The present Short Communication deals with the Mn_{25} SMM complex of full formula $[Mn^{II}_6Mn^{III}_{18}Mn^{IV}O_{18}(OH)_2(N_3)_{12}(pdm)_6(pdmH)_6]X_2$ [(**1**); X = Cl or N_3; $pdmH_2$ is 2,6-pyridinedimethanol]. The $X = Cl^-$ salt was the original one prepared [5a] but the present work has been carried with the $X = N_3^-$ salt, available in a much better yield of 75% from a related procedure. The Mn_{25} cation of **1**[1] has a barrel-like cage structure with twelve μ_4-O^{2-}, six μ_3-O^{2-}, and two μ_3-OH^- ions holding the core together (Fig. 1, top). The peripheral ligation is provided by chelating/bridging pdm^{2-}/$pdmH^-$ and both terminal and end-on bridging N_3^- groups. The core may be dissected into five layers of three types with an ABCBA arrangement (Fig. 1, bottom). Layer A is a Mn^{II}_3 triangular unit with a capping μ_3-OH^- ion; layer B is a Mn^{III}_6 triangle comprising three corner-sharing Mn^{III}_3 triangles; and layer C is an Anderson-type Mn^{III}_6 hexagon with a central Mn^{IV} ion. Each layer is held together and linked to its neighboring layers by a combination of O^{2-}, OR^-, and/or N_3^- bridges.

[1] Crystal structure data for $\mathbf{1}\cdot 10MeCN$: $C_{104}H_{122}Mn_{25}N_{64}O_{44}$, $M_r = 4345.98$, triclinic, space group $P\bar{1}$, $a = 15.9646(12)$, $b = 16.5361(13)$, $c = 17.3483(14)$ Å, $\alpha = 97.895(2)$, $\beta = 101.094(1)$, $\gamma = 117.345(1)°$, $V = 3855.8(5)$ Å^3, $Z = 1$, $\rho_{calcd} = 2.085$ g cm^{-3}, $T = 173(2)$ K, 21329 reflections collected, 13437 unique ($R_{int} = 0.0335$), $R_1 = 0.0519$ and $wR_2 = 0.1546$, using 13437 reflections with $I > 2\sigma(I)$. Crystal structure data for $\mathbf{2}\cdot x$MeCN$\cdot y$MeOH: $C_{121}H_{130}Mn_{25}N_{24}O_{74}Cl_6$, $M_r = 4690.67$, rhombohedral, space group $R\bar{3}c$, $a = 22.0975(9)$, $c = 69.811(5)$ Å, $V = 29522(3)$ Å^3, $Z = 6$, $\rho_{calcd} = 1.495$ g cm^{-3}, $T = 173(2)$ K, 16378 reflections collected, 4080 unique ($R_{int} = 0.0756$), $R_1 = 0.0674$ and $wR_2 = 0.1860$, using 4080 reflections with $I > 2\sigma(I)$.

Scheme 1. The pyridyl–alcohol ligands discussed in the text (top), and the crystallographically established coordination modes of the hmp^-, $pdmH^-$, and pdm^{2-} ligands present in complexes **1** and **2** (bottom).

The $[Mn_{25}O_{18}(OH)_2(N_3)_{12}(pdm)_6(pdmH)_6]^{2+}$ cation has an $S = 51/2$ ground state, and we undertook the challenge of tweaking this spin value without core structural change.

We have extensive experience with pyridine-based alkoxide ligands in Mn cluster chemistry, and have seen that the anion of 2-(hydroxymethyl)pyridine (hmp^-), like $pdmH^-$ and pdm^{2-} (Scheme 1), is a versatile N,O-chelating and bridging ligand that often yields ferromagnetic coupling between metal atoms [5b,6]. We thus targeted replacement of the twelve azide ions of **1** by six hmp^- groups, and this ultimately proved successful.

The reaction of **1** ($X = N_3^-$), Na(hmp), and $NaClO_4 \cdot H_2O$ in a 1:6:6 molar ratio in MeCN/MeOH[2] gave a dark brown solution from which were subsequently isolated crystals of $[Mn_{25}O_{18}(OH)(OMe)(hmp)_6(pdm)_6(pdmH)_6](N_3)_2(ClO_4)_6 \cdot x\text{MeCN} \cdot y\text{MeOH}$ ($\mathbf{2} \cdot x\text{MeCN} \cdot y\text{MeOH}$) in 63% yield. The crystal structure[1] shows the core of **2** to be isostructural with that in **1**; Mn oxidation states and the protonation levels of all O atoms in the molecule were established by Mn and O bond valence sum (BVS) calculations [7],[3] inspection of metric parameters, and detection of Mn^{III} Jahn-Teller (JT) elongation axes. The main difference is that the twelve bound azides of **1** are now replaced by six $\eta^1{:}\eta^2{:}\mu_2$ hmp^- ligands in **2** and also a μ_3-OH^- group of **1** is substituted by a μ_3-MeO^- ligand in **2** (Fig. 2). As a result, all intra- and inter-layer bridges, as well as all M_2 pairwise exchange interactions, are now through oxo-atoms, and there are consequently small metric differences between the cores of **1** and **2**.[4] There will thus some changes expected to many of the exchange interactions in the molecule. Considering that the ground state of such a large molecule consisting of both ferro- and antiferromagnetic interactions will be acutely sensitive to the relative magnitudes of the multiple exchange interactions, many of them competing, it was considered likely that the ground state S value might change, and this was therefore explored by detailed magnetochemical measurements.

Solid-state DC magnetic susceptibility (χ_M) data for dried $\mathbf{2} \cdot 4\text{MeCN}$ were collected in the temperature range 5.0–300 K in an applied field of 1 kG (0.1 T). $\chi_M T$ steadily increases from 120.20 $cm^3\,mol^{-1}\,K$ at 300 K to a maximum of 457.42 $cm^3\,mol^{-1}\,K$ at 20 K, before dropping to 401.94 $cm^3\,mol^{-1}\,K$ at 5.0 K (Fig. 3). The spin-only ($g = 2$) value for a non-interacting $[Mn^{II}_6Mn^{III}_{18}Mn^{IV}]$ unit is 82.125 $cm^3\,mol^{-1}\,K$, indicating at least some ferromagnetic exchange interactions within **2**, and the 20 K data strongly suggest a very large ground-state spin (S) value. The low temperature data are consistent with an S in the 59/2 to 65/2 range, depending on the g value, significantly greater than the $S = 51/2$ of **1**.

In order to determine the ground state of $\mathbf{2} \cdot 4\text{MeCN}$, magnetization ($M$) data were collected in the 0.1–1.0 T and 1.8–10.0 K ranges, and these are plotted as $M/N\mu_B$ versus H/T in Fig. 4. We used only low field data ($\leqslant$1.0 T), as we previously did for **1**, to avoid problems associated with M_s levels from excited states with higher S values crossing with the ground state, which would lead to an erroneously high value for the ground-state S. The data were fit by matrix-diagonalization to a model that

[2] It is pertinent to ask whether the Mn_{25} core structure stays intact in the MeCN/MeOH solvent used for the ligand substitution. Although we cannot answer this directly on the present system because of its complexity, we know from experience on related, higher symmetry Mn clusters (e.g. Mn_{12}, Mn_4, etc.), which we can study by NMR, that systems with higher average oxidation states and lots of oxide bridges retain their structures in solution. Compound **2** is one such molecule. Also the fact that the product is indeed of the same core structure as the starting material supports this in the present case.

[3] Bond-valence sum (BVS) calculations for Mn^{II}, Mn^{III} and Mn^{IV} ions of **2** gave oxidation state values of 1.94 (Mn^{II}), 2.88–2.99 (Mn^{III}) and 4.18 (Mn^{IV}) and for the oxygen atoms of O^{2-}, OH^-, hmp^-, $pdmH^-$, pdm^{2-} values of 1.84–2.03 (O^{2-}), 1.16–1.17 (OH^-, OMe^-, OR^-).

[4] A detailed comparison will be provided in the full paper of this work.

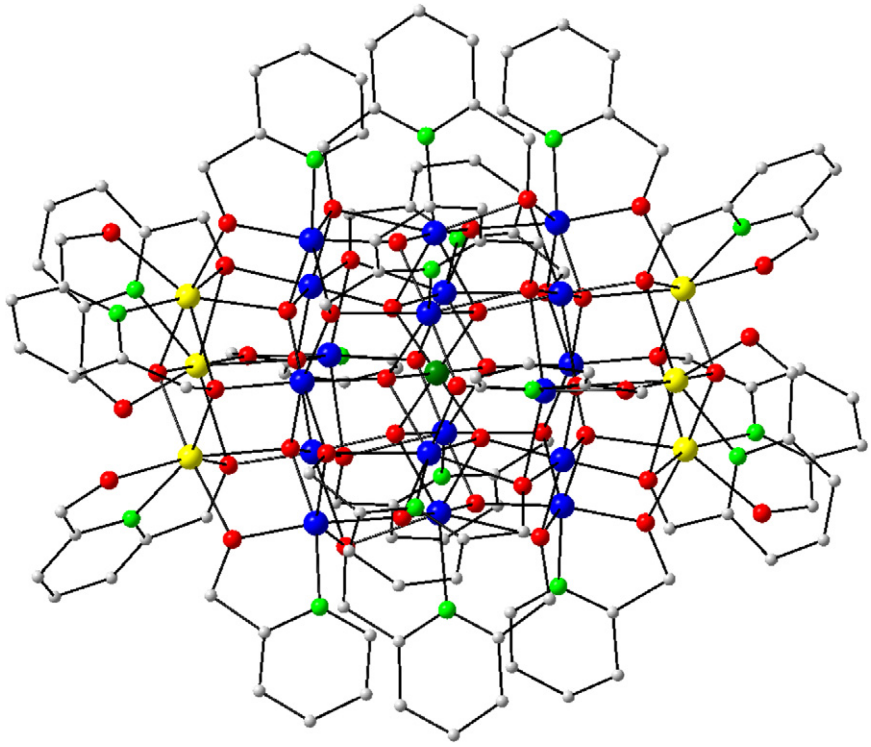

Fig. 2. Structure of the cation of **2**. Color code: Mn^{II} yellow, Mn^{III} blue, Mn^{IV} olive, O red, N green, C gray. H atoms have been omitted for clarity. (For interpretation of the references in colour in this figure legend, the reader is referred to the web version of this article.)

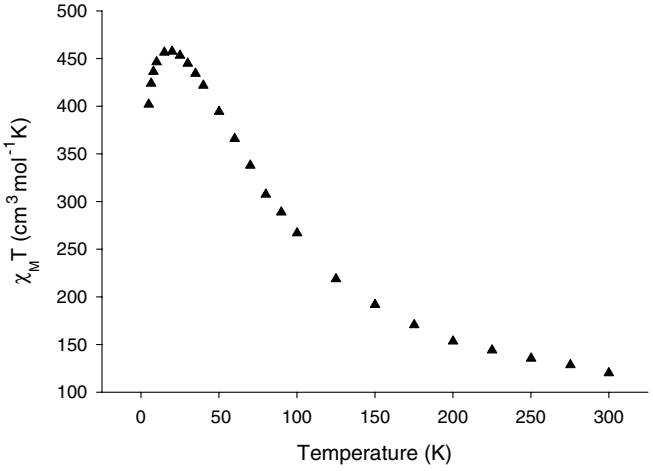

Fig. 3. $\chi_M T$ vs. T plot for complex **2** · 4MeCN in a 1 kG field.

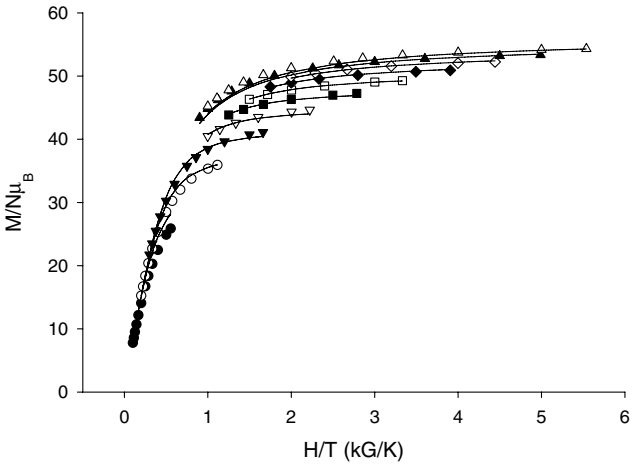

Fig. 4. Plot of reduced magnetization ($M/N\mu_B$) vs. H/T for **2** · 4MeCN in the temperature range 1.8–10 K and in fields of 0.1 T (●), 0.2 T (○), 0.3 T (▼), 0.4 T (▽), 0.5 T (■), 0.6 T (□), 0.7 T (◆), 0.8 T (◇), 0.9 T (▲), and 1.0 T (△). Solid lines are the fit; see the text for the fitting parameters.

assumes only the ground state is populated, includes axial zero-field splitting ($D\widehat{S}_z^2$) and the Zeeman interaction, and carries out a full powder average. The best fit (solid lines in Fig. 4) gave $S = 61/2$, $g = 1.92(1)$ and $D = -0.0120(1)\ cm^{-1}$. The fits for $S = 59/2$, 63/2, and 65/2 were inferior, with best-fit parameters of $g = 1.98(1)/D = -0.0128(1)\ cm^{-1}$, $g = 1.86(1)/D = -0.0113(1)\ cm^{-1}$, and $g = 1.79(1)/D = -0.0106(1)\ cm^{-1}$, respectively. We conclude that **2** has a ground state of $S = 61/2 \pm 1$.

Confirmation of the ground state S of **2** · 4MeCN was obtained by alternating current (ac) susceptibility experiments. Ac susceptibility studies use no dc field and thus are an excellent complementary tool for determining S by avoiding potential complications from a large dc field. The in-phase susceptibility (χ'_M) for **2** · 4MeCN is shown as $\chi'_M T$ versus T in Fig. 5, and extrapolation of the $\chi'_M T$ signal to 0 K from above ~8 K (to avoid the effects of intermolecular interactions at lower temperatures) gives a value of 440–470 $cm^3\ mol^{-1}$ K, consistent with the dc data

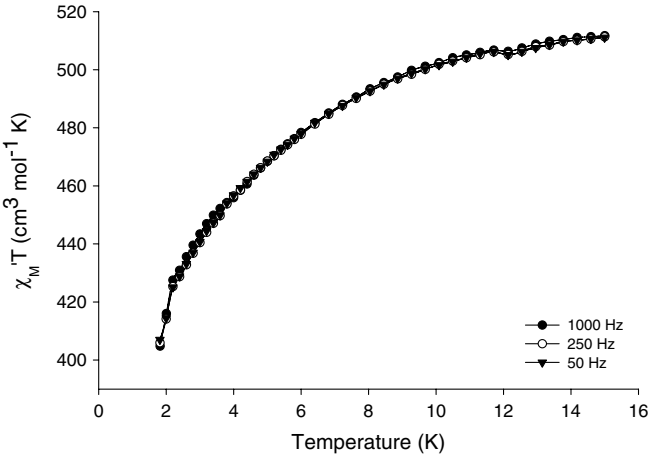

Fig. 5. In-phase ac susceptibility ($\chi'_M T$) measurements of complex **2** · 4MeCN measured below 15.0 K at the indicated frequencies.

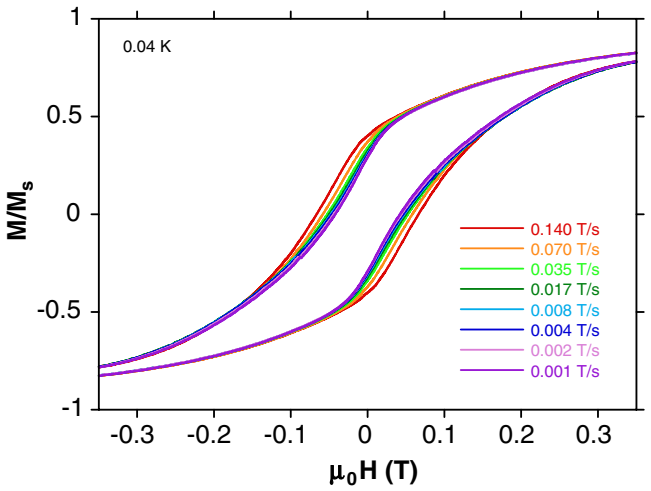

Fig. 6. Magnetization (M) vs field (H) hysteresis loops for a single-crystal of complex **2** · 4MeCN at the indicated field sweep. The magnetization is normalized to its saturation value (M_s).

of Fig. 3. A value of 455 $cm^3\ mol^{-1}$ K is consistent with: (i) $S = 59/2$ and $g = 2.01$, (ii) $S = 61/2$ and $g = 1.95$, and (iii) $S = 63/2$ and $g = 1.89$. The AC data thus confirm a high ground state spin of $S = 61/2 \pm 1$.

The $S = 61/2$ ground state and the negative D value suggested that **2** might be an SMM. Indeed, at temperatures <4.0 K, frequency-dependent tails were seen in the out-of-phase (χ''_M) ac susceptibility signals for **2** · 4MeCN whose maxima lie below the operating minimum temperature of our SQUID instrument (1.8 K). Such signals are an indication of the superparamagnetic-like slow relaxation of a SMM, although they do not prove an SMM because intermolecular interactions and phonon bottlenecks can also lead to such signals. The upper limit to the relaxation barrier is $U = (S^2 - 1/4)|D|$ for a half-integer spin, or only 11.2 cm^{-1} (=16.20 K) for **2** · 4MeCN, but the actual (or effective) barrier (U_{eff}) will be significantly less due to magnetization quantum tunneling through the barrier. In order to confirm whether **2** is an SMM, magnetization versus applied dc field data down to 0.04 K were collected on single-crystals using a micro-SQUID apparatus [8]. The resulting magnetization responses at different field sweep rates and a constant temperature of 0.04 K are shown in Fig. 6. The corresponding magnetization responses at different temperatures and a fixed field sweep rate of 0.14 T/s. Hysteresis loops are seen below ~1.0 K whose coercivities increase with increasing sweep rate and with decreasing temperature, as expected for the superparamagnet-like properties of a SMM. This confirms **2** to be an SMM. An Arrhenius plot, constructed from magnetization decay data, gave $U_{eff} = 6.43\ cm^{-1} = 9.3$ K and $\tau_0 = 5 \times 10^{-11}$, where τ_0 is the pre-exponential factor.

In summary, we have shown that it really is possible to significantly adjust, or tweak, the spin of an already high-spin molecule by altering the peripheral ligation in a way that does not alter the core structure but nevertheless perturbs the exchange coupling. The spin-tweaking is accomplished in this prototypical case by replacement of a bridging and terminal pair of azides with a chelating/bridging hmp^- group, the chelate ring introducing new types of bridging atoms and also some structural restrictions. As a result, the ground state spin increases from $S = 51/2$ to $61/2$.

ity of these oxalate complexes from 1D chains [13] to 2D honeycomb-like layers [14]. All these examples behave as ferromagnets with critical temperatures below 3.5 K. Even in the chain compound {[K(18-crown-6)][$Mn(H_2O)_2$-$Cr(ox)_3$]0.5(18-crown-6) [13] magnetic ordering is observed due to the presence of weak ferromagnetic interchain interactions. This is favored by the short contacts between chains, that appear strongly related by hydrogen bond interactions between the water molecules that act as ligands. Attending to the interest in the magnetic behavior of chain compounds, particularly since the discovery of the so-called "single-chain-magnets", we have used organic chelating ligands, such as 2,2′-dipyridyl, to substitute the water molecules in order to enlarge the interchain distance, and to decrease the interchain magnetic interactions.

Crystals of [K(18-crown-6)][$Mn(bpy)Cr(ox)_3$] (**1**) were obtained by slow diffusion of a methanolic solution of [K(18-crown-6)]$_3$[$Cr(ox)_3$] into an aqueous solution of $Mn(bpy)Cl_2$.[1] It is important to point out that this compound can only be obtained by slow reaction. Analogous bulk reactions yielded rapid precipitation of insoluble products different from **1**, kinetic products that have to be characterized yet.

[K(18-crown-6)][$Mn(bpy)Cr(ox)_3$] crystallizes in the $P2_12_12_1$ orthorhombic space group.[2] It is built by neutral layers formed by anionic $[Mn(bpy)Cr(ox)_3]^-$ oxalate-bridged bimetallic chains and cationic $[K(18\text{-crown-6})]^+$ complexes (Fig. 1). The bimetallic chains are composed by $[Cr(ox)_3]^{3-}$ complexes and Mn^{II} ions bridged through bidentate oxalate ligands. Each Cr^{III} center presents regular octahedral coordination geometry, with all Cr–O distances within a 0.01 Å range of each other. The octahedral Mn^{II}centers are chelated by two oxalate bridging units and one 2,2′-dipyridyl molecule. There is also little distortion from perfect octahedra, with slightly longer Mn–N distances (2.224 Å for 2.155(3) Å for the shortest M–O distance) and bite angles close to 73° for the chelating bpy. The metal centers along a chain possess opposite chirality, with Cr centers adopting Λ configuration, and all Mn centers adopting Δ configuration. Since there is only one crystallographically independent position for the Mn and Cr centers, this means that all Cr and Mn centers in a single crystal possess identical configuration, since **1** crystallizes in a chiral space group.

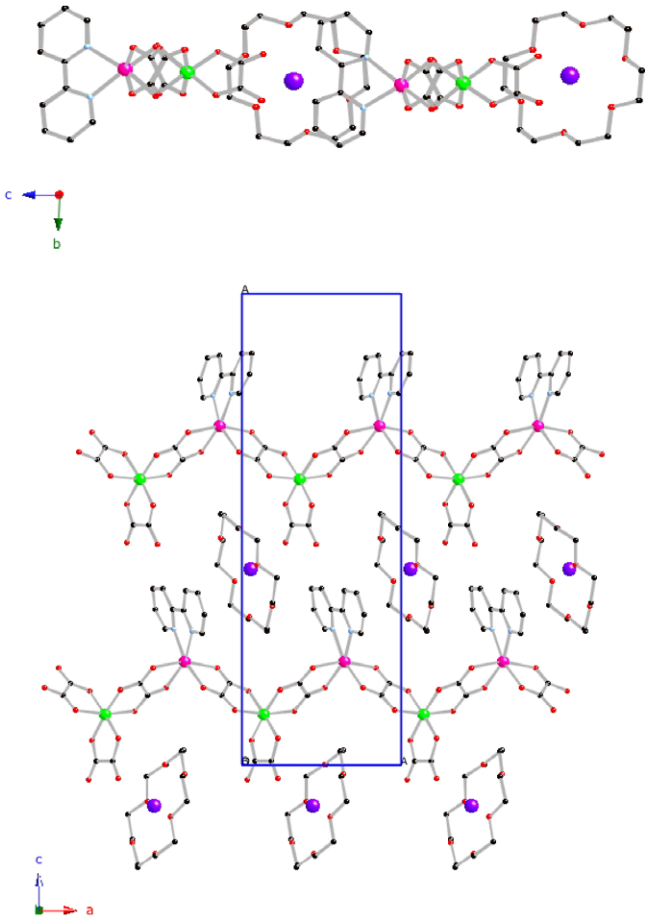

Fig. 1. View of the structural units packing of **1** along the *a* axis (top) and of the structure of the anionic chains in the *ac* plane (down): Cr, green; Mn, pink; K, purple; O, red; C, black. (For interpretation of the references in colour in this figure legend, the reader is referred to the web verison of this article.)

This natural resolution has to be related to the special packing of these chains in the crystal (Fig. 1). Given one chain, all bpy ligands point towards the same direction, with the cations located on the opposite side of the chain, at an intermediate distance to two terminal adjacent oxalate groups, and occupying the holes left by these two oxalate ligands and two bpy ligands from the adjacent chain. The potassium atoms slightly deviate from the crown ether mean plane, as a result of a stronger electrostatic interaction to one of the terminal oxalate ligands (O_{ox}–K = 2.687 Å). For this effective packing all chains need to adopt the same configuration.

There are important differences in comparison to the analogous $[Mn(H_2O)_2Cr(ox)_3]^-$ chain [13], where both enantiomers present show alternating chirality by pairs (–ΔΔΛΛ–) along the chain. The strong hydrogen bonding between chains in the latter compound has been destroyed in this new case by the inclusion of the bpy ligand

[1] Single dark blue crystals were prepared by the slow layering of a 10 mL water solution of $MnCl_2 \cdot 4H_2O$ (0.198 g; 1 mmol) and 2,2′-dipyridyl (0.156 g; 1 mmol) into a 15 mL methanolic solution of [K(18-crown-6)]$_3$-[$Cr(ox)_3$] (0.751 g; 1 mmol). After a few days the prismatic crystals which grew in the interphase were hand collected, washed thoroughly with methanol and dried in air. $KMnN_2O_{18}CrC_{28}H_{32}$ (M_W = 830.6) *Anal.* Calc. (found) for **1**: C, 30.95 (40.49); H, 3.85 (3.88).

[2] Crystal data for **1**. Data were collected with a Nonius KappaCCD diffractometer using graphite monochromatic Mo Kα radiation (λ = 0.71073 Å) at 293 K. The structure was solved by direct method (SIR97) followed by Fourier synthesis, and refined on F^2 (SHELXL-97). The non-hydrogen atoms were refined anisotropically. $KMnN_2O_{18}CrC_{28}H_{32}$, M_W = 830.6, orthorombic, $P2_12_12_1$, a = 9.0510(2) Å, b = 14.4710(3) Å, c = 26.8060(8) Å, V = 3510.97(1) Å^3, T = 293(1) K, Z = 4, ρ_{calc} = 1.571 g/cm^3, $F(000)$ = 1704, μ = 0.868 mm^{-1}, 6328 reflections (R_{int} = 0.000), 2θ max = 54.96°, $R(F)$ = 0.0505 and $Rw(F^2)$ = 0.1073 for 4575 reflections [$I > 2\sigma(I)$].

occupying the position of water molecules. Now the shortest M–M distance is 7.847(1) Å, instead of 6.897(1) Å. The absence of H bonding and longer interchain distances provides better magnetic isolation of the chains in the crystal.

DC magnetic measurements were performed on hand collected grained single crystals between 2 and 300 K under an applied field of 100 G. The $\chi_m T$ product value at 300 K is 6.04 emu K mol^{-1} (Fig. 2), it remains almost constant while the sample is cooled from room temperature down to 150 K, and then it starts to increase exponentially, going over 35 emu K mol^{-1}at 2 K. This fast increase corresponds to an abrupt jump in the $\chi_m$versus T plot. Experimental data in the 50–300 K interval can be fitted to a Curie–Weiss law, with a Curie constant of 5.95 emu K mol^{-1}, in good agreement with the expected spin-only value of 6.25 emu K mol^{-1} ($g \approx 1.95$) corresponding to the sum of the contributions of a Cr^{III} ($S = 3/2$) and a Mn^{II} ($S = 5/2$) ion. The sign of the θ value (+3.78 K) is indicative of the presence of ferromagnetic interactions between the metallic centers through the oxalate bridging ligands. There is no sign of magnetic ordering for **1** above 2 K. The data can be fitted in the 2–300 K range to the equation developed for a Heisenberg 1D chain with alternating spins (a mean g value for both the ions was used for the model) [15]. The obtained results are very satisfactory (Fig. 2) giving a g value of 2.08(2) and a J constant equal to +7.8(7) cm^{-1}. The sign and order of this constant corresponds fairly well with previously reported values in other oxalate-bridged Mn–Cr compounds [16]. As previously observed, the nature of the magnetic exchange involving Mn–Cr ions bridged through an oxalate ligand in its bis-chelating form is ferromagnetic.

The field dependent magnetization of **1** at 2 K (Fig. 3) confirms the ferromagnetic exchange between metallic centers along the chain. The M value increases rapidly at very low fields reaching a 7.73 μ_B value at 5 T, in excellent agreement with the expected value for a parallel alignment of the two interacting spins (8 μ_B).

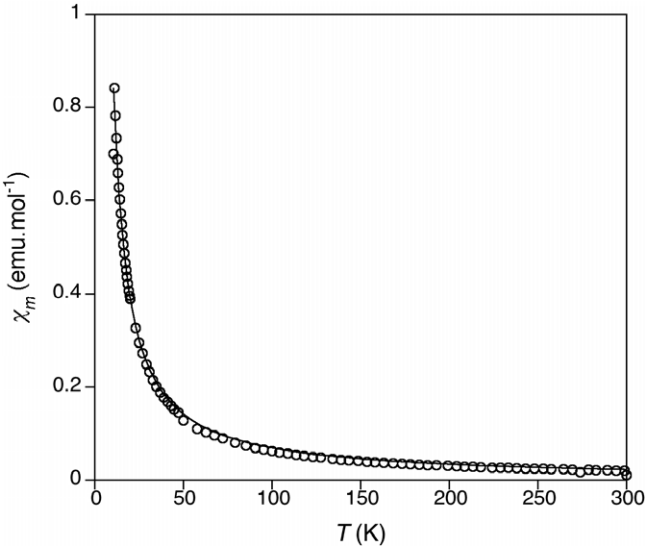

Fig. 2. Thermal dependence of the χ_m value for **1** with the best fitting to a 1D bimetallic Heisenberg chain model in the 2–300 K range.

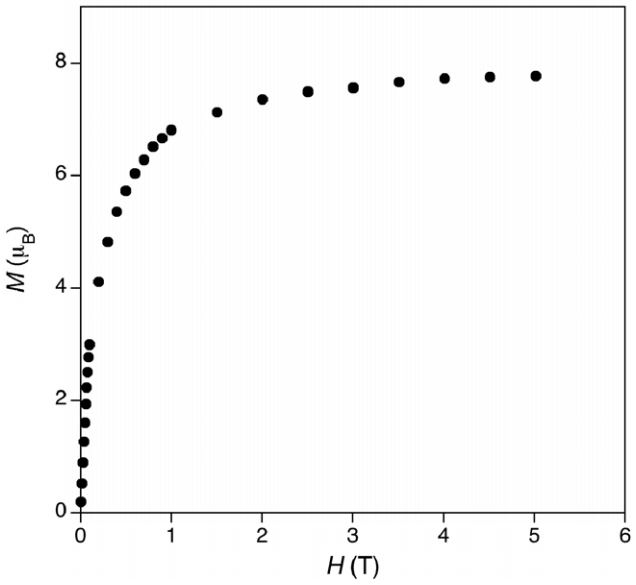

Fig. 3. Field dependence of the magnetization at 2 K for **1**.

In conclusion, we have prepared and characterized the oxalate bridged bimetallic chain [K(18-crown-6)][Mn(bpy)-Cr(ox)$_3$] (**1**). Magnetically, it behaves as a quasi-1D Heisenberg system because, structurally, the introduction of organic capping ligand leads to a good enough magnetic isolation. Nevertheless, the ferromagnetic chains do not show "single-chain magnet" behavior, [17] but rather behave as a ferromagnetic chain, down to 2 K. This same strategy can now be extended to other metals to increase the magnetic exchange and the magnetic anisotropy, both key parameters for the appearance of relaxation phenomena.

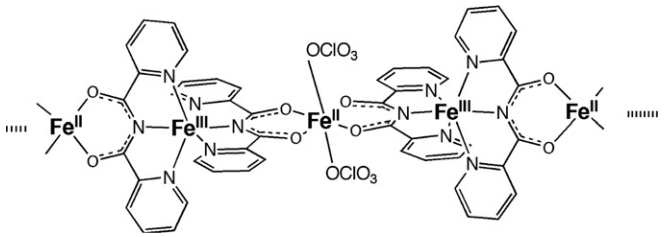

Fig. 1. Structure of high-spin Fe(II)/low-spin Fe(III) alternate single chain magnet **1**.

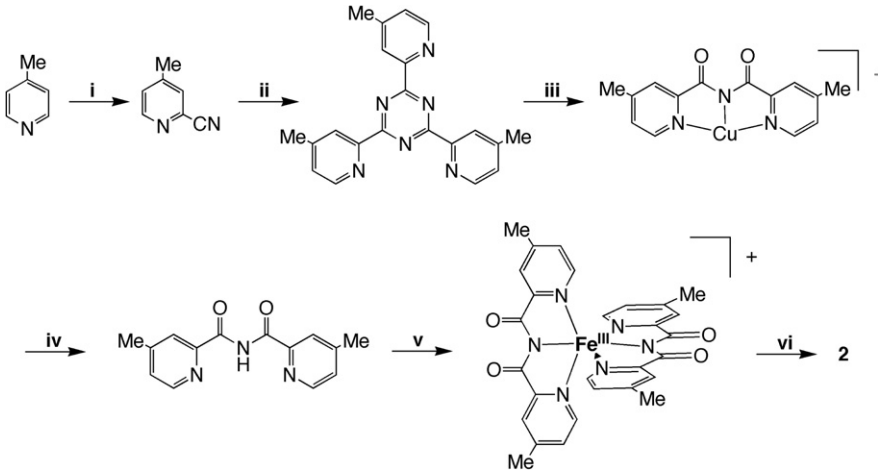
[7,8]. Hence it was desired to develop a synthetic method for derivatives of Hbpca ligand. To realize the fine-tuning of the complex ligand $[M(bpca)_2]$ and $[M'(bpca)_2]^+$, introduction of alkyl group(s) on the pyridyl rings bound to metal ion would be effective. Here, we will report the synthesis, structure, and magnetic property of the second example of high-spin Fe^{II} and low-spin Fe^{III} alternate SCM, *catena*-$[Fe^{II}(ClO_4)(H_2O)\{Fe^{III}(bmpca)_2\}](ClO_4)_2$ (**2**), which is constructed by the use of methyl-substituted Hbpca ligand, Hbmpca (bis(4-methyl-2-pyridylcarbonyl)amine).

Scheme 1 shows the synthetic scheme of complex **2**. The common synthetic procedure for Hbpca and Hbpmca (bis(2-pyrimidylcarbonyl)amine [6]) adopts the hydrolysis reaction of appropriate tris-2-pyridyltriazine or tris-2-pyrimidyltriazine under the presence of Cu(II) ions [6,9,10a]. The resulting $bpca^-$ and $bpmca^-$ ligands are obtained as copper(II) complexes formulated as $\{Cu(bpca)\}^+$ or $\{Cu(bpmca)\}^+$. Along this line, we first synthesized the 1,3,5-tris(4-methyl-2-pyridyl)triazine according to the reported method with a slight modification [10b]. 4-Methyl-2-cyanopydine was obtained by the reaction of 4-methylpridine N-oxide and trimethylsilylcyanide according to the reported procedure [10c], then the cyanopyridine was heated up to 125 °C for 24 h with the presence of a catalytic amount of sodium hydorate to form 1,3,5-tris(4-methyl-2-pyridyl)triazine by the trimerization reaction. The crude product was purified by alumina chromatography using chloroform as an eluent and yellow oil was obtained. The further purification was performed by recrystallization from heptane/dichloromethane (1:1) and nearly pure triazine was obtained as yellow crystal. The triazine was reacted with an excess amount of copper nitrate in water/EtOH solution to afford the hydrolysis reaction, and copper complex of $[Cu(bmpca)(H_2O)_2]NO_3$ (**3**) was crystallized as blue plates.[1] The free organic ligand was obtained by the treatment of **3** with an excess amount of Na_4edta in the water/chloroform mixture, and Hbmpca was obtained as pale yellow crystals. Overall yield from 4-methylpyridine was about 10%.

Mononuclear Fe(III) complex $[Fe(bmpca)_2]ClO_4$ (**4**) was formed by the reaction of iron(III) nitrate, Hbmpca and $Et_4N(ClO_4)$ in 1:2:5 reaction ratio from water/acetone solution. Fig. 2 shows the crystal structures of mononuclear complex **4**.[2] The whole structure was very similar with the reported complex $[Fe(bpca)_2]ClO_4$ (**5**) [9]. The iron(III) ion in **4** takes low-spin state in a strong ligand-field with the short Fe–N bonding of 1.955(4)–1.971(4) Å for pyridyl nitrogen atoms and 1.894(4)–1.924(4) Å for imide nitrogen atoms, respectively, showing the similar bond distances with $bpca^-$ compound (1.960(3)–1.980(3) Å for pyridyl nitrogens and 1.908(3) Å imide nitrogens, respectively). The introduction of the methyl group on pyridyl ring does not affect on the coordination of $bpca^-$ ligand.



Electrochemical properties of **4** and **5** were investigated by means of cyclicvoltammetry in nitromethane solutions (Fig. 3). Both complexes show reversible redox waves assigned to Fe(II)/Fe(III) couples. The redox potential of **4** is more positive than **5**. The presence of an electron donating methyl group at 4-position on the pyridyl ring stabilizes the trivalent iron ion. This indicates that we can control the electronic state of the central Fe(III) ion by the introduction of one or more substitutional group(s) on the coordinating pyridyl ring.

The alternating Fe(II)–Fe(III) chain complex **2** was synthesized by the reaction of **4** and $Fe(H_2O)_6(ClO_4)_2$ in nitromethane solution under nitrogen atmosphere. Black rod-like crystals were afforded for X-ray analysis, and the resulting structure of cationic part of **2** is shown in Fig. 4.[3] Complex **2** is composed of an alternating arrangement of $\{Fe(bmpca)_2\}^+$ units and$\{Fe(ClO_4)(H_2O)\}^+$ units to form infinite chains. The crystal involves two independent pairs of $\{Fe(bmpca)_2\}^+$ and $\{Fe(ClO_4)(H_2O)\}^+$ units with the similar structures. High-spin Fe(II) ion in the $\{Fe^{II}(ClO_4)(H_2O)\}$ unit is in an elongated octahedoral geometry with four equatorial carbonyl oxygen atoms (Fe–O = 2.059(3)–2.075(2) Å) and two axial oxygen atoms from one perchlorate anion and a water molecule with a distances of 2.144(3) Å and 2.154(3) Å for the former and 2.123(3) Å and 2.131(3) Å for the later, respectively. The π-donor character of $O_{carbonyl}$ splits the t_{2g} orbitals into e_g and b_{2g} orbitals, and therefore the orbital angular momentum should be quenched as found in **1**. The ground state of the Fe(II) ions is $^5B_{2g}$ rather than $^5T_{2g}$. This coordination geometry again leads to a uniaxial zero-field splitting parameter of $D > 0$. Thus the $S = 2$ spin on the Fe(II) ions would have a hard-axis type anisotropy along the

[1] Crystallographic data for **3**: triclinic, space group $P\bar{1}$, $a = 6.6921(7)$ Å, $b = 15.6931(17)$ Å, $c = 18.756(2)$ Å, $\alpha = 84.596(3)°$, $\beta = 85.398(3)°$, $\gamma = 80.204(3)$ °, $V = 1928.2(4)$ Å^3, $T = 100$ K, $Z = 2$, 19366 reflections were observed, of which 8827 were independent, $R_1 = 0.0463$ ($I > 2\sigma(I)$) and $wR_2 = 0.1223$ (all data) for 527 parameters.

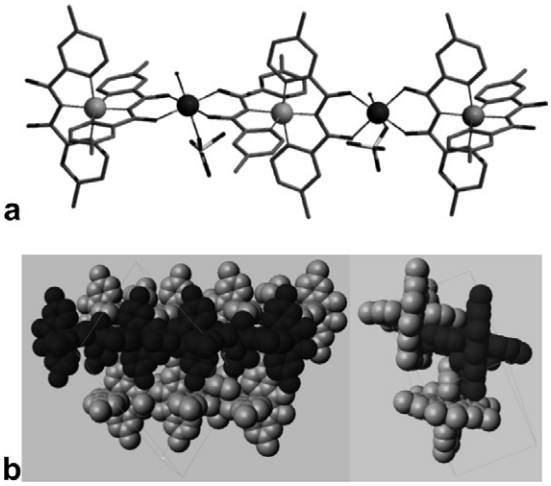

Fig. 4. (a) Crystal structure of the chain complex **2**. Black and gray spheres represent Fe(II) and Fe(III) ions, respectively. Packing diagram of **2**.

O_B–Fe–O_B axis, or easy-plane type. The shortest intra- and inter chain Fe–Fe distances were estimated as 5.2161(9) Å (Fe(II)–Fe(III)) for the former and 10.6468(12) Å (Fe(II)–Fe(III)) for the later, respectively.

The magnetic properties of complex **2** were studied using a polycrystalline sample. The temperature dependence of $\chi_m T$ for **2** is clearly consistent with the presence of ferrimagnetic interactions (Fig. 5). As the temperature was lowered, $\chi_m T$ gradually decreased to a minimum value at 18 K (2.79 emu K mol^{-1}), and then abruptly increased to a maximum value at 1.8 K (19.1 emu K mol^{-1}). The temperature at which the $\chi_m T$ reaches the minimum is slightly lower than that of **1** (22 K), indicating that the magnetic interaction between adjoining Fe(II)–Fe(III) ions would be weaker than **1**. No evidence for long-range ordering was observed even at the lowest temperatures studied.

Ac magnetic susceptibility measurements were performed to observe the frequency dependence of χ''_m (Fig. 5b). Complex **2** shows a typical SCM behavior below 3 K; with cooling, the in-phase signal χ'_m increased in accordance with the Curie law to a maximum value and then decreased, eventually approaching zero, with the corresponding appearance of the out-of-phase signal χ''_m. As the frequency was swept from 1000 Hz to 5 Hz, the temperature of maximum χ''_m shifted from 2.3 K

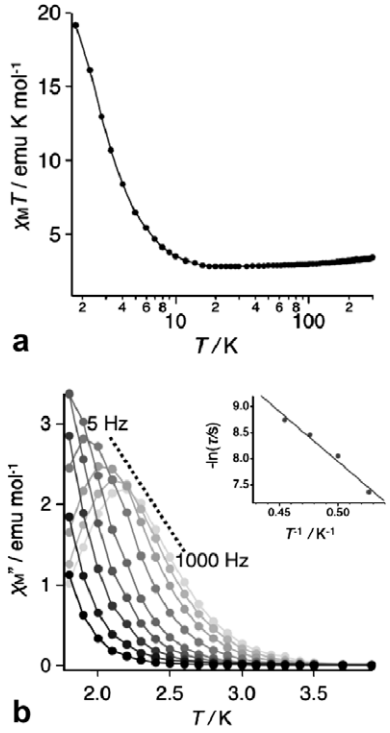

Fig. 5. (a) Temperature dependence of $\chi_m T$ for **2**. (b) Temperature dependence of χ''_m. inset: Arrhenius plot.

(1000 Hz) to 1.9 K (50 Hz). The temperature for the maximum χ''_m in the lower frequency fields were lower than this temperature range. At fixed temperatures between 1.8 and 1.9 K, semicircle Cole–Cole plots were obtained with small α parameters in the range of 0.24(7)–0.26(1), which indicates that relaxation occurs via a single process. This typical SCM behavior is again attributed to a mutually orthogonal arrangement of the Fe(II) molecular axes inducing Ising interactions along the chain observed in **1** [3]. The relaxation times $\tau(T)$ extracted from the ac susceptibility were used to construct an Arrhenius plot, giving an estimated activation energy Δ of 19(1) K. This Δ value is smaller than that of **1** reported as 27(1) K, reflecting the smaller Fe(II)–Fe(III) interaction suggested by the temperature dependence of dc susceptibility. The detailed investigation of magnetic interactions is now on undergoing.

In conclusion, we developed a synthetic route for substituted bpca$^-$ ligands and synthesized the second example of Fe(II)–Fe(III) alternate single chain magnet by the introduction of methyl group on the coordinating pyridyl rings. This twisting easy-plane system is unique since which exhibits easy-axis anisotropy over the whole chain, giving rise to slow magnetization reversal despite single-ion anisotropy of the constituent Fe(II) ions with easy-plane [4,11]. The substitution of alkyl group on bpca$^-$ ligand is very effective to control the SCM behavior since the introduction of methyl group affects on the dc susceptibility as well as the activation energy Δ.

Supplementary material

CCDC 622578, 622579 and 622580 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

than benzoic acid which was added slowly into 30 mL of a toluene suspension of $Mn(O_2CCH_3)_2$ (1.00 g, 5.78 mmol) with constant stirring. The solution changed from yellow to dark brown after 5 h reaction at elevated temperature. The pale pink product was washed with toluene and dried under vacuum (yield, 1.64 g). Elemental analysis (duplicate) was performed at Galbraith Laboratories, Inc. (Knoxville, TN). *Anal.* Calc for $C_9H_8O_{4.1}Mn_1$: C, 45.67; H, 3.41. Found: C, 44.12; H, 3.26%.

2.2. Crystallography

The structure was examined by X-ray powder diffraction collected using a Phillips PW3040 X'pert-MPD Multipurpose Diffractometer in Bragg–Brentano geometry (Cu Kα radiation) with a Cu monochromator, programmable divergence, scatter and receiving slits, and soller slits on both incident and diffracted beams.

2.3. XANES

X-ray absorption near edge structure (XANES) data were collected at the Center for Advanced Microstructures and Devices synchrotron radiation facility using the X-ray microprobe double crystal monochromator beamline. The monochromator is of the Lemonnier type equipped with a pair of Ge(220) crystals [12]. Mn(0) foil was used to calibrate the energy scale of the monochromator. The energy threshold E_0 of the Mn(0) metal foil was determined from the first inflection point in the XANES spectrum (6539 eV). XANES spectra of MnO and Mn_2O_3 powders were measured to place the K edge positions and to determine the chemical shift of these oxides relative to Mn(0) foil in order to explore the valency of compound **1**. A thin powder layer of these oxide powders and compound **1** were prepared on a piece of Kapton tape for the XANES measurement. All measurements were performed in a transmission mode by using an ionization chamber filled with 1 atm. air for MnO and Mn_2O_3 samples. XANES spectra of the pristine form of **1** was acquired while holding the sample in a dry nitrogen purged sample container and later was exposed to atmosphere for periods of 10 min and 2 days to explore the effect of ambient background. A linear background was subtracted and normalization of spectra to **1** at 6640 eV photon energy was performed using commercially available Athena software [13]. XANES spectra were scanned with −100; −20; +40; +200 eV intervals relative to Mn K edge with a step of 2, 0.4, 1 eV per respective energy interval and an integration time of 1 sec. per step.

2.4. Magnetometry

The magnetic data were collected with a Quantum Design PPMS using the VSM option for M(H,T) measurements and the ACMS option for the in and out-of-phase susceptibility determinations. Calibrations were competed using DyO and Pd references. Custom nylon sample holders and pharmaceutical gel caps used for holding sample powders demonstrated less than 10^{-8} emu diamagnetic background; the data presented are without diamagnetic correction.

3. Results and discussion

3.1. Physical structure

Powder diffraction of **1** (Fig. 1) is found to superpose on the powder diffractogram of **2**, the single crystal reported in [11], with additional peaks whose origin remains under investigation. A paper detailing the synthesis and complete structure of **1** is forthcoming. Because of the good diffraction fit, we propose and will assume through the remainder of this paper that the honeycomb structure solved by Liu et al. (Fig. 2) is the foundational structure with additional coordinates (e.g., H_2O, μ-O) causing the extraneous peaks. Such extra peaks do not fit with any known manganese or manganese oxide impurity like phase; also, background magnetization and NMR studies of the starting materials showed paramagnetic behavior with coercive crossings of less than one oersted indicating clean starting materials.

With regard to explaining the low temperature magnetic behavior, it is important to note certain key features of the structure: (1) the Mn_{12} hexagon rings with carboxylate bridging; (2) the two-dimensional honeycomb sheets built from the edge sharing Mn_{12} hexagons; and, (3) the benzyl, methyl and possible water positions between neighboring sheets. Such structural information combined with the valency is critical in explaining the subtle differences between static and dynamic structural reorientations that form the basis for each magnetic transition. An example of a subtle structural change can be the temperature dependence of the bond angles between two manganese through oxygen. This effect, supported in general by Goodenough–Kanamori theory [14], has been shown to invert the exchange interaction from ferromagnetic to antiferromagnetic with as little as a 10° angle change [9].

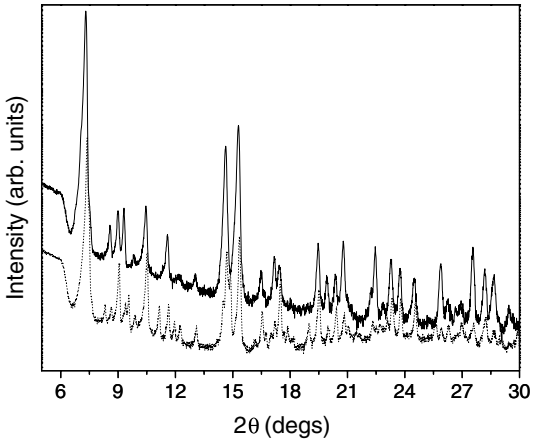

Fig. 1. Powder diffraction of **1** (---) and **2** (—) demonstrating the superposition of **1** on **2** plus extraneous peaks.

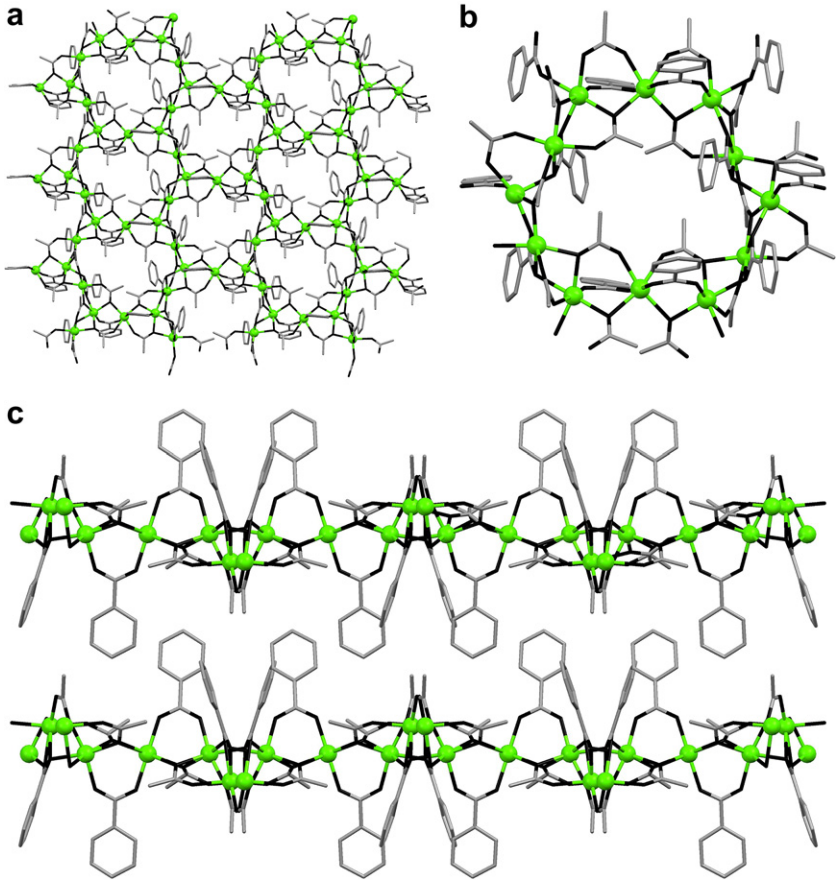

Fig. 2. Nominal structure of **1** showing the (a) top view of the edge sharing hexagon rings; (b) top view detail of one ring; and (c) side view showing layering, alignment and interplane ligands. *Note*: the benzyl rings in (c) are more than 10 Å apart and do not π-stack.

3.2. Oxidation state

XANES spectroscopy, which is highly sensitive to local chemical and thus the electronic environment of the excited atom, has been used to determine the formal oxidation state of compound **1** (pristine form). The XANES data, shown in Fig. 3, present spectra from compound **1** (pristine form) relative to the Mn(II) and Mn(III) standards. It is qualitatively obvious that the K-edge of compound **1**, located at 6548 eV, lies between the 2+ (6544 eV) and 3+ (6552 eV) states, indicating a mixed valence state. Exposure of **1** to atmosphere did not significantly change its valence states (not shown) as determined by the superposition of K edges at 6548 eV. The attempt to reproduce the compound **1** spectra by a linear combination fit of references spectra MnO (II) and Mn_2O_3 (III), using standard fitting procedures in Athena [13], reveals a quantitative valence split of 71 ± 12% Mn(II) and 29 ± 12% Mn(III). 13 eV below and 10 eV above the K edge of compound **1** were chosen as a fitting range in the fitting procedure. Given this result and the chemical anaylsis (vide supra), it is speculated that the complex has the following nominal formula "$Mn(II)_{0.8}Mn(III)_{0.2}(OAc)(OBz)(\mu\text{-}O)_{0.1}$" whereby oxygen reacts with neighboring Mn(II) metal centers to give Mn(III)-O-Mn(III) μ-oxo bridges.

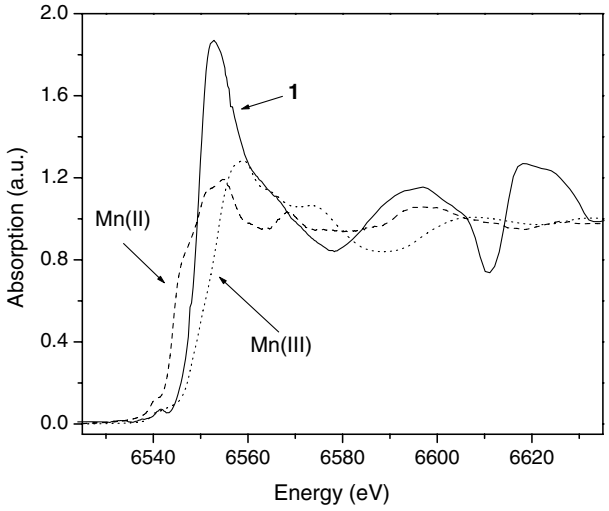

Fig. 3. XANES spectra of MnO, Mn_2O_3 and 1. K edge position of 1 (—) located between the K edge positions of MnO (– – –), and Mn_2O_3 (----) indicates a mixed valence state.

3.3. Magnetic structure

The low temperature magnetic behavior of **1** contains various transitions that exist as a function of the manganese valency, the intramolecular exchange due to the

honeycomb structure with carboxylate mediation and the interplanar exchange mediated by the benzyl, methyl, hydrogen and possible H_2O pathways. We discuss the exchange type and assign the magnetic character in various temperature and applied field regions from ac and dc extraction methods.

3.3.1. Temperature dependent magnetization and susceptibility

The magnetization (M), in-phase susceptibility (χ') and out-of-phase susceptibility (χ'') of **1** (Fig. 4) demonstrate three distinct magnetic states; the first from 1.9 to 2.1 K is labeled A; the second from 2.1 to 7.9 K denoted B; and 7.9 K onward labeled C. Also shown is the inverse susceptibility $\chi^{-1}(T)$ and susceptibility temperature product $\chi T(T)$ in Fig. 5 which reveal Weiss constants which reverse sign at $T = 2.3$ and 11 K as well as respective slope changes $d(\chi T)/dT$ between the regions A, B and C. In regions B and C, the Weiss constants are $\theta = +7$ and -50 Oe. Such combined pieces of evidence, along with the mixed Mn(II)/Mn(III) valency, lead to suggest that the low temperature regions A, B and C are represented by ferrimagnetic ordering (AFM exchange), ferromagnetic ordering and back to ferrimagnetic ordering. Further support for this conjecture is demonstrated in Fig. 6 where the coercivity versus temperature is shown to approach zero at 10 K, representative of the ferromagnetic to ferrimagnetic transition point (7.9 K). Low temperature transition behavior of this kind is common among the Mn-carboxylate systems where the interplanar ligand mediated exchange can play a vital role [7]. In addition to the ferrimagnetic ordering could be antiferromagnetic spin canting as observed by Price et al. [3] and/or an order/disorder transition that will be discussed further with regard to applied field measurements.

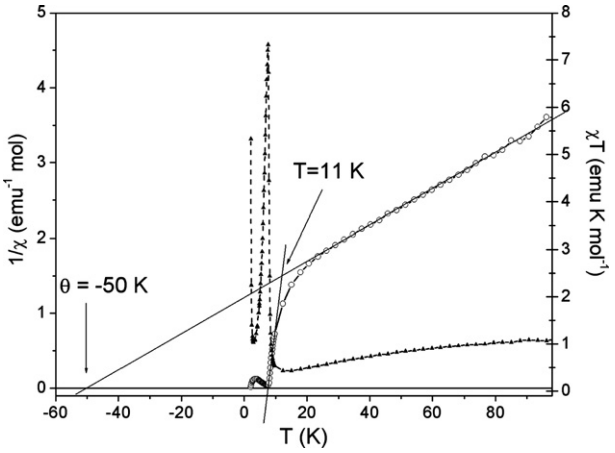

Fig. 5. Inverse susceptibility (○) and the susceptibility temperature product (▲) are shown as a function of temperature for **1** with an applied field of 10 Oe, in the non-field cooled configuration at $v = 7919$ Hz.

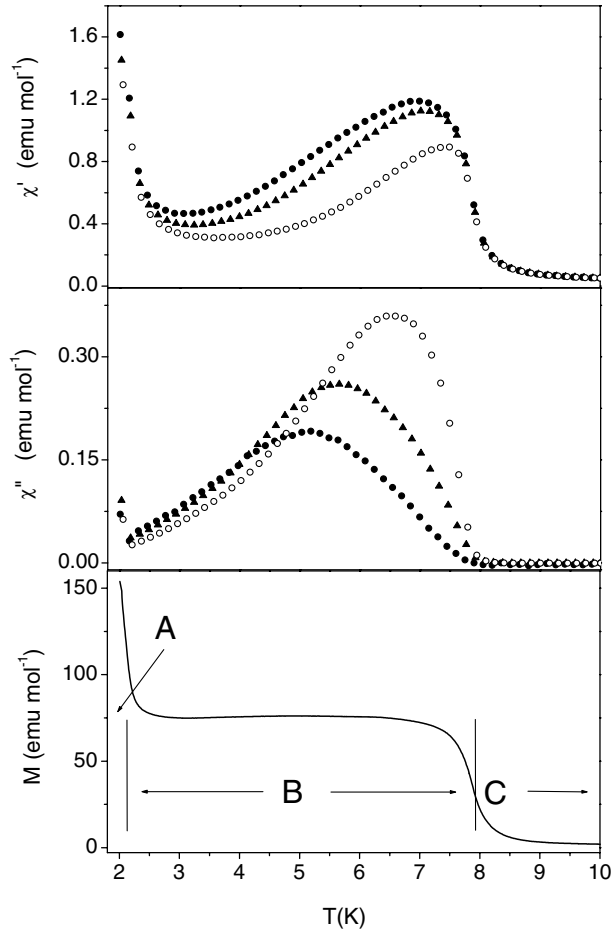

Fig. 4. Temperature and frequency dependence of the (top) in-phase susceptibility and (middle) out-of-phase susceptibility and (bottom) magnetization of **1**. The three frequencies are represented as (●), (▲) and (○) for $v = 17$, 727 and 7919 Hz. All measurements were completed with $H_{dc} = 0$ Oe and the susceptibility at $H_{ac} = 3$ Oe.

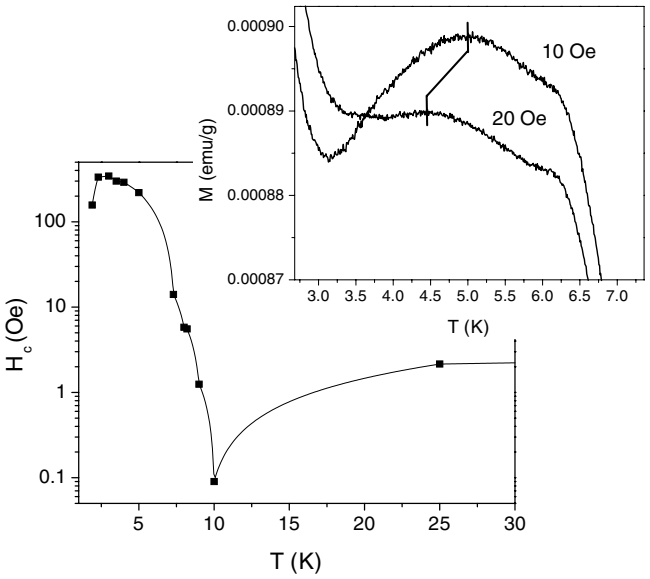

Fig. 6. Coercivity and (inset) magnetization as a function of temperature. Both measurements were completed under non-field cooled conditions. It is interesting to note the trend in coercivity with the magnetization in Fig. 4 and exchange field in Fig. 8.

3.3.2. Spin-glass behavior

The inset to Fig. 6 demonstrates a shift in the peak position in the ferromagnetic region B, where the zero-field-cooled (ZFC) magnetization was measured as a function of temperature and applied field. The peak shift with applied field is similar to the results found for spin glasses, wherein the glass transition temperature decreases as higher fields are applied. Fig. 8 shows a concavity change in the FC data through the temperature range of 6–8 K, that is not observed in the ZFC curve, and inflection in either susceptibility component is absent as well. Such behavior is indicative of an unthawing glass or superparamagnetic transition wherein the magnetocrystalline anisotropy is lifted [15]. Lastly, both the real and imaginary components of the susceptibility in the 2.1–7.9 K range are frequency dependent wherein as the applied field frequency increases, so does the transition temperature indicating glass like behavior [15]. The general superparamagnetic or glassy behavior has been observed by others for the Mn-carboxylate based complexes [3,4]. It is because of the combined frequency dependence (Fig. 4) and field dependence (Fig. 6 inset) that we attribute glass or superparamagnetic behavior rather than domain wall motion for frequency dependence only.

3.3.3. Metamagnetic transition

Metamagnetism is a transition phenomena that can occur by application of field, temperature or pressure and is usually recognized by dramatic changes in the magnetization or susceptibility [16e]. Fig. 7 demonstrates the magnetization and susceptibility components as a function of applied field at 1.7 K; from Section 3.3.1 the zero-field ordering was found to be ferrimagnetic up to 2.3 K, where indeed the step behavior of M(H) vanishes. In the low field isothermal (1.7 K) region (Fig. 7a) an abrupt increase in the magnetization is observed at ~200 Oe and continues to saturation at 4 T. We posit that this field value marks an intramolecular transition from ferrimagnetic to weak-ferromagnetic or spin-canted ferrimagnetic order. However, a lack of either susceptibility component in this 200–40000 Oe range does not directly support the above claim, raising even more questions as to the exact nature and type of transition. A similar metamagnetic effect was observed by Price et al. [3] for $\{[Mn(\mu\text{-}OH)(\mu\text{-}OAc)_2]\cdot HOAc\cdot H_2O\}_n$ linear chains wherein the transition was assigned as antiferromagnetic to spin-canted antiferromagnetic and that a ferromagnetic alignment was not observed below 5 T, helping to support the above postulate.

With respect to the magnetization climb from 6 to 9 T we can only remark that this response is rigorously unexplainable, especially given the negative concavity. Even grossly speculative arguments such as lifting of interlayer anisotropy [4] or quenched angular momentum are difficult to invoke, although we should expect that a transition from canted ferrimagnetic to ferromagnetic will be convoluted at high field due to their superposition. One qualitative

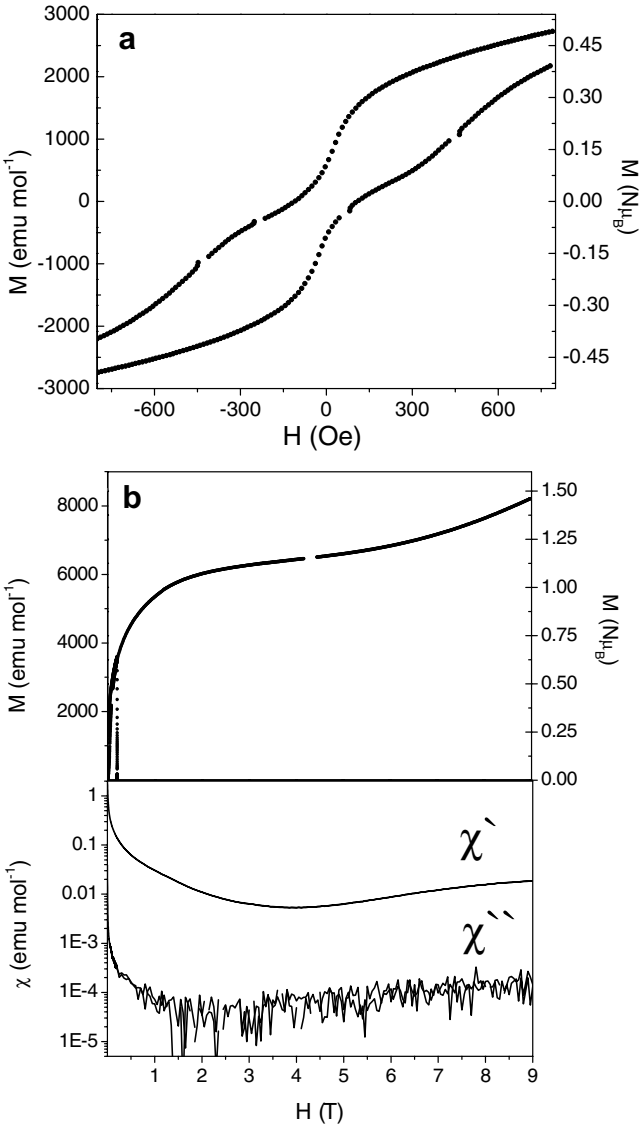

Fig. 7. Magnetic field dependence of the magnetization, in-phase and out-of-phase susceptibility of **1** completed at $T = 1.7$ K. (a) Shows the low field dependent metamagnetic transitions and (b) the high field.

observation from this work, is an inflection point at 6 T, which in previous work on the canted antiferromagnet $[Mn(bipyridine)(N_3)_2]_n$ [17] was attributed to the beginning of a spin flop transition, but is still not enough to account for such a high moment above manganese. This inflection point is also supported by the rise in susceptibility beginning at 4 T (Fig. 7). Furthermore, in such two-dimensional systems and especially in the manganese carboxylate based materials, canted antiferromagnetism at low temperatures is common. Lastly, it is interesting to note the difference in the minimum observed at 2 versus 4 T for the out-of-phase versus in-phase susceptibility components, which may suggest frustration is further complicating these magnetization dynamics. Higher fields, lower temperatures and varying transition metal types, may help understand this rather unusual transition.

3.3.4. Exchange anisotropy

Exchange anisotropy was first reported in 1956 [18] when the field dependent magnetization of ferromagnetic cobalt covered by a thin antiferromagnetic cobalt oxide, demonstrated a non-symmetric hysteresis loop about zero field. Since then, an entire sub-field of magnetism has been devoted to understanding this rather elusive effect [19]. The root of exchange anisotropy is not yet fully understood; the present and most simple theory holds that exchange anisotropy is a phenomenon induced by interfacial pinning, typically between a ferromagnet and antiferromagnet or by a ferromagnet and some structural defect [19]. For organic-based magnets, this phenomenon has rarely been reported and is attributed to intermolecular ferromagnetic exchange between two intramolecular antiferromagnetic Ni or Mn single molecular magnets [20]. The evidence which led to a determination of exchange anisotropy in the single molecular magnets was a non-symmetric field dependence of the resonant quantum tunneling of the magnetization.

In the present work, we indeed find a hysteresis loop whose center is shifted from zero and whose magnitude (H_{ex}) is temperature dependent (Fig. 8). Because exchange anisotropy exists due to ferromagnetic/antiferromagnetic interaction, the value of H_{ex} should provide a means by which to measure the interlayer exchange. From Section 3.3.1, we know above 7.9 K, that the intrasheet exchange is antiferromagnetic with the intersheet exchange being ferromagnetic at all temperatures. The enhanced exchange bias or anisotropy field H_{ex} as observed in Fig. 8 follows the temperature trend of the magnetization. Although this response is rather crude and weak, compared with standard inorganic exchange anisotropy, it nevertheless does provide a means by which to gauge intersheet exchange coupling and is worth further measurement and consideration.

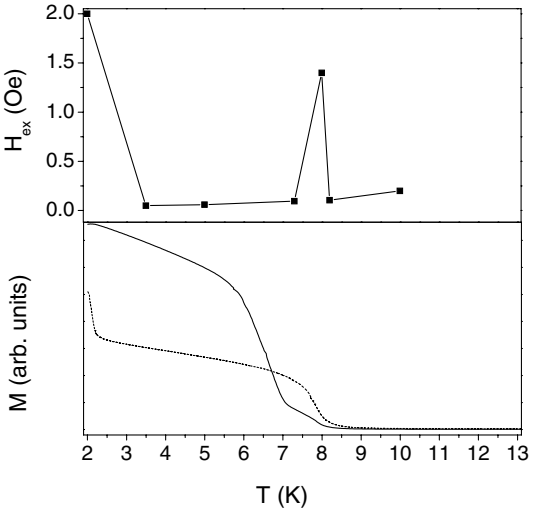

Fig. 8. Exchange bias (H_{ex}) and magnetization as a function of temperature. The dashed curve (---) represents the non-field cooled while the solid line (—) is the field cooled magnetization. *Note*: the concavity change between 6 and 8 K in the field cooled data which is not observed in the non-field cooled curve is attributed to a thawing (magnetocrystalline anisotropy lifting) of the moments rather than an exchange transition.

3.3.5. Magnetic properties of other honeycomb systems

A number of different honeycomb structures have been reported that contain 6 [21] or 12 [22] atoms per edge sharing hexagon as well as lower symmetry sheet structures [16]. A general trend in the low temperature region is the ferromagnetic to antiferromagnetic exchange transition (positive to negative Weiss behavior) which for single valency result in a finite moments by canted antiferromagnetic ordering. Other trends include quick rises to saturation (within tens of oersted), strong communication within the layers and weak interlayer exchange. Such strong antiferromagnetic exchange due to the increased dimensionality was highlighted by Kahn [22a] and encouraged as a means by which higher ordering temperatures and technologically relevant materials might succeed. It is therefore our intention to endeavor to understand how the intra and interlayer exchange may be enhanced so that high temperature remnant behavior may be applied.

4. Conclusions

Three distinct temperature transitions and three applied field dependent transitions have been shown to occur in the low temperature region of a manganese mixed carboxylate complex we are speculating as "$Mn(OAc)(OBz)(\mu\text{-}O)_{0.1}$". XANES K edge determination finds a mixed valence of 71% Mn(II) and 29% Mn(III). Explicity, transitions from ferrimagnetic to ferromagnetic to ferrimagnetic are observed in the region from 1.9 to 8.5 K as observed by temperature dependent magnetization and susceptibility. Frequency dependence of the susceptibility reveals relaxation effects typically attributed to glass like behavior. Metamagnetic behavior was also seen at 2.3 K and below as is explainable within a field dependent transition model where the ferrimagnetic moments rotate at a strong enough field to align parallel, although field greater than 6 T result in an unexplainable 7.3 μ_B moment. Lastly, a crude trend is found in the coercivity offset with temperature that is attributed to exchange anisotropy and assigned as a monitor of the interlayer exchange which will be further investigated. Overall, this carboxylate-mediated layered system opens the door for systematic synthesis to help understand antiferromagnetic intralayer exchange and interlayer ligand-mediated exchange through variation of the transition metal types, valencies and ligands to vary the spin–orbit coupling, number of available ground states and nearest-neighbor spacing. Polaronic incorporation to enhance the state of metallicity [22d,23] may provide application enhancement in addition to the physical structure (two-dimensionality) and will be a focus of future research.

$$\mathscr{H}_{\mathrm{U}} = J_1 \sum_i^6 (\mathbf{s}_{2i-1}\cdot\mathbf{S}_{2i} + \mathbf{S}_{2i}\cdot\mathbf{s}_{2i+1}) + D\sum_i^6 (\mathbf{S}_{2i}^z)^2$$

$$\begin{aligned}\mathscr{H}_{\mathrm{T}} = \mathscr{H}_{\mathrm{U}} + J_3 \sum_i^3 [\{&(1-\alpha)(\mathbf{s}_{4i-3}\cdot\mathbf{S}_{4i-2})(\mathbf{S}_{4i-2}\cdot\mathbf{s}_{4i-1}) \\ &+(1-\alpha)(\mathbf{s}_{4i-1}\cdot\mathbf{S}_{4i-2})(\mathbf{S}_{4i-2}\cdot\mathbf{s}_{4i-3})\} \\ &+\{(\mathbf{s}_{4i-1}\cdot\mathbf{S}_{4i})(\mathbf{S}_{4i}\cdot\mathbf{s}_{4i+1}) + (\mathbf{s}_{4i+1}\cdot\mathbf{S}_{4i})(\mathbf{S}_{4i}\cdot\mathbf{s}_{4i-1})\}\end{aligned}$$

$$\mathscr{H}_{\mathrm{F}} = \mathscr{H}_{\mathrm{U}} + J_2 \sum_i^3 \{(1-\alpha)\mathbf{s}_{4i-3}\cdot\mathbf{s}_{4i-1} + \mathbf{s}_{4i-1}\cdot\mathbf{s}_{4i+1}\}$$

Here $\mathbf{S}_i$ ($\mathbf{s}_i$) represents the spin operator at an $S = 5/2$ ($S = 1/2$) spin site. The periodic boundary condition, $\mathbf{s}_{13} = \mathbf{s}_1$, is imposed in these models because of the ring structure of Mn_6R_6. Although $\mathscr{H}_{\mathrm{U}}$ with $D = 0$ was proposed by Caneschi et al. [4], the single-ion anisotropy exists at $S = 5/2$ sites in general. $\mathscr{H}_{\mathrm{T}}$ contains the three-spin interaction and the bond alternation of J_3. Kostyuchenko et al. proposed $\mathscr{H}_{\mathrm{T}}$ with $D = 0$ and $\alpha = 0$ [5]. The third one contains the interaction between NN radicals J_2 and the bond alternation of J_2. $\mathscr{H}_{\mathrm{F}}$ with $D = 0$ and $\alpha = 0$ was proposed by present authors [7–9].

In spite of the zero-point spin deviation, the local spin density in the ferrimagnetic spin system usually remains to be finite. To determine the effective spin model for such a system, we propose a new criterion that the model should reproduce the spatial configuration of the local spin densities as well as the low-energy excitation spectrum. The spin densities are integrated in a separated area and assigned to "a magnetic unit" in a reference calculation. We call this method the spin density reference (SDR) method. The reference is given by the hybrid density-functional-theory calculation (UB3LYP) in this work. This technique is sufficiently accurate for calculating the spin density of NN-radicals [11,12]. The computation is performed by the GAUSSIAN-03 program packages [13]. The spin density of the spin model is calculated by the exact diagonalization based on the householder method.

To reduce the computational cost in the ab initio calculations, we consider three types of cut molecules terminated by hydrogen atoms hereafter rather than Mn_6R_6. Since the cut molecule has open ends, we adopt the open boundary condition for the corresponding spin models. The schematic pictures of these molecules are depicted in Fig. 1. The first molecule which is called MOL1 contains two NN radicals and a manganese atom. The manganese unit is determined to be a manganese atom with two hfac ligands, hereafter. The second MOL2 contains three NN radicals and two manganese units. The third MOL3 contains four NN radicals and three manganese units. Applying the SDR method to cut molecules, the spin density profile is modified depending on the shape and the size of the molecule. The obtained spin model should be valid for a rather general condition, if we can determine the effective interaction valid for cut molecules and Mn_6R_6. Actually, our result suggests that spin interactions are almost the same for MOL2 and MOL3 as shown below.

Now, we examine the validity of hydrogen termination. The terminated hydrogen atom (H0) connects to an oxygen atom (O1) in NN radical. The O1 connects to a nitrogen atom (N2) and the N2 connects to a carbon atom (C3). N2 and C3 form a pentagon on NN radical. Thus there are three parameters specifying the termination. The variable r represents the bond distance between H0 and O1. The variable a represents the bond angle formed by H0–O1–N2. The variable d represents the dihedral angle formed by H0–O1–N2–C3. We confirm the validity of hydrogen termination using the result of MOL1. The way of the termination is adjusted with respect to these parameters so that the energy minimum point is well realized.

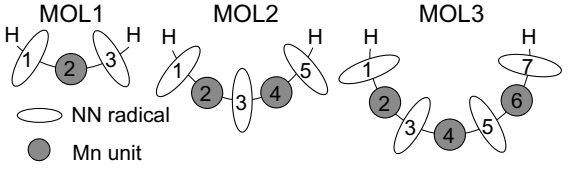

Fig. 1. Schematic pictures of cut molecules of Mn_6R_6. Gray circles represent manganese units. White ellipses represent NN radicals. The numbers written in circles or ellipses show indexes of the spin site. Each of the two ends of a molecule is terminated by a hydrogen atom.

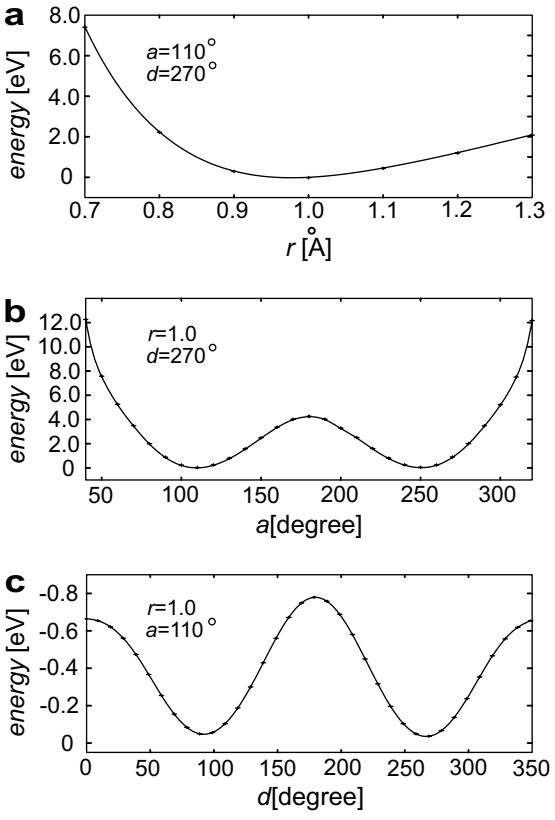

Fig. 2. The total energy of MOL1 obtained by the hybrid density-functional-theory calculation with the 6-31G(d,p) basis set. Three parameters a, r, and d are changed to find the minimum. In all figures, the energy of a configuration with $r = 1.0$ Å, $a = 110°$, $d = 270°$ is taken to be 0 eV.

Fig. 2 shows the total energy of MOL1. Fig. 2a is the result of the calculation when $a = 110°$ and $d = 270°$. In this situation, the energy minimum point exists at $r = 1.0$ Å. Fig. 2b is the result for $r = 1.0$ Å and $d = 270°$. In this situation, the energy minimum point exists at $a = 110°$. Fig. 2c is the result for $r = 1.0$ Å and $a = 110°$. In this situation, the energy minimum point exists at $d = 270°$. These results indicate that the condition of ($r = 1.0$ Å, $a = 110°$, $d = 270°$) is the most stable condition of hydrogen termination. Recall that the condition in which O2 for real Mn_6R_6 connects to the manganese atom is ($r \sim 2.1$ Å, $a \sim 129°$, $d \sim 278°$). The direction toward manganese atom from O2 is approximately the same as that given by the optimized two angles a and d. Therefore, we calculate the spin density at the condition of ($r = 1.0$ Å, $a = 110°$, $d = 270°$).

Results of the spin density obtained by ab initio calculation are shown in Table 1. In these calculations, we consider states with $S = 3/2$, $S = 7/2$ and $S = 11/2$ as the relevant spin states displaying ferrimagnetic spin configuration for MOL1, MOL2 and MOL3, respectively. The spin density at each magnetic site is calculated as the sum of the spin densities of all the atoms in each magnetic unit. The 6-31G basis sets are selected for all the atomic species. We test the effect of the polarization function included for light atoms. The 6-31G(d,p) basis and 6-31G(d) basis give approximately the same result and the polarization does not affect the spin density drastically. Now the z-component of the spin at an NN radical and that at a manganese unit are deviated from 1/2 and 5/2, respectively. The origin of this deviation is considered to be the quantum effect detected in the reference calculation. Since the molecules are finite size systems, it is reasonable that the spin density at NN radical site is shrinked from 1/2 and that the spin density of manganese unit is shrinked from 5/2.

Results of the spin densities obtained by the exact diagonalization of the effective spin model are shown in Fig. 3 and fitted to the reference calculation of UB3LYP/6-31G(d,p). D and α are fixed at ($D = -0.01$, $\alpha = 0.3$), respectively. The spin densities of each model are not drastically affected by D and α. On the contrary, the configuration of the spin densities is very sensitive to the change of the variables J_3/J_1 and J_2/J_1. This means that the configuration of the spin densities gives an essential knowledge for construction of the effective spin model.

In order to detect the optimum condition, we define the following parameter Y:

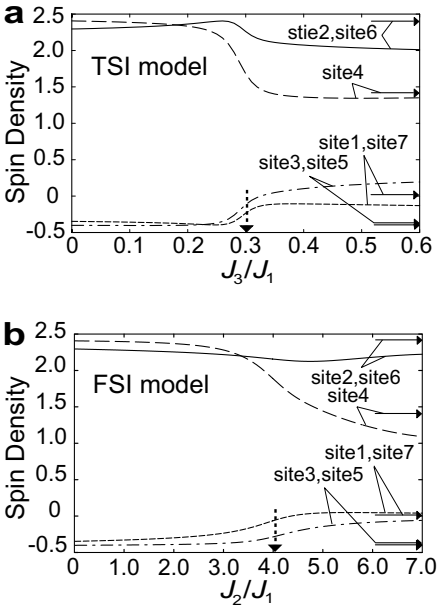

Fig. 3. The result of the spin density calculated by the exact diagonalization of the TSI model and the FSI model. The conditions, $D = -0.01$, $\alpha = 0.3$, are imposed in each model.

$$Y = Y_{5/2} + Y_{1/2}$$

$$Y_{5/2} = \sum_i \left(\frac{\langle S_i^z \rangle_G}{2.5} - \frac{\langle S_i^z \rangle_M}{2.5} \right)^2$$

$$Y_{1/2} = \sum_i \left(\frac{\langle S_i^z \rangle_G}{0.5} - \frac{\langle S_i^z \rangle_M}{0.5} \right)^2$$

Here, $\langle S_i^z \rangle_G$ and $\langle S_i^z \rangle_M$ represent the spin densities obtained by the ab initio calculation and that of the effective spin model, respectively. Y is minimized at the optimized parameters of J_3/J_1 and J_2/J_1. The optimum conditions for MOL3 are shown by dotted arrows in Fig. 3. There is qualitative difference between the TSI model and the FSI model at the optimum condition. In the FSI model, the order of the magnitude of the spin density at site 1 (site 7) and site 3 (site 5) obtained by the exact diagonalization is consistent with the result of the ab initio calculation. On the contrary, the TSI model does not show this consistency. Optimum conditions are summarized in Table 2. These results clearly show the following two facts. Firstly, the USI model can never reproduce the reference. Secondly, the results of MOL2 and MOL3 show that Y_{min} of FSI model is

Table 1

Table 2
Determined optimum conditions of interaction strength and Y_{min} of each model. The USI model is given by $J_2 = J_3 = 0$

	Optimum	Y_{min}
MOL1		
USI model		0.8283
TSI model	$J_3/J_1 > 0.24$	0.0001
FSI model	$J_2/J_1 > 3.61$	0.0001
MOL2		
USI model		1.1050
TSI model	$J_3/J_1 = 0.31$	0.6536
FSI model	$J_2/J_1 = 4.09$	0.3311
MOL3		
USI model		2.0671
TSI model	$J_3/J_1 = 0.30$	1.9304
FSI model	$J_2/J_1 = 4.05$	0.1950

The exact diagonalization of the Hamiltonian for MOL1 shows that the wave function of each ground state of TSI model and FSI model does not change in each region shown by the inequality.

getting smaller for a larger molecule. On the contrary, Y_{min} of TSI model is getting larger for a larger molecule. Approaching to Mn_6R_6, FSI model fits well the ab initio calculation. Hence one can say that the FSI model is more appropriate model for Mn_6R_6 than the TSI model and the USI one.

In concluding the present work, the SDR method clearly shows that the FSI model is the suitable model for the nano scale ferrimagnetic ring Mn_6R_6. The main point in this study is that the configuration of the spin densities is an essential quantity for determination of the effective spin model. Of course, one can also determine the model from the spin density obtained by the precise experimental observation. As a final point, we should emphasize that the SDR method is a powerful method for determination of the effective spin model for a nano scale magnet which has a finite magnetization.

present in $[Cu_4(bipy)_4V_4O_{11}(PO_4)_2]nH_2O$ ($n \sim 5$) (**1**), for which the used analytical models did not give a good fit of the experimental magnetic data. The theoretical methods used in the present work are based on density functional theory [12–14].

In the present work, we will discuss the magnetic behaviour of three hybrid organo-inorganic compounds which present different bridging forms of the phosphate/phosphonate/oxovanadium groups, showing different bulk magnetic properties. Compounds (**2**) and (**3**) correspond to $[Cu_2(phen)_2(PO_4)(H_2PO_4)_2(VO_2) \cdot 2H_2O]$ and $[Cu_2(phen)_2(O_3PCH_2PO_3)(V_2O_5)(H_2O)]H_2O$, respectively.

2. Experimental

The syntheses of compounds (**1**), (**2**) and (**3**) were previously reported [9,15,10].

3. Computational details

All the calculations for compound (**1**) were performed using the crystal structure of the molecule [10]. Single point calculations were performed with the GAUSSIAN03 code [16] using the quadratic convergence approach (convergence criteria 0.02 cm^{-1}) with the hybrid B3LYP functional [17] and a guess function generated with the JAGUAR 5.5 code [18]. We have employed a triple-ζ all electron Gaussian basis set for all atoms [19]. Since the crystal structure corresponds to an extended system which contains tetranuclear copper cores connected by phosphovanadates moieties, a tetranuclear unit was used for the calculations, see Fig. 1. This tetranuclear unit was obtained using four pentacoordinated copper(II) centres, each metal centre bonded to a bipyridine and to three oxygen atoms from phosphate and oxovanadium groups. In the case of an oxo-vanadium group bridging in a 1,1 form, hydrogen atoms were added to the two oxygen atoms which were originally bonded to a phosphate group. In the case of a phosphovanadate group bridging in a 1,3 form, one hydrogen atom was added to a oxygen atom originally bonded to a phosphate group. The hydrogen atoms added to the structure were optimized with MM+ molecular mechanics force field using the TITAN package [20]. The fragment has four different Cu–Cu distances (3.19; 4.10; 5.38 and 5.01 Å), and therefore four different exchange coupling constants (J_1, J_2, J_3 and J_4) are expected. Therefore, the studied system can be described with the phenomenological Hamiltonian

$$\hat{H} = -J_1[\hat{S}_1\hat{S}_2 + \hat{S}_3\hat{S}_4] - J_2[\hat{S}_1\hat{S}_3 + \hat{S}_2\hat{S}_4] - J_3[\hat{S}_2\hat{S}_3] - J_4[\hat{S}_1\hat{S}_4]$$

In order to obtain the four different J values, five calculations are needed: a high spin solution ($S = 2$), three solutions with $S = 0$, and one solution with $S = 1$. The calculated temperature dependence of the magnetic susceptibility was obtained with the MAGPACK code [21] using $g = 2.00$.

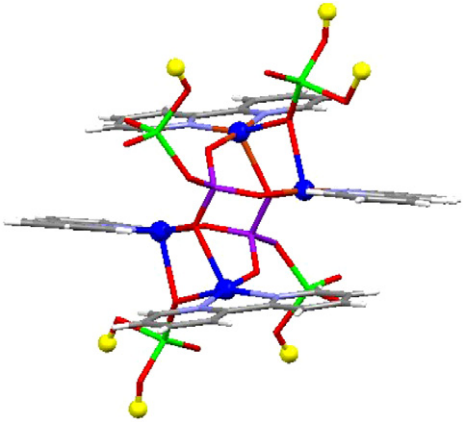

Fig. 1. Tetranuclear copper(II) model of compound (**1**) used for the calculations. The four central deep blue spheres correspond to copper atoms. The six peripherical yellow spheres correspond to added hydrogen atoms. Phosphorous, purple; vanadium, green; oxygen, red; nitrogen, light blue; carbon, grey. 4. Results and discussion

4.1. Structural description

The three reported hybrid organo-inorganic copper(II) compounds, based on the vanadium(V)/phosphorus/oxygen substructure (VPO) have different extended structures. In compound (**1**), the existing tetranuclear copper(II) species are connected by the $V_4P_2O_{19}$ chain-like fragments to form infinite chains running parallel [1 0 0] [9]. In compound (**2**), the vanadium octahedral and phosphorous tetrahedra share common corners to form infinite chains based on the VP_2O_{12}. An extra phosphorous tetrahedron acts as a single bridge between two copper(II) centres, giving rise to the existence of $Cu_2(phen)_2(PO_4)^+$ species. These cationic species are interconnected by μ_2-oxo bridges of phosphorous and vanadium forming infinite chains, which propagate along the a direction [15]. In compound (**3**), the vanadium tetrahedra and diphosphonate groups share common corners to give infinite zig-zag chains, $[V_2O_5O_3PCH_2PO_3]$ running along the [1 0 0] direction. The infinite chains are connected by the tetrameric units to form layers [10].

In all the reported copper(II) compounds, the metal centres present a square pyramidal geometry. However, different type of bridges between the copper(II) centres are observed in each case. The copper(II) tetranuclear unit present in compound (**1**) is the most complex, in relation to the bridges that exist between the metal centres. The two nearest copper(II) centres (d_{Cu-Cu} 3.19 Å) are linked by three bridges: a 1,1-oxo-vanadium group, a 1,1-phosphate group, and a 1,3-phosphate group. These dinuclear species are interconnected by two 1,3-phosphate group, thus giving rise to a rhombohedral tetranuclear unit (d_{Cu-Cu} 4.10 Å). The internal diagonals of this rhombohedral struc-

ture correspond to two 1,3-phosphate bridges each, with distances of 5.03 and 5.38 Å (Fig. 2).

In compound (**2**), the dinuclear copper(II) unit is formed with the presence of one 1,3-phosphate bridge ($d_{Cu–Cu}$ 3.46 Å) (Fig. 3). In compound (**3**), the tetranuclear species is formed by the central bis 1,1-oxo bridged dimer ($d_{Cu–Cu}$ 3.25 Å) and the two external copper(II) atoms with 1,3-bis phosphate bridges ($d_{Cu–Cu}$ 5.13 Å) (Fig. 4).

5. Magnetic behaviour

Only compound (**2**) presents Curie–Weiss behaviour in the whole temperature range (3–300 K), while all three compound show this behaviour for the high temperature region (>100 K). The magnetic behaviour of compound (**3**) has been analyzed elsewhere; the obtained J values being $J_{intra} = -30\ cm^{-1}$ and $J_{inter} = -8.5\ cm^{-1}$ [10].

For compound (**1**) the magnetic behaviour below 60 K is complex, and the analytical expression used did not give a good fit of the experimental magnetic data. A theoretical model with four exchange pathways was used in order to describe the magnetic behaviour of the rhombohedral tetranuclear species. The experimental magnetic data for compound (**1**) (Fig. 5a) is well described with the following calculated J parameters: $J_1 = +3.29$, $J_2 = -0.63$, $J_3 = -2.23$ and $J_4 = -46.14\ cm^{-1}$ (Fig. 5b). The overall antiferromagnetic behaviour at low temperatures is due mainly to a inter-dimer exchange interaction, while the intra-dimer exchange interaction due to the existence of the three bridges results slightly ferromagnetic. Therefore, the 1,1-oxo-vanadium bridge present in the dinuclear unit may be acting counter complementary in relation to the two phosphate bridges. The Cu_2–Cu_3 diagonal ($d_{Cu–Cu}$ 5.01 Å) presents the phosphate ligands with the most symmetrical copper–oxygen distances (Cu_2O: 1.92; Cu_3O: 1.95; Cu_2O': 1.95 and Cu_3O': 1.92 Å). This fact may influence the magnitude of the J value ($J_4 = -46.14\ cm^{-1}$), in comparison to the much smaller obtained J values ($J_2 = -0.63$, $J_3 = -2.23\ cm^{-1}$). For this latter exchange pathways greater differences in the Cu–O distances are observed, ranging from 1.89 Å (shortest) to 2.29 Å (longest). It is known that geometrical factors greatly influence the magnitude of the magnetic exchange coupling between paramagnetic metal centres.

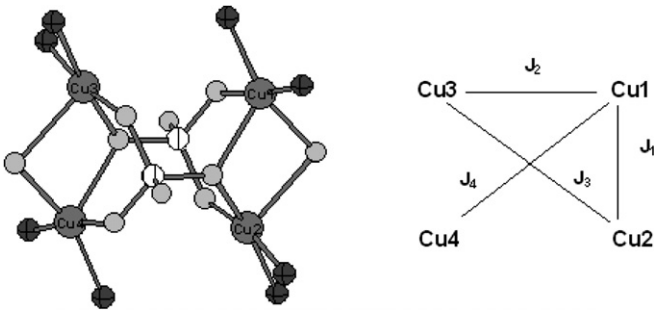

Fig. 2. Tetranuclear copper(II) core of compound (**1**) with all the oxygen atoms involved in the magnetic exchange phenomenon. Dark gray, nitrogen; light gray, oxygen; dashed, phosphorus. Schematic diagram of the four different magnetic exchange pathways.

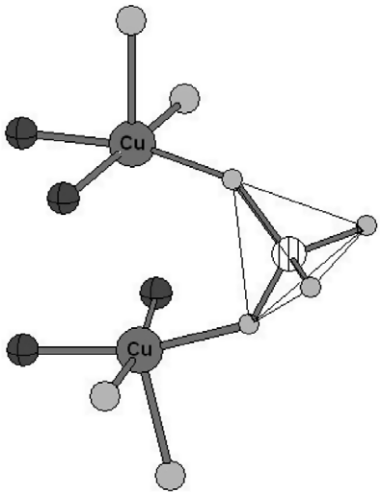

Fig. 3. Binuclear copper(II) core of compound (**2**) showing the 1,3-phosphato bridge. Dark gray, nitrogen; light gray, oxygen; dashed, phosphorus.

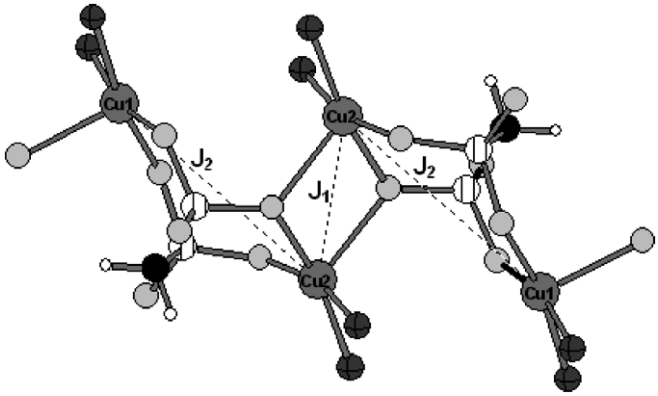

Fig. 4. Tetranuclear copper(II) core of compound (**3**) showing all the phosphate bridges involved in the magnetic exchange phenomenon. Dark gray, nitrogen; light gray, oxygen; dashed, phosphorus. J_1, J_2: magnetic exchange constants.

When a simpler model was used to describe the tetranuclear unit of compound (**1**) in which the two diagonals are taken as equal, assuming a perfect rectangular geometry for the species, the following j values were obtained: $J_1 = +4.93$, $J_2 = -0.63$, $J_3 = -24.2\ cm^{-1}$ [11]. Even though the same trend is obtained in the sign of the j values, these do not reproduce the low temperature behaviour of compound (**1**) as can be seen in Fig. 5c. It is interesting to point out that the J_3 value of the rectangular model corresponds to the mean value of the J_3 and J_4 values of the rhombohedral model.

The fact that compound (**2**) does not show antiferromagnetism in the whole temperature range, may be due to the fact that the bridged copper(II) centres of the

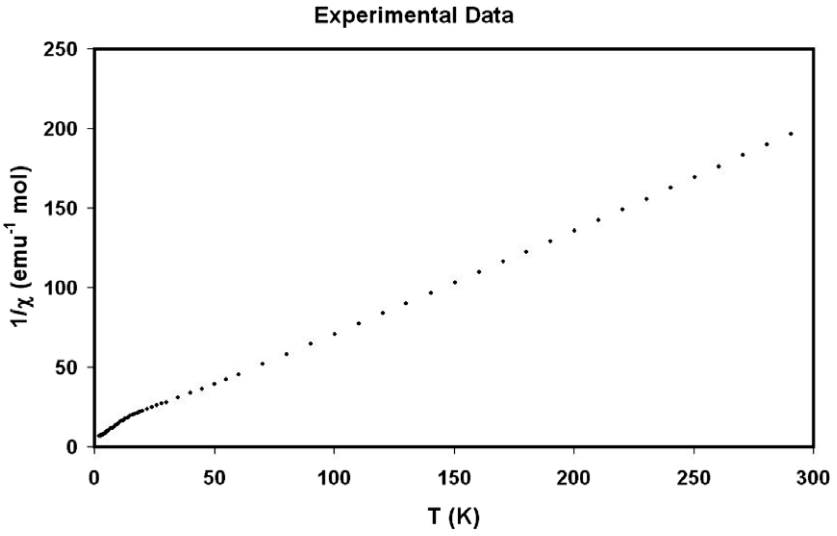

Fig. 5a. Experimental magnetic data of compound (**1**). $1/\chi$ vs. T.

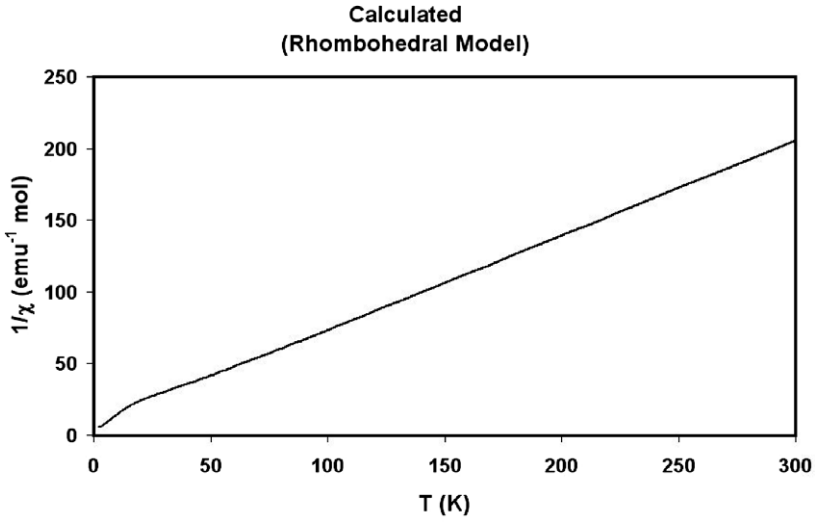

Fig. 5b. Calculated magnetic data of compound (**1**) using the rhombohedral model. $1/\chi$ vs. T.

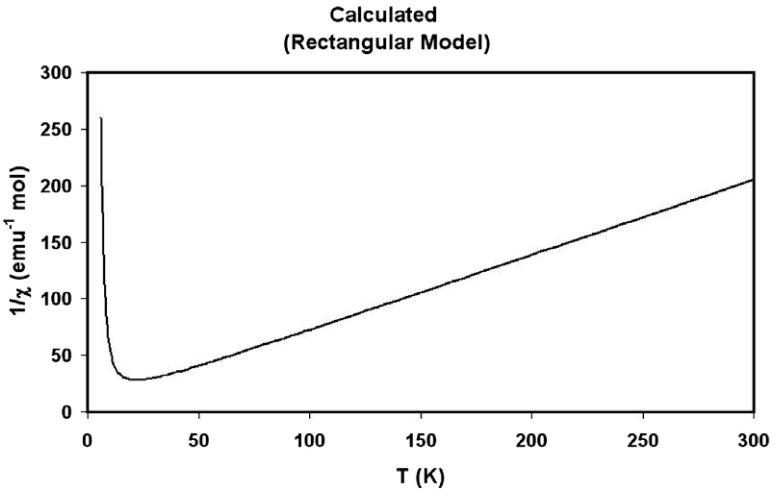

Fig. 5c. Calculated magnetic data of compound (**1**) using the rectangular model. $1/\chi$ vs. T.

$Cu_2(phen)_2(PO_4)^+$ fragment are located on different planes, and present only one chelate phosphate bridge. Thus the only possible pathway for the magnetic exchange interaction is not adequately located to be effective.

Compound (**3**) presents a typical antiferromagnetic behaviour with a maximum at 64 K. The two 1,1-phosphate bridges link the two copper(II) centres at a short distance of 3.25 Å, and represent adequate magnetic exchange pathways ($J_1 = -30.0\ cm^{-1}$). The 1,3 mode of bridging of the two phosphate groups of the phosphonate ligands assure an inter-dimer antiferromagnetic exchange interaction with $J_2 = -8.5\ cm^{-1}$.

6. Conclusions

The different modes of bridging of the phosphate and oxo-vanadium ligands give rise to completely different magnetic behaviour of the three hybrid organo-inorganic copper(II) compounds.

Phosphates bridges permit the existence of antiferromagnetic exchange coupling between the copper(II) centres. The exchange interaction being stronger when the copper(II) oxygen distances involved are similar in length giving a more symmetrical structure.

basis functions were also considered for Cu. We enabled and disabled use of integral symmetry corresponding to the standard orientation and in the specified *Z*-matrix orientation for **1**. For the calculation of original singly occupied molecular orbitals (SOMOs) of investigated complex, the geometries revealed by X-ray crystal structure analyses were used without any reduction of size for **1**.

3. Calculated results and discussion

For open-shell system, correct SOMOs for high-spin states those show the nature of ferro- or antiferromagnetic coupling for investigated complexes are the most interested calculated results. Because the restricted open-shell DFT calculation (RO-DFT) prevents the spin contamination, we will investigate the dependence of SOMO distribution with various calculation techniques, for comparison, the unrestricted DFT calculation (U-DFT) are also involved. For U-DFT calculation, one of the most important parameters obtained is the total angular momentum of each state ($\langle S^2 \rangle$), by which the spin contamination can be determined compared with the expected one. Our previous calculation [7] suggests that U-DFT calculation usually results in serious spin contamination for low-spin states. Herein, we only pay more attention to the calculated $\langle S^2 \rangle$ for high-spin (quartet) state.

Among the U-DFT calculations with various functionals, basis sets, orientation of geometry, and symmetry constraints, the obtained smallest $\langle S^2 \rangle$ value for quartet high-spin state of complex **1** is 3.772 (expected value 3.750). Where UB3LYP calculation are performed with 6-31G(d) basis sets for C, H, O, N, F and pure LanL2DZ for Cu, under disabled use of integral symmetry. The corresponding SOMO distribution for high-spin state with smallest $\langle S^2 \rangle$ value is shown in Fig. 1. Where three SOMOs are consisting of one $d_{x^2-y^2}$ from Cu^{II} (1a) and two sets of p orbitals (1b, 1c) on organic radicals, respectively. UB3LYP/6-31G(d) calculation under disabled use of integral symmetry suggests the $d_{x^2-y^2}$ lies in the plane of hfac [8]. It is found

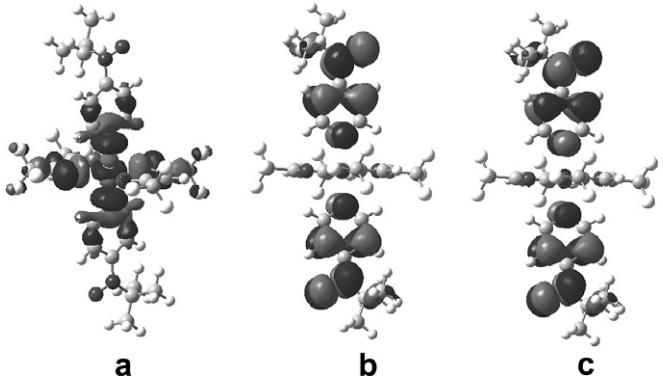

Fig. 1. SOMO distribution of complex **1** by UB3LYP with 6-31G(d) basis sets for C, H, O, N, F and pure LanL2DZ for Cu^{II}, under disabled use of integral symmetry.

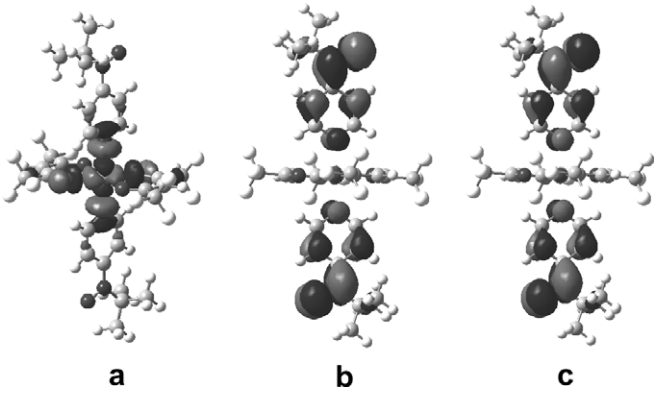

Fig. 2. SOMO distribution of complex **1** by ROB3LYP approach.

that UB3LYP calculations are sensitive to the basis sets and orientation of investigation system. All UBLYP, UPBE, and UPBE0 calculations failed to give reasonable SOMO distribution. Therefore unrestricted DFT calculation is a plausible approach for the SOMO distribution of investigated complex **1**.

RO-B3LYP calculations are tolerant for the different basis sets and orientation of investigation system, except for the Cartesian LanL2DZ for Cu^{II} with standard orientation for the complex **1**. All RO-PBE, RO-PBE0, RO-BLYP, and most of the RO-B3LYP calculation can offer reasonable SOMO distribution for complex **1** as shown in Fig. 2. It is shown in Fig. 2 that the magnetic orbitals are consisting of three near-degenerate MOs. 2a is formed by d_σ type atomic orbital (AO), i.e. $d_{x^2-y^2}$ from Cu^{II}, the σ AOs from two oxygens of hfac forming *X*-axis and σ AOs from two nitrogens of pyridine rings forming *Y*-axis. 2b and 2c are from p AOs of organic radical parts, which is alternatively distributed on 4NOPY, i.e. there are nodes between neighboring p orbitals. Moreover, according to the coefficients of AOs for three SOMOs, they are orthogonal to each other. Therefore, near degenerate and orthogonal SOMOs in **1** contribute to form the ferromagnetic coupling between three hetero-spin centers. RO-BLYP, RO-PBE, and ROPBE0 calculations can give same SOMOs for **1** when LanL2DZ is used for Cu^{II}. It is worth to note that the approaches mentioned above are also valid for other complexes consisting with aminoxyl radicals possessing bipyridyl ligands and $Cu(hfac)_2$.

4. Conclusion

In summary the calculations presented here reveal that the SOMOs for complex **1** is calculation technique dependent, and RO-B3LYP, RO-BLYP, RO-PBE, and RO-PBE0 in combination with LANL2DZ basis set are promising approaches for offering correct SOMOs of investigated system, which can offer a visible image for the magnetic orbitals. It can be expected that our findings may give a general method for further investigation of SOMOs of other hetero-spin systems.

parallel. This group has not previously been used in manganese chemistry, but we have found that it yields interesting products. We herein report two mixed-valent (Mn^{II}_6, Mn^{III}_6, Mn^{IV}) tridecanuclear Mn clusters obtained using the ndc^{2-} ligand. In addition, a route has been found to an analogous Mn_{13} species with only monocarboxylate groups. The magnetic properties vary significantly within this family, and a qualitative magnetostructural correlation has provided some insight into the influence on the observed properties of the mono- versus dicarboxylate ligation.

The reaction of $Mn(O_2CMe)_2 \cdot 4H_2O$ in DMF with 1,8-naphthalic anhydride and NEt_3 led to subsequent isolation, on layering with Et_2O, of $[Mn_{13}O_8(OH)_6(ndc)_6] \cdot 8DMF \cdot H_2O$ (**1**) in ~70% yield. When the same reaction solution was layered with EtOH, the product was $[Mn_{13}O_8(EtO)_{5.5}(OH)_{0.5}(ndc)_6] \cdot 6MeCN \cdot 2H_2O$ (**2**) in similar yield. Finally, reaction of preformed $[Mn_3O(O_2CPh)_6(pyr)_2(H_2O)]$ [5] with NEt_3 in EtOH produced $[Mn_{13}O_8(EtO)_6(O_2CPh)_{12}] \cdot 7H_2O$ (**3**) in ~80% yield. Fuller details of the syntheses will be provided in the full paper [6].

Complex **1** crystallizes in the triclinic space group $P\bar{1}$ with the molecule on an inversion center. The core of the cluster (Fig. 1) contains one Mn^{IV}, six Mn^{II}, and six Mn^{III} ions held together by six μ_5-O^{2-}, two μ_3-O^{2-}, and six μ_3-OH^- ions. Peripheral ligation is provided by six ndc^{2-} groups whose carboxylate arms each bridge two Mn atoms. The only Mn^{IV} atom (Mn6) is located at the center of the cluster, surrounded by a nearly planar ring of six Mn^{II} atoms (Mn3, Mn4, Mn7, and their symmetry equivalents). The six Mn^{III} atoms (Mn1, Mn2, Mn5, and their symmetry equivalents) form two equilateral triangles, one above and one below the nearly planar Mn^{II}_6 ring. The OH^- groups are O atoms O14, O15, O17, and their symmetry partners. Alternatively, the $[Mn_{13}O_{14}]$ core can be described as eight face-fused $[Mn_4O_4]$ cubane units with a common vertex at the central Mn^{IV} atom (Mn6). Each cubane shares three of its faces with its neighbors, creating a larger cubane-like unit whose eight vertices are all O atoms; in this description, the Mn atoms each lie at the mid-point of an edge and at the center of the larger cubane. The thirteen Mn ions in **1** are all six-coordinate with near-octahedral geometry, and their assigned oxidation states were established by charge considerations, bond valence sum calculations [6], and the clear Jahn–Teller (JT) distortions (elongations) at the Mn^{III} ions.

Complex **2** crystallizes in the triclinic space group $P\bar{1}$. The core of the cluster again contains one Mn^{IV}, six Mn^{II}, and six Mn^{III} ions, but now held together by six μ_5-O^{2-}, two μ_3-O^{2-}, and six μ_3-OEt^- ions. Thus, the six OH^- groups in **1** are now EtO^- groups in **2**; however, one EtO^- group is disordered with a OH^- group, with ~50:50% relative occupancies. Peripheral ligation is again by six ndc^{2-} groups. Complex **2** is thus structurally very similar to **1**, with small differences as summarized in Table 1.

Complex **3** crystallizes in the monoclinic space group $C2/c$. The core of the cluster again contains one Mn^{IV}, six Mn^{II}, and six Mn^{III} ions, held together as in **2** by six μ_5-O^{2-}, two μ_3-O^{2-}, and six μ_3-OEt^- ions (with no disorder in the occupancies of the latter). However, the peripheral ligation is now provided by 12 benzoate groups, each bridging two Mn atoms (Fig. 2). The core is thus very similar with those of **1** and **2**, with various small differences as summarized in Table 1. Note that complex **3** has also been previously obtained by others from a very different procedure [7].

The cores of the structures of **1**–**3** are thus overall very similar to each other, except for the OH^- versus EtO^- difference (Figs. 1–3). Closer inspection of the structures and the metric parameters in Table 1 reveal few major differences. The biggest, of course, is the C···C separation between two adjacent carboxylate groups. In **1** and **2**, this is only 2.899 ± 0.042 and 2.909 ± 0.017 Å, respectively, since the two carboxylate groups are attached to the

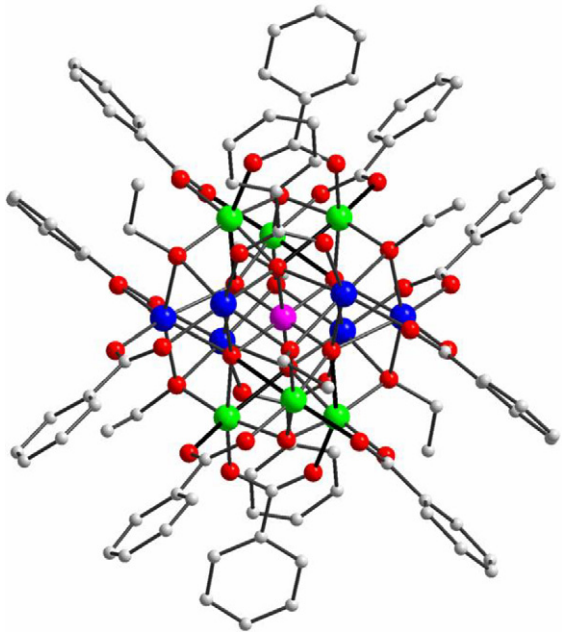

Fig. 2. The structure of complex **3**. Color code: Mn^{II} blue, Mn^{III} green, Mn^{IV} purple, O red, C grey. (For interpretation of the references in color in this figure legend, the reader is referred to the web version of this article.)

naphthalene backbone, and these are much shorter than the 3.434 ± 0.043 Å between two separate benzoate groups in **3**. However, this strain imposed on the disposition of the peripheral carboxylate ligands does not appear to have a significant effect on the distances and angles within the $[Mn_{13}O_{14}]$ core. The metric parameters of benzoate complex **3** are essentially all within the ranges of the corresponding values of either **1** or **2**, or both. In approximately half the entries in Table 1, there are no differences between the three complexes. Among the remainder, it is interesting to note that for some parameters ($Mn^{III}\cdots Mn^{III}$, $Mn^{II}\cdots Mn^{III}$ distances, and Mn^{III}–μ_3-O^{2-}–Mn^{III} angles), the values for **1** are closer to those **3** than those for **2**. This suggests that for many of the metric parameters, changes caused by the HO^{-}-to-EtO^{-} substitution (**1** to **2**) are essentially equal and opposite to those due to the ndc^{2-}-to-$PhCO_2^{-}$ substitution (**2** to **3**), resulting in some parameters for **1** being the same as those for **3**. In other cases, the values for **2** are closest to those for **3** (e.g. $Mn^{II}\cdots Mn^{II}$, $Mn^{II}\cdots Mn^{IV}$, and $Mn^{III}\cdots Mn^{IV}$ distances, Mn^{II}–O^{2-}–Mn^{IV} angles) showing the values are dominated by the EtO^{-} versus OH^{-} difference.

With respect to the magnetic properties to be discussed below, a probably significant difference within Table 1 is found in the Mn^{II}–RO^{-}–Mn^{II} angles, where R = H (**1**) or Et (**2**, **3**). In this case, the values for the latter two are both smaller than that of **1**. This is likely a contributory factor in the observed differences in magnetic properties to be discussed below, because it is well known that even very small changes in the angles at monoatomic bridges between two metal atoms can have a significant effect on the magnitude of the resulting superexchange interaction [8]; this was first demonstrated in the classic work on bis-hydroxo-bridged Cu(II) dimers [9].

Solid state, variable-temperature magnetic susceptibility measurements were performed on vacuum-dried microcrystalline samples of complexes **1**, **2**, and **3** suspended in eicosane to prevent torquing. The dc magnetic susceptibility (χ_M) data were collected in the 5.0–300 K range in a 0.1 Tesla (T) (1000 Oe) magnetic field. The obtained data are plotted as $\chi_M T$ versus T in Fig. 4, and it can be seen that the overall profiles are very similar for the three complexes, $\chi_M T$ steadily decreasing with decreasing temperature and thus suggesting dominant antiferromagnetic interactions between the metal centers in the molecule. However, the plots for **1** and **3** are the most similar, which

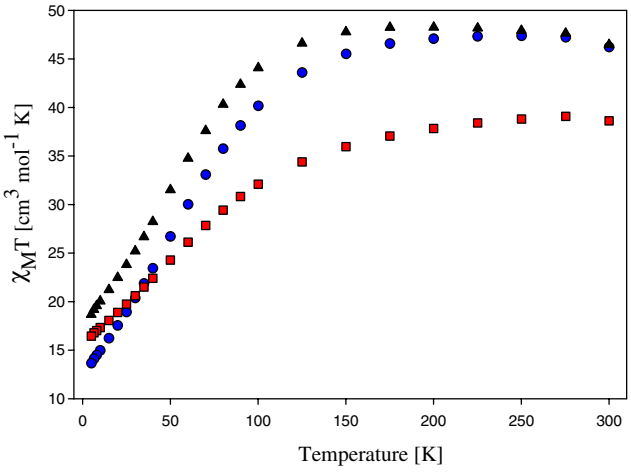

Fig. 4. $\chi_M T$ vs. T for complexes **1** (●), **2** (■), and **3** (▲) in a 0.1 T applied dc field.

likely reflects the fact that these two complexes have several similar core metric parameters, as described above.

For all three compounds, the 5.0 K data suggest that the complexes all possess ground states with significant S values. This would not be unexpected for such a complicated Mn_{13} topology with multiple inequivalent exchange parameters, most of which, if not all, being almost certainly antiferromagnetic. This is because of the spin frustration effects expected within the many Mn_3 triangular units within the Mn_{13} structure. We define spin frustration here in its more general form as competing exchange interactions of comparable magnitude that prevent (frustrate) the preferred pairwise antiparallel spin alignments that would give small (0 or 1/2) ground states.

In order to determine the ground states of complexes **1**, **2**, and **3**, magnetization (M) data were collected in the magnetic field and temperature ranges of 0.1–7 T and 1.8–10 K, respectively. Attempts to fit the resulting data using the program MAGNET [10], which assumes that only the ground state is populated at these temperatures, includes axial zero-field splitting (ZFS) and the Zeeman interaction with the applied field, and carries out a full powder average, did not lead to satisfactory fits. In our experience, this is the case when there are low-lying excited states that are consequently populated even at these relatively low temperatures and/or excited states that are more separated from the ground state but have S values greater than that of the ground state and thus their larger M_S levels rapidly decrease in energy due to the applied magnetic field and approach (or even cross) those of the ground state. Such situations are expected for **1**–**3** because of their high Mn^{II} content (exchange interactions involving Mn^{II} are known to be very weak and almost always antiferromagnetic, yielding small energy separations between the ground state and many nearby excited states with larger S values), and will lead to poor fits of the magnetization data since the fitting program assumes population of only the ground state levels. As we have described elsewhere on multiple occasions [11], these complications can sometimes be avoided by using only data collected at the lowest fields. For complex **1**, a satisfactory fit was obtained using data collected in the field range 0.1–0.8 T, as shown in Fig. 5, with fit parameters $S = 9/2$, $g = 2.00(1)$ and $D = -0.14(1)\ cm^{-1}$. However, attempts to fit the magnetization data for complexes **2** and **3** collected at only the lower fields still did not lead to acceptable fits. Therefore, we turned to the use of more reliable methods based on ac magnetic susceptibility measurements [12], which do not employ a dc field, to identify the ground state spins of **2** and **3**, and also confirm (or otherwise) our initial conclusion of an $S = 9/2$ ground state for **1**.

Alternating-current magnetic susceptibility studies were performed on vacuum-dried microcrystalline samples of **1**–**3** in the temperature range 1.8–15 K in a zero dc field and a 3.5 Oe ac field oscillating at frequencies between 250 and 1000 Hz. The resulting data are plotted as $\chi'_M T$ versus T in Fig. 6, where χ'_M is the in-phase component of the ac susceptibility. For all three complexes, $\chi'_M T$ decreases essentially linearly with decreasing temperature, this downward slope supporting a decreasing population of excited

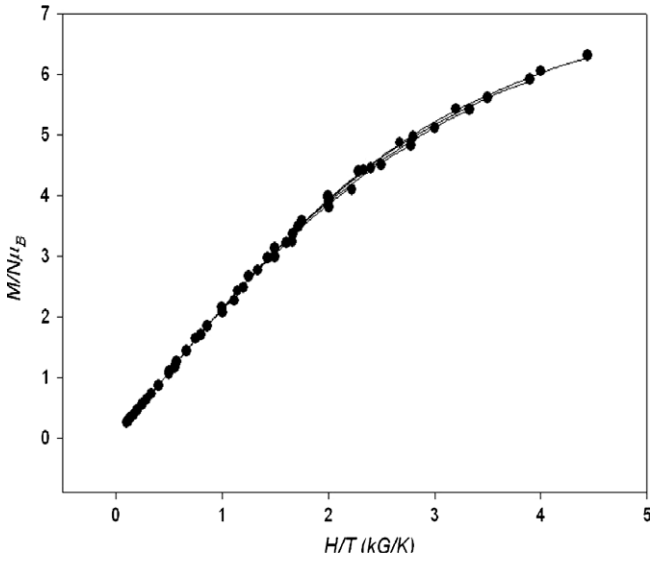

Fig. 5. Plot of the reduced magnetization, $M/N\mu_B$, vs. H/T for complex **1**; the solid line is the fit of the data (see the text for the fitting parameters and the fields used).

states with a larger S than the ground state, in agreement with the statements above re the dc magnetization fitting problems. A linear extrapolation of the data for **1** to 0 K, where only the ground state will be populated, gives an approximate $\chi'_M T$ of $\sim$13 $cm^3\,mol^{-1}$ K, indicating an $S = 9/2$ ground state (expected spin-only ($g = 2.0$) value for $S = 9/2$ is 12.4 $cm^3\,mol^{-1}$ K). This is satisfyingly consistent with the conclusion from the dc magnetization fit in Fig. 5. For complexes **2** and **3**, the $\chi'_M T$ values are significantly higher, and extrapolations to 0 K give approximate values of $\chi'_M T$ of $\sim$16.2 and $\sim$17 $cm^3\,mol^{-1}$ K, respectively, consistent with a $S = 11/2$ ground states for these complexes (spin-only value for $S = 11/2$ is 17.88 $cm^3\,mol^{-1}$ K).

It is interesting that complexes **1** and **3** have the overall more similar $\chi_M T$ versus T behavior up to 300 K (Fig. 4) but that **2** and **3** are the more similar at very low temperatures and in their ground states (Figs. 4 and 6). The former observation is consistent with the several structural similarities between **1** and **3** seen in Table 1, even though they differ in both the EtO^- versus OH^- and benzoate versus ndc^{2-} identities, whereas the difference in ground state is perhaps due to the significantly different $Mn^{II}Mn^{II}$ exchange interactions via the Mn^{II}–RO^-–Mn^{II} superexchange pathways. These are likely the weakest interactions in the molecule, their impact thus becoming evident only at the lowest temperatures, and given the significant difference in the angles at the bridging HO^- or EtO^- atoms mentioned earlier, it seems reasonable that differences in this exchange parameter could cause a flip in the relative energies of some of the closely separated, lowest-lying spin states, causing a change in the ground state.

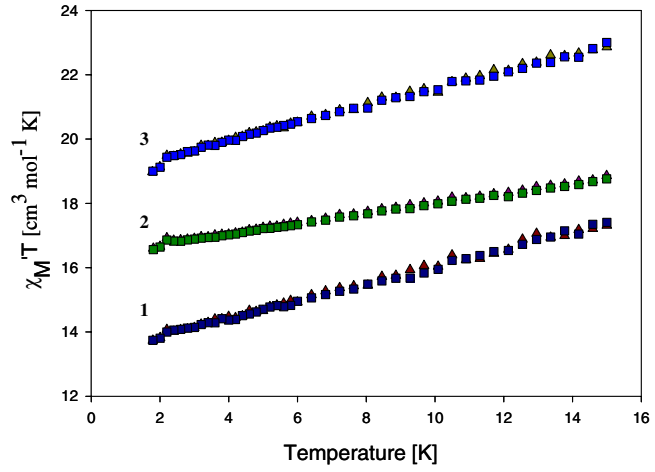

Fig. 6. Plot of the in-phase (χ'_M) ac magnetic susceptobility (as $\chi'_M T$) vs. T for complexes **1**, **2**, and **3** in a 3.5 Oe field oscillating at 250 (▲) and 1000 (■) Hz. The blips at 2.2 K are instrumental artifacts.

In summary, the initial use of the ndc^{2-} group in Mn chemistry has led to two mixed-valent Mn_{13} clusters containing three different oxidation states of this metal and differing only in the HO^- versus EtO^- identity of some of the bridging ligands. In addition, a rational and convenient synthesis has been developed for the corresponding benzoate version, which was already known in the literature. The unusual $\eta^1{:}\eta^1{:}\eta^1{:}\eta^1{:}\mu_4$ coordination mode adopted by the ndc^{2-} group suggests that it may prove a route to a variety of new metal clusters with other transition metals or lanthanides. Examination of the structural parameters of the three complexes **1**, **2**, and **3** led to the conclusion that the inflexible ndc^{2-} group actually imposes little significant structural change on the core of the molecule, and what is seen appears comparable with the HO^- versus EtO^- effect. Complexes **1**–**3** were determined to have $S = 9/2$, 11/2, and 11/2 ground states, respectively; a fuller rationalization of this difference will be provided in the full report of this work.

also reported the ferromagnetism of $[Mn(C_5Me_5)_2]^+$-$[TCNE]^-$ and $[Cr(C_5Me_5)_2]^+[TCNE]^-$ systems [9,10]. Because Cr(III) has a d^3 (a_{1g}^1 e_{2g}^2) electronic configuration and Mn(III) has d^6 (a_{1g}^2 e_{2g}^2), they should exhibit antiferromagnetic coupling if forward-charge-transfer mechanism was appropriate.

Tchougreeff et al. presented another charge transfer mechanism, namely back-charge-transfer. In this mechanism, up-spin in π^* orbital on acceptor (A^-) back transferred to the e_{1g}^* orbitals in metal site resulting in A^0D^0 state [11,12].

Kollmar et al. notified that the sign of spin population on the cyclopentadienyl ring was a keypoint to determine which mechanism were appropriate [13]. The back-charge-transfer put an up-spin in e_{1g}^* orbitals which are mixed with π-orbitals in cyclopentadienyl rings therefore, the sign of the spin density on cyclopentadienyl rings is positive. On the other hand, spin-polarization mechanism cause negative spin density on the carbon ring.

Yamaguchi et al. reported spin densities on the cyclopentadienyl ring by UHF calculation of $[Fe(C_5Me_5)_2]^+$, $[Cr(C_5Me_5)_2]^+$, $[Mn(C_5Me_5)_2]^+$ and $[Ni(C_5Me_5)_2]^+$ [14]. Their results showed the negative spin densities on the carbon ring in case of $[Fe(C_5Me_5)_2]^+$, $[Cr(C_5Me_5)_2]^+$, and $[Mn(C_5Me_5)_2]^+$. Otherwise, in case of $[Ni(C_5Me_5)_2]^+$, the positive spin densities were appeared on the cyclopentadienyl ring. Ni(III) had one electron in e_{1g}^* orbitals therefore, this result seemed to be reasonable.

In our previous paper, we demonstrated the calculated results of the broken-symmetry hybrid DFT methods on the reduced model complex of $[Fe(C_5Me_5)_2]^+[TCNE]^-$ system [15]. The calculated effective exchange integrals reproduced the experimental result and we concluded that McConnell I mechanism via spin polarization of cyclopentadienyl ring could explain the ferromagnetism.

In this study, we applied hybrid-DFT calculation to the reduced model complex of $[Cr(C_5(CH_3)_5)_2]^+[TCNE]^-$(**1**) and $[Mn(C_5(CH_3)_5)_2]^+[TCNQ]^-$ (**2**) systems by using available structures of X-ray crystallographic data. The effective exchange integrals of 3-site chain reduced model of realistic 3D systems were calculated by using broken-symmetry method. The spin density distributions were also examined for both model complexes. From those calculated results, the effectiveness of McConnell I mechanism (spin-polarization mechanism) was demonstrated. In addition, the way of orbital interaction between metal site and accepter molecule ($TCNE^-$ or $TCNQ^-$) was discussed by using natural orbital analysis of the broken-symmetry hybrid-DFT solutions.

2. Theoretical background and computational details

2.1. Effective exchange integrals

To describe the magnetic interaction between the magnetic sites, Heisenberg Hamiltonian was employed

$$\widehat{H} = -2\sum_{ab} J_{ab} S_a S_b \tag{1}$$

Recent computational developments of ab initio calculation and the density functional theory enable us to calculate the effective exchange integral for transition metal complexes. The details about a derivation of the effective exchange integral were described in elsewhere [16]. J_{ab} value can be calculated as follows:

$$J = \frac{E_{LS} - E_{HS}}{\langle S^2 \rangle_{HS} - \langle S^2 \rangle_{LS}} \tag{2}$$

E_X and $\langle S^2 \rangle_X$ denote the total energy and the total spin angular momentum, respectively. The structure of the reduced model complex is shown in Fig. 1. Fig. 2(a) shows the spin aliment of high-spin (HS) and low-spin (LS) states and site number.

In order to apply Eq. (2) to this model, we used simple assumption that we only considered magnetic interactions between the sites 1 and 2 (J_{12}) and between sites 2 and 3 (J_{23}). The magnetic interaction between site 1 and site 3 (J_{13}) were neglected. Therefore, calculated effective exchange integral was single $J = J_{12} = J_{23}$.

2.2. Computational methods

The Kohn–Sham (KS) density functional theory [17] is one of the most popular approaches in computational chemistry. The energy expression is given by

$$E = T_0[\{\psi_i\}] + V_{Ne}[\rho] + V_{clumb}[\rho] + E_{xc}[\rho] \tag{3}$$

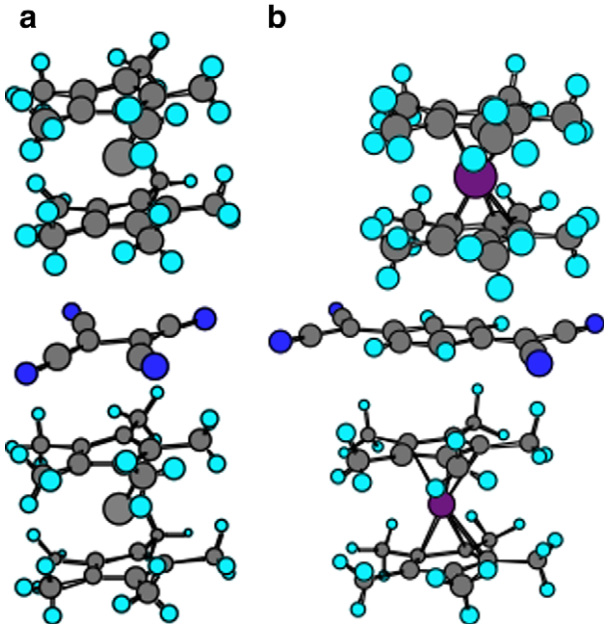

Fig. 1. (a) The reduced model complexes of $[Cr(C_5(CH_3)_5)_2]^+[TCNE]^-$ system (model **1**) and (b) is the reduced model of $[Mn(C_5(CH_3)_5)_2]^+$-$[TCNQ]^-$ system (model **2**). Each model have three spin sites.

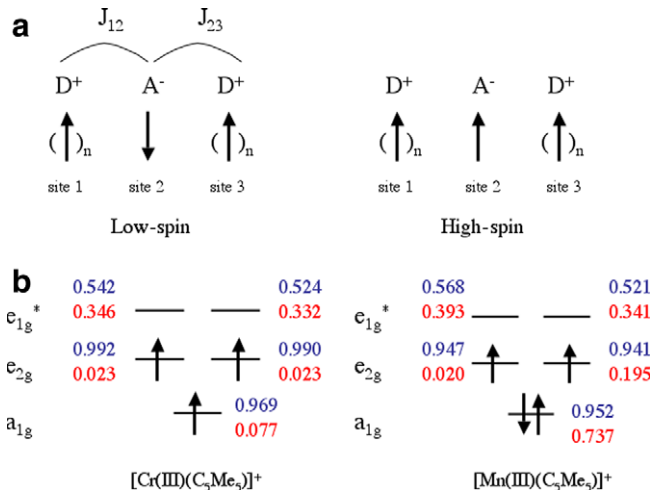

Fig. 2. (a) The spin alignments of high-spin (HS) and low-spin (LS) states. J_{12} means the interaction between spin site 1 and site 2. D^+ indicates the transition metal (=Cr(III) or Mn(III)) and A^- indicate the acceptor (=$TCNE^-$ or $TCNQ^-$). The n is 3 in case of Cr(III) and 2 in case of Mn(III), respectively. (b) Schematic views of electron configurations in 3d-orbital in Cr(III) and Mn(III) in reduced model complexes. The values in upper row (blue) indicates the population of α electron and values in lower row (red) indicates the population of β electron. The values indicate the one of two transition metals. The values of the other metal show same tendency.

where T_0, V_{Ne} and V_{clumb} are the kinetic energy of electron, nuclear attraction energy and classical coulomb term respectively. E_{xc} is the exchange-correlation term [18]. In hybrid-DFT [19], the exchange-correlation term is described as

$$E_{xc} = C_1 E_x^{HF} + C_2 E_x^{Slater} + C_3 E_x^{Becke88} + C_4 E_c^{VWN} + C_5 E_c^{LYP} \quad (4)$$

where E_x^{HF}, E_x^{Slater}, and $E_x^{Becke88}$ denote the Hartree–Fock, Slater and Becke's exchange functionals, respectively. E_c^{VWN} and E_c^{LYP} denote the Vosko, Wilk and Nusair (VWN) [20] and Lee, Yang and Parr (LYP) [21] correlation functionals, respectively. c_i ($i = 1$–5) are the mixing parameters. They are (0.5, 0.5, 0.5, 1.0, and 1.0) and (0.2, 0.8, 0.72, 1.0, and 0.81) for B2LYP (Becke's half and half LYP) and UB3LYP, respectively [22–24].

All calculations were performed by using GAUSSIAN 98 program package [25] and geometries of model complexes were prepared using X-ray crystallographic data from Cambridge Structural Data-base (CSD). Huzinaga's MIDI+p basis set (533(21)/53(21)/(41)) is employed for Mn and Cr [26]. 6-31G* basis sets are adopted for C and N atoms. For all H atoms, we used 4-31G level basis sets.

2.3. Natural orbital and occupation number

Although the broken-symmetry (BS) hybrid-DFT method could approximately include the static electron correlation, the obtained orbitals are often different from familiar MOs, namely symmetry-adapted (SA) MOs. In order to obtain the SA MO picture from the broken-symmetry (BS) solutions, the natural orbital (NO) analysis has been carried out. The NOs of broken-symmetry solution is determined by diagonalizing first-order density matrices [27] as

$$\rho(r, r') = \sum n_i \phi_i(r) \phi_i(r')^* \quad (5)$$

where n_i and ϕ_i denote the occupation number and natural orbital, respectively. The occupation numbers of bonding and antibonding NOs are almost 2.0 and 0.0, respectively. Occupation numbers of magnetic orbitals are usually close to 1.0 occupation number. These orbitals are also called as singly occupied natural orbitals (SONO). The spin-polarized MOs ψ^+ and ψ^- for up and down spins can be connected with the in- and out-of phase combinations of the bonding and antibonding natural orbitals:

$$\psi_i^{\pm} = \cos\theta_i \phi_i \pm \sin\theta_i \phi_i \quad (i = 1, 2, 3, \ldots, N) \quad (6)$$

where θ_i the orbital mixing parameter and N is the number of bonding natural orbitals. The occupation numbers of the bonding and antibonding natural orbitals are expressed by using T_i value

$$n_i = 1 + T_i, \quad n_i^* = 1 - T_i \quad (7)$$

where T_i values are orbital overlap which are expressed as

$$T_i = \langle \psi_i^+ | \psi_i^- \rangle \quad (8)$$

3. Results and discussions

3.1. Electronic structure of $[Cr(C_5Me_5)_2]^+[TCNE^-]^-[Cr(C_5Me_5)_2]^+$ and $[Mn(C_5Me_5)_2]^+[TCNQ^-]^-[Mn(C_5Me_5)_2]^+$

In Fig. 2(b), gross orbital populations in 3d-orbitals of Cr and Mn in reduced model complex were summarized. This tables only presented the UB3LYP results. UB2LYP results were same tendency.

Table 1 summarized the spin density distributions on the both type of model complexes. The magnitude for α spin ($s = 1/2$) and β spin ($s = -1/2$) were defined to be 1.0 and −1.0, respectively. In case of UB3LYP calculation, the spin densities on two Cr and Mn were about 3.3 and 2.3, respectively.

Table 1 also showed NBO (natural bond orbital) natural charge distribution of metal and TCNE sites. The charge populations on TCNE and TCNQ were close to their formal charges i.e. −1.0 in both cases of model **1** and model **2**. However, the charge populations on Cr site were about 1.1 and 1.3 in case of UB3LYP and UB2LYP, respectively and populations on Mn site were about 1.1 and 1.2. These results showed the strong donation from cyclopentadienyl rings to a metal center.

3.2. Effective exchange integrals

Table 2 summarized calculated effective exchange integrals (J values). Both UB3LYP and UB2LYP calculations

Table 1
Spin density and NBO natural charge distributions

	Spin density		Charge density	
	High-spin	Low-spin	High-spin	Low-spin

(a) and (b) are results of **1** and **2**, respectively.

have reproduced positive J values, which correspond to ferromagnetic interactions of experimental results. The experimental values of model **1** and model **2** were 6.3 cm^{-1} [28] and 9.7 cm^{-1} [7], respectively. Calculated results are qualitatively consistent with the experimental results. Comparing the results of UB3LYP with those of UB2LYP, it was clear that both methods showed close results. So, differences from functionals used in hybrid-DFT calculations could not be detected. Because effective exchange integral is sensitive to electronic structure we could conclude that the calculated electronic structures were sufficient and reliable for further discussions.

3.3. Spin density and McConnell mechanisms

As was discussed in introduction of this paper, charge transfer mechanism (McConnell II mechanism) causes positive spin densities on cyclopentadienyl rings. Otherwise, spin-polarization mechanism (McConnell I mechanism) causes negative spin densities on the ring. In Figs. 3 and 4, we presented the spin densities on cyclopentadienyl rings in case of model **1** and model **2**, respectively. In

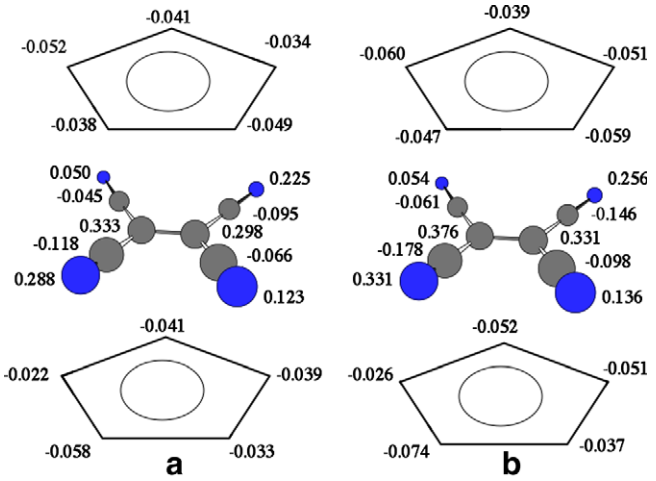

Fig. 3. Spin density distributions in case of **1**. (a) The result of UB3LYP and (b) is the result of UB2LYP.

Fig. 4 we neglected the hydrogen atoms in TCNQ for simplicity. The calculated results in both case of UB3LYP and UB2LYP calculations showed that the sign of spin

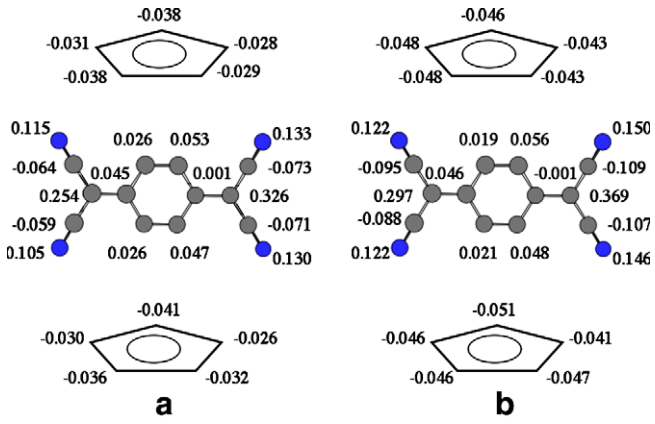

Fig. 4. Spin density distributions in case of **2**. (a) The result of UB3LYP and (b) is the result of UB2LYP. Hydrogen atoms in TCNQ are neglected for simplicity.

densities on the rings was negative, therefore these results supported the spin-polarization mechanism proposed by C.Kollmar et al [3,13].

3.4. Natural orbital analysis, occupation numbers and effective exchange integral

We have confirmed that spin-polarization effect has some contribution to the ferromagnetism of these systems. However, the orbital interactions of these systems have not been discussed yet. In order to consider the relation between magnetic property and electronic structure, we performed natural orbital analysis. Figs. 5 and 6 presented the natural orbitals (NOs) and their occupation numbers. These figures indicated the NOs whose occupation numbers were close to 1.0, therefore other NOs had about 2.0 or 0.0 in occupation numbers. The singly occupied NOs (SONO) were degenerated. From the figures of NOs, it was clear that NOs whose orbital numbers are (203) and (209) represented the interaction between d-orbital in Cr

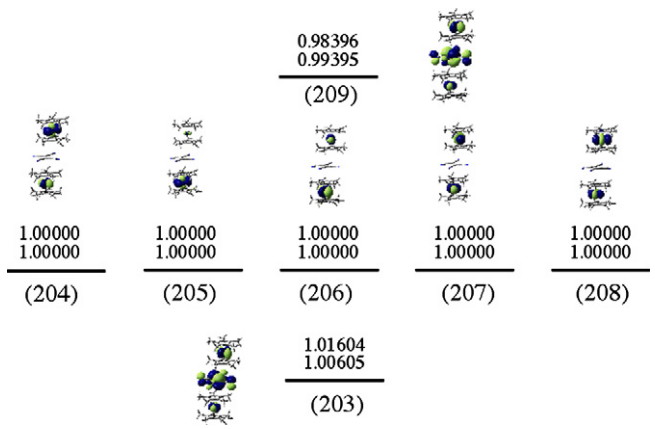

Fig. 5. Singly occupied natural orbitals (SONOs) and occupation numbers of **1**. The numbers in parentheses indicate orbital numbers. Occupation numbers in upper row indicate the results of UB3LYP and occupation numbers in lower row indicate the results of UB2LYP.

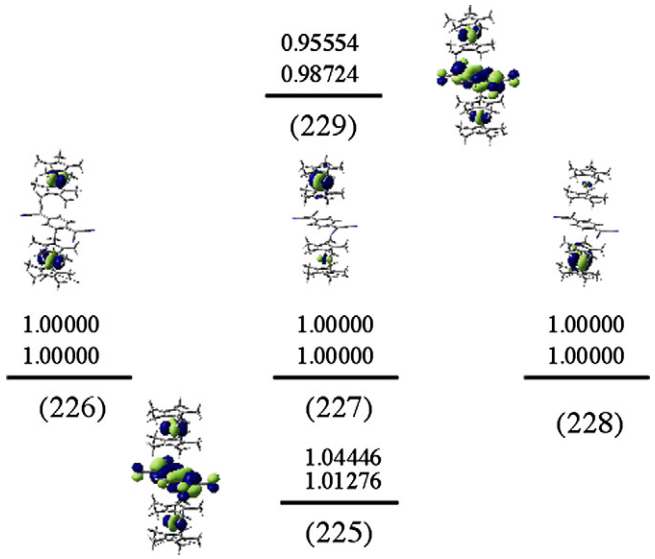

Fig. 6. Singly occupied natural orbitals (SONOs) and occupation numbers of **2**. The numbers in parentheses indicate orbital numbers. Occupation numbers in upper row indicate the results of UB3LYP and occupation numbers in lower row indicate the results of UB2LYP.

and HOMO of $TCNE^{-}$ anion in case of **1**. The other NOs represented SONOs which localized only on metal site. In case of **2**, NOs of number 225 and 229 represented the interaction between d-orbital in manganese and HOMO of TCNE anion.

In Table 3, T_i of each SONO were summarized. In case of **1**, NO of orbital number 203 had almost no orbital overlap (T). This result indicated that SOMO on Cr and SOMO on TCNE anion were orthogonal. The same discussion could be applicable to the orbital number 225 in **2**. According to the Kanamori–Goodenough rule [28–30], ferromagnetic interaction could be expected if SOMO–SOMO overlap was zero.

Previously, we have discussed on the ferrimagnetic behavior of charge transfer manganese porphyrin and TCNE system [16]. The T value of NO which represented the SOMO–SOMO interaction between d-orbital in manganese and TCNE anion was 0.30. This result showed the large overlap of SOMO–SOMO caused the antiferromagnetic interaction.

Table 3
Orbital overlap T_i (i = orbital number)

	203	204	205	206	207	208	209
(a)							
T_i(UB3LYP)	0.01604	0.00	0.00	0.00			
T_i(UB2LYP)	0.00605	0.00	0.00	0.00			

	225	226	227	228	229
(b)					
T_i(UB3LYP)	0.04446	0.00	0.00		
T_i(UB2LYP)	0.01276	0.00	0.00		

(a) is the results of **1** and (b) is the results of **2**.

3.5. Decomposition of J value and ferromagnetism

In unrestricted Hartree–Fock approximation scheme, effective exchange integral is generally expressed by different terms as

$$J_{ab} = J_{ab}(\mathrm{KE}) + J_{ab}(\mathrm{PE}) + J_{ab}(\mathrm{SP}) \quad (9)$$

$$J(\mathrm{KE}) = -cS_{ab} \quad (10)$$

$$J(\mathrm{PE}) = K_{ab} \quad (11)$$

$$J(\mathrm{SP}) = -\sum A\rho_a\rho_b \quad (12)$$

where kinetic (KE) and potential (PE) terms are represented by SOMO–SOMO orbital overlap S_{ab} (T value in formula Eq. (8)) and exchange integral K_{ab}, respectively [31,32]. c and A are parameters determined by ab initio calculation. Spin-polarization (SP) term was given by the product of spin densities ρ. In DFT scheme, it is unclear how to express the exchange (J(PE)) term explicitly, however this type of decomposition could be available on assumption that J(PE) is always positive considering the Hund rule. Considering the orbital overlap was almost zero, calculation results could be explained that negative J(KE) was nearly zero and J(PE) was positive therefore, the net magnetic interaction by J(PE) plus J(KE) contributed to positive J_{ab}.

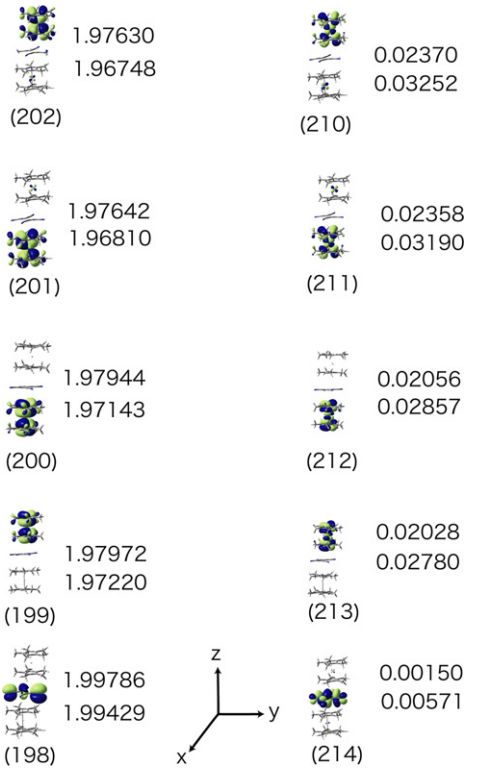

Fig. 7. Natural orbitals around SONOs and their occupation numbers in case of **1**. The numbers in parentheses are orbital numbers. NOs of orbital numbers 198 and 214 are bonding and anti-bonding pair, and so on. Occupation numbers in upper row indicate the results of UB3LYP and those in lower row indicate the results of UB2LYP.

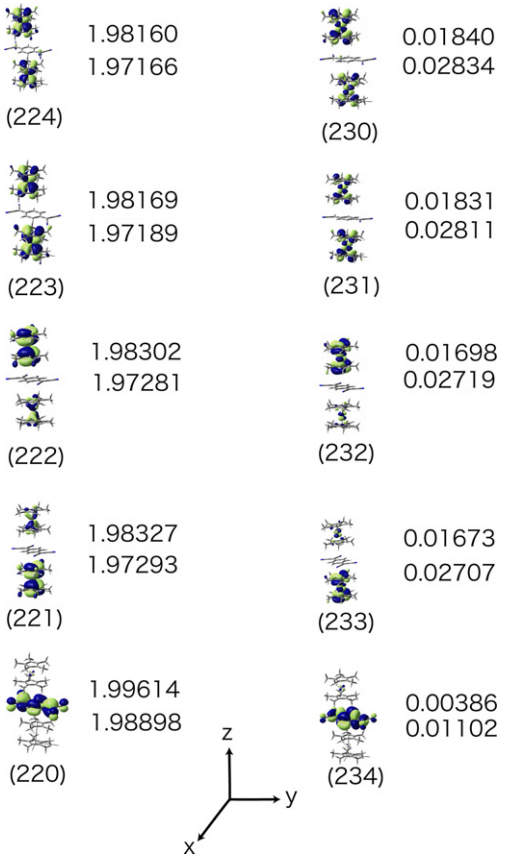

Fig. 8. Natural orbitals around SONOs and their occupation numbers in case of **2**. The numbers in parentheses are orbital numbers. NOs of orbital numbers 220 and 234 are bonding and anti-bonding pair, and so on. Occupation numbers in upper row indicate the results of UB3LYP and those in lower row indicate the results of UB2LYP.

To estimate the effect of spin polarization, occupation numbers around singly occupied natural orbitals (SONOs) and shapes of these NOs were depicted in Figs. 7 and 8. From Fig. 7, NOs of number 199–202 of **1** whose occupation numbers were about 1.97 showed localization on cyclopentadienyl ring. These results suggested the existence of spin-polarization effect of the ring, because the NOs of occupation number 2.0 were described as RHF like picture, which showed no spin-polarization. The same discussion could be applied to **2**. Therefore, it might be suggesting that spin-polarization effect had some contribution to positive J_{ab} value. To examine the effect of J(SP) term quantitatively, we need to perform multi-reference calculations beyond single reference broken-symmetry method.

4. Conclusion

To explain the ferromagnetism of donor–acceptor systems of $[Cr(C_5Me_5)_2]^+[TCNE^-]^-$ and $[Mn(C_5Me_5)_2]^+[TCNQ^-]^-$, hybrid-DFT calculation of reduced model complexes was performed. By using broken-symmetry hybrid-DFT method, effective exchange integrals were calculated. Those effective exchange integrals reproduced the experimental values well. Therefore, electronic structures

of model complexes could be considered as good models of real systems. The results of spin density distributions showed the spin-polarization and the sign of spin densities on cyclopentadienyl rings was negative. These results supported the so-called McConnell I mechanism. On the other hand, natural orbital analysis made it clear that the SOMO–SOMO overlap between metal site and TCNE or TCNQ anion site were almost zero. Therefore orbital orthogonality might be the important key point for explaining the ferromagnetism of these systems. By using decomposition of effective exchange integral, effects by both exchange term and spin-polarization term for ferromagnetism was explained well. To estimate the spin-polarization effect for ferromagnetism quantitatively, multi-reference methods are necessary, however it is impossible because of computing cost at this stage. Therefore, broken-symmetry hybrid-DFT was powerful method to analyze those electronic structures.

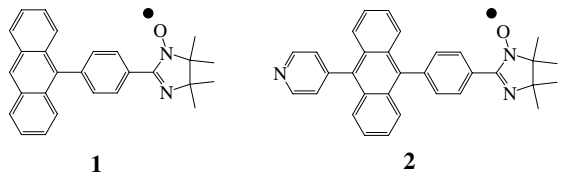

Fig. 1. Molecular structures of organic radicals which has photo-excited quartet state.

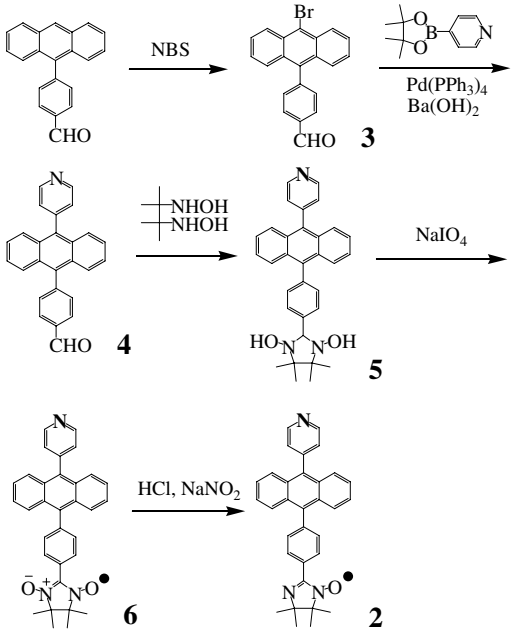

2. Experimental

2.1. Materials

2,3-Bis(hydroxyamino)-2,3-dimethylbutane [7] and 9-(4-formylphenyl)anthracene [1] were prepared according to the literature methods. **2** was synthesized according to Scheme 1.

2.1.1. 9-(4-Formylphenyl)-10-bromoanthracene (3)

A mixture of 4.23 g (15 mmol) of 9-(4-formylphenyl)-anthracene and 2.67 g (15 mmol) of NBS in DMF anhydrous (180 ml) was stirred at room temperature for 24 h. After toluene was added, the organic layer was extracted, washed with brine, and dried ($MgSO_4$). After filtration, evaporation, and recrystallization from toluene gave **3** in 73% yield as yellow prisms: mp 225–226 °C; ^1H NMR ($CDCl_3$) δ 7.40 (dd, $J = 8.7$, 6.3 Hz, 2H, ArH), 7.53–7.63 (m, 6H, ArH), 8.12 (d, $J = 7.9$ Hz, 2H, ArH), 8.64 (d, $J = 9.0$ Hz, 2H, ArH), 10.20 (s, 1H, CHO); *Anal.* Calc. for $C_{21}H_{13}OBr$: C, 69.82; H, 3.63. Found: C, 70.03; H, 3.63%.

Scheme 1. Synthesis of 4-pyridinyl-phenylanthracene-stable radicals **2**.

2.1.2. 9-(4-Formylphenyl)-10-(4-pridyl)anthracene (4)

A mixture of 3.61 g (10.0 mmol) of **3**, 2.05 g (10.0 mmol) of 4-(4,4,5,5-tetramethyl-1,3,2-dioxa-borolan-2-yl)pyridine, 5 mol% of $Pd(PPh_3)_4$, 9.5 g of $Ba(OH)_2 \cdot 8H_2O$ in 1,4-dioxane (350 ml)-H_2O (100 ml) was refluxed under Ar for 72 h. After ethylacetate was added, the organic layer was extracted, washed with brine, and dried ($MgSO_4$). After filtration and evaporation, chromatography (silica-gel, the first developing solvent was toluene, the second one is toluene:ethyl acetate = 2:1) and recrystallization from toluene gave **4** in 30% yield as yellow powder: mp > 300 °C; ^1H NMR ($CDCl_3$) δ 7.36–7.43 (m, 4H, ArH), 7.50 (d, $J = 6.0$ Hz, 2H, ArH), 7.59–7.69 (m, 6H, ArH), 8.16 (d, $J = 7.9$ Hz, 2H, ArH), 8.90 (d, $J = 6.1$ Hz, 2H, ArH), 10.22 (s, 1H, CHO); *Anal.* Calc. for $C_{26}H_{17}NO$: C, 86.88; H, 4.77; N, 3.90. Found: C, 87.11; H, 4.87; N, 3.72%.

2.1.3. 9-[4-(4,4,5,5-Tetramethyl-1,3-dihydroxyimidazolidin-2-yl)phenyl]-10-(4-pyridyl)anthracene (5)

A mixture of 0.84 g (2.3 mmol) of **4**, 0.83 g (5.6 mmol) of 2,3-bis(hydroxyamino)-2,3-dimethylbutane, 0.14 g of 2,3-bis(hydroxyamino)-2,3-dimethylbutane dihydrogen sulfate in MeOH (50 ml)–$CHCl_3$ (50 ml) was refluxed under Ar for 24 h. After filtration, the deposit was washed with MeOH and H_2O to give **5** in 68% yield as white powder (crude).

2.1.4. 9-[4-(4,4,5,5-Tetramethyl-4,5-dihydro-1H-imidazolidin-1-oxyl-3-oxide)phenyl]-10-(4-pyridyl)anthracene (6)

A suspension of 0.94 g (1.9 mmol) of **5** in 100 ml of toluene was added a solution of 1.5 g of $NaIO_4$ in 50 ml of H_2O, and for 3 h. The organic layer was separated, washed with brine, dried ($MgSO_4$). After filtration and evaporation, recrystallization from MeOH gave **5** in 79% yield as blue powder: *Anal.* Calc. for $C_{32}H_{28}N_3O_2$: C, 78.99; H, 5.80; N, 8.64. Found: C, 78.95; H, 5.83; N, 8.36%.

2.1.5. 9-[4-(4,4,5,5-Tetramethyl-1-yl-oxyimidazolidin-2-yl)-phenyl]-10-(4-pyridyl)anthracene (2)

The mixture of 0.70 g (1.44 mmol) of **5** and 2.07 g of $NaNO_2$ in CH_2Cl_2 (80 ml)–H_2O (30 ml). 18 ml of 0.1 M HCl was added dropwise to the mixture at 0 °C. The organic layer separated, washed with brine, dride ($MgSO_4$). After filtration and evaporation, the residue was purified by chromatography (silicagel, dichloromethane:ethyl acetate = 5:1) and recrystallization from hexane/toluene gave **2** in 88% yield as orange powder: mp 263–264 °C (decomp.); *Anal.* Calc. for $C_{32}H_{28}N_3O$: C, 81.67; H, 6.00; N, 8.93. Found: C, 81.55; H, 5.94; N, 8.83%.

2.1.6. Cu(II)(hfac)$_2$(2)$_2$ and Mn(II)(hfac)$_2$(2)$_2$

In order to remove the water of crystallization, the solution of $M(hfac)_2 \cdot xH_2O$ (M = Cu(II) or Mn(II)) in heptane was dried by concentration at 100 °C. To the solution was added a toluene solution of **2** and the mixture was stirred

1 h. After cooling, the deposit was corrected by filtration. Recrystallization from hexane/toluene gave Cu(II)-(hfac)$_2$(**2**)$_2$ as orange prisms: *Anal*. Calc. for $C_{74}H_{58}F_{12}N_6O_6Cu \cdot 0.5C_7H_8$ (toluene): C, 63.54; H, 4.27; N, 5.74. Found: C, 63.67; H, 4.28; N, 5.71%. (The existence of toluene of crystallization was confirmed by a X-ray crystallographical analysis described later.) Repeating recrystallization from hexane/toluene and from hexane/dichloromethane gave Mn(II)(hfac)$_2$(**2**)$_2$ as red prisms: *Anal*. Calc. for $C_{74}H_{58}F_{12}N_6O_6Mn \cdot 0.5C_6H_{14}$ (hexane): C, 63.64; H, 4.51; N, 5.78. For $C_{74}H_{58}F_{12}N_6O_6Mn \cdot 0.5\,C_7H_8$ (toluene): C, 63.92; H, 4.30; N, 5.71. Found: C, 63.76; H, 4.30; N, 5.71%. (The existence of toluene or hexane of crystallization was suggested by elemental analysis.)

2.2. Measurements

TRESR spectra were measured with a JEOL TE300 X-Band ESR spectrometer modified to the TRESR measurements and a Nd:YAG pulse laser was used for a excitation ($\lambda = 355$ nm, pulse width <7 ns). The temperature was controlled by Oxford ESR 910 He gas flow system. The details of TRESR setup were described in our previous paper [1]. Magnetic susceptibility measurement were carried out with a SUQID magnetometer (Quantum Design MPMS2). The X-ray crystallographic data of the metal complexes were collected on a Rigaku/MSC Mercury CCD diffractometer with graphite-monocromated Mo Kα radiation. The structure was solved by a direct method (SIR 97) and expanded using Fourier techniques DIRDIF 99 [8,9].

2.3. Molecular orbital calculations

Molecular orbital calculations were performed based on the density functional theory (UHF Becke 3LYP hybrid method) by GAUSSIAN 98 program using 6-311G^{++} basis set [10].

3. Results and discussion

Fig. 2 shows the TRESR spectrum of **2** in isopentane/dietylether 2:3 glass matrix at 30 K. The spectral simulation was carried out with the eigenfield [11]/exact-diagonalization hybrid method taking dynamic electron polarization into account [1]. The TRESR spectrum is assigned to a photo-excited quartet state. The spin Hamiltonian parameters were determined to be $S = 3/2$, $g = 2.0043$, $D = 0.0220\ \text{cm}^{-1}$, $E = 0.0004\ \text{cm}^{-1}$ for **2**. The D value of **2** is about 6% smaller than that of **1**. The decrease of D shows that the unpaired electrons are delocalized slightly to the 4-pyridyl group. It was interesting to note that 3-pyridyl group shows an opposite effect to that of 4-pridyl group [12]. Thus in 3-pyridyl substituted phenylanthracene-iminonitroxide radical, D value is slightly bigger than that of **1** [1]. This difference comes from the position of a nitrogen atom in the pyridyl group, suggesting a difference of the electronic effect.

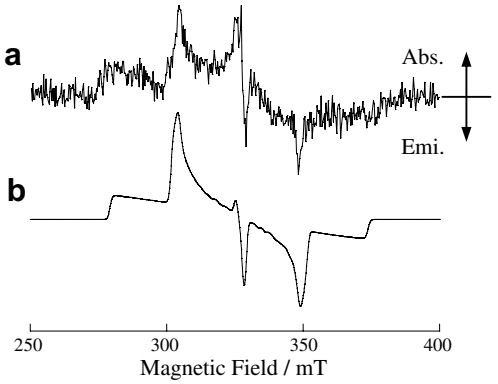

Fig. 2. Typical TRESR spectra and simulations. (a) Observed spectrum of **2** at 0.76 μs after LASER pulse, 280 times accumulated, (b) spectral simulation.

Fig. 3 shows electron spin density distributions of **2** in the doublet ground state and the lowest excited quartet spin state obtained by the ab-initio molecular orbital calculations. As shown in Fig. 3(a), the unpaired electron of **2** distributed in almost only the iminonitroxide radical moiety in the doublet ground state. In contrast, in the excited quartet state, the spin densities were distributed in whole of molecule **2** as shown in Fig. 3(b). By looking the coefficients of each one-electron molecular orbitals, it has been clarified that the α spin densities in the pyridyl moiety are arising from the delocalization of the unpaired spins of the triplet state of the anthracene moiety. The unpaired electrons of the anthracene moiety is strongly coupled to the radical spin [1,2]. Therefore, if **2** is used as a ligand of the metal complex, a strong exchange interaction between paramagnetic center of the metal ion and the photo-excited quartet spin state of π-radical is expected upon photo-excitation.

Crystallographic data of Cu(II)(hfac)$_2$(**2**)$_2$ are shown in Table 1. Fig. 4 shows an ORTEP drawing of Cu(II)-(hfac)$_2$(**2**)$_2$. Two radicals are coordinated symmetrically with the Cu(II) ion in a trans configuration from both side of Cu(II)(hfac)$_2$ plane. The bond distance of Cu–N3 is 1.99 Å. As shown in Fig. 4, a toluene molecule is incorporated into the crystal, which has supported the result of the elemental analysis. For Mn(II)(hfac)$_2$(**2**)$_2$, the single crystals with a suitable size for the X-ray analysis was not obtained at the moment, and only fine crystals were obtained.

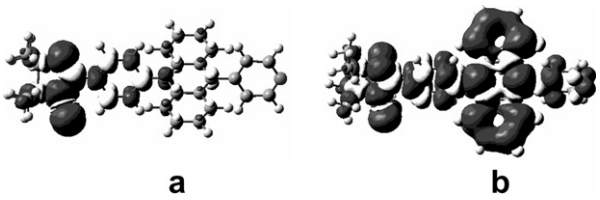

Fig. 3. Calculated spin density of **2**, dark: α spin, light: β spin. (a) Doublet ground state, (b) lowest excited quartet state.

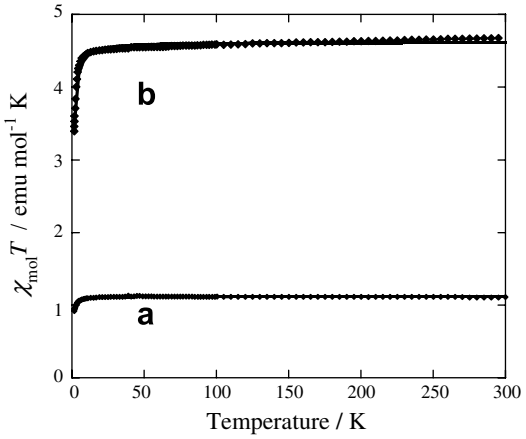

Fig. 5. Temperature dependences of magnetic susceptibility and fitting curve based on Eq. (1) or (2). (a) Cu(II)(hfac)$_2$(**2**)$_2$, (b) Mn(II)(hfac)$_2$(**2**)$_2$.

Fig. 5 shows the temperature dependences of the magnetic susceptibilities of Cu(II)(hfac)$_2$(**2**)$_2$ and Mn(II)-(hfac)$_2$(**2**)$_2$. The temperature dependence of the molar magnetic susceptibility of Cu(II)(hfac)$_2$(**2**)$_2$ shown in Fig. 5(a) was analyzed by three-spin cluster model $S_1 - S_{Cu} - S_2$ ($S_1 = S_2 = S_{Cu} = 1/2$) given by

$$\chi = \frac{N_A g^2 \beta^2}{4k_B(T-\theta)} \times \frac{1 + \exp(2J/k_BT) + 10\exp(3J/k_BT)}{1 + \exp(2J/k_BT) + 2\exp(3J/k_BT)} \quad (1)$$

Here, J is intramolecular exchange interaction between the metal ion and π-radical **2** in ground states, and θ is Weiss constant, $g = 2.006$ was used (the g value of **1** which similar to **2** [1]). $J/k_B = 1.0$ K, $\theta = -0.6$ K were estimated with for Cu(II)(hfac)$_2$(**2**)$_2$ in the ground states. The exchange interaction between Cu(II) ion and **2** was a weak ferromagnetic. The magnitude of J/k_B was estimated from the fitting using the data in high-temperature region, 50–300 K. The slight decrease observed lower than 10 K in Fig. 5(a) is due to the intermolecular antiferromagnetic exchange.

The temperature dependence of the molar magnetic susceptibility of Mn(II)(hfac)$_2$(**2**)$_2$ was well analyzed by three-spin cluster model $S_1 - S_{Mn} - S_2$ ($S_1 = S_2 = 1/2$, $S_{Mn} = 5/2$) given by

$$\chi = \frac{N_A g^2 \beta^2}{4k_B(T-\theta)} \times \left[\frac{10 + 35\exp(5J/k_BT) + 84\exp(12J/k_BT) + 35\exp(7J/k_BT)}{2 + 3\exp(5J/k_BT) + 4\exp(12J/k_BT) + 3\exp(7J/k_BT)}\right] \quad (2)$$

Here, $g = 2.006$ was used. The exchange interaction between Mn(II) and **2** is determined to be $J/k_B = -0.2$ K, and $\theta = -0.1$ K. The intramolecular exchange interaction is antiferromagnetic in this case. The sign change between the Cu(II) and Mn(II) complexes is a well known phenomena which is originated from the nature of the molecular orbitals coordinated by the pyridyl group. It was clarified that the spin exchange interactions between metal ion and ligand **2** were weak in the ground states. This result was supported by the molecular orbital calculations for ligand **2** in the doublet ground state, in which the unpaired electron is almost localized in the radical moiety of **2** in the ground state.

4. Conclusions

In this work, we synthesized 4-pyridyl-phenylanthracene-iminonitroxide radical **2**, which can make the coordination to metal ion by a pyridyl group. We confirmed by

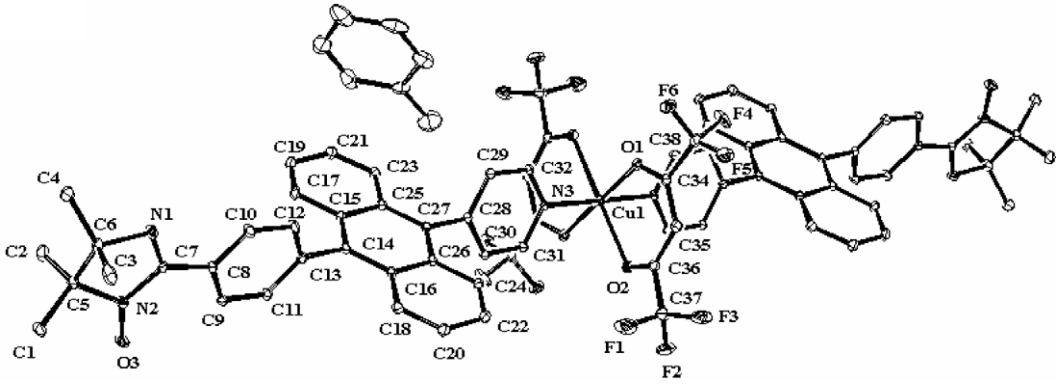

Fig. 4. ORTEP drawing of Cu(II)(hfac)$_2$(**2**)$_2$. A toluene molecule is incorporated into the crystal.

TRESR that **2**, has a photo-excited quartet ($S = 3/2$) state. Calculated spin density is very small in the N atom of the 4-pyridyl group, leading to a weak exchange interaction between the radical **2** and Cu(II) or Mn(II) in the electronic ground state. In contact, it is expected that the exchange interaction in photo-excited state becomes stronger because of the delocalization of the unpaired electrons.

To clarify the interaction between the paramagnetic center of the metal ions and the photo-excited quartet spin state of the π-radical **2**, trials to detect the photo-excited states of the metal complexes are in progress.

although the details about them have not still been understood well.

Our group has been studying about magnetic interactions between metal ions in 1-D complexes by theoretical calculations of the effective exchange integrals (J_{ab}) [10–13], in addition to a development of unrestricted hybrid density functional theory (DFT) method for quantitative calculations of J_{ab} values [15,16]. Understanding of the magnetic interactions is a very effective way to study their electronic structures because the magnetic properties in those complexes are easily affected by their ligand-effects and so on.

In this study, we focused on the variety of the structural phases in $Ni_2(dta)_4I$ and $Pt_2(dta)_4I$ complexes explained above. In order to elucidate the relation among structures, electronic states and magnetic interactions, we carried out the unrestricted hybrid DFT (UHDFT) calculations by using reduced model clusters of those complexes. As a first step, we verified basic information about their electronic structures by using experimental structures. Next, potential and J_{ab} surfaces were examined by using theoretical calculations in order to explain structural phases of those complexes.

2. Theoretical background

2.1. Effective exchange integrals (J_{ab})

The magnetic properties of transition metal complexes were usually investigated by the use of Heisenberg–Dirac–van Vleck spin Hamiltonian [17–19]. For example, the effective exchange interaction between localized spins is described by the total spin form of the spin-coupling Hamiltonian,

$$H = -2\sum J_{ab}\mathbf{S}_a \cdot \mathbf{S}_b, \tag{1}$$

where J_{ab} is the orbital-averaged effective exchange integrals between the spin site a and b with total spin operators $\mathbf{S}_a$ and $\mathbf{S}_b$, respectively. J_{ab} values are usually determined by experiments such as magnetic susceptibility. Recent developments in computational quantum chemistry enabled us not only estimations of molecular structure of large polymetal complexes [20,21] but also the quantitative estimation of J_{ab} values by using broken-symmetry (BS) ab initio and DFT methods [10–16].

The BS approach can be performed at a low computing cost. In singlet biradicals and low-spin (LS) species, however, it suffers from the spin contamination of high-spin (HS) states. Our group proposed spin projection scheme as follows:

$$J_{ab} = \frac{E(\mathrm{LS}) - E(\mathrm{HS})}{\langle S^2\rangle(\mathrm{HS}) - \langle S^2\rangle(\mathrm{LS})}, \tag{2}$$

where $E(X)$ and $\langle S^2\rangle(X)$ denote the total energy and total spin angular momentum for the spin state X (X = LS and HS), respectively [22,23]. In this paper, the magnetic interactions between MM units were discussed J_{ab} values calculated by using the equation.

2.2. Natural orbital analyses

Usual orbital-correlation diagram, which helps us to understand orbital interactions, is not obtained by the BS calculation because of 'different orbitals for different spins (DODS)' approach. In order to clarify the effective exchange interactions in the complexes by using expression like closed-shell MOs, we introduced natural orbitals (NOs), which were determined by diagonalizing their first order density matrices as

$$\rho(r, r') = \sum n_i \{\phi_i(r)\}^* \phi_i(r') \tag{3}$$

where n_i denoted the occupation number of NO ϕ_i [24,25]. If an occupation number of a magnetic orbital is close to 1.0, then two electrons in the orbital are almost localized on each spin site. On the other hand, n_i should be equal to 2.0 if stable chemical bond exists. In other words, the occupation numbers of the BS method contain an important information to understand the nature of chemical bonds and electron localizations in MMX complexes.

To assess a degree of spin localization, instability value (y_i) for a magnetic orbital i (i expresses such as σ, π, δ orbitals) is introduced here as follows:

$$y_i = 2W_D^2 = \frac{n_i^2 - 4n_i + 4}{n_i^2 - 2n_i + 2}, \tag{4}$$

where n_i and n_i^* are occupation numbers of bonding and anti-bonding NO, respectively and W_D denotes a weight of double excitation for orbital i [26]. If a chemical bond (or interaction between spin orbitals) of orbital i is stable, y_i is close to zero. On the other hand, if chemical bond of orbital $i$is unstable and spins are localized like radicals, then y_i is close to unity. Especially, $y_i/2$ is consistent to a weight of the doubly exited configuration in the MCSCF theory [25,26]. In this way, bond natures and degrees of spin-localization can be discussed by using the index.

2.3. Construction of two unit model

In order to analyze a spin–spin interaction in detail from a viewpoint of molecular orbital and to reduce computing costs, we construct two MM units models, namely model complex **1-Ni** and **2-Pt** for $Ni_2(dta)_4I$ and $Pt_2(dta)_4I$, respectively, as illustrated in Fig. 1a. Initial atomic coordinates of **1-Ni** and **2-Pt** were constructed from data of X-ray crystal structure analyses that were available in the Cambridge Structural Database (CSD). The structural parameters used in this study are summarized in Table 1. The definition of metal–iodine distance (d(M–In) ($n = 1,2,\ldots,4$)) is depicted in Fig. 2b.

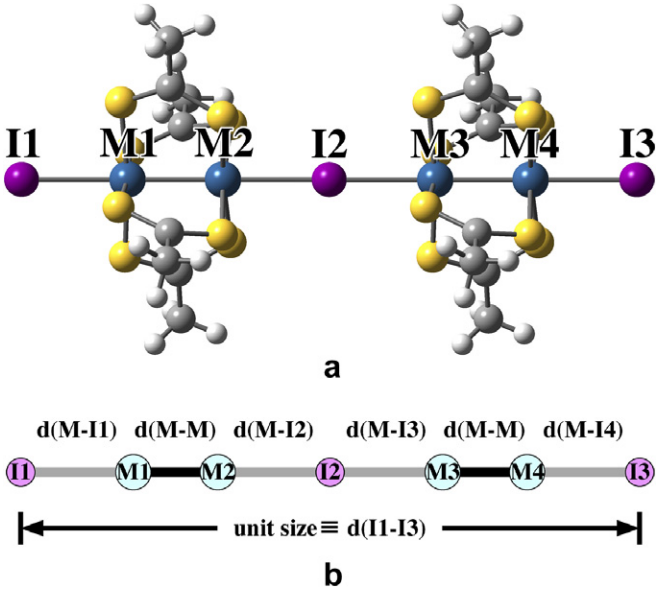

Fig. 1. (a) Illustration of calculated model complex, which is constructed by two MM units. (b) Definition of d(M–In) ($n = 1,2,\ldots,4$), which is expressing a metal–iodine distance. External point charges were added for model complex **1** (see text).

Table 1
Experimental structural parameters[a] of $Ni_2(dta)_4I$ and $Pt_2(dta)_4I$ complexes

Complex	d(M–M) (Å)	d(M–I1) (=d(M–I3)) (Å)	d(M–I2) (=d(M–I4)) (Å)	Ref.
$Ni_2(dta)_4I$	2.514	2.928	2.940	[2]
$Ni_2(dta)_4I$	2.538	2.920	2.923	[3]
$Pt_2(dta)_4I$	2.677	2.975	2.981	[4]

[a] Notations of d(M–M), d(M–In) ($n = 1,2,\ldots,4$) in the table are explained in Fig. 1.

2.4. Computational details

All calculations were performed by use of Tatewaki–Huzinaga MIDI plus p (533(21)/53(21)/(41)) basis set [27] for Ni atoms, LANL2DZ [28] basis set for Pt atoms and 4-31G basis sets for dta^- ligand. For axial iodide ions, MIDI plus d (3333(21)/333(21)/331) basis set and LANL2DZ basis set were used for **1-Ni** and **2-Pt**, respectively. Unrestricted hybrid DFT methods (UB3LYP [29]) were applied for all calculations on GAUSSIAN98 [30].

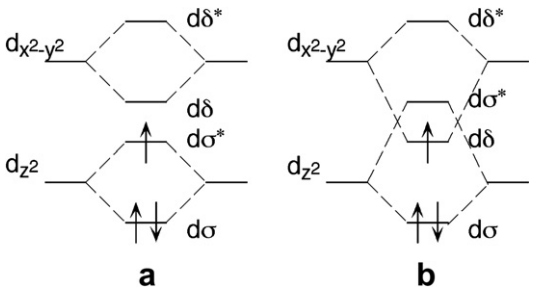

Fig. 2. Two possible electron (spin) configurations in MM unit: (a) the σ spin model and (b) δ spin model, respectively.

3. Calculated results and discussion

3.1. Calculated results of Ni and Pt model complexes by using X-ray structure

In order to elucidate fundamental information about those complexes in terms of magnetic interactions, their electronic structures were examined using experimental (X-ray) structure. The MM unit has a spin because formal charge of metal ion is +2.5 [9]. As already pointed out, there were two possible electron (spin) configurations in those complexes [10]. One is σ spin model and another is δ spin model as illustrated in Figs. 2a and b, respectively. In this study, σ spin model was adopted because our previous calculated results suggested a possibility of σ spin model [10].

The magnetic coupling of two spins causes an energy gap between singlet and triplet spin states. In order to calculate the magnetic coupling parameter (J_{ab}), singlet and triplet spin states were calculated for **1-Ni** and **2-Pt**. The calculated negative J_{ab} values indicated that antiferromagnetic spin coupling between neighboring MM unit for both **1-Ni** and **2-Pt** (see Table 2). J_{ab} value of **1-Ni** was $-488\ cm^{-1}$ and in good agreement with our previous data calculated by the use of rich basis sets ($-403\ cm^{-1}$) [10]. The results showed that the basis sets used here were appropriate to estimate electronic structure of **1-Ni** even if they were small in comparison with previous ones. The absolute values of J_{ab}s were considerably large, especially for **2-Pt**. Such a strong antiferromagnetic interaction might not be recognized as magnetic material but diamagnetic material by experimental [9]. Because there were no bridge ligands except for halogen ion, the origin of strong antiferromagnetic interaction must be a super-exchange interaction between MM units through halogen ion.

In order to make sure whether calculated results were appropriate ones, Mulliken spin densities of singlet state are summarized in Table 3. One electron spin was equally distributed to two metal ions in MM unit. Each spin was found in each MM unit and they coupled antiferromagnetically. Spin densities on MM units of **2-Pt** decreased in comparison with ones of **1-Ni**. It suggested that large spin orbital overlap interaction through iodide ion between Pt dimer units existed in **2-Pt**. Because larger overlap usually induced larger antiferromagnetic interaction [26], the results explained stronger antiferromagnetism in **2-Pt**. Spin densities of terminal iodide ions could not be negligible for **2-Pt**, while very small spin densities on terminal iodide ions for **1-Ni**. This problem strongly related to model structure.

Table 2
Calculated J_{ab} values of model complexes **1-Ni** and **2-Pt**

Models	J_{ab} (cm^{-1})
1-Ni	−488 (−403)[a]
2-Pt	−1274

Table 3
Calculated Mulliken spin densities on atoms of one-dimensional axis[a]

Atoms	Models	
	1–Ni	2–Pt
I1	0.061	−0.199
M1	0.469	−0.174
M2	0.373	−0.132
I2	−0.005	−0.001
M3	−0.396	0.121
M4	−0.445	0.182
I3	−0.057	0.205

[a] Notations of atom numbers in the table are explained in Fig. 1.

Here, infinite MMX chain was reduced into two MM-unit models for a reduction of computing costs. For the construction of the model complexes, we tested several model structures in order to obtain appropriate electronic configuration. The result showed us that positive point charges at locations of neighboring Ni ions were effective for **1-Ni**. Because the terminal positive charges attracted the valence electrons in iodide ions, iodide ions could remain closed shell type (I^{2-}) structures. On the other hand, the point charges easily changed σ spin configuration into δ spin configuration for **2-Pt**. For that reason, the terminal point charges could not be used in order to keep σ spin structure. The lacking of positive charges on terminal position made valence electrons of edge iodide ions delocalizing into MM units. Therefore, edge iodide ions could not keep their closed shell type electron structure because of strong on-site Coulomb repulsion.

In order to examine details about spin–spin interaction between MM units, natural orbital (NO) analyses were carried out for both model complexes **1-Ni** and **2-Pt**. NOs of magnetic orbitals of **1-Ni** and **2-Pt** are depicted in Fig. 3. The NOs were obviously showing that magnetic orbitals were σ orbitals of MM units. The highest occupied NO (HONO) and lowest unoccupied NO (LUNO) were results of 'in phase' and 'out of phase' interactions between two dσ orbitals of MM units, respectively, for both **1-Ni** and **2-Pt**. The figure suggested larger delocalization of NOs in **2-Pt** in comparison with ones of **1-Ni**. Occupation numbers of NOs and instability values summarized in Table 4 clearly indicated it. Calculated y value of **1-Ni** was 50%, while y value of **2-Pt** was only 8%. The results indicated that orbital overlap between two spins on MM units were very large in **2-Pt**. On the other hand, two spins had almost localized at each MM units in **1-Ni**. The delocalized spin orbitals of **2-Pt** made interactions between MM units easier. The difference between **1-Ni** and **2-Pt** seemed to reflect the difference in the nature of 3d and 5d electrons directly, because 3s orbitals usually shrank although 4d and 5d electrons tended to delocalize. Originally σ orbitals in 1-D complexes tend to delocalize along its 1-D axis [10,11]. Such strong delocalizing nature of 5d electrons seems to enhance the overlapping between MM units through iodide anion. Our previous results suggested that four MM units model was preferable for the quantitative study. In order to relieve the influence of spin densities of terminal iodide anion, four MM units model seemed to be necessary. However, two MM units model, which used here is enough for semi-quantitative discussion from the calculated results.

3.2. Potential and J_{ab} surfaces

Finally, potential and J_{ab} surfaces with relative position of metal and iodide ions were examined by using model structures. In pure AVSDW state, all metal–iodine (M–I) bond-length should be same i.e. d(M–I1) = d(M–I2) = d(M–I3) = d(M–I4) [3], where d(M–In) was defined in Fig. 2b. Experimental data summarized in Table 1, how-

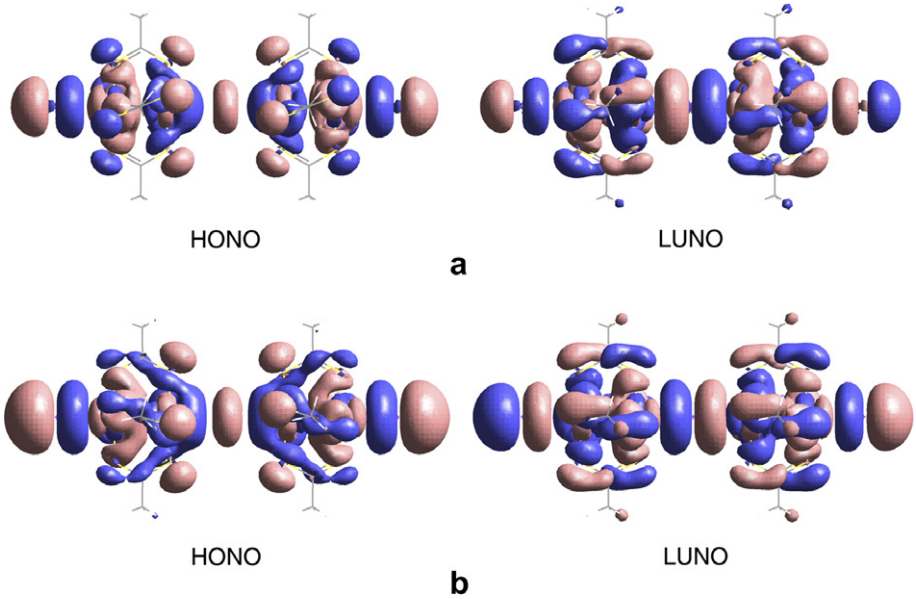

Fig. 3. The highest occupied NO (HONO) and lowest unoccupied NO (LUNO) of **1-Ni** and **2-Pt**: (a) **1-Ni** and (b) **2-Pt**, respectively.

Table 4
Calculated occupation numbers of HONO, LUNO and y values

Models	HONO	LUNO	y Value (%)
1-Ni	1.268	0.732	50.0
2-Pt	1.661	0.339	8.0

ever, were indicating that the complexes were not pure AVSDW structure but rather CP structure. In other words, the M–I bonds were classified into two types i.e shorter d(M–I2), d(M–I3) and longer d(M–I1), d(M–I3). In order to focus on a relation among stability, magnetic interaction, metal–metal distance and metal–halogen distance, we assumed model displacement as illustrated in Fig. 4. Starting from the pure AVSDW structure, artificial structural distortions were added in the model complexes. The added distortions were symmetric and anti-symmetric ones. The anti-symmetric distortion leads the complex to CP-type structure, while symmetric distortion leads the complex to ACP-type structure. Because the position of iodide ion was fixed during the procedure, unit size (d(I1–I3)) was constant.

Calculated results of **1-Ni** are depicted in Fig. 5. Oblique dash lines expressed the points of d(M–I1) = d(M–I2) = d(M–I3) = d(M–I4). In other words, the line meant the point, where the model complex was pure AVSDW structure. Within surveyed area, shape of potential surfaces of singlet and triplet state were, roughly, similar each other

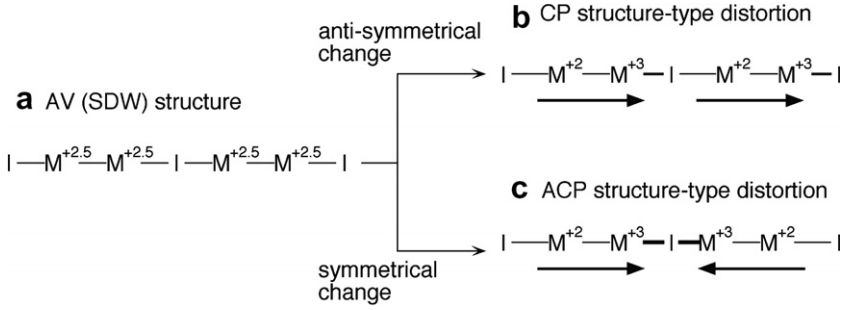

Fig. 4. Illustration of model displacement added to model complexes **1-Ni** and **2-Pt**. Starting from the formal AVSDW structure (a), symmetric and anti-symmetric artificial structural distortions were added to metal ions in the complexes, but position of iodide ion was fixed. The anti-symmetric distortion leads the complex to CP type structure (b), while symmetric distortion leads the complex to ACP type structure (c).

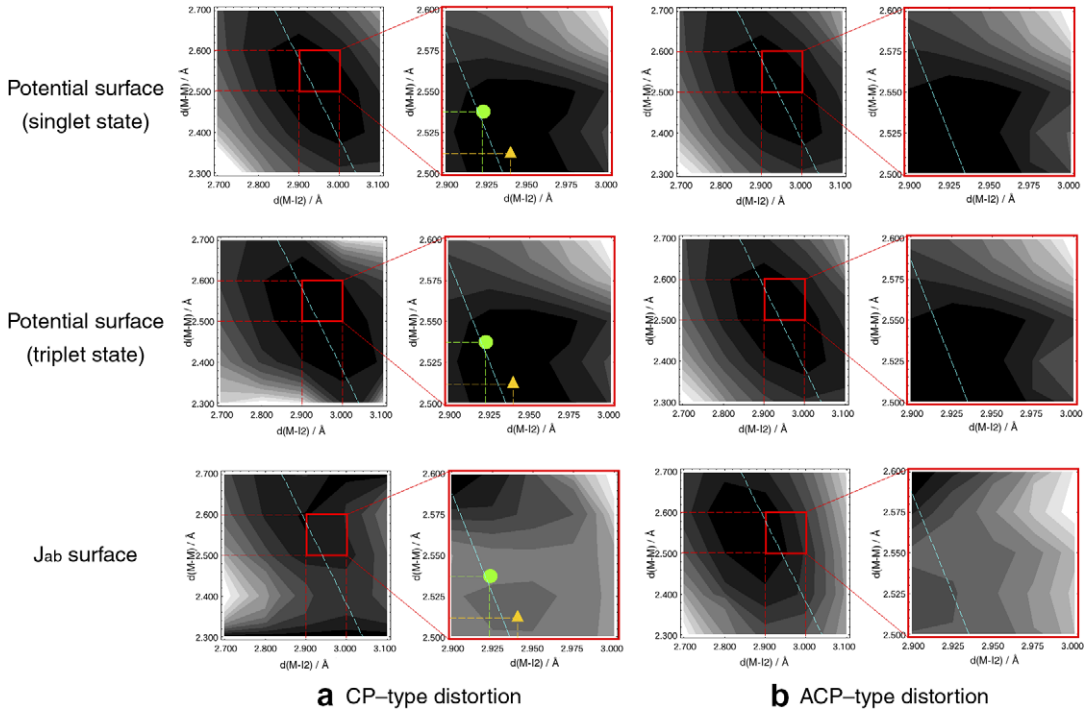

Fig. 5. Potential surfaces and J_{ab} surfaces of **1-Ni**. (a) and (b) are surfaces when CP-type and ACP-type distortion were added to AVSDW structure, respectively. Darker area indicated more stable area in potential surfaces (or more negative J_{ab} values). Oblique dash lines expressed the points that AVSDW structure (see text). ▲ and ● expressed experimental structure in Refs. [2,3], respectively. Left pictures on each group were enlarged ones.

in regard to both CP- and ACP-type structural changes. In addition, J_{ab} values were negative in all area, so the singlet state was stable in whole area. Although CP surface was slightly stable in comparison with ACP surface, the only one stable area, which was very close to the oblique dash lines, was found. It indicated that stable structure had the only minimum and AVSDW structure was the only possible structure. The result was consistent with experimental ones [2,3]. Two experimental structures mapped in the figures (▲ [2] and ● [3]) were located on the broad and most stable region along oblique dash lines.

On the other hand, two minima were observed in **2-Pt** as illustrated in Fig. 6. One stable minimum was located along AVSDW oblique dash lines on surface of ACP-type structure. Another meta-stable minimum was found in CP-type surface. This meta-stable minimum was energetically unstable in comparison with global minimum on ACP-type surface at least 0.6 eV within the calculated model. Of course, the energy difference between global minimum and meta-stable minimum must be smaller if rearrangement of ligands' structure was taken into account. As mentioned before, experimental results indicated that $Pt_2(dta)_4I$ complex as classified into AVSDW structure at higher temperature ($T > 300$ K), however CP structure and ACP structure were observed at lower temperature, $300 > T > 80$ K and $T < 80$ K, respectively [9]. The calculated results supported such experimental results at lower temperature.

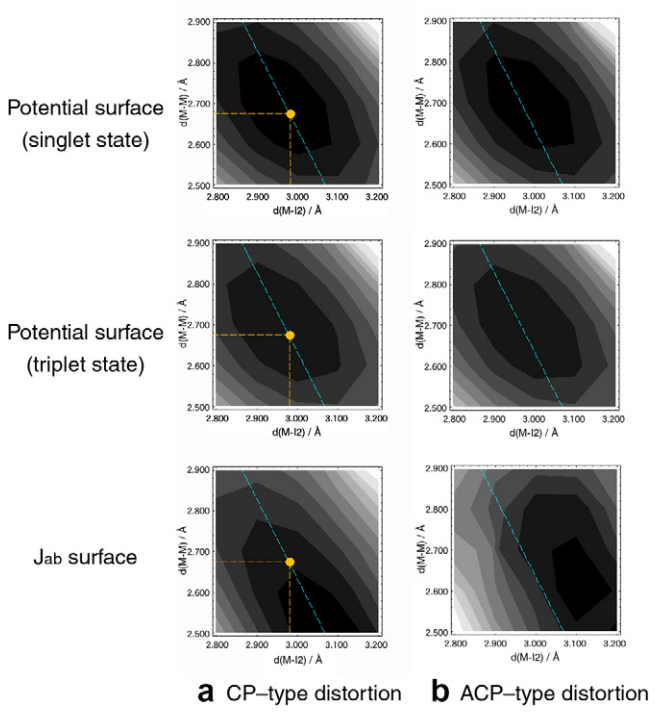

Fig. 6. Potential surfaces and J_{ab} surfaces of **2-Pt**. (a) and (b) are surfaces when CP-type and ACP-type distortion were added to AVSDW structure, respectively. Darker area indicated more stable area in potential surfaces (or more negative J_{ab} values). Oblique dash lines expressed the points that AVSDW structure (see text). ● expressed experimental structure in Ref. [4].

Unfortunately, we could not compare those obtained structures (minima) with experimental structures because there were no available data of X-ray structural analyses for CP and ACP structure. Interestingly, experimental structure [4], which was indicated by orange circle in the figure, was not classified into both minima, but located at intermediate position between both minima. The result of X-ray crystallography analysis might be an averaged structure of both CP and ACP structure.

4. Conclusion

The electronic structures of model clusters of $Ni_2(dta)_4I$ and $Pt_2(dta)_2I$ complexes were examined by using UB3LYP calculations. The calculated results indicated strong antiferromagnetic interactions between spins on MM units. Estimated orbital overlap between two spin orbitals on MM units indicated that spins were delocalized along 1-D chain in $Pt_2(dta)_2I$, while they were almost localized on MM units in $Ni_2(dta)_4I$. Calculated potential surfaces of **1-Ni** that had the only minimum at AVSDW structure supported the experimental results that no other phases except for AVSDW were reported. On the other hand, two minima were found in **2-Pt**. The global minimum located on ACP surface but it was very close to AVSDW structure. The meta-stable minimum was on CP surface. The results were supporting that existence of stable and meta-stable phases i.e. CP and ACP structure in $Pt_2(dta)_2I$. Those calculations were carried out under an approximation of fixed ligands. In real systems, ligands must rearrange in order to stabilize a total energy of the crystal. For the further quantitative analyses, the effects of those rearrangements should be taken into account.

Although Heisenberg Hamiltonian was used here to estimate magnetic interactions between MM units, it is desirable to use Peierls–Hubbard Hamiltonian in order to consider the physical meanings of calculated results in detail. Yamamoto [31] has reported calculated phase diagrams by using Peierls–Hubbard Hamiltonian for 5/6-filled one-dimensional two-band three-orbital systems,

$$\begin{aligned} H = & \sum_{m,s}\sum_{j=1,2}\left(\varepsilon_M - \beta l_{j:n}\right)n_{j:m,s} + \sum_{m,s}\varepsilon_X n_{3:m,s} \\ & - \sum_{m,s}\sum_{j=1,2}\left(t_{MX} - \alpha l_{j:n}\right)\left(a^{\dagger}_{j:n,s}a_{3:n,s} + a^{\dagger}_{3:n,s}a_{j:n,s}\right) \\ & - \sum_{m,s} t_{MM}\left(a^{\dagger}_{1:n,s}a_{2:n-1,s} + a^{\dagger}_{2:n-1,s}a_{1:n,s}\right) \\ & + \sum_{m}\sum_{j=1,2} U_M n_{j:m,+}n_{1:m,-} + \sum_{m} U_X n_{3:n,+}n_{3:n,-} \\ & + \sum_{m,s,s'}\sum_{j=1,2} V_{MX} n_{j:m,s}n_{3:m,s'} + \sum_{m,s,s'} V_{MM} n_{1:m,s}n_{2:m-1,s'} \\ & + \sum_{m}\sum_{j=1,2}\frac{K}{2} l^2_{j:m}, \end{aligned} \tag{5}$$

where $n_{j:m,s} = a^{\dagger}_{j:m,s}a_{j:m,s}$ with $a^{\dagger}_{j:m,s}$ being the creation operator of an electron with spin $s = \pm$ (up and down) for the M

d_{z^2} ($J = 1,2$) or X p_z ($j = 3$) in the mth MXM unit, and $l_{j:m} = (-1)^j(u_{j:m} - u_{3:m})$ with $u_{j:m}$ being the chain-direction displacement of a metal ($j = 1,2$) or halogen ($j = 3$) in the mth MXM unit from its equilibrium position. α and β are the inter-site and intra-site electron-lattice coupling constants, respectively, while K is the metal–halogen spring constant. For further investigation of physical properties using ab initio or DFT calculations, projection of calculated results onto such Hamiltonian is necessary.

Up to now, many kinds of MMX complexes consist of Pt such as $R[Pt_2(pop)_4I]\cdot nH_2O$ (R = counter ion, pop = $P_2O_5H_2^{2-}$) has been reported [5,8,32]. The complexes take several phases as their ligands. Those ligands seem to control not only relative stability of potential minima but also their properties [32,33]. The existence of two minima would be useful for material design because it is meaning that physical properties of the complexes could be controlled by external fields such as photon, magnetic fields and so on, if intra-chain structure could be controlled by them. In fact, photo-induced phase transition from CDW to CP state was reported in $R[Pt_2(pop)_4I]\cdot nH_2O$ [32]. In this sense, it is meaningful to examine relation between structure of bridging ligands and potential surfaces by theoretical calculations.

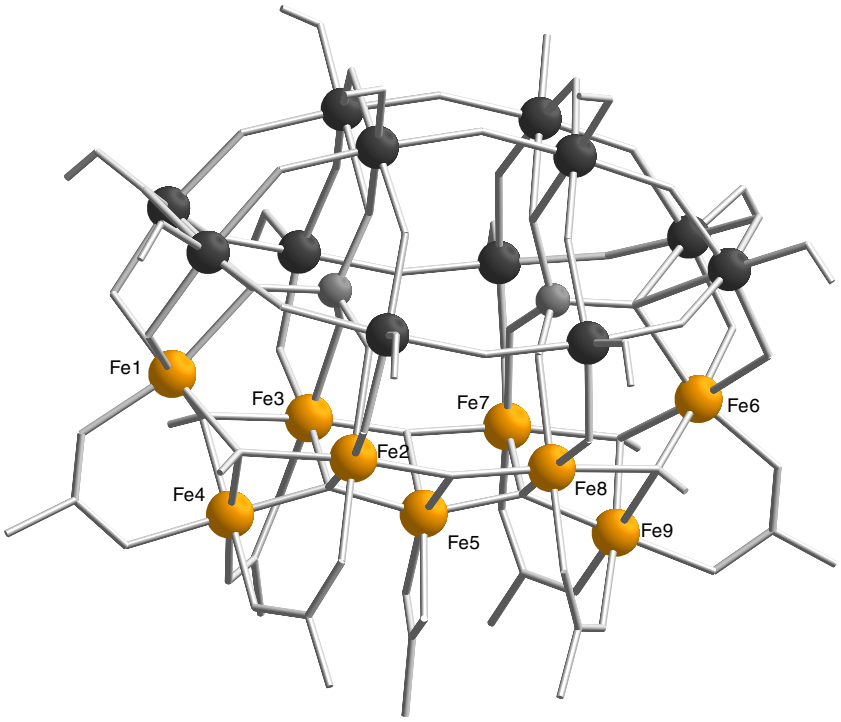

Fig. 1. Representation of the molecular structure of the $[H_4P_2W_{12}Fe_9O_{56}(OAc)_7]^{6-}$ anion. The iron, phosphorus and tungsten atoms are represented as orange, gray and black spheres, respectively. (For interpretation of the references in colour in this figure legend, the reader is referred to the web version of this article.)

theory provide an accurate description of the exchange interaction present in such systems [12]. In all cases, there is a clear relationship between the exchange coupling constants and the kind of bridging ligand present in the exchange pathway. Thus, the exchange interactions are usually antiferromagnetic, with the strongest interactions being mediated by μ_3-oxo bridging ligands, although a double bridging ligand present in an Fe_8 complex favors ferromagnetic coupling [9]. Hence, the aim of this communication is to report a study of the J values in this Fe_9W_{12} complex using methods based on density functional theory.

2. Results and discussion

The analysis of the structure (see Fig. 1) indicates that seven different exchange coupling constants must be considered. Hence, the spin Hamiltonian, considering only the exchange coupling terms, can be expressed as:

$$\begin{aligned}\hat{H} = &-J_1[\hat{S}_3\hat{S}_7 + \hat{S}_2\hat{S}_8] - J_2[\hat{S}_2\hat{S}_5 + \hat{S}_3\hat{S}_5 + \hat{S}_7\hat{S}_5 \\ &+ \hat{S}_8\hat{S}_5] - J_3[\hat{S}_2\hat{S}_3 + \hat{S}_7\hat{S}_8] - J_4[\hat{S}_1\hat{S}_4 + \hat{S}_6\hat{S}_9] \\ &- J_5[\hat{S}_1\hat{S}_3 + \hat{S}_1\hat{S}_2 + \hat{S}_6\hat{S}_7 + \hat{S}_6\hat{S}_8] - J_6[\hat{S}_2\hat{S}_4 \\ &+ \hat{S}_3\hat{S}_4 + \hat{S}_7\hat{S}_9 + \hat{S}_8\hat{S}_9] - J_7[\hat{S}_4\hat{S}_5 + \hat{S}_5\hat{S}_9] \qquad (1)\end{aligned}$$

where $\hat{S}_i$ are the spin operators of each paramagnetic Fe^{III} center (see Fig. 2). A detailed description of the procedure used to obtain the exchange coupling constants can be found in previous papers [13–15] and a summary is provided in the Computational Details section. Despite that hybrid functionals provide a better description of the exchange interaction than generalized gradient approximation (GGA) ones, we have found for Fe^{III} polynuclear complexes that the results obtained with the numerical code SIESTA and a GGA functional reproduce very well experimental J values [16]. Taking into account this fact and due to the large size of the Fe_9W_{12} complex, we have employed such less CPU time consuming approach instead of the usual calculations with Gaussian functions and hybrid functionals. Due to the high sensitivity of the exchange coupling constants to small structural changes, we have employed the crystallographic structure, to include also the packing effects present in solid state to be closer to the experimental measurement conditions.

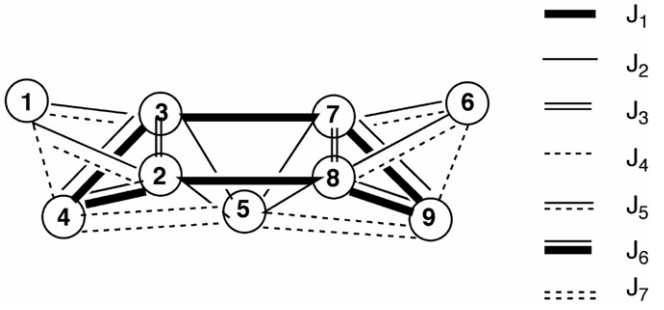

Fig. 2. Scheme showing the topology of the seven exchange interaction.

The calculated exchange coupling constants are presented in Table 1. They show similar trends than previously

Table 1
Description of the bridging ligands, average metal–metal and metal–oxygen distances (Å), Fe–O–Fe bond angles (°) and calculated exchange coupling constants J (cm^{-1}) for the Fe_9W_{12} complex

	Bridging ligands	Fe···Fe	Fe–O	Fe–O–Fe	J_{PBE}
J_1	μ_3-O	3.762	1.895	166.3	−73.9
J_2	μ_3-O, μ_4-O	2.925	2.044, 1.949	90.0, 96.7	−3.1
J_3	μ_4-O, μ_2-O_2P	3.588	2.002, 2.105	127.3	−42.0
J_4	μ_2-OH, μ_2-OH, μ_2-O_2CMe	2.913	2.115, 2.030	87.1	+26.9
J_5	μ_3-OH, μ_2-O_2P	3.733	2.097, 2.029	125.8	+3.0
J_6	μ_4-O, μ_3-OH, μ_2-O_2CMe	2.948	1.963, 2.020, 2.048	97.4, 88.0	−3.9
J_7	μ_4-O	3.659	1.910	146.6	−59.8

found for other polynuclear Fe^{III} complexes [6–10]: (i) The single μ_3-O bridges provide the strongest antiferromagnetic coupling (J_1) even larger than the μ_4-O bridges (J_7), probably due to the large Fe–O–Fe bond angle; (ii) the simultaneous presence of the μ_4-O and μ_3-O bridges between two iron atoms with relatively small Fe–O–Fe bond angles, as in the case of the J_2 interaction results in a weak antiferromagnetic coupling; (iii) a μ_4-O bridge combined with a μ_2-O_2P one yields significantly antiferromagnetic coupling (J_3); (iv) a double hydroxo bridge together with a μ-acetato bridge (J_4) produce a ferromagnetic coupling, probably favored by the small Fe–O–Fe bond angle (87.1°) and the large out-of-plane shift of the hydrogen atoms (O···O–H angle of 140.4°) [10,11]; and (v) the coupling through a μ_3-OH bridging ligand is weak and the sign of the interaction depends on the other bridging ligands present in the exchange pathway (J_5 and J_6).

The exact diagonalization of the Hamiltonian matrix is computationally very demanding due to the large number of states involved, more than 1×10^7. We would need around 30 GB of memory to store the largest block (88 900 states) corresponding the $S = 9/2$ states. Thus, we have carried out a study of the single determinant state energies, and found that the ground state corresponds to an $S = 15/2$ situation with all iron atoms having spin up, except for Fe3, Fe5 and Fe8 (or the equivalent Fe2, Fe5 and Fe7) atoms. The lowest excited single determinants, 403.5 cm^{-1} above the ground state, are four degenerate $S = 5/2$ solutions with four spin-down iron atoms {Fe1, Fe2, Fe5, Fe7}, {Fe1, Fe3, Fe5, Fe8}, {Fe2, Fe5, Fe6, Fe7} and {Fe3, Fe5, Fe6, Fe8}.

Finally, we have analyzed the distribution of the spin density in the Fe_9W_{12} complex in its $S = 15/2$ single determinant ground state (see Fig. 3). The spin density is mostly localized at the Fe^{III} cations, even if the GGA functionals used here provide a more delocalized picture than the hybrid ones [17,18], with local magnetic moments of around 4.3 e^-. Significant spin delocalization towards donor atoms is observed from the outermost iron cations, especially to oxygen atoms even toward the polyoxometalate part of the molecule and also to the two phosphorus atoms. It is worth noting that there is no spin density at the tungsten atoms, which suggests that the role of these metal atoms is only to provide a scaffold for the arrangement of the magnetic iron atoms.

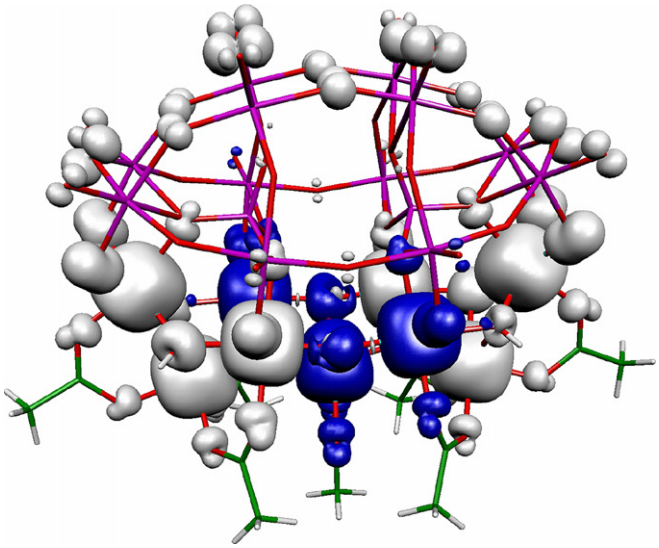

Fig. 3. Representation of the spin density map for the single-determinant ground state $S = 15/2$ of the Fe_9W_{12} complex. The isodensity surface represented corresponds to a value of 0.05 $e^-/bohr^3$ (clear and dark regions indicate positive and negative spin populations, respectively).

3. Computational details

All calculations have been carried out using the version 1.3 of the SIESTA program (Spanish Initiative for Electronic Simulations with Thousands of Atoms) [19]. This computer code has been developed for efficient calculations in large low-symmetry systems [20]. As exchange-correlation functional, we have employed the generalized-gradient approximation one proposed by Perdew et al. (PBE) [21]. Only valence electrons are included in the calculations, the cores are replaced by norm-conserving scalar relativistic pseudopotentials factorized in the Kleinman–Bylander form [22]. These pseudopotentials are generated following to the procedure proposed by Trouiller and Martins [23] from the ground state atomic configurations for all the atoms except for Fe, for which the $[Ar]3d^74s^1$ configuration was employed. The core radii for the s, p and d components of Fe are all 2.00 a.u. while 2.74, 2.24 and 2.24 were employed for tungsten atoms and we have included partial-core corrections for a better description of the core regions [24]. The cutoff radii were 1.15 for oxygen and

hydrogen atoms, 1.25 for carbon and 1.83 for phosphorus atoms, respectively.

We have employed a numerical basis set of triple-ζ quality with polarization functions for the iron and tungsten atoms and a double-ζ one with polarization functions for the main group elements. In this kind of calculations, there are two fundamental parameters that control the accuracy of the numerical calculation [20]. The numerical wavefunction is zero at distances larger than the chosen confinement radius r_c, whose value is different for each atomic orbital. The energy radii of different orbitals is determined by a single parameter, *the energy shift*, that corresponds to the energy increase of the atomic eigenstate due to the confinement. The integrals of the self-consistent terms are calculated with the help of a regular real space grid in which the electron density is projected. The grid spacing is determined by the *maximum kinetic energy* of the plane waves that can be represented in that grid. We have studied the influence of these two parameters on the calculated J values in many transition metal complexes. Thus, the values of 50 meV for the energy shift and 250 Ry for mesh cutoff provide a good compromise between accuracy and computer time needed to calculate the exchange coupling constants [16].

Twelve calculations were performed on the $[H_4P_2W_{12}Fe_9O_{56}(OAc)_7]^{6-}$ complex in order to obtain by least-squares fitting the seven exchange coupling constant, solutions corresponding to the high spin solution ($S = 45/2$), three solutions with $S = 15/2$ {Fe1, Fe5, Fe6}, {Fe4, Fe5, Fe9} and {Fe3, Fe5, Fe8} and eight calculations with $S = 5/2$ {Fe1, Fe2, Fe6, Fe7}, {Fe1, Fe3, Fe6, Fe7}, {Fe1, Fe2, Fe3, Fe4}, {Fe2, Fe3, Fe7, Fe8}, {Fe1, Fe4, Fe6, Fe9}, {Fe2, Fe4, Fe7, Fe9}, {Fe3, Fe4, Fe8, Fe9} and {Fe2, Fe6, Fe7, Fe9}, where the indicated iron atoms are those with spin down.

4. Conclusions

Due to the problems to obtain of a proper experimental magnetic susceptibility curve and the large number of exchange interactions, the use of theoretical methods seems to be the only way to obtain a detailed description of the exchange interactions present in a polyoxometalate Fe_9W_{12} complex. We have found for those interactions the same trends and values than for other polynuclear Fe^{III} complexes, with the μ_3-O bridging ligands mediating the strongest antiferromagnetic coupling. The strength of the antiferromagnetic interactions through oxo-bridging ligands seems to be related with the Fe–O–Fe bond angles. The presence of hydroxo bridging ligands favors the presence of ferromagnetic or very weak antiferromagnetic interactions. Our calculations predict an $S = 15/2$ single determinant ground state, and a four-degenerate first excited state with $S = 5/2$.

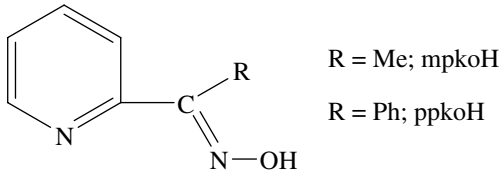

Fig. 1. The general formula of the 2-pyridyl oximes used in this work.

[1b]. The metal ions are antiferromagnetically coupled, and these complexes are not therefore SMMs. We are now pleased to report that the reactions of $[Mn_3^{III}O(O_2CR)_6(py)_3](ClO_4)$, where py is pyridine, with 2-pyridyl oximes (L′H) [5] give a family of oxide-centered triangular, ferromagnetically coupled $[Mn_3^{III}O(O_2CR)_3L'_3](ClO_4)$ complexes [6], which are the first triangular Mn SMMs. The ligands used are methyl 2-pyridyl ketone oxime (mpkoH) and phenyl 2-pyridyl ketone oxime (ppkoH); see Fig. 1.

Reactions of $[Mn_3O(O_2CMe)_6(py)_3](ClO_4)$ (**1**) with mpkoH, $[Mn_3O(O_2CEt)_6(py)_3](ClO_4)$ (**2**) with mpkoH, and $[Mn_3O(O_2CMe)_6(py)_3](ClO_4)$ (**1**) with ppkoH, in a 1:3 ratio in MeOH/MeCN gave dark brown solutions. These were evaporated to dryness under reduced pressure at room temperature, and the residues dissolved in CH_2Cl_2 and layered with *n*-hexane to slowly give dark brown crystals of $[Mn_3O(O_2CMe)_3(mpko)_3](ClO_4)\cdot 3CH_2Cl_2$ (**3**$\cdot 3CH_2Cl_2$), $[Mn_3O(O_2CEt)_3(mpko)_3](ClO_4)\cdot 1.2CH_2Cl_2\cdot 1.4H_2O$ (**4**$\cdot 1.2CH_2Cl_2\cdot 1.4H_2O$) and $[Mn_3O(O_2CMe)_3(ppko)_3](ClO_4)\cdot 2CH_2Cl_2$ (**5**$\cdot 2CH_2Cl_2$) in very good isolated yields (>70%). All three complexes gave very good analytical results.[1] The formation of the representative complex **4** can be summarized in the following balanced equation:

$$\underset{\mathbf{2}}{[Mn_3O(O_2CEt)_6(py)_3](ClO_4)} + 3mpkoH \xrightarrow{MeCN/MeOH/CH_2Cl_2} \underset{\mathbf{4}}{[Mn_3O(O_2CEt)_3(mpko)_3](ClO_4)} + 3EtCO_2H + 3py \quad (1)$$

The structure[2] of the cation of **3** (Fig. 2a) consists of an almost equilateral Mn_3^{III} triangle capped by the central oxide ion, O(61). Each edge of the triangle is bridged by a diatomic oximate group and an $\eta^1:\eta^1:\mu$-$MeCO_2^-$ group. The $mpko^-$ anions behave as $\eta^1{:}\eta^1{:}\eta^1{:}\mu$-ligands forming five-membered chelate rings. The oxide ion lies 0.295 Å above the plane defined by the three Mn^{III} ions. The coordination geometry of the metal ions is distorted octahedral. The O^{2-} character of O(61) and the Mn^{III} oxidation states were confirmed by charge considerations, bond lengths, bond valence sum (BVS) calculations [7] and the presence of Mn^{III} Jahn–Teller elongation axes [O(1)–Mn(1)–O(31), O(11)–Mn(2)–O(51), O(21)–Mn(3)–O(42)]. The trinuclear cations of complexes **4**$\cdot 1.2CH_2Cl_2\cdot 1.4H_2O$ (Fig. 2b) and **5**$\cdot 2CH_2Cl_2$ (Fig. S1) have very similar structures; their capping oxide ion lies 0.308 and 0.313 Å above the Mn_3^{III} plane, respectively.

Solid-state, direct current (DC) magnetic susceptibility (χ_M) data for dried **3**–**5** were collected in the temperature range 5.0–300 K in an applied field of 1 kG (0.1 T).[3] The $\chi_M T$ of **3** steadily increases from 13.01 $cm^3\,mol^{-1}\,K$ at 300 K to a maximum of 19.39 $cm^3\,mol^{-1}\,K$ at 30 K, before dropping to 17.41 $cm^3\,mol^{-1}\,K$ at 5.00 K (Fig. 3). This behaviour is indicative of ferromagnetic exchange between the metal centers resulting in an $S = 6$ ground state, with the low temperature decrease assigned to zero-field splitting, Zeeman effects and/or intermolecular antiferromagnetic interactions. The theoretical $\chi_M T$ (spin-only, $g = 2$) for $S = 6$ is 21 $cm^3\,mol^{-1}\,K$, close to the experimental value at 30.0 K. The data were fit to the theoretical expression for a Mn_3^{III} isosceles triangle [8]. The fit gave $J = +14.1\ cm^{-1}$, $J' = +3.8\ cm^{-1}$, $g = 1.91$, and 0.9% paramagnetic impurity term, assumed to be Mn^{II}. The corresponding fit values for **5** are $J = +31.1\ cm^{-1}$, $J' = +6.7\ cm^{-1}$, $g = 1.91$, and 1.5% paramagnetic impurity term.

In order to confirm the spin ground states of the complexes, magnetization data were collected in the ranges 1–70 kG and 1.8–10.0 K, and these are plotted as reduced magnetization ($M/N\mu_B$) versus H/T for **3** in Fig. 4. For a cluster entirely populating the ground state and experiencing no zero-field splitting, the isofield lines should superimpose and saturate at a $M/N\mu_B$ value equal to gS. The data were fit by matrix diagonalization to a model that assumes only the ground state is populated, includes axial zero-field splitting ($D\widehat{S}_z^2$) and the Zeeman interaction, and carries out a full powder average. The best fit (solid lines in Fig. 4) gave $S = 6$, $g = 1.92$ and $D = -0.34\ cm^{-1}$. The corresponding data for the other two complexes are $S = 6$, $g = 1.93$, $D = -0.34\ cm^{-1}$ for **4**, and $S = 6$, $g = 1.91$, $D = -0.36\ cm^{-1}$ for **5**.

The magnitude of S and sign of D suggested these complexes might be SMMs, and AC susceptibility studies were therefore carried out in the 1.8–10.0 K range in a 3.5 G field oscillating at frequencies up to 500 Hz. Frequency-dependent out-of-phase AC susceptibility signals were seen

[2] Crystallographic data in brief: For complex **3**$\cdot 3CH_2Cl_2$: $C_{30}H_{36}N_6O_{14}Cl_7Mn_3$, 1117.64 g mol^{-1}, monoclinic, $P2_1/c$, $a = 12.986(5)$ Å, $b = 14.978(6)$ Å, $c = 23.150(10)$ Å, $\beta = 93.82(2)°$, $Z = 4$, $V = 4493(3)$ Å^3, $\rho_{calc} = 1.492$ g cm^{-3}, $T = 293(2)$ K, R_1 (on F) = 0.0696, wR_2 (on F^2) = 0.1936. For complex **4**$\cdot 1.2CH_2Cl_2\cdot 1.4H_2O$: $C_{31.2}H_{41.2}N_6O_{15.4}Cl_{3.4}Mn_3$, 1032.06 g mol^{-1}, monoclinic, $P2_1/c$, $a = 12.988(5)$ Å, $b = 15.111(6)$ Å, $c = 27.740(10)$ Å, $\beta = 94.82(1)°$, $Z = 4$, $V = 5425(4)$ Å^3, $\rho_{calc} = 1.264$ g cm^{-3}, $T = 293(2)$ K, R_1 (on F) = 0.0738, wR_2 (on F^2) = 0.2065. For complex **5**$\cdot 2CH_2Cl_2$: $C_{44}H_{40}N_6O_{14}Cl_5Mn_3$, 1218.92 g mol^{-1}, monoclinic, $P2_1/c$, $a = 13.566(2)$ Å, $b = 29.859(2)$ Å, $c = 26.085(3)$ Å, $\beta = 98.87(1)°$, $Z = 4$, $V = 10439.72(16)$ Å^3, $\rho_{calc} = 1.341$ g cm^{-3}, $T = 100(2)$ K.

[3] The magnetic behaviour of the three complexes is similar; detailed magnetic data are presented only for cluster **3**.

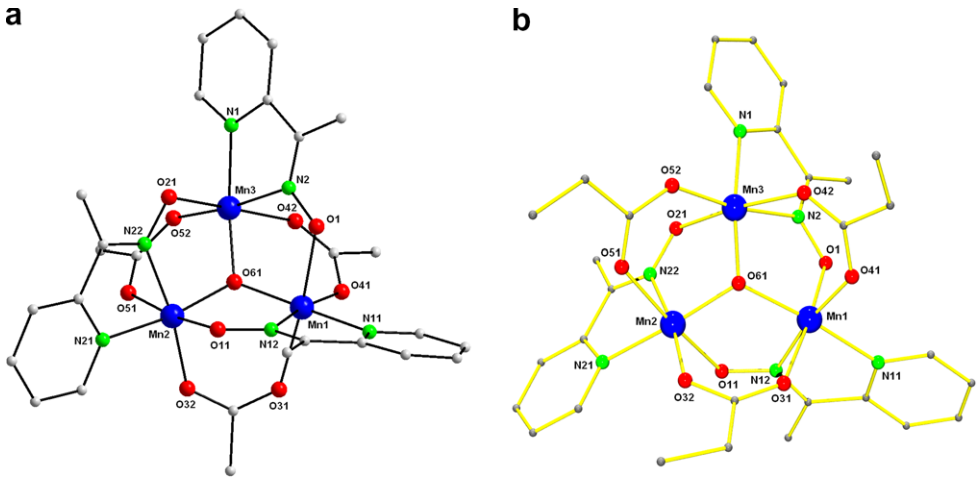

Fig. 2. Partially labeled plots of the trinuclear cations of (a) $\mathbf{3}\cdot 3CH_2Cl_2$ and (b) $\mathbf{4}\cdot 1.2CH_2Cl_2\cdot 1.4H_2O$.

for the three complexes below 3 K (but no peaks were observed) along with a concomitant decrease in the in-phase signal, indicative of SMM behaviour. The data for **4** are shown in Fig. 5.

In order to probe the possible SMM behaviour further, single-crystal hysteresis loop and relaxation measurements were performed for $\mathbf{3}\cdot 3CH_2Cl_2$ and $\mathbf{5}\cdot 2CH_2Cl_2$ using a micro-SQUID apparatus [9]. Fig. 6 presents typical magnetization (M) versus applied DC field measurements at 0.04 K for $\mathbf{3}\cdot 3CH_2Cl_2$. A hysteresis loop, the diagnostic property of a magnet, was observed below 1 K, whose coercivity increases with decreasing temperature and increasing field sweep rate, as expected for the superparamagnetic-like behaviour of an SMM. The loops show the step-like features indicative of quantum tunneling of magnetization (QTM) between M_s levels of the $S = 6$ ground state; the temperature-independent coercivity below 0.3 K indicates ground-state QTM. Magnetization decay versus time data and AC data to lower T were collected on

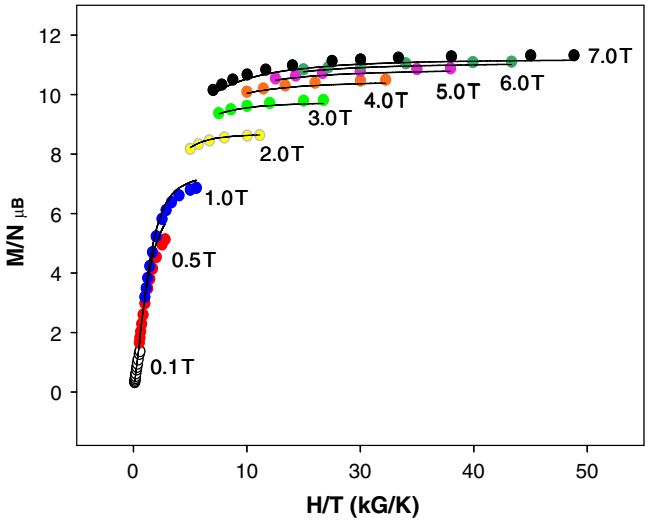

Fig. 4. Plot of the reduced magnetization, $M/N\mu_B$, vs. H/T for complex **3** at the indicated fields. The solid lines are the fit of the data; see the text for the fit parameters.

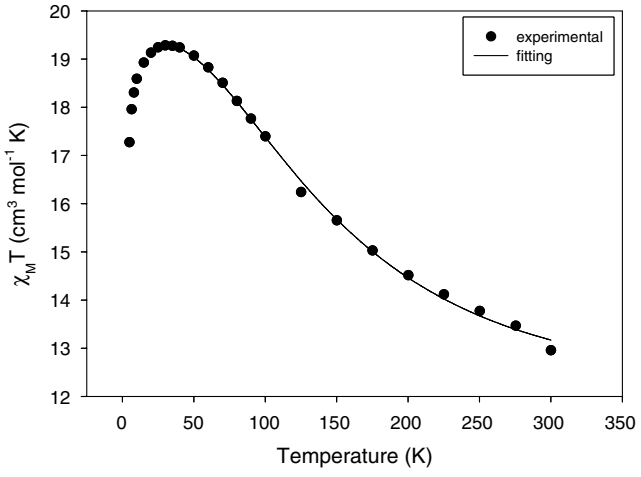

Fig. 3. $\chi_M T$ vs. T plot for complex **3** in the temperature range 5.0–300 K in a 1000 G (0.1 T) applied DC field; the solid line is the fit of the data (see the text for details).

$\mathbf{3}\cdot 3CH_2Cl_2$ and used to construct an Arrhenius plot (Fig. S2); fitting of the thermally activated region to the equation $\tau = \tau_0 \exp(U_{eff}/kT)$ gave $U_{eff} = 10.9$ K and $\tau_0 = 5.7\times 10^{-8}$ s, where U_{eff} is the effective magnetization relaxation barrier. Below 0.3 K, the relaxation is temperature-independent, consistent with relaxation by ground-state QTM. Slightly different SMM properties are observed for $\mathbf{5}\cdot 2CH_2Cl_2$ due to the presence of two crystallographically independent trinuclear cations in the crystal.[4]

An important question is the following: why are **3**–**5** ferromagnetically coupled and SMMs, whereas **1** and **2** (and many similar $[Mn_3O(O_2CR)_6L_3]^+$ complexes) are antiferromagnetically coupled and are not SMMs? A probable contributory factor is that **3**–**5** have their central oxide ligand ~0.3 Å above the Mn_3 plane due to the tridentate

[4] Details will be given in the full paper.

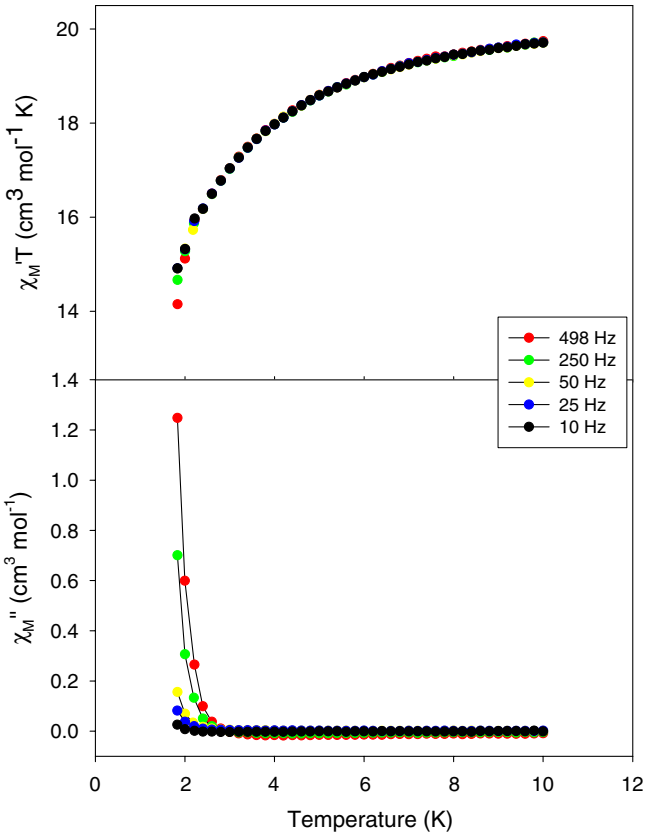

Fig. 5. Plots of the in-phase (χ'_M) as $\chi'_M T$ (top), and out-of-phase (χ''_M) (bottom) AC magnetic susceptibilities vs. T in a 3.5 G field oscillating at the indicated frequencies for complex **4**. The solid lines are visual aids.

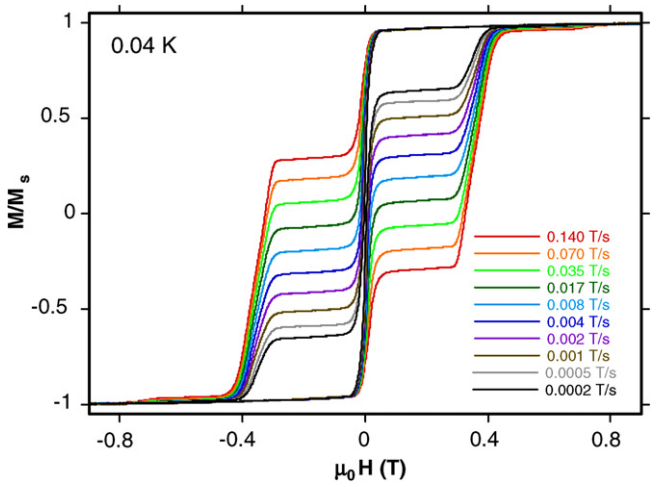

Fig. 6. Magnetization (M) vs. DC field hysteresis loops for a single crystal of $\mathbf{3} \cdot 3CH_2Cl_2$ at 0.04 K at the indicated field scan rates. The magnetization is normalized to its saturation value, M_s.

coordination of mpko$^-$ or ppko$^-$. In contrast, the oxide ion in **1**, **2** and related species is coplanar with the three metal ions. This distortion from planarity in **3**–**5** weakens the antiferromagnetic contributions (via $Mn^{III}_{d\pi}$–$O^{2-}_{p\pi}$–$Mn^{III}_{d\pi}$ orbital overlap) to the observed exchange between two Mn^{III} ions, and the latter (which is the sum of ferro- and antiferromagnetic contributions) becomes ferromagnetic leading to $S = 6$ ground states.

In summary, reactivity studies of the well known and well studied antiferromagnetically coupled $[Mn_3O(O_2CR)_6(py)_3](ClO_4)$ "starting materials" with 2-pyridyl oximes have led to a new family of triangular, oxide-centered, mixed carboxylate/2-pyridyloximate Mn(III) complexes that are ferromagnetically coupled with an $S = 6$ ground state. Complexes **3**–**5** are SMMs, the first for 3d metal complexes with a triangular topology. Given this success, the use of 2-pyridyl oxime ligands in Mn carboxylate chemistry continues to be investigated.

2. Experimental

2.1. Materials and instrumentation

$[Cr_3O(CO_2Me)_6(MeOH)_3]Cl$ was prepared as previous literature [9]. All manipulations were performed under aerobic conditions using materials (reagent grade) and solvents as received without further purification. X-ray diffraction data were collected using a Siemens SMART APEX CCD diffractometer with Mo Kα radiation and a graphite monochromator. Magnetic measurement was performed in the range of 2–300 K with a Quantum Design MPMS-XL SQUID magnetometer at an applied field of 100 Oe. Elemental analyses (C, H) were performed on a Vario EL CHN Elementar Analyzer.

2.2. Preparation of complex $[Cr_{10}(\mu\text{-}O_2CMe)_{10}(\mu\text{-}OMe)_{10}(\mu\text{-}OEt)_{10}]$ (1)

$[Cr_3O(CO_2Me)_6(MeOH)_3]Cl$ (100 mg) in EtOH (10 ml) was placed in a Teflon-lined autoclave and heated to 413 K for 3 d, and then cooled at 6 K h^{-1} to room temperature, dark-green crystals of **1** deposited on the walls of container, were collected and air-dried. Yield: ~60%. $C_{50}H_{110}Cr_{10}O_{40}$ (Fw: 1871.38) *Anal.* Calc. C, 32.06; H, 5.92. Found: C, 32.70; H, 5.73%.

2.3. Single-crystal structure determination for complex 1

Single crystal X-ray diffraction was performed on a CCD area detector with graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) [10] in the range of $0.915 < \theta < 28.65°$. The structure was solved in $P2_1/n$ by the direct method and refined by the Full-matrix least squares on F^2 using the SHELXTL-97 software [11]. 10 (O)Me groups those located inside of the 'wheel' **1** showed twofold disorder. Crystal data for **1** are shown in Tables 1 and 2.

2.4. Magnetic measurement of complex 1

Magnetic susceptibility measurement on complex **1** was obtained on a finely ground polycrystalline sample with the use of a Quantum Design SQUID magnetometer MPMS-XL. The direct current measurements were collected from 2.0 to 300 K under 100 Oe. Experimental data were also corrected for the sample holder and for the diamagnetic contribution calculated from Pascal constants [12].

3. Results and discussion

3.1. Structural data for complex 1

The ORTEP drawing for complex **1** presented in Figs. 1–3 presents the packing diagram of **1** viewed down the crystallographic *a*-axis and crystallographic *b*-axis, respectively. As shown in Fig. 1, the complex $[Cr_{10}(\mu\text{-}O_2CMe)_{10}(\mu\text{-}OMe)_{10}(\mu\text{-}OEt)_{10}]$, consists of 10 Cr(III) ions forming a ring structure. Each of the two neighboring metal atoms are bridged by one μ-acetate, one μ-ethoxide, and one μ-methoxide ligands, with a Cr···Cr average distance of 2.995(6) Å, this distance is similar to 2.995(2) Å reported in the $[Cr_{10}(\mu\text{-}O_2CMe)_{10}(\mu\text{-}OEt)_{20}]$, while that of complex bridged by methoxide was 2.990(8) Å [3b]. The Cr atom adopts a distorted octahedral coordination geometry. It is bonded to two neighboring bidentate acetate anions pointing to the outside of the "wheel" through two of their oxygen atoms, two neighboring methoxide anions pointing to the inside of the "wheel" through two of their oxygen atoms, and two neighboring ethoxide anions pointing to the outside of the "wheel" through two of their oxygen atoms in *trans* position. Therefore, all the methoxide ligands line in the cavity pointing to the inside of the "wheel" alternately above and below the Cr_{10} ring. All the ethoxide ligands bridge Cr atoms around the outside of the "wheel", alternately above and below the ring. The oxygen atoms of acetato ligands are in the *trans* positions to those methoxide groups, hence, all the acetato ligands are pointing to the outside of the "wheel" alternately above and below the Cr_{10} ring. The distances for Cr···Cr in *trans* position in the ring are in the range 9.664–9.748 Å. The average value of the bond angle Cr–O(Et)–Cr of **1** is 99.64°, which is 99.30° in $[Cr_{10}(\mu\text{-}O_2CMe)_{10}(\mu\text{-}OEt)_{20}]$ [3b]. The average value of the bond angle Cr–O(Me)–Cr of **1** is 98.67°, while it is 99.34° in $[Cr_{10}(\mu\text{-}O_2CMe)_{10}(\mu\text{-}OMe)_{20}]$ [3b].

The unit cell parameters of complex **1** are *a* 9.4752(18) Å, *b* 16.056(3) Å, *c* 28.627(5) Å, *β* 90.921(4)°, which are almost the same as those of $[Cr_{10}$-

(μ-$O_2CMe)_{10}(\mu$-$OEt)_{20}$], and different from those of [$Cr_{10}(\mu$-$O_2CMe)_{10}(\mu$-$OMe)_{20}$] [3b]. This is may ascribed to the bridged ligands around the outside of the "wheel" being the main factors for molecular stacking in this series.

3.2. Magnetic properties for complex *1*

Fig. 4 shows the magnetic behavior of **1** at an applied field of 100 Oe in the form of $\chi_M T$ vs T plot. The $\chi_M T$ value of 10 Cr(III) at 300 K is 15.6 emu K mol^{-1}, lower than the spin-only value (18.4 emu K mol^{-1}) expected for a magnetically isolated high-spin Cr(III) ion with $g = 2.00$. As the sample is cooled from room temperature, the $\chi_M T$ first keeps constant in the temperature range 150–300 K, then

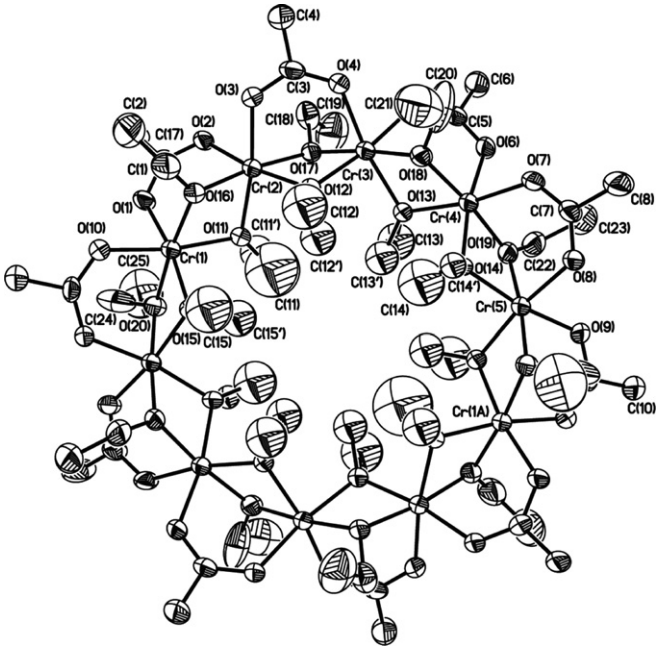

Fig. 1. Molecular structure (30% thermal ellipsoids) of complex **1**. The 10 (O)Me groups in **1** showed twofold disorder. Bond length ranges: Cr–O(Me) 1.960(4)–1.985(4) Å, Cr–O(Et) 1.953(4) –1.975(4) Å, Cr–O(acetate) 1.971(4)–2.000(4) Å. Bond angle ranges: Cr–O(Me)–Cr 98.28(17)–99.05(16)°, Cr–O(Et)–Cr 98.69(17)–100.58(19)°.

decreases slowly from 150 to 50 K, and finally more quickly to a value of 9.25 emu K mol^{-1} at 2 K. The $1/\chi_M$ vs T plot is almost linear in the entire temperature range (not shown here), and the data (above 4 K) can be fitted to the Curie–Weiss law with $C = 15.79$ cm^3 mol^{-1} K and $\Theta = -1.33$ K. The Cr $\cdots$ Cr exchange can then be calculated from Θ [13], giving $J = +0.37$ cm^{-1}.

The magnetic behavior of **1** indicates the presence of very weak intra-molecular antiferromagnetic exchange interactions between Cr(III) ions. The magnetic behavior of **1** may be ascribed to the fact that the mixing methoxide and ethoxide ligand in **1** results in the mixing magnetic

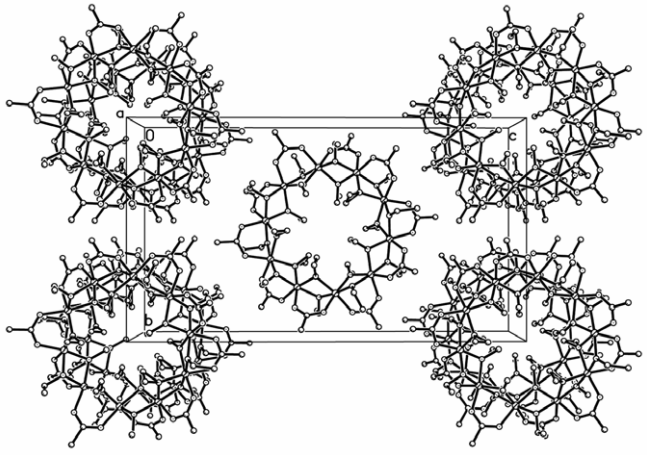

Fig. 2. Packing diagram of **1** viewed down the crystallographic *a*-axis. All hydrogen atoms are omitted for clarity.

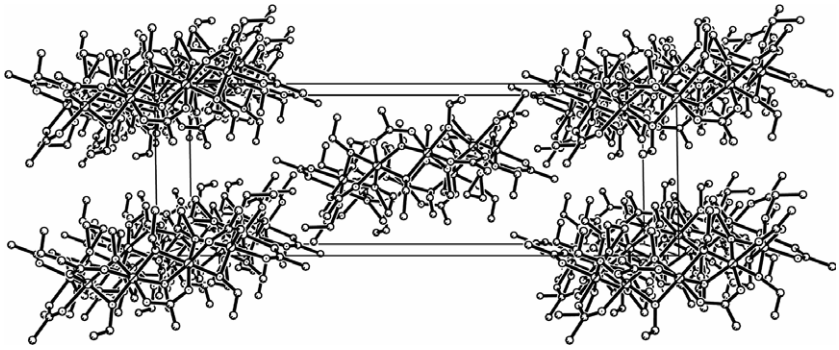

Fig. 3. Packing diagram of **1** viewed down the crystallographic *b*-axis. All hydrogen atoms are omitted for clarity.

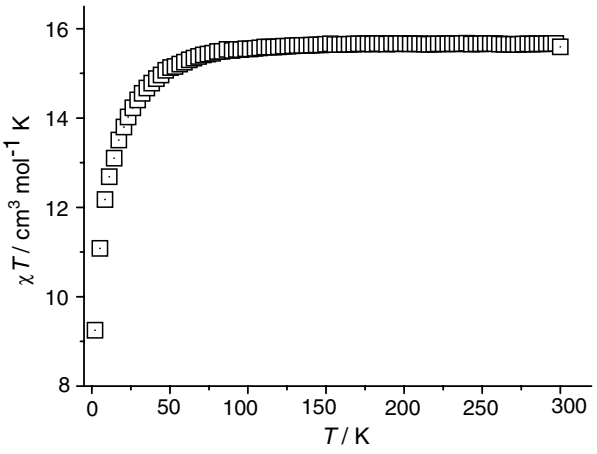

Fig. 4. Temperature dependence of $\chi_M T$ for **1**.

properties for pure methoxide (ferromagnetic) and ethoxide (antiferromagnetic) ligand, respectively.

4. Conclusions

In summary, we have described a new nano-decanuclear cyclic Cr(III) complex, $[Cr_{10}(\mu\text{-}O_2CMe)_{10}(\mu\text{-}OMe)_{10}(\mu\text{-}OEt)_{10}]$ (**1**), bridged by ethoxide, methoxide, and acetate ligands under solvothermal conditions. Structural and the unit cell parameters of complex **1** are more similar to those of $[Cr_{10}(\mu\text{-}O_2CMe)_{10}(\mu\text{-}OEt)_{20}]$, possibly due to ethoxide ligand outside of the "wheel" is the main factor for molecular stacking. The complex **1** shows more weak antiferromagnetic exchange interaction than that of $[Cr_{10}(\mu\text{-}O_2CMe)_{10}(\mu\text{-}OEt)_{20}]$ due to the mixing ethoxide and methoxide ligands.

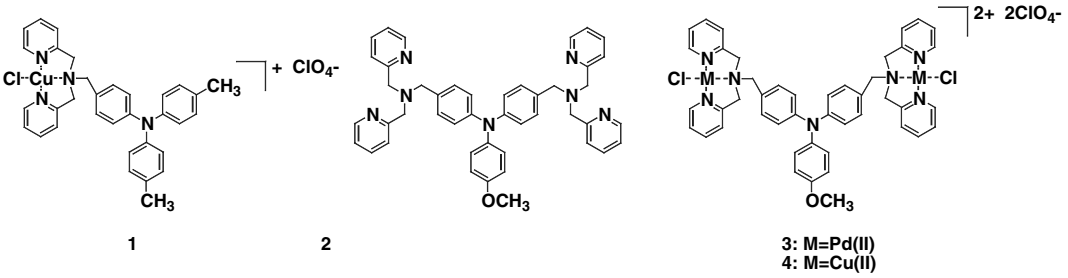

Fig. 1. Structures of compounds **1**–**4**.

[4]. CV measurements of **1** showed reversible Cu^{I}/Cu^{II} and TPA/TPA^{+} redox couples. The spin–spin interaction of the copper complex with pendant TAA cation radical, generated upon one electron oxidation of **1**, was examined by ESR measurements. This result encouraged us to examine more complicated systems.

In this study, we report on a novel ligand (**2**) and its dinuclear palladium (**3**) and copper (**4**) complexes. The ligand is expected to be a promising redox-active building unit of supramolecular transition metal clusters. The methoxy group was introduced to improve the stability of the TAA cation radical (see Fig. 1).

2. Experimental

Synthetic detail will be reported elsewhere. All new compounds were fully characterized by spectroscopic methods. Data only for **3** and **4** are given below.

Compound **3**: pale yellow powder, ^{1}H NMR (CD_3CN); 3.78 (s, 3H), 4.10 (s, 4H), 4.51 (d, 4H, $J = 16$ Hz), 5.26 (d, 4H, $J = 16$ Hz), 6.44 (d, 4H, $J = 7.6$ Hz), 6.67 (d, 2H, $J = 7.6$ Hz), 6.96 (d, 2H, $J = 7.6$ Hz), 7.47 (d, 4H, $J = 5.1$ Hz,), 7.50 (t, 4H, $J = 8.2$ Hz), 7.69 (d, 4H, $J = 7.6$ Hz), 8.05 (dt, 4H, $J = 8.2$ Hz, 1.5 Hz), 8.56 (d, 4H, $J = 5.1$ Hz,), **4**; blue crystals, HRMS: Calcd.: 893.1698 for $C_{45}H_{43}Cl_2N_7OCu_2$, obsd.: 893.1477.

Caution: Although no problem was encountered in the preparation of the perchlorate salts, suitable care should be taken when handling such potentially hazardous compounds.

3. Results and discussion

3.1. Synthesis of the ligand, and the Pd(II) and Cu(II) dinuclear complexes

The ligand, 4-methoxy-4′,4″-bis[*N*,*N*-bis(2-pyridylmethyl)aminomethyl]triphenyl-amine (**2**), was synthesized as shown in Fig. 2. Ullmann coupling reaction of diphenylamine with iodoanisole gave 4-methoxytriphenylamine in 75% yield. This compound in turn was transformed into 4,4′-diformyl-4″-methoxytriphenylamine by the reaction with phosphoryl chloride in 82% yield. The formylation occurred regiospecifically and successfully at the two *para* positions of triarylamine, and no mono-substituted derivative was found. Treatment of 4,4′-diformyl-4″-methoxytriphenylamine with 2-picolylamine and sodium borohydride gave the secondary amine, 4-methoxy-4′,4″-bis[*N*-(2-pyridylmethyl)]aminomethyltriphenyl-amine. This compound then was reacted with 2-(bromomethyl)pyridine hydrobromide under a basic condition to give the target compound, **2**, in excellent isolated yield (67%). The complex **3** and **4** were prepared by reacting **2** with palladium (II) chloride and copper (II) chloride in the presence of sodium perchrolate, respectively.

3.2. UV/Vis spectrum measurements

In order to examine the spectroscopic properties of the metal complexes, UV/Vis absorption-spectrum measurements were examined. The spectra of those compounds are shown in Fig. 3. In acetonitrile solution, **3** and **4** exhibited a strong absorption around 300 nm, which is characteristic for triarylamine chromophores [5]. In addition, **4** exhibited a weak absorption at 623nm ($\varepsilon = 280^{-1}\ cm^{-1}$). This peak can be assigned to the d-d transition of the copper (II) ion.

3.3. Cyclic voltammetric measurements

Electrochemical behavior of **3** and **4** was studied by cyclic voltammetry in *n*-butyronitrile at ambient temperature. Upon sweeping anodically, **3** exhibited reversible redox waves ($E^0 = 0.473$ V versus Fc/Fc^{+}) as shown in Fig. 4, which can be assigned to the one electron oxidation process of the triarylamine unit. Compound **4** also showed similar redox couple ($E^0 = 0.477$ V versus Fc/Fc^{+}). On the other hand, upon sweeping cathodically, the copper complex exhibited one set of quasi-reversible redox waves ($E^0 = -0.690$ V versus Fc/Fc^{+}). Upon repeating sweeps several times in potential ranging from 1.0 to −1.0 (V versus Fc/Fc^{+}), no decrease in the current peak intensity was observed, indicating the three possible species ($Cu(I)_2$–TAA, $Cu(II)_2$–TAA and $Cu(II)_2$–TAA^{+}) are stable in terms of the time scale of cyclic voltammetry.

3.4. Electron transfer stopped-flow (ETSF) method

The detail of the ETSF method was described previously [6]. The ETSF measurements were carried out in dehydrated acetonitrile as solvent at ambient temperature. In this study,

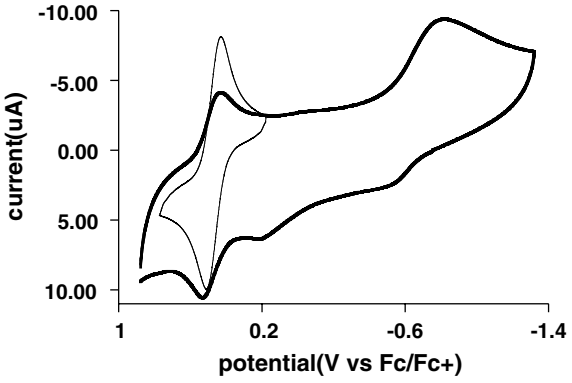

Fig. 4. The cyclic voltammogram of **3** (plain), **4** (bold) in *n*-butyronitrile.

tris(2,4-dibromophenyl)amine cation radical ($TDBPA^{+\cdot}$)[1] was employed. Complex **3**, upon mixing with one equivalent of $TDBPA^{+\cdot}$, exhibited a broad absorption peak at 718 nm ($\varepsilon = 1.56 \times 10^4\ M^{-1}\ cm^{-1}$), and no significant decrease in the peak intensity was observed over 100 s, indicating the generation of the stable monocation. Similarly, complex **4** exhibited a peak at 718 nm ($\varepsilon = 1.51 \times 10^4\ M^{-1}\ cm^{-1}$), and no decrease in the peak intensity was observed.

3.5. Two-dimensional NMR measurements

COSY (correlated spectroscopy) and NOESY (nuclear Overhauser effect spectroscopy) are widely employed powerful NMR techniques in the field of organic chemistry. COSY and NOESY can observe through-bond and through space dipolar H–H interaction, respectively. NOESY cross peaks can be observed only for nuclei that are proximate in space (<3.5 Å), which enables the determination of the geometrical structure of molecules in solution. COSY and NOESY measurements were applied to **3** to examine its conformation in CD_3CN solution. In the NOESY spectrum of **3** at 25 °C, correlations were seen between the Ha, Hb, Hc peaks and Hd peak. Similar correlations were also seen between the Ha, Hb, Hc peaks and He peak. These results indicate that Hd and He are proximate to the pyridine rings in space, respectively. The data clearly show that **3** prefers a "folded conformation" (Fig. 5) due to intramolecular stacking interactions. Upon heating to 75 °C, The cross peaks described above

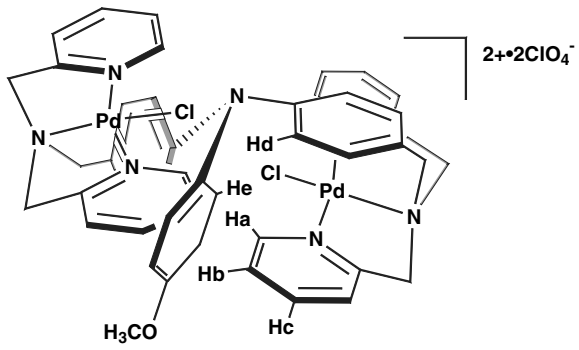

Fig. 5. An estimated conformation of **3** in CD_3CN solution.

[1] TDBPA was synthesized by WAKO Pure Chemicals Ltd. after receiving our special order. See also Ref. [6].

disappeared completely, indicating the preference of "opened conformation" at this condition. The detail will be reported elsewhere.

3.6. ESR measurements

The magnetic properties of **4** and its oxidized species were examined by cw-ESR measurements in propionitrile at 77 K. Tri(*p*-tolyl)amine cation radical (**5**) and a copper complex (**6**) without the triarylamine unit (Fig. 6), were also examined under the same conditions for comparison (Fig. 7). Compound **6** gave an ESR Cu-hyperfine structure ($S = 1/2$) shown in Fig. 7b, which is characteristic of copper bis(2-picolyl)amine complexes with $S = 1/2$. On the other hand, compound **4** exhibited a broad ESR spectrum with a similar Cu-hyperfine splittings to that of **6** except their reduced intensity (Fig. 7c), indicating that the broadened ESR spectrum is due to the intramolecular exchange-coupled dinuclear copper system with the total spin quantum number $S = 1$. The Cu-hyperfine tensor $\boldsymbol{A}$ for the dinuclear copper complex **4** is described as $\boldsymbol{A} = (\boldsymbol{A}_1 + \boldsymbol{A}_2)/2$ with $S = 1$ in the strong exchange limit, where $\boldsymbol{A}_i$ ($i = 1, 2$) denotes the Cu-hyperfine tensor of the local Cu site i of **4**. We safely assume that the component Cu-hyperfine $\boldsymbol{A}_i$ is similar to that of **6**. Considering the molecular symmetry of **4**, we obtain the structural relationship between the tensor $\boldsymbol{A}_1$ and $\boldsymbol{A}_2$. In compound **4**, $\boldsymbol{A}_1 \cong \boldsymbol{A}_2$ interprets the triplet Cu-hyperfine structure with $\boldsymbol{A}_1 \cong \boldsymbol{A}_2$ for 4 as well as $\mathbf{g} \cong \mathbf{g}_1$. Upon addition of one equivalent of cerium ammonium nitrate (CAN), the color of the solution immediately changed from light blue to deep purple, which revealed the generation of the TAA cation radical chromophore. The ESR spectrum of the oxidized species is shown in Fig. 7d, indicating the occurrence of an intramolecularly exchanged system in which the two local Cu site is bridged by the open-shell ligand **5**. In the oxidized **4**, exchange-coupled doublet and quartet states with reduced anisotropy for the resultant $\boldsymbol{g}$ and $\boldsymbol{A}$ tensors, which is due to the isotropic g-value of **5** and no contribution to the Cu-hyperfine structure from **5**, are anticipated. The observed Cu-hyperfine splittings with the reduction factor of 2/3 (Fig. 7d), as well as the reduction of the observed $\boldsymbol{g}$-anisotropy, are strongly indicative that the observed ESR spectrum arises from an exchange-coupled quartet state. Only the cw-ESR spectrum observed at 77 K (Fig. 7d) does not give straightforward information on the location of the exchange-coupled doublet states. For complete analyses of the ESR spectra, pulse-based electron spin transient nutation spectroscopy for the oxidized copper complex is underway.

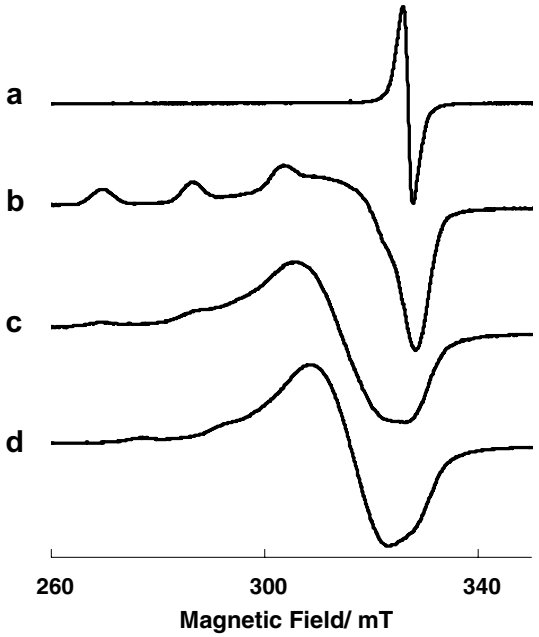

Fig. 7. ESR spectra of: (a) **5**, (b) **6**, (c) **4** and (d) **4** oxidized with CAN in C_2H_5CN at 77 K.

4. Conclusions

A novel ligand having a redox active triarylamine group and two coordinating groups was designed and synthesized. The corresponding palladium and copper complex were also successfully prepared. The cyclic voltammetry and ETSF study revealed that the complexes gave novel stable complexes with a pendent radical, respectively. The COSY and NOESY studies revealed that the palladium complex prefers the "folded conformation" in solution at ambient temperature. The ESR study of the oxidized dinuclear copper complex showed that the exchange-coupled high-spin entity in the quartet ground state is generated by the oxidation of the central ligand, triaryamine.

large cluster, it is important to elucidate the magnetic interaction between the organic stable radicals grafted on the same aspect of a cluster. Therefore, the stable nitroxide molecules grafted onto Au slab type cluster models (Au_{10} slab–nitroxide hybrid model systems) were investigated as it is difficult to investigate the large Au clusters, such as Au_{38}, Au_{55} and etc., due to the limit of the computer resources. Moreover, the electronic state of Au clusters could be modified by the surrounding environment, such as support materials. This is mainly due to the charge polarization effect. In order to investigate this effect, the background charges were induced instead of the support materials for Au cluster models.

The present theoretical study has been undertaken to investigate the magnetic interaction of Au slab–nitroxide hybrid model systems as a first step for understanding the magnetic interaction of radical molecules grafted on a same aspect of Au cluster. Hybrid density functional theory (HDFT) calculations have been carried out for Au slab–nitroxide hybrid model systems.

2. Calculation method and models

2.1. Calculation method

All the computations were performed by GAUSSIAN 03 program packages [12]. Unrestricted hybrid DFT (UB3LYP) calculation was used for the model systems computations using D95** basis set for C, N, O, and H and the LANL2DZ basis set for Au. The LS–HS energy gap of the system was calculated by the spin-polarized DFT expression.

In the case of organic radical molecules, the spin polarization and the spin delocalization of the π-electrons are the dominant factors to determine the spin alignment between the localized radical spins while the spin polarization of the conduction electrons are also the important factor for the spin alignment in the case of metal clusters. In order to investigate the magnetic interaction in the model system, the effective exchange integral of Heisenberg model was calculated using Noodleman–Yamguchi equation [13,14]. Natural orbital analysis was also carried to examine these features for the investigated model systems.

2.2. Calculated models

The schematic illustrations of SPN-hex and SPN-hex grafted Au cluster are shown in Fig. 1(a) and (b). This illustration shows that many organic radicals are densely grafted on a surface of a large cluster. Therefore, it is important to elucidate the magnetic interaction between the organic stable radicals grafted on the same aspect of a cluster. The model systems that the model nitroxide molecules (Fig. 1(c)) were grafted onto Au_{10} slab type cluster as shown in Fig. 2(a) and (b) were investigated as it is difficult

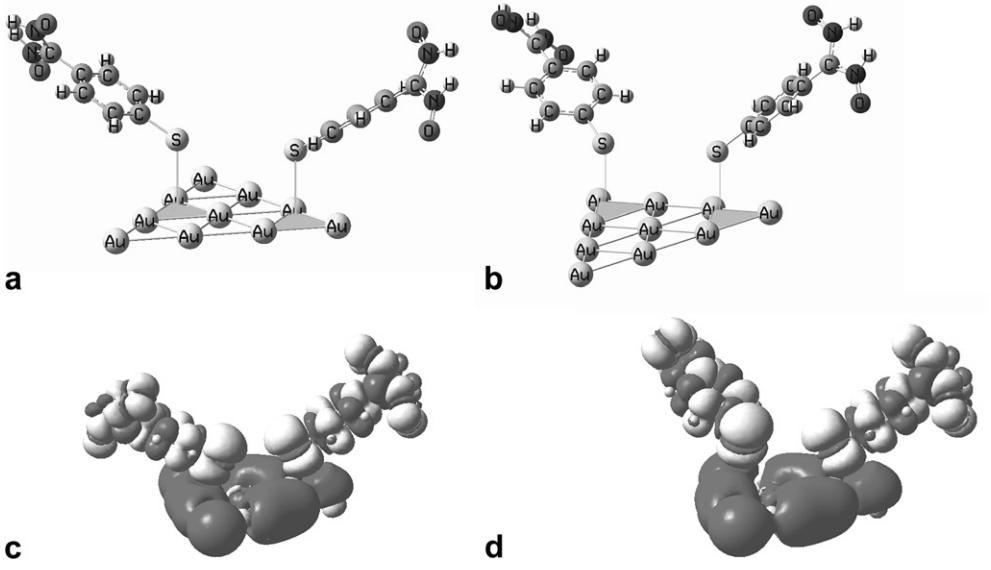

Fig. 2. The illustrations of the Au_{10}–organic spin molecule model system: (a) type I, (b) type II, (c) spin density of type I (triplet state) and (d) spin density of type II (triplet state).

to investigate the large Au clusters, such as Au_{38}, Au_{55} and etc., due to the limit of the computer resources. The model systems depicted in Fig. 2(a) and (b) were named type I and type II, respectively. The geometry of the organic spin molecule was based on the geometry of NPNN molecule.

3. Results and discussion

3.1. Au_{10} model system

As shown in Table 1, it was found that the triplet state was the ground state in Au_{10} slab cluster, while the energy gap between the triplet and singlet states is very small. Mulliken spin densities of the perimeter Au atoms and the center Au atom in Au_{10} slab cluster were 0.23 (average) and −0.06 and the Mulliken charge densities of the center atom, the side atoms and the vertex atoms were 0.42, 0.04 (average) and −0.22 (average), respectively. Therefore, it shows that the perimeter Au atoms have the homogeneous spin densities and the vertex Au atoms are only negatively charged in this cluster. The energy levels of HOMOs in α and β orbitals and LUMOs in α and β orbitals of this cluster were −0.23053, −0.22984, −0.12892 and −0.19310, respectively. As the small energy gaps are existed in this cluster, Au_{10} slab cluster has a semiconducting feature.

From the calculation results shown in Table 1, it was found that the triplet state was the ground state in these systems. The triplet states of spin densities of these two models shown in Fig. 2(a) and (b) were also depicted in Fig. 2(c) and (d), respectively. The results showed that the parallel spin moments were presented on the S atoms and nitroxide groups in the organic radical fragments and the magnetic interaction between two organic radical molecules were ferromagnetic in these model systems. Natural orbital analysis for the triplet states of the type I model system was carried out in order to understand the electronic state of this model system. The schematic diagrams of the two natural orbitals whose occupation numbers are 1.0 are shown in Fig. 3. These natural orbitals are localized onto the nitronyl nitroxide group. Therefore, they are the radical orbitals (SOMOs) of the organic radical molecules. From these results it was found that the ferromagnetic interaction between the stable organic radicals through Au slab cluster could be possible.

Table 1
Total energies and total spin angular momenta of the Au_{10} model systems

Model	Spin state	Energy[a]/h	S^2	ΔE[b]/h	J/cm^{-1}

[b] $\Delta E = E(\text{triplet}) - E(\text{singlet})$.

3.2. Spin crossover of Au_{10} model system

The present work showed that the ground states of both of the Au_{10} model systems were triplet. It is well known that the electronic state of Au cluster deposited on a support was polarized by the hetero-junction with a support in Au catalysts [15]. Moreover, it might be possible to

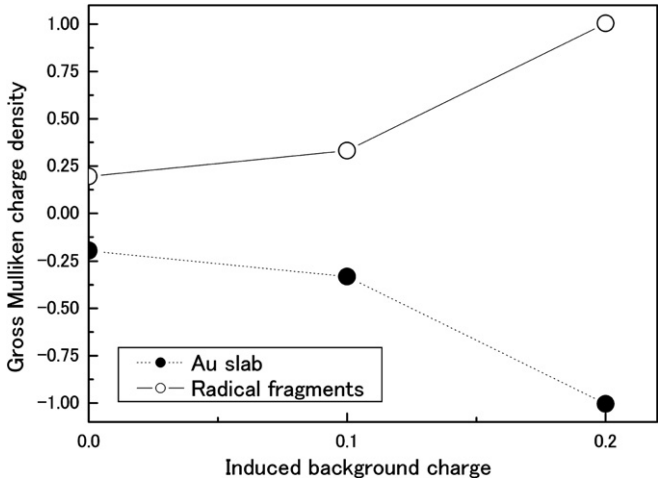

Fig. 5. Variation of gross Mulliken charges in Au_{10} slab and radical fragments for different point charges.

modulate the electronic state of Au cluster by induced external field. As an addition of artificial point charges to the theoretical calculation model also makes such polarizations in the model systems, the model systems with point charges instead of a support are examined in order to investigate the polarization effect for the magnetic interactions in the model systems.

The spin crossover in Au_{10} model system (type I) is examined using the point charges in order to consider the polarization of the Au clusters. The positive point charges ranging from 0.1 to 0.2 were placed under the Au_{10} slab as shown in Fig. 4. The calculation results are summarized in Table 2. The results showed that quintet state was the ground sate in the case of the model with the point charge (0.1) and singlet state was the ground sate in the case of the model with the point charge (0.2). In Fig. 5, the gross Mulliken charges of Au_{10} slab and organic radical fragments were depicted. This shows that the induction of point charges boosts the charge transfer from organic radical fragments to Au_{10} slab. These results suggest that the modulation of Au_{10} slab by the point charge greatly affects the magnetic interaction between the organic radical molecules grafted on Au cluster.

3.3. Rational design of molecular magnet

From these results, it was found that the point charge introduction into this model system could modulate the magnetic interaction of the model system. Therefore, it could be presumed that the hetero-junction with the support materials and Au–organic spin molecule system and/or the induction of the electric field to Au–organic spin molecule system might be practical for the modulation of the magnetic interaction in the real system.

4. Conclusions

From the calculation results, it was found that the Au_{10} model systems have the ferromagnetic interaction between the organic radical molecules grafted on Au slab and the magnetic interactions of them were dramatically changed depending on the addition of the point charges.

and its incorporation into a Mn cluster does not complicate the magnetic analysis. The investigated reactions have resulted in the isolation of a number of Mn–Ce compounds that can be divided into three general types on the basis of the Mn and Ce oxidation states, Mn^{IV}–Ce^{IV}, Mn^{III}–Ce^{IV}, and Mn^{III}–$Ce^{III/IV}$ [8,9]. These results will be described in this paper.

2. Mn^{IV}–Ce^{IV} compounds

Six Mn^{IV}–Ce^{IV}compounds have been prepared and crystallographically characterized [8]. These were the first Mn–Ce compounds to be discovered, and they possess three different types of aesthetically pleasing structural motifs. They were all prepared by addition of Ce^{IV} to a solution of a Mn^{II} salt in aqueous acetic acid. This reaction system was a modification of the comproportionation reaction between $[Mn(O_2CMe)_2]\cdot 4H_2O$ and $KMnO_4$ (in a Mn^{II}:Mn^{VII} ratio giving an average of $Mn^{3.33+}$) in concentrated aqueous acetic acid that is the well known procedure for the preparation of $[Mn_{12}O_{12}(O_2CMe)_{16}(H_2O)_4]$ [10]. Our modification involved substituting $(NH_4)_2[Ce(NO_3)_6]$ as the oxidant in place of $KMnO_4$, hoping for mixed-metal products, and this was indeed what was observed. In addition, we also explored a range of Mn:Ce ratios, the use of other Mn^{II} reagents, and the effect of the presence of chelate groups. Selected results will be presented below.

The reaction of $Mn(NO_3)_2\cdot xH_2O$ and bpy with $(NH_4)_2Ce(NO_3)_6$ in a 1:1:2 molar ratio in 25% aqueous acetic acid gave $[Mn_2CeO_3(O_2CMe)(NO_3)_4(H_2O)_2(bpy)_2](NO_3)$ (**1**) in 40% yield. The structure of the cation of **1** (Fig. 1) comprises a familiar $[Mn^{IV}_2(\mu\text{-}O)_2(\mu\text{-}O_2CMe)]^{3+}$ unit linked to a Ce^{IV} ion through a linear oxide bridge.

In contrast, the reaction of $[Mn(O_2CMe)_2]\cdot 4H_2O$ and $(NH_4)_2[Ce(NO_3)_6]$ in a 2:3 molar ratio in concentrated (50%) aqueous acetic acid gave $[Mn_6CeO_9(O_2CMe)_9(NO_3)(H_2O)_2]$ (**2**). When this was repeated but with a 0.5 M solution of $Ce(ClO_4)_4$ in aqueous $HClO_4$ as the oxidizing agent in place of $(NH_4)_2[Ce(NO_3)_6]$, and with a few drops of methanol to help solubility, the product was now $[Mn_6CeO_9(O_2CMe)_9(H_2O)_2(MeOH)](ClO_4)$ (**3**), which is structurally very similar to **2**.

The structures of **2** (Fig. 2) and **3** consist of an unprecedented Mn^{IV}_6 wheel. Its edges are bridged alternately by $(\mu_2\text{-}O)(\mu_3\text{-}O)(\mu\text{-}O_2CMe)$ and $(\mu_3\text{-}O)(\mu\text{-}O_2CMe)_2$ ligand sets. The six $\mu_3\text{-}O^{2-}$ ions are those bound to, and thus holding in place, the central Ce^{IV} ion, which lies slightly out of the almost planar Mn_6 ring. Apart from being the first Mn^{IV}_6 wheels, complexes **2** and **3** are also the first wholly Mn^{IV} complexes with only oxide and carboxylate ligands, and their $[M_7O_9]$ core is of a structural type never seen before for any metal.

Further mixed-metal Mn–Ce products were obtained from reactions performed in the presence of 2-hydroxy-6-methylpyridine (mhpH). The addition of potentially chelating mhpH was based on the observation that it had been successfully employed by others for the synthesis of mixed metal 3d-4f complexes [11]. Indeed, the reaction of $Mn(O_2CMe)_2\cdot 4H_2O$, $(NH_4)_2[Ce(NO_3)_6]$ and mhpH in a 2:3; ~4.4 ratio in 30% aqueous acetic acid gave $[Mn_2Ce_3O_6(O_2CMe)_6(NO_3)_2(mhpH)_4]$ (**4**) (Fig. 3).

The $[Ce_3Mn_2O_6]^{8+}$ core consists of a Ce^{IV}_3 isosceles triangle, each edge of which is bridged by two $\mu_3\text{-}O^{2-}$ ions that also bridge to the two Mn^{IV} ions lying one each above and below the Ce^{IV}_3 plane forming an M_5 trigonal bipyramid. Peripheral ligation is completed by bridging acetate, chelating nitrate and terminal mhpH groups, the latter

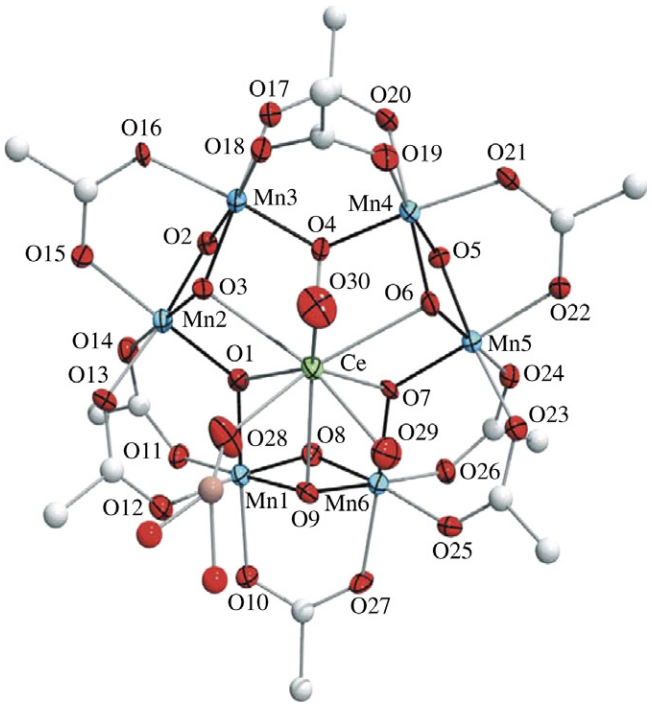

Fig. 2. Labelled ORTEP plot (at the 50% probability level) of **2**. Color scheme: Mn (blue), Ce (green), O (red), N (brown), C (grey). (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

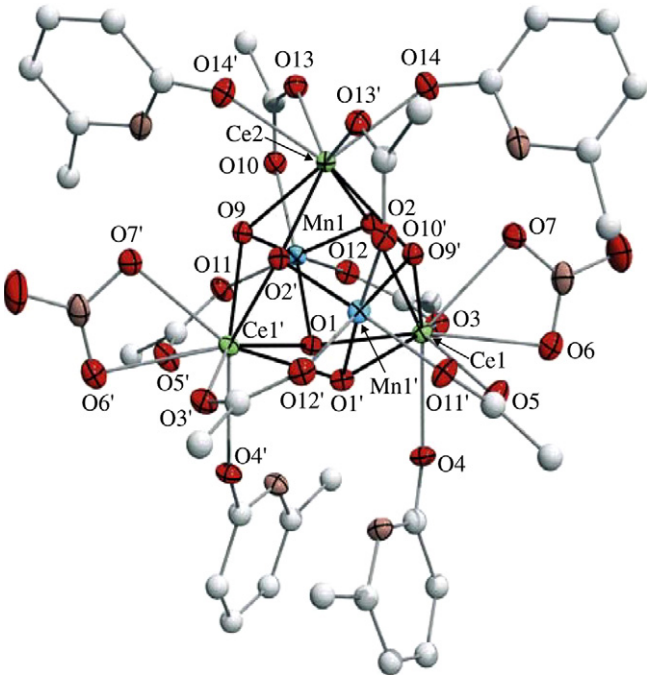

Fig. 3. Labelled ORTEP plot (at the 50% probability level) of **4**. Color scheme: Mn (blue), Ce (green), O (red), N (brown), C (grey). (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

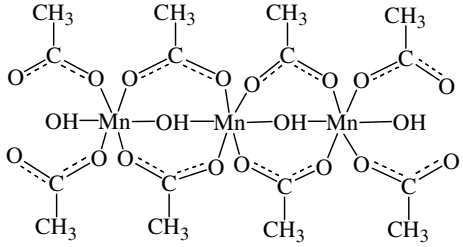
protonated at their N atoms and binding only through their O atoms (O4 and O14). The Ce_3Mn_2 trigonal bipyramidal topology has been observed in mixed 4f/3d chemistry only once before, in a $Nd^{III}_3Cr^{III}_2$ complex that contains hydroxide bridges, rather than oxide ones as in **4** [12].

We found it interesting that the mhpH stayed protonated and bound in a monodentate fashion (*vide infra*), and the reaction was thus repeated with a similar organic molecule, 2-pyrrolidinone (pyroH) [13], instead of mhpH; clean product was obtained using a slightly more concentrated (37%) aqueous acetic solution, and it was identified as $[Mn_2Ce_3O_6(O_2CMe)_6(NO_3)_2(pyroH)_2(H_2O)_3]$ (**5**). Compound **5** is very similar to **4** in that it contains the same $[Mn_2Ce_3(\mu_3\text{-}O)_6]^{8+}$ core. The main differences between the two compounds are: (i) the pyroH vs mhpH terminal ligands, and (ii) all three Ce ions in **5** are nine-coordinate, whereas only two of those in **4** are nine-coordinate, the other being eight-coordinate.

Finally, the procedure was repeated but with an excess of pyridine instead of mhpH or pyroH, and the same Mn_2Ce_3 core was again obtained, but this time within the polymer $\{\{(pyrH)_3[Mn_2Ce_3O_6(O_2CMe)_{7.5}(NO_3)_3]\cdot(HO_2CMe)_{0.5}\cdot(H_2O)_2\}_2(NO_3)\}_n$ (**6**). The structure can be alternatively described as a dimer of $[Mn_2Ce_3(\mu_3\text{-}O)_6]^{8+}$ units linked by two acetate bridging ligands, which is connected to the other dimer units by an acetate group to form a polymer of dimers.

Solid-state, magnetic susceptibility measurements were carried out on vacuum-dried, microcrystalline samples of complexes **1**–**6** in the temperature range 5.0–300 K in a 0.5 T field. All paramagnetism of the Mn^{IV}–Ce^{IV} compounds is associated with the Mn^{IV} ions, since Ce^{IV} is diamagnetic (f^0). The $\chi_M T$ values at 300 K of all compounds decreases rapidly with decreasing temperature reaching values close to zero at 5 K. This behavior suggests the existence of antiferromagnetic interactions resulting in an $S_T = 0$ ground state.

The various products described span a wide range of Mn:Ce ratios, from Mn_2Ce_3 in **4**–**6**, Mn_2Ce in **1**, to Mn_6Ce in **2** and **3**. Other combinations are no doubt also possible as this work is extended.



3. Mn^{III}–Ce^{IV} compounds

Four enneanuclear $Mn^{III}_8Ce^{IV}$ clusters $[Mn_8CeO_8(O_2CMe)_{12}(H_2O)_4]$ (**7**), $[Mn_8CeO_8(O_2CMe)_{12}(py)_4]$ (**8**), $[Mn_8CeO_8(O_2CPh)_{12}(MeCN)_4]$ $[Mn_8CeO_8(O_2CPh)_{12}(dioxane)_4]$ (**9**) and $[Mn_8CeO_8(O_2CCHPh_2)_{12}(H_2O)_4]$ (**10**) have been isolated.

Compound **7** was the first Mn^{III}–Ce^{IV} cluster to be isolated. It was originally obtained by accident in low yield from a solution of **2** in $MeCN/Et_2O$ that had stood for a long time. With the identity and properties of **7** established, it was clear that a rational synthesis was crucial and this was developed using an oxophilic Ce^{4+} ion as the template around which wrapped the linear Mn^{III} polymer $\{[Mn^{III}(OH)(O_2CMe)_2]\cdot(MeCO_2H)\cdot(H_2O)\}_n$ (**11**) as Ce^{4+}–OH^- contacts developed. With a Ce:Mn ratio of 1:8, this reaction caused all the very insoluble polymer **11** (Scheme 1) to dissolve as the reaction proceeded to yield **7**, which was obtained in 55% isolated yield.

The structure of **7** (Fig. 4) consists of a non-planar, saddle-like $[Mn_8O_8]^{8+}$ loop attached to the central Ce^{4+} via the O^{2-} ions (Fig. 5). Eight μ- and four μ_3-acetate groups and four terminal water molecules provide the peripheral ligation. The $[Mn_8O_8]$ loop is the same as that found in $[Mn_{12}O_{12}(O_2CMe)_{16}(H_2O)_4]$ (**12**), where

there is a central $[Mn_4O_4]$ cubane instead of the smaller Ce atom. The eight Ce–O^{2-}bonds are undoubtedly crucial to the formation of **7**, and cause a greater folding of the $[Mn_8O_8]$ ring than in **12**. Another important difference between **12** and **7** is that the Mn^{III} Jahn–Teller (JT) elongation axes of **7** divide into groups that are nearly perpendicular to each other, in contrast to the situation in **12**. A close examination of the packing of **7** revealed the existence of

intermolecular hydrogen-bonding interactions involving the Mn-bound as well as the lattice H_2O molecules.

Solid-state dc magnetic susceptibility studies on **7** showed that the $\chi_M T$ value at 300 K increases rapidly with decreasing temperature suggesting the existence of ferromagnetic interactions. This was confirmed by variable field magnetization studies where the fit of the data gave $S = 16$, $D = -0.10(1)\ cm^{-1}$, and $g = 1.98(1)$. An $S = 16$ ground state and a negative D value for **7** suggested that it might have a sufficient barrier to magnetization relaxation to be a single-molecule magnet. The existence of hysteresis loops below ~0.6 K with coercivities that increase with decreasing temperature confirmed that **7** is a new SMM. The hysteresis loops do not show the steps that are characteristic of quantum tunneling of magnetization, probably due to the existence of intermolecular interactions mediated by the hydrogen-bonds and dipolar interactions. The low temperature at which **7** is a SMM is clearly due to the small D value, which is consistent with some of the Mn^{III} JT axes being nearly perpendicular. We thus, also prepared Mn_8Ce derivatives with bulky carboxylates in an attempt to minimize the intermolecular interactions, and which might also lead to a flattening of the Mn_8O_8 loop to a more planar configuration thereby increasing the D value. We initially performed reactions between $(NH_4)_2Ce(NO_3)_6$ and preformed Mn^{III}-containing carboxylate clusters such as $[Mn_3O(O_2CMe)_6(py)_3]$ ($2Mn^{III}$, $1Mn^{II}$) (**13**) and $(NBu^n_4)[Mn_4O_2(O_2CPh)_9(H_2O)]$ (**14**) ($4Mn^{III}$), common stepping-stones to higher nuclearity complexes [3,7e,14].

The reaction of **13** with Ce^{4+} in MeCN in an approximately 3:1 ratio gave $[Mn_8CeO_8(O_2CMe)_{12}(py)_4]$ (**8**) in 60% yield. This is structurally similar to **7**, except that the four terminal water molecules have been replaced by pyridine (py) molecules, thereby eliminating intermolecular interactions via hydrogen-bonding at these positions. Similarly, reaction of **14** with Ce^{IV} in a 1:2 ratio in MeCN with subsequent employment of dioxane to obtain crystals gave $\{[Mn_8CeO_8(O_2CPh)_{12}(MeCN)_4]\,[Mn_8CeO_8(O_2CPh)_{12}(dioxane)_4]\}$ (**9**) in 45% yield. Complex **9** is again structurally very similar to **7** (and **8**), with the unit cell containing two separate Mn_8Ce complexes with either MeCN or dioxane terminal ligands.

A further derivative of **7** possessing an even bulkier carboxylate group was prepared using diphenylacetic acid (Ph_2CHCO_2H) in a carboxylate substitution reaction with **7**; such ligand substitution methods are a common way of derivatizing Mn carboxylate clusters [1,3c,4a,5a]. Hence, complex **7** was treated with an excess (20 equiv.) of diphenylacetic acid and the free acetic acid removed under vacuum as its toluene azeotrope. This successfully gave $[Mn_8CeO_8(O_2CCHPh_2)_{12}(H_2O)_4]$ (**10**) in 60% isolated yield.

The magnetic properties of compounds **8** and **10** were investigated by both dc and ac methods. These studies revealed that the small structural perturbations resulting from the modifications to the nature of the carboxylate ligands and the water vs pyridine terminal ligation significantly affected the exchange interactions within the Mn_8Ce core, these no longer being all ferromagnetic as in **7**. Thus, the ground states spin values of **8** and **10** are $S = 5$ and 6, respectively, with the D values of both compounds being $\sim -0.3\ cm^{-1}$. Nevertheless, ac magnetic susceptibility studies of **8** and **10** revealed the presence of out-of-phase signals at low temperatures (close to 2 K) suggesting SMM behavior. Single-crystal hysteresis studies are in progress.

4. Mn^{III}–$Ce^{III/IV}$ compounds

Addition of $(NBu^n_4)_2Ce(NO_3)_6$ to an MeCN solution of **14** followed by filtration and layering of the filtrate with

MeOH gave the unusual complex $[Mn_{10}Ce_4O_{10}(OMe)_6(O_2CPh)_{16}(NO_3)_2(MeOH)_2(H_2O)_2]\cdot 4H_2O$ (**15**) (Fig. 6 top).

This is the only member of this family of Mn–Ce compounds with mixed valency in its Ce component. In fact, **15** is the first 3d/4f cluster of any type with mixed-valency in the lanthanide component. The $[Mn_{10}Ce_4O_{10}(OMe)_6]^{18+}$ core of **15** (Fig. 6, bottom) consists of a central $[Mn^{III}_4Ce^{IV}_2O_6(OMe)_2]$ unit attached at either end to a $[Mn^{III}_3Ce^{III}O_2(OMe)_2]$ distorted-cubane unit, giving a tubular structure.

The magnetic properties of **15** were studied by employing both dc and ac methods. The dc magnetic studies revealed the existence of antiferromagnetic interactions within the structure of **15** resulting in an $S = 4$ ground state. Out-of-phase ac magnetic susceptibility studies showed the existence of a signal at low temperatures suggesting SMM behavior. However, single-crystal micro-SQUID measurements revealed only very little hysteresis, and whose coercivity did not increase with either decreasing T or increasing scan rate. This is not the behavior expected for a SMM, and the small coercivity is probably mainly due to a phonon bottleneck rather than a real barrier to magnetization relaxation. This result thus represents an important caveat against taking such out-of-phase ac magnetic susceptibility signals in molecular species as proof of the presence of a SMM.

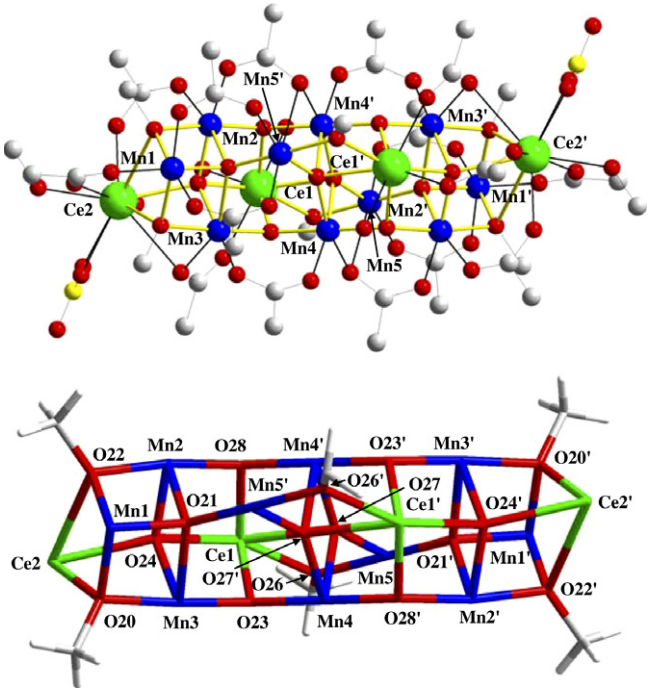

Fig. 6. (top) The structure of centrosymmetric **15** with the benzoate rings removed for clarity, except for the *ipso* C atom. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

5. Conclusions

We have described a powerful synthetic method for the preparation of new heterometallic Mn–Ce clusters. This method involves addition of Ce^{IV} to various Mn sources and has so far resulted in the isolation of eleven new compounds. These compounds have been divided in three categories (Mn^{IV}–Ce^{IV}, Mn^{III}–Ce^{IV} and Mn^{III}–$Ce^{III/IV}$) on the basis of the oxidation states of the constituent metal ions. All the compounds have aesthetically pleasing structures and some of them interesting magnetic properties. Further exploration of this area is expected to result in the isolation of further Mn–Ce species. In addition, we have recently shown that the method can also be extended to actinides, and have reported the preparation of the first Mn/Th complex [15]. Further extension of this strategy is currently under exploration.

Scheme 1.

physical (e.g. shape) and chemical (e.g. hydrogen-bonding) properties to influence or ideally, to template structures has been a subject of considerable interest [19–21]. For example, counterions that contain phenyl-groups often assemble using ''phenyl embraces'' of π–π stacking interactions that influence the accompanying coordination polymer geometry [22]. In anionic metal oxalate networks the choice of cation influences the formation of 2-D (6, 3) sheets or 3-D chiral (10, 3) networks [23,24].

The structural effect of such cations in metal dicyanamide (dca) polymers of the form [cation]{M(dca)$_3$} has been particularly well-studied, yielding a wide range of different structural motifs as a function of the size and shape of the cations [20,25–28]. For example, increasing the size and π–π stacking ability of the cations in 3-D systems such as [EtPh$_3$P]{Ni(dca)$_3$} to larger ones such as $[Ph_4P]^+$ induces a reduction in structural dimensionality as the 3-D system cannot flex to accommodate the cation bulk [27,28]. The dca anion is a divergent, bent bridging unit that can also bind metals via the central nitrogen donor (Scheme 1a); the five-atom bridge is not linear but subtends *c.a.* 120–125° angles through the central nitrogen and M–M distances range from 7 to 8 Å when only the ends are bound ($\mu_{1,5}$-binding) [29]. In comparison, the cyanometallate $[Au(CN)_2]^-$ also contains a five-atom bridging unit but is essentially linear (C–Au–C angles are generally >175°), leading to M–M distances of 10–11 Å through the dicyanoaurate. Also, while the central Au-atom cannot bind to other transition metals, it can readily form attractive aurophilic interactions that can increase the structural dimensionality of the polymer (Scheme 1b) [30]. As part of our investigations into coordination polymers containing the $[Au(CN)_2]^-$ building block [12,13,31–33], and given the diverse structural motifs generated by modifying countercations in the related dca-based systems, we initiated an examination of the analogous [organic cation]{M[Au(CN)$_2$]$_3$} system. We hereby report the first structures of metal tris-cyanoaurate systems with organic cations and their magnetic properties.

2. Experimental

2.1. Reagents and general procedures

All reagents were purchased from commercial sources and used as received. Infrared spectra were recorded on a Thermo Nicolet Nexus 670 FT-IR spectrometer with samples prepared as KBr pressed pellets. Microanalyses (C, H, N) were performed by Miki Yang using a computer-controlled Carlo Erba (Model 1106) CHN analyzer. Thermogravimetric analyses (TGA) were performed in an air atmosphere on a Shimadzu TGA-50 instrument at a rate of 5 °C per minute.

Solid-state UV–Vis–NIR absorption spectra of **1**–**5** were measured by reflectance using an Ocean Optics SD2000 spectrophotometer equipped with tungsten halogen and deuterium lamps. Prior to analysis, the samples were ground into fine powders, dispersed in water, deposited on a glass plate and left to dry completely. Magnesium oxide powder, prepared in the same fashion, was used as a reference.

2.2. Synthesis of $^nBu_4N[Au(CN)_2]\cdot 0.5H_2O$

A 30 mL aqueous solution of $^nBu_4NBr$ (2.325 g, 7.21 mmol) was added to a 30 mL aqueous solution of $KAu(CN)_2$ (2.002 g, 6.95 mmol) while stirring. A white solid immediately precipitated and was stirred for 30 min. The powder of $^nBu_4N[Au(CN)_2]\cdot 0.5H_2O$ was isolated by filtration and dried overnight. Yield: 3.409 g (97%). *Anal.* Calc. for $C_{18}H_{37}N_3AuO_{0.5}$: C, 43.20; H, 7.45; N, 8.40. Found: C, 43.24; H, 7.48; N, 8.11%. IR (KBr, cm^{-1}): 2962 (s), 2932 (s), 2875 (m), 2865 (sh), *ν*(CN) 2146 (s), 1630 (w), 1488 (m), 1463 (m), 1384 (w), 1156 (w), 1111 (w), 1054 (w), 1030 (w), 882 (m), 805 (w), 740 (m), 490 (s).

2.3. Synthesis of $^nBu_4N\{Ni[Au(CN)_2]_3\}$ (*1*)

A 5 mL ethanolic solution of $Ni(NO_3)_2\cdot 6H_2O$ (28 mg, 0.096 mmol) was added to a 5 mL ethanolic solution of $^nBu_4N[Au(CN)_2]\cdot 0.5\ H_2O$ (153 mg, 0.31 mmol). The solution was left to evaporate for several days. When *c.a.* 5 mL of solvent were left, a purple powder of $^nBu_4N\{Ni[Au(CN)_2]_3\}$ (**1**) was collected by filtration and air dried. Yield: 44 mg (44%). *Anal.* Calc. for $C_{22}H_{36}N_7Au_3Ni$: C, 25.21; H, 3.46; N, 9.35. Found: C, 25.52; H, 3.59; N, 9.62%. IR (KBr, cm^{-1}): 2961 (s), 2933 (s), 2887 (m), *ν*(CN) 2195 (s), 1479 (m), 1377 (m), 1150 (w), 1106 (w), 1051(w), 1024 (w), 880 (m), 800 (w), 736 (m), 491 (s). UV–Vis–NIR (nm): 305, 355, 564 (broad) and 910 (broad).

Crystals of **1** suitable for single crystal X-ray diffraction analysis were obtained by recrystallization of the purple powder under hydrothermal conditions in a sealed glass ampoule inserted into a stainless steel vessel and heated in a Lindberg Heavy-Duty furnace equipped with a programmable temperature controller. Specifically, a sample of $^nBu_4N\{Ni[Au(CN)_2]_3\}$ (90 mg in 3 mL of water) was heated to 125 °C over a period of 2 h, maintained at this temperature for 6 h, and slowly cooled to 25 °C at a rate of 1 °C per hour. The crystals and the powder had identical powder X-ray diffractograms and IR spectra.

2.4. Synthesis of $Co[Au(CN)_2]_2(H_2O)_2$

A 5 mL acetonitrile solution of $^nBu_4N[Au(CN)_2]\cdot 0.5\ H_2O$ (98 mg, 0.20 mmol) was added to a 5 mL acetonitrile

solution of $Co(ClO_4)_2 \cdot 6H_2O$ (38 mg, 0.10 mmol). An immediate pink precipitate was obtained but was left covered overnight. The powder of $Co[Au(CN)_2]_2(H_2O)_2$ was then collected by filtration and air dried. Yield: 44 mg (38%). *Anal.* Calc. for $C_4H_4N_4Au_2CoO_2$: C, 8.10; H, 0.68; N, 9.45. Found: C, 8.37; H, 0.77; N, 9.33%. IR (KBr, cm^{-1}): 3143 (b), ν(CN) 2204 (s), ν(CN) 2168 (s), $\nu(^{13}CN)$ 2118 (w), 1530 (m), 886 (w), 755 (w), 542 (w), 467 (m).

2.5. Synthesis of $^nBu_4N\{Co[Au(CN)_2]_3\}$ (2)

$^nBu_4N[Au(CN)_2] \cdot 0.5H_2O$ (40 mg, 0.080 mmol) and $Co[Au(CN)_2]_2(H_2O)_2$ (31 mg, 0.052 mmol) were dissolved completely in 15 mL of ethanol by stirring for 10 min. Once dissolved, the stirring was discontinued and the peach solution was left to evaporate to dryness at room temperature, yielding peach crystals covered with white precipitate. To this mixture 3 mL of ethanol was added and the solution was lightly stirred and then filtered after 3 min. The filtrate was separated and the pink precipitate of $^nBu_4N\{Co[Au(CN)_2]_3\}$ (**2**) was washed with 3 mL of water and 3 mL of cold ethanol. The separated filtrate was evaporated to dryness and subjected to the same treatment to increase the yield. Yield: 29 mg (52%). *Anal.* Calc. for $C_{22}H_{36}N_7Au_3Co$: C, 25.20; H, 3.46; N, 9.35. Found: C, 25.42; H, 3.54; N, 9.39%. IR (KBr, cm^{-1}): 2960 (s), 2933 (m), 2873 (m), ν(CN) 2189 (s), $\nu(^{13}CN)$ 2157 (vw), 1479 (m), 1462 (w), 1377 (w), 1175 (vw), 1149 (w), 1104 (vw), 1053 (vw), 1024 (w), 879 (w), 800 (vw), 734 (w), 484 (w). UV–Vis–NIR (nm): 470 (broad), 490 (sh), 515 (sh), 1030.

2.6. Synthesis of $\{Co[Au(CN)_2]_2(H_2O)_2\} \cdot {}^nBu_4N[Au(CN)_2]$ (3)

$^nBu_4N[Au(CN)_2] \cdot 0.5H_2O$ (40 mg, 0.080 mmol) and $Co[Au(CN)_2]_2(H_2O)_2$ (35 mg, 0.059 mmol) powders were mixed together, suspended in a 1 mL mixture of ethanol/water (9:1, v/v) and sealed with parafilm. The precipitate slowly turned pink, and formed small pink rectangular prism crystals of $\{Co[Au(CN)_2]_2(H_2O)_2\} \cdot {}^nBu_4N[Au(CN)_2]$ (**3**) after three days. The solution was then filtered and the crystals isolated. Yield: 49 mg (77%). *Anal.* Calc. for $C_{22}H_{38}N_7O_2Au_3Co$: C, 24.37; H, 3.72; N, 9.04. Found: C, 24.55; H, 3.79; N, 9.26%. IR (KBr, cm^{-1}): 3454 (b), 3207 (m), 2960 (s), 2930(m), 2872 (m), ν(CN) 2183 (s), ν(CN) 2147 (s), 2108 (vw), 1600 (m), 1469 (m), 1380 (w), 1164 (vw), 1104 (vw), 1068 (vw), 1032 (vw), 926 (vw), 881 (w), 731 (vw), 490 (m). UV–Vis–NIR (nm): 470, 500, 1040.

Crystals of **3** suitable for single crystal X-ray diffraction analysis were obtained by a different route: A 5 mL ethanol/water (1:1 v/v) solution of $^nBu_4N[Au(CN)_2] \cdot 0.5H_2O$ (105 mg, 0.210 mmol) was added slowly to a 5 mL ethanol/water solution of $Co(ClO_4)_2 \cdot 6H_2O$ (26 mg, 0.071 mmol). The pink solution immediately became peach colored, and was left to slowly evaporate. Pink/red rectangular prism crystals of **3** and white $^nBu_4N(ClO_4)$ crystals formed as the ethanol evaporated. The solution was then filtered, and the crystals of **3** were separated by hand; they can be cleaned with ethanol, but are somewhat soluble. Yield: 25 mg (33%). The crystals and the powder had identical powder X-ray diffractograms and IR spectra.

2.7. Synthesis of $PPN[Au(CN)_2]$

A 10 mL aqueous solution of $KAu(CN)_2$ (251 mg, 0.872 mmol) was added to a 20 mL mixture of ethanol/water (1:1 v/v) solution of bis(triphenylphosphoranylidene)ammonium chloride (PPNCl) (525 mg, 0.915 mmol) while stirring. An immediate white precipitate formed. After standing for 30 min, the solid of $PPN[Au(CN)_2]$ was filtered, washed with water and air-dried overnight. Yield: 666 mg (97%). *Anal.* Calc. for $C_{38}H_{30}N_3AuP_2$: C, 57.95; H, 3.84; N, 5.38. Found: C, 57.71; H, 3.86; N, 5.17%. IR (KBr, cm^{-1}): 3088 (vw), 3075 (w), 3055 (m),3038 (w), 3022 (w), 3008 (vw), 2990 (vw), ν(CN) 2145 (s), 1589 (m), 1483 (m), 1456 (m), 1439 (s), 1434 (s), 1285 (s), 1267 (s), 1180 (m), 1160 (w), 1116 (s), 997 (m), 796 (m), 743 (s), 726 (s), 690 (s), 548 (s), 531 (s), 496 (s). A different preparation of this salt, via $[AuCl_2]^-$, has previously been reported [34].

2.8. Synthesis of $PPN\{Ni[Au(CN)_2]_3\}$ (4)

A 5 mL ethanolic solution of $PPN[Au(CN)_2]$ (100 mg, 0.127 mmol) was added slowly to a 5 mL ethanolic solution of $Ni(NO_3)_2 \cdot 6H_2O$ (13 mg, 0.044 mmol). A solid immediately precipitated from the solution, which changed from blue to completely colorless. A very fine pale blue powder of $PPN\{Ni[Au(CN)_2]_3\}$ (**4**) was obtained upon filtration. Yield: 39 mg (69%). *Anal.* Calc. for $C_{42}H_{30}N_7Au_3NiP_2$: C, 37.53; H, 2.25; N, 7.29. Found: C, 37.30; H, 2.34; N, 7.19%. IR (KBr, cm^{-1}): 3076 (w), 3055 (m), 3021 (w), 3009 (w), 2998 (vw), 2971 (vw), ν(CN) 2192 (s), ν(CN) 2151 (vw), 1588 (w), 1476 (w), 1436 (m), 1383 (s), 1330 (m), 1302 (w), 1272 (w), 1186 (w), 1160 (vw), 1117 (s), 1026 (w), 997 (w), 738 (w), 723 (s), 688 (w), 550 (m), 531 (s), 499 (m). UV–Vis–NIR (nm): 335, 562 (broad) and 895 (broad).

Crystals suitable for X-ray crystallography were obtained using an H-tube technique. On one side of a 55 mL H-shaped tube filled with ethanol, a 2 mL ethanolic solution of $PPN[Au(CN)_2]$ (96 mg, 0.121 mmol) was deposited at the bottom. On the other side, a 0.5 mL ethanolic solution of $Ni(NO_3)_2 \cdot 6H_2O$ (15 mg, 0,052 mmol) was deposited. The H-shaped tube was sealed, and after 10 days, light purple cubic crystals of **4** formed. The crystals and the powder had identical powder X-ray diffractograms and IR spectra.

2.9. Synthesis of $PPN\{Co[Au(CN)_2]_3\}$ (5)

A 7 mL ethanolic solution of $PPN[Au(CN)_2]$ (150 mg, 0.190 mmol) was added slowly to a 7 mL ethanolic solution of $Co(ClO_4)_2 \cdot 6H_2O$ (23 mg, 0.060 mmol). A peach powder

immediately precipitated from the solution, which changed from pink to completely colorless. A very fine peach powder of PPN{Co[Au(CN)$_2$]$_3$} (**5**) was obtained upon filtration. Yield: 40 mg (71%). *Anal.* Calc. for $C_{42}H_{30}N_7Au_3CoP_2$: C, 37.52; H, 2.25; N, 7.29. Found: C, 37.77; H, 2.15; N, 7.47%. IR (KBr, cm^{-1}): 3145 (vw), 3076 (w), 3055 (m), 3021 (w), 3009 (w), 2989 (vw), ν(CN) 2187 (s), ν(CN) 2175 (sh), 1588 (w), 1476 (w), 1438 (m), 1384 (s), 1330 (m), 1320 (m), 1302 (w), 1272 (w), 1186 (w), 1160 (vw), 1117 (s), 1026 (w), 997 (w), 881 (vw), 840 (vw), 800 (vw), 738 (w), 723 (s), 690 (w), 550 (m), 531 (s), 499 (m). UV–Vis–NIR (nm): 475 (broad), 490 (sh), 510 (sh) and 990.

2.10. X-ray crystallographic analysis

Powder X-ray diffractograms of all compounds were measured on a Rigaku RAXIS-Rapid Auto diffractometer equipped with a Cu Kα source ($\lambda = 1.54056$ Å). Samples were mounted on a glass fiber using grease and were exposed, as the phi axis was spun (10° s^{-1}), for a period of 40–60 min.

Single crystals of **1**, **3** and **4** were mounted on glass fibers using epoxy adhesive. Single crystal X-ray diffraction data for **1**, **3** and **4** were recorded on an Enraf Nonius CAD4F diffractometer equipped with a Mo Kα source ($\lambda = 0.71073$ Å) and controlled by the DIFRAC program [35] in the following ranges: **1**, $4° < 2\theta < 51°$; **3**, $4° < 2\theta < 48°$; **4**, $4° < 2\theta < 55°$. The NRCVAX Crystal Structure System was used to perform a psi-scan absorption correction (in the transmission range 0.0135–0.0409 for **1**, 0.1068–0.1707 for **3** and 0.0303–0.1154 for **4**) and data reduction, including Lorentz and polarization corrections. The crystal structure of each compound was solved using the Sir 92 routine and refined through Fourier techniques using the CRYSTALS software package [36].

Crystallographic data for compounds **1**, **3** and **4** are collected in Table 1. For **1**, the Ni and Au atoms were refined anisotropically while the C and N atoms were kept isotropic due to the limited number of observed data. Full matrix least-squares refinement for **1** (1540 reflections included) on F (156 parameters) converged to $R_1 = 0.0483$, $wR_2 = 0.0529$ ($I_o > 2.5\sigma(I_o)$). For **3**, all non-hydrogen atoms were refined anisotropically except for the C atoms of the ^{n}Bu-groups that were kept isotropic due to their very large thermal motion. Full matrix least-squares refinement for **3** (689 reflections included) on F (87 parameters) converged to $R_1 = 0.0406$, $wR_2 = 0.0469$ ($I_o > 2.5\sigma(I_o)$). For **4**, all non-hydrogen atoms were refined anisotropically. Full matrix least-squares refinement for **4** (1172 reflections included) on F (87 parameters) converged to $R_1 = 0.0303$, $wR_2 = 0.0411$ ($I_o > 2.5\sigma(I_o)$). Hydrogen atoms were placed in geometric positions in all compounds and their coordinates allowed to ride with their associated atoms.

Diagrams were prepared using ORTEP-3 (version 1.076) [37] and POV-RAY (version 3.6.0) [38]. Selected bond lengths and angles for **1**, **3** and **4** are reported, respectively, in Tables 2–4.

Table 1
Crystallographic data and structural refinement details for **1**, **3** and **4**

Compound	**1**	**3**	**4**
Formula	$C_{22}H_{36}N_7Au_3Ni$	$C_{22}H_{40}N_7Au_3CoO_2$	$C_{42}H_{30}N_7Au_3NiP_2$

Goodness-of-fit	1.3778	1.4542	1.888

$R_1 = \sum|(|F_o| - |F_c|)|/\sum|F_o|$, for observed data ($I_o > 2.5\sigma(I)$), $wR_2 = [\sum(w(|F_o| - |F_c|)^2)/\sum(wF_o)^2]^{1/2}$, for observed data ($I_o > 2.5\sigma(I)$), GOF = $[\sum(w(|F_o| - |F_c|)^2)/\text{degrees of freedom}]^{1/2}$.

2.11. Magnetometry

Magnetization measurements were performed with a Quantum Design MPMS-XL-7S SQUID magnetometer with an Evercool-equipped liquid helium dewar. Microcrystalline samples of **1**–**5** were packed in gelatin capsules and mounted in diamagnetic plastic straws. Direct current (dc) magnetization was measured for all samples upon

cooling from 300 to 1.8 K under an applied dc field of 1 kOe. Measurements for all compounds were also performed under an applied field of 100 Oe and no field dependency was observed. The magnetic susceptibility of each compound was corrected for the diamagnetic contribution of the constituent atoms using Pascal's constants [39].

3. Results

3.1. Synthesis and structural characterization of $^nBu_4N\{Ni[Au(CN)_2]_3\}$ (1) and $^nBu_4N\{Co[Au(CN)_2]_3\}$-(2)

The reaction of Ni(II) with $^nBu_4N[Au(CN)_2]\cdot 0.5H_2O$ in ethanol afforded, over a period of several hours, a purple precipitate whose composition was consistent with $^nBu_4N\{Ni[Au(CN)_2]_3\}$ (**1**) by elemental analysis. When the same reaction was performed with Co(II), a mixture of $^nBu_4N$-salts and Co-containing products were obtained, probably due to the higher solubility of the Co-analogue. To eliminate the resulting separation problem, $Co[Au(CN)_2]_2(H_2O)_2$ was dissolved in ethanol and used as the Co(II) source, to which was added one equivalent of $^nBu_4N[Au(CN)_2]\cdot 0.5H_2O$, thereby yielding the byproduct-free $^nBu_4N\{Co[Au(CN)_2]_3\}$ (**2**). The FT-IR spectra of **1** and **2** show only one cyanide vibration frequency at 2195 and 2189 cm^{-1}, respectively, blue-shifted with respect to the ν_{CN} frequency of 2146 cm^{-1} for $^nBu_4N[Au(CN)_2]\cdot 0.5\ H_2O$, consistent with all *N*-cyano groups binding to the transition metal [9].

Dark blue crystals of $^nBu_4N\{Ni[Au(CN)_2]_3\}$ (**1**) suitable for single crystal X-ray diffraction analysis were obtained by hydrothermal recrystallization. The solid-state structure determined for $^nBu_4N\{Ni[Au(CN)_2]_3\}$ (**1**) is shown in Fig. 1. The Ni(II) centers are coordinated to six *N*-cyano groups, with an average bond length of 2.04(3) Å (Fig. 1a, Table 2), yielding a distorted octahedral geometry. Each $[Au(CN)_2]^-$ unit in **1** bridges two Ni(II) centers, generating a three dimensional network (Fig. 1). The structure is built up by a series of two-dimensional (4, 4) rectangular grids, each oriented in a different direction. Each rectangular unit in each grid contains six Ni(II) centers connected by $[Au(CN)_2]^-$ units: one Ni(II) center at each corner and two Ni(II) centers along one pair of opposite edges (Fig. 1b). Each Ni(II) center occupies the edge position on three intersecting fused grids (shown in black in Fig. 1c). Additional $[Au(CN)_2]^-$ units allow the formation of another set of three grids that intersect at the same Ni(II) center (edge-position of the first set of grids) which now occupies the corner position in each of this latter set of grids (shown in grey in Fig. 1c). In other words, six rectangular grids intersect at one Ni center: each Ni center occupies an edge position on three grids and a corner position on the other three grids. No interpenetration of additional networks occurs.

The pores generated by this network accommodate the $^nBu_4N^+$ cations. The central *N* atom lies above an $[Au(CN)_2]^-$ unit while the *n*-butyl groups spread on both sides to occupy the empty space. Thus, the structure of $^nBu_4N\{Ni[Au(CN)_2]_3\}$ (**1**) does not contain any empty pores. In addition, no Au–Au (aurophilic) interactions are present in this system, perhaps a result of the ''insulating'' *n*-butyl groups that surround the $[Au(CN)_2]$ units.

Although no crystal of **2** suitable for single crystal X-ray diffraction analysis could be obtained, the powder diffractogram of **2** was found to be superimposable to that generated from the single-crystal structure of **1** (Fig. 2); this is excellent evidence to suggest that **2** is isostructural with **1**.

The solid state UV–Vis–NIR absorption spectra of **1** and **2** (Figure S1) show maxima attributable to $d-d$ transitions at 305, 355, 564 (br) and 910 nm for **1** and 470 (with shoulder peaks at 490 and 515 nm) and 1030 nm for **2**. These spectra are as expected for octahedral Ni(II) and Co(II) systems with moderate ligand fields [40].

3.2. Synthesis and structural characterization of $\{Co(H_2O)_2[Au(CN)_2]_2\}\cdot {}^nBu_4N[Au(CN)_2]$ (3)

When water was added to the reaction of pale pink $Co[Au(CN)_2]_2(H_2O)_2$ with $^nBu_4N[Au(CN)_2]$ in ethanol, a product with a different colour was obtained. The composition of this dark red-pink product was consistent with $\{Co(H_2O)_2[Au(CN)_2]_2\}\cdot {}^nBu_4N[Au(CN)_2]$ (**3**) by elemental analysis; hence, it was different than **2**, which is anhydrous. The FT-IR spectrum of $\{Co(H_2O)_2[Au(CN)_2]_2\}\cdot {}^nBu_4N[Au(CN)_2]$ (**3**) shows two different cyanide vibration frequencies, 2182 and 2147 cm^{-1}, which suggests the presence

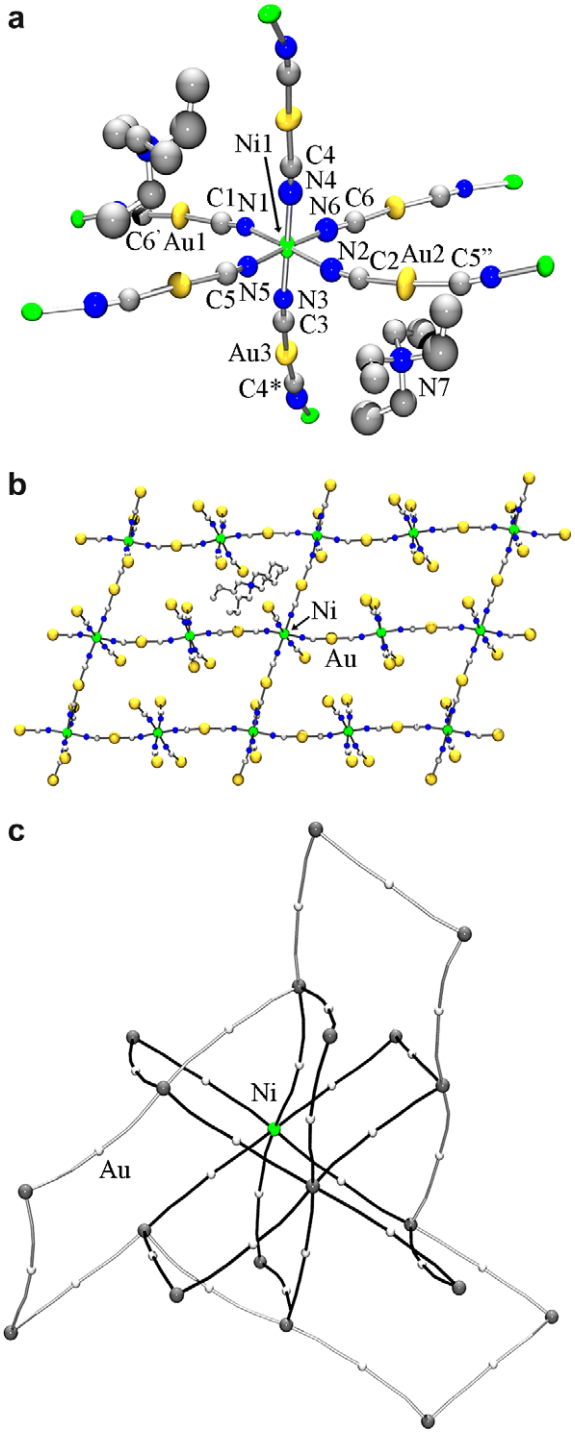

Fig. 1. (a) Coordination sphere around the Ni(II) center (only two cations are shown; butyl groups were simplified for clarity); (b) Extended network showing a two dimensional rectangular (4, 4) grid and the position of one $^{n}Bu_4N^+$ cation; (c) Six rectangular grids intersecting at one Ni(II) center (labelled): the Ni center occupies an edge position on three grids (shown in black) and a corner position on the other three grids (shown in grey) (C and N atoms were removed for clarity and Au atoms are shown smaller and pale grey).

of bound *N*-cyano groups as well as free or weakly interacting *N*-cyano groups; complex **2** had only one ν_{CN} band at 2189 cm^{-1}.

The structure of $\{Co(H_2O)_2[Au(CN)_2]_2\}\cdot{}^{n}Bu_4N[Au(CN)_2]$ (**3**) contains octahedral Co(II) centers that are coordinated to four *N*-cyano groups in the equatorial plane (Co–N = 2.096(12) Å) and two water molecules (Co–O = 2.089(16) Å) in the axial sites (Fig. 3, Table 3); thus, **3** is not a true polymorph of **2** but rather a pseudo-polymorph [41] or, more appropriately, a solvent adduct. A 2-D square grid is formed through the cobalt-bridging $[Au(CN)_2]$ units with the water molecules lying above and below the grid (Fig. 3a). Free $[Au(CN)_2]$ units are also present and lie above and parallel to opposing edges of the $Co[Au(CN)_2]_2$ square array. Each free $[Au(CN)_2]$ unit interacts with the underlying grid both through hydrogen-bonding between the terminal *N*-cyano atoms and the hydrogen of the water molecules, and also through aurophilic (Au–Au) interactions (Au1–Au2 = 3.4250(13) Å, Fig. 3b). Aurophilic interactions are considered to exist when the distance between two Au atoms is smaller than the sum of the van der Waals radii, 3.6 Å [42–44]. The alignment of each layer of free $[Au(CN)_2]$ units alternates 90° with the two pairs of parallel edges of the square arrays. Hence, through aurophilic interactions and hydrogen-bonding, a 3-D network is obtained. The $^{n}Bu_4N^+$ cations occupy the empty sites in the layer of unbound $[Au(CN)_2]$ units. Overall, $\{Co(H_2O)_2[Au(CN)_2]_2\}\cdot{}^{n}Bu_4N[Au(CN)_2]$ (**3**) can be considered to be a layered polymer that contains neutral sheets of $\{Co(H_2O)_2[Au(CN)_2]_2\}$ which are separated by $^{n}Bu_4N[Au(CN)_2]$ layers.

The geometry around the Au atom in the bridging $[Au(CN)_2]$ unit (C(1)–Au(1)–C(1*) = 171.5(10)°) differs from that observed in the free unit (C(2)–Au(2)–C(2″) = 179.7(13)°): a clear bending of the $[Au(CN)_2]$ units within the 2-D grid can be observed (Fig. 3). Theoretically, an angle of 173.6° was calculated for an anionic dimer of $[Au(CN)_2]$ units, with a Au–Au interaction of 3.742 Å and a torsion angle of 90° [45]. Hence, the experimentally observed acute C–Au–C angle could reflect the presence of Au–Au interactions, even though the torsion angle is different, or this unusually large distortion from linearity around the Au atom could reflect the need to accommodate the large $^{n}Bu_4N^+$ cation incorporated between the grids.

The basic 2-D grid structure of $\{Co(H_2O)_2[Au(CN)_2]_2\}\cdot{}^{n}Bu_4N[Au(CN)_2]$ (**3**) is similar to that reported for other solvent adducts, such as $\{Co(dmf)_2[Au(CN)_2]_2\}$ [45], $\{Mn(H_2O)_2[Au(CN)_2]_2\}$ [46] and $\{Cu(pyridine)_2[Au(CN)_2]_2\}$ [12]. In these polymers, no extra $^{n}Bu_4N[Au(CN)_2]$ layer is present and the solvent molecules, binding through their donor atom, replace the water molecules in **3**. The packing of the 2-D square grids is different in these other systems as the grids are offset to allow direct aurophilic interactions of ~3.1 Å between two grids [45,46] or π–π interactions between the pyridine rings [12].

Interestingly, heating a sample of **3** at 150 °C for 90 min to remove the bound water molecules cleanly generated the dehydrated 3-D array of **2** as indicated by X-ray diffractograms and FT-IR spectra that were superimposable with those of independently synthesized **2**. This significant

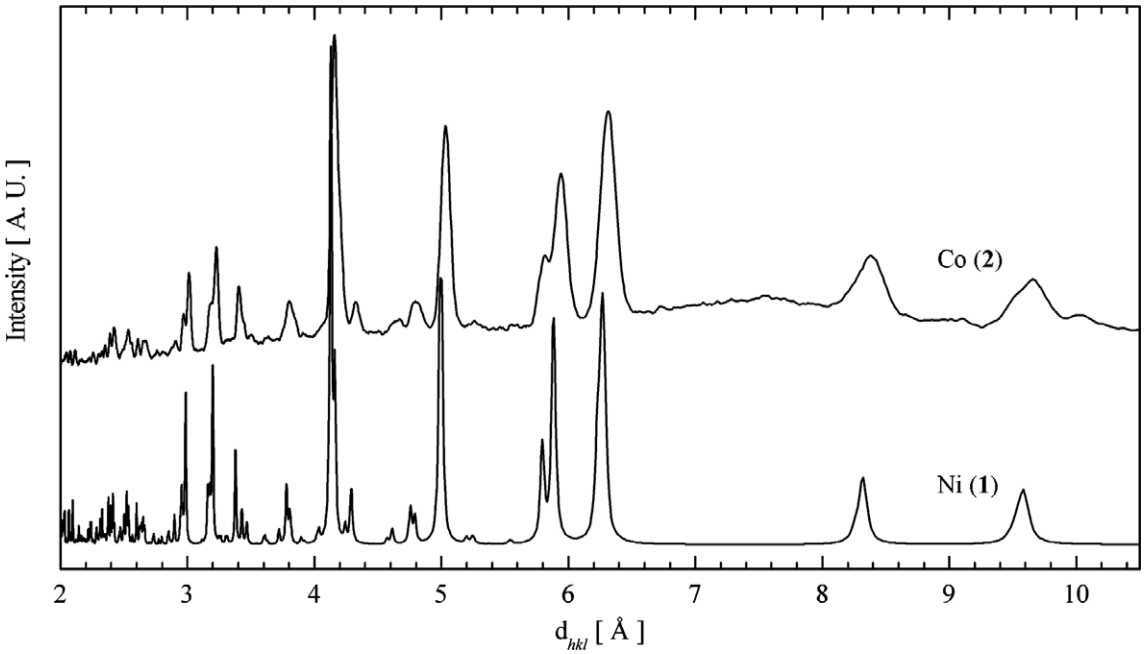

Fig. 2. Powder X-ray diffractograms generated for $^{n}Bu_4N\{Ni[Au(CN)_2]_3\}$ (**1**) from the single crystal diffraction data and measured for $^{n}Bu_4N\{Co[Au(CN)_2]_3\}$ (**2**).

structural rearrangement in the solid state is a strong indication of the flexible nature of cyanoaurate-based coordination polymers [12]. Note that **3** is not regenerated in the solid state by exposure to water vapour.

3.3. Synthesis and structural characterization of *PPN{Ni[Au(CN)$_2$]$_3$}* (*4*) and *PPN{Co[Au(CN)$_2$]$_3$}* (*5*)

The reaction of $PPN[Au(CN)_2]$ with M(II) salts (M = Ni and Co) in ethanol immediately yielded very fine precipitates. Elemental analysis confirmed that the product compositions were consistent with $PPN\{M[Au(CN)_2]_3\}$ (M = Ni (**4**); Co (**5**)). FT-IR spectroscopy showed one cyanide vibration frequency for **4** at 2192 cm^{-1} and two barely resolved frequencies for **5** at 2187 and 2175 cm^{-1}. This suggests that all the cyanide groups are in a similar environment in **4** while a slight structural difference among the cyanide groups exists in **5**, likely due to broken symmetry. No ν_{CN} band corresponding to free $[Au(CN)_2]$ (~2140 cm^{-1}) could be observed in the FT-IR spectrum of either **4** or **5**, suggesting that all *N*-cyano units are coordinated to the metal centers.

Pale purple crystals of $PPN\{Ni[Au(CN)_2]_3\}$ (**4**) were obtained through slow diffusion of reagents in an H-shaped tube. The structure determined for **4** is shown in Fig. 4. As for **1**, the Ni(II) centers have an octahedral geometry and coordinate to six *N*-cyano groups (Table 4). Each $[Au(CN)_2]$ unit bridges two Ni(II) centers to create a 3-D Prussian-Blue-type pseudo-cubic array. The PPN^+ cation occupies the space in the center of each cube, preventing the interpenetration of a second network. This "expanded Prussian Blue" analogue, with 10.269 Å edges (Ni–Ni), can be compared with other examples such as $Fe_4[Re_6Te_8(CN)_6]_3 \cdot xH_2O$ [47] and $[Ni(en)_2]_3[Fe(CN)_6](PF_6)_2$ [48] which have edges of 14.1285 and 9.908 Å, respectively.

The powder X-ray diffractograms of **4** and **5** are nearly superimposable (Fig. 5), which indicates that an identical arrangement of the building blocks is present in the two polymers. This is also consistent with the FT-IR spectra; the small difference in cyanide vibration frequency can be attributed to the difference between *N*-cyano group binding to Ni or Co.

The solid-state UV–Vis–NIR absorption spectra of **4** and **5** (Figure S1) were found to have two *d–d* maxima at 562 and 895 nm for **4** and 475 nm (with shoulder peaks at 490 and 510 nm) and 990 nm for **5**; absorptions below 400 nm are obscured by strong PPN-based peaks. The absorption spectra of the $PPN\{M[Au(CN)_2]_3\}$ polymers are very similar to those of their respective $^{n}Bu_4N\{M[Au(CN)_2]_3\}$ analogues, consistent with the observation that the geometry and coordination sphere of the metal centers are similar in both pairs of compounds.

3.4. Templating effects of the cation

The structures of **1**–**5** can be contrasted with the related $K\{Fe[Au(CN)_2]_3\}$ [46], $K\{Co[Au(CN)_2]_3\}$ [49] and $K\{Mn[Ag(CN)_2]_3\}$ [50] structures, which contain triply interpenetrated pseudo-cubic 3-D cyanometallate arrays. The switch of the non-steric K^+ cation for the $^{n}Bu_4N^+$ cation has eliminated the interpenetration and modified the form of the 3-D network, but has not caused a reduction in dimensionality. Hydration of the Co(II) in **3** does, however, cause a reduction in dimensionality in terms of the coordinate bond network. Finally, the PPN^+ cation rather surprisingly also does not force any reduction in

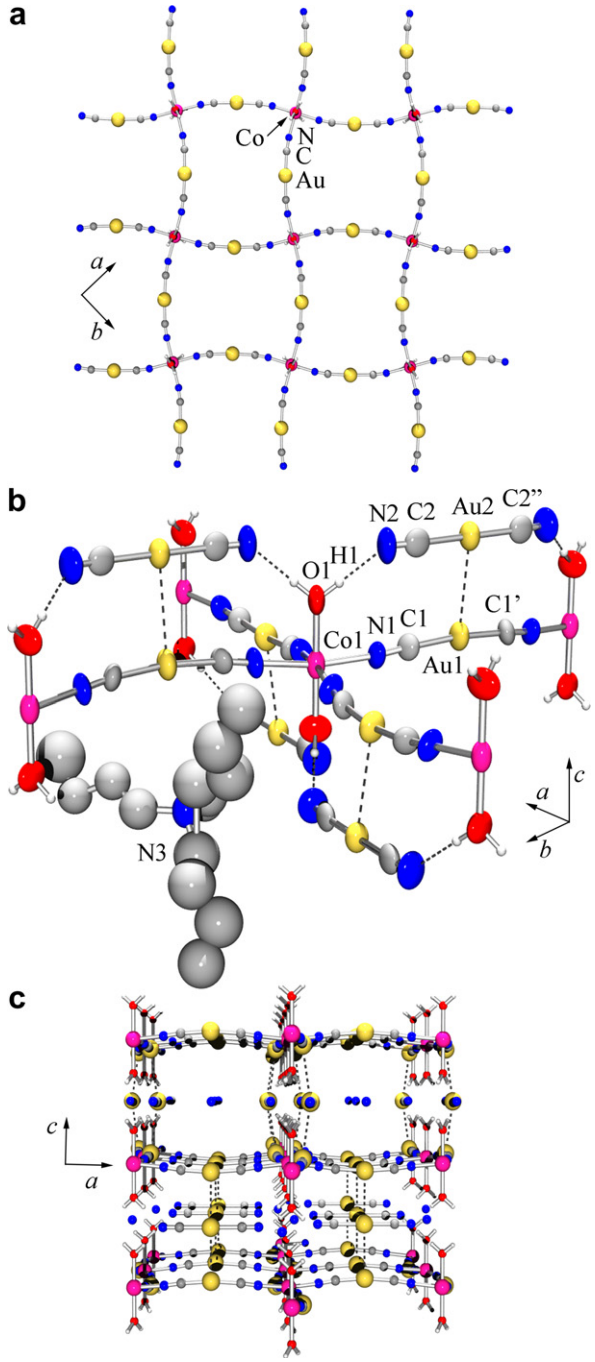

Fig. 3. (a) 2-D square grid of $\{Co(H_2O)_2[Au(CN)_2]_2\} \cdot {}^nBu_4N[Au(CN)_2]$ (**3**) showing the 2-D square grids viewed down the *c*-axis; (b) Coordination sphere around a Co(II) center in **3**; (c) Interactions between the grids and the free $[Au(CN)_2]$ units along the *c*-axis. ^{n}Bu groups were omitted for clarity.

dimensionality; indeed, this non-interpenetrated structures is strain-free and nearly identical to a single pseudo-cubic network found in the K^+-analogues.

3.5. Thermal stability

Thermogravimetric analysis data from 25 to 500 °C were collected for **1**, **2**, **3** and up to 820 °C for **4** and **5**.

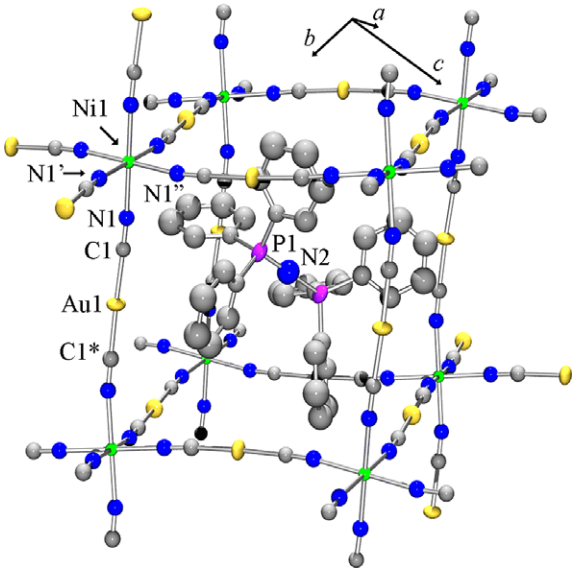

Fig. 4. Extended structure of $PPN\{Ni[Au(CN)_2]_3\}$ showing the coordination sphere around the Ni(II) centers and the Prussian-Blue-type pseudo-cubic array.

Compounds **1**–**3** decompose within the same narrow temperature range, losing the six cyanide groups and the cation all at once. The nickel compounds have slightly higher decomposition temperatures, with **1** being stable until 295 °C, then losing cyanides and the $^nBu_4N^+$ cation, leaving gold and nickel oxide at 330 °C (observed: 64.0%; calculated: 63.5%). Complex **4** starts decomposing at 325 °C, with a slow decomposition of the PPN^+ cation occurring up to 750 °C, obtaining $Ni(P_2O_3)$ and gold (final mass observed: 55.0%; calculated: 56.5%). In the case of the cobalt compounds, **2** is stable until to 260 °C, and then loses the cyanides and $^nBu_4N^+$ cation until 338 °C, leaving gold and cobalt oxide (observed: 62.5%; calculated: 63.9%). Hydrated **3** first loses its two water molecules between 100 °C and 120°C (observed: 4.0%; calculated: 3.3%) then further decomposes along the same path as **2**, losing all cyanides and $^nBu_4N^+$ in the same 260–338 °C temperature range (observed: 60.3%; calculated: 61.8%). Complex **5** follow the same pattern as **4**, slowly decomposing after 275 °C up until 730 °C, forming $Co(P_2O_3)$ and gold as the end products (final mass observed: 56.7%; calculated: 56.5%).

Thus, the tris-cyanoaurate frameworks are in general stable until 260–325 °C. These decomposition temperatures are typical for cyanometallate systems [51] but lower than for cyanoaurate arrays that show substantial aurophilic interactions such as $M(pyrazine)[Au(CN)_2]_2$, which loses its cyanides at a remarkable 406 °C for M = Ni and 360 °C for Co [32].

3.6. Magnetic properties of $^nBu_4N\{M[Au(CN)_2]_3\}$ (Ni, **1**; Co, **2**)

The magnetization of $^nBu_4N\{M[Au(CN)_2]_3\}$ (M = Ni (**1**); Co (**2**)) was measured upon cooling from 300 to

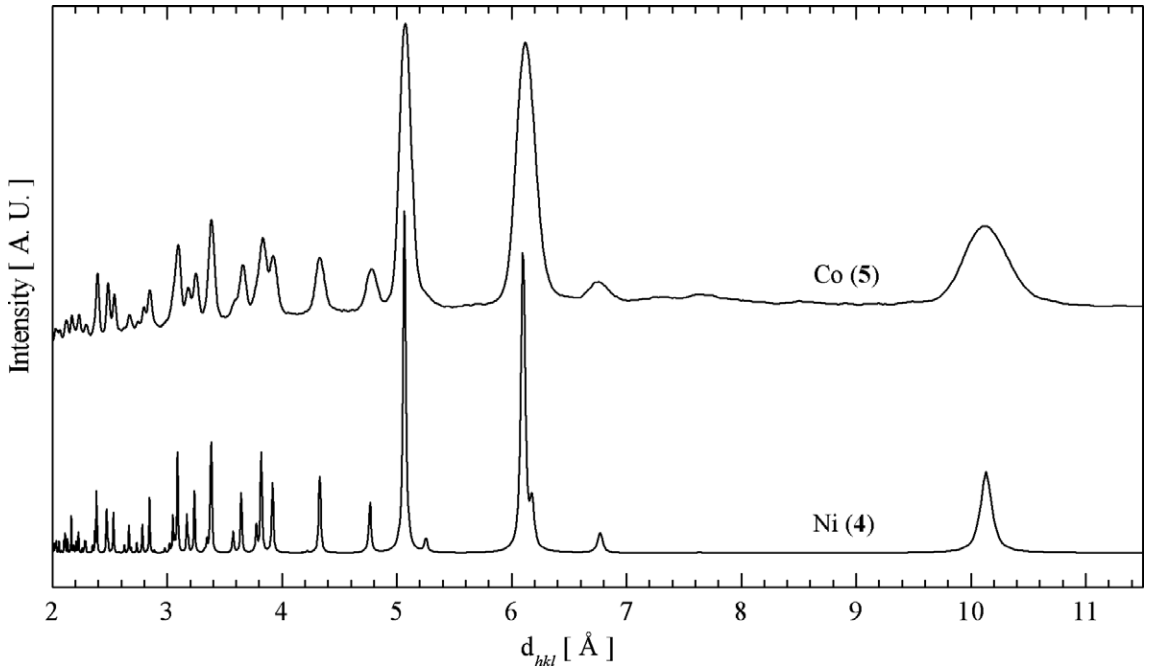

Fig. 5. Comparison between the powder X-ray diffractogram of PPN{Co[Au(CN)$_2$]$_3$} (**5**) and the diffractogram predicted from the single-crystal structure of PPN{Ni[Au(CN)$_2$]$_3$} (**4**).

1.8 K in a 1 kOe applied magnetic field. The calculated effective magnetic moments ($\mu_{\text{eff}} = 2.828\sqrt{\chi_{\text{M}}T}$) of **1** and **2** as a function of temperature are shown in Fig. 6. At 300 K, a value of 3.03 μ_{B} is observed for **1**, which is consistent with isolated spin-only $S = 1$ Ni(II) centers.[52] As the temperature is lowered, the μ_{eff} of **1** remains constant until 30 K and then decreases to reach 2.22 μ_{B} at 1.8 K. The inverse of the susceptibility χ_{M}^{-1} of **1** can be fit to the Curie–Weiss expression, [52] yielding a g of 2.166(2) and a θ value of −1.27(5) K.

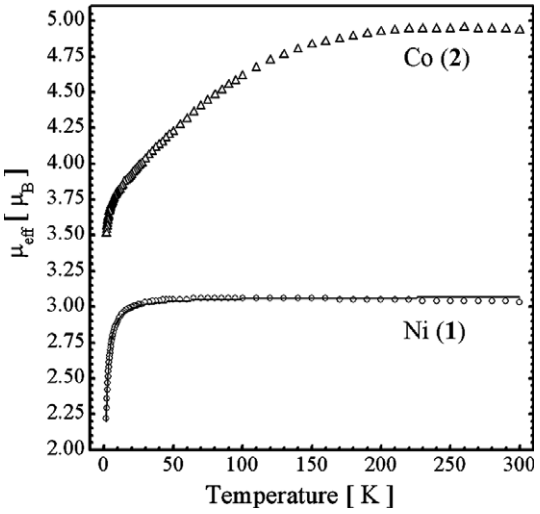

Fig. 6. Temperature dependence of the effective magnetic moment (μ_{eff}) for ^{n}Bu$_4$N{Ni[Au(CN)$_2$]$_3$} (**1**, ○) and ^{n}Bu$_4$N{Co[Au(CN)$_2$]$_3$} (**2**, Δ). The solid line represents the theoretical fit to the zfs expression with a molecular field approximation for the Ni(II) analogue (see text).

The drop in the μ_{eff} of **1** at low temperature could be due to either zero field splitting (zfs) or weak antiferromagnetic interactions mediated through the [Au(CN)$_2$]-units or a combination of both. The product of the susceptibility by the temperature ($\chi_{\text{M}}T$) for **1** can be fitted to the zfs expression for an $S = 1$ system, [52] yielding a D of 5.4(1) cm^{-1} and a g of 2.13(1). The fit of $\chi_{\text{M}}T$ for **1** was improved by introducing a molecular field approximation to estimate the magnetic coupling between the Ni(II) centers:

$$\chi_{\text{mf}} = \frac{\chi_{\text{zfs}}}{\left(1 - \frac{2zJ}{Ng^2\mu_{\text{B}}^2}\chi_{\text{zfs}}\right)} \quad (1)$$

where zJ is the exchange coupling constant with the neighboring Ni(II) centers. This second fit yielded a D of 2.7(1) cm^{-1}, a g of 2.173(2) and zJ/k_{B} of −0.85(2) cm^{-1}. Values of D for related octahedral Ni(II) centers, such as in Ni(tren)[Au(CN)$_2$]$_2$, range from 1 to 4 cm^{-1} [53]. The value for a symmetric octahedral Ni(II) center such as that found in **1** should be on the low side of this range. Hence, these values are reasonable and suggest very weak interactions between the Ni(II) centers may be present at best.

For **2**, an effective moment of 4.93 μ_{B} is observed at 300 K (Fig. 6), which is larger than the spin-only value of an $S = 3/2$ system, but is in the range expected for an octahedral high-spin Co(II) center (4.1–5.2 μ_{B}), [40] for which a large first-order orbital contribution is present. As the temperature decreases, the μ_{eff} remains constant down to 175 K, after which it decreases steadily and reaches 3.51 μ_{B} at 1.8 K. The decrease in the μ_{eff} of **2** can be due to a

combination of single-ion effects and very weak antiferromagnetic interactions; no maximum was observed in the magnetic susceptibility (χ_M) versus temperature plot. No attempt was made to model this behaviour as any coupling through the $[Au(CN)_2]$ units would have a very small magnitude and would be difficult to distinguish from the single-ion effects. In related Co(II) dicyanamide complexes with $\mu_{1,5}$-bridging dca units, any coupling was shown to be below 1 cm^{-1}, with single-ion effects dominating [29].

3.7. Magnetic properties of $\{Co(H_2O)_2[Au(CN)_2]_2\} \cdot {}^nBu_4N[Au(CN)_2]$ (3)

Despite the different structural arrangement described for **2** and **3**, the temperature dependence of the effective magnetic moment of both compounds is nearly identical: **3** has an effective moment of 4.88 μ_B at 300 K and 3.57 μ_B at 1.8 K (not shown).

The magnetic behaviour of $\{Co(H_2O)_2[Au(CN)_2]_2\} \cdot {}^nBu_4N[Au(CN)_2]$ (**3**) is similar to that reported for other coordination polymers containing Co(II) centers linked via $[Au(CN)_2]$-units in a 2-D grid array. $\{Co(dmf)_2[Au(CN)_2]_2\}$ [45] and $\{Co(pyrazine)_2[Au(CN)_2]_2\}$ [32] have effective moments of 4.92 and 5.21 μ_B, respectively, at 300 K, which decrease to reach 3.79 and 3.64 μ_B at 1.8 K.

3.8. Magnetic properties of $PPN\{M[Au(CN)_2]_3\}$ (M = Ni (4), Co (5))

The magnetization of **4** and **5** was also measured upon cooling from 300 to 1.8 K in a 1 kOe external magnetic field and the temperature dependence of the effective magnetic moments are shown in Fig. 7. At 300 K, a value of 3.05 μ_B is observed for **4**, as expected for an $S = 1$ Ni(II) center. The μ_{eff} remains constant until 20 K and then decreases slightly to a value of 2.22 μ_B at 1.8 K. The inverse of the susceptibility of **4** was fitted to the Curie–Weiss expression and yielded a g of 2.173(1) and a θ of −1.11(4) K. As for **1**, the $\chi_M T$ of **4** could be fitted to the zfs expression and yielded a D of 5.0(1) cm^{-1} and a g of 2.145(4). When a molecular field approximation was added to the fit (Eq. (1)), a D of 2.6(1) cm^{-1}, a g of 2.180(2) and a zJ/k_B of −0.75(2) cm^{-1} were obtained. As for **1**, these values indicate the presence of very weak interactions between the Ni(II) centers. Similarly, the effective moment of 5.06 μ_B determined for **5** at 300 K, which is consistent with an octahedral Co(II) center, drops to 3.69 μ_B at 1.8 K. As for **2** and **3**, the behaviour of **5** is dominated by Co(II) single-ion effects.

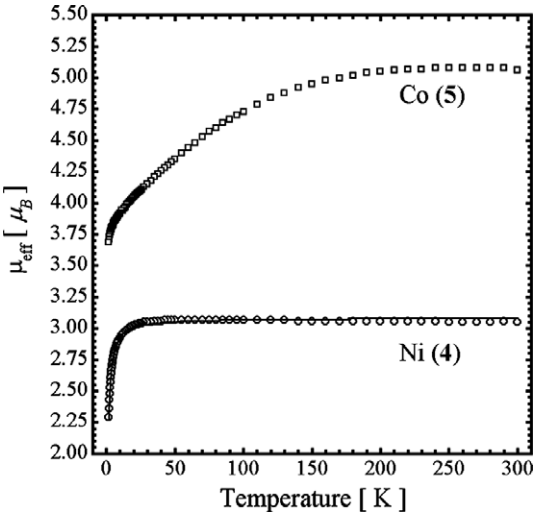

Fig. 7. Temperature dependence of the effective magnetic moment of $PPN\{M[Au(CN)_2]_3$ (M = Ni (**4**, ○) and Co (**5**, □)) with a 1 kOe applied magnetic field.

3.9. Magneto-structural conclusions and comparison with other complexes

To summarize, these results indicate that $[Au(CN)_2]$ is a poor mediator of magnetic exchange in these 2-D and 3-D systems, although in other reported $[Au(CN)_2]$-based coordination polymers, significant coupling can be observed [31,54]. It is possible that, in these high dimensionality/high symmetry systems, competing ferromagnetic and antiferromagnetic interactions might contribute to cancel out the overall coupling. The lack of any significant magnetic interactions, even in the structurally cohesive, pseudo-cubic 3-D cyanoaurate polymers **4** and **5** is comparable to the observation that magnetic coupling through $\mu_{1,5}$-dca bridges is generally very weak [18,19,29].

4. Conclusion

This preliminary study has shown that 3-D $\{M[Au(CN)_2]_3\}^-$ coordination polymers can be readily prepared. The structures of ${}^nBu_4N\{M[Au(CN)_2]_3\}$ and $PPN\{M[Au(CN)_2]_3\}$ (M = Ni and Co) contain two distinct 3-D anionic frameworks of $\{M[Au(CN)_2]_3\}^-$, thus the framework was sensitive to the cation, but not to the identity of the metal center. Despite using large cations such as ${}^nBu_4N^+$ or PPN^+, a 3-D structure is maintained (except when the metal remains solvated), contrary to the reduction in structural dimensionality observed in dicyanamide (dca) systems [18,19]. The longer reach of linear $[Au(CN)_2]^-$ compared to bent dca may account for this difference. A further increase in cation bulkiness or the introduction of hydrogen-bonding moieties into the cations is likely to eventually result in a significant superstructure rearrangement [55,56] and we are pursuing these avenues.

Unfortunately, despite the presence of 2-D and 3-D networks with strongly N-bound cyanoaurates, including a pseudo-cubic Prussian Blue-type array, no magnetic ordering was detected above 1.8 K; indeed, almost no significant coupling through the $[Au(CN)_2]$ units was observed, indicating that the linear d^{10}-$Au(CN)_2$ bridge is a very weak mediator of magnetic exchange in these systems.

sized by the reaction of a known "butterfly" complex with a $[Mn_4^{III}(\mu_3\text{-}O_2)]^{8+}$ core, with the tripodal ligand triethanolamine (H_3tea). The small $Mn_2^{III}Mn_2^{II}$ core allows us to use a full Hamiltonian matrix diagonalization approach, in addition to the simple Kambe approach, to fit the magnetic susceptibility data for complex **1**. The full Hamiltonian matrix is 900×900 and includes Zeeman, zero-field and magnetic (both isotropic and antisymmetric) interactions.

2. Experimental

2.1. Materials

All reactions were performed under aerobic conditions. The ligands 9-anthracenecarboxylic acid (Hanca), dibenzoylmethane (Hdbm), triethylamine (Et_3N) and triethanolamine (H_3tea) were purchased from Sigma–Aldrich and used without further purification.

2.2. Synthesis

*$[Mn_4(anca)_4(Htea)_2(dbm)_2] \cdot 2.5Et_2O$ (**1**).* (0.25 g, 0.124 mmol) $[Mn_4O_2(anca)_6(dbm)_2] \cdot 3CH_2Cl_2$ [10] was added to a solution of Et_3N (0.075 g, 0.740 mmol) in methanol (30 mL) and then was allowed to stir for 30 min. H_3tea (0.11 g, 0.740 mmol) was added to the resulting opaque, brown solution dropwise over 5 min. The solution was allowed to stir for 1 h followed by gravity filtration to remove unreacted starting material. Layering of the filtrate with 50 mL of a 1:1 mixture of diethyl ether and hexanes produced red-brown analytically pure crystals (**1**) suitable for X-ray diffraction studies after 30 days. *Anal.* Calc. for $C_{102}H_{84}Mn_4N_2O_{18}$ (**1**): C, 66.36; H, 4.59; N, 1.51. Found: C, 66.64; H, 4.21; N, 1.69%. Yield: 5% based on manganese. Selected FT-IR data (KBr, cm^{-1}): 3418(m,b), 2923(s), 2825(m), 1574(s), 1524(s), 1479(m), 1440(m), 1384(s), 1348(m), 1320(s), 1277(w), 1068(m), 1025(w), 885(w), 761(w), 733(m), 686(w), 649(w), 559(w), 474(w,b), 421(w).

2.3. Physical techniques

FT-IR spectra were collected using a Thermo-Nicolet Avatar series spectrometer. Elemental analysis was performed by NuMega Resonance Labs (San Diego, CA). *Note*: The formula listed for the elemental analysis of complex **1** does not include ether solvent molecules as they are lost upon removal from the mother liquor. The dc magnetic susceptibility data were collected on a Quantum Design MPMS-5 magnetometer with a 5.5 T magnet. Microcrystalline samples were restrained with eicosane to prevent torquing. Diamagnetic corrections of magnetic susceptibility data were made employing Pascal's constants.

2.4. Crystal structure determination

Mo $K\alpha = 0.71073$ Å; crystal system, triclinic; space group, $P\bar{1}$; $Z = 1$, $Z' = 0.5$; unit cell dimensions: $a = 12.8242(17)$ Å, $b = 13.2663(17)$ Å, $c = 14.3325(19)$ Å, $\alpha = 80.355(2)°$, $\beta = 82.983(2)°$, $\gamma = 85.730(2)°$, and $V = 2382.3(5)$ Å^3; temperature = −173 °C; total reflections measured = 20 310 [10 365 independent, $R_{int} = 0.0313$]; completeness to θ [25.00°] = 98.9%. A red plate-shaped crystal ($0.30 \times 0.20 \times 0.08$) was mounted on a Bruker Smart Apex CCD diffractometer, integrated using Bruker SAINT software program, and corrected for absorption using the Bruker SADABS program. Electron density associated with a hydrogen atom H9B attached to oxygen O9 (distance 1.288 Å) was allowed to refine. Unresolved solvent were accounted for by using the PLATON program SQUEEZE which found 106 electrons or 2.5 molecules of diethyl ether (42 electrons/molecule). All other hydrogen atoms were placed using a riding model and their positions constrained relative to their parent atom using the appropriate HFIX command in SHELXL-97. Full-matrix least-squares refinement on F^2 for 10 365 data and 572 parameters gave final R indicies of $R(F) = 0.0522$ and $R_w(F^2) = 0.0883$ (where $R = \sum\|F_o| - |F_c\|/\sum|F_o|$ and $R(wF^2) = \{\sum[w(F_o^2 - F_c^2)^2]/\sum[w(F_o^2)^2]\}^{1/2}$) [11–13].

3. Results and discussion

3.1. Synthesis

In this study a $[Mn^{III}O_2]^{8+}$ "butterfly" complex was reacted with a 1:1 molar ratio of Et_3N and the tetradentate ligand H_3tea yielding the solvent dependent, mixed-valent wheel, complex **1**. In the absence of a base to deprotonate the H_3tea ligand, reaction conditions favored formation of the mono-nuclear species $[Mn(dbm)_3]$. Conversely, if an excess of base is used, no product was obtained. Under the reaction conditions used in this study, yields for complex **1** were very low (5% by manganese); however, low product yields have been previously reported and are not uncommon in polynuclear transition metal complexes. This is due to a number of factors inherent in the synthetic process that include solubility, pH control and competing products.

3.2. Crystal structure

$[Mn_4(anca)_4(Htea)_2(dbm)_2] \cdot 2.5Et_2O$ (**1**) crystallizes in the triclinic $P\bar{1}$ space group (ORTEP and Mn_4 core shown in Figs. 1 and 2, respectively). Table 1 gives selected bond distances and angles for complex **1**. Since the molecule sits on an inversion center, the symmetry transformations of $-x + 2$, $-y + 2$, and $-z + 1$ were used in order to generate the equivalent atoms in the target complex. The $[Mn_4O_4]$ core consists of two 6-coordinate Mn^{III} atoms in the wing positions and two 6-coordinate Mn^{II} atoms in the body positions, all of which are nearly coplanar. Each Mn^{II} atom interacts with two neighboring Mn^{III} atoms via a μ_2-alkoxide group from the $Htea^{2-}$ ligand and a bridging $anca^-$ ligand. The structure is capped by two dbm^- ligands, filling the remaining two coordination sites of the

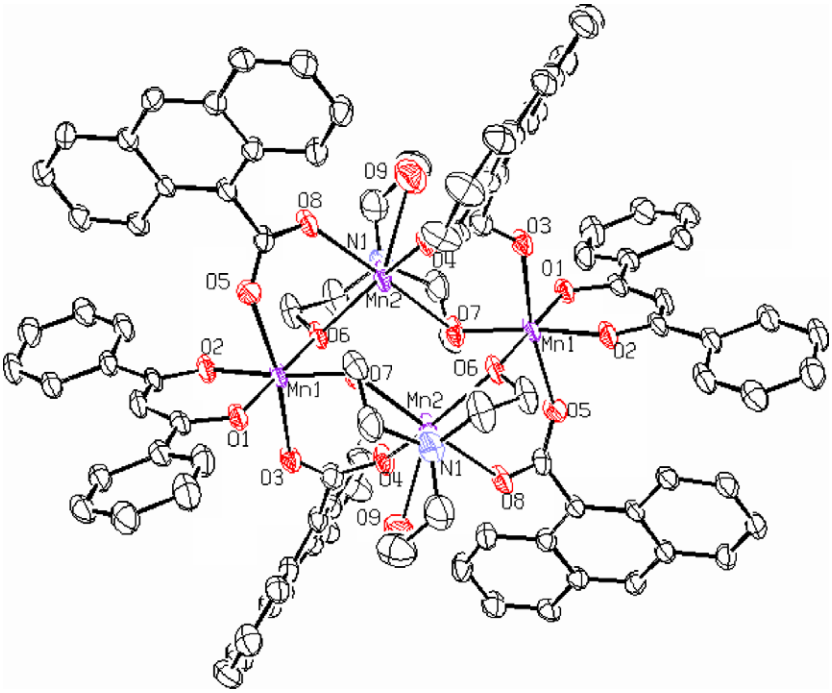

Fig. 1. ORTEP of $[Mn_4(anca)_4(Htea)_2(dbm)_2]\cdot 2.5Et_2O$ (**1**) showing 50% probability of thermal ellipsoids. The ether solvate molecules were not refined.

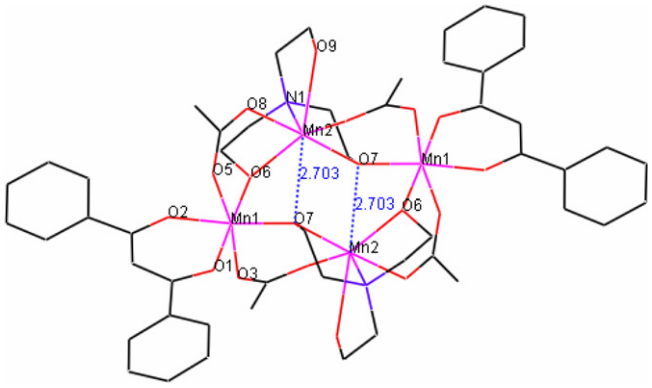

Fig. 2. Mn_4 core of $[Mn_4(anca)_4(Htea)_2(dbm)_2]\cdot 2.5Et_2O$ (**1**) (anthracene rings omitted for clarity) illustrating the magnetic exchange pathways and across-wheel $Mn^{II}\cdots O$ distance of 2.703 Å.

Jahn–Teller axes and through-wheel $Mn^{II}\cdots O$ distance highlighted.

Mn^{III} atoms. All three arms of the $Htea^{2-}$ ligands are coordinated to the body Mn^{II} atoms, although one of the arms (O(9)) remains protonated.

The valency of the Mn atoms was confirmed by the presence of Jahn–Teller distortion around the Mn(1) atom. The Mn(1)–O(3) and Mn(1)–O(5) bonds (2.1591(18) Å and 2.2255(18) Å, respectively) are significantly longer than the Mn(1)–O bonds making up the square planar portion of the distorted octahedron (1.87–1.94 Å). The Jahn–Teller axes are oriented orthogonal to the plane of the dbm ligands which deviate slightly from planarity.

The crystal data for this complex give some evidence for the presence of a wheel-shaped molecule as opposed to a pseudo-dicubane structure. The Mn(2)···O(7) body–body distance of 2.703 Å (Fig. 2) is ~0.4–0.8 Å longer than the corresponding bond in known dicubanes [14–18]. This distance is also considerably longer than the sum of the ionic radii of Mn^{2+} and O^{2-} (~2.2 Å) [19]. Since the molecule is a wheel, the interaction between the two Mn^{II} ions in the body positions (body–body coupling constant, J_{bb}) is negligible and the complex can be assumed to have only one exchange pathway between the Mn atoms (wing–body, J_{wb}), as established further by the fitting of the susceptibility data (vide infra).

3.3. Magnetic measurements

Variable-temperature dc magnetization data were collected for complex **1** at 0.1 T from 300 K to 1.8 K. A maximum molar susceptibility of ~10.6 $cm^3\,mol^{-1}\,K$ is observed at 300 K (Fig. 3), which gradually decreases when the temperature is decreased to 50 K. A decline in susceptibility with decreasing temperature results from intramolecular antiferromagnetic exchange interactions. The observed $\chi_m T$ value of ~10.6 $cm^3\,mol^{-1}\,K$ at 300 K is

smaller than the theoretical spin-only value of 14.8 cm^3 K mol^{-1} calculated for two Mn^{II} and two Mn^{III} non-interacting ions. The rapid decline in magnetic susceptibility at temperatures below ~20 K is due to zero-field splitting and Zeeman interactions. The $\chi_m T$ values determined below 5 K plateau at a value of approximately ~0.8 cm^3 K mol^{-1}.

Two approaches were used in the fitting of dc molar magnetic susceptibility data: the simple Kambe approach [20] that only accounts for Heisenberg isotropic magnetic exchange between pairs of Mn atoms, and a full Hamiltonian matrix diagonalization approach. In the latter approach, the Zeeman interaction, single-ion zero-field and even antisymmetry in the exchange interactions are explicitly included.

3.3.1. Fitting of susceptibility by the Kambe approach

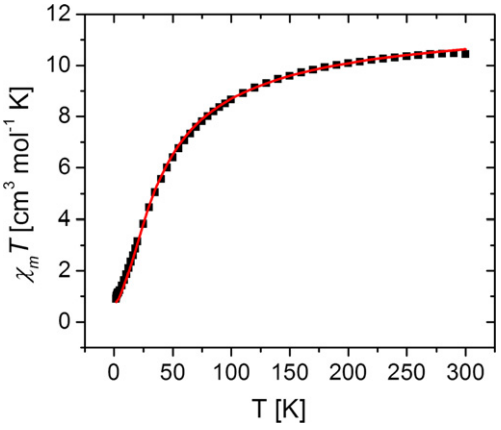
Scheme 1 illustrates the one J-value Kambe vector coupling scheme used to model the magnetic exchange pathways in complex **1**, assuming there are no across-wheel exchange interactions. The model incorporates a single coupling constant (J) which represents exchange coupling between Mn^{II} and Mn^{III} atoms, where Mn(1) and Mn(3) are Mn^{III} atoms, and Mn(2) and Mn(4) are Mn^{II} atoms

$$\widehat{H} = -2J\left[\widehat{S}_1\widehat{S}_2 + \widehat{S}_2\widehat{S}_3 + \widehat{S}_3\widehat{S}_4 + \widehat{S}_4\widehat{S}_1\right] \quad (1)$$

$$\widehat{S}_A = \widehat{S}_1 + \widehat{S}_3; \quad \widehat{S}_B = \widehat{S}_2 + \widehat{S}_4; \quad \widehat{S}_T = \widehat{S}_A + \widehat{S}_B \quad (2)$$

$$E(S_T) = -J[S_T(S_T+1) - S_A(S_A+1) - S_B(S_B+1)] \quad (3)$$

The Heisenberg spin Hamiltonian for complex **1** is given in Eq. (1). Application of the appropriate Kambe vector coupling scheme (Eq. (2)) and substitution of equivalent terms into Eq. (1) leads to Eq. (3). Least squares analysis of the observed molar magnetic susceptibility, in conjunction with the Van Vleck equation [21], produced a good theoretical fit as illustrated by the solid line in Fig. 3. Theoretical fitting parameters were calculated to be $g = 1.8$ and $J = -2.1$ cm^{-1} with a spin ground state of $S = 1$.



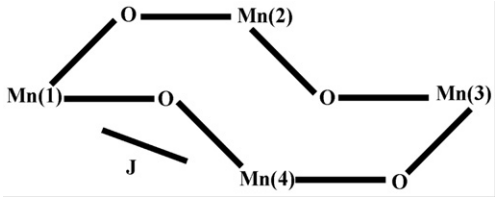


Fig. 3. DC magnetic susceptibility vs. temperature data for $[Mn_4(anca)_4(Htea)_2(dbm)_2]\cdot 2.5Et_2O$ (**1**) collected from 300 K to 1.8 K in an applied field of 0.1 T. (■ observed). The solid line represents the best theoretical fit obtained through least squares fitting employing one J-value as depicted in Scheme 1.

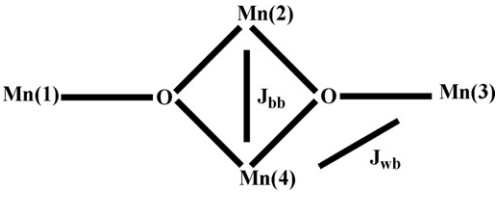
Scheme 1. Kambe exchange model illustrating magnetic exchange pathways for $[Mn_4(anca)_4(Htea)_2(dbm)_2]\cdot 2.5Et_2O$ (**1**), where Mn(1) and Mn(3) represent Mn^{III} ions and Mn(2) and Mn(4) represent Mn^{II} ions.

Theoretical fits of the magnetic susceptibility data were also carried out employing the same Kambe strategy (Scheme 2) that has been applied to previously reported Mn_4 "dicubane" and "butterfly" complexes with two coupling constants (J_{wb} and J_{bb}) [22,23]



$$\widehat{H} = -2\left[J_{12}\left(\widehat{S}_1\cdot\widehat{S}_2\right) + J_{23}\left(\widehat{S}_2\cdot\widehat{S}_3\right) + J_{24}\left(\widehat{S}_2\cdot\widehat{S}_4\right) + J_{34}\left(\widehat{S}_3\cdot\widehat{S}_4\right) + J_{41}\left(\widehat{S}_4\cdot\widehat{S}_1\right)\right] \quad (4)$$

$$E(S_T) = -J_{wb}[S_T(S_T+1) - S_A(S_A+1) - S_B(S_B+1)] - J_{bb}[S_A(S_A+1)] \quad (5)$$

The Heisenberg spin Hamiltonian that represents the spin-coupling for the two-J model (J_{wb} and J_{bb}), as previously reported, is given in Eq. (4), and the resulting eigenvalue equation (5). Theoretical fitting parameters for g, J_{wb}, and J_{bb}, and were calculated to be 1.8, -2.2 cm^{-1} and -0.7 cm^{-1}, respectively. The fitting incorporating two J-values, one for the across-wheel $Mn^{II}\cdots Mn^{II}$ interaction, is **not** better than the fit for one J-value. The two theoretical fits are essentially identical. Furthermore, when we examined the change in error of fitting as J_{bb} is changed from -0.7 cm^{-1}, we find there is little response and $J_{bb} = 0$ is just as good as $J_{bb} = -0.7$ cm^{-1}. We conclude that only one J-value (J_{wb}) is needed to fit the data for complex **1** and, thus, complex **1** is a wheel complex.

3.3.2. Fitting of susceptibility by full matrix diagonalization approach

It has been shown that the simple Kambe approach does not fully describe systems where there exist low-lying

Scheme 2. The Kambe coupling model illustrating magnetic exchange pathways for $[Mn_4(anca)_4(Htea)_2(dbm)_2]\cdot 2.5Et_2O$, where Mn(1) and Mn(3) represent Mn^{III} ions and Mn(2) and Mn(4) represent Mn^{II} ions. In this case it is assumed that there is an across-wheel exchange interaction between the two Mn^{II} ions.

excited states [24]. In addition to the HDVV type (isotropic) of super-exchange discussed in Section 3.3.1, the Dzialoshinsky–Moriya type antisymmetric exchange interactions [25,26], zero-field splitting, and Zeeman interactions were also factored in order to fully model the spin Hamiltonian of the system (Eq. (6)):

$$\widehat{H} = \widehat{H}_{\mathrm{ex}} + \widehat{H}_{\mathrm{DM}} + \widehat{H}_{\mathrm{zfs}} + \widehat{H}_{\mathrm{Zeeman}} \tag{6}$$

$$\widehat{H}_{\mathrm{ex}} = -2J_{\mathrm{wb}}\left(\widehat{S}_1 + \widehat{S}_3\right)\cdot\left(\widehat{S}_2 + \widehat{S}_4\right) - 2J_{\mathrm{bb}}\widehat{S}_2\widehat{S}_4 = J_{\mathrm{wb}}\left(\widehat{S}_{13}^2 + \widehat{S}_{24}^2 - \widehat{S}_{\mathrm{T}}^2\right) + J_{\mathrm{bb}}\left(\widehat{S}_2^2 + \widehat{S}_4^2 - \widehat{S}_{24}^2\right) \tag{7}$$

$$\widehat{H}_{\mathrm{DM}} = d_{12}\cdot\widehat{S}_1\times\widehat{S}_2 + d_{23}\cdot\widehat{S}_2\times\widehat{S}_3 + d_{34}\cdot\widehat{S}_3\times\widehat{S}_4 + d_{41}\cdot\widehat{S}_4\times\widehat{S}_1 \tag{8}$$

$$\widehat{H}_{\mathrm{zfs}} = \sum_{j=1,3} D\left(\widehat{S}_{j\zeta}^2 - \frac{1}{3}\widehat{S}_j^2\right) = \sum_{j=1,3} D\left[\left(\widehat{S}_j^x\cos\phi_j\sin\theta_j + \widehat{S}_j^y\sin\phi_j\sin\theta_j + \widehat{S}_j^z\cos\theta_j\right)^2 - \frac{1}{3}\widehat{S}_j^2\right] = \sum_{j=1,3} D\left[\left(\frac{\sin\theta_j}{2}\mathrm{e}^{-\mathrm{i}\phi_j}\widehat{S}_j^+ + \frac{\sin\theta_j}{2}\mathrm{e}^{+\mathrm{i}\phi_j}\widehat{S}_j^- + \widehat{S}_j^z\cos\theta_j\right)^2 - \frac{1}{3}S_j(S_j+1)\right] \tag{9}$$

$$\widehat{H}_{\mathrm{Zeeman}} = -g\beta\sum_{j=1}^{4}\left(H_x\widehat{S}_j^x + H_y\widehat{S}_j^y + H_z\widehat{S}_j^z\right) \tag{10}$$

where $\widehat{S}_j$ stands for the spin operator of j-th spin ($S = 5/2$ for Mn^{II} and $S = 2$ for Mn^{III}), $\widehat{S}_{13} \equiv \widehat{S}_1 + \widehat{S}_3$, $\widehat{S}_{24} \equiv \widehat{S}_2 + \widehat{S}_4$ and $\widehat{S}_{\mathrm{T}} \equiv \widehat{S}_{13} + \widehat{S}_{24}$ are the partial-sum and the resultant spin operators, respectively, J_{wb} and J_{bb} are defined as in Eq. (4), $\boldsymbol{d}_{ij}$ is the Dzialoshinsky–Moriya vector for the interaction between i-th and j-th ions (Eq. (8)), D is the uniaxial zero-field splitting parameter for each ion, (ϕ_j, θ_j) are the azimuthal and polar angles of single-ion anisotropy axis ζ for j-th ion (Eq. (9)), g is the Landé g factor, β is the Bohr magneton, and H_α is α-component of external magnetic field $\boldsymbol{H}$ (Eq. (10)).

Due to the symmetry of the $Mn_2^{III}Mn_2^{II}$ cluster, the quantization axes in the anisotropy term $\widehat{H}_{\mathrm{zfs}}$ were aligned in the same direction, and were taken as parallel, i.e. $(\phi_1, \theta_1) = (\phi_3, \theta_3) = (0°, 0°)$. The Jahn–Teller elongation axes for the two Mn^{III} ions in complex **1** are parallel. In order to avoid over-parameterization, the Dzialoshinsky–Moriya vectors for the Mn–O–Mn interaction pathways were taken to be identical, and perpendicular to the molecular plane [2], i.e. $\boldsymbol{d}_{12} = \boldsymbol{d}_{23} = \boldsymbol{d}_{34} = \boldsymbol{d}_{41} = (0, 0, d)$. Other interactions, such as biquadratic exchange interaction, were omitted in the present treatment since their contribution to thermodynamic quantities is not dominant.

Based on this spin Hamiltonian, magnetization values $M(H, T)$ are evaluated by the conventional way as given in the following equation:

$$M(H,T) = \frac{Ng\mu_{\mathrm{B}}}{4\pi}\int \mathrm{d}\cos\theta\int \mathrm{d}\phi\,\frac{\langle \boldsymbol{S}_{\mathrm{T}}\rangle\cdot\boldsymbol{H}}{H} \tag{11}$$

where

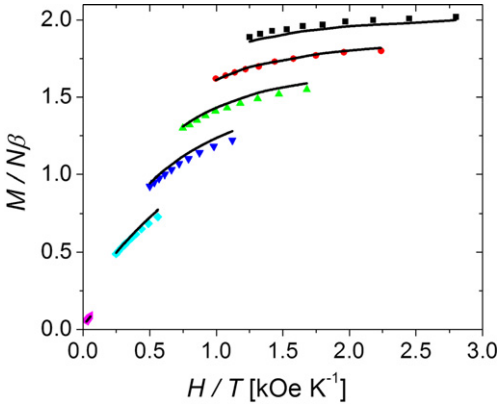
$$\langle \boldsymbol{S}_{\mathrm{T}}\rangle = Tr\left[\widehat{S}_{\mathrm{T}}\exp(-\widehat{H}(\boldsymbol{H})/k_{\mathrm{B}}T)\right]\Big/Z(\boldsymbol{H}) \tag{12}$$

and

$$Z(\boldsymbol{H}) \equiv Tr\left[\exp\left(-\widehat{H}(\boldsymbol{H})/k_{\mathrm{B}}T\right)\right] \tag{13}$$

where N is Avogadro's number, and (θ, ϕ) are polar and azimuthal angles of the external field $\boldsymbol{H}$, k_{B} is the Boltzmann constant, T is the temperature, and the trace is evaluated using a set of energy eigenvectors $|E_i\rangle$, i.e. $\mathrm{Tr}[A] = \sum_i \langle E_i|A|E_i\rangle$, following the full-matrix diagonalization of the spin Hamiltonian by an LAPACK subroutine ZHEEV [27]. The powder average procedure over (θ, ϕ) is approximated by spherical gaussian quadrature using 43-point Lebedev grid on a hemisphere [28]. Temperature-independent contribution from the Van Vleck paramagnetism χ_{TIP}, was also considered. The optimized parameter set (g, J_{wb}, J_{bb}, d, D, χ_{TIP}) for complex **1** is obtained by minimizing a square deviation sum of effective magnetic moment, $\sum[\mu_{\mathrm{eff}}(\mathrm{obs}) - \mu_{\mathrm{eff}}(\mathrm{calc})]^2$ ($\mu_{\mathrm{eff}} = \sqrt{3Mk_{\mathrm{B}}T/NH}$), using a downhill simplex algorithm [29–32].

Fig. 4 illustrates a plot of the reduced magnetization ($M/N\beta$) versus H/T data for complex **1** employing the full-matrix diagonalization approach. Data were collected at 5, 4, 3, 2, 1, 0.5 and 0.1 T in the temperature range of 1.8–4 K. The solid lines represent a theoretical fit the of data that gave fitting values of $S = 1$, $g = 2.2$, $D = -9.2\ \mathrm{cm}^{-1}$, and $J = -2.8\ \mathrm{cm}^{-1}$. It should be noted that theoretical fit depicted in Fig. 4 (solid lines) is based on a model employing a single J-value (Scheme 1) and is preliminary, however, it can be seen in Fig. 4 that the fit is quite good. It is not possible to fit these magnetization



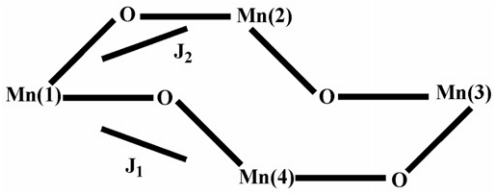


Fig. 4. Plot of reduced magnetization ($M/N\beta$) vs. H/T data for complex **1**, where M is the molar magnetization, N is Avogadro's number, and β is the Bohr magneton. Data were collected at 5 (■), 4 (●), 3 (▲), 2 (▼), 1 (◆) and 0.1 T (◀) in the temperature range of 1.8–4 K. The solid lines represent a theoretical fit of the data employing the full (900 × 900) Hamiltonian matrix diagonalization on each iteration. This gave preliminary fitting values of $S = 1$, $g = 2.2$, $D = -9.2\ \mathrm{cm}^{-1}$, and $J = -2.8\ \mathrm{cm}^{-1}$. See text for details of analysis.

Scheme 3. Illustration of an exchange model with two J-values as dictated by the symmetry of complex **1**. It is not possible to use the Kambe approach to simplify the spin Hamiltonian for this case. The full matrix diagonalization approach is required.

data assuming only an isolated $S = 1$ ground state. A full matrix diagonalization approach is needed and it shows that there is considerable mixing of excited spin states.

4. Conclusion

A new Mn_4 complex has been prepared that appears to be a wheel complex. This is supported by the relatively long Mn–O contact distances across the wheel and by the success of fitting the susceptibility data with only one J-value. Since there are low-lying excited states, the Kambe approach is a simplified method. The full Hilbert space (900×900) Hamiltonian matrix (set up in the uncoupled basis set and incorporating single-ion zero-field and Zeeman interactions) has to be diagonalized on fitting iterations. Preliminary results from the full-matrix diagonalization approach (Fig. 4) show that the reduced magnetization data for both complexes can be fit employing only one J-value. However, the value of $g = 2.2$ calculated in preliminary fits of magnetization data employing a full matrix diagonalization approach is larger than the expected value of $g \leqslant 2.0$ reported for similar mixed-valent polynuclear manganese complexes. Furthermore, the value of $g = 2.2$ calculated using a full matrix diagonalization approach is not in agreement with $g = 1.8$ calculated employing the Kambe model, suggesting the need for further investigation. Additional full-matrix diagonalization calculations are in progress for both variable temperature dc susceptibility data and reduced magnetization data employing a two J-value model (Scheme 1) and a symmetry dictated two J-value model (Scheme 3) where there are alternating coupling constants around the periphery of the wheel. These calculations will be fully described in a later paper.

employing short bridging ligands having not more than three bridging diamagnetic atoms is important in constructing porous magnets [8–10]. In last two years we and other authors [11–16] have reported a novel porous family of $[M_3(HCOO)_6]$ constructed by the smallest and shortest carboxylate connector, $HCOO^-$. They show permanent porosity, thermal stability, a wide spectrum of guest inclusion and interesting guest-sensitive magnetism. In this paper we summarize the achievement and report briefly recent develop on the study of this porous magnet family based on our own work.

2. Synthesis

The novel family of porous $[M_3(HCOO)_6]$, where M = Mn, Fe, Co, Ni, Zn and Mg, has been recently discovered by us and other groups independently employing different synthetic methods. Albeit the compounds have been synthesized through solvo-thermal methods by other authors [13–15], we have developed a simple solution chemistry method at ambient temperature [11,12,16–19]. The compounds of this series, Mn, Fe, Co, Ni, and Zn, can be easily prepared with satisfactory yield by the reaction of the common divalent metal salt hydrate with formic acid neutralized by triethylamine in methanol at room temperature, though we have not test the Mg salt. For Mn and Zn, simply mixing the methanol solution of metal salt with that of formic acid and triethylamine produces good quality crystals of the porous frameworks with guest of methanol and water, while for Fe and Co diffusion methods are needed for obtaining crystals of good quality, and for the Ni compound good crystals have not been obtained but the phase is proved by powder X-ray diffraction (PXRD, Fig. 1). Carefully applied diffusion method should be further tested to obtain good crystals of Ni compound. In our approach, the usage of bulky triethylamine and non-coordinating solvent such as methanol are the two key requirements for producing these porous framework compounds, because the former inhibits the formation of anionic frameworks, as what observed for the small amine cations as templates [20], and the later avoids the formation of metal-formates with coordinating solvent as co-ligands [21]. The de-solvated $[M_3(HCOO)_6]$ samples with empty channels could be easily obtained by treating the samples of the parent compound under dynamic vacuum at ca. 90 °C to remove the guests, and the de-solvated samples still show good crystallinity, which is important for further study of guest-inclusion by single crystal X-ray diffraction method (SXRD). By exposing samples of de-solvated $[M_3(HCOO)_6]$ to the vapor of guests used, a series of guest-inclusion compounds could be prepared. Compared to the solvo-thermal techniques employed by other groups, our approach seems to be milder, easier, and beneficial for guest inclusion or exchange study. Finally, the mixed-metal frameworks with different ratio and kind of metal could be prepared by our method.

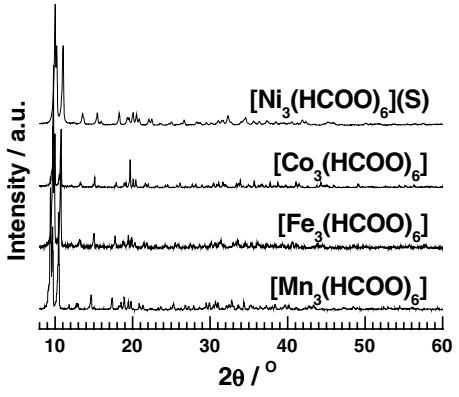

Fig. 1. PXRD patterns of $[M_3(HCOO)_6]$ for M = Mn, Fe, Co, and $[Ni_3(HCOO)_6](S)$ where S is presumed to be one CH_3OH by TGA (not presented here). Peak shift to higher two theta from M = Mn to Ni indicated the lattice shrinkage.

3. Thermal property, permanent porosity and guest inclusion behavior

The $[M_3(HCOO)_6]$ porous frameworks are thermally stable. This has been proved by both thermal analyses (TGA/DSC) and PXRD study (Fig. 2). For $[Mn_3(HCOO)_6]$, the framework was found to keep the porous phase up to 220 °C, then a phase transition, probably a collapse of the porous framework, occurred with energy release of 11 $kJmol^{-1}$, and it finally decomposed around 260 °C. Other members, Fe [19], Co [12] and Ni, seem to be thermally stable up to 270 °C, without any phase transition before the framework decomposition. The stability is clearly related to the diamond structure and further contribution of concerted C–H···O hydrogen bonds in the structure. The permanent porosity of $[M_3(HCOO)_6]$ has also been proved by gas (N_2/H_2) adsorption experimental [12,13,15,19]. Regarding currently great interest in H_2 storage [22] the $[M_3(HCOO)_6]$ family is a class of H_2 storage materials of middle capacity of ca. 1% wt.

The study on the guest inclusion chemistry of the $[M_3(HCOO)_6]$ family [11,15–19] revealed that the porous frameworks are robust as well as flexible for guest inclusion/exchange, and they display a wide spectrum of guest absorption. Our investigation on the Mn [11,17,18] and Fe [19] (and non-magnetic Zn [16]) compounds demonstrated that both can absorb various guests and the possible limitation for guest inclusion is the size of the guests. Especially, $[Mn_3(HCOO)_6]$ has undergone an extended investigation on its guest inclusion chemistry performed by us, and over 40 kinds of guests have been successfully inserted into the pores. The guests can be liquid or volatile solid, polar as carboxylic acids and alcohols or non-polar as alkanes and benzene, small as acetonitrile and formic acid and large as tetrathiafulvalene, and enantiomer-pure guests and the racemic mixture. Although guest-inclusion behaviors of many porous metal-organic framework systems [5–10,23] have been investigated, it is the present

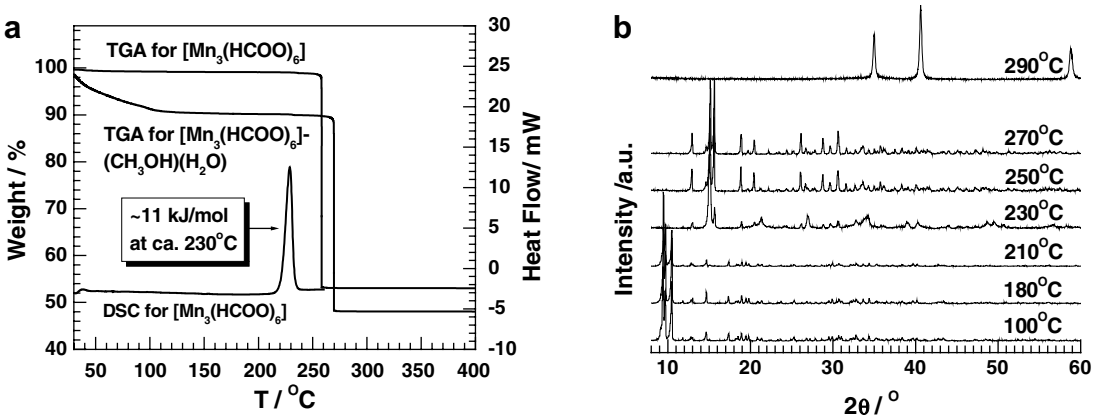

Fig. 2. (a) TGA and DSC runs for $[Mn_3(HCOO)_6]$ parent compound and its de-solvated form. For Fe, Co, and Ni compounds similar traces were observed except that they showed no phase transition before the framework decomposition. (b) PXRD patterns for $[Mn_3(HCOO)_6]$ samples pretreated at different temperatures. The structure of the phase after collapse is still unknown.

family of porous $[M_3(HCOO)_6]$ frameworks that shows such widest spectrum of guest inclusion.

4. Structures

4.1. The structure of $[M_3(HCOO)_6]$ framework

The compounds of the $[M_3(HCOO)_6]$ family are isostructural (Table 1 and Fig. 1). The porous framework (Fig. 3) is a diamond net consisting of the apex-sharing M-centered MM_4 tetrahedron nodes, in which all metal atoms possess octahedral coordination geometry, a striking feature of the family because it is usually known that most diamondoid coordination frameworks have metal atoms in tetrahedral coordination geometry [24]. The MM_4 tetrahedron node has one central M^{2+} ion, four apical M^{2+} ions, and six edges of $HCOO^-$ groups, which link the metal ions in *syn–syn/anti* mode (Fig. 3a). The four central to apical M–M linkages are two with one pair of M–O–M bridge and one *syn–syn* M–O–C–O–M bridge, and two with one M–O–M bridge and one pair of *syn–syn* M–O–C–O–M bridge, and the six apical to apical M–M linkages are all single *syn–anti* M–O–C–O–M bridge. It worth noting that due to the complicated metal–metal linkages described above giving rise to multiple super-exchange pathways and competition between them might be possible. M–O bond distances are in good agreement with the ionic radii of the divalent ions (Table 1), and this results in the size sequence of the frameworks from largest Mn to probably smallest Ni. The important M–O–M angles are around 97° for the double M–O–M connections, and around 112° for the single M–O–M ones. The framework is further strengthened by C–H···O hydrogen bonds [25] involving all $HCOO^-$ ligands.

The openness of the framework is shown by the empty channels running along the *b* direction and in an

[a] Data for the Ni analogue without guest is currently not available. The cell parameters (at 300 K) for Ni analogue with guests of formic acid and water, reported by Powell et al. [14] and transformed according to space group setting $P2_1/c$, are: $a = 11.1586$, $b = 9.7789$, $c = 17.9410$ Å, $\beta = 126.998°$, $V = 1563.53$ Å^3. The temporary cell parameters obtained from the PXRD data (Fig. 1) for $[Ni_3(HCOO)_6](S)$ are $a = 11.117$, $b = 9.741$, $c = 17.834$ Å, $\beta = 127.4°$, $V = 1534$ Å^3. The Ni framework should be the smallest one in the series regarding the smallest radius of Ni^{2+} (0.83 Å).

[b] Data available from the supporting information of [12].

[c] Data of $[Zn_3(HCOO)_6]$ and $[Mg_3(HCOO)_6]$ are for the purpose of comparison. For $[Mg_3(HCOO)_6]$ the cell parameters have been transformed according to space group setting $P2_1/c$, with the same e.s.d.'s we presumed.

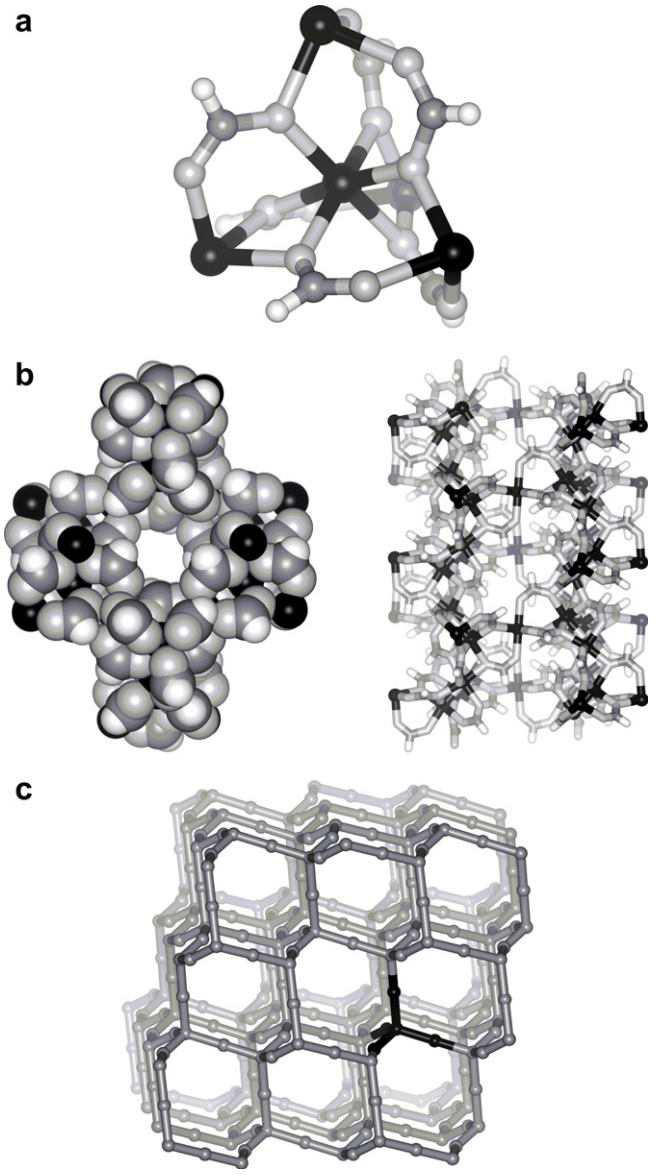

Fig. 3. The structure of the porous diamond framework of $[M_3(HCOO)_6]$ formed by the M-centred MM_4 tetrahedra as nodes sharing apices and showing open channels. (a) The MM_4 tetrahedron unit, (b) the top, space filling view and side view of one channel and (c) the diamond framework with one tetrahedral node highlighted in black. Atomic scheme is M black, C grey, O light grey and H white, in (a) and (b).

approximately honeycomb arrangement (Fig. 3b and c), with cross-section of ca. 4×5 Å. It is apparent that the large nodes or thick walls prohibit the interpenetration thus result in the permanent porosity of the framework. The void spaces are ca. 30%, depending on the kind of metal. It is worth noting that for the available de-solvated $[M_3(HCOO)_6]$ the frameworks change from the smallest $[Co_3(HCOO)_6]$ with the cell volume of 1608.2 $Å^3$ to the largest one for $[Mn_3(HCOO)_6]$ of 1779.9 $Å^3$ (Table 1), therefore the framework has ca. 20% lattice volume change by using the metal ions of different ionic radii. Due to the different orientations of the $HCOO^-$ groups the channel is zigzag like. It is lined by alternate arrays of C–H groups and oxygen atoms thus shows an amphiphilic character. The framework is flexible and it could breath to accommodate guests of different size. Finally, the channel is chiral because it lies at the 2_1-axis. These are the structural basis for the experimental observations of the wide and interesting guest inclusion behavior of the porous materials.

4.2. The structure of guest inclusion compounds of $[M_3(HCOO)_6](G)$ (G = guest)

As mentioned above, the $[M_3(HCOO)_6]$ frameworks can absorb guests of wide range. Due to the robust and flexible character of the porous framework, the guest inclusion compounds have good crystallinity in most cases, therefore the structures of guest inclusion compounds of $[M_3(HCOO)_6](G)$ can be determined by SXRD. Four representatives of $[Mn_3(HCOO)_6](CH_3CN)$ (acetonitrile), $[Mn_3(HCOO)_6](C_3H_4N_2)$ (imidazole), $[Mn_3(HCOO)_6]$-$(C_6H_5NO_2)$ (nitrobenzene) and $[Mn_3(HCOO)_6](R\text{-}CH_3\text{-}C^*HClCH_2OH)$ (*R*-chloropropan-1-ol), which have not been published yet, are shown in Fig. 4. The host framework displays considerable flexibility for accommodating guests of different size, where small guests like acetonitrile made the host framework shrink while large ones such as nitrobenzene expand it (notes in Fig. 4). For the Mn framework the volume of the lattice can be modulated by as much as 11%, and still retains crystalline, while for Fe framework a lattice volume change of 8.3% has been observed upon guest inclusion [19]. The guest molecules form zigzag array (Fig. 4) in the confined space of the zigzag like channel, and the host–guest interaction are mainly the weak hydrogen bonds [25] between hydrogen bond donors/acceptors of guest molecule and acceptors/donors of framework. Guests can have possible interaction between themselves. For example, imidazole molecules in the channel form $(imidazole)_n$ chain *via* N–H···N hydrogen bonds (Fig. 4b, N–H···N geometry: 3.04 Å, 163°) between them and the chain can be considered as proton wire [26]. It merits to point out that the polar guests form polar molecular array in one channel, indicating the uniaxial or chiral character of the channel, and the channel is wide enough for guests molecules of not so large size to rotate to find their energetically favorable positions and orientations in the channel. The larger or longer guests such as nitrobenzene (Fig. 4c) are unable to rotate freely in the channel, consequently, they are found to display two orientations in one channel. Finally, it has been observed that the chirality of the channel results in some selectivity for chiral guests upon their inclusion as found in compound of $[Mn_3(HCOO)_6](R\text{-}CH_3C^*HClCH_2OH)$ (Fig. 4d) [17].

The effect of guest-inclusion upon the molecular geometries of the host framework is subtle and complicated, and regular changes are mainly observed for the important M–O–M angles and the M···M distances that show increasing tendency with the size of the guest, and this

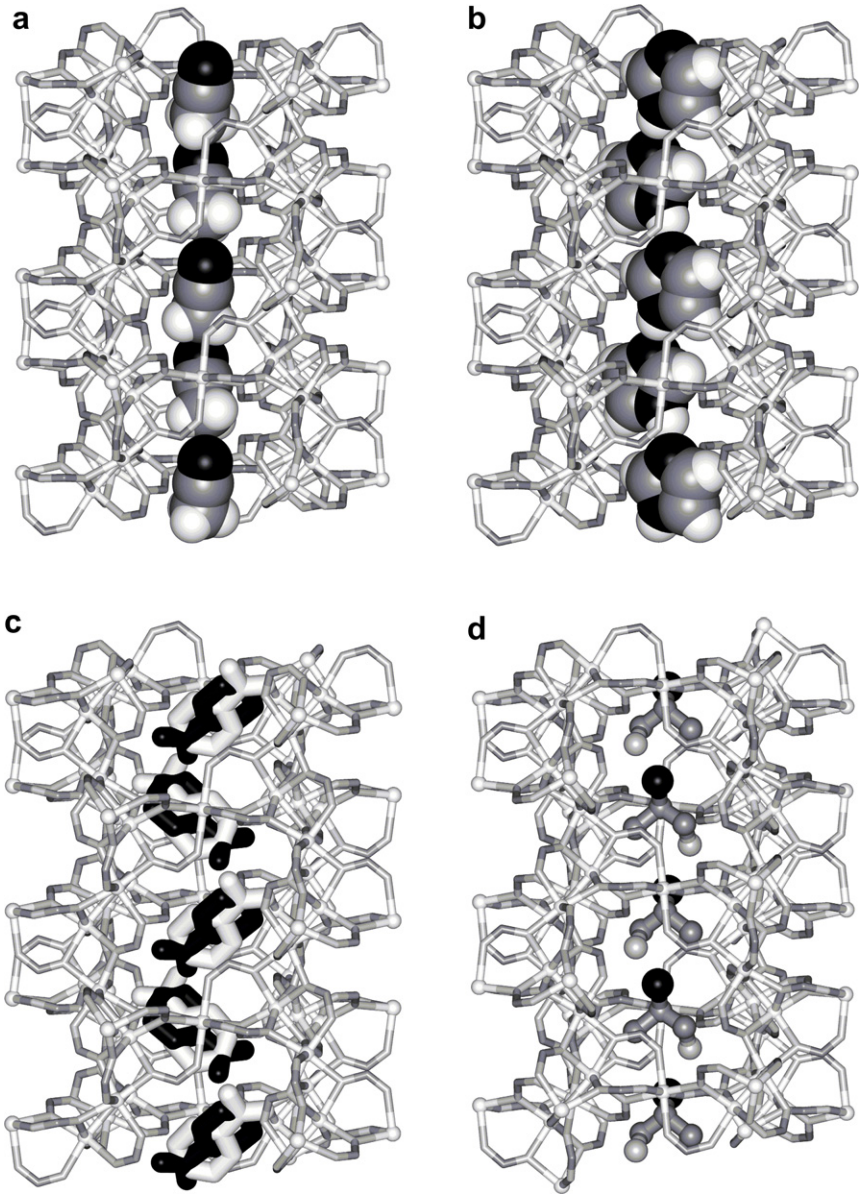

Fig. 4. Four representative structures guest-inclusion compounds of $[Mn_3(HCOO)_6](G)$: (a) $[Mn_3(HCOO)_6](CH_3CN)$ (acetonitrile), (b) $[Mn_3(HCOO)_6](C_3H_4N_2)$ (imidazole), (c) $[Mn_3(HCOO)_6](C_6H_5NO_2)$ (nitrobenzene) and (d) $[Mn_3(HCOO)_6](R\text{-}CH_3C^*HClCH_2OH)$ (*R*-chloropropan-1-ol). Atomic scheme for frameworks (without H) is Mn white, C grey, O light grey, and different styles for guests, CPK for acetonitrile and imidazole with C grey, N black and H white in (a) and (b), thick stick for nitrobenzene in (c) with black and white indicating two orientations of the guest molecule, and ball and stick for *R*-chloropropan-1-ol with C grey, O light grey, and Cl black in (d). Noting in (d) the R-guest is order in the channel of one handedness (in this case the *M*-channel) while disordered in the channel of opposite handedness (the *P*-channel, not shown here). Lattice volumes are (a) 1681.3(4), (b) 1718.0(6), (c) 1886.0(1) and (d) 1792.1(1) $Å^3$.

reflects the host framework expansion from small to large guests, and reveals the flexibility or breathing character of the host framework upon guest inclusion. The difference in the lattices of $[M_3(HCOO)_6]$ due to the metal ion arise subtle effect on the guest-inclusion behavior and host–guest interaction. For instance, it is found that included iodine molecules shows different host–guest and guest–guest interaction in $[Mn_3(HCOO)_6]$ compared to $[Fe_3(HCOO)_6]$ probably due to the size effect of the void space [11,19].

5. Magnetism

5.1. Magnetism of $[M_3(HCOO)_6]$

The magnetic properties of the $[M_3(HCOO)_6]$ series have been investigated [11,12,14,17–19]. The compounds display different magnetic behaviors (Fig. 5) depending on the kind of metal ion, that is the spin state. While Mn and Fe compounds are considered as ferrimagnets with critical temperatures of 8.0 K and 16.1 K, respectively,

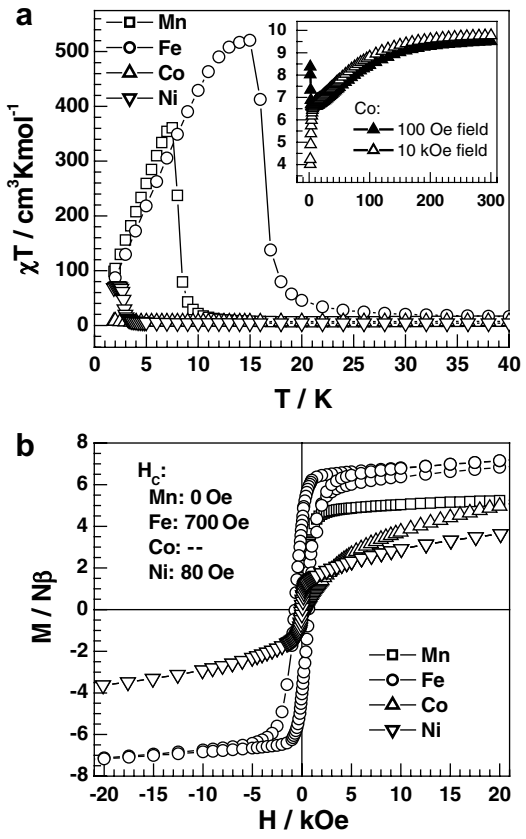

Fig. 5. Temperature dependence of susceptibility for $[M_3(HCOO)_6]$ of M = Mn, Fe, Co, and $[Ni_3(HCOO)_6](S)$ under 100 Oe field. Inset is detail for $[Co_3(HCOO)_6]$. (b) Field dependent magnetizations of the compounds at ca. 2 K.

the Co analogue is probably an antiferromagnet with a spin canting arrangement below 2 K, and the Ni compound might show 3D long-range ferrimagnetic ordering at 2.7 K. Mn and Ni compounds are soft magnets while the Fe compound is quite hard magnet. Detailed investigation on the magnetism of Mn and Fe compounds at low fields (Fig. 6) revealed that there should be a second magnetic transition below the critical temperature, indicating possible spin re-orientation [11,17–19]. It is merit to point out that the framework is closely related to the pyrochlore structure [27] except for the presence of the central metal site of the corner-shared tetrahedral nodes. This similarity might provide possible geometrical frustration. On the other hand, the diamond framework has several superexchange pathways between the metal sites and the possible competition among them due to the similar coupling strengths [28]. Consequently the frameworks of $[Mn_3(HCOO)_6]$ and $[Fe_3(HCOO)_6]$ should be magnetic competition systems [29]. Based on these observations we think that the magnetic structures might not be simply collinear and non-collinear spin arrangement is possible. The possible spin re-orientation or multiple magnetic transitions might result from these magnetically structural features. It is apparent that more investigations will be needed to elucidate the nature of the magnetism for these compounds.

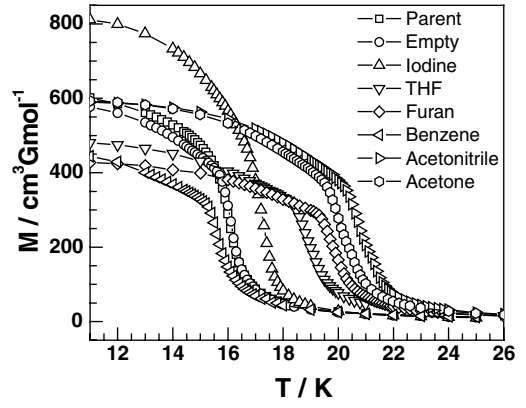

Fig. 6. FC measurements of $[Fe_3(HCOO)_6]$ and its guest-inclusion compound series with the guest names shown under an applied field of 10 Oe. Parent is the parent compound with guests of methanol and water and Empty is the framework without guest.

5.2. Guest-modulated magnetism of $[M_3(HCOO)_6](G)$ (M = Mn, Fe)

Guest-dependent magnetism has been observed and investigated for Mn and Fe frameworks [11,17–19]. The main effect of guest inclusion on the magnetic property of the framework is the change of the critical temperature. For $[Mn_3(HCOO)_6](G)$, T_C were modulated by guests in range of 4.8–9.7 K [11], compared with 8.0 K for $[Mn_3(HCOO)_6]$ without guest. While for $[Fe_3(HCOO)_6](G)$, T_C changes from 15.6 to 20.7 K compared to 16.1 K for the guest-free $[Fe_3(HCOO)_6]$ (Fig. 6), together with higher coercive fields (H_C) and remanant magnetizations (R_M) for $[Fe_3(HCOO)_6](G)$ materials with higher T_C [19]. The guest-sensitive magnetism might come from (a) the subtle changes in the important M–O–M angles of the host framework, where materials with larger M–O–M angles have lower T_C, and (b) host–guest interactions, mainly the H-bonds, where the existence of more strong host–guest H-bonds seems to favor high T_C. Finally, enantiomer pure and racemic guest have small but significant different influence on the magnetism [17]. The guest inclusion does not change the framework structure much more, but modifies the key structural parameters thus the coupling strengths therefore finally change the magnetic behavior. However, more detailed studies are needed to reveal the nature of guest-dependent magnetism for these porous magnets of $[M_3(HCOO)_6]$.

5.3. Magnetism of mixed-metal porous magnets of $[Fe_xZn_{3-x}(HCOO)_6]$

Finally, we briefly present here recent results on the series of mixed-metal porous magnet of $[Fe_xZn_{3-x}(HCOO)_6]$.

[a] The x values were calculated by comparing the Curie constants of the mixed-metal compounds to that of $[Fe_3(HCOO)_6]$. The x values from ICP analysis are 2.38, 2.15, 1.64, 0.92 and 0.25, slightly lower than but agreeable to that obtained from magnetic measurement.

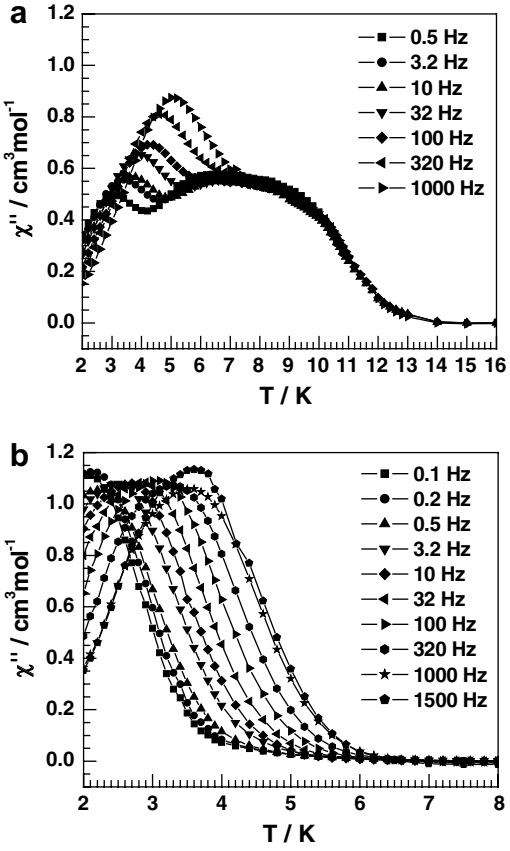

Fig. 7. The ac susceptibilities (out of phase components presented here only) measured with amplitude of 1 Oe and different oscillating frequencies in zero dc-field for two $[Fe_xZn_{3-x}(HCOO)_6]$ compounds with $x = 2.22$ (a) and 1.78 (b). For $x = 2.43$ the system displays mainly the high temperature broad peaks at ca. 11 K showing small frequency dependence with ϕ (defined as $\Delta T_p/[T_p\Delta(\log f)]$) [30] of 0.015, indicating spin glass behavior (not shown here). For $x = 2.22$, the high temperature broad peaks at ca. 9 K characterize spin glassy components in the system with a $\phi = 0.033$ while the low temperature peaks at ca. 4 K characterize superparamagnetic components (or single molecular magnet) with ϕ of 0.194. For $x = 1.78$ of further dilution, only low temperature peaks at ca. 3 K, showing strong frequency-dependence, with $\phi = 0.125$, were observed. For $x = 1.03$ the low temperature peaks have $\phi = 0.222$ (no shown here). And finally for $x = 0.26$, only paramagnetism was observed.

The isomorphs nature of the $[M_3(HCOO)_6]$ family allow the possibility to prepare the mixed metal frameworks with different ratio and kind of metal, thus the continuous change in lattice volume as well as pore size, and modulation of the magnetic property, can be expected. Indeed, for the $[Fe_xZn_{3-x}(HCOO)_6]$ series this has been realized (Table 2 and Fig. 7). When x decreases from 3 for the pure $[Fe_3(HCOO)_6]$ by increasing the component of diamagnetic and smaller Zn^{2+} in the framework, the lattice shrinks, and most interesting, the series undergoes systematic change from 3D long-range-ordering *via* spin glass (small frequency dependence in ac susceptibility) [30] to superparamagnetic behavior or possible single molecule magnet (SMM) (large frequency dependence in ac susceptibility) [31] and finally to paramagnet. This could be expected for the continuous dilution of the 3D magnetic system by diamagnetic component. However, it now occurs in porous materials. This will be of much interesting in view of creating and understanding different magnetic behaviors and possible guest-sensitive character in different magnetic materials such as porous SMM and porous spin glass. The study is going further and details will be reported in near future.

6. Conclusion

In summary, the family of porous magnets of $[M_3(HCOO)_6]$ can be easily prepared by a mild solution chemistry method. The frameworks exhibit permanent porosity, thermal stability, a wide spectrum of guest inclusion behavior and 3D long-range magnetic ordering. The robust but still flexible porous diamond frameworks allowed the successful preparation of guest-inclusion compounds as well as their structural characterization by SXRD. The guest molecules form zigzag molecular arrays in the channels of host framework, and the host–guest H-bonding provides the main host–guest interaction. These guest-inclusion compounds exhibit guest-modulated magnetism, which might be due to the guest induced subtle changes of the molecular geometry of the framework and the nature of host–guest interaction. The mixed-metal $[Fe_xZn_{3-x}(HCOO)_6]$ series exhibits systematic change from 3D long-range ordering to spin glass to superparamagnet and finally to paramagnet upon the increase of diamagnetic component of zinc in the series. Future study on this interesting porous magnet family will be (a) elucidating the real magnetic structure by neutron diffraction and detailed specific heat studies, (b) exploring

more guests to reveal the nature of guest-dependent magnetism, (c) studying mixed metal systems with different magnetism, and (d) combining functional guests such as organic radical, optical, photoactive or conductive units within the porous magnetic framework to explore multi-functionality. These researches are in progress.

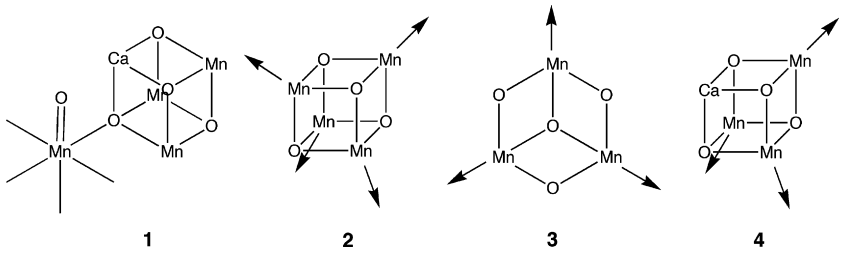

Fig. 1. $CaMn_4O_5$ cluster (**1**) in the photosynthesis II and related cubane Mn_4O_4 (**2**), triangular Mn_3O_4 (**3**), and cubane $CaMn_3$ (**4**) clusters. **2** and **3** exhibit the tetrahedral and triangular (antiferromagnetic) spin alignments, respectively, at the low-spin state.

tetranuclear manganese complex $Mn(IV)Mn(III)_3Cl_7(O_2CCCH_3)_3]^{3-}$, a cubane complex, has been carried out to elucidate its electronic and spin states [16]. Belinskii [18] has carried out the theoretical studies on the mixed-valence $Mn(III)_3Mn(IV)$ and $Mn(IV)_3Mn(III)$ clusters on the basis of the quantum Heisenberg models, assuming trapezoid, butterfly, bent, T-type and distorted tetrahedron structures. Possible ground spin states for these five structures have been elucidated, changing effective exchange interactions between manganese ions.

We have examined possible spin structures of tetranuclear (**2**) [19] and trinuclear (**3**,**4**) [20] manganese clusters in Fig. 1 on the basis of the spin vector model [21]. The strong spin frustration [15] in **3** and **4** [20] has provided non-collinear spin structures such as triangular spin structure in Fig. 1, on the assumption of the experimentally determined effective exchange integrals (J_{ij}). The J_{ij} values for the binuclear manganese complexes [22,23] have been calculated using the hybrid DFT method to elucidate the mechanisms for effective exchange interactions between Mn ions [24]

$$J_{ij} = \frac{^{LS}E(X) - {}^{HS}E(X)}{^{HS}\langle \widehat{S}^2\rangle(X) - {}^{LS}\langle \widehat{S}^2\rangle(X)}, \quad (2)$$

where $^{Y}E(X)$ and $^{Y}\langle \widehat{S}^2\rangle(X)$ are the total energy and total angular momentum for the state Y(= LS; the lowest spin state, HS; the highest spin state) by the method X (= UHF, UMPn, UDFT, etc.). It was shown that the sign of J_{ij} is negative because of the greater stability of LS than HS, and the magnitude of J_{ij} values is variable with the oxidation numbers of Mn ion. The calculated J_{ij} values have been consistent with the experiments available. Very recently, Yamanaka et al. [25] have performed the DFT calculation of cubane-type $Mn(II)_4$ cluster (**2**) using the general spin orbitals (GSO), namely, two component spinor. The resulted spin structure of **2** was consistent with the tetrahedral type in Fig. 1.

The variations of charge and spin populations of manganese oxo (MnO) bonds with the oxidation number of Mn ion were also examined by the unrestricted Hartree–Fock (UHF) method [24]. It was concluded that the nature of oxygen atom in the manganese oxo bond (X = O in **5**) varies from nucleophilic to electrophilic with the change of formal charge of Mn ion from low (II) to high (V) valent as illustrated in Fig. 2. The oxygen atom in the Mn(V)O core exhibited the radical character responsible for the radical reactivity for water [24–28]. These results enabled us to propose three possible models of oxygenation reactions of substrates by metal–oxo species: (1) SE_2 model, (2) ^{1}O-model and (3) ^{3}O-model as shown in Fig. 3 [25,26]: note that singlet and triplet states of atomic oxygen undergoes, respectively, insertion and abstraction reactions with X–H bonds (X = CH_3, OH, etc.). Similar situations are expected for low-spin (LS) and high-spin (HS) metal-oxo species.

As a first step toward theoretical approaches to water oxidation in OEC, Isobe et al. [28] have performed the DFT calculation of the model compound $XH_3Mn(IV)O_2Mn(IV)H_3Y$ (X,Y = O, H) (**6**) for the Limburg compound $[(terpy)(H_2O)Mn(\mu\text{-}O)_2Mn(terpy)(H_2O)]^{3+}$ (**7**) [29] as shown in Fig. 2. It was found that electron correlation plays a crucial role to determine the nature of manganese–oxygen bonds in **7**. Diradical or nonradical mechanism is found to be feasible for the oxygen atom transfer from water to high-valent manganese–oxo bond Mn(V)=O

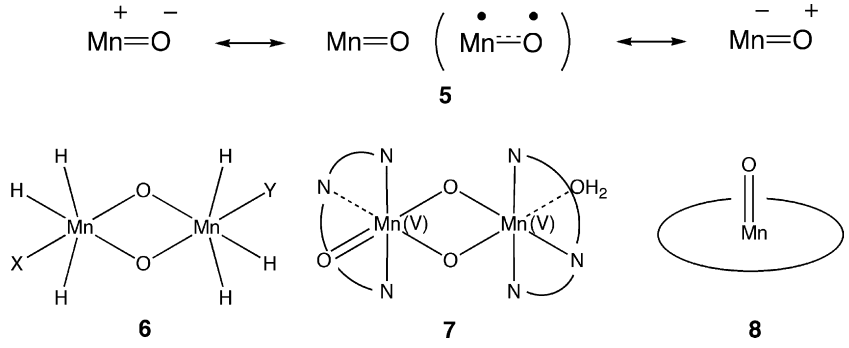

Fig. 2. Variations of electronic structures of the manganese–oxo bond (**5**), and Mn–oxo model complexes (**6**, **7**, and **8**) for oxygen evolution center (OEC).

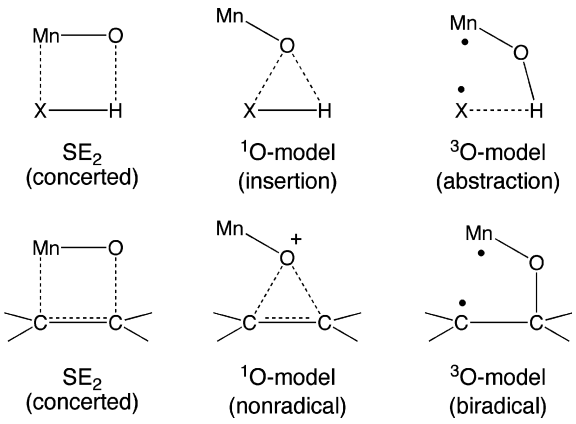

Fig. 3. SE_2, ^1O- and ^3O-models for oxygenation reactions of X–H ($X = CH_3$, OH, etc.), bonds and expoxidation reactions of C–C double bonds in Refs. [24,28]. The discrete radicals are generated in the ^3O-model, though such species are hardly detectable in the ^1O-model because of rapid recombination (or insertion).

in **7**. The environmental effects such as solvent are considered to play an important role for control of the mechanism. The electronic and spin structure of the $CaMn_3O_4$ cluster **4** in **1** have been elucidated on the basis of both classical (spin vector) and quantum Heisenberg models [30]. The GSO DFT calculations of the cluster **4** were also performed to elucidate charge and spin populations and non-collinear spin structure (see **4** in Fig. 1). Possible reaction mechanisms of **1** have been proposed on the theoretical and experimental grounds [30]. However, the detailed computations of the metal–oxo part in **1** have not been performed yet.

As a continuation of previous work [24–28,30], we here perform theoretical studies on the high-valent Mn–O bonds in OEC and porphyrin model complexes **8**. The electronic structures of these species are investigated from the viewpoint of charge and spin populations, and diradical character. The strong diradical character of the Mn(V)=O bonds in the model complexes is consistent with the ^1O- and/or ^3O-models for oxygenations of X–H bonds. The SE_2 mechanism in Fig. 3 is also examined as a possible model of the transition state of the O–O bond formation process. Implications of the calculated results are discussed in relation to possible mechanisms of oxygen evolution in OEC. Our previous [22–28,30] and present calculations conclude that Mn(V)=O (**5a**) or Mn(IV)=O (**5b**) plays a crucial role in both native (**1**) and artificial (**8**) OEC systems.

2. Theoretical background and computational details

Electronic structures of Mn–oxo model complexes of OEC and Mn–oxo porphyrine complex were investigated using the unrestricted B3LYP (UB3LYP) method [31,32] with the Huzinaga's MIDI+F basis set (533(21)/53(21)/(41)) [33] for Mn ion and the 6-31G* basis set [34] for other atoms [35]. The coordinates of model complexes of OEC were taken from the X-ray crystallographic structure in Protein Data Bank (PDB code 1S5L) [1]. All calculations were performed with the Gaussian 98 program package [34].

To obtain the symmetry-adapted (SA) picture for the broken-symmetry (BS) UB3LYP calculations, we have used the natural orbitals, which are determined by diagonalizing their spin-traced first-order density matrices γ [23–28] as

$$\gamma(\mathbf{r},\mathbf{r}') = \sum_i n_i \phi_i(\mathbf{r})\phi_i^*(\mathbf{r}'), \tag{3}$$

where n_i denotes the occupation number of a natural orbital ϕ_i, ranging from 0 to 2. The spin-polarized BS molecular orbitals ($\psi_i^{\pm}$) for the up-spin and down-spin states are derived by bonding (ϕ_i) and antibonding (ϕ_i^*) natural orbitals as

$$\psi_i^{\pm} = \cos\theta_i\phi_i \pm \sin\theta_i\phi_i^* \quad (i = 1,2,\ldots,N), \tag{4}$$

where θ_i is the orbital mixing parameter and N is the number of bonding natural orbitals. The orbital overlap T_i between the up-spin and down-spin orbitals is defined as a measure of orbital splitting by

$$T_i = \langle\psi_i^+|\psi_i^-\rangle = \cos 2\theta_i. \tag{5}$$

T_i is unity for closed-shell systems ($\theta_i = 0$) and $0 \leqslant T_i < 1$ for open-shell systems ($0 < \theta_i \leqslant \pi/4$). The occupation numbers of the bonding and antibonding natural orbitals are expressed by the orbital overlap T_i as

$$n_i = 1 + T_i, \quad n_i^* = 1 - T_i. \tag{6}$$

This means that contribution of doubly excited configuration $\left|\phi_i^*\overline{\phi_i^*}\right|$ is significant because of small orbital-energy gap and strong electron repulsion (correlation). The diradical character y is defined with the weight (W_D) of the contribution of doubly excited configuration [23–28] as

$$y_i = 2W_D = 1 - \frac{2T_i}{1+T_i^2}. \tag{7}$$

In the extreme case of BS solutions ($\theta_i = \pi/4$, $T_i = 0$, and $n_i = n_i^* = 1$), the up- and down-spin orbitals are simply in- and out-of phase combinations of bonding and antibonding natural orbitals, respectively, as shown in Eq. (8), showing strong electron localizations at different fragments A and B

$$\psi_i^{\pm} = \frac{1}{\sqrt{2}}\phi_i \pm \frac{1}{\sqrt{2}}\phi_i^* \quad (\psi_A \equiv \psi_i^+ \quad \text{and } \psi_B \equiv \psi_i^-). \tag{8}$$

3. Results and discussion

3.1. The nature of metal–oxo bonds in OEC

The models 1, 2 and 3 with and without extra two waters are examined as the active site of **1** in OEC. As a continuation of previous work [30], we examine the high-valent Mn(V)=O cores with the ligand fields revealed by the X-ray diffraction method [1]. In the model 1, three waters and two CH_3COO anions were employed as the ligands,

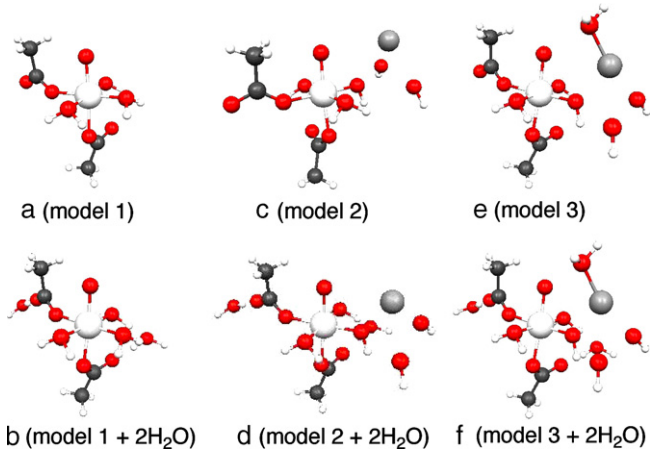

Fig. 4. Computational model 1: $[Mn(V)=O\ (CH_3CO_2)_2\ (H_2O)_3]^{+1}$ without (a) and with (b) extra $2H_2O$, model 2: $[Mn(V)=O\ (CH_3CO_2)_2(H_2O)_2(OHCa(OH)_2)]^0$ without (c) and with (d) extra $2H_2O$, and model 3: $[Mn(V)=O\ (CH_3CO_2)_2(H_2O)_2(OHCa(OH)_2)(H_2O)]^0$ without (e) and with (f) extra $2H_2O$.

while one water in model 1 is replaced with the $(OH)Ca(OH)_2$ anion in the model 2 as shown in Fig. 4. Further one water is added to the Ca(II) ion in model 3. As shown previously [24], the Mn(V)=O core has the so-called oxene structure $(\sigma)^2(d\pi_x–p\pi_x)^2(d\pi_y–p\pi_y)^2$ with one $d\sigma–p\sigma$ and two $d\pi–p\pi$ bonds.

However, the $d\pi–p\pi$ bonds are usually spin-polarized because of strong electron correlation, and the resulting magnetic orbitals (ψ_i) in Eq. (4) are more or less localized on the Mn and O sites, respectively. Here, ligand field effects on the Mn–O bonding are examined by our methods described in Section 2.

Table 1 summarizes spin densities (Mulliken charge) on Mn, O, and ligand obtained by the UB3LYP calculations. The negative spin densities are populated on the O-site, in accord with the diradical character ($\cdot\uparrow$Mn–O$\cdot\downarrow$) of the Mn=O bond. Interestingly, the negative spin densities also appear on the ligands, namely CH_3COO ligands in model 1 and $Ca(OH)_2$ part in models 2 and 3, respectively. This means that the charge transfer (CT) from ligands (L) to the $d\pi_y–p\pi_y$ antibonding orbital is not negligible, showing a contribution of the $[\cdot\uparrow Mn(IV)=OL^{\cdot+}\downarrow]$ structure. Thus, the situation in the Mn(V)=O bond is similar to that of the high-valent Fe(V)=O and Mn(V)=O cores in porphyrine complex: $[\cdot\uparrow Fe(IV)=OPor^{\cdot+}\downarrow]$ and $[\cdot\uparrow Mn(IV)=OPor^{\cdot+}\downarrow]$.

However, the CT from ligands to Mn(V)=O is a little suppressed by addition of two extra waters as shown in the model 1 with $2H_2O$. The diradical character of the $d\pi_x–p\pi_x$ bond is also decreased with change of the ligand field. For example, coordination of water to the Ca(II) ion largely reduced the spin density on the O-atom of MnO. The CT diradical character is rather significant in the models 2 and 3 with extra $2H_2O$. This implies that the cubane unit $CaMn_3O_4$ (**4**) in **1** play important roles in regulation of the nature of chemical bonds of the Mn–oxo part in **1**. The present results indicate that the electrophilic character of the high-valent Mn(V)=O bond should be enhanced with suppression of the CT biradical character with $CaMn_3O_4$ in **1**. This entails a possibility of the SE_2 mechanism instead of the ^{1}O- and/or ^{3}O-models for oxygen evolution from waters, though the latter(s) are rather conceivable from strong diradical character of the Mn=O bonds in models 1 and 2, which can be regarded as models for synthetic manganese–oxo complexes [12–16,29].

The natural orbital analysis of the broken-symmetry (BS) UB3LYP solutions for the six models in Fig. 4 have been performed to obtain the natural orbitals and their occupation numbers, which are also available by the symmetry-adapted (SA) CASSCF procedure. Table 2 summarizes the occupation numbers of bonding (antibonding) $d\sigma–p\sigma$ and $d\pi_x–p\pi_x$ orbitals, together with those of the ligand orbital (L) and $d\pi_y–p\pi_y$ antibonding orbitals. The $d\sigma–p\sigma$ orbitals are almost doubly occupied, showing the nonradical character. While, the occupation numbers of the antibonding $d\pi_x–p\pi_x$ orbitals are 0.602 (model 1), 0.562 (model $1 + 2H_2O$), 0.831 (model 2), 0.423 (model $2 + 2H_2O$), 0.748 (model 3), and 0.336 (model $3 + 2H_2O$), respectively. This in turn means that the orbital overlaps (T_i) between the magnetic $d\pi_x–p\pi_x$ orbitals ($\psi_i^{\pm}$) are 0.398, 0.438, 0.169, 0.577, 0.252, and 0.664, respectively. Thus the diradical character of the $d\pi_x–p\pi_x$ bond is sensitive to the ligand fields. On the other hand, the orbital overlaps (T_i) between the magnetic CT ($d\pi_y–\pi_y$) orbitals are 0.113, 0.324, 0.002, 0.171, 0.210, and 0.184, respectively, indicating the strong CT diradical character. This indicates that contribution of the $[Mn(IV)=OL^{\cdot+}]$ structure is significant in the model complexes 1, 2, and 3.

Judging from the occupation numbers in Table 2, the four active orbitals and four active electrons [4,4] are at least crucial for the complete active space (CAS) for SA CASCI treatment of the models 1, 2, and 3. However, inclusion of the bonding and antibonding $d\sigma–p\sigma$ orbitals

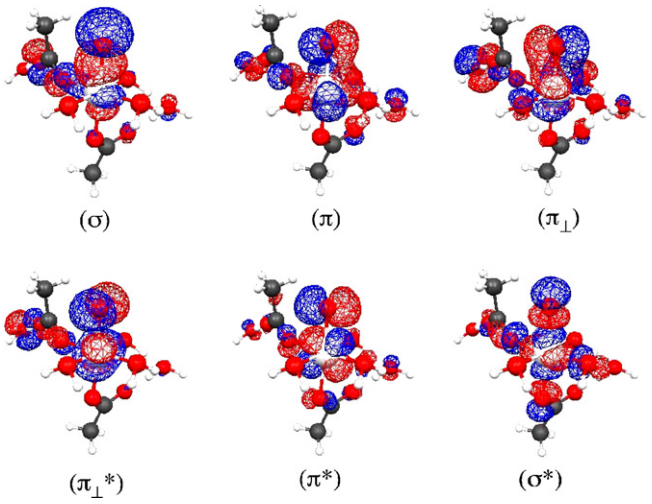

Fig. 5. Graphic drawings of the bonding and antibonding pairs of dσ–pσ(σ), $d\pi_x$–$p\pi_x(\pi)$, and $d\pi_y$–$p\pi_y(\pi)$ type natural orbitals of MnO in the model 1 with extra $2H_2O$ (b in Fig. 4).

becomes essential for MO-theoretical tracing of the dissociation process of the Mn=O bond. The six natural orbitals for the model complex **1** with $2H_2O$ are depicted in Fig. 5

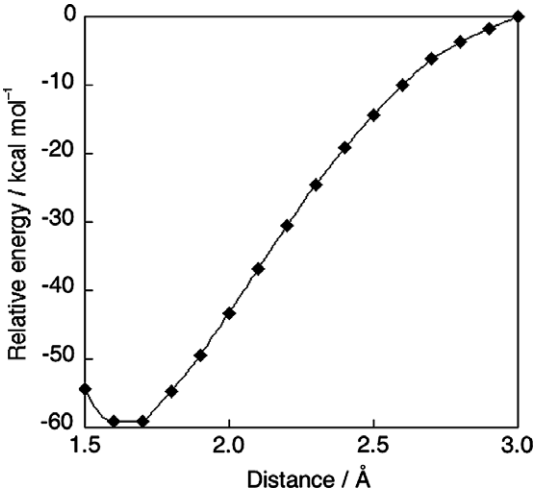

Fig. 6. Potential curve of the Mn(V)=O porphyrine complex (**7**) with change of the Mn–O distance.

as an example. These natural orbitals are utilized for successive SA computations of the complexes, 1, 2, and 3. The CASCI results will be published elsewhere.

3.2. Electronic structures of Mn–oxo porphyrine complex

Here, a manganese–oxo porphyrin complex (**8**), [Mn(V)=OPor](H_2O) is examined as an example of artificial high-valent manganese–oxo species. Fig. 6 shows variations of the potential curve of **8** with changing the Mn–O bond distance (R). At the dissociation limit ($R = \infty$), **8** is regarded as the exchange-coupled low-spin (LS) state constructed of the triplet state of [Mn(III)Por](H_2O) and triplet atomic oxygen (^3O) as illustrated in Fig. 7. This characteristic property remains even at $R \ll \infty$. For example, the spin density (Mulliken charge) of Mn and porphyrine of **8** at $R = 3.0$ Å, namely [Mn(III)Por](H_2O) fragment, are 2.57 (1.22) and −0.63 (−0.38), respectively. Then the π-electron of porphyrine is spin-polarized because of the internal magnetic field of triplet Mn(III) ion. The net charge of Mn(III) is largely reduced by the coordination of porphyrine dianion. The oxygen site of **8** is regarded as triplet oxygen with negative spin density (−1.94). These results are consistent with the triplet O (^3O) model in Fig. 3.

The Mn–O distance at the equilibrium geometry of **8** is calculated to be 1.6 Å and the binding energy is 59.12 kcal/mol. The spin density (Mulliken charge) of Mn, O and porphyrine are 1.53 (1.42), −0.47 (−0.43) and −1.06 (−0.15), respectively. Judging from the orbital spin densities, the $d\pi_x$–$p\pi_x$ covalent bond is considerably spin-polarized, namely $[\uparrow\delta\cdot\mathrm{Mn}(0.47)\text{–}\mathrm{O}(-0.47)\delta\cdot\downarrow]$ (where spin densities are given in parentheses), because of strong electron correlation. On the other hand, the charge transfer from the π-bonding closed-shell orbital of porphyrine to the $d\pi_y$–$p\pi_y$ antibonding orbital of the MnO site occurs at the geometry, giving rise to the porphyrine π-cation radical, which is responsible for the CT biradical structure: $[\uparrow\cdot\mathrm{Mn(IV)}\text{–}\mathrm{O}(1.06)\mathrm{Por}^{\cdot+}(-1.06)\downarrow](H_2O)$. This behavior is similar to that of the models 1, 2, and 3 for the Mn=O bond in OEC.

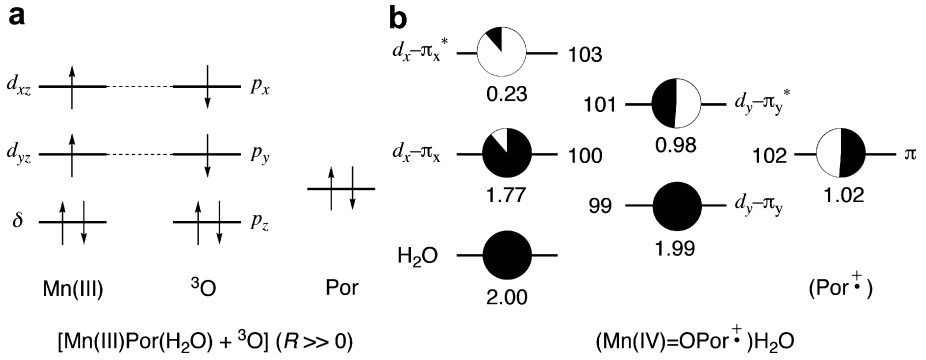

Fig. 7. (a) The exchange-coupled low-spin (singlet) state between triplet Mn(III) and triplet oxygen atom (^3O) with the closed-shell porphyrine at a dissociated ($R = 3.0$ Å) manganese–oxo porphyrine complex. (b) Schematic illustrations of the occupation numbers of natural orbitals for the charge transfer (CT) diradical (singlet) state constructed of doublet Mn(IV)=O and doublet cation radical of porphyrine.

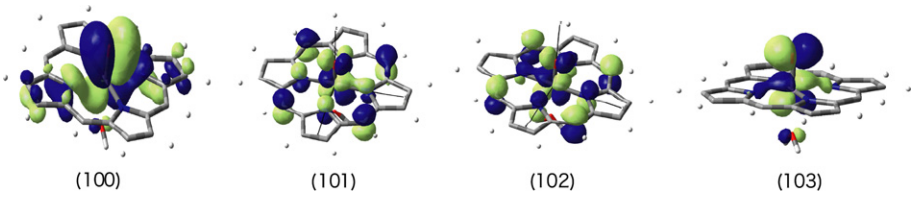

Fig. 8. Graphical drawings of the bonding (100) and antibonding (103) pairs of the $d\pi_y$–$p\pi_y$ type natural orbital and those (101 and 102) of the CT type orbitals, which are constructed of the porphyrine π- and $d\pi_y$–$p\pi_y$ antibonding orbitals. The CT diradical property is variable with Mn–O distance.

The natural orbital analysis of the broken-symmetry (BS) UB3LYP solution of **8** at the equilibrium geometry has been performed to elucidate symmetry-adapted (SA) CASSCF picture. Figs. 7 and 8 illustrate, respectively, populations of occupation numbers and shapes of natural orbitals. From Fig. 8, the natural orbitals (ϕ_i) 101 and 102 are delocalized over both Mn=O and porphyrine groups, and their occupation numbers are almost 1.0. Then the magnetic orbitals ($\psi_i^{\pm}$) given by the mixing of them are localized on the Mn=O group ($\psi_i^{+} = \psi_A$) and porphyrine group ($\psi_i^{-} = \psi_B$), respectively, leading to the singlet biradical configuration. On the other hand, the natural orbitals 100 and 103 are the bonding and antibonding $d\pi_x$–$p\pi_x$ orbitals. The occupation number of the antibonding orbital is 0.23, indicating a homolytic diradical character. However, this small number does not suppress significantly the electron accepting property of this LUMO. This is compatible with the electrophilic property of MnO. Thus the high-valent Mn–O bond in porphyrine complex exhibits similar characteristic to that of the model complexes 1 and 2 for OEC in Fig. 4.

4. Possible mechanisms of oxygen evolution

4.1. Importance of the Mn(V)=O bond

Past two decades [22–28], Yamaguchi et al. elucidated electronic structures and spin states of transition-metal oxides on the basis of ab initio broken-symmetry (BS) (UHF UDFT, GHF and GDFT) calculations followed by the approximate spin projection. It was found that the oxygen atom in the metal-oxo species MO (M = Cr, Mn, Fe) exhibits the nucleophilic character $M^{+}O^{-}$ in the case of the lower-valent stage of M^{+}; M(II) and Mn(III). For example, the Mn(III) ion forms an ionic bond with hydroxide anion, $[Mn(III)–OH]^{2+}$, as shown in Fig. 2. On the other hand, the oxygen atom in the high-valent metal-oxo species such as Mn(V)=O may have singlet or triplet oxygen atom (O) character, showing an electrophilic property to many substrates as illustrated in Fig. 3, for example:

$$Mn(V)=O + {}^{-}OH \rightarrow Mn(IV)—OOH \quad (9a)$$

$$Mn(V)=O + H—OH \rightarrow Mn(IV)—OH + \cdot OH \quad (9b)$$

$$Mn(V)=O + H—OH \rightarrow Mn(III) + HOOH \quad (9c)$$

The reaction (9a) may be operative in ion reactions to generate the O–O bond. The hydrogen abstraction from water by Mn(V)=O in (9b) is also conceivable for high-spin states of manganese–oxo species, though the insertion (or very fast rebound mechanism) is more reasonable in the low-spin (LS) state of them (in Eq. (9c)).

Isobe et al. [28] have performed the DFT calculations of the model compound (**6**) for the Limburg compound (**7**). They have found that the metal–oxo bonds (Mn(V)=O) in **6** show the diradical character ·Mn–O· (see Fig. 2), and therefore the oxygen atom in Mn(V)=O in **7** may undergo electrophilic reactions with substrates in Eq. (9): note that singlet biradical character of the low-spin (LS) Mn(V)=O bond decrease significantly in the case of insertion-type reaction in Fig. 3. Several evidence [29] suggests that chloride anion plays an important role for oxygen evolution in Limburg reaction systems (**7**) like native OEC (**1**) in Fig. 1. This implies that SE_2-like mechanism is also conceivable as discussed later (see Fig. 10).

Koizumi et al. [35] have carried out the DFT calculations of dimer of manganese–oxo (MnO) porphyrin (PO) synthesized and characterized by Naruta's group [36]. They have investigated variations of the electronic structures of POMn(X)=O with the change of oxidation number (X) of the Mn ion. It was found that the Mn(V)=O bond in Naruta's oxygen evolution system has the oxygen-diradical character, which may entail the oxygen-atom radical coupling as follows:

$$(POMn(V)=O)_2 \rightarrow POMn(IV)—O—O—Mn(IV)PO \rightarrow (POMn(III))_2 + O_2 \quad (9d)$$

However, more complex mechanisms involving ionic processes are conceivable even in this case. For example, Fig. 9a illustrates the radical coupling mechanism for the formation of molecular oxygen in Eq. (9d), which is theoretically feasible because of the biradical nature of the Mn=O bond as shown in Figs. 7 and 8. On the other hand, strong electrophilic nature of the high-valent [Mn(V)=O^{+} Por] and/or [Mn(IV)=O Por $^{\cdot+}$] bonds indicates a possibility of the ionic (SE_2) process [24] in Fig. 9b, where electrophilic attack of the oxygen of MnO to the lone pair of water is a key step for the O–O bond formation in oxygen evolution. Thus our theoretical studies on native OEC and artificial OEC [28,30,35] systems have revealed the crucial role of the high-valent Mn(V)=O and/or Mn(IV)=O bonds.

4.2. SE_2 mechanism of oxygen evolution

The present computational results indicate that the insertion (or rapid rebound) mechanism, ^{1}O-model [24], is

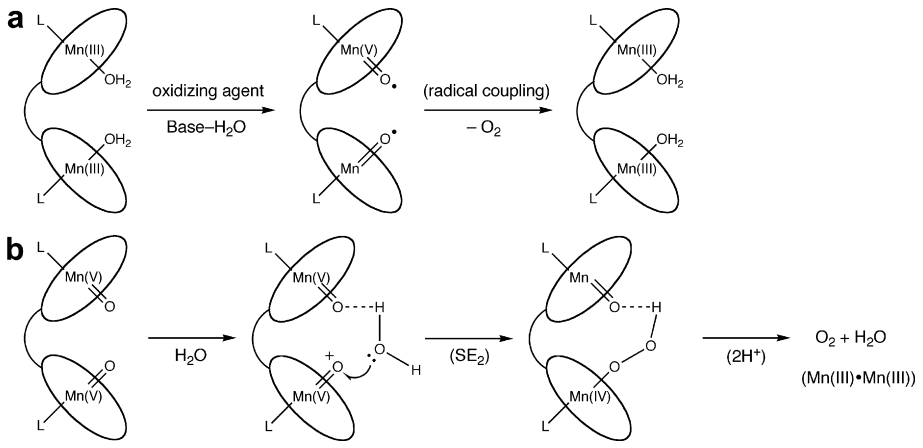

Fig. 9. (a) Radical coupling mechanism of the O–O bond formation in the artificial OEC system and (b) ionic (SE_2) mechanism of the O–O bond formation. The latter mechanism is closely related to that of OEC in Fig. 10.

applicable to the oxygenation by high-valent Mn–oxo species examined here because of strong diradical characters. However, the diradical character of the Mn–O bond is found to be sensitive to environmental effects such as hydrogen bonding and clustering of waters (see Tables 1 and 2). This in turn indicates that the nature of Mn=O bonds in **1** is variable depending on the electronic states of the cubane unit $CaMn_3O_4$. Therefore, three mechanisms in Fig. 3 are conceivable theoretically.

Present computational results indicate a possibility of our previous bimolecular electrophilic substitution (SE_2) mechanism (see Fig. 3) for oxygen evolution reaction in OEC as illustrated in Fig. 10. From Fig. 10, the oxygen site of the high valent manganese–oxo bonds [Mn(V)=O$^+$ **4**] and/or [Mn(IV)=O **4** $^{\cdot+}$] in OEC undergoes the electrophilic attack of lone pair of water molecule, followed by the concerted proton migration with base (for example hydrogen-bonding networks involving protein side chains within local environment). This SE_2 reaction produces the Mn(IV)–hydroperoxide anion complex, which undergoes second proton migration to afford the low-spin Mn(IV)–superoxide anion complex. The regulation of charge on O_2 fragment by $CaMn_3O_4$ (**4**)part is feasible in the case of **1**. The back electron transfer from superoxide anion to Mn(IV) generates triplet molecular oxygen and triplet Mn(III) complex as follows:

$$^1[\mathrm{Mn(IV)O_2^-}] \rightarrow {}^1[{}^3\mathrm{Mn(III)}{}^3\mathrm{O_2}] \rightarrow {}^3\mathrm{Mn(III)} + {}^3\mathrm{O_2} \qquad (9e)$$

It is noteworthy that $^3O_2$ is generated without spin inversion via spin–orbit interaction. The key point of the SE_2 mechanism is the electrophilic nature of oxygen site in the high-valent manganese–oxo bonds [24]. The SE_2 mechanism in Fig. 10 is consistent with the proposal by Iwata and Barber on the experimental ground [37,38]. The reaction scheme in Fig. 10 is now under further investigation in our laboratory.

4.3. Implications to related oxygenation reactions

Finally, implications of the previous [24–28] and present computational results are briefly discussed in relation to other oxygenation reactions by metal–oxo species. For

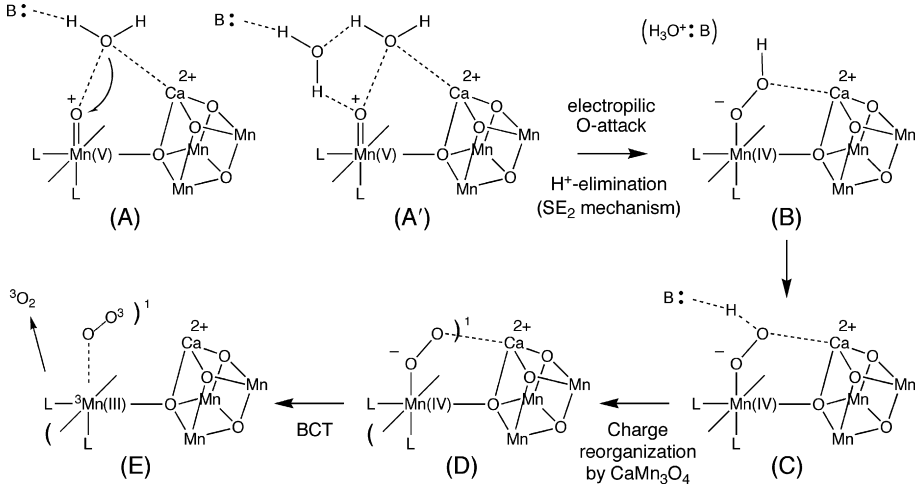

Fig. 10. Possibility of the bimolecular electrophic substitution (SE_2) mechanism of oxygen evolution reaction from water in OEC of the photosynthesis II. The SE_2 mechanism is a direct extension of that in Fig. 3 (see text). It does not entail the formation of hydroxyl radical as in the case of the ^3O-model.

example, the conversion of methane to methanol is catalyzed at the active site of a metalloenzyme known as methane monooxygenase (MMO) (Mn ions in **6** and **7** are replaced with Fe ions in MMO)

$$CH_4 + NADH + H^+ + O_2 \rightarrow CH_3OH + NAD^+ + H_2O \quad (10)$$

Both cationic and radical intermediates (or transition structures) have been proposed for this reaction on the experimental grounds [39]. Past decade, several computations have been performed to elucidate the nature of the intermediate in MMO. According to our previous proposal [24], computational results on the iron–oxo (Fe(IV)=O) species in MMO are classified into three categories illustrated in Fig. 3.

Yoshizawa et al. [40,41] have proposed a concerted (four-centered) mechanism between Fe=O and H–CH_3 fragments on the basis of the spin-restricted (RHF) calculations. Their mechanism is similar to the SE_2 (concerted) mechanism in Fig. 3, though our SE_2 mechanism is based on the high-spin configuration of the Fe(IV) center instead of their closed-shell (RHF) configuration. On the other hand, Basch, Morokuma and co-workers [42,43] have been proposed a hydrogen-abstraction mechanism for hydroxylation reaction by MMO, assuming the four unpaired spins at each Fe(IV) center of **Q** (namely the high-spin ^{9}A dimer) in the spin-unrestricted DFT (UDFT) calculations. The hydrogen-abstraction mechanism in the ^{9}A dimer model is similar to the ^{3}O (abstraction)-model in Fig. 3 since the reaction site is regarded as the ^{3}O plus H–CH_3 system. Siegbahn et al. [44,45] have proposed a hydrogen abstraction model in the high-spin mixed-valence (MV) state: **Q** = [Fe(II)(S = 5/2) Fe(IV)(S = 2/2)O-radical]. Siegbahn model is regarded as a high-spin (^{3}O) model in our terminology (Fig. 3) [24]. Friesner, Lippard and their co-workers [46,47] proposed a bound-radical pair model, assuming the low-spin (antiferromagnetic) dimer state of the high-spin iron (Fe(IV)) centers. Friesner–Lippard model is similar to the ^{1}O (insertion)-model, where both insertion and rapid recombination between the singlet radical pair (·OH plus ·CH_3) are feasible, depending on the reaction conditions [24,26].

Table 3 summarizes the proposed reaction mechanisms of methane monooxygenation (MMO) by several theoretical groups. The conclusions are dependent on the assumed anti (AF) and ferro (F) magnetic spin couplings of the iron oxo cores (Fe_2O_2) in MMO. However, the low-spin (LS) AF broken-symmetry usually involves the high-spin (HS) component. Therefore use of an approximate spin projected (AP) BS solution [23–28] is desirable for location of transition structure on the pure LS surface. This situation clearly indicates necessity of further theoretical investigations based on more realistic reaction-site and spin-state models including protein environments. Both radical and ionic mechanisms are also proposed for hydroxylation reactions of P450 with the active site: [Fe(IV)=O·Por$^{\cdot+}$] [48]. The situation is quite similar to those of MMO and OEC in the photosynthesis II system.

Table 3
Classifications of the reaction mechanisms of methane monooxygenation by several theoretical groups

Our proposals[a]	Recent computational results	Methods
SE_2 model	Yoshizawa (concerted) model[b]	RHF
^{1}O-model	Friesner–Lippard (bound-radical) model[c]	^{1}UDFT
^{3}O-model	Morokuma–Basch (hydrogen abstraction) model[d]	^{9}A by UDFT
	Siegbahn (hydrogen abstraction) model[e]	high spin MV by UDFT

[a] Refs. [24,26].
[b] Refs. [40,41].
[c] Refs. [46,47].
[d] Refs. [42,43].
[e] Refs. [44,45].

This in turn indicates that theoretical and computational efforts may provide a unified picture and key concepts for understanding of oxygenation reactions in general [24,26].

5. Concluding remarks

The nature of high-valent manganese–oxo (Mn(V)=O) bonds has been investigated on the basis of the hybrid DFT calculations of the model complexes 1, 2, and 3 for oxygen evolution center (OEC) and the Mn–oxo prophyrine complex (**8**). It is found that charge transfer from ligands to Mn(V)=O occur to indicate significant contribution of the [Mn(IV)=O L$^{\cdot+}$] configuration. Therefore the high-valent (HV) Mn–O bond is regarded as the superposed state of these two configurations in general,

$$\Psi(\mathrm{Mn(HV)}{=}\mathrm{O}) = C_1\Psi_1(\mathrm{Mn(V)}{=}\mathrm{O}\cdot\mathrm{L}) + C_2\Psi_2(\mathrm{Mn(IV)}{=}\mathrm{O}\cdot\mathrm{L}^{\cdot+}), \quad (11)$$

where C_i denotes the mixing coefficients, which are variable with ligands and environmental effects as shown in this paper. The dual character of the HV Mn–O bond would be a key factor for theoretical understanding of complex behaviors of chemical reactions by HV Mn–O compounds. Similar situations are also found in HV iron–oxo species in MMO and P450. The hybrid DFT (HDFT) followed by the natural orbital analysis is a useful and practical method for theoretical investigations of metalloenzymes as shown in this series of papers [49].

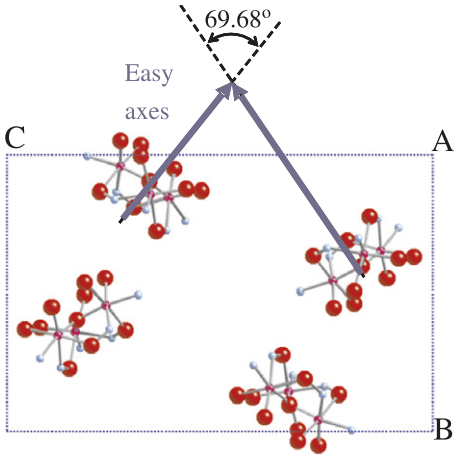

Fig. 1. Crystal structure showing the two sites in the lattice with differently oriented magnetic axes.

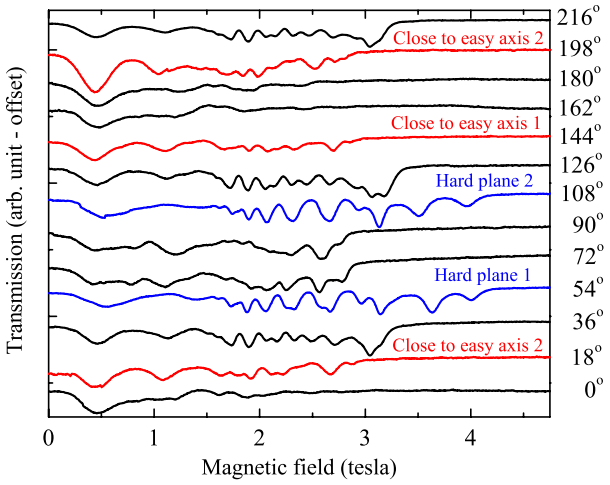

Fig. 2. Angle-dependent spectra taken at 62 GHz and 5 K; the angles are given on the right hand side. The blue curves correspond to the directions of the two hard planes. The red curves correspond to the closest approaches to the two easy axes. (For interpretation of the references in color in this figure legend, the reader is referred to the web version of this article.)

In this work, we perform high-frequency electron paramagnetic resonance (HFEPR) measurements to quantitatively determine the zero-field-splitting (zfs) parameters in the spin Hamiltonian based on the giant spin approximation [4]. HFEPR measurements were performed at various temperatures and frequencies from 60 to 170 GHz, with magnetic fields applied at different orientations relative to a single crystal. The HFEPR spectra were obtained at fixed frequencies and temperatures while varying the DC magnetic field strength. Details of the experiments can be found elsewhere [5]. These studies allow us to identify the ground state spin quantum number and to construct the Zeeman diagram associated with this state. By comparing the experimentally constructed Zeeman diagram to simulations obtained via exact diagonalization of the spin Hamiltonian, the zfs parameters can be determined quantitatively.

3. Data and discussion

The HFEPR study of this complex is complicated due to the existence the two inequivalent sites in the lattice, with differently oriented magnetic axes, neither of which align with the principal crystallographic axes (see Fig. 1). Shown in Fig. 2 are the angle-dependent spectra taken at 62 GHz and 5 K. The appearance of multiple peaks spanning a wide field range is indicative of a molecular species with an appreciable spin quantum number and significant anisotropy [6]. If one assumes an easy axis type of anisotropy (negative D value), then one expects to see the strongest peaks appearing at low fields when the field is aligned near to the easy axis, while the strongest peaks should appear at high fields when the field is in the hard plane. Clearly, the data in Fig. 2 exhibit both of these behaviors.

Since the orientation of the crystal was not known a priori, we do not know the exact plane of rotation relative to either the crystallographic axes or the magnetic axes associated with the two sites in the lattice. However, for rotation over more than a 180° angle range, we are guaranteed to pass through the hard planes associated with both sites (not necessarily coincidentally); we are also likely to pass close to the easy axes, but it is not guaranteed that we will hit those directions exactly. As can be seen from the coloring of the curves in Fig. 2, there exist two field orientations (54° and 108°, colored blue) exhibiting essentially identical spectra, with strong EPR peaks extending to the highest fields. These orientations, which are separated by about 50° (see Fig. 4 below), correspond to the two hard planes associated with each lattice site. The fact that the obtained separation is less than the ~70° separation of the easy axes confirms that the plane of field rotation is inclined relative to the plane containing the two easy axes. Nevertheless, we do expect to pass close to the easy axes for field orientations 90° away from the hard planes, i.e. 18°, 144° and 198°. One can indeed see from these traces (colored in red) that the spectra do resemble easy axis data at low fields, i.e. broader, well spaced peaks decreasing in strength with increasing field [7]; the cluster of small peaks at higher fields originate from the other species.

Fig. 3 shows an expanded view of the 54° data in Fig. 2. At high fields, one clearly sees two series of more-or-less evenly spaced peaks marked by blue squares and red arrows. The highest field series (blue squares) correspond to the main peaks associated with one of the hard planes; the field is exactly in the hard plane for these sites (species 1). Meanwhile, the field is ~50° from the other hard plane, i.e. ~40° from the easy axis associated with the other sites (species 2). For such an orientation, one expects to observe remanences of both the easy axis spectrum (strong low-field peaks) and the hard plane spectrum (strong peaks at moderately high fields). The second series of closely spaced high-field peaks (marked by red arrows) and the two broad peaks at low fields (marked by black dots) correspond to the second species. The peaks marked by the red arrows

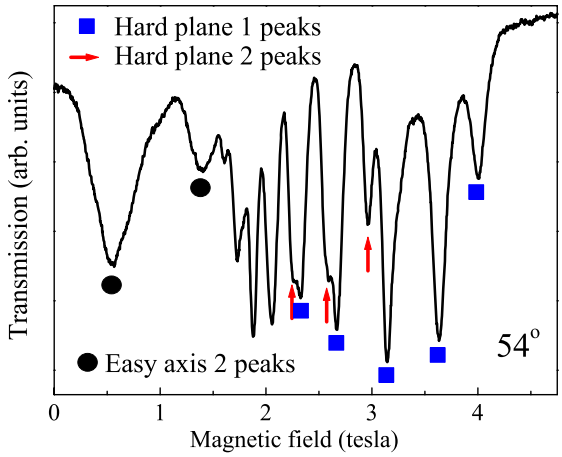

Fig. 3. An expanded view of the 54° data from Fig. 2 (field ‖ hard plane 1). The blue squares mark the resonances corresponding to the field parallel to hard plane 1 (species 1). The remaining resonances are due to the second species: the low-field peaks marked with black dots are remnants of the easy axis spectra, while the higher field peaks marked with red arrows are remnants of the hard plane spectra (see text). The field is oriented approximately 42° away from the easy axis of the second species. (For interpretation of the references in color in this figure legend, the reader is referred to the web version of this article.)

occur at lower fields than those marked by the blue squares because the field is significantly out of the hard plane for the second species.

Angle dependent measurements were also performed at a frequency of 129 GHz. Fig. 4 displays the angle dependence of the strongest peak positions. For a uniaxial system (easy axis or easy plane) in the high-field limit, $g\mu_B B \gg DS$ (= 2 T), one expects each peak to approximately follow a $(1 - 3\cos^2\theta)$ angle dependence about the isotropic position ($g = 2$ line), where θ is the orientation of the field relative to the principal (z-) axis (not the experimental angle from Fig. 4). As can be seen from the figure, each peak does

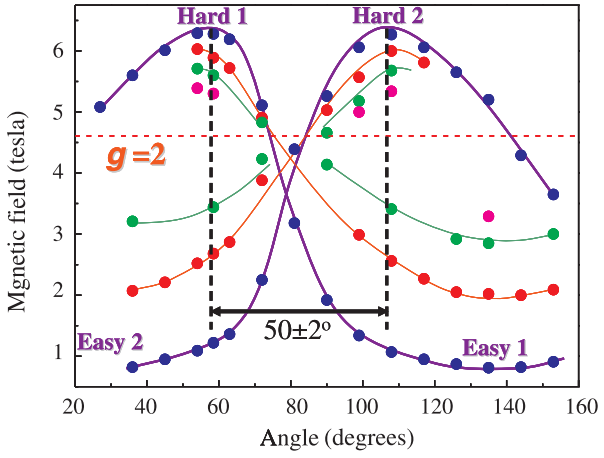

Fig. 4. EPR peak positions plotted vs. angle extracted from data obtained at a higher frequency of 129 GHz; the temperature is 5 K. Each peak exhibits an asymmetric twofold pattern (180° periodicity). The hard and easy directions are indicated in the figure for each species. The $g = 2$ line for a frequency of 129 GHz is also shown as a guide.

oscillate about $g = 2$. Furthermore, as expected, the deviation to the low-field side (field close to z-direction) of $g = 2$ is roughly twice the deviation to the high field side (field ‖ xy-plane) for each transition. The solid curves through the data points were generated by hand. Assuming D to be negative (see below), the locations of the two hard planes (dashed vertical lines) were estimated from the maxima of the blue curves.

There are multiple reasons for the departure from a perfect $(1 - 3\cos^2\theta)$ angle dependence seen in Fig. 4. First, when the field is near to the easy axis, the $g\mu_B B \gg DS$ condition is not satisfied; this causes sharper maxima and broader minima. Second, the field rotation plane is not orthogonal to the two hard planes, i.e. it does not coincide with the two easy axes. Consequently, there is a variation in the in-plane field component for each species as the magnetic field is rotated. Thus, the data in Fig. 4 provide the first evidence for transverse (in-plane) anisotropy. If there was no in-plane anisotropy, one would expect the angle dependence to be symmetric about the hard plane directions. This is clearly not the case, i.e. for hard plane 1, the fall off in the position of the peak is much sharper to the right of the hard plane than to the left (vice versa for hard plane 2). Consequently, there must be two anisotropies at play, one which depends only on the out-of-plane field component which is symmetric about the hard plane, and another that depends only on the in-plane field component, which need not necessarily be symmetric about the hard plane (this depends on the orientations of the hard and medium axes relative to the intersection between the hard plane and the field rotation plane).

In order to quantify the zfs parameters, frequency dependent measurements were performed with the magnetic field applied within the hard plane of one of the species of molecules, corresponding to 54° in Fig. 2 (hard plane 1). The positions of the observed resonances are plotted in the frequency versus field plot displayed in Fig. 5. We limited this analysis to the highest field series of evenly spaced peaks which we associate with the hard plane of one of the species (1), i.e. those marked by blue squares in Fig. 3, together with the strongest low-field peaks which we associate with the other species (2). We then simultaneously fit each series of peak positions to the usual spin Hamiltonian [4], using identical zfs parameters, since the two lattice sites are related by a simple rotation. We made the assumption that $S = 6$. However, similar attempts to fit the data were made with larger and smaller S values, and the quality of the best fits were significantly worse. In other words, the data plotted in Fig. 5 appear to confirm the spin quantum number of $S = 6$ deduced from magnetic measurements [1].

The red and blue curves in Fig. 5 correspond to the frequency differences between Zeeman split levels which differ in m_s by ±1, i.e. levels between which there are allowed magnetic dipole transitions. The red curves were fit to the red low-field data points and the blue curves to the high-field blue data points. We made the assumption that the

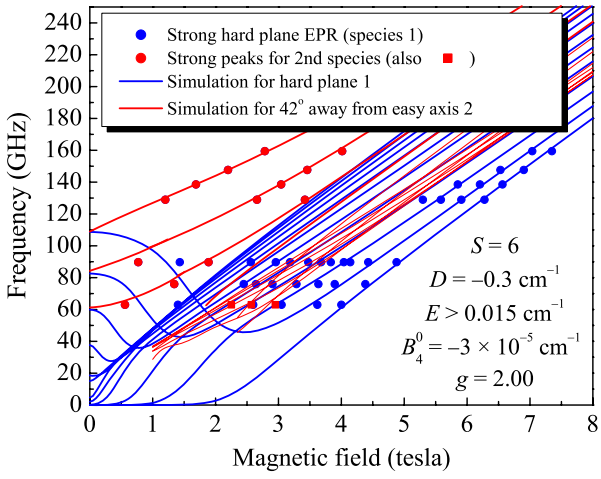

Fig. 5. Frequency dependence of the main EPR peaks observed at 5 K for the field applied parallel to hard plane 1 (54°). The solid blue circles correspond to species 1 and the solid red circles to the low-field peaks associated with species 2; the solid red squares correspond to the peaks marked by red arrows in Fig. 3. The curves represent the best fit to both data sets, yielding the zfs parameters given in the figure. The blue curves correspond DC fields applied in the hard plane for species 1, and red curves for fields applied 42° away from the easy axis associated with species 2. (For interpretation of the references in color in this figure legend, the reader is referred to the web version of this article.)

field was exactly in the hard plane for the blue curves, while the orientation of the field was adjusted for the red curves. The red data place the strongest constraint on the axial D and B_4^0 parameters, as well as determining the orientation of the field relative to the easy axis of the second species. In order to maintain a good fit to the low-field data, whilst simultaneously fitting the blue data points, we found it necessary to include a significant transverse anisotropy. Since we do not know the exact plane of rotation, we cannot determine the precise value of the transverse anisotropy parameter. Furthermore, we cannot determine its symmetry, as has been done for other SMMs via field rotation studies within the hard plane [8,9]. Nevertheless, to get some idea of the degree of transverse anisotropy, we use the standard rhombic interaction of the form $E(\hat{S}_x^2 - \hat{S}_y^2)$ [4].

The optimum fits to the data in Fig. 5 yield: $S = 6$, $D = -0.3\ \mathrm{cm}^{-1}$, $B_4^0 = -3 \times 10^{-5}\ \mathrm{cm}^{-1}$, $g = 2.00$ and a significant $E \geqslant 0.015\ \mathrm{cm}^{-1}$. For the second species, the field is found to be $42° \pm 2°$ away from the easy axis ($48° \pm 2°$ away from the hard plane), which agrees with the angle dependent measurements. The reason for the lower bound on E is because our fits assumed that the field was precisely along the hard axis for the high field data points (species 1, blue data points). One could include a larger E value and rotate the field slightly towards the medium axis (within the hard plane) and obtain an equally good fit. To place this in context, an E/D ratio of 0.05 is about a quarter of that found for the biaxial Fe_8 SMM [7,10]. Therefore, the transverse anisotropy is fairly significant.

Also seen in Fig. 5 are a series of thinner red curves which overlap the lower field blue curves. These red lines correspond to the higher field peaks expected of the second species (marked by red arrows in Fig. 3). We did not consider these peaks when fitting the data. However, three data points (red squares) are included in Fig. 5 corresponding to the peaks marked by red arrows for the 62 GHz data in Fig. 3. As can be seen, the locations of these peaks agree reasonably well with the thinner red curves in Fig. 5. Thus, the earlier explanation for these peaks appears to be sound. The slight deviations between the red square positions and the thin red curves may be attributed to the fact that we do not know the precise orientation of the field within the hard plane, i.e. one does not expect perfect agreement due to the uncertainty in the E value.

Finally, Fig 6 displays 129 GHz data obtained at 10 K and 5 K with the field parallel to the hard plane of species 1. The two insets display the Zeeman diagrams generated using the obtained zfs parameters for two field orientations: 42° away from the easy axis (left) and parallel to the hard plane (right). The red bars in these insets represent the observed EPR transitions. As can be seen from the figure, the EPR intensity transfers to the lowest and highest field peaks upon lowering the temperature, i.e. the transitions from the lowest lying levels in the two Zeeman diagrams. This behavior can only be explained assuming a negative D value. We note that changing the sign of D would not affect the fits displayed in Fig. 5. However, changing the sign of D would invert the Zeeman diagrams. Were this the case, one would expect the EPR intensity to shift to intermediate fields (around $g = 2$) upon lowering the temperature. Consequently, the temperature depen-

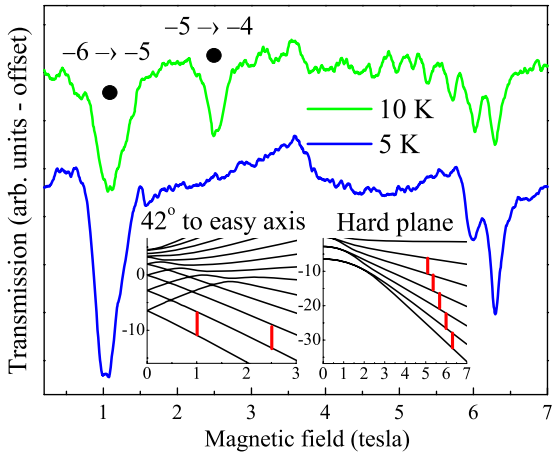

Fig. 6. Temperature dependence of the 129 GHz spectra obtained with the field parallel to hard plane 1 (54°). The two insets display the Zeeman diagrams generated using the obtained zfs parameters for two field orientations: 42° away from the easy axis (left) and parallel to the hard plane (right). The red bars in these insets represent the observed EPR transitions. The low-field transitions have been labeled according to the m_s values involved in the transitions. (For interpretation of the references in color in this figure legend, the reader is referred to the web version of this article.)

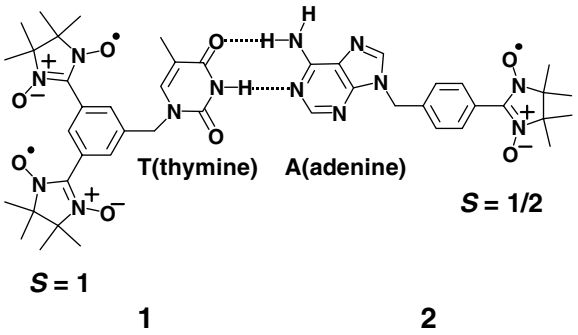
dence provides spectroscopic confirmation of a negative D value, thereby verifying that Mn_3 is in fact a SMM.

4. Summary



Multi-high-frequency single-crystal EPR measurements have enabled a quantitative determination of the zfs parameters of the first triangular Mn SMM. The obtained parameters are in good agreement with previously published values deduced from thermodynamic measurements, thereby providing spectroscopic evidence that Mn_3 is indeed a SMM.

Scheme 1. Heterospin nucleobase pair composed of thymine-substituted biradical T-bisNN **1** ($S = 1$) and adenine-substituted monoradical **2** ($S = 1/2$).

ferrimagnets, we have proposed a bio-inspired scheme in which the hydrogen bonding between the nucleobase substituents serves to assemble organic radicals in a controllable manner [5]. Two kinds of nucleobases with different spin quantum numbers should be connected by complementary hydrogen bonds to give a two-component heteromolecular assemblage suitable for a ferrimagnetic spin alignment. An example of the hydrogen-bonded aggregation is shown in Scheme 1. In this communication, we report synthesis and characterization of a thymine-substituted nitronyl nitroxide biradical T-bisNN (**1**) as a building block of heterospin nucleobase pairing of thymine and adenine. We examine X-ray crystallography and magnetic properties of the biradical **1**. Intermolecular hydrogen bonding motifs and the ground-state spin multiplicity of **1** are presented. Potentiality of **1** as a building block for bio-inspired ferrimagnet is discussed.

2. Experimental

2.1. Synthesis

The thymine-substituted biradical **1** was synthesized by a direct coupling of thymine with a 5-chloromethylphenyl derivative of nitronyl nitroxide **3**, as shown in Scheme 2. The precursor **3** has been prepared from hexatriene [6] according to the literature procedures [7,8]. The precursor **3** (100 mg, 0.23 mmol) was added to a suspension of thymine (43.9 mg, 0.35 mmol), K_2CO_3 (46.8 g, 0.34 mmol), and KI (53.6 mg, 0.32 mmol) in CH_3CN (6 ml). The reaction mixture was stirred at 80 °C for 18 h. After filtration, the reaction solution was concentrated and chromatographed on silicagel using CH_2Cl_2/acetone (4/1 in volume) as an eluent to yield a blue solid of **1** (61.7 mg, 50.9%). A polyvinylchloride (PVC) film, used as magnetically diluted samples, was prepared by slow evaporation of a dichloromethane solution of PVC and **1** (26.9 wt%).

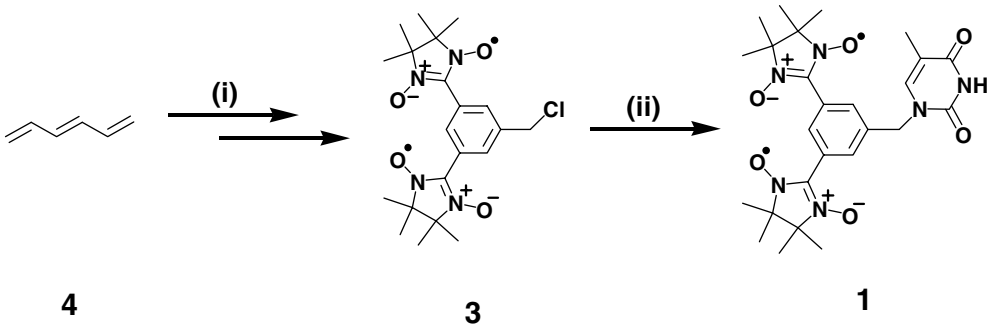
2.2. Crystal structure analysis

Single crystals of T-bisNN (**1**) were obtained by recrystallization from a mixed solution of dichloromethane and hexane. Single crystal diffraction data of **1** were collected on a Rigaku Mercury CCD diffractometer with graphite monochromated Mo Kα radiation at 193 K. The crystal structure was solved by using direct methods in a program package CRYSTALSTRUCTURE[1]. Anisotropic thermal parameters analysis was applied for non-hydrogen atoms. Hydrogen atoms with isotropic thermal parameters were refined as riding models.

2.3. Magnetic susceptibility measurements

The static paramagnetic susceptibility χ_p was measured for polycrystals and diluted samples in the PVC films on a SQUID magnetometer with an applied magnetic field of 0.1 T in the temperature range of 1.9–300 K. The magnetic responses were corrected with diamagnetic blank data of the sample holder obtained separately. The diamagnetic contribution of the sample itself was estimated from Pascal's constants.

3. Results and discussion



3.1. Crystal structure

The crystalline solid of **1** was stable under aerated conditions at room temperature. The crystallographic data for **1** are listed in Table 1. The crystal contains one mole of dichloromethane as crystal solvent. The molecular structure is shown in Fig. 1 with the atom numbering. The phenyl and the thymine rings have a large dihedral angle of 81.0° around the methylene bridge. It is expected that the delocalization of unpaired electron spin in **1** is truncated at the methylene bridge. It was found from molecular orbital calculations that the thymine moiety has little spin density[2]. Thus, the thymine group in **1** should play a role primarily in determining the molecular packing instead of propagating intermolecular magnetic interactions.

Twofold hydrogen bonds are found between the thymine substituents of inversion-related nearest-neighbor molecules, as shown in Fig. 2(a). The length of the hydrogen bond is N6H30–O5 = 2.863(4) Å. This is very close to those of pristine thymine [9]. In another pair of molecules related by an inversion center, a short contact of 3.222(5) Å is found between the nitronyl nitroxide oxygen atom (O4) and the central carbon atom (C7), as depicted in Fig. 2b. This kind of oxygen–carbon contact for nitronyl nitroxide radicals is expected to have a contribution to intermolecular ferromagnetic interaction, as found in other nitronyl nitroxide derivatives [10].

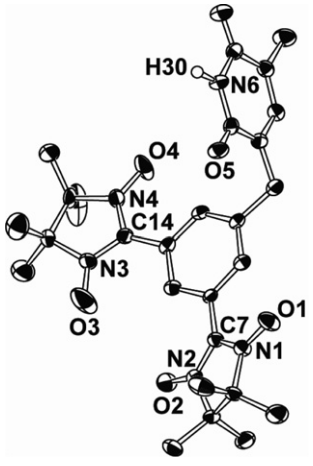

Fig. 1. ORTEP view of the asymmetric unit of T-bisNN (**1**) with the thermal ellipsoids at the 50% probability level. The hydrogen atoms are omitted for clarity except those in the hydrogen bonding moiety.

3.2. Magnetic susceptibility

The intramolecular exchange interaction in **1** is examined by paramagnetic susceptibility χ_p for the sample dispersed in the PVC film, in which the radical molecules are diluted and the intermolecular magnetic interactions are suppressed. The χ_pT value of the magnetically diluted system increases as the temperature is lowered, as shown in Fig. 3. This indicates the occurrence of ferromagnetic interactions within the molecule. A decrease in χ_pT is ascribed to residue of intermolecular exchange interactions due to incomplete dispersion of the molecules in the film, as found in other nitroxide compounds in organic polymer matrices [10d,11]. The temperature dependence of χ_pT is analyzed by assuming the thermal equilibrium of the singlet and triplet states [12]:

$$\chi_p = \frac{\alpha N_A g^2 \mu_B^2}{k_B(T-\theta)} \frac{2}{3+\exp(-2J(\pi)/k_BT)} \quad (1)$$

where the singlet–triplet energy gap is denoted by $2J(\pi)$. The mean field θ in Eq. (1) represents the residue of intermolecular interactions. The purity of the sample is designated by α. The observed χ_pT was reproduced by Eq. (1) with the parameters $2J(\pi)/k_B = 21.4 \pm 0.2$ K, $\theta = -0.8 \pm 0.1$ K, $\alpha = 0.88$ and the g-factor of $g = 2.006$, which was observed from the ESR spectrum of **1**. The reduced purity of 88% is attributed to decomposition of **1** during the preparation of the PVC film, as found in other radical compounds in PVC matrices [10d,11]. From the susceptibility measurements, the intramolecular exchange interaction of **1** has been found to be ferromagnetic, which gives a triplet ground state.

The magnetic susceptibility of **1** measured for the neat polycrystals is compared with that of the diluted sample in Fig. 3. With decreasing temperature the χ_pT value of the polycrystal increased and reached a rounded maximum at 13 K. The increase in χ_pT indicates that the dominating exchange interaction is ferromagnetic in the crystalline solid of **1**, which is attributed to the intramolecular interaction $J(\pi)$ or to the intermolecular interaction originating from the short contact at O4–C7 in the dimeric structure shown in Fig. 2b. The decrease in χ_pT at lower temperature tells us that additional weak antiferromagnetic interactions occur between the dimers. The magnetic coupling of **1** in the dimeric structure is approximated by a spin cluster consisting of four $S = 1/2$ spins, as described by a Heisenberg Hamiltonian:

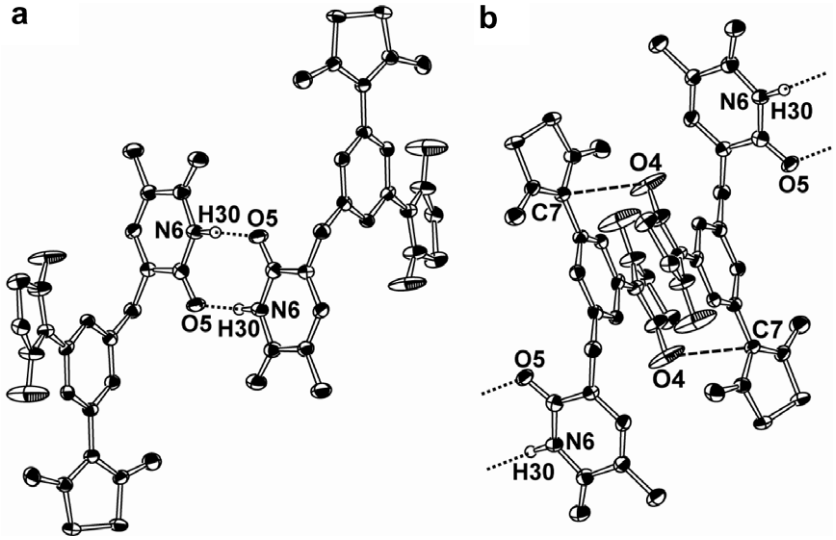

Fig. 2. (a) Hydrogen-bonded pair of inversion-related molecules. (b) Intermolecular contacts in the dimer. The methyl groups are omitted for clarity.

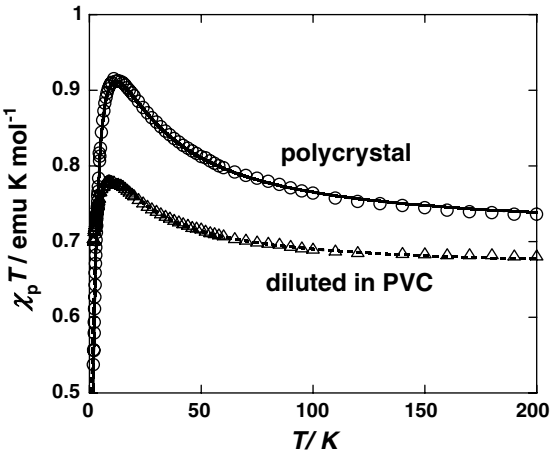

Fig. 3. Magnetic susceptibility χ_p of the T-bisNN (**1**) in the χ_pT vs. T plots. The circles represent the χ_pT value of the randomly oriented polycrystals. The solid line is calculated from Eq. (2) and Eq. (3). The triangles denote the χ_pT value of the diluted sample in the PVC film. The dashed line indicates the calculation from Eq. (1).

$$H = -2J_1(\mathbf{S}_1 \cdot \mathbf{S}_2 + \mathbf{S}_3 \cdot \mathbf{S}_4) - 2J_2(\mathbf{S}_1 \cdot \mathbf{S}_3 + \mathbf{S}_2 \cdot \mathbf{S}_4) \qquad (2)$$

where J_1 and J_2 represent the intra- and intermolecular interactions, respectively. The Hamiltonian equation (2) retains the inversion symmetry of the dimeric structure of **1**. The spin Hamiltonian was numerically diagonalized to give energy eigenvalues E_i and spin eigenvalues S_i for the ith eigenstate [13], from which the temperature dependence of χ_pT was calculated as

$$\chi = \frac{N_A g^2 \mu_B^2}{6k_B(T-\theta)} \cdot \frac{\sum_i [S_i(S_i+1)(2S_i+1)\exp(-E_i/k_BT)]}{\sum_i [(2S_i+1)\exp(-E_i/k_BT)]} \qquad (3)$$

The parameter θ represents the weak interdimer interaction in the mean field approximation. The observed temperature dependence of χ_pT was reproduced by the parameters $2J_1/k_B = 36.8 \pm 0.4$ K, $2J_2/k_B = 10.2 \pm 0.1$ K, $\theta = -3.1 \pm 0.1$ K and $\alpha = 0.94$. In the model of Eq. (2), we are not allowed to distinguish between the intra- and the intermolecular interactions within the dimer. Both $2J_1/k_B = 36.8$ K and $2J_2/k_B = 10.2$ K are different from $2J/k_B = 21.4$ K estimated from the magnetically diluted system[3]. The discrepancy of the magnitude of the intramolecular exchange interaction results from a possible change in the dihedral angles of the molecule **1** in the crystalline solid and the organic matrix of the polymer film. The range of the amplitude of the intramolecular ferromagnetic interaction, $2J/k_B = 20$–40 K, is consistent with 1,3-diyl phenyl nitronyl nitroxide biradicals with 5-alkyl substituents [6,14].

4. Conclusion

The biradical **1** with a thymine substituent has been synthesized. The ground state spin multiplicity of **1** has been found to be triplet ($S = 1$) from the magnetic susceptibility measurements. It has been found from the X-ray crystallographic analysis that the thymine substituents of **1** form aggregates based on intermolecular hydrogen bonds. The hydrogen bonding motif of **1** is the same as that of pristine thymine. Thus, introduction of the radical substituent into the nucleobase results in little disturbance to the molecular arrangement usually found in nucleobase molecules or intermolecular hydrogen bonding motifs. Thymine has been found to be an efficient element for molecular assembly of bio-inspired molecule-based magnets in terms of crystal engineering for nucleobase-substituted radicals. The present results indicate that the biradical **1** serves as

[3] Fixing one of the two adjustable parameters in Eq. (2) as estimated from the magnetically diluted samples ($2J_1/k_B = 21.4$ K) has resulted in a poor fit to the observed temperature dependence of χ_pT, which has not been repaired by reoptimization of the other parameter J_2.

an $S = 1$ component of the bio-inspired molecule-based ferrimagnets. Complexation of **1** with an adenine-substituted monoradical **2** is in progress.

single crystal that would afford structural determination by X-rays. The results of this paper speak to the isolation of a crystalline material, $\{Mn_5(OC(O)CH_3)_6(OC(O)C_6H_5)_4\}_\infty$ or ($\{Mn_5(OAc)_6(OBz)_4\}_\infty$), that we anticipate is directly related to the aforementioned room-temperature metal-organic ferromagnet.

2. Experimental

2.1. Preparation of $\{Mn_5(OAc)_6(OBz)_4\}_\infty$ (1)

Single crystals of **1** ($\{Mn_5(OAc)_6(OBz)_4\}_\infty$) were prepared by solvothermal reaction with all manipulations performed under anaerobic conditions using an N_2-filled Innovative Technologies (IT) glovebox and standard Schlenk techniques. Dried, deoxygenated toluene was collected from an IT solvent treatment system and degassed with N_2 for 10 min prior to introduction into the glovebox. Anhydrous Mn(acetate)$_2$ (98%) and benzoic acid (99.5%) were used as received from Aldrich. A typical procedure for the isolation of **1** consisted of loading Mn(OAc)$_2$ (0.210 g, 1.21 mmol) and benzoic acid (0.150 g, 1.23 mmol) into a 120 mL PTFE-lined Parr autoclave reactor with three mL toluene added as a crystallization solvent. After appropriate sealing in the glovebox, the bombs were introduced into an oven with temperature controlled via an Omega CN9600. The thermal profile that resulted in the formation of **1** was heating from room temperature to 110 °C at 20 °C/h with a 36 h soak followed by cooling to 30 °C at a rate of 4 °C/h. *Warning:* these reaction conditions are above the flash point of the toluene solvent and appropriate consideration should be made to safely manage thermal runaway and reactor rupture.

The Parr reactors were then loaded back into the glovebox with single crystals being stored under Fomblin oil and samples for analysis washed with 3 × 5 mL aliquots of dry toluene prior to being dried under vacuum. The total yield for this reaction was 0.251 g (93% based on Mn). Sealed capillary melting point data was measured with an Electrothermal melting point apparatus, m.p. 260–264 °C (dec.). Elemental analysis was performed at Galbraith Laboratories, Inc. (Knoxville, TN). *Anal.* Calc. for $C_{40}H_{38}O_{20}Mn_5$: C, 43.10; H, 3.40. Found: C, 42.56; H, 3.36%. IR spectra were recorded on KBr pellets using a Bruker FT-IR Vertex 70 spectrophotometer. Selected IR data (KBr, cm^{-1}): 3069 (m), 3015 (w) 2935 (w), 1591 (vs), 1554 (s), 1504 (s), 1494 (s, sh), 1409 (vs), 1342 (s), 1310 (m), 1284 (w), 1181 (w), 1159 (w), 1103 (vw), 1070 (m), 1049 (m), 1025 (s), 944 (m), 859 (m), 839 (m), 824 (w), 724 (s), 674 (s, sh), 663 (s), 614 (m), 573 (w), 534 (w), 511 (w), 461 (m), 429 (m).

2.2. X-ray crystallographic studies

Data for complex **1** was collected at 150 K on a Nonius Kappa CCD diffractometer with a graphite monochromator utilizing Mo Kα radiation (0.71073 Å, λ). Data collection parameters are listed in Table 1. Cell parameters were refined using up to 8182 reflections. An absorption correction by integration was applied, based on the measured indexed crystal faces. The structure was solved by direct methods using SHELX 97 [3] and refined using full-matrix least squares on F^2_{obs}. Non-hydrogen atoms were refined anisotropically, whereas the hydrogen atoms were placed in ideal, calculated positions with isotropic thermal parameters residing on their respective carbon atoms. Some disorder was observed in **1** (see Supporting Information) for one of three acetate ligands. In this instance, the acetate was refined anisotropically in two parts using respective site occupancy factors. The acetate ligand adopts two sets of alternate positions related by a 54° rotation of the acetate ligand with two components being defined as follows: component 1 – C41, C42, O41, O42; and component 2 – C41, C42a, O41a O42a. Each component exhibits a site occupancy factor of 50%.

Table 1
Crystal data and structure refinement for **1**

Empirical formula	C_{40} $H_{38}Mn_5O_{20}$
Formula weight	1113.40
Crystal system	orthorhombic
Space group	*Aba2* (41)
a (Å)	19.643(4)
b (Å)	24.014(5)
c (Å)	10.173(2)

D_{calc} (mg/m^3)	1.541
Color of crystal	colorless
Crystal size (mm)	0.23 × 0.15 × 0.03
T (°C)	−123
Radiation (λ, Å)	Mo Kα (0.71073)
μ (mm^{-1})	1.353
Maximum and minimum transmission	0.9605 and 0.7460
Scan mode	ω at 55/−55
2θ Limits (°)	3.98–50.04
$\pm h$	23
$\pm k$	28
$\pm l$	12
Number of reflections measured	8182
Number of unique reflections	4176
Restraints	7
Number of variables	323
R_1 [$I > 2\sigma(I)$]	0.0599
wR_2 (all data)	0.1538
R_{int}	0.0386
Goodness-of-fit	1.055

2.3. Other measurements

The magnetic data of powdered, microcrystalline samples were collected with a 9 T Quantum Design PPMS using the VSM option for M(H) measurements and the ACMS option for the in-phase and out-of-phase susceptibility determinations. Calibrations were competed using DyO and Pd references. Nylon sample holders and pharmaceutical gel caps showed less than 10^{-7} emu diamagnetic background.

3. Results and discussion

3.1. Synthesis

Previous reports teach the utility of ligand exchange reactions for the formation of mixed carboxylate manganese complexes [2,4,5]. An excellent description of the equilibria involved has been provided by Christou et al. who find that while mixed ligand complexes are readily observed, complete ligand substitution typically require either: (i) isolation of a mixed ligand complex followed by further treatment in the presence of excess carboxylic acid or (ii) azeotropic removal of acetic aced when an acetate-containing Mn complex is used as a starting material [5]. It is almost certain that the product reported in this work is the consequence of an equilibrium ligand exchange where the reaction of manganese acetate and benzoic acid in toluene under solvothermal conditions results in the isolation of **1** (Eq. 1). It seems plausible that there are several $Mn_x(OAc)_y(OBz)_z$ species present in the reaction mixture with the kinetics of crystallization favoring the formation of **1** under these conditions (i.e., ratio of reagents, dielectric properties of the solvent, etc.). It might be noted that excessive quantities of solvent give microcrystalline products but diffraction-quality crystals of **1** are observed after a reaction time of 36 h and a slow cooling to room temperature.

$$5Mn(OC(O)CH_3)_2 + 4HOC(O)C_6H_5 \xrightarrow[\text{Toluene}]{\Delta} \{Mn_5(OC(O)CH_3)_6(OC(O)C_6H_5)_4\}_\infty + 4CH_3CO_2H \quad (1)$$

It is noteworthy that $Mn(OAc)_2$ is not freely soluble in refluxing toluene but ^1H NMR control experiments show it to be at least slightly soluble at room temperature. While manganous acetate appears to be freely soluble in alcohols (e.g., MeOH and EtOH), these solvents were avoided given their propensity to co-crystallize with manganese carboxylates (e.g., $[Mn_4(OAc)_8(MeOH)_2]_n$ [6]). It seems reasonable to speculate that under the solvothermal conditions employed in this study, both the $Mn(OAc)_2$ starting reagent and the equilibrium products are soluble in toluene and that **1** crystallizes during the cooling period of the thermal treatment. Further experimentation toward understanding the kinetics of crystallization are ongoing.

3.2. Structure of $\{Mn_5(OAc)_6(OBz)_4\}_\infty$ (1)

Crystals of $\{Mn_5(OAc)_6(OBz)_4\}_\infty$ (**1**) are colorless with hexagonal thin plate-shape. A single crystal with the size of $0.03 \times 0.15 \times 0.23$ mm^3 was utilized for structural analysis. Crystallographic data and selected bond lengths/angles for **1** are listed in Tables 1 and 2, respectively. Compound **1** crystallizes in the orthorhombic *Aba2* space group and the asymmetric unit (Fig. 1) has the nominal formula $Mn_{2.5}(OC(O)CH_3)_3(OC(O)C_6H_5)_2$. Mn1, Mn2 and Mn3 are linked together through three acetate and two benzoate ligand bridges with Mn3 located on a C_2 axis special position. All of the Mn atoms maintain sixfold distorted octahedral coordination via acetate and benzoate ligands (Fig. 2). One benzoate and four acetate ligands are bonded to Mn1 (Fig. 2a) while Mn2 is bound by three benzoates and three acetates (Fig. 2b). Mn3 exhibits the least distorted O_h geometry with the two benzoate ligands occupying axial positions and four different acetate groups located along the equatorial plane.

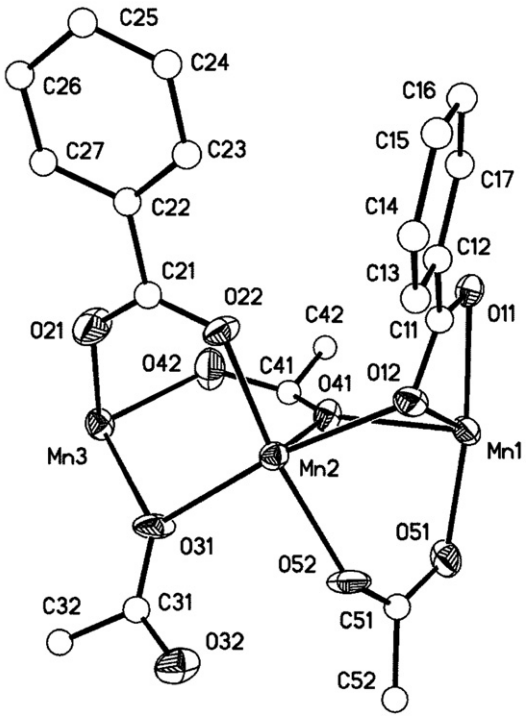

Fig. 1. ORTEP representation of the asymmetric unit of **1** with 50% probability thermal ellipsoids for Mn and O.

Acetate and benzoate ligands connect manganese atoms through four bridging modes which are shown in Fig. 3. All acetate ligands bridge three metal centers in a 3.21 (Harris notation) mode (Fig. 3a) or a disordered 3.21 mode (Fig. 3b). Benzoate ligands exhibit symmetric coordination and adopt either the 3.22 mode (Fig. 3c) or 2.11 mode (Fig. 3d). Overall, Mn-O distances range from 2.058 to 2.328 Å in this mixed ligand complex with mono-coordinating oxygen bonds always shorter than bridging carboxylates.

Fig. 4 shows ball-and-stick representations of manganese carboxylates that exhibit the rare 3.22 (or μ_3-symmetric) bridging mode. While the acetate ligand has been observed to bridge in this manner in both anhydrous γ-$Mn(OAc)_2$ (Fig. 4b) and $[Mn_4(OAc)_8 \cdot 2MeOH]_n$ (Fig. 4c), the observation of a 3.22 bridging mode for a benzoate ligand (Fig. 4a) appears to be unprecedented. It is interesting to note that for these μ_3-symmetric bridges, the distances between manganese atoms in **1** (3.317 and 3.405 Å in Fig. 4a) are shorter than those reported for both γ-$Mn(OAc)_2$ (3.840 Å in Fig. 4b) and $[Mn_4(OAc)_8 \cdot 2\ MeOH]_n$ (3.887 Å in Fig. 4c) presumably due to a strong coordination behavior of benzoate ligand.

Compound $\{Mn_5(OAc)_6(OBz)_4\}_\infty$ (**1**) has a unique two-dimensional structure as shown in Fig. 5. The sheets are defined as the *ac*-plane and consist of Mn_{12} loops as the basic units arranged in a honeycomb-like pattern. The symmetry relations of the metal centers within the 2D sheet is shown schematically in Fig. 6. The sheet may be described by defining an asymmetric unit (Mn3–Mn2–Mn1) as subunit a_1. A C_2 operation on a_1 generates subunit a_2 (Mn1–Mn2–Mn3). The sum of these two subunits (i.e., a_1 and a_2) defines block A. Next, a symmetric operation $(0.5 + X, 0.5 - Y, Z)$ on a_1 gives b_1 (Mn1–Mn2–Mn3) with

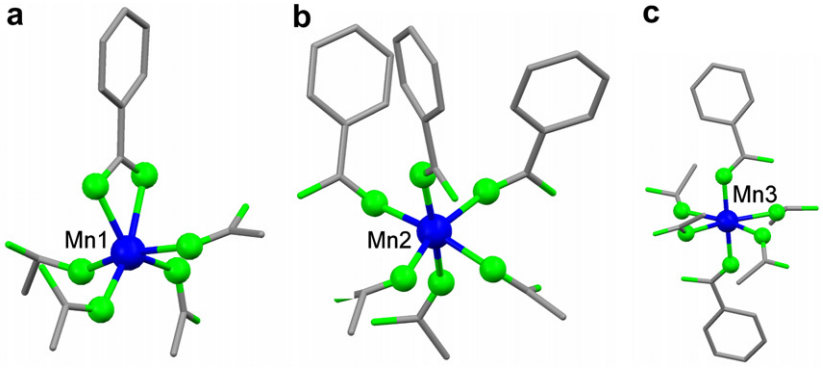

Fig. 2. Local coordination environments in **1** for: (a) Mn1, (b) Mn2 and (c) Mn3.

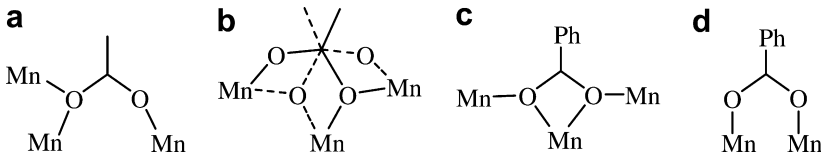

Fig. 3. The four types of bridging modes observed in the mixed carboxylate complex **1** with Harris notation of: (a) 3.21 acetate, (b) 3.21 acetate (disordered), (c) 3.22 benzoate and (d) 2.11 benzoate.

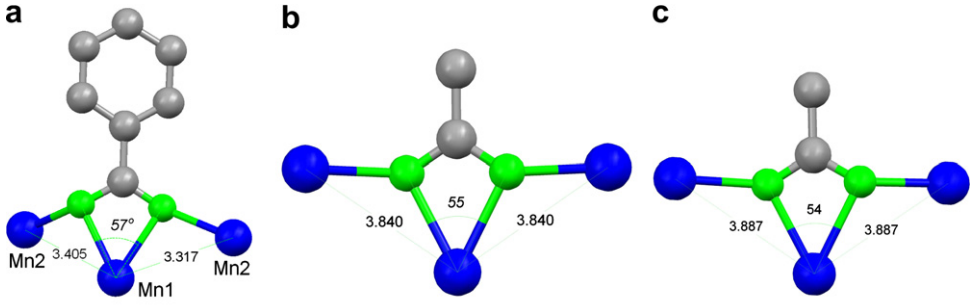

Fig. 4. Ball-and-stick rendering of the rare μ_3-symmetric (or 3.22) bridging mode in: (a) **1**, (b) γ-$Mn(OAc)_2$ (from Ref. [13]) and (c) $[Mn_4(OAc)_8 \cdot 2MeOH]_n$ (from Ref. [6]).

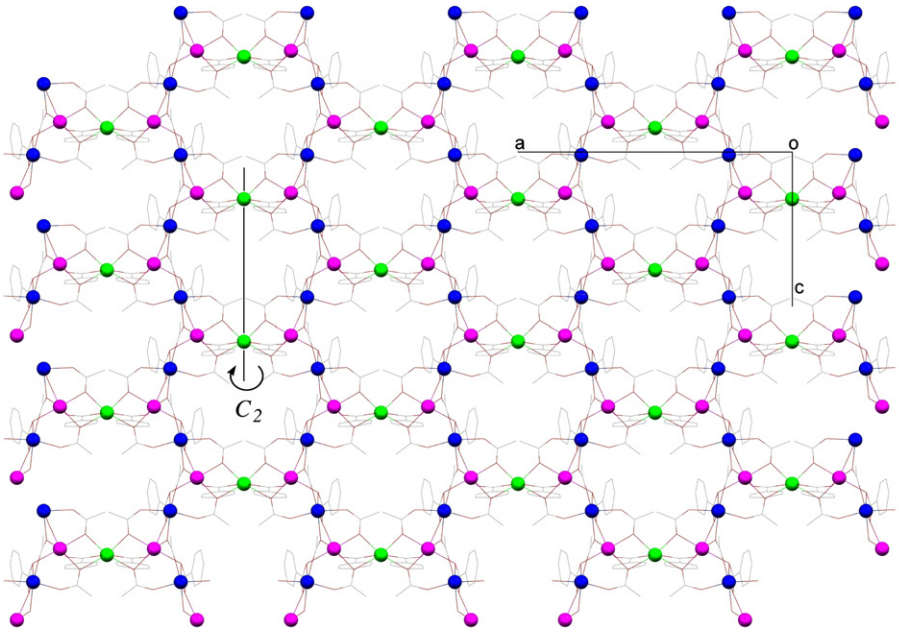

Fig. 5. A 2D sheet of **1** described in terms of a Mn2–Mn3–Mn2–$(Mn1)_2$ motif and a C_2 symmetry operation viewed along the *b*-axis. Mn atoms are drawn as balls (Mn3 in green, Mn2 in magenta and Mn1 in blue). Carbon and oxygen atoms are drawn as grey and red wire frames, respectively, and hydrogen atoms are omitted for clarity.

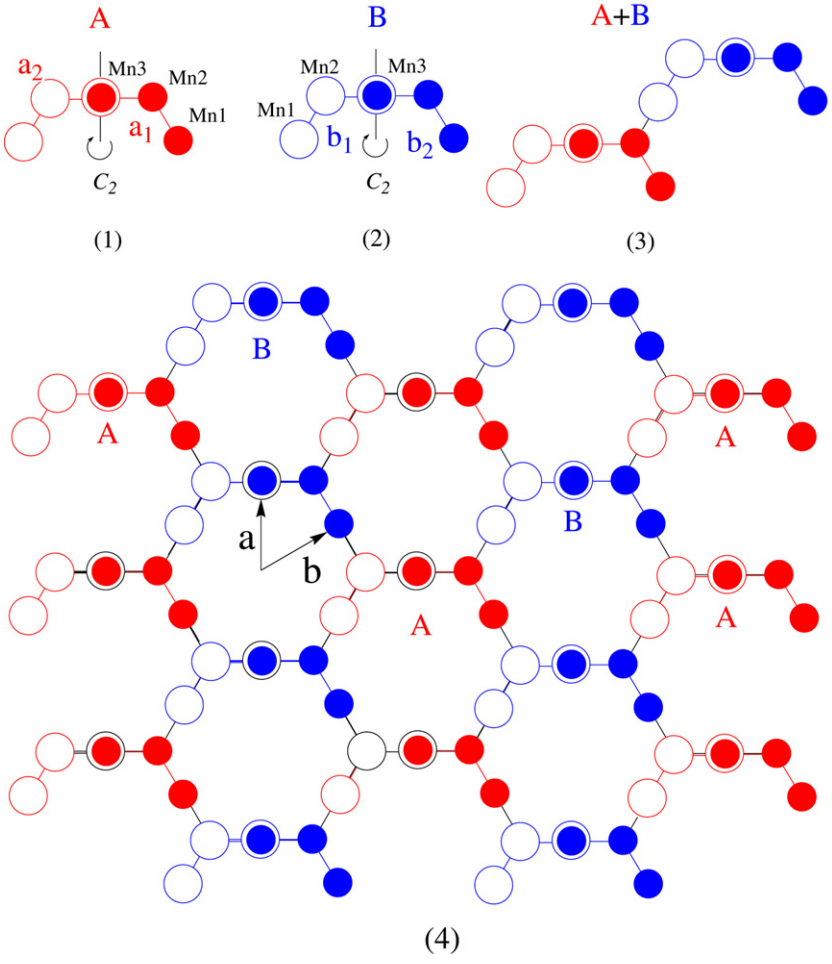

Fig. 6. Schematic diagram illustrating symmetry relations of metal centers in **1**. Red and blue parts are the two different repeating units $A + B$.

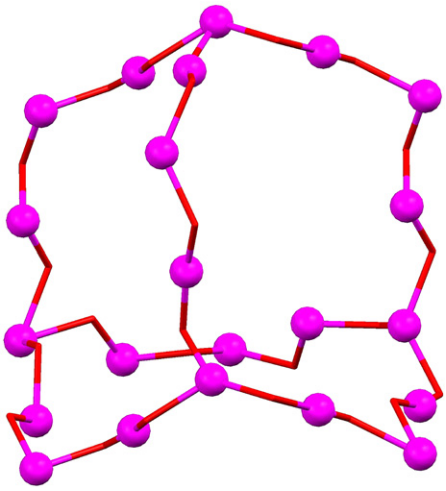

Fig. 7. Diamond-like structural arrangement of Mn_{12} loops observed in β- and γ-$Mn(OAc)_2$.

b_2 (Mn3–Mn2–Mn1) generated through a C_2 rotation on Mn3. The sum of these two units defines the second block, B ($B = b_1 + b_2$). $A + B$ is the basic repeating unit with hexagonal Mn_{12} loops generated through translations of $A + B$. A two-dimensional sheet emerges from the further extension of the structure through the same operation repeating in an ABA fashion as shown in Fig. 6. The crystal structure of $[Mn_{12}(OAc)_{14}(mda)_8] \cdot CH_3CN$ (where mda = methyldiethanolamine) was recently determined and Mn_{12} loops are reported [7]. However, $[Mn_{12}(OAc)_{14}(mda)_8] \cdot CH_3CN$ is different from **1** in that the Mn_{12} loops comprising the former exist as discrete molecules in the solid state whereas the loops in the latter are joined in a two-dimensional infinite array.

It is interesting to note that while both the β- and γ-phases of $Mn(OAc)_2$ are comprised of Mn_{12} loops, a diamond-like structure is observed (Fig. 7) versus a 2D sheet as in **1**. Two kinds of Mn atoms are reported with Mn–Mn distances of 3.283 and 3.840 Å. If other atoms are omitted, Mn1 is surrounded by four Mn2 atoms and Mn2 is connected to two Mn1 atoms. By way of comparison, the distances between Mn atoms in **1** are shorter at 3.317, 3.405 and 3.398 Å.

Fig. 8 shows a ball-and-stick representation of two layers of **1** viewed down the *ac*-plane. The distance between adjacent layers is 12.007 Å which is equivalent to one half the *b*-axis. It is shown that the Mn2 and Mn3 atoms are located in a plane with Mn1 atoms dispose slightly above and below the plane in a periodic fashion. The differential orientations of benzoate ligands led to different environments for the Mn_{12}-based hexagons that exist in a chair configuration akin to cyclohexane. It is interesting to note that there is no π–π overlap between the phenyl rings of adjacent sheets with the closest C—C distance being 3.740 Å. In addition, there is only one C—C contact between adjacent phenyl rings and the dihedral angle is nearly 90°. This is similar to the structure of $\{Mn(OBz)_2 \cdot 2H_2O\}_\infty$ where Mn_4 squares are arranged in 2D sheets that also exhibit no intersheet π–π interactions [8]. By way of comparison, π-stacking is observed between neighboring benzoate groups in the one-dimensional chain polymer $[Mn(OMe)(OBz)_2]_n$ where an average interchain phenyl-to-phenyl C—C distance of 3.719 Å was reported [9]. The authors report the π-interactions could be responsible for weak ferromagnetism observed at $T < 8$ K where the antiferromagnetically coupled chains presumably begin to align with neighboring chains through the benzoate linkages. A related 1D chain compound (i.e., $[Mn(OMe)(OAc)_2]_n$) contains no phenyl groups for such π interactions but exhibits nearly identical magnetic behavior at low temperature (i.e., weak ferromagnetic interaction between chains) [10]. A similar, yet more pronounced effect has been reported for $\{[Mn(OH)(OAc)_2] \cdot H_2O \cdot HOAc\}_n$ where stronger interchain interactions are presumably mediated via hydrogen-bonding [6,11].

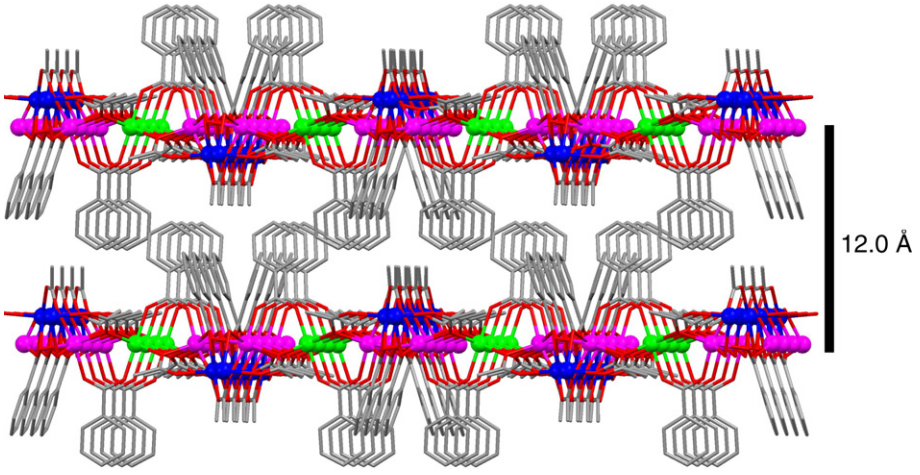

Fig. 8. The molecular structure of **1** viewed along the *c*-axis illustrating interplanar interaction. Mn atoms are drawn as balls (Mn3 in green, Mn2 in magenta and Mn1 in blue). Carbon and oxygen atoms are drawn as grey and red wire frames, respectively, and hydrogen atoms are omitted for clarity.

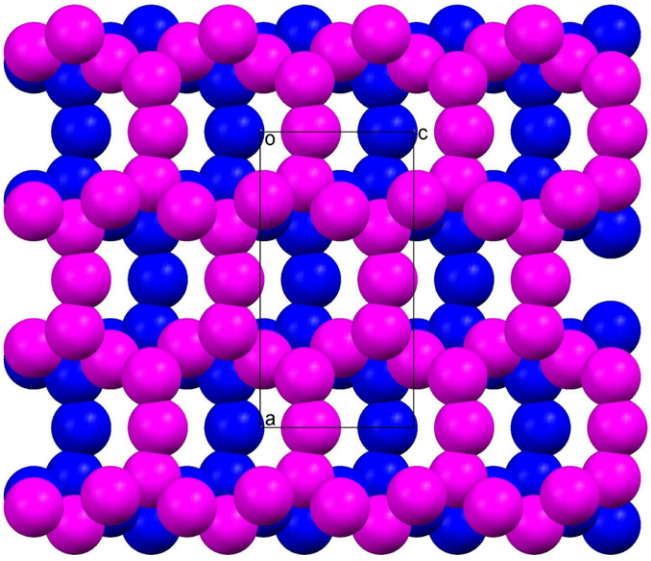

Fig. 9. Spacefill packing diagram of Mn atoms in **1** viewed along the *b*-axis illustrating the eclipsed packing of a first layer (magenta) and second layer (blue).

The stacking of the sheets in **1** is illustrated in Fig. 9 where two layers of the Mn atoms are viewed along the *b*-axis. The honeycomb-like sheets are again apparent with the first layer shown in magenta. The second layer (blue) lies below the first and is translated by one-half the *c*-axis with no translation along the *a*-direction (implicit in this figure is a translation of one-half the *b*-axis).

3.3. Magnetic properties of *1*

Thermomagnetic ac and dc characterization were completed on the title compound as represented by Fig. 10. Although single crystals were available for XRD, they were too small in volume and mass for individual magnetic measurements such that the following results represent a collection of single crystals packed into a holder with isotropic axis orientation. A ferromagnetic to antiferromagnetic transition is observed at 9.5 K as evidenced by the following: Curie-Weiss temperature transition from $\theta = +4$ K to $\theta = -53$ K at $T = 10$ K; a finite value of the out of phase susceptibility $\chi'' > 0$ and coercivity $H_c > 0$ for $T < 9.5$ K; a $d(\chi T)/dT$ sign change at $T = 12$ K; and, a reduction in the saturation moment above $T = 10$ K. Although each of the magnetic observations alone could constitute some other type of magnetic exchange and response, the combined pieces of evidence led to suggest that a FM to AFM exchange occurs. Similar magnetic transition behavior has been observed for various phases of anhydrous manganese (II) acetate where the low temperature magnetic behavior is described in terms of canted antiferromagnetism with transition temperatures of 4.5, 15 and 40 K for the α-, β- and γ-phases, respectively [12,13]. In addition, $\{Mn(OBz)_2 \cdot 2H_2O\}_\infty$ is also a canted antiferromagnet with $T_c \sim 3.5$ K [8].

From the inverse susceptibility curve (Fig. 10a) it is interesting to note a transition to stronger antiferromagnetic exchange with increasing temperature where the Weiss temperature increases from $\theta = -53$ K to $\theta = -165$ K at $T = 159$ K. Future directions will include

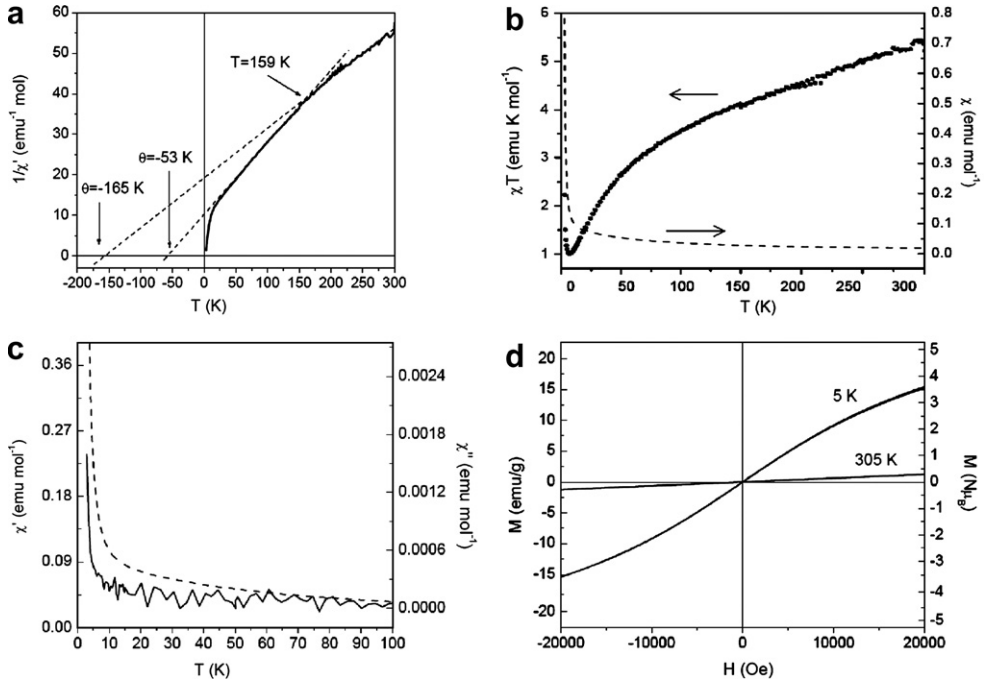

Fig. 10. Magnetic characterization of **1** showing: (a) inverse susceptibility; (b) susceptibility temperature product (•) and susceptibility (---) vs. temperature; (c) low temperature region of real (---) and imaginary (—) susceptibility components; and (d) magnetization as a function of applied field.

growth of larger single crystals that will allow for separation of $\chi_{\perp}$ from $\chi_{\parallel}$ to compare with the expected result for non-interacting high spin Mn(II) as well as any information regarding the role played by intersheet exchange.

4. Conclusions

A new mixed carboxylate manganese (II) complex is reported. $\{Mn_5(OAc)_6(OBz)_4\}_{\infty}$ (**1**) has a 2D structure that consists of Mn_{12} loops arranged in a honeycomb-like fashion. The structure is related to another manganese (II) carboxylate, $\{Mn(OBz)_2 \cdot 2H_2O\}_{\infty}$, and both 2D complexes exhibit little or no π-π overlap between phenyl groups of adjacent sheets. In addition, both complexes are canted antiferromagnets with transition temperatures of 9.5 and ~3.5 K for **1** and $\{Mn(OBz)_2 \cdot 2H_2O\}_{\infty}$, respectively. Future synthetic efforts will be aimed at the formation of single crystals with targeted *x*:*y*:*z* ratio (i.e., for $Mn_x(OAc)_y(OBz)_z$) as a means of proving the structure of a related complex that exhibits remnant moment at room temperature. In order to allow application of **1** in magnetoelectronics, control over thin film formation and an increase in the state of metallicity will need to be realized. These needs are being addressed via vapor deposition/ligand exchange and ligand replacement by radical (polaron) ligands, respectively.

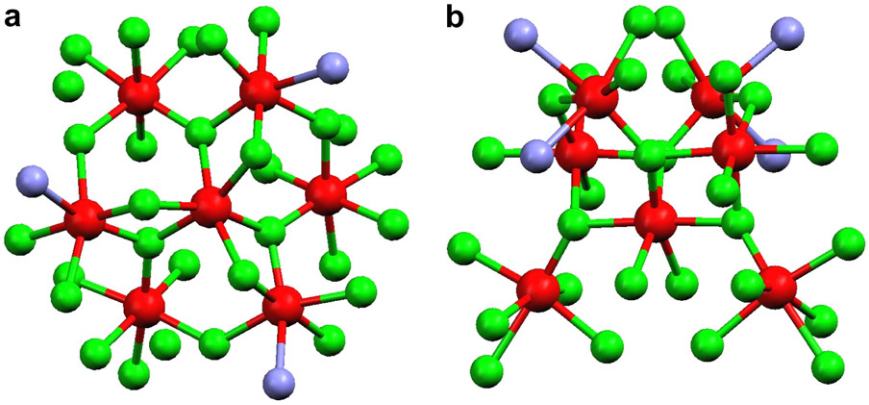

Fig. 1. (a) Structure of complex **1**; hydrogen atoms and t-butyl groups have been omitted for clarity. The C_3 symmetry axis is out of the page. Color code: Fe^{III} – red; O – green; N – blue. (b) Structure of complex **2**; hydrogen atoms and phenyl rings have been omitted for clarity. Color code: Fe^{III} – red; O – green; N – blue. (For interpretation of the references in color in this figure legend, the reader is referred to the web version of this article.)

grease to prevent solvent loss during cooling in helium gas at atmospheric pressure. A sensitive cavity-perturbation technique and a millimeter-wave vector network analyzer (MVNA) were used to detect the EPR signals (details are given elsewhere [8,9]). The spectra were obtained at fixed microwave frequencies and temperatures while sweeping the DC magnetic field.

3. Data and discussion

The magnetic axial direction of complex **2** was hard to determine due to its low symmetry. Therefore, single-axis angle-dependent HFEPR studies only allow us to locate the plane perpendicular to the axial direction. Extensive measurements at various temperatures and frequencies were then performed with DC fields applied in this plane to determine the ground state transitions and zero-field splitting (zfs) parameters in the spin Hamiltonian, $\widehat{H} = D\widehat{S}_z^2 + E(\widehat{S}_x^2 - \widehat{S}_y^2) + g\mu_B\vec{B}\cdot\widehat{S}$.

Fig. 2 shows temperature-dependent spectra for complex **2** taken at 197 GHz, with the field in the (xy-) plane perpendicular to the axial (z-) direction. A total of five main peaks are observed, thus confirming the $S = 5/2$ ground state of the molecule. Each peak exhibits fine structures which are most probably caused by weak disorder, which leads to distributions in the zfs parameters. The lowest field peak (labeled a) corresponds to the excitation from the ground state within the $S = 5/2$ multiplet, since it clearly becomes stronger upon lowering the temperature. Based upon this observation, we conclude that the magnetic anisotropy of complex **2** is of the easy-plane type, i.e. it possesses a positive D value. The inset to Fig. 2 displays the Zeeman diagram for a spin $S = 5/2$ system with a positive D value and the field applied within the easy plane. The five observed transitions (a–e) are indicated in the inset.

We note that it is possible to fit the spectra in Fig. 2 assuming a negative D value. However, we cannot account for the angle dependence on the basis of such an assignment. Consequently, it is clear that D must be positive. Further frequency dependent studies were subsequently performed with the magnetic field applied within the easy plane in order to quantify the zfs parameters for complex **2**. Fig. 3 displays the positions of the observed EPR peaks plotted versus frequency. Superimposed on the data is the best fit to the above Hamiltonian; the curves correspond to the energy differences between levels connected by the arrows in the Zeeman diagram in Fig. 2. The obtained zfs parameters are: $D = +0.62\ \mathrm{cm}^{-1}$, $g_{xy} = 2.00$ and a significant rhombic anisotropy, $|E| \geqslant 0.067\ \mathrm{cm}^{-1}$. The obtained value of E is a lower limit, as the orientation of the field within the easy plane is not exactly known. In order to determine the precise value of E, angle-dependent studies would have to be performed within the easy plane. However, since this complex does not appear to be a SMM, such studies were not performed.

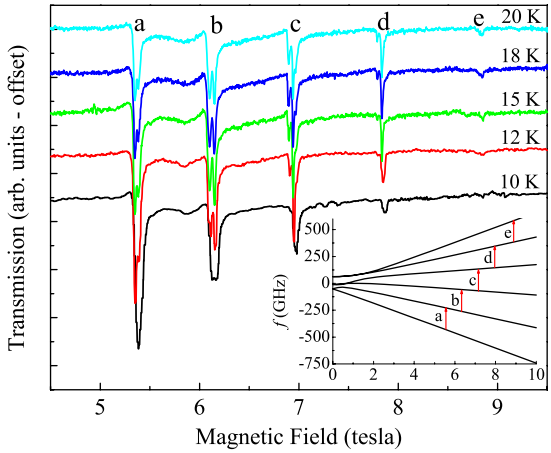

Fig. 2. Temperature-dependent EPR spectra of complex **2** taken at 197 GHz with the DC magnetic field applied within the easy plane. The inset shows the simulated Zeeman diagram for a positive D system. Transitions labeled 'a' (ground state transition) to 'e' in the spectra are also indicated in the inset. For the negative D case (see Fig. 3), the ground state transition would appear at the highest fields.

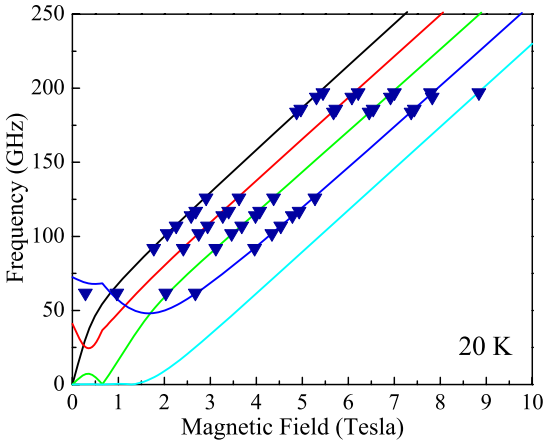

Fig. 3. Easy plane EPR peak positions for complex **2** plotted versus frequency. The solid lines are simulations using the zfs parameters given in the text.

On the other hand, complex **1** exhibits SMM-like EPR spectra. Fig. 4 shows single crystal data obtained at 51.8 GHz and at different temperatures, with the DC magnetic field applied within the hard-plane. Once again, five EPR peaks are observed (labeled 1–5), confirming the $S = 5/2$ ground state of this molecule. The fact that the strongest peak is seen at the highest field (opposite to what was observed for complex **2**) indicates that D is negative. Another set of three weaker peaks can be seen as shoulders on three of the main peaks (labeled with subscripts x). There are several possible explanations for these weaker peaks, including: a low lying $S = 3/2$ excited state; intermolecular exchange interactions; or disorder-induced strains in the sample leading to different molecular species [10]. Recent calculations seem to exclude the possibility of low lying excited states [6]. However, further studies are required for precise determination of the origin of the weaker EPR peaks.

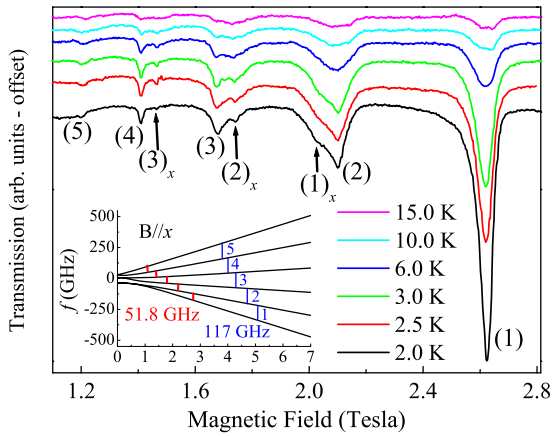

Fig. 4. HFEPR spectra of complex **1** taken at 51.8 GHz, at temperatures from 2 to 15 K. The inset shows the simulated Zeeman diagram for a negative D system. Transitions labeled (1) (ground state transition) to (5) in the spectra are also indicated in the inset for two different frequencies.

The inset to Fig. 4 shows the Zeeman diagram for a spin $S = 5/2$ system with a negative D value and the field applied within the hard plane. The five observed transitions (1–5) are shown for two different EPR frequencies (51.8 and 117 GHz). Because the energy differences between Zeeman-split levels are much smaller at lower fields, less thermal energy is required to populate the higher-lying levels within the $S = 5/2$ state. Higher frequency EPR

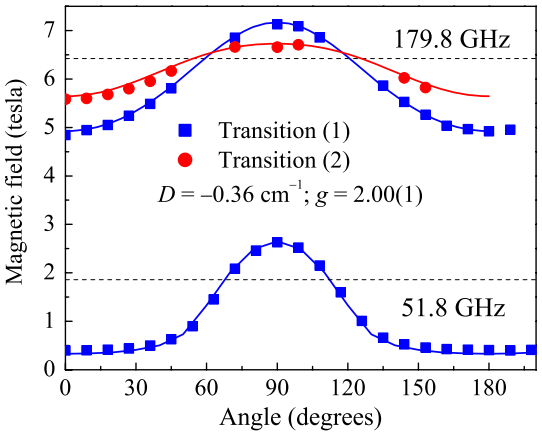

Fig. 5. Plot of the HFEPR peak positions for complex **1** obtained from angle-dependent measurements at 51.8 and 179.8 GHz, while rotating the field from the c-axis (0°) to the ab-plane (90°). The dashed lines represent the $g = 2.00$ references for each frequency, and the solid lines are simulations with the given parameters.

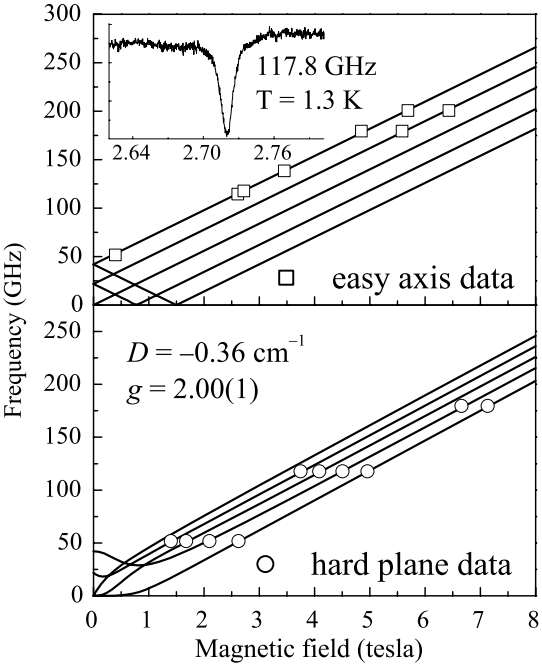

Fig. 6. Energy difference diagrams for complex **1** constructed from frequency-dependent measurements with the field along both the easy-axis and within the hard-plane. The solid lines are simulations with the given parameters. The inset shows a typical easy-axis EPR peak for a crystal of complex **1**, with a line width of about a hundred gauss.

spectra (not shown here) taken at 117.8 GHz show only peak (1) at 1.3 K.

Angle-dependent measurements from the *c*-axis to *ab*-plane were performed at 6 K, and frequencies of 51.8 and 179.8 GHz, as shown in Fig. 5. Superimposed on the data points are simulations using the following simple Hamiltonian (the parameters are listed in the figure): $\widehat{H} = D\widehat{S}_z^2 + g\mu_B\vec{B}\cdot\widehat{S}$. The solid blue squares represent the transition from the ground state [labeled (1) in Fig. 4]; the red circles correspond to transition (2). The two dashed lines indicate the isotropic positions ($D = 0$, $g = 2.00$). The fact that the peaks shift approximately twice as far to the low field side of the $g = 2.00$ reference, as compared to the high field side, implies a uniaxial anisotropy with a negative D parameter. Indeed, the high frequency data fit very well to a $(1 - 3\cos^2\theta)$ angle dependence, which is expected for a SMM in the high field limit. The angle corresponding to $\theta = 0°$ marks the easy axis orientation.

Precise determination of the spin Hamiltonian parameters D and g is achieved through EPR spectra taken at various frequencies (50–200 GHz) for both the easy-axis and hard-plane orientations, as shown in Fig. 6. Simulations for both the easy-axis and hard-plane diagrams suggest that the system is best described with $D = -0.36\ \text{cm}^{-1}$ and $g = 2.00(1)$. These parameters were used to simulate the angle-dependent EPR peak positions at 179.8 and 51.8 GHz, as shown in Fig. 5.

It is worth noting that the line width of the easy-axis EPR peak (inset of Fig. 6) is much sharper than the hard-plane ones. Further study is required to identify the cause of this difference. The easy-axis line width for complex **1** is ~0.01 T, which is considerably narrower than other well studied SMMs [10,11]. The extraordinary sharpness of the EPR spectra seems to confirm the reduced decoherence in this system ($T_2 \approx 3$ ns) relative to other known SMMs, thus making it an interesting candidate for studies of coherent quantum magnetization dynamics.

4. Summary and conclusions

On the basis of detailed frequency and field orientation dependent HFEPR studies, we show that $[Fe_7O_3(O_2CBu^t)_9(mda)_3(H_2O)_3]$ (**1**) represents a rare example of a half-integer-spin ($S = 5/2$) iron SMM, having a negative uniaxial zero-field-splitting parameter $D = -0.36\ \text{cm}^{-1}$. Meanwhile, $[Fe_7O_4(O_2CPh)_{11}(dmem)_2]$ (**2**) is not a SMM. The EPR linewidth for complex **1** is considerably narrower in comparison to spectra obtained for other SMMs, making it an interesting candidate for studies of coherent quantum magnetization dynamics.

(CH_2Cl_2)] [24]. Nonetheless, immediate reactions occur for A = BQ, CA, DCNQ, and $BQ(OH)_2$ forming a dark, amorphous product of nominal $VA_2 \cdot zCH_2Cl_2$ composition (Eq. (1)).

In addition we report on the precipitates formed from the reaction of $[V(NCMe)_6][BF_4]_2$ with both $[CA]^{\cdot-}$ and $[DDQ]^{\cdot-}$ (Eq. (2)). This latter route has been successful in preparing magnets of nominal $M[TCNQ]_2$ composition, albeit the T_c for magnets prepared via this route are typically reduced with respect to those of similar composition prepared via other routes [9,25].

$$V(CO)_6 + 2A \rightarrow VA_2 \cdot zCH_2Cl_2 + 6CO \quad (1)$$

$$[V^{II}(NCMe)_6]^{2+} + xA^- \rightarrow VA_x \quad (2)$$

2. Experimental

All manipulations involving the use of vanadium compounds were performed under a nitrogen atmosphere (<1 ppm O_2 and <1 ppm H_2O) using standard Schlenk techniques and Vacuum Atmospheres DriLab gloveboxes. CH_2Cl_2 was sparged with nitrogen and passed through two columns of activated alumina prior to use [26]. $V(CO)_6$ was prepared from $[NEt_4][V(CO)_6]$ and phosphoric acid and purified by sublimation at 25° C and 0.05 Torr [27]. $[V(NCMe)_6][BF_4]_2$ [28,29] and $[NEt_4][DDQ]$ [13,30] were prepared by a literature method. $[NEt_4][CA]$ was prepared by a modified literature method [31], as $[NEt_4]Cl$ was slowly added to an acetone solution of NaCA in a dry-ice bath under N_2(g) atmosphere. After stirring for 1 h, the white precipitate was filtered, and the filtrate was concentrated *in vacuo* to ca. one fifth, and the dark red solid was collected, and recrystallized from a CH_2Cl_2/hexane mixture. The benzoquinones were purchased from Acros or Aldrich and purified by sublimation or recrystallization from toluene except for 2,3-dicyano-1,4-naphthoquinone (DCNQ) that was prepared according to a published procedure [32].

V[BQ]$_2$. $V(CO)_6$ (50.9 mg, 0.232 mmol) was dissolved in ~5 mL of CH_2Cl_2 and the bright yellow solution was added dropwise to a stirred yellow solution of 1,4-benzoquinone (BQ) (50.2 mg, 0.464 mmol) dissolved in ~2 mL of CH_2Cl_2. A rapid reaction occurred and the mixture became black and CO evolved. After the evolution of CO had ceased the vial containing the mixture was closed and allowed to stand for 12 h before the black solids were collected by suction filtration (Yield: 60.0 mg; 98%). IR(KBr, cm^{-1}): 1570, 1482(s), 1194(s), 831(s). *Anal.* Cal. for $V[BQ]_2$, $C_{12}H_8O_4V$: C, 53.95; H, 3.02; N, 0.00. Found: 54.16, 2.93, <0.2%.

V[CA]$_2$. $V(CO)_6$ (26.0 mg, 0.119 mmol) was dissolved in ~5 mL of CH_2Cl_2 and the bright yellow solution was added dropwise to a stirred suspension of *p*-chloranil (CA) (58.1 mg, 0.236 mmol) in ~10 mL of CH_2Cl_2. A rapid reaction occurred and the mixture became black and CO was evolved. After the evolution of CO had ceased the vial containing the mixture was closed and allowed to stand for

12 h before the black solids were collected by suction filtration (Yield: 55.5 mg: 84%). IR(KBr, cm^{-1}): 1528, 1391(s), 1170, 931(s), 721, 581. Anal. Calc. for $V[CA]_2 \cdot 0.15CH_2Cl_2$, $C_{12.15}H_{0.3}Cl_{8.3}O_4V$: C, 26.28; H, 0.05; N, 0.00; V, 9.17. Found: 26.52, <0.2, <0.2, 8.90%.

V[DCNQ]$_2$. $V(CO)_6$ (28.4 mg, 0.130 mmol) was dissolved in ~5 mL of CH_2Cl_2 and the bright yellow solution was added dropwise to a stirred yellow solution of 2,3-dicyano-1,4-naphthoquinone (DCNQ) (53.4 mg, 0.257 mmol) dissolved in ~10 mL of CH_2Cl_2. A rapid reaction occurred and the mixture became black and CO was evolved. After the evolution of CO had ceased the vial containing the mixture was closed and allowed to stand for 12 h before the black solids were collected by suction filtration (Yield: 65.7 mg: 99%). IR(KBr, cm^{-1}): 2223, 1385(s), 1015, 896. *Anal.* Calc. for $V[DCNQ]_2 \cdot 0.10CH_2Cl_2$, $C_{24.1}H_{8.2}Cl_{0.2}N_4O_4V$: C, 60.84; H, 1.74; N, 11.78. Found: 61.09, 1.70, 11.38%.

V[BQ(OH)$_2$]$_2$. $V(CO)_6$ (39.4 mg, 0.180 mmol) was dissolved in about 5 mL of CH_2Cl_2 and the bright yellow solution was added dropwise to a stirred suspension of 2,5-dihydroxy-1,4-benzoquinone ($BQ(OH)_2$) (49.9 mg, 0.356 mmol) in about 10 mL of CH_2Cl_2. A slower reaction occurred and the mixture gradually became black over a period of about 30 min. The vial containing the mixture was then closed and allowed to stand for 6 h before the black solids were collected by suction filtration. Yield: 59.5 mg. The product was visibly contaminated with unreacted $BQ(OH)_2$. IR(KBr, cm^{-1}): 1502(s, br), 1360, 1248, 1159, 878. *Anal.* Calc. for $V[BQ(OH)_2]_2$: $C_{12}H_8O_8V$: C, 43.53; H, 2.44; N, 0.00. Found: 43.43, 2.25, <0.2%.

[NBu$_4$]$_{0.5}$V[CA]$_{2.5}$ · 0.34MeCN. $[V(NCMe)_6][BF_4]_2$ (32 mg, 0.068 mmol) was dissolved in 10 mL of CH_2Cl_2 to which $[NBu_4][CA]$ (102 mg, 0.21 mmol) dissolved in CH_2Cl_2/MeCN (10 mL, v/v, 9.5:0.5) was added at room temperature, and a black precipitate slowly formed. After stirring for 2 h the black solid was isolated by suction filtration, washed with CH_2Cl_2, and dried *in vacuo* (Yield: 42 mg: 77%). IR(KBr, cm^{-1}): 2964, 2876, 1532, 1401(s), 1170, 920(s), 717, 554. *Anal.* Calc. for $[NBu_4]_{0.5}V[CA]_{2.5} \cdot 0.34MeCN$, $C_{23.68}H_{19.02}Cl_{10}N_{0.84}O_5V$: C, 35.52; H, 2.39; N, 1.47. Found: 35.73, 2.82, 1.27%.

[NBu$_4$]V[DDQ]$_3$ · 0.1MeCN. $[V(NCMe)_6][BF_4]_2$ (39 mg, 0.083 mmol) was dissolved in 10 mL of CH_2Cl_2 to which $[NBu_4][DDQ]$ (118 mg, 0.25 mmol) dissolved in CH_2Cl_2/MeCN (10 mL, v/v, 9.5:0.5) was added at room temperature, and a dark green precipitate slowly formed. After stirring for 2 h the dark green solid was isolated by suction filtration, washed with CH_2Cl_2, and dried *in vacuo* (Yield: 51 mg: 63%). IR(KBr, cm^{-1}): 2964, 2878, 2250(sh), 2226, 1542, 1408(s), 1235, 1093, 1001, 908, 575. *Anal.* Calc. for $[NBu_4]V[DDQ]_3 \cdot 0.1MeCN$, $C_{40.2}H_{36.3}Cl_6N_{7.1}O_6V$: C, 49.94; H, 3.75; N, 9.90. Found: 49.35, 3.74, 10.16%.

Infrared spectra were taken from 400 to 4000 cm^{-1} using a Bruker Tensor 37 FTIR spectrometer (±1 cm^{-1}). Samples were prepared as KBr pellets under an inert atmosphere. Magnetic susceptibility measurements were made between 5 and 300 K using a Quantum Design MPMS-5XL 5 T SQUID magnetometer equipped with a reciprocating sample measurement system as previously described [33]. Measurements were made on powders contained in airtight Delrin holders packed with quartz wool to prevent sample movement in the holder. The data were corrected for the diamagnetism of the holders.

3. Results and discussion

Hexacarbonylvanadium(0) readily reacts with benzoquinone (BQ) and three related compounds: CA, $BQ(OH)_2$, and DCNQ, to form materials of $V^{II}(A)_2 \cdot zCH_2Cl_2$ ($z \leqslant 0.1$) composition. During the reaction the quinone likely forms a coordination complex with vanadium, followed by the release of CO and electron transfer in which V(0) ultimately undergoes a two electron oxidation to vanadium(II) and two quinones, A, are reduced to semiquinones, $A^{\cdot -}$. In all cases the major ν_{CO} features of the IR spectra of the benzoquinones are broadened and shifted to lower energy consistent with the formation of coordination to vanadium and the formation of radical anions, and formation of V=O, as evidenced by a new absorption ~1000 cm^{-1}, does not occur. For example, $[NBu_4][CA]$ and $[NBu_4][DDQ]$ have strong ν_{CO} absorptions at 1523 and 1570 cm^{-1} that upon coordination to V(II) ions are shifted to lower frequencies, i.e. 1401 cm^{-1} for $(NBu_4)_{0.5}V[CA]_{2.5}$ and 1408 cm^{-1} for $(NBu_4)V[DDQ]_3$. Likewise, when nitriles are present, the ν_{CN} is shifted to lower energy.

In contrast, the metathesis reaction of $[V(NCMe)_6][BF_4]_2$ with $[CA]^{\cdot -}$ and $[DDQ]^{\cdot -}$ forms precipitates of different composition, namely, $(NBu_4)_{0.5}V[CA]_{2.5}$ and $(NBu_4)V[DDQ]_3$, respectively. Both compounds show split absorptions at 2964 and 2876 cm^{-1} for $(NBu_4)_{0.5}V[CA]_{2.5}$ and at 2964 and 2878 cm^{-1} for $(NBu_4)V[DDQ]_3$, indicative of $[NBu_4]^+$ cation. In the IR spectrum of $(NBu_4)_{0.5}V[CA]_{2.5}$, the strong, single absorptions characteristic of coordinated $[CA]^{\cdot -}$ are observed at 1401 and 920 cm^{-1}. These peaks are slightly different to those of $V[CA]_2$ that made from $V(CO)_6$ that occur at 1391 and 931 cm^{-1}. In the IR spectrum of $(NBu_4)V[DDQ]_3$, the strong peak characteristic of coordinated DDQ is appeared at 1408 cm^{-1}. Additionally, the ν_{CN} peak shows at 2250 and 2226 cm^{-1}, indicative of the coordination of cyano group.

Powder diffraction data, like those observed for $V[TCNE]_x$ [6a], indicate that each of these materials is amorphous. Unlike $V^{II}[A]_2 \cdot zCH_2Cl_2$ (A = BQ, CA) have semiquinones that can solely bridge between two V^{II}s and these materials are proposed to nominally have the structure illustrated in Fig. 2b. For A = DCNQ, DDQ, and $BQ(OH)_2$ the nitrile nitrogens for the former, and chelating nature of the latter's oxygens can lead to an extended structure with octahedral V(II) sites. Further studies are in progress to elucidate the structure.

The 5–300 K magnetic susceptibility, $\chi(T)$, reported as $\chi T(T)$ and $\chi^{-1}(T)$ was determined for **V[BQ(OH)$_2$]$_2$**, **V[BQ]$_2$**, **V[DCNQ]$_2$**, and **V[CA]$_2$**. The room temperature

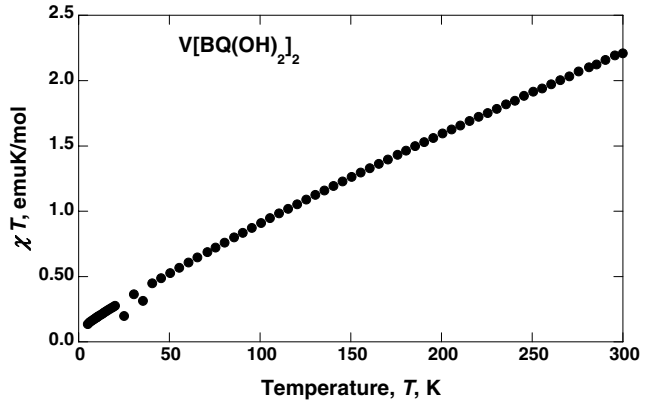

Fig. 3. The 5–300 K $\chi T(T)$ for **V[BQ(OH)$_2$]$_2$**.

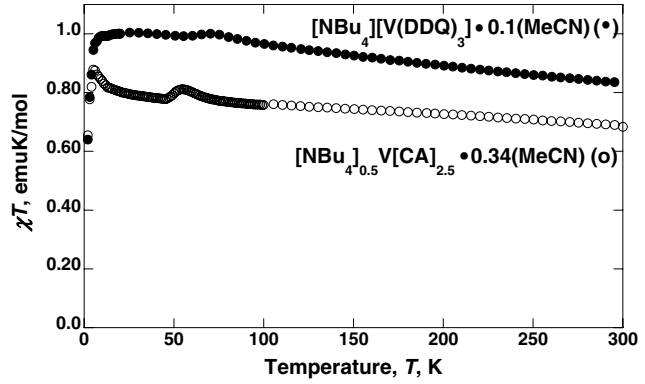

Fig. 4. The 5–300 K $\chi T(T)$ for $[NBu_4]V[DDQ]_3 \cdot 0.1(MeCN)$ (●) and $[NBu_4]_{0.5}V[CA]_{2.5} \cdot 0.34(MeCN)$ (○).

χT value for **V[BQ(OH)$_2$]$_2$** is 2.20 emuOe/mol, which is less than the expected spin-only value of 2.63 emuOe/mol, indicative of antiferromagnetic coupling, Fig. 3. Strong antiferromagnetic coupling is observed from the $\chi T(T)$ data that decreases almost linearly with decreasing temperature down to 5 K. The same trend of strong antiferromagnetic coupling with the lack of evidence for magnetic ordering is also observed for **V[BQ]$_2$**, **V[DCNQ]$_2$**, and **V[CA]$_2$**.

$[NBu_4]V[DDQ]_3 \cdot 0.1MeCN$ and **$[NBu_4]_{0.5}V[CA]_{2.5} \cdot 0.34MeCN$** have reduced room temperature χT values 0.83 and 0.68 emuOe/mol (Fig. 4), respectively, that suggests stronger antiferromagnetic coupling than observed for **V[BQ(OH)$_2$]$_2$**, **V[BQ]$_2$**, **V[DCNQ]$_2$**, and **V[CA]$_2$**. However, $\chi T(T)$ increases with decreasing temperature until below 8 K when it drops in value, This suggests ferromagnetic coupling, albeit weak, is present; however, magnetic ordering does not occur. Due to the lack of magnetic ordering, ferro-, ferri-, or antiferro-magnetic, further detailed studies were not execute.

4. Conclusion

The reaction of either quinones with $V^o(CO)_6$ or $[quinones]^{\cdot -}$ with $[V^{II}(NCMe)_6]^{2+}$ forms materials, albeit of differing compositions, possessing $[quinones]^{\cdot -}$ bonded to V(II). The $S = 1/2$ $[quinones]^{\cdot -}$ antiferromagnetically coupling to the $S = 3/2$, but do not yield magnetically ordered materials. This is in contrast to $S = 1/2$ cyanocarbons radical anions, and is attributed to the greater number of V(II) sites that can magnetically couple to a cyanocarbon with respect to the two for a $[quinones]^{\cdot -}$.

were carried out under anaerobic conditions using standard Schlenk apparatus and degassed solvents to avoid oxidation by atmospheric dioxygen. $MnCl_2 \cdot 4H_2O$ (59 mg, 0.3 mmol) was dissolved in a deoxygenated water (ca. 10 cm^3) in a 50 ml Schlenk apparatus. To this solution were added an aqueous solution (ca. 10 cm^3 each) of diethylenetriamine (21 mg, 0.2 mmol) and that of $K_3[Cr(CN)_6]$ (65 mg, 0.2 mmol) in turn. Resulting mixture was allowed to stand for several hours to give pale green plates of **1**. These crystals were collected, washed with water and dried in vacuo. In the atmosphere, **1** rapidly effloresced and changed to a dehydrated form $[Mn_3(dien)_2(H_2O)_2][Cr(CN)_6]_2$ (**1a**). Compound **1a** did not adsorb water and not recover the initial hydrated form **1**. When the molar ratio of Mn^{2+}:dien was 1:1 and water–ethanol (2:1) mixture was used as solvent, crystals of **1** were obtained with yellow cubic crystals of $[Mn(dien)]_3[Cr(CN)_6]_2 \cdot 2H_2O$ (**2**).[1] Elemental analysis (%): *Anal*. Calc. for $[Mn_3(dien)_2(H_2O)_2][Cr(CN)_6]_2$ (**1a**), $C_{20}H_{30}N_{18}Cr_2Mn_3O_2$: C, 29.17; H, 3.67; N, 30.62. Found: C, 29.09; H, 3.70; N, 30.50%. As the efflorescent nature of **1**, the dehydrated form **1a** was basically used for physical measurements.

2.2. X-ray crystallography

X-ray diffraction data of **1** were collected at −30 °C on Rigaku Mercury CCD diffractometer with graphite-monochromated Mo Kα radiation ($\lambda = 0.71070$ Å). The maximum 2θ value is 55.0°. A total of 1240 oscillation images were collected on five sweep setting. The structure was solved by direct methods (SIR-92) and followed successive Fourier and difference Fourier syntheses and refined by full-matrix least-squares on *F*. All nonhydrogen atoms were refined anisotropically. All hydrogen atoms were added geometrically and refined by using a riding model. All calculations were performed using the teXsan crystallographic software package of MSC. Crystal data for **1**: $C_{20}H_{38}N_{18}O_6Cr_2Mn_3$, FW = 895.44; pale green plate, crystal dimensions $0.08 \times 0.08 \times 0.02$ mm^3, triclinic, space group $P\bar{1}$, $a = 7.755(5)$ Å, $b = 10.939(7)$ Å, $c = 12.544(8)$ Å, $\alpha = 71.92(3)°$, $\beta = 71.26(3)°$, $\gamma = 61.71(3)°$, $V = 930.5(1)$ $Å^3$, $Z = 1$, $D_{calc} = 1.598$ g cm^{-3}, μ(Mo Kα) = 16.15 cm^{-1}, $T = -30$ °C, $R = 0.126$, $R_w = 0.155$ [$I > 0.00\sigma(I)$], GOF = 1.50.[2] The structure was not completely refined, because the crystals were very thin and gave poor diffraction data. Reproducibility of the structure was confirmed by single crystal and powder X-ray diffraction, many times. The structure of the dehydrated form **1a** was tentatively solved based on poor diffraction data. Crystal data for **1a**: $C_{20}H_{30}N_{18}O_2Cr_2Mn_3$, FW = 823.38; green plate, crystal dimensions $0.12 \times 0.12 \times 0.04$ mm^3, triclinic, space group $P\bar{1}$, $a = 7.9263(2)$ Å, $b = 10.606(2)$ Å, $c = 11.317(3)$ Å, $\alpha = 87.99(6)°$, $\beta = 73.07(5)°$, $\gamma = 69.70(5)°$, $V = 851.2994$ $Å^3$, $Z = 1$, $D_{calc} = 1.606$ g cm^{-3}, μ(Mo Kα) = 17.49 cm^{-1}, $T = -30$ °C, $R = 0.167$, $R_w = 0.253$ [$I > 0.00\sigma(I)$].

2.3. Magnetic measurements

DC and ac magnetic measurements of polycrystalline hydrated form **1** and dehydrated form **1a** were performed on a Quantum Design MPMS-5XL SQUID magnetometer in the temperatures range of 2–300 K under applied dc field of 500 G and 2–300 K under ac field of 3 G with oscillation 1–100 Hz, respectively. Field-dependences of magnetization were measured under the field range of 0–50 kG. All data were corrected for the magnetization of the sample holder and capsule used. Diamagnetic corrections for the constituting atoms were made using Pascal's constants. During the magnetic measurements, **1** was partially dehydrated in SQUID.

2.4. MCD spectra

Magnetic circular dichroism (MCD) of **1a** was measured as Faraday ellipticity using KBr disks under an applied field parallel to the incident light in the temperature range of 6–300 K. A circular dichroism spectrometer (JASCO J-820) equipped an electromagnet ($H = -15$ to $+15$ kG) and a cryostat, was used for the actual measurements. KBr disks containing ca. 1% of sample were prepared by applying a pressure of 8000 kg/cm^2.

3. Results and discussion

3.1. IR spectrum

Infrared spectra were measured using a KBr disk with a Perkin–Elemer Spectrum BX FT-IR system. IR spectrum of **1a** shows an intense ν(C≡N) band at 2156, 2147 and 2139 cm^{-1}. The IR bands at 2156 and 2147 cm^{-1} and 2131 cm^{-1} are attributed to the bridging and non-bridging cyanide groups, respectively.

3.2. TG analyses

In order to confirm the stability of compounds **1** and **1a** the thermal gravimetry (TG) were carried out under nitrogen atmosphere with a Rigaku Instrument TG8120 (Fig. 1). TGA curve of the as-synthesized sample **1** shows a decrease with ca. 8% weight loss from RT to 70 °C, which suggests that efflorescence starts from RT and all lattice water molecules are removed until 70 °C. Above 70 °C, **1** shows an additional decrease with ca. 2% weight loss corresponding to two water molecules coordinated to Mn^{II}. On the other hand, **1a** does not show any weight loss until 100 °C, which means **1a** does not adsorb moisture in the atmosphere. Then it shows one step decrease with ca.

[1] Details about compound **2** are omitted, because the structure was not solved.

[2] CCDC-623090 contains the supplementary crystallographic data for this paper.

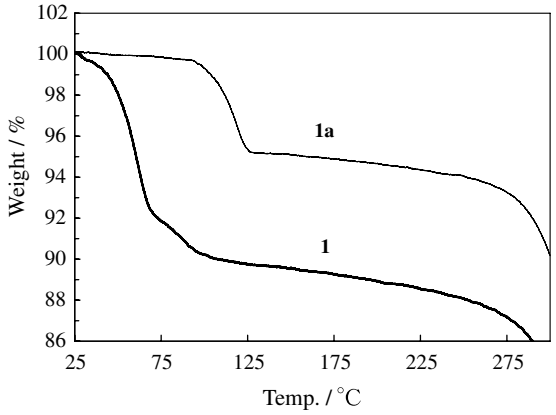

Fig. 1. TGA curves of **1** (thick line) and **1a** (thin line).

4.5% weight loss corresponding to two coordinated water molecules, and decomposition above 250 °C.

3.3. Crystal structures

The asymmetric unit of $[Mn_3(dien)_2(H_2O)_2][Cr(CN)_6]_2 \cdot 4H_2O$ (**1**) consists of one Mn1, one $[Mn2(dien)(H_2O)]^{2+}$ cation and one $[Cr(CN)_6]^{3-}$ anion (Fig. 2). Five cyanide groups of $[Cr(CN)_6]^{3-}$ are involved in the coordination to adjacent Mn ions. The co-ligand of triamine dien acts as a {bidentate + monodentate} ligand and bridges between Mn1 and Mn2. Mn1 resides at the inversion center and is in a pseudo-octahedral geometry with four cyano nitrogen atoms (N1, $N1^{\#1}$, $N3^{\#2}$ and $N3^{\#3}$; #1, #2 and #3 indicate symmetry operations of $(-x, -y, -z)$, $(x-1, y, z)$ and $(-x+1, -y, -z)$) on the equatorial positions and two monodentate-sites of dien (N7 and $N7^{\#1}$) at the axial positions. On the other hand, Mn2 has a pseudo-octahedral geometry with a bidentate-site of dien (N8 and N9) and three cyano nitrogen atoms (N2, $N4^{\#4}$ and $N6^{\#5}$; #4 and #5 indicate symmetry operations of $(-x, -y, -z+1)$ and $(-x+1, -y, -z+1)$) and one water oxygen atom (O1). The dien bridges between Mn1 and Mn2, and forms a Mn2–Mn1–$Mn2^{\#1}$ trinuclear unit, $[Mn_3(dien)_2(H_2O)_2]^{6+}$. In the lattice, 1-D zigzag chains are formed along the *a*-axis by alternate array of $[Mn2(dien)(H_2O)]^{2+}$ and $[Cr(CN)_6]^{3-}$ through Cr–C4N4–Mn2 and Cr–C6N6–Mn2 linkages. The chains are combined by Mn1 through two Cr–C1N1–Mn1 and two Cr–C3N3–Mn1 bridges. All the above-mentioned cyanide bridges are in the same plane and forms a 1-D ribbon structure along the *a*-axis. Furthermore, the ribbons are interlocked by complementary Cr–C2N2–Mn2 bridges where N2 coordinate to the apical position of Mn2 atom in the next ribbon. Also Mn1–dien–Mn2 linkage connects the ribbons and finally a unique 2-D hollow sheet structure comprising defective cubes with three Cr, one Mn1, and three Mn2 atoms at the seven corners and nine Cr–CN–Mn edges, is formed on the *ac*-plane (Fig. 3). Lattice water molecules are located in the defective cubes and form hydrogen bonds with coordinated water (O1···O2 and O1···O3 separations are 3.309 and 2.883 Å, respectively).

Although the quality was not sufficient, the crystal structure of the dehydrated form **1a** was tentatively determined (Fig. 4). The asymmetric unit and the 2-D sheet structure of **1a** is essentially same as **1**. However, the bridging dien of **1a** is remarkably bended toward inside of the defective cube and the hollow sheet structure is shrunk by the lost of the lattice water molecules. With the bend of dien, C1–N1–Mn1 and C3–N3–Mn1 bond angles in **1a** (157(1)° and 150(1)°, respectively) notably decrease compared to those of **1** (164.7(8)° and 171.9(8)°, respectively).

3.4. Magnetic properties

The temperature dependences of χ_M for **1** and **1a** are shown in Fig. 5. At room temperature, the μ_{eff} value of the dehydrated form **1a** per $Mn_3^{II}Cr_2^{III}$ unit is 8.91 μ_B, which is smaller than the spin-only value, 11.6 μ_B, expected for magnetically isolated three Mn^{II} ($S = 5/2$) and two Cr^{III} ($S = 3/2$) ions. The μ_{eff} value gradually decreases upon cooling down to a minimum value of 8.16 μ_B at 115 K, suggesting an antiferromagnetic interaction between Mn^{II} and Cr^{III} ions through cyanide bridges. The μ_{eff} value increases gradually upon further cooling, then shows an abrupt

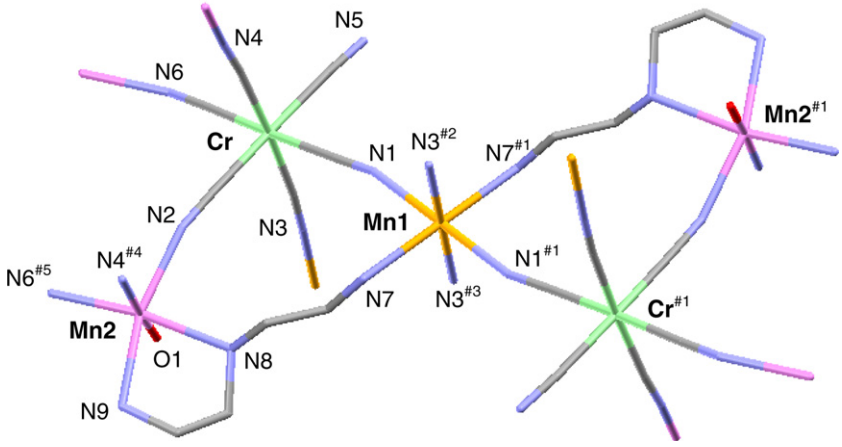

Fig. 2. Structure of **1** with atom numbering scheme (omitted lattice water).

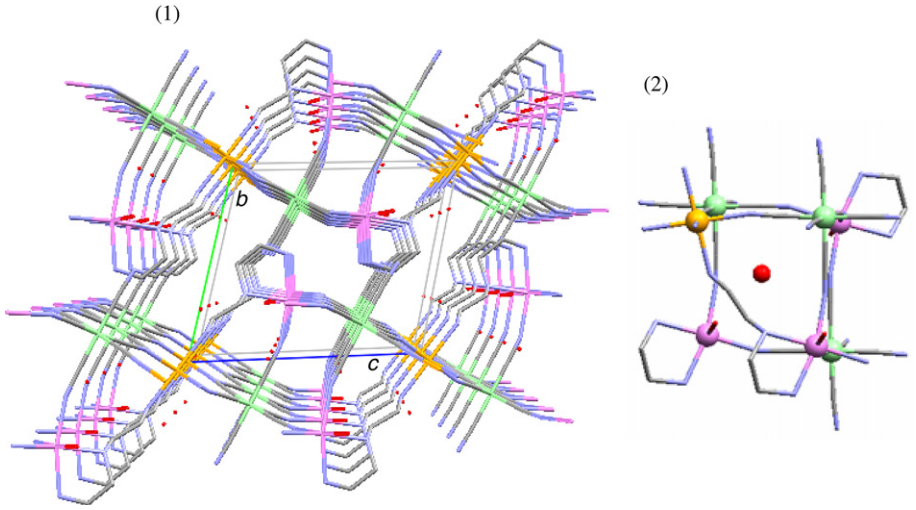

Fig. 3. Projection of the 2-D hollow sheet structure of **1** onto the *bc*-plane (1) and the Cr_3Mn_4 defective cube (2). Atoms: Mn1 (orange) Mn2 (pink), Cr (green), N (blue), O (red), C (gray). (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

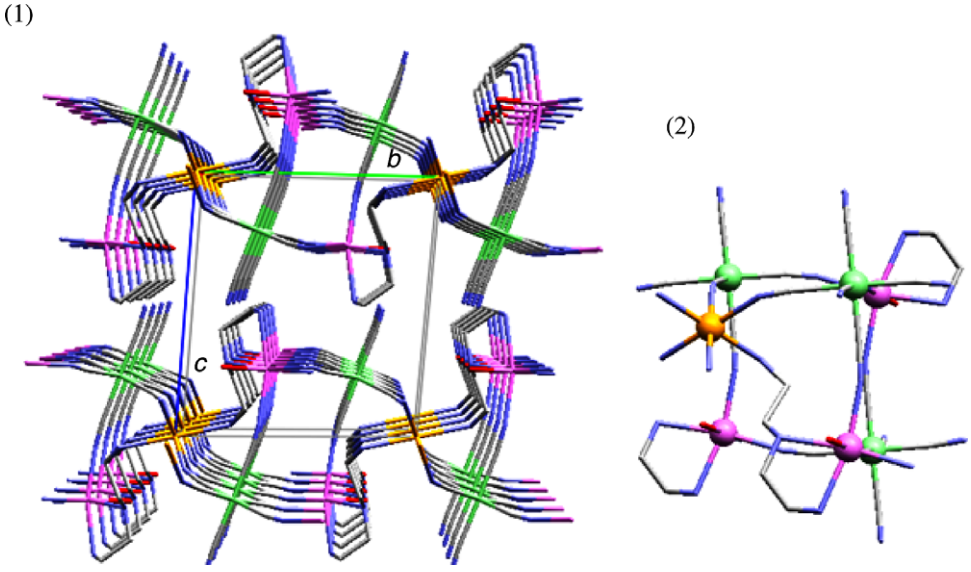

Fig. 4. Structure of **1a** onto the *bc*-plane (1) and the Cr_3Mn_4 defective cube (2). Atoms: Mn1 (orange) Mn2 (pink), Cr (green), N (blue), O (red), C (gray). (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

increase below 60 K up to a maximum value of 89.0 μ_B at 32 K. Below 32 K, the μ_{eff} decreases down to 28.1 μ_B at 2 K because of the saturation of the magnetization. Compound **1** also shows essentially the same behaviour as **1a**. The dM/dT vs. T plots of **1a** shows a minimum at 40 K with very small minima around 34 and 50 K, while that of **1** shows a minimum at 34 K with small minima around 40 and 48 K (Fig. 5, inset). The magnetic phase transition temperature (T_C) is determined to be 30 K for **1** and 40 K for **1a** by the weak-field magnetization measurement under 5 G, the dM/dT differential plot and the ac magnetic susceptibility. It means that the ferrimagnetic ordering temperature increases by 10 K with the compression of the hollow sheet by dehydration. Temperature-dependences of the χ'_M and χ''_M of **1a** and **1** are shown in Figs. 6 and 7. The χ'_M versus T plot of **1a** shows a gradual increase below 54 K, an abrupt increase below 40 K, a gradual decrease below 38 K, and a subtle frequency-dependence around 10 K. The χ''_M of **1a** slightly increases below 54 K, then suddenly increase below 40 K, and shows three round peaks around 35, 30 and 10 K. These dc and ac magnetic results suggest that the dehydrated form **1a** changes the magnetic phases at least twice below T_C. The multi-step magnetic phase change would be concerned with the ferrimagnetic ordering over the lattice originated from the complicated 2-D network structure based on the 1-D ferrimagnetic ribbons. The 1-D ribbon consists of Cr–CN–Mn1, Cr–CN–Mn2, and Mn1–dien–Mn2 bridges. From the X-ray crystallographic results, it is sure that comparable antiferromagnetic interaction operates between Cr and each Mn ion (J_{CrMn}). The Mn1···Mn2

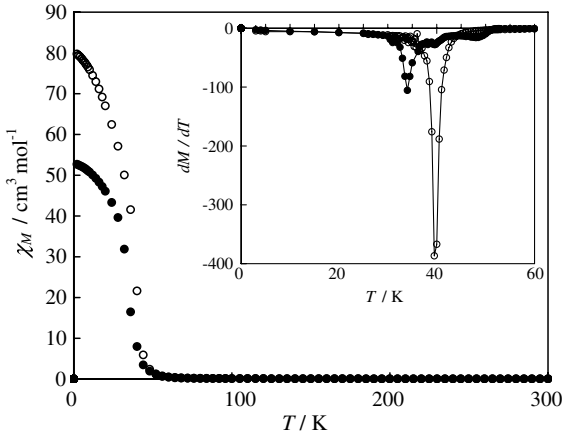

Fig. 5. χ_M vs. T plots of **1** (closed circle) and **1a** (open circle) under an applied dc field of 500 G. Inset: dM/dT vs. T plots of **1** (closed circle) and **1a** (open circle) calculated by field-cooled magnetization data under dc 5 G.

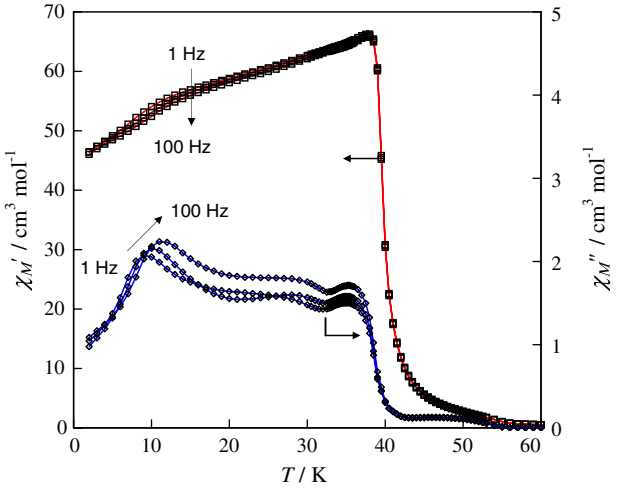

Fig. 6. χ' and χ'' vs. T plots for **1a** under an applied ac magnetic field of 3 G.

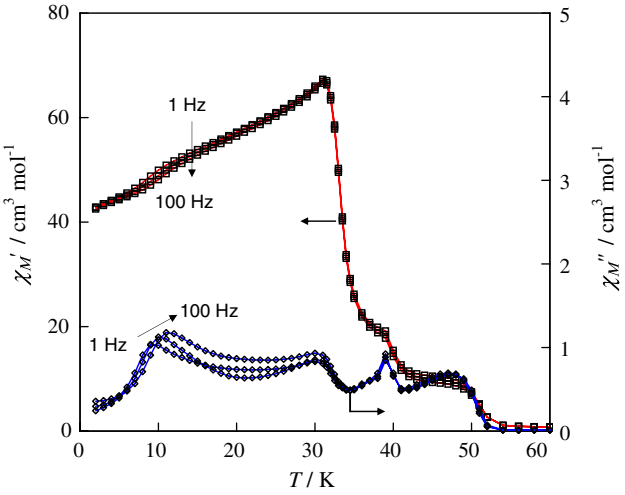

Fig. 7. χ' and χ'' vs. T plots for **1** under an applied ac magnetic field of 3 G.

distance through dien-bridge is about 6.369(5) Å, in which a through-space antiferromagnetic interaction (J_{Mn1Mn2}) will operate and make an antiferromagnetic triangle spin arrangement in CrMn1Mn2 unit. Of course the J_{CrMn} is dominant within the sheet (average intrasheet Cr···Mn1 and Cr···Mn2 separation through the cyanide-bridge are 5.310(5) and 5.393(7) Å, respectively), however, the effect of J_{Mn1Mn2} cannot be neglected in the low temperature region. Also, the nearest intersheet Cr···Mn2 and Mn2···Mn2 separation are, respectively, 6.412(7) and 5.952(7) Å, in which an intersheet antiferromagnetic interaction will operate. Such complicated magnetic interactions would cause a spin re-orientation and be the origin of the unusual magnetic behaviour. In the case of **1**, the χ_M'' versus T plot shows four round peaks around 10, 30, 40 and 48 K. As **1** was partially dehydrated during the measurement, the peak around 40 K would be attributed to contamination of the dehydrated form **1a**. The peak around 48 K was almost vanished after dehydration. However, the multi-step magnetic phase change below T_C is common between **1** and **1a**. The magnetic behaviour was confirmed by other samples prepared in different batches many times. However, the exact reason of the magnetic anomaly of **1** and **1a** are unclear at this time. Compound **1** which was heated at 400 K for 3 h in SQUID also shows the same magnetic behaviour to **1a**. Judged from the reproducibility, co-existence of any by-products is unlikely (T_C of the by-product **2** is 63 K). We need to carry out more detailed measurements using single crystals.

The field-dependence of the magnetization of **1a** measured at 2 K. The saturation magnetization value per $Mn_3^{II}Cr_2^{III}$ unit at 50 kG is 9.64$N\beta$ which corresponds to the value expected for antiferromagnetically coupled three Mn^{II} ($S = 5/2$) and two Cr^{III} ($S = 3/2$) ions. The theoretical curve based on the Brillouin function for $S = 9/2$ is shown as the solid line in Fig. 8, where $g = 2.16$ is used. The shape of M versus H curve strongly supports the ferrimagnetic ordering of **1a** in the bulk. The magnetic hysteresis loop of **1a** at 2 K is given in Fig. 8. The hysteresis curve shows a typical shape of soft ferrimagnet with a small remnant magnetization of 0.487$N\beta$ and a small coercive field of 20 G. The small coercive field must be associated with the isotropic electronic configuration of high-spin Mn^{II} ($S = 5/2$) and Cr^{III} ($S = 3/2$).

3.5. Magneto-optical properties

MCD spectra for **1a** at 6 K under ±15 kG are given in Fig. 9 as Faraday spectra. The spectrum shows peaks at 243 (−), 253 (−), 268 (+), 288 (−), 314 (−), 350 (−), 388 (−) and 430 (−) nm under the applied field of +15 kG, and the spectral pattern is inverted by the change of the direction of the external magnetic field. The intense band around 300 nm would be associated with the allowed transition of $t_{2u}(\sigma) \rightarrow t_{2g}(\pi)$, which is experimentally and theoretically assigned based on the spectrum of $[Cr(CN)_6]^{3-}$ ion [14,15]. The temperature dependence of the molar Faraday

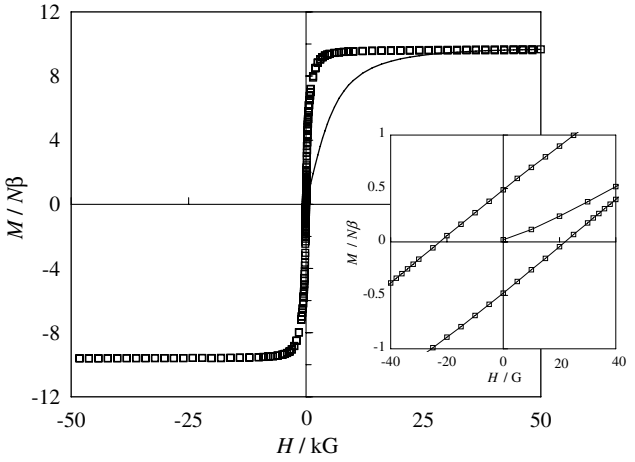

Fig. 8. Magnetic hysteresis loop for **1a** at 2 K. Solid line expresses Brillouin function for $S = 9/2$ with $g = 2.16$. The inset is an expansion in the range of −40 to +40 G.

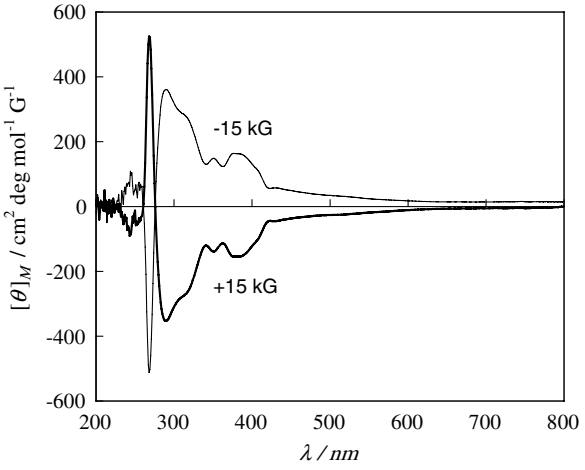

Fig. 9. MCD spectra for **1a** at 6 K under ±1 5 kG.

ellipticity $[\theta]_M$ in the region of 250–500 nm was measured in the temperature range of 6–60 K under an applied magnetic field of 250 G (Fig. 10). Faraday ellipticity increased

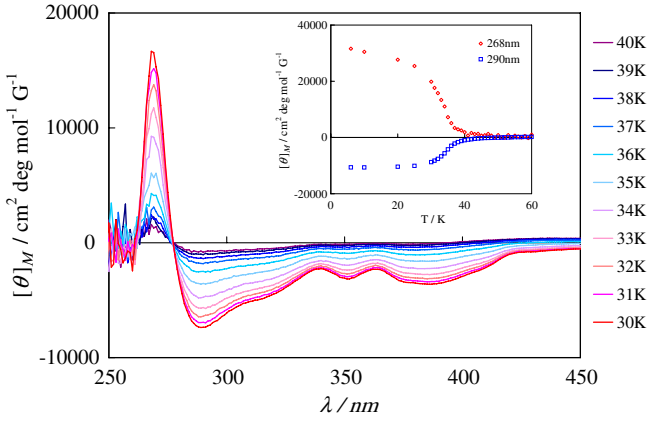

Fig. 10. Temperature dependence of Faraday ellipticity for **1a** under an applied field of 250 G. Inset $[\theta]_M$ vs. T plots at 268 (red) and 290 (blue) nm. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

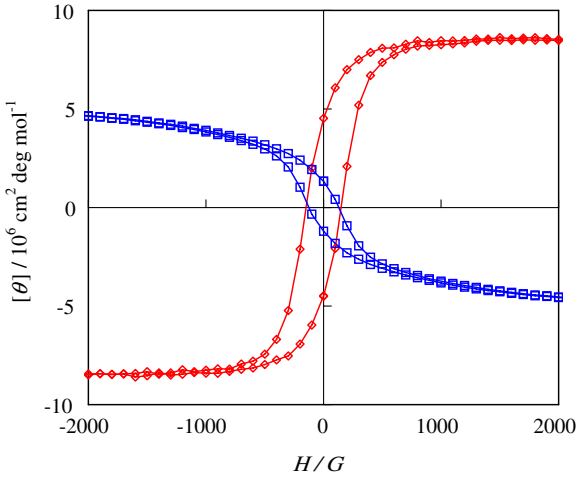

Fig. 11. MCD hysteresis loops for **1a** measured at 6 K and at 268 (red), and 290 (blue) nm. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

on decreasing temperature and reached a maximum value, ca. 100 times as large as the values above T_C, at 6 K. The $[\theta]_M$ versus T plots at 268 and 290 nm are given in the inset of Fig. 10. The shapes of $[\theta]_M$ versus T curves have a marked resemblance to that of χ_M versus T curve (see Fig. 5) with two-step like increase on decreasing temperature. This result demonstrates that the large enhancement of Faraday ellipticity is strongly associated with the magnetic ordering. The field dependence of the Faraday ellipticity at 268 and 290 nm are shown in Fig. 11. The $[\theta]$ versus H plots show a hysteresis with a small remnant $[\theta]$ and a small coercive field as well as the magnetic hysteresis.

4. Conclusion

A new $Mn^{II}Cr^{III}$ bimetallic assembly, $[Mn_3(dien)_2(H_2O)_2][Cr(CN)_6]_2 \cdot 4H_2O$ (**1**), has been prepared and evaluated its structural and magnetic changes associated with dehydration. This compound formed a unique 2-D cyanide-bridged hollow sheet constructed by the 1-D ribbon networks which contain dien-bridged Mn^{II} trimer units and μ_5-$[Cr(CN)_6]^{3-}$ bridges. Compound **1** was efflorescent and irreversibly changed to the dehydrated form **1a**. Magnetic results revealed that **1** and **1a** are ferrimagnets below 30 K and 40 K, respectively, and provides unusual magnetic behavior with a tendency of multiple magnetic phase changes until 2 K owing to the complicated intra- and inter-sheet structure. MCD spectra of **1a** demonstrated a large Faraday ellipticity around 300 nm with a characteristic spectrum pattern. The Faraday ellipticity was remarkably enhanced below T_C in line with the long-range ferrimagnetic ordering. These results suggest compound **1** potentially can act as a humidity-reactive colored-transparent magnet.

synthesis and characterization of these new materials. Lattice dynamics have been preliminarily probed in the HS and LS states using ^{57}Fe Mössbauer spectroscopy.

2. Experimental

2.1. Materials

All syntheses were carried out in solution and in air. Chemicals were commercially available and solvents were not dried prior to use.

2.2. Synthesis of $[Fe(NH_2trz)_3](AF_6)\cdot nH_2O$

Iron salts were prepared in situ by stirring iron powder and the respective acids at room temperature for 30 min, the solution of which was filtered leading to a green solution. This procedure was not carried out for the tin salt which was directly obtained from aqueous solutions of $FeCl_2\cdot 4H_2O$ and $(NH_4)_2SnF_6$. The coordination polymers were obtained as follows: 15 ml of a methanolic or ethanolic solution of 1 mmol of the iron(II) salts and ascorbic acid (0.1 g), to prevent oxidation to iron(III), were added to a hot alcoholic solution (15 ml) (methanol or ethanol) of 3 mmol of NH_2trz. The complexes precipitated immediately as white powders which were stirred for ~1 h, filtered off, washed with a 5–10 ml of water and dried in air.

C1. $[Fe(NH_2trz)_3](TiF_6)\cdot 0.5H_2O$ (from MeOH). Yield: 0.61 g, 83%. *Anal.* Calc for $FeC_6H_{13}N_{12}O_{0.5}TiF_6$: C, 15.05; H, 2.74; N, 35.09; Fe, 11.66. 2.3. Physical techniques

Elemental analyses were performed at University College London (UK). Atomic absorption analyses were carried out on a Perkin–Elmer 3110 spectrometer. Sampling was carried out in aqueous solutions containing nitric acid (65%). Standard solutions were prepared with Mohr's salt. IR spectra were collected on a BioRad FTS-135 spectrometer on KBr pellets. Thermogravimetric analyses were performed in air from 293 K to 400 K at a heating rate of 1 °C/min using a Mettler Toledo TGA/SDTA851^e analyzer. UV–Vis solid-state spectra were recorded with a CARY 5E Varian spectrophotometer using the diffuse reflectance technique with polytetrafluoroethylene as a reference. Powder X-ray diffraction patterns were recorded on a Siemens D5000 counter diffractometer working with Cu Kα radiation and operating at room temperature. The samples were mounted on the support with silicon grease. ^{57}Fe Mössbauer spectra were recorded in transmission geometry over the temperature range (78–300 K) with conventional Mössbauer spectrometers equipped with a ^{57}Co(Rh) radioactive source operating at room temperature. The samples were sealed in aluminum foil and mounted on a nitrogen cryostat. The spectra were fitted to the sum of Lorentzians by a least-squares refinement using Mossfit [6] or Recoil 1.05 Mössbauer Analysis Software [7]. All isomer shifts refer to α-Fe at room temperature. Magnetic susceptibilities were measured in the temperature range 50–300 K using a MPMS-5 SQUID magnetometer. Data were corrected for magnetization of the sample holder and diamagnetic contributions, which were estimated from the Pascal constants.

3. Results and discussion

3.1. Synthesis and characterization

The coordination compounds were precipitated as powders from MeOH or EtOH media, and successfully characterized by CHN and TGA analyses, atomic absorption, X-ray powder diffraction, infrared, UV–Vis and ^{57}Fe Mössbauer spectroscopies. Thermogravimetric and elemental analyses did not show the presence of alcoholic solvents but instead revealed non-coordinated water molecules, allowing us to derive the general formula $[Fe(NH_2trz)_3]AF_6\cdot nH_2O$. Syntheses carried out in MeOH or EtOH lead to hemihydrates or monohydrates, respectively, except for the zirconium derivative. This series of materials have essentially identical infrared and X-ray powder diffraction patterns. At room temperature, the compounds appear as

white powders and present a reversible thermochromism to pink on cooling. These colors depend on the spin state of the iron(II) centers. The white color is due to the fact that the spin-allowed lowest energy d–d transition, $^5T_{2g} \rightarrow {}^5E_g$, for the HS sites occurs in the near infrared region ($\sim$11 800 cm^{-1}) [2b]. The pink color is due to the $^1A_{1g} \rightarrow {}^1T_{1g}$ d–d transition of LS iron(II) sites occurring at $\sim$520 nm. Mössbauer spectroscopy revealed the absence of oxidation and confirmed the presence of only one FeN_6 site undergoing spin crossover behavior on cooling. ^{57}Fe Mössbauer parameters are typical of coordination polymeric chains with 4-amino-1,2,4-triazole as ligand [8].

3.2. Magnetic susceptibility measurements and Mössbauer spectroscopy

The magnetic properties of $[Fe(NH_2trz)_3]TiF_6 \cdot nH_2O$ (**C1**, **C2**) and $[Fe(NH_2trz)_3]SnF_6 \cdot 0.5H_2O$ (**C5**) were recorded on cooling and warming over the temperature range (300–70 K) (Fig. 1). At room temperature, $\chi_M T$ is equal to 3.64 $cm^3\,K\,mol^{-1}$ for **C1**, which coincides with the expected value for a HS iron(II) ion, as confirmed by Mössbauer spectroscopy ($\delta^{HS} = 1.047(1)$ mm s^{-1} and $\Delta E_Q^{HS} = 2.782(1)$ mm s^{-1}). $\chi_M T$ decreases slightly down to $\sim$235 K and quite abruptly down to $\sim$140 K. Below this temperature, $\chi_M T$ decreases smoothly down to $\sim$0.54 $cm^3\,K\,mol^{-1}$ at 90 K, indicating an incomplete ST. This incomplete character was confirmed by Mössbauer spectroscopy at 78 K which revealed the presence of HS and LS iron(II) ions ($\delta^{LS} = 0.531(1)$ mm s^{-1} and $\Delta E_Q^{LS} = 0.297(1)$ mm s^{-1}, $A_{HS}/A_{tot} = 0.16$). As the temperature is increased, similar behavior is observed, with a thermal hysteresis width of 6 K. The transition temperatures on cooling and warming are $T_{1/2}\downarrow = 194$ K and $T_{1/2}\uparrow = 200$ K, respectively. The ST behavior of **C2** is similar with a hysteresis loop of width 7 K, shifted to lower temperatures ($T_{1/2}\downarrow = 189$ K and $T_{1/2}\uparrow = 196$ K). The ST is complete at 300 K and incomplete at low temperature, as confirmed by Mössbauer spectroscopy at 78 K ($A_{HS}/A_{tot} = 0.27$). The ST behavior of $[Fe(NH_2trz)_3]SnF_6 \cdot 0.5H_2O$ is somewhat different. On cooling, $\chi_M T$ remains constant at 3.02 $cm^3\,K\,mol^{-1}$ down to $\sim$ 230 K, after which $\chi_M T$ decreases abruptly at $T_{1/2}\downarrow = 211$ K and then smoothly down to 0.64 $cm^3\,K\,mol^{-1}$ at 70 K indicating an incomplete ST which is also confirmed by Mössbauer at 78 K ($A_{HS}/A_{tot} = 0.20$). This lower $\chi_M T$ value at room temperature compared to that of **C1**–**2** indicates the presence of LS iron(II) ions which are also probed by Mössbauer. It can be noted that the ST proceeds more smoothly on warming with $T_{1/2}\uparrow = 223$ K.

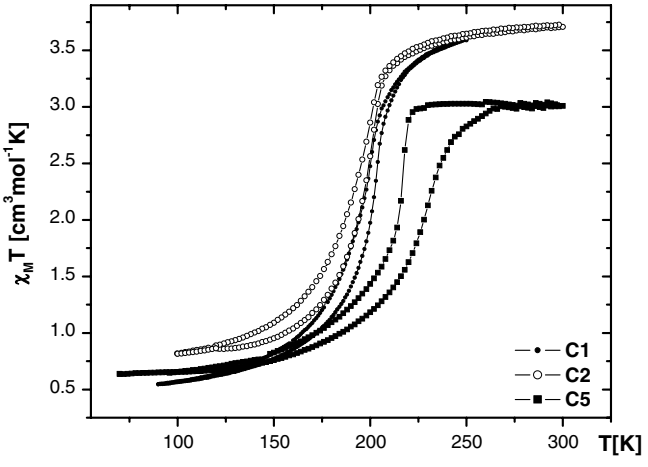

Fig. 1. $\chi_M T$ vs. T on cooling and warming modes for $[Fe(NH_2trz)_3]TiF_6 \cdot nH_2O$ ($n = 0.5$ (●); $n = 1$, (○)) and $[Fe(NH_2trz)_3]SnF_6 \cdot 0.5H_2O$ (■).

The ST of these materials range around 200 K which nicely fit with the relation between the transition temperatures and the anions radii suggested by Lavrenova for the $[Fe(NH_2trz)_3]A_2$ series [8] since the radii of AF_6 anions are found above 2.5 Å [9].

The origin of the incomplete ST at low temperature can be addressed. It could be due to crystal defects, HS FeN_6-sites or end of chains coordinated to water molecules. A closer look at the Mössbauer spectra of **C1**–**6** at 78 K reveals only one iron(II) site being in the LS and HS states. Thus, there is no indication of an FeN_3O_3 environment which would be characteristic of three terminal coordinated water molecules [10] provided these are present in enough concentration. Nevertheless, ends of chains with two coordinated water molecules may not be detected by Mössbauer [11] and thus cannot be excluded. Interestingly, the addition of half a water molecule per iron(II) has a noticeable effect on the ST behavior of **C1**–**2** since a shift of the curve of $\sim$4 K downwards is observed and the HS plateau at 78 K increases. This shift has been confirmed by tracking the ST by Mössbauer spectroscopy thanks to the A_{HS}/A_{tot} ratio recorded over the whole temperature range of investigation. The increase of water molecules per formula unit could be attributed to the increase in the number of terminal coordinated solvent molecules setting a lower ligand field strength and thus preventing a spin state change. This hypothesis is validated by the fact that the abrupt character of the ST of **C1**–**2** is not affected by this incorporation which could lead to chains of different lengths that would show different cooperative behaviors [12].

At room temperature, ΔE_Q^{HS} remains constant at $\sim$2.78(1) mm s^{-1} whatever the inserted anion (Table 1). This indicates that the local distortion around the HS iron(II) ions is not modified by the position of the non-coordinated anions in the crystal lattice. This result suggests the location of these anionic species in the external coordination sphere. This was observed in the crystal structure of $[Cu(NH_2trz)_3](ZrF_6) \cdot H_2O$ where the hexafluorozirconate anion is connected to the amino groups of the NH_2trz ligand through hydrogen bonding. The anion as well as a non-coordinated water molecule, which are situated in the interchain space whose dimension is 10.997(4) Å, are part of a dense hydrogen bonding network establishing supramolecular bridges between copper(II) chains [13]. At 78 K where all

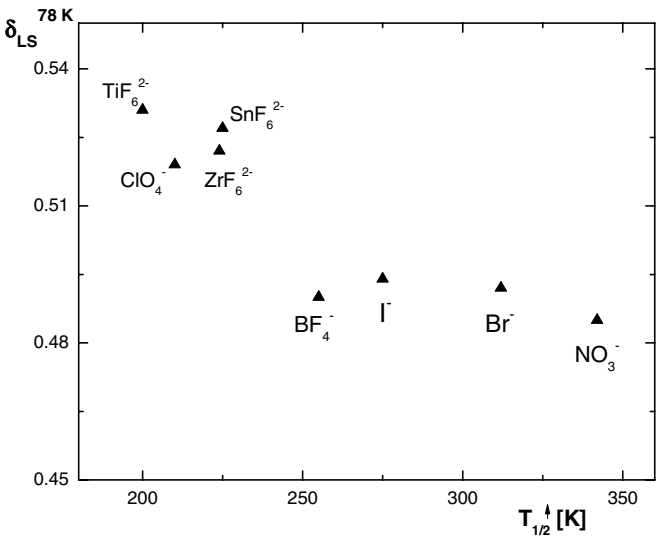

Fig. 2. $\delta_{LS}^{(78\ K)}$ *vs.* $T_{1/2}^{\uparrow}$ for $[Fe(NH_2trz)_3]A_{x(x=1,2)}$ prepared in MeOH. The data for monovalent anions are from [8].

compounds are in the LS state, ΔE_Q^{LS} also remains constant at 0.30(1) mm s^{-1} (Table 1). The lattice contribution to the quadrupole splitting thus indicates that the iron(II) sites are distorted, as expected for these metal centers connected within a chain by three *N*1,*N*2-1,2,4-triazole bridges.

Fig. 2 shows the evolution of $\delta_{LS}^{(78\ K)}$ versus $T_{1/2}^{\uparrow}$ for cationic chains $[Fe(NH_2trz)_3]^{2+}$ incorporating monovalent [8] and divalent anions, prepared in MeOH. The isomer shift decreases when the transition temperature increases which necessarily implies an increase in the degree of Fe–N bond covalency.

The Debye temperature, θ_D, was preliminarily determined for **C1-6** in the HS and LS states in order to investigate the rigidity of these switchable networks. To derive these terms, we have recorded several spectra at various temperatures. The Debye temperatures are listed in Table 1.

The LS lattice is more rigid than the HS one since the vibrational frequencies decrease during the LS to HS transition, as a result of the increase in the Fe–N bond lengths. For comparison, the Debye temperatures in the HS state of **C1**–**2** are similar for $[Fe(NH_2trz)_3](ClO_4)_2$ with $\theta_D^{(HS)} = 188(12)$ K [8]. Overall, the variation of the lattice rigidity, $\Delta\theta_D = \theta_D^{(LS)} - \theta_D^{(HS)}$, accompanying the ST is on the same order of magnitude (~21 K). The present θ_D values are however overestimated since thickness corrections were neglected [14] and for a careful evaluation, effective mass variation during the ST must be considered. Such investigations are in progress.

4. Conclusion

In this work, new 1D ST chain compounds including novel fluorinated counteranions have been investigated. Lattice dynamics were preliminarily evaluated in the LS and HS states using the Debye Model. Insertion of novel inorganic counteranions in iron(II) ST coordination polymers is continuing in our laboratories.

where the ladder rungs are constructed of double $\mu_{1,5}$-dca bridges and the legs with single $\mu_{1,5}$-dca bridges [15]. These ladders are linked into a two-dimensional array through hydrogen bonding interactions between terminal dicyanamide and water molecules that are coordinated to the periphery of the ladder. We have recently reported that the $(PPh_4)_3[Cu_4(dca)_{11}]$ salt possesses a novel triple ladder structure in which the rungs are comprised of single $\mu_{1,5}$-dca bridges while the sides are constructed of double $\mu_{1,5}$-dca bridges. No terminal ligands are attached to these triple ladders, resulting in close, through space metal separations of 4.003(1) Å [16].

Square, two-dimensional anionic frameworks are formed through the infinite coupling of ladders. This is observed in the $(PPh_4)M(dca)_3$ (M = Mn and Co) and $(AsPh_4)M(dca)_3$ (M = Mn, Co and Ni) structures [11,14,17]. The $(Et_4N)[Cd(dca)_3]\cdot 3/4H_2O$ structure contains the same two-dimensional anionic topology [18]. Two-dimensional hexagonal honeycomb sheets with double $\mu_{1,5}$-dca bridges result when cations such as $[M(bipy)_3]^{2+}$ (M = Fe and Ni; bipy = 2,2′-bipyridine) are used as templates [19]. We have recently found that when partially oxidized bis(ethylenedithio)tetrathiafulvalene (BEDT-TTF) is used as the templating cation, a novel triangular anionic layer with single $\mu_{1,5}$-dca bridges is formed [20].

Several three-dimensional motifs are also known in (cation)$M(dca)_3$ salts. Superlattices of a simple cubelike (also called perovskite, α-polonium, or ReO_3) structure with single $\mu_{1,5}$-dca bridges form through use of the $(BzR_3N)^+$ (Bz = benzyl, R = Bu and Et) [21], $(SPh_3)^+$ [22], $[N(C_3H_7)_4]^+$ [23], and $(Cp^*_2M)^+$ [24] counter ions. A triple-rutile type structure is found in the salts with $[N(C_4H_9)_4]^+$ [23] and $[RPh_3P]^+$ (R = Me and Et) [17,25] cations. Although in both of these salts, the metal centers are five-connecting (each end of a $\mu_{1,5}$-dca doubly bridged unit is linked to four equivalent units through single $\mu_{1,5}$-dca bridges), the anionic lattice topologies are different. Finally, we have found that the $[N(C_5H_{11})_4]^+$ templates a lithium antimonate structure which is formed by linking *cis* bibridged $\mu_{1,5}$-dca chains through single $\mu_{1,5}$-dca bridges [23].

Clearly, very small differences in the coordination geometry of divalent first row transition elements and crystallization conditions can affect the identity of the crystallized product. Taking, for example, the very similar EPh_4^+ (E = P and As) cations, three different anionic cobalt(II) dicyanamide structural motifs have been reported: chains, ladders, and sheets. When copper(II) is substituted for cobalt(II), a triple ladder structure results.

Almost all of the anionic dicyanamide complexes that have been reported contain divalent manganese, iron, cobalt, or nickel. A couple of structures contain divalent cadmium and there is one lone example of an anionic divalent copper salt. Anionic copper(I) dca salts have only been studied to a slightly greater extent: the $[Rb(18\text{-crown-}6)]_3Cu_2(dca)_5$ salt contains both tetrahedrally and triangularly coordinated copper, while $[Tl(18\text{-crown-}6)]Cu(dca)_2$ contains only tetrahedrally coordinated copper [26]. Anionic copper(I) dicyanamide anions are also important for the preparation of superconducting charge transfer salts in the $(BEDT\text{-}TTF)_2Cu(dca)X$ (X = Br and Cl) [27,28].

2. Experimental

2.1. Synthesis

2.1.1. $(PPh_4)(dca)$

Tetraphenylphosphonium bromide (22.674 g, 54.07 mmol, Aldrich) was dissolved in 400 ml water. Sodium dicyanamide (4.813 g, 54.07 mmol, Lonza) was dissolved in 200 ml water. These two solutions were combined and stirred thoroughly. The heavy white precipitate of $(PPh_4)(dca)$ was collected by suction filtration, rinsed with deionized water, and dried with diethyl ether. This product was recrystallized from hot ethanol: $(PPh_4)(dca)$ (14.3 g, 35.27 mmol) was dissolved in 50 ml hot ethanol, filtered, and slowly cooled to yield colorless crystals. *Anal.* Calc. for $C_{26}H_{20}N_3P$: C, 77.02; H, 4.97; N, 10.37. Found: C, 77.04; H, 5.00; N, 10.40%. Mp: 215–217 °C. IR (cm^{-1}): 2228m, 2189 m, 2129vs, 2100w, 1585w, 1482m, 1438s, 1307s, 1189w, 1163w, 1106vs, 1074w, 1028w, 996m, 932w, 901w, 862w, 760m, 753m, 722vs, 690s.

2.1.2. $(PPh_4)Cu(dca)_3(H_2O)$ (**1**)

$(PPh_4)(dca)$ (811 mg, 2 mmol) was dissolved in 25 ml ethanol (Aaper, 200 proof). Copper(II) tetrafluoroborate hydrate (118 mg, 0.5 mmol, Aldrich) was dissolved in 10 ml water. The precipitate that formed immediately when these two solutions were combined was removed by filtration. The filtrate was allowed to slowly evaporate. After 2 days, some green crystals of the title compound formed. *Anal.* Calc. for $C_{30}H_{22}N_9OPCu$: C, 58.20; H, 3.58; N, 20.37. Found: C, 58.72; H, 4.29; N, 19.77%. IR (cm^{-1}): 2349w, 2309m, 2252m, 2237m, 2177m, 2169vs, 1484w, 1436m, 1376m, 1364m, 1338w, 1313w, 1189w, 1163w, 1109s, 1052w, 995m, 758m, 722s, 687s.

2.1.3. $(PPh_3Bu)_2Cu(dca)_4$ (**2**)

Butyltriphenylphosphonium bromide (399 mg, 1 mmol, Aldrich) was dissolved in 10 ml of ethanol and combined with a solution of sodium dicyanamide (208 mg, 2 mmol, Lonza) in 10 ml of water. This mixture was layered on top of a solution of copper(II) tetrafluoroborate hydrate (237 mg, 1 mmol, Aldrich) in 10 ml of water. After 1 month, green, rod shaped crystals were collected by filtration. Mp: 109 °C. *Anal.* Calc. for $C_{52}H_{48}P_2N_{12}Cu$: C, 64.62; H, 5.01; N, 17.39. Found: C, 64.78; H, 5.20; N, 17.26%. IR (cm^{-1}): 2967w, 2930w, 2906w, 2870w, 2289m, 2245m, 2238m, 2167vs, 1441m, 1437m, 1352m, 1228w, 1184w, 1160w, 1114m, 1091w, 996w, 961w, 918w, 905w, 803w, 769w, 753m, 738m, 721m, 712w, 687m.

2.1.4. Synthesis of $Cu(dca)_2$

$Cu(dca)_2$ was prepared according to the literature procedure [5]. Aqueous solutions of copper(II) nitrate hydrate

(1396 mg, 6 mmol, Aldrich) and sodium dicyanamide (1068 mg, 12 mmol, Lonza) were combined and the precipitate collected by filtration and dried in air. IR (cm^{-1}): 2417w, 2328m, 2272s, 2194vs, 1356s, 1061w, 1006w, 956m, 678m.

2.2. Single crystal X-ray diffraction

The crystal structures of **1** and **2** were determined by X-ray diffraction using a Siemens SMART single crystal diffractometer equipped with a CCD-based area detector and a sealed-tube Mo Kα source (graphite monochromator). The detector frames were integrated by use of the program SAINT [29] and the intensities corrected for absorption by Gaussian integration based on the measured crystal shape using the program XPREP of SAINT. Other systematic variations were corrected by the analysis of replicate reflections using the program SADABS [30]. The structures were solved by use of direct methods, while full-matrix least-squares refinement on F^2 (including all data) was performed, both using the program package SHELXTL [31]. A summary of the crystallographic data is given in Table 1, while selected bond lengths and angles are listed in Tables 2 and 3 for the two compounds, respectively. The atomic numbering schemes are illustrated in Figs. 1 and 5 (anions) and in the Supporting information Figs. S1 and S2 (cations), and further details of each structure are available in the CIF files also deposited as electronic Supplementary information.

2.3. X-ray powder diffraction

X-ray powder diffraction patterns were collected on a PANalytical X'Pert Pro diffractometer fitted with an X'Celerator detector using Co radiation. Samples were lightly ground in order to reduce preferred orientation and placed on a zero-background Si(5 1 0) substrate sample holder. Powder patterns were calculated from single crystal data through use of the program CrystalDiffract (CrystalMaker software, version 1.0.3).

2.4. Magnetic measurements

The direct current (dc) magnetizations of **1** and **2** were measured between 5 and 300 K and 3.25 and 240 K, respectively, using a Quantum Design (San Diego, CA) MPMS-7 SQUID magnetometer. A collection of crystals of each compound was tightly packed in gelatin capsules, mounted in a plastic straw and affixed to the end of the sample rod. Sample masses were 23.1 mg and 75.4 mg for **1** and **2**,

respectively. Samples were cooled in zero magnetic field to the lowest temperature. As shown in Fig. S3, the magnetization was measured as a function of field up to 7 T at 2 K. The magnetizations approach the expected value of 5585 emu Oe/mol at 7 T. The dc field was then changed to 1 T, which is within the linear portion of the magnetization versus field curve, and the magnetization data were recorded upon warming. All magnetic data were corrected for core diamagnetism using Pascal's constants.

2.5. Fourier transform infrared spectroscopy (FTIR)

FTIR spectra were collected using a Bruker Vertex 70 spectrometer equipped with a mercury cadmium telluride (MCT) detector and a Pike ATR accessory.

3. Results

3.1. Crystal structures

The crystal structure of **1** was determined at room temperature (RT). As illustrated in Fig. 1, the coordination

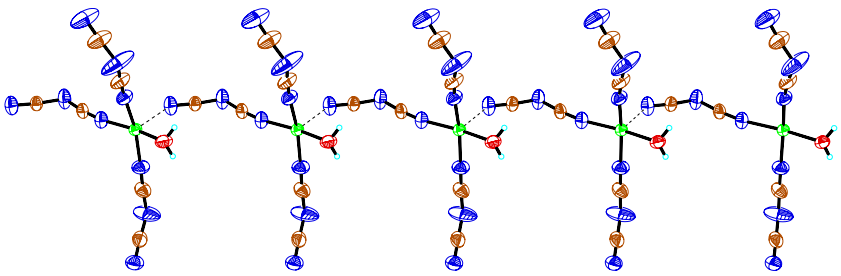

Fig. 2. The anionic one-dimensional chain motif in **1** lies parallel to the *a*-axis. Thermal ellipsoids are drawn at the 50% probability level.

geometry of the Cu^{2+} is distorted square pyramidal. The basal plane consists of three dicyanamide anions and one water molecule. These equatorial Cu–N bonds range from 1.961(3) to 1.984(3) Å, with the Cu–O bond length of 1.987(2) Å. A nitrile nitrogen atom of a bridging dca anion occupies the axial site with a Cu–N bond distance of 2.263(3) Å. Within the equatorial plane, the N–Cu–N′ bond angles are 91.94(12)°, 90.58(11)°, and 164.75(12)°, whereas the N–Cu–O bond angles are 90.39(11)°, 84.10(11)°, and 167.67(11)°. The N(8)–Cu–N/O bond angles involving the axial nitrogen atom range from 92.47(10)° to 99.26(10)°. The equatorial Cu–N–C bond angles are relatively linear, with angles ranging from 169.7(3)° to 172.3(3)°, while the axially coordinated ligand is considerably more bent, with a bond angle of 139.6(3)°. The average nitrile bond length is 1.132(7) Å, while the average amide bond length is 1.293(12) Å, indicating that these bonds have triple and single bond character, respectively. The average amide C–N–C bond angle is 123(2)°, which is typical for the dicyanamide anion. Due to thermal effects, there is clearly some 'wagging' of the dca ligands, as is evident in the elongated atomic displacement ellipsoids perpendicular to the ligand molecular plane at room temperature. This effect is especially noticeable in the amide nitrogen atoms of the mono-coordinated dca ligands.

As illustrated in Fig. 2, the $[Cu(dca)_3(H_2O)]^-$ anions form a one-dimensional chain along the *a*-axis. The Cu···Cu separation through the *cis* singly bridged $\mu_{1,5}$-dca chains corresponds to the *a*-axis length, which is 7.409(1) Å. This separation is significantly shorter than the 8.159(1)–8.352(1) Å intrachain separation in *trans* singly bridged $\mu_{1,5}$-dca chains in the previously reported $(PPh_4)_3Cu_4(dca)_{11}$ salt [16].

As illustrated in Fig. 3, the anionic $[Cu(dca)_3(H_2O)]^-$ chains are linked together through hydrogen bonding interactions to form two-dimensional sheets parallel to the *ac*-plane. Specifically, the two hydrogen atoms of the coordinated water molecule form hydrogen bonds to the two non-coordinated nitrile nitrogen atoms. The O–H(1)···N(5) distance is 2.727 Å and the angle 164.6°, while the O–H(2)···N(2) distance is 2.845 Å with an angle of 177.4°. The closest interchain Cu···Cu separations are 8.995(1) and 9.274(1) Å, while the closest interlayer Cu···Cu separations are 12.459(2) Å. It is noted that **1** crystallizes in the non-centrosymmetric space group $P2_1$, and all the coordinated water molecules lie on the same side of each anionic sheet.

The packing of the PPh_4^+ cations is shown in Fig. 4. As they are given by unit cell translations, the P···P separations mirror those of Cu···Cu: 7.409(1) Å along the *a*-axis cationic PPh_4^+ chain and interchain separations of 8.995(1) and 9.274(1) Å along the *c*-axis and *ac*-diagonal. It is likely that concerted phenyl embraces [32] are responsible for the templating effect for the anion.

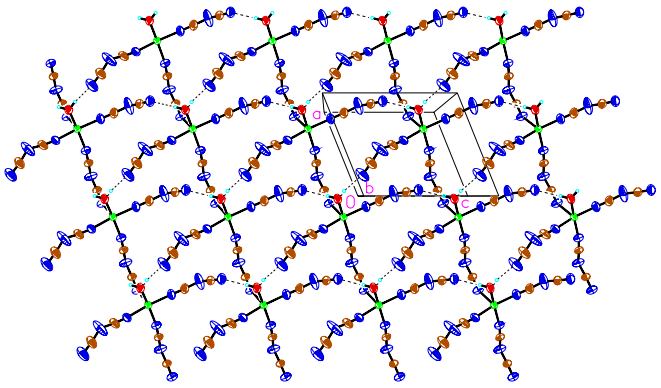

Fig. 3. The one-dimensional chains in **1** are linked into a two-dimensional sheet through hydrogen bonding interactions. These anionic sheets lie in the *ac*-plane. Atomic displacement ellipsoids are drawn at the 50% probability level.

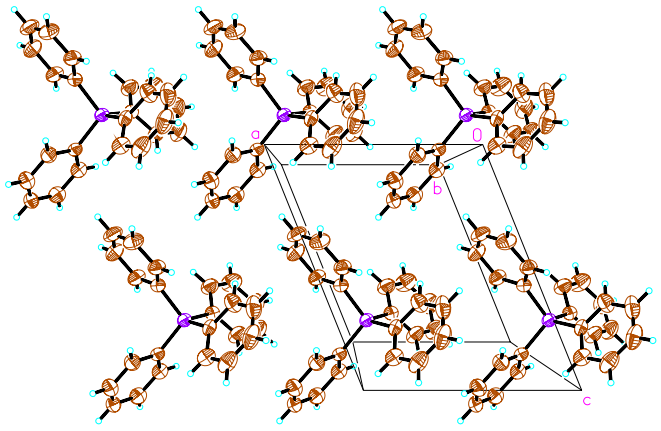

Fig. 4. One-dimensional chains of the PPh_4^+ cations in **1** lie along the *a*-axis. These chains are packed into a two-dimensional motif within the *ac*-plane. Atomic displacement ellipsoids are drawn at the 50% probability level.

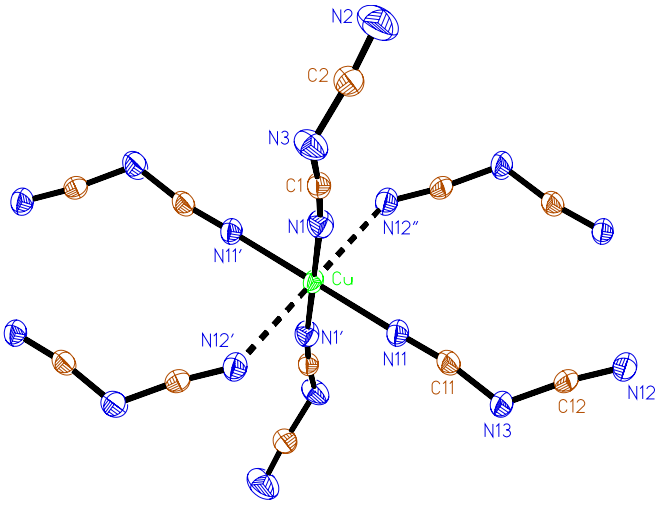

Fig. 5. Atomic numbering scheme of the $[Cu(dca)_4]^{2-}$ anion in the $(PPhBu)_2[Cu(dca)_4]$ salt at 150 K. Displacement ellipsoids are drawn at the 50% probability level.

The crystal structure of **2** was determined at both RT and 150 K. As illustrated in Fig. 5, the coordination geometry of the Cu^{2+} is a Jahn–Teller distorted octahedron with equatorial Cu–N bonds of 1.963(2) and 1.996(2) Å with the axial bond 2.504(2) Å at 150 K. At RT, the equatorial bonds shorten to 1.959(2) and 1.991(2) Å while the axial bond expands to 2.569(2) Å. This coordination geometry is similar to that observed in $Cu(dca)_2$, where the average equatorial distance is 1.975(1) Å and the average axial distance is 2.478(2) Å at 293 K [33]. The N–Cu–N′ bond angles are only slightly distorted from ideal, with the largest discrepancy being 93.14(6)° at RT and 92.64(7)° at 150 K. The equatorial Cu–N(1)–C(1) and Cu–N(11)–C(11) bond angles of 174.0(1)° and 175.4(2)° at 150 K [173.2(2)° and 173.7(2)° at RT] are only slightly non-linear, while the axial Cu–N(12)–C(12) bond angle of 133.9(2) at 150 K [135.8(2)° at RT] is significantly bent. The average cyanide and amide bond distances are both slightly longer at 150 K than RT: the C≡N bonds increase from 1.133(5) Å at RT to 1.146(3) Å at 150 K, while the C–N bonds increase from 1.295(5) to 1.305(7) Å upon cooling. This observation is likely due to foreshortening of the apparent interatomic distances compared to the true distances due to librational thermal motion at the higher temperature.

As illustrated in Fig. 6, the $[Cu(dca)_4]^{2-}$ anions form a one-dimensional chain along the *b*-axis. The Cu···Cu separation through the doubly bridged $\mu_{1,5}$-dca chains (corresponding to the *b*-axis length) is 7.526(1) Å at RT and contracts to 7.460(5) Å at 150 K. This separation is slightly longer than the 7.1911(4) Å intrachain separation for doubly bridged $\mu_{1,5}$-dca chains in the previously reported $(PPh_4)_3Cu_4(dca)_{11}$ salt [16]. The shortest interchain Cu···Cu separation of 12.399(1) Å shortens to 12.302(6) Å at 150 K.

The PPh_3Bu^+ cations are similarly packed into chains, as illustrated in Fig. 7. It is likely that concerted phenyl embraces [32] are responsible for the templating effect of this cation, which dictates a chain type packing motif for the anion. Note that the P···P separation is also equivalent to the *b*-axis length.

The cyano stretching region of the infrared spectra for **1** and **2** is compared to that of $PPh_4(dca)$ and $Cu(dca)_2$ in Fig. 8. As compared to the non-coordinated dca^- anion in the $PPh_4(dca)$ salt, the absorption bands are shifted to higher wavenumbers in the metal complexes. The bands below 2250 cm^{-1} have been assigned to $(\nu_{as})_{C\equiv N}$ and $(\nu_s)_{C\equiv N}$ modes, while those at higher wavenumbers have been assigned to $(\nu_{as}+\nu_s)_{C\equiv N}$ combination modes [6]. The spectra of **1** and **2** in this region are similar to the

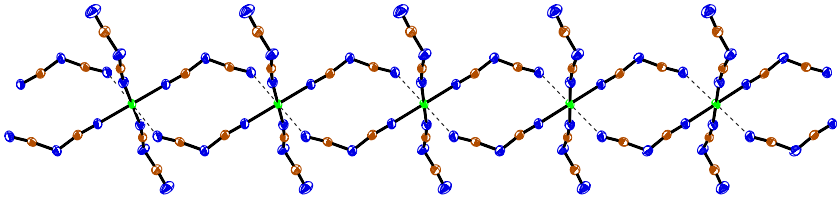

Fig. 6. The one-dimensional polymeric chain motif of the $[Cu(dca)_4]^{2-}$ anion in the $(PPh_3Bu)_2[Cu(dca)_4]$ salt at 150 K. Thermal ellipsoids are drawn at the 50% probability level.

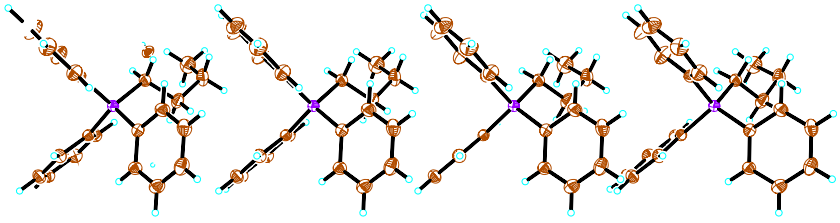

Fig. 7. The one-dimensional chain motif of the PPh_3Bu^+ cation in the $(PPh_3Bu)_2[Cu(dca)_4]$ salt at 150 K. The P···P separation coincides with the Cu···Cu separation in the anion layer, and is equivalent to the *b*-axis length. Atomic displacement ellipsoids are drawn at the 50% probability level.

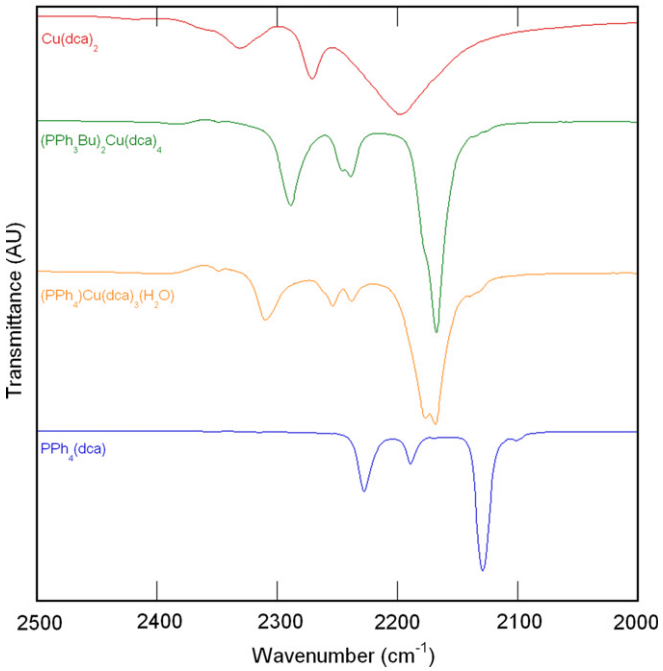

Fig. 8. Comparison of the cyano stretching region of the infrared spectrum of **1** and **2** as compared to the model compounds $Cu(dca)_2$ and $PPh_4(dca)$. Spectra are offset for clarity.

$(NR_4)[M(dca)_3]$ ($R = C_3H_7$, C_4H_9 and C_5H_{11}; M = Mn and Ni) salts [23].

3.2. Magnetic properties

The temperature-dependent magnetic susceptibility for **1** and **2** is illustrated in Fig. 9. From the data it can be seen that there is no maximum observed for either compound down to the lowest measured temperature suggesting the presence of only weak magnetic interactions. This is not surprising in that all of the reported Cu-dicyanamide compounds show negligible exchange along Cu–N≡C–N–C≡N–Cu pathways.

The magnetic data for **1** and **2** were fitted to the Curie–Weiss expression, $\chi = 0.125g^2S(S+1)/(T-\theta)$(emu/mol), yielding good agreement for $g = 2.123(1)$ and $\theta = -0.063(4)$ K and $g = 2.081(1)$ and $\theta = -0.063(5)$ K. The very small θ-values confirm the negligibly small interaction mediated by the dca ligands. Landé g-values expectedly exceed the free electron value of 2.0023 due to anisotropy of the g-tensor which is not a result of single-ion effects but rather due to the structural distortion of the Cu chromophores.

4. Discussion

It is often not appreciated how subtle changes in crystallization conditions can result in the formation of entirely different crystalline structures. We recently reported the synthesis of $(PPh_4)_3[Cu_4(dca)_{11}]$ [16], but had difficulty producing this material in pure form. To grow crystals of $(PPh_4)_3[Cu_4(dca)_{11}]$, ethanolic solutions of $(PPh_4)(dca)$ and $Cu(NO_3)_2 \cdot xH_2O$ were combined. Although small amounts of water were in the crystallization solution from the hydrated copper salt and exposure to atmospheric moisture, there was apparently not enough water present to preferentially crystallize the hydrated $(PPh_4)Cu(dca)_3H_2O$ complex **1** described in this paper. However, under the synthetic conditions reported in this paper, in which the $Cu(BF_4)_2 \cdot xH_2O$ was dissolved in water prior to mixing with an ethanolic solution of $(PPh_4)(dca)$, the hydrated phase crystallized in high purity. Ethanol has a higher vapor pressure than water, and thus the crystallization solution was mostly water when the $(PPh_4)Cu(dca)_3H_2O$ complex crystallized. We are confident that the crystalline material reported in this paper is of high purity, because no sign of impurities such as $(PPh_4)_3[Cu_4(dca)_{11}]$, $Cu(dca)_2$, or $(PPh_4)(dca)$ were observed in the X-ray powder diffraction pattern shown in Fig. 10.

Small differences in the coordination environment of the metal atom can entirely change the topology of the anion framework, even with the same templating cation. When EPh_4^+ (E = P and As) is used as a templating cation with the divalent first row transition elements Co(II), Mn(II), and Ni(II), the two-dimensional square lattice motif is commonly observed. A ladder structure has also been observed in the $(AsPh_4)_2[M_2(dca)_6(H_2O)] \cdot H_2O \cdot xCH_3OH$ (M = Co and Ni) salts, and a chain structure only for the cobalt derivative, $(PPh_4)_2Co(dca)_4$. Perhaps due to the Jahn–Teller distortion of the Cu^{2+} ion, these structural types have not yet been observed for that metal. Instead,

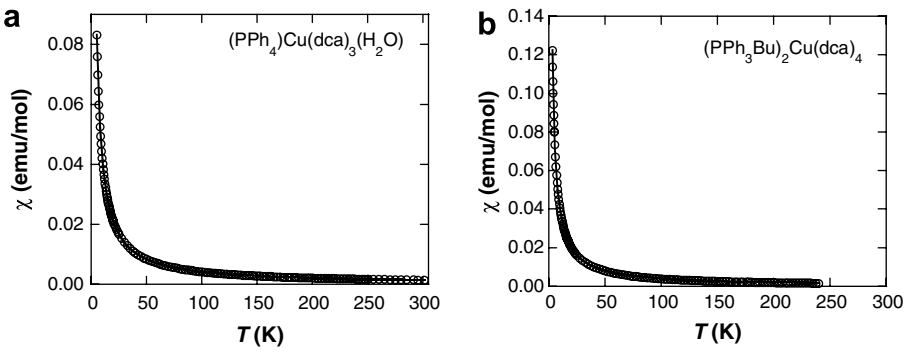

Fig. 9. Plots of the magnetic susceptibility (χ) vs. temperature (T) for **1** and **2**. Solid lines represent fits to the Curie–Weiss law as described in the text.

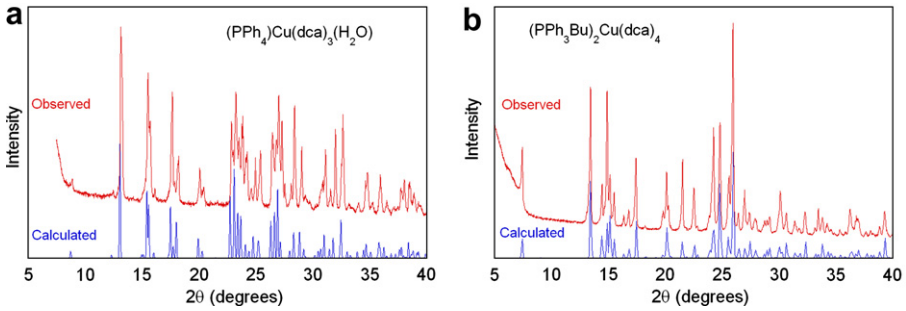

Fig. 10. The X-ray powder diffraction pattern of **1** (left) and **2** (right). The observed patterns (top) are compared to the calculated pattern (bottom).

two new anionic topologies have now been discovered in $(PPh)_3Cu_4(dca)_{11}$ and $PPh_4Cu(dca)_3H_2O$.

It has previously been shown that replacing one of the four phenyl groups of PPh_4^+ with methyl or ethyl results a breakdown of the lower dimensional lattice types and the formation of a three-dimensional distorted triple-rutile structural motif in the $(PPh_3R)M(dca)_3$ (R = Me and Et, M = Fe, Co, Ni and Mn) salts. The related $(NBzR_3)$-$M(dca)_3$ (R = Bu and Et; M = Mn, Co and Fe) structures, in which three of the phenyl groups have been replaced with small alkyl groups, also results in the formation of a three-dimensional structural motif: perovskite. We have also found three-dimensional structural motifs for the $[N(C_nH_{2n+1})_4]M(dca)_3$ salts ($n = 3$–5; M = Mn and Ni). It is interesting that no three-dimensional anionic structures of Cu^{+2} have yet been observed.

The $PPh_4Cu(dca)_3(H_2O)$ salt is chiral and crystallizes in a non-centrosymmetric space group. Such salts are of interest for possible non-linear optical behavior. Because the $Cu(dca)_3(H_2O)^-$ anion can crystallize in a non-centrosymmetric space group, it will be of interest to attempt to incorporate this anion into salts containing non-centrosymmetric cations with large β values which would enhance the non-linear optical properties.

5. Conclusion

Cationic templation often determines the anionic structural motif in dicyanomidometallate salts. These salts provide model compounds and precursor materials for the possible synthesis of hybrid materials that combine various properties such as magnetism, conductivity, non-linear optical behavior, etc. Among the dicyanamide salts, anionic coordination polymers containing divalent copper have rarely been studied. We have crystallized and magnetically characterized the $(PPh_4)Cu(dca)_3H_2O$ and $(PPh_3Bu)_2Cu(dca)_4$ salts. The former crystallizes in a chiral structure that contains singly bridged *cis* $\mu_{1,5}$-dca chains that are linked into a two-dimensional network through hydrogen bonding through coordinated water molecules. An entirely different structural motif, a triple ladder, forms when the crystallization occurs under anhydrous conditions. Replacement of one of the cation's phenyl groups with a butyl group results in the formation of the $(PPh_3Bu)_2Cu(dca)_4$ salt, which contains doubly bridged $\mu_{1,5}$-dca chains. Because the copper ions are bridged through long $\mu_{1,5}$-dca linkages, only negligibly weak magnetic interactions were observed in both compounds.

TEM grid. A representative image is shown in Fig. 1. In addition, selected area electron diffraction was compared to published powder X-ray diffraction patterns to confirm the structure (Fig. 2). Using Image J imaging software [19], the TEM images were analyzed to obtain the particle size distribution, and these data were fit to a log-normal distribution that yielded a characteristic diameter of 10 (±2) nm, Fig. 3.

To isolate particles, three volumes of acetone were added to the synthesis solution, which was centrifuged, and then further washed with acetone and dried under vacuum. Chemical analysis was obtained from a combination of CHN combustion analysis and ICP-MS. The formula was determined to be $Rb_{1.8}Co_4[Fe(CN)_6]_{3.2}$ and the ratio of PVP repeat unit to cobalt was found to be 55. The formula corresponds to a bulk composition known to show photoinduced magnetism [3]. The room temperature IR characterization of the sample of nanoparticles revealed one peak in the cyanide stretching region at 2124 cm^{-1}, and the result is consistent with a Fe^{II}–Co^{III} (ls) pair [4].

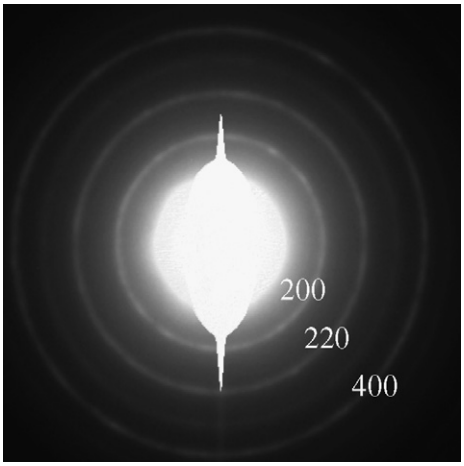

Fig. 2. Nanoparticle selected area electron diffraction pattern of a large agglomerate consisting of over 100 particles with the 200, 220 and 400 reflections identified.

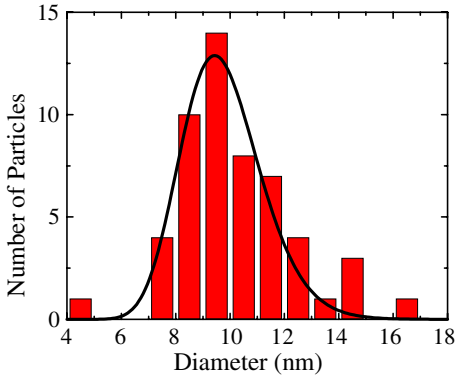

Fig. 3. Histogram of the nanoparticle size measured from HRTEM. The result of a log-normal fit is shown by the solid line.

3. Magnetic behavior

Samples were mounted to commercial transparent tape for magneto-optical measurements. A bundle of optical fibers, connected to a room temperature halogen light source, were introduced to the sample [20], and magnetic measurements were performed using a commercial SQUID magnetometer. The temperature dependent DC magnetic susceptibility of the particles in the light and dark states is shown in Fig. 4. Upon irradiation with light at 5 K, the nanoparticles show an increase in the field-cooled (FC) susceptibility. The difference between the FC susceptibilities of the light and dark states, i.e. $\Delta\chi$ plotted in the inset of Fig. 4, can only arise from the photoinduced magnetism. The nanoparticle FC magnetism increased by 40% when photoexcited at 5 K.

There is an increase in T_C from 15 K to 17 K and an increase in T_B (defined as the peak in ZFC magnetization) from 8 K to 10 K. Similar shifts are known for bulk

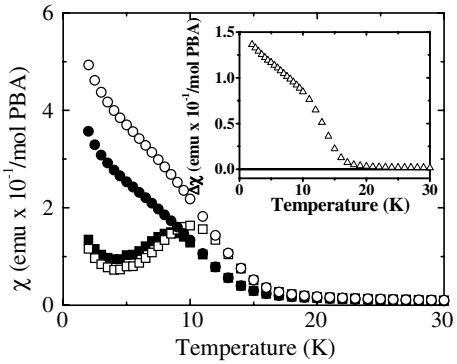

Fig. 4. Zero-field-cooled (ZFC) and field-cooled (FC) magnetic susceptibility versus temperature measured in a 100 G DC magnetic field for dark and light states. Dark state ZFC data (filled squares, ■) were obtained after cooling in zero applied field from 300 K, and dark state FC data (filled circles, ●) were taken after cooling in 100 G from 300 K. The light state was established after field cooling the samples from 300 K to 5 K in 100 G and subsequently illuminating with white light for 5 h. Light state FC data (open circles, ○) were obtained after cooling from 30 K in 100 G, and light state ZFC data (open squares, □) were taken after cooling from 30 K in zero applied field. The inset displays the difference between the light state FC data and dark state FC data.

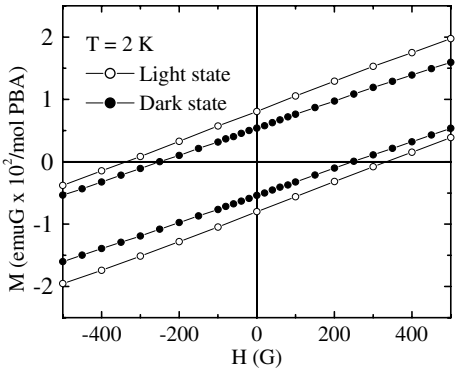

Fig. 5. Magnetization vs. field at 2 K. A coercive field of 250 G is present for the particles in the dark state (●) that increases to 330 G for the particles after 5 h of illumination (○).

material and are attributed to increased interaction lengths when the spins generated by the photoswitchable pairs increase the magnetic domain size.[1] There is a related increase in coercive field from 250 G in the dark state to 330 G in the light state (Fig. 5). The corresponding bulk material had a coercive field increase from 700 G to 1000 G.[1] The Co–Fe PBAs are characterized by glassy behavior that manifests itself in the DC data as a bifurcation in the FC and ZFC susceptibility plots below the blocking temperature. A similar response is observed for the nanoparticle sample (Fig. 4) in both light and dark states.

The data presented in Fig. 4 suggest that the nanoparticle sample possesses a distribution of particle sizes. This range of sizes leads to a distribution of transition temperatures, the highest being 15 K similar to the ferrimagnetic ordering temperature of the bulk, and is responsible for the gradual increase in susceptibility as the temperature is decreased. In contrast, the temperature dependence of the increase in the FC susceptibility weakens below T_B for bulk powder samples of the same formula [3]. In the nanoparticle sample with a range of particle diameters, smaller particles order at lower temperatures due to their restricted domain size. The particle size distribution is also reflected in the temperature dependent difference between FC light and dark susceptibilities, which increases with a steady slope as temperature is lowered.

4. Conclusion

Cobalt iron Prussian blue analogue nanoparticles have been synthesized and characterized. The nanoparticles have chemical formulas and structures consistent with the bulk material of the same composition. Analysis of TEM images shows the particles have an average size of 10 ± 2 nm. The ferrimagnetism observed in the bulk material is also seen in the nanoparticles, although the DC magnetization is altered by the reduced particle size and dispersion in particle diameter. Like the bulk, the nanoparticles are capable of exhibiting long-lived photoinduced magnetism. There is an effect of size on the magnetic behavior. A detailed study of the magnetic properties of nanoparticles of different sizes will be reported elsewhere.

[1] Unpublished results of Co–Fe PBA powder prepared without PVP using the same solution concentrations as the nanoparticles.

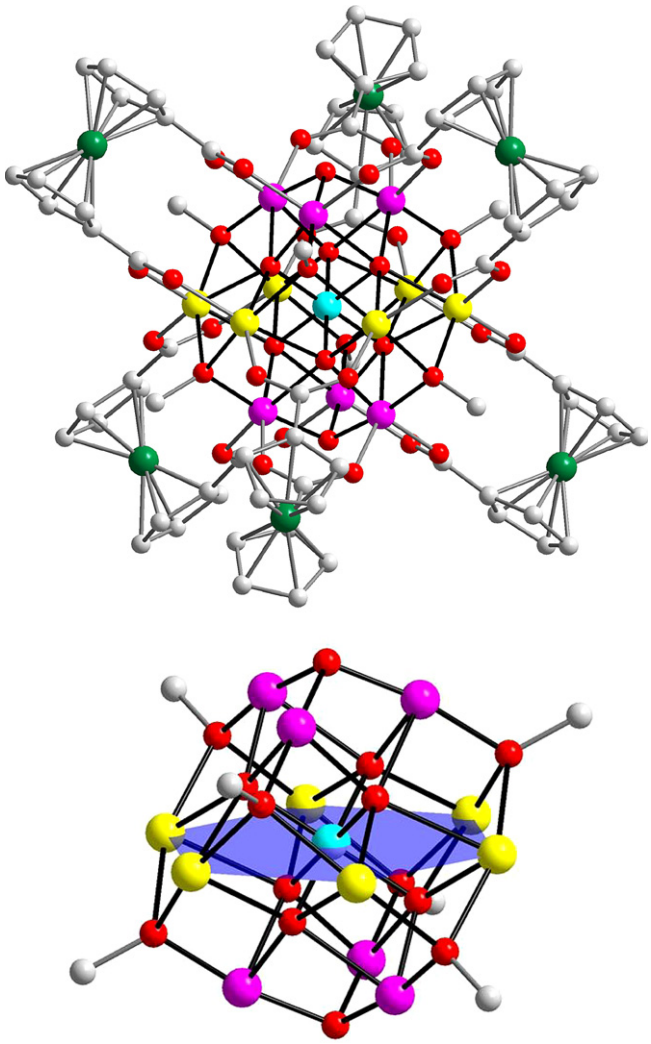

Fig. 1. Pov-Ray representation of **1** (top) and its core (bottom): Mn^{IV} (cyan), Mn^{III} (purple), Mn^{II} (yellow), O (red), Fe (green). Hydrogen atoms have been omitted for clarity. (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

The reaction between $[Mn_{12}O_{12}(O_2CMe)_{16}(H_2O)_4]\cdot 2MeCOOH\cdot 4H_2O$ and $fdcH_2$ in a 1:4 molar ratio in CH_2Cl_2/MeOH (1:1) gave a dark brown suspension, which was filtered. The filtrate slowly forms dark brown needles of $[Mn_{13}O_8(OMe)_6(fdc)_6]\cdot 8CH_2Cl_2$ (**1** · $8CH_2Cl_2$) suitable for X-ray crystallography.[1] The same product resulted from reactions in different solvent mixtures such as MeCN/MeOH. The core can be described as consisting of three layers: there is a central layer comprising a Mn^{II}_6 hexagon with a central Mn^{IV} atom, and a Mn^{III}_3 triangular unit above and below this (Fig. 1). The core is held together by bridging O^{2-} and MeO^- groups, and the peripheral ligation is provided by six μ_4-fdc^{2-} groups. Complex **1** is a known compound, having been obtained previously by Horiba et al. using a different procedure [3], and the same Mn_{13} core has also been observed with benzoate ligation by Sun et al. [6]. We have also prepared the ethoxide analogue of **1** by repeating the reaction in CH_2Cl_2/EtOH, which gave $[Mn_{13}O_8(OEt)_6(fdc)_6]\cdot 7EtOH$ (**2** · 7EtOH). The complex was not structurally characterized by X-ray crystallography, but instead it was identified by the similarity of its IR spectrum and magnetic properties with those of **1**, and by its elemental analysis. The procedure to complex **2** is actually superior to that for **1** in that it gives a cleaner reaction and a higher yield of product. In particular, the crystallization solutions show no sign of minor side-products, as sometimes plagues the preparation of **1**.

The filtration residue from the reaction that gives **1** or **2** was treated with DMF resulting in a dark brown suspension. This was filtered and the filtrate left undisturbed to slowly yield dark brown needles of the novel complex $[Mn_8O_4(fdc)_6(DMF)_2(H_2O)_2]\cdot 4DMF\cdot 4H_2O$ (**3** · 4DMF · $4H_2O$) suitable for X-ray crystallography.[2] Complex **2** contains a core comprising a central $[Mn^{III}_4(\mu_4\text{-}O)_4]^{4+}$ cubane to each O^{2-} ion of which is attached a Mn^{II} atom (Fig. 2). The Mn_8 topology is thus two concentric Mn_4 tetrahedra. There are six fdc^{2-} groups, each carboxylate group of which bridges a Mn^{II}/Mn^{III} pair in the same *syn*, *syn* $\eta^1{:}\eta^1{:}\mu_2$-mode seen in **1**. The peripheral ligation is completed by a terminal DMF ligand on two of the Mn^{II} atoms, and a terminal H_2O ligand on the remaining two. As a result, the Mn^{III} and Mn^{II} atoms are six- and five-coordinate with near-octahedral and trigonal bipyramidal geometries, respectively. The metal oxidation states were again confirmed by charge considerations, bond valence sum (BVS) calculations [7,8], and the observation of Mn^{III} Jahn–Teller distortions. The torsion angles between the two carboxylate groups of the fdc^{2-} ligands vary: four fdc^{2-} groups have torsion angles of $<30°$ (synperiplanar configuration) and the other two have angles between 30° and 90° (synclinal configuration) [9].

Since $fdcH_2$ had given two interesting complexes from its reactions with $[Mn_{12}O_{12}(O_2CMe)_{16}(H_2O)_4]\cdot 2MeCOOH\cdot 4H_2O$, we also explored other reactions with various Mn^{II} starting materials. The reaction of $Mn(ClO_4)_2\cdot 6H_2O$ and $fdcH_2$ in a 1:1 molar ratio in DMF/MeOH (ratio 1:1) formed an orange suspension. This was filtered and the filtrate layered with Et_2O. Dark brown crystals of $[Mn_7O_3(OMe)(fdc)_6(H_2O)_3]\cdot 3DMF\cdot 3MeOH$ (**4** · 3DMF · 3MeOH) slowly grew as hexagonal plates that were suitable for X-ray crystallography.[3] The structure of **4** is somewhat

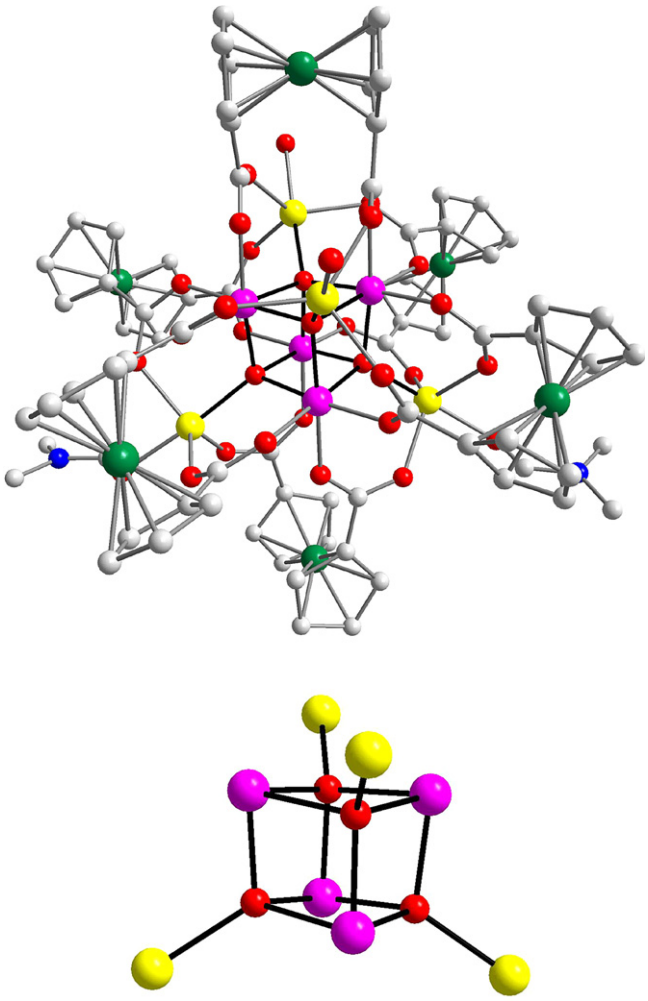

Fig. 2. Pov-Ray representation of **3** (top) and its core (bottom): Mn^{III} (purple), Mn^{II} (yellow), O (red), N (blue), Fe (green). Hydrogen atoms have been omitted for clarity. (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

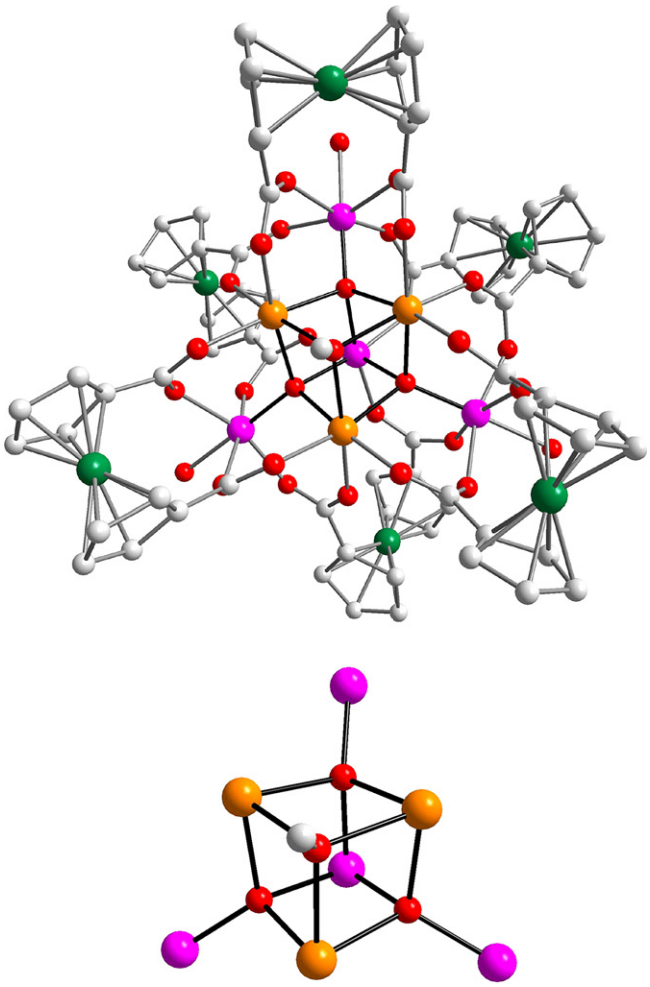

Fig. 3. Pov-Ray representation of complex **4** (top) and its core (bottom). Mn^{III} (purple), disordered $2Mn^{II}$ plus Mn^{III} (orange), O (red), Fe (green). Hydrogen atoms have been omitted for clarity. (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

similar to that of **3** in that there is a central Mn_4O_4 cubane, but one of the O atoms is now part of a MeO^- group, rather than an O^{2-} ion, and thus there are only a total of three additional Mn atoms, each attached to one of the three O^{2-} ions of the central cubane (Fig. 3). The overall $[Mn_7(\mu_4\text{-}O)_3(\mu_3\text{-}OMe)]$ core is unprecedented.

The Mn oxidation states of **4** are not analogous to those in **3**, and this represents another major difference between the two structures. The oxidation states have been probed by BVS calculations, and the results were overall consistent with charge balance considerations based on the electroneutrality of the complex, and assuming none of the ferrocene groups are in the oxidized form, but with a few uncertainties in the precise details. The following preliminary conclusions have been reached: the three exterior Mn atoms attached to the cubane are all clearly Mn^{III}. The three Mn atoms in the central cubane core bridged by the MeO^- group are related by the crystallographic C_3-axis and thus give the same BVS value, which is characteristic of an average oxidation state less than 2.5+. We thus conclude that these three Mn atoms comprise one Mn^{III} and two Mn^{II} that are statically disordered by the symmetry axis. In other words, their Mn–O bond lengths are in-between those typical for true Mn^{III}–O and Mn^{II}–O bonds. The remaining Mn atom in the cubane and diagonally opposite the MeO^- group (Fig. 3) was expected, on the basis of charge neutrality, to be Mn^{III} but had a BVS lower than expected, and we believe this may be due to a Mn^{III}/ferrocene versus Mn^{II}/ferrocenium static disorder, i.e. one of the ferrocenes may be oxidized. At this time, we cannot unequivocally conclude anything more definite, but this point is currently under further investigation and will be discussed in more detail in the full paper.

There are again six fdc^{2-} groups providing the peripheral ligation about the core, which can be divided into two sets with equivalent torsion angles and binding modes within each set. In fact, this is the first case in this work where we have seen the fdc^{2-} groups to adopt different binding conformations, and no doubt this is due to the

lower symmetry of **4** compared to **1** and **3**. The three Mn^{III} atoms outside the cubane define a plane that divides the two sets of fdc^{2-} groups; the set lying on the opposite to the methoxide has the same kind of binding mode as in **1** and **3**, i.e. each fdc^{2-} attaches to a total of four Mn atoms in an $\eta^1{:}\eta^1{:}\eta^1{:}\eta^1{:}\mu_4$ bridging mode with a torsion angle of 6.48°. In contrast, the other set of fdc^{2-} groups bind to a total of three Mn atoms in an $\eta^1{:}\eta^1{:}\eta^1{:}\eta^1{:}\mu_3$-mode with a torsion angle of 26.67°. Thus, each carboxylate O atom is still attached to only a single Mn atom, but two of them are now attached to the same Mn^{III} atom, the one external to the cubane. Finally, there is a terminal H_2O group bound to each external Mn^{III} atom, and all Mn atoms are consequently six-coordinate with near-octahedral geometries.

Magnetic susceptibility (χ_M) data were collected for complexes **1**–**4** on polycrystalline samples in a 0.1 T DC field in the 5.00–300.00 K temperature range. The data for **1** and **2** were essentially superimposable, and thus we report here only the data for complexes **2**, **3** and **4** (Fig. 4). $\chi_M T$ for **2** is almost constant at ~47 cm^3 K mol^{-1} from 300 to 150 K and then decreases steadily to 11.54 cm^3 K mol^{-1} at 5.00 K. This suggests the presence of dominant antiferromagnetic exchange interactions within the cluster. $\chi_M T$ for **3** remains almost constant with decreasing temperature, with a value close to ~15 cm^3 K mol^{-1} for the entire temperature range. It fluctuates with decreasing temperature before reaching a value of 13.64 cm^3 K mol^{-1} at 5.00 K. $\chi_M T$ for **4** decreases steadily from 12.00 cm^3 K mol^{-1} at 300 K to 2.43 cm^3 K mol^{-1} at 5.00 K, again indicating dominant antiferromagnetic interactions within the molecule.

Complexes **2**, **3** and **4** are too large and/or too low symmetry for easy determination of the various pairwise exchange parameters J_{ij} between two Mn atoms Mn_i and Mn_j, and we therefore concentrated instead on determining their ground state spin (S) values. This was carried out by two independent methods, fitting of their variable-temperature (T) and -field (H) DC magnetization data, and AC susceptibility measurements. DC magnetization (M) data were collected in the 1.8–10.0 K range in fields varying between 0.1 and 7 T, and fit to a model that assumes only the ground state is populated, includes axial zero-field splitting ($\widehat{S}_z^2 D$) and the Zeeman interaction ($g\mu_B\mu_0\widehat{S}\cdot H$), and incorporates a full powder average. The obtained best-fit S, g and D values for complexes **2**–**4** are listed in Table 1. In order to avoid complications from low-lying excited states, data collected in very high DC fields were not employed. For **2** and **4**, we could only get good fits by using data collected only in fields up to 0.8 T. For **3**, data up to higher field values could be employed.

The ground state S values for **2**–**4** were confirmed by AC susceptibility measurements in the temperature range 1.8–15 K using a 3.5 G AC field oscillating at a frequency of 50, 250 and 997 Hz. AC susceptibility studies are performed in the absence of a DC field and therefore avoid the problems caused by low-lying excited states. The real, or in-phase, AC susceptibility (χ'_M) of complexes **2**–**4** is plotted as $\chi'_M T$ versus T in Fig. 5. Extrapolation of the plots to 0 K, from temperatures above ~4 K to avoid the effects of weak intermolecular interactions (dipolar and superexchange), gives values of ~11, ~13 and ~2.5 cm^3

Table 1
The g and D values obtained from fits of magnetization data for complexes **2**–**4**

Complex	Fields (T)	S	g[a]	D (cm^{-1})[b]

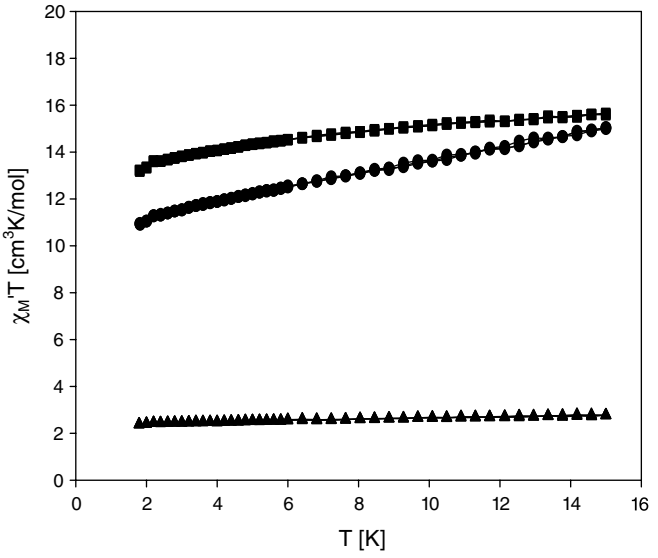

Fig. 5. Plot of $\chi'_M T$ vs. T for complexes **2** (●), **3** (■) and **4** (▲); the signals at 50, 250 and 997 Hz are essentially superimposed.

K mol^{-1}, confirming ground state S values of 9/2, 5 and 2, respectively (with $g < 2$, as expected for Mn), in satisfying agreement with the DC magnetization fits. None of the complexes displayed out-of-phase (χ''_M) AC susceptibility peaks above 1.8 K, the operating limit of our SQUID magnetometer. There were some signs of the beginnings of signals whose peaks lie below 1.8 K, and these may correspond to the very small dips in the $\chi'_M T$ plots of Fig. 5 at $T < 2$ K. Studies at temperatures below 1.8 K are in progress to explore this point further.

In summary, the use of $fdcH_2$ in Mn cluster chemistry has led to an interesting family of ferrocene-rich Mn_7, Mn_8 and Mn_{13} complexes. The latter two were obtained by a carboxylate substitution reaction on $[Mn_{12}O_{12}(O_2CMe)_{16}(H_2O)_4] \cdot 2MeCOOH \cdot 4H_2O$, which caused structural changes to the core. Although the core of Mn_{13} has been seen before, the present work has provided both a convenient synthetic route and also a means to prepare the previously unknown ethoxide analogue. All three structural types possess non-zero ground state spin values, although they do not seem to be new examples of single-molecule magnets, at least based on data collected at >1.8 K. The described work represents the desired synthetic breakthrough into this area of ferrocene-rich Mn clusters, and work is currently in progress to investigate the electrochemical properties of these clusters. Indeed, preliminary results on **4**, the easiest to study because of its high solubility, show rich redox behavior with multiple reversible processes.

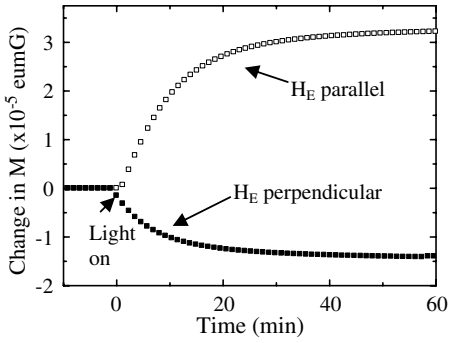

Fig. 1. Anisotropy in the photoinduced magnetism of a 75 nm film of Co–Fe PBA, measured at 5 K with the measuring field of 200 G oriented parallel (□) and perpendicular (■) to the film.

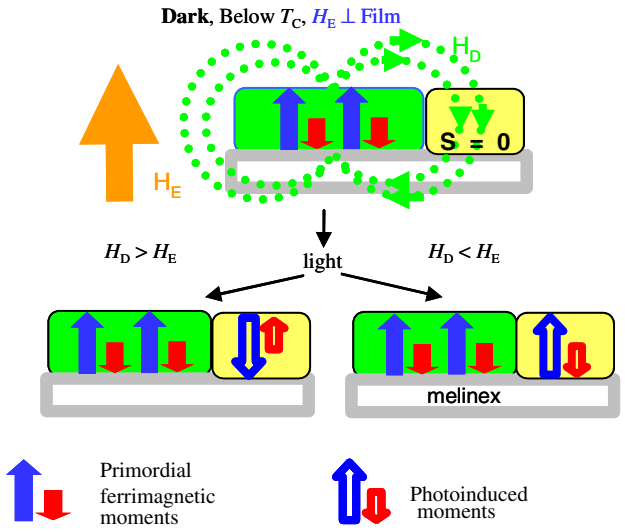

Fig. 2. The photoinduced magnetism in a quasi-two-dimensional film of Co–Fe PBA. The direction of the induced moments will depend on the vector sum of the dipolar field (H_D) from the primordial moments and the applied magnetic field (H_E).

nature of the thin film. If correct, then the anisotropic response should be influenced by the film thickness. In order to investigate this conjecture, a method of generating continuous, thickness-controlled films of the Co–Fe PBA is needed. This fabrication protocol would allow the generation of progressively thicker films possessing an evolution of photomagnetic behavior.

Methods of generating Prussian blue films and their analogues include electrochemical methods [17–23], which are the most common, dip-coating or spin casting of colloidal solutions [20,24], adsorption onto sol–gel films [25,26], adsorption at Langmuir monolayers [27–34], and multiple sequential adsorptions (MSA) [14–16,35–39] at modified surfaces. The MSA method offers the advantages of homogeneous film generation, availability of different substrates, fine thickness control, and the ability to easily tailor the composition of the generated film. We have adapted the MSA methods to prepared photoactive Co–Fe PBA thin films possessing a range of thickness. In this article, we investigate the influence of film thickness on the anisotropic photoinduced magnetism in Co–Fe PBA thin films. Whereas thinner films (<~200 nm) show the anisotropic behavior previously reported, we show here that the magnitude of the photoinduced decrease diminishes as the film thickness increases until the film behaves like the three-dimensional powder with a photoinduced increase in magnetism in all orientations.

2. Experimental

2.1. Sample preparation of $Rb_{0.7}Co_4[Fe(CN)_6]_{3.0} \cdot nH_2O$ thin films

Method 1, fast growth [15]. A hydrophilic solid support such as silicon or Melinex® was used as a substrate. The substrate was quickly immersed five times in a 5 mM aqueous solution of cobalt(II) nitrate over 3 s. The excess solution was drained and the substrate was quickly immersed five times in an aqueous solution of 20 mM potassium ferricyanide and 12.5 mM rubidium nitrate over 3 s. The substrate was then rinsed with deionized water for 5 s. This process was repeated 1, 5, 10, 20 or 40 times to generate films increasing in thickness (Films 1a–e). After deposition, the film was rinsed with methanol and dried under vacuum.

Method 2, slow growth [37]. A sheet of Melinex® was placed in a 5 mM aqueous solution of cobalt nitrate for 60 s. The film was rinsed with DI water for 10 s then rinsed with methanol for 2 s and dried with a stream of N_2. The film was then placed in a solution containing 20 mM potassium ferricyanide and 0.125 mM rubidium nitrate for 60 s. The film was rinsed with DI water for 10 s then rinsed with methanol for 2 s and dried with a stream of N_2 to complete one cycle. The process was repeated for 5, 10, 20, 40, and 75 cycles (Films 2a–e) to generate films of varied thickness.

2.2. Instrumentation

The elemental analyses were performed by inductively coupled plasma mass spectrometry (ICP-MS) on a Thermo-Finnigan Element-2 spectrometer. FTIR spectra were recorded using a Bruker Vector 22 spectrometer. Atomic force microscopy (AFM) measurements were performed using a Digital Instruments multimode scanning probe microscope. Scanning electron microscopy (SEM) images were obtained using a Hitachi S-4000 FE-SEM. Magnetic measurements were made using a Quantum design MPMS XL superconducting quantum interference device (SQUID) magnetometer. A bundle of 10 optical fibers, 270 μm OD (Ocean Optics Model 200), was used to introduce a room temperature halogen light source of 1–2 mW power into the SQUID magnetometer.

2.3. Analysis preparations

Solid supports were cut to 8 cm × 2.5 cm and cleaned. Silicon wafers, used for transmission FT-IR experiments,

were cleaned using the RCA procedure [40] and 20 cycles of material using Method 1 was deposited. Melinex® 535/380 gauge obtained from DuPont Teijin films was cleaned using methanol and used for all other processes. ICP-MS samples of the 40 cycle films from both methods were prepared by digesting the film and substrate in 2 mL of 100 °C concentrated sulfuric acid for 4 h, resulting in a black liquid. Concentrated nitric acid (0.5 mL) was then added dropwise, before diluting the mixture to 100 mL with DI water. The samples were compared to matrix matched metal blends between 1 ppm and 1 ppb. For magnetic measurements the samples were cut into squares $\sim$10.5 mm^2 and stacked, with the surfaces parallel, into a polycarbonate sample holder. Background contributions of the container and Melinex were measured separately and subtracted from the signals obtained from the samples.

3. Results and discussion

3.1. Film generation and characterization

As described in the preceding section, the solid support was first immersed in a solution containing Co^{II} ions followed by immersion in a solution containing Rb^+ and $[Fe(CN)_6]^{-3}$. For Method 1, substrates were immersed in both solutions before rinsing, resulting in a film that developed quickly. In Method 2, the substrate was rinsed between changing solutions, limiting the amount of material deposited during each cycle. Thickness and roughness data were obtained by averaging the measurements of five different 4 μm^2 AFM scans. Both methods display a linear increase of thickness with number of cycles (Fig. 3). Although the slow growth Method 2 affords finer control of the film thickness, the roughness of films generated by the two methods are comparable at similar thickness, as indicated in Table 1.

The homogeneity of the films prepared by each method can be compared by SEM, Figs. 4 and 5. After only one cycle of Method 1 (Fig. 4a) the substrate is still visible, indicating that uniform coverage is not yet achieved. After 5 cycles, Film 1b, the substrate is completely covered with

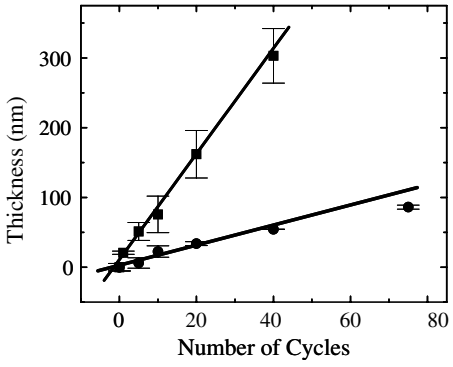

Fig. 3. Thickness vs. number of cycles for the fast growth, Method 1 (■), and slow growth, Method 2 (●), using multiple sequential adsorption deposition to generate thin films of the Co–Fe PBA.

Table 1
Thickness and roughness data for MSA films of Co–Fe PBA

Film	Number of cycles	Thickness (nm)	RMS roughness (nm)
Fast growth			
1a	1	21 ± 3.2	11
1b	5	51 ± 7.5	17
1c	10	75 ± 21	23
1d	20	160 ± 29	62
1e	40	300 ± 34	100
Slow growth			
2a	5	6.1 ± 2.1	2.0
2b	10	22 ± 2.7	8.8
2c	20	34 ± 2.7	12
2d	40	71 ± 14	22
2e	75	86 ± 2.6	37

powder-like features. The surface morphology is retained as the film develops beyond 5 cycles (Fig. 4). Films generated using Method 2 deposit more slowly. The average thickness of a 20 cycle Film 2 is 34 nm in contrast to the 20 cycle film from Method 1 which has an average thickness of 160 nm. The SEM images for Method 2 confirm the slower deposition rate (Fig. 5). Complete coverage is not obtained until 20 cycles, at which point the films show similar morphology to those generated using Method 1. After 75 cycles of Method 2 the morphology changes with larger blocks taking form.

All films are a light pink with uniform coloration over the surface of the substrate. The room temperature IR spectra of a 20 cycle fast growth film (Fig. 6) shows two peaks in the cyanide stretching range, a sharp peak at 2169 cm^{-1} attributed to the Fe^{III}–Co^{II}(hs) bridging cyanide and a broad peak centered at 2103 cm^{-1} that is attributed to the Fe^{II}–Co^{II}(hs) bridging cyanide stretch. The energy of these stretches agrees with previously reported powder samples [2].

3.2. Magnetic behavior of Films 1b–e

The photomagnetic response of four films, 1b–e, with nominal thicknesses of 51, 75, 160 and 300 nm were measured at $T = 5$ K using dc magnetometry with $H_E =$ 200 G applied perpendicular to the plane of the films, Fig. 7. Only Method 1 films are described because we were interested in monitoring changes in behavior as a function of film thickness, and significant changes were only realized for thicker films. The 51, 75, and 160 nm thick films all show a decrease in magnetization upon illumination. The magnitude of the effect (not corrected for the film thickness) increases as the thickness increases from 51 to 75 nm, but then diminishes for the 160 nm thick film. For the 300 nm film, illumination increases the magnetization, as is known for bulk samples.

The magnetic behavior confirms that the thin-film geometry is necessary to observe the photoinduced decrease in magnetization. The result is consistent with the proposed mechanism whereby the photoswitchable

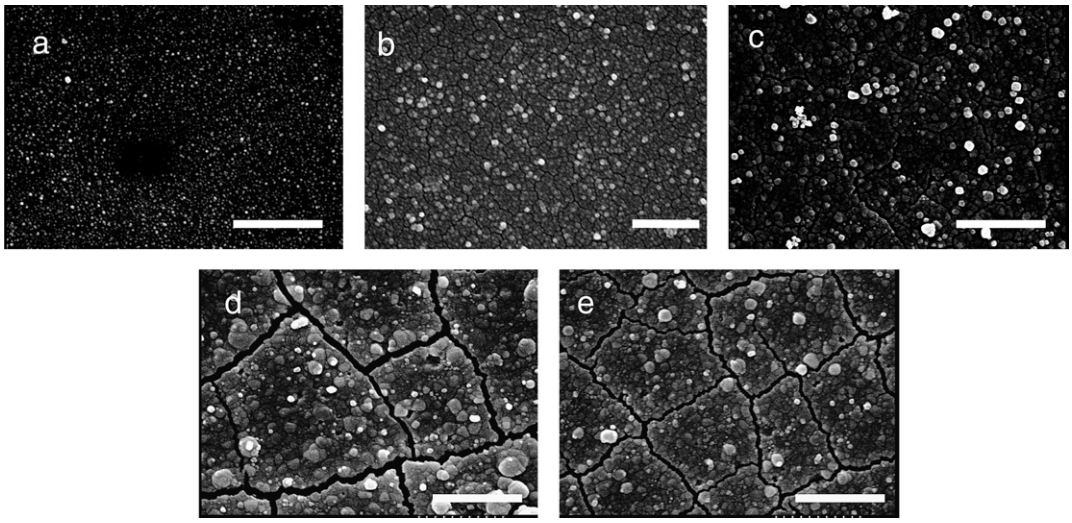

Fig. 4. SEM images of Method 1 Films, 1a–e, with thicknesses of 21, 51, 75, 160, and 300 nm, respectively. A 1 μm scale bar is shown for each. The MSA method develops a homogeneous film after 5 cycles. The surface morphology is retained as the film develops beyond 5 cycles.

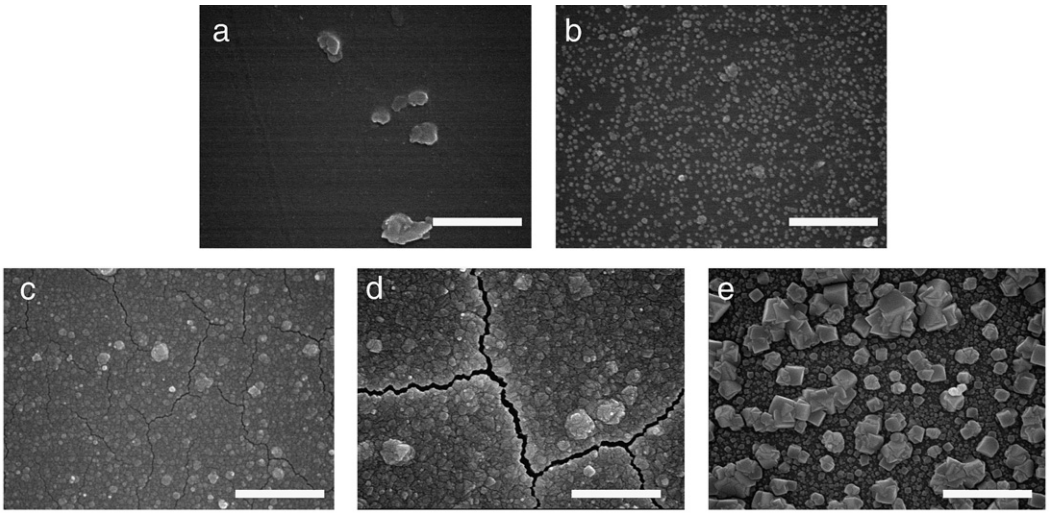

Fig. 5. SEM images of Method 2 Films, 2a–e, with thicknesses of 6.1, 22, 34, 71, and 86 nm, respectively. A 1 μm scale bar is shown for each. Uniform coverage is achieved after 20 cycles; less material is deposited by Method 2 when compared to Method 1. Method 2 films show roughness and surface coverage similar to Method 1 images of similar thicknesses.

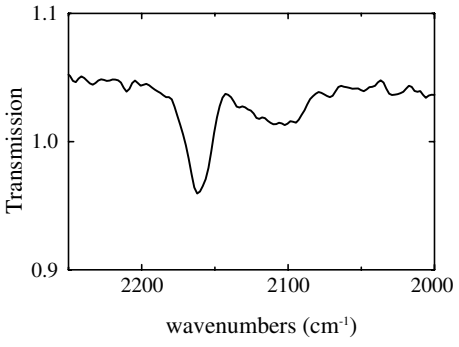

Fig. 6. FT-IR of a 20 cycle fast growth film on silica at room temperature. IR bands are similar to those found in powder samples of the same composition. A sharp peak at 2169 cm^{-1} is attributed to the Fe^{III}–Co^{II}(hs) bridging cyanide stretch and the broad peak centered at 2103 cm^{-1} is attributed to the Fe^{II}–Co^{II}(hs) bridging cyanide stretch.

moments are influenced by the dipolar field generated by the primordial ferrimagnetic domains. For thin films, the photoswitchable moments are only influenced by neighbors within the plane of the film, and so these dipolar fields orient perpendicular to the film, opposing the applied field. As the film grows into a random three-dimensional powder, the neighboring moments become more random, losing the directional influence. For the films studied here, the transition to three-dimensional behavior begins for thicknesses greater than 75 nm, suggesting that the important interaction length is of this order. By 300 nm, bulk-like behavior is seen.

It was previously observed that the influence of the internal dipolar field can be cancelled with a sufficiently strong external field causing the photoinduced moments to increase the overall magnetization instead of decreasing

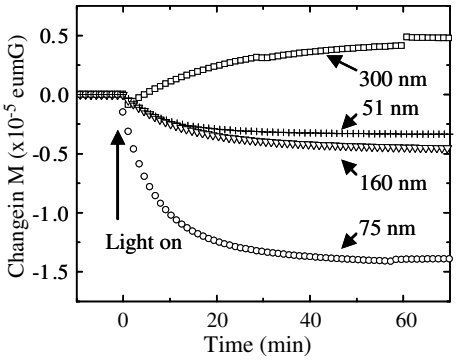

Fig. 7. Thickness dependence of the photoinduced magnetization in Co–Fe PBA thin films with H_E perpendicular to the film plane, Film 1b (+) 51 nm, 1c (○) 75 nm, 1d (△) 160 nm, and 1e (□) 300 nm. The films less than 200 nm thick show a decrease in magnetization upon illumination. As the film thickness increases further the photoinduced increase in magnetization becomes similar to that of bulk powder samples.

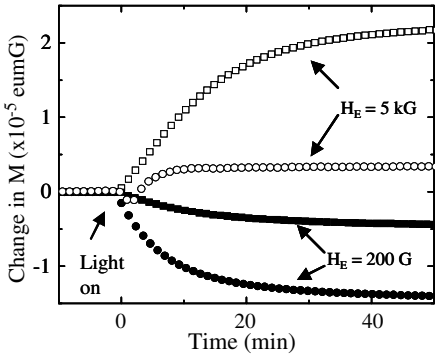

Fig. 8. Applied field dependence of the photoinduced magnetism with H_E perpendicular to the plane of the film. The 75 nm Film 1c measured with $H_E = 200$ G (●) and 5 kG (○) and the 160 nm Film 1d with $H_E = 200$ G (■) and 5 kG (□).

it. To confirm this behavior, the 75 and 160 nm films were measured in $H_E = 5$ kG oriented perpendicular to the films (Fig. 8), and both samples show a photoinduced increase in magnetization in this higher field, consistent with the mechanism illustrated in Fig. 2.

4. Conclusions

The anisotropy in the photoinduced magnetism of thin films of Co–Fe PBA is dependent on several factors. There must be residual ferrimagnetic moments present in the film to align with H_E, generating an internal dipolar field that influences the surrounding photoswitchable moments. The film geometry needs to be quasi-two-dimensional so that the overlapping dipolar fields do not cancel. In this paper, the effect of film thickness on the quasi-two-dimensional character of the film was explored. The photoinduced decrease in magnetism is maintained for films ~100 nm and less, but the effect diminishes for thicker films and is eliminated for films greater than ~200 nm. The MSA method provides sufficient thickness control and film homogeneity to easily generate Prussian blue analogue thin films that meet the requirements for observing this phenomenon unique to continuous thin films.

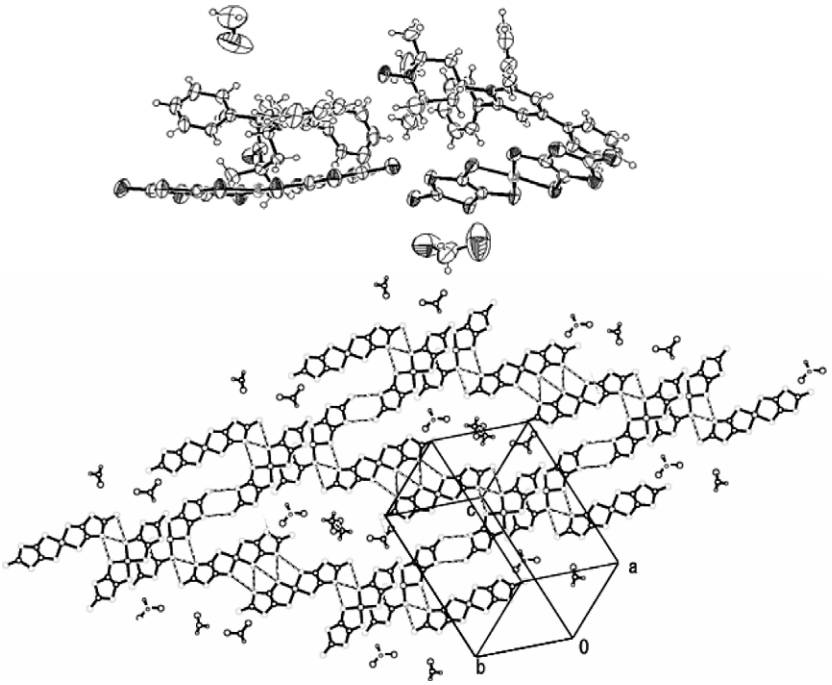

Fig. 1. (Upper) Crystal structure of **III** · $[Ni(dmit)_2](CH_2Cl_2)_{0.75}$ salt. (Lower) 2D structural feature of the anion layer in the same salt.

amount of $[n\text{-}Bu_4N]^+[Ni(dmit)_2]^-$ in a mixed solution of acetone–dichloromethane (1:1), dark greenish solid was precipitated, which then was filtered to give a radical salt. The single crystal grown from dichloromethane solution was then analyzed by X-ray crystallography to reveal that the cation-to-anion ration is 1:1 with incorporation of dichloromethane in a ratio of 0.75 in the crystal (Fig. 1, upper).[1] There exist a couple of crystallographically independent ion pairs being composed of the pyridinium and the anion and no close contact is seen between the spins on aminoxyls and also between the oxygen atoms and neighboring $[Ni(dmit)_2]$ anions, suggesting the paramagnetic behavior of isolated aminoxyl spins of $S = 1/2$. However, several S–S contacts are observed between the $[Ni(dmit)_2]$ anions as shown in Fig. 1(lower) to propagate in the crystal forming sheet-like structures in two-dimensional manner and inferring significant magnetic interactions between the spins on the nickel atoms.

The magnetic data of the salt are shown in Fig. 2(left). Weak antiferromagnetic interaction is discerned in the lower temperature region with the values of Curie constant of 0.66 emu K mol^{-1} and Weiss temperature −0.68 K, respectively. Its larger value than that of isolated $S = 1/2$ spin (0.375 emu K mol^{-1}) suggests the contribution χ–χ_{TEMPO} from the spins on $[Ni(dmit)_2]$ anions to the total χ-values. The χ-χ_{TEMPO} values can be well expressed by 2D Heisenberg model [4] as indicated in Fig. 2 (right), thus reflecting 2D structural feature found in the crystal (*vide supra*). However, the exchange interactions are estimated to be rather weak ($J = -3.11$ K) from the data.

The air oxidation of the **III** · $[Ni(dmit)_2]$ (1:1) salt in an acetone solution containing acetic acid and acetic anhydride yielded black powdery solid and the results of the elemental analyses indicate the formation of a 1:6 salt with somewhat larger anion ratio than that of most salts previously reported [1]. The magnetic data of the salt showed CW behavior with Curie constant of 0.67 emu K mol^{-1} and Weiss temperature 1.87 K, respectively. The resistivity measurement was performed for the compressed pellet of the salt, using the standard four-probe method and the data of Arrhenius plot are shown in Fig. 3. Thus, the salt shows semi-conducting behavior with room temperature conductivity of 1.55 S cm^{-1} and relatively small activation energy E_A of 85 meV.

2.2. *Pd(dmit)$_2$ complexes and Ni(mnt)$_2$ complexes of* ***III***

The $\mathbf{III}_2$ · $[Pd(dmit)_2]$ (2:1) salt was prepared by the reaction of **III** with 0.5 molecular amount of $[n-Bu_4N]_2^+[Pd(dmit)_2]^{2-}$ in an acetone solution and the cation-to-anion ration is substantiated from the crystal structure obtained by the X-ray analysis of a single crystal of the salt.[2] Very weak antiferromagnetic interaction of CW behavior is observed in the salt between the aminoxyl spins with Curie constant of 0.37 emu K mol^{-1} and Weiss

[1] Crystal data for **III** · $[Ni(dmit)_2]_2$ (1:1) salt: $C_{38}H_{34}N_2OCl_2NiS_{10}$, $F_W = 984.91$, triclinic ($P-1$), $a = 14.813(3)$ Å, $b = 16.499(2)$ Å, $c = 19.430(4)$ Å, $\alpha = 76.226(5)°$, $\beta = 73.446(2)°$, $\gamma = 78.889(2)°$, $V = 4380.8(12)$ $Å^3$, $T = 296$ K, $Z = 4$, $D_{calc} = 1.493$ mg cm^{-3}, $R = 0.1052$, $R_W = 0.1050$ [9175 observed reflections and 982 parameters, $I > 3\sigma(I)$].

[2] Details of the crystal data will be reported in a full paper.

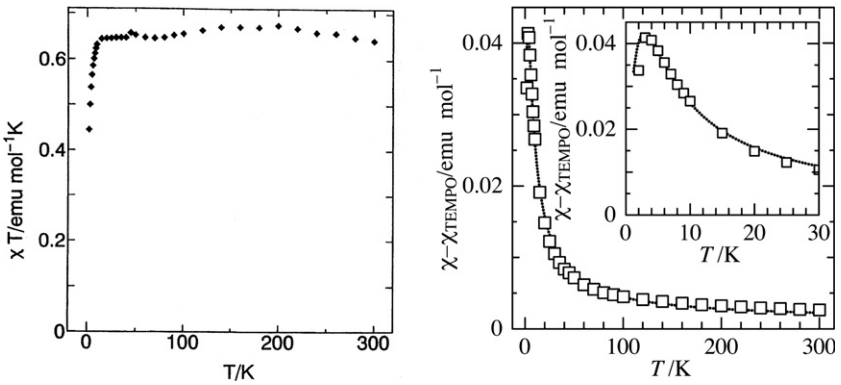

Fig. 2. (Left) The χT–T data of **III** · $[Ni(dmit)_2](CH_2Cl_2)_{0.75}$ salt. (Right) Contribution from χ–χ_{TEMPO} data and an enlarged figure at lower temperature region is inserted as inset. The solid line indicates the theoretical one calculated by 2D Heisenberg model.

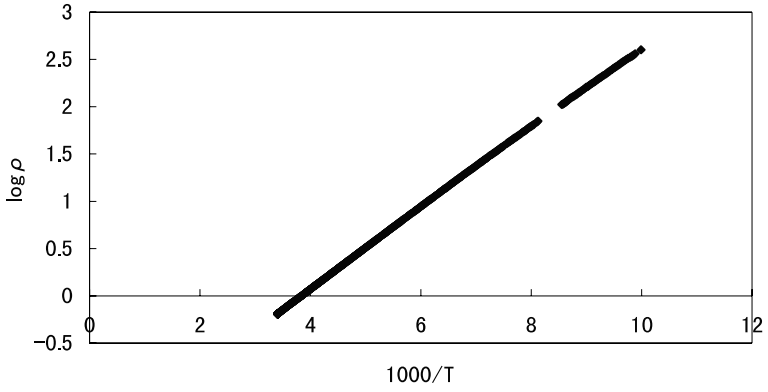

Fig. 3. The Arrhenius plot of resistivity data for the oxidized salt of **III** · $[Ni(dmit)_2]_6$.

temperature of −0.13 K. Air oxidation of the salt yielded the corresponding oxidized salt again with the cation-to-anion ratio of 1:6 and the semi-conducting property is also observed in the salt with room temperature conductivity of 6.44 S cm^{-1} and activation energy E_A of 85 meV.

Similar treatment of the pyridinium tetrafluoroborate (**III**) with either $[n-Bu_4N]_2^+[Ni(mnt)_2]^{2-}$ or $[n\text{-}Bu_4N]^+$-$[Ni(mnt)_2]^-$ gave the corresponding salts and their crystal structure analyses on the single crystals obtained from acetonitrile revealed that the cation-to-anion ratio of the former salt is 2:1 with inclusion of one acetonitrile molecule in the unit cell and the latter salt has the ratio of 4:5 with two acetonitrile molecules.[2] Only weak antiferromagnetic interactions are observed in the spins of both salts with CW behavior ($C = 0.39$ emu K mol^{-1} and $\theta = -0.80$ K for the former salt and $C = 0.37$ emu K mol^{-1} and $\theta = -0.96$ K for the latter salt), indicating absence of significant interactions between the spin centers in both salts and the room temperature conductivity measurements of both salts reveal them to be almost insulating. Although the oxidation by using iodine is so far unsuccessful for both salts, we are still trying to prepare the oxidized species by other conditions and/or methods such as electrocrystallization with regulated current.

In summary, we have prepared several magnetic salts derived from a TEMPO-substituted 2,4,6-triphenyl pyridinium (**III**) with $Ni(dmit)_2$, $Pd(dmit)_2$ or $Ni(mnt)_2$ as counter anions and the structures and magnetic properties of the salts have been investigated. While only weak antiferromagnetic interaction of CW behavior derived from $S = 1/2$ spin is predominantly observed in the salts of **III**$_2$ · [Pd-$(dmit)_2$], **III**$_2$ · $[Ni(mnt)_2]$, and **III** · $[Ni(mnt)_2]$, the magnetic behavior of **III** · $[Ni(dmit)_2]$ can be explained by the summation of $S = 1/2$ spin and the contribution from the spins on $[Ni(dmit)_2]$ anions (χ–χ_{TEMPO}), which obeys 2D Heisenberg model and reflects its crystal structure with 2-D structural feature. The electrical conductivities of **III** · $[Ni(dmit)_2]$, **III**$_2$ · $[Pd(dmit)_2]$, and a couple of $Ni(mnt)_2$ salts are less than 10^{-6} S cm^{-1} but the oxidized salts of the $Ni(dmit)_2$ as well as $Pd(dmit)_2$ salts show semi-conducting properties with relatively high conductivities and low activation energies.

3. Supplementary material

CCDC 624575 contains the supplementary crystallographic data for **III** · $[Ni(dmit)_2]_2$. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

CN linker, and those attached to the nitrogen end. The superexchange mechanism in these solids involves delocalization of spin density via π backbonding of unpaired t_{2g} electrons from the metals in the carbon sites into the bridging cyanide π^* orbitals; more efficient delocalization typically leads to larger exchange couplings (J) and higher magnetic ordering temperatures (T_C or T_N). The magnetic ordering temperatures of Prussian blue analogues can be maximized by constructing them from metal centers bearing electrons in high-energy d-orbitals: such centers are capable of back bonding strongly into the cyanide π^* orbitals and maximizing the extent of spin delocalization [7–9].

For hexacyanometalate ions of first-row transition metals, the energies of the d-electrons depend on two parameters. The first of these parameters is the oxidation state of the metal. Metals in lower oxidation states have more electrons to screen the nuclear charge, and the increased screening leads to an increase in the energies of all the valence electrons. Although hexacyanometalates are known in the +1 oxidation state, all are diamagnetic and thus ill-suited for preparing Prussian blue magnets; the lowest oxidation state accessible for paramagnetic hexacyanometalate ions is +2. The second parameter that controls the energies of the d-electrons is the position of the metal in the first-row of the periodic table. Other things being equal, metals early in the d-block have higher-energy d-electrons because they have lower nuclear charges. This fact explains why the highest ordering temperatures seen to date are for Prussian blue analogues that contain vanadium(II) centers: early transition metal ions in low oxidation states have electrons in high-energy, radially expanded d-orbitals, and these electrons delocalize quite readily into the cyanide π^* orbitals, thus increasing the exchange coupling between adjacent spin centers, and affording magnetic materials with higher magnetic ordering temperatures.

Because substitution of early transition metals into the Prussian blue structure gives magnets with unusually high ordering temperatures, we have long been interested in preparing a Prussian blue analogue that contains the earliest first-row transition metal, titanium. In 1997, we described the synthesis of the hexacyanotitanate(III) ion, and had high hopes for preparing new magnets from this building block in which the Ti^{III} center occupied the carbon sites of the Prussian blue structure [10]. Unfortunately, all attempts to prepare magnetic phases from this starting material have been unsuccessful. The $[Ti^{III}(CN)_6]^{3-}$ ion is instantly hydrolyzed in water, so this medium cannot be used for the synthesis of Prussian blue analogues from this starting material. Although the $[Ti^{III}(CN)_6]^{3-}$ ion is soluble in acetonitrile, and its solutions afford precipitates upon the addition of transition metal cations such as V^{II}, Cr^{II}, or Mn^{II}, the solids obtained are non-crystalline and non-magnetic, probably because the precipitation is rapid and irreversible in this poorly coordinating solvent, so that there is no opportunity for an ordered Prussian blue structure to form [6].

In the present study, we report our attempts to prepare Prussian blues in which the titanium(III) center is not in the carbon site, but rather in the nitrogen site of the PB structure. Despite the fact that the titanium(III) center carries only one unpaired electron, so that few spin exchange pathways are available, the low value of the effective nuclear charge of the titanium(III) ion means that this electron will reside in a very high energy d-orbital. As a result, incorporating Ti^{III} into a PB should afford solids with high magnetic ordering temperatures because the one d-electron should delocalize significantly into the cyanide π^* orbital.

The high energy of the d-orbitals on titanium(III) ion means that it is a strong reductant, a fact that is well known from its electrochemistry and solution reaction chemistry. Thus, in order to use this cation as a starting material for the synthesis of Prussian blues, we chose to investigate its reactions with an anion that is relatively difficult to reduce: the hexacyanochromate(III) ion $[Cr(CN)_6]^{3-}$. The redox potentials suggest that these two reactants should not undergo a redox reaction. We find that these two building blocks do react to generate a Prussian blue phase, but not one containing both titanium and chromium. Instead, the product has been identified as a nanocomposite of titanium dioxide with an all-chromium Prussian blue. Such nanocomposites have recently been shown to be useful in the construction of photoelectrodes [11].

2. Results and discussion

2.1. Attempts to synthesize titanium(III) hexacyanochromate(III) in water

We began our investigations with the reaction of titanium(III) ions with hexacyanometalates in aqueous solutions. The hexaaquotitanium(III) ion is known to be stable in water only if the pH is kept below ~1 [12]. At higher pH values, the hexaaqua ion undergoes ionization reactions to produce $[Ti^{III}(OH)(OH_2)_5]^{2+}$ and other, more highly condensed species. Therefore, we dissolved titanium(III) *p*-toluenesulfonate in water that had been acidified to pH ~2 with *p*-toluenesulfonic acid, and to this solution we added $[NEt_4]_3[Cr(CN)_6]$. From the mixture, we isolated a gray solid, which was isolated by centrifugation, washing, and drying; we will refer to this product as **1**. The metal weight percentages (Cr, 19.4; Ti, 17.4) were consistent with those calculated (Cr, 19.0; Ti, 17.5) for the molecular formula "$Ti[Cr(CN)_6]\cdot H_2O$".

The X-ray powder diffraction pattern of **1** contains several peaks, all of which can be indexed to a face-centered cubic cell with a lattice constant of 10.36 Å (Fig. 1). The symmetry of the cell and its cell parameters are strongly indicative of the presence of a Prussian blue phase. The average crystallite size, which was estimated from the widths of the diffraction peaks using the Debye–Scheerer equation [13], is 224 Å.

The infrared spectrum of **1** features a single intense cyanide stretching absorption at 2181 cm^{-1}. The shifting

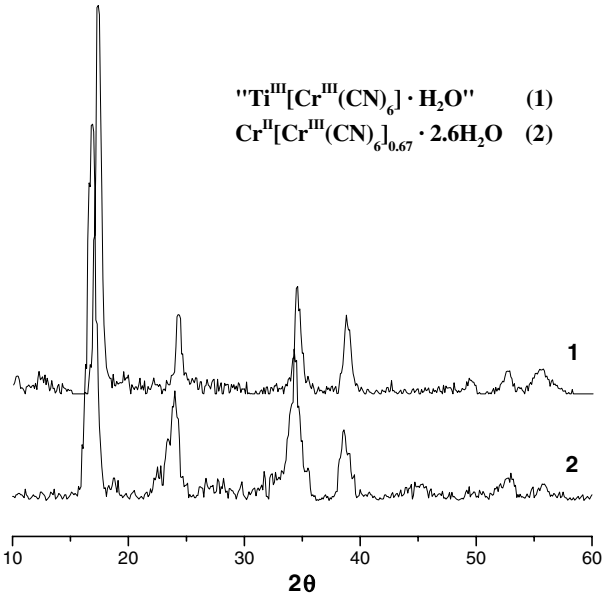

Fig. 1. Base-line-corrected powder X-ray diffraction patterns of **1** (top) and **2** (bottom). The seven main peaks are the 200, 220, 400, 420, 440, 442, and 620 reflections (left–right).

of the ν_{CN} stretching absorption to higher energies relative to that of 2112 cm^{-1} in $[NEt_4]_3[Cr(CN)_6]$ is diagnostic for the formation of cyanide groups that bridge between two metal centers. The frequency lowering is the consequence of the depopulation of the cyanide 5σ orbital upon formation of a bond between the nitrogen atom and a second metal center [14].

For Prussian blue analogues, (and other magnetic solids constructed from two interpenetrating lattices), the sign of the local exchange interactions can usually be determined from the shape of the μ_{eff} versus T curve: for ferrimagnetic solids there is a minimum in μ_{eff} above the ordering temperature owing to the effects of short-range antiferromagnetic correlations that cancel spins [15–19]. Such a minimum is observed in **1** and thus it is clearly a ferrimagnet (Fig. 2). The minimum is rather shallow and appears at *ca.* 325 K. At lower temperatures, the magnetic moment increases dramatically as the magnetic ordering temperature is approached Fig. 2.

The magnetic ordering temperature can be deduced from plots of χ^{-1} versus T (Fig. 3). The curve can be fit to Néel's hyperbolic equation, $1/\chi = (T-\theta)/C - \zeta/(T-\theta')$, where θ and C are the Weiss and Curie constants, and θ' and are ζ are proportional to $\eta_A\eta_B\, C[\eta_A - \eta_B]$ and $\eta_A\eta_B C$, where η_i is the fractional occupancy of each sublattice site [20,21]. The sign of the Weiss constant is negative; this feature is characteristic of ferrimagnets. The intersection of the hyperbola with the temperature axis gives the magnetic ordering temperature (T_N). The derived value for **1** is 265 K, although a slightly different value was determined from the magnetization curves (see below), and the Weiss and Curie constants are provided in Table 1.

At 350 K, the magnetic moment per formula unit (reckoned according to the formula given above) is 4.50 μ_B and this value suggests that **1** is composed of $S = {}^3/_2$ Cr^{III} and $S = {}^1/_2$ Ti^{III} metal centers in a 1:1 ratio: the value of μ_{eff} calculated for randomized Ti^{III} and Cr^{III} spins with $g = 2$ is 4.52 μ_B.

The temperature dependence of the field-cooled, zero-field cooled, and remnant magnetization for **1** clearly show the onset on long-range magnetic order at 255 K (Fig. 4); the ordering temperature is the point at which the field-cooled and zero-field curves diverge, and also the point at which the magnetization goes to zero. The magnetic ordering temperature defined in this way is more accurate than that deduced from the χ^{-1} versus T curve.

The magnetization value of **1** (Table 1) at 5 K is 5.0 kG cm^3 mol^{-1} (again, for the formula unit given above) at an applied magnetic field of 70 kG (Fig. 5). The magnetization has not saturated even at 70 kG, but if we extrapolate to large fields, we can estimate that the saturation magnetization should be near 11 kG cm^3 mol^{-1}. For the formula "$Ti[Cr(CN)_6]\cdot H_2O$," the calculated saturation magnetization for antiferromagnetically coupled Ti^{III} and Cr^{III} centers is 11.2 kG cm^3 mol^{-1}. Compound **1**

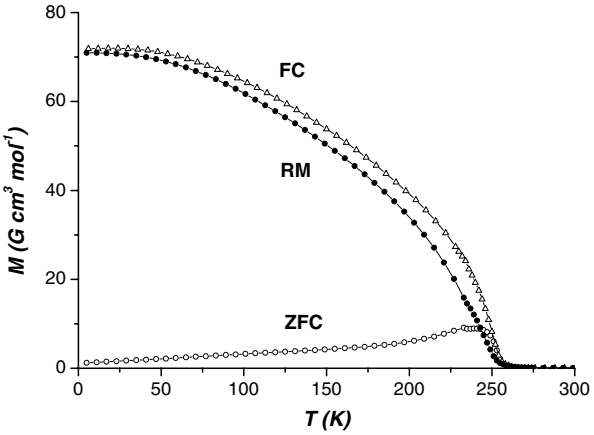

Fig. 4. Temperature dependence of the zero-field cooled (ZFC, ○), field-cooled (FC, △) and remnant magnetization (RM, ●) curves for **1** at $H_{dc} = 1$, 1, and 0 G, respectively.

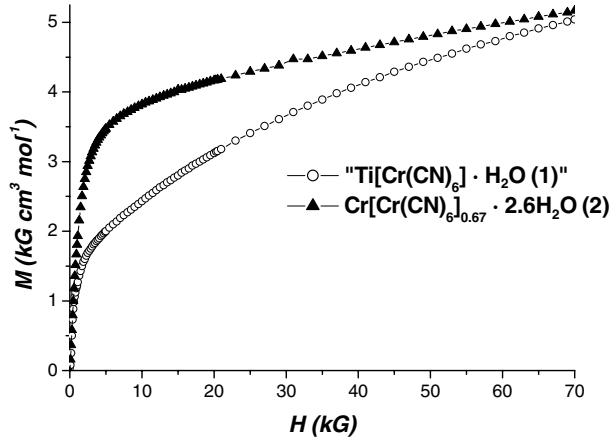

Fig. 5. Field dependence of the magnetization for **1** (○) and **2** (▲) at 5 K.

also exhibits hysteresis below its magnetic ordering temperature (Fig. 6). The coercive field measured at 5 K is 260 G (Table 2).

To summarize the results above, the metal content and all the spectroscopic data suggested that **1** was the first Prussian blue magnet containing Ti^{III}. One measurement was inconsistent with this conclusion, however: the experimentally determined carbon, hydrogen, and nitrogen analyses (C, 8.75; H, 2.49; N, 14.0) disagreed with those calculated for the formula "$Ti[Cr(CN)_6]\cdot H_2O$" (C, 26.3; H, 0.74; N, 30.7). We, therefore, were forced to reconsider

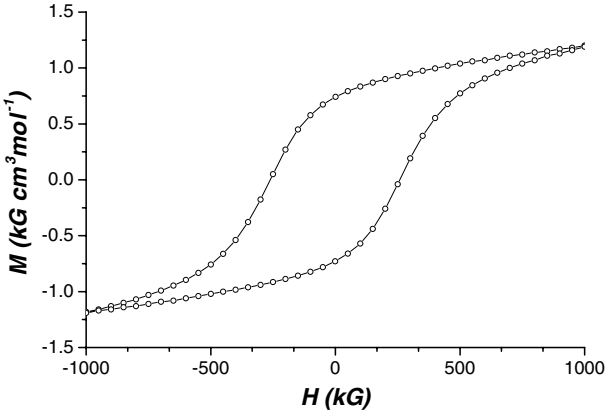

Fig. 6. Hysteresis of **1** at 5 K.

our findings about the nature of **1**. Before we discuss our conclusions, we describe a related Prussian blue compound that will be relevant to this discussion.

2.2. Synthesis and characterization of a chromium(II) hexacyanochromate(III)

Combining aqueous solutions of chromium(II) *p*-toluenesulfonate and $[NEt_4]_3[Cr(CN)_6]$ immediately affords a red-brown suspension from which an air sensitive red-brown solid of stoichiometry $Cr^{II}[Cr^{III}(CN)_6]_{0.67}\cdot xH_2O$ (**2**) can be isolated ($x \sim 2.6$).

The infrared spectrum of **2** exhibits an intense cyanide stretching band at 2180 cm^{-1}, and the high frequency of this band clearly suggests that the bridging cyanide ligands are C-bound to Cr^{III} centers. A weaker low frequency band at 2075 cm^{-1} is most likely due to cyanide groups C-bound to Cr^{II}. The powder X-ray diffraction pattern can be indexed to a face-centered cubic cell having a cell constant of 10.44(4) Å (Fig. 1). The average crystallite size, which was estimated using the Debye–Scheerer equation [13], is 102 Å.

As judged from the temperature dependence of the magnetization of **2** in an applied field of 1 G, the magnetic ordering temperature is 242 K (Figs. 7 and 8). At this temperature, the field-cooled (1 G) and zero-field-cooled (1 G) curves diverge and the remnant magnetization curve goes to zero. A fit of the χ^{-1} versus T plot (25 G) to Néel's hyperbolic function gives an essentially identical value for the magnetic ordering temperature of 237 K. The hysteresis curve for **2** is shown in Fig. 9.

Table 2
Remnant magnetizations and coercive fields for the new molecular magnets at 5 K; estimation of exchange coupling parameters (J) from the observed magnetic ordering temperatures

Compound	M_r (G cm^3 mol^{-1})	H_C (G)	J (cm^{-1})	T_N (K)
"$Ti^{III}[Cr^{III}(CN)_6]\cdot H_2O$ (**1**)"	753	260	−57	255
$Cr^{II}[Cr^{III}(CN)_6]_{0.66}\cdot 2.6H_2O$ (**2**)	760	275	−36	242

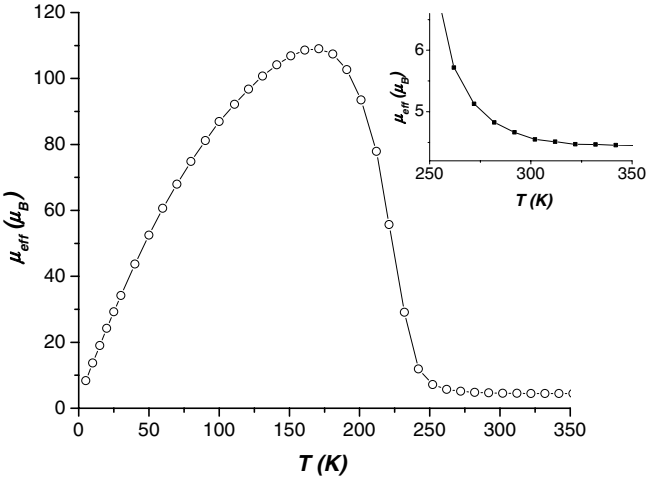

Fig. 7. Temperature dependence of **2** at $H_{dc} = 25$ G. Inset: minimum observed at *ca.* 300 K. on cooling from the high temperature limit.

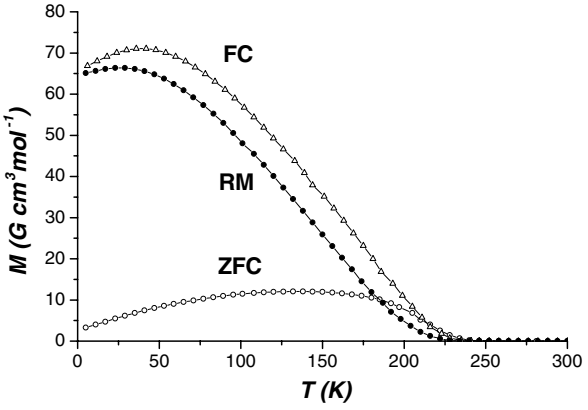

Fig. 8. Temperature dependence of the zero-field cooled (ZFC, ○), field-cooled (FC, △), and remnant magnetization (RM, ●) for **2** at $H_{dc} = 1$, 1, and 0 G, respectively.

The measured saturation magnetization of 5.17 kG cm^3 mol^{-1} (5 K, 70 kG) suggests that about half of the Cr^{II} ions are low spin and the other half are high spin, but that both types of Cr^{II} centers are coupled antiferromagnetically to the Cr^{III} center (Fig. 5). Specifically, if all of the low-spin Cr^{II} ions were low spin, then the saturation magnetization would be 0.056 kG cm^3 mol^{-1}, whereas if all of the Cr^{II} ions were high spin, then the saturation magnetization would be 11.1 kG cm^3 mol^{-1}. The slow approach to saturation could mean that **2** is a canted antiferromagnet or that it has some spin glass character [22,23]. Verdaguer has reported a similar distribution of both low and high

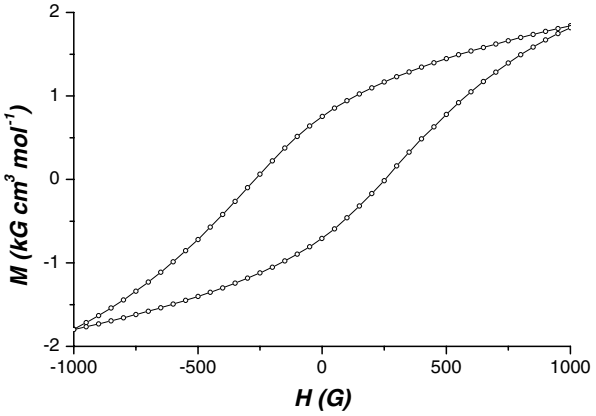

Fig. 9. Hysteresis for **2** at 5 K.

spin Cr^{II} centers in the solid $Cs_{0.75}Cr_{1.025}[Cr(CN)_6]\cdot 5H_2O$ [24].

The plot of the magnetic moment versus temperature (μ_{eff} versus T) at 25 G does not exhibit the shallow minimum just above T_N that is expected for a ferrimagnetic material (Fig. 7). It is possible that this minimum is located above 350 K, the upper limit of our data set. The observed value of the magnetic moment at room temperature (4.66 μ_B at 292 K and 4.547 μ_B at 320 K) again suggests that both low- and high-spin Cr^{II} centers are present: if all had been low-spin, then μ_{eff} should be ~4.25 μ_B, whereas if all had been high-spin, then μ_{eff} should be ~5.84 μ_B.

Verdaguer has described a similar reaction, using $CrCl_2$ as the Cr^{II} source, and has formulated the gray product as $Cr_5(CN)_{12}\cdot 10H_2O$ (or, equivalently, $Cr[Cr(CN)_6]_{0.67}\cdot 3.3H_2O$) [24]. In addition, Miller and Hashimoto have reported that thin films of mixed Cr^{II}/Cr^{III} cyanometalates, can be prepared from $CrCl_3$ and $K_3[Cr(CN)]_6$ at negative applied potentials [25–28]. Also described by Verdaguer is the green all-Cr^{II} compound $Cs_{0.75}Cr_{1.025}[Cr(CN)_6]\cdot 5H_2O$, which exhibits IR absorptions at 2187 and 2069 cm^{-1}, and is ferromagnetic below $T = 190$ K [24].

2.3. Reformulation of *1*

As mentioned above, treatment of $[Ti(OH_2)_6]^{3+}$ with $[Cr(CN)_6]^{3-}$ in water affords a gray solid whose spectroscopic properties and metal content were entirely consistent with it being a Prussian blue analog of stoichiometry $Ti[Cr(CN)_6]\cdot H_2O$. However, this formulation is inconsistent with elemental analysis carbon, hydrogen, and nitrogen values expected for **1**; several lines of evidence suggest that it is not a Prussian blue analogue containing

Ti^{III}. (1) The XRD pattern of **1** (which can be indexed to a fcc cell with a cell constant of 10.36 Å) is almost identical to the 10.44 Å value seen for $Cr^{II}[Cr^{III}(CN)_6]_{0.67} \cdot xH_2O$. The absence of peaks due to the TiO_2 component is consistent with the known behavior of nanophase titania, which generally remains amorphous until heated to temperatures above 250 °C [29]. (2) The infrared spectrum of **1** (which contains a strong absorption at 2180 cm^{-1} and a weaker broad absorption at 2075 cm^{-1}) closely resembles that of the all-chromium complex $Cr^{II}[Cr^{III}(CN)_6]_{0.67} \cdot xH_2O$. The presence of TiO_2 is signaled by the IR band at 800 cm^{-1}, which is assigned to the longitudinal optical (LO) mode of the Ti-O bonds in rutile, which appears at 806 cm^{-1} [30]. (3) The magnetic ordering temperature ($T_N = 255$ K) for **1** is close to the magnetic phase transition temperature ($T_N = 242$ K) for $Cr^{II}[Cr^{III}(CN)_6]_{0.67} \cdot xH_2O$.

These facts strongly suggest that **1** is a mixture of $Cr^{II}[Cr^{III}(CN)_6]_{0.67} \cdot xH_2O$ and some other titanium-containing phase. In fact, all the properties of **1**, including the microanalytical data, are consistent with the conclusion that it is a mixture of $Cr^{II}[Cr^{III}(CN)_6]_{0.67} \cdot xH_2O$ and $TiO_2 \cdot nH_2O$ in the ratio of 1–1.6.

These results suggest that Ti^{III} reduces $[Cr^{III}(CN)_6]^{3-}$ to generate Ti^{IV} and Cr^{II}. The electrochemical potentials for $[Cr(CN)_6]^{3/4-}$ (−1.140 V versus SHE) [31], and Ti^{3+}/TiO^{2+} (0.008 V versus NHE) [32,33] suggest that the $[Cr^{III}(CN)_6]^{3-}$ ion should not be reduced by Ti^{III}. Of course, there will be some equilibrium concentration of the redox products of this reduction; we hypothesize that the hexaquotitanium(III) ion reduces some of the $[Cr^{III}(CN)_6]^{3-}$ ions to Cr^{II}; the latter ion is kinetically labile and will lose its CN ligands, thus providing the source of aquated Cr^{II} ions necessary to produce $Cr^{II}[Cr^{III}(CN)_6]_{0.67} \cdot x\ H_2O$. In this process the Ti^{3+} ions are oxidized to Ti^{4+}, which in aqueous solutions at low pH will generate hydrated $TiO_2 \cdot nH_2O$ [33].

2.4. Attempts to synthesize titanium(III) hexacyanochromate(III) in methanol

Treatment of $[NEt_4]_3[Cr(CN)_6]$ with $Ti(OTs)_3$ in methanol affords a dark purple suspension which slowly becomes a gel over 24 hours. The solid was collected after 3 days by centrifugation and washed with methanol to afford a dark blue solid. Consistent with the results described above, our characterization of this solid strongly suggests that it is best formulated not as a mixed Ti–Cr Prussian blue, but rather as the biphasic material $Cr[Cr(CN)_6]_{0.67} \cdot 7MeOH \cdot 1.67TiO_2$, **3**. Its XRD pattern is consistent with a fcc unit cell with a cell constant essentially identical to that described above for **1**, but the material is less crystalline, as judged from the widths of its diffraction peaks. This difference is not unexpected, because water is a better solvent than methanol, and should better facilitate the annealing out of defects in the structure as it is assembled from solution during the synthesis. The infrared spectrum of **3** exhibits an intense cyanide stretching absorption at 2168 cm^{-1} that is lower than that of 2181 cm^{-1} observed for **1**, but still consistent with the presence of $[Cr^{III}(CN)_6]^{3-}$ centers in which the CN ligands bridge to another metal center. The magnetic ordering temperature for **3** (54 K; Fig. 10) is lower than the ordering temperature observed for **1**, probably because the PB component is less crystalline.

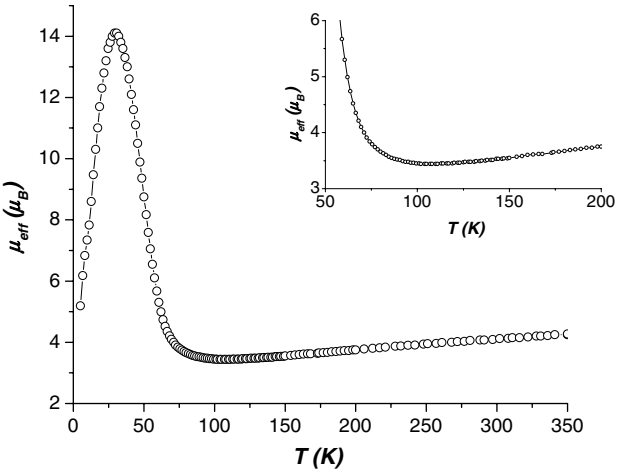

Fig. 10. Temperature dependence of the effective moment per formula unit for $Cr^{II}[Cr^{III}(CN)_6]_{0.67} \cdot 7MeOH \cdot 1.67TiO_2$ (**3**) in an applied field of 25 G. The inset shows the minimum observed near 80 K on cooling from the high temperature limit.

3. Experimental

3.1. General considerations

All operations were conducted in vacuum or under an argon atmosphere by using standard Schlenk techniques. Transfers of solutions containing cyanide were carried out through teflon cannulas. Solvents were distilled under dinitrogen from CaH_2 (acetonitrile), Mg turnings (methanol), or sodium-benzophenone (diethyl ether) and sparged with argon before use. Deionized water was sparged with argon. The salts $Cr(OTs)_2$, $Ti(OTs)_3$, and $[NEt_4]_3[Cr(CN)_6]$ are described elsewhere [34,35]. The IR spectra were recorded as Nujol mulls between KBr plates on a Perkin–Elmer 1600 FTIR instrument. Magnetic measurements were conducted on Quantum Design MPMS and MPMS^2 SQUID magnetometers. Diamagnetic corrections were estimated using Pascal's constants [36]: $\chi_{dia} = -150 \times 10^{-6}$ cm^3 mol^{-1} for **1** and -108×10^{-6} cm^3 mol^{-1} for **2**. Microanalyses were performed by the University of Illinois Microanalytical Laboratory. Powder diffraction measurements were carried out on a Bruker P4RA/GADDS wide angle diffractometer using a Cu Kα radiation source.

3.2. $Ti[Cr(CN)_6] \cdot H_2O$ (1)

To a solution of $Ti(OTs)_3$ (0.51 g, 0.908 mmol) and $HOTs \cdot H_2O$ (0.06 g, 0.315 mmol) in water (20 mL) was

added a solution of $[NEt_4]_3[Cr(CN)_6]$ (0.50 g, 0.835 mmol) in water (20 mL) over 10 s, affording an orange solution. After 10 min, a gray solid precipitated and the mixture was centrifuged at 3000 r.p.m. for 10 min. The supernatant was discarded and the gray solid was washed with water (2×40 mL), centrifuging and discarding the supernatant each time. The gray solid was washed with acetonitrile (15 mL) and was dried under vacuum at room temperature overnight. Yield: 0.094 g (34%). *Anal.* Calc. for $Ti[Cr(CN)_6] \cdot H_2O$ ($C_6H_2N_6OCrTi$): Cr, 19.0; Ti, 17.5. Found: C, 8.75; H, 2.49; N, 14.0; Cr, 19.4; Ti, 17.4%. *Anal.* Calc. for $Cr[Cr(CN)_6]_{0.67} \cdot 7H_2O \cdot 1.67TiO_2$ ($C_4H_{12}N_4O_{9.33}Cr_{1.67}Ti_{1.67}$): Cr, 19.2; Ti, 17.8. IR (cm^{-1}): 3270 (vs), 2181 (s), 2069 (w), 1614 (w), 1305 (w), 1261 (m), 1151 (m), 1074 (m), 1023 (m), 800 (vs), 525 (vs, br).

3.3. $Cr[Cr(CN)_6]_{0.67} \cdot 2.6H_2O$ (2)

To a solution of $[NEt_4]_3[Cr(CN)_6]$ (0.30 g, 0.501 mmol) in water (20 mL) was added a solution of $Cr(OTs)_2 \cdot 3.2H_2O$ (0.39 g, 0.863 mmol) in water (10 mL) over 25 s to afford a fine red-brown suspension. The mixture was transferred to an argon-filled centrifuge bottle and was centrifuged at 3000 r.p.m. for 10 min. The pale red supernatant was discarded and the brown solid was washed with water (2×50 mL), centrifuging and discarding the supernatant each time. The solid was then suspended in acetonitrile (20 mL) and the slurry was transferred to a flask. The solvent was removed in vacuum and the red-brown solid was dried for 10 h in vacuum at room temperature. Yield: 0.068 g (38%). *Anal.* Calc. for $Cr[Cr(CN)_6]_{0.67} \cdot 2.6H_2O$: C, 20.3; H, 2.20; N, 23.6; Cr, 36.5. Found: C, 20.8; H, 2.56; N, 18.1; Cr, 36.5%. IR (cm^{-1}): 3606 (s, br), 3302 (s, br), 3192 (s, br), 2180 (s), 2075 (w), 1623 (w), 530 (s).

3.4. Attempts to synthesize titanium(III) hexacyanochromate(III) in methanol

To a solution of $[NEt_4]_3[Cr(CN)_6]$ (0.30 g, 0.501 mmol) in methanol (10 mL) was added a solution of $Ti(OTs)_3$ (0.31 g, 0.561 mmol) in methanol (10 mL). The initially dark purple suspension slowly became a gel over the course of one day. After 3 days, the dark blue solid was transferred to an argon-filled centrifuge bottle washing with methanol (5 mL) and centrifuged. The clear supernatant was discarded and the blue solid was washed with xmethanol (2×35 mL), centrifuging and discarding the clear supernatant each time. The solid was transferred to a flask by washing with methanol (25 mL). The solvent was removed under vacuum and the blue solid was dried under vacuum overnight. Yield: 0.127 g (89%). *Anal.* Calc. for $Cr[Cr(CN)_6]_{0.67} \cdot 7MeOH \cdot 1.67TiO_2$; $C_{11}H_{28}N_4O_{10.34}Cr_{1.67}Ti_{1.67}$: C, 24.0; H, 5.09; N, 10.2; Cr, 15.8; Ti, 14.9. Found: C, 27.0; H, 3.88; N, 12.8; Cr, 16.7; Ti, 14.9. IR (cm^{-1}): 2168 (vs), 1121 (s), 1078 (s), 1033 (s), 605 (s, sh), 504 (vs, br).

spin-orbit coupling in the former [13]. Therefore, the usual giant spin approximation must be modified to account for the orbital contribution to the magnetic properties. However, as we shall see, only the lowest Kramers' doublet contributes to the low-temperature (<20 K) HFEPR spectrum of complex **1**, thus reducing the problem to that of an effective spin $S' = 1/2$. The magnetic properties can then be simulated in terms of a simple Zeeman Hamiltonian, $\widehat{H} = \mu_B \widehat{S}' \cdot \overleftrightarrow{g}' \cdot \vec{B}$, where $\overleftrightarrow{g}'$ represents an effective Landé g-tensor associated with the effective spin $S' = 1/2$. We also show from angle-dependent single-crystal HFEPR measurements that the easy-axis associated with each Co^{2+} ion is significantly tilted away from the c-axis of the crystal. More detailed studies of both complexes will be discussed in a future paper [14].

2. Experimental details

Single-crystal HFEPR measurements were carried out using a sensitive cavity perturbation technique. A millimeter-wave vector network analyzer (MVNA) acted as both a continuously tunable microwave source and phase sensitive detector covering a broad frequency range (8–700+ GHz). Detailed descriptions of the instrumentation can be found in the literature [15,16]. A detailed account of the synthesis of complex **1** will be published elsewhere; we note that the procedure is similar to the previously reported synthesis of a related Co_4 complex [17]. The unit cell details are found in Table 1. Crystals with dimensions on the order of a few millimeters on a side, having the shape of a square based pyramid with four clean sides forming a sharp apex, were carefully selected so that the principal crystallographic axes could be aligned with respect to the applied magnetic field.

The ratio of Zn to Co in the crystals employed in this investigation was 0.995:0.005. As long as there is little difference in the heats of formation for complex **1** and the analogous Co_4 complex, the Co^{2+} ions should be randomly distributed throughout complex **1**. For the 0.995:0.005 Zn to Co ratio, the Zn_4 and Zn_3Co species respectively make up 98% and 1.97% of the molecules in the crystal, while the remaining species (Zn_2Co_2, $ZnCo_3$, Co_4) account for the remaining .03%. Therefore, the overwhelming contribution to the HFEPR spectra will come from the Zn_3Co molecules.

Crystal size (mm^3)	$0.29 \times 0.17 \times 0.15$

X-ray crystallographic data taken for a single crystal of complex **1**.

Analogous to the Ni complexes, the core of each molecule forms a distorted cube (the c direction being slightly longer than the equivalent a and b directions, see Table 1) with pseudo S_4 site symmetry about the crystallographic c-axis, with metal atoms (Zn or Co) and oxo-atoms from the alkoxy-arm of the deprotonated Hhmp ligand occupying alternate vertices. Each of the four metal centers is additionally coordinated to an hmp nitrogen atom, a chloride ion and a dmb ligand in a distorted 6-coordinate octahedral geometry. The oxygens of the dmb ligands remain protonated. For each molecule, there are four possible sites for the Co^{2+} ion to reside, related by the S_4 symmetry operation.

3. Results and discussion

At the lowest temperatures, one can make the assumption that only the ground state for each Co^{2+} ion is populated. Furthermore, as we shall see below, the ground state is a well isolated Kramers' doublet. Thus, each Co^{2+} ion may be expected to contribute only one peak to the HFEPR spectrum (containing some fine structure due to disorder-induced strain). Thus, assuming the magnetic axes associated with the four possible Co^{2+} sites on the Zn_3Co molecule are non-collinear, one should observe four separate HFEPR peaks for arbitrary field orientations (one for each Co^{2+} site). For field orientations along certain symmetry directions, two or more of these transitions may become degenerate, thus reducing the number of peaks.

Fig. 1 displays frequency-dependent data for complex **1** obtained at 2 K, with the field tilted 32° away from the c-axis of the crystal in the (1 0 0) plane (vide infra, see Fig. 3). The inset to Fig. 1 shows a typical spectrum obtained at a frequency of 51.8 GHz. As can be seen, absorptions are grouped into three clusters. The position of each peak is plotted versus frequency in the main part of the figure for measurements performed on higher-order cavity modes. As can be seen, each peak lies on an absolutely straight line which passes exactly through the origin. Landé g-factors have been assigned to each of the peaks based on the slope of the straight line through each set of data points. The shapes of the data points (solid and open circles and squares) have been chosen for comparison with Fig. 3 below. We believe the fine structures are caused by disorder induced g-strain (as was found from similar studies of the Ni/Zn analog [8,10]).

Based on the angle-dependent studies discussed below, we find that the $g = 4.2$ branch in Fig. 1 is in fact degenerate, consisting of two HFEPR transitions. This explains the observation of only three peaks. The relative intensities of

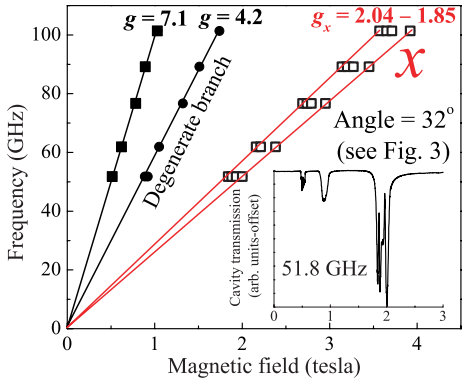

Fig. 1. Frequency-dependent data for complex **1** obtained at 2 K, with the field tilted ~32° away from the *c*-axis (see also Fig. 3). The inset shows a typical spectrum obtained at a frequency of 51.8 GHz. The positions of each of the three main peaks are plotted versus frequency in the main part of the figure. Landé *g*-factors have been assigned to each of the peaks based on the slope of the straight line through each set of data points; the field is oriented such that the highest field peak corresponds approximately to the *x*-component of the *g*-tensor. The shapes of the data points (solid and open circles and squares) have been chosen for comparison with Fig. 3.

the peaks may be understood in terms of the transition rates [18], which depend on the respective Landé *g*-factors (smaller *g*-factor, larger transition rate). The fact that each resonance lies on a perfectly straight line is a clear indication that the transitions occur within a very well isolated effective spin $S' = 1/2$ Kramers' doublet. The anisotropy is contained entirely within the effective Landé *g*-tensor. Further confirmation comes from the temperature dependence in Fig. 2. These data were obtained for the same frequency and field orientation as the data in Fig. 1; one can see that the field alignment is not precisely the same due to the slight splitting of the degenerate branch. Nevertheless, all peaks increase in intensity upon lowering the temperature, thus confirming the assignment of the ground state as a spin $S' = 1/2$ Kramers' doublet.

By far the most detailed information comes from angle-dependent studies. For an arbitrary rotation plane each spectrum should consist of four peaks. However, for high symmetry rotation planes there will be degeneracies and some resonance peaks will superimpose upon one another. The highest symmetry direction corresponds to a magnetic field applied along the *c*-axis of the crystal, where only one peak should be seen. A magnetic field applied at an arbitrary angle within the *ab*-plane of the crystal will give rise to two peaks. Any misalignments of the sample with respect to the applied field will lift this degeneracy and give rise to up to four major peaks.

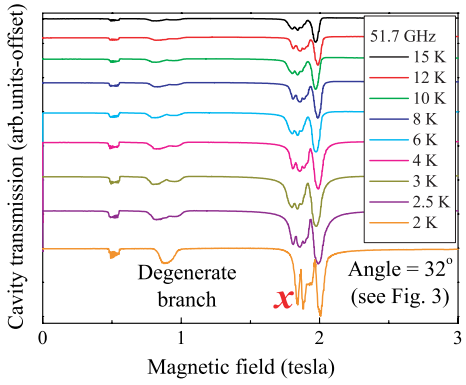

Fig. 2. Temperature dependence of the HFEPR spectra for approximately the same frequency and field orientation as the data in Fig. 1.

The first experiment (rotation **1**) involved rotating the magnetic field in the (1 1 0) plane from the *c*-axis to the *ab*-plane (Fig. 3a). The second experiment (rotation **2**) involved rotating the magnetic field within the *ab*-plane (Fig. 3b). For rotation **1** we observe three resonance branches, which collapse into approximately 1 peak for $\theta = 0°$ (field//*c*-axis) and approximately two peaks for $\theta = 90°$ (field//*ab*-plane, 45° from *a* and *b*). Since only three branches are observed in Fig. 3a, we must assume that one of them is degenerate (solid circles).

Based on simple geometrical considerations, we can immediately determine the nature of the anisotropy at the individual Co^{2+} sites. Due to the octahedral coordination, we assume the anisotropy will be approximately axial (easy-plane or easy-axis [19]). First of all, it is clear from Fig. 3a that the local magnetic axes are tilted with respect to the crystallographic axes (and, therefore, with respect to each other). Starting with the field along *c* (Fig. 3a): when one tilts the field away from this symmetry direction, it necessarily tilts away from three of the local *z*-axes and towards three of the *xy*-planes; conversely, it tilts towards one of the *z*-axes and away from one of the *xy*-planes. Considering the two-fold degeneracy of the branch represented

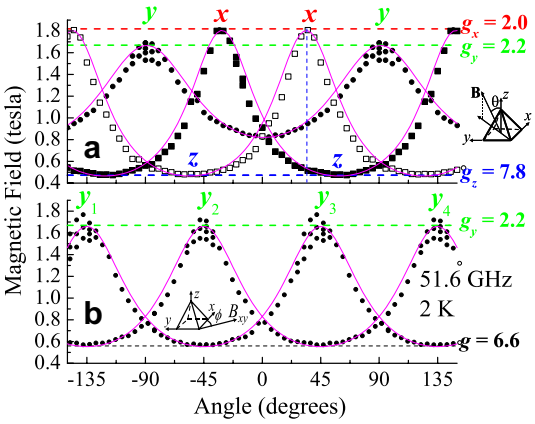

Fig. 3. Angle dependence of the HFEPR peak positions observed for a frequency of 51.6 GHz and a temperature of 3 K, for field rotation in (a) the (1 1 0) plane, and (b) the *ab*-plane. In (a), the angle is referenced to the crystallographic *c*-axis while, in (b), the angle is referenced to either the *a* or *b* axes. In (a), the degenerate branch is indicated by the solid circles, while the squares denote rotations along a plane intersecting two of the easy-axes (labeled *z*). The schematic insets illustrate the two field rotation planes relative to the pyramid shaped single crystal. The *g*-values associated with the extreme positions in the angle-dependence are indicated on the right. The magenta curves are simulations based on the obtained extreme *g*-values for each plane of rotation. The directions of the local magnetic axes (*x*, *y*, *z*) are indicated in the figure.

by the solid circles, upon tilting the field away from c one sees that three of the branches move to higher fields (they become harder), whereas only one moves to lower field (it becomes easier). Therefore, based on the above geometrical consideration, one can conclude that the planes are hard, while the axes are easy, i.e. the anisotropy is of the easy-axis type.

Upon rotating the field over a 180° interval, one is guaranteed to find all four hard planes. These directions correspond to the maxima at −90° (two planes), −32° and +32° (the peak at +90° is equivalent to the one at −90°) in Fig. 3a, and the maxima at $[(n \times 90°) + 45°]$ in Fig. 3b, where n is an integer. Since we observe a degenerate branch in Fig. 3a, this implies that orientation of the field, as it rotates, is the same for both ions contributing to the branch. Thus, the field rotation plane must be perpendicular to the easy-axis tilt plane for these two ions and, therefore by symmetry, it must be parallel to the easy axis tilt plane for the other two ions. Therefore, we conclude that the two minima labeled z correspond precisely to the easy axes. One can then immediately determine that $g_z = 7.80$ (indicated by blue dashed line). The minimum at 0° in Fig. 3a corresponds to the point of closes approach of the field to the other two easy axes. From the positions of the maxima and minima, we determine that the easy axes (hard planes) are tilted about 58° (32°) away from the crystallographic c-axis, and the easy axes are tilted in the $(1\,1\,0)$ and $(1\,\bar{1}\,0)$ planes.

It is notable in Fig. 3a that the heights of the maxima at ±90° and ±32° are slightly different, corresponding to g-values close to 2.00 and 2.20. This observation implies weak in-plane anisotropy, suggesting a weak orthorhombic distortion at the individual Co^{2+} sites. The lesser of the two g-values corresponds to $g_x \approx 2.00$ (the hard axis, red dashed line) and the intermediate value to $g_y \approx 2.20$ (the medium axis, green dashed line).[1] From the hard-plane rotations (Fig. 3b), we see that the maxima coincide with $g_y \approx 2.20$ in Fig. 3a. Therefore, we can conclude that the medium axes lie along the intersections of the four hard planes, within the ab-plane of the crystal [along $(1\,1\,0)$ and $(1\,\bar{1}\,0)$]. The hard axes are, therefore, directed maximally out of the ab-plane [with projections also along $(1\,1\,0)$ and $(1\,\bar{1}\,0)$], tilted 32° away from c. The minima in Fig. 3b correspond to the projection of the easy axis anisotropy onto the ab-plane, i.e. $g = g_z \times \cos 32° = 6.61$ (marked by horizontal black dashed line). Finally, the vertical dashed line in Fig. 3a denotes the orientation of the data presented in Figs. 2 and 3. As can be seen, the data points are coded similarly to the corresponding 51.8 GHz data in Fig. 1.

As already discussed, the Hamiltonian for a well isolated effective spin $S' = 1/2$ Kramers' doublet takes the form $\widehat{H} = \mu_B \widehat{S}' \cdot \overleftrightarrow{g}' \cdot \vec{B}$, where $\overleftrightarrow{g}'$ represents an effective Landé g-tensor that parameterizes all of the anisotropy associated with the spin-orbit coupling. The resulting relation between the measurement frequency, f, and the resonance field, B_{res}, is then $hf = g(\theta)\mu_B B_{res}$. Thus, for a fixed frequency measurement, $B_{res} = hf/g(\theta)\mu_B$. One can therefore attempt to fit the data in Fig. 3 assuming a simple angle dependence of the form $g(\theta) = g_{min} + \delta g \cos^2(\theta - \theta_o)$, where g_{min} is the minimum g-value for a particular plane of rotation, δg is the difference between the minimum and maximum g-values, and θ_o is the angle corresponding to g_{min}. The magenta curves in Fig. 3 correspond to such fits. As can be seen, the agreement is quite good.

4. Conclusions

The orientations of the magnetic axes, with respect to the crystal lattice, were determined for single Co^{2+} ions doped into a nonmagnetic Zn_4 complex. Frequency and temperature dependence studies confirm the ground state to be an effective spin $S' = 1/2$ Kramers' doublet with a highly anisotropic g-factor. The anisotropy is found to be of the easy-axis type, with the single-ion easy axis directions tilted away from the crystallographic c direction by 58°. The g-factor anisotropy ($g_z = 7.8$ and $g_x \approx 2.0$) is close to the maximum expected for an octahedral Co^{2+} complex [19], suggesting a huge axial zero-field-splitting. It is presently unclear how the Kramers ions could combine into a Co_4 complex to give rise to SMM behavior.

MO methods. The relations between magnetic interaction and configurations were discussed.

2. Theoretical background

As well known, the Heisenberg spin model is useful to describe magnetic interaction between spins. The J values based on Heisenberg Hamiltonian can indicate magnitude of magnetic interaction. The spin–Hamiltonian is defined as

$$\mathbf{H} = \sum -2J_{ij}\mathbf{s}_i \cdot \mathbf{s}_j, \tag{1}$$

where $\mathbf{s}_i$ is total spin operator at ith site, and J_{ij} is the effective exchange integral between ith and jth sites. The physical meaning of J_{ij} is energy difference between lower spin state (LS) and higher spin state (HS) in systems. The positive value of J_{ij} means ferromagnetic interaction in the ground state, while the negative value of J_{ij} means antiferromagnetic interaction in the ground state.

By using *ab initio* MO computational techniques, J_{ij} values can be estimated quantitatively. For unrestricted calculations, broken-symmetry approach with our spin projected scheme [7], which eliminates spin contamination, can calculate the J_{ij} with the following equation:

$$J_{ij} = -\frac{^{HS}E(X) - {}^{LS}E(X)}{^{HS}\langle S^2\rangle - {}^{LS}\langle S^2\rangle}, \tag{2}$$

where $E(X)$ and $\langle S^2\rangle$ denote, respectively, total energy and total spin angular momentum.

In series of our studies, theoretical calculations by using the KS-DFT (Kohn–Sham hybrid density functional theory) methods were carried out [8]. The UB3LYP method has been employed to elucidate electronic properties. Here, Becke's three parameter exchange [9], and Lee, Yang, and Parr's correlation functionals were chosen for our calculations [10]. Our calculations were carried out by Gaussian98 program packages [11], and SCF conversion were controlled in 10^{-8} a.u. level.

3. Crystal structure and model preparation

The crystal structure of κ-$(BETS)_2FeCl_4$ were illustrated in Fig. 1b. The X-ray crystallographic data in Cambridge Structural Database (CSD) were employed. It is found that both layers of BETS donors and $FeCl_4^-$ anions are stacked alternatively. The complexes of **1** have unit cells classified by the space group *Pnma* and the cell parameter sets are $a = 11.483(4)$ Å, $b = 35.720(15)$ Å, and $c = 8.383(3)$ Å. The bond lengths of all Fe–Cl bonds in $FeCl_4^-$ anion are 2.178, 2.198, 2.198, and 2.205 Å. The average of bond lengths of Fe–Cl bonds is 2.195 Å.

The four $FeCl_4^-$ anions (A, B, C, and D) from crystal structure were extracted. The three pairs (A–B, A–C, and A–D) were proposed. The distances of Fe–Fe in A–B pair, A–C pair, and A–D pair were 8.383, 5.775, and 9.658 Å, respectively. In the following section, we proposed dimer models, which were based on these pairs.

4. Computational results

4.1. The geometry optimization of monomer model

First, let us investigate the most suitable basis sets for both Fe and Cl atoms in $FeCl_4^-$ monomer. With the various basis functions, ionization potential (IP) for Fe atom and electron affinity (EA) for Cl atom were calculated by the UB3LYP method. The following basis functions were employed: STO-3G, 6-31G, 6-31G*, 6-31+G, 6-31+G*, 6-311G, 6-311G*, 6-311+G, and 6-311+G* in the GAUSSIAN program packages. As shown in Table 1, the calculated first, second, and third IPs with 6-31G basis sets for Fe atom were 7.72, 16.08, and 31.31 eV, respectively. The calculated EA with 6-31+G basis sets for the Cl atom were 3.751 eV. As optimum basis functions, 6-31G and 6-31+G basis sets for Fe and Cl atoms were employed, respectively. Our calculated results could denote the near tendency of reference data [12].

Next, structure of $FeCl_4^-$ monomer with regular tetrahedron was optimized by using of UB3LYP method. All the bond lengths of Fe–Cl bonds (R_{Fe-Cl}) in $FeCl_4^-$ anion were varied, though all angles and dihedral angles were fixed to regular tetrahedron structure. The obtained value of R_{Fe-Cl} was 2.27 Å, which was 0.075 Å longer than numerical average of Fe–Cl lengths in the $FeCl_4^-$ anion in crystal **1**. In the following, the optimized structure was successfully used.

Table 1
Calculated IPs for the Fe atom and EA for the Cl atom by using UB3LYP method

	Fe atom/eV			Cl atom/eV
	First	Second	Third	
STO-3G	4.91	16.95	24.43	−0.586
6-31G	7.72	16.08	31.31	3.194
6-31G*	7.72	16.08	31.32	3.155
6-31+G	8.07	16.43	31.65	3.751
6-31+G*	8.07	16.43	31.66	3.712
6-311G	7.74	16.26	31.37	3.699
6-311G*	7.74	16.26	31.39	3.661
6-311+G	8.00	16.48	31.56	3.762
6-311+G*	8.00	16.48	31.57	3.724
Ref. [12]	7.87	16.18	30.651	3.615

4.2. The J values in simple dimer models

In this section, simple dimer models of $FeCl_4^-$ anion were assembled by using the previous optimized monomer model in order to examine various magnetic *d–d* interactions. As shown in Fig. 2, the following three types of dimer models were proposed: 1–1 model, 1–2 model, and 1-3 model. The 1–1 model denoted that Cl(A) in $FeCl_4$(A) came close to Cl(B) in $FeCl_4$(B).

First, magnetic *d–d* interactions dependency on rotation angles were evaluated. For 1–1 model, $FeCl_4$(A) was fixed and $FeCl_4$(B) was rotated θ degrees clockwise on this paper as shown in Fig. 2a. The distance of Fe(A) to Fe(B) (R_{Fe-Fe}) was fixed to be 7.0 Å. As the results of rotation, ferromagnetic structures ($\theta = 70°$ (inset in Fig. 3) and 180°) were found and the J values were 0.04 cm^{-1}. These

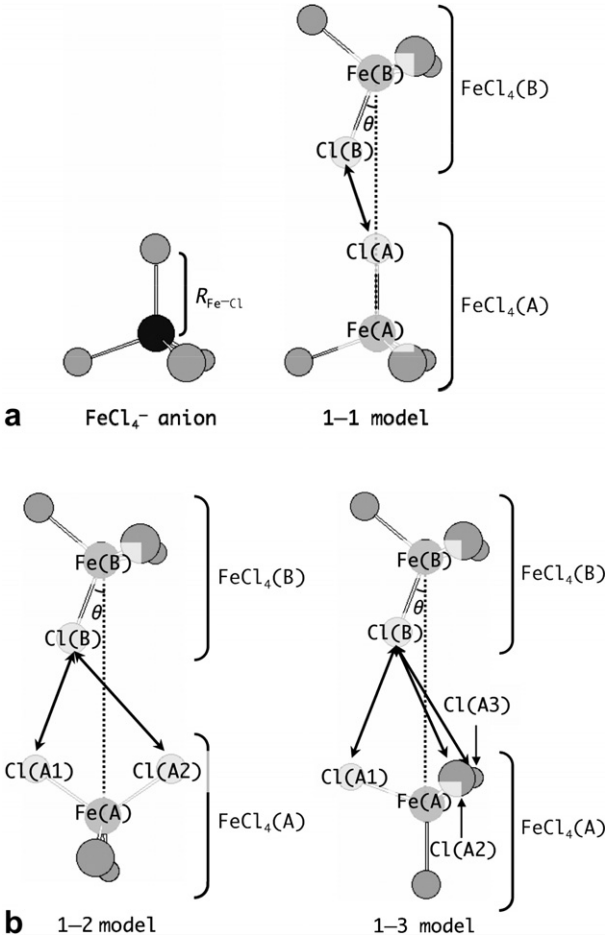

Fig. 2. Dimer models of $FeCl_4^-$ anion: (a) 1–1 model and (b) 1–2 and 1–3 models.

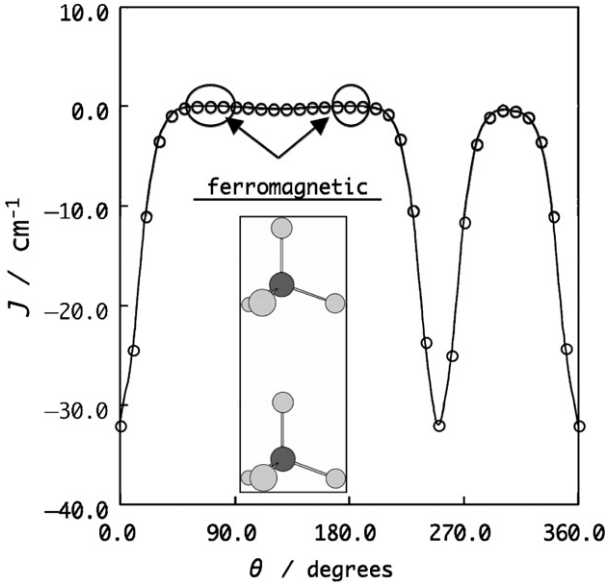

Fig. 3. Calculated J values in 1–1 model by using UB3LYP method were plotted against rotation angle θ. Inset illustrated the interesting structure where the evaluated magnetic interaction is ferromagnetic.

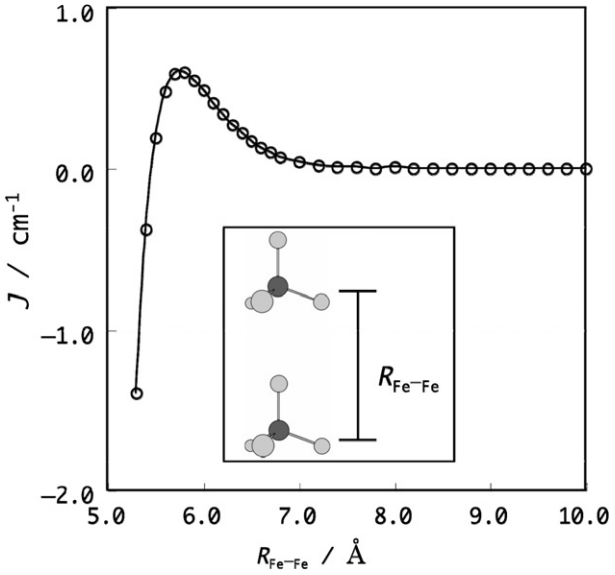

Fig. 5. Calculated J values in ferromagnetic structure in 1–1 model by using UB3LYP method were plotted against interatomic distance R_{Fe-Fe}.

ferromagnetic structure denoted that Cl(A) of $FeCl_4$(A) came close to three Cl atoms of $FeCl_4$(B). On the other hand, magnetic interactions in almost all configurations were antiferromagnetic.

In a similar way, magnetic d–d interaction dependency on rotation angles for both 1–2 model and 1–3 model were investigated as shown in Fig. 2b. The 1–2 model denoted that Cl(A1) and Cl(A2) in $FeCl_4$(A) came close to Cl(B) in $FeCl_4$(B). The 1–3 model denoted that Cl(A1), Cl(A2), and Cl(A3) in $FeCl_4$(A) came close to Cl(B) in $FeCl_4$(B). The value of R_{Fe-Fe} was also fixed to be 7.0 Å. In 1–2 model, magnetic interactions in all configurations were antiferromagnetic. As shown in Fig. 4, ferromagnetic structures ($\theta = 0°$ and 250°) were found in 1–3 model and the J values were 0.04 cm^{-1}. These ferromagnetic structure was the same as the ferromagnetic structure in 1–1 model. Magnetic interactions in almost all configurations in 1–3 model were antiferromagnetic.

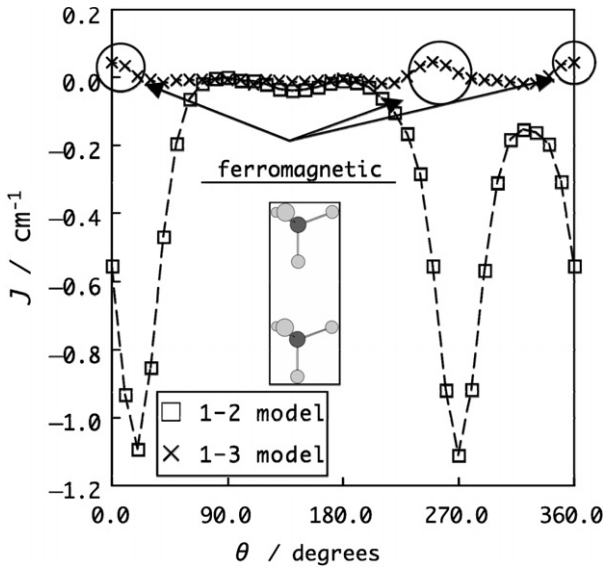

Fig. 4. Calculated J values in 1–2 and 1–3 models by using UB3LYP method were plotted against rotation angle θ.

Next, in order to evaluate d–d interaction dependency on distance, the value of R_{Fe-Fe} was varied from 5.3 to 10.0 Å in the ferromagnetic structure in 1–1 model. As shown in Fig. 5, the largest ferromagnetic interaction can be yielded in the structure with $R_{Fe-Fe} = 5.8$ Å and J value was 0.60 cm^{-1}. On the other hand, when $FeCl_4$(B) was brought too close to $FeCl_4$(A), magnetic interactions turned to be antiferromagnetic. There was no interaction when the value of R_{Fe-Fe} was from 8.0 to 10.0 Å.

5. Conclusion

In our studies, the ferromagnetic conformations between $FeCl_4^-$ anions were found. This configuration denoted that one Cl atom of $FeCl_4$(A) came close to three Cl atoms of $FeCl_4$(B). It seemed that this structure was feasible for crystal structure. The largest J value was 0.6 cm^{-1} when the value of R_{Fe-Fe} was 5.8 Å. Unfortunately, these magnetic interactions were relatively small.

In addition to these calculations for simple model systems, we investigated magnetic d–d interactions of $FeCl_4^-$ anion pairs in the real crystal of **1**. The evaluated J values of A–B pair, A–C pair, and A–D pair in Fig. 1b were −0.05, −0.05, and 0.00 cm^{-1}, respectively.

In a similar way, dimer models of $FeBr_4^-$ anion were also assembled in order to check difference between Cl and Br atoms to magnetic d–d interaction. The structure of $FeBr_4^-$ monomer with regular tetrahedron was optimized by using UB3LYP method with 6-31G and 6-311G

basis set for Fe and Br atoms, respectively. The obtained value of the Fe–Br bond length was 2.42 Å. To evaluate magnetic *d–d* interaction dependency on rotation angle and distance, the dimer models were used: 1–1, 1–2, and 1–3 models. As a result of rotation, the ferromagnetic interaction was found in a certain structure. In 1–1 model, the J value in ferromagnetic structure ($\theta = 70°$ and 180°) was 0.13 cm^{-1}. In 1–3 model, the J value of ferromagnetic structure ($\theta = 0°$ and 250°) was 0.13 cm^{-1}. These structure were very resembled to ferromagnetic structure of $FeCl_4^-$ anion dimer. As a result of variation of distance, when the distance between Fe(A) in $FeBr_4$(A) and Fe(B) in $FeBr_4$(B) was 6.1 Å, where the J value was 0.77 cm^{-1}.

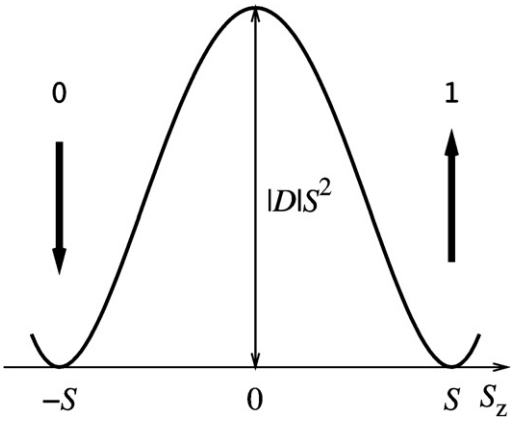

Fig. 1. Energy diagram of the ZFS Hamiltonian when $D < 0$. The height of the energy barrier between the ground states is $|D|S^2$. The pair of states can be taken as a memory bit for the use of data storage.

2. Computational scheme to calculate ZFS parameters

The one-center spin–orbit coupling (SOC1) mainly causes the ZFS of transition metal complexes. The SOC1 Hamiltonian is

$$\hat{H}_{\mathrm{SOC1}} = \frac{1}{i}\sum_j \hat{\mathbf{V}}(\mathbf{r}_j)\cdot\hat{\mathbf{s}}_j, \quad \hat{\mathbf{V}}(\mathbf{r}) \equiv -\frac{1}{2c^2}\nabla\times\mathbf{E}(\mathbf{r}), \tag{2}$$

where $\mathbf{r}_j$ and $\hat{\mathbf{s}}_j$ are coordinates and spin operator of jth electron, c is the speed of light, and $\mathbf{E}(\mathbf{r})$ is the electric field of the nuclei. The ZFS parameters can be calculated with the second order perturbation theory of the SOC1 energy with non-relativistic broken-symmetry mean-field theories taken as the zeroth-order description [10]. The perturbation energy is

$$E_{\mathrm{SOPT2}} = {}^t\mathbf{SDS}, \tag{3}$$

$$\mathbf{D} = \frac{1}{4S^2}\begin{pmatrix} N_{xx}+N'_{yy}+N'_{zz} & N_{xy}+N'_{xy} & N_{zx}+N'_{zx} \\ N_{xy}+N'_{xy} & N'_{xx}+N_{yy}+N'_{zz} & N_{yz}+N'_{yz} \\ N_{zx}+N'_{zx} & N_{yz}+N'_{yz} & N'_{xx}+N'_{yy}+N_{zz} \end{pmatrix}, \tag{4}$$

$$N_{pq} \equiv M^{\alpha\alpha}_{pq} + M^{\beta\beta}_{pq}, \quad N'_{pq} \equiv M^{\alpha\beta}_{pq} + M^{\beta\alpha}_{pq}, \tag{5}$$

$$M^{\sigma\tau}_{pq} \equiv \sum_a^{\sigma\text{-occupied}} \sum_s^{\tau\text{-virtual}} \frac{\langle\psi^\sigma_a|\hat{V}_p|\psi^\tau_s\rangle\langle\psi^\tau_s|\hat{V}_q|\psi^\sigma_a\rangle}{\varepsilon^\tau_s - \varepsilon^\sigma_a}, \tag{6}$$

where $\mathbf{S}$ is the total spin vector, and $|\psi^\sigma_a\rangle$ and ε^σ_a are the ath σ-spin molecular orbital and the orbital energy, respectively. We could find the ZFS parameters by diagonalizing the $\mathbf{D}$ tensor.

$$E_{\mathrm{SOPT2}} = {}^t\mathbf{S}'\mathbf{d}\mathbf{S}', \tag{7}$$

$$\mathbf{d} = \mathbf{U}\mathbf{D}'^t\mathbf{U}, \quad \mathbf{S}' = \mathbf{U}\mathbf{S}, \tag{8}$$

$$D = d_z - \frac{d_x+d_y}{2}, \quad E = \frac{d_x-d_y}{2}, \tag{9}$$

and the primary axis is $\mathbf{u}_z$ of $\mathbf{U} = (\mathbf{u}_x\mathbf{u}_y\mathbf{u}_z)$. Here, the coordinates are chosen so that $|D| > 2|E|$.

3. Calculations, results, and discussion

3.1. Manganese porphyrin complex $[MnP]^+$

We performed ab initio calculations of a manganese porphyrin complex $[MnP]^+$ (Fig. 2). $[MnP]^+$ was used as a model complex of $[MnTBrPP]^+$, which is the main source of spin of $[MnTBrPP]^+[TCNE]^-$. The X-ray crystal structure of $[MnTBrPP]^+[TCNE]^-$ was used, and hydrogen atoms were substituted for TBrP. We used the UDFT (UBLYP) and hybrid UDFT (UB3LYP, UB2LYP [11]) for the calculations. We employed Huzinaga's MIDI+P basis sets (533(21)/53(21)/(41)) for the transition metals [12] and 6-31G* basis sets by Pople et al. for the other atoms.

Table 1 shows the computational results. The spin magnitude S of the ground state is 2. All the D values are negative, and the magnetic easy axes are perpendicular to the porphyrin plane. In fact, the real $[MnP]^+$ has a negative D value as shown in the Refs. [13,14]. The calculated D values are in good agreement with $[MnP]^+$ quantitatively. Since the real $[MnP]^+$ has the uniaxial symmetry, the E value is zero. However, all the calculated E values are much smaller than the D values but not zero because of the slight distortion of the porphyrin in the $[MnTBrPP]^+[TCNE]^-$ X-ray crystal structure.

3.2. $[MnP]^+[TCNE]^-[MnP]^+$

Next, we performed calculations of a manganese porphyrin dimer linked by TCNE, $[MnP]^+[TCNE]^-[MnP]^+$ (MTM) (Fig. 3). The same computational methods, basis sets, and scheme of getting the geometry as the previous subsection were employed.

Table 1 shows the results. The low spin state ($\uparrow\downarrow\uparrow$) is preferred rather than the high spin state ($\uparrow\uparrow\uparrow$), and the spin magnitude S is 7/2. Although the uniaxial symmetry is

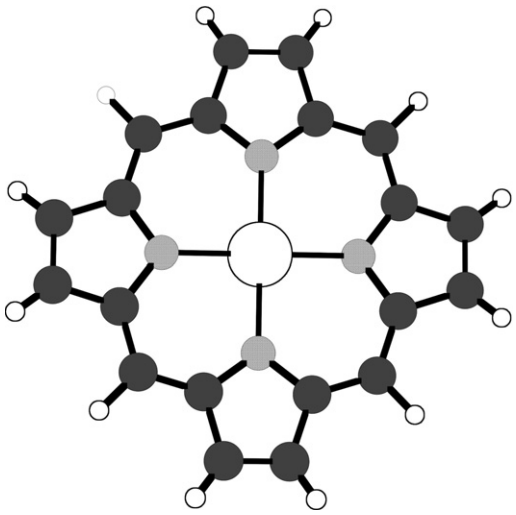

Fig. 2. Structure of the manganese porphyrin complex.

Exp.[a]	−2.30	0.000	09.2						

[a] Refs. [13,14].

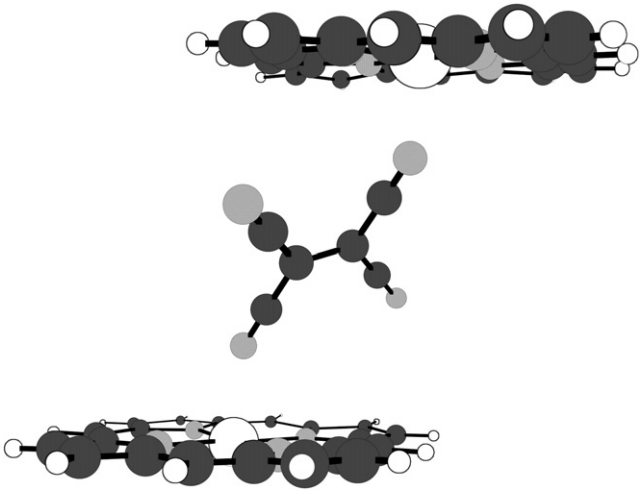

Fig. 3. Structure of $[MnP]^+[TCNE]^-[MnP]^+$.

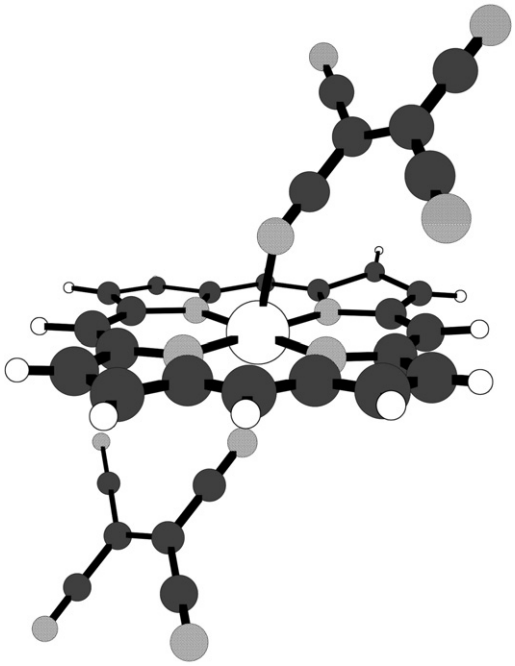

Fig. 4. Structure of $[TCNE]^-[MnP]^+[TCNE]^-$.

broken, all the E values are very small and the easy axes are almost the same as that of $[MnP]^+$. The D values become smaller than those of $[MnP]^+$, but the energy barriers $|D|S^2$ become larger. The energy barriers are twice as large as those of $[MnP]^+$. Therefore, the coordination of $[TCNE]^-$ hardly affect the magnetic anisotropy of $[MnP]^+$.

3.3. $[TCNE]^-[MnP]^+[TCNE]^-$

Finally, we performed calculations of manganese porphyrin with two $[TCNE]^-$, $[TCNE]^-[MnP]^+[TCNE]^-$ (TMT) (Fig. 4). The same conditions as above were employed.

Table 1 shows the results. The UBLYP calculation was failed. The low spin state ($\downarrow\uparrow\downarrow$) is preferred rather than the high spin state ($\uparrow\uparrow\uparrow$), and the spin magnitude S is 1. The D values are negative, and the E values are very small. The easy axes are almost the same as that of $[MnP]^+$. The energy barriers $|D|S^2$ are almost the same as that of $[MnP]^+$. Also in this case, the $[TCNE]^-$ ligands play almost no role in the magnetic anisotropy.

3.4. Minimal model

The bridging ligands TCNEs are important to the ferrimagnetic alignment of the SCM [4,6]. The exchange interaction between MnTBrPP and TCNE is antiferromagnetic, and the effective exchange integral J is $-178\ cm^{-1}$ [4]. However, it is found from the present model calculations that coordinating TCNEs is not important to the magnetic anisotropy of the manganese porphyrin complexes. The contribution of the spin–spin dipole coupling to the ZFS, which is important to the organic radicals as TCNE, is not considered in the present paper. However, it is ignorable, since the D values of organic radicals are normally one order less than those of the transition metal complexes and the spin magnitude S of TCNE is also small.

These results can be summarized as the following minimal model Hamiltonian is

$$H = -|J_{\mathrm{MnTXPP-TCNE}}| \sum_{\langle i,j\rangle}^{\langle \mathrm{MnTXPP,TCNE}\rangle} \mathbf{S}_i \cdot \mathbf{S}_j - |D_{\mathrm{MnTXPP}}| \sum_i^{\mathrm{MnTXPP}} S_i^2, \quad (10)$$

where $\langle i,j\rangle$ runs over all the nearest-neighbor pairs.

4. Concluding remarks

We investigated the magnetic anisotropy of $[MnTXPP]^{+}[TCNE]^{-}$, which is a SCM, with ab initio calculations. MnTXPP was reduced to MnP for reducing the computational cost. The ZFS parameters of the MnP were in good agreement with the experimental values quantitatively. From the calculations of the model complexes, we found that TCNE hardly affect the magnetic anisotropy of MnP. Therefore, the TCNEs are important only to the ferrimagnetic alignment.

complete-active-space self-consistent field (CASSCF) results [11,12]. They performed CAS computations using up to the [6,6] active space, and discussed that the [26,26] active space is required for discussions of magnetic interaction in various general stacking modes of the phenalenyl radical dimer. It is not feasible from the viewpoint of the present computational resource. On the other hand, the multistate MR second-order perturbation (MRMP2) calculations using perfect pairing type of two-configuration MR reference [13,14] have been performed for modeled phenalenyl dimers with omitting *tert*-butyl groups by Head-Gordon and his co-workers [13]. They have showed a reasonable potential curve, of which binding energy, 11 kcal/mol, is consistent with the experimental enthalpy in CH_2Cl_2 solution (−9.5 kcal/mol).

As an alternative MR theory, the multireference version of DFT has been recently developed [18–20]. We also have developed some versions of multireference DFT approaches [18,19]. In this theory, electrons exhibiting quantum spin behaviors are treated by an MR wavefunction, while remaining correlation effects by DFT. In this study, we present the CASCI[2,2]-DFT study of phenalenyl dimeric systems. This is a minimum treatment for multireference wavefunction part that is compatible with the MRMP2 based on 2×2 VB configurations in Ref. [13]. We examine the antistacking 2,5,8-tri-*tert*-butyl-phenalenyl dimer [1] and its simplified model as a though-space interacted phenalenyl radical. The recently synthesized di-phenyl-IDPL [1] is also examined as a through-bond interacted model compound. The computational results are discussed in relation to the experimental ones, hybrid DFTs' [21] results, and physics behind the CASCI[2,2]-DFT treatment for phenalenyl radical systems.

2. Complete-active-space (CAS) DFT method

We briefly describe the theoretical background of our approach, CAS-DFT. A starting point is the Hohenberg–Kohn theorem [16] that states the ground-state energy for the system under the external potential $V_{\text{ext}}(\mathbf{r})$ is determined by density:

$$E_0 = \text{Min}_{\rho(\mathbf{r})\to N}[F[\rho(\mathbf{r})] + \int \mathrm{d}\mathbf{r}\rho(\mathbf{r})V_{\text{ext}}(\mathbf{r})]. \tag{1}$$

In the usual Kohn–Sham DFT, the universal functional,

$$F[\rho(\mathbf{r})] = \text{Min}_{\Psi\to\rho(\mathbf{r})}\langle\Psi|\hat{T} + \hat{V}_{\text{ee}}|\Psi\rangle, \tag{2}$$

is divided into noninteracting kinetic term, classical Coulomb, and exchange correlation terms,

$$F[\rho(\mathbf{r})] = \text{Min}_{\Phi\to\rho(\mathbf{r})}\langle\Phi|\hat{T}|\Phi\rangle + \frac{1}{2}\int\frac{\rho(\mathbf{r}_1)\rho(\mathbf{r}_2)}{r_{12}}\mathrm{d}\mathbf{r}_1\,\mathrm{d}\mathbf{r}_2 + E_{\text{XC}}[\rho(\mathbf{r})]. \tag{3}$$

Note that the constrained search region for the first term is limited to the single-determinant wavefunctions, leading to the effective one electron problem, i.e. the Kohn–Sham equation.

In the CAS-DFT, the universal functional is divided into the modified universal functional, $F^{\text{CAS}}[\rho(\mathbf{r})]$ and the residual correlation (RC) functional, $E_{\text{RC}}^{\text{CAS}}[\rho(\mathbf{r})]$, as

$$F[\rho(\mathbf{r})] = F^{\text{CAS}}[\rho(\mathbf{r})] + E_{\text{RC}}^{\text{CAS}}[\rho(\mathbf{r})]. \tag{4}$$

Here $F^{\text{CAS}}[\rho(\mathbf{r})]$ is defined as

$$F^{\text{CAS}}[\rho(\mathbf{r})] = \text{Min}_{\Psi\to\rho(\mathbf{r})}^{\text{CAS}}\langle\Psi|\hat{T} + \hat{V}_{\text{ee}}|\Psi\rangle. \tag{5}$$

The point to note is that the constrained search region denoted as $\text{Min}_{\Psi\to\rho(\mathbf{r})}^{\text{CAS}}$, is that of the CAS type of the wavefunction expansion. All of classical Coulomb, exchange, and correlation parts of CAS wavefunction are covered by the modified universal functional given by Eq. (5). The remaining RC term then covers correlations beyond the CAS wavefunction

$$E_{\text{RC}}^{\text{CAS}}[\rho(\mathbf{r})] = \int \mathrm{d}\mathbf{r}\rho(\mathbf{r})\varepsilon_{\text{RC}}^{\text{CAS}}[\rho(\mathbf{r})]. \tag{6}$$

In order to construct the residual correlation energy $\varepsilon_{\text{RC}}^{\text{CAS}}[\rho(\mathbf{r})]$ from the usual DFT correlation energy, the portion of correlation effects covered by CAS wavefunction must be projected out from the original DFT correlation functional. For this purpose, we employed the Lee–Yang–Parr correlation functional with Miehlich–Stoll–Savin–Gräfenstein–Cremer (MSS–GC) prescription. For details, please refer Refs. [18–20].

A remarkable point of CAS-DFT is that the working equation is not for one-electron orbital, but for many-body wavefunction given by

$$(\hat{T} + \hat{V}_{\text{ee}} + \hat{V}_{\text{ext}} + \hat{V}_{\text{RC}}^{\text{CAS}})|\Psi\rangle = E_{\text{CAS-DFT}p}|\Psi\rangle. \tag{7}$$

Here the coordination representation of the RC potential operator, $\hat{V}_{\text{RC}}^{\text{CAS}}$ is

$$V_{\text{RC}}^{\text{CAS}}(\mathbf{r}) = \frac{\delta E_{\text{RC}}^{\text{CAS}}[\rho(\mathbf{r})]}{\delta\rho(\mathbf{r})} = \varepsilon_{\text{RC}}^{\text{CAS}}[\rho(\mathbf{r})] + \rho(\mathbf{r})\frac{\delta\varepsilon_{\text{RC}}^{\text{CAS}}[\rho(\mathbf{r})]}{\delta\rho(\mathbf{r})}. \tag{8}$$

Since the RC potential depends on the CAS solution itself, Eq. (7) must be solved by a self-consistent manner. Another noteworthy point is that the approximated excited state can also be obtained by solving Eq. (7).

In the context of CAS-DFT, we assume that there are two types of electron: first one is so-called "active electrons", i.e., explicitly interacting electrons that occupy valence orbitals with fractional occupation numbers. In molecular magnetic systems, these electrons are responsible for magnetic properties. Other electrons do not play a primary role for any spin property, but affect on the properties via the effective correlation potential field given by Eq. (8). We call these electrons as "inactive electrons". This is the physical picture behind the application of CAS-DFT approach.

3. Results and discussions

In this section, we present the computational results. All of CAS-DFT calculations are performed using our original code, while the usual Kohn–Sham DFT computations by

Gaussian 03 [22]. The 6-31G** basis is employed for all calculations.

3.1. Monomer

We consider the 2,5,8-tri-*tert*-butyl-phenalenyl monomer (**1**) illustrated in Fig. 1(a). The geometry is fixed to be that of the reported X-ray structure [1]. Carbon sites that are mainly responsible for magnetic properties are C_1–C_{13} in this figure. As is already reported [7], a simple molecular orbital calculation like the Hückel approximation yields the orbital energy spectrum and the single-occupied molecular orbital (SOMO), shown in Fig. 1(b) and (c), respectively. The ability to three-redox states is obviously due to this orbital energy spectrum: both of removal and addition of one-electron lead to stable configurations.

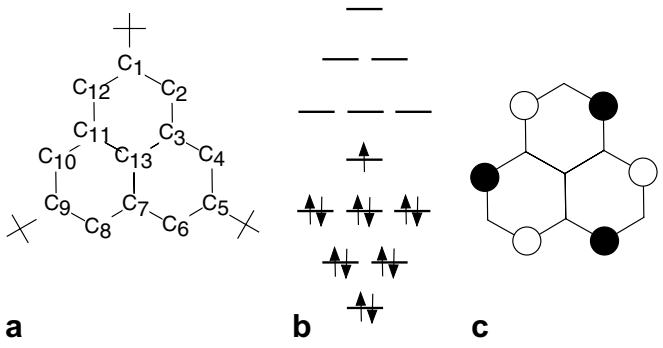

Fig. 1. (a) A schematic illustration of 2,5,8-tri-*tert*-butyl-phenalenyl monomer (**1**). (b) Orbital energy diagram of the phenalenyl radical. The horizontal axis denotes occupation numbers for the case of UHF natural orbitals. (c) Schematic illustration of singly occupied molecular orbital of the phenalenyl radical.

In the neutral state, a main radical source is the electron occupied in SOMO that is schematically illustrated in Fig. 1(c). Thus, the spin densities of phenalenyl radical also appear on C_2, C_4, C_6, C_8, C_{10}, C_{12}. Morita and his co-workers have determined the spin density population of phenalenyl monomer using ENDOR spectra with McConnel, Heller, Fraenkel–Karplus equations [5]. We can see from their data shown in Fig. 2(a) that the primary part of the unpaired electron populates over C_2, C_4, C_6, C_8, C_{10}, C_{12}. But note that the spin populations on other sites are not negligible. This might result, in part, from the experimental condition of ESR: since the local magnetic fields for all carbon sites exist during the ESR experimental process, the observed population might deviate from that of the (nonrelativistic) quantum solution. The spin-unrestricted

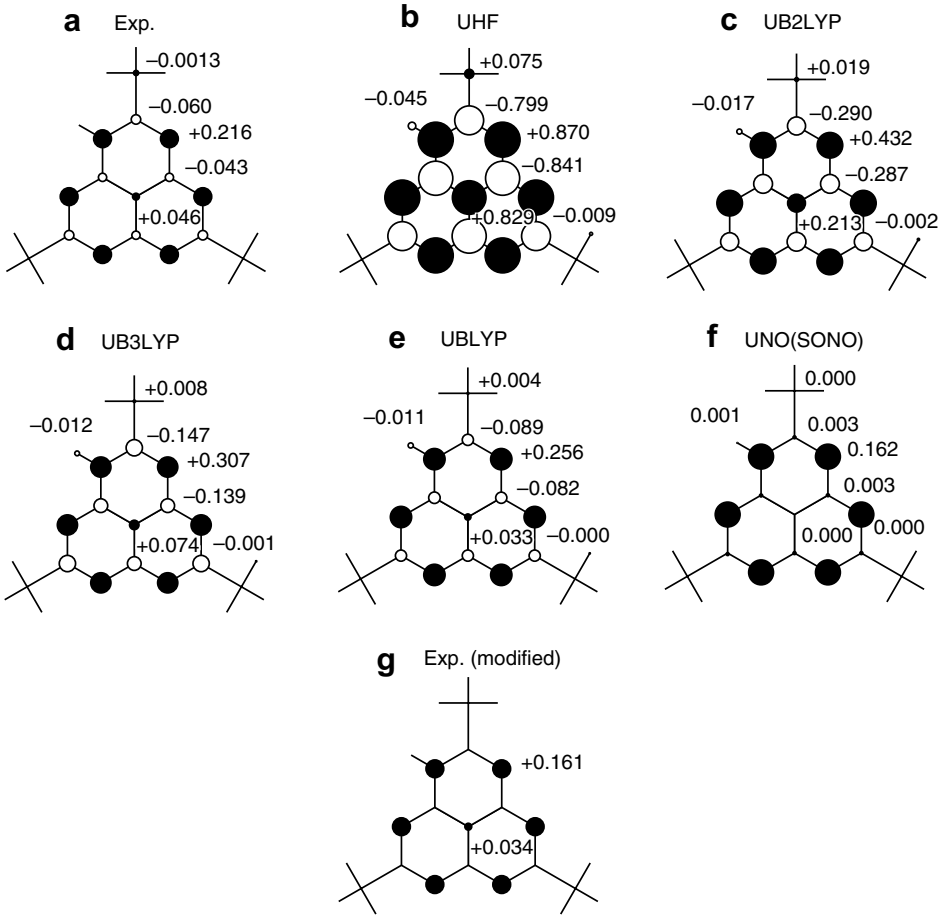

Fig. 2. Spin-density distribution of **1** estimated by (a) the ENDOR experiment [5], (b) UHF, (c) UB2LYP, (d) UB3LYP, (e) UBLYP solutions, (f) singly occupied UHF natural orbital(UNO). (g) A spin-density distribution modified by removing negative spin density of the ENDOR result.

DFT and hybrid DFT results, on the other hand, involve the artificial effective exchange-correlation (XC) magnetic field. Indeed, UHF, UB2LYP, UB3LYP, and UBLYP results show nonzero spin populations on sites besides C_2, C_4, C_6, C_8, C_{10}, C_{12} as shown in Fig. 2(b)–(e). Since the magnitude of XC magnetic field varies with the individual's XC functional, the magnitudes of spin populations are different each other as we can see from Fig. 2(b)–(e). Judging from these results, the artificial XC magnetic fields yielded in UHF and Hybrid DFT (UB2LYP and UB3LYP) calculations are too large to mimic the local magnetic field of the ESR experiment, while the XC term of pure DFT (UBLYP) provides the field comparable with the experimental one. This is consistent with the previous computational results obtained by Morita et al. [5].

Next, we computed UHF natural orbitals (UNO) of phenalenyl monomer. The UNO's spectrum ordered by their occupation numbers is similar to Fig. 1(b). The spin density of singly occupied UNO (SONO) presented in Fig. 2(f) is similar to that of experimental one, but missed the negative populations on C_1, C_3, C_5, C_7, C_9, C_{11}, C_{13} and underestimated the spin-magnitudes on other sites slightly. Indeed, if we remove the negative spin density population in Fig. 1(a) and then scale the positive spin densities to conserve S_z value (+1/2), we obtain the spin population presented in Fig. 1(g). The spin population calculated using SONO is very similar to this modified spin population. Based on this fact, we assume that the active electron responsible for magnetic properties of phenalenyl radical species is the SONO electron. In other words, "one active electron per one phenalenyl radical picture" is employed throughout this paper.

3.2. Phenalenyl dimer

Now, we proceed to phenalenyl radical dimers that are illustrated in Fig. 3.

At first, the face-to-face antistacking dimer of 2,5,8-tri-*tert*-butyl-phenalenyl radicals (**2**: Fig. 3(a)) is considered. This is a fundamental dimeric unit in the solid state, of which geometry has been observed by the X-ray analysis [1]. The geometry of monomer is slightly distorted from a plane with D_{3h} symmetry. So we examined the dimer of simplified monomer illustrated in Fig. 3(b) (**3**), of which geometry is determined in the previous study [11] by averaging the atomic distances and fixing the intermolecular distance to that of experimental value (3.3 Å).

The inspection of spin population of monomer discussed above leads to the physical picture of CASCI-DFT illustrated in Fig. 4. We select the bonding-and-antibonding MOs pair as the active space, which is indicated by the dotted square in this figure. So two electrons occupied in these MOs are "active electrons". The gray arrow from the bonding MO to the antibonding MO denotes quantum fluctuation effects covered by the CASCI[2,2] wavefunction, which is just the origin of the quantum biradical character of this species. Two striped arrows, denoted as (2a) and (2b), are DFT correlation effects from active electrons themselves (2a), and from inactive electrons (2b), respectively. This is a minimum treatment of CASCI-DFT, in which all correlations besides the biradical character are covered by DFT correlation.

Judging from the intermolecular distance ($R = 3.3$ Å) that is determined by the solid-state X-ray observation, the intermolecular bond of **2** is expected to exhibit an intermediate character between covalent bond and pure

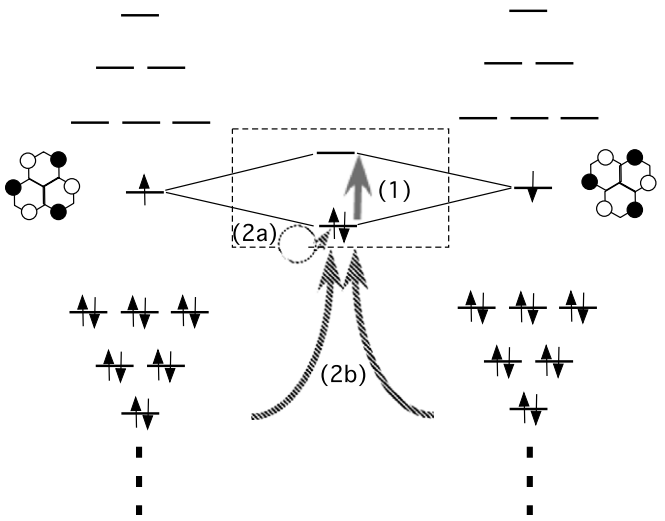

Fig. 4. Schematic illustration of CASCI-DFT solution of **2** and **3**. The dotted square is the active space (CASCI[2,2]) we employed. The gray arrow indicates the explicit quantum correlation effects covered by CASCI[2,2], while the remaining DFT correlation effects are denoted as striped arrows.

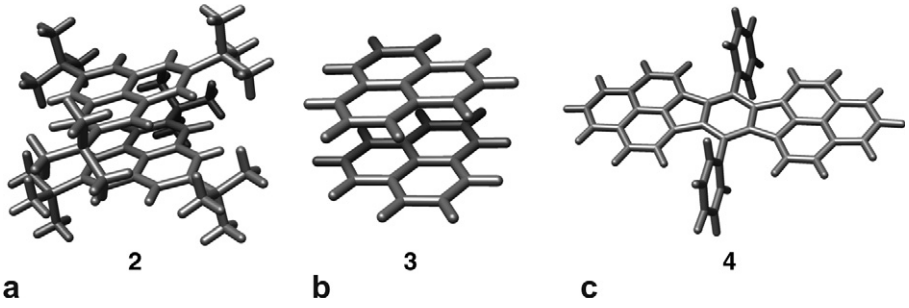

Fig. 3. Phenalenyl dimer (a and b) and carbon radicals containing two phenalenyl moieties (c). (a) 2-5-8 tri-*tert*-butyl-phenalenyl radical dimer [1], (b) a simplified model of (a) [11,12], (c) di-phenyl-IDPL [9].

biradical. Indeed, the occupation number of bonding natural orbital of UNO-CASCI[2,2]-DFT solution becomes approximately 1.7, implying that this dimer shows the weak covalent bonding with the biradical character. We computed the effective exchange interaction (J_{ab}) of the Heisenberg model

$$\hat{H} = -2J_{ab}\hat{\mathbf{S}}_a \cdot \hat{\mathbf{S}}_b. \tag{9}$$

via the expression,

$$J_{ab} = \frac{^{\mathrm{LS}}E_X - {}^{\mathrm{HS}}E_X}{^{\mathrm{HS}}\langle\hat{\mathbf{S}}^2\rangle_X - {}^{\mathrm{LS}}\langle\hat{\mathbf{S}}^2\rangle_X}, \tag{10}$$

using energies (E_X) and spin expectation values ($\langle\hat{S}^2\rangle$) of low-spin (LS) and high-spin (HS) states calculated by ab initio method (X). The computational values of UHF, UDFT, Hybrid DFT, CASCI-DFT, together with the experimental value [2,3] are listed in Table 1. The values in parentheses are of the simplified model (Fig. 3(b)). CASCI[2,2]-DFT computations using two types of molecular orbitals, UHF natural orbitals (UNO) and canonical Hartree–Fock orbitals (RHF), yield similar results each other. However these $|J_{ab}|$ values ($\sim$2253 cm^{-1}) are larger than the experimental one (1318 cm^{-1}). On the other hand, the UHF and hybrid DFT (B2LYP and B3LYP) results yield good estimation of J value, being consistent with the previous report [11]. This difference is attributable to the description of the high-spin (HS) state, rather than of the low-spin state. That is, the UHF exchange term, which is known to cause the spin-polarization of the inner shells in a high-spin case, results in over-stabilization of the HS state. Indeed, the J value of UHF result is less antiferromagnetic than that of experimental one, while $|J_{ab}|$ value of UBLYP, in which UHF exchange effect is not included, is larger than that of CASCI[2,2]-DFT. The $|J_{ab}|$ of CASCI[2,2]-DFT is also attributable to its description of HS state: it is noteworthy that the CASCI[2,2]-DFT for the HS state reduces to an usual open-shell HF plus DFT correlation method.

The first excited energy is also calculated by CASCI[2,2]-DFT. In contrast to J value, the molecular orbitals employed in CASCI-DFT computations affect the results: the RHF-CASCI-DFT value is smaller than the UNO-CASCI-DFT value. The reason is that since UNO is obtained by the variational UHF procedure with succeeding natural orbital analysis for the singlet-biradical state it is appropriate for the ground-state but not for the singlet excited state involving an ionic character. The RHF orbitals do not show the diradical character, so improve the excited energy slightly. However, compared with the experimental one, the excited energy calculated by RHF-CASCI-DFT is still larger than the experimental one, indicating that there is room for improvement of CASCI[2,2]-DFT approach.

Table 1
Effective exchange integral values and lowest-lying excited energies for **2**

Method	J (cm^{-1})	First excitation energy (eV)
UHF	−1212.22 (−1085.00)	
UB2LYP	−1361.82 (−1413.20)	
UB3LYP	−1496.12 (−1827.10)	
UBLYP	−2332.79 (−2256.80)	
UNO-CASCI[2,2]-DFT	−2253.33 (−2032.00)	3.312
RHF-CASCI[2,2]-DFT	−2253.49 (−2417.95)	3.190
Experiment	−1318	2.065

The corresponding values for **3** are in parentheses.

3.3. Di-phenyl-IDPL

Next, we consider the di-phenyl-IDPL (**4** in Fig. 3) [9]. For this system, we also assume that the two-electrons in two-orbitals play essential role for the magnetic interaction. However, the two-orbitals are newly formed HOMO and LUMO as shown in Fig. 5. This set of HOMO and LUMO that is reported in Ref. [9] is consistent with our UHF natural orbitals (UNOs). The active space is circled by the dotted square. The HOMO constitutes from LUMO of benzene and antibonding type of two phenalenyl HOMOs. On the other hand, the LUMO is the antibonding type of MO constructed from the second HOMO of benzene and the bonding MO of two-phenalenyl HOMOs. The occupation number of the natural orbital of UNO-CASCI[2,2]-DFT solution is 1.43, which exhibits the stronger biradical character than that of **2**. The computational J values are presented in Table 2. All of $|J_{ab}|$ values calculated by UHF, UB2LYP, UB3LYP, and UB3LYP are larger than the experimental one. One possible reason is the well-known over-stabilization of the LS state of diradical molecules by the symmetry-broken feature and the approximated XC functional [23]. On the other hand, the UNO-CASCI[2,2]-DFT result shows the excellent agreement with the experimental one. This might be because the LUMO of **4** is not a straightforward antibonding type

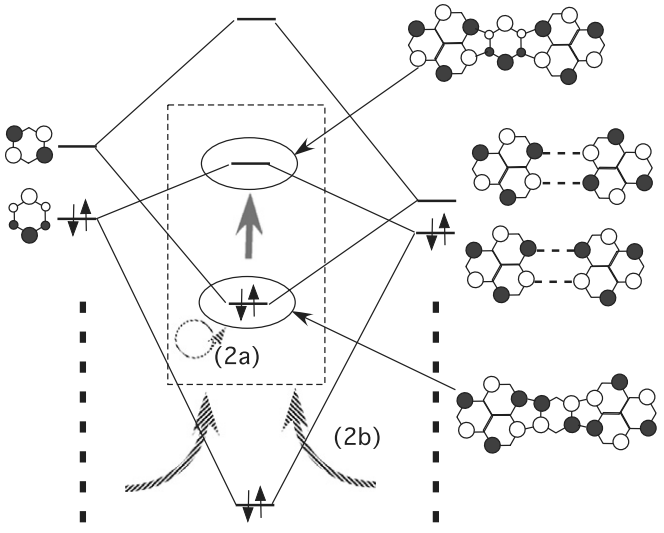

Fig. 5. Schematic illustration of CASCI-DFT solution of **4**. The dotted square is the active space (CASCI[2,2]) we employed. The gray arrow indicates the explicit quantum correlation effects covered by CASCI[2,2], while the remaining DFT correlation effects are denoted as striped arrows.

Table 2
Effective exchange integral values and lowest-lying excited energies for **4**

Method	J (cm^{-1})	First excitation energy (eV)
UHF	−967.70	
UB2LYP	−993.37	
UB3LYP	−1117.39	
UBLYP	−1515.74	
UNO-CASCI[2,2]-DFT	−770.55	3.905
Experiment	−764.5	1.661

of MO. However, the first excited energy calculated by UNO-CASDFT is much larger than the experimental one, implying that the points to be improved remain besides the reference MOs for well-balanced description among the ground and excited states.

4. Discussion and concluding remarks

So far, we present a CASCI-DFT study of phenalenyl dimeric systems based on a modest active space (CAS[2,2]). We found that this CASCI-DFT treatment works well at the quality level for J values, but that there remain slight deviations from the experimental values, in particular, of the excited spectrum.

There are several ways to improve our approach. First one is the bull force computation by increasing the size of the active space. This is a most straightforward way to cover the many-body quantum effects explicitly, but is not feasible at present. For instance, CASCI[14,14]-DFT and CASCI[20,20]-DFT are required for **2** and **3**, respectively if we intend all of π electrons. Such CAS spaces are too large to compute large molecular systems. The ad hoc CI-DFT treatment with selecting important configurations is a second idea. When the resonating valence bond (VB) picture is more effective than molecular orbital picture, the VB-CI-DFT with essential VB configurations becomes better than the present CASCI-DFT approach based on molecular orbitals. In these, we intend to improve the wavefunction part of multireference DFT, i.e. $F^{\mathrm{CAS}}[\rho(\mathbf{r})]$ in Eq. (4). Another way is to refine the DFT correlation part of CAS-DFT, i.e., $E_{\mathrm{RC}}^{\mathrm{CAS}}[\rho(\mathbf{r})]$ in Eq. (4) without changing the wavefunction part. Indeed, the RC term used in this study is originally designed for the ground-state. This is a possible reason why the excited energies of CASCI[2,2]-DFT are not so good. For better description of the excited states, the state-specific correlation terms might be needed. For such a purpose, we have recently proposed an orbital-dependent correlation correction for CAS-DFT [19]. Using this alternative CAS-DFT, the computational results of excited states of phenalenyl systems are expected to be improved further.

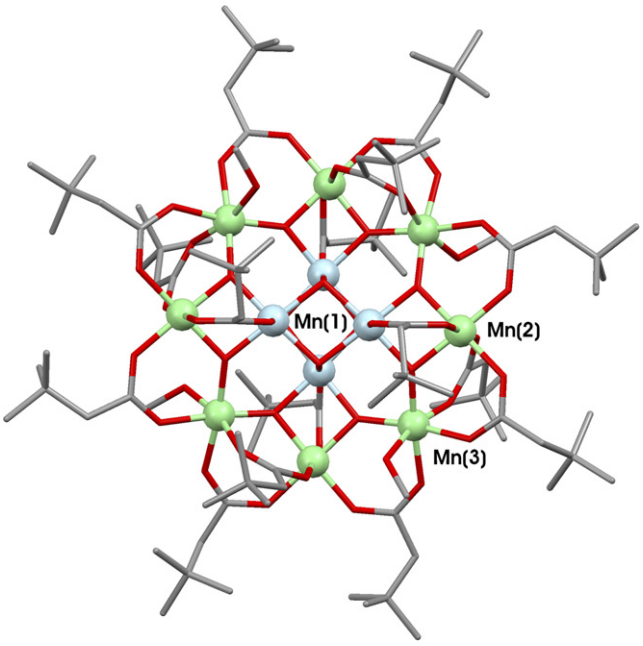

Fig. 1. Mn_{12}-*t*-Bu crystal structure.

Mn^{3+} ions are ferromagnetically coupled to each other and form a ring around the cubane-like (Mn_4O_4) structure of the Mn^{4+} ions, which are also ferromagnetically coupled. The interaction between the Mn^{3+} and Mn^{4+} ions, however, is antiferromagnetic, giving a total spin, $S_T = 10$. The electronic Hamiltonian representing this system is then given (assuming a giant spin model) as

$$\mathscr{H} = \mu_B H \cdot g \cdot S + DS_z^2 + B_4^0 O_4^0 + B_4^4 O_4^4 + \mathscr{H}',$$

where the first term represents the Zeeman interaction, and for our purposes is zero (because we apply no external field). D is the axially anisotropic zero-field splitting parameter and is followed by higher order crystal field terms; the last term representing rather small perturbations. For the case of Mn_{12}-*t*-Bu: $D = -0.665$ K, $B_4^0 = -0.036$ mK, and $B_4^4 = -0.062$ mK, as established by EPR [11]. The negative axial anisotropy makes the $m_S = \pm 10$ levels the ground state and can be thought of as a type of double potential well. Because our experiments are performed at 3 K and below, our only excitations occur in the ground state of the system, which is where we would like to probe the QTM mechanism. The nuclei at these temperatures are relaxed through the coupling of the electrons to the phonons, thus, nuclear relaxation measurements give insight into the dynamics of the electronic system, which is why this technique has been chosen. To this end we have measured the spectrum and spin–lattice relaxation (T_1) of Mn_{12}-*t*-Bu and show that, in zero external field, the electron relaxation from 700 mK to 400 mK does not occur dominantly through a tunneling mechanism.

2. Synthesis and crystal growth

Mn_{12}-*t*-Bu is synthesized by a carboxylate substitution of Mn_{12}-Ac followed by re-crystallization with CH_3OH/Et_2O, as described elsewhere [8b]. The crystals were dark with a brick shape and had dimensions of 1 mm × 1 mm × 2 mm.

3. NMR experimental details

^{55}Mn NMR measurements were made using a locally developed MAGRes2000 Integrated Wideband NMR spectrometer with quadruture detection and a home built high frequency probe [12,13]. For the measurement of the spectrum, samples were prepared by removing the crystal from its mother liquor and immediately covering in 5-min epoxy to prevent crystal fractures after thermal cycling. Immediately after the epoxy was set, the sample was mounted into the coil and cooled in a dewar of liquid Helium. The spectrum was acquired at 1.45 K, below the blocking temperature, T_B, of ~3 K because of fast T_2 times above this temperature. A Hahn echo pulse sequence was used while the frequency was scanned from 220 MHz to 400 MHz, usually taking 0.25 MHz steps. Frequency scans were necessary because of the large peak widths (~5–20 MHz). Pulse lengths were of the order of 500 ns.

Preparation of the sample for He-3 measurements consists of surrounding the crystal with N-grease before placing into a coil. He-3 experiments were performed in a Janis cryostat. The system is capable of maintaining ~380 mK for 12 h with the heat load from the NMR probe and pulses. After that time, the He-3 is re-condensed. T_1 measurements were conducted on the Mn^{4+}, Mn(1) peak, down to 390 mK. In order to saturate any quadrupole split peaks, we apply a frequency hopping comb pulse, discussed in a previous publication [9]. This comb pulse is repeated up to 20 times to ensure the spins are perturbed from equilibrium. Evidence for this is seen in the good fits of the relaxation data to a single exponential function. Any deviation from exponential is due to the fact that we are unable to achieve full saturation. The T_1 data are fit to the following exponential, as reported earlier [9]: $M(t) = (M_\infty - M_0)[1 - \exp(-t/T_1)] + M_0$, where $M(t)$ is the time dependent nuclear magnetization, M_∞ is the equilibrium magnetization, t is the time between the saturation sequence and the observation spin-echo, M_0 is the remnant magnetization immediately following the saturation comb, and T_1 is the longitudinal (spin–lattice) relaxation time.

4. Results

As shown in Fig. 2, the ^{55}Mn NMR spectrum of Mn_{12}-*t*-Bu exhibits three sets of peaks, the two Mn^{3+} ion environments and the Mn^{4+} ion environment, essentially similar to those for Mn_{12}-Ac and Mn_{12}-BrAc [9,10,14,15]. Peaks are assigned by considering the number of unpaired electrons at each Mn site, along with any Jahn–Teller distortion

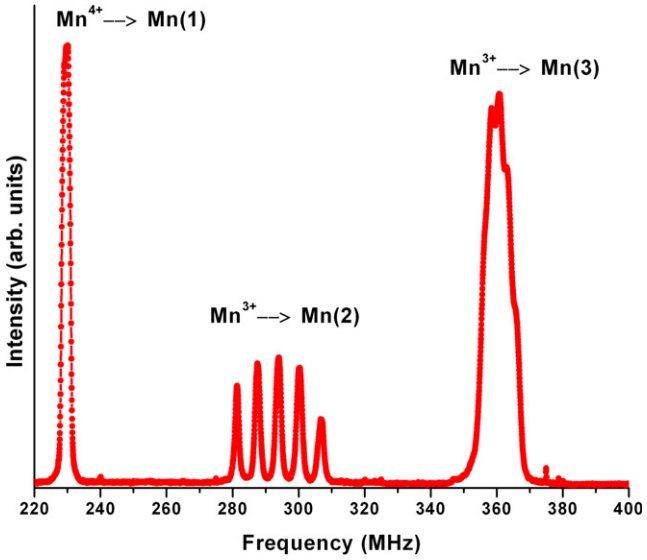

Fig. 2. Single crystal ^{55}Mn NMR spectrum of Mn_{12}-*t*-Bu.

[14]. Because the Mn^{4+} ions have one less electron than the Mn^{3+} ions, it is expected that the Mn^{4+} Fermi Contact hyperfine field will be smaller, thus resulting in a lower resonance frequency. Also, because the Mn^{4+} ion is in an environment of electron distribution which is close to cubic, we do not expect there to be a large quadrupole splitting. The Mn(1) peak at 230.1 MHz (21.91 T) can then be assigned to the Mn^{4+} ions. The full width at half maximum (FWHM) is 2.8 MHz, which is broad when compared against the Mn(2) peaks FWHM of 1.9 MHz. A closer examination of the Mn(1) peak shows structure at the apex, indicating the presence of quadrupolar interactions, which would result in a broadened peak. Isomers could also increase the peak width, similar to that seen in Mn_{12}-Ac [10], however, there is no clear evidence for isomers after examination of the Mn(2) peak. If in fact the Mn(1) peak is split by quadrupole effects, then the Mn^{4+} ions no longer exist in a cubic environment.

The Mn(2) and Mn(3) peaks are assigned by considering their X-ray structure (Fig. 1). The angle the local Jahn–Teller axis makes with the molecular *c*-axis governs the strength of the quadrupole and dipolar interaction. The smaller the angle, the larger the quadrupole splitting and dipolar contribution will be. Because the dipolar hyperfine term is opposite in sign to the Fermi contact term (the main contributor to the hyperfine field), a larger dipole interaction will result in a smaller effective hyperfine field (lower resonant frequency) felt at the nuclear site [14].

The Mn(2) peak, with the largest quadrupole frequency and lower resonant frequency, can then be assigned to the four Mn^{3+} ions which are slightly tilted away from the *c*-axis with an angle of ~13.7°. The central peak for the quadrupolar split resonance is located at 294.0 MHz, has an internal field of 28.00 T, and a FWHM of 1.9 MHz. The separation between each resonance, $\Delta\nu_Q \sim 6.4$ MHz, results in $e^2qQ \sim 46.6$ MHz; with the quadrupole energies being obtained from the following equation:

$$E_m = -\gamma_n \hbar H_0 m_n + \frac{e^2qQ}{4I(2I-1)}\left(\frac{3\cos^2\theta - 1}{2}\right)[3m_n^2 - I(I+1)]$$

The first term is a result of the effective hyperfine splitting and the second term is the quadrupole perturbation. eQ is the electric quadrupole moment, eq is the gradient of the electric field along the *z*-axis, and θ is the angle the Jahn–Teller axis makes with the crystallographic *c*-axis. Taking the energy difference between two neighboring m_n levels allows the calculation of e^2qQ.

The Mn(3) peak has a central frequency of 360.8 MHz resulting in an internal field of 34.36 T. It is also split by quadrupole interactions as a result of its 36.6° tilt of the local Jahn–Teller axis with respect to the molecular *c*-axis. Because of the larger angle, the quadrupolar and dipole terms are smaller, making assignment of this peak straight forward. For Mn(3), $e^2qQ \sim 36.1$ MHz is calculated taking the separation between each resonance, $\Delta\nu_Q \sim 2.5$ MHz.

While the bulkier ligands provide a greater separation among Mn_{12} molecules, diminishing intercluster dipolar effects, they also provide a small distortion in the local electron symmetry, evidenced by the quadrupole splitting of the Mn(1) peak. Although isomers do not appear to be present in this system, the loss of local symmetry gives Mn_{12}-BrAc the advantage of a being the model system for SMMs. However, in terms of sample stability, it seems that Mn_{12}-*t*-Bu is superior, as no asymmetry is seen in any of the resonance signals. Previous studies on Mn_{12}-BrAc do show asymmetry in the first and third peaks and are thought to be a result of sample degradation [10,11]. Even the freshest crystals of Mn_{12}-BrAc exhibit this behavior. Thus, the bulkier ligands in Mn_{12}-*t*-Bu seem to protect the core molecule from the effects that interstitial solvent loss may have on smaller systems.

T_1 measurements of the Mn(1) peak show very similar behavior to the two previously studied Mn_{12} compounds (Mn_{12}-Ac and Mn_{12}-BrAc) in the high temperature limit (Fig. 3) and are fit in a similar manner to that previously reported [9,16] (solid line in Fig. 3) using,

$$T_1^{-1} \approx C\exp(-\Delta E/T), \text{ with } C \approx \frac{\gamma_N^2\langle h_\perp^2\rangle}{\omega_N^2\tau_0},$$

resulting in a pre-exponential factor of $C \sim 1.64 \times 10^5\ s^{-1}$ and a activation energy of $\Delta E = 13.1$ K, corresponding well with the separation between the $m_S = \pm 10$ and $m_S = \pm 9$ states.

Upon reducing the temperature below 0.8 K, we see a dramatic increase in the spin–lattice relaxation time. In fact, at 400 mK $T_1 \sim 1000$ s, roughly three times as long as Mn_{12}-BrAc and an order of magnitude longer than Mn_{12}-Ac, partly a result of the bulkier ligands. The data at these temperatures follows either a T^2 or exponential type of dependence (Fig. 4). It is obvious that QTM is not the dominant relaxation mechanism in this temperature range as this would produce a temperature-independent relaxation region.

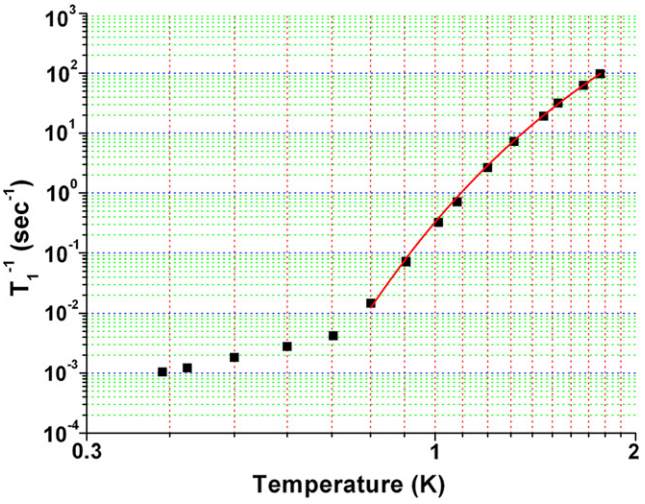

Fig. 3. Inverse T_1 of the Mn(1) peak of Mn_{12}-*t*-Bu single crystal.

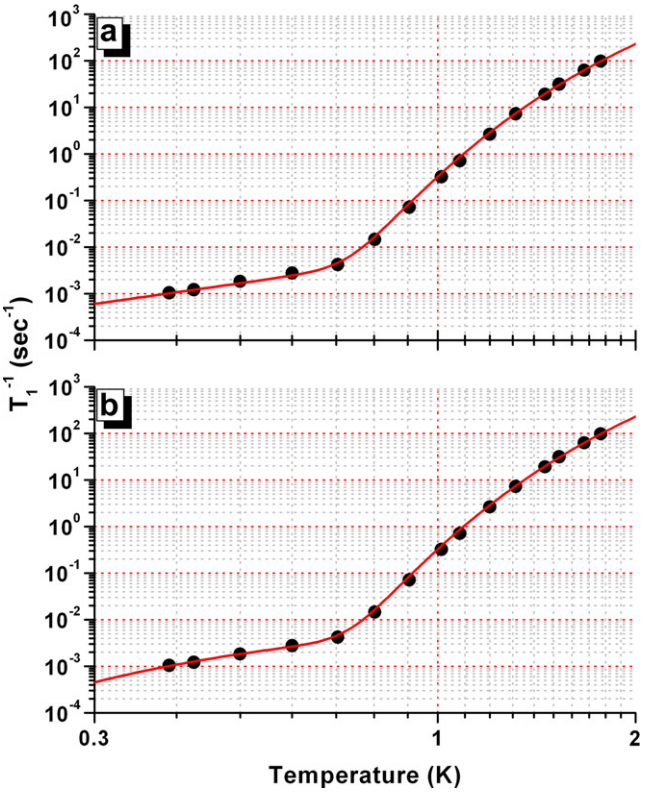

Fig. 4. Inverse T_1 of the Mn(1) peak of Mn_{12}-*t*-Bu single crystal with high and low temperature fit: (a) low temperature fit is a T^2 dependence and (b) low temperature fit is exponential in temperature.

5. Discussion and conclusion

This study again shows that ^{55}Mn NMR using single crystals consistently provides higher resolution data than crushed aligned powders. Of the high symmetry molecules, Mn_{12}-BrAc and Mn_{12}-*t*-Bu, both offer impressive potential for investigation as new model SMM compounds. While Mn_{12}-*t*-Bu shows evidence for the loss of cubic symmetry at the Mn^{4+} site, the sample shows no asymmetry in its peaks, in contrast to Mn_{12}-Ac and Mn_{12}-BrAc, thus attesting to be a more solvate-tough lattice.

The bulky ligands of the Mn_{12}-*t*-Bu also reduce intercluster interactions, greatly increasing the length of T_1 for this compound in the low temperature limit ($T_1 \sim 1000$ s at 400 mK). The data also clearly show a temperature dependence over the entire range studied, indicating that tunneling is not the dominant mechanism by which the nuclei are relaxed. The low temperature (below 0.7 K) thermally-activated nuclear T_1 observed for Mn_{12}-*t*-Bu here, and earlier for Mn_{12}-BrAc [9] is in sharp contrast to the temperature-independent behavior reported for Mn_{12}-Ac by Morello et al. [16], and ascribed to the relaxation caused by the so-called 'fast relaxing' isomers (estimated to be present in 5–8% concentration in crystals of Mn_{12}-Ac). These fast-relaxing isomers have a much lower anisotropy barrier, and lower symmetry (Jahn–Teller axes deviating from their easy axes), and they exhibit tunneling in zero field. On the other hand, the standard Mn_{12}-Ac molecules have their Jahn–Teller axes parallel to the easy (*c*-axis), including the solvent isomers [1,17]. Since no such fast-relaxing species are present in Mn_{12}-*t*-Bu, one may surmise that this compound should show a different nuclear relaxation behavior than Mn_{12}-Ac. Nevertheless, both Mn_{12}-BrAc and Mn_{12}-*t*-Bu show a definitive change in the slope of their nuclear T_1 below about 0.8 K.

Above 0.8 K, the T_1 follows the model of nuclear relaxation via electronic spin fluctuations between the $M_S = \pm 10$ and $M_S = \pm 9$ states. Clearly, once nuclear relaxation by spin fluctuations freezes out below ~0.8 K, some other relaxation process takes over. The details of this new process remain unclear at this point, although the exponential fit to the data between 0.39 K and 0.70 K reveals that there might be a lower temperature barrier of about 1.1 K. Further studies using Mn_{12}-Ac, and at temperatures lower than 0.39 K should prove helpful to understand this process, and are being contemplated.

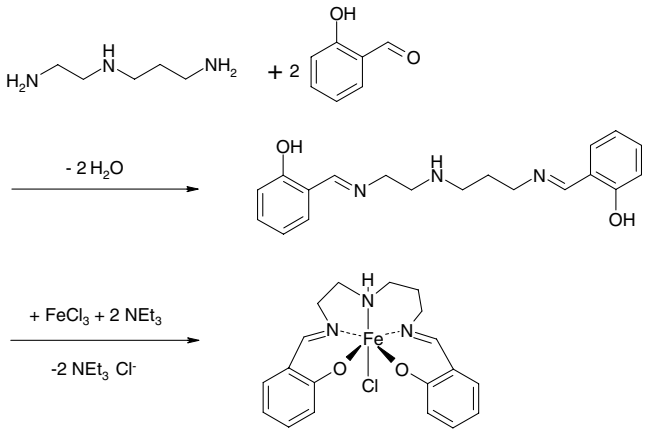

Fig. 1. Synthesis of the [Fe(^{5X}L)Cl] precursor (with X = N).

butterfly''). Molecular dynamic as well as Monte Carlo simulations, both on an empirical level, confirm this modality.

Fig. 5 and Table 1 show results of temperature-dependent Mössbauer spectroscopy of the dodecanuclear star compounds. At 300 K, the spectra indicates a quadrupole splitted doublet which is common for Fe(III) in the high-spin state. For the N-star this signal has been assigned to two positions with only weak deviations. One explanation may be a *cis–trans* isomerisation within the ligand around the Fe(III) centers (as seen above). Beside that, there certainly exists a distribution of the anions. There is no evidence for Fe(III) in the low-spin state. The Mössbauer parameters of N-star and the S-star in comparison with the mononuclear precursor clearly indicate coordination. Apparently the N-star deviates much stronger in isomer shift and quadrupol splitting then the S-star. This can be understood on the basis of the HSAB concept: the hard N-donor suits better to the Fe(III) compared to the soft S-donor (see Fig. 6).

Beside the Fe(III)-HS, the spectra indicates another small quadrupole splitted doublet which is characteristic for an Fe(II) in the low-spin state. This signal is characteristic and expected for the $[Fe(II)(CN)_6]^{4-}$core. The area fraction in the N-star at 20 K accounts well for the expected 1/11, i.e. 9%. The S-star overshoots with 15%. This may be due to low Debeye–Waller factor in the soft Fe(III)–S coordination.

The dodecanuclear star-cluster have been characterized by IR spectrum. The characteristic splitting of the C–N stretching vibration band support the octahedral symmetry around the Fe(II) and Co(III) centers and their CN bridge. Evidently three types are expected Fe–CN, Co–CN, and the Fe–CN–Co bridge. The splitting was absent for the hepta and nonanuclear clusters as only M–CN–Fe was present. The shift of the CN-band varies within the N-star and the S-star: 2123; 2054 cm^{-1} and 2128; 2070; 2051 cm^{-1}. The S-star shows an resolved additional peak while the N-star shows only a shoulder in that region. This

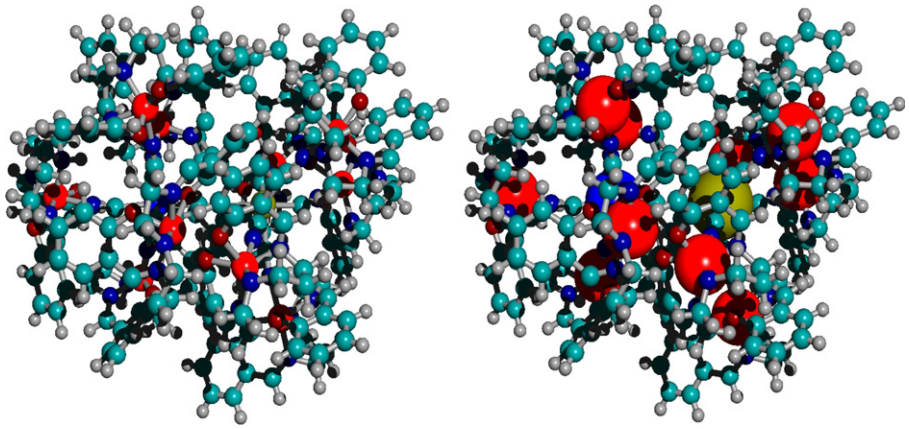

Fig. 3. MM+ model of the $[(^{5N}LFe(III)\text{-}NC)_5Fe(II)\text{-}CN\text{-}Co(III)(CN\text{-}Fe(III)^{5N}L)_5]Cl_4$ cluster (normal and enlarged metal centers).

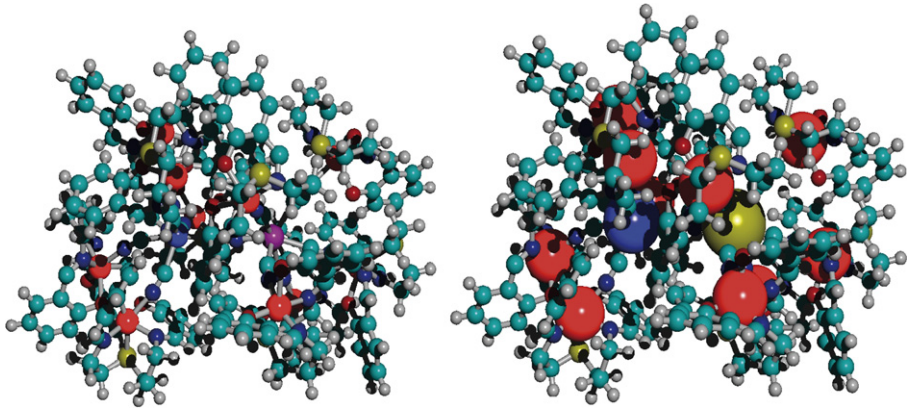

Fig. 4. MM+ model of the $[(^{5S}LFe(III)\text{-}NC)_5Fe(II)\text{-}CN\text{-}Co(III)(CN\text{-}Fe(III)^{5S}L)_5]Cl_4$ cluster (normal and enlarged metal centers).

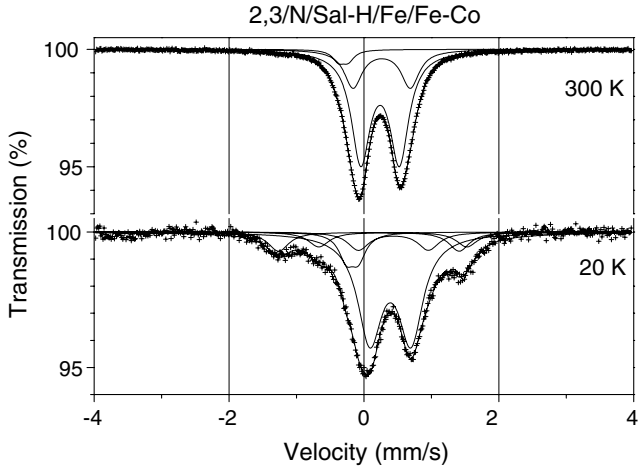

Fig. 5. Mössbauer spectra of the dodecanuclear $[(^{5X}LFe(III)\text{-}NC)_5Fe(II)\text{-}CN\text{-}Co(III)(CN\text{-}Fe(III)^{5X}L)_5]Cl_4$ cluster (with X = N) at 300 K and 20 K.

supports the conclusion indicated by Mössbauer spectroscopy.

At 20 K the Mössbauer spectra of the S-star conserves the same features (Fe(III)-HS and Fe(II)-LS) as at room temperature beside some HS–HS transitions within the distribution. However, the N-star exhibits two additional doublets characteristic for Fe(III) in the low-spin state [2,3].

This indicates that in the dodecanuclear complex $[(^{5N}LFe(III)\text{-}NC)_5Fe(II)\text{-}CN\text{-}Co(III)(CN\text{-}Fe(III)^{5N}L)_5]Cl_4$ a thermally induced transition between an HS to LS state exists. The area fraction of the respective doublets $A(Fe^{III}\text{-high-spin}):A(Fe^{III}\text{-low-spin})$ is 72.8:17.7. This accounts for 19.5% in the LS state.

In the N-star case several Fe(III) centres exhibit electronic switching. This enables us to talk about a multiple electronic transition. This is the first example for electronic switching in a dodecanuclear complex compound. On the other hand, the S-star remains in the HS state between 20 and 300 K.

Magnetic investigation are in progress and will further resolve the switching in our stars. The difficulties in the evaluation of the magnetic properties, such as coupling, in pure high-spin compounds usually rises, at least exponentially, with the number of spin centers in the molecule. Now the dodecanuclear stars are orders of magnitude higher in complexity compare to the hepta- and nonanuclear-stars. On top of the usual high-spin problems they change to different total high-spin states, i.e. spin transition, as a function of temperature.

Table 1
Mössbauer parameter of the dodecanuclear $[(^{5X}LFe(III)\text{-}NC)_5Fe(II)\text{-}CN\text{-}Co(III)(CN\text{-}Fe(III)^{5X}L)_5]Cl_4$ clusters (with X = N, S) at 300 K and 20 K

The technological transfer from the molecular switchability in mononuclear spin transition to multinuclear systems has been achieved. The dodecanuclear star-shaped compounds open a new dimension of switching between 10 and 50 unpaired electrons per star ontop of novel synergysms.

2. Experimental

2.1. Ligand $^{5N}LFeCl$

Partly prepared in analogy to the literature [4]. The pentadentate ligand $L_1 = N,N'$-bis (1-hydroxy-2-benzyliden) 1,6-diamino-3-azahexane has been prepared by a Schiff base condensation between N^1-(2-amino-ethyl)-propan-1,3-diamine and salicylaldehyde at a ratio of 1:2. A mixture of the salicylaldeyde (0.2 mol) and 1,6-diamino-3-azahexane (0.1 mol) in methanol (100 cm^3) was boiled for 10 min and the solution subjected to crowding. The yellow oily material resulted and used without any purification. NMR spectra agree with the expected structure.

A solution of anhydrous iron(III) chloride (10 mmol) in methanol (50 cm^3) was added to a solution of the pentadentate ligand ^{5N}L (10 mmol) in methanol (40 cm^3). The mixture was stirred at 50 °C for 10 min and then triethylamine (20 mmol) was added. The resulting solution was stirred at 50 °C for 1 h and after cooling until black crystals precipitated. These were collected, washed with methanol and diethyl ether, and dried in vacuum.

2.2. Ligand $^{5S}LFeCl$

Partly prepared in analogy to the literature [4]. The pentadentate ligand $^{5S}L = N,N'$-bis (1-hydroxy-2-benzyliden) 2-aminoethyl-3-aminopropylsulfide has been prepared by a Schiff base condensation between 2-aminoethyl-3-aminopropylsulfide and salicylaldehyde at a ratio of 1:2. A mixture of the salicylaldeyde (0.2 mol) and 2-aminoethyl-3-aminopropylsulfide (0.1 mol) in methanol (100 cm^3) was boiled for 10 min and the solution subjected to crowding. The yellow oily material resulted and used without any purification. NMR spectra agree with the expected structure.

A solution of anhydrous iron(III) chloride (10 mmol) in methanol (50 cm^3) was added to a solution of the pentadentate ligand ^{5S}L (10 mmol) in methanol (40 cm^3). The mixture was stirred at 50 °C for 10 min and then triethylamine (20 mmol) was added. The resulting solution was stirred at 50 °C for 1 h and after cooling until black crystals precipitated. These were collected, washed with methanol and diethyl ether, and dried in vacuum.

2.3. Binuclear complexes $Ba_3[(NC)_5Fe(II)\text{-}CN\text{-}Co(III)(CN)_5]$

Partly prepared in analogy to the literature [5]. $K_6[(NC)_5Fe(II)\text{-}CN\text{-}Co(III)(CN)_5]$ has been prepared with 4.8g (0.02 mol) $CoCl_2 \cdot 6H_2O$ in 200 cm^3 H_2O. 6.5 g (0.1 mol) KCN in 100 cm^3 H_2O were added under nitrogen atmosphere.

The well stirred mixture has been cooled down to 0 °C and 6.6 g (0.02 mol) $K_3[Fe(III)(CN)_6]$ in 300 cm^3 H_2O were added drop wise. The mixture is stirred for further 5–10 min and 1000 cm^3 ethanol has been added. The precipitated crystals were collected. It is a mixture K_6 $[(NC)_5Fe(II)\text{-}CN\text{-}Co(III)(CN)_5]$ and K_3 $[Fe(II)(CN)_6]$. Yield: 13.89 g of the mixture.

13.77 g of the mixture has been solved in 23 cm^3 water and 16.7 g (0.069 mol) $BaCl_2 \cdot 2H_2O$ in 23 cm^3 water has been added. The solution has been cooled down to 0 °C. After adding 150 cm^3 of ethanol light yellow crystals of Ba_3 $[(NC)_5Fe(II)\text{-}CN\text{-}Co(III)(CN)_5]$, were collected from the solution. Yield: 4.13 g (0.005 mol) ≈ 25%.

2.4. Dodecanuclear complexes $[(^{5N}LFe(III)\text{-}NC)_5Fe(II)\text{-}CN\text{-}Co(III)(CN\text{-}Fe(III)^{5N}L)_5]Cl_4$

Partly prepared in analogy to the literature [3,4]. A methanol solution (50 cm^3) of $[L_1FeCl]$ (2 mmol) was combined with (20 cm^3) aqueous–methanol solution (1:1) of Ba_3 $[(NC)_5Fe(II)\text{-}CN\text{-}Co(III)(CN)_5]$ (0.2 mmol). The dark-black precipitate was stirred for 30 min. About 60% of the solvent was evaporated using a rotary evaporator at temperatures never higher than 35 °C. Approximately 50 ml of water were then added in order to precipitate the complex. It was cooled in order to enhance the yield. The complexes were filtered using a Fritta IV filter and cleaned with cold water and diethylether and dried under vacuum for 24 h, the filtered off on the Frita funnel, washed twice with methanol and dryed under argon. Yield: −79%.

IR (KBr): ν (cm^{-1}) = 3384 (NH, val.), 2945 (CH_2, val.), 2123, 2054 cm^{-1} (C≡N, val. splitted), 1620 cm^{-1} (C=N, val.), 1600–1500 cm^{-1} (aromat. C=C, val.), 790–750 cm^{-1} (C–H, o. o. p.). Cyanide valence band splitted in fact of the different coordination between iron and cobalt.

2.5. Dodecanuclear complexes $[(^{5S}LFe(III)\text{-}NC)_5Fe(II)\text{-}CN\text{-}Co(III)(CN\text{-}Fe(III)^{5S}L)_5]Cl_4$

Partly prepared in analogy to the literature [3,4]. A methanol solution (50 cm^3) of $[L_2FeCl]$ (2 mmol) was combined with (20 cm^3)g aqueous-methanol solution (1:1) of Ba_3 $[(NC)_5Fe(II)\text{-}CN\text{-}Co(III)(CN)_5]$ (0.2 mmol). The dark-black precipitate was stirred for 30 min. About 60% of the solvent was evaporated using a rotary evaporator at temperatures never higher than 35 °C. Approximately 50 ml of water were then added in order to precipitate the complex. It was cooled in order to enhance the yield. The complexes were filtered using a Fritta IV filter and cleaned with cold water and diethylether and dried under vacuum for 24 h, the filtered off on the Frita funnel, washed twice with methanol and dried under argon.

Yield: 71.1%; reaction time: 30 min;

IR (KBr): ν (cm^{-1}) = 2917 (CH_2, val.), 2128, 2070, 2051 cm^{-1} (C≡N, val.), 1615 cm^{-1} (C=N, val. splitted), 1600–1500 cm^{-1} (aromat. C=C, val.), 760–750 cm^{-1} (C–H, o. o. p.). Cyanide valence band splitted in fact of the different coordination between iron and cobalt.

2.6. Mössbauer spectroscopy

Mössbauer spectroscopy is performed in a conventional spectrometer in scanning the Mössbauer spectra at 20 K and room temperature (^{57}Co/Rh source kept at room temperature; isomeric shifts are relative to the source).

isomerization has been observed. This allows the pentadentate to adapt. Molecular dynamics as well as Monte Carlo simulations, both on an empirical level, confirm this modality.

Fig. 4 and Table 1 show results of temperature-dependent Mössbauer spectroscopy of the heptanuclear S-star compounds. At 300 K the spectra indicates a quadrupole split doublet which is common for Fe(III) ions in the high-spin state. For both S–Co-stars the signal has been assigned to two positions with only weak deviations. One explanation may be a *cis–trans* isomerization within the ligand around the Fe(III) centers (as seen above). There is no evidence for Fe(III) in the low-spin state. The Mössbauer parameters of the S-stars in comparison with the mononuclear precursors clearly indicate coordination.

Beside the Fe(III)-HS, the spectra of the S–Fe-stars indicate another small quadrupole split doublet which is characteristic for an Fe(II) in the low-spin state. This signal is characteristic and expected for the $[Fe(II)(CN)_6]^{4-}$ core. The area fraction in the 3EtO–S–Fe-star at 20 K accounts well for the expected 1:7, i.e. 15%. The H–S–Fe-star overshoots that ratio. This may be due to deviations in the Debye–Waller factor.

The heptanuclear star-cluster have been characterized by IR spectrum. The characteristic non-split band of the C–N stretching vibration supports the octahedral symmetry around the Fe(II) or Co(III) centers and their CN bridge. No splitting was observed for the heptanuclear clusters.

At 20 K the Mössbauer spectra of the S-stars conserves the same features (two Fe(III)-HS and one Fe(II)-LS) as at room temperature beside an altered area ratio among the two HS signals within the distribution. In both S–Co-star cases, the HS–Fe(III)-position with the wider quadrupol splitting gained area-fraction on cooling. This indicates a multiple HS–HS transition. Such transitions have not been detected in both S–Fe-star compounds.

Magnetic investigation are in progress and will further resolve the switching in our stars. The difficulties in the evaluation of the magnetic properties, such as coupling, in pure high-spin compounds usually rises, at least exponentially, with the number of spin centers in the molecule.

2. Experimental

2.1. 2-Aminoethyl-3-aminopropylsulfid (aeaps)

Aeaps was prepared as described in the literature [8]. The colorless liquid was characterized by ^{1}H NMR (400 MHz, CD_3OD): 4.73 ppm (s, 4H, NH_2); 2.80–2.78

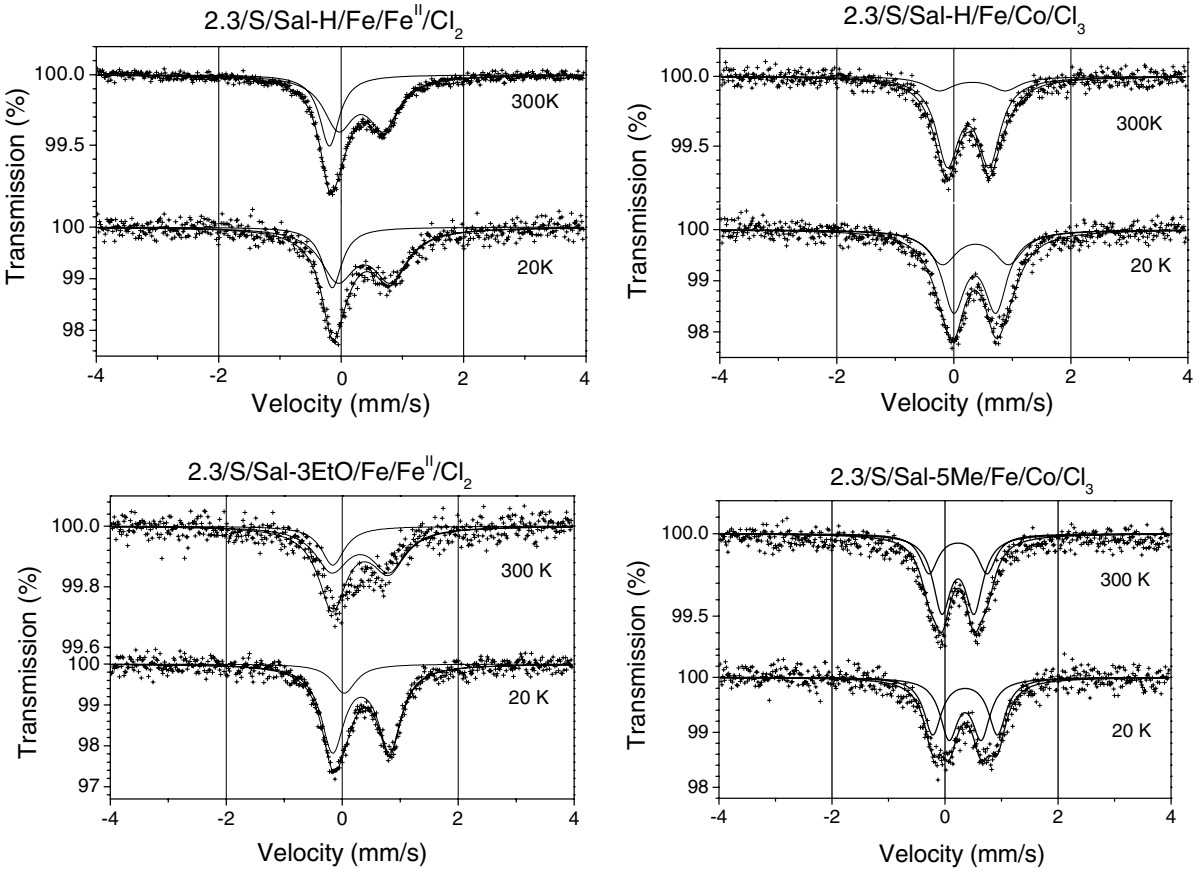

Fig. 4. Mössbauer spectra of the heptanuclear (from top): [2,3/S/Sal-H/Fe/Fe(II)/Cl_2], [2,3/S/Sal-3EtO/Fe/Fe(II)/Cl_2], [2,3/S/Sal-H/Fe/Co/Cl_3], and [2,3/S/Sal-5Me/Fe/Co/Cl_3].

2.2. Precursor

The precursors were prepared as described in the literature [7]. The dark red-brown powders were characterized by IR and mass spectroscopy and by elemental analysis.

2.2.1. [2,3/S/Sal-H/Fe/Cl]

Yield: 72.8%. *Anal.* Calc. for $C_{19}H_{20}N_2SO_2FeCl$: C, 52.8; N, 6.5; H, 4.6; S, 7.4. Found: C, 51.4; N, 6.7; H, 5.8; S, 6.3%. EI MS $m/z = 396.3$ (100%, $[2,3/S/Sal\text{-}H/Fe]^+$).

2.2.2. [2,3/S/Sal-3EtO/Fe/Cl]

Yield: 90.0%. *Anal.* Calc. for $C_{23}H_{28}N_2SO_4FeCl$: C, 53.1; N, 5.4; H, 5.4; S, 6.2. Found: C, 53.7; N, 5.6; H, 5.8; S, 6.1%. EI MS $m/z = 484.4$ (100%, $[2,3/S/Sal\text{-}3EtO/Fe]^+$).

2.2.3. [2,3/S/Sal-5Me/Fe/Cl]

Yield: 95.4%. *Anal.* Calc. for $C_{21}H_{24}N_2SO_2FeCl$: C, 54.9; N, 6.1; H, 5.3; S, 7.0. Found: C, 51.5; N, 5.9; H, 5.7; S, 6.1%. EI MS $m/z = 424.4$ (100%, $[2,3/S/Sal\text{-}5Me/Fe]^+$).

2.3. Heptanuclear complexes

The heptanuclear complexes were prepared in analogy to the literature [5–7] except for the reaction time which was increased from 30 min to seven days. The products were characterized by IR-, ESI- and Mössbauer spectroscopy.

2.3.1. [2,3/S/Sal-H/Fe/Fe(II)/Cl_2]

Yield: 78.4%; reaction time: 30 min; ESI MS $m/z = 1294.5$ (85.5%, $[2,3/S/Sal\text{-}H/Fe/Fe(II)]^{2+}$]).

IR (KBr): ν (cm^{-1}) = 2916 (CH_2, val.), 2068 cm^{-1} (C≡N, val.), 1616 cm^{-1} (C=N, val.), 1600–1500 cm^{-1} (aromat. C=C, val.), 760–750 cm^{-1} (C–H, o. o. p.).

2.3.2. [2,3/S/Sal-3EtO/Fe/Fe(II)/Cl_2]

Yield: 95.6%; reaction time: 10 d; ESI MS $m/z = 1558.9$ (0.3%, $[2,3/S/Sal\text{-}3EtO/Fe/Fe(II)]^{2+}$]).

IR (KBr): ν (cm^{-1}) = 2903 (CH_2, val.), 2073 cm^{-1} (C≡N, val.), 1616 cm^{-1} (C=N, val.), 1600–1500 cm^{-1} (aromat. C=C, val.), 760–750 cm^{-1} (C–H, o. o. p.).

2.3.3. [2,3/S/Sal-H/Fe/Co/Cl_3]

Yield: 71.1%; reaction time: 30 min;

IR (KBr): ν (cm^{-1}) = 2919 (CH_2, val.), 2128 cm^{-1} (C≡N, val.), 1615 cm^{-1} (C=N, val.), 1600–1500 cm^{-1} (aromat. C=C, val.), 760–750 cm^{-1} (C–H, o. o. p.).

2.3.4. [2,3/S/Sal-5Me/Fe/Co/Cl_3]

Yield: 48.5%; reaction time: 7 d;

IR (KBr): ν (cm^{-1}) = 2919 (CH_2, val.), 2129 cm^{-1} (C≡N, val.), 1621 cm^{-1} (C=N, val.), 1600–1500 cm^{-1} (aromat. C=C, val.), 760–750 cm^{-1} (C–H, o. o. p.).

2.4. Mössbauer spectroscopy

Mössbauer spectroscopy was performed in a conventional spectrometer in scanning the Mössbauer spectra at 20 K and room temperature (300 K) (^{57}Co/Rh source kept at room temperature; isomeric shifts are relative to the source).

(GSO) descriptions are inevitable [9]. A number of theoretical and experimental studies were reported for the series of the iron–sulfur clusters, however, the first principle calculations for the noncollinear spin structures have not been reported, to our knowledge.

At the reduced form the [2Fe–2S] cluster has one odd electron which could delocalize over iron centers [5,6,10]. The formal charge can be either $Fe^{3+}Fe^{2+}$ or $Fe^{2.5+}Fe^{2.5+}$. The former state is a trapped valence (TV) state, where the odd electron is localized at one iron center. On the other hand, the latter state is a mixed valence (MV) state, where the electron is delocalized over the iron centers. The BS approach has been successfully applied to the study of the electronic structures of these transition metal complexes, however, for the incomplete treatment of the non-dynamical correlation, the MV state could not be described. So, only the electronic structure of the TV state has been investigated by BS methods.

In this study, the spin structures and magnetic orbitals of [2Fe–2S] clusters at the GSO spin states are investigated using the GSO–DFT methods. The orbital interactions and noncollinear spin structures are characterized by natural orbitals.

2. Theoretical backgrounds

2.1. Generalized spin orbital (GSO) method

The unrestricted method based on the different orbitals for different spins is inappropriate to describe the helical or the noncollinear spin structures [11–13]. For such cases, the generalized spin orbital (GSO) description is necessary to expand the spin space of the wavefunctions. The GSO $\{\varphi_i\}$ is defined as

$$\varphi_i(\mathbf{x}) = \chi_i^{\alpha}(\mathbf{r})\alpha(\varpi) + \chi_i^{\beta}(\mathbf{r})\beta(\varpi), \tag{1}$$

which can take both alpha and beta spin spaces with different spatial orbitals $\{\chi_i^{\omega}\}$. Unrestricted wavefunctions are only one case of Eq. (1) that the orbital is in either alpha or beta spin. The special orbitals are expressed as a linear combinations of atomic orbitals

$$\chi_i^{\omega}(\mathbf{x}) = \sum_{\lambda}^{K} C_{\lambda i}^{\omega}\phi_{\lambda}, \tag{2}$$

where K is a number of orbitals. The expansion coefficients $C_{\lambda i}^{\omega}$ are complex numbers. Density matrix ($\mathbf{P}$) is a $2K\times 2K$ matrix defined by

$$\mathbf{P}_{\lambda\sigma} = \sum_{a}^{N} C_{\lambda a}C_{\sigma a}^{*}. \tag{3}$$

The $\mathbf{P}_{\lambda\sigma}$ is expressed by a 2×2 matrix in terms of the spin space

$$P_{\lambda\sigma} = \begin{pmatrix} P^{\alpha\alpha} & P^{\alpha\beta} \\ P^{\beta\alpha} & P^{\beta\beta} \end{pmatrix}_{\lambda\sigma} \tag{4}$$

Charge density matrix ($\mathbf{D}$) is obtained from the density matrixes as

$$\mathbf{D}_{\lambda\sigma} = \sum_{i=j}^{\alpha,\beta} \mathbf{P}_{\lambda\sigma}^{ij} = \mathbf{P}_{\lambda\sigma}^{\alpha\alpha} + \mathbf{P}_{\lambda\sigma}^{\beta\beta}. \tag{5}$$

The SCF equation of the GSO is given as

$$\mathbf{FC} = \mathbf{SC}\boldsymbol{\varepsilon}, \tag{6}$$

where $\mathbf{F}$, $\mathbf{S}$ and $\boldsymbol{\varepsilon}$ are a Fock matrix, an orbital overlap matrix and an orbital energy matrix, respectively. The $2K\times 2K$ matrix equation of Eq. (6) becomes

$$\begin{pmatrix} \mathbf{F}^{\alpha\alpha} & \mathbf{F}^{\alpha\beta} \\ \mathbf{F}^{\beta\alpha} & \mathbf{F}^{\beta\beta} \end{pmatrix}\begin{pmatrix} \mathbf{C}^{\alpha} \\ \mathbf{C}^{\beta} \end{pmatrix} = \varepsilon\begin{pmatrix} \mathbf{S}^{\alpha\alpha} & \mathbf{0} \\ \mathbf{0} & \mathbf{S}^{\beta\beta} \end{pmatrix}\begin{pmatrix} \mathbf{C}^{\alpha} \\ \mathbf{C}^{\beta} \end{pmatrix}. \tag{7}$$

The difference between the GSO equation and unrestricted equation is only the off-diagonal terms: $F_{\mu\nu}^{\alpha\beta}$ and $F_{\mu\nu}^{\beta\alpha}$. The Fock matrix $\mathbf{F}$ of the GSO–HF method is given by

$$\begin{aligned}\mathbf{F}_{\lambda\sigma} =& \begin{pmatrix} \mathbf{h}_{\lambda\sigma}^{\alpha\alpha} & \mathbf{0} \\ \mathbf{0} & \mathbf{h}_{\lambda\sigma}^{\beta\beta} \end{pmatrix} + \mathbf{D}_{\lambda\sigma}^{ii}\begin{pmatrix} \left(\begin{matrix}\alpha\alpha \\ \mu\nu\end{matrix}\middle|\begin{matrix} ii \\ \sigma\lambda\end{matrix}\right) & 0 \\ 0 & \left(\begin{matrix}\beta\beta \\ \mu\nu\end{matrix}\middle|\begin{matrix} ii \\ \sigma\lambda\end{matrix}\right) \end{pmatrix} \\ & - \begin{pmatrix} \mathbf{P}_{\lambda\sigma}^{\alpha\alpha}\left(\begin{matrix}\alpha\alpha \\ \mu\lambda\end{matrix}\middle|\begin{matrix}\alpha\alpha \\ \sigma\nu\end{matrix}\right) & \mathbf{P}_{\lambda\sigma}^{\alpha\beta}\left(\begin{matrix}\alpha\alpha \\ \mu\lambda\end{matrix}\middle|\begin{matrix}\beta\beta \\ \sigma\nu\end{matrix}\right) \\ \mathbf{P}_{\lambda\sigma}^{\beta\alpha}\left(\begin{matrix}\beta\beta \\ \mu\lambda\end{matrix}\middle|\begin{matrix}\alpha\alpha \\ \sigma\nu\end{matrix}\right) & \mathbf{P}_{\lambda\sigma}^{\beta\beta}\left(\begin{matrix}\beta\beta \\ \mu\lambda\end{matrix}\middle|\begin{matrix}\alpha\alpha \\ \sigma\nu\end{matrix}\right) \end{pmatrix},\end{aligned} \tag{8}$$

where $\mathbf{h}$ is one-electron operator given by the kinetic term and the potential energy term of electronic field from nucleuses

$$h = -\frac{1}{2}\nabla^2 - \sum_{A}\frac{Z_A}{r_A}. \tag{9}$$

The two-electron integrals is defined as

$$\left(\begin{matrix}\omega_i & \omega_j \\ i & j\end{matrix}\middle|\begin{matrix}\omega_k & \omega_l \\ k & l\end{matrix}\right) = \int d\mathbf{x}_1 d\mathbf{x}_2 \phi_i^{\omega_i *}(\mathbf{x}_1)\phi_j^{\omega_j *}(\mathbf{x}_1)\mathbf{r}_{12}^{-1}\phi_k^{\omega_k}(\mathbf{x}_2)\phi_l^{\omega_l}(\mathbf{x}_2). \tag{10}$$

The Fock matrix of the GSO–DFT method is given by

$$\mathbf{F} = \begin{pmatrix} \mathbf{h}^{\alpha\alpha} & 0 \\ 0 & \mathbf{h}^{\beta\beta} \end{pmatrix} + \begin{pmatrix} \mathbf{V}_{\mathrm{ee}} & 0 \\ 0 & \mathbf{V}_{\mathrm{ee}} \end{pmatrix} + \begin{pmatrix} \mathbf{V}_{\mathrm{XC}}^{\alpha\alpha} & \mathbf{V}_{\mathrm{XC}}^{\alpha\beta} \\ \mathbf{V}_{\mathrm{XC}}^{\beta\alpha} & \mathbf{V}_{\mathrm{XC}}^{\beta\beta} \end{pmatrix}, \tag{11}$$

where $\boldsymbol{V}_{\mathrm{ee}}$ and $\boldsymbol{V}_{\mathrm{XC}}$ are the classical Coulomb term and an exchange correlation potential.

Tilted spins is expressed by spinor

$$|\theta,\phi\rangle = \begin{pmatrix} \cos\frac{\theta}{2}\mathrm{e}^{-\mathrm{i}\frac{\phi}{2}} \\ \sin\frac{\theta}{2}\mathrm{e}^{\mathrm{i}\frac{\phi}{2}} \end{pmatrix}, \tag{12}$$

where θ is a direction angle and ϕ is a oblique angle in the spin space. For example, alpha ($S_z = 1/2$), beta ($S_z = -1/2$), S_x, $-S_x$, S_y, $-S_y$ spins are given by

$$\left\{\begin{matrix} |\alpha\rangle = \frac{1}{2}\begin{pmatrix}1\\0\end{pmatrix} \\ |\beta\rangle = \frac{1}{2}\begin{pmatrix}0\\1\end{pmatrix}\end{matrix}\right., \quad \left\{\begin{matrix} |x\rangle = \frac{1}{\sqrt{2}}\begin{pmatrix}1\\1\end{pmatrix} \\ |-x\rangle = \frac{1}{\sqrt{2}}\begin{pmatrix}-\mathrm{i}\\ \mathrm{i}\end{pmatrix}\end{matrix}\right., \quad \left\{\begin{matrix} |y\rangle = \frac{1}{2}\begin{pmatrix}1-\mathrm{i}\\ \mathrm{i}+\mathrm{i}\end{pmatrix} \\ |-y\rangle = \frac{1}{2}\begin{pmatrix}1+\mathrm{i}\\ 1-i\end{pmatrix}\end{matrix}\right.. \tag{13}$$

Note that the phase factor of the spin states does not change the expected values

$$|\text{state}\rangle' = e^{i\phi}|\text{state}\rangle. \tag{14}$$

Thus, the spin density matrices for S_x, S_y and S_z are given by

$$P^{Sx} = P^{\alpha\beta} + P^{\beta\alpha}, \tag{15a}$$

$$P^{Sy} = i(P^{\alpha\beta} - P^{\beta\alpha}), \tag{15b}$$

$$P^{S_z} = (P^{\alpha\alpha} - P^{\beta\beta}), \tag{15c}$$

respectively. The expectation value of total squared-magnitude of the spin, S^2, can be written as

$$S^2 = \sum_{I}^{x,y,z}\sum_{i}^{N}\sum_{j}^{N} s_I(i)s_I(j) = S_- \cdot S_+ + S_z + S_z^2. \tag{16}$$

The first term of Eq. (16) simplifies to

$$\begin{aligned} S_- \cdot S_+ &= \sum_{i}^{N}\sum_{j}^{N} s_-(i)s_+(i) \\ &= \sum_{i}^{N} s_-(i)s_+(j) + \sum_{i\neq j}^{N} s_-(i)s_+(j) \\ &= N_\beta + \sum_{i\neq j}^{N} s_-(i)s_+(j). \end{aligned} \tag{17}$$

These terms of Eq. (17) can be written in terms of $P^{\beta\beta}$, **S** and **C** as

$$N_\beta = \sum_{i}^{N}\sum_{j}^{N} P_{ij}^{\beta\beta}\cdot S_{ij}, \tag{18a}$$

$$\sum_{i\neq j}^{N} s_-(i)s_+(j) = \sum_{i\neq j}^{N,N}\left\{\sum_{k,l}(C_{ik}^{\beta *}\cdot C_{il}^{\alpha} S_{k,l})\cdot\sum_{k,l}(C_{jk}^{\beta}\cdot C_{jl}^{\alpha *} S_{k,l})\right\}. \tag{18b}$$

Natural orbitals are evaluated by solving the generalized eigenvalue equation of the charge density matrix:

$$\mathbf{DSf} = \mathbf{nf}, \tag{19}$$

where **f**, **n** and **S** are $K\times K$ matrices for natural orbitals, occupation numbers and orbital overlaps, respectively.

2.2. Spin Hamiltonian of mixed valence states

The broken-symmetry (BS) approach has been a practical first principle method for strongly correlated electron systems such as multinuclear transition metal complexes [1–8,10]. However, one of the problems for the BS method is an incomplete treatment of the nondynamical correlations. In fact, a BS solution is not a pure spin state and the total energy is slightly higher for the spin contamination. For the strongly correlated systems composed of localized spins, the Heisenberg spin Hamiltonian has been applied to the BS states. The spin Hamiltonian is defined by

$$H = -2\sum_{\langle i,j\rangle} J_{ij} S_i \cdot S_j, \tag{20}$$

where J_{ij} is an exchange interaction between the ith spin (S_i) and the jth spin (S_j). The energy levels and the magnetic properties could be evaluated by solving the spin Hamiltonian [1,2]. On the other hand for delocalized systems, the adequate model Hamiltonian is the Heisenberg exchange term and the double exchange term, like t–J model as

$$H = -2\sum_{\langle i,j\rangle} J_{ij} S_i \cdot S_j + b_{ij}\cos\frac{\theta_{ij}}{2}, \tag{21}$$

where b_{ij} and θ_{ij} is a transfer integral and an angle between vector spin S_i and S_j, respectively [4,5]. The second term of Eq. (21) is for the electron delocalization between spin centers. The electron delocalization occurs with a $\theta/2$ rotation for the spinor nature of the spin. For two spin sites systems, the energy levels are given by

$$E = -JS(S+1) \pm \sqrt{\frac{\Delta^2}{4} + B^2\left(S+\frac{1}{2}\right)^2}, \tag{22}$$

where B, Δ and S are resonance parameter, potential energy difference between spin sites and total spin state, respectively. The B is given in terms of b and S as

$$B = \frac{b}{2S+1}. \tag{23}$$

The tilt angle θ depends on the total spin state S as

$$\cos\frac{\theta}{2} = \frac{S+1/2}{S_{\max}+1/2}, \tag{24}$$

where $S_{\max}$ is a total spin at the ferromagnetic coupling state ($\theta = 0$).

On the approximation of neglecting the overlaps (T) between spin orbitals, expected S^2 values at the TV state and MV state are given by

$$S_{\text{TV}}^2 = \frac{5}{4}\cos^2(\theta) + 10\cos(\theta) + \frac{27}{2}, \tag{25a}$$

$$S_{\text{MV}}^2 = \frac{9}{8}(\cos^2(\theta) + 9\cos(\theta) + 12), \tag{25b}$$

respectively. At the ferromagnetic state ($\theta = 0$), both Eqs. (25a) and (25b) give $S^2 = 99/4$ values. At the antiferromagnetic state ($\theta = 180°$), these are $S_{\text{TV}}^2 = 4.75$ and $S_{\text{MV}}^2 = 4.5$. The S_{TV}^2 is slightly larger than S_{MV}^2 as θ increase, though the difference between S_{TV}^2 and S_{MV}^2 is very small. The spin orbital overlap (T) effect has greater influence on the S^2 value than these charge state differences. S^2 value decreases as the T value increases.

3. Computational procedures

GSO and unrestricted calculations were carried out by employing the GSO-X program package, which is developed by Yamanaka et al. [11–13]. The B3LYP exchange-correlation functional was used and a Huzinaga's MINI basis set [14] and STO-3G basis sets were used for iron and other atoms, respectively. These basis sets were

single-ζ quality (SZ). A pruned (75, 305) integral grid, having 75 radial shells and 305 angular points per shell was used. The total SCF energy was converged to a threshold of 10^{-6} a.u. For a geometry optimization, unrestricted method was carried out using the Gaussina98 program package [15]. The BLYP functional with a Huzinaga's MIDI basis set and 6-31G* basis sets was employed for the optimization calculation. These basis sets were valence double-ζ quality (VDZ).

4. Calculated results

Two theoretical models for a ferredoxin-type [2Fe–2S] cluster are examined (Fig. 1). One is a symmetrical [2Fe–2S] model (**1a**) whose geometrical parameters were taken based on native ferredoxin-type clusters. The potential energy difference of **1a** is zero ($\Delta = 0$) for the symmetrical core. The other model (**1b**) is an optimized structure performed by the BS-BLYP/VDZ method. The geometrical core structure of **1b** is asymmetrical by the electron localization of the BS state. The structural parameters are summarized in Table 1. It is clear that the asymmetrical distortion of **1b** is very small.

Using these models (**1a** and **1b**), three spin states are investigated. They are ferromagnetic spin state (F), antiferromagnetic spin state (AF) and generalized spin state (G). These spin states are shown in Fig. 2. The initial θ values of G states was 170°. The F and AF spin states are in the collinear spin states. The S_z values of F and AF are $S_F = 9/2$ and $S_{AF} = 1/2$, respectively. Calculated total energies and S^2 results are summarized in Table 2. By the structure optimization, all the spin states of **1b** are stabilized in energies by about 0.021 hartree (13 kcal mol^{-1}) in comparison with **1a**. The energy gaps between F and AF spin states (ΔE_{F-AF}) are in the 10^{-3} hartree orders and **1b** has larger ΔE_{F-AF} value than **1a**. It is because the electron delocalization at the F state is more stabilized for **1a**. The energy gaps between G and AF states were almost zero for **1a** and **1b**. Thus the energy stabilization by an odd electron delocalization is little at the ground state. It is shown that the energy stabilization of exchange interactions is stronger than that of the electron delocalization mechanism in the [2Fe–2S] cluster.

The S^2 values at the F state are close to the ideal $S^2 = 24.75$. For the AF states, the S^2 values are smaller than the $S^2_{TV} = 4.75$ values. The S^2 values at G states are larger than those of AF states for the tilted spin structures. $S^2_{MV} = 6.48$ and $S^2_{TV} = 4.77$ values are expected by Eq. (25) for **1a** and **1b** using calculated angle $\theta = 139.2°$ and $\theta = 176.2°$, respectively. The calculated S^2 values for **1a** and **1b** are 6.01 and 4.505. The decrease of the calculated S^2 values are ascribed for the T effects as discussed in later.

The charge and spin density distributions of **1a** and **1b** are summarized in Table 3. The F and G state of **1a** show the MV state, where the charge and spin densities are

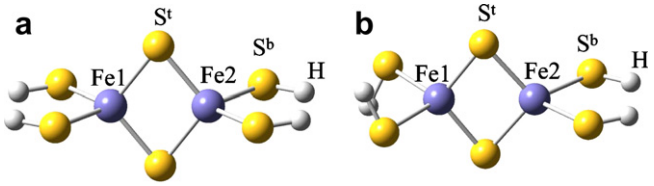

Fig. 1. Molecular structure of the [2Fe–2S] cluster ($Fe_2S_2(SH)_4^{3-}$) used in this study. Compound **1a** is a theoretical model with a symmetrical [2Fe–2S] core. Compound **1b** is an optimized structure obtained by the BS-BLYP/VDZ method. The core is slightly asymmetrical.

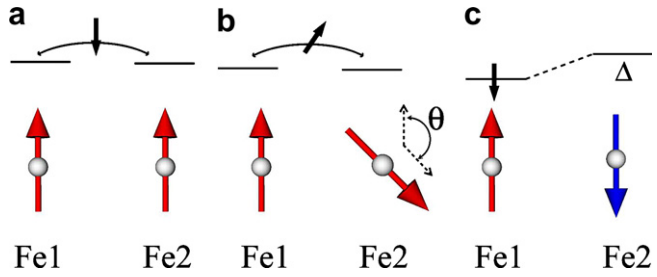

Fig. 2. Schematic representations of the electron delocalizations and the spin states. (a) At the ferromagnetic (F) spin state, the odd electron delocalizes over spin centers. (b) At the generalized (G) spin state, the odd electron delocalizes over spin centers with rotation. (c) At the antiferromagnetic (AF) spin state with potential energy difference such as the asymmetrical core structures or asymmetrical ligand termination, the odd electron is localized at one spin center.

Table 1
Structural parameters[a] of $Fe_2S_2(SH)_4^{3-}$ molecules (**1a** and **1b**)

Molecule	Distance (Å)					Angle (°)
	Fe–S^b	Fe–S^t	Fe···Fe	S^b···S^b	S^t···S^t	Fe–S^b–Fe
1a[b]	2.26	2.38	2.77	2.56	3.72	75.66
1b[c]	2.26	2.52	2.86	3.60	3.93	76.93
	(2.34)	(2.50)			(3.74)	

[a] b, bridging; t, terminal.
[b] Parameters are taken from the ferredoxin-type [2Fe–2S] cluster [4,5]. The [2Fe–2S] core is symmetrical.
[c] An optimized structure calculated by the BS-BLYP/VDZ method. In parentheses, parameters of the Fe(II) center, Fe2, are given. The [2Fe–2S] core is asymmetrical.

Table 2
Calculated total energy (E), energy difference (ΔE)[a] and S^2 values at the F, AF, G spin states[a] of the $Fe_2S_2(SH)_4^{3-}$ molecules (**1a** and **1b**) by the GB3LYP/SZ method

Molecule	Spin state	Total energy (a.u.)	ΔE (cm^{-1})	S^2
1a	F	−4890.2691636	1.01×10^3	24.751
	AF	−4890.2737439	0	4.46
	G	−4890.2737267	4.	6.01
1b	F	−4890.2913205	2.55×10^3	24.751
	AF	−4890.3029449	0	4.484
	G	−4890.3029289	4.	4.505

[a] ΔE: energy difference from the most stable spin state; F: ferromagnetic spin state ($S_z = 9/2$); AF: antiferromagnetic spin state ($S_z = 1/2$), which is same as a broken-symmetry solution of the spin-unrestricted method; G: generalized spin state with a noncollinear spin structure.

Table 3

	G[a]	0.424	0.369	−0.638	−0.611	176.2
		(1.744)	(1.688)	(0.185)	(0.088)	

[a] Magnitudes of the spins at atomic centers are listed for the G state.

approximately equal at two Fe centers. The AF state of **1a** show a typical electronic structure of a TV state despite the symmetrical core model. At the AF state, the odd electron is mainly localized at the one iron center: Fe2. The atomic spin distribution (S_x, S_y, S_z) of G state are (0.712, 0.0000, 1.5386) and (0.9693, 0.0000, −1.3905) for Fe1 and Fe2 centers, respectively, indicating that the spins are slightly tilt to the S_x direction. The angle θ between the spins is 139.2°. The noncollinear spin structure of the G state is the MV state at the antiferromagnetically coupled spin state. It is noteworthy that the θ is decreased from the initial spin state, indicating that the spins rotated by the double exchange interaction. On the other hand for **1b**, both the AF and G states show the TV state. The atomic spin distributions of the G state are (−0.0807, 0.0000, 1.7420) and (0.1903, 0.0000, −1.6777) for Fe1 and Fe2 centers. The angle θ between the spins is 176.2°. Atomic charges and spin population at the G state show that the electronic structure is very close to those of the AF state ($\theta = 180°$). For the asymmetrical core geometry of **1b**, the double exchange interaction is suppressed and the electron localization is stabilized by the geometrical reorientation. The odd electron mainly localizes at the Fe2 center at the AF state. The F state shows more delocalized structures. Thus the electronic structure of GSO solution is largely influenced by the geometrical asymmetry.

The natural orbitals (NO) can clearly show the magnetic orbital interactions between the antiferromagnetically coupled spin centers. For each coupling pair, bonding and antibonding NOs are obtained in pairs. According to the occupation number of these NOs, they are classified into highest occupied natural orbitals (HONOs) and lowest unoccupied natural orbitals (LUNO). Non-pairing orbital is single occupied natural orbital (SONO). The occupation numbers of the HONO and LUNO pears satisfy the following relations:

$$2 = n(\mathrm{HONO}) + n(\mathrm{LUNO}), \tag{26}$$

where n is the occupation number. In general, using the orbital overlap T between site orbitals and angle θ between spin directions, the n are given by

$$n(\mathrm{HONO}) = \frac{(1+T)\left(1 - T\cos^2\frac{\theta}{2}\right)}{1 - T^2\cos^2\frac{\theta}{2}}, \tag{27a}$$

$$n(\mathrm{LUNO}) = \frac{(1-T)\left(1 + T\cos^2\frac{\theta}{2}\right)}{1 - T^2\cos^2\frac{\theta}{2}}. \tag{27b}$$

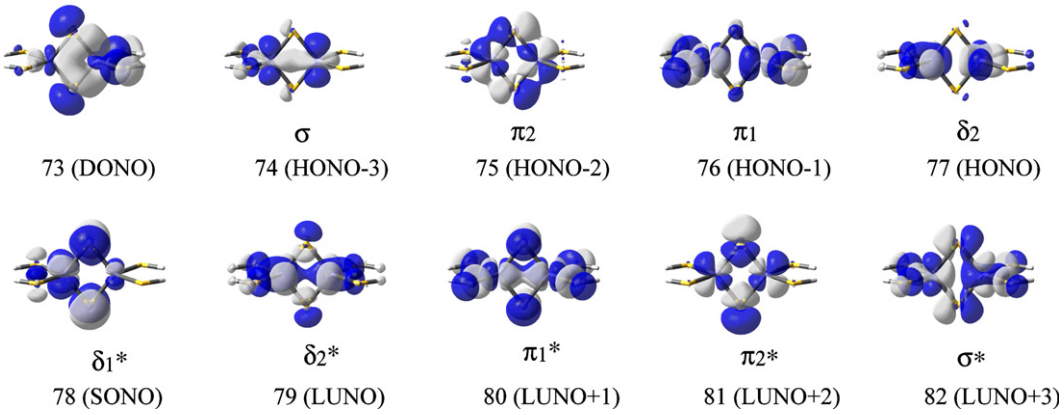

Fig. 3. Natural orbitals of **1a** at the antiferromagnetic spin (AF) state.

Table 4
Calculated occupation numbers of natural orbitals at the AF and G spin states[a] of the $Fe_2S_2(SH)_4^{3-}$ molecules (**1a** and **1b**) by GB3LYP/SZ methods

No.	Molecule and spin state			
	1a AF	**1a** G	**1b** AF	**1b** G
73	1.9997	1.9245	1.9990	1.9947
74	1.3771	1.3374	1.3329	1.3174
75	1.3762	1.3362	1.3069	1.2909
76	1.0900	1.0755	1.2382	1.1937
77	1.0577	1.0633	1.0829	1.0831
78	1.0000	1.0509	1.0000	1.0001
79	0.9423	0.9493	0.9171	0. 9169
80	0. 9100	0.9384	0.7618	0. 8064
81	0. 6238	0.6641	0.6931	0.7092
82	0. 6229	0.6627	0.6671	0.6836

[a] AF: antiferromagnetic spin state ($S_z = 1/2$); G: generalized spin state.

As the θ decreases from 180° to 0°, the difference of the occupation numbers (n(HONO) − n(LUNO)) decrease. The bond order is given by

$$b = \frac{n(\mathrm{HONO}) - n(\mathrm{LUNO})}{2}. \quad (28)$$

It is reasonable that the b value decrease as the θ decreases.

The NOs of **1a** at the AF state are shown in Fig. 3. SONO is an δ_1 type NO(78), which are mainly populated on the Fe1 and bridging sulfur centers. HONOs and LUNOs are pairing with each other for σ, π_1, π_2 and δ_2 type interactions in order of the occupation numbers (Table 4). NO(73) is double occupied natural orbital (DONO). Thus it is clearly shown that the AF state is an δ_1 doped TV state. The NOs of **1a** at the G state are shown in Fig. 4. These NOs are also pairing. The pairing HONO and LUNO can be classified as δ_1, σ, π_1, π_2, δ_2 type interactions in order of occupation numbers. The DONO is an δ_1 type NO(73), which are pairing to the NO(76). It is noteworthy that these NOs are symmetric. Thus it is clear that the G state is δ_1 doped MV state. By Eq. (27a), the occupation number (n) at the G state can be estimated from those at AF state. The n(HONO) values for π_1, σ, δ_1 and π_2 type HONOs are 1.3371, 1.3363, 1.0791 and 1.0507, respectively. These values are close to those of the SCF results. The AF and G states are both δ_1 doped states and the spin orbitals have σ, π_1, π_2 and δ_2 type interactions in the same order. The NOs at AF state of **1b** are shown in Fig. 5. These NOs are very similar to those of G state (not shown). The SONO is an δ_1 type NO(78), which is localized at the Fe1 side. HONOs and LUNOs are π_1, σ, π_2 and δ_2 in order of the orbital interactions. The n(HONO) values at AF state are larger than those of G state. The estimated n(HONO) values for G state from the n(HONO) values at AF state by Eq. (27a) are 1.3326, 1.3066, 1.2380 and 1.0828, respectively. These n(HONO) values become slightly smaller than those of AF state, because the angle θ of the G state is near to 180°. The SCF calculated

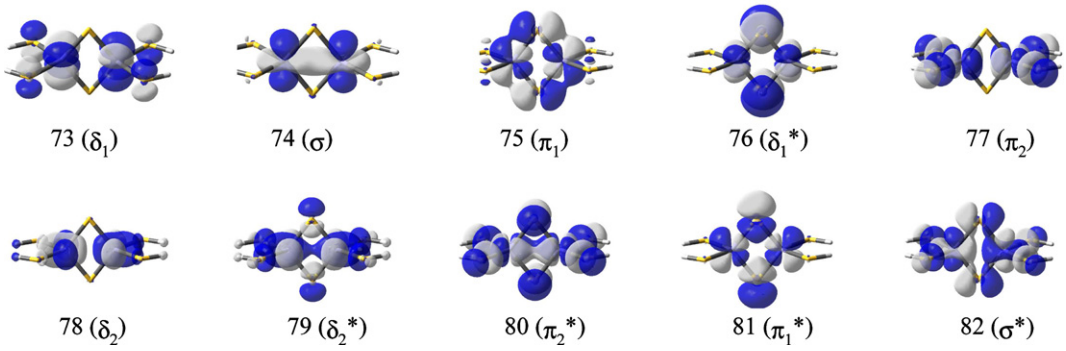

Fig. 4. Natural orbitals of **1a** at the generalized spin (G) state.

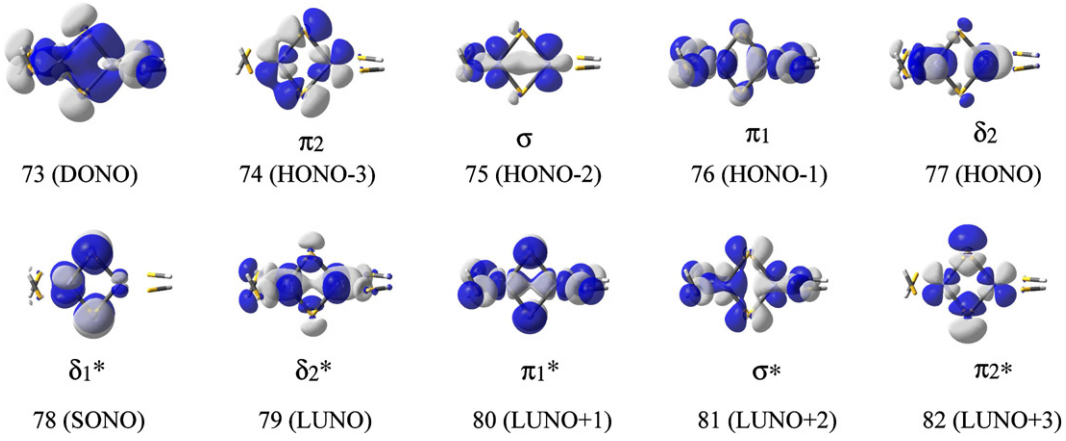

Fig. 5. Natural orbitals (NOs) of **1b** at the antiferromagnetic spin (AF) state. These NOs are indistinguishable from those of the generalized spin (G) state.

n(HONO) values at the G state are smaller than those of the estimated *n*(HONO) values, indicating that the electronic structure is slightly changed during the spin rotations. It is shown that the AF and G states are both in the δ_1 doped states.

5. Conclusion

Using the generalized spin orbital (GSO) approach, the electronic and spin structure of the reduced form of the [2Fe–2S] clusters were examined. Ferromagnetic (F), antiferromagnetic (AF), and generalized (G) spin states were calculated for the symmetrical and asymmetrical [2Fe–2S] core models (**1a** and **1b**). It was found that the delocalization of the odd electron highly depends on the core structure. For **1a**, the G state was in the mixed valence (MV) state. For **1b**, the G state was in the trapped valence (TV) state. On the other hand for the AF state, TV states are only evaluated for both **1a** and **1b**. The MV state of the **1a**-G state had a tilted spin structure for the double exchange interaction and the TV state of the 1b-G state was very close to the electronic structure of the AF state. Natural orbitals (NOs) clearly showed the electronic structures. Magnetic orbital interactions are discussed from the NOs and the occupation numbers. It was found that the energy differences between the G and AF states are very small. However, it is shown the GSO approach can describe more flexible spin and charge states.

NMR spectrum over the wide temperature region revealed the microscopic picture of this conversion between the low-spin and high-spin states. The result indicated a rapid electron exchange between SQ and Cat in the low-spin state. We measured dielectric constant in the cryogenic temperature region to characterize a fluctuation of molecular dipole moment due to an electron exchange between SQ and Cat.

2. Experiment

[Co(3,5-di-*t*-butyl-1,2-benzoquinone)$_2$(2,2′-bipyridine)] (**1**) was prepared from a tetramer [Co^{II}(3,5-di-*t*-butyl-1,2-benzoquinone)$_2$]$_4$ according to the procedure reported previously [2,7]. The specimen was once heated up to 390 K to remove crystal solvent molecules and to obtain the stable crystalline phase. Valence tautomerism did not occur for the virgin sample recrystallized from toluene solution but occurred in the stable crystalline phase [7].

[Co(3,6-di-*t*-butyl-1,2-benzoquinone)$_2$(2,2′-bipyridine)] (**2**) was prepared according to a similar method for manganese complex [8]. Three reactants, i.e. 3,6-di-*t*-butyl-1,2-benzoquinone, $Co_2(CO)_8$, and 2,2′-bipyridine, were treated in toluene for 5 h under Argon atmosphere. Evaporation of the solvent gave black powder. Powder X-ray diffraction confirmed the reported structure of **2**. Since fractional coordinates in the crystal of this compound are not reported in Ref. [9], we used the fractional coordinate of isomorphic crystal of manganese complex to estimate the powder X-ray diffraction pattern [8,9]. 3,6-Di-*t*-butyl-1,2-catechol was prepared by a reaction of catechol and isobutene under Ti/Cat catalyst in an autoclave at 140 °C. This catechol was oxidized with Ag_2O to obtain 3,6-di-*t*-butyl-1,2-benzoquinone.

Sample **1** was characterized by thermogravimetry combined with differential thermal analysis (TG–DTA) with TG/DTA 220 U (Seiko Epson) under argon gas flow to confirm the stable phase [7]. Direct current magnetic susceptibility was measured at an external magnetic field of 1 T with SQUID magnetometer (Quantum Design MPMS 5). The solid-state high-resolution ^{13}C NMR spectra were measured for polycrystalline sample at a magic angle spinning (MAS) speed of ca. 9 kHz and at a resonance frequency of 75.4 MHz, with a Bruker DSX300 spectrometer. Polycrystalline sample was packed into a center of a zirconia rotor of 4 mm diameter within a length of ca. 5 mm to minimize the temperature gradient of the sample. The thermometer of the MAS NMR probe was carefully calibrated [10,11]. The shifts of ^{13}C NMR spectra were measured from an external second reference of hexamethylbenzene (CH_3: 17.17 ppm). Dielectric constant was measured for a disk of compressed powder crystals by four terminals method with HP-4824A Precision LCR Meter between 10 and 295 K in a frequency region between 1 and 100 kHz. The size of the disk was 10 mm diameter and 0.3 mm thickness. Temperature was kept constant for each measurement.

3. Results and discussion

Thermal hysteresis of magnetic susceptibility of **1** is shown in Fig. 1. After the virgin sample was cooled down to 6 K, three runs of the measurements were continued. In the first run (step 1 in Fig. 1), the magnetic susceptibility was measured on heating up to 390 K. Then, two successive measurements were continued on cooling down to 6 K (step 2) and on heating up to 390 K (step 3). The first run (step 1) for the virgin sample indicated a sharp increase of χT value around 360 K due to a phase change from the meta-stable to the stable phase. After the phase change occurred, a reversible temperature dependence of the χT value was observed in the steps 2 and 3. This result shows the valence tautomeric interconversion between low-spin-[Co^{III}(SQ)(Cat)(bpy)] and high-spin-[Co^{II}(SQ)$_2$(bpy)] in the stable phase [7]. Almost only the low-spin state exists at 186 K both for the meta-stable and stable phases. It can be determined by ^{13}C NMR spectrum whether an electron exchange occurs or not between SQ and Cat in the low-spin state. Solid-state magic angle spinning (MAS) ^{13}C NMR spectra of the meta-stable and stable phases are compared at 186 K in Fig. 2. For meta-stable phase, relatively sharp and temperature independent peak (γ) was observed at 30 ppm. Since this shift is typical for methyl carbon of diamagnetic 3,5-di-*t*-butyl-1,2-benzoquinone [12], the peak γ was assigned to the diamagnetic Cat ligand. Broad peaks (α and β) around 100–150 ppm were assigned to methyl carbons of SQ. Shifts of peaks α and β were temperature dependent due to an electron spin of SQ, while the shift of peak γ

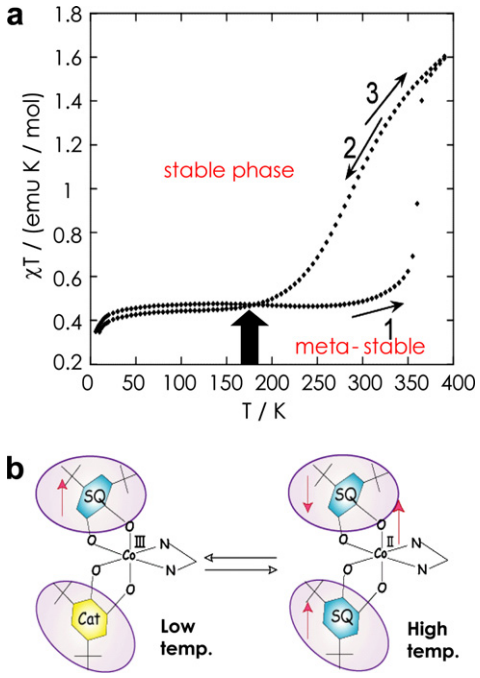

Fig. 1. (a) Magnetic susceptibility of [Co(3,5-di-*t*-butyl-1,2-benzoquinone)$_2$(2,2′-bipyridine)] in the meta-stable and stable phases. Three successive runs for the measurements were continued, step 1: from 6 to 390 K, step 2: from 390 to 6 K, and step 3: from 6 to 390 K. (b) A schematic view of valence tautomerism in the stable phase.

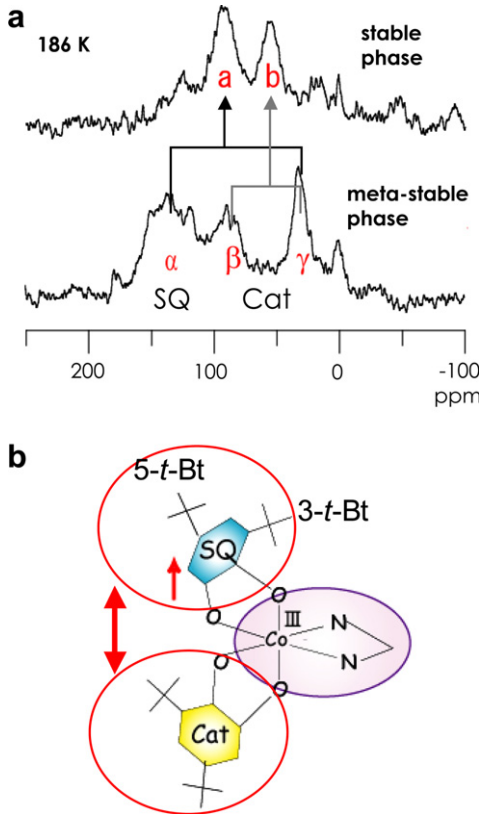

Fig. 2. (a) Magic angle spinning ^{13}C NMR spectrum of methyl carbon of 3 and 5-*t*-butyl groups of [Co(3,5-di-*t*-butyl-1,2-benzoquinone)$_2$(2,2′-bipyridine)] measured at 186 K in the meta-stable and stable phases. (b) A schematic view of rapid averaging between semiquinoate (SQ) and catecholate (Cat) in the low-spin state.

was almost independent of temperature. Since SQ and Cat were distinguished, no electron exchange occurred between SQ and Cat in the meta-stable phase. In contrast to the meta-stable phase, ^{13}C MAS NMR signals of the stable phase were observed near 55 (b) and 95 ppm (a), where the peak at 55 ppm (b) is an average of the two peaks at 30 (Cat, γ) and 90 (SQ, β) ppm in the meta-stable phase and the peak at 95 ppm (a) is an average of the two peaks at 30 (Cat, γ) and 150 (SQ, α) ppm. Both the shifts of 55 and 95 ppm signals were temperature dependent. This result clearly indicates that an exchange of electron spin between SQ and Cat states was directly detected by the NMR spectrum. The exchange rate is much larger than the NMR time scale of ca. $5\times10^4\ s^{-1}$ at 186 K.

Temperature dependence of magnetic susceptibility of **1** and **2** is shown in Fig. 3. For a random equilibrium between the high-spin (HS) and low-spin (LS) states, the observed magnetic susceptibility χ can be expressed by magnetic susceptibility of HS state (χ_{HS}) and LS state (χ_{LS}) as follows,

$$\chi = \chi_{HS}\cdot f_{HS} + \chi_{LS}\cdot f_{LS} = \frac{C_{HS}}{T}\cdot f_{HS} + \frac{C_{LS}}{T}\cdot f_{LS},$$
$$\chi T = 0.125\left(\frac{\mu_{eff}}{\mu_B}\right)^2 = C_{HS}\cdot f_{HS} + C_{LS}\cdot f_{LS}, \quad (1)$$

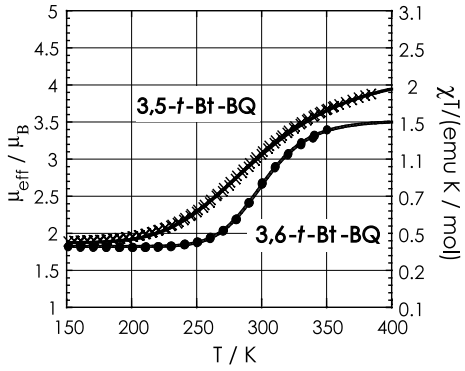

Fig. 3. Effective magnetic moment of [Co(3,5-di-*t*-butyl-1,2-benzoquinone)$_2$(2,2′-bipyridine)] (3,5-*t*-Bt-BQ) and [Co(3,6-di-*t*-butyl-1,2-benzoquinone)$_2$(2,2′-bipyridine)] (3,6-*t*-Bt-BQ) plotted as a function of temperature.

where C_{HS} and C_{LS} are Currie constants for HS state and LS state, respectively, and the fractions of HS state (f_{HS}) and LS state (f_{LS}) can be written by

$$f_{LS} = \frac{\exp\left(-\frac{\Delta S}{R}+\frac{\Delta H}{RT}\right)}{1+\exp\left(-\frac{\Delta S}{R}+\frac{\Delta H}{RT}\right)}, \quad f_{HS} = \frac{1}{1+\exp\left(-\frac{\Delta S}{R}+\frac{\Delta H}{RT}\right)}. \quad (2)$$

The observed χT value of **1** was fitted by Eq. (1) and values of entropy and enthalpy change between HS and LS states were estimated to be $\Delta S = 53\ J\ K^{-1}\ mol^{-1}$ and $\Delta H = 17\ kJ\ mol^{-1}$ [7]. The same procedure gave very large thermodynamic parameters of $\Delta S = 145\ J\ K^{-1}\ mol^{-1}$ and $\Delta H = 44\ kJ\ mol^{-1}$ for **2**. These values are very different from the reported values of $\Delta S_{trs} = 48\ J\ K^{-1}\ mol^{-1}$ and $\Delta H_{trs} = 15\ kJ\ mol^{-1}$, which were estimated from an excess heat capacity of this compound [13]. This result indicates that Eq. (1) for random equilibrium of non-interacting molecules cannot be applied to the crystalline phase of **2**. Then we assumed domain or cluster formation due to a cooperative effect for the isomer conversion of **2** in the crystalline phase. Sorai et al. proposed a domain model for spin crossover transition [14–16]. One domain contains n molecules and they changes spin state cooperatively. In this model, fraction of the high-spin state can be described by,

$$f_{HS} = \frac{1}{1+\exp[n\Delta H_{trs}/R\cdot(1/T-1/T_{1/2})]}, \quad (3)$$

where $T_{1/2}$ is the center of the temperature region of transition. When the number n becomes infinite, transition is the first order phase transition with a definite transition temperature. The number n of molecules in a domain was estimated to be 3.6 from reported excess heat capacity [13]. Three or four molecules change their spin state cooperatively in average. In a framework of this domain model, thermodynamic parameters of $\Delta S_{trs} = 40\ J\ K^{-1}\ mol^{-1}$ and $\Delta H_{trs} = 12\ kJ\ mol^{-1}$ were estimated from the temperature dependence of χT value shown in Fig. 3. These values are almost consistent with those estimated from the excess heat capacity, $\Delta S_{trs} = 48\ J\ K^{-1}\ mol^{-1}$ and $\Delta H_{trs} = 15\ kJ\ mol^{-1}$

[13]. Magnitude of the spin was estimated to be $S = 3/2$ from the high temperature limiting value of the effective moment both for **1** and **2**. Assuming an isotropic g tensor ($g = 2$), effective moment (μ_{eff}/μ_B) is 1.7, 3.9 and 5.9 for $S = 1/2$, 3/2 and 5/2, respectively. Therefore a strong antiferromagnetic coupling exists in the high temperature region. Entropy difference estimated from the change of spin multiplicity is 11.5 J K^{-1} mol^{-1}, which is much smaller than the observed value. The large entropy change may be ascribed to a change of vibrational density of state, since metal ligand coordination bond length of high-spin Co(II) form is longer than that of low-pin Co(III) form by ca. 0.02 nm in general, and vibrational frequencies become lower for the high-spin Co(II) form [2,6,17,18].

Since averaging process between SQ and Cat in the low-spin sate may be detected by solid-state high-resolution ^{13}C NMR spectrum, temperature variation of ^{13}C MAS NMR spectrum of **2** was measured. The spectrum at 293 K is shown in Fig. 4. We found two large signals (peaks 1 and 2) and two small signals (peaks 3 and 4). Large signals were assigned to methyl carbons of *t*-butyl groups at 3 and 6 positions, while small signals to the center carbon of the two *t*-butyl groups. SQ and Cat states are averaged by rapid exchange of electron spin. This behavior is similar to the stable phase of **1**. Spectral region of **2** is narrow compared with **1**, since electron spin density is smaller at the substitution position 6 compared with the position 5 for SQ in general [19]. Only the four signals were observed in the temperature region investigated as shown in Fig. 5. This result indicates that the exchange of electron spin between SQ and Cat is rapid even at 200 K. The domain model used for the χT values in Fig. 3 could be also applied for the temperature variation of the sift of NMR signals

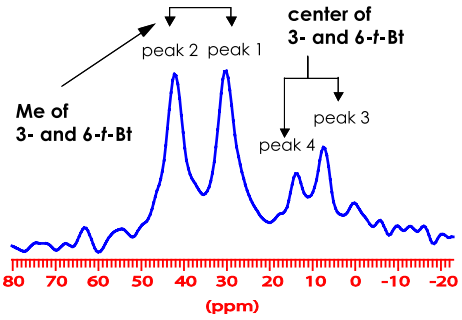

Fig. 4. Magic angle spinning ^{13}C NMR spectrum of methyl carbon of 3 and 6-*t*-butyl groups of [Co(3,6-di-*t*-butyl-1,2-benzoquinone)$_2$(2,2′-bipyridine)] measured at 293 K. A group of large peaks 1 and 2 was assigned to the methyl carbons of two *t*-butyl groups, whereas a group of small peaks was assigned to the center carbons of two *t*-butyl groups.

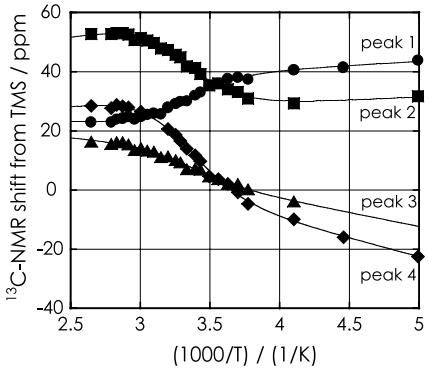

Fig. 5. Temperature variation of shifts of magic angle spinning ^{13}C NMR spectrum of [Co(3,6-di-*t*-butyl-1,2-benzoquinone)$_2$(2,2′-bipyridine)]. Solid curves were obtained by fitting a model equation, in which strong antiferromagnetic interaction between the two semiquinoate ligands in the high-spin state was assumed.

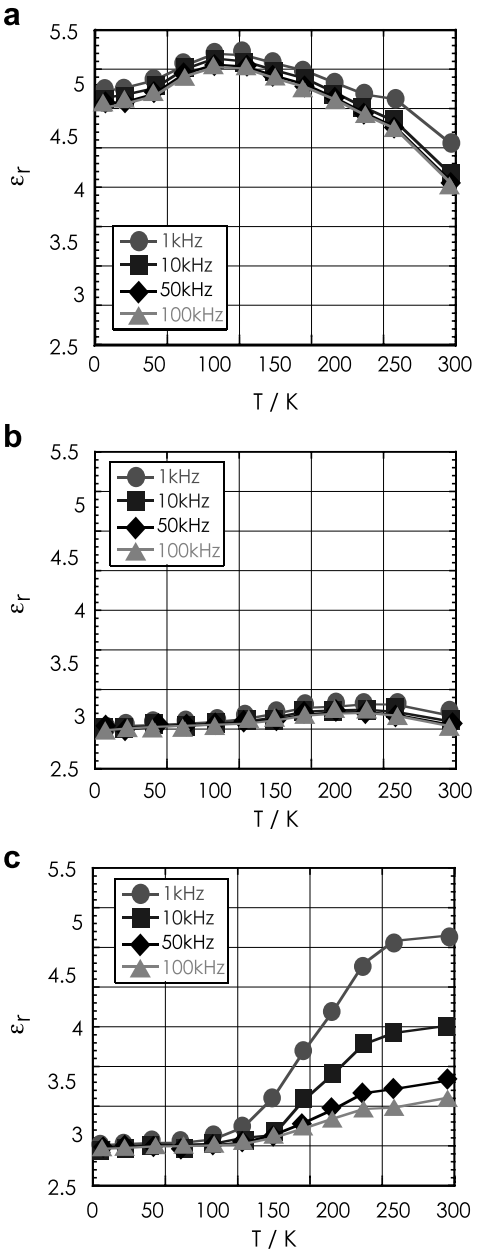

Fig. 6. Temperature and frequency dependence of dielectric constant.(a) [Co(3,6-di-*t*-butyl-1,2-benzoquinone)$_2$(2,2′-bipyridine)], (b) stable phase of [Co(3,5-di-*t*-butyl-1,2-benzoquinone)$_2$(2,2′-bipyridine)], (c) virgin metastable phase of [Co(3,5-di-*t*-butyl-1,2-benzoquinone)$_2$(2,2′-bipyridine)]·$x(C_6H_5CH_3)$.

and almost the same values were obtained for ΔS_{trs} and ΔH_{trs} of transition from low-spin to high-spin state.

It may be obtained from dielectric measurements whether the electron exchange between SQ and Cat freezes or not as the temperature is decreased into cryogenic temperature region, since the electron exchange between SQ and Cat states induces a fluctuation of molecular dipole moment. Observed dependence of dielectric constant on frequency and on temperature is shown in Fig. 6 for **1** and **2**. No significant anomaly was observed both for the stable phase of **1** (Fig. 6b) and **2** (Fig. 6a), both of which exhibited valence tautomerism. The spin and charge exchanges between SQ and Cat are considered to be much faster than 100 kHz at 10 K. Meta-stable phase of **1** showed a remarkable frequency dependence of dielectric constant in the high temperature region as shown in Fig. 6c. However, this anomaly was attributed to molecular motion of toluene in the crystalline lattice.

In conclusion, [Co(3,6-di-*t*-butyl-1,2-benzoquinone)$_2$-(2,2′-bipyridine)] showed a cooperative effect for valence tautomerism in the crystalline phase, whereas the cooperative effect is small in the case of the stable phase of a similar compound [Co(3,5-di-*t*-butyl-1,2-benzoquinone)$_2$(2,2′-bipyridine)]. The origin of the cooperative effect is not clear at present. The spin and charge exchange between SQ and Cat in the low-spin state was clarified by solid-state high-resolution ^{13}C NMR spectrum. This exchange did not freeze above 10 K.

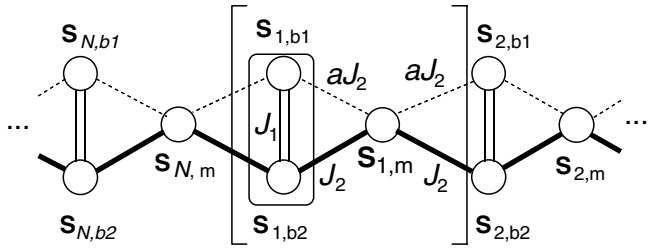

Fig. 1. Schematic view of the Heisenberg spin Hamiltonian (Eq. (1)). The rounded rectangle represents the biradical molecule with two unpaired electron spins ($\mathbf{S}_{i,b1} = 1/2$ and $\mathbf{S}_{i,b2} = 1/2$) interacting with the adjacent monoradicals with $\mathbf{S}_{i,m} = 1/2$. The intramolecular exchange interaction in the biradical is defined as J_1. The solid and dashed lines denote the intermolecular interactions J_2 and aJ_2 ($0 < a < 1$), respectively.

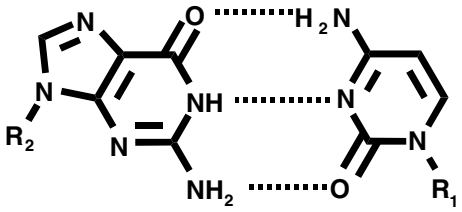
A problem in constructing molecule-based heterospin systems such as generalized ferrimagnetics is co-crystallization of two kinds of open-shell molecules. We have proposed several approaches [2] to attain co-crystallization in purely organic heteromolecular systems, one of which employs nucleobases (nucleic acid bases) such as guanine, cytosine, adenine, and thymine [2b]. Multiple-point hydrogen bonds feature in the nucleobases, which are superior to conventional hydrogen-bonding compounds such as phenols, carboxylic acids, and pyridines with respect to selectivity and directionality of hydrogen bonding as found in a DNA duplex. Hydrogen-bonded pairs of nucleobases substituted with open-shell groups can be a building block for bio-inspired heterospin assembly, as shown in Scheme 1.



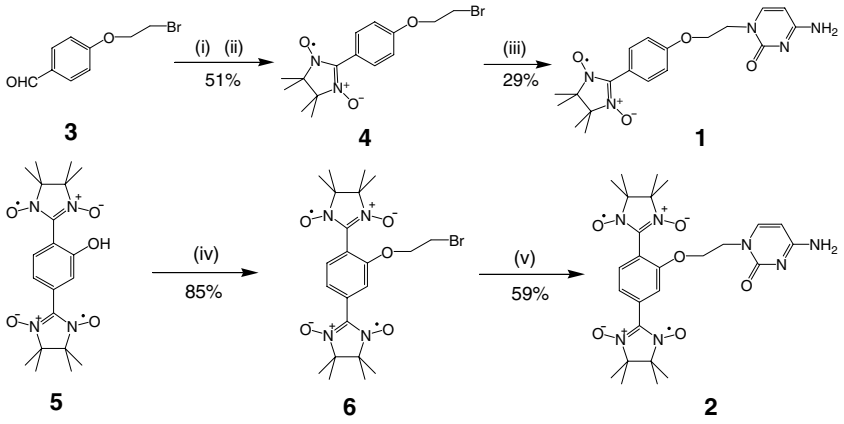
In this communication, we report on syntheses of building block molecules for generalized ferrimagnets based on the nucleobase pairing approach. Syntheses, crystal structures, and magnetic properties are described for a cytosine-substituted nitronyl nitroxide monoradical **1** and a biradical **2** in a singlet ($S = 0$) ground state. The radicals **1** and **2** are expected to form a hydrogen-bonded pair with guanine-substituted radicals,[1] leading to a heterospin, heteromolecular system consisting of the ground-state singlet biradicals and monoradicals.

2. Experimental

2.1. Synthesis

The synthetic routes for the monoradical **1** and the biradical **2** are shown in Scheme 2.

*Monoradical **1***. A suspension of 4-(2-bromoethoxy)-benzaldehyde **3** [3] (480 mg, 2.10 mmol) and 2,3-dimethyl-2,3-dihydroxylaminobutane (313 mg, 2.11 mmol) in dry benzene (30 ml) was refluxed under Ar atmosphere for 21.5 h to give a colorless powder of an adduct. The precipitate was filtered and washed with benzene, and then dried. An aqueous solution of $NaIO_4$ (278 mg, 1.30 mmol) was added to a suspension of the adduct (467 mg, 1.30 mmol) in a mixed solution of CH_2Cl_2 (30 mL) and H_2O (10 mL). The reaction mixture was stirred for 40 min to give a blue solution. The aqueous phase was extracted with CH_2Cl_2. The combined organic phase was dried over $MgSO_4$. The solvent was evaporated under reduced pressure, and the residue was chromatographed on silica gel. The elution with CH_2Cl_2/acetone (6: 1) gave **4** as a blue solid (380 mg, 1.06 mmol, 50.5%). A mixture of **4** (381 mg, 1.31 mmol), cytosine (217 mg, 1.96 mmol), K_2CO_3 (271 mg 1.96 mmol) and KI (325 mg, 1.96 mmol) in dry MeCN (50 ml) was stirred for 43 h at 90 °C. After the precipitate was filtered, the solvent was evaporated under reduced pressure, and then the residue was purified on silica gel. The elution with CH_2Cl_2/MeOH (9: 1) gave **1** as a blue solid (147 mg, 0.381 mmol, 29.1%). Elemental *Anal.* Calc. for $C_{19}H_{24}N_5O_4$: C, 59.06; H, 6.26; N, 18.12. Found: C, 58.79; H, 6.28; N, 17.85%. ESI-MS *m*/*z* 385.4 (M^-).



Scheme 1. Hydrogen-bonded Watson–Crick pair of nucleobases substituted with radical groups R_1 and R_2.

*Biradical **2***. Phenolic biradical **5** was prepared according to the procedure reported previously [4]. A mixture of 5 (207 mg, 0.511 mmol) and K_2CO_3 (271 mg 0.759 mmol) in dry DMF (8 ml) was stirred for 35 min at 60 °C. To the mixture was added 1,2-dibromoethane. After the mixture was stirred for 6.5 h at 60 °C, the precipitate was filtered. To the filtrate were added CH_2Cl_2 and a small amount of hexane, and the solution was washed with brine. The solvent was evaporated under reduced pressure, and the residue was purified on silica gel. The elution with CH_2Cl_2/acetone (4:1) gave **6** as a purple solid (240 mg, 0.468 mmol, 91.6%). A mixture of **6** (1.44 g, 2.80 mmol), cytosine (477 mg, 4.31 mmol) and *t*-BuOK (491 mg 4.38 mmol) in dry DMF (56 ml) was stirred for 24 h at 55 °C. After the precipitate was filtered, the solvent was evaporated under reduced pressure, and the residue was purified on silica gel. The elution with CH_2Cl_2/MeOH (10:1) and CH_2Cl_2/MeOH (7:1) gave **2** as a purple solid (891 mg, 1.65 mmol, 58.7%). Elemental *Anal.* Calc. for $C_{26}H_{35}N_7O_6CH_3OH$: C, 55.71; H, 6.85; N, 16.24. Found: C, 55.61; H, 6.47; N, 16.86%. *m*/*z* (FAB^+) (NBA): 542.3 $[M+H]^+$.

2.2. Crystal structure analysis

The X-ray diffraction measurements of **1** were made on a Rigaku Mercury CCD diffractometer at 193 K with graphite monochromated Mo Kα radiation up to $2\theta_{max} = 55°$. The crystal structure was solved by direct methods (SIR92) [5] and succeeding Fourier syntheses fol-

[1] A guanine-substituted nitronyl nitroxide radical has been synthesized as a counterpart of **1** and **2**. Full characterization of the radical is under way and will be reported in a separate paper.

Scheme 2. Synthesis of cytosine-substituted nitronyl nitroxide monoradical **1** and biradical **2**: (i) 2,3-bis(hydroxyamino)-2,3-dimethylbutane, benzene; (ii) $NaIO_4$, CH_2Cl_2, H_2O; (iii) cytosine, K_2CO_3, KI, MeCN. (iv) 1,2-dibromo-ethane, K_2CO_3, DMF; (v) cytosine, *t*-BuOK, DMF.

lowed by the full-matrix least-squares refinement with the anisotropic approximation for non-hydrogen atoms. Positions of the hydrogen atoms were calculated and included in the final refinement. All the calculations were made using a program package CRYSTALSTRUCTURE by Rigaku/Molecular Structure Corporation [6].

2.3. Magnetic susceptibility measurements

The magnetic susceptibilities of **1** and **2** were measured for randomly oriented polycrystalline samples on a Quantum Design SQUID magnetometer MPMS-XL with an applied magnetic field of 0.1 T in the temperature range of 1.9–298 K.

3. Results and discussion

3.1. Crystal structure

The crystallographic data for **1** are listed in Table 1. Neighboring cytosine moieties in **1** related by an inversion center form two-fold hydrogen bonds of N5H–N4 = 3.013(3) Å, as shown in Fig. 2a. The hydrogen bond length is close to that in pristine cytosine [7] and an analogous cytosine derivative [2b].

Table 1
X-ray crystallographic data for **1**

Formula	$C_{19}H_{24}N_5O_4$
Crystal system	triclinic
Space group	$P\bar{1}$
a (Å)	8.647(3)
b (Å)	9.378(3)
c (Å)	13.052(4)
α (°)	106.748(6)
β (°)	92.677(5)
γ (°)	105.587(6)
V (Å^3)	967.2(5)
Z	2
D_{calc} (g cm^{-3})	1.327
T (K)	193
Unique reflections used ($I > 3\sigma(I)$)	2907
R_1[a], R_w[b]	0.056, 0.134
Goodness-of-fit	1.108

[a] $R = \sum||F_o| - |F_c||/\sum|F_o|$.
[b] $R_w = (\sum w(|F_o| - |F_c|)^2/\sum wF_o^2)^{1/2}$, $w = 1/[0.0010F_o^2 + 3\sigma(F_o^2) + 0.5000]/(4F_o^2)$.

Between the nitronyl nitroxide moieties are found two kinds of short contacts close to sum of van der Waals radii [8]. One is found between the carbon atom C10 on the phenyl ring and the nitroxide oxygen atom O2 with the length of C10–O2 = 3.438(3) Å. The other contact is between C12 and O1 (3.544(3) Å). These contacts lead to a ladder structure of $S = 1/2$ spins, as schematically shown in Figs. 2b and c.

3.2. Magnetic susceptibility

3.2.1. Monoradical *1*

The temperature dependence of paramagnetic susceptibility χ_p for a randomly oriented polycrystalline sample of **1** is shown in Fig. 3a in the χ_pT versus T plots. The χ_pT value of 0.37 emu K mol^{-1} at room temperature corresponds to 1 mol of $S = 1/2$ spins. The χ_pT value decreases as the temperature is lowered, indicating that antiferromagnetic interactions are dominating in the crystalline solid state.

The temperature dependence of χ_pT was analyzed using the two-leg ladder model in Fig. 2c

$$H = \sum_{i=1}^{N}[-2J_1\mathbf{S}_{i,1}\cdot\mathbf{S}_{i,2} - 2J_2(\mathbf{S}_{i,1}\cdot\mathbf{S}_{i+1,1} + \mathbf{S}_{i,2}\cdot S_{i+1,2})], \qquad (2)$$

where $\mathbf{S}_{i,1}$ and $\mathbf{S}_{i,2}$ denote the spin-1/2 operators in the *i*th unit cell and N is the number of unit cells. The Hamiltonian was numerically diagonalized to give an eigenenergy E_j, and an eigenvalue S_j for the *j*th eigenstate, from which the temperature dependence of χ_pT was calculated as

$$\chi_p = \frac{1}{2N}\cdot\frac{N_A g^2\mu_B^2}{3k_BT}\cdot\frac{\sum_j\left[S_j(S_j+1)(2S_j+1)\exp\left(-\frac{E_j}{k_BT}\right)\right]}{\sum_j\left[(2S_j+1)\exp\left(-\frac{E_j}{k_BT}\right)\right]}. \qquad (3)$$

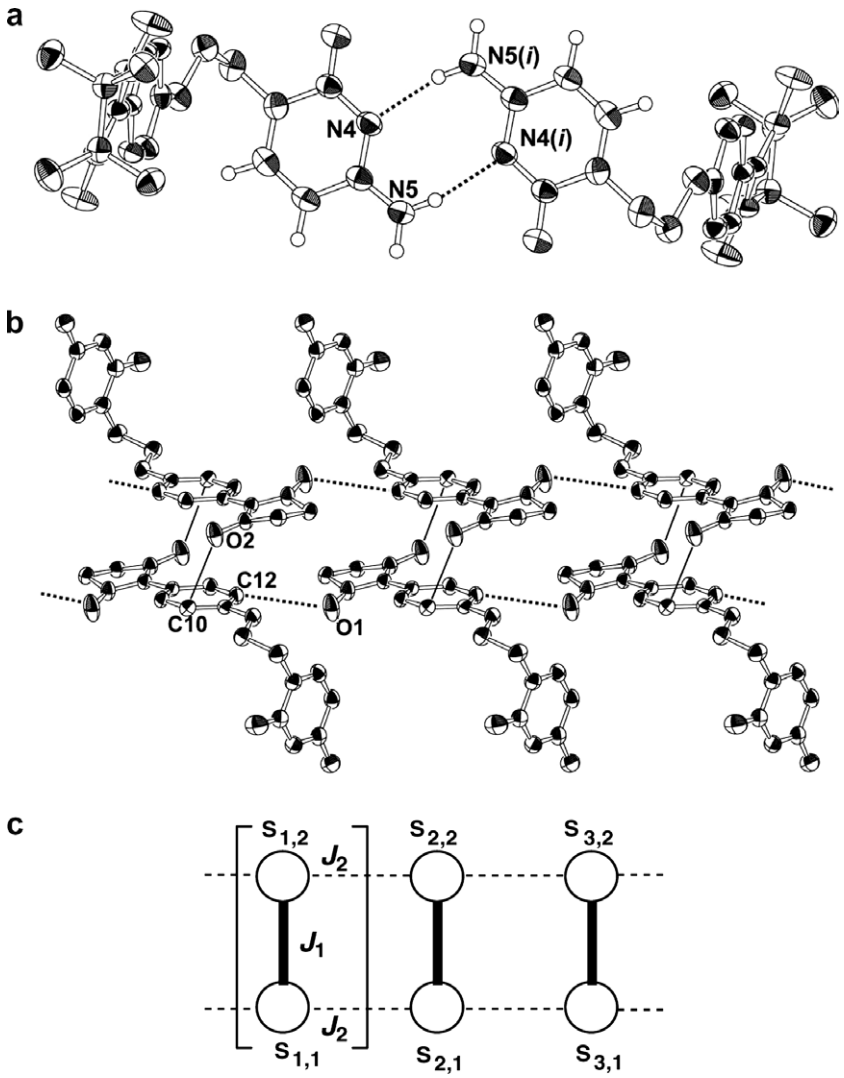


Fig. 2. (a) Hydrogen-bonded pair of **1**. (b) Molecular chain of **1** along the *a*-axis. Two kinds of short contacts are depicted by the dotted and solid lines. (c) Schematic view of the exchange pathway in the molecular chain. The exchange couplings J_1 and J_2 are attributed to the contact C10–O2 and C12–O1 in (b), respectively. The bracket represents the repeating unit of the chain.

The symbols N_A, g, μ_B and k_B stand for Avogadro constant, the g-factor, Bohr magneton and Boltzmann constant, respectively. In the calculations of Eqs. (2) and (3), periodic boundary condition is imposed for $N = 6$ repeating units with twelve $S = 1/2$ spins.[2] The model, however, provided unsatisfactory fit to the observed temperature dependence of $\chi_p T$. The poor fitting implies the presence of weak exchange interactions between the ladder chains. A dimer model with the singlet–triplet energy gap of $2J_1$ plus an interdimer mean field failed to improve the fitting as well.

To obtain an estimate for the intermolecular exchange interactions for **1**, the temperature dependence of $\chi_p T$ was fitted to the Curie–Weiss law

$$\chi = \frac{C}{(T-\theta)}. \tag{4}$$

Optimized parameters of $C = 0.37$ emu K mol^{-1} and $\theta = -1.4$ K were obtained from the fitting in which the larger weight was applied for the observed χ_p value at the higher temperature, as depicted in the inset of Fig. 3a. The Curie constant of $C = 0.37$ emu K mol^{-1} indicates a satisfactory purity of 100%, which is consistent with the chemical analysis. The mean field of $\theta = -1.4$ K is an estimate for the average of the interactions J_1, J_2, and possible interchain interactions in the high-temperature approximation.

3.2.2. Biradical **2**

Fig. 3b shows the temperature dependence of paramagnetic susceptibility χ_p measured for randomly oriented polycrystalline sample of **2**. A maximum in χ_p is found at 6.5 K, indicating that antiferromagnetic interactions

[2] For even number N of unit cells, the spin chain of $N = 6$ gives the largest dimension of the spin Hamiltonian, for which we are allowed to diagonalize numerically the Hamiltonian matrix. Hamiltonian matrices for $N > 8$ are too large to diagonalize numerically giving all eigenenergies.

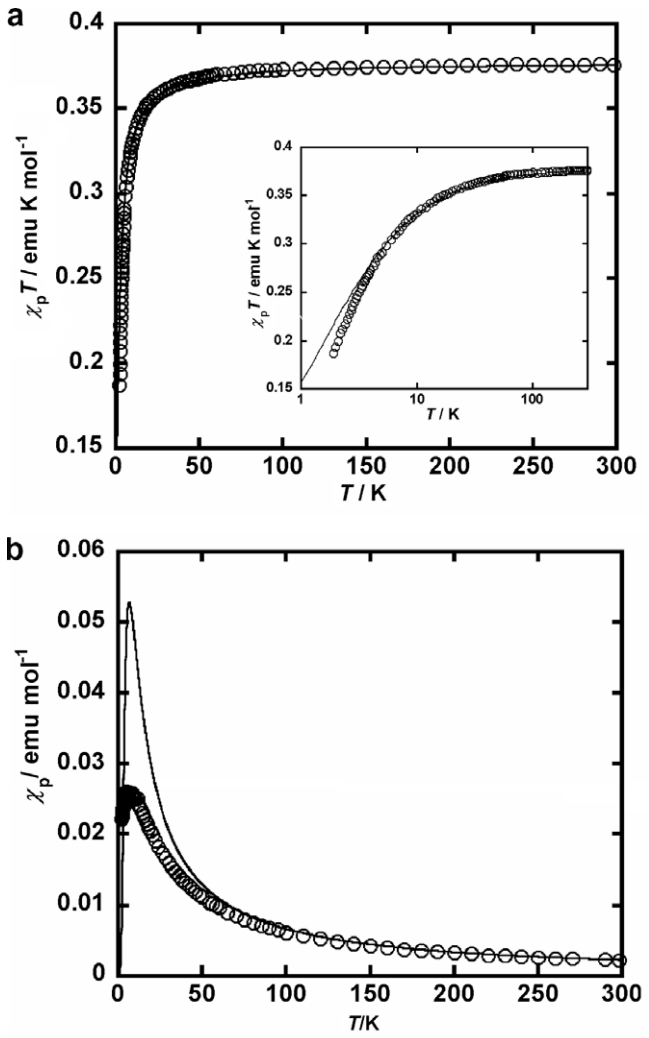

Fig. 3. Temperature dependence of magnetic susceptibility χ_p. (a) The $\chi_p T$ vs. T plots of **1**. The solid line depicts the calculated curve based on the Curie–Weiss law. The inset shows the logarithmic plot. (b) The χ_p vs. T plots of **2**. The solid line depicts the theoretical curve from Eq. (5).

are operative in a dimer, a one-dimensional chain, or other low-dimensional lattices of $S = 1/2$ spins. Singlet ground states with intramolecular antiferromagnetic interactions have been found in *p*-phenylene-based biradicals substituted with nitronyl nitroxide radical groups [4,9,10] having molecular structures similar to that of **2**. Thus, the biradical **2** is likely to have an intramolecular antiferromagnetic exchange interaction. The temperature dependence of χ_p was analyzed by using the singlet–triplet model

$$\chi_p = \frac{N_A g^2 \mu_B^2}{3k_B T} \frac{2}{3 + \exp(-2J/k_B T)}, \quad (5)$$

where J represents the exchange parameter. Numerical differentiation of χ_p in Eq. (5) with respect to T gives the temperature T_{max} where χ_p has a maximum

$$T_{max} = 1.247|J|/k_B \quad (6)$$

as a function of $|J|$. The observed $T_{max} = 6.5$ K gives the exchange parameter of $J/k_B = -5.2$ K. The solid line in Fig. 3 is calculated with the exchange parameter of $J/k_B = -5.2$ K and the purity of 93.9%. The model of Eq. (5) gives χ_p values larger than the observed one around T_{max}. The discrepancy is not attributed to the unsatisfactory purity, i.e., impurities of paramagnetic molecules with only one unpaired electron or diamagnetic molecules considering the χ_p values at higher temperatures. This indicates the presence of additional antiferromagnetic interactions. Introduction of an intermolecular mean field into Eq. (5) did not improve the fitting. It is premature that the coupling constant $J/k_B = -5.2$ K is assigned solely to the intramolecular interaction within the biradical. X-ray single crystal structure analyses are underway to improve the exchange coupling model. The exchange interaction of $J/k_B = -5.2$ K is an estimate for the intramolecular exchange interaction.

4. Conclusion

The cytosine derivatives of nitronyl nitroxide monoradical **1** and biradical **2** have been prepared and isolated as stable crystalline solids under ambient atmosphere. The molecular packing of **1** features in intermolecular hydrogen bonding of the cytosine moiety, giving a spin ladder chain structure based on nitronyl nitroxide radical moieties. For the biradical **2**, the magnetic susceptibility suggests the singlet ground state with an estimated intramolecular antiferromagnetic exchange interaction of $J/k_B \sim -5$ K. These radicals can be components for the Watson–Crick base pairing, leading to hydrogen bonding-based heteromolecular assembly.

building blocks are allowed to self-assemble into a common structural archetype, thus allowing for the systematic tuning of the optical and magnetic properties of the resulting reaction products, and accurate magneto-structural correlations to be described; examples include photomagnetic lattices [10–14], room temperature magnets [3–5], and polynuclear complexes [8] and low-dimensional chains that exhibit slow relaxation of the magnetization [9].

The radial extent and diffuseness of second- and third-row transition metal centers present in $[M^n(CN)_8]^{(n-8)}$ anions (Mo, W) are expected to exhibit enhanced π-backbonding, charge delocalization, and efficient superexchange interactions between metal centers in networks and clusters constructed from M(μ-CN)M′ units [22]. Octacyanometalate anions generally adopt square antiprismatic, bicapped trigonal prismatic, or dodecahedral structures and are capable of forming up to eight cyanide bridges to adjacent metal centers. These factors are expected to afford cyanometalate materials that exhibit markedly different magnetic and optical properties than hexa- and heptacyanometalate derivatives. Octacyanometalates are also attractive building blocks because they undergo facile photoejection of electrons and often form lattices and clusters that exhibit long-lived photo-induced magnetization changes, with several reports indicating that $Cu^{II}/[Mo(CN)_8]^{n-}$ and $Co^{II/III}/[W(CN)_8]^{n-}$ units being the most useful for constructing such photoresponsive networks and clusters [10–14]. While the first examples of lattices containing octacyanometalate anions, $M^{II}_2[Mo^{IV}(CN)_8]\cdot nH_2O$ $(2 \leqslant n \leqslant 9)$ $(M^{II} = Mn, Fe, Co, Ni, Cu, and Zn)$, were reported in 1927 relatively few octacyanometalate clusters and networks have been reported, in comparison to better known hexacyanometalate analogues [15–21].

Recently pentadecanuclear octacyanometalate(V) clusters of $Co^{II}[Co^{II}(MeOH)_3]_8[M^V(CN)_8]_6\cdot n$MeOH stoichiometry ($M^V = Mo$, W) were reported to exhibit slow relaxation of the magnetization that is characteristic of superparamagnetic compounds [22a]. These cyanide-bridged polynuclear complexes are typically prepared in alcoholic media and are often prone to rapid desolvation and aggregation under mild conditions [22]; we rationalized that DMF might be a more suitable donor ligand than alcohols for stabilizing the cluster framework. Methanolic mixtures of these clusters treated with DMF rapidly afforded precipitates while combination of divalent 3d tosylates with octacyanometalate(V) salts in DMF give a series of structurally related one-dimensional chains that are essentially isostructural to "glassy" networks reported by Tang et al. [23,24]. We rationalized that substitution of Mn^{II} for more anisotropic metal centers (e.g. Ni^{II}) might afford magnetic chain analogues that exhibit higher blocking temperatures than Mn^{II} analogues, assuming that efficient superexchange interactions are maintained. Moreover, we rationalized that octacyanometalates may be promising building blocks for constructing polynuclear complexes and lattices that exhibit markedly different and/or enhanced properties (e.g. photomagnetism, magnetism) relative to 3d hexa- and heptacyanometalate analogues [1–5,13–15]. In the present contribution we describe the syntheses, crystallographic, spectroscopic, and magnetic details of several one- and two-dimensional octacyanometalate(V) networks containing a series of paramagnetic 3d transition metal centers.

2. Experimental

2.1. General considerations

All operations were conducted while dark in a vacuum or under an argon atmosphere by using standard Schlenk and drybox techniques. Transfers of solutions containing cyanides were carried out through stainless steel cannulas. The salts Cs(OTs), $Mn(OTs)_2$, $Co(OTs)_2$, $Ni(OTs)_2$, $[NBu_3H]_3[Mo(CN)_8]$, and $[NBu_3H]_3[W(CN)_8]$ were prepared according to modified literature methods [16,17,25–28]. Solvents were distilled under dinitrogen from sodium-benzophenone (diethyl ether) or Mg turnings (methanol and ethanol) and were sparged with argon prior to use. DMF (Baker) was dried over activated Linde 13-X molecular sieves and sparged with argon prior to use. $FeCl_3$ (Cerac), nitric acid (Baker), tributylamine (Aldrich), Celite (Aldrich), and deionized water were used as received.

The IR spectra were recorded as Nujol mulls between KBr plates on a Mattson Galaxy 5200 FTIR instrument. Room temperature powder susceptibility measurements were collected on a Johnson–Matthey magnetic susceptibility balance. Variable temperature and magnetic field measurements were performed at the Frederick Seitz Materials Research Laboratory at the University of Illinois at Urbana-Champaign (U.I.) and Virginia Tech University (V.T.) on Quantum Design MPMS (U.I. and V.T.) and MPMS2 (U.I.) SQUID magnetometers. Diamagnetic corrections were estimated using Pascal's constants [29,30]: $\chi_{dia} = -771.36\times10^{-6}\,cm^3\,mol^{-1}$ for **5**, $\chi_{dia} = -771.36\times10^{-6}\,cm^3\,mol^{-1}$ for **6**, $\chi_{dia} = -827.36\times10^{-6}\,cm^3\,mol^{-1}$ for **5**, $\chi_{dia} = -749.36\times10^{-6}\,cm^3\,mol^{-1}$ for **7**, and $\chi_{dia} = -827.36\times10^{-6}\,cm^3\,mol^{-1}$ for **8**. Microanalyses were performed by the University of Illinois Microanalysis Laboratory.

2.2. Preparation of complexes and networks

2.2.1. $[HBu_3N]_3[Mo(CN)_8]$ (1)

Treatment of aqueous (80 mL) $K_4[Mo(CN)_8]\cdot 2H_2O$ (25.04 g, 50.4 mmol) with concentrated HNO_3 (110 mL) over 5 min. affords a brown solution. Subsequent addition of water (200 ml) followed by tributylamine (40 mL, 168 mmol) while stirring affords a pale brown suspension over 10 min; water (1200 mL) was added and the mixture was allowed to stir an additional 30 min. The crude product was isolated by suction filtration and washed with water (3×50 mL) followed by Et_2O (50 mL). The remaining yellow solid was dissolved into absolute EtOH (250 mL), filtered through Celite, and the pale yellow

filtrate was concentrated under vacuum (60 °C) to *ca.* 100 mL volume. Addition of Et_2O (200 mL) afforded a pale yellow solid that was isolated by suction filtration, washed with Et_2O (2 × 20 mL), and dried under vacuum for 2 h at room temperature (29 °C). Yield: 24.51 g (56.3%). *Anal.* Calc. for $C_{44}H_{84}N_{11}Mo$: C, 61.17; H, 9.83; N, 17.84; Mo, 11.11. Found: C, 61.51; H, 9.70; N, 17.82; Mo, 10.89%. IR (Nujol, cm^{-1}): 3027 (vs, br), 2962 (vs, br), 2935 (vs), 2871 (vs), 2853 (vs), 2798 (vs), 2141 (s), 2114 (w), 1224 (w), 1156 (w), 1107 (w), 1066 (w), 1035 (w), 984 (vw), 931 (w), 902 (vw), 802 (vw), 741 (w), 499 (vw), 487 (vw), 451 (vw).

2.2.2. $[HBu_3N]_3[W(CN)_8]$ (**2**)

Treatment of aqueous (120 mL) $K_4[W(CN)_8]\cdot 2H_2O$ (24.98 g, 42.7 mmol) with concentrated HNO_3 (120 mL) over 3 min. affords a dark purple solution. Subsequent addition of water (200 ml) followed by tributylamine (40 mL, 168 mmol) with stirring gradually affords a pale purple suspension over 10 min; addition of water (750 mL) gradually afforded a pale purple suspension over 30 min. The crude product was isolated via suction filtration and was washed with water (3 × 50 mL) followed by Et_2O (50 mL). The remaining pale purple solid was dissolved into anhydrous EtOH (300 mL) and the mixture was filtered through Celite. The pale purple filtrate was concentrated under vacuum (60 °C) to *ca.* 100 mL volume and Et_2O (100 mL) was added. The precipitated white solid was isolated via suction filtration, washed with Et_2O (3 × 50 mL), and dried under vacuum for 2 h at room temperature (29 °C). Yield: 30.43 g (74.9%). *Anal.* Calc. for $C_{44}H_{84}N_{11}W$: C, 55.52; H, 8.92; N, 16.19. Found: C, 55.57; H, 8.8; N, 16.07%. IR (Nujol, cm^{-1}): 3343 (w), 3321 (w), 3298 (w), 3027 (vs), 2936 (vs), 2871 (vs), 2854 (vs), 2798 (vs), 2748 (s), 2663 (m), 2548 (w), 2144 (m), 2120 (w), 1277 (w), 1224 (w), 1156 (w), 1107 (w), 1066 (w), 1034 (w), 985 (w), 931 (w), 902 (vw), 803 (w), 741 (w), 440 (w).

2.2.3. $Cs_3[Mo(CN)_8]$ (**3**)

Treatment of **1** (5.14 g, 5.95 mmol) in MeOH (50 mL) with methanolic (125 mL) CsOTs (4.94 g, 18.2 mmol) rapidly precipitated a yellow solid. The mixture was allowed to stir for 5 min and the yellow solid was isolated via suction filtration, washed with EtOH (2 × 25 mL) and Et_2O (30 mL), and dried under vacuum for 2 h at room temperature (29 °C). Yield: 4.04 g (91.8%). *Anal.* Calc. for $C_8N_8Cs_3Mo$: C, 13.66; H, 0; N, 15.94; Cs, 56.73; Mo, 13.65. Found: C, 13.72; H, 0; N, 15.31; Cs, 55.98; Mo, 13.22%. IR (Nujol, cm^{-1}): 3615 (w), 3480 (w, br), 3348 (w), 3321 (w), 3298 (w), 2143 (vs), 2135 (s, sh), 2114 (w), 1606 (vw), 505 (w), 471 (w).

2.2.4. $Cs_3[W(CN)_8]$ (**4**)

Treatment of CsOTs (6.11 g, 22.5 mmol) in MeOH (50 mL) with methanolic **2** (7.24 g, 7.61 mmol) rapidly affords a pale yellow suspension. The mixture was allowed to stir for 15 min. and subsequently filtered via suction filtration. The yellow precipitate was washed with EtOH (2 × 10 mL) and Et_2O (2 × 15 mL) and dried for 2 h under vacuum at room temperature (30 °C). Yield: 5.18 g (86.0%). *Anal.* Calc. for $C_8H_8N_8Cs_3W$: C, 12.14; H, 0; N, 14.16; Cs, 50.43; W, 23.25. Found: C, 12.31; H, 0.03; N, 13.6; Cs, 48.57; W, 20.19%. IR (Nujol, cm^{-1}): 3603 (w), 3532 (w), 2144 (m), 2131 (m), 1619 (w), 446 (w), 420 (w).

2.2.5. $\{[trans\text{-}Mn^{II}(DMF)_4][cis\text{-}Mn^{II}(DMF)_4]_2[W^{V}(CN)_8]_2\}_n$ (**5**)

Treatment of a DMF (20 mL) solution of $Mn(OTs)_2$ (1.25 g, 3.15 mmol) with **2** (1.98 g, 2.08 mmol) in DMF (20 mL) afforded an amber solution that was allowed to stand for 4 d at room temperature (20 °C). The brown crystals were isolated via filtration, washed with DMF (2 × 5 mL) and Et_2O (3 × 5 mL), and dried under vacuum for 2 min at room temperature (20 °C). Yield: 1.25 g, (65.8%). *Anal.* Calc. for $C_{52}H_{84}N_{28}O_{12}Mn_3W_2$: C, 34.21; H, 4.64; N, 21.48; Mn, 9.03; W, 20.14. Found: C, 34.02; H, 4.11; N, 20.87%. IR (Nujol, cm^{-1}): 3144 (s), 3062 (s), 2157 (vs), 2130 (m, sh), 2114 (w), 1645 (vs), 1560 (s), 1540 (s), 1496 (vs), 1454 (vs), 1421 (vs), 1251 (vs), 1154 (m), 1110 (vs), 1062 (s), 1016 (m), 865 (m), 678 (s), 675 (s), 439 (s), 421 (s).

2.2.6. $\{[trans\text{-}Mn^{II}(DMF)_4][cis\text{-}Mn^{II}(DMF)_4]_2[W^{V}(CN)_8]_2\}_n$ (**6**)

Treatment of a DMF (20 mL) solution of $Mn(OTs)_2$ (1.17 g, 2.94 mmol) with **2** (2.59 g, 2.72 mmol) in DMF (20 mL) afforded an amber solution that was allowed to stand for 4 d at room temperature (28 °C). The brown crystals were isolated by filtration, washed with DMF (2 × 5 mL) and Et_2O (3 × 5 mL), and dried under vacuum for 2 min at room temperature (28 °C). Yield: 1.51 g, (84.4%). *Anal.* Calc. for $C_{52}H_{84}N_{28}O_{12}Mn_3W_2$: C, 34.21; H, 4.64; N, 21.48; Mn, 9.03; W, 20.14. Found: C, 34.05; H, 4.31; N, 20.83%. IR (Nujol, cm^{-1}): 3143 (s), 3060 (s), 2156 (vs), 2129 (m, sh), 2113 (w, sh), 2029 (w), 2016 (w, sh), 1645 (vs), 1559 (s), 1540 (s), 1496 (vs), 1456 (vs), 1420, (vs), 1252 (vs), 1152 (m), 1110 (vs), 1062 (s), 1017 (m), 865 (m), 678 (s), 674 (s), 439 (s), 421 (s), and 403 (s).

2.2.7. $\{[trans\text{-}Ni^{II}(DMF)_4][cis\text{-}Ni^{II}(DMF)_4]_2[Mo^{V}(CN)_8]_2\}_n$ (**7**)

Treatment of a DMF (20 mL) solution of $Ni(OTs)_2$ (1.25 g, 3.12 mmol) with **1** (1.95 g, 2.25 mmol) in DMF (20 mL) afforded a lime-green solution that was allowed to stand for 4 d at room temperature (26 °C). The pale green crystals were isolated by filtration, washed with DMF (2 × 5 mL) and Et_2O (3 × 5 mL), and dried under vacuum for 2 min. at room temperature (26 °C). Yield: 1.07 g, (62.1%). *Anal.* Calc. for $C_{52}H_{84}N_{28}O_{12}Mo_2Ni_3$: C, 37.58; H, 5.09; N, 23.60; Ni, 23.61; Mo, 11.55. Found: C, 36.98; H, 4.85; N, 22.91%. 2.2.8. {[*trans*-$Ni^{II}(DMF)_4$][*cis*-$Ni^{II}(DMF)_4$]$_2$-[$W^V(CN)_8$]$_2$}$_n$ (**8**)

Treatment of a DMF (20 mL) solution of $Ni(OTs)_2$ (1.25 g, 3.12 mmol) with **2** (2.16 g, 2.27 mmol) in DMF (20 mL) afforded a lime-green solution that was allowed to stand for 4 d at room temperature (26 °C). The pale green crystals were isolated by filtration, washed with DMF (2 × 5 mL) and Et_2O (3 × 5 mL), and dried under vacuum for 2 min at room temperature (26 °C). Yield: 1.21 g, (63.3%). *Anal.* Calc. for $C_{52}H_{84}N_{28}O_{12}Ni_3W_2$: C, 33.99; H, 4.61; N, 21.35; Ni, 9.58; W, 20.01. Found: C, 33.54; H, 3.96; N, 20.54%. IR (Nujol, cm^{-1}): 3142 (w), 3052 (m, sh), 2186 (m), 2170 (m, sh), 2137 (w), 1671 (vs), 1643 (vs), 1548 (m), 1499 (s), 1454 (vs, sh), 1440 (vs), 1422 (vs), 1378 (vs), 1255 (s), 1150 (m, sh), 1114 (vs), 1096 (s, sh), 1063 (s), 1017 (m), 869 (w), 816 (w, sh), 693 (s, sh), 684 (s), 658 (w), 478 (w), 454 (m).

2.2.9. [$Fe^{II}(DMF)_6$]$_2$[$W^{IV}(CN)_8$] (**9**)

Treatment of a DMF (15 mL) solution of $FeCl_3$ (0.17 g, 1.05 mmol) with **2** (1.01 g, 1.06 mmol) in DMF (15 mL) afforded a dark orange solution; after 3 d (20 °C) Et_2O (20 mL) was layered on top of the yellow mixture forming yellow crystals within 1 week. The crystals were isolated via filtration, washed with DMF (3 × 5 mL) and Et_2O (3 × 5 mL), and dried under vacuum for 16 h at room temperature (20 °C). Yield: 0.86 g (60.9%). *Anal.* Calc. for $C_{44}H_{84}N_{20}O_{12}Fe_2W$: C, 38.24; H, 6.14; N, 20.28. Found: C, 37.88; H, 5.75; N, 19.69%. IR (Nujol, cm^{-1}): 3142 (w), 3053 (vs), 2923 (vs), 2854 (vs), 2181 (w), 2164 (w), 2151 (w), 2121 (w), 1683 (vs, sh), 1671 (vs, sh), 1645 (vs), 1496 (m), 1455 (s), 1439 (s), 1378 (vs), 1254 (m), 1152 (w), 1117 (s), 1094 (m), 1064 (m), 1019 (m), 685 (m), 671 (m, sh), 661 (w), 447 (m), 403 (s). μ_{eff} (μ_B) = 6.79. Upon standing several months DMF/Et_2O mixtures of **9** afford small quantities of {[*trans*-$Fe^{II}(DMF)_4$][*cis*-$Fe^{II}(DMF)_4$]$_2$-[$W^V(CN)_8$]$_2$}$_n$ (**10**) as brown crystals. IR (Nujol, cm^{-1}): 3144 (m), 3056 (m), 2280 (w, sh), 2155 (m, sh), 2145 (m), 2127 (m), 2116 (m), 2029 (w), 1658 (vs), 1642 (vs), 1495 (s), 1456 (vs), 1439 (vs), 1253 (s), 1150 (w), 1115 (vs), 1064 (s), 866 (w), 805 (w), 683 (vs), 441 (m), 417 (s).

2.3. Structure determinations and refinements

Crystals of **5**–**8** were grown from DMF solutions of either $Mn(OTs)_2$ (**5**, **6**), $Ni(OTs)_2$ (**7**, **8**), or $FeCl_3$ (**9**, **10**) treated with **1** or **2**. X-ray diffraction data were collected at 90.0(2) K on a Nonius kappaCCD diffractometer from irregular shaped crystals, mounted in Paratone-N oil on glass fibers. Initial cell parameters were obtained (DENZO) [31] from ten 1° frames and were refined via a least-squares scheme using all data-collection frames (SCALEPACK) [31]. Lorentz/polarization corrections were applied during data reduction. The structures were solved by direct methods (SHELXS97) [32] and completed by difference Fourier methods (SHELXL97) [32]. Refinement was performed against F^2 by weighted full-matrix least-squares (SHELXL97) [32] and empirical absorption corrections (either SCALEPACK [31] or SADABS [32]) were applied. Hydrogen atoms were found in difference maps and subsequently placed at calculated posi-

tions using suitable riding models with isotropic displacement parameters derived from their carrier atoms. Non-hydrogen atoms were refined with anisotropic displacement parameters. Atomic scattering factors were taken from the International Tables for Crystallography vol. C.3 [33]. Crystal data, relevant details of the structure determinations, and selected geometrical parameters are provided in Tables 1–3.

3. Results and discussion

3.1. Syntheses and infrared characterization

We had initially anticipated that a series of isostructural clusters of $M^{II}[M^{II}(DMF)_3]_8[M^{V}(CN)_8]_6 \cdot n$DMF stoichiometry, would be obtained upon treatment of binary transition metal *p*-toluenesulfonates with tri(butyl)ammonium octacyanometalates in DMF at room temperature. Instead of clusters several networks are obtained, suggesting that solvent choice is a critical factor in preparing octacyanometalate materials. Treatment of several binary transition metal *p*-toluenesulfonates $[M^{II}(OTs)_2]$ with **1** or **2** in DMF readily affords one- and two-dimensional crystalline octacyanometalate networks of $[M^{II}(DMF)_4]_3[M^{V}(CN)_8]_2$ (M^{V} = Mo, W; M^{II} = Mn, **5**, **6**; Ni, **7**, **8**) stoichiometry [23,24]; Attempts to prepare iron(II) analogues from $Fe^{II}(OTs)_2$ salts consistently afford intractable amorphous precipitates while iron(III) chloride initially affords a trimetallic salt $[Fe^{II}(DMF)_6]_2[W^{IV}(CN)_8]$ (**9**), and small crystalline quantities of $\{[Fe^{II}(DMF)_6]_3[W^{V}(CN)_8]_2\}_n$ (**10**) after standing for several months.

The infrared spectra of **1**–**4** exhibit several high-energy cyano stretching absorptions (ν_{CN}) that are characteristic of octacyanometalate(V) salts. The ν_{CN} stretches are found between 2114 and 2144 cm^{-1} for tributylammonium salts (**1** and **2**) while cesium analogues range from 2131 to 2143 cm^{-1} (**3** and **4**). The energies of the ν_{CN} absorptions fall within expected value ranges and elemental analysis data support their formulation as octacyanometalate(V) salts [20,45].

Likewise, compounds **5**–**8** and **10** exhibit several intense, high-energy ν_{CN} absorptions in their infrared spectra. The highest energy cyano stretching absorptions are shifted to higher energies in comparison to those seen in **1** and **2**, and appear to scale as a function of divalent metal center electronegativity, consistent with the presence of $M^{II}(\mu\text{-NC})M^{V}$ units in **5**–**8**. Generally, the ν_{CN} absorptions range from 2129 to 2193 cm^{-1} suggesting that both bridging and terminal cyanides are present. The Mn^{II} analogues (**5** and **6**) exhibit low-energy ν_{CN} absorptions near 2156 cm^{-1}, while the Ni^{II} derivatives (**7**, **8**) have absorptions that are shifted to much higher energies (2183–2193 cm^{-1}), suggesting that these modes are due to bridging cyanides; this trend is generally consistent with increasing π backbonding and decreasing depopulation of the cyanide 5σ orbital within the $M^{II}(\mu\text{-NC})M^{V}$ unit progressing from Ni^{II} to Mn^{II} [20,36–45]. Additional ν_{CN} stretches are also present at lower energies in the infrared spectra of **5**–**8** and **10** being close in energy to those found for **1** and **2**; we tentatively assign these as terminal cyanide ν_{CN} absorptions. For **10**, ν_{CN} stretching absorptions are found at 2155, 2127, and 2116 cm^{-1}, suggesting that bridging and terminal cyanides are also present. Assuming that kinematic effects [46] are absent in **5**–**8** and **10** we conclude that the bridging and terminal cyano stretching absorptions are those between *ca.* 2156–2193 cm^{-1} and 2129–2138 cm^{-1}, respectively [10b,18a,20–22,36–47].

For **9**, the infrared spectrum exhibits cyano stretching absorptions that are comparable in energy to ionic octacyanotungstate(IV) salts that are absent of μ-CN linkages. Octacyanometalate(IV) compounds generally exhibit ν_{CN} stretches that range from 2060 to 2160 cm^{-1} and 2085 to 2141 cm^{-1} for terminal and bridging cyanides, respectively [20,34–47]. In the infrared spectrum of **9** three medium intensity cyano stretching absorptions [2145, 2127, 2116 cm^{-1}] are found, in addition to a weak ν_{CN} at 2029 cm^{-1}, suggesting that $[M^{IV}(CN)_8]^{4-}$ centers are present. The energy of the ν_{CN} absorptions found for **9** are markedly different than those observed for $K_4[W^{IV}(CN)_8] \cdot 2H_2O$ (2125, 2095, and 2056 cm^{-1}) and bi- and trimetallic clusters of $[M^{II}(en)_3][cis\text{-}M^{II}(en)_2(OH_2)(\mu\text{-NC})M^{IV}(CN)_7] \cdot 2H_2O$ and $[M^{II}(en)_2(OH_2)]_2[(\mu\text{-NC})_2M^{IV}(CN)_6] \cdot 6H_2O$ stoichiometry (2142–2062 cm^{-1}) [20x,44].

3.2. Crystallographic studies: one-dimensional chains

Compounds **5** and **8** crystallize in the monoclinic ($P2_1/n$) and triclinic ($P\bar{1}$) space groups, respectively (Table 1). The neutral networks consist of an alternating array of distorted $\{[cis\text{-}M^{II}(DMF)_4(\mu\text{-NC})_2M^{V}(CN)_5(\mu\text{-CN})]_2\}^{2-}$ squares that are linked via bridging cyanides to adjacent $[trans\text{-}(\mu\text{-CN})M^{II}(DMF)_4(\mu\text{-NC})]^{2+}$ units, leaving five terminal cyanides per three-connected $[W^{V}(CN)_8]^{3-}$ center. The one-dimensional $\{[trans\text{-}M^{II}(DMF)_4][cis\text{-}M^{II}(DMF)_4]_2[(\mu\text{-NC})_3W^{V}(CN)_5]_2\}_n$ chains (Figs. 1 and 2) are separated by coordinated DMF ligands and have closest $M^{II}\cdots M^{II}$ interchain contacts of *ca.* 7.61(3) and 8.43(3) Å for **5** and **8**, respectively [23,24]; this structural motif has been previously reported by Shore, Tang, and Colacio for "expanded Prussian blues" and a few octacyanometalate(V) lattices [15,20–24,48].

For the octacyanotungstate(V) centers the W–C bond lengths differ slightly, ranging from 2.157(2) to 2.184(2) Å and 2.159(3) to 2.169(3) Å for **5** and **8**, respectively (Table 2). For **5**, the C–W–C bond angles range from 70.64(8) to 142.88(8)° while the W–C–N bond angles are nearly linear, ranging from 175.7(2) to 179.1(2)° (Table 3). For **8**, the C–W–C bond angles range from 72.0(1) to 140.1(1)° and nearly linear W–C–N bond angles are again found (Table 3); the bridging cyanide C2–W1–C6 and C1–W1–C2 angles are 70.64(8) and 131.81(8)° for **5** and 71.6(1) and 130.8(1)° for **8**. The coordination geometries of the $[W^{V}(CN)_8]^{3-}$ centers are best described as distorted square antiprismatic (Fig. 1) [20–24,34–47].

The $\{M^{V}_2(\mu\text{-CN})_4M^{II}_2\}$ fragments in each chain appear to distort as a function of the divalent center present. The M^{II}–N bond distances present in the $[cis\text{-}M^{II}(DMF)_4(\mu\text{-NC})_2]^{2+}$ units contained within the $\{M^{V}_2(\mu\text{-CN})_4M^{II}_2\}$ fragments appear to scale as a function of divalent metal center ionic radii, with the longest M^{II}–N distances found in **5** [2.245(2) and 2.258(2) Å], while those in **8** [2.064(3) and 2.073(3) Å] are shorter. The M^{II}–

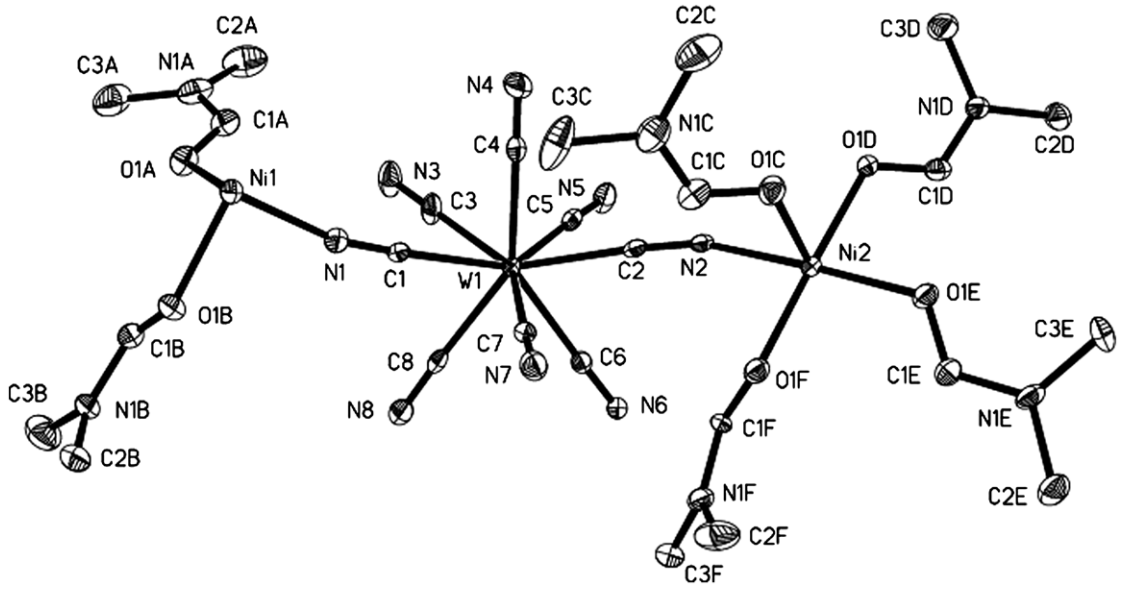

Fig. 1. Asymmetric unit of **8**. Thermal ellipsoids are at the 50% level and all hydrogen atoms are removed for clarity.

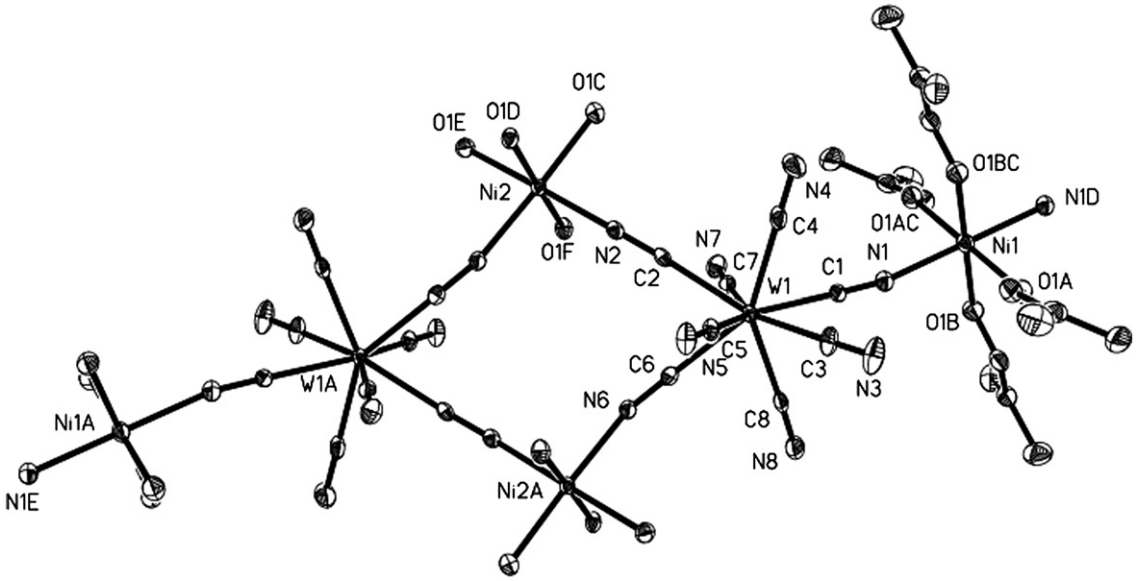

Fig. 2. X-ray structure of **8** illustrating the one-dimensional chain of squares motif present. Thermal ellipsoids are at the 50% probability level and all hydrogen atoms and selected carbon and nitrogen atoms are removed for clarity.

O_{DMF} bond distances range from 2.156(2) to 2.172(2) Å and 2.047(2) to 2.064(2) Å for **5** and **8**, with no discernable trends regarding their relationship to the coordinated cyanides (Table 2). The twisting of the imbedded tetranuclear fragments can be described via the distance of the metal centers from a mean plane defined the atoms present within the $\{M^{V}_{2}(\mu\text{-}CN)_{4}M^{II}_{2}\}$ fragment; the tungsten and manganese centers in **5** are *ca.* ±0.27(1) and ±0.23(2) Å from this plane, while the tungsten and nickel centers in **8** are located at slightly larger and smaller distances [*ca.* ±0.41(2) and ±0.05(4) Å], respectively. As a final means of comparison, the $M^{II}\cdots M^{II}$ and W···W contacts are slightly larger in **5** [6.59(2) and 8.64(2) Å], while those in **8** [6.39(3) and 8.39(2) Å] are smaller, suggesting that the $\{M^{V}_{2}(\mu\text{-}CN)_{4}\text{-}M^{II}_{2}\}$ fragment size depends on the divalent metal centers present.

Significant distortion of the $\{M^{V}_{2}(\mu\text{-}CN)_{4}M^{II}_{2}\}$ fragments is also apparent in the N–M^{II}–N and N–M^{II}–O bond angles present in **5** and **8**. The smallest N–M^{II}–N and largest N–M^{II}–O bond angles are found for **5**, suggesting that M^{II}–N bond distances are related to the electronegativity and radius of the divalent centers present, affording highly distorted $\{M^{V}_{2}(\mu\text{-}CN)_{4}M^{II}_{2}\}$ fragments within the one-dimensional chains (Table 3). The N–M^{II}–N bond angles are more acute in **5** [91.34(7)°] in comparison to those seen for **8** [93.7(1)°], while larger N2–M2–O1C and N2–M2–

O1E bond angles are found for **5** [92.28(6) and 178.93(6)°]. Consistent with expected periodic trends compound **8** has slightly smaller N2–M2–O1C and N2–M2–O1E angles [88.99(9) and 177.65(9)°] in comparison to those seen in **5**.

The remaining [*trans*-$M^{II}(\mu\text{-}NC)_2(DMF)_4]^{2+}$ units in **5** and **8** have M^{II}–N and M^{II}–O bond distances that are comparable to those seen in the $\{M^{V}_2(\mu\text{-}CN)_4M^{II}_2\}$ units. The average M^{II}–N and M^{II}–O bond distances are 2.252(2) and 2.165(2) Å for **5**, while **8** exhibits smaller distances [2.069(3) and 2.060(2) Å] (Table 2). The shortest M^{II}–N bonds are again found for the most electronegative analogues (**8**, Ni^{II}) with larger values found for early metal derivatives (**5**, Mn^{II}). The N1–M1–N1A bond angles are linear while the N1–M1–O bond angles range from 85.90(6) to 94.10(6)° and 87.9(1) to 92.1(1)° for **5** and **8**, respectively (Table 3) [20g,45]. The W(1)···W1A and M2···M2A contacts are 8.644(3) and 6.590(3) Å for **5** while comparatively smaller values [8.394(3) and 6.382(3) Å] are found for **8**.

3.3. Crystallographic studies: two-dimensional sheets

Crystals of **6** and **10** crystallize in the monoclinic $P2_1/n$ and $P2_1/c$ space groups, respectively (Table 1). The neutral, corrugated two-dimensional sheets contain [*cis*-$M^{II}(DMF)_4(\mu\text{-}NC)_2]^{2+}$, [*trans*-$M^{II}(DMF)_4(\mu\text{-}NC)_2]^{2+}$, and three-connected $[M^{V}(CN)_5(\mu\text{-}CN)_3]^{3-}$ units that are linked via cyanides into 12-membered rings in a 4:2:6 ratio (Fig. 2), respectively; the asymmetric unit and 12-membered ring fragments present in **6** are illustrated in Figs. 3 and 4. The 12-membered rings are the basic building units of the corrugated two-dimensional sheets (Fig. 3), with each offset by *ca.* 5 Å and linked via shared [*trans*-$M^{II}(\mu\text{-}NC)_2(DMF)_4]^{2+}$ units to adjacent $[M^{V}(CN)_8]^{3-}$ centers. The ruffled sheets are separated by *ca.* 6.8 [Mn···Mn] and 7.0 Å [Fe···Fe] for **6** and **10**, respectively, and are comparable to those reported (*ca.* 7.0 Å) for structurally related two-dimensional $Mn^{II}_3Mo^{V}_2$ lattices (**11**) [20g,45]. The ring dimensions are *ca.* 10 [W1A···W1E] × 18 Å [W1A···W1B] and 11 [W1···W1A] × 18 [W1···W1E] for **6** and **10**, respectively, being slightly smaller than reported for 2-D $Mn^{II}_3Mo^{V}_2$ (**11**) analogues (*ca.* 9 × 24 Å) [45].

The W–C bond distances and C–W–C angles are within the ranges expected for octacyanometalate networks (Table 2). The W–C bonds vary from 2.158(3) to 2.179(3) Å for **6** and 2.155(6) and 2.177(6) Å for **10**, while the C–W–C bond angles range from 70.60(9) to 148.13(9)° and 70.5(2) to 148.0(2)° for **6** and **10**, respectively; again the tungsten centers have distorted square antiprismatic coordination geometries. The terminal and bridging cyanide W–C–N angles are also nearly linear ranging from 176.2(2) to 179.1(2) and 174.9(4) to 179.7(5)° for **6** and **10**, respectively (Table 3).

In **6** and **10** the two-dimensional lattices consist of 12-membered rings that are composed of [*trans*-$M^{II}(\mu\text{-}NC)_2(DMF)_4]^{2+}$ and [*cis*-$M^{II}(\mu\text{-}NC)_2(DMF)_4]^{2+}$ units. The [*trans*-$M^{II}(\mu\text{-}NC)_2(DMF)_4]^{2+}$ units have M–N and M–O bond distances that are slightly longer than those seen in the [*cis*-$M^{II}(\mu\text{-}NC)_2(DMF)_4]^{2+}$ fragments (Table 2). The M–N and M–O bond distances in the [*trans*-$M^{II}(\mu\text{-}NC)_2(DMF)_4]^{2+}$ fragments are 2.232(2) and 2.154(4) Å, while those for the [*cis*-$M^{II}(\mu\text{-}NC)_2(DMF)_4]^{2+}$ units are slightly shorter, being 2.217(2) and 2.170(4) Å for **6** and **10**, respectively; similar bond distance trends are observed in **5**, **7**, and **8**.

The N–M–N and O–M–O bond angles also exhibit structure-dependent changes depending on their location within the 2-D sheets (Table 3). For [*trans*-$M^{II}(\mu\text{-}NC)_2(DMF)_4]^{2+}$ fragments, the symmetry related N–M–N angles are 180°, while the O–M–O angles range from 87.4(3) to 180° for **6** and 88.6(1) to 180° for **10**. In comparison, the N–M–N and O–M–O angles for the [*cis*-$M^{II}(\mu\text{-}NC)_2(DMF)_4]^{2+}$ fragments range between 88.57(7) and 169.66(6)° and 86.8(1) and 173.2(2)° for **6** and **10**, respectively, being close to those seen for structurally related $Mn^{II}_3Mo^{V}_2$ (**11**) lattices [20g,45].

3.4. Crystallographic studies of 9

Crystals of **9** are in the monoclinic $P2_1/c$ space group and crystallize as trimetallic salts of $[Fe^{II}(DMF)_6]_2[W^{IV}(CN)_8]$ stoichiometry (Table 1). The W–C bond distances range from 2.167(3) to 2.181(3) Å while the C–W–C bond angles are between 70.9(2) and 145.3(1)°; the W–C–N angles are nearly linear, ranging from 178.7(3) to 179.3(3)° (Fig. 5). The Fe–O lengths are all slightly different, ranging from 1.975(2) [Fe1–O1A] to 2.196(2) Å [Fe2–O1F], while the O–Fe–O bond angles are nearly octahedral, ranging from 87.49(9) to 93.05(9)° [O1D–Fe2–O1F and O1A–Fe1–O1B]. The $[Fe^{II}(DMF)_6]^{2+}$ and $[W^{IV}(CN)_8]^{4-}$ ions are well-separated and are not related by rotational symmetry; the Fe1···Fe2, Fe1···W1, and Fe2···W1 contacts are 9.66(2), 7.16(3), and 8.88(3) Å, respectively (see Fig. 6).

3.5. Magnetic studies

Magnetic studies of suggest that the magnetic exchange interactions present in the $Mn^{II}(\mu\text{-}NC)W^{V}$ units of **5** and **6** are antiferromagnetic [20g]. The room temperature χT values for **5** and **6** [13.73 and 14.15 emu K mol^{-1}] are close to the spin-only value (13.88 emu K mol^{-1}) expected for a 3:2 ratio of non-interacting W^{V} ($S = 1/2$; $g = 2$) and Mn^{II} ($S = 1/2$; $g = 2$) centers. The sign of the local exchange interactions can often be predicted from the shape of the χT versus T curve. A shallow minimum is often found when short-range antiferromagnetic correlations compensate spins [49] and such minima are observed at *ca.* 75 and 200 K for **5** and **6**, respectively. At lower temperatures the χT product monotonically increases reaching maximum values of 24.82 and 151.2 emu K mol^{-1} at 3.7 and 10.0 K, with χT again decreasing towards minimum values of 23.41 and 99.7 emu K mol^{-1} at 1.8 and 5 K, for **5** and **6**, respectively. Fitting of the χ^{-1} versus T data (at $H_{dc} = 1$ kG) with the Curie–Weiss expression affords negative Weiss constants (−0.66 K for **5** and −4.78 K for **6**) ver-

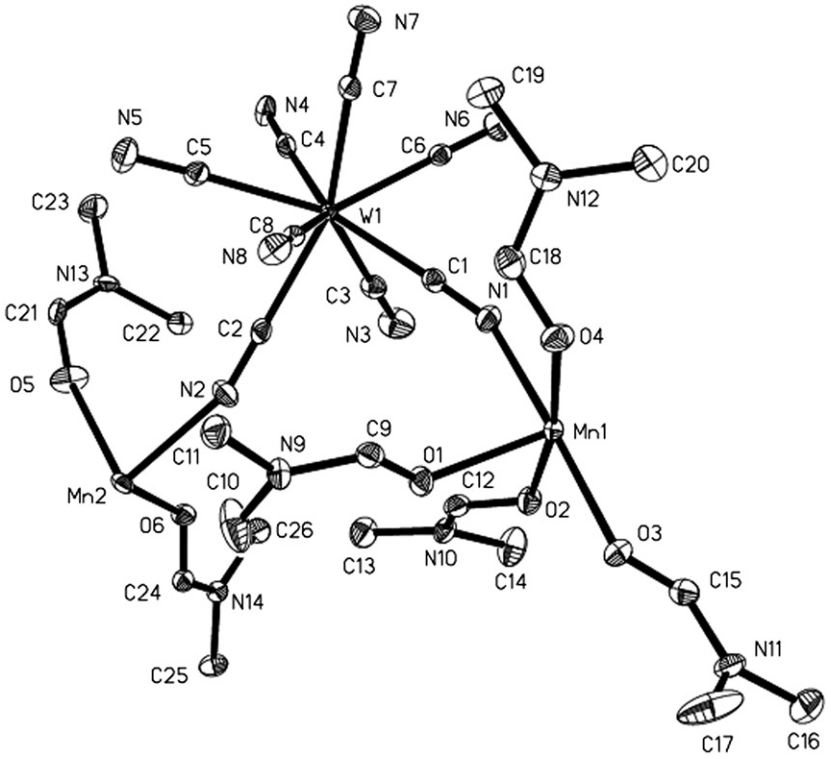

Fig. 3. Asymmetric unit of **6**. Thermal ellipsoids are at the 50% level and all hydrogen atoms are removed for clarity.

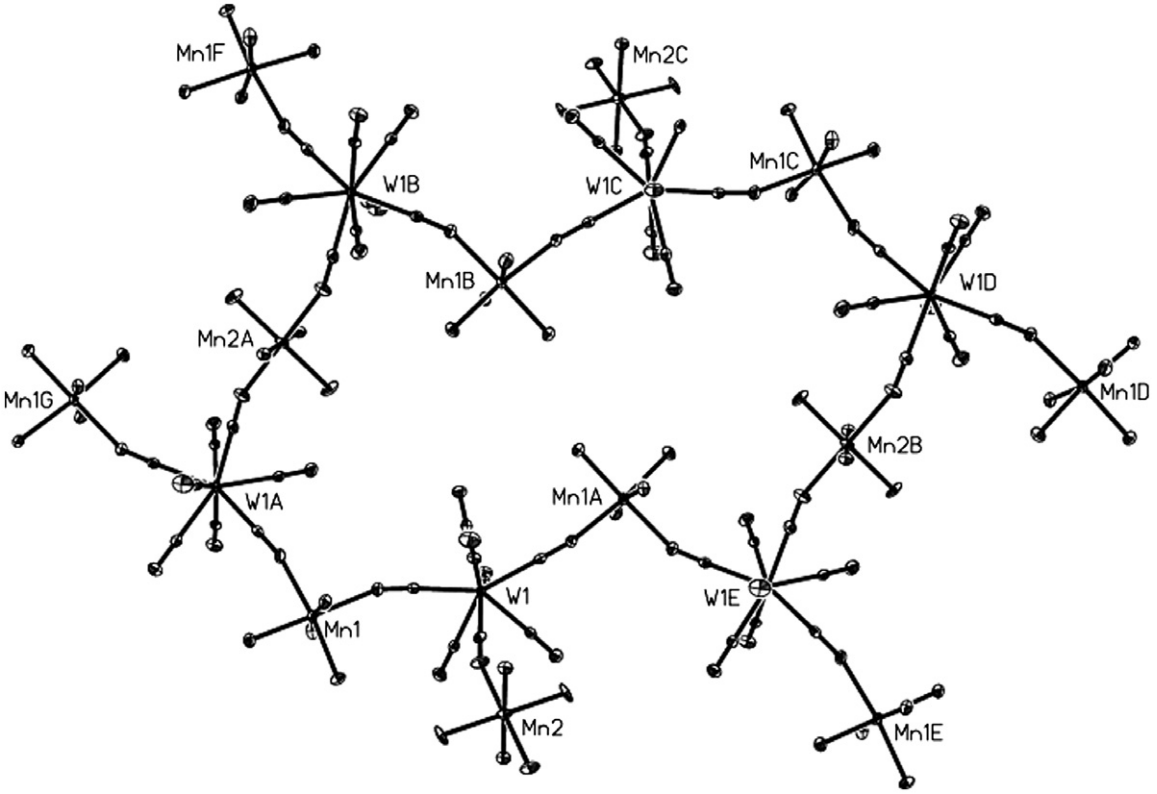

Fig. 4. X-ray structure of **6** illustrating the 12-membered rings present. Thermal ellipsoids are at the 50% level, DMF ligands are truncated, and all hydrogen atoms are removed for clarity.

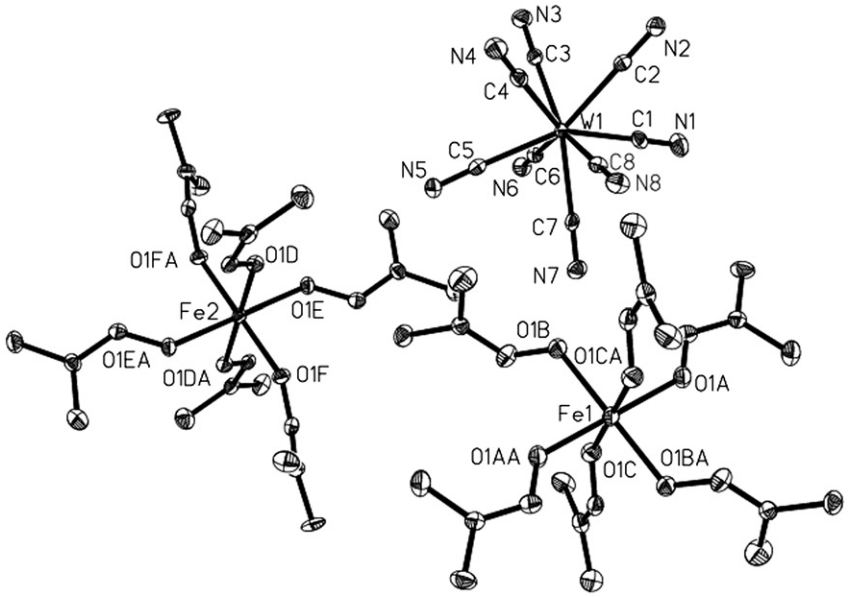

Fig. 5. X-ray structure of **9**. Thermal ellipsoids are at the 50% probability level and all hydrogen atoms are removed for clarity.

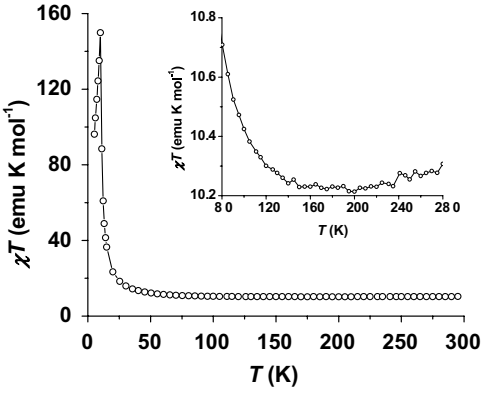

Fig. 6. Temperature dependence of χT for **6** at $H_{dc} = 1$ kG.

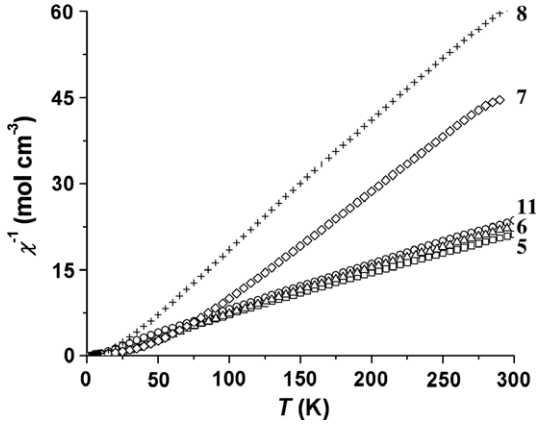

Fig. 7. Temperature dependence of the reciprocal susceptibility for **5**–**8** and **11** at $H_{dc} = 1$ kG.

ifying that local antiferromagnetic interactions are present. As judged from the divergence of the zero-field-cooled and field-cooled magnetization curves ($H_{dc} = 2$ G) we conclude that $T_N = 8$ K for **6** (Fig. 8), while **5** does not appear to exhibit long-range magnetic ordering above 1.8 K.

The field dependence of the magnetization at 2 K further indicates that the Mn^{II} and W^{V} ions in **5** and **6** engage in antiferromagnetic exchange interactions. The experimental saturation magnetization values ($H_{dc} = 70$ kG) for **5** and **6** are 72.3 and 73.4 kG cm^3 mol^{-1} and are close to the expected value of 72.61 kG cm^3 mol^{-1} assuming that $g = 2$. Both **5** and **6** exhibit closed hysteresis loops and small coercive fields (Fig. 9) consistent with the presence of isotropic metal ions.

For **7** and **8** cyanide-mediated superexchange within the $Ni^{II}(\mu\text{-NC})M^{V}$ units is expected to be ferromagnetic (Ni^{II}, $S = 1$) assuming that the magnetic orbitals are orthogonal and that Goodenough–Kanamori rules are applicable [1–8h,50]. Using crushed single crystals of **7** and **8** the room-

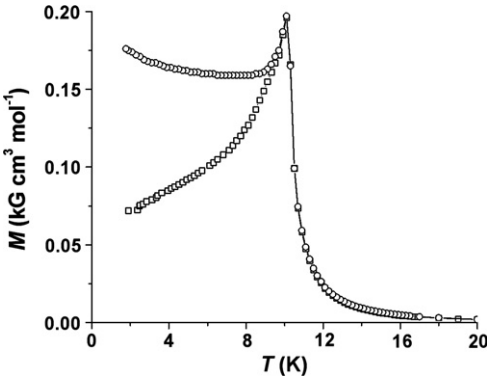

Fig. 8. Temperature dependence of zero-field-cooled (□) and field-cooled (○) magnetization for **6** ($H_{dc} = 2$ G).

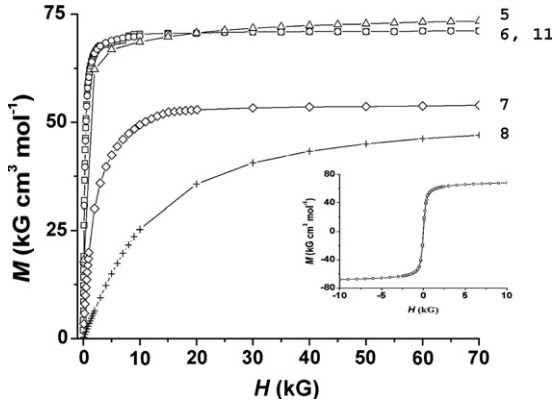

Fig. 9. Field dependence of the magnetization for **5**–**8** and **11** at 2 K. Inset: Hysteresis of **6** at 2 K.

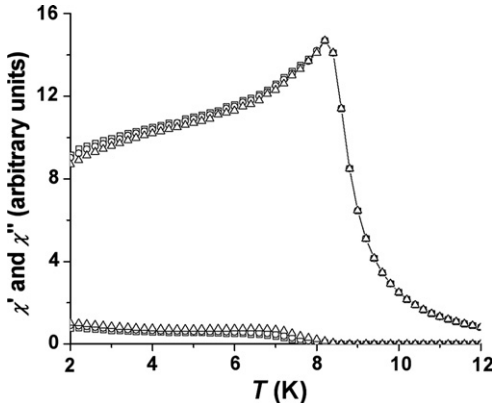

Fig. 10. Temperature dependence of the real (χ', top) and imaginary components (χ'', bottom) of the ac susceptibility for **6** ($H_{dc} = 0$ Oe; $H_{ac} = 3$ Oe) at 1 (○), 10 (△), and 100 (□) Hz.

temperature χT values [6.43 and 5.32 emu K mol^{-1}] are near the expected (5.92 emu K mol^{-1}, $g_{Ni} = 2.2$ assumed) value for a 3:2 ratio of non-interacting Ni^{II} ($S = 1$) and M^{V} ($S = 1/2$; Mo, W) spin centers. The temperature dependence of the χT product ($H_{dc} = 1$ kG) suggests that the Ni^{II} and M^{V} (Mo^{V} and W^{V}) centers undergo short-range ferromagnetic exchange interactions, with χT increasing as a function of decreasing temperature, reaching maximum values [36.72 emu K mol^{-1} for **7** and 50.03 emu K mol^{-1} for **8**] at 19 and 3.8 K for **7** and **8**, respectively. Fitting the χ^{-1} versus T data via the Curie-Weiss expression affords positive Weiss constants (47.56 K for **7** and 11.87 K for **8**) verifying that local ferromagnetic interactions are present (Fig. 7) [20g].

The field dependence of the magnetization data suggests that the cyanide-bridged transition metal centers present in **7** and **8** are ferromagnetically coupled at 1.8 K and large H_{dc} (Fig. 9). Assuming that $g = 2$ the expected saturation magnetization value is 48.03 kG cm^3 mol^{-1} and is between the experimental values found for **7** and **8** [53.9 and 47.0 kG cm^3 mol^{-1}]. Lastly the field dependence of the magnetization indicates that **7** and **8** exhibit closed hysteresis loops with negligible coercive fields at 1.8 K [20g].

ac susceptibility measurements suggest that χ'' is frequency-dependent for **6** despite the presence of isotropic metal ions, while **5**, **7**, and **8** exhibit no frequency-dependent behavior ($H_{dc} = 0$ G; $H_{ac} = 3.5$ G). Using freshly-prepared, crushed crystals of **5**, we find that χ'' is invariant with respect to changing frequency, in stark contrast to reports claiming that structurally-related 1-D $[Mn^{II}(bpy)_2]_3[W^{V}(CN)_8]_2$ lattices exhibit frequency-dependent χ'' maxima [23,24]. However for samples of **5** (*ca.* 2 weeks) unsymmetrical and broad frequency-dependent maxima (Fig. 10) are observed in plots of χ'' versus T, that appear to increase in intensity with respect to time and increasing temperature; the frequency-dependent peaks in χ'' are qualitatively similar to those found for Tang's 1-D chains, **6**, and a recently reported 2-D $[Mn^{II}(DMF)_4]_3[Mo^{V}(CN)_8]_2$ lattice (**11**) [23,24,45]. The unsymmetrical χ'' peak is suggestive of multiple relaxation processes, the presence of multiple magnetic phases, and/or that **5**, **6**, and $[Mn^{II}(DMF)_4]_3[Mo^{V}(CN)_8]_2$ are unstable under the conditions of the ac susceptibility measurements [20g]. For freshly prepared samples of **5**, **7**, and **8** we tentatively propose that they exhibit incipient magnetic ordering in the presence of large H_{dc} fields.

3.6. Chemical and thermal stability of networks

Heating crystalline samples of **5** and **6** decreases the intensity of the DMF $\nu_{C=O}$ stretching absorption while the energies and intensities of the ν_{CN} absorptions remain unchanged. We previously reported that heated samples of **11** afford additional magnetic phases ($T_N \sim 21$ K), that are not due to linkage isomerism [2c,51], but rather desolvation followed by aggregation [20h,45]. Unfortunately all attempts to structurally characterize the microcrystalline and amorphous solids precipitated from hot reaction mixtures containing crystals of **5**–**8** or **11** have consistently met with failure.

Furthermore, the isolation of one- and two-dimensional phases (**5** and **6**) from essentially the same reaction conditions (at or near 300 K) suggests that the M^{II}(μ-NC)M^{V} linkages can be ruptured to form a variety of aggregated products under relatively mild conditions. At lower reaction temperatures (20 °C) and short reaction times a 1-D chain of squares lattice (**5**) is obtained, while longer reaction times and higher temperatures (28 °C) appear to afford 2-D phases (**6**); to date only 2-D lattices have been obtained when using **1** as a starting material. In the absence of counterions ($HNBu_3^+$ and OTs^-) crystals of **5** do not transform into **6** when stored at room temperature (28 °C) in DMF over 3 weeks, in addition to small quantities of DMF-insoluble amorphous precipitates. However, in the presence of counterions (DMF solution, 28 °C) **5** transforms into **6** over a period of weeks, as judged via indexing several crystals removed from the reaction mixture. In addition, wet DMF mixtures of **1** or **2** in the pres-

ence of manganese(II) tosylate exclusively affords 2-D phases in addition to amorphous precipitates. Apparently wet DMF accelerates the transformation of **5** into **6** and attempts to insert other metal centers (e.g. Fe^{II}, Co^{II}, Ni^{II}) into the lattice affords intractable precipitates. To date only Mn^{II} analogues appear to undergo slow one- to two-dimensional phase changes. We propose that formation **5** precedes **6**, being highly dependent on the quantity of water and counterions present. In the presence of counterions we presume that for **5**, labilization of coordinated DMF and rupture of the $Mn^{II}(\mu\text{-NC})M^{V}$ linkages afford soluble species that undergo aggregation, gradually transforming the chains into the two-dimensional corrugated sheets found in **6** [46e].

4. Conclusions

We have described the synthesis, structural, infrared, and magnetic characterization of a trimetallic salt and several one- and two-dimensional networks derived from octacyanometalate(V) centers. Coordinated DMF appears to limit the number of cyano linkages formed and the dimensionality of the resulting lattices. The one-dimensional chains appear to exhibit short-range magnetic interactions but no spontaneous magnetic ordering above 1.8 K. Surprisingly, conversion of one- to two-dimensional crystalline phases in the presence of counterions occurs in solution, while heating of crystalline samples introduces an additional magnetic phases without linkage isomerism. Two-dimensional phases containing Mn^{II} centers appear to be the sole product when wet DMF is used as a reaction solvent. The experimental evidence suggests that coordinated DMF ligands are labile and the $M^{II}(\mu\text{-NC})M^{V}$ linkages are susceptible to fragmentation.

and pyrazine groups (pyz) (or 2-methylpyrazin groups (2-mpyz)). The nano-pores were shown as zigzag-type one-dimensional channels. The X-ray structural studies for single crystals showed both position and orientation of O_2 molecules in nano-pores. In this study, we especially employed the crystal **2** in order to investigate crystal constructions and magnetic properties by using of theoretical treatments.

Magnetic measurement also has been carried out for each crystal and interesting magnetization with stable spins in O_2 molecules was found. It was expected that magnetic interactions between O_2 pairs existed and these cooperation might run in the nano-porous cavity. These results will lead new approach to arrangement of spin sources in organic radicals. Thus, several *ab initio* molecular orbital (MO) methods were employed in order to evaluate magnetic interaction quantitatively.

In addition, structure–function relationships were theoretically elucidated by using of molecular dynamics (MD), MO and statistical mechanics theories [11–15]. For example, the Monte Carlo (MC) procedures in MD simulation enable–us to evaluate number of adsorbed molecules. The Hartree–Fock (HF) and density functional (DFT) methods as MO-based methods can give us information of both position and orientation of guest molecules.

2. Crystal structure and model preparation

Takamizawa, Mori and their co-workers have been reported the series of nano-porous crystals of organometallic conjugation complexes. These solids of dinuclear transition-metal carboxylates can be constructed by using of dicarboxylates (M = Cu(II), Mo(II), Ru(II, III) and so on) or monocarboxylates (M = Rh(II), Cu(II) and so on). In addition, physical adsorption of small size molecules into such organometallic conjugation complexes can be achieved. Reversibly adsorption of a large number of gases such as N_2, O_2, Ar and Xe were reported. Especially, the crystal **2** with adsorption of O_2 molecules will be studies in this paper.

Building units of the organometallic conjugation compound **2** were $Rh_2(bza)_4(pyz)_2$ molecules. According to their experiments, coordination of both four benzoate and two pyrazine ligands in equatorial and axial direction, respectively, are illustrated in Fig. 1a. Pairing of two Rh atoms can be achieved with multiple binding between two metal atoms and indirect binding with coordination of these ligands. As mentioned in our previous paper [11–15], di-carboxylates can elongate building units with coordination in both ends of carboxyl groups as shown in the crystal **1**. On the other hand, in mono-carboxylate systems such bridges between two building units can not be achieved. Thus, construction is made by face-to-face contact between two phenyl groups. Takamizawa and his coworkers reported that they could make single crystals of **2** with adsorption of O_2 molecules. The obtained crystal in $T = 10$ K are illustrated in Fig. 1b, though structural analysis by their X-ray diffraction studies successfully carried out in various temperatures ($T = 10$ K, 90 K and 190 K).

Four fragments in a white circle in the left figure indicate adsorbed O_2 molecules. Such alignment of O_2 molecules indicates existence of one-dimensional channels. We can find two-dimensional arrangements of such channels. The right figure indicates another view of the left figure and two unit cells are shown. It is found that zigzag alignment of adsorbed O_2 molecules. We can find three O_2 molecules in a white square, though each structural disorder causes fluctuation of spatial positions for oxygen atoms. The disorder is much remarkable when experimental temperature is made higher. They studied structural measurement for $T = 10$ K, 90 K and 190 K, though uncertainty of oxygen atoms much increased at $T = 190$ K. Apart from the effects of kinetic motion of O_2 molecules, three O_2 molecules per one unit cell occupy nano-porous cavity.

In the following section, let us employ this structure for our studies. Throughout the MD simulation, this experimental structure in $T = 10$ K was employed, though already adsorbed O_2 molecules were removed. For the evaluation of magnetic interaction between adsorbed O_2 molecules, alignment of O_2 molecules was extracted for our studies as shown in Fig. 1c, though structural disorder was inherent for this crystal. In this figure, each O_2 molecule is indicated O_2(A), O_2(B) and O_2(C) in one unit cell and O_2(A′) is equivalent to O_2(A) in the next cell. Bond lengths in each O_2 molecules are 1.184 (average) and 1.179 Å and intermolecular distances are 3.130 and 3.354 Å. Zigzag orientation between O_2 molecules was expected, though angles and dihedral angles between two O_2 molecules were not described in this figure. The spatial relation between the pairs O_2(A)–O_2(B) and O_2(A′)–O_2(C) are equivalent, since the unit cell has symmetry operation (inverse). In addition, periodic condition for the unit cell requires repeating of two types of magnetic interaction along O_2 chains.

3. Magnetic interactions in spin arrangements of triplet oxygen molecules

First, we investigated magnetic interactions among radical spins on the adsorbed O_2 molecules. Theoretical schemes for magnetic parameter have been highly progressed and *ab initio* MO methods can evaluate magnetic interaction quantitatively. Thus, the effective exchange integrals between radical spins were theoretically evaluated with unrestricted(U)-HF, post-HF and DFT computational methods. It is well known that the energy gaps between both higher (quintet) and lower (singlet) spin states can be well reproduced by these methods. The unrestricted-based methods can cause broken-symmetry (BS) solutions for each spin state [16]. However, such solutions are permitted to involve spin contamination. Thus, the spin projection were applied to the results, which reduced the spin contamination including higher-order spin states.

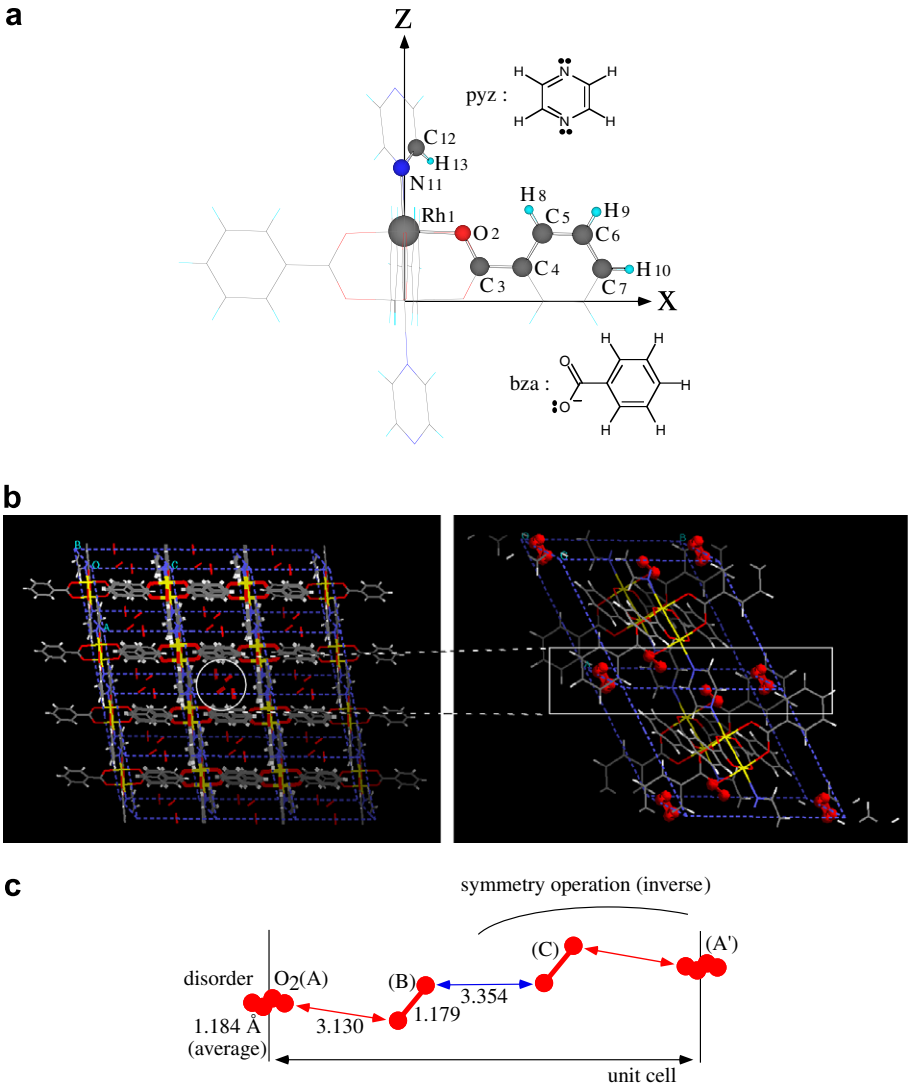

Fig. 1. (a) Building units $Rh_2(bza)_4(pyz)_2$ for the organometallic conjugation compounds $[Rh_2(bza)_4(pyz)]_n$ (**2**). Indices for each atom were referred in Table 2. (b) Alignment of the adsorbed O_2 molecules in cavities, which was reported in experimental studies in $T = 10$ K by Mori, Takamiza and their co-workers. (c) Spatial relations between each O_2 molecule. Structural disorder was reported in O_2(A) molecule.

Here, two types of magnetic interaction were expected, that is, direct and indirect ones. The former was the intermolecular interaction between two O_2 molecules in one-dimensional cavities, though the latter was more complex by use of indirect paths through frame atoms. First, we considered only the former, because two Rh^{2+} metal ions had no magnetic spins, which will be made sure in the following section in this paper. For the latter effect, more extended studies will be done in our following studies.

The O_2(A) molecule had structural disorder and we employed three types of structure: disorder 1, disorder 2 and average. All the calculated results were summarized in Table 1. The evaluate values by the UHF, UCCSD(T) and UB3LYP methods for the pair O_2(A:average)–O_2(B) were small plus and indicated weak ferromagnetic interaction. On the other hand, the values by UCCSD(T) and UB3LYP methods but the UHF methods for the pair O_2(B)–O_2(C) indicated weak antiferromagnetic interaction. Judging from the obtained values and crystal structure in Fig. 1c, only two types of magnetic parameters can deduce the style of spin arrangement in the infinite O_2 chains i.e., $\ldots O_2(A) = O_2(B) - O_2(C) = O_2(A') = O_2(B') - O_2(C') \ldots$ (=: +0.78 cm^{-1} (ferromagnetic); –: −0.29 cm^{-1} antiferromagnetic) by UCCSD(T) methods. Spin arrangement –

Table 1
Evaluated magnetic interactions by HF (UHF/4-31G), post-HF (UCCSD(T)/4-31G) and DFT (UB3LYP/4-31G) methods for all pairs in one unit cell of O_2 molecular chain

Pair	J_{ab} (cm^{-1})		
	UHF	UCCSD(T)	UB3LYP
O_2(A:average) – O_2(B)	1.06	0.78	0.41
O_2(A:disorder 1) – O_2(B)		0.37	
O_2(A:disorder 2) – O_2(B)		1.53	
O_2(B) – O_2(C)	0.08	−0.29	−1.46

$[\uparrow\uparrow\uparrow-\downarrow\downarrow\downarrow-]_\infty$ ($\uparrow$: $S = 1$) was expected and ferromagnetic trimer clusters were coupled with antiferromagnetic interaction, though the implied trimer was not so clear. Anyhow, it was expected that magnetic behaviour from only direct interaction between O_2 molecules will be not remarkable, since magnitude of the all evaluated magnetic interactions was very small. On the other hand, the experimental studies had reported interesting magnetic behaviour at about $T = 60$ K. We could not explain such the experimental results. Indirect interaction between metal complex (host) and O_2 molecules (guest) will be worth considering and it will be mentioned in our following studies.

4. Position of oxygen molecules in cavity of crystals

4.1. The details for molecular simulations

In addition to development of synthetic technique, theoretical calculation methods have also progressed and they enable us to evaluate number of adsorbed molecules with MD simulation methods. In addition, position of each O_2 molecule can be calculated. Furthermore, MO methods can give us information of orientation of molecules by using geometry optimization technique. Our calculations in this paper will give a theoretical insight of gas-adsorption behaviour. Our systematic procedures have the following two steps: (Step 1) Decision of parameters for MD. simulations (Step 2) Execute MD simulation.

Here, let us start Step 1 and this step is important to the following steps. A series of grand canonical Monte Carlo (GCMC) simulations of single-gas adsorption were performed in order to elucidate the experimental results. For reliable simulation, force-field (FF) condition must be decided carefully. Suitable FF types on each atom in both frameworks and adsorbed molecules were assigned manually. Through this simulation a general FF parameter sets of "UNIVERSE_OFF 1.02" in the CERIUS2 program package were employed. The parameter sets include a set of hybridization atomic bond radii, a set of hybridization angles, van der Waals (VDW) parameters, torsional and inversion barriers and a set of effective nuclear charges.

For charge densities on each atom in both frame and adsorbed molecules, additional computations were performed with the UHF and UB3LYP methods. During our calculations LanL2DZ and 4-31G basis sets for metal complex and O_2 molecules were employed, respectively. The broken-symmetry procedure were used in order to realize spin polarized states. GAUSSIAN 98 program package was used for these calculations [17]. The evaluated charge densities for metal complex were summarized in Table 2, where indices for each atom were already defined in Fig. 1a. In addition, the obtained spin densities by UHF and UB3LYP methods were illustrated in Fig. 2a and b, respectively. Here, total spin states were fixed to singlet ($\uparrow$–$\downarrow$). In the results by the UHF method, spin densities on two pyrazine groups were overestimated by huge spin contamination. Thus, we concluded that the UHF method without post-HF procedures was not suitable. On the other hand, only small spin densities on Rh atoms were given by the UB3LYP method and decreased according to requiring of more severe SCF conversion In this system metal complex will tend to get non-magnetic spin distribution. In the following simulation, we employed charge densities by the UB3LYP methods in order to account Coulomb interaction.

Table 2
Calculated charge densities in each atoms in $Rh_2(bza)_4(pyz)_2$ molecules by UB3LYP methods. Summations to Rh, bza and pyz group were also listed

Atom	Number	Charge densities
Rh	1	0.369
O	2	−0.368
C	3	0.402
C	4	0.213
C	5	−0.401
C	6	−0.293
C	7	−0.285
H	8	0.332
H	9	0.297
H	10	0.297
N	11	−0.078
C	12	−0.256
H	13	0.323
Rh		0.369
bza		−0.241
pyz		0.113

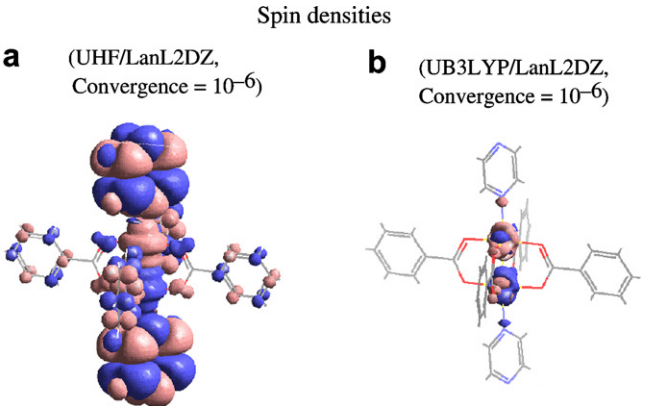

Fig. 2. (a) The evaluated spin densities by using UHF/LanL2DZ (a) and UB3LYP/LanL2DZ (b) methods.

A series of the MC simulation of single-gas adsorption was performed and we employed CERIUS2 program packages for this purpose. Next step was equivalent to Step 2. We have to employ many trial and dispose some initial samplings in order to improve the precision, because MC steps progress by random samplings. Thus, in this study our sampling number is 6000000 and the first 1000000 cycles are discarded.

For guest molecules, a O_2 molecule was employed as radical species with $S = 1$ spin per one molecule. In addition, a carbon dioxide molecule (CO_2) was also focused, since detailed experimental data were also reported by Takamizawa and his co-worker.

4.2. The results for molecular simulations

The MC simulation was carried out in the condition of P (external pressure) = 1 atm and T = 77 K, which is boiling temperature of liquid nitrogen. In Fig. 3a the obtained simulation results were described with cloud of mass density of O_2 molecules. From the results, alignment of O_2 molecules in channels was found. The obtained distribution of O_2 molecules showed structural interaction between host frames and guest molecules. The some experimental studies in the condition of several temperatures were already reported: T = 10 K, 90 K and 190 K. It was reported that uncertainty of spatial position of O atoms turned to be more small in the lower temperature. The simulation results in these temperatures were obtained and their mass cloud of O_2 molecules were illustrated in this figure. Distribution of mass center of O_2 molecules was shrunk and position got more sharp in lower temperature. On the other hand, in higher temperature kinetic motion of O_2 molecules got large. In this simulation temperature dependency of mass distribution is very reasonable.

In order to study the temperature dependence, not only mass distribution but also the number of adsorbed O_2 molecules was also simulated. Schematic calculations in all range of temperature as shown in Fig. 3b, where left and right scales indicated converted values to number (mole-

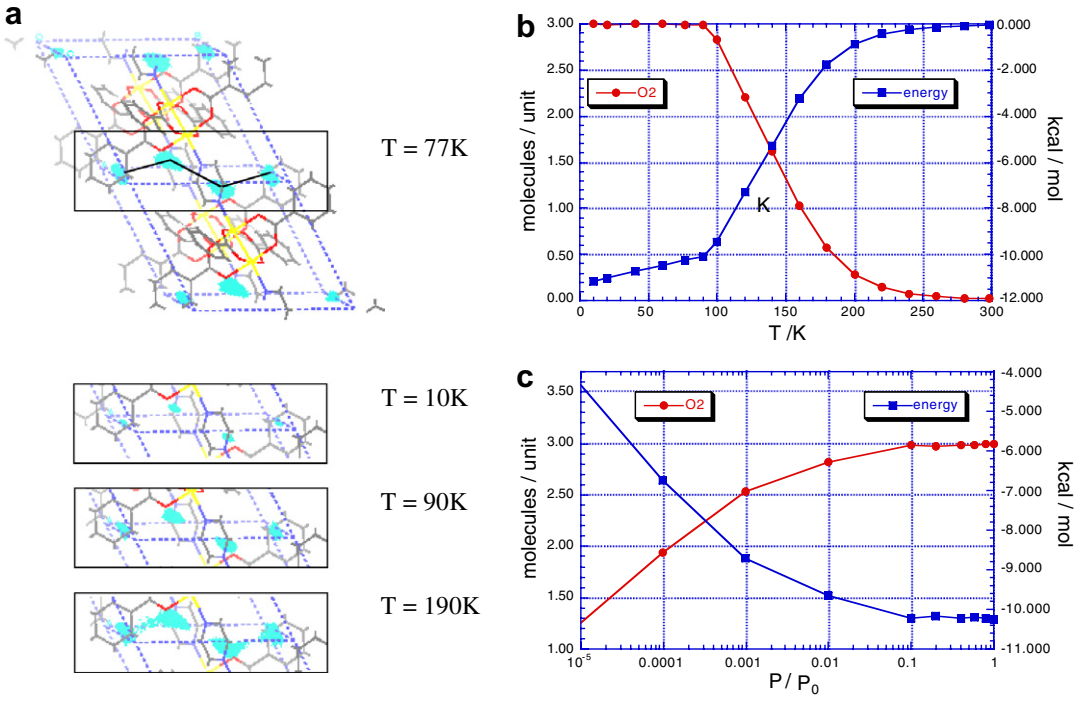

Fig. 3. The results of O_2 adsorption into crystal **2** by using MD simulation. (a) The evaluated cloud of mass densities in condition of various temperature. Dependency of number of adsorbed O_2 and stabilization energies on temperature (b) and external pressure (c).

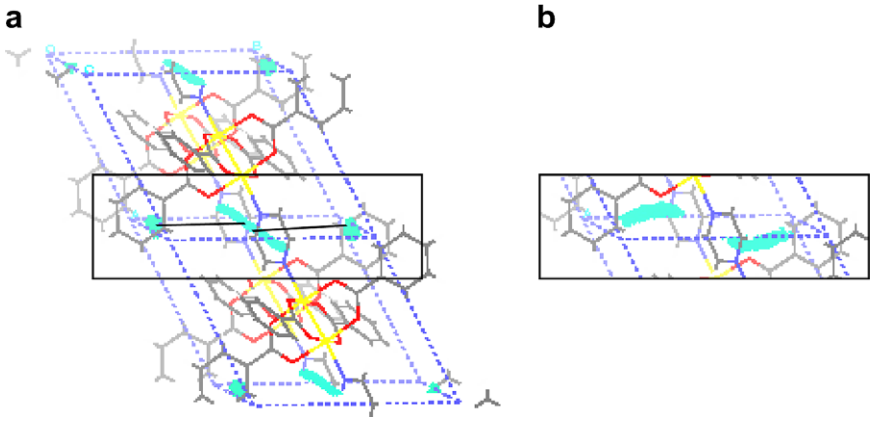

Fig. 4. The results of CO_2 adsorption into crystal **2** by using MD simulation. The evaluated cloud of mass densities by calculation with (a) and without (b) Coulomb interaction.

cules/unit) and stabilization energy (kcal/mol), respectively. The number of adsorption decreased gradually over 100 K and become to nearly zero above 240 K. The saturated value reached about 3.00 molecules of O_2 per 1 unit cell. It was equivalent to experimental reports of 3 molecules/unit at $T = 10$ K.

Table 3
Evaluated number of molecules and stabilization energies for various simulation type

Simulation type	Number of molecules	Stabilization energies
Guest = O_2		
With all interaction	2.99[a]	−10.242[b]
Without only Coulomb interaction	2.99	−10.231
Without only VDW interaction	3.00	−10.204
Guest = CO_2		
With all interaction	2.00	−14.745
Without only Coulomb interaction	1.99	−11.254

[a] Molecules/unit.
[b] kcal/mol.

The external pressure dependence of O_2 adsorption calculated by using molecular simulation was shown in Fig. 3c. In this figures, left scale indicated number of adsorption molecules per one unit cell and right one indicated stabilization energies. The plots were depicted as log-plot of P/P_0 (P: external pressure; P_0: 1 atm). The adsorption values increased and were saturated above $P/P_0 = 0.1$. The saturated values for O_2 molecules reached about 3.00 molecules per one unit cell. In the crystal number of adsorbed gas will be controlled by external pressure effectively.

Here, we tried similar simulation to a CO_2 as guest molecules. Though the O_2 molecules had no charge densities on it, the CO_2 molecules were induced charge distribution because of the structure ($O^{\delta-} - C^{\delta+} - O^{\delta-}$). The simulated results were depicted in Fig. 4a and the cloud

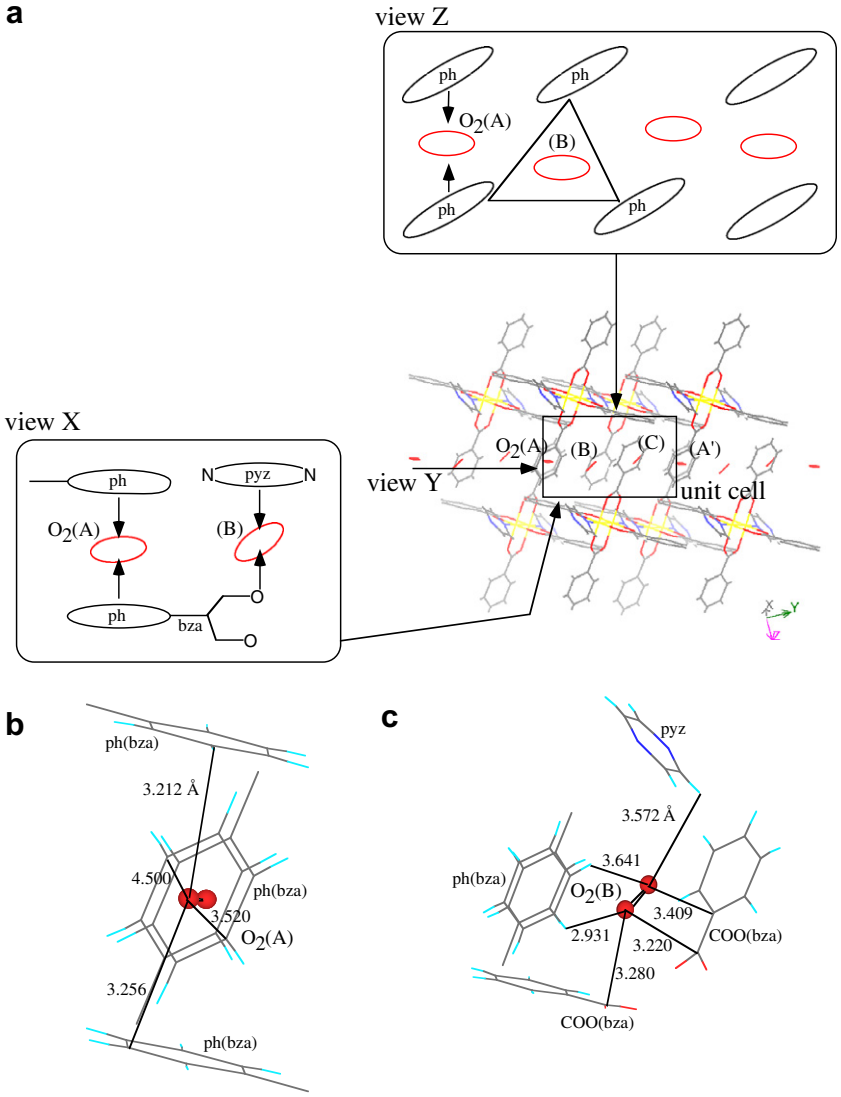

Fig. 5. Orientation of the adsorbed O_2 molecules in the cavities (a) and the detailed spatial interaction for O_2(A) (b) and O_2(B) (c).

of mass densities located in both ends and center in our squire box. The saturated values for CO_2 molecules reached about 2.00 molecules per one unit cell. When we used CO_2 molecules instead of O_2 molecules as guest gas, number of adsorbed gas were reduced. We could first assume that possibility of difference of size of each molecule. We attempted to re-calculate distribution of mass densities by controlling three interactions (hybridization between atoms; van der Waals interaction; Coulomb interaction) in MC simulation procedures. From our calculation it was found that Coulomb interaction was very important for all simulation. For example, the evaluated stabilization energies per one unit cell for CO_2 molecules were −14.745 and −11.254 kcal/mol for with and without Coulomb interaction, though number of CO_2 molecules was equal to each other (2.00 and 1.99), respectively, as summarized in Table 3. In Fig. 4a and b clouds for both simulations were given and it was easily found that style of distribution of CO_2 molecules were so different. The Coulomb interaction could control position of adsorbed molecules in cavities. The calculations of charge densities by using MO methods were essential for CO_2 molecules. However, for O_2 molecules this Coulomb interaction was negligible, since no charge densities were induced because of two same atoms. In addition, simulation for O_2 molecules with and without VDW interaction was carried out. As summarized in Table 3, 2.99 and 3.00 molecules/unit for adsorbed number and −10.242 and −10.204 kcal/mol for stabilization energies were evaluated, respectively. It was concluded that VDW interaction was not important.

5. Orientation of oxygen molecules in cavity of crystals

In the above MD simulation with the interaction parameters evaluated by MO calculations, the obtained cloud of mass densities statistically showed positions of adsorbed molecules. However, in experimental structural studies both position of orientation could be directly measured in the condition of low temperature. Here, we focus on orientation as well as potion of each adsorbed O_2 molecule.

First, we investigated local interaction between host frames and guest molecules. Fig. 5a shows how each O_2 molecule located in cavities. Simplified illustration in this view in *X*- and *Z*-axes will help us to understand spatial contact. It is found that O_2(A) and O_2(B) are suppressed by two phenyl groups and pyrazin – carboxyl groups in view *X*, respectively. In addition, in view *Z* two O_2 molecules occupy the space between two phenyl groups and among three phenyl groups, respectively. Thus, spatial pockets for each O_2 molecule are already prepared. In Fig. 5b and c, coordination distances among O_2(A) and O_2(B) are summarized. The range of these distances was about 3.0 Å.

Here, let us discuss the orientation for O_2(A) mainly. The nearly contacted phenyl groups were replaced by four benzene molecules in order to execute theoretical calculation effectively as shown in Fig. 6a. There were two pairs of two face-to-face benzene molecules and two planes (plane 1, plane 2) could be defined. With our rough estimation the O_2 molecules were suppressed in intersection of two planes, since O_2 molecules will avoid π-electrons on benzene molecules. Indeed, O_2 molecules in experimental

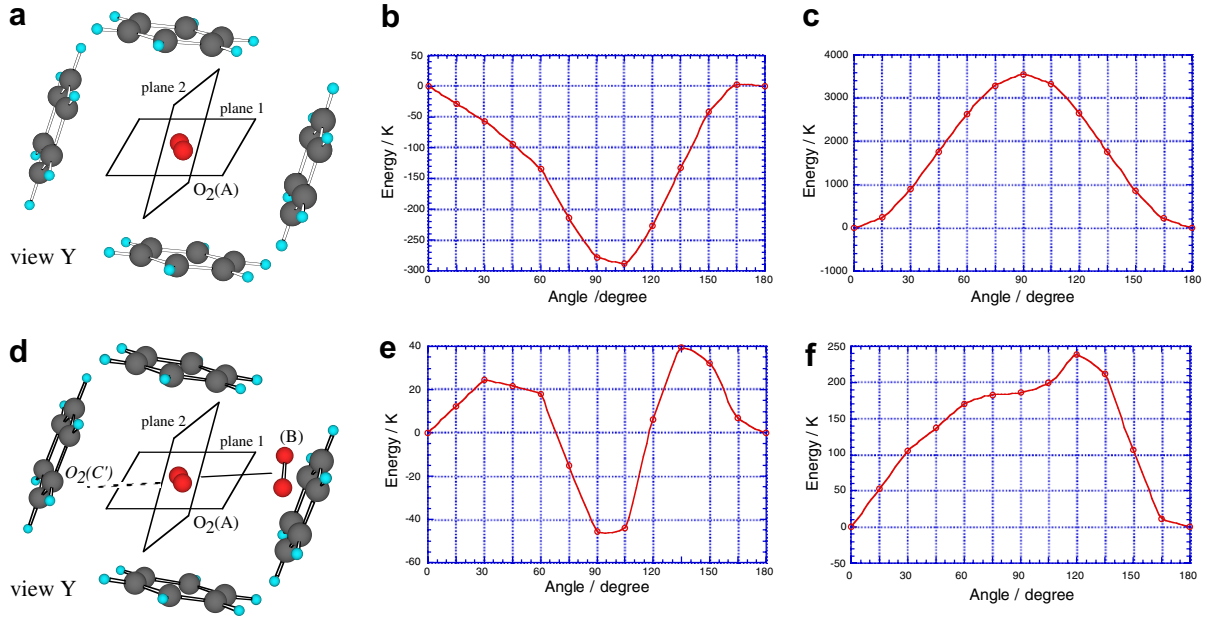

Fig. 6. Simple model for O_2(A) molecule which was surrounded by four benzene molecules (a). Variation of total energies by UB3LYP method by rotating O_2(A) molecule on plane 1 (b) and plane 2 (c). In addition, simple model for O_2(A) molecule which was surrounded by not only four benzene molecules but also the one/two next O_2 molecules (d). Variation of total energies for the systems of O_2(A)–O_2(B) (e) and O_2(C″)–O_2(A)–O_2(B) (f).

studies located in these orientation ($\theta_1 = 17,\ \theta_2 = 0$). In order to ensure this speculation several geometry was made by rotating one O_2 molecule in each plane. Energy calculations were carried out by using UB3LYP method and angle dependency was illustrated in Fig. 6b and c. Here, zero-points of energy were defined to the evaluated total energies in the conformation without rotation. Unit of energies a.u. (atomic unit) can be convert to another unit: 1 a.u. = 27.211 eV = 219470 cm^{-1} = 315771 K. The last relation (a.u. – K) was very useful in case of studying freedom of orientation to temperature. For rotation in plane 1, the most stable orientation was given in $\theta_1 = 105$, though original structure of $\theta_1 = 17$ was concluded to be very unstable. For rotation in plane 2, original structure $\theta_2 = 0$ was very stable and consistent to experimental results. These orientations were much steady, since the energy scale for plane 2 was very large than temperature range (up to room temperature). On the other hand, potential valley in plane 1 was not so large and rotation of the O_2 molecule was rather free.

In addition, let us locate another O_2(B) molecule besides the target O_2(A), which was reasonable because of existence of O_2 chains in cavities. In Fig. 6d, the rotation model with the next O_2 molecule O_2(B) was illustrated. Similar calculations carried out and transition of energies were illustrated in Fig. 6e. Judging from this curvature, orientation around $\theta_1 = 0$ become more stable and local minimum region ($\theta_1 = 0$–30, 135–180) appeared. It was natural that we expected the most stable orientation when second O_2 molecule (italic-face O_2(C″) in Fig. 6d) was also introduced in the opposite site. Fortunately, the obtained energy curvature concluded that global minimum appeared in this situation as shown in Fig. 6f. Interaction between target O_2 molecule and two the next O_2 molecules in the chain was important, though that between target O_2 molecule and four benzene molecules was not negligible. Theoretical calculations could reproduce experimental facts.

6. Concluding remark

Adsorption properties of magnetic species in nano-porous crystals were studied theoretically. The crystal **2** was one of very suitable systems for our purpose. Especially, a O_2 molecule ($S = 1$) for adsorbed magnetic radical species was treated. Weak magnetic interaction between O_2 molecules in cavities existed and two types of magnetic interaction (ferro- and antiferro-magnetic) made alignment of trimer spin structure.

In addition, this study demonstrated importance of nano-porous organometallic conjugation systems for gas adsorption by using MD simulation and MO calculations. These theoretical calculations could decide not only position but also orientation of the adsorbed O_2 molecules. For the former, cloud of mass densities of O_2 molecules by MD simulation showed stacking style in nano-pores statistically and number of adsorbed gas was estimated to be 3.00 molecules/unit. The distribution of O_2 molecules get sharper in case of lower temperature. These results could explain experimental results by Takamizawa and his coworkers. For the latter, orientation of the O_2(A), which was surrounded four phenyl groups, was stabilized by contribution of the two next O_2 molecules as well as phenyl groups. All results in this study will lead new approach to arrangement of organic spin radical sources.

is one of the main challenges in molecular material science in order to utilise them for information processing and information storage [8]. Furthermore, the design of spin-crossover compounds with multi-function, supramolecular structure and porous materials, has been noted because of leading specific magnetic or optical properties [9,10]. For some iron(II) spin-crossover (high-spin ($S = 2$) ↔ low-spin ($S = 0$)) compounds, light-induced low-spin → high-spin conversion can be observed by green light illumination into a d–d or MLCT (metal-to-ligand charge transfer) absorption band at temperatures well bellow the thermal transition temperature. A mechanism for this phenomenon, denoted as "light-induced excited spin state trapping" (LIESST), has been proposed [11,12]. The development of novel compounds exhibiting LIESST is one of the main challenges in this field [7,13,14]. The LIESST compounds can be used as optical switching molecular devices, and various functional materials including the optical switches can be constructed.

Here we focused on the spin-crossover iron(II) compounds in order to control liquid crystals not only by temperature but also magnetic field and photo-illumination. The spin-crossover iron(II) compounds exhibit spin conversion between diamagnetism ($S = 0$) and paramagnetism ($S = 2$), and the LIESST effect. The design of metallomesogens containing spin-crossover iron(II) center stimulates producing unexpected advanced materials by combining spin-crossover and LIESST with liquid-crystal properties [15,16].

The iron(II) compounds $[Fe(1C16\text{-}O\text{-}bzimpy)_2](BF_4)_2$ (**1**) and $[Fe(2C16\text{-}bzimpy)_2](BF_4)_2$ (**2**) were designed in order to construct a spin-crossover and LIESST material with liquid-crystal properties, where 1C16-O-bzimpy and 2C16-bzimpy are tridentate ligands (Fig. 1). Because the iron(II) compound $[Fe(bzimpy)_2](ClO_4)_2 \cdot 0.25H_2O$ exhibits spin-crossover above room temperature ($T_c\uparrow = 403$ K and $T_c\downarrow = 415$ K), the ligand bzimpy of the complex was modified as long alkyl substituent derivatives [17] (Fig. 2).

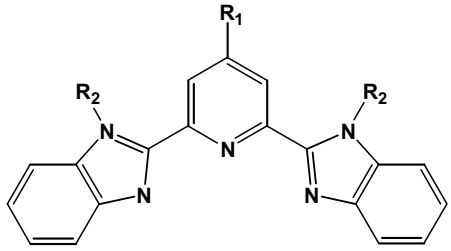

Fig. 1. Structure of the ligands.

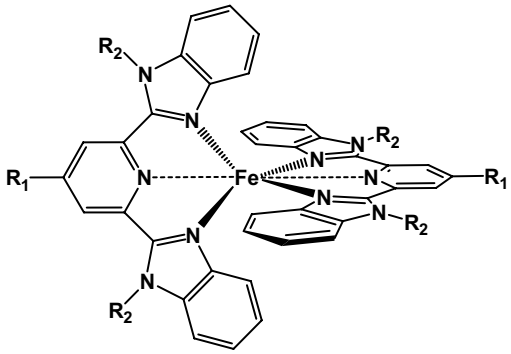

Fig. 2. Chemical structure of the compounds **1** and **2**.

2. Experimental

2.1. Preparation of the ligands [18,19]

2.1.1. Preparation of 2,6-bis(benzimidazol-2′-yl)pyridine (*bzimpy*)

2,6-Pyridinedicarboxylic acid (5.0 g, 27.5 mmol) and *o*-phenylenediamine (6.49 g, 58.7 mmol) were suspended in phosphoric acid (85%, 55 ml). The mixture was kept at 210–220 °C for 6 h with vigorous stirring. After cooling to room temperature, the mixture was poured into ice-water (400 ml), and the precipitate was filtered off and added to hot 10% aqueous Na_2CO_3 solution (340 ml). The resulting solid was filtered off and added to hot methanol saturated with Na_2CO_3. Then the solution was diluted with water (100 ml) and acidified with 15% hydrochloric acid to pH 1. The white precipitate was filtered off and extracted several times with boiling methanol. The collected extracts were evaporated until precipitation began. The colorless product was filtered and dried under vacuum; yield: 3.9 g (42%); white solid. ^{1}H NMR (DMSO): $\delta = 8.45$ (d, $J = 8.13$ Hz, 2H), 8.31 (*t*, $J = 7.53$ Hz, 1H), 7.84–7.82 (m, 4H), 7.44–7.42 (m, 4H). 2,6-Bis(benzimidazol-2′-yl)-4-hydroxypyridine (**OH-bzimpy**) was prepared in the same way as **bzimpy**; yield: 6.3 g (71%), white solid. ^{1}H NMR (DMSO): $\delta = 7.91$ (s, 2H), 7.86–7.84 (m, 4H), 7.49–7.46 (m, 4H).

2.1.2. Preparation of 2,6-bis(benzimidazol-2′-yl)-4-hexadecyloxypyridine (*1C16-O-bzimpy*)

OH-bzimpy (1.0 g, 3.06 mmol) and K_2CO_3 (0.64 g, 4.58 mmol) were mixed in DMF (35 ml). The mixture was stirred at 80 °C. After 30 min, 1-bromohexadecane (1.40 ml, 4.58 mmol) was added and stirred overnight at 80 °C. The solution was evaporated and the residue was recrystallized from $CHCl_3$; yield: 0.99 g (62%), white solid. ^{1}H NMR ($CDCl_3$): $\delta = 7.98$ (s, 2H), 7.89–7.87 (m, 2H), 7.50–7.48 (m, 2H), 7.33–7.31 (m, 4H), 4.15 (t, $J = 6.49$ Hz, 2H), 2.17–1.22 (m, 30H), 0.88 (t, $J = 6.98$ Hz, 3H).

*2.1.3. Preparation of 2,6-bis(N-hexadecylbenzimidazol-2′-yl)pyridine (**2C16-bzimpy**)*

NaH (oil dispersion, 60%: 0.51 g, 12.85 mmol) was washed with *n*-hexane and then suspended in dried DMF (20 ml) under Ar atmosphere. To this suspension was added **bzimpy** (1.0 g, 3.21 mmol), and the mixture was stirred and heated to 80 °C for 2 h. 1-Bromohexadecane (4.31 ml, 12.9 mmol) in DMF (20 ml) was added dropwise and then heated to 100 °C. After being cooled room temperature, the solution was poured into 10% aqueous NH_4Cl (100 ml), and then extracted with $CHCl_3$. The extract was washed with water and aqueous NaCl solution, and then dried by $MgSO_4$. The solution was evaporated, and the residue was purified by column chromatography on silica gel with ethyl acetate/hexane; yield: 0.61 g (50%), white solid. ^{1}H NMR ($CDCl_3$): 8.32 (d, $J = 7.93$ Hz, 2H), 8.05 (t, $J = 8.10$ Hz, 1H), 7.88–7.86 (m, 2H), 7.47–7.45 (m, 2H), 7.36–7.31 (m, 4H), 4.70 (t, $J = 7.32$ Hz, 4H), 1.75–1.00 (m, 60H) 0.88 (t, $J = 6.52$ Hz, 6H).

2.2. Preparation of the iron(II) compounds

*2.2.1. Preparation of [Fe(1C16-O-baimpy)$_2$](BF$_4$)$_2$ (**1**)*

To a solution of **1C16-O-bzimpy** (0.2 g, 0.36 mmol) $CHCl_3$/MeOH (20 cm^3) was added MeOH solution (10 cm^3) of $FeCl_2 \cdot 4H_2O$ (0.036 g, 0.18 mmol) and $NaBF_4$ (0.040 g, 0.36 mmol). The reaction mixture was stirred and refluxed for 30 min. The resulted solution was concentrated to precipitate the product. The red-purple product was collected by filtration and dried in vacuo; yield: 0.35 g (72%). *Anal*. Calc. for $C_{70}H_{90}B_2F_8FeN_{10}O_2$: C, 62.23; H, 6.86; N, 10.37. Found: C, 62.30; H, 6.90; N, 10.40%.

*2.2.2. Preparation of [Fe(2C16-bzimpy)$_2$](BF$_4$)$_2$ (**2**)*

To a solution of **2C16-bzimpy** (0.2 g, 0.40 mmol) $CHCl_3$/MeOH (20 cm^3) was added MeOH solution (10 cm^3) of $FeCl_2 \cdot 4H_2O$ (0.040 g, 0.20 mmol) and $NaBF_4$ (0.044 g, 0.40 mmol). The reaction mixture was stirred for a few minutes. The resulted solution was concentrated to precipitate the product. The red-purple product was collected by filtration and dried in vacuo; yield: 0.46 g (65%). *Anal*. Calc. for $C_{102}H_{154}B_2F_8FeN_{10}$: C, 70.01; H, 8.87; N, 8.00. Found: C, 70.00; H, 8.86; N, 8.07%.

2.3. Measurements

Elemental analyses of carbon, hydrogen, and nitrogen were carried out at The Service Center of Elemental Analyses of Kyushu University.

^{1}H NMR were measured on a Bruker AVANCE SERIES DPX 400 instrument operating at 400 MHz (using the deuterated solvent as the lock and the residual solvent or tetramethylsilane as the internal reference).

Magnetic susceptibilities of ground samples were measured on a Quantum Design MPMS-5S. Samples were put into a gelatin capsule, mounted inside the straw, and then fixed to the end of the sample transport rod. Illumination experiment was done using an Hg–Xe lamp ($\lambda = 550$ nm, 1.5 mW/cm^2) as a light source. The light passing through IR and green filters was guided via an optical fiber into the SQUID magnetometer. The sample was placed on the edge of the optical fiber.

The Mössbauer spectra (isomer shift versus metallic iron at room temperature) were measured using a Wissel MVT-1000 Mössbauer spectrometer with a ^{57}Co/Rh source in the transmission mode. All isomer shifts are given relative to α-Fe at room temperature. The measurements at low temperature were performed with a closed-cycle helium refrigerator cryostat (Iwatani Co., Ltd.)

Differential scanning calorimetry (DSC) thermal analysis was carried out on a SHIMADZU DSC50 differential scanning calorimeter.

X-Ray powder diffraction (XRD) studies were performed on a Rigaku X-ray diffractometer RAD-2A with a 2.0 kW Cu Kα X-ray.

Optical polarized microscopy was carried out on a Nippon Chemical Industrial corporation polarization microscope OPTICAL POL with a Yanagimoto factory MODEL MP-J3 micro melting point meter.

3. Results and discussion

3.1. Structure of the compounds

Single crystals of the compounds **1** could not be grown, therefore geometry optimization for the compounds were performed by computer simulation. Boča et al. reported that the iron atom is hexacoordinated by six nitrogen atoms belonging to the two tridentate ligands, which are located perpendicular to each other [17]. In consideration of the structure of the spin-crossover iron(II) compounds, that of the compound **1** has been optimized. The resulted geometry structure has been shown in Fig. 3. The long alkyl chains $C_{16}H_{33}O$ are stuck out of 4 position in the pyridine moiety, and the total is rod-like structure. On the other hand, the single crystal X-ray analysis was done for the iron(II) compound [Fe(2C10-bzimpy)$_2$](BF$_4$)$_2$ (**2′**) instead of the compound **2**, but the *R* value of the X-ray analysis did not decrease. However, we could estimate about the structure of **2** from that of **2′**. Fig. 3 shows the estimated structure of **2**. The iron atom is also hexacoordinated by six nitrogen atoms belonging to two tridentate ligands, which are located perpendicular to each other. The long alkyl chains $C_{16}H_{33}$ are stuck out of the N position in the imidazol moiety. Two long chains lengthen for one bzimpy plane up and down, and four long chains for one molecule intersect each other.

3.2. Differential scanning calorimetry (DSC)

Phase transition enthalpies were measured by carrying out DSC thermal analysis for the compounds **1** and **2**. The results of the DSC for **1** and **2** are shown in Table 1.

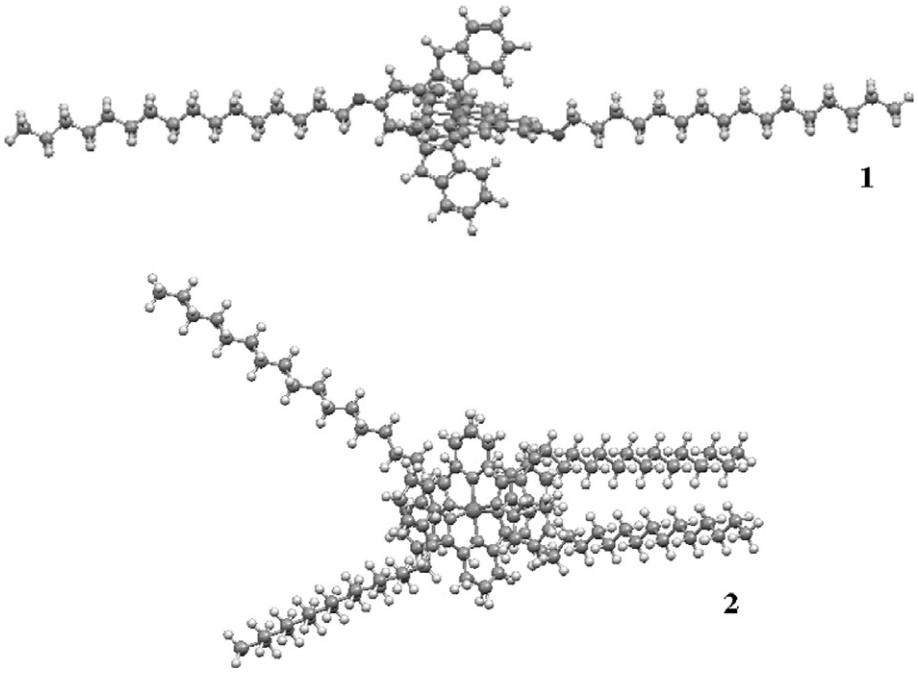

Fig. 3. Computer simulation of the molecular structure of the compounds **1** and **2**.

Table 1
Phase transition temperatures for **1** and **2**

Compound	Transition temperature (K)		SCO	*T* (LIESST)
	Cr–LQ	LQ–L		
1	547	607	225	47
2	322	525		

Cr is solid state, LQ is liquid crystal state and L is liquid state.

Two peaks were observed for **1** at 547 K and 607 K. The DSC peak at 547 K ($\Delta H = 27$ kJ mol^{-1}) corresponds to a crystal-mesophase transition, and that at 607 K is assigned to a mesophase-liquid transition. Two peaks were also observed for **2** at 322 K and 525 K. The first peak at 322 K ($\Delta H = 40$ kJ mol^{-1}) refers to a crystal-mesophase transition, and the second peak at 525 K is assigned to a mesophase-liquid transition. The compounds **1** and **2** exhibit two endothermic peaks in the heating cycles. A large peak at low temperature is assigned to the solid-mesophase transition, and a small peak at high temperature, assigned to mesophase-liquid transition. DSC were measured in the temperature range from crystal to liquid crystal on the warming and cooling mode reversibly. On cooling, the transition temperatures from mesophase to crystal for the compounds **1** and **2** are 540 K and 313 K, respectively. The free ligands, **1C16-O-bzimpy** and **2C16-baimpy**, exhibit only one peak, being assigned to solid-to-liquid transition.

3.3. Polarizing optical microscopy (POM)

The mesophase was studied by hot-stage polarized optical microscopy (POM) for **2**, and the texture of the liquid crystal state was observed by optical microscopy. The compound **2** is in the solid state at room temperature. Upon heating on the stage of the optical microscope under polarized light, the compounds exhibited mesomorphism. On heating, the compounds undergo a transition from the solid to birefringent viscous fluid, and exhibited a characteristic mosaic texture. When the compounds were cooled from the isotropic liquid to room temperature, the same mosaic texture as before heating was observed. An example of the texture under crossed polarizers for **2** is shown in Fig. 4. The identification of the phase of the liquid crystal

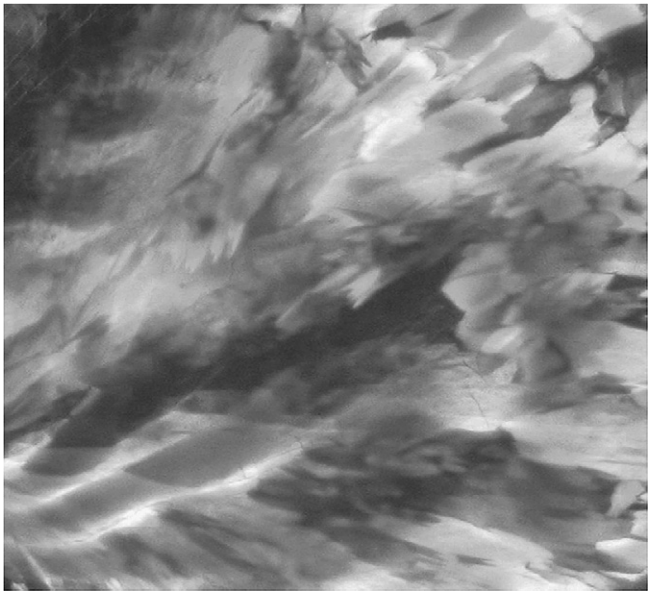

Fig. 4. Texture of the compound **2** under crossed polarizers at 330 K.

state based on the texture observed by optical microscopy was not possible.

3.4. Powder X-ray diffractions

Temperature-dependent X-ray diffraction measurements were carried out to confirm this mesophase. Fig. 5 shows the powder X-ray diffraction patterns of the crystal and the mesophase states for the compound **2** observed in the temperature range from 293 K to 328 K. A sharp reflection in the small-angle ($2\theta = 5.8°$) with *d*-spacing of 15.3 Å was detected at 293 K. This *d*-spacing may correspond to the distance between the iron atom and the long alkyl chain ($l = 16$ Å). At 328 K, the peak at $2\theta = 5.8°$ decreased and a new peak appeared at $2\theta = 2.7°$ ($d = 32.7$ Å). The peak at $2\theta = 19$–$23°$ ($d = 4.6$–3.8 Å) observed below 320 K becomes broad at the same time. The formation of the mesophase is completed at 323 K in accordance with the result observed by DSC.

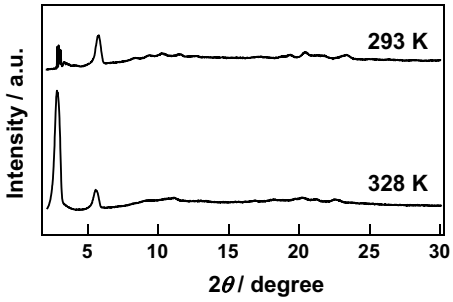

Fig. 5. Temperature dependence of powder XRD pattern of the compound **2**.

3.5. Magnetic properties

Iron(II) spin-crossover compounds with crystal-mesophase transition should be in the low-spin state at room temperature, i.e. have high T_c. We have first focused on the iron(II) compound $[Fe(bzimpy)_2](ClO_4)_2 \cdot 0.25\ H_2O$ with high T_c. Boča et al. have reported that the iron(II) compound exhibits spin-crossover above room temperature ($T_c\uparrow = 415$ K and $T_c\downarrow = 403$ K) [17]. The spin-crossover phenomenon between the high-spin and low-spin states for the compound **1** was followed by measurements of the molar magnetic susceptibility χ_m as a function of temperature. The $\chi_m T$ versus T plots for **1** are given in Fig. 6. The $\chi_m T$ value for the compound **1** is equal to 2.1 $cm^3\ K\ mol^{-1}$ at 50 K, which shows that about 64% of the iron(II) ions remain in the high-spin state.The decrease of the $\chi_m T$ value below 50 K is due to zero-field splitting. On warming, the $\chi_m T$ values were almost constant from 50 K to 100 K, then gradually increased near the spin transition temperature $T_{1/2} = 225$ K. The $\chi_m T$ value at 300 K is ca. 3.3 $cm^3\ K\ mol^{-1}$, showing that the spin transition from the low-spin to the high-spin state is induced. When the samples of the compound **1** were illuminated at 5 K for

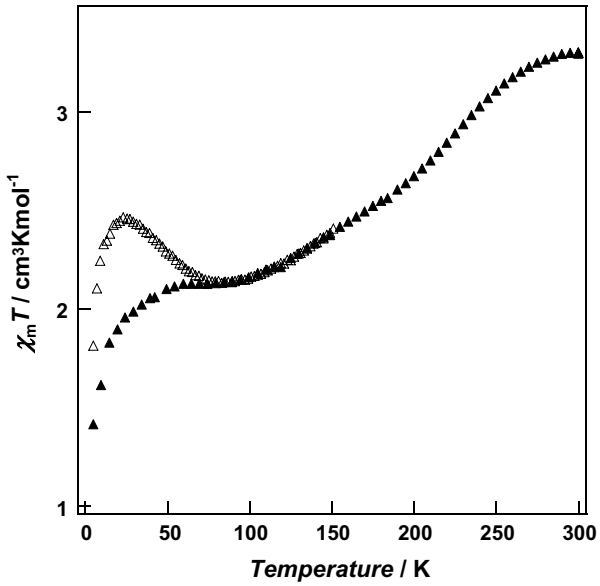

Fig. 6. $\chi_m T$ vs. T plots for the compound **1** (▲). $\chi_m T$ vs. T plots for LIESST experiment were recorded in the warming mode (△).

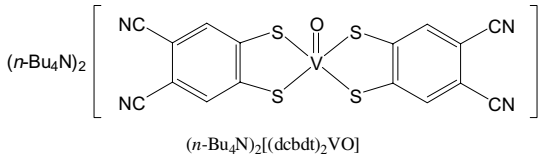
1 h, the $\chi_m T$ value was increased (Fig. 6). The change in the $\chi_m T$ value persisted for many hours, even after the illumination was stopped. This suggests that the transition from the low-spin state to the high-spin state can be induced by illumination. The relaxation temperature of the LIESST effect is defined as T (LIESST) [20], the temperature dependence of $\chi_m T$ after illumination shows that the $\chi_m T$ value decreases with the increase in temperature and that the thermal relaxation to the ground state occurs. The T (LIESST) is 47 K, the compound **1** can exhibit photo-switching below 47 K. About 12% of the metastable high-spin fraction were induced by illumination. The $\chi_m T$ value for **2** was 0 $cm^3\ K\ mol^{-1}$ in the temperature range of 5–400 K. Spin-crossover was not observed, and the compound **2** was in the low-spin state ($S = 0$). The Mössbauer spectra were also measured in the temperature range between 80 K and 300 K. Mössbauer spectra at 80 K and 300 K show a doublet peak with quadrupole-split doublet (quadrupole-splitting $\Delta Q = 0.42$ mm s^{-1}, isomer shift $\delta = 0.34$ mm s^{-1} at 80 K, and $\Delta Q = 0.38$ mm s^{-1}, $\delta = 0.26$ mm s^{-1} at 300 K) representing the low-spin state. The compound **2** exhibits the crystal-mesophase transition at 322 K, but the compound was in the low-spin state even above 322 K.

We are now measuring the magnetic and mesophase properties of the iron(II) compound $[Fe(3C16\text{-}O\text{-}bzimpy)_2](BF_4)_2$ (3C16-O-bzimpy = 2,6-bis(*N*-hexadecylbenzimidazol-2′-yl))-4-hexadecyloxypyridine eventually exhibiting a spin-crossover behavior induced by mesophase transition or a mesophase transition induced by LIESST.

4. Conclusion

The iron(II) compounds **1** and **2** with long alkyl chains have been synthesized, the properties of these compounds



were characterized. The compounds **1** and **2** exhibited liquid-crystal properties which were confirmed by DSC, XRD diffractions, and texture under crossed polarizers. The compound **2** was in the low-spin state. The compound **1** exhibited spin-crossover and LIESST phenomena, i.e. three physical properties, spin-crossover, LIESST effect and liquid-crystal properties, can coexist in a single compound. Geometrical flexibility in the molecules is very important in order to achieve co-occurrence of various physical properties in the functional molecular-based materials. We believe that our approach, i.e., the co-occurrence of spin-crossover, LIESST and liquid-crystal properties, can be widely applied, not only in the design of LIESST compounds with liquid-crystal properties but also in the design of a variety of optically switchable molecular compounds.

$(n\text{-}Bu_4N)_2[(dcbdt)_2VO]$

Scheme 1.

2. Experimental

$(n\text{-}Bu_4N)_2[(dcbdt)_2VO]$ was prepared in accordance with the literature [9]. Glass substrates (Matsunami, Japan) were washed with pure water, acetone and dried under UV irradiation before fabrication. Positively charged polystyrene particles (214 ± 19 nm, trimethylammonium latex, Merck) were used for absorption. Fig. 1 shows schematic fabrication process of deposition by colloidal lithography.

Ultrasonic irradiation of glass substrates in the solution of particles was performed for 5 min before immersion. Immersion time was 30 min to allow the absorption to reach saturation. Excess particles were removed during the substrate dipping in 98 °C pure water for 30 s. The substrates were then dipped in cold water and dried with clean air. Monolayered particles were obtained on the substrate (Fig. 1a). Cast process of the dithiolene metal complex solution was performed as follows. Firstly 0.13 ml of an acetonitrile solution of the metal complex (45.4 mg/l) was cast on a glass substrate in a vacuum desiccator. Under reduced pressure of 100 mm Hg, the solvent on the substrate was evaporated within 5 min. After the solvent evaporation the particles were selectively removed by an adhesive tape (Fig. 2c). Finally ring structure deposits were obtained on the substrate (Fig. 2d).

The deposits were examined with an analytic scanning electron microscope (JSM-6360LA, JEOL Ltd.), an atomic force microscope (VN-8000, Keyence Corp.) and a scanning probe microscope (SPI 3700, SII Nanotechnology Inc.).

3. Results and discussion

In fabricating the ordered domains of molecules, controllability of the adsorption of polystyrene particles is important because the adsorbed particles are used as a template of ring structures. First we examined the relationship between particle concentration and surface coverage. Surface coverage was measured as an area of particles divided by total area. Fig. 2a shows a SEM image of the substrate surface after immersion in particle concentration of 1% (by weight). Multilayered particles were observed after rinsing of excess particles in pure water. When particle concentration of 0.1% (by weight) was used for immersion, a particle monolayer film of coverage 0.30 was observed (Fig. 2b). Below this concentration, such as particle concentration of 0.01% (by weight), particles did not uniformly cover a substrate surface and only gave particles islands (Fig. 2c).

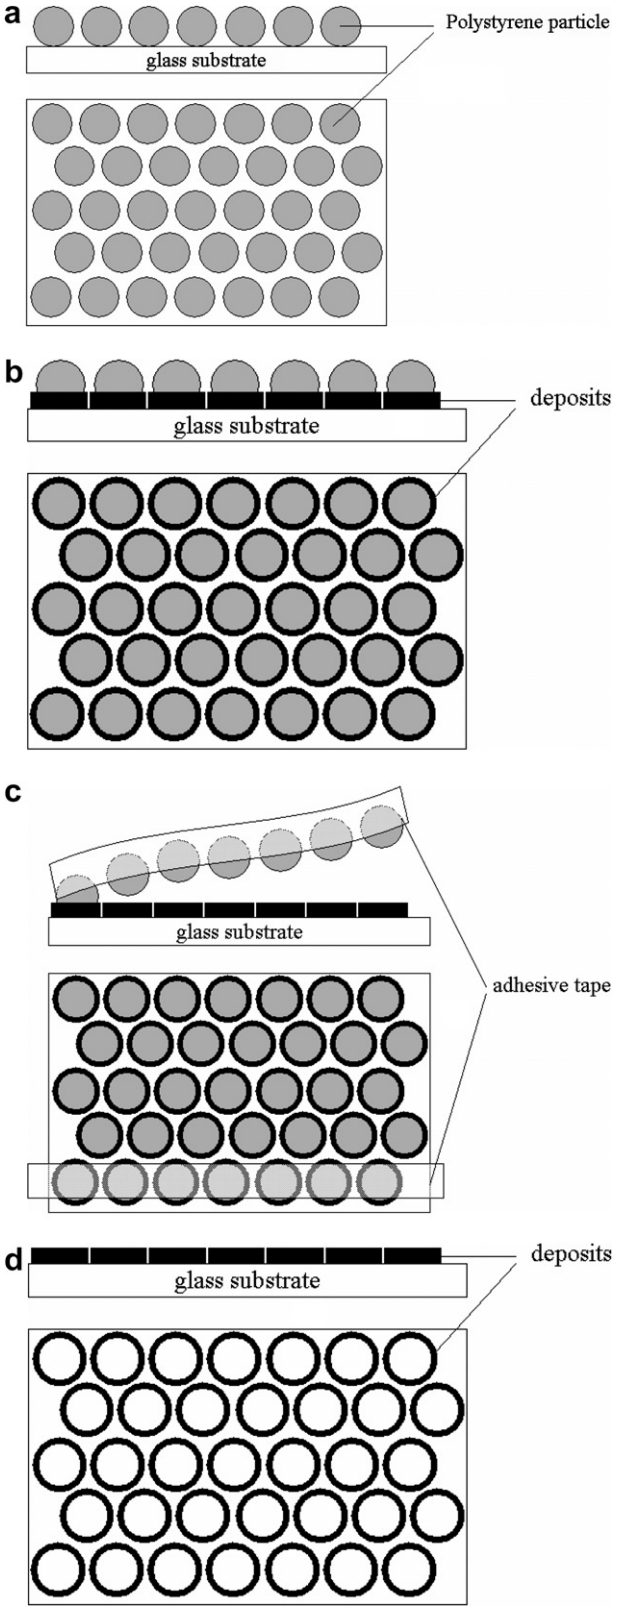

Fig. 1. Schematic side and top view illustrations of the fabrication process of nano-scale rings using colloidal lithography: (a) adsorption of polystyrene particles on a glass substrate, (b) deposition obtained by cast of the metal complex solution and rapid solvent evaporation, (c) removal of the particles by an adhesive tape and (d) deposits having regulated size and position.

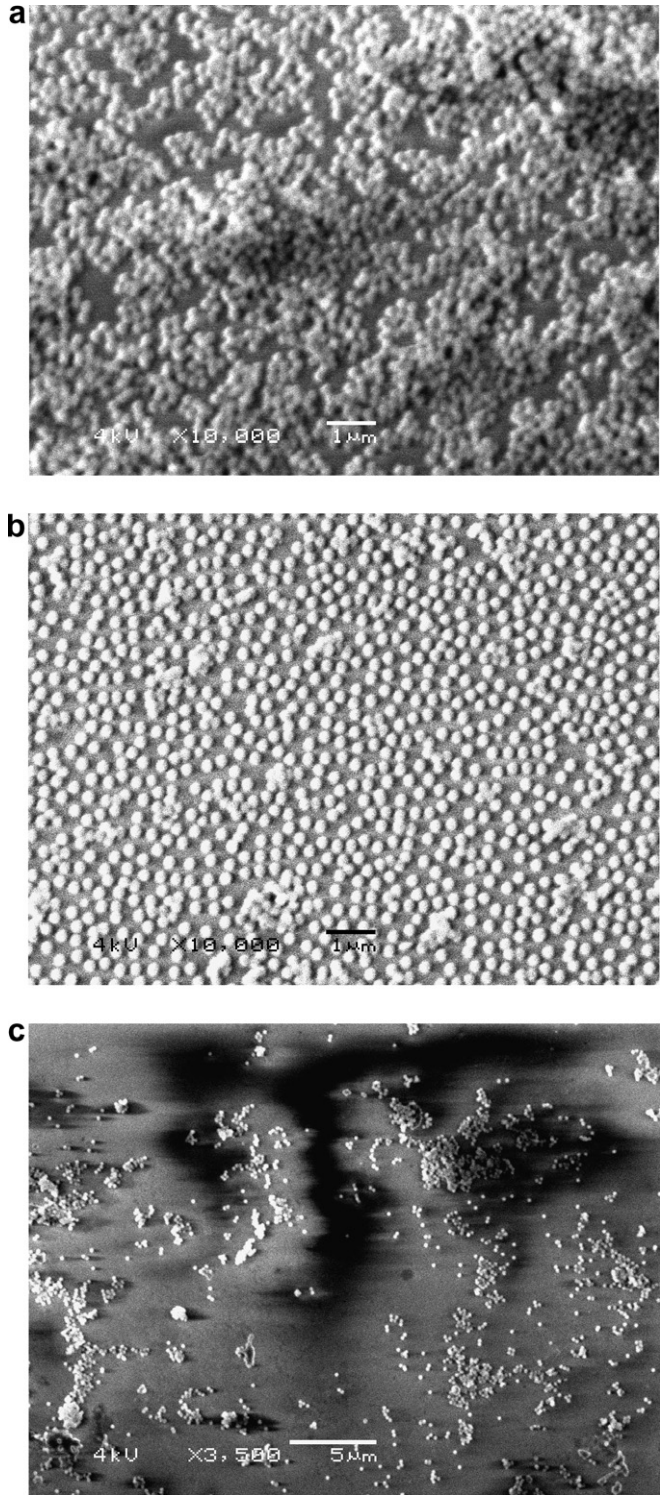

Fig. 2. Particle concentration dependence of adsorbed particles distribution: (a) 1 wt% (b) 0.1 wt% and (c) 0.01 wt% concentration, respectively.

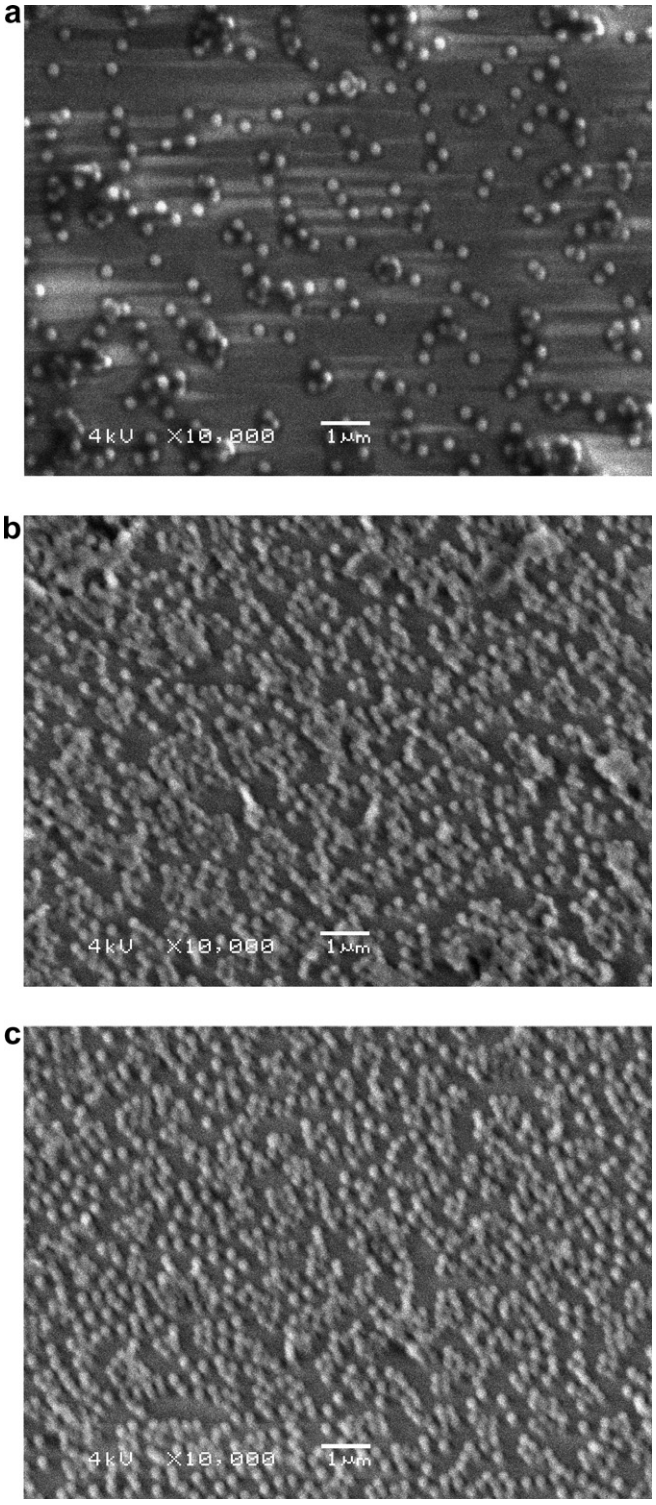

Fig. 3. Acetonitrile evaporating time dependence of adsorbed particles expansion: (a) 20 min, (b) 10 min and (c) 5 min evaporating time, respectively.

Second we examined the relationship between exposing time of particles to acetonitrile and their appearance change because polystyrene is known to adsorb commonly used organic solvents. When solvent evaporating time over 20 min under ambient pressure, 120% expansion of particles and particle aggregation was found (Fig. 3a).

This aggregation of the particles could be explained as follows. During solvent exposure the particles absorbed the solvent and changed their shape to expand their diameter. This shape change reduced the adhesive force to the substrate surface. The aggregation of particles on the sur-

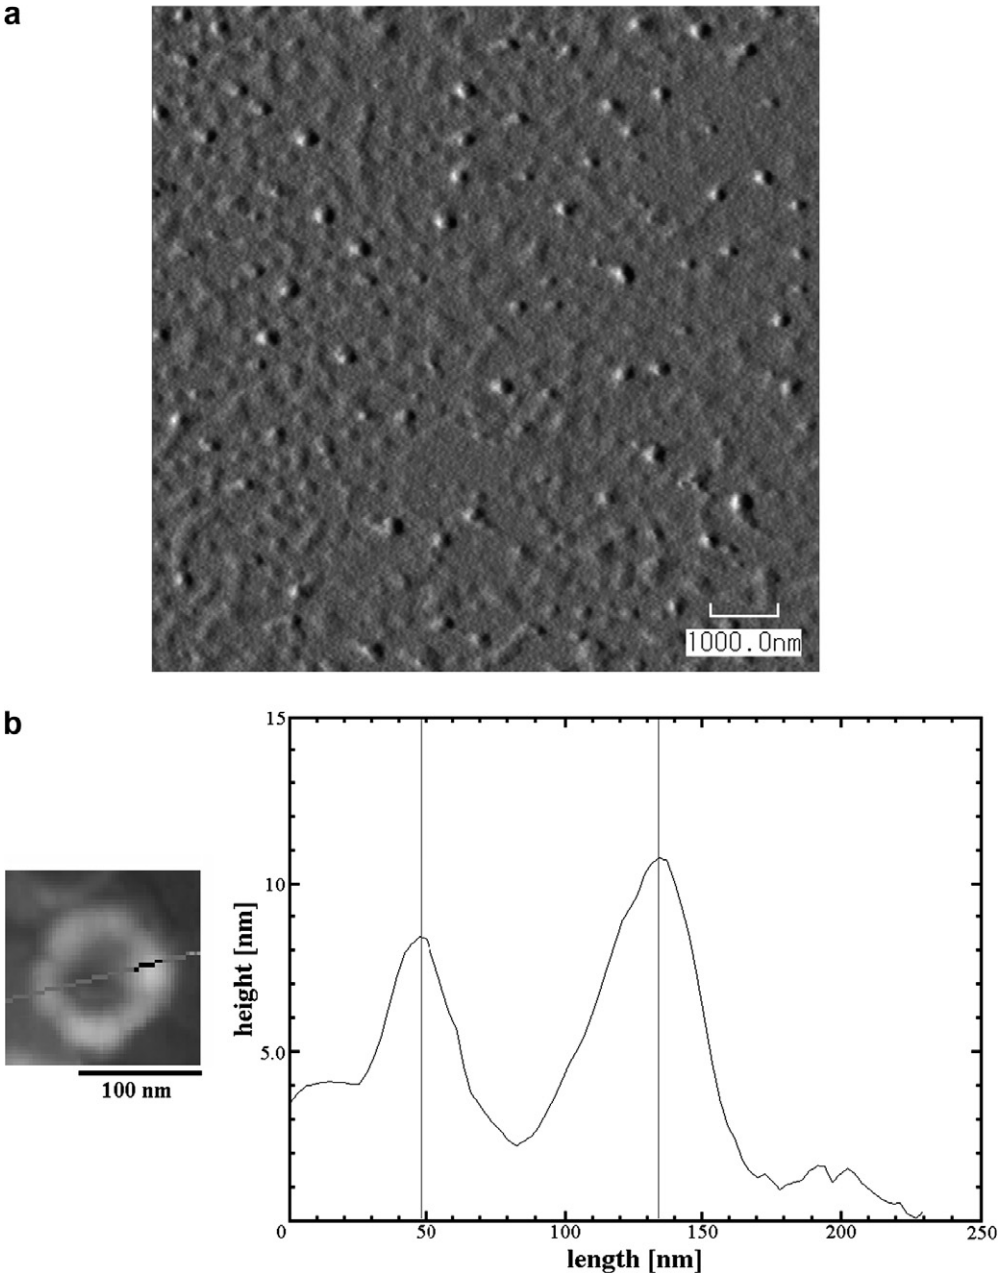

Fig. 4. A top view AFM image of the deposits (a) and a cross section diagram of the corresponding deposits (b).

face is normally ascribed to capillary forces created by the menisci between particles as the solvent evaporates [12]. So further evaporation of solvent made particles aggregate by capillary forces. To suppress the particle aggregation, evaporation of solvent should be terminated before particle shape change not to lose adhesive force to the surface. We examined more rapid evaporating condition. For 10 min at less than 250 mm Hg only 5% particle expansion was observed and there was no aggregated particles on the substrate (Fig. 3b). Further shorter evaporating time of 5 min did not show obvious improvement (Fig. 3c). We adopted the 5 min solvent evaporating as a metal complex deposition condition. An AFM image of the ring structure deposits appeared after removal of the particles by an adhesive tape revealed that average diameters of deposits are around 150 nm (Fig. 4a). Furthermore the cross section diagram of deposits showed that the ring structure deposits a ring structure of the outer diameter of 130 nm has a thickness of around 10 nm (Fig. 4b).

This result suggests that the polystyrene particle acted as a template of nano-scale ring of the complex and the ring position was regulated by the template polystyrene particle.

4. Summary

We have successfully fabricated nano-scale ring structures of paramagnetic metal complex, (n-Bu_4N)[$(dcbdt)_2$-VO], on a glass substrate using a simple and easy colloidal

lithography for the first time. Our simple and easy technique can be applicable to low cost nano-scale lithography. We are now experimentally investigating relationship between magnetic properties and size-dependence of the ring structures and the results will be reported elsewhere.

carboxylates [11], sulfonates [12–15], glucose [16], phosphonates [17], polyoxyethylene [18], amino [19] and carboranyl groups [20] have been reported. Most of these compounds are highly aggregated in aqueous media, this phenomenon being most-easily recognized by severe broadening of the absorption bands in their optical spectra. Tetrasulfonated phthalocyanines are well known with their great theoretical and practical significance thanks to their high solubility in aqueous solution in a wide range of pH and their easy preparation [12–15]. The expanded π orbitals of condensed multicyclic aromatic compounds (e.g., naphthalocyanines) create a large oscillator strength in the Q band region and result in high quantum yields of fluorescence for photoemission studies [21]. Introduction of naphthalenyl groups with bulky electron rich units on the macrocycle core is expected to enhance photophysical or electrochemical properties of phthalocyanines in solution or film states [7a,21a,22].

We have recently reported the synthesis, electrochemical and spectroelectrochemical properties of mono metal phthalocyanines [23–25], dimeric phthalocyanine [26], double-decker phthalocyanines [27–29] and some *vic*-dioxime metal complexes [30–34] in aqueous and non-aqueous media. We report herein the synthesis and characterization of a new highly water-soluble metal-free phthalocyanine bearing naphthoxy-4-sulfonic acid sodium salt. This new compound exhibits the characteristic monomeric UV–Vis absorption of phthalocyanine in methanol and DMSO. In most applications of phthalocyanine complexes, a good understanding of the redox properties of these complexes is important. Spectroelectrochemical studies of phthalocyanines facilitate understanding of the nature of the redox processes that may take place at either the central metal atom or the phthalocyanine ring. Such processes cannot usually be distinguished by electrochemistry only [35]. Spectroelectrochemical studies of phthalocyanines are also important with regard to their possible use as electrochromic materials, where several colors are displayed depending on the potential applied to the electrode surface [23–29]. Considering these purposes in our work, the results of the electrochemical and spectroelectrochemical investigation of 2,9,16,23-tetrakis-(4-(1-naphthoxy-4-sulfonic acid sodium salt))phthalocyanine are also reported in detail in our study.

2. Experimental section

2.1. Chemicals and reagents

1-Naphthol-4-sulfonic acid sodium salt **2** (Merck, 70%) was purified by column chromatography (silica gel, MeOH–CH_2Cl_2, 5:1) before used. DMSO was dried over a molecular sieve of 4 Å. 4-Nitrophthalonitrile **1** was prepared and purified according to the methods described in the literature [36]. Electrochemical grade tetrabutylammonium perchlorate (*n*-Bu_4NClO_4, TBAP, Fluka Chemical Company) (0.1 mol dm^{-3}) was employed as the supporting electrolyte.

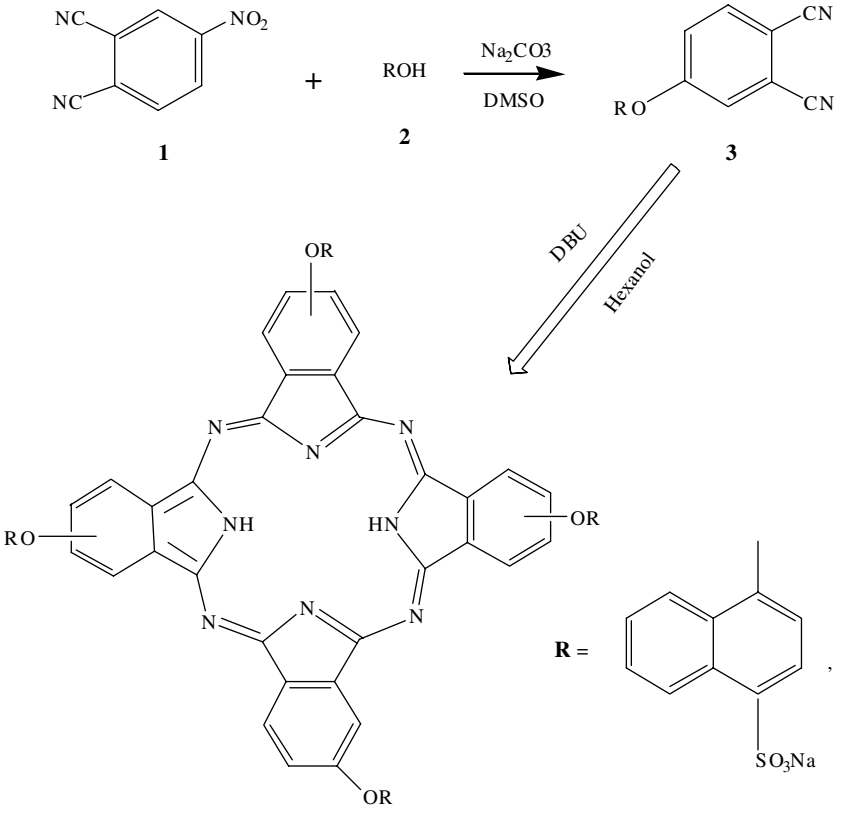
2.2. Instrumentation

^{1}H NMR spectra were recorded on a Bruker 250 MHz spectrometer. (FTIR) spectra were recorded on a Perkin–Elmer FTIR spectrophotometer where samples were dispersed in KBr. Elemental analyses were carried out in the Marmara Research Center. UV–Vis spectra were recorded on an Agillent Model 8453 diode array spectrophotometer. Cyclic voltammograms (CV) were carried out using CV measurements with a Princeton Applied Research Model 2263 potentiostat controlled by an external PC. A three electrode system (BASI (Bioanalytical System Incorporation) model solid cell stand) was used for CV measurements in DMSO and consisted of a 2 mm sized platinum disc electrode as a working electrode, a platinum wire counter electrode and a pseudo Ag/AgCl reference electrode. The reference electrode was separated from the bulk solution by a fritted-glass bridge filled with the solvent/supporting electrolyte mixture. The ferrocene/ferrocenium couple (Fc/Fc^+) was used as an internal standard but all potentials in the paper are referenced to the pseudo Ag/AgCl reference electrode. Solutions containing **$NhtH_2Pc$** were deoxygenated by a stream of high purity nitrogen for at least 5 min before running the experiment and the solution was protected from air by a blanket of nitrogen during the experiment. Controlled potential electrolysis (CPE) was performed with a Princeton Applied Research Model 2263 potentiostat/galvanostat. A BASI model electrolysis cell with a fritted glass to separate the cathodic and anodic portions of the cell was used for bulk electrolysis. The sample and solvent were placed in the electrolysis cell under nitrogen. UV–Vis spectroelectrochemical experiments were performed with a home-built thin-layer cell that utilized a light transparent platinum gauze working electrode [37]. A platinum wire counter electrode and a pseudo Ag/AgCl reference electrode were used for the spectroelectrochemical cell. Potentials were applied and monitored with a Princeton Applied Research Model 2263 potentiostat. Time-resolved UV–Vis spectra were recorded on an Agillent Model 8453 diode array spectrophotometer.

2.3. Synthesis of 4-(1-naphthoxy-4-sulfonic acid sodium salt)phthalonitrile (3)

4-Nitro-phthalonitrile **1** (1.00 g, 5.78 mmol) and 1-naphthol-4-sulfonic acid sodium salt **2** (1.18 g, 5.78 mmol) were stirred and dissolved in 10 ml of dry DMSO at 45 °C. Anhydrous Na_2CO_3 was added portionwise over 2 h under a nitrogen atmosphere, then the reaction mixture was stirred vigorously for a further 48 h. After reaction completed, the mixture was cooled to ambient temperature and then filtered off to remove undesired inorganic salts. The filtration that was collected was poured onto 10 ml of cold chloroform. The precipitated thus obtained was collected and filtered off, then washed with chloroform, cold ethanol and acetone, respectively. The crude product was dissolved in 15 ml of methanol and precipitated by adding 50 ml of

ethanol. It was then further purified by column chromatography (silica gel, MeOH–CH_2Cl_2, 5:1) This compound is soluble in water, methanol and in DMSO. Yield: 1.13 g (53%). *Anal.* Calc. for $C_{18}H_9NaN_2O_4S$ (M_w: 372.33): C, 58.07; H, 2.44; N, 7.52. Found: C, 57.57; H, 2.51; N, 7.21%. IR [(KBr)ν_{max}/cm^{-1}]: 3073 (Ar H), 2233 (–CN), 1593, 1564 (Ar), 1275 (Ar–O–Ar), 1190 (O–S–O), 777, 655. ^{1}H NMR ([D_4]-methanol): δ ppm = 7.20–8.90 (m, 9H, ArH). UV–Vis (MeOH): λ_{max} = 290.



2.4. Synthesis of 2,9,16,23-tetrakis(4-(1-naphthoxy-4-sulfonic acid sodium salt))phthalocyanine (**NhtH$_2$Pc**)

4-(1-Naphthoxy-4-sulfonic acid sodium salt)phthalonitrile **3** (0.50 g, 1.2 mmol), 1-hexanol (5 ml) and 1.8-diazabicyclo[5.4.0]undec-7-ene (DBU) (0.7 ml) were mixed together. The mixture was refluxed for 30 h under a nitrogen atmosphere. After the reaction completed, the mixture was cooled to ambient temperature. Ethanol (50 ml) was added into the reaction mixture to completely precipitate the crude product, which was then filtered off and washed with ethanol and acetone. The crude product, taken into 50 ml of ethanol, was refluxed for 30 min, then the hot mixture was filtered off. The same procedure was repeated for three times. The obtained product was purified by column chromatography (silica gel, MeOH–CH_2Cl_2, 10:1). This compound is soluble in water, methanol and DMSO. Yield: 0.33 g (16%). *Anal.* Calc. for $C_{72}H_{42}Na_4N_8O_{16}S_4$ (M_w: 1495.38): C, 57.83; H, 2.83; N, 7.49. Found: C, 57.09; H, 2.61; N, 7.17%. IR [(KBr)ν_{max}/cm^{-1}]: 3383 (NH), 3073 (Ar H), 1590, 1574 (Ar), 1275 (Ar–O–Ar), 1183 (O–S–O), 763, 688. ^{1}H NMR ([D_6]-DMSO)): δ ppm = 7.01–8.90 (m, 36H, ArH). UV–Vis (MeOH): λ_{max} (log ε) = 290 (5.06), 340 (5.05), 662 (5.17), 696 (5.22).

3. Results and discussion

3.1. Synthesis

4-(1-Naphthoxy-4-sulfonic acid sodium salt)phthalonitrile **3** was prepared through the displacement reaction of 4-nitrophthalonitrile **1** with 1-naphthol-4-sulfonic acid sodium salt **2** in DMSO solution in a moderate yield. Conversion of **3** into the corresponding metal-free phthalocyanine **NhtH$_2$Pc** was accomplished in anhydrous 1-hexanol in the presence of 1,8-diazabicyclo[5.4.0]undec-7-ene (Scheme 1). Column chromatography with methanol/dichloromethane (5:1) eluent on silica gel was employed to obtain the pure product. As expected, the dark green product was soluble in water, methanol and DMSO thanks to the introduction of the naphthoxy-sulfonic acid sodium salt which has hydrophilic character on

Scheme 1. Synthetic route to metal-free phthalocyanine **NhtH$_2$Pc**.

the peripheral position of the phthalocyanine core. Elemental analysis and spectroscopic data (IR, ^{1}H NMR and UV–Vis) confirmed the assigned structure for **NhtH$_2$Pc**. Comparing the IR spectrum of **1** with that of phthalonitrile derivative **3** confirmed the proposed structure of **3** by the disappearance of the aromatic –NO$_2$ band at 1548 cm^{-1} and the appearance of new bands at 1275 (Ar–O–Ar) and 1190 cm^{-1} (O–S–O). After conversion of **3** to the metal-free phthalocyanine **NhtH$_2$Pc**, the characteristic band corresponding to the C≡N vibration at 2233 cm^{-1} disappeared. The characteristic NH stretching absorption of the inner core of the metal-free phthalocyanine was observed around 3300 cm^{-1} besides the absorption bands observed at 1275 (Ar–O–Ar), and 1183 cm^{-1} (O–S–O).

The ^{1}H NMR spectra of **3** and **NhtH$_2$Pc** are given in Fig. 1a and b. The aromatic protons of **3** and **NhtH$_2$Pc** (aromatic core on the phthalocyanine unit and naphtho groups) appeared as multiplets between at 7.01 and 8.90 ppm (m, 9H, ArH) for **3** and (m, 36H, ArH) for **NhtH$_2$Pc**. The N–H protons of the metal-free phthalocyanine were also observed as a weak–broad peak upfield ($\delta = -3.60$ ppm), probably due to its low solubility in the solution used for the ^{1}H NMR spectrum.

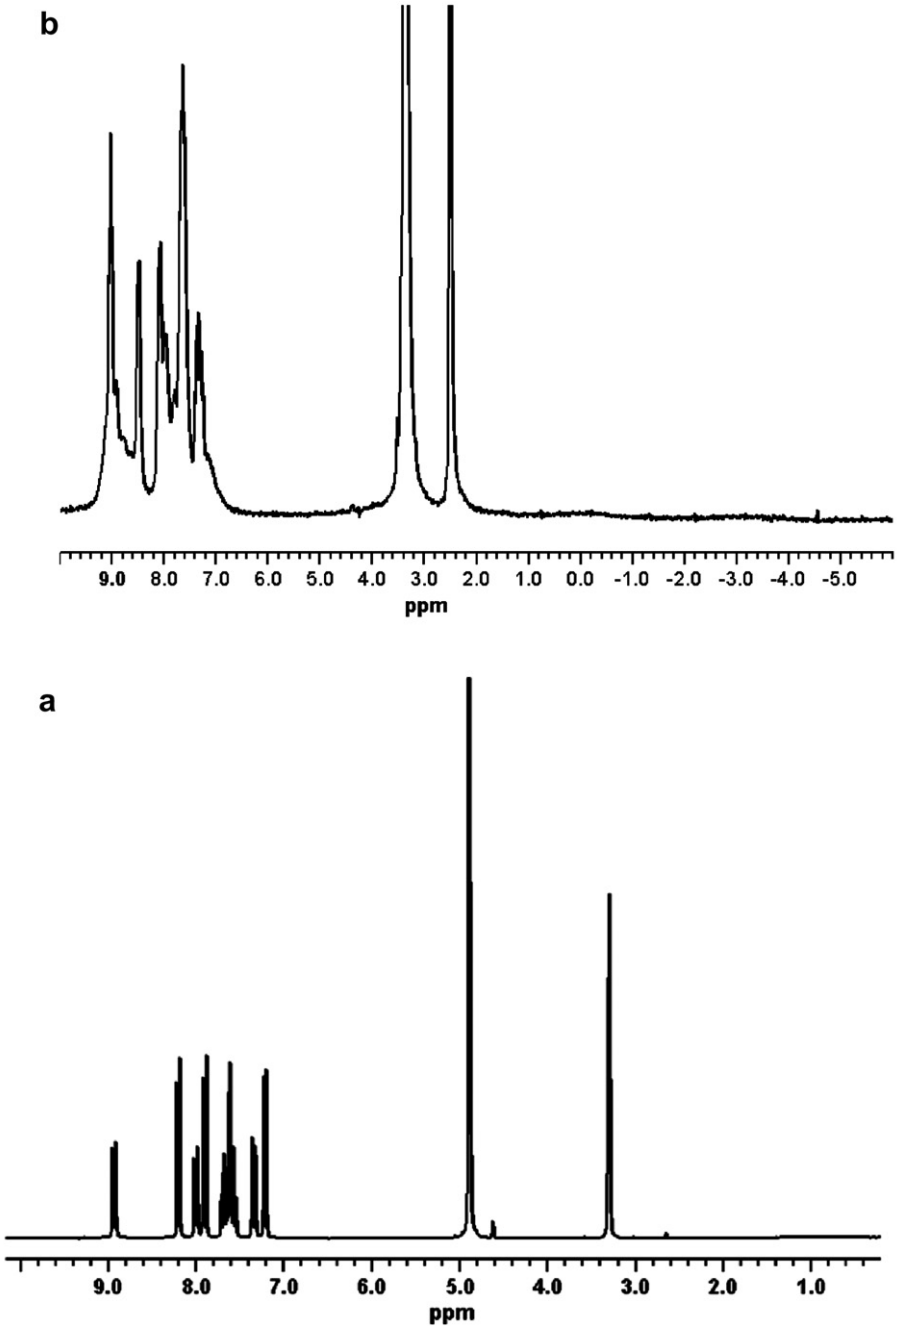


Fig. 1. ^{1}H NMR spectra of **3** (a) and **NhtH$_2$Pc** (b).

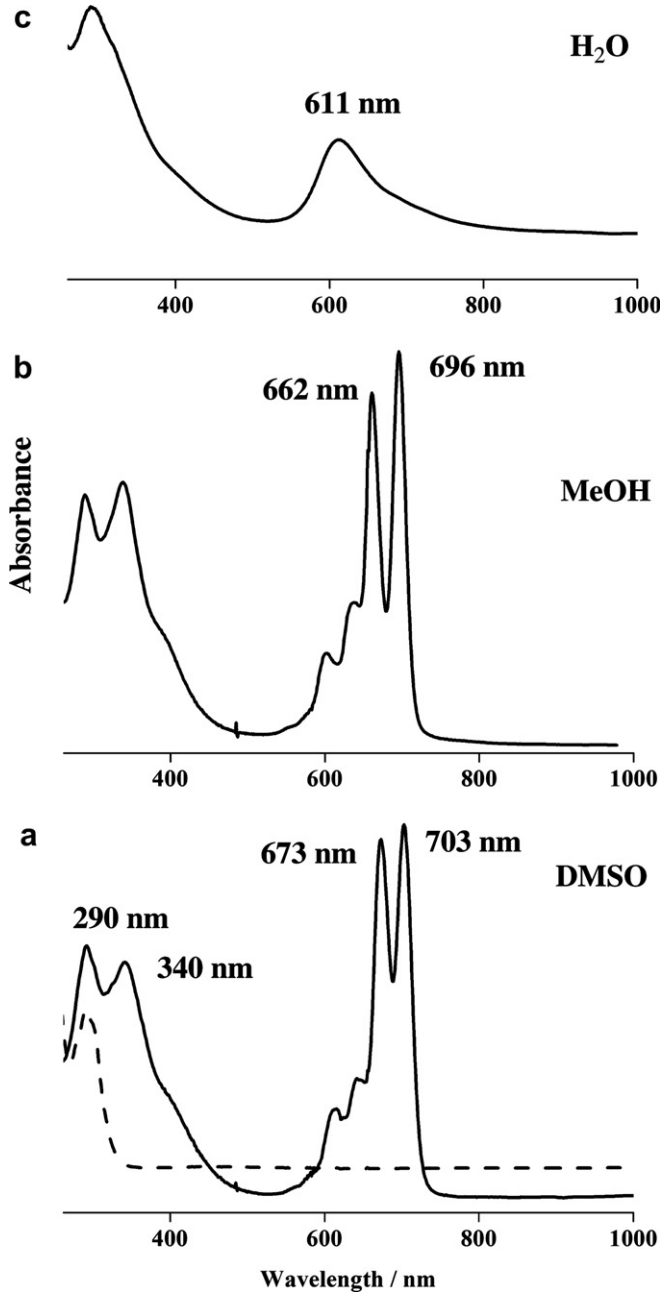

Fig. 2. UV–Vis spectra of **3** (a) (dashed line), **NhtH$_2$Pc** (a) (solid line) in DMSO; **NhtH$_2$Pc** (b) in MeOH; **NhtH$_2$Pc** (c) in H_2O.

The UV–Vis absorption spectra of **3** and **NhtH$_2$Pc** in protic and aprotic solvents are given in Fig. 2. As can be seen from Fig. 2a (the dashed line), compound **3** shows the characteristic absorption band at 290 nm corresponding to a $\pi\rightarrow\pi^*$ transition due to the existence of the naphthalenyl group on the molecule. In the case of **NhtH$_2$Pc**, two main split intense bands, (Q_1 and Q_2 bands) and B (soret bands) were observed at 703, 673 and 340 nm in DMSO, respectively (Fig. 1a, solid line). The $\pi\rightarrow\pi^*$ transitions of the naphthalenyl groups integrated on phthalocyanine core were also observed at 290 nm. It could be seen that the $\pi\rightarrow\pi^*$ transitions of the naphthalenyl groups attached on the phthalocyanine main core are not affected in spite of

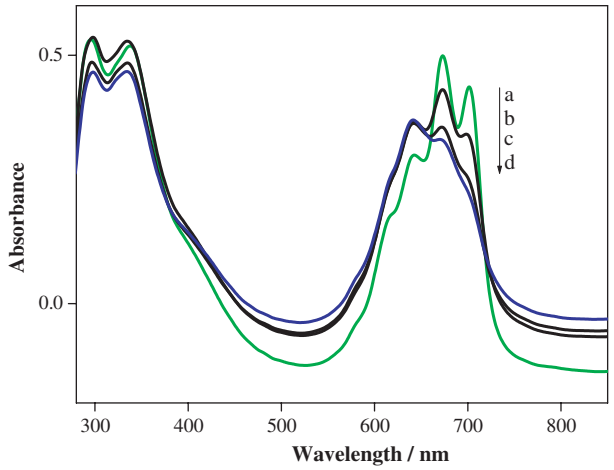

Fig. 3. UV–Vis spectral changes on aggregation of **NhtH$_2$Pc**.

integration of the π-electrons of the naphthalenyl substituent into the phthalocyanine system. Because the full conjugation of the π-systems is not changed with this integration, no large shifts toward the near IR region for the Q and B bands in the UV–Vis spectrum of **NhtH$_2$Pc** were observed compared with those of phthalocyanine fused aromatic rings (e.g., naphthalocyanines) [38]. It can also be seen from Fig. 2a and b that the Q bands in DMSO solution shift to lower energy by about 10 nm compared with those in methanol solution. Fig. 2c shows that the **NhtH$_2$Pc** molecules aggregate in water but not in methanol (Fig. 2b) and DMSO solutions (Fig. 2a, solid line). The band corresponding to the aggregated form of the molecules in water appears as broad peak at 611 nm (Fig. 2c) as expected. The aggregation study of **NhtH$_2$Pc** molecules was performed by UV–Vis spectral changes for a methanol solution where water was added step by step into the methanol solution to understand the degree of aggregation depended upon the ratio of methanol and water used in the experiment. The UV–Vis spectral changes showed at the 611 nm peak, and the 662 and 696 nm peaks in the case of the 1:1 ratio of methanol and water, which refer to both aggregated and non-aggregated mono phthalocyanine forms in the methanol–water solution (Fig. 3, blue[1] solid line).

3.2. Electrochemistry

The electrochemical behavior of **NhtH$_2$Pc** was investigated using a cyclic voltammetric (CV) technique in a DMSO solution containing 0.1 M TBAP. The data obtained in this work and some selected data from the literature are summarized in Table 1. Fig. 4 shows the CV of **NhtH$_2$Pc**, which displays three reversible one-electron reductions with the corresponding anodic waves and one irreversible oxidation without a corresponding anodic wave at a 0.100 V s^{-1} scan rate in DMSO containing the pseudo

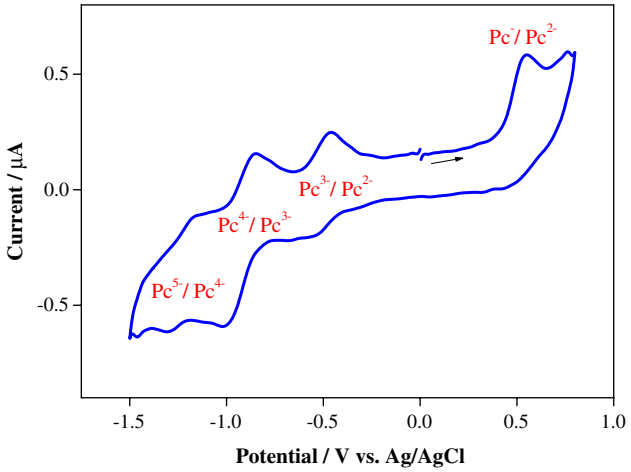

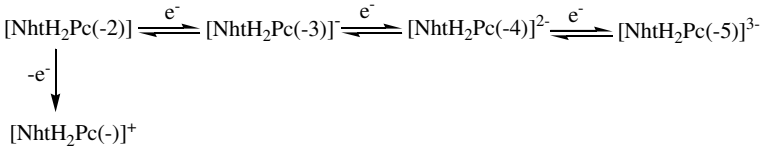

Fig. 4. Cyclic voltammogram of **$NhtH_2Pc$** in DMSO solution containing 0.1 M TBAP. Scan rate = 0.100 V s^{-1}.

Ag/AgCl electrode system. The lack of reversibility of the oxidation process is probably due to the increasing polarization effect by means of four sulfonates groups attached on the phthalocyanine ring. Similar behavior was observed for some *vic*-dioxime complexes having four carboxylate groups on the oxime moiety [39]. It is clear that the reduction waves are assigned to the macrocycle system, and these are indicated in Fig. 4 and Table 1 as Pc^{3-}/Pc^{2-}, Pc^{4-}/Pc^{3-} and Pc^{5-}/Pc^{4-} couples, respectively. Even if highly reduced states of the metal-free phthalocyanine are frequently mentioned, the reduction of the proton bound to the macrocycle has never been reported [40]. So all the reduced forms observed in this study were attributed to the macrocycle system. It can be seen from Table 1 that the electrochemical half-wave potentials of the first, second and third reduction processes are located at $E_{1/2} = -0.510$, -0.924 and -1.24 V, respectively while the anodic potential of the oxidation process displays at $E_{1/2} = 0.590$ V versus pseudo Ag/AgCl. The values of the cathodic to the anodic peak separation (0.062–0.011 V) for the reduction processes are listed in Table 1, which were assigned to reversible character for the reduced species in DMSO solution within the scan rate 0.025–0.25 V s^{-1}. The half-wave potentials of the first and second reductions for **$NhtH_2Pc$** were positively shifted by 0.150 and 0.136 V as compared to those for unsubstituted metal-free phthalocyanine (H_2Pc) [40]. These shift values are almost the same with those of $[(SO_3)_4H_2Pc]$ [40]. The results indicate that the electron-withdrawing naphthalenyl units with sulfonate groups make $NhtH_2Pc$ easier to reduce as observed in the case of $[(SO_3)_4H_2Pc]$ where four sulfonate groups are directly attached to the phthalocyanine core. The potential difference between the first and second reduction processes of **$NhtH_2Pc$** is 0.414 V, which refers to an average separation for the first and second reduction processes of metal-free phthalocyanines on the phthalocyanine ring system [40]. This potential difference is almost the same as those of H_2Pc and $[(SO_3)_4H_2Pc]$. On the other hand, oxidation potentials of electroactive molecules are expected to be positively shifted if the molecule contains electron-withdrawing substituents. However, **$NhtH_2Pc$** did not exhibit this tendency in our case. It could be attributed to interaction of the oxidized phthalocyanine species having four sulfonate groups and the counter anions of the supporting electrolyte [25,27,29], which resulted in the fixed oxidation potential of $NhtH_2Pc$. The redox processes of **$NhtH_2Pc$** were examined as a function of potential scan rate in order to ascertain the mode of mass transport. The cathodic and anodic currents for the reduction couples in DMSO each increased in direct proportion to the square root of scan rate between 0.025 and 0.25 V s^{-1}, thus suggesting the redox reactions in solution are controlled by diffusion [41]. The controlled potential coulometric (CPC) study indicated that the number of electrons transferred for the electrochemical reactions of the complex was one for each oxidation and reduction processes. The proposed electron-transfer mechanism of **$NhtH_2Pc$** on the electrode surface is given in Scheme 2.

Scheme 2. The proposed electron-transfer mechanism of **$NhtH_2Pc$**.

3.3. UV–Vis spectra of electro-oxidized and electro-reduced complexes

The spectroelectrochemical behavior of **$NhtH_2Pc$** was investigated using an in situ spectroelectrochemical technique including chronoamperometry and UV–Vis spectroscopy in a DMSO solution containing 0.2 M TBAP. The UV–Vis spectral changes for the first reduced species of **$NhtH_2Pc$** obtained in a thin layer cell with the applied potential ($E_{app} = -0.70$ V) are given in Fig. 5, where the inset figure corresponds to the CV of **$NhtH_2Pc$** in a thin-layer cell. The convenient applied potential value for the in situ spectroelectrochemical experiment was determined to be $E_{app} = -0.70$ V by taking the CV of **$NhtH_2Pc$** in a thin-layer cell (the inset figure in Fig. 5). As can be seen from Fig. 5, the main Q band almost disappeared in the course of the reduction process and new bands appeared at 573 and 445 nm. This spectral change arises from the rearrangement of the molecular orbital on addition of one electron into the present system, as expected [42]. At the beginning of the spectroelectrochemical measurements in DMSO solution, two main Q bands of the neutral state of **$NhtH_2Pc$** observed in the regular UV–Vis experiment (Fig. 2a and b) were seen as a lifted degeneracy. It is probably due to DMSO being basic, often resulting in a single Q band when studied at high concentration. The evaluation of the UV–Vis spectral changes upon the first reduction of **$NhtH_2Pc$** showed that the reduced form of **$NhtH_2Pc$** was assigned to a one-electron reduction process on the macrocycle and is accompanied with a change of color from green to blue. As can be expected, there is no change in the energy or the absorption intensity of the $\pi \rightarrow \pi^*$ transitions corresponding to the naphthalenyl groups on the phthalocyanine core due to the long-distance interaction between the naphthalenyl and macrocycle units. As can also be seen from Fig. 5, the isosbestic points of the UV–Vis spectral changes were found at 415, 613 and 571 nm, which clearly confirm the formation of the reduced species of **$NhtH_2Pc$**. The spectrum of $[NhtH_2Pc]^-$ is typical of Pc^{3-}/Pc^{2-} species, and is similar to that of the reduced mono-phthalocyanines based on the same macrocycle [25,42]. It can be deduced from monitoring the redox reaction that the electron-transfer reaction is reversible on the spectroelectrochemical timescale, and the original spectrum (and color) of the compounds is obtained upon re-oxidation. Thus, the reduced phthalocyanine remains fully stable throughout the experiment. These results obtained from the study of the in situ spectroelectrochemistry are consistent with those from the study of CV, which provide a good understanding of the reversible one-electron reaction process with long-term stability for the mono-anionic species $[NhtH_2Pc]^-$.

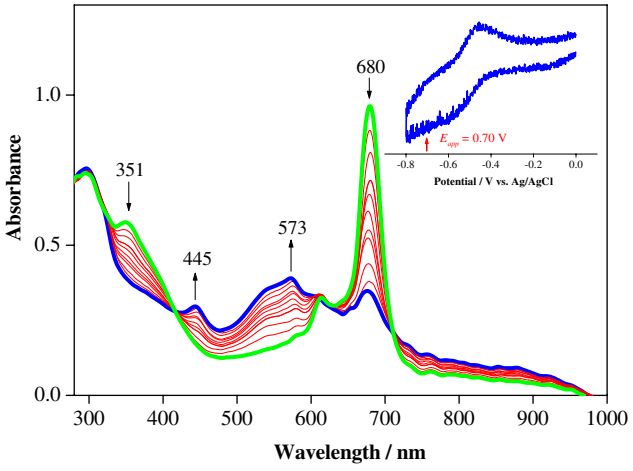

Fig. 5. Time-resolved UV–Vis spectral changes of **$NhtH_2Pc$** during the first reduction at $E_{app} = -0.70$ V in DMSO solution containing 0.2 M TBAP where the inset figure shows the cyclic voltammogram of **$NhtH_2Pc$** in DMSO solution containing 0.2 M TBAP in thin-layer cell. Scan rate = 0.100 V s^{-1}.

4. Conclusion

In this study, a new water-soluble metal-free phthalocyanine, 2,9,16,23-tetrakis(4-(1-naphthoxy-4-sulfonic acid sodium salt))phthalocyanine **$NhtH_2Pc$**, was synthesized. The aggregation study of **$NhtH_2Pc$** showed that **$NhtH_2Pc$** had both aggregated and non-aggregated mono phthalocyanine forms in the case of the 1:1 ratio of methanol and water, whilst it exhibited the characteristic UV–Vis absorption spectrum of monomeric phthalocyanine in methanol and DMSO. It is clear that this new molecule, having anionic character with naphthoxy sulfonate groups on the phthalocyanine core, may be a potential candidate molecule in the application of photodynamic therapy thanks to its enhanced fluorescence and water-solubility properties.

On the other hand, the studies of CV and in situ spectroelectrochemistry for **$NhtH_2Pc$** in DMSO solution provide useful information on the electron-transfer reactions of the reduced species on the electrode surface.

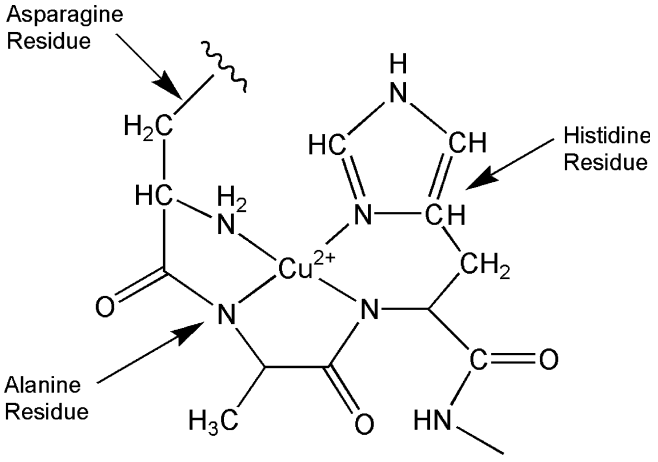
of interest in metal ion therapeutics for both diagnosis and treatment [7,8]. For example Cu(II)-L-histidine [9] has been used in the treatment of Menkes disease [10,11]. Such interest has been due to the biochemical and pharmacological properties of the metal–ligand system, with extensive research carried out to determine the role of the ligand in copper uptake into cells. On the other hand many articles [12,13], indicating the effective role of various copper chelating agents in the alleviation of inflammation associated with RA have also appeared in literature, indicating the physiological importance of these agents as well as their therapeutic applications. Important in this regard is the ability of biologically essential metal ions such as Cu(II), Ca(II), Zn(II) and Ni(II) to interact with various ligand systems, particularly those containing a pseudo-peptide-mimic of the N-terminus of serum albumin [14–18].

Serum albumin (SA) is a major metal binding protein in the body, with about 40 μg of copper able to bind to the albumin contained in 1 ml of human plasma [19]. The Cu(II) transport site of serum albumin is one of the most extensively studied binding site of any protein [20]. The proposed structure (Fig. 1) of the major Cu(II) binding site in HSA involves the α-NH_2 nitrogen, two peptide nitrogens, and the imidazole nitrogen of the N-terminal Asp-Ala-His residues [12]. Recently, we have shown, using animal experiments, that Cu(II)-*N*-(2-(2-aminoethylamino)ethyl)picolinamide ([H(555)–N]), a system related to Cu(II)–HSA, is capable of surviving *in vivo* [21] with a relatively long biological half life. Encouraged by these results, we have extended our efforts to the thermodynamic and spectroscopic study of the solution equilibria of Cu(II), Ca(II), Zn(II) and Ni(II) with 2-amino-*N*-(2-oxo-2-(2-(pyridin-2-yl)ethyl amino)ethyl)acetamide ([H_2(556)–N]) (Fig. 2). The major difference between [H_2(556)–N] and HSA is the replacement of the imidazole group by a pyridyl system. Speciation modelling studies [22] have shown that ligands containing the pyridyl group have a higher Cu(II) mobilizing ability than analogous ligands with the imidazole group. Presumably this is related to metal ion specificity and hence *in vivo* competition with



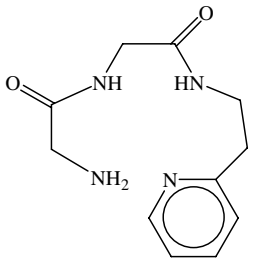


Fig. 1. Copper binding site in Human Serum Albumin (HSA).

[H_2(556)-N]

Fig. 2. Schematic structure of chelating agent.

Ca(II) and Zn(II) which are present in much higher concentration than Cu(II) in blood plasma [20,23].

2. Experimental

Formation constants were measured at 298 K and an ionic strength of 0.15 M (NaCl) using a procedure described previously [24]. The reagents used were all of analytical grade and the synthesis of the metal chelating agent was based on a method described previously [17]. The overall formation constant, β_{pqr}, refers to the equilibrium below, where p, q and r are the stoichiometric coefficients of the components in the complex

$$pM + qL + rH \rightleftharpoons M_pL_qH_r \quad (1)$$

$$\beta_{pqr} = \frac{[M_pL_qH_r]}{[M]^p[L]^q[H]^r} \quad (2)$$

The species formed in the investigated systems can be characterized by this general equilibrium process (1) where charges are omitted. The formation constants (β_{pqr}) given by (2) for the generalized reaction (1) were evaluated from the pH-potentiometric titration data using the Equilibrium Simulation for Titration Analysis (ESTA) computer program [25].

Molecular mechanics calculations were performed on a SyncMaster 1100p workstation using the Discover module of InsightII software [26]. The extensible systematic force field (esff) [27] was used for all energy calculations. All calculations were done in vacuum.

Electronic spectra in aqueous solution were recorded in 1.00-cm quarts cells using a Varian UV-Cary 100 spectrophotometer equipped with a temperature-controlled cell holder.

Water/octanol partition coefficients were measured as a function of pH using the shake flask method [28–30]. The aqueous solutions in the vials at different pH were spiked with $^{64}CuCl_2$ solution of activity 7.50–9.00 mCi, before shaking with an equal volume of water saturated octan-1-ol. An equal amount (1 ml) of each phase was counted in a Minaxi Auto gamma counter (5000 Series-Packard) using a window set at 340–540 keV [31–34].

Blood plasma modelling was carried out by incorporation of the formation constants determined in this study into the blood plasma model consisting of data for 10

metal ions and more than 5000 ligands [23]. This enlarged database was efficiently and conveniently interrogated by the Evaluation of Constituent Concentrations in Large Equilibrium System (ECCLES) computer program [20] to yield results pertaining to the influence of the chelating agents on the equilibria in terms of the plasma mobilizing index (p.m.i) of each agent. P.m.i., defined as the ability to move metal from a protein bound form to a low-molecular weight form, can be represented by the following expression:

$$\text{p.m.i.} = \frac{(\text{total concentration of low-molecular-weight metal complex species in the presence of drug})}{(\text{total concentration of low-molecular-weight metal complex species in normal plasma})}$$

The superoxide dismutase (SOD) mimetic activity of the $CuLH_{-2}$ species was determined using the nitroblue tetrazolium (NBT) assay as described by González-Álvarez et al. [35] and Auclair and Voisin [36]. The procedure and concentrations of various species were as reported by Nomkoko et al. [37].

3. Results and discussion

3.1. Protonations

The two protonation constants that were determined by ESTA optimization [25] of the potentiometric data for $[H_2(556)–N]$ are: $pK_1 = 5.18$ and $pK_2 = 7.91$. The first value (pK_1) corresponds to the protonation constant of the pyridyl ring and the second value (pK_2) to that of the amino group. The pK_2 value is close to the pK_2 value of glycylglycylhistamine, Gly-Gly-Ha (7.85) [17] and alanylglycylhistamine, Ala-Gly-Ha (7.87) [18]. However the pK_1 suggests reduced basicity in the pyridyl nitrogen of $[H_2(556)–N]$ as compared to that for 2-ethyl pyridine ($pK_{a,1} = 6.07$). This can be attributed to the electron-withdrawing properties of the two CONH-groups [38] present in the ligand, capable of drawing electrons towards themselves through inductive effects.

For Gly-Gly-Ha and Ala-Gly-Ha it is proposed that because the pK_as of the two protonation sites were so similar, that protonation occurred at both sites simultaneously. In the case of $[H_2(556)–N]$ the pK_as differ by ~3.0 log units and so such a microprotonation pathway is unlikely.

3.2. Complexation

Two functions [39–41], which are derived from the experimental data and are quantitatively related to the $\log \beta_{pqr}$'s were used to investigate the reproducibility of the experimental data and the reliability of evaluated β_{pqr} values. The complex formation function, Z_M-bar, measures the average number of ligands bound per metal ion due to complexation. This function is plotted against the negative logarithm of the free ligand concentration (pL).

On the other hand the deprotonation function, Q-bar, indicates the average number of protons released due to complexation and is plotted against the pH of the solution. Q-bar is evaluated in conjunction with the n-bar function, which measures the average number of protons that would be bound to the ligand in the absence of complexation.

These two functions serve two purposes. Firstly they give one a visual check on the experimental data and secondly their shape gives one an idea of the speciation model applicable to the system. Theoretically, the complex formation function (Z_M-bar) is only defined for simple, stepwise complexation and the curves at different metal to ligand ratios should be superimposable. If the curves are not superimposable, this indicates that polynuclear species are present. Fanning back of the Z_M-bar curves indicates the presence of hydroxo and/or mixed hydroxo species [42].

Fig. 3 shows the complexation (Z_M-bar) and deprotonation (Q-bar) function for the Cu(II)–$[H_2(556)–N]$ system at different metal to ligand ratios. Z_M-bar for different metal–ligand ratios are superimposable indicating the absence of polynuclear species. The fact that Z_M-bar is not levelling off at 1.0 suggest that simple stepwise complexation does not occur in solution thereby indicating that mononuclear species of 1:1 metal–ligand stoichiometry are not the dominant species in solution. The titration curves, obtained for ligand to metal ratios higher than 1:1, indicate that there is no formation of complexes including more than one ligand molecule per metal ion while fanning back of this function indicates the loss of the amide protons upon metal ion coordination [43].

At pH values less than 4.00 the deprotonation function, Q-bar, is zero indicating that no protons have been displaced due to complexation. The protonation function n-bar has a value of 2.0 at this pH confirming that the ligand is still protonated at low pH. For pH values above 4.00, Q-bar rapidly rises to intersect the protonation curve, n-bar, at a pH of 5.00, reaching a maximum value of about 3.3 at pH 5.60. At this pH, the difference between Q-bar and n-bar is 2 indicating that complexation has resulted in the loss of a total of four protons from the ligand. Since the protonated ligand has only two possible dissociable protons these extra protons are suggested to come from the amide groups. Above this pH the Q-bar curves run parallel to the protonation curve and then levels off at a value of 2.2, in the strongly alkaline region. Since the two curves, n-bar and Q-bar are parallel, this means that there is no change in the number of protons displaced by complexation and so no further complexation can be detected potentiometrically.

The analysis of the curves for the functions given in Fig. 3 using the ESTA suite of programs [25] resulted in

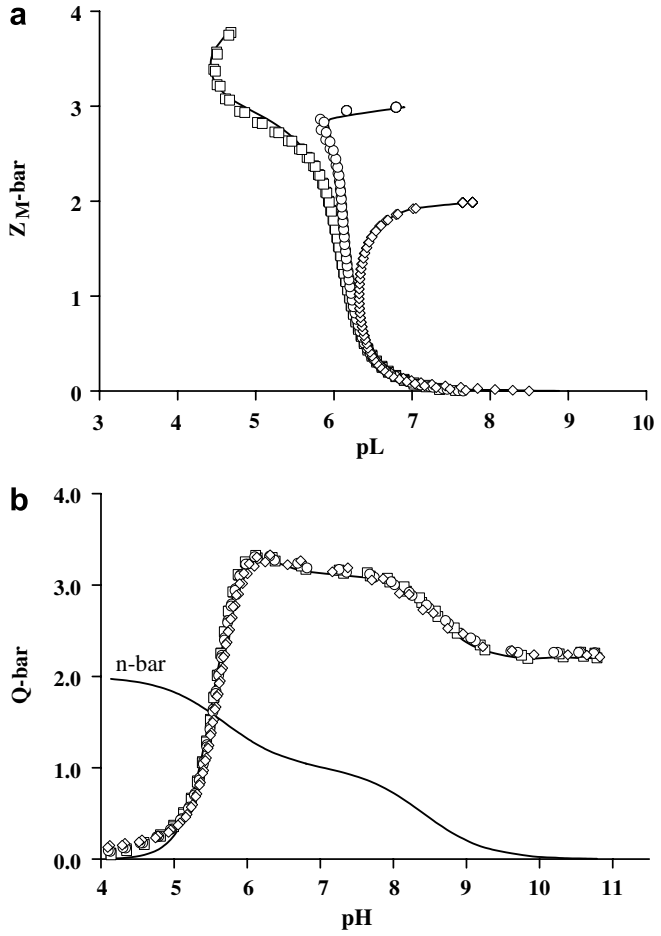

Fig. 3. (a) Formation and (b) deprotonation curves for the Cu–[H_2(556)–N] system. Experimental data are shown for titration at 1:2 (◇), 1:3 (○) and 1:4 (□) metal:ligand concentration ratios. The theoretical data (solid line) was calculated using model 4 given in Table 2.

the determination of five models (Table 1) which describe the experimental data equally well. Within these models, formation of the following Cu(II) complexes: MLH, ML MLH_{-1}, MLH_{-2} and MLH_{-3} with [H_2(556)–N] was observed. In each of these models the *R*-factor, R_f^H, which represents the 'goodness of fit' is $<R_{lim}$. R_{lim} is calculated from the random errors in the experimental data and is the minimum value of R_f^H that is statistically significant. Hence there is no difference between the 'goodness of fit' of these five models.

Table 1
Various models generated from potentiometric analysis of the Cu(II)–[H_2(556)–N] system using ESTA suite of programs

Model	*p q r*	$\log\beta_{pqr}$	(σ_{pqr})	n_P	n_T	pH range	R_f^H (R_{lim}^H)
1	1 1 1	10.97	(0.088)	678	6	3.0–11.0	0.010 (0.022)
	1 1 0	5.75	(0.005)				
	1 1 −2	−3.90	(0.024)				
2	1 1 0	5.85	(0.011)	678	6	3.0–11.0	0.014 (0.027)
	1 1 −2	−4.09	(0.004)				
3	1 1 0	5.85	(0.009)	678	6	3.0–11.0	0.011 (0.027)
	1 1 −2	−4.09	(0.004)				
	1 1 −3	−12.59	(0.028)				
4	1 1 0	5.82	(0.021)	678	6	3.0–11.0	0.013 (0.027)
	1 1 −1	−0.39	(0.026)				
	1 1 −2	−4.10	(0.006)				
5	1 1 0	5.80	(0.018)	678	6	3.0–11.0	0.011 (0.027)
	1 1 −1	−0.19	(0.135)				
	1 1 −2	−4.10	(0.028)				
	1 1 −3	−12.60	(0.028)				

This is a problem that occurs commonly in the computational analysis of potentiometric data when two or more models describe the experimental data equally well. In this situation additional information must be used to decide between the different models. Model 1 was dismissed on chemical grounds. This model has an MLH species which implies that while the pyridyl nitrogen is coordinated the amino nitrogen is still protonated. This structure is unlikely due to the chelate effect.

Models 3 and 5 can be dismissed by inspection of the theoretical *Q*-bar curves (not shown). These models have an MLH_{-3} species which is formed at high pH. However, the *Q*-bar curves level off at 2 indicating that only an MLH_{-2} species is formed at this pH. The theoretical *Q*-bar curves for these models level off at 3.

The final 2 models have the same beta values and only differ in the postulate of an intermediate MLH_{-1} species. Since complexation is likely to take place stepwise, this species is a reasonable intermediate and hence we have chosen model 4 to represent the Cu(II)–[H_2(556)–N] system. Vacca et al. [44] has also suggested that in situations like this, the choice of the chemical model(s) becomes a matter of personal judgement. A speciation plot (Fig. 6) shows the MLH_{-1} species is a minor species and this is why it does not affect the statistical error significantly.

The influence of substituents on the coordinating ability of peptides has been widely reported [17,18]. Due to the multidentate nature of [H_2(556)–N], and of all serum albumin mimicking pseudo-peptides, monomeric complexes, are formed, with the MLH_{-2} species in the Cu(II)–[H_2(556)–N] system predominating at physiological pH. The formation constants determined in this study are somewhat lower than those of analogous ligands containing an imidazole ring. For example, the following formation constants have been reported for the MLH_{-2} species: Gly-Gly-Ha [17] $\log\beta_{11-2} = -2.48$; Ala-Gly-Ha [18] $\log\beta_{11-2} = -2.86$; Gly-Gly-His [14,15] $\log\beta_{11-2} = -1.80$; Gly-Gly-His-*N*-methylamide [45] $\log\beta_{11-2} = -0.48$ and Asp-Ala-His-*N*-methylamide [46] $\log\beta_{11-2} = -0.55$. The difference in stability of these imidazole containing ligands has been attributed to the effect of the various substituents [14,15,17,18,45] present.

A noticeable feature about the two peptides Gly-Gly-Ha and Ala-Gly-Ha is the stability associated with the MLH_{-1} species which was difficult to detect in the Cu(II)–[H_2(556)–N] system, which is only seen as a minor species in both Figs. 6 and 7a. This suggests that the two amides in [H_2(556)–N] are dissociated in overlapping steps. This is not unusual as it has been reported for the Cu(II)-*N*,*N*′-diglycyltrimethylenediamine system [47] and can be

explained in terms of the pH delayed coordination of either the second amide nitrogen or both amide nitrogen donors once the terminal nitrogen donors are coordinated in the Cu(II)–[H_2(556)–N] system.

Table 2 lists the formation constants of the final Cu(II)–[H_2(556)–N] model together with those of Ni(II) and Zn(II). The formation constants all have low standard deviations and Hamilton *R*-factors, indicating that the models are good descriptions of the equilibria occurring in solution. The agreement between the theoretical and experimental formation and deprotonation functions as well as the reproducibility of the titrations at different metal:ligand ratios lends confidence to the results. Slow kinetics was observed in the Ni(II)–[H_2(556)–N] system. However, despite the known difficulty of measuring equilibrium constants under conditions of slow kinetics, excellent agreement between the experimental and theoretical complexation and deprotonation functions was obtained. The titrations, while slow, were found to be reversible and reproducible.

As expected, the two metal ions Ni(II) and Zn(II) form reasonably stable complexes with [H_2(556)–N], but their stability is much lower than that of Cu(II), particularly for the physiologically important MLH_{-2} species. A noticeable feature with these two metals is the prevalence of the MLH species. The presence of protonated MLH species in the Ni(II)–[H_2(556)–N] ($\log\beta_{111} = 10.91$) and Zn(II)–[H_2(556)–N] ($\log\beta_{111} = 11.36$) systems is an indication of the inability of these two metal ions to readily deprotonate the ligand. It is also observed that $\log\beta_{pqr}$'s for the MLH and ML species in the Zn(II)–[H_2(556)–N] system are slightly higher than those for the Ni(II)–[H_2(556)–N] system, a clear violation of the Irving–Williams series [48].

Unlike Cu(II), Ni(II) and Zn(II), Ca(II) was found to form very weak complexes with [H_2(556)–N]. Several attempts, using different metal to ligand concentrations, failed to detect any interaction between Ca(II) and the ligand [H_2(556)–N]. Similar results have been found for a majority of ligands with soft nitrogen donor atoms such as glycylglycine [49]. Generally, there are no reported constants of this metal ion with the majority of ligands containing nitrogen donor atoms [49]. This behaviour of Ca(II), which is classified as a Hard Lewis Acid (HSAB classification), is expected as this metal ion prefers ligands with hard donor atoms such as oxygen [50]. Thus failure to form any complexes with [H_2(556)–N] is therefore a result of such behaviour.

Table 2
Formation constants ($\log\beta_{pqr}$) and derived data for Cu(II), Ni(II) and Zn(II) complexes of [H_2(556)–N], $\beta_{pqr} = [M_pL_qH_r]/[M]^p[L]^q[H]^r$, $I = 0.15$ mol dm^{-3} (NaCl), $T = 298$ K

Metal	*p q r*	$\log\beta_{pqr}$ (σ_{pqr})	n_P	n_T	pH range	R_f^H (R_{lim}^H)
H^+	0 1 1	7.91 (0.004)	453	3	3.0–11.0	0.007 (0.011)
	0 1 2	13.09 (0.005)

σ_{pqr} denotes the standard deviation in $\log\beta_{pqr}$; R_f^H and R_{lim}^H is the Hamilton *R*-factor and its limit. n_T and n_P are the number of titrations and titration points. The general formula of a complex is $M_pL_pH_r$.

3.2.1. Structure of complexes

In their study of glycylglycylhistamine (Gly-Gly-Ha) and alanylglycylhistamine (Ala-Gly-Ha) Gadja et al. [17] and Gizzi et al. [18] postulated that metal ion coordination occurred simultaneously at both the imidazole nitrogen and the terminal amine. The pK_a's of these two groups were very similar and so the metal ion would not show a preference for one above the other. [H_2(556)–N] also has two basic sites but in this case the pyridyl nitrogen and the amino group have very different pK_a's. Hence the metal ion is expected to bind exclusively to the more basic amine. In this position it is also possible for the metal ion to coordinate to the adjacent amide group. Hence, the structure of the MLH species is as depicted in Fig. 4a(i) with the pyridyl nitrogen still protonated. Deprotonation of this nitrogen to form the ML species occurs with a pK_a of 5.2 ($\log\beta_{111} - \log\beta_{110}$). This is the same as p$K_1$ which has been assigned to the pyridyl group. This structure is depicted in Fig. 4b(i). The fact that the pK_a of the MLH species and pK_1 of the free ligand are so similar supports the proposed structure for both MLH and ML.

If the structure of ML is as depicted in Fig. 4b(i) then metal assisted deprotonation of the adjacent amide leads to a structure in which the carbonyl of the second amide may or may not be coordinated. Fig. 4c shows two possible structures for the MLH_{-1} complex. Finally, deprotonation of the second amide would lead to structures given in 4d as two possible structures for the MLH_{-2} species. In both these structures metal assisted deprotonation of the second amide has occurred leading to the MLH_{-2} stoichiometry. The difference between the two structures is the coordination of the pyridyl nitrogen. Considering the formation of MLH_{-1} from ML, the pK_a of this process is 6.2 ($\log\beta_{110} - \log\beta_{11-1}$). If structure 4b(i) is correct, this pK_a refers to metal assisted deprotonation of the first amide. Formation of the MLH_{-2} species from MLH_{-1} has a pK_a of 3.7 ($\log\beta_{11-2} - \log\beta_{11-1}$). Again if structure 4c(i) and d(i) are correct this refers to metal assisted deprotonation of the second amide. The fact that this second deprotonation step is so much easier than the first deprotonation suggests the coordination involvement of the pyridyl nitrogen as shown in Fig. 4d(i). This would also explain why the MLH_{-1} species is difficult to detect because it readily converts to the MLH_{-2} species (see Fig. 6, the speciation distribution curve).

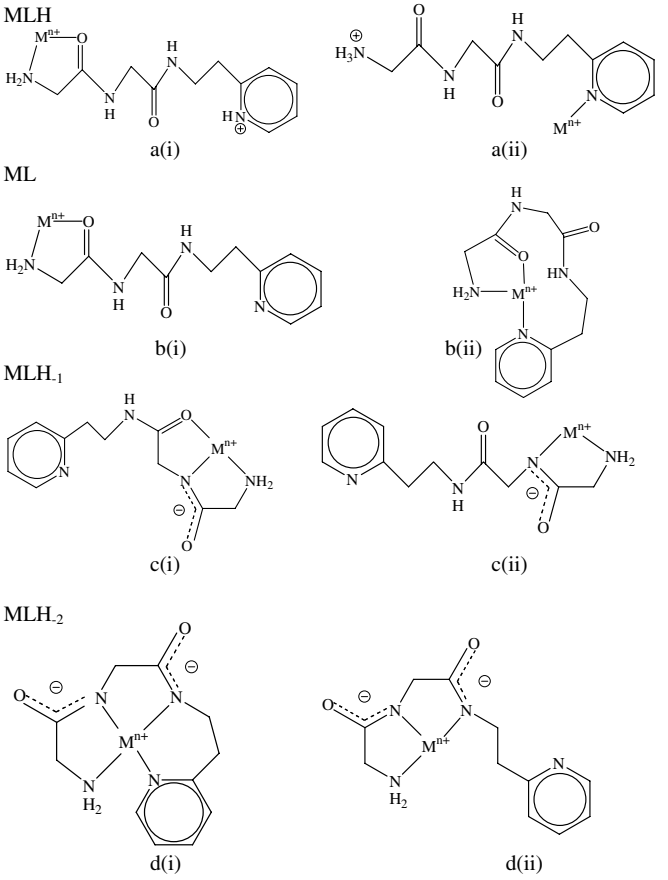

Fig. 4. Possible structures for different copper complexes showing the site of metal-ion coordination. For simplicity the axial H_2O ligands are omitted in these structures.

3.2.2. Molecular mechanics

When a ligand binds to a metal ion it loses rotational freedom and may have to adopt a less favourable conformation. This is an energy penalty that must be paid in order to form the complex. Molecular mechanics (MM) can be used to calculate this potential energy penalty. Table 3 lists the potential energy penalty associated with structures 4d(i) and d(ii) while Fig. 5 shows the energy minimised structures respectively.

Interestingly the total internal energy of 4d(i) is half that of 4d(ii) even though 4d(i) is more constrained than 4d(ii). The bond, angle and torsion angle contributions to the total internal energy are all higher. The main reason for this is shown in Fig. 5 (5,5) where the distortion of the octahedral coordinate geometry around the copper is clearly seen.

Table 3
Internal energy (kcal mol^{-1}) associated with structures Fig. 4d(i) (5,5,6) and Fig. 4d(ii) (5,5)

	5,5,6	5,5
Total	23.4	58.2
Bond	5.9	17.5
Angle	11.3	31.0
Torsion	6.0	9.1
Out-of-plane	0.1	0.6

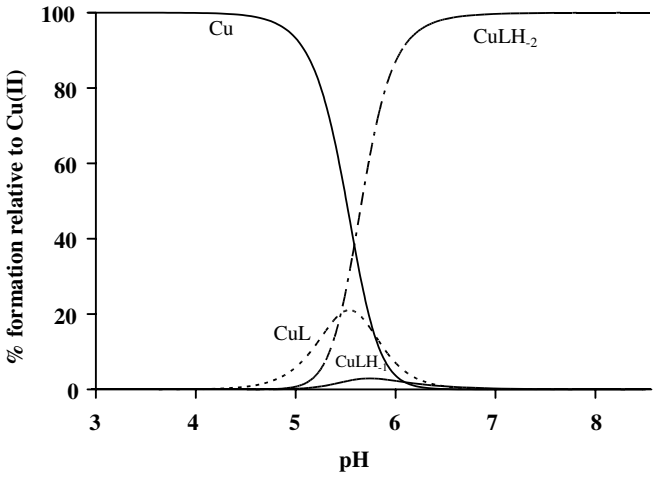

Fig. 6. Distribution diagram for the different species in the Cu(II)–[H_2(556)–N] system at 298 K as a function of pH, metal to ligand ratio is 1:4.

3.3. Spectroscopy and solution structures

The formation of the Cu(II)–[H_2(556)–N] and Ni(II)–[H_2(556)–N] complexes can be followed by UV–visible spectrophotometry because distinct colour changes occur as a result of the changing speciation of the solution with pH. By recording the spectra at different component concentrations and at different pH values, using a deconvolution algorithm, it is possible to calculate the spectrum of each individual species. The calculated aqueous UV–visible spectra for the Cu(II)–[H_2(556)–N] and Ni(II)–[H_2(556)–N] systems are shown in Fig. 7. The peaks corresponding to three species, CuL, $CuLH_{-1}$, $CuLH_{-2}$ can clearly be seen for the Cu(II)–[H_2(556)–N] system. The calculated λ_{max} and ε values for Cu(II), CuL, $CuLH_{-1}$, $CuLH_{-2}$ are: 800 nm ($\varepsilon = 29.0\ M^{-1}\ cm^{-1}$), 540 nm (20.0 $M^{-1}\ cm^{-1}$), 540 nm (2.6 $M^{-1}\ cm^{-1}$) and 530 nm (233.9) $M^{-1}\ cm^{-1}$) respectively. Pure aqua ion of Cu(II) have been reported to have an extinction coefficient value of 12 $M^{-1}\ cm^{-1}$ at a λ_{max} of 810 nm [51].

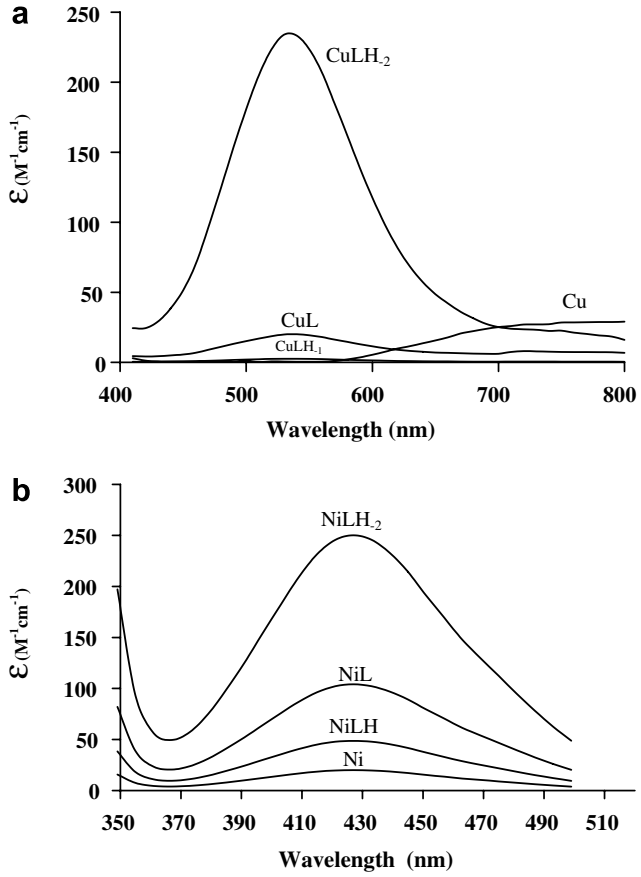

Fig. 7. Individual spectra $\varepsilon = f(\lambda)$ of the corresponding (a) Cu(II)–[H_2(556)–N] and (b) Ni(II)–[H_2(556)–N] system as a function of pH ([Cu(II)/Ni(II)] = 0.01 M:[L] = 0.04 M at 298 K).

The λ_{max} and ε values for $CuLH_{-2}$ allows us to make some conclusions to the coordination of the amino, the pyridyl and two deprotonated peptide nitrogen groups in accordance to similar reported literature data [17,18,52,53]. The λ_{max} and ε values are very close to those reported for Gly-Gly-His [17] and Ala-Gly-His [18].

Direct evidence for the amide proton dissociation on complexation has been widely reported [54–56] for Cu(II) complexes in solution. Moreover, results of X-ray crystallographic studies [57] have also shown unequivocally that the amide proton displacement takes place in the solid with the coordination of the resulting negative amide groups occurring to the metal ion. The crystallographic structures of the $CuLH_{-2}$ complexes for different, but related models have also been reported for Cu(II)-glycylglycylhistamine [17], Cu(II)-alanylglycylhistamine [18], Cu(II)-glycylglycylhistidine-*N*-methylamide [58] and Cu(II)-(α,β-didehydro-glycylglycylhistamine) [59]. The solid state structures of these related Cu(II)-peptides indicate coordination of Cu(II) by four nitrogen atoms; an amino, two peptides and imidazole-N3 nitrogen atoms forming a slightly distorted square planar arrangement. Our results also suggest the same coordination mode in the $CuLH_{-2}$ complex as shown in Fig. 4d(i).

Octahedral six coordinate Ni(II) complexes, being d^8, should give rise to three electronic $d \rightarrow d$ transitions involving three spin allowed transitions from $^3A_{2g}$ to $^3T_{2g}$, $^3T_{1g}$ and $^3T_{1g}(P)$ with intensities less than 30 M^{-1} cm^{-1} [60]. The absorption spectra of octahedral nickel hexahydrate ion, $Ni(H_2O)_6$ has been reported [60] to show three characteristic bands, one at around 400 nm and two broad bands above 600 nm. From Fig. 7b, the band at a λ_{max} of 427 nm ($\varepsilon = 20$ M^{-1} cm^{-1}) corresponds to octahedral six coordinate $Ni(H_2O)_6$. The calculated λ_{max} and ε values for NiLH, NiL and $NiLH_{-2}$ are: 427 nm ($\varepsilon = 48.7$ M^{-1} cm^{-1}), 427 nm (104.1 M^{-1} cm^{-1}) and 427 nm (250 M^{-1} cm^{-1}) respectively. This characteristic absorption band (427 nm) for the three species falling within the range 425–435 nm is assigned to $^1A_{1g} \rightarrow {}^1A_{2g}$ transition [61]. The band starts to increase above pH 7.00, reaching a maximum above pH 9.00 with a change in colour of solution from light green to yellow. A similar species for Ala-Gly-Ha, a related peptide has been reported [18] to give an absorption band at a λ_{max} value of 417 nm at pH 6.30.

It has been reported [62] that Ni(II) complexes with the tetraamine ligand, trien (1,4,7,10-tetraazadecane), has an equilibrium mixture of the yellow, diamagnetic square planar species $[Ni(trien)]^{2+}$ and of the blue, high-spin, diaqua octahedral species $[Ni(trien)(H_2O)_2]^{2+}$. Based on this assertion and the observed predominance of the yellow colour during titration, the dominant species ($NiLH_{-2}$ at pH 9.69) in the Ni(II)–[H_2(556)–N] system is suggested to be diamagnetic and square planar. Moreover, most Ni(II) complexes coordinated to amide-nitrogen atoms have been reported to be square-planar and diamagnetic [63], with the two deprotonated amide groups providing a strong ligand field leading to a singlet ground state. Like $CuLH_{-2}$, $NiLH_{-2}$ does not react with hydroxide in accordance with the planar nature of this chelate. The absorption band at 427 nm is, however, obscured by a ligand to metal charge transfer (LMCT) band centred at 301 nm. The LMCT transition originates from the carbonyl oxygen or deprotonated peptide nitrogen to the vacant $^1A_{2g}$ orbital of the metal ion. The high molar extinction coefficients of the LMCT bands for the NiLH, NiL and $NiLH_{-2}$ species in the range of 1000–5000 M^{-1} cm^{-1} in this study indicate the charge transfer character of the system.

3.4. Partition coefficients measurements

Partition coefficients measurements can be used as extra-thermodynamic reference parameters for "hydrophobic bonding" in biochemical and pharmacological systems.

Octanol/water partition coefficients were used to give an estimation of the trans-dermal transport of the Cu(II)–[H_2(556)–N] complexes. For a drug to be considered lipophilic, the $\log P_{oct/aq}$ value should be at least 0.60. The octanol/water partition coefficients results as a function of pH for the Cu(II)–[H_2(556)–N] system are given in Fig. 8. A noticeable feature about Fig. 8 is that all

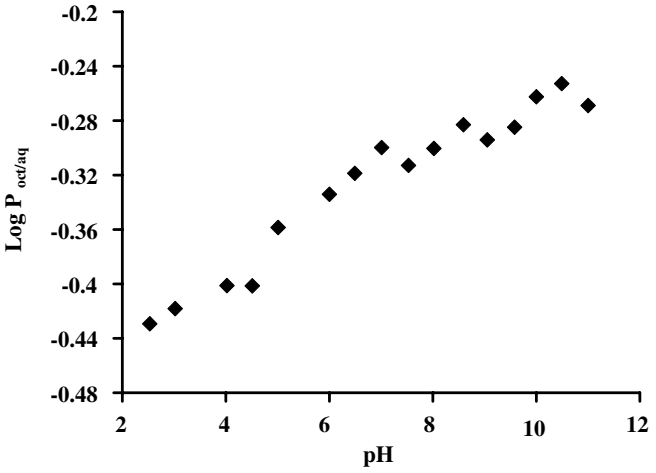

Fig. 8. Log $P_{oct/aq}$ of Cu(II)–[H_2(556)–N] complexes plotted as a function of pH.

log $P_{oct/aq}$ values are negative but increase with pH. Negative values of log $P_{oct/aq}$ suggest that these complexes are largely hydrophilic.

From Fig. 8 the log $P_{oct/aq}$ values for the two systems at physiological pH (7.40) can be estimated as −0.30, indicating a 30% extraction of copper into the octanol phase. From the species distribution curves (Fig. 6), at this pH, the $CuLH_{-2}$ species predominates and so the partition coefficient can be assigned to this species. Above pH 10.00 log-$P_{oct/aq}$ decreases.

A comparison of our partition coefficients with those reported in literature [64] for related chelating agents show an improvement factor of 6–14. To our knowledge, the ^{67}Cu(II) and ^{64}Cu(II)-labelled [*N*(2-pyridylmethyl-*N*1-(salicylaldimino)-1,3-propanediamine] and pyruvaldehyde-bis(N^4-methylthiosemi-carbazone) derivatives studied by Green and co-workers [65,66] are the only Cu(II) containing complexes to have high, positive log $P_{oct/aq}$ values ranging from 1.97 to 3.61. Using a predictive model for skin permeation rate developed by Michaels et al. [67,68] a trans-dermal flux value of 7.71×10^{-2} cm h^{-1} is determined for the Cu(II) complex of [H_2(556)–N]. This trans-dermal flux rate is encouraging enough to merit membrane crossing of the complex by passive transport.

3.5. Blood-plasma simulation studies

In order to establish the true selectivity of [H_2(556)–N] for Cu(II) over Ca(II) and Zn(II) *in vivo*, the blood-plasma mobilizing index (p.m.i.) has been calculated. This calculation takes into account competition with some 10 metal ions and more than 5000 ligands present in plasma. The index is defined as the concentration of low molecular mass Cu(II) complex species in the presence of a drug divided by their concentration in the absence of the drug [20]. The Cu(II) p.m.i. of [H_2(556)–N] was calculated by incorporating the formation constants measured in this study into a computer model of blood plasma [23]. The total ligand concentration ($[L]_T$) was varied over the range 10^{-3}–10^{-9} M and p.m.i. calculated at each point. The results are shown in Fig. 9. For comparison, results for [H(555)–N] are also shown.

From this we see that although [H(555)–N] is some three orders of magnitude better than [H_2(556)–N] at mobilizing Cu(II) *in vivo*. Both [H(555)–N] and [H_2(556)–N] are able to cause a 10-fold increase in low molecular weight (l.m.w.) Cu(II) concentration at total ligand concentration of 10^{-5} and 10^{-2} M respectively. The remarkably high mobilizing ability of [H(555)–N] by a factor of three log units compared to [H_2(556)–N] is related to the presence of two electron withdrawing CONH-group in [H_2(556)–N]. However, at the aforementioned ligand concentrations, the Zn(II) and Ca(II) p.m.i.'s are insignificant. Hence the speciation of these two essential metal ions is not disturbed. Thus, in spite of the higher concentrations of Zn(II) and Ca(II) than Cu(II) *in vivo*, their weak binding strength with the ligand make them insignificant competitors for Cu(II).

3.6. Superoxide dismutase mimetic activity of the $CuLH_{-2}$ complex

Copper–zinc superoxide dismutase is an enzyme that catalyses the dismutation of the superoxide anion radical to molecular oxygen, water and/or hydrogen peroxide [35,36,69]. Low molecular weight Cu(II) complexes are also able to catalyse the dismutation of the superoxide anion radical albeit with a much lower activity [69]. In view of this observation, we have investigated the SOD mimetic activity of the Cu(II)–[H_2(556)–N] complex.

By using the nitroblue tetrazolium (NBT) assay in the presence of ethylenediaminetetraacetic acid (edta) as an *in vitro* chelation simulator [35,36,69], the results given in Fig. 10 were obtained. From Fig. 10, an IC_{50} value of 6.25 μM was determined. Roberts and Robinson [69] have reported an IC_{50} value of 0.011 μM for the native CuZn-SOD, which is more than 500 times less. Based on this comparison, it can be concluded that the $CuLH_{-2}$ complex for the Cu(II)–[H_2(556)–N] system is a poor mimic of the

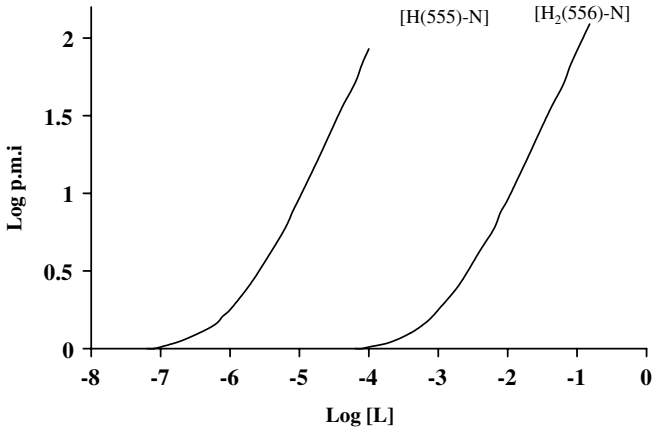

Fig. 9. Cu(II) plasma mobilizing index for [H(555)–N] and [H_2(556)–N].

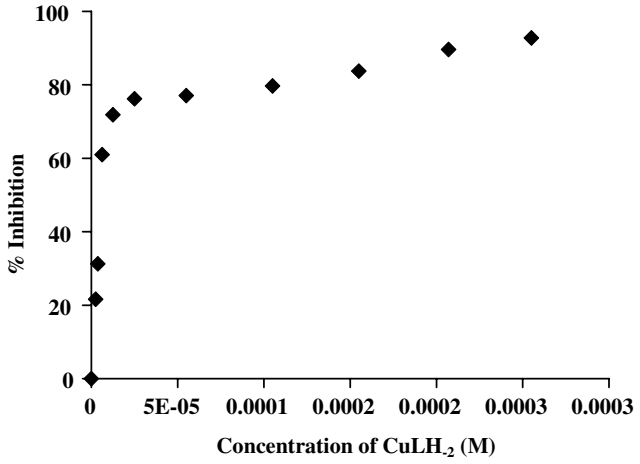

Fig. 10. % Inhibition as a function of the concentration of the $CuLH_{-2}$ species for the Cu(II)–[H_2(556)–N] system.

enzyme. This is a common observation for square planar copper complexes where the very weak axial coordination does not catalyse the dismutation of the superoxide radical.

4. Conclusion

This study has shown the computational problems associated with the design and study of copper-based therapeutics suggesting that great caution has to be exercised in model selection. However despite these limitations, the *in vitro* selectivity for Cu(II) over the *in vivo* competitors of [H_2(556)–N] is suggested based on thermodynamic investigations, molecular mechanics calculations and blood plasma simulations.

The coordination modes in the different complexes formed in solution were proposed using both potentiometric and UV–visible spectroscopic data. Although the $CuLH_{-2}$ species is a poor mimic of the native CuZnSOD enzyme, blood plasma simulations indicate that the complex is unlikely to dissociate *in vivo*. The use of percutaneous drug therapy is a promising method as incorporation of bulky groups within the chelating agents improved octanol/water partition coefficients, indicating enhanced trans-dermal absorption of the copper complexes.

crystals are arranged in fan shaped aggregates. The other form produces a blue to blue-green botryoidal crust.

2. Experimental

2.1. Minerals

Selected hemimorphite minerals were obtained from the Mineral Research Company (http://www.minresco.com/default.htm) and other sources including Museum Victoria (Museum Victoria, Melbourne, Victoria, Australia). The samples were phase analysed by powder X-ray diffraction and for chemical composition by EDX measurements.

2.2. Raman microprobe spectroscopy

The crystals of hemimorphite were placed and oriented on the stage of an Olympus BHSM microscope, equipped with 10× and 50× objectives and part of a Renishaw 1000 Raman microscope system, which also includes a monochromator, a filter system and a Charge Coupled Device (CCD). Raman spectra were excited by a HeNe laser (633 nm) at a resolution of 2 cm^{-1} in the range between 100 and 4000 cm^{-1}. Repeated acquisition using the highest magnification was accumulated to improve the signal to noise ratio. Spectra were calibrated using the 520.5 cm^{-1} line of a silicon wafer. In order to ensure that the correct spectra are obtained, the incident excitation radiation was scrambled. Previous studies by the authors provide more details of the experimental technique. Spectra at liquid nitrogen temperature were obtained using a Linkam thermal stage (Scientific Instruments Ltd, Waterfield, Surrey, England). Details of the technique have been published by the authors [4–7].

2.3. Mid-IR spectroscopy

Infrared spectra were obtained using a Nicolet Nexus 870 FTIR spectrometer with a smart endurance single bounce diamond ATR cell. Spectra over the 4000-525 cm^{-1} range were obtained by the co-addition of 256 scans with a resolution of 4 cm^{-1} and a mirror velocity of 0.6329 cm/s. Spectra were co-added to improve the signal to noise ratio.

Spectral manipulation such as baseline adjustment, smoothing and normalisation were performed using the Spectracalc software package GRAMS (Galactic Industries Corporation, NH, USA). Band component analysis was undertaken using the Jandel 'Peakfit' software package which enabled the type of fitting function to be selected and allows specific parameters to be fixed or varied accordingly. Band fitting was done using a Lorentz–Gauss cross-product function with the minimum number of component bands used for the fitting process. The Lorentz–Gauss ratio was maintained at values greater than 0.7 and fitting was undertaken until reproducible results were obtained with squared correlations of $r^2 > 0.995$.

3. Results and discussion

3.1. Factor group analysis

The classic rules of vibrational spectroscopy show that the free SiO_4^{4-} tetrahedron of T_d symmetry has a

vibrational set $\Gamma = 1A_1 + 1E + 1F_1 + 3F_2$. By eliminating translations and rotations, the reduced representation $\Gamma' = 1A_1 + 1E + 2F_2$. Thus all in all, four vibrations with the E vibration twice degenerate and the F vibration 3 times degenerate match up with the nine vibrations under the 3N-6 rule.

The linear $Si_2O_7^{6-}$ ion of assumed symmetry $\bar{3}_m$ has a vibration set $\Gamma_2 = 3A_{1g} + 1A_{1u} + 1A_{2g} + 4A_{2u} + 4E_g + 5E_u$ and without rotations and translations $\Gamma'_2 = 3A_{1g} + 1A_{1u} + 1A_{2g} + 2A_{2u} + 3E_g + 4E_u$. So 14 vibrations with seven degenerate match up with the 21 vibrations under the 3N-6 rule. For the $Si_2O_7^{6-}$ ion of *mm*2 binary symmetry i.e., with non-linear SiOSi bridges, the irreducible representation $\Gamma_{3=}8A_1 + 5A_2 + 6B_2 + 8B_1$. This reduces to, upon elimination of the rotational and translational modes to $\Gamma_{3=}7A_1 + 4A_2 + 4B_2 + 6B_1$. Thus 21 predicted vibrations would be expected.

3.2. Raman spectroscopy

The Raman spectra of hemimorphite from three different origins are shown in Fig. 2. The results of the Raman and infrared spectroscopic analysis are reported in Table 1. Table 1 shows a comparison of the Raman spectroscopic data from three hemimorphite samples together with the infrared data from one sample. The table reports the peak position (cm^{-1}), the relative intensity of the component bands as a percentage and the width of the bands (cm^{-1}). A very sharp band is observed in each of the three spectra at 930 cm^{-1}. This band is not symmetric. This means there are two component bands making up the spectral profile. This band may be band component analysed into two components at 931 and 926 cm^{-1}. The band width as full width at half peak maximum (FWHM) is 9.0 cm^{-1} for the first peak and between 13.7 and 15.0 cm^{-1} for the second peak. These bands are attributed to the SiO stretching vibration of the Si_2O_7 units. An intense band is observed at 1093 cm^{-1} for the white hemimorphite from Sardinia. This band is not observed in the Raman spectra of the other hemimorphite samples. It is interesting that Brunel and Verne reported a band in this position to the A_{1g} vibrational mode of the $Si_2O_7^{6-}$ units [8]. In the light of these Raman spectra this assignment is open to question. This band is ascribed to the symmetric stretching vibration of a carbonate impurity. Poulet and Mathieu assigned the band at 930 cm^{-1} to the A_1 mode of the $Si_2O_7^{6-}$ units [9]. No Raman spectra were reported in their article, only the results of the spectra were reported. In the infrared spectrum of the hemimorphite from Arizona, an intense band at 933 cm^{-1} is observed (Fig. 2). Brunel and Vierne reported the infrared band at 932 cm^{-1} for a single crystal of hemimorphite and attributed the band to the B_1 vibrational mode [8]. These authors showed that the position of this band varied in position, if the hemimorphite was powdered. Farmer ([10, p. 296]) showed there was a correlation between the wavenumber of the SiO antisymmetric stretching vibration and the SiO bond length [10]. The ν_{as}

vibration is localised on the bridging oxygen. Lazarev showed that this wavenumber is determined by the OSiO bond angle.

A band common to all the three hemimorphite minerals is the band at 674 cm^{-1}. Brunel and Vierne identified an infrared band in this position and assigned the band to an A_1 vibration [8]. These workers showed that the position of this band varied according to the infrared techniques used for measurement. In the infrared spectrum, (Fig. 3) an intense band is observed at 676 cm^{-1}. Poulet and Mathieu observed a Raman band in this position and an infrared band at 677 cm^{-1} of medium intensity [9]. The band position varied according to the experimental settings of the single crystal experiment. They assigned the band to a O–Si–O bending vibration [9]. The band observed at 729 cm^{-1} for the white hemimorphite sample is ascribed to a carbonate bending mode. The band is not observed in the Raman spectra of the other two hemimorphite samples. A low intensity band is observed in all of the Raman spectra at 556 cm^{-1}. A distinct infrared band of hemimorphite is observed at 597 cm^{-1} (Fig. 3). Poulet and Mathieu observed a Raman band at 554 cm^{-1} in the Raman spectrum and at 545 cm^{-1} in the infrared spectrum [9]. Brunel and Vierne also defined a band at 563 cm^{-1} [8]. In this later work, the position of the band depended on the infrared technique used and upon the amount of sample in the KBr disc. This tends to suggest that there was an interaction between the hemimorphite and the KBr. Such a problem is avoided by using reflectance techniques as reported in this research. In the spectrum of the brown hemimorphite sample, a Raman band is observed at 979 cm^{-1}. Such a band was observed by Poulet and Mathieu [9] and was attributed to A_2(ab) vibration. The band is also observed for the hemimorphite from Arizona but is of very low intensity.

A number of infrared bands are observed at 1078, 1049, 1043 and 1027 cm^{-1} (Fig. 3). Poulet and Mathieu also observed infrared bands at 1380, 1170, 1085 and 1020 cm^{-1} and assigned these bands to δ OH vibrations. Brunel and Vierne also observed an infrared band at around 1090 cm^{-1}. However they attributed the band to E_u modes of the Si_2O_7 units. No Raman bands were observed in these positions which tends to suggest that the assignment of Poulet and Mathieu is perhaps more accurate. A number of infrared bands are observed at 1386, 1357 and 1336 cm^{-1} (Fig. 4). The probable assignment of these bands is to the δ OH deformation modes. The $\nu_{antisym}$ vibration is localised on the bridging oxygen. Lazarev showed that this wavenumber is determined by the OSiO bond angle. In the figure developed by Farmer,

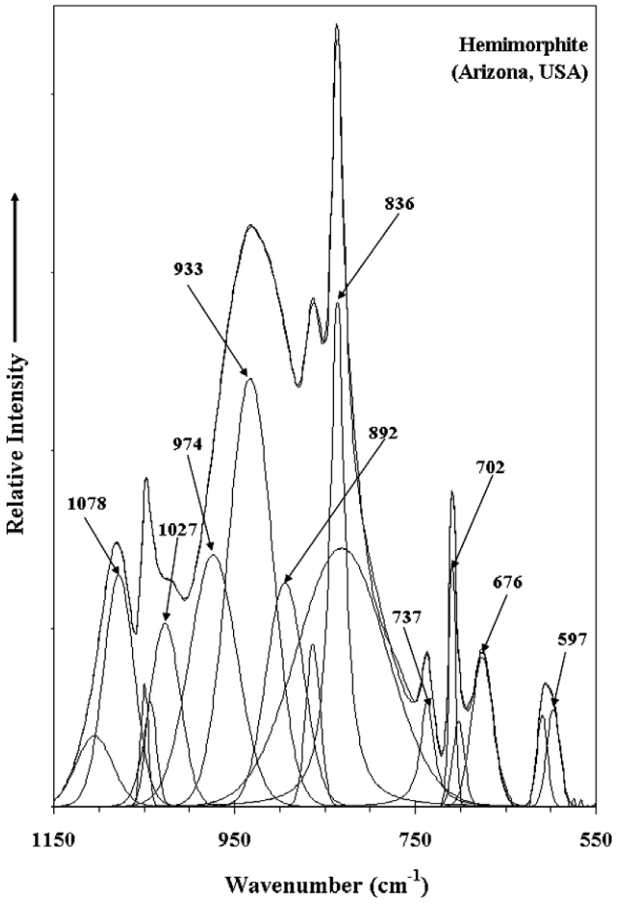

Fig. 3. Infrared spectra of hemimorphite in the 550–1150 cm^{-1} range.

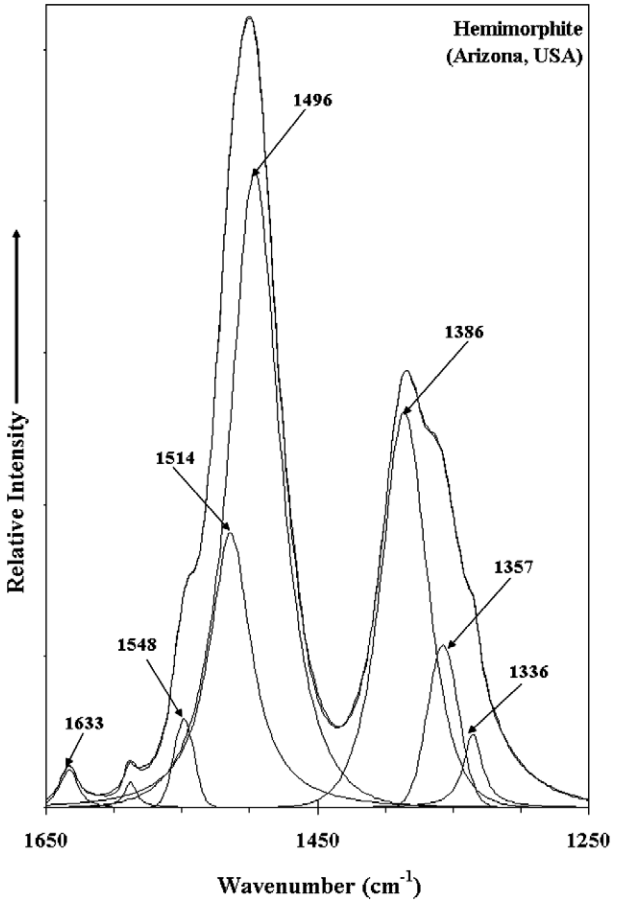

Fig. 4. Infrared spectra of hemimorphite in the 1250–1650 cm^{-1} range.

a band assigned to the antisymmetric stretching vibration at around 1110 cm^{-1} for pyromorphite is shown and is assigned to the SiO antisymmetric stretching vibration. Thus it is likely that the infrared bands observed by Poulet and Mathieu at 1170 and 1085 cm^{-1} are the infrared active Raman inactive antisymmetric stretching vibrations.

Two Raman bands are observed at 451 and 400 cm^{-1} (Fig. 5). These bands are attributed to out-of-plane bending vibrations of the Si_2O_7 units. Poulet and mathieu also observed Raman bands in these positions and described the bands as "déformations angulaires et réseau". They also observed an infrared band at 450 cm^{-1}. Bands in these positions are not able to be detected using the ATR technique with the diamond anvil cell as the cell absorbs at wavenumbers below 550 cm^{-1}. An intense Raman band is observed at 330 cm^{-1}. This band is attributed to the Zn–O stretching vibration. A second band is observed at around 280 cm^{-1}. This band may also be assigned to a ZnO stretching vibration. The band at 303 cm^{-1} for the white hemimorphite from Sardinia is considered to be due to a ZnO stretching vibration of the zinc carbonate impurity. The intense bands at 168 and 132 cm^{-1} are ascribed to the OZnO bending vibrations.

In the Raman spectra, bands of significant intensity are observed around 1634 cm^{-1} (Fig. 6). In the infrared spectrum (Fig. 4), a distinct band is observed at 1633 cm^{-1}. These bands are attributed to δ H_2O vibrations. In some ways it is unusual to observe the water bending mode in the Raman spectrum. The band is normally intense in the infrared spectrum and is of very low intensity or is not at all observed in the Raman spectrum. These results compare well with those of Brunel and Vierne and also Poulet and Mathieu [8,9]. Both previous studies showed the infrared bands of water in hemimorphite. In the structure of hemimorphite, perpendicular to the *C* axis, four, six and eight-fold tetrahedral rings are formed. The six and eight fold rings are connected along the *C* axis in wide1 channels which are occupied by water molecules. It is these water molecules which give the deformation modes at 1630 cm^{-1}. These water molecules must be in an ordered arrangement to give a water bending mode in the Raman spectrum of significant intensity.

The Raman spectra of hemimorphite from three different localities show consistently similar spectra, especially in the OH stretching region (Fig. 7). Two Raman bands are observed at around 3510–3565 and 3436–3455 cm^{-1}.

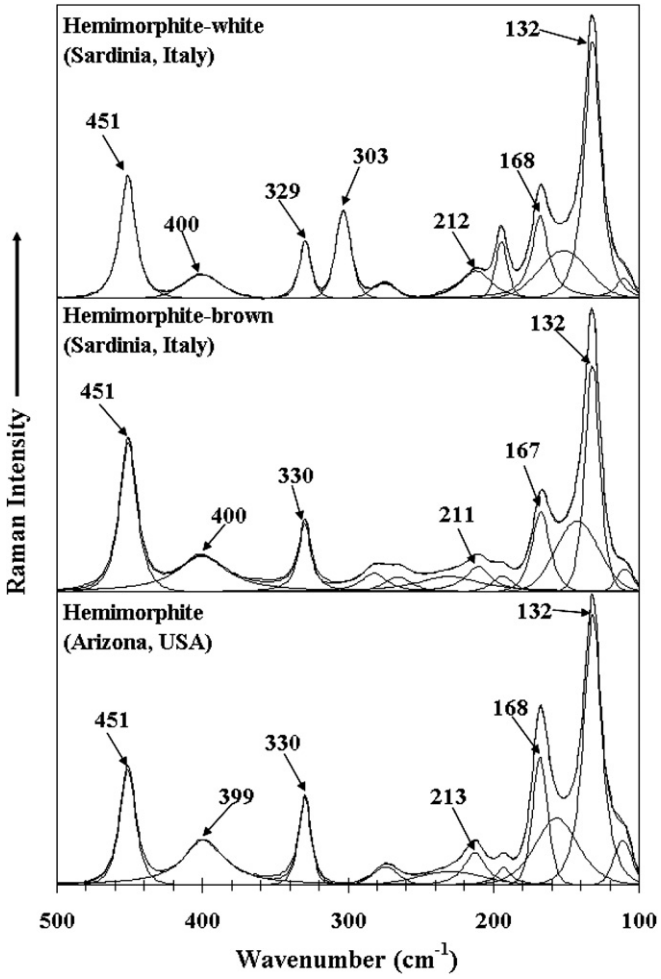

Fig. 5. Raman spectra of hemimorphite in the 100–500 cm^{-1} range.

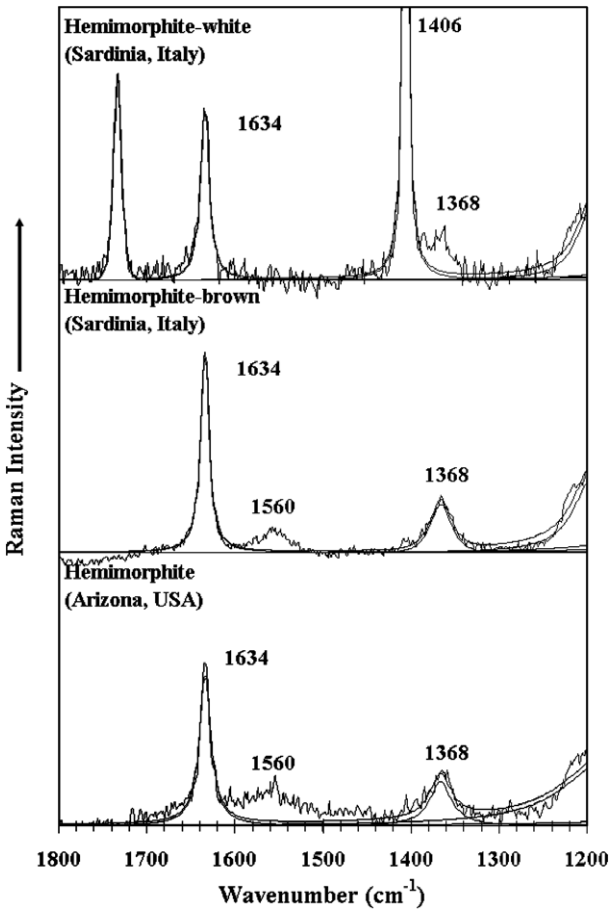

Fig. 6. Raman spectra of hemimorphite in the 1200–1800 cm^{-1} range.

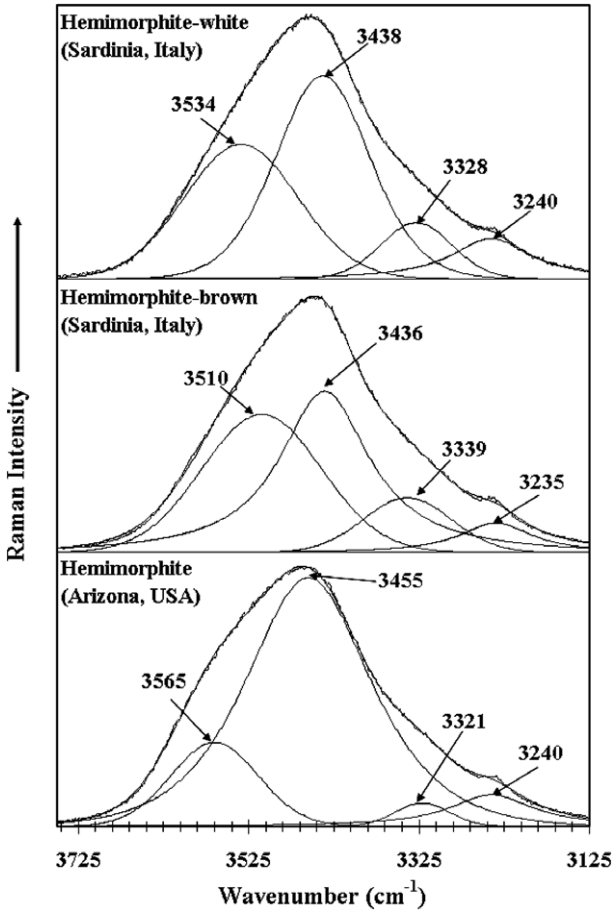

Fig. 7. Raman spectra of hemimorphite in the 3125–3725 cm^{-1} range.

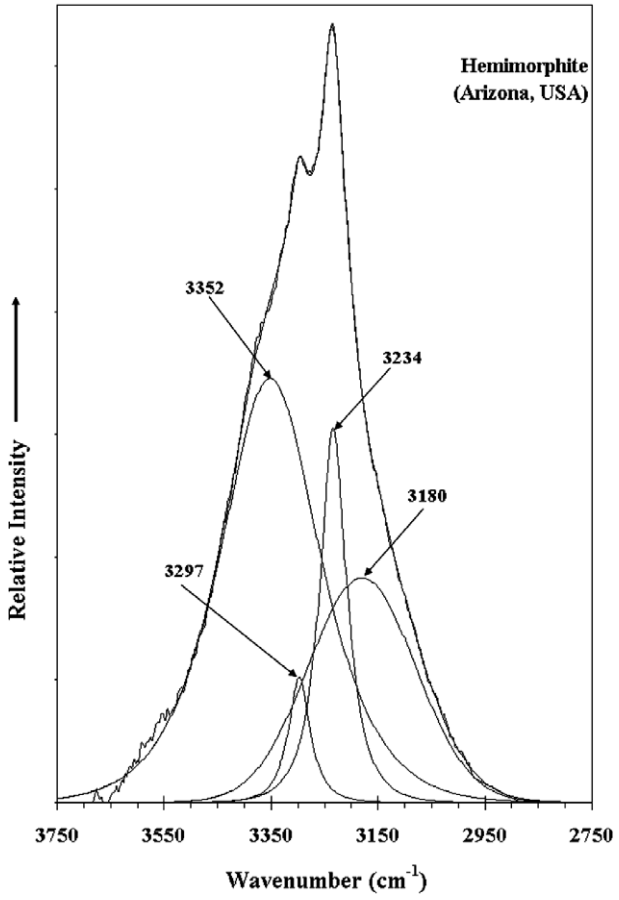

Fig. 8. Infrared spectra of hemimorphite in the 2750–3750 cm^{-1} range.

These bands are assigned to OH stretching vibrations of the mineral $Zn_4Si_2O_7(OH)_2 \cdot H_2O$. Raman bands are observed at around 3328 and 3240 cm^{-1} and are attributed to the OH stretching vibrations of the OH units. Polarized FTIR absorption spectra of oriented hemimorphite crystals have been published [11,12]. Infrared spectra of the Aizona hemimorphite in the OH stretching region are shown in Fig. 8.

Studies have shown a strong correlation between OH stretching frequencies and both O···O bond distances and H···O hydrogen bond distances [13–16]. Libowitzky (1999) showed that a regression function can be employed relating the hydroxyl stretching frequencies with regression coefficients better than 0.96 using infrared spectroscopy [17]. The function is described as: $v_1 = (3592 - 304) \times 109^{\frac{-d(O-O)}{0.1321}}$ cm^{-1}. Thus OH···O hydrogen bond distances may be calculated using the Libowitzky empirical function. The values for the OH stretching vibrations listed above provide hydrogen bond distances of 3510 cm^{-1} giving a calculated hydrogen bond distance of 0.2910 pm, 3436 cm^{-1}→ 0.2825 pm, 3739 cm^{-1}→ 0.2762 pm and 3235 cm^{-1} → 0.2716 pm. The conclusion may be drawn that the hydrogen bond distances formed from the water units are stronger than those formed from the OH units.

4. Conclusions

Hemimorphite because of its nature is most interesting to study using vibrational spectroscopic techniques. In this paper we report the study of hemimorphite minerals from three different origins and show that a carbonate impurity is found in some of the mineral samples. Raman bands observed at 3510 to 3565 and 3436 to 3455 cm^{-1} are assigned to OH stretching vibrations. Using a Libowitzky type formula, these OH bands provide hydrogen bond distances of 2.910, 2.825, 2.762 and 2.716 Å. Water bending modes are observed in the Raman spectrum at 1633 cm^{-1}. An intense Raman band at 930 cm^{-1} is attributed to SiO symmetric stretching vibration of the Si_2O_7 units.

dimensions <2 nm and is superparamagnetic [5]. Here, "superparamagnetic" denotes a magnetic system that has an anisotropy energy (or a zero field splitting) resulting in a fixed moment at low temperatures, and a fluctuating moment at temperatures above the corresponding anisotropy energy. Fe_8 is one of the best chemically and magnetically characterized materials. Much of the focus of the research on SMMs has been geared towards its fundamental chemical [6], EPR spectroscopic [7–12], and magnetic properties [13–15]. Potential solid-state applications of SMMs are use in high density magnetic memory, quantum computing [16], and spintronics devices such as high-frequency spin-based oscillators and signal processors [17].

Three recent studies have indicated potential applications of these materials dissolved in aqueous solution as versatile MRI contrast agents [2–4]. Rodriguez et al. published a comprehensive work comparing MRI phantoms at 64 MHz (1.5 T), and nuclear magnetic resonance (NMR) results at 400 MHz (9.4 T) for $Fe_{8(aq)}$ with Gd-DTPA (DTPA = diethylenetriamine-pentacetic acid) obtained as the commercial preparation Magnevist [2]. They found that the relaxivities of $Fe_{8(aq)}$ were about equal to that of Magnevist at 64 MHz and possibly superior at higher resonance frequencies [2]. They also examined the cytotoxicity of Fe_8 and found a lethal concentration for 50% mortality, LC_{50}, of ~1 mM [2]. Isaacman et al. also compared Fe_8 versus Magnevist using NMR relaxivity at 400 MHz [3]. They found, however, that $Fe_{8(aq)}$ was much less efficient than Magnevist for MRI contrast applications [3]. In a study of tailored iron-based imaging agents using MRI phantoms at 64 MHz, Barker et al. compared de-ionized (DI) water and DI water containing the dissolved Fe_8, and found that $Fe_{8(aq)}$ had potential as a contrast agent for both the T_1 and T_2 weighted contrast experiments [4]. Barker et al., however, did not provide any quantitative comparisons with Magnevist [4]. To resolve the conflict we undertook the current study to determine the relative merits of $Fe_{8(aq)}$ and Magnevist as a function of concentration.

The spin arrangement of the SMM Fe_8 at low temperatures can be thought of as a spin $S = 10$ particle where six $S = 5/2$ Fe^{3+} are aligned antiparallel to two $S = 5/2$ Fe^{3+} [5]. In general, this compound is modeled using a double-well potential with each well minimum corresponding to the preferred moment orientations. The depth of this well, $\Delta E/k$, (where k is the Boltzmann constant and ΔE is the anisotropy energy or barrier to reorientation) is about 24 K [18,19]. This results in Arrhenius-like thermally activated slow relaxation of the magnetization such that the magnetization fluctuation time is, $\tau = \tau_0 e^{\Delta E/kT}$, where τ_0 is the characteristic oscillation time in the energy well and T is the temperature. At temperatures of less than 1 K the dc magnetization of Fe_8 becomes constant relative to the typical measurement time of 100 s [20]; some SMMs have been shown to take months to relax [5]. This phase will be referred to as the blocked phase. Above 1 K each Fe_8 molecule fluctuates rapidly relative to this measurement time scale and the dc magnetization begins to decrease with increasing temperature, similar to a paramagnet, and due to the large moment per molecule is referred to as the superparamagnetic phase. This temperature dependent fluctuation time will lead to a frequency-dependent susceptibility. At room temperature the magnetic structure is less well known and will be more complex than an $S = 10$ macrospin particle.

The attractive qualities of Fe_8 for MRI contrast are aqueous solubility, possible ligand modification for bioconjugation, the large moment per molecule; and, unlike larger iron particles derived from solvo-thermal synthesis and top–down deposition techniques, these molecules are homogenous, identical units. The unknown quantities investigated here are the relaxivity over a range of concentrations spanning both previous studies using NMR and MRI techniques at 300 and 64 MHz, respectively, and the solution phase chemical identity using a novel ac susceptibility (χ_{ac}) study as a function of concentration. We then correlate the results from χ_{ac} with the relaxivity data to demonstrate why, in fact, both previous studies are correct at the relevant range of concentration.

2. Experimental

2.1. Synthesis

Fe_8 was synthesized in single crystal form using the original method of Weighardt [6] and summarized in earlier reports [7,9,21].

2.2. Ac susceptibility

The χ_{ac} data were obtained at zero applied dc magnetic field using a commercial 1.8–400 K susceptometer. The magnitude of the ac field was 0.65 mT and the frequency range was 200–1400 Hz . The samples consisted of differing concentrations of dissolved Fe_8 in deionized (DI) H_2O, ~100 μL measured within three hours of mixing in a sealed acrylic sample holder. The χ_{ac} of the holder with DI H_2O was negligible from 1.8 to 3 K.

2.3. NMR relaxometry

The NMR relaxation rates were obtained with a commercial 300 MHz (7 T) NMR system at room temperature within 3 h of mixing. In order to avoid radiation damping (a strong feedback between the transverse magnetization of the aqueous protons and the rf circuit) [22] the Fe_8 and Gd-DTPA (obtained as the commercial preparation Magnevist) were dissolved in a deuterated phosphate buffered saline solution (PBS). The NMR relaxivity r_1 results were obtained by a standard inversion recovery, $\pi_x - \tau - \pi/2_\phi$ – detect, sequence where the protons of the residual water in the sample are initially aligned along the applied field axis z, π_x is a pulse along axis x of such duration and power to invert the spins 180°, τ is a series of times between 0.01 and 2 s varied to obtain the relaxa-

tion along the z-axis, and a $\pi/2_{\phi}$ pulse is used to read out the remaining z-magnetization after the τ delay. A standard cyclically ordered phase sequence (ϕ) is used with the read pulse to eliminate quadrature artifacts. The T_2 relaxation of the H_2O was obtained by the Carr–Purcell–Meiboom–Gill sequence of $\pi_x/2 - (\tau - \pi_y - \tau)_n$ – detect, where multiple echoes were used over the range of 0.01–2 s to measure the spin–spin relaxation in the transverse plane prior to detection of the magnetization. A minimum of eight points were generated for each sequence; these data were processed by the internal NMR software system to generate T_1 and T_2 values for each concentration. The study in Ref. [2] was carried out in an aqueous non-dueterated PBS solution, and that in Ref. [3] in D_2O with the pH adjusted by NaOH.

2.4. MRI

Magnetic resonance images of the contrast agents were obtained with a commercial MRI operating at 64 MHz (1.5 T). Each sample tube was loaded upright in the circularly polarized extremity coil. A series of spin echo sequences were obtained with the following parameters: image matrix 256×256, pixel spacing 0.59 mm × 0.59 mm, slice thickness 5 mm, flip angle 180°, imaging frequency 63.67 MHz, magnetic field strength of 1.5 T, 1 average. The time to repetition (t_r) was 2500 ms and the time to echo (t_e) was varied over a series of 16 images starting at 22 ms and increased at 22 ms increments to 352 ms. A custom program using a simplex algorithm was used to calculate a T_2 map of each sample dilution.

3. Results and discussion

3.1. NMR relaxivity at 300 MHz

The basis of imaging in MRI is the difference in relaxation rates of the imaged aqueous protons due to the local biological environmental. The T_1 weighted image uses fast pulse repetition rates which produce brighter images for shorter T_1 times. T_2 weighted images sample the spin echo at long times weighting protons with long T_2's, which are then brighter. The concept of contrast enhancement using magnetic particles is to selectively shorten either T_1 or T_2 by placing them within proximity of structures of interest, such as lesions and tumors. This is quantified by the relation [23], $(1/T_i)_{obs} = (1/T_i)_d + r_i[M]$ $(i = 1, 2)$, where $(T_i)_{obs}$ is the observed relaxation time of the solvent in the presence of the paramagnetic contrast agent M, and $(T_i)_d$ is the observed relaxation time in the absence of M, and r_i is the relaxivity coefficient that describes the concentration dependence of M. Contrast is generally based on maximizing the difference in relaxation times; therefore a large value of r_i (conventionally in units of $s^{-1}\,mM^{-1}$) indicates large contrast potential. The slope of $(1/T_i)$ as a function of $[M]$ provides r_i.

An examination of the r_i data presented by Refs. [2,3] showed one major difference in the experiments: the concentration range investigated. Here, the relaxivity of Fe_8 is investigated over the entire range of both studies. Fig. 1 shows the inverse T_1 of Magnevist and Fe_8 as a function of concentration over the range of 0.1–3.7 mM. The Magnevist exhibits linear behavior over this range with relaxivity, $r_1 = 5.7\ s^{-1}\,mM^{-1}$, in general agreement with Ref. [3]. On the other hand, Fe_8 exhibited two distinct linear regions, one at low concentration <1.5 mM and one at higher concentrations. The r_1 value at low concentration was $5.4\ s^{-1}\,mM^{-1}$, which compares well to the value of Ref. [2] of $5.1\ s^{-1}\,mM^{-1}$ at 9.4 T. The r_1 value at concentrations above 1.5 mM was $1.1\ s^{-1}\,mM^{-1}$, which compares well with the value reported by Ref. [3] of $1.2\ s^{-1}\,mM^{-1}$, also at 9.4 T. The conflict in the literature is attributed to the concentration range that each group studied.

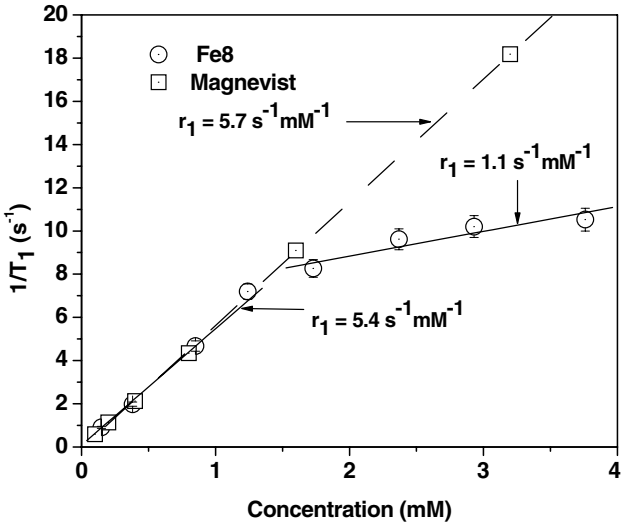

Fig. 1. The inverse proton longitudinal relaxation time T_1^{-1} of 0.1% H_2O in D_2O of Fe_8 and Magnevist solutions as functions of concentration. The Magnevist data are linear across the range investigated. The Fe_8 data, however, show two distinct linear regions above and below 1.5 mM as marked. The slope (r_1) of the low concentration region agrees with Ref. [2], and the slope of the high concentration region agrees with Ref. [3]. These data explain the discrepancy in the literature.

The behavior of T_2^{-1} as a function of contrast agent concentration is shown in Fig. 2. Gd-DTPA (Magnevist) is linear over the entire concentration range with an r_2 of $7.3\ s^{-1}\,mM^{-1}$. In contrast Fe_8 shows two distinct linear regions. Below 1.5 mM the r_2 value is $8.2\ s^{-1}\,mM^{-1}$, compared with Ref. [2] of $8.04\ s^{-1}\,mM^{-1}$. Above 1.5 mM r_2 is $3.2\ s^{-1}\,mM^{-1}$, compared with Ref. [3] of $3.1\ s^{-1}\,mM^{-1}$. Once again, the discrepancy between the two works is attributed to the concentration ranges investigated.

3.2. MRI relaxivity at 64 MHz

The behavior of Fe_8 and Magnevist was investigated using MRI phantoms in DI H_2O at 64 MHz (1.5 T). The MRI signal intensity as a function of the echo time, $S(t_e)$, is related to the transverse relaxation T_2 by [24], $S(t_e) = S_o \exp(-t_e/T_2)$, where S_o is a fit parameter related

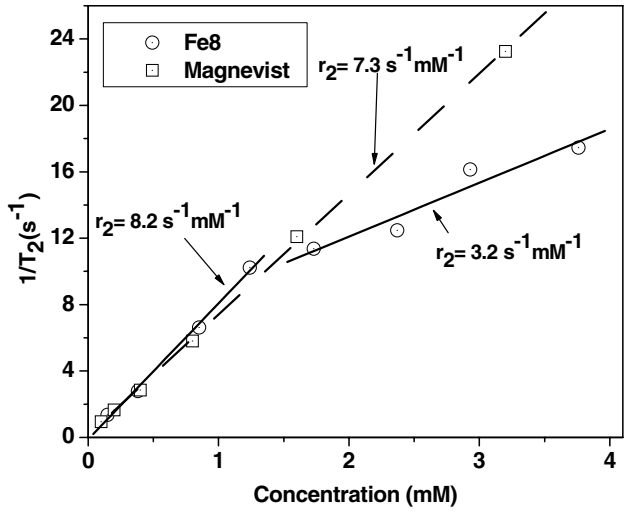

Fig. 2. The inverse transverse relaxation T_2^{-1} of Fe_8 and Magnevist as functions of concentration. In agreement with the relaxation data of Fig. 1, below 1.5 mM the data agree with Ref. [2], and above 1.5 mM the data agree with Ref. [3].

to the initial height of the free induction decay. The values of T_2^{-1} obtained this way as a function of contrast agent concentration are given in Fig. 3. The r_2 for Fe_8 below 1 mM is 4.9 s^{-1} mM^{-1} which compares well with the value in Ref. [2] of 5.01 s^{-1} mM^{-1} obtained by NMR at 1.4 T. Similar to data in Figs. 1 and 2 there is a dramatic decrease in the slope above 1 mM, although more points are needed. This indicates that the concentration dependence of the relaxivity, obtained here by NMR at 300 MHz (7 T), are valid in terms of in vitro MRI at 64 MHz (1.5 T). The relaxivity values are tabulated in Table 1. While the varying conditions and frequencies of these three studies compli-

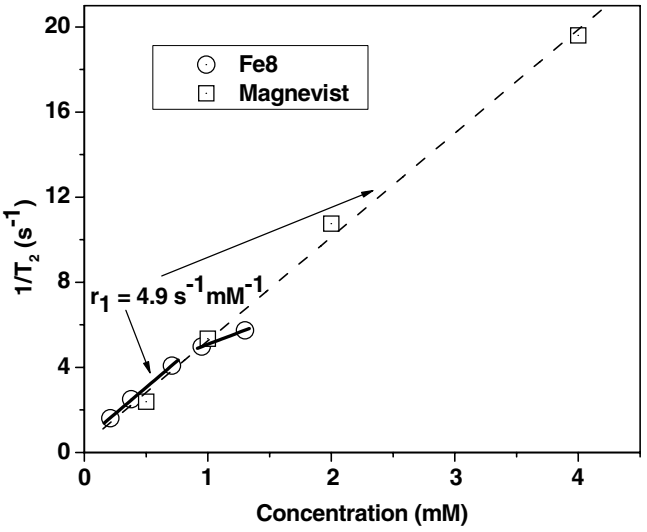

Fig. 3. The inverse transverse relaxation T_2^{-1} of Fe_8 and Magnevist as functions of concentration as obtained from MRI phantoms at 64 MHz (1.5 T). Notice that the $Fe_{8(aq)}$ shows a slope change above 1 mM. This indicates that the data in Figs. 2 and 2 are translatable to clinical in vitro MRI.

Table 1
Comparison of *r*-values

Sample	r_1 (mM^{-1} s^{-1})	r_2 (mM^{-1} s^{-1})	ν (MHz)	Ref.
Fe_8 (<1 mM)	5.10 ± 0.3	8.04 ± 0.12	400	[2]
(<1 mM)	4.76 ± 0.07	5.01 ± 0.08	64	[2]
(<1 mM)		4.9 ± 0.3	64 (MRI)	this work

	5.7 ± 0.3	7.3 ± 0.3	300	this work
	5.5	7.0	400	[3]

cate direct *r*-value comparisons, the essential point of concentration dependent *r*-values for Fe_8 seems very clear, and should not depend on the frequency investigated. We are currently evaluating Fe_8 over a wide frequency and temperature range.

3.3. Frozen solution ac susceptibility

In order to assess the degree of stability of the Fe_8 in aqueous solution, we carried out a systematic study of its ac susceptibility using frozen solutions. $Fe_{8(solid)}$ is known to exhibit a frequency-dependent response in the out-of-phase ac susceptibility (χ'') at temperatures of 1.8–5 K [19]. The ac susceptibility of a 6 mM Fe_8 frozen solution was measured by quick insertion into the 1.8 K cryostat of a commercial SQUID magnetometer. In Fig. 4, the dependence of χ''_{ac} as a function of temperature (1.8–3.5 K) and frequency (200–1400 Hz) is shown. A series of maxima which shift to higher temperatures with higher frequencies are present. They are qualitatively similar to the known response of $Fe_{8(solid)}$ observed by Barra et al. [19],

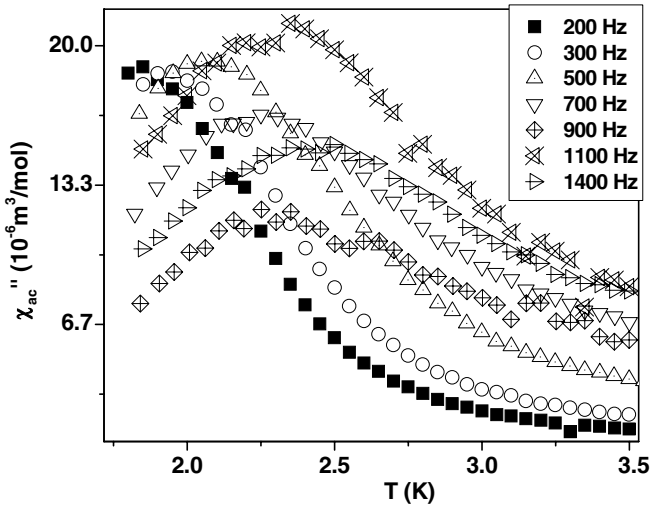

Fig. 4. The χ''_{ac} of a 6 mM frozen solution of Fe_8 in deionized H_2O at an ac field amplitude of 0.65 mT and zero applied dc field. This response is very similar to the response of Fe_8 powder, with the maxima being shifted to lower temperature.

with an overall shift to slightly lower temperature. These data show that in the frozen solution there exists species whose magnetic moment is blocked on the ac time scale at temperatures below 3 K and superparamagnetic above.

The depth of the potential well required to explain the χ'' frozen solution data is of interest for comparison with the Fe_8 solid. For each ac frequency, the temperature of the maxima, T_{max}, in χ'' is inversely related to τ such that at T_{max}, $\tau = (2\pi\upsilon_{ac})^{-1}$. In Fig. 5, the $\ln\tau$ versus the reciprocal of the temperature is plotted and a thermally activated Arrhenius behavior is present. From the slope, $\Delta E/k$ is 14 K and from the intercept $\tau_0 = 3.2\times10^{-7}$ s. The literature values of $\Delta E/k = 24.5$ K and $\tau_0 = 3.4\times10^{-8}$ s have been obtained for $Fe_{8(solid)}$ [18,19]. This approximate agreement suggests the blocked species in Fig. 4 is due to some of the Fe_8 retaining its essential magnetic identity in a frozen solution. The lower value of $\Delta E/k$ with the shift of the maxima to lower temperature implies that the barrier is particle-size and/or conformation dependent: a point that needs additional systematic investigation.

Given the concentration dependence of the relaxivity, the concentration dependence of the χ_{ac} of the Fe_8 frozen solutions was investigated. In Fig. 6. the in-phase response is given, which is sensitive to both blocked as well as paramagnetic species, of the frozen solution at 300 Hz as a function of concentration. At high concentrations, 5 mM for example, a profile characteristic of slow relaxation similar to Fe_8 solid is present, i.e. an inflection point leading to a maximum. This species is then blocked at these time scales and temperatures, and superparamagnetic at temperatures above. At 1 mM, however, a monotonic decrease with increasing temperature is observed indicative of components whose fluctuations are very rapid compared to the observation frequency, such as a paramagnet. The inset shows the molar χ' at 1.8 K as a function of concentration. There is an increase in the χ' as a function of decreasing concentration. Molar susceptibilities should be independent of concentration, this will be discussed later.

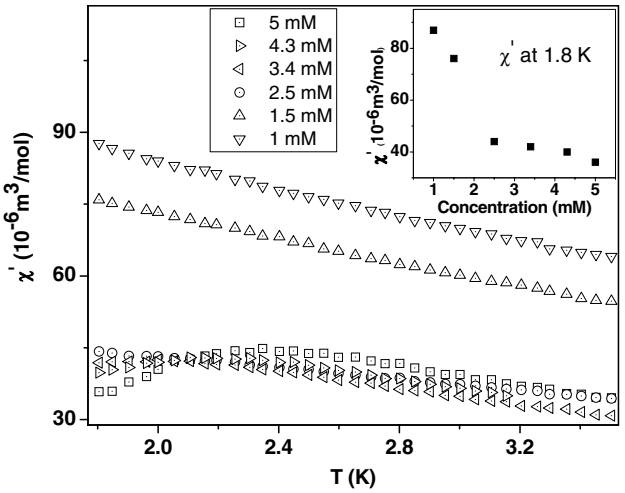

Fig. 6. The concentration dependence of the molar in-phase ac susceptibility at 300 Hz (ac field amplitude of 0.65 mT). The inset shows the χ'_{ac} at 1.8 K as a function of concentration. Note that there is an increase with χ'_{ac} with decreasing concentration.

The out-of-phase susceptibility, which is sensitive only to slow relaxation relative to the observation frequency is given in Fig. 7. At higher concentrations a strong response is observed in the χ'' indicating that the slow relaxation of the magnetic moment is present. As the concentration is lowered below 1.5 mM the maxima in χ'' is much less pronounced. The inset to Fig. 7 shows the maxima in χ'' as a function of concentration. There is a strong increase in the signal at concentrations above 1.5 mM, which roughly corresponds to the break in the $Fe_{8(aq)}$ relaxivity data at room temperature of Figs. 1 and 2.

The data for both low temperature frozen solutions and room temperature relaxivity have demonstrated non-linear

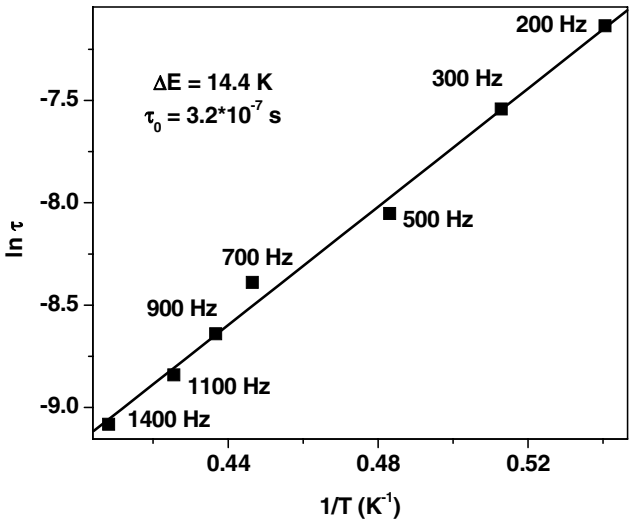

Fig. 5. An Arrhenius plot of the data from Fig. 4 that shows the natural logarithm of the relaxation time as a function of the inverse temperature.

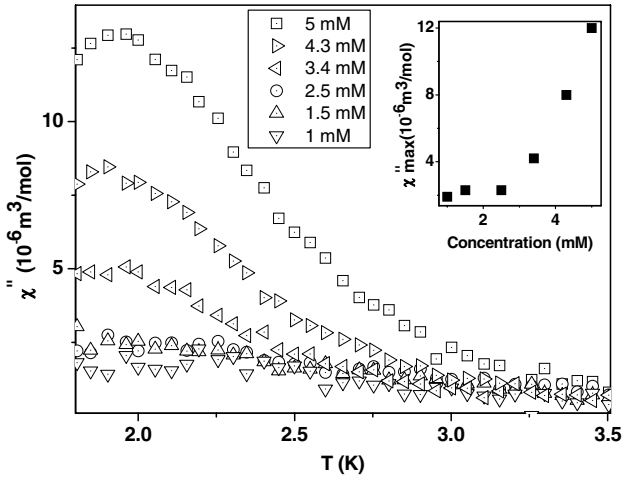

Fig. 7. The concentration dependence of the out-of-phase ac susceptibility at 300 Hz (ac field amplitude of 0.65 mT). Inset shows the maximum as a function of concentration. Notice that there is a non-linear decrease in the molar χ''_{ac} with increasing concentration.

behavior with a break point at ~1.5 mM. In works at concentrations above 1.5 mM both Refs. [3,25] demonstrated that Fe_8 is unstable in aqueous solution. Ref. [3] showed at >1 mM concentrations a partial decomposition into the precursor $Fe(tacn)Cl_3$ occurred. Ref. [25] used Mössbauer spectra of frozen solutions (similar to the conditions in Figs 4 and 5) at concentrations of 5 mM and temperatures of 4 K. Ref. [25] postulated three components; two paramagnetic representing 75% of the spectral area, and a magnetically split (blocked on the Mössbauer time scale) component comprising the remaining 25%. Our high concentration results agree with both works, i.e., that the Fe_8 is unstable in aqueous solutions, and these solutions exhibit blocked superparamagnetic behavior when frozen to low temperatures. However, the data in Fig. 7 show that the molar χ'', which is only sensitive to the blocked superparamagnetic component, seems to decrease at concentrations below 1 mM; while the molar χ' shown in Fig. 6, which is sensitive to the paramagnetic as well as superparamagnetic species, increases as the concentration decreases. In fact, at low concentrations, the molar χ' is essentially paramagnetic in nature.

These results are interpreted as the breakdown of the Fe_8 into small paramagnetic clusters and by-products at low concentrations. As the concentration is increased to around 1.5 mM a saturation of the solution begins to occur. The saturated solution has a much higher degree of relative antiferromagnetic coupling between Fe centers and therefore a lower overall moment per mol or χ'. The species in solution at high concentrations are such, that, when frozen they crystallize out as a compound which has a blocked superparamagnetic component. This component possesses a molar χ'' response similar to Fe_8 powder, but shifted to lower temperatures. This component does not appear to be significantly present at low concentrations.

Does the concentration dependence of the frozen solution data correlate with the room temperature relaxivity? In general, relaxivity scales with moment and sites available for labile water exchange [23]. At concentrations less than 1.5 mM only small paramagnetic Fe clusters or single ions are present. Little antiferromagnetic coupling is present, therefore more moment per mol is available to interact with the aqueous protons. These small clusters and single ions will have more sites available for labile water conjugation directly to the metal centers. At concentrations above 1.5 mM the solution saturates and more Fe–O–Fe interactions come into play. These interactions are antiferromagnetic which reduces the moment per mol as well as the sites available for water exchange, and therefore the relaxivity.

4. Conclusion

We have demonstrated that the discrepancy in the literature regarding the comparative enhancement of relaxation of $Fe_{8(aq)}$ versus the commercial preparation Magnevist is due to the different concentration ranges investigated by each group. Specifically, below 1.5 mM, Fe_8 appears to be competitive with Magnevist, in agreement with Ref. [2], whereas above 1.5 mM it would appear to not compare well with Magnevist, in agreement with Ref. [3]. While the exact nature of the iron particles in the solution phase is unknown, frozen solution χ'' data at concentrations above 1.5 mM strongly suggest that the Fe_8 cores survive in some fashion that contains a magnetically blocked component at low temperatures and superparamagnetic above. Below 1.5 mM the Fe_8 solutions appear to be composed of smaller units that fluctuate magnetically fast on the time scales used in this experiment. The methods here developed of sampling the χ''_{ac} of frozen solutions as a function of frequency and concentration may provide a guideline for future research into the identity and utility of aqueous magnetic species for MRI contrast.

In terms of in vivo utility three factors come to play, toxicity, non-linear relaxivity, and aqueous stability. Ref. [2] pointed out that the concentration normally employed clinically in the extracellular fluid space would be around 0.5 mM. This number is well within the toxicity value of ~1 mM given by Ref. [2]. It is also well within the linear relaxivity range shown in this work of 1 mM or less. While true understanding of the aqueous phase species is desirable, given that the relaxivity at clinical concentrations is comparable to Magnevist, linear, and well within toxicity limits, in vivo experiments would seem to be in order. Further, if the transition from low relaxivity to high relaxivity shown in Figs. 1 and 2 could be taken advantage of, as alluded to in the pH dependence experiments of Ref. [3], perhaps this system could realize a smart contrast mechanism that turns on in the presence of areas of medical interest.

Acknowledgements

We thank Ron Goldfarb of NIST for helpful discussions of aqueous magnetometry and careful reading of the manuscript, and Ruchira Garg of The Department of Pediatric Cardiology, The Childrens Hospital, Denver, CO 80218, for MRI scans, and NSF-DMR (Grant #0506946) for partial support.

on a BRUKER AM 300 spectrometer. ^{1}H NMR shifts were recorded relative to residual ^{1}H resonances of the deuterated solvent and ^{31}P{^{1}H} chemical shifts are relative to external 85% H_3PO_4 with downfield values reported as positive. Elemental analyses on a FISONS 1108 instrument.

2.1.1. IrCl(COD)(CQ) (1)

A solution of $[Ir(COD)Cl]_2$ (100 mg, 0.15 mmol) in ethanol (30 ml) was stirred until complete dissolution was achieved and then CQ (144 mg, 0.45 mmol) was added. The stirring was continued for 50 min at room temperature. The volume of the solvent was reduced under a nitrogen stream and diethyl ether was added until the solution became turbid; on cooling to −5 °C overnight the yellow product precipitated, it was isolated by filtration, washed with diethyl ether, and dried under vacuum. Yield: 63%. *Anal*. Calc. for $IrC_{26}H_{42}N_3Cl_2O_3$: C, 43.94; H, 6.20; N, 5.92. Found: C, 44.19; H, 5.44; N, 6.07%. M.p.: 290 °C. IR (cm^{-1}): *v*(N–H) 3332, *v*(C=C) 1590, *v*(C=N) 1609. ^{1}H NMR ($(CD_3)_2SO$) (ppm) 7.32 (br) NH, 8.36 (d, $J = 6.13$ Hz H2), 6.55 (d, $J = 6.13$ Hz, H3), 8.42 (d, $J = 8.54$ Hz, H5), 7.51 (d, $J = 8.54$ Hz, H6), 8.45 (s, H8), 3.33 (br, H1′), 1.22 (d, $J = 6.33$ Hz, H1″), 1.67 (m, H2′, H3′), 2.49 (m, H4′, H5′), 0.93 (t, $J = 7.14$ Hz, H6′), COD 3.76 (br, CH), 2.50 (br, 4H), 2.20 (br, 4H). ^{13}C{^{1}H} NMR (ppm) C2 151.9, C3 99.4, C4 147.9, C5 124.6, C6 125.4, C7 133.7, C8 127.2, C9 149.9, C10 117.9, C1′ 47.9, C1″ 19.8, C2′ 33.9, C3′ 31.3, C4′ 40.3, C5′ 51.8, C6′ 11.1, CH (AA′, BB′), 64.4 (d, $J_{C-Rh} = 9.43$ Hz), CH2 22.9 (s).

2.1.2. $Ir_2Cl_6(CQ)\cdot 3H_2O$ (2)

To a solution of $IrCl_3\cdot 3H_2O$ (250 mg, 0.72 mmol) in methanol (45 ml) CQ was added (463 mg, 1.45 mmol). The mixture was stirred and refluxed for 6 h. During the reaction a yellow-green solid was formed. The product was isolated by filtration, washed with water and diethyl ether and dried under vacuum. Yield: 56%. *Anal*. Calc. for $Ir_2C_{18}H_{32}N_3Cl_7O$: C, 22.24; H, 3.29; N, 4.32. Found: C, 21.80; H, 3.36; N, 4.47%. IR (cm^{-1}): *v*(N–H) 3488, *v*(C=C) 1613, *v*(C=N) 1628. ^{1}H NMR ($(CD_3)_2SO$) (ppm) 8.12 (br) NH, 8.54 (d, $J = 6.13$ Hz H2), 6.83 (d, $J = 6.13$ Hz, H3), 8.54 (d, $J = 8.54$ Hz, H5), 7.67 (d, $J = 8.54$ Hz, H6), 7.89 (s, H8), 4.02 (br, H1′), 1.28 (d, $J = 6.33$ Hz, H1″), 1.69 (m, H2′, H3′), 3.10 (m, H4′, H5′), 1.12 (t, $J = 7.14$ Hz, H6′). ^{13}C{^{1}H} NMR (ppm) C2 151.3, C3 98.9, C4 148.0, C5 124.8, C6 124.8, C7 135.0, C8 124.8, C9 151.3, C10 116.8, C1′ 47.9, C1″ 19.7, C2′ 32.6, C3′ 20.4, C4′ 48.2, C5′ 50.8, C6′ 8.6.

2.1.3. $[Ir(CQ)((CH_3)_2CO)_2]PF_6$ (3)

A solution of $[Ir(COD)Cl]_2$ (160 mg, 0.24 mmol) in ethanol (30 ml) was stirred until complete dissolution was achieved, then CQ (220 mg, 0.70 mmol) was added, the mixture was stirred for 15 min at room temperature. KPF_6 was added (220 mg, 1.44 mmol) and the reaction was continued for 4.5 h at room temperature. The solvent was removed under reduced pressure, the dry residue was redissolved in acetone and a white solid (KCl) separated. The solution was filtered through celite, the volume of the solvent was reduced under vacuum and diethyl ether was added until the solution became turbid; on cooling −5 °C overnight, the yellow product precipitated. It was isolated by filtration, washed with water and diethyl ether, and dried under vacuum. Yield: 89%. *Anal*. Calc. for $IrC_{21}H_{34}ClN_3OPF_6$: C, 34.15; H, 4.48; N, 6.66. Found: C, 34.37; H, 4.63; N, 5.73%. IR (cm^{-1}): *v*(N–H) 3220, *v*(C=C) 1588, *v*(C=N) 1616, vPF_6^- 838. ^{1}H NMR ($(CD_3)_2SO$) (ppm) 7.91 (br) NH, 8.50 (d, $J = 6.13$ Hz H2), 6.73 (d, $J = 6.13$ Hz, H3), 8.46 (d, $J = 8.54$ Hz, H5), 7.60 (d, $J = 8.54$ Hz, H6), 7.85 (s, H8), 3.94 (br, H1′), 1.27 (d, $J = 6.33$ Hz, H1″), 1.69 (m, H2′, H3′), 3.05 (m, H4′, H5′), 1.14 (t, $J = 7.14$ Hz, H6′). ^{13}C{^{1}H} NMR (ppm) C2 149.1, C3 98.9, C4 146.5, C5 124.8, C6 124.8, C7 135.0, C8 124.8, C9 151.3, C10 116.8, C1′ 47.9, C1″ 19.7, C2′ 32.3, C3′ 20.4, C4′ 46.4, C5′ 50.8, C6′ 8.61. ^{31}P{^{1}H} NMR PF_6^- 141.3 ppm (hept).

2.1.4. In vitro test for anti-malarial activity

Anti-malarial activity of the experimental compounds **1**–**3** were first assessed on short-term in vitro cultures of *P. berghei* and the further evaluation on *P. falciparum* is in progress. The working solutions of **1**–**3** were 18 mM in RPMI medium containing 0.16% (v/v) DMSO (Sigma). Chloroquine diphosphate (Sigma) was diluted in RPMI-1640 (GIBCO-BRL) medium without serum/plasma to obtain a working solution of 19.4 μM. Drug testing was performed in triplicate in 96-well, flat bottomed plates (Linbro, Flow Lab. Inc., VA) with cultures containing mostly ring stages. Short-term cultures of *P. berghei* were prepared according to the protocol described by Kamiyama and Matsubara [9]. In brief, infected blood was obtained from mice harboring low parasitemias (3–5%) for which predominant blood stages were rings and young trophozoites (one nucleus). Blood was washed with RPMI medium supplemented with HEPES (*N*-(2hydroxyethyl)piperazine-*N*′-2-ethanesulfonic acid, 2 nM L-glutamine, 18 mM sodium bicarbonate, 3.25 μM reduced glutathione and 5% (v/v) normal rat serum which had been previously inactivated at 56 °C/30 min. The same batch of rat serum gathered from animals 4–6 weeks old was used throughout the experiments. Suspensions of uninfected and infected erythrocytes in complete culture medium were mixed to obtain a working cell suspension containing 2×10^7 parasitized cells and 1.8×10^8 uninfected erythrocytes per mL. Uninfected erythrocytes (2×10^8/mL) served as controls. One hundred microliters of the cell suspension and 25 μL of the tested compound or medium alone (with or without 0.16% DMSO) were mixed in the appropriate well followed by 25 μL of the [^{3}H]hypoxanthine (Amersham International) solution (0.5 μCi) in culture medium. After a 24 h incubation period in an atmosphere of 5% CO_2, 10% O_2 and 85% N_2, the cells were collected on glass-fiber disks (934 AH, Whatman, Inc., NJ) using a cell

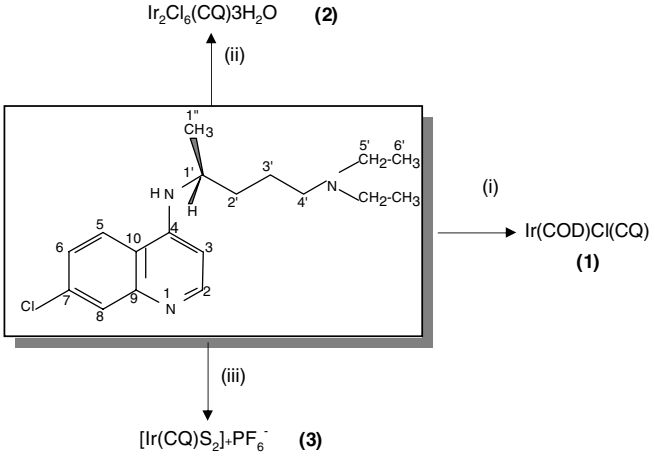
harvester (MASH II; Microbiological Associates, MD), counted in a liquid scintillation counter (LKB 1217 Rackbeta). Dose–response curves for each compound were generated and the IC_{50} values calculated from the corresponding regression line.

3. Results and discussion

3.1. Chemistry

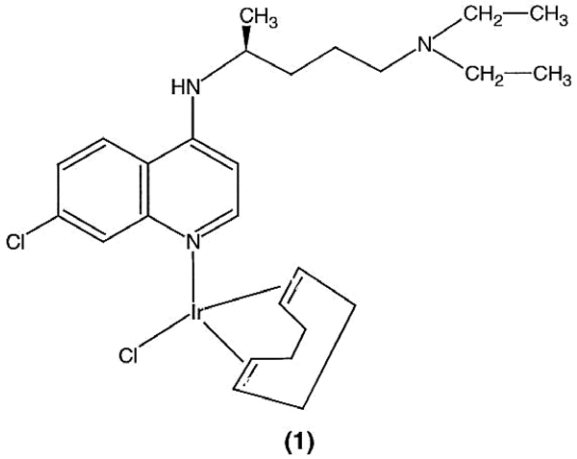
CQ reacts readily with appropriate iridium salts or complexes under mild conditions to produce a variety of Ir–CQ complexes in high yields as summarized in Scheme 1. The new compounds are air stable in the solid state and in solution, a necessary condition for biological use. They were characterized by a combination of elemental analysis, IR and NMR spectroscopy, as described in Section 2. The elemental analysis of these complexes is in agreement with the molecular formulas for all of them. The IR spectra displayed peaks clearly associated with the presence of the coordinated ligands, and of the counteranions, where present. All ^1H NMR resonances could be unequivocally assigned on the basis of 1D- and 2D-correlated COSY and HETCOR experiments (for complete NMR data see Section 2; atom numbering for CQ in Scheme 1). The selected NMR data are collected in Table 1. The ^1H chemical shift variation of each signal with respect to those of the free ligand ($\Delta\delta$) was used as a parameter to deduce the mode of bonding of CQ to the metal. It has been previously shown [2,10] that the largest variations are always observed for the protons located in the vicinity of the N-atom attached to the iridium.

3.1.1. $IrCl(COD)(CQ)$ (1)



Reaction of $[IrCl(COD)]_2$ with 3 equiv. of CQ under mild conditions leads to the new complex IrCl(COD)(CQ) (**1**), which was isolated in good yields. Besides elemental analysis, and IR spectroscopy the new complex has been well characterized by NMR spectroscopy. Selected data contained in Table 1 indicates that in complex **1** CQ binds to iridium through the quinoline ring N(1) atom. Correspondingly, the largest shift with respect to the free ligand is observed for H8 ($\Delta\delta = 0.70$ ppm) located in the vicinity of N(1). All the other CQ protons shift $\angle 0.15$ ppm, except NH which moves 0.42 ppm downfield. Further support for this structural assignment came from the analysis of ^1H longitudinal relaxation times and NOESY spectra which showed the overall motion and internal flexibility of the CQ ligand in **1** were not significantly different from that of free CQ. According with these data the formulation for thus correspond to the usual 16-electron square-planar configuration for Ir (I) as show in Fig. 1, similar to the Rh analog previously reported [2].

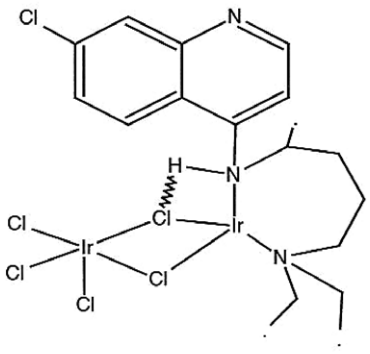
Table 1
Selected ^1H NMR data for complexes **1**–**3**



Assignment	$\Delta\delta_{H\ (ppm)}$		
	1	**2**	**3**
H2	0.03	0.19	0.15
H3	0.09	0.37	0.30
H8	0.70	0.14	0.10
NH	0.42	1.22	1.10
H4′H5′	0.15	0.76	0.71

3.1.2. $IrCl_6(CQ)\cdot 3H_2O$ (2)

The reaction of iridium chloride salts with CQ produces **2** whose proposed structure is shown in Fig. 2. The elemental analysis of the complex agreed with the molecular formula calculated for the proposed structure, the IR spectrum displays peaks associated with the presence of coordinated CQ. The NMR proton shifts indicate that CQ binds to the iridium in **2** through both N4 and N4′ atoms, since large shifts with the respect free CQ were observed for H4′H5′ ($\Delta\delta = 0.76$ ppm), NH which moves 1.22 ppm downfield, and H1′ ($\Delta\delta = 0.35$ ppm) located in the vicinity of NH. The NH signal showed an unexpected



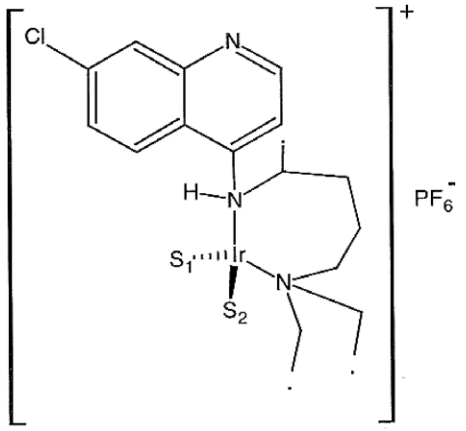
Scheme 1. Synthesis of new complexes. (i) $[Ir(COD)Cl]_2$ in MeOH, CQ for 50 min RT. (ii) $IrCl_3\cdot 3H_2O$ in MeOH, CQ reflux 6 h. (iii) $Ir(COD)Cl]_2$ in EtOH, KPF_6 4.5 h RT.

(1)

Fig. 1. Proposed structure for **1**.

(2)

Fig. 2. Proposed structure for **2**.



behavior on treatment with D_2O. Instead of the usual fast interchange with the deuterium, the sample had to be warmed up and after a few days the NH finally disappeared. This can be explained by the presence of a hydrogen bridge between the NH and one of the chlorine atoms directly bonded to the metallic center, as is shown in Fig. 2. The T_1 measurements (Table 2) for complex **2** indicate that the proton relaxation times are smaller than those for the free CQ, suggesting a dinuclear structure for complex **2**.

3.1.3. *[Ir(CQ)(S)$_2$]PF$_6$ (3)*

Removal of the chloride ligand of **1** by NH_4PF_6 produces complex **3** for which the proposed structure is shown in Fig. 3. The elemental analysis of the complex agreed with the molecular formula calculated for the proposed structure, the IR spectrum displays peaks associated with the presence of coordinated CQ, plus a band at 843 cm^{-1} characteristic of the PF_6 anion. The ^1H, $^{13}C\{H\}$, COSY and HETCOR NMR spectra allowed us to assign all the protons and carbons in the molecule. The variation in the chemical shifts observed for NH ($\Delta\delta = 1.10$ ppm), H1′ ($\Delta\delta = 0.31$ ppm) located in the vicinity of NH as well as for H4′–H5′ ($\Delta\delta = 0.71$ ppm) of the coordinated CQ with respect to the free ligand, indicate that the binding to the metal is through N4 and N4′. Besides, the T_1 measurements (Table 2) for complex **3** indicate that the proton relaxation times are similar to those of the free drug an evidence of a similar molecular volume that points toward a mononuclear structure.

Table 2
Measurement of the T_1 (ms) for complexes **2** and **4**

	CQ T1 (ms)	Complex **1** T_1 (ms)	Complex **2** T_1 (ms)	Complex **3** T_1 (ms)
H1″	344.5	365.1	270.9	325.1
H6′	941.1	1064.5	417.8	636.4
H3	450.6	448.3	281.6	430.4
H5	1269.1	1058.7	279.9	908.7
H6	1586.0	1931.1	869.9	1814

(3)

Fig. 3. Proposed structure for **3**.

The NOESY spectra shows dipolar couplings between the aliphatic protons H1″, H4′, H5′, H6′ and the aromatic protons, indicating the metallacycle conformation of the complex and the free rotation of the single bond between the quinoline ring and the aliphatic chain of the CQ. The ^{31}P spectrum exhibits a heptuplet at 141.3 ppm due to the PF_6 anion. The proposed geometry of **3** is square planar, corresponding to an Ir(I) d^8 of 16 electrons, typical for this metal.

3.2. Biology

Chloroquine resistance of *P. falciparum* represents today a major health care problem in malaria endemic countries [1]. Current evidence indicate that PfCRT, a member of the drug/metabolite transporter superfamily, plays a central role in the resistance of *P. falciparum* to CQ linked with polymorphisms within the *pfcrt* gene [11–14]. Since PfCRT is involved in carrier-mediated CQ efflux from resistant cells [15] it is attractive to speculate that binding of CQ to transition metals moderates its efflux from resistant cells leading to improved CQ activity.

Preliminary experiments carried out to determine the anti-malarial activities of complexes **1**–**3** were set up using short-term in vitro cultures of *P. berghei*. Inhibition of the uptake of [^{3}H]-hypoxanthine served as a measure of parasites viability. The biological tests were carried using DMSO as the solvent in which the complexes are stable. Final parasitemia and hematocrit were 2% and 1%, respectively. Parasite cultures were exposed to increasing concentrations of either parental compound or the corresponding complexes **1**–**3** for 24 h. Cells were harvested, their viability was assessed, and the concentration of drug for 50% inhibition (IC_{50}) was determined for each compound [16,17]. The effect of the assayed compounds on the development of *P. berghei* are summarized in Table 3. In three separate experiments the IC_{50} was estimated to be 72 nM for chloroquine diphos-

Table 3
Effect of CQDP and complexes **1**–**3** on the in vitro growth of *P. berghei*

Compound	IC_{50} (nM)	$IC_{50\,ratio}$CQDP
CQDP	72	
Ir(COD)(CQ)Cl (**1**)	72	1.0
$Ir_2Cl_6(CQ)\cdot 3H_2O$ (**2**)	59	1.2
$[Ir(CQ)_2(S)_2]^+PF_6^-$ (**3**)	126	0.6

phate (CQDP) whereas that for complexes **1**, **2** and **3** were 72, 59, 126 nM, respectively. The ratio of IC_{50} (parental compound)/ IC_{50} (metal complex) indicated that complex **2** is slightly better than CQ, whereas complex **1** has similar activity to that of CQDP. In contrast the ratio for complex **3** was <1. Unfortunately, no clear activity trend as a function of molecular structure or oxidation state of the iridium from the data obtained for these complexes. It was noted however, that **1** and the previously described Rh(CQD)(CQ)Cl [2] display similar structures both sharing inability to modify the parental drug anti-malarial activity. A previous study reported [18] the synthesis of Ir (II)-CQ complexes which were tested in vitro for their activity against tumor cells and African trypanosomes but anti-malarial activity was not examined.

Control cultures treated with medium containing 0.16 % (v/v) DMSO in the culture medium, equivalent to the level of DMSO in the cultures containing the complexes, did not show any inhibition of parasite growth, indicating that the observed inhibition was solely due to the presence of the drug in the medium.

In summary, three new iridium-CQ complexes were synthesized all of them showing antimalarial activity against *P. berghei* in vitro. Complex **3** was found more active than CQDP. These results further illustrate the potential of coordinating transition metals to CQ in order to improve the anti-malarial activity of this drug.

Acknowledgements

We thank Dr. Julio Urbina for help in NMR discussion, Dr. Roberto Sanchez Delgado for his useful comments and José Bolívar and Mercedes de la Rosa for technical help. This work was supported in part by CONICIT Grants RPV-0032-6, S1-2696 and S1-98000945.

organic acids have been used to diprotonate the porphyrin core [5].

In the present work, we have used a series of carboxylic acids weaker than CF_3COOH to diprotonate different porphyrins. Interestingly, we have found that even propionic acid is able to diprotonate arylporphyrins (Fig. 1) and *meso*-tetra(*n*-Pr)porphyrin, H_2t(*n*-Pr)p. Also, the effects of porphyrin core saddling, *meso*-aryl- and alkyl-substituents and electron donation to acceptors, i.e. carboxylic acids, on the UV–Vis spectra of porphyrins have been studied.

2. Results and discussion

Diprotonation of H_2t(*n*-Pr)p and arylpor with weak and strong carboxylic acids (Table 1) led to a spectral shift of the Soret and Q(0,0) bands.

2.1. H_2t(*n*-Pr)p

Interaction of H_2t(*n*-Pr)p with different carboxylic acids, including trifluoroacetic acid, chloroacetic acid, oxalic acid, formic acid, acetic acid and propionic acid, led to a red shift of the Soret band and a blue shift of the Q(0,0) band (Table 2). However, due to the weaker acid strengths of acetic acid and propionic acid with respect to the other carboxylic acids (Table 2), excess amounts (beyond 2:1 molar ratio of acid/porphyrin) of the acids have been used to complete the reaction (Fig. 2). It should be noted that due to the weak interaction of carboxylic acids such as acetic acid and propionic acid with porphyrins, their adducts may be considered as hydrogen-bonded charge-transfer complexes.

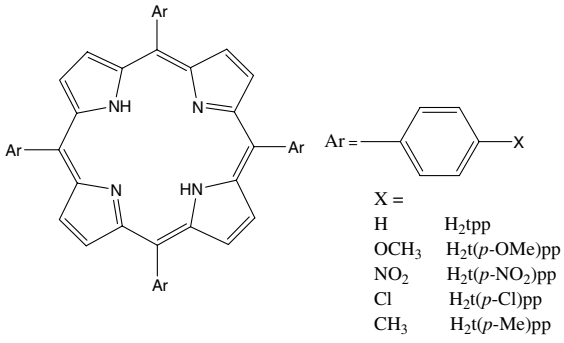

Fig. 1. *para*-Substituted *meso*-tetraphenylporphyrins used in this study.

Table 1
pK_a values for the carboxylic acids

Acids	pK_a	Acids	pK_a
CH_3COOH	4.76	$ClCH_2COOH$	2.86
CH_3CH_2COOH	4.87	$H_2C_2O_4$	1.25, 4.27
HCOOH	3.75	CF_3COOH	

2.2. The Soret band

The Soret bands of the dications are red shifted relative to that of the free base H_2t(*n*-Pr)p (Table 2). The absorption spectra of $(C_2H_5COOH)_2H_2$t(*n*-Pr)p is shown in Fig. 2. The observed red shifts are in the range 346.22–1060.50 cm^{-1}.

Diprotonation of the porphyrins leads to (i) the shift of electron density from the pyrrolenine nitrogen atoms to the central acceptors, i.e. the carboxylic acids and in the case of *meso*-tetraarylporphyrins, (ii) the saddling of the porphyrin core and (iii) enhanced coplanarity of the *meso*-aryl groups with the porphyrin core [5e,6].

Although propionic acid is the weakest acid of the series, it causes the greatest red shift of the Soret band. The observed red shift of the Soret band for H_2t(*n*-Pr)p $(CF_3COOH)_2$ is only 346.22 cm^{-1}, which is the smallest

Table 2
UV–Vis spectral data for the dications of H_2t(*n*-Pr)p with different carboxylic acids in CH_2Cl_2 at 25 °C

Porphyrin and dications	Soret band (λ/nm)	Q(0,0) band (λ/nm)	Q(0,0) band ($\lambda_{corr.}$/nm)[a]

$\Delta\upsilon$ (cm^{-1})	−1060.5	365.78	−439.04

[a] $\lambda_{corrected}(\lambda_{corr.})$ are calculated as follows: $10^7/\lambda_{corr.} = 10^7/\lambda_{Q(0,0)} - 804.81$ (cm^{-1}); 804.81 cm^{-1} is the minimum estimated blue shift of the Q(0,0) band caused by the diprotonation of the porphyrin core (see the text).

[b] $\Delta\upsilon$ (cm^{-1}) $= (1/\lambda_2 - 1/\lambda_1)10^7$.

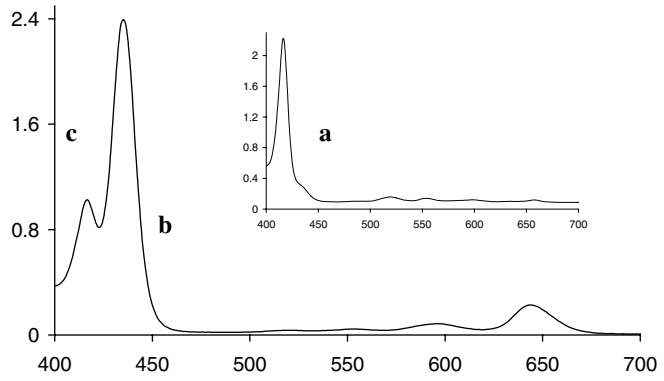

Fig. 2. UV–Vis spectra for $H_2t(n\text{-Pr})p$ (7×10^{-5} M): (a) $H_2t(n\text{-Pr})p(C_2H_5COOH)_2$, (b) in CH_2Cl_2, and in a 0.1 cm cell; (c) the Soret band of the free base porphyrin due to the partial dissociation of $(C_2H_5COOH)_2H_2t(n\text{-Pr})p$ in solution.

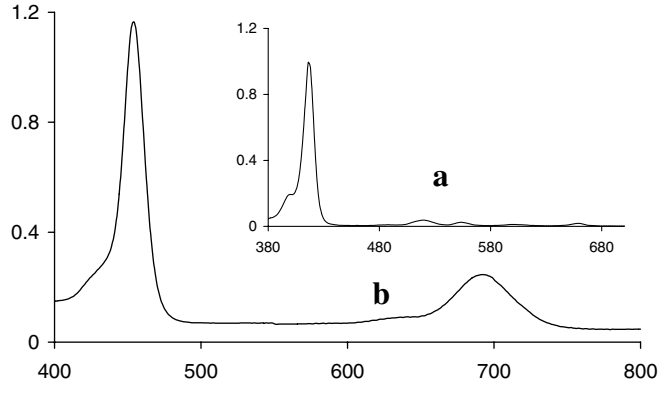
one of the series (Table 2). On the basis of the four orbital model of porphyrins, the Soret band is due to the a_{1u} to e_g transition. For the a_{1u} orbitals the electron densities are largest on the pyrrole carbon atoms and the methene bridges lie on nodal planes [7]. Accordingly, it is reasonable to think that the shift of non-bonding electron density from the pyrrolenine nitrogen atoms to the pure σ-acceptors by itself leads to little or no change on the energy of the a_{1u} to e_g transition. Such a suggestion is more reasonable especially in the case of $H_2t(n\text{-Pr})p(CH_3CH_2COOH)_2$ or $H_2t(n\text{-Pr})p(CH_3COOH)_2$ adducts in which the central acceptors are very weak acids. The carboxylic acid orbital involved in the adduct formation may be considered as the σ^* orbital of the O–H bond or the 1s orbital of the bare proton. But due to the contact dication-carboxylate ion pair in nearly non-coordinating solvents such as CH_2Cl_2, the former description seems to be more convenient.

It is notable that the electronic effects of the *n*-propyl groups are nearly the same in the free base porphyrin or the dications. Introduction of four *n*-propyl substituents on the *meso*-positions of porphine (H_2p) led to a 1342.25 cm^{-1} red shift of the Soret band. Also, comparison of the Soret bands for the corresponding dications shows that the Soret band of $H_2t(n\text{-Pr})p(CF_3COOH)_2$ is ca. 1263.41 cm^{-1} red shifted relative to that of the porphine dication (see Table 3).

The various red shifts of the dications in Table 2 may be properly explained on the basis of porphyrin core saddling upon diprotonation of the porphyrin macrocycle. The core protonation of porphyrins has to result in an out-of-plane tilting of the individual pyrrole rings as four hydrogen atoms do not fit into the central core of the macrocycle while maintaining a square-planar N_4-unit [5b,5c,5d,5e]. Also, it has been shown that the degree of saddling for $H_4tpp(X)_2$ ($X=F^-$, Cl^-, Br^- and I^-) increases with the increasing size of halide, suggesting that the necessity to optimize the hydrogen bond interactions between the halides and the dication is an additional factor in determining the actual degree of saddling [8]. It has been observed that in spite of the stronger X···N–H hydrogen bond for $X=F^-$ with respect to the other halides, the largest amount of core saddling has been observed for $X=Br^-$.

Accordingly, the larger red shift of the Soret band for $H_2t(n\text{-Pr})p(CH_3COOH)_2$ relative to that of $H_2t(n\text{-Pr})p(CF_3COOH)_2$, in spite of very similar sizes of counter ions, seems to be due to the enhanced $H_4t(n\text{-Pr})p$···carboxylate hydrogen bonding in the former. Due to very close acid strength of propionic and acetic acid, the hydrogen bonding in $H_2t(n\text{-Pr})p(CH_3CH_2COOH)_2$ is expected to be similar to that of $H_2t(n\text{-Pr})p(CH_3COOH)_2$. Therefore, the larger red shift of the Soret band for the former may be attributed to the larger size of propionate ion relative to the acetate ion. In the case of oxalic acid, there are two identical COO groups to form hydrogen bonding with $[H_4t(n\text{-Pr})p]^{2+}$ from every sides of the porphyrin mean plane. Also, for $CH_2ClCOOH$ the chlorine atom would be available for hydrogen bonding, as well as the carboxylate ion (Scheme 1). However, it is reasonable to accept that the observed red shifts of the $H_2t(n\text{-Pr})p$ Soret band, through adduct formation with the carboxylic acids, is mainly due to the saddling of the porphyrin core.

According to the four orbital model of porphyrins, the a_{1u} and e_g orbitals have 4 and 5 nodes, respectively (Fig. 4). The saddling of the porphyrin core that is accompanied with the alternate tilting of the pyrrole rings up and down with respect to the porphyrin mean plane is proposed to decrease the antibonding interactions between the



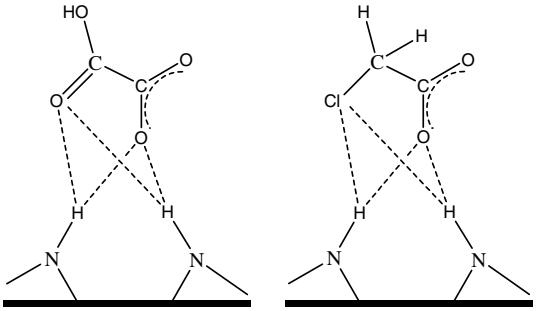


Fig. 3. UV–Vis spectra for $H_2t(p\text{-OMe})pp$ (a) and $(C_2H_5COOH)_2H_2t(p\text{-OMe})pp$ (b) in CH_2Cl_2.

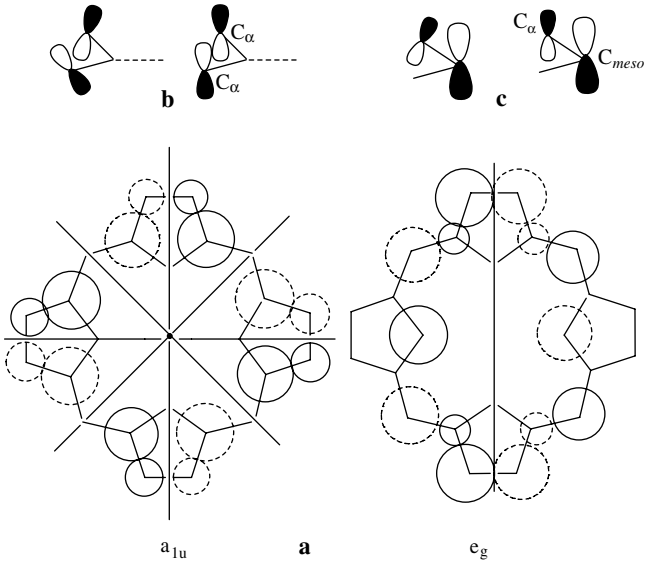
Table 3
Comparison of the Soret bands of H_2p, $H_2t(n\text{-Pr})p$ and the corresponding dications with CF_3COOH

Porphyrin	Soret band (λ/nm)
Porphine [10]	394
$H_2t(n\text{-Pr})p$	416
$\Delta\upsilon$ (cm^{-1})	−1342.25
$H_2p(CF_3COOH)_2$ [10]	401
$H_2t(n\text{-Pr})p(CF_3COOH)_2$	422.4
$\Delta\upsilon$ (cm^{-1})	−1263.41

Scheme 1. Pattern of hydrogen bonding in $H_2t(n\text{-Pr})p(H_2C_2O_4)_2$ and $H_2t(n\text{-Pr})p(CH_2ClCOOH)$.



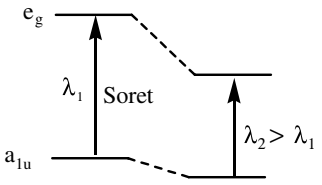


Fig. 4. The a_{1u} and one of the e_g orbitals (a) [7] and schematic demonstration of decreased antibonding interactions in the a_{1u} (b) and e_g (c) orbitals caused by the saddling of the porphyrin core.

electron densities on C_α positions with those at the alternate C_α (Fig. 4b) and adjacent C_{meso} (Fig. 4c) in a_{1u} and e_g orbitals, respectively. So the out-of-plane deformation of the porphyrin core seems to decrease the energy levels of both a_{1u} and e_g orbitals. Due to the larger distance between the alternate C_α positions relative to that between the adjacent C_α and C_{meso} atoms, it seems reasonable to assume that the saddling of the porphyrin core would lead to more stabilization of the e_g orbital with respect to the a_{1u} orbital and consequently the red shift of the Soret band (Scheme 2).

Scheme 2. Greater stabilization of the e_g orbital relative to the a_{1u} orbital upon saddling of the porphyrin core.

2.3. The Q(0, 0) band

The data in Table 2 clearly indicate that the Q(0,0) band of $H_2t(n\text{-Pr})p$ shows a substantial blue shift upon adduct formation with carboxylic acids. It can be seen that the smaller the red shift of the Soret band, the larger the blue shift of the Q(0,0) band. The observed blue shifts may be the result of saddling of the porphyrin core or/and electron donation from the porphyrin core to the σ-acceptors.

The a_{2u} to the e_g transition is responsible for the Q(0,0) band. The a_{2u} electron densities are largest on the methene carbons and pyrrole nitrogens. Therefore, the shift of electron densities from the nitrogen atoms to the central acceptors seems to affect the energy level of the a_{2u} orbital. It is noteworthy that the reaction of arylporphyrins with haloboranes in the absence of significant tilting of the porphyrin core, led to very large blue shifts of the Q(0,0) bands (40–50 nm), whereas the dihedral angles between the aryl groups and the porphyrin mean planes remained essentially unchanged with respect to those of the corresponding free base porphyrins [9].

To quantify the net effects of protonation on the shifts of Q(0,0) bands of the porphyrins upon reaction with carboxylic acids, we have used the spectral data for the protonation of porphine. This porphyrin with no substituent at the *meso* positions is convenient to this study. The porphine dication that is used in this discussion is a hypothetical dication with a saddling angle of 23.4° and its spectral data are obtained by subtracting the contributions of *n*-butyl groups from the spectral data of $H_4t(n\text{-Bu})p^{2+}$.

Comparison of the UV–Vis data for porphine and $H_2t(n\text{-Bu})p$ in the same solvents (Table 4) shows that upon substitution of four *n*-butyl groups (also any other primary alkyl groups) a red shift of 1399.89 cm^{-1} for the Soret band and 1138.71 cm^{-1} for the Q(0,0) band are observed. Accordingly, we assume that subtraction of these differences from those of $H_4t(n\text{-Bu})p^{2+}$ should give the spectral data for a porphine acid dication with a tilting angle of 23.4°, i.e. the saddling angle reported for $H_4t(n\text{-Bu})p^{2+}$

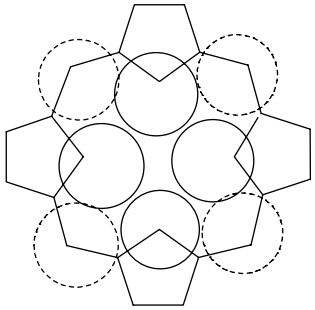

Table 4
The Q(0,0) and Soret bands for some porphyrins and their dications

Compounds	Soret (λ/nm)	$Q_I(0,0)$ (λ/nm)	Conformation	Solvent
$H_2t(n\text{-Bu})p$	417	659	planar	CH_2Cl_2

Porphine		617.5	sad. (25)[f]	

[a] CF_3COOH has been used to prepare the dications.
[b] The values in parentheses are tilting (saddling) angles in the solid state.
[c] Estimated values (see the text).
[d] It has been observed as a shoulder and cannot be evaluated exactly [10].
[e] It has not been reported.
[f] Artificial dihedrally constrained saddle-shaped porphine.

[5c]. The results are in good agreement with the reported spectrum for the porphine acid dication in benzene solvent [10]. It should be noted that, according to the reported spectrum for the porphine dication in benzene, the long wavelength band has very low intensity and has been observed as a shoulder on the adjacent band. Also, comparison of the reported spectra for H_4tpp^{2+} in benzene [10] with the corresponding spectral data in CH_2Cl_2 (Table 7), demonstrates that although the wavelength of the Soret band is the same in the two solvents, the Q(0,0) band depends on the solvent and a red shift of about 168.5 cm^{-1} occurs upon change of the solvent to CH_2Cl_2. Thus, 168.5 cm^{-1} should be subtracted from the wavenumber of the reported Q(0,0) band of the porphine dication in benzene (ca. $10^7/571$ cm^{-1}) to obtain that of CH_2Cl_2 (i.e. 17344.6 cm^{-1} or 576.54 nm). On the other hand, the Q(0,0) bands for different dihedrally constrained saddle-shaped porphine conformers have been calculated by DiMagno [11]. We have used the calculated Q(0,0) band wavelength for a dihedral angle of 25°, which is very close to the saddling angle of 23.4°. Subtraction of the Q(0,0) band wavenumber of our hypothetical porphine dication (dihedral angle = 23.4°) from that of saddled porphine (dihedral angle = 25°) calculated by DiMagno, indicates that the contribution to the shifts of the Q(0,0) band by porphyrin core protonation is ca. 804.81 cm^{-1}, which is a considerable value. On the other hand, using 571 nm as the wavelength of the Q(0,0) band of porphine gives a value of 1318.80 cm^{-1}. Therefore, it may be concluded that diprotonation of the porphyrin core, by itself, leads to a blue shift of 804.81–1318.80 cm^{-1} in the Q(0,0) band of porphyrins.

Accordingly, adding −804.81 cm^{-1} to the observed blue shifts of the Q(0,0) band in Table 2 changes them into red shifts in the range 187.85–439.04 cm^{-1}. It may be concluded that the saddling of the porphyrin core leads to the red shift of the Q(0,0) band. The a_{2u} orbital is shown in Fig. 5. Due to the position of the nodal planes, it seems that the saddling of the porphyrin core, which decreases the antibonding interactions in the HOMOs and LUMOs of the macrocycle, stabilizes the e_g orbital more than the a_{2u} orbital and leads to the red shift of the Q(0, 0) band. The

a_{2u}

Fig. 5. The a_{2u} orbital [7].

e_g orbital has more antibonding character than the a_{1u} and e_g orbitals together, so it is reasonable to think that the decrease of antibonding interaction destabilizes the e_g orbitals more than the HOMOs of the porphyrin.

Upon diprotonation of $H_2t(n\text{-Pr})p$ with the carboxylic acids, the values of red shifts for the Soret band (364–1060.5 cm^{-1}) are about two times of those of the Q(0,0) band (187–439 cm^{-1}) which suggests that the Soret band is more affected by the saddling of the porphyrin core. X-ray crystallographic studies have shown a tilting angle of ca. 23.4–29.9° for the dications of the *meso*-tetraalkylporphyrins (primary and secondary alkyl residues = *n*-butyl, *iso*-propyl and 1-ethylpropyl) with CF_3COOH [5c]. Therefore, the observed red shifts of the Soret (364 cm^{-1}) and Q(0,0) band (187 cm^{-1}) upon diprotonation of $H_2t(n\text{-Pr})p$ with CF_3COOH results in saddling of the porphyrin core by ca. 23°. On the other hand, a comparison of the tilting angles for the dications of four alkylporphyrins (Table 5), using $H_2t(n\text{-Bu})p(CF_3COOH)_2$ as the zero level for determining red shifts, shows that a 5.1°, 6.4° and 17.3° increase in tilting angle causes 222.86 (167.27), 295.76 (386.66) and 1602.85 (1424.96) cm^{-1} red shifts in the Q(0,0) band (and the Soret bands, the data in parentheses), respectively. We have shown that a 23.4° saddling of the porphyrin core led to a red shift of only 187 cm^{-1} for the Q(0,0) and 364 cm^{-1} for the Soret band of $H_2t(n\text{-Pr})p$. It may be concluded that saddling angles larger than ca. 25° are needed to cause significant red shifts in the Q(0,0) or the Soret bands (see Table 5). Although using the other carboxylic acids may increases the observed shifts of the bands, in the following discussion we will show that the presence of aryl substituents at the *meso*-positions causes the enhanced red shifts of the Soret and Q(0,0) bands so that the observed red shifts of the Soret and Q(0,0) bands of the dications of arylpor are comparable to those of $H_2t(tert\text{-Bu})p(CF_3COOH)_2$.

2.4. Arylporphyrins

The UV–Vis spectra of $H_2t(p\text{-OMe})pp$ and the 1:2 adduct with propionic acid are presented in Fig. 3. Diprotonation of *para*-substituted *meso*-tetraarylporphyrins with carboxylic acids led to the red shifts of the Soret ($\Delta\upsilon_1$, Table 7) and Q(0,0) bands ($\Delta\upsilon_2$, Table 7) with respect to the corresponding bands of the free base porphyrins. We have shown that diprotonation of the porphyrin core, by

Table 5
The Q(0,0) bands and tilting angles for some *meso*-tetraalkylporphyrins in $CHCl_3$[5c]

Dications	Q(0,0) (λ/nm)	Soret (λ/nm)	Saddling angles
$H_2t(n\text{-Bu})p(CF_3COOH)_2$	631	422	23.4
$H_2t(iso\text{-Pr})p(CF_3COOH)_2$	640	425	28.5
$H_2t(1\text{-ethylpropyl})p(CF_3COOH)_2$	643	429	29.9
$H_2t(tert\text{-Bu})p(CF_3COOH)_2$	702	449	41.7

itself, causes a blue shift of at least 804.81 cm^{-1} of the Q(0,0) bands. Subtracting 804.81 cm^{-1} from the red shift of the Q(0,0) bands ($\Delta\upsilon_2$) gives the shifts of these bands ($\Delta\upsilon_3$) resulting from the effects of porphyrin core saddling and the enhanced coplanarity of the aryl substituents with the porphyrin mean plane. It is observed that the introduction of better π-electron donating groups such as (4-OMe)-phenyl at *meso*-positions enhances the ratio of $\Delta\upsilon_3/\Delta\upsilon_1$. It is expected that electron-donating substituents will raise the energy of the a_{2u} orbital by increasing its electron density and lead to the red shift of the Q(0,0) band [5a].

The upfield shift of the H_β signal of the porphyrin core may be attributed to the ring current decrease upon out-of-plane deformation of the macrocycle [4b]. The observed chemical shifts of this signal for the dications of H_2t(*n*-Bu)p (δ 9.27 ppm), H_2t(*iso*-Pr)p (δ 8.84 ppm), H_2t(1-ethylpropyl)p (δ 8.78 ppm) and H_2t(*tert*-Bu)p (δ 8.0 ppm) with CF_3COOH correlate well with the solid state tilting angles of the dications, i.e. 23.4°, 28.5°, 29.9° and 41.6°, respectively [5c]. The chemical shifts of H_β for H_2tpp-$(CF_3COOH)_2$, H_2t(4-OMe)p$(CF_3COOH)_2$, H_2t(4-Me)p-$(CF_3COOH)_2$ and H_2t(4-Cl)p$(CF_3COOH)_2$ are similar and are, respectively, as follows: 8.61, 8.53, 8.53 and 8.59 ppm. So, it seems reasonable to assume that the substitution of groups such as OCH_3, CH_3, Cl, NO_2 at the *para*-position of the phenyl ring have little effect on the saddling angle of the porphyrin dications; the *ortho*-positions are the most effective ones that affect the conformation of the porphyrins [12]. X-ray crystallographic studies have shown that upon diprotonation with CF_3COOH the tilting

Table 6

[a] See Table 2.
[b] $\Delta\upsilon_3$ (cm^{-1}) = $\Delta\upsilon_2$ − 804.81 (see the text).

angle of *meso*-tetraalkylporphyrins (with primary and secondary alkyl residues) are very similar to that of $H_2tpp(CF_3COOH)_2$ (Table 6) [5c]. Therefore, the red shifts of the Soret (1416.41 cm^{-1}) and Q(0,0) (1189.40 cm^{-1}) bands of $H_2t(4\text{-}OCH_3)pp(CF_3COOH)_2$with respect to those of $H_2t(n\text{-}Pr)p(CF_3COOH)_2$ may reflect the π-donation of the aryl groups to the porphyrin core. Diprotonation of *meso*-tetraarylporphyrins decreases the dihedral angle between the porphyrin mean plane and the aryl group plane, which would lead to greater π-donation to the porphyrin core. Also, the red shifts of the Q(0,0) band of $H_2t(4\text{-}OCH_3)pp(CF_3COOH)_2$ relative to those of the other arylpor dications with CF_3COOH (Table 7) correlate with the order of π-donor ability of the *para*-substituents.

A comparison of the Soret bands of different *para*-substituted *meso*-tetraarylporphyrins (Table 7) shows that for a given acid, e.g. CF_3COOH, the largest red shifts of the Soret band are observed for the dications of $H_2t(4\text{-}OCH_3)pp$ and $H_2t(4\text{-}NO_2)pp$. The value of the red shifts are very similar for the adducts of $H_2t(4\text{-}OCH_3)pp$ and $H_2t(4\text{-}NO_2)pp$ (Table 7, entries 23–35). The range of red shifts, using H_2tpp as the zero level for determining red shifts, for different acids is demonstrated in Table 8. It may be assumed that in spite of the placement of nodes on *meso*-positions, a weak interaction between the proper HOMO of the aryl group (one of the e_{1g} orbitals) and the a_{1u} orbital of the porphyrin causes the observed red shifts of the Soret band (Fig. 6). Very weak basicity of $H_2t(4\text{-}NO_2)pp$ indicates that, contrary to the other arypor, *meso*-aryl groups of $H_2t(4\text{-}NO_2)pp$ are electron withdrawing with respect to the porphyrin π-system [5a]. Accordingly, the observed red shifts of the Soret band of $H_2t(4\text{-}NO_2)pp$ upon diprotonation with different carboxylic acids may be due to the stabilization of the e_g orbitals (Fig 4a) through overlap with the unoccupied π^* orbitals of the electron withdrawing aryl group, $(4\text{-}NO_2)$phenyl in the excited state, i.e. $a_{1u}^1e_g^1$ [1]. The e_g orbitals have no nodes at the *meso*-positions and so may overlap with the π-system of the aryl substitents. However, comparison of the values of red shifts of the Soret and Q(0,0) bands of the dications of different arylpor with respect to those of the corresponding free base porphyrins and also the dications of $H_2t(n\text{-}Pr)p$ clearly indicates the importance of π-resonance interactions in the observed spectral shifts of the Soret and Q(0,0) bands, so it may be concluded that in the presence of strong π-electron donating groups the red shifts of the Soret and Q(0,0) bands are predominantly due to the electronic effects of *meso*-substituents rather than the out-of-plane deformation of the porphyrin core. Also, we have shown that the large red shift of the Soret band may be observed in the presence of either strong π-electron donating, (4-OMe)phenyl, or π-electron withdrawing, $(4\text{-}NO_2)$phenyl, substituents at the *meso*-positions. But large red shifts of the Q(0,0) bands are observed only in the case of strong π-electron donating groups at the *meso*-positions.

Table 8
Range of red shifts for the acids in the presence of different porphyrins, using the bands of corresponding dication of H_2tpp as the zero-level

Acids	Range of red shifts of the Soret bands (cm^{-1})	Range of red shifts of the Q(0,0) bands (cm^{-1})
CF_3COOH	1023.62–1488.36	867.39–1617.58
$H_2C_2O_4$	1265.64–1614.47	799.16–1644.77
$ClCH_2COOH$	1327.70–1860.53	814.35–1700.36
HCOOH	1265.64–1614.47	859.72–1726.67
CH_3COOH	1458.98–1720.55	827.59–1700.36
CH_3CH_2COOH	1393.53–1720.59	828.65–1725.54

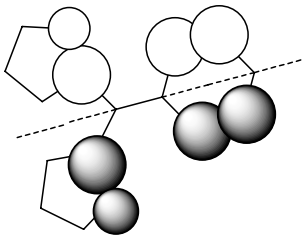

Fig. 6. Interaction between the a_{1u} orbital of the porphyrin and one of the e_{1g} orbitals of the aryl group.

3. Experimental

The free base porphyrins H_2tpp, $H_2t(4\text{-}OMe)pp$ [13], $H_2t(4\text{-}Me)pp$ [13], $H_2t(4\text{-}Cl)pp$ [13], $H_2t(4\text{-}NO_2)pp$ [14] and $H_2t(n\text{-}Pr)p$ [15] were prepared and purified by methods reported previously. Benzaldehyde, *para*-substituted benzaldehydes, butyraldehyde, trifluroacetic acid (⩾98%), glacial acetic acid, propionic acid (for synthesis) (Fluka and Merck), formic acid (⩾96%, Sigma–Aldrich) and oxalic acid (⩾97%, Fluka) were used as received. Pyrrole (Fluka, for synthesis) was distilled before use.

The dications were prepared according to the method previously described by Senge for the conversion of porphyrins to the corresponding ditrifluroacetate [5c]. Due to the relative thermal instability of the diprotonated species of the porphyrins with acetic acid, propionic acid and formic acid, with respect to the other carboxylic acids, the corresponding diprotonated porphyrins have been obtained by slow evaporation of dichloromethane and excess amounts of the corresponding carboxylic acid at room temperature. In the absence of an excess amount of the carboxylic acids, there is an equilibrium between the diprotonated species and the free base porphyrins in dichloromethane solution.

The electronic absorption spectra were recorded utilizing a Multispect-1501 Shimadzu within the wavelength 350–800 nm. ^1H NMR spectra were obtained on a Bruker Avance DPX 250 MHz spectrometer.

4. Conclusion

In summary, it may be concluded that even very weak carboxylic acids such as propionic acid are able to diprotonate the porphyrins. Saddling of the porphyrin core leads to a red shift of both the Soret and Q(0,0) bands

of H_2t(*n*-Pr)p. For a given carboxylic acid, the observed red shifts of the Soret and Q(0,0) bands of the arylpor are significantly larger than those of H_2t(*n*-Pr)p, which demonstrates the importance of the π-conjugation mediated electron coupling of the *meso*-aryl substituents to the porphyrin core. Although the saddling of the porphyrin core causes a red shift of the Soret band, the presence of strong π-electron donating groups at *meso*-positions may also lead to a red shift of this band, through stabilization of the a_{1u} orbital. On the other hand, strong π-electron accepting *para*-substituents, through the stabilization of the e_g orbitals, may also lead to a shift of the Soret band to longer wavelengths. The values of red shifts of the Q(0,0) bands are as large as those of the Soret bands. Again, strong π-electron donating *para*-substituents lead to the substantially large red shifts of the Q(0,0) bands. Also, it has been observed that in the case of the dications of arylpor, the red shifts of the Soret and Q(0,0) bands are similar to those of the severely saddled porphyrin, H_2t(*tert*-Bu)p$(CF_3COOH)_2$. Accordingly, upon diprotonation of arylpor, the Soret and Q(0,0) bands seem to be more strongly affected by the π-resonance effects of the aryl-groups than the saddling of the porphyrin core.

characterization, solvatochromism and luminescence properties of $M(CO)_4$\{*N*-[(2-pyridyl)methyliden]-α(or β)-aminonaphthalene (α or β-NaiPy)\}.

α-NaiPy (**a**) β-NaiPy (**b**) **1-3** (M = Cr(**1**), Mo(**2**), W (**3**))

2. Experimental

2.1. Materials and measurements

α-Naphthylamine and β-naphthylamine were purchased from Thomas Baker and Co, pyridine-2-carboxaldehyde was purchased from Lancaster Ltd., England. *N*-[(2-pyridyl)methyliden]-α (or β)-aminonaphthalene (α or β-NaiPy) were synthesized by equimolar condensation of pyridine-2-carboxaldehyde and naphthylamine in ethanol following a previously reported procedure [25,26]. $M(CO)_6$ (M = Cr, Mo) and $Me_3NO \cdot 2H_2O$ were Sigma–Aldrich reagents. Dehydrated Me_3NO was obtained by reduced pressure sublimation of the purchased compound. Reactions were carried out under extremely dry oxygen free atmosphere under Atmos bags (Sigma–Aldrich). THF and *n*-heptane were dried before use [27]. All other chemicals used were of A.R. quality and were used as received from SRL, India.

For the solution spectral studies spectroscopic grade solvents were used from Lancester, UK Microanalyses (C, H, N) were performed using a Perkin–Elmer 2400 CHN elemental analyzer. Spectroscopic measurements were carried out using the following instruments: UV–VIS spectra, Lambda 25 Perkin–Elmer; FT-IR spectra (KBr disk, 4000–450 cm^{-1}), RX-1 Perkin–Elmer; ^1H NMR and ^{13}C NMR spectra in $CDCl_3$ Bruker 300 MHz FT NMR spectrometers in the presence of TMS as an internal standard. The luminescence properties were measured using a LS-55 Perkin–Elmer fluorescence spectrophotometer at room temperature (298 K) in benzene solution with a 1 cm path length quartz cell. FAB-MS was collected from a JEOL-JMS 600. Electrochemical measurements were carried out with the use of a computer controlled EG & G PARC VersaStat model 250 Electrochemical instrument using a Pt-disk working electrode and Pt-wire auxiliary electrode under inert (dry N_2) environment in CH_2Cl_2. The solution was IR compensated and the results were collected at 298 K. The reported results were referenced to Ag/AgCl in CH_2Cl_2 and were uncorrected for junction potential, [*n*-Bu_4N][ClO_4] was used as the supporting electrolyte.

Solvatochromism was examined using at best 15 dry solvents (non-hydroxylic: hexane, heptane, benzene, toluene, dichloromethane, chloroform; hydroxylic solvents: tetrahydrofuran, methanol, 2-propanol, *tert*-butanol, 2-methoxy ethanol, nitromethane, acetonitrile, *N*,*N*-dimethylformamide, dimethylsulfoxide) and the plots of $E_T(30)$ versus E_{MLCT} were generated by Origin 6.1. The effect of solvent dipole moment and refractive indices $f(D, \eta^2)$ on the E_{MLCT} were examined [28].

The fluorescence quantum yield of the complexes was determined using Coumarin-120 laser dye as a reference with a known ϕ_R of 0.63 in MeCN. The complex and the reference dye were excited at 340 nm, maintaining nearly equal absorbance (~0.1), and the emission spectra were recorded from 350 to 600 nm. The area of the emission spectrum was integrated using the software available in the instrument and the quantum yield is calculated according to the following equation:

$$\phi_S/\phi_R = [A_S/A_R] \times [(Abs)_R/(Abs)_S] \times [\eta_S^2/\eta_R^2]$$

Here ϕ_S and ϕ_R are the fluorescence quantum yields of the sample and reference, respectively. A_S and A_R are the areas under the fluorescence spectra of the sample and the reference, respectively, $(Abs)_S$ and $(Abs)_R$ are the respective optical densities of the sample and the reference solution at the wavelength of excitation, and η_S and η_R are the values of refractive index for the respective solvent used for the sample and reference.

2.2. Preparation of $Mo(CO)_4$(α-NaiPy) (*1a*)

A representative case of $[Mo(CO)_4$(α-NaiPy)] (**2a**) is described below.

To $Mo(CO)_6$(50 mg, 0.189 mmol) dissolved in dry THF (15 cm^3), Me_3NO (30 mg, 0.40 mmol) was added and the solution was stirred for 50 min. To the resulting yellow solution α-NaiPy (43.95 mg, 0.189 mmol) was added, the solution was stirred for 4 h and the colour of the solution changed from light yellow to deep purple. Then the solvent was evaporated under low pressure and the crude product was chromatographed in a neutral Al_2O_3 column prepared in petroleum-ether (60–80° fraction). A blue-violet portion was eluted with benzene. Removal of the solvent afforded analytically pure product, $[Mo(CO)_4$(α-NaiPy)] in 65% yield.

In analogous reactions treatment of $Cr(CO)_6$, $W(CO)_6$ with two equimolar quantities of Me_3NO and an equimolar quantity of α-NaiPy, β-NaiPy afforded the complexes $[Cr(CO)_4$(α-NaiPy)] (**1a**) (yield 45%; blue), $[Cr(CO)_4$(β-NaiPy)] (**1b**) (yield 46%; blue), $[Mo(CO)_4$(β-NaiPy)] (**2b**) (yield 45%; purple), $[W(CO)_4$(α-NaiPy)] (**3a**) (yield 55%; purple), $[W(CO)_4$(β-NaiPy)] (**3b**) (yield 57%; purple).

Micro-analytical data are as follows: *Anal.* Calc. for $[Cr(CO)_4$(α-NaiPy)] (**1a**), $C_{20}H_{12}N_2O_4Cr$, C, 60.6; H, 3.03; N, 7.07. Found C, 60.0; H, 3.04; N, 7.05%. Decomposition

temperature, 72 ± 2 °C. *Anal.* Calc. for Cr(CO)$_4$(β-NaiPy)] (**1b**), $C_{20}H_{12}N_2O_4Cr$, C, 60.6; H, 3.03; N, 7.07. Found C, 60.1; H, 3.04; N, 7.08%. Decomposition temperature, 85 ± 2 °C. *Anal.* Calc. for [Mo(CO)$_4$(α-NaiPy)] (**2a**), $C_{20}H_{12}N_2O_4Mo$, C, 54.55; H, 2.73; N, 6.36. Found C, 54.50; H, 2.74; N, 6.38%. Decomposition temperature, 75 ± 1 °C. *Anal.* Calc. for [Mo(CO)$_4$(β-NaiPy)] (**2b**), $C_{20}H_{12}N_2O_4Mo$, C, 54.55; H, 2.73; N, 6.36. Found C, 54.51; H, 2.71; N, 6.34%. Decomposition temperature, 88 ± 2 °C. *Anal.* Calc. for [W(CO)$_4$(α-NaiPy)] (**3a**), $C_{20}H_{12}N_2O_4W$, C, 45.45; H, 2.27; N, 5.30. Found C, 45.42; H, 2.25; N, 5.33%. Decomposition temperature, 70 ± 1 °C. *Anal.* Calc. for [W(CO)$_4$(β-NaiPy)] (**3b**), $C_{20}H_{12}N_2O_4W$, C, 45.45; H, 2.27; N, 5.30. Found C, 45.40; H, 2.20; N, 5.36%; Decomposition temperature 80 ± 1 °C.

3. Results and discussion

3.1. Synthesis

The equimolar reaction of α/β-NaiPy and M(CO)$_6$ (M = Cr, Mo, W) under stirring conditions in dry THF in the presence of two equivalents of Me_3NO under nitrogen environment for a period of 4–6 h has synthesized blue or green complexes in 45–65% yield. The ligands, *N*-[((2-pyridyl)methyliden)-α/β-aminonaphthalene] (α-NaiPy, **a**; β-NaiPy, **b**) are a *N*,*N*′ chelating system where *N* and *N*′ refer to *N*(pyridyl) and *N*(imine) donor centres, respectively. Use of Me_3NO has reduced the reaction time to one-tenth in the absence of it and also increases the yield of product from <5% to >45%. The composition of the complexes, *cis*-[M(CO)$_4$(NaiPy)] (M = Cr **1a** for α-NaiPy and **1b** for β-NaiPy); Mo (**2a** for α-NaiPy and **2b** for β-NaiPy), W (**3a** for α-NaiPy and **3b** for β-NaiPy) has been supported by microanalytical and spectroscopic data. We have attempted to crystallize these complexes but failed to get a good quality diffracting crystals. Use of excess ligands to synthesise *cis*-[M(CO)$_2$(NaiPy)$_2$] and [M(NaiPy)$_3$] failed and in each experiment (at varied temperature and solvent) we get only an intractable brown solid.

$$M(CO)_6 + 2Me_3NO + \alpha/\beta\text{-NaiPy} \rightarrow [M(CO)_4(\alpha/\beta\text{-NaiPy})] + 2CO_2 + 2Me_3N \quad (1)$$

The complexes are soluble in polar solvents like DMF as well as non-polar solvents like heptane. Solutions of *cis*-[M(CO)$_4$(α/β-NaiPy)] in benzene are blue-violet, but in DMF they are orange-red. They are non-electrolytes and are diamagnetic.

3.2. Spectroscopic characterization

3.2.1. FT-IR and mass spectra

FT-IR spectra were taken in KBr discs and in CH_2Cl_2 solution. The carbonyl stretching frequencies of the complexes are presented in Table 1. The spectra show three or four bands three bands appear in the intensity ratio 1:2:1 (intensity is compared from the area measurement using the Origin 6.0 program) (Fig. 1). The spectra in solution (CH_2Cl_2) show *ν*(CO) at 5–30 cm^{-1} higher frequency than that of the KBr-phase data. The mean value of three or four *ν*(CO) in these cases is lower ($\Delta\nu$(CO) = 15–25 cm^{-1}) than that of [M(CO)$_4$(2-PAP)] (2-PAP = 2-(phenylazo)pyridine) [4]. This supports weaker π-acidity of naphthylazoimidazoles than that of phenylazopyridine. On comparing with the spectral pattern and frequency of CO stretches of [M(CO)$_4$(2-PAP)] [4] and [M(CO)$_4$-(RaaiR′)] [12] (RaaiR′ = 1-alkyl-2-(arylazo)imidazole), the present complexes are assigned to *cis*-tetracarbonyl complexes with octahedral coordination where the ligand α/β-NaiPy binds as a bidentate chelating agent. The *ν*(N=N) and *ν*(C=N) bands appear at 1390–1400 and 1590–1600 cm^{-1}, respectively. The mass fragmentation by FAB-MS of the complexes support the expected fragmentation pattern of M^+, $(M–CO)^+$, $(M–2CO)^+$, $(M–3CO)^+$, $(M–4CO)^+$ (Table 1). This information also helps us to identify the tetracarbonyl complexes of α/β-NaiPy.

3.2.2. UV–Vis spectra and solvatochromism

The spectra show two characteristic bands, one at lower wavelength (295, 335 nm) for an intra-ligand charge transfer transition and an intense broad band appearing at >550 nm. This longer wavelength transition is assigned to a MLCT band d(M(0)) → π* (ligand) (Table 2, Fig. 2). The energy of the MLCT transition state of the compounds follows the order Mo > W > Cr, which is similar to the previously reported [M(CO)$_4$(α-diimine)] compounds [10,16,17].

Table 1
FT-IR and mass spectral data of [M(CO)$_4$(α/β-NaiPy)] (**1–3**)

Compound	ν_{CO} (cm^{-1}) value	*m*/*z* value (% conversion)

In KBr disc (values in parentheses are from CH_2Cl_2 solution).

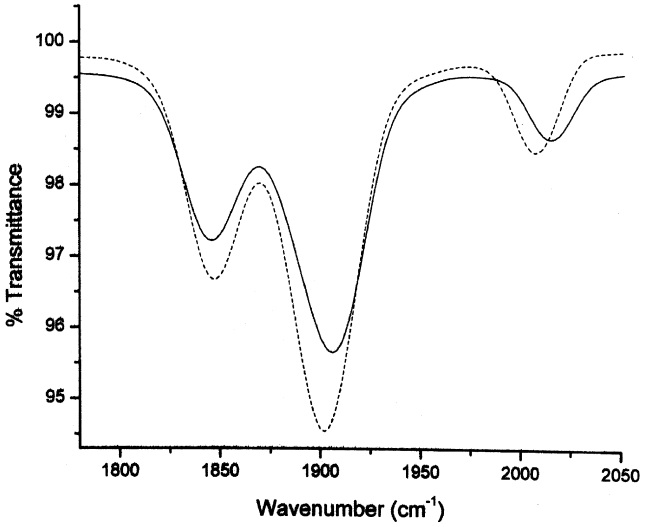

Fig. 1. Solution IR spectra of $[Mo(CO)_4(\alpha\text{-NaiPy})]$ (−), $[Cr(CO)_4(\alpha\text{-NaiPy})]$ (...) in CH_2Cl_2.

The effect of solvent polarity on this MLCT band was examined for a series of non-hydroxylic and hydroxylic solvents (Fig. 3). The plots of Reichardt's solvent parameters [28] $E_T(30)$ versus the E_{MLCT} are separately linear (Fig. 4). The effect of solvent polarity is examined by plotting E_{MLCT} versus $f(D, \eta^2)$ of the different solvents (D = dipole moment; η = refractive index) [29–31] Positive slopes of the plots (Fig. 5) support the lower dipolar property of the complexes at the excited state compared to that of the ground state (data are given as supplementary material). With increasing solvent polarity the MLCT band is blue shifted and in general the solvent effect is described negative solvatochromism. The MLCT maxima shifts 100–110 nm on changing the solvent polarity (Fig. 3). This can be attributed to superior solvation of the dipolar ground state and inferior solvation of the less dipolar excited state by polar solvent. There is a decrease in dipole moment during the electronic transition, the excited state in a solvent cage of oriented dipoles does not have the correct disposal to efficiently stabilize the excited state. Thus with increasing solvent polarity, the energy of the ground state is lowered more than that of the excited state and describes a hypsochromic effect [16,17,28]. A change in geometry by the solvation process is excluded due to hydrogen bonding as the band structure of the CT transition remains unchanged in the non-hydrogen bonded solvent. Kamlet and Taft's Π^* solvent polarity parameter [16,17,32] is also used to correlate to a high degree the metal to ligand charge transition energies. The resultant correlations are shown in Fig. 6. The high energy transitions are almost independent of solvent polarity.

3.2.3. ^1H and ^{13}C NMR spectra

The ^1H NMR spectra were assigned on comparing with the free ligand values [21]. An important observation is the downfield shifting of the pyridine protons (3- to 6-H) by

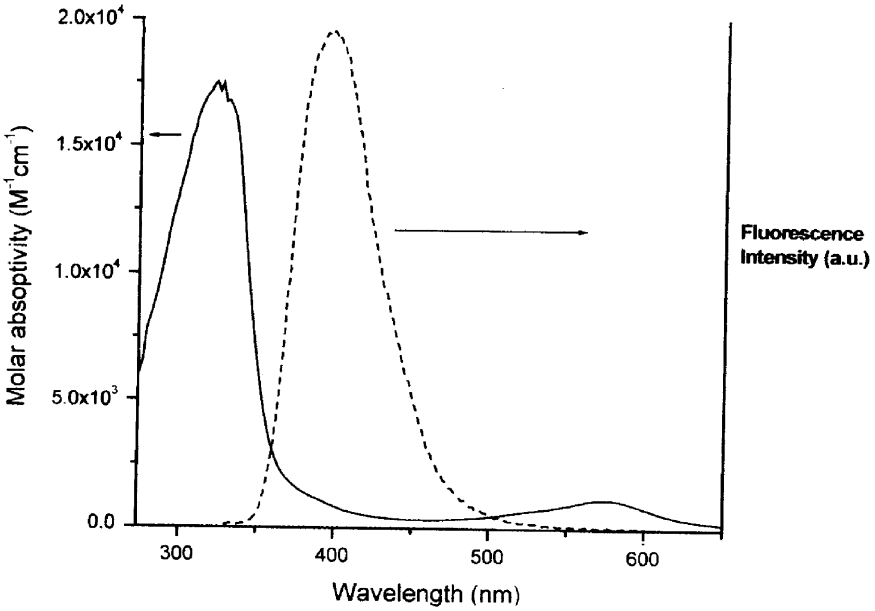

Fig. 2. UV–Vis spectrum of *cis*-[W(CO)$_4$(α-NaiPy)] (–); fluorescence spectrum of *cis*-[W(CO)$_4$(α-NaiPy)] (...) in benzene at 298 K.

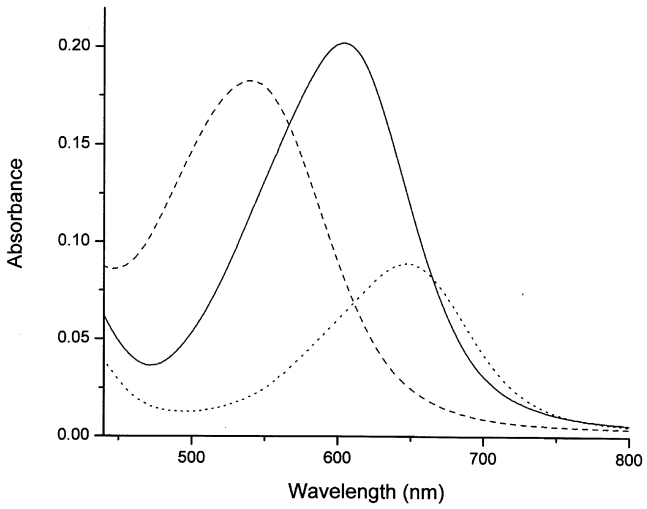

Fig. 3. Electronic spectra of [Cr(CO)$_4$(β-NaiPy)] (–) in benzene, (...) in DMF, (---) in heptane. Red shift of λ_{max} with increase in solvent polarity (DMF > benzene > heptane) suggests negative solvatochromism.

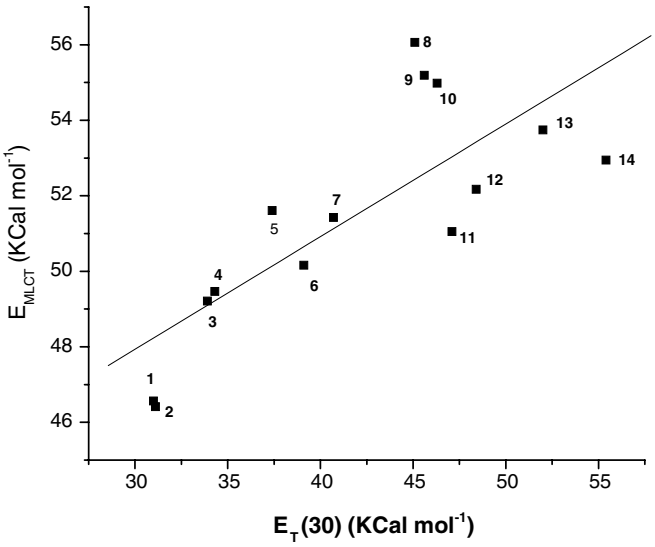

Fig. 4. Energies of the MLCT absorption (E_{MLCT}) of [W(CO)$_4$(β-NaiPy)] plotted against E_T (30) values. 1, hexane; 2, heptane; 3, toluene; 4, benzene; 5, tetrahydrofuran; 6, chloroform; 7, dichloromethane; 8, dimethylsulfoxide; 9, acetonitrile; 10, nitromethane; 11, *t*-butanol, 12, 2-propanol; 13, 2-methoxy ethanol; 14, methanol.

0.2–0.4 ppm. This supports the coordination of pyridine-N to the metal centre. Naphthyl protons (8-H to 15-H) experience a small perturbation and the chemical shift data are comparable with the free ligand data. The imine proton (–CH=N–) appears as a singlet at 8.6–8.9 ppm (data are given as supplementary material).

The ^{13}C NMR spectra are complicated due to the large number of C-centres. The assignment has been done on comparing with the spectra of the free ligands. A DEFT study has also distinguished the primary, secondary, tertiary and quaternary C-centres. Most downfield signals observed at 210–220 ppm are due to C in CO. Mo(CO)-complexes show higher chemical shift data than the Cr(CO)-system and follow the sequence Mo > Cr > W.

3.2.4. Emission spectra

The Schiff bases exhibit photoluminescence with emissions at 414 and 405 nm for α-NaiPy and β-NaiPy, respectively at room temperature in $CHCl_3$ solution upon excitation at 330 nm [24,25]. The excitation at >350 nm shows a low intense emission while [M(CO)$_4$(NaiPy)] exhibit high intense emission properties upon excitation at the

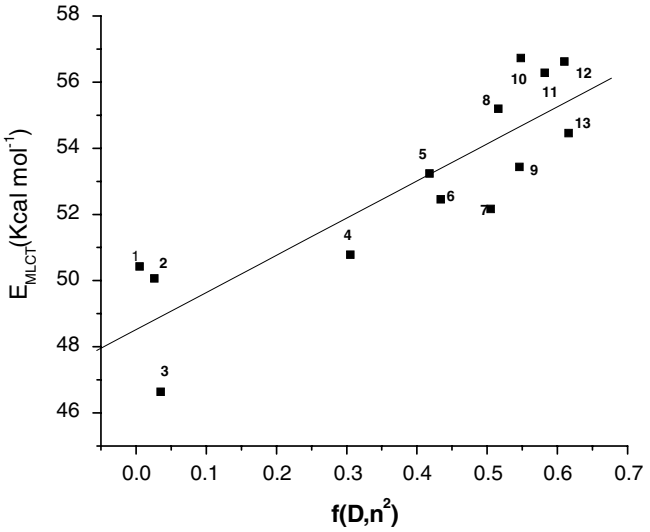

Fig. 5. Energies of the MLCT absorption (E_{MLCT}) of [Mo(CO)$_4$(β-NaiPy)] plotted against $f(D,n^2)$ values: 1, benzene; 2, toluene; 3, hexane; 4, chloroform; 5, tetrahydrofuran; 6, dichloromethane; 7, *t*-butanol; 8, 2-methoxy ethanol; 9, 2-propanol; 10, dimethylformamide; 11, nitromethane; 12, acetonitrile; 13, methanol.

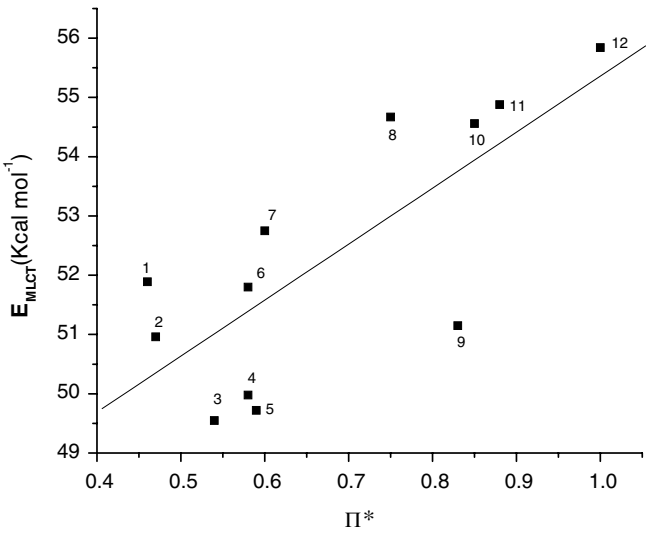

Fig. 6. Energies of MLCT absorption (E_{MLCT}) of [W(CO)$_4$(α-NaiPy)] plotted against Π^* value, 1, 2-propanol; 2, *t*-butanol; 3, toluene; 4, chloroform; 5, benzene; 6, thf; 7, methanol; 8, acetonitrile; 9, dichloromethane; 10, nitromethane; 11, dimethylformamide; 12, dimethylsulfoxide.

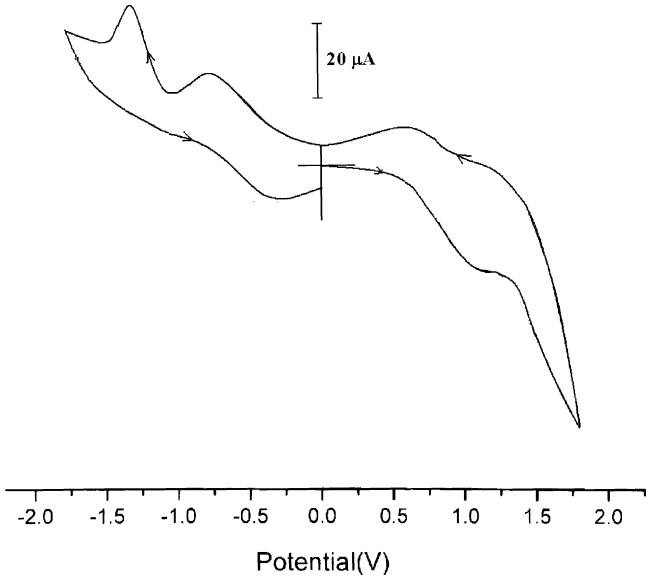

Fig. 7. Cyclic voltammogram of [W(CO)$_4$(β-NaiPy)] in CH_2Cl_2 using a Pt-disk milli electrode, Pt-wire auxiliary electrode and Ag, AgCl reference electrode.

π–π* transition wavelength (320–345 nm) (Table 2). We did not observe any emission when the complexes were excited at the MLCT wavelength (>550 nm). It has been reported that the metal ions can enhance or quench the fluorescence emission of pyridine containing compounds [32,33]. In the absence of metal ions the fluorescence of the ligand is probably quenched by the occurrence of a photoinduced electron transfer (PET) process due to the presence of a lone pair of nitrogen atoms. Such a PET process is prevented by the complexation of ligand with metal ions; due to rigidity of the chelate ring. Intersystem crossing due to spin-orbit coupling introduced by the metal centre may also influence the emission intensity. This enhances the fluorescence intensity upon coordination to the metal ion. This in fact happens to the group 6 metal carbonyl complexes of NaiPy. The intraligand charge transfer band shows a very high intensity emission, greater than the MLCT band. There are two or three bands <400 nm which are characterized as ligand centred transitions (n–π* and π–π* transitions) (Table 2). We found an identical emission pattern upon excitation at the *n*–π* and π–π* positions. We have taken the π–π* transition in the complexes to investigate the emission properties (Fig. 2). The quantum yields (ϕ) vary from 0.4 to 0.55. [M(CO)$_4$(α-NaiPy)] complexes, in general, shows higher quantum yields than [M(CO)$_4$(β-NaiPy)]. One would expect that excitation into the π–π* state would lead to rapid internal conversion to the lowest energy excited state, which is presumably the MLCT state, and that emission should occur from the MLCT state. However, it appears that the emission in these complexes is occurring from the high energy π–π* state, which has ruled out the possibility of competitive energy transfer to the MLCT state. The free ligands are considerably more fluorescent and one possible explanation is either the presence of free ligand impurity or free ligand produced as a result of photodissociation. This possibility is also ruled out by running ^{1}H NMR spectra of [M(CO)$_4$(NaiPy)] after irradiation for 5 min in $CDCl_3$ solution. The spectra of non-radiated and irradiated [M(CO)$_4$(NaiPy) are identical in all aspects.

Both the absorption and emission maxima are dependent on solvent polarity. In low polar solvents like hexane the emission maxima are almost same for all α-Naipy and β-NaiPy tetra-carbonyl compounds and the emissions occur at about 45–50 nm longer wavelength than the

excitation. Whereas in polar solvents the emission maxima occur about 100 nm longer wavelength for [M(CO)$_4$(α-NaiPy)] and about 70 nm longer wavelength for [M(CO)$_4$(β-NaiPy)]. These facts reveal that the excited state has higher stability as the polarity of the solvent increases, i.e. the excited state is more polar than the ground state. Again from the difference of the shift of emission maxima it is clear that the excited states of [M(CO)$_4$(α-NaiPy)] are more polar than those of [M(CO)$_4$(β-NaiPy)].

3.2.5. Electrochemistry

The electrochemical properties of the complexes were investigated by cyclic voltammograms (CV) in 0.1 M [*n*-Bu$_4$N][ClO$_4$] in CH_2Cl_2 solution at a scan rate of 50 mV S^{-1}. All CV data were collected under a nitrogen environment and potentials are expressed with reference to Ag/AgCl. The results are collected in Table 2. A representative voltammogram is shown in Fig. 6. All of the compounds show one oxidation and two reductions. By analogy with similar types of α-diimine complexes [1] and [M(CO)$_4$(2-PAP)] (2-PAP = 2-(phenylazo)pyridine) [4] we suggest that the oxidation is primarily a metal-centred electron extraction. In almost every case only one oxidation ($M^0 \rightarrow M^+$) is observed, it is irreversible in nature and the cathodic peak does not appear on scan reversal (Fig. 7). The second oxidation ($M^+ \rightarrow M^{2+}$) is observed only in one case. The reduction is referred to electron accommodation of the π^* MO of the chelated ligand. The first reduction in each case appears at a more positive potential than that of the free ligand, reflecting the stabilization of the π^* MO upon coordination. The reduction is referred to the accommodation of an electron in the imine based orbital.

4. Conclusion

Cis-[M(CO)$_4$(α/β-NaiPy)] (M = Cr(0), Mo(0), W(0); α/β-NaiPy = *N*-[(2-pyridyl)methyliden]-α (or β)-aminonaphthalene) are characterized by different spectroscopic tools (FT-IR, UV–Vis, Mass, ^{1}H and ^{13}C NMR). The mass fragmentation pattern shows successive removal of CO. The ligands belong to the π-acidic diimine family and stabilize efficiently the M(0) oxidation state. Cyclic voltammograms gives metal centred oxidation, M^+/M^0 and ligand centred reductions. The complexes exhibit a high efficient π–π^* emission; *cis*-[M(CO)$_4$(α-NaiPy)] emits at higher energy than *cis*-[M(CO)$_4$(β-NaiPy)].

Acknowledgements

Financial support from the Department of Science and Technology, New Delhi are gratefully acknowledged. One of us (PD) thanks the Council of Scientific and Industrial Research, New Delhi for a fellowship. Our sincere thanks are due to Prof. S. Bagchi, Department of Chemistry, Burdwan University, India for his kind help in evaluating the solvatochromism properties of the complexes.

stable in the gas phase until deposition on the substrate. Therefore, temperature variable MS and TGA-IR spectra of the gases evolved during the decomposition processes will be described in the presented paper. Data from the latter studies will be use for elaboration of the fragmentation schemes. Moreover, the fragmentation schemes of coordinated ligands, should provide unique knowledge about the chemistry of silver(I) complexes in the gas phase. The article is also intended to describe a mechanism of carboxylates thermal decomposition, therefore VT-IR spectra were measured and discussed.

2. Experimental

2.1. Chemicals and instrumentation

$CH_3CH_2C(CH_3)_2COOH$ (97%), trimethylphosphine (PMe_3) (1 M solution in THF), triethylphosphine (PEt_3) (1 M solution in THF), triethylorthoformate (TEOF) were purchased from Aldrich, $AgNO_3$, $NaHCO_3$ and C_2H_5OH were purchased from POCh (Poland), and all compounds were used as received. Ethanol was dried by standard methods.

Thermal studies (TG, DTG, DTA) were performed on a SDT 2960 TA analyser. Decomposition processes were studied in a dynamic atmosphere of dry nitrogen flowing at 40 ml min^{-1}, heating rate 2.5 °C min^{-1}, heating range up to 400 °C and sample mass 2–5 mg. Gaseous products of thermal decomposition were detected by a FT IR Bio-Rad Excalibur spectrophotometer equipped with a thermal connector for gases evolved from a SDT 2960 TA analyser. The thermal connector was heated to 200 °C. Powder X-ray diffraction data for the thermal analysis residues were obtained with a Philips X'PERT diffractometer using Cu Kα radiation. Variable temperature mass spectra were registered using a Finnigan MAT 95 spectrometer with the EI technique (heating range 30–300 °C). ^1H and ^{13}C NMR spectra in CD_3CN or C_6D_6 were collected with a Varian Gemini 200 MHz spectrometer using TMS as the standard, and 85% H_3PO_4 for ^{31}P NMR (80.96 MHz). IR spectra were recorded using a Perkin–Elmer 2000 FT IR spectrometer in the range 4000–400 cm^{-1}, in KBr discs. Variable temperature IR (VT-IR) studies in the solid phase were carried out with a SPECAC (Perkin–Elmer) temperature variable cell. The composition of vapors formed during the thermolysis of the studied compounds was determined by VT-IR spectroscopy. Spectra of vapors transported with the carrier gas (Ar) were recorded using the equipment as reported [21]. Silver was determined argentometrically (after complex mineralization), whereas C, H, P were determined by elemental microanalysis.

2.2. Synthesis

2.2.1. $[Ag_2(CH_3CH_2C(CH_3)_2COO)_2]$ (1)

2,2-Dimethylbutyric acid (3.5 mmol) and potassium nitrate (0.43 mmol) were suspended in a water–ethanol solution (1:1), heated to 40 °C and stirred 1 h, followed by silver nitrate (3.5 mmol) addition (all manipulations were carried out in the darkness). The obtained precipitate was filtered, washed with water, ethanol and dried. *Anal.* Calc. for $C_{12}H_{22}Ag_2O_4$: C, 32.2; H, 5.0; Ag, 48.3. Found: C, 32.0; H, 5.2; Ag, 48.7%. IR: 1555, 1477, 1405, 1366, 1357, 1290 cm^{-1}; ^1H NMR (CD_3CN): 0.83 ppm (3H, t, CH_3), 1.10 ppm (6H, s, CH_3), 1.49 ppm (2H, q, CH_2); ^{13}C NMR (CD_3CN): 10.3 ppm (CH_3), 26.9 ppm $(CH_3)_2$, 35.5 ppm (CH_2), 44.7 ppm (C), 183.9 ppm (COO).

2.2.2. $[Ag_2(CH_3CH_2C(CH_3)_2COO)_2(PMe_3)_2]$ (2) and $[Ag_2(CH_3CH_2C(CH_3)_2COO)_2(PEt_3)_2]$ (3)

Complexes were synthesized, in dried argon, using Schlenk techniques, in the darkness. In a general procedure: **1** (4 mmol) in C_2H_5OH (40 cm^3) was mixed with 5 cm^3 of TEOF and PR_3 (4 mmol) (THF solution), where R = Me, Et. The mixture was stirred at room temperature for 4 h, filtered and solvents evaporated on a vacuum line. $[Ag_2(CH_3CH_2C(CH_3)_2COO)_2(PMe_3)_2]$ (**2**) was obtained as white crystals, which were recrystallized from ethanol, whereas $[Ag_2(CH_3CH_2C(CH_3)_2COO)_2(PEt_3)_2]$ (**3**) was obtained as a green–yellow oil and was analyzed directly after evaporation. *Anal.* Calc. for $C_{18}H_{40}Ag_2O_4P_2$ (**2**): C, 36.1; H, 6.7; P, 10.3; Ag, 36.1. Found: C, 36.3; H, 6.9; P, 10.2; Ag, 36.4%. IR: 1550, 1472, 1399, 1359, 1286, 960 cm^{-1}. ^1H NMR (CD_3CN, ppm): 0.81 (3H, t, CH_3), 1.03 (6H, s, CH_3), 1.34 (9H, d, PCH_3), 1.46 (2H, q, CH_2); ^{13}C NMR (CD_3CN, ppm): 9.7 (CH_3), 14.8 P(CH_3), 26.1 $(CH_3)_2$, 34.6 (CH_2), 43.0 (C), 184.4 (COO); ^{31}P NMR (CD_3CN, ppm): −35.4.

Anal. Calc. for $C_{24}H_{52}Ag_2O_4P_2$ (**3**): C, 42.2; H, 7.7; P, 9.1; Ag, 31.6. Found: C, 42.3; H, 7.4; P, 9.0; Ag, 31.1%. IR: 1549, 1458, 1405, 1364, 1045, 764 cm^{-1}. ^1H NMR (CD_3CN, ppm): 0.84 (3H, t, CH_3), 1.07 (6H, s, CH_3), 1.18 (9H, t, PEt_3), 1.47 (2H, q, CH_2), 1.69 (2H, q, PEt_3). ^{13}C NMR (CD_3CN, ppm): 9.19 (CH_3), 10.5 P(CH_2CH_3), 16.9 P(CH_2CH_3), 26.8 $(CH_3)_2$, 35.0 (CH_2), 43.6 (C), 185.8 (COO); ^{31}P NMR (CD_3CN, ppm): 28.2.

2.3. CVD experiments

The deposition experiments were carried out using horizontal *hot-wall* CVD reactor as described [11]. Silver films were deposited on Si(1 1 1) and steel substrates, under 2 mbar, and in the deposition temperature 200–280 °C. The films were characterized by X-ray diffraction (XRD). XRD data were collected with a Philips X'PERT diffractometer, in 30–80° 2Θ ranges, using CuKα irradiation and sample spinning (step size – 0.1°, program. res. slit – 0.5, measuring time – 11 s per point). The silver films' morphology were studied by a scanning electron microscopy (SEM – LEO 1460 V) and an atomic force microscopy instrument (Veeco, Multimode, Nanoscope IIIa Controler, Taping Mode AFM).

3. Results and discussion

3.1. Preparation

All silver compounds were synthesized in the darkness. Silver 2,2-dimethylbutyrate **1** was obtained by the reaction of 2,2-dimethylbutyric acid and silver nitrate in a 1:1 ratio in a water–ethanol solution. This reaction is fast and the white product can be simply isolated. Both silver 2,2-dimethylbutyrate complexes with phosphines $[Ag_2(CH_3CH_2C(CH_3)_2COO)_2(PMe_3)_2]$ (**2**) and $[Ag_2(CH_3CH_2C(CH_3)_2COO)_2(PEt_3)_2]$ (**3**) were synthesized by the direct reaction of silver carboxylate and the respective phosphine in a 1:1 ratio, using ethanol as solvent and in dried argon. **2** was obtained as white crystals, which were recrystallized from ethanol, whereas **3** was a green–yellow oil.

3.2. IR and NMR spectra

Table 1 demonstrates characteristic absorption bands in the IR spectra, which can be assigned to the stretching modes of the COO group. Carboxylates can coordinate in many modes such as: unidentate, chelating or bridging bidentate [22–24]. The carboxylate coordination can be proposed by analysis of the parameter $\Delta\nu_{COO} = \nu_{asym} - \nu_{sym}$, calculated for studied compounds and identical sodium salts. In the case of silver 2,2-dimethylbutyrate the COO bands were detected at: $\nu_{asym} = 1548\ cm^{-1}$, $\nu_{sym} = 1405\ cm^{-1}$. For complexes **2** and **3** $\Delta\nu_{COO}$ was $153\ cm^{-1}$ and $159\ cm^{-1}$, respectively, which suggest similar coordination as for **1**. The calculated Δ parameters for the discussed compounds are bigger than those for the appropriate sodium salts. This fact suggests a bridging coordination mode of the carboxylic group and a polymeric structure [9,25]. Absorption bands of phosphines derived from P–C stretching vibrations are shifted for **2** by $32\ cm^{-1}$ and for **3** by $19\ cm^{-1}$ in comparison to the free phosphines, which confirms the coordination of the ligands [26,27].

The ^{13}C and ^{31}P NMR spectral chemical shifts of **1–3** are listed in Table 2. One might expect that the ^{13}C signal of the COO carbon should give the most significant changes upon coordination. However, the ^{13}C NMR spectra of **1–3** revealed the COO carbon line at 184.0–185.8 ppm, with a coordination shift (0.9–2.7 ppm) downfield in comparison to the free acid spectra. In the case of perfluorinated silver carboxylates, this signal was observed at higher field (159.1–165.7 ppm) [32]. The observed chemical shifts suggest an opposite effect on the COO carbon due to the inductive effect imposed by the fluorine atoms. However, the coordination shifts of the COO carbon in perfluorinated carboxylates (~1 ppm) were similar to the value calculated for **1**, which reveal comparable silver–carboxylate interactions for fluorinated and non-fluorinated silver salts. In the case of complexes **2** and **3**, the carbonyl carbon exhibited weak singlets at 184.4 and 185.8 ppm, respectively. For $[Ag_2(PPh_3)_2(\mu\text{-}RCOO)_2]$, R – aliphatic chain and $[Ag(PPh_3)(RCOO)]$, R – silylated radical, COO singlets were detected in the range 180.8–187.7 ppm [28,29]. However, in the case of silver complexes with perfluorinated carboxylates $[Ag_2(PR'_3)_2(\mu\text{-}RCOO)_2]$ (R′ = Me, Et), resonances of COO were observed upfield (161.3–163.2 ppm) [30,34]. The coordination shifts for **2** of 1.3 and **3** of 2.7 ppm were close to the values calculated for the compounds $[Ag_2(PR'_3)(RCOO)]$. Therefore, the bridging mode of the silver–carboxylate linkage in $[Ag_2(PR'_3)(RCOO)]$ salts can be similar for aliphatic, silylated and perfluorinated carboxylates. Single ^{31}P resonances appeared at −35.4 **2** and 28.2 ppm **3** – Table 2. The values of chemical and coordination shifts for **2** are close to those observed for perfluorinated carboxylate complexes $[Ag_2(PMe_3)_2(\mu\text{-}RCOO)_2]$. However, for **3** only the coordination shift is similar to the value registered for $[Ag_2(PEt_3)_2(\mu\text{-}RCOO)_2]$, but the signal was detected at higher fields (13.5–13.1 ppm) [30,34].

Table 2
^{13}C, ^{31}P NMR spectral analysis data [ppm]

Compound	^{13}C		^{31}P	
	δ COO	Δ_1	δ	Δ_2
$[Ag_2(CH_3CH_2C(CH_3)_2COO)_2]$ (**1**)	184.0	0.9		
$[Ag_2(CH_3CH_2C(CH_3)_2COO)_2(PMe_3)_2]$ (**2**)	184.4	1.3	−35.4	24.9
$[Ag_2(CH_3CH_2C(CH_3)_2COO)_2(PEt_3)_2]$ (**3**)	185.8	2.7	28.2	46.3

$\Delta_1 = \delta$ COO(complex) − δ COO(acid); δ COO(acid) = 183.1 ppm.
$\Delta_2 = \delta - \delta$ PR_3; $\delta(PMe_3) = -60.3$ ppm; $\delta(PEt_3) = -18.1$ ppm.

3.3. Analysis of variable temperature IR spectra

An application of **1–3** as CVD precursors requires determination of their thermal stability and composition of the vapors formed during their thermolysis. Therefore variable temperature IR (VT-IR) studies have been carried out and the results are presented in Figs. 1–4. IR spectra of **1–3**, registered between 20 and 250 °C, revealed differences in the mechanism of their thermal decomposition (Fig. 1). In the case of **1** and **2**, the thermolysis proceeds with complete decomposition of these compounds. Bands registered at 1676, $1608\ cm^{-1}$ **1** and 1680, $1598\ cm^{-1}$ **2**, at 250 °C,

Table 1
Selected IR band (cm^{-1}) of the studied compounds

Compound	ν_{as}(COO)	ν_s(COO)	$\Delta\nu$(COO)	ν(P–C)
$[Ag_2(CH_3CH_2C(CH_3)_2COO)_2]$ (**1**)	1548	1405	143	
$[Ag_2(CH_3CH_2C(CH_3)_2COO)_2(PMe_3)_2]$ (**2**)	1549	1396	153	740
$[Ag_2(CH_3CH_2C(CH_3)_2COO)_2(PEt_3)_2]$ (**3**)	1553	1394	159	689

$\Delta\nu_{COO(sodium\ salt)} = 119\ cm^{-1}$.

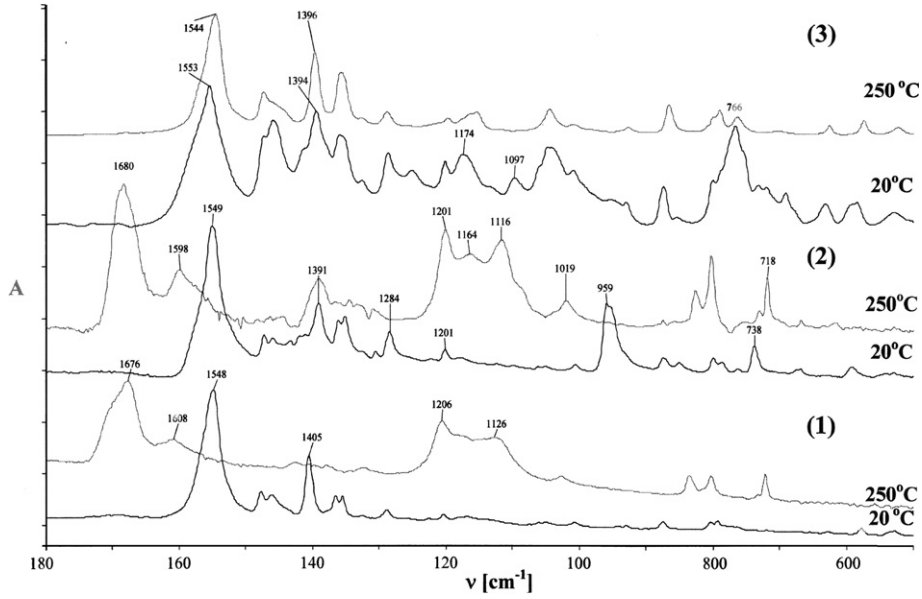

Fig. 1. Variable temperature IR spectra of **1**–**3**, registered at 20 and 250 °C.

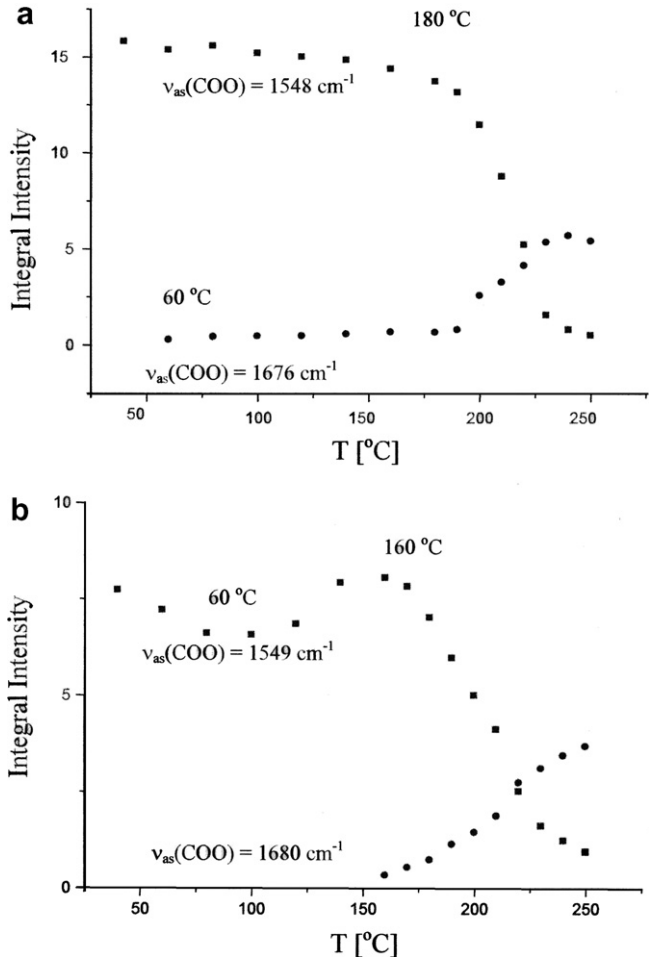

Fig. 2. Temperature dependence of the integral intensity of bands assigned to ν_{as}(COO) and ν(CO), observed between 1480 and 1800 cm^{-1}, in spectra of **1** (a) and **2** (b).

suggest formation of a different type of Ag–OOCR linkage in the solid residue than at room temperature. Calculated $\Delta\nu$ parameters exhibit the increase from 208 to 252 cm^{-1} for **1** and from 239 to 291 cm^{-1} for **2**, in comparison to spectra registered at 20 °C (Table 1). The latter suggests decomposition of the polymeric structure of **1** and **2**, where carboxylate ligands form *syn–syn* bidendate bridges, and the formation of another type of Ag(I) interaction with the carboxylate ligands [22,23].

The differences in the decomposition pathway of **1** and **2** are also observed on the plot of integral intensity of ν_{as}(COO) bands versus temperature (Fig. 2). The relatively high thermal stability of **1** can be noted between 40 and 180 °C. However, the presence of a weak band at 1676 cm^{-1} suggests decomposition process onset at 60 °C. Above 180 °C a rapid increase of this band's intensity is observed, while the ν_{as}(COO) = 1548 cm^{-1} band reveals the opposite effect. The latter can be related to complete decomposition of **1** with the evolution of carboxylic acid. Between 180 and 230 °C (Fig. 3) the main components of the gas phase of **1** are: CO_2 (2359, 667 cm^{-1}), ester species ($\nu_{C=O}$ = 1767, δ_{OCO} = 1116 cm^{-1}), and fragments containing carboxylate acid groups (ν_{OH} = 3520, $\nu_{C=O}$ = 1716 cm^{-1}). Bands that could be assigned to volatile silver–carboxylate species were not found, which confirms the postulated decomposition pathway by DTA/TGA studies. The latter is in favor of decomposition of **1** leaving silver containing species in the solid phase.

For **2**, the dependence of the integral intensity of ν_{as}-(COO) bands versus temperature changes stepwise, exhibiting the first step at 60 °C, with the second one at 160 °C (Fig. 2b). Simultaneously CH_3 librational modes (rocking and/or wagging) at 959 cm^{-1} and ν(P–C) (738 cm^{-1}) bands

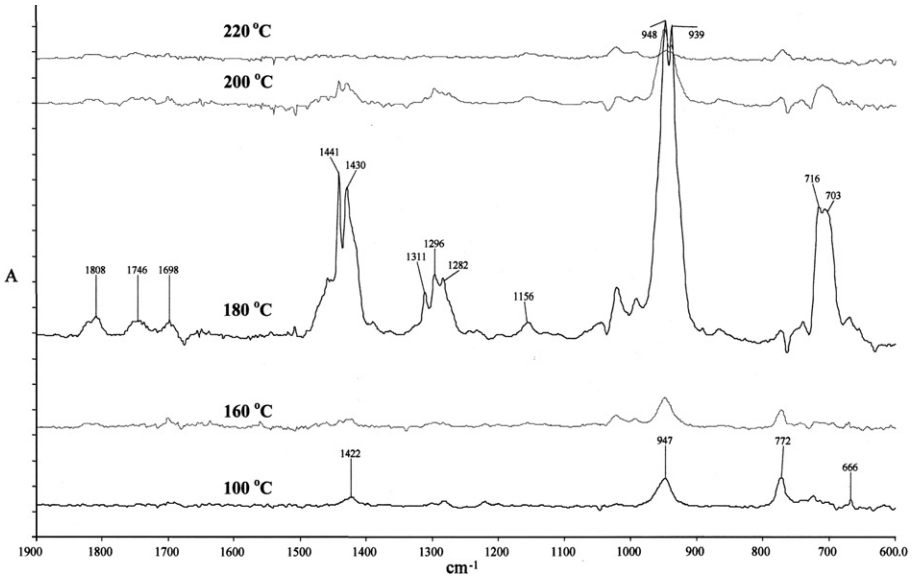

Fig. 3. VT-IR spectra of vapors formed during the thermal decomposition of **2**.

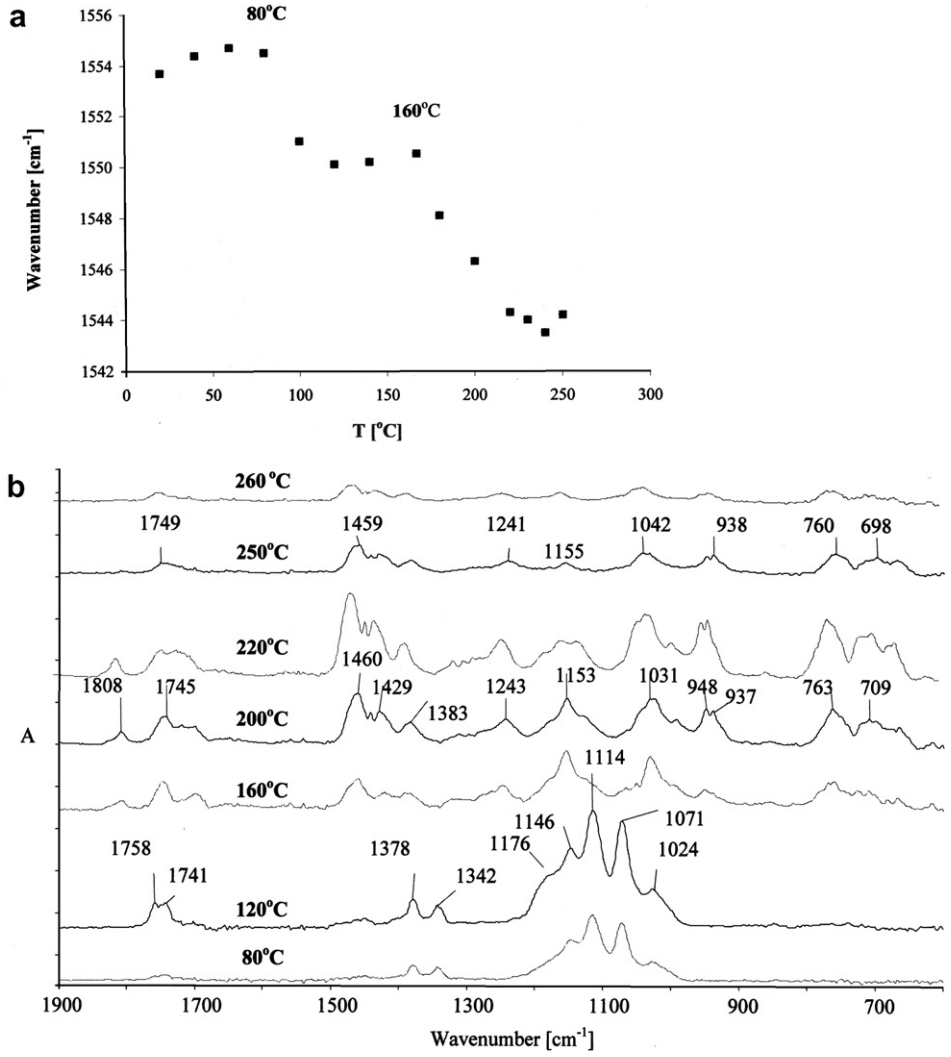

Fig. 4. The dependence of the frequency of ν_{as}(COO) motions vs. temperature (a), and changes of the vapor composition during the thermal decomposition of **3** (b).

revealed intensity decrease. Hence, the phase transition at lower temperatures can be attributed to phosphine detachment from **2**. The same as for **1**, the main decomposition product appears to be Ag(I) carboxylate intermediates. However, their complete decomposition processes was observed above 160 °C, (bands at 1680 and 1549 cm^{-1}), which indicate low thermal stability of these species.

Analysis of vapors spectra, registered in the range 160 and 200 °C, revealed phosphine bands: $\delta(CH_2)$ 1430–1441 cm^{-1}, $\delta_{sym}(CH_3)$ 1282–1311 cm^{-1}, $\delta(CH_3)$ 939–948 cm^{-1} and ν_{asym}(P–C) 703–716 cm^{-1}. The latter is in favor of phosphine species (PCH_2, PCH_3), which are predominant in the vapors of **2**. Besides that, weak bands observed in the range 1698–1808 cm^{-1}, (registered at 180 °C), can be assigned to a volatile acid anhydride (1808, 1746 cm^{-1}) and aliphatic carboxylate (1698 cm^{-1}).

Comparison VT-IR and MS data confirms the proposed decomposition mechanism of **2**. According to MS data (Table 3), the complete decomposition of **2**, proceeds between 80 and 260 °C, with volatile species formation. The main constituents are: $[PH(CH_3)]^+$, $[P(CH_3)_2]^+$ and $[P(CH_3)_3]^+$ fragments, whereas only trace quantities of $[AgP(CH_3)_3]^+$ were noticed. Carboxylate silver bonded fragments (e.g. $[Ag_2(OOCC(CH_3)_2CH_2CH_3)]^+$) were not observed in the vapors. This can be explained by the low stability of species containing the above fragments and their rapid decomposition.

In comparison to **1** and **2**, the thermolysis pathway of **3** is different (Fig. 1). The dependence between frequency of ν_{asym}(COO) bands and temperature (Fig. 4a) suggests that the decomposition pathway of **3** proceed in two stages, with the first step near 80 °C and second one at 160 °C. Moreover, significant differences in the vapors composition in the temperature ranges 60–140 °C and 160–260 °C were observed (Fig. 4b). Species containing ester groups (1741, 1758, and 1176 cm^{-1}) and aliphatic ethers (group of bands between 1024 and 1146 cm^{-1}) were the main volatile components at lower temperatures. Above 160 °C, the composition of the vapors changes and bands at 763, 1031, 1243 and 1460 cm^{-1} indicate the presence of Ag–phosphine derivatives as the main volatile decomposition products. When compared to the room-temperature spectrum of **3** the bands assigned to $Ag–PEt_3$ groups are almost identical (766, 1046, 1250 and 1459 cm^{-1}). Simultaneously, absorption bands derived from volatile species containing Ag–OOCR fragments were not observed. In the temperature range 160–260 °C, only bands from acid anhydride (1745, 1808 cm^{-1}) and ester derivatives (1153, 1720–1750 cm^{-1}) were noticed.

According to the VT-IR results it can be concluded that **1** and **2** are not suitable precursors for CVD of silver, due to their low thermal stability in the temperature range 20–250 °C. In contrast, the formation of volatile and stable silver–phosphine intermediates between 160 and 260 °C during the decomposition of **3** suggests its potential usability as a Ag CVD precursor, as was confirmed by CVD experiments (*vide infra*).

3.4. Mass spectra analysis

Variable temperature mass spectra were studied to detect the metallated species, which can be transported in the gas phase during precursor heating in a CVD process. EI-MS spectra of **1**, **2** and **3** were recorded in the range 30–300 °C and the results are listed in Table 3. The following most intensive organic ions: $[CH_3CH_2CH_2]^+$, $[CH_3CH_2C{=}CH_2]^+$ and $[CH_3CH_2C(CH_3)_2]^+$, as well as $[COO]^+$ and $[COOH]^+$, were detected in the studied tem-

Table 3
Mass spectra analysis data

Fragmentation ion	*m/z*	Compound/Temperature/Int. (%)

xxx, unable to observe.

perature range. Moreover, analysis of the spectra revealed the presence of certain metallated species formed in the strictly defined temperature ranges. The spectrum of **1** (at 197 °C) exhibited $[(CH_3CH_2C(CH_3)_2COO)Ag_2]^+$ (R.I. = 38%) as the most intensive signal. Similar disilver species were observed in MS spectra of perfluorinated and aliphatic non-fluorinated silver carboxylates [20,31]. The latter silver(I) salts form dimers or aggregates of these dimers in the solid phase with bridging carboxylates, and likewise the same can be suggested for **1**. The observed silver bonded species can be formed by detachment of RCOO$^{\cdot}$ at the temperature characteristic for the studied precursor (e.g. 197 °C for **1**). In the next stage, the $[(CH_3CH_2C(CH_3)_2COO)Ag_2]^+$ fragment decomposes to Ag_2^+ and organic ions, which is evident from the characteristic line pattern for Ag_2^+ [3 lines, R.I. = 1:1.860:0.865, natural isotopic abundance of ^{107}Ag (51.4%) and ^{109}Ag (48.6%)].

In the case of **2** between 30 and 120 °C the following phosphorous containing species $[(CH_3)_2P]^+$ (R.I. = 100% at 86 °C and 107 °C), $[(CH_3)_3P]^+$ (R.I. = 84% at 86 °C; R.I. = 45% at 107 °C), $[(CH_3)_2HP]^+$ (R.I. = 24% at 86 °C; R.I. = 13% at 107 °C) and $[Ag(PCH_3)]^+$ (R.I. = 2.6% at 86 °C; R.I. = 3.5% at 107 °C) were detected. These phosphorous embodied fragments are in favor of trimethylphosphine detachment and complex decomposition in the 30–120 °C range. At higher temperatures (160–240 °C), the desirable metallated ions $[(CH_3CH_2C(CH_3)_2COO)Ag_2]^+$ (R.I. = 82% at 220 °C), $[Ag_2]^+$ (R.I. = 11% at 220 °C) and $[Ag]^+$ (R.I. = 4% at 220 °C) appeared (Fig. 5). Fragments detected in the spectrum of **2** (30–300 °C) suggest detachment and fragmentation of trimethylphosphine followed by RC–COO bond dissociation (absence of RCOO and RCO ions) [31]. The latter causes silver bonded species formation, which decompose in the last stage to Ag_2^+ and Ag^+ (Fig. 5).

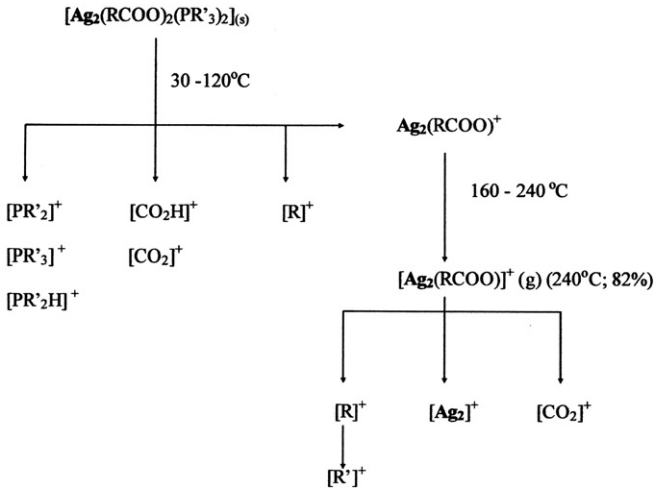

Fig. 5. Fragmentation scheme for $[Ag_2(CH_3CH_2C(CH_3)_2COO)_2(PMe_3)_2]$ (**2**).

In the case of **3**, below 200 °C, phosphorous containing metallated fragments $[AgP(C_2H_5)_3]^+$ (R.I. = 77% at 116 °C; R.I. = 15% at 182 °C) were registered, which suggest a stronger Ag–P bond in comparison to the trimethylphosphine complex **2**. Phosphine bonded fragments are less desirable in CVD of metals, due to possible increase of film contamination with P. The $[Ag_2]^+$ signals revealed similar intensity (R.I. = 10%) for both complexes, whereas $[Ag]^+$ appeared only for **2**. The above demonstrate that the most stable volatile silver coordinating fragment for **1**–**3** is the $[(CH_3CH_2C(CH_3)_2COO)Ag_2]^+$ ion.

In the case of complex **2** abundance of $[(CH_3CH_2C(CH_3)_2COO)Ag_2]^+$ ion was twofold higher than for **3**, which corresponds to the detachment of the PR_3 from **2** in the first stage. For **3** the lower relative intensity of $[(CH_3CH_2C(CH_3)_2COO)Ag_2]^+$ can be related to the presence of the stable phosphine (PEt_3) bonded silver(I) ions. The formation of $[AgP(C_2H_5)_3]^+$ and other similar ions can be explained by higher stability of the Ag–P bond, coming from the stronger σ-electron donor character of PEt_3 than PMe_3.

Above results demonstrate that compounds **1**, **2** and **3** can be used for the deposition of silver layers using the CVD method, due to formation of the volatile metallated species (e.g. $[(CH_3CH_2C(CH_3)_2COO)Ag_2]^+$, $[AgP(C_2H_5)_3]^+$).

3.5. Results of thermal analysis (TGA/DTG/DTA)

Thermal properties of the studied compounds are also important for the assessment of their future usage in CVD of silver layers. The temperature of decomposition process onset and temperature of silver formation are two factors which determine CVD procedure parameters. The results of thermal analysis are listed in Table 4 [10]. Salt **1** decomposes in one endothermic process (onset = 125 °C, maximum rate of reaction = 198 °C). The mass loss on the TG curve corresponds to detachment of carboxylate and the final residue is metallic silver formed at $T_f = 208$ °C. The observed silver formation temperature is below 250 °C, which makes **1** a promising precursor for hot-wall CVD of silver layers. When comparing **1** to perfluorinated silver(I) carboxylates it is evident that they decompose at higher temperatures (e.g. $CF_3(CF_2)_2COOAg$; $T_f = 470$ °C) [32]. The latter suggests that perfluorinated ligands revealed improved volatility, but they are more thermally stable then branched non-fluorinated carboxylates. In the case of **2** and **3** one endotherm was also observed on the DTA, with onset temperatures of 164 °C and 170 °C, respectively. The onset temperatures are almost in the range of instrument accuracy; hence one may presume that decomposition starts with the partial dissociation of the carboxylate residue, which has further evidence in the MS spectra of **1**–**3**. Analysis of the TG curves indicates mass losses which correspond to the detachment of carboxylate residue and phosphine in the same endothermic reaction. The maximum reaction rates (DTG) were detected at 205 °C and 250 °C, respectively, which confirms

Table 4
Thermal analysis results

Compound	Heat effect on DTA	Temperature (°C)			Residue (%)	
		T_{init}	T_{max}	T_f	Calc.	Found
$[Ag_2(CH_3CH_2C(CH_3)_2COO)_2]$ (**1**)	Endo	125	197	208	48.4	52.9
$[Ag_2(CH_3CH_2C(CH_3)_2COO)_2(PMe_3)_2]$(**2**)	Endo	50	205	206	36.1	35.5
$[Ag_2(CH_3CH_2C(CH_3)_2COO)_2(PEt_3)_2]$ (**3**)	Endo	60	250	290	31.6	32.8

T_{init}, initial temperature; T_{max}, maximum temperature; T_f, final temperature.

MS observations that PEt_3 forms a stronger Ag–P σ-donor, π-acceptor bond than PMe_3. A similar phenomenon was observed for $[Au(RCOO)(PR_3)]$ and $[Ag(RCOO)(PR_3)]$ complexes with the studied phosphines and perfluorinated carboxylates [30,34]. The decomposition reaction was completed at: T_f **2** = 206 °C, T_f **3** = 290 °C. In both cases, metallic silver was confirmed by TG calculations and detected by XRD studies of the residue in the crucible. The observed diffractogram lines (0.2352, 0.2026, 0.1179, 0.1444, 0.1233 nm) correspond to metallic silver (Powder Diffraction File) [33]. Temperatures of silver formation are accept for CVD purposes with the heating device working below 300 °C.

Considering decomposition mechanism of **2** and **3**, one can propose simultaneous or very close in time, consecutive carboxylate residue and phosphine detaching reactions. In comparison to the reported silver perfluorinated carboxylates complexes with PPh_3 (T_f = 219–340 °C), the studied complexes exhibited significantly lower temperatures of silver formation [34]. The latter makes them much more promising CVD precursors of metallic silver than analogues with heavier (aromatic) phosphines.

Analysis of the IR spectra of the gases evolved during the thermal decomposition of **1** suggest the presence of acid ($\nu_{(OH)} = 3577\ cm^{-1}$, C–H stretching at 2967 cm^{-1}, $\nu_{(C=O)} = 1752\ cm^{-1}$, $\nu_{(C-O)} = 1258\ cm^{-1}$, $\delta_{(O-C=O)} = 668\ cm^{-1}$) which was also detected in the gaseous products of the silver acetate thermal decomposition reaction [17].

TGA/IR studies of the gas phase from decomposition reactions of **2** and **3** revealed the characteristic absorption bands for acid anhydride ($\nu_{a(COO)} = 1816\ cm^{-1}$, $\nu_{s(COO)} = 1759\ cm^{-1}$) (Fig. 1). Moreover, bands typical for the phosphines were observed.

3.6. Results of CVD experiments

Silver films were deposited using precursor **3** and *hot-wall* CVD equipment. The substrates were Si(1 1 1) and steel plates, at a deposition temperature between 200 and 280 °C, under 2.0 mbar of the total reactor vaccum, in argon atmosphere. The vaporization temperature was fixed at 170 °C for CVD experiments resulting in an efficiency of 75–83%. The fabricated silver films revealed thickness below 50 nm, and were whitish colored and slightly matt. Variation of the deposition temperature and the amount of precursor used in the CVD experiments (100–300 mg) appeared to be the main parameters which have an impact on the thickness of the silver layers. Deposition rates of the films were calculated from the change of films weights determined on a microbalance. Tendency for rate increase between 200 and 250 °C (from 0.3 to 0.8 nm min^{-1}), was observed, whereas above 250 °C the opposite trend was noted. The changes of the deposition parameters seems to be a consequence of: (a) the significant decrease of deposition efficiency, caused by the partial decomposition of silver species transported in the vapors, (b) deposition of metallic films on other parts of the CVD reactor (not only on substrate surfaces). XRD studies exhibit characteristic peaks of polycrystalline cubic metallic silver (38.4, 44.6, 64.7, 77.9 [deg], assigned to (1 1 1), (2 0 0), (2 2 0), (3 1 1) lines) as reported by JCPDS (International Centre for Diffraction Data) without preferential orientation.

The SEM and AFM micrographs of the films produced from **3** are presented in Fig. 6. It can be noted that at vaporization temperatures below 220 °C and deposition temperatures below 250 °C, films deposited on Si(1 1 1) substrates were composed of the separated Ag grains with diameters of 30–60 nm. Further heating resulted in coalescence of silver grains and the increase of their size (diameter 60–280 nm), as well as packing density (Fig. 6a). SEM and AFM studies of Ag films, deposited from **3** on steel substrates, under similar conditions, turned out to be very thin and dispersed, with an average grain size between 50 and 90 nm (Fig. 6b).

4. Conclusions

Analysis of variable temperature MS and IR data revealed that thermolysis of **1** and **2** proceed with complete decomposition of these compounds in the temperature range 20–250 °C. However, volatile silver containing species were not detected in the gas phase during the decomposition processes, resulting in exclusion of **1** and **2** from further thermally induced CVD experiments. Formation of volatile and stable silver–phosphine intermediates during decomposition of **3** suggested its usage as a precursor in CVD methods. However, partial decomposition of a silver bonded species during transport in the gas phase of **3** seems to be the main disadvantage in the application of this complex in metallization processes. Performed CVD experiments using **3** as a precursor proved deposition of thin silver films on Si(1 1 1) and steel substrates. In general procedures, nanometric silver films (thicknesses below 50 nm), at moderate temperature (220–250 °C) can be produced from **3**.

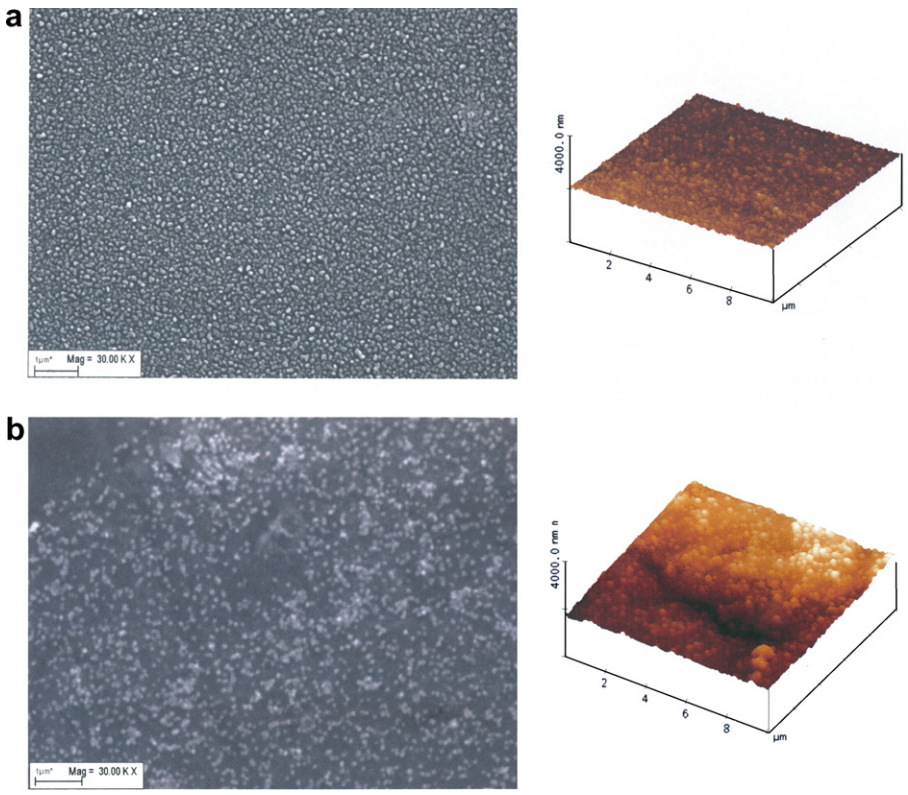

Fig. 6. SEM and AFM micrographs of silver films deposited on (a) Si(1 1 1) and (b) steel surfaces ($T_V = 170$ °C, $T_D = 240$ °C, $p = 2$ mbar, Ar).

and X-ray crystal structures of 3-*tert*-butyl-4-cyanopyrazole ($Hpz^{t\text{-}Bu,4CN}$)[1] and its complexes with cobalt(II), copper(II) and manganese(II).

2. Results and discussion

2.1. 3-*tert*-butyl-4-cyano pyrazole

A number of syntheses have been reported for pyrazoles with cyano substituents in the 4-position [4]. Many of these syntheses require the use of extreme reaction conditions or highly toxic reactants such as cyanoform or dimethyl sulfate. Tupper and Bray reported the synthesis of 4-cyano-3-phenylpyrazole ($Hpz^{Ph,4CN}$) from *t*-butylcyanoacetate [5]. Replacement of benzoyl chloride in this synthesis with trimethylacetyl chloride allows for the isolation of a new compound, 3-*tert*-butyl-4-cyanopyrazole ($Hpz^{t\text{-}Bu,4CN}$) in good yield. X-ray quality crystals of the neutral pyrazole were isolated from a toluene solution. An ORTEP drawing of the structure is shown in Fig. 1 with data collection parameters in Table 1 and selected bond distances and angles in Table 2. The pyrazole crystallizes in the monoclinic space group *C*2/*m* with the pyrazole ring, CN substituent, and one methyl group (C6) coincident with a crystallographic mirror plane. Crystal structures of neutral pyrazoles generally show some form of intermolecular hydrogen bonding. Four classes of hydrogen bonding are common: linear chains, cyclic dimers, cyclic trimers, and cyclic tetramers. $Hpz^{t\text{-}Bu,4CN}$ forms a cyclic dimer with an N(1)···N(2)′ distance of 2.859 Å and an N–H···N angle of 124.17°.

This hydrogen-bonding distance is in the range of that seen in other pyrazoles which display cyclic dimers; the average N···N distance is 2.897 Å [6] with a minimum of 2.630 Å [7] for $Hpz^{i\text{-}Pr2,4NO_2}$ and a maximum of 3.017 Å [8] for $Hpz^{Ph2,4NO_2}$. The most obvious comparison is to the structure of $Hpz^{t\text{-}Bu2}$, which has been reported eight times with N···N distances ranging from 2.856 to 2.900 Å [9]; the distance in $Hpz^{t\text{-}Bu,4CN}$ is in line with these other structures. The structure of $Hpz^{t\text{-}Bu}$ shows a cyclic tetramer, rather than a cyclic dimer [10].

2.2. Transition metal complexes

Reaction of $Hpz^{t\text{-}Bu,4CN}$ with salts of divalent transition metal ions in THF solution, followed by crystallization from toluene, results in the isolation of pink $Co(Hpz^{t\text{-}Bu,4CN})_4Cl_2$, colorless $Mn(Hpz^{t\text{-}Bu,4CN})_2(CF_3SO^3)_2(H_2O)_2$, and blue $Cu(Hpz^{t\text{-}Bu,4CN})_2Cl_2$. ORTEP drawings of these complexes are shown in Figs. 2–4, respectively, with data collection parameters in Table 1 and selected bond distances and angles in Tables 3–5. The structures of these complexes are described below.

[1] Substituted pyrazoles will be referred to as follows: 3-R^1,4-R^2-substituted pyrazoles – $Hpz^{R^1,4R^2}$; 3,5-R_2-substituted pyrazoles – Hpz^{R2}; 3-R^1,5-R^2–substituted pyrazoles – $Hpz^{3R^1,5R^2}$; 3,5-R^1_2,4-R^2-substituted pyrazoles – $Hpz^{R^12,4R^2}$.

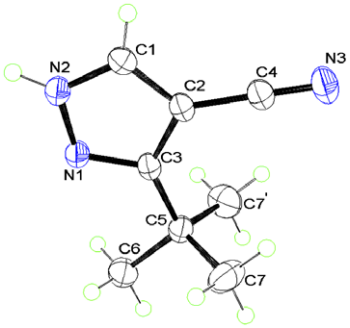

Fig. 1. ORTEP diagram of $Hpz^{t\text{-}Bu,4CN}$ showing 50% thermal ellipsoids.

The octahedral $Co(Hpz^{t\text{-}Bu,4CN})_4Cl_2$ crystallizes on an inversion center in the monoclinic space group $P2_1/n$. A disordered area of solvent is also present.[2] As is true with all 3(5)-substituted pyrazoles, the cobalt is coordinated to the N atom furthest from the substituted ring C atom. The coordination environment of the Co shows the four pyrazole N donors in a plane and two axial chlorides. The pyrazole rings are approximately perpendicular to the CoN_4 plane and are protonated at the non-coordinated ring N atom. There are two other reported structures of octahedral Co(II) complexes containing pyrazoles and halides, $Co(Hpz^{3OH,5CH_3})_4Cl_2$ [11] and $Co(Hpz^{prm})_2Cl_2(H_2O)_2$. [12] The Co–N bond distances in $Co(Hpz^{t\text{-}Bu,4CN})_4Cl_2$ are comparable to those in the other two structures.

The octahedral $Mn(Hpz^{t\text{-}Bu,4CN})_2(CF_3SO_3)_2(H_2O)_2$ crystallizes on an inversion center in the triclinic space group $P\bar{1}$. This formulation differs from the other Mn/pyrazole complexes which have been reported, all of which have the formula $Mn(Hpz)_4X_2$ ($X = H_2O$, Br, or Cl) or $Mn(Hpz)_6^{2+}$ [13]. The reaction was carried out with a Mn:Hpz stoichiometry of 1:2, so the stoichiometry of the resulting complex may simply reflect the reaction stoichiometry or it could stem from steric and electronic factors in the Mn/$Hpz^{t\text{-}Bu,4CN}$/OTf^- system. The pyrazole rings are approximately parallel to the OTf-Mn-OTf axis. A hydrogen bonding network (Fig. 3b) is built up consisting of interactions between the CN group and one of the water protons (N3···O4 2.946 Å) and between a triflate O atom and the other water proton (O1···O4 2.744 Å). An intramolecular hydrogen bond also exists between another triflate O atom and the ring N atom of a pyrazole bound to the same Mn (N2···O2 2.806 Å). This results in a linear double chain of Mn complexes running parallel to the crystallographic B face.

$Cu(Hpz^{t\text{-}Bu,4CN})_2Cl_2$ crystallizes on a general position in the triclinic space group $P\bar{1}$. The geometry of this complex is slightly distorted square-planar, with an almost linear N(1)–Cu–N(3) angle (179.3°), but a Cl(1)–Cu–Cl(2) angle of 166.1°. This structure is unique, as other crystallographically characterized Cu(II) complexes of pyrazoles are

[2] The solvent area was modeled with seven full-occupancy carbon atoms, in agreement with the toluene molecule inferred in the elemental analysis results.

either octahedral with four pyrazoles and two halides coordinated to the copper center [14], tetrahedral with two pyrazoles and two halides [15], or distorted square-planar with both Cl–Cu–Cl and N–Cu–N angles deviating significantly from 180° towards tetrahedral [14b,16]. The distortion in $Cu(Hpz^{t\text{-}Bu,4CN})_2Cl_2$ is caused by a short contact between Cu and a N atom (Cu···N6′ 2.81 Å) from one of the cyano groups on an inversion-related Cu complex. This creates a pseudodimer with each Cu atom displaying a slightly distorted square-pyramidal coordination geometry when the CN···Cu interaction is included. The infrared spectrum of this complex shows the expected splitting of the CN stretching frequency, with bands at 2229 and 2238 cm^{-1} representing the non-interacting and interacting CN groups. Cu–N and Cu–Cl bond lengths are similar to those seen in other Cu(II)–pyrazole complexes, including $Cu(Hpz^{t\text{-}Bu})_4Cl_2$.

3. Conclusions

Transition metal complexes of the new pyrazole ligand, 3(5)-*tert*-butyl-4-cyanopyrazole, have been synthesized and structurally characterized. Structural parameters of the coordination of this ligand to transition metals are not significantly different from those for related pyrazole ligands. The effect of the CN substituent is noticed, however, in the formation of a hydrogen-bonding network involving the coordinated water molecules in the Mn(II) structure, and in the formation of a pseudodimer by weak axial coordination of the CN group in the Cu(II) complex. This final structure exemplifies the effect that we hope to realize with these molecules and the polypyrazolylborate ligands derived therefrom, namely the ability to form coordination polymers with interesting electronic and magnetic properties.

4. Experimental

4.1. General

Unless otherwise stated, all solvents and reagents were used as received from Aldrich, Acros, TCI, and Fisher Scientific without further purification. IR spectra were recorded on a Nicolet Avatar 360 FTIR. Electrospray mass spectra were obtained on a Finnigan LCQ DECA spectrometer. NMR spectra were obtained using either a Varian Mercury 300 MHz NMR or Varian Inova 400 MHz NMR. Elemental analyses were obtained from M-H-W Laboratories, Phoenix, AZ. When dry solvents are specified, they were prepared by distillation from sodium/benzophenone.

4.2. 3-tert-Butyl-4-cyanopyrazole, $Hpz^{t\text{-}Bu,4CN}$

A suspension of sodium hydride (60% dispersion in mineral oil, 2.812 g, 70.3 mmol) in 150 mL dry toluene was put under nitrogen and cooled by means of an ice/water bath. To this suspension a solution of *tert*-butylcyanoacetate (10 mL, 70.3 mmol) in 10 mL of dry toluene was added dropwise with bubbles appearing immediately. The mixture was stirred 18 h. The solution became viscous, and to this was added, dropwise, trimethylacetyl chloride (8.65 mL, 70.3 mmol) in 10 mL of dry toluene. The solution immediately became less viscous and slightly yellow. After stirring overnight, 100 mL of aqueous 0.2 M sodium hydroxide was added and the aqueous layer was separated from the organic layer. The organic layer was extracted with two more portions (100 mL each) of 0.2 M sodium hydroxide. The yellow aqueous layers were combined and washed once with ethyl ether. The aqueous solution was acidified with 100 mL of 2 M HCl – an amount that neutralizes the NaOH used for extraction,

and provides two additional equivalents to fully protonate the product. A white precipitate came out immediately with the addition of HCl. The acidified solution with precipitate (pH ~ 1) was then extracted with three portions of ethyl ether (100 mL each), which were combined, and dried over magnesium sulfate. After filtration, the solvent was removed under reduced pressure to yield 6.69 g (29.7 mmol, 42.3%) of *tert*-butyl-2-cyano-3-oxo-4,4-dimethylpentanoate. The product was then dissolved in dry toluene (150 mL), to which was added *p*-toluenesulfonic acid (0.56 g, 2.97 mmol). This solution was heated at reflux for 18 h and then filtered to remove some insoluble material. The solvent was removed under reduced pressure to yield 3-oxo-4,4-dimethylpentanenitrile (4.70 g, 26.7 mmol, 90%), as a yellow solid. This product was redissolved in 150 mL of dry toluene and 3.90 mL (29.37 mmol) of DMF-dimethylacetal was added. The mixture was stirred for 18 h under nitrogen. The solvent was removed under reduced pressure, and the product was chromatographed using a silica gel column (100–200 mesh) with CH_2Cl_2 as the mobile phase. The desired product had a very low retention time, and almost all other products adsorbed onto the silica very strongly. Eluent from the column was evaporated under reduced pressure, yielding 2-*tert*-butyl-3-dimethylaminoacrylonitrile as a yellow solid (4.17 g, 23.2 mmol, 86.77%). This product was dissolved in 100 mL of methanol and was treated with hydrazine monohydrate (2.25 mL, 46.4 mmol). This mixture was stirred for 18 h, resulting in slightly lighter color. The solvent was removed under reduced pressure and the product was chromatographed using a silica gel column (100–200 mesh) with 50/50 ethyl acetate/hexanes to give 3-*tert*-butyl-4-cyanopyrazole (very light yellow solution) as the first fraction. The solvent was removed under reduced pressure, yielding 3-*tert*-butyl-4-cyanopyrazole as a pale yellow solid (1.95 g, 13.1 mmol, 56.41%). IR (KBr disc, cm^{-1}): 1366(m), 2226(ν_{CN}, vs), 3234(w). ^1H NMR ($CDCl_3$): 1.451(s, 9H), 7.82(s, 1H). ESI-MS (THF, negative detection): $m/z = 148.3$ $[pz^{t\text{-}Bu,4CN}]^-$. Elemental *Anal.* Calc. for $C_8H_{11}N_3$: C, 64.40; H, 7.43; N, 28.16. Found: C, 64.16; H, 7.56; N, 26.70%. X-ray quality crystals were grown by slow evaporation from the toluene solution.

4.3. Dichlorotetrakis(3-tert-butyl-4-cyanopyrazole)cobalt(II), $[Co(Hpz^{t\text{-}Bu,4CN})_4Cl_2]$

Anhydrous $CoCl_2$ (0.8 g, 6.15 mmol) and $Hpz^{t\text{-}Bu,4CN}$ (3.67 g, 24.6 mmol) were mixed in dry THF and stirred for an hour. The solvent was removed by rotary evaporation and the product was redissolved in toluene. The solution was filtered, the toluene was removed under reduced pressure and $[Co(pz^{t\text{-}Bu,4CN})_4Cl_2]$ was collected as a pink solid (3.33 g, 4.59 mmol, 74.6%). IR (KBr, cm^{-1}): 2235(ν_{CN}, s). Elemental *Anal.* Calc. for $C_{32}H_{44}N_{12}CoCl_2 \cdot H_2O \cdot$ toluene: C, 55.98; H, 6.50; N, 20.09. Found: C, 55.42; H, 5.88; N, 20.99%. X-ray quality crystals were grown by slow evaporation of the toluene solution.

4.4. Diaquabis(3-tert-butyl-4-cyanopyrazole)bis(trifluoromethylsulfonato)manganese(II), $[Mn(Hpz^{t\text{-}Bu,4CN})_2(CF_3SO_3)_2(H_2O)_2]$

A solution of $Mn(CF_3SO_3)_2 \cdot 2CH_3CN$ (0.2 g, 0.46 mmol) in 10 mL dry THF was put under nitrogen and a solution of $Hpz^{t\text{-}Bu,4CN}$ (0.14 g, 0.92 mmol) in 10 mL of dry THF was added. The mixture was stirred for an hour. The solvent was removed by evaporation and the resulting solid was redissolved in CH_2Cl_2. The solution was filtered, the CH_2Cl_2 was removed under reduced pressure and $[Mn(Hpz^{t\text{-}Bu,4CN})_2(CF_3SO_3)_2(H_2O)_2]$ was collected as a white solid (0.23 g, 0.33 mmol, 72.1%). IR (KBr, cm^{-1}): 2233(ν_{CN}, s). Elemental *Anal.* Calc. for $C_{18}H_{26}N_6O_8S_2F_6Mn$: C, 31.45; H, 3.81; N, 12.22. Found: C, 31.24; H, 3.98; N, 12.41%. X-ray quality crystals were grown by slow evaporation of the CH_2Cl_2 solution.

4.5. Dichlorobis(3-tert-butyl-4-cyanopyrazole)copper(II), $[Cu(Hpz^{t\text{-}Bu,4CN})_2Cl_2]$

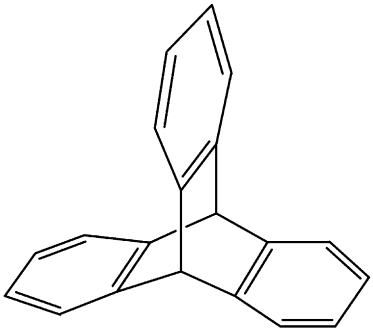
To a solution of anhydrous $CuCl_2$ (0.9 g, 6.69 mmol) in 10 mL dry THF was added $Hpz^{t\text{-}Bu,4CN}$ (1.99 g, 13.4 mmol) in 10 mL of dry THF. The mixture was stirred for an hour. The solvent was removed by rotary evaporation and the resulting solid was redissolved in toluene. After filtration and removal of the toluene under reduced pressure, $[Cu(Hpz^{t\text{-}Bu,4CN})_2Cl_2]$ was collected as blue solid (2.0 g, 4.62 mmol, 69.1%). IR (KBr, cm^{-1}): 2229(ν_{CN}, s), 2238(ν_{CN}, s). Elemental *Anal.* Calc. for $C_{16}H_{22}N_6CuCl_2$: C, 44.40; H, 5.12; N, 19.42. Found: C, 44.55; H, 5.29; N, 19.35. X-ray quality crystals were grown by slow evaporation of the toluene solution.

4.6. X-ray crystallography

Data were collected using a Nonius CAD4 diffractometer (Mo Kα, $\lambda = 0.71069$ Å) equipped with an Oxford Cryosystems Cryostream 700 low-temperature apparatus. Suitable crystals were identified using a polarizing microscope, affixed to a glass fiber using Paratone-N oil (Exxon) and were immediately transferred to the cold stream of the diffractometer. The unit cells were determined from the setting angles of 24 reflections with $20° < 2\theta < 24°$. The data were processed and the structures solved and refined using the WinGX software package [17]. The data were corrected for Lorentz and polarization effects and an empirical absorption correction based on azimuthal scans of three intense reflections (Mn and unmetallated pyrazole structures) or using the DIFABS program [18] (Co and Cu structures) was applied. The structures were solved by direct methods [19] and refined by full-matrix least-squares techniques [20] with values for $\Delta f'$ and $\Delta f''$ from Creagh and McAuley [21]. All non-hydrogen atoms, except those in the disordered toluene molecule in the Co structure, were refined with anisotropic temperature factors. Hydrogen atoms were included at idealized positions, but were not

refined. The hydrogen atoms on the coordinated water molecules in the Mn structures were included at positions determined from the difference Fourier map, but not refined. Pertinent details are given in Table 1.

Acknowledgments



The authors thank Wichita State University for funding and Dr. Colin Thomas for synthesizing [Mn-($Hpz^{t\text{-}Bu,4CN}$)$_2$(CF_3SO_3)$_2$(H_2O)$_2$] for elemental analysis.

Appendix A. Supplementary material

CCDC 626487, 626488, 626489 and 626490 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2006.12.035.

Triptycene
(tpty)
Schematic view of the ligand

2. Experimental

All manipulations were performed under an argon atmosphere using Schlenk techniques. Organic solvents were reagent grade, and were dried and distilled using standards methods before use. Triptycene, silver perchlorate and silver triflate were purchased from Aldrich, all other chemicals were purchased from Wako Pure Chemical Co., Japan, and were used as receive without further purification. IR spectra were measured as KBr disks on a JASCO FT/IR-8000 spectrometer. TG analysis was performed on a Rigaku Thermo Plus TG 8120 spectrometer at 20 °C/min and under argon. All crystallizations of the silver complexes were performed in the dark.

Safety note: Perchlorate salts with organic ligands are potentially explosive! Only small amounts of materials should be prepared and they should be handled with great care.

2.1. Synthesis

2.1.1. $[Ag(tpty)(THF)_2](ClO_4)$ (1)

A solution of $AgClO_4 \cdot H_2O$ (19.1 mg, 0.08 mmol) in 5 ml of THF was added to triptycene (10.2 mg, 0.04 mmol). After 20 min of stirring, the resultant colorless solution was filtered. The filtrate was introduced into a narrow-diameter glass tube and carefully layered with 2 ml of *n*-pentane as a diffusion solvent. The glass tube was sealed under Ar and wrapped with aluminum foil. The filtrate was allowed to stand at room temperature for two weeks, upon which colorless platelet crystals of **1** were obtained. *Anal*. Calc. for $AgClO_6C_{28}H_{30}$: C, 55.46; H, 4.95. Found: C, 55.75; H, 5.21%. Main IR bands (KBr, ν/cm^{-1}): 2969(w), 1456(s), 1144(s), 1111(s), 1086(s), 797(m), 741(s), 627(s).

2.1.2. $[Ag_6(tpty)_4(CF_3SO_3)_2(H_2O)_6](CF_3SO_3)_4$ (2)

A solution of $Ag(CF_3SO_3) \cdot H_2O$ (27.1 mg, 0.1 mmol) in toluene (5.0 ml) was added to tpty (12.7 mg, 0.05 mmol). The mixture was stirred at room temperature for 20 min, and the resultant colorless solution was filtered. The filtrate was transferred to a 7 mm diameter glass tube under argon and was layered with *n*-pentane as a diffusion solvent. The glass tube was sealed under argon and wrapped with aluminum foil. The filtrate was left standing at room temperature for two weeks. Colorless brick single crystals of **2** were obtained. *Anal*. Calc. for $Ag_6S_6F_{18}O_{24}C_{86}H_{56}$: C, 37.87; H, 2.11. Found: C, 38.17; H, 2.31%. Main IR bands (KBr, ν/cm^{-1}): 3750(m), 2966(m), 2371(s), 2353(s), 2342(s), 1458(s), 1300(s), 1235(s), 1178(s), 1042(s), 1026(s), 797(m), 741(s), 646(s), 640(s), 625(s).

2.2. Crystallography

Diffraction data for **1** were collected at a temperature of -73 ± 1 °C on a Quantum CCD area detector coupled with a Rigaku AFC8 diffractometer, and for **2** on a Rigaku AFC7 diffractometer with graphite-monochromated Mo Kα radiation ($\lambda = 0.71069$ Å) at a temperature of 23.0°. Intensity data were collected by using standard scan techniques (ω–2θ) to a maximum 2θ value of 55.2° for **1** and 55.7° for **2**. All intensity data were corrected for Lorentz and polarization effects.

The structures were solved by direct methods (SIR-88 [9] for **1** and SIR-97 [10] for **2**) and expanded using Fourier techniques [11]. All non-H atoms were refined with anisotropic thermal parameters. The final cycle of full-matrix least-squares refinements [12] for all the structures were performed on these data having $I > 2\sigma(I)$ and included anisotropic thermal parameters for non-hydrogen atoms. Reliability factors are defined as $R = \sum \| F_o| - |F_c| \| / \sum |F_o|$ and $R_w = [\sum w(F_o^2 - F_c^2)^2 / \sum w(F_o^2)^2]^{1/2}$. All crystallographic computations were performed using the teXsan

package [13]. Details of the X-ray experiments and crystal data are summarized in Table 1. Selected bond lengths and angles for the three complexes are given in Table 2.

3. Results and discussion

In order to probe the influence of the ligand stereochemical preference with different anions on the coordination of a porous complex of silver(I), the study was carried out with the ligand tpty and the perchlorate and triflate counter anions. While single crystals of **1** show a 1D chain structure using ClO_4^- anions; when $CF_3SO_3^-$ is employed as the counter anion, complex **2** gives a 3D porous structure with a cavity including guest molecules by using THF as the solvent. The IR spectra of the two complexes exhibit bands that can be readily assigned to ClO_4^- with strong bands at 1144, 1111 and 1086 cm^{-1} for **1**, and to $CF_3SO_3^-$ with strong bands at 1235, 1178 and 1042 cm^{-1} for **2**. Compared to the criteria for non-coordination of ClO_4^-, with strong non-split broad bands at 1140, 1109 and 1087 cm^{-1}, and $CF_3SO_3^-$, with strong non-split broad bands at 1256, 1179 and 1036 cm^{-1}, it indicates that ClO_4^- and $CF_3SO_3^-$ are present not as ionic species, but as coordinated ones. The two complexes exhibit a strong ν(C–C) absorption at 1456 cm^{-1} as expected for the presence of tpty.

3.1. 1D chain of $[Ag(tpty)(THF)_2](ClO_4)$ (**1**)

The crystallographic studies reveal that complex **1** consists of a one-dimensional chain of [Ag(tpty)(THF)$_2$] units, in which the crystallographically independent metal ions are bridged by triptycene. The structure of the trimeric molecular unit of the crystals is shown in Fig. 1a with the atomic numbering scheme employed. The Ag(1) ion has a tetrahedral coordination geometry, coordinated to two aromatic carbon atoms with Ag–C bond distances of 2.392(4) and 2.498(4) Å, and two THF groups at Ag–O distances of 2.357(3) and 2.299(3) Å, Table 2. One crystallographically independent ligand bridges the silver(I) atoms in a μ–η^1–η^1 mode and gives a 1D chain in which the

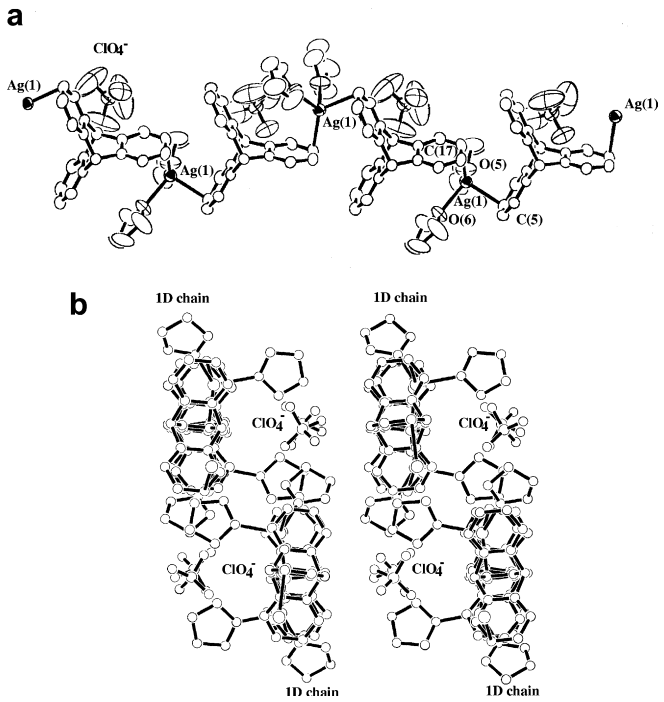

Fig. 1. (a) 1D chain structure of the complex $[Ag(tpty)(THF)_2](ClO_4)$ (**1**). (b) Molecular packing of complex **1**.

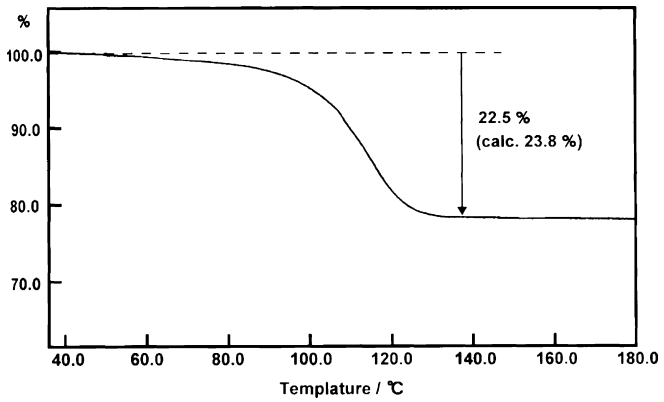

Fig. 2. TG curve of $[Ag(tpty)(THF)_2](ClO_4)$ (**1**).

perchlorate groups occupy the space between the chains, Fig. 1b. From the TG analysis results of complex **1** (Fig. 2), the weight loss of 22.5% at 70 °C indicates the severing of the two THF molecules (calculated value: 23.8%) which coordinated to Ag(I).

3.2. 3D porous structure of $[Ag_6(tpty)_4(CF_3SO_3)_2(H_2O)_6](CF_3SO_3)_4$ (2)

Complex **2** consists of a 2D sheet of $[Ag_6(tpty)_4(CF_3SO_3)_2(H_2O)_6]$ units (shown in Fig. 3), in which the six crystallographically independent metal ions are bridged by ligands and oxygen atoms. Ag(1) and Ag(5) are coordinated to three hydrate oxygen atoms and one triflate oxygen atom. Ag(2) is coordinated to three tpty moleculars in a η^2/η^1-mode and one triflate oxygen atom. Ag(3) and

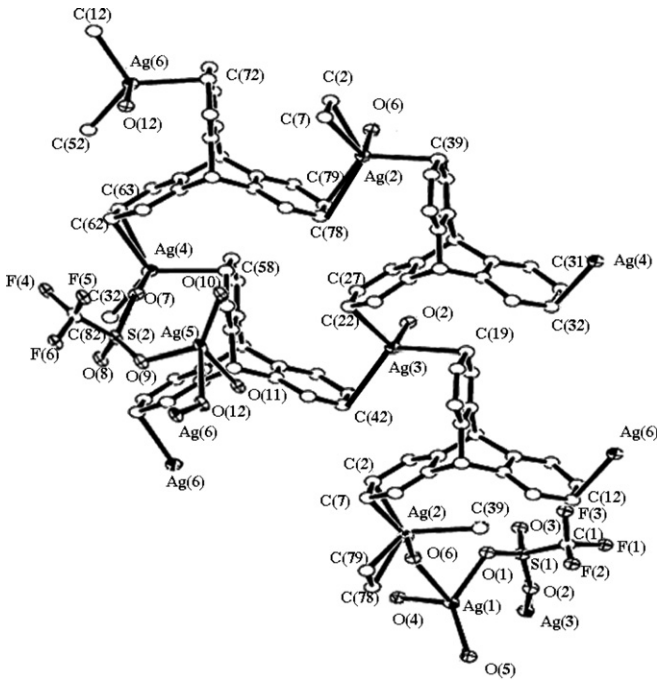

Fig. 3. Molecular structure of $[Ag_6(tpty)_4(CF_3SO_3)_2(H_2O)_6](CF_3SO_3)_4$ (**2**).

Ag(6) are coordinated to three tpty moleculars in a η^1-coordination mode and one hydrate oxygen. Interestingly, Ag(4) is coordinated to two tpty moleculars in a η^1-coordination mode, one tpty in a η^2-mode and one triflate oxygen. So the Ag(I) ions are all four-coordinated and have a tetrahedral coordination geometry. The Ag–O bond distances are from 2.249(7) to 2.502(6) Å for Ag(1), 2.444(6) Å for Ag(2), 2.446(6) Å for Ag(3), 2.526(6) Å for Ag(4), from 2.321(6) to 2.498(5) Å for Ag(5) and 2.436(5) Å for Ag(6), whereas Ag–C bond distance range from 2.437(7) to 2.679(9) Å for Ag(2), from 2.446(8) to 2.570(9) Å for Ag(3), from 2.437(8) to 2.483(8) Å for Ag(4) and from 2.489(9) to 2.550(9) Å for Ag(6), Table 2. Because of the rigid triangular molecule of tpty, the Ag–O bond distances do not show any significant variations in this complex.

The molecule also contains four crystallographically independent ligands with distinctly different coordination modes, two with a μ–η^1–η^1–η^1 fashion bridging Ag(2), Ag(3), Ag(4) and Ag(6) ions, and the other two involve μ–η^1–η^1–η^2 and μ–η^1–η^2–η^2 fashions bridging four silver centers. A 2D sheet is thus formed in which the ligands are arranged alternately such that twofold in two lines up in one direction and the next four stand in the same direction (Fig. 4a). The two adjacent sheets are connected by a bridging triflate group and one hydrate linking Ag(1) or Ag(5) with Ag(2) and Ag(3) or Ag(4) and Ag(6), leading to a 3D porous polymer (Figs. 4b and 5a) with a cavity size of 5.0×4.8 Å and 5.0×4.3 Å (Fig. 5b). In addition, cavities are occupied by triflate anions. So there are two types of triflate group: one is used as a bridging group and the other exists in a cavity. The cavity is difficult to use owing to the triflate anions, but not to neutral small solvent mol-

ecules located at cavities in which the triflate guests desorption does not occur on heating. This is dissimilar to silver(I) coordination complexes $[Ag_3(tpty)_3(ClO_4)_3](toluene)_2$ in our previous work [7,8].

3.3. Coordination types of tpty with metal ions

The triangular molecule triptycene is a very special hydrocarbon with a relatively rigid molecular geometry, having three equivalent benzene rings mutually inclined at 120°. Prior to the present work, some X-ray crystal structures of triptycene π complexes have been reported, such as $[Cr(tpty)(CO)_3]$ [14], $[Co_4(tpty)(CO)_9]$ [14], $[SnCl(tpty)(AlCl_4)]_2$ [15], $[Cr_2(tpty)CO]_6$ [16] and $[(Cp^*Ru)_3(tpty)](CF_3SO_3)_3$ [17]. Fig. 6 cites instances of illustrations of the coordination mode from these complexes and the present complexes. For smaller metal atoms, it tends to interact with one metal atom by one arene ring in type (a) with a small widening of the inter-arene angles [14,17], such as $[Cr(tpty)(CO)_3]$, $[Co_4(tpty)(CO)_9]$ and $[(Cp^*Ru)_3(tpty)](CF_3SO_3)_3$, while with the larger metal atom tin it offers bis(arene) coordination with type (b) in $[SnCl(tpty)(AlCl_4)]_2$, sandwiching the cation, with the angle between the two arene rings contracted to 108.2° and the remaining inter-arene angles widened accordingly to 125.8° and 126.0° [15]. In addition, type (c) also exist in $[(Cp^*Ru)_3(tpty)](CF_3SO_3)_3$ with the coordination of three tpty arene rings with the metal atoms. Triptycene in these complexes exhibits only a η^6-mode by one to three benzene rings, the η^1-mode and η^2-mode are never observed. In the present Ag(I) coordination complexes with triptycene, $[Ag(tpty)(THF)_2](ClO_4)$ (**1**), $[Ag_6(tpty)_4(CF_3SO_3)_2(H_2O)_6](CF_3SO_3)_4$ (**2**) and $[Ag_3(tpty)_3(ClO_4)_3](toluene)_2$ [7], tpty exhibits an unprecedented η^1-and η^2-fashion bridging two or three Ag atoms, by (d) type in $[Ag(tpty)(THF)_2](ClO_4)$, by (c) type in $[Ag_6(tpty)_4(CF_3SO_3)_2(H_2O)_6](CF_3SO_3)_4$, and by (c) and (d) coordination type in $[Ag_3(tpty)_3(ClO_4)_3](toluene)_2$ [7], affording novel polymeric materials. Surprisingly, the tpty framework was found to involve relatively little deformation as compared to the metal-free hydrocarbon and the variation of the three inter-arene angles (115.6–124.4°) is relatively small regardless of bis- or tris(arene) coordination. Such an eased conformation of the aromatic may in part be the contributing factor for the stable three-dimensional complex network formed and the relatively similar Ag–O bond distances observed.

4. Conclusion

In this paper, two silver(I)–tpty complexes have been synthesized and characterized by single-crystal X-ray determination, IR, TG analysis and element analysis. In two silver(I)–tpty complexes, the structure of the silver(I) coordination polymer is closely related to the ligand geometry and coordination site as well as coordination direction. In addition, the anion and solvent also play an important role in the construction of the complexes. In the tpty/$AgClO_4$/THF system, silver(I) ions are bridged by tpty and give rise to a 1D chain coordination complex $[Ag(tpty)(THF)_2](ClO_4)$ (**1**). In addition, the solvent THF is coordinated to the silver(I) ions. Using a larger size anion, $CF_3SO_3^-$ instead of ClO_4^-, a 3D porous complex $[Ag_6(tpty)_4(CF_3SO_3)_2(H_2O)_6](CF_3SO_3)_4$ (**2**), with large cavities, with a size of 5.0×4.8 Å and 5.0×4.3 Å, has been obtained in toluene solvent. Although $CF_3SO_3^-$ is included

in the cavity, it is impossible to desorption and incorporate triflate molecules.

the luminescent properties of the supramolecular compounds [28,29]. The combination of organic emitting units with suitable metal ions and supramolecular interactions could fabricate a variety of luminescent materials. H_2aip is a good candidate for assembling such complexes due to its interesting structural characteristics. Compared with the ip ligand (H_2ip = isophthalic acid), the introduction of an amino group in H_2aip results in the following two effects at least: (i) a supramolecular effect, namely, providing more hydrogen-bonding donor or acceptor sites in the construction of supramolecualr packing; (ii) a coordination effect, namely, adding a new coordination site to coordinate with more metal centers. To the best of our knowledge, only a few supramolecular complexes with H_2aip have been reported so far [30–35]. Furthermore, the introduction of *N*-containing ligands [such as atz or amtz (amtz = 2-amino-5-mercapto-1,3,4-thiadiazole)] may induce new structural evolution. The atz or amtz ligand is important in maintaining the desired low dimensional coordination polymer and may provide potential supramolecular recognition sites for hydrogen bonding and π–π aromatic stacking interactions. We assumed that the H_2aip ligand could be useful in the formation of interesting supramolecular networks with some important features in the presence of atz or amtz ligand. So, we have started a systematic study on metal(II) coordination with the mixed H_2aip and atz or amtz ligands. One of the aims of this project is to analyze the influence that factors such as hydrogen bonding, rigidity and the possibility of specific attractive interactions between aromatic rings can exert on the structure and functional properties of aip containing metal(II) complexes. In the present paper, we report two novel three dimensional supramolecular coordination polymers $[Cd(Haip)_2(H_2O)_2]\cdot 2H_2O$ (**1**) and $[Zn(aip)(atz)]\cdot 3H_2O$ (**2**) based on mixed H_2aip and atz ligands. These complexes have been found to exhibit blue photoluminescence at room temperature.

2. Experimental

2.1. Materials and characterization

All reagents were purchased commercially and were used without further purification. Elemental analyses (C, H and N) were carried out on a 240C Elemental analyzer. FT-IR spectra (400–4000 cm^{-1}) were recorded from KBr pellets in a Magna 750 FT-IR spectrophotometer. Solid state emission spectra of the compounds were recorded using a 48000DSCF fluorescence spectrometer. Thermogravimetric analysis (TG) was taken on a NETZSCH STA 409 PG/PC instrument.

2.2. Synthesis

2.2.1. $[Cd(Haip)_2(H_2O)_2]\cdot 2H_2O$ (*1*)

Amtz (2-amino-5-mercapto-1,3,4-thiadiazole) (0.0258 g, 0.165 mmol) was dissolved in water (3 ml) and then an aqueous solution of $CdCl_2\cdot 2.5H_2O$ (0.0510 g, 0.165 mmol) in water–methanol (v:v = 1:1; 3 ml) was added whilst stirring. To this solution a mixture of H_2aip (0.0300 g, 0.165 mmol) and NaOH (0.0080 g, 0.200 mmol) in water–methanol (v:v = 1:1; 10 ml) was added and stirred for 10 min, and then filtered. The filtrate was kept at ambient temperature for several days and colorless crystals were formed. They were filtered and washed thoroughly with methanol and dried in a vacuum (41% based on H_2aip). *Anal*. Calc. for $C_{16}H_{20}CdN_2O_{12}$: C, 27.13; H, 2.28; N, 12.66. Found: C, 26.85; H, 2.25; N, 12.10%.

2.2.2. $[Zn(aip)(atz)]\cdot 3H_2O$ (*2*)

Atz (0.0140 g, 0.165 mmol) was dissolved in water (3 ml) and then an aqueous solution of $Zn(NO_3)_2\cdot 6H_2O$ (0.0492 g, 0.165 mmol) in water–methanol (v:v = 1:1; 3 ml) was added whilst stirring. To this solution a mixture of H_2aip (0.0300 g, 0.165 mmol) and NaOH (0.0132 g, 0.330 mmol) in water (8 ml) was added and stirred for 10 min, and then filtered. The solution was kept at ambient temperature for several days and brown crystals formed. They were filtered and washed thoroughly with methanol

2.3. X-ray single-crystal structure determination

Crystallographic data for the complexes **1** and **2** were collected at 293(2) K with a Siemens SMART CCD diffractometer using graphite-monochromated (Mo Kα) radiation ($\lambda = 0.71073$ Å), ψ and ω scans mode. The structures were solved by direct methods and refined by the full-matrix least-squares on F^2 method. Intensity data were corrected for Lorenz and polarization effects and an empirical absorption correction was performed. All non-hydrogen atoms were refined anisotropically. The carbon-bound hydrogen atoms were added geometrically and allowed to ride on their respective parent atoms. The oxygen-bound hydrogen atoms were located in the difference Fourier map and kept fixed in that position. The contribution of these hydrogen atoms was included in the structure factor calculations. All calculations were carried out on a PC computer using the SHELXL-97 program [36]. Details of crystal data, collection and refinement are listed in Table 1.

3. Results and discussion

3.1. Preparation

The solvent used to synthesize the compound and the method to grow single crystals usually has great effect on the structure of the compound. Self-assembly of stoichiometric amounts of H_2aip, amtz, $CdCl_2 \cdot 2.5H_2O$ and NaOH in the mixed water–methanol solvent and slow evaporation of solution in open air provided metal-organic three-dimensional supramolecular network **1**, while the reaction of $Cd(O_2CCH_3)_2 \cdot 2H_2O$, H_2aip and H_2O under hydrothermal conditions leads to the formation of a three-dimensional (3,4)-connected network $[Cd(aip)(H_2O)] \cdot H_2O$ [30]. The title complexes are stable in the open air. The N-donor ligand (amtz) is very important for the quality of the crystal **1**. Although this ligand does not appear in complex **1**, omission of it leads to the formation of polycrystals instead of single crystals.

3.2. Structural analysis of $[Cd(Haip)_2(H_2O)_2] \cdot 2H_2O$ (1)

The self-assembly of $CdCl_2 \cdot 2.5H_2O$ with H_2aip and amtz in the presence of NaOH gives a two-dimensional framework **1** which is quite different from the reported complex $[Cd(aip)(H_2O)] \cdot H_2O$ [30]. Determination of the structure of the complex $[Cd(Haip)_2(H_2O)_2] \cdot 2H_2O$ (**1**) by X-ray crystallography reveals that the asymmetric unit consists of one Cd atom, two Haip ligands, two coordinated water molecules and two lattice water molecules, as shown in Fig. 1. The Cd atom is six-coordinated with a greatly distorted octahedral geometry (Fig. 1). The equatorial plane is occupied by two monodentate carboxylate

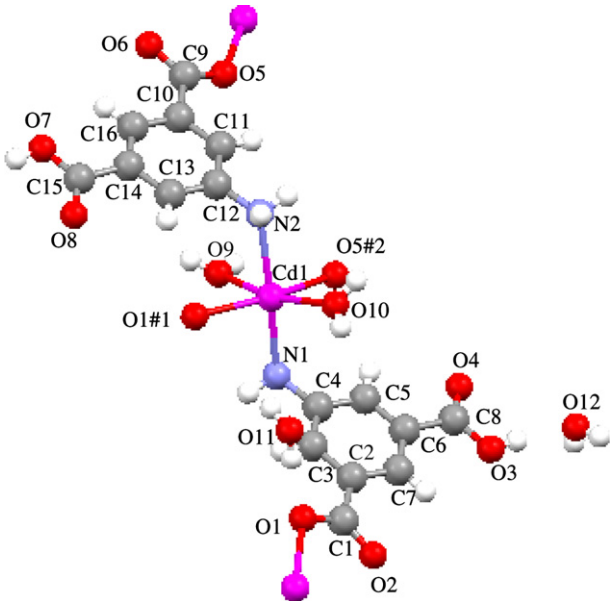

Fig. 1a. Molecular structure of complex **1** showing the coordination environment of the Cd(II) ion.

oxygen atoms from two Haip ligands [Cd(1)–O(1)#1 2.2542(15) Å; Cd(1)–O(5)#2 2.3016(15) Å] and two water oxygen atoms [Cd(1)–O(9) 2.4309(12) Å; Cd(1)–O(10) 2.2746(12) Å], while the axial sites are occupied by two nitrogen atoms of the amino groups from two Haip ligands [Cd(1)–N(1) 2.3323(18) Å; Cd(1)–N(2) 2.3810(18) Å]. The angles subtended the Cd atom ranges from 80.53(5)° to 172.97(6)°. The bond angles of O(1)#1–Cd(1)–O(10) and O(1)#1-Cd(1)–O(5)#2 in the equatorial plane are 167.95(9)° and 114.44(5)°, respectively, which deviate from linearity greatly. Selected bond distances and angles are listed in Table 2. It should be noted that the Haip ligand in complex **1** uses one of its two carboxylate groups to coordinate monodentately to one Cd(II) ion, whereas the other protonated carboxylate group does not participate in coordination to the Cd(II) center. The amino group of Haip coordinates to a second Cd(II) atom. Complex **1** is the first example where only one carboxylate group of H_2aip ligand coordinates to a metal(II) ion in a monodentate fashion, compared with the reported complexes with H_2aip ligands [30–35]. It is interesting that the dihedral angles of the carboxylate groups O(5)C(9)O(6), O(7)C(15)O(8) and the amino group $N(2)H_2$ with the corresponding benzene ring C(10)C(11)C(12)C(13)C(14)C(16) are 11.80°, 5.99° and 62.15°, respectively, while those of O(3)C(8)O(4), O(1)C(1)O(2) and the amino group $N(1)H_2$ with the benzene ring C(2)C(3)C(4)C(5)C(6)C(7) are 3.19°, 15.06° and 60.68° respectively. So, the carboxylate groups are almost in the same plane with the corresponding benzene ring, but the amino group is not. Each Haip ligand in the complex **1** acts as a bidentate ligand linking to two Cd(II) centers, while the aip ligand in the reported complex $[Cd(aip)(H_2O)] \cdot H_2O$ links to four Cd(II) centers through one amino group, one monodentate carboxylate group

and one chelating/bridging carboxylate group [30]. As a result, **1** forms a novel two-dimensional framework with a 28-membered macrometalcycle (Fig. 1b), while the reported complex $[Cd(aip)(H_2O)]\cdot H_2O$ exhibits a three dimensional (3,4)-connected network [30]. Interestingly, there are strong $\pi\cdots\pi$ stacking interactions between the adjacent layers. The centeroid–centeroid distance and the dihedral angles of the parallel benzene rings in the nearest adjacent layers are 3.716 Å and 3.27°, respectively (Fig. 2a). Furthermore, there are extensive hydrogen bonds between the layers. The system of hydrogen bonds, which includes carboxylate oxygen atoms [O(1), O(2), O(3), O(4), O(6), O(7) and O(8)], nitrogen atoms N(1) and N(2) from the Haip ligand, four oxygen atoms from coordinated and lattice water molecules [O(9), O(10), O(11) and O(12)] and one carbon atom C(3) from the benzene ring, is very complicated as shown in Table 3. Thus, a novel three-dimensional supramolecular network is formed as a result of strong intermolecular hydrogen bonding and $\pi\cdots\pi$ stacking interactions between the adjacent layers (Fig. 2b). Both $\pi\cdots\pi$ stacking interactions and hydrogen bonding are very important in the construction of supramolecular architectures [37]. Undoubtedly, both the hydrogen bonding and $\pi\cdots\pi\cdots\pi$ interactions play important roles in the stabilization of the supramolecular network of **1**.

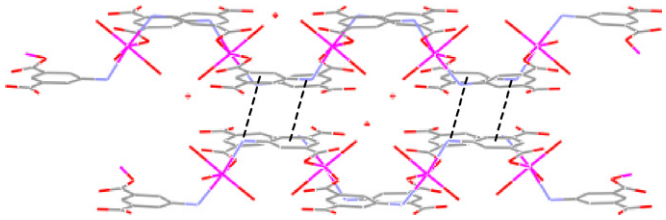

Fig. 2a. View of the strong interlayer π–π stacking interactions indicated by the black dashed lines in **1**.

3.3. Structural analysis of $[Zn(aip)(atz)]\cdot 3H_2O$ (2)

When we investigated the coordination chemistry of a Zn(II) salt with H_2aip and atz in the presence of NaOH, a 2D coordination polymer (**2**) was formed. The single crystal analysis reveals that the asymmetric unit of complex **2** consists of one Zn atom, one aip ligand, one atz ligand and three lattice water molecules, as shown in Fig. 3. The important bond distance and angles are listed in Table 4. The Zn (II) centre lies in a distorted $[ZnN_2O_2]$ tetrahedral coordination sphere, with two oxygen atoms and one nitrogen atom from three aip ligands, as well as one nitrogen atom from one atz ligand. The Zn(1)–N(1) (atz) distance [1.9978(16) Å] is

O(2)–Zn(1)–N(5)#2	110.46(6)		
N(1)–Zn(1)–N(5)#2	104.90(6)		

Symmetry transformations used to generate equivalent atoms:
#1 $x-1/2, -y+3/2, z-1/2$; #2 $x-1/2, -y+1/2, z-1/2$; #3 $x+1/2, -y+3/2, z+1/2$; #4 $x+1/2, -y+1/2, z+1/2$.

slightly shorter than that of Zn(1)–N(5)#1 (amino) [2.0613(15) Å]. The Zn(1)–O (carboxylate) distances are almost the same as those in the reported zinc complex [35]. The dihedral angle between the carboxylate plane and the benzene ring is 6.10°, whilst that between the amino group and the benzene ring is 60.35°, which indicates that the carboxylate groups are almost in the same plane with the benzene ring but the amino group is not. Different from the

coordination mode in complex **1**, all the carboxylate groups participate in coordination with the Zn(II) center. Each aip ligand in complex **2** employs its two monodentate carboxylate groups and one amino group to coordinate to three zinc atoms. Therefore three metal centers are linked by three ligands into a 21-membered macrometalcycle, which is further linked to six nearest-neighbour zinc centers by three independent aip ligands to give rise to a lattice plane with a cavity of 8.643 × 8.279 Å (Fig. 4). The lattice water $H_2O(5)$ lies in the cavity. It is interesting that the atz ligands are arranged at one side of the layer. The two-dimensional network layers are parallel with each other as shown in Fig. 5. The adjacent layers recognize each other through offset π–π stacking interactions of the atz ligand and the pyridyl ring in the aip ligand (the centeroid-centeroid distances of adjacent aromatic rings are 3.747 Å for pyridyl rings and 4.166 Å for atz rings).

The 2D grids are further assembled by strong hydrogen bonds, in addition to the π–π stacking interactions, leading to the formation of an extended three-dimensional supramolecular framework with dimensions of 9.278 × 7.099 $Å^2$, featuring an "ABAB" packing mode along the *b* axis, as shown in Fig. 6. Two lattice water molecules, $H_2O(6)$ and $H_2O(7)$, lay in the channel. Hydrogen bonds exist extensively in complex **2**. Details of the hydrogen bonds are listed in Table 5.

3.4. FT-IR Spectra

The FT-IR spectra of both complexes **1** and **2** show broad peaks in the range 3600–3151 cm^{-1} due to the existence of hydrogen bonding between water molecules and amino groups. IR results are commonly employed to distinguish the coordination modes of carboxylate groups. A correlation of the carboxylate coordination mode to metal ions is usually made by examining the difference $\Delta\nu(COO) = \nu_{as}(COO) - \nu_s(COO)$ of the complexes [38]. The vibrations of $\nu_{as}(COO)$ and $\nu_s(COO)$ are at 1686,

1629, 1569 and 1470, 1394 cm^{-1} for complex **1**. Among them, the characteristic band at 1686 cm^{-1} is attributed to the protonated carboxylate group of the Haip ligand. Compared with complex **1**, ν_{as}(COO) are at 1613, 1574 cm^{-1} and ν_s(COO) are at 1441, 1376 cm^{-1} for complex **2**. The absence of the expected characteristic bands at 1730–1680 cm^{-1}, which are attributed to the protonated carboylate group, indicate the complete deprotonation of aip in complex **2**. The IR results indicate that the carboxylate groups of the aip ligand acts n the monodentate coordination mode in these complexes. In all these cases, the results of the X-ray analysis allowed the unambiguous assignment of the binding modes of the carboxylate groups.

3.5. Thermogravimetric analysis

To study the thermal stability of the title complexes, thermogravimetric analysis (TG) was performed on polycrystalline samples under a nitrogen atmosphere in flowing N_2 with a heating rate of 10 °C min^{-1} in the temperature range 25–800 °C. The TG curve of complex **1** is divided into three stages. The first weight loss of 5.5% occurs in the temperature range 92–237 °C, which can be attributed to the loss of lattice water molecules (calculated value 6.6%). Subsequent to this, there is a distinct weight loss stage of 6.9% in the temperature range 257–307 °C, corresponding to the loss of two coordinated water molecules (calculated value 6.6%). Above 321 °C, the product begins to decompose. Free H_2aip decomposes at 303 °C [35]. This indicates that complex **1** is more stable than the free H_2aip ligand.

The thermal behavior of the coordination compound **2** has also been deduced from the TG analysis. The weight loss of 12.02% in the temperature range 42–249 °C can be attributed to the removal of three lattice H_2O molecules (calcd. 14.14%), and then the compound continues to decompose to lose its organic ligands above 272 °C and complete decomposition is not achieved until above 800 °C.

3.6. Photoluminescence properties

It is well known that metal-organic polymeric complexes with a d^{10} closed-shell electronic configuration have been found to exhibit fluorescent properties. The solid-state photoluminescence spectrum of complex **1** at room temperature is depicted in Fig. 7. H_2aip exhibits a broad fluorescent emission centered on 450 nm with an excitation maximum at 300 nm. In the case of the metal-organic coordination polymer **1**, a blue-shifted photoluminescence with the main emission at 411 nm and with a shoulder at about 587 nm ($\lambda_{ex} = 271$ nm) is observed. This emission may arise from a ligand-to-metal charge transfer (LMCT). The fluorescent properties of complex **2** and atz are also examined in the solid state at room temperature. The excitation bands of complex **2** under the emission wavelength 335 nm possess two peaks at 255 and 267 nm, and the one located at 267 nm is the main peak (see supplementary data). As shown in Fig. 8, the emission spectrum of complex **2** under the excitation wavelength 267 nm shows two intense maximum emissions at 335 nm and 450 nm, which are equal to those of the atz ligand. The excitation wavelength of the atz ligand ($\lambda_{ex} = 269$ nm) is almost the same as that of complex **2**. Therefore, the emission bands of complex **2** may be mainly ascribed to the π–π^* transition of the atz ligand. Thus, these complexes may be good candidates for highly thermally stable and solvent-resistant photoactive materials because they are almost insoluble in common polar and non-polar solvents.

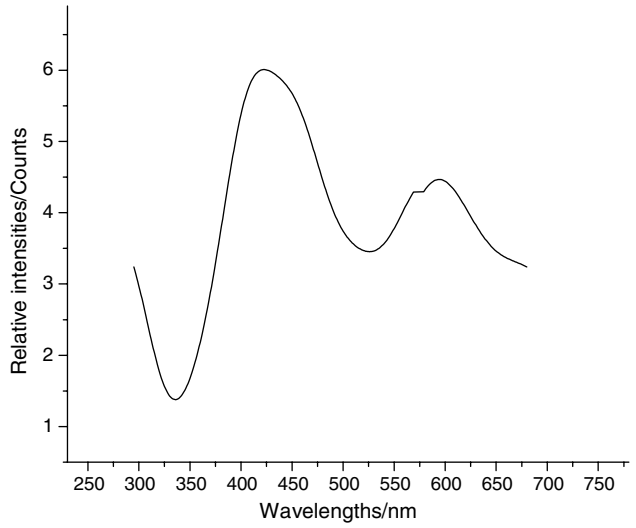

Fig. 7. The emission spectrum of **1** in the solid state at room temperature. The corresponding excitation wavelengths, λ_{ex}, is 271 nm.

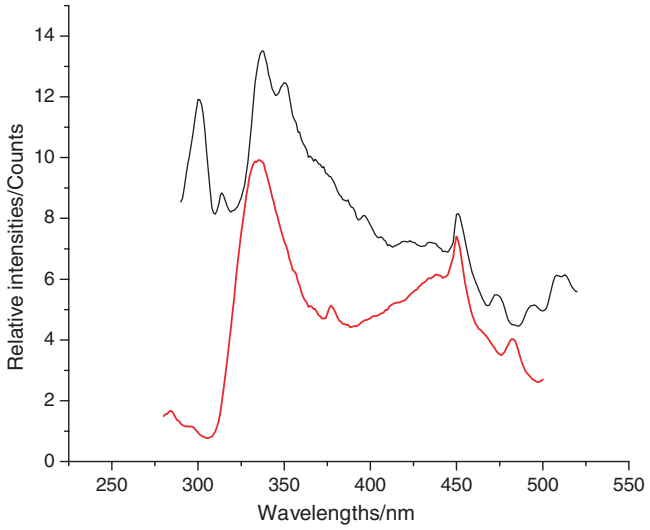

Fig. 8. The emission spectra of atz (black) and **2** (red) in the solid state at room temperature. The corresponding excitation wavelengths (λ_{ex}) are almost the same, and are 269 and 267 nm, respectively. (For interpretation of the colour representation in this figure legend the reader is referred to the web version of this article.)

4. Conclusion

In conclusion, two novel 3D supramolecular coordination polymers based on the H_2aip ligand have been obtained by self-assembly. The aip ligand exhibits different coordination modes in these complexes. There are strong interlayer π–π stacking interactions in complex **1**, which further stabilizes the whole 3D supramolecular network. Complex **2** forms a novel 3D supramolecular network due to the strong hydrogen bonds and interlayer π–π stacking interactions. The fact that their skeletons are thermally stable up to 321 and 272 °C, respectively, and their fluorescent emission of $\lambda_{em} = 411$ nm and $\lambda_{em} = 450$, 335 nm, shows they may be promising as optoelectronic devices.

clear need to synthesize and investigate novel species of this type.

Here, we present the synthesis, crystal, molecular and electronic structure of the *fac*-[Re(CO)$_3$(bpzpy)Cl] tricarbonyl with 2,6-bis(pyrazo-1-yl)-pyridine (bpzpy). The ligand shows superficial similarity to 2,2′:6′,2″-terpyridine. However, incorporation of different heterocycles into the ligand framework, with their differing basicities and π-orbital energies, may have a substantial effect on the photochemical properties of the resultant metal complexes [13].

The molecular orbital diagram of the examined complex has been calculated with the density functional theory (DFT) calculations. Currently DFT method is commonly used to examine the electronic structure of transition metal complexes. It meets with the requirements of being accurate, easy to use and fast enough to allow the study of relatively large molecules of transition metal complexes [14]. The spin-allowed singlet–singlet electronic transitions of *fac*-[Re(CO)$_3$(bpzpy)Cl] have been calculated with the time-dependent DFT method (TDDFT method), and a good assignment with the experimental spectrum has been observed.

2. Experimental

2.1. General procedure

The reaction was performed under argon atmosphere. The solvents were dried before use, using the appropriate drying reagents. Re(CO)$_5$Cl was purchased from Aldrich, and used as received. 2,6-Bis(pyrazo-1-yl)-pyridine (bpzpy) was prepared according to the literature method [13].

IR spectrum was recorded on a Nicolet Magna 560 spectrophotometer in the spectral range 4000–400 cm^{-1} with the samples in the form of KBr pellets. Electronic spectrum was measured on a spectrophotometer Lab Alliance UV–Vis 8500 in the range 1000–200 nm in dichloromethane solution. Elemental analyses (C, H, N) were performed on a Perkin–Elmer CHN-2400 analyzer.

2.2. Preparation of [Re(CO)$_3$(bpzpy)Cl]

Re(CO)$_5$Cl (0.2 g, 0.55 mmol) and bpzpy (0.13 g, 0.60 mmol) in toluene (80 cm^3) were refluxed for 6 h. The resulting reaction mixture was allowed to cool to room temperature and reduced in volume to ~1 ml. An off-yellow solid was filtered off, washed with hexane, diethyl ether, and dried; yield 85%.

Single crystals of [Re(CO)$_3$(bpzpy)Cl] were grown by the slow diffusion of diethyl ether into a solution of the complex dissolved in dichloromethane.

IR (KBr, cm^{-1}): $\nu_{CO} = 2025$, 1917 and 1897 cm^{-1}; ν_{CN} and $\nu_{C=C} = 1614$, 1568 and 1520 cm^{-1}.

Anal. Calc. $C_{14}H_9N_5O_3ClRe$: C, 32.53; H, 1.75; N, 13.55. Found: C, 32.70; H, 1.60; N, 13.40%.

2.3. Crystal structures determination and refinement

The yellow crystal of [Re(CO)$_3$(bpzpy)Cl] was mounted on a KM-4-CCD automatic diffractometer equipped with a CCD detector, and used for data collection. X-ray intensity data were collected with graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at temperature of 293.0(2) K, with ω scan mode. Thirty-three seconds exposure time was used and all Ewald sphere reflections were collected up to $2\theta = 50.0°$. The unit cell parameters were determined from least-squares refinement of the setting angles of 12 165 strongest reflections respectively. Details concerning crystal data and refinement are given in Table 1. Lorentz, polarization and empirical absorption corrections [15] were applied. The structure was solved by the Patterson method and subsequently completed by the difference Fourier recycling. All the non-hydrogen atoms were refined anisotropically using full-matrix, least-squares technique. The hydrogen atoms were treated as ''riding'' on their parent carbon atoms [d(C–H) = 0.93 Å] and assigned isotropic temperature factors equal 1.2 times the value of equivalent temperature factor of the parent carbon atom. SHELXS97 [16], SHELXL97 [17] and SHELXTL [18] programs were used for all the calculations. Atomic scattering factors were those incorporated in the computer programs.

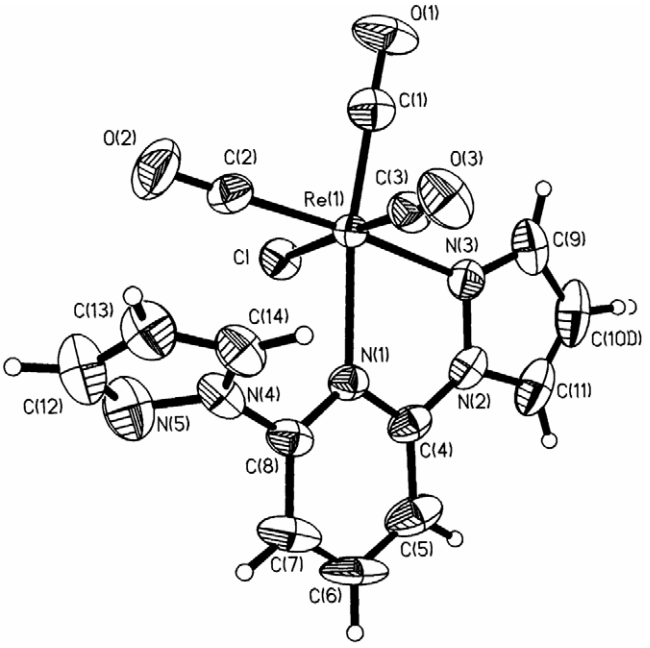

Fig. 1. Thermal ellipsoid plot of $[Re(CO)_3(bpzpy)Cl]$ showing the atom numbering scheme (50% probability ellipsoids).

2.4. Computational details

Gaussian03 program [19] was used in the calculations. The geometry optimization was carried out with the DFT method with the use of B3LYP functional [20,21]. The electronic spectrum was calculated with the TDDFT method [22]. The calculations were performed by using ECP basis set on the rhenium atom, the standard 6-31+G** basis for chlorine, oxygen, carbon and nitrogen, and 6-31G basis for hydrogen atoms. The Xe core electrons of Re were replaced by an effective core potential and DZ quality Hay and Wadt Los Alamos ECP basis set (LANL2DZ) [23] was used for the valence electrons. Additional *d* function with exponent $\alpha = 0.3811$ and *f* function with exponent $\alpha = 2.033$ on the rhenium atom were added.

3. Results and discussion

3.1. Preparation and infrared data

The $[Re(CO)_3(bpzpy)Cl]$ complex was prepared by refluxing the $[Re(CO)_5Cl]$ compound with a small excess of 2,6-bis(pyrazo-1-yl)-pyridine in toluene. The complex was isolated as air-stable, microcrystalline solid, soluble in common organic solvents. The infrared spectrum of the complex displays three bands in the carbonyl stretching region: a sharp intense band at 2025 cm^{-1} and two lower-energy bands closely spaced (1917 and 1897 cm^{-1}). This pattern corresponds to three CO units in a *fac* isomer arrangement [24]. The characteristic bands of the C=C

and C=N stretching modes of 2,6-bis(pyrazo-1-yl)-pyridine are observed in the range 1620–1510 cm^{-1} [25].

3.2. Crystal structure

The crystallographic data for the title complex are given in Table 1. The perspective drawing of the $[Re(CO)_3(bpzpy)Cl]$ complex with atomic numbering is shown in Fig. 1. The coordination geometry at the Re atom is a distorted octahedron with the three carbonyl ligands arranged in a *facial* fashion. The deviation of the rhenium coordination sphere from an ideal octahedron is ascribed to the small bite angle of the five membered chelate ring [73.97(15)°]. The selected bond lengths and angles of $[Re(CO)_3(bpzpy)Cl]$ are given in Table 2. The Re–C and Re–N bond distances are within the range expected for such complexes [26]. A noticeable difference between Re–N(pyrazole) and Re–N(pyridine) bond lengths indicates different donor strength of these two nitrogen atoms. The pyridine ring favours π-back donation from the rhenium ion to the carbonyl in *trans* position. Hence, the Re–C(1) is shorter in comparison with the Re–C(2), whereas the C(1)–O(1) bond is longer than the C(2)–O(2).

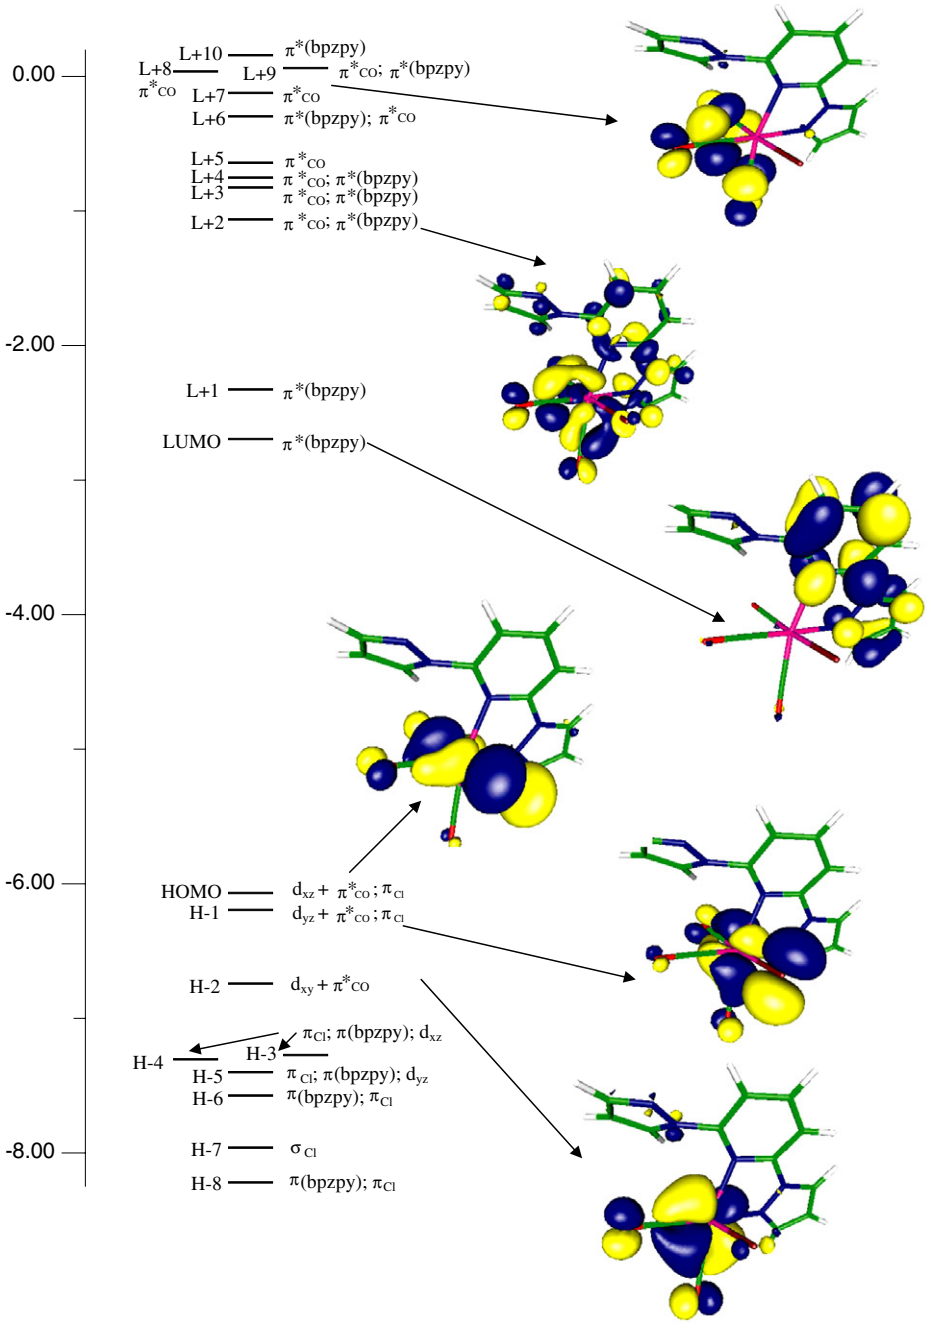

Fig. 2. The energy (eV), character and some contours of the unoccupied molecular orbitals of $[Re(CO)_3(bpzpy)Cl]$.

3.3. Optimized geometry

The geometry of $[Re(CO)_3(bpzpy)Cl]$ was optimized in a singlet state by the DFT method with the B3LYP functional. The optimized geometric parameters are gathered in Table 2. The calculated bond lengths and angles are in agreement with the values based upon the X-ray crystal structure data, and the general trends observed in the experimental data are well reproduced in the calculations.

3.4. Charge distribution

The atomic charges from the Natural Population Analysis (NPA) for $[Re(CO)_3(bpzpy)Cl]$ are shown in Table 3. The calculated charge on the rhenium atom of $[Re(CO)_3(bpzpy)Cl]$ is lower than the formal charge +1, as a result of significant charge donation from the ligands. The charges on the carbon atoms of the carbonyl ligands are positive, whereas the oxygen atoms are negatively charged. The largest positive charge is localized on the C(1) atom, whereas the least positive is carbon in the trans position to the chloride ion (π-donor ligand).

The populations of the $5d_{xy}$, $5d_{xz}$, $5d_{yz}$, $5d_{x^2-y^2}$ and $5d_{z^2}$ orbitals of the central atom in $[Re(CO)_3(bpzpy)Cl]$ are following: 1.050, 1.490, 1.380, 1.522 and 1.229. The smaller electron density on the $5d_{yz}$ in comparison with the $5d_{xz}$ rhenium orbital confirms stronger π-back donation from the rhenium ion to the carbonyl in *trans* position to the pyridine ring, and correlates well with the differences between the Re(1)–C(1) and Re(1)–C(2) bond lengths.

3.5. Electronic structure

The $[Re(CO)_3(bpzpy)Cl]$ complex is a closed-shell structure. Its molecular orbital diagram with several HOMO and LUMO contours is presented in Fig. 2. The HOMO–LUMO gap equals to 3.37 eV. The low-lying virtual orbitals correspond to π^*_{bpzpy} and π^*_{CO}, and the energy of the π^*_{bpzpy} is lower than π^*_{CO} orbitals. The three highest occupied molecular orbitals are predominately localized on the rhenium atom, corresponding to the $(5d_{xy})^2\ (5d_\pi)^4$ occupation of the central ion. They are, to a large extent, formed by Re 5d orbitals mixed with CO π^* orbitals. The HOMO and HOMO-1 orbitals contain also an admixture of chloride p_π orbitals.

3.6. Electronic spectrum

The experimental (measured in dichloromethane solution) and calculated electronic spectra of $[Re(CO)_3(bpzpy)Cl]$ are presented in Fig. 3. Each calculated transition is represented by a gaussian function $y = ce^{-bx^2}$ with the height (c) equal to the oscillator strength and b equal to 0.04 nm^{-2}.

Table 4 shows the spin-allowed singlet–singlet electronic transitions calculated with the TDDFT method for $[Re(CO)_3(bpzpy)Cl]$. For the high energy part of the spectrum, only transitions with oscillator strengths larger than 0.010 are listed in Table 4. The assignment of the calculated transitions to the experimental bands is based on the criterion of the energy and oscillator strength of the calculated transitions.

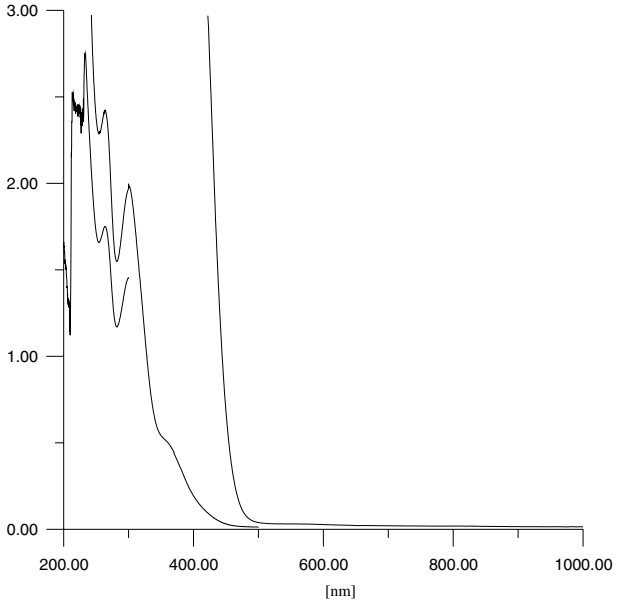

Fig. 3. The experimental (—) and calculated (---) electronic absorption spectrum of $[Re(CO)_3(bpzpy)Cl]$.

The mixed metal/chloride character of the HOMO and HOMO-1 orbitals implies that the lowest excited states have a mixed MLCT ($d \rightarrow \pi^*_{bpzpy}$) and LLCT ($\pi_{Cl} \rightarrow \pi^*_{bpzpy}$) character. The low-energy absorption band of $[Re(CO)_3(bpzpy)Cl]$ appears at 370.8 nm, and is similar to those observed for $[Re(CO)_3(bipy)Cl]$ (370 nm), $[Re(CO)_3(bipy)Br]$ (378 nm) and $[Re(CO)_3(phen)Br]$ (370 nm) [7].

The experimental absorption bands at 301.6, 264.0 and 233.6 nm result from *Metal–Ligand Charge Transfer* (occurring from the rhenium ion to the π-antibonding orbitals of the N–N ligand or π-antibonding orbitals of the carbonyl group), *Ligand–Ligand Charge Transfer* and intraligand (IL) transitions. The last excitations have a major contribution into the absorption band at 264 nm.

4. Conclusions

A novel $Re(CO)_3^+$ complex has been prepared and structurally as well as spectroscopically characterized. X-ray and IR studies confirm a *facial* geometry of the carbonyl ligands in the $[Re(CO)_3(bpzpy)Cl]$ complex. The molecular orbital diagram of the title complex has been calculated with the density functional theory (DFT) method. The HOMO, HOMO-1 and HOMO-2 orbitals are predominantly of d_{Re} orbital character corresponding to the $(5d_{xy})^2\ (5d_\pi)^4$ occupation. The low-lying virtual orbitals correspond to π^*_{bpzpy} and π^*_{CO}. The spin-allowed electronic transitions of *fac*-$[Re(CO)_3(bpzpy)Cl]$ have been calculated

with the time-dependent DFT method, and a good agreement between calculated and experimental spectra is observed.

5. Supplementary material

CCDC 623385 contains the supplementary crystallographic data for $C_{14}H_9N_5O_3ClRe$. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Acknowledgements

The Gaussian03 calculations were carried out in the Wrocław Centre for Networking and Supercomputing,

WCSS, Wrocław, Poland. Crystallographic part was financed by funds allocated by the Ministry of Science and Higher Education to the Institute of General and Ecological Chemistry, Technical University of Łódź. This work was supported by The State Committee for Scientific Research, Project No. 3 T09A 147 29.

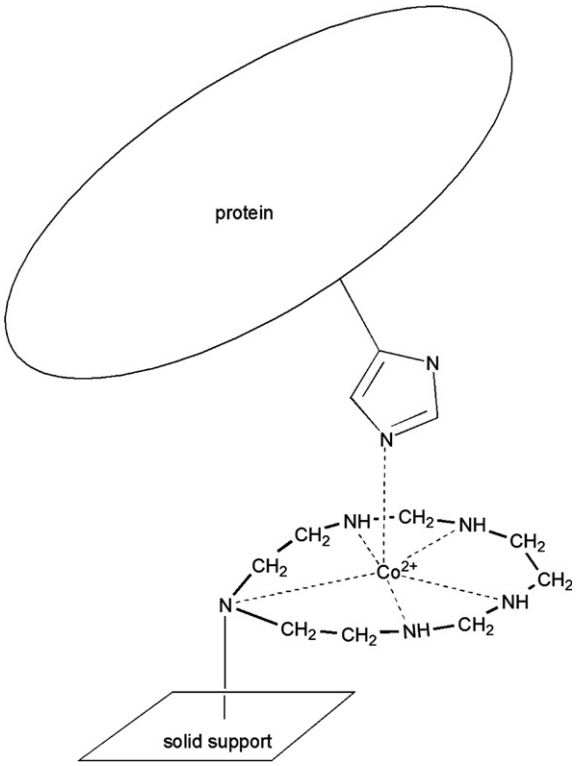

Fig. 1. Schematic illustration of a protein binding to a metal–chelator system on a surface.

and cyclotridecanes, however, make them good candidates as cobalt chelators with high affinity toward amino acids. These systems can also be prepared in a relatively easy, two-step reaction, with *N′*-(2-aminoethyl)-ethane-1,2-diamine as the starting agent (Fig. 2) [16].

In this work we present a density functional theory (DFT) study of twelve cyclododecanes and cyclotridecanes derivatives complexing cobalt and their ability to bind histidine. The obtained affinity values are compared to the results for the IDA–cobalt system commonly used in the protein purification [17,18]. The results of this work may lead to synthesis of better chelators for use as new immobilizing systems in IMAC, as well as in manufacturing of nanoscale biosensors and electronic devices.

2. Computational methods

Twelve different derivatives of cyclododecanes and cyclotridecanes: 1-pentaaza-cyclotridecane **1**, 1,3,6,8,11-pentaaza-cyclotridec-4-ene **2**, 1,3,6,8,11-pentaaza-cyclotridec-4-yne **3**, 1,3,6,8,11-pentaaza-cyclotrideca-1,7-diene **4**, 1,3,6,8,11-pentaaza-cyclotrideca-8,13-diene **5**, 1,3,6,8,11-pentaaza-cyclotrideca-9,12-diene **6**, 1,8-dimethyl-1,3,6,8,11-pentaaza-cyclotridecane **7**, 1,8-dichloro-1,3,6,8,11-pentaaza-cyclotridecane **8**, 1,4,7,10-tetraaza-cyclododecane **9**, 1,3,5,7,10-pentaaza-cyclododecane **10**, 1,3,5,7,10-pentaaza-cyclododeca-2,5-diene **11**, and [1,3,5,8]-tetrazecane **12** (Fig. 3), have been studied in this work. For each of the 12 derivatives four different molecular model systems have been considered: an empty chelator, a chelator loaded with cobalt, and a chelator loaded with cobalt and interacting with either a water molecule or an imidazole molecule (a model for histidine) (Fig. 4). To investigate the chelator–histidine interactions the following set of reactions have been considered:

$$\text{chelator–Co} + H_2O \rightarrow \text{chelator–Co–}H_2O, \quad (1)$$

$$\text{chelator–Co} + \text{imidazole} \rightarrow \text{chelator–Co–imidazole}, \quad \text{and} \quad (2)$$

$$\text{chelator–Co–}H_2O + \text{imidazole} \rightarrow \text{chelator–Co–imidazole} + H_2O. \quad (3)$$

Reaction (1) allows to evaluate the theoretical affinity of chelators loaded with cobalt toward a water molecule, whereas reaction (2) provides the theoretical affinity of the loaded chelator system toward imidazole. Reaction (3) allows to quantify the relative affinity of the chelator–Co–imidazole system with respect to the chelator–Co–water system, which is the key value for this study because it characterizes the strength of the chelator–amino acids interaction.

The geometries of the studied systems have been fully optimized at the DFT level of theory. The DFT calculations have been carried out with the three-parameter density functional B3LYP [19,20] using the standard 6-31+G* basis set. Harmonic frequency calculations have been performed for the equilibrium DFT geometries and the frequency results have been used to account for the zero-point vibrational-energy corrections. The calculations have been performed using the quantum chemistry package Gaussian 03 [21].

3. Results and discussion

Based on the previous theoretical works in this field one can point at three properties of the chelating systems that directly influence their binding abilities [12–14]. Clearly, the ability to strongly bind water or imidazole depends directly on the molecular structure of the complex. The derivatives of cyclododecanes and cyclotridecanes considered in this work are tetra- or pentadentate chelators, but they widely differ in the structural flexibility of their main molecular chains. This feature is important because it is

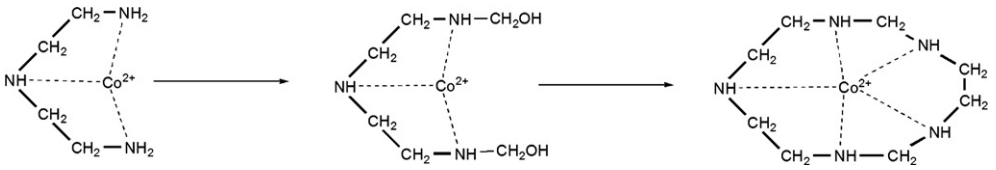

Fig. 2. Synthesis of cyclotridecane derivative loaded with Co.

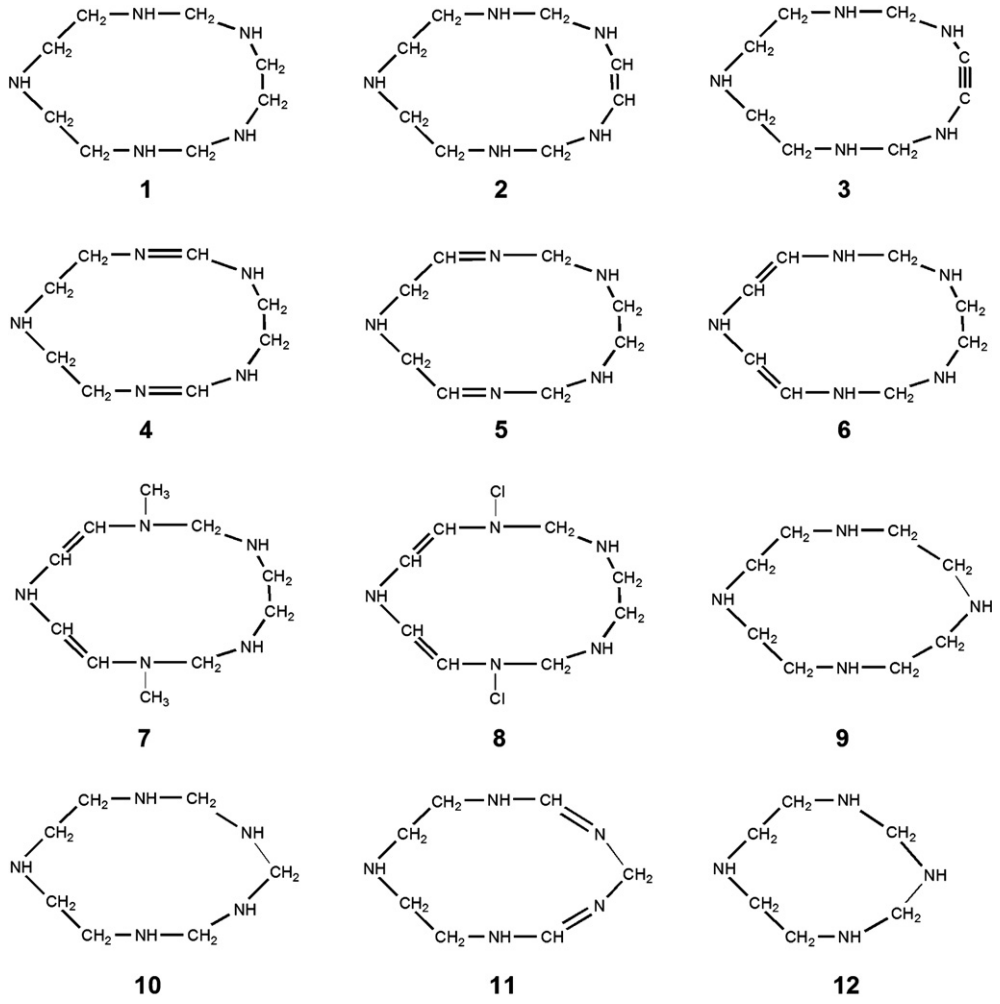

Fig. 3. Schematic representation of the twelve cyclododecanes and cyclotridecanes derivatives studied in this work.

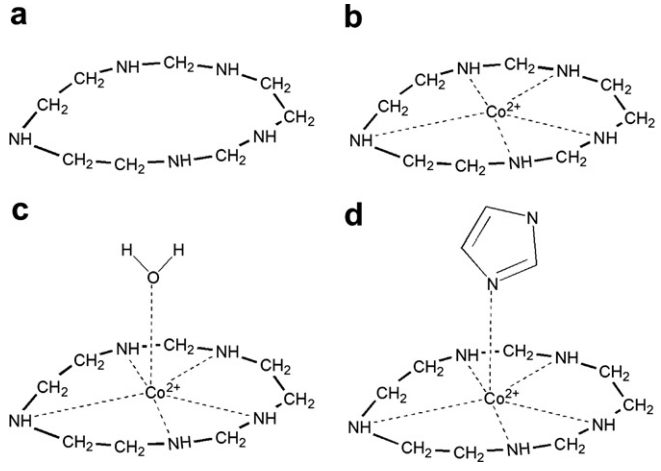

Fig. 4. Schematic representation of the systems studied in the theoretical calculations, a: an empty chelator **1**, b: system **1** chelating cobalt, c: system **1** chelating cobalt and interacting with water molecule, d: system **1** chelating cobalt and interacting with imidazole molecule.

responsible for the geometry of the complex which is formed upon the chelator binding either water or imidazole. Some systems are flexible enough to attain a geometry close to the most-energetically favorable one around the cobalt while others, which are more rigid, may have this ability significantly reduced.

The second important feature responsible for the selectivity of the interaction is the size of the bound molecule. If only the flexibility of the main chain of the chelator were determining the affinity energy, all those energies would be similar for water and imidazole. This is, however, not the case, since imidazole introduces additional steric, and possibly also chemical interactions, which may change the affinity value in either direction.

The third and the last feature determining the affinity value is the ability of the chelator and the bound molecule to donate electrons. There is a clear difference between the water and the imidazole molecules in this respect, since they include either an oxygen atom or a nitrogen atom as the electron donor. The difference in the interaction energy between the cobalt ion and the O-donor or the N-donor leads to a difference in the affinity value. The ability to donate/accept electrons can also be affected by functionalizing the chelator side of the complex by electron-withdrawing or electron-donating moieties.

The affinity of the chelator toward a certain molecule depends on the interplay of all three above-mentioned factors. The quantum chemical models used in this work allow to determine the role of each of them in the calculation of the affinity value. With that one can investigate systems that have not yet been synthesized.

In Table 1 the chelator–cobalt–water, chelator–cobalt–imidazole, and relative imidazole/water affinity values for systems studied in this work are presented. The values of ~−20–60 kcal/mol are typical for systems used in IMAC [14]. These values may also be directly compared to the values obtained for IDA–Co complexes, which are −46.5 kcal/mol (IDA–cobalt–water), −61.4 kcal/mol (IDA–cobalt–imidazole), and −14.9 kcal/mol (relative imidazole/water affinity), respectively. The results shown in Table 1 suggest that most of the new compounds considered in this work have similar molecular affinities toward imidazole as IDA. Interestingly, there are also some derivatives with higher affinities toward imidazole much above the IDA–cobalt–imidazole level.

It is interesting to note that in most cases a high affinity toward imidazole goes along with a high affinity toward water, so the relative imidazole/water affinity remains at a similar level. On the other hand, even small changes in the geometrical parameters of the chelator–cobalt–water and chelator–cobalt–imidazole systems may affect their relative affinities. This, for example, is the case for compounds **1** and **2**. The structures of these two cyclotridecanes derivatives are very similar with the only difference being a double bond connecting the carbon atoms 4 and 5 in compound **2** instead of a single bond in compound **1**. This small change in the molecular structure does not affect much the affinity of the two systems toward water, but affects the imidazole binding energy leading to a 25% rise of the relative water/imidazole affinity value.

The second interesting comparison can be made for systems **1**, **7**, and **8**. The first of these three systems is an unsubstituted 1,3,6,8,11-pentaaza-cyclotrideca-9,12-diene, while the other two are also the same dienes but with two methyl groups (compound **7**) or two chlorine atoms (compound **8**) introduced in positions 1 and 8. Those additional moieties act as electron-donating or electron-withdrawing groups leading to a change in the chelator interaction with cobalt and affecting the chelator affinity toward imidazole. The addition of the electron-donating methyl groups destabilizes the whole system lowering the affinity of the chelator toward both water and imidazole. By contrast, the addition to **1** of two chlorine moieties, which are electron-withdrawing groups, stabilizes the system, resulting in higher affinities of the chelator toward the two ligands. In both cases, however, the stabilization/destabilization is similar for both the water and imidazole complexes.

Another interesting system is derivative **12**, which does not form stable complexes with either water or imidazole. The reason for the instability of the tetrazece complex can be found in the geometry of the complex. The tight binding of the cobalt ion in this small complex leaves little space available for the interacting ligand, which results in steric hindrance and the overall instability of the system. A similar trend is observed for derivatives **5** and **6**. These compounds are larger than derivative **12**, but due to multiple double bonds they are relatively rigid and form similarly tight complexes with cobalt. The final result is the same as in the previous case, since the interaction with the ligand introduces a number of sterical hindrances leading to the instability of the whole system.

The goal of this work is to design and identify those derivatives, which have much higher molecular affinities toward imidazole than the commonly used IDA. Two compounds seem to be the good candidates for such potent chelators. The first one is 1,3,6,8,11-pentaaza-cyclotrideca-1,7-diene **4**. This system has a relatively low affinity toward the water molecule, but a high affinity toward imidazole resulting in a large value of the relative affinity. The second candidate is the 1,3,5,7,10-pentaaza-cyclododeca-2,5-diene **11**, which has high affinities toward both water and imidazole. Both of these systems have the relative imidazole/water affinities approximately two times higher than those for the IDA–cobalt system.

The two systems with the highest affinities predicted by the computational approach have common geometrical features. A detailed analysis of the geometries of these two chelators reveals an unusual geometry around the central ion. In most of the studied systems all four or five Co–N bonds are similar, with their lengths between 2.05 and 2.2 Å. This feature allows for strong cobalt bonding by the chelator. On the other hand all the studied systems are planar or mostly planar systems, forcing the non-octahedral geometry around the central ion. In the case of systems **4** and **11,** however, two of the Co–N bonds are much longer (between 3.2 and 3.3 Å), thus are much weaker (Fig. 5). This additional feature makes the Co^{2+} even more flexible and allows the whole system chelating the imidazole to acquire a more favorable geometry from the energetical point of view.

Table 1
Affinities for the chelator–Co–water and chelator–Co–water–imidazole systems, and relative imidazole–water affinities (see reactions (1)–(3)) predicted with the DFT method (in kcal/mol)

Chelator	H_2O affinity	Imidazole affinity	Relative imidazole/H_2O affinity
1	−20.2	−39.4	−19.2
2	−19.8	−43.8	−24.0
3	−25.3	−49.1	−23.8

4. Conclusions

In this work quantum mechanical calculations have been used to demonstrate that some of the new derivatives of cyclotridecanes and cyclododecanes considered in this work are good candidates for new potent chelating compounds. The calculations performed with the density functional theory method of 12 derivatives allowed us to identify two compounds, 1,3,6,8,11-pentaaza-cyclotrideca-1,7-diene and 1,3,5,7,10-pentaaza-cyclododeca-2,5-diene, with high molecular affinity toward imidazole, which in the calculations is modeling a histidine molecule. Upon synthesis these two derivatives may become interesting alternatives to IDA for use in IMAC and other experiments relying on the immobilization of biomacromolecules.

This work is also a step toward forming LigMIP, a theoretical database of ligand–metal ion–protein interactions. Such a database with the quantitatively described interactions between ligands, metal ions, and amino acids could serve as a useful tool in selecting the best possible chelating compounds for different applications, as well as in facilitating designing of novel chelating systems.

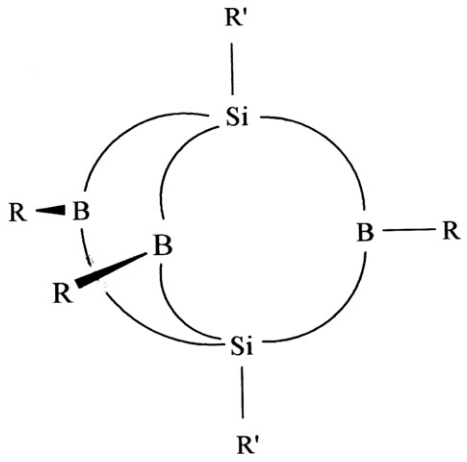

Diagram 1.

"spherical" cage borosiloxanes with the syntheses of 11 analogues of [R′Si(OBRO)$_3$SiR′] with a wide variety of R groups, Diagram 1.

The details of the structures of five of these compounds have been determined with X-ray crystallography. Additionally, we have studied the reactions between [Bu^{t}Si{O(PhB)O}$_3$SiBu^t] (**1**) and (a) pyridine or (b) *N*,*N*,*N*′,*N*′-tetramethyl-ethylenediamine and established the solid-state structure of the adduct [Bu^{t}Si{O(PhB)O}SiBu^t] · NC$_5$H$_5$ (**12**).

2. Results and discussion

2.1. Syntheses and structural studies of [R′Si(ORBO)$_3$SiR′] borosiloxanes 1 to 11

All the borosiloxane cages with the formulae [R′Si(ORBO)$_3$SiR′] were synthesised in a Dean-Stark apparatus by water elimination reactions between R′Si(OH)$_3$ (R′ = Bu^t or *cyclo*-C$_6$H$_{11}$) and boronic acids RB(OH)$_2$ in a 2:3 molar ratio in toluene solution heated at the reflux temperature, Eq. (1). In general the *tert*-butyl compounds were isolated in 30–40% higher yields than the corresponding *cyclo*hexyl derivatives with the same R groups.

$$2R'Si(OH)_3 + 3RB(OH)_2 \rightarrow [R'Si(ORBO)_3SiR'] \quad (1)$$

where R′ = Bu^t and R = Ph (**1**), 4-PhC$_6$H$_4$ (**2**), 4-Bu^{t}C$_6$H$_4$ (**3**), 3-NO$_2$C$_6$H$_4$ (**4**), 4-CH(O)C$_6$H$_4$ (**5**), CpFeC$_5$H$_4$ (**6**), 4-C(O)CH$_3$C$_6$H$_4$ (**7**), 4-ClC$_6$H$_4$ (**8**), 2,4-F$_2$C$_6$H$_3$ (**9**), and R′ = *cyclo*-C$_6$H$_{11}$ and R = C$_6$H$_5$ (**10**), and 4-BrC$_6$H$_4$ (**11**).

An alternative route via the reactions between *tert*-butyltrichlorosilane or *cyclo*hexyltrichlorosilane and boronic acids in the presence of an amine, either Et$_3$N or aniline, afforded the products **1** to **9** in 5–10% lower yields and compounds **10** and **11** in ca. 30% lower yields. Attempts to use phenyl- or tolyltrichlorosilane reagents afforded boroxines as the only characterisable products.

Initial characterisation of **1**–**11** by chemical analysis was followed by spectroscopic (FT-IR, NMR) and, in some cases, mass spectrometric analysis. For the compounds with R′ = Bu^t and R = 4-PhC$_6$H$_4$ (**2**), 4-Bu^{t}C$_6$H$_4$ (**3**), 3-NO$_2$C$_6$H$_4$ (**4**), CpFeC$_5$H$_4$ (**6**), and 2,4-F$_2$C$_6$H$_3$ (**9**), single-crystal X-ray diffraction studies were carried out. A summary of crystal data for these compounds is given in Section 4.

2.2. Crystal and molecular structures of [Bu^{t}Si{O(4-PhC$_6$H$_4$B)O}$_3$SiBu^t] (2), [Bu^{t}Si{O(4-Bu^{t}C$_6$H$_4$B)O}$_3$SiBu^t] (3), [Bu^{t}Si{O(3-NO$_2$C$_6$H$_4$B)O}$_3$SiBu^t] (4), [Bu^{t}Si{O(CpFeC$_5$H$_4$B)O}$_3$SiBu^t] (6), and [Bu^{t}Si{O(2,4-F$_2$C$_6$H$_3$B)O}$_3$SiBu^t] (9)

Comparison of the structures of compounds [Bu^{t}Si(OBRO)$_3$SiBu^t] where R = 4-PhC$_6$H$_4$ (**2**), 4-Bu^{t}C$_6$H$_4$ (**3**), 3-NO$_2$C$_6$H$_4$ (**4**), CpFeC$_5$H$_4$ (**6**) and 2,4-F$_2$C$_6$H$_3$ (**9**) reveals that the structural details of the Si$_2$O$_6$B$_3$ cages are remarkably similar, Table 1.

All five compounds contain two tetrahedral Bu^{t}SiO$_3$-units and three trigonal planar RBO$_2$-units held together by an 11-atom Si(OBO)$_3$Si framework. Figs. 1–3 show ORTEP views of molecules with R = 4-PhC$_6$H$_4$ (**2**), 4-Bu^{t}C$_6$H$_4$ (**3**) and CpFeC$_5$H$_4$ (**6**) from a general perspective.

The structures of compounds **2** and **6** are shown viewed along the axes passing through both silicon atoms in Figs. 4 and 5, respectively. The *tert*-butyl groups attached to the silicon atoms in compounds **2** and **6** are in "eclipsed" arrangements. The same structural motif is found in **3**, **4**, **6** and **9**.

The C$_6$-rings attached to the boron atoms in **2** and **3** are arranged in a "paddlewheel" formation, see Fig. 4, and are almost co-planar with the adjacent Si–O–B–O–Si bonded sequence. The same structural motif was observed in **3**, **4**, and **9**, and in the compound [Bu^{t}Si{O(4-BrC$_6$H$_4$B)O}$_3$SiBu^t] [4]. A similar situation is observed in the ferrocenyl compound [Bu^{t}Si{O(CpFeC$_5$H$_4$B)O}$_3$SiBu^t] (**6**), where the C$_5$H$_4$ ring is almost co-planar with the attached borosiloxane group, Fig. 5. The reason for the preference for co-planarity may reside in a partial overlap of the π system of the aromatic C$_6$-ring and some delocalised bonding in the Si–O–B–O–Si sequence. However, it is also possible that the co-planarity is due to "crystal packing" forces. It is interesting to note that in the case of **6** the ferrocenyl groups are not all arranged to give a pseudo-D_{3h} molecular symmetry. The reasons are unclear but may be due either to weak intramolecular H···π–C$_5$H$_5$ ring interactions or more general "crystal packing" forces.

The B–O lengths in **2**, **3**, **4**, **6** and **9** range from 1.348(5) to 1.380(4) and are at the upper end of the reported range for trigonal boron species with Si–O–B bonds i.e. 1.313(2) in (OBF)(OSiBu$^t_2$)$_2$(OSiMe$_2$) (**13**) [9] to 1.374(7) Å in [B(OSiPh$_2$SiPh$_2$O)$_3$B] (**14**) [5]. They are similar to B–O distances in the previously reported spherical cage [Bu^{t}Si{O-(4-BrC$_6$H$_4$B)O}$_3$SiBu^t] (**15**) [4], which were

Table 1

1.364(11)–1.372(10) Å and in the cube-based structure [(Bu^{t}Si)$_4$(CH$_2$=CHC$_6$H$_4$B)$_4$O$_{10}$] [6] (1.361(4)–1.369(4) Å). A mean value of 1.367 Å has been reported for B–O distances where the boron is tricoordinated [10] and the mean values of the B–O distances reported here are all the same within one s.u.

The Si–O distances in **2**, **3**, **4**, **6** and **9** vary between 1.603(3) and 1.638(3) Å, but the mean values of the six Si–O distances are remarkably similar at about 1.620 Å, Table 1. The range of previously reported Si–O distances for borosiloxanes containing trigonal boron was 1.603(2) [7] to 1.655(5) [4,11]. The mean values of Si–O distances

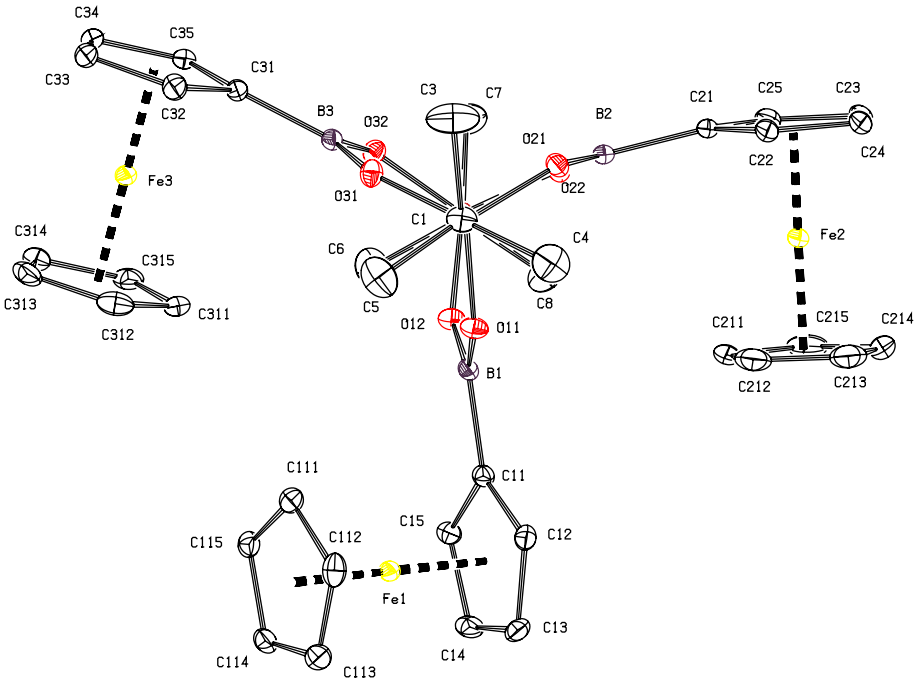

Fig. 5. ORTEP view of [Bu^{t}Si{O(CpFeC$_5$H$_4$B)O}$_3$SiBu^t] (**6**) along the Si···Si axis.

in [B(OSiPh$_2$SiPh$_2$O)$_3$B] (**14**) [5], [Bu^{t}Si{O(4-BrC$_6$H$_4$B)O}$_3$SiBu^t] (**15**) [4] and [(Bu^{t}Si)$_4$(CH$_2$=CHC$_6$H$_4$B)$_4$O$_{10}$] [6], were 1.631(2), 1.621(5) and 1.616(4) Å, respectively, and a mean value of 1.631(2) Å has been reported for Si–O distances where the silicon is four coordinated [10].

The mean B–C distances in **2**, **3**, **4**, **6** and **9** range from 1.541(5) to 1.559(6) Å. The B–C$_{Ph}$ distances in PhB(OSiPh$_3$)$_2$, **16** [12] and (PhBO)$_2$(OSiPh$_2$)$_2$ (**17**) [13], were 1.558(8) and 1.555(6) Å, respectively, and the B–C distances reported in [Bu^{t}Si{O(4-BrC$_6$H$_4$B)O}$_3$SiBu^t] (**15**) [4] ranged from 1.541(11) to 1.585(11) Å, with a mean value of 1.566 Å.

The average value of the Si–C distances in **2**, **3**, **4**, **6** and **9** were 1.833(3), 1.841(5), 1.829(4), 1.853(4) and 1.846(9) Å, respectively. A mean value of 1.863 Å has been reported for Si–C bonds, where C is sp^3-hybridised and bonded to carbon or hydrogen atoms only and the silicon atom is four coordinated [10].

B–O–Si angles at trigonal boron atoms are known to be very flexible [12] in both acyclic and cyclic compounds. Examples include the two chemically equivalent B–O–Si angles in PhB(OSiPh$_3$)$_2$ (**18**), {139.8(4)° and 157.9(3)°} [12], and in cyclic systems, 128.89(14)° in (PhBO)(Ph$_2$SiO)$_2$ (**19**) [14] and 160.9(3)° in (PhBO)$_2$(Ph$_2$SiO)$_2$ (**17**) [13]. Hence, it is noteworthy that in the compounds **2**, **3**, **4** and **6** the variation is relatively small at ca. ±4° from a mean angle of ca. 138°, Table 1. The six B–O–Si angles in **2** vary from 135.3(2)° to 142.9(2)° with a mean value of 138.6(2)° and those in **3** show an almost identical range of 135.0(3)–143.0(3)° and a mean value of 138.8(3)°. In **4** these angles vary from 134.0(3)° to 143.0(3)° with a mean value of 138.5(3)°. The B–O–Si angles in **6** range from 133.9(3)° to 142.4(3)° with a mean value of 137.8(9)°. Compound **9** has a symmetry determined single B–O–Si angle of 139.5(4)°. All B–O–Si angles for **2**, **3**, **4**, **6** and **9** are notably similar to those for [B(OSiPh$_2$SiPh$_2$O)$_3$B] (**14**) [5], and [Bu^{t}Si{O(4-BrC$_6$H$_4$B)O}$_3$SiBu^t] (**15**) [4] where the B–O–Si angles varied over the range 137.89(18)–140.03(18)° with a mean value of 138.6(18)° for **14** and 137.5(6)–140.7(6)° with a mean value of 138.6(6)° for **15**, respectively. In the more open structure of the cube-based [(Bu^{t}Si)$_4$(CH$_2$=CHC$_6$H$_4$B)$_4$O$_{10}$] [6], the B–O–Si angles vary more from 137.5(2)° to 154.4(2)°.

Like the B–O–Si angles, the O–B–O angles in **2**, **3**, **4**, **6** and **9** are notably similar and close to 121°, Table 1. The three O–B–O angles in [Bu^{t}Si{O(4-BrC$_6$H$_4$B)O}$_3$SiBu^t] (**15**) [4] varied from 119.9(8)° to 124.0(8)° the mean value being 122.2(8)° and the four O–B–O angles in [(Bu^{t}Si)$_4$(CH$_2$=CHC$_6$H$_4$B)$_4$O$_{10}$] [6], varied from 120.7(3)° to 120.9(3)° with a mean value of 120.8(3)°.

The O–Si–O and O–B–C angles in **2**, **3**, **4**, **6** and **9** are even more remarkably similar with ranges and means which are almost identical, Table 1. The range over all the compounds for O–Si–O angles is from 107.29(15)° to 110.90(15)° both of which were observed in [Bu^{t}Si{O(CpFeC$_5$H$_4$B)O}$_3$SiBu^t] (**6**). The mean value of O–Si–O angles in **2**, **3**, **4**, **6** and **9** was 109.12° which was very close to the mean value observed in [(Bu^{t}Si)$_4$(CH$_2$=CHC$_6$H$_4$B)$_4$O$_{10}$] [6]. For [B(OSiPh$_2$SiPh$_2$O)$_3$B] (**14**) [5], the three O–Si–O angles ranged from 108.78(12)° to 109.34(10)° with a mean

value of 109.12(12)°. In [Bu^{t}Si{O(4-BrC$_6$H$_4$B)O}$_3$SiBu^t] (**15**) [4] the O–Si–O angles ranged from 108.5(3)° to 109.7(3)° with a mean value of 109.2(3)°. The O–B–C angles range from 118.0(3)° to 120.4(3)° which are both found in **2**. The mean values in compounds **2**, **3**, **6** and **9** are all close to 119.5° and that in **4** is 119.1°. The O–B–C angles in compound **15** range from 116.6(9)° to 120.7(8)° with a mean of 118.9(8)°.

As with the O–Si–O angles, the O–Si–C angles are close to the tetrahedral value in all cases.

2.3. Reactions between the borosiloxane cage [Bu^{t}Si(OPhBO)$_3$SiBu^t] and pyridine or N,N,N′,N′-tetramethylethylenediamine

2.3.1. Synthesis and structural study of [Bu^{t}Si(OPhBO)$_3$SiBu^t] · NC$_5$H$_5$ (12)

The reaction between [Bu^{t}Si{O(PhB)O}$_3$SiBu^t] (**1**), and three equivalents of pyridine in ether at r.t. for 16 h followed by crystallisation of the solid product from dichloromethane–heptane (1:3) afforded [Bu^{t}Si{O(PhB)O}$_3$SiBu^t] · NC$_5$H$_5$ (**12**) in 73% yield. This compound was soluble in toluene, dichloromethane, ether and acetone at room temperature. Chemical analysis for C, H, B and N supported the formulation of **12** as a 1:1 adduct. The ^{11}B NMR spectrum of **12** showed two signals in a 2:1 ratio with one corresponding to three coordinate boron at 25.4 ppm and one associated with four coordinate boron at 0.6 ppm, respectively. Crystals of [Bu^{t}Si{O(PhB)O}$_3$SiBu^t] · NC$_5$H$_5$ (**12**) suitable for X-ray diffraction studies were grown by the slow evaporation of a dichloromethane–heptane solution of **12**. Fig. 6 is an ORTEP plot showing a general view of [Bu^{t}Si{O(PhB)O}$_3$SiBu^t] · NC$_5$H$_5$ (**12**), and the atom numbering scheme is shown in Fig. 6. Significant bond distance and bond angle data for **12** are given in Table 2. The basic Si$_2$O$_6$B$_3$ cage structure of [Bu^{t}Si{O(PhB)O}$_3$SiBu^t] · NC$_5$H$_5$ (**12**) is very similar to the Si$_2$O$_6$B$_3$ cage in the borosiloxanes **2**, **3**, **6** and **9** reported above. The structure of **12** also involves near-eclipsed arrangements of the *tert*-butyl groups at Si(1) with those at Si(21) and a "paddlewheel" arrangement of the three phenyl groups and the pyridine group is adopted as can be seen if the structure is viewed above the Si(1)···Si(21) axis.

The four B–O distances in [Bu^{t}Si{O(PhB)O}$_3$SiBu^t] · NC$_5$H$_5$ (**12**) for the tricoordinate boron atoms span a relatively wide range from 1.354(17) to 1.394(18) Å. The two B–O distances for the tetracoordinate bonded boron atom in **12** are 1.457(18) and 1.469(18) Å, Table 2. These values are similar to data from the tetrahedrally coordinated boron compounds Ph(OSiR$_2$R′)B{O(CH$_2$)$_3$N} (**20**), where the boron atom is directly bonded to two oxygen atoms, a Ph group and the nitrogen atom and R or R′ = Ph or Me. These compounds have B–O$_{Si}$ distances of 1.439(4) [15] and 1.443(6) [16] in the Ph$_2$Me and PhMe$_2$ derivatives, respectively. The increased B–O distance at the tetrahedral boron site may be associated with the removal of any B–O π-bonding component on going from trigonal to tetrahedral coordination at boron.

The Si–O distances in **2**, **3**, **4**, **6** and **9** varied between 1.603(3) and 1.638(3) Å, with a mean value of 1.621 Å and these values are comparable with the four Si–O distances in [Bu^{t}Si{O(PhB)O}$_3$SiBu^t] · NC$_5$H$_5$ (**12**) which range from 1.625(9) to 1.631(9) Å where the boron atom is tricoordinate. The average value is 1.628 Å. The two Si–O distances where the boron atom is tetracoordinate are notably shorter with values of 1.585(7) and 1.594(9) Å suggesting that electron density has increased in the Si–O bond corresponding to the decrease in B–O electron density.

The B–N distance in [Bu^{t}Si{O(PhB)O}$_3$SiBu^t] · NC$_5$H$_5$ (**12**) was 1.655(17) Å. For simple borosiloxane Ph(OSiR$_2$R′)B{O(CH$_2$)$_3$N} species, **20**, the B–N distances are 1.639(4) [15] and 1.639(6) Å [16] in the Ph$_2$Me and PhMe$_2$ derivatives, respectively. A value of 1.556 Å has been reported for B–N distances where the boron atom is tetracoordinate [10].

The two B–C distances in **12** with the boron atom tricoordinate were 1.552(19) Å and 1.594(19) Å. Similar B–C distances in **2**, **3**, **4**, **6** and **9** with mean values of 1.553(4), 1.546(6), 1.559(6), 1.541(5) and 1.544(10) Å were noted in Table 1. A mean value of 1.556 Å has been reported for B–C$_{ar}$ distances, where the boron atom is tricoordinate and the carbon atom is part of an aromatic system [10]. The B–C distance in **12** where the boron atom is tetracoordinate was 1.58(2) Å which is within 3x s.u. of the two other B–C distances. The mean Si–C distance in **12** was typical of such distances at 1.832(15) Å.

In [Bu^{t}Si{O(PhB)O}$_3$SiBu^t] · NC$_5$H$_5$ (**12**) the four B–O–Si angles in which the boron is tricoordinate range from 134.4(10)° to 140.7(9)° which is a similar range to the corresponding angles in **2**, **3**, **6** and **9**, Table 1. The two B–O–Si angles in **12** where the boron is tetracoordinate are 134.2(8)° and 138.0(9)°.

The O–B–O angles in [Bu^{t}Si{O(PhB)O}$_3$SiBu^t] · NC$_5$H$_5$ (**12**) vary from 111.6(11)° at the tetracoordinate boron atom to 121.1(13)° and 122.3(13)° at the tricoordinate boron atoms. These angles are close to the 109° and 120° expected for tetrahedral and trigonal planar geometries, respectively. Likewise the O–Si–O angles in **12** range from 108.2(5)° to 111.0(5)° with a mean value of 109.6(5)° which is normal for tetrahedral silicon and the four O–B–C angles in [Bu^{t}Si{O(PhB)O}$_3$SiBu^t] · NC$_5$H$_5$ (**12**) where the boron is trigonal planar range from 117.9(12)° to 120.1(13)°. The two O–B–C values in **12** where the boron atom is tetrahedral had values greater than 109° at 112.6(11)° and 115.5(12)°, respectively.

The six O–Si–C angles in **12** ranged from 106.4(6)° to 112.6(5)° with a mean value of 109.4(6)° but the angles where the oxygen is bonded to a tetracoordinate boron atom, mean value 112.4(6)°, appeared to be larger than the O–Si–C angles where the oxygen is bonded to a trigonal boron, mean value 107.9(6)°.

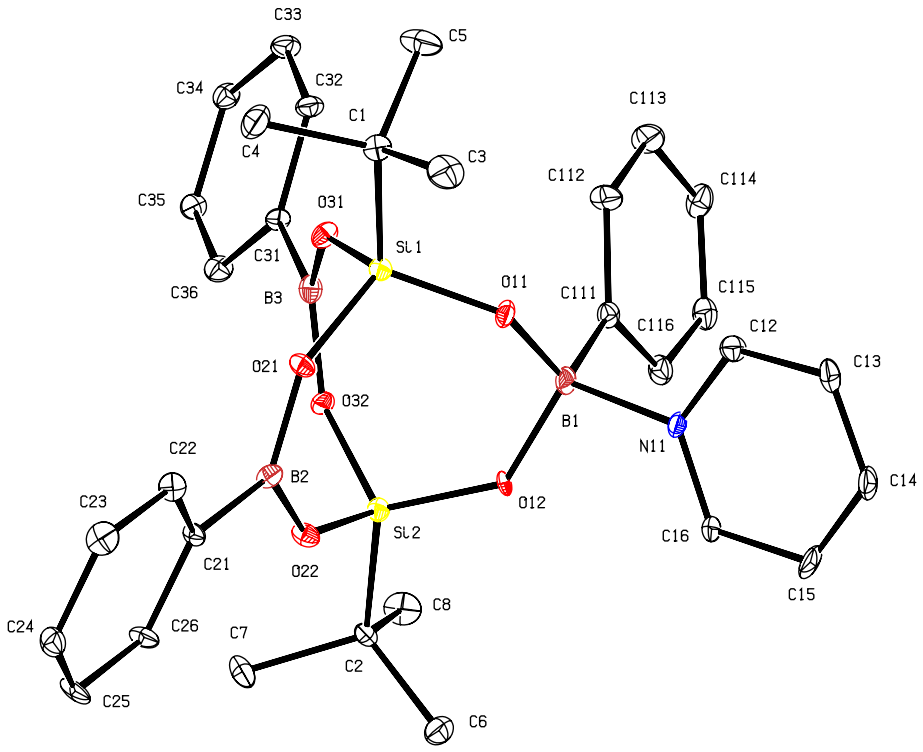

Fig. 6. An ORTEP view of $[Bu^tSi(OPhBO)_3SiBu^t]\cdot NC_5H_5$ (**12**), with atom numbering. Selected interatomic distances (Å) and angles (°): Si(1)–O(11) 1.594(9), Si(1)–O(21) 1.630(9), Si(1)–O(31) 1.631(9), Si(1)–C(1) 1.832(15), Si(2)–O(12) 1.585(7), Si(2)–O(22) 1.626(9), Si(2)–O(32) 1.625(9), Si(2)–C(2) 1.831(14), B(1)–N(11) 1.655(17), B(1)–O(11) 1.457(18), B(1)–O(12) 1.469(18), B(1)–C(111) 1.58(2), B(2)–O(21) 1.394(18), B(2)–O(22) 1.370(17), B(2)–C(21) 1.552(19), B(3)–O(31) 1.354(17), B(3)–O(32) 1.375(19), B(3)–C(31) 1.594(19); O(11)–Si(1)–O(21) 111.0(5), O(11)–Si(1)–O(31) 109.6(5), O(21)–Si(1)–O(31) 108.2(5), O(11)–Si(1)–C(1) 111.8(6), O(21)–Si(1)–C(1) 106.4(6), O(31)–Si(1)–C(1) 109.7(6), O(12)–Si(2)–O(22) 109.3(5), O(12)–Si(2)–O(32) 110.6(5), O(22)–Si(2)–O(32) 108.6(5), O(12)–Si(2)–C(2) 112.6(5), O(22)–Si(2)–C(2) 106.4(6), O(32)–Si(2)–C(2) 109.2(6), B(1)–O(11)–Si(1) 138.0(9), B(2)–O(21)–Si(1) 139.7(9), B(3)–O(31)–Si(1) 134.4(10), B(1)–O(12)–Si(2) 134.2(8), B(2)–O(21)–Si(2) 137.3(9), B(3)–O(32)–Si(2) 140.7(9), O(12)–B(1)–O(11) 111.6(11), O(11)–B(1)–C(111) 115.5(12), O(12)–B(1)–C(111) 112.6(11), O(11)–B(1)–N(11) 103.2(10), O(12)–B(1)–N(11) 104.9(11), C(111)–B(1)–N(11) 107.9(10), O(21)–B(2)–C(21) 120.1(13), O(21)–B(2)–C(22) 118.8(12), O(21)–B(2)–O(22) 121.1(13), O(31)–B(3)–O(32) 122.3(13), O(32)–B(3)–C(31) 117.9(12), O(31)–B(3)–C(31) 119.8(13).

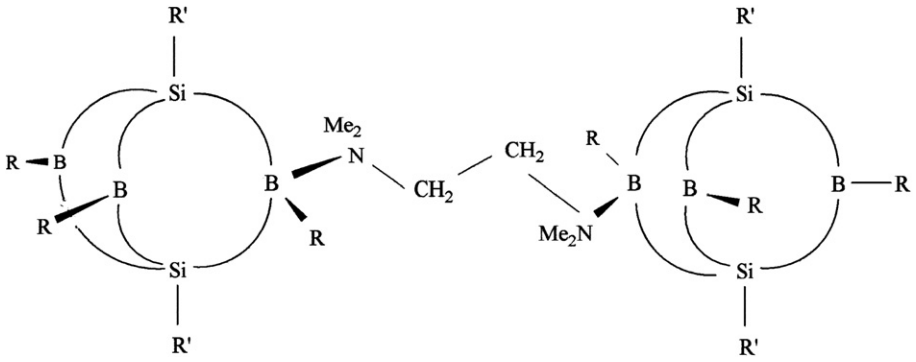

Diagram 2.

2.4. Synthesis of $[Bu^tSi\{O(PhB)O\}_3SiBu^t]_2 \cdot Me_2NCH_2CH_2NMe_2$ (13)

The reaction between $[Bu^tSi\{O(PhB)O\}_3SiBu^t]$ (**1**), and one equivalent of *N*,*N*,*N*′,*N*′-tetramethylethylenediamine in ether at r.t. for 8 h afforded $[Bu^tSi\{O(PhB)O\}_3SiBu^t]_2 \cdot Me_2NCH_2CH_2NMe_2$ (**13**) in low yield (27%) after crystallisation of the crude product from CH_2Cl_2–heptane (1:2) solution. As with compounds **1**–**12**, this compound was soluble in typical organic solvents such as toluene, dichloromethane, ether and acetone at room temperature. Chemical analysis for C, H, B and N suggested the formulation of **13** as a 2:1 adduct and FT-IR and multinuclear NMR spectroscopy supported this formulation. The ^{11}B NMR spectrum showed signals at 31.8 and 2.8 ppm in a ratio of 2:1 which correspond to three and four coordinate boron environments, respectively. On the basis of these data we suggest that the overall structure of **13** is as shown in Diagram 2.

Unfortunately, crystals suitable for an X-ray diffraction study could not be obtained even after many attempts from many different solvents.

3. Conclusions

Eleven borosiloxane $[R'Si(ORBO)_3SiR']$ cage compounds ($R' = Bu^t$ and R = Ph (**1**), 4-PhC_6H_4 (**2**), 4-$Bu^tC_6H_4$ (**3**), 3-$NO_2C_6H_4$ (**4**), 4-$CH(O)C_6H_4$ (**5**), $CpFeC_5H_4$ (**6**), 4-$C(O)CH_3C_6H_4$ (**7**), 4-ClC_6H_4 (**8**) and R = 2,4-$F_2C_6H_3$ (**9**), and R′ = *cyclo*-C_6H_{11} and R = Ph (**10**) and 4-BrC_6H_4 (**11**)) have been synthesized and characterized by spectroscopic (IR, NMR), mass spectrometric and for compounds where $R' = Bu^t$ and R = 4-PhC_6H_4 (**2**), 4-$Bu^tC_6H_4$ (**3**), 3-$NO_2C_6H_4$ (**4**), $CpFeC_5H_4$ (**6**) and 2,4-$F_2C_6H_3$ (**9**) X-ray diffraction studies. These compounds contain trigonal planar RBO_2 and tetrahedral $R'SiO_3$ units located around 11-atom "spherical" $B_3Si_2O_6$ cores. The reaction between $[Bu^tSi\{O(PhB)O\}_3SiBu^t]$, **1**, and excess pyridine yields a 1:1 adduct while the reaction between **1** and *N*,*N*,*N*′,*N*′-tetramethylethylenediamine in equimolar amounts affords a 2:1 borosiloxane:amine adduct.

It is clear from the structural analyses of 2, 3, 4, 6 and 9 that the $B_3Si_2O_6$ core structures are very similar and those in 2 and 3 being almost identical. All the structures involve near eclipsed arrangements of the *tert*-butyl groups at Si(1) and Si(2) when viewed along the Si···Si axis. The B–O–Si angles in the $B_3Si_2O_6$ cores of 2, 3, 4, 6 and 9 are found in a relatively narrow range from 134.0° to 143.0°. The structure of the pyridine adduct, 12, was determined with X-ray techniques. It had two trigonal planar RBO_2 units and one tetrahedral RBO_2N unit and a number of features in common with the unadducted compounds including a narrow range of B–O–Si angles (133.2–140.9°).

4. Experimental

All reactions were carried out under an inert atmosphere of dry nitrogen. Solvents were dried and distilled prior to use. Both *tert*-butylsilanetriol and *cyclo*-hexylsilanetriol were prepared according to the literature synthesis of $Bu^tSi(OH)_3$ [17]. All boronic acids used were obtained from either Aldrich or Lancaster Chemical Co. and used as supplied. Infrared spectra were recorded as KBr disks on a Perkin–Elmer Paragon 1000 FT-IR Spectrometer. ^1H and ^{13}C NMR spectra were recorded in $CDCl_3$ solvent on a JEOL FT NMR Spectrometer, GSX-270 Series or, for ^{11}B and ^{29}Si NMR spectra, on a Bruker AM 400. Chemical shifts δ are expressed in ppm relative to $\Xi = 100$ MHz for δ (^1H) (quoted ±0.05 ppm) (standard $SiMe_4$) and $\Xi = 32.083\,971$ MHz for δ (^{11}B) (quoted ±0.5 ppm) (nominally F_3BOEt_2 in $CDCl_3$). Mass spectra (EI, 70 eV) were recorded on a Kratos Profile GC–MS Spectrometer. Elemental analyses were carried out on a Perkin–Elmer 240C elemental analyser at the Microanalytical Laboratory, University College, Cork.

4.1. Syntheses of borosiloxane $[R^1Si(ORBO)_3SiR^1]$ cage compounds ($R^1 = Bu^t$ and R = Ph (1); 4-PhC_6H_4 (2); 4-$Bu^tC_6H_4$ (3); 3-$NO_2C_6H_4$ (4); 4-$CH(O)C_6H_4$ (5); $CpFeC_5H_4$ (6); 4-$C(O)CH_3C_6H_4$ (7); 4-ClC_6H_4 (8); 2,4-$F_2C_6H_3$ (9); and R^1 = *cyclo*-C_6H_{11} and R = Ph (10); 4-BrC_6H_4 (11))

4.1.1. Synthesis of $[Bu^tSi\{O(PhB)O\}_3SiBu^t]$ (1)

A mixture of *tert*-butylsilanetriol (0.507 g, 3.72 mmol) and phenylboronic acid (0.680 g, 5.58 mmol) in toluene

(50 ml) was heated at reflux temperature in a Dean-Stark apparatus for 10 h. After cooling, the removal of toluene on a rotary evaporator (40 °C) yielded a colourless solid. This was crystallised from hot benzene (50°C) affording [$Bu^tSi\{O(PhB)O\}_3SiBu^t$] (153, 0.943 g, 95.7%), m.p. 220–222°C. *Anal*. Calc. for $C_{26}H_{33}B_3O_6Si_2$: C, 58.9; H, 6.3; B, 6.1. Found: C, 59.05; H, 6.2; B, 6.0%. FT-IR (KBr) ν_{max}/cm^{-1}: 1305(vs), 1133(vs), 677(s). ^1H NMR ($CDCl_3$, 294 K): δ: 7.91–7.22 [m, 5H, C_6H_5]; 1.35 [s, 6H, $C(CH_3)_3$]. ^{13}C NMR ($CDCl_3$, 294 K) δ: 135.5, 133.4, 132.2, 127.9 [all C_6H_5]; 25.5 [$C(CH_3)_3$]; 16.6 [$C(CH_3)_3$]. MS, *m*/*z*: 530 $[M]^+$, 473 $[M-Bu]^+$, 453 $[M-Ph]^+$.

4.1.2. Synthesis of [$Bu^tSi\{O(4\text{-}C_6H_5C_6H_4)BO\}_3SiBu^t$ (2)

The procedure was the same as that described for **1**. The quantities used were: *tert*-butylsilanetriol (0.1536g, 1.13 mmol); 4-biphenylboronic acid (0.3254g, 1.64 mmol); toluene 50ml; reaction time 18 h. Crystallisation from CH_2Cl_2–heptane (1:3) afforded [$Bu^tSi\{O(4\text{-}C_6H_5C_6H_4)BO\}_3SiBu^t$], **2** (0.35 g, 81.1%), mp 282–284 °C. *Anal*. Calc. for $C_{44}H_{45}O_6B_3Si_2$: C, 69.7; H, 6.3. Found: C, 69.6; H, 6.3%. FT-IR (KBr) ν_{max}/cm^{-1}: 1299(vs), 1132(vs), 660(s). ^1H NMR ($CDCl_3$, 294 K): δ 8.03–7.21 [m, 3H, $C_6H_4C_6H_5$], 1.33 [s, 2H, $C(CH_3)_3$], ^{11}B NMR ($CDCl_3$, 294 K) δ 28.3, ^{13}C NMR ($CDCl_3$,294 K) δ 144.4, 141.0, 135.9, 131.0, 127.9, 126.8, 126.5 [all $C_6H_4C_6H_5$], 26.6 [$C(CH_3)_3$], 16.3 [$C(CH_3)_3$], ^{29}Si NMR ($CDCl_3$, 294 K) δ −57.5. Crystal data for **2**, see Table 1.

4.1.3. Synthesis of [$Bu^tSi\{O(4\text{-}Bu^tC_6H_4)BO\}_3SiBu^t$] (3)

The procedure was the same as that described for **1**. The quantities used were: *tert*-butylsilanetriol (0.1311 g, 0.96 mmol); *tert*-butylphenylboronic acid (0.2548 g, 1.43 mmol); toluene 50 ml; reaction time 15 h. Crystallisation from CH_2Cl_2–heptane (1:2) afforded [$Bu^tSi\{O\text{-}(4Bu^tC_6H_4)BO\}_3SiBu^t$] (**3**) (0.24 g, 74.9%). mp 253–255 °C. Found: C, 65.3; H, 8.2. *Anal*. Calc. for $C_{38}H_{57}O_6B_3Si_2$: C, 65.3; H, 8.2. Found: C, 65.3; H, 8.2. FT-IR (KBr) ν_{max}/cm^{-1}: 1302(vs), 1137(s), 660(m). MS, *m*/*z*: 698 $[M]^+$, 641 $[M-Bu]^+$, 57 $[Bu]^+$. Crystal data for **3**: see Table 1.

4.1.4. Synthesis of [$Bu^tSi\{O(3\text{-}NO_2C_6H_4)BO\}_3SiBu^t$] (4)

The procedure was the same as that described for **1**. The quantities used were: *tert*-butylsilanetriol (0.430 g, 3.16 mmol), 3-nitrophenylboronic acid (0.789 g, 4.73 mmol), toluene, 50ml; reaction time 10 h. The product, [$Bu^tSi\{OB(3\text{-}C_6H_4NO_2)O\}_3SiBu^t]\cdot(0.5C_7H_8)$, crystallised from a toluene solution at room temperature. Yield 0.913 g (87.1%) of **4**, m.p. 176–178°C. Found: C, 49.9; H, 4.9; N, 5.8; B, 4.3%. *Anal*. Calc. for $C_{29.5}H_{34}B_3N_3O_{12}Si_2$: C, 49.8; H, 4.8; N, 5.9; B, 4.6. Found: C, 49.9; H, 4.9; N, 5.8; B, 4.3%. FT-IR (KBr) ν_{max}/cm^{-1}: 1300(vs), 1143(vs), 657(m). ^1H NMR ($CDCl_3$, 294 K): δ: 8.67–7.31 [m, 2H, $C_6H_4NO_2$]; 1.43 [s, 3H, $C(CH_3)_3$]. ^{13}C NMR ($CDCl_3$, 294 K) δ: 148.4, 141.4, 134.2, 130.0, 128.7, 127.1 [all $C_6H_4NO_2$]; 25.7 [$C(CH_3)_3$]; 16.6 [$C(CH_3)_3$]. MS, *m*/*z*: 665 $[M]^+$, 619 $[M-NO_2]^+$, 608 $[M-Bu]^+$, 451 $[M-2NO_2-C_6H_4NO_2]^+$, 122 $[C_6H_4NO_2]^+$, 57 $[Bu]^+$.

4.1.5. Synthesis of [$Bu^tSi\{O(4\text{-}CHOC_6H_4)BO\}_3SiBu^t$] (5)

The procedure was the same as that described for **1**. The following quantities were used: *tert*-butylsilanetriol (0.4021 g, 2.96 mmol); 4-formylphenylboronic acid (0.6621 g, 4.41 mmol); toluene, 50 ml; reaction time 18 h. This afforded [$Bu^tSi\{O(4\text{-}CHOC_6H_4)BO\}_3SiBu^t$] (**5**) as a colourless crystalline solid (0.75 g, 82.1%), mp 194–196 °C. *Anal*. Calc. for $C_{29}H_{33}O_9B_3Si_2$: C, 56.7; H, 5.4. Found: C, 56.5; H, 5.6%. FT-IR (KBr) ν_{max}/cm^{-1}: 1298(vs), 1128(vs), 681(s). ^1H NMR ($CDCl_3$, 294 K): δ 9.98 [s, 3H, C_6H_4CHO], 8.00–7.19 [m, 4H, C_6H_4CHO], 1.27 [s, 6H, $C(CH_3)_3$], ^{13}C NMR ($CDCl_3$, 294 K): δ 192.4 [C_6H_4CHO], 138.7, 135.8, 128.9 [all C_6H_4CHO], 25.8C($CH_3)_3$], 16.2 [$C(CH_3)_3$]. MS, *m*/*z*: 614 $[M]^+$, 105 $[C_6H_4CHO]^+$, 57 $[Bu]^+$.

4.1.6. Synthesis of [$Bu^tSi\{O(CpFeC_5H_4)BO\}_3SiBu^t$] (6)

The procedure was the same as that described for **1**. The following quantities were used: *tert*-butylsilanetriol (0.1971 g, 1.45 mmol); ferrocenylboronic acid (0.5211 g, 2.25 mmol); toluene, 60 ml; reaction time 15 h. Crystallisation from CH_2Cl_2–heptane (1:3) afforded orange crystals of [$Bu^tSi(OC_5H_4FeCpBO)_3SiBu^t$] (**6**) (0.50 g, 82.2%), m.p. 244–246 °C. *Anal*. Calc. for $C_{38}H_{45}O_6B_3Fe_3Si_2$: C, 53.4; H, 5.3. Found: C, 53.4; H, 5.3%. FT-IR (KBr) ν_{max}/cm^{-1}: 1316(s), 1290(s), 621(m). MS, *m*/*z*: 854 $[M]^+$, 186 $[(C_5H_5FeC_5H_5)]^+$. Crystal data for **6**: see Table 1.

4.1.7. Synthesis of [$Bu^tSi\{O(CH_3C(O)C_6H_4B)O\}_3SiBu^t$] (7)

The procedure was the same as that described for **1**. The following quantities were used: *tert*-butylsilanetriol (0.3024 g, 2.22 mmol); 4-acetylphenylboronic acid (0.5511 g, 3.31 mmol); toluene, 50 ml; reaction time 18 h. This afforded [$Bu^tSi\{O(CH_3C(O)C_6H_4B)O\}_3SiBu^t$] (**7**) as a crystalline solid (0.54 g, 75.2%), m.p. 134–135 °C. *Anal*. Calc. for $C_{32}H_{39}O_9B_3Si_2$: C, 58.5; H, 6.0. Found: C, 58.6; H, 6.1%. FT-IR (KBr) ν_{max}/cm^{-1}: 1301(vs), 1133(s), 632(m). ^1H NMR ($CDCl_3$, 294 K): δ 8.04–7.26 [m, 4H, C_6H_4]; 2.62 [s, 3H, $C(O)CH_3$]; 1.27 [s, 6H, $C(CH_3)_3$]. ^{13}C NMR ($CDCl_3$, 294 K): δ 198.1 [$C(O)CH_3$]; 139.8, 137.2, 135.9, 134.1, 127.9 [all C_6H_4]; 27.0 [$C(O)CH_3$]; 25.5 [$C(CH_3)_3$], 16.3 [$C(CH_3)_3$]. MS, *m*/*z*: 656 $[M]^+$, 599 $[M-Bu]^+$, 57 $[Bu]^+$.

4.1.8. Synthesis of [$Bu^tSi\{O(4\text{-}ClC_6H_4)BO\}_3SiBu^t$] (8)

The procedure was the same as that described for **1**. The quantities of starting materials used were: *tert*-butylsilanetriol (0.1541 g, 1.13 mmol); 4-chlorophenylboronic acid (0.2641 g, 1.67 mmol); toluene 60 ml; reaction time 16 h. Crystallisation from a toluene–heptane (ca. 1:3) solution afforded [$Bu^tSi\{O(4\text{-}ClC_6H_4)BO\}_3SiBu^t$] (**8**) (0.29 g, 34.1%), m.p. 304–308 °C. *Anal*. Calc. for $C_{26}H_{30}O_6B_3Cl_3Si_2$: C, 49.4; H, 4.7. Found: C, 49.6; H, 4.5%.

FT-IR (KBr) ν_{max}/cm^{-1}: 1306(vs), 1130(m), 678(m). ^1H NMR ($CDCl_3$, 294 K): δ 7.81–7.20 [m, 2H, C_6H_4Cl];. 1.26 [s, 3H, $C(CH_3)_3$]. (HR-MS), *m/z*: Found 632.094. Calculated for $^{12}C_{26}{}^1H_{30}{}^{11}B_3{}^{35}Cl_3{}^6O_6{}^{28}Si_2$ 632.017.

4.1.9. Synthesis of [$Bu^tSi\{O(2,4\text{-}F_2C_6H_3)BO\}_3SiBu^t$] (9)

The procedure was the same as that described for **1**. The following quantities were used: *tert*-butylsilanetriol (0.4112 g, 3.0 mmol); 2,6 difluorophenylboronic acid (0.6821 g, 4.4 mmol); toluene, 60 ml; reaction time 15 h. Crystallisation from CH_2Cl_2–heptane (1:3) afforded [Bu^t-$Si\{O(2,4\text{-}F_2C_6H_3)BO\}_3SiBu^t$] (**9**) (0.75 g, 87.3%), m.p. 183–185°C. *Anal*. Calc. for $C_{36}H_{27}B_3F_6O_6Si_2$: C, 49.0; H, 4.3. Found: C, 50.1H, 4.4%. FT-IR (KBr), ν_{max}/cm^{-1}: 1310(s), 1130(vs), 651(m). ^1H NMR ($CDCl_3$, 294 K): δ 7.80–6.75[m, 1H, C_6H_3], 1.26[s, 2H, $C(CH_3)_3$]. ^{29}Si NMR ($CDCl_3$, 294 K) δ −58.12. Crystal data for **9**, see Table 2.

4.1.10. Synthesis of [$C_6H_{11}Si\{O(PhB)O\}_3SiC_6H_{11}$] (10)

The procedure was essentially the same as that described for **1**. The quantities used were: *cyclo*hexylsilanetriol (0.4162 g, 2.54 mmol); phenylboronic acid (0.4599 g, 3.77 mmol); toluene 50 ml; reaction time 14 h. Crystallisation from CH_2Cl_2, toluene and heptane (1:1:2) afforded [$C_6H_{11}Si\{O(PhB)O\}_3SiC_6H_{11}$] (**10**) (0.30 g, 42.2%), m.p. 192–194 °C. *Anal*. Calc. for $C_{30}H_{37}O_6B_3Si_2$: C, 61.8; H, 6.4. Found: C, 62.1; H, 6.3%. FT-IR (KBr), ν_{max}/cm^{-1}: 1306(vs), 1140(vs), 639(s). ^1H NMR ($CDCl_3$, 294 K): δ 7.53–7.17 [m, 15H, C_6H_5]; 2.12–1.12 [m, 22H, C_6H_{11}].

4.2. Synthesis of [$C_6H_{11}Si\{O(4\text{-}BrC_6H_4B)O\}_3SiC_6H_{11}$] (11)

The procedure was essentially the same as that described for **1**. The quantities of reagents were: *cyclo*hexylsilanetriol (0.3199 g, 1.97 mmol), bromophenylboronic acid (0.7011 g, 3.49 mmol); toluene 50 ml; reaction time 10 h. A benzene solution was layered with *cyclo*hexane (ca. 1:3). The microcrystalline product was [$C_6H_{11}Si\{O(4\text{-}BrC_6H_4B)O\}_3$-$SiC_6H_{11}$] (**11**) (0.44 g, 57.3%), m.p. 252–254 °C. *Anal*. Calc. for $C_{30}H_{34}O_6B_3Br_3Si_2$: C, 44.0; H, 4.2; Br, 29.3. Found: C, 44.0; H, 4.3; Br, 29.4%. FT-IR (KBr), ν_{max}/cm^{-1}: 1300(vs), 1129(vs), 636(s). ^1H NMR ($CDCl_3$, 294 K): δ 7.90–7.25[m, 6H, C_6H_4Br]; 2.17–2.13 [m, 11H, C_6H_{11}].

4.3. Reactions between [$Bu^tSi\{O(PhB)O\}_3SiBu^t$] (1) and (a) pyridine, (b) N,N,N′,N′-tetramethylethylenediamine

4.3.1. Synthesis of [$Bu^tSi\{O(PhB)O\}_3SiBu^t$] · C_5H_5N (12)

Compound **1**, [$Bu^tSi\{O(PhB)O\}_3SiBu^t$] (0.11 g, 0.275 mmol) was dissolved in ether (30 ml). While vigorously stirring, pyridine (0.05 g, 6.23 mmol) was added via micopipette. The reaction mixture was stirred for 16 h. Removal of ether on a rotary evaporator afforded a colourless product. Crystallisation from CH_2Cl_2–heptane (1:3) yielded [$Bu^tSi\{O(PhB)O\}_3SiBu^t$] · C_5H_5N (**12**) (0.046 g, 73.4%), m.p. 218–219 °C. *Anal*. Calc. for $C_{31}H_{38}O_6B_3NSi_2$: C, 61.1; H, 6.2; N, 2.3; B, 5.4. Found: C, 61.7; H, 6.3; N, 2.9; B, 5.1%. FT-IR (KBr) ν_{max}/cm^{-1}: 1327(s), 1297(s), 1194(s), 1103(s), 1051(s), 1018(s), 701(s). ^1H NMR ($CDCl_3$, 294 K): δ 8.80–7.21 [m, 10H, C_6H_5 and C_5H_5], 1.32 [s, 9H, $C(CH_3)_3$]. ^{13}C NMR ($CDCl_3$, 294 K): δ 147.3, 137.7, 134.3, 130.0, 127.4, 124.3 [all C_6H_5 and C_5H_5], 25.6 [$C(CH_3)_3$], 16.6 [$C(CH_3)_3$]. ^{11}B NMR ($CDCl_3$, 294 K): δ 25.5 OB(Ph)O, 0.6 $OPhBO(NC_5H_5)$. Crystal data for **12**: see Table 2.

4.3.2. Synthesis of [$Bu^tSi\{O(PhB)O\}_3SiBu^t]_2$ · $Me_2NCH_2CH_2NMe_2$ (13)

Compound **1** (0.251 g, 0.473 mmol) was dissolved in ether (40 ml). *N*,*N*,*N*′,*N*′-Tetramethylethylenediamine (0.055 g, 0.472 mmol) was added via micropipette and a colourless precipitate formed. With further stirring, this almost completely dissolved. After 8 h, the solution was filtered. Removal of the solvent gave a colourless powder. Crystallisation from CH_2Cl_2–heptane (1:2) afforded [Bu^t-$Si\{O(PhB)O\}_3SiBu^t]_2 \cdot Me_2NCH_2CH_2NMe_2$ (**13**) (0.151 g, 27.3%), m.p. 233–234 °C. *Anal*. Calc. for $C_{58}H_{82}O_{12}B_6N_2$-Si_4:C, 59.2; H, 7.0, N, 2.4; B, 5.6. Found: C, 58.8; H, 6.9; N, 2.2; B, 5.4%. FT-IR (KBr) ν_{max}/cm^{-1}: 1439(s), 1356(s), 1308(vs), 1165(s), 1172(s), 1085(s), 1032(s), 680(s), 652(s). ^1H NMR ($CDCl_3$, 294 K): δ 7.81–7.14 [m, 15H, C_6H_5]; 2.62 [m, 2H, $Me_2NCH_2CH_2NMe_2$], 2.21 [s, 6H, $(CH_3)_2NCH_2$-$CH_2N(CH_3)_2$], 1.34 [s, 18H, $C(CH_3)_3$], ^{13}C NMR ($CDCl_3$, 294 K): δ 135.5, 134.9, 131.2, 129.7, 127.4 [all, C_6H_5], 55.4 [$Me_2NCH_2CH_2NMe_2$], 44.9[$(CH_3)_2NCH_2$-$CH_2N(CH_3)_2$], 26.1 [$C(CH_3)_3$], 16.3 [$C(CH_3)_3$]. ^{11}B NMR ($CDCl_3$, 294 K): δ 31.8 OB(Ph)O and 2.8 $OPhBO(Me_2NCH_2)_2$.

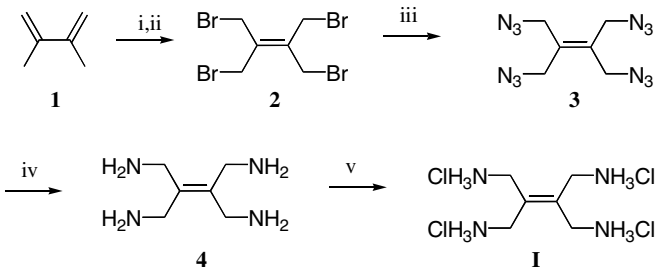
4.3.3. Data Collection and structure refinement for compounds 2, 3, 4, 6, 9 and 12

Data for **2**, **3** and **4** were collected on an Enraf-Nonius CAD-4 diffractometer with graphite-monochromatised Mo Kα radiation ($\lambda = 0.71073$ Å). Data for **6**, **9** and **12** were collected on a Nonius MACH3 diffractometer with graphite-monochromatised Mo Kα radiation ($\lambda =$ 0.71073 Å). Data analysis for **2**, **3**, **4** [18], **6**, **9** and **12** [19] were carried out to provide 8018, 7964, 7780, 9117, 3379 and 5384 independent reflections, respectively. The structures were solved using direct methods [20]. Non-hydrogen atoms were refined with anisotropic thermal parameters. The hydrogen atoms bonded to carbon were included in geometric positions and given thermal parameters equivalent to 1.2 times those of the atom to which they were attached, although a 1.5 factor was used for the methyl groups. A Gaussian absorption correction on **2** was carried out [18]. For **9** there was disordered solvent present which could not be modelled correctly and was removed using the SQUEEZE algorithm [21].

The structures were refined on F^2 [22] to R_1 0.055, 0.064, 0.074, 0.043, 0.083 and 0.071 for 3389, 3115, 3338, 6403, 496 and 1589 reflections, respectively, with $I > 2\sigma(I)$ and

wR_2 0.127, 0.193, 0.177, 0.129, 0.155 and 0.238 for all independent reflections.

Acknowledgements



The ^{11}B and ^{29}Si NMR spectra were kindly recorded on a Bruker AM 400 instrument at the University of Leeds by Prof. J.D. Kennedy. G.F. and S.E.L. thank NSERC Canada and University College Cork for funds for diffractometers.

Appendix A. Supplementary material

CCDC 615803, 615804, 615805, 615806, 615807 and 615808 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2006.12.045.

Scheme 1. Reagents and conditions: (i) Br_2, CCl_4, 0 °C; (ii) NBS, 24 h, reflux, 60% (over two steps); (iii) NaN_3 (4.4 equiv.), DMF, −40 °C, 20 h; (iv) PPh_3 (4.4 equiv.), H_2O (6 equiv.), THF, −40 °C, 20 h; (v) HCl_{aq}, 80% (over three steps).

(210 mL, 4.4 equiv., 20.1 mmol), the solution was stirred for 1 h. The separated aqueous phase was washed with ethyl acetate (250 mL). The tetramine tetrachlorhydrate (**I**) was obtained after water removal as a solid (1.34 g, 80% yield, 4 mmol). ^{1}H NMR (400 MHz, D_2O), δ (ppm, DSS): 4.05 (s, 8H), 4.78 (s, 12H). ^{13}C NMR (100 MHz, D_2O): 38.0, 136.0.

2.2. Synthesis of $[H_4ten]\cdot(AlF_5)_2$ (*II*)

A microcrystalline powder of $[H_4ten]\cdot(AlF_5)_2$ was prepared from Al_2O_3, *ten* (obtained after Cl^-/OH^- exchange on an anionic resin.), HF, H_2O in 1:0.5:10:515 molar ratios by microwave heating assisted hydrothermal synthesis (Fig. 1). The solid product was washed with deionised water and dried at room temperature. XRD powder patterns indicated that the $[H_4ten]\cdot(AlF_5)_2$ (**II**) sample was contaminated with pyrochlore $(Al_2[(OH),F]_6\cdot H_2O$ [14]).

2.3. Determination of crystal structure

A single-crystal of **I**, suitable for X-ray diffraction, was selected by using an optical microscope. The crystal cell parameters were obtained from a random reflection search and X-ray diffraction data were collected on a Siemens AED2 four-circle diffractometer. Chlorine atoms were located by direct methods using the SHELXS-86 program [15]. Nitrogen and carbon atoms were found by difference Fourier maps and the positions of hydrogen atoms were geometrically constrained (HFIX option). Structure refinements were performed using the SHELXS-97 program [16]. The positions of all non-hydrogen atoms were refined anisotropically and a unique isotropic thermal motion was used for all hydrogen atoms.

The indexation of the XRD pattern of $[H_4ten]\cdot(AlF_5)_2$ was carried out with the McMaille [17] software from the 20 first lines. A monoclinic solution was found with satisfactory figures of merit ($M(20) = 47$, $F(20) = 75$ (0.0054, 48) and was confirmed at the structure factor extraction stage using the FULLPROF program [18] (Le Bail method [19]). Directs methods failed to provide structure solutions. Calculations were then performed with Espoir, a reverse Monte Carlo program with a pseudo simulated annealing code for ab initio crystal structure determination by the direct space method. The strategy consisted of the introduction of three objects, translated and rotated randomly, until a satisfying fit to a pseudo powder pattern regenerated from the extracted structure factors was obtained: one *ten* molecule (hydrogen atoms omitted), one AlF_6 octahedron and one AlF_4 square plane. The geometry of *ten* was deduced from the structure of $[H_4ten]Cl_4$. In the first stage, the structure was determined in the non-centrosymmetric *Pc* space group and a model with $(AlF_5)_\infty$ chains was obtained. This model was introduced into the Rietveld method (Fullprof) for refinement (Fig. 2). It was found that two Al atoms and the center of $[H_4ten]^{4+}$ cations were compatible with the presence of an inversion center and consequently, the final results are given in the *P*2/*c* space group.

The conditions of data collection are summarized in Table 1. Atomic coordinates and main bond lengths are given in Tables 2–5.

3. Results and discussion

The tetra(azidation-Staudinger) route we previously described for pentaerythrityl tetramine [20] was applied for the preparation of $[H_4ten]Cl_4$. However, this three step pathway from the known 2,3 di-2-bromomethyl 1,4 bromonobut-2-ene (**2**) [21] depicted in Scheme 1 proved to lead to $[H_4ten]Cl_4$ (**5**) in good purity and yield only after extensive optimization of the reaction conditions.

Indeed, conventional azidation of the tetrabromide **2**, carried out at 100 °C in DMF or DMSO, led to a mixture of the expected tetrazide **3** and its regioisomer **3′** (Table 6). The formation of **3′** is explained by a concerted [3,3]′-sigmatropic rearrangement of **3** (Fig. 3), as suggested for

Table 6
Effect of reaction conditions on the **3**/**3′** allyl azide isomerisation ratio[a]

T (°C)	DMF	DMSO
100	30/70	50/50
20	40/60	60/40
−40	100/0

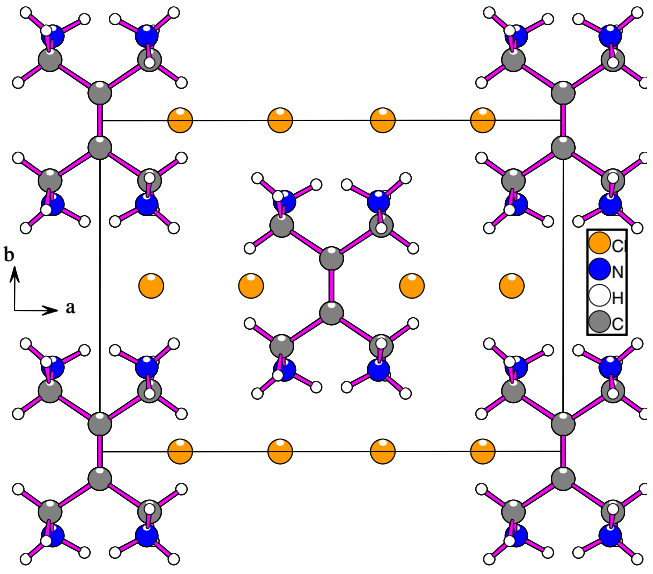

Fig. 3. Crystal structure of $[H_4ten]Cl_4$.

the interconversion of allylic azides [22]. This rearrangement occurs to a large extent even at room temperature (Table 5). In contrast, when produced at −40 °C in DMF, tetrazide **3** is stable and can be isolated in a pure isomeric form.

Unfortunately, in the next step, applying classical Staudinger conditions to pure tetraazide **3** at room temperature led to tetramine **4** contaminated by a significant amount of pre-isomerized tetramine **4′**. These results exemplify that (i) a significant [3,3]-sigmatropic equilibration process occurs under these conditions and (ii) that the formation of the primary allylamine **4** is not selective with respect to those of the tertiary one **4′**, in contrast with previous findings reported in geranyl versus linalyl series [23]. However, we disclosed that the side *in situ* isomerization process could be efficiently suppressed by performing the Staudinger reaction on **3** at −40 °C in THF. Under these conditions and after acidification, $[H_4ten]Cl_4$ (**5**) was thus obtained in 80% overall yield from **2** as a crystalline pure product. The structure of $[H_4ten]Cl_4$ was determined by single crystal X-ray diffraction (Fig. 4).

The structure of $[H_4ten]\cdot(AlF_5)_2$ is built up from [0 1 0] $(AlF_5)_\infty$ chains of corner sharing AlF_6 octahedra (Fig. 5). Charge balance is ensured by tetraprotonated $[H_4ten]^{4+}$ cations. Two crystallographically non-equivalent aluminum atoms Al(1) and Al(2) are coordinated to six fluoride anions. Aluminum to bridging fluorine distances (≈1.88 Å) are longer than aluminum to terminal fluoride distances (≈1.78 Å). Similar chains of trans-connected octahedra are encountered in $[H_4tetra]\cdot(AlF_5)_2$ [19]. Hydrogen bond interactions, established between terminal NH_3 groups of the amine cations and fluoride anions, ensure the cohesion of the structure.

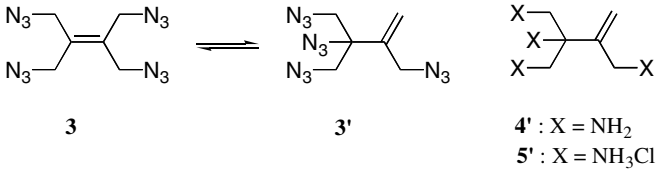

Fig. 4. Concerted [3,3]-sigmatropic rearrangement of **3** as a potential source of by-products **3′**–**5′**.

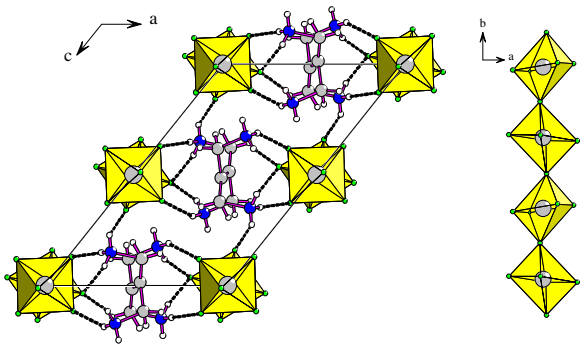

Fig. 5. Crystal structure of $[H_4ten]\cdot(AlF_5)_2$ (left), projections of trans $(AlF_5)_\infty$ chains (right).

4. Conclusion

In summary, an efficient synthesis of a new allyl tetramine, labelled *ten*, has been achieved in good overall yield. The hydrothermal synthesis of the Al_2O_3–*ten*–HF–H_2O system leads to the first *ten* fluoroaluminate. The structure is *ab initio* determined from X-ray powder data by using the geometry of $[H_4ten]^{4+}$ cations which was obtained from single-crystal analysis of $[H_4ten]Cl_4$. A broad study of the influence of the amine geometry on the template effect is currently ongoing. Both planar *ten* amine and the saturated analog (labelled *tan*) will be tested. The crystallization fields of the solids will be determined on large concentration domains of the starting materials.

Appendix A. Supplementary materials

CCDC 621905 and 621906 contain the supplementary crystallographic data for **I** and **II**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2006.12.041.

have studied and described in the literature the reactivity of the ligand bdtp with different metals such as Ni(II), Co(II), Cu(I), Zn(II), Ag(I), Cd(II) and Re(I) [9], and our research group recently has reported the reactivity of the ligand bdtp with Pd(II). We have demonstrated the hemilabile properties of this ligand when coordinated to Pd(II) [7c].

In this paper, we have studied the reactivity of the ligand bdtp [7c,8] towards Pt(II), under various conditions and with several platinum starting materials.

2. Results and discussion

2.1. Synthesis and spectroscopic properties

Reaction of 1,5-bis(3,5-dimethyl-1-pyrazolyl)-3-thiapentane (bdtp) [7c,8] (Scheme 1) with several platinum starting materials, such as K_2PtCl_4, $PtCl_2$, $[PtCl_2(CH_3\text{- }CN)_2]$ [10] and $[PtCl_2(PhCN)_2]$ [11], have been developed under different conditions (Scheme 2). In general, and in contrast to the Pd(II) complexes, these reactions take a longer time and need higher temperatures to occur. This same behaviour is observed with the ligands 1,8-bis-(3,5-dimethyl-1-pyrazolyl)-3,6-dithiaoctane (bddo), 1,9-bis(3,5-dimethyl-1-pyrazolyl)-3,7-dithianonane (bddn) and 1,6-bis(3,5-dimethyl-1-pyrazolyl)-2,5-dithiahexane (bddh) [12].

The reaction did not yield pure products. Unfortunately, isolation of the different isomers by silica gel chromatography was unsuccessful. Recrystallisations of the mixture with different solvents have been carried out but pure products could not be obtained.

The resulting products of these reactions have been characterised by elemental analyses, and infrared and NMR spectra.

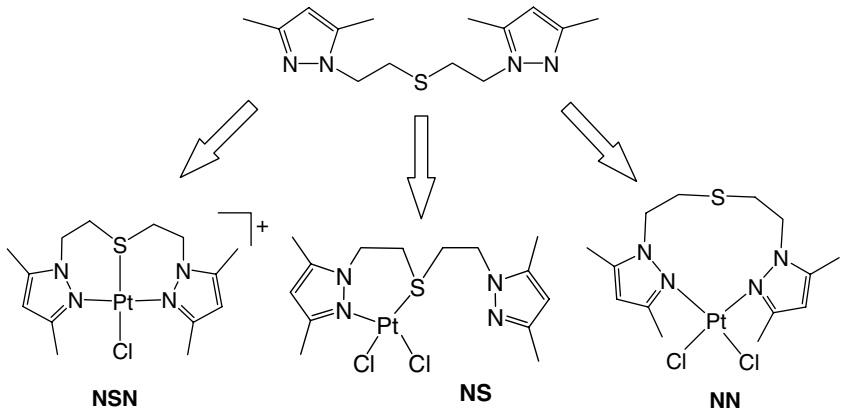
The ratio of NS, NSN and NN products has been calculated through ^{1}H NMR experiments (integration of C–H_{pz} signals, see Section 4) (see Fig. 1).

The different isomers were distinguished using the following criteria:

Isomer NSN: pure NSN complex (δ(C–H_{pz}) = 6.03 ppm) could be obtained when the platinum starting material is $[PtCl_2(CH_3CN)_2]$.

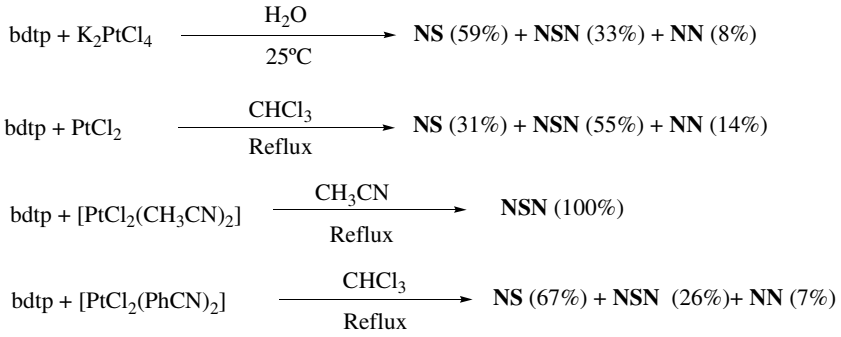
Isomer NS: two signals can be observed for the C–H_{pz} of the coordinated ligand in this isomer. One of them appears at the same position as the free ligand (δ(C–H_{pz}) = 5.76 ppm) and the other one at δ(C–H_{pz}) = 5.82 ppm. Integration of both peaks is identical.

Isomer NN: this is a third isomer, which was characterised by comparison to the complex $[PdCl_2(bdtp)]$ (δ(C–H_{pz}) = 5.90 ppm) [7c].



Elemental analyses are consistent with the mixtures.

The IR spectra of the complexes with bdtp show bands at 1555–1553 cm^{-1} (ν(C=C), ν(C=N))$_{ar}$, 1465–1418 cm^{-1} (δ(C=C), δ(C=N))$_{ar}$, 1100–1021 cm^{-1} δ(C–H)$_{ip}$ and 801–800 cm^{-1} δ(C–H)$_{oop}$, indicating the presence of the unaltered coordinated ligand [7c,8]. Coordination to platinum is demonstrated in the IR spectra between 500 and 100 cm^{-1} of the mixture of compounds. According to IR data, the Pt atom is coordinated to nitrogen atoms [ν(Pt–N) between 444 and 441 cm^{-1}], sulfur atoms [ν(Pt–S) between 419 and 380 cm^{-1}] and chlorine atoms [ν(Pt–Cl) between 333 and 326 cm^{-1}] [13].



The ^{1}H NMR, ^{13}C{^{1}H} NMR, HMQC, COSY and NOESY spectra were recorded in $CDCl_3$. The NMR experiments corroborate the obtaining of mixtures and the coordination of the ligands around the metallic centre. This ligand can act as tridentate (NSN) or bidentate (NS or NN) chelates depending on the Pt(II) starting material.

In order to be able to isolate one of the isomers (NSN) from the mixture, treatment of the bdtp mixture with $NaBPh_4$ was carried out. This reaction gave a compound of the formula $[Pt(bdtp)](BPh_4)$ (**1**) as a pure products (NSN isomer).

When the complex **1** was heated under reflux in a solution of Et_4NBr in CH_2Cl_2/MeOH (1:1) for 24 h, mixtures of complexes were again obtained (NSN (55%) and NN (45%) isomers with bromides instead of chlorides bonded to the metallic centre). This proves the type III hemilability of the ligand bdtp towards Pt(II) [1a]. The elemental analysis of **1** is consistent with the formula $[PtCl(bdtp)](BPh_4)$. The positive ionisation electrospray mass spectrum of **1** gave a peak with a m/z value of 509 $[PtCl(bdtp)]^+$ (molecular peak of the cation is observed with the same isotope

Scheme 1.

The ratio of the species has been calculated through ^{1}H-NMR experiments, especially from the integration of the pyrazolic proton

Scheme 2.

distribution as the theoretical one). The conductivity measurements in DMF for **1**, show that the complex behaves as 1:1 electrolyte in solution [14].

The IR spectrum of complex **1** is similar to that of the ligand, the most characteristic bands being those attributable to the pyrazolyl group: ν(C=C), ν(C=N) at 1579, 1576 cm^{-1} and δ(C–H)$_{oop}$ at 799 cm^{-1}. The ν(B–C) band at 736 cm^{-1} is characteristic for **1** [15]. The ν(Pt–N), ν(Pt–S) and ν(Pt–Cl) bands can be attributable to the signals appearing at 442 cm^{-1}, 380 cm^{-1} and 326 cm^{-1}, respectively [13].

^{1}H and ^{13}C{^{1}H} NMR spectra of compound **1** were recorded in [D$_6$]acetone solution, and show the signals of the coordinated ligands. NMR spectroscopy data are reported in Section 4 (see Fig. 1).

The ^{1}H NMR spectrum of complex **1** shows that the two protons of each CH$_2$ moiety in the S–CH$_2$–CH$_2$–N chains are diastereotopic, thus leading to four groups of signals, which can be associated to a single hydrogen atom in each chain. This happens because of the rigid conformation of the ligand when complexed. Thus, each group of signals can be assigned as doublets of doublets of doublets (Fig. 2). The HMQC spectrum allowed us to assign the two doublets of doublets of doublets of lower δ to 7-H and the ones at higher δ to 6-H (Fig. 3). Study of the S–CH$_2$–CH$_2$–N fragment as an AA′XX′ system gave a set

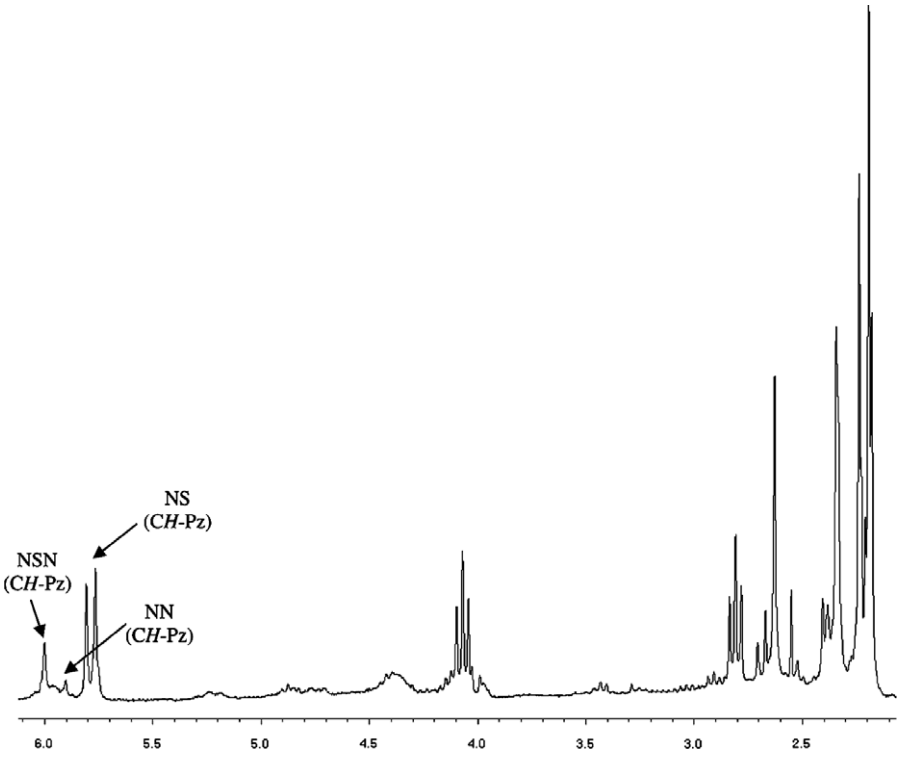


Fig. 1. ^{1}H NMR 250 MHz spectrum of the mixture bdtp + [PtCl$_2$(PhCN)$_2$].

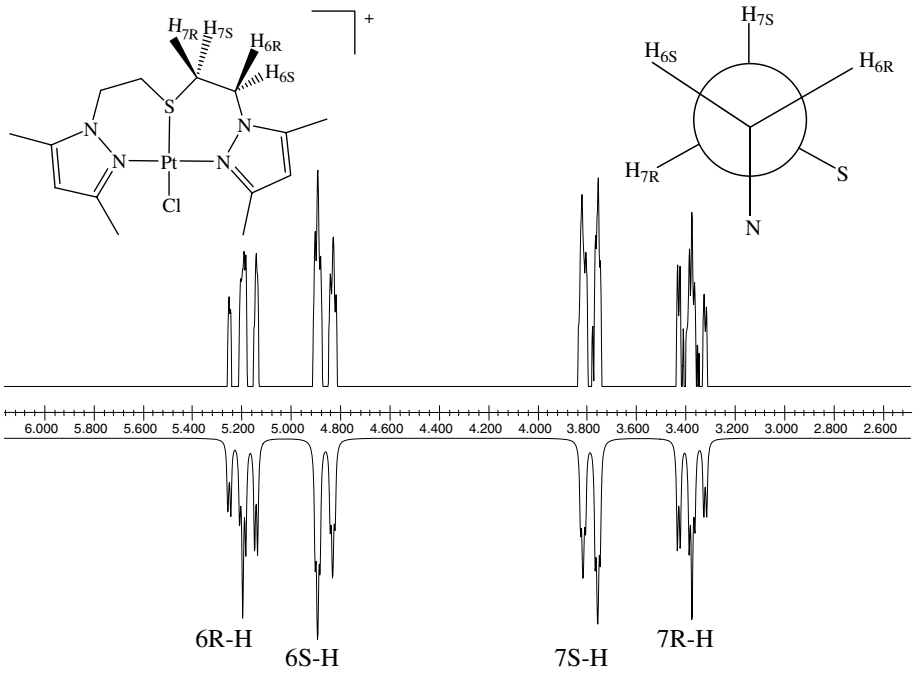

Fig. 2. The 250-MHz ^{1}H NMR and the simulated *g*NMR spectrum for the NCH_2CH_2S fragment of [PtCl(bdtp)](BPh$_4$) (**1**) including the numbering and the dihedral angles for the NCH_2CH_2S fragment.

of coupling constants (Table 1). These constants were consistent with the simulated spectra obtained with the aid of the *g*NMR program [16].

In the NOESY spectrum it can be seen that the methyl group at $\delta = 2.48$ ppm shows a NOE interaction with the doublet of doublets of doublets at $\delta = 4.87$ ppm, but not with the one at $\delta = 5.19$ ppm. From the X-ray structure of **1**, it can be observed that the nearest proton to the $CH_3(5)$ moiety is 6S-H (Figs. 2 and 4) and therefore it should be the one with the NOE interaction (2.70 Å cation **A** and 2.73 Å cation **B**). This information leads us to assign 6S-H to the doublet of doublets of doublets at $\delta = 4.87$ ppm and 6R-H to the signal at $\delta = 5.19$ ppm. The coupling constants enabled us to differentiate 7S-H

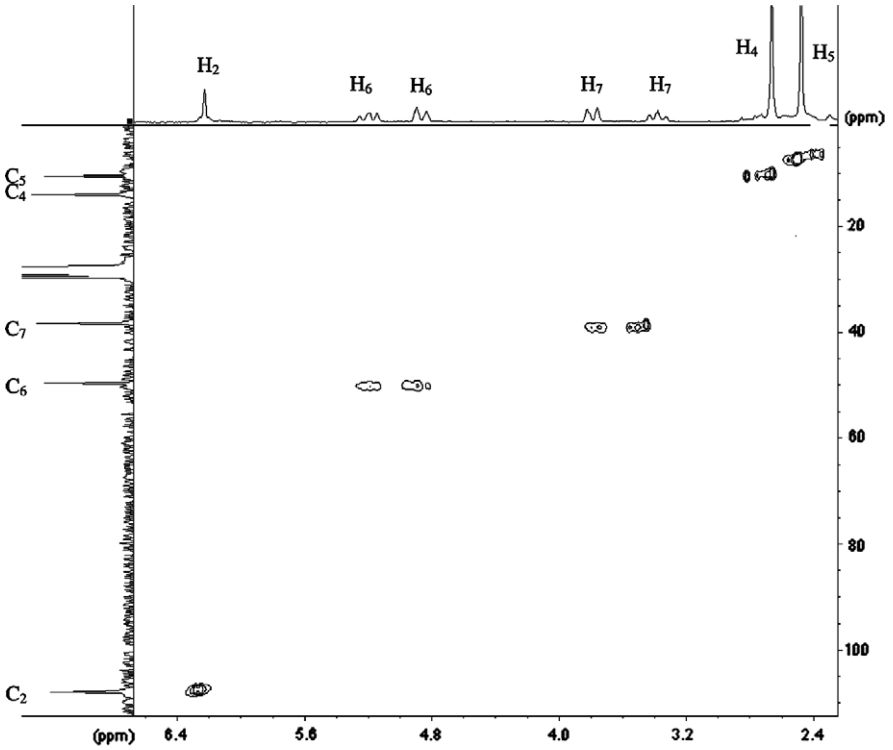

Fig. 3. The 250-MHz 2D HMQC spectrum of [PtCl(bdtp)](BPh$_4$) (**1**).

^3J(6S-H, 7R-H)	2.09

and 7R-H. These coupling constants agree with the conformation of the S–CH_2–CH_2–N chain as seen in the X-ray crystal structure (Figs. 2 and 4). Geminal ^2J and ca. 180°, ^3J coupling constants have significantly higher values than ca. 30° and ca. 60° ^3J coupling constants. Thus, 7R-H should correspond to the doublet of doublets of doublets at 3.38 ppm and 7S-H to the one at $\delta = 3.79$ ppm [15,17].

Additional ^{195}Pt{^{1}H} NMR experiments for complex **1** at 298 K revealed only one band ($\delta = -1880$ ppm). The ^{195}Pt{^{1}H} chemical shifts are downfield compared to other complexes with [PtN_2SCl] cores (−4098, −2312 ppm) [18].

2.2. Crystal structure of [PtCl(bdtp)](BPh$_4$)-CH$_3$CN

The crystal structure of **1** contains two kinds of discrete [PtCl(bdtp)]$^+$ cations (cations **A** and **B**) (Fig. 4), two BPh_4^- anions and two acetonitrile solvent molecules. Table 2 lists some selected bond distances and angles.

The cations **A** and **B** have the same structure, [PtCl(bdtp)]$^+$. In both, the cationic complex is mononuclear, and the Pt(II) is coordinated to the bdtp ligand by its three donor atoms (two nitrogen atoms of the pyrazolyl group and one sulfur atom), along with one chlorine atom, in a slightly distorted square-planar geometry. Tetrahedral distortion can be observed from the bond angles and from the largest deviation to the mean plane (0.039(4) Å cation **A** and 0.072(4) Å cation **B**) of the atoms coordinated to the Pt atom in relation to the mean plane that contains these four atoms and the Pt atom (cation **A**: N(1), N(4), S(1), Cl(1); cation **B**: N(8), N(5), S(2), Cl(2)). The dihedral angle between the planes N(1)–Pt(1)–Cl(1) and N(4)–Pt(1)–S(1); and N(5)–Pt(2)–Cl(2) and N(8)–Pt(2)–S(2) are 4.10(2)° and 5.88(2)°, respectively. The bdtp ligand acts as a tridentate chelate and forms two six-membered rings, with a boat form for Pt(1)S(1)C(8)C(9)N(3)N(4) and Pt(1)S(1)C(7)C(6)N(2)N(1) (cation **A**) and with a twist-boat form for Pt(2)S(2)C(22)C(23)N(7)N(8) and a boat conformation for Pt(2)S(2)C(21)C(20)N(6)N(5) (cation **B**).

The [PtN_2SCl] core is present in 45 complexes in the literature. Only in 13 of them is the S a thioether [19]. The Pt–Npz bond lengths [2.025(4) and 1.999(5) Å (cation **A**); 2.008(4) and 2.014(4) Å (cation **B**)], the Pt–S bond lengths [2.2616(12) Å (cation **A**); 2.2559(12) Å (cation **B**)] and the

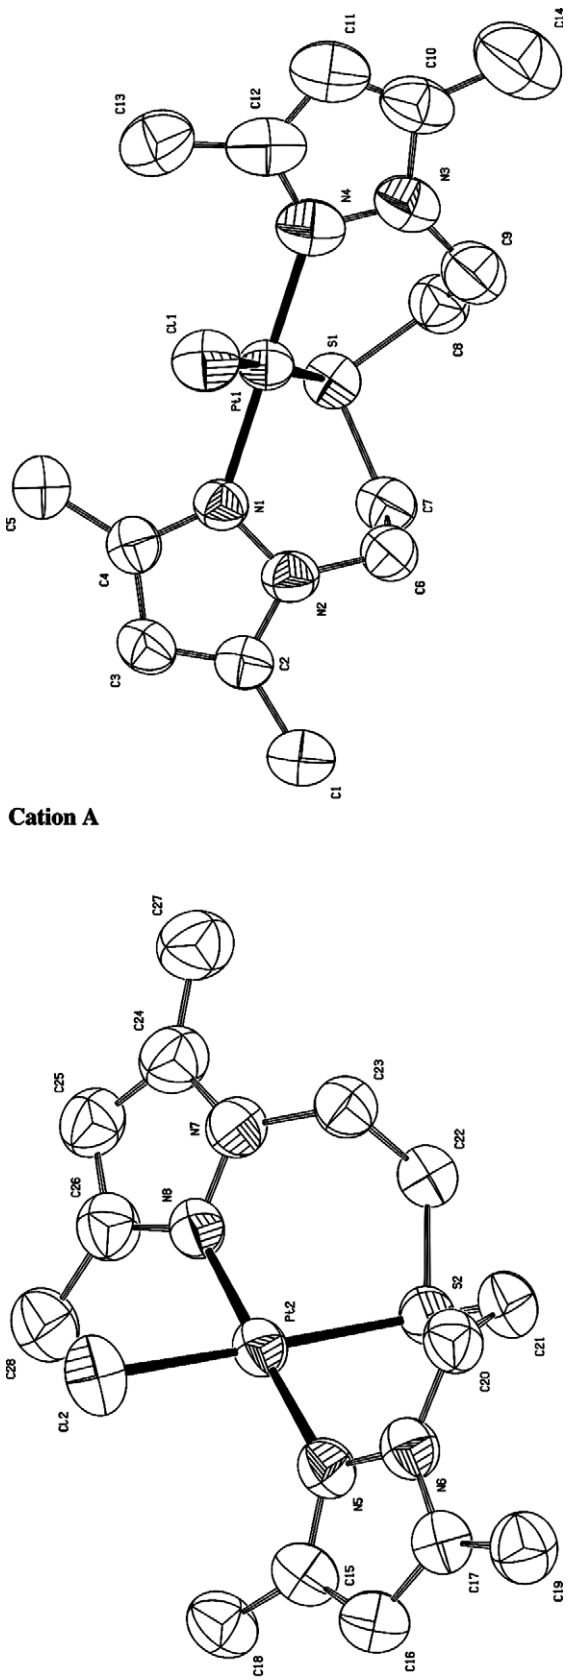

Fig. 4. ORTEP drawing of [PtCl(bdtp)]$^+$ (a: cation **A**, b: cation **B**) showing all non-hydrogen atoms and the atom numbering scheme; 50% probability amplitude displacement ellipsoids are shown.

Table 2
Selected bond lengths (Å) and bond angles (°) for $[PtCl(bdtp)](BPh_4)\cdot CH_3CN$

*Cation **A***			
Pt(1)–N(1)	2.025(4)	Pt(1)–S(1)	2.2616(12)
Pt(1)–N(4)	1.999(5)	Pt(1)–Cl(1)	2.3168(14)
N(4)–Pt(1)–N(1)	179.44(17)	N(4)–Pt(1)–S(1)	91.87(15)
N(4)–Pt(1)–Cl(1)	91.05(15)	N(1)–Pt(1)–S(1)	88.60(11)
N(1)–Pt(1)–Cl(1)	88.47(11)	S(1)–Pt(1)–Cl(1)	174.97(5)
*Cation **B***			
Pt(2)–N(8)	2.008(4)	Pt(2)–S(2)	2.2559(12)
Pt(2)–N(5)	2.014(4)	Pt(2)–Cl(2)	2.3139(14)
N(8)–Pt(2)–N(5)	177.62(15)	N(8)–Pt(2)–S(2)	91.81(11)
N(8)–Pt(2)–Cl(2)	91.06(11)	N(5)–Pt(2)–S(2)	86.42(11)
N(5)–Pt(2)–Cl(2)	90.86(12)	S(2)–Pt(2)–Cl(2)	173.63(5)

Pt–Cl bond lengths [2.3168(14) Å (cation **A**); 2.3139(15) Å (cation **B**)] can be regarded as normal compared with the distances found in the literature. For Pt–N_{pz}, the literature describes values between 1.930 and 2.021 Å [20], for Pt–S(thioether) between 2.18 and 2.46 Å [19,21], and for Pt–Cl between 2.198 and 2.381 Å [20].

The N_{pz}–Pt–S bite angles of the ligand are 91.87(15)° and 88.60(11)° (cation **A**) and 91.81(11)° and 85.42(11)° (cation **B**), and are similar to the corresponding bite angles in the complex $[PdCl(bdtp)](BF_4)$ (90.5(2)° and 88.5(2)°) [7c].

3. Conclusion

Reaction of the bdtp ligand with different Pt(II) starting materials forms different mixtures of the NN, NS and NSN isomers. A similar reaction with $[PdCl_2(CH_3CN)_2]$ as the starting material yielded the NN and NS isomers (the NSN isomer was not observed with Pd before addition of $AgBF_4$) [7c] in a dynamic equilibrium in solution at room temperature. This equilibrium is not observed for the Pt(II) mixture on the NMR timescale (under the same conditions), showing that Pt(II) forms more inert complexes with bdtp than Pd(II).

In order to isolate the NSN isomer, we performed the reaction of the bdtp mixture of isomers with $NaBPh_4$, obtaining $[Pt(bdtp)](BPh_4)$ as a pure product. In this case, the only coordination observed is NSN (similar behaviour to Pd(II)). When this product is refluxed in CH_2Cl_2/CH_3OH in the presence of Et_4NBr a new mixture of NN, NS and NSN isomers is obtained. This proves the hemilability of this ligand with Pt(II) [1a], as was observed for Pd(II).

4. Experimental

4.1. General details

The reactions were carried out under nitrogen atmosphere using vacuum line and Schlenk techniques. Solvents were dried and distilled according to standard procedures and stored under nitrogen. Elemental analyses (C, H, N, S) were carried out by the staff of the Chemical Analyses Service of the Universitat Autònoma de Barcelona on a Carlo Erba CHNS EA-1108 instrument. Conductivity measurements were performed at room temperature (r.t.) in 10^{-3} M DMF solutions, employing a CyberScan CON 500 (Euthech instrument) conductimeter. Infrared spectra were run on a Perkin–Elmer FT spectrophotometer, series 2000 cm^{-1} as KBr pellets or polyethylene films in the range 4000–100 cm^{-1}. ^1H NMR, $^{13}C\{^1H\}$ NMR, HMQC, COSY, NOESY spectra were recorded on a NMR-FT Bruker AC-250 MHz spectrometer in $CDCl_3$, and [D_6]acetone solutions at room temperature. $^{195}Pt\{^1H\}$ NMR spectra were recorded at 25 °C and 77.42 MHz on a DPX-360 Bruker spectrometer using aqueous solutions of $[PtCl_6]^{2-}$ (0 ppm) as an external reference and delay time 0.01 s. All chemical shifts values (δ) are given in ppm. Positive ion ESI-MS mass spectrometer experiments were performed by the Scientific technique Services of the Universitat de Barcelona on a ZQ (Micromass Instruments, UK). The electrospray interface (pneumatically assisted) was operated under the following conditions: the nebulizing nitrogen gas flow was 25 l h^{-1} and the drying nitrogen 250 l h^{-1}, source temperature 100 °C with a capillary voltage of 3.5 kV and cone voltage 20 V. The flow rate was 100 µl min^{-1}. Samples were dissolved in a 1:1 mixture of H_2O/CH_3CN.

Samples of $[PtCl_2(CH_3CN)_2]$ [10] and $[PtCl_2(PhCN)_2]$ [11] were prepared as described in the literature. 1,5-bis(3,5-dimethyl-1-pyrazolyl)-3,7-thiapentane (bdtp) [7c,8] was prepared according to the published methods (Scheme 1).

4.2. Reactions of bdtp with K_2PtCl_4 in H_2O

0.23 mmol (0.065 g) of the bdtp ligand dissolved in 10 ml of water was added to a solution of 0.23 mmol (0.095 g) of K_2PtCl_4 in 10 ml of water. The solution was stirred at room temperature for 24 h (until the red colour of the starting material K_2PtCl_4 had completely disappeared), and a yellow solid precipitated. It was filtered off, washed twice with 5 ml of cold water and dried in vacuum.

4.3. Reactions of bdtp with $PtCl_2$

To 0.26 mmol (0.070 g) of $PtCl_2$ in 15 ml of chloroform, 0.27 mmol (0.070 g) of the bdtp ligand dissolved in 15 ml of the same solvent was quickly added. The mixture was refluxed for 48 h. The yellowish solution was filtered to separate Pt(0) and the starting material $PtCl_2$. The solvent was evaporated to dryness leaving a white solid, which was filtered off, washed with 10 ml of CH_2Cl_2/diethyl ether (1:1) and dried in vacuum.

4.4. Reactions of bdtp with $[PtCl_2(CH_3CN)_2]$

0.24 mmol (0.067 g) of the bdtp ligand dissolved in 15 ml of acetonitrile was added to a solution of 0.24 mmol (0.085 g) $PtCl_2(CH_3CN)_2$ in 15 ml of acetonitrile. The solu-

tion was refluxed for 24 h. The solvent was evaporated to dryness leaving a yellow solid, which was filtered off, washed with 10 ml of CH_2Cl_2/diethyl ether (1:1) and dried in vacuum.

4.5. Reaction of bdtp with $[PtCl_2(PhCN)_2]$

0.20 mmol (0.055 g) of the bdtp ligand dissolved in 15 ml of chloroform was added to a solution of 0.20 mmol (0.095 g) of $[PtCl_2(PhCN)_2]$ in 15 ml of the same solvent. The mixture was refluxed 24 h. From the yellow solution the solvent was evaporated to dryness yielding a yellow solid, which was filtered off, washed with 10 ml of CH_2Cl_2/diethyl ether (1:1) and dried in vacuum.

4.6. Complexes $[PtCl(bdtp)](BPh_4)$ (**1**)

A solution of $NaBPh_4$ (0.14 mmol, 0.050 g) in 10 ml acetonitrile/methanol 1:1 was added dropwise with vigorous stirring to a solution of $[PtCl_2(bdtp)]$ (0.14 mmol, 0.075 g) in 10 ml of acetonitrile/methanol 1:1. The solution was stirred at room temperature for 12 h. The yellowish solution was filtered to separate NaCl. When the volume of the resultant solution had been reduced to roughly 5 ml,

diethyl ether (5 ml) was then added to induce precipitation. The resulting precipitate was then filtered and washed with 5 ml diethyl ether.

Yield: 79% (0.076 g). *Anal.* Calc. for $C_{38}H_{44}N_4SClPtB$: C, 65.82; H, 4.72; N, 5.31; S, 5.41. Found: C, 65.80; H, 4.71; N, 5.74; S, 5.39%. MS (*m*/*z*) (%) = 509 (100%) $[PtCl(bdtp)]^+$. 4.7. X-ray crystal structure for compound $[PtCl(bdtp)](BPh_4)\cdot CH_3CN$

Suitable crystals for X-ray diffraction of compound *cis*-$[PtCl(bdtp)](BPh_4)\cdot CH_3CN$ were obtained through crystallisation from an acetonitrile:*n*-pentane solution. A prismatic crystal was selected and mounted on a MAR345 diffractometer with a image plate detector. Unit-cell parameters were determined from 8310 reflections ($3 < \theta < 31°$) and refined by least-squares method. Intensities were collected with graphite-monochromatised Mo Kα radiation. 39970 reflections were measured in the range $2.62° \leqslant \theta \leqslant 30.00°$, 20296 of which were non-equivalent by symmetry (R_{int}(on I) = 0.039). 19908 reflections were assumed as observed applying the condition $I > 2\sigma(I)$. Lorentz-polarisation but no absorption corrections were made.

The structure was solved by direct methods, using the SHELXS computer program [22], and refined by the full-matrix least-squares method with SHELX-97 computer programs [23] using 39970 reflections (very negative intensities were not assumed). The function minimised was $\sum w||F_o|^2 - |F_c|^2|^2$ where $w = [\sigma^2(I) + (0.0444P)^2 + 6.5332P]^{-1}$, and $P = (|F_o|^2 + 2|F_c|^2)/3$. All H atoms were computed and refined, using a riding model, with an isotropic temperature factor equal to 1.2 times the equivalent temperature factor of the atom to which they are linked. The final $R(F)$ factor and $R_w(F^2)$ values as well as the number of parameters and other details concerning the refinement of the crystal structure are gathered in Table 3.

Table 3
Crystallographic data for $[PtCl(bdtp)](BPh_4)\cdot CH_3CN$

Empircal formula	$C_{82}H_{93}B_2Cl_2N_{11}Pt_2S_2$
Formula weight	1779.49
Temperature (K)	293(2)
Crystal system	triclinic
Space group	$P\bar{1}$
Unit cell dimensions	
a (Å)	14.446(6)
b (Å)	15.306(6)
c (Å)	19.500(4)
α (°)	88.71(2)
β (°)	74.43(2)
γ (°)	76.08(2)
V (Å^3)	4027(2)
Z	2
D_{calc} (g cm^{-3})	1.467
μ (mm^{-1})	3.638
F(000)	1788
Crystal size (mm^{-1})	$0.2\times0.1\times0.1$
θ Range (°)	2.62–30.00
Index range	$-19 \leqslant h \leqslant 20$, $-19 \leqslant k \leqslant 19$, $0 \leqslant l \leqslant 27$
Reflexions collected/unique (R_{int})	39970/20296 (0.0393)
Completeness to θ (%)	86.3
Absorption correction	empirical
Data/restraints/parameters	20296/3/917
Goodness-of-fit	1.188
Final R_1, wR_2	0.0469, 0.1146
R_1 (all data), wR_2	0.0476, 0.1152
Extinction coefficient	0.00310(14)
Maximum and minimum residual electron density (e Å^{-3})	0.715 and −0.596

5. Supplementary material

CCDC 620335 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

thermal dependence of the Stark level populations has to be implicitly taken into account. However, when the lanthanide ion is Gd(III), the magneto-structural correlations are not complicated since the f^7 system has no orbital momentum [1h]. With this advantage some magnetically coupled 3d–4f complexes containing Gd(III) have been reported and in most of the cases the magnetic studies are limited to Gd(III)–Cu(II) systems [1a,1d,10a,10b,10c,10g,10l,11c,18,19], with a few exceptions [10l][20]. The interactions between Gd(III) and Cu(II) ions are mostly ferromagnetic with a few exceptions [19a,19c,21]. The nature of the ferromagnetism is generally very weak (J values typically smaller than 10 cm^{-1} [22]) and the extent of the ferromagnetism appears not to depend on the structural details. It is of note that there are a few reports addressing the problem of analysing the magnetic interaction in Ln(III)–Cu(II) couples other than Gd(III)–Cu(II) [10c, 10l,12e,12g,12h,23].

For an assessment and a better understanding of the magnetic interactions between Ln(III)–Cu(II) couples we report here the synthesis, single crystal structure, magnetic property and thermal study of $[Cu_3(IDA)_6Ln_2]\cdot n(H_2O)$ [IDA = iminodiacetate dianion; Ln = Gd, $n = 3$ (**1**); Ln = Nd, $n = 6$ (**2**); Ln = Sm, $n = 6$ (**3**)] and of $[Cu(Cl)(NTA)Sm(H_2O)_6]\cdot(ClO_4)\cdot(H_2O)$ (**4**) [NTA = nitrilotriacetate trianion]. We used IDA and NTA anions since they are flexible and contain nitrogen and oxygen donors suitable for generating heterometallic (3d–4f) systems.

2. Experimental

2.1. Materials

High purity neodymium nitrate hexahydrate, samarium chloride hexahydrate and gadolinium nitrate hexahydrate were purchased from Aldrich Chemical Co. Inc. and were used as received. All other chemicals were of AR grade.

2.2. Physical measurements

Elemental analyses (carbon, hydrogen and nitrogen) were performed using a Perkin–Elmer 240C elemental analyzer. IR spectra were measured from KBr pellets on a Nicolet 520 FTIR spectrometer. The magnetic measurements were carried out in the ''Servei de Magnetoquímica (Universitat de Barcelona)'' on polycrystalline samples (30 mg) with a Quantum Design MPMS XL-5 SQUID susceptometer operating at a magnetic field of 0.1 T between 2 and 300 K. The diamagnetic corrections were evaluated from Pascal's constants. Thermogravimetric analyses were carried out using a Perkin–Elmer DIAMOND TG/DTA machine.

2.3. Synthesis

2.3.1. $[Cu_3(IDA)_6Gd_2]\cdot 3(H_2O)$ (*1*)

An aqueous solution (5 ml) of disodium iminodiacetate (0.177 g, 1 mmol) was added to an aqueous solution (5 ml) of copper perchlorate hexahydrate (0.185 g, 0.5 mmol), resulting in a deep blue solution. To it an aqueous-ethanol (2:1) solution (5 ml) of gadolinium nitrate hexahydrate (0.225 mg, 0.5 mmol) was added drop by drop under stirring conditions. The resultant reaction mixture was transferred into a Teflon-lined steel vessel and heated for 14 h at 140 °C. Overnight cooling of the vessel to room temperature (~27 °C) resulted in shining blue crystals (72 % yield) suitable for X-ray analysis. *Anal.* Calc. $Cu_3Gd_2C_{24}H_{36}N_6O_{27}$ (1345.71): C, 21.40; H, 2.67; N, 6.24. Found: C, 21.41; H, 2.66; N, 6.25%. The infrared spectra exhibited bands in the following regions: 3470–3020 (sbr), 2930 (s), 1627 (vs), 1575 (vs), 1495 (vw), 1453 (w), 1407 (s), 1322 (w), 1115 (w), 1074 (w), 1029 (vw), 946 (vw), 728 (s), 539 (s) cm^{-1}.

2.3.2. $[Cu_3(IDA)_6Nd_2]\cdot 6(H_2O)$ (*2*)

This was synthesized adopting the same procedure as in **1**, using neodymium nitrate hexahydrate (0.219 g, 0.5 mmol) instead of the gadolinium salt. Deep blue crystals for X-ray diffraction were obtained after overnight cooling of the reaction vessel. Yield 70%. Elemental analyses are in good agreement with the calculated values. *Anal.* Calc. $Cu_3Nd_2C_{24}H_{42}N_6O_{30}$ (1373.74): C, 20.96; H, 3.05; N, 6.11. Found: C, 20.97; H, 3.04; N, 6.11%. The infrared spectra exhibited bands in the following regions: 3480–3025 (sbr), 2931 (s), 1622 (vs), 1570 (vs), 1453 (vw), 1407 (s), 1320 (s), 1256 (vw), 1113 (w), 1073 (w), 1028 (w), 946 (w), 726 (s), 539 (s) cm^{-1}.

2.3.3. $[Cu_3(IDA)_6Sm_2]\cdot 6(H_2O)$ (*3*)

An aqueous solution (5 ml) of disodium iminodiacetate (0.177 g, 1 mmol) was added to an aqueous solution (5 ml) of copper perchlorate hexahydrate (0.185 g, 0.5 mmol) under stirring conditions. The resultant blue colored solution was mixed with an aqueous solution (10 ml) of samarium chloride hexahydrate (0.182 g, 0.5 mmol) and refluxed for 1 h and allowed to cool to ambient temperature. The resultant solution was filtered and the filtrate kept in a $CaCl_2$ desiccator. After a few weeks bright blue crystals suitable for X-ray diffraction were obtained. Yield: 68%. *Anal.* Calc. $Cu_3Sm_2C_{24}H_{42}N_6O_{30}$ (1385.96): C, 20.77; H, 3.03; N, 6.06. Found: C, 20.76; H, 3.02; N, 6.07%. The infrared spectra exhibited bands in the following regions: 3490–3015 (sbr), 2932 (s), 1621 (vs), 1571 (vs), 1484 (vw), 1452 (w), 1407 (s), 1320 (w), 1120 (w), 1074 (w), 1027 (vw), 946 (w), 726 (s), 539 (s) cm^{-1}.

2.3.4. $[Cu(Cl)(NTA)Sm(H_2O)_6]\cdot(ClO_4)\cdot(H_2O)$ (*4*)

This was synthesized following the same procedure as for **3** by using trisodium nitrilotriacetate (0.257 g, 1 mmol) instead of disodium iminodiacetate. Blue crystals suitable for X-ray analysis were obtained from the $CaCl_2$ desiccator after two weeks. Yield: 65%. *Anal.* Calc. $CuSmC_6H_{20}NO_{17}Cl_2$ (663.02): C, 10.85; H, 3.01; N, 2.11. Found: C, 10.84; H, 3.01; N, 2.12%. The infrared spectra exhibited bands in the following regions: 3435–3180 (sbr), 2931 (s), 1575 (vs), 1093 (vs), 1115 (s), 927 (w), 624 (w) cm^{-1}.

2.4. Crystallographic data collection and refinement

Crystal data and details of refinements for the structures reported are summarized in Table 1. The data collections of complexes **1** and **2** were carried out on a Bruker-Nonius FR591 rotating anode (Cu Kα, $\lambda = 1.54178$ Å) equipped with a Kappa CCD detector, those of complexes **3** and **4** at 293(3) K by using Mo Kα radiation ($\lambda = 0.71073$ Å) on a Nonius DIP-1030 H system. Cell refinement, indexing and scaling of the data sets were performed using the programs MOSFLM [24], Denzo and Scalepack [25]. The lattice water molecule in **4** was found to be disordered over two close positions (each with an occupancy of 0.5). In **2** and **3**, two peaks were interpreted as water oxygens with half occupancy. The H atoms of these disordered lattice water molecules were not located. All the structures were solved by direct methods and Fourier analyses and refined by the full-matrix least-squares method based on F^2 with all observed reflections [26]. The calculations were performed using the WINGX System, Ver 1.70.01 [27].

3. Results and discussion

3.1. Description of the structures

3.1.1. Complexes *1*, *2* and *3*

The X-ray diffraction analyses indicate that complexes **1**–**3** are isomorphous and show a 3D coordination framework. The copper ion, located on an inversion center, exhibits a highly distorted octahedral coordination sphere, being ligated by nitrogen and carboxylate oxygen donors from two IDA anions, as shown in Fig. 1. The equatorial Cu–O bond distances (1.954(5)–1.964(4) Å) are ca. 0.05 Å shorter in comparison to the Cu–N ones (2.011(4)–2.020(3) Å, Table 2). On the other hand, the apical Cu–O bond lengths are considerably longer (~2.39 Å). The lanthanide ion resides on a crystallographic three-fold axis and is coordinated by three unidentate carboxylate groups through O(2) and chelated by three carboxylate groups through oxygens O(3) and O(4) (Fig. 2). A selection of coordination bond lengths and angles is reported in Table 2, while the shortest intermetallic distances are shown in Table 3. The 3D crystal packing represented in Fig. 3 shows a tubular channel running parallel to the *c* axis, and Fig. 4 is a view down axis *a*. In complexes **2** and **3** these empty spaces are occupied by six lattice water molecules per formula unit, while only three water molecules were located in the crystal of **1**, the potential volume available for solvent being about 28% in these unit cells (Table 3), as calculated with the program PLATON. It is interesting to note that the water molecules do not form H-bonds with the framework atoms, but only amongst themselves: the channels appear in fact hydrophobic in character, the methylene $C(3)H_2$ groups drawing the inner channel surface. Table 4 lists the isomorphous $[Cu_3(IDA)_6M_2]\cdot nH_2O$ structures, crystallizing in the space group *P*-3*c*1, reported to date. An analysis of these data indicates that there is a linear trend of the crystal

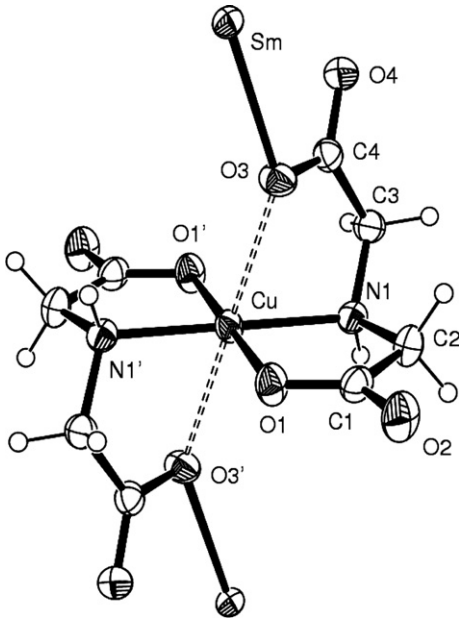

Fig. 1. Centrosymmetric coordination sphere of the copper ion in complex **3** (ORTEP drawing, 40% probability ellipsoid) [the same scheme applies also to **1** and **2**].

parameters *a* and *c*, as well as of the cell volume with the atomic radius of the respective metal ion(III). The number of water molecules per unit formula of the structures (Table 4) varies between 0 and 8. This feature seems also to modulate small differences observed in the crystal structure parameters. In fact Long et al. reported a thermogravimetric studies for a series of Cu/M polymers (M = La, Eu) [28]. They observed that

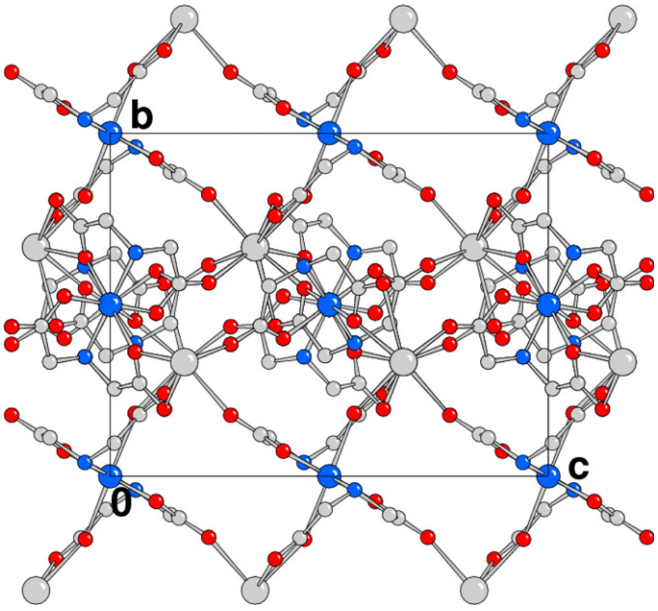

Fig. 4. View of crystal packing of complex **3** down axis *a* (water molecules not shown for clarity).

after dehydration the number of water molecules reabsorbed by the frameworks is less than the original one, i.e. five versus eight of the starting material. Moreover, the cell axes and the cell volume are slightly larger after this process (see entries of La and Eu of Table 3). This trend is confirmed in the Nd derivatives: the cell parameters of complex **2**, containing six water molecules, appear slightly larger than the values reported in the literature [28] for the structure with eight molecules. This effect is even more enhanced in Gd (complex **1**) in comparison to the structure reported [29]. The latter complex, which does not contain any lattice water molecule, retains a volume 70 $Å^3$ more.

3.1.2. Complex *4*

The structure shows a 1D polymeric chain of alternating copper and samarium ions connected by NTA (Fig. 5) in a *zig-zag* arrangement. The Cu–Sm distance is 4.687(2) Å with a Sm–Cu–Sm′ angle of 129.71(3)°. Both the Cu–Cu

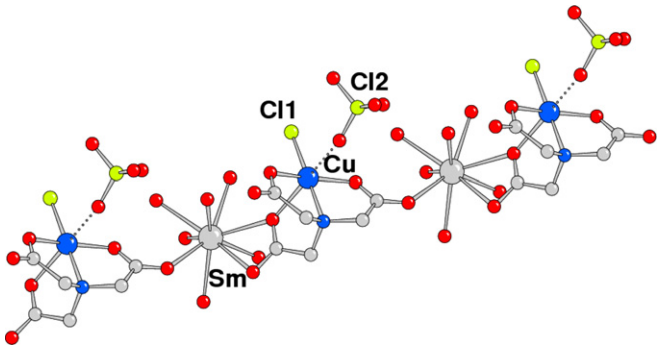

Fig. 5. 1D polymeric chain of complex **4**.

and Sm–Sm intermetallic distances along the chain are 9.479(3) Å, corresponding to the crystallographic *c* axis. The copper coordination sphere is distorted square pyramidal, being coordinated in the basal plane by two carboxylate oxygens, the nitrilotriacetate nitrogen donor and by a chloride, while the apical position is occupied by an oxygen from the third carboxylate group of the NTA ligand. The equatorial Cu–O bond lengths (Cu–O(3) 1.961(6), Cu–O(1) 1.980(6) Å) are slightly shorter than the Cu–N one (2.051(6) Å). The Cu–Cl(1) bond distance is 2.231(2) Å and the apical Cu–O(5) one is 2.269(5) Å. The geometrical parameters are as expected for this kind of complex, with bond angles that show significant deviations from the ideal values (Table 5). The atoms in the equatorial plane are coplanar to within ±0.16 Å, with the copper displaced from the mean plane by 0.12 Å towards O(5). However, it is worth noting that the copper(II) ion appears also to interact with a perchlorate oxygen at a longer distance (2.83(1) Å). The samarium(III) ion is nine coordinated by six water molecules, a chelating NTA carboxylate group, and by another oxygen O(4) from a symmetry related carboxylate of NTA (Fig. 6). The Sm–O distances fall in the range 2.451(6)–2.596(5) Å, the longest values being those relative to the chelating carboxylate, and the corresponding O(5)–Sm–O(6) bond angle is the narrowest at 50.34(17)°.

The crystal packing shows an extensive H-bonding scheme occurring between coordinated and lattice water

molecules with carboxylate and perchlorate oxygen atoms, as reported in Table 6, leading to a 3D architecture. The cell parameters of complex **4** are longer than those measured in the isomorphous Gd complex [32], in agreement with the smaller Gd(III) ion radius. The cited paper reports other complexes of the general formula $[Cu(Cl)(NTA)Ln(H_2O)_6]\cdot(ClO_4)\cdot(H_2O)$ (Ln = La, Gd, Er), crystallizing in different space groups.

3.2. Magnetic properties

The electronic configuration, the ground and low-lying excited states, the g value of the ground state, the energy average difference between these two states and the standard $\chi_M T$ values for the four Ln(III) ions utilized in this work are given in Table 7.

3.2.1. Complex *1*

The temperature dependence of $\chi_M T$ for complex **1** is shown in Fig. 7 (χ_M being the molar magnetic susceptibility for a Cu_3Gd_2 entity). $\chi_M T$ at 300 K is 17 $cm^3\,mol^{-1}\,K$, a value that is as expected for three isolated Cu^{II} plus two Gd^{III} ions (16.87 $cm^3\,mol^{-1}\,K$ assuming $g = 2.00$). Decreasing the temperature, $\chi_M T$ values increase monotonically to 24.6 $cm^3\,mol^{-1}\,K$ at 2 K. The shape of the curve indicates weak ferromagnetic coupling, in agreement with the coupling reported for these Cu^{II}–Gd^{III} systems (vide supra). Taking into account the three-dimensional character of the net, it is impossible to fit the $\chi_M T$ values. The curve of the reduced magnetization ($M/N\beta$) versus H is shown in Fig. 7 (inset). The experimental data tend to 17 $N\beta$ (electrons), which is in perfect agreement with the number of electrons for the formula unit (Cu_3Gd_2).

Gd^{III} is an f^7 ion, with an ^8S ground state. Since the excited states are relatively high in energy, the zero-field splitting of the ground state is fairly small (less than 1 cm^{-1}) so that $S = 7/2$ is a good quantum number. Thus, the coupling of the spin momentum of gadolinium and copper can be described by the typical isotropic spin Hamiltonian $H = -J_{ij}\Sigma S_i S_j$. This is not true for any other lanthanide(III) ions. The ferromagnetic character of the interaction between Cu^{II} and Gd^{III} is rather general and was attributed to the coupling between the 4f–3d ground configuration and the excited configuration coming from the 3dCu → 5dGd electron transfer [1d,33], following a mechanism first suggested by Goodenough [34]. This electron transfer integral involves the singly occupied copper orbital and the five 5d gadolinium orbitals. Several magneto-structural studies concerning the Cu^{II}–Gd^{III} spin carriers separated by mono- or polyatomic bridges have shown the occurrence of a significant ferromagnetic interaction between these cations in di- [35], tri- [1b,10a,10b,36], tetra- [11c], penta-nuclear [12h,37], ladder-like [12a] and tube-like [12b,12c] structures. However, the hypothesis that ferromagnetism is an intrinsic property of the Cu^{II}–Gd^{III} couple, irrespective of the nuclearity and the nature of the bridging ligand, was questioned by Costes et al. who recently reported on the first magneto structurally characterized examples of discrete dinuclear [Cu^{II}–Gd^{III}] [38] and trinuclear [Cu^{II}–Gd^{III}–Cu^{II}] [10l,19a] unit species showing weak antiferromagnetism. These results point out the need of more experimental/theoretical studies

Table 6

about this heterometallic system in order to get a clear answer on the nature and pathway of the involved magnetic coupling.

3.2.2. Complex *2*

Taking into account the molecular formula of **2**, the magnetic properties have been given for a Nd_2Cu_3 unit. Thus the $\chi_M T$ and $1/\chi_M$ (inset) versus *T* plots (χ_M is the molar magnetic susceptibility for the Nd_2Cu_3 entity) are shown in Fig. 8. The value of $\chi_M T$ at 300 K is 4.08 $cm^3\ mol^{-1}$ K, which is slightly smaller than the value expected for two magnetically quasi-isolated Nd^{III} ions ($2 \times 1.64\ cm^3\ mol^{-1}$ K) [39] plus three isolated Cu^{II} ions (ca. $3 \times 0.4\ cm^3\ mol^{-1}$ K), namely 4.48 $cm^3\ mol^{-1}$ K. The value of 1.64 $cm^3\ mol^{-1}$ K for a Nd^{III} free ion ($g = 8/11$) [39] can change in a given complex, but the variation should be small, owing to the character of the f^n complexes [39]. The $\chi_M T$ values monotonically decrease from r.t. to approximately 20 K and then quickly decreases to 1.716 $cm^3\ mol^{-1}$ K at 2 K. The extrapolation of the $1/\chi_M$ curve (Fig. 8, inset) will cut the *T* axis at negative temperature. At a first approach this feature may indicate antiferromagnetic character, but as suggested by Kahn, 'it is important to point out that the deviation with respect to the Curie law may have other origins than the magnetic interactions' [39]. In particular, for elements with strong spin–orbit coupling, like Nd^{III} (f^3), the deviation from the Curie law is not necessarily an indication of ferro- or antiferromagnetic interactions.

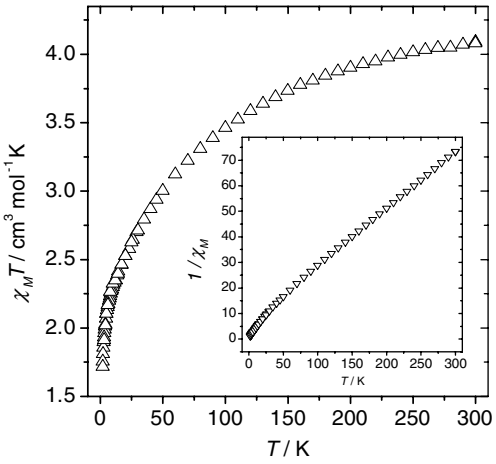

Fig. 8. Plot of $\chi_M T$ vs. *T* and $1/\chi_M$ vs. *T* (inset) for complex **2**.

3.2.3. Complexes 3 and 4

The theoretical $\chi_M T$ value for the Sm^{3+} ion would be ca. 0.1 $cm^3\ mol^{-1}\ K$ if the ground multiplet were the only populated. However the spin–orbit coupling is of the order of 200 cm^{-1}, such that the first excited state $^6H_{7/2}$ can be populated at room temperature (a gap between ground and first excited state of ca. 1000 cm^{-1}). For this reason, the average experimental $\chi_M T$ values are close to 0.3–0.4 $cm^3\ mol^{-1}\ K$ rather than 0.1 [39,40]. When the temperature approaches to 0 K, $\chi_M T$ tends to 0.09 $cm^3\ mol^{-1}\ K$ [39].

The $\chi_M T$ versus T plot for **3** (for $2Sm^{III} + 3Cu^{II}$ ions) is shown in Fig. 9. The expected (theoretical) $\chi_M T$ value at room temperature should be ca. 0.6 $(2Sm^{3+}) + 1.2$ $(3Cu^{2+}) \approx 1.8\ cm^3\ mol^{-1}\ K$, in good agreement with the experimental value (Fig. 10). The decrease of the curve from room temperature to 10 K is due to the effect of spin–orbit coupling of the Sm^{3+} ion. At very low temperature the pronounced decrease in the shape of the curve could indicate small antiferromagnetic coupling.

The $\chi_M T$ versus T plot for **4** ($1Sm^{III} + 1Cu^{II}$ ions per formula unit) is shown in Fig. 10. The expected $\chi_M T$ value at room temperature should be ca. 0.4 $(1Sm^{3+}) + 0.4$ $(1Cu^{2+}) \approx 0.8\ cm^3\ mol^{-1}\ K$, slightly smaller than the experimental value (Fig. 10) (vide infra, complex **2**). The monotonous decrease of the curve from room temperature to 2 K is due to the spin–orbit coupling effect of the Sm^{3+} ion. Thus there is no evidence of any magnetic coupling. For complexes **3** and **4**, as it occurs with all lanthanide (with the exception of Gd^{3+}) it is impossible for any calculation of the J parameter.

3.3. TGA and XRPD studies

Thermogravimetric analyses (Fig. 1S) reveal that complexes **1**–**3** lose water molecules in a single step, showing weight decreases of 4.013%, 7.862% and 7.792% corresponding to the loss of three, six and six water molecules, respectively, that corroborates the content of water molecules found in the crystal lattice. The initial (T_i) and final (T_f) temperatures of deaquation are $T_i = 50$ °C, $T_f = 75$ °C for **1**; 40, 80 °C for **2**, and 60, 100 °C for **3**, and the deaquated species of complexes **1**–**3** are stable up to 290, 340 and 320 °C, respectively. On exposure to humid atmosphere (RH ~ 90%), they revert as evidenced by IR spectra, TGA and X-ray powder diffraction (XRPD) studies (Fig. 11). However, the XRPD patterns of the initially

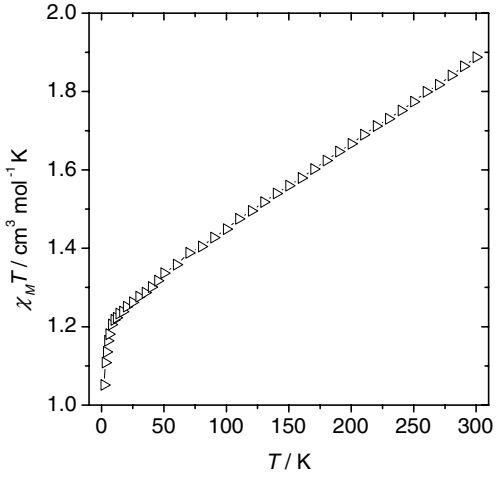

Fig. 9. Plot of $\chi_M T$ vs. T for complex **3**.

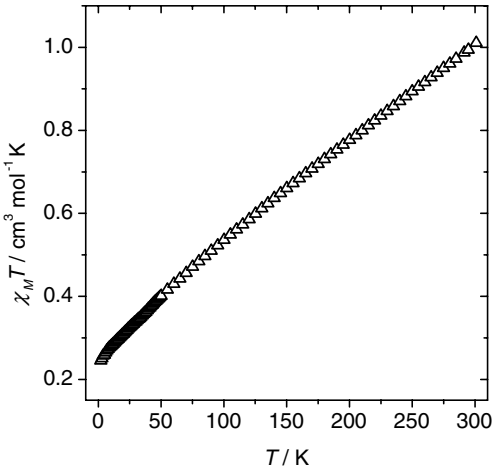

Fig. 10. Plot of $\chi_M T$ vs. T for complex **4**.

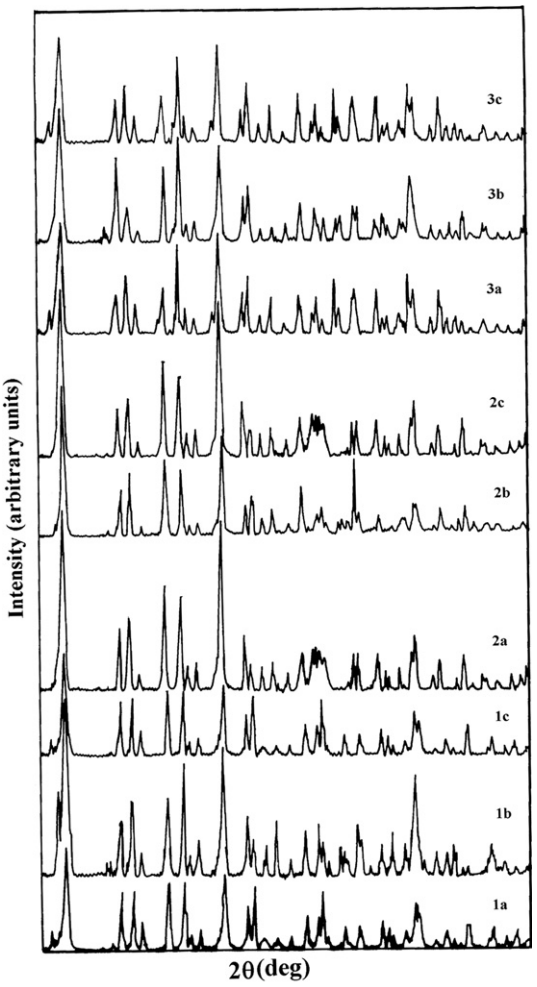

Fig. 11. XRPD patterns of complexes **1**–**3**: (a) as synthesized, (b) dehydrated, (c) rehydrated.

synthesized complexes and their corresponding deaquated species are very similar, which questions the stability of the deaquated species at ambient temperature. By carrying out the XRPD measurement at lower humidity (RH ~ 60%) the absorption of water molecules from atmosphere is avoided. The above mentioned observations suggest that the basic metal-organic frameworks are highly stable and remain practically unaffected even after removal of lattice water molecules, which have no strong interaction with the host network. Finally, the thermogravimetric analysis for complex **4** is hampered by the presence of the perchlorate anion that immediately explodes upon heating.

4. Conclusion

In summary, we have prepared and structurally characterized four heterometallic 3d–4f polymeric architectures. Complexes **1**–**3** are isomorphous, having a covalent bonded 3D polymeric network with tubular channels occupied by lattice water molecules. Complex **4** is a covalent bonded 1D chain which through H-bonding transforms into a 3D supramolecular network. Low temperature magnetic study indicates ferromagnetic behavior in the case of complex **1**. Covalent bonded networks are stable up to ~300 °C in the solid state and the deaquated networks show very similar XRPD patterns as the hydrated species, which indicates the basic metal-organic frameworks remain almost unchanged after removal of channel water molecules.

of *trans*-bis(ferrocenecarboxylato)(5,10,15,20-tetraphenylporphyrinato)tin(IV).

2. Experiments

2.1. Materials and measurements

Ferrocenecarboxylic acid was purchased from Aldrich, and *trans*-dihydroxo(5,10,15,20-tetraphenylporphyrinato)-tin(IV), **Sn(TPP)(OH)$_2$** was prepared by the reported procedure [11]. CH_2Cl_2 was purified by distillation over CaH_2. UV–Vis and IR spectra were recorded on a Hewlett-Packard 8453 diode array and a Jasco FTIR-460 Plus spectrophotometers, respectively. ^{1}H and ^{13}C NMR spectra were obtained on a Bruker DRX-500 spectrometer. MALDI-TOF mass spectra were recorded on a Bruker Daltonics Reflex III spectrometer. Elemental analyses were performed on a ThermoQuest EA 1110 analyzer.

2.2. Synthesis

2.2.1. trans-Bis(ferrocenecarboxylato)(5,10,15,20-tetraphenylporphyrinato)tin(IV) Sn(TPP)(FcCOO)$_2$

trans-Dihydroxo(5,10,15,20-tetraphenylporphyrinato)-tin(IV) (100 mg, 0.13 mmol) and ferrocenecarboxylic acid (59 mg, 0.26 mmol) were dissolved in anhydrous CH_2Cl_2 (20 mL). The reaction mixture was stirred at room temperature. After 24 h, the solution was filtered through a Celite pad. The solvent of the filtrate was evaporated under reduced pressure to give a crude product. It was then recrystallized from CH_2Cl_2/CH_3CN solution to afford crystalline solids of *trans*-bis(ferrocenecarboxylato)(5,10,15,20-tetraphenylporphyrinato)tin(IV) **Sn(TPP)(FcCOO)$_2$**. Yield: 100 mg (66%). ^{1}H NMR (500 MHz, $CDCl_3$): δ 9.25 (s, 8H, β-pyrrolic H, ^4J(Sn–H) = 14.3 Hz), 8.36 (d, J = 6.76 Hz, 8H, *o*-Ph), 7.81 (m, 12H, *m*-Ph + *p*-Ph), 3.19 (s, 4H, η^5-C_5H_4COO), 2.57 (s, 10H, η^5-C_5H_5), 2.13 (s, 4H, η^5-C_5H_4COO). ^{13}C NMR ($CDCl_3$): δ 166.5, 147.3, 141.3, 135.2, 133.0, 128.6, 127.2, 121.8, 74.4, 68.7, 68.5, 68.4. UV–Vis (CH_2Cl_2, nm): λ_{max} (log ε) 404(4.00), 424(5.16), 521(2.95), 560(3.68), 600(3.41). IR (KBr, cm^{-1}): ν_{CO} 1644, 1299. MS (MALDI-TOF): m/z 961.08 [(M–O_2CFc)$^+$ requires 961.13]. *Anal.* Calc. for $C_{66}H_{46}N_4O_4Fe_2Sn$: C, 66.64; H, 3.90; N, 4.71. Found: C, 66.82; H, 3.48; N, 4.91%.

2.3. X-ray crystal structure determination

Single crystals suitable for X-ray work were grown by slow diffusion of CH_3CN into a CH_2Cl_2 solution of **Sn(TPP)(FcCOO)$_2$**. A crystal covered with Paratone-N hydrocarbon oil on a glass fiber was mounted on a Bruker AXS SMART APEX II single crystal diffractometer equipped with a graphite monochromated Mo Kα (λ = 0.71073 Å) radiation source and a CCD area detector. Three sets of 20 frames of two-dimensional diffraction images were collected and processed to deduce a cell parameter and orientation matrix. Data collection was performed at 100 K. Crystal data and structure refinement for **Sn(TPP)(FcCOO)$_2$** are summarized in Table 1. The intensity data were corrected for Lorentz and polarization effects. Empirical absorption correction was also applied (SADABS) [12]. The structure was solved by the direct method and refined initially by full-matrix least-squares method (SHELXTL) [13]. All atoms were refined anisotropically for non-hydrogen atoms and isotropically for hydrogen atoms. Final block-diagonal matrix least-squares refinement on F^2 with all 6154 reflections and 349 variables converged to R_1 ($I > 2\sigma(I)$) = 0.0342, wR_2 (all data) = 0.0814, and GOF = 1.040.

2.4. Electrochemistry

Cyclic voltammetry and square wave voltammetry were performed with a Princeton Applied Research potentiostat/galvanostat 2273 multipurpose instrument interfaced to a personal computer. Anhydrous THF (Aldrich) was used as the solvent under an argon atmosphere, and 0.2 M tetrabutylammonium hexafluorophosphaste (Bu_4NPF_6) was used as the supporting electrolyte. Cyclic voltammograms were obtained from approximately 5×10^{-4} M solutions of the samples in 0.2 M Bu_4NPF_6/THF inside Faraday cage. A standard three-electrode cell was

Table 1

R indices (all data)	R_1 = 0.0565, wR_2 = 0.0814

$R_1 = \sum(|F_o| - |F_c|)/\sum|F_o|$; $wR_2 = [\sum w(F_o^2 - F_c^2)^2/\sum w(F_o^2)^2]^{0.5}$

used, with a glassy carbon working electrode (diameter: 3.0 mm), a platinum counter electrode, and a silver wire electrode as a pseudo reference electrode. All the redox potential values are reported relative to the ferrocene/ferrocenium (Fc/Fc^{+}) redox couple used as the internal standard. All solutions were deoxygenated by purging with argon gas and maintained under an inert atmosphere during the electrochemical experiments.

3. Results and discussion

Bis(ferrocenecarboxylato)tin(IV) porphyrin complex **Sn(TPP)(FcCOO)$_2$** was synthesized by the reaction of *trans*-dihydroxo(5,10,15,20-tetraphenylporphyrinato)tin(IV) complex **Sn(TPP)(OH)$_2$** with 2 equiv. of ferrocenecarboxylic acid, **FcCOOH**, as shown in Scheme 1. The complex **Sn(TPP)(FcCOO)$_2$** was fully characterized by various spectroscopic methods and elemental analysis. In the ^{1}H NMR spectrum of **Sn(TPP)(FcCOO)$_2$**, three singlet resonances attributed to the protons of the cyclopentadienyl ring in ferrocenecarboxlate moiety are significantly shifted to higher field compared to those of free **FcCOOH**, as depicted in Fig. 1. The significant upfield shifts of these resonances due to the large shielding by the porphyrin ring current strongly support that ferrocenecarboxlate moiety is linked to the tin(IV) porphyrin moiety via tin(IV)-carboxylate coordination. The IR spectrum of **Sn(TPP)- (FcCOO)$_2$** also indicates the tin(IV)-carboxylate coordination, since the absorbing frequency for the C=O stretching mode of **Sn(TPP)(FcCOO)$_2$** appears at 1644 cm^{-1} which is lower than that at 1657 cm^{-1} of free **FcCOOH**. The MALDI-TOF mass spectrum of **Sn(TPP)(FcCOO)$_2$** exhibits a

Scheme 1.

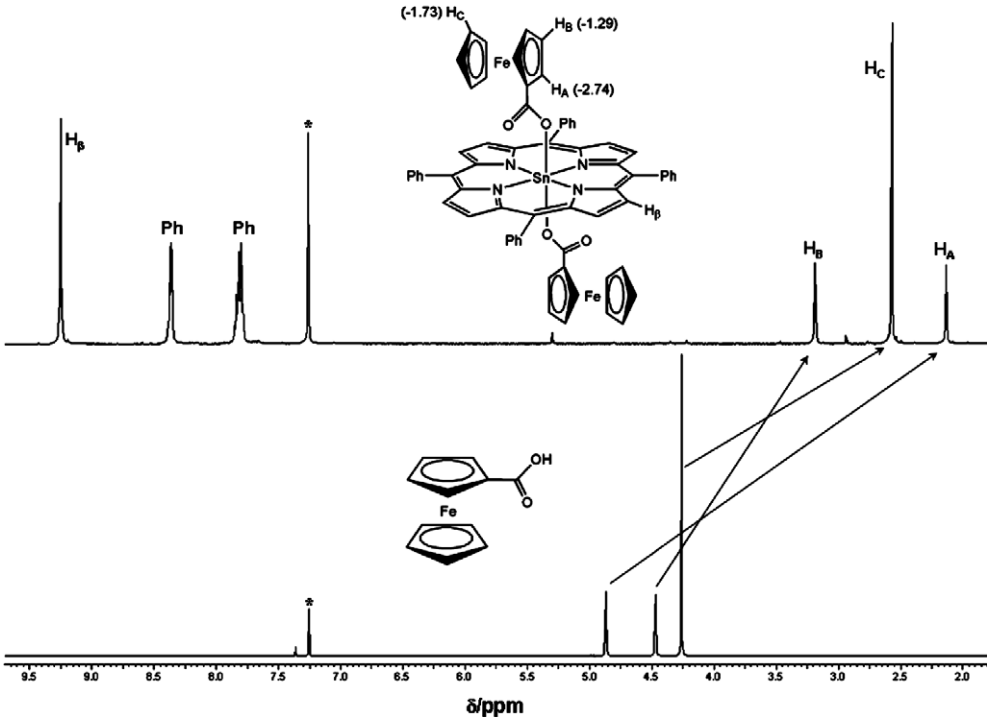

Fig. 1. ^{1}H NMR spectra of **Sn(TPP)(FcCOO)$_2$** (top) and free ferrocenecarboxylic acid (bottom). Porphyrin-induced shifts ($\Delta\delta$/ppm) are shown with the chemical structure of **Sn(TPP)(FcCOO)$_2$** in which $\Delta\delta = \delta$(complex) $- \delta$(free acid). The resonances represented by asterisk correspond to a residual $CHCl_3$ peak.

parent ion peak at $m/z = 961.08$ resulting from the loss of one ferrocenecarboxlate ligand although the molecular ion peak was not observed under our condition. Such ligand lability of tin(IV) porphyrin complexes in the mass spectrometry has been commonly observed [11].

The structure of **Sn(TPP)(FcCOO)$_2$** has been confirmed by X-ray crystallography. Single crystals of **Sn(TPP)(FcCOO)$_2$** suitable for X-ray crystallography were grown from the slow diffusion of CH_3CN into a CH_2Cl_2 solution of **Sn(TPP)(FcCOO)$_2$**. The X-ray structural analysis of **Sn(TPP)(FcCOO)$_2$** revealed the expected axially coordinated structure with 1:2 stoichiometry of the tin(IV) porphyrin and ferrocenecarboxylate moieties, as illustrated in Fig. 2. The tin center is octahedrally coordinated by the porphyrin occupying the square base and axial coordination of two ferrocenecarboxylato ligands. The tin atom lies on an inversion center, so that the two ferrocenecarboxylato ligands are exactly oriented to opposite sides with respect to each other. Such *anti* orientation of the carboxylato ligands is commonly found in other carboxylato-tin(IV) porphyrin complexes [3b,7a,14] as well as in structures where ferrocene molecules bind to metals in porphyrin rings [15].

The selected bond distances and angles for **Sn(TPP)(FcCOO)$_2$** are given in Table 2. The two Sn–N bond distances (2.094(2) and 2.093(2) Å) are almost identical to each other, and the Sn–O distance is found to be 2.0730(16) Å. Comparing these structural parameters with those found in a phthalocyaninato-silicon(IV) analogue **Si(Pc)(FcCOO)$_2$** [16], the much longer bond lengths in **Sn(TPP)(FcCOO)$_2$** than those (av. Si–N 1.906(4) and av. Si–O 1.751(3) Å) in **Si(Pc)(FcCOO)$_2$** are mainly caused by the larger ionic radius of Sn^{IV} (0.83 Å) versus Si^{IV} (0.54 Å) [17]. On the other hand, the Sn–O distance in **Sn(TPP)(FcCOO)$_2$** is longer than that (2.055(5) Å) of the corresponding benzoate complex **Sn(TPP)(PhCOO)$_2$** [14a]. Ligands of high basicity generally have short Sn–O

Table 2
Selected bond distances (Å) and angles (°) for **Sn(TPP)(FcCOO)$_2$**

Sn–N1	2.095(2)	O1–Sn–O1$^{\#1}$	180.00(16)
Sn–N2	2.093(2)	O1–Sn–N2	95.72(7)
Sn–O1	2.0730(16)	O1$^{\#1}$–Sn–N2	84.28(7)
Fe–C24	2.027(2)	N2–Sn–N2$^{\#1}$	180.00(19)

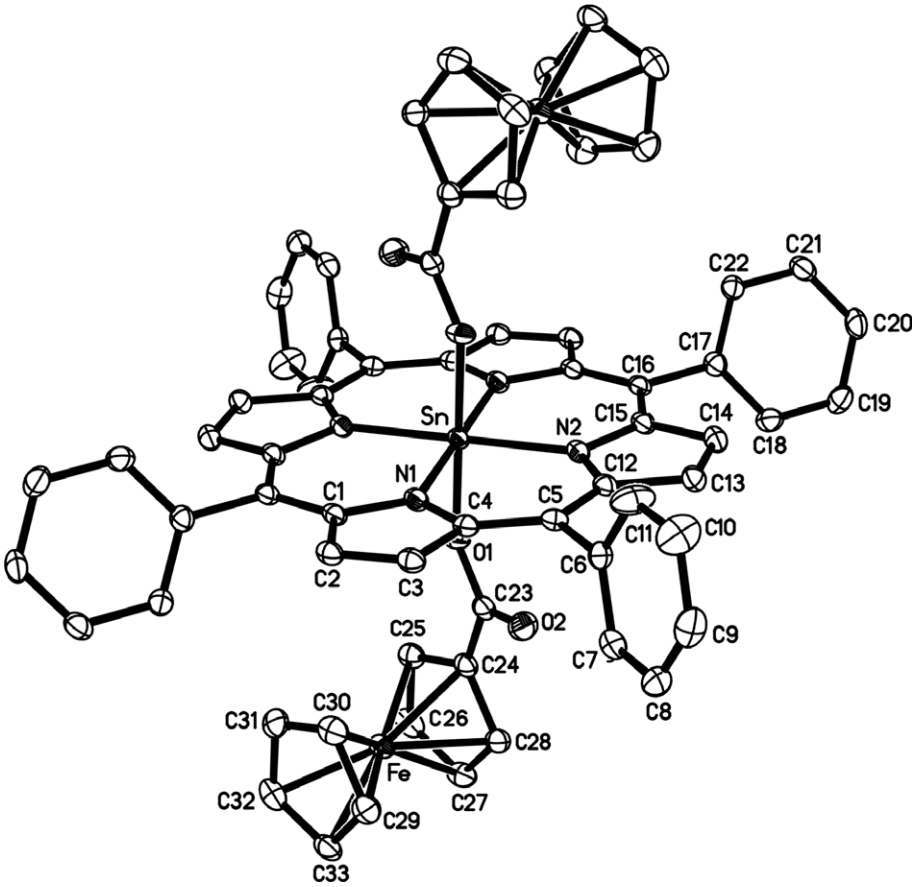

Fig. 2. An ORTEP view of the molecular structure of **Sn(TPP)(FcCOO)$_2$** drawn at 50% probability level. The hydrogen atoms are omitted for clarity.

bonds in the tin(IV) porphyrin complexes [1a]. It can be thus deduced that the basicity of the ferrocenecarboxylate ligand would be weaker than that of benzoate ligand.

The second carboxylate oxygen being 3.325 Å from the tin(IV) ion strongly suggests that the interaction of the carboxylate group with the tin(IV) ion is purely monodentate. The bond lengths for the two carbon–oxygen bonds of carboxylate unit are significantly different. The nonbonding C═O length (C23–O2; 1.228(3) Å) is much smaller than the bonding C–O length (C23–O1; 1.301(3) Å). Furthermore, the former length is even smaller than that (1.26 Å) found in ferrocenedicarboxylic acid [18] which forms hydrogen-bonded dimer in the crystal lattice, but is comparable to those found in diacetylferrocene (1.217 Å) [19]. The monodenate binding of the carboxylate groups in **Sn(TPP)(FcCOO)$_2$** revealed by X-ray crystallography further confirms the IR spectroscopic method of assigning bond type of the carboxylates in **Sn(TPP)(FcCOO)$_2$**. The frequency difference between the asymmetric (1644 cm^{-1}) and symmetric (1299 cm^{-1}) C–O vibration is 345 cm^{-1}. This is indicative of monodentate binding because the ionic bidentate carboxylates normally exhibit frequency differences less than 160 cm^{-1} [20].

The Fe(II) center of the ferrocenecarboxylato ligand lies 5.703 Å from the tin(IV) center of the porphyrin ring. The bond distances associated with the ferrocenecarboxylato ligand of **Sn(TPP)(FcCOO)$_2$** are within the usual range found in other structures containing this ligand. The carboxylate groups are approximately coplanar with the cyclopentadienyl ring to which they bond (torsion angle of O1–C23–C24–C28, 170°). The η^5-C_5H_4COO and η^5-C_5H_5 rings in each ferrocenecarboxylato ligand are coordinated the Fe(II) ion with the eclipsed conformation. But the two cyclopentadienyl rings are not perfectly parallel to each other. The η^5-C_5H_4COO ring is slightly tilted with respect to the η^5-C_5H_5 ring by about 7.6(5)°, and the bond distances of Fe–C24 (2.027(2) Å) and Fe–C30 (2.029(3) Å) are rather shorter than those between the Fe(II) ion and other carbons (2.034(3)–2.055(3) Å) in the cyclopentadienyl rings.

The electrochemical behavior of **Sn(TPP)(FcCOO)$_2$** was examined by cyclic voltammetry and square wave voltammetry. The cyclic and the square wave voltammograms of **Sn(TPP)(FcCOO)$_2$** are compared with those of **Sn(TPP)(OH)$_2$** and free **FcCOOH**, as shown in Fig. 3. Their half-wave redox potentials are also summarized in Table 3. The half-wave potentials were determined using square wave voltammetry relative to a ferrocene/ferrocenium redox potential. The half-wave potential of the ferrocenecarboxylato groups in **Sn(TPP)(FcCOO)$_2$** was found to be at 0.11 V as a single reversible oxidation wave, which implies that they apparently undergo simultaneous rather than sequential oxidation and reduction. The oxidation potential of the ligand is more negative than that of free **FcCOOH** at 0.22 V in the same solvent. It is thus easier to oxidize this moiety when it is complexed to Sn(TPP) moiety than it is uncomplexed. On the other hand, two

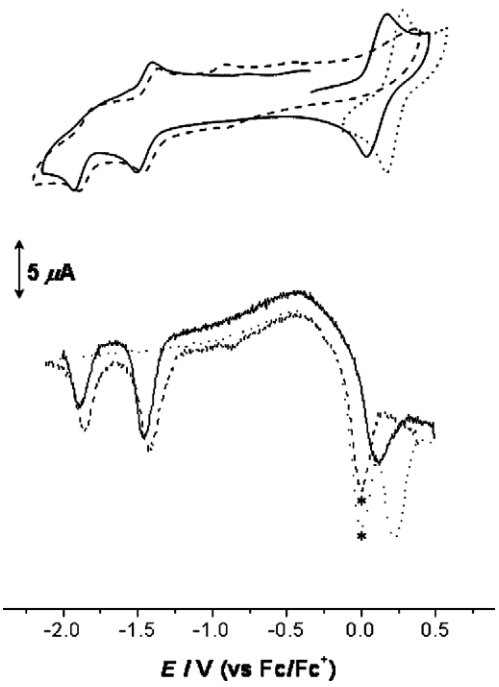

Fig. 3. Cyclic voltammograms (top) and square wave voltammograms (bottom) at scan rate 0.1 V s^{-1} of **Sn(TPP)(FcCOO)$_2$** (solid), **Sn(TPP)(OH)$_2$** (dashed), and free **FcCOOH** (dotted) in THF with 0.2 M Bu_4NPF_6 as the supporting electrolyte. The redox peaks represented by asterisk are attributed to the ferrocene/ferrocenium redox couple used as the internal standard.

Table 3
Half-wave potentials (V vs. Fc/Fc$^+$) of **Sn(TPP)(FcCOO)$_2$**, **Sn(TPP)(OH)$_2$**, and **FcCOOH** in THF, 0.2 M Bu_4NPF_6

Complex	Oxidation (ferrocene moiety)	Reduction (porphyrin ring)
Sn(TPP)(FcCOO)$_2$	0.11	−1.47, −1.89
Sn(TPP)(OH)$_2$		−1.42, −1.85
FcCOOH	0.22	

reduction waves were clearly observed at −1.47 and −1.89 V, which are caused by the reduction of the porphyrin ring in **Sn(TPP)(FcCOO)$_2$**. The first reduction wave is apparently quasi-reversible and the second one appears to be irreversible. The half-wave potentials of the both reduction for **Sn(TPP)(FcCOO)$_2$** are shifted to slightly more negative potential compared to those of **Sn(TPP)(OH)$_2$** (−1.42, −1.85 V).

4. Conclusion

We have synthesized and fully characterized *trans*-bis(ferrocenecarboxylato)(5,10,15,20-tetraphenylporphyrinato)tin(IV) complex, **Sn(TPP)(FcCOO)$_2$**. The molecular structure of **Sn(TPP)(FcCOO)$_2$** has been confirmed by X-ray crystallography, in which the tin(IV) center is octahedrally coordinated by the porphyrin occupying the square base and axial coordination of two ferrocenecarboxylato ligands in an *anti* orientation with respect to

each other. The cyclic voltammetry for **Sn(TPP)-(FcCOO)$_2$** exhibits three distinctive redox couples consisting of one oxidative wave and two reductive waves due to the ferrocenecarboxylato ligands and the porphyrin ring, respectively. We have also carried out the investigation of photophysical properties in conjunction with the process of the photoinduced electron transfer in **Sn(TPP)(FcCOO)$_2$** [21].

Schlenk tube under nitrogen for 12 days at −25 °C led to the deposition of colourless, needle-shaped crystals. The ^{1}H NMR spectrum of this compound showed two methylene signals at δ 3.28 and δ −1.11 in a 1:1 intensity ratio, commensurate with O-bound and Mg-bound CH_2SiMe_3, respectively, and suggested the formation of a magnesium alkyl alkoxide. The corresponding two $SiMe_3$ signals appeared at δ 0.28 and 0.11.

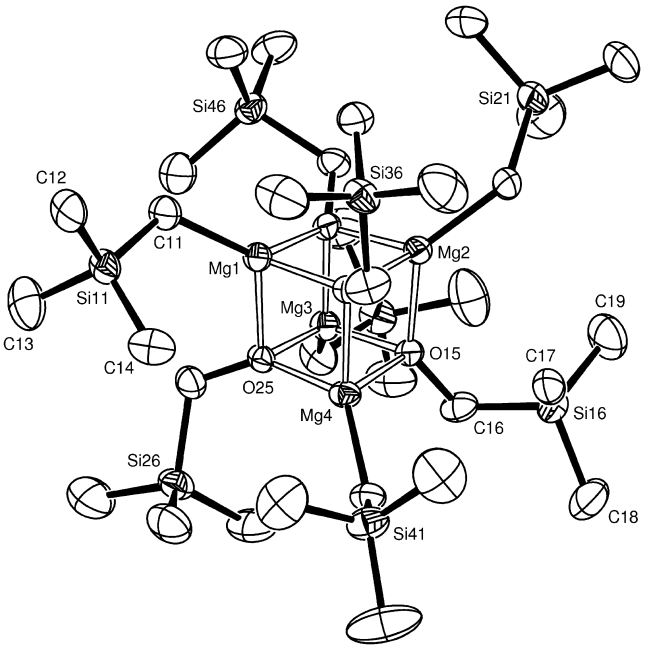
Crystals of sufficient quality for single-crystal X-ray diffraction were obtained from a light petroleum solution at −25 °C. The compound was identified as $[Mg(CH_2SiMe_3)(\mu^3\text{-}OCH_2SiMe_3)]_4$ (**1**). There are two independent molecules in the crystal differing principally in their orientation. The structure of one of these molecules is depicted in Fig. 1. Selected bond lengths and angles are collected in Table 1.

Each magnesium atom has essentially tetrahedral coordination and is bonded to one alkyl ligand and three bridging oxygen atoms of the cluster core. Whereas the O–Mg–O angles are acute (mean angle 85.05(12)°), the Mg–O–Mg angles are noticeably obtuse (mean 94.73(13)°). The mean Mg···Mg distance in the two molecules of **1** is 3.018(5) Å. The CH_2SiMe_3 groups are bound to the Mg and O atoms in directions that deviate slightly from the direction of the corresponding cubane space diagonals, presumably as the result of steric interactions of the bulky CH_2SiMe_3 groups; the deviations about the O atoms are significantly greater than those about the Mg atoms (Table 1). We note that there are two groups of Mg–O–C angles (denoted #1 and #2 in Table 1), one at *ca* 135° and two at *ca* 114°, at each O atom; similarly, the three C–Mg–O angles at each Mg show a wide range of values, but these are divided less clearly into three groups, with angles of *ca* 123°, 128° and 133°. We cannot identify any systematic pattern in the arrangement of $SiMe_3$ groups about the central Mg_4O_4 core. There are no noteworthy intermolecular contacts.

Table 1
Selected mean and ranges of bond lengths (Å) and angles (°) in the two molecules of **1**

	Mean length	Range of lengths
Mg···Mg	3.018(5)	2.993(2)–3.043(2)
Mg–O	2.051(2)	2.032(3)–2.067(3)
Mg–C	2.092(3)	2.080(4)–2.102(4)
(Mg)C–Si	1.841(2)	1.834(4)–1.845(4)
$(MgCH_2)Si–C_{Me}$	1.867(3)	1.843(5)–1.885(4)
O–C	1.463(3)	1.453(4)–1.473(4)
(O)C–Si	1.878(3)	1.866(4)–1.887(4)
$(OCH_2)Si–C_{Me}$	1.855(2)	1.838(5)–1.873(4)
	Mean angle	Range of angles
O–Mg–O	85.05(12)	83.79(11)–85.95(11)
C–Mg–O	128.6(9)	119.73(14)–135.29(15)
Mg–O–Mg	94.73(13)	93.82(10)–95.60(11)
Mg–O–C (#1)	135.5(11)	131.5(2)–139.9(2)
Mg–O–C (#2)	114.3(5)	111.7(2)–118.7(3)
Mg–C–Si (#1)	127.8(3)	127.1(2)–128.3(2)
Mg–C–Si (#2)	122.5(3)	122.0(2)–123.3(3)
O–C–Si	117.7(4)	116.4(2)–119.9(3)
C–Mg···O[a]	174.7(8)	171.39(13)–177.87(14)
Mg···O–C[a]	166.0(10)	161.6(2)–169.3(2)

#1 and #2 denote distinct groups of angles.
S.ds of the mean values and e.s.ds of the individual results in the ranges, are in parentheses. Values in the disordered $SiMe_3$ group were not included in the mean value calculations.
[a] Here, Mg···O denotes a cubane space diagonal.



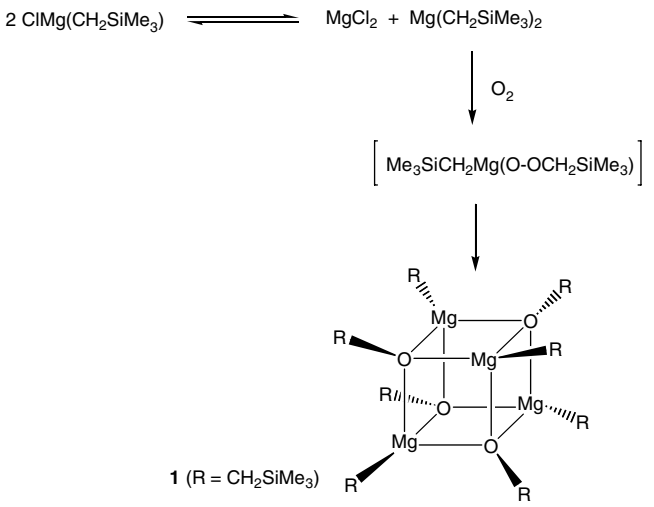


Fig. 1. View of one of the two crystallographically independent molecules of $[Mg(CH_2SiMe_3)(\mu^3\text{-}OCH_2SiMe_3)]_4$, showing the atom numbering scheme. Hydrogen atoms are omitted for clarity. Thermal ellipsoids are drawn at the 50% probability level.

Grignard reagents in solutions form a number of association and ligand exchange equilibria [14]. The most significant of those is the Schlenk equilibrium. The formation of **1** can be explained by the existence of equilibrium concentrations of magnesium dialkyl which undergoes preferential oxidation (Scheme 1). The reaction conditions leading to

Scheme 1. Postulated reaction sequence leading to the formation of **1**.

the isolation of **1** did not allow the detection of the possible alkylperoxide intermediate.

3. Experimental

All manipulations were performed under an atmosphere of dry nitrogen using standard Schlenk techniques. Light petroleum was purified by distillation under nitrogen from sodium–potassium alloy (b.p. 40–60 °C). Deuterated benzene was degassed by several freeze–thaw cycles and dried over activated 4 Å molecular sieves. NMR spectra (^{1}H, ^{13}C) were recorded on a Bruker Avance DPX-300 spectrometer. ^{1}H NMR spectra were referenced to residual solvent protons.

3.1. Synthesis and characterization of *1*

Colorless needle-shaped crystals of $[Mg(CH_2SiMe_3)(\mu^3\text{-}OCH_2SiMe_3)]_4$ (**1**) (0.6 g, 0.7 mmol, 3%) were obtained from a solution of $ClMgCH_2SiMe_3$ (3.23 g, 22 mmol) in petrol/diethyl ether (9/1) and the serendipitous introduction of oxygen, after cooling to −25 °C for a period of 12 days.

^{1}H NMR (300 MHz, 25 °C, C_6D_6): δ 3.84 (s, 8H, OCH_2-$SiMe_3$), 0.28 (s, 36H, $OCH_2Si\mathit{Me}_3$), 0.11 (s, 36H, $MgCH_2Si\mathit{Me}_3$), −1.11 (s, 8H, $MgCH_2SiMe_3$). ^{13}C NMR (75.47 MHz, 25 °C, C_6D_6): δ 52.1 (OCH_2SiMe_3), 19.3 ($MgCH_2SiMe_3$), 0.2 ($OCH_2Si\mathit{Me}_3$), −1.1 ($MgCH_2Si\mathit{Me}_3$).

3.2. Crystal structure

Crystal data: $C_{32}H_{88}Mg_4O_4Si_8$, $M = 859.0$. Triclinic, space group $P\bar{1}$ (No. 2), $a = 10.7614(8)$, $b = 21.680(2)$, $c = 24.724(2)$ Å, $\alpha = 100.854(8)$, $\beta = 89.542(7)$, $\gamma = 96.211(7)°$, $V = 5631.3(8)$ Å^3. $Z = 4$, $D_{calc} = 1.013$ g cm^{-3}, $F(000) = 1888$, $T = 180(1)$ K, μ(Mo Kα) = 2.6 cm^{-1}, λ (Mo Kα) = 0.71069 Å.

Crystals are colourless prisms. From a sample under oil, one, *ca* 0.89 × 0.32 × 0.16 mm, was mounted on a glass fibre and fixed in the cold nitrogen stream on an Oxford Diffraction Xcalibur-3 CCD diffractometer equipped with Mo Kα radiation and graphite monochromator. Intensity data were measured by thin-slice ω- and ϕ-scans. Total number of reflections recorded, to $\theta_{max} = 23.8°$, was 50073 of which 16847 were unique ($R_{int} = 0.077$); 8479 were 'observed' with $I > 2\sigma_I$. Data were processed using the CRYSALIS-CCD and -RED [15] programs. The structure was determined by the direct methods routines in the SHELXS program and refined by full-matrix least-squares methods, on F^2's, in SHELXL [16].

There are two independent molecules in the crystal. One $SiMe_3$ group was disordered in two orientations. The non-hydrogen atoms were refined with anisotropic thermal parameters. Hydrogen atoms were included in idealised positions and their U_{iso} values were set to ride on the U_{eq} values of the parent carbon atoms. At the conclusion of the refinement, $wR_2 = 0.118$ and $R_1 = 0.125$ for all 16847 reflections weighted $w = [\sigma^2(F_o^2) + (0.0566P)^2]^{-1}$ with $P = (F_o^2 + 2F_c^2)/3$; for the 'observed' data only, $R_1 = 0.051$. In the final difference map, the highest peak (*ca* 0.4 e Å^{-3}) was close to Mg(3).

Scattering factors for neutral atoms were taken from Ref. [17]. Computer programs used in this analysis have been noted above, and were run through WINGX [18] on a Dell Precision 370 PC at the University of East Anglia.

4. Supplementary material

CCDC 625225 contains the supplementary crystallographic data for $[Mg(CH_2SiMe_3)(\mu^3\text{-}OCH_2SiMe_3)]_4$. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

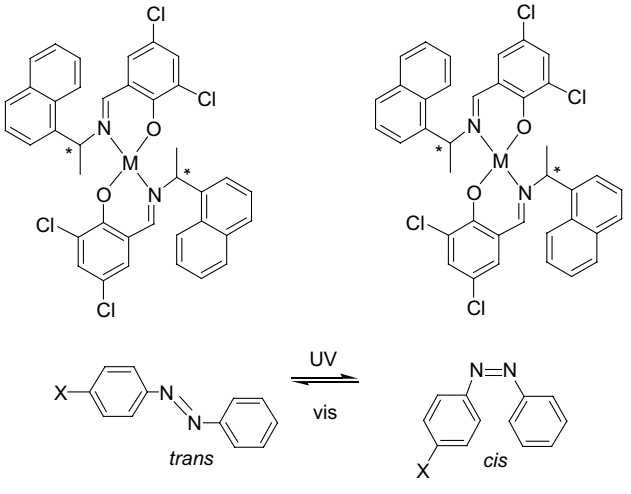
exhibit thermally-induced structural phase transition [24–26] even if they are chiral compounds [27,28].

In this paper, we describe preparations, crystal structures, electronic spectra of chiral Schiff base complexes, bis(*N*-*R*-1-naphthylethyl-3,5-dichlorosalicydenaminato)nickel(II) (**1**), copper(II) (**2**), and zinc(II) (**3**) (Scheme 1). Absorption and circular dichroism (CD) spectra of **1**–**3** were recorded in *N*,*N*′-dimethylformamide (DMF), acetone, methanol, chloroform, and toluene solutions to discuss spectral shifts by structural changes. Moreover, we estimate mechanism of photoinduced conformational changes of the complexes caused by three photochromic compounds, azobenzene (**AZ**), 4-hydroxyazobenzene (**AZOH**), and 4-aminoazobenzene (**AZNH$_2$**), by comparing various conditions of experiments.



2. Experimental

2.1. Synthesis

Chemicals of the highest commercial grade available (Aldrich and Wako) were used as received without further purification.

2.1.1. Synthesis of bis(*N*-*R*-1-naphthylethyl-3,5-dichlorosalicydenaminato)nickel(II) (*1*)

To a solution of 3,5-dichlorosalicylaldehyde (0.48 g, 2.5 mmol) dissolved in methanol (50 ml), *R*-(+)-1-naphthylethylamine (0.43 g, 2.5 mmol) was added dropwise and stirred at 313 K for 2 h to give orange solution of ligand. Nickel(II) acetate tetrahydrate (0.31 g, 1.25 mmol) was added to the resulting solution to give brown precipitates. After stirring for 2 h, this crude brown compound was filtered and recrystallized from acetone to give brown prismatic single crystals suitable for X-ray analysis. Yield 0.63 g (68.5%). *Anal.* Calc. for $C_{38}H_{28}Cl_4N_2NiO_2$: C, 61.25; H, 3.79; N, 3.76. Found: C, 60.90; H, 3.84; N, 4.16%. IR (KBr, cm^{-1}): 447(w), 547(w), 780(s), 864(w), 906(w), 964(w), 1043(w), 1106(s), 1172(w), 1211(w), 1211(w), 1286(w), 1334(w), 1458(s), 1529(w), 1613(s), 2929(w), 2979(w), 3945(w), 2987(w), 3435(s). m.p. 559 K (decomposition). $\mu_{eff}/\mu_{BM} = 0$ at 298 K (diamagnetism).

Scheme 1. Structures of **1**–**3** and **AZ**, **AZOH**, and **AZNH$_2$** and their photoisomerization induced by UV and visible light irradiation.

2.1.2. Synthesis of bis(*N*-*R*-1-naphthylethyl-3,5-dichlorosalicydenaminato)copper(II) (*2*)

To a solution of 3,5-dichlorosalicylaldehyde (0.48 g, 2.5 mmol) dissolved in methanol (50 ml), *R*-(+)-1-naphthylethylamine (0.43 g, 2.5 mmol) was added dropwise and stirred at 313 K for 2 h to give orange solution of ligand. Copper(II) acetate (0.23 g, 1.25 mmol) was added to the resulting solution to give brown precipitates. After stirring for 2 h, this crude compound was filtered green plate-like single crystals suitable for X-ray analysis. Yield 0.66 g (70.4%). *Anal.* Calc. for $C_{38}H_{28}Cl_4CuN_2O_2$: C, 60.85; H, 3.76; N, 3.74. Found: C, 60.70; H, 3.52; N, 4.02%. IR (KBr, cm^{-1}): 452(w), 489(w), 510(w), 552(w), 600(w), 632(w), 658(w), 779(s), 863(w), 974(w), 1028(w), 1049(w), 1107(w), 1175(w), 1207(w), 1291(w), 1324(w), 1460(s), 1518(w), 1618(s), 2870(w), 2928(w), 2975(w), 3952(w), 2086(w), 3435(s). m.p. 566 K (decomposition).

2.1.3. Synthesis of bis(*N*-*R*-1-naphthylethyl-3,5-dichlorosalicydenaminato)zinc(II) (*3*)

To a solution of 3,5-dichlorosalicylaldehyde (0.48 g, 2.5 mmol) dissolved in methanol (50 ml), *R*-(+)-1-naphthylethylamine (0.43 g, 2.5 mmol) was added dropwise and stirred at 313 K for 2 h to give orange solution of ligand. Zinc(II) acetate dihydrate (0.23 g, 1.25 mmol) and $NaHCO_3$ (0.17 g, 2.0 mmol) was added to the resulting orange solution to give yellow precipitates. After stirring for 2 h, this crude compound was filtered yellow plate-like single crystals suitable for X-ray analysis. Yield 0.68 g (72.3%). *Anal.* Calc. for $C_{38}H_{28}Cl_4N_2O_2Zn$: C, 60.71; H, 3.75; N, 3.73. Found: C, 60.70; H, 3.58; N, 4.16%. IR (KBr, cm^{-1}): 541(w), 769(w), 869(w), 980(w), 1975(w), 1112(w), 1160(s), 1212(w), 1301(w), 1413(w), 1442(s), 1518(w), 1616(s), 2934(w), 2975(w), 3054(w), 3429(s). m.p. 615 K (decomposition).

2.2. Physical measurements

Elemental analyses (C, H, N) were performed by an Elemetar Vario EL analyzer at Keio University. IR spectra were recorded as KBr pellets on a JASCO FT-IR 660 plus spectrophotometer in the range of 4000–400 cm^{-1} at 298 K. Thermal analysis was performed on a SHIMADZU DSC-60 differential scanning calorimeter (DSC), where the heating rate was 10 K min^{-1} in the range of 313–673 K. Diffuse reflectance spectra were measured on a JASCO V-560 spectrophotometer equipped with an integrating

sphere in the range of 850–220 nm at 298 K. Absorption spectra were measured on a JASCO V-560 spectrophotometer in the range of 900–200 nm at 298 K. Circular dichroism (CD) spectra were measured on a JASCO J-720WI spectropolarimeter in the range of 900–200 nm at 298 K. Magnetic susceptibility was measured with a Sherwood Scientific magnetic susceptibility balance at 298 K. Luminescence spectra (emission by $\lambda_{ex} = 27000\ cm^{-1}$) were measured on a JASCO FP-6500 spectrofluorometer at 298 K. Photoillumination were carried out using a lamp ($1.0\ mW/cm^2$) with optical filters (UV $\lambda = 200$–400 nm) leading to a sample by using optical fibers through optical filters.

2.3. X-ray crystallography

Intensity data were collected on a Rigaku AFC-7R four-circle diffractometer with graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). Data analysis was carried out with a teXsan program package [29]. The structure was solved by direct methods with a SIR 92 program [30] and refined by full-matrix least-squares methods based on F^2 using the program SHELXL-97 [31]. An empirical absorption correction was applied based on ψ scans. No significant decay in the intensity of three standard reflections was observed throughout the data collection. All non-hydrogen atoms were readily located and refined by anisotropic thermal parameters. All hydrogen atoms were located at geometrically expected positions and refined using riding models.

The size of crystal **2** served for measurement was relatively small (or thin), and there was large void space made by bulky organic ligands in the crystal of **2**, which was an essential problem of this compound. The intensity of diffraction was weak for the crystal of **2**, which resulted in poor result. However, the *R*-factor of 0.0800 for **2** was sufficient quality to discuss overall molecular structure except for detailed molecular geometries with large esds.

Crystal data for **1**: $C_{38}H_{28}Cl_4N_2NiO_2$, crystal dimension $0.50 \times 0.40 \times 0.40\ mm^3$, $M_w = 745.11$, orthorhombic, space group $P2_12_12_1$, $a = 12.862(5)$ Å, $b = 30.27(2)$ Å, $c = 8.682(3)$ Å, $V = 3380(3)$ Å^3, $Z = 4$, $D_{calc} = 1.464\ mg/m^3$, $F(000) = 1528$, $R_1 = 0.0396$, $R_w = 0.0953$, $S = 0.991$, Flack parameter $= -0.02(2)$.

Crystal data for **2**: $C_{38}H_{28}Cl_4CuN_2O_2$, crystal dimension $0.50 \times 0.20 \times 0.20\ mm^3$, $M_w = 749.97$, orthorhombic, space group $P2_12_12$, $a = 32.243(8)$ Å, $b = 8.758(3)$ Å, $c = 12.813(4)$ Å, $V = 3618.2(19)$ Å^3, $Z = 4$, $D_{calc} = 1.377\ mg/m^3$, $F(000) = 1532$, $R_1 = 0.0800$, $R_w = 0.2280$, $S = 1.518$, Flack parameter $= -0.03(4)$.

Crystal data for **3**: $C_{38}H_{28}Cl_4N_2O_2Zn$, crystal dimension $0.50 \times 0.20 \times 0.20\ mm^3$, $M_w = 751.81$, tetragonal, space group $I4_1$, $a = b = 22.001(4)$ Å, $c = 14.135(4)$ Å, $V = 6842(3)$ Å^3, $Z = 8$, $D_{calc} = 1.460\ mg/m^3$, $F(000) = 3072$, $R_1 = 0.0394$, $R_w = 0.0848$, $S = 0.984$, Flack parameter $= -0.013(17)$.

3. Results and discussion

3.1. Description of the structures

3.1.1. Crystal structure of *1*

The molecular structure of **1** is depicted in Fig. 1 and selected bond distances and angles are given in its caption. Complex **1** affords a square planar *trans*-[NiN_2O_2] coordination geometry with a step conformation. The molecule in the crystal examined is Δ(*R*,*R*) conformation. Coordination bonds of Ni1–O1 = 1.823(4), Ni1–O2 = 1.823(4), Ni1–N1 = 1.936(4), and Ni1–N2 = 1.935(4) Å and imine double bond distances of N1–C7 = 1.280(7) and N2–C26 = 1.283(7) Å are normal values for Schiff base Ni^{II} complexes [9,11,19]. Both naphthyl groups are almost perpendicular to six-membered rings with dihedral angles of C1–C6/C10–C19 = 86.58(16)° and C20–C25/C29–C38 = 92.85(22)° and N1–Ni1–O1/N2–Ni1–O2 = 4.91(1)°. The crystal packing is formed by weak van der Waals force mainly without both hydrogen bonds and π–π stacking interactions.

3.1.2. Crystal structure of *2*

The molecular structure of **2** is depicted in Fig. 2 and selected bond distances and angles are given in its caption. Complex **2** affords a square planar *trans*-[CuN_2O_2]

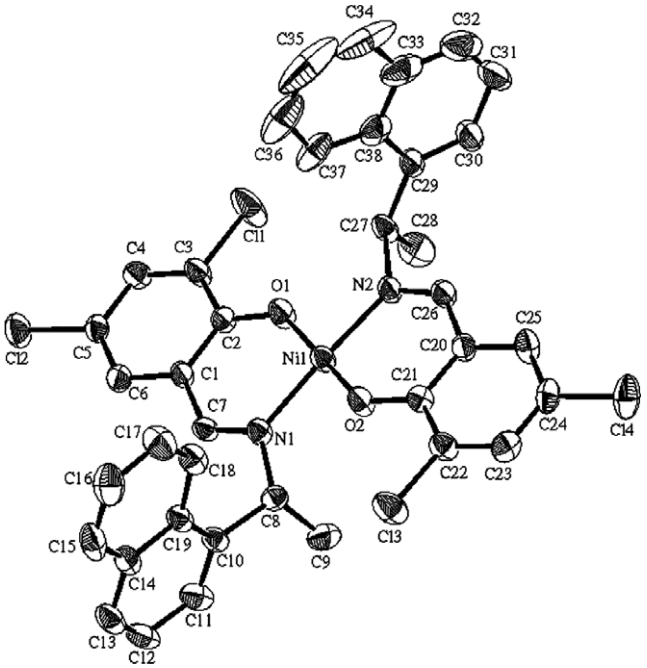

Fig. 1. The molecular structure of **1** showing the atom labeling scheme. Displacement parameters are drawn at the 30% probability level. H atoms are omitted for clarity. Selected bond lengths (Å) and angles (°): Ni1–O1 = 1.823(4), Ni1–O2 = 1.823(4), Ni1–N1 = 1.936(4), Ni1–N2 = 1.935(4), O1–C2 = 1.298(7), O2–C21 = 1.299(7), N1–C7 = 1.280(7), N1–C8 = 1.507(7), N2–C26 = 1.283(7), N2–C27 = 1.526(7), O1–Ni1–O2 = 176.8(2), O1–Ni1–N1 = 92.1(2), O1–Ni1–N2 = 88.2(2), O2–Ni1–N1 = 87.9(2), O2–Ni1–N2 = 92.0(2), N1–Ni1–N2 = 176.1(2), C7–N1–C8 = 115.8(4), C26–N2–C27 = 114.4(4).

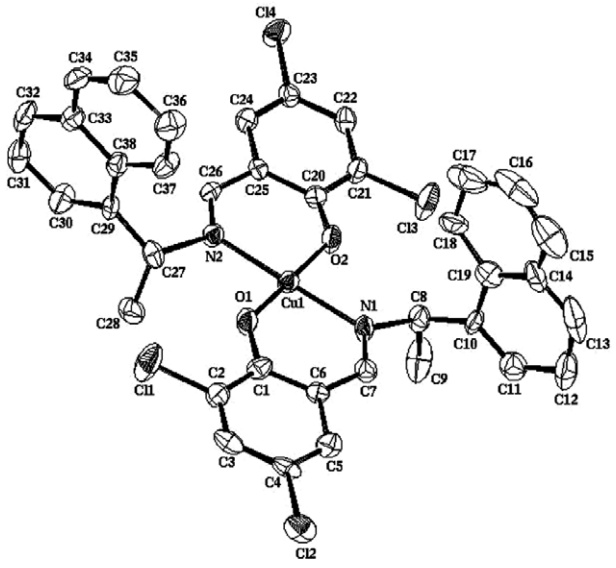

Fig. 2. The molecular structure of **2** showing the atom labeling scheme. Displacement parameters are drawn at the 30% probability level. H atoms are omitted for clarity. Selected bond lengths (Å) and angles (°): Cu1–O1 = 1.885(8), Cu1–O2 = 1.900(8), Cu1–N1 = 2.044(8), Cu1–N2 = 2.051(8), O1–C1 = 1.316(13), O2–C20 = 1.268(12), N1–C7 = 1.290(12), N1–C8 = 1.487(12), N2–C26 = 1.283(13), N2–C27 = 1.548(12), O1–Cu1–O2 = 176.6(4), O1–Cu1–N1 = 91.5(3), O1–Cu1–N2 = 89.3(3), O2–Cu1–N1 = 88.7(3), O2–Cu1–N2 = 90.5(3), N1–Cu1–N2 = 179.0(4), C7–N1–C8 = 116.7(9), C26–N2–C27 = 116.5(9).

coordination geometry with a step conformation, and overall structure of **2** is similar to that of **1**. The molecule in the crystal examined is $\Delta(R,R)$ conformation. Coordination bonds of Cu1–O1 = 1.885(8), Cu1–O2 = 1.900(8), Cu1–N1 = 2.044(8), and Cu1–N2 = 2.051(8) Å and imine double bond distances of N1–C7 = 1.290(12) and N2–C26 = 1.283(13) Å are normal values for Cu^{II} complexes having Schiff base ligands [10,11,24–28]. Elongation of coordination bond lengths of **2** than that of **1** is due to the difference of radii of Cu^{II} and Ni^{II} ions. Both naphthyl groups are almost perpendicular to six-membered rings with dihedral angles of C1–C6/C10–C19 = 95.45(31)° and C20–C25/C29–C38 = 86.25(30)° and N1–Cu1–O1/N2–Cu1–O2 = 3.47(1)°. No hydrogen bonds and π–π stacking are found in molecular crystals packed by weak van der Waals force.

3.1.3. Crystal structure of 3

The molecular structure of **3** is depicted in Fig. 3 and selected bond distances and angles are given in its caption. Complex **3** affords a distorted tetrahedral *trans*-[ZnN_2O_2] coordination geometry, and overall structure of **3** is quite different from those of **1** and **2**. The molecule in the crystal examined is $\Delta(R,R)$ conformation. Some coordination bonds among Zn1–O1 = 1.914(5), Zn1–O2 = 1.914(5), Zn1–N1 = 2.033(6), and Zn1–N2 = 2.003(6) Å are longer than the corresponding ones of **1** and **2**, which is due to both ionic radii of Zn^{II} and distortion of coordination environment. The imine double bond distances are N1–C7 = 1.274(8) and N2–C26 = 1.251(9) Å for **3**. Selected dihedral angles are as follows: N1–Zn1–O1/N2–Zn1–

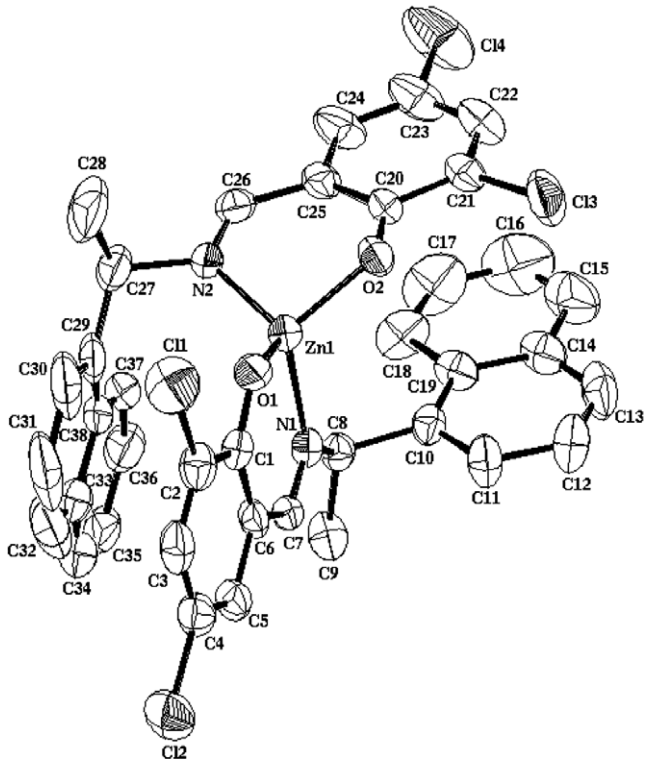

Fig. 3. The molecular structure of **3** showing the atom labeling scheme. Displacement parameters are drawn at the 30% probability level. H atoms are omitted for clarity. Selected bond lengths (Å) and angles (°): Zn1–O1 = 1.914(5), Zn1–O2 = 1.914(5), Zn1–N1 = 2.033(6), Zn1–N2 = 2.003(6), O1–C1 = 1.290(8), O2–C20 = 1.288(8), N1–C7 = 1.274(8), N1–C8 = 1.470(8), N2–C26 = 1.251(9), N2–C27 = 1.494(8), O1–Zn1–O2 = 118.0(2), O1–Zn1–N1 = 96.4(2), O1–Zn1–N2 = 119.5(2), O2–Cu1–N1 = 115.3(2), O2–Zn1–N2 = 93.9(2), N1–Zn1–N2 = 115.4(2), C7–N1–C8 = 121.4(6), C26–N2–C27 = 117.6(7).

O2 = 90.49(1)°, C1–C6/C10–C19 = 85.10(28)°, C20–C25/C29–C38 = 77.24(35)°, C1–C6/C29–C38 = 77.24(35)°, and C20–C25/C10–C19 = 5.18(29)°. In general, σ-character of Zn–N coordination bonds is stronger than that of dπ–pπ interaction [32]. In contrast to **1** and **2**, two π-conjugated moieties, naphthyl groups (C14–C16) and six-membered rings (C20–C25) of the opposite side of ligands and ring moieties (Zn1–N1–C1–C6–C7–O1/C29–C30–C31–C32–C33–C38) do not interact strongly. There are no hydrogen bonds in the crystals of **3**.

3.2. Structural phase transition

In the solid state, DSC curves on heating exhibited endothermic peaks at 521 and 547 K for **1** and **2**, respectively. It is well known that the analogous Ni^{II} and Cu^{II} complexes occur thermally-induced structural phase transition from square planar (or less distorted tetrahedral) to tetrahedral coordination environment [18]. The transition temperature was 456 K for the related Ni^{II} complex incorporating 1-phenylethylamine moieties [9], and higher temperature of **1** incorporating 1-naphthylethylamine moieties may be attributed to molecular weight mainly. Furthermore, compressed tetrahedral complex **3** also

exhibited similar endothermic peak at 523 K, which was observed for the first time among the analogous Zn^{II} complexes as far as we know. In analogy with **1** and **2**, the thermally-induced structural phase transition for **3** may be attributed to changes of the degree of distortion deviated from regular tetrahedral geometry. In this way, coordination environment was flexible for not only Ni^{II} (**1**) and Cu^{II} (**2**) complexes but also Zn^{II} complex (**3**) at least even in the solid state.

3.3. IR and electronic spectroscopy in the solid state

IR spectra exhibited characteristic peaks of imine bands at 1610, 1618, and 1616 cm^{-1} for **1**, **2**, and **3**, respectively. These values are reasonable by comparing with the analogous Ni^{II}, Cu^{II}, Zn^{II}, and other Schiff base complexes [33].

By the way, it is known that tautomers of free Schiff base ligands without coordinated metal ions exhibit photochromism as well as thermochromism in the solid state [34–36]. However, such metal complexes do not possess hydrogen atom transferring sites, and we cannot observe such phenomenon for **1**–**3** by means of IR spectroscopy in the solid state and solutions. Therefore, we can confirm that photoirradiation effects on Schiff base moieties do not concern with metal complexes.

As shown in Fig. 4, diffuse reflectance spectra showed broad d–d bands around 15300 cm^{-1} for **1** and 14000 cm^{-1} for **2**. As for **1**, the spectral features of spin-allowed $^1A_g \rightarrow {}^1B_{1g}$ and $^1A_g \rightarrow {}^1B_{3g}$ transitions and spin-forbidden $^1A_g \rightarrow {}^3B_{1g}$ transition are consistent with both diamagnetism and a square planar coordination geometry. In addition, there also appeared LMCT bands around 21000 cm^{-1} as shoulder and broad π–π^* bands around 25000 cm^{-1} for **1**–**3**.

3.4. Electronic, CD, and emission spectra in solutions

Absorption and CD spectra for **1**–**3** in various solvents are shown in Figs. 5–7, respectively. These absorption spectra are different from the corresponding diffuse reflectance spectra, which suggest drastic structural changes of **1**–**3** between solid state and solutions. The sign of CD spectra is due to $\Delta(R,R)$ absolute configuration for **1**–**3**. Physical properties of the solvents are as follows [37]: *N*,*N*′-dimethylformamide (DMF) ($\mu = 3.82$; $\varepsilon = 36.710$; $n_D^{20} = 1.428$), acetone ($\mu = 3.11$; $\varepsilon = 20.700$; $n_D^{20} = 1.356$), methanol ($\mu = 2.97$; $\varepsilon = 32.630$; $n_D^{20} = 1.326$), chloroform ($\mu = 1.11$; $\varepsilon = 4.806$; $n_D^{20} = 1.444$), and toluene ($\mu = 0.37$; $\varepsilon = 2.438$; $n_D^{20} = 1.494$). The values in parentheses denote dipole moment, μ (Debye), dielectric constant, ε, and refractive index, n_D^{20}, respectively.

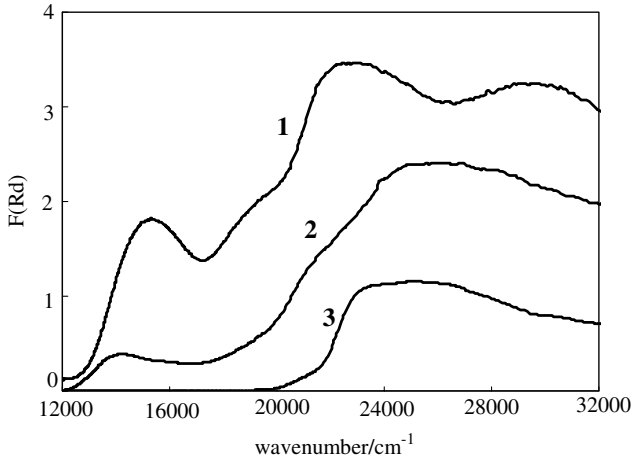

Fig. 4. Diffuse reflectance spectra for **1**–**3**.

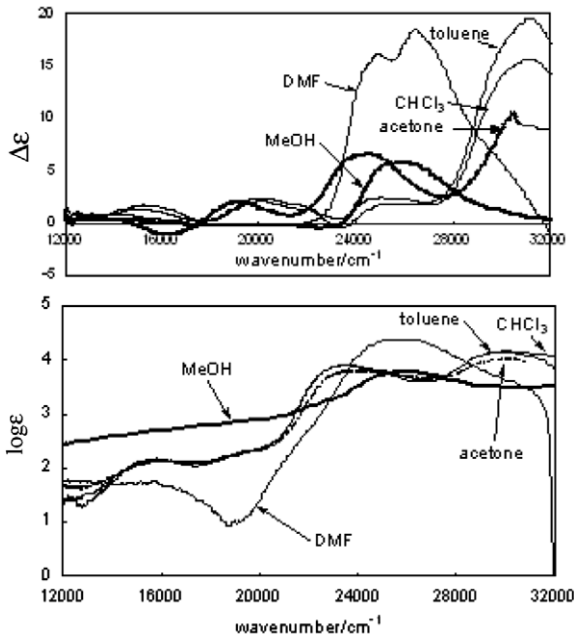

Fig. 5. Absorption and CD spectra of **1** in 0.1 mM various solvents.

In D_{2h} symmetry, absorption bands for Ni^{II} complexes can be assigned as follows [38,39]: $^1A_g \rightarrow {}^3B_{1g}$ (12000 cm^{-1}), $^1A_g \rightarrow {}^1B_{1g}$ (16000 cm^{-1}), $^1A_g \rightarrow {}^3B_{3g}$ and $^1A_g \rightarrow {}^3B_{2g}$, and LMCT (20000 cm^{-1}), $^1A_g \rightarrow {}^1B_{2g}$ (24000 cm^{-1}), $^1A_g \rightarrow {}^1B_{3u}$, $^1B_{2u}$ (28000 cm^{-1}), and $^1A_g \rightarrow {}^1B_{3u}$ (30000 cm^{-1}), and π–π^* bands (more than 30000 cm^{-1}). On the other hand, as for Cu^{II} complexes, a broad d–d band composed of $^2A_1 \rightarrow {}^2A_1$, $^2A_1 \rightarrow {}^2B_1$, and $^2A_1 \rightarrow {}^2B_2$ transitions (*ca.* 16000–20000 cm^{-1}), CT and π–π^* bands (*ca.* 24000–28000 cm^{-1}) can be expected in C_{2v} symmetry [39–41]. Since Zn^{II} complexes exhibit no d–d transition, all spectral bands in UV region in Fig. 7 are attributable to LMCT and π–π^* transitions of ligands (more than 24000 cm^{-1}) [32]. In the CD spectra for **3**, solvent dependence of intensities and wavenumbers can be observed except for toluene showing large deviation from other solvents. In particular, spectral shifts depending on solvents of Ni^{II} (**1**) complex are larger than those of Cu^{II} (**2**) and Zn^{II} (**3**) complexes regardless of concentration of solutions or types of photochromic solutes (see also 'solution paramagnetism' in later section).

In order to refer previous assignments established for the related Schiff base complexes, we employed wavenumber

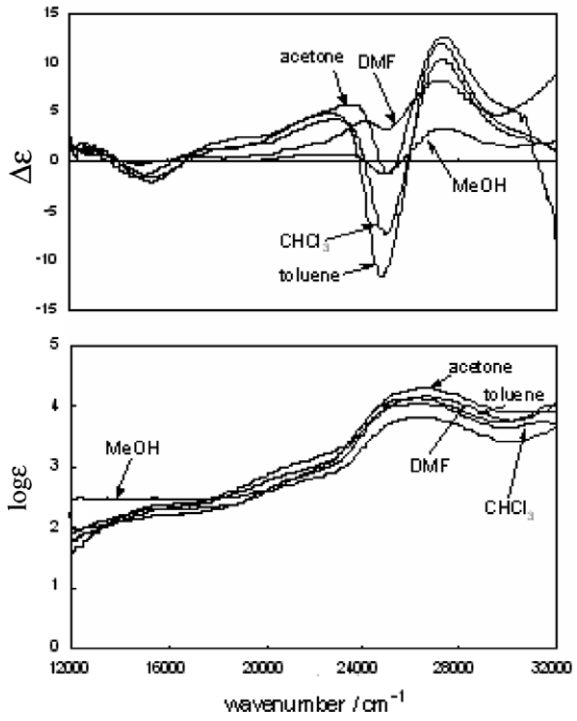

Fig. 6. Absorption and CD spectra of **2** in 0.1 mM various solvents.

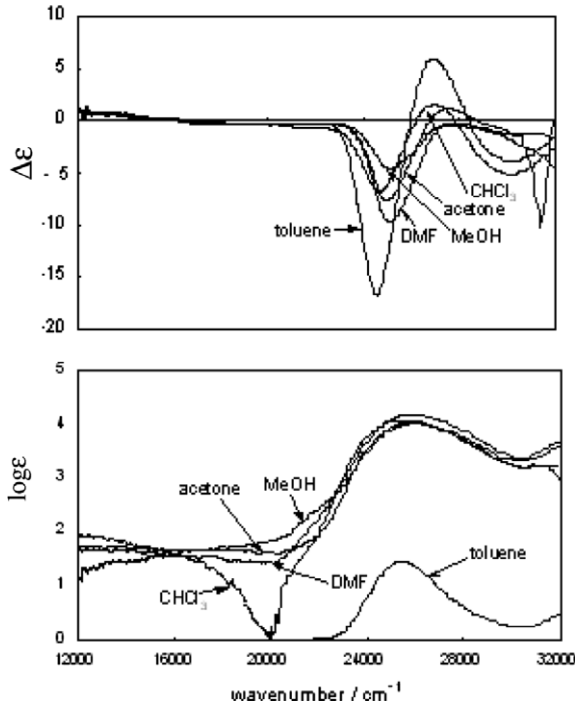

Fig. 7. Absorption and CD spectra of **3** in 0.1 mM various solvents.

scale for all spectra in this paper. On the other hand, intensity was plotted in $\log\varepsilon$ (or $\Delta\varepsilon$) scale in order for determining spectra of sole solute. While they are plotted in absorbance (or θ) scale in order for expressing the magnitude of difference observed for mixed solutions being dependent on concentration clearly. Variation with solvents was reproducible as far as we measured at the same time. However, in particular for CD spectra, unexpected artifact or noise might be observed at UV region of quite intense absorption. In addition, particle size of solutes (azobenzenes and complexes) does not show scattering for light of this wavenumber.

Emission spectra of **3** ($\lambda_{ex} = 27\,800\ cm^{-1}$) at 298 K in various solvents are shown in Fig. 8. Solvent dependence of the peaks is as follows: 21 300 cm^{-1} for toluene, chloroform, and methanol, 21 500 cm^{-1} for acetone, and 22 100 cm^{-1} for DMF. There is not distinct linear correlation between peaks (wavenumber or intensity) and polarity (dielectric constants) of the solvents. The fact suggests that electronic transitions concerned with emission occur between different molecular orbital levels, in other words, it is not solvatochromism keeping the identical molecular structures having the identical molecular orbitals [42]. In addition, large conformational changes of **3** can be expected in different solvents. Detailed molecular structures in each solution are unclear at present.

3.5. Photochromic solute induced structural changes in solutions

In order to elucidate appropriate conditions for the phenomenon, we compared several conditions of the supramolecular systems containing chiral complexes (**1**–**3**) and photochromic compounds (azobenzene (**AZ**), 4-hydroxyazobenzene (**AZOH**), and 4-aminoazobenzene ($\mathbf{AZNH_2}$)) in the five organic solvents (0.1 mM). Although we prepared both solutions of 0.1 mM and 0.01 mM, we could not prepare 1 mM solutions because of low solubility. For both concentrations, π–π^* bands in UV region were strong, while d–d bands in visible region were relatively weak. However, 0.01 mM solutions were too dilute to detect the phenomenon clearly. Thus we employed 0.1 mM solution for investigation after all. As elucidated later, weak intermolecular interactions between chiral metal complexes and photochromic azobenzenes play an

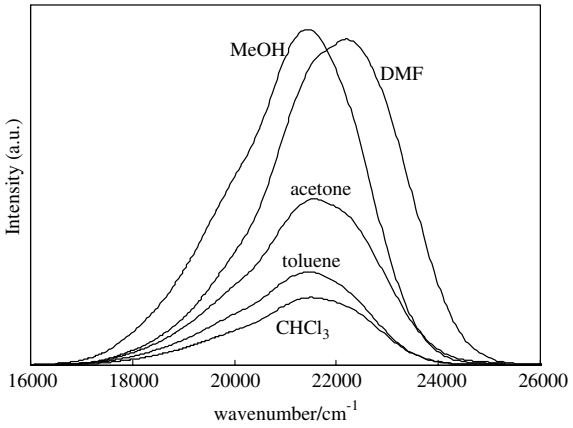

Fig. 8. Emission spectra ($\lambda_{ex} = 27\,800\ cm^{-1}$) of **3** at 298 K in 0.1 mM various solvents.

important role in the phenomenon. Serious changes must be expected for supramolecular solution systems by using different concentrations.

Firstly, we investigated appropriate solvents for the phenomenon. According to the previous study (Ni^{II} complex and **AZOH**) [9], we examined a system containing **1** and **AZOH** in chloroform and observed smooth changes of both π–π* and d–d bands (Fig. 9). As for acetone, DMF, and methanol solutions (not shown), little spectral changes could be observed in both π–π* (*ca.* 28 000 cm^{-1}) and d–d (*ca.* 22 000 cm^{-1}) bands. As for toluene solution (not shown), we could observe reversible change of π–π* bands and little change of d–d bands. Thus, we selected 0.1 mM chloroform solutions for later discussion.

Secondly, we deal with steric effects of largely extended π-conjugate chiral ligands. The CD (and absorption) spectra exhibited somewhat irreversible changes in both π–π* and d–d bands for **1** and **AZOH** (Fig. 9). In contrast, CD spectra previous system of Ni^{II} complex incorporating 1-phenylethylamine moieties and **AZOH** exhibited almost reversible changes of weak d–d and strong π–π* bands [9]. We can extract the following possibility from the comparison: (1) Incomplete reversible conformational changes of the chiral complexes indicate that bulky ligands is kept a certain conformation, in other words, weak intermolecular interactions is necessary for transferring mechanisms of the effects between azobenzenes and chiral complexes. (2) The axial coordination sites opened by the bulky ligands enable **1** to coordinate **AZOH** molecules as ligands or to exhibit so-called 'solution paramagnetism' to coordinate solvent molecules as ligands [43]. As mentioned above, only **1** may drastically convert from a square planar geometry (diamagnetic) in the solid state or in a certain solvent to a tetrahedral (paramagnetic) geometry in solutions. Moreover, it is also well known that the related four-coordinated Ni^{II} complexes (diamagnetic) can convert to six-coordinated ones (paramagnetic) by coordinating solvent molecules as ligands. Anyway, characteristic behavior of spectra for **1** may be ascribed to such equilibrium in the solutions.

Thirdly, we investigate the effects of polar (–OH and $–NH_2$) groups of azobenzene derivatives as follows: (1) Is there possibility of additional coordination to axial site(s) especially for Ni^{II} complexes (**1**) as mentioned above? (2) Is isotropic electrostatic effects of polarity (dielectric constants) of solutions induced by photoisomerization of azo groups effective or not? Difference between *cis* and *trans* forms is *ca.* 3 Debyes for non-substituted azobenzene [9,10]. In the case of **1** and **AZ** in chloroform (Fig. 10), both CD and absorption spectra exhibited almost reversible changes in both π–π* and d–d bands smoothly. This result of **AZ** reveals that polar groups are not essential to enhance spectral changes. Of course, the phenomenon with **AZ** is not in connection with axial coordination. However, the system of **1** and $\mathbf{AZNH_2}$ in chloroform (Fig. 11) showed relatively larger changes of a d–d band (20 000 cm^{-1}) in absorptions spectra than that of **1** and **AZ** (Fig. 10). In this way, $\mathbf{AZNH_2}$ and **AZOH** may coordinate to the axial sites of **1**, but **AZ** without the polar groups can also occur the phenomenon with **1**.

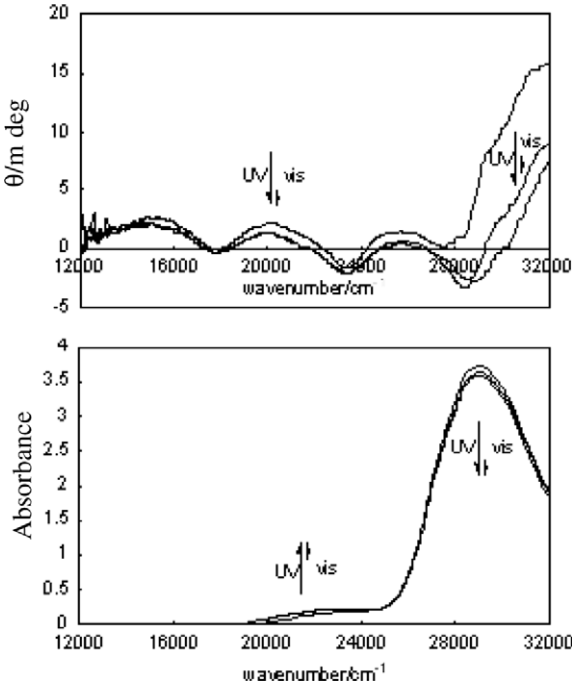

Fig. 9. Absorption and CD spectra of **1** and **AZOH** in 0.1 mM chloroform solution and before and after UV and visible light irradiation for 5 min.

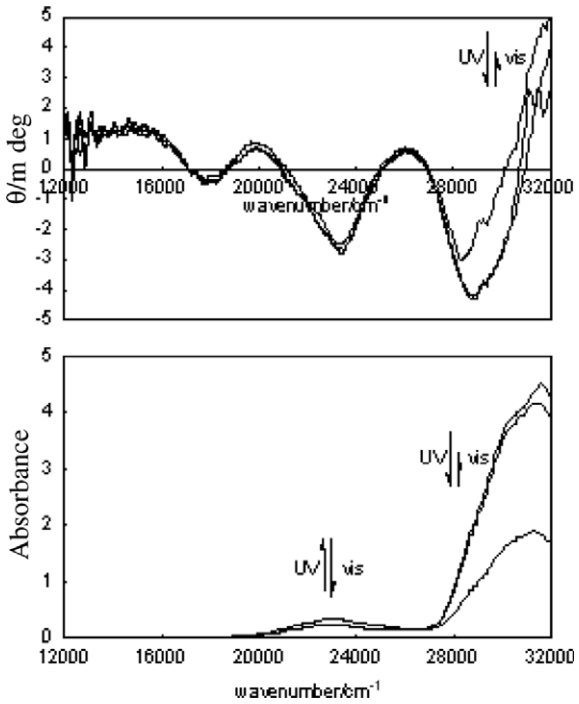

Fig. 10. Absorption and CD spectra of **1** and **AZ** in 0.1 mM chloroform solution and before and after UV and visible light irradiation for 5 min.

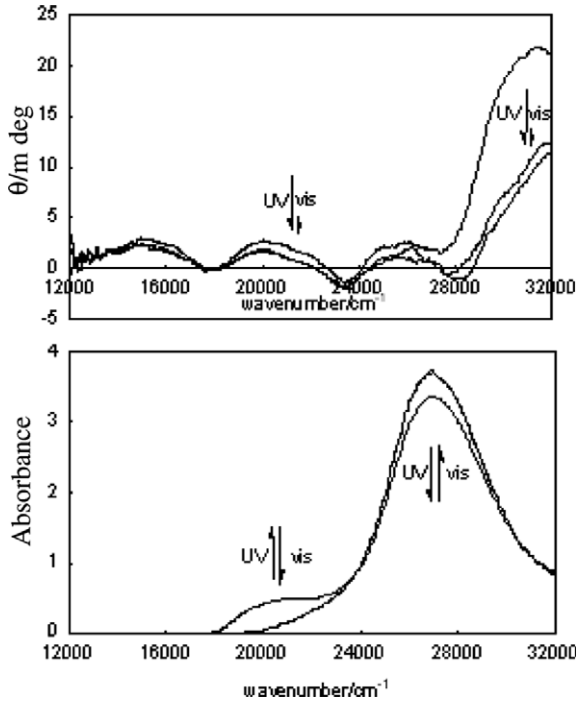

Fig. 11. Absorption and CD spectra of **1** and $\mathbf{AZNH_2}$ in 0.1 mM chloroform solution and before and after UV and visible light irradiation for 5 min.

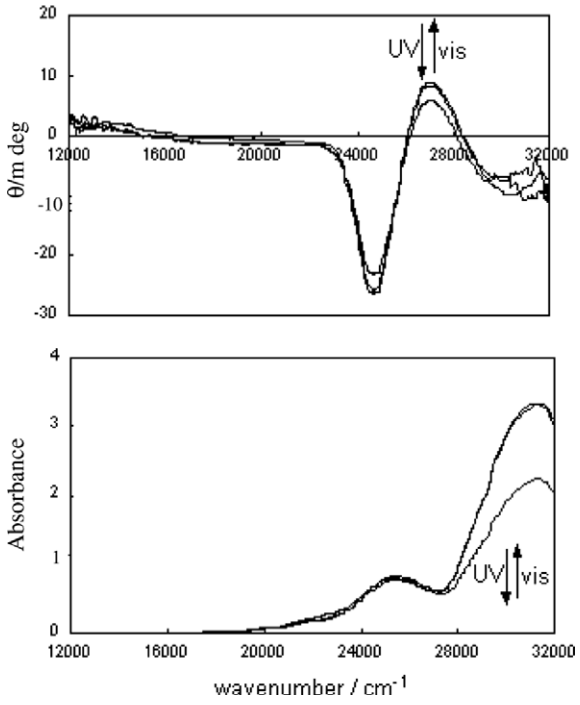

Fig. 13. Absorption and CD spectra of **3** and **AZ** in 0.1 mM chloroform solution and before and after UV and visible light irradiation for 5 min.

By the way, not all azobenzene molecules in solutions exhibit photoisomerization after UV or visible light irradiation generally. Therefore, many systems do not return to an original state after alternate irradiation of UV and visible light. In particular, the present supramolecular systems use weak intermolecular interactions to conduct the influences, namely photoisomerization of azobenzenes to chiral metal complexes. Even if photoisomerization of azobenzene can occur completely, not all molecules of complexes can convert their conformation smoothly. Thus, the fact also supports contribution of intermolecular interactions between azobenzenes and complexes.

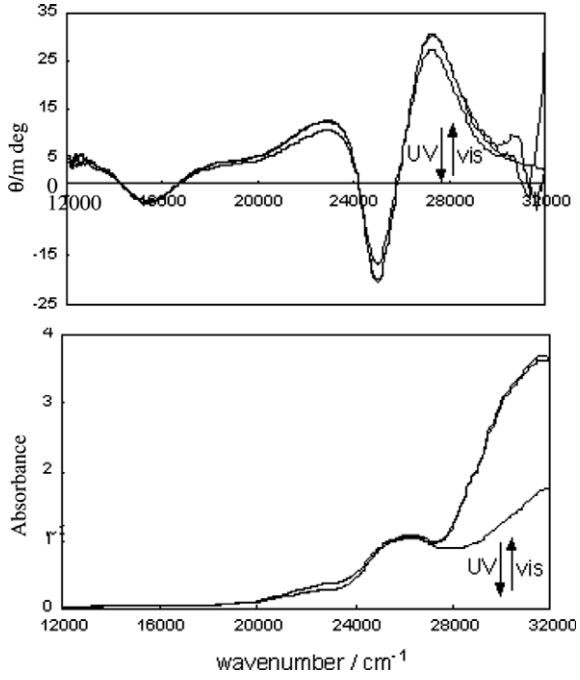

Fig. 12. Absorption and CD spectra of **2** and **AZ** in 0.1 mM chloroform solution and before and after UV and visible light irradiation for 5 min.

Finally, to confirm that the conformational changes are attributed to π-conjugated chiral ligands and/or coordination environment, we compare flexible Cu^{II} complex (**2**) and rigid Zn^{II} complex (**3**) in Figs. 12 and 13, respectively. Regardless of transition metals, both **2** and **3** exhibited reversible spectral changes mainly in π–π* region (little in d–d region). Consequently, the phenomenon is concerned with conformational changes of π-conjugated moieties of the ligands rather than coordination spheres.

To separate overlap of bands of achiral azozenzene and chiral metal complexes, we employed not only absorption spectra but also CD spectra to detect conformational changes for the present study. However, detailed conformation of the complexes in solutions is unclear at present.

4. Concluding remarks

In summary, we examined the conditions conformational changes induced by photoisomerization of azobenzenes via intermolecular interactions in solutions by comparing complexes **1**–**3**, photochromic compounds **AZ**, **AZOH**, and $\mathbf{AZNH_2}$, and five organic solvents. Chloroform is best solvent to observe the phenomenon. Among **1**–**3**, **1** exhibits conformational changes most smoothly.

That rigid **3** also exhibits the conformational changes suggests that it is due to not only π-conjugate moiety of the chiral ligands predominantly but also coordination environment. The phenomenon can be occurred by **AZ** as well as**AZOH** and **AZNH$_2$** solutes, which suggest that the phenomenon is independent of polarity or coordination of photochromic solutes. Incomplete reversible conformational changes of chiral complexes indicate that bulky ligands are kept a certain conformation. Accordingly, weak intermolecular interactions are necessary for transferring mechanisms of the effects of photoisomerization between azobenzenes and flexible chiral complexes.

Since we understand that this phenomenon can control long-range order of solutes in solutions, we will apply this methodology to various photofunctional supramolecular materials containing metal complexes, for example magnetic ionic liquids [44].

and (v) triple oxygen coordination or formation of secondary building blocks, enhance the construction of novel frameworks. Malonic acid ($n = 1$, H_2mal) offers the additional advantage of the relative location of the carboxylato groups in the 1,3-positions supporting simultaneous chelating bidentate and various carboxylato-bridging coordination modes leading to multi-dimensional polymers [8]. Moreover, its combination with other chelating and/or bridging ligands affects dramatically the identity of the products leading to the formation of monomers, dimers, trimers, tetramers as well as 1D, 2D and 3D polymers [9–15]. An additional parameter, which can influence the coordination versatility of mal^{2-} and consequently the structural characteristics of the products, is the induction of steric hindrance effects due to the presence of substituents in the aliphatic carbon, which lower the conformational freedom of the carbon backbone. Within this respect we have recently started to investigate the copper(II) chemistry of substituted malonates in the presence of neutral heterocyclic N-donor ligands.

We present herein our initial work on methylmalonate ($Memal^{2-}$) i.e. the synthesis, structural, spectroscopic and magnetic characterization of 1D coordination polymers presenting the [Cu(L)(Memal)] repeating unit [L = 1,10-phen (**1**), 2,2′-bpy (**2**)].

2. Experimental

2.1. Complex preparations

All manipulations were performed under aerobic conditions using materials as received (Aldrich Co). All chemicals and solvents were of reagent grade.

2.1.1. *[Cu(phen)(Memal)]n · nMeOH (1 · nMeOH) and [Cu(bpy)(Memal)]n (2)*

Solid 1,10-phen · H_2O (0.099 g, 0.50 mmol) and $CuCl_2 \cdot 6H_2O$ (0.043 g, 0.25 mmol) for **1**, or solid 2,2′-bpy (0.078 g, 0.50 mmol) and $CuCl_2 \cdot 6H_2O$ (0.085 g, 0.50 mmol) for **2**, were added to a refluxed methanolic solution (20 mL) of H_2Memal (0.059 g, 0.50 mmol) and $LiOH \cdot H_2O$ (0.042 g, 1.0 mmol). The colour of the solution in both cases immediately turned to blue and the reflux continued for 15 min, during which time no noticeable colour change or solid precipitation was observed. Blue-turquoise crystals of **1** suitable for X-ray analysis were obtained either by slow evaporation or by vapour diffusion of Et_2O (2:1 v/v) to the blue solution after 1 week (Yield: 0.067 g, ~75%). Blue-turquoise crystals of **2** suitable for X-ray analysis were obtained by vapour diffusion of Et_2O (2:1 v/v) to the blue reaction solution after 1 week (Yield: 0.092 g, ~55%). In both cases the crystals were collected by filtration and dried in vacuo. The resulting powder of **1** was analyzed as solvent-free. *Anal.* Calc. for (**1**) ($C_{16}H_{12}CuN_2O_4$): C, 53.41; H, 3.36; N, 7.79. Found: C, 52.34; H, 3.29; N, 7.63%. *Anal.* Calc. for (**2**) ($C_{14}H_{12}CuN_2O_4$): C, 50.08; H, 3.60; N, 8.34. Found: C, 49.08; H, 3.53; N, 8.17%.

2.2. General and physical measurements

Elemental analysis for carbon, hydrogen, and nitrogen was performed on a Perkin Elmer 2400/*II* automatic analyzer. Infrared spectra were recorded as KBr pellets in the range 4000–400 cm^{-1} on a Bruker Equinox 55/S FT-IR spectrophotometer. X-band Electron Paramagnetic Resonance spectra were recorded with a Bruker ER200D spectrometer equipped with an NMR-Gaussmeter, an Anritsu microwave frequency counter, and an Oxford ESR9 cryostat. Variable temperature magnetic susceptibility measurements were carried out on polycrystalline samples of **1** and **2** in the 5–300 K temperature range using a Quantum Design MPMS SQUID susceptometer under a magnetic field of 1 T. Magnetization isotherms between 0 and 5.4 T were collected at 5 K. Diamagnetic corrections for the complexes were estimated from Pascal's constants. The error factor R is defined as $R = \sum \frac{(x_{\text{exp}} - x_{\text{calc}})^2}{N x_{\text{exp}}^2}$, where N is the number of experimental points.

2.2.1. *X-ray crystallography and solution of structures*

Blue-turquoise prismatic crystals of **1** and **2** were mounted in capillaries. Diffraction measurements were made on a Crystal Logic Dual Goniometer diffractometer using graphite monochromated Mo Kα radiation. Important crystal data and parameters for data collection are reported in Table 1. Unit cell dimensions were determined and refined by using the angular settings of 25 automatically centered reflections in the range $11° < 2\theta < 23°$. Three standard reflections monitored every 97 reflections showed less than 3% intensity fluctuation and no decay. Lorentz, polarization and psi-scan absorption corrections (for **2** only) were applied using Crystal Logic software. The structures were solved by direct methods using SHELXS-86 [16]

All non-H atoms were refined anisotropically. Further experimental crystallographic details for **2**: $2\theta_{max} = 50°$, scan speed 1.0 °/min; scan range $1.6 + \alpha_1\alpha_2$ separation; reflections collected/unique/used, 2612/2325 [$R_{int} = 0.0506$]/2325; 227 parameters refined; $(\Delta/\sigma)_{max} = 0.004$; $(\Delta\rho)_{max}/(\Delta\rho)_{min} = 0.403/-0.590$ e/Å^3. Hydrogen atoms of the methyl group were introduced at calculated positions as riding on bonded atoms, the rest H-atoms were located by difference maps and were refined isotropically. All non-H atoms were refined anisotropically.

3. Results and discussion

3.1. Syntheses and diagnostic IR bands

The $CuCl_2/H_2Memal$/phen reaction mixture in MeOH in the 1:1:1 respective molar ratio, in the presence of stoichiometric amounts of $LiOH \cdot H_2O$ to ensure full deprotonation of the acid, yielded blue solutions which upon standing for slow evaporation, afforded blue-turquoise crystals of **1** after 1 week (Eq. (1)).

$$CuCl_2 \cdot 6H_2O + H_2Memal + \text{ phen} \cdot H_2O + 2LiOH \cdot H_2O \xrightarrow{MeOH} \underset{\mathbf{1}}{[Cu(phen)(Memal)]_n} + 2LiCl + 11\ H_2O \quad (1)$$

The initial $CuCl_2/H_2Memal$/phen stoichiometry employed is reflected in the stoichiometry of the repeating unit of the polymeric complex **1**. To further investigate the parameters affecting the identity of the products derived from the $CuCl_2/H_2Memal$/phen reaction system we employed different molar ratios and various crystallization methods. Thus, the 1:1:2, the 1.5:1:1 and the 1:2:2 respective molar ratios followed by different crystallization methods (slow evaporation, vapor diffusion or layering with Et_2O) afforded only complex **1**[1]. Therefore, compound **1** was judged to be the less soluble (and probably the most stable) product of the reaction system, albeit the presence of other species in the reaction mixture cannot be excluded.

In order to investigate to what extend the nature of the neutral heterocyclic N-donor ligand might affect the identity of the products we also studied the $CuCl_2/H_2Memal$/bpy reaction system. Thus, the 1:1:1 respective molar ratio reaction mixture in MeOH, in the presence of stoichiometric amounts of $LiOH \cdot H_2O$ to ensure full deprotonation of the acid, yielded blue solutions which afforded blue-turquoise crystals of **2** upon vapor diffusion of Et_2O after 1 week (Eq. (2)).

$$CuCl_2 \cdot 6H_2O + H_2Memal + \text{ bpy} + 2LiOH \cdot H_2O \xrightarrow{MeOH} \underset{\mathbf{2}}{[Cu(bpy)(Memal)]_n} + 2LiCl + 10H_2O \quad (2)$$

As in the case of **1**, the initially employed stoichiometry is reflected in the stoichiometry of the repeating unit of the polymeric complex **2**.

In the IR spectrum of **1** and in the 1600–1200 cm^{-1} region the ν(C⋯C) and ν(C⋯N) stretching vibrations of the phen are observed [18], which are known to shift to slightly higher frequencies upon complexation. However, some of these bands are unobserved due to overlaps with the carboxylate asymmetric and symmetric stretching vibrations. Thus, we can identify some of those bands having shifted to 1622, 1568, 1520, 1494, 1431 and 1226 cm^{-1}. The bands of the free phen in the 1050–700 cm^{-1} region are shifted to lower frequencies upon complexation, and in the spectra of **1** these bands appear at 855 and 723 cm^{-1}. The symmetric stretching vibration of the carboxylate group ν_s(COO) in the spectra of **1**, is observed in the region 1375–1340 cm^{-1}, while the ν_{as}(COO) is difficult to assigned, due to overlaps with the characteristic bands of the phen appeared in the same region. In the IR spectra of **2**, and in the region 1600–1200 cm^{-1} we identify some of the characteristic bands of the bpy attributed to the ν(C⋯C) and ν(C⋯N) stretching vibrations, having shifted to 1605, 1561, 1496, 1418 and 1225 cm^{-1} upon complexation. The asymmetric stretching vibration of the carboxylate group is difficult to be assigned due to overlaps with the above bands, while the symmetric stretching vibration ν_s(COO) is observed at 1366 cm^{-1}. The bands of the free bpy in the 1050–700 cm^{-1} region are shifted to lower frequencies upon complexation, and in the spectra of **2** these bands appear at 840 and 729 cm^{-1}.

3.2. Structural description of $[Cu(phen)(Memal)]_n \cdot nMeOH$ ($1 \cdot nMeOH$)

An ORTEP plot of **1** is given in Fig. 1. Selected bond distances and angles are listed in Table 2. The molecular structure of **1** reveals the presence of the [Cu(phen)(Memal)] repeating unit leading to 1D polymeric arrays (extended parallel to the *a*-axis) promoted by the bidentate [chelating] + unidentate coordination mode of the Memal^{2-} ligand. This type of coordination of the Memal^{2-} ligand has been also observed in the molecular structure of $\{[Co(NH_3)_6][UO_2(C_4H_4O_4)(C_5H_6O_4)]\}_2Cl_2 \cdot 6H_2O$ [19] ($C_4H_4O_4$ = the dianion of methylmalonic acid, $C_5H_6O_4$ = the dianion of dimethylmalonic acid), as well as in malonato containing complexes [20]. The closest intrachain Cu⋯Cu distance is equal to the *a* axis i.e. 4.889 Å. The coordination geometry around each Cu^{II} ion is square pyramidal ($\tau = 0.05$); the phen and the chelating oxygen atoms of the Memal^{2-} (O(1) and O(4)) occupy

[1] The identity of the products in each case was confirmed by unit cell determination.

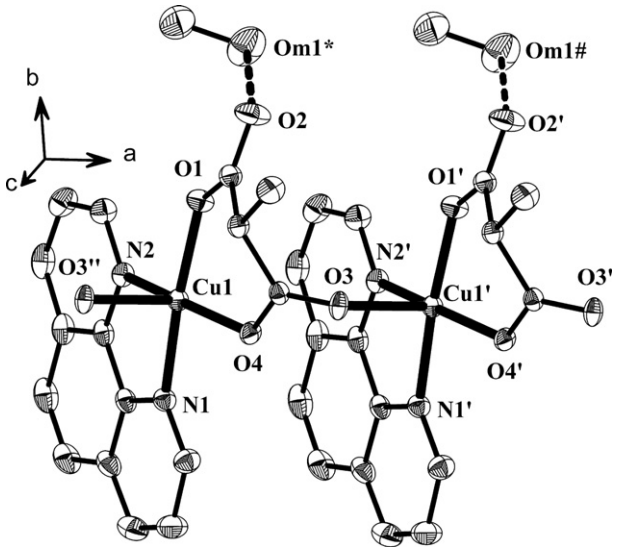

Fig. 1. Partially labelled ORTEP plot of the polymeric structure of **1** at 30% thermal probability ellipsoids (H-bonds are shown as black dashed lines). Symmetry operations to generate equivalent atoms: $' = 1 + x, y, z$, $'' = -1 + x, y, z$, $* = x, 1 - y, -0.5 + z$, $\# = 1 + x, 1 - y, -0.5 + z$.

$'' = -1 + x, y, z$ (for **1**) and $1 + x, y, z$ (for **2**).

the equatorial plane and the apical position is occupied by the unidentate oxygen of a neighbouring $Memal^{2-}$ (O(3″)) ligand. The Cu–N and Cu–O bond lengths in the equatorial plane fall in the range 1.918(3)–2.022(3) Å, the $Cu–O_{ax}$ bond distance is 2.296(2) Å. The forth oxygen atom (O(2)) of the $Memal^{2-}$ ligand is strongly hydrogen bonded to the solvate methanol (Om1···O2 (x, $1 - y$, $0.5 + z$) = 2.862 Å, HOm1···O2 = 2.095 Å, Om1–HOm1···O2 = 170.0°) thus preventing polymerization to that direction.

3.3. Structural description of [Cu(bpy)(Memal)]$_n$ (2)

An ORTEP plot of **2** is given in Fig. 2. Selected bond distances and angles are listed in Table 2. The molecular

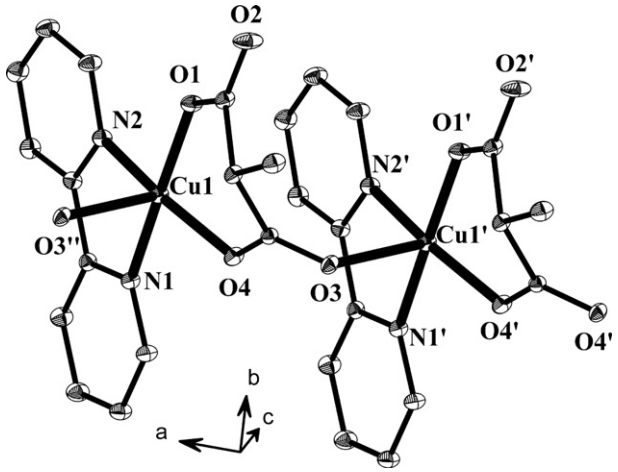

Fig. 2. Partially labelled ORTEP plot of the polymeric structure of **2** at 30% thermal probability ellipsoids. Symmetry operations to generate equivalent atoms: $' = -1 + x, y, z$, $'' = 1 + x, y, z$.

structure of **2** is analogous to that of **1** and will be discussed in less detail. The one-dimensional coordination polymer contains the [Cu(bpy)(Memal)] repeating unit, with the methylmalonato ligand adopting the bidentate [chelating] + unidentate coordination mode. The coordination geometry around the Cu^{II} ion is square pyramidal, the trigonality index τ is 0.13. The closest intrachain Cu···Cu distance is equal to the a axis, i.e. 4.862 Å. The Cu–N and Cu–O bond lengths in the equatorial plane fall in the range 1.914(4)–2.004(4) Å, the $Cu–O_{ax}$ bond distance is 2.258(4) Å.

In both compounds, the forth oxygen atom of the $Memal^{2-}$ ligand, although deprotonated, does not participate in metal coordination which would promote higher-dimensionality polymeric networks. This behaviour might be attributed either to the limited conformational freedom of the carbon backbone due to the methyl substituent, or to the blocking of two metal coordination sites by the phen or bpy ligands. The former does not seem to play any significant role, since bpy [13,21] or phen [10a]/mal^{2-} mixed-ligand complexes stabilize 1D polymeric structures through coordination or hydrogen bonds and 2D polymeric structures only through hydrogen bonding interactions, whereas higher dimensionality coordination polymers require the simultaneous presence of other bridging ligands, such as 4,4′-bpy [14]. On the other hand, the ability of both mal^{2-} [15e] and $Memal^{2-}$ [22] ligands to form 3D coordination polymers in the absence of other chelating ligands, lead us to assume that the blocking of certain metal coordination sites by phen or bpy plays the predominant role in the case of **1** and **2**.

3.4. Magnetic behaviour

The $\chi_M T$ product at 300 K is 0.41 $cm^3\,mol^{-1}\,K$ for **1** and 0.42 $cm^3\,mol^{-1}\,K$ for **2**, slightly above the value predicted for an isolated $S = 1/2$ spin with $g = 2.0$ (0.37 $cm^3\,mol^{-1}\,K$). This remains practically unchanged down to

The Malonates Bridge between the apical and basal coordination positions of the adjacent Cu^{II} ions, in the bidentate [chelating] + unidentate mode. Where possible, complexes with ligands similar to those of **1** and **2** were selected for reasons of comparison.
[a] bpym = 2,2′-bipyrimidine, Im = imidazole, meIm = 2-methylimidazole, bpe = 1,2-bis(4-pyridyl)ethylene.
[b] Mean values.

20 K for both complexes, below which temperature a slight increase is observed (Fig. 3) This is attributed to weak ferromagnetic intrachain interactions mediated by the $Memal^{2-}$ bridges. The complexes obey the Curie–Weiss law (Fig. S1) with $C = 0.42\ cm^3\ mol^{-1}\ K$ and $\Theta = +0.7\ K$ for **1** $C = 0.42\ cm^3\ mol^{-1}\ K$ and $\Theta = +0.5\ K$ for **2**, consistent with weak ferromagnetic coupling. The data were fitted with an analytical expression derived from a high-temperature series expansion, which simulates the magnetic behaviour of ferromagnetic $S = 1/2$ Heisenberg chains [23]:

$$\chi_M = \frac{Ng^2\beta^2}{4kT}\left(\frac{N}{D}\right)^{2/3} \quad (3)$$

where

$$N = 1.0 + 5.7979916y + 16.902653y^2 + 29.376885y^3 + 29.832959y^4 + 14.036918y^5,$$

$$D = 1.0 + 2.79799y + 7.0086780y^2 + 8.6538644y^3 + 4.5743114y^4$$

and $y = J/2kT$.

The fitting procedure yielded best-fit parameters $J = 0.24(4)\ cm^{-1}$, $g = 2.11(1)$ and $R = 2.4 \times 10^{-5}$ for **1** and $J = 0.09(4)\ cm^{-1}$, $g = 2.12(1)$ and $R = 1.2 \times 10^{-5}$ for **2**.

Fits considering a Curie-law behaviour along with a mean-field correction according to the Hamiltonian $\hat{H} = -2zJ\langle S_z\rangle\hat{S}_z$, to account for the exchange interactions, yielded practically identical results[2].

To verify these results, simulations on the magnetization isotherms of **1** and **2** at 5 K were carried out (i) by assuming a Brillouin behaviour for an $S = 1/2$ spin (g fixed to the best-fit value from the magnetic susceptibility data) and (ii) by approximating the chain with a Cu_{10} ring in which intramolecular J and g parameters are fixed to the best-fit values from the magnetic susceptibility data [24]. In both cases the simulations considering a Cu_{10} ring were closer to the experimental data than the Brillouin curves, thus corroborating our previous conclusions. It should be stressed that for such weak couplings, the absolute values may not be precisely determined, however, we are confident about their order of magnitude and their relative strengths.

The sign and size of the exchange couplings within **1** and **2** may be understood by examining the bridging mode of the $Memal^{2-}$ ligands. The carboxylato groups of the $Memal^{2-}$ ligands are in a *syn–anti* bridging mode, occupying a basal coordination position of one Cu atom (with the *syn*-coordinated donor atom O(4)) and the apical one of the adjacent Cu atom (with the *anti*-coordinated donor atom O(3)). The *syn–anti* bridging mode is known to minimize the overlap of the magnetic orbitals, which is inherently antiferromagnetic, thus enhancing ferromagnetism [25]. The very weak values of the exchange couplings may be viewed as a consequence of the participation of an apical coordination position to the exchange pathway

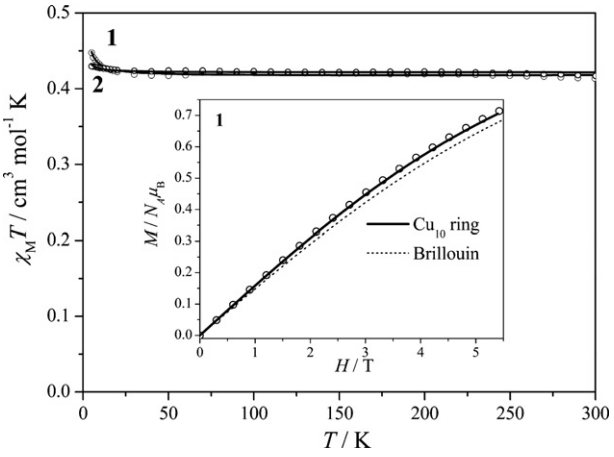

Fig. 3. $\chi_M T$ vs T experimental data for complexes **1** and **2**, and the best-fit theoretical curves based on model discussed in the text. Magnetization M vs applied magnetic field H data (○) at 5 K for complex **1** are shown in the inset. The calculated curves are based on the Cu_{10} ring model (solid line) and on an $S = 1/2$ Brillouin curve (dashed line) using the best-fit parameters from the magnetic susceptibility data. The case is similar for complex **2** (not shown).

[2] Using the expression $\chi_M = \frac{\chi_{Curie}}{1-\left(\frac{2zJ}{Ng^2\beta^2}\chi_{Curie}\right)}$, best-fit parameters were: $g = 2.107$, $zJ = 0.50\ cm^{-1}$, with $R = 2.6 \times 10^{-5}$ for **1** and $g = 2.120$, $zJ = 0.17\ cm^{-1}$, with $R = 1.2 \times 10^{-5}$ for **2**. Considering that for a 1D chain $z = 2$, then we obtain that $J = 0.25\ cm^{-1}$ for **1** and $J = 0.08\ cm^{-1}$ for **2**, in agreement with the results derived from the treatment described in the text.

(atom O(3)). This position is mainly characterized by a d_{z^2} orbital, which is not a magnetic one, and interactions are propagated due to geometrical distortions from ideal geometries, square pyramidal in our case ($\tau = 0.05$ and 0.13 for **1** and **2**, respectively). In any case these are very weak if not null.

The values of the exchange couplings in **1** and **2** fall within the range (+0.05 to +1.9 cm^{-1}) derived for other complexes containing the *syn–anti* bridging mode between a basal (or equatorial) and an apical (or axial) coordination position [26].

Indicative examples of analogous complexes with different malonato bridges are shown on Table 3. From a first survey of the data, it seems that the nature of the malonato sidegroup does not influence the magnitude of the intrachain exchange coupling.

3.5. EPR spectroscopy

X-band EPR spectra from powdered samples of **1** and **2** at 293 K are shown in Fig. 4. The spectra from both compounds are quite similar which is consistent with the almost identical stereochemistry around the Cu^{II} ions. They consist of almost axial signals with $g_{\|} > g_{\perp}$ consistent with and $d_{x^2-y^2}$ ground orbital state as it is expected for a square pyramidal symmetry [27]. The lack of hyperfine patterns especially at the $g_{\|}$ peak is attributed to narrowing effects [28] due to exchange interactions in agreement with the bulk magnetic properties of the complexes.

Both spectra are fitted [29] assuming the anisotropic $S = 1/2$ spin Hamiltonian:

$$\hat{H} = \beta \hat{\mathbf{S}} \tilde{\mathbf{g}} \mathbf{H} \quad (4)$$

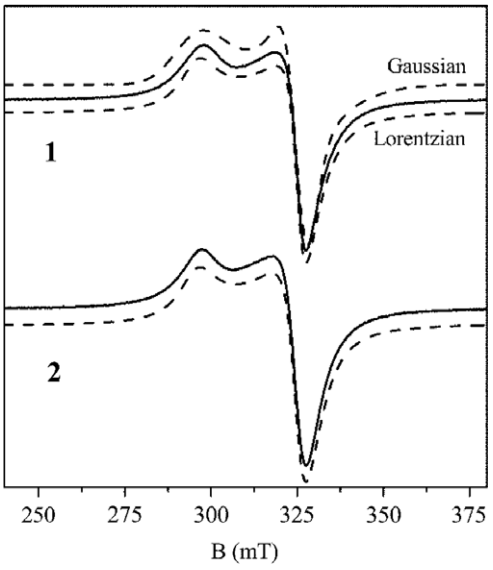

Fig. 4. X-band EPR spectra from powdered samples of **1** and **2** at 293 K. Solid lines: experimental spectra; dashed lines: theoretical curves resulting from the fitting procedure assuming either Gaussian or Lorentzian lines for **1** or Lorentzian for **2**. EPR conditions: microwave power, 2.2 mW, modulation amplitude 1.0 G_{pp}, microwave frequency 9.41 GHz.

Table 4
EPR parameters from the 293 K spectra for complexes **1** and **2**

Complex	$g_{\|}(\sigma g_{\|})$	$g_{\perp 1}(\sigma g_{\perp 1})$	$g_{\perp 2}(\sigma g_{\perp 2})$	LW(G)
1	2.274(0.04)	2.068(0.06)	2.046(0.00)	38.2
2	2.274(0.04)	2.071(0.05)	2.052(0.00)	46.0

During the fitting process we introduced a small rhombicity in the *g*-tensor by allowing for two different perpendicular components $g_{\perp 1}$ and $g_{\perp 2}$. In order to reproduce the spectra we assumed a distribution tensor, σg, for the g-tensor. For each orientation (θ, φ) of the magnetic field with respect to the *g*-tensor a linewidth of $\sigma g(\theta, \varphi)$ was computed in magnetic field units. To this an additional width, LW was added. The line at each orientation was a Gaussian or Lorentzian of width $\sigma = (\sigma g(\theta, \varphi)^2 + \mathrm{LW}^2)^{1/2}$. The spectra for both complexes were better reproduced assuming Lorentzian lineshapes; the simulations assuming Gaussian lineshapes are of lower quality (Fig. 4). The results of the fitting are listed in Table 4.

We also examined the temperature dependence of the EPR spectra for **1** in the region 4.2–293 K. The spectra are essentially the same with the room temperature one exhibiting only subtle changes in the line-shape.

4. Conclusions

The work presented herein describes our initial attempts to verify the key factors affecting the identity of the $CuCl_2$/H_2Memal/L (L = phen, bpy) reaction system. In both cases 1D coordination polymers, $[Cu(L)(Memal)]_n$ have been isolated. In the particular case of L = phen, several synthetic attempts revealed that variation of the molar ratios or crystallization methods employed do not affect the identity of the product. Employment of bpy instead of phen also led to the analogous product. It was thus concluded that (i) Use of $Memal^{2-}$ leads to a specific type of 1D coordination polymers for a wide range of reaction conditions. This may be due to its higher thermodynamic stability, or lower solubility with respect to other products that might be present in solution. (ii) The use of bpy instead of phen seems to have little or no effect to the final product. Weak ferromagnetic intrachain interactions have been confirmed both by magnetic susceptibility measurements and X-band EPR spectra of **1** and **2**, and attributed to the *syn–anti* bridging mode of the $Memal^{2-}$ ligands. The bidentate [chelating] + unidentate coordination mode of the $Memal^{2-}$ ligand in both compounds, provides possibilities for coordination of the forth carboxylato oxygen atom, a work that is currently under investigation in our group.

easy to use and fast enough to allow the study of relatively large molecules of transition metal complexes [15]. The spin-allowed singlet–singlet electronic transitions of *fac*-[Re(CO)$_3$(tbtmma)Cl] have been calculated with the time-dependent DFT method (TDDFT method), and a good assignment with the experimental spectrum has been observed.

2. Experimental

2.1. General procedure

The reaction was performed under argon atmosphere. The solvents were dried before use, using the appropriate drying reagents. Re(CO)$_5$Cl and 2-thienyl-*N*,*N*-bis(2-thienylmethylene)methanediamine (tbtmma) were purchased from Aldrich, and used as received.

IR spectrum was recorded on a Nicolet Magna 560 spectrophotometer in the spectral range 4000–400 cm^{-1} with the sample in the form of KBr pellet. Electronic spectrum was measured on a spectrophotometer Lab Alliance UV–VIS 8500 in the range 1000–200 nm in dichloromethane solution. Elemental analyses (CHN) were performed on a Perkin-Elmer CHN-2400 analyzer.

2.2. Preparation of [Re(CO)$_3$(tbtmma)Cl]

Re(CO)$_5$Cl (0.2 g, 0.55 mmol) and tbtmma (0.18 g, 0.58 mmol) in toluene (80 cm^3) were refluxed for 6 h. The resulting reaction mixture was allowed to cool at room temperature and reduced in volume to ~10 ml. An off-yellow solid was filtered off, washed with hexane, diethyl ether, and dried; yield: 85%.

X-ray quality crystals of complex [Re(CO)$_3$(tbtmma)Cl] were grown by the vapour diffusion of diethyl ether into a solution of the complex dissolved in dichloromethane.

IR (KBr, cm^{-1}): $\nu_{CO} = 2018$, 1910 and 1898 cm^{-1}; $\nu_{CN} = 1613$ cm^{-1}.

2.3. Crystal structures determination and refinement

The yellow crystal of [Re(CO)$_3$(tbtmma)Cl] was mounted on a KM-4-CCD automatic diffractometer equipped with a CCD detector, and used for data collection. X-ray intensity data were collected with graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at temperature of 293(2) K. Details concerning crystal data and refinement are given in Table 1. Lorentz, polarization and empirical absorption correction using spherical harmonics implemented in SCALE3 ABSPACK scaling algorithm [16] were applied. The structure was solved by the Patterson method and subsequently completed by the difference Fourier recycling. All the non-hydrogen atoms were refined anisotropically using full-matrix, least-squares technique. The hydrogen atoms were treated as, ''riding'' on their parent carbon atoms [d(C–H) = 0.930 (phenyl) and 0.970 (methylene) Å] and assigned isotropic temperature factors equal 1.2 times the value of equivalent temperature factor of the parent carbon atom. SHELXS 97 [17], SHELXL 97 [18] and SHELXTL [19] programs were used for all the calculations. Atomic scattering factors were those incorporated in the computer programs.

Table 1
Crystal data and structure refinement for [Re(CO)$_3$(tbtmma)Cl]·CH$_2$Cl$_2$

Empirical formula	$C_{19}H_{14}Cl_3O_3N_2S_3Re$
Formula weight	707.05

Independent reflections [R_{int}]	4189 [0.0234]
Completeness to 2θ (%)	97.2
Maximum and minimum transmission	0.644 and 0.271
Data/restraints/parameters	4189/0/280
Goodness-of-fit on F^2	1.002
Final R indices [$I > 2\sigma(I)$]	$R_1 = 0.0243$, $wR_2 = 0.0583$
R indices (all data)	$R_1 = 0.0296$, $wR_2 = 0.0592$
Largest difference in peak and hole (e Å^{-3})	1.337 and −0.737

2.4. Computational details

GAUSSIAN 03 program [20] was used in the calculations. The geometry optimization was carried out with the DFT method with the use of B3LYP functional [21,22]. The electronic spectrum was calculated with the TDDFT method [23]. The calculations were performed by using ECP basis set on the rhenium atom, the standard 6-31+g** basis for chlorine, oxygen, carbon, nitrogen and sulphur, and 6-31G basis for hydrogen atoms. The Xe core electrons of Re were replaced by an effective core potential and DZ quality Hay and Wadt Los Alamos ECP basis set (LANL2DZ) [24] was used for the valence electrons. Additional d function with exponent $\alpha = 0.3811$ and f function with exponent $\alpha = 2.033$ on the rhenium atom were added. Natural bond orbital (NBO) calculations were performed with the NBO code [25] included in GAUSSIAN 03.

3. Results and discussion

3.1. Preparation and infrared data

The $[Re(CO)_3(tbtmma)Cl]$ complex was prepared by refluxing the $[Re(CO)_5Cl]$ compound with a small excess of 2-thienyl-*N*,*N*-bis(2-thienylmethylene)methanediamine in toluene. The complex was isolated as air-stable, microcrystalline solid, soluble in common organic solvents. The infrared spectrum of the complex displays three bands in the carbonyl stretching region: a sharp intense band at 2018 cm^{-1} and two lower-energy bands closely spaced (1910 and 1898 cm^{-1}). This pattern corresponds to three CO units in a *fac* isomer arrangement [26]. The band of the C=N stretching modes of 2-thienyl-*N*,*N*-bis(2 thienylmethylene)methanediamine is observed at 1613 cm^{-1} [27].

3.2. Crystal structure

The $[Re(CO)_3(tbtmma)Cl]$ complex crystallises as the $[Re(CO)_3(tbtmma)Cl] \cdot CH_2Cl_2$ solvate in the triclinic space group $P\bar{1}$. There are no significant contacts involving the dichloromethane molecule and the tricarbonyl complex, with the possible exception of some rather weak hydrogen bonds [28,29]: C(14)–H(14)···Cl(2) $(-x, -1-y, 1-z)$ with D···A distance 3.664(4) Å and D–H···A angle 148.0°. The perspective drawing of the $[Re(CO)_3(tbtmma)Cl]$ complex with atomic numbering is shown in Fig. 1. The coordination geometry at the Re atom is a distorted octahedron with the three carbonyl ligands arranged in a *facial* fashion. Upon coordination of 2-thienyl-*N*,*N*-bis(2-thienylmethylene)methanediamine to a metal, a four-membered cycle (made by the two nitrogen atoms, the rhenium atom and the carbon atom) is formed. The small bite angle of the four-membered ring [62.31(13)°] is responsible for deviation of the rhenium coordination sphere from an ideal octahedron. The all thienyl rings are planar in the range of experimental error. The central ring makes dihedral angles of 88.51(15)° and 72.24(15)° with the side rings, and these last ones are inclined at 20.1(2)°. The C5–C4–N1–C14–N2–C9–C10 moiety torsion angles are 178.3(4)°, 164.3(3)°, −163.7(3)°, 179.0(4)°, respectively and C(15)–C(14)–N(1)–C(4), C(15)–C(14)–N(2)–C(9) torsion angles are 40.2(5)°, −39.5(5)°, thus the complex has a pseudo symmetry mirror plane going through Re(1),

Cl(1), C(14), H(14), C(16), H(16), C(17), H(17), C(18), H(18), and S(3) atoms.

The selected bond lengths and angles of [Re(CO)$_3$(tbtmma)Cl] are given in Table 2. The Re–C and Re–N bond distances are within the range expected for such complexes [30].

3.3. Optimised geometry

The geometry of [Re(CO)$_3$(tbtmma)Cl] was optimised in a singlet state by the DFT method with the B3LYP functional. The optimised geometric parameters are gathered in Table 2. Generally, the calculated bond lengths and angles are in agreement with the values based upon the X-ray crystal structure data.

3.4. Electronic structure and NBO analysis

The [Re(CO)$_3$(tbtmma)Cl] complex is a closed-shell structure. Its molecular orbital diagram with several HOMO and LUMO contours is presented in Fig. 2. The HOMO–LUMO gap equals to 3.27 eV. The low-lying virtual orbitals correspond to $\pi^*(SC_4H_3)/\pi^*$ (N=C) orbitals of 2-thienyl-*N*,*N*-bis(2-thienylmethylene)methanediamine

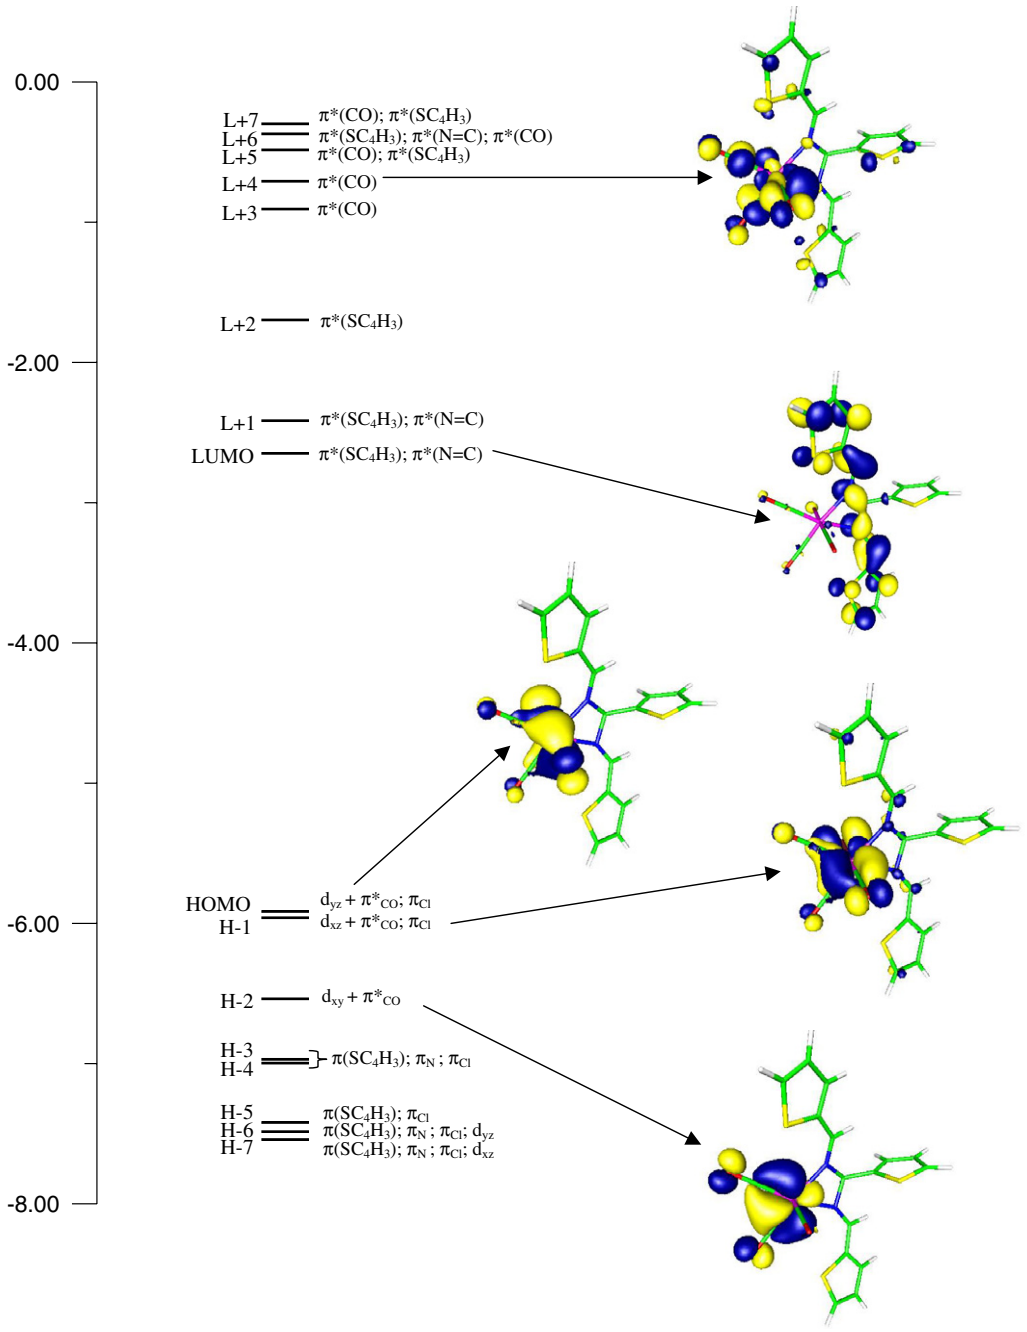

Fig. 2. The energy (eV), character and some contours of the unoccupied molecular orbitals of [Re(CO)$_3$(tbtmma)Cl].

Table 3
The occupancies and hybridization of the calculated Re–C and C–O natural bond orbitals (NBOs) for [Re(CO)$_3$(tbtmma)Cl]

	1.996 (0.221)	$0.497(p)_C + 0.868(p)_O$

BD denotes 2-center bond.

and π^*_{CO}. The HOMO, HOMO − 1 and HOMO − 2 orbitals are predominantly of d_{Re} orbital character corresponding to the $(5d_{xy})^2(5d_\pi)^4$ occupation of the central ion.

Table 3 presents the occupancies and hybridization of the calculated Re–C and C–O natural bond orbitals (NBOs) for [Re(CO)$_3$(bpzpy)Cl].

Each natural bond orbital (NBO) σ_{AB} can be written in terms of two directed valence hybrids (HHOs) h_A i h_B on atoms A and B:

$$\sigma_{AB} = c_A h_A + c_B h_B$$

where c_A i c_B are polarization coefficients. Each valence bonding NBO must in turn be paired with a corresponding valence *anti*-bonding NBO:

$$\sigma*_{AB} = c_B h_A - c_A h_B$$

to complete the span of the valence space. The Lewis-type (donor) NBOs are thereby complemented by the non-Lewis-type (acceptor) NBOs that are formally empty in an idealized Lewis picture. The interactions between 'filled' Lewis-type NBOs and 'empty' non-Lewis NBOs lead to loss of occupancy from the localized NBOs of the idealized Lewis structure into the empty non-Lewis orbitals, and they are referred to as 'delocalization' corrections to the zeroth-order natural Lewis structure [31].

For each carbonyl group of the [Re(CO)$_3$(tbtmma)Cl] complex, three natural bond orbitals were detected for the C–O bond, and one orbital – for the Re–C bond. All the Re–C bond orbitals are polarized towards the carbon atom, and the C–O bond orbitals are polarized towards the oxygen end. Each oxygen atom of the carbonyl ligand possesses one lone pair (LP) orbital. The occupancies of the *anti*-bonding NBOs are given in round brackets.

The resonance structure $M-C\equiv O^{+}:$, which presents the best bonding between CO ligands and Re ion in [Re(CO)$_3$(tbtmma)Cl], is consistent with the values of the calculated atomic charges. The atomic charges from the Natural Population Analysis (NPA) for [Re(CO)$_3$(tbtmma)Cl] are shown in Table 4. The calculated charges on the carbon atoms of the carbonyl ligands are positive, whereas the oxygen atoms are negatively charged. The least positive is carbon in the *trans* position to the chloride ion. The calculated charge on the rhenium atom of [Re(CO)$_3$(tbtmma)Cl] is lower than the formal charge +1. The populations of the $5d_{xy}$, $5d_{xz}$, $5d_{yz}$, $5d_{x^2-y^2}$ and $5d_{z^2}$ orbitals of the central atom in [Re(CO)$_3$(tbtmma)Cl] are following: 0.951, 1.568, 1.555, 1.558 and 1.029.

Table 4

spectrum, only transitions with oscillator strengths larger than 0.010 are listed in Table 5.

The assignment of the calculated transitions to the experimental bands is based on the criterion of the energy and oscillator strength of the calculated transitions. In the description of the electronic transitions only the main components of the molecular orbital are taken into consideration.

The low-energy absorption band at 381.6 nm is attributed to MLCT transitions occurring from the rhenium center to the π-antibonding orbitals of the chelating ligand. The experimental absorption band at 338.4 nm is ascribed to the d → $\pi^*(SC_4H_3)/\pi^*(N{=}C)$ transitions (calculated at 364.9 and 342.4 nm) and ligand–ligand charge transfer transition at 330.7 nm. The oscillator strength of the last one is considerable larger than f values of the MLCT transitions; it has main contribution to this band. The experimental absorption bands at 308.0, 274.2 and 230.4 nm result from metal–ligand charge transfer (occurring from the rhenium ion to the π-antibonding orbitals of the N–N ligand or π-antibonding orbitals of the carbonyl group) and ligand–ligand charge transfer transitions. The oscillator strengths of LLCT transitions are generally considerable larger than that ones of MLCT transitions.

4. Conclusions

A novel $Re(CO)_3^+$ complex has been prepared and structurally as well as spectroscopically characterized. X-ray and IR studies confirm a *facial* geometry of the carbonyl ligands in the [$Re(CO)_3$(tbtmma)Cl] complex. The molecular orbital diagram of the title complex has been calculated with the density functional theory (DFT) method. The HOMO, HOMO − 1 and HOMO − 2 orbitals are predominantly of d_{Re} orbital character corresponding to the $(5d_{xy})^2(5d_{\pi})^4$ occupation. The low-lying virtual orbitals correspond to π-antibonding orbitals of the N–N ligand or π-antibonding orbitals of the carbonyl group. The spin-allowed electronic transitions of *fac*-[$Re(CO)_3$(tbtmma)Cl] have been calculated with the time-dependent DFT method, and a good agreement between calculated and experimental spectra is observed.

Supplementary material

CCDC 626360 contains the supplementary crystallographic data for $C_{19}H_{14}Cl_3O_3N_2S_3Re$. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Acknowledgement

The GAUSSIAN 03 calculations were carried out in the Wrocław Centre for Networking and Supercomputing, WCSS, Wrocław, Poland.

observation on isomers differing in charge distribution together under equilibrium condition giving rise to valence tautomerism [4–6].

Our interest is focused on studying mixed-valence complexes with SQ and Cat ligands and nitrogen-donor ancillary ligand. Our previous work on manganese and iron complexes with 3,6-DBBQ and pyridine ancillary ligand demonstrated complexes that exhibit valance tautomerism in the solid state [7–9]. The electronic spectra of such complexes show intense low-energy intervalence charge-transfer (IVCT) transition between catecholate and semiquinonate ligands.

In the literature there are number of complexes that contain mixed-valence quinone ligand and nitrogen-donor ancillary ligand. In almost all the cases either the *cis*- or the *trans*-isomer could be separated from the reaction medium. In the present work, we describe the synthesis and characterization of the two geometrical isomers of $Cr(py)_2$(chrySQ)(chryCat). The magneto-structural correlation has been studied. The electronic properties of the two isomeric complexes have been studied using ZINDO/S-CI routine. The electrochemical behaviors of the two complexes are described as well.

2. Experimental

The ligand 5,6-chrysenequinone, chryQ, was synthesized following a previously reported method [10]. All solvents were dried according to the standard procedures. For cyclic voltammetry measurements, acetonitrile solvent was further purified by vacuum distillation from calcium chloride and stored over molecular sieves. All other compounds were of reagent grade and were used as received.

The infrared spectra were recorded on a Thermo Nicolet Nexus 670 FTIR spectrometer with samples prepared as KBr pellets. Elemental analyses were performed using a Perkin–Elmer 2400 CHN elemental analyzer. Variable-temperature magnetic measurements were carried out on an Oxford Faraday magnetometer. The electronic absorption spectra (190–1100 nm) were recorded on a Cary 50 spectrophotometer in acetonitrile solution. Cyclic voltammograms were obtained with a model 303 HMDE in conjunction with a PAR model 173 potentiostat and PAR 175 universal programmer. A Ag/Ag^+ reference electrode was used that consisted of acetonitrile solution of $AgPF_6$ in contact with a silver wire placed in glass tubing with a Vycor frit at one end to allow ion transport. A 3.0 mm diameter glassy carbon disc was used as working electrode and a platinum wire as auxiliary electrode. Tetrabutylammonium hexafluorophosphate was used as the supporting electrolyte.

The semiempirical calculations in this study have been carried out using the HYPERCHEM 6.01 program package [11]. The Polak–Ribiere version of the conjugate gradient method was used in all energy minimization calculations with a coverage criterion less than 0.0001 kcal mol^{-1} $Å^{-1}$. First and separately chrysenesemiquinone and chrysenecatecholate ligands have been optimized and the results obtained have been applied in each calculation thereafter. The values of Cr–O and Cr–N bond lengths and angles in the literatures were used as the starting inputs [12–17]. Initial optimization of the two isomeric complexes was performed with molecular mechanics (MM+). The geometry was further refined using parameterized PM3 method. Available parameters for Cr metal were implemented in PM3 semiempirical method [18]. The parameterized PM3 was used for geometry optimization of the complexes under study. Triplet state URH spin pairing has been selected in addition to the standard SCF (with accelerated convergence). Theoretical harmonic vibrational frequencies are related to the experimental fundamentals by optimum scaling factor λ determined through a least-squares procedure giving by $\lambda = \sum_i^{all} \omega_i^{theor} \nu_i^{exp\,t} / \sum_i^{all} (\omega_i^{theo})^2$, where ω_i^{theor} and $\nu_i^{exp\,t}$ are the ith theoretical harmonic and ith experimental fundamental frequencies (in cm^{-1}) [19]. The molecular root mean square error (rms) was calculated by the square root of the sum over all the modes of Δ_{min} given in Ref. [19], where Δ_{min} is the minimized residual for each mode. The ZINDO/S-CI method parameterized to produce UV–Vis electronic transitions has been used to estimate the molecular orbital diagram of the complexes under study [20,21]. Electronic transition energies and oscillator strengths of both complexes were calculated using all valence electrons. The maximum excitation energy for configuration interaction calculations was 8.0 eV. The overlap weighing factors $f_{\sigma\sigma}$ and $f_{\pi\pi}$ were taken as 1.267 and 0.585 which had been used with good success for transition metals [22,23].

2.1. Synthesis of [Cr(py)$_2$(chrySQ)(chryCat)] complexes

2.1.1. Method 1

A mixture of chromium hexacarbonyl (0.15 g, 0.68 mmol) and chrysenequinone (0.35 g, 1.36 mmol) was dissolved in 50 mL of acetonitrile solvent under an inert atmosphere of dry nitrogen. The mixture was photolyzed with a Hg-lamp and heated at 65 °C for 3 h. To the purple solution obtained was added 0.2 mL (2.47 mmol) of pyridine and the solution is continued to heating for 12 h more. A solution color was then changed to brown. The solution was then rotary evaporated until dryness. A concentrated solution of the crude solid in acetonitrile was subjected to chromatography on neutral Al_2O_3 column. Three bands were separated by CH_2Cl_2 eluent; the red-brown and the dark-brown ones was found out to be *cis*- and the *trans*-$Cr(py)_2(ChryQ)_2$ complexes, respectively, whereas the orange band was identified by spectroscopy to be the unreacted chrysenequinone ligand. Slow evaporation of the solvent with a flow of dry nitrogen has resulted in microcrystals of the complexes. The products were obtained in 23% (*cis*-isomer) and 48% (*trans*-isomer) yields.

Anal. Calc. for $C_{46}H_{30}CrN_2O_4$ (MW = 726.76): C, 76.02; H, 4.16; N, 3.85. Found for *cis*-isomer: C, 75.85;

H, 4.24; N, 3.8%. Found for *trans*-isomer: C, 76.11; H, 4.13; N, 3.88%.

2.1.2. Method 2

The *tris*-[Cr(chrySQ)$_3$] complex was prepared as described in literature [24]. A 0.3 g (0.36 mmol) of [Cr(chrySQ)$_3$] was dissolved in 50 mL pyridine and refluxed at 100 °C. The solution turned form from purple to dark-brown over a period of 12 h. The resultant solution was then rotary evaporated until dryness. The crude solid was washed several times with petroleum ether (b.p. 40–60 °C). A concentrated solution of the crude solid in acetonitrile was subjected to chromatography on neutral Al_2O_3 as described in method 1. The products were obtained in 33% (*cis*-isomer) and 56% (*trans*-isomer) yields.

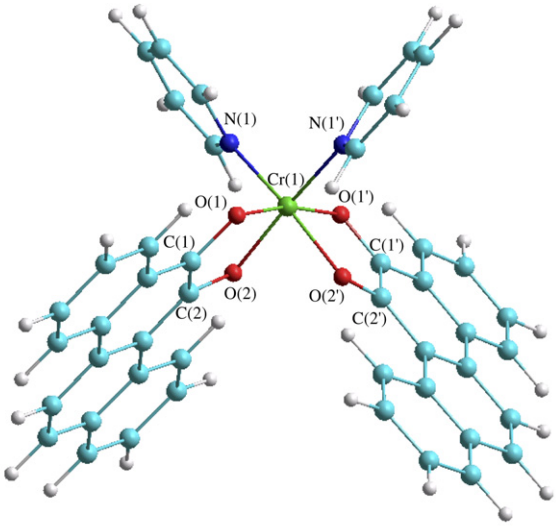
Anal. Found for *cis*-isomer: C, 75.87; H, 4.21; N, 3.82%. Found for *trans*-isomer: C, 76.08; H, 4.11; N, 3.87%.

3. Results and discussion

Irradiation of solutions containing a mixture of metal carbonyls, *o*-quinone ligand and nitrogen-donor coligand has been used as a general route for the synthesis of [M(N-base)$_n$(SQ)(Cat)] complexes, where $n = 1$ for bipyridine and $n = 2$ for pyridine ligands [7,25,26]. Photolysis of a solution containing either $Fe(CO)_5$, $Mn_2(CO)_{10}$ or $Co_2(CO)_8$ and 3,6-di-*tert*-butyl-1,2-benzoquinone in presence of *tert*-butyl-pyridine as a co-ligand had led to the formation of *trans*-isomer as the only isolated product [7,25]. Similar reactions with $Ni(CO)_4$ and $Co_2(CO)_8$ had led to the *cis*-[M(py)$_2$(phenSQ)$_2$], where phenSQ is phenanthrene-semiquinonate ligand [26].

In the present study, *cis*- and *trans*-[Cr(py)$_2$(chrySQ)-(chryCat)] complexes were synthesized by two different synthetic routes, where chrySQ and chryCat are chrysene-semiquinone and chrysenecatecholate, respectively. In the first procedure, a solution containing a mixture of chromium hexacarbonyl, chrysenequinone, chryQ and pyridine were photolyzed by a Hg-lamp. Another route for the synthesis of the complexes is by the displacement of one semiquinonate ligand in the *tris*-[Cr(chrySQ)$_3$] complex with two molecules of pyridine ligand. Isolation of chrysenequinone ligand from the reaction medium suggests that [Cr(py)$_2$(chrySQ)(chryCat)] complex might be formed as a result of one electron transfer from the displaced semiquinonate to one of the coordinated chrysenesemiquinone. In both of the synthetic procedures it was noticeable that the yield of the *cis*-isomer is lower than that of the *trans*-isomer. This may reflect the stability of the *trans*-isomer compared to the *cis*-isomer (vide infra).

The infrared spectra of the two isomeric complexes are dominated by a strong absorption near 1450 cm^{-1} due to CO stretching mode of the semiquinone ligand [27]. Characteristic bands assigned to the C–O stretching vibration and the ring stretching mode of the catecholate moiety of the complex, respectively, were observed for the *cis*-isomer at 1238 and 1485 cm^{-1} and for the *trans*-isomer at 1227 and 1486 cm^{-1} [28,29]. The IR data clearly demonstrate the ligand-based mixed-valence state of the chrysenequinone ligand in both complexes. Vibrations attributed to the coordinated pyridine were observed in the 750–630 cm^{-1} region of the spectra. There is no band observed at 605 cm^{-1} due to the C–H out-of-plane bending of the free pyridine. This is a clear indication of pyridine coordination to chromium metal ion in both complexes [29].



The spectroscopic techniques give no information about the geometry of the complex. Unfortunately, there is no structural data available for the two isomeric complexes due to the poor quality of the crystals obtained. Also to our knowledge there have not been crystal structures reported for chrysenequinone ligand or its complexes. Hence, it is considered worthwhile to model the two isomers using semiempirical parameterized PM3 method and calculate their vibrational frequencies.

The heat of formation calculated for *cis*- and *trans*-[Cr(py)$_2$(chrySQ)(chryCat)] using parameterized PM3 were −79.3 and −82.1 kcal/mol, respectively. This could explain the higher yield of the more stable *trans*-isomer obtained

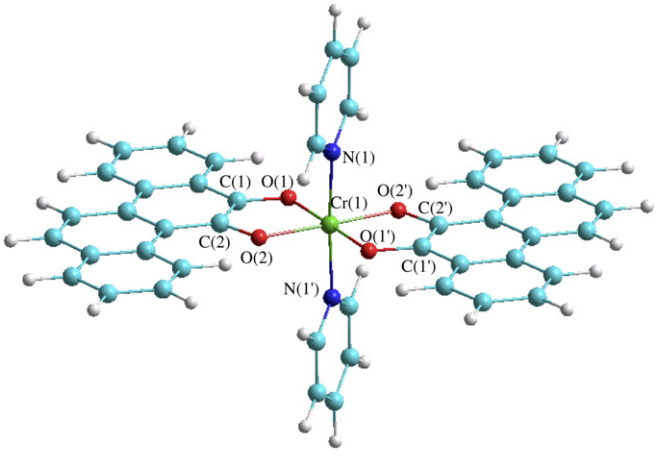


Table 1
Selected bond lengths (Å) and angles (°) for *cis*- and *trans*-[Cr(py)$_2$(chrySQ)(chryCat)] obtained from parameterized PM3 geometry optimization

	cis-Isomer	*trans*-Isomer
Bond lengths		
Semiquinonate		
Cr(1)–O(1)	1.953	1.946
Cr(1)–O(2)	1.941	1.940
O(1)–C(1)	1.319	1.299
O(2)–C(2)	1.293	1.322
C(1)–C(2)	1.441	1.436
Catecholate		
Cr(1)–O(1′)	1.931	1.926
Cr(1)–O(2′)	1.929	1.930
O(1′)–C(1′)	1.364	1.359
O(2′)–C(2′)	1.357	1.368
C(1′)–C(2′)	1.416	1.417
Pyridine		
Cr(1)–N(1)	1.987	2.031
Cr(1)–N(1′)	1.973	2.031
Bond angles		
O(1)–Cr(1)–O(2)	82.5	82.6
O(1′)–Cr(1)–O(2′)	85.6	86.1
O(1)–Cr(1)–O(1′)	169.3	178.8
O(2)–Cr(1)–O(2′)	85.8	177.7
O(1)–Cr(1)–O(2′)	88.4	95.1
O(2)–Cr(1)–O(1′)	88.0	96.2
N(1)–Cr(1)–N(1′)	96.7	176.3
O(1)–Cr(1)–N(1)	93.7	91.5
O(1)–Cr(1)–N(1′)	89.2	91.5
O(2)–Cr(1)–N(1)	88.6	91.3
O(2)–Cr(1)–N(1′)	172.8	91.3
O(1′)–Cr(1)–N(1)	94.7	88.6
O(1′)–Cr(1)–N(1′)	96.4	88.6
O(2′)–Cr(1)–N(1)	173.8	88.8
O(2′)–Cr(1)–N(1′)	89.1	88.8

from the two synthetic procedures. The calculated bond lengths and angles obtained from the semiempirical PM3 geometry optimization for the two isomers are summarized in Table 1. The optimized geometries for the *cis*- and *trans*-[Cr(py)$_2$(chrySQ)(chryCat)] are shown in Fig. 1. The chromium center is six-coordinated with four oxygen donors from the two chrysenequinone based ligands and two nitrogens atoms from the pyridine ligand. The average Cr–O bond distances calculated for the *cis*-isomer were 1.947 Å (SQ) and 1.930 Å (Cat). The values reported for *cis*-[Cr(bpy)(SQ)(Cat)] were 1.949 Å (SQ) and 1.939 Å (Cat) and those reported for [Cr(Cl$_4$SQ)$_3$] and [Cr(3,5-DBSQ)$_3$] were 1.949 Å (SQ) and 1.939 Å (SQ), respectively [13,15,30]. The average Cr–O bond distances calculated for the *trans*-isomer were 1.943 Å (SQ) and 1.928 Å (Cat) and those reported for the *trans*- [Cr(CH$_3$CN)$_2$(Cl$_4$SQ)-(Cl$_4$Cat)] were 1.935 Å and 1.929 Å [13]. The Cr–N bond distances with an average value of 2.031 Å for the *trans*-isomer, are slightly longer than the corresponding average for the *cis*-isomer (1.980 Å) and compares well with those reported for Cr–N bond distances [15,16]. While the Cr–O bond distance is an indicative of chromium oxidation state, the C–O and C–C bond distances are the evidence of oxidation state of the quinone ligand. The average C–O bond distances calculated for the *cis*- and the *trans*-isomers were 1.306 and 1.362 Å and 1.311 and 1.364 Å, respectively. The average C–O value reported for the semiquinonate and the catecholate ligands in the [Cr(bpy)(DTBSQ)-(DTBCat)] were 1.297 and 1.358 Å, respectively [31]. However, those reported for the phenenthrenesemiquinonate and phenanthrenecatecholate were 1.321 and 1.346 Å, respectively [32,33]. These structure differences imply a mixed-valence state for the two quinone based ligands. Another difference between SQ and Cat ligands can be found in the bit angle which is approximately 2° smaller in SQ than that of the Cat ligand [13]. This can be seen in the structure of the two isomers, where the calculated O(1′)–Cr(1)–O(2′) angle (Cat) for the *cis*- and *trans*-siomers were, respectively, 85.6° and 86.1° larger than the 82.5° and 82.6° of O(1)–Cr(1)–O(2) angle (SQ).

cis-[Cr(py)$_2$(chrySQ)(chryCat)]

trans-[Cr(py)$_2$(chrySQ)(chryCat)]

Fig. 1. The geometrical structures of [Cr(py)$_2$(chrySQ)(chryCat)] complexes optimized using parameterized PM3 method.

The vibrational frequencies based on the optimized geometries were calculated and compared with the observed fundamental frequencies in Table 2. The optimized scale factors determined for *cis*- and *trans*-isomers were 0.998362 and 0.996720, respectively. As can be seen in Table 2, the calculated harmonic vibrational frequencies compare well with the fundamental experimental frequencies. The calculated root mean square error (rms) per molecule is 58.5 and 47.2 cm^{-1} for *cis*- and *trans*-isomers, respectively. The rms values compare very well with those reported for vibrational frequencies calculations using HF/6-311 G(df, p) (rms = 56), MP2-fc/6-311 G(d, p) (rms = 60) and B-LYP/6-31 G(d) (rms = 45) [34].

Table 2
Characteristic calculated and observed vibrational frequencies (cm^{-1}) for *cis*- and *trans*-[Cr(py)$_2$(chrySQ)(chryCat)] complexes

cis-Isomer		*trans*-Isomer		Assignment
Calculated	Observed	Calculated	Observed	
1601	1609	1595	1600	νC=C (Cat)
1578	1594	1525	1537	νC=C (SQ)
1510	1516	1510	1513	νC=N (py)
1498	1485	1492	1486	ring deformation (Cat)
1452	1445	1443	1450	νC=O (SQ)
1335	1330	1336	1337	νC–O (SQ)
1232	1238	1230	1227	νC–O (Cat)

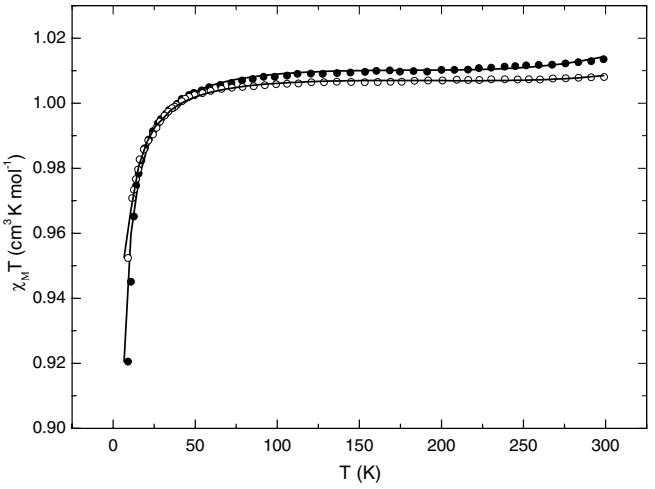

Fig. 2. Plots of the temperature dependence of $\chi_M T$ for *cis*- (•) and *trans*- (○) isomers of [Cr(py)$_2$(chrySQ)(chryCat)] complex. The solid lines represent the non-linear least-squares fits of the experimental data to theoretical equation given in text.

The temperature dependence of the magnetic susceptibility in the range 10–300 K for solid samples of the two isomeric complexes is shown in Fig. 2. At 300 K, the values are 1.013 and 1.008 cm^3 K mol^{-1} for the *cis*- and *trans*-isomers, respectively. They are close to the theoretical value of 1.00 cm^3 K mol^{-1} expected for an $S = 1$ spin ($g = 2.00$). The $S = 1$ ground state could be attributed to the intramolecular antiferromagnetic interactions between an $S = 3/2$, spin on the Cr(III) ion and an $S = 1/2$ spin on the chrySQ ligand. With these values of $\chi_M T$ and the little temperature dependence observed in the region of 53–300 K for the two complexes, it must be concluded that the coupling is strongly antiferromagnetic with a ground state $S = 1$. These results are similar to those reported for *trans*-[Cr(Cl$_4$SQ)(Cl$_4$Cat)(CH$_3$CN)$_2$] and *cis*-[Cr(Cl$_4$SQ)-(Cl$_4$Cat)(bpy)] containing the same spin components as the present complexes [15]. At temperature below ~50 K the $\chi_M T$ decreases below the spin-only value to 0.92 and 0.95 cm^3 K mol^{-1} for the *cis*- and *trans*-isomers, respectively. This decrease of $\chi_M T$ values at lower temperatures may be attributed to weak antiferromagnetic intermolecular interaction (θ) between the neighboring complexes [8,15].

The electron exchange between Cr(III) metal ion and chrySQ ligand in the two complexes can be described by the simple Heisenberg Hamiltonian, $H = -2JS_1 \cdot S_2$ ($S_1 = 3/2$, $S_2 = 1/2$), where J is the electron exchange integral that gauges the magnitude of electronic coupling between the spin centers. The exchange interaction J between chromium ion and chrySQ ligand was estimated by the non-linear least-squares fits for the magnetic susceptibilities, χ_M, given by the following equation:

$$\chi_M = (N\beta^2 g^2/k(T-\theta))[(2\exp(-4J/kT) + 10) /(3\exp(-4J/kT) + 5)] + \mathrm{TIP} \quad (1)$$

where N, β, g, k have their usual meaning. The Weiss constant (θ) is introduced in the equation to gauge intermolecular magnetic interaction at lower temperature and the temperature-independent paramagnetism (TIP) is to account for the slight positive slope observed in the data with increasing temperature [16]. The non-linear least-squares fits of the $\chi_M T$ to 52 experimental data points through the above equation yielded $J = -365 \pm 6$ cm^{-1}, $g = 2.01 \pm 0.0006$, $\theta = -0.35 \pm 0.007$ cm^{-1}, TIP $= 2 \times 10^{-5} \pm 1.07 \times 10^{-6}$ cm^3 mol^{-1} with $R = 6.3 \times 10^{-4}$ (*cis*-isomer) and $J = -395 \pm 4$ cm^{-1}, $g = 2.01 \pm 0.0003$, $\theta = -0.24 \pm 0.005$ cm^{-1}, TIP $= 2 \times 10^{-5} \pm 1.5 \times 10^{-6}$ cm^3 mol^{-1} with $R = 4.3 \times 10^{-4}$ (*trans*-isomer). The function minimized in the curve fitting was $R = (\sum(\chi_M T^{obs} - \chi_M T^{calc})^2 / \sum(\chi_M T^{obs})^2)^{1/2}$. The fits are illustrated in Fig. 2 as solid lines. The results obtained from the curve fitting agree well with those reported by Benelli et al. for [Cr(CTH)(DTBSQ)]$_2$Cl(PF$_6$)$_3$ and Wheeler and McCusker for [Cr(tren)(3,6-DTBSQ)](PF$_6$)$_2$ [16,35].

The electrochemical properties of [Cr(py)$_2$(chrySQ)-(chryCat)] complexes were studied by cyclic voltammetry in acetonitrile solvent. The results are given in Fig. 3 and Table 3. The dominant feature of the voltammograms is one-electron oxidation and reduction of the ligand moieties

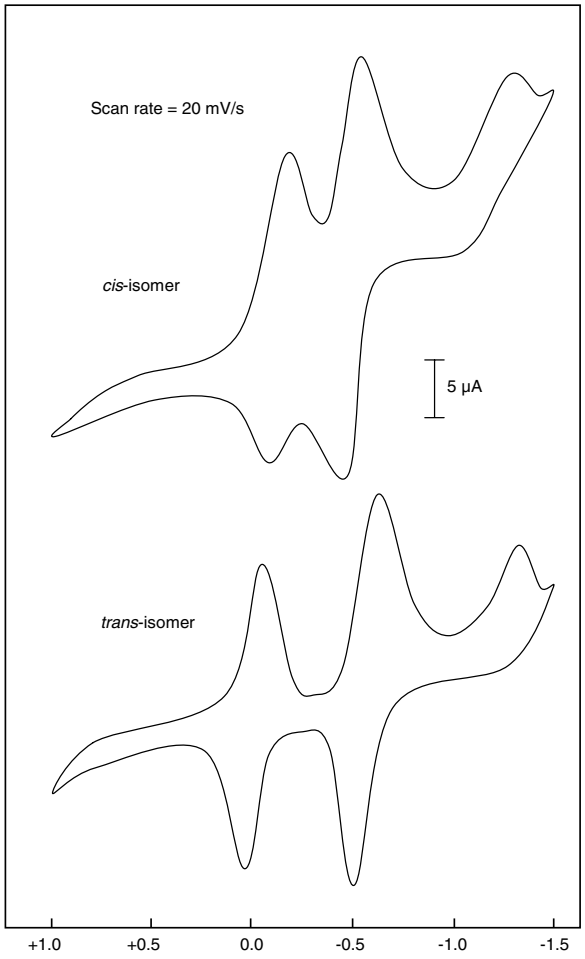

Fig. 3. Cyclic voltammograms of [Cr(py)$_2$(chrySQ)(chryCat)] complexes.

[b] Separation between $E_{1/2}$(+1/0) and $E_{1/2}$(0/−1) is 302 mV (*cis*-isomer) and 551 mV (*trans*-isomer).

since the chromium ion retains a trivalent state in this potential region. The reduction wave was observed for the *cis*- and *trans*-isomers near −495 and −561 mV *versus* $Ag/Ag^+/CH_3CN$, respectively. Surprisingly, the oxidation wave for the *trans*-isomer was observed at more positive potential (−10 mV) compared to that for the *cis*-isomer (−139 mV). Also, the separation between the redox waves for oxidation and reduction processes was surprisingly 302 and 551 mV for the *cis*- and *trans*-isomers, respectively. This could be attributed to charge delocalization between mixed-valence ligands which is greater in the *trans*-isomer. The degree of charge delocalization can be determined by calculating the comproportionation constant, $K_c = \exp(\Delta EF/RT)$ [36,37]. As the degree of delocalization increases, ΔE and also K_c increase. The K_c values calculated for *cis*- and *trans*-isomers were 1.3×10^5 and 2.1×10^9, respectively. The calculated values indicate greater degree of delocalization between the SQ and Cat ligands in the *trans*-isomer. In agreement with these results, X-ray structural studies of *trans*- [Cr(Cl_4SQ)(Cl_4Cat)(CH_3CN)$_2$] indicated charge delocalization between the SQ and Cat ligands while for *cis*-[Cr(Cl_4SQ)(Cl_4Cat)(bpy)] the charge is localized on the ligands [15]. The two one-electron processes can be represented by Eq. (2). The one-electron reduction would provide $[Cr^{III}(py)_2(chryCat)_2]^-$ species (right) with two

$$[Cr(py)_2(chrySQ)_2]^+ \overset{+e}{\underset{-e}{\rightleftharpoons}} [Cr(py)_2(chrySQ)(chryCat)] \overset{+e}{\underset{-e}{\rightleftharpoons}} [Cr(py)_2(chryCat)_2]^- \quad (2)$$

Cat ligands, while the oxidation affords a cationic $[Cr^{III}(py)_2(SQ)_2]^+$ species (left) with two SQ ligands. Finally, both complexes showed additional irreversible one-electron reduction waves near −1300 mV. The process could be attributed to the reduction of the Cr(III) to the Cr(II) ion.

The electronic absorption spectra of the *cis*- and *trans*-isomers in acetonitrile solution in the region 350–1100 nm are shown in Figs. 4 and 5, respectively. The dominant feature of the electronic spectra of the two isomers is intense bands at 392, 443 and 566 nm, with shoulders at 486 and 517 nm for the *cis*-isomer, and 396, 445 and 566 nm, with a shoulder at 511 nm for the *trans*-isomer. Lower intensity bands were observed at 681, 786 and 968 nm for the *cis*-isomer and 732, 804 and 968 nm for the *trans*-isomer. A low-energy band of medium intensity ($\log \varepsilon = 3.35$) was observed at 1085 nm for the *cis*-isomer. Benelli et al. reported the electronic spectrum of $[Cr(CTH)(TCSQ)]^{2+}$ that revealed bands at 990 nm with shoulders at 1136 and 877 nm which were assigned as diagnostic of semiquinone ligand and were attributed to transitions to the HOMO from the second highest occupied molecular orbital [35].

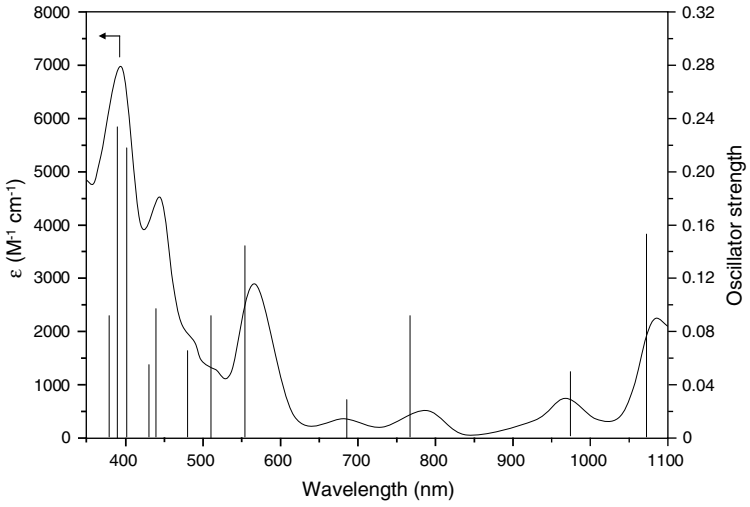

Fig. 4. The observed electronic spectrum in acetonitrile (curve) and the computed transitions resulted from ZINDO/S-CI calculations (lines) of *cis*-[Cr(py)$_2$(chrySQ)(chryCat)].

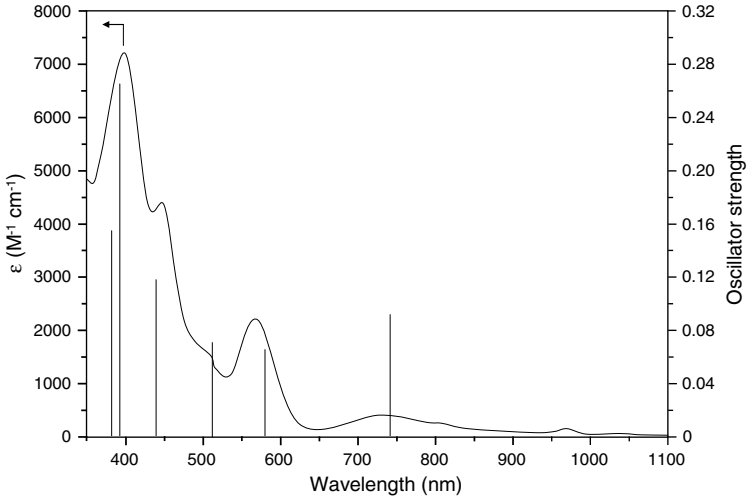

Fig. 5. The observed electronic spectrum in acetonitrile (curve) and the computed transitions resulted from ZINDO/S-CI calculations (lines) of *trans*-[Cr(py)$_2$(chrySQ)(chryCat)].

Another band was observed for the $[Cr(CTH)(TCSQ)]^{2+}$ complex near 400 nm and was attributed to internal ligand transitions. However the metal-to-ligand charge-transfer transition was observed at 498 and 458 nm. Chang et al. reported similar metal-to-ligand charge-transfer transition at 526 nm for *cis*-[Cr(bpy)(Cl_4SQ)(Cl_4Cat)] complex [15]. In addition, a transition attributed to bpy ligand was observed at 476 nm. In fact the assignment of the spectra for the *cis*- and *trans*-[Cr(py)$_2$(chrySQ)(chryCat)] is not straightforward especially with a system that shows a strong exchange coupling interaction between Cr(III) metal ion and SQ ligand. To interpret these spectra one has to include the effect of the exchange coupling on the electronic states of the complexes under study. To accomplish this goal, the ZINDO/S-CI method was used to interpret the spectra of both complexes.

The ZINDO/S method parameterized to produce the UV–Vis electronic transitions has been used to estimate the molecular orbitals of the two complexes. This method has been previously used to reproduce the spectra of several complexes of the first transition-metal series and more particularly for studying the spectroscopy of the

[a] L and H represent LUMO and HOMO, respectively. L + *n* indicates the *n*th molecular orbital above the LUMO and H − *n* indicates the *n*th molecular orbital below the HOMO.

[b] V, S and O represent unoccupied (virtual), singly occupied and doubly occupied molecular orbitals, respectively.

internal d–d excitations [38]. Also, it was successful in studying the electronic spectrum of dinuclear Co(III) and Cr(III) complexes of bis(ditholene) radical [39].

Table 4 lists the results of ZINDO/S-CI energies, composition, and main character of some frontier molecular orbitals. The shape of the magnetic (HOMO and HOMO − 1) and the doubly occupied (HOMO − 2) molecular orbitals for the two isomers are pictorially shown in Fig. 6. As can been seen, the two singly occupied molecular orbitals (HOMO and HOMO − 1) are more delocalized on metal, SQ and Cat in the *trans*-isomer compared to those for the *cis*-isomer. Also, the highest doubly occupied molecular orbital (HOMO − 2) is delocalized over SQ and Cat ligands in the *trans*-isomer while is localized on the Cat ligand in the *cis*-isomer.

Results of the calculated electronic transitions for the *cis*- and *trans*-isomers are shown in Figs. 4 and 5, respectively. The assignment of the computed electronic transitions is listed in Table 5. There is a good agreement between the computed active transitions and the observed bands. As expected for complexes having the general formula [M(N-base)(SQ)(Cat)], where M is a transition metal and N-base is pyridine, bipyridine, or phenanthroline ligands, to show varieties of charge-transfer transitions [9,15,40–44]. For the complexes under studies the possible charge-transfer transitions are metal-to-ligand (MLCT) from Cr(d_π) to acceptor orbitals on SQ and py and/or ligand-to-metal (LMCT) from Cat and SQ to Cr(III),

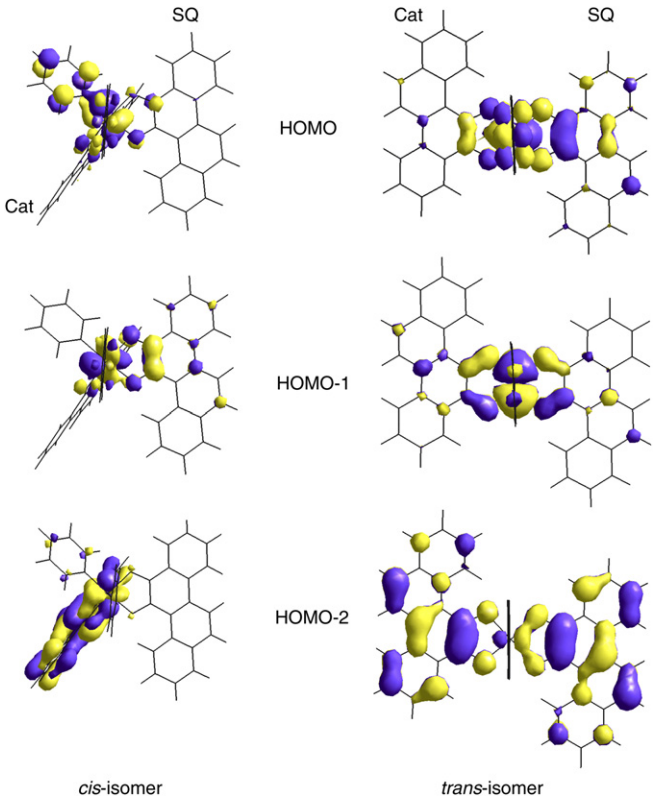

Fig. 6. The two singly occupied (HOMO and HOMO − 1) and the highest doubly occupied (HOMO − 2) molecular orbitals for *cis*- and *trans*-[Cr(py)$_2$(chrySQ)(chryCat)] complexes.

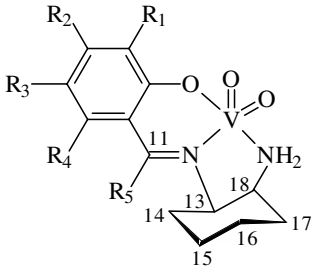
and interligand charge-transfer (ILCT) transitions from Cat to SQ, Cat to py and/or SQ to py.



The most characteristic band in the electronic spectra of [Cr(py)$_2$(chrySQ)(chryCat)] complexes observed at 566 nm was well predicted by ZINDO/S calculations. It was assigned as Cr → SQ metal-to-ligand charge-transfer transition with major configurations 0.59(H → L + 3) and 0.5(H − 1 → L + 3) for the *cis*- and *trans*-isomers, respectively. Where the H in the *cis*-isomer has 60.1% metal character and the H− 1 in the *trans*-isomer has 63.7% metal character, whereas the L + 3 in both complexes have SQ as a major contribution to the molecular orbital. In agreement with this assignment the [Cr(DTBSQ)$_3$] complex showed a strong band at 570 nm [28]. Also, the electronic spectrum of $[Cr(CTH)(TCSQ)]^{2+}$ are dominated by a strong absorption band at 498 nm that was assigned as Cr → SQ MLCT transition [35]. Transitions of the type Cat or SQ → Cr(III) LMCT were also predicted by ZINDO/S calculations to be the bands observed for the *cis*-isomer at 986 (SQ → Cr) and 517 nm (Cat → Cr) with major configurations 0.46(H − 3 → H) and 0.91(H − 2 → H), respectively and for the *trans*-isomer at 511 nm (Cat → Cr and SQ → Cr) with major configurations 0.99(H − 2 → H − 1). Transitions involving the pyridine ligand were assigned to absorption bands at 486, 443 and 392 nm for the *cis*-isomer and at 445 and 396 for the *trans*-isomer with major configurations shown in Table 5. Interestingly, the ZINDO/S calculations indicated that the intense band observed near 445 nm is Cr → py MLCT

for the *trans*-isomer whereas for the *cis*-isomer it is composed of Cr → py and SQ → py transitions. Also, the absorption band near 392 nm has a contribution from Cat → py and SQ → py ILCT transitions with more contribution form the former for the *cis*-isomer. The most spectacle observation of the spectrum of the *cis*-isomer is a lower-energy band at 1085 nm ($\log\varepsilon = 3.35\ M^{-1}\ cm^{-1}$) which was predicted by ZINDO/S calculation as Cat → SQ intervalence charge-transfer (IVCT) transition with major configuration $0.51(H-2 \rightarrow H-1)$. This transition occurs between the highest doubly occupied and the lowest singly occupied molecular orbitals. Consistence with this assignment the electronic absorption spectrum of *cis*-[Fe(bpy)(phenSQ)(phenCat)] showed a transition that attributed to Cat → SQ intervalence charge-transfer transition at 1131 in THF solution and at 1050 nm in the solid state as KBr pellet, while these bands was not observed for $[Fe(DBSQ)_3]$ [29]. It was striking that the *trans*-isomer did not show this transition. This could be attributed to higher charge delocalization between the Cat and SQ ligands in the *trans*-isomer which might show this transition at much lower energy of the IR region of the spectrum. Finally, ligand field (LF) transitions, $Cr(t_{2g}) \rightarrow Cr(e_g)$ were well predicted for the low-intensity transitions observed at 687 and 681 nm for the *cis*-isomer and at 732 nm for the *trans*-isomer. The computed LF transitions for the *cis*-isomer were 766 and 785 nm with major configurations $0.49(H \rightarrow L+1)$ and $0.49(H-1 \rightarrow L+1)$, respectively, whereas that computed for the *trans*-isomer was 739 nm with a major configuration $0.51(H \rightarrow L+1)$. These transitions were expected to be spin-forbidden however its intensity is several hundred times compared with that observed for $[Cr(tren)(DTBCat)]^+$ and $[Cr(acac)_2(en)]^+$ [16,45]. Such enormous enhancement in the spin-forbidden transition was ascribed to the exchange coupling between Cr(III) and the SQ radical [35]. These observations agree with the results of ZINDO/S calculations which show that H in the *trans*-isomer composed of 41.9% Cr and 26.9% SQ and H − 1 in the *cis*-isomer composed of 44.1% Cr and 43.5% SQ.

as well bulk mixtures of vanadyl, aldehyde and chiral amine [24] are effective catalyst in the reaction of asymmetric oxidation of prochiral sulfides to sulfoxides. Chiral sulfoxides form an important class of compounds finding an increasing use as chiral auxiliaries in asymmetric syntheses of biologically active compounds [25]. Recently [26] we have shown that the coordination geometry of vanadium in VO_2L, where L is the deprotonated product of 1:1 condensation of 2-methyl-1,2-diaminopropane and 4,6-dimethoxysalicylaldehyde, is approximately trigonal bipyramidal and that the complex catalyses the oxidation of methyl phenyl sulfide to the methyl phenyl sulfoxide. Optically active *trans*-1,2-diaminocyclohexane singly condensed with salicylaldehyde residue attached to a resin was synthesized by Sherington et al. [27] and used as a starting material for preparation of resin-supported chiral metal–salen complexes to form a basis of immobilized catalysis. In continuation of our studies on synthesis, structure, spectroscopic and catalytic properties of vanadium complexes incorporating a product of single condensation of a diamine [26], we prepared a series of new chiral dioxovanadium(V) complexes comprising coordinated single condensation products of *RR*(−) and *SS*(+)-1,2-diaminocyclohexane with aromatic *o*-hydroxyaldehydes and *o*-hydroxyketones presented in Fig. 1. We examined their spectroscopic (^{1}H, ^{13}C, ^{51}V NMR, UV–Vis, IR) and catalytic properties in the asymmetric oxidation of methyl phenyl sulfide by cumene hydroperoxide. Crystal and molecular structure of the

2. Experimental

2.1. Measurements

Carbon, hydrogen and nitrogen contents were determined on a Carlo Erba MOD 1106 elemental analyser. FT-IR spectra of solid samples (KBr pellets) were run on a Brucker IFS 66, and electronic spectra on the Perkin–Elmer LAMBDA 18 spectrophotometer. ^{1}H and ^{51}V spectra were obtained in DMSO-d_6 solutions at 50 °C with a Varian Mercury-400BB (400 MHz) spectrometer using TMS (^{1}H) and $VOCl_3$ (^{51}V) as reference compounds. Chromatography was carried out with a Hewlett–Packard 1050 chromatograph.

2.2. X-ray investigations

Diffraction data for **9r** were collected at 293(2) K using a Nonius Kappa CCD diffractometer with graphite monochromatized Mo Kα radiation ($\lambda = 0.71073$ Å). Details of cell data, data collection and refinement are summarized in Table 1. Compound **9r** is monoclinic, for which the space group $P2_1$ was uniquely assigned from systematic absences. The structure was solved by direct methods using SHELXS-97 [28] and refined with all data on F^2 with the aid of SHELXL-97 [29]. H atoms attached to carbon were placed in calculated positions and allowed to ride on their parent atoms with $U_{iso}(H) = 1.2U_{eq}(C)$ with the exception of methyl protons for which $U_{iso}(H) = 1.5U_{eq}(C)$ was inserted. H atoms linked with nitrogen atoms were located in the difference map and refined freely. Analysis utilizes the 2003 version of the program PLATON [30]. Selected bond lengths and angles are listed in Table 2.

2.3. Catalytic oxidation of sulfides

A DMSO solution containing a dioxovanadium(V) Schiff base complex (4×10^{-5} mol) and cumene hydroperoxide (4×10^{-3} mol) was stirred for 5 h at 20 °C. To the resulting yellow solution thermostated to 20 or 50 °C the methyl phenyl sulfide (4×10^{-4} mol) was added. The kinetics of the oxidation reaction was investigated by high performance chromatography. Samples of the reaction mixture were withdrawn at intervals and then analysed with a Hewlett–Packard 1050 chromatograph equipped with a Shimadzu C-R4A Chromatopack area peak calculator and with a Kromasil-100 C-8 column (Knauer GmBH, Germany) using acetonitrile–water (4:6 v/v) as an eluent. Chromatography was carried out with a flow rate of 1 ml min^{-1} and components were detected with a UV Detector ($\lambda = 254$ nm). The enantiomeric excesses (ee) were determined either from the specific rotation at 589 nm of the sulfoxide isolated by chromatographic elution or by measurement of intensities of ^{1}H

NMR signals of sulfoxide in the presence of chiral shift reagent Eu(hfc)$_3$ [31]. In order to perform the latter procedure the sample (10 ml) withdrawn from of the reaction mixture was poured in the 40% aqueous solution (30 ml) of sodium bisulfite and the resulting suspension was extracted several times by methylene chloride. The collected extracts were dried over sodium sulfate, filtered and evaporated to dryness under diminished pressure. The solid product dissolved in $CDCl_3$ was analysed by ^{1}H NMR in the presence of chiral shift reagent.

2.4. Complexes

The complexes were obtained in a template/complexation reactions analogous to those described for preparation of dioxovanadium(V) complexes with monocondensation products of 1,2-diaminopropane and its derivatives [26,32]. A sample of 10 mmol of *RR*(−)-1,2-diaminocyclohexane in 10 ml of EtOH was added with stirring to a freshly filtered solution of triethyl vanadate (10 mmol) in 250 ml of absolute EtOH producing a dark suspension of an intermediate. An aromatic *o*-hydroxyaldehyde (salicylaldehyde, 3-methoxysalicylaldehyde, 5-methoxysalicylaldehyde, 4,6-dimethoxysalicylaldehyde, 5-methylsalicylaldehyde, 5-bromosalicylaldehyde, 5-nitrosalicylaldehyde, 2-hydroxy-1-naphthaldehyde) or an aromatic *o*-hydroxyketone (1-hydroxy-2-acetonaphthone) dissolved in absolute EtOH was added to the aforementioned suspension. After refluxing of the resulting mixture for 2 (aldehydes) or for 10 h (ketones) and its cooling to room temperature the separated solids were filtered off, washed several times with EtOH, recrystallized from DMSO–EtOH mixtures and dried over molecular sieves. {*RR*(−)-1-amino-2-*N*-[(2′-oxido-κ*O*-5′-nitrophenyl)methylene]aminopropane-κ^2*N*}dioxovanadium(V) (**10r**), was prepared in a similar way as described above using 5-nitrosalicylaldehyde, *R*(−)-1,2-diaminopropane and triethyl vanadate as reactants.

3. Results and discussion

The complexes were not accessible by the preformed ligand strategy used by us earlier for the preparation of Ni(II) and Pd(II) complexes with monocondensed diamines [33,34], but may be obtained in a template reaction proceeding in the refluxed ethanol solution containing aromatic *o*-hydroxycarbonyl compound, enantiopure 1,2-diaminocyclohexane and triethyl vanadate in 1:1:1 ratio. All the complexes derived from hydroxyaldehydes precipitated from the reaction mixtures as yellow powders, but the **9r** complex derived from 1-hydroxy-2-acetonaphthone separated slowly yielding crystals containing solvent molecules. The template reaction proceeds as evidenced by the **9r** structure.

3.1. Crystal and molecular structure of *9r*

The asymmetric unit contains two symmetry independent complex molecules A and B, one molecule of water and one molecule of ethanol, as shown in Fig. 2. The atom numbering scheme is included. The molecules A and B are of similar structure since A can be superimposed by B with a rms value of 0.08 Å by the 61° rotation about the (pseudo)-axis [0 $\bar{1}$ 0], where bracketed numbers are direction cosines with orthogonal cell. Since B is similar in structure to A we restraint our analysis to the latter molecule. The coordination geometry about the vanadium (V1A) atom can be considered as distorted trigonal bipyramidal containing both oxo (O2A and O3A) ligands and the azomethine nitrogen (N1A) in the equatorial plane but the phenolic oxygen (O1A) and the primary amino nitrogen (N2A) in apical position. The extent of the distortion, quantified by the distance between trigonal bipyramid and square pyramid along the Berry pseudorotation coordinate [35–37], is 39.4%. The metal deviates from the equatorial trigonal plane by 0.11 Å towards O1. The five-membered ring containing V1A, N1A, C13A, C18A, N2A atoms adopts an envelope conformation on N2A in contrast to the carbon centered folding of five-membered chelate rings in the [*N*-(3-methyl-6-*tert*-butylsalicylidene)-*N*′-methylethylenediaminato]dioxovanadium(V) [38] and 2-(4-amino-4-methyl-2-aza-1-penten-1-yl-κ^2N)-3,5-dimethoxyphenolato-κ*O*-dioxovanadium(V) [12] complexes possessing a distorted trigonal bipyramidal arrangement around the vanadium. The much smaller angle of N1A–V1A–N2A [75.3(2)°] than other angles in the five-membered chelate ring (104.9–115.0°) seems to arise from the equatorial positions of both nitrogen atoms in the cyclohexane-1,2-diamine fragment which restrict the N1A···N2A distance so that the bite angle formed by V1A–N1A and V1A–N2A bonds has a limited range. The six-membered chelate ring formed by O1A, N1A, C1A, C1OA, C11A, V1A atoms assumes an envelope (sofa) conformation with vanadium (V1A) atom deviating by 0.880(5) Å from the least squares plane through the remaining atoms. The Cremer and Pople puckering parameters [39] of $Q = 0.607(8)$ Å, $\Theta = 8.4(4)°$ and $\sigma = 335(4)°$ for the cyclohexane ring compared with the map of cyclohexane conformations reported by Boeyens [40] indicate that the cyclohexane ring is almost in a chair conformation with a very small distortion towards half-chair and envelope forms. The hydrogen atoms linked to the secondary carbon atoms (C13 and C18) occupy axial positions. The distances 1.604(5) and 1.622(5) Å for V=O2A and V=O3A respectively are typical of non-hydrogen or weak hydrogen bonded V=O bond lengths [41,42]. The V1A–N1A, V1A–N2A distances are ca 0.05 Å longer than the averaged values of V–N(amine) bond lengths (2.090 Å), but the V1A–O1A distance agrees within 0.01 Å with the averaged V–O(phenolic oxygen) bond lengths (1.917 Å) reported by Orpen et al. [43]. Crystal structure of **9r** is stabilized by hydrogen bonds linking complex and solvent molecules in rings and chains as shown in Fig. 3. Parameters of hydrogen bonding geometry are given in Table 3. Short intramolecular contact between C12 and C14 (shown in Table 3) indicates steric strains in the ethylidene part of the molecule.

3.2. Spectroscopic properties of complexes

The IR spectra of solid complexes display two bands in the range of 3200–3300 cm^{-1} corresponding to the asymmetric ν_{as} and symmetric ν_{sym} N–H stretching modes of the complexed primary amino group. In addition the **9r** complex shows a broad absorption at ca. 3450 cm^{-1} derived from ν(O–H) of solvated water and ethanol molecules. The ν(C=N) observed below 1634 cm^{-1} is characteristic of N-bound complexes [44]. In the spectrum of **r** and **s** **1**–**7** complexes two intense bands are observed, one sharp in the 936–916 cm^{-1} region, and the other broadened in 864–834 cm^{-1} range which can be assigned to the ν_{as} and ν_s vibration of the *cis*-VO_2 group [22].

Section 2 lists electronic spectral data of complexes in DMSO. The low energy band $\varepsilon_{max} = (3000–6000)$ $dm^3\,mol^{-1}\,cm^{-1}$ between 354 and 405 nm may be assigned as a ligand-to-metal charge transfer (LMCT) transition originating from the p_π orbital on the phenolate oxygen to the empty d orbitals of the metal [42]. A more intense, $\varepsilon_{max} = (11\,000–20\,000)$ $dm^3\,mol^{-1}\,cm^{-1}$, band with λ_{max} between 262 and 272 nm is considered to arise from π to π*

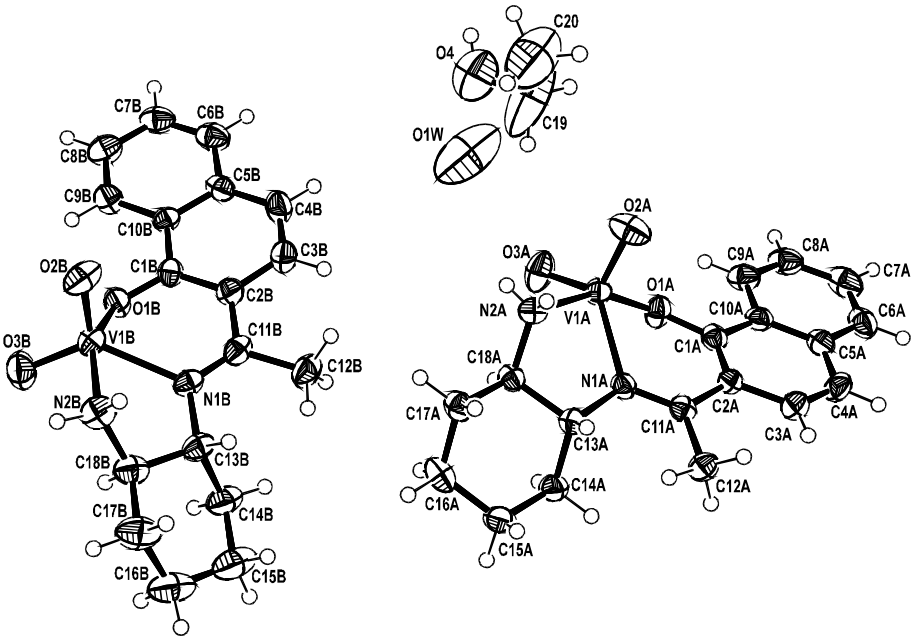

Fig. 2. An ORTEP drawing of **9r** complex molecule (A), its crystallographically independent form (B) together with molecules of water and ethanol, showing atom-labelling system. Displacement ellipsoids are drawn at the 30% probability level.

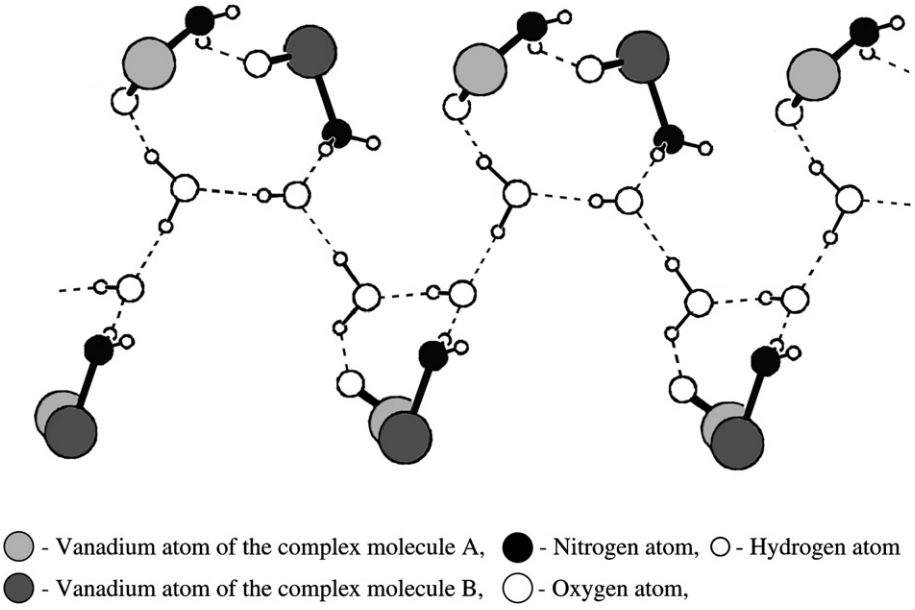

Fig. 3. A fragment of the crystal structure of **9r** showing the arrangement of complex and solvent molecules in rings and chains generated by hydrogen bonding interactions. For the sake of clarity atoms which are not involved in the structure build from hydrogen bonds were omitted. Hydrogen bonds are depicted as dashed lines.

transitions in the aromatic ring. The circular dichroism measurements revealed an additional absorption in the 290–350 nm range, which by comparison with the CD spectra of Cu(sal)$_2$(*RR*(−)chxn) [45], VO(sal)$_2$(*RR*(−)chxn) [46] and Zn(sal)$_2$pn [47] chelates, may be assigned to π–π^* transitions encompassing the azomethine chromophore. Fig. 4 shows CD spectra of **7r**, **7s** and **10r** complexes, the latter included for comparison. The spectra of **7r** and **10r** do not bear a mirror image relationship noticed for the CD spectra of V(V), V(IV), Cu(II) and Ni(II) complexes comprising double condensation products of chiral 1,2-diaminocyclohexane when they are compared with the spectra of their counterparts derived from 1,2-diaminopropane in the same absolute configuration [8,45,46,48]. Since the sign of the Cotton effect of a given transition reflects the conformation of the central chelate ring [45], they revealed identical signs of Cotton effects in the spectra of **7r** and **10r** suggest the same predominant conformational helicity of

five-membered chelate rings of these compounds in DMSO solution.

^{1}H, ^{13}C and ^{51}V NMR spectra of complexes were obtained in DMSO-d_6. Since the ^{1}H NMR spectra of complexes derived from *RR*(−) and *SS*(+)-1,2-diaminocyclohexane are superimposable, Section 2 list NMR data only for the former complexes. ^{1}H NMR signals were assigned on the basis of intensity, spin–spin coupling pattern, chemical shifts, deuteration experiment, ^{1}H, ^{1}H COSY, and double resonance techniques. In addition the HSQC experiment was included to achieve a clear differentiation of the geminal AB system of individual CH_2 groups. Chemical shifts and coupling constants of aromatic protons do not differ distinctly from those which were reported recently [26] for dioxovanadium complexes with monocondensation products derived from the same aromatic hydroxycarbonyl compounds but from different diamines. The amine protons, which were identified by deuteration experiment, are magnetically inequivalent. The resonance in the 5.348–5.565 ppm range is a doublet and the resonance in the 4.851–5.038 ppm range is a triplet, the multiplicity of the latter signal is recognized as due to geminal and vicinal (Ha18) coupling. Signals of the protons on carbon atoms as the N atoms (Ha13, Ha18) are shifted downfield on account of the electron withdrawing effect of N-atoms and can be readily recognized. It is more difficult to assign the resonances of (**1**–**7**)**r** complexes in the 1.5–1.6 ppm range because of signal overcrowding. On the other hand the signals of **8r** and **9r** complexes appear as separate two one-proton quartets and one two-proton multiplet in the above range, and could be easily analysed on the basis of homonuclear (COSY, double resonances) and heteronuclear (HSQC) shift correlations. The most deshielded azomethine proton, H11, and the Ha13 proton of the cyclohexane fragment in **8r** are involved in a long range coupling apparently analogous to the allylic like coupling observed in systems where one of the intervening carbon atoms has been replaced by nitrogen [49]. Positioning of Ha13 was the starting point for the assignment of all remaining protons of the cyclohexane moiety. Table 4 lists assignments of ^{1}H and ^{13}C resonances of the cyclohexane fragments of the **8r** and **9r** complexes read from the gHSQC plots and confirmed by the 1D spectra. It is seen (Table 4) that axial protons of CH_2 groups (1.2–1.5 ppm) are more shielded than their equatorial coupling partners on the same C atom as a result of anisotropic effects; they show pseudoquartets because of the geminal and diaxial coupling It can also be seen that the methyl group in **9r** results in a shift of C13A resonance to more shielded but of Ha13 to less shielded positions relative to the corresponding resonances in **8r**. These spectroscopic changes may be a result of strong intramolecular steric interactions reflected by short contact shown in Table 3. Steric crowding of proton bearing carbon atoms C13A and C12A being in γ disposition results in their shielding as expected from the γ effect observed in the ^{13}C NMR spectroscopy [50]. Steric perturbation of C13A–Ha13 bond results in the electrons moving away from hydrogen atom towards the carbon atom thus resulting in C13A being shielded and Ha13 deshielded. The deshielding of the He14 proton in **8r**, respectively to that in **9r** might be substantially attributed to the van der Waals effect that arises by strong H11, He14 steric interaction presumed on the basis of a short C12A···C14A contact (Table 3) in **9r** and on the position of H11 in **8r** which like C12 in **9r** is joined to the methine carbon atom, C11, of the ═C11═N2 ═C13═C14═He14 structural fragment. According to the ring current model and the additivity of contributions of individual aromatic rings to the chemical shift [51] the decrease in shielding of the azomethine proton by going from (**1**–**7**)**r** ($\delta = 8.81 \pm 0.07$) to **8r** ($\delta = 9.539$ ppm) equal on average to $\Delta\sigma = -0.73$ ppm indicates that in **8r** that proton, H11, is located in plane of, close and exterior to two aromatic rings and that the ring current effect originating in the C5–C10 ring of naphthalene moiety contributes significantly to the decrease of its shielding. The contribution of the C5–C10 ring to the shielding of H11 in **8r**, $\Delta\sigma'$, equal to −0.508 ppm was calculated with the help of equation $\Delta\sigma'$ [ppm] $= -0.0276R^{-3}$ [51] and with $R = 0.379$ nm where R in this formula stands for the

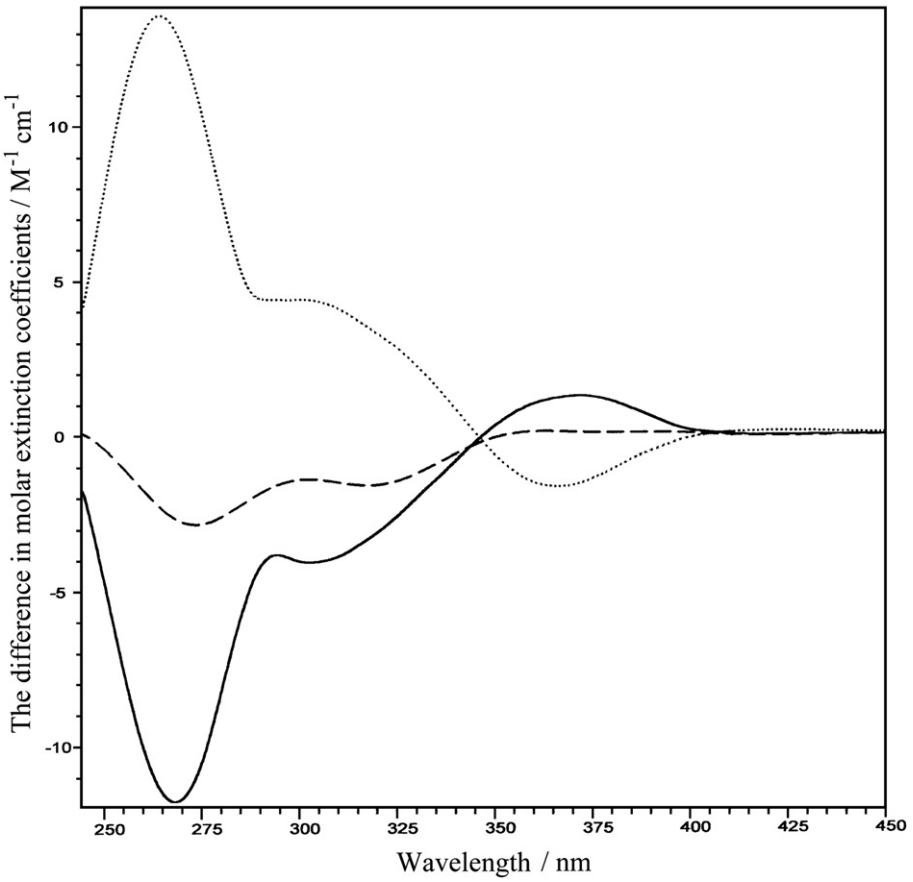

Fig. 4. CD spectra of **7r** (—), **7s** (···) and **10r** (---) complexes, containing *RR*(−)-1,2-diaminocyclohexane, *SS*(+)-1,2-diaminocyclohexane and *R*(−)-1,2-diaminopropane singly condensed with 5-nitrosalicylaldehyde respectively, in DMSO solution.

calculated separation of H11 to the center of the C5–C10 aromatic ring. A considerably high deshielding of Ha18 proton in **9r** may be due to its specific solvation by water and/or ethanol molecules present in the solution of hemihydrated and hemiethanol solvated compound. All the complexes exhibit a single ^{51}V resonance in the −548.0 to −552.1 ppm range, which is close to the reported (−553) to (−556) ppm [32] and (−547.8) to (−552.0) ppm [26] ^{51}V chemical shift ranges for diovanadium(V) complexes comprising single condensation products of aromatic hydroxyaldehydes with 1,2-diaminopropane and 2-methyl-1,2-diaminopropane respectively.

3.3. Catalytic oxidation of methyl phenyl sulfide (thioanisole)

Complexes **2r**, **3r** which incorporate singly condensed products of *RR*(−)-1,2-diaminocyclohexane with 3- or 5-methoxysalicylaldehyde as well as their analogues derived from *SS*(+)-1,2-diaminocyclohexane **2s** and **3s** act as catalyst to the oxidation of thioanisole by cumene hydroxyperoxide. Changes in sulfide and sulfoxide concentrations indicated that oxidations carried out in conditions of a large excess of cumene hydroperoxide at 20° and also at 50° proceed as reactions of first order. Yields of the conversion of thioanisole to the corresponding sulfoxide after 24 h in 20° and after 4 h at 50° exceed 96%. Complexes **2r**, **2s**, **3r** and **3s** exhibit also an asymmetric induction. The *S*-configurated sulfoxide was obtained in the reaction at 20° with 21% enantiomeric excess (ee) when **2r** or **3r** were used, and *R* was obtained with 19% and 23% ee using **2s**

and **3s** respectively. The influence of the OCH_3 substituent in 3 or 5 position of the aryl group (but not in positions 2 and 4) on the catalytic activity and asymmetric induction indicated the importance of electronic factors on enantioselective catalysis in sulfide oxidation. Enantiomeric excesses of sulfoxidation products are higher than those obtained in the reaction catalysed by VO(V) complexes incorporating double condensation product of *trans-RR*-1,2-diaminocyclohexane with 3-methoxysalicylaldehyde and chloride (11% ee) or perchlorate (0% ee) as counterions [23].

ligands containing variable neutral middle chain, characterization of these complexes by $^{31}P\{^{1}H\}$ NMR and by IR spectroscopy, and mainly the molecular structures of these compounds.

2. Results and discussion

The complexes **1** to **5** were prepared by the reaction of 4-methoxyphenyltellurium trichloride with the respective ligand in dichloromethane. The formation of product was indicated by the change of color from pale yellow to darker shades or even orange. The crystalline products were then obtained by the diffusion of hexane into concentrated mixtures. Most compounds were reasonably stable with the exception of **4**, which rapidly decomposed on air. Therefore, the characterization of the latter is mainly limited to the X-ray diffraction experiment on its single crystals. The complexes are characterized by singlets in their ^{31}P NMR spectra as expected from identically coordinated P═S ligand endings. In IR spectra, the P═S stretching frequencies are lowered by ca. 40 cm^{-1} in comparison to the uncoordinated ligands.

All binuclear compounds are centrosymmetric, thus the asymmetric part of the unit cell contains only one half of the complex. The exception is the compound with $dpphS_2$ (**2**), having two crystallographically independent halves of the complex in the unit cell. The tellurium atoms in all present compounds have pseudo-octahedral coordination with the aryl and the lone electron pair in axial positions relative to the $TeCl_3S$ equatorial plane. The attempts to fit tellurium, sulfur and chlorines into the best common plane provide the r.m.s. deviations varying from 0.038 to 0.100 Å. When least squares planes are calculated through sulfur and three chlorine atoms, the Te atoms all deviate outwards the aryl group, within 0.047(1) and 0.112(1) Å. Because of the strong disorder affecting the coordination polyhedra in **2**, the values for them were excluded from the above comparison.

As pointed out in Section 1, there are two types of five-coordinate complexes known, resulting from the interaction of 4-methoxyphenyltellurium trichloride with diphosphine disulfides. With negatively charged ligands of the $[R_2P(S)\text{-}N\text{-}P(S)R_2]^-$ general formula, one of the chloride anions was displaced from the coordination sphere of the tellurium, and chelates of the $4\text{-}MeOC_6H_4TeCl_2\{R_2P(S)\text{-}N\text{-}P(S)R_2\}$ type were formed [5]. Another class of complexes are binuclear compounds with neutral diphosphine disulfides, like those described here [6,7]. No six-coordinate complexes with $4\text{-}MeOC_6H_4TeCl_3$ are known, while the octahedral complex resulting from $TeCl_4$ was prepared and crystallographically characterized [8]. We were interested whether the tendency of 4-methoxyphenyltellurium trichloride to form pseudo-octahedral complexes is given by the presence of the aryl, or there is some restriction arising from the structure of the bidentate ligand which is not capable of closing the chelate ring using its another donor. We have therefore performed the reaction between $4\text{-}MeOC_6H_4TeCl_3$ and the simple monodentate ligand Ph_3PS, triphenylphosphine sulfide, in 1:1 and 1:2 molar ratios. Although the formation of $[(4\text{-}MeOC_6H_4\text{-}TeCl_3)Ph_3P(S)]$ (**5**) was predictable in a 1:1 ratio, no other complexes were isolated even in the presence of excess ligand. It is therefore legitimate to infer that the formation of five-coordinate complexes **1** to **5** is entirely the consequence of nature of the parent tellurium compound.

In the crystal structure of **1**, we find intermolecular Te···Cl contacts, almost collinear with the Te–C bonds. Comparing their length of 3.614(2) Å to the sum of the respective van der Waals radii (3.81 Å) [9], we may consider them very weak. As a result of these secondary bonding interactions, the molecules are knit together into chains, extending in the crystallographic *a* direction. The secondary bonding within tellurium complexes is rather common, as illustrated by reviews in this area [4,10]. In our report, however, **1** is the only compound with intermolecular Te···Cl contacts, other complexes do not show secondary bonding in crystals. The presence of secondary bonds is closely related to the stereochemical role of the Te(IV) lone pair. In the absence of additional intermolecular contacts in **2** to **5** the stereochemistry of the coordination polyhedron can be understood using the VSEPR model, with lone pair of electrons being stereochemically active and pointing opposite to the Te–C bond. In the distorted octahedral arrangement involving the weak secondary Te···Cl bond in **1**, the lone pair should not lie in the direction of that bond in accordance with the rules proposed by Alcock [11]. Either the lone pair is somewhat deflected from the direction of the secondary Te···Cl bond as previously suggested by Husebye and Maartmann-Moe [12], or simply the Alcock's rules are not always followed [11].

The selected bond lengths and angles for binuclear complexes **1** to **4** and complex with triphenylphosphine sulfide **5** are listed in Table 2 which also includes two previously reported binuclear compounds with diphosphine disulfides for comparison. The P═S bond lengths agree well with the values for other coordinated phosphine sulfides found in the Cambridge Structural Database (CSD) [13]. In all listed compounds there are two distinct sets of chloride ligands. The first includes Cl atoms positioned *trans* to the sulfur donors. As apparent from the table, their distances from tellurium centres are shorter than for Cl atoms *trans*-positioned to each other. This is a reflection of weak donating properties of sulfur donors, and hence ability of opposite chlorides to get closer to tellurium. Accordingly the bonding distances Te–S are relatively long. Using CSD we have selected partly the homoleptic coordination compounds with Te–S bonds, partly the heteroleptic complexes in which the opposite coordination sites are occupied by identical S-donor ligands. Moreover, the complexes in which the coordination sphere might be distorted by geometrical reasons were excluded. Therefore, the complexes with either monodentate or sufficiently large bidentate ligands were present in the final hit list. The analysis of obtained parameters showed that the maximum number of Te–S

						173.25(2)	177.00(5)

Cl(1) is *trans* to S, Cl(2) is *trans* to Cl(3). In compounds **1**, **3** and **4**, the two halves of the binuclear complex are related by symmetry, thus only one value is given. For **6** and **7** values for both crystallographically independent molecular fragments are listed. The crystal structure of **2** was subject to a considerable disorder and only the average parameters from all corresponding disordered parts were calculated.

bond distances lies at ca. 2.7 Å. When compared to the values in Table 2, the sulfur atoms in our complexes are rather strongly expelled by the *trans* influence of opposite Cl atoms.

To conclude, we have prepared four complexes of 4-$MeOC_6H_4TeCl_3$ with ligands of diphosphine disulfide type. Consistently with previous data, we have observed that the coordination sphere of tellurium in 4-methoxyphenyltellurium trichloride is not capable of extending the coordination number above 5 (neglecting secondary bonding) and forming chelates with these ligands similarly to $TeCl_4$. The bidentate ligands are then coordinated toward tellurium using only one sulfur atom, and form binuclear addition complexes regardless of the length and flexibility of their central moieties.

3. Experimental

3.1. General and instrumental

The $^{31}P\{^1H\}$ NMR were recorded in dichloromethane on a Bruker Avance DRX 300 instrument using 85% H_3PO_4 as external standard. IR spectra (KBr pellets, 4000–400 cm^{-1}) were recorded using an EQUINOX 55/S/

NIR FTIR spectrometer. Microanalyses were performed on a Thermo Finnigan CHN Analyzer Flash EA 1112, and melting points were measured on a Boëtius melting-point apparatus. $Ph_2PNH(C_6H_4)NHPPh_2$ was prepared similarly to $[Ph_2PN(Me)]_2CO$ [14], using Ph_2PCl and *p*-diaminobenzene as starting materials and Et_3N as a base to remove HCl. $Ph_2P(C_6H_4)_2PPh_2$ was synthesized according to the literature [15], using Ph_2PCl and dilithiated biphenyl salt. $Ph_3P(S)$ and $Ph_2P(S)(CH_2)_nP(S)Ph_2$ ($n = 2$, 4) were prepared by heating commercially available Ph_3P and $Ph_2P(CH_2)_nPPh_2$ with sulfur in toluene. $Ph_2P(S)(C_6H_4)_2P(S)Ph_2$ and $Ph_2P(S)NH(C_6H_4)NHP(S)Ph_2$ were prepared from $Ph_2PNH(C_6H_4)NHPPh_2$ and $Ph_2P(C_6H_4)_2PPh_2$ using the same method. $4\text{-}MeOC_6H_4TeCl_3$ was synthesized according to the literature [16].

The complexes were prepared by the following general procedure. A mixture of $MeOC_6H_4TeCl_3$ and the respective ligand in dichloromethane (20–25 ml) was stirred for 30 min at ambient temperature and subsequently the volume was reduced by 30–50% under the vacuum. Then the solution was overlayered by hexane and the crystals were formed within the period of 5–24 h.

3.7. Crystallography

Diffraction data were collected on a KUMA KM-4 κ-axis diffractometer equipped with a CCD detector with Mo Kα radiation ($\lambda = 0.71073$ Å). The temperature during data collection was 120(2) K. The structures were solved by direct methods and refined by full-matrix least-squares methods. The software packages used were: Xcalibur CCD system for the data collection/reduction [17], and SHELXTL for the structure solution, refinement, and drawing preparation [18]. The thermal ellipsoids in figures were drawn at the 50% probability level. Details of the data collection and structure refinement are listed in Table 1.

Acknowledgments

This work was supported by the Grant Agency of the Czech Republic (203/07/1657). We thank Professor Zdenek Travnicek, Palacky University, Olomouc, for elemental analyses.

Appendix A. Supplementary material

CCDC 621468, 621469, 621470, 621471 and 621472 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2007.01.001.

ligands [7]. Also, it may be noted that in most of the reported mononuclear metal complexes all the coordination positions are satisfied by the same ligand and ternary complexes have not been reported. Recently we have reported a tridentate phenolate ligand having N_1O_2 donor sites [11]. We thought to explore the ligation capability of the ligand towards copper. Our aim was to synthesize ternary complexes of copper using the tridentate ligands along with a monodentate co-ligand. Herein we report the synthesis, characterization and structure of the copper complex, $[CuL^1(H_2O)(Pyz)]$ (**1**) [L^1H_2 = {(3,5-di-*tert*-butyl-2–hydroxybenzyl)amino}acetic acid; Pyz = pyrazole]. Also, reported herein is the synthesis and characterization of a new optically active tridentate ligand, *S*(−)2-(3,5-di-*tert*-butyl-2-hydroxy-benzylamino)-3-methyl-butyric acid (L^2H_2), derived form L-valine, and its copper complex, $[CuL^2(H_2O)(Pyz)]$ (**2**).

2. Experimental

2.1. General remarks

All the chemicals used were reagent grade products. The ligand, {(3,5-di-*tert*-butyl-2-hydroxybenzyl)amino}acetic acid (L^1H_2) was prepared by the reported procedure [11]. ^1H NMR spectra were recorded on a Bruker AC 200, 200 MHz NMR spectrometer in $CDCl_3$ solutions at room temperature. EPR spectra were recorded on a Bruker EMX X-band spectrometer. IR spectra were recorded on a Thermo Nicklet Model 870 FT IR spectrometer. The UV–visible spectra were recorded on a Shimadzu UV 600 spectrophotometer. CD spectral measurements were done in methanol using a JASCO CD polarimeter, model J-810. Specific rotations were measured in methanolic solutions of the compound using a JASCO P1020 polarimeter. Cyclic voltammetry experiments were performed using a fully automated CH Instruments electrochemical analyzer (Model 620a) and a three-electrode set-up consisting of a glassy carbon working electrode, a platinum wire counter electrode and an Ag/AgCl reference electrode. All experiments were performed in dry CH_3CN containing tetra-*N*-butylammonium perchlorate (0.2 mol dm^{-3}) as the background electrolyte. The magnetic measurements were done using the Gouy method. The C, H and N contents were estimated using microanalyses on a Perkin Elmer microanalyser, 2400. For the mass spectral measurements a 1:1 methanol/water solution of the compounds was taken and the mass spectra were recorded on a Waters LCT mass spectrometer using the electrospray ionization (ES^- mode) technique.

2.2. Synthesis of the mono sodium salt of S-(−)2-(3,5-di-tert-butyl-2-hydroxy-benzylamino)-3-methyl-butyric acid (L^1H_2)

L-Valine (1.17 g; 10 mmol) was dissolved in an aqueous solution (20 cm^3) of NaOH (0.450 g; 11.25 mmol). To this was added 40% aqueous formaldehyde (8 cm^3; 100 mmol) and the solution was heated for 20 min on a water bath. To the reaction solution was added an ethanolic solution (40 cm^3) of 2,4-di-*tert*-butyl phenol (2.06 g; 10 mmol) dropwise. The reaction mixture was then heated for 5 h on an oil bath at 50 °C. The reaction solution was cooled to room temperature and allowed to stand overnight. The precipitated mono sodium salt of the ligand 2-(3,6-di-*tert*-butyl-2-hydroxy-benzylamino)-3-methyl-butyric acid (L^2H_2) was filtered washed with water and hexane and finally dried in vaccuo. Yield: 3.08 g; 86.5%. *Anal.* Calc. for $C_{20}H_{32}NO_3Na$ (357.46): C, 67.20; H, 9.02; N, 3.92. Found (%): C, 67.18; H, 8.89; N, 3.88. IR (KBr pellet, ν [cm^{-1}]): 3434, 2959, 2361, 1585, 1476, 1226, 1122. UV–visible [λ_{max} (nm) (ε)]: 279 (2205), 227 (3056). ^1H ($CDCl_3$) (ppm): 1.00 (br, m, 6H), 1.26 (s, 9H), 1.45 (s, 9H), 2.21 (br, 1H), 3.35 (d, $J = 4$ Hz), 3.89 (d, $J = 14$ Hz, 1H), 4.36 (d, $J = 14$ Hz 1H), 6.95 (d, $J = 1$ Hz, 1H), 7.30 (d, $J = 1$ Hz, 1H). Mass (significant peak and its assignment): m/z 334.2212 [$C_{20}H_{32}NO_3^-$, M^-].

2.3. Syntheses of $[CuL^1(H_2O)(Pyz)]$ (1) and $[CuL^2(H_2O)(Pyz)]$ (2)

Compounds **1** and **2** were prepared by a similar procedure and the general procedure is given below. The ligand (1 mmol) was dissolved in methanol (25 cm^3) in a beaker. To this was added solid NaOH (0.08 g; 2 mmol) followed by addition of water (5 cm^3) (Solution A). Pyrazole (1 mmol) was added to a methanolic solution (10 cm^3) of $Cu(ClO_4)_2 \cdot 6H_2O$ (1 mmol) in another beaker (Solution B). To this solution (Solution B) was then added the solution of sodium salt of the ligand (Solution A) and the reaction solution was stirred for an hour. The reaction solution on standing overnight afforded crystalline **1** or **2**. The compound was filtered, washed with water, and finally recrystallized from acetonitrile. Recrystallization of **1** from acetonitrile afforded crystals suitable for X-ray diffraction. Yield: 0.335 g; 76% (**1**), 0.338 g; 70% (**2**). *Anal.* Calc. for $C_{20}H_{31}CuN_3O_4$ (**1**) (441.02): C, 54.47; H, 7.08; N, 9.53. Found: C, 54.40; H, 7.02; N, 9.47%. *Anal.* Calc. for $C_{23}H_{37}CuN_3O_4$ (483.1) **2**: C, 57.18; H, 7.72; N, 8.70. Found: C, 57.08; H, 7.67; N, 8.61%. IR (KBr pellet, ν [cm^{-1}]) (**1**): 3436, 2956, 1631, 1057, 1140, 1111, 939, 758. IR (KBr pellet, ν [cm^{-1}]) (**2**): 3439, 2958, 1629, 1471, 1384, 1087, 1140, 1114, 759. UV–visible [λ_{max} (nm) (ε)] (**1**): 630 (80), 380 (420), 237 (3887), 278 (1890); [λ_{max} (nm) (ε)] (**2**): 635 (145), 431 (463), 245 (3945), 293 (3247).

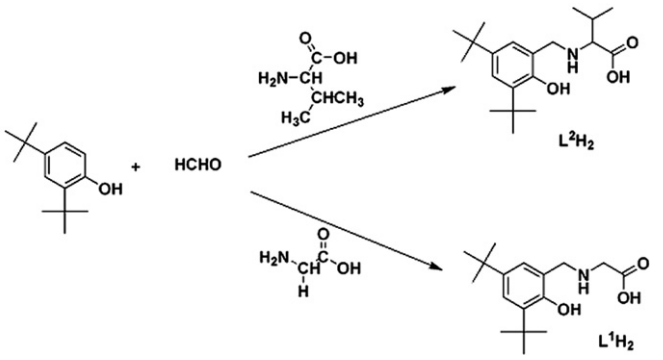
2.4. X-ray crystallographic study

Suitable crystals of $[CuL^1(H_2O)(DMPZ)]$ (**1**) were grown from a dilute acetonitrile solution at room temperature over a period of 5–6 days. The single crystal data was collected on a Nonius Kappa CCD X-ray diffractometer using graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) by the Φ scan and ω-scan methods. The

structure was solved using the program SIR-97 [12]. The refinement and all further calculations were carried out using SHELXL-97 [13]. The H-atoms were refined isotropically except those involved in disordered moieties which were included in calculated positions and treated as riding atoms using SHELXL default parameters. The non-H atoms were refined anisotropically using weighted full-matrix least-squares on F^2. The three methyl groups of the *tert*-butyl linked to the C8 atom and the $C3H_2$–N1H moiety were found to be disordered and were refined over two positions with occupancies of 0.656(9) and 0.344(9), respectively. An empirical absorption correction was applied using the SORTAV routine [14]; transmission factors: $T_{min}/T_{max} = 0.856/0.949$. Crystal data: Empirical formula: $C_{20}H_{31}CuN_3O_4$, MW = 441.02, monoclinic, space group $P2_1/a$, $a = 10.6217(2)$ Å, $b = 10.1645(2)$ Å, $c = 19.4909(5)$ Å, $\beta = 90.7729(9)°$, $V = 2104.13(8)$ Å^3, $Z = 4$, d (calcd.) = 1.392 Mg/m^3, $F(000) = 932$, $T = 150$ K, $\mu = 1.068$ mm^{-1}, crystal size = $0.36 \times 0.15 \times 0.05$ mm^3, data collection range $2.96 \leqslant \theta \leqslant 27.00°$, $-13 \leqslant h \leqslant 13$, $-12 \leqslant k \leqslant 12$, $-24 \leqslant l \leqslant 24$. Reflections measured: 23 131, 4566 unique ($R_{int} = 0.0680$, $R_\sigma = 0.0517$), $R_1 = 0.0527$, $wR_2 = 0.1203$ for 3457 reflections with $I > 2\sigma(I)$ and $R_1 = 0.0760$, $wR_2 = 0.1303$ for all data.

3. Results and discussion

3.1. Synthesis and characterization of the mono sodium salt of L^2H_2



This ligand has been synthesized from a one pot Manich reaction of L-valine with 2, 4-di-*tert*-butyl phenol and formaldehyde in aqueous ethanol under basic conditions (Scheme 1). The ligand has been characterized by elemental analyses, mass spectrometry, IR, UV–visible, circular dichroism (CD) and ^{1}H NMR spectroscopy. The elemental analyses agree well with the composition. The high resolution mass spectrum (HRMS) of the monosodium salt of the compound shows a molecular ion peak at m/z 334.2212 due to $M^-(CH_{32}NO_3^-)$. The IR spectrum of the compound shows –COO^- stretches at 1585 and 1476 cm^{-1} along with other characteristic bands. The ^{1}H NMR spectrum of the ligand shows signals at δ 1.00 ppm (br m, 6H) due to –CH_3 protons of the *iso*-propyl group, δ 1.26 ppm (s, 9H) and δ 1.45 ppm (s, 9H) due to the –CH_3 protons of the *tert*-butyl groups. The signal due to the –CH proton of the *iso*-propyl group appears as a broad signal at δ 2.21 ppm (1H) and the –CH proton (αH) adjacent to the –COOH group appears at δ 3.35 ppm (d, $J = 4$ Hz, 1H). The assignment of the –CH protons and the methyl protons of the *iso*-propyl group and the –CH proton (αH) adjacent to the –COOH group was further confirmed from proton decoupling experiments. The methylene protons of the –$HNCH_2$ group appear at δ 3.89 ppm (d, $J = 14$ Hz, 1H) and δ 4.36 ppm (d, $J = 14$ Hz, 1H). The aromatic protons appear at δ 6.95 ppm (d, $J = 1$ Hz, 1H) and δ 7.30 ppm (d, $J = 1$ Hz, 1H).

The UV–visible spectrum of the compound shows bands at 279 nm ($\varepsilon = 2205$) and 227 nm ($\varepsilon = 3056$) due to aromatic π–π^* transitions. The circular dichroism spectrum (CD) spectrum (Fig. 1) of the ligand shows a signal with a positive Cotton effect at 211 nm and one signal with a negative Cotton effect at 276 nm due to π–π^* transitions.The specific rotation of the ligand was found to be $-15.89°$ $\{[\alpha]_D^{24.5}\}$. Thus, the spectral measurements agree well with the formulation and structure of the ligand.

3.2. Synthesis and characterization of 1 and 2

The compounds **1** and **2** have been synthesized from the reaction of the sodium salt of the corresponding ligand with preformed pyrazole complex of copper, which was prepared from a reaction of pyrazole with $Cu(ClO_4)_2 \cdot 6H_2O$ in aqueous methanol.

Compounds **1** and **2** have been characterized by elemental analyses, IR, UV–visible and EPR spectral studies, and also by electrochemical and magnetic susceptibility measurements. Compound **2** was further characterized by CD spectroscopy. The elemental analyses agree well with the formulations of the compounds. The IR spectra of the compounds show a band at *ca.* 1620 cm^{-1} due to a

Scheme 1.

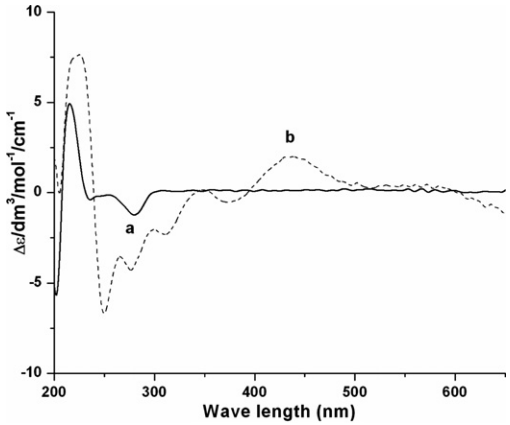


Fig. 1. Circular dichroism spectra of solutions of the monosodium salt of L^2H_2 (—) in methanol (10^{-3} M) (a) and its copper complex **1** (- - -) (b) in methanol (10^{-3} M).

carboxylate stretch. The marked shift of the carboxylate stretch from those of the ligand clearly shows that the ligand is bonded to the metal center through the carboxylate oxygen. The room temperature magnetic moment of compounds **1** and **2**, measured by the Gouy method, was found to be *ca.* 1.81 BM, which is typical for Cu(II) mononuclear complexes.

The electronic spectrum of **1** shows a band due to d–d transitions at 640 nm ($\varepsilon = 207$). Apart form the d–d transition, compound **1** shows a band at 440 nm (sh) ($\varepsilon = 380$). This may be assigned to a ligand to metal charge transfer (LMCT) transition. In **1** the ligand internal π–π^* transitions appear at 250 nm ($\varepsilon = 3570$) and 280 nm (sh) ($\varepsilon = 3430$). In **2** the d–d transition appears at 630 nm ($\varepsilon = 201$) and the LMCT transitions appear at 450 nm ($\varepsilon = 420$) and 390 nm ($\varepsilon = 530$). The ligand internal π–π^* transitions appear at 260 nm ($\varepsilon = 3740$) and 300 nm (sh) ($\varepsilon = 3460$). The marked shift of the ligand internal π–π^* transition as well as appearance of the LMCT band clearly show that the ligand is bonded to the metal center.

The CD spectrum of **2** (Fig. 1) shows a band with a positive Cotton effect at 224 nm and a band with a negative Cotton effect at 276 nm. A comparison with the ligand CD spectrum indicates that these signals are due to intra-ligand π–π^* transitions. In addition to the intra-ligand transitions, two bands with negative Cotton effect appear at 310 and 373 nm and a band with positive Cotton effect appears at 440 nm. These may originate from LMCT transitions. The specific rotation of **2** was found to be −214.85 $\{[\alpha]_D^{24.5}\}$.

The EPR spectra of frozen solutions of **1** and **2** at 77 K shows an anisotropic $S = 1/2$ signal at $g = <2$ (Figs. 2a and 3a, respectively) ($A_{\parallel} = 161 \times 10^{-4}\ cm^{-1}$). The observed g values ($g_{\parallel} = 2.28$ and $g_{\perp} = 2.01$ for **1** and $g_{\parallel} = 2.29$ and $g_{\perp} = 2.04$ for **2**), that is $g_{\parallel} > g_{\perp} > 2$, indicate that the ground state is $d_{x^2-y^2}$ in both complexes.

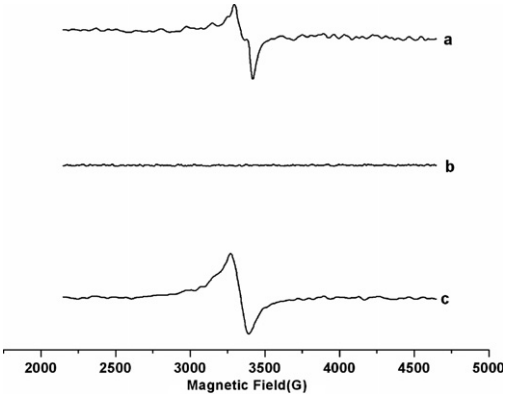

Fig. 2. X-band EPR spectra of **1**. (a) Frozen solution (acetonitrile) spectrum of **1**. (b) (a) + $(NH_4)_2Ce(NO_3)_6$ [1:1]. (c) (a) + $(NH_4)_2Ce(NO_3)_6$ [1:2]. General conditions: temperature = 77 K, microwave frequency = 9.57 GHz, microwave power = 1.00 mW, modulation frequency = 50 kHz, modulation amplitude = 5 G, receiver gain = 2.52×10^5. Sweep width = 2500 G. Time constant = 655.36 ms. Conversion time = 162.84 ms; $g_{dpph} = 2.0032$.

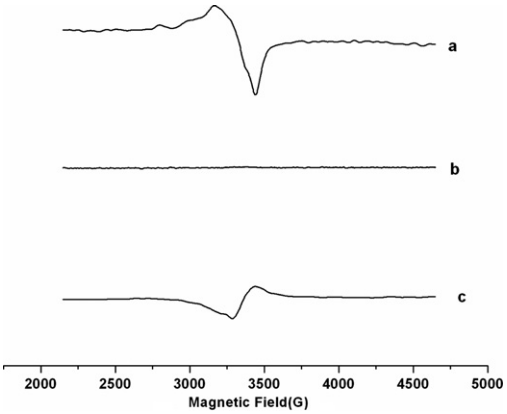

Fig. 3. X-band EPR spectra of **2**. (a) Frozen solution (acetonitrile) spectrum of **2**. (b) (a) + $(NH_4)_2Ce(NO_3)_6$ [1:1]. (c) (a) + $(NH_4)_2Ce(NO_3)_6$ [1:2]. General conditions: temperature = 77 K, microwave frequency = 9.59 GHz, microwave power = 1.00 mW, modulation frequency = 50 kHz, modulation amplitude = 5 G, receiver gain = 2.52×10^5. Sweep width = 2500 G. Time constant = 655.36 ms. Conversion time = 162.84 ms; $g_{dpph} = 2.0032$.

The room temperature solution (acetonitrile) EPR spectra (Fig. 4a and b) of **1** and **2** are isotropic in nature, with four equally spaced lines due to the coupling of the electron with the $I = 1/2$ nuclear spin on both ^{63}Cu and ^{65}Cu isotopes ($g_{iso} = 2.12$ and $A_{iso} = 83\ 4 \times 10^{-4}\ cm^{-1}$).

3.3. Structure of *1*

Compound **1** was characterized by single crystal X-ray crystallography. The compound crystallizes as green plates in the space group $P2_1/a$ from acetonitrile. The X-ray analysis reveals that the asymmetric unit contains one molecule of **1** (Fig. 5).

The ligand L^1 binds the copper center in a tridentate fashion and is bonded to Cu(II) through a phenolate oxygen {Cu1···O3 = 1.870(3) Å}, one carboxylate oxygen

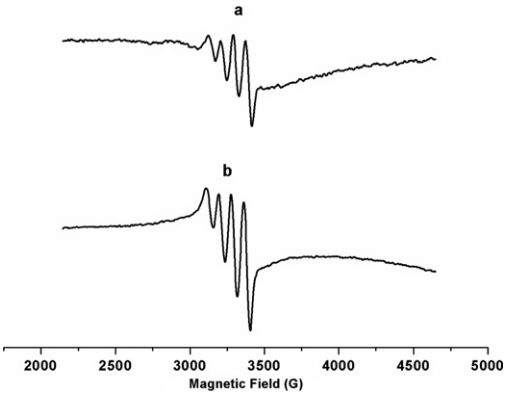

Fig. 4. Room temperature solution (acetonitrile) X-band EPR spectra of **1** (a) and **2** (b). General conditions: temperature = 298 K, microwave frequency = 9.64 GHz, microwave power = 1.00 mW, modulation frequency = 50 kHz, modulation amplitude = 5 G, receiver gain = 2.52×10^5. Sweep width = 2500 G. Time constant = 655.36 ms. Conversion time = 162.84 ms; $g_{dpph} = 2.0032$.

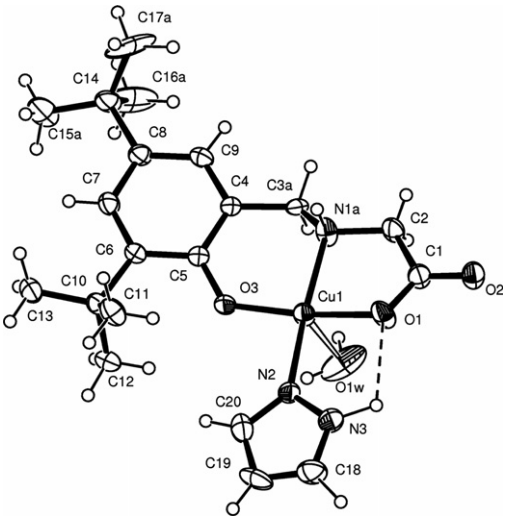

Fig. 5. ORTEP drawing of **1** (thermal ellipsoids at 30% probability). The disorder in the methyl carbons (C15, C16, C17) of the *tert*-butyl group, methylene (C3) and nitrogen (N1) have not been shown.

{Cu1···O1 = 1.966(3) Å} and a nitrogen (N1). In addition the copper center is bonded to one pyrazole nitrogen {Cu1···N2 = 1.989(3) Å} and a water molecule {Cu1···O1W = 2.374(3) Å}. Thus, the copper center is in a distorted square pyramidal environment.

The equatorial positions are occupied by the two oxygens (O1 and O3) (∠O1Cu1O3 = 169.07(13)°) and one nitrogen (N1) of the ligand L^1, and the fourth position is occupied by the pyrazole nitrogen (N2) (∠O1Cu1N2 = 88.28(9)°). The oxygen atoms, O1 and O3, lie in the equatorial plane. The two nitrogen atoms, N1B and N2, and the copper atom lie slightly above the plane by 0.156, 0.150 and 0.019 Å, respectively. The axial position is occupied by the water molecule (O1W) (∠O1Cu1O1W = 90.24(13)°; ∠O1WCu1O3 = 100.52(13)°; ∠O1WCu1N2 = 90.00(12)°). The compound shows crystallographic disorder. In one of the *tert*-butyl groups of the ligand, the carbon atom (C14) is surround by six methyl carbons of 0.656 (9) and 0.344 (9) occupancy each. In addition, the methylene carbon C3 and the nitrogen N1 of the ligand also show disorder. Due to the disorder in N1, the Cu1···N1 distance is not reliable {Cu1···N1A = 1.987(4) Å, Cu1···1N1B = 1.957(7) Å}. Similarly, the bond angles are also not reliable. The pyrazole ring lies roughly on the Cu1 coordination plane owing to the intramolecular hydrogen bond interaction between N3–H and O1 of the carboxylate group {N3···O1 = 2.767(4) Å}. Some important bond distances and bond angles are given in Table 1.

Table 1
Selected bond lengths (Å) and bond angles (°) of **1**

Bond distances (Å)		Bond angles (°)	
Cu1–O1	1.965(2)	O1–Cu1–O1W	90.24(13)
Cu1–O1W	2.374(4)	O1–Cu1–O3	169.07(13)
Cu1–O3	1.870(3)	O1–Cu1–N1A	82.82(17)
Cu1-N1A	1.987(4)	O1–Cu1–N2	88.28(9)
Cu1–N2	1.990(2)	O1–Cu1–N1B	85.7(3)
Cu1–N1B	1.958(7)	O1W–Cu1–O3	100.52(13)
		O1W–Cu1–N1A	98.50(19)
		O1W–Cu1–N2	90.00(12)
		O1W–Cu1–N1B	81.7(3)

3.4. Cyclic voltammetry and chemical and electrochemical oxidation of *1* and *2*, and generation of phenoxyl radical

Cyclic voltammetry of **1** (Fig. 6a) shows two quasi-reversible oxidative peaks at half-wave potentials ($E_{1/2}$) of 0.775 V ($\Delta E_P = 138$ mV) and 1.09 V ($\Delta E_P = 134$ mV) versus Ag/AgCl. These oxidative responses are attributed to the following oxidation process. The first is due to the ligand based oxidation, which is phenoxide to phenoxyl radical oxidation, (Eq. (1)) and the second is due to Cu(II) to Cu(III) oxidation (Eq. (2)) (*vide infra*).

Similarly, compound **2** (Fig. 6b) shows quasi-reversible oxidative responses at $E_{1/2} = 0.813$ V ($\Delta E_P = 150$ mV) and $E_{1/2} = 1.157$ V ($\Delta E_P = 153$ mV). In this case the oxidative responses are assigned to Cu(II) to Cu(III) oxidation and phenoxide to phenoxyl radical oxidation respectively (Eqs. (3) and (4)) (*vide infra*). Along with these peaks, unlike compound **1**, compound **2** shows an irreversible peak at 0.505 V. This may be due to oxidative decarboxylation.

$$[Cu^{II}L^1(Pyz)(H_2O)] \underset{+e}{\overset{-e}{\rightleftharpoons}} [Cu^{II}L^1(Pyz)(H_2O)]^{\cdot+} \quad (1)$$

$$[Cu^{II}L^1(Pyz)(H_2O)] \underset{+e}{\overset{-e}{\rightleftharpoons}} [Cu^{III}L^1(Pyz)(H_2O)]^{\cdot 2+} \quad (2)$$

$$[Cu^{II}L^1(Pyz)(H_2O)] \underset{+e}{\overset{-e}{\rightleftharpoons}} [Cu^{III}L^1(Pyz)(H_2O)]^{+} \quad (3)$$

$$[Cu^{III}L^1(Pyz)(H_2O)] \underset{+e}{\overset{-e}{\rightleftharpoons}} [Cu^{III}L^1(Pyz)(H_2O)]^{\cdot 2+} \quad (4)$$

The results of the electrochemical measurements lead us to investigate further the formation of the copper coordinated phenoxyl radical. The compounds were oxidized electrochemically. The spectral changes observed upon one

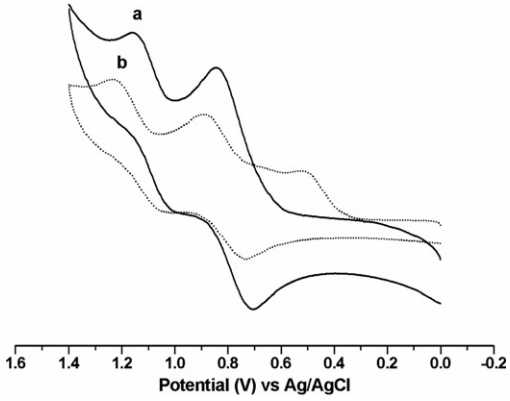

Fig. 6. Cyclic voltammogram of compound **1** (a, —) and compound **2** (b, ···) with an Ag/AgCl reference electrode, glassy carbon working electrode and a platinum wire auxiliary electrode. Scan rate = 0.2 V/s.

electron and two electron oxidation of **1** are shown in Fig. 7. After one electron oxidation of **1** the observed d–d transition at 640 nm is shifted to 600 nm ($\varepsilon = 240$) with an increase in intensity. The shoulder at 450 nm in **1** completely disappears and a new band appears at 380 nm ($\varepsilon = 1810$). This may be assigned to the LMCT transition phenolate – Cu(II). Thus, appearance of the 380 nm band shows that the first oxidative response is due to the phenoxide to phenoxyl radical generation [1–7,15–17]. Upon two electron oxidation, the d–d transition shifts to 670 nm ($\varepsilon = 68$). In the case of **2**, upon one electron oxidation the d–d band shifts to 675 nm ($\varepsilon = 41$) and the bands at 350 and 490 disappear. Unlike that observed in **1**, no band could be observed in the region of 380–410 nm in **2**. This clearly shows that, the first oxidative response is due to metal based oxidation. Upon two electron oxidation, a new high intensity band appears at 390 nm ($\varepsilon = 2500$) (Fig. 8). This clearly shows that the second oxidative response is due to phenoxide to phenoxyl radical oxidation.

The oxidation process was further investigated by in situ EPR spectral measurements. The EPR spectral changes observed at 77 K during the chemical oxidation of **1** and **2** have been shown in Figs. 2 and 3. Upon addition of Ce(IV) to the acetonitrile solution of **1** and **2** in a 1:1 ratio, the EPR signal disappears (Figs. 2b and 3b). In the case of **1** the diamagnetic nature of the intermediate may be explained in terms of antiferromagnetic coupling between the unpaired electrons on the Cu(II) center and the ligand [14]. This is in commensurate with the observed UV–visible spectral studies. When another equivalent of Ce(IV) is added to this solution a new isotropic signal appears at $g = 2.04$ (Figs. 2c and 3c). This signal may be attributed to the generation of Cu(III), a diamagnetic d^8 system, coordinated phenoxyl radical. In the case of **2**, the disappearance of the EPR signal can be attributed to the generation of Cu(III), a d^8 system. Upon second oxidation the generation of a phenoxyl radical is responsible for the appearance of the EPR signal. The observed higher g values of the radical species as well as the broad nature of the signals suggest that the unpaired electron is in a delocalized orbital which has a substantial amount of metal character [18].

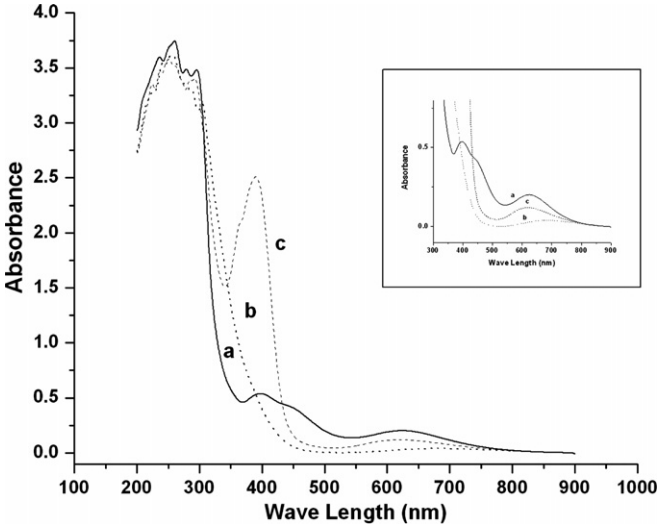

Fig. 8. UV–visible spectra of **2**. (a) Spectrum of the original compound (—). (b) One electron oxidized species (···). (c) Two electron oxidized species. Inset: enhanced spectra of (a), (b) and (c) in the region 300–900 nm.

4. Conclusion

In conclusion, it has been shown that using multidentate ligands containing phenoxide, carboxylate and nitrogen donor sites, a stable copper (III) coordinated phenoxyl radical can be generated. The parent complexes have been fully characterized using various spectroscopic techniques and one of the compounds has been characterized by single crystal X-ray structure determination. Radical species have been characterized by UV–visible and EPR spectroscopy.

In this report we focus on the examinations of the reactions of $[ReOCl_3(OAsPh_3)(AsPh_3)]$ and $[ReOCl_3(PPh_3)_2]$ with bis(pyrazol-1-yl)methane (bpzm) and present the synthesis, spectroscopic data, crystal, molecular, and electronic structures of $[ReOCl_3(bpzm)]$. Contrary to phenanthroline, the course of the reaction does not depend on the starting oxocomplex. In the both reactions only formation of $[ReOCl_3(bpzm)]$ has been observed.

The electronic structure of $[ReOCl_3(bpzm)]$ has been determined on the basis of the density functional theory (DFT) calculations, and additional information about binding has been obtained by NBO analysis. Currently density functional theory (DFT) is commonly used to examine the electronic structure of transition metal complexes. It meets with the requirements of being accurate, easy to use and fast enough to allow the study of relatively large molecules of transition metal complexes [8]. The spin-allowed electronic transitions of the $[ReOCl_3(bpzm)]$ complex have been calculated with the time-dependent DFT method (TDDFT), and the UV–Vis spectrum of the title compound has been discussed on this basis. The recent calculations with TD-DFT method for open- and closed-shell of 5d-metal complexes (including rhenium complexes) have supported the TD-DFT method to be applicable for such systems giving good assignment of experimental spectra [9,10].

2. Experimental

2.1. General procedure

All the reagents used to the syntheses were commercially available and were used without further purification. The $[ReOCl_3(AsPh_3)(OAsPh_3)]$ [11], $[ReOCl_3(PPh_3)_2]$ [12], and bis(pyrazol-1-yl)methane [13] were prepared according to the literature methods.

IR spectrum was recorded on a Nicolet Magna 560 spectrophotometer in the spectral range 4000–400 cm^{-1} with the samples in the form of KBr pellets. Electronic spectrum was measured on a spectrophotometer Lab Alliance UV–Vis 8500 in the range 1000–200 nm in dichloromethane solution. Elemental analyses (C H N) were performed on a Perkin–Elmer CHN-2400 analyzer.

2.2. Preparation of $[ReOCl_3(bpzm)]$ (*1*)

Method A. A mixture of $[ReOCl_3(AsPh_3)(OAsPh_3)]$ (0.5 g, 0.53 mmol), bpzm (0.1 g, 0.67 mmol), and acetone (50 ml) was stirred for 12 h. A turquoise powder was precipitated from the reaction mixture. It was filtered off, washed with diethyl ether and dried. Yield 80%.

Method B. A similar procedure with $[ReOCl_3(PPh_3)_2]$ (0.5 g, 0.60 mmol) and bpzm (0.11 g, 0.74 mmol) in acetone was used.

IR (KBr): 3121 (m) and 3022 (m) ν_{C-H}; 1520 (m) ν_{CN} and $\nu_{C=C}$; 978 (s) $\nu_{Re=O}$.

Anal. Calc. for $C_7H_8N_4Cl_3ORe$: C, 18.41; H, 1.77; N, 12.27. Found: C, 18.55; H, 1.75; N, 12.35%.

2.3. X-ray diffraction studies

A blue crystal of $[ReOCl_3(bpzm)]$ was mounted on a KM-4-CCD automatic diffractometer equipped with a CCD detector, and used for data collection. X-ray intensity data were collected with graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at temperature of 293(2) K. Details concerning crystal data and refinement are given in Table 1. Lorentz, polarization and empirical absorption correction using spherical harmonics implemented in SCALE3 ABSPACK scaling algorithm [14] were applied. The structure was solved by the Patterson method and subsequently completed by the difference Fourier recycling. All the non-hydrogen atoms were refined anisotropically using full-matrix, least-squares technique. The hydrogen atoms were treated as ''riding'' on their parent carbon atoms and assigned isotropic temperature factors equal 1.2 times the value of equivalent temperature factor of the parent atom. SHELXS97 [15], SHELXL97 [16], and SHELXTL [17] programs were used for all the calculations. Atomic scattering factors were those incorporated in the computer programs. At the end of refinement on the difference Fourier synthesis maximum peak/hole are located 0.7 Å from rhenium atom. The next peaks/holes are distinctly smaller (<1 e $Å^{-3}$).

3. Computational details

Gaussian03 program [18] was used in the calculations. The geometry optimization of the $[ReOCl_3(bpzm)]$ complex was carried out with the DFT method with the use of B3LYP functional [19,20]. The electronic spectrum of the $[ReOCl_3(bpzm)]$ complex was calculated with the TDDFT method [21]. The solvent effect was simulated using the polarizable continuum model (PCM). The calculations were performed by using ECP basis set on the rhenium atom, the standard 6-31+g** basis for chlorine, oxygen, and nitrogen, 6-31g* basis for carbon and 6–31G basis for hydrogen atoms. The Xe core electrons of Re were replaced by an effective core potential and DZ quality Hay and Wadt Los Alamos ECP basis set (LANL2DZ) [22] was used for the valence electrons. Additional d function with exponent $\alpha = 0.3811$ and f function with exponent $\alpha = 2.033$ on the rhenium atom were added. Natural bond orbital (NBO) calculations were performed with the NBO code [23] included in Gaussian03.

4. Results and discussion

4.1. Preparation

The reactions of the $[ReOCl_3(AsPh_3)(OAsPh_3)]$ or $[ReOCl_3(PPh_3)_2]$ oxocompounds with a small excess of bis(pyrazol-1-yl)methane in acetone at ambient temperature lead to the formation of $[ReOCl_3(bpzm)]$ in high yield.

Largest difference in peak and hole (e Å^{-3})	3.468 and −1.844

The complex is slightly soluble in most polar solvents, and it has been recrystallized from acetonitrile.

4.2. Infrared data

The IR spectrum of [$ReOCl_3$(bpzm)] exhibits strong band at 978 cm^{-1} assignable to ν(Re=O) mode. This value compares well with those reported for monooxo rhenium(V) complexes with chelating ligands: [$ReOBr_3$(dppen)] (dppen = *cis*-$Ph_2PCH{=}CHPPh_2$) – 984 cm^{-1}, [$ReOBr_3$(dppm)] (dppm = $Ph_2PCH_2PPh_2$) – 980 cm^{-1}, and [$ReOBr_3$(dppe)] (dppe = $Ph_2PCH_2CH_2PPh_2$) – 982 cm^{-1} [24]. The characteristic band corresponding to the ν(CN), ν(C=C) mode of the bpzm ligand appears at 1520 cm^{-1} [25].

4.3. Crystal structure

The [$ReOCl_3$(bpzm)] complex crystallises in $P\bar{1}$ space group. The molecules are linked *via* weak intermolecular hydrogen bonds [26,27]: C(4)–H(4A)···Cl(1) $(x, y-1, z)$ with D···A distance 3.400(4) Å and D–H···A angle 119.1°; C(4)–H(4A)···Cl(2) $(x, y-1, z)$ with D···A distance 3.647(4) Å and D–H···A angle 163.7° and C(4)–H(4A)···Cl(3) $(x, y-1, z)$ with DA distance 3.405(4) Å and D–H···A angle 119.0°. The intramolecular hydrogen bond linking C(4)–H(4B)···O(1) (D···A distance 3.131 (5) Å and D–H···A angle 118.5°) provides additional stabilization of *fac* geometry of the [$ReOCl_3$(bpzm)] molecule. It can not exist in *mer*-configuration of [$ReOCl_3$(bpzm)].

The molecular structure of [$ReOCl_3$(bpzm)] is given in Fig. 1. The pseudooctahedral environment of Re center in [$ReOCl_3$(bpzm)] shows clear distortions, induced by the multiple bonding ligand (oxo). The high concentration of electronic density along the Re–O axis strongly influences the positions of the adjacent chlorine and nitrogen atoms, which are pushed away. The chloride ions are arranged in a *facial* fashion, and the oxo ligand occupies the *trans* position to the Cl(2) ion. The *fac* geometry of the ReX_3 fragment has been found for some other oxo-rhenium(V) complexes, but it is definitely rarer observed than *mer* arrangement. Presumably, π-acceptor capability of bis(pyrazol-1-yl)methane sustains the *fac* geometry in the title complex. The *cis*-location of π-acid ligands in relation to the oxo group seems to be dominated by electronic influence of the multiply bonded ligand, which forces the metal nonbonding d electrons to lie in the plane perpendicular to the M–O bond axis. This general rule appears to hold for isonitrile, carbonyl, olefin, acetylene, thioether and often phosphine ligands [28–30].

Upon coordination of bis(pyrazol-1-yl)methane to the rhenium, a six-membered cycle (made by the four nitrogen atoms, the rhenium atom and the carbon atom) is formed. This six-membered ring shows a *boat* arrangement, with the rhenium and the carbon atoms off the plane defined by the four nitrogen atoms.

The most important bond lengths and angles for [$ReOCl_3$(bpzm)] are reported in Table 2. The Re–O bond in [$ReOCl_3$(bpzm)] is a typical example of reported terminal multiple Re–O_{oxo} distances in mononuclear $[ReO]^{3+}$ compounds and indicates the presence of a triple bond Re≡O [31]. The Re(1)–Cl(2) distance, affected by *trans* influence of the oxo ligand, is significantly longer than the Re(1)–Cl(1) and Re(1)–Cl(3) bond lengths.

4.4. Geometry optimization

The geometry of [$ReOCl_3$(bpzm)] was optimized in a singlet state by the DFT method with the B3LYP functional. The optimized geometric parameters are gathered in Table 2. The calculated bond lengths and angles are in agreement with the values based upon the X-ray crystal structure data, and the general trends observed in the experimental data are well reproduced in the calculations.

4.5. Charge distribution

Table 3 presents the atomic charges from the natural population analysis (NPA) for [$ReOCl_3$(bpzm)]. The calculated charge on the rhenium atom is considerable lower than the formal charge 5+. The populations of the $5d_{xy}$, $5d_{xz}$, $5d_{yz}$, $5d_{x^2-y^2}$ and $5d_z^2$ orbitals of the central atom in [$ReOCl_3$(bpzm)] are following: 0.920, 0.867, 0.851, 1.938 and 0.917. This is a result of significant charge donation from the ligands; the charges on the chloride and oxo ligands are significantly smaller than −1 and −2, respectively. The

			N(3)–Re(1)–Cl(2)	82.54(9)	79.59
			N(3)–Re(1)–Cl(3)	90.40(8)	89.83

Table 3
Atomic charges from the natural population analysis (NPA) for [$ReOCl_3$(bpzm)]

Atom	Charge
Re(1)	1.060
O(1)	−0.432
Cl(1)	−0.351
Cl(2)	−0.444
Cl(3)	−0.351
N(1)	−0.221
N(2)	−0.314
N(3)	−0.314
N(4)	−0.221

considerable differences in values of charges are observed for the chloride ligands – less negative are chloride ions in the *cis* position to the terminal oxo ligand. It indicates the higher electron density delocalization from these ligands towards the rhenium center and corresponds to differences in the Re–Cl bonds lengths.

4.6. NBO analysis

Table 4 presents the occupancy and hybridization of the calculated Re–O_t natural bond orbitals (NBOs) for [$ReOCl_3$(bpzm)].

Table 4
The occupancies and hybridization of the calculated natural bond orbitals (NBOs) between the rhenium and the oxo ligand for [$ReOCl_3$(bpzm)]

BD	Occupancy	Hybridization of NBO	BD[a]	Occupancy
Re–O	1.964	$0.493(sd^{3.78})_{Re} + 0.870(sp^{2.23})_O$	$0.870(sd^{3.78})_{Re} - 0.493(sp^{2.23})_O$	0.358
Re–O	1.985	$0.573(d)_{Re} + 0.820(p)_O$	$0.820(d)_{Re} - 0.573(p)_O$	0.288
Re–O	1.981	$0.566(d)_{Re} + 0.824(p)_O$	$0.824(d)_{Re} - 0.566(p)_O$	0.313

BD denotes 2-center bond.
[a] Denotes antibond NBO.

Each natural bond orbital (NBO) σ_{AB} can be written in terms of two directed valence hybrids (HHOs) h_A and h_B on atoms A and B:

$$\sigma_{AB} = c_A h_A + c_B h_B$$

where c_A and c_B are polarization coefficients. Each valence bonding NBO must in turn be paired with a corresponding valence *anti*-bonding NBO:

$$\sigma^*_{AB} = c_B h_A - c_A h_B$$

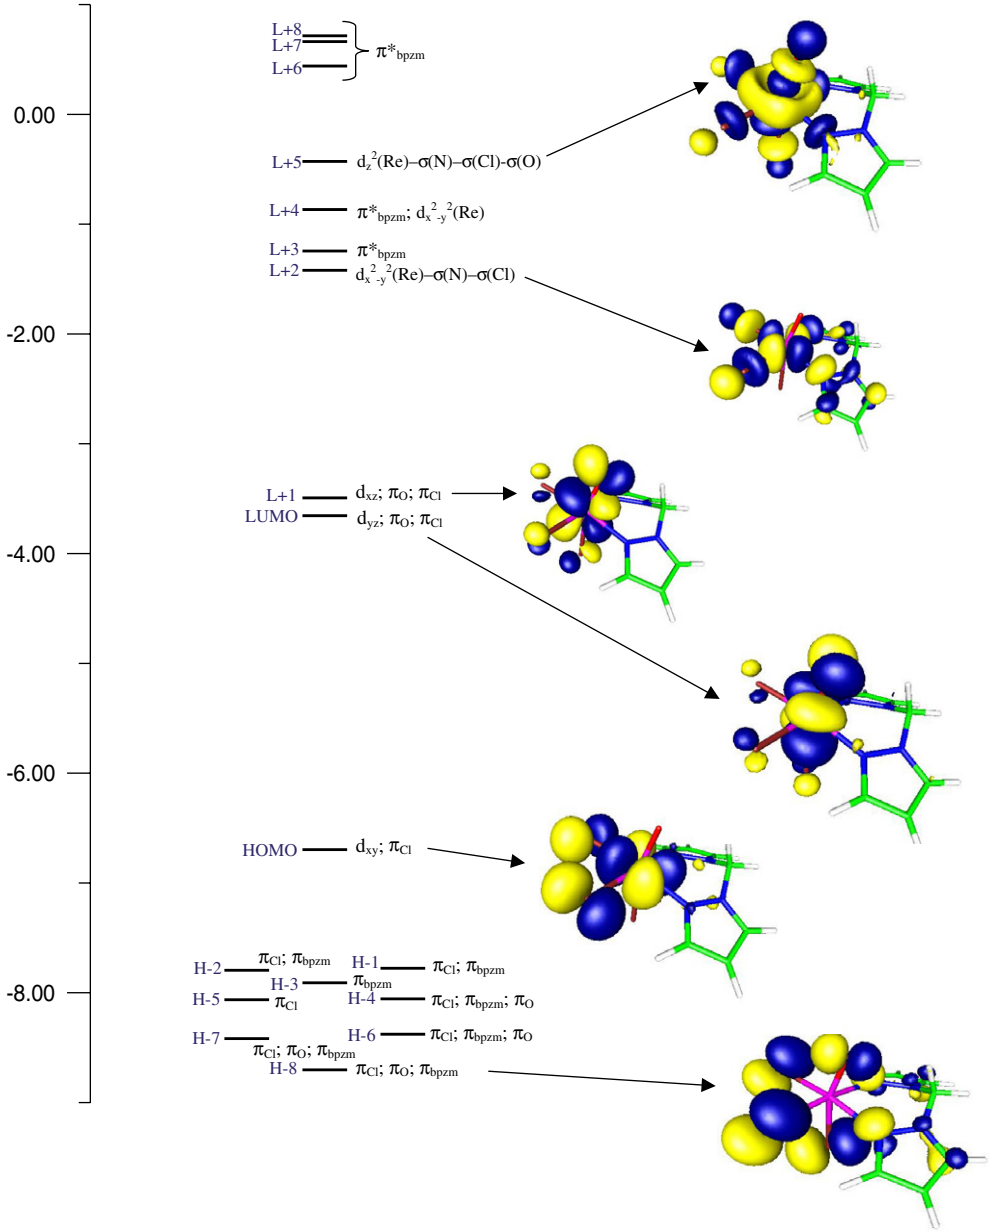

Fig. 2. The energy (eV), character, and some contours of the unoccupied and occupied molecular orbitals of [$ReOCl_3$(bpzm)].

to complete the span of the valence space. The Lewis-type (donor) NBOs are thereby complemented by the non-Lewis-type (acceptor) NBOs that are formally empty in an idealized Lewis picture. The interactions between 'filled' Lewis-type NBOs and 'empty' non-Lewis NBOs lead to loss of occupancy from the localized NBOs of the idealized Lewis structure into the empty non-Lewis orbitals, and they are referred to as 'delocalization' corrections to the zeroth-order natural Lewis structure [32].

For $[ReOCl_3(bpzm)]$ complex, three natural bond orbitals were detected. The s and p oxygen orbitals and s and d rhenium orbitals take part in the σ_{Re-Ot} bond formation, whereas the π_{Re-Ot} bond orbitals result from overlapping of the empty d_{xz} and d_{yz} rhenium orbitals with the occupied p_x and p_y orbitals of the terminal oxygen ligands. Both the σ and π Re–O bonds are clearly polarized towards the oxygen end.

4.7. Electronic structure

ε – molar absorption coefficient [$dm^3\ mol^{-1}\ cm^{-1}$], f – oscillator strength, H – highest occupied molecular orbital, L – lowest unoccupied molecular orbital.

occupied molecular orbitals (HOMO or H) of [$ReOCl_3$(bpzm)] are presented in Fig. 2. The HOMO–LUMO gap is 3.04 eV. The highest occupied MO of [$ReOCl_3$(bpzm)] is of d_{xy} type with an antibonding contributions from p_π chlorine orbitals. The remaining four d-type orbitals of rhenium are found among unoccupied MOs. The LUMO and LUMO+1 are closely spaced in energy and they can be ascribed as π-antibonding rhenium–oxygen molecular orbitals.

The rhenium atom uses six valence orbitals, $5d_{x^2-y^2}$, $5dz^2$, 6s, $6p_x$, $6p_y$ and $6p_z$ to form σ-bonds with the six ligands, the occupied $5d_{xy}$ orbital of the Re ion remains nonbonding, and empty $5d_{yz}$ and $5d_{xz}$ orbitals interact with the filled $2p_y$ and $2p_x$ orbitals of the terminal oxo ligand to give two π-bonding and two π-antibonding molecular orbitals.

4.8. Electronic spectrum

The experimental and calculated electronic spectra of [$ReOCl_3$(bpzm)] are presented in Fig. 3. Each calculated transition is represented by a Gaussian function $y = ce^{-bx^2}$ with the height (c) equal to the oscillator strength and b equal to 0.04 nm^{-2}.

Table 5 shows the spin-allowed singlet–singlet electronic transitions calculated with the TDDFT method for [$ReOCl_3$(bpzm)]. For the high energy part of the spectrum, only transitions with oscillator strengths larger than 0.0050 are listed in Table 5.

The UV–Vis spectrum of [$ReOCl_3$(bpzm)] exhibits a few intense absorption bands in the range 400–200 nm and a weak absorption in the low energy range – at 692.4 nm.

The longest wavelength experimental band of [$ReOCl_3$(bpzm)] is attributed to the transition of d → d character with small oscillator strengths calculated at 738.4 nm.

The absorption band at 370 nm is assigned to the electronic transitions calculated in the range 390–309 nm. They have *LMCT* (*Ligand–Metal Charge Transfer*) character and originate from the chlorine, oxo and bpzm ligands to the d_{Re} orbitals.

The experimental bands below 300 nm result mainly from *Ligand–Metal Charge Transfer*: π(Cl)/π(O)/π(bpzm) → d, *Ligand–Ligand Charge Transfer*: π(Cl)/π(O) → π*(bpzm) transitions and intraligand (IL) transitions: π(bpzm) → π*(bpzm).

5. Supplementary material

CCDC 625233 contains the supplementary crystallographic data for $C_7H_8N_4Cl_3ORe$. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Acknowledgement

The Gaussian03 calculations were carried out in the Wrocław Centre for Networking and Supercomputing, WCSS, Wrocław, Poland.

evaluated and its metal complexes, especially with copper(II), showed an enhanced biological activity with respect to the free ligand. One of these copper *N*-aroyl-*N*′-thioaroylhydrazines derivatives was able to inhibit cell proliferation and induce apoptosis [15]. Copper(II) complexes of α-ketoglutaric acid thiosemicarbazone also inhibited cell proliferation through the apoptosis mechanism [16]. Copper(II) complexes of thiosemicarbazones derived from acyl diazines showed cytotoxic activity against colon adenocarcinoma HT-29 cells and large and small lung carcinoma cells. They inhibit the enzyme ribonucleoside diphosphate reductase and affect the synthesis of DNA. One of these complexes is a potent inducer of apoptosis in Burkitt's lymphoma cells [17].

Cu(II) complexes of thioaroylhydrazines derivatives show significant inhibition of ^{3}H-thymidine and ^{3}H-uridine incorporation into DNA and RNA in P-815 and L-929 tumor cells and have an effect on DNA synthesis. They inhibit tumor growth and that process is associated with induction of apoptosis in lymphocytes, but the detailed mechanism of inhibition is still unclear. The inhibition in tumor cell blastogenesis could be a direct result of the interaction of the metal complexes with DNA, thus interfering with the normal process of its replication. The inhibition of uridine incorporation suggests their influence on the activity of enzymes involved in DNA replication, especially DNA endonucleases causing DNA fragmentation [18].

Over recent years, increasing attention has been paid to pyrazoles, pyrimidines and related N-containing heterocyclic derivatives, which play an important role in many biological processes due to their coordinating ability for metal ions [19]. The studies have been stimulated by promising pharmacological [20], analytical [21] and agrochemical [22] applications. Pyrazoles and their complexes with metals, besides having antitumor activity, are analgesic and antiinflammatory agents, such as the pyrimidinopyrazole derivative – mepirizole [19]. Some mixed chelate copper-based drugs have exhibited greater antineoplastic potency than cisplatin in in vitro and in vivo studies of a variety of tumor cell lines [23]. Pyrazol-thioketone derivatives have antimicrobial activity. They inhibit growth of *Staphylococcus aureus*, *Staphylococcus typhii*, *Candida albicans* and *Mycobacterium tuberculosis* [24]. *O*-Hydroxyphenylopyrazoles are used as UV stabilizers, analytical reagents in the complexation of metal ions, analgesic agents and platelet aggregation inhibitors [21]. Diarylopyrazoloquinolinones have affinity for the benzodiazepine receptor and their activity is similar to that of diazepam [25].

Here we present the synthesis of the new chelating ligands 5-(2-hydroxybenzoyl)-3-methyl-1-(2-pyridinyl)pyrazol-4-carboxylic acid methyl ester (**2**) and 3-methyl-1 -(2-pyridinyl)-1*H*-chromene[4,3-*c*]pyrazol-4-on (**3**), as well as their solid pyrazole complexes with Cu(II). Physical and the protolytic properties of the ligands as well as their interaction with Cu(II) in solution are also shown.

2. Experimental

2.1. Materials

All substances were used without further purification. Chloroform-D solvent for NMR spectroscopy was obtained from Dr. Glaser AG Basel. Solvents for synthesis (toluene, methanol, dimethylformamide, acetone) were reagent grade or better and were dried according to standard methods. The melting points were determined using an Electrothermal 1A9100 apparatus and they are uncorrected. The IR spectra were recorded on a Pye-Unicam 200G Spectrophotometer in KBr and CsI. The ^{1}H NMR spectra were registered at 300 MHz on a Varian Mercury spectrometer. The MS data were obtained on a LKB 2091 mass spectrometer (70 eV ionization energy). The MS-FAB data were determined on Finnigan Matt 95 mass spectrometer (NBA, Cs^{+} gun operating at 13 keV). For the new compounds satisfactory elemental analyses (±0.3% of the calculated values) were obtained using a Perkin–Elmer PE 2400 CHNS analyzer.

2.2. Synthesis of the ligands

2.2.1. Synthesis of 5-(2-hydroxybenzoyl)-3-methyl-1-(2-pyridinyl)pyrazol-4-carboxylic acid methyl ester (2)

2-Hydrazinopyridin (5 mmol) in EtOH (5 mL) was added at room temperature to a solution of 2-methyl-4-oxo-4*H*-chromene-3-carboxylic acid methyl ester (**1**) (5 mmol) in EtOH (10 mL). The mixture was refluxed for 1 h. The solid crude product, which precipitated after 24 h, was filtered off, dried and crystallized from ethanol. The pure compound was obtained as a white solid.

Yield: 942 mg (61%), mp: 158.5–159.9 °C. IR: ν_{max}/cm^{-1} 3190 (OH); 1705 (C=O); 1613 (C=N) cm^{-1}. ^{1}H NMR ($CDCl_3$): $\delta = 2.57$ (s, 3H, C–CH_3); 3.62 (s, 3H, O–CH_3); 6.83–8.34 (m, 8H, aromat) ppm. ^{13}C NMR ($CDCl_3$): $\delta = 14.55$ (C–CH_3); 51.53 (O–CH_3); 164.46 (C=O) ppm. MS *m*/*z*: 309.0. *Anal*. found: C, 65.97; H, 4.67; N, 13.30. Calc. for $C_{17}H_{13}N_3O_3$ (309.311): C, 66.01; H, 4.89; N, 13.59.

2.2.2. Synthesis of 3-methyl-1-(2-pyridinyl)-1H-chromene[4,3-c]pyrazol-4-on (3)

N-Methylhydrazin (0.5 mmol) was added at room temperature to a solution of 5-(2-hydroxybenzoyl)-3-methyl-1-(2-pyridin)pyrazol-4-carboxylic acid methyl ester (**2**) (0.5 mmol) in MeOH (10 mL). The mixture was refluxed for 1 h. The solid product, which precipitated after 1 h, was filtered off, dried and crystallized from ethyl acetate. The pure compound was obtained as a white crystal solid.

Yield: 88 mg (63%), mp: 202.8–205.1 °C. IR: ν_{max}/cm^{-1} 1742 (C=O); 1615 (C=N) cm^{-1}. ^{1}H NMR ($CDCl_3$): $\delta = 2.71$ (s, 3H, CH_3); 7.41–8.76 (m, 8H, aromat) ppm. ^{13}C NMR ($CDCl_3$): $\delta = 13.32$ (C–CH_3); 158.12 (C=O) ppm. MS *m*/*z*: 278.0. *Anal*. found: C, 68.91; H, 3.51; N,

15.17. Calc. for $C_{16}H_{11}N_3O_2$ (277.269): C, 69.30; H, 4.0; N, 15.16.

2.3. Synthesis of copper(II) complexes 4 and 5

2.3.1. Synthesis of complex 4

Copper(II) chloride (0.1 mmol) in MeOH (2 mL) was slowly added at room temperature to a solution of 5-(2-hydroxybenzoyl)-3-methyl-1-(2-pyridinyl)pyrazol-4-carboxylic acid methyl ester (**2**) (0.1 mmol) in MeOH (10 mL). The mixture was left at room temperature for 24 h. The yellow solid product which precipitated was filtered off and crystallized from acetonitryl. The pure compound was obtained as a yellow crystal solid.

Yield: 36 mg (81%), mp: 197.4–199.1 °C. IR: ν_{max}/cm^{-1} 3221 (OH); 1717 (C=O); 455 (Cu–N); 295 (Cu–Cl) cm^{-1}. FAB-MS *m/z*: 443.0. *Anal* found: C, 46.01; H, 3.32; N, 9.41. Calc. for $C_{17}H_{15}N_3O_3CuCl_2$ (443.35): C, 46.05; H, 3.41; N, 9.48.

2.3.2. Synthesis of complex 5

Copper(II) chloride (0.1 mmol) in ethyl acetate (3 mL) was slowly added at room temperature to a solution of 3-methyl-1-(-2-pyridinyl)-1*H*-chromene[4,3-c]pyrazol-4-on (**3**) (0.1 mmol) in ethyl acetate (10 mL). The green solid precipitated after a few minutes. The product was filtered off. The pure compound was obtained as a green crystal solid.

Yield: 22 mg (53%), mp: 297–298 °C. IR: ν_{max}/cm^{-1} 1749 (C=O); 457 (Cu–N); 302 (Cu–Cl) cm^{-1}. FAB-MS *m/z* 412.0. *Anal*. found: C, 46.41; H, 2.62; N, 10.21. Calc. for $C_{16}H_{11}N_3O_2CuCl_2$ (411.619): C, 46.68; H, 2.69; N, 10.21.

2.4. Potentiometric studies

The protonation constants of ligands **2** and **3** were determined by pH-metric titration of 4 cm^3 samples, at 25 ± 0.1 °C. The total concentration of ligand **2** in each sample ranged within $3.75–6.25 \times 10^{-4}$ mol dm^{-3}. For ligand **3** the concentration range amounted to $3.75–6.25 \times 10^{-4}$ mol dm^{-3}. Owing to the very low solubility in pure water, the mixed 5% v/v 1,4-dioxane–water solvent was used for ligands **2** and **3**, respectively. The titrations were carried out with carbonate-free NaOH solution of known concentration (0.1 mol dm^{-3}). The value of $pK_w = 13.77$ resulted from our acid–base calibrations in the same solvent. The hydrolysis constants of the aquo-ion were determined under the same conditions as in the titrations in the presence of ligand.

The metal–ligand interaction was studied by pH-metric titration of the same volume, medium and temperature as described for the ligand alone. The ligand was in excess – the L:M molar ratio amounted to 4:1, 5:1 and 6:1 at a total metal concentration within $1.1–5.0 \times 10^{-4}$ mol dm^{-3}. $Cu(NO_3)_2$ purum p.a. of Fluka AG was used. The standard solution was titrated with the disodium salt of EDTA in the presence of murexide.

The pH was measured with a Molspin Ltd. (Newcastle upon Tyne, England) automatic titration set and combined OSH 10-10 electrode (Metron, Poland). The total volume of the Hamilton microsyringe in the autoburette was 250 µl, the volume increments amounted to 0.0025 ml. The experiments were performed using MOLSPIN.EXE software.

The electrode was calibrated in the $-\log[H^+]$ scale by titration of 0.005 M HNO_3 (in 5% dioxane) with 0.1 M NaOH, temperature 25 °C. Then concentration overall protonation constants $\beta_{lh} = [L_lH_h]/[L]^l[H]^h$ were calculated by the SUPERQUAD computer program [26].

2.5. X-ray measurements

The light white single crystal of ligand **2** was used for measurement on an AFC5S Rigaku diffractometer [27]. X-ray intensities were collected using graphite monochromated Mo Kα radiation and the ω scan technique. After each group of 150 reflections three standard reflections were monitored and insignificant (<2%) intensity fluctuation was observed. All data were corrected for Lorentz and polarization effect [28].

The structure of ligand **2** was solved by direct methods (SHELXS97 [29]) and refined on F^2 by the full-matrix least-squares technique (SHELXL97 [27]). All non-hydrogen atoms were refined anisotropically. During the refinement the atoms of the C13–C17 pyridyl ring were found to be disordered. Two components of the disorder were modelled, using rigid planar hexagons for the phenyl rings. Refinement of the site-occupation factors of the disordered atoms indicated that the two conformations were approximately equally occupied. Finally, the occupancies of the disordered atoms were fixed at 0.5 and similar restraints were applied to the atomic displacement parameters of those disordered atoms. The distances between atom pairs N2/C13A and N2/C13B were restrained to be equal, with an effective s.u. of 0.003 Å.

Carbon-bonded H-atoms were included in calculated positions (C–H = 0.93–0.98 Å) and constrained to ride on their parent atoms with isotropic displacement parameters equal to $1.2U_{eq}$(C) (or $1.5U_{eq}$ for methyl C atoms). The oxygen-bonded H-atoms (H3 and H41, H42 in the water molecule) were located from the difference map and refined isotropically.

Selected crystal data and details of the structure refinement are collected in Table 2. Geometrical calculations and drawings were performed with PLATON [30].

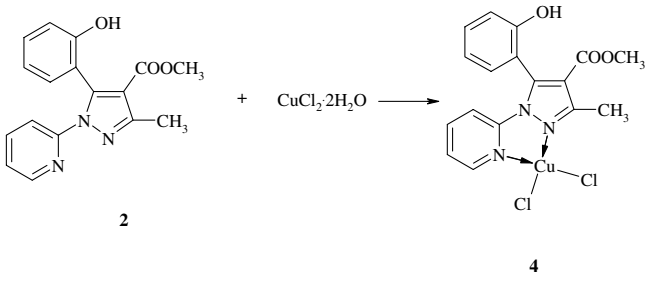
3. Results and discussion

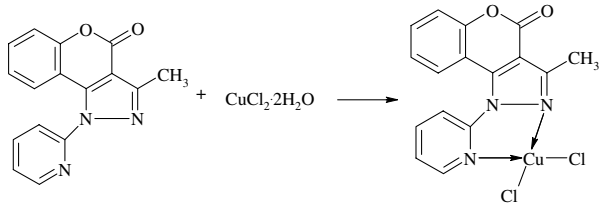
3.1. Preparation of the ligands and their complexes



It has been reported that certain copper(II) complexes catalyze radical formation while others seem to have antioxidant properties [31]. Their actual behavior depends upon the chemical environment and the nature of chelating agents. In the reaction of 2-methyl-4-oxo-4*H*-chromene-3-carboxylic acid methyl ester (**1**) and 2-hydrazinepyridin (1:1) in boiling methanol we have obtained 5-(2-hydroxybenzoyl)-3-methyl-1-(2-pyridin)pyrazol-4-carboxylic acid methyl ester (**2**) with a good yield (61%). This compound easily cyclizes under basic conditions to form 3-methyl-1-(2-pyridinyl)-1*H*-chromene[4,3-*c*]pyrazol-4-on (**3**) (see Scheme 1).

The physical data are given in Section 2.

3.2. Synthesis of the complexes



Complex **4**, of the formula $Cu(L)Cl_2$, was obtained by treatment of the corresponding ligand **2** with $CuCl_2 \cdot 2H_2O$ (in a 1:1 molar ratio) in methanol. Complex **5** was not formed in methanolic solution, most likely due to methanolysis (see Schemes 2 and 3) as we have isolated the free ligand **3**. We have obtained complex **5** in the reaction of **3** and $CuCl_2 \cdot 2H_2O$ in ethyl acetate. Under this condition methanolysis or hydrolysis is not possible and the complex is formed.

The IR spectra of the complexes are similar to those of the free ligands (see Table 1). The most characteristic bands are those at 1612 and 1580 cm^{-1}, attributable to the pyraz-

Scheme 3. Synthesis of complex **5**.

1 2 3

Scheme 1. The synthesis of ligands **2** and **3**.

olyl ν(C=C) and ν(C=N) groups. The band at 3200 cm^{-1} is characteristic of the OH group in ligand **2** and its complex **4**.

The IR spectra of the Cu complexes in the region 500–100 cm^{-1} were also recorded and show well-defined bands corresponding to ν(Cu–Cl) at 295 and 303 cm^{-1}. Bands attributable to ν(Cu–N) at 455 and 457 cm^{-1} are also present.

The $\nu_{C=N}$ band observed for compound **2** at 1543 cm^{-1} is shifted towards higher frequencies (to 1554 cm^{-1}) for complex **4**. This observation can be explained by participation of the nitrogen atom in the coordination with the metal ions in the complex [32].

3.3. Crystal and molecular structure of ligand 2

The molecular structure of ligand **2** is shown in Fig. 1. The molecule consists of four fragments: pyridyl and phenolic rings, methyl and carboxylate groups substituted on the pyrazole ring. The pyridyl rings have been found to be disordered (see Section 2.5). Both components of the disordered pyridyl rings are refined to be planar, the dihedral angle between their planes is 30(1)°. The pyrazole and benzene rings are also planar with a dihedral angle equal to 66(1)°. The bond lengths and angles listed in Table 3 are within the normal ranges, hence no detailed discussion is needed. The principal structural interest lies in the molecular interactions. Hydrogen-bonding geometries are listed in Table 4. The molecules of structure **2** are linked into two-dimensional layers by a combination of O–H···O and O–H···N hydrogen bonds. These layers are stacked along the [0 1 0] direction. Fig. 2 presents the hydrogen-bonding network projected on the *ac* plane. There are only weak C–H···O contacts between neighboring layers and no specific interactions are observed; in particular, aromatic π–π stacking interactions are absent from the structure of **2**.

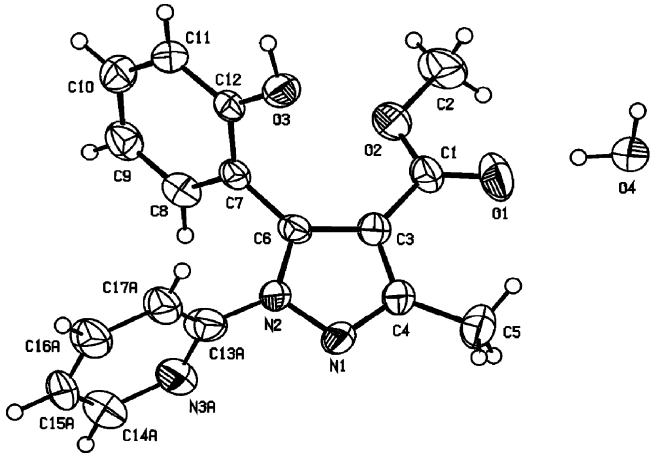

Fig. 1. The molecular structure of ligand **2** with the atom numbering scheme. The second component of the disordered pyridyl ring (C13*B*–C17*B*) has been omitted for clarity. Displacement ellipsoids are drawn at the 40% probability level and H atoms are shown as small spheres of arbitrary radii.

3.4. Determination of protonation constants

As a result of the protonation constants, it follows that ligand **2** behaves as a triprotonated molecule, whereas ligand **3** is indicative of two functional groups. The stepwise protonation constants $\log K$ reported here (Table 5) may be compared with the corresponding values of relatively simple heterocyclic compounds – corresponding to the groups found in ligands **2** and **3**.

Table 5
Experimental conditions of potentiometric titrations and values of overall protonation constants of **2** and **3** at 25 °C

	Ligand **2**		Ligand **3**

Solvent: 5% v/v 1,4-dioxane–H_2O. Standard deviations in parentheses. The literature data correspond to the same temperature.
L^- in the case of ligand **2** denotes the form with deprotonated phenol OH.
[a] Equilibrium: $L^- + H^+ \rightleftharpoons LH$.
[b] Equilibrium: $L^- + 2H^+ \rightleftharpoons LH_2^+$.
[c] Equilibrium: $L^- + 3H^+ \rightleftharpoons LH_3^{2+}$.
[d] Equilibrium: $L + H^+ \rightleftharpoons LH^+$.
[e] Equilibrium: $L + 2H^+ \rightleftharpoons LH_2^{2+}$.

3.5. Determination of stability constants (ligand **2**)

In the case of ligand **2** with a deprotonated phenol ring (L^-), the metal renders accessible six coordination sites (Table 6). The three consecutive equilibria are accepted in the refinements although none of the assumed bridged dimeric species has been found suitable in the model. *N*-Pyridine and *N*-pyrazole are the most probable electron pair donors, giving rise to highly favourable five-membered chelate rings. At lower pH, however, when the OH group is undissociated, only a complex with a L:M ratio of 2:1 could be confirmed (Fig. 3).

Table 6

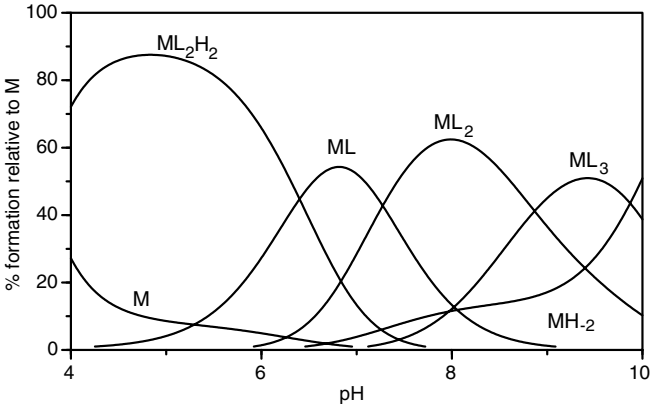

Fig. 3. Species distribution in a solution containing M = Cu from $Cu(NO_3)_2$ and L = ligand **2** at a 1:4 molar ratio. Solv. 5% v/v 1,4-dioxane–water. $C_{Cu} = 3.4 \times 10^{-4}$ mol dm^{-3}. Temperature 25 °C.

The interaction of **3** with copper(II) during the titration was very weak in spite of the protolytic properties of the nitrogen functions being quite similar to **2** (Table 5). This resulted in a visible precipitation already at pH ~ 5.

As can be seen in Fig. 3 the MH_{-1} monohydroxo complex is completely overhelmed by a dihydroxo MH_{-2} complex and the formation of significant amounts of the MH_{-2} complex occurs essentially at pH > 8.5.

4. Spectrophotometric studies of the Cu(II)–ligand interaction

With a L:M molar ratio of 4:1, due to high concentrations of the metal (1.25×10^{-3} mol dm^{-3}), the experiments needed for this method were made in 1,4-dioxane–water solutions (10% v/v). The basicity of the solution was enhanced by adding small portions of 0.1 M NaOH of known density (20–40 μl) to a sample with an initial volume of 2.4 cm^3. The accurate number of millimoles was evaluated by weighing the cell after each addition.

As can be seen in Fig. 4, a rise in absorbance occurred already at pH ~ 4. With alkalization the solution became more and more yellow (up to dark-yellow) until pH = 8.63 when the precipitation disturbed further absorption measurements.

As it is well known for hexacoordinate Cu(II) compounds [36,37] in a tetrahedral environment, the crystal field splitting leads to three transitions (both for a tetragonal bipyramid elongated along the *z*-axis – ground state $^2B_{1g}$ and for the shortened bipyramid – ground state $^2A_{1g}$). Accordingly, in our spectra we may propose to assign the broad maximum at ~700 nm (shifting from 730 to 707 nm) as the lowest energy band. The second band, initially only an inflection, becomes visible at higher pH, at ca. 430–440 nm, together with the rising complex formation, whereas the third band is probably masked by the highly intensive tail below 400 nm (Fig. 4). The very high intensity (ε exceeding 10^4) indicates the tail of a strong charge transfer band. Moreover, the rise of absorbance within the observed tail makes it impossible to observe

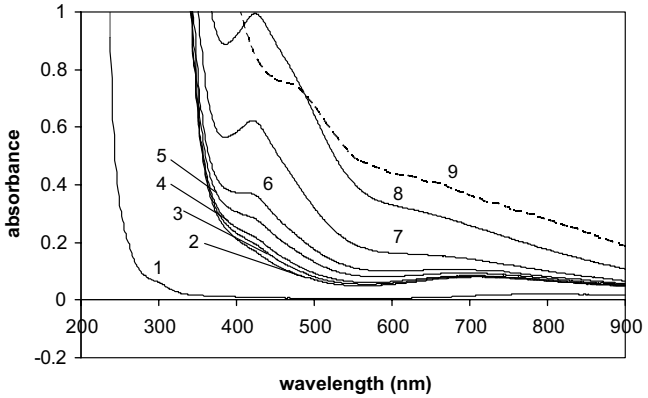

Fig. 4. Absorption spectra in a solution containing $Cu(NO_3)_2$ and ligand **2** at a 1:4 molar ratio (starting from the aquo-ion; curve 1). Solv. 10% v/v 1,4-dioxane–water $C_{Cu} = 1.25 \times 10^{-3}$ mol dm^{-3}. Curves 2–9 denote the spectra scanned after adding a consecutive portion of acid. pH: 2 – 4.07; 3 – 4.32; 4 – 4.68; 5 – 5.26; 6 – 6.92; 7 – 7.94; 8 – 8.63. Curve 9 – precipitation.

the blue shift of the much weaker d–d band near 430 nm – the shift is slightly towards longer wavelengths.

5. Conclusions

In this paper, we have shown a simple and convenient route for the synthesis of new chelating ligands and their copper(II) complexes. The newly synthesized ligands **2** and **3** create neutral complexes of the general type $MLCl_2$. The molecular structure of ligand **2**, which crystallizes as a monohydrate, has been confirmed by X-ray analysis. The crystal packing of **2** consists of two-dimensional layers generated by hydrogen bonds. Between these layers weak C–H···O contacts are observed.

The complexing properties of **2** with Cu(II) in solution could be related to the phenol 2-hydroxy group. In alkali medium, the ionization of this group, introducing an additional negative charge, enhances the donor properties of the potential nitrogen functions (pyridine and Me-pyrazole) by an inductive effect. As a result the refinements confirm the presence of three consecutive complexes (ML, ML_2 and ML_3) where the chelate rings use up to all six coordination sites. On contrary, in more acidic medium (pH 4–6) only one of the potential coordination modes was accepted: the ML_2H_2 species with undissociated OH.

The lack of inductive effects in the case of **3** leads to a very weak interaction with the metal in solution, which in connection with the low first hydrolysis constant of $Cu(II)_{aq.}$ (as follows from Table 6: $\log K_{OH} = -\log \beta_{10-1} = 7.22$) results in precipitation at relatively low pH.

Studies on the biological activity (cytotoxicity) of the synthesized compounds are in progress.

6. Supplementary material

CCDC 621681 contains the supplementary crystallographic data for the compound referred in this paper. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: +(44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

(I) H_2L

(II) = 5-phenyl,1,3,4-oxadiazole-2-thiol (pot)

2. Experimental

2.1. Synthesis

Commercial reagents were used without purification and all experiments were carried out in open atmosphere. Addition of carbondisulfide to benzoic acid hydrazide using the literature procedure [15] afforded *N*-benzoyldithiocarbazate (H_2L) in reasonably good yield. The transition metal complexes were obtained as a precipitate by reacting H_2L with the respective metal acetate in a 1:2 molar ratio. These were isolated and suspended in $CHCl_3$–MeOH mixture to which an excess of en was added. The mixture was refluxed at 60 °C for 30 min, until total dissolution of complex or permanent colour change was observed. The resulting clear solution of **1** was filtered off. On keeping this solution of the Cu(II) complex for 3–4 days, purple crystals of **1** suitable for an X-ray crystallographic study were obtained. Other complexes were obtained as precipitates which were filtered off, washed with ethanol and finally dried *in vacuo*.

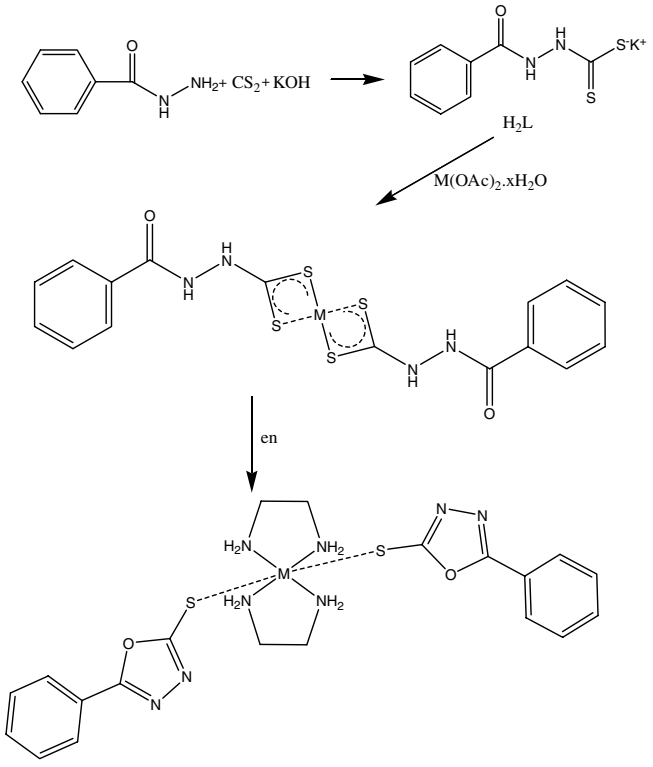
2.2. Physical measurements

The complexes were analyzed for their metal content, after decomposition with a mixture of conc. HNO_3 and HCl, followed by conc. H_2SO_4. Carbon, hydrogen and nitrogen contents were estimated on a Carlo Erba 1108 model microanalyser. Magnetic susceptibility measurements were performed at room temperature on a Cahn Faraday balance using $Hg[Co(NCS)_4]$ as the calibrant. Electronic spectra were recorded on a CARY 100 Varian EL01055314 UV–Vis spectrophotometer in MeOH, DMF or DMSO. IR spectra were recorded in the 4000–400 cm^{-1} region as KBr pellets on a JASCO FT-IR-5300 spectrophotometer. ^1H and ^{13}C NMR spectra were recorded in DMSO-d_6 on a JEOL AL300 FT NMR spectrometer using TMS as an internal reference.

3. Crystal structure determination

Data for the structure were collected on a Bruker three-circle diffractometer equipped with a SMART 6000 CCD detector and with a mirror-system-monochromated Cu Kα source. Intensity measurements were performed on a rapidly cooled crystal. The structure was solved by direct methods (SHELXS-97) and refined against all data by full-matrix least-squares on F^2 using anisotropic displacement parameters (Table 1) for all non-hydrogen atoms. All hydrogen atoms were included in the refinement at geometrically ideal positions and refined with a riding model [16,17]. The DIAMOND [18] and MERCURY [19] packages were used for molecular graphics.



4. Results and discussion

The potassium salt of *N*-benzoyldithiocarbazate (H_2L) generates 5-phenyl,1,3,4-oxadiazole-2-thiol(pot^-) in an alkaline medium by an internal ring closure reaction *via* desulfurization [20]. In view of this, the work described here is quite unusual and interesting because the above reaction has been found to take place with the complexes of H_2L in the presence of an excess en. Compounds **1–4**

Table 1
Crystal refinement parameters of $[Cu(en)_2](pot)_2$

Formula	$C_{20}H_{26}CuN_8O_2S_2$
F_w	538.15
Crystal system	triclinic
Space group	$P\bar{1}$

	$-13 \leqslant l \leqslant 14$
Number of reflections collected	5762
Number of indent reflections (R_{int})	1606
Number of data/restraints/parameters	1606/6/167
Goodness-of-fit on F^2	1.101
R_1[a], wR_2[b] ($I > 2\sigma(I)$)	0.0213, 0.550
R_1[a], wR_2[b] (all data)	0.0220, 0.0556
Largest difference in peak/hole (e Å^{-3})	0.179 and −0.261

[a] $R_1 = \sum \|F_o| - |F_c\| / \sum |F_o|$.
[b] $R_2 = [\sum w(|F_o^2| - |F_c^2|)^2 / \sum w|F_o^2|^2]^{1/2}$.

Scheme 1.

were obtained by refluxing $[M(HL)_2]$ with an excess of ethylenediamine in chloroform–methanol medium. The elemental analyses and physical measurements indicated towards very surprising results, where signals due to hydrazinic C(O)NHNHC(S) protons were found to be absent and one sulfur atom was missing. These observations suggest that H_2L underwent cyclisation to give 1,3,4-oxadizole derivatives. The preparation of complexes **1–4** is depicted in Scheme 1.

The infrared spectra of the complexes have been interpreted in the light of earlier investigations. The absorptions in the region of 3300–3200 cm^{-1} are due to the N–H stretching vibrations of en which are shifted to lower frequency than those encountered in the free en [21]. These shifts and the appearance of a new band near 490(±30) cm^{-1} suggest formation of a chelate. On the other hand, IR spectra of the complexes are observed to be devoid of any peak due to ν(NH) hydrazine (3108 cm^{-1}), which was present in metal–ligand precursor complexes. Additionally, ν(C=O) (1665 cm^{-1}), ν(C=S) (1145 cm^{-1}) and ν(C–S) (940 cm^{-1}) disappeared and new peaks appeared in the region of 1610–1590 (due to the endocyclic C=N bond), 1280–1260 (C–O–C) and 855–840 (C–S) cm^{-1} suggesing cyclisation of the acyclic dithiocarbazate moiety. The IR data are thus consistent with the presence of a 1,3,4-oxadiazole moiety in the compounds [10].

In addition to the IR spectral measurement, magnetic moments and electronic spectral data were used to determine the geometry of the isolated solid complexes. $[Cu(en)_2](pot)_2$ shows a magnetic moment of 1.74 BM, which corresponds to the presence of one unpaired electron. The presence of a broad band around 16130 cm^{-1} assigned to the envelope of $^2B_{1g} \rightarrow {}^2A_{1g}$, $^2B_{2g}$, ^2E_g transitions suggest a square planar geometry for the molecule. $[Mn(en)_2(pot)_2]$ exhibits a magnetic moment of 5.90 BM showing the presence of five unpaired electrons and the band at 19530 cm^{-1} due to the $^6A_{1g} \rightarrow T_{1g}$ transition suggests a high-spin octahedral geometry for the complex. $[Ni(en)_2(pot)_2]$ exhibits a magnetic moment of 2.9 BM and shows two bands at 15040 and 22320 cm^{-1}, which are considered to arise from the $^3A_{2g} \rightarrow {}^3T_{1g}$ (F) (ν_2) and $^3T_{1g}$ (P) (ν_3) transitions, respectively, in the distorted octahedral geometry around nickel(II). The high energy band at 28570 cm^{-1} in the ligand and in the region of 23260–30770 cm^{-1} in the diamagnetic complexes may be due to intraligand and/or charge transfer transitions [23].

The ^{1}H and ^{13}C NMR spectra of $[Zn(en)(pot)_2]$ in DMSO-d_6 were interpreted by comparing the spectra of 5-phenyl-1,3,4-oxadiazole-2-thione synthesized in the laboratory. The ^{1}H NMR spectrum of $[Zn(en)(pot)_2]$ shows a signal at 4.53 ppm due to NH_2 protons. The signals due to the phenyl ring protons, appearing at 7.83 ppm (m, 5 H) in the ligand, remain practically unchanged. The ^{13}C NMR spectral data of the compound was very informative. The peak due to the C9 carbon appears at 166.71 ppm as

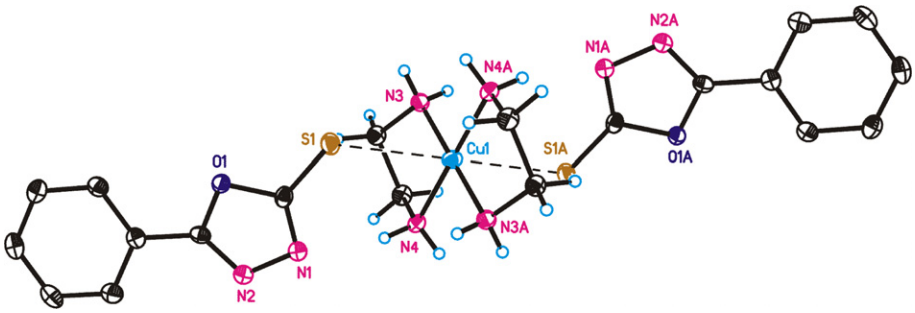

Fig. 1. Molecular structure of $[Cu(en)_2](pot)_2$ with the atom labelling, showing weak Cu···S interactions.

compared to 176.74 ppm in the oxadiazole, which suggests bonding through sulfur.

The X-ray crystal structure analysis of **1** shows that the Cu(II) compound has a composition, $[Cu(en)_2](pot)_2$ with an extended H-bonded structure (Fig. 1). The crystallographic asymmetric unit consists of the complex cation $[Cu(en)_2]^{2+}$ and the 1,3,4-oxadiazole thiol(pot^-) anions. The complex cation consists of two ethylenediamine molecules which chelate Cu(II) in equatorial positions and two 1,3,4-oxadiazole-2-thiol anions occupy apical positions. The Cu–N distances are in the range 2.01(15)–2.02(15) Å which is normal for Cu–N amine coordination. The bite angles for the CuN_4 five membered rings are 95.95(6)° and 85.05(6)°, indicating a substantial distortion in the molecule. Similar geometrical parameters for the coordination sphere have been reported for other diaquabis(ethylenediamine)Cu(II) salts [23,24]. In the complex under study Cu(II) resides in the plane formed by the nitrogen atoms of two en ligands arranged equitorially and the thiol S from two pot anions occupying the apical positions in a *trans* manner. Each $[Cu(en)_2]^{2+}$ forms a pair of weak intermolecular Cu···S bond interactions (3.02 Å). This distance is well within the distance of 3.2 Å for the sum of van der Waal radii of Cu and S [25]. The observed Cu···S distance suggests a comparatively strong interaction (Table 2). The propensity towards such an interaction is probably due to the tendency of Cu(II) to increase its coordination number.

The Cu atom in C_{2h} symmetry is bonded to four N atoms of two en molecules which offer interesting hydrogen bonding to the packing. The elements of the structure are joined to each other in the crystal packing (Figs. 2a, 2b and 3) by means of an extended system of H-bonds where the protons belonging to the NH_2 group are participating in the structure. The hydrogen bonding parameters are listed in Table 3. The N4 atom of the symmetrical half unit forms an intermolecular hydrogen bond with N1 of pot^- [N4–H4″···N1 2.17(2) Å], holding two pot anions on diagonally opposite ends. Whereas, N3–H3′ shows an interaction with N2 of the neighbouring anionic unit [N3–H3′···N2 2.19(18) Å]. Few other hydrogen bonding interactions viz N4–H4′···N1 2.36 (19) and C3–H3A···O1 2.53 Å help to propagate the bonded units along the *b* axis. Adjacent chains arrayed in a parallel mode are further linked by weak CH–π interactions to form a 2-dimensional planar network. In the solid state, the molecules are self-assembled *via* N–H···S and N–H···N intermolecular hydrogen bonding and π–π weak interactions (Figs. 2a, 2b and 3). Crystal packing in the complex $[Cu(en)_2](pot)_2$ is stabilised through C–H···π interactions and face to face π–π stacking (π–π distances = 3.666 Å) between ring centroids. The arrangement of $[Cu(en)_2]^{2+}$ at a dihedral angle of 49.43° to pot^- provides a network of intermingled chains that lead to a π–π stacked 3-dimensional framework.

In conclusion, to the best of our knowledge we report here for the first time metal-assisted transformation of N–benzoyldithiocarbazate to its 1,3,4-oxadiazole derivative in the presence of ethylenediamine, involving desulfurisation followed by cyclisation. This strategy offers an easy and facile route to complex the unstable 1,3,4-oxadiazole as its stable metal complexes. Moreover, we anticipate that this procedure would allow a rational synthetic protocol to biologically active molecules.

of the presence of metal–sulfur and metal–nitrogen bonds at the active sites of several oxidoreductases such as hydrogenase, xanthine-oxidase and nitrogenase [21,22] have stimulated interest in pyrimidine chemistry [23–28] with mixed sulfur and nitrogen donor atoms. Synthesis, characterization, structure and reactivity studies of such complexes with N, S and N, N, S donor ligands lead to valuable information toward understanding the functions of different enzymes at the molecular level [21]. Nucleic acids, vitamins and coenzymes containing the pyrimidine ring systems provide potential binding sites for metal ions. A variety of nitrogen and sulfur donors have been investigated involving both five and six membered heterocyclic thiosemicarbazones and dithiocarbazates [29–33]. Most of such studies have largely been concentrated on various pyridine-derived ligands [34–36]. However, the higher π-acidity and presence of more than one hetero atom in pyrimidine play an important role in its coordination chemistry compared to that of pyridine bases and serve as better models in biological systems [37–40]. Comparatively less research has centered on the transition metal chemistry with the Schiff base ligands having pyrimidine as the heterocyclic part. This has inspired us to explore the chemistry of pyrimidine based dithiocarbazate ligands with different metal ions. We report here for the first time, the syntheses and ligational behaviour of two pyrimidine derived dithiocarbazate ligands HL_1 and HL_2 towards Ni(II), Co(III) and Fe(III) metal ions. The crystal and molecular structures, magnetism and electronic spectra of $[Ni(HL_1)(L_1)]ClO_4$, $[Co(L_2)_2]ClO_4$ and $[Fe(L_2)_2]ClO_4$ complexes have been investigated.

2. Experimental

2.1. Materials

Ethyldiethoxyacetate and d_6-DMSO were purchased from Aldrich Chemical Company, USA and were used as received. All other solvents and reagents were obtained from commercial sources and purified by standard procedures [41]. *S*-Methyl dithiocarbazate was synthesized following the literature method [42]. *S*-Benzyl dithiocarbazate was prepared by an analogous method using benzyl chloride instead of methyl iodide. 2-*S*-Methylmercapto-6-methylpyrimidine-4-carbaldehyde was synthesized following the established method [43].

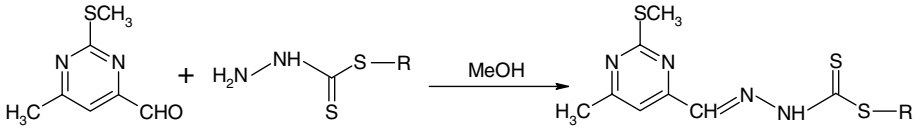
Caution! Although we have not encountered any problems, it should be kept in mind that perchlorate compounds of metal ions are potentially explosive especially in the presence of organic ligands. Only a small amount of the material should be prepared and it should be handled with care.

2.2. Physical measurement

Elemental analyses (carbon, hydrogen, nitrogen and sulfur) of the ligands HL_1 and HL_2 and the metal complexes were determined with a Perkin–Elmer CHNS/O analyzer 2400 at the Indian Association for the Cultivation of Science, Kolkata. The molar conductance values of the complexes were measured in purified CH_3OH solution with a Systronic model 304 digital conductivity meter. The electronic spectra of the complexes in purified CH_3OH solution and the diffuse reflectance spectra of the complexes were recorded on a Hitachi model U-3501 spectrophotometer. IR spectra (KBr pellet, 4000–400 cm^{-1}) were recorded on a Perkin–Elmer model 883 infrared spectrophotometer. ^1H NMR spectra of the ligands were recorded in d_6-DMSO with a Bruker AM 300L (300 MHz) superconducting FTNMR. Mass spectra of the ligands were done at the Indian Institute for Chemical Biology, Kolkata with a JEOLJMS-AX 500 mass spectrometer. Room temperature magnetic susceptibilities were measured with a PAR 155 vibrating sample magnetometer.

2.3. Preparation and characterization of the ligands

2-*S*-Methylmercapto-6-methylpyrimidine-4-carbaldehyde was condensed with the respective dithiocarbazate in a 1:1 molar ratio (Scheme 1). Details are described below.



The two ligands HL_1 and HL_2 were synthesized in a similar way by refluxing a methanolic solution (10 cm^3) of 2-*S*-methylmercapto-6-methylpyrimidine-4-carbaldehyde (0.168 g, 1 mmol) with *S*-methyl dithiocarbazate (0.122 g, 1 mmol) and *S*-benzyl dithiocarbazate (0.198 g, 1 mmol) respectively, also taken in methanol (10 cm^3). Reflux was continued for ca. 2 h at water bath temperature during which a solid microcrystalline compound separated. It was filtered off, washed several times with cold methanol and dried in vacuo over fused $CaCl_2$. Single crystals of HL_2, suitable for X-ray diffraction were obtained by slow evaporation of a methanolic solution of the ligand.

HL_1: pale yellow; yield, 0.217 g (80%); m.p. (°C) 186, *m*/*z* 272 (M^+, 100%). *Anal.* Calc. for $C_9H_{12}N_4S_3$: C, 39.70; H, 4.41; N, 20.58; S, 35.29. Found: C, 39.83; H, 4.72; N, 20.52; S, 35.23%.

HL_2: yellow; yield, 0.278 g (80%); m.p. (°C) 175, *m*/*z* 348 (M^+, 100%). *Anal.* Calc. for $C_{15}H_{16}N_4S_3$: C, 51.72; H, 4.59; N, 16.09; S, 27.05. Found: C, 51.84; H, 4.89; N, 16.01; S, 27.51%.

The elemental analyses (C, H, N and S) and IR spectral data [characteristic bands (cm^{-1})] at 2940 (ν_{NH}); 1511 ($\nu_{CH=N}$); 1570 ($\nu_{C=Npym}$); 774 ($\nu_{C=S}$) in HL_1 and 2945 (ν_{NH}); 1523 ($\nu_{CH=N}$); 1570 ($\nu_{C=Npym}$); 776 ($\nu_{C=S}$) in HL_2 are in good agreement with the structure in Scheme 1. The absence of any band in the 2600–2200 cm^{-1} region of the IR spectra of the free ligands suggest that the ligands exist in the thione form in the solid state. In solution spectra, the ligands exhibit intraligand CT bands at ca. 380 nm, ca. 370 nm and ca. 355 nm.

The ^1H NMR spectra (δ_H ppm) in d_6-DMSO at 300 MHz of the ligands HL_1 and HL_2 give a singlet at δ 2.50(3H) for HL_1 and at δ 2.44(3H) for HL_2, which are assignable to C_2–SCH_3 (ring pym). Similarly singlets at δ

HL_1 ; R = -CH_3

HL_2 ; R = -$CH_2C_6H_5$

Scheme 1.

2.52(3H) HL_1 and at δ 2.49(3H) for HL_2 are due to C_6–CH_3 (ring pym). The C_5–H (ring pym) appears as a singlet at δ 8.06 for HL_1 and HL_2. A singlet at δ 7.40 for HL_1 and a slightly broad singlet at δ 7.34 for HL_2 are ascribed to HC=N. The terminal S–CH_3 signal is observed as a singlet at δ 2.50 for HL_1. Similarly, a singlet at δ 4.51 for HL_2 is ascribed to S–CH_2–C_6H_5. A narrow split multiplet at δ 7.44, 7.32 and 7.29 for HL_2 are ascribed to the *o*-, *p*- and *m*- hydrogen atoms (benzene ring) respectively. Singlets at δ 13.63 for HL_1 and at δ 13.67 for HL_2 confirm the presence of thioimine NH in the two ligands.

2.4. Preparation of the complexes

2.4.1. $[Ni(L_1)(HL_1)]ClO_4$ (1)

A methanolic solution (5 cm^3) of $Ni(ClO_4)_2 \cdot 6H_2O$ (0.0915 g, 0.25 mmol) was added dropwise to a solution of HL_1 (0.136 g, 0.5 mmol) in the same solvent (15 cm^3) with constant stirring. The resulting light green solution was further stirred for ca. 15 min and then refluxed at water bath temperature for ca. 2 h. The solution was cooled to room temperature and filtered. The filtrate was kept for slow evaporation. After two days, X-ray quality crystals of **1** were isolated. Yield, 0.49 g (70%). *Anal.* Calc. for $C_{18}H_{23}ClN_8NiO_4S_6$ (**1**): C, 30.77; H, 3.27; N, 15.95; S, 27.35. Found: C, 30.95; H, 3.59; N, 15.97; S, 27.39%. IR: ν (cm^{-1}) 2923 (ν_{NH}); 1579 ($\nu_{C=Npym}$); 1500 ($\nu_{CH=N}$); 1313, 1271 ($\nu_{C=S}$); 1086 (ν_{N-N}); 762 [$\nu_{C=S(protonated)}$]; 714 [$\nu_{C=S(deprotonated)}$]. UV–Vis, λ_{max}: 451, 836 nm. DRS: 378, 454, 833 nm. λ_M (MeOH, $ohm^{-1}\,cm^2\,mol^{-1}$): 92. μ_{eff} (at 298 K): 2.96 B.M.

2.4.2. $[Co(L_2)_2]ClO_4$ (2)

$Co(ClO_4)_2 \cdot 6H_2O$ (0.061 g, 0.16 mmol) was dissolved in methanol (20 cm^3). Solid HL_2 (0.116 g, 0.33 mmol) was added to the above methanolic solution with constant stirring using a magnetic stirrer. The resulting pink coloured solution was stirred for an additional 15 min and was refluxed at water bath temperature for ca. 3 h. The solution was cooled to room temperature, filtered and the filtrate was kept for slow evaporation. After three days, single crystals, suitable for X-ray diffraction were separated. Yield, 0.17 g (60%). *Anal.* Calc. for $C_{30}H_{30}ClN_8CoO_4S_6$ (**2**): C, 42.18; H, 3.51; N, 13.12; S, 22.49. Found: C, 42.29; H, 3.57; N, 13.13; S, 22.51%. DRS: 412, 514, 741 nm. λ_M (MeOH, $ohm^{-1}\,cm^2\,mol^{-1}$): 86. μ_{eff} (at 298 K): 1.83 B.M.

2.5. Single crystal X-ray crystallography

Relevant crystallographic data are summarized in Table 1. The intensity data for complexes **1**, **2** and **3** were collected on a Bruker SMART 1K CCD diffractometer, using graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) in the ω–2θ scan mode at 103(2) K. Those of ligand HL_2 were collected on a Bruker SMART APEX CCD diffractometer, using graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) in the ω scan mode at 100(2) K. Accurate unit cell parameters and orientation matrices for data collection were obtained from least-squares refinement using the programs SMART and SAINT [44] and the data were corrected for absorption using SADABS [44]. All structures were solved using SHELXTL and the SHELX-97 packages of programs [44] i.e. SHELXS-97 for the solution of the structure and refined by full-matrix least-squares technique based on F^2 (SHELXL-97). Positions of H-atoms were treated as riding on their parent atoms with an isotropic thermal parameter varying as 1.2 or 1.5 times the U_{eq} of the parent atoms.

3. Results and discussion

3.1. Syntheses

Two new tridentate monoanionic ligands HL_1 and HL_2 both having an NNS donor atom set were synthesized by the 1:1 condensation reaction of the precursor 2-*S*-methylmercapto-6-methylpyrimidine-4-carbaldehyde with *S*-methyl/*S*-benzyl dithiocarbazates in purified methanol. Some complexation reactions of these ligands were investigated. All the complexes (**1**–**3**) of these ligands were obtained from

a refluxing mixture of the respective ligand and the corresponding hydrated metal salts, taken in a 2:1 molar proportion in methanol. X-ray quality crystals of these ligands were obtained upon slow evaporation of the respective reaction mixture at room temperature. All the three complexes were characterized by elemental analyses, solution electrical conductivity, magnetic susceptibility, IR, UV–Vis and ^{1}H NMR spectroscopy (for **2**). The results are consistent with the proposed mononuclear formulation. The complexes were found to be fairly soluble in most common organic solvents. Molar conductivities of all the three complexes are in accord with 1:1 electrolyte behavior.

3.2. Description of crystal structures

Perspective views of the ligand HL_2 and those of the complexes **1**, **2** and **3** with atom numbering schemes are shown in Figs. 1–4 respectively. Selected metrical parameters are listed in Table 2. The unit cell of HL_2 and **1** comprises of two molecules and those for **2** and **3** comprise of four molecules.

The ligand HL_2 crystallizes in the space group $P2_1$. It is non-centrosymmetric and the absolute structure parameter for HL_2 is 0.09(9). The structure of HL_2 (Fig. 1) shows that the pyrimidyl nitrogen atom N(1a), azomethine nitrogen atom N(2a) and the thione sulfur atom S(1a) are *trans* oriented to each other. Upon chelation of the ligand, the above donor atoms are arranged in a *cis*-fashion toward the metal center. The *cis* conformation of the ligand is necessary for its participation as a tridentate NNS chelate ligand. The

Here M stands for the corresponding metal ion.

C(8)–S(1) [a and b] bond distances [except S(1a)–C(8a) in **1**] in **1**, **2** and **3** appear to be longer (Table 2) than those reported for free thiosemicarbazones, such as 1.678(2) Å in 4-formylpyridinethiosemicarbazone [45] and 1.684(4) Å in 2-keto-3-ethoxybutyraldehyde-bis(thiosemicarbazone) [46]. In all the complexes the C(8)–N(4) and C(7)–N(2) [b only in **1** and a, b for **2**, **3**] bond distances show partial double bond character due to delocalization of π-electrons throughout the whole molecule [47] [except in the ligand moiety 'a' in **1**] where the ligand molecules exist in the deprotonated thiol form. However, in **1**, the C(8a)–N(4a) bond distance, being comparable to that in HL_2 and also being longer than the corresponding C(8b)–N(4b) bond (Table 2), suggests that the ligand moiety 'a' utilizes its thione sulfur in its 'thione' form for coordination where C(8a)–N(4a) is perfectly of double bond character. Likewise, the double bond character in C(7a)–N(2a) is quite obvious from the comparison of this length with that in the free ligand (Table 2).

The ligand HL_2 is stabilized through a network of hydrogen bonding (Fig. 5). It shows that there is a weak H-bond interaction through the H(4b) and N(1a) atoms between the two parallel lying HL_2 molecules. This results in formation of an infinite 2D straight chain throughout the crystal. The geometrical details of the hydrogen bonds are given in Table 3.

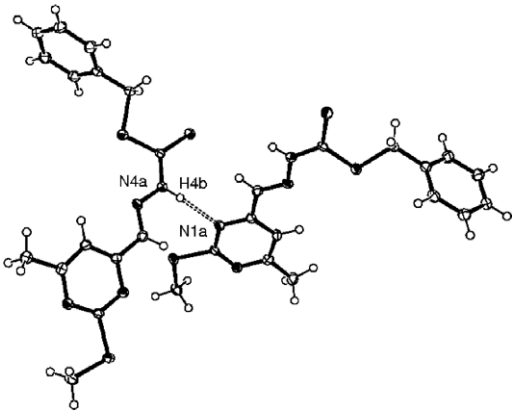

Fig. 5. Intermolecular H-bonding in HL_2 shown as a dotted line (50% thermal ellipsoids).

The complex **1** contains a $[Ni(L_1)(HL_1)]^+$ cation and a ClO_4^- anion, while complexes **2** and **3** contain $[M(L_2)_2]^+$ cations and ClO_4^- anions (M = Co for **2** and Fe for **3**). It is interesting to note that in **1**, one ligand molecule acts as a uninegative one and the other acts as a neutral molecule, whereas in **2** and **3**, each ligand molecule acts as a uninegative tridentate. In the structures of **1**, **2** and **3** the sulfur and pyrimidyl nitrogen atoms are positioned *cis* to each other while the azomethine nitrogen atoms are *trans* oriented to each other i.e. the ligands coordinate the metal in a meridional fashion. The meridional configuration of the NNS tridentate thiosemicarbazone ligands around the metal ion have been found in other similar bis-ligated metal chelates [48,49]. The coordination polyhedron around the metal centers is best described as a distorted octahedral geometry with an N_4S_2 chromophore. The equatorial positions are occupied by the two pyrimidyl nitrogen atoms [N(1a) and N(1b)] and the two thiolato sulfur atoms [S(1a) and S(1b)] (in **1**, one is thiolato sulfur and other is thione sulfur). In all the complexes, the atoms defining the equatorial plane lie 0.453, 0.425, −0.486 and −0.391 Å in **1**; 0.266, 0.237, −0.262 and −0.242 Å in **2** and 0.327, 0.284, −0.333 and −0.279 Å in **3**, respectively, out of the least-squares plane through them. The axial positions are occupied by the two remaining azomethine nitrogen atoms [N(2a) and N(2b)] which is evident from the N(2a)–Ni–N(2b) angles (173.32° in **1**, 168.62° in **2** and 168.11° in **3**).

The equatorial M–S bond distances in **2** and **3** are nearly same, ranging from 2.212 to 2.229 Å, but for **1** [Ni–S(1a) 2.467 Å. Ni–S(1b) 2.383 Å], they show a significant variation because of the different coordination modes of the S atoms in the two ligand molecules toward the Ni center. The axial M–N bond in **1** is significantly larger (average distance 2.021 Å) than that in **2** (average distance 1.899 Å) and **3** (average distance 1.918 Å). These values compare well with those of other six-coordinate Ni(II) complexes of related NNS ligands [50,51]. The N–M–N, N–M–S and S–M–S angular distributions indicate that the coordination polyhedron is distorted in each complex. This distortion of the metal ion coordinated polyhedron results from the steric interactions and asymmetric nature of the ligand molecules (HL_1 and HL_2). The maximum distortions from the ideal octahedral geometry occur for N(1a)–Ni–N(2a) (76.06°), N(2a)–Ni–S(1a) (80.57°) and N(2a)–Ni–N(1b) (108.55°) angles in **1**; N(1a)–Co–N(2a) (81.45°) and N(2a)–Co–N(1b) (107.22°) angles in **2** and N(1a)–Fe–N(2a) (79.82°) and N(2a)–Fe–N(1b) (108.53°) angles in **3**. Similar distortions have been reported previously in the literature [52]. Encapsulation of the metal ions by the coordination of six donor atoms results in the formation of four five membered chelate rings [M, N(1), C(6), C(7), N(2) (Ia,Ib)]; [M, N(2), N(4), C(8), S(1) (IIa, IIb)] in **1**, **2** and **3**, where M stands for the corresponding metal ion. The analysis of torsion angles Table 4 and a puckering analysis [53] Table 5 of the five membered chelate rings reveals that they are basically planar with none of the weighted average torsion angles being larger than 12.69° [for the ring Ni–N(1a)–C(6a)–C(7a)–N(2a)]. For each of the complexes, each set of two chelate rings have weighted average torsion angles above 5°. The maximum puckering amplitude, again measured for Ni–N(1a)–C(6a)–C(7a)–N(2a), is 0.195(2) Å. In both ligands HL_1 and HL_2, the chelate rings and the pyrimidine ring lie nearly in the same plane and the angles between the planes are 6.64(10)° and 87.83(9)° for **1**, 7.53(6)° and 5.77(6)° for **2**, and 6.03(13)° and 8.63(13)° for **3**. The pyrimidine ring thus makes an extended coplanar system with the two chelate rings. These extended coplanar ring systems of the two ligands approach each other orthogonally. This is evident from the analysis of their bond angles Table 2.

In **1**, a weak hydrogen bond interaction involving the perchlorate oxygen O(4) atom and hydrogen H(4ad) of

the thioimine nitrogen atom is present (Fig. 2) . The details of hydrogen bonding parameters are presented in Table 3.

4. Characterization of the complex species

All the three complexes gave satisfactory C, H, N and S analyses. Spectral properties of these complexes are described below in details.

4.1. IR spectra of the complexes

A comparative study of the IR spectral data of the reported complexes with those of the uncomplexed ligand gives meaningful information regarding bonding sites of the ligand molecules. All the Schiff bases contain a proton adjacent to the thiocarbonyl group and consequently can exhibit thione–thiol tautomerism. The IR spectra of the ligands, however, display no band at ca. 2600 cm^{-1} corresponding to ν_{S-H} [54], indicating that the ligands remain as a thione tautomer. The ligand (HL_2) when dissolved in methanol in the presence of Co(II) salts quickly converts to the corresponding 'thiol' form with the concomitant formation of cobalt(III) complexes of the deprotonated mercaptide form of the ligand. Thus oxidation to Co(III) occurs during preparation of the complex. Although the mechanism of this oxidation is not proven we can safely assume that the starting cobalt(II) salt presumably undergoes aerial oxidation in presence of the ligand in methanolic solution.

Some characteristic and recognizable spectral changes have been noticed in the IR spectra of the complexes as compared to that of the free ligands and the data can be successfully utilized for an additional support of the bonding mode. A red shift of $\nu_{(C=N)}$ from 1511 cm^{-1} (in HL_1) and 1523 cm^{-1} (in HL_2) to 1500 cm^{-1} (in **1** and **3**), 1510 cm^{-1} (in **2**) is consistent with coordination of the azomethine nitrogen [55]. The presence of a band at ca. 550 cm^{-1} is also assignable to $\nu_{(M-N)}$. A blue shift of $\nu_{(C=Npym)}$ from 1570 cm^{-1} in the uncomplexed ligand towards 1580 cm^{-1} in all the complexes is also consistent with coordination of the pyrimidine nitrogen [55]. For all the complexes, the thioamide band at ca. 775 cm^{-1} in the free ligand due to $\nu_{(C=S)}$ undergoes a red-shift by ca. 50–60 cm^{-1}, pointing to the sulfur atom of thiol as a possible coordination site [55]. The additional peak at 762 cm^{-1} in **1** indicates the protonated 'thione' sulfur as a possible coordination site from one ligand molecule.

4.2. UV–Vis and DRS of the complexes

The diffuse reflectance spectra of **1** is characterized by three main bands at 833, 454 and 378 nm which may be assigned as $^3A_{2g}$ (F) → $^3T_{2g}$ (F) (ν_1), $^3A_{2g}$ (F) → $^3T_{1g}$ (F) (ν_2) and $^3A_{2g}$ (F) → $^3T_{1g}$ (P) (ν_3) transitions respectively in an Oh symmetry. The calculated value of the ligand field parameters Dq = 1200 cm^{-1}, $B = 831$ and $\beta = 0.78$ furnish reasonable support for the octahedral geometry from a

comparison with similar N_4S_2 chromophores [48]. The electronic spectral data of the above nickel(II) complex in methanol indicate no gross deviation in electronic or geometric environment on dissolution in the same solvent. The solution spectrum is also characterized by two bands in the same region as in the solid state. The third band may be obscured by the intense LMCT band. The complex shows an intense band at 355 nm. This is an intraligand CT band as obvious from the UV-spectrum of the corresponding ligand.

The DRS of **2** exhibits a broad band at ca. 433 nm with two distinct shoulders at the low energy side (at ca. 483 and ca. 685 nm). The broad band is due to the S → Co(III) charge transfer transition as is also evident from the solution spectral study. The other two bands may be assigned as $^1A_{1g} \rightarrow {}^1T_{1g}$ and $^1A_{1g} \rightarrow {}^3T_{2g}$ transitions, respectively [56]. In methanolic solution, it displays a S → Co(III) charge transfer transition (LMCT) at 411 nm with one d–d band at 711 nm. The intense band at ca. 350 nm is due to the intraligand CT band.

The DRS of **3** shows a band at 412 nm which may be due to a S → Fe(III) transition. Two other bands at 514 and 741 nm are assigned as d–d transitions for the spin paired d^5 iron(III) ions [57]. The methanolic solution exhibits one strong absorption band at 351 nm with a shoulder at 403 nm. This band is assigned to a LMCT transition. Two comparatively low intense bands at 607 and 701 nm are due to d–d transitions [58]. Likewise to **2**, the intense band at 351 nm is assigned as the intraligand CT band.

4.3. ^1H NMR spectrum of 2

Table 6 gives a listing of the ^1H NMR assignments of the cobalt complex as compared with those of the corresponding free ligand. The peak at ca. δ 13.67 ppm due to the azomethine NH in the free ligand disappears after complexation. This indicates that during complexation the ligand in its thiol form undergoes deprotonation followed by coordination to the Co(III) ion through the thiolato sulfur atom. The S–CH_2 peak at δ 4.51 ppm, showing a slight downfield (δ 4.61 ppm) shift, is ascribed to coordination of the thiol sulfur. An upfield shift occurs with the C_5–H (ring pym) proton, appearing at δ 7.35 ppm in the complex compared to δ 8.06 ppm in the uncomplexed ligand. This is due to coordination of the pyrimidine nitrogen atom to the central Co(III) ion. The ^1H NMR spectrum also gives an additional support for the bonding characteristics of the ligands in forming complexes with Co(III) through the pyrimidine ring nitrogen (tertiary), azomethine nitrogen and thiolato sulfur atoms.

Table 6
^1H NMR spectral data (d_6-DMSO, δ in ppm) of HL_2 and the cobalt(III) complex relative to TMS

Compound	NH	C_5–*H* (ring)	C_6–CH_3 (ring)	Azomethine *CH*	Pyrimidine S–CH_3	Terminal S–CH_2–C_5H_5
HL_2	13.67	8.06	2.49	7.34	2.44	4.51
2		7.35	2.51	7.61	2.45	4.61

5. Conclusion

We have prepared a Ni(II) complex of HL_1 and Co(III), Fe(III) complexes of HL_2 where HL_1 and HL_2 are similar pyrimidine derived Schiff base ligands. In case of the Ni-complex, one ligand molecule in its deprotonated thiol form functions as a mononegative tridentate and another ligand in its thione form acts as neutral tridentate, whereas for the Co(III) and Fe(III) complexes, each of the ligand molecules in its deprotonated thiol form functions as a uninegative tridentate.

Scheme 1. Limiting condition of paddle-wheel structure going to mononuclear structure.

we pursued reactions of cadmium(II)acetate with aromatic carboxylic acids followed by reaction with nitrogen donor ligands such as 3,5-dimethylpyrazoles or pyridine and the results are presented in this article.

2. Experimental

The X-ray diffraction data were collected at room temperature [296(2) K] on a Bruker 3-circle diffractometer (Bruker Nonius SMART APEX 2) equipped with CCD area detectors, and using graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) from 60W microfocus Siemens Microsource with glass polycapillary optics. X-ray diffraction data for all the crystals were collected using Bruker SMART software. This software was also used for indexing and determining unit cell parameters. The structures were solved by direct methods and refined by full-matrix least squares against F^2 for all data using SHELXTL software. All non-H atoms were refined by full-matrix least squares in the anisotropic approximation and the hydrogen atoms attached to these atoms the hydrogen atoms have been located on the difference Fourier maps. In all cases the hydrogen atoms attached to polar atoms such as O and N were located on the difference Fourier maps and refined in the final structure in isotropic approximation. Experimental absorption correction method is none in all cases. The crystal data are given in Table 1. The proton NMR spectra were recorded in a Varian 400 MHz spectrophotometer at room temperature while the FT-IR spectra were recorded in NICOLET IMPACT-410 spectrometer using OMNIC software.

3. Experimental procedure for preparation of the complexes 1–9

To a well-stirred solution of benzoic acid/substituted benzoic acid (2 mmol) in methanol (10 ml) a solution of cadmium acetate dihydrate (0.266 g, 1 mmol) in methanol (5 ml) was added. The resulting homogeneous solution was stirred at room temperature for 4 h. To this homogeneous solution 3,5-dimethylpyrazole (2 mmol) or pyridine (2 mmol) was added and the colorless mixture was further stirred for 2 h. The solution was filtered and the filtrate on standing led to crystallization of the product.

4. Crystalline yield and spectroscopic data of the compounds

Complex **1**: Crystalline yield 61%, ^{1}H NMR (DMSO-d_6) 7.98–7.96(m, 2H), 7.47–7.39(m, 3H), 5.76(s 1H), 2.13 (s, 6H). 5. Results and discussion

The reaction of cadmium acetate with aromatic carboxylic acid followed by treatment with 3,5-dimethylpyrazole (L_a) led to mixed ligand cadmium complexes. The number of (L_a) ligand/s in cadmium carboxylate complexes varies with the aromatic carboxylic acid from which it is

prepared. Either two nitrogen donor ligands or one nitrogen donor ligand per cadmium ion are observed depending on the substituents present in the aromatic carboxylate. For example, the reaction of cadmium acetate dihydrate with aromatic carboxylic acids such as benzoic acid, 2-chlorobenzoic acid, 2-hydroxybenzoic acid or 4-hydroxybenzoic acid in the presence of (L_a) led to the formation of corresponding benzoate complexes having two benzoate groups and two (L_a) ligands. The 2-nitro-, 4-nitro-, 4-chloro-benzoic acids and 1-naphthoic acid led to complex having one (L_a) and two carboxylate ligands per cadmium. However, the 2-nitrobenzoate complex of cadmium contains an additional aqua ligand; which is absent in the case of 4-nitrobenzoate complex. The results are depicted Scheme 2.

The crystal structure of each of these complexes is determined and the structures of the complexes **1**–**4** are shown in Fig. 1. Trigonal prismatic geometry with six co-ordination around cadmium ions are observed in the cases of the complexes **1**–**4**. The bond angles and bond distances of the complexes are listed in Table 2 and structures of the complexes are shown in Fig. 1. It may be mentioned that in the case of **1** two types of cadmium ligand bonds in terms of bond length are observed. There are four cadmium–ligand bonds of similar length and two other are slightly longer. It has been already reported [3a] that in cadmium complexes outer and inner co-ordination spheres are possible and the outer Cd–N bond lengths are in the range of 2.5–2.7 Å whereas inner ones are less by about 0.3 Å from the outer ones. In our system also the bond distances of the four Cd–N and Cd–O bonds are comparable and makes a pseudo tetrahedral inner structure comprising of Cd–O3, Cd–O4, Cd–N1 and Cd–N4 bonds. The other two Cd–O1 and

Cd–O4 bonds have bond length 2.561 and 2.480 Å and with bond angles O1–Cd–O4 137.62°, respectively. This suggests that under suitable condition these two atoms would serve as bridging group if another metal atom can approach. However, in this case presence of two 3,5-dimethylpyrazole ligands prevents further approach oxygen to the cadmium ion to form co-ordination polymer. The 2-chlorobenzoate complex **2** has a more symmetric trigonal prismatic structure. Both the compounds **1** and **2** have similar hydrogen bonding interactions and they remain as hydrogen bonded self-assemblies. In these two complexes the N–H bond of 3,5-dimethylpyrazole interacts with the carbonyl group of co-ordinated carboxylate ligand of another molecule to form self-assemblies. Such assemblies are further held by C23–H···O2 interaction between C–H of a methyl group with an oxygen atom of carboxylate group of another molecule (Fig. 1a). The important bond angles and distances for compound **1** are listed in Table 2. Cadmium complex of 4-amino-carboxylic acid adopts two dimensional polymeric hydrogen bonded structure [7]. The structure of the complexes **3** and **4** are shown in Fig. 1c and e respectively. Both these complexes have six co-ordinations with distorted trigonal prismatic geometry and in the solid state they form H-bonded self-assembly. The complex **3** has a one dimensional layer structure held by N–H···O interactions between the N–H of 3,5-dimethylpyrazole un-coordinated nitrogen atoms with carbonyl oxygen of 2-hydroxybenzoate. There is also intra-molecular hydrogen bonding (O6–H···O2) between the hydroxy groups with the carbonyl oxygen of the benzoate (Table 3). In the 4-hydroxybenzoate complex **4**, hydrogen bonding between hydroxy groups and the carbonyl oxygen of another molecule adjacent to it takes place. In addition to this, the opposite side of the molecule is associated with N–H···O interactions with another neighboring molecule as illustrated in Fig. 3f. These interactions result in the formation of three-dimensional hydrogen bonded network. It is already reported that the picolinic acid forms six-coordinated polymeric network. Our results also support that N1O5 environment around cadmium [1n,2] can lead to co-ordination polymer in one-dimension.

The nitro-substituent on the aromatic carboxylic acid affects the structure as well as the co-ordination environment of cadmium complexes. The complex **5** has an aqua-ligand and it is a tetra nuclear complex as shown in Fig. 2a. The formation of such tetra nuclear complex is attributed to the variation in composition due to the steric effect of nitro-group at *ortho*-position leading to a thermodynamically stable product. The complex **5** has eight co-ordination around two central cadmium ion and the other two cadmium ions at both the ends of the tetra nuclear complex have six co-ordination geometry. Polymeric cadmium complexes having seven co-ordination is common in co-ordination chemistry of cadmium [1a], however the complex **5** is a rare example of tetra nuclear complex having eight co-ordination. It is interesting to note that each of the tetra nuclear complex possesses aqua-ligand at the end cadmium atoms; each and these aqua ligands interacts with

the carbonyl group of another tetra-nuclear complex making an one dimensional self-assembled polymeric structure. Some of the important hydrogen bonding interactions present in the hydrogen bonded assembly is listed in Table 4. This structure is also important from another point of view is that it is an exception to the structure that is observed as mononuclear complex from 2-chlorobenzoic acid and 2-hydroxybenzoic acid which are *ortho*-substituted aromatic carboxylates. However, it is observed that the solid phases reaction of 2-nitrobenzoic acid with cadmium acetate with (L_a) results in the formation of mononuclear hexa-coordinated species namely tetra (3,5-dimethylpyrazole) cadmium(II) (2-nitrobenzoate). In the case of solid phase reaction we did not observe tetra nuclear species rather observed a mononuclear species; this suggests that tetra nuclear species may be a kinetic control product. In fact tetra-nuclear complex on heating transforms to mononuclear hexa-coordinated complex.

The complex **6** has a polymeric structure with the carboxylate oxygen atoms as bridging atoms to the cadmium ions. The structure of the complex **6** is shown in Fig. 3a. The 4-nitrobenzoate complex **6** does not have aqua ligand as compared to that of **5**. Thus, it may be said that the position of water molecule is occupied up by bridging oxygen atom of a carboxylate group leading to co-ordination polymer. In the one-dimensional polymer all the cadmium are in seven co-ordination environment. The metal–ligand bond geometries are listed in Table 5. Similar structures are obtained in the case of 4-chlorobenzoate complex **7** as well as in the 1-naphthoate complex **8**. Important bond distances are listed in Table 5. In these two cases the metal–ligand composition of the complex is identical to that of **6**. A similar reason may be put forward in these cases for explaining polymer formation. The attack of one nitrogen donor ligand is favored in these three complexes due to steric reasons and this makes approach of another molecule to form bridging carboxylate bonds between two discrete units. Careful analysis of the structure shows (Fig. 3b) that every carboxylate can be a bridging as well as chelating in the polymeric system. Such system can be constructed from the dinuclear building blocks as depicted in Fig. 3f. Support to this fact arises from the fact that there are two different Cd–Cd distances in each of these complexes in alternating manner. For example the Cd–Cd distances in 4-nitrobenzoate, 4-chlorobenzoate and 1-naphthoate complexes are 4.138 Å, 3.748 Å; 4.119 Å, 3.745 Å and 4.152 Å, 3.801 Å respectively. The observation of long and short separation clearly indicates that there is a part of the poly-

mer having paddlewheel type structure and another unit has features of mononuclear structure and combination of which is leading to the co-ordination polymers. Thus, formation of mononuclear complexes may be imagined to be from cleavage of such polymeric species. It may be proposed that that the polymeric units are having mononuclear and dinuclear paddlewheel structure and each paddlewheel can be squeezed to give mononuclear species if the diagonal bridging atoms can be connected to the cadmium atom. Such distortion in paddlewheel would preferentially take the system to a mononuclear species. This is illustrated in Scheme 1, where arrows are indicating the approach of an oxygen atom to cause distortion to a limiting case and beyond which distortion would make two mononuclear chelate from one parent bridged binuclear system. We have observed in the case of copper [6a] and cobalt [6e] and in nickel [6b,6c] that similar reactions are highly sensitive to the reaction conditions. However, the present study is designed such a way that all the reactions are carried out under identical molar ratios and identical condition. The driving force in the case of cadmium complexes to have polymeric form thus arises from the competition between the steric factor and attack of a bridging ligand to form co-ordination polymer. The (4-chloro-2-methylphenoxy) acetate complex of cadmium(II) complex has polymeric structures having six coordination number of cadmium [8]. In this complex, two water molecules and a carboxylate group serves as bridging ligand [8]. All the complexes presented in this manuscript are also characterized by recording their proton-NMR. The integration of protons confirmed that they have the same composition in solution and solid state. However, it is found that for complex **5** and **9** in DMSO the water signals of the complexes are merged with the water signal from dissolved water in the solvent. Each of the complexes has characteristic N–H stretching frequency from the 3,5-dimethylpyrazole ring however, at a different position. For example, complex **1** has absorption at 3434 cm^{-1} for N–H stretching whereas the 3,5-dimethyl pyrazole has absorption at 3201 cm^{-1}. The compound has absorption frequencies that have

characteristic features of bi-dentate carboxylate ligand [9]. For example the complex **1** has absorption at 1538(ν_{as}) and 1404(ν_s) cm^{-1} due to the bidentate carboxylic acid group. The parent benzoic acid has absorptions at 1682 and 1421 cm^{-1}. The other mono-nuclear complexes also have similar trends in absorptions over the parent carboxylic acid, confirming bi-dentate nature of the carboxylate groups. The complexes **6**, **7**, **8** have both bidentate and bridging carboxylates from crystallographic study. Although, in these cases clear distinction could not be made between the two type of binding mode from the IR-absorptions but some inference can be made; for example in the case of **7**, the absorptions from carboxylate groups occurs at 1590, 1500, 1411 and 1390 cm^{-1} in contrast to the parent carboxylic acid namely 4-chlorobenzoic acid, which has absorptions at 1683, 1592, 1424 cm^{-1}.

Since we have obtained a polymeric structure for the 1-naphthoate complex **8**, we extended our study to the reaction of cadmium acetate with 1-naphthoic acid and pyridine

$$Cd(OAc)_2 2H_2O + 1\text{-}C_{10}H_7COOH + L_b \rightarrow \underset{\mathbf{9}}{[Cd(C_{10}H_7COO)_2(L_b)_2(H_2O)]} \quad (1)$$

where Lb = pyridine

This reaction led to complex having composition $[M(L)_2(L_b)_2(H_2O)]$ (**9**) where L is 1-naphthoate and L_b is pyridine. As expected from the trend from the composition that in this class of compound there is no polymeric structure, we have found it to be so for the complex. It is found that the complex has a distorted pentagonal bipyramidal seven co-ordination geometry as shown in Fig. 4a. Four oxygen atoms from naphthoate groups and oxygen atom of the aqua ligand form the basal plane. The axial positions are taken up by two pyridine ligands. The complex in solid state has extensive hydrogen bonded structure through the interaction of the aqua

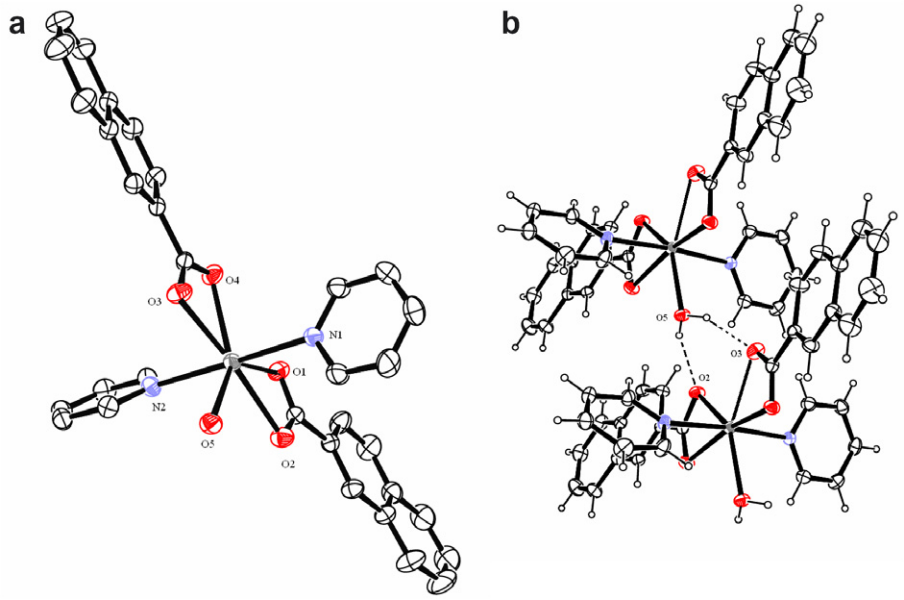

Fig. 4. (a) The structure of **9** (hydrogen atoms are omitted for clarity). (b) The hydrogen bond interactions between two molecules of **9** (drawn with 20% thermal ellipsoid).

ligand with the oxygen of carboxylate groups. The hydrogen bonded chain like structures are formed from O5–H···O3 with 0.901 (d_{D-H}), 1.934 ($d_{H\cdots A}$), 2.766 ($d_{D\cdots A}$), 152.759 (∠D–H···A/°) and O5–H···O2 with 0.809 (d_{D-H}), 1.995 ($d_{H\cdots A}$), 2.727 ($d_{D\cdots A}$) 150.18 (∠D–H···A/°). The hydrogen bonding between two molecules of **9** is shown in Fig. 4b.

In conclusion it has been possible to rationalize the relation between composition and structure in 3,5-dimethypyrazole containing cadmium carboxylates. The cadmium carboxylate complex having composition $[Cd(L)_2(L_a)_2]$ leads to mononuclear structure and the composition $[Cd(L)_2(L_a)]$ leads to polynuclear co-ordination polymers, whereas the complex having the composition $[Cd(L)_2(L_a)(H_2O)]$ leads to tetranuclear complex. It is also observed that the compositions are more important than the substituent at the *ortho* or *para*-position of the aromatic carboxylate ligands, however, to a great extent the composition of L_a containing cadmium carboxylates are decided by the substituents; keeping a close correlation between the steric factor with thermodynamic control of synthesis. The overall structure in solid state is stabilized by various weak interactions. The cadmium complex having the composition $[M(L)_2(L_b)_2(H_2O)]$ leads to mononuclear pentagonal bipyramid structure.

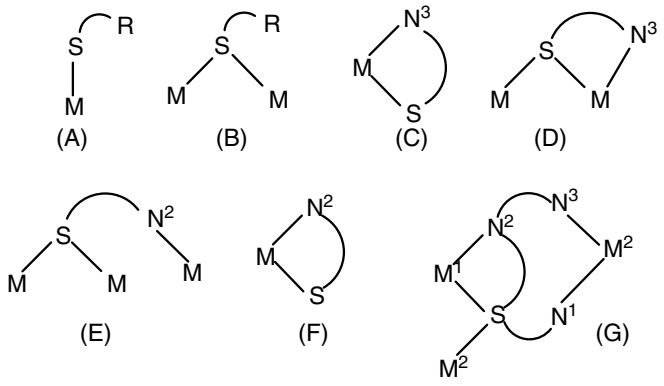

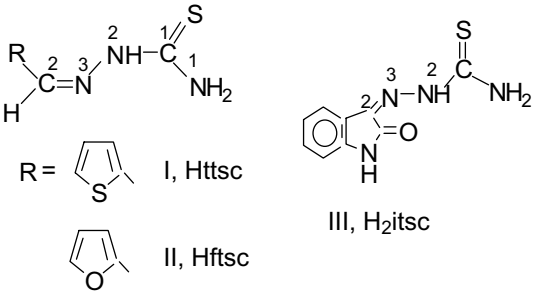

Chart 1.

mode G are also present. Mode G involves N^2, S-chelation to one metal, and N^1, N^3-chelation to second metal with sulfur also bridging another metal center [23].

The coordination chemistry of thiophene-2-carbaldehyde thiosemicarbazone (I, Httsc) and furanaldehyde thiosemicarbazones (II, Hftsc) is limited [24–26], and likewise only a few complexes of isatin-3-thiosemicarbazone (III, H_2itsc) are known [9a]. We have been interested in the study of the interaction of d^{10} metal ions (Cu, Ag) with thiosemicarbazones by changing the R groups at the C^2 carbon and the halogen bonded to the M^I center [10]. Reaction of thiophene-2-carbaldehyde thiosemicarbazone (Httsc) and furanaldehyde thiosemicarbazones (Hftsc) with copper(I) iodide formed iodo-bridged dimers and with copper(I) bromide formed sulfur bridged dimers [10a], while isatin-3-thiosemicarbazone (H_2itsc) formed monomers for X = Br, I [9a]. In this paper, we report the reactions of copper(I) chloride with Httsc, Hftsc and H_2itsc, and the products are characterized using elemental analysis, spectroscopy and X-ray crystallography (**1**, **3**).

2. Experimental

2.1. Materials and techniques

Copper(I) chloride was prepared by the reduction of $CuSO_4 \cdot 5H_2O$ using SO_2 in the presence of NaCl in distilled water [2]. Ph_3P was procured from Aldrich Sigma Ltd. C, H, N analysis were obtained with a Carbo-Ebra 1108 instrument. IR spectra were recorded using KBr pellets on a Nicolet 320 FTIR spectrophotometer in the 4000-200 cm^{-1} range. ^1H NMR spectra were recorded on a JEOL AL300 FT spectrometer at 300 MHz in $CDCl_3$ with TMS as the internal reference. ^{31}P NMR spectra were recorded at 121.5 MHz with TMP $\{(CH_3O)_3P\}$ as the external reference taken as zero position.

2.2. Preparation of the ligands (Httsc, Hftsc, H_2itsc)

Thiophene-2-carbaldehyde thiosemicarbazone, furanaldehyde thiosemicarbazone and isatin-3-thiosemicarbazone were prepared by condensation of thiophene-2-carbaldehyde, furan-2-carbaldehyde and isatin with thiosemicarbazide in a 1:1 molar ratio in methanol using a procedure similar to that given in the literature [27].

2.3. Synthesis of the complexes

2.3.1. Synthesis of $[Cu_2Cl_2(\mu\text{-}S\text{-}Httsc)_2(PPh_3)_2] \cdot 2\,H_2O$ (**1**)

To a stirred solution of copper(I) chloride (0.025 g, 0.252 mmol) in acetonitrile (20 mL) was added solid Httsc (0.046 g, 0.252 mmol) and the contents were stirred for 4 h. This was followed by the addition of solid Ph_3P (0.066 g, 0.252 mmol), and stirring was continued for a further period of 1 h. The clear solution formed was filtered, allowed to evaporate at room temperature and a yellow colored crystalline product was formed (yield: 0.087 g, 59%; m.p.: 136–138 °C). The complex is highly soluble in $CHCl_3$ and CH_2Cl_2 and warm CH_3CN. *Anal.* Calc. for $C_{48}H_{48}Cu_2Cl_2N_6O_4P_2S_4$: C, 51.1; H, 4.28; N, 7.44. Found: C, 50.8; H, 4.12; N, 7.38%. Main IR peaks (KBr, cm^{-1}): ν(O–H) 3553s; ν(N–H) 3450m, 3410m, 3331m; ν(–NH–) 3162m; ν(C–H) 3051m, 2949m, 2822m; $\delta(NH_2) + \nu(C{=}N) + \nu(C{-}C)$ 1591s, 1556s; ν(C=S) 820s (thioamide moiety); $\nu(P{-}C_{Ph})$ 1095s. ^1H NMR data (δ, ppm; J, Hz, $CDCl_3$): 12.78 (s, N^2H), 8.36 (s, C^2H), 6.97 (s, N^1H_2), 7.49 (d, C^6H), 7.43 (d, C^4H), 7.06 (dd, C^5H), 7.29–7.42 (m, 30H, Ph); ^{13}C NMR data (δ, ppm; *J*, Hz, $CDCl_3$): 173.8 (C^1), 142.2 (C^2), 137.6 (C^3), 129.3 (C^4), 127.9 (C^5), 132.8 (*i*-C, J_{P-C}, 30.9 PhP), 133.9 (*o*-C, J_{P-C}, 14.3, PhP), 128.6 (*m*-C, J_{P-C}, 9.2, PhP), 129.8 (*p*-C, PhP). ^{31}P NMR data (δ, ppm; *J*, Hz, $CDCl_3$): −111.03, ($\Delta\delta = \delta_{complex} - \delta_{ligand}$) 2.12. ^{31}P NMR of PPh_3 $\delta = -113.15$ ppm. The crystals were grown and stored in CH_3CN for X-ray structure determination as in the absence of solvent they turn opaque.

2.3.2. Synthesis of $[Cu_2Cl_2(Hftsc)_2(PPh_3)_2] \cdot 2H_2O$ (**2**)

Complex **2** was prepared similarly. (Color: orange, yield: 0.074 g, 54%; m.p.: 117–119 °C.) The complex is poorly soluble in $CHCl_3$ and CH_2Cl_2, but highly soluble in dmso-d_6 and warm CH_3CN. *Anal.* Calc. for $C_{48}H_{48}Cu_2Cl_2N_6O_4P_2S_2$: C, 52.6; H, 4.41; N, 7.66. Found: C, 52.5; H, 4.13; N, 7.23%. Main IR peaks (KBr, cm^{-1}): ν(O–H) 3560s; ν(N–H) 3450m, 3310m; ν(–NH–) 3162m; ν(C–H) 3100m; $\delta(NH_2) + \nu(C{=}N) + \nu(C{-}C)$ 1596s, 1550s, 1529s; ν(C=S) 832s (thioamide moiety); $\nu(P{-}C_{Ph})$, 1094s. ^1H

NMR data (δ, ppm; J, Hz, $CDCl_3$): 12.32 (s, N^2H), 8.12 (s, C^2H), 7.53 (d, C^6H), 6.79 (d, C^4H), 6.51 (dd, C^5H), 7.38–7.46 (m, 30H, Ph + N^1H_2); ^{31}P NMR data (δ, ppm; *J*, Hz, $CDCl_3$): −110.0, ($\Delta\delta = \delta_{complex} - \delta_{ligand}$) 3.15.

2.3.3. [CuCl(H$_2$itsc)(Ph$_3$P)$_2$] · 2CH$_3$CN (3)

Complex **3** was also prepared similarly except that two moles of Ph_3P were used. (colour: orange; yield: 0.14 g, 62%; m.p.: 210–212 °C). *Anal.* Calc. for $C_{49}H_{44}CuClN_6OP_2S$: C, 64.3; H, 4.7; N, 7.0. Found: C, 63.8; H, 4.55; N, 6.58%. Main IR peaks (KBr, cm^{-1}): ν(N–H) 3421m, 3325m; ν(–NH–) 3153m; (NH, pyrrole) 3075m; ν(C–H) 2920m; ν(C=O) 1691s; $\delta(NH_2) + \nu$(C=N) + ν(C–C) 1612 ms, 1593s; ν(C=S) 850s (thioamide moiety); ν(P–C_{Ph}) 1099s.

2.4. Crystallography

Yellow prismatic crystals of compound **1** and orange prismatic crystals of **3** were mounted on glass fibres and used for data collection. Crystal data were collected at 100(2) K for **1** and 103(2) K for **3** using a Bruker SMART CCD 1000 diffractometer. Graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) was used throughout. The data were processed with SAINT [28] and corrected for absorption using SADABS [29]. The structure was solved by direct methods using the program SHELXS [30], and refined by full-matrix least squares techniques against F^2 using SHELXL-97 [31]. Positional and anisotropic atomic displacement parameters were refined for all non-hydrogen atoms. Hydrogen atoms were placed geometrically and positional parameters were refined using a riding model. The crystal data are given in Table 1.

3. Results and discussion

3.1. Synthesis and infrared spectroscopy

Reaction of copper(I) chloride with thiophene-2-carbaldehyde thiosemicarbazone (Httsc) and furan-2-carbaldehyde thiosemicarbazone (Hftsc) in the presence of Ph_3P formed complexes of formulas $[CuCl(Httsc)(Ph_3P)]_2 \cdot 2CH_3CN$ (**1**) and $[CuCl(Hftsc)(Ph_3P)]_2 \cdot 2H_2O$ (**2**), respectively. The reaction of copper(I) chloride with isatin-3-thiosemicarbazone and Ph_3P yielded a monomer complex, $[CuCl(H_2itsc)(Ph_3P)_2] \cdot 2CH_3CN$ (**3**) (Scheme 1). In order to establish the bonding and structures, single crystal X-ray crystallography of **1** and **3** has been carried out. The crystals were stored in CH_3CN, as they get opaque in its absence. Complex **1** is soluble in chloroform, while complexes **2** and **3** are partially soluble in this solvent; all three are soluble in warm acetonitrile.

The IR spectra of complexes **1**, **2** and **3** show a set of two bands at 3450m, 3331m (**1**), 3450, 3310 cm^{-1} (**2**) and 3421m, 3325m cm^{-1} (**3**), due to ν(N–H) of the NH_2 group, and one band at 3162 cm^{-1} in (**1**, **2**) and 3153m cm^{-1} (**3**), due to ν(–NH–). The presence of these bands suggest that the thiosemicarbazone ligands are coordinating to the copper center in the neutral form. The ν(O–H) band in complexes **1** and **2** appeared at 3553 and 3560 cm^{-1}, respectively, which supports the presence of water molecules as the solvent of crystallization. The $\delta(NH_2)$, ν(C=N) and ν(C=C), vibrational modes appear at 1591s,1556s cm^{-1} in **1**, in the range 1596–1529 cm^{-1} in **2**, and at 1612m cm^{-1} in **3**, while the characteristic thioamide bands, ν(C=S), appear in the range 820–850 cm^{-1} in the complexes (ν(C=S) 837s Httsc; 830s Hftsc; 852s H_2itsc). The ν(C=O) band in complex **3** appears at 1691 cm^{-1}, and shows a lower energy shift as compared with the free carbonyl group due to its involvement in strong intra-molecular hydrogen bonding with the imino (N^2H) hydrogen of the thiosemicarbazone. The appearance of characteristic ν(P–C_{Ph}) bands at 1095 cm^{-1} in **1**, 1094 cm^{-1} in **2** and at 1099 cm^{-1} in **3** indicates the presence

Scheme 1.

of Ph_3P in the complexes, similar to the literature trend [10].

3.2. Crystal structures of the complexes

3.2.1. Dimer

The atom numbering scheme for complex **1** is given in Fig. 1, and selected bond lengths and bond angles are given in Table 2 (also includes data for **3**). In complex **1**, the Cu is bonded to one Cl atom, one P atom of Ph_3P and one S atom, forming a three coordinate unit, {$CuCl(Ph_3P)$-(Httsc)}, and two such units dimerize via the bonded S atoms to yield a sulfur-bridged dimer $[Cu_2Cl_2(\mu\text{-S-Httsc})_2(PPh_3)_2]\cdot 2CH_3CN$ (**1**) (Fig. 1). The central Cu_2S_2 core forms a parallelogram with two unequal Cu–S bond distances, {2.3626(5), 2.4298(5) Å}, which are longer than the terminal Cu–S distance, 2.3505(9) Å in the iodide bridged dimer, $[Cu_2(\mu\text{-I})_2(\eta^1\text{-S-Httsc})_2(Ph_3P)_2]$ (**4**). Further, each Cu atom is bonded to one PPh_3 with a Cu–P bond distance of 2.2402(5) Å, and one Cl atom with a Cu–Cl distance of 2.3392(5) Å, and these distances are similar to 2.2309(6) and 2.3280(6) Å, respectively, as observed in the analogous S-bridged dimer, $[Cu_2Cl_2(\mu\text{-S-Hbtsc})_2(Ph_3P)_2]$ (**5**) (Hbtsc = benzaldehyde thiosemicarbazone) [10a]. Compound **2** has two water molecules per dimer and is isostoichiometric with compound **1**, and is thus believed to have a similar structure.

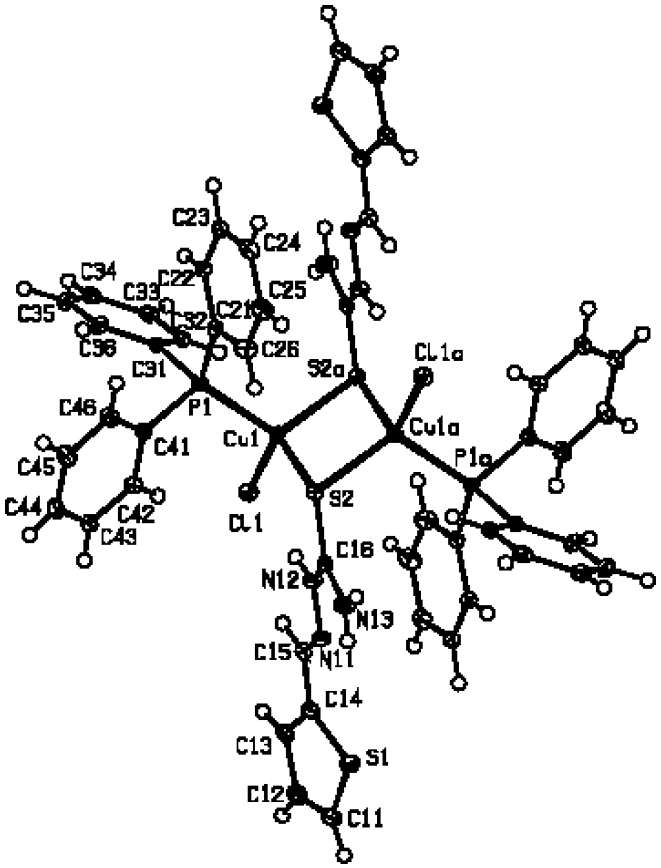

Fig. 1. Structure of complex **1** with the numbering scheme.

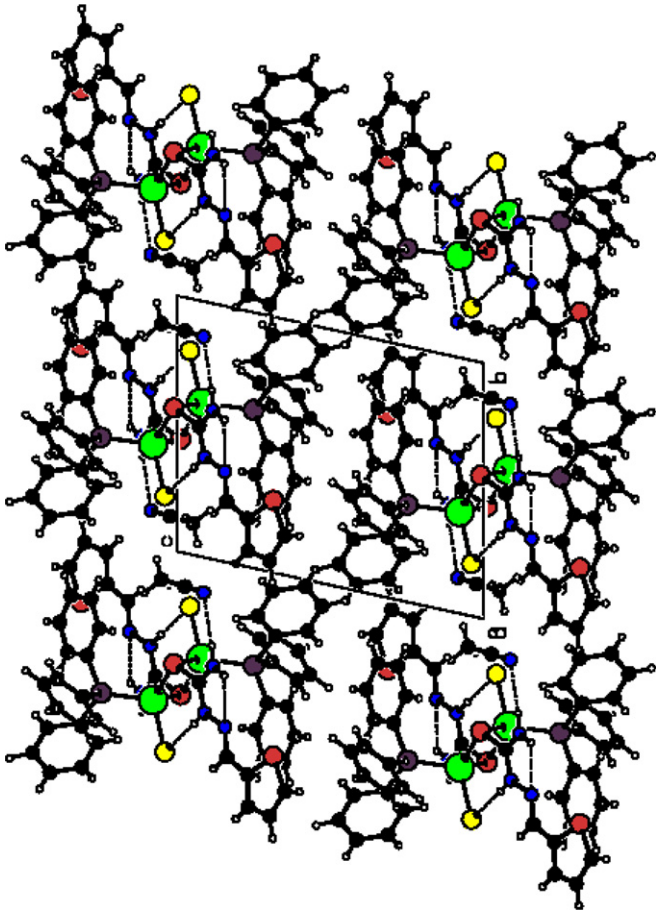

Fig. 2. Packing diagram of complex **1**.

From the packing diagram of **1** (Fig. 2), it can be seen that the amino group forms H-bonds, one intramolecular with N^3 of the thiosemicarbazone ($H^1NH\cdots N^3$) and a second intermolecular one with nitrogen of a CH_3CN molecule, viz., $H^1NH\cdots NCCH_3$ (Table 3). Further, two methyl hydrogens of acetonitrile are H-bonded to the same chlorine atom, {$NCCHH_2\cdots Cl$, 2.62, 2.79 Å}, a similar intermolecular interaction with chlorine was observed in the analogous sulfur-bridged dimer, $[Cu_2Cl_2(\mu\text{-S-Hbtsc})_2(Ph_3P)_2]\cdot 2CH_3CN$ (**5**) [10a]. Thus there is no inter-dimer interaction in compound **1**, while in the latter complex dimer-dimer interactions led to the formation of a linear chain polymer via acetonitrile hydrogen bonds, as just mentioned.

Table 4 shows S–Cu–S and Cu–S–Cu angles within the Cu_2S_2 core in **1** and other analogous dimeric complexes, **8**–**10** (the Table also includes iodide-bridged dimers **4**, **6** and **7** for comparison). In Httsc compounds, **1** (Cl)·$2CH_3CN$ and **9** (Br)·$2H_2O$, Cu–S–Cu angles are 70.66° and 84.88° respectively, while in Hptsc compounds **8**(Br)·$2H_2O$ and **10**(Cl)·$2H_2O$, the same Cu–S–Cu angles are 77.99° and 77.40° respectively. Likewise, compounds **1**(Cl)·$2CH_3CN$ and **5**(Cl)·$2CH_3CN$ have Cu–S–Cu angles of 70.66° and 72.16° respectively. The S–Cu–S angles at Cu, vary in a complementary manner vis-à-vis the Cu–S–Cu angles. It is also observed that a change in the bridging atom from sulfur to iodine in **4**, **6** and **7** leads

Table 4

to higher I–Cu–I angles (104.47–112.00°) and smaller Cu–I–Cu angles (67.99–75.58°). From the above it can be concluded that the Cu–S–Cu angles appear to (i) be independent of the nature of the halogen, (ii) depend upon the nature of the ring at the C^2 carbon, and (iii) depend upon the presence of solvent, notably acetonitrile (different hydrogen patterns). In contrast, the Cu–I–Cu angles depend upon the nature of the ring at the C^2 carbon. The angles at iodine vary with the change in the substituent at the C^2 carbon of the thiosemicarbazone in the order: **4** > **7** > **6**. Finally, the Cu···Cu separation is smallest in compound **1** (2.7719 Å), next in order is compound **5** (2.8131 Å), while all other compounds, as listed in Table 4, show this separation in the range: 2.98 –3.232 Å. A smaller angle at S or iodine brings two Cu atoms closer Fig. 3.

3.2.2. Monomer

In complex **3**, the copper is coordinated via the thione sulfur, chloride atom and two P atoms from two Ph_3P ligands to complete its tetra-coordination. The angles around Cu, in the range, 104.8–121.8°, suggest a distorted tetrahedral geometry. The Cu–S bond distance of 2.3323(5) Å is smaller than in the analogous complexes with bromide {2.3566(10) Å} and iodide {2.399(2) Å} [9a]. This Cu-S bond distance increases in the order Cl < Br < I with the decrease in electronegativity of the halogen atom. The Cu–Cl bond distance, 2.3892(6) Å, is comparable with 2.4097 Å in a similar type of complex of copper(I) chloride with pyridine-2-carbaldehyde thiosemicarbazone [10a]. The Cu–Cl bond distances are much less than the sum of the ionic radii of Cu^+ and Cl^- ions, (2.58 Å) [2]. The Cu–P bond distances, {2.2621(5), 2.2773(6) Å} are close to other monomeric complexes with two Ph_3P ligands in the literature [9a,10a]. Further, amino ($-HN^1H-$) and imino ($-N^2H-$) hydrogens are engaged in intramolecular hydrogen bonding with chlorine ($-HN^1H\cdots Cl$) and with the oxygen atom of the isatin ring ($-N^2H\cdots O_{(isatin)}$) (Fig. 4, Table 3).

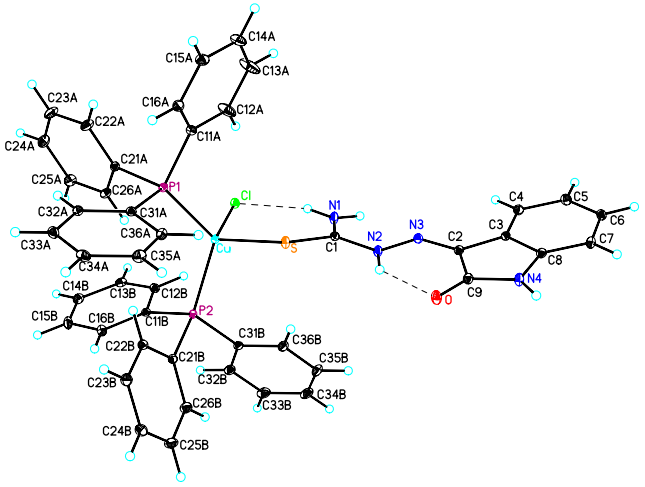

Fig. 3. Structure of complex **3** showing the atomic numbering scheme.

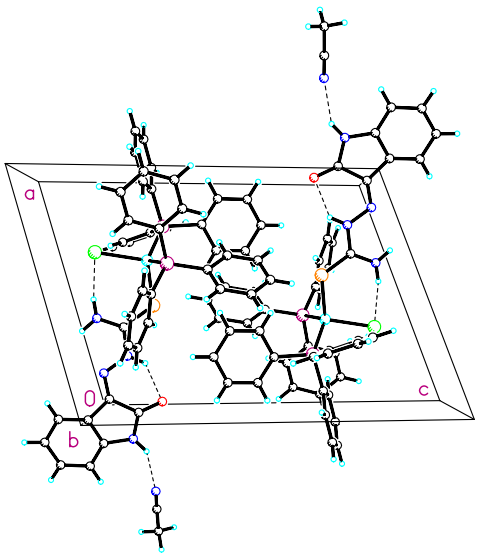

Fig. 4. Packing diagram of complex **3**.

It may be pointed out here that the analytical data of **1** showed two water molecules per dimer, and the crystal structure showed the presence of two acetonitrile molecules per dimer unit. Thus water, as shown by elemental analysis, was replaced by acetonitrile when stored in this solvent and vice versa. Theoretical calculations on dimeric copper(I) complexes with a model thisemicarbazone {H_2C=N–NH–C(=S)–NH_2} and PH_3 predicted that only the halogen bridging is stable [10a], and that the presence of water of crystallization (or some solvent such as CH_3CN) is necessary for stability of sulfur-bridged dimers, in which case the halogens formed hydrogen bonds with the solvents mentioned. Examples **1**, **2**, **5**, **8**–**10** provide testimony to this fact, but it may be pointed out that it was generally true for more electronegative halogens (Cl, Br), and not for iodide, which formed iodo-bridged dimers (**4**, **6**, **7**) (Table 4). Weaker hydrogen bonding with iodide and a tendency of softer iodide for bridging probably explain iodo-bridging in **4**, **6** and **7**, and no acetonitrile was found in these complexes.

In complex **3**, hydrogen bonding of acetonitrile is different from that in complex **1**. A strong H-bond is formed between the nitrogen of acetonitrile and NH of the pyrrole group of isatin, ($NH_{(pyr)}\cdot NCCH_3$, 2.19 Å) (Fig. 4), and thus methyl hydrogens orient away from the chlorine atom. It may be pertinent to bring to notice that in the isatin complex **3**, a 1:1:1 molar ratio formed an insoluble product and addition of a further one mole of PPh_3 was needed to form a clear solution, and product was established as monomer **3**. The lack of formation of a dimer by isatin thiosemicarbazone with copper(I) chloride may be due to a different pattern of hydrogen bonding as discussed above. Alternatively, the difference could be due to the nature of the substituents at the C^2 carbon, more flexible groups such as thiophen etc. provide more structure and bonding possibilities versus a rigid isatin group which only forms tetrahedral monomers as in the present case and in the literature

[9a]. Further, the presence of two Ph rings at the C^2 carbon was found to favor only monomeric complexes [32].

It is added here that theoretical calculations favored only monomers or dimers and no other geometry tested was found to be stable [10a].

3.3. Solution phase behavior

The N^2H proton signals appear at low field positions, 12.28 and 12.3 ppm in complexes **1** and **2** respectively, compared to the free ligands {δ 9.45 (sb) ppm, Httsc, δ11.4 (sb) ppm Hftsc} [27c], and it confirms the coordination of the neutral thiosemicarbazone ligands via S-donor atoms. Only one NH_2 signal of **1** appeared, at δ 6.97 ppm, with the second signal obscured by the signals due to Ph_3P in the range δ 7.26–7.53 ppm. The C^2H proton showed a slight downfield shift at δ 8.36 ppm (free Httsc, 8.01 ppm) in **1** and δ 8.11 ppm in **2** (free Hftsc, δ 7.78) [27c]. Ring protons peaks are given in the experimental section and show slight upfield shifts with respect to the free ligands [27c].

The ^{13}C NMR signal due to the C^1 carbon appears at δ 173.8 ppm in complex **1** which is upfield relative to the free ligand [27c], whereas the C^2 carbon at δ 142.2 ppm is shifted downfield on complexation; other ring carbons appeared at δ 137.6 (C^3), 129.3 (C^4), 127.9 (C^5) ppm. The ortho, para and meta carbons of the triphenyl phosphine ligands are clearly resolved vis-à-vis the free ligand. The ^{31}P NMR spectra showed a coordination shift ($\Delta\delta = \delta_{complex} - \delta_{ligand}$) of 2.12 ppm in **1** and 3.1 ppm in **2**, similar to the literature trends [32].

It is concluded that for R = thiophene, furan and pyrrole at the C^2 carbon with X = Cl or Br, sulfur bridging is favored as stabilized by the solvent, and X = I favors only iodide bridging. Further, the presence of acetonitrile as a solvent of crystallization can have diverse influence on the nature of the compounds. While in some cases it is bonded to the ring of the ligand (e.g. **3**), in other cases it is bonded to the halogen via the methyl hydrogen (e.g. **1**, **5**) and still in other cases such as, $[CuCl(Hpytsc)(PPh_3)_2]\cdot CH_3CN$ (Hpytsc = pyridine-2-carbaldehyde thiosemicarbazone) [10a], it is lying as non-bonded in the lattice.

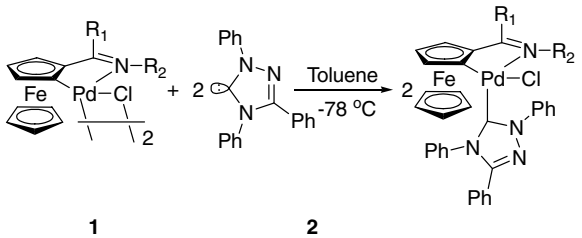
2. Results and discussion

2.1. Synthesis and characterization of complexes 2a–d

The synthetic route for the novel NHC adducts of cyclopalladated ferrocenylimines is shown in Scheme 1. These new compounds were characterized by IR, ^{1}H NMR, MS and high-resolution mass spectrometry. They are air- and moisture-stable and can be recrystallized in dichloromethane/petroleum ether.



The IR spectra of the free ferrocenylimines show an intense sharp band in the range 1620–1640 cm^{-1}. However for the new complexes **2a**–**d**, this band shifted to lower energy (1562–1594 cm^{-1}), indicating that the nitrogen atom of the ferrocenylimines is coordinated with palladium through its lone pair [13]. The strong absorptions at *ca.* 765 and 694 cm^{-1} observed in these compounds, a feature of a mono-substituted benzene ring, are assigned to the δ (CH) of the carbene's phenyl rings.

The ^{1}H NMR spectra indicate that **2a**–**d** exist as a mixture of two isomers. The molar ratios are 3.28:1, 3.51:1, 3.88:1 and 17.46:1 for **2a**, **2b**, **2c** and **2d** respectively. Attempts to separate the two isomers by column chromatography and fractional recrystallization were unsuccessful. It is, therefore, difficult unequivocally to define the structures of the isomers. Even so, it is our belief that this isomerism must be in relation to the carbene group, and it is likely that there is steric hindrance of the three phenyl rings in the carbene group which influences the free rotation of the Pd–C (carbene) bond, consequently resulting in two isomers.

2.2. Structural characterization of complexes 2a–d

The single-crystal structures of **2a**–**d** were determined by single-crystal X-ray analysis. These molecular structures are shown in Figs. 1–4. Crystallographic and data collection parameters are summarized in Table 1. Selected bond lengths and angles are listed in Table 2.

The Pd atom in each complex is in a slightly distorted square-planar environment bonded to the carbon atom of the carbene, the chlorine atom, the nitrogen atom and the carbon atom of the ferrocenyl moiety. In all cases the plane of Pd is defined by N, C (Cp ring), Cl, C (carbene) atoms with a deviation of Pd1 of 0.1087 Å, 0.1140 Å, 0.1146 Å and 0.0239 Å for **2a**, **2b**, **2c** and **2d**, respectively. The plane of the carbene is approximately orthogonal to the square plane (95.9°, 95.8°, 95.8° and 94.1° for **2a**, **2b**, **2c** and **2d**, respectively). The bicyclic system formed by the palladacycle and the C_5H_3 moiety is approximately coplanar (dihedral angle 3.3°, 3.4°, 3.3° and 3.6° for **2a**, **2b**, **2c** and **2d**, respectively), and the dihedral angles between the two Cp rings in **2a**, **2b**, **2c** and **2d** are 3.2°, 3.4°, 4.2° and 0.6°. The Pd–C (carbene) bond lengths (1.965–1.977 Å) are shorter than those of the related carbene complexes (1.992–2.123 Å) [4a,4d,11], and Pd–C (Cp) bond lengths (1.945–1.974 Å) are also shorter than those of the related PCy_3, PPh_3 adducts (2.019, 2.006 and 1.998 Å) [7f,14].

2d $R_1 = H$, $R_2 = Cy$

Scheme 1. Synthesis of complexes **2a**–**d**.

2.3. Suzuki–Miyaura cross-coupling reaction

Initially, we performed a brief investigation on the reactivity of catalyst **2a** in the presence of different bases and solvents. The cross-coupling reaction of 4-bromoanisole with phenylboronic acid was used as the test system without the protection of an inert gas (Table 3). It can be seen from Table 3 that the reaction proceeded smoothly in toluene and more than 99% isolated yield was obtained after only 45 min with $K_3PO_4 \cdot 7H_2O$ as a base and 0.01 mol% catalyst loading (Table 3, entry 8).

To test the catalytic activities of these new catalysts, we used them in comparison with the cyclopalladated ferrocenylimine (**1a**). We chose the cross-coupling between 4-bromoanisole with phenylboronic acid as a model, under the optimized conditions with a catalyst loading of 0.01 mol%. As shown in Table 4, carbene adducts **2a**, **2b** and **2d** showed high activity towards this reaction, while the carbene adduct **2c**, with a strong electron-withdrawing group, only gave 75% isolated yield (Table 4, entry 4), which implied that the substituent in the N-phenyl ring of the ferrocenylimine could influence the catalytic activity of the cyclopalladated complex.

Under the optimized conditions, a wide array of aryl bromides (including *ortho*-substituted and electronically deactivated substrates) could react with phenylboronic acid to provide the cross-coupling products in excellent yields by using **2a** as catalyst (Table 5). However, when the catalyst loading was reduced to 0.001 mol%, only 47% isolated yield was obtained, even after 8 h for 4-bromoanisole which has a strongly electron-donating group (Table 5, entry 2). As to the electron-deficient aryl bromides, the coupling reaction just need 0.5 h, using 0.01 mol% of Pd to give high yields (Table 5, entries 11, 12 and 14), when the catalyst loading was reduced to 0.001 mol%. These reactions also gave excellent yields by prolonging the reaction time to 8 h (Table 5, entries 13 and 15). *ortho*-Substituents were also tolerated and even the very sterically hindered 2-bromo-*m*-xylene provided the biaryl product

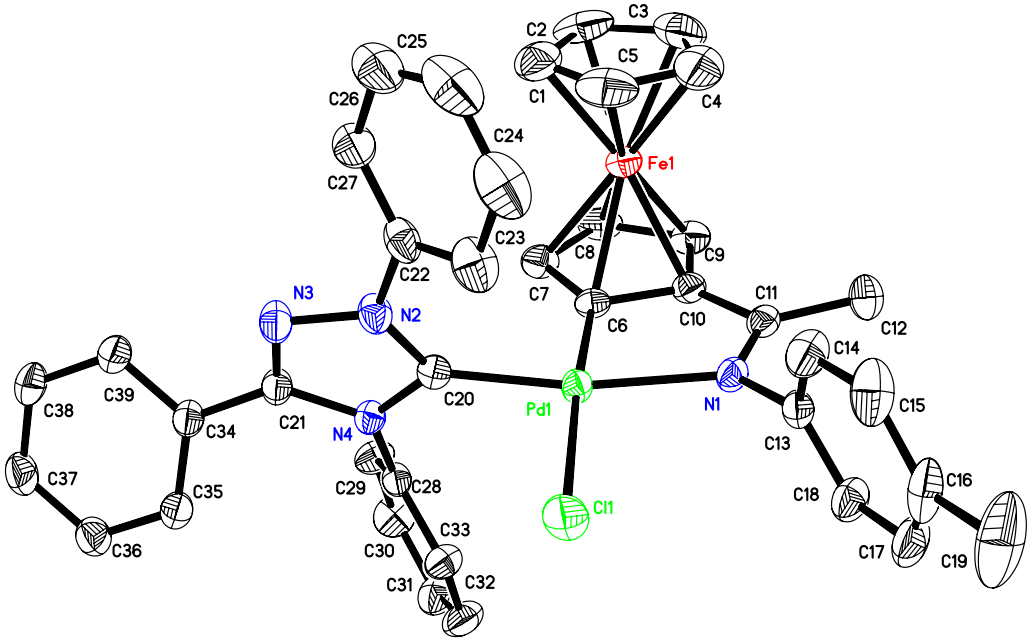

Fig. 1. Molecular structure of complex **2a**.

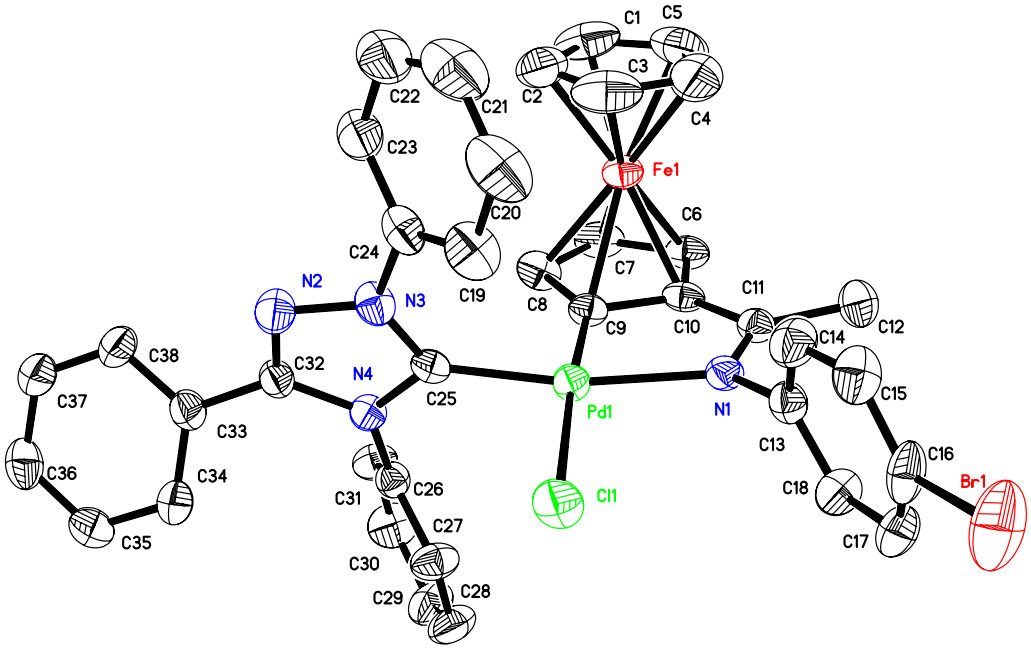

Fig. 2. Molecular structure of complex **2b**.

in 88% isolated yield by using 0.01 mol% of **2a** (Table 5, entry 6).

3. Conclusion

In summary, we have prepared a series of novel, air-stable *N*-heterocyclic carbene adducts of cyclopalladated ferrocenylimines and obtained the crystal structures of these compounds. These new complexes were found to be effective for the Suzuki–Miyaura reaction.

4. Experimental

4.1. General comments

Melting points were measured on a WC-1 microscopic apparatus and are uncorrected. IR spectra were recorded on a Bruker VECTOR22 spectrophotometer. ^{1}H NMR spectra were recorded on a Bruker DPX-400 spectrometer in $CDCl_3$ with TMS as an internal standard. Mass spectra were measured on a LC-MSD-Trap-XCT instrument.

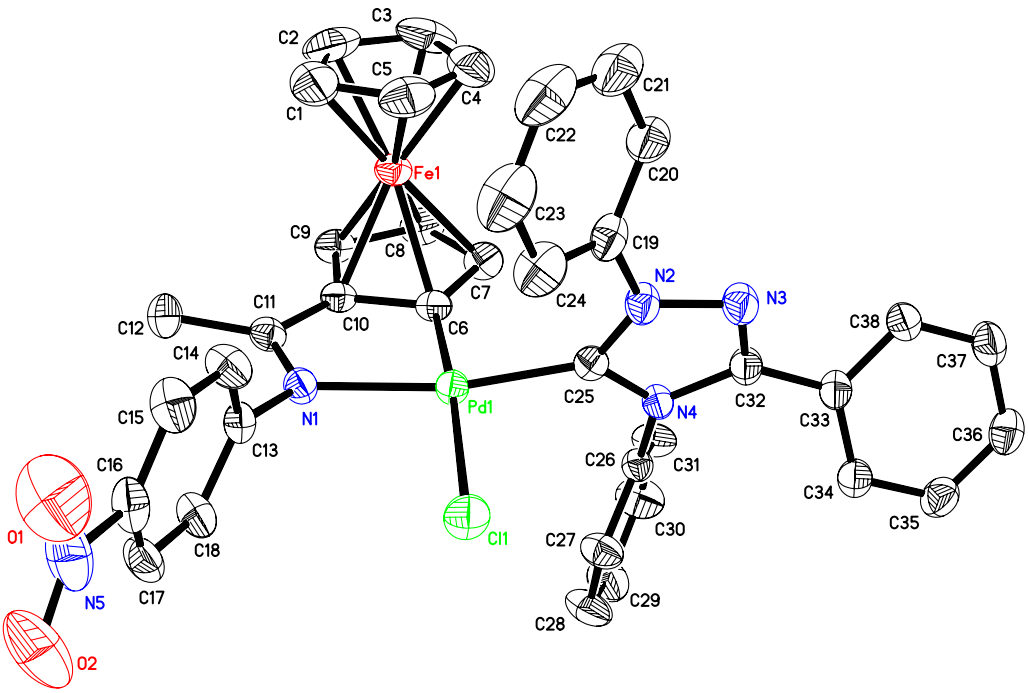

Fig. 3. Molecular structure of complex **2c**.

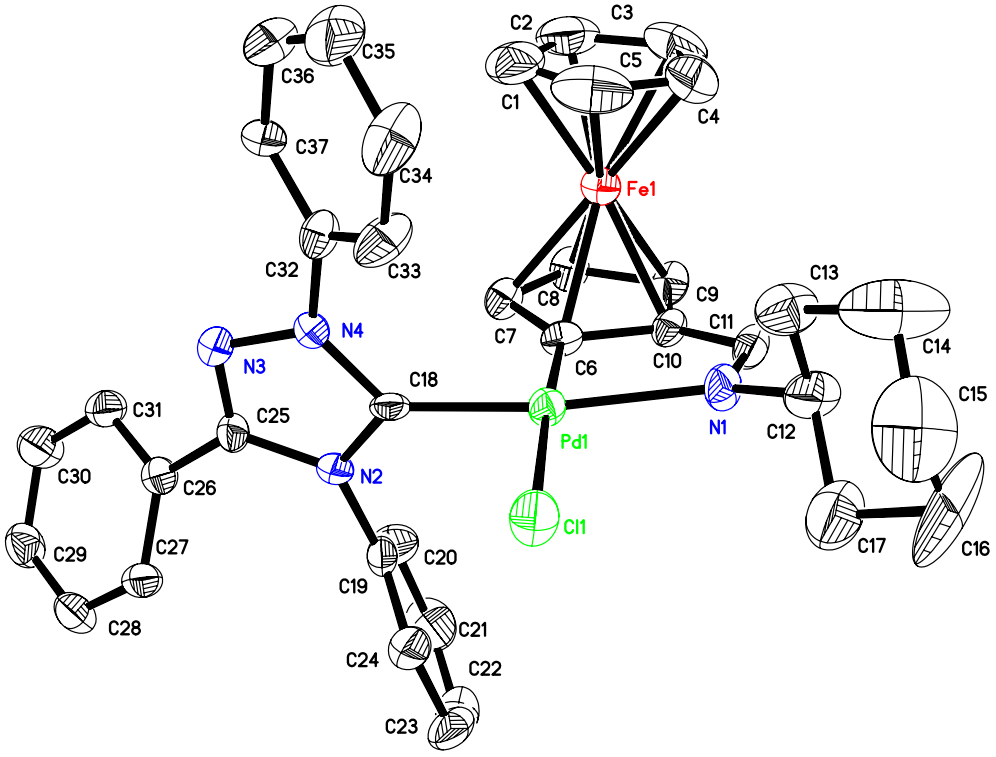

Fig. 4. Molecular structure of complex **2d**.

High-resolution mass spectra were measured on a Waters Q-T of Micro spectrometer.

All the solvents were purified by standard methods. The chloride-bridged palladacyclic dimers [13,15] and *N*-heterocyclic carbene [16] were prepared according to the published procedures. The phenylboronic acid was prepared according to the literature [17]. The aryl bromides for the Suzuki–Miyaura reaction were obtained from commercial sources and were used without purification.

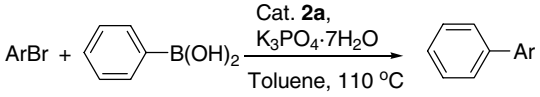
[b] Isolated yields.



4.2. General procedure for the preparation of catalysts **2a–d**

The free carbene 1,3,4-triphenyl-4,5-dihydro-1*H*-1,2,4-triazolin-5-ylidene (0.5 mmol) and the cyclopalladated ferrocenylimines (0.2 mmol) were dissolved in dry toluene and cooled to −78 °C, respectively. The carbene solution was slowly added via a syringe to the dimers under the protection of N_2, then slowly warmed to room temperature and stirred for 2.5 h. The solvent was then removed in vacuo, and the remaining solid was dissolved in a small amount of CH_2Cl_2. The product was separated by flash chromatography column using $CHCl_3$ as eluent. Recrystallization from dichloromethane and petroleum ether afforded the corresponding catalysts with 63–77 % yields.

4.2.1. Characterization data for **2a–d**

Compound **2a**: mp 256 °C (dec.). IR (KBr pellet): 3447, 3052, 1565, 1495, 1462, 1389, 1331, 1228, 1105, 1024, 765, 694 cm^{-1}. ^1H NMR (400 MHz, 300 K, $CDCl_3$): δ 8.74 (2H, d, $J = 7.6$ Hz), 7.67 (3H, m), 7.50–7.31 (10H, m), 7.21 (2H, m), 6.80 (2H, d, $J = 7.4$ Hz), 4.29 (1H, m, C_5H_3), 4.19 (1H, m, C_5H_3), 3.69 (6H, m, C_5H_3 and

Compound **2c**: mp >280 °C. IR (KBr pellet): 3446, 3065, 1594, 1559, 1515, 1340, 1234, 1107, 1003, 765, 693 cm^{-1}. ^1H NMR (400 MHz, 300 K, $CDCl_3$): δ 8.74 (2H, d, $J = 7.0$ Hz), 8.30 (2H, m), 7.68-7.30 (11H, m), 7.30 (2H, m), 7.01 (2H, d, $J = 7.7$ Hz), 4.39 (2H, m, C_5H_3), 3.74 (6H, m, C_5H_3 and C_5H_5), 1.92 (3H, s, CH_3). MS (FAB) *m/z* (%): 1535 ($2M^+-Cl^-$), 750.0 (M^+-Cl^-). HRMS (positive ESI) calc. for $C_{38}H_{30}ClFeN_5O_2Pd$: 750.0784, found: 750.0777.

Compound **2d**: mp 252 °C (dec.). IR (KBr pellet): 3449, 3054, 2927, 2852, 1592, 1494, 1450, 1390, 1330, 1105, 1071, 765, 693 cm^{-1}. ^1H NMR (400 MHz, 292 K, $CDCl_3$): δ 8.83 (2H, d, $J = 7.8$ Hz), 7.80 (1H, s), 7.66 (2H, t, $J = 7.7$ Hz), 7.60–7.56 (2H, m), 7.47 (1H, t, $J = 7.3$ Hz), 7.42–7.38 (3H, m), 7.34–7.30 (5H, m), 4.22 (1H, s, C_5H_3), 4.08 (1H, s, C_5H_3), 3.81–3.79 (1H, m), 3.61–3.54 (6H, m, C_5H_3 and C_5H_5), 2.27 (1H, d, $J = 11.2$ Hz), 1.86–1.78 (3H, m), 1.70 (1H, d, $J = 12.6$ Hz), 1.51–1.35 (3H, m), 1.23–1.14 (2H, m). MS (FAB) *m/z* (%): 1429 ($2M^+-Cl^-$), 697 (M^+-Cl^-). HRMS (positive ESI) calc. for $C_{37}H_{35}ClFeN_4Pd$: 697.1246, found: 697.1226.

4.3. General procedure for the Suzuki–Miyaura reaction

A 5 ml round-bottom flask was charged with the aryl bromides (0.5 mmol), phenyl boronic acid (0.6 mmol) and base (1.0 mmol). The catalyst was introduced as a toluene solution (0.01 mmol/ml) via syringe, and additional toluene was added to obtain a total volume of 2.5 ml. The reaction mixture was stirred at reflux temperature (110 °C) in air. After the completion of the reaction, the mixture was quenched by 5 ml water and then extracted with ethyl acetate (3×10 ml). The combined organic layer was dried over $MgSO_4$. After removal of the solvent in vacuo, the product was obtained by preparative TLC, eluting with ethyl acetate/petroleum ether and the yield was calculated based on the aryl bromides (the purified products were identified by ^1H NMR spectra and comparison of the melting points with the literature data [18]).

4.4. Crystal structure determination

Intensity data of **2a**–**d** were measured on a Rigaku-Raxis-IV X-ray diffractometer using graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å), The data were corrected for Lorentz and polarization factors. The structures were solved by direct methods [19] and expanded using Fourier techniques and refined by full-matrix least-squares methods. All calculations were performed using the TEXSAN [20] crystallographic software package of the Molecular Structure corporation.

2. Experimental

2.1. Synthesis

IR spectra were recorded on a Shimadzu FTIR-8300 Fourier Transform Infrared spectrophotometer using KBr pellets, UV–VIS spectra on a Shimadzu UV-1601 UV–Vis spectrophotometer, and ^{1}H and ^{13}C NMR spectra on a Varian UNITY INOVA 500 MHz spectrometer. Elemental analysis were performed by the Instrumental Analysis Laboratory of the TUBITAK Marmara Research Centre. Mass spectra were recorded on a Varian 711 spectrometer. 4-Nitrophthalonitrile was synthesized according to the reported procedure [14] and 4-hydroxyphenylacetic acid was purchased from Fluka Chemical Company, and was used as purchased. All reagents and solvents were of reagent-grade quality obtained from commercial suppliers. All solvents were dried and purified. The solvents were stored over molecular sieves (4 Å). The homogeneity of the products were tested in each step by TLC (SiO_2).

2.1.1. p-(3,4-Dicyanophenoxy)phenylacetic acid (**1**)

4-Hydroxyphenylacetic acid (0.88 g, 5.78 mmol) and 4-nitrophthalonitrile (1.0 g, 5.78 mmol) were dissolved in dry DMF (100 ml) under nitrogen and anhyd. K_2CO_3 (1.60 g, 11.56 mmol) was added. After stirring for 24 h at 50–60 °C, the reaction mixture was treated with diluted HCl under ice cooling. The pure precipitate was filtered, washed with water to neutralize, and dried. Yield: 0.812 g (50.73%). M.p. 177–180 °C. FT-IR (KBr), $\nu_{max}/(cm^{-1})$: 3500 (carboxylic acid OH), 3067–3050 (Ar–CH), 2930–2918 (aliphatic CH), 2231 (C≡N), 1703 (C=O), 1588–1488 (Ar C=C), 1246 (Ar–O–Ar), 1205, 1161, 1079, 942, 842, 801, 664 and 523. ^{1}H NMR (*d*-DMSO 500 MHz, δ ppm): 12.36 (s, 1H, COOH), 8.09 (d, 1H, Ar–H), 7.77 (d, 1H, Ar–H), 7.39 (d, 1H, Ar–H), 7.35 (dd, 2H, Ar–H), 7.15 (dd, 2H, Ar–H), 3.63 (s, 2H, CH_2). ^{13}C NMR (*d*-DMSO 500 MHz, δ ppm): 173.20 (acid C=O), 161.83 (Ar–C), 153.17 (Ar–C), 137.02 (Ar–C), 133.38 (Ar–C), 132.28 (Ar–C), 123.38 (Ar–C), 122.58 (Ar–C), 120.81 (Ar–C), 117.40 (Ar–C), 116.61 (C≡N), 116.09 (C≡N), 108.80 (Ar–C). MS (LC–MS, Scan ES$^+$) *m*/*z*: 278 [M$^+$]. UV–Vis λ_{max} (nm) ($\log\varepsilon$) in $CHCl_3$: 306 (3.73).

2.1.2. 2,9,16,23-Tetrakis(4-phenyloxyacetic acid)phthalocyanine (**2**)

Compound **1** (0.5 g, 1.80 mmol) and lithium metal (0.2 g, 28.6 mmol) were heated and stirred at 170 °C for 3 h under nitrogen in a mixture of 1,2-dichlorobenzene (4 ml) and pentanol (4 ml). After cooling to room temperature, acetonitrile was added in order to precipitate the product. The green precipitate was filtered and then washed with water and acetonitrile. It was dissolved in a small amount of methanol and precipitated by diluted HCl. In this mixture, the Li_2pcs formed was converted into H_2pcs. The green precipitate was filtered and washed with water, hot acetonitrile, hot methanol, chloroform and diethyl ether, and dried. It is soluble in DMF, DMSO and pyridine. Yield: 0.255 g (51%). M.p. >300 °C. *Anal*. Calc. for $C_{64}H_{42}N_8O_{12}$: C, 68.94; H, 3.77; N, 10.05. Found: C, 68.89; H, 3.68; N, 10.11%. FT-IR (KBr), $\nu_{max}/(cm^{-1})$: 3410 (carboxylic acid OH), 3290 (NH), 3037 (Ar–CH), 2955–2866 (aliphatic CH), 1715 (C=O), 1603–1474 (Ar C=C), 1232 (Ar–O–Ar), 1165, 1090, 1013, 932, 831, 745, 644 and 608. ^{1}H NMR (*d*-DMSO 500 MHz, δ ppm): 12.40 (br s, 4H, COOH), 7.24–6.02 (m, 28H, Ar–H), 3.97 (s, 8H, CH_2), −7.22 (br s, 2H, NH). 2.1.3. General procedure for the 2,9,16,23-tetrakis (4-phenyloxyacetic acid)phthalocyaninatometal derivatives (**2a–d**)

A mixture of compound **2** (0.05 g, 0.045 mmol) and 0.45 mmol metal salts [$CoCl_2\cdot 6H_2O$ 0.11 g, $Zn(AcO)_2\cdot 2H_2O$ 0.10 g, $NiCl_2\cdot 6H_2O$ 0.11 g or $CuCl_2$ 0.06 g] in dry DMF (1.5 ml) was heated and stirred at 155 °C for 24 h under N_2 in a sealed glass tube. After cooling to room temperature, the reaction mixture was treated with diluted HCl. After that, the precipitated green-blue solid was filtered off. The product was washed with water, hot methanol, hot acetonitrile and diethyl ether, and dried.

*2.1.3.1. 2,9,16,23-Tetrakis(4-phenyloxyacetic acid)phthalocyaninatocobalt (II) (**2a**).* This is soluble in THF, DMF, DMSO and pyridine. Yield: 0.029 g (55%). M.p. >300 °C. *Anal*. 2.2. Electrochemistry

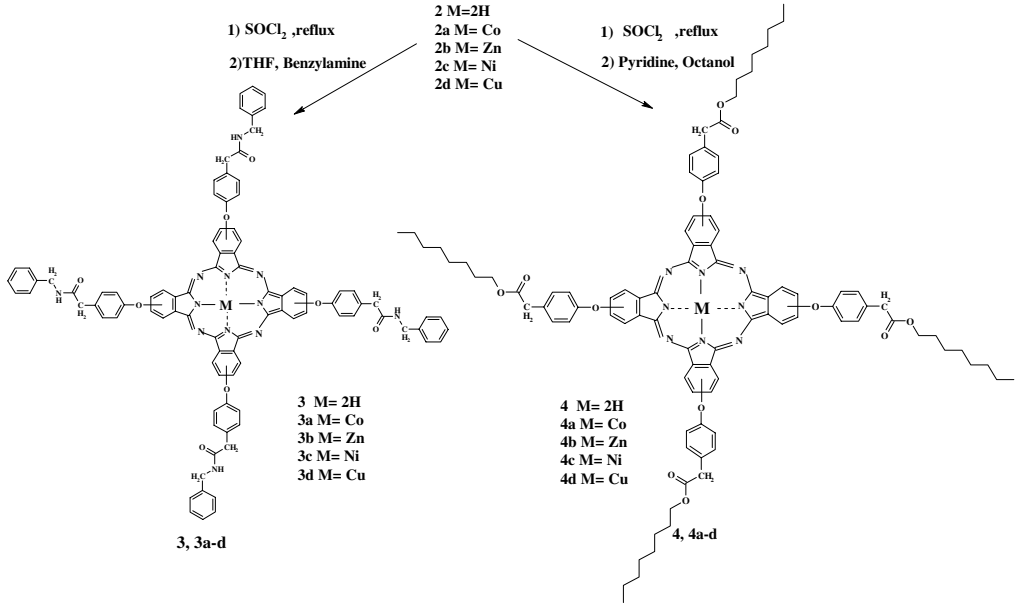
The cyclic voltammetry, differential pulse voltammetry and controlled potential chronocoulometry measurements were carried out with a Princeton Applied Research Model Versostat II potentiostat/galvanostat controlled by an external PC and utilizing a three-electrode configuration at 25 °C. The working electrode was a Pt plate with a surface area of 0.10 cm^2. The surface of the working electrode was polished with a H_2O suspension of Al_2O_3 before each run. The last polishing was done with a particle size of 50 nm. A Pt wire served as the counter electrode. A saturated calomel electrode (SCE) was employed as the reference electrode and separated from the bulk of the solution by a double bridge. Ferrocene was used as an internal reference. Electrochemical grade tetrabutylammonium perchlorate (TBAP) in extra pure dimethylsulfoxide (DMSO) was employed as the supporting electrolyte at a concentration of 0.10 mol dm^{-3}. High purity N_2 was used for deoxygenating the solution for at least 20 min prior to each run and to maintain a nitrogen blanket during the measurements. For CPC studies, a Pt gauze working electrode (10.5 cm^2 surface area), Pt wire counter electrode separated by a glass bridge and a SCE as a reference electrode were used.

3. Results and discussion

3.1. Synthesis and characterization



p-(3,4-Dicyanophenoxy)phenylacetic acid (**1**) was obtained by the base-catalyzed nucleophilic aromatic nitro displacement of 4-nitrophthalonitrile with 4-hydroxyphenylacetic acid (Scheme 1) [15,16]. The reaction was carried out in a single-step synthesis using K_2CO_3 as the nitro-displacing base at 50–60 °C in dry DMF under a N_2 atmosphere. Conversion of **1** into the metal-free phthalocyanine (**2**) is accomplished in a mixture of 1,2-dichlorobenzene and pentanol in the presence of lithium [17]. Dilithium Pcs can be labile towards water and acid, and can easily be converted to the metal-free phthalocyanine (**2**). The metallophthalocyanines (**2a**–**d**) [M = Co(II),

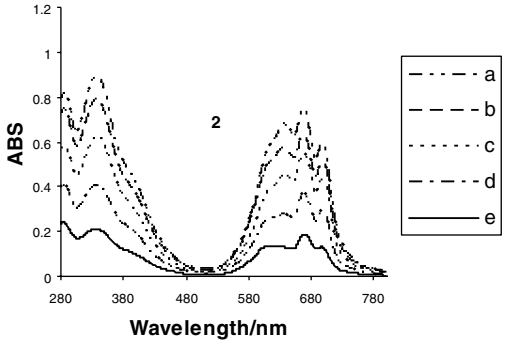
Scheme 1. *p*-(3,4-Dicyanophenoxy)phenylacetic acid (**1**) and phthalocyanines derived from it.

Zn(II), Ni(II) and Cu(II)] were prepared from compound **2** and the corresponding metal salts [$CoCl_2 \cdot 6H_2O$, $Zn(AcO)_2 \cdot 2H_2O$, $NiCl_2 \cdot 6H_2O$ and $CuCl_2$] in dimethylformamide [17]. Further reactions of these phthalocyanines (**2**, **2a**–**d**) with thionylchloride and benzylamine in tetrahydrofuran, and octanol in pyridine gave amide (**3**, **3a**–**d**) and ester (**4**, **4a**–**d**) derivatives, respectively (Scheme 2) [18]. Formation of the amides and esters from the phenyloxyacetic acid groups of the phthalocyanine derivatives (**2**, **2a**–**d**) was carried out in order to show the reactivity of these side groups.

The four polar peripheral substituents conferred upon these macromolecules (**2**, **2a**–**d**, **3**, **3a**–**d**) good solubility in polar solvents such as pyridine, DMF and DMSO. The products (**2**, **2a**–**d**, **3**, **3a**–**d**) were obtained in sufficient purity after successive washing with different solvents. The ester derivatives (**4**, **4a**–**d**) show good solubility in organic solvents such as $CHCl_3$, THF and CH_2Cl_2. The products

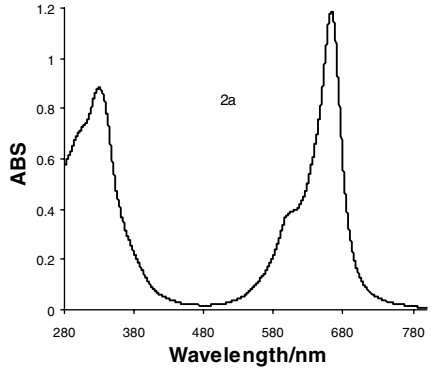
Scheme 2. Phthalocyanines bearing *N*-benzyl-4-phenyloxyacetamide and octyl 4-phenyloxyacetate moieties.

(**4**, **4a–d**) were purified by silica gel column chromatography with chloroform as the eluent.



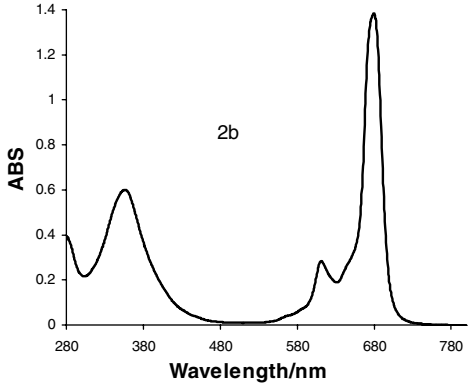
Characterization of the products involved a combination of methods including elemental analysis, FT-IR, UV–Vis, mass and ^{1}H NMR spectroscopy. The spectroscopic data of the new compounds were in accordance with the structures.

When the IR spectrum of 4-nitrophthalonitrile is compared with that of **1**, a distinct difference is the disappearance of the aromatic –NO_2 band at 1548 cm^{-1} and the appearance of a new absorption at 1246 cm^{-1}, attributable to aromatic (C–O–C). In the IR spectrum of **1** the presence of C≡N and C=O groups is indicated by intense stretching bands at 2231 cm^{-1} and 1703 cm^{-1}, respectively. The ^{1}H NMR spectrum of **1** in deuterated DMSO gave a singlet at δ 12.36 ppm (COOH), a singlet at δ 3.63 ppm (CH_2) and the doublets at δ 8.09–7.15 ppm correspond to aromatic protons. The ^{13}C NMR spectrum of **1** indicated nitrile carbons at δ 116.61 and 116.09 ppm as expected. Protonated aromatic and unsaturated carbon atoms appeared in the range δ 161.83–108.80 ppm. Also the carbon atom of carboxylic acid was observed at the lowest field value at δ 173.20 ppm.



Cyclotetramerization of the dinitrile (**1**) into the phthalocyanine (**2**) was confirmed by the disappearance of the sharp C≡N vibration at 2231 cm^{-1}. The IR band characteristic of the metal-free phthalocyanine ring is an N–H stretching at 3290 cm^{-1}. The IR spectra of the metal-free (**2**) and metallo (**2a–d**) phthalocyanines are very similar, except the ν(NH) vibrations of the inner phthalocyanine core in the metal-free molecule. These protons are also very well characterized by the ^{1}H NMR spectra which show a peak at δ −7.22 ppm, −8.0 ppm and −7.80 ppm for **2**, **3** and **4**, respectively, and the signals disappeared after the addition of D_2O. The ^{1}H NMR spectrum of **2** indicates carboxylic acid protons (COOH) at δ 12.40 ppm as a singlet, aromatic protons at δ 7.24–6.02 ppm as a broad peak and aliphatic protons (CH_2) δ 3.97 ppm as a singlet. ^{1}H NMR measurements were precluded owing to the paramagnetic nature of the cobalt (II) phthalocyanines (**2a**, **3a** and **4a**) and copper (II) phthalocyanines (**2d**, **3d** and **4d**). The only difference between the ^{1}H NMR spectra of the metal-free phthalocyanines (**2**, **3** and **4**) and the metallo derivatives (**2b**, **2c**, **3b**, **3c**, **4b** and **4c**) is the lack of broad chemical shifts of the inner core NH protons. The ^{1}H NMR spectra of the phthalocyanines are rather broad, owing probably to the aggregation of the phthalocyanines which is frequently encountered at the concentrations used for NMR spectroscopy [2].

Comparison of the IR spectral data indicated the formation of compounds **3**, **3a–d** by the disappearance of the COOH band of compounds **2**, **2a–d** at 3400–3500 cm^{-1}, and the appearance of amide NH bands at 3290 and 1655 cm^{-1}. In the ^{1}H NMR analysis of **3** in deuterated DMSO, the aromatic protons appear as a broad peak at δ 7.63–7.11, the amide NH protons as a singlet at δ 8.65 and the NH$\underline{CH_2}$Ar protons as a doublet at δ 4.31 ppm. The phthalocyanines containing octyl 4-phenyloxyacetate moieties (**4**, **4a–d**) were confirmed by the disappearance of the COOH band of **2**, **2a–d** at 3400–3500 cm^{-1}, and the appearance of ester C–O bands at 1157–1101 cm^{-1} and more intense aliphatic CH_2 bands at 2926–2858 cm^{-1}. The ^{1}H NMR spectrum of **4** showed the aromatic protons as a broad peak at δ 8.21–6.75 and the COOCH_2R protons as a triplet at δ 4.11 ppm. The –CCH_2C– protons in the long aliphatic chain appear at δ 1.72–1.08 and the CH_3 at the end of the chain as a triplet at δ 0.89 ppm.



The phthalocyanines **2**, **2a–d**, **3**, **3a–d**, **4** and **4a–d** show typical electronic spectra with two strong absorption regions, one of them in the UV region at about 300–350 nm (B band) and the other in the visible part of the spectrum around 600–700 nm (Q band) [19]. The Q band of all the compounds was attributed to the $\pi \rightarrow \pi^*$ transition from the highest occupied molecular orbital (HOMO) to the lowest unoccupied molecular orbital (LUMO) of the phthalocyanine (−2) ring [20,21]. The B band of all the phthalocyanines arise from the deeper π levels → LUMO transitions [20–22]. The electronic absorption spectrum of the metal-free phthalocyanine **2** exhibits a partly split Q band absorption at 699 and 667 nm, that of **3** at 704 and 682 nm and **4** at 681 and 644 nm. There is a shoulder at the slightly higher energy side for each phthalocyanine (**2**, **3** and **4**) at 638 nm, 646 nm and 619 nm, respectively. The B band of these pcs appeared in the UV region at 340 nm, 330 nm and 320 nm, respectively. The metallo derivatives (**2a–d**, **3a–d** and **4a–d**) show only an intense single Q band absorption for the $\pi \rightarrow \pi^*$ transitions at around 660–680 nm with weaker absorptions at around 609–620 nm. Weaker absorptions on the higher energy side of the Q bands are generally observed in the case of metallophthalocyanines, indicating the presence of aggregated species together with the monomeric ones which are essentially responsible for the intense absorption occurring in the main Q bands [2]. When the electronic spectra of the metal-free phthalocyanine (**2**), nickel and copper phthalocyanines (**2c–d**, **3c–d** and **4c–d**) were carefully examined, a clear difference from the usual phthalocyanines could be easily observed. The Q band of **2** was split into three peaks. The Q band of the nickel and copper phthalocyanines was split into two peaks (Fig. 1). At higher concentrations, the intensity of the higher energy peak corresponding to aggregated species increased while that of the monomeric ones at lower energy decreased. At lower concentrations, the intensity of the peak corresponding to monomeric species increased. ZnPc (unsubstituted) dye is characterized by a band with a maximum at 673 nm as observed in the literature for ZnPc [23]. The zinc metallophthalocyanines (**2b**, **3b**, and **4b**) showed a bathochromic shift of 6 nm, 10 nm, 7 nm, respectively. The B band absorptions of these pcs were observed at 356 nm, 360 nm and 353 nm, respectively (Fig. 2).

3.2. Electrochemistry

The solution redox properties of ligand **2** and its metal complexes (**2a**–**d**) were studied using cyclic voltammetry, differential pulse voltammetry and controlled potential chronocoulometry in DMSO on a platinum electrode. Voltammetric data and the assignment of the redox couples recorded for the ligand and its complexes are listed in Table 1.

Fig. 3 shows the cyclic voltammogram of the metal-free phthalocyanine **2** in DMSO containing TBAP. It gives three one-electron reduction processes labelled as R_1 at −0.65 V, R_2 at −0.96 V and R_3 at −1.78 V, and a one-electron oxidation process labelled as O_1 at 0.83 V vs. SCE at 0.100 V s^{-1} scan rate. Reduction and oxidation redox processes, usually associated with the transfer of one electron and thus the formation of anionic and cationic radicals, occur only at the ligand in metal-free phthalocyanines and in some metallophthalocyanines involving a redox-inactive metal center, while they occur both at the metal center and at the phthalocyanine ring in those with redox-active metal centers [6,24–30]. Thus, all the couples of **2** are assigned undoubtedly to the phthalocyanine ring. The ratio of the anodic to cathodic peak currents for these couples are usually close to unity, suggesting reversible redox processes. Anodic to cathodic peak separations

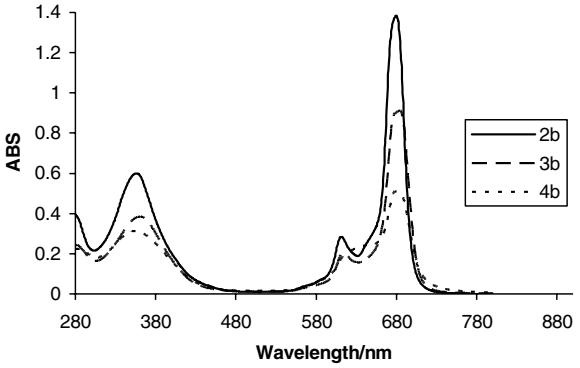

Fig. 2. Electronic spectra of **2b**, **3b** and **4b** in DMF.

(ΔE_p) changed from 0.050 to 0.160 V within the scan rates from 0.010 to 0.500 V s^{-1} (ΔE_p changed from 0.060 to 0.140 V for ferrocene), providing additional support for a reversible electron transfer. The peak currents increased linearly with the square root of the scan rates for scan rates ranging from 0.010 to 0.500 V s^{-1}, indicating purely diffusion-controlled behavior [31].

Voltammetric studies revealed that the redox behaviour of metallophthalocyanines **2b**, **2c** and **2d** is very similar to that of the metal-free phthalocyanine **2** (Table 1). The inset in Fig. 3 exemplifies a typical cyclic voltammogram of **2c**. This similarity suggests that all the one-electron redox processes of **2b**, **2c** and **2d** are phthalocyanine ring based. However, the redox potentials of these metallophthalocyanines occur usually at potentials slightly more negative as compared to **2**. The shift in the potentials can be attributed to the polarizing effect of the M(II) ions. When we compare the redox potentials of the phthalocyanines bearing four 4-phenyloxyacetic acid moieties with those of the relevant unsubstituted phthalocyanines in the literature [24] it is clear that the redox potentials of **2**, **2a**, **2b**, **2c** and **2d** shift to relatively more positive potentials, probably due to the electron withdrawing effect of the phenyloxyacetic acid substituents (Table 1). Reduction of the phthalocyanine ligand is associated with the position of the LUMO, whereas oxidation of the ligand is associated with the position of the HOMO. Thus, the difference between the potentials of the first oxidation and the first reduction processes ($\Delta E_{1/2}$) reflects the HOMO–LUMO gap for the metal free Pcs and it is closely related with the HOMO–LUMO gap in MPc species involving the redox inactive metal center. The $\Delta E_{1/2}$ values recorded for **2**, **2b**, **2c** and **2d** in this study are in agreement with the values reported previously for the relevant phthalocyanines [24].

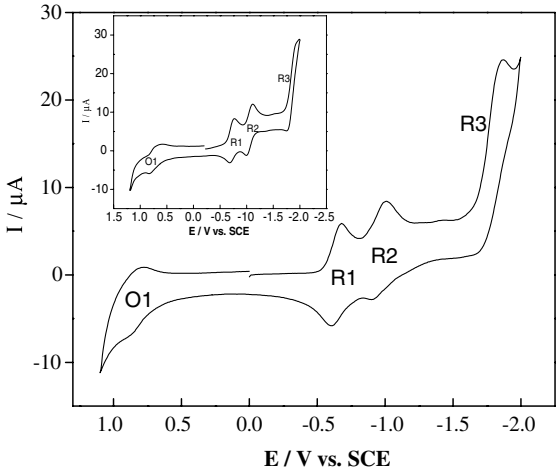

Fig. 3. Cyclic voltammogram of **2** and **2c** (inset) at 0.100 V s^{-1} in TBAP/DMSO.

Table 1
The electrochemical data of **2**, **2a**, **2b**, **2c** and **2d**

Complex	Redox processes	$E_{1/2}$ (V vs. SCE)[a]	ΔE_p (mV)[b]	I_{pa}/I_{pc}[c]	$\Delta E_{1/2}$ (V)[d]
2	R1	−0.65	0.070	0.96	1.48
	R2	−0.96	0.080	0.98	
	R3	−1.78	0.160	[e]	
	O1	0.83	0.060	[e]	
2a	R1	−0.37	0.100	1.00	0.82
	R2	−1.28	0.080	0.95	
	O1	0.45	0.100	0.94	
2b	R1	−0.73	0.080	0.96	1.44
	R2	−1.06	0.080	0.98	
	R3	−1.84	0.100	[e]	
	O1	0.71	0.120	1.00	
2c	R1	−0.72	0.080	0.94	1.45
	R2	−1.05	0.090	1.00	
	R3	−1.84	0.120	[e]	
	O1	0.73	0.140	0.98	
2d	R1	−0.71	0.090	0.94	1.45
	R2	−1.06	0.080	1.00	
	R3	−1.82	0.100	[e]	
	O1	0.74	0.150	0.98	

[a] $E_{1/2} = (E_{pa} + E_{pc})/2$ at 0.100 V s^{-1}.
[b] $\Delta E_p = E_{pa} - E_{pc}$ at 0.100 V s^{-1}.
[c] I_{pa}/I_{pc} for reduction, I_{pc}/I_{pa} for oxidation processes at 0.100 V s^{-1}.
[d] $\Delta E_{1/2} = E_{1/2}$(first oxidation) − $E_{1/2}$ (first reduction). This value reflects the HOMO–LUMO gap for the ligand and its complexes, except **2a**.
[e] ΔE_p could not be determined due to an ill-defined redox wave.

The redox potential of **2a** is considerably different as compared with that of **2**, **2b**, **2c** and **2d**. Fig. 4 shows the cyclic and differential pulse voltammograms of **2a** in DMSO containing TBAP. Within the electrochemical window of TBAP/DMSO, compound **2a** undergoes a quasi-reversible one-electron oxidation and two quasi-reversible one-electron reductions at 0.45, −0.37 and −1.28 versus SCE at 0.100 V s^{-1} scan rate, respectively. The difference in the voltammetric behaviour of **2a** is due to the fact that metallophthalocyanines such as MnPc, CoPc and FePc, having a metal that possesses energy levels lying between the HOMO and the LUMO of the phthalocyanine ligand, in general exhibit redox processes centered on the metal [24–26,28,29]. For CoPc complexes, the first oxidation and first reduction processes occur on the metal center in polar solvents such as DMF and DMSO, however the first oxidation process occurs on the Pc ring in non-polar solvents such as DCM and THF. Therefore, the first reduction and the first oxidation processes of **2a** could be

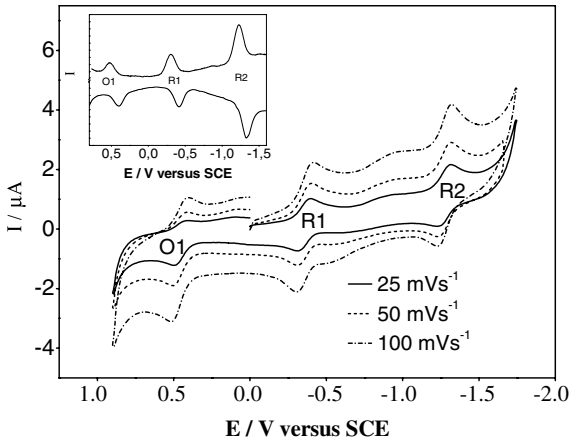

Fig. 4. Cyclic and differential pulse voltammograms of **2a** in TBAP/DMSO.

assigned easily to the $[Co(II)Pc(-2)]/[Co(I)Pc(-2)]^{1-}$ and $[Co(II)Pc(-2)]/[Co(III)Pc(-2)]^{+}$ redox couples and the second reduction process to the phthalocyanine ring as $[Co(I)Pc(-2)]^{-}/[Co(I)Pc(-3)]^{2-}$. The separation between the first oxidation and the first reduction potentials of the metal center (~0.82 V) is comparable with the relevant values in the literature [24–26,28,29], and does not reflect the HOMO–LUMO gap.

In conclusion, we have described the synthesis and spectral characterization of some new phthalocyanines with 4-phenyloxyacetic acid, *N*-benzyl-4-phenyloxyacetamide and octyl 4-phenyloxyacetate substituents on the periphery. Cyclic voltammetry of these compounds is also presented. Esterification of carboxy groups brings forward more soluble products in less polar solvents such as chloroform, THF and dichloromethane.

we report the syntheses, crystal structures, intra-and intermolecular second-sphere hydrogen-bonded interactions of five coordination compounds with mixed ligands of 4,4′-bipy and arenesulfonates, namely $[Zn_2(N,N'\text{-}4,4'\text{-bipy})(N\text{-}4,4'\text{-bipy})_2(H_2O)_8](bpds)_2 \cdot 5H_2O$ (**1**), $[Ag_2(N,N'\text{-}4,4'\text{-bipy})_2(bpds)]$ (**2**), $[Cd(N,N'\text{-}4,4'\text{-bipy})(H_2O)_4]_2(4\text{-abs})_4 \cdot 5H_2O$ (**3**), $[Cu(N,N'\text{-}4,4'\text{-bipy})(O\text{-bs})_2(H_2O)_2] \cdot 4H_2O$ (**4**), and $[Zn(N,N'\text{-}4,4'\text{-bipy})_2(H_2O)_2](4,4'\text{-bipy})(bs)_2 \cdot 4H_2O$ (**5**) (bpds = 4,4′-biphenyldisulfonate, 4-abs = 4-aminobenzenesulfonate, bs = benzenesulfonate).

2. Experimental

2.1. Materials and methods

All materials were commercially available and used as received. Elemental analyses were carried out with a Vario EL elemental analyzer. FTIR spectra were obtained on a Bruker EQUINOX 55 FTIR spectrometer with KBr pellets. TGA was performed using a Netzsch TG 209 analyzer in flowing nitrogen.

2.2. Syntheses and characterization

2.2.1. $[Zn_2(N,N'\text{-}4,4'\text{-bipy})(N\text{-}4,4'\text{-bipy})_2(H_2O)_8](bpds)_2 \cdot 5H_2O$ (1)

The aqueous solution of $Zn(CH_3COO)_2 \cdot 2H_2O$ (0.11 g, 0.5 mmol), 4,4′-bipy (0.10 g, 0.5 mmol) and Na_2(bpds) (0.18 g, 0.5 mmol) was stirred for 20 min at 50 °C. After filtration, a clear solution was obtained and allowed to stand at room temperature. Colorless crystals of **1** were collected after 6 days (yield: 66% based on Zn). *Anal*. Calc. for $C_{54}H_{66}N_6O_{25}S_4Zn_2$ (**1**): C, 44.48; H, 4.56; N, 5.71. Found: C, 44.31; H, 4.62; N, 5.79%. IR (cm^{-1}, KBr): 3363(s), 3055(w), 1636(s), 1603(s), 1501(m), 1490(m), 1414(s), 1297(m), 1200(s), 1124(s), 1074(s), 1032(s),1007(s), 833(m), 807(m), 700(s), 700(s), 629(s) 566(m).

2.2.2. $[Ag_2(N,N'\text{-}4,4'\text{-bipy})_2(bpds)]$ (2)

$AgNO_3$ (0.085 g, 0.5 mmol), Na_2(bpds) (0.18 g, 0.5 mmol), and 4,4′-bipy (0.10 g, 0.5 mmol) were dissolved in 10 mL of distilled water, and stirred for 30 min. The resulting solution was sealed in a Teflon-lined stainless autoclave and heated at 150 °C for 3 days under autogenous pressure, then cooled to room temperature. Purple crystals of **2** were collected in 40% yield (based on Ag). *Anal*. Calc. for $C_{16}H_{12}AgN_2O_3S$ (**2**): C, 45.73; H, 2.88; N, 6.67. Found: C, 45.65; H, 2.79; N, 6.59%. IR (cm^{-1}, KBr): 3468(s), 3041(w), 1598(s), 1551(m), 1510(m), 1411(s), 1384(s), 1208(s), 1131(s), 1041(s), 1028(s), 1012(m), 997(s), 806(s), 726(s), 712(m), 613(s), 568(s), 544(w).

2.2.3. $[Cd(N,N'\text{-}4,4'\text{-bipy})(H_2O)_4]_2(4\text{-abs})_4 \cdot 5H_2O$ (3)

$Cd(CH_3COO)_2 \cdot 2H_2O$ (0.133 g, 0.5 mmol), 4-abs (0.17 g, 1 mmol), and 4,4′-bipy (0.10 g, 0.5 mmol) were dissolved in a mixed solvent of distilled water and CH_3CN (V:V = 1:1), and stirred for 30 min. The pH of the resulting solution was adjusted to 7.0 by NaOH (0.1 M). After filtration, a clear solution was obtained and allowed to stand at room temperature. Purple crystals of **3** were collected in 55% yield (based on Cd). *Anal*. Calc. for $Cd_2C_{44}H_{66}N_8$- $O_{25}S_4$ (**3**): C, 36.19; H, 4.56; N, 7.67. Found: C, 36.28; H, 4.61; N, 7.62%. IR (cm^{-1}, KBr): 3406(s), 1611(s), 1698(s), 1535(s), 1498(s), 1414(s), 1208(s), 1131(s), 1070(s), 1040(s), 1015(s), 998(s), 823(m), 809(s), 725(s), 642(m), 616(s), 570(s).

2.2.4. $[Cu(N,N'\text{-}4,4'\text{-bipy})(O\text{-bs})_2(H_2O)_2] \cdot 4H_2O$ (4)

The procedure used to synthesize compounds **4** and **5** was the same as that of compound **2**. The yield was 30% based on Cu. *Anal*. Calc. for $CuC_{22}H_{30}N_2O_{12}S_2$ (**4**): C, 41.15; H, 4.71; N, 4.36. Found: C, 41.20; H, 4.78; N,

2.3. X-ray crystallography

Single crystals were mounted on a Bruker Smart CCD using Mo Kα radiation and a graphite monochromator at room temperature for compounds **1**, **2**, **4** and **5**, and at 173 K for compound **3**. Absorption corrections were performed by using the SADABS program [12]. All the structures were solved by direct methods and refined by full-matrix least-squares fitting on F^2 by SHEXLS [13,14]. All of the non-hydrogen atoms were refined anisotropically. Hydrogen atoms attached to C atoms and N atoms were located at geometrically calculated positions and refined with isotropic thermal parameters. Hydrogen atoms of water molecules in the structures of **4** and **5** were located from the difference Fourier map at the final state of refinement, and refined as riding atoms with coordinates riding on the oxygen atoms to which they are attached. The hydrogen atoms of water molecules in the structures of **1** and **3** could not be located from the difference Fourier map. The crystallographic data are given in Table 1. Selected bond distances and angles are shown in Table 2.

3. Results and discussion

3.1. Thermal analyses

molecules in the temperature range of 114–216 °C (Calc: 6.1%, 9.9%, Found: 6.2%, 5.7%), and another weight loss of 26.2% (Calc: 32.1%) at 331 °C, contributed by the release of 4,4′-bipy. TGA result of compound **2** reveals that it is stable until 320 °C. There is a successive weight loss of 37.4% (Calc: 37.1%) in the range of 320–386 °C, and another weight loss of 24.4% (Calc: 33.3%) at 552 °C, contributed by the release of 4,4′-bipy and decomposition of bpds, respectively. Compound **3** releases the lattice water molecules and the coordinated water molecules in multiple steps in the temperature range of 68–180 °C (Found: 16.2%, Calc: 15.9%), with the second batch of release followed by the loss of 4,4′-bipy (Found: 21.3%, Calc: 21.4%), and decomposition of 4-abs at 309 °C and 524 °C, respectively. TGA curve of compound **4** shows a successive weight loss in the range of 69–700 °C, where compound **4** releases the lattice water molecules and the coordinated water molecules in 69–173 °C (Found: 16.8%, Calc: 16.9%), and losses 4,4′-bipy in multiple steps in the range of 190–270 °C (Found: 27.1%, Calc: 24.3%). Compound **5** releases the lattice water molecules and the coordinated water molecules in multiple steps in the range of 90–180 °C (Found: 9.9%, Calc: 11.3%), and losses the 4,4′-bipy molecules in multiple steps in the range of 250–600 °C (Found: 49.9%, Calc: 44.7%) with the decomposition of the framework.

After the removal of the clathrate water molecules, PXRD patterns show that compounds **1**, **3**, **4** and **5** lose their identity as a network.

3.2. Description of the structures

The structure of $[Zn_2(N,N'\text{-}4,4'\text{-bipy})(N\text{-}4,4'\text{-bipy})_2(H_2O)_8](bpds)_2 \cdot 5H_2O$ (**1**) is shown in Fig. 1a. It is a binuclear octahedral metal complex constructed by two Zn centers linked by one μ_2 4,4′-bipy bridging ligand (Zn–N3 = 2.224 Å). Each Zn center is further coordinated by one monodentate 4,4′-bipy ligand (Zn–N1 = 2.199 Å) and four aqua molecules (Zn–O = 2.117–2.174 Å). The angles of *cis* O–Zn–O are in the range of 87.71–92.16°, indicating that the octahedral geometry is distorted slightly. The pyridine ring of the bridging 4,4′-bipy ligand is coplanar, while the monodentate 4,4′-bipy ligand is twisted by 22.79°. Bpds exists as a counter anion with the aryl rings twisted by 38.07°. The $[Zn_2(N,N'\text{-}4,4'\text{-bipy})(N\text{-}4,4'\text{-bipy})_2(H_2O)_8]$ complex units are linked by the lattice water molecules via hydrogen bonds formed between the coordinated water molecules and the lattice water molecules (Ow1···Ow6 = 2.731 Å, Ow2···Ow7 = 2.720 Å), between the lattice water molecules (Ow7···Ow6 = 3.192 Å), and between the lattice water molecules and N atoms from the 4,4′-bipy ligands (N2···Ow6 = 2.811 Å), resulting in 2D cationic sheets as shown in Fig. 1b. The bpds anions are located between the hydrogen-bonded sheets, and connect the sheets via hydrogen bonds formed between the sulfonate oxygen atoms and the coordinated water molecules [O3···Ow3 = 2.891 Å, Ow4···O6 = 2.841 Å, O6···Ow3 = 2.772 Å], and between the sulfonate oxygen atoms and the lattice water molecules [O3…Ow7 = 2.879 Å, O4···Ow5 = 2.892 Å, O1···Ow6 = 2.999 Å], finally generating 3D hydrogen bonding networks.

Compound $[Ag_2(N,N'\text{-}4,4'\text{-bipy})_2(bpds)]$ (**2**) forms 1D chains as shown in Fig. 2a. The 4,4′-bipy ligands bridge the Ag centres with Ag1–N1 = 2.180 Å and Ag1–N2 = 2.170 Å to form 1D Ag-bipy chains similar to those reported previously [15]. There are weak coordination interactions between Ag and the sulfonate oxygen atoms (Ag1–O1 = 2.832 Å, Ag1A–O2 = 2.856 Å, Fig. 2a). The pyridyl rings of the 4,4′-bipy ligand are twisted by 29.38°. The aryl rings of bpds anion are coplanar, which is different from that observed in compound **1**. The most interesting features of this structure are that Ag–Ag interactions are formed between the 1D chains which are generated by inversion centers (Ag–Ag = 3.398 Å), resulting in 1D ribbons. As shown in Fig. 2b, these ribbons are connected by bpds via weak coordination interactions between Ag and the sulfonate groups, generating a 2D layered structure. π···π interactions between layers, formed by the bipy ligands with distance of 3.46 Å, are also observed.

The asymmetric unit of $[Cd(N,N'\text{-}4,4'\text{-bipy})(H_2O)_4]_2(4\text{-abs})_4 \cdot 5H_2O$ (**3**) is shown in Fig. 3a. There are four independent 4-abs anions in the asymmetric unit. The Cd centre is coordinated by four water molecules and two N atoms from two different bipy ligands, resulting in infinite chains

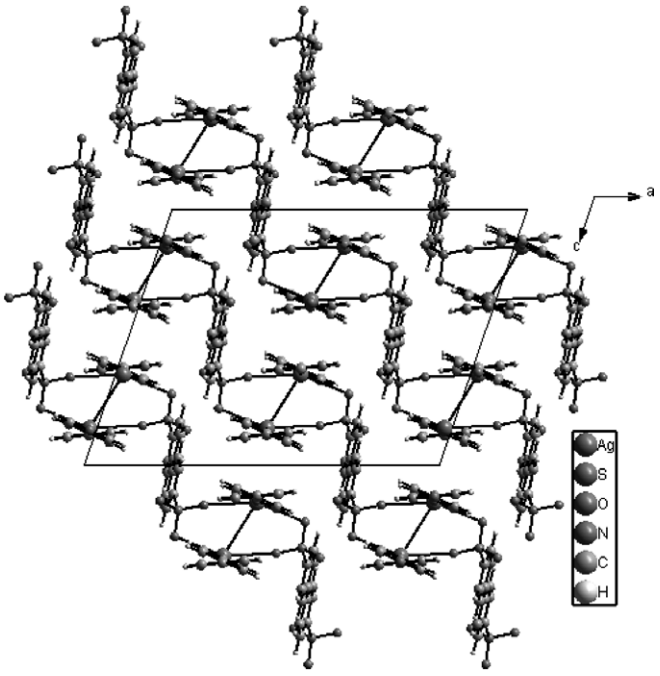

Fig. 2b. Packing structure of compound **2** along *b* axis.

packing alone the crystallographic *c* axis. The Cd–N bond lengths are in the range of 2.312–2.327 Å. The Cd–Ow bond lengths are in the range of 2.247–2.352 Å. The angles of *cis* O–Cd–O are in the range of 83.48–94.46°. The pyridyl rings of 4,4′-bipy are twisted with dihedral angles of 10.96° and 10.00°, respectively. Six 4-abs anions arranged in head-to-tail fashion are held together via hydrogen-bonding interactions between N atoms and the sulfonate oxygen atoms of 4-abs [N5···O11 = 3.009 Å, N6···O8 = 3.059 Å, N7···O6 = 3.225 Å, N7···O10 = 3.238 Å, N8···O3 = 3.094 Å], between the lattice water molecules and N atoms of 4-abs [N5···Ow9 = 3.037 Å, N7···Ow13 = 3.109 Å, N8···Ow11 = 2.946 Å], and between the sulfonate oxygen atoms and the lattice water molecules (O···Ow = 2.760 Å), to produce hexameric aggregates. These hexameric aggregates are furthered connected via hydrogen bonds to formed 1D columns running along crystallographic *c* axis. The [Cd(4,4′-bipy)$_2$(H$_2$O)$_4$] chains are located inside the hexameric channels formed by the 4-abs anions and water molecules, as shown in Fig. 3b.

The structure of [Cu(*N*,*N*′-4,4′-bipy)(*O*-bs)$_2$(H$_2$O)$_2$]·4H$_2$O (**4**) is shown in Fig. 4a. The Cu atom is coordinated by two water molecules (Cu–O = 1.980 Å), two sulfonate groups of the bs ligands (Cu–O = 2.382 Å), and two nitrogen atoms from two bridging 4,4′-bipy ligands (Cu–N = 2.027 Å), and form a 1D polymeric structure. The pyridyl rings of 4,4′-bipy are coplanar, which is different from that observed in compound **3**. The bs ligands are located between the chains in head to head fashion and connect

the chains through hydrogen bonds between the uncoordinated sulfonate oxygen atoms and the coordinated water molecules [O2···O1w = 2.893 Å, O1w···O2 = 2.859 Å] to form 2D hydrogen-bonded square grids as shown in Fig. 4b. The square cavity has dimensions of 11.487 × 7.75 Å which hosts a pair of phenyl rings from the bs ligands. The lattice water molecules are located between hydrogen-bonded layers, which are anchored by extensive hydrogen bonds formed with the sulfonate groups and coordinated water molecules.

Compounds [Zn(*N*,*N*′-4,4′-bipy)$_2$(H$_2$O)$_2$](4,4′-bipy)(bs)$_2$ · 4H$_2$O (**5**) and [Cu(*N*,*N*′-4,4′-bipy)(*O*-bs)$_2$(H$_2$O)$_2$] · 4H$_2$O (**4**) have the same ligand components and synthesized via similar procedures. Interestingly, a total different structural topology is adopted in compound **5** and the structure is shown in Fig. 5a. The Zn centre is six-coordinated by two aqua ligands (Zn–O = 2.133 Å) and four nitrogen atoms from four different bipy bridging ligands (Zn–N = 2.147–2.211 Å), resulting in a 2D grid structure as shown in Fig. 5b. The grid structure is similar to those reported by Chen [16,17]. The square cavity has dimensions of 11.146 × 11.383 Å and accommodates a pair of centrosymmetrically-orientated bs anions with the hydrophobic groups embedded in the cavity. The separation of the two aryl groups is 3.518 Å, indicating that there is weak aromatic interaction between these bs anions. Aside from the aromatic interactions, the bs anions also make contact with the host

grids through C–H···π interactions, and form hydrogen bonds with the lattice water molecules. The uncoordinated bipy ligands are located between the coordination layers and anchored by hydrogen bonds formed with the lattice water molecules (Ow2···N4 = 2.891 Å), as shown in Fig. 5c.

4. Conclusions

Compounds **1**–**5** show structural varieties to a great extend and there are three different coordination modes adopted by both the 4,4′-bipy ligand and the sulfonate molecules. The 4,4′-bipy molecule presents both as a monodentate and μ_2 bridging ligand in compound **1**, solely as a μ_2 bridging ligand in compounds **2**–**4**, and a μ_2 bridging ligand and an intercalated molecule in compound **5**. The sulfonate molecules do not have any direct interactions with the metal centers in compounds **1**, **3** and **5**. In compound **2**, both of the sulfonate groups of the bpds ligand form weak coordination interactions in η_2 fashion to Ag. While in compound **3**, the sulfonate group of the bs ligand coordinates monodentately to Cu.

4,4′-Bipy is a well-studied rigid ligand with μ_2 bridging as the most commonly observed coordination mode. In comparison, sulfonates are soft ligands with flexible coordination behaviors. Our results demonstrate that by adopting rigid and soft ligands, coordination complexes with diversified structural frameworks could be produced; and the presence of sulfonates, either as counter anions or soft ligands, can diversify the extended structures formed by the strong transition metal-bipy interactions. For instance, in compound **1**, a discrete binuclear complex is formed in which the bipy ligand shows two different coordination modes to Zn(II). In compounds **2**–**4**, conventional 1D chains are formed by the μ_2 bridging 4,4′-bipy ligands, and further extended into 3D structures via Ag–Ag and Ag–sulfonate interactions in compound **2**. While in **5**, a unique 2D grid layered structure is constructed by two bridging 4,-4′-bipy ligands, and free 4,4′-bipy molecules are intercalated between the layers.

Finally, it is interesting to note that, even in the presence of strong and dominant ligands such as water molecules and 4,4′-bipy, the bulky arenesulfonate can still form coordination interactions with transition metals such as in compounds **2** and **4**, and adjusting the formation of the extended framework via strong hydrogen bonds.

Phenylazoimidazole (**i**) Naphthylazoimidazole (**ii**)

2. Experimental

2.1. Reagents/materials

The complexes were prepared by a reported procedure [19,20]. 8-Quinolinol (SRL, Mumbai) was purified by recrystallization from a hot ethanol solution. Acetonitrile (MeCN) was purified by a known procedure [21,22]. All kinetic and spectroscopic measurements were recorded on an Agilent 8453E UV–visible Spectroscopy System. Quartz cells (1.0 cm path length) from Hellma were used. IR spectra (KBr pellet) were recorded on a FT-IR spectrophotometer Spectrum RX1, Perkin–Elmer. ^{1}H NMR spectra were drawn from a 300 MHz Bruker NMR instrument in CD_3CN using TMS as an internal standard. Microanalyses were carried out on a Perkin–Elmer 2400 CHN elemental analyzer. The specific conductance was measured on a JENCONS 4010 Conductivity Meter. The pH was measured on a SYSTRONICS 361 Digital pH meter. Rate constants and standard deviations were calculated by linear regression using a PC-based program, Microcal-origin version Origin-6.1.

2.1.1. Kinetic measurements

For kinetic measurements, stock solutions of the complexes (*ca.* 10^{-3} mol dm^{-3}) and of 8-quinolinol (HQ) (*ca.* 10^{-2} mol dm^{-3}) were prepared in dry MeCN. Solutions of different concentrations were prepared by quantitative dilution of stock solutions using dry MeCN. All experiments were performed at 298 K (unless otherwise mentioned) by mixing required volumes of the thermostated reactants and transferring the mixture to the absorption cell (1.0 cm length). On addition of 8-quinolinol (HQ) to the solution of Pd(NaiR)Cl_2 in MeCN, the orange solution changed to yellow-orange. The influence of the addition of 8-quinolinol on the spectra of Pd(α-NaiR)Cl_2 is shown in the Fig. 1. The change proceeds through a single isobestic point at *ca.* 472 nm. The decrease in absorbance of the reaction mixture was recorded automatically at *ca.* 500 nm as a function of time (s). A_∞ was measured after ~24 h of mixing, when the absorbance became constant. In all experiments, the initial molar concentration of HQ, $[HQ]_0$, was kept at least ten times in excess so as to maintain a pseudo-first-order kinetic condition. Pseudo-first-order rate constants, k_{obs}, were obtained from the plots of $(A_t - A_\infty)$ versus time (s) (Fig. 2) where A_t = absorbance of the reaction mixture at time t (s) after mixing of the HQ solution and A_∞ = absorbance of same reaction mixture after completion of the reaction.

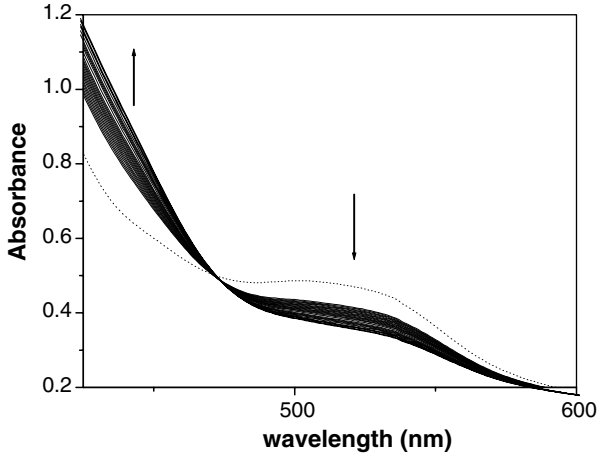

Fig. 1. Spectra of Pd(α-NaiMe)Cl_2in MeCN and a reaction mixture of Pd(α-NaiMe)Cl_2 and HQ in MeCN solution at 298 K. The arrows indicate the decrease and increase of band intensities as the reaction proceeds.

2.2. Synthesis of [Pd(α-/β-NaiR)(Q)](ClO$_4$) (α-NaiR, **3**; β-NaiR, **4**)

A representative synthesis of [Pd(α-NaiMe)(Q)](ClO_4) (**3a**) is given below.

To a MeCN solution of the complex Pd(α-NaiMe)Cl_2 (0.025 g, 6.05×10^{-2} mmol), HQ (0.026 g, 18.15×10^{-2} mmol) was added and the orange colored solution was stirred for about 24 h. It was filtered and allowed to evaporate to dryness at room temperature. The mass was then dissolved in MeOH, and $NaClO_4$ (aq) (1 g) was added to it. The brown precipitate that formed was filtered and washed

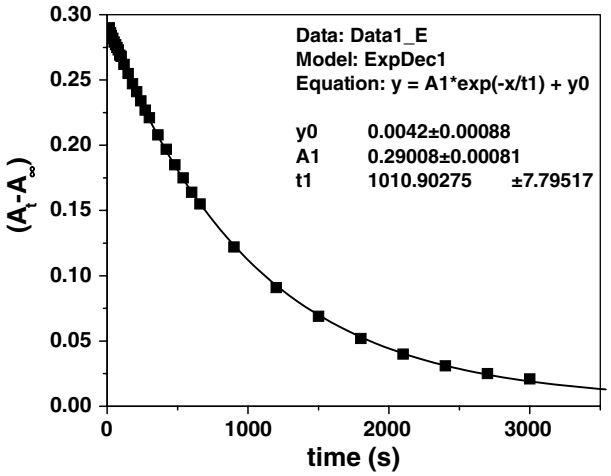

Fig. 2. Plot of $(A_t - A_\infty)$ vs. time (s) for the reaction: [Pd(α-NaiMe)Cl_2]$_0 = 1.09 \times 10^{-4}$ mol dm^{-3}, $[HQ]_0 = 3 \times 10^{-3}$ mol dm^{-3} and temperature = 298 K.

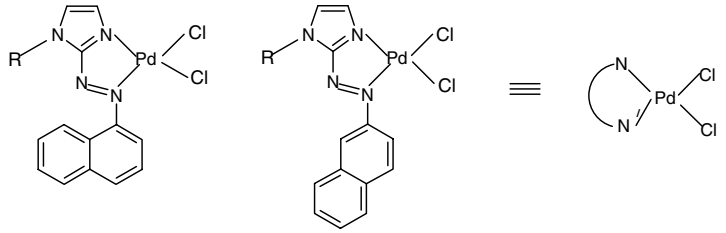
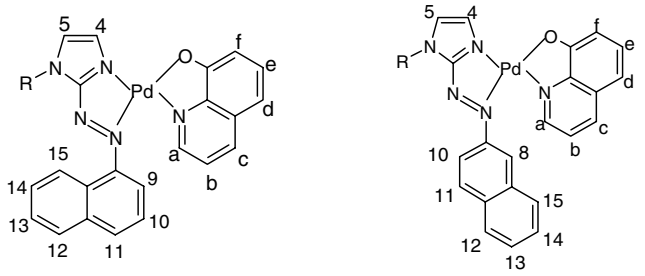
with water. The dried product was then chromatographed over silica gel and MeCN eluted an orange band. Yield: 0.023 g (64.7%).

All other complexes were prepared by the same procedure and the yields varied within 60–70%.



Microanalytical data of the complexes are as follows: For [Pd(α-NaiMe)(Q)][ClO_4) (**3a**): *Anal.* Found: C, 47.00; H, 3.02; N, 11.79%. Calc. for $C_{23}H_{18}O_5N_5PdCl$: C, 47.10; H, 3.07; N, 11.95. For [Pd(α-NaiEt)(Q)][ClO_4) (**3b**) *Anal.* Found: C, 48.08; H, 3.30; N,11.71%. Calc. for $C_{29}H_{22}O_5N_5PdCl$: C, 52.58; H, 3.32; N, 10.58.

3. Results and discussion



3.1. Kinetics and mechanism

Two classes of naphthylazoimidazole complexes of palladium(II) have been used in this work. They are Pd(α-NaiR)Cl_2 (**1**) (α-NaiR = 1-alkyl-2-(naphthyl-α-azo)-imidazole) and Pd(β-NaiR)Cl_2 (**2**) (β-NaiR = 1-alkyl-2-(naphthyl-β-azo)imidazole) [where R = Me (**a**)/Et (**b**)/Bz (**c**)]. The ligands belong to the unsymmetric bidentate *N*,*N*′-donor type and form dichloropalladium(II) complexes, here after we abbreviate the complexes as Pd(*N*,*N*′)Cl_2 (Scheme 1). The reaction kinetics between Pd(*N*,*N*′)Cl_2 and 8-quinolinol (HQ) was examined spectrophotometrically. The reaction is first order in Pd(II) complex as k_{obs}-values are almost constant when all variants are constant except the complex concentration. The k_{obs}-values (Table 1) and the linear plots for the k_{obs} versus $[HQ]_0$ (Figs. 3 and 4) indicate the reaction is first order in HQ. The slope of the plot is the second order rate constant (k_2) of the reaction. The presence of a defined intercept (k_0) indicates the existence of a minor solvent assisted path to the overall reaction products (MeCN is a coordinating solvent).

The rate increases with a rise in temperature, as expected from the Eyring equation. Activation parameters, standard enthalpy of activation ($\Delta^{\ddagger}H^{\circ}$) and standard entropy of activation ($\Delta^{\ddagger}S^{\circ}$) were calculated from Eyring plots (Figs. 5 and 6) and are recorded in Table 2. The $\Delta^{\ddagger}H^{\circ}$ value is actually the sum of the $\Delta^{\ddagger}H^{\circ}$ value for the reaction (for the pre-equilibrium step) and the $\Delta^{\ddagger}H^{\circ}$ value for the second Cl^- displacement. The same is true for the $\Delta^{\ddagger}S^{\circ}$ value also. The activation parameter values corroborate with the experimental k_2-values. The order for $\Delta^{\ddagger}H^{\circ}$ and $\Delta^{\ddagger}S^{\circ}$ are: Pd(NaiEt)Cl_2 > Pd(NaiMe)Cl_2 > Pd(NaiBz)Cl_2 and Pd-(α-NaiR) > Pd(β-NaiR). The iso-kinetic plot (Fig. 7) supports an identical mechanism for the reaction of Pd(*N*,*N*′)Cl_2 with HQ. Kinetic studies in the presence of

Pd(α-NaiR)Cl_2 (**1**) Pd(β-NaiR)Cl_2 (**2**) Pd(N,N′)Cl_2

R = Me (**a**), Et (**b**), CH_2Ph (**c**)

[Pd(α-NaiR)(Q)][ClO_4) (**3**) [Pd(β- NaiR)(Q)][ClO_4) (**4**)

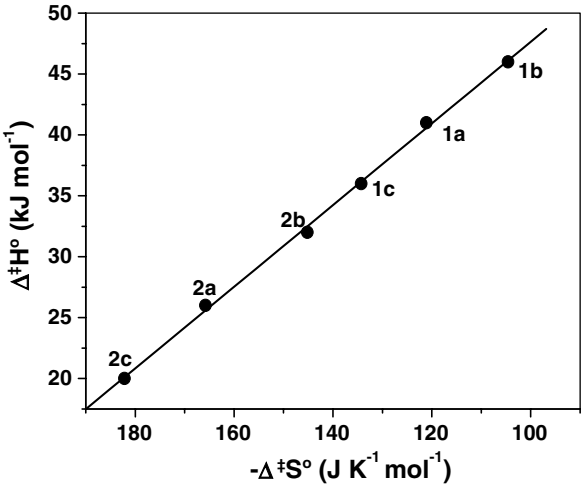
of the second Pd–Cl bond is the rate controlling process and the dissociation of the first Pd–Cl bond is affected by externally added Cl^- ion. The product was isolated and characterized as [Pd(*N*,*N*′)(Q)]ClO_4. The nucleophilic substitution process involves direct displacement of 2 Cl^- ions by 8-quinolinol (Eq. (1)). In the acetonitrile medium, HQ will exist largely in the undissociated form [23].

(1)

The observed rate is

$$\text{Rate} = \{k_0 + k_2[\text{HQ}]_0\}[\text{Pd(R′aiR)Cl}_2] = k_{\text{obs}}[\text{Pd(R′aiR)Cl}_2]$$

(where $k_2 = \frac{kK1}{[\text{Cl}^-]_0}$ = constant at constant $[\text{Cl}^-]_0$ and $k_{\text{obs}} = k_0 + k_2[\text{HQ}]_0$). The k_0 and k_2 are the intercept and the slope of the plot of k_{obs} versus $[\text{HQ}]_0$ respectively. The nucleophile is a undissociated N,OH donor ligand. It is probable that the highly negative O donor will coordinate first with the positively charged metal center, with fast dissociation



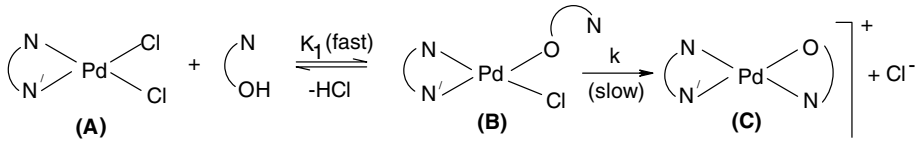


Fig. 7. Plot of $\Delta^{\ddagger}H^{\circ}$ vs. $\Delta^{\ddagger}S^{\circ}$ i.e. iso-kinetic plot for the reactions: Pd(R′aiR)Cl_2 + HQ in MeCN.

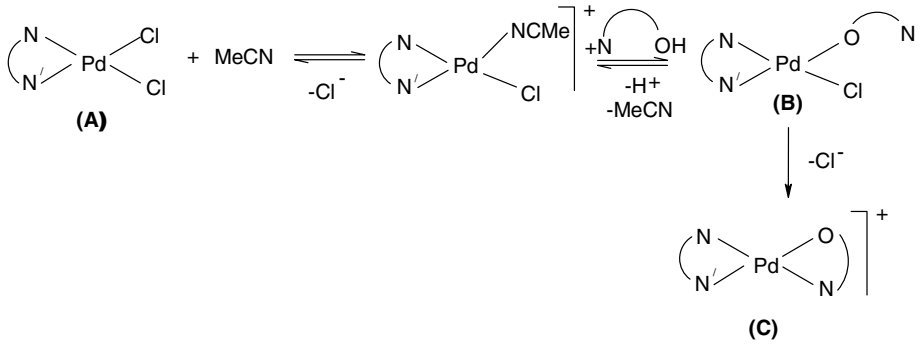
$[\text{Pd(R′aiR)Cl}_2]_0 = 1.00 \times 10^{-4}$ mol dm^{-3}, $[\text{HQ}]_0 = 5.00 \times 10^{-3}$ mol dm^{-3}.



Scheme 2.

of the first Pd–Cl bond, and finally forms a stable four coordinated square planar intermediate complex (**B**). Then quinoline-N (which remains free in **B**) slowly coordinates with Pd(II) as a compulsion of chelate stability. Obviously the latter rate is slower than the former rate. Therefore the second Pd–Cl bond cleavage is the rate-determining step. This is also supported by the effect of externally added Cl^- ions (LiCl). A plausible mechanism is given in Scheme 2. There are two parallel pathways: one is the existence of a minor solvent assisted path where MeCN substitutes Cl^- initially, then MeCN is displaced by HQ and finally forms the reaction product (**C**) (Scheme 3). Although the steric crowding of the α-/β-naphthyl group in the N,N' chelating ligand is significant, its electron withdrawing property, due to conjugation, stabilizes the Pd(N,N') chelated species in preference to de-chelation.

The kinetic data in Table 1 reveal that the magnitude of k increases in the order Pd(α-NaiEt)Cl_2 < Pd(α-NaiMe)Cl_2 < Pd(α-NaiBz)Cl_2. This is because the electron withdrawing tendency of the Bz group is greater than Me, which in turn is slightly greater than Et.

3.2. Product characterization

To a MeCN solution of the complex Pd(N,N')Cl_2, HQ was added and the orange colored solution was stirred for about 24 h. It was filtered and allowed to evaporate almost to dryness at room temperature. The mass so produced was then dissolved in MeOH and $NaClO_4$ (aq) was added. A brown precipitate formed which was filtered and then washed with water and cold MeCN. The dried product was chromatographed over silica gel and MeCN eluted an orange-red band. Finally the dried product was characterized by micro-analytical data (experimental section), UV–Vis, IR. (Table 4) and ^{1}H NMR (Table 5) spectral data. The molar conductance data in MeCN solution (Λ_M = 75–90 S cm^2 mol^{-1}) show a 1:1 electrolytic nature of the complexes. The IR spectra of the complexes display a sharp stretch at 1360–1375 cm^{-1} which corresponds to ν(N=N) and is red shifted by 5–10 cm^{-1} from that of Pd(NaiR)Cl_2 [24]. This may be attributed to the charge delocalization from coordinated Q^- to the chelated NaiR motif. The binding is indirectly established by the disap-

[i] Broad singlet.
[j] Doublet.
[k] Multiplet.

pearance of two *ν*(Pd–Cl) bands corresponding to the *cis*-$PdCl_2$ configuration [24–26] and the appearance of new bands at 1560–1570 and 480–500 cm^{-1} due to *ν*(C–O) and *ν*(Pd–O), respectively. All the complexes exhibit a structureless band at 1090–1100 cm^{-1} corresponding to *ν*(ClO_4), suggesting the lack of any significant interaction in the solid state [27].

The solution electronic spectra of the complexes were recorded in the range 900–200 nm in MeCN. The absorptions below 400 nm are due to intramolecular charge transfer and are not considered further. Two absorptions at 475–485 and 515–525 nm (Fig. 8), absent in the free ligands, may represent charge transfer transitions localized on the metallated fragment [28].

The ^{1}H NMR spectra of the complexes were recorded in CD_3CN and the data are collected in Table 5. The proton numbering pattern is shown in Scheme 1. The data reveal that the signals in the spectra of the complexes are shifted downfield relative to the free ligand values [18]. This supports the coordination of the ligand to Pd(II). An important feature of the spectra is the shifting of the imidazole protons 4-H and 5-H to lower *δ*-values, in general, relative to the naphthyl protons (6-H–13-H). The imidazole protons suffer downfield shifting by 0.1-0.2 ppm compared to the free ligand positions. This supports the strong preference of imidazole-N binding to Pd(II). The naphthyl protons appear as multiplets, except a broad singlet for 6-H and doublet for 8-H in [Pd(β-NaiR)(Q)](ClO$_4$) and a

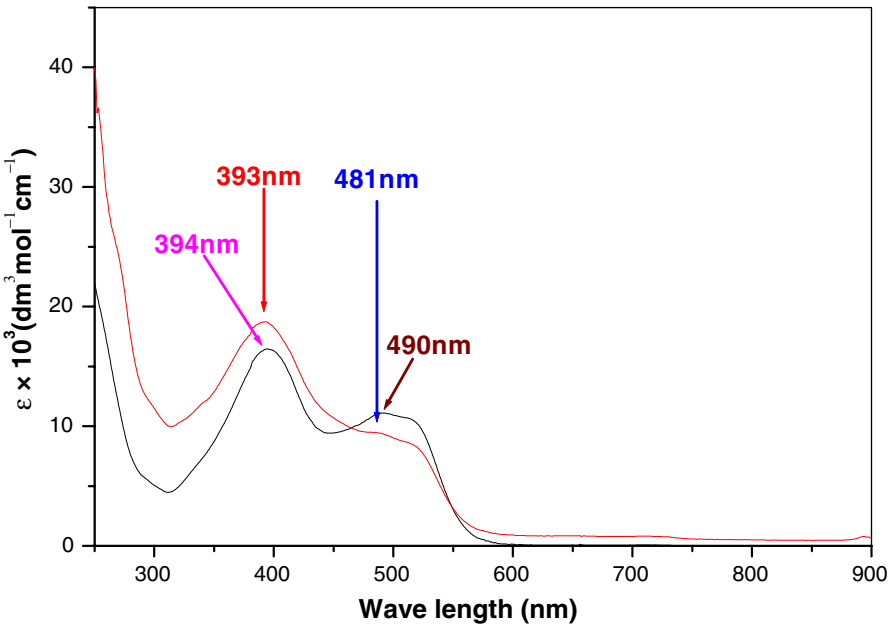

Fig. 8. UV–Vis spectra of [Pd(β-NaiMe)Cl$_2$] (black line) and [Pd(β-NaiMe)(Q)](ClO$_4$) (red line) in MeCN solution. (For interpretation of the references in color in this figure legend, the reader is referred to the web version of this article.)

doublet for 15-H in all the complexes. The 1-alkyl group appears as a singlet for 1-Me in [Pd(α/β-NaiMe)(Q)](ClO$_4$), a quartet for –N–CH$_2$– and a triplet for the –CH$_3$ group in [Pd(α/β-NaiEt)(Q)](ClO$_4$) and a singlet for –CH$_2$– and benzyl protons in the [Pd(α/β-NaiCH$_2$Ph)(Q)](ClO$_4$) complexes.

4. Conclusion

The kinetics of the reactions between Pd(*N*,*N*′)Cl$_2$ and 8-quinolinol (HQ) were examined spectrophotometrically at 500 nm under pseudo-first-order conditions in MeCN. The reactions are first order with respect to the complex and HQ. The rate of the reaction is largely influenced by the π-acidity of the chelating ligand; substitution in the naphthylazoimidazole backbone influences the rate of the substitution process significantly. Activation parameters $\Delta^{\ddagger}H^{\circ}$ and $\Delta^{\ddagger}S^{\circ}$ of the reactions were measured, which corroborates the kinetic rate data. The products isolated from the reaction between Pd(NaiR)Cl$_2$ and HQ in MeCN have been characterized by spectral data and support the composition [Pd(NaiR)(Q)](ClO$_4$).

has an axial ligand such as chlorine, or by introducing bulky peripheral substituents. Bulky peripheral groups prevent an effective π–π interaction between the phthalocyanine subunits [19]. In light of this, (chloro)gallium(III) phthalocyanine derivatives with chlorine atoms at axial positions and bulky peripheral substituents should show no aggregation in solution. The syntheses, photophysical and photochemical studies on some new (chloro)gallium phthalocyanine derivatives are hereby presented.

2. Experimental

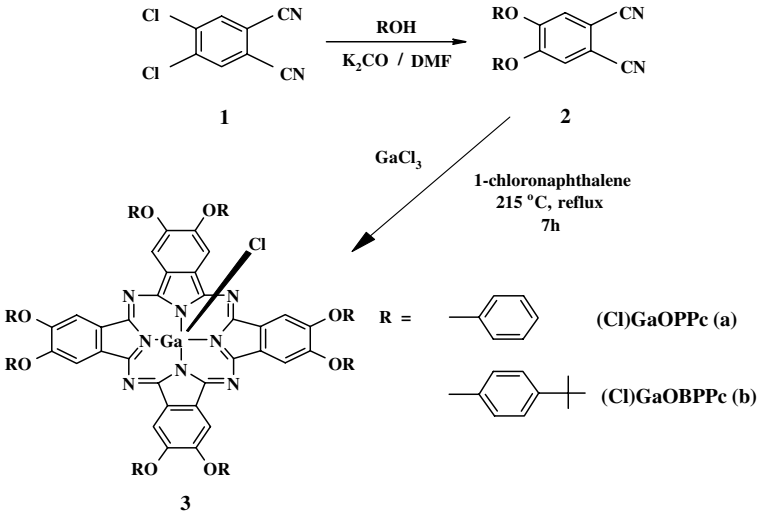
2.1. Materials

2.1.1. Syntheses

Acetic anhydride (Ac_2O), acetone, ammonia solution (NH_4OH), methanol (MeOH), 1-chloronaphthalene, hexane and deuterated chloroform ($CDCl_3$) were obtained commercially and dried before use; formamide ($HCONH_2$), potassium carbonate (K_2CO_3), phthalonitrile, thionyl chloride ($SOCl_2$), phenol and 4-*tert*-butylphenol were purchased from Aldrich and used as received. 4,5-Dichloro-1,2-dicyanobenzene [20] and unsubstituted (chloro)gallium(III)phthalocyanine [21] were synthesized and purified according to the literature procedures.

2.1.2. Photophysics and photochemistry

Zinc(II) phthalocyanine (ZnPc), chlorophyll *a* and 1,3-diphenylisobenzofuran (DPBF) were obtained from Aldrich. Chloroform ($CHCl_3$) dimethylsulfoxide (DMSO), *N*,*N*′-dimethylformamide (DMF, freshly distilled), tetrahydrofuran (THF) and toluene were purchased from SAARCHEM, and dried in alumina before use.



2.2. Equipment

Column chromatography was performed on silica gel 60 (0.04–0.063 mm) and preparative thin layer chromatography was performed on silica gel 60 P F_{254}. Ground state electronic absorption spectra were performed on a Varian Cary 500 UV–Vis–NIR spectrophotometer; infra-red spectra (KBr pellets) on Perkin–Elmer Spectrum 2000 FT-IR spectrometer and ^1H NMR on a Bruker EMX 400 NMR spectrometer. Fluorescence excitation and emission spectra were recorded on a Varian Cary Eclipse Fluorescence spectrophotometer. Photo-irradiations were done using a General electric Quartz line lamp (300 W). A 600 nm glass cut off filter (Schott) and a water filter were used to filter off ultraviolet and infrared radiations, respectively. An interference filter (Intor, 670 nm with a band width of 40 nm) was additionally placed in the light path before the sample. Light intensities were measured with a POWER MAX 5100 (Molelectron detector incorporated) power meter. Triplet absorption and decay kinetics were recorded on a laser flash photolysis system. The excitation pulses were produced by a Nd:YAG laser (Quanta-Ray, 1.5 J/90 ns)-pumped tunable dye laser (Lambda Physic FL 3002, Pyridine 1 dye in methanol). The analyzing beam source was from a Thermo Oriel xenon arc lamp, and a photomultiplier tube (PMT) was used as the detector. Signals were recorded with a Tektronix TDS 360 two-channel digital real-time oscilloscope. Triplet lifetimes were determined by exponential fitting of the kinetic curves using OriginPro 7.5 software.

2.3. Syntheses

2.3.1. Synthesis of 4,5-bis(phenoxy)-1,2-dicyanobenzene (*2a*) (Scheme 1)

4,5-Bis(phenoxy)-1,2-dicyanobenzene (**2a**) was synthesized from 4,5-dichloro-1,2-dicyanobenzene (**1**) and phenol in dried DMSO as reported before [20]. The amounts of the reagents employed were: 4,5-dichloro-1,2-dicyanobenzene (4.01 g, 20 mmol), phenol (3.76 g, 40 mmol), K_2CO_3 (13.8 g, 100 mmol) and dried DMSO (40 ml). Yield: 3.24 g (52%); IR (KBr): ν_{max}/cm^{-1}; 3040–3051 (Ar-H),

Scheme 1. Synthetic pathway to octa-substituted phenoxy and *tert*-butylphenoxy phthalocyaninato gallium chloride.

2237 (C≡N), 1209 (C–O–C); ^{1}H NMR: (DMSO-d_6) δ, ppm; 7.7 (2H, s, Ar-H), 7.4 (4H, t, Ar-H), 7.2 (2H, t, Ar-H), 7.1 (4H, d, Ar-H).

2.3.2. Synthesis of 4,5-bis(4-tert-butylphenoxy)-1,2-dicyanobenzene (**2b**) (Scheme 1)

4,5-Bis(4-*tert*-butylphenoxy)-1,2-dicyanobenzene (**2b**) was synthesized from 4,5-dichloro-1,2-dicyanobenzene (**1**) and 4-*tert*-butylphenol as reported before [20]. The amounts of the reagents employed were: 4,5-dichloro-1,2-dicyanobenzene (**1**) (4.01 g, 20 mmol), 4-*tert*-butylphenol (6.00 g, 40 mmol), K_2CO_3 (13.8 g, 100 mmol) and dried DMSO (40 ml). Yield: 4.07 g (48%); IR (KBr): ν_{max}/cm^{-1}; 3041–3051 (Ar-H), 2213 (C≡N), 1219 (C–O–C); ^{1}H NMR: (DMSO-d_6) δ, ppm; 9.1 (2H, s, Ar-H), 7.1 (4H, d, Ar-H), 6.6 (4H, d, Ar-H), 1.2 (s, 18H, CH_3).

2.3.3. Synthesis of octaphenoxyphthalacyaninato gallium chloride (**3a**, **(Cl)GaOPPc**) (Scheme 1) [22]

A mixture of 4,5-bis(phenoxy)-1,2-dicyanobenzene (**2a**) (3.12 g, 10 mmol), anhydrous $GaCl_3$ (0.88 g, 5 mmol) and 1-chloronaphthalene (4 ml) were placed in a preheated oil bath (215 °C). The reaction mixture was stirred at this temperature for 7 h under a dry nitrogen atmosphere. After cooling the green product was placed in a silica gel column, washed with hexane to remove the brownish layer of 1-chloronaphthalene. THF was then used to elute the green product from the column. THF was then removed by evaporation. Preparative thin layer chromatography (TLC) silica gel plates were used for further purification with chloroform as the eluting solvent. The impurities (brown layers) were then cut from the plates leaving the pure green product. The silica gel/green product was placed in a beaker of chloroform to dissolve the product. The mixture was then filtered, and the solvent was removed by evaporation. Yield: 1.59 g (47%); UV–Vis (DMSO): λ_{max} (log ε); 687 (5.10), 616 (4.56), 370 (4.90); IR (KBr): ν_{max}/cm^{-1}; 3034, 3052 (Ar-H), 1588 (C=C), 1460, 1452, 1407, 1339, 1275, 1201(C–O–C), 1162, 1089, 1089, 1037, 1003, 860; ^{1}H NMR: ($CDCl_3$) δ ppm; 8.6 (d, 8H, Pc-H), 7.4 (t, 16H, phenyl-H), 7.3 (t, 16H, phenyl-H), 7.2 (m, 8H, phenyl-H). Calc. for $C_{80}H_{48}N_8O_8GaCl$: C, 69.10; H, 3.47; N, 8.06. Found: C, 68.14; H, 3.59; N, 7.34. MALDI-TOF-MS *m*/*z*: calc. 1354.34; found, 1352.00 $[M-2]^+$.

2.3.4. Synthesis of octakis(4-tert-butylphenoxy)phthalocyaninato gallium chloride (**3b**, **(Cl)PGaOTBPPc**) (Scheme 1) [22]

Synthesis and purification of compound **3b** was as explained for compound **3a**. However, instead of using **2a**, compound **2b** was used. The amounts of the reagents employed were: **2b** (3.16 g, 7,44 mmol), anhydrous $GaCl_3$ (0.65 g, 3.72 mmol) and 1-chloronaphthalene (4 ml). Yield: 1.11 g (35%); UV–Vis (DMSO): λ_{max} (log ε); 690 (5.31), 620 (3.82), 347 (4.15); IR (KBr): ν_{max}/cm^{-1}; 3034–3052 (Ar-H), 2952–2866 (C–H), 1589 (C=C), 1506, 1489, 1454, 1411, 1338, 1274, 1205 (C–O–C), 1098, 1037, 891, 861, 741; ^{1}H NMR: ($CDCl_3$) δ ppm; 8.6 (broad s, 8H, Pc-H), 7.0–7.4 (m, 32H, phenyl-H), 1.3–1.4 (m, 72H, CH_3). *Anal.* Calc. for $C_{112}H_{112}N_8O_8GaCl$: C, 74.60; H, 6.26; N, 6.21. 2.4. Photophysical and photochemical studies

2.4.1. Fluorescence quantum yields and lifetimes

Fluorescence quantum yields (Φ_F) were determined by the comparative method [23,24] (Eq. (1)):

$$\Phi_F = \Phi_F(\mathrm{Std})\frac{F \cdot A_{\mathrm{Std}} \cdot \eta^2}{F_{\mathrm{Std}} \cdot A \cdot \eta^2_{\mathrm{Std}}} \quad (1)$$

where F and F_{Std} are the areas under the fluorescence curves of the (Cl)GaPc derivatives and the standard, respectively. A and A_{Std} are the respective absorbances of the sample and standard at the excitation wavelengths ($A = 0.05$ in all solvents used), and η and η_{Std} are the refractive indices of the solvents used for the sample and standard, respectively. Chlorophyll *a* in ether ($\Phi_F = 0.32$) [25] was employed as the standard. Both the sample and standard were excited at the same wavelength (630 nm).

Natural radiative lifetimes (τ_0) were determined using the program PhotochemCAD [26]. This determination is based on the method proposed by Strickler and Berg [27], which uses parameters derived from spectral (absorption and emission) data of the fluorescing material. From τ_0 values, fluorescence lifetimes (τ_F) were determined using the following equation:

$$\Phi_F = \frac{\tau_F}{\tau_0}. \quad (2)$$

2.4.2. Triplet quantum yields and lifetimes

The solutions for triplet quantum yields and lifetimes were introduced into a 1 cm pathlength UV–Vis spectrophotometric cell, deaerated using nitrogen and irradiated at the Q band maxima. Triplet state quantum yields (Φ_T) of the (Cl)GaPc derivatives were determined by the triplet absorption method. A comparative method [28] using zinc phthalocyanine as a standard was employed for the calculations, Eq. (3):

$$\Phi_T = \Phi_T^{\mathrm{Std}} \cdot \frac{\Delta A_T \cdot \varepsilon_T^{\mathrm{Std}}}{\Delta A_T^{\mathrm{Std}} \cdot \varepsilon_T} \quad (3)$$

where ΔA_T and ΔA_T^{Std} are the changes in the triplet state absorbances of the (Cl)GaPc derivatives and the standard, respectively. ε_T and ε_T^{Std} are the triplet state molar exctinction coefficients for the (Cl)GaPc derivative and the standard, respectively. Φ_T^{Std} is the triplet quantum yield for the standard, ZnPc ($\Phi_T = 0.65$ in DMSO [29], 0.58 in DMF [30] and 0.65 in toluene [31]). ε_T and ε_T^{Std} were determined from the molar extinction coefficients of their respective ground singlet state (ε_S and ε_S^{Std}), the changes in absorbances of the ground singlet states (ΔA_S

and ΔA_S^{Std}) and changes in the triplet state absorptions (ΔA_T and ΔA_T^{Std}) according to the following equations:

$$\varepsilon_T = \varepsilon_S \frac{\Delta A_T}{\Delta A_S} \quad (4a)$$

$$\varepsilon_T^{Std} = \varepsilon_S^{Std} \frac{\Delta A_T^{Std}}{\Delta A_S^{Std}} \quad (4b)$$

Quantum yields of internal conversion (Φ_{IC}) were obtained from Eq. (5), which assumes that only three processes (fluorescence, intersystem crossing and internal conversion) jointly deactivate the excited singlet state of a (Cl)GaPc molecule

$$\Phi_{IC} = 1 - (\Phi_F + \Phi_T). \quad (5)$$

2.4.3. Singlet oxygen quantum yields

Quantum yields of singlet oxygen were determined in air (no oxygen bubbled) using the relative method with ZnPc as a reference and DPBF as a chemical quencher for singlet oxygen, using the following equation:

$$\Phi_\Delta = \Phi_\Delta^{Std} \cdot \frac{R_{DPBF} I_{abs}^{Std}}{R_{DPBF}^{Std} I_{abs}} \quad (6)$$

where Φ_Δ^{Std} is the singlet oxygen quantum yield for the standard, ZnPc ($\Phi_\Delta = 0.67$ in DMSO [32], 0.56 in DMF [33], 0.58 in toluene [34] and 0.53 in THF [35]). R_{DPBF} and R_{DPBF}^{Std} are the DPBF photobleaching rates in the presence of the (Cl)GaPc derivative under investigation and the standard, respectively. I_{abs} and I_{abs}^{Std} are the rates of light absorption by the (Cl)GaPc derivatives and the standard, respectively. To avoid chain reactions induced by DPBF in the presence of singlet oxygen [33], the concentration of DPBF was lowered to $\sim 3 \times 10^{-5}$ mol dm^{-3}. Solutions of sensitizer (absorbance = 0.2 at the irradiation wavelength) containing DPBF were prepared in the dark and irradiated in the Q band region using the setup described above. DPBF degradation at 417 nm was monitored. The light intensity for singlet oxygen studies was 6×10^{15} photons s^{-1} cm^{-2}. The error in the determination of Φ_Δ was ~10% (determined from several Φ_Δ values).

2.4.4. Photodegradation quantum yields

For determination of photodegradation quantum yields, the usual equation (7) was employed:

$$\Phi_{Pd} = \frac{(C_0 - C_t) V N_A}{I_{abs} S t} \quad (7)$$

where C_0 and C_t (mol dm^{-3}) are the (Cl)GaPc derivative's concentrations before and after irradiation, respectively; V is the reaction volume; S, the irradiated cell area (2.0 cm^2); t, the irradiation time; N_A, the Avogadro's number and I_{abs}, the overlap integral of the radiation source intensity and the absorption of the Pc (the action spectrum) in the region of the interference filter transmittance. The light intensity for photodegradation studies was 7×10^{16} photons s^{-1} cm^{-2}.

3. Results and discussion

3.1. Syntheses and characterization

Scheme 1 gives the synthetic pathways used to synthesize the compounds used in this work. 1,2-Dicyanobenzene was used [20] to prepare 4,5-disubstituted phthalonitrile derivatives through base-catalysed nucleophilic aromatic displacement. The same route was applied to prepare phenoxy and 4,5-bis(*tert*-butylphenoxy) substituted 1,2-dicyanobenzene (**2a** and **2b**) from phenol and 4-*tert*-butylphenol, respectively (Scheme 1). The reactions were carried out in DMSO at room temperature and gave yields of 52% for **2a** and 48% for **2b**.

The preparation of the phthalocyanine derivatives from aromatic 1,2-dicyanobenzenes occur under different reaction conditions. The syntheses of MPc complexes (**(Cl)GaOPPc** and **(Cl)GaOTBPPc**) were achieved by treatment of 1,2-dicyanobenzenes **2a** and **2b** with gallium (III) chloride in 1-chloronaphthalene (Scheme 1). Because gallium is a large atom, high energy is required to insert the metal ion into the phthalocyanine ring, thus a high-boiling solvent such as 1-chloronaphthalene is used to achieve this purpose. Complex **3a** is octaphenoxy substituted and complex **3b** is octa-*tert*-butylphenoxy substituted. Column and preparative thin layer chromatography with silica gel were employed to obtain the pure products from the reaction mixtures.

Generally, phthalocyanine complexes are insoluble in most organic solvents, however, introduction of phenoxy and 4-*tert*-butyl phenoxy substituents on the ring increases the solubility. Unsubstituted phthalocyanines are known to have poor solubility in most organic solvents. They dissolve mostly in coordinating solvents such as pyridine. **(Cl)GaPc** behaves likewise; it dissolves in polar and coordinating solvents such as DMSO, DMF and THF. Both new substituted complexes (**(Cl)GaOPPc** and **(Cl)GaOTBPPc**) exhibit excellent solubility in organic solvents such as dichloromethane, chloroform, THF, toluene, acetone and DMSO. The new compounds were characterized by UV–Vis, IR and NMR spectroscopies, MALDI-TOF mass spectra and elemental analysis. The analyses are consistent with the predicted structures as shown in Section 2. After conversion into gallium phthalocyanines, the characteristic C≡N stretch at 2237 and 2213 cm^{-1} of 1,2-dicyanobenzenes **2a** and **2b** disappeared, indicative of metallophthalocyanine formation. The characteristic vibrations corresponding to ether groups (C–O–C) were observed at 1209 and 1219 cm^{-1} for the dinitrile compounds, 1201 and 1205 cm^{-1} for the phthalocyanine complexes. Aromatic CH stretchings were observed at 3034–3052 cm^{-1}.

^{1}H NMR investigations of 1,2-dicyanobenzene compounds **2a** and **2b** provide the characteristic chemical shifts for the structures as expected. The ^{1}H NMR spectrum for compound **2a** shows a singlet peak at δ 7.7 ppm, a triplet at δ 7.4 ppm, a triplet at δ 7.2 ppm and a doublet at δ 7.1 ppm for the aromatic protons, integrating to 2, 4, 2, 4 protons

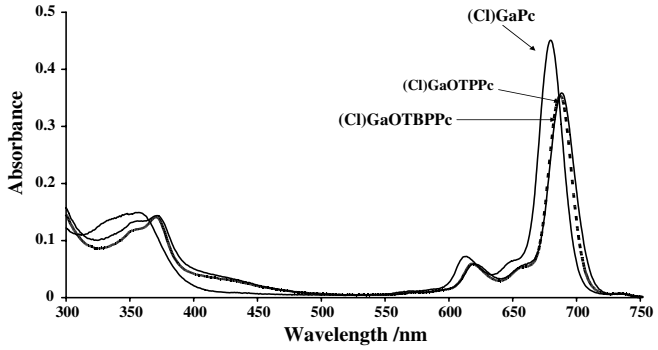

Fig. 1. Ground state electronic absorption spectra of **(Cl)GaPc**, **(Cl)GaOPPc** and **(Cl)GaOTBPPc** in DMSO. Concentration: $\sim 1.5 \times 10^{-6}$ mol dm^{-3}.

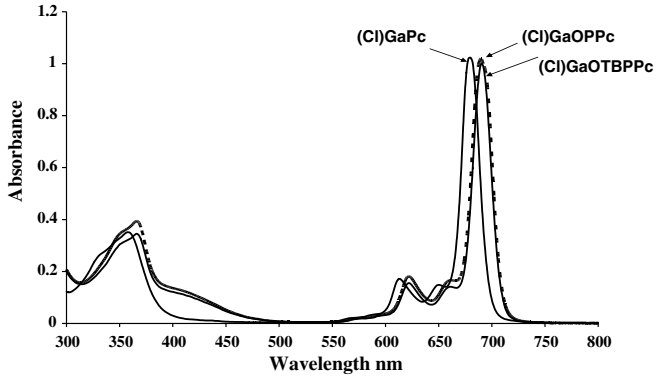

Fig. 2. Ground state electronic absorption spectra of **(Cl)GaPc**,**(Cl)GaOPPc** and **(Cl)GaOTBPPc** in THF. Concentration: $\sim 1.8 \times 10^{-6}$ mol dm^{-3}.

each, respectively, making a total of 12 protons as expected. Compound **2b** shows a singlet peak at δ 9.1 ppm, a doublet at δ 7.1 ppm and a doublet at δ 6.6 ppm for the aromatic protons, integrating to 2, 4, 4 protons each, respectively, making a total of 10 protons as expected, and methyl protons appear as a singlet peak at ca. δ 1.2 ppm, integrating to 18 protons.

The ^{1}H NMR spectrum of the unsubstituted gallium(III) phthalocyanine (**(Cl)GaPc**) shows ring protons as two singlet peaks at δ 9.65 and 8.47 ppm, integrating to 8 protons each. The substituted gallium(III) phthalocyanine complexes were found to be pure by ^{1}H NMR, with all the substituents and ring protons observed in their respective regions. The phenoxy substituted complex **3a** showed the resonances belonging to the ring protons as a doublet at δ 8.6 ppm, a triplet at δ 7.4 ppm, a triplet at δ 7.3 ppm and a multiplet at δ 7.2 ppm, integrating to 8, 16, 16, 8 protons each, making a total of 48 protons as expected. The *tert*-butylphenoxy substituted complex (**(Cl)GaOTBPPc**) showed the resonances belonging to the ring protons as a singlet at δ 8.6 ppm and a multiplet between δ 7.0 and 7.4 ppm for aromatic protons, integrating to 8 and 32 protons each, respectively, making a total of 40 protons as expected. The methyl protons appear as multiplets between δ 1.3 and 1.4 ppm, integrating to 72 protons.

3.2. Ground state electronic absorption and fluorescence spectra

The ground state electronic absorption spectra of **(Cl)GaPc**, **(Cl)GaOPPc** and **(Cl)GaOTBPPc** show sharp single Q bands (Figs. 1 and 2, Table 1), which depict the monomeric nature of these complexes in all solvents studied. The non-aggregated nature of these complexes is not unconnected with their possession of chlorine atoms at axial positions to the central metal atoms. Atoms or groups on MPc axial positions are known to prevent aggregation

Table 1
Spectral, photophysical and photochemical parameters of GaPc derivatives in various solvents

Solvent	MPc	λ_{max}		Φ_F	Φ_T[a]	Φ_{IC}[a]	S_Δ[a,b]	Φ_Δ	Φ_{Pd} (10^5)	τ_T (μs)

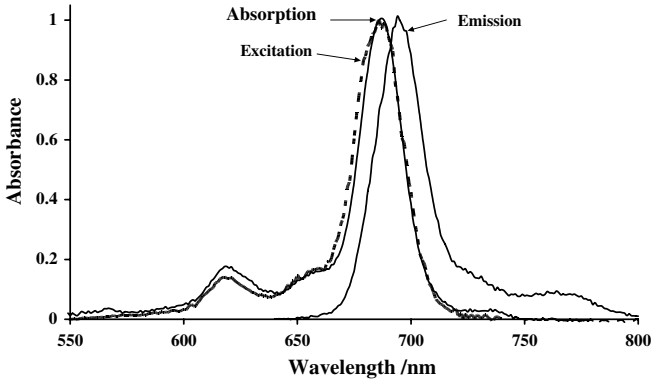

Fig. 3. Absorption, fluorescence excitation and fluorescence emission spectra of **(Cl)GaOPPc** in DMSO.

by restraining the overlap of two MPc units in solution [36]. The positions of the Q band in **(Cl)GaOPPc** and **(Cl)GaOTBPPc** are red-shifted relative to that in **(Cl)GaPc**. The presence of an electron donating phenoxy substituent on the phthalocyanine ring leads to a red-shift of the Q band. For a particular MPc in different solvents, it can be observed that the longest Q absorption wavelengths are obtained in chloroform while the shortest are obtained in THF. This observation could partly be explained by considering the refractive indices of the solvents. It is known that red-shifting of absorption spectra is a function of the solvent's refractive index [34]. In all the solvents studied, **(Cl)GaPc**, **(Cl)GaOPPc** and **(Cl)GaOTBPPc** showed monomeric behaviour up to $\sim 1 \times 10^{-5}$ mol dm^{-3}. For the substituted derivatives, **(Cl)GaOPPc** and **(Cl)GaOTBPPc**, new absorption bands are observed at ~430 nm in both coordinating (Fig. 1) and non-coordinating (Fig. 2) solvents. Since these are observed only for the substituted derivatives, they must be due to charge transfer transitions involving the substituents.

The fluorescence behaviours of the three MPc complexes are similar. Fig. 3 shows the fluorescence excitation and emission spectra for **(Cl)GaOPPc** in DMSO. The excitation spectra are similar to absorption spectra and both are mirror images of the fluorescence spectra.

3.3. Photophysical studies

3.3.1. Fluorescence quantum yields and lifetimes

The fluorescence quantum yield (Φ_F) is the fraction of molecules in the excited singlet state that are deactivated radiatively. Factors like temperature, molecular structure and solvent parameters (polarity, viscosity, refractive index and the presence of heavy atoms in the solvent molecule) are widely known to influence the values of Φ_F. Table 1 shows that the Φ_F values do not vary much among the three MPcs studied; for example in DMSO, the Φ_F values for **(Cl)GaPc**, **(Cl)GaOPPc** and **(Cl)GaOTBPPc** are 0.21, 0.19 and 0.22, respectively. These values are similar (within experimental error limits) hence we conclude that the substituent effect on Φ_F values is not significant among **(Cl)GaPc**, **(Cl)GaOPPc** and **(Cl)GaOTBPPc**. Considering solvent effects on Φ_F values, chloroform gave the lowest values. The low values in chloroform could be attributed to the presence of heavy atoms (chlorine) in chloroform, which could induce spin–orbit coupling, and consequently reduce the number of fluorescing molecules. However, the values of Φ_F listed in Table 1 for **(Cl)GaPc** are lower than the value reported for this complex in chloronaphthalene ($\Phi_F = 0.31$) [37], thus showing it is not only the heavy atom effect that affects these values. The differences in Φ_F values for the remaining complexes were insignificant with the exception of high values obtained for **(Cl)GaPc** and **(Cl)GaOTBPPc** in DMSO compared to DMF, toluene and THF. The relatively high Φ_F values in DMSO for some complexes could to some extent be attributed to solvation by the solvent. Solvation by DMSO makes the fluorescing MPc more rigid and therefore more fluorescent. The coordinating strength of a solvent is a function of its donor ability. DMSO has a higher donor ability (1.24) than DMF (0.72) [38], which is in turn more donating than THF and

Table 2
Rate constants for the excited singlet state deactivation processes

Solvent	MPc	τ_F (ns)	k_F (10^{-7} s^{-1})[a]	k_{ISC} (10^{-8} s^{-1})[a]	k_{IC} (10^{-7} s^{-1})[a]
DMSO	**(Cl)GaPc**	3.8	5.6	1.8	2.7
	(Cl)GaOPPc	2.3	8.3	2.9	6.5
	(Cl)GaOTBPPc	2.1	10.	3.2	6.1
DMF	**(Cl)GaPc**	1.9	6.2	4.0	5.2
	(Cl)GaOPPc	1.3	14	5.9	1.5
	(Cl)GaOTBPPc	4.0	3.6	1.9	2.8
Toluene	**(Cl)GaOPPc**	1.5	9.4	4.4	14
	(Cl)GaOTBPPc	3.8	4.5	2.0	2.1
THF	**(Cl)GaPc**	7.8	2.4		
	(Cl)GaOPPc	1.5	9.1		
	(Cl)GaOTBPPc	1.3	14		
$CHCl_3$	**(Cl)GaOPPc**	1.0	13		
	(Cl)GaOTBPPc	2.0	6.0		

[a] $k_F = \frac{\Phi_F}{\tau_F}$; $k_{ISC} = \frac{\Phi_T}{\tau_F}$ and $k_{IC} = \frac{\Phi_{IC}}{\tau_F}$.

toluene. This partly explains why the MPcs are more fluorescent in DMSO than in the other solvents.

Fluorescence lifetimes τ_F are listed in Table 2. The values do not conform to any particular trend; hence it is difficult to draw any conclusion from them. Comparing the τ_F values with those reported in the literature [39] for other substituted GaPc complexes, shows close similarities. The τ_F values are useful for the calculation of the rate constants for intrinsic processes (fluorescence, intersystem crossing and internal conversion), which jointly deactivate the excited singlet state.

3.3.2. Triplet quantum yields and lifetimes

Fig. 4 shows the triplet decay curve for **(Cl)GaOPPc** in DMSO. The triplet quantum yield (Φ_T) is a measure of the fraction of absorbing molecules that undergo intersystem crossing to the metastable triplet excited state. Since intersystem crossing and fluorescence are two competing deactivating processes for the excited singlet state, their values for a particular species are expected to be complementary. As discussed above, the Φ_F values do not vary much with the introduction of phenoxy and *tert*-butylphenoxy substituents onto the **(Cl)GaPc** ring. This trend is also manifested in the Φ_T values (Table 1), which do not change much with the presence of the substituents. Solvent effects on Φ_T values are opposite to what was obtained in the case of Φ_F; Φ_T values are lower in DMSO than in DMF and toluene. The effect of the phenoxy and *tert*-butylphenoxy substituents on triplet quantum yields is minimal, with Φ_T values ranging between 0.66 and 0.69 in DMSO, and between 0.74 and 0.79 in DMF. The difference in Φ_T values is larger in toluene (0.65 for **(Cl)GaOPPc** and 0.75 for **(Cl)GaOTBPPc**). These values are much higher than the values reported [37] for octabutoxy substituted GaPc in benzene, with $\Phi_T = 0.35$, again showing that the values are highly dependent on the solvent. Sulfonated GaPc derivatives containing different number of sulfonates also gave a low Φ_T value of 0.36 [40] in methanol.

The triplet lifetimes of the complexes are conspicuously higher in DMSO than in all other solvents used in this work. The longer lifetimes in DMSO are attributed to the higher viscosity of this solvent than the other solvents. Molecular movements that lead to the deactivation of the excited state are impeded in viscous solvents, resulting in longer excited state lifetimes. The presence of ring substituents also lengthened the triplet lifetimes in this work (Table 1). The triplet lifetimes are very low in the low viscocity solvents $CHCl_3$ and THF. The triplet lifetime was also found [37] to be low ($\tau_T = 67$ μs) for octabutoxy substituted GaPc in benzene, which is comparable to the values obtained in this work in DMF and toluene. However, τ_T values ranging from 2.1 to 667 μs in toluene were reported for a series of substituted GaPc complexes [39]. The values (2.1 and 71 μs) on the low side were [39] attributed to strong intramolecular interactions existing in the excited state for dimeric complexes. The τ_T values for sulfonated GaPc derivatives containing different number of sulfonates ranged between 300 and 450 μs [40]. Thus some of the values reported here in DMSO are within this range.

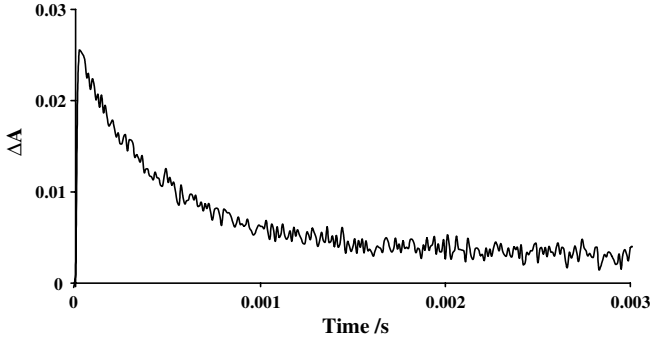

Fig. 4. Triplet decay curve for **(Cl)GaOPPc** in DMSO.

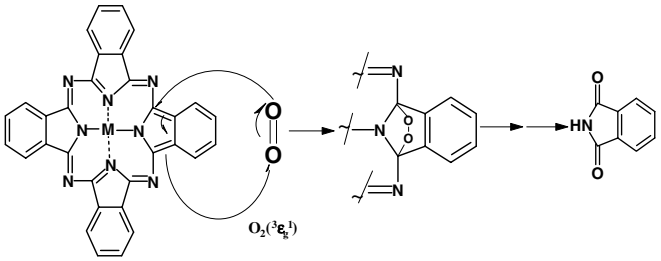

Quantum yields of internal conversion (Φ_{IC}) were calculated according to Eq. (5). Internal conversion is the radiationless transition between energy states of the same spin state (compare with fluorescence, a radiative process). The values of Φ_{IC} indicate the extent to which the excited molecules can de-excite by increasing the thermal energy of their surroundings. However, as can be seen in Table 1, the values of Φ_{IC} do not conform to any particular pattern.

Rate constants for the intrinsic processes (processes that deactivate the excited singlet state) are given in Table 2. The values of these rate constants are a reflection of the efficiency of the respective processes, and should conform to the same trends as the corresponding quantum yields. Calculated k_F, k_{ISC} and k_{IC} values for **(Cl)GaPc**, **(Cl)GaOPPc** and **(Cl)GaOTBPPc** in all solvents were found to be within the excepted range for MPc complexes. k_F values in DMSO and THF increased in the presence of substituents, while k_{ISC} increased in all solvents (DMSO, DMF, toluene) suggesting that substituents encourage intersystem crossing.

3.4. Photochemical studies

3.4.1. Singlet oxygen quantum yields

Singlet oxygen is formed via interaction (energy transfer) between the triplet state of a photosensitizer and ground state molecular (triplet) oxygen. As a result, the efficiency of singlet oxygen generation (quantified as singlet oxygen quantum yield, Φ_Δ) should depend on (i) the triplet state quantum yield, (ii) triplet state lifetime, (iii) efficiency of energy transfer, which depends on the energy of the triplet state, amongst other factors. On the basis of increased triplet lifetimes, the introduction of ring substituents should increase Φ_Δ values, and this is the case in Table 1. Solvent effects on Φ_Δ values are subtle, as seen in Table 1. The values are somewhat smaller in DMSO than in DMF and toluene, which is the same trend observed for Φ_T values. S_Δ is a measure of the efficiency of excitation energy transfer from the triplet photosensitizer molecule to ground state (triplet) molecular oxygen, $O_2(^3\Sigma_g^-)$. Sulfonated GaPc complexes showed much lower Φ_Δ values

Scheme 2. [4+2] cycloaddition reaction of MPc with singlet oxygen.

($\Phi_\Delta \sim 0.4$) in methanol [40], these values were thus comparable to the values shown in Table 1 for chloroform solutions. In Table 1, S_Δ values reveal that energy transfer to $O_2(^3\Sigma_g^-)$ is more efficient (with values closer to unity) with the substituted (Cl)GaPc derivatives than with unsubstituted **(Cl)GaPc**. It is possible that the substituents lower the energy of the triplet states to a level where energy transfer to $O_2(^3\Sigma_g^-)$ is easily achieved.

3.4.2. Photodegradation quantum yields

Photodegradation is brought about by the oxidative attack on the MPc excited triplet state by singlet oxygen. The ability of singlet oxygen to react with macrocyclic metal complexes is well documented [41,42]. Singlet oxygen reacts with tetra-azaporphyrin derivatives in a Diels–Alder [4+2]-cycloaddition, with the MPc ring acting as a diene and singlet oxygen as the dienophile. For MPcs, phthalimide was found to be the photo-oxidation product [42] (Scheme 2). The excited singlet state is deemed not to be a target for singlet oxygen because of its short lifetime ($\sim 10^{-9}$ s), which considerably reduces the state's probability of participating in photochemical reactions; hence the excited triplet state is being considered to be the main target for singlet oxygen. The interaction of the excited triplet state with singlet oxygen can be represented by the following equation:

$$^3\mathrm{MPc}^{\cdot} + O_2(^1\Delta_g) \xrightarrow{k_{Pd}} \text{phthalimide} \quad (8)$$

Therefore, the rate of photodegradation, according to the law of mass action is:

$$R = k_{Pd}[^3\mathrm{MPc}^*][O_2(^1\Delta_g)] \quad (9)$$

where R is the rate of photodegradation; k_{Pd}, the photodegradation rate constant (a bimolecular rate constant); $[^3\mathrm{MPc}^*]$, the concentration of the MPc excited triplet state; and $[O_2(^1\Delta_g)]$, the concentration of singlet oxygen. Therefore from Eq. (8), it could be inferred that the rate of photodegradation is directly proportional to the triplet quantum yield as well as singlet oxygen quantum yield. However, in this study, there is no clear correlation between Φ_{Pd} values and those of Φ_T or Φ_Δ, for the complexes. Considering solvent effects on photodegradation, Φ_{Pd} values for **(Cl)GaOPPc** and **(Cl)GaOTBPPc** are lower in DMSO and DMF (coordinating and highly solvating) than in non-coordinating solvents like toluene and chloroform (Table 1); which implies that these complexes are more photostable in coordinating solvents than in non-coordinating solvents. This observation could be explained in terms of singlet oxygen interaction with the MPc central metal to form a complex (for non-coordinating solvents) [43]. Solvent coordination to the metal centre partly shields the MPc molecule against interaction with singlet oxygen, leading to a decrease in the rate of photodegradation.

4. Conclusion

This work has demonstrated that gallium(III) phthalocyanine derivatives are well-suited for applications that require metastable excited states. The photophysical and photochemical parameters of the complexes reveal that the complexes would find use as photosensitizers in PDT and other applications. We have reported the photochemical and photophysical parameters of **(Cl)GaPc**, **(Cl)GaOPPc** and **(Cl)GaOTBPPc** in different solvents. It was concluded that fluorescence quantum yields vary in different environments. It was also found that substituents do not have a major effect on the results. The triplet and singlet oxygen quantum yields for the new complexes are higher than reported in the literature for other GaPc complexes, making these complexes excellent candidates for use as photosensitizers in, for example, PDT. The Φ_T values range from 0.66 to 0.79 in DMSO and DMF and the Φ_Δ values range from 0.41 to 0.74 in the same solvents.

The continuation of our interest in various dithiophosphate ligands led us to work on the reactions of aryl dithiophosphate nickel complexes with nitrogen donor moieties to examine how the aromatic moiety influences coordination with the metal. Thus, we report the syntheses of nickel (II) adducts of the general type $Ni[S_2P(OR)_2]_2 \cdot nL$ (where R = *o*-, *m*-, *p*-C_6H_4Me; $n = 2$, L = C_5H_5N; $n = 1$, L = $C_{10}H_8N_2$, $C_{14}H_{12}N_2$) and their characterization by various spectroscopic techniques. We also report the molecular structures of $Ni[S_2P(OC_6H_4Me\text{-}p)_2]_2 \cdot C_{10}H_8N_2$ and $Ni[S_2P(OC_6H_4Me\text{-}o)_2]_2 \cdot C_{14}H_{12}N_2 \cdot C_6H_6$.

2. Results and discussion

Reactions of bis (*O*,*O*′-ditolyldithiophosphato)nickel(II) complexes were carried out with pyridine or 2,2′-bipyridyl or 2,9-dimethyl-1,10-phenanthroline in benzene

$$Ni[S_2P(OR)_2]_2 + nL \rightarrow Ni[S_2P(OR)_2]_2 \cdot nL \quad (1)$$

(R = *o*-, *m*-, *p*-C_6H_4Me; $n = 2$, L = C_5H_5N; $n = 1$, L = $C_{10}H_8N_2$, $C_{14}H_{12}N_2$)

The purple colour changed on addition of nitrogen base to give a consistent green colour on addition of a slight excess of base. In each case a green powder (yield, 67–78%), soluble in organic solvents, was obtained.

2.1. IR spectra

The IR spectra of the nitrogen base adducts of bis(*O*,*O*′-ditolyl dithiophosphato)nickel(II) were measured over the range of 4000–200 cm^{-1}. The assignments of the relevant IR bands (Table 1) were made by comparisons with the spectra of the corresponding nickel(II) *O*,*O*′-ditolyldithiophosphate complexes [28]. The two strong intensity bands present in the 1168–1123 and 841–790 cm^{-1} regions are assigned to ν[(P)–O–C] and ν[P–O–(C)] stretching vibrations, respectively. Bands due to $\nu(P–S)_{asym}$ and $\nu(P–S)_{sym}$ observed at 693–656 and 568–516 cm^{-1} in adducts 1–9, indicate a slight change in the bonding patterns of the dithiophosphate moieties upon adduct formation. However, in case of dmphen adducts, 7–9 additional bands corresponding to $\nu(P–S)_{asym}$ and $\nu(P–S)_{sym}$ are also observed suggesting the *S*-mondentate and *S*,*S*-chelating nature of the ligands. The presence of medium to weak bands in the regions 380–362 and 344–324 cm^{-1} have been assigned to ν(Ni–S) vibrations consistent with the metal sulfur bonding. One or two peaks due to ν(C–N) vibrations appears in the region 1604–1579 cm^{-1} suggests the formation of adducts.

2.2. UV–visible spectra

The spectra of the adducts of bis(*O*,*O*′-ditolyl dithiophosphato)nickel(II) recorded in CH_2Cl_2 (Table 2) show three absorption bands corresponding to $^3A_2g \rightarrow {}^3T_2g$, $^3A_2g \rightarrow {}^3T_1g(F)$, $^3A_2g \rightarrow {}^3T_1g(P)$ transitions expected for octahedral nickel species [16,18]. The first band corresponding to $^3A_2g \rightarrow {}^3T_2g$ transition is obtained in the range of 1102–1130 nm. The second absorption $^3A_2g \rightarrow {}^3T_1g(F)$ is observed in the range 727–735, 654–658 for pyridine and bipyridyl adducts, respectively but split in two absorptions in the range 676–686 and 866–886 nm for 2,9-dimethyl-1,10-phenanthroline adducts. This split is probably due to spin-orbit coupling of $^1E(D)$ with ^3T_1g. The third band, $^3A_2g \rightarrow {}^3T_1g$ is seen in the range of 447–451, 416–422 and 423–441 nm for pyridine, bipyridyl and 2,9-dimethyl-1,10-phenanthroline adducts, respectively.

2.3. Magnetic moments measurements

The magnetic measurements (Table 2) for nitrogen base adducts of bis(*O*,*O*′-ditolyldithiophosphato)nickel(II) obtained in the range of 3.20–3.26 BM at 298 K indicate the presence of two unpaired electrons. Similar values are found in the literature for a number of other bis(*O*,*O*′-ditolyldithiophosphato)nickel(II) adducts [16].

2.4. Molecular structures of $Ni[S_2P(OC_6H_4Me\text{-}p)_2]_2 \cdot C_{10}H_8N_2$ (6) and $Ni[S_2P(OC_6H_4Me\text{-}o)_2]_2 \cdot C_{14}H_{12}N_2 \cdot C_6H_6$ (7)

$Ni[S_2P(OC_6H_4Me\text{-}p)_2]_2 \cdot C_{10}H_8N_2$ (**6**) and $Ni[S_2P(OC_6H_4Me\text{-}o)_2]_2 \cdot C_{14}H_{12}N_2 \cdot C_6H_6$ (**7**), crystallize as triclinic and monoclinic in space groups $P\bar{1}$ and $P2_1/c$, respectively. The ORTEP diagrams in Figs. 1 and 2 illustrate that in **6** the nickel atom lies at the centre of a

9	$Ni[S_2P(OC_6H_4CH_3\text{-}p)_2]_2 \cdot N_2C_{14}H_{12}$	1110, 686, 423	3.24

distorted octahedral, NiN_2S_4, chromophore whereas in **7** the geometry around nickel is that of a distorted trigonal bipyramidal, NiN_2S_3 chromophore. Solvent benzene molecules are also incorporated into the crystal of the latter. In **6** the square planar structure of $Ni[S_2P(OC_6H_4Me\text{-}p)_2]_2$ [29] has readily accommodated the introduction of bipy while maintaining the integrity of the two bidentate $S_2P(OC_6H_4Me\text{-}p)_2$ ligands, as was also found for $Ni[S_2P(OC_6H_4Me\text{-}p)_2]_2$(phen) [27]. By contrast, in **7** the analogous distorted square planar structure of $Ni[S_2P(OC_6H_4Me\text{-}o)_2]_2$ [28] with two bidentate ligands is not maintained in the presence of dmphen because the cleavage of one Ni–S bond results in the formation of a monodentate ligand. The presence of methyl groups in **7** on the nitrogen base, dmph increases the crowding near Ni atom resulting the cleavage of one Ni–S bond. Hence one of the ligand is rendered as monodentate and other as bidentate. The *cis* orientation of the nitrogen donor atoms is also responsible for this cleavage.

In $Ni[S_2P(OC_6H_4Me\text{-}p)_2]_2(C_{10}H_8\ N_2)$ (**6**), all four Ni–S bond lengths are fairly similar (2.4757(7) to 2.5096(6) Å) in the two bidentate dithiophosphate ligands and in the range of other analogous six-coordinated compounds, $Ni[S_2P(OBu^n)_2]_2$(bipy) (2.463(2)–2.524(2) Å) [25], $Ni[S_2P(OMe)_2]_2$(phen) (2.47(1)–2.52(1) Å) [24] and $Ni[S_2P(OC_6H_4Me\text{-}p)_2]_2$(phen) (2.486(1)–2.532(1) Å) [27]. The distances are significantly larger and cover a larger range than in the four-coordinate precursors $Ni[S_2P(OC_6H_4Me\text{-}p)_2]_2$ (average 2.332(2) Å) [29] and $Ni[S_2P(OC_6H_4Me\text{-}o)_2]_2$ (average 2.233(8) Å) [28]. By contrast, in $Ni[S_2P(OC_6H_4Me\text{-}o)_2]_2 \cdot (C_{14}H_{12}N_2) \cdot C_6H_6$ (**7**), the bidentate dithiophosphate ligand, with Ni–S bond lengths of 2.352(1) and 2.539(1) Å, might more accurately be defined as anisobidentate, while the second dithiophosphate ligand is clearly monodentate with Ni(1)–S(3) at 2.386(1) Å and Ni(1)–S(4) at 5.462(2) Å. The closest approach of this pendant S atom to the Ni atom of the nearest adjacent molecule is 7.208(2) Å. Similar behavior is seen in the analogous five-coordinate complexes, $Ni[S_2P(OMe)_2]_2$(dmphen) [24] and $Ni[S_2P(OCMe_2CMe_2O)_2]_2$(dmphen) [26], with the monodentate Ni–S bonds 2.42(1) and 2.398(3) Å, respectively, and the (aniso)bidentate ligands having Ni–S distances ranging from 2.30(1) to 2.58(1) Å. The Ni–N bond lengths are similar in **6** (2.060(1) and 2.079(1) Å) and **7** (2.010(1) and 2.009(1) Å) which is in good agreement with the distances found in the six-coordinate analogues, $Ni[S_2P(OBu^n)_2]_2$(bipy) (2.088(4) and 2.089(4) Å) [25], $Ni[S_2P(OMe)_2]_2$(phen) (2.08(1) and 2.09(1) Å) [24] and $Ni[S_2P(OC_6H_4Me\text{-}p)_2]_2$(phen) (2.082(3) and 2.086(3) Å) [27] as well as in the five-coordinate analogues $Ni[S_2P(OMe)_2]_2$(dmphen) (1.97(1) and 2.03(1) Å) [24] and $Ni[S_2P(OCMe_2CMe_2O)_2]_2$(dmphen) (2.005(8) and 2.015(7) Å) [26]. Although the differences are small, the trend of slightly shorter Ni–N bonds in the five coordinate complexes is clear and suggestive of slightly stronger bonding

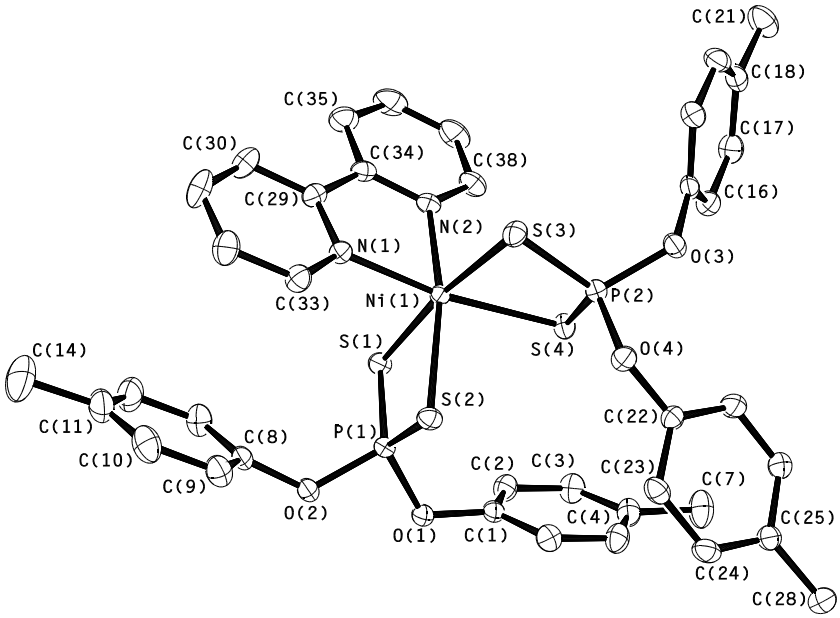

Fig. 1. ORTEP plot of the molecule $Ni[S_2P(OC_6H_4Me\text{-}p)_2]_2 \cdot C_{10}H_8N_2$. The non-hydrogen atoms are drawn with 50% probability ellipsoids.

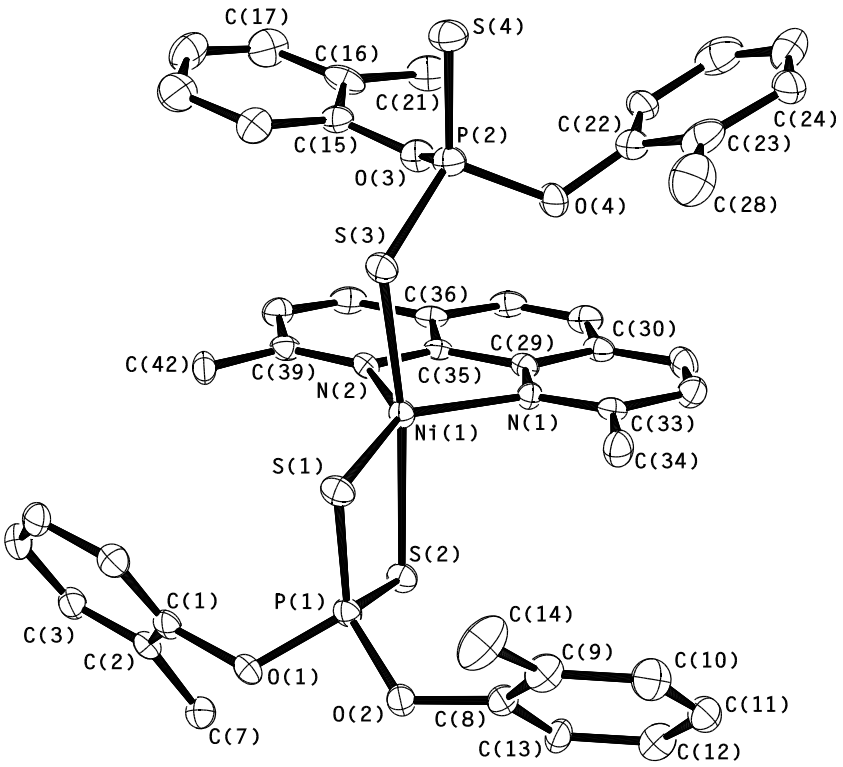

Fig. 2. ORTEP plot of $Ni[S_2P(OC_6H_4Me\text{-}o)_2]_2 \cdot C_{14}H_{12}N_2 \cdot C_6H_6$. The non-hydrogen atoms are drawn with 25% probability ellipsoids and the benzene molecule is omitted for clarity.

when accommodation has been made to incorporate the bulkier nitrogen ligand by the cleavage of an Ni–S bond and reorientation of the resulting monodentate sulfur ligand. The average lengths of the four P–S bonds in **6** are the same as in $Ni[S_2P(OC_6H_4Me\text{-}p)_2]_2$ (average 1.973(6) Å) which suggests that the competitive chelation of sulfur and nitrogen donor atoms has no significant influence on the partial double bond character of these P–S bonds. In **7**, the P(2)–S(4) bond of the pendant, non-interacting sulfur atom is by far the shortest (1.941(2) Å), with the P(1)–S(2) bond associated with the much longer Ni(1)–S(2) bond in the anisobidentate ligand being somewhat longer (1.969(2) Å). The P(1)–S(1) associated with the shorter Ni(1)–S(1) anisobidentate bond and the P(1)–S(3) associated with the monodentate Ni(1)–S(3) bond are longer and essentially the same, 1.997(2) and 1.995(2) Å, respectively.

In $Ni[S_2P(OC_6H_4Me\text{-}p)_2]_2(C_{10}H_8\ N_2)$ (**6**), the S–Ni–S ligand bite angles of 81.33(2) and 81.99(2)° are similar to the values observed in $Ni[S_2P(OBu^n)_2]_2$(bipy) (81.40(7) and 81.63(7)°) [25], $Ni[S_2P(OMe)_2]_2$(phen) (81.3(2)° and 81.6(2)°) [24] and $Ni[S_2P(OC_6H_4Me\text{-}p)_2]_2$(phen) (81.13 and 81.57(2)°) [27]. The bite angle of the chelating ligand in $Ni[S_2P(OC_6H_4Me\text{-}o)_2]_2 \cdot C_{14}H_{12}N_2 \cdot C_6H_6$ (**7**) is similar (82.05(4)°) and comparable to that in $Ni[S_2P(OMe)_2]_2 \cdot$ dmphen (81.7(1)° [24] and $Ni[S_2POCMe_2CMe_2O)_2]_2 \cdot$ dmphen (82.1(1)°) [26]. The N–Ni–N bite angles of 79.10(5)° in **6** and 82.6(2)° in **7**, are typical of the values found in the corresponding six-coordinate, $Ni[S_2P(OBu^n)_2]_2 \cdot$ bipy, $Ni[S_2P(OMe)_2]_2 \cdot$ phen and $Ni[S_2P(OC_6H_4Me\text{-}p)_2]_2 \cdot$ phen (average 79.4(3)°) and five coordinate analogues $Ni[S_2P(OCMe_2CMe_2O)_2]_2 \cdot$ dmphen and $Ni[S_2P(OMe)_2]_2 \cdot$ dmphen (average 82.5(0.3)°), respectively. In **6**, the least deviation from 180° involves the two shorter (stronger) Ni–S bonds in the bidentate ligands (S(1)–N(1)–S(4) (173.09(2)°), while those involving the donor and the longer Ni–S bonds are slightly more deviated with N–Ni–S angles of 171.63(4)° and 168.03(4)°. The three cis S–Ni–S angles, other than the ligand bite angles, cover the range 91.33–93.53°, whereas the six involving S–Ni–N angles range from 88.41(4)° to 97.18(4)°. In **7**, the axial positions of the distorted trigonal bipyramid are occupied by the Ni–S bond of the monodentate ligand and the longer Ni–S bond of the (aniso)bidentate ligand (S(2)–Ni(1)–S(3) 167.05(5)°). The sum of the three angles in the trigonal plane (S(1)–Ni(1)–N(1) 134.3(1)°, S(1)–Ni(1)–N(2) 142.1(1)° and N(1)–Ni(1)–N(2) 82.6(2)°) is 359.1°. The dmphen group is also essentially in the equatorial plane. Similar corresponding angles have been reported for $Ni[S_2POCMe_2CMe_2O)_2]_2 \cdot$ dmphen (axial S–Ni–S 169.1(1)°; equatorial S–Ni–N 131.1(3)°, S–Ni–N 144.3(2)° and N1–Ni–N 82.5(3)°) [26] and $Ni[S_2P(OMe)_2]_2 \cdot$ dmphen (axial S–Ni–S 165.8(1)°; equatorial S–Ni–N 130.2(3)°, S–Ni–N 145.7(2)° and N1–Ni–N 82.4(43)°) [24].

In **6** the S–P–S bond angles for the bidentate ligands are 110.34(2)° and 112.53(3)° as was reported for the six-coordinate analogues $Ni[S_2P(OC_6H_4Me\text{-}p)_2]_2 \cdot$ phen (110.37(6)–112.81(5)°) [27] and $Ni[S_2P(OMe)_2]_2 \cdot$ phen

(110.8(2)–111.6(2)°) [24]. In **7**, the two angles differ considerably with the S–P–S bond angle of 116.1(1)° for the monodentate ligand being considerably larger than that of the (aniso)bidentate ligand (108.27(8)°). These values are similar to those found in the analogous five-coordinated complexes, $Ni[S_2P(OMe)_2]_2 \cdot dmphen$ (116.9(2)° and 111.1(2)°) [24] and $Ni[S_2P(OCMe_2CMe_2O)_2]_2 \cdot dmphen$ (117.2(2)° and 108.0(2)°) [26].

3. Experimental

Solvents (benzene, dichloromethane, *n*-hexane, diethyl ether) were dried by standard methods before use. All reactions were carried out in pre-dried glassware under anhydrous conditions. Literature methods were used for the preparation of bis(*O*,*O*′-ditolyldithiophosphato)nickel(II) [28] and ammonium salts of *O*,*O*-ditolyldithiophosphoric acids [30,31].

3.1. Preparations

3.1.1. $Ni[S_2P(OC_6H_4Me\text{-}o)_2]_2 \cdot 2C_5H_5N$ (**1**)

$Ni[S_2P(OC_6H_4Me\text{-}o)_2]_2$ (0.489 g, 0.723 mmol) was dissolved in dry benzene (20 ml). Pyridine was added until the purple colour of the solution changed to green. The solution was concentrated under vacuo. Diethylether was added to the concentrated solution to obtain a green precipitate. The adduct was recrystallized using a dichloromethane/ether mixture (1:2 v/v). Yield: 0.328 g, 67%. *Anal.* Calc. for $C_{38}H_{38}O_4N_2S_4P_2Ni$: Ni, 7.02; S, 15.35. Found: Ni, 6.83; S, 15.17%.

3.1.2. $Ni[S_2P(OC_6H_4Me\text{-}m)_2]_2 \cdot 2C_5H_5N$ (**2**)

Method as above gave a green powdery solid. Yield: 0.401 g, 73%. *Anal.* Calc. for $C_{38}H_{38}O_4N_2S_4P_2Ni$: Ni, 7.02; S, 15.35. Found: Ni, 6.94; S, 15.48%.

3.1.3. $Ni[S_2P(OC_6H_4Me\text{-}p)_2]_2 \cdot 2C_5H_5N$ (**3**)

Yield: 0.205 g, 69%. *Anal.* Calc. for $C_{38}H_{38}O_4N_2S_4P_2Ni$: Ni, 7.02; S, 15.35. Found: Ni, 7.10; S, 15.51%.

3.1.4. $Ni[S_2P(OC_6H_4Me\text{-}o)_2]_2 \cdot C_{10}H_8N_2$ (**4**)

Yield: 0.263 g, 78.2%. *Anal.* Calc. for $C_{38}H_{36}O_4N_2S_4P_2Ni$: Ni, 7.04; S, 15.39. Found: Ni, 7.25; S, 15.52%.

3.1.5. $Ni[S_2P(OC_6H_4Me\text{-}m)_2]_2 \cdot C_{10}H_8N_2$ (**5**)

Yield: 0.349 g, 74%. *Anal.* Calc. for $C_{38}H_{36}O_4N_2S_4P_2Ni$: Ni, 7.04; S, 15.39. Found: Ni, 7.25; S, 15.72%.

3.1.6. $Ni[S_2P(OC_6H_4Me\text{-}p)_2]_2 \cdot C_{10}H_8N_2$ (**6**)

Yield: 0.357 g, 77.5%. *Anal.* Calc. for $C_{38}H_{36}O_4N_2S_4P_2Ni$: Ni, 7.04; S, 15.39. Found: Ni, 7.11; S, 15.48%.

3.1.7. $Ni[S_2P(OC_6H_4Me\text{-}o)_2]2 \cdot C_{14}H_{12}N_2$ (**7**)

Yield: 0.288 g, 69.7%. *Anal.* Calc. for $C_{42}H_{40}O_4N_2S_4P_2Ni$: Ni, 6.84; S, 14.96. Found: Ni, 6.75; S, 14.72%.

3.1.8. $Ni[S_2P(OC_6H_4Me\text{-}m)_2]_2 \cdot C_{14}H_{12}N_2$ (**8**)

Yield: 0.321 g, 71.9%. *Anal.* Calc. for $C_{42}H_{40}O_4N_2S_4P_2Ni$: Ni, 6.84; S, 14.96. Found: Ni, 6.81; S, 14.90%.

3.1.9. $Ni[S_2P(OC_6H_4Me\text{-}p)_2]_2 \cdot C_{14}H_{12}N_2$ (**9**)

Yield: 0.426 g, 73.4%. *Anal.* Calc. for $C_{42}H_{40}O_4N_2S_4P_2Ni$: Ni, 6.84; S, 14.96. Found: Ni, 6.79; S, 14.87%.

3.2. Physical measurements

Sulfur was estimated gravimetrically as barium sulfate (Messengers method) and nickel as dimethylglyoximate. IR spectra were recorded in the range 4000–200 cm^{-1} on a Perkin–Elmer 983G spectrophotometer (Nujol mull). Electronic spectra in the range 200–1200 nm were recorded on a Perkin Elmer UV/VIS/NIR spectrometer-Lambda 19 in CH_2Cl_2. The magnetic measurements at 298 K were determined using the Evans NMR method [32].

Table 3
Crystal data and structure refinements for $Ni[S_2P(OC_6H_4Me\text{-}p)_2]_2 \cdot C_{10}H_8N_2$ and $Ni[S_2P(OC_6H_4Me\text{-}o)_2]_2 \cdot C_{14}H_{12}N_2 \cdot C_6H_6$

Index ranges	$-14 \leqslant h \leqslant 13$, $-15 \leqslant k \leqslant 15$, $-21 \leqslant l \leqslant 21$	$-16 \leqslant h \leqslant 16$, $-26 \leqslant k \leqslant 27$, $-17 \leqslant l \leqslant 15$
Reflections collected	40 064	41 699
Independent reflections [R_{int}]	8756 [0.0289]	8062 [0.1040]
Max. and min. transmission	0.9197 and 0.8483	0.9513 and 0.8693
Refinement method	Full-matrix least-squares on F^2	Full-matrix least-squares on F^2
Data/restraints/parameters	8756/0/461	8062/0/551
Goodness-of-fit on F^2	1.037	1.019
Final *R* indices [$F^2 > 4\sigma(F^2)$]	$R_1 = 0.0277$, $wR_2 = 0.0703$	$R_1 = 0.0590$, $wR_2 = 0.1083$
R indices (all data)	$R_1 = 0.0328$, $wR_2 = 0.0730$	$R_1 = 0.1097$, $wR_2 = 0.1260$
Extinction coefficient	0.0029(5)	
Largest difference in peak and hole (e $Å^{-3}$)	0.489 and −0.390	0.738 and −0.564

3.3. Crystal structure determination

A translucent green, block crystal of $Ni[S_2P(OC_6H_4Me\text{-}p)_2]_2 \cdot C_{10}H_8N_2$ (**6**) and a green prism crystal of $Ni[S_2P(OC_6H_4Me\text{-}o)_2] \cdot C_{14}H_{12}N_2 \cdot C_6H_6$ (**7**) were mounted on a glass fibre. Data were collected on a Bruker-Nonius Kappa CCD area detector diffractometer, with ϕ and ω scans chosen to give a complete asymmetric unit. Cell refinement [33] gave cell constants corresponding to a triclinic cell for **6** and a monoclinic cell for **7** whose dimensions are given in Table 3 along with other experimental parameters. The crystal of **7** was a monoclinic pseudo merohedral twin with beta approximately 90° emulating orthorhombic. An absorption correction was applied [34].

The structures were solved by direct methods [35] and refined using the WinGX version [36] of SHELX-97 [37]. All of the non-hydrogen atoms were treated anisotropically. Hydrogen atoms were included in idealized positions with isotropic thermal parameters set at 1.2 times that of the carbon atom to which they were attached. The final cycle of full-matrix least-squares refinement was based on 8756 observed reflections (7822 for $F^2 > 4\sigma(F^2)$) and 461 variable parameters for **6** and 8062 observed reflections (5543 for $F^2 > 4\sigma(F^2)$); and 551 variable parameters for **7** and converged (largest parameter shift was 0.001 times its esd).

Selected distances and bond angles are given in Tables 4 and 5 for molecules **6** and **7**, respectively and the molecules are displayed as ORTEP diagrams in Figs. 1 and 2.

4. Concluding comments

We have successfully prepared and characterized the following complexes, $Ni[S_2P(OR)_2]_2 \cdot nL$ ((R = *o*-, *m*-, *p*-C_6H_4Me; $n = 2$, $L = C_5H_5N$; $n = 1$, $L = C_{10}H_8N_2$, $C_{14}H_{12}N_2$). The IR, UV–visible and magnetic measurements of all of these nickel adducts and molecular structures of two representative complexes, $Ni[S_2P(OC_6H_4Me\text{-}p)_2]_2 \cdot C_{10}H_8N_2$ and $Ni[S_2P(OC_6H_4Me\text{-}o)_2]_2 \cdot C_{14}H_{12}N_2 \cdot C_6H_6$ suggest the distorted octahedral for complexes **1**–**6** and distorted trigonal bipyramidal environ-

ments around nickel for complexes **7**–**9** and are consistent with the proposed structures for the analogous complexes $Ni[S_2P(OMe)_2]_2 \cdot phen$, $Ni[S_2P(OMe)_2]_2 \cdot dmphen$ and $Ni[S_2POCMe_2CMe_2O)_2]_2 \cdot dmphen$.

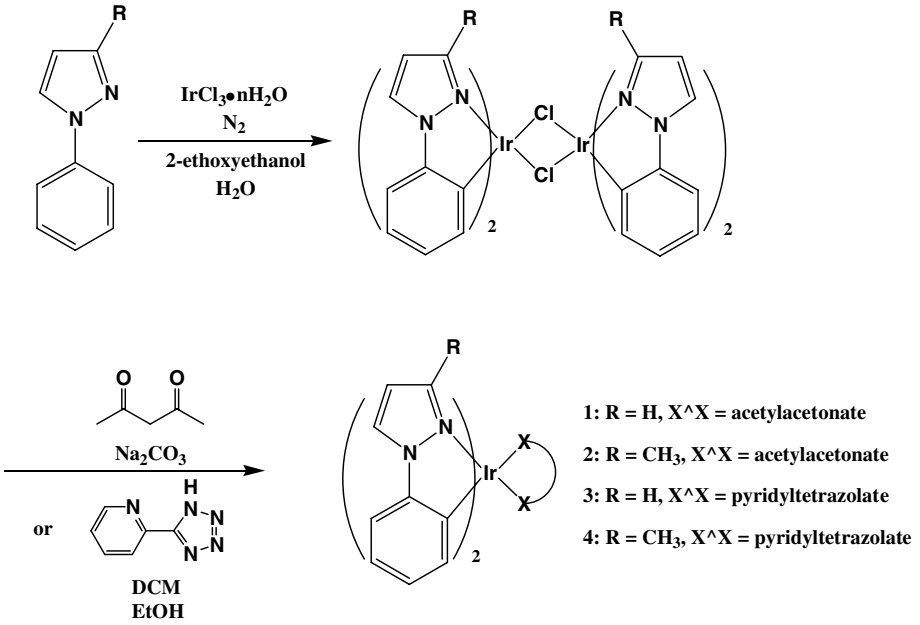
is expected to disturb the HOMO and LUMO of the metal complexes, and afford a subtle color tuning via substituting either pyrazolate, tetrazolate or acetylacetonate sites.

2. Experimental

2.1. General information and materials

All materials including the *N*-phenylpyrazole ligands were obtained from Aldrich, Acros or TCI and were used without further purification. 5-(2′-Pyridyl)tetrazole is a known compound and can be prepared easily in one step from commercially available 2-cyanopyridine and sodium azide [16]. Scheme 1 outlines how the iridium dimers were synthesized by the method reported by Nonoyama and were utilized for preparing a series of $(C^N)_2Ir(O^O)$ or $(C^N)_2Ir(N^N)$ complexes [17,15]. All synthetic procedures and manipulations involving $IrCl_3 \cdot H_2O$ and other Ir(III) species were carried out under N_2.

Column chromatography was carried out using 70–230 mesh silica gel. ^1H NMR and ^{13}C NMR spectra were recorded in CD_2Cl_2 solution on Bruker Avance-300 (300 MHz) or AMX-400 (400 MHz) NMR spectrometers with tetramethylsilane (TMS) as the internal standard; all chemical shifts were reported in ppm from TMS. Elemental analyses were performed on a Heraeus CHN-RAPID elemental analyzer and Elementar vario EL III analyzer. The EI-Mass spectra were recorded on Bruker APEX II and VG 70-250S spectrometers. HRMS spectra were obtained using a MAT-95XL high resolution mass spectrometer. The UV–Vis spectra were measured in a 1.0×10^{-5} M CH_2Cl_2 solution on an Agilent 8453 spectrophotometer, and the photoluminescence spectra were recorded in a 1.0×10^{-5} M CH_2Cl_2 solution with a HITACHI model F-2500 fluorescence spectrophotometer.



2.2. General information for the preparation of the iridium complexes

Scheme 1 outlines the synthetic process for an example of the iridium complexes $(C^N)_2Ir(O^O)$ or $(C^N)_2Ir(N^N)$. Detailed procedures of the preparation, the ^1H NMR spectra and chemical analysis data of the iridium complexes are given afterwards.

2.3. Synthesis of bis(1-phenylpyrazolato-*N*,$C^{2'}$)iridium(III)(acetylacetonate) (**1**)

The dimer $[(C^N)_2IrCl]_2$ was synthesized according to a previous report [17]. 1-Phenylpyrazole (1.22 g, 8.38 mmol) and iridium trichloride ($IrCl_3 \cdot nH_2O$, 1.0 g, 3.34 mmol) were dissolved in a 1:3 mixture of water and 2-ethoxyethanol. The mixture was refluxed at 110 °C for 24 h under a nitrogen atmosphere and then cooled to room temperature. After cooling, the product was isolated by filtration and washed with several portions of distilled water and then vacuum dried. The solid was collected by filtration and pumped to dry to give crude $[(1\text{-ppz})_2IrCl]_2$, 1.16 g (67.8%).

After cyclometallated Ir(III) μ-chloro-bridged dimers were obtained, 1.16 g of the dimer was dispersed in 2-ethoxyethanol in a flask, followed by addition of acetylacetone (0.56 g, 6.78 mmol) and sodium carbonate (1.32 g, 12.43 mmol), and the mixture was stirred under nitrogen for 15 min. After that, the mixture was refluxed at 126 °C for 15 h and then cooled to room temperature. The crude product was isolated by filtration and washed with distilled water, *n*-hexane and ether. (77% crude product yield) The crude product was chromatographed using ethyl acetate/*n*-hexane (1:1) to yield a yellow green powder, **1**. ^1H NMR (CD_2Cl_2, 400 MHz) δ 8.19 (s, 2H), 7.61 (s, 2H), 7.23 (d, $J = 7.7$ Hz, 2H), 6.92 (dd, $J = 7.7$, 7.5 Hz, 2H),

Scheme 1. Synthesis of the iridium(III) complexes.

6.73 (t, $J = 7.4$ Hz, 4H), 6.30 (d, $J = 7.5$ Hz, 2H), 5.28 (s, 1H), 1.85 (s, 6H); ^{13}C NMR (CD_2Cl_2, 100 MHz) δ 175.3, 134.8, 128.0, 124.9, 118.5, 116.2, 115.2, 111.6, 100.7, 96.9, 90.1, 18.0; FABMS: m/z 578, $[M+H]^+$; HRFABMS calcd for $C_{23}H_{22}O_2N_4Ir$, 578.1295, found 578.1291. *Anal*. Calc for $C_{23}H_{21}O_2N_4Ir \cdot 1/6n$-hexane: C, 48.28; N, 9.39; H, 3.91. Found: C, 48.13; N, 9.12; H, 4.19%.

2.4. Synthesis of bis(3-methyl-1-phenylpyrazolato-$N,C^{2'}$)iridium(III)(acetylacetonate) (2)

Yield: 65%; yellow green powder; ^{1}H NMR (CD_2Cl_2, 400 MHz) δ 7.91 (d, $J = 2.5$ Hz, 2H), 7.05 (d, $J = 7.6$ Hz), 6.76 (dd, $J = 7.6$, 7.4 Hz, 2H), 6.61 (t, $J = 7.3$ Hz, 2H), 6.30 (d, $J = 2.5$ Hz), 5.28 (s, 1H), 2.35 (s, 6H), 1.70 (s, 6H); ^{13}C NMR (CD_2Cl_2, 100 MHz) δ 175.6, 140.8, 135.0, 124.9, 117.5, 116.5, 114.7, 111.6, 100.0, 97.3, 91.3, 17.9, 1.9; FABMS: m/z 606, $[M+H]^+$; HRFABMS calc. for $C_{25}H_{26}O_2N_4Ir$, 606.1608, found 606.1603. *Anal*. Calc. for $C_{25}H_{25}O_2N_4Ir$: C, 49.57; N, 9.25; H, 4.13. Found: C, 49.38; N, 9.11; H, 4.27%.

2.5. Synthesis of bis(1-phenylpyrazolato-$N,C^{2'}$)iridium(III)[5-(2′-pyridyl)tetrazolate] (3)

Crude dimer $[(C\hat{}N)_2IrCl]_2$ (0.35 g, 0.34 mmol), 5-(2′-pyridyl)tetrazole (0.13 g, 0.85 mmol), dichloromethane and ethanol were added to a flask. The mixture was stirred at room temperature for 4–6 h. After drying in a vacuum the solid was washed with distilled water, *n*-hexane and ether. The crude product was chromatographed using chloroform/acetone (1:1) to yield a yellow powder, **3**. (58%) ^{1}H NMR (CD_2Cl_2, 500 MHz) δ 8.38 (d, $J = 7.9$ Hz, 1H), 8.10–8.07 (m, 2H), 8.00 (d, $J = 5.6$ Hz, 1H), 7.95 (td, $J = 7.9$, 1.4 Hz, 1H), 7.30 (dd, $J = 7.2$, 6.8 Hz, 2H), 7.22 (ddd,$J = 7.4$, 5.6, 1.4 Hz, 1H), 7.11–6.89 (m, 2H), 6.83–6.81 (m, 4H), 6.48–6.44 (m, 2H), 6.41 (dd, $J = 7.4$, 1.0 Hz, 1H), 6.32 (dd, $J = 7.4$, 1.0 Hz, 1H); ^{13}C NMR (CD_2Cl_2, 125 MHz) δ 154.5, 140.6, 140.4, 133.8, 133.3, 129.1, 129.0, 127.6, 123.9, 123.8, 119.2, 116.6, 116.5, 116.4, 116.0, 115.4, 112.9, 112.6, 112.5, 101.5, 101.3, 97.9, 97.6, 19.9; FABMS: m/z 626, $[M+H]^+$; HRESIMS calcd for $C_{24}H_{19}N_9Ir$, 626.1393, found 626.1396.

2.6. Synthesis of bis(3-methyl-1-phenylpyrazolato-$N,C^{2'}$)iridium(III)[5-(2′-pyridyl)tetrazolate] (4)

Yield: 65%; yellow green powder; ^{1}H NMR (CD_2Cl_2, 300 MHz) δ 8.37 (d, $J = 7.8$ Hz, 1H), 7.96 (d, $J = 6.7$ Hz, 2H), 7.91 (d, $J = 7.5$ Hz, 2H), 7.27–7.18 (m, 3H), 7.06–7.00 (m, 2H), 6.97–6.76 (m, 2H), 6.45 (d,$J = 7.4$ Hz, 1H), 6.33 (d, $J = 7.5$ Hz, 1H), 6.00 (s, 2H), 1.65 (s, 3H), 1.53 (s, 3H); ^{13}C NMR (CD_2Cl_2, 75 MHz) δ 154.3, 141.5, 140.5, 134.0, 133.7, 128.9, 124.0, 123.8, 123.1, 120.0, 117.9, 116.9, 116.7, 116.0, 115.6, 115.5, 112.9, 112.6, 104.8, 100.9, 100.6, 98.0, 97.8, 85.1; FABMS: m/z 606, $[M+H]^+$; HRESIMS calc. for $C_{26}H_{23}N_9Ir$, 654.1706, found 654.1707. *Anal*. Calc. for $C_{25}H_{25}O_2N_4Ir \cdot CH_2Cl_2$: C, 43.96; N, 17.09; H, 3.26. Found: C, 44.13; N, 17.03; H, 3.45%.

3. Electrochemistry

Cyclic voltammograms (CV) were performed with a Voltammetric Analyzer (Bioanalytical Model CV-50W). All CV measurements were carried out in CH_2Cl_2 containing 0.1 M tetrabutylammonium perchlorate (n-Bu_4NClO_4) as the supporting electrolyte. A Pt disk electrode was used as the working electrode, a Pt wire as the counter electrode, and $Ag/AgNO_3$as the reference electrode. The ferrocenium/ferrocene redox couple in CH_2Cl_2/n-Bu_4NClO_4 occurs at $E^{\circ\prime} = +0.35$ V versus $Ag/AgNO_3$. The oxidation potential of the Ir complexes is reported versus the ferrocenium/ferrocene redox couple.

4. X-ray crystallographic analyses

Crystals of **1**, **2** and **4** were obtained from solutions of CH_2Cl_2-Ether. The crystal data were selected for indexing and intensity data collection on a Siemens SMART CCD diffractometer equipped with a normal focus, 3-kW sealed tube X-ray source at 21–23 °C. No significant decay was observed for all samples during the data collection. Data were processed on a PC using the Bruker AXS SHELXTL NT software package. Neutral atom scattering factors were taken from Cromer and Waber. The crystals of **1** and **2** belong to the orthorhombic space group *Pca*2(1) and *Pbca*, respectively. The crystal of **4** belongs to the Prism space group *P*2(1)*cn*. All the structures were solved by direct methods. All non-hydrogen atoms were refined anisotropically. The positions for all hydrogen atoms were either calculated or located directly from difference Fourier maps and their contributions to structural factor calculations were included. The crystallographic data of **1**, **2** and **4** are given in Table 1, and selected bond lengths and angles are summarized in Table 2.

5. Results and discussion

5.1. Synthesis and characterization

The ligands 1-phenylpyrazole and 3-methyl-1-phenylpyrazole were purchased from Aldrich and were used without further purification. According to the procedure in the literature [16], 5-(2′-pyridyl)tetrazole could be synthesized by the cyclization of 2-cyanopyridine and sodium azide. The iridium complexes, $(C\hat{}N)_2Ir(O\hat{}O)$, were prepared from the phenylpyrazole ligands and iridium trichloride hydrate to form a dimer, $[(C\hat{}N)_2IrCl]_2$, followed by the reaction with acetylacetone in the presence of sodium carbonate. On the other hand, the iridium complexes, $(C\hat{}N)_2Ir(N\hat{}N)$, were prepared by reacting the dimer with 5-(2′-pyridyl)tetrazole in the presence of dichloromethane and methanol [15]. All procedures involving Ir(III) species were carried out under a nitrogen gas atmosphere. All these materials

were characterized by elemental analysis, ^{1}H and ^{13}C NMR, and mass spectrometry. Whereas **1**, **2** and **4** were further identified using single-crystal X-ray analysis to establish their three-dimensional structures, complex **3** is a yellow powder, and we could not get reliable elemental analysis data for this complex. The HRESIMS, ^{1}H and ^{13}C NMR spectra of **3** are given in the Supplementary material.

The single-crystal structures of complexes **1**, **2** and **4** are presented with an ORTEP diagram in Fig. 1. They were obtained from solutions of dichloromethane–ether. As shown in Fig. 1, complexes **1** and **2** reveal a distorted octahedral geometry around the iridium atom with two cyclometallated phenylpyrazole (C^N) ligands and one anionic acetylacetone (O^O) ligand. Complex **4** also shows a distorted octahedral geometry around the iridium atom but with two cyclometallated phenylpyrazole (C^N) ligands and one anionic pyridyltetrazole (N^N) ligand. These three complexes crystallized in different space groups, complexes **1**, **2** and **4** belong to the orthorhombic space group *Pca*2(1), the orthorhombic space group *Pbca* and the *Prism* space group *P*2(1)*cn*, respectively. The diversity of the space groups of these complexes suggests that the packing of these complexes is very sensitive to the different substituents of the ligands. The phenylpyrazole ligands mutually adopt an eclipsed configuration with the nitrogen atoms residing in trans locations, and the Ir–N distances lie between 2.011(5) and 2.019(5) Å for **1**, 2.037(3) and 2.035(3) Å for **2**, and 2.014(2) and 2.065(2) Å for **4**. The longer Ir–N distance is believed to be caused by the 3-methyl substituent of the phenylpyrazole. The cyclometallated carbon atoms are mutually cis on the iridium and show similar distances between 1.991(4) to 2.030(2) Å. The overall structural arrangement is similar to several previously reported examples [11,12,14].

Interestingly, the third small acetylacetone ligand shows big bite angles of 87.54°(2) for **1** and 88.11°(2) for **2**, and the phenylpyrazole ligands show big bite angles of

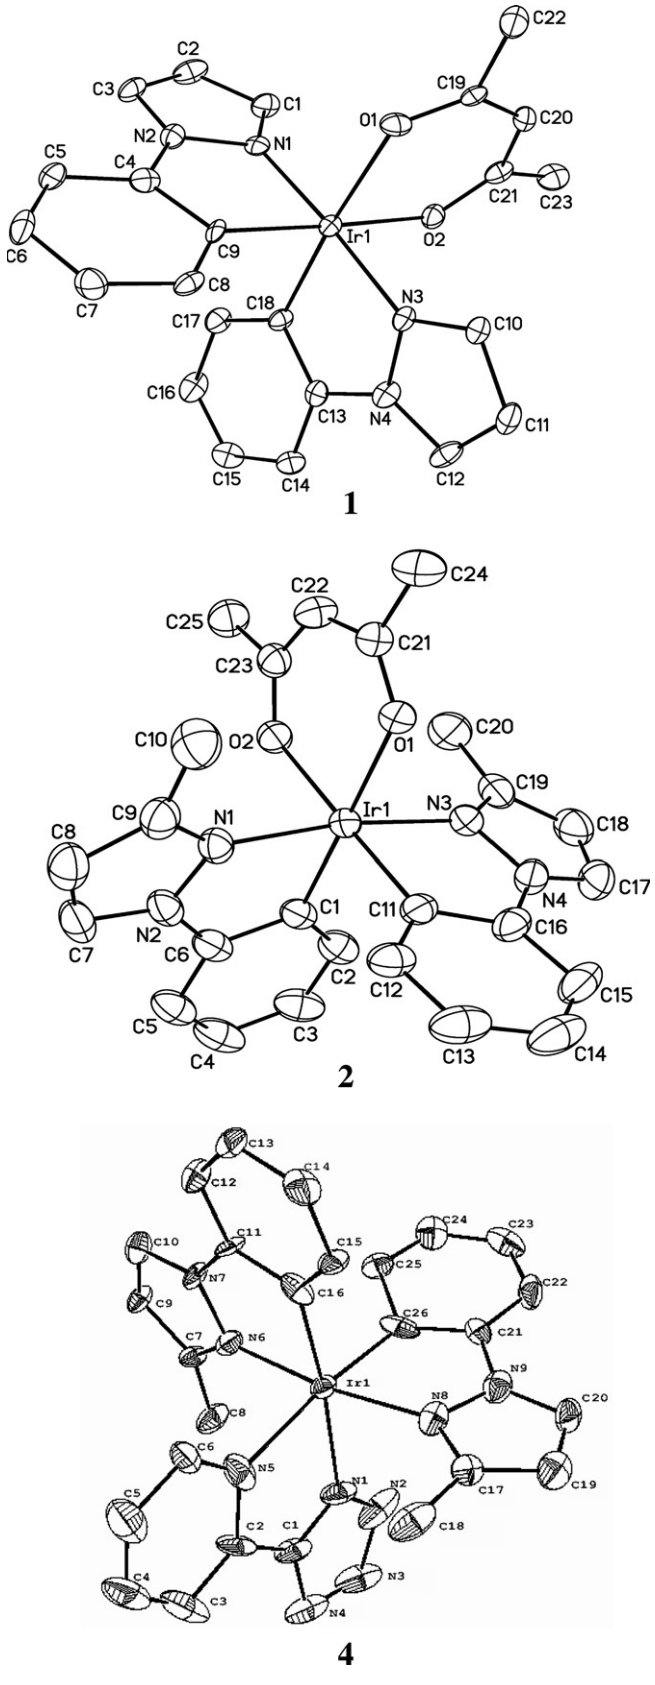

Fig. 1. ORTEP diagrams of **1**, **2** and **4**.

80.2°(2) to 80.74°(2). With the introduction of the third big pyridyltetrazole ligand to replace acetylacetone, the bite angle is small (76.2°(8)) and the phenylpyrazole ligands show smaller bite angles of 77.4°(10) to 79.4°(7). This result can be ascribed to the big molecular structure of the pyridyltetrazole ligand. Moreover, X-ray data show that the dihedral angles between the two planes for **4** (1.199° to 5.184°) and **2** (1.923° to 3.619°) are much larger than **1** (1.133° to 2.032°). This result suggests that the methyl group on the C-3 site of pyrazole creates the largest steric hindrance amongst the complexes.

6. Photophysical data

Figs. 2 and 3 show the UV–Vis absorption and emission spectra of complexes **1**–**4** at 298 K. The data of all the iridium(III) complexes are summarized in Table 3. In general, the dominant absorption band in the spectra region of 250–270 nm is attributed to the local $^1\pi\pi^*$ transition of the phenylpyrazole ligands. The structureless bands at 280–350 nm can be assigned to a combination of intra-ligand

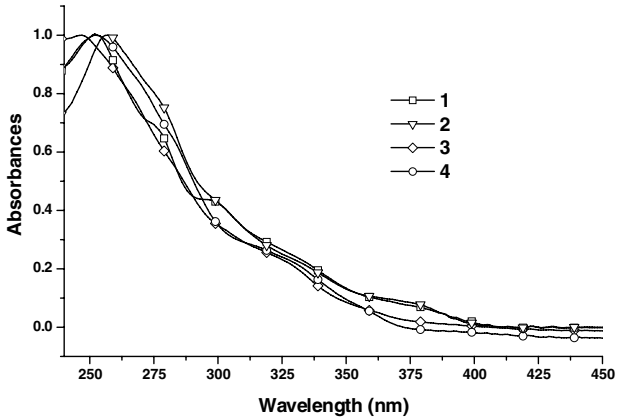

Fig. 2. Normalized UV–Vis spectra of the iridium complexes in CH_2Cl_2.

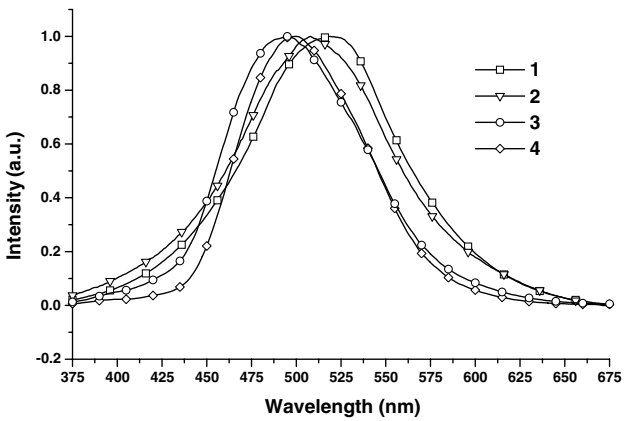

Fig. 3. Normalized photoluminescence spectra of the iridium complexes in CH_2Cl_2.

charge transfer (ILCT) and metal to ligand charge transfer (MLCT) in the singlet manifold. The lower lying band that is located at 350–400 nm can be assigned to the mixing of ^{3}MLCT and $^3\pi\pi^*$ transition character bands. Complexes **3** and **4** exhibit ~5–10 nm blue shift in comparison with **1** and **2**. This result is predictable because the stronger electron-withdrawing ligand 5-(2′-pyridyl)tetrazole is introduced for the N^N site coordination.

As depicted in Table 3 and Fig. 3, all of the iridium complexes exhibit a bluish green emission at 495–520 nm in CH_2Cl_2. Complexes **3** and **4** exhibit blue shift (about 8–25 nm) in comparison to complexes **1** and **2**. Accordingly, the third ligand (O^O or N^N) contributes to the lowest T_1–S_0 transition. Interestingly, the 3-methyl substituent at phenylpyrazole shows different effects in the (O^O) and (N^N) coordination complexes. Complex **2** is blue shift but complex **4** is red shift. The electron-donating group (methyl group) plays only a part in the contribution. After introducing the third different ligands, the degree of perturbation in the iridium center and ligands is different and causes different lowest T_1–S_0 transitions.

The emission intensities of complexes **1** and **2** were found to be relatively weak by using FIrN4 (iridium(III)bis(4,6-difluorophenylpyridinato)-5-(pyridine-2-yl)-1*H*-tetrazolate) as a reference in degassed CH_2Cl_2 [8]. This result agreed with reports about phenylpyrazolate iridium complexes. Surprisingly, complexes **3** and **4** exhibit stronger quantum efficiency. After introducing pyridyltetrazole ligand as the third ligand for N^N coordination, the photophysical properties of the iridium complexes are changed. Evidently, the radiative constant (k_r) of complexes **3** and **4** is faster than the non-radiative constant (k_{nr}), and this changes the temperature-dependent characteristics of phenylpyrazolate iridium complexes.

Table 3
λ_{max} of UV–Vis and photoluminescence data of the iridium(III) complexes

Complex	Absorbance[a] λ_{max} (nm) (log ε)	FWHM (nm)	Emission[a] λ_{max} (nm)	$\Phi_{degassed}$[b]
1	255(4.71), 302(4.30), 331(4.07)	99	520	0.02
2	260(4.96), 305(4.54), 338(4.23)	98	508	0.005
3	250(4.51), 330(3.82)	90	495	0.18
4	256(4.36), 327(3.72)	81	500	0.13

[a] All data were obtained in CH_2Cl_2 solution (concentration = 10^{-5} M). The unit of ε is M^{-1} cm^{-1}.

[b] The quantum yields (Φ, relative emission intensities) in degassed CH_2Cl_2 solution were measured at 298 K and used $FIrN_4$ ($\Phi = 1$) as a standard.

7. Redox chemistry

Cyclic voltammetry was conducted at a Pt disk electrode (BAS Co.) in CH_2Cl_2 solutions containing 0.001 M of the iridium complexes and 0.1 M tetra-*n*-butylammonium perchlorate as the supporting electrolyte. The voltammograms of the iridium complexes are shown in Fig. 4 together with the voltammogram of ferrocene. The electrochemical data of these compounds are collected in Table 4. It shows that complexes **1** and **2** undergo a reversible one-electron oxidation (peak potential separation ~60 mV) with no reduction process observed within the solvent cathodic potential limit. Complexes **3** and **4** undergo a quasi-reversible oxidation because of the instability of the oxidative intermediates. The energy level of the LUMO was evaluated from the long-wavelength absorption edge using the theory reported by Burrows et al. [18,19]. The summarized $E_{1/2}$, HOMO, LUMO and energy gap data of complexes **1** and **2**, shown in Table 4, are very close to each other. This

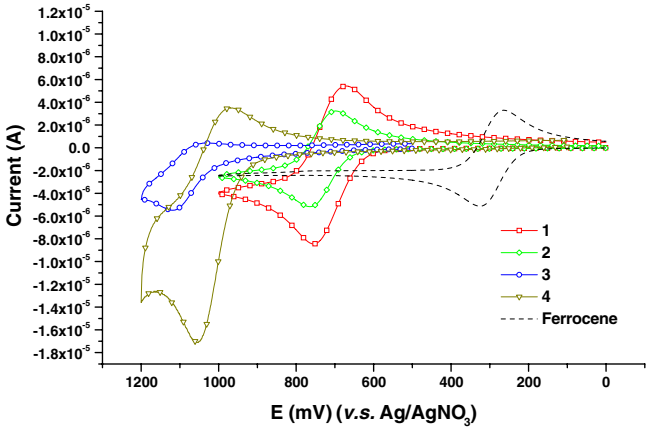

Fig. 4. Cyclic voltammograms of the iridium complexes. CV data were measured in CH_2Cl_2 solution with Pt disk electrode, $Ag/AgNO_3$ electrode and Pt electrode as working, reference and counter electrode, respectively. The scan rate was 100 mV/s, using ferrocene as a reference.

Table 4
Electrochemical data, HOMO, LUMO and energy gap of the iridium(III) complexes

Complex	$E^a_{p(ox)}$ (mV)	$E^c_{p(ox)}$ (mV)	$E_{1/2(ox)}$[a] (mV)	HOMO[c] (eV)	Energy gap[d] (eV)	LUMO[e] (eV)
1	756	670	713 [420][b]	−5.22	2.98	−2.24
2	766	696	713 [420][b]	−5.22	2.98	−2.24
3	1118	1036	1077 [340][b]	−5.54	3.22	−2.32
4	1060	964	1012 [340][b]	−5.47	3.33	−2.14

[a] Data were collected in CH_2Cl_2 solution.

[b] $E_{1/2(ox)}$ vs ferrocene/ferrocenium.

[c] Data were collected in CH_2Cl_2 solution containing 0.001 M of the iridium(III) complexes by cyclic voltammetry.

[d] Data were collected in CH_2Cl_2 solution by UV–Vis spectrophotometry.

[e] Data were calculated from the HOMO + energy gap.

result implies that the contribution of the methyl group in $(ppz)_2Ir(O\hat{}O)$ complexes is small and does not affect the photo- and electrochemical properties. After replacing the acetylacetone with pyridyltetrazole, the $E_{1/2(ox)}$ of **3** and **4** shifts to 1077 and 1012 mV in comparison to **1** and **2**. This result indicates that the effect of introducing the strong electron-withdrawing pyridyltetrazole is stronger than for acetylacetone. This effect also shows the same shift in the HOMO and energy gap. The electron-donating effect in $(ppz)_2Ir(N\hat{}N)$ complexes is apparent, **4** is oxidized more easily than **3** because of the electron-donating character of the methyl group. The methyl substituent in pyrazole donates electron density and makes oxidation of the iridium center occur more easily.

8. Conclusion

This work reports the detailed synthesis and electrochemical and photophysical properties of phenylpyrazolate iridium(III) complexes. Among these iridium(III) complexes, **3** and **4** show excellent quantum yields because the electron density is perturbed by introducing the pyridyltetrazole ligand and makes $k_r > k_{nr}$. This concept is helpful for ligand design in the future.

Appendix A. Supplementary material

CCDC 261556, 261557 and 601712 contain the supplementary crystallographic data for **1**, **2** and **4**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit @ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2007.01.030.

2.1. Synthesis of [RuCl(CO)(PPh$_3$)$_2$(C$_5$H$_4$ NCOO)] (1)

A suspension of [RuHCl(CO)(PPh$_3$)$_3$] (0.95 g; 1×10^{-3} mol) and 2-benzoylpyridine (0.36 g; 2×10^{-3} mol) in dimethoxyethane (100 cm^{-3}) was refluxed until the solid dissolved, then the solution was cooled and filtered. Brown crystals suitable for X-ray crystal analysis were obtained by slow evaporation of the reaction mixture. Yield 72%.

Anal. Calc. for $C_{90}H_{82}Cl_2N_2O_{10}P_4Ru_2$: C, 61.82; H, 4.73; Cl, 4.06; N, 1.60; O, 9.15; P, 7.09; Ru, 11.56. Found: C, 62.01; H, 4.63; N, 1.66%.

IR (KBr, cm^{-1}): 3566 ν_{OH}; 3058 ν_{CH}; 2897 $\nu_{CH-phenyl}$; 1946 $\nu_{C\equiv O}$; 1647 ν_{CN}; 1568 asν_{COO}; 1482 $\delta_{(C-CH\ in\ plane)}$; 1433 $\nu_{Ph(P-Ph)}$; 1344 sν_{COO}; 1094 $\delta_{(C-CH\ in\ plane)}$; 997 $\delta_{(C-C\ out\ of\ plane)}$; 748 $\delta_{(C-C\ out\ of\ plane)}$; 692 $\delta_{(C-C\ in\ plane)}$; 598 ν_{P-Ph}.

^{1}H NMR (δ, CDCl$_3$): 7.24–7.82 (m, PPh$_3$/pyridine), 8.54 (s 1H pyridine ring).

^{31}P NMR (δ, CDCl$_3$): 31.61 (s, PPh$_3$).

UV–Vis [nm] in CH_2Cl_2 (log ε): 370.0 (2.24); 264.2 (3.93); 216.0 (4.37).

2.2. Synthesis of [RuCl$_2$(C$_{12}$H$_9$NO)$_2$] (2)

A suspension of $[(C_6H_6)RuCl_2]_2$ (0.25 g; 5×10^{-4} mol) and 2-benzoylpyridine (0.18 g; 1×10^{-3} mol) in dimethoxyethane (100 cm^{-3}) was refluxed until the solid dissolved, then the solution was cooled and filtered. The dark blue crystals suitable for X-ray crystal analysis were obtained by slow evaporation of the reaction mixture. Yield 68%.

Anal. Calc. for $C_{24}H_{18}Cl_2N_2O_2Ru$: C, 53.54; H, 3.37; Cl, 13.17; N, 5.20; O, 5.94; Ru, 18.77. Found: C, 53.01; H, 3.23; N, 5.16%.

IR (KBr, cm^{-1}): 3056 ν_{CH}; 2918 $\nu_{CH-phenyl}$; 1663 ν_{CN}; 1594 $\nu_{C=O}$; 1449 $\nu_{C=C}$; 1335 $\nu_{C=O}$; 1155 δ_{CH}; 1011 δ_{CH}; 696 δ_{ring}.

^{1}H NMR (δ, CDCl$_3$): 7.51, 7.53, 8.08 (Ph), 8.75, 7.93, 7.81 (pyridine ring hydrogens).

UV–Vis [nm] in CH_2Cl_2 (log ε): 737.6 (2.39); 600.0 (2.06); 462.0 (sh); 370.4 (1.96); 266.0 (3.28); 218.2 (4.12).

2.3. Physical measurements

Infrared spectra were recorded on a Nicolet Magna 560 spectrophotometer in the spectral range 4000–400 cm^{-1} with the sample in the form of a KBr pellet. Electronic spectra were measured on a Lab Alliance UV–Vis 8500 spectrophotometer in the range 800–200 nm in dichloromethane solution. Elemental analyses (C, H, N) were performed on a Perkin–Elmer CHN-2400 analyzer. The ^{1}H NMR spectra were obtained at room temperature in $CDCl_3$ using a INOVA 300 spectrometer.

2.4. DFT calculations

The GAUSSIAN-03 program [10] was used in the calculations. The geometry optimisation was carried out with the DFT method with the use of the B3LYP functional [11,12]. The electronic transitions were calculated with the PCM model [13] in dichloromethane as the solvent. The calculation was performed using the DZVP basis set [14] with *f* functions with exponents 1.94722036 and 0.748930908 on the ruthenium atom, and polarization functions to all other atoms: 6-31g(2d,p) – chlorine, 6-31g** – carbon, nitrogen, oxygen and 6-31g(d,p) on hydrogen atoms. Natural bond orbital (NBO) calculations were performed with the NBO code [15] included in GAUSSIAN-03.

2.5. Crystal structure determination and refinement

A brown prism of complex **1** and dark-blue needle of **2** were mounted in turn on a KM-4-CCD automatic diffractometer equipped with a CCD detector, and were used for data collection. X-ray intensity data were collected with graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at a temperature of 291.0(3) K, with the ω scan mode. The full Ewald sphere reflections were collected up to $2\theta = 51.2°$ for complex **1** and $2\theta = 50.2°$ for **2**. The unit cell parameters were determined from least-squares refinement of the setting angles of 7697 and 3604 strongest reflections for complexes **1** and **2**, respectively. Details concerning crystal data and refinement are gathered in Table 1. The reference frames monitored every 40 measurement frames show 1.01% decay for the crystal of compound **1** and none for the crystal of compound **2**. During the data reduction above, the decay correction coefficient was taken into account. Lorentz, polarization and numerical absorption [16] corrections were applied. The structures were solved using the Patterson method combined with a partial structure expansion procedure. All the non-hydrogen atoms were refined anisotropically using full-matrix, least-squares techniques on F^2. The hydrogen atoms were found from difference Fourier synthesis after four cycles of anisotropic refinement, and refined as "riding" on the adjacent atom with individual isotropic temperature factors equal to 1.2 times the value of the equivalent temperature factor of the parent atom. SHELXS97 [17,18] and SHELXTL [19] programs were used for all the calculations. Atomic scattering factors were those incorporated in the computer programs.

3. Results and discussion

The reactions of $[RuHCl(CO)(PPh_3)_3]$ and $[(C_6H_6)RuCl_2]_2$ with 2-benzoylpyridine have been examined in the same solvent and under the same conditions, as may be seen in Fig. 3. In the first case, the oxidation of 2-benzoylpyridine was observed. As the two reactions have been made in air under the same conditions, we consider the hydrido ligand or the hydrido ruthenium complex plays the role in this oxidation rather than the molecular oxygen.

The reaction between $[RuHCl(CO)(PPh_3)_3]$ and 2-benzoylpyridine in dimethoxyethane solution, under atmospheric conditions, yielded the mononuclear ruthenium(II) compound $[RuCl(CO)(PPh_3)_2(C_5H_4NCOO)]$ with a 2-pyridinecarboxylate ligand as a brown, air-stable, crystalline solid. The infrared spectrum of the complex exhibits characteristic bands of the COO stretching mode: an asymmetric vibration at 1568 cm^{-1} and a symmetric vibration at 1344 cm^{-1}. The C=N stretching modes are visible at 1647 cm^{-1}. The $\nu_{Ph(P-Ph)}$ absorption band is visible at 1433 cm^1. The strong band at 1946 cm^{-1} is assigned to the ν_{CO} stretching of the carbonyl bonded to the ruthenium centre.

The pyridinecarboxylato and triphenylphosphine ligands give signals at 8.54 ppm (position six of the 2-pyridinecarboxylate ring) and in the 7.24–7.82 ppm region, respectively. The singlet at 31.61 ppm in the ^{31}P NMR spectrum indicates the coordinated triphenylphosphine ligands.

The reaction of $[(C_6H_6)RuCl_2]_2$ with 2-benzoylpyridine in the same solvent gave the ruthenium(II) chloride complex with coordinated benzoylpyridine ligands. In this reaction, the 2-benzoylpyridine is not oxidized to 2-pyridylocarboxylate.

The infrared spectrum of the complex exhibits characteristic bands of the C=N stretching modes, visible at 1663 cm^{-1}. The bands at 1594 and 1335 cm^{-1} are assigned to ν_{CO} stretching of the carbonyl bonded to the ruthenium centre. In the ^1H NMR spectrum, the sets of signals characteristic of the 2-benzoylpyridine ligand are visible.

3.1. Crystal structures

Complex **1** crystallizes as the solvate $\mathbf{1} \cdot DME \cdot 2H_2O$ (where DME = 1,2-dimethoxyethane). The crystal data of the complexes $\mathbf{1} \cdot DME \cdot 2H_2O$ and **2** are given in Table 1. The molecular structures of **1** and **2** are presented in Figs. 1 and 2, respectively. The complexes crystallize respectively in the triclinic $P\bar{1}$ and monoclinic *Cc* space group. The most important angles and bond lengths for **1** and **2**are reported in Tables 2 and 3, respectively. The weak intra- and intermolecular hydrogen bonds [20,21] of $\mathbf{1} \cdot DME \cdot 2H_2O$ are presented in Table 4.

The ruthenium atom in the complex $[RuCl(CO)(PPh_3)_2(C_5H_4NCOO)]$ (**1**) has a distorted octahedral environment with *trans* triphenylphosphine ligands (P(1)–Ru(1)–P(2) 174.50(2)°). The carbonyl ligand is in a *trans* position to the pyridine N donor atom (C(43)–Ru(1)–N(1) 176.60(9)°) and the chloride ion lies *trans* to the coordinated oxygen from the COO group at an angle of 169.98(5)°. All Ru-ligand distances, such as Ru–Cl 2.4037(7) Å, Ru–P 2.3942(7), 2.3961(7) Å, Ru–N

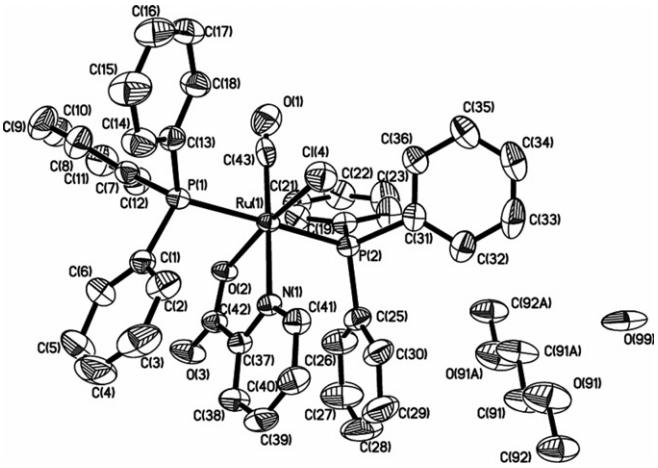

Fig. 1. ORTEP drawing of $[RuCl(CO)(PPh_3)_2(C_5H_4NCOO)]$ with 50% probability thermal ellipsoids. The hydrogen atoms are omitted for clarity.

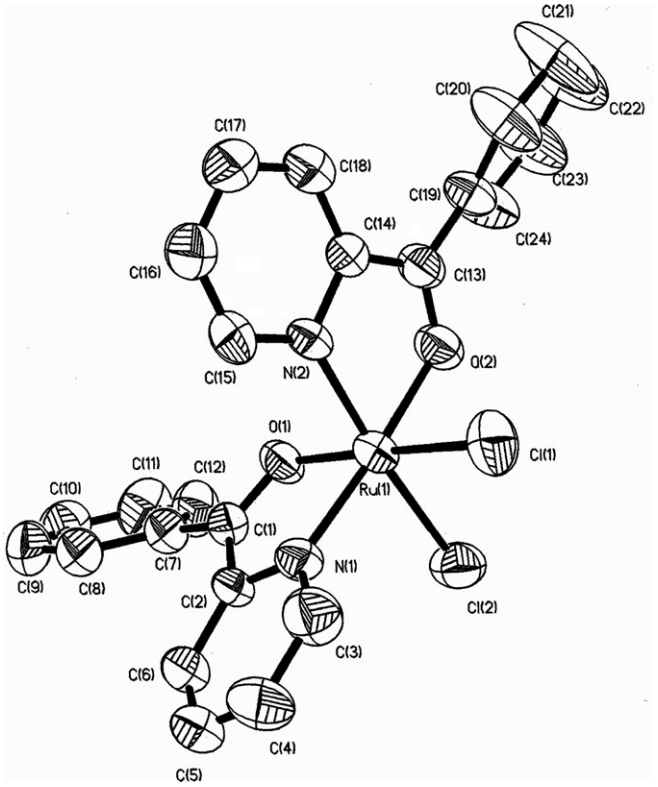

Fig. 2. ORTEP drawing of $[RuCl_2(C_{12}H_9NO)_2]$ with 50% probability thermal ellipsoids. The hydrogen atoms are omitted for clarity.

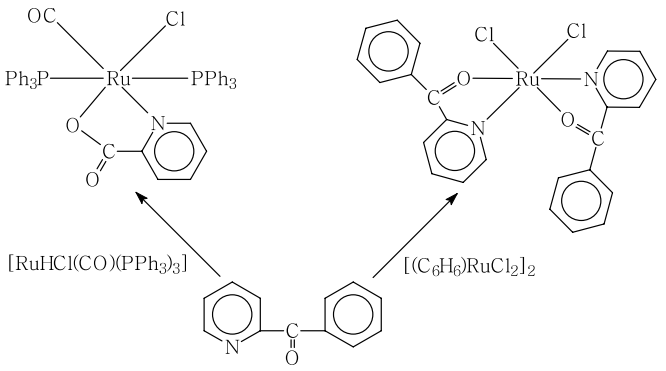

Fig. 3. The scheme of the reactions between 2-benzoylpyridine and $[RuHCl(CO)(PPh_3)_3]$ and $[(C_6H_6)RuCl_2]_2$ complexes.

Table 2
Selected bond lengths (Å) and angles (°) for $[RuCl(CO)(PPh_3)_2(C_5H_4NCOO)]$

	Experimental	Calculated
Bond lengths (Å)		
Ru(1)–C(43)	1.978(4)	1.872
Ru(1)–O(2)	2.1195(16)	2.129
Ru(1)–N(1)	2.1439(19)	2.196
Ru(1)–P(1)	2.3942(7)	2.474
Ru(1)–P(2)	2.3961(7)	2.474
Ru(1)–Cl(4)	2.4037(7)	2.451
C(42)–O(2)	1.300(3)	1.306
C(42)–O(3)	1.228(3)	1.226
C(43)–O(1)	0.922(4)	1.159
Bond angles (°)		
C(43)–Ru(1)–O(2)	99.29(9)	99.19
C(43)–Ru(1)–N(1)	176.60(9)	175.71
O(2)–Ru(1)–N(1)	77.41(7)	76.51
C(43)–Ru(1)–P(1)	89.09(8)	87.58
O(2)–Ru(1)–P(1)	87.98(5)	88.21
N(1)–Ru(1)–P(1)	91.59(6)	92.24
C(43)–Ru(1)–P(2)	89.04(8)	87.58
O(2)–Ru(1)–P(2)	87.22(5)	88.21
N(1)–Ru(1)–P(2)	89.98(6)	92.25
P(1)–Ru(1)–P(2)	174.50(2)	173.46
C(43)–Ru(1)–Cl(4)	90.61(8)	94.09
O(2)–Ru(1)–Cl(4)	169.98(5)	166.71
N(1)–Ru(1)–Cl(4)	92.71(5)	90.20
P(1)–Ru(1)–Cl(4)	90.71(3)	92.37
P(2)–Ru(1)–Cl(4)	94.48(3)	92.37

2.1439(19) Å Ru–C 1.978(4) Å and Ru–O 2.1195(16) Å, are normal and are comparable with the distances in other ruthenium complexes containing heterocyclic ligands [22–24]. The conformation of the molecule is stabilised by three weak intramolecular hydrogen bonds, two between phenyl CH and O(2) (COO) (the D···A distance varies from 3.112(3) to 3.250(3) Å and the D–H···A angle varies from 141.9° to 143.5°) and one linking the pyridine C(41)–H(41) and Cl(4) (D···A distance 3.354(3) Å and D–H···A angle 123.1°). The fourth intermolecular hydrogen bond is formed between water and dimethoxyethane molecules – O(99)–H(99)···O(91) (D···A distance 2.842(6); D–H···A angle 135.0).

The $[RuCl_2(C_{12}H_9NO)_2]$ (**2**) complex possesses chlorine ligands in a *cis* arrangement. The distortions from the ideal octahedral geometry are particularly distinct in the angles between O(1)–Ru(1)–N(1) – 79.03(12)°, N(2)–Ru(1)–O(2) – 78.55(12)° and N(1)–Ru(1)–N(2) – 100.96(13)°. The Ru-ligand distances are normal. No unusual short intermolecular contacts can be found in the structure.

Table 3
Selected bond lengths (Å) and angles (°) for $[RuCl_2(C_{12}H_9NO)_2]$

	Experimental	Calculated
Bond lengths (Å)		
Ru(1)–Cl(1)	2.3893(11)	2.3952

O(99)–H(99)···O(91)	0.96	2.09	2.842(6)	135.0

3.2. Geometry optimisation

The geometries of **1** and **2** were optimised by the DFT method with the B3LYP functional. The optimised geometry parameters for the studied complexes are gathered in Tables 2 and 3. In general, the predicted bond lengths and angles are in good agreement with the values based upon the X-ray crystal structure data, and the general trends observed in the experimental data are well reproduced in the calculations. The calculated bond lengths and angles for $[RuCl(CO)(PPh_3)_2(C_5H_4NCOO)]$ (**1**) agree with the experimental results; the largest difference is found for the Ru(1)–C(43) bond (~0.1 Å). The maximum difference between the calculated and experimental angles is visible for O(2)–Ru(1)–Cl(4) and it is close to 3.3°.

The largest differences for complex $[RuCl_2(C_{12}H_9NO)_2]$ (**2**) between the experimental and calculated geometry are visible in the Ru(1)–O(1) distance (~0.06 Å) and O(1)–Ru(1)–O(2) angle – 4.81°.

3.3. Charge distribution and NBO analysis

The calculated charge on the ruthenium atom in the complex $[RuCl(CO)(PPh_3)_2(C_5H_4NCOO)]$ (**1**) is considerable lower than the formal +2 charge, and it is close to 0.3. This is a result of significant charge donation from the ligands. The charges on the P atoms are positive and close to 1.15; the charge on the chloride ligand is significantly smaller than −1 (−0.57), the charge on the pyridinecarboxylate ligand is close to −0.544. Three natural bond orbitals were detected for the C≡O bond in the complex, and one for the Ru–C bond.

The Ru–C bond orbitals are polarized towards the carbon atom, and the C–O bond orbitals are polarized towards the oxygen end. The oxygen atom of the carbonyl ligand has one lone pair (LP) orbital. The occupancies and hybridization of the CO and Ru–C bonds are given in Table 5 (*anti*-bonding NBOs are given in round brackets). The occupancies of the ruthenium d orbitals, obtained from NBO analysis, are as follows: d_{xy} – 1.76; d_{xz} – 1.93; d_{yz} – 1.39; $d_{x^2-y^2}$ – 1.13; d_{z^2} – 1.13.

The central ruthenium ion in complex **2** has a formal charge of +2. Its natural charge from Natural Populations Analysis is close to 1.01. The charges on the chloride ligands are −0.565 and −0.564; the O and N donors have −0.540, −0.520 and −0.424, −0.428 charges, respectively. The Re–Cl, Ru–N and Ru–O natural bonds were not detected in the complex, indicating predominant Coulomb-type interactions between the central ion and the chloride and 2-benzoylpyridine ligands. The occupancies of the ruthenium d orbitals, obtained from NBO analysis, are as follows: d_{xy} – 0.84; d_{xz} – 1.40; d_{yz} – 1.74; $d_{x^2-y^2}$ – 1.69; d_{z^2} – 1.02.

3.4. Electronic structure

The energies and characters of several highest occupied and lowest unoccupied molecular orbitals of the studied complexes are presented in Table 6. The percent shares of the atomic orbitals in the HOMO and LUMO orbitals are given in round brackets. The HOMO–LUMO gaps for complexes **1** and **2** are 4.19 and 2.43 eV, respectively. In both cases, the ruthenium atom possesses a d^6 configuration, the highest MO is of d_{xz} type with antibonding contributions from p_π chlorine and p_π oxygen orbitals for complex **1** and p_π chlorine ligands for **2**. The remaining four d-type orbitals of ruthenium are found in HOMO − 1,

Table 5
The occupancies and hybridization of the calculated Ru–C and C–O natural bond orbitals (NBOs) for $[RuCl(CO)(PPh_3)_2(C_5H_4NCOO)]$

BD (2-center bond)	Occupancy	Hybridization of NBO
Ru(1)–C(43)	1.935 (0.322)	$0.550(sd^{5.08})_{Ru} + 0.835(sp^{0.54})_C$
C(43)–O(1)	1.997 (0.204)	$0.553(spd^{1.97})_C + 0.833(spd^{1.36})_O$
	1.997 (0.012)	$0.496(p)_C + 0.868(p)_O$
	1.994 (0.076)	$0.554(sp^{1.85})_C + 0.833(sp^{1.14})_O$

3.5. Electronic spectrum

The experimental and calculated allowed singlet transitions, with the TDDFT method, electronic spectra of complexes **1** and **2** are presented in Figs. 4 and 5. With the use of this method, 100 electronic transitions were calculated for the studied complexes using the DZVP with *f* functions basis set on the ruthenium atom.

The first experimental band at 370.0 nm in [RuCl(CO)(PPh_3)$_2$(C_5H_4NCOO)] (**1**) consists of d → d (LF – ligand field) and d → $\pi^*_{pyridine}$ (MLCT – metal–ligand charge transfer) transitions. The second one was calculated as a LLCT (ligand–ligand charge transfer). The transitions are interligand type between $\pi_{phosphine}$ and $\pi^*_{pyridine}$ orbitals with contribution of MLCT – excitation between ruthenium d and $\pi^*_{phosphine}$ orbitals.

The UV–Vis spectrum was calculated to ~226 nm, so the shortest wavelength experimental bands cannot be assigned to calculated transitions. However, considering that the solution spectra of PPh_3 and pyridenecarboxylic acid exhibit intense absorption bands in the 260–200 nm region, some additional intraligand and interligand transitions are expected to be found at higher energies in the calculations.

In the case of [$RuCl_2(C_{12}H_9NO)_2$] (**2**), the low energy unsymmetrical experimental band with a maximum at 737.6 nm was assigned to the transition from HOMO, HOMO − 1 and HOMO − 2 to LUMO and LUMO + 1 molecular orbitals. As the LUMO and LUMO + 1 orbitals are composed of ruthenium d and π^* orbitals of 2-benzoylpyridine, the transitions are LF (ligand field) ones with a contribution of MLCT type. The next maximum in the experimental spectrum at 600.0 nm results from the excitation between d-type HOMO orbitals to LUMO + 1, LUMO + 2 and LUMO + 7 MOs. The excitations are also of LF and MLCT type.

The band with a maximum at 3760.4 nm is composed mainly from the excitation from π_{Cl} to LUMO MOs composed of ruthenium d and $\pi^*_{2\text{-benzoylpyridine}}$ orbitals. This is a

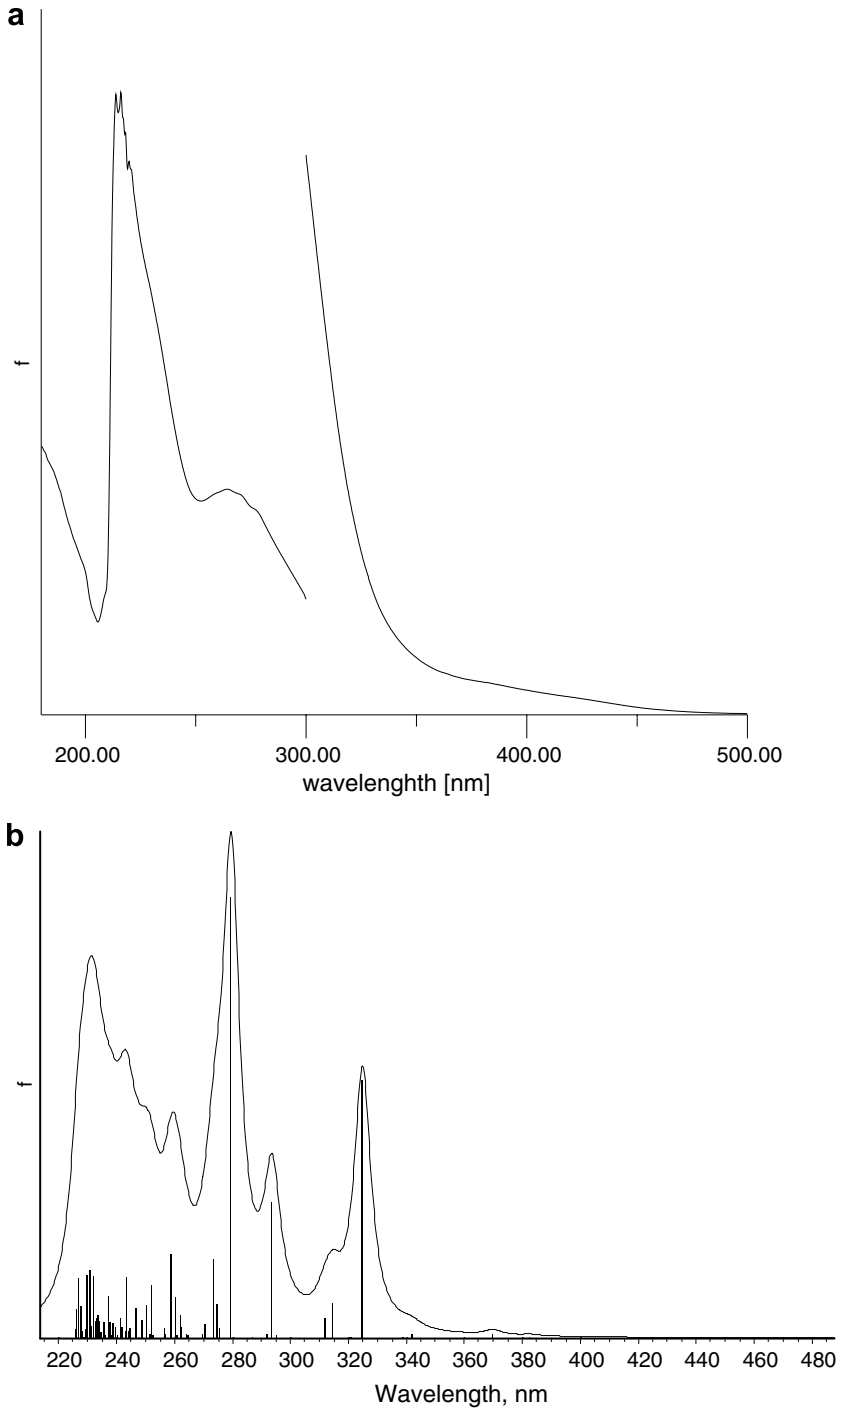

Fig. 4. The UV–Vis spectra of $[RuCl(CO)(PPh_3)_2(C_5H_4NCOO)]$ (a) experimental; (b) calculated.

LMCT type. The LLCT transitions play a role in the high energy experimental bands with maxima at 266.0 and 218.2 nm. The first band is mainly composed of interligand transitions ($\pi_{phosphine} \rightarrow \pi^*_{pyridine}$; $\pi_{Cl} \rightarrow \pi^*_{pyridine}$) with contribution of MLCT transitions ($d \rightarrow \pi^*_{pyridine}$). In the highest energy band (maximum at 218.2 nm), mainly the intra- and interligand transitions are observed ($\pi_{phosphine} \rightarrow \pi^*_{pyridine}$; $\pi_{pyridine} \rightarrow \pi^*_{pyridine}$; $\pi_{Cl} \rightarrow \pi^*_{pyridine}$).

4. Supplementary material

CCDC 626007 and 626449 contain the supplementary crystallographic data for **1** and **2**. The data can be obtained free of charge via htpp://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Scheme 1. Ligand H_3acshz (a) and the basic bonding sites of H_3acshz in compounds (b).

diethyl ketipinate [16], 3-hydroxy-2-pyridone [17] or 3-thione-1,2-dithione-4,5-dithiolato [18] also been used for metallacrown preparation. Metallacrowns can be molecular building blocks, forming one, two and three dimensional network structures by facial interactions and anion bridging [19–22], and stacking metallacrowns [23,16], a variety of dimers as well as fused metallacrowns [4b,8,24] have been found.

To examine the mode of binding and possible antagonistic or synergetic effects, much research has been carried out. Antibacterial screening data showed that 15-$MC_{Mn(III)N(shi)}$-5 and 12-$MC_{Mn(III)N(shi)}$-4 metallacrowns are more active than the simple manganese herbicide or carboxylate complexes, and the number of chlorides in the second ligand is likely to affect the efficiency of the compounds [25]. Whereas all the metallacrowns relative to the studies are of the hydroxamic acid type, our interests are focused on salicylhydrazide derivatives. Another important reason is that these ligands are not only propitious for the preparation of metallacrowns but they also have biological activities [11,12,26].

In this paper, we report a new potential pentadentate ligand H_3acshz, *N*-acetyl-5-chlorosalicylhydrazide, and two novel metal(III) 18-metallacrown-6 complexes, $[Mn_6(acshz)_6(H_2O)_6]\cdot 18H_2O$ (**1**) and $[Fe_6(acshz)_6(CH_3OH)_6]\cdot 6CH_3OH\cdot 6H_2O$ (**2**). The triply deprotonated $acshz^{3-}$ of the compounds may bridge the neighboring metal ions through its hydrazide N–N group as shown in Scheme 1. Minimum inhibitory concentrations (MIC) of the metallacrown complexes against four different bacteria species were also measured.

2. Experimental

2.1. Materials

All reactions were carried out in air. The following solvents were used as received with no further purification: methanol and *N*,*N*-dimethylformamide (DMF). 5-Chlorosalicylic acid, sulfuric acid, hydrazine hydrate, acetic anhydride, tetrabutylammonium perchlorate (tbap), $Mn(OAc)_2\cdot 4H_2O$ and $Fe(NO_3)_3\cdot 9H_2O$ were purchased from China Sinopharm Group Chemical Reagent Co., Ltd. All chemicals and solvents were reagent grade. *Staphylococcus aureus* (*S. aureus*), *Escherichia coli* (*E. coli*), *Bacillus subtilis* and *Proteus vulgaris* (*P. vulgaris*) were purchased from the China Center for Type Culture Collection.

2.2. Physical measurements

^1H and ^{13}C NMR spectra were recorded on a Varian Inova 600 MHz NMR spectrometer at 25 °C. Chemical shifts were referenced to the residual solvent peak. IR spectra were recorded on AVATAR 360 FT-IR spectrophotometer. UV–Vis spectra were recorded on a Shimadzu-UV-2501 spectrophotometer. Melting points were obtained with a digital melting-point apparatus, TP Micro Printer S-X6. Elemental analyses were performed on a Perkin–Elmer 2400 CHN elemental analytical instrument for C, H, N and Perkin–Elmer OPTIMA 2000 DV Optical Emission Spectrometer for Mn and Fe. Positive and negative electrospray ionization mass spectra (ESI(±)-MS) were performed on API-2000 LC/MS/MS system for the metallacrown **1** dissolved in methanol and DMF. Cyclic voltammetry (CV) studies were performed on Eco Chemie Autolab Eletrochemical analyzer. The experiments were carried out in a three-electrode cell with a platinum electrode, a glass–carbon electrode as the working electrode and a Ag/AgCl electrode saturated with KCl as the reference electrode. The supporting electrolyte was tetrabutylammonium perchlorate (tbap) recrystallized twice from ethanol and dried under vacuum. Pure nitrogen was insufflated in the solution of the compounds to remove the oxygen. All electrochemical measurements were carried out at room temperature.

2.3. Synthesis of the ligand H_3acshz

5-Chlorosalicyhyrazide was synthesized according to the literature procedure [27]. Acetic anhydride (6.8 g, 66.8 mmol) and 5-chlorosalicylhydrazide (11.0 g, 56.0 mmol) were added to 120 mL of chloroform with an external ice-water bath. The reaction mixture was slowly warmed to room temperature and stirred for 8 h. After leaving overnight in a refrigerator, the resulting white precipitate was filtered and rinsed with chloroform and diethyl ether. Yield: 12.2 g, 95.3%. Melting point: 209–210 °C. *Anal.* Calc. for $C_9H_9N_2O_3Cl$: C, 47.24; H, 3.96; N, 12.26. Found: C, 47.18; H, 3.98; N, 12.19%. IR (KBr pellet, cm^{-1}): 3446 m; 3190 vs, broad; 2710 w; 1650 m; 1625 s; 1605 vs; 1572 m; 1488 m; 1405 m; 1220 w; 1178 w; 817 m; ^1H NMR (600 MHz, DMSO-d_6, 25 °C), δ ppm: 11.94 (s, 1H, Ar–OH); 10.54 (s, 1H, Ar–CO–NH–); 10.31 (s, 1H, Me–CO–NH–); 7.90 (s, 1H, *o*-Ar–H); 7.49 (1H, *p*-Ar–H); 7.01 (1H, *p*-Ar–H); 1.94 (s, 3H, –CH_3). ^{13}C NMR (150.9 MHz, DMSO-d_6, 25 °C), δ ppm: 168.35 (Me–CO–); 165.38 (Ar–CO–); 157.82 (ArC–OH); 134.11 (*p*-ArC); 128.70 (*o*-ArC); 123.43 (ArC–); 119.85 (*m*-ArC); 117.37 (*m*-ArC–Cl); 21.08 (–CH_3).

2.4. Preparation of the compounds

$[Mn_6(acshz)_6(H_2O)_6]\cdot 18H_2O$ (**1**). H_3acshz (0.11 g, 0.50 mmol) was dissolved in 40 mL of 20:1 methanol + DMF, and 0.13 g (0.50 mmol) of $Mn(OAc)_2\cdot 4H_2O$ was

dissolved in 5 mL methanol. The two solutions were mixed and stirred for 2 h with the color of the mixture changing to dark brown, then the mixture was filtered. After slow evaporation of the mother liquor over 2 weeks, dark brown block crystals suitable for X-ray diffraction were obtained. Yield: 85.2%. *Anal.* Calc. for $C_{54}H_{84}Cl_6Mn_6N_{12}O_{42}$: C, 30.65; H, 4.00; N, 7.94; Mn, 15.58. Found: C, 30.94; H, 3.89; N, 8.01; Mn, 15.96%. IR (KBr pellet, cm^{-1}): 3437 m, broad; 1656 m; 1607 ms; 1561 m; 1512 s; 1398 vs; 1317 w; 1275 w; 640 w; 562 w. UV–Vis (CH_3OH, nm) [$\lambda_{max}(\varepsilon)$, L mol^{-1} cm^{-1}]: 234 (137840), 297 (51040), 374 (19430), 472 (3580).

$[Fe_6(acshz)_6(CH_3OH)_6] \cdot 6CH_3OH \cdot 6H_2O$ (**2**). This compound was prepared in a manner analogous to the manganese metallacrown above, without DMF in the solvent mixture. Three equivalents of anhydrous sodium acetate were added to adjust the pH of the solvent. After a few days some black block crystals were obtained. Yield: 88.6%. *Anal.* Calc. for $C_{66}H_{96}Cl_6Fe_6N_{12}O_{36}$: C, 36.34; H, 4.43; N, 7.71; Fe, 15.36. Found: C, 36.18; H, 4.28; N, 8.01; Fe, 15.64%. IR (KBr pellet, cm^{-1}): 3441 m, broad; 1657 m; 1608 ms; 1562 m; 1508 vs; 1405 vs; 1318 m; 1274 w; 633 w; 564 w. UV–Vis (CH_3OH, nm) [$\lambda_{max}(\varepsilon)$, L mol^{-1} cm^{-1}]: 224 (140284), 276 (82606), 318 (51313), 506 (5648).

2.5. Crystallographic data collection and refinement of the structures

Suitable crystals of the compounds **1** and **2** were mounted in glass capillaries with the mother liquor to prevent the loss of the structural solvent molecules during X-ray diffraction data collection. Intensity data were collected with graphite monochromatic Mo Kα radiation ($\lambda = 0.71073$ Å) at 292(2) K on a Bruker Smart APEX diffractometer. For **1**, from a total of 47540 reflections corrected by SADABS [28,29] in the $1.96 \leqslant \theta \leqslant 25.50°$ range, 3211 were independent with $R_{int} = 0.0613$, of which 2533 observed reflections with $I > 2\sigma(I)$ were used in the structural analysis. For **2,** from a total of 21265 reflections corrected in the $1.76° \leqslant \theta \leqslant 25.00°$ range, 8471 were independent with $R_{int} = 0.1076$, of which 5277 observed reflections with $I > 2\sigma(I)$ were used in the structural analysis. The structures were solved by direct methods and all non-hydrogen atoms were refined with anisotropic thermal parameters. All hydrogen atoms were located in calculated positions and/or in the positions from difference Fourier map. The positions and anisotropy from differences of non-hydrogen atoms were refined on F^2 by full-matrix least-squares techniques with the SHELXTL program package [29,30]. The crystallographic data are given in Table 4.

From the structure analysis, compound **1** consists of a Mn6 cluster and 18 water molecules of crystallization. Parts of the latter molecules were disordered and could not be modelled properly, thus the SQUEEZE subroutine of the PLATON program suite [31,32] was used to calculate the solvent disorder area and to remove its contribution to the overall intensity data.

Similarly, compound **2** consists of a Fe6 cluster, six methanol and six water molecules of crystallization. Difference electron density maps revealed the presence of the six disordered lattice water molecules which were ultimately modelled by use of SQUEEZE, and the atom C30 in the coordinated methanol (C30 H30A H30B H30C O12 H12) showed some disorder with a large U_{eq}. So the carbon atom and oxygen atom in this methanol molecule were refined anisotropically with splitting over two sites. The atoms H30A, H30B and H30C attached to the C30 atom were fixed geometrically and constrained to ride on the parent atom, C30.

2.6. Biological activity

The antimicrobial activity of the complexes was assessed by their ability to inhibit the growth of *S. aureus*, *E. Coli*, *B. subtilis* and *P. vulgaris* in Mueller–Hinton broth medium. The minimum inhibitory concentration in μg/mL against the four bacteria species was measured. The bacteria concentration was 500–800 cfu/mL and concentrations of 1600, 800, 400, 200, 100, 50 and 25 μg/mL of the complexes in methanol and DMF were tested. The solvents showed no antimicrobial action.

3. Results and discussion

3.1. Synthesis and characterization

One of the most important considerations is to have readily accessible or, at least, easily prepared building blocks when designing metal–cluster macrocyclic assemblies. From the first reported metallacrown compound, metallacrowns are typically prepared from hydroxamic acids and/or ketonoximic acids as the constructing ligand. In our report, the metallacrowns were synthesized by the reaction of another suitable ligand with transitional metal salts in an open system.

In the synthesis of compound **1**, dioxygen acts as the oxidant in the following reaction :

$$6H_3acshz + 6Mn(OAc)_2 + 18H_2O + 3O_2 \xrightarrow{\downarrow CH_3OH \text{ and DMF}} (\mathbf{1}) + 12HOAc \quad (1)$$

$$6H_3acshz + 6Fe(NO)_3 + 18NaOAc + 6H_2O + 12CH_3OH \xrightarrow{\downarrow CH_3OH} (\mathbf{2}) + 18HOAc \quad (2)$$

In the synthesis of compound **2**, there is no oxidation in the reaction (Eq. (2)). NaOAc was added to regulate the pH of the mother liquid.

In the ligand IR spectrum, there is a medium intensity band at 3446 cm^{-1} and strong intensity band at 3190 cm^{-1}, assigned to $\nu(OH)_{phenolic}$ and $\nu(NH)$ stretching vibrations, respectively. A strong intensity band at

1605 cm^{-1} and a medium intensity band at 1572 cm^{-1} are assigned to ν(C=O) and ν(N–C=O) vibrations of the salicyhydrazide ligand [33]. The frequency of $\delta(C–H)_{acetyl}$ at 1405 cm^{-1} differs from the δ-bending of the normal methyl in alkyls. Weak bands at 1220 and 1178 cm^{-1} should be assigned to ν(N–C) and δ(NH), respectively. In the compounds' IR spectra, the absence of the ν(N–H) band and the weakness of the ν(C=O) stretching vibration bands are consistent with the deprotonation of the CONH groups and coordination to the Mn(III) or Fe(III) ion. The deprotonation and coordination is also confirmed by the bands at 640 or 633 cm^{-1}, attributed to M–O linkages (phenolic and enolic oxygen), and the bands at 562 or 564 cm^{-1} assigned to M–N linkages [34,11b]. The medium intensity broad band at 3437 cm^{-1} in **1** and 3441 cm^{-1} in **2** are reasonably assigned to coordinated H_2O and crystal water molecules [35]. The N–C=O framework can be seen at 1572 cm^{-1} in the ligand and this band is shifted to 1561 and 1562 cm^{-1} on coordination to Mn and Fe atoms, and its relative intensity decreased. The disappearance of the bands at 3190 and 2710 cm^{-1} and the appearance of bands at 1317 and 1275 cm^{-1} support the involvement of the phenolic oxygen in coordination through deprotonation.

The electronic spectra were recorded in methanol for the ligand and the compounds. The spectrum of the ligand displayed absorption peaks at 244 nm (ε, 29 550) and 312 nm (ε, 22 898). The spectrum of compound **1** displayed absorption peaks at 234, 297, 374 and 472 nm. The bands at 234 nm can be attributed to internal ligand $\pi \rightarrow \pi^*$ or $n \rightarrow \pi^*$ transitions of the benzene rings, the substituted group of acetylhydrazide and π conjugation. The absorption maxima at 374 nm can be assigned to metal to ligand $M(d\pi) \rightarrow O(\pi)$ charge transfer (MLCT) transitions and the absorption maxima at 472 nm is assigned to a d–d transition of the transitional metal ions. The spectrum of compound **2** in methanol shown absorption peaks at 224, 276, 318 and 506 nm. Their assignments are analogous to the ones in compound **1**.

Cyclic voltammetry suggested that the metallacrowns **1** and **2** are electrochemical inactive in DMF in the range +1.5 to −1.5 V, which is consistent with the conjecture and conclusions in the earlier literature [7,25,36]. The absence of any redox activity of metallacrowns indicates that the metallacrown rings are redox stable. Notably, this ligand can stabilize three valent manganese ions in DMF.

3.2. Description of the structures of *1* and *2*

A perspective of the complete Mn6 cluster molecule of $[Mn_6(acshz)_6(H_2O)_6] \cdot 18H_2O$ is provided in Fig. 1. Compound **1** crystallizes in the rhombohedral system and space group $R\bar{3}c$. Important bond distances and bond angles are presented in Table 1.

The structure of compound **1** exhibits a hexanuclear ring of manganese atoms linked by six hydrazide N-N groups. The deprotonated ligand $acshz^{3-}$ acts as a trianionic pentadentate ligand, one phenolate oxygen, one carbonyl oxygen and one hydrazine nitrogen in the ligand are bound to one Mn^{3+} cation, and the other carbonyl oxygen plus the other hydrazide nitrogen in the same ligand are chelated to an adjacent Mn^{3+} cation. The ligand forces all Mn^{3+} cations into a propeller configuration with alternating Λ/Δ stereochemistry as $\Lambda\Delta\Lambda$ forms. Three water groups coordinated at the metal centers with Λ configuration are found on one face of the metallacrown, and the three remaining water groups coordinated to the other metal centers with

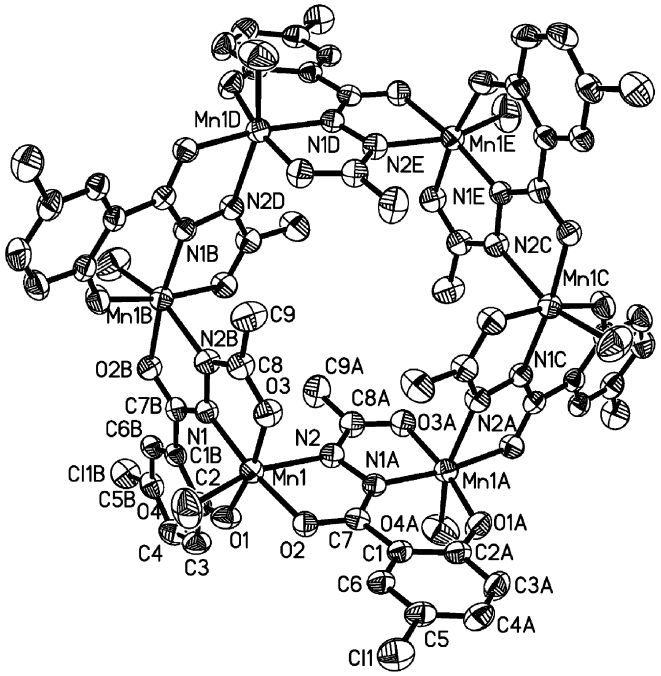

Fig. 1. Perspective view of compound **1**, solvent molecules and all hydrogen atoms have been omitted for clarity.

Table 1

Mn1–O1 1.8651(2)	Mn1–O2 1.9677(2)	Mn1–O3 1.9170(2)	Mn1–O4 2.236(3)
Mn1–N1 1.941(2)	Mn1–N2 2.252(2)	N1–N2 1.408(3)	
O1–Mn1–O3 170.03(8)	O1–Mn1–N1 90.74(8)	O3–Mn1–N1 79.89(8)	O1–Mn1–O2 97.60(8)
O3–Mn1–O2 91.91(7)	N1–Mn1–O2 171.34(8)	O1–Mn1–O4 88.99(1)	O3–Mn1–O4 88.77(1)
N1–Mn1–O4 96.91(1)	O2–Mn1–O4 85.61(1)	O1–Mn1–N2 94.17(9)	O3–Mn1–N2 91.19(8)
N1–Mn1–N2 102.42(8)	O2–Mn1–N2 74.77(7)	O4–Mn1–N2 160.36(1)	

Δ configuration are found on the other face of the metallacrown. The two faces of the hexanuclear ring have opposite chiralities to each other. This organization results in an 18-membered hexanuclear core ring system with a [Mn–N–N] repeat unit. The approximate dimensions of the oval-shaped cavity are estimated by SHELXTL, to be about 6.97 Å in diameter at the entrance and about 9.53 Å at its largest diameter at the center of the cavity. It is also observed that all the atoms in the ligand are almost coplanar and the metal ion 6-membered ring is in a chair conformation. All manganese ions in compound **1** are in an octahedral MnN_2O_4 environment with a very distinct Jahn–Teller extension. The average neighboring Mn···Mn separation is 4.874 Å. There are no solvent molecules in the 'host' cavity of the metallacrown. In the packing diagram, the molecules translated one unit cell along the *a*-axis are stacked with minimum short contacts for $O3\cdots C7^{i}$ (3.36 Å) and $O3\cdots O2^{i}$ (2.79 Å) symmetry code (i): $[x-y, x, -z]$. The crystal packing may also be stabilized by intermolecular Cl–O interactions for each Cl atom in the structure, with an unusually short distance of 3.21 Å.

A perspective view of the complete Fe6 cluster molecule of $[Fe_6(acshz)_6(CH_3OH)_6]\cdot 6CH_3OH\cdot 6H_2O$ is provided in Fig. 2. This compound crystallizes in the triclinic system and space group $P\bar{1}$. Important bond distances and bond angles are presented in Table 2.

The metallacrown containing Fe6 cluster is analogous to **1**. It has the same backbone ligand and chelating mode of the central metal ion, except for the sixth coordinating atom from methanol. Although the chiralities of the metal

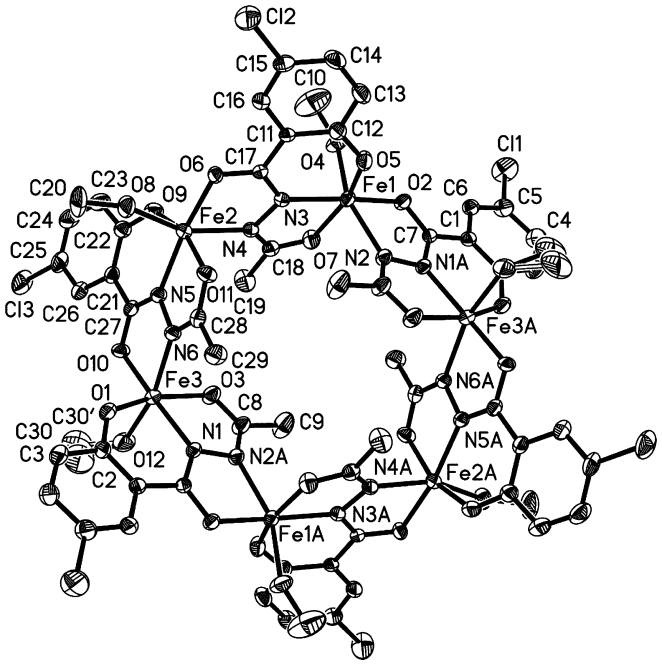

Fig. 2. Perspective view of compound **2**, solvent molecules and all hydrogen atoms have been omitted for clarity.

centers in complex **2** are between the Δ and Λ forms, it linked as a ΔΛΔ turn. The alternation of the chiralities force the cyclic ring system of **2** to form as the following train: –Fe1–N3–N4–Fe2–N5–N6–Fe3–N1–N2A–Fe1A–N3A–N4A–Fe2A–N5A–N6A–Fe3A–N1A–N2–. The cavity sizes of the **1** and **2** are different. The approximate

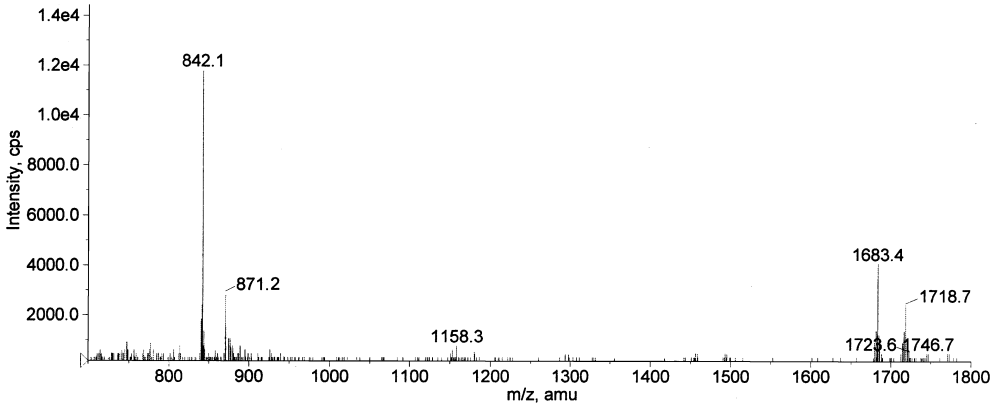

Fig. 3. The positive electrospray ionization mass spectra of **1** in methanol.

dimensions of the oval-shaped cavity are about 7.94 Å in diameter at the entrance and about 10.24 Å at its largest diameter at the center of the cavity in compound **2**. The change of the cavity size is probably caused by the metal ions themselves. There are some hydrogen bonds in the compound and their bond distances range from 2.616 to 2.888 Å. In particular, the phenolate–methanol (solvent)–methanol (coordinated) linkages formed by hydrogen bonds maybe are partly responsible for the difference in cavity shapes between the two complexes. The shortest distance of two neighboring iron(III) ions is 4.882 Å, which is longer than the distance of the two neighboring Mn(III) ions in **1**. The longest distance is 4.909 Å between Fe1 and Fe2 in **2**.

Comparing the above structures to $[Co_6(ashz)_6(CH_3OH)_6]\cdot 6CH_3OH$[11b], the chelating mode and coordination environment of the metal ions is similar. The M···M distances of the compounds in this paper are longer than those of the latter compound (Co···Co, 4.477 Å), and there are some distinct differences in the diameter of cavities (about 4.75 Å diameter at the entrance and 6.45 Å at its widest point in the latter compound). The cause of these differences maybe is from the little discriminating ligands and different metal ion arranged in the rings.

3.3. Structural integrity and stability in methanol

Electrospray ionization (ESI) mass spectroscopy, a soft ionization technique, has been proved useful in providing solution molecular weights of formally neutral metallacrown salt complexes [37]. The methanol solution of the Mn-containing cluster gave some peaks at *m*/*z* 1718.7, 1683.4 and 842.1 in ESI(+)-MS. These peaks correspond to the hexanuclear cluster ions $[Mn_6(acshz)_6(H_2O)_2+H]^+$, $[Mn_6(acshz)_6+H]^+$ and $[Mn_6(acshz)_6+2H]^{2+}$, respectively (Fig. 3). To explore the solution stability of the complexes in methanol solution, the concentration-dependent absorbance was measures at 374 and 506 nm for compounds **1** and **2**, respectively (Figs. 4 and 5). For **1**, the absorbance increases linearly with the concentration in the range between 3.1 and 100 μM [38], while for **2**, the concentration is between 3.8 and 75 μM. No change was observed for the absorption of the two solutions after two weeks. The results indicate that complexes **1** and **2** retain the integrity of the rings and are stable at least in these concentration ranges in methanol.

3.4. Antimicrobial activity

Minimum inhibitory concentrations of the ligand and compounds **1** and **2** against *S. aureus*, *E. coli*, *B. subtilis* and *P. vulgaris* are listed in Table 3. As can be clearly seen from the table, none of the compounds have strong antimicrobial activity against most of the tested microorganisms, except that compound **2** may restrain the propagation of *B. subtilis* effectively. Moreover, in this study,

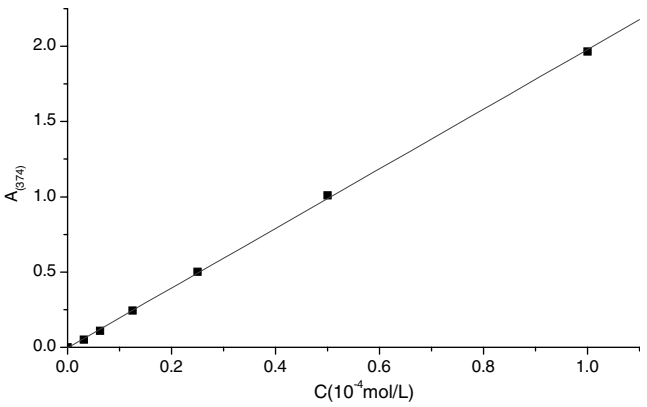

Fig. 4. The concentration dependent absorbance of complex **1** in methanol was measured at 374 nm.

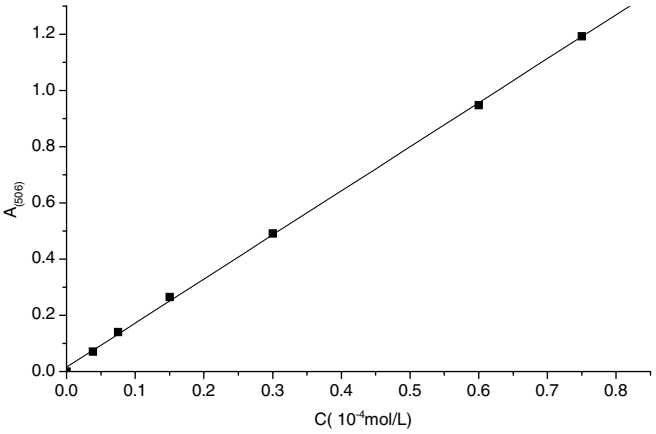

Fig. 5. The concentration dependent absorbance of complex **2** in methanol was measured at 506 nm.

Table 3
Minimum inhibitory concentration (MIC) of the ligand *N*-acetyl-5-chlorosalicylhdrazide and compounds **1** and **2** in μg/mL

Microorganisms	Complexes		
	Ligand	**1**	**2**
S. aureus (Gram+)	100	1600	200
E. coli (Gram−)	400	1600	200
B. subtilis (Gram+)	400	400	25
P. vulgaris (Gram−)	300	1600	200

the results do not indicate specificity against Gram-positive or Gram-negative bacteria although it is generally expected that a much greater number would be active against Gram-positive than Gram-negative bacteria [39]. In terms of the ligand H_3acshz, its antimicrobial activities are stronger than those in the foregoing literature [40]. Antibacterial screening data indicated that metallacrown **1** has an antagonistic effect to the ligand H_3acshz, resulting in the huge reduction of the antimicrobial activity, while metallacrown **2** has stronger antimicrobial activity against *B. subtilis*. One of reasons for it maybe is the difference of the bond capability of the Mn ion and the Fe

[b] $wR_2(F2) = [\sum w(F_o^2 - F_c^2)^2 / \sum w(F_o^2)^2]^{1/2}, w = 1/[\sigma^2(F_o^2) + (0.1005P)^2 + 0.0000P]$ for **1** and $w = 1/[\sigma^2(F_o^2) + (0.0574P)^2 + 0.0000P]$ for **2**, $P = ((F_o^2 + 2F_c^2)/3)$.

ion to the ligand. The different coordinated solvent molecules are likely to affect the antimicrobial activity of these compounds.

4. Conclusion

Compounds **1** and **2** are the first examples of 18-metallacrown-6 compounds containing Mn^{3+} and Fe^{3+} as ring ions with the ligand *N*-acetyl-5-chlorosalicylhdrazide. Due to the meridional coordination of the ligand to the Mn^{3+} and Fe^{3+} ions, the ligand enforces the stereochemistry of the Mn^{3+} and Fe^{3+} ions as a propeller configuration with alternating Λ/Δ or Δ/Λ forms, respectively. The other important structural feature in $[Mn_6(acshz)_6(H_2O)_6]\cdot 12H_2O$ and $[Fe_6(acshz)_6(CH_3OH)_6]\cdot 6CH_3OH\cdot 6H_2O$ is that there is not only a vacant cavity in the center of the 18-metallacrown-6 core ring, but also opposite chiralities on the two faces of the metallacrown ring system. Although the two metallacrown compounds are constructed with the same ligand, there are great differences between them in terms of antimicrobial activity. Antibacterial screening data showed that metallacrown **1** has an antagonistic effect to the ligand H_3acshz resulting in a huge reduction of the antimicrobial activity, while metallacrown **2** has stronger antimicrobial activity against *B. subtilis*.
