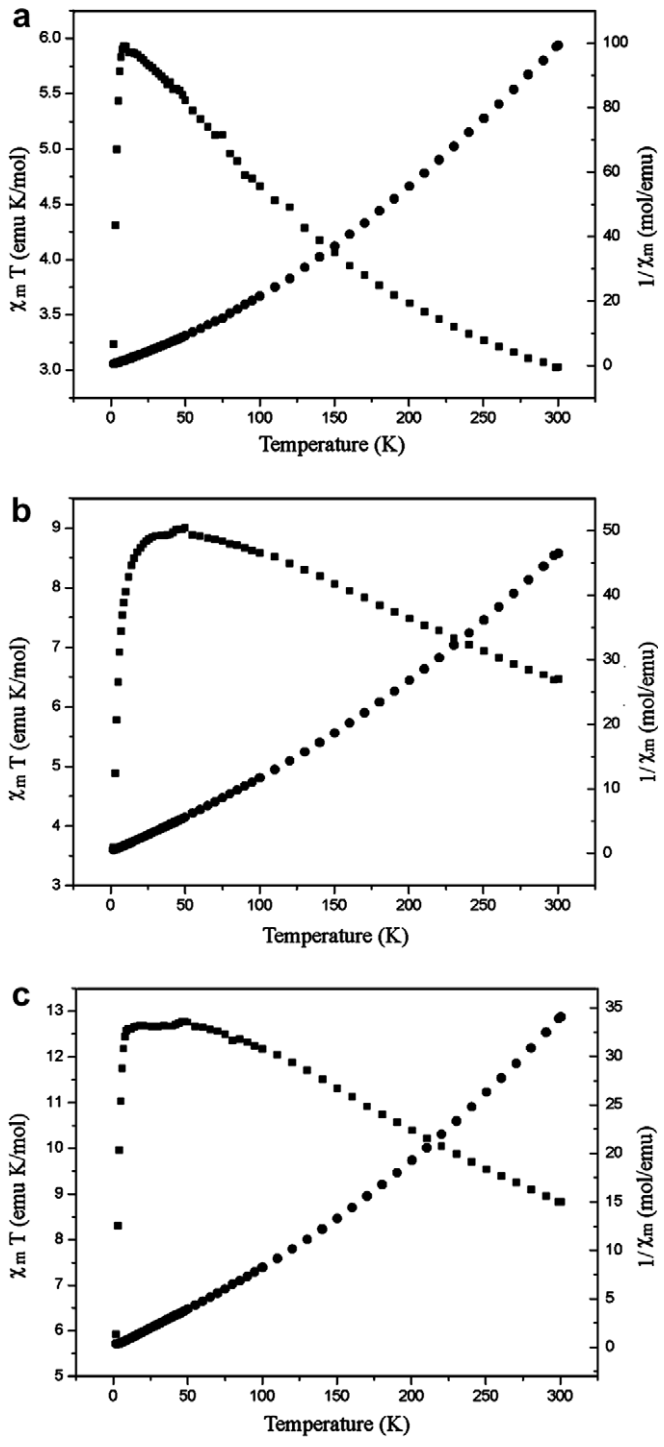

Fig. 6. Thermal variation of $\chi_m T$ and $1/\chi_m$ for compounds **1**′, **3** and **4**. (a) Compound **1**′, (b) compound **3**, and (c) compound **4**.

3.4. Magnetic properties of compounds 3, 4 and 5

The variable-temperature magnetic susceptibilities of **1**′, **3** and **4** were measured between 2 and 300 K at 10000 Oe. The magnetic data of compound **1**′ is included for comparison. The thermal variations of $\chi_m T$ and $1/\chi_m$ are displayed in Fig. 6 (where χ_m is the measured magnetic susceptibility). In the case of compounds **1**′, **3** and **4**, the $\chi_m T$ products at 300 K are 3.02 emu K mol^{-1} (4.92 μ_B), 6.47 emu K mol^{-1} (7.19 μ_B) and 8.82 emu K mol^{-1} (8.40 μ_B), respectively. The $\chi_m T$ values of **1**′ and **4** are smaller than the expected values for two uncorrelated M^{2+} (Ni^{2+}: $S = 1$, Mn^{2+}: $S = 5/2$) and seven V^{4+} ($S = 1/2$) centers per formula unit ($\chi_m T$ (**1**′) = 4.63 emu K mol^{-1}, 6.08 μ_B; $\chi_m T$ (**4**) = 11.38 emu K mol^{-1}, 9.54 μ_B), but the $\chi_m T$ value of **3**(two uncoupled $S = 3/2$ for Co^{2+}, seven uncoupled $S = 1$ for V^{4+}) is higher than the expected value ($\chi_m T$ (**3**) = 6.38 emu K mol^{-1}, 7.14 μ_B). The products $\chi_m T$ increase on cooling to a maximum 5.93 emu K mol^{-1} at 8 K for **1**′, 9.00 emu K mol^{-1} at 50 K for **3** and 12.70 emu K mol^{-1} at 48 K for **4**, which indicates the presence of ferrimagnetic exchange coupling. Subsequently, the curves drop abruptly below 8 K, 50 K and 48 K for **1**′, **3** and **4**, respectively, which may be caused by the zero-field splitting contributions, intercluster magnetic interactions or saturation effects are likely to influence the data in this temperature range. The measured data of **1**′, **3** and **4** were fitted by using the Curie–Weiss equation $\chi_m = C_m/(T - \theta)$

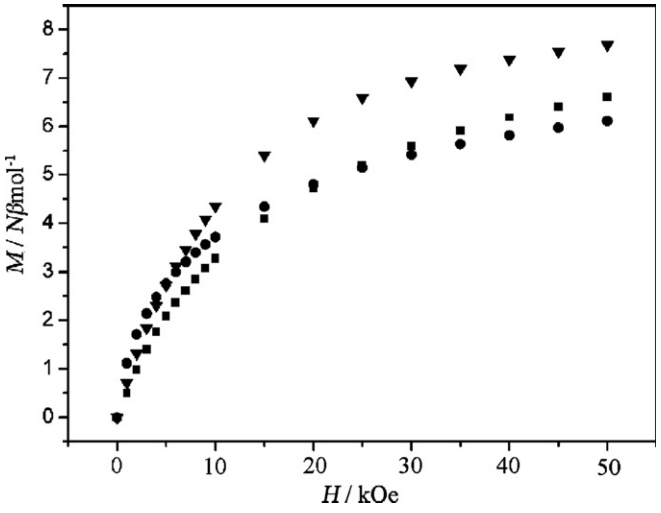

Fig. 7. Field dependence of the magnetizations for complexes **1**′ (■), **3** (●) and **4** (▼).

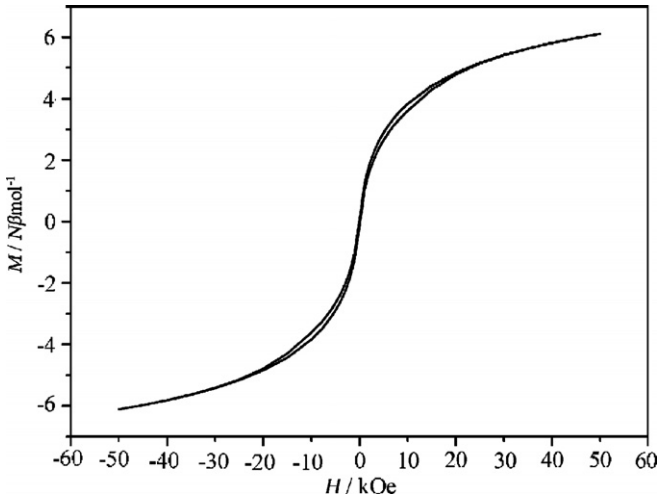

Fig. 8. Hysteresis loop of **3** at 1.8 K.

at $T > 150$ K, where C_m is the Curie constant and θ is the Weiss constant, with $C_m = 2.39$ emu K mol^{-1} and $\theta = 65.85$ K for **1′**, $C_m = 5.32$ emu K mol^{-1} and $\theta = 55.91$ K for **3** and $C_m = 7.16$ emu K mol^{-1} and $\theta = 60.22$ K for **4**.

The variable-temperature magnetic susceptibility of **5** was also measured between 2 and 300 K at 10 000 Oe. $\chi_m T$ versus T shows a value of 6.68 emu K mol^{-1} (7.31 μ_B) at 300 K, higher than the expected total value (6.00 emu K mol^{-1}, 6.93 μ_B) of eight uncoupled $S = 1/2$ spins of V^{4+} atoms and three uncoupled $S = 1$ spins of Ni^{2+} atoms (Fig. S8). The $\chi_m T$ values remain almost constant from 300 K to 18 K, and then decrease on further cooling, reaching a value of 3.74 emu K mol^{-1} at 2 K, which indicates paramagnetic properties in compound **5**. The fit for the curve of the $1/\chi_m$ versus T plot of **5** to the Curie–Weiss law gives a good result in the temperature range 2–300 K with $C_m = 6.66$ emu K mol^{-1} and $\theta = 0.20$ K (see Figs. 7 and 8).

4. Conclusion

In summary, the combination of cage-like polyoxovanadate clusters with metal–organic complexes provides a series of hybrid materials **1**–**5** with different structures and physical properties. Compounds **1**–**4** have 3D coordination complex $[\{Mbpy\}^{2+}]_n$ cationic scaffoldings that incorporate vanadium oxide clusters into their void spaces. The successful preparation of compound **5** and $[Ni(en)_2][V_6O_{14}]$ indicates that organic ligands can dramatically influence the inorganic oxide microstructure. The effects of different reaction factors were discussed in the paper, such as the source of the transition metal salts, organic ligands and central templates, which provide an optional method to design and synthesize novel hybrid materials. Furthermore, the magnetic properties of compounds **3** and **4** could make them excellent candidates for potential applications in magnetic materials.
