The reagents employed in the synthetic procedures were purchased to Aldrich or Merck, and were used without further purification. All the organic solvents employed in synthetic procedures or physical determinations were dried and freshly distilled before used, following standard procedures. The precursor complex $Ru(dmso)_4Cl_2$ [17] and the ligand *N*-(2-methylpyridyl) 1,4,8,11-tetraazacyclotetradecane [18] were synthesized according to previously published procedures. A vacuum line and Schlenk glassware were employed when the manipulations required exclusion of air.

2.2. Synthesis of $[Ru(L^{py})NO](PF_6)_3$ (*I*)

One hundred and seventy milligrams (0.35 mmols) of $Ru(dmso)_4Cl_2$ where added to 35 mL of an ethanolic solution of 102.6 mg of L^{py} (0.35 mmol) under argon. The solution was refluxed for 4 h, reaching a deep orange color. The mixture was allowed to cool down to room temperature. 0.50 g (7.2 mmol) of $NaNO_2$ were added to the reaction mixture, which was further refluxed for 5 h. After cooling down, the reaction mixture was treated with 6.5 mL of HCl 6 M, and the volume reduced to a few mL by vacuum distillation. Addition of 5 mL of a saturated water solution of NH_4PF_6 induced the precipitation of 300 mg of a brownish microcrystalline powder. Recrystallization of this solid by diffusion of diethyl ether into an acetonitrile solution yielded 155 mg (52%) of analytically pure **I**, as revealed by elemental analysis and ^1H and ^{13}C NMR spectroscopy. *Anal.* Calc. for $C_{16}H_{29}F_{18}N_6OP_3Ru$: C, 22.4; H, 3.4; N, 9.8. Found: C, 22.2; H, 3.6; N, 9.7%. ν_{NO} (KBr) = 1917 cm^{-1}. δ_H (CD_3CN): Aromatic protons, 8.59 (1H, d), 8.36 (1H, t), 7.89 (1H, d), 7.85 (1H, t). Amine protons, 9.70 (1H), 9.33 (1H), 6.91 (1H) observed as broad signals. Aliphatic protons, 5.10 (1H, d), 4.88 (1H, d), 3.83 (1H), 3.72 (3H), 3.38 (1H), 3.31 (4H), 3.18 (1H), 3.09 (1H), 2.99 (1H), 2.89 (1H), 2.77 (1H), 2.54 (1H), 2.37 (1H), 2.33 (1H), 2.23 (1H) partially obscured by the solvent, 2.09 (1H), 2.02 (1H). The multiplicity of the signals is not given due to the complexity of the coupling pattern. See text for a detailed discussion. δ_C (CD_3CN): Aromatic carbons, 161.8, 153.9, 144.9, 128.1, 124.9. Aliphatic carbons, 73.6, 65.2, 60.0, 58.2, 56.2, 54.0, 51.0, 50.7, 48.1, 26.6, 23.3.

2.3. Physical measurements

Microanalytical data for C, H, N and O were obtained at INQUIMAE, with a Carlo Erba EA 1108 analyzer. UV–Vis spectra were recorded with either an HP8453 or an HP8452A diode array spectrometer. IR spectral measurements were carried out using alternatively one of two FT spectrophotometers, a Nicolet 150P and a Thermo Nicolet AVATAR 320. Spectra were collected from KBr disks. NMR data were acquired on a Bruker AM500 spectrometer operating at 500.13 MHz for ^1H. Standard pulse sequences were used for two-dimensional (2D) heteronuclear single quantum coherence (HSQC), correlated spectroscopy (COSY) and nuclear Overhauser enhancement spectroscopy (NOESY). Cyclic voltammetry (CV) and square wave voltammetry (SWV) measurements were done in aqueous 0.1 M $HClO_4$ or in organic medium (0.1 M Bu_4NPF_6 as supporting electrolyte) with a standard three electrode cell [19] containing a Pt working electrode (1.5 mm ∅) or a vitreous carbon electrode (3 mm ∅), and a Pt wire as a counterelectrode. As a reference in aqueous media, a commercial Ag/AgCl (BAS) electrode was used. In organic medium, a Ag wire and ferrocene as internal standard was used [20]. Throughout this work, all the reported redox potentials are referred to Ag/AgCl, 3 M NaCl (0.21 V versus NHE). The potential of the working electrode was controlled with one of two commercial potentiostats (Princeton Applied Research 273A or TEQ-03). The spectroelectrochemical experiments in the UV–Vis region were done in a homemade cell containing a quartz cuvette (1 cm path). The potential was controlled with a TEQ-03 potentiostat, using either 0.1 M $HClO_4$ or 0.1 M Bu_4NPF_6 in acetonitrile as supporting electrolyte. A commercial Ag/AgCl reference electrode was used in

aqueous solution whereas a $Ag/AgNO_3$ (0.01 M Ag^+ in acetonitrile) electrode was the reference employed in organic medium. The working and counter electrodes were a Pt net and a Pt wire, respectively. The system was maintained at 25 ± 0.1 °C for the experiments in water and at -30 ± 1 °C for those in acetonitrile (RC6 LAUDA thermostat), and was entirely purged with N_2. In a typical experiment, the solution was electrolyzed at sufficiently low potential (*ca.* 200 mV below the E^0 values registered by CV) in several cathodic steps. Between consecutive reduction periods, the solution was allowed to equilibrate and the open-circuit potential (E_{oc}) together with the UV–Vis spectrum were recorded. Redox potentials and disclosed UV–Vis spectra of the reduced and oxidized species were then obtained by global analysis [21]. This procedure involves a simultaneous multi-wavelength fitting to the Nernst equation [22].

2.4. Theoretical calculations

We employed density functional theory (DFT) computations to fully optimize the geometries of the cations $[Ru(L^{py})NO]^{3+}$, $[Ru(L^{py})NO]^{2+}$, $[Ru(L^{py})NO_2]^{+}$ and $[Ru(L^{py})Cl]^{+}$ in vacuo, without symmetry constraints. The calculations were performed with *Gaussian 03* [23], at the B3LYP level, employing the LanL2DZ basis set, which proved to be suitable for geometry predictions in coordination compounds containing metals of the second and third raw of the transition elements in the Periodic Table [11,24]. We used tight SCF convergence criteria and default settings in the geometry optimizations. Depending on the case (see text below) several minima along the potential energy surface were explored by scanning one particular internal coordinate. The true nature of all the found stationary points, which correspond to (local) minima in the potential energy surface were confirmed by numerical vibrational frequency computations. In all cases the absence of negative frequencies confirmed that the optimized geometries correspond to stable configurations in the potential energy surfaces. Time dependent (TD)DFT computations at the equilibrium geometry were employed as an assistant tool in the interpretation and assignment of the electronic spectra.

3. Results and discussion

3.1. Synthetic strategy and structural characterization of $[Ru(L^{py})NO]^{3+}$

Mono *N*-substitution of 1,4,8,11-tetraazacyclotetradecane (cyclam) can be performed under controlled reaction conditions, employing a large excess of cyclam with respect to the alkylating agent [18,25]. *N*-(2-methylpyridyl) cyclam (L^{py}) is therefore prepared in good yield by the reaction of 2-(chloromethyl)pyridine and a large excess of cyclam in DMF. Separation of the product from the unreacted macrocycle can be easily achieved because of the notoriously different solubility properties of both species. The pentadentate ligand is conveniently incorporated into the coordination sphere of Ru(II) by reaction with $Ru(dmso)_4Cl_2$ in ethanol in the absence of oxygen. This process seems to yield a mixture of products (most probably $[Ru(L^{py})Cl]^{+}$, $[Ru(L^{py})dmso]^{2+}$ and $[Ru(L^{py})(solv)]^{n+}$) that are difficult to isolate and purify. Nevertheless, the reaction of this mixture with nitrite leads to the formation of the nitro derivative $[Ru(L^{py})NO_2]^{+}$. Acidification of the reaction mixture induces acid–base changes in the coordinated ligand as in Eq. (1) [5,26–28], and yields the desired $\{RuNO\}^6$ core.

$$[Ru(L^{py})NO_2]^{+} + 2H^{+} \rightleftarrows [Ru(L^{py})NO]^{3+} + H_2O \quad (1)$$

The ^1H NMR spectrum of **I** in CD_3CN (Supplementary material) consists of 29 partially or totally overlapped signals that also show extensive scalar coupling. This spectrum is a consequence of the rigidity of the macrocycle combined with the lack of symmetry elements, which makes all protons non-equivalent. The ^1H NMR resonances at 8.59, 8.36, 7.89 and 7.85 ppm, referred to as H_{18}, H_{20}, H_{21} and H_{19}, respectively (see Fig. 1 for proton numbering), can be safely ascribed to the pyridine moiety by comparison with the free ligand. Note that complex **I** can potentially present isomerism leading to *cis*- or *trans*-species. However, the observation of a single set of signals for the aromatic protons seems to be consistent with the occurrence of a single isomer.

The three broad features at 9.70, 9.33 and 6.91 ppm, not observed when the spectrum is recorded in D_2O solution, can be attributed to the three exchangeable N*H* protons. The pyridine linker methylene N–CH_2-py protons give rise to two doublets at 4.88 and 5.10 ppm, coupled by one large $^2J(HH) \approx 17.5$ Hz. The remaining features in the range between 2 and 4 ppm, can be altogether assigned to the geminal pairs of CH_2 protons in the cyclam backbone. The ^{13}C NMR spectrum in CD_3CN, shows signals from each one of the 16 macrocyclic ligand carbon atoms (Supplementary material).

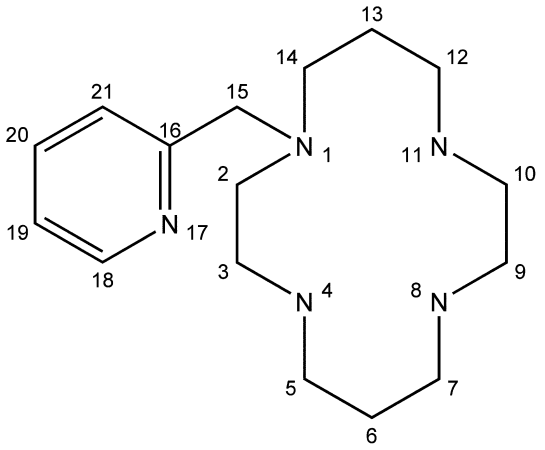

Fig. 1. Atom numbering used to identify the nuclei in the NMR discussion.

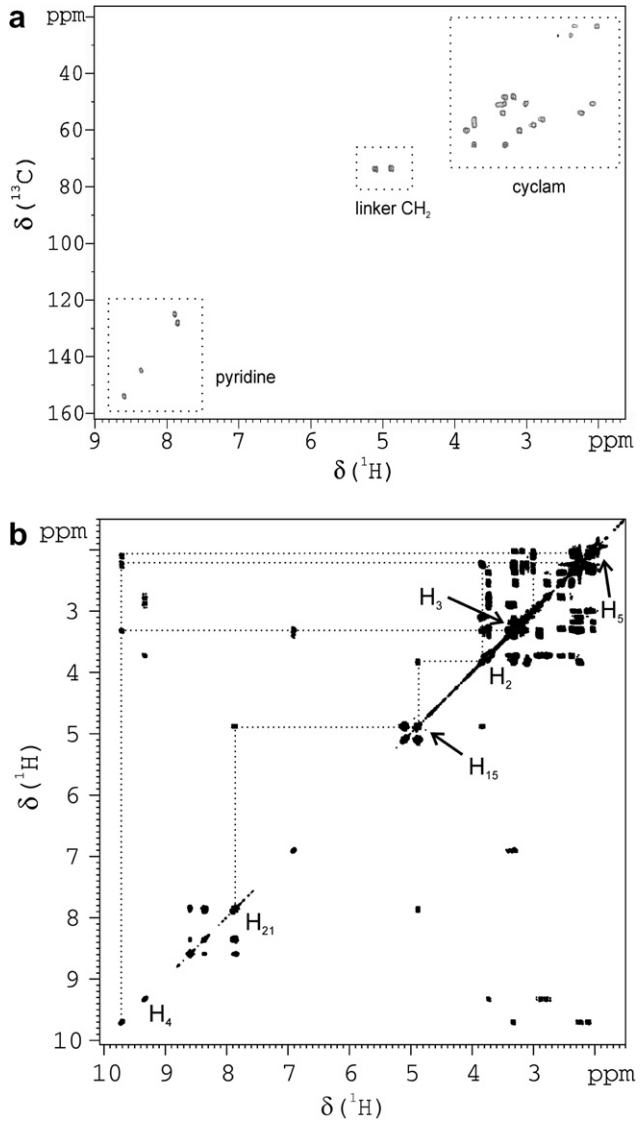

Fig. 2. (a) 2D [^{1}H,^{13}C] HSQC NMR. spectrum of **I** in CD_3CN solution. (b) 2D COSY NMR spectrum of **I** in CD_3CN solution. The dotted lines represent a few steps in the strategy employed in the assignment of the NMR spectrum (see text).

The 2D [^{1}H, ^{13}C] HSQC NMR spectrum (Fig. 2a) shows cross-peaks between 26 of the 29 ^{1}H NMR signals previously described and 16 ^{13}C NMR signals. Among these cross-peaks, it is possible to identify the four single protons from the pyridine moiety, and the 11 paired peaks arising from the geminal CH_2 protons, in agreement with the assignments performed above. Moreover, this NMR experiment confirms the presence of only one spin system (and therefore only one major isomer for **I**) and proved valuable in identifying the geminal pairs of CH_2 protons and assigning them to the corresponding ^{13}C signals.

In combination with all the information gathered up to now, a 2D COSY spectrum (Fig. 2b) allows to find the scalar connectivities and perform a sequential assignment of the ^{1}H NMR spectrum. The pyridine ^{1}H NMR resonance at 7.89 ppm (H_{21}) can be taken as a starting point for the analysis. This proton couples to one that gives rise to a signal at 4.88 ppm, and corresponds to one of the linker methylene protons (H_{15a} or H_{15b}). The latter correlates sequentially with a proton resonating at 3.83 ppm (H_{2a} or H_{2b}). This signal shows additional connectivities with signals at 3.33, 3.09 and 2.23 ppm. From the 2D [^{1}H,^{13}C] HSQC data, protons with chemical shifts of 3.09 and 3.83 ppm are known to be geminal, as well as those at 3.33 and 2.23 ppm. Consequently, these two last resonances can be assigned to their vicinal protons H_{3a}/H_{3b}, both of which are also associated through COSY correlations with the signal at 9.70 ppm. The latter arises from one of the N*H* protons and is now identified as H_4. This proton is scalar-coupled to the one at 2.08 ppm, which in turn couples to a proton at 2.99 ppm. These two last resonances correspond to a pair of geminal protons, that we assign to H_{5a} or H_{5b}. Application of this systematic approach leads to the full assignment of the ^{1}H and ^{13}C NMR spectra. However, the geminal specificity at every CH_2 group still remains unknown. A direct measurement of the $J(^1H^1H)$ coupling constants for these protons helps to eliminate this uncertainty. The *J* values listed in Table 1 reveal two kinds of signals, those split by only one large

Table 1
^{1}H and ^{13}C NMR chemical shifts (δ) in CD_3CN solution, and geminal ^2J(HH) and axial–axial ^3J(HH) scalar coupling constants for compound **I**

$^2J(H_{15a},H_{15b}) = 17.5$ Hz; $^2J(H_{13a},H_{13b}) = 17.0$ Hz; $^2J(H_{6a},H_{6b}) = 16.4$ Hz; $^2J(H_{7a},H_{7b}) = 15$ Hz; $^2J(H_{2a},H_{2b}) = {}^2J(H_{3a},H_{3b}) = {}^2J(H_{5a},H_{5b}) = 14.0$ Hz; $^2J(H_{9a},H_{9b}) = {}^2J(H_{10a},H_{10b}) = 13.5$ Hz; $^2J(H_{12a},H_{12b}) = {}^2J(H_{14a},H_{14b}) = 13.0$ Hz.

$^3J(H_{2a},H_{3a}) = 14.0$ Hz; $^3J(H_{5a},H_{6a}) = {}^3J(H_{9a},H_{10a}) = 13.5$ Hz; $^3J(H_{6a},H_{7a}) = {}^3J(H_{12a},H_{13a}) = {}^3J(H_{13a},H_{14a}) = 13.0$ Hz; $^3J(H_4,H_{5a}) = {}^3J(H_8,H_{9a}) = {}^3J(H_{10a},H_{11}) = {}^3J(H_{11},H_{12a}) = 11.0$ Hz; $^3J(H_{3a},H_4) = 10.0$ Hz.

^2J(HH) constant, due to geminal coupling exclusively, and those which show at least two large splittings, a ^2J(HH) splitting due to coupling with a geminal partner plus one or two sizeable ^3J(HH) values, depending on whether they are connected to one or two vicinal protons through axial–axial scalar coupling. This information allows discriminating between signals that arise from protons bound to the same carbon atom in the aliphatic backbone. The specific assignment of the methylene N–CH_2-Py resonances requires the study of their dipolar connectivities (see later). Table 1 shows the resulting ^{1}H and ^{13}C NMR assignments.

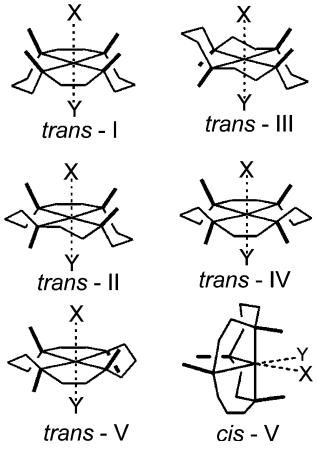

Fig. 3. Different configurations of metal cyclam complexes showing the different alignment of the NH protons.

The NMR analysis presented so far evidences the existence of a single isomer. When attached to a metal center, the macrocyclic 1,4,8,11-tetraazacyclotetradecane (cyclam) could present as much as five configurations at the nitrogen stereogenic centers that give rise to several isomers (labeled *trans*-I–V and *cis*-V, Fig. 3) [29]. In order to determine which of these forms is adopted by compound **I**, a 2D [^{1}H,^{1}H] NOESY NMR data set was recorded in CD_3CN solution. Provided that the difference between configurations resides on the spatial alignment of the NH bonds, special attention has to be paid to these protons. Fig. 4a shows the portion of the NOESY spectrum corresponding to the NH resonances. An intense NOESY cross peak from resonance at 9.70 ppm (H_4) to a signal at 9.33 ppm (H_{11}) indicates that these protons are close in space. They are attached to non-adjacent N atoms and point in the same direction. This observation discards the *trans*-III and *trans*-IV configurations. The remaining NH at 6.91 ppm (H_8) is not dipolar coupled to the other two amine protons (H_{11} or H_4) and is most likely pointing to the opposite side. This last consideration suggests that configurations *trans*-I and *trans*-II should also be disregarded, leaving only two possible configuration, that is *trans*-V or its folded form *cis*-V. The occurrence of NOESY cross-peaks (see Fig. 4b) between protons H_{11}–H_{2a}, H_4–H_{9a}, and H_4–H_{11}

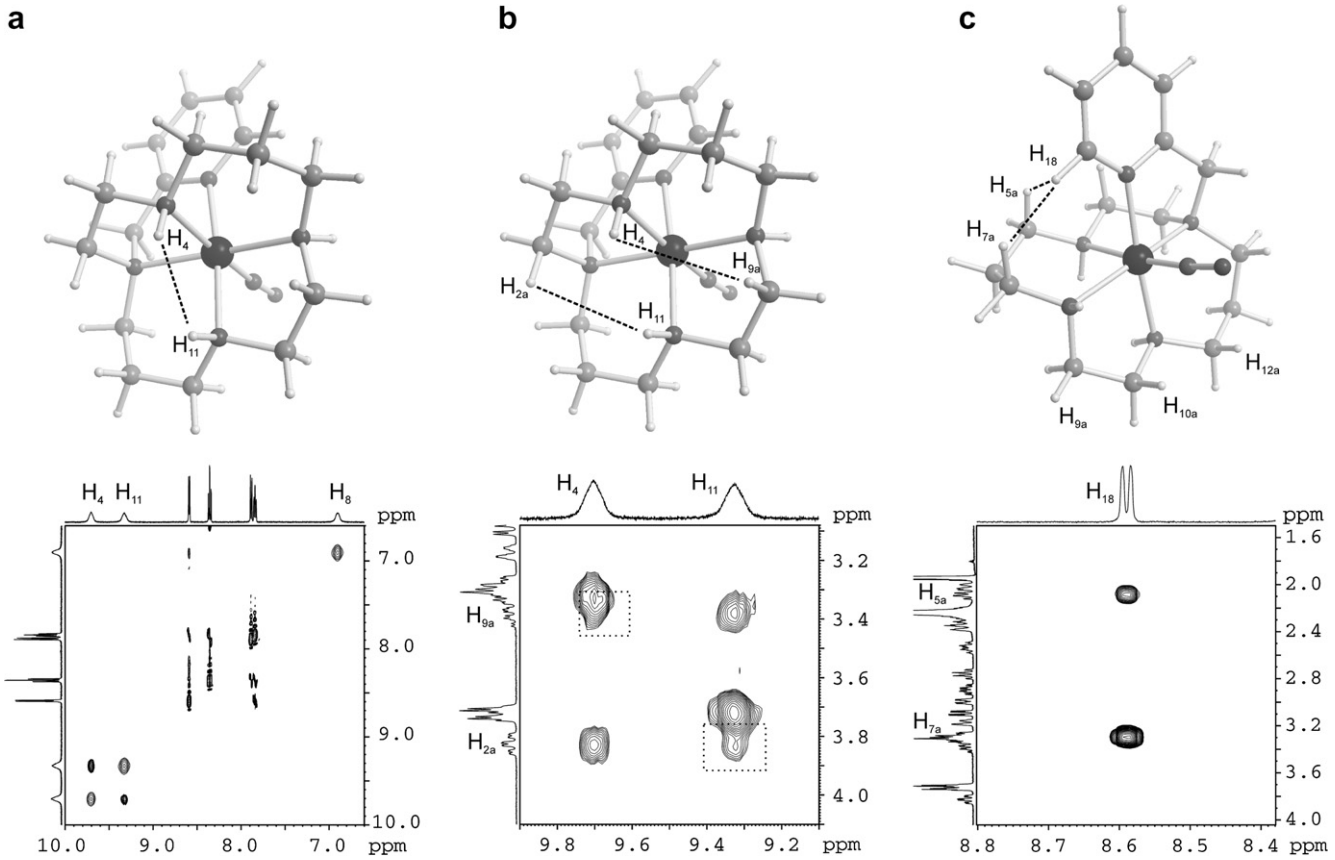

Fig. 4. Selected regions of the 2D [^{1}H,^{1}H] NOESY NMR spectrum of **I** in CD_3CN solution.

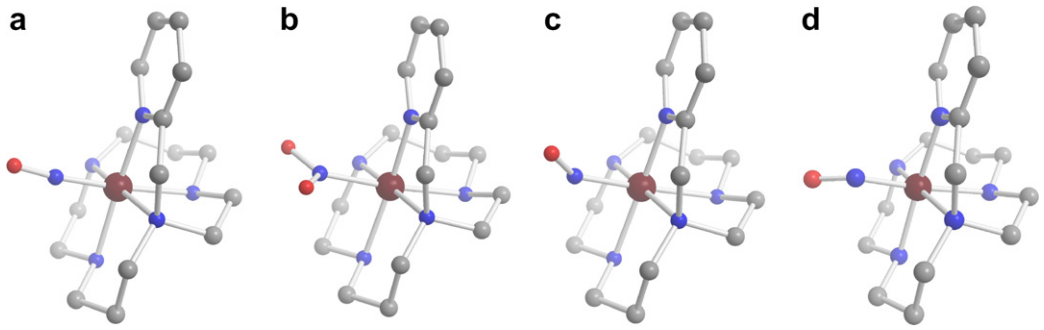

Fig. 5. DFT optimized geometries (in vacuo) for the (a) *cis*-$[Ru(L^{py})NO]^{3+}$ (**I**), (b) *cis*-$[Ru(L^{py})NO_2]^{+}$ (**II**), (c) *cis*-$[Ru(L^{py})NO]^{2+}$ (configuration $\mathbf{III}_a$) and (d) *cis*-$[Ru(L^{py})NO]^{2+}$ (configuration $\mathbf{III}_b$).

disfavors the *trans*-V form. Additionally, the observation of dipolar connectivities between the pyridine H_{18} proton (8.59 ppm) and protons H_{5a} (2.09 ppm) and H_{7a} (3.30 ppm) but not with protons H_{9b}, H_{10a} or H_{12a} (Fig. 4c) confirms a folded *cis*-V configuration. This leaves only two possibilities (actually two pairs of enantiomers) for the structure of **I**, but the only one consistent with all the NMR information and its DFT optimized structure is presented in Fig. 5a. As for the assignment of the methylene N–CH_2-Py protons, the occurrence of NOESY cross-peaks between signals at 4.88 and 3.29 ppm (H_{14a}), and 5.10 and 3.08 ppm (H_{2b}) permitted to know the spatial orientation of these protons. (see Supplementary material for a complete description of the ^{1}H NMR assignment of complex **I**).

It is not trivial to rationalize which factors lead to the isolation of only one configuration. A DFT geometry optimization *in vacuo* of the compound $[Ru(L^{py})Cl]^{+}$ (a presumed intermediate in the preparation of **I**) reveals that the energy of the *cis*-V conformer is *ca.* 10 kJ mol^{-1} lower than the one of the *trans*-III isomer. The situation remains essentially the same if solvation effects are introduced by means of the PCM approximation, where the solvent is treated as a continuum dielectric medium. The computed energy difference suggests a certain degree of thermodynamic control for the reaction. Nevertheless, kinetic effects and even solubility properties cannot be ruled out.

The theoretically optimized *cis*-V geometry obtained for **I**, either in vacuo or with the molecule immersed in a dielectric medium to take into account the influence of the solvent, is consistent with the NMR results. The calculations position the diagnostic H_4–H_{11}, H_4–H_{9a}, H_{11}–H_{2a}, H_{18}–H_{5a}, H_{18}–H_{7a} and H_{18}–H_{9b} pairs of protons at distances of 2.28, 3.06, 3.05, 2.69 and 1.99 Å, respectively. These values are consistent with the observation of the NOESY crossed peaks described above. At the same time, the much larger computed distances H_{18}–H_{9b}, H_{18}–H_{10a} and H_{18}–H_{12b} of 5.05, 5.42 and 6.24 Å, respectively, explain the lack of signals for these proton pairs. Table 2 contains some relevant computed structural parameters and Fig. 5a displays the geometry of the optimized cation. The ruthenium atom is placed in a distorted octahedral N_6 environment, generated by the nitrosyl ligand and the five donor nitrogen atoms of the substituted macrocycle. The Ru–N(nitrosyl) (labeled Ru–N_{22}) bond reveals as significantly shorter than the five remaining Ru–N bonds. The Mayer bond order [30] for this bond (1.08) confirms the higher degree of covalency for Ru–N_{22} compared to the Ru–N(amine) (average of 0.52) and Ru–N(py) (0.53) bonds in the same compound. The computed N_{22}–O_{23} distance and the linear nature of the RuNO moiety are consistent with the expectations for a $\{RuNO\}^6$ species [3,31].

3.2. Vibrational and electronic spectroscopy

The IR spectrum of $[Ru(L^{py})NO](PF_6)_3$ in a KBr disk displays a sharp intense band at 1917 cm^{-1}, assignable to the N–O stretching vibration, ν_{NO}. This value is slightly higher than the ones found for *trans*-[Ru(NO)Cl(cyclam)]$(PF_6)_2$ (1875 cm^{-1}) [32] and $[Ru^{II}(NH_3)_5(NO)]Br_3$ (1913 cm^{-1}) [33], comparable to those reported for several *cis*- and *trans*-$[Ru(NH_3)_4L(NO)]^{3+}$ species (1923–1942 cm^{-1}) [6], and smaller than the values observed in other Ru(II) compounds that carry electron-withdrawing co-ligands (1946 and 1959 cm^{-1} for [Ru(trpy)(bpy)(NO)]-$(PF_6)_3$ and [Ru(tpm)(bpy)(NO)]$(ClO_4)_3$, respectively) [9,11]. This ν_{NO} frequency has been usually employed to qualitatively establish the degree of electronic interaction between the NO ligand and the metal center. In this case the ν_{NO} value suggests an $[Ru^{II}NO^{+}]$ electronic distribution where the NO^{+} character is well preserved [2], in agreement with the DFT bonding picture. The calculated frequency of 1849 cm^{-1} is lower than the measured one. Though this discrepancy is not unusual for calculations at this level of theory [10,11,13,14,24], there might be some contribution to the observed difference arising from hydrogen-bond interactions in the solid state.

The spectral region between 750 and 900 cm^{-1} has been usually employed to differentiate between *cis* and *trans* geometries in cyclam compounds [34,35]. In our case, besides this region is partially obscured by the PF_6^- vibrations, the pendant-arm leaves the complex with no symmetry elements no matter the configuration of the macrocycle. For this reason, the number of signals does not depend on the cyclam configuration and the low energy N–H vibrations are not informative.

Table 2
Selected bond lengths and angles for **I**, **II** and **III** obtained from the DFT optimized structures

Distance	I in vacuo (Å)	I in H_2O (Å)	I in acn (Å)	II in vacuo (Å)	III_a in vacuo (Å)	III_b in vacuo (Å)

Fig. 6 displays the electronic spectra of **I** in water (pH 1.0, $HClO_4$) and acetonitrile. Apart from the complete lack of strong bands in the visible region of the spectrum, the most remarkable features when the spectrum was recorded in water include intense absorptions in the UV region, a slight shoulder at *ca.* 236 nm ($\varepsilon = 5770\ M^{-1}\ cm^{-1}$), a much better resolved transition at *ca.* 257 nm ($\varepsilon = 4660\ M^{-1}\ cm^{-1}$), and a progression of weak bands at 313 nm (sh, $\varepsilon = 335\ M^{-1}\ cm^{-1}$), 355 nm (sh, $\varepsilon = 110\ M^{-1}\ cm^{-1}$) and 450 nm ($\varepsilon = 40\ M^{-1}\ cm^{-1}$). Ru(II) species holding amine ligands usually display solvent dependent electronic spectroscopy due to solute–solvent specific (hydrogen-bonding) interactions that can modulate the electronic density on the metal ion [36–39]. This same effect was described for species containing cyclam and π-acceptor ligands [35,40,41]. However, the spectrum of **I** in acetonitrile is virtually identical to the one measured in water, with only minor shifts of the bands to 232 nm ($\varepsilon = 6475\ M^{-1}\ cm^{-1}$), 258 nm ($\varepsilon = 4900\ M^{-1}\ cm^{-1}$), 317 nm (sh, $\varepsilon = 420\ M^{-1}\ cm^{-1}$), 350 nm (sh, $\varepsilon = 180\ M^{-1}\ cm^{-1}$) and 445 nm ($\varepsilon = 40\ M^{-1}\ cm^{-1}$).

The calculations establish that the HOMO is mainly located on the pyridine ring. The degeneracy of the t_{2g} set of metal orbitals is fully lifted because of the symmetry of the compound. One of these orbitals is not properly oriented and remains essentially non-bonding with respect to the nitrosyl moiety, being the majority component of the HOMO − 1 molecular orbital. The other two are strongly stabilized because of the fairly strong π interactions with the nitrosyl, and appear as the main constituents of the bonding HOMO − 5 and HOMO − 6 molecular orbitals. Conversely the LUMO and LUMO + 1 orbitals are mainly located on the NO fragment, but have some metal character resulting from the interaction between the π^* orbitals of the nitrosyl group with $t_{2g}(d_\pi)$ metal orbitals. Thus, the back-donation to the nitrosyl partially shifts electronic density from the metal ion into the π^* orbitals of the coordinated NO^+. The stabilization of the metal centered orbitals and the destabilization of the nitrosyl ones enlarge the HOMO–LUMO energy difference up to 3.2 and 3.6 eV, estimated in vacuum and in solution, respectively. These large values are responsible for the shift of the electronic spectrum to higher energies. The $Ru(II) \rightarrow \pi_{py}$ transition normally expected in the visible region [36–39] is therefore not observed there, but probably at much higher energy. We were not able to observe this band in our experimental conditions, but the analogous transition has been reported at 230 nm in the related systems $[Ru(NH_3)_4L(NO)]^{3+}$ (L = isonicotinamide or pyrazine) [6a,6b]. The π back-donation effect overcomes the subtle electronic changes expected to be induced by the specific interactions with the solvent. This explains the insensitivity of the electronic spectrum toward solvent changes.

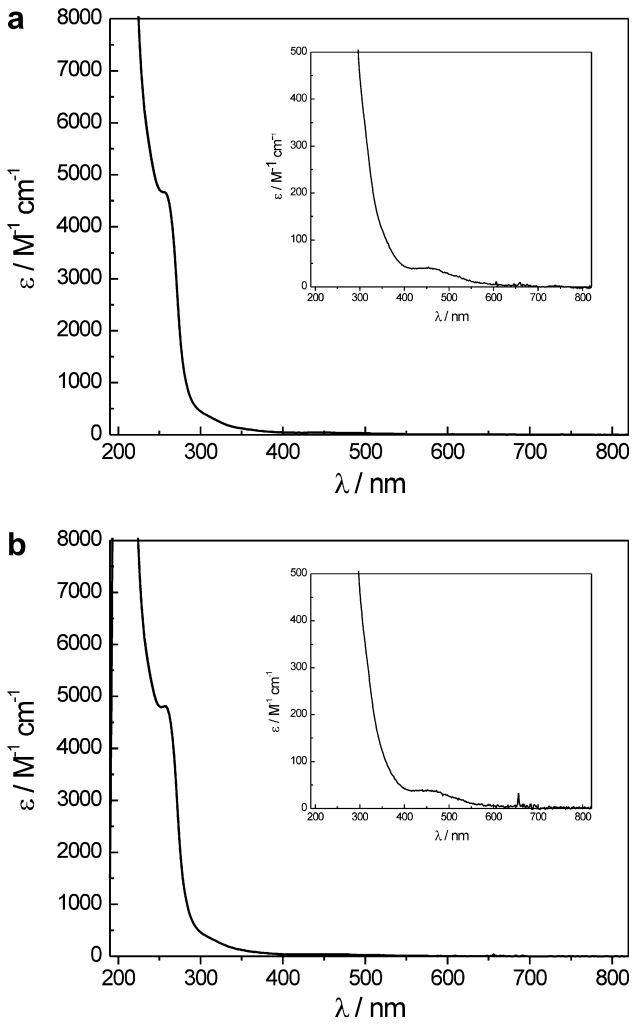

Fig. 6. Experimental UV–Vis spectra of **I** in water and organic medium. (a) Aqueous $HClO_4$ 0.1 M, (b) acetonitrile.

The interpretation of the electronic spectra of nitrosyl complexes is not unambiguous. In our case, the low symmetry of the species might lead to substantial orbital mixing that further complicates the analysis. (TD)DFT has proven as a valuable tool to assist in the assignment of the spectra of several related species [6c]. In the case of **I**, the calculated transitions reproduce qualitatively the experimental spectra. The computations position the Ru(II) $\rightarrow \pi_{py}$ MLCT at 208 nm, though superimposed with d–d and ligand-based transitions, and the lowest lying $\pi_{py} \rightarrow \pi^*_{py}$ intraligand transition at 257 nm. The extra features at lower energy involve several weak transitions with mixed d–d, MLCT (Ru(II) $\rightarrow \pi^*_{NO}$) and LL′CT ($\pi_{py} \rightarrow \pi^*_{NO}$) character. The agreement between the computed and experimental spectra is very good and supports the theoretical treatment.

3.3. Reactions with nucleophiles: formation of $[Ru(L^{py})NO_2]^+$

In spite of the backbonding effect, the coordinated nitrosyl still has a large nitrosonium character. The $[Ru^{II}NO^+]$ electronic distribution manifests experimentally not only in the ν_{NO} values, but also in the expected reaction of **I** with nucleophiles [5,26]. Aqueous solutions of **I** in non-acidic medium undergo rapid spectral changes with formation of $[Ru(L^{py})NO_2]^+$ (**II**), as described by Eq. (1). The reaction with OH^- is reversible and a full recovery of the nitrosyl reactant can be achieved upon acidification. Fig. 7 displays the spectra recorded in the stepwise conversion of the nitrosyl into the nitro compound. The presence of well defined isosbestic points suggests the absence of processes other than the one of interest. A multi-wavelength treatment of the absorption spectra by factor analysis also reveals the presence of only two colored species. This kind of reactions has been extensively studied in the past [5,26–28]. The nucleophilic attack of an OH^- ion leads to the formation of a covalent N–O bond. Afterwards, the intermediate nitrous acid complex deprotonates to yield the nitro derivative [9–11,28,42].

The spectrum of **II** is dominated by strong absorption bands at 264 nm ($\varepsilon = 4260\ M^{-1}\ cm^{-1}$), 308 nm ($\varepsilon = 4440\ M^{-1}\ cm^{-1}$) and 474 nm ($\varepsilon = 5590\ M^{-1}\ cm^{-1}$). As a comparison, the related compound *trans*-$[Ru(NH_3)_4(4\text{-Mepy})(NO_2)]^+$ (4-Mepy = 4-methyl pyridine) displays only one broad MLCT band at 378 nm with a shoulder at higher energies [10].

To understand the electronic structure of this species, we performed a theoretical geometry optimization, whose results are summarized in Table 2 and Fig. 5b. The coordination sphere of the Ru(II) ion in **II** remains very similar to the one described for **I**. The stable structure shows a dihedral N(py)–Ru–N–O angle close to 90° and a slight asymmetry in the coordinated NO_2^-, probably due to the intramolecular hydrogen-bond interaction with the closest N–H at *ca.* 2 Å. A full scan of this dihedral angle shows two minima in the potential energy surface. They correspond to equivalent geometries that result from a 180°

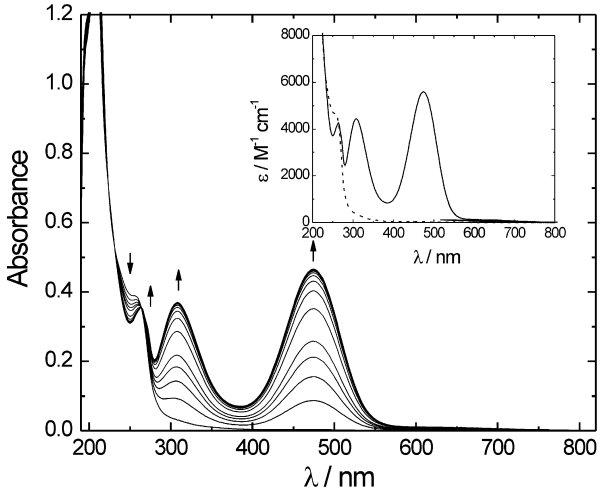

Fig. 7. Consecutive spectra for the reaction of **I** with OH^-. $[OH^-] = ca.\ 10^{-6}$ M, [complex] $= 8.4 \times 10^{-5}$ M. The arrows indicate the spectral changes along the reaction. Inset: Deconvoluted spectra of **I** (dashed line) and **III** (full line).

rotation of the NO_2^- moiety around the Ru–N axis followed by relaxation of the internal coordinates. These two minima are separated by a barrier of 33 kJ mol^{-1} (in vacuo), suggesting that the coordinated nitrite is not freely rotating in this species (or at least rotation around this axis has to be very slow in solution).

The nitro group is a poorer π-acceptor than the nitrosyl (and a better σ-donor). This results in an overall electronic picture with a lower degree of metal–ligand covalency and a higher electronic density located on the metal, as revealed by an average Mayer bond order of 0.36 for Ru–N(cyclam) and 0.49 for $Ru–N_{22}$. The filled frontier orbitals can now be clearly identified as the t_{2g} set. The lowest lying empty molecular orbitals are mostly located on the pyridine and the NO_2^- fragments, but to our surprise the calculations revealed a substantial degree of mixing between pyridine- and nitro-centered orbitals, feasible because of the low symmetry of this species.

The (TD)DFT calculated energy and intensity of the MLCT transitions does not accurately reproduce the experimental observations. This is not completely unexpected, because the electronic structure of this species has to be more sensitive to the medium. Consequently, the theoretical prediction of the electronic spectrum becomes much more difficult. Several approaches [38,43] have been employed in the past to deal with solute–solvent specific interactions, but the implementation of these strategies is beyond the scope of this manuscript. We perform here a tentative assignment of the donor–acceptor charge transfer spectroscopy employing qualitative arguments and comparing with related systems.

The literature values for the MLCT maxima of $[Ru(NH_3)_5NO_2]^+$ and $[Ru(NH_3)_5py]^{2+}$ in water are 368 and 407 nm, respectively [44]. The substitution of an ammonia by the poorer σ-donor pyridine molecule in the coordination sphere of $[Ru(NH_3)_5NO_2]^+$ is expected to shift the $Ru(II) \rightarrow NO_2^-$ MLCT band to higher energies. Using the same argument, the replacement of an ammonia by a nitrite should shift also the band to higher energies (lower wavelengths) than in $[Ru(NH_3)_5py]^{2+}$. This explains reasonably the occurrence of only one band in the spectrum of *trans*-$[Ru(NH_3)_4(4\text{-Mepy})(NO_2)]^+$ that results from the overlap of a $Ru(II) \rightarrow \pi_{py}$ and a $Ru(II) \rightarrow NO_2^-$ absorption both shifted to higher energy if compared to the pentaamine case.

The substantial mixing between the acceptor fragments suggested by the DFT calculations perturbs this description, shifting the two CT bands in opposite directions. We therefore assign the 308 nm band as involving the coordinated nitrite as the acceptor fragment and the 474 nm one as arising from a $Ru(II) \rightarrow \pi_{py}$ MLCT, both of them shifted with respect of the ones in *trans*-$[Ru(NH_3)_4(4\text{-Mepy})(NO_2)]^+$ as a consequence of the orbital mixing.

3.4. $\{RuNO\}^{6,7}$ interconversion

The cyclic voltammogram of **I** in aqueous solution (pH 1, $HClO_4$, $\mu = 0.1$ M) shown in Fig. 8a displays a single reversible wave at −0.02 V, arising from the one-electron interconversion between **I** and the $\{RuNO\}^7$ species $[Ru(L^{py})NO]^{2+}$ (**III**). Further exploration at more reducing potentials was not attempted because of the solvent electrochemical window.

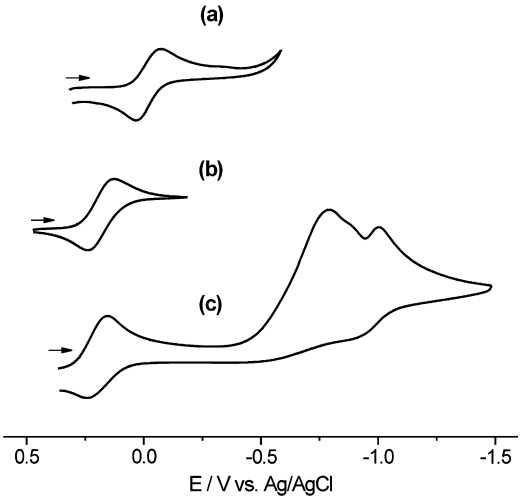

Fig. 8. Cyclic voltammograms of I in H_2O/0.1 M $HClO_4$ (a) and acetonitrile/0.1 M $TBAPF_6$ solution (b and c). Conditions: glassy carbon working electrode, scan rate 200 mV s^{-1}. The arrows indicate the direction of the scan.

The observed redox potential for the reduction of the coordinated nitrosyl is higher than the one reported for the related *trans*-$[Ru(NH_3)_4(4\text{-Mepy})(NO)]^{3+}$, −0.25 V ($\mu = 0.1$ M CF_3COOH/CF_3COONa, pH 4). Even when the difference might be partially ascribed to the differences between *cis*- and *trans*-configurations, it should be noted that a similar shift, which might originate in solvation issues related to the macrocylic ligand was reported when comparing other tetrammine- and cyclam-based nitrosyls [32,35]. For these related systems, the cyclic voltammograms reveal a series of chemical reactions coupled to the electron transfer process, that have been interpreted in terms of labilization of the co-ligands and NO^0 [6,32,35,45]. None of these complications seems to be associated to the $\{RuNO\}^{6,7}$ conversion in our system.

The cyclic voltammograms in acetonitrile (Fig. 9b) reveal the same reversible one-electron reversible process, though shifted to $E^0 = 0.18$ V. An increase of 0.125 V was reported for the same process in *trans*-[Ru(NO)Cl(cyclam)]$^{2+}$, and an even larger difference of *ca.* 0.30 V has been measured in $[Ru(tpm)(bpy)NO]^{3+}$ [11]. The differences can be traced back to changes in the dielectric properties of the solvents, which would favor the reduction process in less polar media. In addition, the larger donor number (DN)[46] of water if compared to acetonitrile (18.1 versus 14.1 for water and acetonitrile, respectively) contributes to increase the electronic density in the coordinated nitrosyl, via specific hydrogen-bond interaction with the amine protons [36]. The general increment in the redox potential, combined with a wider electrochemical window than in water, allowed to explore the reduction of the

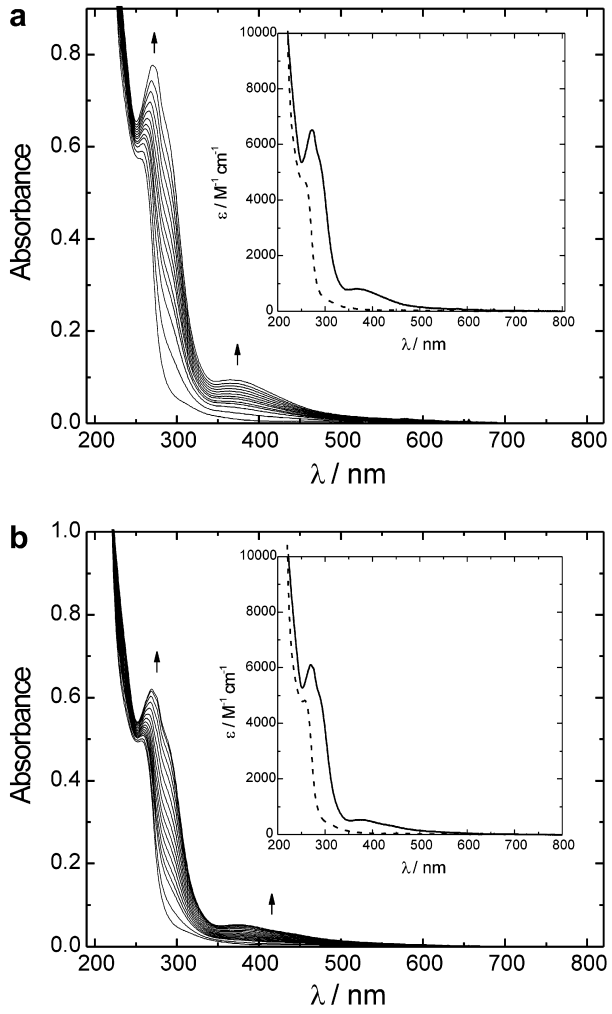

Fig. 9. Spectroelectrochemical conversion of **I** into **III** in water and organic medium under controlled potential conditions. (a) Aqueous $HClO_4$ 0.1 M, (b) acetonitrile/0.1 M $TBAPF_6$, [complex] = 1.2×10^{-4} M and 1.0×10^{-4} M for water and acetonitrile, respectively. The arrows indicate the spectral changes upon reduction. Insets: deconvoluted spectra for **I** (dashed line) and **III** (full line) obtained by factor analysis (see text).

$\{RuNO\}^7$ species. At more negative potentials (*ca.* −0.75 V) a complex pattern involving consecutive electron transfer processes can be detected. All this extra waves appear as irreversible in the CV time scale. The first of such electron transfer process might be tentatively ascribed to the formation of a $\{RuNO\}^8$ species [8,14]. This species appears to be unstable in the CV timescale, even if the experiments are performed at −30 °C and some complementary characterization would be required in order to improve its description.

Fig. 9 shows the stepwise **I** → **III** conversion under controlled potential conditions both in acidic conditions and in acetonitrile solution. The reduction processes proceed smoothly, and the factor analysis of the recorded spectra reveals only two colored species in both solvents. The integrated current, as well as the absorbance versus open-circuit potential curves obtained during the electrolysis are also consistent with a 1-electron process with $E^0_{NO+/NO} = -0.02$ and 0.21 V for water and acetonitrile, respectively. These values are in very good agreement with the ones obtained in the cyclic voltammetry experiments. The slight shift detected in acetonitrile is mostly due to the different temperatures employed in both determination. This experiment confirms the reversibility of the $\{RuNO\}^{6,7}$ redox interconversion. The electrogenerated reduced species in aqueous solution seems to be stable if protected from oxygen, but reoxidizes rapidly in the presence of air to quantitatively regenerate **I**. In acetonitrile, the oxidation by molecular oxygen is much slower, and no spectral changes were observed in the minute timescale. Electrochemical reoxidation leads, in both cases, to quantitative recovery of **I,** even after 2 h. The reversibility of the NO^+/NO conversion indicates that the whole coordination sphere in **III** (including the coordinated NO·) is strongly inert toward substitution reactions. As we mentioned above, this is not always the case, and release of NO or NO-induced *trans* labilization has been observed for several complexes [32,35]. The spectroelectrochemistry confirms that this is not the case with **III**, making this system particularly useful to be studied in both $\{RuNO\}^{6,7}$ oxidation states.

One-electron reduction is expected to induce a bending of the Ru–N–O angle [2,3]. A DFT geometry optimization confirms this expectation. The computation performed in vacuo included a potential energy surface scan of the dihedral O–N–Ru–N(py) angle, which revealed two possible stable geometries $\mathbf{III}_a$ and $\mathbf{III}_b$ for this $\{RuNO\}^7$ species (Fig. 5). The two situations minimize the steric interactions between the NO fragment and the L^{py} ligand. In contrast with **II** and other $\{MNO\}^7$ systems [14], there seem to be no signs of intramolecular N–O ⋯ H–N(cyclam) hydrogen-bond. These two conformers have slightly different thermodynamic stabilities, with $\mathbf{III}_a$ laying 5.4 kJ mol^{-1} below $\mathbf{III}_b$. Overall, the potential energy surface is rather flat and the interconversion of $\mathbf{III}_a$ into $\mathbf{III}_b$ involves a small energy barrier of 6.7 kJ mol^{-1} (1.3 kJ mol^{-1} in the opposite direction). Even when the presence of solvent molecules interacting specifically with the amine protons might hinder the interconversion between conformers, our calculations imply that the NO fragment is freely rotating in the $\{RuNO\}^7$ species. Table 2. collects the most significant structural parameters for $\mathbf{III}_a$ and $\mathbf{III}_b$. The overall features are very similar for both, with a practically identical co-ligand environment. The most significant structural change upon reduction involve, as expected, the lengthening of the Ru–N_{22} and N_{22}–O_{23} to 1.90 and 1.22 Å, and the bending of the Ru–N_{22}–O_{23} angle to *ca.* 143°. These parameters, combined with the reduction of the N_{22}–O_{23} Mayer bond order to 1.56 reflect the population of a formally π-antibonding orbital located mostly on the NO fragment. In fact, the calculations confirm that the SOMO is mostly located on the NO fragment with partial delocalization onto the metal center, a common feature to many $\{RuNO\}^7$ species [9,11,12,16].

The calculations also reveal an overall reduction of the covalency of the Ru–N(L^{py}) bonds, which show an average Mayer bond order of 0.41. Particularly, the Ru–N_4 bond order of 0.38 is the lowest, suggesting the onset of a *trans*-effect. In spite of this, the coordination sphere remains structurally unaffected due to the rigidity of the whole macrocyle. The electronic structure of this species is also affected by π-backbonding. Two metallic orbitals belonging to the t_{2g} set reveal some degree of mixing with the π^* orbitals located on the NO fragment, while the third remains as non-bonding because of the symmetry of the complex. The backbonding interaction is overall smaller than in **I**, revealing NO as a poorer π-acceptor. The lowest lying empty molecular orbitals correspond essentially to the ligand-centered π^* orbitals. Their relatively low energy, in contrast with the computations performed on **I**, permit the development of CT transitions in the visible region. The electronic spectrum of **III** displays an intense absorption at 271 nm ($\varepsilon = 6500\ M^{-1}\ cm^{-1}$), a shoulder at 287 nm ($\varepsilon = 5500\ M^{-1}\ cm^{-1}$) and a weaker band at 365 nm ($\varepsilon = 810\ M^{-1}\ cm^{-1}$), when recorded in water. In acetonitrile the positions of these bands remain almost unchanged at 270 nm ($\varepsilon = 6100\ M^{-1}\ cm^{-1}$), 287 nm ($\varepsilon = 5010\ M^{-1}\ cm^{-1}$) and 369 nm ($\varepsilon = 520\ M^{-1}\ cm^{-1}$).

The (TD)DFT results suggest that the low energy bands, predicted at 378 nm and observed at *ca.* 365 nm are better described as the spin-allowed $\pi_{NO} \rightarrow d_{Ru}$ LMCT with some $\pi_{NO} \rightarrow \pi^*_{py}$ character. The same computations assign the intense absorption at *ca.* 270–290 nm as arising from a $d_{Ru} \rightarrow \pi^*_{py}$ transition, though extensively overlapped with the intraligand $\pi_{py} \rightarrow \pi^*_{py}$, the $d_{Ru} \rightarrow \pi^*_{NO}$ MLCT and weak d–d transitions. It is surprising that even when the absorption bans appear to have CT character, there seems to be little solvent dependency. Though this fact can be indicative of extensive π-backbonding interactions [36,38,39,47], it is not clear that this is the case for **III** and a broader range of solvents has to be explored to asses this issue.

4. Conclusions

This pendant-arm cyclam complex of Ru(II) proved as a valuable platform to investigate the NO^+/NO^0 redox chemistry. The marked inertness of the coordination sphere on both $\{RuNO\}^6$ and $\{RuNO\}^7$ oxidation states, the strong color changes associated to the redox processes and the preliminary results concerning the reaction of this species with O_2 are promising, and open the possibility to a systematic study of redox reactivity. Variations in the identity of the pendant-arm could be used in the future to generate a series of nitrosyl compounds with control over $E^0_{NO^+/NO^0}$ in a region of potentials with scarce examples in the literature.

The abundant experience in connection with the derivatization of cyclam envisages many possible variations leading to macrocyclic species with different donor/acceptor capabilities. The parallelism with the related *trans*-$[Ru(NH_3)_4(4\text{-Mepy})(NO)]^{3+}$ and *trans*-$[Ru(NO)Cl(cyclam)]^{2+}$ series of compounds and the use of theoretical approaches as the ones employed here stand as valuable predictive tools that might be of significant help in the selection of the appropriate substituents. We are currently exploring this possibility.

We found a minimum (**4** and Fig. 1) in which N_2O is exactly *trans* (179.1°) to the amide N with an entirely linear RhNNO unit. Bond lengths within the N_2O unit are altered by less than 0.02 Å from those calculated for free N_2O. Results of fixed geometry scan (Table 1) show the minimum.

Apparently (PNP)Rh lacks the reducing power to form N_2O^{2-}, in part because the resulting Rh^{III} would have such an atypical (four-coordinate) coordination geometry for a d^6 configuration. Since a 5d metal is always more reducing than its 4d analog, we did geometry optimization of (PNP)Ir(N_2O). Indeed, this has a minimum (Fig. 2) bent at N_β, but linear at N_α. This is best described by Lewis structure **5**, which indeed has N_2O^{2-} as the ligand, but with additional donation of the N_α lone pair to Ir in the $(PNP)Ir^{2+}$ fragment. Such donation creates an Ir/N_α triple bond but demands localization of the PNP amide lone pair on that N, hence lengthening that bond. The Ir–NSi_2 distance is 2.08 Å in (PNP)Ir(N_2O) but only 1.84 Å in $(PNP)Ir^{2+}$; comparing these, the Mayer Ir–NSi_2 bond order nearly doubles, from 0.80 to 1.51. Table 1 shows that this potential curve is even softer than that for Rh

5

The optimized geometries (Fig. 2) for (PNP)Ir(N_2O) and the isoelectronic and more electron rich $(PNP)Os(N_2O)^{-1}$ are both half-bent, with structural parameters compared in Scheme 1 (where values for Os are shown in parentheses). For the more reducing $(PNP)Os^{-1}$ fragment, the M/N1 distance is shorter and the N1/N2 and N2/O3 distances are longer, while the angle is more linear at N1 and bent to

6

Scheme 1.

Table 1
Bending potential (B3LYP/cc-pVTZ(-f) energies, in kcal mol)

N–N–O (in °)	130	140	150	160	170	180
(PNP)Rh(N_2O)	10.4	6.4	4.4	3.4	2.6	0.0
(PNP)Ir(N_2O)	1.7	−0.2	−0.4	0.3	0.4	0.0

nearly sp^2 at N2. Together, these support the idea of greater participation by structure **6** from Ir to Os. Comparison to the structure of (PNP)Rh(N_2O) shows Rh to be the least reducing, in line with conventional thinking. The Ir/N1 and Os/N1 distances are short enough to qualify as multiple bonds. The M/(amide N) distances become longer when the *trans* distance shortens, consistent with competition between two nitrogens for one empty metal d_π orbital. Atomic charges from an electrostatic potential calculation confirm this: Rh(Ir) are +0.20 and +0.47, while N_2O is −0.14(Rh) and −0.37(Ir).

2.2. Doubly bent N_2O

To probe the claim of Ir/N_α triple bond above, it is necessary to consider N_2O binding geometries when the L_nM fragment already carries 16 valence electrons. For this purpose, we considered two reducing moieties, $(Me_3P)_4Ir^+$ and $(Me_3P)_4Os$, each d^8 and singlet. By removing the π-donor

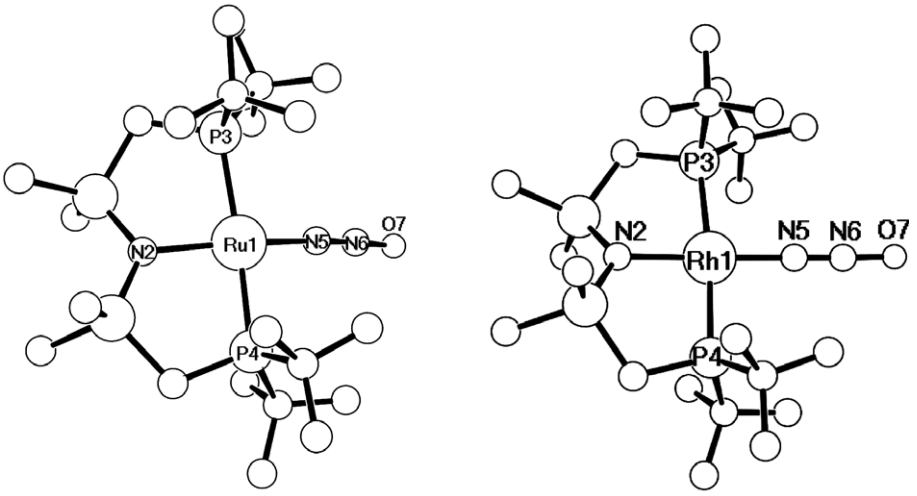

Fig. 1. DFT structures for (PNP)M(N_2O) for M = Ru (left) and Rh (right).

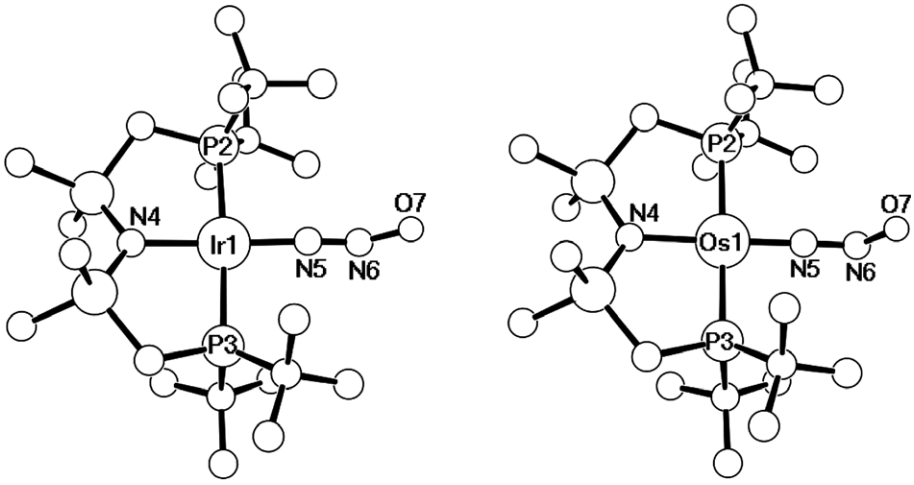

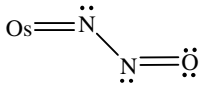

Fig. 2. DFT structures for (PNP)Ir(N_2O) (left) and (PNP)Os(N_2O)$^{-1}$ (right).

amide ligand of PNP, we simplify analysis of the results. The osmium example indeed has an energetic minimum of the sort we seek (Fig. 3), and where the OsNNO unit is *doubly* bent. This is in full accord with Lewis structure **7**. This should then be considered five-coordinate and d^6, and the observed geometry is close to square pyramidal, with the "dominant" ligand, N_2O^{2-}, apical. The small deviation of the Os(PMe_3)$_4$ substructure from C_4 symmetry is attributed to the electronic anisotropy of the Os/N $\sigma + \pi$ bond, causing the NO group to destroy rigorous C_4 symmetry.

7

It is interesting that geometry optimization of doubly bent $(Me_3P)_4Ir(N_2O)^+$, from a variety of starting geometries, dissociates the Ir/N bond, showing the absence of a significant energy minimum and showing N_2O to not be bound to Ir^I in Ir(PMe_3)$_4^+$. Since this cation is clearly less reducing than neutral Os(PMe_3)$_4$, we attribute the purely dissociative character to inadequate reducing power of Ir(PMe_3)$_4^+$, together with the special stability of the d^8 configuration when it is square planar (i.e. the empty d orbital, x^2–y^2, associated with its "unsaturation," has very high energy because it is σ^*_{Ir-P}).

One electron reduction of this Ir^I species, to form the doublet radical $(Me_3P)_4Ir(N_2O)$, gives a species (Fig. 3) which is a minimum (i.e. Ir–N_2O does not dissociate on geometry optimization) and with doubly bent N_2O. Spin densities (0.05 on Ir and 0.89 on N_2O) show this to be Ir^I binding an N_2O^{-1} radical anion, consistent with good reducing power from the 17 electron Ir(PMe_3)$_4$ center. The Ir–N2 distance is 0.18 Å longer than in $(Me_3P)_4Os(N_2O)$, but distances within the N_2O unit differ negligibly.

2.3. More complicated examples

2.3.1. Singlet (PNP)Ru(NO)(N_2O)

The species (PNP)Ru(NO)(N_2O) optimizes to a geometry (Fig. 4) which has linear N_2O (hence 2e donor and

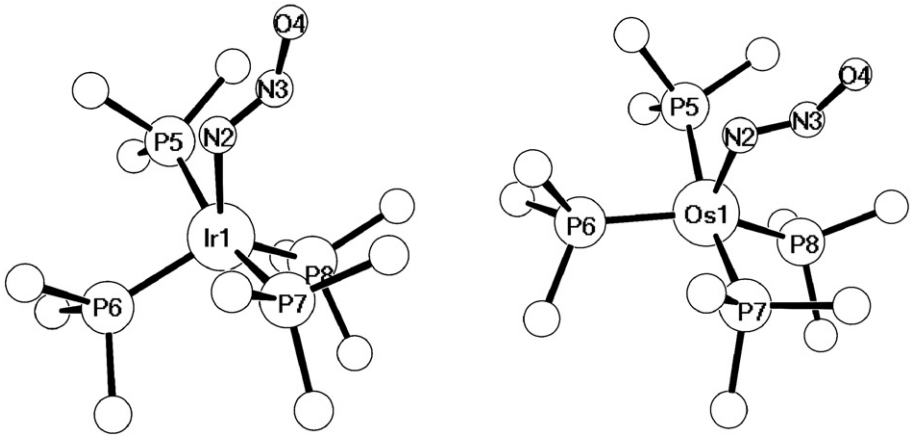

Fig. 3. DFT structures for doublet $(Me_3P)_4Ir(N_2O)$ and singlet $(Me_3P)_4Os(N_2O)$. Selected angles (°) for Ir(Os): M–N2–N3, 119.3 (111.0); N2–N3–O4, 133.7 (134.6).

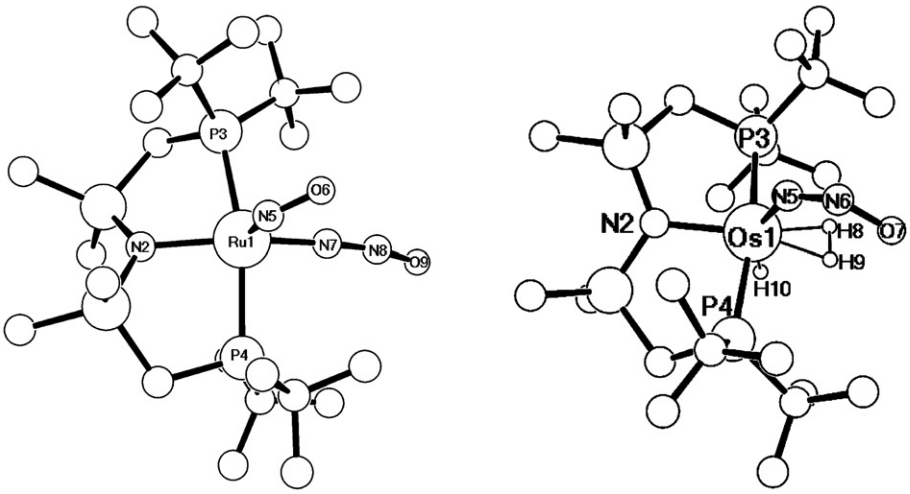

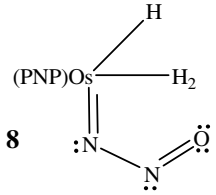

Fig. 4. DFT structures for (PNP)Ru(NO)(N_2O) and (PNP)OsH(H_2)(N_2O).

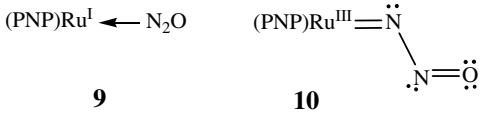
not reduced) but bent (124.4°) RuNO. This latter bend is needed to achieve an 18-electron configuration (with PNP donating its amide lone pair), and this bend is absent after N_2O is lost from Ru in the planar ground state geometry of (PNP)Ru(NO), which has linear RuNO, hence NO^+ and Ru^0. The distances within N_2O in (PNP)Ru(NO)(N_2O) are only a little changed (<0.02 Å) from those in free N_2O. Altogether then, the (PNP)$Ru^{II}(NO^{-1})$ fragment cannot reduce its coordinated N_2O.

2.3.2. (PNP)Os(H)$_3$ + N_2O

(PNP)$Os(H)_3$ is an operationally unsaturated (16/18 valence e) complex with C_{2v} symmetry and a distorted octahedral structure [2]. When N_2O binds to this molecule *cis* to amide, we located a doubly bent singlet minimum (Fig. 4).[1] The Os/N_α distance, 2.015 Å, is consistent with drawing **8**

8



Metal-to-N_2O electron transfer is also evident in an additional characteristic of the minimum found for (PNP)OsH_3(N_2O). When N_2O binds to this trihydride of Os^{IV}, two hydrides respond by reductively coupling (Fig. 4) to form η^2-H_2, with redox transfer of 2e to Os; the product, (PNP)OsH(H_2)(N_2O), thus retains the +4 oxidation state of the reagent. The Os^{VI} alternative is so oxidizing that two hydrides reduce it. In short, the dihydride/dihydrogen outcome is diagnostic of the Os/N_2O interaction having redox character, not mere dative bonding.

2.3.3. The radical (PNP)Ru(N_2O)

Another interesting example is the redox fate of (PNP)Ru^{IV}(≡N) when the NO radical binds Eq. (1) to the nitride nitrogen (Fig. 1). Here N_2O is

$$(PNP)RuN + NO \rightarrow (PNP)Ru(N_2O) \quad (1)$$

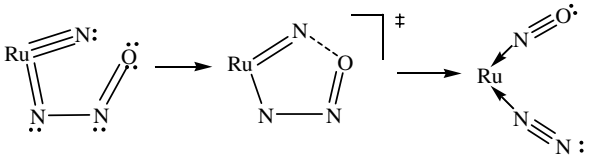
formed by N/N bond formation. The resulting $S = 1/2$ complex could be **9** or **10**. The fact that

9 **10**

the minimum found (even starting from a *doubly bent* geometry) has an entirely linear RuNNO structure indicates that d^7 (PNP)Ru^I in the product lacks the reducing power to produce *N*-nitrosoimide. The overall N/N coupling reaction Eq. (1) is thus a 3-electron reduction of Ru^{IV}

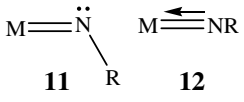
$$N^{3-} + NO \rightarrow N_2O + 3e^- \quad (2)$$

Ruthenium is close to planar in this spin doublet species and there is very little change (0.01–0.03 Å) in the bond lengths within the N_2O fragment from those in free N_2O. Structural parameters are within 0.03 Å of those of (PNP)Rh(N_2O), which has one more valence electron. The spin densities, +1.049 on Ru and −0.04 on the N_2O moiety and only +0.02 on the amide N, are consistent with d^7 Ru^I, and support the conclusion that the (PNP)Ru moiety, like (PNP)Rh, lacks 2-electron reducing power.



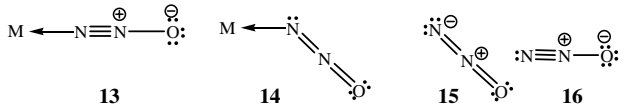
[1] These are not necessarily the most stable of adduct structures, but the structural implication of electron transfer remains true.

3. Discussion



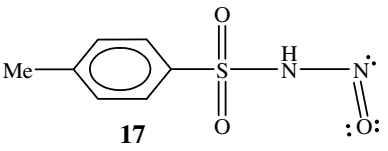
Our initial location of doubly bent N_2O minima involved N_2O addition to $(PNP)Os^{IV}(H)_3$ and to $(PNP)Ru^{IV}N$ [9]. It is remarkable that *one* of these high oxidation states (Ru), and a d^4 electron configuration, retains enough reducing power to transfer 2 electrons to arriving N_2O in the resulting adduct.[1] Reduction of N_2O in the Os case relies on each hydride ligand to furnish one electron. In the osmium case, the bending is central to migration of H-ligands to O, which ultimately forms H–Os ← N≡N:, with liberation of H_2O

$$(PNP)Os(H)_3 + N_2O \rightarrow (PNP)OsH(N_2) + H_2O \quad (3)$$



In the latter case, double bending is key to reactivity which transfers O to nitride

(4)

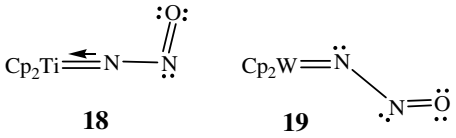


Based on the paucity of examples, N_2O is clearly a very weak ligand (as is its isoelectronic analog CO_2). This can be offered as the cause of why N_2O generally functions only poorly as an oxygen atom transfer reagent (i.e. $N_2O \rightarrow N_2 + O$), in spite of the attractive co-product, N_2. If N_2O binds only poorly to a metal, this becomes the rate determining step, in spite of good thermodynamics of subsequent steps; the O-transfer reaction fails for kinetic reasons. In some sense, it is surprising that the new, 2e redox mode of η^1-binding N_2O to a metal was not proposed until now. While it requires a strongly reducing L_nM reagent, the reaction is wholly analogous to (RN_3-derived) imide binding to a metal; for N_2O^{2-}, the difference focuses on possible conjugation of M=N with N=O when R is the bent nitroso group (**11** and **12**)

11 **12**

The traditional mode postulated for η^1-N bound coordination of N_2O is always found to be linear at both N, **13**, which is curious given the allene (or cumulene) structure (**14**) normally drawn for N_2O (hence bent at N_α). Structure **15** has more nucleophilic N than any N in structure **16** and structure **15** is more consistent with the observed NN and NO bond lengths (Scheme 1)

13 **14** **15** **16**



The half-bent versus doubly bent L_nMN_2O structures described here for coordinated N_2O^{2-} have the effect of weakening the N_α/N_β bond (the two reducing equivalents occupy an orbital which is heavily $\pi^*_{N\alpha N\beta}$). This suggests that both bent N_2O ligands may react by NO^q transfer, the value of q being determined by L_nM as well as the specific NO^q receptor reagent. This is a feature shared with the "Diazald" NO transfer reagent **17** [10]: it leaves behind a moiety which can stabilize emerging anion or radical character, as the N/N bond breaks

17

In addition, one can imagine protonation of N_β (or even O) of bent N_2O^{2-}, or attack by an electrophile

(5)

Perhaps the most successful use of N_2O as an oxygen transfer reagent is its reactivity towards low valent, early transition metal metallocenes [11–14], Cp_2M for M = Ti, V, Cr. Here the products are invariably μ-oxo clusters $(CpM)_m(O)_n$. Based on the results presented here, it is possible [15,16] that species like **18** and **19** mediate these reactions and thus that the *N*-nitrosoimide ligand is the source of oxidizing oxygen, with formation, then liberation of N_2. These principles also indicate that binding of N_2O to a solid surface containing reducing equivalents may also involve an *N*-nitrosoimide form

18 **19**

It is interesting that, with the PNP ligand, going to a monovalent 5d metal effects 2-electron reduction of N_2O, whereas a 4d analog does not, in spite of coordination number 4 being unfavorable even for d^6 Ir(III). In that regard, it is important to note [17] that the d^6 (linear) imides (arene)OsNR and Cp*IrNR are both "tetrahedral", or in fact C_{3v}, and this is probably the electronically preferred coordination geometry for L_3MNR, but clearly is structurally impossible for a PNP ligand species.

To encourage experimental discovery of the various structures described here, it will be useful to know their vibrational spectroscopic signatures. Shown in Table 2 are the calculated frequencies of wholly linear, singly bent and doubly bent cases. The wholly linear example has the high frequency characteristic of free N_2O itself, a value which is so high due to strong vibrational coupling of the two different multiple bond stretches (analogous to free

Table 2
Calculated stretching frequencies and bond lengths (Å)

	cm^{-1}	N1–N2	N2–O3
(a) Linear			
Free N_2O	2367	1.15	1.20
(PNP)Rh(N_2O)	2362	1.19	1.21
(PNP)Ru(N_2O)$^{\cdot}$	2330	1.15	1.22
(b) Singly bent			
(PNP)Ir(N_2O)	2059	1.17	1.24

$(Me_3P)_4$Os(N_2O)	1644	1.21	1.26

CO_2), when they are mutually *trans* (high interaction force constant). As the triatomic bends singly, then doubly, the frequencies decrease to the values appropriate to an N=O bond. These values support the conclusions from Lewis structures that reduction (metal-to-ligand redox) weakens bonds within N_2O, and this bodes well for improved predictability of how to do oxygen atom transfer. . ..or NO transfer from coordinated N_2O.

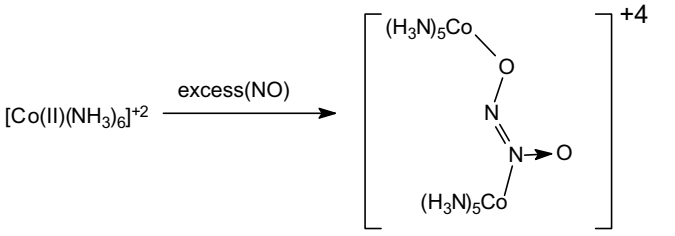
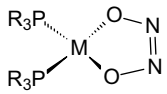
the form of metal catalyzed disproportionation. And of course any disproportionation, metal catalyzed or not, leads to the formation of the very strongly oxidizing nitrogen dioxide. It is significant that the original syntheses of $Cr(NO)_4$ involves a photolytic substitution under a stream of nitric oxide at atmospheric pressure [3,9,10], conditions which favor the binding monomeric nitric oxide and not nitric oxide disproportionation or the reaction of the complex with the nitric oxide dimer.



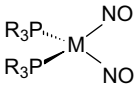
In addition to these fundamental synthetic limitations there is an additional reactivity pattern possible for polynitrosyl complexes which is not observed for polycarbonyls: metal mediated nitric oxide coupling to give N–N bonded derivatives either as hyponitrite [11–14], or nitrous oxide [15] or in some cases ultimately to give dinitrogen [16]. Unfortunately, the evidence for the direct coupling of two nitrosyls in the coordination sphere of a metal is limited and a clear unambiguous example of the reaction in Eq. (3) would help us understand the nature of this transformation. The ambiguity present here is mechanistic: Are either of the nitrosyls coordinated to the metal before N–N bond formation, Eq. (3), or do these N–N coupled products result from the reaction of the dimer **1** with the metal, Eq. (4)?

Examples of metal mediated nitric oxide reductive coupling which give isolable hyponitrite complexes are rare and correspond to the nitrosylation of several electron rich late transition metal complexes, Eqs. (5)–(8) [12–14]. In the ruthenium and platinum examples the corresponding dinitrosyl complexes were not isolated, and have not been reported. The reaction of $Pt(PPh_3)_4$ with nitric oxide proceeds in a straightforward manner involving the reductive dimerization of nitric oxide to yield a *cis*-hyponitrite ligated Pt(II) complex (Eq. (5)) [12]. A more complicated reaction between $Co(CO)_3(NO)$ and excess nitric oxide also proceeds via reductive dimerization of nitric oxide, Eq. (7). In this case the formation of the putative $[Co(NO)_3]$ intermediate is also proposed [13]. Finally, the example shown of the reductive coupling of two Co(II) nitrosyl complexes in Eq. (8), $\{CoNO\}^8$ in the Feltham–Enemark scheme [17], is a well studied [18–20] example known since Werner's pioneering chemistry [21]. In the absence of added reductants nitric oxide coupling can occur with metal oxidation [16] or by nitric oxide disproportionation, Eq. (2). Thus, the reductive nitric oxide coupling which occurs in Eqs. (5)–(8) are likely to be quite common and most likely related to the general metal catalyzed disproportionation of NO by transition metals [15,22] and more recently by lanthanides [23]. The current scarcity of hyponitrite complexes as products of reductive nitrosylation reactions is in part due to their instability and in particular their tendency to lose nitrous oxide [24].



The facile loss of nitrous oxide from the *cis*-hyponitrite complex is one of its key reactivity patterns; it is also important for the uncoordinated ligand. We have attributed this to the instability of the monoalkyl or monoprotonated *cis*-hyponitrite. To demonstrate this point the contrast with *trans*-hyponitrite and its conjugate acid and esters is illustrative. Thus although a series of monoalkylated and protonated *trans*-hyponitrites are now recognized, these correspond to the kinetically activated form which releases nitrous oxide. Unlike *trans*-hyponitrite for which stable dialkylated and diprotonated derivatives can be isolated and characterized, neither is known for the *cis* isomer. We attribute this tendency to the instability of the monoprotonated and monoalkylated *cis*-hyponitrite: addition of the second electrophile can not compete with loss of nitrous oxide. This hypothesis accounts for the instability of *cis*-hyponitrite complexes: any coordination sphere lability which leads to a monohapto *cis* hyponitrite could rapidly lose nitrous oxide. A second consequence of this hypothesis is that the preparation of *cis*-hyponitrite complexes will most likely require prior coordination of the oxygens in the precursor or oxidative addition of the nitric oxide dimer, rather than by direct coordination of the preformed dianion. In this paper, we report: (1) the preparation and characteristics of *cis*-hyponitrite complexes; (2)

the redetermination of the structure of one of these, $Pt(PPh_3)_2(N_2O_2)$, with a significantly improved precision; (3) the syntheses and characterization of new dinitrosyl complexes of ruthenium and osmium with chelating phosphines; and (4) the structures of two of these derivatives, $Ru(dppf)(NO)_2$ and $Os(dppe)(NO)_2$.



2. Results and discussion

Two streams of experimental data are contrasted in this paper: the stable group 10 M(II) hyponitrite complexes, **2**, for which the corresponding dinitrosyls are not known, and the stable group 8 dinitrosyls, **3**, for which stable mononuclear hyponitrite complexes have not been described

2

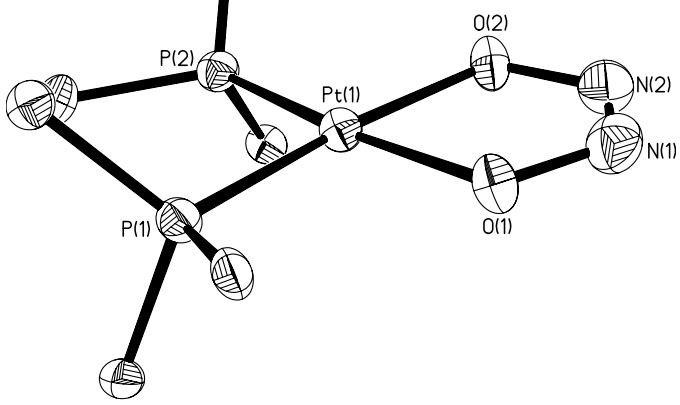
M = Pt, Ni

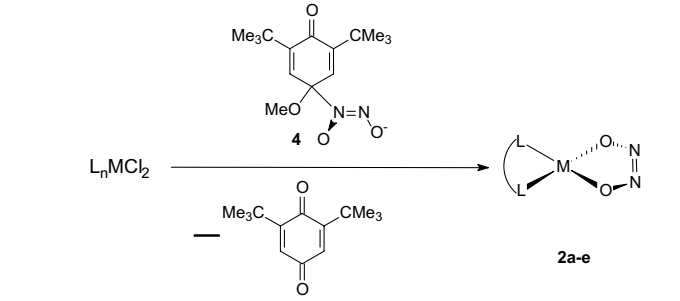
3

M = Ru, Os

2.1. Coordinated hyponitrite

It remains remarkable how few *cis*-hyponitrite complexes there are and how poorly developed the chemistry of this ostensibly simple dianion remains: in part this reflects the extreme reactivity of its simple salts [24], of which the disodium salt was only thoroughly characterized in 1996 [25,26]. In contrast, there are many more reports related to *trans*-hyponitrite, it is easier to prepare and it has greater stability [27,28]. The first and until recently unique example of the mononuclear *cis*-hyponitrite complexes **2a** with $L = PPh_3$ and M = Pt was first prepared by treating $Pt(PPh_3)_4$ with NO [11,12]. In 2002, we described a new way to prepare these derivatives by treating MCl_2L_2, M = Ni, Pt, with the diazeniumdiolate **4**, Eq. (9). In addition to the generality of the possible substrates for the generation of **2** their yields and purity are higher with this synthesis. Detailed spectroscopic and characteristic data are listed in Section 4, **2a**–**e**, and the structure for **2a** has been redetermined since the original had large esd's for the metric parameters for the hyponitrite ligand, and the modeled solution had a very high *R* factor, $R > 10\%$ [12]. Although these crystallographic problems limited the detailed interpretation of the structure of **2a** it did confirm its composition. These limitations are due to the original data being acquired at room temperature, where there is considerable decomposition. Our redetermination corresponds to the −100 °C structure. A side on view of the inner coordination environment of **2a** is shown in Fig. 1, and key metric parameters are included in the caption. The geometry adopted by the *cis*-hyponitrite in **2a** is similar to that in $Ni(dppf)(N_2O_2)$ [24] and the metric parameters are similar to the dianion in its sodium salt [25], but the latter structure is based on the Rietveld refinement of its powder data and the key anion bond lengths and angles have high esd's, cf. O(1)–N(1)=1.40(3); N(1)–N(2) = 1.20(3); N(2)–O(2) = 1.41(3) Å and N(2)–N(1)–O(1) = 120.8(4)°, N(1)–N(2)–O(2) = 117.6(4)° which limits their interpretation.





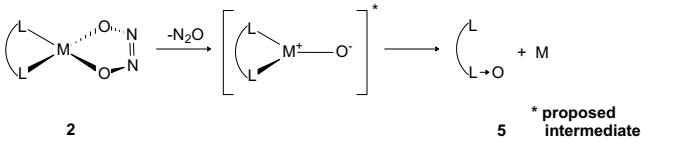


Fig. 1. ORTEP representation of the inner coordination sphere of **2a**. Probability elliposoids shown at 45% and key metric parameters (Å, °): O(1)–N(1) = 1.370(8); N(1)–N(2) = 1.230(9); N(2)–O(2) = 1.363(8); O(1)–Pt(1) = 2.013(4); O(2)–Pt(1) = 2.023(5); Pt(1)–P(1) = 2.2417(17); Pt(1)–P(2) = 2.2671(18) Å; Pt(1)–O(1)–N(1) = 112.1(4); O(1)–N(1)–N(2) = 118.9(7); N(1)–N(2)–O(2) = 118.5(7); N(2)–O(2)–Pt(1) = 112.3(5); O(1)–Pt(1)–O(2) = 78.2(2); O(1)–Pt(1)–P(1) = 93.23(15); O(1)–Pt(1)–P(2) = 168.56(15); O(2)–Pt(1)–P(1) = 171.40(15); O(2)–Pt(1)–P(2) = 90.79.15(15); P(1)–Pt(1)–P(2) = 97.80(7)°.

(9)

In prior work [24], we have termed the reaction in Eq. (9) an umpolung of the C–N bond: on a formal level the bond cleaves heterolytically to give $[N_2O_2]^{2-}$ rather than to generate two NO radicals as do many diazeniumdiolates [29]. The quinone by-product has been quantified and corresponds well to the yield of **2**. Typically, two equivalents of **4** are used for every metal complex, but when the stoichiometry is 1:1 the yield of **2a** is only slightly less than if two equivalents are used. In understanding this transformation the origin of the 4-oxygen of the quinone is crucial, but uncertain. On the one hand the diazeniumdiolate **4** seems

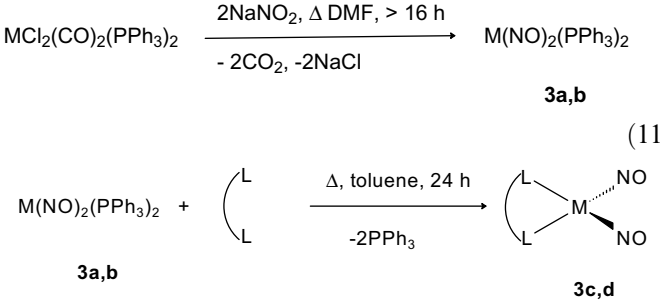
to require the methyloxy substituent as its alkyl substituted relatives do not react as rapidly with acids to release nitrous oxide as readily as **4**. This observation suggests that coordination of **4** might lead to its facile demethylation and that the oxygen is thus retained in the quinone. On the other hand, when the reaction in Eq. (9) is performed for $Pt(PPh_3)_2Cl_2$ with anhydrous solvents the yield drops from 72% to 11%. Thus a hydrolytic mechanism is implicated in Eq. (9). Curiously none of our numerous attempts to adapt this preparation to the related palladium complexes has returned isolable crystalline products or products with the key IR bands at circa 1260, 790 cm^{-1}. Regardless of the mechanistic details of these syntheses, the facile formation of new *cis*-hyponitrite complexes, and the first examples of their nickel complexes, allows for the systematic examination of their chemistry [24].

2 **5**

(10)

These group 10 square planar divalent hyponitrite complexes are sensitive to heat, light, acids, and oxidation. Their thermal decomposition has been monitored by differential scanning calorimetry and they typically decompose exothermally at $T > 85$ °C. To date the only well characterized products of these reactions are the oxide of the phosphine, nitrous oxide, and in the case of the platinum complexes, the colloidal metal. Phosphine oxide is also produced when the decomposition is done with strict exclusion of oxygen. This suggests that decomposition follows the stoichiometry in Eq. (10) where colloidal platinum metal results from the reductive formation of the phosphine oxide, after loss of nitrous oxide. The observed kinetics of nitrous oxide release and complex decomposition are both first order with the same rate constant, within experimental error [24]. The trapping of the oxo intermediate with carbon disulfide and carbon dioxide support its intermediacy [24], and we note that a stable terminal platinum oxide in a Pt(IV) complex has recently been reported [30]. What remains absent in all of the decomposition products of **2** are complexes with nitrosyl ligands as demonstrated by the absence of nitrosyl peaks in their IR spectra. There is no evidence that nitric oxide coupling is reversible in this system, nor is there evidence for stable nitrous oxide complexes in the products.

Based on the yield of $Pt(PPh_3)_2I_2$ and the observed formation of triphenylphosphine oxide, the stoichiometric equation was proposed to involve two moles of **2a** and one mole of iodine:



$$2Pt(PPh_3)_2(O_2N_2) + I_2 \rightarrow Pt(PPh_3)_2I_2 + 2N_2O + 2OPPh_3 + Pt(0)$$

When the reaction between **2a** and iodine was monitored by ^{31}P NMR with the proposed stoichiometry, the amount of triphenylphosphine oxide formed was integrated against a triphenylphosphine sulfide standard, and the integrated ratio was identical to the calculated mole ratio.

The oxidative addition reactions of $Pt(PPh_3)_2(N_2O_2)$ with methyl iodide, methyl triflate, iodine, and hydrochloric acid have been examined to determine if it is possible to isolate a Pt(IV) complex with a hyponitrite ligand. With iodine as a solution in methylene chloride there is a rapid reaction which ensues at −78 °C and goes to completion as the reaction is warmed over an hour to give a bright yellow precipitate of *trans*-$Pt(PPh_3)_2I_2$. This same product forms only slowly and in low yield when **2a** is treated with iodomethane under these conditions. In the later case even after 48 h most of the **2a** has not reacted and is recovered from the reaction. In the latter case a peak for *trans*-$Pt(PPh_3)_2(CH_3)I$ is not seen in the ^{31}P NMR spectrum [31]. With methyltriflate a white precipitate of $[Pt(PPh_3)_2(\mu\text{-}OH)]_2[OSO_2CF_3]_2$ forms in 71% yield in the course of the warming the reaction mixture from −78 °C to room temperature.

2.2. Dinitrosyls

Although the dinitrosyls of group 8 metals were some of the first prepared, *cf.* Roussin's red and black salts of iron [32], the isolation of a ruthenium dinitrosyl complex, $[RuCl(NO)_2(PPh_3)_2]BF_4$, with both a bent and linear nitrosyl ligands remains an excellent example of the amphoteric nature of the nitrosyl ligand [6,33]. Perhaps equally remarkable is the reduced neutral analog, $Ru(NO)_2(PPh_3)_2$ which has two linear nitrosyls and remains one of the few isolable tetrahedral low valent ruthenium derivatives [34]. In spite of their early and facile preparation, Eq. (11), which has since been optimized [35], the chemistry of these derivatives remains surprisingly limited to reports of its oxygenation [34], oxidative addition [36–39], catalytic CO/NO metathesis [40–42], and electrochemistry [43].

(11)

(12)

Although nitric oxide exchange is reported to be fast for **3a** [44], attempts to prepare pyridine, 2,2′-bipyridine, and 1,10-phenanthroline complexes by ligand exchange with the triphenylphosphine failed to generate new nitrogen

base analogs of **3a** [35]. The inability of nitrogen based donors, even chelating donors, to substitute for triphenylphosphine is not surprising given that many low oxidation state osmium complexes are known for phosphines but few for ammines. We hypothesized that a chelating phosphine could substitute for the two triphenylphosphine in **3a**,**b** and demonstrated this with the facile preparation of the bisdiphenylphosphinoferrocene complex of ruthenium **3c**, and the diphenylphosphinoethane complex of osmium **3d**, Eq. (12). Both of these substitution reactions have to be carried out in the strict exclusion of oxygen, but the products form in high yield and are readily isolated by recrystallization of the reaction mixtures. All of the dinitrosyl complexes **3** are a red-brown color which is due to a long tailing UV band which has considerable extinction in the visible. In the process of characterizing the UV–Vis activity of **3c,d** a slow oxygen independent photochemical decomposition process was discovered. Nevertheless, **3d** in particular is very reactive towards oxygen in solution or as a solid and rapidly decomposes within 20 min of exposure to oxygen. This is in contrast to the behavior of **3a,d** which decompose much more slowly and are readily purified by recrystallization in the open. As was found for **3b** the product of the reaction of oxygen and **3d** is a mononitrosyl with a coordinated nitrate [34]. There is no precedence in this system for nitrosyl coupling to give a stable or intermediary hyponitrite ligand analogous to **2**.

To understand the structure and reactivity of **3c,d** both complexes have been characterized by single crystal X-ray diffraction. ORTEP representations for both are depicted in Figs. 2 and 3, with representative bond lengths listed in the captions. As with $M(NO)_2(PPh_3)_2$ which have been characterized for M = Os [45] and Ru [46,47] both structures have a distorted tetrahedral geometry at the metal with the angle separating the two nitrosyl ligands being substantially larger, ca 139° as compared to the angle between the two phosphorus atoms which are 101.8° and 84.3° in **3c** and **3d**, respectively. Although the angle between the nitrosyl ligands is very similar to those found for the bistriphenylphosphine complexes, 139.2° and 139.1°, the chelating phosphines in **3c** and **3d** in these structure reduces the angle between the phosphorus atoms from 103.9° and 103.5° for **3a,b**, respectively to 84.3° in **3d**. This change in structure is also reflected in the nitrosyl stretching bands for **3c,d**, which are separated by slightly greater energies than in **3a,b**. It is difficult to attribute the increased reactivity of **3d** with dioxygen to any one particular structural change found by crystallography. In general alkyl phosphines are better donor ligands than their corresponding aryl phosphine analogs. Therefore the increased sensitivity of **3d** to dioxygen may be simply due to increased electron density on the metal from the better donor phosphine.

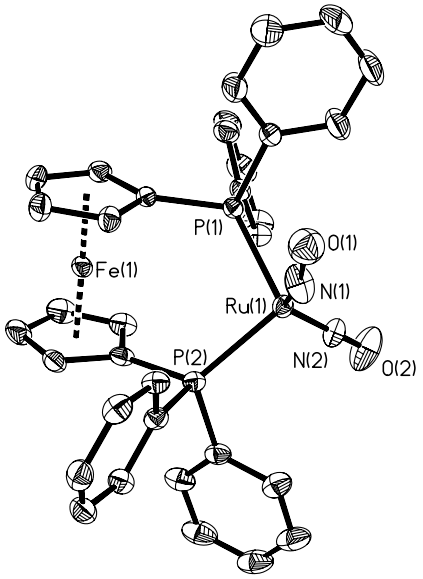


Fig. 2. ORTEP representation of **3c** at 30% probability level and hydrogens omitted. Key metric parameters: Ru(1)–P(1) = 2.3478(14), Ru(1)–P(2) = 2.3667(13), Ru(1)–N(1) = 1.762(5), Ru(1)–N(2) = 1.781(4) Å; N(1)–Ru(1)–N(2) = 132.1(2), P(1)–Ru(1)–P(2) = 101.80(5), P(1)–Ru(1)–N(1) 97.2(2), P(1)–Ru(1)–N(2) 108.98(16), P(2)–Ru(1)–N(1) = 111.50(18), and P(2)–Ru(1)–N(2) = 101.729(16)°.

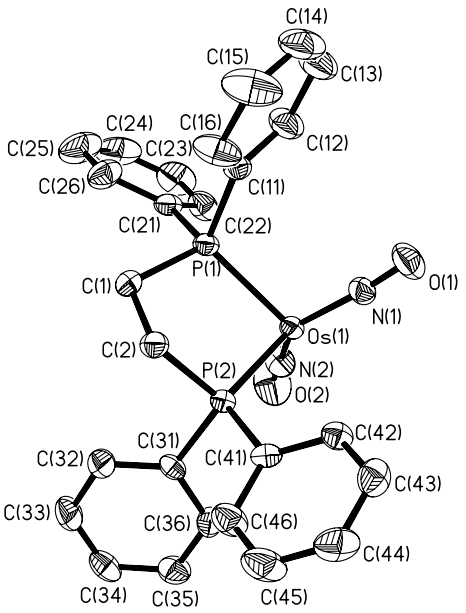

Fig. 3. ORTEP representation of **3d** at 30% probability level and hydrogens omitted. Key metric parameters: Os(1)–P(1) = 2.3143(15), Os(1)–P(2) = 2.3210(14), Os(1)–N(1) = 1.782(5), Os(1)–N(2) = 1.783(4) Å; N(1)–Os(1)–N(2) = 138.7(2), P(1)–Os(1)–P(2) = 84.30(5), P(1)–Os(1)–N(1) 98.80(16), P(1)–Os(1)–N(2) 109.98(19), P(2)–Os(1)–N(1) = 107.42(17), and P(2)–Os(1)–N(2) = 104.42(17)°.

3. Conclusions

While the amphoteric coordination character of nitric oxide, with its concomitant ability to bind in bent and linear geometries, is well known, another potential manifestation of its redox balance with transition metals is its ability to couple to give a hyponitrite complex such as the five examples described in this paper. But does the coordinative

reductive coupling of nitric oxide represent a real reactivity pattern or mechanism? Among the ways to answer this question would be with examples of the formation of a nitrosyl complex from hyponitrite, or alternatively, the formation of hyponitrite complex from a dinitrosyl complex. At this time there are no unambiguous examples of either reaction: the predominant reaction of hyponitrite complexes is elimination of nitrous oxide, and polynitrosyl complexes are not necessarily precursors to hyponitrites. An important origin for this mechanistic uncertainty is nitric oxide's ability to dimerize and thus, as with many of nitric oxides reactions, one of the key questions remains does nitric oxide react as the monomer or dimer? Moreover, is the absence of stable homoleptic polynitrosyls in part due to their tendency to undergo reductive coupling as the first step in an oxidative decomposition pathway? Until we have clear evidence for the presence of these metal bound intermediates in these reactions, this hypothesis remains suggestive.

4. Experimental

4.1. General

The reagents and solvents used were reagent grade and used as supplied. Nitric oxide gas was obtained from Scott Specialty Gases and was purified by passing through a column packed with sodium hydroxide pellets. The nitrosylation apparatus and instrumental methods for these experiments are as described in prior publications [48,49]. Reagents were purchased from Aldrich and used as provided or purified as described in prior reports. Specific precursors were prepared by the literature methods including $PtCl_2(PR_3)_2$ [50,51], $Ni(dppe)Cl_2$ [52], $Pt(dppf)Cl_2$ [53], $Ni(dppf)Cl_2$ [52], $Ru(NO)_2(PPh_3)_2$ [54,34], and $Os(NO)_2(PPh_3)_2$ [34], $Ni(N_2O_2)(dppf)$ [24], sodium-(*Z*)-1-{4-(2,6-di-*tert*-butyl-4-methoxycyclohexadienonyl)}diazen-1-ium-1,2-diolate [49], **4**, and sodium-(*Z*)-1-{4-(2,6-di-*tert*-butyl-4-methylcyclohexadienonyl)}diazen-1-ium-1,2-diolate (**6**) [49].

4.2. Preparation of complexes

4.2.1. $Pt(PPh_3)_2(N_2O_2)$ (**2a**)

$Pt(PPh_3)_2Cl_2$ (0.221 g, 0.280 mmol) is dissolved in 20 mL of acetonitrile/methylene chloride (1:1) and sodium-(*Z*)-1-{4-(2,6-di-*tert*-butyl-4-methoxycyclohexadienonyl)}diazen-1-ium-1,2-diolate (0.196 g, 0.616 mmol), **4**, dissolved in 25 mL of methanol, is added with constant stirring. The solution immediately turns yellow, and the mixture is allowed to stir for 5 min before all solvents are removed in vacuo. The resulting brownish solid material is taken up in 30 mL methylene chloride and allowed to stand for 10 min and filtered to remove any insoluble materials. Ethanol, 30 mL is then added, and solution volume concentrated to roughly half its volume and crystallization induced. Further concentration to 5 mL followed by filtration and successive washes with 5 mL each of ethanol, ether, and hexanes gives 0.158 g, 72.4% of **2a**. DSC: $T_{onset} = 86.9$ °C, $T_{max} = 103.8$ °C, $\Delta H = 68.1$ cal/g (53.1 kcal/mole). IR (KBr, cm^{-1}): 1263 m, 1001 sh, 900.7 m, 793.7 m, 502.4 s.

UV–Vis (CH_2Cl_2, λ_{max}, nm (ε, $M^{-1}\,cm^{-1}$)): 238 (28 674). ^1H NMR (CD_2Cl_2, 400 MHz) δ 7.20 (t, 12H), 7.32–7.40 (m, 18H); ^{13}C NMR (CD_2Cl_2, 400 MHz) δ 134, 131, 129, 128. ^{31}P NMR (CD_2Cl_2, 400 MHz) δ 11.0 ($^1J_{PtP} = 3564$ Hz). The literature method [11] for the preparation of **2a** involves treating $Pt(PPh_3)_4$ with NO in benzene followed by recrystallization. In addition to **2a** a variety of other products appear to be formed and in our hands the synthesis above gives a higher yield of pure *cis*-hyponitrite complex.

4.2.2. $Pt(PPh_2Me)_2(N_2O_2)$ (**2b**)

$Pt(PPh_2Me)_2Cl_2$ (0.3775 g, 0.566 mmol), and **4**, 0.441 g, 1.34 mmol of are treated as for **2a**, to give 0.254 g, 68.4% **2b** as yellow crystals. *Anal*. Calc. for $PtP_2C_{26}H_{26}N_2O_2$: C, 47.64; H, 4.00; N, 4.27. Found: C, 47.54; H, 4.10; N, 3.89%. DSC: $T_{onset} = 87.6$ °C, $T_{max} = 99.0$ °C, $\Delta H = 63.9$ cal/g (41.9 kcal/mole). IR (KBr, cm^{-1}): 1286.4 w, 980.7 w, 851.5 w, 785.9 m, 608.5 m. UV–Vis (CH_2Cl_2, λ_{max}, nm (ε, $M^{-1}\,cm^{-1}$)): 238, 268sh (27 856, 10 585) ^1H NMR (CD_2Cl_2, 400 MHz) δ 1.86 (d, 4H), 7.30 (t, 8H), 7.38–7.48 (m, 12H); ^{13}C NMR (CD_2Cl_2, 100 MHz) δ 133, 132, 129, 128, 15.2. ^{31}P NMR (CD_2Cl_2, 161.9 MHz) δ −11.6.

4.2.3. $Pt(dppf)(N_2O_2)$ (**2c**)

$Pt(dppf)Cl_2$ (0.103 g, 0.13 mmol), and 0.087 g, 0.27 mmol of **4** are treated as for **2a** to give 0.69 g,79% **2b** as yellow crystals. *Anal*. Calc. for $PtFeP_2C_{34}H_{38}N_2O_2$: C, 49.83; H, 4.67, N, 3.42. Found: C, 50.15; H, 3.87; N, 3.55%. DSC: $T_{onset} = 85.1$ °C, $T_{max} = 99.0$ °C, $\Delta H = -52.5$ cal/g, 43.1 kcal/mol. IR (KBr, cm^{-1}): 1330.5 m, 974 m, 890 s, 780.1 s, 611 s. UV–Vis (CH_2Cl_2, λ_{max}, nm (ε, $M^{-1}\,cm^{-1}$)): 238, 268sh (27 856, 10 585) ^1H NMR (CD_2Cl_2, 400 MHz) δ 7.71 (m, 4H), 7.50 (m 8H), 7.40 (m, 8H), 4.41 (m, 4H), 4.24(d, $J = 1.8$ Hz, 4 H); ^{13}C NMR (CD_2Cl_2, 100 MHz) δ 145.7, 134.8, 131.8, 128.8, 77.4 (d, $J = 21$ Hz), 76.4 (t, $J = 2$H), 74.2. ^{31}P NMR (CD_2Cl_2, 161.9 MHz) δ 4.7 ($^1J_{PtP} = 3625.5$ Hz).

4.2.4. $Ni(dppe)(N_2O_2)$ (**2d**)

$Ni(dppe)Cl_2$ (0.2581 g, 0.489 mmol) was dissolved in acetonitrile (120 mL) and a solution of sodium-(*Z*)-1-{4-(2,6-di-*tert*-butyl-4-methoxycyclohexadienonyl)}diazen-1-ium-1,2-diolate (0.3127 g, 0.982 mmol) in 50 mL of methanol was added under nitrogen with constant stirring. The solution immediately turns from reddish to yellow or orange color and stirred for about 15–20 min. The solvent was removed in vacuo. The crude yellow solid material was dissolved in methylene chloride and allowed to stand for 10 min, and the solution filtered to remove any insoluble material. The solvent was removed in vacuo. The crude product was successively washed with ether until the ether

washing is colorless. (Yield: 0.216 g, 77%), *Anal*. Calc. for $NiP_2C_{26}H_{24}N_2O_2$: C, 60.39; H, 4.68; N, 5.42. Found: C, 59.59; H, 4.73; N, 4.92%. DSC: $T_{onset} = 97.3$ °C, $T_{max} = 104.1$ °C, $\Delta H = 136.9$ cal/g (70.8 kcal/mole). IR (KBr, cm^{-1}): New hyponitrite bands are obscured by dppe bands. UV–Vis (CH_2Cl_2, λ_{max}, nm (ε, $M^{-1}\,cm^{-1}$)): 236, 268, 408 (29 513, 19 539, 1012). ^1H NMR (CD_2Cl_2, 400 MHz) δ 2.43 (d, 4H), 7.45–7.52 (m, 12H), 7.87–7.91 (m, 8H); ^{13}C NMR (CD_2Cl_2, 100 MHz) δ 133, 132, 130, 129, 25.9, ^{31}P NMR (CD_2Cl_2, 161.9 MHz) δ 46.4.

4.2.5. *Ru(dppf)(NO)$_2$ (**3c**)*

$Ru(NO)_2(PPh_3)_2$, **3a**, 81 mg, 0.012 mmol, and 1.2 equiv. of dppf, 74 mg, 0.014 mmol, were heated at reflux for 14 h in 20 mL toluene under an atmosphere of nitrogen. After cooling the mixture was brought out of the inert atmosphere box and the solvent removed in vacuo to give a crude red-orange product which was dissolved in 10 mL dichloromethane and recrystallized by the addition of 20 mL ethanol and concentration on a rotory evaporator to give 132 mg, of **3c** in 85% yield. Crystals suitable for X-ray diffraction were grown from dichloromethane/ethanol. *Anal*. Calc. for $C_{34}H_{28}FeN_2O_2P_2Ru$: C, 56.29; H, 5.28; N, 3.86. Found: C, 56.52; H, 3.87; N, 3.54%. IR (cm^{-1}), KBr pellet: ν(NO):1673.2s, 1629.8s, other characteristic bands: 3350 br, 1304.8w, 1264.3w,1164.9m, 836.1w, 819.7m. UV–Vis (CH_2Cl_2), λ_{max}, nm (ε, $M^{-1}\,cm^{-1}$): 422 (1330) ^1H NMR ($CDCl_3$, 400 MHz) δ 4.31 (t, $J = 1.7$, 4H), 4.24 (dd, $J = 1.7$, 1.9, 4H), 7.35–7.37 (m, 12H), 7.53–7.58 (m, 8H); ^{13}C NMR ($CDCl_3$, 100 MHz) δ 71.8(s), 75.1 (t, $J = 4.9$), 84.17 (d, $J = 51.4$), 128.4 (t, $J = 5.8$), 130.1 (s), 133.6 (t, $J = 6.7$), 136.4 (dd, $J = 46.3$, 4.5) ^{31}P NMR ($CDCl_3$, 161.9 MHz) δ 47.5.

4.2.6. *Os(dppe)(NO)$_2$ (**3d**)*

$Os(NO)_2(PPh_3)_2$, (**3b**) 65 mg, 0.0084. mmol, and 2.5 equiv. of bisdiphenylphosphinoethane, dppe, 83 mg, 0.0021 mmol, were heated at reflux for 30 h in 15 mL toluene under an atmosphere of nitrogen. After cooling the mixture was stripped of solvent and the residue crystallized twice in the inert atmosphere box from dichloromethane and ethanol to give 45 mg of **3d** as oxygen sensitive red-brown crystals in 82% yield. Crystals suitable for X-ray diffraction were grown from dichloromethane/ethanol. *Anal*. Calc. for $C_{26}H_{24}N_2O_2P_2Os$: C, 47.99; H, 3.72; N, 4.31. Found: C, 48.28; H, 3.97; N, 4.33%. IR (cm^{-1}), KBr pellet: ν(NO): 1656.8s, 1604.7s. UV–Vis (CH_2Cl_2), λ_{max} 288 nm. ^1H NMR (CD_2Cl_2, 400 MHz) δ 2.51 (d, 4H), 7.48–7.56 (m, 12H), 7.93–7.99 (m, 8H); ^{13}C NMR (CD_2Cl_2, 100 MHz) δ 134, 132, 130, 127, 28.1, ^{31}P NMR (CD_2Cl_2, 161.9 MHz) δ 31.4.

4.3. Reaction of hyponitrite complexes (*2*) with electrophiles

Reaction of HCl with Pt(PPh$_3$)(N$_2$O$_2$) to give cis-Pt(PPh$_3$)$_2$Cl$_2$: **2a** (0.05 g, 0.07 mmol) was dissolved in CH_2Cl_2 (2 mL). HCl (0.15 mmol) in CH_3OH (0.17 mL) was added; gas was observed and a light beige precipitate formed. The solid was collected and washed with hexanes. Yield: 25 mg (40%). The identity of *cis-Pt(PPh$_3$)$_2$Cl$_2$* was confirmed by the absence of the IR bands characteristic of **2a**, as well as a comparison with the literature ^{31}P NMR spectrum of *cis*-$Pt(PPh_3)_2Cl_2$ as prepared by Goel [55].

Compounds **2a**–**c** (0.05 g) were each suspended in ethanol and treated with dilute HCl solution. There was immediate effervescence with gas evolution. The solid residue was collected and characterized by NMR, IR and compared with respective authentic dichloride samples. In order to analyze the evolved gas upon addition of dilute HCl solution, about 0.02 g of compound (**2a**) was placed in an IR gas chamber and HCl gas was bubbled into the gas chamber. The analysis of the evolved gas by FT-IR confirms the presence of N_2O.

Reaction of iodine with Pt(PPh$_3$)$_2$(N$_2$O$_2$) to give trans-Pt(PPh$_3$)$_2$I$_2$: **2a** (0.1 g, 0.13 mmol) and triethylamine (0.05 mL) were dissolved in methylene chloride (10 mL), and degassed by freeze–thaw cycles. The amine is a preventative measure to ensure that the solution remains basic. The solution was cooled to −78 °C and iodine (0.07 g, 0.26 mmol) was added. The reaction was allowed to warm to room temperature over the span of 1 h. A bright yellow precipitate formed and was collected by filtration. Yield: 0.056 g (45%) which is spectroscopically identical by IR, and ^{31}P NMR to literature results for $Pt(PPh_3)_2I_2$ [56] this same product is the only isolable compound from the reaction of methyliodide or hydroiodic acid with **2a**. In the case of methyl iodide there is no evidence for a transitory product corresponding[31] to *trans*-$Pt(PPh_3)_2(CH_3)I$ as its peak at 28.1 ppm ($^1J_{Pt-P} = 3460$ Hz) was not seen by ^{31}P NMR of the monitored reaction mixtures which are dominated by peaks corresponding to the starting material and diiodide product.

4.4. The stoichiometry of the reaction between Pt(PPh$_3$)$_2$(N$_2$O$_2$) with iodine

The platinum complex **2a** (0.025 g, 0.032 mmol) was dissolved in CD_2Cl_2 (0.5 mL) in an NMR tube. Iodine (0.004 g, 0.016 mmol) was added and the mixture was sonicated for 3 h. Once all of the *cis*-hyponitrite had reacted, as confirmed by ^{31}P NMR, a solution of triphenylphosphine sulfide (0.018 g, 0.061 mmol) in CD_2Cl_2 (0.3 mL) was added to the NMR tube and the ^{31}P NMR was measured, with a delay time of 1 s. The integration between triphenylphosphine sulfide and triphenylphosphine oxide was measured and compared to the expected value. Expected ratio ($P(S)Ph_3$:$P(O)Ph_3$) 1.9:1. Measured ratio ($P(S)Ph_3$:$P(O)Ph_3$) 2.1:1.

Reaction of Pt(PPh$_3$)$_2$(N$_2$O$_2$) with CF$_3$SO$_3$CH$_3$: **2a** (0.1 g, 0.13 mmol) was dissolved in methylene chloride (5 mL), and degassed through freeze–thaw methods. The solution was cooled to −78 °C and $CF_3SO_3CH_3$ (0.02 mL, 0.2 mmol) was added. The reaction was allowed

to warm to room temperature in the absence of light over 12 h. The white precipitate which formed was collected filtration. Yield: 0.065 g (71%). The precipitate is insoluble in organic solvents, alcohols, water, acetonitrile, and DMSO. On the basis of IR the compound is determined to be $[Pt(PPh_3)_2(\mu\text{-}OH)]_2[OSO_2CF_3]_2$. IR (KBr, cm^{-1}): 3548 m (ν_{OH}), 1273vs (ν_{SO}), 1032vs (ν_{SO}). An authentic sample of the product was also synthesized for comparison by treating, $Pt(PPh_3)Cl_2$ (0.05 g, 0.06 mmol), in 20 mL chloroform/acetone (1:1) to which water (1 mL) and $AgOSO_2CF_3$ (0.02 g, 0.06 mmol) were then added. After 1 h the silver chloride precipitate was removed by filtration through diatomaceous earth and diethyl ether (10 mL) was added to the filtrate. On standing for 12 h, a white precipitate of $[Pt(PPh_3)_2(\mu\text{-}OH)]_2[OSO_2CF_3]_2$ was collected whose IR spectrum contained the same ν_{OH} band at 3550 cm^{-1}. This band is also present in $[Pt(PPh_3)_2(\mu\text{-}OH)]_2[BF_4]_2$, prepared by Phillips and coworkers [57].

5. X-ray crystallographic data

X-ray diffraction data for **2** · CH_2Cl_2, **3c**, and **3d** were collected on a Bruker P4 diffractometer equipped with a molybdenum tube and a graphite monochromator, Table 1 contains diffraction data for **2** · CH_2Cl_2, **3c**, and **3d**. Unit-cell dimensions were determined from several accurately centered reflections in high 2θ angles using XSCANS program. Three standard reflections measured after every 97 reflections exhibited no significant loss of intensity. The data were corrected for Lorentz-polarization effects and absorption. The structure was solved by direct methods and refined by least-squares techniques on F^2 using SHELXTL.

The *cis* hyponitrite complex **2** is a redetermination of a structure originally reported [12] as a benzene solvate from crystals obtained from benzene/dichloromethane which refined to $R = 10.8\%$. In this original structure the unit cell corresponds to the triclinic space group $P\bar{1}$, with $a = 12.199(6)$, $b = 10.747(6)$, $c = 15.730(8)$ Å, $\alpha = 108.75(4)$, $\beta = 95.57(4)$, and $\gamma = 69.98(4)°$ with $Z = 2$, and $V = 1834.6$ Å^3. In our redetermination crystals were obtained from dichloromethane/ethanol and crystallize in monoclinic space group $P2_1n$, with $a = 13.037(2)$, $b = 15.685(3)$, $c = 17.023(3)$ Å, $\alpha = \gamma = 90$, and $\beta = 98.020(10)°$ with $Z = 4$, and $V = 3446.9(10)$ Å^3. The monoclinic form has a dichloromethane solvate that is well defined and refined anisotropically in the last least squares cycles to give a final R_1 of 3.44%, and S_{gof} of 1.027, and a relatively flat electron density map with the largest difference peak being close to the metal center.

The dinitrosyl complexes **3c** and **3d** were crystallized from dichloromethane/ethanol as large deep orange blocks. The diffraction data collection, solution, and refinement all followed the outline above for **2a** with key data

Table 1
Crystallographic and structure refinement data for compounds **2**, **3c** and **3d**

Compound	**2**	**3c**	**3d**
Molecular formula	$C_{37}H_{32}Cl_2N_2O_2P_2Pt$	$C_{34}H_{30}FeN_2O_3P_2Ru$	$C_{26}H_{24}N_2O_2OsP_2$

throughout the experiments. Ruthenium trichloride ($RuCl_3 \cdot 3H_2O$/Johnson Matthey) was the starting reagent for the synthesis of ruthenium complexes. Ionic strength was adjusted with $NaCF_3COO$ ($\mu = 0.3$ mol L^{-1}).

2.2. Synthesis of the ruthenium compounds

The $[Ru(NH_3)_5Cl]Cl_2$ [16], *trans*-$[Ru(NH_3)_4(P(OEt)_3)_2]^{2+}$ [1], *trans*-$[Ru(NH_3)_4P(OEt)_3H_2O]^{2+}$ [1] and *trans*-$[Ru(NH_3)_4P(OEt)_3NO_2](PF_6)$ [17] compounds were prepared and characterized as described in the literature. All syntheses and measurements were performed under inert atmosphere (argon).

2.3. Instrumentation

The UV–Vis measurements were carried out in a 1 cm quartz cell on a Hitachi spectrophotometer U-3501. Infrared spectra measurements were performed in solution using a HATR (Horizontal Attenuated Total Reflectance) Trough Plate System, with 45° ZnSe Crystal in a FTIR Bomen MB-102 spectrometer; the ^{31}P NMR measurements were carried out in D_2O on a Bruker 4.7 T Model AC – 200 spectrophotometer, using hexafluorophosphate as internal standard.

2.4. Formation constant for trans-$[Ru(NH_3)_4P(OEt)_3(NO_2)]^+$

The formation constant for *trans*-$[Ru(NH_3)_4P(OEt)_3NO_2]^+$, K_N, was measured using the Indicator Colorimetric Method [18,19], which considers different values of molar absorptivities (ε) and maximum absorptions of the species involved. The equilibrium constant determination was based on reactions of Eqs. (1)–(3), using pyrazine as the auxiliary ligand.

$$t\text{-}[Ru(NH_3)_4P(OEt)_3H_2O]^{2+} + pz \rightleftharpoons t\text{-}[Ru(NH_3)_4P(OEt)_3pz]^{2+} + H_2O \quad K_{pz} \tag{1}$$

$$t\text{-}[Ru(NH_3)_4P(OEt)_3H_2O]^{2+} + NO_2^- \rightleftharpoons t\text{-}[Ru(NH_3)_4P(OEt)_3NO_2]^{+} + H_2O \quad K_N \tag{2}$$

$$t\text{-}[Ru(NH_3)_4P(OEt)_3pz]^{2+} + NO_2^- \rightleftharpoons t\text{-}[Ru(NH_3)_4P(OEt)_3NO_2]^{+} + pz \quad K_I \tag{3}$$

The spectrum of *trans*-$[Ru(NH_3)_4P(OEt)_3H_2O]^{2+}$ presents λ_{max} at 316 nm ($\varepsilon = 6.5 \times 10^2$ M^{-1} cm^{-1}) [20] and the *trans*-$[Ru(NH_3)_4P(OEt)_3NO_2]^+$ presents λ_{max} at 334 nm ($\varepsilon = 1.8 \times 10^3$ M^{-1} cm^{-1}) [17], at 380 nm ($\varepsilon = 8.0 \times 10^2$ M^{-1} cm^{-1}) and at 400 nm ($\varepsilon = 2.5 \times 10^2$ M^{-1} cm^{-1}). This method allows for the indirect determination of the product formed. Considering that the ligands, pyrazine and NO_2^- should compete for *trans*-$[Ru(NH_3)_4P(OEt)_3H_2O]^{2+}$, and that the equilibrium is rapidly established, is possible to combine the three equations to obtain:

$$K_I = \frac{K_N}{K_{pz}} = \frac{[RuNO_2] \cdot [pz]}{[Rupz] \cdot [NO_2^-]} \tag{4}$$

where $[RuNO_2] = [trans\text{-}[Ru(NH_3)_4P(OEt)_3(NO_2)]^+]$; $[Rupz] = [trans\text{-}[Ru(NH_3)_4P(OEt)_3(pz)]^{2+}]$; and $C_{Ru(II)} = C_{trans-[Ru(NH_3)4P(OEt)3(H2O)](PF6)2}$.

The initial analytical concentration of $C_{Ru(II)}$ was kept constant in all the experiments equal to 1.4×10^{-4} mol L^{-1}. Hence considering $C_{Ru(II)} \ll C_{NO_2^-}$, the nitrite concentration $[NO_2^-]$ should be $\cong C_{NO_2^-}$, and $C_{Ru(II)} \ll C_{pz}$, and thus $[pz] \cong C_{pz}$. The $[Rupz]^{2+}$ concentration was be measured spectrophotometrically ($\varepsilon = 3.8 \times 10^3$ M^{-1} cm^{-1} at 380 nm and 2.5×10^3 M^{-1} cm^{-1} at 400 nm).

The formation constant for the *trans*-$[Ru(NH_3)_4P(OEt)_3pz]^{2+}$ complex, K_{pz}, is 20 M^{-1} [1] while the electronic spectrum of this species did not show any changes for the range of hydrogenionic concentrations studied ($10.5 \leqslant pH \leqslant 11.5$). According to the observations, the values of the absorptivities for NO_2^- are $\varepsilon = 12$ M^{-1} cm^{-1} (380 nm) and < 1 M^{-1} cm^{-1} (400 nm) (see Fig. 1c).

2.5. Nitrite ligand aquation in trans-$[Ru(NH_3)_4P(OEt)_3(NO_2)]^+$

The specific rate constant for the release of nitrite ions in *trans*-$[Ru(NH_3)_4P(OEt)_3(NO_2)]^+$ was measured using pyrazine as auxiliary ligand (Eqs. 5 and 6). These measurements were carried out at pH 10.9; $\mu = 0.3$ mol L^{-1} $NaCF_3COO$ and $T = (25 \pm 0.2)$ °C. The solid *trans*-$[Ru(NH_3)_4P(OEt)_3(NO_2)](PF_6)$ was added into the solutions containing a large excess of pyrazine ($\geqslant 3600$), quickly stirred, and the absorbance changes were followed at 380 nm. The specific rate constant values were calculated through the plots

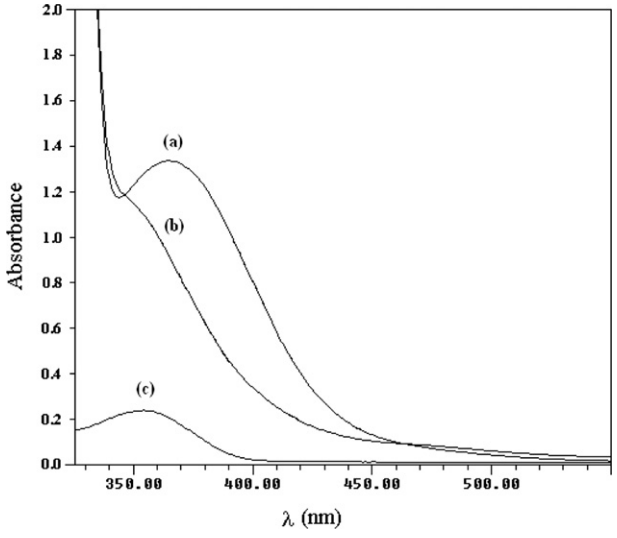

Fig. 1. Electronic spectrum of: (a) the product of reaction between *trans*-$[Ru(NH_3)_4P(OEt)_3(H_2O)](PF_6)_2$ and pyrazine; (b) after the addition of nitrite ions; (c) $NaNO_2$. $C_{Ru} = 4.0 \times 10^{-4}$ mol L^{-1}; $C_{pz} = 1.0$ mol L^{-1}; $C_{NO_2^-} = 0.010$ mol L^{-1}; $\mu = 0.3$ mol L^{-1} ($NaCF_3COO$); pH 11.0; $T = (25 \pm 0.2)$ °C.

of $\ln(A_\infty - A_t)$ versus time and corresponds to the average of five independents experiments.

$$t\text{-}[Ru(NH_3)_4P(OEt)_3NO_2]^+ + H_2O \overset{\text{slow}}{\rightleftharpoons} t\text{-}[Ru(NH_3)_4P(OEt)_3H_2O]^{2+} + NO_2^- \quad (5)$$

$$t\text{-}[Ru(NH_3)_4P(OEt)_3H_2O]^{2+} + pz \overset{\text{fast}}{\rightleftharpoons} t\text{-}[Ru(NH_3)_4P(OEt)_3pz]^{2+} + H_2O \quad (6)$$

2.6. Conversion of the nitro compound into the analogous nitrosyl

The conversion of the nitro, *trans*-$[Ru(NH_3)_4P(OEt)_3(NO_2)]^+$, compound into the corresponding nitrosyl was followed through UV–Vis, ^{31}P NMR and Infra Red spectroscopies.

2.6.1. Infrared measurements in aqueous solutions

Argon degassed solution (1.0×10^{-2} mol L^{-1}) of *trans*-$[Ru(NH_3)_4P(OEt)_3(NO_2)]^+$ at pH 8.0 was added into the HATR Trough Plate System with 45° ZnSe Crystal using syringes and the IR spectrum recorded. The solution pH was then adjusted, with previous degassed 6.0 mol L^{-1} trifluoroacetic acid, to pH 4.5 and new spectrum was recorded.

2.6.2. ^{31}P nuclear magnetic resonance

An alkaline solution (2.0×10^{-3} mol L^{-1}) of *trans*-$[Ru(NH_3)_4P(OEt)_3(NO_2)](PF_6)$ complex was anaerobically injected with a Hamilton gas tight syringe to a NMR tube containing deoxygenated aqueous buffered solution ($T = (25 \pm 0.2)$ °C, 0.2 mol L^{-1} K_2HPO_4, pH 10) to obtain a final concentration of 1.0×10^{-3} mol L^{-1}, and the NMR spectrum recorded. The solution pH was then adjusted to 2.0 with previous degassed 6.0 mol L^{-1} trifluoroacetic acid and another spectrum was obtained.

3. Results and discussion

As a consequence of the reaction between the aqua compound, *trans*-$[Ru(NH_3)_4P(OEt)_3H_2O](PF_6)_2$, and the pyrazine molecule, a band at λ_{max} at 366 nm ($\varepsilon = 4.2 \times 10^3$ M^{-1} cm^{-1}) (Fig. 1a) is developed. In the present study, when nitrite was added to this solution, a decrease in the absorbance was observed (Fig. 1b), due to the conversion of the pyrazine derivate into the nitro compound ($\lambda_{max} =$ 334 nm). This conversion was used to determine the formation constant for the nitro compound, *trans*-$[Ru(NH_3)_4P(OEt)_3NO_2](PF_6)$, as described in Section 2.

The spectra of the final solution obtained for the reaction between the aqua compound *trans*-$[Ru(NH_3)_4P(OEt)_3H_2O](PF_6)_2$ and nitrite ions, in alkaline solution, corresponds to spectra of the *trans*-$[Ru(NH_3)_4P(OEt)_3(NO_2)]^+$ in solution (λ_{max} at 334 nm; $\varepsilon = 1.8 \times 10^3$ mol L^{-1} cm^{-1}) [17].

The concentrations and equilibrium constant data for the nitro complex ion *trans*-$[Ru(NH_3)_4P(OEt)_3NO_2]^+$ formation are resumed in Table 1.

With the pK for reaction (Eq. (7)) having been estimated as 8.6 [3], most of the studies were performed at $C_{H^+} < 10^{-10}$ mol L^{-1} to ensure that the experimental conditions where those for which the nitro species is the predominant product.

$$trans\text{-}[Ru(NH_3)_4P(OEt)_3NO]^{3+} + 2OH^- \overset{k_{OH^-}}{\rightleftharpoons} trans\text{-}[Ru(NH_3)_4P(OEt)_3NO_2]^+ + H_2O \quad (7)$$

By using the experimental data of Table 1, it was possible to determine the formation constant, K_N, as $(5.2 \pm 0.6) \times 10^3$ M^{-1}.

The aquation of the NO_2^- ligand in *trans*-$[Ru(NH_3)_4P(OEt)_3NO_2]^+$ was investigated spectrophotometrically (see Section 2) and k_{-N} was calculate as being $(1.2 \pm 0.3) \times 10^{-1}$ s^{-1}, the latter value being the average of five independent determinations.

Ongoing preliminary studies using stopped-flow technique have shown that the reaction between the *trans*-$[Ru(NH_3)_4P(OEt)_3(H_2O)]^{2+}$ compound and NO_2^- in

Table 1
Concentrations and formation constant[a] for *trans*-$[Ru(NH_3)_4P(OEt)_3NO_2]^+$ for the reaction between *trans*-$[Ru(NH_3)_4P(OEt)_3H_2O]^{2+}$ and nitrite ions in the presence of pyrazine[b]

pH	$C_{RuNO_2} \times 10^4$ (mol L^{-1})	$C_{Rupz} \times 10^4$ (mol L^{-1})	$K_N \times 10^{-3}$ (M^{-1})
10.5	2.99	1.02	5.8 ± 0.8
11.0	2.77	1.09	5.1 ± 0.4
11.5	2.80	1.14	4.9 ± 0.6

[a] Calculated using the Eq. (4), each value corresponds to an average of six independent determinations.
[b] $C_{Ru} = 4.0 \times 10^{-4}$ mol L^{-1}; $C_{pz} = 1.0$ mol L^{-1}; $C_{NO_2} = 0.010$ mol L^{-1}; $\mu = 0.3$ mol L^{-1} ($NaCF_3COO$); $T = (25 \pm 0.2)$ °C.

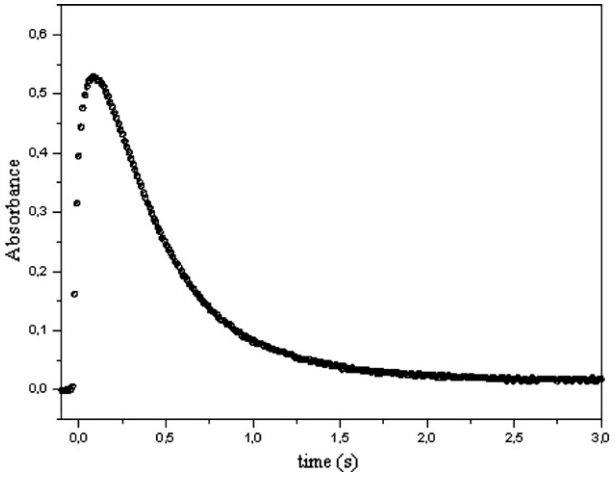

Fig. 2. Plot of absorbance against time for the reaction between *trans*-$[Ru(NH_3)_4P(OEt)_3H_2O]^{2+}$ and nitrite ions. $C_{Ru} = 4.0 \times 10^{-4}$ mol L^{-1}; $C_{NO_2^-} = 1.0 \times 10^{-2}$ mol L^{-1}; pH 10; $\mu = 0.3$ mol L^{-1} ($NaCF_3COO$); 25 °C; 330 nm.

alkaline media ($C_{H^+} < 10^{-10}$ mol L^{-1}) occurs through two distinct steps (Fig. 2), the first process being faster than the second one.

According to study on similar system [21], the first step should account for the formation of both the nitro and nitrito isomers, *trans*-$[Ru(NH_3)_4P(OEt)_3(NO_2)]^+$ and *trans*-$[Ru(NH_3)_4P(OEt)_3(ONO)]^+$, respectively (Eq. (8)).

$$\textit{trans}\text{-}[Ru(NH_3)_4P(OEt)_3H_2O]^{2+} \underset{}{\overset{k_O}{\rightleftharpoons}} \textit{trans}\text{-}[Ru(NH_3)_4P(OEt)_3ONO]^+$$
$$\textit{trans}\text{-}[Ru(NH_3)_4P(OEt)_3H_2O]^{2+} \underset{}{\overset{k_N}{\rightleftharpoons}} \textit{trans}\text{-}[Ru(NH_3)_4P(OEt)_3NO_2]^+ \quad (8)$$

According to preliminary data obtained from plots of k_{obs} versus $C_{NO_2^-}$, k_1 (the sum of $k_N + k_O$) is equal to $(1.25 \pm 0.1) \times 10^3$ M^{-1} s^{-1} (pH 11; $\mu = 0.3$ mol L^{-1}; 25 °C).

The second step should be a consequence of the isomerization of the nitrito into the more stable nitro species (Eq. (9)).

$$\textit{trans}\text{-}[Ru(NH_3)_4P(OEt)_3ONO]^+ \xrightarrow{k_i} \textit{trans}\text{-}[Ru(NH_3)_4P(OEt)_3NO_2]^+ \quad (9)$$

The X-ray structure [17], shown that the isolated product of the reaction between *trans*-$[Ru(NH_3)_4P(OEt)_3(H_2O)]^{2+}$ and NO_2^- in alkaline media, is the nitro isomer. The UV–Vis spectrum of the final product of the reaction between NO_2^- and *trans*-$[Ru(NH_3)_4P(OEt)_3(H_2O)]^{2+}$ is identical to one obtained from dissolving solid *trans*-$[Ru(NH_3)_4P(OEt)_3(NO_2)](PF_6)$ in aqueous solutions at the same experimental conditions. Therefore, it is likely to suppose that the nitro isomer is more stable than the nitrito one and thus the final product of the reaction.

According to the experimental data collected insofar, the rate of this isomerization, k_i, is equal to $(6.9 \pm 1.3) \times 10^2$ M^{-1} s^{-1} (pH 11; $\mu = 0.3$ mol L^{-1}; 25 °C). This system is now under investigation aiming to obtaining a complete understanding of the reactions involved.

From the observed UV–Vis spectrophotometric measurements at pH 10.0, it can be concluded that solutions containing *trans*-$[Ru(NH_3)_4P(OEt)_3(NO_2)]^+$ are stable in basic solutions. However, increasing hydrogenionic concentration leads to the nitro/nitrosyl conversion. At a pH of 4.0 for example, the nitro complex is shown to be quantitatively converted into the nitrosyl in a time scale of minutes ($k_{obs} = 2.2 \times 10^{-3}$ s^{-1}), as illustrated in Fig. 3. This conversion (Eq. (10)) was also observed through ^{31}P NMR and Infrared spectroscopies experiments.

$$\textit{trans}\text{-}[Ru(NH_3)_4P(OEt)_3NO_2]^+ + 2H^+ \rightarrow \textit{trans}\text{-}[Ru(NH_3)_4P(OEt)_3NO]^{3+} + H_2O \quad (10)$$

Conversion was also observed to occur at a pH of 5 (results not shown). However, at this pH, it found to be slower than that at pH 4, thus proving the importance of the hydrogenionic concentrations on this equilibrium.

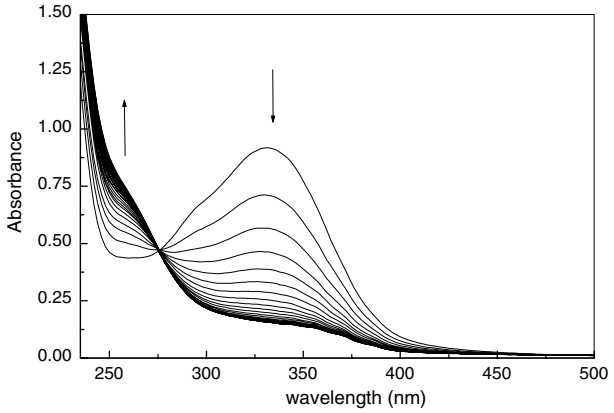

Fig. 3. Spectra changes associated with the quantitative conversion of *trans*-$[Ru(NH_3)_4P(OEt)_3(NO_2)]^+$/ into *trans*-$[Ru(NH_3)_4P(OEt)_3(NO)]^{3+}$. $C_{Ru} = 6.2 \times 10^{-4}$ mol L^{-1}; $\mu = 0.3$ ($NaCF_3COO$) mol L^{-1}; $T = (25 \pm 0.2)$ °C; total time = 1 h, time interval = 2 min; pH 4.

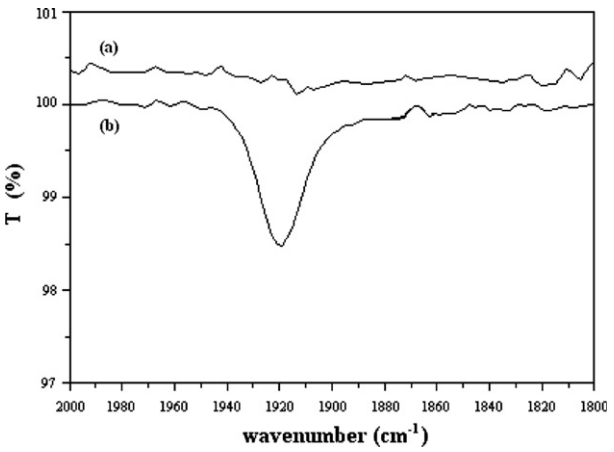

Fig. 4. Infrared spectra of *trans*-$[Ru(NH_3)_4P(OEt)_3NO_2](PF_6)$ in aqueous solution. $C_{Ru} = 2.0 \times 10^{-3}$ mol L^{-1}; pH 8.0 (a) and 4.5 (b); $\mu = 0.3$ ($NaCF_3COO$) mol L^{-1}; $T = (25 \pm 0.2)$ °C.

When the IR spectrum of the nitro compound was obtained at pH 8, no signal that can be attributed to the nitrosyl ligand was observed (Fig. 4). However, after the addition of acid into the solution, a band at 1918 cm^{-1} as observed to form, evidencing the formation of the nitrosyl complex formation since *trans*-$[Ru(NH_3)_4P(OEt)_3NO]^{3+}$ ν_{NO} is observed at 1918 cm^{-1} [3].

As described in the Experimental section, this conversion was also observed through ^{31}P NMR (see Fig. 5).

The ^{31}P NMR spectrum of *trans*-$[Ru(NH_3)_4P(OEt)_3NO_2]^+$ at pH 10 showed a peak at 149 ppm [17], corresponding to nitro species (Fig. 5). Upon solution acidification to pH 2, the signal at 149 ppm was found to completely disappear with a concomitant appearance of another signal at 80 ppm. This new signal strongly enforces the formation of *trans*-$[Ru(NH_3)_4P(OEt)_3NO]^{3+}$ which presents a ^{31}P signal in this area [3].

From the observed results, it can be confirmed that the above reported conversion of the nitro to nitrosyl compound (Eq. (10)) in acid medium is quantitative for the time and under the conditions studied.

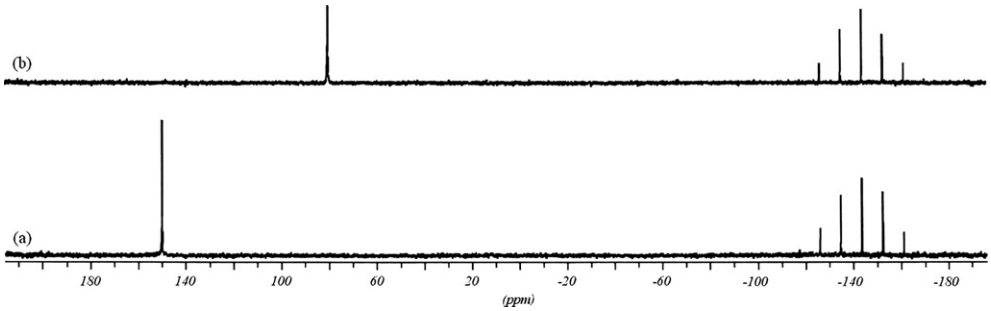

Fig. 5. ^{31}P NMR spectra for *trans*-$[Ru(NH_3)_4P(OEt)_3NO_2]^+$ for different hydrogenionic concentrations. $C_{Ru} = 2.0 \times 10^{-3}$ mol L^{-1}; solvent: deuterated water; (a) pH 10 and (b) pH 2.

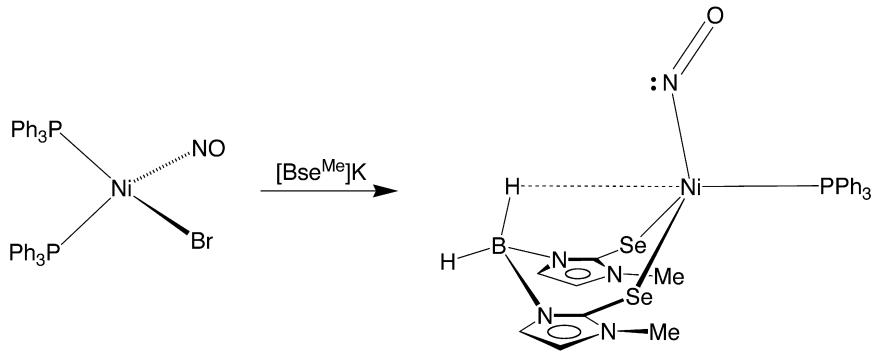
The inverse reaction, conversion of the nitrosyl into the nitro compound, has already been described for other compounds in alkaline medium [7,22–24]. Under the conditions studied, the nitrosyl ligand was said to undergo a nucleophilic attack by the hydroxide ion, thus forming the corresponding nitro complex. However, this conversion apparently is not so simple when the studied system involves the phosphite complex *trans*-$[Ru(NH_3)_4P(OEt)_3NO]^{3+}$. Results obtained by the authors strongly suggest that the nucleophilic attack occurs not only at the NO^+ ligand, as expected, but also at the phosphite ligand [25]. These data will be published later.



Some studies have also been carried out with the aim of verifying the vasodilator ability of *trans*-$[Ru(NH_3)_4P(OEt)_3NO_2](PF_6)$ in aorta rings without endothelium [26]. In these studies, the observed intensity and time of relaxation of maximum effect were found to be 68% in 114 min. The fact that the nitrosyl exhibits some instability at physiological hydrogenionic concentrations and since the nitro compound is quantitatively converted into the corresponding nitrosyl species at this pH, the use of nitro complexes could be an interesting source of *trans*-$[Ru(NH_3)_4P(OEt)_3(NO)](PF_6)_3$ *in situ*. Furthermore, since the nitro compound has a longer "shelf life" than *trans*-$[Ru(NH_3)_4P(OEt)_3(NO)](PF_6)_3$, storage in the form of the nitro complex instead of nitrosyl could be an interesting alternative. This system is presently under study and results will soon be published.

Scheme 1.

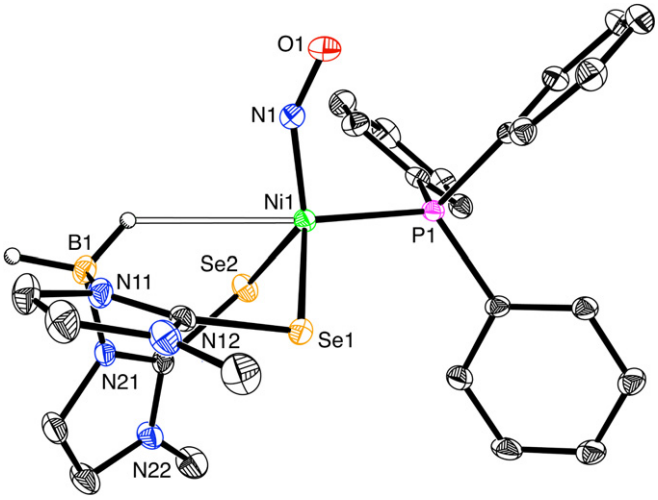

Fig. 1. Molecular structure of [Bse^{Me}]Ni(PPh$_3$)(NO) (only one of the two crystallographically independent molecules is shown).

Structural Database [6] have Ni–N–O bond angles in the range 151.8–179.2°, with a mean value of 169.5°.[2] Since (i) the [Se$_2$P] donor array provided by a [Bse^{Me}] and PPh$_3$ ligand combination is electronically analogous to the [Se$_3$] array of a [Tse^{Mes}] ligand and (ii) both [Bse^{Me}]-Ni(PPh$_3$)(NO) and [Tse^{Mes}]NiNO belong to the same {MNO}^{10} Enemark–Feltham classification [7], the observation of a bent nickel nitrosyl moiety for [Bse^{Me}]-Ni(PPh$_3$)(NO) and a linear nickel nitrosyl moiety for [Tse^{Mes}]NiNO warrants explanation.

Further inspection of the molecular structure of [Bse^{Me}]-Ni(PPh$_3$)(NO) indicates that the [Bse^{Me}] ligand does not coordinate in a simple bidentate κ^2–*Se*$_2$ manner; rather, the B–H group also interacts weakly with the nickel center. Specifically, the Ni···H distances for the two crystallographically independent molecules (2.70 Å and 2.77 Å) are intermediate between the sum of the van der Waals radii (3.2 Å) [8] and sum of the covalent radii (1.5 Å) [9] of nickel and hydrogen. Since both crystallographically independent molecules exhibit this interaction, it is evident that it cannot be simply ascribed to crystal packing forces. As such, the overall coordination geometry of [Bse^{Me}]-Ni(PPh$_3$)(NO) may be described as a distorted trigonal bipyramid, which is of note because there are no five (or six) coordinate nickel nitrosyl compounds listed in the Cambridge Structural Database [6].

In view of the presence of the Ni···H–B interaction, [κ^3–*Se*$_2$*H*–Bse^{Me}] may be viewed as a five-electron [L$_2$X] ligand rather than a three-electron [LX] ligand [1]. On this basis, a simple explanation to account for a bent nitrosyl moiety in [Bse^{Me}]Ni(PPh$_3$)(NO) is that coordination of the B–H group competes effectively with that of the nitrosyl ligand, which thereby bends to prevent the nickel center from adopting a 20-electron configuration. In order to evaluate this proposal in more detail, we have performed density functional theory (DFT) calculations to determine the extent to which the interaction with the B–H group is responsible for the bending of the nitrosyl ligand in [Bse^{Me}]Ni(PPh$_3$)(NO).

The geometry optimized structure of [Bse^{Me}]-Ni(PPh$_3$)(NO) is illustrated in Fig. 2 and reproduces the essential features of the experimental structure with respect to both the Ni–N–O angle (149.2°) and the Ni···H–B interaction (2.74 Å). To evaluate the extent to which the bending of the nitrosyl ligand is caused by the Ni···H–B interaction, additional geometry optimization calculations were performed on [Bse^{Me}]Ni(PPh$_3$)(NO) with constrained Ni–N–O bond angles of 120° and 180° (Fig. 2). As illustrated in Table 1, the Ni···H–B bond distance does correlate with the constrained Ni–N–O bond angle; however, the variation is not large. For example, if the Ni–N–O bond angle is constrained to 180°, the Ni···H–B bond distance increases to 2.89 Å, only 0.1 Å greater than the fully geometry optimized value of 2.79 Å. On this basis, while it is possible that the Ni···H–B interaction does have an effect on the Ni–N–O bond angle, the magnitude of the effect is small and an alternative explanation is required to rationalize the Ni–N–O bond angle.

In this regard, while the occurrence of bent and linear nitrosyl compounds is sometimes predicted by the application of simple electron counting procedures in which these ligands respectively contribute one and three elec-

[2] These values exclude SOQTOH, a metastable state of Cp*NiNO with a side-bound nitrosyl ligand, and CLTPNN01, a disordered structure of (Ph$_3$P)$_2$Ni(NO)Cl.

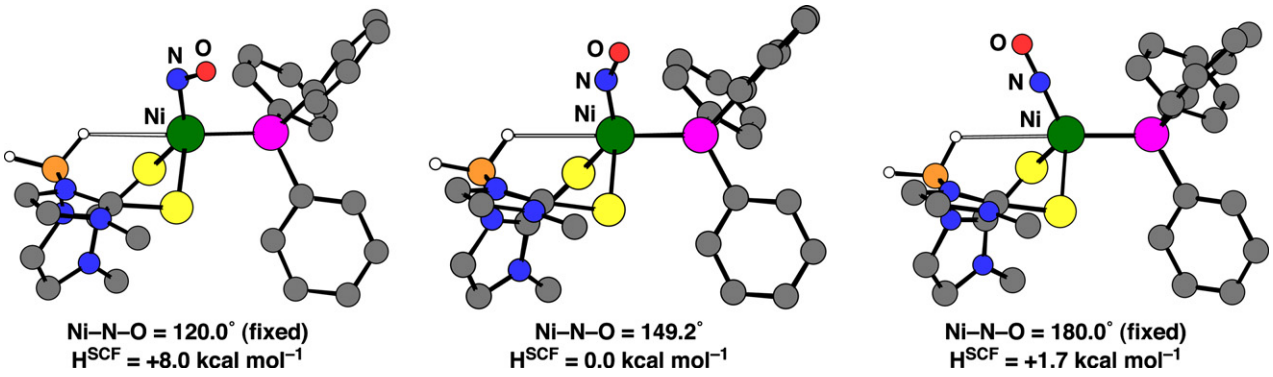

Fig. 2. DFT geometry optimized structures of $[Bse^{Me}]Ni(PPh_3)(NO)$ and their relative H^{SCF} values. The structure in the center is fully geometry optimized, while the left and right structures have been optimized subject to the constraints that the Ni–N–O angles are fixed at 120° and 180°, respectively.

Table 1
Selected data for DFT geometry optimized structures of $[Bse^{Me}]Ni(PPh_3)(NO)$

	"Boat-like"			"Chair-like"
Ni–N–O/°	120.0 (fixed)	149.2	180.0 (fixed)	154.4
Ni···H–B/Å	2.65	2.79	2.89	3.86
H^{SCF}(rel)/ kcal mol^{-1}	8.0	0.0	1.7	3.1

trons to a metal center [10], it is evident that this approach is of limited applicability because exceptions to the 18-electron rule are commonplace [11]. For example, $Ir(PPh_3)_2(NO)Cl_2$ [12] and $Mn(CO)_4(NO)$ [13] are two early examples of five-coordinate complexes that have strongly bent and linear nitrosyl groups, respectively. The latter has an 18-electron configuration, whereas the former has a 16-electron configuration, even though an 18-electron configuration could be achieved if the nitrosyl ligand were to be linear.

A more reliable approach for predicting the geometry of a metal nitrosyl ligand is based on a consideration of the molecular orbital diagrams for the molecule in question [14,15]. Such analyses indicate that, for metal centers with a high d^n configuration, bending provides a means to stabilize orbitals with M–N antibonding character. For example, several previous studies have pointed out that the driving force for bending the M–N–O group in certain complexes is to stabilize the M–N σ^* antibonding orbital [14,15]. Specifically, bending of the nitrosyl ligand reduces the σ-overlap between the sp nitrogen lone pair of the nitrosyl ligand and the metal d_{z^2} orbital (assuming that z is the bond axis) and thereby stabilizes the M–N σ^* antibonding orbital; furthermore, this orbital gains additional stabilization upon bending because one of the NO π^* orbitals is now of appropriate symmetry to interact with the d_{z^2} orbital (Fig. 3) [14,15]. If the $\langle \pi^*(NO), d_{z^2} \rangle$ orbital is occupied, bending provides a means to stabilize the molecule, so long as the higher energy counterpart orbital, $\langle d_{z^2}, \pi^*(NO) \rangle$, is unoccupied. Such bending, however, reduces the π-backbonding component and so the observed geometry reflects a compromise between the two effects which depends critically on the compound in question (*cf.* $Ir(PPh_3)_2(NO)Cl_2$ and $Mn(CO)_4(NO)$ with a common $\{MNO\}^8$ configuration).

To provide further evidence that the nature of the nitrosyl ligand of $[Bse^{Me}]Ni(PPh_3)(NO)$ is not determined by the Ni···H–B interaction, the molecular structure of $[Bse^{Me}]Ni(PPh_3)(NO)$ was geometry optimized with a "chair-like" conformation of the eight-membered $\{[Bse^{Me}]Ni\}$ ring, thereby preventing the B–H group from interacting with the nickel center (Fig. 4). Significantly, geometry optimized "chair-like" $[\kappa^2\text{–}Bse^{Me}]Ni(PPh_3)(NO)$, for which the Ni···H–B separation (3.86 Å) well exceeds the sum of the van der Waals radii of nickel and hydrogen (3.2 Å) [8], also possesses a bent nitrosyl ligand, with a Ni–N–O bond angle of 154.4°. As such, it provides excellent evidence that the Ni···H–B interaction has little effect on the coordination mode of the nitrosyl ligand. The Ni···H–B interaction may, nevertheless, exert an influence with respect to the stability of the molecule, with "chair-like" $[Bse^{Me}]Ni(PPh_3)(NO)$ being 3.1 kcal mol^{-1} higher in energy than the experimentally observed "boat-like" conformation with a Ni···H–B interaction.

Evidence that four-coordinate $[\kappa^2\text{–}Bse^{Me}]Ni(PPh_3)(NO)$, with a "chair-like" conformation that is devoid of Ni···H–B interaction, should also possess a bent nitrosyl ligand is provided by comparison with several other $[L_2X]NiNO$ complexes, such as $(Ph_3P)_2Ni(NO)X$ (X = Cl, N_3, NCS) [16]. However, as noted above, there are also a variety of $[L_2X]NiNO$ complexes that possess linear nitrosyl ligands and data for a selection of these complexes are summarized in Table 2. The feature which distinguishes these two classes of $[L_2X]NiNO$ compounds (which also possess the same $\{NiNO\}^{10}$ Enemark–Feltham description) is that $\{[L_2X]Ni\}$ moieties of the linear nitrosyl compounds are highly symmetric, *e.g.* $\{(R_3P)_3Ni\}$, $\{[Tp^{Me_2}]\}Ni$, $\{[Tse^{Mes}]Ni\}$ and $\{Cp^*Ni\}$, whereas those with bent nitrosyl ligands have lower symmetry. Mingos has pointed out that distortion from linearity is not favored

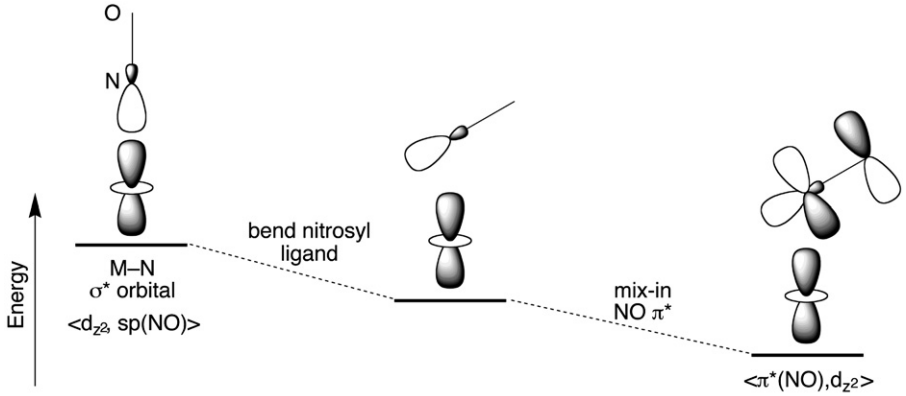

Fig. 3. Influence of bending the nitrosyl ligand on the energy of the M–N σ* orbital of a linear geometry. Bending of the nitrosyl ligand (i) reduces the σ-overlap between the sp nitrogen lone pair and the metal d_{z^2} orbital and (ii) allows one of the NO π* orbitals to interact with the d_{z^2} orbital. See Ref. [14].

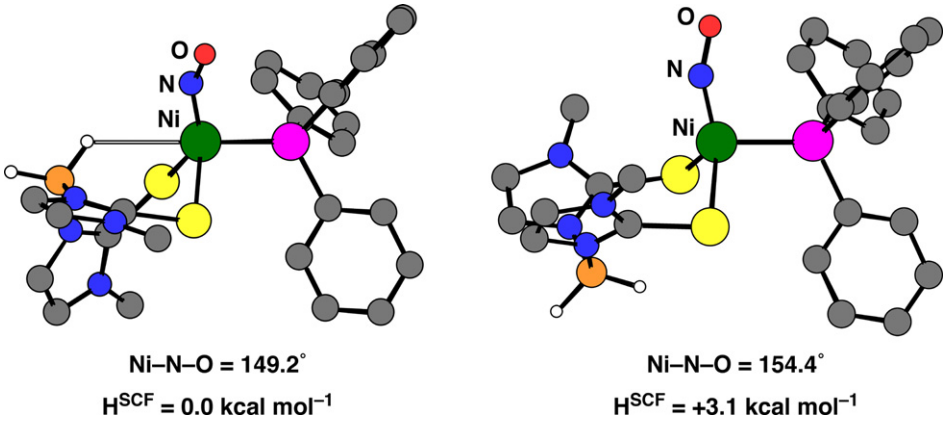

Fig. 4. Comparison of DFT geometry optimized structures of $[Bse^{Me}]Ni(PPh_3)(NO)$ with "boat-like" (left) and "chair-like" (right) conformations, and their relative H^{SCF} values.

[a] $X = NO_3$.
[b] $X = BPh_4$.

for C_{3v} geometries with $\{NiNO\}^{10}$ configurations because both $\langle \pi^*(NO), d_{z^2} \rangle$ and $\langle d_{z^2}, \pi^*(NO) \rangle$ orbitals are fully occupied, and the stabilization afforded one orbital upon bending is cancelled by the destabilization of the other [14b]. For nitrosyl complexes that are incapable of adopting C_{3v} symmetry, distortions from linearity afford an overall net

stabilization because the orbital that is destabilized upon bending is unoccupied.

Finally, it is noteworthy that the mononitrosyl complex [Bse^{Me}]Ni(PPh$_3$)(NO) is characterized by two frequencies in the ν(NO) region at 1731 cm^{-1} and 1692 cm^{-1}.[3] Possible explanations for this observation are (*i*) the signals correspond to the "boat" and "chair" conformations described above, and *(ii)* the signals correspond to isomers with linear and bent nitrosyl ligands. In this regard, it should be noted that a variety of other mononitrosyl compounds have been reported to exhibit two ν(NO) stretching frequencies which have been suggested to correspond to linear and bent isomers [17].

3. Experimental

3.1. General considerations

All manipulations were performed using a combination of glovebox, high vacuum, and Schlenk techniques under a nitrogen or argon atmosphere unless otherwise specified [18]. Solvents were purified and degassed by standard procedures. ^{1}H NMR spectra were measured on a Bruker 300 DRX spectrometer. ^{1}H chemical shifts are reported in ppm relative to SiMe$_4$ ($\delta = 0$) and were referenced internally with respect to the protio solvent impurity (δ 7.16 for C$_6$D$_5$H) [19]. ^{11}B NMR spectra are reported with reference to external BF$_3$(OEt$_2$) (δ 0.0). Coupling constants are given in hertz. Infrared spectra were recorded on Nicolet Avatar 370 DTGS spectrometer and are reported in cm^{-1}. Mass spectra were obtained on a JMS-HX110/110 Double Focusing mass spectrometer using fast atom bombardment (FAB). [Bse^{Me}]K was obtained by the literature method [5].

3.2. X-ray structure determination

X-ray diffraction data were collected on a Bruker P4 diffractometer equipped with a SMART CCD detector and crystal data, data collection and refinement parameters are summarized in Table 3. The structure was solved using direct methods and standard difference map techniques, and was refined by full-matrix least-squares procedures on F^2 with SHELXTL (Version 5.10) [20].

3.3. Computational details

All calculations were carried out using DFT as implemented in the Jaguar 6.5 suite of *ab initio* quantum chemistry programs [21]. Geometry optimizations were performed with the B3LYP density functional [22] and the 6-31G** (C, H, N, B, P, and O), LAV3P (Se) and LACVP (Ni) [23] basis sets.

[3] The borodeuterated analogue [d$_2$–Bse^{Me}]Ni(PPh$_3$)(NO) has very similar ν(NO) absorptions at 1731 cm^{-1} and 1689 cm^{-1}.

3.4. Synthesis of [Bse^{Me}]Ni(PPh$_3$)(NO)

A solution of [Bse^{Me}]K (10 mg, 0.027 mmol) in CH$_3$CN (0.5 mL) was added drop-wise to a solution of Ni(PPh$_3$)$_2$(NO)Br (19 mg, 0.027 mmol) in CH$_3$CN (0.5 mL) giving a dark blue solution. The solution was filtered and allowed to evaporate slowly, thereby depositing [Bse^{Me}]Ni(PPh$_3$)(NO) as a dark blue crystalline material, which was isolated by filtration, washed with pentane (1 mL), and dried *in vacuo* (11 mg, 60% yield). X-ray quality crystals were grown from CH$_3$CN. ^{1}H NMR (C$_6$D$_6$): 2.87 [s, 6H of –CH$_3$], 5.76 [br, 2H of imidazole], 6.64 [br, 2H of imidazole], 7.04–7.07 [m, 9H of phenyl], 7.57–7.63 [br, 6H of phenyl]. ^{11}B NMR (CDCl$_3$): −9.4 ppm. Anal. Calc. for $C_{26}H_{27}BN_5NiOPSe_2$: C, 45.7; H, 4.0; N, 10.2. Found: C, 45.8; H, 3.7; N, 10.3%. Mass spectrum: $m/z = 655.3$ {M–NO}$^+$. IR Data (KBr pellet, cm^{-1}): 3158 (w), 3134 (w), 3117 (w), 3064 (w), 3044 (w), 3003 (w), 2978 (w), 2933 (w), 2479 (m), 2394 (m), 2349 (m), 1731 (ν_{NO}, s), 1715 (m), 1692 (ν_{NO}, vs), 1652 (m), 1557 (m), 1539 (m), 1479 (m), 1455 (s), 1434 (s), 1408 (m), 1371 (s), 1325 (m), 1296 (m), 1181 (s), 1151 (s), 1132 (m), 1114 (s), 1094 (s), 1028 (m), 747 (m), 727 (m), 694 (s), 667 (m), 518 (s), 506 (m), 496 (m).

4. Conclusions

In summary, [Bse^{Me}]Ni(PPh$_3$)(NO) has been synthesized by the reaction of Ni(PPh$_3$)$_2$(NO)Br with [Bse^{Me}]K. X-ray diffraction studies demonstrate that the B–H group of the [Bse^{Me}] ligand interacts with the nickel center such that the Ni···H distances for the two crystallographically independent molecules are intermediate between the sum of the van der Waals radii and sum of the covalent radii of nickel and hydrogen. As such, [Bse^{Me}]Ni(PPh$_3$)(NO) is an

uncommon example of a nickel nitrosyl complex with a distorted trigonal bipyramidal geometry. The nickel nitrosyl moieties in both crystallographically independent molecules are significantly bent, with Ni–N–O bond angles of 149.1(3)° and 153.1(3)°, in marked contrast to the linearity observed for [Tse^{Mes}]NiNO (180.0°). A series of DFT geometry optimization calculations demonstrate that the Ni···H–B interaction is not responsible for causing the nitrosyl ligand to bend and that the difference between [Tse^{Mes}]NiNO and [Bse^{Me}]Ni(PPh$_3$)(NO) is due to the [Tse^{Mes}] ligand allowing the molecule to adopt a structure with C_3 symmetry. In contrast, the asymmetry of [Se$_2$P] donor array of the [Bse^{Me}] and PPh$_3$ ligand combination prevents [Bse^{Me}]Ni(PPh$_3$)(NO) from having C_3 symmetry and the nitrosyl ligand bends to stabilize the occupied M–N σ^* antibonding orbital.

Note added in proof

The related *bis*(2-mcrcapto-1-methylimidazolyl)hydroborate complex, [Bm^{Me}]Ni(PPh$_3$)(NO), has been synthesized and structurally characterized by X-ray diffraction. L. S. Maffett, K. L. Gunter, K. A. Kreisel, G. P. A. Yap and D. Rabinovich *Polyhedron* this issue.

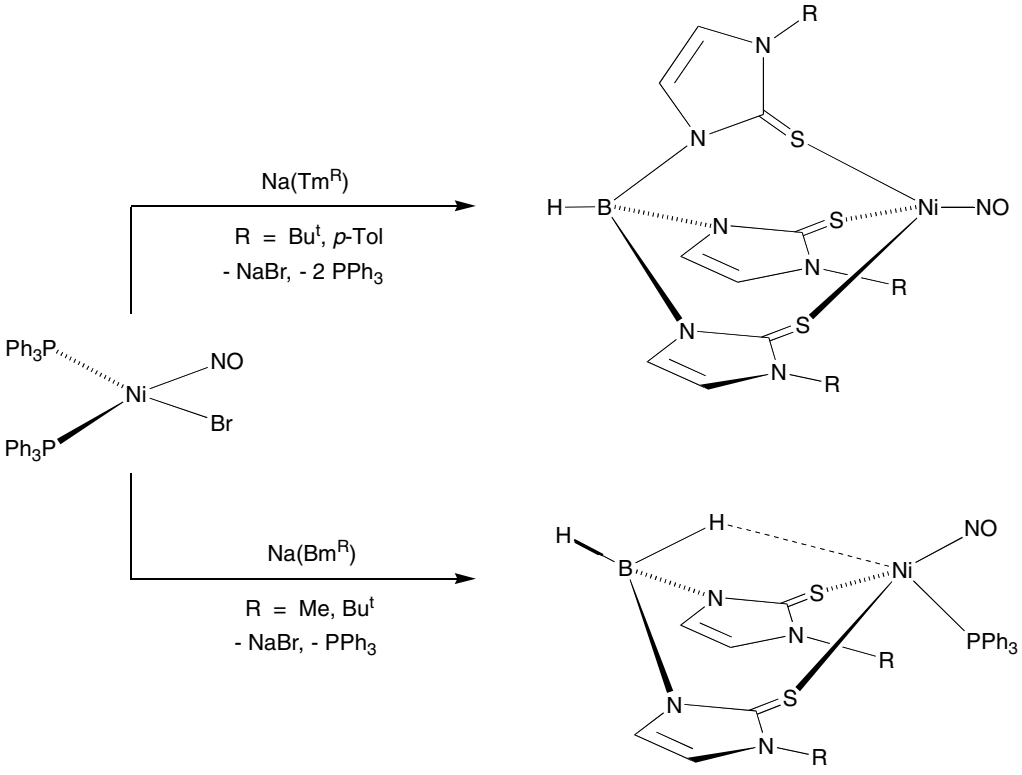
coworkers [27]. Nickel nitrosyl compounds containing sulfur-donor ligands, examples of which include tetrahedral xanthate derivatives $(Ph_3P)Ni(S_2COR)(NO)$ [28,29] and the heterodinuclear complexes $(Cp'V)_2(\mu\text{-}S)_4\{Ni(NO)\}_2$ [30] and $(ON)Ni\{(\mu\text{-}SCH_2CH_2)_2S\}Fe(NO)_2$ [31], are less common. A compound particularly relevant to our work is the tris(thioether)borate derivative $\{PhB(CH_2SBu^t)_3\}$-Ni(NO), reported almost a decade ago [32], which was until now the only mononuclear nickel nitrosyl complex supported by an $[S_3]$ donor set.



Seeking to further explore the synthesis of nickel nitrosyl complexes in a sulfur-rich environment, we turned our attention to the tris(mercaptoimidazolyl)borate (Tm^R) [33] and bis(mercaptoimidazolyl)borate (Bm^R) [34] ligand systems, which we have previously used to model certain structural elements of the nickel center in [NiFe] hydrogenases [35,36]. We describe in this paper the preparation and characterization of the first nickel nitrosyl complexes containing poly(mercaptoimidazolyl)borate ligands, namely $(Tm^R)Ni(NO)$ and $(Bm^R)Ni(PPh_3)(NO)$ [37,38]. These species, together with Parkin's recently reported tris(pyrazolyl)borate and tris(selenoimidazolyl)borate complexes $(Tp^{Me2})Ni(NO)$ and $(Tse^{Mes})Ni(NO)$ that feature $[N_3]$ and $[Se_3]$ donor groups [39], expand the pool of nickel mononitrosyl complexes now available for the comparative study of their molecular structures and spectroscopic properties.

2. Results and discussion

2.1. Syntheses of nickel nitrosyl complexes

The tris(mercaptoimidazolyl)borate complexes (Tm^R)-Ni(NO) (R = Bu^t, *p*-Tol) were readily prepared by reacting equimolar amounts of the purple triphenylphosphine complex $Ni(PPh_3)_2(NO)Br$ [10] and the corresponding $Na(Tm^R)$ reagents (Scheme 1), and the turquoise (R = Bu^t) or greenish blue (R = *p*-Tol) products were isolated in ca. 40–50% yield after the appropriate work-up. The bis(mercaptoimidazolyl)borate derivatives $(Bm^R)Ni$-$(PPh_3)(NO)$ (R = Me, Bu^t), which are the first transition metal nitrosyl complexes containing Bm^R ligands to be synthesized, were similarly obtained as slate green (R = Me) or indigo (R = Bu^t) microcrystalline solids in ca. 65–80% yield. All the new complexes are air-stable in the solid state and dissolve in a variety of organic solvents, including acetone, acetonitrile, benzene, dichloromethane, tetrahydrofuran (THF), and toluene, to give solutions that are markedly more sensitive to oxygen.

The four new complexes, all of which have a $\{Ni(NO)\}^{10}$ configuration in the Enemark–Feltham notation [40], were characterized by a combination of analytical and spectroscopic techniques, including elemental analyses (CHN) and IR and NMR spectroscopies. The observation of sharp resonances in their ^1H and ^{13}C NMR spectra and the

magnetic equivalency of the mercaptoimidazolyl groups in the NMR time scale are consistent with the presence in each case of diamagnetic, pseudo-tetrahedral metal complexes in solution. FT-IR spectroscopy was conveniently used to evaluate the electronic nature of the complexes *via* the ν(NO) stretching frequencies of the nitrosyl groups. More specifically, the ν(NO) frequencies of (Tm$^{p\text{-Tol}}$)Ni(NO) (1752 cm^{-1}) and (Tm$^{t\text{Bu}}$)Ni(NO) (1741 cm^{-1}) reflect a considerable degree of backbonding to the NO π^* orbitals and are among the lowest observed for nickel mononitrosyl complexes (Table 1). Thus, there is mounting evidence suggesting that the Tm^{R} ligands are more electron releasing than their hard nitrogen-donor counterparts, the ubiquitous tris(pyrazolyl)borates (Tp$^{RR'}$) [41–43], and that they are electronically comparable to other soft ligands such as the tris(phosphino)borates [27] and the tris(seleno-imidazolyl)borates [39].

The ν(NO) frequencies of the (Bm^{R})Ni(PPh$_3$)(NO) complexes (1688 and 1728 cm^{-1} for R = Me and Bu^t, respectively) are even lower than those found for the (Tm^{R})Ni(NO) derivatives described above. Even though the correlation between ν(NO) frequencies and the extent of bending in the M–N–O moieties of metal nitrosyl complexes is notoriously unreliable [4], this situation suggests that some deviation from linearity in the NiNO units of the (Bm^{R})Ni(PPh$_3$)(NO) compounds may be taking place nevertheless (vide infra). In this regard, a Ni–N–O angle of 152.7° was found in the nickel azide complex Ni(PPh$_3$)$_2$(NO)(N$_3$), which displays a ν(NO) frequency of 1710 cm^{-1} [44]. It is also worth noting that DFT calculations on the closely related bis(selenoimidazolyl)borate complex (Bse^{Me})Ni(PPh$_3$)(NO) suggest that the nitrosyl ligand bends in order to stabilize the occupied M–N σ^* antibonding orbital [45].

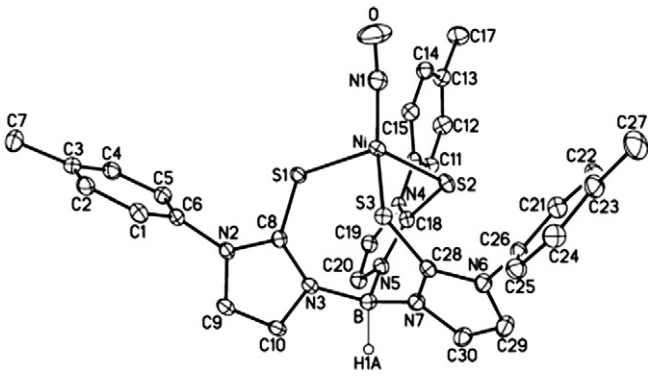

Fig. 1. Molecular structure of (Tm$^{p\text{-Tol}}$)Ni(NO).

2.2. Molecular structures of (Tm$^{p\text{-Tol}}$)Ni(NO) and (Bm^{Me})Ni(PPh$_3$)(NO)

The molecular structure of (Tm$^{p\text{-Tol}}$)Ni(NO) (Fig. 1) was determined using a single crystal obtained at room temperature by slow diffusion of pentane into a THF solution of the complex, and selected bond lengths and angles are given in Table 2. It is a rare example of a structurally characterized mononuclear nickel nitrosyl complex having a [NiS$_3$N] core, second only to Riordan's {PhB(CH$_2$SBu^t)$_3$}-Ni(NO) [32]. As expected, (Tm$^{p\text{-Tol}}$)Ni(NO) presents a slightly distorted tetrahedral geometry, with the three mercaptoimidazolyl groups of the Tm$^{p\text{-Tol}}$ ligand in a propeller-like arrangement around the metal center, canted relative to the pseudo-C_3 axis that contains the boron atom and the fairly linear NO moiety [Ni–N–O = 173.9(4)°]. The average S–Ni–S and S–Ni–N angles (101.5° and 116.6°, respectively) deviate only slightly from the ideal tetrahedral value.

The Ni–S bond distances in (Tm$^{p\text{-Tol}}$)Ni(NO), between 2.319 and 2.350 Å, are longer than those found in a variety of four-coordinate nickel complexes containing thioureas or heterocyclic thiones, which are in the approximate range 2.14–2.30 Å [9]. However, they are shorter than those in Ni(Tm^{Me})$_2$ [2.440(1)–2.483(1) Å] [46], a disparity likely to arise from the higher coordination number of the nickel center in the latter. Despite these differences, the Ni–N

and N–O bond lengths [1.665(3) and 1.131(4) Å, respectively] are within the corresponding ranges of values observed for such bonds in four-coordinate nickel nitrosyl complexes (1.58–1.69 and 1.12–1.19 Å, respectively) [9]. It is also worth noting that compelling structural and computational evidence implying that the M–N interactions in linear nitrosyl complexes have actually multiple bond character has recently been provided [39]. More specifically, a combination of X-ray crystallography and DFT calculations performed on $(Tp^{Me2})Ni(NO)$ and $(Tse^{Mes})Ni(NO)$ indicate that a multiply bonded resonance form such as $Ni{\equiv}N^{+}{-}O^{-}$ is a dominant contributor to the bonding scheme in this type of compounds, which exhibit quite short Ni–N bond distances [39].

The molecular structure of $(Bm^{Me})Ni(PPh_3)(NO)$ (Fig. 2) was also determined using a single crystal obtained at room temperature by slow diffusion of pentane into a THF solution of the complex, and selected bond lengths and angles are listed in Table 3. It is the first structurally characterized transition metal nitrosyl complex bearing a Bm^R ligand and only the second having a $[NiS_2PN]$ core, following the cyclopentylxanthate derivative $(PPh_3)Ni(S_2COC_5H_9)(NO)$ [29]. The geometry of the complex can be best described as trigonal pyramidal, with the two thione sulfurs of the Bm^{Me} ligand and a bent NO group [Ni–N–O = 149.6(2)°] that is tilted towards the phosphine making up the base of the pyramid. This spatial arrangement, unprecedented in nickel nitrosyl chemistry, is facilitated by the unique spatial disposition of the Bm^{Me} ligand, which forms an eight-membered ring in an "extended boat" conformation, and the presence of a weak intramolecular Ni···H–B interaction trans to the apical triphenylphosphine ligand. Although $(Bm^{Me})Ni(PPh_3)(NO)$ could be alternatively regarded as a five-coordinate complex displaying a trigonal bipyramidal geometry, we tend to favor the preceding description given the electronic saturation of the metal center (i.e., an 18-electron count) and the ensuing weakness of the Ni···H–B interaction. In this regard, the latter is characterized by a Ni···H separation [2.51(3) Å] that is considerably longer than those previously observed for such interactions, in the range 1.47–2.15 Å [35,36,47–56].

A number of metrical parameters suggest that the trigonal pyramidal structure of $(Bm^{Me})Ni(PPh_3)(NO)$ is slightly distorted towards a tetrahedral geometry. This include the observation of moderately obtuse P–Ni–X angles (average = 99.2°) and a sum of angles around the nickel center in the basal plane (352.4°) that is less than a full circle. In the same vein, the nickel atom is located ca. 0.5 Å above the plane defined by S(1), S(2) and N(1), and the calculated four-coordinate geometry index τ_4 recently introduced by Houser [57] (0.78) is somewhat lower than the value corresponding to a perfect trigonal pyramid (0.85). The Ni–S bond distances in $(Bm^{Me})Ni(PPh_3)(NO)$, 2.315(1) and 2.323(1) Å, are virtually identical to those in $(Tm^{p\text{-}Tol})$-Ni(NO) and the Ni–N and N–O bond lengths [1.689(2) and 1.170(3) Å, respectively] are marginally longer but still within the ranges mentioned above for such bonds in four-coordinate nickel nitrosyl complexes.

3. Conclusions

The first bis- and tris(mercaptoimidazolyl)borate nickel nitrosyl complexes have been readily prepared and fully characterized. The observation of fairly low ν(NO) stretching frequencies in their IR spectra provides evidence that the Bm^R and Tm^R ligands are strongly electron-donating tripodal $[S_3]$ ligands. Whereas $(Tm^{p\text{-}Tol})Ni(NO)$ displays the expected slightly distorted tetrahedral geometry and features a linear nitrosyl ligand, $(Bm^{Me})Ni(PPh_3)(NO)$ constitutes the first trigonal pyramidal nickel nitrosyl complex to be structurally characterized. The reactivity of these complexes towards thiols and thiolates, aimed at the generation of *S*-nitrosothiols [58,59], will be investigated in due course.

4. Experimental

4.1. General considerations

All reactions were performed under aerobic conditions unless otherwise noted, solvents were purified and degassed by standard procedures, and all commercially available reagents were used as received. Whereas $Na(Bm^R)$ ($R = Me$, Bu^t) [60] and $Na(Tm^R)$ ($R = Bu^t$, *p*-Tol) [61,62] were prepared as reported, the nickel nitrosyl complex $Ni(PPh_3)_2(NO)Br$ was synthesized by a combination of literature procedures [10,63], as described below. ^1H and ^{13}C NMR spectra were obtained on Varian Gemini (300 MHz) or JEOL ECA-500 (500 MHz) FT spectrometers. Chemical shifts are reported in ppm relative to $SiMe_4$ ($\delta = 0$ ppm) and were referenced internally with respect to the solvent resonances (^1H: δ 2.49 for DMSO-d_5, 7.15 for C_6D_5H, 7.24 for $CHCl_3$; ^{13}C: δ 39.5 for DMSO-d_6, 77.0 for $CDCl_3$, 128.0 for C_6D_6); coupling constants are given in hertz (Hz). IR spectra were recorded from KBr pellets on a Thermo Mattson Satellite 3000 FT-IR spectrophotometer and are reported in cm^{-1}; relative intensities of the absorptions are indicated in parentheses (vs = very strong, s = strong, m = medium, w = weak). Elemental analyses were determined by Atlantic Microlab, Inc. (Norcross, GA).

4.2. Synthesis of $Ni(PPh_3)_2(NO)Br$

Tetrahydrofuran (20 mL) was added to a 100-mL round-bottom flask containing $Ni(PPh_3)_2Br_2$ (1.00 g, 1.346 mmol), triphenylphosphine (0.36 g, 1.373 mmol), and $NaNO_2$ (1.60 g, 23.188 mmol), and the resulting purple suspension was stirred and refluxed under argon for 35 min. The suspension was allowed to cool to room temperature, filtered, and the solvent was removed under reduced pressure from the filtrate to give a purple solid, which was washed with methanol (15 mL) and dried *in vacuo* for 18 h (0.676 g, 73%). IR data: 1733 (vs) [ν_{NO}].

4.3. Synthesis of $(Bm^{Me})Ni(PPh_3)(NO)$

Methanol (5 mL) was added to a 4-dram glass vial containing a mixture of $Ni(PPh_3)_2(NO)Br$ (1.092 g, 1.575 mmol) and $Na(Bm^{Me})$ (0.417 g, 1.591 mmol), resulting in the formation of a purple suspension and, within minutes, a slate green solid suspended in a grey-green solution. After stirring the suspension for 3 h, the product was isolated by filtration and dried *in vacuo* for 18 h (0.740 g, 80%). Mp = 147–149 °C (dec.). NMR data (in C_6D_6): ^1H δ 2.79 (s, 6H, CH_3), 4.60 (br s, 2H, BH_2), 5.63 (d, $^3J_{H-H} = 2.0$, 2H, imidazole *H*), 6.49 (d, $^3J_{H-H} = 2.0$, 2H, imidazole *H*), 7.03 (m, 9H, C_6H_5), 7.56 (m, 6H, C_6H_5); ^{13}C δ 34.3 (q, $^1J_{C-H} = 140$, 2C, CH_3), 118.7 (dd, $^1J_{C-H} = 195$, $^2J_{C-H} = 13$, 2C, imidazole *C*), 122.1 (d, $^1J_{C-H} = 194$, 2C, imidazole *C*), 128.7 (dd, $^1J_{C-H} = 163$, $^3J_{P-C} = 8$, 6C, C_m in C_6H_5), 129.4 (d, $^1J_{C-H} = 163$, 3C, C_p in C_6H_5), 134.4 (dd, $^1J_{C-H} = 160$, $^2J_{P-C} = 16$, 6C, C_o in C_6H_5), 160.4 (s, 2C, C=S), C_{ipso} not observed. IR data: 2918 (w), 2849 (w), 2475 (m), 2396 (m), 2359 (m), 1688 (vs) [ν_{NO}], 1558 (s), 1479 (w), 1456 (m), 1434 (m), 1413 (m), 1381 (s), 1186 (m), 1164 (w), 1123 (m), 1095 (m), 747 (w), 725 (m), 696 (s), 520 (m), 508 (w). *Anal.* Calc. for $C_{26}H_{27}BN_5NiOPS_2$: C, 52.9; H, 4.6; N, 11.9. Found: C, 53.3; H, 4.7; N, 10.9%.

4.4. Synthesis of $(Bm^{tBu})Ni(PPh_3)(NO)$

Under a nitrogen atmosphere, tetrahydrofuran (5 mL) was added to a 4-dram glass vial containing a mixture of $Ni(PPh_3)_2(NO)Br$ (0.202 g, 0.291 mmol) and $Na(Bm^{tBu})$ (0.100 g, 0.291 mmol), resulting in the formation of a purple suspension and, within minutes, a deep blue solution. After stirring for 3 h, the solution was concentrated to ca. 1 mL and addition of pentane (ca. 3 mL) lead to the separation of the product as a dark indigo solid, which was isolated by decantation and dried *in vacuo* for 16 h (0.125 g, 64%). Mp = 121–123 °C (dec.). NMR data (in $CDCl_3$): ^1H δ 1.64 [s, 18H, $C(CH_3)_3$], 6.59 (s, 2H, imidazole *H*), 6.71 (s, 2H, imidazole *H*), 6.90–7.40 (m, 15H, C_6H_5); ^{13}C δ 28.9 [q, $^1J_{C-H} = 126$, 6C, $C(CH_3)_3$], 58.9 [s, 2C, $C(CH_3)_3$], 117.1 (dd, $^1J_{C-H} = 194$, $^2J_{C-H} = 14$, 2C, imidazole *C*), 121.2 (d, $^1J_{C-H} = 193$, 2C, imidazole *C*), 128.7 (d, $^1J_{C-H} = 160$, 6C, C_m in PPh_3), 130.2 (d, $^1J_{C-H} = 154$, 3C, C_p in PPh_3), 132.4 (s, 3C, C_{ipso} in PPh_3), 134.3 (d, $^1J_{C-H} = 159$, 6C, C_o in PPh_3), 158.7 (s, 2C, C=S). IR data: 2974 (m), 2918 (m), 1728 (vs) [ν_{NO}], 1567 (m), 1480 (s), 1434 (s), 1366 (s), 1314 (m), 1237 (m), 1095 (s), 745 (s), 694 (vs), 521 (s). *Anal.* Calc. for $C_{32}H_{39}BN_5NiOPS_2$: C, 57.0; H, 5.8; N, 10.4. Found: C, 58.1; H, 5.9; N, 7.9%. Repeated attempts to obtain a better elemental analysis for this compound have not been successful.

4.5. Synthesis of $(Tm^{tBu})Ni(NO)$

In a Schlenk tube under an atmosphere of argon, a purple stirred suspension of $Ni(PPh_3)_2(NO)Br$ (0.399 g, 0.575 mmol) in methanol (15 mL) was treated dropwise with a solution of $Na(Tm^{tBu})$ (0.288 g, 0.575 mmol) in the same solvent (25 mL), resulting in the formation of a turquoise microcrystalline solid suspended in a blue solution. After stirring for 30 min, the suspension was concentrated under reduced pressure to ca. 5 mL and the product was isolated by filtration and dried *in vacuo* for 1 h (0.156 g, 48%). Mp = 78–79 °C (dec.). ^1H NMR data (in DMSO-d_6): δ 1.92 [s, 27H, $C(CH_3)_3$], 6.61 (s, 3H, imidazole *H*), 7.11 (s, 3H, imidazole *H*), B*H* not observed; ^{13}C NMR data (in $CDCl_3$): δ 29.1 [q, $^1J_{C-H} = 127$, 9C, $C(CH_3)_3$], 59.2 [s, 3C, $C(CH_3)_3$], 115.3 [dd, $^1J_{C-H} = 194$, $^2J_{C-H} = 12$, 3C, imidazole *C*], 122.3 [dd, $^1J_{C-H} = 194$, $^2J_{C-H} = 6$, 3C, imidazole *C*], 159.2 (s, 3C, C=S). IR data: 3206 (w), 3135 (w), 2965 (m), 2916 (w), 2387 (w), 2297 (w), 2233 (w), 1741 (vs) [ν_{NO}], 1565 (m), 1483 (w), 1418 (m), 1398 (m), 1361 (vs), 1302 (m), 1260 (w), 1228 (m), 1198 (s), 1176 (s), 1132 (w), 1071 (w), 1030 (w), 928 (w), 823 (w), 760

(m), 727 (m), 687 (m), 591 (w), 553 (w), 497 (w), 462 (w). *Anal.* Calc. for $C_{21}H_{34}BN_7NiOS_3$: C, 44.5; H, 6.1; N, 17.3. Found: C, 44.4; H, 6.2; N, 17.1%.

4.6. Synthesis of $(Tm^{p\text{-}Tol})Ni(NO)$

In a Schlenk tube under an atmosphere of argon, a purple stirred suspension of $(PPh_3)_2Ni(NO)Br$ (0.300 g, 0.433 mmol) in methanol (20 mL) was treated dropwise with a solution of $Na(Tm^{p\text{-}Tol})$ (0.261 g, 0.433 mmol) in the same solvent (20 mL), resulting in the formation of a greenish-blue microcrystalline solid suspended in a dark blue solution. After stirring for 30 min, the suspension was concentrated under reduced pressure to ca. 5 mL and the spectroscopically pure product was isolated by filtration and dried *in vacuo* for 1 h (0.115 g, 40%). Mp = 70–71 °C (dec.). NMR data (in DMSO-d_6): ^{1}H δ 2.39 (s, 9H, CH_3), 6.97 (s, 3H, imidazole *H*), 7.35 (s, 3H, imidazole *H*), 7.37 (d, $^3J_{H-H} = 8.1$, 6H, H_o or H_m), 7.57 (d, $^3J_{H-H} = 8.1$, 6H, H_o or H_m), B*H* not observed; ^{13}C δ 20.7 (q, $^1J_{C-H} = 125$, 3C, CH_3), 120.6 (d, $^1J_{C-H} = 199$, 3C, imidazole *C*), 124.4 (d, $^1J_{C-H} = 199$, 3C, imidazole *C*), 126.5 (d, $^1J_{C-H} = 162$, 6C, C_o or C_m), 129.4 (d, $^1J_{C-H} = 159$, 6C, C_o or C_m), 135.4 (s, 3C, C_{ipso} or C_p), 138.0 (s, 3C, C_{ipso} or C_p), 158.7 (s, 3C, C=S). IR data: 2919 (w), 2850 (w), 2413 (w), 2368 (w), 2343 (w), 1752 (vs) [ν_{NO}], 1513 (m), 1476 (w), 1428 (m), 1362 (s), 1271 (m), 1192 (s), 1093 (w), 1022 (w), 821 (m), 742 (m), 695 (m). *Anal.* Calc. for $C_{30}H_{28}BN_7NiOS_3$: C, 53.9; H, 4.2; N, 14.7. Found: C, 52.9; H, 4.4; N, 12.8%.

4.7. X-ray structure determinations

X-ray diffraction data were collected on a Bruker-AXS APEX CCD diffractometer using Mo Kα radiation ($\lambda = 0.71073$ Å). A summary of crystal data collection and refinement parameters for $(Bm^{Me})Ni(PPh_3)(NO)$ and $(Tm^{p\text{-}Tol})Ni(NO)$ is presented in Table 4. Crystals were selected and mounted on glass fibers or plastic loops with viscous oil and cooled to the data collection temperature. All data sets were treated with SADABS absorption corrections. Unit cell parameters were determined by sampling three different sections of the Ewald sphere. No symmetry higher than triclinic was observed in the diffraction data and structural solution in the centrosymmetric space group option, $P\bar{1}$, yielded chemically reasonable and computationally stable results of refinement for $(Bm^{Me})Ni(PPh_3)(NO)$. The systematic absences in the diffraction data were uniquely consistent for the reported space group $P2_1/c$ for $(Tm^{p\text{-}Tol})Ni(NO)$. All non-hydrogen atoms were refined with anisotropic displacement parameters. The hydrogen atoms on the boron atoms were located from the difference map and refined with isotropic parameters constrained as $0.20U_{eq}$ of the boron atom. All other hydrogen atoms were treated as idealized contributions. Structure factors are contained in the SHELXTL (version 6.12) program library [64].

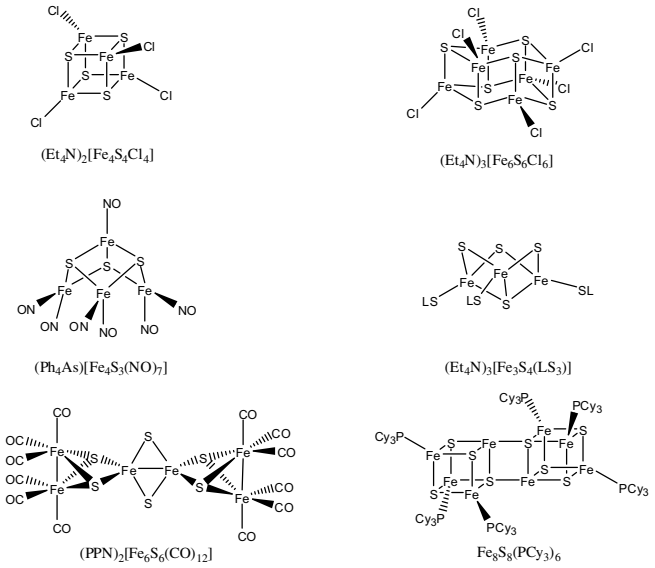
Table 4
Crystallographic data for $(Tm^{p\text{-}Tol})Ni(NO)$ and $(Bm^{Me})Ni(PPh_3)(NO)$

	$(Tm^{p\text{-}Tol})Ni(NO)$	$(Bm^{Me})Ni(PPh_3)(NO)$
Formula	$C_{30}H_{28}BN_7NiOS_3$	$C_{26}H_{27}BN_5NiOPS_2$
Formula weight	668.29	590.14
Crystal system	monoclinic	triclinic
Space group	$P2_1/c$ (no. 14)	$P\bar{1}$ (no. 2)
Temperature (K)	120(2)	120(2)
Unit cell dimensions		
a (Å)	19.196(9)	9.747(2)
b (Å)	10.047(5)	11.399(3)
c (Å)	17.976(8)	13.015(3)
α (°)	90	85.365(3)
β (°)	115.262(6)	89.817(3)
γ (°)	90	67.581(3)
V (Å^3)	3135(2)	1331.8(5)
Z	4	2
ρ_{calc} (g cm^{-3})	1.416	1.472
μ(Mo Kα) (mm^{-1})	0.855	0.976
θ_{max} (°)	28.20	28.05
Number of data	7171	5738
Number of parameters	394	342
R_1 ($I > 2\sigma(I)$)[a]	0.0502	0.0368
wR_2 ($I > 2\sigma(I)$)[a]	0.1233	0.0966

[a] $R_1 = \sum(|F_o| - |F_c|)/\sum|F_o|$; $wR_2 = \left\{\sum\left[w(F_o^2 - F_c^2)^2\right]/\sum[w(F_o^2)^2]\right\}^{1/2}$.

5. Supplementary material

CCDC 640731 and 640732 contain the supplementary crystallographic data (excluding structure factors) for $(Bm^{Me})Ni(PPh_3)(NO)$ and $(Tm^{p\text{-}Tol})Ni(NO)$. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.



Acknowledgements

We thank the Camille and Henry Dreyfus Foundation, Inc. for a Henry Dreyfus Teacher-Scholar Award to D.R., the donors of the Petroleum Research Fund, administered by the American Chemical Society, and The University of North Carolina at Charlotte for support of this research. We also thank Prof. Marcetta Darensbourg (Texas A&M University) for helpful discussions and Prof. Gerard Parkin (Columbia University) for insightful advice and a preprint of Ref. [45].

Scheme 1. Examples of different arrangements of Fe/S clusters.

2. Experimental

All Reactions have been performed under a dinitrogen atmosphere in a glove box and standard shlenck line techniques. All solvents have been distilled and degassed, except of DMF that was not distilled.

$(NH_4)[Fe_4S_3(NO)_7]$ [24], $(PPN)_2[Fe_4(CO)_{13}]$ [25], Benzyl trisulfide (Bz_2S_3) [26], $Mo(CO)_3(MeCN)_3$ [27], $[Ni(MeCN)_6](BF_4)_2$ [28] were synthesized according to published procedures. $[Cu(MeCN)_4]PF_6$, $Fe(CO)_5$, SCl_2 and Bu_4NSH were purchased from commercial sources.

IR spectra were obtained on a Perkin–Elmer BX FT-IR spectrometer (mid-IR) and a Nicolet 740 FT-IR spectrometer (Far-IR) in KBr pellets. Mass Spectra were collected on a Micromass LCT Time-of-Flight mass spectrometer. Elemental analyses were performed by the Microanalytical Laboratory at the University of Michigan. Microbeam Electron Analysis was performed at The University of Michigan Electron Microbeam Analysis Laboratory (EMAL). and Cyclic Voltammetry experiments were carried out on a Glass Carbon working electrode and Ag/AgCl reference electrode with 0.1 M Bu_4NPF_6 supporting electrolyte on a EG&G Princeton Potentiostat/Galvanostat model 263 A. The reduction potentials are reported against a standard calomel electrode SCE.

2.1. Bis(Bis(triphenylphospine)iminium) hexasulfido-octairon-octanitrosyl, $(PPN)_2[Fe_8S_6(NO)_8)]$

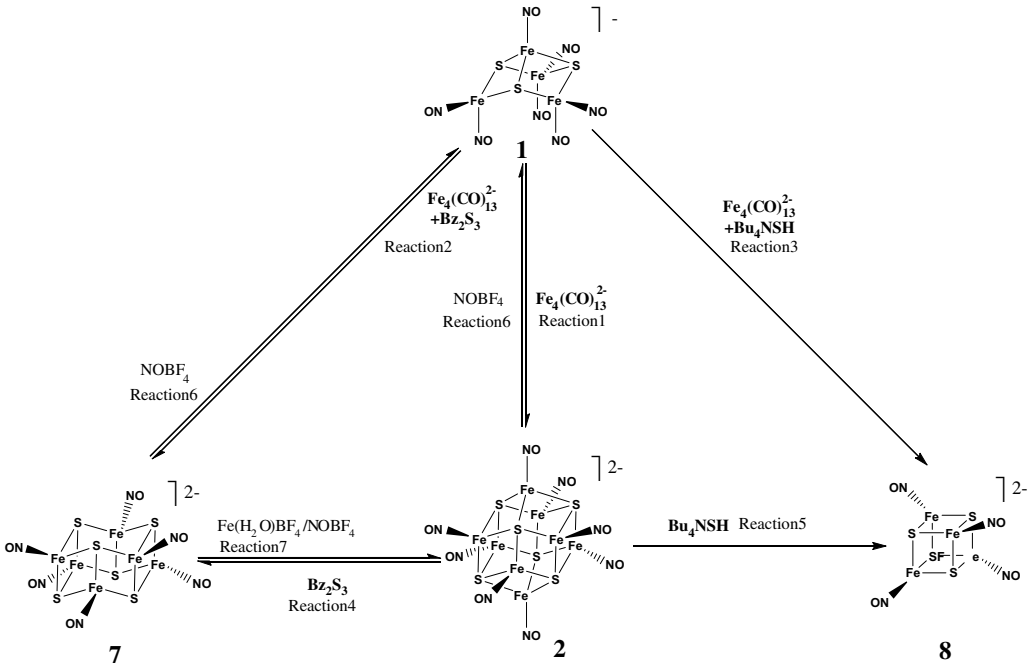
An amount of $(NH_4)[Fe_4S_3(NO)_7]$ (0.50 g, 0.87 mmol) and $(PPN)_2[Fe_4(CO)_{13}]$ (2.17 g 1.30 mmol) were dissolved in 20 ml MeCN and allowed to stir for 24 h. The precipitate obtained by filtration was washed with 5 ml MeCN, dissolved in 15 ml DMF and the resulting solution layered with ca. 150 ml ether, affording 0.80 g of a black crystalline product.

Yield 0.41 mmol 94% of $(PPN)_2[Fe_8S_6(NO)_8]$ yield based on $[Fe_4S_3(NO)_7]^-$ as the only source of Fe. Elemental *Anal.* Calc. for $(PPN)_2[Fe_8S_6(NO)_8]\cdot DMF$ $C_{75}H_{67}N_{11}O_9P_4S_6Fe_8$: C, 44.39; H, 3.33; N, 7.59. Found: C, 44.75, H, 3.48, N, 7.36%. IR: 3054(w), 2690(m), 2928(m), 2868(w), 1684(vs)(ν_{N-O}), 1427(m), 1263(m), 1113(m), 797(w), 744(w), 723(m), 690(m), 550(m), 532(m), 526(w), 495(w). MS: (ESI +) 537.8 (PPN^+). CV: (DMF solution, 0.017 M) $E_{1(rev)} = -482$ mV, $E_{2(rev)} = -616$ mV, $E_{3(rev)} = -1202$ mV, $E_{4(rev)} = -1295$ mV.

2.2. Bis(Bis(triphenylphospine)iminium) hexasulfido-hexairon-hexanitrosyl, $(PPN)_2[Fe_6S_6(NO)_6)]$

2.2.1. Method A (Scheme 2, Reaction 2)

An amount of $(PPN)[Fe_4S_3(NO)_7]$ (0.50 g, 0.47 mmol) and $(PPN)_2[Fe_4(CO)_{13}]$ (0.78 g, 0.47 mmol) were dissolved in 20 ml MeCN, and Bz_2S_3 (0.39 g, 1.40 mmol) was added. The resulting mixture was heated under reflux for 24 h. The precipitate formed was washed with 5 ml MeCN, dissolved in 15 ml DMF and layered with ca. 150 ml ether, affording 0.88 g of a black crystalline product. Yield 0.49 mmol, 79% of $(PPN)_2[Fe_6S_6(NO)_6]$, based on total Fe content.



2.2.2. Method B (Scheme 2, Reaction 4)

An amount of $(PPN)_2[Fe_8S_6(NO)_8]$ (0.23 g, 0.12 mmol) was dissolved in 10 ml DMF and Bz_2S_3 (0.1 g, 0.36 mmol) was added and the solution stirred for 24 h. The solution was filtered and layered with ca. 100 ml ether, affording 0.18 g of crystalline product. Yield 0.10 mmol, 84% of $(PPN)_2[Fe_6S_6(NO)_6]$. Elemental *Anal.* Calc. for $(PPN)_2[Fe_6S_6(NO)_6]$, $C_{72}H_{60}N_8O_6P_4S_6Fe_6$: C, 48.46; H, 3.39; N, 6.28. Found: C, 47.90; H, 3.65; N, 7.33%. IR: 2690(m), 2928(m), 2868(w), 1679(vs) (ν_{N-O}), 1669(vs) (ν_{N-O}), 1435(m), 1262(m), 1116(m), 803(w), 743(w), 723(m), 692(m), 687(m), 546(m), 531(m), 523(w), 498(w). MS: (ESI −) *m/z* 1245.31 $(PPN)Fe_6S_6(NO)_6^-$, 707.26 $Fe_6S_6(NO)_6^-$, 647.27 $Fe_6S_6(NO)_4^-$, 617.28 $Fe_6S_6(NO)_3^-$, 587.28 $Fe_6S_6(NO)_2^-$, 557.31 $Fe_6S_6(NO)^-$, 471.49 $Fe_4S_4(NO)_4^-$, 441.49 $Fe_4S_4(NO)_3^-$, 411.52 $Fe_4S_4(NO)_2^-$ and several smaller molecular weight fragments were observed below 400. MS: (ESI +): 537.78 (PPN^+). CV: (DMF solution, 0.019 M) $E_{1(rev)} = -690$ mV, $E_{2(rev)} = -1521$ mV.

2.3. Bis(Bis(triphenylphospine)iminium) tetrasulfido-tetrairon-tetranitrosyl, $(PPN)_2[Fe_4S_4(NO)_4]$

2.3.1. Method A (Scheme 2, Reaction 3)

An amount of $(PPN)[Fe_4S_3(NO)_7]$ (0.50 g, 0.47 mmol) and $(PPN)_2[Fe_4(CO)_{13}]$ (1.17 g, 0.70 mmol) were dissolved in 20 ml MeCN, followed by the addition of Bu_4NSH (0.13 g, 0.47 mmol) in 5 ml MeCN and the mixture was heated under reflux for 24 h. After cooling at room temper-

Scheme 2. Schematic representations of the transformations of Fe/S/NO clusters discussed in this article.

ature the mixture was filtered, and the precipitate was washed with MeCN and extracted with ca. 15 ml DMF and layered with ca. 100 ml ether, affording 0.35 g of microcrystalline product. Yield 0.23 mmol 48.9% of $(PPN)_2$-$Fe_4S_4(NO)_4$ based on $Fe_4S_3(NO)_7^-$. Elemental *Anal.* Calc. for $(PPN)_2[Fe_4S_4(NO)_4]$ $C_{72}H_{60}N_6O_4P_4S_4Fe_4$: C, 55.39; H, 3.90; N, 5.43. Found: C, 51.49; H, 3.49; N, 5.96%.

2.3.2. Method B (Scheme 2, Reaction 5)

An amount of $(PPN)_2[Fe_8S_6(NO)_8]$ (0.20 g, 0.10 mmol) and Bu_4NSH (0.17 g, 0.62 mmol) were dissolved in 10 ml DMF and heated at 80 °C for 24 h. The resulting mixture was cooled at room temperature, filtered, and the solution was layered with ca. 100 ml ether, affording 0.22 g of microcrystalline product. Yield 0.14 mmol, 68.75% of $(PPN)_2Fe_4S_4(NO)_4$. Elemental *Anal.* Calc. for $(PPN)_2$-$[Fe_4S_4(NO)_4]$ $C_{72}H_{60}N_6O_4P_4S_4Fe_4$: C, 55.39; H, 3.90; N, 5.43. Found: C, 52.04; H, 4.10; N, 5.88%. IR:, 2960(m), 2928(m), 2868(w), 1652(vs) (ν_{N-O}), 1435(m), 1262(m), 1116(m), 803(w), 743(w), 723(m), 692(m), 687(m), 546(m), 531(m), 523(w), 498(w). MS: (ESI −) *m/z* 471.5 Fe_4S_4-$(NO)_4^-$, 441.5 $Fe_4S_4(NO)_3^-$, 411.5 $Fe_4S_4(NO)_2^-$ and several smaller molecular weight fragments were observed below 400. MS: (ESI +): 537.7 (PPN^+). CV: (DMF solution, 0.022 M) $E_{1(rev)} = -202$ mV, $E_{2(rev)} = -1279$ mV.

2.4. Bis(Bis(triphenylphospine)iminium) tetrasulfido-tetrairon-hexanitrosyl, $(PPN)_2[Fe_4S_4(NO)_6]$

An amount of $(NH_4)[Fe_4S_3(NO)_7]$ (0.20 g, 0.35 mmol) and $(PPN)_2[Fe_4(CO)_{13}]$ (0.87 g 0.52 mmol) were dissolved in 15 ml MeCN, the mixture was cooled at −20 °C and a solution of Bu_4NSH (0.05 g, 0.19 mmol) in 2 ml MeCN was added. The mixture was stirred for 8 h at −20 °C, filtered, and the precipitate was washed with MeCN and extracted with ca. 5 ml DMF and layered with ca. 50 ml ether, left for 2 days in the freezer, filtered again to remove any $(PPN)_2[Fe_4S_4(NO)_4]$ that formed and the filtrate layered with additional 100 ml ether, affording 0.08 g of green brown microcrystalline product. Yield 0.07 mmol, 14% of $(PPN)_2[Fe_4S_4(NO)_6]$ based on $[Fe_4S_3(NO)_7]^-$. Elemental *Anal.* Calc. for $(PPN)_2[Fe_4S_4(NO)_6]\cdot 2DMF$ $C_{78}H_{74}N_{10}$-$O_8P_4S_4Fe_4$: C, 53.38; H, 4.25; N, 7.98. Found: C, 53.92; H, 4.20; N, 7.33%. IR:, 2962(w), 2930(w), 2861(w), 1700(vs) (ν_{N-O}), 1668(vs) (ν_{N-O}), 1435(m), 1262(m), 1115(m), 840(w), 746(w), 723(m), 692(m), 687(m), 546(m), 531(m), 523(w), 496(w). MS: (ESI −): *m/z* 525.4 $Fe_4S_4(NO)_6^-$, 495.6 $Fe_4S_4(NO)_5^-$, 467.8 $Fe_4S_4(NO)_4^-$ 438.1 $Fe_4S_4(NO)_3^-$. MS: (ESI +): *m/z* 535.3 (PPN^+).

2.5. Bis(Bis(triphenylphospine)iminium) hexasulfido-hexairon-hexanitrosyl bis(tricarbonyl-molybdenum) $(PPN)_2[Mo_2Fe_6(NO)_6(CO)_6]$

An amount of $(PPN)_2[Fe_6S_6(NO)_6]$ (0.5 g, 0.28 mmol) and $Mo(CO)_3(MeCN)_3$ (0.17 g, 0.56 mmol) were dissolved in 15 ml dichloroethane and the solution stirred overnight. The mixture was filtered, and the filtrate layered with ca. 60 ml ether, affording 0.45 g of crystalline material. Yield 0.20 mmol, 71.3% of $(PPN)_2[(CO)_6Mo_2Fe_6S_6(NO)_6]$. Elemental *Anal.* Calc. for $(PPN)_2[(CO)_6Mo_2Fe_6S_6(NO)_6]$ $C_{78}H_{60}N_8O_{12}P_4S_6Fe_6Mo_2$: C, 43.68; H, 2.82; N, 5.22. Found: C, 43.48; H, 2.70; N, 5.16%. IR:, 3055(w), 2957(w), 2926(w), 2861(w), 1926(vs) (ν_{C-O}), 1877(ν_{C-O}), 1723(sh) (ν_{N-O}), 1695(vs) (ν_{N-O}), 1670(sh) (ν_{N-O}), 1437(m), 1384(m), 1258(m), 1113(m), 744(w), 723(m), 691(m), 690(m), 594(m) (ν_{Mo-C}), 548(m), 532(m), 498(w). CV: (DMF solution, 0.031 M) $E_{1(rev)} = -641$ mV, $E_{2(rev)} = -1247$ mV.

2.6. Hexasulfido-hexairon-hexanitrosyl bis(tripropylphosphino-copper) $(PPr_3)_2Cu_2Fe_6S_6(NO)_6$ and Hexasulfido-tetrairon-tetranitrosyl tetrakis(tripropylphosphino-copper) $(PPr_3)_4Cu_4Fe_4S_6(NO)_4$

In 5 ml MeCN, $[Cu(MeCN)_4]PF_6$ (0.21 g, 0.56 mmol) was dissolved and tripropyl phosphine (PPr_3) (0.12 ml, 0.60 mmol) was added dropwise and the solution stirred for 30 min. This solution was added dropwise to a dichloroethane solution (15 ml) containing $(PPN)_2[Fe_6S_6(NO)_6]$ (0.5 g, 0.28 mmol) and the mixture was stirred overnight. The mixture was filtered and the precipitate was washed with small amounts of ether, extracted with a THF/Ether 1:1 mixture and layered with hexanes affording 0.2 g of crystalline $(PPr_3)_2Cu_2Fe_6S_6(NO)_6$. The filtrate was taken to dryness and the residue stirred in ether affording a colored solution and a white powder identified as $PPNPF_6$. Following filtration, the ether solution was dried affording approx. 0.05 g of oily $(PPr_3)_4Cu_4Fe_4S_6(NO)_4$. Crystals suitable for X-ray diffraction were obtained by redissolving in ether and allowing for slow evaporation to occur.

$(PPr_3)_2Cu_2Fe_6S_6(NO)_6$ Elemental *Anal.* Calc. for $(PPr_3)_2Cu_2Fe_6S_6(NO)$ $C_{18}H_{42}N_6O_6P_2S_6Fe_6Cu_2$: C, 18.72; H, 3.67; N, 7.28. Found: C, 18.51; H, 3.63; N, 7.05%. Yield 0.17 mmol, 60% of $(PPr_3)_2Cu_2Fe_6S_6(NO)_6$ based on Fe. IR:, 2957(m), 2927(m), 2867(w), 1766(sh) (ν_{N-O}), 1750(sh) (ν_{N-O}), 1729(vs) (ν_{N-O}), 1660(sh) (ν_{N-O}), 1450(m), 1410(m), 1080(m), 1000(m), 851(w), 736(w). Microprobe analysis confirms the 2:6 ratio of Cu to Fe. CV: (THF solution, 0.029 M) $E_{1(rev)} = -169$ mV, $E_{2(rev)} = -1035$ mV, $E_{3(rev)} = -1667$ mV.

$(PPr_3)_4Cu_4Fe_4S_6(NO)_4$ Elemental *Anal.* Calc. for $(PPr_3)_4Cu_4Fe_4S_6(NO)_4$ $C_{36}H_{84}N_4O_4P_4S_6Fe_4Cu_4$: C, 30.22; H, 5.92; N, 3.92%. Found: C, 32.90; H, 6.35; N, 3.08%. Yield 0.04 mmol 28.5% $(PPr_3)_4Cu_4Fe_4S_6(NO)_4$ based on Cu. IR: 2957(m), 2928(m), 2869(w), 1724(vs) (ν_{N-O}), 1712(vs) (ν_{N-O}), 1457(m), 1080(m), 840(w). Microprobe analysis confirms the 1:1 ratio of Cu to Fe. CV: (THF solution, 0.011 M) $E_{1(rev)} = -153$ mV, $E_{2(rev)} = -1021$ mV, $E_{3(rev)} = -1537$ mV, $E_{4(irr)} = -2077$ mV.

2.7. Hexasulfido-hexairon-hexanitrosyl bis(tripropylphosphino-nickel) $(PPr_3)_2Ni_2Fe_6S_6(NO)_6$ and Hexasulfido-tetrairon-tetranitrosyl tris(tripropylphosphino-nickel) $(PPr_3)_3Ni_3Fe_4S_6(NO)_4$

In 5 ml MeCN, $[Ni(MeCN)_6](BF_4)_2$ (0.27 g, 0.56 mmol) was dissolved and PPr_3 (0.12 ml, 0.60 mmol) was added dropwise and the solution stirred for 30 min. This solution was added dropwise to a dichloroethane solution (15 ml) containing $(PPN)_2[Fe_6S_6(NO)_6]$ (0.5 g, 0.28 mmol) and the mixture was stirred overnight. The mixture was filtered and the precipitate was washed with small amounts of ether and extracted with a THF/Ether 1:1 mixture and layered with hexanes affording 0.15 g of crystalline $(PPr_3)_2Ni_2Fe_6S_6(NO)_6$. The filtrate was taken to dryness and the residue stirred in ether affording a colored solution and a white powder identified as $PPNBF_4$. The resulting ether solution was dried and washed with hexanes and ether and extracted with THF using silica gel as a filtration agent, affording approx. 0.04 g of oily $(PPr_3)_3Ni_3Fe_4S_6(NO)_4$. Crystals suitable for X-ray diffraction were obtained by recrystalization from THF/Hexanes.

$(PPr_3)_2Ni_2Fe_6S_6(NO)_6$ Elemental *Anal.* Calc. for $(PPr_3)_2Ni_2Fe_6S_6(NO)_6$ $C_{18}H_{42}N_6O_6P_2S_6Fe_6Ni_2$ C, 18.88; H, 3.70; N, 7.34. Found: C, 19.12; H, 3.77; N, 7.26%. Yield 0.13 mmol, 46% of $(PPr_3)_2Ni_2Fe_6S_6(NO)_6$ based on Fe. IR: 2958(m), 2927(m), 2868(w), 1763(s) (ν_{N-O}), 1745(sh) (ν_{N-O}), 1725(vs) (ν_{N-O}), 1663(sh) (ν_{N-O}), 1449(m), 1405(m), 12181(m), 1076(m), 1041(m), 851(m), 762(w), 731(m), 586(w), 435(w). Microprobe analysis confirms the 2:6 ratio of Ni to Fe. CV: (THF solution, 0.029 M) $E_{1(rev)} = -1$ mV, $E_{2(rev)} = -717$ mV, $E_{3(rev)} = -1431$ mV.

$(PPr_3)_3Ni_3Fe_4S_6(NO)_4$ Elemental *Anal.* Calc. for $(PPr_3)_3Ni_3Fe_4S_6(NO)_4C_{27}H_{63}N_4O_4P_3S_6Fe_4Ni_3$ C, 27.19; H, 5.32; N, 4.70. Found: C, 31.57; H, 5.91; N, 5.31%. Yield 0.033 mmol, 17.83% $(PPr_3)_3Ni_3Fe_4S_6(NO)_4$ based on Ni. IR: 2957(m), 2927(m), 2868(w), 1720(s) (ν_{N-O}), 1698(vs) (ν_{N-O}), 1679(s) (ν_{N-O}), 1452(m), 1404(m), 1221(m), 1073(m), 1038(m), 849(m), 724(m), 584(w), 440(w). Microprobe analysis confirms the 3:4 ratio of Ni to Fe.

2.8. Reactions of $(PPN)_2[Fe_6S_6(NO)_6]$ with Fe^{2+} or Fe^0

2.8.1. With $Fe(H_2O)_6(BF_4)_2$/ PPr_3 (Scheme 2, Reaction 7)

An amount of $(PPN)_2[Fe_6S_6(NO)_6]$ (0.2 g, 0.11 mmol) and $Fe(H_2O)_6(BF_4)_2$ (0.08 g, 0.24 mmol) were suspended in 20 ml of THF/MeCN 1:1 ratio, and PPr_3 (0.05 ml, 0.25 mmol) was added dropwise. The mixture was stirred overnight, filtered, and the solution layered with ether affording 0.12 g of crystalline material. The material was identified as $(PPN)_2[Fe_8S_6(NO)_8]$ by IR, MS and cyclic voltammetry, without any evidence suggesting the presence of a different species. Yield 0.06 mmol, 55% of $(PPN)_2[Fe_8S_6(NO)_8]$.

2.8.2. With $Fe(CO)_5$

An amount of $(PPN)_2[Fe_6S_6(NO)_6]$ (0.2 g, 0.11 mmol) was dissolved in a solution of 20 ml THF/MeCN 1:1 ratio and $Fe(CO)_5$ (0.03 ml, 0.23 mmol) was added dropwise. The mixture was stirred overnight, filtered, and the filtrate layered with ether affording 0.10 g of a microcrystalline material. The material was identified as $(PPN)_2[Fe_8S_6(NO)_8]$ by IR and MS. Yield 0.05 mmol, 46% of $(PPN)_2[Fe_8S_6(NO)_8]$.

2.9. Reactions of $(PPN)_2[Fe_8S_6(NO)_8]$ with oxidizing agents

2.9.1. With O_2

An amount of $(PPN)_2[Fe_8S_6(NO)_8]$ (0.2 g, 0.11 mmol) was dissolved in 10 ml DMF and O_2 was bubbled through

the solution for 5 min. the mixture was stirred for 1 h and filtered to remove a light brown powder and layered with ether affording 0.10 g of crystalline material. The material was identified as $[Fe(DMF)_6][Fe_6S_6(NO)_6]$ by IR, MS and Unit Cell determination. Yield 0.08 mmol, 75.64% of $[Fe(DMF)_6][Fe_6S_6(NO)_6]$.

2.9.2. With $[Fe(Cp)_2]PF_6$

An amount of $(PPN)_2[Fe_8S_6(NO)_8]$ (0.2 g, 0.11 mmol) was dissolved in 10 ml DMF and $[Fe(Cp)_2]PF_6$ (0.14 g, 0.42 mmol) was added. The mixture was stirred overnight, filtered, and the filtrate layered with ether affording 0.05 g of crystalline $[Fe(DMF)_6][Fe_6S_6(NO)_6]$ as identified by IR and MS. Yield 0.04 mmol, 37.8% of $[Fe(DMF)_6]$-$[Fe_6S_6(NO)_6]$.

2.9.3. With SCl_2

An amount of $(PPN)_2[Fe_8S_6(NO)_8]$ (0.2 g, 0.11 mmol) was dissolved in 20 ml dichloroethane and a 10% SCl_2 solution in dichloroethane (0.07 ml, 0.11 mmol) was added dropwise and the solution was stirred for 1 h. The mixture was filtered and the precipitate was dissolved in DMF and layered with ether affording a powder that was identified by IR as $[Fe(DMF)_6]$-$[Fe_6S_6(NO)_6]$.

The filtrate of this solution was layered with ca. 20 ml ether, filtered to remove a white powder of PPNCl, and then layered with additional 40ml ether to obtain 0.08 g light green needle shaped crystals.

The unit cell was identical to the known (PPN)-$[Fe(CO)_3(NO)]$ complex [29], and IR showed characteristic peaks at 1794 cm^{-1} (ν_{N-O}) and 350 cm^{-1} (ν_{Fe-Cl}). Elemental analysis confirmed that the crystals are (PPN)-$[FeCl_3(NO)]$, apparently isomorphous to the (PPN)$[Fe(CO)_3(NO)]$ complex. Yield 0.17 mmol, 80% of (PPN)$[FeCl_3(NO)]$.

2.10. Crystallographic data

Diffraction data were collected on a Siemens SMART CCD-based X-ray diffractometer, equipped with a Mo Kα probe on a wavelength of 0.71073 Å. Space groups were determined on systematic absences and intensity statistics. Full Matrix least-squares refinement based on F^2 was performed. All non-hydrogen atoms were refined anisotropically, and hydrogen atoms were placed in ideal positions and refined as rigid atoms with individual isotropic thermal displacement parameters. The specific crystallographic data for each compound are presented in Table 1.

3. Results and discussion

The synthesis of the octanuclear iron sulfur nitrosyl cluster $(PPN)_2[Fe_8S_6(NO)_8]$ proceeds through the reaction of $(NH_4)[Fe_4S_3(NO)_7]$ with $(PPN)_2[Fe_4(CO)_{13}]$ in a 2:3 molar ratio affording $(PPN)_2[Fe_8S_6(NO)_8]$ in high yields. The byproducts of this reaction, that were isolated and verified by IR and MS are mainly (PPN)$[Fe(CO)_3(NO)]$ and a small amount of (PPN)$[Fe_4N(CO)_{12}]$. The reaction appears to proceed through the abstraction of nitrosyl ligands from $[Fe_4S_3(NO)_7]^-$ by the $[Fe_4(CO)_{13}]^{2-}$ cluster and the possible formation of an $[Fe_4S_3(NO)_4]^-$ intermediate which subsequently self couples to form the $[Fe_8S_6(NO)_8]^{2-}$ cluster. (PPN)$[Fe(CO)_3(NO)]$ seems to be the main product formed by the reaction of the $[Fe_4(CO)_{13}]^{2-}$cluster with NO^+. The generation of the $[Fe_4N(CO)_{12}]^-$ cluster also is possible considering the reported synthesis of this cluster by the reaction of $Fe_3(CO)_{12}$ with $[Fe(CO)_3(NO)]^-$ [30,31].

In the synthesis of $(PPN)_2[Fe_6S_6(NO)_6]$ (Reaction 2, Scheme 2), the yield of the Fe_6S_6 "prismane" is unreasonably high, assuming that $[Fe_4S_3(NO)_7]^-$ is the only source of Fe. It appears therefore that the $[Fe_4(CO)_{13}]^{2-}$ cluster also provides Fe in the formation of $(PPN)_2[Fe_6S_6(NO)_6]$. In addition, it is known that $[Fe(CO)_3(NO)]^-$ upon reaction with S^0 produces $[Fe_4S_4(NO)_4]^-$ [32] so the pathway to the formation of $(PPN)_2[Fe_6S_6(NO)_6]$ through reaction 2 may be more complicated than the initial formation of $(PPN)_2[Fe_8S_6(NO)_8]$ and further reaction with Bz_2S_3 as shown by reactions 1 and 4 (Scheme 2). The $[Fe_6S_6(NO)_6]^{2-}$ cluster has been synthesized previously with different counter ions but in lower yields [7].

The $[Fe_4S_4(NO)_4]^{2-}$ cluster has not been isolated in this oxidation level previously. The IR spectrum shows a NO stretching vibration at 1652 cm^{-1} which is lower when compared to the 1760 cm^{-1} and 1700 cm^{-1} reported for $Fe_4S_4(NO)_4$ and $[Fe_4S_4(NO)_4]^-$ respectively [32]. The lower frequency of the NO stretching vibration in $(PPN)_2[Fe_4S_4(NO)_4]$ is consistent with the expected increase in the Fe–NO backbonding in the dianionic $(PPN)_2[Fe_4S_4(NO)_4]$. Elemental analysis also is consistent with the $(PPN)_2[Fe_4S_4(NO)_4]$ formula, however we were not able to obtain a satisfactory crystal structure due to high distortion of the PPN^+ cations in the crystal lattice. Nevertheless, the presence of a $[Fe_4S_4(NO)_4]^{2-}$ cluster and two PPN^+ cations has been confirmed.

The synthesis of the $[Fe_4S_4(NO)_6]^{2-}$ (Fig. 1) and $[Fe_4S_4(NO)_4]^{2-}$ clusters from the Roussin anion is not unexpected. The reactions of $[Fe_4S_3(NO)_7]^-$ with SH^-, in polar solvents (L), may well lead in cluster fragmentation and generation of dimeric species such as $\{Fe_2S_2(NO)_3(L)\}^-$ and $\{Fe_2S_2(NO)_2(L)_2\}^-$. Coupling of these units can lead to the formation of the $[Fe_4S_4(NO)_6]^{2-}$ and $[Fe_4S_4(NO)_4]^{2-}$ clusters respectively. As in the case of all $[Fe_4S_3(NO)_7]^-$/$[Fe_4(CO)_{13}]^{2-}$ reactions, the main byproduct in the synthesis of either $[Fe_4S_4(NO)_4]^{2-}$ or $[Fe_4S_4(NO)_6]^{2-}$ is $[Fe(CO)_3(NO)]^-$. The apparent role of $[Fe_4(CO)_{13}]^{2-}$ as a

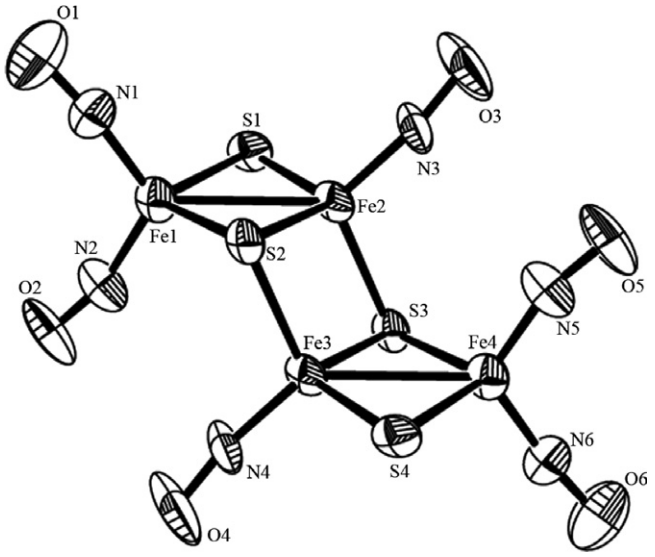

Fig. 1. Ortep diagram of $[Fe_4S_4(NO)_6]^{2-}$ with 50% probability ellipsoids.

NO abstracting reagent is affected by both time and temperature and this explains the formation and isolation of $[Fe_4S_4(NO)_6]^{2-}$ at low temperatures.

The formation of $Fe_4S_4(NO)_4$ from the reaction of $[Fe_4S_3(NO)_7]^-$ and elemental sulfur has been reported [32] and this cluster was studied several years ago, although the mechanism of this reaction is not clear. Based on experimental observations and theoretical calculations by Glidewell and Hoffmann [33,34] the formation of $Fe_4S_4(NO)_4$ from $[Fe_4S_3(NO)_7]^-$ could proceed through a mechanism of fragmentation and reassembly of the latter cluster.

The isolation of $(PPN)_2[Fe_4S_4(NO)_6]$ has been achieved by repeating the reaction that yields $(PPN)_2[Fe_4S_4(NO)_4]$ but at low temperatures. According to the formal oxidation levels, there is a two electron oxidation from $[Fe_4S_3(NO)_7]^-$ to $[Fe_4S_4(NO)_6]^{2-}$ and an additional two electron oxidation to $[Fe_4S_4(NO)_4]^{2-}$. The isolation of this edge fused double dimer can be envisioned as the coupling product of two $\{Fe_2S_2(NO)_3^-\}$ fragments while the cubane as the product of two $\{Fe_2S_2(NO)_2^-\}$ fragments.

The procedure reported here for the synthesis of $(PPN)_2[Fe_4S_4(NO)_6]$ is not an easily reproducible process and seems to be sensitive to time and temperature of crystallization. Both the hypothetical $\{Fe_2S_2(NO)_3(L)\}^-$ and $\{Fe_2S_2(NO)_2(L)\}^-$ fragments possibly involved in the formation of $[Fe_4S_4(NO)_6]^{2-}$ and $[Fe_4S_4(NO)_4]^{2-}$ respectively, may be preset at the same time in various amounts. Therefore isolation of $[Fe_4S_4(NO)_6]^{2-}$ or the more stable $[Fe_4S_4(NO)_4]^{2-}$ will depend on the exact conditions of the experiment, and such conditions are not easily reproduced/obtained. Although $[Fe_4S_4(NO)_6]^{2-}$ has been detected several times in mixtures obtained from this reaction, analytically pure crystalline material has only been obtained once thus far.

3.1. Transformations of $(PPN)_2[Fe_8S_6(NO)_8]$

The $(PPN)_2[Fe_8S_6(NO)_8]$ cluster, stable at high temperatures, upon oxidation transforms to the $[Fe_6S_6(NO)_6]^{2-}$ "prismane". This occurs using O_2, SCl_2 and $[Fe(Cp)_2]PF_6$. In all three cases it seems that there is loss of two {Fe(NO)} fragments rather than rearrangement of the clusters. In coordinating solvents, the main product isolated is $[Fe^{II}(L)_6][Fe_6S_6(NO)_6]$ (L = DMF, THF, MeCN). The $[Fe_6S_6(NO)_6]^{2-}$ anion is structurally related to the $[Fe_8S_6(NO)_8]^{2-}$ pentlandite. The former is obtained from the latter when two {Fe(NO)} moieties are removed from the body diagonal of the pentlandite cube. In addition to the $[Fe_6S_6(NO)_6]^{2-}$ prismane, a yellow brown powder also forms. In the case of the SCl_2 reaction this byproduct was identified and characterised as $(PPN)[FeCl_3(NO)]$ both analytically and spectroscopically (by the NO stretch at 1794 cm^{-1}, the Fe–Cl stretch at 350 cm^{-1} and characteristic PPN stretches in the 800–500 cm^{-1} region). The unit cell dimensions of this byproduct were nearly identical to those of the known $(PPN)[Fe(CO)_3(NO)]$ complex [29]. Although this particular complex has not been synthesized previously, its crystallographic structure determination and further characterizations were not of particular interest in this study and were not further pursued. The $[Fe(L)_6][Fe_6S_6(NO)_6]$ complex isolated has exactly the same infrared spectral pattern for the NO stretching vibrations as the pattern for the previously reported $[Fe(DMF)_6][Fe_6S_6(NO)_6]$ [7]. A counter-ion exchange of $[Fe(DMF)_6]^{n+}$ with PPN^+ gives $(PPN)_2[Fe_6S_6(NO)_6]$. The latter is verified by elemental analysis and confirms that the iron in the $[Fe(L)_6]^{n+}$ counter-ion is divalent ($n = 2$).

For the reaction of $(PPN)_2[Fe_8S_6(NO)_8]$ with eight equivalents of $NOBF_4$ the products isolated are $Fe(DMF)_6[Fe_6S_6(NO)_6]$, $(PPN)[Fe_4S_3(NO)_7]$ and $PPNBF_4$ suggesting that in order to form the more reduced $[Fe_4S_3(NO)_7]^-$ cluster some of the $[Fe_8S_6(NO)_8]^{2-}$ cluster has to be oxidized to produce the necessary electrons since NO^+ cannot act as a reducing agent.

In contrast, when gaseous NO is used both $[Fe_8S_6(NO)_8]^{2-}$ and $[Fe_6S_6(NO)_6]^{2-}$ produce $[Fe_4S_3(NO)_7]^-$ in nearly quantitative yields.

3.2. Reactivity of $(PPN)_2[Fe_6S_6(NO)_6]$

The cyclohexane-like Fe_3S_3 units of the $[Fe_6S_6]$ core can serve as ligands for two additional metal ions and form $[M_2Fe_6S_6]$ clusters, [19,35,36]. The latter were obtained in reactions carried out with coordinatively-unsaturated complexes containing Fe, Mo, Cu and Ni.

In the reaction of $(PPN)_2[Fe_6S_6(NO)_6]$ with $[Fe(H_2O)_6]^{2+}/PPr_3$, or $Fe(CO)_5$, the only product isolated was $[Fe_8S_6(NO)_8]^{2-}$. The formation of $[Fe_8S_6(NO)_8]^{2-}$ even at NO deficient conditions can be explained if fragmentation of the cluster to {Fe(NO)} units occurs. The later under reducing conditions form the $[Fe_8S_6(NO)_8]^{2-}$ preferentially.

In order to increase the yield of $[Fe_8S_6(NO)_8]^{2-}$ the reaction of $(PPN)_2[Fe_6S_6(NO)_6]$ with $[Fe(H_2O)_6]^{2+}$ was carried out in the presence of $NOBF_6$. The only products isolated were $(PPN)[Fe_4S_3(NO)_7]$ and $[Fe(DMF)_6][Fe_6S_6(NO)_6]$ suggesting that the formation of $[Fe_4S_3(NO)_7]^-$ is more favorable in the presence of NO^+.

As in the case of $(Et_4N)_2[Fe_6S_6Cl_6]$, [35] the reaction of $(PPN)_2[Fe_6S_6(NO)_6]$ with $Mo(CO)_3(MeCN)_3$ yields $(PPN)_2[(CO)_6Mo_2Fe_6S_6(NO)_6]$ (Fig. 2) even in molar ratios less than 1:1 suggesting that the $[MoFe_6S_6]$ core, if it forms at all, disproportionates to the $[Mo_2Fe_6S_6]$ and $[Fe_6S_6]$ clusters.

The reaction of $(PPN)_2[Fe_6S_6(NO)_6]$ with $[Cu(MeCN)_4]^+/PPr_3$ affords $(PPr_3)_2Cu_2Fe_6S_6(NO)_6$ (Fig. 3) as the main product, and in a lower yield the $(PPr_3)_4Cu_4Fe_4S_6(NO)_4$ (Fig. 4) cluster. Formation of the $(PPr_3)_4Cu_4Fe_4S_6(NO)_4$ cluster could be explained in terms of fragmentation of the $[Fe_6S_6(NO)_6]^{2-}$ cluster to smaller Fe/S/NO units (i.e. $\{Fe_2S_2(NO)_2\}$ units), The latter in the presence of $Cu(PR_3)$ form $(PR_3)CuS_2Fe(NO)$ units which couple to form the final product. In both cases the Fe_6Cu_2 and Fe_4Cu_4 clusters form due to the superior thermodynamic stability of the Cu–S bond relative to the Fe–S bond. Previously, we have reported on the substitution of Fe atoms by Cu atoms in Fe/S clusters [19,37].

These two products form regardless of the ratio of the Cu used, and their separation was achieved due to their slightly different solubilities. Similar reactions of $[Fe_6S_6(NO)_6]^{2-}$ with $[Ni(MeCN)_6]^{2+}/PPr_3$, give the neutral $(PPr_3)_2Ni_2Fe_6S_6(NO)_6$ (Fig. 5) cluster as the main product, but unlike the case of copper where the byproduct formed

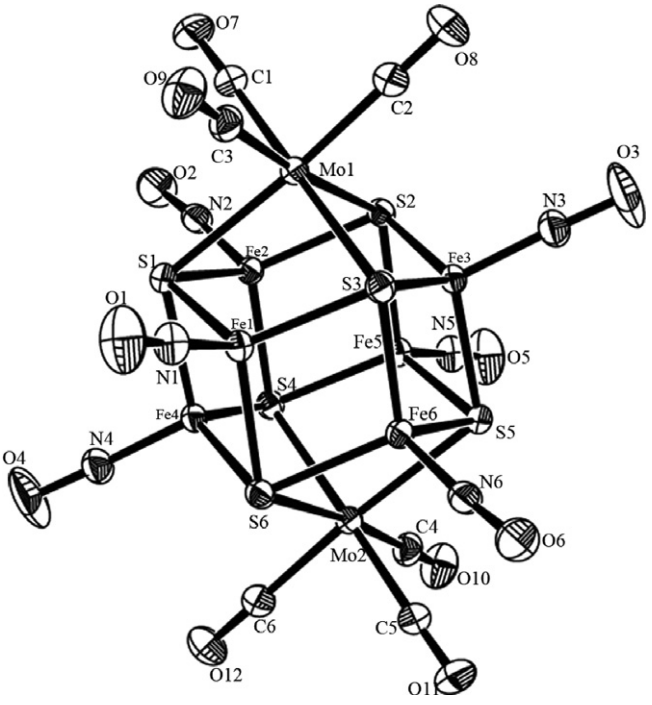

Fig. 2. Ortep diagram of $[(CO)_6Mo_2Fe_6S_6(NO)_6]^{2-}$ showing ellipsoids with 50% probability.

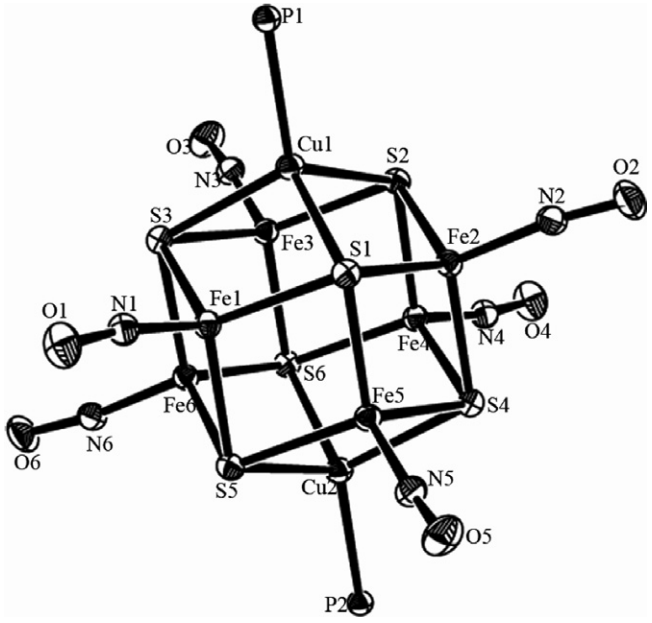

Fig. 3. Ortep diagram of $(PPr_3)_2Cu_2Fe_6S_6(NO)_6$ showing ellipsoids with 50% probability. The carbons of the phosphines have been omitted for clarity.

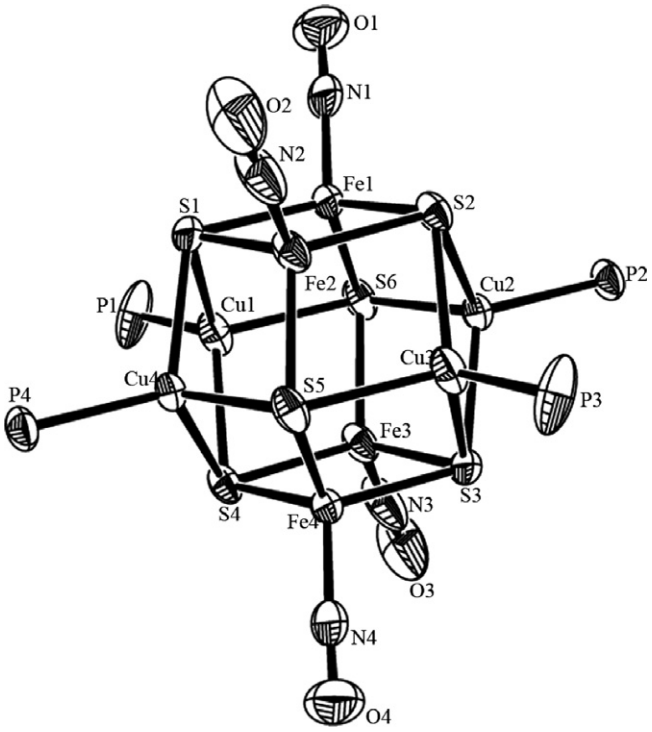

Fig. 4. Ortep diagram of $(PPr_3)_4Cu_4Fe_4S_6(NO)_4$ showing ellipsoids with 50% probability. The carbons of the phosphines have been omitted for clarity.

is $(PPr_3)_4Cu_4Fe_4S_6(NO)_4$, with nickel the other isolable byproduct is the unique Ni/Fe/S cluster $(PPr_3)_3Ni_3Fe_4S_6(NO)_4$ (Fig. 6). This cluster contains the ''voided–cubic'' M_7S_6 core which previously has been found in $(PPr_3)_4Fe_7S_6Cl_3$ [38], $Co_7S_6I_3(PEt_3)_4$ [39], and Co_7S_6-

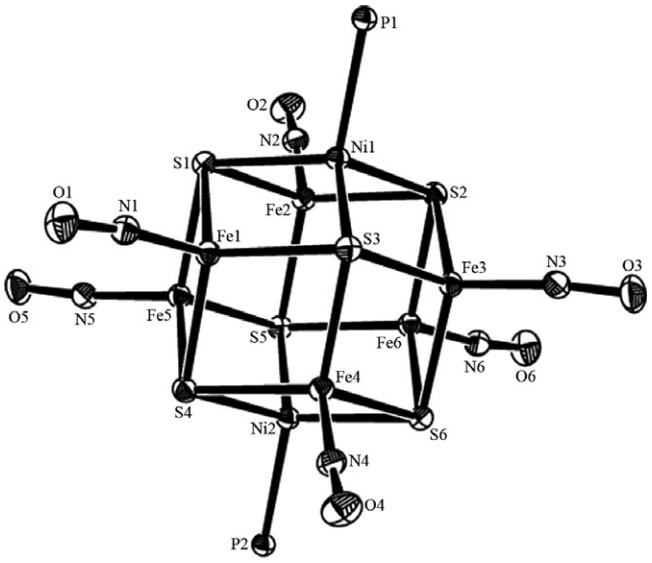

Fig. 5. Ortep diagram of $(PPr_3)_2Ni_2Fe_6S_6(NO)_6$ showing ellipsoids with 50% probability. The carbons of the phosphines have been omitted for clarity.

$X_3(PPh_3)_4$ (X=Cl$^-$ [23], Br$^-$ [40]) but not in mixed metal systems. The $(PPr_3)_3Ni_3Fe_4S_6(NO)_4$ is the only byproduct isolated from a mixture that appears to contain three compounds. The separation of these species is relatively difficult as their solubilities are relatively similar, with $(PPr_3)_3Ni_3Fe_4S_6(NO)_4$ being less soluble in ether and hexanes than the other two species. Unfortunately we ware not able to obtain any crystals from the other two byproducts as they seem relatively unstable. Nevertheless these two species also contain phosphine and nitrosyls as shown by infrared spectroscopy, with the main N–O stretching peak at 1696 cm^{-1} for $(PPr_3)_3Ni_3Fe_4S_6(NO)_4$ (THF fraction), 1739 cm^{-1} (Ether fraction) and 1711 cm^{-1} (Hexanes Fraction). The IR spectra of the Ether fraction is very similar to the pattern of $(PPr_3)_4Cu_4Fe_4(NO)_4$ and since the $[Ni_4Fe_4S_4]$ core is known for $(PPr_3)_4Ni_4Fe_4S_4Cl_4$ [19] and $(PPh_2Me)_4Ni_4Fe_4S_4I_4$ [20], we expect the nitrosyl cluster to have a similar structure.

3.3. Structures

Crystallographic determination of $(PPN)_2[Fe_4S_4(NO)_6]$ reveals a Fe_4S_4 core that can be described as the fusion of two $[(NO)_2Fe(\mu\text{–}S)_2Fe(NO)]^-$ dimers to give a *nido* $[Fe_4S_4(NO)_6]^{2-}$ cluster (Fig. 1) with an inter-dimer Fe–Fe distance of 2.77 Å and an average intra-dimer Fe–Fe distance of 2.68 Å. The Fe–NO distances are almost equivalent at 1.66 Å (1.65–1.67 Å) with average Fe–N–O bond angles of 167° within a range of 163°–171°.

In the $(PPN)_2[(CO)_6Mo_2Fe_6S_6(NO)_6]$ cluster, the M_8S_6 cuboctahedral core exhibits average Mo–Fe and Fe–Fe distances are at 2.89 Å and 2.69 Å, respectively, and Mo–S and Fe–S distances at 2.58 Å and 2.25 Å, respectively. As expected, by comparison to $[Fe_8S_6(NO)_8]^{2-}$, the Mo_2Fe_6 cluster is elongated along the three-fold axis that contains the Mo atoms (Fig. 2). The cluster topology is identical to the MoFe/S/Cl analogues $(Et_4N)_3[(CO)_6Mo_2Fe_6S_6Cl_6]$ and $(Et_4N)_4[(CO)_6Mo_2Fe_6S_6Cl_6]$ [35].

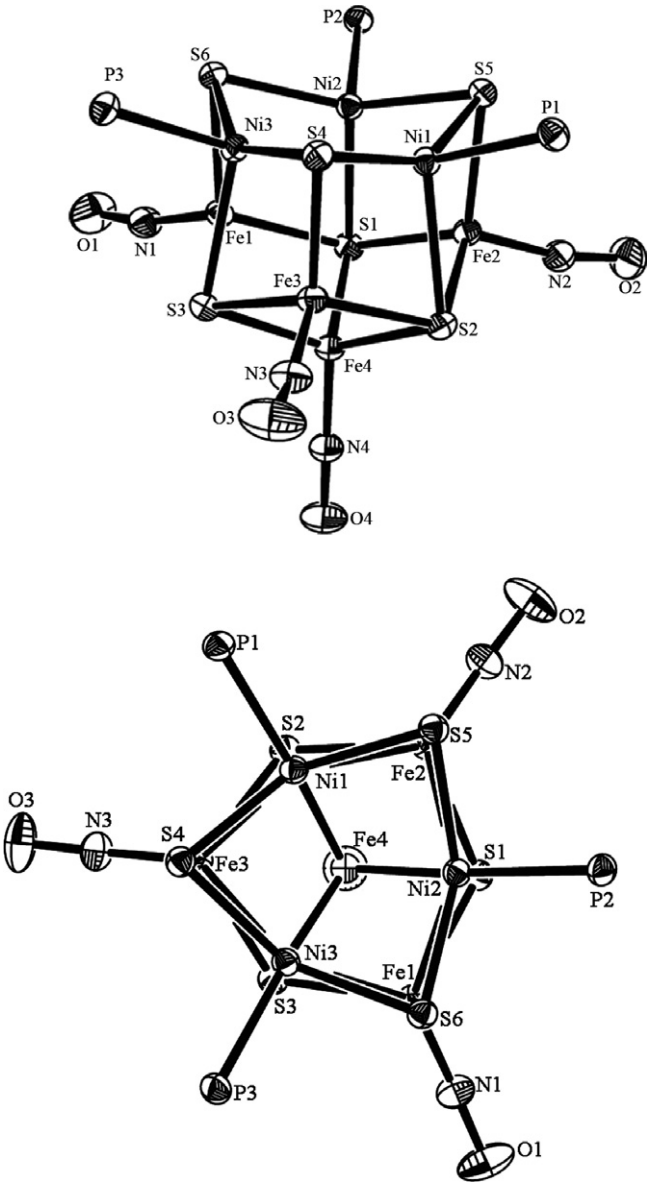

Fig. 6. Ortep diagram of $(PPr_3)_3Ni_3Fe_4S_6(NO)_4$ (side and top view) showing ellipsoids with 50% probability. The carbons of the phosphines have been omitted for clarity.

Both of the Cu/Fe/S/NO structures exhibit the typical cubic arrangement of metals capped by sulfur atoms and have structures similar to those of their Cu/Fe/S/Cl analogues $(Bu_4N)_2[(PPr_3)_2Cu_2Fe_6S_6Cl_6]$ and $(PPr_3)_4Cu_4Fe_4S_6Cl_6$ [19]. In the case of $(PPr_3)_2Cu_2Fe_6S_6(NO)_6$ (Fig. 3) the average Cu–Fe and Fe–Fe distances are 2.70 Å and 2.65 Å and the Cu–S and Fe–S bonds are found at 2.38 Å and 2.24 Å. In $(PPr_3)_4Cu_4Fe_4S_6(NO)_4$ (Fig. 4) the metals in the Cu_4Fe_4 core are arranged in D_{2h} geometry (mutually perpendicular Fe_4 and Cu_4 squares) with average metal–metal distances of 2.74 Å and average Cu–S and Fe–S bond distances of 2.36 Å and 2.26 Å respectively.

The neutral $(PPr_3)_2Ni_2Fe_6S_6(NO)_6$ (Fig. 5) possesses the same core structure as the copper analogue, but is slightly more compact with average Ni–S and Fe–S distances of 2.25 Å and 2.26Å, respectively, and Ni–Fe and Fe–Fe distances at 2.59Å and 2.65Å, respectively. A similar Ni_2Fe_6 core is also found in the Ni/Fe/S/halide analogues, $(Et_4N)_2[(PPr_3)_2Ni_2Fe_6S_6Cl_6]$ [19] and $[PhCH_2NEt_3]_2[(Ph_2MeP)_2Ni_2Fe_6S_6I_6]$ [20].

The $(PPr_3)_3Ni_3Fe_4S_6(NO)_4$ (Fig. 6) cluster can be viewed as a $Fe_4S_3(NO)_4$ unit coupled with a nearly trigonal planar $Ni_3S_3(PPr_3)_3$ unit. In this structure the Iron atoms show a tetrahedral coordination geometry while the Nickel atoms show a trigonal pyramidal geometry. The Fe–Fe distances in the equatorial triangle (defined by Fe1, Fe2 and Fe3) have a mean value of 3.82 Å. These irons are located 2.74 Å from the capping iron. The Ni–Fe distances and Ni–Ni distances are at found at 2.61 and 2.79 Å, respectively, and the Fe–S and Ni–S distances are 2.23 Å and 2.25 Å, respectively.

As shown in Table 2, the M/Fe/S (M=Mo,Cu,Ni) clusters reported in this paper have shorter metal–metal and iron–sulfur distances in a more compact overall structure than their corresponding analogues with halogens. An exception is the $(PPr_3)_3Ni_3Fe_4S_6(NO)_4$ cluster which is of similar size to the structurally similar $[Fe_7S_6]$ and $[Co_7S_6]$ clusters. In the M_7S_6 clusters the "uncapped" M_3S_3 unit shows a triangular M_3 array with distances nearly 1 Å shorter than the distances found in the hexagonal faces of the M_6S_6 prismanes. At present we are exploring the possible function of the "uncapped" unit as a ligand to other metal atoms.

$Fe–S_{(axial)}$	2.204(5)	2.276(3)	2.184(5)

The volume of the metal formed cuboidal unit has been calculated approximating it as a cube, using average metal–metal distances.

[a] The distances of interest are denoted as shown in Fig. 6 using the equivalent metal positions for Fe_7S_6 and Co_7S_6 since in the case of $Ni_3Fe_4S_6$ they are more easily defined and recognized.

[b] The Fe–Fe plane is the trigonal plane defined by Fe1–Fe2–Fe3, and the Fe–Fe(capping) is the distance of Fe4 to the trigonal Fe plane. Fe–S (capping) is the Fe4–S3 distance, Fe–S (equatorial) is the Fe3–S3 distance and Fe–S (axial) is the Fe3–S4 distance.

Table 3

[a] Crystal structure of $(Et_4N)[Fe_4S_3(NO)_7]$ taken from Ref. [46].
[b] The heterometals are assigned as Cu(I), Ni(II) and Mo(0) assuming that they did not undergo change of oxidation state during the reaction.

3.4. The NO ligands

In metal nitrosyl complexes it is difficult to determine precise oxidation states for the metal atoms since NO could be described as NO^+, NO or NO^-. Thus, in $[Fe_4S_3(NO)_7]^-$ two descriptions have been proposed for the cluster based on the assignment of the NO ligand state. These are: $4Fe^{3+}/NO^-$ [41] and $3Fe^{-1}$,Fe^+/NO^+ [42].

Spectroscopic and structural data for the Fe/S/NO and M/Fe/S/NO clusters (Table 3) show the N–O stretching vibrations in the range from 1652 to 1766 cm^{-1}, the M–N–O angle in the range from 171.8° to 180.0°, the Fe–N bond in the range from 1.67 Å to 1.71 Å and the N–O bond between 1.14 Å and 1.18 Å. Within 3σ (at times as high as .01–.02 Å) the N–O and Fe–NO distances are nearly indistinguishable. The Fe–NO bond is short enough consistent with a considerable amount of multiple bond character. The high standard deviations often associated with the N–O bonds make the bond order difficult to evaluate. The M–N–O angles are all near 180° which is expected for NO^+ coordination as opposed to 120° for NO^- taken in extreme cases, but on the basis of the IR data the NO ligands may be even considered as NO^- given that the typical range for lineal NO is 1450–1950 cm^{-1} and 1400–1720 cm^{-1} for bent NO [10]. Unfortunately there is great overlap in ranges, and given that in a series of $[M(NO)(CN)_5]^{n-}$ complexes (M=V, Cr, Mn, Fe and $n = 2, 3$) the position of ν_{NO} depends upon the cation present and variations up to 100 cm^{-1} have been observed for a given anion [43,44]. This makes the ν_{N-O} vibration unreliable for determining NO oxidation. As described by Enemark and Feltham [45] the transition metal-nitrosyl systems are better described as highly covalent entities using a $\{M–NO\}^n$ notation with n the sum of metal d and NO π^* electrons. Any reference to change of oxidation states of the clusters in this article is in accordance with this notation.

An examination of the structural parameters in the $\{[(R_3P)M]_xFe_{8-x}(L)_{8-x}S_6\}^{n-}$ clusters for L = NO vs Cl^- (Table 2) shows that the NO clusters are characterized by significantly shorter Fe–M, Fe–Fe and Fe–S bond lengths. The data are consistent with the expected π back bonding from the Fe atoms into the NO π^* orbital which in turn results in electron deficient Fe atoms, significant M–Fe and Fe–Fe bonding and Fe–S multiple bonding. At present ^{57}Fe Moessbauer spectroscopy appears to be needed for an assignment of oxidation states to the Fe metals and the NO ligands, by a comparison of the Moessbauer spectra of the NO clusters to those of the corresponding chloro clusters. The Moessbauer spectra of the Cu_2Fe_6, Cu_4Fe_4 and Ni_2Fe_6 clusters (L = Cl^-), with isomer shifts of 0.345 mm/s, 0.341 mm/s and 0.355 mm/s, respectively, are consistent with an Fe oxidation state around +3 and Cu^{+1}, Ni° or Ni^{+1}.

3.5. Electrochemistry

Electrochemical studies of the clusters reported here, show mainly reversible, multielectron reductions (Table 4).

Table 4
Reduction potentials of the four M_2 Fe_6S_6 clusters and comparison with their Fe/S/Cl equivalents

Compound	0/−1 couple			−1/−2 couple			−2/−3 couple			−3/−4 couple		
	$E_{1/2}$ (mV)	ΔE	i_{pc}/i_{pa}	$E_{1/2}$ (mV)	ΔE	i_{pc}/i_{pa}	$E_{1/2}$ (mV)	ΔE	i_{pc}/i_{pa}	$E_{1/2}$ (mV)	ΔE	i_{pc}/i_{pa}
$(PPr_3)_2Cu_2Fe_6S_6(NO)_6$	−169	152	0.84	−1035	148	0.99	−1667	152	1.02			
$(Bu_4N)_2[(PPr_3)_2Cu_2Fe_6S_6Cl_6]$							−228	26		−555	120	
$(PPr_3)_4Cu_4Fe_4S_6(NO)_4$	−153	172	0.39	−1021	156	0.57	−1537	116	0.73	−2065		irr
$(PPr_3)_4Cu_4Fe_4S_6Cl_6$	−17	124		−635	130							
$(PPr_3)_2Ni_2Fe_6S_6(NO)_6$	−1	168	1.10	−717	156	0.61	−1431	334	0.71			
$(Et_4N)_2[(PPr_3)_2Ni_2Fe_6S_6Cl_6]$							−585	156				
$(PPN)_2[(CO)_6Mo_2Fe_6S_6(NO)_6]$							−641	192	0.70	−1247	176	0.68
$(Et_4N)_3[(CO)_6Mo_2Fe_6S_6Cl_6]$										+50	92	1.00

All reductions are reversible unless denoted otherwise.

The $(PPr_3)_2Cu_2Fe_6S_6(NO)_6$ cluster shows three reversible reduction waves (Fig. 7) at −169 mV, −1035 mV, −1667 mV. Following a cyclic scan from 1.8 V to −2 V, the voltammetry shows the appearance of an additional reduction wave at about −633 mV, which suggest that the small peak that appears in that region in the 0 to −2.0 V scan is due to partial oxidation of the cluster during the experiment rather than to the presence of an impurity.

In the case of $(PPr_3)_4Cu_4Fe_4S_6(NO)_4$, although the CV appears to be very similar to $(PPr_3)_2Cu_2Fe_6S_6(NO)_6$ as the first two reductions coincide, (Fig. 8) at high potentials there are different peaks. In addition when two consecutive full scans from −2 V to 1.8 V are performed, there is no appearance of the peak at −0.5 V indicating that it is not a mixture of two species.

For $(PPr_3)_2Ni_2Fe_6S_6(NO)_6$ the cyclic voltammogram (Fig. 9) shows only two reductions at −717 mV and −1431 mV but there is also a reversible wave at −1 mV (not shown), and overall the voltammogram of $(PPr_3)_2Ni_2Fe_6S_6(NO)_6$ is similar to that of $(PPr_3)_2Cu_2Fe_6S_6(NO)_6$ shifted by approx 0.2 V towards more positive potentials. Again after a full range scan there is an emergence of a new reversible wave at −235 V which is also evident in the initial scan but with smaller intensity suggesting that part of the sample had been oxidized during the experimental process.

Contamination of the $(PPr_3)_3Ni_3Fe_4S_6(NO)_4$ cluster with the other unidentified Ni/Fe/S species, did not allow for conclusive electrochemical measurements of this cluster.

For $(PPN)_2[(CO)_6Mo_2Fe_6S_6(NO)_6]$, there are two reduction waves observed at −641 mV and −1247 mV (Fig. 10). In addition there is no significant effect of oxidation as there are no new peaks appearing but the two reductions change in intensity after a full range scan.

As shown in Table 4, by comparison to the corresponding M/Fe/S/Cl species and equivalent couples, the clusters presented herein are more difficult to reduce which is reasonable given that these clusters appear to be more electron rich than their corresponding halogen analogues due to the more covalent nature of the Fe–NO bond that eventually

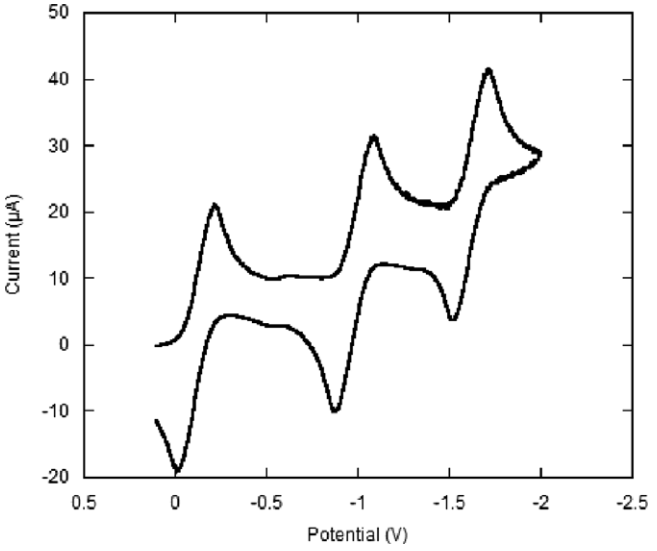

Fig. 7. Cyclic voltammogram of $(PPr_3)_2Cu_2Fe_6(NO)_6$.

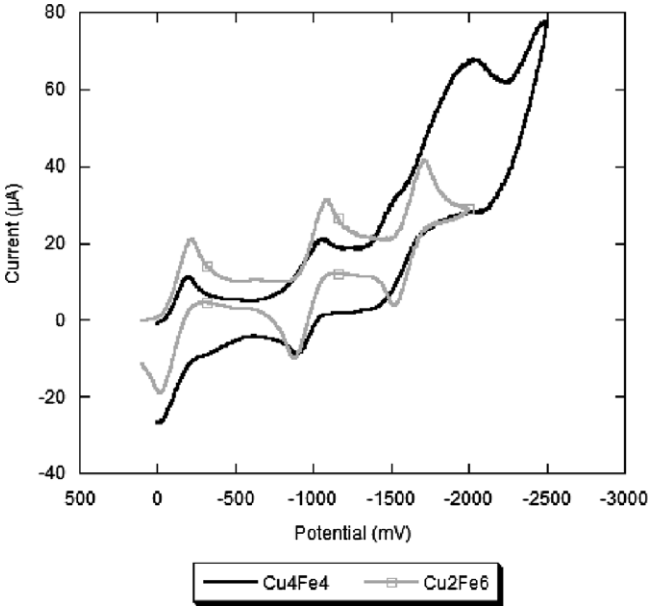

Fig. 8. Cyclic voltammogram of $(PPr_3)_4Cu_4Fe_4S_6(NO)_6$ in comparison with $(PPr_3)_2Cu_2Fe_6S_6(NO)_6$.

disturbs the ability of the metals to accept additional electrons.

4. Conclusions

In this article we have explored the syntheses and reactivities of the Fe/S/NO clusters. These clusters were found structurally similar to their halo and phosphino analogues, exhibiting similar interconversions between their core structures, and the reactivity of $(PPN)_2[Fe_6S_6(NO)_6]$ towards thiophilic metals such as Mo, Cu and Ni, provides almost identical core structures as the Fe/S/Cl clusters.

The reactivity of the Fe/S/NO clusters presented in this paper are in line with the fragmentation/reassembly mechanism proposed by Glidewell and Hoffmann, as the products obtained through various reactions seem to be the four basic and thermodynamically stable core topologies of Fe_4S_3, Fe_4S_4 Fe_6S_6 and Fe_8S_6, however the isolation of the unique $(PPN)_2[Fe_4S_4(NO)_6]$, ''open-cubane'' and the $(PPr_3)_3Ni_3Fe_4S_6(NO)_4$ clusters provides additional evidence that it is possible to obtain new core topologies by varying reaction conditions and stabilizing inherently metastable structures.

remembering excellence comes through living the simple lessons he learned in Coello [10].

Fred dedicated his autobiography [9], "In Loving Memory of My Beloved Wife, Mary and My Parents, Giovanni and Catherina Basolo":

> Regardless of early hardships, I have always considered my early childhood to have been the most enjoyable and most instructive period of my life [9, p. 3].

Most of the miners, including the Basolos, were immigrants from the Piedmont region of northern Italy and spoke the "Piemontese" peasant dialect. Until he attended school, Fred understood but spoke little English. Conditions in the home were primitive—no central heating or plumbing. Watching his mother in the family kitchen made the cooking of Italian dishes one of his favorite hobbies. Fred's legendary concern for his students, colleagues, family, and everyone with whom he came into contact may be traced to his early roots in Coello.

The Great Depression began when Fred was about 10 years old. Since he was too young to work, he attended a four-room elementary school in Coello and then the Christopher Community High School, walking the two miles in all kinds of weather. His first contact with chemistry (he did not even know the meaning of the word) was in high school. The teacher told the class she hated the subject, did not know much about it, and they were going to be largely on their own, which gave Fred the freedom to concentrate on what interested him in both the text and lab experiments.

2. University studies

With a welfare program for college students, Fred enrolled at Southern Illinois Normal School (SIN, now Southern Illinois University, from which he was to receive an honorary doctorate in 1984), where he became a chemistry major and received his B.Ed. degree in 1940. The only person from Coello going to college, today he is still the only Ph.D. from there. Although his parents hoped he would return home as a high school teacher, Chemistry Department chairman James Neckers advised him to go to graduate school. His reaction was, "What is graduate school?" [9, p. 11].

A teaching assistantship allowed Fred to enter the University of Illinois, where he chose as his mentor John C. Bailar, Jr. (1904–1991) [12] (Fig. 1), whom he thought "seemed to be a caring person, with a good understanding of people and their needs" [9, p. 14], qualities for which Fred himself later became well known. The choice was "one of the very best decisions I have ever made" [9, p. 14], and, after his parents, Bailar became his second role model. As most illustrious *Doktorand*, Fred continued Bailar's work with his own students, and after Bailar's death in 1991 he succeeded him as the dean of American coordination chemistry.

Fig. 1. Fred Basolo (left) and John C. Bailar, Jr. (right).

Because Bailar had worked with octahedral cobalt(III) complexes, he wanted to extend his studies to planar platinum(II) and octahedral platinum(IV) complexes. Fred chose for his research the preparation and study of the stereochemical changes that occur during ligand substitution reactions of optically active *cis*-$[PtCl_2\{NH_2CH_2CH_2NH_2\}_2]Cl_2$. His publication [13], describing this research, elicited little interest until more than two decades later, when Barnett Rosenberg serendipitously discovered the antitumor activity of the related *cis*-$[PtCl_2(NH_3)_2]$ (cisplatin), still one of the most widely used anti-cancer drugs [14].

Bailar suggested that Fred finish his research in three years so that he would not be drafted and have to return to Illinois to receive his degree. Fred received his M.S. degree in 1942 and his Ph.D. degree the following year at age 23. He spent three years working on classified research on zirconium fire retardants and mica substitutes at Rohm & Haas Co. in Bridesburg near Philadelphia.

3. University career, marriage, and sabbaticals

In the fall of 1946 Fred accepted a position as Instructor of Chemistry at Northwestern University (NU) in Evanston, Illinois, a Chicago suburb. He married Mary Nutely on June 14, 1947. Their long, happy marriage resulted in three daughters and a son, all of whom became educators and presented the Basolos with 11 grandchildren.

A Guggenheim fellowship enabled the Basolos to spend a year (1954–1955) in Copenhagen, where Fred worked in the laboratory of Jannik Bjerrum [15], whose dissertation popularized the term ligand [16]. They also visited other European countries, including Italy, where they visited Fred's relatives. An enthusiastic golfer, Fred took the opportunity of their time in Scotland to play at the famous course in St. Andrews.

During his Copenhagen year Fred wrote several chapters of the book that was to make an international scientific reputation for him and his NU colleague Ralph G. Pearson, later of hard and soft acid and base (HSAB) fame. Their classic monograph, "Mechanisms of Inorganic

Reactions'' [17], which became the ''Bible of inorganic mechanisms,'' introduced crystal field theory to chemists and showed its ability to explain the properties of coordination compounds and the kinetics and mechanisms of their redox and ligand substitution reactions.

Fred and Mary spent four days during the summer of 1955 at the 3rd International Conference on Coordination Chemistry (3 ICCC) at Amsterdam, where Fred heard the plenary lecture by Technische Universität München's Walter Hieber, the ''father of metal carbonyl chemistry''. In response to Fred's question about the mechanisms involved in the synthesis and reactions of these compounds, Hieber answered him, ''We do chemistry in my laboratory, not the philosophy of chemistry'' [9, p. 101]. Fred realized that here was a neglected field for him and his students to explore.

Fred's doctoral students Andrew J. Wojcicki and Harry B. Gray handled the problem of dealing with toxic metal carbonyls by keeping Linus, a canary who was supposedly more sensitive to fumes than humans, in a cage in the laboratory. Linus died, and his successor, a parakeet named Torpedo, pecked Gray and infected him with parrot fever (psittacosis), from which he recovered quickly, thanks to an early diagnosis and expert care given by the physicians at the Northwestern health center.

The Basolos spent Fred's second sabbatical year, 1961–1962 (he was a Senior NSF Fellow), at Vincenzo Caglioti's institute at the Università di Roma. Fred invited Anthony J. Poë, on his first sabbatical leave from Imperial College, London, to oversee his research group of a dozen graduate students. Poë worked with Fred's student John L. Burmeister on his discovery of linkage isomers of L_nM-NCS and L_nM-SCN [18], the first case of linkage isomerism [19] since Sophus Mads Jørgensen's discovery of the xantho (nitro) ($[Co(NO_2)(NH_3)_5]Cl_2$) and isoxantho (nitrito) $[Co(ONO)(NH_3)_5]Cl_2$ pentaammines of cobalt(III) [20]. Burmeister described the discovery:

> The genesis of this paper [19] may be traced to the moment in 1963 when, hunched over an IR spectrophotometer in a laboratory in Northwestern University's Technological Institute at 1:30 a.m., I watched a pen trace the confirming evidence that I had, indeed, synthesized the first inorganic linkage isomers of the thiocyanate ion. The impacts of this discovery were both immediate and long-range: My doctoral mentor, Fred Basolo, was roused from his slumber by a telephone call to share the joy that always accompanies scientific discovery, light appeared at the end of my Ph.D. tunnel, and, given the green light by Basolo, I initiated a research program that has focused on the coordination chemistry of ambidentate ligands to this very day, some 100 research publications later [21].

During his Rome sabbatical, Fred also wrote the first two chapters of his second book, ''Coordination Chemistry'', a supplementary paperback coauthored with former student Ronald C. Johnson [22,23].

At NU Basolo rose through the ranks—Instructor (1946–1950), Assistant Professor (1950–1955), Associate Professor (1955–1958), Professor (1958–1979), and Charles E. and Emma H. Morrison Professor of Chemistry (1980–1990). He served as Chairman of the Chemistry Department from 1969 to 1972.

4. Basolo and Pearson vs. Ingold and Nyholm

During the second half of the 19th and all of the 20th century, organic chemistry flourished. However, after Alfred Werner's [24] and Sophus Mads Jørgensen's [25] pioneering work, inorganic chemistry languished in the doldrums until World War II, when what Sir Ronald S. Nyholm called the ''Renaissance of Inorganic Chemistry'' occurred [26], a rebirth in which Fred played a preeminent role.

During his work at Rohm and Haas, Fred became interested in studies of the kinetics and mechanisms of substitution reactions on carbon being carried out by organic chemists. He thought that similar studies could be carried out on inorganic coordination compounds such as those of cobalt(III) and platinum(II), with which he was already familiar. He had no experience with kinetics and mechanisms of chemical reactions, but his fellow NU Instructor and physical organic chemist Ralph G. Pearson was performing such studies with carbon compounds. In response to Fred's effort to convince him to collaborate on similar studies on coordination compounds, Ralph first replied, ''There is no interest in inorganic chemistry, so why should I waste my time studying such systems?'' [9, p. 81]. Also, no NU graduate students were interested in inorganic chemistry. Eventually, Fred succeeded in ''seducing'' Ralph into becoming a physical inorganic chemist, and their first joint paper on inorganic kinetics and mechanisms appeared in 1952 [27]. According to Fred,

> Ralph and I arrived at the right place at the right time, resulting in the publication of some 60 co-authored papers on the kinetics and mechanisms of ligand substitution of octahedral and square planar metal complexes. Neither one of us could have done what we did alone, but, by working together, we were *very* successful. The seminal results of our studies are now often used in bioinorganic chemistry research, and in studies on homogeneous catalysis [10, p. 3].

Fred and Ralph and their students discovered that the base hydrolysis of cobalt(III) complexes proceeds by an S_N1CB (substitution, nucleophilic, unimolecular, conjugate base) mechanism. Physical organic chemist Sir Christopher Kelk Ingold (1893–1970) [28], the Nobel-caliber ''high priest of organic mechanisms'', and coordination chemist Sir Ronald Sydney Nyholm (1917–1971) [29,30] – both at University College, London, countered that this view was incorrect, and they published papers stating that the correct mechanism was S_N2 (substitution, nucleophilic, bimolecular). In Fred's words,

> Had our polemic with Ingold and Nyholm, two of the giants of chemistry, not turned out in our favour, we may not have gotten tenure and our department may not now rank among the top four in inorganic chemistry in the U.S. We were very fortunate to have this exchange focus so much favorable attention on our department just at the time when inorganic chemistry in the U.S. was beginning to achieve the importance it now has [9, pp. 90–91].

Considering the significance of their long and intimate collaboration, Pearson's comments, which review the state of the art at the time, are worth quoting:

> Like many others, I owe a large debt of gratitude to Fred. In 1948 he persuaded me to join him in a study of the mechanisms of substitution reactions in coordination compounds. There was almost no work being done in this area. Henry Taube had started to do a little on redox reactions, but there were very few people doing anything that might be called physical inorganic chemistry.
>
> I had already started some work on substitution reactions in organic systems. Physical organic chemistry was already well developed, and the field was dominated by giants like Hughes and Ingold, Winstein and Bartlett. It would have been hard for me to make much of an impression on this field. But, thanks to Fred, he and I became two of the fathers of physical inorganic chemistry.
>
> Our talents were well matched. I knew a lot about studying mechanisms by means of kinetic studies. Fred also knew how to synthesize metal complexes, how to analyze them and how to identify them. We also had just enough in the way of instruments to do what we needed. These included a Cary UV–visible spectrophotometer, a conductivity bridge, and a Rudolph polarimeter.
>
> Our first student was Earl Muetterties, who was a senior at Northwestern, wanting to do some honors research. But graduate students were hard to find. Inorganic chemistry was not popular at that time. It was considered "tombstone chemistry," with a dash of sulfuric acid.
>
> But we were lucky. The atomic energy program had already put some money into the chemistry of metal ions. The success of the Russian Sputnik had increased the interest. There were AEC graduate fellowships available, and Fred and I received a $7000 grant from the AEC to support our work. Such grants were very rare in those days. But we now had graduate students, and very good ones.
>
> We were also fortunate in our choice of research problems for starters. The first, of course, was substitution reactions of octahedral cobalt(III) complexes. The choice was dictated by Fred's doctoral work with John Bailar at Illinois. Cobalt(III) complexes turned out to be the prototype systems for dissociation, or S_N1, mechanisms. We next turned to planar platinum(II) complexes, which were the prototypes for addition, or S_N2, mechanisms. The 16–18 electron rule was working!
>
> Another development in physical inorganic chemistry was happening, and helped us in our interpretation of experimental results. It also increased the interest of the wider chemical community in inorganic chemistry. This was the appearance of crystal field theory, shortly to become ligand field theory, or molecular orbital theory applied to transition metal complexes.
>
> In the 1940s and early 1950s, the theory of inorganic chemistry was dominated by Linus Pauling. His views were based on valence bond theory and mainly used hybrid orbitals and resonance structures to explain things. Actually, it did not work very well. Molecular orbital theory was much better at explanations and approximate calculations. Fred and I published the first edition of "Inorganic Reaction Mechanisms" [17] [The actual title is Mechanisms of Inorganic Reactions—GBK] in 1958. In it we had an introduction to crystal field theory. We also showed pictures of d orbitals and made three-dimensional models of them (Fig. 2).
>
> This was brand new to most chemists. As a result, Fred and I were instrumental in spreading crystal field theory into inorganic chemistry. It had a great impact, since, as one person said, "Inorganic chemistry went from crystal ball to crystal field theory".
>
> We were also lucky that C.K. Ingold and R.S. Nyholm did some work on the mechanism of substitution reactions of metal complexes. Most of what they did was wrong, but Ingold's reputation was so great that much interest in the subject was created. Chemists in other fields began to pay attention.
>
> Fred was also a great teacher. I often quipped that he was a far better teacher than I was. Over the years he taught me much inorganic chemistry, but I was never able to teach him any physical chemistry. He made many other contributions to making inorganic chemistry one of the

Fig. 2. Fred Basolo (left) and Ralph G. Pearson (right) "discover" d-orbitals.

hot research areas of chemistry. Summing up, Fred Basolo was a worthy successor to John Bailar as the Father of American Inorganic Chemistry'' [31].

Fred and Ralph's studies of ligand substitution reactions of octahedral cobalt(III) complexes, acid hydrolysis or aquation of cobalt(III) and chromium(III) metal-ammine complexes, base hydrolysis of metal-ammine complexes, linkage isomers, ligand substitution reactions of Pt(II) square planar complexes, synthetic oxygen carriers, organometallic chemistry, including the indenyl kinetic effect, and biological inorganic chemistry are true chemical classics [32].

The Chemistry Department at Northwestern University is renowned for the strong interaction between its faculty and students. The informal Saturday morning Basolo–Ibers–Pearson (BIP) meetings, where graduate students or postdoctoral fellows present their results on research in progress, are known worldwide and are visited by chemists from around the world.

5. Teaching and professional activities

Like his mentor John Bailar, Fred educated several generations of chemists (58 doctorates, 66 postdoctoral fellows, and countless bachelor's and master's degree candidates). Approximately a third of his students, inspired by his love of teaching, entered academia. The roll of his former students reads like a veritable ''Who's Who'' of inorganic chemistry and chemical education. Like Bailar's, Fred's success as a research supervisor and teacher owed as much to his enduring human qualities as to his profound chemical knowledge.

Fred's former students praise his didactic skills:

> My graduate mentor at Northwestern, Professor Fred Basolo, was a prototypical example of the Mentor Model. . .. he never dealt with us through intermediaries, save for the year he was on sabbatical leave. We discussed our research progress and problems with him on a one-on-one basis, at his behest, at least once a week. We talked about a kaleidoscope of other subjects with him as well, learning a lot about his philosophy of life, in the process. We experienced his culinary and golf skills first hand (get-togethers at his home were frequent, and I never did beat him in a round of golf). In short, he became more than a professor to us—he became a lifelong friend [33].
>
> Fred was the one that taught me how to write a scientific paper. Having taken English composition classes in high school and college, I did not really know how to write a scientific paper, which is very different from a theme for English. So, I spent weeks writing a draft of my first paper. I thought it might be a little long, but overall I was rather pleased with it. A few days after I gave it to Fred, he returned it to me without a mark on it, but it was accompanied by a large stack of yellow hand-written pages. He had rewritten the whole paper! It must have taken many hours. I do not remember talking with him about his version or my version, but I realized what was necessary to write a concise, understandable, accurate, and interesting account of my studies. When I work with my own students who are writing their first papers, I pass on the lessons that I learned from Fred. It is not always an easy process for the student or me, but my expectations for a well-written paper are exactly the same as Fred's [34].
>
> Fred was very flexible and tolerant in his way of directing his PhD students. Fred was a morning person. . ..one of his pet phrases was ''the morning is the mother of the day'', only he first said it in Italian, or more correctly Piemontese, a peasant dialect. He would be in the office at 7:00 AM 6 days a week. .. Fred gave us a long leash; we knew he was there and that he cared, but he did not get in our way of discovering new data and its meaning on our known. .. Fred was a man with an encyclopedia-like mind for chemistry, a quick smile and wink, and a hearty laugh [35].

In his graduate course on coordination chemistry Bailar had lectured on the history of the subject, and Fred condensed Bailar's lecture into a 50-minute lecture for his freshman class to illustrate how science advances. Fred presented this lecture every year for four decades to his students and worldwide to universities and high schools.

Fred was an active force in the Gordon Research Conferences, International Conferences on Coordination Chemistry (ICCC), ACS Petroleum Research Fund Advisory Board, and North Atlantic Treaty Organization (NATO). Elected to the National Academy of Sciences in 1979, he considered among his most important NAS activities his work on ''Opportunities in Chemistry'', a book colloquially known as the ''Pimentel Report'' [36,37]. Despite his numerous professional activities and his more than 380 scientific publications, he was always willing to serve as editor of journals or volumes, write letters of recommendation, award nominations, or forewords to books or monographs.

Fred made a number of speaking tours for the American Chemical Society. In 1970 he was elected Chairman of the ACS Division of Inorganic Chemistry and in 1971 a member of its Executive Committee. Although he thought that he had little chance of being elected President, he agreed to having his name proposed as a petition candidate to oppose the other two candidates loyal to the ACS establishment, who would receive all the establishment votes. To his surprise he was elected 1983 ACS President without any electioneering on his part.

As President, Fred addressed some of his longtime concerns. In his attempts to combat chemophobia he discussed environmental problems with newspaper reporters, radio talk show hosts, and television anchor persons but only if he was given equal time to present the beneficial aspects of chemicals. He also made these views known to congressmen and congressional committees. He received

the ACS George C. Pimentel Award in Chemical Education (1992), the Priestley Medal, the ACS's highest honor (2001) [38], and countless other awards and honorary degrees.

6. Foreign travel

Fred traveled to 40 foreign countries, where his zest for life and remembrance of the humble circumstances of his childhood made him take great delight in each new experience. He considered Italy a second home and traveled there "more times than I can recall" [9, p. 153], lecturing in his "bad, but amusing Italian" [9, p. 156]. He was elected an honorary member of the Società Chimica Italiana (1981) and received honorary doctorates from the Università di Torino (1987), the Università di Padova (1991), and the Università di Palermo (1997) and three Italian medals. He was elected in 1987 to the Accademia Nazionale dei Lincei (Italy's national academy of science), founded in 1603 as the world's oldest scientific society.

Fred made seven trips to China, where he met with Vice-Premier Fang-Yi (the number three governmental official), dined on delicacies like snake soup, drank mao-ti, "which had an odor of kerosene" [9, p. 163], and received an honorary doctorate and a medal. His frequent visits led a Fudan University professor to tell him, "Basolo, you are the Marco Polo of chemistry to China" [9, p. 167].

According to Fred's grandson:

> "He won many awards for his teaching and research. Interestingly, my uncle found most of my grandfather's awards in his sock drawer. My grandfather taught me that you do not hang awards in your house because your work is never more important than your family and you teach to help others and never to win awards" [11].

7. Final years

On August 17–18, 1990, Fred's 70th birthday and his retirement, financially supported by 16 corporations and societies, was celebrated by almost all of his Ph.D. students and postdocs [39]. Sufficient funds were left over from what was known as Basolo 70 (Fig. 3) so that his students and postdoctoral fellows could create an endowment to establish an annual Basolo Medal and Lecture, beginning in 1991. State Governor James Thompson proclaimed August 18, 1990 as "Fred Basolo Day in the state of Illinois".

In 1991 Fred's wife Mary underwent an emergency quadruple heart bypass, after which she began to suffer from Alzheimer's disease. One morning, while driving her to the day-care center, Fred fell asleep at the wheel, probably because of a combination of some new medications and tiredness, and their car hit a tree. Mary succumbed to her injuries and died on February 5, 1997. Five surgeries on Fred's back damaged the nerves from his brain to his legs, and he became unable to walk without two canes, and he used a motorized scooter to get around in the NU Chemistry Building. In spite of pain and shortness of breath, he went to his office every morning, had lunch with his faculty colleagues, and left in the early afternoon.

Fig. 3. George B. Kauffman (left) and Laurie M. Kauffman (right) wearing Basolo 70 T-shirts.

Despite afflictions that would have tested the patience of Job, Fred never felt sorry for himself:

> Men from my grandfather's generation also have a difficult time saying "I Love You". Ironically, it was in his final years that he helped teach the meaning of these words. This previously strong man was confined to a wheel chair. He had become thin and frail. He was unable to garden or play golf. The love of his life, Mary, who he had shared his life with had been killed in a car accident. People had to help him in and out of bed, change him, feed him, and clean him. His final years did not turn out as he had planned. Through all of this though, he never said, "Why Me?" This very strong man allowed himself to become helpless and his body to deteriorate because he knew he was providing a service to God. He was allowing God to use his body to teach the ultimate lesson. That lesson is what "I Love You" means. When my grandfather was very ill one night, I told him "I Love You", and he said, "Those sounds make me feel good." He didn't say those *words*, but those *sounds*. "I Love You" has to be more than words. It must be something we can hear, see, and feel that touches our soul [11].

8. Fred's legacy

Fred Basolo's life is an inspiring tale of an individual committed both to the practice of scientific research and to his profession. In addition to his immense contributions to chemistry, his personality, warmth, sense of humor, charm, and intense interest in people have endeared him to several generations of colleagues and students. Continually aware and proud of his roots, yet humble about his achievements, he wrote:

I can truthfully say that I marvel at what has happened to me during my life. Not in my wildest dreams could I have expected when growing up in the little mining village of Coello that, some day, I would become a successful chemist [9, p. 221].

He will be sorely missed.

$[HPO_4\{W_2O_2(\mu\text{-}O_2)_2(O_2)_2\}]^{2-}$ denoted "PW_2", etc.) [5,9]. All investigations on the mechanism of epoxidation [8,9,16] under Venturello's conditions [5] ($[MO_4]^{2-}$/$[PO_4]^{3-}$/$[H_3O]^+$/H_2O_2–H_2O/phase-transfer catalyst (PTC)/organic solvent/60 °C) and under Ishii's conditions [19–21] ($H_3[PM_{12}O_{40}]\cdot aq/H_2O_2$–$H_2O$/PTC/organic solvent/40–70 °C) indicate that the two catalyst systems involve common oxodiperoxo anions, despite the fact that each group patented its particular set of precursors as novel chemistry. Since then, additional studies support these results [22–24]. On the other hand, the first cases of oxoperoxometalates, related to the Keggin structure, have also been reported (e.g. $[(Nb^{V}O_2)_3PW_9O_{37}]^{6-}$, $[(Co^{II}O_4)\text{-}W_{11}O_{31}(O_2)_4]^{10-}$, etc.) [25–28]; they were also prepared from aqueous H_2O_2. For the silicon analogues, very drastic conditions ($[H_2O_2]/[W] \approx 8000$; 70 wt% aqueous H_2O_2) are necessary to degrade $H_4[SiW_{12}O_{40}]\cdot aq$ and to generate oxoperoxo species [8]. The corresponding silicopolyoxoperoxomolybdates or tungstates have been synthesized, but are difficult to purify [29]. Furthermore, silica and molybdenum (or tungsten) oxoperoxo moieties $\{MO(O_2)_2\}$ and/or $\{M_2O_2(\mu\text{-}O_2)_2(O_2)_2\}$ interact in aqueous acidic medium to form surface oxoperoxo species with characteristic IR and Raman bands $\tilde{\nu}$(O–O) in the 840–870 cm^{-1} range and $\tilde{\nu}_{asym}(M(O_2))$, $\tilde{\nu}_{sym}(M(O_2))$ at 600–520 cm^{-1} [30]. These observations suggest that it might be possible to synthesize low-nuclearity oxoperoxoheterosiloxanes [29,31] involving the various functionalities on the silica surface (i.e. lone (free) geminal silanols and vicinal silanols from siloxane bridges). These complexes are good models for units such as $\{MO(O_2)_2\}$, $\{M_2O_2(\mu\text{-}O_2)_2(O_2)_2\}$ grafted onto a silica surface (vide supra) via silanols. They also lead to a novel and efficient procedure for molybdenum [32] or tungsten [33,34] insertion into silica MCM-41 mesoporous molecular sieves with high metal dispersion. These syntheses avoid the formation of iso (or hetero) polyoxometalates in the counter-ion-mediated $S^+X^-I^+$ *acidic pathway* [32–34] and favour the presence of low-nuclearity oxoperoxo complexes. These moieties lead to unprecedentedly high incorporation levels [(Si:M) molar ratio ≈ 30:1) not known previously in the SiO_2–MO_3 systems, with a nearly homogeneous distribution of the "MO_x" dopants. These MO_x–SiO_2–MCM-41 are catalysts for gas- or liquid-phase reactions [32–34]. One problem is their sensitivity to the medium where they are employed: leaching of the metal-oxo species is due to nucleophilic attack of the neutral centres by solvents, water and/or reactants or products, but this can be avoided by optimized thermal or hydrothermal treatments. If the leaching problem can be overcome, the MO_x–SiO_2–MCM-41 catalysts and analogues, e.g. SBA-15 [35], etc. may have a promising future on a laboratory and even an industrial scale. To avoid or minimize leaching, a number of organosilanes can be used to generate hybrid organic/inorganic mesoporous materials either by co-condensation or grafting techniques, and thus to allow the control of the surface hydrophilic/hydrophobic balance [36], the objective being the synthesis of silica-based materials highly resistant to nucleophilic attack [37,38]. To open up new possibilities, the synthesis of their model oxoperoxo complexes in *neutral or basic medium* with $R_2Si(OR')_2$ precursors ($R_2 = (CH_3)_2$, $(i\text{-}C_4H_9)_2$ or $(CH_3)(CH_2Cl)$) was investigated. Here we report the synthesis and structural characterization of dimeric molybdenum(VI) and tungsten(VI) polyoxoperoxo complexes: $[PPh_4]_2[R_2SiO_2\{M_2O_2\text{-}(\mu\text{-}O_2)_2(O_2)_2\}]$, M = Mo, W. They not only represent a novel type of silicon-based species for oxidation catalysis, but also models for the preparation of organic/inorganic mesophases or silica-supported molybdenum oxide materials under study in our group [37,38].

2. Experimental

2.1. Materials

Molybdenum trioxide MoO_3 (Fluka) and tungstic acid formulated as $WO_3\cdot H_2O$ (Eurotungstène), 30 wt% aqueous solution of hydrogen peroxide, H_2O_2, (stabiliser: stannate; Prolabo, Aldrich), diethoxydimethylsilane (97%, Aldrich), $(CH_3)_2Si(OEt)_2$, diisobutyldimethoxysilane (97%, Lancaster), $(i\text{-}C_4H_9)_2Si(OMe)_2$, (chloromethyl)methyldiethoxysilane (97%, Lancaster), $(CH_3)(CH_2Cl)Si(OEt)_2$ and $P(C_6H_5)_4Cl$ (≥97%, Fluka) were used without further purification.

Chemical analyses were carried out by the Service Centrale d'Analyse (CNRS, Vernaison, France). All other reagents used (cyclooctene, toluene, chloroform, etc.) were analytical grade.

2.2. Crystal structure determinations: data collection and processing

All measurements were carried out at room temperature using a Enraf-Nonius CAD-4 four-circle diffractometer with graphite-monochromated Mo Kα radiation ($\lambda = 0.71069$ Å). Data were obtained with the ω–2θ scan technique. Two standard reflections showed no significant variation in intensity. Corrections were made for Lorentz and polarization effects; an extinction correction was also applied [39]; an empirical absorption correction on the basis of ψ scan data was introduced. The structures were solved by direct methods (SHELXS-86 program) [40] and subsequent Fourier difference techniques. All non-hydrogen atoms were refined anisotropically. All hydrogen atoms were found on difference Fourier maps; their positions were not refined and they were given one overall isotropic parameter. Refinements were carried out with the CRYSTALS program [41] by minimizing the function $\sum w(|F_o| - |F_c|)^2$, where F_o and F_c are the observed and calculated structure factors.

2.3. Physical measurements

The IR spectra (resolution: 2 cm^{-1}) of the solids as powders, in nujol suspension between two caesium bromide

plates or in dry potassium bromide discs, were measured at 4000–400 cm^{-1} on a Bruker Vector 22 Fourier-transform spectrometer. The ^1H and ^{13}C NMR spectra were recorded using 100 scans at room temperature on a Bruker ASX 300 apparatus, using TMS as reference. CD_3CN, provided by Euriso-top (C.E.A. France), was used as the solvent.

2.4. Syntheses of heteropolyoxoperoxoanions

MoO_3 (0.72 g; 5 mmol) ["H_2WO_4" (1.25 g; 5 mmol)] was added to a 30% solution of aqueous hydrogen peroxide (5 mL; 45 mmol). After 1 h stirring at 60 °C, the yellow [colourless] solution was cooled to room temperature [followed by centrifugation (15 min at 2000 rpm)] to give solution A.

$[PPh_4]_2[(CH_3)_2SiO_2\{M_2O_2(\mu\text{-}O_2)_2(O_2)_2\}]$ **1**: M = Mo and **2**: M = W. NaOH (5 M; 950 μL; 4.75 mmol) and $(CH_3)_2Si(OEt)_2$ (860 μL; 5 mmol) were mixed with 20 mL of ethanol and then added dropwise to solution A. The solution B thus obtained turns slightly orange (B–Mo) [colourless (B–W)] and **1** [**2**] was isolated by addition of an aqueous solution of PPh_4Cl (1.87 g; 4 mL; 5 mmol). After 15 min stirring, the yellow [white] precipitate was filtered off, washed with water (2 × 5 mL) and diethylether (2 × 5 mL), then air-dried. Yield relative to M: 2.10 g; 75% for **1** and 2.33 g; 77% for **2**. (The addition of excess sodium hydroxide would favour the undesired formation of $Na_2[M(O_2)_4]$.)

3. Results and discussion

3.1. Description of structures

According to crystal data (Table 1), chemical analyses and infrared spectra, **1** and **2**; **3** and **4**; **5** and **6** are pairs of isostructural compounds (see also supplementary materials, Table S1). Moreover, a detailed analysis of the crystal data reveals that **1** and **5** are isomorphous. The structures of the anions in complexes **1** and **3** are shown in Figs. 1 and 2 with some selected bond lengths and angles. For compounds **1**, **3** and **5**, they are compared in Table S1.

The anionic structure, in all cases, consists of an assembling anion: $[(CH_3)_2SiO_2)]^{2-}$, $[(i\text{–}C_4H_9)_2SiO_2]^{2-}$ or $[(CH_3)(CH_2Cl)SiO_2]^{2-}$ in **1**, **3** and **5**, respectively, and a dimeric moiety $\{Mo_2O_2(\mu\text{-}O_2)_2(O_2)_2\}$. Both molybdenum centres are 7-coordinated by oxygen atoms in a pentagonal bipyramidal arrangement (see Table S2 in supplementary material). These compounds, i.e. **1**–**6**, possess structures similar to that of the previously reported $[Ph_2SiO_2\{M_2O_2(\mu\text{-}O_2)_2(O_2)_2\}]^{2-}$ (M = Mo, W) complexes, prepared with the diphenylsilanediolato ligand, $[(C_6H_5)_2SiO_2]^{2-}$ [29].

Two oxygen atoms O(6) and O(7) of the $[R_2SiO_2]^{2-}$ anion are corner-sharing with the basal planes of the two different pentagonal bipyramids. The two Mo atoms are connected by two μ_2–η^1:η^2-peroxo bridges [O(4)–O(5) and O(9)–O(8)] also observed in several di- or tetranuclear anionic structures [5,9–11,14,15,29,42]. The two associated pentagonal bipyramids share one edge [O(5)···O(8)] on the non-basal plane. The asymmetric dimeric moiety $\{Mo_2O_2(\mu\text{-}O_2)_2(O_2)_2\}$ thus has two distinct pairs of peroxo ligands: there are both η^2- and μ_2-η^1:η^2-peroxo groups on

each metal centre. The pentagonal bipyramids of oxygen atoms surrounding the two molybdenum atoms are almost identical. Each girdle (equatorial plane) is generated by two peroxo groups, one bridging and one non-bridging, and by one oxygen atom of the $[R_2SiO_2]^{2-}$ anion. The oxygen atoms that define the equatorial plane are coplanar to

within 0.006–0.109 Å (Table S2, supplementary materials). As for the octahedral coordination in polyoxometalates and what is also observed with other silicooxoperoxometalates [29], Mo(1) and Mo(2) are located outside the mean plane defined by the five equatorial oxygen atoms (0.37 to 0.40 Å – supplementary materials, Table S2). One of the apical positions of the girdle axis is occupied by the terminal oxo-ligand, and the other by an oxygen atom of the bridging peroxo group with a rather weak and long Mo–O bond (in the range 2.416–2.502 Å for each structure – see Figs. 1 and 2 and Table S1). The non-bridging peroxo groups, [O(2)–O(3) and O(10)–O(11)], are symmetrically coordinated to the Mo atom; the Mo–O distances are nearly equal and correspond to classical single Mo–O bonds (1.911–1.934 Å). In contrast, the bridging peroxo groups μ_2–η^1:η^2 O(5)–O(4) and O(8)–O(9) are dissymmetrically coordinated to Mo(1) and Mo(2), resulting in relatively long Mo(1)–O(5) and Mo(2)–O(8) bonds (1.986–2.006 Å) as expected, and in a shorter bond with the second oxygen atom (1.903–1.934 Å). In all cases, the O–O distances correspond to a classical peroxo bond (1.464–1.483 Å). For instance, in the $[Ph_2SiO_2\{M_2O_2(\mu\text{-}O_2)_2(O_2)_2\}]^{2-}$ anion, the O–O bond lengths were in the range 1.468–1.481 Å [29].

3.2. Infrared spectroscopy

The IR spectra (Fig. 3; Table 2) of complexes **1**–**6** show features comparable to those observed for all other dinuclear species [9–11,29] and support the proposal of isostructural compounds (vide supra). In addition, a band near 1582–1584 cm^{-1} is assigned as $\tilde{\nu}(C\text{–}C)_{arom}$ of the cation and a very sharp band at 1106–1109 cm^{-1} as an in–plane deformation of the phenyl ring with some $\tilde{\nu}$(Si–C) character [29–31]. Consistent with the structural data, there are two strong $\tilde{\nu}$(M=O bands at 971 and 958 cm^{-1} for **1**, at 984 and 964 cm^{-1} for **2**, at 963 and 948 cm^{-1} for **3** and at 973 and 958 cm^{-1} for **4**. For $[(CH_3)(CH_2Cl)SiO_2\{M_2O_2(\mu\text{-}O_2)_2(O_2)_2\}]$ only one very strong maximum at 966 cm^{-1} for M = Mo (**5**) and 971 cm^{-1} for M = W (**6**) can be attributed unambiguously. Si–O stretches appear in the 916–938 cm^{-1} region as very strong maxima for all compounds. Bands at about 865 cm^{-1} for the heteropolyoxoperoxomolybdate anions and near 840 cm^{-1} for tungsten analogues are assigned to $\tilde{\nu}$(O–O) of the peroxo ligands, and bands around 575 and 525 cm^{-1} are assigned to asymmetric and symmetric [$M(O_2)$] stretches, respectively.

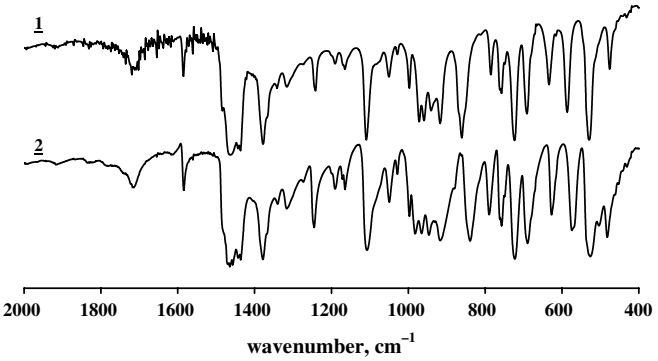

Fig. 3. IR spectra (nujol mull) of $[PPh_4]_2[(CH_3)_2SiO_2\{Mo_2O_2(\mu\text{-}O_2)_2(O_2)_2\}]$ (**1**) and $[PPh_4]_2[(CH_3)_2SiO_2\{W_2O_2(\mu\text{-}O_2)_2(O_2)_2\}]$ (**2**).

4. Conclusion and prospectives

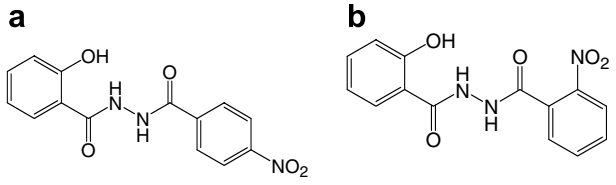
The organosilicate derivatives reported here are structurally related to hydrogenophosphate [9], hydrogenoarsonate [10], sulfate [11], diphenylsilanediolato [29], etc. analogues which belong to a family which is now significantly extended. The chemistry of metallasiloxanes derived from silanediols, disiloxanediols and related Si–OH species is an area of active research, because such compounds are valuable precursors for metal oxides and silicates, and are models for silica-supported or inserted heterogeneous catalysts [37,38]. Novel organically modified silicates have been prepared under alkaline conditions, by direct reaction of $R_2Si(OR')_2$ and oxoperoxo moieties $\{MO(O_2)_2\}$ and/or $\{M_2O_2(\mu\text{-}O_2)_2(O_2)_2\}$ ($R_2 = (CH_3)_2$, $(i\text{-}C_4H_9)_2$ or $(CH_3)(CH_2Cl)$; $R' = CH_3$ or C_2H_5, M = Mo(VI) or W(VI)).

Table 2
Vibrational spectroscopic characteristics (cm^{-1}) of oxodiperoxo complexes **1**–**6** and of three other model complexes

Complexes		$\tilde{\nu}$(M=O)	$\tilde{\nu}$(O–O)	$\tilde{\nu}_{asym}[M(O_2)]$	$\tilde{\nu}_{sym}[M(O_2)]$	Other bands[a]
$[PPh_4]_2[(CH_3)_2SiO_2\{Mo_2O_2(\mu\text{-}O_2)_2(O_2)_2\}]$	**1**	971vs				
		958vs	868vs	585s	528vs	916 $\tilde{\nu}$(Si–O); 1108 $\tilde{\nu}$(Si–C)
$[PPh_4]_2[(CH_3)_2SiO_2\{W_2O_2(\mu\text{-}O_2)_2(O_2)_2\}]$	**2**	984vs				
		964vs	838vs	573s	525vs	916 $\tilde{\nu}$(Si–O); 1106 $\tilde{\nu}$(Si–C)
$[PPh_4]_2[(i\text{-}C_4H_9)_2SiO_2\{Mo_2O_2(\mu\text{-}O_2)_2(O_2)_2\}]$	**3**	963vs				
		948vs	866vs	584s	526vs	918 $\tilde{\nu}$(Si–O); 1109 $\tilde{\nu}$(Si–C)
$[PPh_4]_2[(i\text{-}C_4H_9)_2SiO_2\{W_2O_2(\mu\text{-}O_2)_2(O_2)_2\}]$	**4**	973vs				
		958vs	848vs	572s	527vs	918 $\tilde{\nu}$(Si–O); 1108 $\tilde{\nu}$(Si–C)
$[PPh_4]_2[(CH_3)(CH_2Cl)SiO_2\{Mo_2O_2(\mu\text{-}O_2)_2(O_2)_2\}]$	**5**	966vs	866vs	585s	525vs	933 $\tilde{\nu}$(Si–O); 1106 $\tilde{\nu}$(Si– C)
$[PPh_4]_2[(CH_3)(CH_2Cl)SiO_2\{W_2O_2(\mu\text{-}O_2)_2(O_2)_2\}]$	**6**	971vs	841vs	580s	525vs	938 $\tilde{\nu}$(Si–O); 1107 $\tilde{\nu}$(Si–C)
$(NBu_4)_2[HPO_4\{W_2O_2(\mu\text{-}O_2)_2(O_2)_2\}]$ [9]		983vs	843vs	569s	517vs	1021; 995 $\tilde{\nu}(PO_4)$
$(NHex_4)_3[PO_4\{W_2O_2(\mu\text{-}O_2)_2(O_2)_2\}_2]$ [42]		974vs	845vs	577s	521vs	1084; 1053 $\tilde{\nu}(PO_4)$
$(NHex_4)_3[PO_4\{Mo_2O_2(\mu\text{-}O_2)_2(O_2)_2\}_2]$ [42]		962vs	868vs	590s	542vs	1069; 1040; 1025 $\tilde{\nu}(PO_4)$

[a] $\tilde{\nu}$(Si–O) with a possible contribution of M–O–Si vibration. $\tilde{\nu}$(Si–C) with a possible contribution of $\delta(C\text{–}C)_{arom}$ of the phenyl ring.

The dimers thus characterized, $[PPh_4]_2[R_2SiO_2\{M_2O_2(\mu\text{-}O_2)_2(O_2)_2\}]$, confirm the ability of peroxo ligands to adopt a η^2-bidentate or a bridging unsymmetrical (μ_2-η^2:η^1) role and the ability of disilanol precursors to act as assembling ligands. As in our previous studies [29–31], the alcoholic solvents containing water and hydrogen peroxide provide an environment that promotes the synthesis of low-nuclearity species, even in alkaline hydrogen peroxide (this work), which would favour the formation of $[M(O_2)_4]^{2-}$. These structures would explain the spectroscopic, physical and chemical observations which are involved in the synthesis of organic/inorganic mesophases. Preliminary catalysis tests with not-too-demanding substrates give results poorer than those of the phosphate- or sulfate-based systems [5,9,42–46]. They illustrate the dramatic effects of the assembling ligand, the difficulty encountered in epoxidation with conventional chlorides as phase transfer catalysts and the deleterious effect of sodium chloride, which significantly slows the reaction [46]. The operating conditions of several phase transfer catalysis systems with different anionic mono- to tetranuclear species must be carefully optimized with more demanding alkenes which are of interest in our group as well as the fluxionality of highly active species [22,47]. Catalysis data will be presented later in a fuller report, devoted to comparative studies on d^0 transition metal-based systems and lacunary silicotungstate compounds.



Appendix A. Supplementary material

CCDC 195087, 195088 and 195089 contain the supplementary crystallographic data for **1**, **3** and **5**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2007.06.007.

Scheme 1. Ligands H_3-*o*-nbzshz (a) and H_3-*p*-nbzshz (b).

$Ni_3(shi)_2(Hpko)_2(py)_2$, $[Ni_3(L^2)_2(OAc)_2(MeOH)(H_2O)][BF_4]_2$ and $[Ni_3(oxen)_2(en)][ClO_4]_2$ are reported in the literature [17–19]. Herein, we wish to report the synthesis and crystal structures of three novel trinuclear complexes $[Zn_3(p\text{-nbzshz})_2(C_5H_5N)_4]_n$ (**1**), $Ni_3(p\text{-nbzshz})_2(py)_4$ (**2**) and $Ni_3(o\text{-nbshz})_2(DMF)_2((CH_3)_2O)_2$ (**3**) with two new ligands *N*-*p*-nitrobenzoylsalicylhyldrazidate (H_3-*p*-nbzshz) (Scheme 1a) and *N*-*o*-nitrobenzoylsalicylhydrazidate (H_3-*o*-nbzshz) (Scheme 1b). Complex **1** is the first example of a zinc(II) complex which exhibits a one-dimensional extended polymeric chain structure constructed by *N*-acyl-salicylhydrazides ligands. Complex **2** is the only uncommon bent trinuclear nickel complex with a *N*-acyl-salicylhydrazide, whilst the three nickel atoms in complex **3** are arranged in a strictly linear fashion.

2. Experimental

2.1. General

All reagents for the syntheses were obtained commercially with analytical grade and were used without further purification. Elemental (C, H, N) analysis data were obtained with a Perkin–Elmer Model 240C elemental analyzer. Infrared spectra were collected on an AVATAR 360 FT-spectrometer in the range 4000–400 cm^{-1} (KBr pellets). TG analysis was performed on a Perkin–Elmer DF40 instrument in flowing N_2 with a heating rate of 10 °C min^{-1}.

2.2. Syntheses of the ligands and metal complexes

2.2.1. *N-p-nitrobenzoylsalicylhydrazidate (H_3-p-nbzshz)*

4-Nitro-benzoylchloride (3.10 g, 16.7 mmol), *p*-nitrobenzoic acid (2.78 g, 16.7 mmol), NaOH (0.668 g, 16.7 mmol) and a little tetrabutylammonium bromide were added to chloroform (60 mL). The mixture was filtered after stirring for 4 h at 0 °C. Then salicylhydrazide (4.24 g, 27.7 mmol) was added to the filtrate and it was slowly warmed to room temperature. A light yellow precipitate was obtained and rinsed with chloroform and diethyl ether (yield 1.85 g, 44.37%). Mp: 187–190 °C. *Anal.* Calc. for $C_{14}H_{11}N_3O_5$: C, 55.82; H, 3.68; N, 13.95. Found: C, 55.98; H, 3.46; N, 13.85%. IR (KBr, cm^{-1}): ν(O–H) 3261.64(s), ν(C=O) 1648.04(m), ν_s(>C=N–N=C<) 1614.26(vs), ν_{as}(–NO_2) 1522.90(s), ν_s(–NO_2) 1346.26(s), δ(N–H) + ν(C–N) or ν(C=C) 1507.97(s), ν(C=N) + δ(N–H) 1315.39(m), ν(ArC–O) 1237.52(m).

2.2.2. *N-o-nitrobenzoylsalicylhydrazidate(H_3-o-nbzshz)*

o-Nitrobenzoic acid (1.85 g, 11.1 mmol), 2-nitrobenzoyl chloride (2.07 g, 11.1 mmol) and NaOH (0.445 g, 11.1 mmol) were added to chloroform (60 mL). The mixture was filtered after stirring at 0 °C for half an hour. Then salicylhydrazide (4.24 g, 27.9 mmol) was added to the filtrate to give a light yellow precipitate, which was collected and rinsed with chloroform and diethyl ether (yield 1.60 g, 57.68%). *Anal.* Calc. for $C_{14}H_{11}N_3O_5$: C, 55.82; H, 3.68; N, 13.95. Found: C, 55.88; H, 3.38; N, 13.76%. Mp: 205–207 °C. IR (KBr, cm^{-1}): ν(O–H) 3175.22(s), ν(C=O) 1675.24(w), 1640.68(s), ν_s(>C=N–N=C<) 1608.56(vs), ν_{as}(–NO_2) 1529.39(s), ν_s(–NO_2) 1350.43(s), δ(N–H) + ν(C–N) or ν(C=C) 1562.08(vs), ν(C=N) + δ(N–H) 1308.07(m), ν(ArC–O) 1240.37(m).

2.2.3. *$Zn_3(p\text{-nbzshz})_2(C_5H_5N)_4$ (1)*

A DMF (10 mL) solution of H_3-*p*-nbzshz (0.075 g, 0.25 mmol) was added to a pyridine solution (5 mL) of $Zn(OAc)_2 \cdot 4H_2O$ (0.055 g, 0.25 mmol). The resulting solution was filtered after stirring for 10 min. Orange block crystals were obtained from the filtrate after standing for 10 days. *Anal.* Calc. for $Zn_3(C_{14}H_8N_3O_5)_2(C_5H_5N)_4$: C, 51.99; H, 3.27; N, 12.63. Found: C, 52.18; H, 3.15; N, 12.26%. IR (KBr, cm^{-1}): ν_s(>C=N–N=C<) 1599.13(s), ν_{as}(–NO_2) 1521.25(vs), ν_s(–NO_2) 1343.41(s), ν(C=N) 1545.99(m), ν(C–O) 1399.24(s), ν_s(ArC–O) 1236.63(m), ν(M–O) 593.53(w), 523.55(w), ν(M–N) 471.05(w).

2.2.4. *$Ni_3(p\text{-nbzshz})_2(C_5H_5N)_4$ (2)*

A DMF (10 mL) solution of H_3-*p*-nbzshz (0.075 g, 0.25 mmol) was added to a methanol solution (5 mL) of $Ni(OAc)_2 \cdot 4H_2O$ (0.062 g, 0.25 mmol). The resulting solution was filtered after stirring for 10 min. Crystals were obtained from the filtrate after standing for 4 days. The red block crystals were recrystallized form DMF/pyridine (1:1). *Anal.* Calc. for $Ni_3(C_{14}H_8N_3O_5)_2(C_5H_5N)_4$: C, 52.94; H, 3.33; N, 12.86. Found: C, 53.25; H, 3.01; N, 12.58%. IR (KBr, cm^{-1}): ν_s(>C=N–N=C<) 1600.28(s), ν_{as}(–NO_2) 1518.94(vs), ν_s(–NO_2) 1339.42(s), ν(C=N) 1565.29(s), ν(C–O) 1418.18(s), ν_s(ArC–O) 1265.03(w), ν(M–O) 598.52(w), 540.52(w), ν(M–N) 471.05(w).

2.2.5. *$Ni_3(o\text{-nbzshz})_2(C_3H_7NO)_2(C_2H_6O)_2$ (3)*

A DMF (10 mL) solution of H_3-*o*-nbzshz (0.075 g, 0.25 mmol) was added to a methanol solution (5 mL) of $Ni(OAc)_2 \cdot 4H_2O$ (0.062 g, 0.25 mmol). The resulting solution was filtered after stirring for 10 min. Red block crystals were obtained from the filtrate after 40 days. *Anal.* Calc. for $Ni_3(C_{14}H_8N_3O_5)_2(C_3H_7NO)_2(C_2H_6O)_2$: C, 45.15; H, 4.19; N, 11.08. Found: C, 45.08; H, 3.98; N, 11.48%. IR (KBr, cm^{-1}): ν(C=O) 1653.26(vs), ν_s(>C=N–N=C<) 1600.09(s), ν_{as}(–NO_2) 1526.86(s), ν_s(–NO_2) 1336.56(m), ν(C=N) 1569.52(s), 1553.67(s), ν(C–O) 1412.35(s), δ(N–H) + ν(C–N) 1386.72(m), ν_s(ArC–O) 1263.35(m), ν(M–O) 589.60(w), 547.08(w), ν(M–N) 493.59(w).

2.3. X-ray crystallographic studies

Suitable crystals of the three title compounds were mounted on glass fibers. The data were recorded on a Rigaku Weissenberg IP diffractometer with graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å), the scan mode being ω. The structures were solved by direct methods and refined by full-matrix least-squares. All the non-hydrogen atoms were refined with anisotropic thermal parameters. Most of the hydrogen atoms were found from the difference Fourier syntheses and geometrical calculation. All calculations were performed on a Pentium IV PC computer with the SHELXL-97 program package.

Crystallographic data are summarized in Table 1. Selected bond lengths and angles for complexes **1**–**3** are listed in Tables 2–4.

3. Results and discussions

3.1. Description of the structures

3.1.1. $[Zn_3(p\text{-nbzshz})_2(C_5H_5N)_4]_n$ (1)

Complex **1** is composed of three Zn^{II} atoms, two *p*-nbzshz^{3-} ligands and four pyridine molecules, as shown in Fig. 1 It is the first trinuclear zinc(II) complex with a *N*-acyl-salicylhydrazide ligand. The central Zn(2) atom is located on a crystallographic twofold rotation axis. It is coordinated by two *p*-nbzshz^{3-} ligands through the carbonyl oxygen atoms in *trans* positions [O(2)–Zn(2)–O(2B) 179.8(1)°], two hydrazine nitrogen atoms in *cis* positions [N(2)–Zn(2)–N(2B) 103.1(1)°] and two pyridine molecule *cis* to each other [N(5)–Zn(2)–N(5B) 84.3(1)°]. This N_4O_2 donor set forms a distorted octahedral coordination geometry around the Zn(2) atom. The Zn(2)–O(carbonyl) and Zn(2)–N(hydrazide) bond distances are 2.042(2) Å and 2.149(2) Å, respectively, and Zn(2)–N(py) length is 2.233(2) Å. The Zn(1) and Zn(1B) atoms have a distorted square pyramidal geometry. The basal plane of the square pyramid [root mean square (r.m.s.) deviation 0.1390 Å] is comprised of two phenolic oxygen atoms of two different *p*-nbzshz^{3-} ligands, one carbonyl oxygen atom and one hydrazine nitrogen atom from one *p*-nbzshz^{3-} ligand, and the axial coordination site is occupied by one pyridine ligand with a Zn(1)–N(4) bond distance of 2.080(2) Å. The Zn(II) deviates from the basal mean equatorial plane of the square pyramid towards the apical N(4) atom by 0.4568 Å.

The triply deprotonated *p*-nbzshz^{3-} ligand of compound **1** bridges the neighboring Zn^{2+} cations through its hydrazide N–N group, forming trinuclear zinc units with neighboring Zn···Zn interatomic distances of 4.6958(3) Å. The arrangement of three Zn atoms is slightly curved, with the Zn(1)–Zn(2)–Zn(1B) angle being 146.92°, which is larger than that reported for the trinuclear $Zn_3(2\text{-CEQ})_6 \cdot 2H_2O$ (2-CEQ = 2-[2-(4-cyanophenyl)ethenyl]-8-quinolinolato) (109.2°) [20]. The most remarkable characteristic of this compound is that the adjacent trinuclear zinc units, related by a crystallographic center of symmetry, are linked by two phenolic oxygen atoms of two ligands to form one dimensional wave-like chain structure, as shown in Fig. 2. The bridge is asymmetric and the Zn(1)–O(1) bond [2.082(2) Å] is longer than the Zn(1)–O(1A) bond [2.028(1) Å]. The Zn(1)–O(1)–Zn(1A) bridging angle is 99.53(6)° and the four atoms of the $Zn_2(\mu_2\text{-O})_2$ ring are coplanar with a mean deviation of 0.00 Å from the plane. Di- or poly-nuclear species have been reported for bridging deprotonated phenol groups with two zinc ions [21–24], but a one-dimensional chain structure is rarely reported [25].

3.1.2. $Ni_3(p\text{-nbzshz})_2(py)_4$ (2)

Complex **2** was synthesized from $Ni(OAc)_2 \cdot 4H_2O$ and *N*-*p*-nitrobenzoylsalicylhydrazidate as a ligand in mixed solvents. As illustrated in Fig. 3, the coordination geometry of Ni(2) is octahedral and those of Ni(2) and Ni(3) are square planar. The Ni(2) atom is bound to two carbonyl oxygens, O(2), O(7), two hydrazine nitrogens, N(2), N(5), of two ligands and two nitrogen atoms, N(8), N(9), of solvent pyridine. O(2) is *trans* to O(7) [O(2)–Ni(2)-O7 177.4(2)°], N(2) is *cis* to N(5) [N(2)–Ni(2)–N(5) 82.2(3)°] and N(8) is *cis* to N(9) [N(8)–Ni(2)–N(9) 87.4(3)°]. The

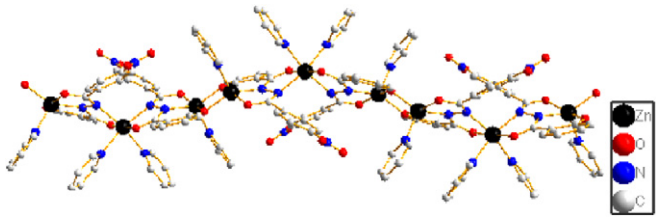

Fig. 2. A view showing the one dimensional wave-like structure of complex $[Zn_3(C_{14}H_8N_3O_5)_2(C_5H_5N)_4]_n$ (**1**).

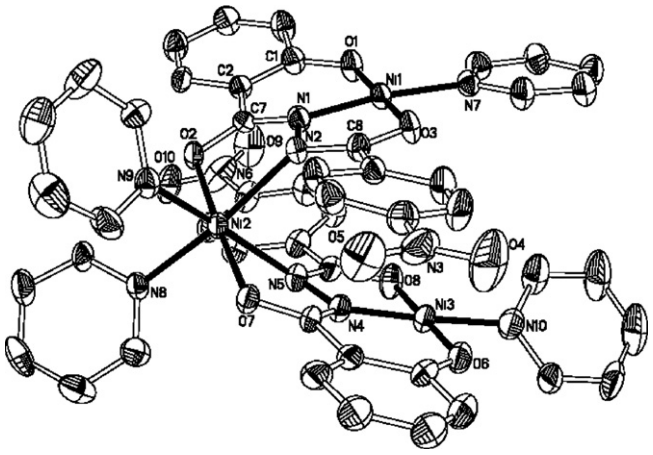

Fig. 3. Molecular structure of $Ni_3(p\text{-nbzshz})_2(C_5H_5N)_4$ with the atom-labelling scheme. Non-hydrogen atoms are represented by their 30% probability thermal ellipsoids.

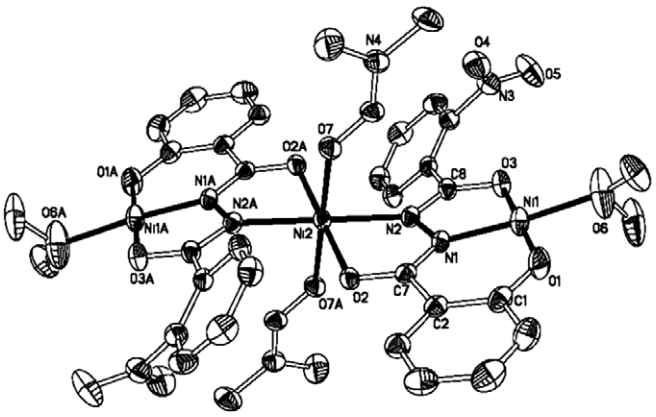

Fig. 4. Molecular structure of $Ni_3(o\text{-nbzshz})_2(DMF)_2((CH_3)_2O)_2$ with the atom-labelling scheme. Non-hydrogen atoms are represented by their 30% probability thermal ellipsoids. Symmetry operation used to generate equivalent atoms: (A) $-x, -y+1, -z+1$.

bond angles above are similar to the corresponding values of 179.8(1)°, 103.1(1)° and 84.3(1)° in complex **1**, but different from those in related complexes [7] which are all close to 180°. The average deviation from the mean plane defined by the N(5)N(9)O(2)O(7) and N(2)N(8)N(5)N(9) sets of atoms is 0.0233 Å and 0.2507 Å, respectively.

For two equivalent Ni(1) and Ni(3) atoms, the regular square planar geometry is realized with carbonyl oxygen, hydrazine nitrogen, phenolic oxygen and pyridine nitrogen atoms. The Ni–N and Ni–O bond distances for Ni(1), Ni(3) atoms (on average, 1.875 Å and 1.839 Å, respectively) are shorter than the corresponding bond lengths of the Ni(2) atom (on average, 2.134 Å and 2.015 Å, respectively). This difference may be attributed to the difference in stereochemistry between the central and terminal Ni^{2+} atoms (octahedral versus square-planar).

The array of three nickel atoms in trinuclear complex **2** is bent with a dihedral angle Ni(1)–Ni(2)–Ni(3) of 62.36°, which is larger than that of the corresponding values of 46.50° in the bent trinuclear Ni(II) complex with a different ligand [17], smaller than the corresponding values of 130.9° and 119.0° in the other two bent trinuclear Ni(II) complex with different ligands [18,19] and is very different from that in other trinuclear nickel complexes [7] with linear metal assemblies. The neighboring Ni···Ni interatomic distances are 4.507(2) Å and 4.557(2) Å, respectively, which are shorter than those in related complexes [7]. The Ni(1)···Ni(3) separation is 4.693 Å, longer by 1.2 Å than that (3.56 Å) reported for the similar bent configuration [17].

3.1.3. $Ni_3(o\text{-nbshz})_2(DMF)_2((CH_3)_2O)_2$ (**3**)

The linear trinuclear structure of complex **3** with a different ligand *N*-*o*-nitrobenzoylsalicylhydrazidate is shown in Fig. 4. The coordination geometry of the three Ni atoms follows a square-planar/octahedral/square-planar mode. The molecule exhibits crystallographic centrosymmetry. The Ni(2) atom, on a symmetry center, is coordinated by the carbonyl oxygen atoms and the hydrazine nitrogen atoms of two ligands and the oxygen atoms of two DMF molecules, giving an all-*trans* octahedral adduct. The two carbonyl oxygen atoms (Ni–O 2.015(2) Å) and the two hydrazine nitrogen atoms (Ni–N 2.068(2) Å) make up a square plane, and two oxygen atoms of two DMF molecules occupy the apical positions with longer distances (Ni–O 2.151(2) Å). The coordination bond angles involving the equivalent *trans* ligands are 180° by symmetry, which is different from that in complex **2**.

For Ni(1) and Ni(1A), the other hydrazine nitrogen (Ni–N 1.824(2) Å), carbonyl oxygen (Ni–O 1.851(2) Å) and phenolic oxygen (Ni–O 1.815(2) Å) of one ligand and methyl ether oxygen atom (Ni–O 1.952(3) Å) form a square plane. The average deviation from the mean plane is 0.0274 Å and the nickel atom is 0.0067 Å out of this plane. The bond distances are normal and are similar to those found in complex **2**, The neighboring nickel distance of 4.5573(4) Å is almost identical with that determined for complex **2**.

3.2. TG analysis of the complexes

The TG curves of compounds **1** and **2** exhibit three steps of weight losses. The first weight loss is 15.73% from 46 to 214 °C and the second is 13.11% in the range 214-363 °C for compound **1**. For compound **2**, the first weight loss is 12.20% in the temperature range 121–232 °C and the second is 13.95% between 232 and 364 °C. Both weight losses are all assigned to the removal of four pyridine molecules. The observed total weight losses in the first and second step (28.84% and 26.15%) are in agreement with the calculated values (28.49% and 29.01%) for the two compounds, respectively. The four pyridine molecules decompose in two steps, which may be due to their different coordination environments. The third weight losses are 25.34% for compound **1** from 363 to 697 °C and 42.73% for compound **2** from 364 to 697 °C, which may result from the decomposition of the ligands.

4. Conclusion

In this paper, we present the syntheses and crystal structures of three trinuclear transition metal complexes with two new ligands *N*-*p*-nitrobenzoylsalicylhydrazidate and *N*-*o*-nitrobenzoylsalicylhydrazidate. Three Zn atoms in compound **1** exhibit alternating square pyramidal and octahedral geometries, while three Ni atoms in compound **2** and **3** follow a square-planar/octahedral/square-planar coordination geometry mode. Complex **1** exhibits a one-dimensional wave-like chain structure resulting from the linkage of the phenolate oxygen donor atoms of neighboring two ligands between two zinc atoms. Complex **2** exhibits a curved Ni_3 metal arrangement with a Ni(1)–Ni(2)–Ni(3) angle of 62.36°, while the three nickel atoms in complex **3** are arranged in a strictly linear fashion with an angle of 180°. It is interesting to note that the molecular structures are remarkably different with the same ligand and same coordinated solvent molecule but different bivalent transition metals in compounds **1** and **2**, while the change of the terminal group location of the ligand and different solvents also results in a remarkably different molecular configuration in compounds **2** and **3**.

minetetraacetate ion (1,3-pdta), has been used for preparation of hexadentate complexes with many metal ions [1–9]. The structural characteristics of the hexadentate $[M(1,3\text{-pdta})]^-$ (M(III) = Co [1], Cr [2], Rh [2], Fe [3] and V [4]), $[M(1,3\text{-pdta})]^{2-}$ (M(II) = Cu [5], Ni [6], Co [7], Mg [8] and Zn [9]), $[Ca(1,3\text{-pdta})(H_2O)]^{2-}$ [8] and $[Cd(1,3\text{-pdta})(H_2O)]^{2-}$ [9] complexes have been determined by single-crystal X-ray crystallography. Four out of seventeen 1,3-pdta complexes: $Na[Cr(1,3\text{-pdta})]\cdot 3H_2O$ [2], $Na[V(1,3\text{-pdta})]\cdot 3H_2O$ [4], $Na[Fe(1,3\text{-pdta})]\cdot 3H_2O$ [3b] and $K[Co(1,3\text{-pdta})]\cdot 2H_2O$ [1] have been spontaneously resolved by crystallization. Crystals of the first three complexes have been found to be isomorphic (space group $P2_12_12_1$) with those of $Na[Rh(1,3\text{-pdta})]\cdot 3H_2O$ [2] which were resolved based on different solubility of diastereomeric salt pairs using as a resolving agent $(-)_{589}$-$[Co(en)_2(ox)]Br\cdot H_2O$. In the case of $K[Co(1,3\text{-pdta})]\cdot 2H_2O$ [1] the spontaneous resolution has lead to the enantiomerically enriched product which crystallizes in space group $C222_1$ (standard setting). However, the conglomerate crystallization[1] has not been evidenced thus far neither in the case of (1,3-propanediaminetetraacetato)metal(II) [5–9] nor 1,4-bdta [1,4-butanediaminetetraacetate ion] complexes [10,11].[2]. The metal(II) ions of the ionic radii of about 0.8–0.9 Å with 1,3-pdta ligand form octahedral complexes of the $[M(H_2O)_6][M'(1,3\text{-pdta})]\cdot 2H_2O$ type (M(II), M′(II) = Mg,Cu [5a]; Mn,Cu [5b]; Mg,Ni [6]; Mg,Co [7]; Co,Co [7]; Mg,Mg [8]; Mg,Zn [9] and Zn,Zn [9]), which crystallize in the space group *Pnna*, forming the isomorphic series. The 1,3-pdta ligand with spherically symmetric metal ions of the ionic radii greater than 0.9 Å tends to form hexadentate complexes of CN higher than six, as evidenced by the crystal structures of the $[Ca(H_2O)_3Ca(1,3\text{-pdta})(H_2O)]\cdot 2H_2O$ [8] (CN = 8, space group $P\bar{1}$), and isomorphic hexaaquamagnesium(II) crystals of seven-coordinated $[Cd(1,3\text{-pdta})(H_2O)]^{2-}$ [9] and $[Mn(1,3\text{-pdta})(H_2O)]^{2-}$ [12] complexes which crystallize as dihydrates in *Pbcn* space group.

Due to the presence of the six-membered backbone diamine ring in the M-1,3-pdta system, the 1,3-pdta complexes are less strained with respect to the corresponding edta (edta = ethylenediaminetetraacetate ion) complexes [6]. The hexadentate ligand, 1,4-bdta, has lengthened diamine chain with respect to both ligands, edta and 1,3-pdta (Scheme 1), and is able to form a seven-membered backbone diamine ring upon coordination with metal ions. However, stabilization due to chelation, known as a chelate effect, is usually most pronounced for 5- and 6-membered rings. Larger rings offer a rapidly decreasing advantage for coordination to the second site [13]. This might be

n = 2: edta; *n* = 3: 1,3-pdta; *n* = 4: 1,4-bdta

Scheme 1.

one of the reasons why crystallographic results concerned with the hexadentate complexes of 1,4-bdta are rather scarce, being limited to only $[Co(1,4\text{-bdta})]^-$ [10], $[Cr(1,4\text{-bdta})]^-$ [11] and $[V(1,4\text{-bdta})]^-$ [11]. In this paper we report the syntheses of new hexadentate $[Mg(H_2O)_6][Co(1,4\text{-bdta})]\cdot 3H_2O$ (**a**) and $[Mg(H_2O)_6][Ni(1,4\text{-bdta})]\cdot 3H_2O$ (**b**) complexes, as well as the $Ba_2(1,4\text{-bdta})\cdot 2H_2O$ complex which was used for the preparation of the complexes (**a**) and (**b**). For complexes (**a**) and (**b**) we provide electronic absorption spectroscopy characterization and the description of their crystal structures. From the solutions of $[Mg(H_2O)_6][Co(1,4\text{-bdta})]\cdot 3H_2O$ (**a**) and $[Mg(H_2O)_6][Ni(1,4\text{-bdta})]\cdot 3H_2O$ (**b**), conglomerate crystallization has been observed. The incidence of conglomerate crystallization, being a subject of intense study by Bernal and co-workers [14–20], is relatively rare: to the best of our knowledge the reported crystal structures represent the first case of spontaneous resolution involving 1,4-bdta ligand and one of a few reports dealing with conglomerate crystallization of transition metal(II) complexes with N_2O_4 type of ligands [21–25].

2. Experimental

2.1. Compounds preparation

All commercially obtained reagent-grade chemicals were used without further purification.

2.1.1. Preparation of barium 1,4-butanediaminetetraacetate dihydrate, $Ba_2(1,4\text{-bdta})\cdot 2H_2O$

Monochloroacetic acid (86.00 g, 0.91 mol) was dissolved in 100 cm^3 of H_2O and cooled in an ice bath. A cooled solution of NaOH (36.40 g, 0.91 mol) in 90 cm^3 H_2O was added drop by drop, and the rate of addition was adjusted so that the temperature remained below 15 °C. To this solution, 1,4-butanediamine (17.63 g, 0.20 mol) dissolved in 50 cm^3 of H_2O was added, and the solution was allowed to stir for 10 min at 15 °C. Then, the reaction mixture was refluxed (80–90 °C) for 4 h, and an additional amount of NaOH (36.00 g, 0.90 mol) in 60 cm^3 of H_2O was added drop by drop to keep the pH in the range 7–8. The volume of the resulting solution was reduced to 200 cm^3 and the deposited NaCl was filtered out. The filtrate was heated at 90 °C and pH was adjusted to *ca.* 9, then to this filtrate a hot solution of $BaCl_2\cdot 2H_2O$ (98.0 g, 0.40 mol) in 200 cm^3 of H_2O was added. Stirring with maintenance of the temperature at 90 °C was continued for 2 h. The insoluble white precipitate of $Ba_2(1,4\text{-bdta})\cdot 2H_2O$ was collected

[1] Conglomerate crystallization is the phenomenon wherein a solution of racemate precipitates enantiomorphic crystals each of which contains exclusively a single enantiomer (homochiral crystals).

[2] The *P*1 chiral space group, assigned to $K[Cr(1,4\text{-bdta})]\cdot H_2O$ crystals [11a] has been corrected by Herbstein and co-workers [11b] to centrosymmetric $P\bar{1}$.

by filtration, washed with hot water, ethanol, then ether and air-dried. Yield was 117.20 g (93.47%). *Anal.* Calc. for Ba_2(1,4-bdta) · $2H_2O$, $C_{12}H_{20}O_{10}N_2Ba_2$ (*FW* = 626.95): C, 22.99; H, 3.22; N, 4.47. Found: C, 23.01; H, 3.01; N, 4.23%.

2.1.2. Preparation of 1,4-butanediaminetetraacetic acid, H_4 1,4-bdta · $2H_2O$

The 1,4-butanediaminetetraacetic acid ($H_4$1,4-bdta) was prepared according the procedure which is usually used for the preparation of diaminopolycarboxylic acids [26,27]. The solid Ba_2(1,4-bdta) · $2H_2O$ (46.34, 0.074 mol) was added to 1 dm^3 of water and to this suspension 2 equiv. of H_2SO_4 (147.80 cm^3 of 1 M H_2SO_4, 0.148 mol) were added. The obtained mixture was heated at 90 °C with stirring for 5 h. During this time the pH of the solution was kept constant at pH 2.0 by slow addition of 1 M H_2SO_4. The hot reaction mixture was filtered off to remove precipitated $BaSO_4$ and filtrate was evaporated to *ca.* 250 cm^3 and than left to cool at room temperature. White crystals of $H_4$1,4-bdta · $2H_2O$ were collected, washed with ethanol, and air-dried. Yield 22.40 g (85%). The crude product was recrystallized from hot water. *Anal.* Calc. for $H_4$1,4-bdta · $2H_2O$, $C_{12}H_{24}O_{10}N_2$ (*FW* = 356.33): C, 40.45; H, 6.79; N, 7.86. Found: C, 40.57; H, 6.59; N, 7.80%.

2.1.3. Preparation of hexaaquamagnesium (1,4-butanediaminetetraacetato)cobaltate(II) trihydrate, $[Mg(H_2O)_6][Co(1,4\text{-}bdta)] \cdot 3H_2O$ (**a**)

2.81 g (0.01 mol) of $CoSO_4 \cdot 7H_2O$ were dissolved in 50 cm^3 of H_2O at 70 °C. To this solution, solid Ba_2(1,4-bdta) · $2H_2O$ (6.27 g, 0.01 mol) was added and the reaction mixture was heated at 70 °C with stirring for 30 min. The precipitated $BaSO_4$ was removed by filtration. To the obtained dark-purple filtrate, 2.28 g (0.01 mol) of $MgSO_4 \cdot 6\,H_2O$ was added and heating (70 °C) was continued for 30 min. After the precipitated $BaSO_4$ was removed by filtration, to the obtained filtrate 5–6 ml of ethanol was added and the solution was left in a refrigerator overnight. The dark-purple crystals of $[Mg(H_2O)_6][Co(1,4\text{-}bdta)] \cdot 3H_2O$ were collected, washed with ethanol and air-dried. Yield was 2.80 g (50%). The complex was recrystallized by dissolving in hot water, adding of ethanol, and then cooling in a refrigerator. *Anal.* Calc. for $[Mg(H_2O)_6][Co(1,4\text{-}bdta)] \cdot 3H_2O$, $MgCoC_{12}H_{34}O_{17}N_2$ (*FW* = 561.65): C, 25.66; H, 6.10 ; N, 4.99. Found: C, 25.51; H, 6.56; N, 5.00%.

2.1.4. Preparation of hexaaquamagnesium (1,4-butanediaminetetraacetato)nickelate(II) trihydrate, $[Mg(H_2O)_6][Ni(1,4\text{-}bdta)] \cdot 3H_2O$ (**b**)

7.89 g (0.03 mol) of $NiSO_4 \cdot 6H_2O$ were dissolved in 80 cm^3 of H_2O at 80°C. To this solution an equivalent amount of solid Ba_2(1,4-bdta) · $2H_2O$ (18.81 g, 0.03 mol) was added. The obtained mixture was heated at 80°C with stirring for 3 h and then precipitated $BaSO_4$ was removed by filtration. After cooling to room temperature the filtrate was passed through a 5×60 cm column supplied with the Dowex 1-X8 (200–400 mesh) anion-exchange resin in the Cl^- form. The column was then washed with water and then eluted with 0.05 M $MgCl_2$ solution for 3 days. Only one band for a complex with 2- charge appeared. The eluate was evaporated to 5 cm^3 and desalted by passage trough a G-10 Sephadex column, with distilled water as the eluant. The eluate containing $[Mg(H_2O)_6][Ni(1,4\text{-}bdta)] \cdot 3H_2O$ complex was concentrated to a volume of 8 cm^3 and then it was left to stand in a refrigerator for several days. Blue crystals of $[Mg(H_2O)_6][Ni(1,4\text{-}bdta)] \cdot 3H_2O$ were filtered off, washed with ethanol and air-dried. Yield 2.5 g (42%). The complex was recrystallized by dissolving in hot water, and then cooling at a room temperature. *Anal.* Calc. for $[Mg(H_2O)_6][Ni(1,4\text{-}bdta)] \cdot 3H_2O$, $MgNiC_{12}H_{34}O_{17}N_2$ (*FW* = 561.43): C, 25.67; H, 6.10; N, 4.99. Found: C, 25.80; H, 6.00; N, 4.90%.

2.2. Physical measurements

The electronic absorption spectra were recorded on a Perkin–Elmer Lambda 35 spectrophotometer and for these measurements about 5×10^{-2} mol/dm^3 aqua solutions were used. Elemental microanalyses for carbon, hydrogen, and nitrogen were done by the Faculty of Chemistry, University of Belgrade.

2.3. Crystallographic data collection and refinement of the structures

Crystal data for $[Mg(H_2O)_6][Co(1,4\text{-}bdta)] \cdot 3H_2O$ (**a**) and $[Mg(H_2O)_6][Ni(1,4\text{-}bdta)] \cdot 3H_2O$ (**b**) and the parameters of data collection are summarized in Table 1. The intensity data were measured with a KM-4CCD kappa-geometry diffractometer [28] using graphite monochrommated Mo Kα radiation ($\lambda = 0.71073$ Å) at 295(2) K. The structures were solved by direct methods using SHELXS97 [29] and refined by least-squares techniques with SHELXL97 [30]. The intensity data were corrected for Lp effects, as well as, for absorption and extinction. Anisotropic thermal parameters were employed for the non-hydrogen atoms. The positions of the hydrogen atoms attached to the C-atoms were calculated at standardized distances of 0.96 Å. Water hydrogen atoms were located from difference Fourier maps but their bond distances have been standardized to a value of 0.85 Å. All hydrogen atoms were refined using a riding model with the atomic displacement parameters 30% higher than the displacement parameters for the atoms to which they are bonded. The absolute configuration of the $[Co(1,4\text{-}bdta)]^{2-}$ and $[Ni(1,4\text{-}bdta)]^{2-}$ complexes (crystals selected by chance from the optically inactive crystalline masses) was established on the basis of the Flack's absolute structure parameter [31] which refined to a value of 0.027(15) and 0.030(8), respectively, indicating that the corresponding atomic coordinates represent the correct enantiomer (Λ).

3. Results and discussion

*3.1. The crystal structures of $[Mg(H_2O)_6][Co(1,4\text{-bdta})]\cdot 3H_2O$ (**a**) and $[Mg(H_2O)_6][Ni(1,4\text{-bdta})]\cdot 3H_2O$ (**b**) complexes*

Single crystals of the complexes (**a**) and (**b**), grown from racemic solution, are isomorphic and form conglomerates, that is, the Λ and Δ enantiomers crystallize separately in space groups $P6_1$ and $P6_5$, respectively. An ORTEP drawing of the $[Mg(H_2O)_6]^{2+}$ complex cation and $[Co(1,4\text{-bdta})]^{2-}$ complex anion, possessing Λ absolute configuration at the metal center, is depicted in Fig. 1, where the numbering scheme adopted for the respective atoms is also given. As (**a**) and (**b**) form isostructural crystals, a drawing of the unit that constitutes complex (**b**) has not been provided. Selected metal-ligand bond lengths and valence angles are listed in Table 2. For the sake of comparison, the structural data for the $[Co(edta)]^{2-}$ [33], $[Co(1,3\text{-pdta})]^{2-}$ [7], $[Ni(edta)]^{2-}$ [34] and $[Ni(1,3\text{-pdta})]^{2-}$ [6] complexes are also given in Table 2.

The structural units of (**a**) and (**b**) consist of discrete $[M(1,4\text{-bdta})]^{2-}$ (M(II) = Co (**a**) and Ni(**b**)) and $[Mg(H_2O)_6]^{2+}$ octahedra, illustrated in Fig. 1, and three water solvent molecules (O6W, O7W and O8W). For the seven-membered 1,4-butanediamine ring label "B" is introduced. Two out-of-plane glycinate rings (R rings), as well as two in-plane glycinate rings (G rings) are assigned according to the notation suggested by Weakliem and Hoard [35]. The seven-membered 1,4-butanediamine ring (B ring) adopts twist-chair δ conformation (provided that the helicity is defined by the line connecting the two nitrogen

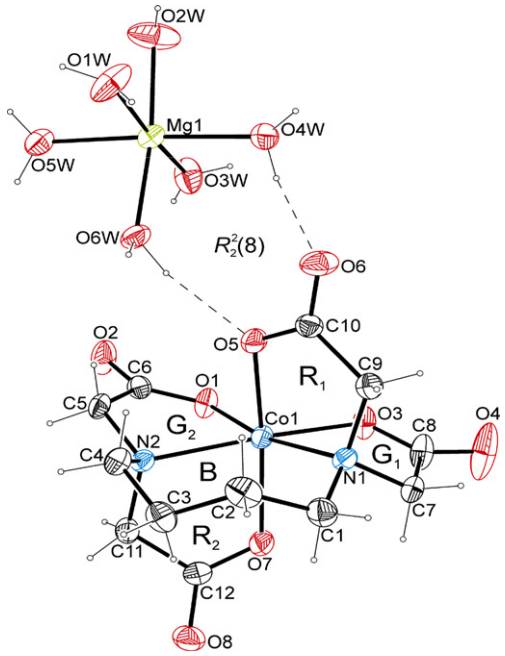

Fig. 1. Molecular structure of the complex cation and anion in $[Mg(H_2O)_6][Co(1,4\text{-bdta})]\cdot 3H_2O$ (**a**). Thermal ellipsoids are drawn at the 40% probability level. Hydrogen atoms are represented as spheres of arbitrary radius.

atoms and the line connecting the methylene carbon atoms that are directly attached to the nitrogen atoms) as expected for the Λ configuration of the complex anion. The highly puckered glycinate rings of the G type are envelopes, while the glycinates of the R type are less strained and have twist form. In $[Co(1,4\text{-bdta})]^{2-}$ and $[Ni(1,4\text{-bdta})]^{2-}$ complexes two out-of plane bond lengths ($M–O_R$) as well as two in-plane bond lengths ($M–O_G$) are comparable both within and between the two sets, whereas in $[Ni(1,3\text{-pdta})]^{2-}$ [6] and $[Co(1,3\text{-pdta})]^{2-}$ [7] complexes, which by virtue of C_2 symmetry have the two $M–O_R$ and the two $M–O_G$ distances equalized, the $M–O_R$ distances are longer than the $M–O_G$ distances. This lengthening of the $M–O_R$ bonds might be a consequence of the constraints imposed by C_2 symmetry of the complex anions. Unlike in pdta, in the asymmetric edta complexes differentiation between the two $M–O_R$ and the two $M–O_G$ distances in both Co(II) and Ni(II) series is significant, so the C_2 molecular symmetry is completely lost. One of the possible reasons why such differentiation takes place might be formation of catena structures by Co(II) and Ni(II) edta complexes and the absence of such motifs in $[M(1,3\text{-pdta})]^{2-}$ and $[M(1,4\text{-bdta})]^{2-}$ (M = Co or Ni) crystals. The mean M–N distances are nearly the same as the mean M–O distances in the $[Ni(edta)]^{2-}$ [34] and $[Ni(1,3\text{-pdta})]^{2-}$ [6] complexes, while in all other complexes listed in Table 2 the mean M–N bond lengths are significantly longer than the mean M–O bond lengths. However, while in the edta and 1,3-pdta complexes the M–N bond lengths are nearly the same in value, they become much longer (weaker) in the analogous 1,4-bdta complexes. Simultaneously, as the size of the backbone diamine ring increases, we observe a steady increase of the N–M–N bite angle. The two geometrical effects might signal an existing disadvantage for coordination to the second nitrogen atom and a consequent loss of chelating properties of the 1,4-bdta ligand, as observed in Hg(1,4-bdta complex) [36]. Unlike the N–M–N bite angle, the O–M–O open angle decreases with an increasing

size of the backbone diamine ring. In the investigated complexes (**a**) and (**b**), the octahedral O–M–O bond angles are close to the ideal value of 90° (Table 2). The two coordinated oxygen atoms (O1 and O3), situated in the girdle plane and forming the O–M–O angle of 90°, are particularly well suited to act as hydrogen bond acceptors from two water molecules (O1W and O6W) of the hexaaquamagnesium cation also situated at the right angle. The resulting supramolecular $R_2^2(8)$ motif (for description of the graph set notation see Bernstein et al. [37]) can be found in Fig. 2 (right). Constitutionally different, but topologically the same $R_2^2(8)$ motifs are also formed when two neighboring water molecules from the aqua-ion donate their hydrogens to the oxygen atoms constituting the same carboxylate group (Figs. 1 and 2 (right)). Besides, two neighboring water molecules from hexaaquamagnesium cation donate one of their hydrogens to the uncoordinated carboxylate oxygen, which results in $R_2^1(6)$ motif. The described multiple-point hydrogen bond interactions between cationic and anionic species lead to formation of the various types of ring motifs and operate within layers parallel to the symmetry equivalent sets of (1 0 0) planes. One of these layers is illustrated in Fig. 2 (right). At the interception of these ionic layers infinite channels are formed (Fig. 3a), which are filled with uncoordinated water molecules. The channels are chiral as the arrangement of all structural units within and around the channel is dictated by 6_1 screw axis (Fig. 3b). Antidromic hydrogen bonded cycles formed by two uncoordinated carboxylate oxygens (O2 and O4) and all solvent water molecules (O7W, O8W and O9W) fill the center of the channel and are connected in a spiro fashion, with O8W acting as a spiro atom and aspiring to the role of the chirality center at the supramolecular level. This is illustrated in Fig 2 (bottom), while the hydrogen bond parameters are listed in Table 3.

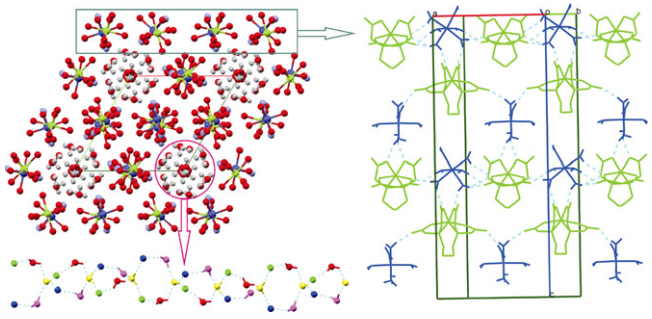

Fig. 2. View along [0 0 1] depicts chiral hydrophilic channels (encircled) and {1 0 0·} ionic layers (marked with a rectangle) in the crystal structures of complex (**a**). The layers contain alternating hydrogen bonded complex anions and cations (right), while the hydrophilic channels contain crystalline water molecules. Mono-spiro chain consisting of twelve-membered hydrogen bond rings (bottom) propagates in a helical manner along the *c*-direction.

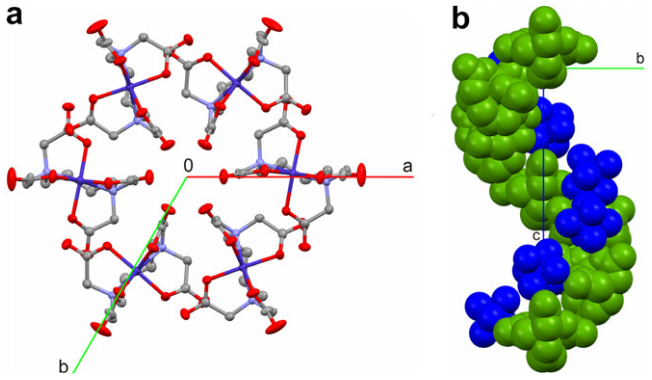

Fig. 3. (a) Top view of the water channels (water molecules not shown) illustrates the concentration of uncoordinated carboxylate oxygens on the channel's walls (b) side view of the channel depicts chiral arrangement of complex cations and anions along the channel dictated by 6_1 screw axis.

3.2. Strain analysis of Co(II)- and Ni(II)-edta-type chelates

The results of a comparative study of the strain characteristics of related series of Co(II)- and Ni(II)-edta-type chelates are given in Table 4. The major contributions to strain were considered to be: (i) the octahedral angles around the metal ion, (ii) the ring angle sums of the various kinds of rings, (iii) the M–O–C bond angles, and (iv) the bond angles that the chelating nitrogen atom makes with its connectors.

Strain-analysis data are available [6,38] for the $[Co(edta)]^{2-}$, $[Ni(edta)]^{2-}$ and $[Ni(1,3\text{-pdta})]^{2-}$ complexes. For the other complexes listed in Table 4 the corresponding data are reported in this paper. In general, the Co(II) complexes with edta-type ligands exhibit greater octahedral strain than the corresponding ones of Ni(II). The total deviation of the octahedral angles for the Ni(II) complexes varies from 60° for $[Ni(1,3\text{-pdta})]^{2-}$ to 85° for $[Ni(edta)]^{2-}$. These values are greater for a group of Co(II) complexes, and vary from 71° for $[Co(1,3\text{-pdta})]^{2-}$ to 106° for $[Co(edta)]^{2-}$. The calculated $\sum\Delta(O_h)$ values for the analyzed structures (Table 4) clearly demonstrate the effect of the diamine ring size on the octahedral distortion of the complex. The Ni(II) and Co(II) complexes with 1,3-pdta ligand are closer to the ideal octahedral geometry than those with 1,4-bdta and edta ligands. In addition, it is interesting to note that the hexadentate $[Co(1,4\text{-bdta})]^{2-}$ and $[Ni(1,4\text{-bdta})]^{2-}$ complexes containing bulky seven-membered diamine ring (5–7–5 ring system in the G plane) are less distorted than the corresponding ones of edta with the 5–5–5 ring system in an equatorial plane.

As expected, the five-membered glycinate rings of the G type are much more strained than those of the R type. The total deviation from the ideal chelate ring bond angle sum (538.5°) varies from −10° to −13° and from +1° to −4° for the G and R type of the glycinate rings, respectively.

Important source of stain in edta-type complexes is the bonding geometry made by the chelating nitrogens. Each N atom makes four bonds with six ideally 109.5° bond angles. The total deviation about the chelating N atoms

[a] Abbreviations of ligands: edta = ethylenediaminetetraacetate, 1,4-bdta = 1,4-butanediaminetetraacetate and 1,3-pdta = 1,3-propanediaminetetraacetate.
[b] $\Sigma\Delta(O_h)$ is the sum of the absolute values of the deviations from 90° of the L–M–L′ bite angles. All values rounded off to the nearest degree.
[c] $\Delta\Sigma$(ring) is the deviation from the ideal of the corresponding chelate rings' bond angle sum. A mean value of the two rings (R or G) is reported for complexes having an approx. C_2 molecular symmetry.
[d] Δ(M–O–C) (ring) is the mean value of the deviation of the corresponding rings' M–O–C bond angle from 109.5°.
[e] $\Sigma\Delta$(N) is the sum of the absolute values of the deviations from 109.5° of the six bond angles made by the nitrogen atoms. A mean value for the two nitrogens is reported.
[f] The average values are given for the two complexes: $Co[Co(1,3\text{-pdta})]\cdot 8H_2O$ and $Mg[Co(1,3\text{-pdta})]\cdot 8H_2O$ that form isomorphic crystals.

in edta and 1,4-bdta complexes varies from 21° to 23°, and from 20° to 23°, respectively, while this value for 1,3-pdta complexes sums 11°. The greatest deviation about the N atoms in edta structures is not consistently and specifically due to any one of the six bond angles. However, the considerable strain formed about the N atoms in the investigated $[Ni(1,4\text{-bdta})]^{2-}$ and $[Co(1,4\text{-bdta})]^{2-}$ structures can be attributed to the strain formed in the M–N–C(B) bond angles. Obviously, this strain could be released if the 1,4-bdta ligand, which has a relatively long chain, spanned between two different metal centers, instead of chelating only one metal center.

*3.3. Electronic absorption spectra of $[Mg(H_2O)_6][Co(1,4\text{-bdta})]\cdot 3H_2O$ (**a**) and $[Mg(H_2O)_6][Ni(1,4\text{-bdta})]\cdot 3H_2O$ (**b**) complexes*

The electronic absorption spectrum of $[Co(1,4\text{-bdta})]^{2-}$ complex is presented in Fig. 4 and for comparison in the same figure the spectrum of $[Co(1,3\text{-pdta})]^{2-}$ complex, containing six-membered 1,3-propanediamine ring in the equatorial plane [7], is also given. The electronic absorption data of these two complexes are reported in Table 5 and these data are compared with those for the $[Co(H_2O)_6]^{2+}$ complex [33a]. The electronic absorption spectra of

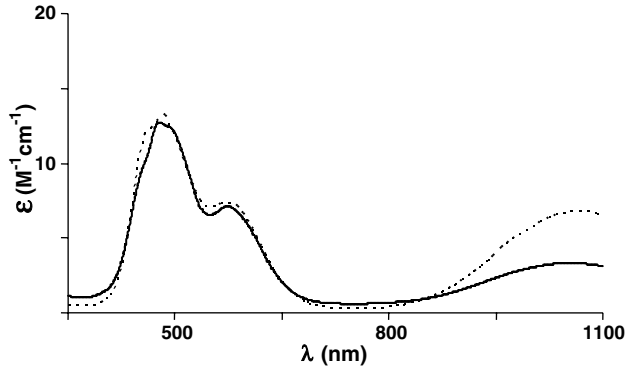

Fig. 4. Electronic absorption spectra of $[Mg(H_2O)_6][Co(1,4\text{-bdta})]\cdot 3H_2O$ (—) and $[Mg(H_2O)_6][Co(1,3\text{-pdta})]\cdot 2H_2O$ (· · · · · ·) [7] complexes.

Table 5
Electronic absorption data of $[Mg(H_2O)_6][Co^{II}(1,4\text{-bdta})]\cdot 3H_2O$. For comparison corresponding data for $[Co^{II}(H_2O)_6]^{2+}$ and $[Co^{II}(1,3\text{-pdta})]^{2-}$ complexes have been also given

Complex	Absorption		
	λ (nm)	ε (M^{-1} cm^{-1})	
$[Co^{II}(H_2O)_6]^{2+}$ [33a]	1234.0	1.4	$^4T_{1g} \rightarrow {}^4T_{2g}$
	625.0	0.3	$^4T_{1g} \rightarrow {}^4A_{2g}$
	515.0	4.9	$^4T_{1g} \rightarrow {}^4T_{1g}(P)$
	462.0(sh)		
$[Mg(H_2O)_6][Co^{II}$	1062.8	6.6	
$(1,3\text{-pdta})]\cdot 2H_2O$ [7]	572.5	7.3	
	483.0	12.9	
	460.0(sh)	11.7	
$[Mg(H_2O)_6]$	1053.1	3.5	
$[Co^{II}(1,4\text{-bdta})]\cdot$	574.0	7.4	
$3H_2O$ [This work]	487.4	13.2	
	457.2(sh)	10.2	

$[Co(1,4\text{-bdta})]^{2-}$ and $[Co(1,3\text{-pdta})]^{2-}$ complexes are similar in the shape and positions of the absorption maxima and both of these spectra with C_2 symmetry and Co^{II}–N_2O_4 chromophore of the ligand field showed similar multiplicity and band positions with those for octahedral $[Co(H_2O)_6]^{2+}$ complex with O_h symmetry assigned as: $^4T_{1g} \rightarrow {}^4T_{2g}$; $^4T_{1g} \rightarrow {}^4A_{2g}$; $^4T_{1g} \rightarrow {}^4T_{1g}(P)$ (Fig. 4 and Table 5). However, the electronic absorption spectra of $[Co(edta)]^{2-}$ [33a] and $[Co(o\text{-phdta})]^{2-}$ (*o*-phdta = *o*-phenylenediaminetetraacetate ion) [33a] complexes with the same Co^{II}-N_2O_4 chromophore as the investigated $[Co(1,4\text{-bdta})]^{2-}$ and $[Co(1,3\text{-pdta})]^{2-}$ [7] complexes, exhibit higher multiplicity and clear bands separation. This can be explained by taking into account that the 1,3-pdta- and 1,4-bdta-Co(II) systems, with flexible 1,3-propanediamine six-membered and 1,4-butanediamine seven-membered rings in the equatorial plane are less strained and much closer to the ideal octahedral configuration than $[Co(edta)]^{2-}$ and $[Co(o\text{-phdta})]^{2-}$ complexes. This has been clearly demonstrated previously by comparison of edta- and 1,3-pdta-Co(II) complexes [7], and it is additionally supported in this paper by analyzing $[Co(1,4\text{-bdta})]^{2-}$ system (octahedral strain is released in the order edta, 1,4-bdta, 1,3-pdta; see Section 3.2. and Table 4).

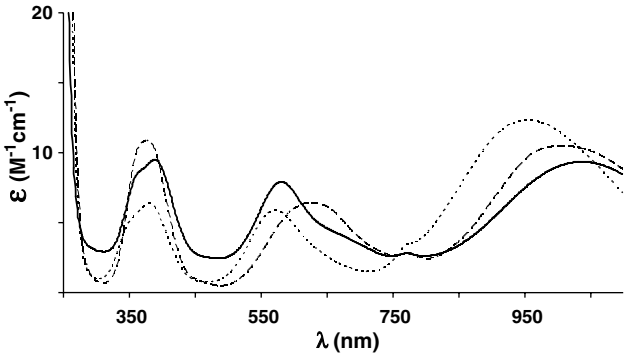

Fig. 5. Electronic absorption spectra of $[Mg(H_2O)_6][Ni(1,4\text{-bdta})]\cdot 3H_2O$ (——), $[Mg(H_2O)_6][Ni(1,3\text{-pdta})]\cdot 2H_2O$ (· · · · · ·) [6] and *trans*(O_5)-$[Ni_2(1,3\text{-pddadp})(H_2O)_4]\cdot 4H_2O$ (– – – –) [39] complexes.

The electronic absorption spectrum of $[Ni(1,4\text{-bdta})]^{2-}$ complex is given in Fig. 5. This spectrum has been compared with the corresponding spectra for $[Ni(1,3\text{-pdta})]^{2-}$ [6] and *trans*(O_5)-$[Ni(1,3\text{-pddadp})]^{2-}$ [39] complexes. The corresponding numerical data for these Ni(II) complexes are given in Table 6. The electronic absorption spectra of $[Ni(1,3\text{-pdta})]^{2-}$ [6] and *trans*(O_5)-$[Ni(1,3\text{-pddadp})]^{2-}$ [39] complexes have been previously discussed in detail and here they have only been repeated for the sake of comparison with the spectrum of $[Ni(1,4\text{-bdta})]^{2-}$ complex. In general, it has been shown, that the spectra of Ni(II)-1,3-pdta-type complexes containing the six-membered diamine ring (T ring), with respect to Ni(II)-edta-type complexes containing the five-membered diamine ring (E ring), exhibit broadening of the first absorption band located at the lowest energy due to the influence of tetragonality on the spectrochemical behavior of these complexes (D_{4h} model) [6,38,39]. In accordance to previously established results for the Ni(II)-edta-type [38] and most other Ni(II) complexes [40–44], the interpretation of the electronic absorption spectrum of $[Ni(1,3\text{-pdta})]^{2-}$ complex [6] has been done by using an octahedral model (O_h): $^3A_{2g} \rightarrow {}^3T_{2g}$ (*F*) (band I); $^3A_{2g} \rightarrow {}^3T_{1g}$ (*F*) (band III) and $^3A_{2g} \rightarrow {}^3T_{1g}$ (*P*) (band IV) (Table 6). Due to the general similarities in the shape between the electronic absorption spectra of

Table 6

	IV	376.2	13.6	
$[Mg(H_2O)_6][Ni(1,$	I	1038.7	11.7	
$4\text{-bdta})]\cdot 3H_2O$	II	771.1	3.5	
[This work]	III	581.0	9.9	
	IV	388.7(sh)	11.9	

$[Ni(1,3\text{-pdta})]^{2-}$ [6] and $[Ni(1,4\text{-bdta})]^{2-}$ complexes the same octahedral (O_h) model can be applied for interpretation of the corresponding spectrum of the examined $[Ni(1,4\text{-bdta})]^{2-}$ complex.

The shape of the electronic spectrum of *trans*(O_5)-$[Ni(1,3\text{-pddadp})]^{2-}$ is different from those for $[Ni(1,3\text{-pdta})]^{2-}$ [6] and $[Ni(1,4\text{-bdta})]^{2-}$ complexes. These differences are mainly manifested in the fourth absorption maximum located at the highest energy, where the later two complexes exhibit a tendency for splitting of this absorption band. The absence of the resolution of this absorption band for *trans* (O_5)-$[Ni(1,3\text{-pddadp})]^{2-}$ can be attributed to the fact that this complex with two 3-propionate six-membered rings in an equatorial position constitutes a less strained system than the other two complexes. Additionally, a slight difference between electronic absorption spectra of $[Ni(1,4\text{-pdta})]^{2-}$ and $[Ni(1,3\text{-bdta})]^{2-}$ complexes can be observed in Fig. 5. These differences, manifested through the broadening and splitting in the region of the fourth absorption maximum, as well as in the slight broadening and splitting in the region of the third absorption band for the electronic spectrum of $[Ni(1,4\text{-bdta})]^{2-}$ complex, can be attributed to the fact that this complex with a seven-membered 1,4-butanediamine ring (B ring) in an equatorial plane constitutes a more strained system than $[Ni(1,3\text{-pdta})]^{2-}$ complex having six-membered 1,3-propanediamine ring. The fact that $[Ni(1,4\text{-bdta})]^{2-}$ is more strained system in comparison with $[Ni(1,3\text{-pdta})]^{2-}$ complex can be notified by observing of the strain analysis data given in Table 4.

Finally, in each electronic spectrum of these three Ni(II) complexes there is a shoulder at approximately 770 nm (band II, Table 6) that occurs on the higher-energy side of the spin-allowed band. Previously, it has been discussed that this band probably arises from a spin-forbidden triplet-to-singlet transition [6,39].

4. Concluding remarks

Stereochemically labile hexadentate cobalt(II) and nickel(II) complexes with 1,4-bdta ligand have been shown to undergo a spontaneous resolution upon crystallization, an unprecedented instance with this type of ligand, and to form isostructural, high symmetry crystals. Even though the bridging 1,4-butanediamine group is longer than in other edta-like ligands and thus provides less rigidification, the metal/ligand complexation is enhanced by strong CFSE, and by topological constraints through ligand and water supramolecular structures. The geometry around the Co(II) and Ni(II) ions is flexibly changed by the chelate-ring size, as evidenced by a steady increase of N–M(II)–N and decrease of O_G–M(II)–O_G valence angles on going from E, through T to B rings. The strain of octahedral complex anion is more severe when either edta or 1,4-bdta ligand is used as compared with a less strained 1,3-pdta complex, which is reflected in their electronic absorption spectra.

Supplementary material

CCDC 636017 and 636018 contain the supplementary crystallographic data for $[Mg(H_2O)_6][Co(1,4\text{-bdta})]\cdot 3H_2O$ (**a**) and $[Mg(H_2O)_6][Ni(1,4\text{-bdta})]\cdot 3H_2O$ (**b**). These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

subject has been reviewed [10]. The SO_4^{2-} anion is the exclusive product in the oxidation with substitution inert complexes whereas both SO_4^{2-} and $S_2O_6^{2-}$ ions are the products in the oxidation by labile complexes [11]. The oxidation of S(IV) has been extensively studied mainly by one-electron oxidants[1] The oxidation by $Os(bpy)_3^{3+}$ [12], Cu(III) [13], dodecatungstocobaltate(III) [14] and Fe^{3+}(aq) [15] are sensitive to dissolved oxygen in the distilled water whereas no such effect is observed in the oxidations by alkaline MnO_4^- [16], [Mn(acac)$_3$] (Hacac = acetylacetone) [17], [Mn(III)(cydta)] [18] and in the presence of excess Fe^{3+}(aq) ion [19].

Oxidation with the Tl^{3+}(aq) ion [20] involved the formation of weak sulfite-complexes whereas the oxidation with $AuCl_4^-$ and $AuCN_2X_2^-$ (X = Cl, Br) ions [21] proceeded directly. These ions did not participate in any catalytic cycle [22,23], and a free radical chain was not initiated as in the photo induced auto-oxidation of S(IV) [24]. It was considered imperative to examine the oxidation by the $[Ag(H_2L)]^{3+}$ ion with the view of whether it binds itself with S(IV), since its electron affinity is high [25] and structurally it can have axial coordination [26] as reported in the oxidation of H_2O_2 [27] and aliphatic and aromatic alcohols [28].

2. Experimental

2.1. Materials

The orange red ethylenebis(biguanide)silver(III) nitrate, $Ag(H_2L)(NO_3)_3$, was prepared using the method of Ray and Chakravorty [29]. The purity of the prepared sample and its concentration in solution was checked with a HP8452A spectrophotometer[2] (λ_{max} 372 nm, $\varepsilon = 1205$; λ_{max} 370 nm, $\varepsilon = 1210$ in solution $0.01 < [H^+] < 0.1$ mol dm^{-3} [30]).

The suitably diluted $HClO_4$ (E. Merck, GR) was standardised against a standard alkali solution. The $LiClO_4$ solution was prepared by neutralising LiOH (Sigma) by standard $HClO_4$ and standardised as described [31]. The solutions of Na_2SO_3 (Baker, AR) were freshly prepared and standardised as described earlier [18]. The estimated concentration includes the concentrations of the SO_2(aq), HSO_3^- and SO_3^{2-} species and is represented by [S(IV)]. All the chemicals used were either analytical or purified grade and all the solutions were prepared in twice-distilled water.

2.2. Kinetic measurements

Initially solutions of $Ag(H_2L)^{3+}$ and Na_2SO_3 were freshly prepared in distilled water degassed with nitrogen for a sufficient time and diluted suitably with stock solutions of degassed $HClO_4$ and $LiClO_4$ to have the desired concentrations. However, the solutions were not degassed later since the rate constants from the degassed and non-degassed solutions agreed within the experimental limits (3–4%). The S(IV) solution was used within 2 h of preparation because such a solution in perchloric acid is stable over this period [20]. The ionic strength was maintained at 0.5 mol dm^{-3} with $LiClO_4$ unless stated otherwise.

A photoelectric SFA 11 colorimeter, working on the principle of a stopped-flow instrument and connected to a programmable printer to print the absorbance at fixed intervals of time, was used to measure the rate. The temperature of the stock syringes, filled with the reactant solutions, and the cell compartment was maintained at the desired temperature (±0.1 °C) by circulating water from a Haake D8G refrigerated circulatory water bath. The reactant solutions were manually pushed into the reaction cell. The start switch was activated by the piston of the syringe collecting the waste solution from the reaction cell.

The kinetics, under pseudo first-order reaction conditions ($[S(IV)] \gg [Ag(H_2L)]^{3+}$), were studied by following the disappearance of $Ag(H_2L)^{3+}$ at 420 nm [17], at which the Ag(III) complex absorbs and the S(IV) solution is transparent. The absorbance of the reaction mixtures at infinite time was measured the next day.

Each run was studied at least thrice. The plots of $\ln(A_t - A_\infty)$ against time, obtained by using the EXCEL PROGRAM, were linear for more than three half-lives of the reaction. The k_{obs} (s^{-1}) value was computed from the slope of the plots. The deviation between the mean k_{obs} value, reported in the Tables, and those obtained from multiple runs was within ±3–4%.

2.3. Test for free radical

Acrylonitrile (1–2 ml) was added to each of the reactant solutions purged with nitrogen. The solutions, remaining clear over few minutes, were mixed to initiate the reaction. The appearance of a white precipitate in the reaction mixture indicated the formation of free radicals during the course of the reaction.

2.4. Stoichiometry

In one set of experiments the stoichiometry was studied under the kinetic conditions (excess of [S(IV)]) and in the other set $[Ag(H_2L)^{3+}]$ was taken in slight excess over [S(IV)]. Each set consisted of several reaction mixtures with different $[H^+]$, and these were left for sufficient time in glass stoppered flasks to ensure completion of the reaction. The unreacted S(IV) and $Ag(H_2L)^{3+}$ were estimated volumetrically [18], and spectrophotometrically at 370 nm respectively.

Reaction mixtures with similar concentrations were prepared in another set of experiments and after the completion of the reaction, nitrogen was bubbled through the

[1] The exhaustive reference to the studies by various one-electron oxidants is given in Ref. [20].

[2] The instrument could not be used for the kinetic study because its cell compartment could not be thermostated for a constant temperature.

spent reaction mixtures for sufficient time to expel excess $SO_2 \cdot H_2O$. Thereafter a slight excess of $BaClO_4$ solution was added to precipitate the SO_4^{2-} ion for its gravimetric estimation. The estimated amount of SO_4^{2-} ion from these sets agreed within $(99.8 \pm 0.6)\%$.

The results based on the estimation of unreacted S(IV) and Ag(III) and SO_4^{2-} ion indicated a stoichiometric ratio, $\Delta[Ag(enbbg)^{3+}]/\Delta[S(IV)]$, of 1.02 ± 0.02 and therefore the stoichiometry is represented by Eq. (1).

$$Ag(H_2L)^{3+} + H_2SO_3 + H_2O \rightarrow Ag(H_2L)^{+} + SO_4^{2-} + 4H^{+} \quad (1)$$

2.5. Absence of Ag^+ and free ethylenebis(biguanide) in the spent reaction mixtures

The addition of NaCl solution to the spent reaction mixtures did not result in the precipitation of AgCl indicating that the free Ag^+ ion was absent as a reaction product. A similar absence of a precipitate in the reaction mixtures treated with $CuSO_4$ solution was an indication that free ethylenebis(biguanide) was also absent in the spent reaction mixture. Hence, it is concluded that the reduction product of $Ag(H_2L)^{3+}$ is the $Ag(H_2L)^{+}$ ion.

2.6. Absence of $S_2O_6^{2-}$ in the reaction product

The spent reaction mixtures with a deficient amount of S(IV) were treated with a known amount of Cr(VI) solution in 1 mol dm^{-3} H_2SO_4. The Cr(VI) in these reaction mixtures was estimated at 348 nm [32] after some time. The results of estimation indicated that no Cr(VI) was used by the reaction mixtures. It was, therefore, concluded that no detectable amount of $S_2O_6^{2-}$ ion was produced during the reaction. This method is suitable for the detection of $S_2O_6^{2-}$ concentrations as low as 5×10^{-6} mol dm^{-3}.

2.7. Spectral studies

The rapid scanning of the reaction mixture ($10^5[Ag(H_2L)]^{3+} = 7.0$, $10^3[S(IV)] = 1.5$ and $[HClO_4] = 0.2$ mol dm^{-3}) on a HP UV–Vis 8452A spectrophotometer was similar to that of $Ag(H_2L)^{3+}$ solution of the same concentration at 370 and 420 nm. This indicated that either there is no formation of complex(es) between $[Ag(H_2L)]^{3+}$ and [S(IV)] or the complexes were weak if such complexes were formed.

2.8. Distribution of S(IV) species

The three forms of S(IV) which are in equilibrium in aqueous solution are considered in the equilibria (2)–(4). The relative concentrations of these species are pH dependent and the hydrated species, $(SO_2 \cdot H_2O)$, is the dominant species at pH values <2 [33].

$$SO_2H_2O \overset{K_{a1}}{\rightleftharpoons} HSO_3^- + H^+ \quad (2)$$

$$HSO_3^- \overset{K_{a2}}{\rightleftharpoons} SO_3^{2-} + H^+ \quad (3)$$

$$2HSO_3^- \overset{K_d}{\rightleftharpoons} S_2O_5^{2-} + H_2O \quad (4)$$

The fractional concentrations of these species, based on the equilibria (2) and (3), were calculated for a total $[S(IV)] = 0.02$ mol dm^{-3} over $0.01 \leqslant [H^+] \leqslant 0.5$ mol dm^{-3} using the equilibrium constants $K_{a1} = 4.30 \times 10^{-2}$ and $K_{a2} = 4.57 \times 10^{-7}$ mol dm^{-3}, respectively, at 25 °C [34]. The fraction is equal to the quotient of the concentration of the particular species divided by the total [S(IV)]. The calculated values of the fraction for each of the species are given in Table 1 and the distribution is graphically illustrated in Fig. 1. From the distribution plot it is inferred that not only the fraction concentration of SO_3^{2-} (found between 10^{-6} and 10^{-8} mol dm^{-3}) but its significance as a possible reaction partner is negligible. Hence, the reactive S(IV) species are $SO_2 \cdot H_2O$ and the HSO_3^- ion.

The reason for neglecting equilibrium (4), $K_d = 8.8 \times 10^{-2}$ dm^3 mol^{-1} at 25 °C [35], while calculating the concentrations of the above species was circumscribed by the fact that no second-order dependence in S(IV) was observed and $S_2O_6^{2-}$ was not the reaction product. Hence, equilibrium (4) has no kinetic significance in the present investigation.

2.9. Distribution of Ag(III)-complex species

The distribution of the fractions of Ag(III)-complex species, governed by equilibria (5) and (6), was similarly calculated for [Ag(III)-complex] $= 3 \times 10^{-4}$ mol dm^{-3} over the same range of $[H^+]$ as in the case of S(IV) using $K_{Ag1a} = 1.58 \times 10^{-4}$ and $K_{Ag2a} = 1.58 \times 10^{-7}$ mol dm^{-3} at 25 °C [36]. The values, in Table 2, are plotted in Fig. 2 from which it is contingent that the fraction of the $Ag(H_2L)^{3+}$ species is ~1, even at the lowest hydrogen ion concentration. The fraction values of $Ag(HL)^{2+}$ and $Ag(L)^{+}$ decrease with increase in hydrogen ion concentration. The $Ag(L)^{+}$

$10^6 \times SO_3^{2-}$	37	15.5	8.95	5.9	4.23	1.37	0.68	0.406	0.27	0.191	0.111	0.0725

$[S(IV)]_o = 0.02$ mol dm^{-3}.

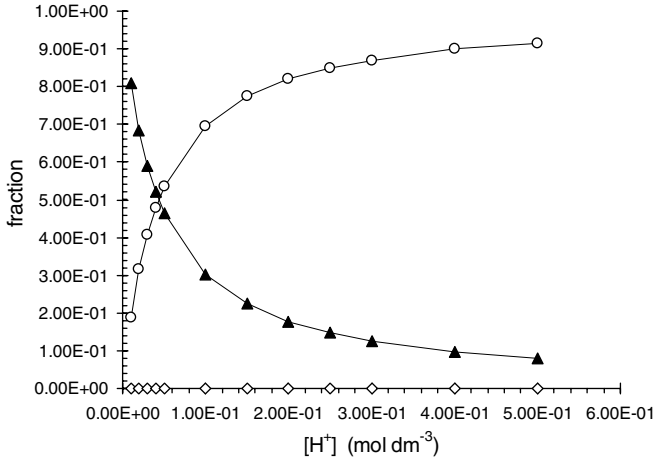

Fig. 1. The plot of the distribution of SO_2(aq), HSO_3^- and SO_3^{2-} species as fractions (= concentration of the species/ $[S(IV)]_o$) at different hydrogen ion concentrations at 25 °C. SO_3(aq) (○),HSO_3^- (▲) and SO_3^{2-} (◇). $[S(IV)]_o = 0.02$ mol dm^{-3}.

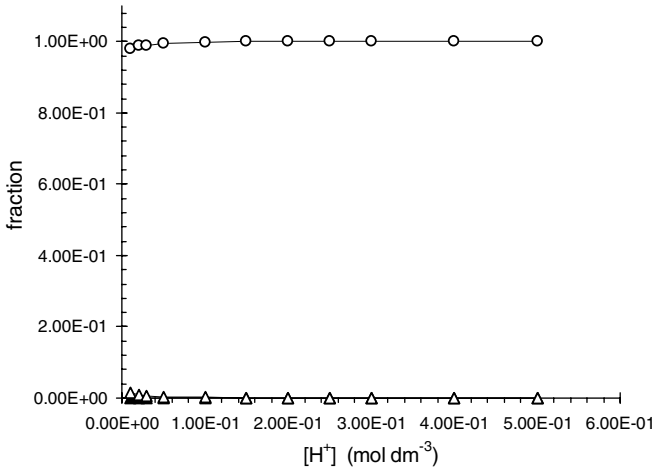

Fig. 2. The distribution of AgH_2L^{3+}, $AgHL^{2+}$ and AgL^+ species as fractions (= concentration of the species/$[Ag(III)\ complex]_o$) at different hydrogen ion concentrations at 25 °C. AgL^+ (▲), $AgHL^{2+}$ (△) and AgH_2L^{3+} (○). $[Ag(III)\text{-complex}]_o = 3 \times 10^{-4}$ mol dm^{-3}.

fraction (found between 10^{-7} and 10^{-8} mol dm^{-3}) is hardly visible in the plot whereas the $Ag(HL)^{2+}$ fraction is about one thousandth of the total concentration of the Ag(III)-complex. Thus, the species $Ag(HL)^{2+}$ and $Ag(L)^+$ are unlikely to contribute to the observed rate of the reaction and therefore can be neglected. Equilibrium (6), for the same reason, has no kinetic significance:

$$Ag(H_2L)^{3+} \overset{K_{Ag1}}{\rightleftharpoons} Ag(HL)^{2+} + H^+ \quad (5)$$

$$Ag(HL)^{2+} \overset{K_{Ag2}}{\rightleftharpoons} Ag(L)^+ + H^+ \quad (6)$$

3. Results

The invariance of $10^4 k_{obs} = 6.73 \pm 0.15$ s^{-1}, ($10^2[S(IV)] = 5.0$; $[H^+] = 0.2$ and ionic strength $\mu = 0.5$ mol dm^{-3}), over a 20-fold variation in $[Ag(H_2L)^{3+}]$ at 30 °C is consistent with the first-order dependence in the $Ag(H_2L)^{3+}$ ion. There is a proportionate increase in k_{obs} with [S(IV)], Table 3, and the plots between k_{obs} and [S(IV)], Fig. 3, are linear and pass through the origin indicating the first-order dependence in [S(IV)]. k_{obs} decreased with the increase in $[H^+]$ and the k_{obs} values at four temperatures are in Table 4. The plot of $k_{obs}(1 + K_{a1}[H^+]^{-1})/[S(IV)]$ against $[H^+]^{-1}$, Fig. 4, is non-linear whereas the plot of $k_{obs}/[S(IV)]$ against $[H^+]^{-1}$, Fig. 5, is linear.

The k_{obs} value was independent of [Ag(I)], (Table 5), suggesting that the electron transfer does not take place in a reversible step in which Ag(I) is a product. The rate was also independent of free ligand L (= ethylenebis(biguanide)) indicating that there is no substitution of L by S(IV) species. An increase in ionic strength (μ, $LiClO_4$), Table 6, decreased k_{obs}, indicating that ions of opposite charges are involved in the reaction. The Davies equation (7) is applicable at the relatively high ionic strength [37,38], and accordingly the plot of $\log k_{obs}$ against $(\sqrt{\mu}/1 + \sqrt{\mu}) - 0.01\mu$, Fig. 6, is linear with the slope $(z_a z_b) = -3.07$:

$$\log k_{obs} = \log k_o + z_a z_b \left(\frac{\sqrt{\mu}}{1 + \sqrt{\mu}} - 0.01\mu \right) \quad (7)$$

4. Mechanism and discussion

The retardation in the rate with increasing $[H^+]$ indicates the presence of a deprotonation equilibrium preceding the rate limiting step. In the present reaction both S(IV) and the Ag(III) complex have a deprotonation equilibrium, as considered in Eqs. (2) and (3) for S(IV), and (6) and (7) for the Ag(III) complex. However, the discussion on the distribution of the S(IV) and Ag(III) complex species had indicated that the effective equilibrium are (2) and (5), respectively.

μ (mol dm^{-3})	0.1	0.2	0.3	0.4	0.5	0.6	0.8	1.0
10^4k_{obs} (s^{-1})	34.4	18.5	12.8	11.0	9.68	8.80	6.97	5.05

On consideration of the stoichiometry of the reaction, a first-order dependence of the reaction in Ag(III) complex and S(IV), and the SO_4^{2-} ion being the product of the reaction with no indication for the formation of an intermediate from the UV–Vis spectra of the reaction mixture, the following reactions are likely to be part of the proposed mechanism under Scheme I, where reactions (8) and (9) are rate determining.

Scheme I:

$$SO_2(aq) \overset{K_{a1}}{\rightleftharpoons} HSO_3^- + H^+ \quad (2)$$

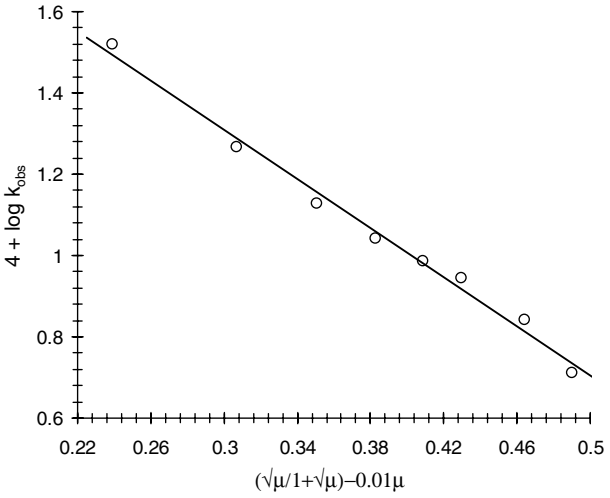

Fig. 6. The linear plot of log k_{obs} against $(\sqrt{\mu}/(1+\sqrt{\mu}) - 0.01\mu)$ has a slope = -3.07 ± 0.16 $10^4[Ag(H_2L)]^{3+} = 3.0$, [S(IV)] = 0.02 and $[H^+]$ = 0.1 mol dm^{-3} at 45 °C.

$$Ag(H_2L)^{3+} \overset{K_{Ag1}}{\rightleftharpoons} Ag(HL)^{2+} + H^+ \quad (5)$$

$$Ag(H_2L)^{3+} + SO_2(aq) \overset{k}{\rightarrow} SO_3^{-\cdot} + Ag(H_2L)^{2+} + 2H^+ \quad (8)$$

$$Ag(H_2L)^{3+} + HSO_3^- \overset{k_o}{\rightarrow} SO_3^{-\cdot} + Ag(H_2L)^{2+} + H^+ \quad (9)$$

$$Ag(H_2L)^{2+} + SO_3^{-\cdot} + H_2O \overset{k_3(fast)}{\rightarrow} Ag(H_2L)^{+} + SO_4^{2-} + 2H^+ \quad (10)$$

The free radical $SO_3^{-\cdot}$ in aqueous solution is supported by esr spectroscopy [39]. The rate law in view of the reactions (2), (5) and (8)–(10) is expressed by the following equation:

$$\text{rate} = \frac{-d[Ag(III)]_o}{dt} = (k + k_o K_1[H^+]^{-1})[SO_2(aq)][Ag(H_2L)^{3+}] \quad (11)$$

The correlation of the concentrations of $SO_2(aq)$ with the analytical concentration $[S(IV)]_o$ in view of equilibria (2) and (3) is expressed by Eq. (12), which changes to Eq. (13) on the assumption that $(1 + K_{a1}[H^+]^{-1}) \gg K_{a2}K_{a1}[H^+]^{-2}$ which is consistent with the fraction of the respective species shown in Fig. 1 over a given range of hydrogen ion concentrations:

$$[SO_2] = \frac{[S(IV)]_o}{1 + K_{a1}[H^+]^{-1} + K_{a1}K_{a2}[H^+]^{-2}} \quad (12)$$

or

$$[SO_2(aq)] = [S(IV)]_o(1 + K_{a1}[H^+]^{-1})^{-1} \quad (13)$$

Similarly, the correlation of the concentration of $Ag(H_2L)^{3+}$ with its analytical concentration, [Ag(III) complex]$_o$, in view of equilibria (5) and (6) is given by Eq. (14), which with the assumption that $1 \gg K_{Aga1}[H^+]^{-1} + K_{Aga1}$-$K_{Aga2}[H^+]^{-2}$ is reduced to Eq. (15). Eq. (15) is consistent with the plot in Fig. 2 where the fraction value of Ag-$(H_2L)^{3+} \sim 1$ even at the lowest hydrogen ion concentration:

$$[Ag(H_2L)^{3+}] = \frac{[Ag(III)\text{-complex}]_o}{1 + K_{Ag1a}[H^+]^{-1} + K_{Ag1a}K_{Ag2a}[H^+]^{-2}} \quad (14)$$

$$[Ag(H_2L)^{3+}] = [Ag(III)\text{-complex}]_o \quad (15)$$

Eq. (16) is obtained on substituting the respective values of $[SO_2(aq)]$ and $[Ag(H_2L)^{3+}]$ from Eqs. (13) and (15) into Eq. (11):

$$\frac{-d[Ag(III)]}{dt} = \left(\frac{k + k_o K_{a1}[H^+]^{-1}}{1 + K_{a1}[H^+]^{-1}}\right)[S(IV)]_o[Ag(III)\text{-complex}]_o \quad (16)$$

or

$$k_{obs}(1 + K_{a1}[H^+]^{-1})/[S(IV)]_o = (k + k_o K_{a1}[H^+]^{-1}) \quad (17)$$

The desired plot of the left side of Eq. (17) against $[H^+]^{-1}$ is illustrated in Fig. 4, which is concave indicating that $k_{obs}(1 + K_{a1}[H^+]^{-1})/$ [S(IV)] increased more rapidly than the $[H^+]^{-1}$ value. Since the term $(1 + K_{a1}[H^+]^{-1})$ cannot be neglected, Scheme I is unlikely to represent the mechanism of the reaction.

The alternate Scheme II considers the involvement of the weak intermediates most likely. The intermediates evaded both kinetic and spectrophotometric detections because of their weak nature.

Scheme II

$$SO_2(aq) \overset{K_{a1}}{\rightleftharpoons} HSO_3^- + H^+ \quad (2)$$

$$Ag(H_2L)^{3+} \overset{K_{Ag1}}{\rightleftharpoons} Ag(HL)^{2+} + H^+ \quad (5)$$

$$Ag(H_2L)^{3+} + SO_2(aq) \overset{K_1}{\rightleftharpoons} Ag(H_2L)SO_2^{3+} \quad (18)$$

$$Ag(H_2L)^{3+} + HSO_3^- \overset{K_2}{\rightleftharpoons} Ag(H_2L)HSO_3^{2+} \quad (19)$$

$$Ag(H_2L)SO_2^{3+} \overset{k'}{\rightarrow} Ag(H_2L)^{2+} + SO_3^{-\cdot} \quad (20)$$

$$Ag(H_2L)HSO_3^{2+} \overset{k''}{\rightarrow} Ag(H_2L)^{2+} + SO_3^{-\cdot} + H^+ \quad (21)$$

$$Ag(H_2L)^{2+} + SO_3^{-\cdot} + H_2O \overset{k_3(fast)}{\rightarrow} Ag(H_2L)^{+} + SO_4^{2-} + 2H^+ \quad (10)$$

The proposed inner-sphere mechanism has similarity with those of alcohols [28], H_3PO_2 [40] and ascorbic acid [41], and $Tl^{3+}(aq)$ oxidation of $SO_2(aq)$ under similar conditions of H^+ ions [20]. The rate in terms of reactions (17)–(20) and (14) is given by the following equation:

$$\text{rate} = \frac{-d[Ag(III)]_o}{dt} = (k'K_1 + k''K_2K_1[H^+]^{-1})[Ag(H_2L)^{3+}][SO_2(aq)] \quad (22)$$

The correlation between $[Ag(H_2L)]^{3+}$ and [Ag(III) complex]$_o$ in terms of Eqs. (18) and (19) is given by Eq. (23), whereas Eq. (13) holds good for the correlation between $[SO_2(aq)]$ and [S(IV)]:

$$[Ag(H_2L)^{3+}] = \frac{[Ag(III)]_o}{1 + K_1[SO_2(aq)] + K_1K_2[SO_2(aq)][H^+]^{-1}} \quad (23)$$

The substitution of the proper values of $[SO_2(aq)]$ from Eq. (13) and that of $[Ag(H_2L)^{3+}]$ from Eq. (23) into Eq. (22) gives the following equation:

$$\frac{-d[Ag(III)]}{dt} = \frac{(k'K_1 + k''K_2K_1[H^+]^{-1})[Ag(III) - complex]_o[S(IV)]_o/(1 + K_{a1}[H^+]^{-1})}{(1 + (K_1 + K_1K_2[H^+]^{-1}))[S(IV)]_o/(1 + K_{a1}[H^+]^{-1})} \quad (24)$$

The terms $(1 + K_{a1}[H^+]^{-1})$, appearing both in the numerator and denominator, cancel each other and therefore Eq. (24) is transformed into Eq. (25):

$$\frac{-d[Ag(III)]}{dt} = \frac{(k'K_1 + k''K_2K_1[H^+]^{-1})[Ag(III) - complex]_o[S(IV)]_o}{(1 + (K_1 + K_1K_2[H^+]^{-1}))[S(IV)]_o} \quad (25)$$

Since $1 \gg (K_1 + K_1K_2[H^+]^{-1})[S(IV)]_o$ because of the microscopic values of K_1 and K_2, the Eq. (25) is reduced to Eq. (26) where $k_1 = k'K_1$ and $k_2 = k''K_2K_{a1}$:

$$k_{obs}/[S(IV)]_o = (k_1 + k_2[H^+]^{-1}) \quad (26)$$

Eq. (26) is consistent with the linear plot of $k_{obs}/[S(IV)]_o$ against $[H^+]^{-1}$ in Fig. 5, with intercepts on the rate ordinate. The inner-sphere mechanism is thereby supported. The formation of the intermediate $Ag(H_2L)HSO_3^{2+}$ through reaction (19) is preferred because it is consistent with the slope value ($z_az_b = -3.07$) of the plot in Fig. 6. The alternate route in Eq. (27) is kinetically indistinguishable from the reaction in Eq. (19) because of the identity that $K_2K_{a1} = K'_2K_1$, as shown below:

$$Ag(H_2L)SO_2(aq)^{3+} \overset{K'_2}{\rightleftharpoons} Ag(H_2L)HSO_3^{2+} + H^+ \quad (27)$$

or

$$[Ag(H_2L)HSO_3^{2+}] = K'_2K_1[Ag(H_2L)^{3+}][SO_2(aq)][H^+]^{-1} \quad \text{(from (27) and (18))} \quad (28)$$

$$= K_2K_{a1}[Ag(H_2L)^{3+}][SO_2(aq)][H^+]^{-1} \quad \text{(from (19) and (2))} \quad (29)$$

The values of the estimated rate constants k_1 and k_2 from the least square values of the intercepts and slopes, at different temperatures, are given in Table 7. It is noted that at lower temperatures $k_2 > k_1$, but the difference narrows as the temperature increases. The Arrhenius plots corresponding to k_1 and k_2 are given in Figs. 7 and 8, respectively. The significance of the activation parameters is not discussed because these are based on the product of the rate limiting and equilibrium constants and the values of the equilibrium constants remain indeterminate. However, it seems that the combination of reactions (18) and (20) is enthalpy controlled ($\Delta H^{\ddagger}_{k1} = 70 \pm 3$ kJ mol^{-1} and $\Delta S^{I}_{k1} = -42 \pm 10$ J K^{-1} mol^{-1}), and the combination of reactions (2), (19) and (21) is driven by the entropy, ($\Delta H^{I}_{k2} = 9 \pm 1$ kJ mol^{-1} and $\Delta S^{I}_{k2} = -225 \pm 2$ J K^{-100} mol^{-1}). The trend that $\Delta S^{I}_{k1} > \Delta S^{I}_{k2}$ is similar to that observed in the oxidation of alcohols for which $\Delta H^{\ddagger}_{k1}$ and ΔH^{I}_{k2} are fairly similar [28]. Both ΔH^{I}_{k2} and ΔS^{I}_{k2} are almost of the same magnitude as in the oxidation of H_3PO_2 for a similar path [40]. Such a similarity is a pointer and supportive of the proposed inner-sphere mechanism.

The coordination number in Ag(III) (d^8) could be either four (planar) or six (octahedral). The diamagnetic $[Ag(H_2L)]^{3+}$ complex is square planar and the Ag(III) ion is tetra-coordinated by four nitrogen atoms of the ethylene-bisbiguanidinium ion. Thus $SO_2(aq)$ has to be axially coordinated. A water molecule is also axially coordinated to make the sulfito-complex octahedral.

It seems that the generalisation that the one or two-electron oxidation of S(IV) by metal ions and their complexes results in the formation of $S_2O_6^{2-}$ or SO_4^{2-}, respectively [11] needs reconsideration. The oxidation by one electron

Table 7
Values of k_1 and k_2 (dm^3 mol^{-1} s^{-1})

Temp (°C)	25	30	35	40	45
10^3k_1 (dm^3 mol^{-1} s^{-1})	3.23	4.73	8.27	13.4	18.9

oxidants such as $IrCl_2^-$ and $[Os(bpy)_3]^{3+}$ [12], $[Mn(acac)_3]$ [17], $Fe^{3+}(aq)$ [19], alkaline MnO_4^- [16] and $[Fe(edta)]^-$ [42] results in the formation of SO_4^{2-} as the sole product. On the other hand one electron oxidants such as 12-tungstocobaltate(III) [14], $[Ni^{IV}L^1_2]^{2+}$ and $[Ni^{IV}L^2]^{2+}$ (HL^1 = 6-amino-3-methyl-4-azahex-3-en-2-one oxime, $H_2L^2 = 3$, 14-dimethyl-4,7,10,13-tetra-azahexadeca-3,13-diene-2,15-dione dioxime) [43], *trans*-(diaqua)(*N*,*N*′)-propylene 1,2 bis(salicylidinim inato)Fe(III) [44], (tetraethylenepentamine)Fe(III) [45] produce both SO_4^{2-} and $S_2O_6^{2-}$ ions, though in certain cases $S_2O_6^{2-}$ is the exclusive product at high [S(IV)] [14,43].

The exclusive formation of SO_4^{2-} or $S_2O_6^{2-}$ or both in different proportions is dependent on the fate of $SO_3^{-\cdot}$ formed during the oxidation of S(IV) by one electron oxidants. The exclusive product is SO_4^{2-} ion if k_3 (see reaction (10)) $\gg k_4$ (see reaction (30)) and if $k_4 \gg k_3$, the exclusive product would be the $S_2O_6^{2-}$ ion. When k_3 and k_4 are of comparable magnitude, the product ratio SO_4^{2-}:$S_2O_6^{2-}$ would depend on the k_3:k_4 ratio.

$$SO_3^{-\cdot} + SO_3^{-\cdot} \xrightarrow{k_4(\text{fast})} S_2O_6^{2-} \qquad (30)$$

2. Results and discussion

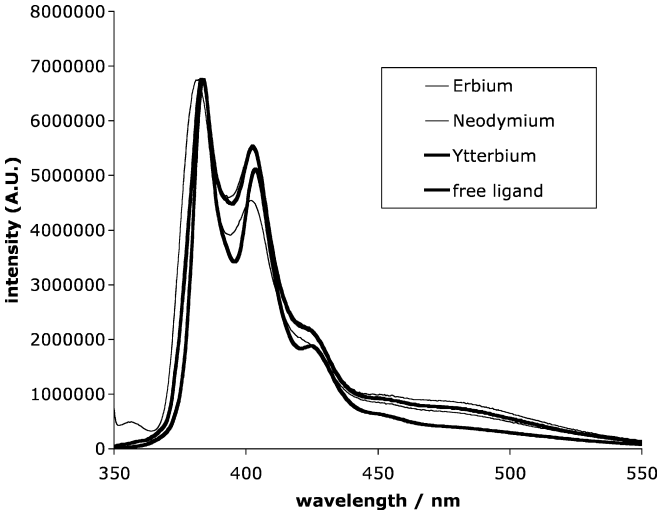
Scheme 1 shows the synthetic route to the complexes. The bis-pyrene ligand, $\mathbf{L}^{pyr}$, was accessed by the reaction of 2 equiv. of 1-aminopyrene with diethylenetriaminepentaacetic diacidanhydride (DTPAA), in the presence of triethylamine. The reaction mixture was stirred at room temperature for 24 h and the resultant crude product was purified, first by washing with dichloromethane, and then chromatographically (silica). The free ligand was isolated as a light brown solid and the corresponding lanthanide complexes $\mathbf{Ln}\cdot\mathbf{L}^{pyr}$ (Ln = Nd, Gd, Er, Yb) were prepared by addition of 1 equiv. $Ln(OTf)_3$. The purity of the complexes was assessed using thin layer chromatographic analysis to ensure that no free ligand remained following complexation.

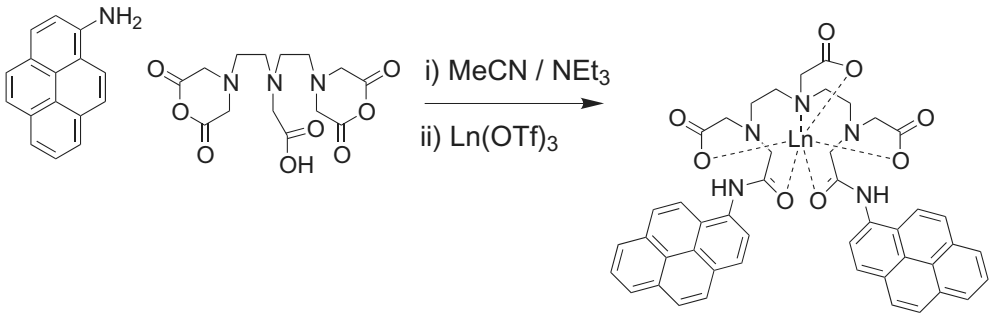
The free ligand $\mathbf{L}^{pyr}$ was characterised using ^1H NMR, elemental analyses, mass spectrometry, IR and UV–Vis. The complexes were isolated in good yields. MALDI-TOF spectra were obtained for each of the complexes and gave peak clusters with the correct isotopic distributions, corresponding to the parent ion $\{M-H\}^+$, in each case. Vibrational IR studies are insightful for carboxylate derivatives of this type, and for the complexes they show a low energy shift for ν(C=O) when compared to the free ligand [16]. The hygroscopic nature of the complexes prevented reproducible elemental analyses from being obtained.

3. Photophysical studies

The absorption spectra of $\mathbf{L}^{pyr}$ showed a typical spectral profile associated with a pyrene containing species. The distinctive features at 300–350 nm correspond to IL π–π^* transitions. The spectra of the corresponding complexes $\mathbf{Ln}\cdot\mathbf{L}^{pyr}$ revealed very similar properties with only minor deviations in absorption maxima from the free ligand.

The luminescence features of these species were then analysed. Fig. 1 shows the steady state UV–Vis emission spectra of the free ligand, $\mathbf{L}^{pyr}$, and corresponding complexes, $\mathbf{Ln}\cdot\mathbf{L}^{pyr}$, in air-equilibrated methanolic solutions at a concentration of approximately 1×10^{-6} M. An excitation wavelength of 340 nm was utilised and corresponds to selective irradiation of the pyrene chromophore. Fig. 1 shows that, for $\mathbf{L}^{pyr}$, pyrenyl emission dominates with vibronically structured features between 300 and 450 nm, assigned to intraligand transitions ($^1\pi\pi^*$). Pyrene luminescence in this region corresponds to monomeric pyrene as opposed to aggregated pyrene units, which are prone to excimer emission. The significantly weaker, broadened feature from 450 to 550 nm may be due to the presence of a pyrene excimer. However, at the concentration used in this study intermolecular excimer formation (usually observed around 480 nm) should not be favoured [13]. For the complexes, $\mathbf{Ln}\cdot\mathbf{L}^{pyr}$, the fluorescence emission spectra are again dominated by pyrenyl emission although the relative intensities of the vibronic transitions between 350 and 455 nm have changed and there is a slightly more pronounced broad band around 450–550 nm. Although weak in comparison to the higher energy transitions, the intensity of the excimer band in the complexes is twofold that of the parent ligand, $\mathbf{L}^{pyr}$. However, the absence of a dominating band at 450–500 nm suggests that the pyrene units are probably kept sufficiently separated, due to the coordination geometry of the ligand.





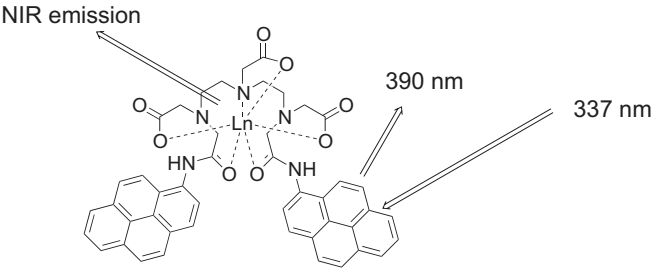


Fig. 1. Comparison of the pyrene based emission from the free ligand and complexes. Spectra are normalised about the 384 nm peak. Samples were prepared as 8×10^{-7} M methanol solutions (λ_{ex} = 340 nm).

Scheme 1. Synthesis of $\mathbf{Ln}\cdot\mathbf{L}_{pyr}$ (Ln = Nd, Gd, Er and Yb).

Time-resolved emission studies on the pyrene-based fluorescence were undertaken on aerated solutions of the complexes. A rapidly pulsed excitation source (NanoLED at 355 nm operating at 500 kHz) was used in conjunction with a time-correlated single photon counting apparatus monitoring the emission at 390 nm. In each case, two lifetimes were obtained when analysing the decay profile: typically these were one component of ~6 ns and another much shorter of ~0.5 ns. The relative weightings of the contributions are shown in Table 1. The observation of these short-lived components, in aerated solution, is consistent with the excited states being singlet in nature. The existence of two components may well be a conformational effect on the pyrenyl groups. For comparison, the Gd^{III} complex was also measured. The emissive state of Gd^{III} lies above the excited states of pyrene thus rendering the metal ion non-emissive, but a useful analogue for studying the excited states of chromophoric units. The results in this study show that the time-resolved emissive characteristics of the ligand do not vary much between the lanthanides, suggesting that the dominant energy transfer mechanism between the pyrene units and emissive lanthanide ions probably involves the pyrene triplet state as observed in related systems (see Scheme 2).

The emission of the lanthanide ions was analysed using near-infrared luminescence (see Figs. 2–4). An excitation wavelength of 337 nm was used and ideally suited to effectively sensitising the pyrene chromophoric units ($\lambda_{max} = 343$ nm). Measurements were conducted in deuteriated and non-deuteriated methanolic solutions and lifetime values were obtained by iterative reconvolution with the detector response using established procedures. In each case sensitised lanthanide emission was observed, the lifetimes for which are shown in Table 1 and the wavelengths for which are consistent with the metal present [Nd^{III}, $^4F_{3/2} \rightarrow {}^4F_{13/2}$ at 1055 and 1340 nm, respectively; Er^{III}, $^4F_{13/2} \rightarrow {}^4F_{15/2}$ at 1530 nm; Yb^{III}, $^2F_{5/2} \rightarrow {}^2F_{7/2}$ at 980 nm]. Time-resolved emission spectra (TRES) were recorded for each of the complexes (see Fig. 2) in CD_3OD and reveal the spectral profile in relation to the lifetime. In the cases of $\mathbf{Ln} \cdot \mathbf{L}^{pyr}$ (Ln = Nd, Yb), the lifetimes are unremarkable and typical of dtpa- or dota-like complexes in protic media [4,17]. However, the observation of Er^{III} emission in protic, non-deuteriated solvent is noteworthy and rare (see Fig. 3). The observed lifetime of 134 ns is shorter than both the Nd^{III} and Yb^{III} analogues reflecting the more pronounced sensitivity of Er^{III} to quenching *via* O–H oscillators. In CD_3OD, the lifetime is of microsecond order and comparable to previous observations for related Er^{III} species in deuteriated media [17].

Scheme 2. Possible mode of lanthanide sensitisation.

For the Yb^{III} example it is possible to utilise the lifetime measurements to deduce an approximation of inner sphere solvent coordination (denoted q) by application of the following equation based originally on Horrocks' work and developed further by Parker, Beeby and co-workers:

$$q = 2[(k_{CH_3OH} - k_{CD_3OD}) - 0.05]$$

where k_{CH_3OH} and k_{CD_3OD} are the observed rate constants for luminescence in CH_3OH and CD_3OD, respectively. This results in an inner-sphere hydration number (q) of 0.84 for $\mathbf{Yb} \cdot \mathbf{L}^{pyr}$. For Nd^{III} the equation used is:

$$q = 290(k_{CH_3OH} - k_{CD_3OD}) - 0.4$$

Here deduction of the inner sphere hydration state of Nd^{III} species is less clear cut due to non-radiative quenching *via* other oscillators such as C–H and N–H [18,19]. Despite this the above equation has been shown to hold well for aminocarboxylate ligands and is thus applied in this case. From the lifetimes of $\mathbf{Nd} \cdot \mathbf{L}^{pyr}$ q, is obtained as 0.53. Thus for both examples $q < 1$ which is entirely reasonable given that the ligand itself possesses eight potential donor atoms and large hydrophobic chromophores which may inhibit the approach of protic solvent molecules. In the Yb^{III} and Er^{III} cases, the quality of the data fits was significantly

Table 1

[d] $\lambda_{ex} = 337$ nm.
[e] Inner sphere hydration number.

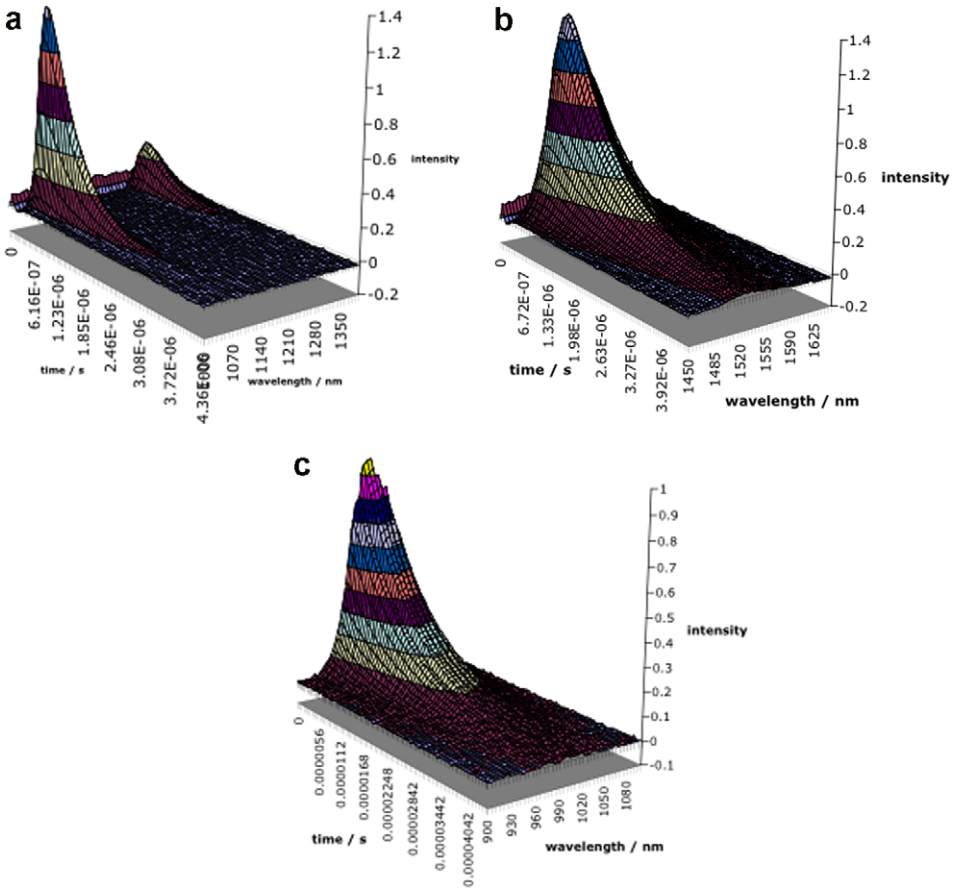

Fig. 2. Time-resolved emission spectra for $\mathbf{Ln} \cdot \mathbf{L}^{pyr}$ in CD_3OD ($\lambda_{ex} = 337$ nm).

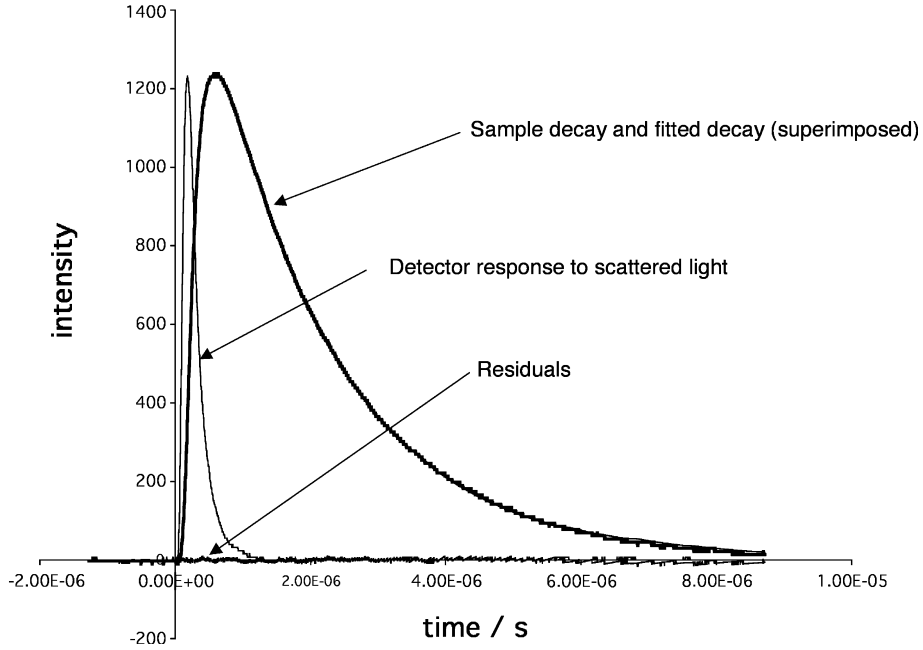

Fig. 3. Lifetime decay profile for $\mathbf{Yb} \cdot \mathbf{L}^{pyr}$ in CH_3OH. The lifetime is 1802 ns, the rise-time 18 ns following excitation at 337 nm and detection at 980 nm.

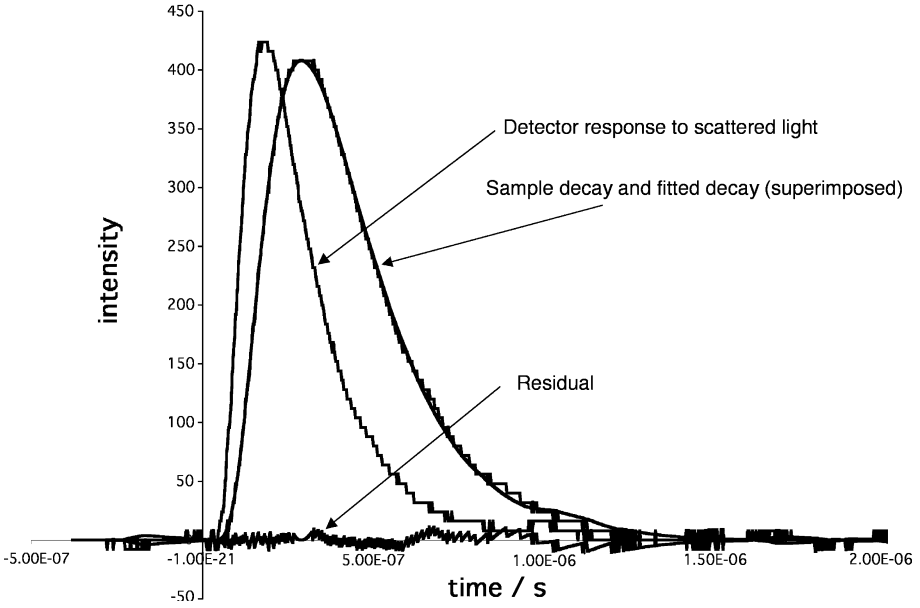

Fig. 4. Lifetime decay profile for $\mathbf{Er} \cdot \mathbf{L}^{pyr}$ in CH_3OH. The lifetime is 134 ns following excitation at 337 nm and detection at 1530 nm.

improved by incorporating short rise-time components (of equal weighting to the decay component). Rise-time data can often be informative when considering energy transfer efficiency. A short rise time within the duration of the laser pulse (<5 ns) implies efficient energy transfer whilst longer values may well be indicative of less efficient processes. We have shown previously with pyrene appended DOTA-like complexes that increasing the length of the spacer linking the chromophore to the complex reduces energy transfer efficiency as evidenced in a longer rise time [4]. For $\mathbf{Ln} \cdot \mathbf{L}^{pyr}$ (Ln = Er, Yb) the rise times are all <30 ns and therefore comparable to previous examples where the linker between chromophore and complex is short, and consequently energy transfer, regardless of the mechanism, seems reasonably efficient. Rise-time exponentials were not required for the Nd^{III} indicating an even more efficient energy transfer process from the pyrene to Nd^{III}. Mechanisms involving Förster [20] energy transfer and Dexter [21,22] exchange have previously been proposed to elucidate sensitisation of lanthanide ions by organic chromophores. The Förster mechanism is a through space dipole–dipole process which shows a distance dependency of r^{-6} (where r is the donor–acceptor separation) whereas Dexter exchange should proceed with e^{-r} and occurs in cases where there is a significant electronic interaction between the donor and acceptor. Assuming energy transfer occurs *via* the conventional triplet excited state of the pyrene we need to consider the phosphorescence spectrum. Unfortunately, room temperature measurements conducted on a de-aerated solution of $\mathbf{Gd} \cdot \mathbf{L}^{pyr}$ did not allow the triplet state of the pyrenyl components to be obtained. However, it is likely that Nd^{III} possesses f–f levels which overlap with the $^3pyr^*$ level (which usually resides between 600 and 700 nm) and this may explain the apparent efficiency of energy transfer in $\mathbf{Nd} \cdot \mathbf{L}^{pyr}$ where the rise time <5 ns [23]. In contrast Yb^{III} has just one f–f level at ~980 nm which will overlap less effectively with $^3pyr^*$ and hence the observation of a rise time >5 ns. However, because of the structure of the complexes $\mathbf{Ln} \cdot \mathbf{L}^{pyr}$ where the pyrenyl amide is coordinated to the lanthanide, it is possible that Dexter exchange may also contribute to the energy transfer process. Additionally, in the case of $\mathbf{Yb} \cdot \mathbf{L}^{pyr}$ it is also important to consider the formation of Yb^{II} intermediates *via* LMCT [24].

4. Conclusions

This paper demonstrates how pyrene can act as an effective sensitiser for neodymium, erbium and ytterbium in protic media. This includes a rare report of Er^{III} emission in non-deuteriated protic solvent and in the future may allow a more detailed study into the non-radiative quenching pathways associated with this lanthanide ion. Despite the incorporation of two pyrene chromophores within the ligand, the formation of the complexes induces only subtle changes in the relative intensities of the luminescent signals originating from monomer and excimer emissions. This suggests that the chromophores are distant from one another and that the coordination requirements of the lanthanide ion dominate the solution state structure of the ligand.

5. Experimental

Diethylenetriaminepentaacetic dianhydride, lanthanide trifluoromethanesulfonate salts and 1-aminopyrene were all purchased from the Aldrich Chemical company. Infrared spectra were recorded as solids using an ATR (Attenuated Total Reflectance)-fitted Bruker Equinox 55 spectrometer over the range 4000–800 cm^{-1} for 64 scans. Mass spectra were obtained using positive or negative

electrospray in acetonitrile solutions on a Micromass Platform II, or by MALDI using methanol solutions with an ALPHA matrix on a Micromass Tofspec2. Electronic absorption spectra were obtained on a double-beam Cary Varian 500 Scan UV–Vis–NIR spectrophotometer as methanol solutions. ^{1}H and $^{13}C\{^{1}H\}$ NMR spectra were recorded on a Bruker Avance 400 MHz spectrometer at 298 K. CHN analyses were performed by the Microanalytical Laboratory, University of Manchester using a Carlo Erba Instruments CHNS-O EA 1108 Elemental Analyser. The steady state luminescence measurements were determined using a Horiba Yobin-Yvon Fluorolog. In the case of near-IR measurements of the Nd^{III}, Er^{III} and Yb^{III} complexes, the sample was excited using a pulsed nitrogen laser (PTI-3301, 337 nm) operating at 10 Hz. Light emitted perpendicular to the excitation beam was focused onto the slits of a monochromator (PTI120), which was used to select the appropriate wavelength. The growth and decay of the luminescence at selected wavelengths was detected using a germanium photodiode (Edinburgh Instruments, EI-P) and recorded using a digital oscilloscope (Tektronix TDS220) before being transferred to a PC for analysis. Time-resolved emission spectra (TRES) were obtained by measuring the growth and decay of the luminescence at each of a series of wavelengths. Luminescence lifetimes were obtained by iterative reconvolution of the detector response (obtained by using a scatterer) with exponential components for growth and decay of the metal-based luminescence, using a spreadsheet running in Microsoft Excel. The details of this approach have been discussed elsewhere [19]. Fitting to a double exponential decay yielded no improvement in fit, as judged by minimisation of residual squared and reduced χ^2, except where indicated.

6. Synthesis of L^{pyr}

A 2.2 equiv. of 1-aminopyrene (0.4 g, 1.85 mmol) were added to 1 equiv. of DTPAA (0.3 g, 0.84 mmol) in stirring acetonitrile under a dinitrogen atmosphere. Excess triethylamine was added dropwise and the solution allowed to stir, initially at room temperature (2 h) and then at 50 °C for a further 18 h. The volume was reduced to dryness in vacuo and the dark brown residue was taken up in the minimum volume of methanol. This concentrate was then added to rapidly stirring, ice cold, diethylether to form a cream precipitate which was isolated by filtration using Schlenk apparatus. The solid was washed with more diethylether and dichloromethane to remove unreacted aminopyrene. The product can be further purified by being introduced to a silica loaded column and eluted initially with 10% MeOH in DCM (to remove any unreacted amino pyrene) and then 50% MeOH in DCM to isolate the desired product (yield, 0.41 g, 62%). IR (KBr disc) $\nu = 3036$, 2962, 2842, 1636, 1522, 1444, 1404, 1328, 1286, 1162, 1104, 990, 962, 924, 842, 712 cm^{-1}. UV–Vis (MeOH) λ_{max} (ε/mol^{-1} dm^3 cm^{-1}) 348 (31 700), 325 (34 000), 275, (66 900), 267 (64 500), 245 (81 600) nm. ES^- MS (MeCN): m/z 790 $\{M-H\}^-$. *Anal.* Calc. for $C_{46}H_{41}N_5O_8 \cdot 2H_2O$: C, 66.74; H, 5.48; N, 8.46. Found: C, 66.79; H, 5.17; N, 8.41%. ^{1}H NMR (400 MHz, MeOD, 300 K) $\delta_H = 8.25$–7.31 (18H, m, pyr), 4.20-2.10 (18H, m, CH_2).

7. Synthesis of $Nd \cdot L^{pyr}$

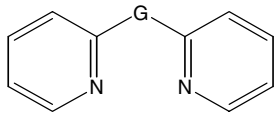
L^{pyr} (0.05 g, 0.063 mmol) was dissolved in methanol (5 cm^3) and 1 equiv. of $Nd(OTf)_3$ (0.037 g, 0.063 mmol) added. The mixture was stirred at 50 °C for 24 h. The reaction mixture was then cooled and the reaction volume reduced to a minimum. The concentrate was then added dropwise to stirring, ice cold diethyl ether (20 cm^3) inducing precipitation (yield, 0.051 g, 86%). IR (KBr disc) $\nu = 3042$, 2968, 1618, 1540, 1438, 1406, 1272, 1250, 1164, 1030, 994, 962, 914, 846, 714 cm^{-1}. UV–Vis (MeOH) λ_{max} (ε/mol^{-1} dm^3 cm^{-1}) 339 (14 500), 326 (14 100), 276 (23 900), 266 (22 300), 241 (37 800) nm: MALDI (3-NOBA) m/z 933 $\{M+H\}^+$ with correct isotopic distribution.

8. Synthesis of $Er \cdot L^{pyr}$

As for $\mathbf{Nd \cdot L^{pyr}}$ but using $Er(OTf)_3$ (0.039 g, 0.063 mmol). (Yield 0.052 g, 87%). IR (KBr disc) $\nu = 3044$, 2976, 2922, 1624, 1538, 1438, 1406, 1242, 1164, 1084, 1030, 714 cm^{-1}. UV–Vis (MeOH) λ_{max} (ε/mol^{-1} dm^3 cm^{-1}) 341 (19 600), 323 (21 300), 275 (40 600), 266 (39 400), 244 (49 500) nm. MALDI (3-NOBA): m/z 957 $\{M+H\}^+$ with correct isotopic distribution.

9. Synthesis of $Yb \cdot L^{pyr}$

As for $\mathbf{Nd \cdot L^{pyr}}$ but using $Yb(OTf)_3$ (0.039 g, 0.063 mmol). (Yield 0.051 g, 84%). IR (KBr disc) $\nu = 3042$, 2970, 2922, 1618, 1540, 1436, 1404, 1272, 1250, 1166, 1092, 1031, 712 cm^{-1}. UV–Vis (MeOH) λ_{max} (ε/mol^{-1} dm^3 cm^{-1}) 348 (17 100), 312 (20 100), 264 (39 800), 248 (43 400) nm. MALDI (3-NOBA): m/z 963 $\{M+H\}^+$ with correct isotopic distribution.



Acknowledgements

The author thanks the Universities of Cardiff and Manchester for support. Mrs. Valerie Boote of the School of Chemistry, The University of Manchester is acknowledged for mass spectrometry, and Dr. Rebecca Laye for assistance with the infrared measurements.

Fig. 1. Di-(2-pyridyl) ligands.

2. Experimental

2.1. Reagents and general procedures

All manipulations of air and moisture sensitive materials were carried out under dinitrogen using Schlenk techniques. Solvents were dried before use by standard methods. Di-(2-pyridyl)ketone, $NaS_2CNEt_2 \cdot 3H_2O$ and $PdCl_2$ were obtained commercially (Aldrich) and used as received. Melting points were recorded on a Mel-Temp II apparatus and are uncorrected. EI mass spectra were recorded on a Hewlett Packard 5989A spectrometer and FAB-mass spectra on a Jeol JMS-AX505HA mass spectrometer. Elemental analyses were performed on a Finnigan Flash EA 1112NC. IR spectra were recorded on a FT-IR 200 Perkin–Elmer spectrophotometer in the 4000–400 cm^{-1} range using KBr and CsI pellets. NMR spectra were recorded on a Jeol GSX 400 spectrometer. ^1H (399.78 MHz) and ^{13}C (100.53 MHz) spectra were obtained in DMSO-d_6. Chemical shifts (ppm) are relative to $Si(CH_3)_4$. NMR assignments of **1**–**7** were made by two-dimensional heteronuclear and homonuclear correlation experiments (hetcor, coloc and cosy). Single-crystal X-ray structures determination of compounds **3**–**7** were performed at room temperature on a Bruker Smart 6000 CCD diffractometer using graphite monochromated Mo Kα radiation (0.71073 Å). Structures of compounds **3**–**6** were solved by direct methods and the structure of the compound **7** was solved by Patterson method (SHELXTL NT 5.10) [18]. All non-hydrogen atoms were refined anisotropically. The positions of the hydrogen atoms were kept fixed with a common isotropic displacement parameter.

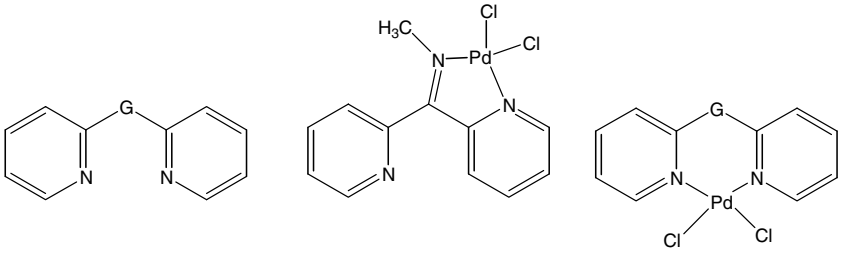
2.2. Synthesis of di-(2-pyridyl)methane ligands **1**–**4**

Ligands **1** [19], **2** and **3** [20] were prepared as previously described; these ligands were characterized by means of NMR in $CDCl_3$ solution; for the sake of this work we have characterized them in DMSO-d_6 solution and reported below.

2.2.1. Di-(2-pyridyl)-N-methylimine (**1**)

Moisture-sensitive yellow solid. M.p. 67–68 °C. ^1H NMR (DMSO-d_6) δ: 8.66 (dd, 1H, H-12, $^3J_{H12-H11} = 4.85$ Hz, $^4J_{H12-H10} = 1.83$ Hz), 8.43 (dd, 1H, H-6, $^3J_{H6-H5} = 4.76$ Hz, $^4J_{H6-H4} = 1.83$ Hz), 8.14 (d, 1H, H-9, $^3J_{H9-H10} = 8.05$ Hz), 7.89 (m, 2H, H-4, H-10), 7.42 (m, 2H, H-5, H-11,), 7.32 (dd, 1H, H-3, $^3J_{H3-H4} = 7.68$, $^4J_{H3-H5} = 1.09$ Hz), 3.19 (s, 3H, N-CH_3); ^{13}C {^1H} NMR (DMSO-d_6) δ: 168.4 (C-13), 157.0 (C-2), 155.3 (C-8), 149.8 (C-12), 148.9 (C-6), 137.2 (C-4), 136.7 (C-10), 125.0 (C-5), 124.2 (C-3), 123.6 (C-11), 121.8 (C-9), 41.3 (N-CH_3).

2.2.2. Di-(2-pyridyl)methanol (**2**)



Yellow oil. ^1H NMR (DMSO-d_6) δ: 8.47 (d, 1H, H-6, $^3J_{H6-H5} = 4.40$ Hz), 7.78 (dd, 1H, H-4, $^3J_{H4-H3} = 7.68$, $^3J_{H4-H5} = 7.72$ Hz), 7.57 (d, 1H, H-3, $^3J_{H3-H4} = 7.68$ Hz), 7.22 (ddd, 1H, H-5, $^3J_{H5-H6} = 4.40$ Hz, $^3J_{H5-H4}$=7.72 Hz, $^4J_{H4-H6} = 1.48$ Hz), 6.28 (d, 1H, OH, $^3J_{OH14-H13} = 4.76$ Hz), 5.83 (d, 1H, CH-13, $^3J_{H13-OH14} = 5.12$ Hz); ^{13}C {^1H} NMR (DMSO-d_6) δ: 163.2 (C-2), 148.9 (C-6), 137.2 (C-4), 122.9 (C-5), 121.7 (C-3), 77.5 (C-13).

2.2.3. Di-(2-pyridyl)methylchloride (**3**)

Colorless solid. Dec. 67–69 °C. ^1H NMR (DMSO-d_6) δ: 9.03 (d, 1H, H-6, $^3J_{H6-H5} = 5.12$ Hz); 8.19 (dd, 1H, H-4, $^3J_{H4-H3} = 7.32$ Hz, $^3J_{H4-H5} = 7.60$ Hz); 7.95 (d, 1H, H-3, $^3J_{H3-H4} = 7.32$ Hz); 7.68 (dd, 1H, H-5, $^3J_{H5-H6} = 5.12$ Hz, $^3J_{H5-H4} = 7.60$ Hz); 7.18 (s, 1H, CH-13). ^{13}C {^1H} NMR (DMSO-d_6) δ: 155.3 (C-6); 151.9 (C-2); 142.0 (C-4); 126.8 (C-5); 126.6 (C-3); 60.8 (C-13).

2.2.4. Di-(2-pyridyl)methyl-N,N-diethyldithiocarbamate (**4**)

A mixture of **3** (0.100 g, 0.443 mmol) and sodium diethyldithiocarbamate trihydrate (0.120 g, 0.532 mmol) in

1 G= CNMe
2 G= CH(OH)
3 G= CH(Cl)
4 G= $CH(S_2CNEt_2)$

5

6 G= CH(OH)
7 G= $CH(S_2CNEt_2)$

Fig. 2. Ligands and complexes synthesized.

25 mL of dry $CHCl_3$ was refluxed for 16 h. The colorless solution obtained was cooled to room temperature, filtered and dried by means of a column of Celite and Na_2SO_4. The solvent was evaporated to dryness in vacuum to give colorless crystals. Yield: 78% (0.120 g). M.p. 69 °C. *Anal*. Calc. for $C_{16}H_{19}N_3S_2$; C, 60.53; H, 6.03; N, 13.24. Found: C, 60.30; H, 6.18; N, 12.92%. IR (KBr, cm^{-1}) $\nu = 3066$, 3040 (Ar–H); 2979, 2860 (Aliph-H); 1642 (C=N); 1582, 1493, 1471 (C=C); 1271 (C=S). ^{1}H NMR (DMSO-d_6) δ: 8.48 (d, 1H, H-6, $^3J_{H6–H5} = 4.02$ Hz); 7.75 (ddd, 1H, H-4, $^3J_{H4–H5} = 7.68$ Hz, $^3J_{H4–H3} = 8.05$ Hz, $^4J_{H4–H6} = 1.83$ Hz); 7.58 (d, 1H, H-3, $^3J_{H3–H4} = 8.05$ Hz); 7.24 (dd, 1H, H-5, $^3J_{H5–H4} = 7.68$ Hz, $^3J_{H5–H6} = 4.02$ Hz); 6.64 (s, 1H, CH-13), 3.91 (q, 2H, CH_2, $^3J_{H18–H19} = 7.00$ Hz), 3.77 (q, 2H, CH_2, $^3J_{H20–H21} = 7.00$ Hz); 1.21 (t, 3H, CH_3 $^3J_{H19–H18} = 17.00$ Hz), 1.13 (t, 3H, CH_3, $^3J_{H21–H20} = 7.00$ Hz). ^{13}C {^{1}H} NMR (DMSO-d_6) δ: 192.7 (C=S); 159.5 (C-2); 149.7 (C-6); 137.4 (C-4); 123.7 (C-3); 122.9 (C-5); 63.2 (C-13); 49.9 (CH_2-18), 47.2 (CH_2-20); 13.1 (CH_3-19), 11.9 (CH_3-21).

2.3. Synthesis of cis-dichloropalladium(II) complexes (5–7)

2.3.1. cis-Dichloro[di-(2-pyridyl)-N-methylimine]palladium(II) (5)

0.112 g (0.56 mmol) of **1** were added to a solution of $PdCl_2$ (0.100 g, 0.56 mmol) in 25 mL of dry acetonitrile. The mixture was refluxed for 16 h, cooled to room temperature and after the solvent was evaporated to dryness in vacuum to give yellow crystals. Yield: 90% (0.190 g). Dec. 187–190 °C. *Anal*. Calc. for $C_{12}H_{11}Cl_2N_3Pd$: C, 38.48; H, 2.96; N, 11.22. Found: C, 37.17; H 2.69; N, 11.22%. IR (KBr, cm^{-1}) $\nu = 3093$, 3059 (Ar–H); 2980, 2926 (Aliph-H); 1615 (C=N); 1582, 1568, 1468 (C=C). ^{1}H NMR (DMSO-d_6) δ: 9.12 (d, 1H, H-12, $^3J_{H12–H11} = 4.76$ Hz); 8.87 (d, 1H, H-6, $^3J_{H6–H5} = 4.76$ Hz); 8.21 (ddd, 1H, H-10, $^3J_{H10–H9} = 7.69$ Hz, $^3J_{H10–H11} = 7.87$ Hz, $^4J_{H10–H12} = 1.46$ Hz); 8.15 (ddd, 1H, H-4, $^3J_{H4–H3} = 7.70$ Hz, $^3J_{H4–H5} = 7.51$ Hz, $^4J_{H4–H6} = 1.46$ Hz); 7.91 (m, 2H, H-3, H-11); 7.72 (dd, 1H, H-5, $^3J_{H5–H4} = 7.51$ Hz, $^3J_{H5–H6} = 4.76$ Hz); 7.26 (d, 1H, H-9, $^3J_{H9–H10} = 7.69$ Hz); 3.34 (s, 3H, N-CH_3). ^{13}C {^{1}H} NMR (DMSO-d_6) δ: 176.4 (C-13); 157.3 (C-2); 151.1 (C-6); 151.0 (C-12); 148.7 (C-8); 141.9 (C-10); 138.5 (C-4); 129.6 (C-9); 129.4 (C-11); 126.6 (C-5); 125.5 (C-3); 44.6 (N-CH_3).

2.3.2. cis-Dichloro[di-(2-pyridyl)methanol]palladium(II) (6)

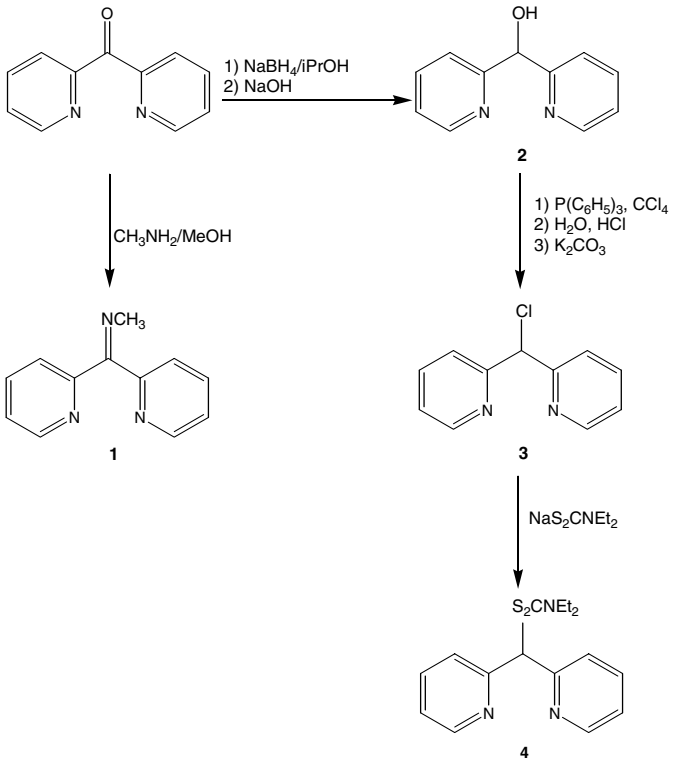
0.500 g (2.70 mmol) of **2** were added to a solution of $PdCl_2$ (0.480 g, 2.70 mmol) in 40 mL of dry acetonitrile. The solution was refluxed for 16 h and after the solvent was evaporated to dryness in vacuum to give yellow crystals. Yield: 92% (0.90 g). Dec. 244–248 °C. *Anal*. Calc. for $C_{12}H_{10}Cl_2N_2OPd$: C, 36.34; H, 2.77; N, 7.71. Found: C, 36.51; H, 2.79; N, 8.82%. IR (KBr, cm^{-1}) ν: 3430 (O–H); 3115 (Ar–H); 2900 (Aliph-H); 1601 (C=N, C=C); 1568, 1463 (C=C). ^{1}H NMR (DMSO-d_6) δ: 8.77 (d, 1H, H-6, $^3J_{H6–H5} = 5.12$ Hz); 8.13 (dd, 1H, H-4, $^3J_{H4–H5} = {}^3J_{H4–H3} = 7.68$ Hz); 7.84 (d, 1H, H-3, $^3J_{H3–H4} = 7.68$ Hz); 7.81 (d, 1H, OH, $^3J_{OH14–H13} = 4.94$ Hz); 7.48 (dd, 1H, H-5, $^3J_{H5–H4} = 7.68$ Hz, $^3J_{H5–H6} = 5.12$ Hz); 6.72 (d, 1H, CH-13, $^3J_{H13–OH14} = 5.12$ Hz). ^{13}C {^{1}H} NMR (DMSO-d_6) δ: 158.2 (C-2); 153.2 (C-6); 141.5 (C-4); 125.3 (C-5); 122.2 (C-3); 75.8 (C-13).

2.3.3. cis-Dichloro[di-(2-pyridyl)methyl-N,N-diethyldithiocarbamate]palladium(II) (7)

0.0685 g (0.215 mmol) of **4** were added to a solution of $PdCl_2$ (0.038 g, 0.214 mmol) in 25 mL of dry acetonitrinile. The suspension was refluxed for 24 h and then cooled to room temperature. The cold suspension was filtered. From the saturated solution were obtained yellow-brown crystals by slow evaporation. Yield: 90% (0.09 g). M.p: 243–245 °C. *Anal*. Calc. for $C_{16}H_{19}Cl_2N_3PdS_2$: C, 38.84; H, 3.87; N, 8.49. Found: C, 38.85; H, 4.44; N, 7.90%. IR (KBr, cm^{-1}) $\nu = 3097$, 3071 (Ar–H); 2920, 2851 (Aliph-H); 1619 (C=N); 1601, 1472, 1438 (C=C); 1183(C=S). ^{1}H NMR (DMSO-d_6) δ: 8.91 (d, 1H, H-6, $^3J_{H6–H5} = 4.76$ Hz); 8.12 (dd, 1H, H-4, $^3J_{H4–H3} = 7.15$ Hz, $^3J_{H4–H5} = 6.90$ Hz, $^4J_{H4–H6} = 1.46$ Hz); 8.03 (d, 1H, H-3, $^3J_{H3–H4} = 7.15$ Hz); 7.58 (dd, 1H, H-5, $^3J_{H5–H4} = 6.90$, $^3J_{H5–H6} = 4.76$ Hz); 7.09 (s, 1H, CH-13); 3.96 (q, 2H, CH_2, $^3J_{H18–H19} = 6.96$ Hz), 3.84 (q, 2H, CH_2, $^3J_{H20–H21} = 6.96$ Hz); 1.27 (t, 3H, CH_3, $^3J_{H19–H18} = 6.96$ Hz); 1.18 (t, 3H, CH_3, $^3J_{H21–H20} = 6.96$ Hz). ^{13}C {^{1}H} NMR (DMSO-d_6) δ: 189.9 (C=S); 153.6 (C-2); 154.5 (C-6); 141.4 (C-4); 127.0 (C-3); 125.9 (C-5); 61.9 (C-13); 50.6 (CH_2-18), 47.8 (CH_2-20); 13.1 (CH_3-19), 11.7 (CH_3-21).

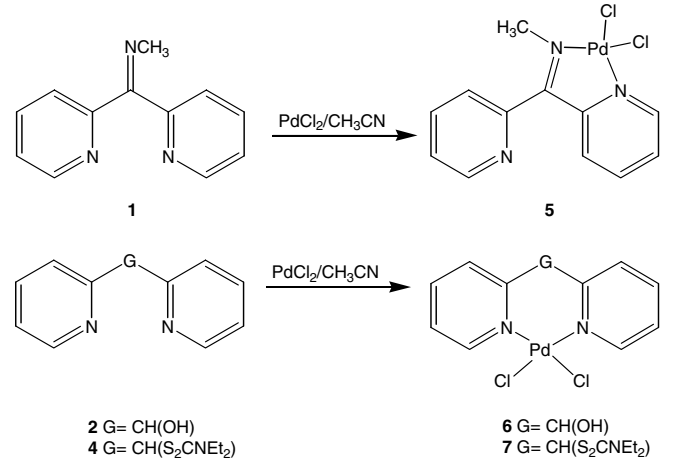
3. Results and discussion

3.1. Synthesis of derivatives of di-(2-pyridyl)methane (1–4)



Ligands **1**–**3** were prepared as previously described [19,20], whereas the ligand **4** was synthesized from the reaction of **3** with an excess of sodium diethyldithiocarbamate trihydrate in hot $CHCl_3$, see Scheme 1.

3.2. Synthesis of palladium(II) complexes (5–7)



The *cis*-palladium(II) complexes **5**–**7** were synthesized from the reaction of di-(2-pyridyl)methane derivatives **1**, **2** and **4** with $PdCl_2$ in equimolar ratios in hot acetonitrile, see Scheme 2.

3.3. Mass spectrometry

EI mass spectra of ligands **1** and **2** showed the molecular ion peaks [$M^{\cdot+}$] at m/z (% intensity) = 197 (38%) and 186 (3%), respectively. For **3** was observed the peak [M^+−H] at 203 (1%) and for **4** was observed the peak [M^+−2H] at 315 (1%). In complexes **5** and **7**, FAB mass spectra showed the [$M^{\cdot+}$−Cl] peaks with the appropriate isotopic ratio at $m/z = 340$ (5%) and 460 (10%), respectively. In complex **6**

Scheme 1.

Scheme 2.

only was observed the $[M^+-PdCl_2H]$ peak at 185 (30%), assigned to the deprotonate free ligand **2**. No more peaks could be assigned.

3.4. Infrared spectroscopy

In ligands **1**–**4**, IR spectra showed a weak band at 1683, 1684, 1645 and 1642 cm^{-1} respectively, assignable to the ν(C=N) absorption. For complexes **5** and **7** the ν(C=N) absorption is shifted to lower wave numbers (1615 and 1619 cm^{-1}, respectively). In **6** the ν(C=N) absorption is overlapped with the ν(C=C) absorption at 1601 cm^{-1}. The ν(C=N) absorption analysis indicates the coordination of the nitrogen atoms to the palladium atom.

3.5. NMR spectra

^1H and ^{13}C NMR spectra of **1**–**7** were obtained at room temperature in DMSO-d_6.

^1H NMR spectra of ligands **2**–**4** displayed four signals in the aromatic region. On the other hand, in the ^1H spectrum of **1** were observed six signals in the same region. In **2**, **3** and **4** the CH group was observed as a single signal at 5.83, 7.18 and 6.64 ppm, respectively, whereas in **1** the N-CH_3 group was observed as a single signal at 3.19 ppm. In **4** the ethyl groups are magnetically nonequivalent. The CH_2 groups were observed at 3.91 and 3.77 ppm as triplet signals and the CH_3 groups as quartet signals at 1.21 and 1.13 ppm. In **4** we used the line-shape analysis method at 20–90 °C in DMSO-d_6 with increments of 10 °C. The activation free energy ($\Delta G_c^{\neq}$) was calculated to be 22.1 kcal/mol with $T_c = 75$ °C. The $\Delta G_c^{\neq}$ value obtained in **4** confirms the restricted C–N bond rotation in the dithiocarbamate fragment as has previously been described in analogue molecules [21].

In **1** the ^{13}C spectrum showed ten signals as reported [19] but ^{13}C spectra of **2**–**4** showed five signals for the pyridinic rings. In ^{13}C spectra the bridging C13 carbon atom was observed at 77.5 for **2**, 60.8 for **3** and 63.2 ppm for **4**. The C=S group in **4** was observed at 192.7 ppm; the magnetically nonequivalent CH_2 and CH_3 groups were observed at 49.9, 47.2 and 13.1, 11.9 ppm, respectively.

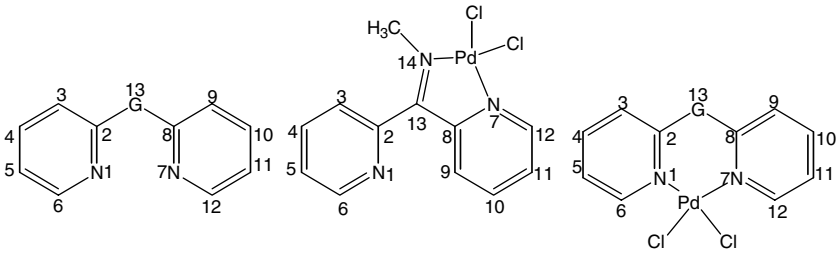
^1H and ^{13}C NMR data for ligands **2**–**4** at room temperature suggest that the bonds formed between the *ipso* carbon of the pyridinic rings and the carbon bridging group rotate freely in solution. The presence of the rigid C=N bond in **1** produces a different environment for pyridinic rings respect to the methyl group (*E*–*Z* position). Due to the existence of signals attributable to two nonequivalent pyridinic rings in the spectra, we can conclude that the iminic bond does not isomerize or the isomerization is very slow [19]. This *E*–*Z* isomerization process has been studied in *N*-substituted imines analogues to **1** and explained by a nitrogen inversion mechanism [22].

^1H NMR spectra of dichloropalladium(II) complexes **5**–**7** and those of ligands **1**, **2** and **4** did not show significant variations in the chemical shifts. On the other hand, ^{13}C data of complexes **5**–**7** showed important variations in the chemical shifts for the C2, C6, C8, C12 and C13 carbons closer to the coordination sites, with respect to the free ligands **1**, **2** and **4**. In Table 1 is showed the variation of chemical shifts, $\Delta\delta$. Negative values of $\Delta\delta$ indicate variations in the chemical shift towards higher frequencies after coordination, whereas $+\Delta\delta$ indicate chemical shifts to lower frequencies (Table 1). In **5**, the C8 and C13 atoms in the five-membered chelate ring are the most protected and unprotected, respectively. These large values can be attributable to the coordination of the iminic nitrogen to the palladium atom. In contrast, in the complexes **6** and

Table 1
Variation of chemical shifts ($\Delta\delta$) of ^{13}C in ppm for the complexes **5**–**7** respect to the free ligands

Complexes	C-2	C-6	C-8	C-12	C-13
5	−0.3	−2.2	+6.6	−1.2	−8.0
6	+5.0[a]	−4.3[b]	+5.0[a]	−4.3[b]	+1.7
7	+5.9[a]	−4.8[b]	+5.9[a]	−4.8[b]	+1.3

[a–b] Carbon atoms observed as averaged signals.



7 where six-membered chelate rings are formed, the C13 carbon atom is slightly protected (small $\Delta\delta$) whilst the C2 and C8 *ipso* carbons are the most protected upon coordination. The metallic coordination also affects the C6 and C12 *ortho* carbons, displaying deshielding effects. These variations of $\Delta\delta$ values for complexes **6** and **7** confirm the coordination of both pyridinic nitrogen atoms to the palladium atom.

3.6. X-ray crystallography

The structures in the crystalline solid state of compounds **3**–**7** were determined by single-crystal X-ray diffraction analyses. Crystallographic data are given in Table 2 and selected bond lengths and angles are given in Table 3.

Molecular structures of ligands **3** and **4** are showed in Figs. 3 and 4. In the unit cell of **3** there are two crystallographic independent molecules named **3a** and **3b**, Fig. 3.

The X-ray structures of **3** and **4** showed that they are not planar; in **3a**, the pyridinic rings are twisted around the bridging carbon and the *ipso* carbon bonds. In order to describe the conformation of the ligands **3** and **4**, we assume a *syn* conformation if the N–C–C–Y torsional angle (Y = Cl for **3** and Y = S for **4**) is lesser than 90 °

[a] Averaged distances for the two crystallographic independent molecules.

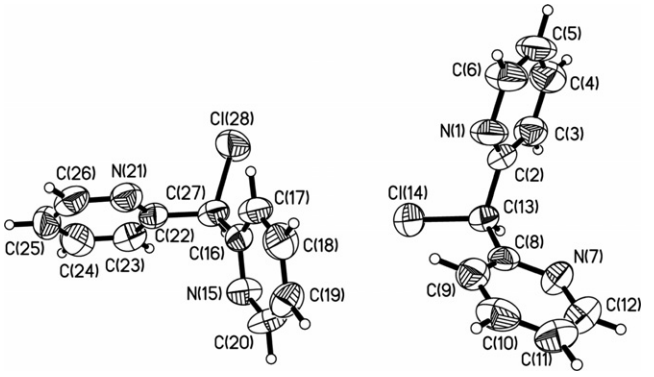

Fig. 3. Molecular structure of **3** with labeled atoms and 50% probability displacement ellipsoids.

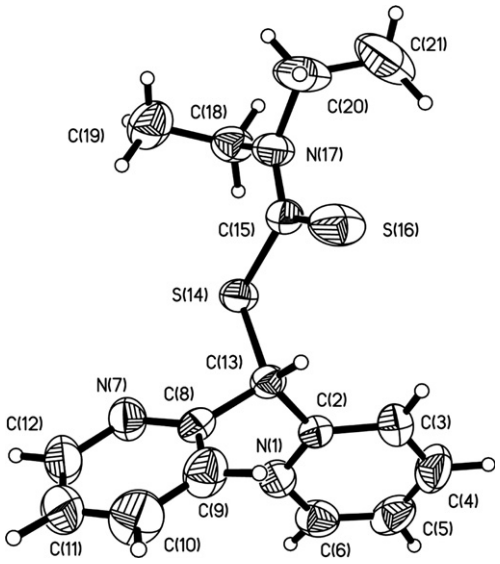

Fig. 4. Molecular structure **4** with labeled atoms and 50% probability displacement ellipsoids.

and *anti* if it is larger [19]. In **3** one of the torsional angles is 72.2(4)° and the other one is 152.4(3)° (see Table 3). Hence, the conformation of **3** can be described as *syn–anti*. In **4**, the torsional angles are 86.5(2)° and 30.1(3)°. The magnitude of these angles indicates that **4** exhibits in solid state a *syn–syn* conformation. There are three sulphur–carbon distances (1.823(2), 1.786(2) and 1.663(2) Å). The first two are consistent with a single bond and the last one with a double bond; they are similar to that found in analogue compounds [1.807(3), 1.758(3) and 1.664(3) Å in ethylene bis(dimethyl–dithiocarbamate) and 1.812(2), 1.778(2) and 1.675(2) Å in butane-1,4-diyl bis(dimethyldithiocarbamate)] [23]. The sum of the angles around nitrogen is close to 360° indicating a planar geometry.

Crystallographic data showed that the ligands **1**, **2** and **4** behave as bidentate ligands when coordinate to Pd(II). The X-ray structures of the palladium complexes **5**–**7** consist of neutral molecules with square planar Pd(II) (Figs. 5–7).

The N–Pd distances in these compounds are significantly the same [2.027(4) and 2.033(4) Å in **5**; 2.028(4) and 2.030(3) Å in **6** and 2.038(7) and 2.045(7) Å in **7**] and are similar to other previously reported for dipyridinic and pyridinic complexes containing N–Pd bonds [13,14,24–26]. The main difference between **5** and the **6** and **7** pair is the coordination mode; in **5** the iminic nitrogen and one pyridinic nitrogen are coordinated to Pd forming a five-membered chelate ring, whereas in **6** and **7** both pyridinic rings are coordinated, forming six-membered chelate rings with bite angles of 80.4(2)°, 87.3(2)° and 87.2(3)°, respectively. These data confirm the results obtained by the NMR analyses. In addition, complexes **6** and **7** are also not planar (dihedral angles between the pyridinic rings are 118.4° and 113.2° for **6** and **7**, respectively).

In the palladium complexes **5**–**7** the pyridinic rings are also twisted as in the free ligands **1** and **4** in solid state. In **5**, the torsional angles N7–C8–C13–N14 and N1–C2–C13–N14 measured around the bridging carbon and the ipso carbon bonds are 1.2(6)° and 76.3(5)°; displaying a *syn–syn* conformation [19]. In **6**, the torsional angles are 177.0(4)° and 177.7(4)° displaying an *anti–anti* conformation, whereas that in **7** the conformer is *syn–syn* with torsional angles of 63.3(1)° and 59.2(9)°.

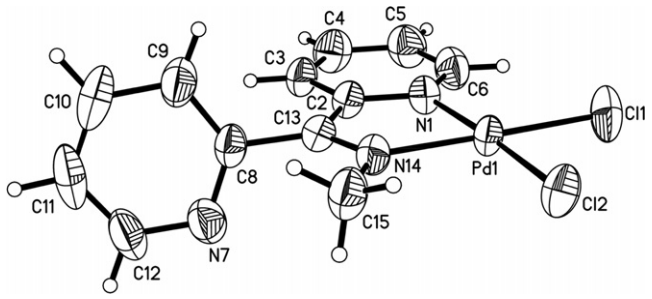

Fig. 5. Molecular structure of **5** with labeled atoms and 50% probability displacement ellipsoids.

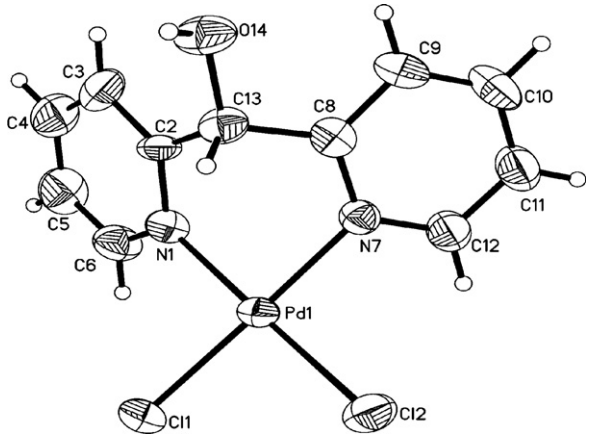

Fig. 6. Molecular structure of **6** with labeled atoms and 50% probability displacement ellipsoids.

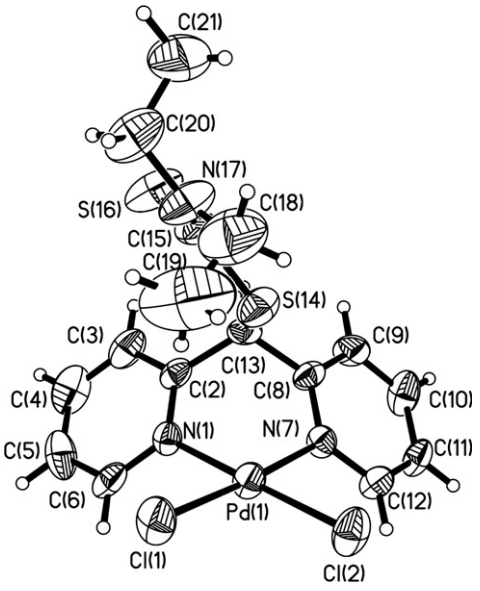

Fig. 7. Molecular structure of **7** with labeled atoms and 50% probability displacement ellipsoids.

Respect to the complexes **6** and **7** where six-membered chelate rings are formed, the central ring in both complexes is in a boat conformation, however the position of the exocyclic ligands is very different. The –OH ligand in **6** is in a bowsprit position whereas the $-S_2CNEt_2$ ligand in **7** is in a flagpole position as the predominant conformers in solid state. This difference can be attributable to an intramolecular contact between the soft acid palladium and the soft base sulphur (Pd—S = 3.054 Å) that is shorter than the van der Waals radii sum ($\sum r_{vdW}(Pd,S) = 3.43$ Å) but longer than the covalent radii sum ($\sum r_{cov}(Pd,S) = 2.33$ Å) [27].

4. Conclusion

Complexes *cis*-dichloro[di-(2-pyridyl)-*N*-methylimine]-palladium(II) (**5**), *cis*-dichloro[di-(2-pyridyl)methanol]palladium(II) (**6**) and *cis*-dichloro[di-(2-pyridyl)methyl-*N*,*N*-diethyldithiocarbamate]palladium(II) have been characterized and synthesized. The presence of donor *N*-methylimine, hydroxy and *N*,*N*-diethyldithiocarbamate fragments bound to the methylene bridge opens the possibility in the free ligands **1**, **2** and **4** to act as a tridentate ligands, however, they solely coordinate to the palladium atom in a bidentate fashion. The complexes differ in the size of the chelate ring; in **6** and **7** the rings are six-membered whereas in **5** is five-membered sized. The difference in the coordination mode can be attributable to the rigidity of the iminic carbon present in **5**.

5. Supplementary material

CCDC 634227, 634228, 634225, 634226 and 634229 contain the supplementary crystallographic data for **3**, **4**, **5**, **6**

and **7**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

structure of transition metal complexes. It meets with the requirements of being accurate, easy to use and fast enough to allow the study of relatively large molecules of transition metal complexes [15]. Recent studies have also supported the TD-DFT method to be applicable for open- and closed-shell 5d-metal complexes, giving good assignment of experimental spectra [16–18].

2. Experimental

2.1. General procedure

All the reagents used for the syntheses were commercially available and were used without further purification. The $[ReCl_3(MeCN)(PPh_3)_2]$ complex was prepared as reported previously [12], and bis(pyrazol-1-yl)methane was synthesised according to the modified literature method [19].

The IR spectrum were recorded on a Nicolet Magna 560 spectrophotometer in the spectral range 4000–400 cm^{-1} with the sample in the form of KBr pellets. The electronic spectrum was measured on a spectrophotometer Lab Alliance UV–Vis 8500 in the range 1000–200 nm in dichloromethane solution. Elemental analyses (C H N) were performed on a Perkin–Elmer CHN-2400 analyzer.

2.2. Preparation of bis(pyrazol-1-yl)methane (bpzm)

Pyrazole (9.6 g, 0.1 mol), $Bu_4N^+HSO_4^-$ (1.7 g, 0.005 mol), potassium carbonate (13.8 g, 0.1 mol), powdered KOH (5,6 g, 0.1 mol), and an excess of dry methylene chloride (300 cm^3) were intensively stirred and refluxed in a water bath for 6 h. After this time, a second portion of KOH (5.6 g, 0.1 mol) and $Bu_4N^+HSO_4^-$ (1.7 g, 0.005 mol) was added and the mixture was intensively stirred and refluxed for an additional 6 h. The liquid layer was removed and the residue was washed three times with 100 cm^3 of methylene chloride. The combined organic layers were dried with anhydrous magnesium sulfate and methylene chloride was removed on a rotary evaporator. The pale yellow residue was purified by vacuum sublimation as previously described [19] (isolated yield 87%, 8.9 g).

2.3. Preparation of $[ReCl_3(bpzm)(PPh_3)] \cdot CH_2Cl_2$

$[Re(MeCN)Cl_3(PPh_3)_2]$ (0.50 g, 0.58 mmol) and bpzm (0.1 g, 0.67 mmol) in dichloromethane (40 cm^3) were refluxed for 4 h. The starting material gradually dissolved and the colour of the reaction solution became dark brown. The volume was condensed to 10 cm^3, diethyl ether (50 cm^3) was added and a brown microcrystalline solid was filtered. The product was washed with EtOH and cold ether, and dried in vacuo (yield 90%). The crystals suitable for X-ray investigation were obtained by recrystallization from a mixture of dichloromethane/methanol.

IR (KBr; ν/cm^{-1}): 1587(w), 1574(w), 1518(m) and 1510 (w) ν_{CN} and $\nu_{C=C}$;

Anal. Calc. for $C_{26}H_{25}Cl_5N_4PRe$: C, 39.63; H, 3.20; N, 7.11. Found: C, 39.75; H, 3.30; N, 7.29%.

2.4. X-ray diffraction studies

A brown crystal of $[ReCl_3(bpzm)(PPh_3)] \cdot CH_2Cl_2$ was mounted on a KM-4-CCD automatic diffractometer equipped with a CCD detector, and used for data collection. X-ray intensity data were collected with graphite monochromated MoKα radiation ($\lambda = 0.71073$ Å) at 295(1) K. Details concerning crystal data and refinement are given in Table 1. Lorentz, polarization and numerical absorption corrections [20] were applied. The structure was solved by the Patterson method and subsequently completed by difference Fourier recycling. All the non-hydrogen atoms were refined anisotropically using the full-matrix, least-squares technique. The hydrogen atoms were treated as ''riding'' on their parent carbon atoms and assigned isotropic temperature factors equal to 1.2 times the value of the equivalent temperature factor of the parent atom. SHELXS97 [21], SHELXL97 [22] and SHELXTL [23] programs were used for all the calculations. Atomic scattering factors were those incorporated in the computer programs.

2.5. Computational details

The GAUSSIAN03 program [24] was used in the calculations. The geometry optimisation of the $[ReCl_3(bpzm)(PPh_3)]$ complex was carried out with the DFT method

Largest difference peak and hole (e Å^{-3})	0.863 and −0.832

with the use of the B3LYP functional [25,26]. The electronic spectrum of the $[ReCl_3(bpzm)(PPh_3)]$ complex was calculated with the TDDFT method [27]. The calculations were performed by using an ECP basis set on the rhenium atom, the standard 6-31+g** basis for chlorine, phosphorus and nitrogen, 6-31g* basis for carbon and 6-31G basis for hydrogen atoms. The Xe core electrons of Re were replaced by an effective core potential and a DZ quality Hay and Wadt Los Alamos ECP basis set (LANL2DZ) [28] was used for the valence electrons. An additional *d* function with exponent $\alpha = 0.3811$ and *f* function with exponent $\alpha = 2.033$ on the rhenium atom were added.

2.6. Magnetic measurement

Magnetic measurements in the temperature range 1.8–300 K were performed using a Quantum Design SQUID-based MPMSXL-5-type magnetometer. The SQUID magnetometer was calibrated with the palladium rod sample (Materials Research Corporation, measured purity 99.9985%). The superconducting magnet was generally operated at a field strength ranging from 0 to 5 T. Measurements were made at a magnetic field of 0.5 T. Corrections are based on subtracting the sample-holder signal and contribution χ_D estimated from the Pascal constants [29] and equal $-363 \times 10^{-6}\,cm^3\,mol^{-1}$ for complex $[ReCl_3(bpzm)(PPh_3)]$. The effective magnetic moment was calculated from the equation, $\mu_{eff} = 2.83(\chi_M T)^{1/2}$ (*B.M.*).

C(22)	Cl(3)	2.49	3.249(4)	134.7

3. Results and discussion

The $[ReCl_3(bzpm)(PPh_3)]$ complex was prepared in good yield by a ligand exchange reaction starting from $[ReCl_3(MeCN)(PPh_3)_2]$ and bis(pyrazol-1-yl)methane (bpzm):

$$[ReCl_3(MeCN)(PPh_3)_2] + bpzm \rightarrow [ReCl_3(bzpm)(PPh_3)] + MeCN + PPh_3$$

It was isolated as a brown microcrystalline solid, soluble in common organic solvents. The elemental analysis of the complex is in good agreement with its formulation. The characteristic bands corresponding to the ν(CN) and ν(C=C) modes of the bpzm ligand appear at 1600–1500 cm^{-1} in the IR spectrum of $[ReCl_3(bzpm)(PPh_3)]$ [30].

3.1. Crystal structure

$[ReCl_3(bzpm)(PPh_3)]$ crystallises as the dichloromethane solvate, and the dichloromethane molecule is not bonded to any atom of the Re(III) complex. No intermolecular interactions with enough strength to govern crystal packing or molecule conformation were found in the structure of $[ReCl_3(bzpm)(PPh_3)]$, only some weak intramolecular hydrogen bonds [31,32] were detected in the $[ReCl_3(bzpm)(PPh_3)]$ molecule and they are gathered in Table 2.

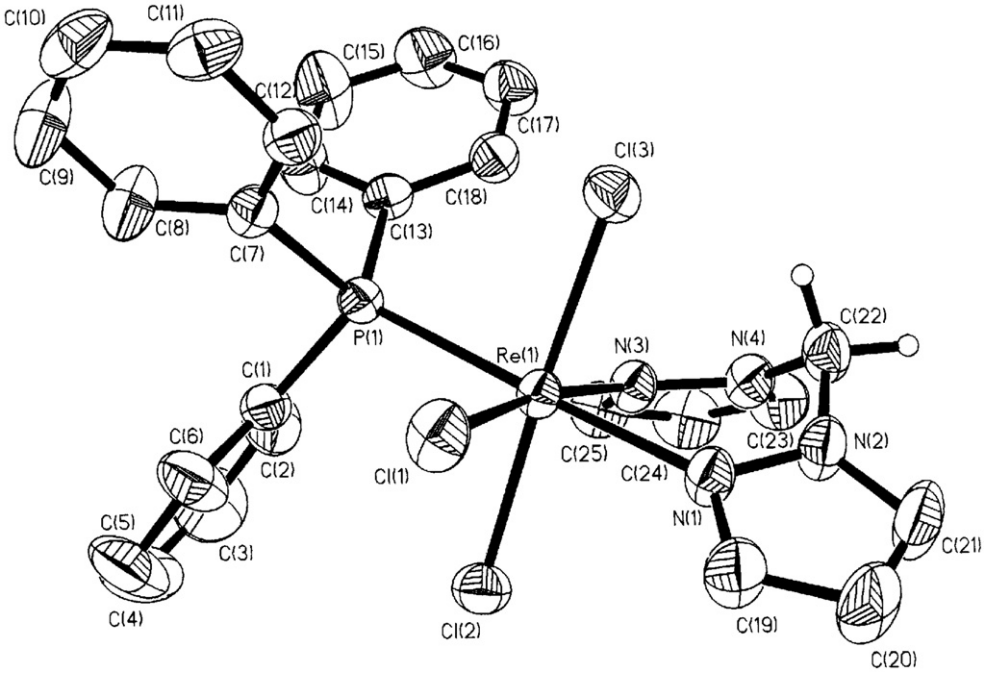

Fig. 1. The molecular structure of $[ReCl_3(bpzm)(PPh_3)]$ (50% probability ellipsoids). The hydrogen atoms of the phenyl and pyrazole rings are omitted for clarity.

The molecular structure of $[ReCl_3(bpzm)(PPh_3)]$ is given in Fig. 1. The pseudooctahedral environment of the Re center in $[ReCl_3(bpzm)(PPh_3)]$ shows clear distortions, induced by the bite angle of the chelating bpzm ligand. Upon coordination of bis(pyrazol-1-yl)methane to the rhenium centre, a six-membered cycle (made by the four nitrogen atoms, the rhenium atom and the carbon atom) is formed, and the formed ring shows a *boat* distorted toward *sofa* conformation with the rhenium and the carbon atoms off the plane defined by the four nitrogen atoms (with deviations from the least squares plane of 0.624(5) and 0.640(5) Å, respectively). The planar, in the range of experimental error, pyrazole rings are inclined at 57.1(2)°.

The chloride ions of $[ReCl_3(bpzm)(PPh_3)]$ are arranged in a *meridional* fashion, and the nitrogen atom of the bpzm ligand occupies the *trans* position to the Cl(1) ion. The *mer* geometry of the ReX_3 fragment has been confirmed for the $[ReCl_3(pzH)_2(PPh_3)]$ and $[ReCl_3(3,5\text{-}Me_2pzH)_2(PPh_3)]$ complexes [14], but in the $[ReX_3(L–L)(PPh_3)]$ compounds with bipy-like ligands the *mer* geometry is definitely rarer than the *fac* arrangement [33]. It seems that electronic factors favour the *meridional* configuration in $[ReCl_3(bpzm)(PPh_3)]$. The *facial* disposition of halide ions in the $[ReCl_3(L–L)(PPh_3)]$ complexes is preferred by the strong π acceptor L–L ligand, as it maximizes the back-bonding effect. It is significant that the Re–N distances in

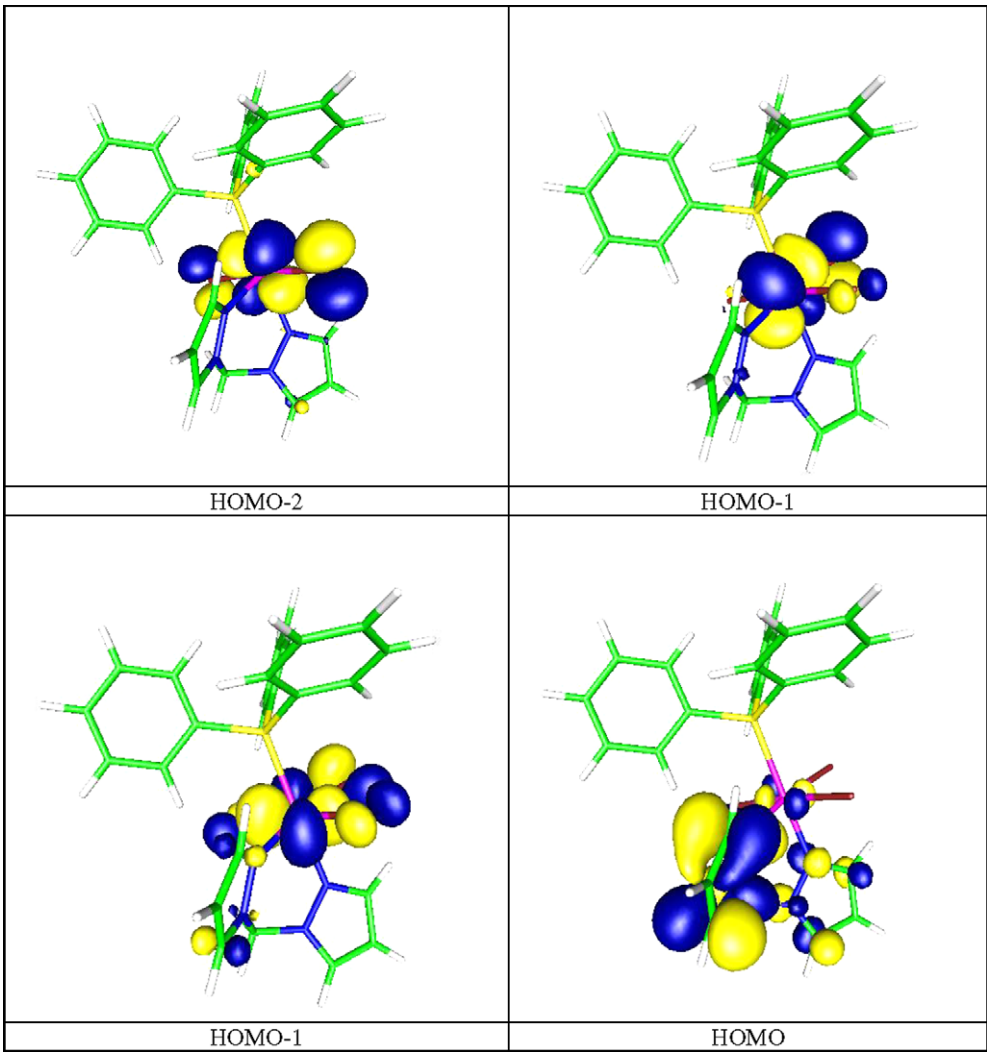

Fig. 2. The selected HOMO and LUMO orbitals with α spin for $[ReCl_3(bpzm)(PPh_3)]$. Positive values of the orbital contour are represented in blue (0.04 au) and negative values – in yellow (−0.04 au). (For interpretation of the references to colour in this figure, the reader is referred to the web version of this article.)

$[ReCl_3(bpzm)(PPh_3)]$ (2.146(3) and 2.122(3) Å) are longer than those in $[ReX_3(bipy)(PPh_3)]$ (2.099(8) and 2.094(8) Å), with the facial disposition of the halide ions [34]. On the other hand, these values are shorter than comparable distances for saturated amine complexes where metal-to-ligand π-back bonding is not possible, for instance, the Re–NH_2 distance in the compound $[Re(N_2)(ampy)(tbpy)(PPh_3)]PF_6$ is 2.197(7) Å [35]. Some differences are observed between the Re(1)–N(1) and Re(1)–N(3) bond lengths as the Re(1)–N(3) distance is affected by the *trans* influence of the triphenylphosphine ligand. The presence of Re–PPh_3 back-bonding diminishes the demand on π*(bpzm) orbitals. The most important experimental bond lengths and angles of $[ReCl_3(bzpm)(PPh_3)]$ are reported in Table 3.

3.2. Geometry optimisation

The geometry of $[ReCl_3(bpzm)(PPh_3)]$ was optimized in the triplet and singlet states using the DFT method with

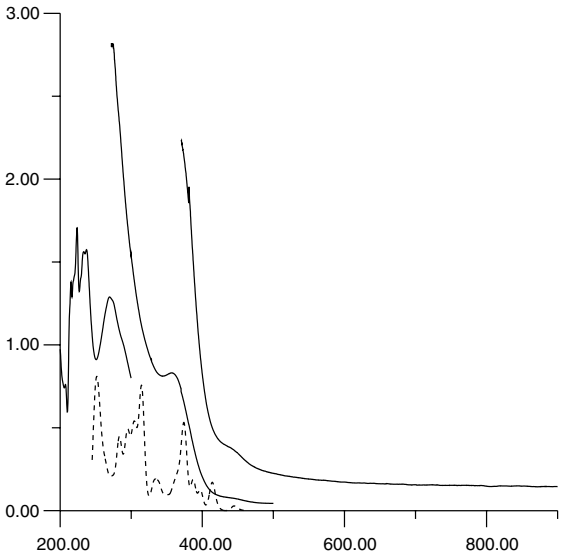

Fig. 3. The experimental (—) and calculated (---) electronic absorption spectra of $[ReCl_3(bpzm)(PPh_3)]$.

the B3LYP functional. The energy of the singlet state is 12.7 kcal higher. The optimized geometric parameters of the triplet state are gathered in Table 3. In general, the predicted bond lengths and angles are in agreement with the values based upon the X-ray crystal structure data, and the general trends observed in the experimental data are well reproduced in the calculations.

3.3. Molecular orbitals

The energies and characters of several highest occupied and lowest unoccupied molecular orbitals of [$ReCl_3$(bpzm)(PPh_3)] are presented in Table 4. The selected HOMO and LUMO orbitals of [$ReCl_3$(bpzm)(PPh_3)] with α spin are depicted in Fig. 2. Among the highest occupied MOs of [$ReCl_3$(bpzm)(PPh_3)], the largest numbers constitute π orbitals of the phenyl rings of PPh_3 and π_{Cl} orbitals. The H-2, H-1 and HOMO orbitals with α-spin and HOMO orbital with β-spin have π_{Re-Cl} character. The lowest unoccupied molecular orbital with α-spin is localised on the π-antibonding orbitals of the bpzm ligand. The LUMO and L+1 orbitals with β-spin can be represented as a combination of π_{Re-Cl}, and π_{bpzm}, with predominant involvement of the former component.

3.4. Electronic spectrum

The experimental and calculated electronic spectra of [$ReCl_3$(bpzm)(PPh_3)] are presented in Fig. 3. Each calculated transition is represented by a gaussian function

$y = ce^{-bx^2}$ with the height (c) equal to the oscillator strength and b equal to 0.04 nm^{-2}.

The spin-allowed triplet–triplet electronic transitions calculated with the TDDFT method for [$ReCl_3$(bpzm)-(PPh_3)] are gathered in Table 5. For the high energy part of the spectrum, only transitions with oscillator strengths larger than 0.0050 are listed in Table 5.

The investigated complex is of large size, the number of basis functions is equal to 605. A hundred electron transitions calculated by the TDDFT method do not comprise all the experimental absorption bands. The UV–Vis spectrum of [$ReCl_3$(bpzm)(PPh_3)] was calculated only to 240 nm, so the shortest wavelength experimental band cannot be assigned to the calculated transitions, and the assignment of the band at 226.8 nm is not complete. Some additional intraligand and interligand transitions are expected to be found at higher energies in the calculation for [$ReCl_3$(bzpm)(PPh_3)].

The electronic absorption spectrum of [$ReCl_3$(bpzm)-(PPh_3)] is similar to those observed for [$ReCl_3$(pzH)$_2$-(PPh_3)] and [$ReCl_3$(3,5-Me_2pzH)$_2$(PPh_3)] [14]. Some intense bands are observed below 300 nm and two considerably weaker absorptions exist in the low energy range. In contrast, the solution spectra of *fac*-[$ReCl_3$(L–L)(PPh_3)] display multiple transitions of moderate intensity in the form of peaks and shoulders in the visible region (400–1000 nm) [34,36].

The experimental bands of [$ReCl_3$(bpzm)(PPh_3)] at 435.0, 356.8 and 269.4 nm are attributed to Ligand–Metal Charge Transfer (π(Cl) → d and π(PPh_3) → d) and Metal–Ligand Charge Transfer (d → π*(PPh_3) and d → π*(bpzm)) transitions.

The absorption band at 226.8 nm results mainly from Ligand–Ligand Charge Transfer and intraligand (IL) transitions.

3.5. Magnetic properties

The magnetic properties of [$ReCl_3$(bpzm)(PPh_3)] under the form μ_{eff} versus T (μ_{eff} the effective magnetic moment) is shown in Fig. 4. The chloro-derivative of rhenium(III), shows a room temperature magnetic moment of 1.74 B.M. (0.379 $cm^3mol^{-1}K$). The magnetic moment of the solid is temperature dependent between 300 and 60 K. Only a slight magnetic anomaly is observed in the temperature range 55–14 K, and below 14 K the value of the χ_{MT} product decreases with temperature lowering. This behavior is characteristic of mononuclear d^4 low-spin octahedral Re(III) complexes ($^3T_{1g}$ ground state) [37–45] and arises because of the large spin–orbit coupling (ζ = 2500 cm^{-1} [46]), which gives a diamagnetic ground state. It seems that at room temperature, in accordance with Boltzmann's distribution, the higher magnetic state is populated, and it is depopulated with temperature lowering and a decrease of the magnetic moment is observed.

The variation of the magnetization M versus the magnetic field H for the complex [$ReCl_3$($OPPh_3$)(dppt)] at

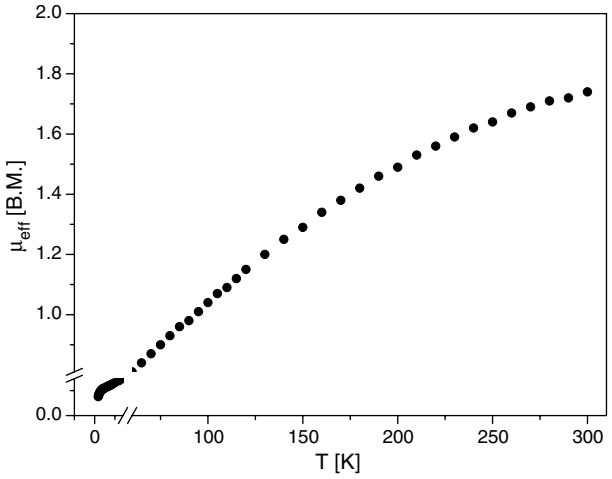

Fig. 4. Plots of the experimental effective magnetic moment μ_{eff} (●) vs. temperature for the complex [$ReCl_3$(bpzm)(PPh_3)].

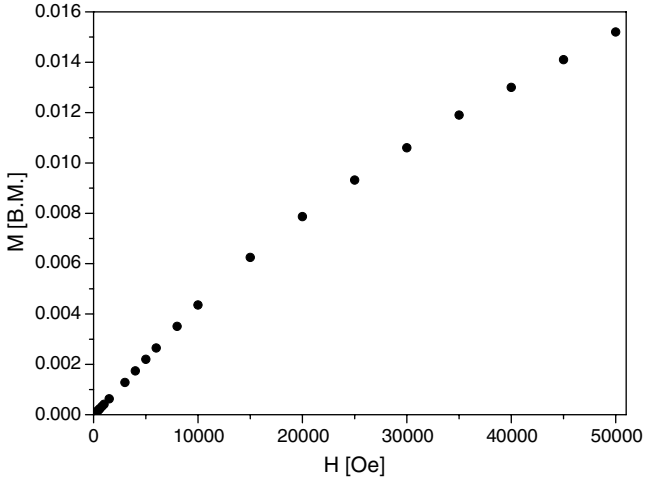

Fig. 5. Field dependence of the magnetization for the complex [$ReCl_3$(bpzm)(PPh_3)] at 2 K.

2 K is shown in Fig. 5. The M versus H curve for the complex very slowly increases and indicates a value of the magnetization near to zero (0.015 B.M.) at 5 T. The magnetization of the sample confirms that the ground state is diamagnetic.

4. Supplementary material

CCDC 640910 contains the supplementary crystallographic data for $C_{26}H_{25}Cl_5N_4PRe$. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or deposit@ccdc.cam.ac.uk.

electron donating ability. Herein we present the kinetic and mechanistic studies of the reaction of picolinic acid (picH) with Pd(α/β-NaiR)Cl_2. Picolinic acid which is a naturally occurring degradation product of tryptophan [35], a DNA base, is a cheap and safe drug facilitating Zn/Cu ion absorption from intestine because of its metal ion chelating activity. Also picolinic acid has an extra clinical antimicrobial chemo-theraupteic application. Phenylazoimidazole (**i**) Naphthylazoimidazole (**ii**)

Phenylazoimidazole (**i**)

Naphthylazoimidazole (**ii**)

2. Experimental

2.1. Reagents/materials

The complexes were prepared by a reported procedure [36,37]. Picolinic acid (picH) (SRL, Mumbai) was purified by recrystallization from boiling toluene. Acetonitrile (MeCN) (SRL, Mumbai) was purified by a known procedure [38,39]. All kinetic and spectroscopic measurements were recorded on an Agilent 8453E UV-Vis Spectroscopy System. Quartz cells (1.0 cm path length) from Hellma were used. IR spectra (KBr pellet) were recorded on a FT-IR Spectrophotometer Spectrum RX1, Perkin–Elmer. ^{1}H NMR spectra were drawn from 300 MHz Bruker NMR instrument in CD_3CN using TMS as an internal standard. Microanalyses were carried out on a Perkin–Elmer 2400 CHN elemental analyzer. The specific conductance was measured on a JENCONS 4010 Conductivity Meter. The pH was measured on a SYSTRONICS 361 Digital pH meter. Rate constants and standard deviations were calculated by linear regression using a PC-based programmed Microcal-origin version Origin-6.1.

2.1.1. Kinetic measurements

For kinetic measurements, stock solutions of the complexes (*ca.* 10^{-3} mol dm^{-3}) and of picolinic acid (picH) (*ca.* 10^{-2} mol dm^{-3}) were prepared in dry MeCN. Solutions of different concentrations were prepared by quantitative dilution of stock solutions using dry MeCN. All experiments were performed at 298 K (unless otherwise mentioned) by mixing required volumes of the thermostated reactants and transferring the mixture to the absorption cell (1.0 cm length). On addition of picolinic acid (picH) to the solution of Pd(NaiR)Cl_2 in MeCN the orange solution changes to yellow–orange. The influence of the addition of picolinic acid (picH) on the spectra of Pd(α-NaiEt)Cl_2 is shown in the Fig. 1. The change proceeds through a single isosbestic point at *ca.* 489 nm. The decrease in absorbance of the reaction mixture was recorded automatically at *ca.* 530 nm as a function of time (s) for at least three halves of the reaction and up to maximum 1000 s. A_∞ was measured after $\sim$ 24 h of mixing, when the absorbance became constant. In all experiments, initial molar concentration of picH, $[picH]_0$, was kept at least ten times in excess so as to maintain pseudo-first-order kinetic condition. Pseudo-first-order rate constants, k_{obs}, were obtained from the slopes of the plots of $(A_t - A_\infty)$ *versus* time (s) (Fig. 2) where A_t is the absorbance of the reaction mixture at time, t (s) after mixing of picH solution and A_∞ is the absorbance of same reaction mixture after completion of the reaction.

2.2. Synthesis of [Pd(α-/β-NaiR)(pic)](ClO$_4$) (α-NaiR,3; β-NaiR,4)

A representative synthesis of [Pd(α-NaiEt)(pic)](ClO_4) (**3a**) is given below.

To a MeCN solution (15 ml) of the complex, Pd(α-NaiEt)Cl_2 (0.025 g, 5.84×10^{-2} mmol), picH (0.0216 g, 17.52×10^{-2} mmol) was added and the orange colored solution was stirred for about 24 h. It was filtered and allowed to evaporate to dryness at room temperature. The mass was then dissolved in MeOH and $NaClO_4$ (aq) (1 g) was added to it. A brown precipitate was filtered and washed with water. Dried product was then chromatographed over silica gel and MeCN eluted orange band. Yield: 0.021 g (65.22%).

All other complexes were prepared by the same procedure and yield varied 60–70%.

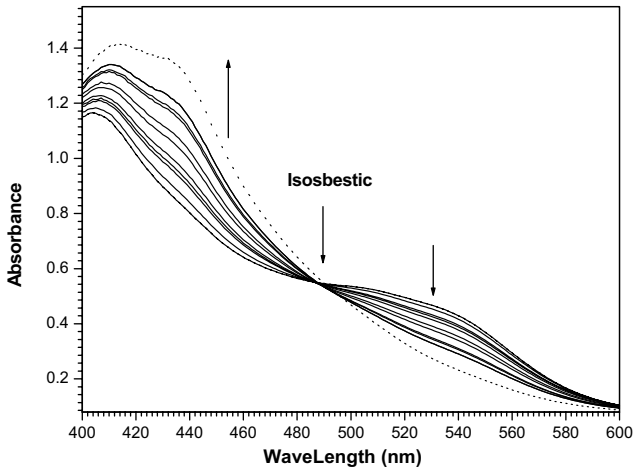

Fig. 1. Spectra of Pd(α-NaiEt)Cl_2(…) in MeCN and a reaction mixture of Pd(α-NaiEt)Cl_2 and picH in MeCN solution at 298 K. The arrows indicate decrease and increase of band intensities as reaction proceeds.

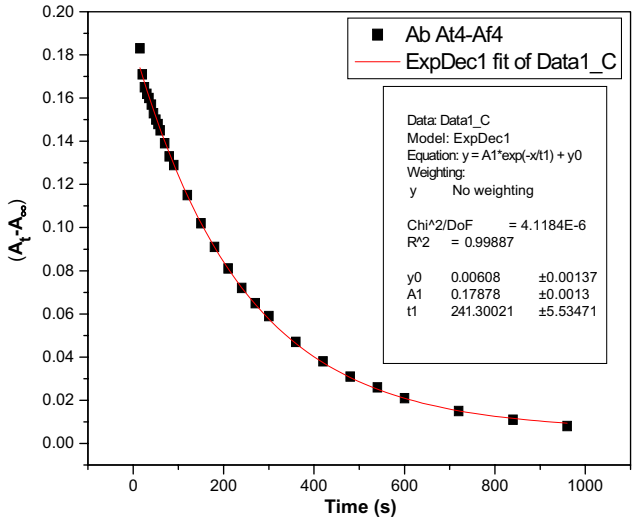

Fig. 2. Plot of $(A_t - A_\infty)$ vs. time (s) for reaction: Pd(α-NaiEt)Cl_2 + picH in MeCN. $[Pd(\alpha\text{-NaiEt})Cl_2]_0 = 1.00 \times 10^{-4}$ mol dm^{-3}, $[picH]_0 = 7 \times 10^{-3}$ mol dm^{-3} and temperature = 298 K.

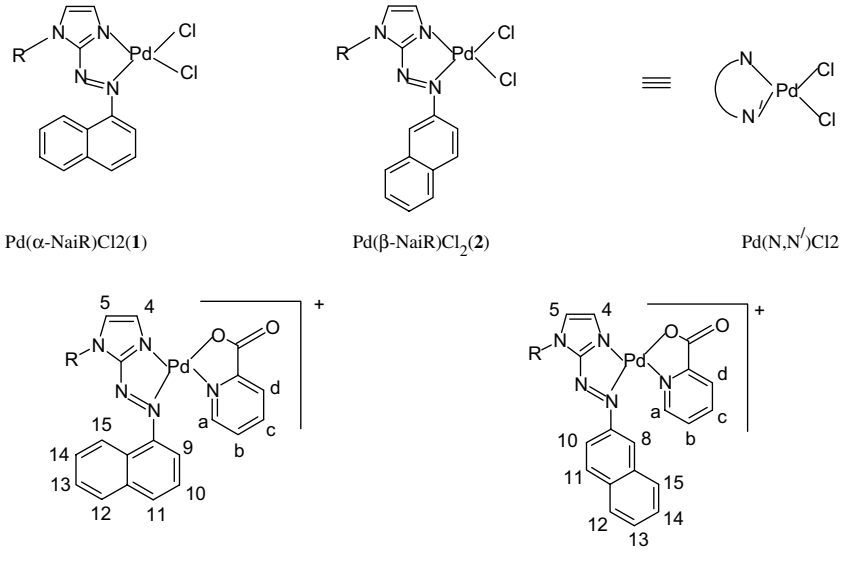

Microanalytical data of the complexes are as follows: For [Pd(α-NaiMe)(pic)](ClO_4) (**3a**): *Anal.* Calc. for $C_{20}H_{16}O_6N_5PdCl$: C, 42.56; H, 2.84; N, 12.41. Found: C, 42.50; H, 2.96; N, 12.36%. For [Pd(α-NaiEt)(pic)](ClO_4) (**3b**): *Anal.* Calc. for $C_{21}H_{18}O_6N_5PdCl$: C, 43.61; H, 3.11; N, 12.11. Found: C, 43.56; H, 3.10; N, 12.13%. For [Pd(α-NaiBz)(pic)](ClO_4) (**3c**): *Anal.* Calc. for $C_{26}H_{20}O_6N_5PdCl$: C, 48.76; H, 3.13; N, 10.94. Found: C, 48.72; H, 3.15; N, 11.01%. For [Pd(β-NaiMe)(pic)](ClO_4) (**4a**): *Anal.* Calc. for $C_{20}H_{16}O6N_5PdCl$: C, 42.56; H, 2.84; N, 12.41. Found: C, 42.52; H, 2.81; N, 12.44%. For [Pd(β-NaiEt)-(pic)](ClO_4) (**4b**): *Anal.* Calc. for $C_{21}H_{18}O_6N_5PdCl$: C, 43.61; H, 3.11; N, 12.11. Found: C, 43.68; H, 3.16; N, 12.12%. For [Pd(β-NaiBz)(pic)](ClO_4) (**4c**): *Anal.* Calc. for $C_{26}H_{20}O_6N_5PdCl$: C, 48.76; H, 3.13; N, 10.94. Found: C, 48.72; H, 3.16; N, 10.89%.

3. Results and discussion

3.1. Kinetics and mechanism

Two classes of naphthylazoimidazole complexes of palladium(II) have been used in this work. They are Pd(α-NaiR)Cl_2 (**1**) (α-NaiR = 1-alkyl-2-(naphthyl-α-azo)-imidazole) and Pd(β-NaiR)Cl_2 (**2**)(β-NaiR = 1-alkyl-2-(naphthyl-β-azo)imidazole) [where R = Me (**a**)/Et(**b**)/Bz(**c**)]. The ligands belong to the unsymmetric bidentate *N*,*N*′-donor type and form dichloropalladium(II) complexes, here after we abbreviate the complex as Pd(*N*,*N*′)Cl_2 (Scheme 1). The reaction kinetics between Pd(*N*,*N*′)Cl_2 and picolinic acid (picH) was studied spectrophotometrically. The reaction is first order in Pd(II) complex as k_{obs}-values are almost constant when all variants are constant except the complex concentration. The k_{obs}-values (Table 1) and the linear plots for the k_{obs} *versus* $[picH]_0$ (Figs. 3 and 4) indicate the reaction is first order in picH. The slope of the plot is second order rate constant (k_2) of the reaction. The presence of intercept (k_0) indicates the existence of a minor solvent assisted path to the overall reaction products (MeCN is a coordinating solvent).

The rate increases with rise of temperature, as expected from the Eyring equation. The second order rate constants (k_2) were measured at different temperatures in the range of 293–313 K for each reaction. Activation parameters, standard enthalpy of activation ($\Delta^{\ddagger}H^{\circ}$) and standard entropy of activation ($\Delta^{\ddagger}S^{\circ}$) were calculated from Eyring plots

Pd(NaiMe)Cl$_2$ > Pd(NaiBz)Cl$_2$ and Pd(α-NaiR)Cl$_2$ > Pd(β-NaiR)Cl$_2$. The iso-kinetic plot (Fig. 7) supports an identical mechanism for the reaction of Pd(N,N')Cl$_2$ with picH. Kinetic studies in the presence of externally added Cl$^-$ (LiCl) reveal that the rate as well as k_{obs} decreases inversely with [Cl$^-$]$_0$ (Table 3), which supports the mechanism given in Scheme 2. The dissociation of the second Pd–Cl bond is the rate-determining step and the dissociation of the first Pd–Cl bond is affected by externally added Cl$^-$ ion. The product was isolated and characterized as [Pd(N,N')(pic)](ClO$_4$). The nucleophilic substitution process involves direct displacement of 2 Cl$^-$ ions by picolinic acid (Eq. (1)). In the MeCN medium picH will exist largely in the undissociated form [40].

[Pd(R′aiR)Cl$_2$]$_0$ = 1.00×10^{-4} mol dm^{-3}, [picH]$_{0=}$$3.00 \times 10^{-3}$ mol dm^{-3}.

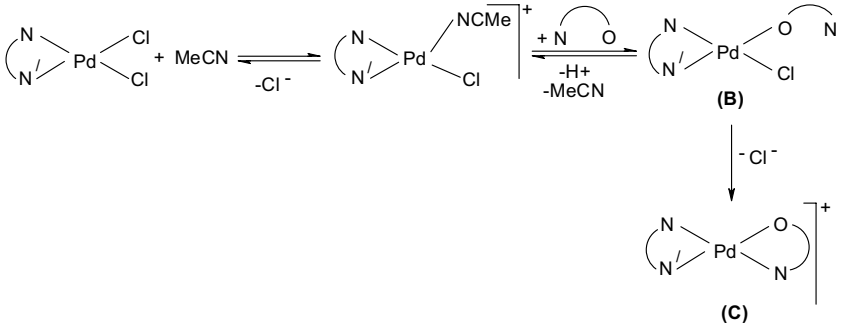
Scheme 2.

The observed rate is

$$\text{Rate} = [k_0 + k_2[\text{picH}]_0]\{\text{Pd(R}'\text{aiR)Cl}_2\}$$
$$= k_{\text{obs}}[\text{Pd(R}'\text{aiR)Cl}_2]$$

(where $k_2 = \frac{kK_1}{[\text{Cl}^-]_0}$, which is constant at constant $[\text{Cl}^-]_0$ and $k_{\text{obs}} = k_0 + k_2[\text{picH}]_0$).

The k_0 and k_2 are the intercept and the slope of the plot of k_{obs} *versus* $[\text{picH}]_0$ respectively. It is probable that the highly negative O donor will coordinate first with the positively charged metal centre, with fast dissociation of the first Pd–Cl bond, and finally forms a stable four coordinated square planar complex (**B**). Then picolinate-N (which remains free in **B**) slowly coordinates with Pd(II) as a compulsion of chelate stability. Obviously the later rate is slower than the former rate. Therefore the second Pd–Cl bond cleavage is the rate-determining step. This is also supported by the effect of externally added Cl^- ions (LiCl). The plausible mechanism is given in Scheme 2. There are two parallel pathways: one is the existence of a minor solvent assisted path where MeCN substitutes Cl^- initially, then MeCN is displaced by picH and finally forms the reaction product (**C**) (Scheme 3).



Although the steric crowding of α-/β-naphthyl group in the *N*,*N*′ chelating ligand is significant, its electron withdrawing property, due to conjugation, stabilizes the Pd(*N*,*N*′) chelated species in preference to de-chelation.

The kinetic data in Table 1 reveal that the magnitude of k increases in the order: $\text{Pd}(\alpha\text{-NaiEt})\text{Cl}_2 < \text{Pd}(\alpha\text{-NaiMe})\text{Cl}_2 < \text{Pd}(\alpha\text{-NaiBz})\text{Cl}_2$. This is because of the electron withdrawing tendency of Bz group is greater than Me which in turn is slightly greater than Et.

3.2. Product characterization

To MeCN solution of the complex, $\text{Pd}(N,N')\text{Cl}_2$, picH was added and the orange colored solution was stirred for about 24 h. It was filtered and allowed to evaporate almost to dryness at room temperature. Mass so produced was then dissolved in MeOH and NaClO_4 (aq) was added. A brown precipitate formed which was filtered and then washed with water and cold MeCN. Dried product was chromatographed over silica gel and MeCN eluted an orange-red band. Finally the dried product was characterized by micro-analytical data (experimental section), ^{1}H NMR (Table 4) spectral data. The molar conductance data in MeCN solution ($\Lambda_M = 90$–$106\ \text{S cm}^2\ \text{mol}^{-1}$) show 1:1 electrolytic nature of the complexes. The IR spectra of the complexes display a sharp stretch at 1380–1410 cm^{-1} which corresponds to ν(N=N) and is red shifted by 5–10 cm^{-1} from that of Pd(NaiR)Cl_2 [36]. This may be attributed to better charge delocalization from coordinated pic^- to the chelated NaiR motif than that of Cl in precursor. The binding is indirectly established by the disappearance of two ν(Pd–Cl) bands corresponding to the *cis*-PdCl_2 configuration [21,36,41] and appearance of new bands at 1450–1460 and 460–500 cm^{-1} due to ν(COO) and ν(Pd–O), respectively. All the complexes exhibit a structure less band at 1050–1100 cm^{-1} corresponding to $\nu(\text{ClO}_4)$ suggesting lack of any significant interaction in the solid state [42].

The ^{1}H NMR spectra of the complexes were recorded in CD_3CN and the data are collected in Table 4. The proton-numbering pattern is shown in Scheme 1. Data reveal that the signals in the spectra of the complexes are shifted downfield relative to the free ligand values [33]. This supports the coordination of the ligand to Pd(II). An important feature of the spectra is the shifting of imidazole protons 4H and 5H to lower δ-values, in general, relative to the naphthyl protons (6H–13H). The imidazole protons suffer downfield shifting by 0.1–0.2 ppm compared to the free ligand position. This supports the strong preference of imidazole-N binding to Pd(II). The naphthyl protons appear as multiplets except a broad singlet of 6H and doublet of 8H (in $[\text{Pd}(\beta\text{-NaiR})(\text{pic})](\text{ClO}_4)$) in the complexes

Scheme 3.

[c] Multiplet.
[d] Doublet.
[e] Triplet.
[f] Ph-H: 7.40–7.50 ppm.

and a doublet of 15H in case of all the complexes. The 1-alkyl group appears as singlet for 1-Me in [Pd(α/β-NaiMe)(Q)](ClO$_4$), a quartet to –N–CH$_2$– and a triplet for the –CH$_3$ group in [Pd(α/β-NaiEt)(pic)](ClO$_4$) and a singlet for –CH$_2$– and benzyl protons in [Pd-(α/β-NaiCH$_2$Ph)(pic)](ClO$_4$) complexes. The pic protons (a–d) appear at higher δ, 8–9 ppm.

4. Conclusion

The kinetics of the reactions between Pd(*N*,*N*′)Cl$_2$ and picolinic acid (picH) were studied spectrophotometrically at 530 nm under pseudo-first-order condition in MeCN. The reactions are first order in Pd-complex and picH. The rate of reaction is largely influenced by the π-acidity of the chelating ligand; substitution in the naphthylazoimidazole backbone influences much the rate of the substitution process. Activation parameters $\Delta^{\ddagger} H^{\circ}$ and $\Delta^{\ddagger} S^{\circ}$ of reactions were measured which corroborates the kinetic rate data. The products isolated from the reaction between Pd(NaiR)Cl$_2$ and picH in MeCN have been characterized by spectral data and support the composition [Pd(NaiR)-(pic)](ClO$_4$).

complexes bearing dps [28–34], there have been several acentric coordination networks constructed from dps, reported for their interesting solvent capture and release [31] and good photoluminescent properties [33]. In addition, the study of copper(II) as a metal center is seldom reported except for a 3D non-interpenetrating framework of $[\{Cu(\mu\text{-dps})_2(SO_4)\}\cdot 3H_2O\cdot DMF]_\infty$ exhibiting an unusual third-order NLO property [34] and a 3D interpenetrating framework of $[Cu_4(\mu\text{-dps})_4(Mo_8O_{26})\cdot 2H_2O]_n$ [35].

In this contribution, we describe the preparation and characterization of a series of Cu(II)/dps complexes. Five novel acentric or chiral Cu(II)/dps coordination compounds were obtained by utilizing different counteranions and solvents: $\{[Cu_3(\mu\text{-dps})_4(\mu\text{-}SO_4)_2(SO_4)(H_2O)_5]\cdot 10H_2O\}_\infty$ (**1** · $10H_2O$) (3D framework), $[Cu(dps)_4(H_2O)_2]\cdot(ClO_4)_2\cdot H_2O$ (**2** · H_2O) (mononuclear complex), $\{[Cu(\mu\text{-dps})_2(DMF)_2](ClO_4)_2\}_\infty$ (**3**) (2D undulating grid), $\{[Cu(\mu\text{-dps})_2(H_2O)_2]\cdot(NO_3)_2\cdot 2H_2O\}_\infty$ (**4** · $2H_2O$) (1D double-stranded chain) and $\{[Cu_3(\mu\text{-dps})_6(DMF)_2(H_2O)_4]\cdot(NO_3)_6\cdot(DMF)\cdot 6H_2O\}_\infty$ (**5** · DMF · $6H_2O$) (2D undulating grid). It was found that the counteranion and solvent have profound effects on the formation of the framework. Three copper salts (sulfate, nitrate and perchlorate) were used as precursors, and the reaction media were DMF or aqueous solutions. All these non-centrosymmetric complexes are SHG-active (second harmonic generation).

2. Experimental

General: All chemicals and solvents are reagent grade. The solvents were used after drying. *CAUTION!* Metal perchlorates with organic ligands are potentially explosive. Only a small amount of material should be handled with great caution. The elemental analysis of C, H and N was obtained by the Elemental Analysis Service with an EA1110-CHNS elemental analyzer. Infrared spectra were measured as KBr disks on a MagNa-550 FT-IR system. The single crystal X-ray diffraction data were recorded on a Rigaku Mercury CCD X-ray diffractometer. Thermal gravimetric (TG) analysis was conducted on a Universal V3.7A TA instrument for **1**, **4** and **5** in flowing N_2 with a heating rate of 10 °C/min^{-1}. The strength of second harmonic generation (SHG) efficiency of the compounds was estimated by measuring a powder pellet. The experimental arrangement includes a high power mode-locked Nd: YAG laser with 200 ps pulse at a repetition rate of 5 Hz at a selected wavelength of 1064 nm. The laser beam is split into two parts, one to generate the SHG signal in the sample and the other to generate the SHG signal in the reference of urea [36].

2.1. Synthesis of $\{[Cu_3(\mu\text{-dps})_4(\mu\text{-}SO_4)_2(SO_4)(H_2O)_5]\cdot 10\,H_2O\}_\infty$ (**1** · $10H_2O$)

Dps (0.15 g, 0.8 mmol) in ethanol (3 mL) was carefully layered onto a blue aqueous solution (5 mL) of $CuSO_4\cdot 5H_2O$ (0.1 g, 0.4 mmol), and a mixture of diethyl ether and methanol was then layered onto the ethanol solution. Blue prisms of $\{[Cu_3(\mu\text{-dps})_4(\mu\text{-}SO_4)_2(SO_4)(H_2O)_5]\cdot 10H_2O\}_\infty$ (**1** · $10H_2O$) were obtained after one day and were isolated by filtration. Yield: 0.16 g (80%). *Anal.* Calc. for $C_{40}H_{62}Cu_3N_8O_{27}S_7$ (1502.0): C, 31.98; H, 4.16; N, 7.46. Found: C, 32.23; H, 4.27; N, 7.38%. IR (KBr pellet, cm^{-1}): 3426 (m), 3048 (w), 1659 (m), 1582 (s), 1535 (m), 1482 (m), 1412 (m), 1188 (s), 1111 (s), 1065 (m), 1026 (m), 996 (s), 810 (m), 725 (m), 617 (m), 540 (m), 494 (m).

2.2. Synthesis of $[Cu(dps)_4(H_2O)_2]\cdot(ClO_4)_2\cdot H_2O$ (**2** · H_2O)

The preparation of **2** is similar to that of **1**, except that $CuSO_4$ was replaced by $Cu(ClO_4)_2$ (0.1 g, 0.4 mmol). Blue crystals of $[Cu(dps)_4(H_2O)_2]\cdot(ClO_4)_2\cdot H_2O$ (**2** · H_2O) were obtained in a few days and isolated by filtration. Yield: 0.34 g (80%). *Anal.* Calc. for $C_{40}H_{38}Cl_2CuN_8O_{11}S_4$ (1069.5): C, 44.92; H, 3.58; N, 10.48. Found: C, 44.52; H, 3.78; N, 10.61%. IR (KBr pellet, cm^{-1}): 3383 (s), 2442 (w), 1670 (w), 1597 (s), 1577 (vs), 1539 (m), 1481 (s), 1412 (s), 1385 (m), 1319 (w), 1219 (m), 1092 (vs), 1061 (s), 1022 (m), 1003 (m), 872 (w), 829 (m), 814 (w), 725 (m), 706 (m), 621 (s), 540 (m), 492 (m), 455 (w).

2.3. Synthesis of $\{[Cu(\mu\text{-dps})_2(DMF)_2](ClO_4)_2\}_\infty$ (**3**)

The preparation of **3** is similar to that of **1**, except that $CuSO_4$ in aqueous solution was replaced by $Cu(ClO_4)_2$ (0.1 g, 0.4 mmol) in acetonitrile solution. Blue crystals of $\{[Cu(\mu\text{-dps})_2(DMF)_2](ClO_4)_2\}_\infty$ (**3**) were obtained in a few days and isolated by filtration. Yield: 0.19 g (60%). *Anal.* Calc. for $C_{26}H_{30}Cl_2CuN_6O_{10}S_2$ (785.1): C, 39.77; H, 3.85;N, 10.70. Found: C, 40.02; H, 3.82; N, 10.81%. IR (KBr pellet, cm^{-1}): 1652 (s), 1606 (s), 1506 (s), 1447 (m), 1384 (m), 1279 (w), 1237 (w), 1167 (m), 1094 (vs), 980 (m), 828 (w), 724 (w), 661 (w), 634 (s).

2.4. Synthesis of $\{[Cu(\mu\text{-dps})_2(H_2O)_2]\cdot(NO_3)_2\cdot 2H_2O\}_\infty$ (**4** · $2H_2O$)

The preparation of **4** is similar to that of **1**, except that $CuSO_4\cdot 5H_2O$ was replaced by $Cu(NO_3)_2\cdot 6H_2O$ (0.12 g, 0.4 mmol). Blue crystals of $\{[Cu(\mu\text{-dps})_2(H_2O)_2]\cdot(NO_3)_2\cdot 2H_2O\}_\infty$ (**4** · $2H_2O$) were obtained in a few days and isolated by filtration. Yield: 0.19 g (76%). *Anal.* Calc. for $C_{20}H_{24}CuN_6O_{10}S_2$ (636.1): C, 37.76; H, 3.80; N, 13.21. Found: C, 37.38; H, 3.95; N, 13.02%. IR (KBr pellet, cm^{-1}): 3457 (m), 3065 (w), 1590 (s), 1482 (m), 1382 (vs), 1212 (m), 1104 (w), 1057 (m), 1026 (w), 826 (m), 725 (m), 540 (m), 494 (m).

2.5. Synthesis of $\{[Cu_3(\mu\text{-dps})_6(DMF)_2(H_2O)_4]\cdot(NO_3)_6\cdot(DMF)\cdot 6H_2O\}_\infty$ (**5** · DMF · $6H_2O$)

The preparation of **5** is similar to that of **3**, but $Cu(ClO_4)_2$ was replaced by $Cu(NO_3)_2\cdot 6H_2O$ (0.12 g, 0.4 mmol). Blue crystals of $\{[Cu_3(\mu\text{-dps})_6(DMF)_2(H_2O)_4]\cdot$

Symmetry transformations used to generate equivalent atoms: #1 $x-1/2$, $-y+1$, z, #2 $x-1/2$, $-y$, z, #3 $x+1/2$, $-y+1$, z, #4 $x+1/2$, $-y$, z.

at the top of a glass fiber. Diffraction data were collected in the ω mode and the collected data were reduced by using the program Crystal-Clear (Rigaku and MSC, Ver. 1.3, 2001), and a semi-empirical absorption correction was applied. The reflection data were also corrected for Lorentz and polarization effects.

The structure was solved by SHELXS-97 (Sheldrick, 1990) and refined using full-matrix least-squares on F^2 with the SHELXL-97 program [38] (Sheldrick, 1997). For **1** · $10H_2O$, all copper atoms, sulfate anions and dps ligands were refined anisotropically and all coordinated water molecules, solvated water and ethanol molecules were refined isotropically without placing any hydrogen atoms. O27 of a solvated water molecule is twofold disordered. Only 32 Hydrogen atoms corresponding to 4 organic ligands were introduced at calculated positions and included in the structure-factor calculations. For **2** · H_2O, **3** and **4** · $2H_2O$, all non-hydrogen atoms were refined anisotropically and hydrogen atoms were introduced at calculated positions and included in the structure-factor calculations. For **5** · DMF · $6H_2O$, the oxygen atoms of free water molecules refined isotropically without placing the hydrogen atoms. The Flack parameters of **1** and **5** were refined together with all the other parameters using twin.

All calculations were performed on a Dell workstation using the SHELX software package. A summary of the key crystallographic information for **1**–**5** is given in Table 1. The selected atomic distances and bond angles of **1**–**5** are listed in Tables 2–6 respectively. The selected atomic distances and bond angles of **5** and the hydrogen bonds of **2** and **4** are listed in the Supplementary material.

3. Results and discussion

3.1. Synthesis and general characterization

Compounds **1**, **2** and **4** were prepared by the reaction of the corresponding Cu(II) salts in aqueous solution with 2 equiv of dps in ethanol solution (Scheme 1). Compounds **3** and **5** were prepared with a similar procedure except that the aqueous solution was replaced by DMF. All of the compounds are blue, air-stable and dissolve in DMF or DMSO solution. Compounds **1**–**5** are characterized by elemental analysis, IR spectra and thermal analysis. The FT-IR spectra of **1**, **2**, **4** and **5** showed a broad band centered at ca. 3400 cm^{-1}, which can be attributed to the O–H stretching of water molecules. The characteristic absorption bands of SO_4^{2-} groups for **1** appear at 1065–1105 and 615 cm^{-1}, and the ClO_4^- anion stretching vibrations appear at 1092 (vs) and 621 (s) cm^{-1} for **2** and 1094 (vs) and 634 (s) cm^{-1} for **3**. For **4** and **5**, the characteristic bands of NO_3^- anions appear at 1382 and 1381 cm^{-1}, respectively.

3.2. Description of crystal structures

3.2.1. $\{[Cu_3(\mu\text{-dps})_4(\mu\text{-}SO_4)_2(SO_4)(H_2O)_5]\cdot 10H_2O\}_\infty$ $(1\cdot 10H_2O)$

Complex **1** · $10H_2O$ consists of a three-dimensional $[Cu(\mu\text{-dps})_2SO_4]$ structure, different from other analogous

CuL_2SO_4 complexes (L = bipyridyl ligand) reported previously [13,34,37]. As shown in Fig. 1a, there are three crystallographically independent Cu(II) atoms in the asymmetric unit. The proximal coordination at the Cu(1) center consists of $[CuN_4O_2]$ units, in which the basal sites are occupied by four pyridyl nitrogen donors from four dps ligands, with Cu–N distances of 1.992(6)–2.059(6) Å, and the axial positions are occupied by two oxygen donors from two sulfate bridges with two elongated Cu–O distances (2.334(5) and 2.420(5) Å). The geometry about the Cu(2) site is defined by *trans* nitrogen donors from two dps ligands and two water molecules in the basal sites, with a sulfate oxygen group and an aqua ligand in the axial positions forming a $[CuN_2O_4]$ unit. The Cu(2)–O(22) (H_2O) distance of 2.559 Å is significantly larger than the equatorial Cu–O (H_2O) distances, whereas the Cu(2)–O(8) distance of 2.455 Å is indicative of a weak Cu–sulfate interaction. The coordination geometry of Cu(3) may be described as a $[CuN_2O_4]$ unit, in which the basal plane consists of two *trans*-N donors and two water molecules and the axial positions are occupied by two oxygen donors of the sulfate ligand. The Cu(3)–O(9) distance of 2.187(7) Å is smaller than Cu(3)–O(3′) 2.385(6) Å, indicating the terminal sulfate anion has a stronger interaction with the copper center than that of the bridging sulfate. Eight copper atoms link into a rhombic $[Cu(\mu\text{-dps})]_8$ ring, including four Cu(1) atoms occupying the grid corners and two Cu(2) and Cu(3) atoms occupying the midpoints of four Cu(dps) lines. The rhombic $[Cu(\mu\text{-dps})]_8$ ring with dimensions of 20.3×20.8 Å (Cu(1)···Cu(1^a)), gives an area of ca. 400 Å^2 (Fig. 1b), which is obviously larger than the reported complexes CuL_2SO_4 (L = bipyridyl ligand) [13,34,37]. Sulfate anions, water molecules are all occupied in the $[Cu(\mu\text{-dps})]_8$ cavities (Fig. 1c). The adjacent [Cu(μ-dps)] layers interlink forming a 3D network via unusual short Cu(2)–sulfate–Cu(1)–sulfate–Cu(3)–sulfate chains

Scheme 1. Preparation of compounds **1**–**5**.

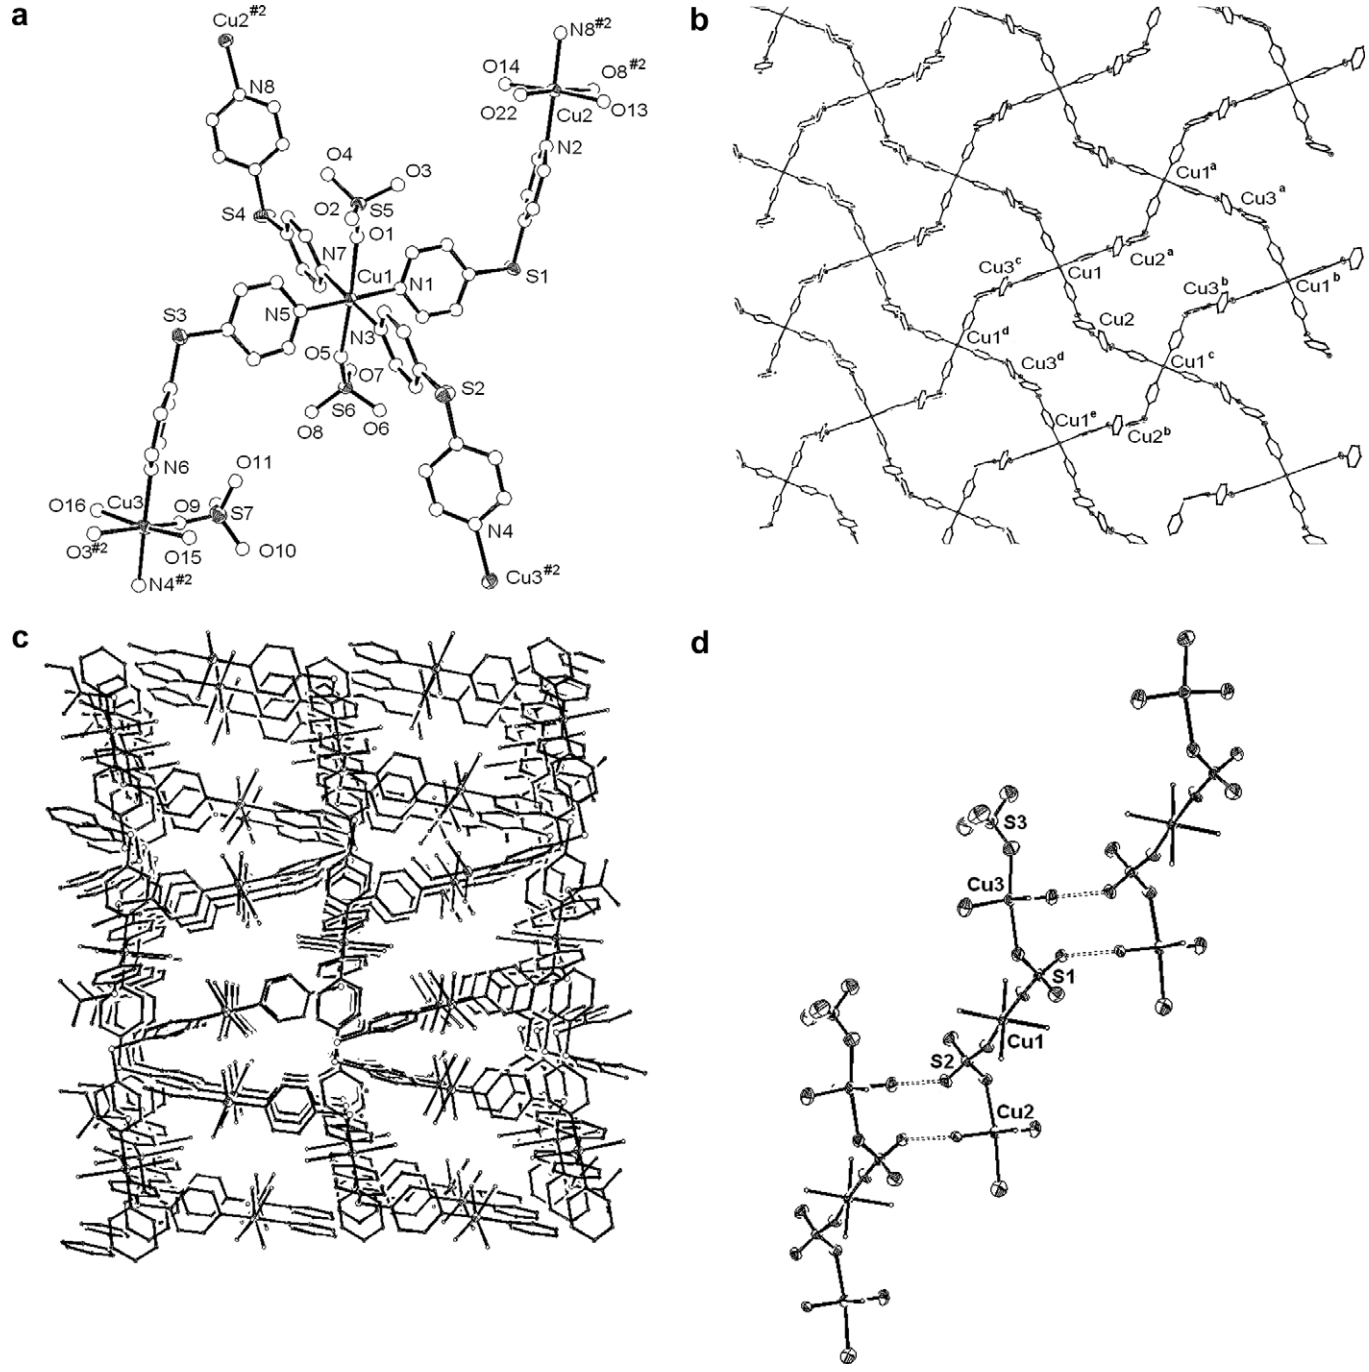

Fig. 1. Structure of $\mathbf{1} \cdot 10H_2O$: (a) the local coordination environment of three Cu^{2+} atoms (hydrogen atoms are omitted for clarity); (b) the lattice layer bridged by dps (sulfate anions, coordinated water molecules and free solvent molecules are omitted); (c) the 3D network bridged by sulfate, viewed along the *a*-axis (free solvent molecules and all hydrogen atoms are omitted for clarity); (d) the short Cu(2)–sulfate–Cu(1)–sulfate–Cu(3)–sulfate chain (dps except N atom, free solvent molecules and all hydrogen are omitted for clarity).

along the *a*-axis, different from the usual infinite Cu–sulfate–Cu chain found in CuL_2SO_4 [17,34] (Fig. 1d).

3.2.2. $\{[Cu(dps)_4(H_2O)_2](ClO_4)_2 \cdot H_2O\}$ ($\mathbf{2} \cdot H_2O$)

The structure of **2** consists of a mononuclear $[Cu(dps)_4(H_2O)_2]^{2+}$ cation, two free ClO_4^- anions and a free water molecule in the asymmetry unit, which is similar to the reported $[Zn(dps)_4(H_2O)_2](ClO_4)_2 \cdot H_2O$ [33], but quite different from other copper–dps coordination polymers. The coordination geometry of the copper atom adopts the typical $[CuN_4O_2]$ octahedral arrangement. Dps in this case acts as a monodentate ligand, in which the bent angles of the sulfur atoms (C–S–C–C) are 101.30(10)° and 100.29(11)°, which is smaller than the bridging ligands in **1** (av. 103.2°). The other N atom of each dps ligand is involved in H-bonding to give a box-like structure

(Fig. 2a). It is the weak non-covalent interaction (H-bond) that blocks the formation of the expected coordination bond (Cu–N(dps)). The O(6) atom of the free water molecule behaves as a double donor and double acceptor, whereas the oxygen atom of the coordinated water molecule (O(1)) acts as a double donor. Three kinds of H-bonds appear in this H-bonded network. The free water molecule (O(6)) H-bonds with the coordinated water molecule (the O(1) atom, forming the O(1)–H···O(6) bond), and with the uncoordinated *cis* N(4) atom, forming the O(1)–H···N(4) bond chain. The coordinated O(1) also links the uncoordinated N(2) atom from the next unit, forming the O(1)–H···N(2) bond. Thus, the O(1)–H···O(6) bond links the complexes along the *c*-axis forming an infinite chain while both O–H···N bonds extend parallel to the *ab*-plane finally forming a 3D H-bonded network (Fig. 2b).

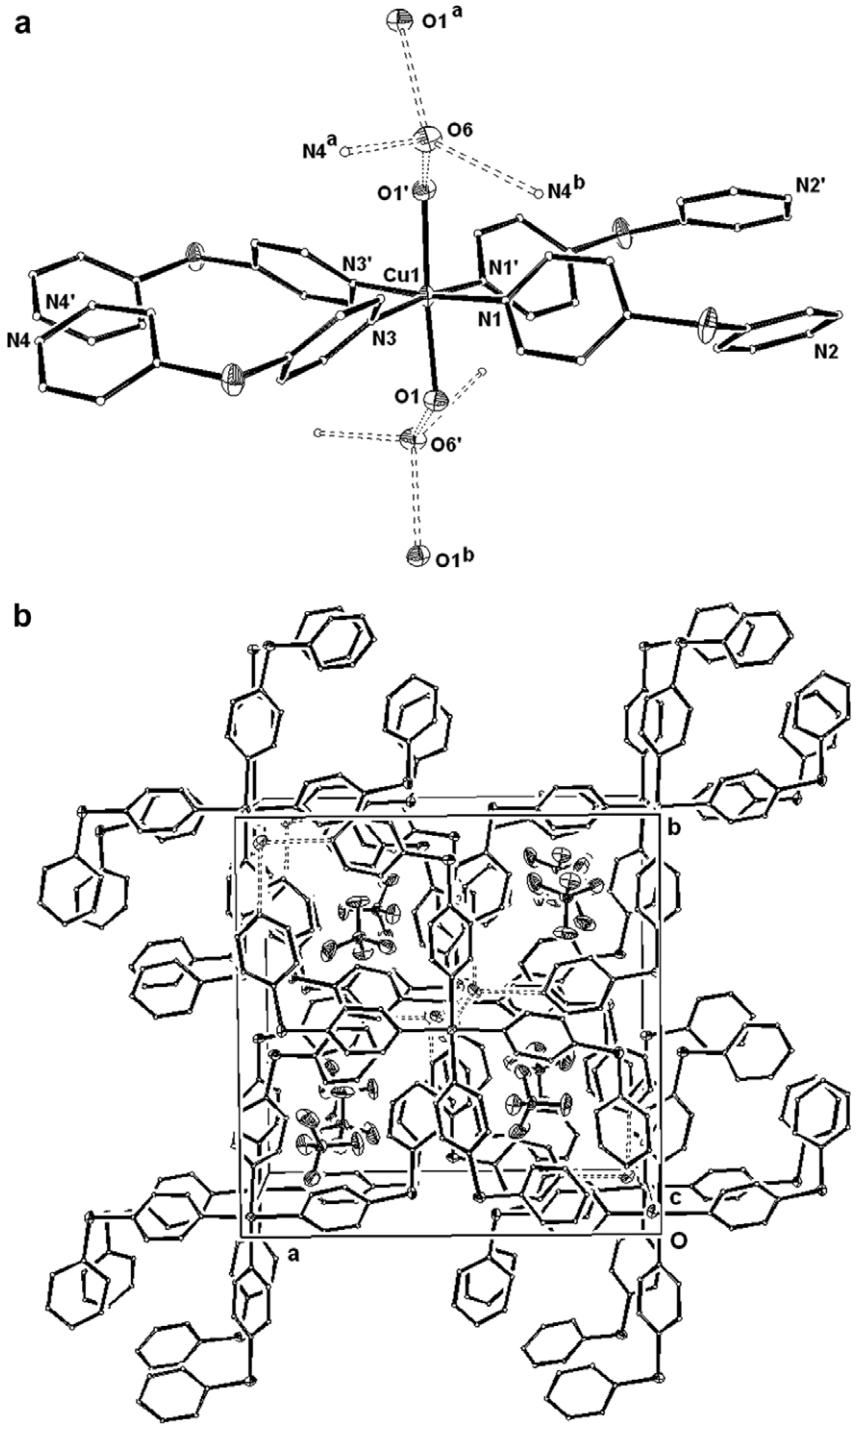

Fig. 2. Structure of $\mathbf{2}\cdot H_2O$: (a) the local coordination environment of the Cu^{2+} atom (hydrogen atoms are omitted for clarity); (b) the packing diagram of $\mathbf{2}\cdot H_2O$, hydrogen bonds are illustrated (hydrogen atoms are omitted for clarity).

3.2.3. $\{[Cu(\mu\text{-dps})_2(DMF)_2](ClO_4)_2\}_\infty$ (3)

The structure of **3** consists of a usual 2D cationic network constructed by $[Cu(\mu\text{-dps})]_4$ metallaboxes which has been observed in $[Co(\mu\text{-dps})_2Cl_2]_\infty$ [29], but the counteranions in this case only provide the appropriate charge balance. The local coordination geometry around the Cu(II) center is also similar with that described in **2**, an octahedral geometry in which four basal sites are occupied by four pyridine nitrogen atoms and two apical sites are occupied by oxygen atoms from DMF solvent molecules (Fig. 3a). The bent angles of the sulfur atoms (C–S–C) in **3** are 101.3(3)–103.6(3)°, comparable with those in **1** and **2**. The Cu···Cu edge dimensions of the 40-membered ring formed by four copper(II) ions and four dps ligands are 10.7×0.5 Å^2, similar to those reported previously [29]. The anions and solvent molecules are occupied in the channels formed by stacking of the cavities (Fig. 3b).

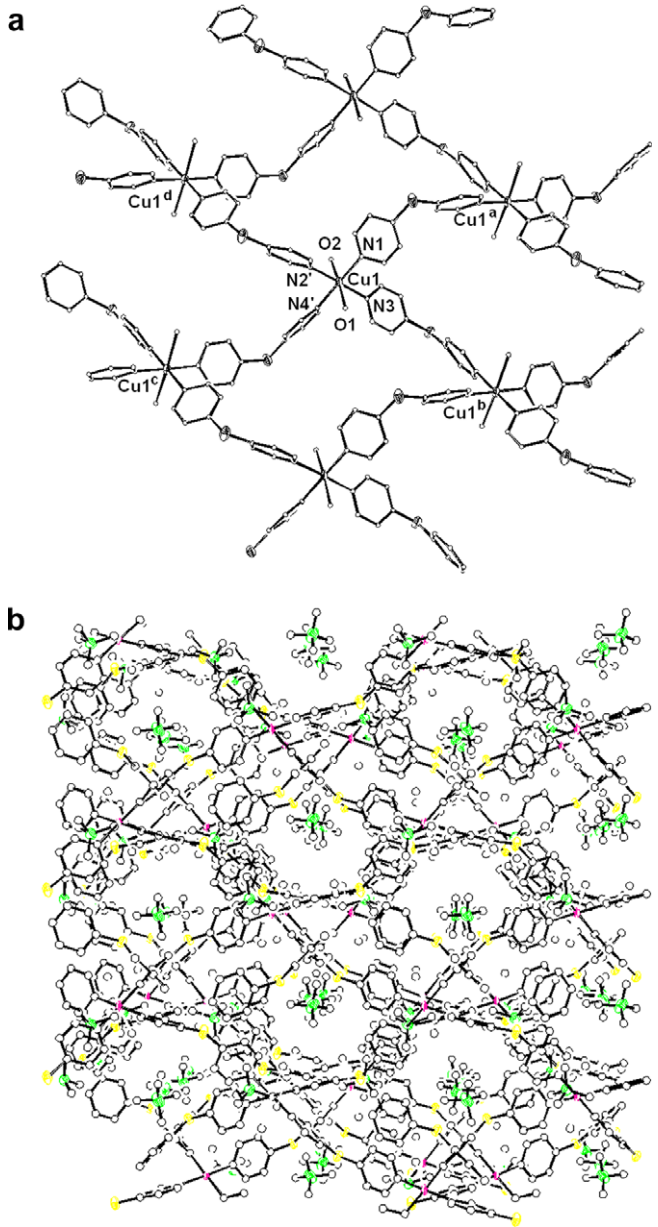

Fig. 3. Structure of **3**: (a) the local coordination environment of the Cu^{2+} atom (only the coordinated oxygen atom of the solvent molecule is preserved and hydrogen atoms of dps molecules are omitted for clarity); (b) view along the [0 0 1] plane showing the 10.69×10.53 Å^2 channels of **3**, the anions are shown in the channels (hydrogen atoms are omitted for clarity).

3.2.4. $\{[Cu(\mu\text{-dps})_2(H_2O)_2]\cdot(NO_3)_2\cdot 2H_2O\}_\infty$ ($4\cdot 2H_2O$)

The structure of complex **4** consists of a cationic 1D infinite double stranded $[Cu(\mu\text{-dps})_2]$ chain, two NO_3^- counteranions and two free water molecules. In **4**, the copper(II) center has an octahedral geometry, being coordinated to two water molecules and four pyridyl groups from four different dps ligands. Dps spacers are linked to the copper(II) atoms in a double-stranded bridge fashion along the *a*-axis, resulting in a 20-membered ring with a smaller cavity (Fig. 4a), which is different from the 1D zigzag chain of $[Zn(\mu\text{-dps})_4(CH_3COO)_2]$, but similar to that of $[Co(\mu\text{-dps})_2(NCS)_2\cdot 2H_2O]_\infty$ and $[Ni(\mu\text{-dps})_2(NO_3)_2\cdot EtOH]_\infty$ [29]. The bent angle of the sulfur atom (C–S–C = 97.6(2)°) is obviously smaller than those of **1**–**3** and those reported previously [29–34]. The closest Cu···Cu intra-chain distance is 9.754 Å, slightly larger than that of the inter-chain Cu···Cu distance (9.583 Å). NO_3^- is not coordinated to the metal, and provides the appropriate charge balance. The free water molecule acts as a double H-bond donor, linking with the nitrate and coordinated water molecule parallel to the $Cu(\mu\text{-dps})_2$ chain. The $Cu(\mu\text{-dps})_2$ chains run parallel to the *ab* plane forming layers, and the adjacent layers are rotated by 90° to produce small rhombic channels in the projection along the *c*-axis (Fig. 4b).

3.2.5. $\{[Cu_3(\mu\text{-dps})_6(DMF)_2(H_2O)_4]\cdot(NO_3)_6\cdot(DMF)\cdot 6H_2O\}_\infty$ ($5\cdot DMF\cdot 6H_2O$)

Complex $5\cdot DMF\cdot 6H_2O$ consists of a usual 2D cationic network constructed by $[Cu(\mu\text{-dps})]_4$ metallaboxes, which has been observed in **3**, and the nitrate counteranions only provide the appropriate charge balance. In the asymmetric unit, there are three crystallographic independent copper atoms with two kinds of coordination mode. The coordination around the Cu(1) and Cu(2) atoms are similar, an octahedral geometry in which four basal sites are occupied by four pyridine nitrogen atoms and two apical sites are occupied by oxygen atoms from a DMF molecule and a water molecule. The Cu–O (DMF) distances are 2.341(10) Å (Cu(1)–O(1)) and 2.298(11) Å Cu(2)–O(3)), and the Cu–O (H_2O) distances are 2.515(9) Å (Cu(2)–O(2)) and 2.494(9) Å (Cu(2)–O(4)), indicating weak interactions between the copper centers and solvated molecules. The Cu(3) center has a more distorted octahedral geometry in which four basal sites are occupied by four pyridine nitrogen atoms and two apical sites are occupied by oxygen atoms from two H_2O molecules, with elongated Cu–O interactions (2.381(19) and 2.846(12) Å). Each copper center coordinates with bridging dps, forming a 2D cat-

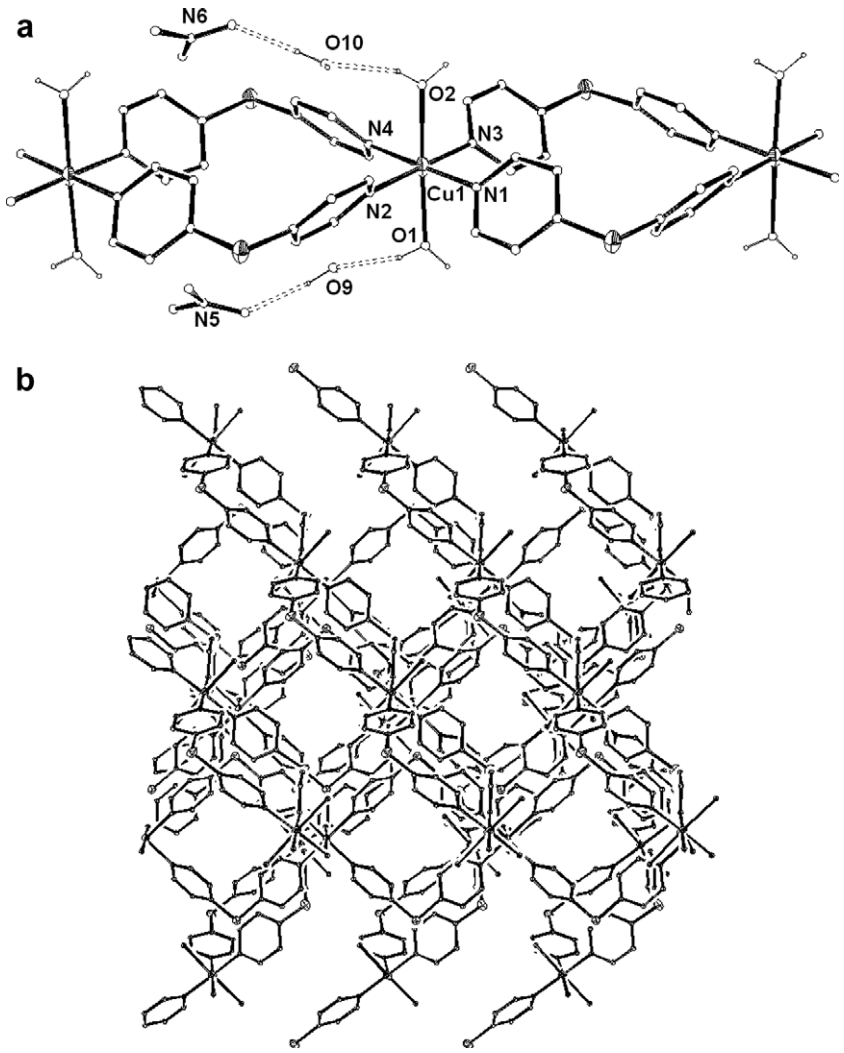

Fig. 4. Structure of $\mathbf{4}\cdot 2H_2O$: (a) the local coordination environment of the Cu^{2+} atom (hydrogen atoms of dps molecules are omitted for clarity) and (b) the stacking of the chains in $\mathbf{4}\cdot 2H_2O$, viewed along the *c*-axis (all hydrogen atoms are omitted for clarity).

ionic network independently. The Cu···Cu edge dimensions of the 40-membered ring formed by the four copper(II) ions and four 4,4′-dps ligands are 10.63×10.74 Å^2, similar with that found in **3** and $[\{Cu(\mu\text{-dps})_2(SO_4)\}\cdot 3H_2O\cdot DMF]_\infty$ [34]. The anions and solvent molecules are occupied in the channels formed by stacking of the cavities (Fig. 5a). The stacking diagram of **5** is shown in Fig. 5b and three different [Cu(μ-dps)] layers stack in turn, but the distances between adjacent layers is different: the smallest interlayer Cu(1)···Cu(2) distance is 8.43 Å and Cu(2)–Cu(3) distance is 8.55 Å and Cu(1′)–Cu(3) distance is 8.59 Å respectively. In addition, it should be noted that nitrate has a stronger inclination to form H-bonds with water molecules than perchlorate, so that more free water molecules are preserved in the unit cell.

3.3. TGA study

To understand the thermal stabilities of the three copper(II)/dps compounds (**1**, **4** and **5**), the samples were analyzed by TGA (the TGA curve is provided in the Supplementary material). Upon heating, samples show a gradual weight loss (18.4%) between 70 and 200 °C for **1**, which ascribes to the loss of all water molecules of crystallization and coordination (18.0% calculated value). There is a further gradual weight loss (60.0%) in two steps in the region 200–693 °C, which is attributed to the release of dps molecules (50.1%, calculated value) and release of sulfate or oxygen (11.4%, calculated value). The final residue of **1** is 21.6%, consistent with the calculated value (21.5%) if a mixture of CuS and Cu_2O is the final product.

The thermal decomposition of **4** is characterized by a dehydration step (8.6%) from 50 to 100 °C, corresponding to the loss of two water molecules of crystallization and a water molecule of coordination (8.5%, calculated value). The second weight loss (38.4%) between 100 and 270 °C is attributed to the release of an additional coordinated water molecule (2.8%, calculated value) and the decomposition of nitrates (19.5%, calculated value) and partly dps molecules. Due to the incomplete decomposition at

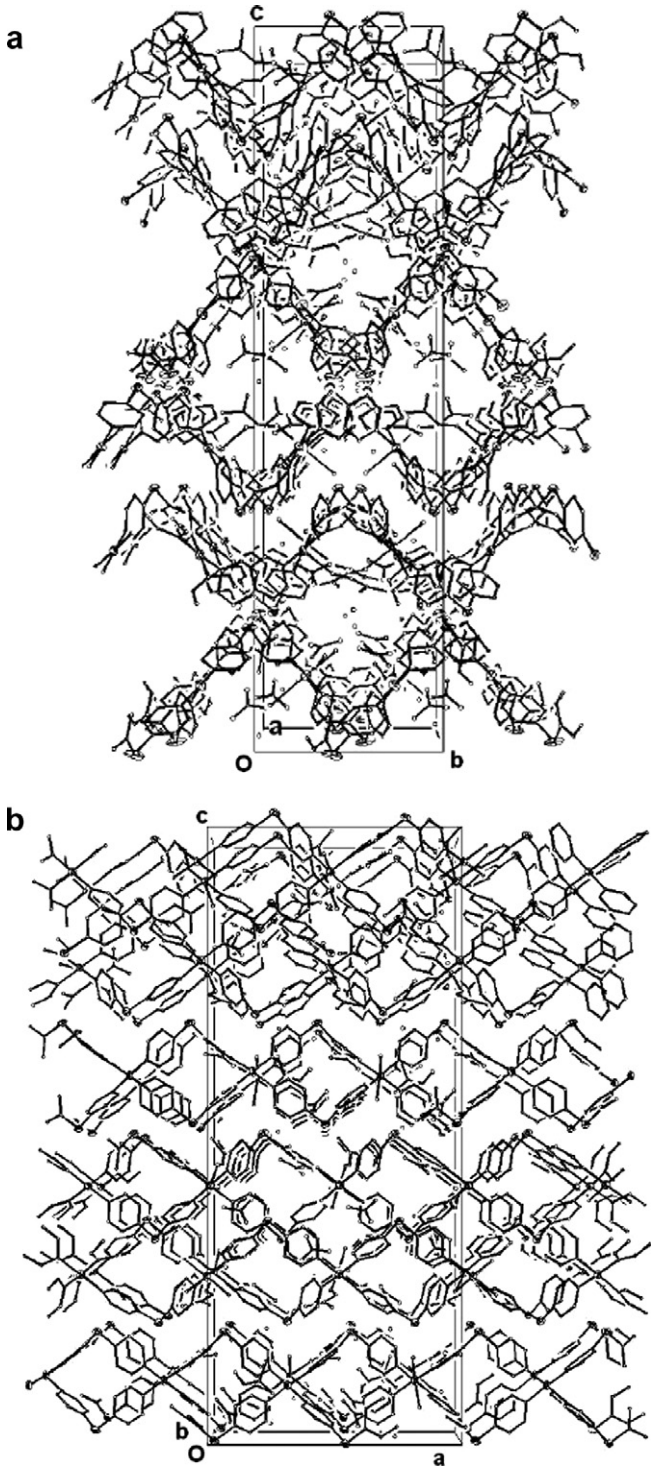

Fig. 5. Structure of $\mathbf{5} \cdot DMF \cdot 6H_2O$: (a) view along the *b*-axis showing the stacking of the grids (hydrogen atoms are omitted for clarity); (b) view along the *a*-axis showing the 10.63x10.74 $Å^2$ channels of $\mathbf{5} \cdot DMF \cdot 6H_2O$, the anions are shown in the channels (hydrogen atoms are omitted for clarity).

300 °C, the residue (40.8%) includes CuS, S (20.1%, calculated value) and organic fragments (totally calculated value of dps except S is 49.1%).

The thermal decomposition of **5** is similar to that of **4**, characterized by a slow dehydration step (11.7%) from 50 to 140 °C corresponding to the loss of all the water molecules of crystallization and coordination (calculated value is 8.6%). The second (42.8%) between 140 and 260 °C is attributed to the release of three DMF molecules (calculated value is 10.5%) and the decomposition of nitrate (17.8%) and partly dps molecules. Due to the incomplete decomposition at 300 °C, the residue (40.5%) includes CuS, S (calculated value is 18.3%) and mainly organic fragments (totally calculated value of dps except S is 46.5%).

As shown by their X-ray crystal structures, all of these samples contain a considerable amount of solvated water and other solvents in their crystalline structures, and hence a considerable weight loss at lower temperature ranges is observed as expected.

3.4. Non-linear optical properties

The second-order non-linear optical properties of the five compounds were also investigated qualitatively. Powder SHG measurements indicate that compounds **1**–**5** are all SHG-active, in agreement with their non-centrosymmetric structures. However, their SHG signals are weaker than that of urea and the intensities are 20% for **1** and **5**, 30% for **2** and **4** and 50% for **3** less than that of urea [37].

3.5. Conclusion

In this paper, a series of non-centrosymmetric Cu/dps complexes have been synthesized and structurally characterized. Among the five compounds **1**–**5**, the coordination geometries of copper atoms adopt a similar (4+2) octahedral arrangement and consist of $[CuN_4O_2]$ or $[CuN_2O_4]$ units. All the structural architectures strongly depend on the counteranions with different coordination abilities. Sulfate coordinates to the copper(II) center in $\{[Cu_3(\mu\text{-dps})_4(\mu\text{-}SO_4)_2(SO_4)(H_2O)_5] \cdot 10H_2O\}_\infty$ ($\mathbf{1} \cdot 10H_2O$) to produce a 3D network with a large cavity, while ClO_4^- and NO_3^- remain as non-coordinating counteranions, and the extended structures more depend on the coordination mode of the copper atom itself, forming 1D or 2D networks. However, the different shapes (tetrahedral, trigonal) of the anions (ClO_4^-, NO_3^-) can affect the topological structures. The tetrahedral ClO_4^- anion in **3** may induce the target product of a 2D grid extended structure, whilst the planar NO_3^- anion in **4** induces a 1D chain. In addition, solvent is another important factor that affects the target structures. Its participation in coordination with the metal center and the formation of hydrogen bonds may result in more complicated assemblies. For instance, compound **1** is obtained from water and owns larger cavities than its analogous complex $[\{Cu(\mu\text{-dps})_2(SO_4)\} \cdot DMF \cdot 3H_2O]_\infty$, obtained from DMF solution [34]. In **2**, the weak non-covalent interaction (H-bond) blocks the formation of the expected coordination bond (Cu–N(dps)).

More interestingly, all these copper complexes are SHG-active. It may provide an effective method to synthesize

non-symmetrical materials by using an achiral flexible ligand under appropriate conditions.

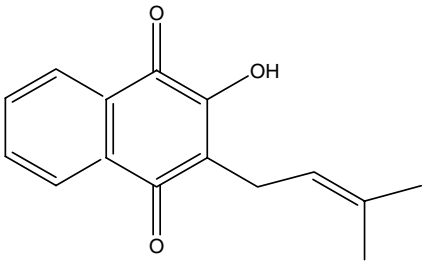

Chart 1. Chart of lapachol.

lapachol were added, giving immediately a bright-red solution. The solution was left at room temperature for 1 h, during which time the product appeared as red needles. The product is moderately soluble in MeOH, EtOH, soluble in diethyl ether. Yield 54 mg (86%). X-ray quality crystals were obtained after slow evaporation of a diluted ethanolic solution. *Anal*. Calc. for $CoC_{34}H_{38}O_8$: C, 64.45; H, 6.05. Found: C, 64.47; H, 5.70%. FAB-MS *m/e* 542 (15%, CoL_2^+), 307 (35%), 289 (10%). IR (4000–400 cm^{-1}, KBr): 3410 vs, 2913 s, 2847 s, 1798 w, 1635 s, 1575 s, 1558 m, 1432 s, 1388 m, 1334 s, 1307 m, 1274 m, 1209 w, 1137 m, 1982 m, 1017 s, 870 w, 597 s broad.

2.2. *[NiL$_2$(EtOH)$_2$] (**2**)*

This compound was prepared in a completely analogous way from 11.4 mg (0.045 mmol) of $Ni(CH_3COO)_2 \cdot 4H_2O$ and 22.2 mg (0.09 mmol) of lapachol, as red needle-shaped crystals. Yield 21 mg (72%). *Anal*. Calc. for $NiC_{34}H_{38}O_8$: C, 64.48; H, 6.05. Found: C, 64.77; H, 5.98%. FAB-MS *m/e* 541 (10%, NiL_2^+), 307 (23%), 289 (7%), 176 (9%). IR (4000–400 cm^{-1}, KBr): 3400 s (br), 2959 w, 2910 m, 2843 w, 1627 s, 1578 vs, 1551 vs, 1355 s, 1337 s, 1288 s, 1266 s, 1239 m, 1222 w, 1186 w, 1957 w, 950 m, 861 w, 785 w.

2.3. *[CuL$_2$py$_2$] (**3**)*

$Cu(CH_3COO)_2 \cdot 2H_2O$ (10 mg, 0.05 mmol) was reacted with lapachol (25 mg, 0.10 mmol) in 5 ml of methanol in the same manner. Then 10 drops of pyridine were added, producing a massive separation of red prismatic crystals. Single crystals of X-ray quality were obtained by ethanol vapour diffusion into a solution in CH_2Cl_2. Yield 26 mg (81%). *Anal*. Calc. for $CuC_{40}H_{36}O_6N_2$: C, 68.22, H, 5.15; N, 3.98. Found: C, 67.92; H, 5.09; N, 3.85%. FAB-MS *m/e* 541 (8%, CuL_2^+), 367 (9%), 307 (19%), 176 (7%).

2.4. Crystallography

Diffraction data were collected at room temperature using a Bruker-Nonius Kappa CCD diffractometer with graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). Frames were collected with the COLLECT program [13], indexed and processed using Denzo SMN and the files scaled together using the HKL2000 program [14]. The absorption correction was applied using a semi-empirical method based on multiple scanned reflections in PLATON program [15]. The structure solution was obtained by direct methods, using the SIR2004 [16] and refined with the SHELXL-97 program [17]. Crystallographic parameters are given in Table 1.

CCDC reference numbers 644610–644612.

2.5. Electrochemistry

Electrochemical measurements were carried out with an AMEL 5000 potentiostat–galvanostat system controlled by a Pentium PC. The electrochemical cell was a conventional one with three electrodes. The reference electrode was Ag/AgCl, the counter electrode was a platinum sheet (Radiometer) and the working electrode was glassy carbon (Metrohm). As supporting electrolyte 0.1 M Bu_4NClO_4 in dichloromethane, deoxygenated by bubbling argon through, was used. The ferrocene/ferrocenium couple was used as an internal reference ($E^{\circ\prime}$ 0.440 V vs NHE). The changes were identified as $1e^-$ processes from bulk electrolysis experiments. $E^{\circ\prime}$ values defined as $1/2(E_a + E_c)$ and ΔE_p defined as $[E_c - E_a]$, where E_a and E_c are the anodic and cathodic peak potentials, were obtained from cyclic voltammetry experiments. From repeated determinations the reproducibility was ±5 mV. The data obtained are summarized in Table 3.

3. Results and discussion

Synthesis. The synthesis of **1**–**3** is rather straightforward and produces the complexes with the M/L ratio 1:2 in high yields. Since a base, acetate, is already present, it is not necessary to add an external base to deprotonate lapachole, and the reaction is driven to completion by the chelate effect and low solubility of the final products in alcohols. An alternative method for the preparation of ZnL_2, CdL_2 and CuL_2 used electrochemical oxidation of the sacrificial metal electrodes in the presence of dissolved lapachol with variable yields (30–75%). Lapachol reduction into semiquinone form (or further) also takes place under the conditions of electrolysis, which may account for lower yields [9–11]. Therefore the method based on the methathesis reactions with acetate salts is more suitable. We also prepared ZnL_2 from $Zn(CH_3COO)_2 \cdot 4H_2O$ and lapachol in the same manner as **1** and **2** in almost quantitative yield, and confirmed its identity by elemental analysis, NMR and FAB-MS. Alternatively, the sodium lapacholate can be prepared first from NaOH and lapachol, and then reacted with a suitable metal salt. This procedure was used to prepare $[ZnL_2(EtOH)_2]$ [9–11].

Structures. The Co and Ni complexes, CoL_2 and NiL_2, form octahedral *trans* adducts **1** and **2** with two molecules of ethanol upon recrystallization from this solvent. Their main geometrical parameters are given in Table 2. The coordination of the two bidentade lapacholate ligands and of two ethanol molecules is all-*trans*. This is different form the *cis*-arrangement of the lapacholate rings observed in $[ML_2(H_2O)(DMF)]$ [11]. In **1** the coordination around Co is distorted octahedral with three sets of Co–O bond lengths, decreasing in the order Co–O(quinonic) 2.15 Å > Co–O(EtOH) 2.10 Å > Co–O(enolic) 2.02 Å. The same order was found in $[ZnL_2(EtOH)_2]$ [10]. In the Ni complex **2** this order is partially reversed: Ni–O(EtOH) 2.10 Å > Ni–O(quinonic) 2.08 Å > Ni–O(enolic) 2.00 Å. In **3** the axial ligands are pyridines, and the distortion is much greater: Cu–O(quinonic) 2.42 Å > Cu–N 2.02 > Cu–O(enolic) 1.95 Å. This can be explained by the well-known tetragonal Jahn–Teller distortion for Cu^{2+}. Apart from this, the three sets of M–O distances differ less between them in the Ni complex, than in the Co or Zn complex, which is probably due to the highest ligand field stabilization energy for high-spin octahedral d^8 configuration (Ni^{2+}) [18]. There is no clear trend in the M–O distances. A 2,2′-bipy adduct, $[CuL_2(bipy)]$, has been structurally characterized. In that case the *cis*-geometry is imposed by the 2,2′-bipy, but this

Table 2
Main bond distances in **1**–**3** and related complexes (Å)

[c] Ref [19].

hardly affects Cu–O distances: 1.92–1.95 Å for enolic coordination, and 2.40–2.44 Å for quinonic coordination [9]. Thus the coordination around Cu both in this complex and in **3** can be described as two isomeric types of square planar CuN_2O_2 coordination (*trans*-CuN_2O_2 in **3** and *cis* in [CuL_2(bipy)]), plus two weakly coordinated quinonic oxygens in the axial positions. The structural difference between the quinonic and enolic C–O groups persists upon coordination: the former are perceptibly shorter (1.22–1.24 Å) than the latter (1.28–1.29 Å). Metal coordination does not affect the quinonic bond distances. The same situation is observed in [CuL_2(bipy)] [9]. Inversely, the C–O enolic distances shorten dramatically upon deprotonation and metal coordination, as compared with free lapachone. This may reflect some degree of bond delocalization within the chelate rings. The M–O distances do not follow the order (Co < Ni < Zn) in which the ionic radii of M^{2+} decrease. Within the quinonoid ring, the C–C bonds inside the MO_2C_2 chelate are the longest and can be regarded as single bonds (1.50 Å), while those between enolic carbon atom and alkyl-substituted carbon atom are shortest (1.38 Å), approaching the normal double bond (1.32 Å) in the 3-methyl-2-butenyl rest.

The molecules are packed in the crystals in a way to permit stacking of the aromatic rings.

The mass-spectra show peaks of the ML_2^+ species which arise from the coordinated solvent loss. Further fragmentation is also observed Figs. 1,2.

In CV (Fig. 3, Table 3) both **1** and **2** show quasi reversible one-electron reduction waves, which most probably correspond to the ligand reduction to the semiquinonic form. The possibility of stabilization of the electrogenerated anion radical by intramolecular hydrogen bonding in different classes of quinones has been extensively

reviewed [20]. The values observed for the redox potentials of compounds **1** and **2** are in the first monoelectronic reduction potential range of isolated lapachol and derivatives compounds [21]. Bubbling CO into the cell does not affect the reduction process which rules out the possibility of metal reduction to M(I) (CO coordination to the reduced metal would shift the reduction waves, as reported for Ni(I) complexes [22]).

R = Ph whilst with the bulkier ligand (R = Cy) only a 1:1 complex was isolated [3c] and $[Li(R_2PC(N^iPr)_2]_n$ forms a dimer with R = Ph, but a less sterically crowded hexamer for R = Cy [7].

We examined a series of lanthanide nitrate complexes with tricyclohexylphosphine oxide to investigate the effect of increasing the steric bulk of the ligand on the structural properties of the resulting complexes. The increased lipophilicity of Cy_3PO compared to Ph_3PO may make its complexes more suited to solvent extraction. In this respect any transition from a neutral to cationic complex may also provide a mechanism for increased selectivity in extraction, with ionic complexes having lower affinity to a non-aqueous phase.

2. Results and discussion

2.1. Synthesis and structures

The reaction of lanthanide nitrates with tricyclohexylphosphine oxide in metal to ligand ratios between 1:3 and 1:4 led to the isolation of $Ln(NO_3)_3(OPCy_3)_3$ as ethanol solvates except for the Eu and Er complexes. The 1:4 complexes which can be formed with Ph_3PO [5] and the smaller Ph_2MePO [8] cannot be obtained with the more bulky Cy_3PO under these conditions. The complexes formed in high yield giving crystals suitable for X-ray diffraction.

The structures comprise two molecules in the unit cell for the La, Nd, Eu and Er complexes and one for Tm and Yb. Details of the data collection and refinement are given in Table 1 and selected bond lengths and angles in Table 2. The geometries about the metals are all distorted *mer*-octahedra if the nitrate ligands are considered to act as pseudo-monodentate ligands bonded via the nitrogen atoms. The "*cis*" angles range from 104.5° to 74.0° with an average of 90.9° over all the complexes, whilst the "*trans*" angles range from 153.4° to 176.9° with an average of 164.7°.

The coordination mode of the nitrate ligands changes with the decrease in the ionic radius of the lanthanide ion. Thus for the larger ions La–Eu the nitrates all act as bidentate ligands and the complexes are 9-coordinate. Where the unit cells contain ethanol molecules, they are not hydrogen bonded to any of the nitrate ligands. The structure of one of the molecules in the unit cell of the lanthanum complex is shown in Fig. 1. The Er structure has two molecules in the unit cell which differ in the binding of the nitrates. One molecule has three bidentate nitrates and a similar overall structure to those of the La, Nd and Eu complexes, whilst the other has two bidentate and one monodentate nitrate and is hence eight-coordinate. It is interesting to note here that the monodentate nitrate is not hydrogen bonded to the lattice ethanol, and this appears to lead to relatively symmetrical bonding to the metal with non-bonded distances between the O–Er of 3.940(6) and 3.979(5) Å. The structures of the Tm and Yb complexes have one molecule in the unit cell in which there are two bidentate and one monodentate nitrate ligands. The structure of the Tm complex is shown in Fig. 2.

In these complexes the monodentate nitrate is hydrogen bonded to the lattice ethanol and this causes a distinct asymmetry in the bonding of the monodentate nitrate. The H-bonded oxygen–Ln distance is over 4.4 Å whilst the non-H-bonded distances are in the region of 3.5 Å for the Tm and Yb complexes.

The Ln–O distances have a good linear correlation with the nine-coordinate (La to Er) and eight-coordinate (Er to Yb) ionic radii of the respective lanthanide ions [9]. A plot of the Ln–O($N_{bidentate}$) and Ln–O(P) distances versus ionic radius is shown in Fig. 3.

In the Er structure the monodentate nitrate has an Er–O(N) distance of 2.287(5) Å compared with longer distances for the Tm (2.310(2) Å) and Yb (2.304(2) Å), respectively. This discrepancy can be explained by the hydrogen bonding between the nitrate and ethanol. In the Tm and Yb complexes, the O···O contacts between the nitrate and ethanol of 2.932(5) Å (Tm) and 2.943(5) Å (Yb) are shorter than the sum of the Van der Waals radius for oxygen (3.04 Å) and are thus indicative of a hydrogen bond.

2.2. Infrared spectroscopy

Infrared spectroscopy has routinely been used as a means of identifying the coordination mode of nitrate ligands to metals [10]. Thus although monodentate and bidentate coordinated nitrates have the same local symmetry the splitting of the N–O stretching modes has been taken as a means of assigning structures. Further, ionic nitrate, with a higher local symmetry should be readily distinguishable by the number of bands observed alone.

We have recently encountered complexes in which formally ionic nitrates are hydrogen bonded to lanthanide coordinated ligands or lattice solvent molecules [11]. The spectra in these instances are typical of bidentate nitrates. It was thus apparent that the use of spectroscopy alone in determining the coordination mode of nitrate ligands was prone to uncertainties when H-bonding ligands were present.

The infrared spectra of the Cy_3PO complexes are as expected for complexes of phosphine oxides with lanthanide nitrates. The P=O stretch decreases on coordination from 1146 cm^{-1} to about 1100 cm^{-1} on coordination to the metal. The spectra of the N–O region in these complexes differ only subtly despite the presence of monodentate nitrates in the Er, Tm and Yb complexes. All complexes show absorptions typical of coordinated nitrate with strong bands in the 1480–1450 cm^{-1} and 1300–1290 cm^{-1} region and a weaker absorption around 1040 cm^{-1}. Complexes which contain both monodentate and bidentate nitrates do not display features which would allow unambiguous identification of the presence of monodentate nitrates.

2.3. Electrospray mass spectrometry

The solution properties of the complexes were examined by electrospray mass spectrometry in methanol solution, and the data and assignments for the complexes studied are given in Table 3. Assignments are made on the basis of calculated *m*/*z* ratios, all of which are within 0.5 Da of the theoretical values and the observation of analogous

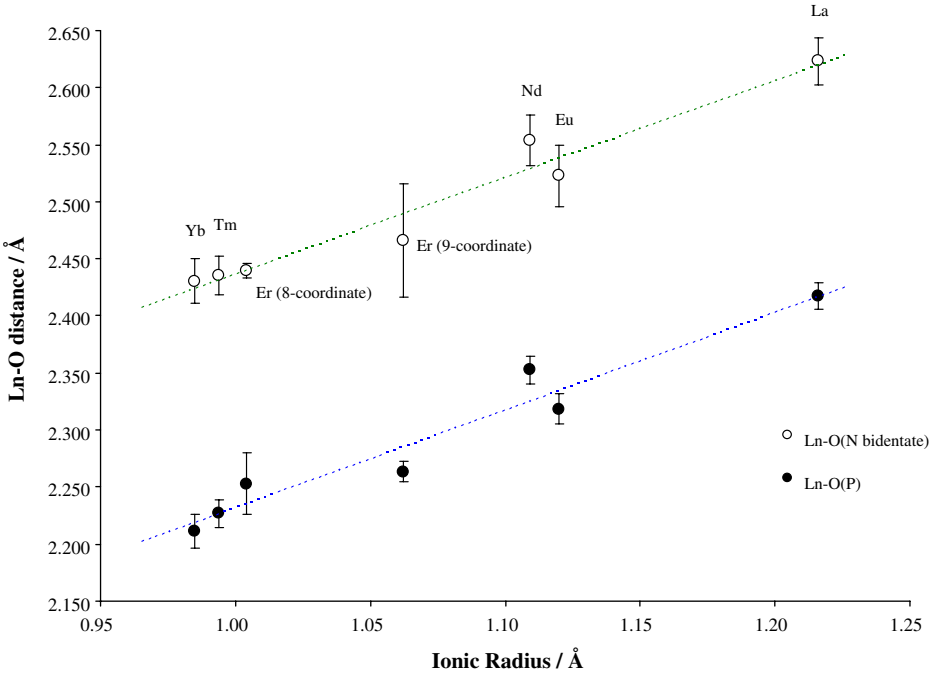

Fig. 3. The variation in Ln–O distances with ionic radius of the lanthanide ion.

[b] Significant fragmentation of this ion was observed as discussed in the text.

species for the series of complexes studied. In addition the theoretical isotope patterns give excellent agreement with those observed. An example for the $[Gd(NO_3)_2L_3]^+$ ion is typical and shown in Fig. 4. The spectra all show strong signals from $[L+H]^+$, $[L+Na]^+$, $[2L+H]^+$ whilst those from lanthanide containing ions indicate that the complexes undergo redistribution reactions in solution. Such redistribution reactions are common for lanthanide complexes and have previously been observed for β-diketonate [12] and a variety of phosphine oxide [13] complexes. Peaks from $[Ln(NO_3)_2L_3]^+$ are observed for all complexes, often as low intensity clusters of signals. The main lanthanide containing signals are derived from loss of nitrate to give $[Ln(NO_3)L_3]^{2+}$ and from loss of nitrate and attachment of further ligand to give $[Ln(NO_3)L_4]^{2+}$. There appears to be no correlation between the abundance of +2 cations and the presence of the monodentate nitrates observed in the solid state structures. In addition to these processes solvolysis reactions are also apparent giving rise to intense signals assigned to $[Ln(OH)L_4]^{2+}$, $[Ln(OMe)L_3]^{2+}$ and $[Ln(OMe)L_4]^{2+}$. Such solvolysis processes have been observed in the spectra of lanthanide salts and complexes before [14] and are thought to be due to gas phase processes rather than reflecting the nature of solution species. The mass spectra of several of the complexes were recorded again after the solutions had aged for about three weeks

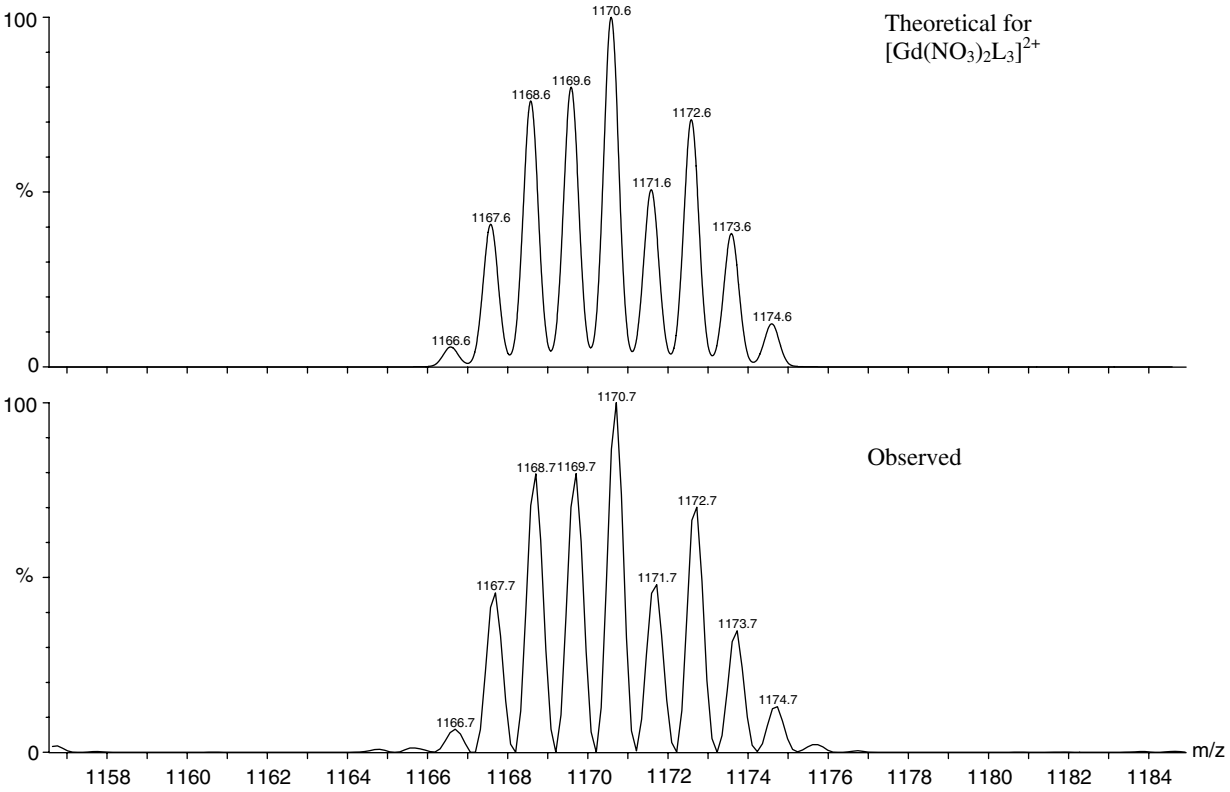

Fig. 4. Theoretical isotope pattern for $[Gd(NO_3)_2L_3]^+$ (L = Cy_3PO) and that observed in the positive ion electrospray mass spectrum.

and showed no significant differences with spectra obtained from fresh solutions. The positive ion ESMS of $Ho(NO_3)_3L_3$ is representative of the spectra obtained and is shown in Fig. 5.

Selected ions were also examined by tandem mass spectrometry to investigate their behaviour in the gas phase. The ions were chosen to represent species which might be expected initially to be present in solution namely

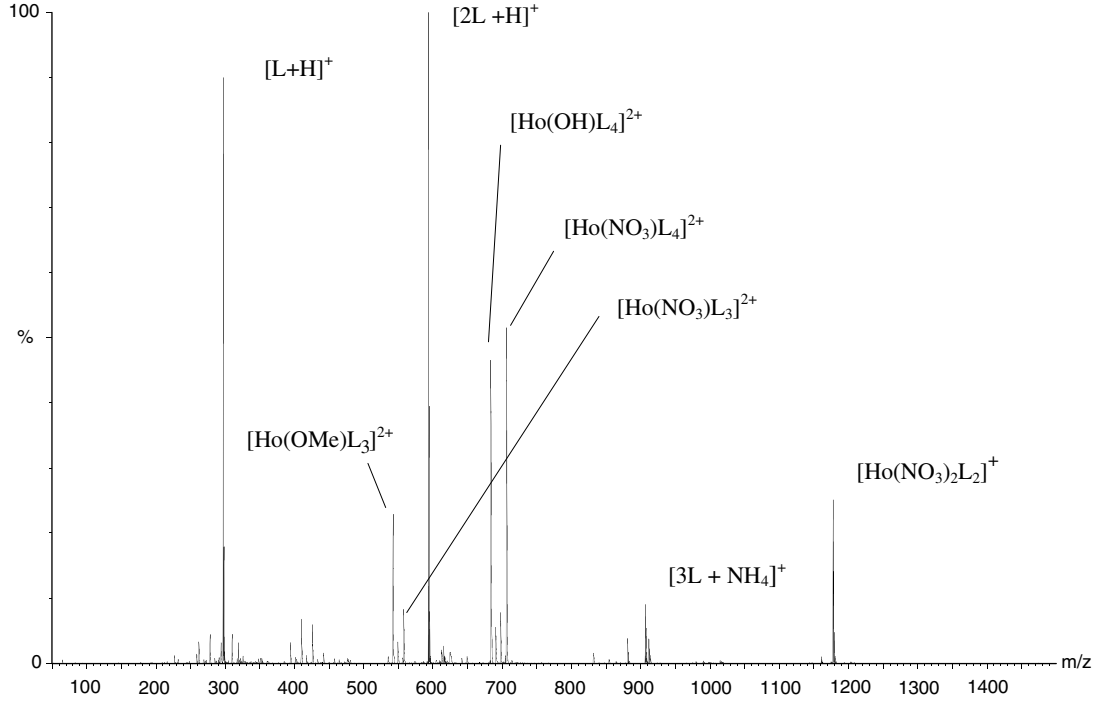

Fig. 5. The positive ion Electrospray mass spectrum of $Ho(NO_3)_3L_3$ (L = Cy_3PO) in methanol/water with principal assignments.

$[Ln(NO_3)_2L_3]^+$ and $[Ln(NO_3)L_4]^{2+}$ and also ions which are more likely to have been formed as part of the electrospray process such as $[Ln(OH)L_4]^{2+}$ and $[Ln(OMe)L_3]^{2+}$. The lanthanum, holmium and ytterbium complexes were studied to represent the range of lanthanides. The tandem mass spectra of most of the ions are simple, showing loss of only one tricyclohexylphosphine oxide ligand for all ions studied. The exception to this was $[Yb(OMe)L_3]^{2+}$ which

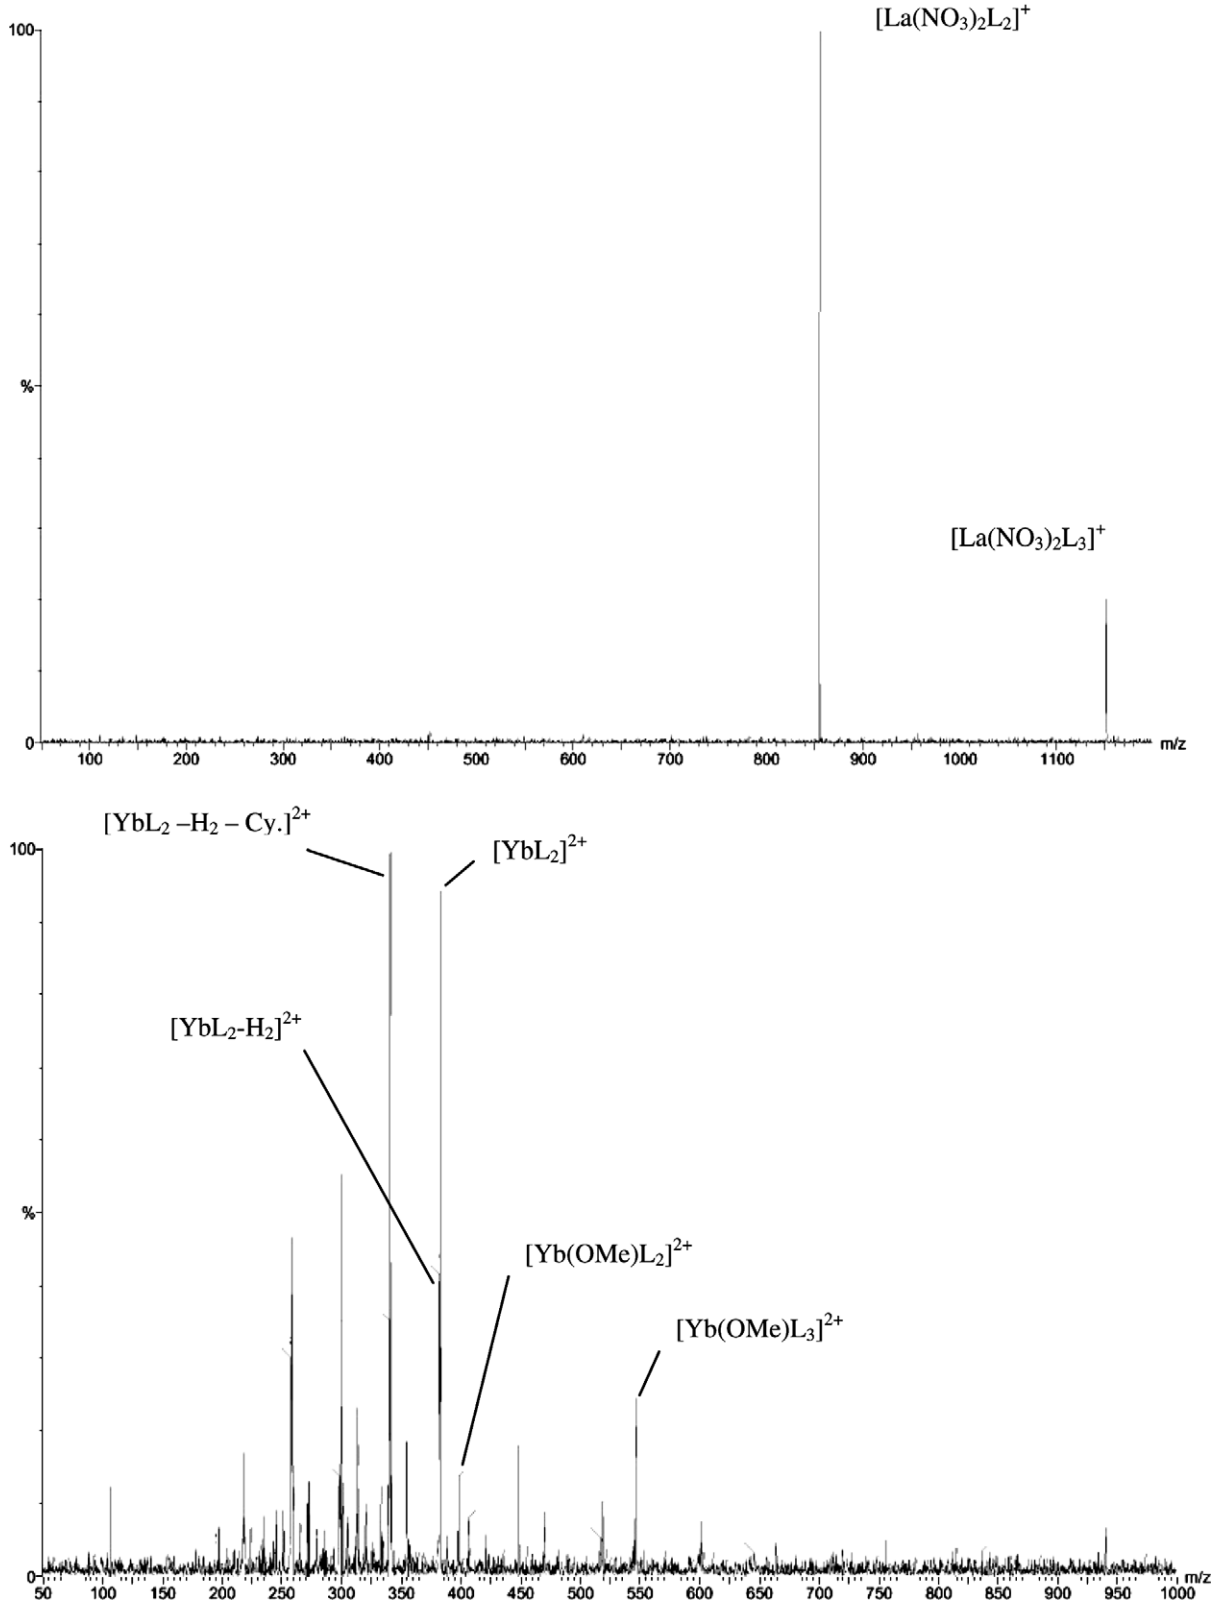

Fig. 6. The tandem mass spectra of the $[La(NO_3)_2L_3]^+$ (upper) and $[Yb(OMe)L_3]^{2+}$ ($L = Cy_3PO$) (lower) ions.

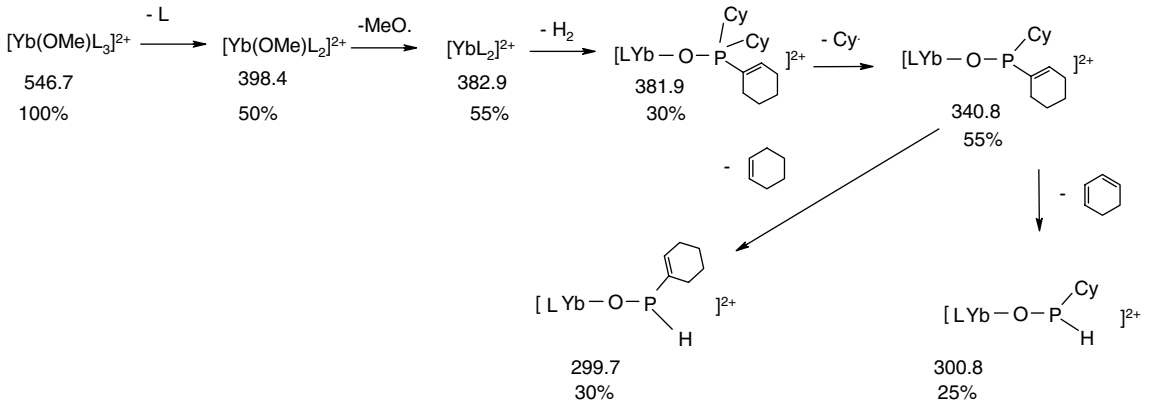

Fig. 7. A possible fragmentation pathway for $[Yb(OMe)L_3]^{2+}$ (L = Cy_3PO).

required a higher collision offset (COFF) to induce fragmentation similar to that of the La and Ho complex ions. Typical spectra for the La and Yb complexes are shown in Fig. 6. The Yb complex ion required COFF 50 eV, whilst the corresponding La and Ho ions yielded simple and meaningful fragment ions with COFF 30–40 eV. The stability of the Yb complex to loss of ligand is presumably due to the higher charge density on the metal ion. Under the harsher conditions required for its fragmentation a more complex spectrum was produced. This showed loss of Cy_3PO with further fragmentation due to loss of MeO·, cyclohexyl radicals and possibly cyclohexadiene. Loss of cyclohexene and cyclohexyl radicals under electron impact has been observed previously in the mass spectra of aromatic cyclohexyl ethers [15] and in $Cy_2P(O)C_2H_4P(O)Cy_2$ [16] and whilst electrospray ionisation is generally less energetic, the application of higher COFF in the tandem mass spectra of the Yb complex presumably supplies sufficient energy for radical formation.

The loss of H_2 from a 2+ charged ion was also apparent by the presence of peaks separated by one *m*/*z* unit. Fig. 7 illustrates a possible fragmentation pathway which accounts for the presence of the major ions observed. It must be noted that the mechanism is tentative. Cleavage of the Yb–OMe bond leading to loss of MeO· generates an Yb(II) fragment which may explain why whilst further decomposition of $[Yb(OMe)L_2]^{2+}$ was observed the corresponding ion for La and Ho, for which the divalent states are less stable, does not undergo this decomposition.

3. Experimental

3.1. Crystal structure determinations

Data were collected by the EPSRC National Crystallography Service at the University of Southampton using previously described procedures [17–19].

The positions of the metal atoms in the La and Yb structures were estimated by Patterson methods using SHELXS-97 [20], and all remaining non-H atom positions were obtained through subsequent Fourier syntheses (SHELXL-97) [21]. Refinement was by full-matrix least-squares on F^2 data using SHELXL-97 [21]. Solutions and all refinements were conducted using SHELX-97 from within the WinGX [22] suite of software.

The Nd, Eu and Er structures were each refined in space group $P2_1$ after isomorphous replacement into the La structure. The Tm structure was solved by similar replacement into the Yb structure (space group $Pc2_1n$) after re-indexing the data and transforming the unit cell axes from the alternative space group setting, $Pbn2_1$ for which the data were collected. The asymmetric unit in each of the La–Er structures consisted of two discrete lanthanide-containing molecules. The asymmetric units of the Tm and Yb structures each consisted of a single lanthanide-containing molecule.

Attempts to refine the Er structure after initial substitution into the La structure showed the positions of the atoms of one of the bidentate nitrate groups in one of the two molecules to be unstable. After deletion of nitrate atoms, peaks were re-located in subsequent Fourier syntheses to build a stable model containing a monodentate nitrate group – consistent with the molecular structure observed in the Yb and Tm complexes.

In each of the structures, non-H atoms were refined anisotropically with the exception of the C atoms of one of the cyclohexyl groups in each of the La and Nd structures and two cyclohexyl groups in the Er structure. The initial, fully anisotropic, models of the La–Er structures displayed marked librational elongation of the thermal ellipsoids of the C-atoms in these groups, and their geometry deviated from that expected for the cyclohexyl moiety. A disordered, isotropic, model consisting of two alternative sites with complementary site occupation factors was adopted for the La, Nd, and Er structures. SIMU restraints were applied to C-atoms of the corresponding group in the Eu structure for which data were poorer.

An ethanol molecule was located near to one of the nitrate groups in each of the La, Nd, Tm and Yb structures. The site occupation factors of the solvent molecules in the La and Nd lattices were initially refined, and finally

fixed at half occupancy. A similar solvent molecule was located in the Er structure apparently H-bonded to one of the bidentate nitrate groups. This site occupation factor of this solvent refined to <0.6%, and made little improvement to the figures of merit. It was excluded from the final structure. No similar solvent could be located in the difference Fourier maps of the Eu structure.

All H atoms were included in the refinements at idealised positions riding on the atoms to which they were bonded (methane C–H = 1.00 Å, methylene C–H = 0.99 Å, methyl C–H = 0.98 Å, O–H = 0.84 Å) The H-atoms of each functional group were assigned a single, refined isotropic displacement parameter, except those of solvent molecules which were assigned a common, refined isotropic displacement parameter.

The non-centrosymmetric structures refined to give Flack absolute structure parameters of −0.011(10), −0.014(8), −0.017(10), −0.020(7), −0.030(4) for the La, Nd, Eu, Er and Yb structures, respectively. The absolute structure of the Tm complex could not be unambiguously determined. ROTAX analysis [23] of the Tm data indicated merohedral or pseudo-merohedral twinning. The Tm structure refinement was repeated assuming racemic twinning by using the default TWIN setting in SHELXL-97 [21], and refinement converged to yield a batch scale factor of 0.520(5).

Molecular graphics were generated using SNOOPI [24]

3.2. Mass spectrometry

Electrospray mass spectra were recorded on a either a Waters ZQ-4000 or a Micromass Quattro II for the MS/MS measurements. Samples in methanol solution were loop injected into a flow of 1:1 methanol: water running at 40μL/min into the electrospray capillary. Nebulisation was pneumatically assisted by a flow of $N_{2(g)}$ at 15 L/min and a drying gas of $N_{2(g)}$ at 100 L/min warmed by a source temperature of 80 °C. The spray voltage was 3.5 kV and the cone voltage varied between 20 V and 90 V depending on the mass and charge of the ions of interest. For tandem mass spectra, $Ar_{(g)}$ at a pressure of 2×10^{-3} mbar was introduced into the collision chamber (termed quadrupole 2 or Q2); ions formed during the ES process and mass selected for individual analysis by the first quadrupole (Q1), were accelerated through this region of relatively high pressure by a voltage termed the collision offset (COFF). The COFF voltage was adjusted to obtain optimal fragmentation for each precursor ion, and the resulting fragment ions analysed by Q3.

3.3. Infrared spectroscopy

Infrared spectra were recorded in the range 400–4000 cm^{-1} on a Thermo Nicolet Avatar 370 instrument operating in ATR mode. Samples were analysed without pre-treatment other than crushing onto the optical surface.

3.4. Synthesis and characterisation

Tricyclohexylphosphine oxide was prepared by oxidation of an acetone solution of tricyclohexylphosphine with 30% H_2O_2. In a typical preparation the phosphine (20.04 g) was suspended in 100 ml of acetone and hydrogen peroxide (9.00 g 30% aqueous solution) was added in portions allowing the vigorous reaction to subside before the next addition. The resulting clear solution was allowed to cool to room temperature and the resulting crystalline solid filtered, washed with a little cold acetone and dried at the pump to give 19.18 g of a waxy colourless solid. NMR (acetone) δ^{31}P 51.6, literature 50.0 [25] ν_{PO} 1146 cm^{-1}.

The nitrate complexes were prepared by mixing hot solutions of tricyclohexylphosphine oxide with the appropriate lanthanide nitrate in ethanol. On cooling crystals formed in 80–100% yield. Representative syntheses and characterisation are described below.

$La(NO_3)_3(Cy_3PO)_3 \cdot 0.5EtOH$. $La(NO_3)_3 \cdot 5H_2O$ (0.23 g 0.55 mmol) in 10 ml hot ethanol was mixed with Cy_3PO (0.71 g 2.4 mmol) in 10 ml hot ethanol. The resulting solution was warmed for 15 min during which time crystals began to form. The mixture was cooled to room temperature and allowed to stand overnight. The colourless crystals were filtered, washed with a small quantity of cold ethanol and dried at the pump to give 0.65 g (99%), ν_{PO} 1097 cm^{-1}.

Anal. Calc. for $La(NO_3)_3(Cy_3PO)_3 \cdot 0.5EtOH$: C, 53.39; H, 8.31; N, 3.40. Found: C, 52.88; H, 8.20; N, 3.28%.

$Nd(NO_3)_3(Cy_3PO)_3 \cdot 0.5EtOH$. $Nd(NO_3)_3 \cdot 6H_2O$ (0.26 g 0.59 mmol) in 5 ml hot ethanol was mixed with Cy_3PO (0.66 g 2.2 mmol) in 10 ml hot ethanol. The mixture was cooled to room temperature and allowed to stand overnight. The lilac crystals which formed were filtered, washed with a small quantity of cold ethanol and dried at the pump to give 0.65 g (99%), ν_{PO} 1099 cm^{-1}.

Anal. Calc. for $Nd(NO_3)_3(Cy_3PO)_3 \cdot 0.5EtOH$: C, 53.16; H, 8.27; N, 3.38. Found: C, 52.63; H, 8.19; N, 3.32%.

$Eu(NO_3)_3(Cy_3PO)_3$. $Eu(NO_3)_3 \cdot 6H_2O$ (0.26 g 0.58 mmol) in 10 ml hot ethanol was mixed with Cy_3PO (0.72 g 2.4 mmol) in 10 ml hot ethanol. The mixture was cooled to room temperature and allowed to stand overnight. The colourless crystals which formed were filtered, washed with a small quantity of cold ethanol and dried at the pump to give 0.63 g (88%) ν_{PO} 1102 cm^{-1}.

Anal. Calc. for $Eu(NO_3)_3(Cy_3PO)_3$: C, 52.85; H, 8.13; N, 3.42. Found: C, 52.38; H, 8.15; N, 3.23%.

$Tm(NO_3)_3(Cy_3PO)_3$. $Tm(NO_3)_3 \cdot 6H_2O$ (0.24 g 0.52 mmol) in 5 ml hot ethanol was mixed with Cy_3PO (0.62 g 2.0 mmol) in 10 ml hot ethanol. The mixture was cooled to room temperature and allowed to stand overnight. The colourless crystals which formed were filtered, washed with a small quantity of cold ethanol and dried at the pump to give 0.55 g (84%), ν_{PO} 1104 cm^{-1}.

Anal. Calc. for $M(NO_3)_3(Cy_3PO)_3$: C, 52.13; H, 8.02; N, 3.38. Found: C, 52.05; H, 8.20; N, 3.15%.

(Scheme 1) and a mechanism, in which a hypomanganate is formed in a two-electron reduction followed by a rapid oxidation of the hypomanganate ion [11] (Scheme 2).

The manganese chemistry involved in these multistep redox reactions is an important source of information as the manganese intermediates are relatively easy to identify when they have sufficiently long life time and oxidation states of the intermediates permit useful conclusions as to the possible reaction mechanisms including the nature of intermediates.

Ciprofloxacin [cyclopropyl-6-fluoro-1,4-dihydro-4-oxo-7-(piperazinyl)-quinolone-3-carboxylic acid] is one of the potent synthetic fluoroquinolone antibacterial agents, that are widely used in human and veterinary medicines [12] and also used in the treatment of infections due to *Bacillus anthracis* (i.e., anthrax infections) [13]. Due to their extensive usage, fluoroquinolones may enter the environment via wastewater effluent and biosolids from sewage treatment plants and via manure and litters from food-producing animal husbandry. There are studies on the modified pharmacological and toxicological properties of these drugs in the form of metallic complexes [14–16].

The presence and accumulation of fluoroquinolone antibiotics in aquatic environments, albeit at low concentrations, may pose threats to the ecosystem and human health by inducing increase and spread of bacteria drug-resistance due to long-term exposure. Chemical oxidation using permanganate has been widely used for treatment of pollutants in drinking water and wastewater applications for over 50 years. The title reaction was extensively investigated to elucidate the behavior of this fluoroquinolone antibacterial agent during wastewater treatment by permanganate. The structure of ciprofloxacin is shown below which consists of piperazine and pyridone moieties.

$$\mathrm{Mn(VII)} + \mathrm{S} \xrightarrow{k_1} \mathrm{Mn(VI)} + \mathrm{S}^{\bullet}$$

$$\mathrm{Mn(VII)} + \mathrm{S}^{\bullet} \xrightarrow{k_2} \mathrm{Mn(VI)} + \mathrm{Products}$$

S=substrate $k_2 >> k_1$

S=substrate $k_4 >> k_3$

Scheme 2.

In view of potential pharmaceutical importance of ciprofloxacin and lack of the literature on the oxidation of this drug by any oxidant except in two cases [17,18] and the complexity of the reaction, a detailed study of the reaction becomes important. The present study deals with the title reaction to investigate the redox chemistry of permanganate in such media and to arrive at a suitable mechanism for oxidation of ciprofloxacin by permanganate on the basis of kinetic results.

2. Experimental

All chemicals used were of analytic reagent grade and double distilled water was used throughout the work. The solution of ciprofloxacin (Bayer AG) was prepared by dissolving known amount of its hydrochloride salt in distilled water. The permanganate (SISCO-CHEM Ltd.) solution was prepared and standardized against oxalic acid by standard procedure [19]. Potassium manganate solution was prepared as described by Carrington and Symons [20]. KOH (BDH, Analar) and KNO_3 (BDH, Analar) were employed to maintain the required alkalinity and ionic strength, respectively, in reaction solutions.

2.1. Instruments used

(a) For kinetic measurements: UV–Vis spectrophotometer (Varian CARY 50 Bio) connected to a rapid kinetic accessory (Hitech SFA-12).

(b) For product analysis:
LC-ESI-MS technique. Hewlet Packard 1100 reverse phase high performance liquid chromatography (HPLC) system with a phenomenes C18 column, hp 1100 series diode array UV/Visible detector and hp 1100 MSD Series mass analyzer.
LC-ESI-MS/MS technique. AGILENT 1100 series high performance liquid chromatography (HPLC) system, AGILENT 1100 variable wavelength detector and Esquire 3000 plus (BRUKER DALTONICS, Germany) mass analyzer.
Twelve microliters of acidified reaction mixture was injected. The mobile phase consisted of acetonitrile (eluent A) and water (Containing 0.1% CH_3COOH) at a flow rate of 1 ml/min. Gradient elution was run to separate substrate and reaction products. Gradient 0 min/20% A–40 min/95% A–45 min/95% A–47 min/20% A. UV detection at 226 and 280 nm.

2.2. Kinetic procedure

The oxidation of ciprofloxacin by permanganate was followed under pseudo-first order conditions where [ciprofloxacin] was excess over [permanganate] at 25 ± 0.1 °C unless otherwise stated. The reaction was initiated by mixing the required quantities of previously thermostatted solutions of ciprofloxacin and permanganate, which also

contained definite quantities of KOH and KNO_3 to maintain the required alkalinity and ionic strength. The progress of reaction was followed by measuring the absorbance of unreacted permanganate in the reaction mixture present in 1 cm cell in a thermostatted compartment of a Varian CARY 50 Bio UV–Vis. spectrophotometer at 526 nm. It was verified that other constituents of the reaction mixture do not absorb significantly at this wavelength. The application of Beer's law to permanganate at 526 nm had been verified and $\varepsilon = 2100 \pm 50\ dm^3\ mol^{-1}\ cm^{-1}$. The reaction was followed more than three half lives. The first order rate constants, k_{obs} were obtained from the plots of $\log(A_t - A_\infty)$ *versus* time. Where A_t refers to absorbance at any time t and A_∞ is at infinite time which excludes the absorbance of any Mn(VI) during the reaction. The plots were linear over 70% completion of the reaction and rate constants were reproducible within ±5%.

The effect of dissolved oxygen on the reaction was studied by preparing the reaction mixture and following the reaction in an atmosphere of nitrogen. No significant difference between the results was observed. In view of ubiquitous contamination of carbonate in basic solutions, the effect of carbonate on the reaction was also studied. Added carbonate had no effect on reaction rate. However, fresh solutions were used during the experiments. Regression analysis of experimental data to obtain the regression coefficient, r and standard deviation, S of points from the regression line was performed using microsoft excel-2003 programme.

3. Results

3.1. Oxidation products of ciprofloxacin

LC-ESI-MS analysis of ciprofloxacin reaction indicated the presence of three products with molecular ions of m/z 348 (Fig. 1(a) (iv)) (Yield 5%), 306 (Fig. 1(a) (ii)) (Yield 32%) and 263 (Fig. 1(a) (iii)) (Yield 55%), respectively. The molecular ion of ciprofloxacin is m/z 332. The m/z 348 corresponds to *N*-oxide product. The m/z 306 (i.e., the M−26 product with respect to ciprofloxacin) corresponds to partial dealkylation of the piperazine ring while the m/z 263 corresponds to full dealkylation of the piperazine ring (i.e., the –NH2 product). These two products were also identified previously as oxidation products [17] and photodegradation products of ciprofloxacin [21].

3.2. Reaction orders

The reaction orders were determined from the slope of $\log k_{obs}$ *versus* log (concentration) plots by varying the concentrations of ciprofloxacin and alkali in turn while keeping all other concentrations and conditions constant.

3.3. Effect of [oxidant]

The oxidant $KMnO_4$ concentration was varied in the range of 4.0×10^{-5}–4.0×10^{-4} mol dm^{-3} and the constant k_{obs} values (Table 1) indicate that order with respect to [$KMnO_4$] was unity. This was also confirmed by linearity and parallel plots of $\log[A_t - A_\infty]$ *versus* time (Fig. 2) ($r \geqslant 0.983$, $S \leqslant 0.016$) up to 75% completion of the reaction.

3.4. Effect of [ciprofloxacin]

The effect of ciprofloxacin concentration on the reaction was studied at constant concentrations of alkali and permanganate and at a constant ionic strength of 0.04 mol dm^{-3} at 25 °C. The substrate, ciprofloxacin was varied in the range of 2.0×10^{-3}–2.0×10^{-2} mol dm^{-3}. The k_{obs} values increased with increase in concentration of ciprofloxacin (Table 1). The order with respect to [ciprofloxacin] was found to be less than unity (0.48) ($r \geqslant 0.9859$, $S \leqslant 0.008$).

3.5. Effect of [alkali]

The effect of increase in concentration of alkali on the reaction was studied at constant concentrations of ciprofloxacin and permanganate at a constant ionic strength of 0.04 mol dm^{-3} at 25 °C. The rate constants increased with increase in alkali concentration (Table 1). The order with respect to [OH^-] was found to be less than unity (0.64).

3.6. Effect of ionic strength and solvent polarity

The effect of ionic strength was studied by varying the potassium nitrate concentration from 0.02 to 0.2 mol dm^{-3} at constant concentrations of permanganate, ciprofloxacin and alkali. It was found that increasing ionic strength had no effect on the rate constant. The effect of relative permittivity ($\in_T$) was studied by varying the *t*-butanol–water content (v/v) in the reaction mixture with all other conditions being maintained constant. Decreasing the dielectric constant of the medium had no effect on the rate of the reaction.

3.7. Effect of initially added products

The manganate ion concentration was varied from 4.0×10^{-5} to 4.0×10^{-4} at constant concentrations of permanganate, ciprofloxacin, alkali and ionic strength. It was found that initially added manganate ion had no effect on the rate constant.

The experimental rate law is given as follows:

$$\frac{-d[MnO_4^-]}{dt} = k[MnO_4^-][CF]^{0.48}[OH^-]^{0.64}$$

3.8. Effect of temperature

The kinetics was studied at four different temperatures under varying concentrations of ciprofloxacin and alkali, keeping other conditions constant. The rate constants were

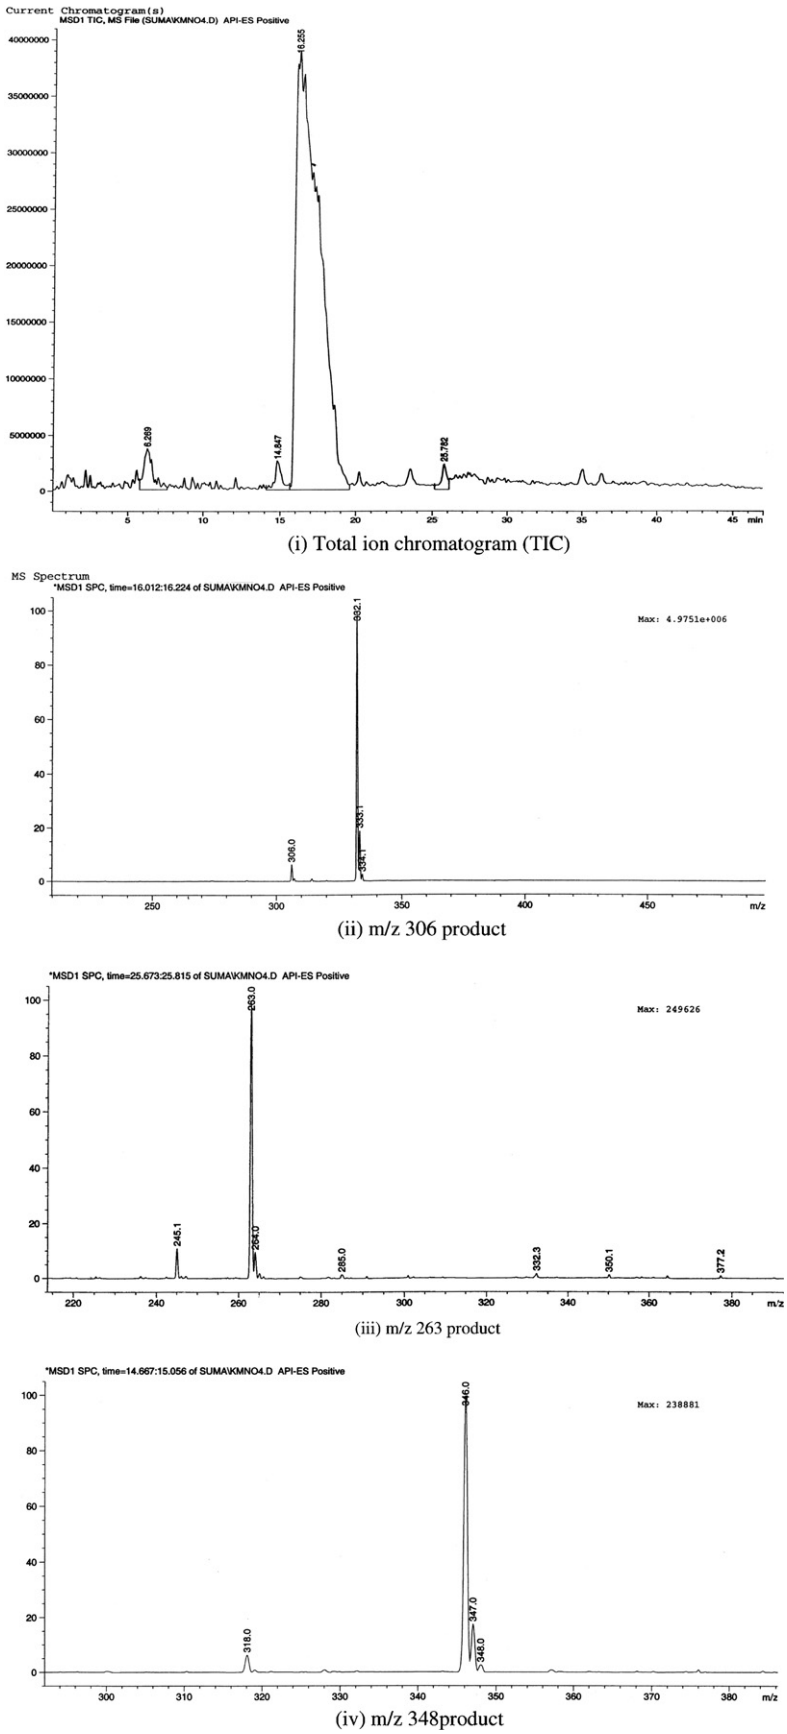

Fig. 1(a). LC-ESI-MS spectra of oxidation products of ciprofloxacin.

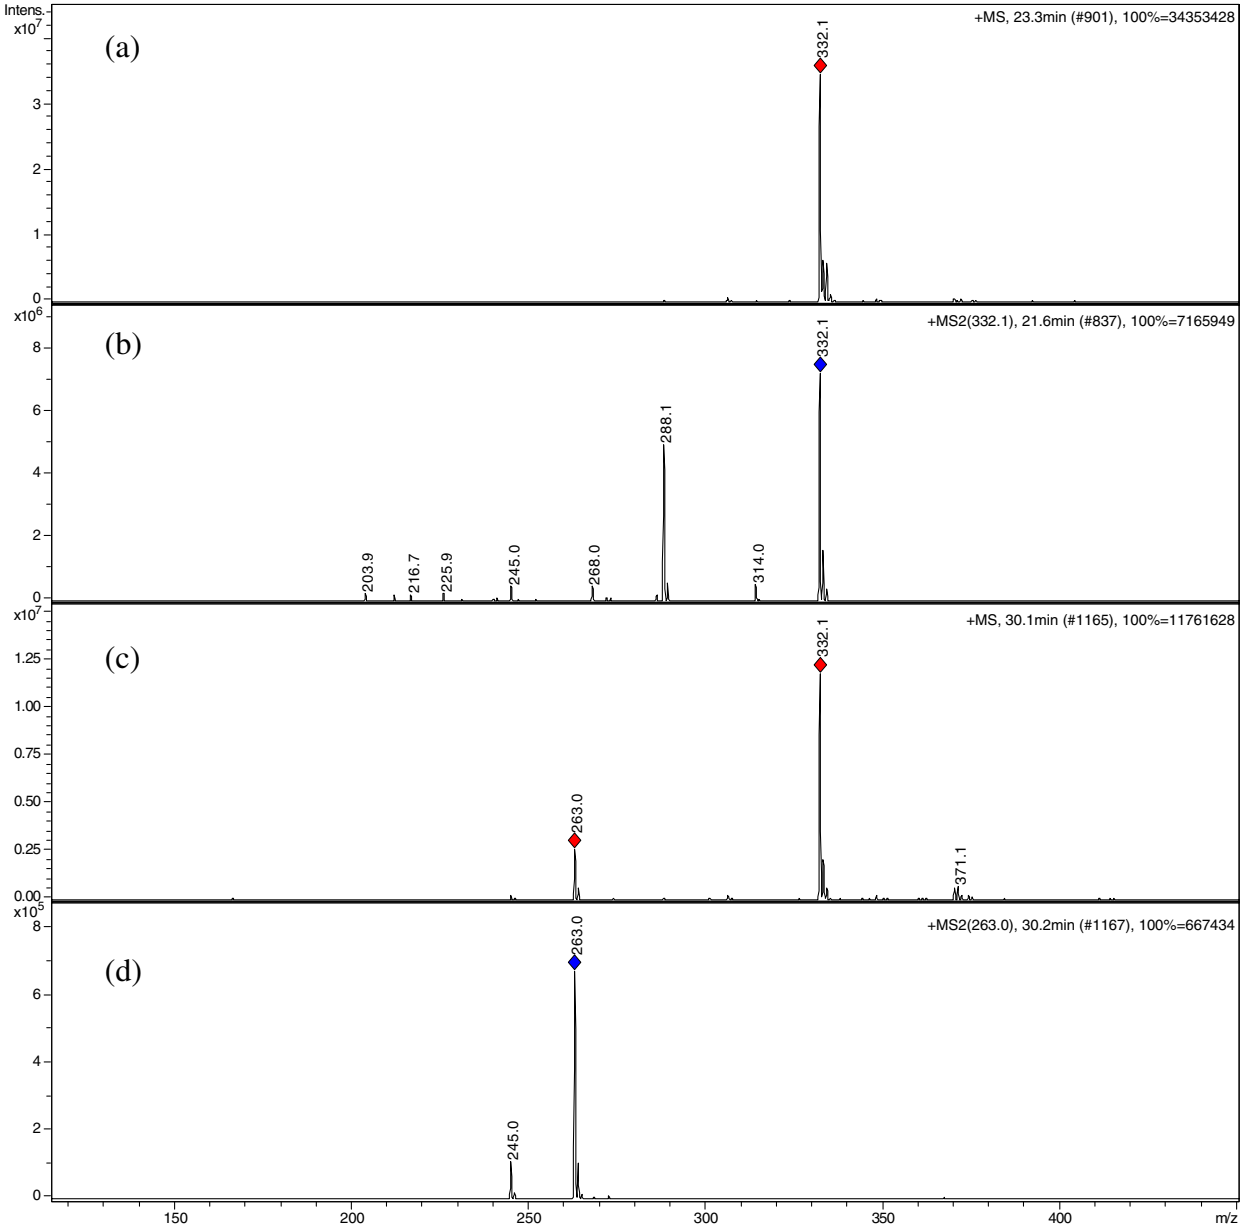

Fig. 1(b). LC-ESI-MS-MS spectra of oxidation products of ciprofloxacin. (a) Molecular ion peak $(M + H)^+$ of ciprofloxacin. (b) Fragmentation of $(M + H)^+$. (c) Molecular ion peaks of *m/z* 332 $(M + H)^+$ and *m/z* 263 (M−69). (d) Fragmentation of (M−69) product.

found to increase with increase in temperature. The rate constant (k) of the slow step of Scheme 1 were obtained from the slopes and intercepts of $1/k_{obs}$ *versus* 1/[CF] and $1/k_{obs}$ *versus* $1/[OH^-]$ plots at four different temperatures. The energy of activation corresponding to these rate constants was evaluated from the Arrhenius plot of $\log k$ *versus* $1/T$ ($r \geqslant 0.9802$, $S \leqslant 0.009$) and from which other activation parameters were obtained (Table 2).

4. Discussion

Permanganate ion, MnO_4^-, is a powerful oxidant in an aqueous alkaline medium. As it exhibits many oxidation states, the stoichiometric results and pH of reaction media play an important role. Under the prevailing experimental conditions at pH > 12, the reduction product of Mn(VII) is stable and further reduction of Mn(VI) might be stopped [10,22]. But during this study, colour of the solution changed from violet to blue and then to green. The spectrum of green solution was identical to that of MnO_4^{2-}. It is probable that blue colour originated from the violet of permanganate and the green from manganate, excluding the accumulation of hypomanganate. The spectral changes during the reaction are shown in Fig. 3. It is evident from the figure that the concentration of MnO_4^- decreases at 526 nm due to Mn(VII) and increases at 603 and 453 nm due to Mn(VI). As the reaction proceeds, slowly yellow turbidity develops, after keeping for a long time the solution turns to colourless resulting in a brown precipitate. This suggests that, the products formed might have undergone

Table 1

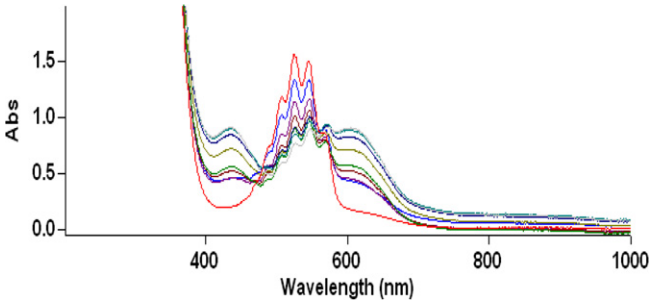

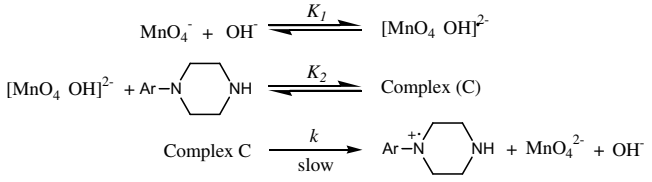

Fig. 3. Spectral changes during the oxidation of ciprofloxacin (CF) by $KMnO_4^-$ at 5 °C. $[MnO_4^-] = 3.0 \times 10^{-4}$, $[CF] = 3.0 \times 10^{-3}$, $[OH^-] = 2.0 \times 10^{-2}$, $I = 0.04$/mol dm^{-3}.

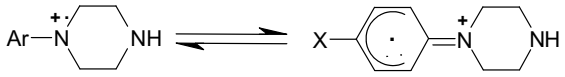
further oxidation resulting in lower oxidation state of manganese, Mn(IV). The results imply that first the alkali combines with permanganate to give an alkali-permanganate species $[MnO_4 \cdot OH]^{2-}$ in a prior equilibrium step [23]. The fractional order with respect to ciprofloxacin presumably results from the complex formation between oxidant and substrate prior to the slow step. Indeed it is to be noted that a plot of $1/k_{obs}$ *versus* 1/[CF] (Michaelis–Menten plot) shows an intercept in agreement with complex formation. The evidence for complex formation was obtained from UV–Vis spectra of oxidant, substrate and reaction mixture, in which bathochromic shift of 7 nm from 315 to 322 nm and hyperchromicity at 322 nm was observed at lower temperature (5 °C). The literature points out that piperazine ring of ciprofloxacin is the reactive moiety towards oxidation [17].

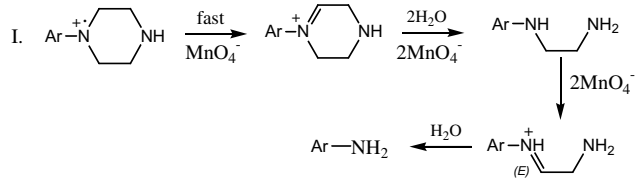


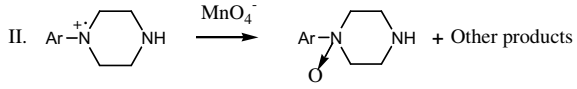
Within the complex one-electron is transferred from ciprofloxacin to Mn(VII). The breaking of this complex (C) is considered to be the slow step, forming ciprofloxacin radical intermediate and product, Mn(VI). The formed radical intermediate may subsequently undergo several different reaction pathways to yield a range of products. Such oxidant–ciprofloxacin complex formation and electron transfer step is considered as rate-limiting step in earlier report also [17]. The effect of ionic strength and dielectric constant on the rate explains qualitatively the involvement of a neutral molecule in the reaction. All the results may be interpreted in the form of following Scheme 3.

Since Scheme 3 is in accordance with the generally well-accepted principle of non-complementary oxidations taking place in sequence of one-electron steps, the reaction

Scheme 3.

between the substrate and oxidant would afford a radical intermediate. This type of radical intermediate shown in the slow step has also been observed in the literature [18]. This formed radical intermediate can be stabilized by resonance of the aromatic ring.





4.1. Further reactions of radical intermediates

Scheme 3 shows that the radical intermediates may undergo several subsequent reactions to generate a range of products observed in this study. Earlier studies have demonstrated that anilinyl radicals most likely undergo coupling via the amino group (head) or the *para* position of the benzene ring (tail) to form head-to-head, head-to-tail, or tail-to-tail coupling products [24]. Coupling of flouroquinolone radicals, however, is likely difficult (as pointed out in Ref. [17]) because of steric hindrance at the N1 position and the blockage at the *para* position in the aromatic ring. This radical formation is followed by other fast steps as given in the following two pathways, which could explain the formation of the oxidation products identified Fig. 1(b).

Pathway I is a *N*-dealkylation process (Scheme 3), in which one electron is transferred from the radical N1 to Mn(VII), yielding an iminium ion [24b,25]. Hydrolysis of the iminium ion follows immediately. Although hydrolysis of an iminium ion with the N atom connecting to an aromatic ring is a relatively slow reaction [17], it may still kinetically compete with the oxidation reaction at the N4 atom. Similar oxidation and hydrolysis occurs at the N4 atom, leading to the production of the partially dealkylated M−26 product. In a similar fashion, the M−26 product is oxidized to its corresponding iminium ion at its inner N1 and finally hydrolyzed to the fully dealkylated M−69 product [26]. In the presence of an excess amount of permanganate, the M−69 product can be further oxidized in a manner similar to oxidation of aniline. Since Scheme 3 is in accordance with the generally well-accepted principle of non-complementary oxidations taking place in sequence of one-electron steps, the reaction between the substrate and oxidant would afford a radical intermediate. This type of radical intermediate shown in the slow step has also been observed in the literature [18]. This radical formation is followed by other fast steps as given in the following two pathways, which could explain the formation of the oxidation products identified.

Pathway II. Based on the kinetic results and product analysis, the possibility of reaction pathways other than the one discussed above cannot be excluded (listed as pathway II in Scheme 3). One example is a pathway leading to the formation of *N*-oxide product (i.e. M+16). Despite the high complexity of the radical reactions, one can expect that the likelihood of the N1 radical intermediate to undergo either of the reaction pathways will be affected by electronic and steric effects on the radical and result in different yields among the various products

Scheme 3 leads to the rate law (6) as follows:
According to Scheme 3

$$\text{Rate} = \frac{-\mathrm{d}[\mathrm{MnO_4^-}]}{\mathrm{d}t} = kK_1K_2[\mathrm{MnO_4^-}][\mathrm{CF}]_\mathrm{f}[\mathrm{OH^-}]_\mathrm{f} \quad (1)$$

The total $[MnO_4^-]$ can be written as

$$\begin{aligned}[\mathrm{MnO_4^-}]_\mathrm{T} &= [\mathrm{MnO_4^-}]_\mathrm{f} + [\mathrm{MnO_4 \cdot OH}]^{2-} + [\mathrm{Complex}] \\ &= [\mathrm{MnO_4^-}]_\mathrm{f} + K_1[\mathrm{MnO_4^-}][\mathrm{OH^-}] + K_1K_2[\mathrm{MnO_4^-}][\mathrm{OH^-}][\mathrm{CF}] \\ &= [\mathrm{MnO_4^-}]_\mathrm{f}(1 + K_1[\mathrm{OH^-}] + K_1K_2[\mathrm{OH^-}][\mathrm{CF}])\end{aligned}$$

where t and f stands for total and free

$$[\mathrm{MnO_4^-}]_\mathrm{f} = \frac{[\mathrm{MnO_4^-}]_\mathrm{T}}{1 + K_1[\mathrm{OH^-}] + K_1K_2[\mathrm{OH^-}][\mathrm{CF}]} \quad (2)$$

Similarly, total $[OH^-]$ can be calculated as

$$[\mathrm{OH^-}]_\mathrm{T} = [\mathrm{OH^-}]_\mathrm{f} + [\mathrm{MnO_4 \cdot OH}]^{2-} + [\mathrm{Complex}]$$

In view of low concentration of MnO_4^- and ciprofloxacin used, above equation can be written as

$$[\mathrm{OH^-}]_\mathrm{T} = [\mathrm{OH^-}]_\mathrm{f} \quad (3)$$

Similarly,

$$[\mathrm{CF^-}]_\mathrm{T} = [\mathrm{CF^-}]_\mathrm{f} \quad (4)$$

Substituting Eqs. (2)–(4) in Eq. (1) we get,

$$\text{Rate} = \frac{kK_1K_2[\mathrm{MnO_4^-}][\mathrm{OH^-}][\mathrm{CF}]}{1 + K_1[\mathrm{OH^-}] + K_1K_2[\mathrm{OH^-}][\mathrm{CF}]} \quad (5)$$

$$\frac{\text{Rate}}{[\mathrm{MnO_4^-}]} = k_\mathrm{obs} = \frac{kK_1K_2[\mathrm{OH^-}][\mathrm{CF}]}{1 + K_1[\mathrm{OH^-}] + K_1K_2[\mathrm{OH^-}][\mathrm{CF}]} \quad (6)$$

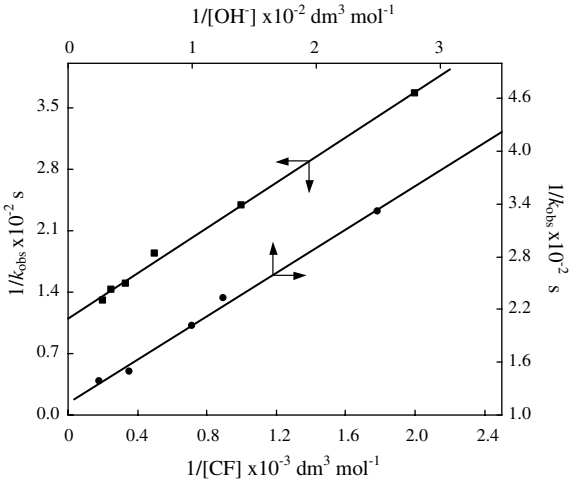


Fig. 4. Plots of $1/k_{obs}$ *versus* 1/[CF] and $1/k_{obs}$ *versus* $1/[OH^-]$ for verification of rate law (6) in the form of (7) on the MnO_4^- oxidation of ciprofloxacin in aqueous alkaline medium at 25 °C. (Conditions as in Table 1.)

Eq. (6) confirms all the observed orders with respect to different species, which can be verified by rearranging it to.

$$\frac{1}{k_{obs}} = \frac{1}{kK_1K_2[OH^-][CF]} + \frac{1}{kK_2[CF]} + \frac{1}{k} \quad (7)$$

According to Eq. (7), other conditions being constant, plots of $1/k_{obs}$ *versus* 1/[CF] ($r \geqslant 0.996$, $S \leqslant 0.012$) and $1/k_{obs}$ *versus* $1/[OH^-]$ ($r \geqslant 0.997$, $S \leqslant 0.013$) should be linear and are found to be so (Fig. 4). The slopes and intercepts of such plots lead to the values of K_1, K_2 and k (Table 2). The value of K_1 is in agreement with the literature [27].

The thermodynamic quantities for the first and second equilibrium steps of Scheme 3 can be evaluated as follows. The [CF] and $[OH^-]$ (as in Table 1) were varied at four different temperatures. The plots of $1/k_{obs}$ *versus* 1/[CF] and $1/k_{obs}$ *versus* $1/[OH^-]$ should be linear. From the slopes and intercepts, the values of K_1 and K_2 were calculated at different temperatures and these values are given in Table 2. van't Hoff's plots were made for variation of K_1 and K_2 with temperature $\log K_1$ *versus* $1/T$ ($r \geqslant 0.9939$, $S \leqslant 0.009$) and $\log K_2$ *versus* $1/T$ ($r \geqslant 0.926$, $S \leqslant 0.0074$). The values of enthalpy of reaction ΔH, entropy of reaction ΔS and free energy of reaction ΔG, were calculated for the first, and second equilibrium steps. These values are given in Table 2. A comparison of the later values (from K_2) with those obtained for the slow step of the reaction shows that these values mainly refer to the rate-limiting step, supporting the fact that the reaction before rate determining step is fairly fast and involves low activation energy [28].

The moderate values of $\Delta H^{\#}$ and $\Delta S^{\#}$ were both favorable for electron transfer processes. The value of $\Delta S^{\#}$ within the range for radical reaction has been ascribed to the nature of electron pairing and unpairing processes and to the loss of degrees of freedom formerly available to the reactants upon the formation of rigid transition state [29]. The negative value of $\Delta S^{\#}$ indicates that the complex (C) is more ordered than the reactants [30].

The observed modest enthalpy of activation and a relatively low value of the entropy of activation as well as a higher rate constant of the slow step indicate that the oxidation presumably occurs via inner-sphere mechanism [31].

5. Conclusion

The results of this investigation indicate that ciprofloxocin of antibiotic class is substantially degraded under conditions yielding lower mass degradates. The results demonstrate that in carrying out this reaction, the role of pH in the reaction medium is crucial. The literature [32] reports that dealkylated products of ciprofloxacin have reduced antimicrobial activity. Since dealkylated products were obtained by permanganate oxidation of ciprofloxacin, it is evident that the products of this title reaction have reduced antimicrobial activity after oxidation. This permanganate oxidation can be effectively used in the wastewater treatment at the sites contaminated by flouroquinolone antibiotics. Insoluble manganese dioxide formed, provides advantages in the removal of phenol and other organic contaminants from the wastewater. Rate constant of slow step and other equilibrium constants involved in the mechanism are evaluated and activation parameters with respect to slow step of reaction were computed. The overall mechanistic sequence described here is consistent with product, mechanistic and kinetic studies.

Ca^{2+}, Hg^{2+} or Pb^{2+}, can be obtained. Moreover, it may allow the design of ''light-controlled ion switches'', for which the cation ejection from, e.g. the crown ether can be triggered by the effective reduction of electron donation at the receptor on excitation of the nearby chromophore [11]. As many of heavy metals are known as fluorescence quenchers via enhanced spin–orbit coupling [12], it is thus intriguing and of both fundamental and application importance to examine the interaction between environmental hazard metals such as Pb^{2+} (or Hg^{2+}) and heavy metal complexes that mainly exhibit room-temperature phosphorescence in solution due to the strong spin–orbit coupling effect.

Aiming at this goal, we present a novel phosphorescence sensor, in which an 3,5-di(pyridyl)pyrazole (py_2pz) moiety is attached to the heteroleptic Ir(III) complex (**1**). This design provides three inherent advantages [13]. First, the Ir(III) metal atom forms highly stable, octahedral coordinated structure and inherits strong phosphorescent emission due to the heavy atom effect induced by the Ir(III) metal center. Moreover, the ancillary cyclometalated *N*-phenyl pyrazole ligands, for which their $\pi\pi^*$ energy levels are far greater than those of the respective MLCT and other ligand-centered $\pi\pi^*$ excited states [14], enable both the HOMO and LUMO to reside predominantly on the ancillary py_2pz segment. Thirdly, the py_2pz fragment is attached to the Ir(III) metal center and then forming a neutral metal complex. Such a charge-neutral characteristic is similar to that of the Re(I) and Pt(II) based sensor complexes, but is in sharp contrast to most of the Ru(II) based polypyridyl sensors [15], for which the net cationic charge on the overall metal complex is expected to reside, in part, at the ligand site, giving a much reduced sensitivity in recognizing metal cations [16]. Finally, the nitrogen atoms of the py_2pz moiety would act as the effective donor site, allowing the direct recognition of the incoming cationic analytes. In other words, the py_2pz segment acts as crab chela and can potentially be used for distinguishing metal ions, simplifying the design strategy (see Scheme 1).

2. Experimental

2.1. General information and materials

Elemental analyses and Mass spectra (operating in FAB mode) were carried out at the NSC Regional Instrument Centre at National Chiao Tung University, Taiwan. ^1H and ^{13}C NMR spectra were recorded on a Varian Mercury 400 instrument; chemical shifts are quoted with respect to internal standard Me_4Si. All synthetic manipulations were performed under N_2 atmosphere, while solvents were used as received. Synthesis of 3,5-di(2-pyridyl) pyrazole (py_2pz)H, 3-phenyl-5-(2-pyridyl) pyrazole (ppypz)H and 1-phenyl-3,5-dimethyl pyrazole (pdpz)H follows the procedures documented in the literature [17]. Treatment of (pdpz)H with $IrCl_3 \cdot nH_2O$ in refluxing methoxyethanol afforded the chloride bridged dimer $[(pdpz)_2IrCl]_2$ in 75% yield [14]; it was then used for subsequent reactions without further purification.

Scheme 1.

2.2. Preparation of [(pdpz)$_2$Ir(py$_2$pz)] (1)

A mixture of $[(pdpz)_2IrCl]_2$ (150 mg, 0.13 mmol), 3, 5-di(2-pyridyl) pyrazole (py_2pzH, 64 mg, 0.29 mmol) and Na_2CO_3 (93 mg, 0.88 mmol) in 2-methoxyethanol (25 mL) was heated to reflux for 6 hours. Excess of water was added after cooling the solution to room temperature. The precipitate was collected by filtration and subjected to silica gel column chromatography, eluting with a mixture of ethyl acetate and methanol (9:1). Pale yellow crystals of $[(pdpz)_2Ir(py_2pz)]$ (**1**) were obtained from repeated recrystallization using a mixture of THF and pentane at room temperature (49 mg, 0.065 mmol, 50%).

Spectral data of **1**: MS (FAB, ^{193}Ir): *m*/*z* 756 (M^+). ^1H NMR (400 MHz, DMSO-d_6, 298 K): δ 8.43 (d, 1H, $J_{HH} = 4.8$ Hz), 7.99 (d, 1H, $J_{HH} = 7.6$ Hz), 7.84 (t, 1H, $J_{HH} = 7.8$ Hz), 7.63 (t, 1H, $J_{HH} = 7.6$ Hz), 7.60 (t, 1H, $J_{HH} = 8.0$ Hz) 7.53 (d, 1H, $J_{HH} = 5.6$ Hz), 7.47 (d, 1H, $J_{HH} = 8.0$ Hz), 7.42 (d, 1H, $J_{HH} = 8.4$ Hz), 7.39 (s, 1H), 7.07 (t, 2H, $J_{HH} = 6.4$ Hz), 6.95 (t, 1H, $J_{HH} = 8.0$ Hz), 6.86 (t, 1H, $J_{HH} = 8.0$ Hz), 6.75 (t, 1H, $J_{HH} = 7.6$ Hz), 6.65 (t, 1H, $J_{HH} = 7.6$ Hz), 6.28 (d, 1H, $J_{HH} = 7.2$ Hz), 6.23 (d, 1H, $J_{HH} = 8.0$ Hz), 6.20 (s, 1H), 6.16 (s, 1H), 2.75 (s, 3H, Me), 2.72 (s, 3H, Me), 1.50 (s, 3H, Me), 1.47 (s, 3H, Me). *Anal.* Calc. for $C_{35}H_{31}IrN_8$: C, 55.61; N, 14.82; H, 4.13. Found: C, 55.37; N, 14.46; H, 4.20%.

2.3. Preparation of [(pdpz)$_2$Ir(ppypz)] (2)

A mixture of $[(pdpz)_2IrCl]_2$ (200 mg, 0.17 mmol), 3-phenyl-5-(2-pyridyl) pyrazole (ppypzH, 85 mg, 0.38 mmol) and Na_2CO_3 (214 mg, 0.21 mmol) in 2-methoxyethanol (25 mL) was heated to reflux for 6 h. Excess of water was added after cooling the solution to room temperature. The precipitate was collected by filtration and subjected to silica gel column chromatography, eluting with a mixture of ethyl acetate and methanol (9:1). Pale yellow crystals of $[(pdpz)_2Ir(ppypz)]$ (**2**) were obtained from repeated recrystallization using a mixture of THF and pentane at room temperature (68 mg, 0.009 mmol, 53%).

Spectral data of **2**: MS (FAB, ^{193}Ir): *m*/*z* 755 (M^+). ^1H NMR (400 MHz, DMSO-d_6, 298 K): δ 7.91 (d, 1H, $J_{HH} = 7.6$ Hz), 7.82 (t, 1H, $J_{HH} = 7.2$ Hz), 7.59 (d, 1H, $J_{HH} = 7.2$ Hz), 7.52 (d, 1H, $J_{HH} = 6.2$ Hz), 7.46 (d, 1H,

$J_{HH} = 8.0$ Hz), 7.40 (d, 1H, $J_{HH} = 8.0$ Hz), 7.24 (t, 2H, $J_{HH} = 8.0$ Hz), 7.19 (s, 1H), 7.08 (t, 1H, $J_{HH} = 7.2$ Hz), 7.04 (t, 1H, $J_{HH} = 6.2$ Hz), 6.93 (t, 2H, $J_{HH} = 7.6$ Hz), 6.84 (t, 1H, $J_{HH} = 8.0$ Hz), 6.74 (t, 1H, $J_{HH} = 7.6$ Hz), 6.63 (t, 1H, $J_{HH} = 7.6$ Hz), 6.27 (d, 1H, $J_{HH} = 7.2$ Hz), 6.22 (d, 1H, $J_{HH} = 7.2$ Hz), 6.19 (s, 1H), 6.15 (s, 1 H), 2.77 (s, 3H, Me), 2.74 (s, 3H, Me), 1.52 (s, 3H, Me), 1.50 (s, 3H, Me). *Anal.* Calc. for $C_{36}H_{32}IrN_7$: C, 57.28; N, 12.99; H, 4.27. Found: C, 57.14; N, 13.01; H, 4.28%.

2.4. Preparation of $[(pdpz)_2Ir(py_2\ pz)Pb(ClO_4)_2]$-(**1**-$Pb^{2+}$)

$Pb(ClO_4)_2 \cdot H_2O$ (18.7 mg, 0.046 mmol) was dissolved in 6 mL acetonitrile and then added into a glass tube with solid sample of **1** (17.4 mg, 0.023 mmol). The light green-yellow crystal suitable for single crystal X-ray diffraction was grown by ether diffusion for several days.

2.5. X-ray diffraction study

Single crystal X-ray diffraction data were measured on a Bruker SMART Apex CCD diffractometer using (Mo Kα) radiation ($\lambda = 0.71073$ Å). The data collection was executed using the SMART program. Cell refinement and data reduction were performed with the SAINT program. The structure was determined using the SHELXTL/PC program and refined using full-matrix least squares.

Crystal data for **1**-Pb^{2+}: $C_{35}H_{31}Cl_2IrN_8O_8Pb$, $M = 1161.97$, monoclinic, space group $P2_1/n$, $T = 150$ K, $a = 19.0572(12)$, $b = 9.9577(6)$, $c = 19.2354(12)$ Å, $\beta = 91.354(2)°$, $U = 3649.2(4)$ Å^3, $Z = 4$, μ (Mo Kα) $= 8.462$ mm^{-1}, 24 109 reflections collected, 8360 unique ($R_{int} = 0.0604$), final $R_1[I > 2\sigma(I)] = 0.0391$, wR_2 (all data) $= 0.0898$.

2.6. UV–Vis and phosphorescence titration of compounds *1* with Pb^{2+} ions

The stock solution of compound **1** (2×10^{-5} M) was prepared by using spectroscopic grade CH_3CN. The solution of Pb^{2+} ions (1×10^{-3} M) was prepared by using $Pb(ClO_4)_2$ hydrate dissolved in CH_3CN. The solutions of **1** in the titration range exhibited a linear dependence of absorption and emission. The absorption and emission spectrum of **1** (3.2 mL of 2×10^{-5} M stock solution) in a quartz cell (1 cm width) were recorded at 298 K. The absorption titration of **1** with Ca^{2+} and Hg^{2+} ions were carried out by a procedure similar to that for Pb^{2+} ion.

2.7. Measurements

Steady-state absorption and emission spectra were recorded by a Hitachi (U-3310) spectrophotometer and an Edinburgh (FS920) fluorimeter, respectively. The association constant K_a of 1:1 **1**/guest complex formation calculated by the UV–Vis absorption method is obtained by the following equation [18]:

$$\frac{A_0}{A_0 - A} = \left(\frac{\varepsilon_M}{\varepsilon_M - \varepsilon_p}\right)\left[\frac{1}{K_a C_g} + 1\right] \quad (1)$$

where C_g is the added guest (e.g. Pb^{2+}) concentration. A_0 (ε_M) and A (ε_p) denote the absorbance (molar extinction coefficient) of free **1**, and solution after adding, e.g. Pb^{2+}, respectively, at a selective wavelength. Eq. (1) can be further extended to the emission titration experiment expressed as

$$\frac{F_0}{F_0 - F} = \frac{\Phi_M \varepsilon_M}{(\Phi_M \varepsilon_M - \Phi_p \varepsilon_p)}\left(\frac{1}{K_a C_g} + 1\right) \quad (2)$$

where $F_0(\Phi_M)$ and $F(\Phi_p)$ denote the photoluminescence (quantum yield) of free **1**, and that of solution after adding Pb^{2+}, respectively, at a selective wavelength. Details of nanosecond lifetime measurements have been described in previous publication [19].

3. Results and discussions

As shown in Fig. 1, ion-free **1** in CH_3CN exhibits a weak 426 nm ($\varepsilon = 235$ M^{-1} cm^{-1}) absorption band, which is assigned to the spin-forbidden $^3\pi\pi^*$ (^{3}ILCT) transition perhaps mixed with a small amount of the ^{3}MLCT transition to the py_2pz ligands. The absorption band around 300 nm ($\varepsilon \sim 10^4$ M^{-1} cm^{-1}) is attributed to the $^1\pi\pi^*$ transition, while transitions associated with ^{1}MLCT are relatively weak and thus are possibly hidden underneath the $^1\pi\pi^*$ bands. In degassed or N_2 purged CH_3CN, **1** exhibits a 485 nm emission with moderate intensity ($\Phi \sim 0.04$, $\tau \sim 70$ ns). Upon aeration, the emission yield is reduced to 0.01 ($\tau \sim 21$ ns). The strong O_2 quenching and a calculated long radiative lifetime of ~2.6 μs lead us to conclude that the emission unambiguously originates from phosphorescnece.

The absorption and luminescence spectra recorded for **1** upon titrated with Pb^{2+} are also depicted in Fig. 1. Note that the titration was performed in the aerated solution.

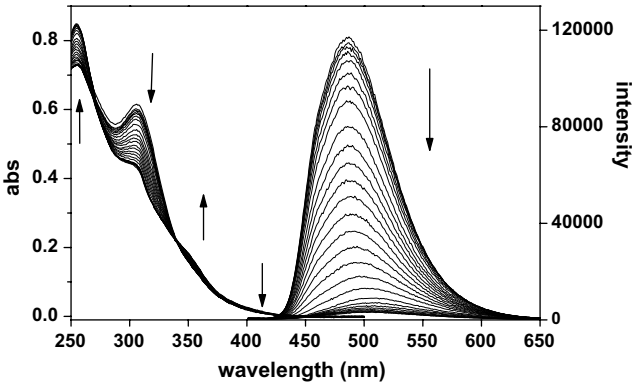

Fig. 1. The absorption and emission spectra of **1** (2.0×10^{-5} in aerated CH_3CN) upon addition of increasing amounts of Pb^{2+} at (a) 0, (b) 0.07, (c) 0.13, (d) 0.20, (e) 0.33, (f) 0.47, (g) 0.60, (h) 0.80, (i) 1.07, (j) 1.27, (k) 1.43, (l) 1.60, (m) 1.77, (n) 1.93, (o) 2.10, (p) 2.27, (q) 2.43, (r) 2.60, (s) 2.77, (t) 2.93, (u) 3.10, (v) 3.27, (w) 3.43, (x) 3.60, (y) 3.77, (z) 3.93, (aa) 4.10, (ab) 4.27 μM of **1**, λ_{ex}: 339 nm.

Evidently, the addition of Pb^{2+} caused a significant change of the absorption spectral profile with an isosbestic point appearing at ~340 nm, indicating the existence of ground-state equilibrium between two species, namely the free and Pb^{2+} linked **1**-Pb^{2+} complexes. Concomitantly, upon excitation at the isosbestic point, the 485 nm phosphorescence was gradually red shifted toward 505 nm, accompanied by the drastic decrease of the emission intensity. Taking the emission peak intensity of **1** and **1**-Pb^{2+} to be F_0 and F, respectively, a straight line plot of $F_0/(F_0 - F)$ versus $\mathbf{1}/[Pb^{2+}]$ at, e.g. 485 nm is depicted in Fig. 2, supporting the 1:1 complexation ratio. Additional evidence was provided by the Job's plot analysis [20], in which decreases of the 485 nm were plotted against molar fractions of **1** and Pb^{2+} under a condition of the constant total concentration. As such, the concentration of **1**-Pb^{2+} reached a turning point when the molar fraction of [**1**]/([Pb^{2+}]+[**1**]) was about 0.5 (see insert of Fig. 2). Accordingly, the association constant K_a was deduced to be as large as $(7.0 \pm 0.3) \times 10^5\ M^{-1}$.

The key-role of crab chela made by the py_2pz segment can be envisaged by the synthesis of complex **2**, in which the pyridyl lariate was replaced by the essentially inert phenyl group. As a result, negligible spectral changes were observed during the Pb^{2+} titration for complex **2** up addition to 10^{-3} M, providing a preliminary spectral evidence for the high activity of py_2pz functional group in **1**. Moreover, the definitive support for the **1**-Pb^{2+} structure is rendered by the single crystal X-ray structural analyses, for which the single crystals of **1**-Pb^{2+} adduct were obtained from a slow diffusion of Et_2O into a concentrated acetonitrile solution of a 1:1 mixture of **1** and $Pb(ClO_4)_2$. Its ORTEP diagram was depicted in Fig. 3, showing the typical pseudo-octrahedral coordination arrangement around the Ir(III) center. Similar to those of related cyclometalated Ir(III) complexes [21], the nitrogen atoms of the pdpz

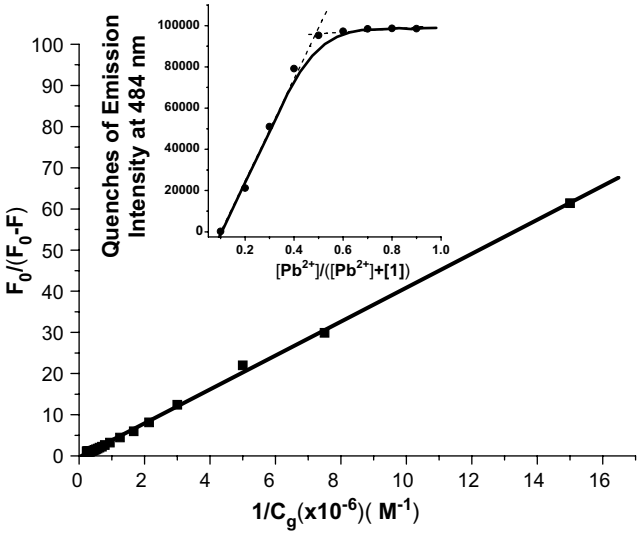

Fig. 2. The plot of $F_0/F_0 - F$ against $1/C_g$ at 486 nm. Insert: Job's plot of a 1:1 complex of **1** and Pb^{2+} cation, where the quenches of emission intensity at 484 nm was plotted against the mole fraction of Pb^{2+}.

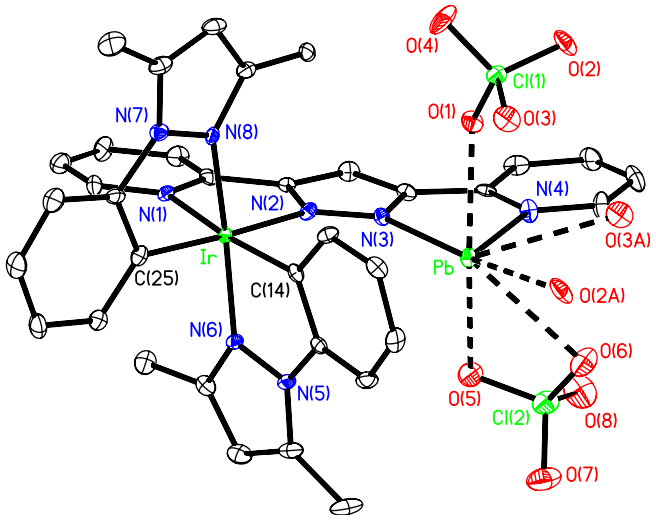

Fig. 3. ORTEP diagram of **1**-Pb^{2+} with thermal ellipsoids shown at 50% probability level; Ir–N(6) = 2.023(5) Ir–N(8) = 2.028(5), Ir–N(1) = 2.167(6), Ir–N(2) = 2.082(5), Ir–C(25) = 1.997(7), Ir–C(14) = 2.002(7), Pb–N(3) = 2.415(6), Pb–N(4) = 2.471(5) Å.

ligands resided at the mutual *trans*-disposition, while the coordinated N atoms of py_2pz ligands occupied the positions trans to the phenyl group of the pdpz ligands. All the Ir–C and Ir–N bond distances are unremarkable, as they falled in the range typical for these heteroleptic Ir(III) complexes reported in literatures. On the other hand, it is notable that the Pb^{2+} ion is linked to the outer pocket of py_2pz ligand with Pb-N distances being 2.415(6) and 2.471(5) Å, which fall within the literature value [22]. Such a bridged py_2pz bonding is akin to those of homodinuclear py_2pz complexes [23] and hybid complex containing lanthanide and transition metal elements such as $[(hfac)_3Ln(py_2pz)Cr(acac)_2]$ [24].

Competitive experiments have been performed using the same titration method for other metal cations, including alkali, alkaline earth metals and certain heavy metals. While there is apparently no spectral changes for alkali metal ions, the associated absorption spectra revealed a small amount of changes for alkaline and Hg^{2+} ions (see Figs. 4 and 5 for Ca^{2+} and Hg^{2+}titration). However, except for Hg^{2+}, none of them revealed appreciable changes in terms of emission profile and intensity in the range of 10^{-6}–10^{-3} M (also see Fig. 6). Addition of Hg^{2+} exhibited an emission quenching effect but with a smaller K_a. Based on a similar approach with that used for the Pb^{2+} titration, the association constant was determined to be $(5.9 \pm 0.3) \times 10^4\ M^{-1}$ and $(1.0 \pm 0.2) \times 10^4\ M^{-1}$ for Hg^{2+} and Ca^{2+} (absorption titration), respectively. The association constant for those selected metal ions are all less than that for Pb^{2+} by more than one order of the magnitude. This can also be illustrated by the phosphorescence intensity ratio of **1** (2×10^{-5} M in acetonitrile) in the presence of selected metal ion (10^{-3} M) before and after adding 10^{-3} M of Pb^{2+} shown in Fig. 6. The highly selective effect can be qualitatively rationalized by the amount of charge

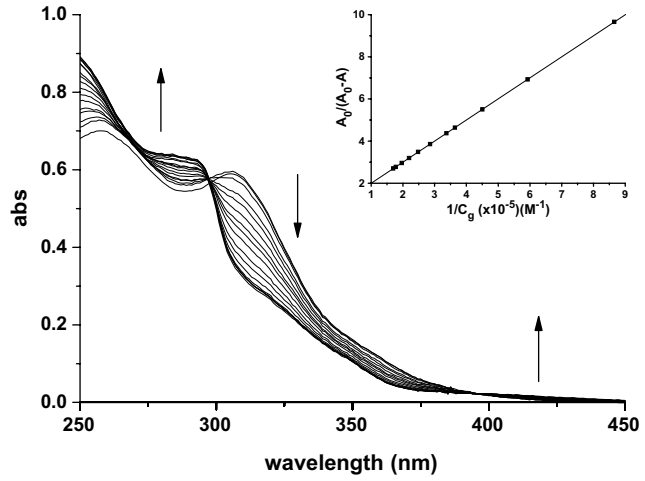

Fig. 4. The absorption spectra of **1** (2.0×10^{-5} in aerated CH_3CN) upon addition of increasing amounts of Ca^{2+} at (a) 0, (b) 1.16×10^{-5}, (c) 1.69×10^{-5}, (d) 2.22×10^{-5}, (e) 2.75×10^{-5}, (f) 2.97×10^{-5}, (g) 3.50×10^{-5}, (h) 4.03×10^{-5}, (i) 4.56×10^{-5}, (j) 5.09×10^{-5}, (k) 5.63×10^{-5}, (l) 5.89×10^{-5} M of **1**. Fig. 5. The absorption spectra of **1** (2.0×10^{-5} in aerated CH_3CN) upon addition of increasing amounts of Hg^{2+} at (a) 0, (b) 0.31, (c) 0.63, (d) 0.94, (e) 1.25, (f) 1.47, (g) 1.88, (h) 2.19, (i) 2.50, (j) 2.81, (k) 3.13, (l) 3.44, (m) 3.75, (n) 4.06, (o) 4.38, (p) 4.61, (q) 5.00, (r) 5.31, (s) 5.63 (t) 5.94, (u) 6.25, (v) 6.56, (w) 6.87, (x) 7.19, (y) 7.50, (z) 7.81, (aa) 8.13, (ab) 8.44, (ac) 8.75, (ad) 9.06, (ae) 9.38 μM of **1**. Insert: the plot of $A_0/(A_0-A)$ against $1/C_g$ at 306 nm.

density, ρ, specified as $\rho = g/(4/3\pi r^3)$ where g and r are the corresponding formal charge (+1 or +2) and radius, respectively. For example, the reciprocal of r^3 (the Shannon effective ionic radius with coordination number of 8: $Pb^{2+}\sim1.29$, $Hg^{2+}\sim1.16$, and $Ca^{2+}\sim1.12$) [25] correlates well with the trend of the association constants.

We have also examined whether a similar recognition capability can be applied in the heterogeneous solid film in aqueous solution. Since **1** is insoluble in water, to simplify the process, a silica-based TLC plate was used as a solid support to soak **1** in CH_3CN so that a complex **1** coated TLC plate was prepared with an optical density of

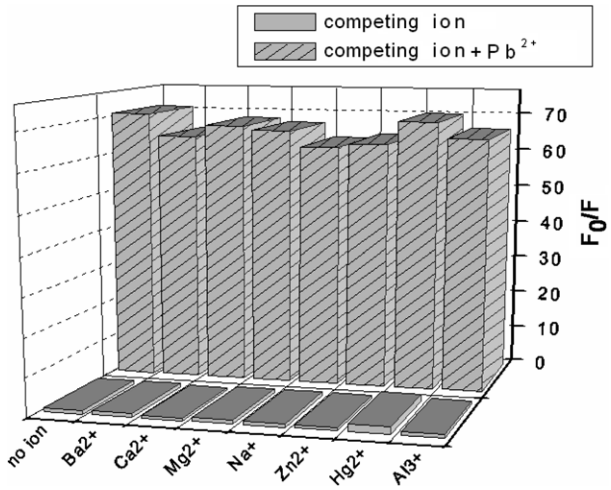

Fig. 6. (Grey) The phosphorescence intensity ratio of ion-free **1** (F_0, 2×10^{-5} M in acetonitrile) versus **1** in the presence of the selected metal ions (10^{-3} M). The phosphorescence intensity ratio of ion-free **1** vs. **1** in the presence of the selected metal ions (10^{-3} M), followed by addition of 10^{-3} M of Pb^{2+} ion (Slash-Grey).

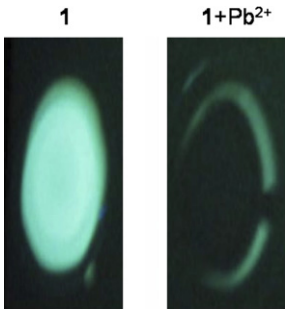

Fig. 7. The color of the sensor developed on a TLC plate with **1** in CH_3CN (left) and with Pb^{2+} solution in H_2O (right) was illuminated under 365 nm (UV lamp) for visualization (see text for the experimental detail). (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

$\sim$1.0 at 350 nm. Then we transfer a drop ($\sim$10 μL) of an aqueous solution (pH $\sim$ 7.0) containing $\sim10^{-4}$ M of $Pb(ClO_4)_2$ solution onto the plate, and then vacuum-dried to remove water. With the use of a commercially available UV-lamp (365 nm), photograph demonstrates a salient change of emission from blue–green (complex **1**) to a nearly dark state upon complexation with Pb^{2+} ion (see Fig. 7), implying the feasibility of **1** in sensing Pb^{2+} in aqueous solution down to nanomolar scales.

4. Conclusions

In conclusion, we apply complex **1** to demonstrate the concept of sensing Pb^{2+} ion based on the rare metal–ion sensitive phosphorescence. The ligated chromophores act as both recognition and signal-transmitting units, while the heavy metal, i.e. both Ir(III) ion and guest Pb^{2+}, serve as perturbing bases to enhance and quench

the phosphorescence, respectively. The emission quenching effect must be due to the affected core chromophores, i.e., the di(2-pyridyl) pyrazolate, that directly linked with Pb^{2+}, provoking the intersystem crossing to another lower-lying triplet state for the host molecule via an enhanced spin–orbit coupling. Consequently, the emission intensity will plausibly be quenched due to a smaller T_1–S_0 energy gap.

On the other hand, the internal motion of the uncoordinated pyridyl substituent can play some crucial role in the emission quenching mechanism. To obtain an enhanced emission, in future, one can design a host molecule which will increase its rigidity after the complexation without affecting its chromophore. In this approach, the current system is versatile in that the functionalization can be achieved with methods similar to that have been strategically designed for the $^1\pi\pi^*$ (i.e. fluorescence) chromophores. In view of oxygen quenching, in a steady state approach, one can then saturate the solution with N_2 so that the enhanced phosphorescence can also serve as an additional signaling to distinguish it from the fluorescence interference. The success in the recognition of Pb^{2+}(aq) in the TLC plate demonstrates its suitability for the conceptual development of a practical recognization device. The results may spark a broad range of interest in both fundamental approach and applications relevant to third-row transition metal complexes.

2. Results and discussion

A priori the most efficient route of reaction is expected to be the same as for iodides – the direct reaction of an organic sulfide with an alkyl halide, bromide or chloride

$$R_2S + R'X \rightarrow (R'R_2S^+)X^- \quad (1)$$

Although iodides may be prepared without solvent or in non-polar solvents under ambient conditions, bromides and chlorides are expected to react extremely slowly under such conditions. Obviously, the reaction conditions must be optimized with respect to the influence of solvent, temperature and reactant concentrations.

2.1. Choice of solvent

Reaction (1) is a typical example of a second-order substitution, S_N2-type. This means that polarity and solvation properties of the solvent will play a very important role in the stabilization of the transition state and thus affect the reaction rate. Product stability ought to be affected as well.

The most commonly used solvents for such reactions are those with a high dielectric constant, e.g., water, methanol, ethanol, acetone or nitromethane. Also, 2,2,2-trifluoroethanol, sulphuric and hydrofluoric acid have been used in some cases [11].

One should also consider that Reaction (1) is reversible and that the product can decompose into the reactants. The decomposition products may of course also interact with all compounds in the reaction mixture. Consequently, the most common side-reactions observed involve alkyl metathesis

$$R_2S + R'X \rightarrow (R'R_2S^+)X^- \rightarrow RX + RR'S \quad (2)$$

As shown by Pocker and Parker [12], the rate of decomposition is higher in non-polar solvents with low ion solvation ability. These observations correspond to the predictions made above. The solvation of the halide anion will give the major contribution to the stabilization of a sulfonium salt in solution. Thus, the higher the dielectric constant of the solvent the better. Strong electrophilic properties of the solvent will enhance the solvation of the halide anion and thereby render a stabilization of the desired product.

From these considerations, water ought to be a good solvent candidate; it has a dielectric constant ε of 81 and quite strong electrophilic properties. Nevertheless, the nucleophilic properties of water are also quite pronounced causing efficient solvolysis, hydrolysis, of sulfonium salts in water.

Therefore, the choice of trifluoroacetic acid may be more suitable, since it combines a high dielectric constant ($\varepsilon = 37$) and marked electrophilic properties, whereas the nucleophilic properties are insignificant.

For the synthesis of dodecyl dimethyl sulfonium iodide it is not necessary to make any other improvements. The synthesis of dodecyl dimethyl sulfonium iodide was reported already in 1940 by Kuhn and Dann [13]:

$$\{n\text{-}CH_3(CH_2)_{11}\}(CH_3)S + MeI \rightarrow [\{n\text{-}CH_3(CH_2)_{11}\}(CH_3)_2S]I \quad (3)$$

The sulfonium iodide was prepared by direct reaction between dodecyl methyl sulfide and methyl iodide without any solvent and during 36 h; the yield was 58%. Using trifluoroacetic acid as a solvent we obtained a yield of 95% in 15 min, and the subsequent analysis of the product demonstrated that recrystallization does not lead to any significant increase in product purity.

A control experiment for the synthesis of dodecyl dimethyl sulfonium bromide was also made: dodecyl bromide and dimethyl sulfide were mixed without solvent. The mixture required more than one year before a significant yield was achieved.

It is notable that some sulfonium salts, especially chlorides, demonstrate a pronounced hygroscopic behaviour, implicating that any presence of water, and even contact with water adsorbed on glass surface, should be avoided. The neglect of dry conditions of synthesis leads to the formation of syrups and product decomposition.

An excess of diethyl ether was used to precipitate, and thus separate, the sulfonium salts from solution. Although the sulfonium iodides required quite small portions of diethyl ether, the bromides and chlorides required much higher amounts. In the case of sulfonium chlorides the separation technique may be further developed.

2.2. Choice of temperature and duration of synthesis

The set of useful temperatures is rather narrow because of the low boiling point of dimethyl sulfide (b.p. 36 °C). However, performing syntheses in sealed glass tubes allow temperatures of at least 70–90 °C. The solvent is expected to stabilize the product and prevent it from decomposition into by-products.

In the present work, the yield of synthesis as a function of applied temperature and reaction time was systematically studied. The yields were determined by argentometric titration of the reaction mixtures (*vide infra*). The results are presented in Table 1.

Table 1
Yield, %, of dodecyl dimethyl sulfonium bromide as a function of temperature and reaction time

T (°C)	Time (h)											
	0.25	0.5	1	2	4	7	10	14	18	22	26	63
90	25.5	44.4	68.2	85.5	88.3	90.9			89.6	91.6	91.4	
70			30.2	45.3	68.1	82.4	90.5	90.8	88.6			85.3

These results show that an increase in reaction temperature does not lead to a decrease of maximum yield indicating that decomposition of the products is considerably slower than the formation. ^{1}H and ^{13}C NMR spectra of the reaction mixtures show that the amount of by-products is low during the synthesis and that the main product is the desired sulfonium halide. These observations are also the motivation for using the observed amount of halide anion as a measure of product yield. The main conclusion is that higher temperatures are preferable for the synthesis yield.

2.3. Choice of reactants and their concentrations

The main factor determining suitable concentrations and the ratio between alkyl halide and organic sulfide reactants is the target sulfonium salt. Sulfonium salts can be used as alkylating agents, and as it was shown by Ray and Levine [14] that improper choice of reactant conditions may cause loss of product through dealkylation of the sulfonium salt, especially in the case when the organic sulfide is in excess with respect to the alkyl halide. One should also consider that decomposition of sulfonium salts leads to the formation of new alkyl halides, which can react with the original organic sulfide. The results by Siegel and Graefe [15] support such explanations and provide further useful information: the higher the ratio of sulfide to alkyl halide, the less are yield and purity.

For these reasons an excess of alkyl halide to organic sulfide was used in this work; normally, two times more alkyl halide than organic sulfide.

For the synthesis of dimethyl dodecyl sulfonium iodide methyl iodide and dodecyl methyl sulphide were used. Methyl iodide has the advantage of being liquid under ambient conditions and is expected to react more readily than the dodecyl one. For syntheses of other salts, dodecyl halides and dimethyl sulfide were used because methyl bromide and chloride are gases and rather difficult to handle under ambient conditions.

After successful experiments using dodecyl derivatives, also hexadecyl dimethyl sulfonium bromide and chloride of good quality and with good yields were synthesized.

2.4. Recrystallization

Recrystallization was used in order to ensure the purity of the prepared samples of the sulfonium salts. Acetone was the primary solvent for this purpose based on the work by Yano et al. [2]. Titration, comparison of signals in NMR spectra and melting points were used to determine the amount of impurities in crude and recrystallized products.

From the results obtained it was concluded that recrystallization does not lead to significant decrease of impurities, and this step in the synthetic procedure is considered facultative. The results showed that samples of dodecyl dimethyl sulfonium bromide contain less than 1% (mol.) of impurities, and after recrystallization the amount of impurities is less than 0.5% (mol.). Samples of dodecyl dimethyl sulfonium chloride contain less than 2% (mol.) of impurities, and after recrystallization their amount is unchanged. It should be noted that dodecyl dimethyl sulfonium chloride is rather difficult to recrystallize because of its hygroscopy and tendency to form syrups. It is not obvious that recrystallization should provide an enhanced purity, since potential decomposition in solvents of low polarity (low dielectric constants) may lead to an overall decrease of purity and yield.

Nevertheless, if recrystallization is desired, the use of ethyl acetate as the medium is recommended. The above described bromides, as well as dodecyl dimethyl sulfonium iodide, recrystallize easily and with high yields. Chlorides are still harder to recrystallize.

2.5. Note about product stability

Trialkylsulfonium bromides are fine white crystals; they are very stable under ambient conditions and could be stored for months.

Trialkylsulfonium chlorides are fine white crystals, which tend to "melt" in contact with an ambient atmosphere, due to water absorption. The product tends to be unstable even when stored in PET-flasks and moisture-free atmosphere. One can speculate that both high hygroscopicity as well as natural instability, caused by a chloride anion attack on the sulfonium cation, lead to an inherent trialkyl sulfonium chloride instability. This could explain some deviations in the results of elemental analysis.

2.6. Crystal structure of $[\{CH_3(CH_2)_{15}\}(CH_3)_2S]Br$

Crystalline products are obtained of all synthesized compounds in this study. The structure of $[\{CH_3(CH_2)_{11}\}(CH_3)_2S]I$ is previously known [16].

Crystals suitable for detailed single crystal diffraction were obtained for the $[\{CH_3(CH_2)_{15}\}(CH_3)_2S]Br$ compound described below. The compound crystallizes in the triclinic system, space group $P\bar{1}$. The structure consists of hexadecyldimethylsulfonium cations and bromide anions. Fig. 1 shows the arrangement of structure in the unit cell.

For this type of compound, typically the inorganic anions form layers in close proximity to the cationic end of the organic ions. The cation tails represent the most predominant structure-driving entity forming double-layers. The present compound is no exception. Two more rare structural features can be identified; (1) the aliphatic tails do not interpenetrate; (2) the angle between the layers formed by the bromide ions and the aliphatic tails is very low, about 32°. The later feature gives quite thin double-layers in relation to the extended hexadecyl tails. The distance between bromide ions in adjacent layers is just over 24 Å. The closest distance between bromide ions within the inorganic layer is about 6 Å. The packing of ions is shown in Fig. 1.

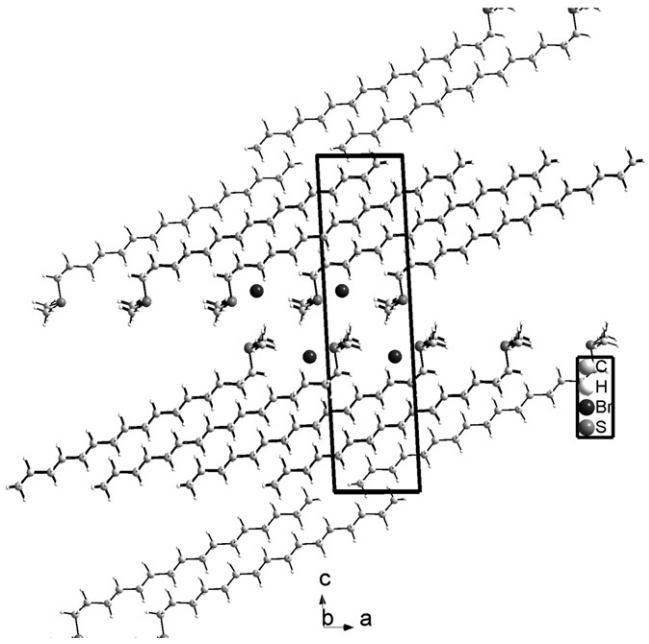

Fig. 1. The structure of $[\{CH_3(CH_2)_{15}\}(CH_3)_2S]Br$.

3. Conclusions

The usage of trifluoroacetic acid as solvent is strongly recommended for the synthesis of trialkyl sulfonium salts. A higher temperature shortens the time of synthesis. In order to prevent loss of product, an excess of alkyl halide should be used. The syntheses give products of quite good quality and suitable for further use without additional purification. If purification is required, ethyl acetate ought to be used for recrystallization.

The designed method for synthesis of non-symmetrical alkyl dimethyl sulfonium halides appears to be universal and was used for the production of a variety of compounds. These compounds have already been used for the subsequent synthesis of low-dimensional organic–inorganic compounds displaying for instance magnetic properties [17].

4. Experimental

Trifluoroacetic acid was distilled over phosphorus pentaoxide (1% mass) to remove traces of water. Standard C, H and S elemental analyses were performed by MikroKemi AB, Uppsala, Sweden. Halogens, Cl, Br and I, were analyzed by argentometric titration. NMR spectra were recorded on a Bruker DMX 500 MHz spectrometer. Solutions for NMR spectroscopic investigations were prepared by dissolving 6–8 mg of reaction products in 1 ml of deuturated chloroform at ambient temperature.

4.1. Synthesis of dodecyl dimethyl sulfonium iodide

3.17 g (22.3 mmol) of methyl iodide, 1.83 g (8.47 mmol) of dodecylmethylsulfide and 3.12 g (27 mmol) of trifluoroacetic acid were mixed in a 25 ml round-bottom flask and the flask was closed with a stopper. The reaction was performed at room temperature without stirring. After 15 min diethyl ether (100 ml) was added to precipitate the product. Yield: 2.89 g (95%), m.p.: 80–82 °C; after recrystallization in 5 ml of acetone, 1.58 g (52%), m.p.: 80–82 °C. *Anal.* Calc. for $(C_{14}H_{31}S)I$: I, 35.4. Found: I, 34.8%. ^1H NMR (500 MHz, $CDCl_3$) δ 3.39 (s, 6H), 3.78 (t, *J* 8.6, 2H), 1.83 (~tt/m, *J* 7–9, 2H), 1.53 (~tt/m, *J* 7–9, 2H), 1.43–1.20 (group, 16H), 0.90 (t, *J* 7.1, 3H).

4.2. Synthesis of dodecyl dimethyl sulfonium bromide

Reaction in sealed tube: 3.30 g (13 mmol) of 1-bromododecane, 0.40 g (6.5 mmol) of dimethylsulfide and 3.00 g (26 mmol) of trifluoroacetic acid were mixed in a glass tube. The mixture was frozen in liquid nitrogen and the tube sealed. The sealed tube was heated in a water bath to the reaction temperature for a known period of time. After the reaction time the sealed tube was cooled in a cold water bath. For the subsequent argentometric titration all contents of the sealed tube was transferred to a 50 ml metric flask and diluted with distilled water.

If precipitation of the product was desired, the content of the sealed tube was instead diluted with diethyl ether (200 ml). Yield: 80% (90 °C, 3 h), m.p.: 62–64 °C. *Anal.* Calc. for $(C_{14}H_{31}S)Br$: C, 54.0; H, 10.0; S, 10.3; Br, 25.5. Found: C, 53.1; H, 10.0; S, 10.5; Br, 25.3%. ^1H NMR (500 MHz, $CDCl_3$) δ 3.40 (s, 6H), 3.78 (t, *J* 8.5, 2H), 1.81 (~tt/m, *J* 7–9, 2H), 1.51 (~tt/m, *J* 7–9, 2H), 1.42–1.22 (group, 16H), 0.90 (t, *J* 7.1, 3H).

Reaction in open system. 6.45 g (25.9 mmol) of 1-bromododecane, 0.53 g (8.6 mmol) of dimethylsulfide and 5.60 g (49 mmol) of trifluoroacetic acid were mixed in a 25 ml round-bottom flask. A long water cooler with absorption tube was connected to the flask. The synthesis was carried out during 3 h at approximately 65–70 °C and intensive boiling was observed. A new portion of 0.26 g (4.3 mmol) of dimethylsulfide was added to the reaction mixture and the reaction continued. After another 3 h the reaction mixture was cooled to room temperature and diethyl ether (600 ml) was added to precipitate the product. Yield: 3.90 g (97%), m.p.: 62–64 °C. A recrystallization from acetone (20 ml) was made to ensure the quality of product. Yield: 3.22 g (80%), m.p.: 62–64 °C. *Anal.* Calc. for $(C_{14}H_{31}S)Br$: Br, 25.5. Found: Br, 25.3%. ^1H NMR (500 MHz, $CDCl_3$) δ 3.40 (s, 6H), 3.78 (t, *J* 8.5, 2H), 1.81 (~tt/m, *J* 7–9, 2H), 1.51 (~tt/m, *J* 7–9, 2H), 1.42–1.22 (group, 16H), 0.90 (t, *J* 7.1, 3H).

Reaction without solvent. 1.94 g (7.79 mmol) of dodecyl bromide and 0.24 g (3.90 mmol) of dimethyl sulphide were mixed in a 5 ml round-bottom flask. Some crystals precipitated on the bottom of the flask after one month. After 18 months the amount of precipitate was enough to allow separation. Yield: 0.61 g (50%).

4.3. Synthesis of dodecyl dimethyl sulfonium chloride

2.52 g (11 mmol) of 1-chlorododecane, 0.35 g (5.6 mmol) of dimethylsulfide and 2.40 g (21 mmol) of trifluoroacetic acid were mixed in a glass tube. The mixture was frozen at liquid nitrogen temperature and the tube sealed. The sealed tube was heated in a water bath to the appropriate temperature for a known period of time. After reaction the sealed tube was cooled in a cold water bath. For the subsequent argentometric titration all contents of the sealed tube was transferred to a 50 ml metric flask and diluted with distilled water.

If precipitation of product was desired, the contents of the sealed tube instead was diluted with diethyl ether (300 ml). Yield: 66% (90 °C, 72 h), m.p.: 58–60 °C; after recrystallization in 10 ml acetone (46%), m.p.: 58–60 °C. *Anal.* Calc. for $(C_{14}H_{31}S)Cl$: C, 63.0; H, 11.7; S, 12.0; Cl, 13.3. Found: C, 49.2; H, 8.1; S, 7.6; Cl, 9.3%. ^1H NMR (500 MHz, $CDCl_3$) δ 3.24 (s, 6H), 3.61 (t, J 8.9, 2H), 1.82 (~tt/m, J 7–9, 2H), 1.51 (~tt/m, J 7–9, 2H), 1.42–1.22 (group, 16H), 0.90 (t, J 7.1, 3H).

4.4. Synthesis of hexadecyl dimethyl sulfonium bromide

24.5 g (80 mmol) of 1-bromohexadecane, 2.54 g (41 mmol) of dimethylsulfide, 19.1 g (168 mmol) of trifluoroacetic acid were mixed in a 100 ml round flask and stirred for 2 days at 60–65 °C. Diethyl ether (400 ml) was added to precipitate the product. Yield: 9.80 g (66%), m.p.: 75 °C. After recrystallization from ethyl acetate: 9.43 g (63%), m.p.: 75 °C. *Anal.* Calc. for $(C_{18}H_{39}S)Br$: C, 59.82; H, 9.20; S, 8.87; Br, 22.11. Found: C, 59.0; H, 10.7; S, 9.0; Br, 21.7%.

4.5. Synthesis of hexadecyl dimethyl sulfonium chloride

20.00 g (77 mmol) of 1-chlorohexadecane, 2.40 g (39 mmol) of dimethylsulfide and 30.00 g (263 mmol) of trifluoroacetic acid were mixed in a 250 ml round-bottom flask. A long water cooler with absorption tube was connected to the flask. The synthesis was carried out during 7 days at approximately 65–70 °C and intensive boiling was observed. Then the reaction mixture was cooled to room temperature and diethyl ether (1000 ml) was added to precipitate the product. Yield: 6.5 g (53%). A recrystallization from ethyl acetate (100 ml) was made to ensure the quality of product. Yield: 3.45 g (28%). m.p.: 73 °C.

4.6. Synthesis of 1,12-dodecanediylbis[dimethylsulfonium]dibromide

3.00 g (9.1 mmol) of 1,12-dibromododecane, 1.14 g (18.4 mmol) of dimethyl sulfide and 15.2 g (133 mmol) of trifluoroacetic acid were placed in 50 ml round flask and stirred at 60–65 °C for 1 day. Diethyl ether (300 ml) was added to precipitate the product. Yield: 1.98 g (48%). Recrystallization from ethylacetate: 1.75 g (44%). *Anal.* Calc. for $(C_{12}H_{24}S_2)Br_2$: C, 42.5; H, 8.0; S, 14.2; Br, 35.3. Found: C, 42.8; H, 8.0; S, 14.1; Br, 39.7%.

4.7. Argentometric titration

A solution of silver nitrate of the approximate concentration 0.05 mol/l was prepared from recrystallized, chemically pure silver nitrate and then standardized using a solution of potassium thiocyanate. For this purpose, a solution of potassium thiocyanate of the concentration 0.1000 mol/l was prepared from a standard sample. A concentrated solution of iron–ammonia alums was used as indicator.

Fifteen milliliters of the standardized solution of silver nitrate was added to 4 ml (or 8 ml for the samples of short reaction times, 0.25 and 0.5 h) of the diluted reaction mixtures (*vide supra*). Subsequently, the excess of silver nitrate was titrated with the standard solution of potassium thiocyanate in the presence of iron–ammonia alums. The yields of the syntheses were determined and compared to the theoretically expected ones.

4.8. Crystal structure determination of $[\{CH_3(CH_2)_{15}\}(CH_3)_2S]Br$

X-ray diffraction data were collected using a Bruker Nonius KappaCCD diffractometer. The compound crystallizes in the triclinic system, space group $P\bar{1}$. All

Scheme 1.

The latter was investigated in general, from the standpoint of its energetic properties. The thermal decomposition and crystal structure of 5-H_2NATZ have been described in detail in [18–20]. The heat of decomposition is equal to 3520 J/g [18], the calculated value of the heat of formation is approximately 500 kJ/mol [19–21]. Activation energies were calculated for 5-H_2NATZ and its mercury and lead salts [22]. The structural chemistry of alkaline metal and ammonium 5-nitroaminotetrazolates are well investigated. Crystal structures of $NH_4CN_6O_2H$ [23], $(NH_4)_2CN_6O_2$ [24], MCN_6O_2H (M = Cs [25], Na [26], Li [27]) $Rb_3(CN_6O_2)(CNNNO_2)\cdot H_2O$ [25] and the K^+ salt of 3-methyl-5-nitroaminotetrazole [28] have been reported. Complexes of 5-NATZ with transition metals are poorly studied, only the crystal structure of the nickel dimeric complex, $Ni_2(NH_3)_6(CN_6O_2)_2$ [29], has been determined. However, 5-H_2NATZ and its derivatives should be an interesting class of ligands, due to the following reasons: (i) 5-H_2NATZ is a dibasic acid that can be easily transformed into mono and di-substituted salts; (ii) anions of 5-NATZ have many sites for coordination by metal ions; and (iii) conjugated systems of five-member rings of tetrazoles can form π–π intermolecular interactions in the crystal structure to build extended 2D and 3D networks. It worth mentioning that the anionic form of tetrazole considered can be strictly controlled by using appropriate conditions. In this context, 5-NATZ is the perspective ligand for construction of high energetic network structures with a combination of physicochemical and explosive properties.

In this work, we present the syntheses and crystal structures of the mono-substituted complex of lead(II) as well as a disubstituted complex of mercury(II). Furthermore, the interpretation of the coordination mode through electronic features of 5-NATZ and its mono- and dianion was performed by means of theoretical modelling.

2. Experimental

2.1. Materials and methods

The guanidine carbonate, potassium nitrite, mercury, silver, lead and copper nitrates were obtained from the Aldrich Chemical Company Ltd. and Fluka, and were used without purification. *N*-Nitro-*N*-aminoguanidine was obtained from nitroguanidine [30], which was obtained from guanidine nitrate [31]. Chemical analyses of the samples dried to a constant weight were performed with a Fisons Instruments 1108 CHNS-O Elemental analyzer. IR spectra in the range 4000–400 cm^{-1} were recorded on a Perkin–Elmer System 2000 FT-IR spectrometer. Decomposition temperatures were determined on an IA 8100 Electrothermal instrument. Lead and silver contents were determined by weight analysis in the forms of $PbMoO_3$ and AgBr. The copper content was determined by iodometric titration.

2.2. Synthesis

2.2.1. Synthesis of potassium 5-nitroaminotetrazolate (*1*)

Complex **1** was prepared by interaction of *N*-nitro-*N*-aminoguanidine with KNO_2 and acetic acid, as described in [17]. Yield: 65%. $T_{decom.} = 248$ °C. *Anal.* Calc. for $KHCN_6O_2$: C, 7.14; H, 0.60; N, 49.98. Found: C, 6.92; H, 0.53; N, 50.13%. IR (Nujol, cm^{-1}): 2726 (*ν*N–H), 1544 (*ν*C–N), 1450 (*ν*N–O), 1318 (*ν*N–NO_2),1224 (*ν*C–N–NO_2), 1146 (*ν*N–N), 1094, 1058 (*ν*N–N), 1030 (*δ*N–H), 998 (*ν*N–N), 864, 774 (*δ*N–NO_2), 746, 698 (*δ*N–H), 462, 418 (*ν*O–K).

2.2.2. Synthesis of bis-potassium 5-nitroaminotetrazolate (*2*)

Complex **2** was obtained by reaction of equimolar amounts of **1** and KOH. Yield: 85%. $T_{decom.} = 400$ °C. *Anal.* Calc. for $K_2CN_6O_2$: C, 5.82; N, 40.78. Found: C, 5.54; N, 40.33%. IR (Nujol, cm^{-1}): 1396 (*ν*N–NO_2), 1294 (*ν*N–O), 1146 (*ν*N–N), 1028 (*ν*C–N), 1010 (*ν*N–N), 862 (*δ*C–N–NO_2), 462, 418 (*ν*O–K).

2.2.3. Synthesis of 5-NATZ (*3*)

Compound **3** was prepared by the procedure described in [17]. The pure product was isolated by extraction with diethyl ether. Yield: 48%. *Anal.* Calc. for $H_2CN_6O_2$: C, 9.23; H, 1.55; N, 64.61. Found: C, 9.11; H, 1.63; N, 64.62%.

2.2.4. Synthesis of lead 5-nitroaminotetrazolate (*4*)

To a solution of $Pb(NO_3)_2$ (0.44 g, 0.625 mmol) in 3 ml of water, a solution of 0.21 g (1.25 mmol) of **1** in 3 ml of water was added. After 1 h, salt **3** started to crystallize as large prisms. The crystals were separated by filtration. Yield: 76%. $T_{decom.} = 230$ °C. *Anal.* Calc. for $PbH_2C_2N_{12}O_4\cdot 4H_2O$: Pb, 38.56; C, 4.47; H, 1.88; N, 31.28. Found: Pb, 38.47; C, 4.68; H, 1.74; N, 31.13%. IR (Nujol, cm^{-1}): 3376 (*ν*O–H), 2726 (*ν*N–H), 1650, 1526 (*ν*C–N), 1462(*ν*N–O), 1342 (*ν*N–NO_2),1254 (*ν*C–N–NO_2), 1158 (*ν*N–N), 1120, 1066 (*ν*N–N), 1034 (*δ*N–H), 996 (*ν*N–N), 866, 770 (*δ*N–NO_2), 740, 700 (*δ*N–H), 416.

2.2.5. Synthesis of copper 5-nitroaminotetrazolate (*5*)

To a solution of $Cu(NO_3)_2\cdot 3H_2O$ (0.242 g, 1 mmol) in 2 ml of water, a solution of 0.168 g (1 mmol) of **1** in 3 ml of water was added. After 5 h, complex **3** precipitated as a dark-green fine crystallized powder, and was separated by filtration. Yield: 69%. $T_{decom.} = 240$ °C. *Anal.* Calc. for $CuCN_6O_2(H_2O)_3$: Cu, 25.92; C, 4.86; H, 2.43; N,

34.01. Found: Cu, 26.13; C, 4.76; H, 2. 32; N, 34.07%. IR (Nujol, cm^{-1}): 3380 (νO–H), 2735 (νN–H), 1630, 1500 (νC–N), 1406 (νN–NO_2), 1298, 1268 (νN–O), 1182 (νN–N), 1020 (νN–N), 1010 (νN–N), 872 (δC–N–NO_2), 748 (δC–N–C), 560, 492.

2.2.6. Synthesis of silver 5-nitroaminotetrazolate (6)

A solution of 0.168 g (1 mmol) of **1** in 3 ml of water was added to solution of $AgNO_3$ (0.34 g, 1 mmol) in 1 ml of water. A white precipitate formed immediately. This substance was separated by filtration. Yield: 83%. $T_{decom.}$ = 345 °C. *Anal.* Calc. for $Ag_2CN_6O_2(H_2O)_3$: Ag, 54.18; C, 3.01; H, 1.50; N, 21.05. Found: Ag, 53.65; C, 2.94; H, 1.67; N, 21.28%. IR (Nujol, cm^{-1}): 3650 (νO–H), 1612, 1546 (νC–N), 1350 (νN–NO_2), 1316 (νN–O), 1238 (νC–N), 1054 (νN–N), 1002 (νN–N), 880 (δC–N–NO_2), 760 (δC–N–C), 736.

2.2.7. Synthesis of mercury 5-nitroaminotetrazolate (7)

To a solution of $Hg(NO_3)_2$ (0.34 g, 1 mmol) in 1 ml of water, a solution of 0.168 g (1 mmol) of **1** in 3 ml of water was added. A white precipitate formed immediately. This substance was separated by filtration. Yield: 83%. $T_{decom.}$ = 165 °C. *Anal.* Calc. for $HgCN_6O_2(H_2O)_2$: C, 3.29; H, 1.11; N, 23.05. Found: C, 3.24; H, 1.23; N, 22.87%. IR (Nujol, cm^{-1}): 3450 (νO–H), 1618, 1488 (νC–N), 1328 (νN–NO_2), 1286 (νN–O), 1184 (νC–N), 1026 (νN–N), 962 (νN–N), 863 (δC–N–NO_2), 756 (δC–N–C).

2.3. Single-crystal X-ray structure determination

Single crystals of **4** suitable for X-ray structure determination were obtained by slow evaporation of the water solution. The crystals of **7** were grown by slow diffusion of mercury(II) nitrate through silica gel containing potassium 5-nitroaminotetrazolate.

Data collection for crystals of **4** was carried out at room temperature on a four-cycle diffractometer using graphite-monochromated Mo Kα radiation (λ = 0.71973 Å), whereas data collection for **7** was carried out on a Stoe IPDS diffractometer (Imaging Plate Detector System) with graphite-monochromated Mo Kα radiation (λ = 0.71073 Å) at 183(2) K using a cold N_2-gas stream. The direct method was used to solve the crystal structures by applying the software options of the program SHELXS-97. The structure refinement was performed with the program SHELXL-97. Non-hydrogen atoms were refined anisotropically by full-matrix least-squares techniques based on F^2. The hydrogen atoms of organic groups were placed in calculated positions within a riding model approximation with a fixed temperature factor. Hydrogen atoms of water molecules were located based on the difference electron-density maps and were refined isotropically with a fixed bond length. Twining was observed for the crystal of **7**, the twining matrix was calculated using the PLATON program. Details of data collection and refinement are given in Table 1.

2.4. Calculation details

Full geometry optimization of the molecular structures were performed at the DFT level of theory using the hybrid Perdew–Burke–Ernzerhof parameter free exchange-correlation functional (PBE0) [32–34] as it is implemented in the PC GAMESS [35] version of the GAMESS-US [36] program package. Standard triple-split 6-311G(d,p) basis sets were used for all atoms of the systems under consideration. Geometry optimization of all the molecules was performed without any symmetry constrains (C_1 point group). The gradient norm was taken to be 10^{-5} a.u. The true minimum was controlled by the Hessian matrix and, as a consequence, harmonic frequencies calculation. The lack of imaginary frequencies indicates that the true minimum was achieved.

Based on the optimized geometry configurations, natural bond orbital (NBO) analysis [37,38] was performed for all systems. Computed data were visualized with help of the CHEMCRAFT program package [39].

In accord with Pearson [40], the chemical hardness (η) can be calculated by the following formula:

$$\eta = \frac{1}{2}\left(\frac{\partial^2 E}{\partial N^2}\right)_v = \frac{1}{2}\left(\frac{\partial \mu}{\partial N}\right)_v = \frac{1}{2}(I - A)$$

where I – ionization potential, A – electron affinity, E – the energy of N-electrons system, N – amount of electrons in the molecule, v – external potential, and μ – chemical potential. However, the Koopmans theorem allows the estimation of the hardness by using only orbital energies of the highest occupied molecular orbital (HOMO) and the lowest unoccupied molecular orbital (LUMO) of the molecule in its ground state as follows:

$$\eta \approx -\frac{1}{2}(\text{HOMO–LUMO})$$

Applicability of the Koopmans theorem to DFT MOs was found and confirmed by Baerends and co-workers [41] and Stowasser and Hoffmann [42].

3. Results and discussion

Potassium 5-nitroaminotetrazolate, obtained from guanidine carbonate, was used as the starting material. Other salts were obtained from the potassium salt **1** and the corresponding metal nitrates in water solution in accordance with the following reactions:

$$2KHCN_6O_2 + Pb(NO_3)_2 = Pb(HCN_6O_2)_2(H_2O)_4 + 2KNO_3$$

$$KHCN_6O_2 + Cu(NO_3)_2 = Cu(CN_6O_2)(H_2O)_3 + KNO_3 + HNO_3$$

$$KHCN_6O_2 + 2AgNO_3 = Ag_2(CN_6O_2)(H_2O)_3 + KNO_3 + HNO_3$$

$$KHCN_6O_2 + Hg(NO_3)_2 = [Hg(CN_6O_2)(H_2O)_2]_n + KNO_3 + HNO_3$$

The main difference between these reactions is that lead forms a mono-substituted salt, while copper, mercury and silver form di-substituted ones. It reflects the great affinity of Cu^{2+}, Hg^{2+} and Ag^{+} to soft ligands, and the propensity of silver to form completely substituted salts. The silver salt has high chemical stability and cannot be destructed by boiling with concentrated nitric acid. All the transition metal salts considered contain water molecules of crystallization. The hydrate composition has been calculated from the elemental analysis. In the case of lead and mercury derivatives, it was further confirmed by the crystal structure determinations.

IR spectra of 5-NATZ and alkali metal salts have been fully described previously [25]. Coordination of the ligand by a metal ion leads to an increase in the stretching vibrations in which atoms of the nitro-group are involved (Table 2).

Stretching displacements in the lead salt are in accordance with its crystal structure, where the metal atom is coordinated by the NO_2 group. Since the nitro-group is fixed, the energy of the stretching vibrations of the N–NO_2 and C–N–NO_2 fragments increases. There are two bands involving NO_2 asymmetric stretching in the copper complex.

Complex **4** crystallizes in the orthorhombic space group *P*bcn with four molecules in the unit cell. This compound has a polymeric structure formed by chains of $(PbO_2)_n$ and anions of 5-NATZ. The coordination number of lead is found to be 10. The lead ion is bound with three different types of oxygen atoms (Fig. 1): (i) oxygen atoms from bridging water molecules, (ii) oxygen atoms from terminal water molecules, and (iii) oxygens from nitro-groups.

The coordination polyhedron can be derived from the icosahedron by removal of two apexes with subsequent compression. The Pb–O bond lengths are in the range 2.653(5) to 2.888(5) Å (Table 3).

The Pb–O(terminal water) distance is equal to 2.653(5) Å, while the Pb–O(NO_2) bond length is 2.888(5) Å. The average Pb–O distance is 2.764(5) Å, being slightly greater than that in $Pb(CH_3COO)_2(H_2O)$, 2.742(6) Å [43], which has a similar polymeric crystal structure.

The anion of 5-NATZ in **4** is found to be monodeprotonated. Bond lengths in the ligand are similar to those for $MHCN_6O_2$, M = Li, Na, Cs [22–24]. The main difference between the 5-nitroaminotetrazolate anion in the lead salt and in alkali metal salts is observed for the bond lengths in the nitro group. The distances considered are significantly different (1.255(5) and 1.283(5) Å), and are longer than those in the case of $CsHCN_6O_2$ (1.243(5) and 1.260(5) Å). The latter can be the result of the coordination of the oxygen atoms with lead. The oxygen atom involved in the shortest Pb–O distance forms the longest N–O bond. The distance C(1)–N(2) (1.370(5) Å) shows the best correlation with the nitro-iminium form of the ligand [15,26]. Hydrogen atoms are connected to the N(6) nitrogen atom.

		N(1)–C(1)–N(5)	133.1(6)

Intramolecular and intermolecular hydrogen bonds are present in the crystal (Fig. 2); the former being observed between the O(4) atom and N(6) atom, the N(6)···O(4) distance is equal to 2.599(6) Å. Each 5-nitroaminotetrazolate ion is connected with a water molecule and adjacent ligands through five hydrogen bonds. All nitrogen atoms except N(2) and N(1) take part in hydrogen bonding. The intermolecular hydrogen bonds are characterized by the distances N–N 2.705(6) Å, N–O 2.828(6) Å and O–O 2.828(6) Å.

$(PbO_2)_n$ chains are stacked in the plane *bc* and form layers consisting only of lead ions and water molecules. 5-NATZ anions are located between the layers (Fig. 3). They

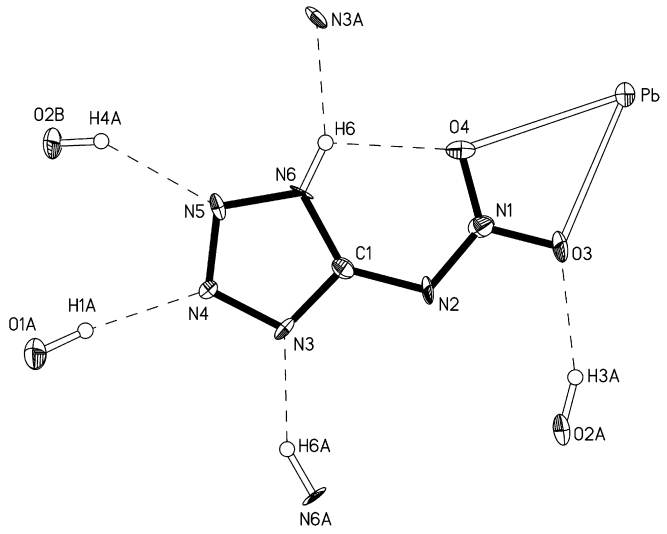

Fig. 2. System of hydrogen bonds around the 5-nitroaminotetrazolate ion, hydrogen bonds are shown as dashed lines.

are linked with lead by Pb–O bonds and are held together by hydrogen bonds, as described in the previous paragraph, and by stacking interactions. The distances between the planes of the tetrazole rings are equal to 3.143(6) Å. From such a point of view, the crystal structure of **4** has a hybrid structure that can be described as an intermediate step between an organometallic coordination polymer and an organic–inorganic hybrid material [44].

The polymeric crystal structure of **7** consists of infinite chains, $[–Hg–CN_6O_2–]_n$, fragments of which are presented in Fig. 4. The formal coordination number of mercury is equal to six. At the same time, the two Hg–N distances are significantly shorter than the Hg–O distances, 2.05(2) Å versus 2.60(2)–2.71(2) Å, respectively. In accord with these, the coordination geometry of mercury can be better described as linear, the N(3)–Hg–N(9) angle is 169° (Table 4). The Hg–N bond lengths are equivalent in the range of standard deviations, its value of 2.05(2) Å is slightly smaller than that for mercury nitrotetrazolate [45]. The difference in length of Hg–O and Pb–O bonds is due to the smaller radius of the Hg atom [46].

The structure of the $5\text{-}NATZ^{2-}$ anion shows differences from the corresponding structure in the alkali metal salts, Ni salt and the calculated geometry. Nitrogen atoms N(3) and N(6) have long N–N (1.40(2) Å) and C–N (1.35(2)–1.42(2) Å) bonds. These lengths are closer to single N–N and C–N bonds and consequently the Hg–N bonds have strong covalent character.

The $[–Hg–CN_6O_2–]_n$ chains are connected by bridged water in the 3D-network, Fig. 5. An extended networks of hydrogen bonds are observed in the crystal structure of the mercury derivative of 5-NATZ.

We have provided theoretical calculations on the equilibrium geometry, charge distribution (Figs. 8a–8c) and chemical hardness of $5\text{-}H_2NATZ$, $5\text{-}HNATZ^-$ and $5\text{-}NATZ^{2-}$ (Table 5) for interpretation of X-ray data and for in-depth consideration of 5-nitroaminotetrazolate coordination properties (for further details see Supplementary material). General numerations of the 5-NATZ atoms in this part are reflected in Fig. 6, and the main possible coordination modes are presented in Fig. 7.

Equilibrium geometrical parameters (Tables S1–S3) are in good agreement with the experimental X-ray diffraction data of $5\text{-}H_2NATZ$ [18] and its salts [25]. The C–N(2) distances, 1.307 and 1.349 Å for $5\text{-}H_2NATZ$ and $5\text{-}HNATZ^-$, respectively, confirm the nitroimino structure of this form. This distance in $5\text{-}NATZ^{2-}$ is 1.394 Å, being closer to the nitroamino form.

Charge distribution in $5\text{-}H_2NATZ$ shows a general pattern in which negative charges are concentrated on the oxygen atoms of the nitro group and the nitrogen atoms N(3) and N(6), but these nitrogen atoms are connected with hydrogens and consequently cannot be coordinated by metal. Therefore, neutral $5\text{-}H_2NATZ$ can really coordinate only through the oxygen atoms, type 1, 6. One hydrogen atom is omitted in the mono-deprotonated form $5\text{-}HNATZ^-$, enabling chelating coordination, type 2. The

negative charges on N(4) and N(5) are increased relative to 5-H_2NATZ, but coordination through these nitrogen atoms is not probable in this case. The di-deprotonated form of

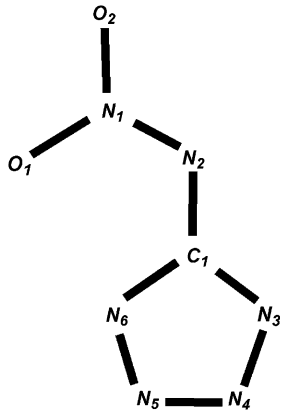

Fig. 6. Numeration scheme for 5-NATZ.

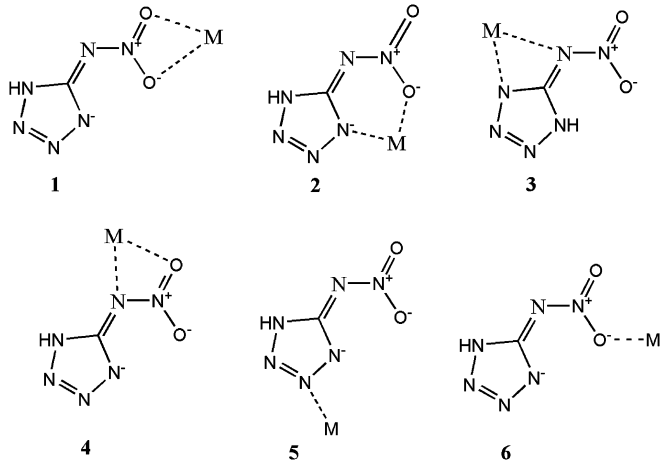

Fig. 7. Possible coordination modes for 5-nitroaminotetrazolates.

5-NATZ^{2-} shows the maximum possible coordination types, the negative charges on N(4) and N(5) continue to increase and that makes coordination through these atoms possible, e.g. as reported for the nickel derivative [29].

The hardness of the system decreases when we pass from the neutral to the di-deprotonated form, and it can lead to

a preferred formation of di-substituted complexes in the case of soft metals such as silver and mercury. In this work such a tendency was illustrated with the structures of the lead and mercury derivatives. Interplay of the values of ionic radii and effective positive charge may play an important role in defining the coordination environment (CN Pb = 10, CN Hg = 6). In our opinion, there are two main reasons why the coordination numbers of lead and mercury differ: (i) the ionic radius of mercury is smaller than that of lead; (ii) the effective positive charge of the Hg atom is lowered due to the mostly covalent character of the Hg–N bond.

The temperatures of decomposition of the salts were determined (Table 6). The tendencies which were found for alkali metal salts [22] are also retained for the salts of heavy metals. The temperature of decomposition of the mono-substituted derivative salt is 1.5 times lower than

Table 6
Temperatures of onset of exothermic decomposition

Substance	T (°C)
$KHCN_6O_2$	245

that for the di-substituted silver one. The low temperature of decomposition of the copper(II) salt can be caused by the catalytic properties of the copper ion in oxidation reactions.

4. Conclusion

In this work, we showed the possibility of building chain-like extended networks using 5-nitroaminotetrazole (5-NATZ) as a ligand, with examples of lead and mercury salts. Calculations of charge distribution and chemical hardness of the systems showed that soft metal ions should give completely replaced salts with N-coordination. On the other hand, a hard metal can form acidic salts with O-coordination. This can be justified based on the crystal structures presented here. Both structures are polymeric, but the lead structure consists of $(PbO_2)_n$ chains with 5-HNATZ$^-$ acting as a terminal ligand coordinated through oxygen atoms. At the same time, use of the mercury ion gave rise to only the completely replaced salt consisting of $[–Hg–CN_6O_2–]_n$ chains with strongly covalent Hg–N bonds. The crystal structures of these salts give information about their potential applications, such as initiators for explosive materials. The lead derivative includes strongly coordinated water molecules that probably cannot be eliminated by heating in a vacuum. Thus, the lead salt is not a perspective initiator. Water molecules in mercury salt are weakly connected with the metal and are likely to be eliminated by heating in a vacuum. The anhydrous compound should exhibit better explosive properties.

Appendix A. Supplementary material

CCDC 626662 and 639048 contain the supplementary crystallographic data for **4** and **7**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Cartesian coordinates for all the calculated molecules; full sets of both experimental and theoretical geometrical parameters for all the molecules; full sets of NBO atomic charges in all the computed molecules; table with absolute energies for all the calculated molecules. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2007.06.035.

a Bruker AC-300 MHz spectrometer operating in the quarter mode. The spectra were collected over a 50-kHz band width with 16 K data points and a 5-μs of 45° pulse. For a typical spectrum, between 1000 and 5000 transients were accumulated with a 50-ms delay time. The signal-to-noise ratio was improved by apodization of the free induction decay. Melting points are uncorrected and were obtained on a Kofler Heizbank Rechart type 7841 melting point apparatus.

2.2. Synthesis of complex [Fe(bipy)Cl_4][bipy · H] (1)

2,2′-Bipyridine (0.31 g, 2 mmol) in 0.1 M HCl (20 ml) was added to a solution of $FeCl_3 \cdot 6H_2O$ (0.27 g, 1 mmol) in water (15 ml) and the resulting red solution was stirred at 55–60 °C for 3 h. The orange colored precipitated product was recrystallized from CH_3CN. After 3 days, orange prismatic crystals of **1** were isolated (yield: 0.39 g, 76.3%, m.p.: 216 °C). IR (KBr, cm^{-1}): 3060m (*ν*(CH)), 1615m, 1599s, 1583s, 1529s, 1494w, 1473m, 1456m, 1443s, 1433m, 1384w, 1367w, 1320m, 1311s, 1270m, 1248w, 1229w, 1174m, 1158m, 110w, 1102w, 1088w, 1068w, 1058w, 1020m, 1010m, 993sh, 929m, 908w, 881m, 808w, 764s, 733m, 724m, 652m, 630m, 610m, 524w, 425w, 441w, 418m, 400w, 393w, 362w, 333w, 308s (*ν*(Fe–Cl)), 290s (*ν*(Fe–Cl)), 255s (*ν*(Fe–N)). *Anal.* Calc. for **1**: C, 46.96; H, 3.33; N, 10.95. Found: C, 46.58; H, 3.51; N, 10.76%.

2.3. Synthesis of complex [Fe(bipy)Cl_3(DMSO)] (2)

Dimethyl sulfoxide (0.44 ml, 6.4 mmol) was added to a solution of [Fe(bipy)Cl_4][bipy · H] (0.4 g, 0.8 mmol) in CH_3OH (40 ml) and the resulting orange solution was stirred at 40–45 °C for 2 h. This solution was left to evaporate slowly at room temperature. After 5 days, yellow prismatic crystals of **2** were isolated (yield: 0.23 g, 72.5%, m.p.: 268 °C). IR (KBr, cm^{-1}): 3060m, 2998m, 2918m (*ν*(CH)), 1605m, 1598s, 1563s, 1493s, 1471s, 1309s 1220m, 1205m, 1152s, 1102m, 1070w, 1059w, 1031m, 1025m, 1014w, 985s, 952s, 939s, 908w, 894w, 810w, 768s, 731s, 717w, 653m, 632m, 546w, 434s, 417m, 361w, 345m, 311s (*ν*(Fe–Cl)), 291s (*ν*(Fe–Cl)), 255s (*ν*(Fe–N)). *Anal.* Calc. for **2**: C, 36.32; H, 3.53; N, 7.06. Found: C, 36.18; H, 3.71; N, 6.89%.

2.4. Synthesis of complex [Fe(phen)Cl_4][phen · H] (3)

1,10-Phenanthrolinum chloride monohydrate (0.474 g, 2 mmol) in 10 ml water was added to a solution of $FeCl_3 \cdot 6H_2O$ (0.273 g, 1 mmol) in water (15 ml) and the resulting red solution was stirred at 55–60 °C for 3 h. The orange colored precipitated product was recrystallized from CH_3CN. After 3 days, orange prismatic crystals of **3** were isolated (yield: 0.44 g, 78.6%, m.p.: 268–270 °C). IR (KBr, cm^{-1}): 3053m (*ν*(CH)), 1616m, 1609m, 1596s, 1583s, 1539s, 1525s, 1518m, 1493m, 1464s, 1423s, 1341m, 1312m, 1278m, 1239m, 1185s, 1145m, 1101m, 1071w, 1036w, 991w, 974w, 965w, 898w, 883w, 868w, 851s, 840s, 817m, 781w, 767s, 723s, 715s, 641m, 620w, 537w, 506w, 461m, 426m, 410w, 399w, 305s (*ν*(Fe–Cl)), 286s (*ν*(Fe–Cl)), 269s (*ν*(Fe–N)). *Anal.* Calc. for **3**: C, 51.51; H, 3.04; N, 10.02. Found: C, 51.21; H, 3.11; N, 9.88%.

2.5. Synthesis of complex [Fe(phen)Cl_3(DMSO)] (4)

Dimethyl sulfoxide (0.92 ml, 13 mmol) was added to a solution of [Fe(phen)Cl_4][phen · H] (0.30 g, 0.54 mmol) in CH_3OH (40 ml) and the resulting orange solution was stirred at 40–45 °C for 2 h. This solution was left to evaporate slowly at room temperature. After 5 days, deep yellow prismatic crystals of **4** were isolated (yield: 0.17 g, 74.8%, m.p.: 233–235 °C). IR (KBr, cm^{-1}): 3072m, 2998m, 2918m (*ν*(CH)), 1623m, 1605m, 1582s, 1563s, 1509s, 1494m, 1425s, 1342s, 1224s, 1146m, 1105s, 1029m, 983s, 948s, 937s, 868m, 810w, 781w, 724s, 642m, 556w, 481w, 436s, 427s, 344m, 311s (*ν*(Fe–Cl)), 264s (*ν*(Fe–N)). *Anal.* Calc. for **4**: C, 39.95; H, 3.33; N, 6.66. Found: C, 39.76; H, 3.24; N, 6.48% (see Table 1).

2.6. Crystal structure determination and refinement

The X-ray diffraction measurements were made on a STOE IPDS-II diffractometer with graphite-monochromated Mo Kα radiation. For [Fe(bipy)Cl_3(DMSO)] (**2**), a yellow prismatic crystal with dimensions $0.40 \times 0.20 \times 0.20$ mm and for [Fe(phen)Cl_3(DMSO)] (**4**), a deep yellow prismatic crystal with dimensions of $0.25 \times 0.20 \times 0.15$ mm was mounted on a glass fiber and used for data collection. Cell constants and an orientation matrix for data collection were obtained by least-squares refinement of the diffraction data from 3396 unique reflections for **2** and 3542 for **4**. Data were collected at a temperature of 293(2) K to a maximum 2θ value of 53.48° for **2** and 53.46° for **4** and in a series of ω scans in 1° oscillations and integrated using the Stoe X-AREA [19] software package. The numerical absorption coefficient, μ, for Mo Kα radiation is 1.555 mm^{-1} for **2** and 1.446 mm^{-1} for **4**. A numerical absorption correction was applied using X-RED [20] and X-SHAPE [21] software. The data were corrected for Lorentz and polarizing effects. The structures were solved by direct methods [22] and subsequent difference Fourier maps and then refined on F^2 by a full-matrix least-squares procedure using anisotropic displacement parameters [22]. All of the hydrogen atoms were located in a difference Fourier map and then after refined isotropically. Subsequent refinement then converged with R factors and parameters errors significantly better than for all attempts to model the solvent disorder. Atomic factors are from the International Tables for X-ray Crystallography [23]. All refinements were performed using the X-STEP 32 crystallographic software package [24]. A summary of the crystal data, experimental details and refinement results is given in Table 2.

3. Results and discussion

3.1. Synthesis of compounds 1–4

Compounds **1** and **3** were synthesised according to the reported procedure for the preparation of compound **1** [25]. Treatment of one equivalent of $FeCl_3 \cdot 6H_2O$ with 2 equivalents of the bidentate chelating ligand, N–N, in the presence of HCl solution affords a compound with the general formula [Fe(N–N)Cl_4][N–N · H] in high yield, 76–78%, Eq. (1):

$$FeCl_3 \cdot 6H_2O + 2N\text{–}N \cdot HCl \xrightarrow{H_2O} [Fe(N\text{–}N)Cl_4][N\text{–}N \cdot N] \quad (1)$$

where **1** when N–N is bipyridine and **3** when N–N is phenanthroline.

The structures of complexes **1** and **3** were obtained by X-ray crystallography and confirmed by means of IR and ^{1}H NMR spectroscopic techniques, so they are unambiguously identified [25,26]. Addition of DMSO to the methanolic solution of **1** and **3** results in the formation of **2** and **4**, respectively, Eq. (2):

$$[Fe(N\text{–}N)Cl_4][N\text{–}N \cdot H] \xrightarrow{CH_3OH/DMSO} [Fe(N\text{–}N)Cl_3(DMSO)] + N\text{–}N \cdot HCl \quad (2)$$

where **2** when N–N is bipyridine and **4** when N–N is phenanthroline.

Solution studies of **1** and **3** show that exchange of a chloride ion by a donor ligand such as DMSO, CH_3OH, DMF and pyridine is fast. Dissolution of **1** and **3** in a donor solvent and subsequent recrystallization produces the neutral complex [Fe(N–N)Cl_3(D)] where D stands for donor ligands. We were able to determine the crystal structure of [Fe(phen)Cl_3(CH_3OH)] by dissolving and recrystallising **3** in CH_3OH solvent, and although the structure was reported before it further proves the formation of the aforementioned complex [26]. The structures of **2** and **4** also were characterized by X-ray diffraction in addition to IR and ^{1}H NMR spectroscopies. Therefore, we introduce the synthesis of complexes with a general formula $[Fe(N\text{–}N)Cl_4]^-[N\text{–}N \cdot H]^+$ as useful precursors for the synthesis of hetro ligand complexes of labile high spin Fe^{III} with the general formula $[Fe^{III}(N\text{–}N)Cl_3(D)]$ were N–N stands for diimines and D stands for donor ligands.

The structures of complexes **1** and **3** consist of alternating stacks of $[Fe(bipy)Cl_4]^-$ and $[Fe(phen)Cl_4]^-$ anions and $(bipy \cdot H)^+$ and $(phen \cdot H)^+$ cations, respectively, linked together by hydrogen bonds. Each anion binds to organic donors through N–H···Cl hydrogen bonds (H···Cl is 2.33(0.029) Å and N–H···Cl is 153.47(7.00)° for **1** and H···Cl is 2.61(0.025) Å and N–H···Cl is 138.15(2.21)° for **3**). It seems that hydrogen bonding between the acidic hydrogen of the cation with one of the coordinated chloride ligands in the anionic part of **1** or **3** has a promoting

effect for the removal of Cl as HCl in the presence of an entering donor ligand [25–27].

The only well-characterized compound with this general formula is [Fe(phen)$Cl_3(H_2O)$], which is prepared in very low yield from the reaction of $FeCl_3 \cdot 6H_2O$ and phenanthroline in 10 M HCl, maybe as a by-product. In contrast, the analytical yields of formation of complexes **2** and **4** are near quantitative [18].

3.2. ^1H NMR investigation

Although iron phenanthroline and bipyridine complexes were made in the last century, most of them were characterized by X-ray analysis and IR spectroscopy, and NMR analyses are rare [18,28–38]. Trace A in Fig. 1 shows the ^1H NMR spectrum of compound **1** in CD_3OD/CH_3OH (98:2). This spectrum was obtained right after dissolution of **1** in the aforementioned solvent. The proton signals of bipyridine are observed at 8.7, 8.4, 8.1 and 7.6 ppm, consistant with the C_2 symmetry of this structure in the solid state. The proton signals of the coordinated bipy are not resolved from bipy · H counter ions under these conditions. The ^1H NMR spectrum of [Fe(bipy)Cl_3(DMSO)] in CD_3OD is indicated in trace B of Fig. 1. Trace C is the spectrum of **1** in CD_3OD:CH_3OH (98:2) 1 h after dissolution of **1** in CD_3OD, and Trace D is the same spectrum after 24 h. In a separate experiment, [Fe(bipy)Cl_3-(CH_3OH)] (**5**), was synthesized [26] and its spectrum was obtained in CD_3OD. ^1H NMR demonstrate this spectrum is the exact spectrum as that in trace D in Fig. 1. This data confirms that the coordinated protons of DMSO are presented as a broad signal at 45.8 ppm in CD_3OD solution at 20 °C. In addition the proton signal of CH_3 for coordinated methanol was observed at 104.6 ppm. ^1H NMR investigation has shown that dissolution of **1** in methanol converts **1** to **5**, and in DMSO **1** is converted to **3**. A similar behavior and ^1H NMR spectrum was obtained for compounds **2**, **4** and [Fe(bipy)Cl_3(CH_3OH)], which proves generality of the method. For phenanthroline complexes, again the proton signal of the CH_3 group in methanol was observed at 104.5 ppm and the methyl group of coordinated DMSO at 45.3 ppm, almost in the same places as the bipyridine complexes. Addition of H_2O or taking the spectrum of **1** in D_2O produces a new feature for the proton signals, and we are working to characterize this. However, addition of 10 μl HCl/D_2O in CD_3OD results in a new complex with a new signal at −5.7 ppm, which may belong to the compound [Fe(bipy)$Cl_3(H_2O)$]. Fig. 2 demonstrates the ^1H NMR spectrum of compound **4**, [Fe(phen)Cl_3(DMSO)], in DMSO-d_6 solvent. In this spectrum, two broad signals appear at 45.4 ppm, which is in the same region as for the methyl signal of DMSO in **4** in accordance with the results presented in Fig. 1. However, another broad signal appears under these conditions at around 13 ppm, with the same intensity as the signal at 45.4 ppm. This can be an indication of [Fe(phen)-Cl_2(DMSO)$_2$]Cl formation according to the following equation:

$$[Fe(phen)Cl_3(DMSO)] \xrightarrow{DMSO} [Fe(phen)Cl_2(DMSO)_2]Cl \quad (3)$$

Notably, the titration process of DMSO in methanol was checked and the results show that the optimum amount for [Fe(phen)Cl_3(DMSO)] formation is about 24 equivalents of DMSO to one equivalent of complex **3**.

3.3. IR and UV–Vis of investigation

IR spectroscopy is a strong tool for identification of iron phenanthroline and iron bipyridine complexes, since a

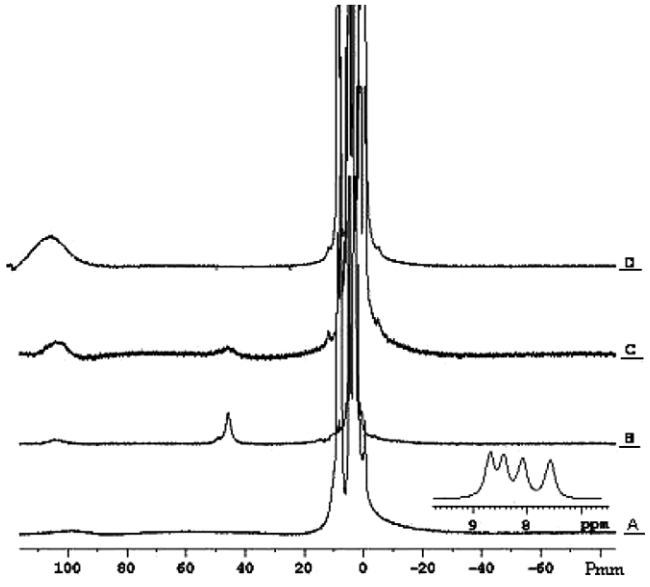

Fig. 1. ^1H NMR spectra of (A) complex **1** in CD_3OD:CH_3OH (98:2) right after dissolution, (B) complex **2** in the above-mentioned solvent, (C) complex **1** after 1 h and (D) complex **1** after 1 day in the above-mentioned solution.

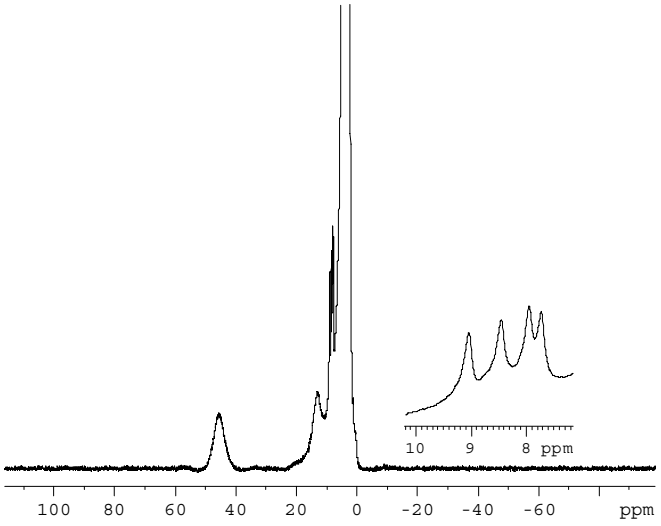

Fig. 2. ^1H NMR of compound **4**, [Fe(phen)Cl_3(DMSO)], in DMSO-d_6 solvent.

Table 3
Selected bond distances (Å) and bond angles (°) for complexes **2** and **4**

Complex	**2**	**4**
Bond distances (Å)		
Fe1–N1	2.181(2)	2.222(2)
Fe1–N2	2.194(2)	2.203(2)
Fe1–Cl1	2.309(1)	2.294(1)
Fe1–Cl2	2.316(1)	2.295(1)
Fe1–Cl3	2.305(1)	2.342(1)
Fe1–O1	2.090(1)	2.069(2)
O1–S1	1.525(1)	1.525(2)
Bond angles (°)		
N1–Fe1–N2	74.17(6)	75.49(2)
N1–Fe1–Cl1	167.14(4)	168.29(8)
N2–Fe1–Cl2	163.03(4)	166.77(6)
Cl3–Fe1–O1	170.74(4)	166.70(6)
Cl1–Fe1–Cl2	98.39(2)	99.26(3)
N1–Fe1–O1	82.83(5)	84.95(8)
N2–Fe1–O1	79.11(6)	82.57(8)

wealth of information is presented in the literature. IR absorption of the free ligands and compounds **1**–**4** are presented in Table 3. The Fe–Cl and Fe–N frequencies in **2** and **4** are mainly distinguishable in comparison with the known complex **1** [26]. In addition new signals at 985 and 984 cm^{-1} in the IR spectra of **2** and **4**, respectively, are assigned to ν(S=O). Other iron(III) DMSO complexes reported in the literature have shown ν(S=O) in the 910–960 cm^{-1} region [38]. The bands at 434 and 436 cm^{-1} were assigned to Fe–O stretching in **2** and **4**, respectively. The IR information confirm the high spin character of the iron center in **2** and **4**, since low spin iron(III) complexes have shown 50–70 cm^{-1} higher Fe^{III}–N frequencies [39]. Magnetic susceptibility measurements for **2** and **4** by the Evans method confirms the high spin character of these complexes ($\mu_{eff} \approx 6$ BM) [40].

UV–Vis spectra of **2** and **4** have no spin allowed signals for d–d transitions (their color is yellow in solution), but a

[b] Axial.

charge transfer bond is seen around 353 nm, in accordance with the high spin character of the iron(III) center.

3.4. Description of the molecular structures of *[Fe(bipy)Cl₃(DMSO)]* (**2**) and *[Fe(phen)Cl₃(DMSO)]* (**4**)

Yellow prismatic crystals of **2** and **4** were grown by recrystallization of their respective microcrystals in CH_3CN over a week. Table 2 shows details of the data collection and refinement of the X–ray crystal structure determinations for **2** and **4**. Selected bond lengths and bond angles are presented in Table 3. The crystal structures of complexes **2** and **4** consist of three chloride ions, one chelating bipyridine (or phenanthroline in **4**) and one DMSO molecule. The ORTEP view with the numbering schemes and packing diagrams for compounds **2** and **4** are shown in Figs. 3–6. The complexes have distorted octahedral geometries. The differences between coordinated ligands, different bond distances for *cis* and *trans* chloride ligands relative to diimine in **2** and **4** are the main factors accounting for these distortions, Table 3. The structures of **2** and **4** are mainly similar. The Fe–N (ave.) distance for complex **2** is 2.19 Å, which is slightly smaller than that found for **4** (2.21 Å), which is compensated by the Fe–Cl bond distances on the opposite sites, in which the Fe–Cl bonds are slightly larger in **2** than those in **4**. DMSO is coordinated to the Fe(III) center by oxygen and the Fe–O bond distances are almost similar in **2** and **4**, as expected.

The metal ligand bond lengths were used to obtain the spin state of the metal center, Table 4. The Fe–N (ave.) bond distances in high spin iron(III) phenanthroline and bipyridine complexes are around 2.2 Å in high spin complexes, and in low spin Fe^{III} complexes Fe–N distances less than 2 Å were reported [18,41]. Therefore, the Fe–N bond distances here show the present complexes are unambiguously high spin d^5. The Fe–O bond distances for **2** and **4** are 2.09 Å and 2.07 Å, respectively. The Fe–O bond distance in $[Fe^{III}(phen)Cl_3(H_2O)]$ was reported to be 2.19 Å, which is considerably longer than the Fe–O bond distances in **2** and **4** [18]. This elongation in the former complex is due to hydrogen bond formation. There are no hydrogen bonds present in complexes **2** and **4**.

As it is shown in Fig. 4, in complex **2** the bipy ligands form π bonding stacks in which each bipy ligand lies between two bipy ligands of adjacent iron complexes. The close contact distance between adjacent aromatic rings is 3.18 Å. In the complex **4**, there are no π–π aromatic interactions between the phen ligands, Fig. 6, and the angles between phen planes are about 25° and 63° in the lattice.

4. Supplementary material

CCDC 298949 and 651953 contain the supplementary crystallographic data for **2** and **4**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

1. Introduction

Hg(II) is a diamagnetic ion and maintains d^{10} electron configuration which minimizes intrinsic coordination geometry preferences while favoring coordination by softer ligands. In 1979, a homo-dinuclear structure was proposed for the bischloromercury(II) complex of *N*-tosylaminoctaethylporphyrin, $C_{45}H_{51}N_5OSCl_2Hg_2$ [or $(HgCl)_2$(N-NTs-OEP); **1**] (NTs = tosylimido, OEP = dianion of octaethylporphyrin), which represented the first X-ray structural proof for the existence of mercury(II) porphyrin sitting-atop (SAT) complexes [1]. Later, the mononuclear mercury(II) porphyrin sitting-atop structure of a *N*-monoalkylated porphyrin, i.e., [chloro(*N*-methyl-*meso*-tetraphenylporphyrinato) mercury(II)] [Hg(*N*-Me-tpp)Cl; **2**] (tpp = dianion of *meso*-tetraphenylporphyrin) was reported [2].

The preparation of *N*-substituted-*N*-aminoporphyrins has been described by three groups [3–7]. Upon replacement of CH_3^- of tosyl by a bulkier and heavier $^tBu^-$ group, the free base *N*-*p*-$HNSO_2C_6H_4CH_3$-Htpp (**3**) became 21-(4-*tert*-butyl-benzenesulfonamido)- 5,10,15,20-tetraphenylporphyrin *N*-*p*-$NSO_2C_6H_4{}^tBu$-Htpp (**4**) [8]. In *N*-substituted-*N*-aminoporphyrin, the H atom of NH_2 when replaced by 2-thiophenecarboxyamino group, it forms a new free aminated porphyrin, namely, *N*-2-thiophenecarboxamido-*meso*-tetraphenylporphyrin (*N*-NHCO-2-C_4H_3S-Htpp; **5**) which is a derivative of 2-acyl-thiophenes [9]. The phenylmercury(II) cation which binds to a variety of ligand sites ranging from N, O and C atoms serves as a good probe ion because it is unifunctional, gives complexes with a well defined stereochemistry and participates readily in electrophilic substitution [10]. A thorough review of the literature shows that there is no prior report on phenylmercury(II) with free bases **4** and **5** [8,9]. The coordination chemistry of phenylmercury(II) explored with anions derived from bases **4** and **5** reveals the formation of the phenylmercury(II) complex of (phenylato)(*N*-2-thiophenecarboxamido-*meso*-tetraphenylporphyrinato) mercury(II) [HgPh(*N*-NHCO-2-C_4H_3S-tpp); **6**] and bisphenylmercury(II) complex of 21-(4-*tert*-butyl-benzenesulfonamido)-5,10,15,20-tetraphenylporphyrin, $[(HgPh)_2$(*N*-*p*-$NSO_2C_6H_4{}^tBu$-tpp); **7**], respectively. The lack of previous work on metal complexes of these two ligands prompted us to undertake the synthesis and structural studies of Hg(II) complexes. Apparently, upon replacing Cl^-, OEP^{2-}, and CH_3^- with $C_6H_5^-$, tpp^{2-}, and the *tert*-butyl anion respectively, the complex **1** became **7** [1]. Likewise, upon replacement of Cl^- and N–CH_3 by $C_6H_5^-$ and N–NHCO-2-C_4H_3S, respectively, the complex **2** became **6** [2]. The compounds **6** and **7** are the first two organomercury(II) porphyrin complexes with the $HgPh^+$ moiety. The ring current effect of the porphyrin was employed to unambiguously assignment of the ^1H resonances of the phenyl group coordinated to Hg(1) in **6** or that group coordinated either to Hg(1) or Hg(2) in **7**. The bulky ^tBu group in this system enhances the crystallization of complex **7** [8]. The complexes **6** and **7** were investigated by ^{199}Hg NMR spectroscopy in order to clarify the coordination behavior of **6** in CD_2Cl_2 and **7** in $CDCl_3$ solutions. In this paper, we describe here on the synthesis, ^1H, ^{13}C and ^{199}Hg NMR spectroscopic characterization of complexes **6** and **7**. Our hope is that such structure-spectroscopic correlations will prove useful in the further development of the degradation reactions for environmental poisoning of mercury.

2. Experimental

2.1. HgPh(N-NHCO-2-C_4H_3S-tpp) (6)

A mixture of PhHgOAc (0.05 g, 1.48×10^{-4} mol) in MeOH (10 cm^3) and *N*-NHCO-2-C_4H_3S-Htpp (**5**) (0.07 g, 9.46×10^{-5} mol) in CH_2Cl_2 (20 cm^3) and CH_3CN (20 cm^3) was refluxed overnight [5,9]. After concentrating, the residue was dissolved in a trace amount of toluene, dried with anhydrous Na_2SO_4, and filtered. The filtrate was concentrated and recrystallized from CH_2Cl_2–hexane [1:2 (v/v)] yielding a bluish purple solid of **6** (0.056 g, 5.49×10^{-5} mol, 58%) which was again dissolved in CH_2Cl_2 and layered with hexane to get bluish purple crystals for single crystal X-ray analysis. ^1H NMR (599.94 MHz, CD_2Cl_2, 20 °C): δ 8.86 [s, H_β(7,8)]; 8.73 [d, H_β(2,13), ^3J(H–H) = 4.8 Hz]; 8.71 [d, H_β(3,12), ^3J(H–H) = 4.8 Hz]; 7.70 [s, H_β(17,18)]; 8.21 [s, *o*-H(22,32) and *o*-H(26,28)]; 8.48 [bs, *o*′-H(38,40) and *o*′-H(34,44)]; 7.76–7.83 (m, *m*, *p*-H), 6.15[d, S–H_5 or H(49), ^3J(H–H) = 5.1 Hz], where S = thiophene group; 6.03 [t, Hg–Ph–H_4 or H(53), ^3J(H–H) = 7.5 Hz], where Hg–Ph is the phenyl group (Ph) coordinated to Hg atom; 5.82 [t, Hg–Ph–H_3,5 or H(52, 54), ^3J(H–H) = 7.8 Hz and ^4J(Hg–H) = 50 Hz]; 5.27 [t, S–H_4 or H(48), ^3J(H–H) = 3.6 Hz]; 3.13 [d, Hg–Ph–H_2,6 or H(51,55), ^3J(H–H) = 6.0 Hz and ^3J(Hg–H) = 194 Hz]; 1.78 [d, S–H_3 or H(47), ^3J(H–H) = 3.0 Hz]; −0.10 [s, NH]. ^{199}Hg NMR (107.24 MHz, CD_2Cl_2, 20 °C): δ −1108 [s, Hg(1)]. MS (FAB): M^+ 1017 (calc. for $C_{55}H_{34}Hg_1N_5O_1S_1$:1017). UV/Vis spectrum, λ(nm) [$\varepsilon\times10^{-3}$ (M^{-1} cm^{-1})] in CH_2Cl_2: 430 (585.2), 546 (26.7), 582 (25.3), 637 (16.6).

2.2. (HgPh)2(N-p-$NSO_2C_6H_4{}^tBu$-tpp) (7)

A mixture of PhHgOAc (0.081 g, 2.41×10^{-4} mol) in MeOH (10 cm^3) and *N*-*p*-$HNSO_2C_6H_4{}^tBu$-Htpp (**4**) (0.05 g, 6.03×10^{-5} mol) in CH_2Cl_2 (20 cm^3) and CH_3CN (20 cm^3) was refluxed for 12 h [5,8]. After concentrating, the residue was dissolved in a trace amount of toluene, dried with anhydrous Na_2SO_4 and filtered. The filtrate was concentrated and recrystallized from $CHCl_3$–hexane [1:1 (v/v)] yielding bluish purple solid of **7** (0.055 g, 3.98×10^{-5} mol, 66%) which was again dissolved in $CHCl_3$ and layered with hexane to get bluish purple crystals for single crystal X-ray analysis. ^1H NMR (299.95 MHz, $CDCl_3$, 20 °C) : δ 8.84 [d, H_β(3,12), ^3J(H–H) = 4.2 Hz]; 8.79 [d, H_β(2,13), ^3J(H–H) = 4.2 Hz]; 8.56 [s, H_β(7,8)];

6.78 [s, H_β(17,18)]; 8.21 (bs) and 8.12 (s) for *o*-H(26,28) and *o*-H (22,32); 7.69–7.78 (m, *m*, *p*-H), 7.04 [d, ^{t}BuBS-$H_{3,5}$ or H(47, 49), ^3J(H–H) = 8.4 Hz], where ^{t}BuBS = 4-*tert*-butylbenzenesulfonyl; 6.72 [t, Hg(1)–Ph–H_4 or H(58), ^3J(H–H) = 7.5 Hz], where Hg(1)–Ph is the phenyl group (Ph) coordinated to Hg(1) atom; 6.63 [t, Hg(1)–Ph–H_3,5 or H(57, 59), ^3J(H–H) = 7.2 Hz]; 6.09 [d, ^{t}BuBS-$H_{2,6}$ or H(46, 50), ^3J(H–H) = 8.4 Hz]; 5.99 [t, Hg(2)–Ph–H_4 or H(64), ^3J(H–H) = 7.5 Hz], where Hg(2)-Ph is the phenyl group (Ph) coordinated to Hg(2) atom; 5.74 [t, Hg(2)–Ph–$H_{3,5}$ or H(63, 65), ^3J(H–H) = 7.5 Hz and ^4J(Hg–H) = 53 Hz]; 4.72 [d, Hg(1)–Ph–$H_{2,6}$ or H(56, 60), ^3J(H–H) = 7.2 Hz and ^3J(Hg–H) = 196 Hz]; 3.08 [d, Hg(2)–Ph–$H_{2,6}$ or H(62, 66), ^3J(H–H) = 7.5 Hz and ^3J(Hg–H) = 198 Hz]; 1.15 [s, t-butyl protons]. ^{199}Hg NMR (107.24 MHz, $CDCl_3$, 20 °C) : δ −1074 [s, Hg(2)]; −1191 [s, Hg(1)]. MS (FAB): M^+ 1379 (calcd for $C_{66}H_{51}Hg_2N_5O_2S$: 1379). UV/Vis spectrum, λ (nm) [$\varepsilon \times 10^{-3}$ (M^{-1} cm^{-1})] in CH_2Cl_2: 433 (516.5), 461 (67.0), 549 (23.1), 585 (24.8), 638 (22.5).

2.3. Spectroscopy

Proton and ^{13}C NMR spectra were recorded at 299.95 (or 599.94) and 75.43 (or 150.87) MHz, respectively, on Varian VXR-300 (or Varian Unity Inova-600) spectrometers locked on deuterated solvent, and referenced to the solvent peak. Proton NMR is relative to CD_2Cl_2 or $CDCl_3$ at $\delta = 5.30$ or 7.24 and ^{13}C NMR to the center line of CD_2Cl_2 or $CDCl_3$ at $\delta = 53.6$ or 77.0. ^{199}Hg NMR was obtained at 107.24 MHz on a Bruker DMX-600 spectrometer locked on deuterated solvent. Chemical shifts of ^{199}Hg were measured relative to an external reference of 0.5 M phenylmercury(II) acetate in DMSO-d6 (−1439.5 ppm) but reported relative to dimethylmercury (0.0 ppm). HMQC (heteronuclear multiple quantum coherence) was used to correlate protons and carbon through one-bond coupling and HMBC (heteronuclear multiple bond coherence) for two- and three-bond proton–carbon coupling. Nuclear Overhauser effect (NOE) difference spectroscopy was employed to determine the ^{1}H–^{1}H proximity through space over a distance of up to about 4 Å.

The positive ion fast atom bombardment mass spectrum (FAB MS) was obtained in a nitrobenzyl alcohol (NBA) matrix using a JEOL JMS-SX/SX 102 A mass spectrometer. UV/Vis spectra were recorded at 20 °C on a HITACHI U-3210 spectrophotometer.

2.4. Crystallography

Table 1 presents the crystal data as well as other information for $\mathbf{6}\cdot CH_2Cl_2\cdot 0.5C_6H_{14}$ and **7**. Measurements were taken on a Bruker AXS SMART-1000 diffractometer using monochromatized Mo Kα radiation ($\lambda = 0.71073$ Å). Empirical absorption corrections were made for both complexes. The structures were solved by direct methods (SHELXTL97) [11] and refined by the full-matrix least-squares method. The phenyl group coordinated to Hg(1) within $\mathbf{6}\cdot CH_2Cl_2\cdot 0.5C_6H_{14}$ is disordered with an occupancy factor of 0.65 for C(52)–C(55) and 0.35 for C(52′)–C(55′). S(1)

[or O(1)] within $\mathbf{6}\cdot CH_2Cl_2\cdot 0.5C_6H_{14}$ is also disordered with an occupancy factor of 0.55 [or 0.55] for S(1) [or O(1)] and 0.45 [or 0.45] for S(1′) [or O(1′)], respectively. One equivalent of CH_2Cl_2 solvent in $\mathbf{6}\cdot CH_2Cl_2\cdot 0.5C_6H_{14}$ is disordered with an occupancy factor of 0.62 [or 0.51] for Cl(1) [or Cl(2)] and 0.38 [or 0.49] for Cl(1′) [or Cl(2′)], respectively. The *tert*-butyl group within **7** is disordered with an occupancy factor of 0.46 [or 0.53] for C(52) [or C(53)] and 0.54 [or 0.47] for C(52′) [or C(53′)], respectively. All disordered atoms and solvent (CH_2Cl_2) were refined with isotropic displacement parameters. All non-hydrogen atoms, except the disordered atoms and solvent (CH_2Cl_2), were refined with anisotropic thermal parameters, whereas all hydrogen atoms were placed in calculated positions and refined with a riding model. Table 2 lists selected bond lengths and angles for complexes $\mathbf{6}\cdot CH_2Cl_2\cdot 0.5C_6H_{14}$ and **7**.

3. Results and discussion

3.1. Molecular structures of $\mathbf{6}\cdot CH_2Cl_2\cdot 0.5C_6H_{14}$ and 7

Using the d^{10} metal mercury(II), new mononuclear mercury $\mathbf{6}\cdot CH_2Cl_2\cdot 0.5C_6H_{14}$ and new bismercury **7** complexes were synthesized. The synthetic strategy is outlined in Scheme 1.

During the metallation of free base *N*-NHCO-2-C_4H_3S-Htpp (**5**) with PhHg(OAc) (Scheme 1) [9], the soft acid Hg^{2+} prefers to retain one phenyl ligand (soft base) and coordinates to the N [i.e., N(2)] of **5** to form a four-coordinate complex $\mathbf{6}\cdot CH_2Cl_2\cdot 0.5C_6H_{14}$ with a seesaw geometry and the angle of N(2)–Hg(1)–C(50) is 173.58(12)° in $\mathbf{6}\cdot CH_2Cl_2\cdot 0.5C_6H_{14}$ (Table 2). The complex $\mathbf{6}\cdot CH_2Cl_2\cdot 0.5C_6H_{14}$ is first example of an *N*-substituted *N*-aminoporphyrin-mercury complex with retention of the *N*-2-thiophenecarboxamido group. Two strongly electronegative oxygen atoms of the sulfonamide group in the free base *N*-*p*-$HNSO_2C_6H_4{}^tBu$-Htpp (**4**) enhance the acidity of the amido proton of $HNSO_2C_6H_4{}^tBu$ ligand in **4** [8]. During the metallation of *N*-*p*-$HNSO_2C_6H_4{}^tBu$-Htpp (**4**) with PhHg(OAc) one Hg^{2+} prefers to retain the phenyl group and coordinate to nitrogen [i.e., N(5)] of the *N*-*p*-HNSO2C6H4^{t}Bu group to form a two-coordinate, linear coordination around Hg(1) atom and with an angle of N(5)–Hg(1)–C(55) = 160.7(3)° in **7**. The other Hg^{2+} retains the phenyl group and attacks the nitrogen [i.e., N(2)] of the porphyrin ring to form a four-coordinate with a seesaw coordination around Hg(2) atom with an angle of N(2)–Hg(2)–C(61) = 167.4(2)° in **7**. The molecular frameworks are depicted in Fig. 1a for $\mathbf{6}\cdot CH_2Cl_2\cdot 0.5C_6H_{14}$ and Fig. 1b for **7**. The metal–ligand bond distances and the angles are summarized in Table 2. The covalent bond of Hg(1)–C(50) = 2.047 (4) Å in $\mathbf{6}\cdot CH_2Cl_2\cdot 0.5C_6H_{14}$ and of Hg(2)–C(61) = 2.064(7) Å and Hg(1)–C(55) = 2.065(8) Å in **7** are smaller than the sum of the covalent radii of Hg and C (2.26 Å) [12]. The mercury nitrogen bond distances [Hg(1)–N(1) = 2.589(3), Hg(1)–N(2) = 2.119(3), and Hg(1)–N(3) = 2.627(3) Å] in $\mathbf{6}\cdot CH_2Cl_2\cdot 0.5C_6H_{14}$ and [Hg(2)–N(1) = 2.566(6), Hg(2)–N(2) = 2.155(6), and

Scheme 1.

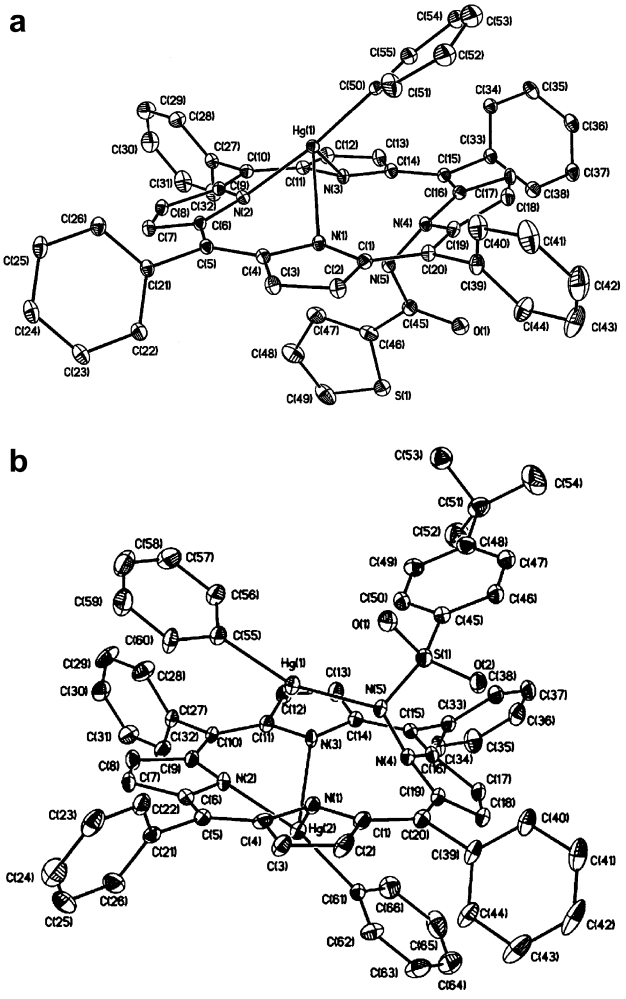

Fig. 1. Molecular configuration and atom-labeling scheme for (a) $\mathbf{6}\cdot CH_2Cl_2\cdot 0.5C_6H_{14}$, and (b) **7**, with ellipsoids drawn at 30% probability. Hydrogen atoms for both compounds and solvent CH_2Cl_2 for $\mathbf{6}\cdot CH_2Cl_2\cdot 0.5C_6H_{14}$ are omitted for clarity.

Hg(2)–N(3) = 2.583(6) Å] in **7**, are well below the upper limit of a typical Hg–N covalent bond [2.75(2) Å] [2,13]. The pyrrole nitrogen N(4) is no longer bonded to the Hg(1) in **6** · CH_2Cl_2 · $0.5C_6H_{14}$ and Hg(2) in **7** as indicated by their longer internuclear distances, 3.171(3) Å for Hg(1)···N(4) in **6** · CH_2Cl_2 · $0.5C_6H_{14}$ and 3.182(6) Å for Hg(2)···N(4) in **7**. Hence, C(50), N(1), N(2), and N(3) are bonded covalently to the Hg(1) atom in **6** · CH_2Cl_2 · $0.5C_6H_{14}$. Hg(1) is bonded to fewer than four nitrogen atoms, and so compound **6** · CH_2Cl_2 · $0.5C_6H_{14}$ may be considered as a Tsutsui's sitting-atop (SAT) complex [14]. In a similar way, the Hg(2) is tetracoordinated with three nitrogen atoms [i.e., N(1), N(2), and N(3)] of porphyrins and one carbon atom [i.e., C(61)] of phenyl group in **7**. The coordination around Hg(2) in **7** is also a mercury(II) porphyrin SAT complex. The similar kind of SAT complex was previously reported for complexes **1** and **2** [1,2].

We adopt the plane of three strongly bound pyrrole nitrogen atoms [i.e., N(1), N(2), N(3)] as a reference plane 3N for **6** · CH_2Cl_2 · $0.5C_6H_{14}$ and **7**. Because of the larger size of Hg^{2+} [$\gamma(Hg^{2+}) = 1.10$ Å with coordination number (CN) = 4 and $\gamma(Hg^{2+}) = 0.83$ Å with CN = 2] [12], Hg(1) and N(5) lie 1.47 and −1.29 Å respectively, above the 3N plane in **6** · CH_2Cl_2 · $0.5C_6H_{14}$, compared to −1.49 Å for Hg(2) and 1.36 Å for N(5) in**7**. The Hg(1) of **7** is 2.12 Å out of its 3N plane in the opposite direction of the Hg(2) atom. The separation between atoms Hg(1) and Hg(2) in **7** is 3.622(6) Å, which is larger than the sum of van der Waals radii of two Hg(II), 3.50(7) Å [13]. Hence, no metallophilic Hg(II)···Hg(II) interaction in **7** may be anticipated. The porphyrin macrocycle is indeed distorted because of the presence of the 2-thiophenecarboxamido (NCO-2-C_4H_3S) and the NSO2C6H4^{t}Bu group in **6** · CH_2Cl_2 · $0.5C_6H_{14}$ and **7**, respectively (Figure S1 in Supplementary material). Thus, N(4) pyrrole rings bearing the 2-thiophenecarboxamido (NCO-2-C_4H_3S) and the $NSO_2C_6H_4{}^tBu$ group in **6** · CH_2Cl_2 · $0.5C_6H_{14}$ and **7** deviate most from the 3N plane and as oriented separately with a dihedral angle of 33.3° and of 42.9°, whereas small angles of 4.9°, 21.0° and 8.7° occur with N(1), N(2), and N(3) pyrroles for **6** · CH_2Cl_2 · $0.5C_6H_{14}$ and 7.7°, 15.2°, and 11.1° with N(1), N(2), and N(3) pyrroles for **7**. In **6**, such a large deviation from planarity for the N(4) pyrrole is also reflected by observing a 10–12 ppm upfield shift in the ^{13}C NMR spectrum of $C_\beta(17,18)$ at 121.0 ppm compared to 133.4 ppm for $C_\beta(3,12)$, 133.2 ppm for $C_\beta(2,13)$, and 131.2 ppm for $C_\beta(7,8)$ (Table S1 in Supplementary material). In **7**, a similar deviation is also found for the N(4) pyrrole by observing a 14–15 ppm upfield shift of the $C_\beta(17,18)$ at 118.8 ppm compared to 134.2 ppm for $C_\beta(2,13)$, 133.4 ppm for $C_\beta(7,8)$, and 132.7 ppm for $C_\beta(3,12)$ (Table S2 in Supplementary material). The dihedral angles between the mean plane of the skeleton (3N) and the plane of the phenyl group are 56.7° [C(24)], 64.4° [C(30)], 49.7° [C(36)], and 59.7° [C(42)] for **6** · CH_2Cl_2 · $0.5C_6H_{14}$ and the corresponding angles are 60.1°, 81.4°, 45.3°, and 50.3° for **7**. Likewise, the dihedral angles between the mean plane of the 3N and the plane of the phenyl group coordinated to the Hg atom are 45.1° [C(53)] for **6** · CH_2Cl_2 · $0.5C_6H_{14}$ and 43.7° [C(58)], and 43.1° [C(64)] for **7**.

3.2. ^1H and ^{13}C NMR for 6 in CD_2Cl_2 and 7 in $CDCl_3$

Complexes **6** and **7** were characterized by ^1H and ^{13}C NMR spectra. In solution, the molecules have effective Cs symmetry with a mirror plane running through the N(2)–Hg(1)–C(50)–N(4) unit for **6** or N(2)–Hg(2)–Hg(1)–N(4) unit for **7**. There are four distinct β-pyrrole protons H_β, four β-pyrrole carbons C_β, four α-pyrrole carbons C_α, two different *meso* carbons C_{meso} and two phenyl-C1 carbons for these two complexes (Tables S1 and S2 in Supplementary material).

Due to the solubility problem, we observed the NMR spectra of **6** in CD_2Cl_2 and **7** in $CDCl_3$. The NMR spectra for a 0.01 M solution of **6** in CD_2Cl_2 (Fig. 2a) and for a

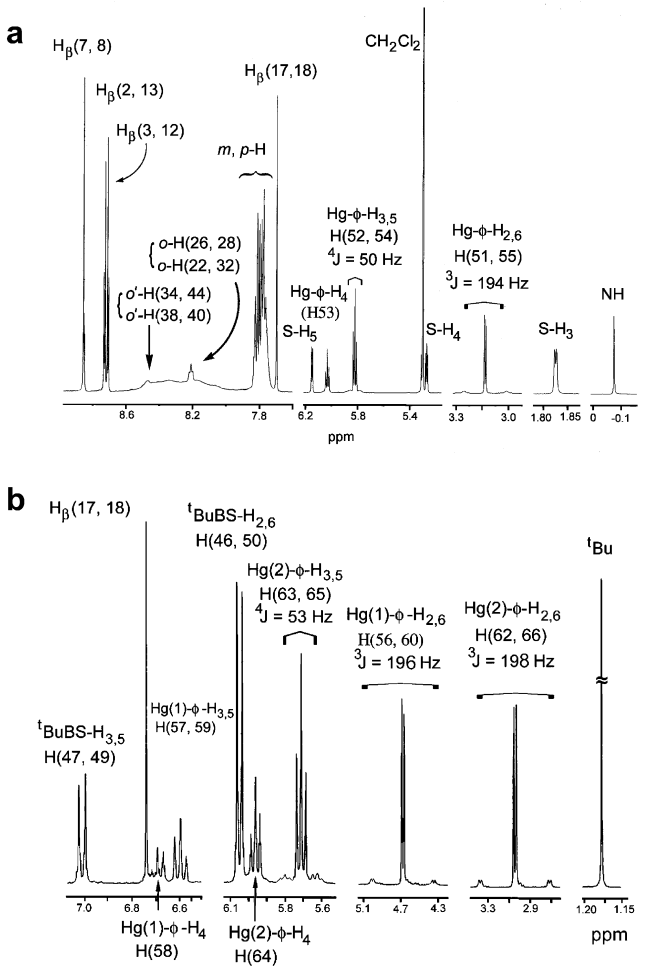

Fig. 2. ^1H NMR spectra at 20 °C (a) for a 0.01 M solution of **6** in CD_2Cl_2 at 599.94 MHz, entire spectrum; (b) for a 0.05 M solution of **7** in $CDCl_3$ at 299.95 MHz, showing Hg(1)-ϕ, Hg(2)-ϕ protons and ^{t}BuBS protons, where S = thiophene group, in **6** and ^{t}BuBS = 4-*tert*-butylbenzenesulfonyl group in **7**, ϕ = phenyl group.

0.05 M solution of **7** in $CDCl_3$ (Fig. 2b and Figure S2 in Supplementary material) showed four different types of H_β at 20 °C. In **6**, the singlet at 8.86 ppm is assigned to $H_\beta(7,8)$ and the doublet at 8.73 ppm to $H_\beta(2,13)$ with $^3J(H–H) = 4.8$ Hz. The doublet at 8.71 ppm is assigned to $H_\beta(3,12)$ with $^3J(H–H) = 4.8$ Hz and the singlet at 7.70 ppm to $H_\beta(7,8)$ (Fig. 2a). Likewise, in **7** the doublet at 8.84 ppm is due to $H_\beta(3,12)$ with $^3J(H–H) = 4.2$ Hz and the other doublet 8.79 ppm is due to $H_\beta(2,13)$ with $^3J(H–H) = 4.2$ Hz. The singlet at 8.56 ppm is due to $H_\beta(7,8)$ and the other singlet at 6.78 ppm is due to $H_\beta(17,18)$ (Fig. 2b and Figure S2 in Supplementary material).

All ^{t}BuBs, Hg–Ph protons in **6** and 2-thiophenecarboxamido (where Hg–Ph = the phenyl group (Ph) coordinated to Hg atom), Hg(2)–Ph, Hg(1)–Ph protons in **7** are shifted upfield compared to their counterparts on free ^{t}BuBs, Hg–Ph, 2-thiophenecarboxamido, Hg(2)–Ph,and Hg(1)–Ph. Such a shift is presumably attributed to the ring current effect. On the basis of the ring model [15], as the distance between the geometrical center (Ct) of the 4N [i.e., N(1), N(2), N(3), and N(4) for **6** and **7**] plane and axial protons gets smaller, the shielding effect becomes larger. In **7**, the average distance between Ct···Hg(2)–Ph–$H_{2,6}$, Ct···Hg(2)–Ph–$H_{3,5}$ and Ct···Hg(2)–Ph–H_4 increases from 3.937, 5.886 to 6.616 Å. Likewise, the average distance between Ct···Hg(1)–Ph–$H_{2,6}$, Ct···Hg(1)–Ph–$H_{3,5}$ and Ct···Hg(1)–Ph–H_4 increases from 4.558, 6.657 to 7.433 Å. The fact that all three distances between Ct···Hg(2)–Ph are shorter than those of Ct···Hg(1)–Ph in **7** indicates that the ring current effect in Hg(2)–Ph protons would be larger and in turn the ^{1}H upfield shifts for Hg(2)–Ph protons would be still higher. This observation is corroborated by the doublet at 3.08 ppm with satellites of $^3J(Hg–H) = 198$ Hz for Hg(2)–Ph–$H_{2,6}$ and the doublet at 4.72 ppm with $^3J(Hg–H) = 196$ Hz for the Hg(1)–Ph–$H_{2,6}$, the triplet at 5.74 ppm with well-resolved $^4J(Hg–H)$ of 53 Hz for the Hg(2)–Ph–$H_{3,5}$ and the triplet at 6.63 ppm with $^4J(Hg–H) = 50$ Hz for Hg(1)–Ph–$H_{3,5}$, the triplet at 5.99 ppm for Hg(2)–Ph–H_4 and the triplet at 6.72 ppm for Hg(1)–Ph–H_4. The ^{1}H NMR also revealed that the aromatic protons of the ^{t}BuBS group in **7** appear as two doublets at 7.04 ppm (^{t}BuBS-$H_{3,5}$) with $^3J(H–H) = 8.4$ Hz and at 6.09 ppm (^{t}BuBS-$H_{3,5}$) with $^3J(H–H) = 8.4$ Hz. This observation is consistent with the fact that the average distance between Ct···^{t}BuBS-$H_{2,6}$ and Ct···^{t}BuBS-$H_{3,5}$ in **7** increases from 5.139 to 6.933 Å. X-ray diffraction analysis unambiguously confirms that **7** is a dimercury complex. In addition, FAB MS indicates that molecular ion (M^+) of **7** is 1379. This further supports that **7** is a dimercury species in the solid phase. The strong diamagnetic shielding observed for all six resonances of the Hg(2)-Ph and the Hg(1)–Ph protons in the ^{1}H NMR spectrum of **7** suggests that **7** remains in a dinuclear mercury(II) complex in the solution phase (Fig. 2b).

In a similar fashion, in compound **6**, the average distance between Ct···Hg–Ph–$H_{2,6}$, Ct···Hg–Ph–$H_{3,5}$ and Ct···Hg–Ph–H_4 increases from 3.932, 5.808 to 6.638 Å. The ^{1}H NMR indicates that the aromatic protons of Hg–Ph in **6** appears as a doublet at 3.13 ppm with a coupled satellites $^3J(Hg–H)$ of 194 Hz for Hg–Ph–$H_{2,6}$, a triplet at 5.82 ppm with $^4J(Hg–H) = 50$ Hz for Hg–Ph–$H_{3,5}$, and a triplet at 6.03 ppm for Hg–Ph–H_4. Broadly, the ^{1}H NMR for phenyl protons of Hg–Ph in **6** is similar to those of Hg(2)–Ph in **7**. Due to the ring current effect, upfield shifts for the ^{1}H resonances of S–H_5, S–H_4 and S–H_3 in **6** with O, S-*cis* conformer in CD_2Cl_2 at 20 °C are $\Delta\delta = -1.48$ [from 7.63 (obtained from 2-acetylthiophene) to 6.15 ppm], −2.42 (from 7.69 to 5.27 ppm) and −5.35 ppm (from 7.13 to 1.78 ppm), respectively.

Heteronuclear coupling constants for ^{199}Hg in alkyl mecurials have been determined to decrease in the order $^1J \gg {}^3J > {}^2J > {}^4J$ [16]. Recently, a Karplus-type relationship was suggested for the magnitude of $^3J(Hg–H)$ which would predict weak coupling for torsion angle (Ψ) close to 90° and the largest coupling for torsion angles that approach 0 or 180° [17]. In **6**, the average torsion angle (Ψ) between Hg(1) and H (51A) [or H(55A)] was 10.5°. In **7**, the average torsion angle (Ψ) between Hg(1) and H(56A) [or H(60A)] was 5.0° while that angle between Hg(2) and H(62A) [or H(66A)] was 11.2°. In **6** and **7**, all the average torsion angles (Ψ) were within 12° of either 0 or 180°. Hence, $^3J(Hg–H)$ of 194 Hz for the Hg–Ph–$H_{2,6}$ protons in **6** was observed and was approximate to that of 197 ± 1 Hz for the Hg(2)–Ph–$H_{2,6}$ and Hg(1)–Ph–$H_{2,6}$ protons in **7**. The proton spectra clearly show $^3J(Hg–H)$ coupling. The presence of the mercury–proton coupling is an important indicator of slow ligand exchange in **6** and **7** [18,19]. The $^4J(Hg–H)$ of 50 Hz was observed for the Hg–Ph–$H_{3,5}$ protons in **6** and for the Hg(2)–Ph–$H_{3,5}$ and Hg(1)–Ph–$H_{3,5}$ protons in **7**. In **6** and **7**, the coupling constant of $^3J(Hg–H) = 197 \pm 1$ Hz is larger than that of $^4J(Hg–H) = 50$ Hz. These two coupling constants are consistent with those of $^3J(Hg–H) = 204$ Hz and $^4J(Hg–H) = 54$ Hz, respectively, for PhHgOAc in DMSO-d6 at ambient temperature [20].

3.3. ^{199}Hg NMR for 6 in CD_2Cl_2 and 7 in $CDCl_3$

The ^{199}Hg spectrum at 20 °C shows a sharp signal at −1074 ppm for a 0.05 M solution of **7** in $CDCl_3$, which is near the position of the Hg(1) signal observed in the spectrum for a 0.01 M solution of **6** in CD_2Cl_2, −1108 ppm (Fig. 3). Hence the signal at δ −1074 ppm of **7** is assigned to the Hg(2) nucleus with a coordination number of four. Therefore, the other signal at δ −1191 ppm of **7** is assigned to the Hg(1) nucleus with a smaller coordination number of two. It is known in the case of Hg NMR spectroscopy that on increasing coordination number generally lowers the chemical shift [16]. This fact explained that the ^{199}Hg signal of the Hg(2) nucleus in **7** lies at a downfield shift of 117 ppm from that of the Hg(1) nucleus. The ^{199}Hg chemical shift δ of Hg(1) in **7** is quite close to that of −1147 ppm for HgPh (DABRd) [where HDABRd = 5-(4′-dimethyl-

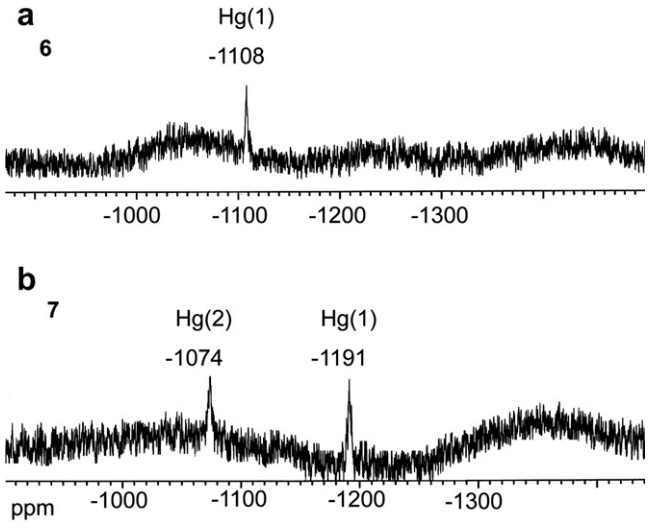

Fig. 3. The ^{199}Hg NMR spectra at 107.24 MHz (a) for a 0.01 M solution of **6** in CD_2Cl_2 at 20 °C and (b) for a 0.05 M solution of **7** in $CDCl_3$ at 20 °C.

aminobenzylidene)rhodanine] [21],−1152 ppm for HgPh (TRd) [where HTRd = 5-(2′-thiophenomethylene)rhodanine] [21] and −1156 ∼ −1346 ppm for the *N*-phenylmecury derivatives of *N*-aryl- and *N*-alkyl-substituted benzenesulfonamides (Ph–Hg–N(R)SO2Ph; R = Me, Et, Pr^i, Bu^t, Ph, 2-NO_2-C_6H_4, 4-NO_2–C_6H_4) [22]. The ^{199}Hg NMR data in $CDCl_3$ solution clearly reveal that there are two different Hg nuclei, i.e. Hg(1) and Hg(2), in **7**. These ^{199}Hg NMR data provide a second evidence that **7** remains as a dimercury(II) species in $CDCl_3$ solution. The chemical shift of ^{13}C for HgPh carbons was controlled by the paramagnetic term and not by the ring current effect [23–25]. Hence, the ^{13}C NMR data revealed that HgPh carbons in Hg(2)–Ph of **7** and Hg(1)–Ph of **6** · CH_2Cl_2 · $0.5C_6H_{14}$ are marginally affected (Tables S1 and S2 in Supplementary material). Moreover, the ^{13}C chemical shift of Hg(2)–Ph–C_1(C61) at an upfield of 3.3 ppm from that of Hg(1)–Ph–C_1(C55) (Table S2 in Supplementary material). This upfield shift is correlated with the ^{199}Hg signal of Hg(2) nucleus that shows a downfield shift from that of the Hg(1) nucleus in **7**.

4. Conclusions

We have investigated two new diamagnetic porphyrin complexes, namely, a mononuclear mercury(II) complex **6** · CH_2Cl_2 · $0.5C_6H_{14}$ and a dinuclear mercury(II) complex **7**, and their X-ray structures are established. These two porphyrin complexes are of a SAT type. NOE difference spectroscopy, HMQC and HMBC were employed to unambiguously assign the ^{1}H and ^{13}C NMR resonances of **6** in CD_2Cl_2 and **7** in $CDCl_3$ at 20 °C. Our results demonstrate the tetracoordination for Hg(1) in **6** · CH_2Cl_2 · $0.5C_6H_{14}$and Hg(2) in **7**. On the other hand, a linear coordination is described for Hg(1) in **7**. The transmetallation and degradation reactions for **6** and **7** are under investigation.

derivative with azide [25], topologically similar to the sulfate salt. It is worth noting that in these copper systems bpds is always doubly bridged irrespective of the metal–ligand ratio. However, bulkier and chelating coordinating anions, such as hexafluoroacetylacetonate [26], malate [27a], acetate, benzoate, and hexanoate [27b], lead to polymers with single bridging bpds ligand. The above facts suggest that dimensionality of the Cu–bpds networks entirely depends on the anion. These observations stimulated us to pursue further studies using different anions. On the other hand, Ryu et al. reported a 2D coordination polymer with bridging bpp [28] using metal/ligand ratio of 1:2. The authors did not give an account on the effect of changing this ratio, but we have obtained a new complex varying the metal–ligand stoichiometry. The present contribution reports the synthesis, crystal structure and magnetic property of two Cu(II) coordination polymers, $[Cu(bpp)(H_2O)_2(ClO_4)_2]_n$ (**1**) and $\{[Cu(bpds)_2(ClO_4)_2]\cdot 1.5\,(H_2O)\}_n$ (**2**) [bpp, 1,3-bis(4-pyridyl)propane and bpds, 4,4′-bipyridyl disulfide].

2. Experimental

2.1. Materials

High purity 1,3-bis(4-pyridyl)propane (98%) (bpp) and 4,4′-bipyridyl disulfide (Aldrithiol-4; 98%) (bpds) were purchased from the Aldrich Chemical Co. Inc. and were used as received. All other chemicals were of AR grade.

2.2. Physical measurements

Elemental analyses (carbon, hydrogen and nitrogen) were performed using a Perkin–Elmer 240C elemental analyzer. IR spectra were measured from KBr pellets on a Nicolet 520 FTIR spectrometer. Magnetic measurements were carried out in the "Servei de Magnetoquímica (Universitat de Barcelona)" on polycrystalline samples (40 mg) with a Quantum Design SQUID MPMS-XL magnetometer working in the 2–300 K range. The magnetic field was 0.1 T. The diamagnetic corrections were evaluated from Pascal's constants.

2.3. Synthesis of complexes

2.3.1. $[Cu(bpp)(H_2O)_2(ClO_4)_2]_n$ (1)

A methanolic solution (10 ml) of bpp (1 mmol, 0.198 g) was added drop wise to an aqueous solution (10 ml) of $Cu(ClO_4)_2\cdot 6H_2O$ (1 mmol, 0.370 g). The reaction mixture was stirred for 30 min and filtered. The filtrate was kept in a $CaCl_2$ desiccator and deep blue single crystals suitable for X-ray analysis were obtained after a few days. Yield: 74%. *Anal.* Calc. for $C_{13}H_{18}Cl_2CuN_2O_{10}$ (496.73): C, 31.40; H, 3.62; N, 5.67%. Found: C, 30.81; H, 3.75; N, 5.44%. The infrared spectra exhibited the following absorptions: 3109–3500(sbr), 2966(s), 2864(s), 1618(vs), 1558(s), 1506(s), 1452(s), 1433(vs), 1363(w), 1278(vs), 1244(vw), 1228(w), 1211(w), 1139(vs), 1114(vs), 1087(vs), 1068(vs), 1029(s), 983(w), 931(vw), 860(w), 817(s), 767(vw), 702(s), 624(vs), 572(s), 518(s) cm^{-1}.

2.3.2. $\{[Cu(bpds)_2(ClO_4)_2]\cdot 1.5(H_2O)\}_n$ (2)

Complex **2** were synthesized following the same procedure adopted for **1** using bpds (1 mmol, 0.220 g) instead of bpp. Blue crystals suitable for X-ray diffraction analysis were obtained from the filtrate kept in $CaCl_2$ desiccator. Yield: 78%. *Anal.* Calc. for $C_{20}H_{19}Cl_2CuN_4O_{9.50}S_4$(730.07) : C, 32.87; H, 2.60; N, 7.67%. Found: C, 32.23; H, 3.10; N, 7.92%. The infrared spectra exhibited the following absorptions: 3120–3579(sbr), 3091(s), 3040(s), 1629(vw), 1589(vs), 1544(s), 1481(vs), 1417(vs), 1321(s), 1222(vs), 1114(vs), 1087(vs), 1058(vs), 1026(s), 987(w), 933(vw), 831(vs), 811(s), 802(s), 717(vs), 624(vs), 499(s), 445(w) cm^{-1}.

2.4. Crystallographic data collection and refinement

Crystal data and details of data collections and refinements for the structures reported are summarized in Table 1. The data collections were carried out at 293(3) K using Mo-Kα radiation ($\lambda = 0.71073$ Å) on a Nonius DIP-1030H system, 30 frames with a φ rotation of 6° and exposure time of 15–20 min. Cell refinements, indexing and scaling of the data sets were performed using programs MOSFLM and SCALA [29]. Two residuals in **2** were assigned to water molecules at 0.5 and 0.25 occupancy factor (H atoms not located). The contribution of hydrogen atoms at calculated positions were included in final cycles of refinements.

[b] Goodness-of-fit $= \{\Sigma[w(F_o^2 - F_c^2)^2]/(n-p)\}^{1/2}$.

The structures were solved by Patterson and Fourier analyses and refined by the full-matrix least-squares method based on F^2 with all observed reflections [30]. All the calculations were performed using the WinGX System, Ver 1.64 [31].

3. Results and discussion

3.1. Description of the structures

3.1.1. Complex *1*

As shown in Fig. 1, complex **1** consists of undulated polymers elongated in the [1 0 1] direction built up by $[Cu(H_2O)_2(ClO_4)_2]$ centrosymmetric units connected by bpp ligands. The metal presents octahedral coordination geometry with axial bond distances considerably distorted for the Jahn-Teller effect, while deviations of bond angles from ideal values do not exceed 2.0°. The Cu–O(perchlorate) bond lengths are 2.568(2) Å, while the Cu–N and Cu–OH_2 distances are of 2.046(2) and 2.010(2) Å, respectively (Table 2). The bpp linker, having central propyl carbon positioned on a twofold axis, adopts a GG (*gauche–gauche*) conformation, with torsion angles about the propane chain of 72.3(2)°, that leads the collinear metals to be separated by 12.298(3) Å. Longer metal–metal distances measured in other polymeric chains (see below) are a direct consequence of the preference for *anti* torsion angles along the propyl chain. In fact, the flexibility of bpp ligand leads to different conformations with a range of N–N distances from 3.9 to 10.1 Å [32], the present being of 8.66 Å. This feature allowed obtaining supramolecular architectures of different dimensionality and topology by using different counter anions [33] or solvent system [34].

The water molecule is located at a distance of 3.00 Å from the coordinated perchlorate oxygen O(2) (Fig. 1), but also at 3.02 and 3.21 Å from two symmetry related ClO_4^- oxygens of adjacent polymers (O(3) and O(2) at $-x+1/2,\ -y+1/2,\ -z+1$ and at $x,\ -y+1,\ z+1/2$, respectively). The positions of water H atoms were successfully refined in the direction of the latter acceptors; however, it is not to be excluded that water H atoms are likely to be disordered giving rise to a 3D architecture where polymers are weakly bound by H bond connections. Among the numerous copper(II)–bpp polymers reported to date, only a few examples show 1D coordination chains with single metals connected by bridging bpp ligands.

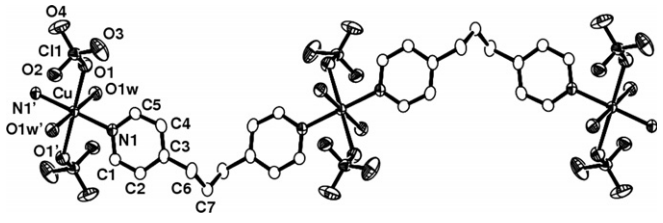

Fig. 1. Polymeric chain (ORTEP drawing) of **1** with atom labeling scheme.

The complex **1** joins those containing thiopheneacetate [21c] (Cu–Cu separation of 12.169 Å), hexafluoroacetonate [22a,22b] (12.848 Å), 2-methylacrylate [22d] (12.385 Å), and chloride [34] (13.480 Å) as metal-bound counter anion. Interestingly all of these are chelating ligands, while in the chloride derivative, the metal coordination sphere is completed by monocoordinated pendant bpp. As a matter of fact, the lacking of water molecules in the perchlorate compounds $[Cu(bpp)_2(ClO_4)_2]_n$ [28,33b] gives rise to 2D layered structures of 4,4 topology, of which one exhibits parallel interpenetration.

3.1.2. Complex *2*

The crystal structure analysis of **2** evidences a double stranded coordination chain and Fig. 2 shows a view of the polymeric arrangement with the atom numbering scheme of the crystallographic independent unit. The metal, which resides on a twofold axis, has a distorted octahedral environment, being surrounded by four nitrogen donors from four bpds ligands in the equatorial plane, and by two oxygen atoms from perchlorate anions occupying the axial positions. The Cu–N bond lengths are 2.031(5) and 2.025(5) Å, and the Cu–O distance is 2.508(4) Å. The *trans* N(1)–Cu–N(2′) bond angle is 173.57(19)° and the *cis* N–Cu–N bond angles are in a close range from 89.8(2) to 90.4(3)° (Table 2). The *gauche* conformation of the bpds spacer is indicated by the C–S–S–C torsion angle of 91.7(2)°, that falls in the range of 83.8(6)–95.5(8)°, found in a series of coordination polymers containing bpds ligands [35]. The py ring mean planes form a dihedral angle of 81.8(2)°. This bpds conformation spans the copper ions at a distance of 10.702(3) Å. Excluding bpds polymers containing Cu_2I_2 fragments and Cu_4I_4 cubane frameworks [23g], the latter value is slightly shorter than that of 10.839 Å found in the 2D network of $[Cu(bpds)_2(N_3)](ClO_4)$ reported by us [25], but sensibly longer than the intermetallic separation of 10.528 Å measured in the 1D $[Cu(bpds)_2(H_2O)](NO_3)_2$ and of 10.547 Å in the 2D assembly $[Cu(bpds)_2(SO_4)]$ [24]. The two-dimensional grid of 4,4 topology, detected in $[Cu(bpds)_2(N_3)](ClO_4)$ [25] and in $[Cu(bpds)_2(SO_4)]$ [24] complexes, has a

Primed atom (′) **1** at $-x+1/2, -y+5/2, -z$, **2** at $-x+3/2, -y+1/2, z$.

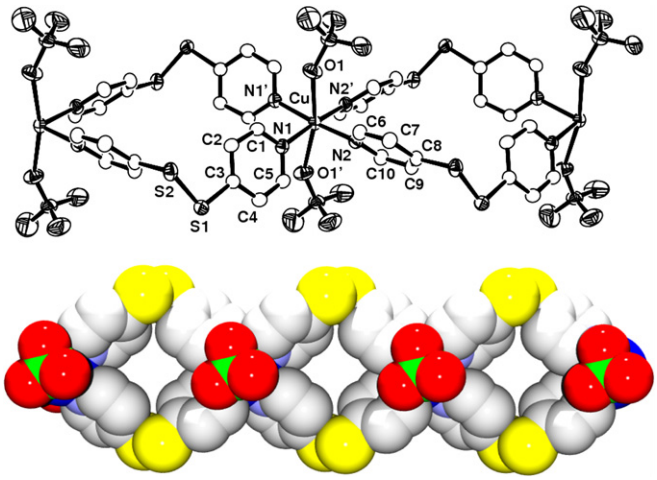

Fig. 2. Polymeric chain (ORTEP drawing) of **2** with atom labeling scheme and space-filling representation.

comparable topology with the nodes occupied by copper ions, the edges by double bpds connectors and by single anion μ-(1,3-N_3) or μ-(SO_4), respectively (Fig. 4). Correspondently the Cu–Cu distance spanned by the azide and sulfate anions are of 6.703 and 7.118 Å, while the shortest intermetallic distance between adjacent polymers in the crystal of **2** is 8.720 Å. It is interesting to note that in the present case the use of ClO_4^- as counter anion induces the formation of 1D polymers which are packed in the crystal in a cogging arrangement (Fig. 3), and no π–π interaction occurs between bpds pyridine rings of adjacent polymeric chains. The packing leaves 11.5% of void space in the unit cell with cavities filled by disordered lattice water molecules, which accounts for a total of 1.5 per metal ion.

3.2. Magnetic properties

3.2.1. Complex *1*

The magnetic properties of complex **1** as $\chi_M T$ versus T plot (χ_M is the molar magnetic susceptibility for one Cu^{II} ion) and the reduced magnetization ($M/N\beta$ versus H) are shown in Fig. 5. The value of $\chi_M T$ at 300 K is 0.437 $cm^3\ mol^{-1}$ K, which is as expected for one magnetically quasi-isolated spin doublet ($g > 2.00$). Starting from room temperature, $\chi_M T$ values are practically constant up to 50 K, then below 50 K they decrease quickly to 0.42 $cm^3\ mol^{-1}$ K at 2 K. This feature is characteristic of weak (almost negligible) antiferromagnetic interactions. The reduced molar magnetization at 2 K (Fig. 5, inset) clearly corroborates that the antiferromagnetic coupling is very small. The $M/N\beta$ value at 5 T is close to 1.0 Nβ and the curve follows the Brillouin function for a g value of 2.18.

Complex **1** is, actually, a 1D copper(II) entity. Thus, we have fitted the experimental data applying the formula for an uniform 1D copper(II) system, given by Bonner and Fisher [36]. The best-fit parameters obtained are

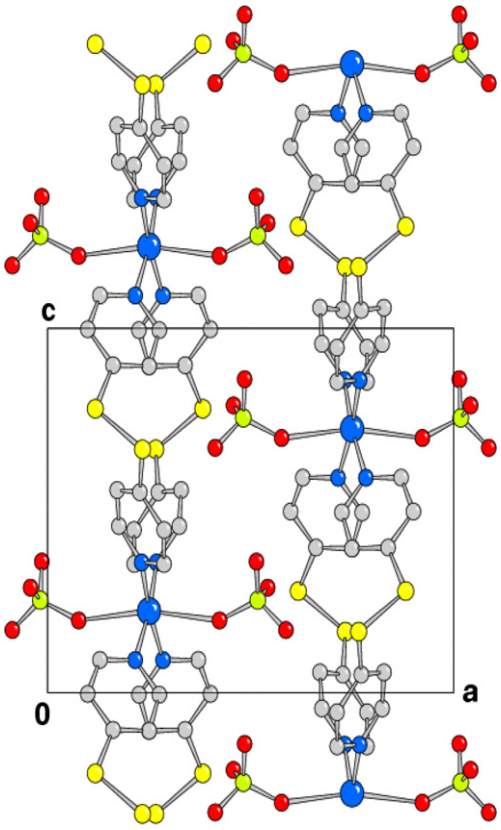

Fig. 3. Crystal packing of **2** viewed down *b*-axis.

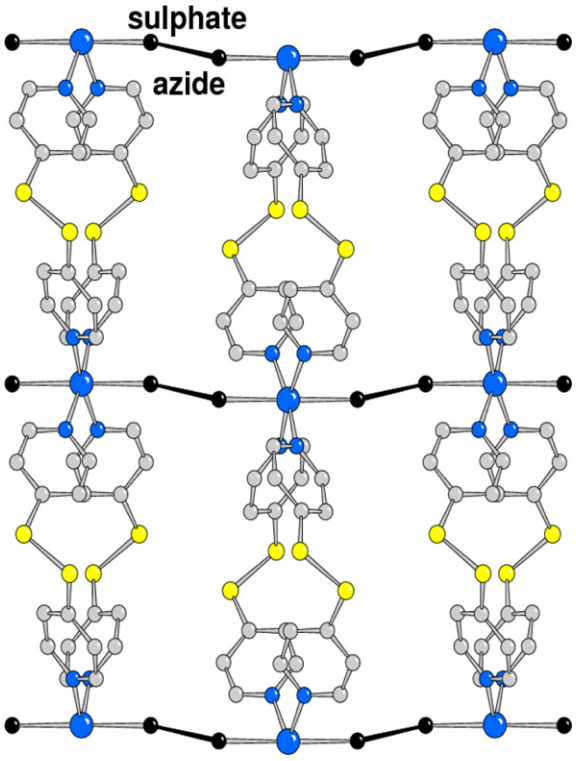

Fig. 4. Sketch of crystal packing of Cu(bpds) polymers in the $[Cu(bpds)_2(SO_4)]$ [24] and $[Cu(bpds)_2(N_3)](ClO_4)$ [25] complexes.

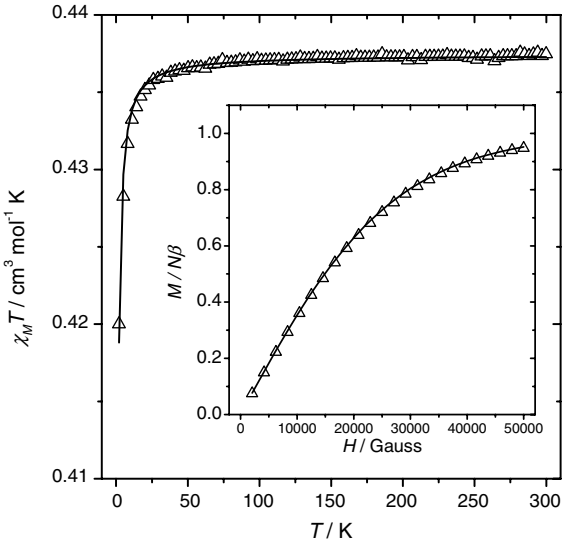

Fig. 5. Plot of $\chi_M T$ vs T for complex **1**. Open points are the experimental data and solid lines represent the best-fit obtained. Inset: plot of the reduced magnetization at 2 K.

$J = -0.1 \pm 0.01$ cm^{-1}, $g = 2.16 \pm 0.01$ and $R = 8.7 \times 10^{-6}$. The very small (negligible) J value can be interpreted as a consequence of the negligible overlap between the copper(II) ions through the long bridge [37].

3.2.2. Complex 2

The magnetic properties of complex **2** as $\chi_M T$ versus T plot (χ_M is the molar magnetic susceptibility for one Cu^{II} ion) and the reduced magnetization ($M/N\beta$ versus H) are shown in Fig. 6. It is also a 1D system and the magnetic data was fitted adopting the same procedure as in **1**. The best-fit parameters obtained are $J = -0.21$ cm^{-1} and $g = 2.11$.

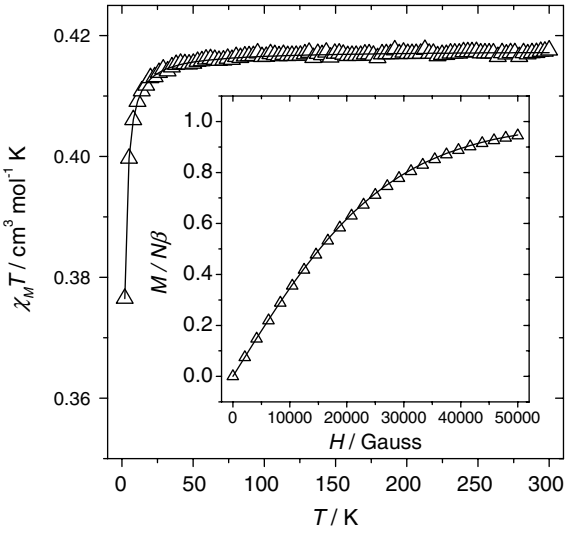

Fig. 6. Plot of $\chi_M T$ vs T for complex **2**. Open points are the experimental data and solid lines represent the best-fit obtained. Inset: plot of the reduced magnetization at 2 K.

4. Conclusion

Here, we have presented the synthesis, crystal structure and magnetic study of two Cu(II) coordination polymers using bpp and bpds as bridging ligand and perchlorate as counter anion. Both complexes show 1D coordination chains: complex **1** displays $Cu(H_2O)_2(ClO_4)_2$ units linked through bridging bpp and **2** has $Cu(ClO_4)_2$ fragments connected by double bpds ligands. The former, synthesized changing the metal–ligand ratio with respect to previously reported complexes, undergoes weak H-bonding interactions resulting a 3D supramolecular architecture. We have showed that dimensionality of the Cu–bpds network depends on the anion: in complex **2** perchlorate acts as mono-coordinated ligand leading to 1D chain, while using azide or sulfate 2D networks are obtained, and conversely the anion remains as lattice moiety, balancing the charge only, in the nitrate derivative.

Appendix A. Supplementary material

CCDC 646196 and 646197 contain the supplementary crystallographic data for **1** and **2**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223 336 033; or e-mail: deposit@ ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j. poly. 2007.06.031.

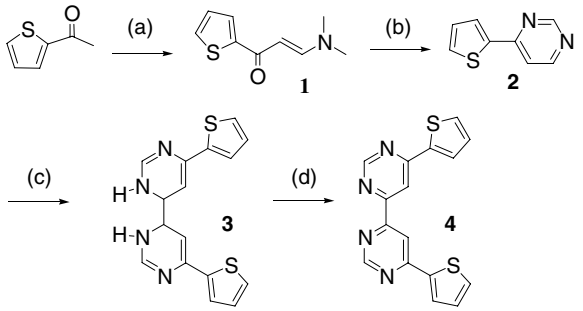
gap law [9,11]. We were thus interested to see if electron rich pendant groups had a significant effect on the properties of red-emitting Ru(II) complexes of bidentate ligands.

We chose thiophene as both an electron-rich pendant sub-unit and the π-accepting bidentate ligand 4,4′-bipyrimidine (bpm) as the metal-binding subunit as it binds to a wide range of metal ions to form complexes with interesting properties [12]. Previous studies of 2,2′-bipyridine (bpy) [13], 1, 10-phenanthaline (phen) [14], and 2,2′:6′,2″-terpyridine (tpy) [15] containing thiophenes as polymerizable units did not discuss the optical properties of the subunits in great detail. In this case, the bpm chelating motif has the advantage of forming complexes with lower energy excited-states than bpy, phen and tpy, particularly with metal ions such as Ru(II) [16] . In particular, Ru(II) complexes of bpm are low energy, red emitters, a much sought after property for biomedical applications [2]. Herein we describe the synthesis and properties of the ligand 6,6′-di(2″-thienyl)-4,4′-bipyrimidine (th_2bpm) and its hetero- and homo-leptic Ru(II) complexes.

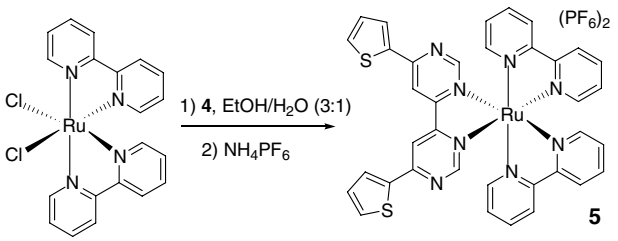


2. Results and discussions

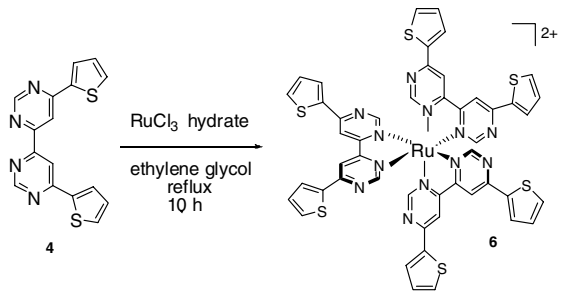
The most straightforward synthesis of the th_2bpm ligand (**4**) would have two thienyl–pyrimidine halves coupled together (Scheme 1). Although one could envisage palladium catalyzed heterocoupling reactions, such as the Suzuki reaction, followed by nickel catalyzed homocoupling reactions [17], we opted to use a catalyst-free approach (Scheme 2). Thus, ligand **4** was obtained in three steps, as outlined in Scheme 2, without the need of oxygen-sensitive catalysts.

In the first step (Scheme 2, step a), enaminone **1** was synthesized from 2-acetylthiophene using a small excess of *N*,*N*-dimethylformamide dimethylacetal following a previously established method [18]. The condensation of **1** (Scheme 2, step b) with three equivalents of formamidine acetate in the presence of three equivalents of sodium ethoxide resulted in the formation of the corresponding 4-(2-thienyl) pyrimidine **2** in moderate yields. The Michael addition of the free amidine on the enaminone followed by the intramolecular cyclisation gives **2** after column chromatography [19].

Scheme 1. Retrosynthetic route to 6,6′-di(2″-thienyl)-4,4′-bipyrimidine (th_2bpm, **4**) via Suzuki heterocoupling reaction and a Ni-catalyzed Ullmann reaction.



Scheme 2. Synthesis of 6,6′-di(2-thienyl)-4,4′-bipyrimidines **4.** Reagents and conditions: (a) EtOH, reflux, 6 h, yield 53%; (b) 3 equiv. formamidine acetate, 3 equiv. NaOEt, EtOH, reflux, 24 h, yield 48%; (c) 3 equiv. Na(s), THF, 36 h, r.t.; (d) air, 1 h, yield 61%.



The desired 6,6′-di(2-thienyl)-4,4′- bipyrimidine **4** was obtained by the radical anion coupling of two molecules of 4-(2-thienyl)-pyrimidine, **2** (Scheme 2, step c). The pyrimidine dimerizes upon treatment with 3 equivalents of sodium in anhydrous THF. As the initial radical anion is generated the solution turns dark purple, then yellow with the formation of dihydrobipyrimidine **3**, which is oxidized by bubbling air through the solution product **4** was then purified by recrystallization from methanol. A radical anion mechanism was previously established for this type of reaction [20].

The heteroleptic complex **5** was readily prepared by allowing a slight excess of th_2bpm to react with the dehydrate of $Ru(bpy)_2Cl_2$ in a boiling mixture of ethanol/water (3:1) overnight (Scheme 3). The addition of a saturated aqueous solution of NH_4PF_6 to the reaction mixture precipitated the complex as its bis(hexafluorophosphate) salt, which was then purified by column chromatography on silica gel eluting with the supernatant of a mixture of acetonitrile: potassium nitrate (7:1). The pure dark red complex was obtained after reprecipitating its PF_6 salt by the addition of NH_4PF_6.

Several attempts to prepare the homoleptic complex $[Ru(6,6'\text{-bis(2-thienyl)-4,4'- bipyrimidine})_3](PF_6)_2$, **6** adopting the same synthetic strategy as for the preparation of complex **5** failed, leading to a uncharacterized green product. However, complex **6** could be successfully prepared by refluxing $RuCl_3 \cdot xH_2O$ with a small excess of 6,6′-bis(2-thienyl)-4,4′-bipyrimidine using more drastic conditions, replacing the $EtOH/H_2O$ solvent mixture by refluxing ethylene glycol, which affords a higher reaction temperature

Scheme 3. Synthesis of heteroleptic complex **5**.

Scheme 4. Synthesis of homoleptic complex **6**.

and a readily oxidized solvent in order to reduce Ru(III) to Ru(II) (Scheme 4).

The ^{1}H NMR data for th_2bpm and its Ru(II) complexes are given in Table 1. The assignment of signals was based on the 2D COSY spectra of the complexes and by comparison of the various spectra with known compounds such as $[Ru(bpy)_2bpm]^{2+}$ and $[Ru(bpm)_3]^{2+}$ [21]. In the ^{1}H NMR spectra of complexes, the proton H_5 of the pyrimidine ring is shifted downfield compared to those of the free ligands, while the proton H_2 is shielded due to the shielding planes of the ancillary ligands. All the aromatic protons of the thienyl subunits resonate downfield compared to those of the free ligand and can be easily recognized by their coupling constants (see Chart 1).

Several attempts were made to obtain single crystals of ligand **4** that would diffract to wide angles; however, the best results from recrystallization in $CHCl_3$/hexane provided yellow crystals of **4** which were only suitable for refinement at small angles. The ORTEP representation of ligand **4** with its atoms labeling scheme is presented in Fig. 1. Details of data collection and refinement are given in Table 2. Ligand **4** crystallizes with four molecules in the asymmetric unit. The *N*-atoms of the central pyrimidine rings are in a *trans* orientation to one another, thereby minimizing the unfavourable electronic interaction between the lone pairs on N(2) and N(3). The thienyl rings are essentially co-planar to their respective pyrimidine rings while the two pyrimidines are almost so, with an angle of 3.2° between the two rings. There is an intermolecular π-stacking interaction between molecules in the solid state. The electron rich thiophene ring of one molecule is stacked above the electron-poor pyrimidine of another, with an intermolecular distance of approximately 3.7 Å (Fig. 2).

The redox potentials of ligand **4** and its Ru(II) complexes **5** and **6**, as determined by cyclic voltammetry and square wave techniques in acetonitrile solution, are summarized in Table 3. For each complex, the cyclic voltammograms exhibit at least one quasi-reversible oxidation wave and three quasi-reversible reduction waves. The oxidation potentials of complexes **5** and **6** are found at +1.39 V and +1.57 V, respectively, and are associated with the removal of an electron from the metal center. The metal-centered oxidation of $[Ru(bpy)_3]^{2+}$ (+1.27 V) suggests that the metal-based orbitals in **5** and **6** are stabilized due to the increased π-acceptor properties of the th_2bpm ligand as compared to bpy. The fact that three th_2bpm ligands are coordinated to the Ru(II) center in **6** leads to a more positive Ru(III/II) oxidation potential in **6** as compared to **5**.

The thiophene oxidation in **4** is not seen in complexes **5** and **6** as it is beyond the solvent potential window.

The two complexes exhibit three successive one-electron ligand-centered reductions. The potential reductions are anodically shifted with respect to those of the bpy ligand due to the fact that the lowest π*-orbital of the substituted bpm ligand is much lower in energy than the lowest π*-orbital of the bpys. However, in both of the cases the ligand reduction processes occur more readily in the complex than in the free ligand (−1.36 V).

The first reduction of the complex is assigned to the reduction of the th$_2$bpm ligand as 4,4′-bipyrimidine is more easily reduced than 2,2′-bipyridine. The first reduction potential of the all complexes is anodically shifted compared to the analogous unsubstituted bpm-based complex $[Ru(bpm)(bpy)_2]^{2+}$ as the lowest π*-orbital of th$_2$bpm is lower in energy than the lowest π*-orbital of the unsubstituted bpm as a result of electron delocalization. The second one-electron reduction of the complex also occurs on the 4,4′-bipyrimidine unit as each pyrimidine can accept an electron much more readily than the bpy ligands, albeit at a more negative potential. The third reduction of complexes **5** and **6** is assigned to the reduction of the bpy ligand (−1.70 V) and to a th$_2$bpm ligand (−1.39 V), respectively.

The difference $\Delta E_{1/2}$ between the oxidation E_{ox} potential and the first reduction E_{red1} potential for the complexes is also included in Table 3. The $\Delta E_{1/2}$ is a measure of the difference between the energy of the HOMO and the LUMO of the Ru(II) complexes and is in good correlation with the ^{1}MLCT absorption energy maxima and reinforces the attribution of this band mainly to the d(Ru) → π*(bpm) transition.

The UV–Vis spectra of the compounds **4**–**6** were recorded in acetonitrile solution and are illustrated in Fig. 3. The absorption data and extinction coefficients are displayed in Table 4. The free ligand and the Ru(II) complexes exhibit intense absorption bands in the UV region, assigned to ligand-centered π → π* transitions. The pyrimidine and pyridine π → π* transitions dominate the 280–

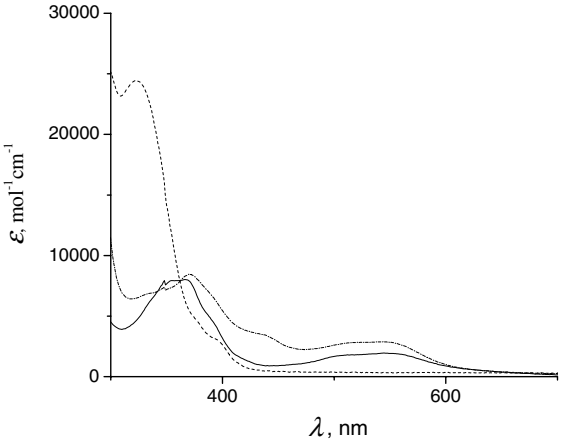

Fig. 3. Absorption spectra of **4** (···), **5** (-·-·-), and **6** (—) recorded in acetonitrile at room temperature.

Table 4
Spectroscopic data for **4**–**6** in deaerated CH_3CN solution

Complex	Absorption	Emission[a]
	λ_{max} (nm) (ε, $M^{-1}\,cm^{-1}$)	λ_{max} (nm)
4	322 (24400) 394 (sh)	
5	548 (2800) 512 (sh) 438 (3400)	770
6	544 (1900) 392 (sh)	722
$[Ru(bpm)_3]^{2+}$[b]	496 (6460) 462 (sh)	700
$[Ru(bpy)_2(bpm)]^{2+}$[b]	526 (3980) 506 (sh) 427 (5620)	742

[a] At 298 K.
[b] Ref. [23].

360 nm region of the spectra and overlap with the band due to the absorption by the thiophene group. The visible region of the spectra is characterized by the presence of two bands that can be attributed to two separate ^{1}MLCT transitions. The band at longer wavelength is associated with a d(Ru) $\rightarrow\pi^*$ (th_2bpm ligand) transitions, whereas the band at 438 nm in **5** is attributed to a d(Ru) $\rightarrow \pi^*$ (bpy) process. In complex **6**, the d(Ru) $\rightarrow \pi^*$ (th_2bpm ligand) transition is bathochromically shifted relative to those of the unsubstituted bpm tris-chelate complex $[Ru(bpm)_3]^{2+}$ (Table 4), as a consequence of the extension of the delocalization in the acceptor th_2bpm ligands. Concomitant with the red shift of the ^{1}MLCT absorption bands in the visible spectrum is a red shift in the ^{3}MLCT emission bands.

The emission spectra of the complexes were recorded in acetonitrile solution and are displayed in Table 4. As complexes **5** and **6** exhibit similar lower-energy MLCT bands in their absorption spectra as compared to $Ru(bpy)_2(bpm)^{2+}$ and $[Ru(bpm)_3]^{2+}$, respectively, the ^{3}MLCT emission bands are also red-shifted (see Table 4). This effect is consistent with the bathochromic shift in absorption and emission λ_{max} complexes with substituted bpm ligands as compared with the unsubstituted bpm ligand [24]. As aryl substituents with extended π systems permit greater delocalization of the excited state, there are fewer bond displacement changes, and, therefore, a concomitant decrease in nonradiative decay.

3. Conclusion

Two new ruthenium (II) complexes with thiophene-substituted 4,4′-bipyrimidine were synthesized and characterized. It has been demonstrated that substitution on the bipyrimidine ligand is an efficient way to tune the energy of the ground and excited states and, consequently, the photophysical properties of the complexes. The low-lying π^* acceptor orbitals of the substituted bidiazine ligands allow the reduction of the complexes at less negative potentials. A more extended π-conjugation of the substituted bipyrimidines stabilizes the empty π^* orbitals of the ligands and thus lowers the absorption and emission energies as compared to the parent $[Ru(bpm)_3]^{2+}$ complex. The new complexes emit at low energy in the red region of the visible spectrum. Although the presence of the 2-thiophene moiety does not produce new π-conjugated polymers by electrochemical polymerization [25], the possibility of introducing 3-thiophene units into the same position or electropolymerizing the free ligand does exist.

4. Experimental

4.1. Materials and methods

$Ru(bpy)_2Cl_2 \cdot 2H_2O$ was prepared by a literature method [26]. The metal complexes were purified by column chromatography on Kiesegel 60 (230–400 mesh) silica gel. Ammonium hexafluorophosphate and potassium nitrate were purchased from Aldrich and used without further purification. Tetrabutylammonium hexafluorophosphate was purchased from Aldrich and purified by recrystallization from toluene–methanol. Acetonitrile for photophysical and electrochemical experiments was of spectroscopic grade. Elemental analyses were performed by Laboratoire d'Analyse Elementaire de l'Université de Montréal.

Nuclear magnetic resonance (NMR) spectra were recorded in CD_3CN at room temperatutre (r.t.) on a Bruker AV400 spectrometer at 400 MHz for ^{1}H NMR and at 100 MHz for ^{13}C NMR. Chemical shifts are reported in part per million (ppm) relative to residual solvent protons (1.93 ppm for acetonitrile-d_3) and carbon resonance (1.79 ppm for methyl resonance of acetonitrile-d_3) of the solvent. Routine absorption spectra and emission spectra were measured in deaerated acetonitrile at r.t. on a Cary 500i UV–Vis–NIR Spectrophotometer and a Cary Eclipse Fluorescence Spectrophotometer, respectively, with errors of ±2 nm. Electrochemistry data were collected in deaerated acetonitrile with 0.1 M Bu_4NPF_6 on a BAS CV-50W Voltammetric Analyzer. Redox potentials were corrected by internal reference ferrocene (395 mV vs SCE).

4.2. Preparation of 2-thienyl enaminone (*1*)

N,*N*-Dimethylformamide dimethyl acetal (24.6 mL, 0.18 mol) was added dropwise to a stirred solution of 2-acetylthiophene (20 mL, 0.18 mol) in boiling absolute EtOH (20 mL) and the stirring was continued for 6 h, at which time hexane was added. A yellow solid precipitated which was isolated by filtration (17.29 g). Yield: 53%. ^{1}H NMR ($CDCl_3$, 400 MHz): δ 8.7 (d, $J = 12.2$ 1 H, H_1), 7.85 (d, $J = 3.7$, 1H, $H_{3'}$), 7.71 (d, $J = 4.9$, 1H, $H_{5'}$), 7.07 (t, $J = 8.6$, 1H, $H_{4'}$), 5.65 d, $J = 12.2$, 1H, H_2), 3.14 (s, 3H, N-CH_3), 2.94 (s, 3H, *N*-CH_3). ^{13}C NMR ($CDCl_3$): δ

181.1, 154.1, 147.7, 130.7, 128.8, 128.0, 92.0, 45.3, 37.4. MS: $m/z = 182.1$. *Anal.* Calc. for $C_9H_{11}NOS$: C, 59.64; H, 6.12; N, 7.73; S, 17.69. Found: C, 59.51; H, 6.17; N, 7.71; S, 17.15%.

4.3. Preparation of 4-(2′-thienyl)-pyrimidine (2)

To a stirred solution of **1** (5.0 g, 0.027 mol) in absolute ethanol (10 mL) at reflux was added formamidine acetate (8.6 g, 0.083 mol) and stirring was continued for 10 min. A solution of Na (1.9 g, 0.083 mol) in absolute EtOH (20 mL) was added to the reaction mixture and the reflux was maintained for 16 h, after which time the reaction mixture was allowed to cool to r.t. The solution was concentrated under vacuum and the solid residue dissolved in CH_2Cl_2 (50 mL). The precipitate was filtered and the filtrate concentrated. The desired compound was purified by column chromatography on alumina (EtOAc:hexane = 1:5) to give 4-(2′-thienyl)- pyrimidine as a white crystalline powder (2.10 g). Yield: 48%. ^{1}H NMR ($CDCl_3$, 400 MHz): δ 9.14 (s, 1H, H_2), 8.70 (d, $J = 5.4$, 1H, H_5), 7.82 (d, $J = 3.7$, 1H, $H_{3'}$), 7.63 (d, $J = 5.5$, 1H, H_6), 7.60 (d, $J = 5.1$, 1H, $H_{5'}$), 7.19 (t, $J = 8.7$, 1H, $H_{4'}$). ^{13}C NMR ($CDCl_3$): δ. 159.3, 159.2, 157.4, 142.5, 130.9, 128.9, 128.1, 115.5. MS: $m/z = 163.2$. *Anal.* Calc. for $C_8H_6N_2S$: C, 59.23; H, 3.73; N, 17.27; S, 19.77. Found: C, 59.03; H, 3.68; N, 17.17; S, 18.98%.

4.4. Preparation of 6,6′-bis(2-thienyl)-4,4′-bipyrimidine (4)

To a solution of **2** (1.13 g, 0.0069 mol) in THF (5 mL) was added sodium metal (0.48 g, 0.020 mol). The solution turned purple and then yellow. The reaction was quenched with EtOH (4 mL) and triethylamine (0.2 mL) to afford **3**, which was then oxidized by bubbling air through the solution for 1 h. The reaction mixture was dissolved in CH_2Cl_2 and washed three times with water. The extract was purified by recrystallization from methanol to afford a cream-coloured product (0.678 g). Yield: 61%. ^{1}H NMR ($CDCl_3$, 400 MHz): δ 9.23 (s, 2H, H_2), 8.78 (s, 2H, H_5), 8.00 (d, $J = 3.5$, 2H, $H_{3'}$), 7.66 (d, $J = 5.1$, 2H, $H_{5'}$), 7.23 (t, $J = 8.6$, 1H, $H_{4'}$). ^{13}C NMR ($CDCl_3$): δ 161.4, 161.1, 159.4, 142.4, 131.3, 129.1, 128.9, 116.0. MS: $m/z = 323.1$. HRMS: calcd [M + 1] for $C_{16}H_{10}N_4S_2$, 323.1942; found, 323.1935.

4.5. Preparation of [Ru(bpy)$_2$(4)](PF$_6$)$_2$ (5)

The complex *cis*-$[Ru(bpy)_2Cl_2] \cdot 2H_2O$ (0.010 g, 0.019 mmol) was suspended in a mixture of ethanol and water (8 mL, 75:25) and was heated for 30 min. 6,6′-Bis(2-thienyl)-4,4′-bipyrimidine (1.2 equiv., 0.0074 g, 0.023 mmol) was added and the mixture was refluxed overnight. The resulting solution was cooled to room temperature and the ethanol was removed under reduced pressure. After filtration, a saturated solution of ammonium hexafluorophosphate was added dropwise to the filtrate to complete precipitation of the product. The precipitate was collected by filtration, washed with water and diethyl ether, and dried. The complex was purified by column chromatography (SiO_2, acetonitrile: KNO_3(aq.), 7:1). The nitrate salt was metathesized to the PF_6 salt and the solvent removed under reduced pressure. The red product (10.7 mg) was finally collected by filtration after dissolving the solid in acetonitrile and precipitating by its addition to ether. Yield: 55%. ^{1}H NMR (CD_3CN, 400 MHz): δ 8.94 (s, 2H, H_5), 8.54 (s, 2H, H_2), 8.51 (d, $J = 5.4$ Hz, 4H, $B_{3,3'}$), 8.30 (d, $J = 5.6$ Hz, 2H, $H_{3'}$), 8.09 (t, $J = 11.7$ Hz, 4H, $B_{4,4'}$), 8.00 (d, $J = 4.9$ Hz, 2H, B_6), 7.85 (d, $J = 4.9$ Hz, 2H, $B_{6'}$), 7.72 (d, $J = 5.5$ Hz, 2H, $H_{5'}$), 7.44 (t, $J = 12.2$ Hz, 4H, $B_{5,5'}$), 7.36 (d, $J = 8.6$ Hz, 2H, $H_{4'}$). ^{13}C (CD_3CN): δ 165.1, 163.7, 160.4, 157.3, 152.8, 143.3, 138.3, 131.6, 129.6, 129.0, 124.8, 124.16, 117.2. ES-MS: $m/z = 367.7$ (M-2 PF_6^+).

4.6. Preparation of [Ru(6,6′-bis(2-thienyl)-4,4′-bipyrimidine)$_3$] (PF$_6$)$_2$ (6)

A solution of $RuCl_3 \cdot 3H_2O$ (0.0065 g, 0.031 mmol) and 6,6′-bis(2-thienyl)-4,4′-bipyrimidine (0.030 g, 0.093 mmol) in ethylene glycol (10 mL) was refluxed overnight. A saturated solution of ammonium hexafluorophosphate was added dropwise to the reaction mixture to complete precipitation. The precipitate was collected by filtration, washed by water and diethyl ether and dried. The complex was purified by column chromatography (SiO_2, acetonitrile:aq.KNO_3, 7:1). The nitrate salt was metathesized to the PF_6 salt and the solvent removed under reduced pressure. The red product (11.4 mg) was finally collected by dissolving the solid in acetonitrile and precipitated by addition to water. Yield: 27%. ^{1}H NMR (CD_3CN, 400 MHz): δ 8.98 (s, 6H, H_5), 8.63 (s, 6H, H_2), 8.31 (d, $J = 3.8$ Hz, 6H, $H_{3'}$), 7.86 (d, $J = 4.7$ Hz, 6H, $H_{5'}$), 7.39 (t, $J = 8.8$ Hz, 6H, $H_{4'}$). ^{13}C (CD_3CN): δ 162.4, 161.8, 159.9, 142.7, 132.0, 129.2, 117.5. ES-MS: $m/z = 533.7$ (M-2 PF_6^+).

5. Supplementary material

CCDC 284567 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

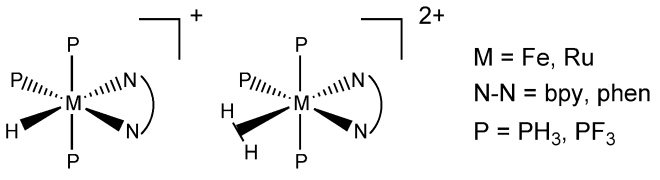
formed *in vacuo* using the hybrid DFT B3LYP method [5] without symmetry constrains, in combination with the polarized, ECP-based LACVP** basis set [6]. The "restricted" formalism was applied in all calculations. An initial refinement of the geometries was obtained using the restricted semi-empirical PM3 calculations [7]. All the resultant stationary points were characterized as true minima (*i.e.*, no imaginary frequencies). Atomic charges derived from Natural population analysis [8]. All calculations were carried out with computers equipped with Intel Pentium 4 660 processors (Prescott 2M) operating at 3.6 GHz frequency. The software used was the SPARTAN '02 [9].



3. Results and discussion

The molecules considered are iron and ruthenium classical and non-classical hydrides of the type *mer*-$[MH(N–N)P_3]^+$ and *mer*-$[M(\eta^2\text{-}H_2)(N–N)P_3]^{2+}$ {M = Fe, Ru; N–N = bpy, phen; P = PH_3, PF_3}, as depicted in Scheme 1. To speed up calculations, the small PH_3 and PF_3 phosphines were considered. Moreover, the use of these ligands strongly reduces the number of possible molecular conformers, thus helping the attainment of the molecular energy minimum during the geometry optimisations. From a chemical point of view PH_3 and PF_3 are quite interesting, having a strongly different co-ordinating behaviour: PF_3 is, in fact, a much more π-acidic ligand than PH_3 and the phosphites considered in Ref. [3] have a π-back-donation ability which is intermediate between that of PH_3 and PF_3 [10], thus the ligands considered in this work can be thought from an electronic point of view as two "borderline cases". Steric effects are usually negligible in acid–base reactions, thus the use of PH_3 and PF_3 instead of the bulkier phosphites did not appear to be too great a simplification.

The experimentally observed [3] acidity differences between iron(II) and ruthenium(II) hydride derivatives for the equilibrium reaction:

$$[M(\eta^2\text{-}H_2)(N–N)P_3]^{2+} \rightleftharpoons [MH(N–N)P_3]^+ + H^+$$

can be correlated with some ground-state calculated properties of the $[MH(N–N)P_3]^+$ and $[M(\eta^2\text{-}H_2)H(N–N)P_3]^{2+}$ cations, such as charge distributions and bond lengths. Table 1 reports the charge distribution on the hydride ligands resulting from the Natural population analyses performed on the geometry-optimised models of the $[MH(N–N)P_3]^+$ cations {M = Fe, Ru; N–N = bpy, phen; P = PH_3, PF_3}.

Scheme 1. $[MH(N–N)P_3]^+$ and $[M(\eta^2\text{-}H_2)(N–N)P_3]^{2+}$ cations.

Table 1
Hydride Natural charge of $[MH(N–N)P_3]^+$ cations

Complex	Natural charge
$[FeH(bpy)(PH_3)_3]^+$	−0.237
$[FeH(phen)(PH_3)_3]^+$	−0.234
$[FeH(bpy)(PF_3)_3]^+$	−0.195
$[FeH(phen)(PF_3)_3]^+$	−0.191
$[RuH(bpy)(PH_3)_3]^+$	−0.127
$[RuH(phen)(PH_3)_3]^+$	−0.123
$[RuH(bpy)(PF_3)_3]^+$	−0.125
$[RuH(phen)(PF_3)_3]^+$	−0.122

As depicted in Fig. 1, the co-ordinated hydrogen atoms have a more negative charge in the Fe(II) derivatives. The more negative charge of the co-ordinated hydrogen atom in the $[FeH(N–N)P_3]^+$ classical hydrides means a greater basicity of the iron(II) derivatives. It is to be noted that the hydride-character of the Fe(II) complexes is strongly influenced by the nature of the considered phosphine, while for both the Fe(II) and Ru(II) hydrides there are not important variations by changing the nitrogen-donor chelate ligand.

Also for the doubly charged non-classical hydrides $[M(\eta^2\text{-}H_2)(N–N)P_3]^{2+}$ {M = Fe, Ru; N–N = bpy, phen; P = PH_3, PF_3} the charge distribution was studied and in Table 2 the average Natural charges of the H atoms of the co-ordinated di-hydrogen molecule are reported.

In the doubly-charged $[M(\eta^2\text{-}H_2)(N–N)P_3]^{2+}$ non-classical hydrides the co-ordinated di-hydrogen molecule has a more positive charge in the Ru(II) derivatives (see Fig. 2). As for the classical hydrides $[MH(N–N)P_3]^+$, the 2,2′-bipyridine and the 1,10-phenanthroline derivatives show practically the same electronic properties. Also the variation of phosphine from PH_3 to PF_3 does not significantly affect the charge of the $\eta^2\text{-}H_2$ fragments. The more positive charge of the co-ordinated di-hydrogen molecule in the $[Ru(\eta^2\text{-}H_2)(N–N)P_3]^{2+}$ non-classical hydrides agrees with the greater acidity of the ruthenium(II) species as compared with the iron(II) analogues.

The computed $r_{H–H}$ bond lengths, reported in Table 3, highlight the differences between $[Fe(\eta^2\text{-}H_2)(N–N)P_3]^{2+}$ and $[Ru(\eta^2\text{-}H_2)(N–N)P_3]^{2+}$ cations. The more acidic character of Ru(II) non-classical hydrides corresponds, in fact, to a slightly longer H–H bond of the co-ordinated $\eta^2\text{-}H_2$ di-hydrogen molecule, as depicted in Fig. 3. The average difference between iron and ruthenium derivatives is 0.033 Å. As expected from the previous considerations, for both the Fe(II) and Ru(II) hydrides there are not meaningful variations by changing the N-donor chelate ligand.

By varying the co-ordinated phosphines from PH_3 to PF_3, a shortening of the H–H bond lengths, which principally affects the $[Ru(\eta^2\text{-}H_2)(N–N)P_3]^{2+}$ derivatives, is observed. It is known [1] that the bond between di-hydrogen and a transition metal can be qualitatively described on

the basis of a σ-bond between the HOMO of H_2 and a d_σ orbital of the metal, enforced by an interaction between a d_π filled orbital of the metal and the LUMO of H_2. The greater π-acidity of PF_3 [10] causes a decrease of the π-electron density of the metal centres, which consequently reduces the back-donation towards the $H_2\sigma^*$ molecular orbital and decreases the H–H elongation.

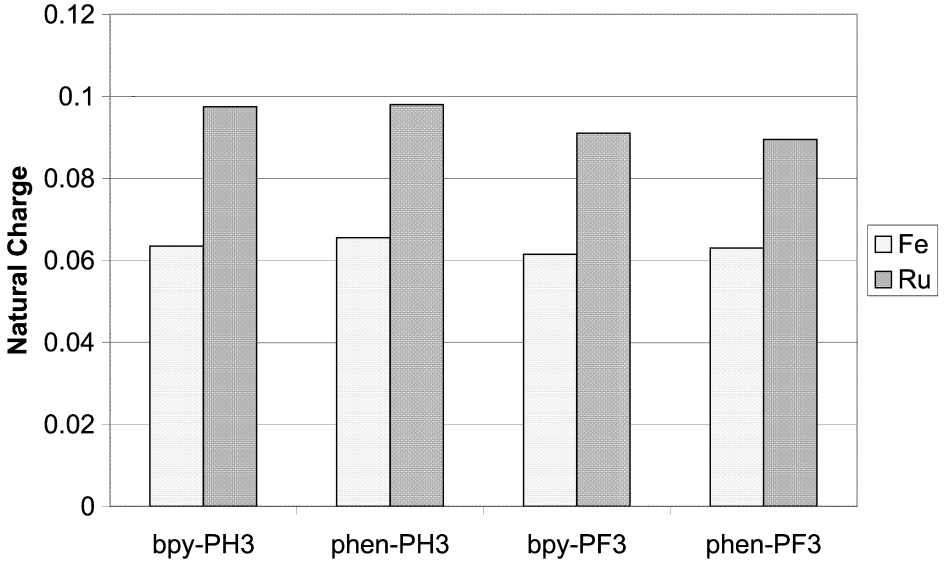

Fig. 2. Natural charge of the co-ordinated hydrogen atoms in the $[M(\eta^2\text{-}H_2)(N–N)P_3]^{2+}$ cations.

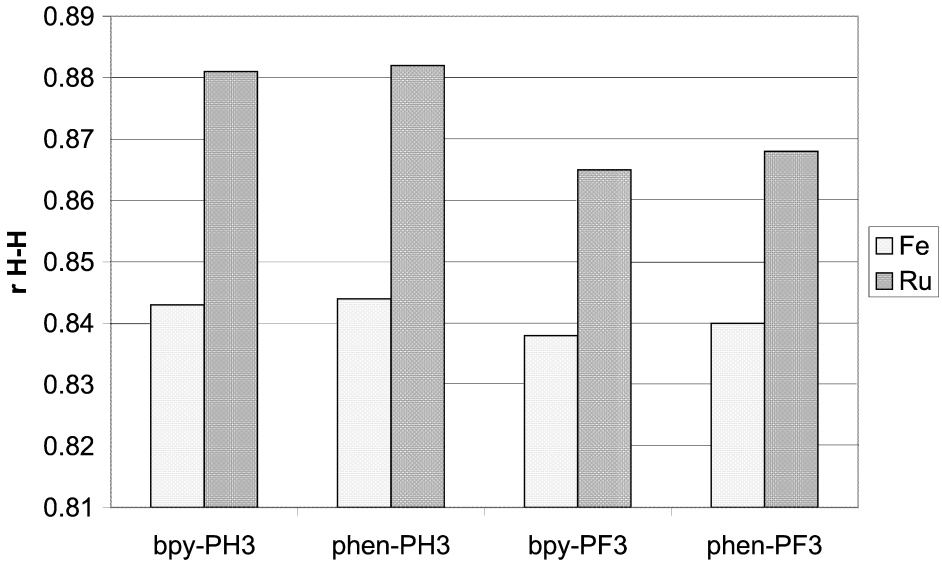

Fig. 3. r_{H-H} bond lengths of $[M(\eta^2\text{-}H_2)(N\text{–}N)P_3]^{2+}$ non-classical hydrides.

The comparison of the global energies of the $[MH(N\text{–}N)P_3]^+$ hydrides ($E_{[M]H}$) and of their conjugated acids $[M(\eta^2\text{-}H_2)(N\text{–}N)P_3]^{2+}$ ($E_{[M]H2}$) represents a more quantitative approach to the different acidities of iron(II) and ruthenium(II) non-classical hydrides. The energy differences between the *in vacuo* dissociation of the iron and ruthenium non-classical hydrides, $\Delta E_{Fe\text{–}Ru}$, can be easily calculated from the $E_{[M]H}$ and $E_{[M]H2}$ values:

$$[Fe(\eta^2\text{-}H_2)(N\text{–}N)P_3]^{2+} \rightarrow [FeH(N\text{–}N)P_3]^{+} + H^{+}$$

$$[Ru(\eta^2\text{-}H_2)(N\text{–}N)P_3]^{2+} \rightarrow [RuH(N\text{–}N)P_3]^{+} + H^{+}$$

$$\begin{aligned}\Delta E_{Fe\text{–}Ru} &= \{E_{[M]H}(Fe) + E_{H+} - E_{[M]H2}(Fe)\} \\ &\quad - \{E_{[M]H}(Ru) + E_{H+} - E_{[M]H2}(Ru)\} \\ &= \{E_{[M]H}(Fe) + E_{[M]H}(Ru)\} \\ &\quad - \{E_{[M]H2}(Fe) - E_{[M]H2}(Ru)\}\end{aligned}$$

The $\Delta E_{Fe\text{–}Ru}$ values reported in Table 4 agree with the experimentally observed higher acidity of the ruthenium(II) species, showing that the dissociation of the Fe(II) non-classical hydrides is always more than 3 Kcal/mol higher than that of the analogues Ru(II) derivatives. As expected from the previous results, the loss of an H^+ ion is energetically more favourable for the ruthenium non-classical hydrides.

The Natural charge distributions of the $[MH(N\text{–}N)P_3]^+$ and $[M(\eta^2\text{-}H_2)(N\text{–}N)P_3]^{2+}$ cationic hydrides allow to better understand the role of both the metal centres and the ancillary ligands in the acidity of these species. As described before (see Tables 1 and 2), the higher acidity of the ruthenium derivatives can be correlated to a more positive charge of the hydride and di-hydrogen ligands. In Table 5 the partial charge of the N-donor chelate ligands (N–N), the sum of charges of the P-donor ligands (P_3) and the Natural charge of the metal ion (M) are reported. It can be clearly observed that the greater charge of the –H and $-(\eta^2\text{-}H_2)$ ligands in Ru(II) derivatives is principally correlated to a strongly reduced partial charge of the metal ion. Quite surprisingly, both the N-donor and P-donor ligands show an increased partial charge in ruthenium classical and non-classical hydrides, as depicted in Fig. 4 for $[MH(bpy)(PH_3)_3]^+$ and $[M(\eta^2\text{-}H_2)(bpy)(PH_3)_3]^{2+}$ complexes {M = Fe, Ru}.

In our opinion, the data on the Natural charge distribution presented in Tables 1, 2 and 5 can be explained in a really simple way, by considering that the electronegativity of ruthenium is greater than that of iron: in fact, commonly

reported Pauling's electronegativity [11] of Ru is 2.2, while the one of Fe is 1.8. The experimentally observed acidity differences between iron and ruthenium non-classical hydrides of the type $[M(\eta^2\text{-}H_2)(N\text{–}N)P_3]^{2+}$, together with the charge distributions of the ancillary ligands in both the classical and non-classical hydrides, can be considered as a consequence of the different electronegativities of the two metal ions.

4. Concluding remarks

In this work, a good correlation between various computed molecular properties and experimental data reported in the literature was highlighted. The observed reactivity of N_2P_3-donor-set Fe(II) and Ru(II) di-hydrogen derivatives found a correlation with ground-state properties such as bond lengths, charge distributions and H^+ dissociation energies. Finally, the charge distributions obtained from DFT calculations allowed to hypothesize that the different acidities of iron and ruthenium non-classical hydrides could be mainly justified on the basis of the difference of electronegativity of the two metal ions considered.

2. Experimental

2.1. Materials

Colloidal borosilicate (CBS) and colloidal silica (CS) were stable dispersions obtained from Nalco Company. Both were samples of commercial products. The content of dispersed phase in CBS was 8.68% by weight and the B/Si molar ratio was 0.04. Colloidal silica contained 15.67% SiO_2 by weight. Sodium tetraborate decahydrate (borax) was purchased from Sigma–Aldrich, while the catechol and DL-tartaric acid were acquired from Alfa Aesar. Both of these reagents were used without further purification.

2.2. Preparation of colloidal silica–borax blend

The blends of colloidal silica with borax having B/Si molar ratio of 0.04 were prepared by mixing 6.64 g of 3% borax solution with 20.0 g of CS dispersion in a 60 ml capped glass jar. The samples were thoroughly mixed, and their pH adjusted to 9.5 with a small amount of hydrochloric acid solution.

2.3. Treatment of borosilicates and silica–borax blends with catechol and tartaric acid

Since catechol is susceptible to oxidation, especially in the alkaline medium, all experiments were carried out in a glove box under a continuous flow of nitrogen. First, solutions of catechol in water were prepared. For the reaction with colloidal borosilicate 0.37 g of catechol was dissolved in 9.56 g of water, while for the reaction with borax/silica blends, 0.69 g of catechol was dissolved in 28.1 g of water. These amounts of catechol were chosen to yield boron-to-chelant molar ratio of 1:3. The prepared catechol solutions were, respectively, added to 20 g of CBS and to 26.64 g of CS/borax blends. The resulting mixtures were shaken thoroughly and their pH was adjusted to 9.5 with a small amount of NaOH solution. All the colloids and solutions (including DI water used to dissolve catechol and solutions used to adjust the pH) were deaerated by bubbling nitrogen through them.

The treatment of borosilicates and colloidal silica/borax blends with the tartaric acid (H_2T) was carried out in the same way as described above. For the reaction with CBS 0.5 g of tartaric acid was dissolved in 9.5 g of deionized water, while for the reaction with CS/borax blend 0.94 g of tartaric acid was dissolved in 27.54 g of deionized water. After complete dissolution, these tartaric acid solutions were added to 20 g of CBS and 26.64 g of CS/borax blend, respectively. These amounts of tartaric acid yielded B:H_2T molar ratio of 1:3. No pH adjustment of the final solutions was performed. Since tartaric acid is stable towards oxidation by air, there was no need to prepare solutions in a glove box.

2.4. NMR spectroscopy

NMR spectra were acquired on a Varian INOVA spectrometer operating at 59 MHz ^{29}Si or 96 MHz ^{11}B. A 10 mm broadband probe fitted with quartz decoupler and broadband inserts, and proprietary top and lower insulators was used. Wilmad 6010 tubes, made of PTFE-FEP, were used in these studies. The hole of a 5 mm spinner turbine was enlarged to accommodate the approximately 8 mm o.d. PTFE tube. In the ^{29}Si spectra, a 90° observe pulse and a 15 s relaxation delay were used. Chemical shifts are referenced to tetramethylsilane (0 ppm) in $CDCl_3$. All ^{11}B NMR spectra were acquired at 27 °C, with a 90° observe pulse and a 2.5 s relaxation delay. In one experiment H_3BO_3 (0.1 M) was used as an external chemical shift standard. All chemical shifts are reported relative to $(CH_3CH_2)_2O \cdot BF_3$.

3. Results and discussion

3.1. Characterization of CBS and CS/borax blends by ^{11}B NMR

The ^{11}B NMR spectra of CBS and CS/borax blend at pH 9.5 are shown in Fig. 1. In the spectrum of CBS the lar-

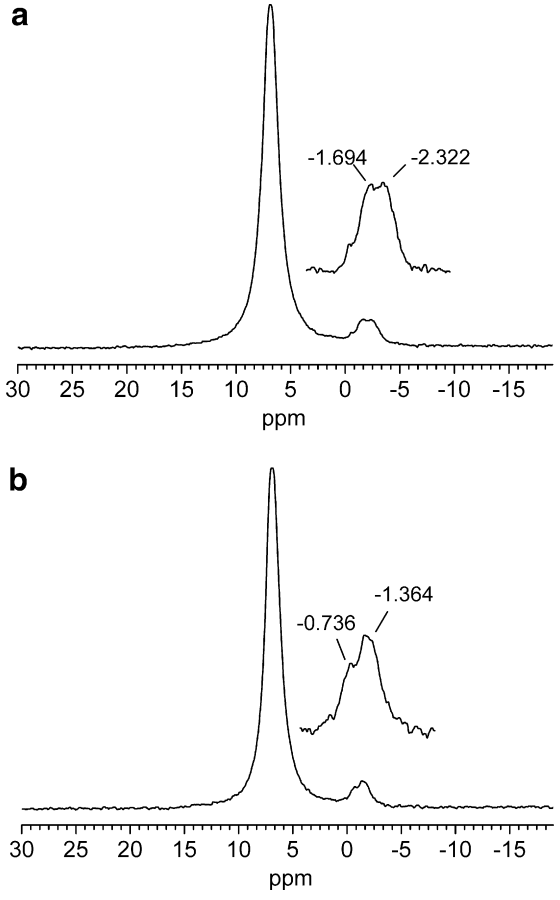

Fig. 1. ^{11}B NMR spectra of colloidal borosilicate (a) and colloidal silica blended with borax (b).

ger, more downfield resonance at 6.858 ppm results from free borate, and the smaller, more upfield group of peaks at −1 to −3 ppm arises from borosilicate species [7]. The ^{11}B NMR spectrum of a mixture of CS with borax solution is similar to the spectrum of CBS, with a large free borate peak at 6.820 ppm, and a group of smaller peaks near 0 to −2 ppm. In both cases boron is associated with the structure of colloidal particle via compounds that can be described by a general formula $B(OSi)_n(OH)_m$, where $n + m = 3$, $n \neq 0$. Overlapping peaks in the 0 to −2 ppm region are probably due to the presence of these compounds in different ratios. Although the spectra look similar, they are not identical: the smaller group of peaks in CBS resonates slightly more upfield than the group of similar peaks in the mixture of CS and borax, indicating differences in the structure of CBS and CS/borax blends. Indeed, in agreement with [2], a more upfield position of peaks in CBS suggests that boron probably forms mostly B–(O–Si)$_3$ bonds, consistent with incorporation into the colloidal particle. In the case of boron-modified colloidal silica, surface silanol groups would interact with soluble boron to form mostly $(OH)_2$–B–O–Si bonds. This is consistent with the observed relative downfield position in the spectrum of CS/borax blend.

3.2. Chelation of borates in CBS and CS/borax blends with catechol

The ^{11}B NMR spectra of CBS and CS/borax mixtures with catechol, acquired immediately after preparation, are shown in Fig. 2. The same figure also shows the ^{11}B spectrum of a mixture of catechol with borax solution. The addition of catechol to CBS, CS/borax blend and borax solution has resulted in the formation of 1:1 and 1:2 catechol:borate complexes at 7.5 and 13.0 ppm, respectively [13–15] via complexation of the free borate (Fig. 1, 6.858 ppm peak). In CBS/catechol mixture, in the region from 0 to −5 ppm, only the upfield component of the group of peaks seen in Fig. 1 is visible at −2.522, while the downfield component, at −1.694 ppm, is not visible. The stability of the upfield component toward catechol complexation must be a consequence of stable, covalent B–O–Si bonding present in the particle interior. In contrast, the facile complexation of the downfield component indicates that the boron–silica interaction is weaker, and is probably an interaction on the surface of the colloidal silica particle. The peaks characteristic of borosilicate remained present in the spectrum recorded on the second day after mixing CBS with the catechol. The peaks became significantly smaller after 6 days of aging.

In the spectrum of mixtures of the CS/borax blend and catechol, no peaks are present in the region between 0 and −5 ppm, indicating the absence of any borosilicate. The peaks that were visible in this region prior to complexation (Fig. 1) are no longer detectable, because the surface borosilicate of the colloidal silica particle is easily complexed by catechol and thereby removed.

Since catechol is known to be aggressive towards colloidal silica, the CS/borax blend was also examined by ^{29}Si NMR prior to and after catechol addition (Fig. 3). Both spectra are typical of colloidal silica [16,17]. Although the chemical shift of a sharp peak at ∼−144 ppm agrees with that of a complex between catechol and silicon [18], the relative amounts of Q^0, Q^1, Q^2, Q^3, and Q^4 appear to be approximately the same in both spectra. This indicates that under current experimental conditions dissolution of substrate in catechol is insignificant and probably limited to the surface of silica particle. The fact that in the ^{11}B NMR spectrum of CBS the borosilicate peak remains present after treatment with catechol, suggests that B–O–Si chemical bonds are within the colloidal particle and not just at the particle surface, as it is in the case with CS/borax blend.

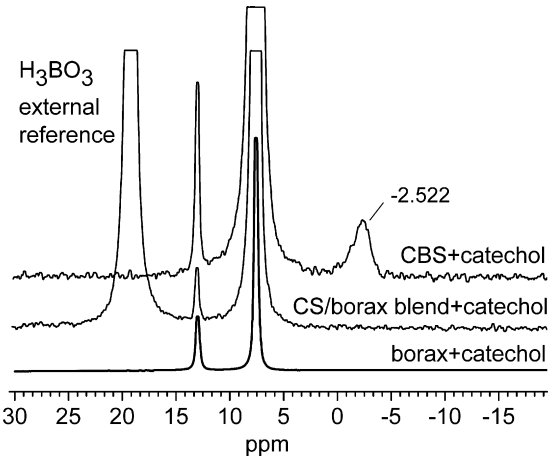

Fig. 2. ^{11}B NMR spectra of borosilicate and colloidal silicaborax blend treated with 3:1 molar excess of catechol.

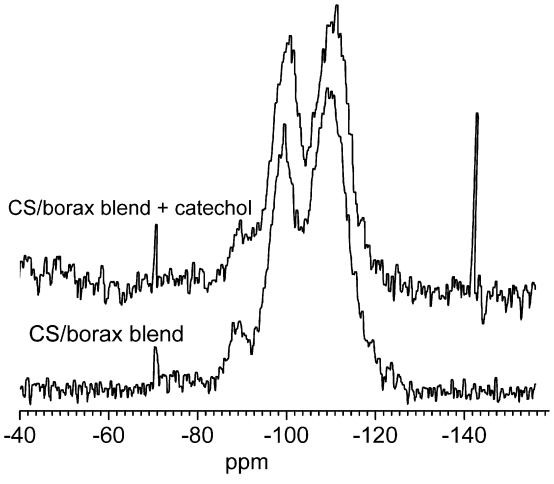

Fig. 3. ^{29}Si NMR spectra of a blend of colloidal silica with borax in the presence and absence of catechol.

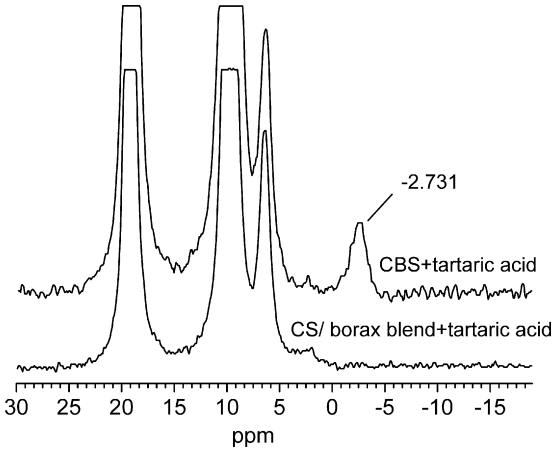

Fig. 4. ^{11}B NMR spectra of borosilicate and colloidal silicaborax blend treated with 3:1 molar excess of tartaric acid.

3.3. Chelation of borates in CBS and CS/borax blends with tartaric acid

Tartaric acid is also known to form complexes with soluble borates [19–21]. However, in contrast to catechol, it does not form complexes with silicon. As such, the risk of degrading colloidal silica and borosilicate particles is greatly diminished. The pH of the CBS and tartaric acid mixture was 3.05, and the pH of the blend and tartaric acid mixture was 3.40. The pH was not adjusted as it was expected that the amount of NaOH that would be required to adjust the pH from ~3 to 9.5 would have likely caused dissolution of a significant portion of the colloidal silica or borosilicate particles.

The spectra of CBS–H_2T mixture and CS/borax blend–H_2T mixture are shown in Fig. 4. The spectrum of H_2T treated CBS exhibits four distinct resonances, at 19.201, 8.710, 6.360, and −2.731 ppm. The resonance at 19.201 ppm represents free borate. The resonances at 8.710 and 6.360 ppm result from acid–borax complexes [21]. The most upfield resonance, at −2.731 ppm, arises from boron incorporated as colloidal borosilicate [7]. No changes were observed in the spectrum of this mixture recorded on the following day.

In the spectrum of tartaric acid added to the CS/borax blend, no signals characteristic of borosilicate are seen between 0 and −5 ppm. The boron species that had been present in this region (Fig. 1) were fully complexed by tartaric acid. These findings confirm the conclusion that boron species at −1.364 and −0.736 ppm in the spectrum of CS/borax blend arise from boron associated with the surface of the colloidal silica particle, which was accessible to tartaric acid contained in the continuous phase. The signals in the spectrum of mixtures of tartaric acid and the blend of CS/borax at 9.691 and 6.360 ppm result from tartaric acid–borate complexes, and the signal at 19.176 results from uncomplexed borate.

4. Conclusions

The results of conducted experiments prove that in CBS boron is incorporated throughout the colloidal particles as stable B–O–Si bonds. Although the chemical shifts of the boron in the CBS and CS/borax blend are similar, they are not equivalent, and represent chemically different boron species. Our complexation studies with catechol and tartaric acid illustrate the obvious difference between the boron species in colloidal borosilicate and colloidal silica/borax blends. The species in the blend were complexed by catechol and tartaric acid, indicating that these boron species are associated with the surface of the colloidal silica particle. In contrast, the observed borosilicate was stable toward the action of catechol and tartaric acid.

Among the nucleobases, adenine and its derivatives shows the widest range of binding possibilities because it can exhibit five donor sites, namely N9 [13], N7 [14], N3 [15], N1 [16–23] and N6 [24] or combinations of them [25–52] and a great variety of complexes with different metal ion binding patterns have been reported with both adenine and 9-substituted adenine.

Following our current research of crystallographic studies on metal–nucleobase systems, we studied reactivity of adenine towards Mg(II) and Mn(II) metal ions through the analysis of their complexes. In terms of ionic radius, coordination geometry, and ligand preferences, Mn^{2+} is considered a good mimic of Mg^{2+} in solution [53], although it is known its rather enhanced preference for soft donor sites such as N and S [54]. However, crystallographic report on coordinative Mn–N linkages, involving isolated nucleobases and their derivatives are scarce [55], being Mn(II) ion usually coordinated to water molecules, exocyclic oxygen atoms of purine or pirimidine rings or phosphate groups [55c–61].

We report herein the synthesis of new adenine containing compounds, $[Mg(H_2O)_6X_2 \cdot 2ade]$ (with $X = Cl^-$ (**1**), Br^- (**2**), ClO_4^- (**3**)), $[Mn(H_2O)_4 \cdot (ade)_2 \cdot (ClO_4)_2]$ (**4**), and $[Mn_2(H_2O)_6 \cdot (ade)_2 \cdot (NO_3)_4 \cdot 2H_2O]$ (**5**), (where ade = adenine) and their characterization by X-ray crystallography. Compounds **1**, **2** and **3** consist of hexaaquo metal ions, ade molecules and chloride (**1**), bromide (**2**) or perchlorate (**3**) ions self-assembled through an extended network of hydrogen bonding interactions. Compound **4** is made up of $[Mn(H_2O)_4 \cdot (ade)_2]^{2+}$ units, with the ade molecules directly coordinated to the metal centres through the N(3) atoms, while compound **5** contains $[Mn_2(H_2O)_6 \cdot (ade)_2]^{2+}$ dimers, with the ade ligands coordinated to the metal centres *via* N(3) and N(9) in a bidentate fashion. Compounds **1**, **2** and **3** represent additional examples of supramolecular assemblies containing Mg(II) hexaaquo ions [62a,63]. Compounds **4** and **5** represent the first example of direct binding between the Mn(II) ion and the adenine molecule. Furthermore, only few complexes containing Mn(II) metal ion directly linked to the N donor site of isolated nucleobases are known [55]. Our results reasonably suggest the greater reactivity of Mn(II) ion toward ade and an increased preference for soft donor sites such as N, when compared with Mg(II) ion, in which case the supramolecular assembly does not evolve towards the species containing direct metal-base links. Another interesting feature in compounds **1**, **2** and **4** is the protonation state of ade, which exists in the less common N9-deprotonated/N7-protonated tautomeric form [64].

2. Experimental

2.1. Materials

All the solvents and reagents for synthesis were commercially available and used as received. Elemental analyses (C, H, N) were performed by the Microanalytical Service of the Università della Calabria.

2.2. Synthesis of the complexes

Single crystals of **1**–**5** (colourless parallelepipeds) have been obtained by slow evaporation at room temperature and in the darkness of equimolar aqueous solutions of MgX_2 ($X = Cl^-$ (**1**), Br^- (**2**), ClO_4^- (**3**)) or MnX_2 ($X = ClO_4^-$ (**4**), NO_3^- (**5**)) and ade. In a typical experiment, the aqueous solution of ade was added dropwise to the aqueous solution containing the Mg(II) or Mn(II) salt with continuous stirring. Yields: 70% (**1**), 75% (**2**) and 70% (**3**), 65% (**4**) and 60% (**5**). Analytical data: *Anal.* Calc. for $C_{10}H_{22}N_{10}O_6Cl_2Mg_1$ (**1**): C, 25.36; H, 4.68; N, 29,58. Found: C, 25.45; H, 4.88; N, 29.21%. *Anal.* Calc. for $C_{10}H_{22}N_{10}O_6Br_2Mg_1$ (**2**): C, 21.35; H, 3.94; N, 24.90. Found: C, 21.56; H, 3.47; N, 24.69%. *Anal.* Calc. for $C_{10}H_{22}N_{10}O_{14}Cl_2Mg_1$ (**3**): C, 19.97; H, 3.69; N, 23.28. Found: C, 19.45; H, 3.36; N, 23.77%. *Anal.* Calc. for $C_{10}H_{18}N_{10}O_{12}Cl_2Mn_1$ (**4**): C, 20.15; H, 3.04; N, 23.50. Found: C, 20.45; H, 3.36; N, 23.79%. *Anal.* Calc. for $C_{10}H_{26}N_{14}O_{20}Mn_2$ (**5**): C, 15.55; H, 3.39; N, 25.39. Found: C, 15.41; H, 3.32; N, 25.77%.

2.3. Crystallographic data collection and structure determinations

X-ray diffraction data were collected using a Bruker R3m/V automatic four-circle for compound **1**–**3** and a Bruker-Nonius X8APEXII CCD area detector diffractometer for the other complexes. Graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) was used in both cases. Lorentz-polarization and empirical absorption corrections through the ψ-scan program [65] was applied for **1**–**3**. The data for compounds **4**–**5** were processed through the SAINT [66] reduction and SADABS [67] absorption software. The structures were solved by direct methods and subsequently completed by Fourier recycling using the SHELXTL software package [68]. Non-hydrogen atoms were refined anisotropically. The hydrogen atoms of the water molecules were located on a ΔF map and refined with three restraints for each molecule (O–H and H–H distances) with thermal factors fixed to 0.06 Å^2. The H7 hydrogen atoms of adenine molecules in compounds **1**, **2** and **4** were located on a ΔF map and refined with thermal factors fixed to 0.06 Å^2, whereas all the others hydrogen atoms of the adenine ligand in all compounds were set in calculated positions and refined as riding atoms. Full-matrix least-squares refinements on F^2, carried out by minimizing the function $\sum w(|F_o| - |F_c|)^2$, reached convergence with values of the discrepancy indices given in Table 1. The graphical manipulations were performed using the XP utility of the SHELXTL system and Crystal Maker Software [69]. Crystallographic data are listed in Table 1 while selected bond lengths and angles around the metal atoms are given in Tables 2 (**1**–**3**), 3 (**4**) and 4 (**5**).

3. Results and discussion

Compounds **1**, **2** and **3** consist of hexaaquo Mg(II) ions, ade molecules and chloride (**1**), bromide (**2**) or perchlorate (**3**) ions. The asymmetric unit of compounds **1**–**3** contains a chloride (**1**), bromide (**2**) or a perchlorate ion (**3**), an ade ligand and an Mg(II) ion, lying on a crystallographic inversion centre with a 0.5 occupancy factor, coordinated to three water molecules. Each Mg(II) metal ion is in a distorted octahedral environment, being bonded to six water molecules. The Mg(II)–O bond distances [mean values 2.060(1) Å (**1**), 2.060(2) Å (**2**) and 2.067(3) Å (**3**)] are in agreement with the values reported for other similar Mg(II) hexaaquo complexes [62,63]. Supramolecular architectures in the isostructural compounds **1**–**2**, and in **3** are different depending on the nature of counterions. In **1** and **2** each

$[Mg(H_2O)_6]^{2+}$ ion is linked through four H-bonds to two molecules of ade, involving two *cis*-coordinated water molecules [O(1) and O(2)] and the N(9) and N(3) atoms of the nucleobase [O(1)···N(3) 2.701(2) Å (**1**) and 2.707(3) Å (**2**); O(2)···N(9) 2.878(2) Å (**1**) and 2.889(3) Å (**2**)], leading to non-covalent stabilization of the 7H-adenine tautomer (Fig. 1a). The existence in the lattice of adenine nucleobase in its 7H-tautomer form has been unambiguously determined by the location of the H7 proton on the ΔF map and confirmed by the careful analysis of the hydrogen bonding pattern, and the observation of the internal angle at N7 (C(8)–N(7)–C(5) 106.1(1) in **1** and 106.6(2) in **2**) which is significantly larger than that involving the deprotonated N9 position (C(8)–N(9)–C(4) 103.6(1) in **1** and 103.4(2) in **2**). It is known that the protonation at N sites in the adenine does not modify substantially the bond distances but it enlarges the endocyclic C–N–C angle up to ca. 4° [70]. For comparison, these angles are 103.5 and 105.6° in the compound (9H-adenine) · $2H_2O$ [71]. The titled compounds represent the second examples of characterization at the solid-state of this minor tautomer as free molecule (without metal coordination) stabilized through non-covalent interactions. The first example of non-covalent stabilization of H7-adenine tautomer has been recently reported for the compound of formula [Mn(μ-ox)(H_2O)]-(7H-ade) [13q], (ox = oxalate). Even in this case, the N3 and N9 atoms of adenine establish strong O_w–H_w···N hydrogen bonds with coordinated water molecules.

The supramolecular architecture in **1**–**2** is built up by means of H-bonding and stacking interactions. Chloride (**1**) or bromide (**2**) anions are held with the cationic moiety $[Mg(H_2O)_6(ade)_2]^{2+}$ by means of H-bonds involving the oxygen atoms of the coordinated water molecules [O(3)···Cl(1) 3.142(2) Å (**1**) and O(3)···Br(1) 3.291(2) Å (**2**)], [O(3)···Cl(1b) 3.203(2) Å (**1**) and O(3)···Br(1b) 3.313(2) Å (**2**); (b) = $-x+1$, $-y+1$, $-z+1$], [Cl(1)···O(1e) 3.206(2) Å (**1**) and Br1)···O(1e)3.334(2) Å (**2**); (e) = $x-1$, $y+1$, z], generating layers developing in

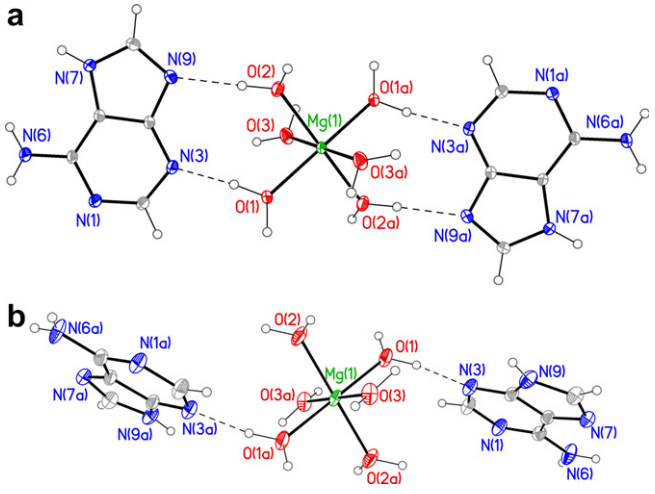

Fig. 1. Ortep drawing and atomic labeling scheme of compounds **1** (a) and **3** (b). Thermal ellipsoids are drawn at the 30% probability level.

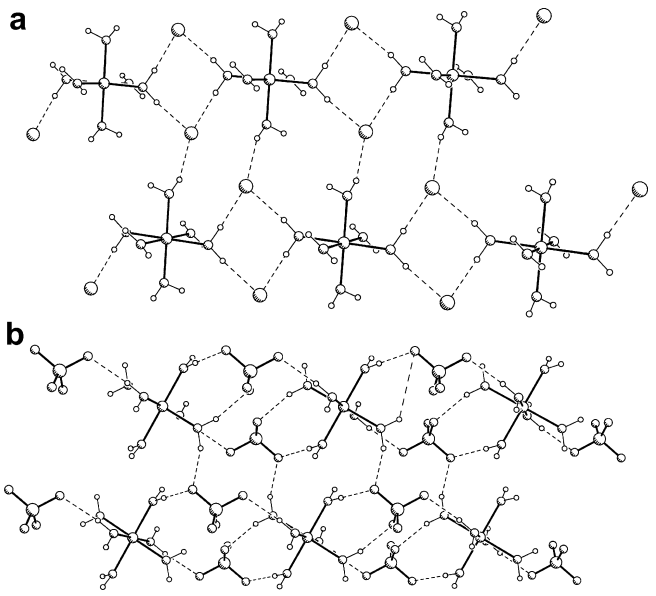

Fig. 2. View along *z*-axis of the inorganic layers of compounds **1**–**2** (a) and **3** (b) showing the H-bonding network.

the *xy* plane (Fig. 2). Layers of ade molecules, which are sandwiched between the planes defined by the $[Mg(H_2O)_6]^{2+}$ cations and the Cl^- or Br^- anions, alternate with the inorganic ones (Fig. 3a). The distances between consecutive Mg(II) ions along *x* and *y* directions correspond to the *a* and *b* crystallographic axes, respectively. The ade molecules within each organic layer are held to the inorganic planes also by means of H-bond interactions between O(2) and the N(1) atoms developing along the *x* direction [O(2)···N(1c) 2.808(2) Å (**1**) and 2.849(3) Å (**2**); (c) = $x-1$, y, z] (Fig. 4). The 3D arrangement is realized by π stacking interactions between purine rings, the interplanar distances being 3.35 (**1**) and 3.36 (**2**) Å (Fig. 5a).

In compound **3** each $[Mg(H_2O)_6]^{2+}$ ion is linked through two hydrogen bonds to two molecules of ade, involving two *trans*-coordinated water molecules [O(1) and O(1a); (a) = $-x$, $-y$, $1-z$] and the N(3) atoms of the nucleobase [O(1)···N(3) 2.712(5) Å] (Fig. 1b). Unlike **1** and **2**, in **3** the N(9) atom is protonated according to the more stable 9H-tautomer of ade, being the non-covalent stabilization of the 7H-tautomer not active in this case. In fact, the N9 atom is not involved in H-bonding interactions with the O(2) coordinated water molecules, as in **1** and **2**, being the suitable H_w on the O(2) atom already engaged in an H-bonding interaction with a ClO_4^- ion. The supramolecular architecture is built up by means of H-bonding and stacking interactions. Perchlorate anions are held with the cationic moiety $[Mg(H_2O)_6(ade)_2]^{2+}$ by means of H-bonds involving the oxygen atoms of the coordinated water molecules [O(2)···O(4) 3.039(6) Å, O(1)···O(6b) 3.105(6) Å, O(3)···O(6c) 2.890(6) Å, O(3)···O(7d) 2.990(6) Å; (b) = x, $y-1$, z; (c) = $-x+1$, $-y+1$, $-z+1$; (d) = $-x$, $-y+1$, $-z+1$], generating layers developing in the *xy* plane (Fig. 2b). The distances between consecutive Mg(II) ions along *x* and *y* directions correspond to the *a* and *b*

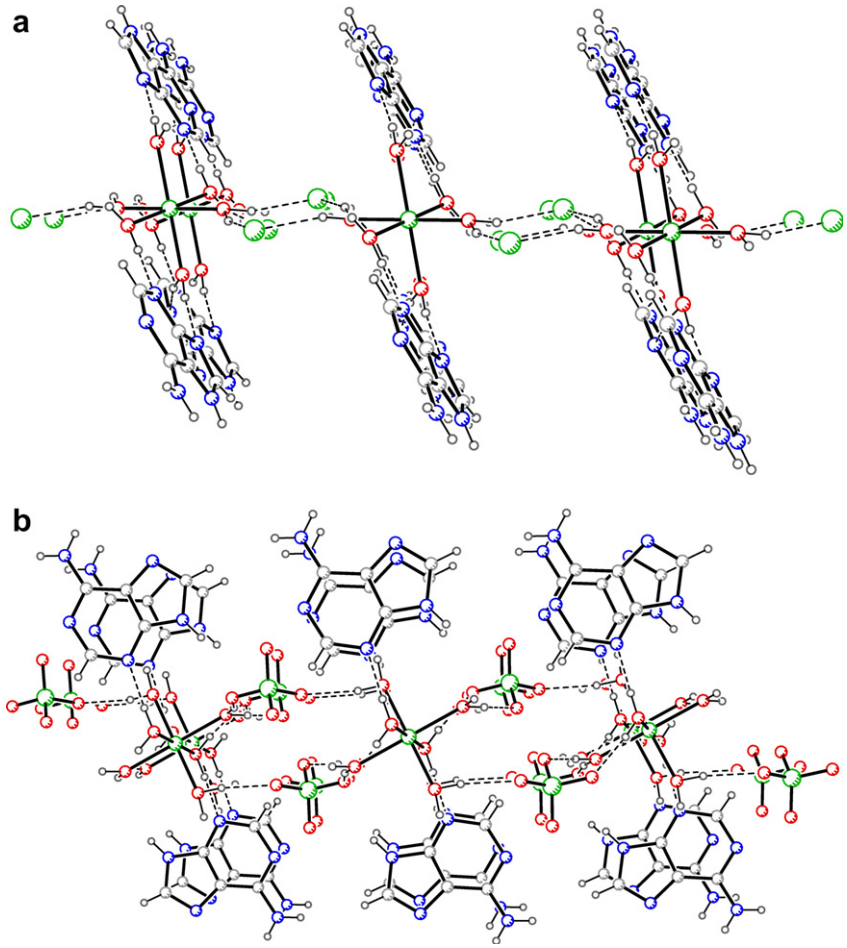

Fig. 3. View of the alternated inorganic and organic layers in *xy* plane in **1**, **2** (a) and **3** (b). Ade rings lie in the *xz* planes in **1**–**2** and in the *yz* plane in **3**.

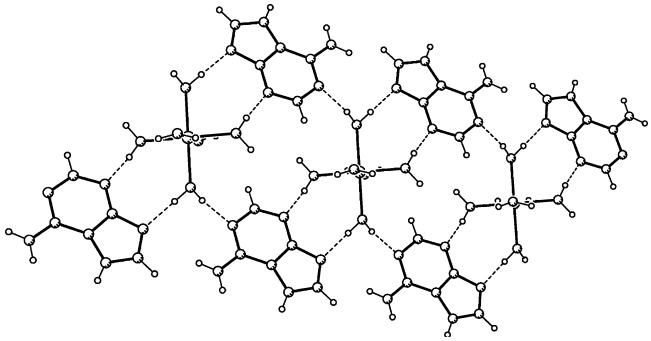

Fig. 4. Perspective view along *y*-axis of the H-bonding interactions between O(2) and the N(1) atoms in **1**–**2**.

crystallographic axes, respectively. Layers of ade molecules, which are sandwiched between the planes defined by the $[Mg(H_2O)_6]^{2+}$ cations and the ClO_4^- anions alternate to the inorganic ones (Fig. 3b). Unlike compounds **1**–**2**, where the ade molecules lie in the *xz* planes, in **3** the purine rings are positioned in the *yz* plane. Ade molecules H-bonded to consecutive inorganic layer are linked each other by means of interactions between the Watson–Crick edges, N1 and N6H [N(6)···N(1e) 2.956(6) Å; (e) = $-x+1, -y-1, -z+2$] (Fig. 6) and to the adjacent inorganic layers by means of the H-bond interactions between O(2) and N(7) [O(2)···N(7f) 2.751(5) Å; (f) = $x-1$, y, $z-1$]. These interactions together with the π-stacking between purine rings [interplanar distances being 3.28 Å] produce a 3D arrangement (Fig. 5b).

We can reasonably presume that the structural differences encountered in compound **1**–**2** and **3** rely on the nature and shape of the counterions.

The non-covalent stabilization of the 7H-adenine tautomer in **1**–**2** is the more evident difference compared with the perchlorate containing compound. From an accurate analysis of the crystal structures of compounds **1**–**2** and **3** it is possible to point out the differences that can leads to the stabilization of the two different 3D supramolecular networks and, consequently, of the 7H- (**1**, **2**) or 9H- (**3**) tautomers. In **1** and **2** each $Mg(H_2O)_6^{2+}$ ion is surrounded by six anions and four ade molecules (Fig. S1a). Four chloride (bromide) ions are H-bonded to O(3) and O(3a) water molecules, while the other two are H-bonded to O(1) and O(1a). Two ade molecules are H-bonded *via* N(3) with O(1) and O(1a), while the O(2) and O(2a) water molecules, not interacting with the anions, are H-bonded to the unprotonated N9 binding site, this non-covalent interaction leading to the stabilization of the H7-tautomer. Two

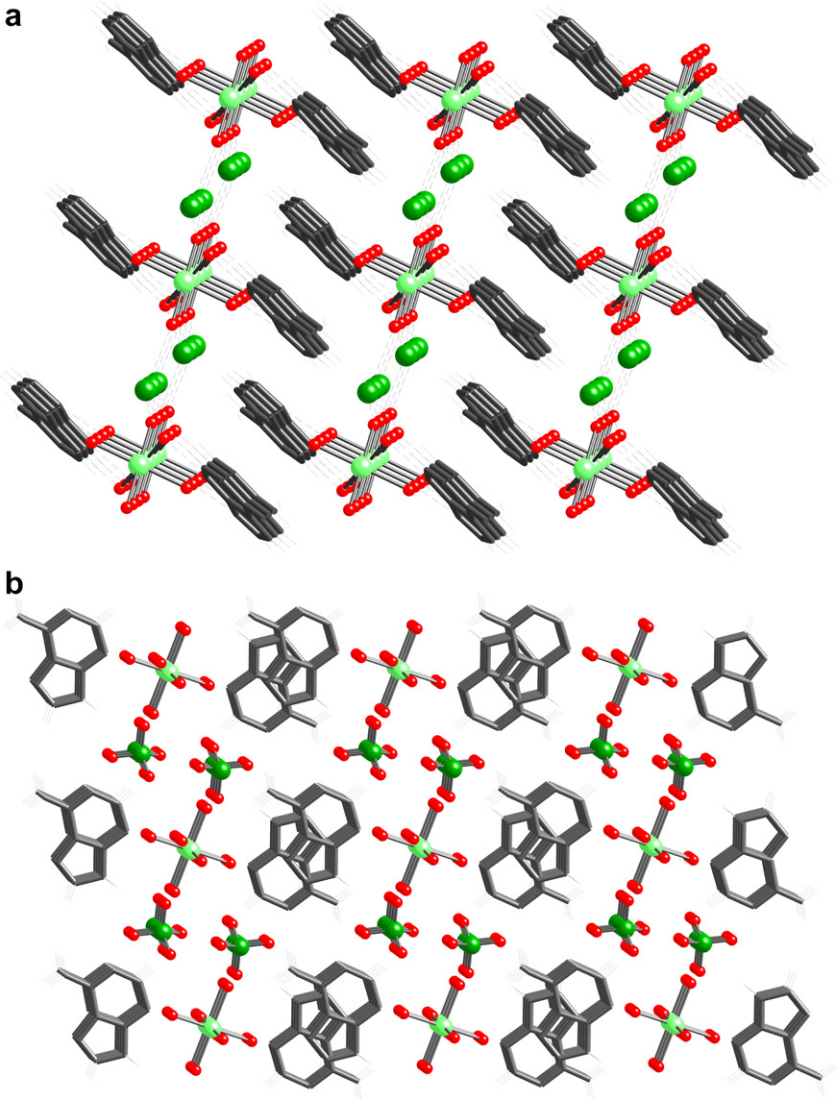

Fig. 5. View of the crystal packing of (a) **1**–**2**, and (b) **3**.

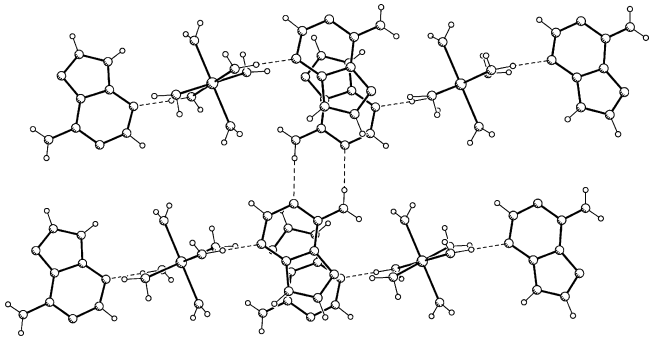

Fig. 6. View along *x*-axes of the Watson–Crick interactions between ade molecules H-bonded to consecutive inorganic layers in **3**.

other ade molecules are H-bonded *via* N1 to O(2). The second coordination sphere of the $Mg(H_2O)_6^{2+}$ ion in **3** is still formed by six anions and four ade molecules. Two of the four perchlorate ions interacting with O(3) and O(3a) water molecules are H-bonded to O(1) and O(1a) as well. Consequently, the remaining two perchlorate ions are H-bonded to O(2) and O(2a), creating sterical hindrance and making the suitable H_w no more available for H-bonding interaction with N(9), which is in this case protonated. Other two ade molecules interact with O(2) *via* N(7). This analysis let us suppose that the H-bonding interactions between the hexaaquo cations and the anions are the driving forces for the supramolecular assembling of the nucleobases, leading as consequential effect to the stabilization of one or the other tautomeric form.

Another observation can support this last hypothesis. A supramolecular architecture similar to that observed in compounds **1**–**2** has been recently described for the 1-Mecyt-containing compounds of formula $[Mg(H_2O)_6(1\text{-Mecyt})_2]Cl_2$, $[Ni(H_2O)_6(1\text{-Mecyt})_2]Cl_2$ [63]. In particular, compounds **1** and **2** present *quasi*-identical inorganic layers, comprising for only difference the lacking of an H-bond between chloride ions and O(2) water molecules if compared with the 1-Mecyt containing compounds. This

difference does not cause modification in the final arrangement of the inorganic net. The nucleobases 1-Mecyt and ade are H-bonded *via* N3/O2 and N3/N9, respectively, to the O(1) and O(2) water molecules in an identical manner. This results also support the hypothesis that H-bonding interactions in the inorganic networks drive the supramolecular assembling of the organic layers, producing very similar 3D architecture, which are independent from the nature of nucleobase.

Crystal structure of compound **4** is made up of $[Mn(H_2O)_4(ade)_2]^{2+}$ units and perchlorate ions. In the complex cation the manganese atom lies on a crystallographic inversion centre and is coordinated to four water molecules and to two *trans* unidentate adenine molecules directly linked *via* N3 (Fig. 7). Similar complexes have been reported in the case of Co(II) and Cu(II) metal ions, containing, respectively, ade and 9-substituted ade as ligand. In both case ade and 9Me-ade act as monodentate ligand, in the first case *via* N9 [13a], while in the second one the coordination occurs *via* N7, being N9 alkilated [14a]. The metal co-ordination in **4** is almost undistorted octahedral, with the ade ligand occupying the apical position of an elongated octahedron [Mn–N(3) = 2.295(1) Å]. The N9 atom of each ade ligand is involved in H-bonding interactions with the coordinated water molecules [O(2)···N(9a) 2.770(2) Å; (a) = $-x+1$, $-y$, $-z+1$], leading to stabilization of the 7H-adenine tautomer. Even in this case, the stabilization of the minor tautomer of ade is due to the existence of non-covalent interaction rather than the coordination to the metal centre. Other two examples exist in literature on complexes containing the tautomer 7H-adenine as ligand coordinated *via* N3 [15b,15f]. The perchlorate ion is anchored to the $[Mn(H_2O)_4(ade)_2]^{2+}$ cation by means of H-bonds involving O(5) and the coordinated water molecule O(1) [O(1)···O(5a) 3.054(2) Å]. The H-bonding interaction between the O(1) atom of a $[Mn(H_2O)_4(ade)_2]^{2+}$ unit and N(1) of another one [O(1)···N(1b) 2.775(2) Å; (b) = $-x$, $-y$, $-z+1$] defines a ribbon-like motif along *x*-axis (Fig. 8). The alternate of these ribbons with the perchlorate anions [O(2)···O(3c) 2.932(2) Å; (c) = $-x+1$, $-y$, $-z+2$] produce layers in the *xz* plane. The hydrogen bonds occurring between adjacent layers [N(6)···O(3d) 3.031(2), N(7)···O(5e) 3.036(2) Å; (d) = $x-1$, $y+1$, $z-1$, (e) = $-x+1$, $-y+1$, $-z+1$] give rise to the 3D supramolecular network.

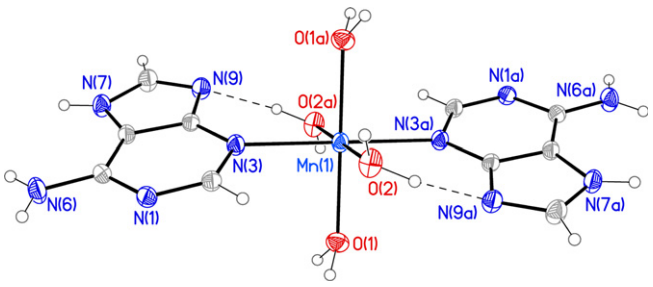

Fig. 7. Ortep drawing and atomic labeling scheme of compound **4**. Thermal ellipsoids are drawn at the 25% probability level.

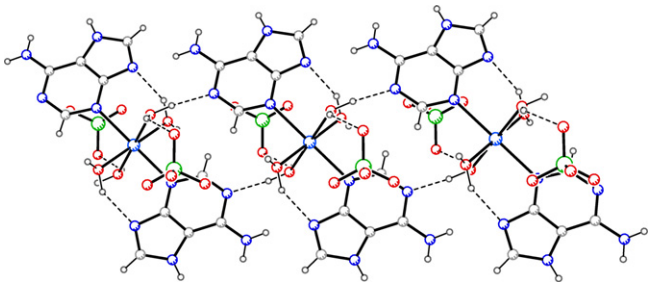

Fig. 8. View along *z*-axis of the ribbon motif in compound **4**.

The structure of **5** contains the centrosymmetric dimeric $[Mn_2(H_2O)_6(ade)_2]^{4+}$ cations, nitrate ions and crystallization water molecules. The two manganese of the dimeric units are bridged by two water molecules and two bidentate adenine ligands, coordinated *via* N3 and N9 (Fig. 9). This mode of base binding to metal ions is not unprecedented [25–29], even if never observed for Mn(II)-ade complexes. Each Mn(II) metal centre is in a distorted octahedral environment. The best equatorial plane is defined by the oxygen atoms O(1), O(2), O(3) and O(3a) of coordinated water molecules [(a) = $-x+1$, $-y+1$, $-z+1$], the maximum deviation being 0.082(1) Å at O(1), with the Mn(II) atom 0.097(1) Å out of this plane. The mean distorsion from octahedral geometry is due to the bidentate coordination of adenine, with the major deviation at the O(1)–Mn(1)–N(3) angle (104.63(5)°). The Mn···Mn distance within the dimeric unit is 3.3514(4) Å.

Anions and crystallization water molecules are held to the dimeric unit by means of hydrogen bonding interactions involving coordinated water molecules [O(2)···O(6) 2.743(2) Å; O(2)···O(10) 2.780(2) Å; O(3)···O(9) 2.657(2) Å; O(10)···O(9) 2.734(2) Å]. The dimeric units are held each other by means of H-bonds running along *z* axis involving the bridging water molecule O(3), the crystallization water molecule and the nitrate anions [O(1)···O(7a) 2.759(2) Å, O(3)···O(10b) 2.689(1) Å; (a) = $-x+1$, $-y+1$, $-z+1$, (b) = $-x+1$, $-y+1$, $-z+2$]. A

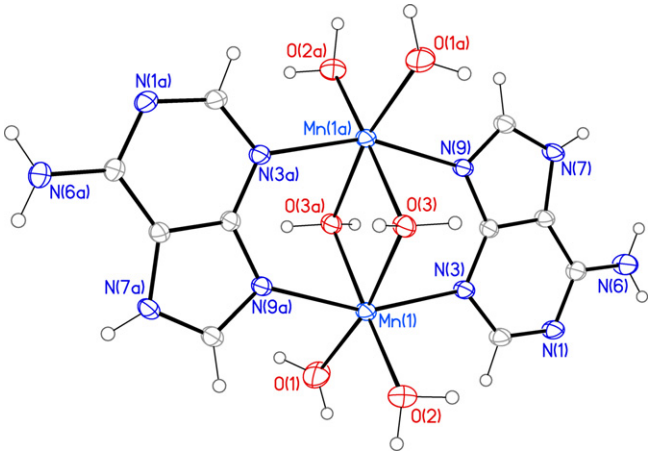

Fig. 9. Ortep drawing and atomic labeling scheme of compound **5**. Thermal ellipsoids are drawn at the 25% probability level.

bidimensional motif in the *xy* plane is obtained by the interaction of adenine ligands and nitrate ions [N(7)···O(6c) 2.792(2) Å, N(6)···O(4c) 2.906(2) Å, (c) = *x*-1,*y*,*z*-1]. The 3D supramolecular arrangement is achieved by further H-bonds [O(1)···O(4d) 2.764(2) Å, O(10)···N(1e) 2.808(2) Å, N(6)···O(8d) 3.077(2) Å; (d) = *x*, $-y+3/2$, $z-1/2$, (e) = *x*, $-y+3/2$, $z+1/2$].

4. Conclusions

Five new complexes with ade and M = Mg(II) or Mn(II) have been synthesized and structurally characterized. Their structural features are related to the different Mg(II) and Mn(II) reactivity with ade nucleobase. The greater reactivity of Mn(II) ion toward ade and an increased preference for soft donor sites such as N has been proved by obtaining two complexes (**4**, **5**), where the direct coordination of ade ligand *via* N3 (**4**) and N3/N9 (**5**) has been observed, in contrast to the Mg(II) ion, that in the same reaction condition, does not form complexes containing direct metal–nucleobase bonds. The detailed analysis of all the non-covalent interactions working in compounds **1**–**3** gives a comprehensive evidence of the influence of counterions on determining the H-bonds pattern involving the $[Mg(H_2O)_6]^{2+}$ cations and ade molecules. The strong H-bonding interactions between coordinated water molecules and the N9 binding site of ade in **1** and **2** lead to the non-covalent stabilization of the less common N9-deprotonated/N7-protonated tautomeric form of ade. A similar driving force is operative in compound **4**. On the contrary, these interactions are hindered by the presence of perchlorate ions in **3**, where the ade exist in the more stable N9-protonated form.

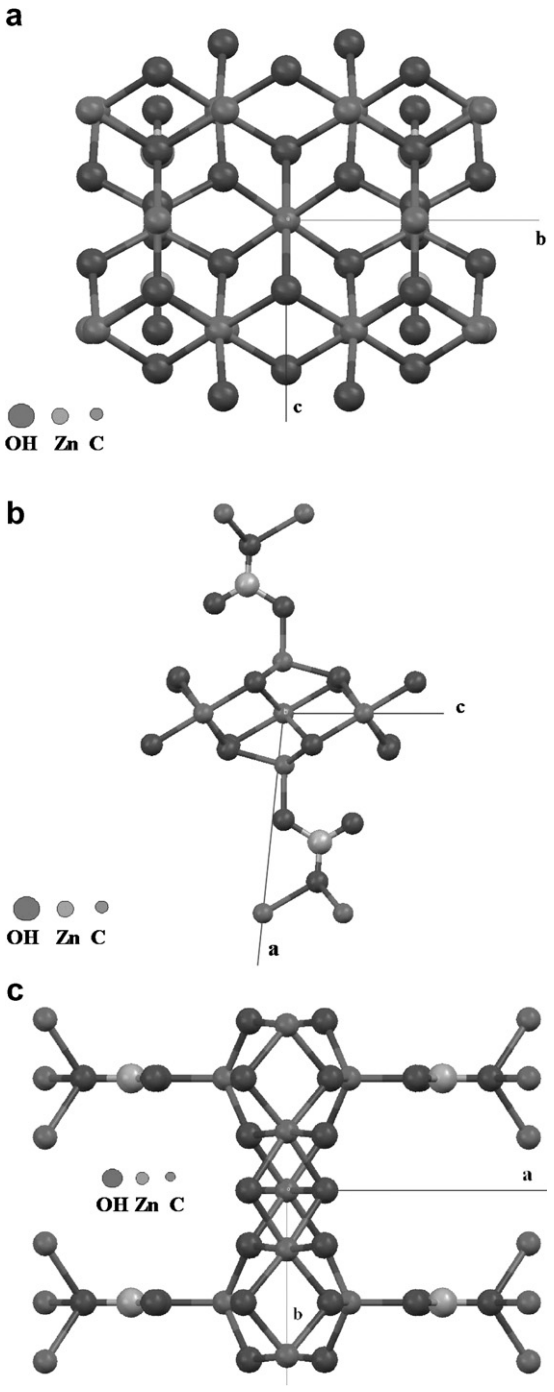

Fig. 1. Model of hydrozincite along the *a*, *b* and *c* axes.

figure displays the structure of hydrozincite looking along the *a*, *b* and *c* axes, respectively.

It is important to study the malachite–hydrozincite–hydrocerrusite assemblage and the stability of the system. The reason is that these minerals are the stable minerals at one atmosphere. One essential method is to use vibrational spectroscopic techniques. Infrared and Raman spectroscopy have been used to investigate carbonates including azurite and malachite [6,7]. A detailed single crystal Raman study of selected mineral carbonates has been undertaken [6,8]. This would seem important in the context of the stability of the hydroxy carbonates of Zn, Cu and Pb. However the vibrational spectroscopy of hydrozincite has not been undertaken. This may be due to the amorphous nature of the hydrozincite crusts. Few infrared spectral studies of related minerals such as the rosasite group have been forthcoming [7,9–11]. An infrared stretching vibration of the hydroxyl unit of azurite was observed at 3425 cm^{-1}, whereas two bands were reported for malachite at 3400 and 3320 cm^{-1}. The observation of two bands for malachite suggests coupling of the hydroxyl stretching vibrations [8]. This coupling was not observed for azurite [8]. Azurite and malachite form the basis of pigments in samples of an archaeological or medieval nature [12–15]. It is not known if hydrozincite was used in medieval paintings. Malachite has a characteristic infrared active intense band at ~430 cm^{-1} and for azurite an intense band at ~400 cm^{-1}. The deformation modes of azurite were reported at 1035 and 952 cm^{-1} and at 1045 and 875 cm^{-1} for malachite [7,16]. Hydrozincites from different origins showed differences in the infrared spectra in the OH stretching region [4]. These variations were accounted for by differences in stacking of the minerals [4]. Minerals in the rosasite mineral group, (a group of copper hydroxy carbonates) namely, rosasite, glaukosphaerite, kolwezite, mcguinnessite, nullaginite and pokrovskite have been studied by Raman spectroscopy at 298 and 77 K [17,18].

Vibrational spectroscopic studies of carbonate minerals have been undertaken over an extended period of time [19–21]. Adler and Kerr showed that differences in the infrared absorption spectra of carbonates were a function of cation size [19]. Some NIR studies have been undertaken [22,23]. Raman studies also have been forthcoming but not in recently [24–26]. Farmer reported the vibrational wavenumbers of calcite structured minerals (Table 12. IX p. 239) [2]. In this table the band positions for smithsonite were listed as 1093 cm^{-1} (v_1 symmetric stretching mode), 1412 and 1440 cm^{-1} (v_3 antisymmetric stretching mode), 870 cm^{-1} (v_2 in-plane bending mode), 733 and 743 cm^{-1} (v_4 out of plane bending mode) with lattice modes at 307, 200, 165 cm^{-1}. Some variation of band positions is found in the literature. Very little spectroscopic information on hydrozincite is available. However a comparison may be made with the mineral aurichalcite. The mineral aurichalcite $(Zn,Cu^{2+})_5(CO_3)_2(OH)_6$ is also monoclinic as are many of the other hydroxy carbonates such as malachite [27–29]. Aurichalcite forms in the oxidation zones of zinc–copper deposits. Crystals are similar to that of hydrozincite and are acicular and fibrous and often found in aggregates. Anthony et al. [1 reports aurichalcite to be acicular to lath-like crystals with prominent crystal growth along the [0 1 0] axis, commonly striated parallel to [0 0 1] axis. The mineral is of point group 2/*m* and space group $P2_1/m$ [1]. The accurate X-ray crystallography of aurichalcite is difficult to obtain because of its very small interwoven needles which makes obtaining single crystal studies difficult [1,3,29,30]. Harding [3 showed that the positions in the structure of

aurichalcite are octahedrally coordinated. The atom positions occupied by zinc have tetrahedral coordination [3]. Spectroscopic studies of aurichalcites and related minerals such as hydrozincite have been sparse. Reports regarding the chemical analysis, ESR, electronic and some limited infrared spectroscopic studies have been published [31]. These workers reported optical spectra revealing the presence of copper in D_{4h} symmetry with crystal field (Dq) and tetragonal field (Ds and Dt). This research was further extended in a comparison of rosasite and aurichalcite [32]. Optical and EPR spectra of aurichalcite accounted for Cu^{2+} ion in the distorted octahedron site [32]. Stoilova et al. [33] reported the infrared spectra of a series of synthetic hydroxy carbonates containing Cu^{2+}.

Raman spectroscopy has proven very useful for the study of minerals [34–36]. Indeed Raman spectroscopy has proven most useful for the study of diagentically related minerals often occurring with carbonate minerals [37–41]. Some previous studies have been undertaken by the authors using Raman spectroscopy to study complex secondary minerals formed by crystallisation from concentrated sulphate solutions [42]. The aim of this paper is to present Raman and infrared spectra of synthetic hydrozincites and smithsonite and to discuss the spectra from the structural point of view. The paper is a part of systematic studies of vibrational spectra of minerals of secondary origin in the oxide supergene zone and their synthetic analogs.

2. Experimental

2.1. Synthesis of hydrozincite and smithsonite

Three different synthesis techniques were trialled during the synthesis of hydrozincite. The first involved weighing out equimolar amounts of the Zinc (II) salt and the carbonate salt, dissolving in a minimum volume of deionised water and combining rapidly in a beaker of adequate size. The two Zinc salts used in the experiment were zinc chloride $ZnCl_2$ and zinc nitrate $Zn(NO_3)_2$. Sodium hydrogen carbonate $NaHCO_3$ was the source of the carbonate ion used for both experiments. The following chemical reaction occurs:

$$5ZnCl_2\ (s) + 10NaHCO_3\ (soln) \leftrightarrow Zn_5(CO_3)_2(OH)_6\ (s) + 8CO_2\ (g) + 10NaCl\ (soln) + 2H_2O$$

Smithsonite is formed according to the following reaction:

$$ZnCl_2\ (soln) + 2NaHCO_3\ (soln) \leftrightarrow ZnCO_3\ (s) + CO_2\ (g) + 2NaCl\ (soln) + H_2O$$

The second experiment involved a similar process of mixing the reactants but at a controlled rate using a peristaltic pump system operating at 10 cm min^{-1}. Both the zinc salt and carbonate salt were made up as standard solutions of equal concentration 0.5 M so that adding equivalent volumes 50 cm^3 of reagents gave the desired amounts of reagents according to the stoichiometry of the reaction. The pH of the reaction was monitored but remained essentially constant at pH = 7.2. The following alternative reaction is envisaged for the formation of smithsonite:

$$Zn_5(CO_3)_2(OH)_6\ (s) + 3CO_2\ (g) \leftrightarrow 5ZnCO_3\ (s) + 3H_2O\ (g).$$

The third synthesis method involved hydro-thermally treating some of the products from the previous two methods in a hydrothermal bomb at 100 °C for 48 h with adequate washing of the products after removal from the bomb. Adequate washing was achieved when the silver chloride test was negative. Thus indicating that all free chloride ions were removed. All of the samples were then washed and dried with ethanol and were placed in an oven at 80 °C over night to dry thoroughly.

From the XRD analysis, it was found that there was an impurity of another synthetic mineral found in the samples that had both used zinc chloride and had then been hydrothermally treated. It can be seen that hydrothermal treatment actually promotes the formation of this synthetic mineral identified as simonkolleite, a zinc chloride hydroxide hydrate mineral with the formula of $Zn_5(OH)_8Cl_2H_2O$. It is apparent that if the sample was synthesised using the $ZnCl_2$ and then hydro-thermally treated, the carbonate yield decreased significantly thereby increasing the yield of simonkolleite.

2.2. X-ray diffraction

XRD analyses were performed on a Philips PANalytical X'Pert PRO X-ray diffractometer (radius: 240.0 mm). Incident X-ray radiation was produced from a line focused PW3373/10 Cu X-ray tube, operating at 40 kV and 40 mA, providing a $K\alpha_1$ wavelength of 1.54 Å. The incident beam was monochromated through a 0.020 mm Ni filter then passed through a 0.04 rad. Soller slit, a 15 mm fixed mask and a 1/2° fixed anti scatter slit. After interaction with the sample, the diffracted beam passed though a secondary 0.04 rad. Soller slit and a 0.25° progressive divergence slit before detection by an X'Celerator RTMS detector. The detector was set in scanning mode, with an active length of 2.022 mm. Samples were analysed utilising Bragg-Brentano geometry over a range of 1.5–70° 2θ with a step size of 0.02° 2θ, with each step measured for 12.1 s. For all XRD analyses, the samples were dispersed in hexane and dropped onto low background quartz plates, forming a thin film upon evaporation of the hexane.

2.3. Raman microprobe spectroscopy

The crystals of hydrozincite or smithsonite were placed and oriented on the stage of an Olympus BHSM microscope, equipped with 10× and 50× objectives and part of a Renishaw 1000 Raman microscope system, which also includes a monochromator, a filter system and a Charge Coupled Device (CCD). Raman spectra were excited by a HeNe laser (633 nm) at a resolution of 2 cm^{-1} in the range

between 100 and 4000 cm^{-1}. Repeated acquisition using the highest magnification was accumulated to improve the signal to noise ratio. Band positions were calibrated using the 520.5 cm^{-1} line of a silicon wafer. In order to ensure that the correct spectra are obtained, the incident excitation radiation was scrambled. Previous studies by the authors provide more details of the experimental technique [43–46].

2.4. Mid-IR spectroscopy

Infrared spectra were obtained using a Nicolet Nexus 870 FTIR spectrometer with a smart endurance single bounce diamond ATR cell. Spectra over the 4000–525 cm^{-1} range were obtained by the co-addition of 64 scans with a resolution of 4 cm^{-1} and a mirror velocity of 0.6329 cm/s. Spectra were co-added to improve the signal to noise ratio.

Spectral manipulation such as baseline adjustment, smoothing and normalisation were performed using the Spectracalc software package GRAMS (Galactic Industries Corporation, NH, USA). Band component analysis was undertaken using the Jandel 'Peakfit' software package, which enabled the type of fitting function to be selected and allows specific parameters to be fixed or varied accordingly. Band fitting was done with the lowest possible number of Lorentz–Gauss cross-product functions. The Lorentz–Gauss ratio was maintained at values greater than 0.7 and fitting was undertaken until reproducible results were obtained with squared correlations of r^2 greater than 0.995.

3. Results and discussion

3.1. Relative stability of hydrozincite and smithsonite

The relative stability of hydrozincite and smithsonite are of importance to understand their formation in nature. Of the secondary minerals containing zinc only smithsonite and hydrozincite are known. The formation of these minerals is controlled by the partial pressure of CO_2 [47,48],

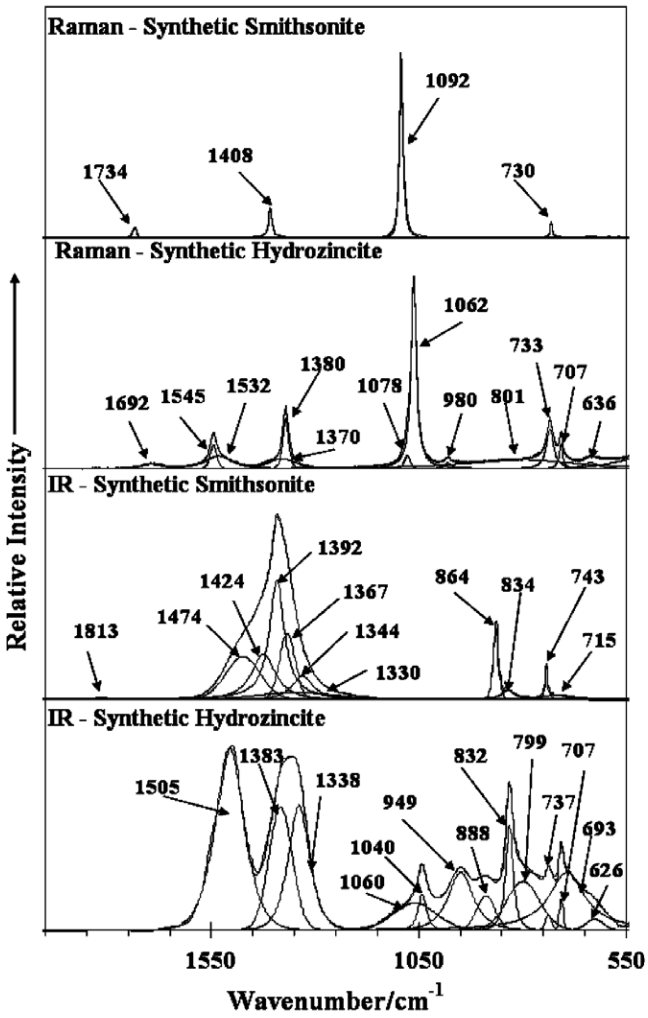

Fig. 3. Raman and infrared spectra of synthetic hydrozincite and smithsonite in the 550–1800 cm^{-1} region.

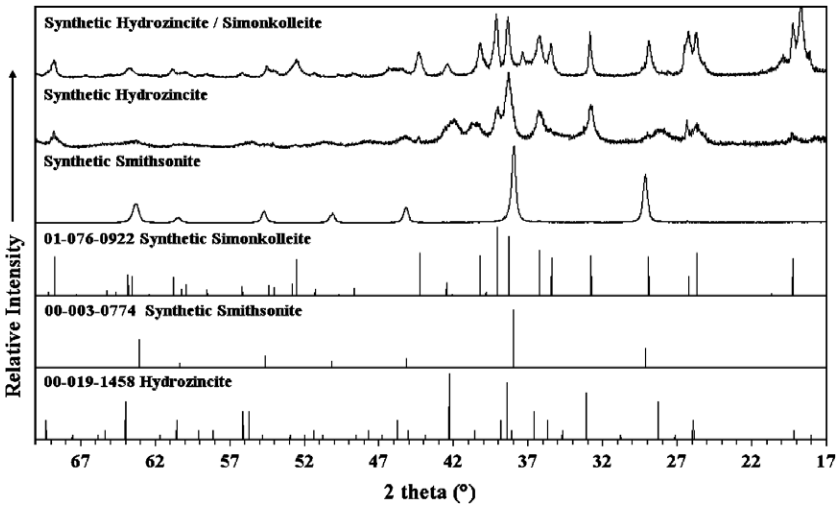

Fig. 2. XRD patterns of synthetic hydrozincite, smithsonite and simonkolleite and the reference patterns.

according to the equation for the formation of hydrozincite with $\log K = 10.32$ [47]. Thus ZnO is unstable with respect to hydrozincite at partial pressures above $10^{-5.16}$. If the partial pressure of CO_2 increases above $10^{-1.41}$ smithsonite formation is favoured according to the reaction $Zn_5(CO_3)_2(OH)_6$ (s) + $3CO_2$ (g) ↔ $5ZnCO_3$ (s) + $3H_2O$ (g). These results provide implications for the relative stability of hydrozincite and smithsonite. It is noted that hydrozincite may form from solutions resulting from oxidised zone of a Pb–Zn ore body [47]. Thus zincite (ZnO) is a rare mineral and smithsonite is only stable at elevated CO_2 partial pressures. The partial pressure range for the stability of hydrozincite according to Williams is limited and no doubt this accounts for the rarity of the mineral in nature [48]. The mineral can be readily synthesised in the laboratory and is often found in corrosion products of zinc [14,29,49]. In the presence of tenerite (CuO) the formation of malachite and/or azurite is favoured at the expense of hydrozincite [48]. Often the assembalge malachite–hydrozincite–hydrocerrusite is the stable system at 1 atm CO_2 pressure. Bouchard and Smith [14] reported the formation of a significant number of phases on metal coins including hydrozincite.

An impurity of simonkolleite with hydrozincite may be synthesised depending upon the starting materials. The conditions for the formation of simonkolleite are the same as that for hydrozincite. It was found that if zinc chloride was used in the synthesis and the sample was

hydrothermally treated, a significant yield of simonkolleite was produced. The sample proved to be a mixed phase of simonkolleite and hydrozincite. It is also interesting that when smithsonite is formed, simonkolleite was not. The XRD patterns together with standard XRD reference patterns of synthetic smithsonite and hydrozincite are shown in Fig. 2. Clearly the pure hydrozincite and smithsonite phases were synthesised as single phases.

3.2. Spectroscopy

The Raman and infrared spectra of synthetic hydrozincite and smithsonite in the 550–1800 cm^{-1} region are shown in Fig. 3. The results of the band component analysis are reported in Table 1. Raman bands are assigned according to published data and by comparison with data for other minerals [18,45,50–58]. The Raman spectrum of synthetic hydrozincite shows an intense sharp band at 1062 cm^{-1}. Other low intensity bands are observed at 1078 and 980 cm^{-1}. The latter Raman band at 980 cm^{-1} is assigned to the δ OH deformation mode. The Raman spectrum of synthetic smithsonite shows a sharp band at 1092 cm^{-1}. These bands are assigned to the v_1 symmetric stretching mode of the carbonate unit. Infrared bands in this position are not observed for smithsonite. However a band at 1040 cm^{-1} is found in the infrared spectrum of synthetic hydrozincite. The $(CO_3)^{2-}$ v_1 band of the hydrozincite compound should not be infrared active. However, because of symmetry reduction of the carbonate anion through distortion the infrared band becomes activated.

A number of low intensity Raman bands are observed in the 1300–1500 cm^{-1} region (Fig. 3). A single band for synthetic smithsonite is observed at 1408 cm^{-1} and for hydrozincite bands at 1545 and 1380 cm^{-1} are found. These bands may be ascribed to the v_3 $(CO_3)^{2-}$ antisymmetric stretching modes. In the infrared spectrum of synthetic smithsonite a broad spectral profile centred on 1392 cm^{-1} is observed and is assigned to the v_3 $(CO_3)^{2-}$ antisymmetric stretching modes. In the infrared spectrum of synthetic hydrozincite bands are observed at 1505, 1383 and 1338 cm^{-1}. The difference in the number of bands in this spectral region of smithsonite and hydrozincite is ascribed to the symmetry reduction of the hydrozincite.

The v_2 bending mode for carbonates varies from around 890 to 850 cm^{-1}. For smithsonite Farmer reported an infrared band at 870 cm^{-1} [2]. For hydrozincite the infrared band was observed at 837 cm^{-1} [2]. In this work no Raman bands are observed for synthetic smithsonite or hydrozincite in this position. In the infrared spectrum of synthetic hydrozincite bands are observed at 888, 832 cm^{-1} with a broad feature at 799 cm^{-1}. In the infrared spectrum of smithsonite two bands are observed at 864 and 834 cm^{-1}. These bands are assigned to the carbonate v_2 bending mode. The observation of more than one v_2 mode suggests symmetry reduction of the carbonate anion in the structure. A comparison may be made with the spectra of other hydroxycarbonates. A mineral similar to hydrozincite is aurichalcite $(Zn,Cu)_5(CO_3)_2(OH)_6$. For aurichalcite two Raman bands may be resolved at 860 and 845 cm^{-1}. Only a single band at 817 cm^{-1} is observed in this region for malachite $Cu_2(CO_3)(OH)_2$. The FTIR spectrum of malachite showed two bands at 879 and 821 cm^{-1} [8]. This FTIR spectral region is more complex for azurite $Cu_3(CO_3)_2(OH)_2$ with bands observed at 872, 837, 815 and 796 cm^{-1}.

Multiple bands are observed for the carbonate v_4 in phase bending modes in the Raman spectrum of hydrozincite with bands at 733, 707 and 636 cm^{-1}. The number of bands observed in this spectral region may be attributed to the structural distortion of the mineral. For smithsonite only a single band at 730 cm^{-1} is observed. Farmer (based upon the work of Moenke [21]) reported two infrared bands for hydrozincite at 738 and 710 cm^{-1} [2]. Farmer also reported only a single band for smithsonite at 733 cm^{-1}. In the infrared spectrum of synthetic hydrozincite a broad complex spectral profile with two bands resolved at 737 and 707 cm^{-1} is observed. In the infrared spectrum of synthetic smithsonite two bands at 743 and 715 cm^{-1} are observed. It is interesting that in the Raman

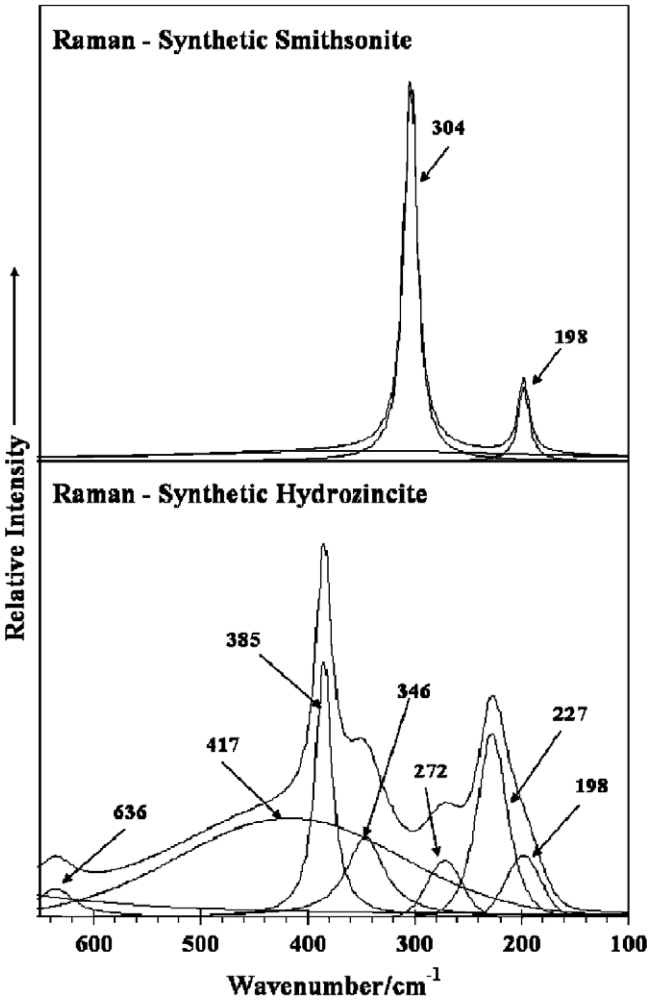

Fig. 4. Raman and infrared spectra of synthetic hydrozincite and smithsonite in the 100–600 cm^{-1} region.

spectrum of aurichalicte three bands are observed at 752, 733 and 708 cm^{-1}. The equivalent Raman bands for malachite are observed at 752 and 717 cm^{-1}. In the infrared spectra bands are observed at 779, 754 and 701 cm^{-1} for azurite and at 780, 750 and 715 cm^{-1} for malachite [8].

In the Raman spectrum of smithsonite in the 100 to 600 cm^{-1} region, two prominent bands are observed at 304 and 198 cm^{-1} (Fig. 4). These bands are assigned to lattice modes. Farmer reported lattice modes in the infrared spectrum of smithsonite at 307, 200 and 165 cm^{-1} [2]. For hydrozincite Raman bands are observed at 385, 346, 272 and 227 cm^{-1}. Bands in this spectral region have not been previously defined. The Raman spectra of the OH stretching region of the three aurichalcite mineral samples are shown in Fig. 5. The Raman spectrum of smithsonite shows two bands at 3472 and 3265 cm^{-1} and the infrared spectrum a single band at 3356 cm^{-1}. These bands are attributed to adsorbed water. For synthetic hydrozincite infrared bands are observed at 3291, 3063 and 2895 cm^{-1} and Raman bands are found at 3541, 3407, 3286 cm^{-1}. Farmer based upon the work of Moenke reported bands for hydrozincite at 3300 and 3260 cm^{-1}. A single symmetric band is observed for aurichalcite at 3338 cm^{-1}. A comparison can be made with rosasite where two distinct bands are observed at 3387 and 3319 cm^{-1}. The bands are assigned to the OH stretching vibration. Bouchard and Smith [14] reported a noticeably broad band in the Raman spectrum of aurichalcite at 3331 cm^{-1}. This value is in good agreement with the results reported in this work. Infrared bands for aurichalcite are observed at 3491, 3350, 3244 and a broad band at 3173 cm^{-1}. The infrared spectrum of a second aurichalcite mineral gave bands at 3359, 3249 and 3106 cm^{-1}. The broad band at around 3163 cm^{-1} may be ascribed to adsorbed water. The first two bands are assigned to OH stretching vibrations.

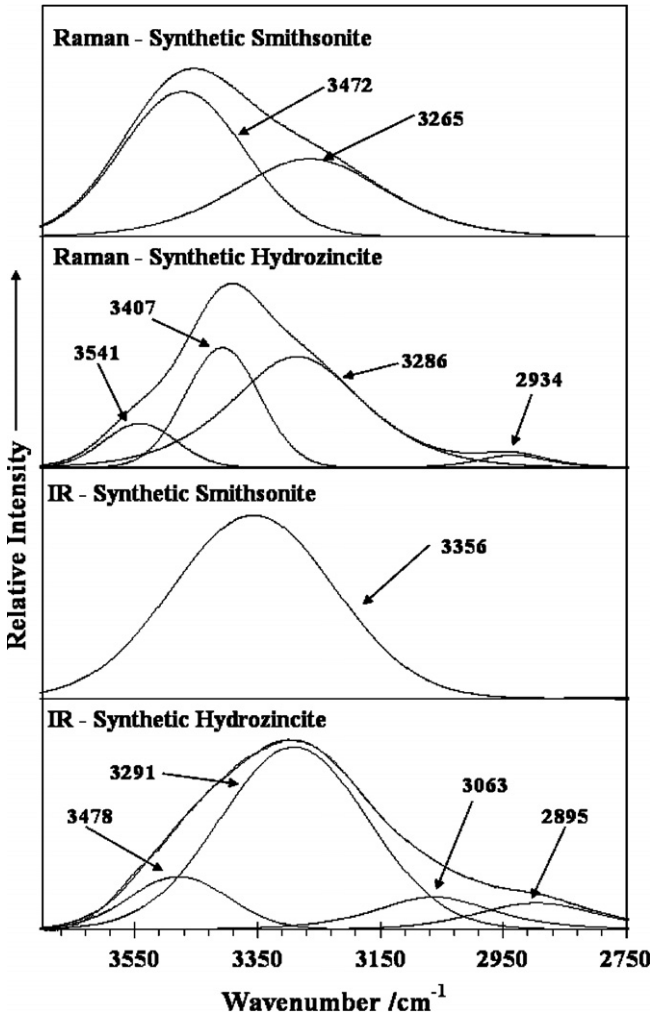

Fig. 5. Raman and infrared spectra of synthetic hydrozincite and smithsonite in the 2750–3600 cm^{-1} region.

4. Conclusions

Of the secondary minerals of zinc only two minerals are known, namely smithsonite and hydrozincite and their formation of is controlled by the partial pressure of CO_2according to the reactions $5ZnO(s) + 2CO_2\ (g) \leftrightarrow Zn_5(CO_3)_2(OH)_6\ (s)$ and $Zn_5(CO_3)_2(OH)_6\ (s) + 3CO_2\ (g) \leftrightarrow 5ZnCO_3\ (s) + 3H_2O\ (g)$. An impurity of simonkolleite with hydrozincite was synthesised depending upon the starting materials

The Raman spectra of synthetic hydrozincite and smithsonite show intense sharp bands at 1062 and 1092 cm^{-1}, assigned to the v_1 symmetric stretching mode of carbonate. Raman bands for synthetic smithsonite is observed at 1408 cm^{-1} and for hydrozincite bands at 1545 and 1380 cm^{-1} and are ascribed to the v_3 $(CO_3)^{2-}$ antisymmetric stretching modes. Multiple bands are observed for the carbonate v_4 in phase bending modes in the Raman spectrum of hydrozincite with bands at 733, 707 and 636 cm^{-1}. The number of bands observed in this spectral region may be attributed to the structural distortion of the mineral. For smithsonite only a single band at 730 cm^{-1} is observed. No Raman bands are observed for synthetic smithsonite or hydrozincite around 850 cm^{-1}. This is the expected position of the v_2 mode. In the infrared spectrum of synthetic hydrozincite bands are observed at 888, 832 cm^{-1} with a broad feature at 799 cm^{-1}.

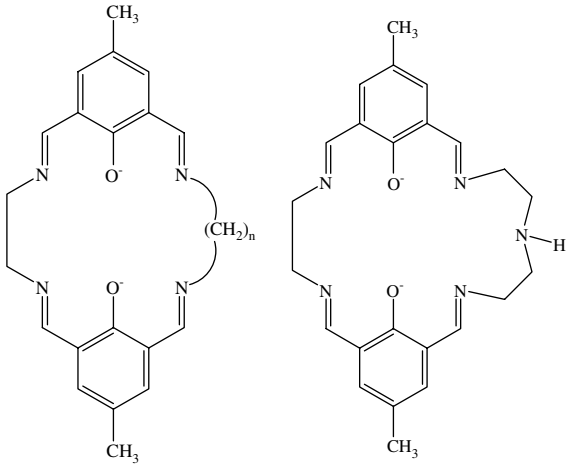

Chart 1.

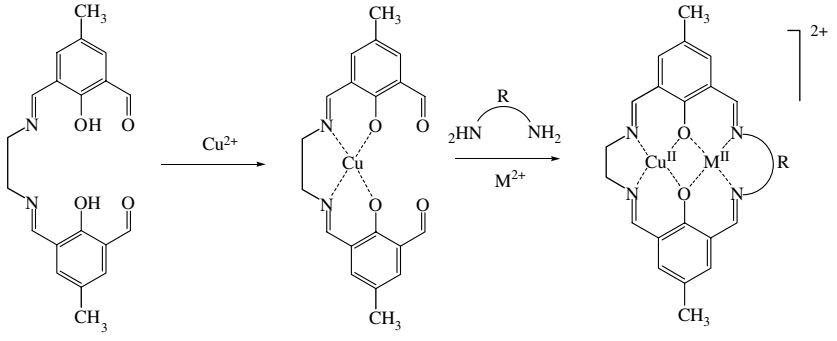
if one were to use various polyamines with methyl(s) or other groups on the lateral diimine chain, and further to evaluate the biological activities. Although a considerable amount of work has been performed on the biological activity of mononuclear, homo- and heterodinuclear complexes [24–29], the quest for the development of new bioactive substances still persists. Consequently the structural study and screening of antibacterial and antifungal activity of the new heterodinuclear complexes will be of interest.

In this report, we describe the synthesis of eight new heterodinuclear complexes (Chart 2), by the template reaction of the Okawa mononuclear Cu(II) precursor, CuL, with *N*,*N*-bis(2-aminoethyl)benzylamine, *N*,*N*-bis(2-aminoethyl)-2-phenyl ethylamine, 2,2-dimethyl-1,3-propanediamine and 1,2-diaminopropane in the presence of Zn^{2+} and/or Pb^{2+} ions, which finally were isolated as solids and characterized. The macrocycles L^1 and L^2 bear a 4-coordination site with a N_2O_2 "salen-like" donor set and a 5-coordination site with a N_3O_2 "saldien-like" donor set. The macrocycles L^3 and L^4 bear two 4-coordination sites with N_2O_2 "salen-like" donor sets.



The structure of $[CuZnL^3(H_2O)](ClO_4)_2$ has been determined by X-ray diffraction and shows that the Zn(II) and Cu(II) centres reside in the N_2O_2 "salen-like" sites of the macrocyclic ligand, sharing the bridging phenolic oxygen atoms. The fifth coordination site for the Zn centre is occupied by a water ligand. The spectral study of all the complexes is reported together with the microanalysis and molar conductivity data.

We also explored the antibacterial and antifungal activities of all the prepared heterodinuclear complexes, as well as CuL, against *Escherichia coli*, *Candida albicans* and *Staphyloccocus aureus*.

2. Experimental

2.1. General Information

All of the chemicals and solvents were purchased from Aldrich and Merck. 2,6-Diformyl-4-methylphenol, *N*,*N*-bis(2-aminoethyl)-2-phenyl-ethylamine three hydrobromide and *N*,*N*′-bis(3-formyl-5-methylsalicylidene)ethane-1,2-diamine (H_2L) and [*N*,*N*′-bis(3-formyl-5-methylsalicylidene)ethane-1,2-diaminato]copper(II), (CuL), were prepared according to the literature method [23,30,31]. ^1H and $^{13}C\{^1H\}$ NMR spectra were obtained on a Bruker Avance 300 MHz spectrometer. IR spectra were recorded as pressed KBr discs, using a Unicom Galaxy Series FTIR 5000 spectrophotometer (200–4000 cm^{-1}). Electronic spectral measurements were carried out using a Perkin–Elmer Lamda spectrophotometer in the range 200–900 nm. C, H and N analyses were performed on a Vario EL III elemen-

H_2L CuL M=Zn, Pb

ligands	R
L^1	$-CH_2CH_2N(CH_2Ph)CH_2CH_2-$
L^2	$-CH_2CH_2N(CH_2CH_2Ph)CH_2CH_2-$
L^3	$-CH_2C(CH_3)_2CH_2-$
L^4	$-CH(CH_3)CH_2-$

Chart 2. The template condensation between CuL and polyamines in the presence of M(II) ions (M = Zn, Pb).

tal analyser. Metal analyses were made on a Perkin–Elmer 2380 atomic absorption/flame emission spectrophotometer. Conductivity measurements were carried out at 20 °C with a Metrohm 712 conductometer using 10^{-3} M solutions of the complexes in DMF.

2.2. X-ray crystal structure determination

Vapor diffusion of diethyl ether into a solution of $[CuZn(L^3)(H_2O)(ClO_4)]$ ClO_4 (**6**) in acetonitrile afforded crystals suitable for study by X-ray crystallography. Crystal data were collected on a STOE IPDS-II diffractometer with graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). Cell constants and an orientation matrix for the data collection were obtained by least-squares refinement of diffraction data from 7150 unique reflections. Data were collected at a temperature of 293(2) K to a maximum 2θ value of 53.74° and in a series of ω scans in 1° oscillations, and integrated using the Stoe X-AREA [32] software package. The numerical absorption coefficients, μ, for Mo Kα radiation are 1.132 mm^{-1} for 1, 1.314 mm^{-1} for 2 and 1.446 mm^{-1} for 3. The numerical absorption coefficient, μ, for Mo Kα radiation is 1.566 mm^{-1}. A numerical absorption correction was applied using X-RED [33] and X-SHAPE [34] software. The data were corrected for Lorentz and Polarizing effects. The structure was solved by direct methods and subsequent difference Fourier maps and then refined on F^2 by a full-matrix least-squares procedure using anisotropic displacement parameters [35]. All of the hydrogen atoms were located in a difference Fourier map and then after refined isotropically. Subsequent refinement then converged with R factors and parameters errors significantly better than for all attempts to model the solvent disorder. All refinements were performed using the X-STEP32 crystallographic software package [36]. Additional details of the data collection and refinement for the structure is given in Table 1.

2.3. Antibacterial and antifungal study

CuL and all the prepared complexes were screened for their activity against *E. coli*, *S. aureus* and *C. albicans* (CA) strains by the disc diffusion method as gram negative, gram positive and fungal organisms, respectively. Muller Hinton agar and Sabouraud dextrose agar were used to culture bacteria and fungi, respectively. The culture media was poured into sterile plates and microorganisms were introduced on the surface of the agar plates individually. The blank sterile discs, measuring 6.4 mm in diameter, were soaked in a known concentration of the test compounds. Then the soaked discs were implanted on the surface of the plates. A blank disc was soaked in the solvent (DMSO) and implanted as a negative control on each plate along with the standard drugs. The plates were incubated at 37 °C (24 h) and 27 °C (48 h) for bacterial and fungal strains, respectively. The inhibition zones were measured and compared with standard drugs. The zone of inhibition values are given in Table 4.

2.4. Synthesis of N,N-bis(2-aminoethyl)benzylamine trihydrobromide (aeba.3HBr)

N,*N*-bis(2-aminoethyl)benzylamine three hydrobromide was prepared by the reaction of benzylamine with *N*-tosylaziridine (1:2) in acetonitrile at room temperature for 5 days followed by detosylation with HBr/AcOH, as described previously for *N*,*N*-bis(2-aminoethyl)-2-phenylethylamine trihydrobromide (aepa.3HBr) [31]. Overall Yield: 54%. ^{1}H NMR (D_2O, ppm) δ 3.35 (t, 4 H), 3.51 (t, 4H), 4.39 (s, 2H), 7.45 (m, 5H).^{13}C{^{1}H}NMR (D_2O, ppm) δ 135.4, 129.3, 129.1, 127.7, 49.7, 33.9, 29.5. *Anal.* Calc. for $C_{11}H_{22}N_3Br_3$: C, 30.29; H, 5.04; N, 9.63. Found: C, 30.2; H, 5.2; N, 9.4%.

Safety note: Perchlorate complexes are potentially explosive. While we have not experienced any problems with the compounds described, they should be treated with caution and handled in small quantities.

2.5. General procedure for the synthesis of **1**, **2**, **3** and **4**

A solution of KOH (1.5 mmol) in absolute EtOH (10 ml) was added to a suspension of the triamine salt (aeba.3HBr or aepa. 3HBr) (0.5 mmol) in absolute EtOH

(10 ml) and the mixture was stirred at room temperature for 15 min. The mixture was filtered and the precipitate was washed well with absolute EtOH (10 ml). This solution was added dropwise to a stirring suspension of CuL (0.5 mmol) and metal salt ($Pb(NO_3)_2 \cdot 3H_2O$ or $Zn(ClO_4)_2 \cdot 6H_2O$) (0.5 mmol) in DMF (30 ml) over a period of 15 min. $NaClO_4$ (1 mmol) was added, and the mixture was stirred for an additional 20 min at ambient temperature. The solution was allowed to settle for 12 h at 0 °C. The resultant product was collected by filtration and washed successively with diethyl ether.

$[CuPb(L^1)(dmf)(ClO_4)](ClO_4)$ (**1**): The solid product was filtered off, washed with EtOH and dissolved in acetonitrile-DMF (1:1). The resulting solution was left to crystallize at room temperature to afford **1** as a brown powder. Yield: 42%. *Anal.* Calc. for $C_{34}H_{40}N_6O_{11}Cl_2CuPb$: C, 38.89; H, 3.81; N, 8.00; Cu, 6.05. Found: C, 38.6; H, 3.5; N, 8.2; Cu, 6.3%. IR (KBr) cm^{-1}: 1640, 1625(C=N), 1327 (C–O), 1092, 1075, 1055, 621, 509, 448, 378, 334. Λ_M: 223 Ω^{-1} cm^2 mol^{-1}. UV–Vis λ_{max} (nm) (ε (M^{-1} cm^{-1})): 274, 380 (12 500), 549 (160) in DMF.

$[CuZn(L^1)(H_2O)](ClO_4)_2$ (**2**): The solid product was filtered off, washed with EtOH and dissolved in acetonitrile–THF (1:1). The resulting solution was left to crystallize at room temperature to afford **2** as a green powder. Yield 53%. *Anal.* Calc. for $C_{31}H_{35}N_5O_{11}Cl_2CuZn$: C, 43.64; H, 4.10; N, 8.20; Cu, 7.44. Found: C, 43.8; H, 4.4; N, 8.5; Cu, 7.8%. IR (KBr) cm^{-1}: 1660, 1639 (C=N), 1340 (C–O), 1087, 621, 502, 485, 356, 338. Λ_M: 232 Ω^{-1} cm^2 mol^{-1}. UV–Vis λ_{max}(nm) (ε (M^{-1} cm^{-1})): 270, 377 (11 800), 480–650 (100) in DMF.

$[CuPb(L^2)(dmf)](ClO_4)_2 \cdot dmf$ (**3**): The solid product was filtered off, washed with EtOH and dissolved in acetonitrile–DMF (1:1). The resulting solution was left to crystallize at room temperature to afford **3** as red microcrystals. Yield 41%. *Anal.* Calc. for $C_{38}H_{49}N_7O_{12}Cl_2CuPb$: C, 40.13; H, 4.31; N, 8.62; Cu, 5.59. Found: C, 40.2; H, 4.4; N, 8.6; Cu, 5.7%. IR (KBr) cm^{-1}: 1642, 1628 (C=N), 1329 (C–O), 1093, 623, 661, 507, 440, 374, 337. Λ_M: 238 Ω^{-1} cm^2 mol^{-1}. UV–Vis λ_{max} (nm) (ε (M^{-1} cm^{-1})): 276, 380 (12 100), 560 (150) in DMF.

$[CuZn(L^2)(H_2O)](ClO_4)_2$ (**4**): The solid product was filtered off, washed with EtOH and dissolved in acetonitrile. The resulting solution was left to crystallize at room temperature to afford **4** as a green powder. Yield 40%. *Anal.* Calc. for $C_{32}H_{37}N_5O_{11}Cl_2CuZn$: C, 44.31; H, 4.27; N, 8.07; Cu, 7.33. Found: C, 44.3; H, 4.3; N, 8.1; Cu, 7.2%. IR (KBr) cm^{-1}:1649, 1620 (C=N), 1327 (C–O), 1091, 623, 510, 486, 359, 336. Λ_M: 242 Ω^{-1} cm^2 mol^{-1}. UV–Vis λ_{max} (nm) (ε (M^{-1} cm^{-1})): 272, 398(12 400), 595(180) in DMF.

2.6. General procedure for the synthesis of *5*, *6*, *7* and *8*

A solution of di-amine (2,2-dimethyl-1,3-propanediamine or 1,2-diaminopropane) (0.5 mmol) in EtOH (20 ml) was added dropwise to a stirred suspension of CuL (0.5 mmol) and metal salt ($Pb(NO_3)_2 \cdot 3H_2O$ or $Zn(ClO_4)_2 \cdot 6H_2O$) (0.5 mmol) in CH_2Cl_2–MeOH (1:1) (20 ml) over a period of 10 min. Except for **5**, $NaClO_4$ (1 mmol) was added. The mixture was stirred for 3 h at ambient temperature. The solution was allowed to settle for 12 h at 0 °C. The resultant product was collected by filtration and washed successively with diethyl ether.

$[CuPb(L^3)(NO_3)](NO_3) \cdot H_2O$ (**5**): The solid product was filtered off, washed with EtOH and dissolved in CH_3OH. The resulting solution was left to crystallize at room temperature to afford **5** as a red powder. Yield 38%. *Anal.* Calc. for $C_{25}H_{30}N_6O_9CuPb$: C, 36.22; H, 3.62; N, 10.13; Cu, 7.66. Found: C, 36.2; H, 3.5; N, 10.0; Cu, 7.4%. IR (KBr) cm^{-1}: 1650, 1630 (C=N), 1324 (C–O), 1449, 1384, 1310, 1040, 610, 567, 502, 469, 423, 348. Λ_M: 215 Ω^{-1} cm^2 mol^{-1}. UV–Vis λ_{max} (nm) (ε (M^{-1} cm^{-1})): 273, 389 (12 300), 580 (130) in DMF.

$[CuZn(L^3)(H_2O)](ClO_4)_2$ (**6**): The product was dissolved in acetonitrile and the solution was diffused with diethyl ether to afford **6** as reddish microcrystals. Yield 43%. *Anal.* Calc. for $C_{25}H_{29}N_4O_{11}Cl_2CuZn$: C, 39.43; H, 3.80; N, 7.35; Cu, 8.34. Found: C, 39.3; H, 3.9; N, 7.5; Cu, 8.0%. IR (KBr) cm^{-1}: 1641, 1620 (C=N), 1321 (C–O), 1109, 624, 509, 453, 334. Λ_M: 240 Ω^{-1} cm^2 mol^{-1}. UV–Vis λ_{max} (nm) (ε (M^{-1} cm^{-1})): 271, 365 (12 100), 518 (170) in DMF.

$[CuPb(L^4)(ClO_4)(CH_3OH)](ClO_4)$ (**7**): The product was dissolved in acetonitrile-methanol (1:1) mixture and the solution was diffused with diethyl ether to afford **7** as red microcrystals. Yield 46%. *Anal.* Calc. for $C_{24}H_{28}N_4O_{11}Cl_2$-CuPb: C, 32.39; H, 3.15; N, 6.29; Cu, 7.13. Found: C, 32.2; H, 3.3; N, 6.5; Cu, 7.3%. IR (KBr) cm^{-1}: 1610, 1634 (C=N), 1317 (C–O), 1101, 1078, 1046, 621, 560, 501, 454, 410, 353. Λ_M: 228 Ω^{-1} cm^2 mol^{-1}. UV–Vis λ_{max} (nm) (ε (M^{-1} cm^{-1})): 270, 370 (12 800), 530 (190) in DMF.

$[CuZn(L^4)(CH_3OH)](ClO_4)_2$ (**8**): The solid product was filtered off, washed with EtOH and dissolved in acetonitrile-methanol (1:1). The resulting solution was left to crystallize at room temperature to afford **8** as a red powder. Yield 43%. *Anal.* Calc. for $C_{24}H_{28}N_4O_{11}Cl_2CuZn$: C, 38.53; H, 3.74; N, 7.48; Cu, 8.49. Found: C, 38.6; H, 3.5; N, 7.6; Cu, 8.9%. IR (KBr) cm^{-1}: 1615, 1639 (C=N), 1320 (C–O), 1097, 623, 507, 449, 352, 338. Λ_M: 235 Ω^{-1} cm^2 mol^{-1}. UV–Vis λ_{max} (nm) (ε (M^{-1} cm^{-1})): 271, 365 (12 200), 520 (180) in DMF.

3. Results and discussion

Schiff base condensation of a mononuclear precursor, such as CuL, with various polyamines in the presence of second metal ion is one of the most classical reactions to synthesise heterodinuclear complexes.

The synthesis of the heterodinuclear Cu(II)–M(II) (M = Pb and Zn) complexes was carried out in DMF (for **1**–**4**) or CH_2Cl_2–MeOH (1:1) (for **5**–**8**) via the template condensation of [*N*,*N*′-bis(3-formyl-5-methylsalicylidene)ethane-1,2-diaminato]copper(II), CuL, and various polyamines in the presence of Zn(II) and/or Pb(II) (Chart 2). The prepared complexes were fully characterized by

microanalysis, IR and UV–Vis spectroscopy. The observed products are air stable solids, moderately soluble in DMF and/or CH_3CN and had elemental analyses consistent with the formulations given in Section 2.

3.1. Infrared spectra

In order to clarify the mode of bonding, the IR spectra of H_2L, the mononuclear fragment CuL, and the heterodinuclear complexes were studied and assigned on the basis of a careful comparison of the latter with the former.

In the IR spectrum of CuL the bands at 1672 and 1633 cm^{-1} can be assigned to the C=O and C=N stretching vibrations, respectively [23]. The υ(C=N) band in CuL is red-shifted by 10 cm^{-1} from that of the H_2L value. This can be ascribed to the withdrawal of electron density from the nitrogen atom owing to coordination. The υ(C–O) band (phenolic) in CuL, at 1298 cm^{-1}, appears at a higher frequency compared to the H_2L value by 44 cm^{-1}. This is in agreement with the phenolato–O single bonded to the metal ion [37,38].

The total absence of the CuL υ(C=O) absorption in the IR spectrum of each heterodinuclear complex together with the appearance of new υ(C=N) absorptions in the range 1647–1657 cm^{-1} clearly indicates that a cyclic Schiff-base has formed in each case. In all the prepared complexes, **1**–**8**, the υ(C–O) band (phenolic) appears at 1317–1340 cm^{-1} and is blue-shifted by 63–86 cm^{-1} from that of H_2L. On comparing with the literature [39], the greater shifting of the υ(C–O) (phenolic) frequency may be due to the phenolato–O bridging two metal centres.

The IR spectrum for the nitrate complex, **5**, show bands at ca. 1449 (υ_5), 1310 (υ_1) and 1040 (υ_2) cm^{-1}, suggesting the presence of a coordinated nitrate group, as well as a band at ca. 1384 cm^{-1} attributable to ionic NO_3^- [40–42]. The $\Delta\upsilon$ separation between the two highest frequency bands of coordinated nitrate falls in the range 130–200 cm^{-1}, suggesting bidentate coordination of the nitrate anion [40,42,43].

The complexes **2**, **3**, **4** and **8** exhibit bands attributable to ionic perchlorate at *ca.* 1090 cm^{-1} (υ_3) and *ca.* 623 cm^{-1} (υ_4). Bands attributable to the perchlorate groups are present in the spectra of **1**, **6** and **7** at *ca.* 1050, 1080 and 1105 cm^{-1}, suggesting the presence of coordinated perchlorate groups [40].

Complexes **1** and **3** show an intense band at ca. 1653 cm^{-1} that can be attributed to the υ(C=O) vibration of a coordinated DMF molecule. The presence of water molecules is confirmed by the appearance of an intense broad band centered at about 3400–3300 cm^{-1} in the IR spectra of **2**, **4** and **6**.

Some new bands with medium to weak intensities appear in the region 630–500 cm^{-1} and 480–330 cm^{-1} in the spectra of all the complexes, which are assigned to υ(M–O) and υ(M–N) vibration modes, respectively [40,44]. These bands are in accordance with data found in the literature and strongly support the involvement of the azomethine nitrogen and the phenolic oxygen atoms in the coordination.

3.2. Description of the crystal structure

The solid-state structure of the cation in **6**, determined by single crystal X-ray diffraction studies, together with the atom labelling scheme is illustrated in Fig. 1. Selected bond lengths (Å), bond angles (°) and torsion angles (°) with estimated standard deviations are given in Tables 2 and 3.

The Cu–N and Cu–O bond lengths in **6** (Table 2) fall in the range reported for CuL, and are shorter than the Zn–N and Zn–O bond lengths for the Zn(II) ion in the N_2O_2 cavity with the propylene lateral chain [45–47].

The Cu–Zn interatomic separation, bridged by two phenolic oxygen atoms, is about 3.0 Å. The Zn in the N_2O_2 site has a square–pyramidal geometry together with one water molecule at the axial site. The in-plane Zn-to-donor bond distances range from 2.010(7) to 2.049(7) Å and the axial Zn–O (water) bond distance is 2.022(7) Å. The structure shows that the equatorial plane for the Zn center is slightly distorted. The sum of the angles subtended by the macrocycle donor atoms at Cu and Zn is 360.0° and 349.7°, respectively, and Zn is displaced from the basal N(amine)$_2$O$_2$ least-squares plane towards the water oxygen. The plane containing N(3), N(4), O(1) and O(2) has a r.m.s. deviation of 0.320 Å with the metal atom being 0.429 (2) Å out of this plane.

3.3. Conductivity measurements and electronic spectra

The molar conductance (Λ_M) of all the prepared complexes, presented in Section 2, fall within the range

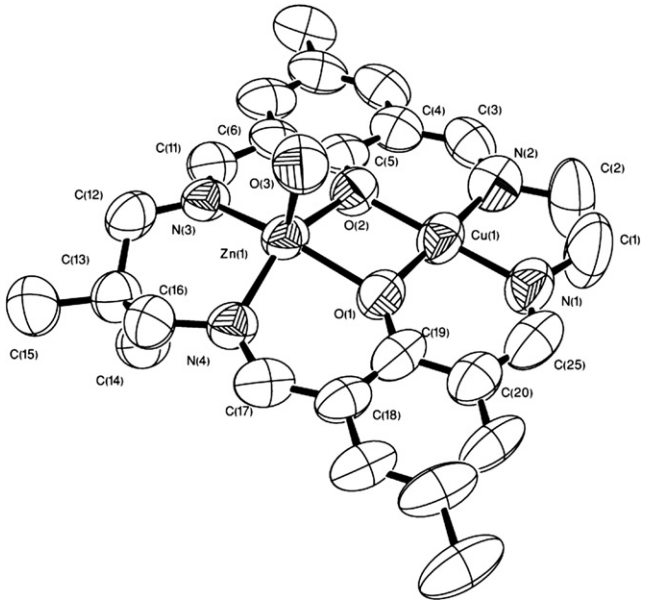

Fig. 1. The molecular structure of **6** showing displacement ellipsoids at the 50% probability level. H atoms are omitted for clarity.

Table 2
Selected bond lengths (Å) and angles (°) for **6**

Bond lengths			
Cu(1)–N(1)	1.918(10)	Zn(1)–N(3)	2.010(7)
Cu(1)–N(2)	1.886(11)	Zn(1)–N(4)	2.041(8)
Cu(1)–O(1)	1.904(7)	Zn(1)–O(1)	2.047(6)
Cu(1)–O(2)	1.887(6)	Zn(1)–O(2)	2.049(7)
Cu(1)–Zn(1)	3.0271(17)	Zn(1)–O(3)	2.022(7)
Bond angles			
Cu(1)–O(1)–Zn(1)	100.0(3)	N(3)–Zn(1)–O(3)	108.1(3)
Cu(1)–O(2)–Zn(1)	100.5(3)	N(4)–Zn(1)–O(3)	103.5(3)
N(1)–Cu(1)–N(2)	86.3(5)	O(1)–Cu(1)–O(2)	83.0(3)
N(1)–Cu(1)–O(1)	94.9(4)	O(1)–Zn(1)–O(3)	96.9(3)
N(2)–Cu(1)–O(2)	95.8(4)	O(2)–Zn(1)–O(3)	98.2(3)
N(3)–Zn(1)–N(4)	99.5(3)		
N(3)–Zn(1)–O(1)	87.6(3)		

reported for 1:2 electrolytes in DMF [48]. This implies that in **1**, **5** and **7** the weakly bonded counter ions in the solid state must be dissociated, at least in DMF solution.

The electronic spectra of the complexes in DMF display main features at 360–400 nm and 540–620 nm. The band at 360–400 nm may be assigned to the π–π^* electronic transition associated with the C=N linkages [10–16,20–22], and that of 540–620 nm to the d–d transitions. The intense absorption band at short wavelengths ca. 270 nm, may be assigned to intraligand π–π^* transitions [49].

The spectra for some of these complexes were also recorded in CH_3CN and DMSO, in an attempt to confirm the nature of these bands, by observing their position in different solvents; unfortunately, the co-presence of different kinds of chromophores, such as imine groups, phenol or phenyl rings, made it impossible to differentiate the exact nature of the bands (Fig. 2).

In some cases, the intensity of the absorption bands changed when the spectra were recorded after a period of 2 days, suggesting the displacement of some coordinated

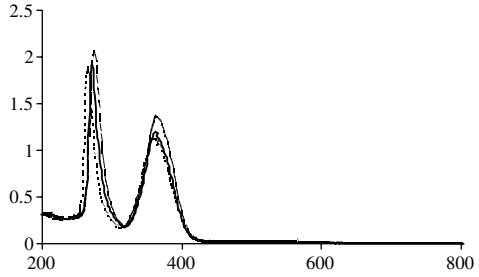

Fig. 2. UV spectra of **6** in DMF(---), CH_3CN (. . .) and DMSO (—).

anions or water molecules by solvent molecules, or a demetallation process [50].

3.4. Biological activities

CuL and all the synthesized heterodinuclear complexes, **1**–**8**, were tested for their anti-microbial activity against bacteria (*E. coli* and *S. Aureus*) and fungi (CA). The results of their biological activity are presented in Table 4. The anti-microbial activity of hetero- and homodinuclear complexes of similar phenol-based macrocyclic [25] and macroacyclic [24,26,29] ligands has been reported. In our study there was no activity observed by the prepared complexes against *E. coli* and CA, whereas compounds **2**, **4**, **6** and **8** had an inhibition zone between 9 and 14 mm on the culture of *S. aureus*. The anti-*S. aureus* activity of **6**, with an inhibition zone of 14 mm, is better than that of the other compounds (Table 4). An interesting result is that the Cu–Zn complexes of all the macrocyclic ligands showed a growth inhibition property, as it was reported for similar heterodinuclear complexes [25,26]. It can be concluded that the presence of the Zn(II) ion is important to have anti-bacterial activity, as the presence of Pb(II) in place of Zn(II) as the second metal ion gives complexes which showed no activity. The biological activ-

ity in compound **6**, as mentioned earlier, is still more than **8**, which can be correlated to the presence of coordinated water [51] as well as one additional methyl group. The presence of coordinated water in **2** and **4** also can be a reason for the biological activity of these compounds. More detailed studies are recommended to understand the possible mechanisms involve in the inhibition of the growth of staph. aureus and to evaluate the differences of the growth inhibition mechanism between the organisms used in this study.

4. Conclusions

A series of Cu^{II}–M^{II} (M = Zn and Pb) heterodinuclear complexes of the macrocycles $(L^n)^{2-}$ ($n = \mathbf{1}$–$\mathbf{4}$) were obtained by cyclocondensation of the Okawa mononuclear Cu(II) precursor, CuL, with various di- and/or tri-amines in the presence of Pb(II) and Zn(II) metal ions. The site selectivity of the metal ions was demonstrated by X-ray crystallography for $[CuZn\ L^3(H_2O)](ClO_4)_2 \cdot CuL$ and its Cu(II)–M(II) (M = Zn and Pb) complexes were tested for anti-microbial activity and the compounds were found to have no activity against the bacteria *E. coli* and CA, but the Cu–Zn complexes were found to be active against *S. aureus*.

We were interested to study the conformational and complexation behaviour of trisubstitued calix[4]arene with Na^+ and K^+ ions with an emphasis to achieve selectivity for K^+ over Na^+. In this paper, we report the synthesis and structural characterization of calix[4]arene derivatives having substituents at three out of the four OH groups in the lower rim, their complexation properties with Na^+ and K^+ ions and also the effect of various substituents on the molecular structure/packing.

2. Experimental

2.1. Materials

The compounds calix[4]arene [8] and 2-(2-chloroethoxy)-ethanol *p*-toluenesulfonate [9] were synthesized following the literature procedures. All the reagents used in this study were purchased from Aldrich and S. D. Fine Chemicals. All solvents were analytical grade and purified by standard procedures before use [10].

2.2. Physical measurements

Elemental analyses (C, H and N) were performed on a model 2400 Perkin–Elmer elemental analyzer. NMR spectra were recorded on a model DPX 200 Bruker FT-NMR instrument. Infrared spectra were recorded on a Perkin–Elmer Spectrum GX FT-IR system. Mass spectra were recorded on a Q-Tof micro™ LC–MS instrument. The UV–Vis spectra were recorded on a CARY 500 scan Varian spectrophotometer. Single crystal structures were determined using a Bruker SMART 1000 (CCD) diffractometer.

2.3. Synthesis of ligands

2.3.1. Synthesis of 25,27-bis(1-propyloxy)calix[4]arene (***L*^{1})

This compound was synthesized following the literature procedure [11], Yield 60%. ^{1}H NMR (200 MHz, $CDCl_3$) δ 8.30 (s, 2H, OH), 7.05, 6.90 (d, $J = 7.4$ Hz, 4H each, Ar), 6.72, 6.67 (t, $J = 7.4$ Hz, 2H each, Ar), 4.30 (d, $J = 13.0$ Hz, 4H, ArCH_2Ar), 3.97 (t, $J = 6.2$ Hz, 4H, OCH_2), 3.37 (d, $J = 13.0$ Hz, 4H, ArCH_2Ar), 2.05 (m, 4H, CH_2), 1.30 (t, $J = 7.4$ Hz, 6H, CH_3). LC–MS *m/z* 531.91 ($\mathbf{L^1} + Na^+$).

2.3.2. Synthesis of 25,26,27-tris(1-propyloxy)calix[4]arene (***L*^{2})

To a suspension of calix[4]arene (0.848 g, 2 mmol) in acetonitrile (80 mL) was added iodopropane (2.04 g, 12 mmol) and K_2CO_3 (1.66 g,12 mmol) in excess and the reaction mixture was stirred under reflux for 34 h. The solvent was then removed under reduced pressure and the residue was treated with 10% HCl (50 mL) and extracted with CH_2Cl_2 (100 mL). The organic phase was separated, washed twice with distilled water (100 mL × 2) and dried over $MgSO_4$. The solvent was removed by rotary evaporation and the product was purified by column chromatography using silica gel as the packing material and ethyl acetate–hexane (1:9) as the eluent. The solvent was removed from the desired fraction and the solid compound was dried under vacuo (yield 330 mg, 30%). Single crystals suitable for X-ray crystallography were obtained by slow evaporation of a dilute solution of the compound dissolved in acetonitrile–hexane (1:1). IR (KBr pellet, cm^{-1}) 3408 (OH). UV–Vis ($CHCl_3$, λ_{max} nm, ε $M^{-1}\,cm^{-1}$), 285 sh (2.57×10^3), 277 (3.46×10^3), 243 (3.3×10^3). ^{1}H NMR (200 MHz, $CDCl_3$) δ 7.25 (s, 1H, OH), 7.06–6.81 (m, 9H, Ar), 6.73–6.62 (m, 3H, Ar), 4.08 (d, $J = 13.2$ Hz, 2H, ArCH_2Ar), 3.95 (m, 2H, OCH_2), 3.84 (s, 2H, ArCH_2Ar), 3.82 (s, 2H, ArCH_2Ar), 3.59 (m, 2H, OCH_2), 3.24 (d, $J = 13.0$ Hz, 2H, ArCH_2Ar), 3.14 (t, $J = 7.6$ Hz, 2H, OCH_2), 1.79 (m, 4H, CH_2), 1.33 (m, 2H, CH_2), 0.99 (t, $J = 7.2$ Hz, 6H, CH_3), 0.57 (t, $J = 7.4$ Hz, 3H, CH_3). LC–MS *m/z* 573.40 ($\mathbf{L^2} + Na^+$). *Anal.* Calc. for $C_{38}H_{45}O_4N$: C, 79.15; H, 7.66; N, 2.36. Found: C, 78.45; H, 7.53; N, 2.21%.

2.3.3. Synthesis of 25,27-bis(1-propyloxy)-26(5-chloro-3-oxapentyloxy)calix[4]arene (***L*^{3})

A mixture of dipropyl calix[4]arene (0.740 g, 1.45 mmol), 2-(2-chloroethoxy)-ethanol *p*-toluenesulfonate (0.405 g, 1.45 mmol) and Cs_2CO_3 (0.474 g, 1.45 mmol) in acetonitrile (50 mL) was heated at reflux for 24 h under nitrogen atmosphere. The reaction mixture was allowed to cool to room temperature, solvent was then removed under reduced pressure and the residue was treated with 10% HCl (50 mL) and 100 mL of CH_2Cl_2. The organic phase was separated, dried over $MgSO_4$ and evaporation of the solvent under reduced pressure afforded a brownish oil. The compound was purified by column chromatography using silica gel as the packing material and ethyl acetate–hexane (1:11) as the eluent. Yield 0.358 g, (40%). Single crystals suitable for X-ray study were grown by slow evaporation of the solution containing THF–hexane (1:5). IR (KBr pellet, cm^{-1}) 3268 (OH). UV–Vis ($CHCl_3$, λ_{max} nm, ε $M^{-1}\,cm^{-1}$) 285 sh (3.46×10^3), 277 (4.1×10^3), 243 (3.75×10^3). ^{1}H NMR (200 MHz, $CDCl_3$) δ 7.32 (s, 1H, OH), 7.24 (d, $J = 3.8$ Hz, 2H, Ar), 7.07–6.89 (m, 7H, Ar), 6.80–6.63 (m, 3H, Ar), 4.10 (d, $J = 13.0$ Hz, 2H, ArCH_2Ar), 3.95 (m, 2H, OCH_2), 3.89 (s, 2H, ArCH_2Ar), 3.87 (s, 2H, ArCH_2Ar), 3.65–3.55 (m, 4H, OCH_2), 3.33 (t, $J = 5.2$ Hz, 2H, OCH_2), 3.26 (d, $J = 13.0$ Hz, 2H, ArCH_2Ar), 2.92 (t, $J = 5.0$ Hz, 2H, OCH_2), 2.64 (t, $J = 5.0$ Hz, 2H, CH_2Cl), 1.73 (m, 4H, CH_2), 0.98 (t, $J = 7.4$ Hz, 6H, CH_3). LC–MS *m/z* 638.30 ($\mathbf{L^3} + Na^+$). *Anal.* Calc. for $C_{38}H_{43}O_5Cl$: C, 74.19; H, 7.04. Found: C, 73.94; H, 6.92%.

2.3.4. Synthesis of 25(o-p-toluenesulfonate)26,28-bis(1-propyloxy)calix[4]arene (***L*^{4})

A mixture containing dipropyl calix[4]arene (0.762 g, 1.5 mmol), *p*-toluenesulfonyl chloride (0.286 g, 1.5 mmol) and Cs_2CO_3 (0.489 g,1.5 mmol) in acetonitrile (50 mL)

was heated at reflux for 20 h under nitrogen atmosphere. The reaction mixture was allowed to cool to room temperature and solvent was removed by rotary evaporation. The residue was treated with 10% HCl (50 mL) and CH_2Cl_2 (100 mL). The organic phase was separated and dried over $MgSO_4$ and evaporation of the solvent under reduced pressure afforded a yellow oil. The compound was purified by column chromatography using silica gel as the packing material and ethyl acetate–hexane (1:16) as the eluent. The desired compound was obtained as a white solid. Yield 0.397 g (40%). Single crystals suitable for X-ray study were grown by slow evaporation of a THF–hexane (1:5) solution. IR (KBr pellet, cm^{-1}) 3452 (OH). UV–Vis ($CHCl_3$, λ_{max} nm, ε $M^{-1}\,cm^{-1}$) 284 sh (3.46×10^3), 276 (4.01×10^3), 243 (4.55×10^3). ^{1}H NMR, (200 MHz, $CDCl_3$) δ 7.34 (d, $J = 7.4$ Hz, 2H, Ar), 7.20 (s, 1H, OH), 7.15 (d, $J = 7.2$ Hz, 2H, Ar), 7.07–7.01 (m, 4H, Ar), 6.75–6.68 (m, 6H, Ar), 6.38 (t, $J = 7.6$ Hz, 2H, Ar), 4.10 (d, $J = 14.8$ Hz, 2H, ArCH_2Ar), 4.04 (d, $J = 13.2$ Hz, 2H, ArCH_2Ar), 3.98–3.87 (m, 2H, OCH_2), 3.75 (d, $J = 14.8$ Hz, 2H, ArCH_2Ar), 3.65–3.53 (m, 2H, OCH_2), 3.22 (d, $J = 13.2$ Hz, 2H, ArCH_2Ar), 2.39 (s, 3H, Ts-CH_3), 1.84–1.53 (m, 4H, CH_2), 0.99 (t, $J = 7.2$ Hz, 6H, CH_3). LC–MS m/z 685.53 ($\mathbf{L^4} + Na^+$). *Anal.* Calc. for $C_{41}H_{42}O_6S$: C, 74.29; H, 6.39; S, 4.84. Found: C, 73.87; H, 6.15; S, 4.58%.

2.4. In situ complexation study by NMR

^{1}H NMR spectra of ligands $\mathbf{L^2}$–$\mathbf{L^4}$ (0.01 mmol each) in $CDCl_3$–CD_3OH (0.5 mL, 4:1) were recorded. Then metal (Na^+/K^+) iodide (20 times molar equivalents) was added into the solution in the NMR tube, the reaction mixture was shaken well to dissolve the metal salt and the NMR spectra of the solutions were recorded at different time intervals. Compound $\mathbf{L^3}$ with KI showed significant changes in the NMR spectra within 6 h. Compounds $\mathbf{L^2}$, $\mathbf{L^3}$ and $\mathbf{L^4}$ with NaI and compounds $\mathbf{L^2}$ and $\mathbf{L^4}$ with KI did not show any significant change in the NMR spectra even after 4 days.

2.5. Synthesis of Na^+ and K^+ complexes

Each of the three ligands (15 mg) were dissolved in a chloroform–methanol mixture (10 mL, 4:1), the required metal iodide (20 M equiv) was added into the solution and the reaction mixture was stirred at room temperature for 4 days. The reaction mixture was filtered using a sintered crucible to remove undissolved metal iodide. The solvent was then removed at reduced pressure, the resulting solid mass was dissolved in $CDCl_3$–CD_3OH (4:1) and filtered, and ^{1}H NMR spectra of the solutions were recorded. The observations are consistent to that found in the in situ NMR experiments. Data for the K^+complex of $\mathbf{L^3}$: IR (KBr pellet, cm^{-1}) 3459, 1624 and 801 cm^{-1} (H_2O), 3269 (OH). ^{1}H NMR (200 MHz, $CDCl_3$) δ 7.45 (s, 1H, OH), 7.32 (d, $J = 7.4$ Hz, 2H, Ar), 7.17–6.96 (m, 7H, Ar), 6.89 (d, $J = 7.4$ Hz, 2H, Ar), 6.83–6.72 (m, 1H, Ar), 4.26 (s, 4H, $2H_2O$),4.10 (d, $J = 13.4$ Hz, 2H, ArCH_2Ar), 4.03–3.99 (m, 2H, OCH_2), 3.95 (s, 2H, ArCH_2Ar), 3.92 (s, 2H, ArCH_2Ar), 3.86–3.81 (m, 2H, OCH_2), 3.67–3.50 (m, 4H, OCH_2), 3.34 (d, $J = 13.2$ Hz, 2H, ArCH_2Ar), 3.20–3.15 (m, 2H, OCH_2), 3.05–3.00 (m, 2H, CH_2Cl), 1.84–1.71 (m, 4H, CH_2), 1.00 (t, $J = 7.4$ Hz, 6H, CH_3). LC–MS m/z = 1305.0 ($2\mathbf{L^3} + K^+ + 2H_2O$), 1287.23 ($2\mathbf{L^3} + K^+ + H_2O$).

2.6. Determination of the association constant (K_a) by NMR titration

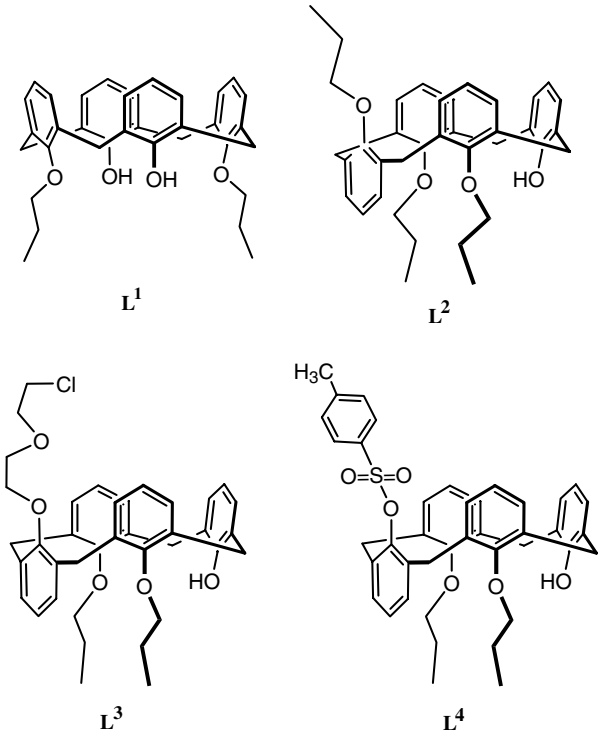
A stock solution of the host compound ($\mathbf{L^3}$, 5.176×10^{-3} M) was prepared in 4:1 $CDCl_3$–MeOH. A portion of this solution (0.5 mL) was taken in an NMR tube and used as the host, in the remaining solution KI was dissolved (16.64×10^{-3} M) and it was used as the guest so that the host concentration remained constant throughout the titration. Successive aliquots (0.1 mL each time) of the guest solution were added to the host in the NMR tube and after 30 min from each addition the ^{1}H NMR spectra were recorded. The changes in chemical shift of the CH_2 protons of the 2-(2-chloroethoxy)-ethanol moiety of the host was measured as a function of guest concentration, and the binding constant (K_a) was calculated following the procedure described in the literature for 2:1 host:guest complexes [12]. The value of K determined is 1.4×10^5 M^{-1}.

2.7. X-ray crystallography for $\mathbf{L^2}$–$\mathbf{L^4}$

The crystallographic data and details of data collection for all the three compounds are given in Table 1. Crystals of a suitable size were selected from the mother liquor and immersed in partone oil, then mounted on the tip of a glass fiber and cemented using epoxy resin. Intensity data for all three crystals were collected at 100 K using Mo Kα ($\lambda = 0.71073$ Å) radiation on a Bruker SMART APEX diffractometer equipped with a CCD area detector. The data integration and reduction were processed with SAINT [13] software. An empirical absorption correction was applied to the collected reflections with SADABS [13b]. The structures were solved by direct methods using SHELXTL [14] and were refined on F^2 by the full-matrix least-squares technique using the SHELXL-97 [15] program package. Graphics are generated using PLATON [16] and MERCURY 1.3 [17]. In all the compounds, non-hydrogen atoms were refined anisotropically until convergence was reached and the hydrogen atoms attached to the ligand moieties were stereochemically fixed.

3. Results and discussion

3.1. Synthesis of ligands $\mathbf{L^1}$–$\mathbf{L^4}$



Compounds $\mathbf{L^1}$–$\mathbf{L^4}$ are shown in Chart 1. For the synthesis of these trisubstituted derivatives, the reaction conditions and the molar proportions of the reactants are crucial to control the reaction to achieve the maximum yield of the desired

product. All these reactions were carried out in acetonitrile under reflux conditions using Cs_2CO_3 as a base. In the case of $\mathbf{L^2}$, double of the required amount of iodopropane was used whereas for $\mathbf{L^3}$ and $\mathbf{L^4}$, molar proportions of the reactants have been used to achieve the maximum yield. These compounds were obtained with low to moderate yield after purification by extensive column chromatography.

All of these compounds gave satisfactory C, H and N analysis. Mass spectra of all these compounds were recorded by LC–MS and the observed e/m values show excellent agreement with the calculated values. It may be noted that e/m values (100%) of all the compounds correspond to the Na^+ adduct (ligand + Na^+), which is a well-known phenomenon when LC–MS is used for the measurement of mass [5]. In the IR spectra, the strong bands at 3408, 3268 and 3452 cm^{-1} for $\mathbf{L^2}$, $\mathbf{L^3}$ and $\mathbf{L^4}$, respectively suggest the presence of an OH group. The difference in band positions is due to various degrees of O–H···O interactions with the adjacent oxygen atom of the calixarene moiety, as evident from the crystal structures. Conformational analysis of the molecules was done by NMR and single crystal X-ray study.

$\mathbf{L^1}$ $\mathbf{L^2}$ $\mathbf{L^3}$ $\mathbf{L^4}$

Chart 1. Structures of the compounds $\mathbf{L^1}$–$\mathbf{L^4}$.

3.2. Conformational study of ligands by NMR spectroscopy

^{1}H NMR spectra of all the compounds were recorded in $CDCl_3$ and the data, with assignment of the signals, are presented in the experimental section. However, signals for the bridged methylene groups (ArCH_2Ar) are noteworthy, particularly in the context of conformational analysis. They exhibit four signals, two doublets and two closely spaced singlets for $\mathbf{L^2}$ and $\mathbf{L^3}$, whereas $\mathbf{L^4}$ exhibits four doublets. The appearance of doublets for the bridged methylene protons is an indication of a typical AB pattern with non-equivalent axial and equatorial hydrogen atoms. The doublets around δ 4.10 (2H) and around δ 3.25 (2H) for $\mathbf{L^2}$ and $\mathbf{L^3}$ suggest that two of the four methylene groups are equivalent. The other two methylene groups exhibit two closely spaced singlets, indicating that the two protons (axial and equatorial) of each methylene group are equivalent but the two methylene groups are non-equivalent. In the case of $\mathbf{L^4}$, the J values indicate that the doublets at δ 4.10 ($J = 14.8$ Hz, 2H) and at δ 3.75 ($J = 14.8$ Hz, 2H) correspond to two equivalent methylene groups with non-equivalent axial and equatorial protons. Similarly, the doublets at δ 4.04 ($J = 13.2$ Hz, 2H) and at δ 3.22 ($J = 13.2$ Hz, 2H) correspond to two equivalent methylene groups with AB type protons. This kind of splitting pattern for the bridged methylene groups suggest a partial cone conformation for these molecules [6b,7,18]. For $\mathbf{L^2}$–$\mathbf{L^4}$, two substituents are common, the third substituent in $\mathbf{L^2}$ and $\mathbf{L^3}$ are similar, but for $\mathbf{L^4}$ it is significantly different. This third substituent has affected the precise geometry of the calix unit and because of this effect the splitting patterns

of the bridged methylene groups for L^2 and L^3 are similar but are different from L^4.

3.3. Molecular structures of the ligands

The ORTEP diagrams of compounds L^2–L^4 are shown in Fig. 1. For all the three compounds, the bond lengths and bond angles are in the usual ranges [1g,1i,5a], and the following discussion refers mainly to the conformation and shape of the calixarene skeleton. The crystal structures clearly show that all the three compounds have adopted partial cone conformations, however the precise shape of the molecules differ due to variations in the substituent. The conformation of the calixarene can also be described by a typical sequence of the signs of the torsion angles around the aromatic units and the σ-bonds connecting

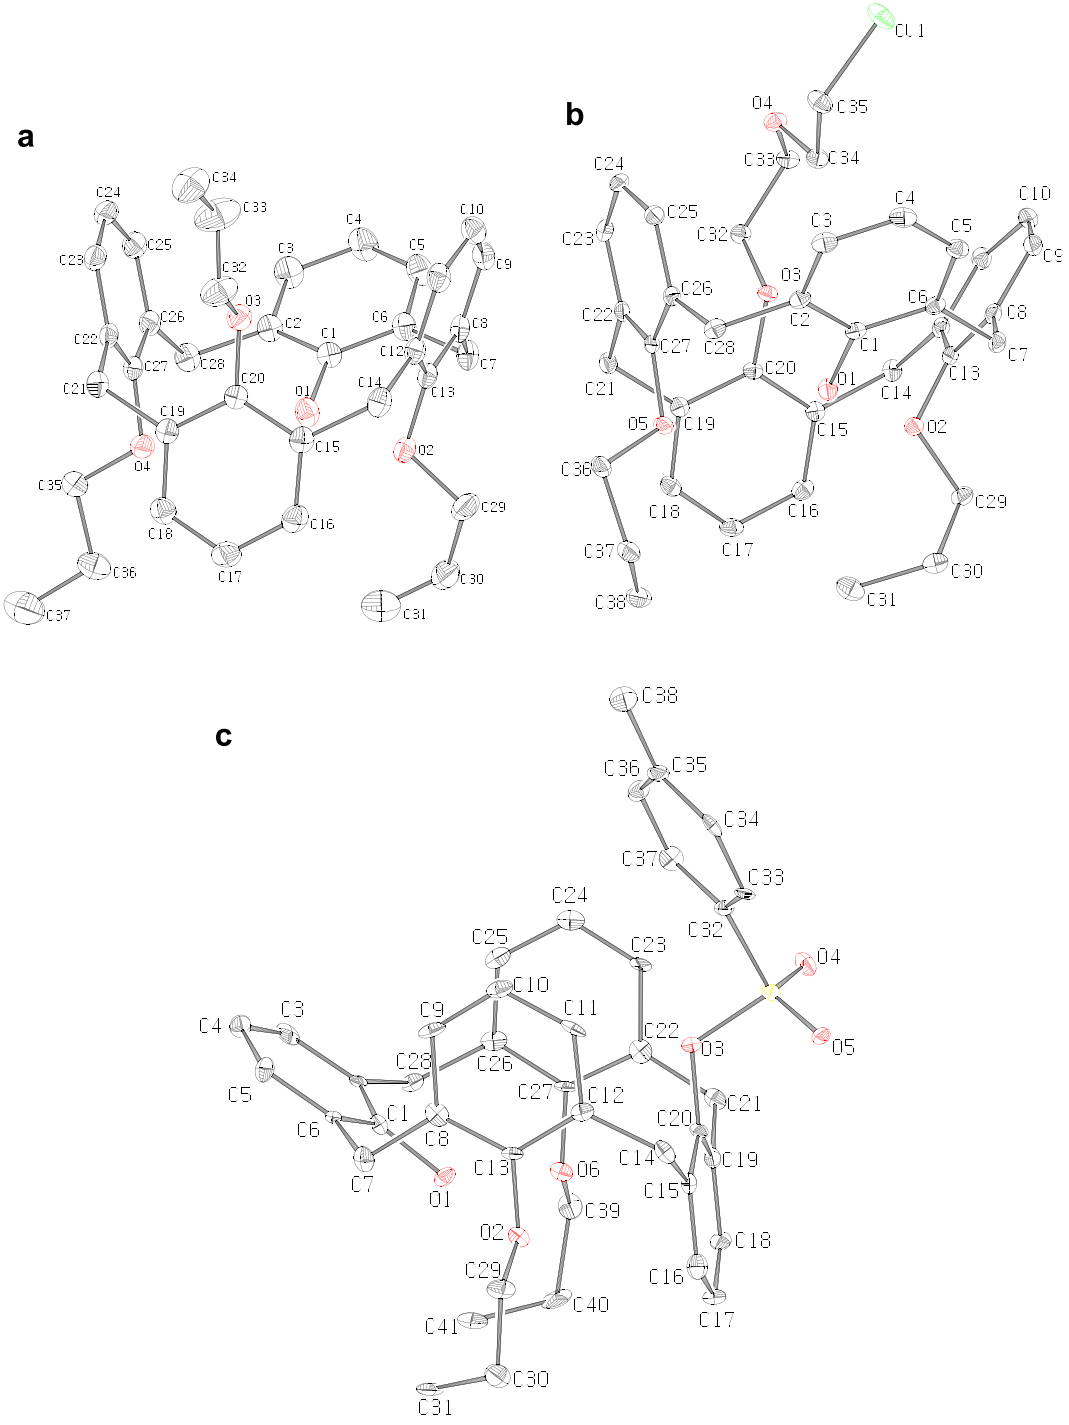

Fig. 1. ORTEP diagrams with the atom numbering scheme depicting the conformation of the calixarene moiety for compounds L^2 (a), L^3 (b) and L^4 (c) (hydrogen atoms are omitted for clarity).

the methylene bridges [19]. These sequences for all the three compounds (Table S1, Supplementary material) are (+,−)(+,+)(−,−)(+,−), which corresponds to the partial cone (paco) conformation.

Compound $\mathbf{L^2}$ encapsulates an acetonitrile molecule inside the calix cone with a strong C–H···π interaction between the hydrogen atoms of the acetonitrile and the centroid of the calix phenyl rings, as depicted in Fig. 2. Details of this C–H···π interaction are given in Table 2. A similar mode of guest encapsulation has also been reported with different substituted calixarene molecules [20]. It may be noted that the phenolic hydrogen H1 makes a strong intramolecular H-bond with O2 of the neighboring *O*-propyl group (Table 3), as depicted in Fig. 2. The propyl groups attached to the third and fourth phenyl rings are in an extended conformation whereas that attached to the second phenyl ring is in a folded conformation, as indicated by the torsion angles (O3–C32–C33–C34 = 175.30°, O4–C35–C36–C37 = 176.94° and O2–C29–C30–C31 = 48.69°). The folded conformation of the propyl group is attributed to the involvement of O2 in intramolecular H-bonding interactions with the adjacent phenolic oxygen O1.

The packing diagram of $\mathbf{L^2}$ viewed down the *a*-axis is shown in Fig. 3, with an offset π stacked array of calix moieties along the *b*-axis. The calixarene molecules are oriented with Cg1 and Cg3 phenyl centroids of adjacent molecules making offset π···π stacking interactions from either side, extending the array along the *b*-axis, Cg1···Cg3 = 4.86 Å with a Cg···Cg perpendicular distance of 3.52 Å, where Cg1 and Cg3 are the centroids of the C1–C6 and C15–C20

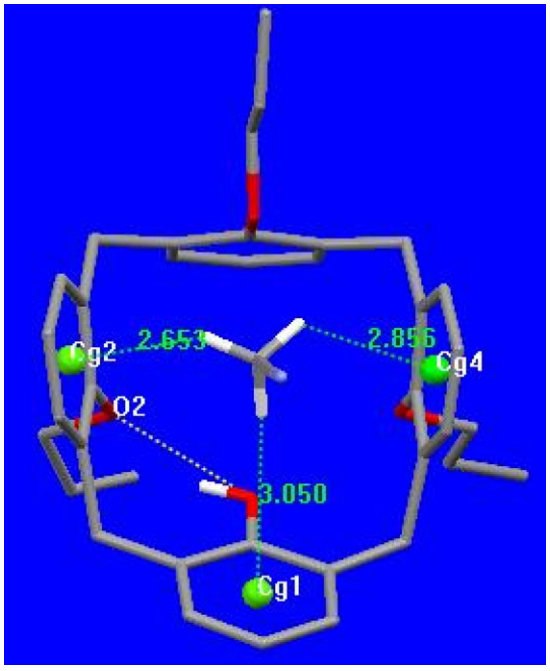

Fig. 2. MERCURY diagram depicting the encapsulated acetonitrile molecule inside the calixarene cone in $\mathbf{L^2}$, and also showing the intramolecular O–H···O interaction.

phenyl rings. Thus the stabilization of the compound in the crystal lattice can be mainly attributed to intermolecular phenyl offset π···π stacking interactions and intramolecular O–H···O and C–H···π interactions.

In the case of $\mathbf{L^3}$, both the methylene hydrogen atoms of 2-(2-chloroethoxy)-ethanol are involved in strong intramolecular C–H···π interactions with the opposite phenyl rings of the calix moiety (Fig. 4), bringing this group in towards to the calix cone and thus preventing the entry of any solvent molecule for encapsulation in the cavity. The phenolic hydrogen H1 is involved in strong intramolecular O–H···O hydrogen bonding with the neighboring oxygen atom attached to the benzene ring. Details of the C–H···π and O–H···O interactions are given in Tables 2 and 3, respectively. The distances and angles of these interactions are well within the values reported by Meyer et al. in their review article [21]. The propyl groups attached to the second and fourth phenyl rings are in a folded conformation (torsion angles O2–C29–C30–C31 = 62.99°, O5–C36–C37–C38 = −65.48°)

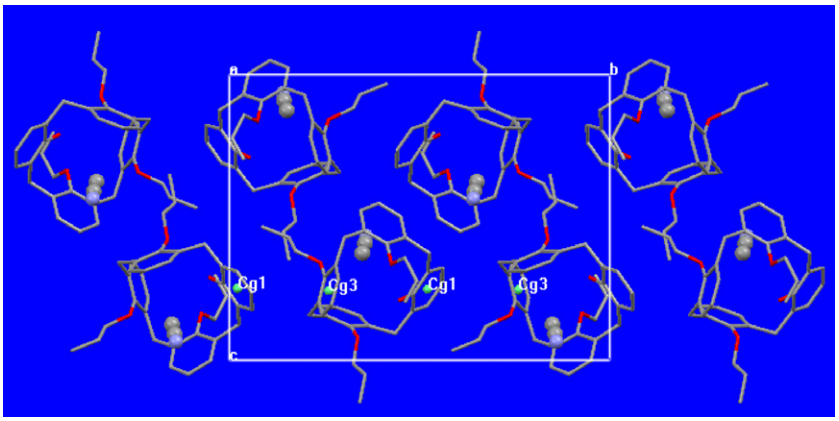

Fig. 3. Packing diagram of $\mathbf{L^2}$ viewed down the *a*-axis showing the orientation of the calixarene moiety with the encapsulated acetonitrile molecule; the calixarene molecules are oriented with Cg1 and Cg3 phenyl centroids of adjacent molecules making offset π···π stacking interactions from either side, extending the array along the *b*-axis.

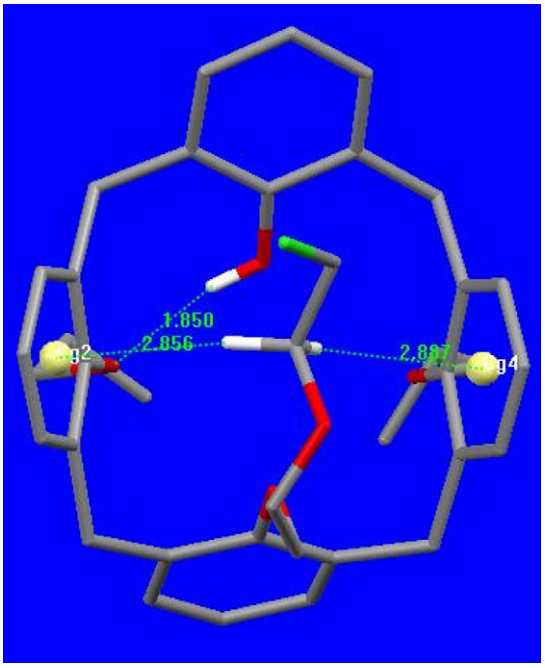

Fig. 4. MERCURY diagram of $\mathbf{L^3}$ depicting the intramolecular O–H···O interaction and C–H···π interaction between the aromatic rings of the calixarene unit and the methylene hydrogen atoms of the attached 2-(2-chloroethoxy)-ethanol moiety.

and are projected outwards from the calix cone. The torsion angle of the attached 2-(2-chloroethoxy)-ethanol moiety (O3–C32–C33–O4 = 66.02°, C32–C33–O4–C34 = 78.66°, C33–O4–C34–C35 = 163°, O4–C34–C35–Cl1 = −68.22°) clearly shows that except for the middle portion of the string, all other parts are in a folded conformation to attain the right orientation for an effective C–H···π interaction of the methylene hydrogens with the phenyl rings, as mentioned above.

The packing arrangement of $\mathbf{L^3}$ is similar to that of $\mathbf{L^2}$, however no significant intermolecular C–H···π interaction is observed between adjacent calix moieties, as in the case of $\mathbf{L^2}$ (Fig. S1, Supplementary material). Intramolecular C–H···π interactions dominate in governing the conformation of the calix moiety and effective crystal packing in $\mathbf{L^3}$.

The packing diagram of $\mathbf{L^4}$ shows that the calix molecules are arranged as hydrogen bonded offset layers along the *c*-axis and can be viewed as a corrugated layer along the *b*-axis (Fig. S2). The screw related calix moieties of the asymmetric units are associated via C–H···π interactions to form a corrugated arrangement along the *b*-axis (Fig. 5). Details of these C–H···π interactions between the calix ring C1–C6 and the methyl hydrogen H79A of the *p*-toluenesulfonate, and C8–C13 and the methylene hydrogen of the propyl moiety are given in Table 2. The offset layers of the ligands oriented along the *c*-axis are formed by strong C–H···O interactions of the sulfonate oxygen atoms from both molecules in the asymmetric unit. Thus sulfonate oxygens O4 and O5 of the first molecule are involved in intermolecular C–H···O interactions with the rim methylene hydrogen H7A along the *c*-axis and with H38A along the *a*-axis, respectively. It is interesting to note that O4 is further involved in an intramolecular C–H···O interaction with the rim methylene hydrogen H21A. The sulfonate oxygen atoms O10 and O11 of the second calix molecule are also involved in C–H···O interactions in similar fashion to that of O4 and O5. Details of all these H-bonding interactions with their pertinent symmetry codes are summarized in Table 3. Thus concomitant C–H···O interactions along the *a*- and *b*-axes with C–H···π interactions create a supramolecular three dimensional network.

3.4. Complexation study with Na^+ and K^+ ions

3.4.1. In situ NMR study

A complexation study of $\mathbf{L^2}$–$\mathbf{L^4}$ with Na^+ and K^+ by NMR experiments was carried out following the method as described in the experimental section. ^{1}H NMR spectra of the ligands and those with excess metal (Na^+/K^+) iodide were recorded at different time intervals in $CDCl_3$–CD_3OH (4:1) at room temperature. The ligand $\mathbf{L^3}$ with the K^+ ion

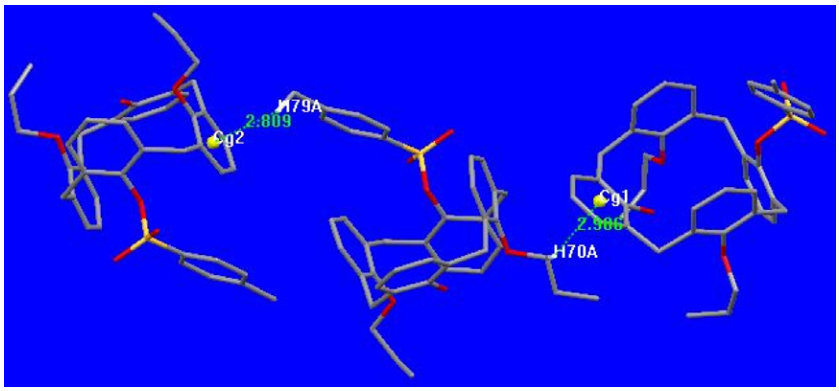

Fig. 5. C–H···π interactions between the aromatic rings of the calixarene moiety and methylene hydrogen (H70A) and methyl hydrogen (H79A) atoms of the propyl and *p*-toluenesulfonate groups, respectively, in $\mathbf{L^4}$.

exhibits a significant downfield shift of all the signals due to the protons of the 2-(2-chloroethoxy)-ethanol moiety ($-OCH_2CH_2OCH_2CH_2Cl$) and also some changes in the aromatic region compared to that of parent compound ($\mathbf{L^3}$), however in all other cases no significant change in the NMR spectra was observed. This observation suggests that complex formation takes place only between $\mathbf{L^3}$ and K^+ and not in any other cases under the experimental conditions. The relevant portions of the NMR spectra of $\mathbf{L^3}$, ($\mathbf{L^3}$ + NaI) and ($\mathbf{L^3}$ + KI) are shown in Fig. 6. It may be noted that in the spectra of ($\mathbf{L^3}$ + KI), the chemical shifts of all the CH_2 protons of the $-OCH_2CH_2OCH_2CH_2Cl$ moiety have moved downfield by 0.23, 0.30, 0.33 and 0.52 ppm, respectively, while the chemical shifts due to all other aliphatic protons remain almost at the same positions as observed for $\mathbf{L^3}$. This data suggests that only the $-OCH_2CH_2OCH_2CH_2Cl$ moiety is involved in complex formation with K^+. For further confirmation, an attempt has been made to synthesize and isolate solid complexes of Na^+ and K^+ with these ligands.

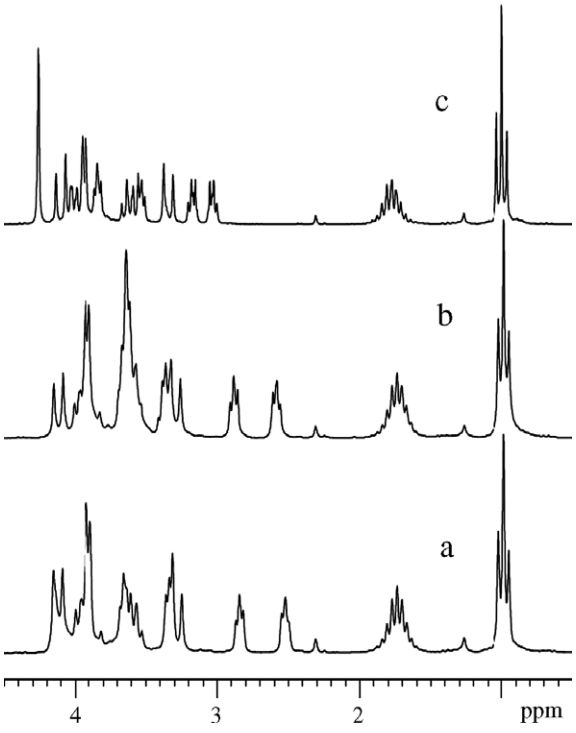

Fig. 6. Selected portion of the ^1H NMR spectra of (a) $\mathbf{L^3}$, (b) [$\mathbf{L^3}$ + NaI] and (c) [$\mathbf{L^3}$ + KI]; recorded in $CDCl_3$–CD_3OH (4:1) at room temperature.

The association constant (K_a) of $\mathbf{L^3}$ with K^+ was determined by NMR titration following the method described in the experimental section. For calixarene, determination of K_a by NMR titration is not very common because of the fact that it is difficult to find a clean separate peak of the host, which shifts with increasing metal ion (guest) concentrations. The value of K_a obtained ($1.4 \times 10^5\ M^{-1}$) is comparable to that found by Beer et al. by NMR titration for K^+ with calix[4]semitubes, where two calix[4]arene units are bridged by two ethylene chains and the K^+ ion is encapsulated in the cavity formed by the calix units and the ethylene bridge [22].

3.4.2. Synthesis of solid complexes

An attempt has been made to synthesis Na^+ and K^+ complexes of these ligands following the method described in Section 2. A solid mass was isolated and the ^1H NMR spectra of all samples were recorded in $CDCl_3$–CD_3OH. The observations are consistent to that found in the in situ NMR experiment; the spectra of the K^+complex of $\mathbf{L^3}$ is similar to that obtained from in situ NMR experiment, whereas for all other cases minor or no changes were observed.

The mass spectra of the K^+ complex of $\mathbf{L^3}$ exhibits a peak with low intensity at $m/z = 1305.0$ and a peak with moderate intensity at $m/z = 1287.23$. The first peak corresponds to the composition [$2\mathbf{L^3} + K^+ + 2H_2O$] and the second peak corresponds to [$2\mathbf{L^3} + K^+ + H_2O$], the observed m/z values are in excellent agreement with the calculated values, 1305.52 and 1287.51, respectively. The data suggest that complex formation takes place with two molecules of ligand, a K^+ ion and two molecules of water. The proposed structure of the complex is shown in Fig. 7. A similar observation was also noted by Beer et al., for calix tubes consisting of two calix units (M), where the proposed com-

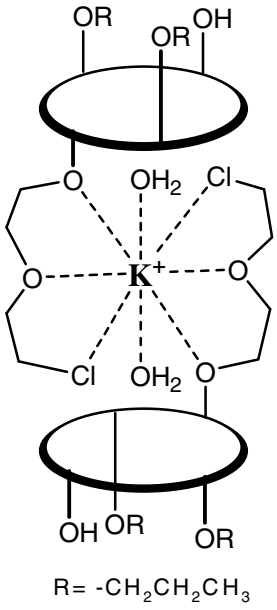

Fig. 7. Proposed structure for the K^+ complex of $\mathbf{L^3}$.

position was ($M+K^+ + 2H_2O$) [23]. In the K^+ complex, the involvement of water molecules in the coordination is also indicated by IR and NMR spectra. The IR spectra of $\mathbf{L^3}$ and its K^+ complex is shown in Fig. 8. Three new strong peaks (compared to $\mathbf{L^3}$), which appear at 3459, 1624 and 801 cm^{-1} are due to ν_s(O–H), the bending mode of H–O–H and the wagging mode of a coordinated water molecule [24]. In the ^1H NMR spectra, a new singlet at δ 4.3 (Fig. 6c), which corresponds to 4H, is assigned to the coordinated water molecules. A free water molecule used to appear at δ 4.8, and the signal due to a coordinated water molecule is expected to move downfield, however in this case it has moved upfield by ~0.5 ppm. From the possible structure of the complex it appears that the protons of the coordinated water molecules are inside or close to the cavity of the calixarene, which is a highly π-electron rich zone due to the presence of four aromatic rings. Because of this high π-electron density in the vicinity, the protons of the water molecules moved to the upfield region. Coordination of an alkali metal ion with chlorine in the presence of a crown ether has also been demonstrated crystallographically [25]. The selective complexation with K^+ is probably because of hole-size matching, the size of the cavity formed by the two 2-(2-chloroethoxy)-ethanol moieties fits well with the ionic size of K^+, the size of Na^+ is probably too small to make strong interactions with all the coordination sites as is required to form a stable complex.

4. Conclusions

A family of calix[4]arenes with three substituents at the lower rim have been synthesized and structurally characterized. Of the three substituents, one is different and the effect of this variable substituent on the metal binding ability and structural arrangement has been investigated. The calixarene moiety of all these three compounds adopts a partial cone conformation, however, all the three compounds exhibit different types of intra- and intermolecular C–H···π interactions, which provide them with different unique structural arrangements. Compound $\mathbf{L^2}$ encapsulates an acetonitrile molecule in the cavity of the calix moiety, whereas in $\mathbf{L^3}$ the third substituent itself moves in towards the cavity to make a strong C–H···π interaction with the phenyl rings, which prevents entry of the solvent molecule in the calix cone. Compound $\mathbf{L^4}$, which contains *p*-toluenesulfonate groups as the third substituent, behaves differently; no encapsulation in the cavity is observed but CH_2 of the propyl group and CH_3 of the *p*-toluenesulfonate group make strong intermolecular C–H···π interactions with the centroid of the phenyl groups of adjacent molecules. The packing diagram of $\mathbf{L^2}$ shows strong π···π stacking interactions, making an array along the *b*-axis, whereas $\mathbf{L^4}$ exhibits intermolecular C–H···O interactions to form a layered three dimensional architecture. A complexation study of all these compounds with Na^+ and K^+ ions reveal that the conformation of $\mathbf{L^3}$ is such that it forms a complex

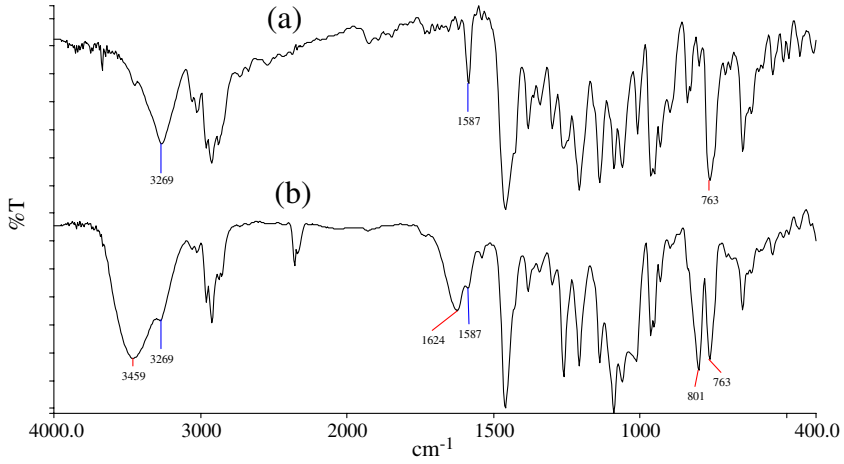

Fig. 8. IR spectra of compound $\mathbf{L^3}$ (a) and its K^+ complex (b).

selectively with K^+, the association constant also indicates strong complex formation, and therefore it may be used as a K^+ selective ionophore in the presence of Na^+.

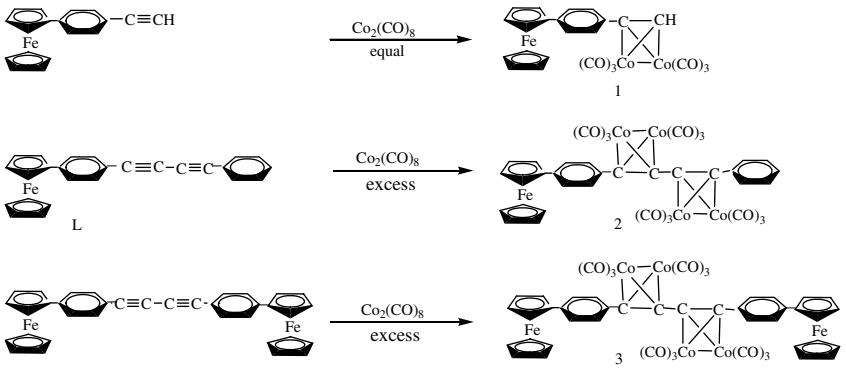
Fc–C_6H_4–C≡CH and C_6H_5–C≡CH. Complexes [Fc–C_6H_4–$(C≡C)_n$–R][$Co_2(CO)_6$]$_{n'}$[Fc = $C_5H_5FeC_5H_4$, R = H, $n = 1$, $n' = 1$ (**1**); R = C_6H_5, $n = 2$, $n' = 2$ (**2**); R = Fc–C_6H_4, $n = 2$, $n' = 2$ (**3**)] were obtained by the reactions of compounds Fc–C_6H_4–C≡CH [24], Fc–C_6H_4–C≡C–C≡C–C_6H_5 (**L**) and Fc–C_6H_4–$(C≡C)_2$–C_6H_4–Fc [25] with excess $Co_2(CO)_8$, respectively (see Scheme 1). Compound **L** contains a linear C_5H_4–C_6H_4–$(C≡C)_2$–C_6H_5 linkage. One alkyne bond (for **1**) or two alkyne bonds (for **2** and **3**) coordinate with the Co–Co bonds in complexes **1**, **2** and **3**. Compound **L** is an orange yellow, air-stable crystalline compound that is soluble in both non-polar solvents such as benzene and polar solvents such as diethyl ether or chloroform. Complexes **2** and **3** are black, air-stable crystalline compounds, with solubilities similar to compound **L**. Complex **1** is a purple-black, air-stable crystalline compound, but it is air-sensitive in solution.

The absorbing peaks of the FT-IR spectra in the region 2100–2013 cm^{-1} correspond to the stretching vibrations of the coordinated CO groups, which confirm that there are coordinated $Co_2(CO)_6$ species. ^1H and ^{13}C NMR spectra reflect that there are the appropriate Fc, Ph, C≡C and CO groups in **L**, **1**, **2** and **3**. The structure and composition of compounds **L**, **1**, **2** and **3** are proven further by their elemental analyses and MS data.

2.2. Molecular structures of compounds *L* and *2*



The crystal and molecular structures of compounds **L** and **2** were determined by X-ray single crystal analysis. Crystal data and relevant structural parameters are given in Table 1. The structures with the atom numbering schemes are shown in Figs. 1 and 2, and the selected bond lengths and angles are listed in Table 2.

The molecule of compound **L** contains a butadiynyl chain, of which the terminal groups are phenyl and *p*-ferrocenylphenyl groups (see Fig. 1). The bond distances C(12)–C(13) [1.198(5) Å] and C(14)–C(15) [1.195(5) Å] show there are two C≡C triple bonds in **L**. The shorter C(9)–C(12) [1.436(5) Å], C(13)–C(14) [1.370(6) Å] and C(15)–C(16) [1.437(5) Å] bond distances, compared to the classical single bond length, are the result of electron delocalization of the C_4 diyne chain, phenyl and ferrocenylphenyl units. The data of the bond angles [C(9)–C(12)–C(13), 178.9(4)°; C(12)–C(13)–C(14), 177.1(4)°; C(13)–C(14)–C(15), 178.8(4)°; C(14)–C(15)–C(16), 178.7(4)°] demonstrate the carbon chain C(9)C(12)C(13)C(14)C(15)C(16) has a nearly linear structure.

The molecule of complex **2** contains two approximately tetrahedral μ-alkyne dicobalt moieties bound to the ferr-

Scheme 1.

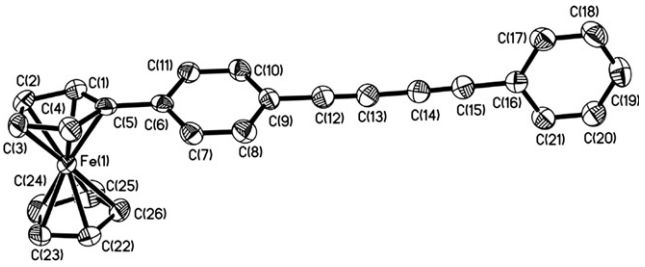

Fig. 1. Molecular structure of **L**.

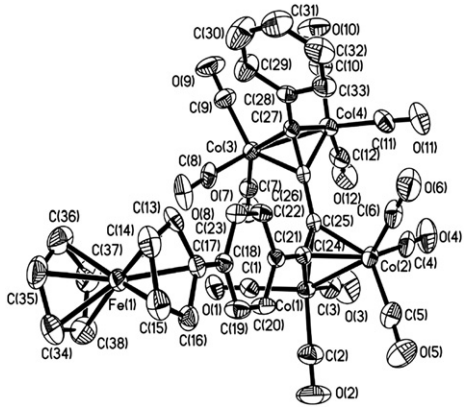

Fig. 2. Molecular structure of **2**.

ocenylphenyl and phenyl units. In **2** the CO ligands coordinated to the Co atoms are terminal (vide IR) and the alkyne bonds adopt the typical μ_2-η^2 coordination fashion, with the alkyne bond lying essentially perpendicular to the Co–Co bond in the C_2Co_2 units. The Co–Co bond distances, in the range 2.452–2.461 Å, are classical values for Co–Co bond lengths of similar complexes. The coordinated alkyne bond lengths of **2** [C(24)–C(25)1.349(7) Å; C(26)–C(27)1.355(8) Å] are longer than that of **L** [C(12)–C(13) (1.198(5) Å) and C(14)–C(15) (1.195(5) Å)] and are similar to the classical alkene bond length due to $Co_2(CO)_6$ units coordinated by diyne bonds. In complex **2** the bond angle data [C(21)–C(24)–C(25), 140.2(5)°; C(24)–C(25)–C(26), 141.1(5)°; C(25)–C(26)–C(27), 141.3(5)°; C(26)–C(27)–C(28), 144.9(5)°] demonstrate the construction of **L** is altered from a linear to a non-linear structure while **L** is coordinated to the $Co_2(CO)_6$ units. It is noteworthy that the $Co_2(CO)_6$ units are coordinated to the alkyne bond in a *trans* arrangement and the two terminal groups (phenyl and ferrocenylphenyl) are in a *cis* arrangement (see Fig. 2). Because of the large ferrocenylphenyl substituted group, the molecular structure of **2** is quite different from [Fc–C≡C–C≡C–C_6H_5][$Co_2(CO)_6$]$_2$ [20].

In **L** the dihedral angle [1.85(0.28)°] between plane 1 [C(22)C(23)C(24)C(25)C(26)] and plane 2 [C(1)C(2)C(3)-C(4)C(5)] shows that the two Cp planes in the Fc group are nearly parallel. The dihedral angle [16.15(0.21)°] between plane 2 and plane 3 [C(6)C(7)C(8)C(9)C(10)C(11)] is deviated from parallel, and the dihedral angle [74.39(0.13)°] between the two phenyl rings, that is plane 3 and plane 4 [C(16)C(17)C(18)C(19)C(20)C(21)], is nearly perpendicular.

In **2** the dihedral angle [0.45(0.59)°] of the two Cp rings shows that they are nearly parallel. It is interesting that the dihedral angle [9.20(0.47)°] between the planes of the Cp ring [C(13)C(14)C(15)C(16)C(17)] and the phenyl ring [C(18)C(19)C(20)C(21)C(22)C(23)] becomes smaller than that of **L**. The dihedral angle between the two phenyl rings [C(18)C(19)C(20)C(21)C(22)C(23)] and [C(28)C(29)C(30)-C(31)C(32)C(33)] alters from 74.39(0.13)° to 86.71(0.23)°. The changes of the dihedral angles in **2** show that the increased steric requirements on the coordinated $Co_2(CO)_6$ groups lead to a twisting of the substituents away from each other.

3. Experimental

3.1. General procedures

All reactions and manipulations were carried out using standard Schlenk techniques under an atmosphere of pure

nitrogen. Solvents were purified, dried and distilled under a nitrogen atmosphere prior to use. Reactions were monitored by TLC. Chromatographic separations and purifications were performed on 200–300 mesh silica gel. $Co_2(CO)_8$ was purchased from Alfa Aesar. The ligands Fc–C_6H_4–C≡CH and Fc–C_6H_4–(C≡C)$_2$–C_6H_4–Fc were prepared according to the literature methods [24,25].

IR spectra were recorded on a Nicolet FT-IR spectrometer, as KBr discs. Elemental analyses were carried out on an Elementar var III-type analyzer. ^{1}H and ^{13}C NMR spectra in $CDCl_3$ were recorded on a Bruker Avance-500 MHz spectrometer. The mass spectra were determined by using a Polaris Q MS, Micromass LCT instrument. Melting points were determined by using XT-4 melting point apparatus.

3.2. Synthesis of compound Fc–C_6H_4–(C≡C)$_2$–C_6H_5 (**L**)

Fc–C_6H_4–C≡CH (57 mg, 0.2 mmol), C_6H_5–C≡CH (40 mg, 0.40 mmol) and CuCl (9 mg, 0.09 mmol) were dissolved in 8 ml pyridine. This solution was stirred for 3 h in air at 60 °C. The solvent was removed under reduced pressure. The resulting mixture was washed with saturated NH_4Cl solution and extracted with CH_2Cl_2. The organic phase was incorporated and then dried using the dehydrated $MgSO_4$ and filtrated. The solvent was removed under reduced pressure. The residue was purified by neutral alumina column chromatography using hexane as the eluant. Crystals of **L** were obtained by recrystallizing solid **L** from hexane at −15 °C. Yield: 28%. m.p. 212–213 °C. *Anal*. Calc. for $C_{26}H_{18}Fe$: C, 80.83; H, 4.66. Found: C, 80.43; H, 4.70%. IR (KBr disk, cm^{-1}) ν 815s, 1004m, 1173 m, 1593s, 1521 m, 2146 m, 2208 m, 2852 m, 2924 m, 2960 m. ^{1}H NMR ($CDCl_3$, δ): 4.07–4.70 (m, 9H, Fc), 7.26–7.54 (m, 9H, C_6H_5, C_6H_4). ^{13}C NMR ($CDCl_3$, δ): 66.7–70.0 (Cp), 73.9–82.1 (2C≡C), 118.7–141.2 (2Ph). MS (EI) 386 (M^+).

3.3. Synthesis of complex [Fc–C_6H_4–C≡C–H][$Co_2(CO)_6$] (**1**)

A benzene solution of $Co_2(CO)_8$ (120 mg, 0.35 mmol) and Fc–C_6H_4–C≡CH (100 mg, 0.35 mmol) was stirred for 4 h at room temperature. The solvent of the resulting dark purple mixture was removed in vacuum. The residue was dissolved in a minimal amount of benzene and subjected to chromatographic separation on a silica gel column (2.0 × 40 cm). Elution with hexane afforded a purple-red band (**1**). Crystals of **1** were obtained by recrystallizing solid **1** from hexane at −20 °C. Complex **1**: Yield: 60%. m.p. 132–134 °C. *Anal*. Calc. for $C_{24}H_{14}O_6Co_2Fe$: C, 50.35; H, 2.45. Found: C, 49.90; H, 2.47%. IR (KBr disk, cm^{-1}) ν_{CO} 2013vs, 2054s, 2095s. ^{1}H NMR ($CDCl_3$, δ): 4.07–4.65 (m, 9H, Fc), 6.4 (s, 1H, –C≡C–H), 7.26–7.43 [m, 4H, C_6H_4]. ^{13}C NMR ($CDCl_3$, δ): 66.6–72.7 (Cp), 90.3, 84.7 (–C≡CH), 126.5–139.9 (C_6H_4), 199.5 (CO). MS (ESI): 572 (M^+).

3.4. Synthesis of complex [Fc–C_6H_4–(C≡C)$_2$–C_6H_5][$Co_2(CO)_6$]$_2$ (**2**)

A benzene solution of $Co_2(CO)_8$ (240 mg, 0.70 mmol) and compound **L** (135 mg, 0.35 mmol) was stirred for 4 h at room temperature. The solvent of the resulting dark mixture was removed in vacuum. The residue was dissolved in a minimal amount of benzene and subjected to chromatographic separation on a silica gel column (2.0 × 40 cm). Elution with hexane afforded a dark band (**2**). Crystals of **2** were obtained by recrystallizing solid **2** from hexane at −20 °C. Complex **2**: Yield: 65%. m.p. 164–165 °C. *Anal*. Calc. for $C_{38}H_{18}O_{12}Co_4Fe$: C, 47.60; H, 1.88. Found: C, 47.08; H, 1.85%. IR (KBr disk, cm^{-1}) ν_{CO} 2013vs, 2054vs, 2084s, 2100s. ^{1}H NMR ($CDCl_3$, δ): 4.04–4.67 (m, 9H, Fc), 7.26–7.51 (m, 9H, C_6H_5, C_6H_4). ^{13}C NMR ($CDCl_3$, δ): 66.5–69.7 (Cp), 84.4 (C≡C), 126.1–139.7 (C_6H_5, C_6H_4), 198.5 (CO). MS (ESI): 959 (M^++1).

3.5. Synthesis of complex [Fc–C_6H_4–(C≡C)$_2$–C_6H_4–Fc][$Co_2(CO)_6$]$_2$ (**3**)

A benzene solution of $Co_2(CO)_8$ (240 mg, 0.70 mmol) and Fc–C_6H_4–(C≡C)$_2$–C_6H_4-Fc (200 mg, 0.35 mmol) was stirred for 4 h at room temperature. The solvent of the resulting dark mixture was removed in vacuum. The residue was dissolved in a minimal amount of benzene and subjected to chromatographic separation on a silica gel column (2.0 × 40 cm). Elution with hexane afforded a black band (**3**). Crystals of **3** were obtained by recrystallizing solid **3** from hexane at −20 °C. Complex **3**: Yield: 69%; m.p. 300 °C (dec.). *Anal*. Calc. for $C_{48}H_{26}O_{12}Co_4Fe_2$: C, 50.44; H, 2.28. Found: C, 50.14; H, 2.91%. IR (KBr disk, cm^{-1}) ν_{CO} 2088vs, 2047vs, 2014s, 2000s. ^{1}H NMR ($CDCl_3$, δ): 4.05–4.67 (m, 18H, Fc), 7.26–7.44 (m, 8H, 2C_6H_4). ^{13}C NMR ($CDCl_3$, δ): 66.5–69.7 (Cp), 84.3–99.7 (2C≡C), 126.1–139.7 (2C_6H_4), 198.5 (CO). MS (ESI): 1142 (M^+).

3.6. X-ray crystallography of compounds **L** (**2**)

The black crystals of compounds **L** and **2** were mounted on a glass fibers. All measurements were made on a Bruker SMART APEX CCD diffractometer with graphite monochromated Mo Kα ($\lambda = 0.71073$ Å) radiation. All data were collected at 20 °C using the ϕ and ω scan techniques. All structures were solved by direct methods and expanded using the Fourier technique [26]. An absorption correction based on SADABS was applied [27]. All non-hydrogen atoms were refined by full matrix least-squares on F^2. Hydrogen atoms were located and refined by the geometry method. The cell refinement, data collection and reduction were done by Bruker SMART and SAINT [28]. The structure solution and refinement were performed by SHELXSL 97 [29]. The further crystal data and details of measurements are shown in Table 1.

4. Conclusion

A new ferrocenylphenyl butadiynyl ligand Fc–C_6H_4–$(C{\equiv}C)_2$–C_6H_5 has been synthesized by the Glaser cross-coupling reaction and three new cobalt coordinated complexes **1**, **2**, **3** have successfully been obtained by the addition reaction of $Co_2(CO)_6$ units to the alkyne bonds of *p*-ferrocenylphenylacetylene compounds. The synthesis and structure of compounds **L** and **2** are reported for the first time. The molecular structure of complex **2** shows that the $Co_2(CO)_6$ units coordinated to the alkyne bonds are in a *trans* arrangement. The molecular structure data demonstrate that the butadiynyl groups of ligand **L** are nearly linear and the coordinated butadiynyl groups in **2** have deviated from a linear structure.

2. Results and discussion

2.1. Synthesis and spectroscopic characterization of complexes 1–4

By reaction of $[(C_5H_4SiMe_2{}^tBu)_2Ln(\mu\text{-}Me)]_2$ with 2 equiv of elemental sulfur in toluene at room temperature, we synthesized new complexes $[(C_5H_4SiMe_2{}^tBu)_2Ln(\mu\text{-}SMe)]_2$ [Ln = Yb (**1**), Er (**2**), Dy (**3**), Y (**4**)] in good yields. The formation of complexes **1-4** was interpreted as one sulfur atom insertion into the Ln–C(Me) bond of $[(C_5H_4SiMe_2{}^tBu)_2Ln(\mu\text{-}Me)]_2$, as shown in Scheme 1.

Complexes **1**–**4** are highly soluble in THF and soluble in toluene and *n*-hexane. They are sensitive to moisture and air. The four methylthiolate complexes were characterized by elemental analysis, IR and MS spectroscopies, which were in good agreement with the proposed structures. The spectroscopic properties of **1**–**4** are very similar, indicating that they have similar structures. Compounds **1** and **3** were also characterized crystallographically. The IR spectra of these complexes show characteristic absorptions of the η^5-$C_5H_4SiMe_2{}^tBu$ group at about 3085, 1460, 1007, 774 cm^{-1}. Although the molecule ion peaks of these complexes are not observed in the mass spectra, their main fragments are observed, such as $[M/2]^+$, $[M/2-Me]^+$, and $[M/2-SMe]^+$.

Complex **1** crystallized from the solvent mixture of tetrahydrofuran and toluene in triclinic system, space group $P\bar{1}$. An ORTEP diagram of **1** is shown in Fig. 1. Selected bond distances and angles are given in Table 1. The X-ray structure of **1** definitively proves that only one sulfur atom is inserted into the Yb–C bond, giving a thiolate ligand. Complex **1** is a solvent-free dimeric structure with each ytterbium coordinated by two η^5-$C_5H_4SiMe_2{}^tBu$ groups and two bridging sulfur atoms. The coordination number of ytterbium atom is eight, which is common as those of many lanthanocene thiolates complexes. The average Yb–S distance of 2.706 Å is comparable with the values found in the related thiolate-bridged complexes $[Cp_2Yb(\mu\text{-}SMe)]_2$ (2.706(4) Å) and $[Cp_2Yb(\mu\text{-}S^nBu)]_2$ (2.707(3) Å) [7], but is shorter than that found in $Cp_2Yb(SBT)(THF)$ (SBT = benzothiazole-2-thiolate) (2.843 Å) [6d]. The S–C bond distance of 1.826(5) Å is in the normal range for a sulfur–carbon (sp^3) single bond [9] and is similar to the values reported in other complexes containing thiolate ligands [7]. In the Yb_2S_2 bridging unit, the angles of Yb–S–Yb and S–Yb–S are respectively 97.4(1)° and 82.6(1)°, which are similar to the corresponding values in $[Cp_2Yb(\mu\text{-}SMe)]_2$ and $[Cp_2Yb(\mu\text{-}S^nBu)]_2$ [7], but very different from the observations in $[(Me_3CC_5H_4)_2Ce(\mu\text{-}SCHMe_2)]_2$ [6c].

As shown in Fig. 1, complex **3** is isostructural to complex **1** and is also a symmetrical dimeric structure. The

$$[(C_5H_4SiMe_2{}^tBu)_2LnMe]_2 \xrightarrow[\text{toluene}]{1/4\ S_8} [(C_5H_4SiMe_2{}^tBu)_2Ln(\mu\text{-}SMe)]_2$$

Ln = Yb(**1**), Er(**2**), Dy(**3**), Y(**4**)

Scheme 1.

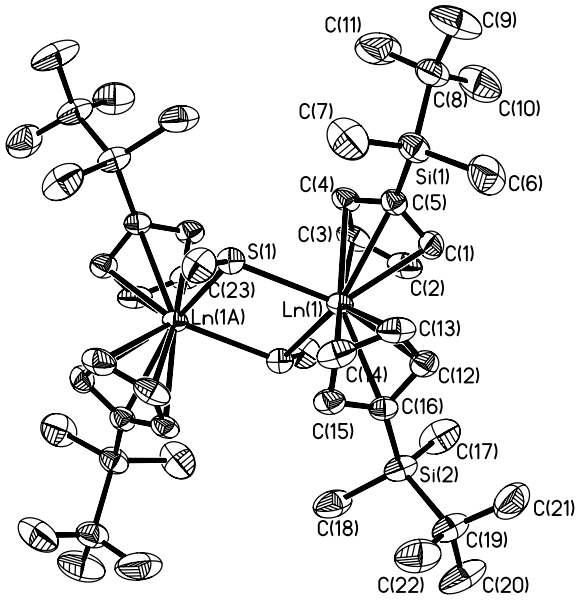

Fig. 1. ORTEP diagram of $[(C_5H_4SiMe_2{}^tBu)_2Ln(\mu\text{-}SMe)]_2$ [Ln = Yb (**1**), Dy (**3**)] with the probability ellipsoids drawn at the 30% level. Hydrogen atoms are omitted for clarity.

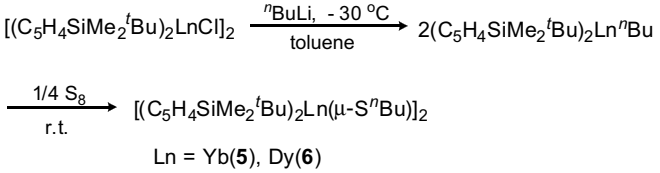
Table 1
Selected bonds lengths (Å) and angles (°) for complex **1** and **3**

	Ln = Yb (**1**)	Ln = Dy (**3**)
Ln(1)–C(1)	2.580(5)	2.655(4)
Ln(1)–C(2)	2.576(5)	2.615(4)
Ln(1)–C(3)	2.602(5)	2.628(4)
Ln(1)–C(4)	2.610(5)	2.661(5)
Ln(1)–C(5)	2.609(5)	2.657(4)
Ln(1)–C(12)	2.578(5)	2.646(4)
Ln(1)–C(13)	2.588(5)	2.619(5)
Ln(1)–C(14)	2.616(5)	2.626(5)
Ln(1)–C(15)	2.617(5)	2.644(5)
Ln(1)–C(16)	2.632(4)	2.640(5)
S(1)–C(23)	1.826(5)	1.825(5)
Ln(1)–S(1)	2.6987(14)	2.7350(14)
Ln(1A)–S(1)	2.7130(15)	2.7536(14)
C(23)–S(1)–Ln(1)	118.8(2)	118.67(18)
Ln(1)–S(1)–Ln(1A)	97.40(4)	96.70(4)
C(23)–S(1)–Ln(1A)	117.0(2)	117.34(19)
S(1)–Ln(1)–S(1A)	82.60(4)	83.30(4)

structural parameters of **3** (Table 1) are very similar to those for complex **1**. The Dy–C(Cp) distances range from 2.615(4) to 2.661(4) Å, and the average value of 2.639(5) Å is similar to those found in other Cp_2Ln-containing lanthanide complexes, such as $Cp_2Dy(SBT)(THF)$ (2.65(3) Å) [6d]. The Dy–S and Dy–C distances are comparable to the corresponding distances in complex **1**, respectively, when the difference in the metal ionic radii is considered [10].



2.2. Synthesis and spectroscopic characterization of complexes 5 and 6

In order to understand the factors affecting the insertion of sulfur into the lanthanide–carbon bond, the reactivity of

the corresponding *n*-butyl complexes with elemental sulfur was also studied. In contrast to the previously observation that reaction of $Cp_2Y(^nBu)$ with elemental sulfur in 1:1 stoichiometric ratio at room temperature yields $[(Cp_2Y)_2(\mu_3\text{-}S)(THF)]_2$ as the metal-containing product with the extrusion of $^nBuS^nBu$ and $^nBuSS^nBu$ [7], under the same conditions $(C_5H_4SiMe_2{}^tBu)_2Ln^nBu$ (prepared in situ from $[(C_5H_4SiMe_2{}^tBu)_2LnCl]_2$ and Li^nBu) undergo smooth insertion of sulfur into Ln–C bond to give the insertion products $[(C_5H_4SiMe_2{}^tBu)_2Ln(\mu\text{-}S^nBu)]_2$ [Ln = Yb (**5**), Dy (**6**)] (Scheme 2). Attempts to obtain the corresponding lanthanocene sulfide or disulfide complexes by reacting $(C_5H_4SiMe_2{}^t\text{-}Bu)_2Ln^nBu$ with a slight excess of elemental sulfur were unsuccessful. The reasons why $[(C_5H_4SiMe_2{}^tBu)_2Ln(\mu\text{-}S^nBu)]_2$ are more stable in solution with S_8 than $[(C_5H_5)_2Ln(\mu\text{-}S^nBu)]_2$ are as yet unclear, but may reflect the greater steric hindrance of *tert*-butyldimethylsilylcyclopentadienyl in comparison to cyclopentadienyl. These results demonstrate that the nature of cyclopentadienyl co-ligands has great influence on the final product from the reaction of lanthanocene alkyls with elemental sulfur. The formation of complexes **5** and **6** further proves that substituted lanthanocene alkyl complexes exhibit high activity toward elemental sulfur, leading to thiolate ligands.

The two butylthiolate complexes are air- and moisture-sensitive. They are readily dissolved in THF and soluble in toluene and *n*-hexane. Complexes **5** and **6** were characterized by elemental analysis, IR, mass spectroscopies and X-ray single crystal diffraction analysis, which were in agreement with the proposed structures. The IR spectra of these complexes show that the characteristic absorptions of the $\eta^5\text{-}C_5H_4SiMe_2{}^tBu$ group.

Complexes **5** and **6** crystallize from the solvent toluene in monoclinic system, space group $P2(1)/c$. The X-ray structures of **5** and **6** definitively prove that only one sulfur atom is inserted into the Ln–C(^{n}Bu) bond, giving a thiolate ligand. Fig. 2 shows the molecule structure of **5** and **6** and their selected bond distances and angles are listed in Table 2. Complexes **5** and **6** are isostructural and centresymmetrical dimeric structures. In the two complexes, each Ln^{3+} ion is coordinated by two $\eta^5\text{-}C_5H_4SiMe_2{}^tBu$ groups and two sulfur atoms. The Yb–S distances are similar to that found in complex **1**. The S–C bond distance of 1.841(12) Å is in the normal range for a sp^3 sulfur–carbon single bond and similar to the distances reported in other complexes containing SR groups [9]. All the distances and angles of complex **6** (Table 2) are in normal range,

Scheme 2.

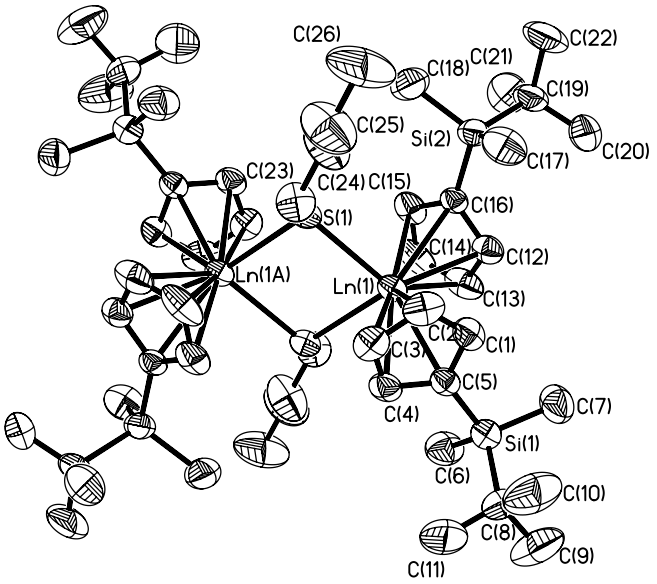


Fig. 2. ORTEP diagram of $[(C_5H_4SiMe_2{}^tBu)_2Ln(\mu\text{-}S^nBu)]_2$ [Ln = Yb (**5**), Dy (**6**)] with the probability ellipsoids drawn at the 30% level. Hydrogen atoms are omitted for clarity.

Table 2

and the angles of Dy–S–Dy [95.4(1)°] and S–Dy–S [84.6(1)°] are similar to the corresponding values in complex **5**, when the different ionic radii of the center metals is considered.

3. Conclusion

The results of this study offer an interesting contrast to the known cyclopentadienyl-type organolanthanide alkyl complexes. With a cyclopentadienyl group as a co-ligand, insertion of sulfur into the Ln–C bond is only available for methyl complexes at room temperature, whereas the *n*-butyl complexes undergo facile conversion to lanthanocene

sulfides via the competitive interaction of the resultant thiolate intermediate with the remaining sulfur, followed by the intermolecular elimination of thioether or organic disulfide. The corresponding insertion intermediate $[Cp_2Ln(\mu\text{-}S^nBu)]_2$ could be only isolated in the presence of excess $Cp_2Ln(^nBu)$ under more mild reaction conditions. In contrast, for the present *tert*-butyldimethylsilylcyclopentadienyl ligand system, under the same reaction conditions, insertion is available for both methyl and butyl complexes, and these complexes undergo smooth insertion of sulfur into lanthanide–alkyl bond to give the corresponding insertion products $[(C_5H_4SiMe_2{}^tBu)_2Ln(\mu\text{-}SMe)]_2$ and $[(C_5H_4SiMe_2{}^tBu)_2Ln(\mu\text{-}S^nBu)]_2$, respectively. All these results confirm that the insertion of sulfur into the lanthanide-alkyl bond is general.

4. Experimental

4.1. General procedures

All operations involving air- and moisture-sensitive compounds were carried out under an inert atmosphere of purified nitrogen using standard Schlenk techniques. The solvents of THF, toluene and *n*-hexane were refluxed and distilled over sodium benzophenone ketyl under nitrogen immediately prior to use. $[Cp^t_2Ln(\mu\text{-}Cl)]_2$ [11], $[Cp^t_2Ln(\mu\text{-}Me)]_2$ [12] and $Cp^t_2Ln^nBu$ ($Cp^t = \eta^5\text{-}C_5H_4SiMe_2{}^tBu$) [13] were prepared by the literature procedures. Methyllithium and *n*-Butyllithium were purchased from Aldrich and were used without further purification. Elemental analyses for C and H were carried out on a Rapid CHN–O analyzer. Infrared spectra were obtained on a NICOLET FT-IR 360 spectrometer with samples prepared as Nujol mulls. Mass spectra were recorded on a Philips HP5989A instrument operating in EI mode. Crystalline samples of the respective complexes were rapidly introduced by the direct inlet techniques with a source temperature of 200 °C. The values of *m*/*z* are referred to the isotopes ^{12}C, ^{1}H, ^{16}O, ^{32}S, ^{28}Si, ^{174}Yb, ^{166}Er, ^{164}Dy, ^{89}Y.

4.2. Synthesis of $[(C_5H_4SiMe_2{}^tBu)_2Yb(\mu\text{-}SMe)]_2$ (1)

To a solution of $[Cp^t_2Yb(\mu\text{-}Me)]_2$ (0.290 g, 0.266 mmol) in toluene (30 mL) was added S_8 (17 mg, 0.066 mmol). After stirring for 10 h, the reaction mixture was concentrated by reduced pressure to give a yellow powder. Recrystallization of the powder from the mixture solution of THF and toluene at −15 °C afforded **1** as orange-red crystals. Yield: 0.211 g (68.6%). *Anal.* Calc. for $C_{46}H_{82}S_2Si_4Yb_2$: C, 47.72; H, 7.14. Found: C, 47.65; H, 7.10%. 4.3. Synthesis of $[(C_5H_4SiMe_2{}^tBu)_2Er(\mu\text{-}SMe)]_2$ (2)

Following the procedure described above for **1**, reaction of $[Cp^t_2Er(\mu\text{-}Me)]_2$ (0.291 g, 0.27 mmol) with S_8 (17 mg, 0.066 mmol) gave complex **2** as pink crystals. Yield: 0.201 g (65%). *Anal.* Calc. for $C_{46}H_{82}S_2Si_4Er_2$: C, 48.20; H, 7.21. Found: C, 48.08; H, 7.16%. 4.4. Synthesis of $[(C_5H_4SiMe_2{}^tBu)_2Dy(\mu\text{-}SMe)]_2$ (3)

Following the procedure described above for **1**, reaction of $[Cp^t_2Dy(\mu\text{-}Me)]_2$ (0.557 g, 0.52 mmol) with S_8 (33 mg, 0.13 mmol) gave complex **3** as pale-yellow crystals. Yield: 0.410 g (69%). *Anal.* Calc. for $C_{46}H_{82}S_2Si_4Dy_2$: C, 48.61; H, 7.27. Found: C, 48.47; H, 7.45%. 4.5. Synthesis of $[(C_5H_4SiMe_2{}^tBu)_2Y(\mu\text{-}SMe)]_2$ (4)

Following the procedure described above for **1**, reaction of $[Cp^t_2Y(\mu\text{-}Me)]_2$ (0.217 g, 0.235 mmol) with S_8 (15 mg, 0.059 mmol) gave complex **4** as colorless crystals. Yield: 0.140 g (60%). *Anal.* Calc. for $C_{46}H_{82}S_2Si_4Y_2$: C, 55.84; H, 8.35. Found: C, 55.79; H, 8.26%. 4.6. Synthesis of $[(C_5H_4SiMe_2{}^tBu)_2Yb(\mu\text{-}S^nBu)]_2$ (5)

To a solution of $[(C_5H_4SiMe_2{}^tBu)_2YbCl]_2$ (0.533 g, 0.47 mmol) in toluene (30 mL) was added ^{n}BuLi (1.60 M, 0.588 mL in hexane) at −30 °C. After stirring for 1 h at the low temperature, the reaction solution was slowly warmed to room temperature and stirred for 1 h, forming a colorless precipitate (LiCl). Then, to the mixture was added S_8 (30 mg 0.117 mmol) at ambient temperature. After stirring for 12 h, the precipitate was removed by centrifugation. Removal of the solvent gave pink powder. Recrystallization of the powder from toluene at −15 °C afforded **5** as orange–red crystals. Yield: 0.327 g (56%). *Anal.* Calc. for $C_{52}H_{94}S_2Si_4Yb_2$: C, 50.29; H, 7.63. Found: C, 50.22; H, 7.72%. IR (Nujol, cm^{-1}): 3086 w, 1463 s, 1377 s, 1360 w, 1249 s, 1179 s, 1043 s, 1007 m, 903 w, 829 s, 805 s, 776 s, 669 w, 665 w. EI-MS: *m*/*z* [fragment, relative intensity (%)] = 620 (M/2−1, 3), 564 (M/2−^{n}Bu, 2), 534 (M/2−S^{n}Bu+2, 80), 404 (M/2−S^{n}Bu−SiMe$_2{}^t$Bu−CH$_3$+2, 4), 362 (M/2−S^{n}Bu−SiMe$_2{}^t$Bu−^{t}Bu+2, 7), 298 (M/2−S^{n}Bu−Cp^t − ^{t}Bu+2, 2), 180 (Cp^{t}H, 6).

4.7. Synthesis of $[(C_5H_4SiMe_2{}^tBu)_2Dy(\mu\text{-}S^nBu)]_2$ (6)

Following the procedure described above for **5**, reaction of $[(C_5H_4SiMe_2{}^tBu)_2DyCl]_2$ (0.450 g, 0.405 mmol) ^{n}BuLi (1.60 M, 0.506 mL in hexane) and subsequently with S_8 (26 mg, 0.10 mmol) gave pale yellow powder. Recrystallization of the powder from toluene at −15 °C afforded **6** as pale yellow crystals. Yield: 0.371 g (75%). *Anal.* Calc. for $C_{52}H_{94}S_2Si_4Dy_2$: C, 51.16; H, 7.76. Found: C, 51.06; H, 7.80%. IR (Nujol, cm^{-1}): 3085 w, 1463 s, 1443 w, 1377 s, 1360 w, 1249 s, 1178 s, 1043 s, 1007 m, 902 w, 829 s, 805 s, 774 s, 721 m, 668 w, 643 w. EI-MS: *m*/*z* [fragment, relative intensity (%)] = 717 (M−2Cp^t−S^{n}Bu−BuH, 13), 610 (M/2−1, 4), 554 (M/2−^{n}Bu, 2), 522 (M/2−S^{n}Bu, 80), 406 (M/2−S^{n}Bu−SiMe$_2{}^t$Bu−1, 6), 390 (M/2−S^{n}Bu−SiMe$_2{}^t$Bu

4.8. X-ray crystal structure determination of complexes *1*, *3*, *5* and *6*

Suitable crystals of complexes **1**, **3**, **5** and **6** were selected and sealed in a thin-walled glass capillary under N_2 for structural analysis. Diffraction data were collected on a Bruker SMART Apex CCD diffractometer using graphite-monochromated Mo Kα ($\lambda = 0.71073$ Å) radiation. During the collection of the intensity data, no significant decay was observed. For **1**, frames were integrated to the maximum 2θ angle of 50.02° with the Siemens SAINT program to yield a total of 5755 reflections, of which 4760 were independent ($R_{int} = 0.0142$). For **3**, frames were integrated to the maximum 2θ angle of 50.02° with the Siemens SAINT program to yield a total of 5835 reflections, of which 4812 were independent ($R_{int} = 0.0188$). For **5**, frames were integrated to the maximum 2θ angle of 50.02° with the Siemens SAINT program to yield a total of 12 712 reflections, of which 5415 were independent ($R_{int} = 0.0584$). For **6**, frames were integrated to the maximum 2θ angle of 50.02° with the Siemens SAINT program to yield a total of 12 885 reflections, of which 5448 were independent ($R_{int} = 0.0405$). The final unit cell parameters were determined from the full-matrix least-squares on F^2 refinement of three-dimensional centroids of 5755 reflections for **1**, 5835 reflections for **3**, 5415 reflections for **5** and 5448 reflections for **6**. The intensities were corrected for Lorentz-polarization effects and empirical absorption with SADABS program [14]. A summary of the crystallographic data and selected experimental information is given in Table 3.

The structures were solved by the direct method using the SHELXL-97 program [15]. All non-hydrogen atoms were found from the difference Fourier syntheses. The H atoms were included in calculated positions with isotropic thermal parameters related to those of the supporting carbon atoms, but were not included in the refinement. All calculations were performed using the Bruker Smart program.

Supplementary material

CCDC 645443, 645447, 645446 and 645445 contain the supplementary crystallographic data for **1**, **3**, **5** and **6**. These data can be obtained free of charge via htpp://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

carbaldehyde thiosemicarbazone (Httsc), pyrrole-2-carbaldehyde thiosemicarbazone (H_2ptsc), salicylaldehyde thiosemicarbazone (H_2stsc) and pyridine-2-carbaldehyde thiosemicarbazone (Hpytsc), which have been used to observe the effect of the different rings at the C^2 carbon on the nature of bonding with palladium (II). In this paper, we report a series of Pd^{II} complexes [18] that have been characterized using analytical data, spectroscopic techniques and X-ray crystallography.

2. Experimental

2.1. Materials and techniques

Furan-2-carbaldehyde, thiophene-2-carbaldehyde, pyrrole-2-carbaldehyde, salicylaldehyde, pyridine-2-carbaldehyde, Ph_3P and $PdCl_2$ were procured from Aldrich Sigma Ltd. The thiosemicarbazone ligands were prepared by the reported methods [19]. Trans-$PdCl_2(PPh_3)_2$ was prepared by reacting a solution of $PdCl_2$ in CH_3CN with two moles of PPh_3 [20]. Elemental analysis for C, H and N were carried out using a thermoelectron FLASHEA1112 analyser. The melting points were determined with a Gallenkamp electrically heated apparatus. The IR spectra were recorded using KBr pellets on a Pye-Unicam SP3-300 spectrophotometer. ^{1}H NMR spectra were recorded on a JEOL AL300 FT spectrometer at 300 MHz in $CDCl_3$ with TMS as the internal reference. The ^{31}P NMR spectra were recorded at 121.5 MHz with $\{(CH_3O)_3P\}$ as the external reference taken as the zero position.

2.2. Synthesis of [Pd(η^2-N^3, S-ftsc)(PPh_3)Cl] (1)

To the *trans*-$PdCl_2(PPh_3)_2$ precursor (0.05 g, 0.07 mmol) suspended in toluene (15 mL) was added solid Hftsc (0.012 g, 0.07 mmol), followed by the addition of Et_3N base (1 mL), and the mixture was stirred for 3 h, during which time a clear light orange solution was formed along with $Et_3NH^+Cl^-$, separating from the solution at the bottom of the flask. The solution was filtered to remove $Et_3NH^+Cl^-$ and allowed to evaporate at room temperature, and after evaporation, a yellow orange crystalline product was formed. Yield: 0.026 g, 65%; m.p. 233–235 °C. *Anal.* Calc. for $C_{24}H_{21}ClN_3OPPdS$: C, 50.30; H, 3.84; N, 7.30. Found: C, 50.83; H, 3.87; N, 7.46%. Main I.R. peaks (KBr, cm^{-1}): ν(NH) 3495s, 3292s, ν(C–H) 3050w, ν(C=N) + δNH_2 + ν(C=C) 1606s, 1589s, 1514s, ν(C=S) 819s, ν(P–C) 1095s. ^{1}H NMR ($CDCl_3$, δ, ppm): 8.60 (d, 1H, C^2H), 7.70–7.77 (m, 6H, *o*-Ph), 7.40–7.54 (m, 11H, *m,p*-Ph + $C^{4,6}$), 6.53 (dd, 1H, C^5H), 4.84 (s, 2H, NH_2). ^{31}P NMR ($CDCl_3$, δ, ppm): −80.5. $\Delta\delta(\delta_{complex}-\delta_{PPh_3}) =$ 32.6 ppm.

2.3. Synthesis of [Pd(η^2-N^3, S-ttsc)(PPh_3)Cl] (2)

Compound **2** was prepared similarly to **1**.

Yield: 0.024 g, 65%, m.p. 233–235 °C. *Anal.* Calc. for $C_{24}H_{21}N_3S_2PClPd$: C, 49.0; H, 3.50; N, 7.13. Found: C, 49.2; H, 3.48; N 7.4%. I.R. (KBr, cm^{-1}): ν(N–H) 3350m, ν(C=N) + δNH_2 + ν(C=C) 1581m, 1514s, 1459sh, ν(C=S) 808s, ν(P–C) 1095s. ^{1}H NMR ($CDCl_3$, δ, ppm): 8.80 (d, 1H, C^2H), 7.71–7.78 (m, 6H, *o*-Ph), 7.63 (d, 1H, C^6), 7.54 (d, 1H, C^4), 7.40–7.52 (m, 9H, m&p-Ph), 7.09 (dd, 1H, C^5), 4.87 (s, 2H, NH_2). ^{31}P NMR($CDCl_3$, δ, ppm): −80.5. $\Delta\delta(\delta_{complex} - \delta_{PPh_3}) = 32.6$ ppm.

2.4. Synthesis of [Pd(η^2-N^3,S-ftsc)$_2$] (3)

To $PdCl_2(PPh_3)_2$ (0.05 g, 0.07 mmol) suspended in toluene (20 mL) was added Hftsc (0.026 g, 0.14 mmol), followed by the addition of Et_3N base (2 mL). The solution was refluxed for around 2 h, and then filtered to remove $Et_3NH^+Cl^-$. A red crystalline product started forming after

a few days. Yield: 0.018 g, 51%, m.p. 188 °C *Anal.* Calc. for $C_{12}H_{12}N_6S_2O_2Pd$: C, 32.6; H, 2.71; N, 19.00. Found: C, 32.0; H, 2.84; N, 18.8%. ^{1}H NMR data ($CDCl_3$, δ, ppm): 8.60 (d, 1H, C^2H), 6.53 (dd, 1H, C^5H), 4.84 (s, 2H, NH_2). Crystals for X-ray study were grown from acetonitrile.

2.5. Synthesis of [Pd(η²-N³,S-ttsc)₂] (4)

Compound **4** was prepared similarly to **3**.

Yield: 0.019 g, 54%, m.p. 223–225 °C. *Anal.* Calc. for $C_{12}H_{12}N_6S_4Pd$: C, 30.37; H, 2.53; N, 17.7. Found: C, 30.81; H, 2.48; N, 17.4%. I.R. (KBr, cm^{-1}): ν(N–H) 3384m, 3363w, 3278s, ν(C–H) 3176m, ν(C=N) + δNH_2 + ν(C=C) 1577s, 1595sh, ν(C–S) 811s. ^{1}H NMR data ($CDCl_3$, δ, ppm): 7.73 (s, 2H, C^2H), 7.65 (d, 2H, C^6H), 7.40 (d, 2H, C^4H), 7.08 (dd, 2H, C^5H), 5.07 (s, 4H, NH_2).

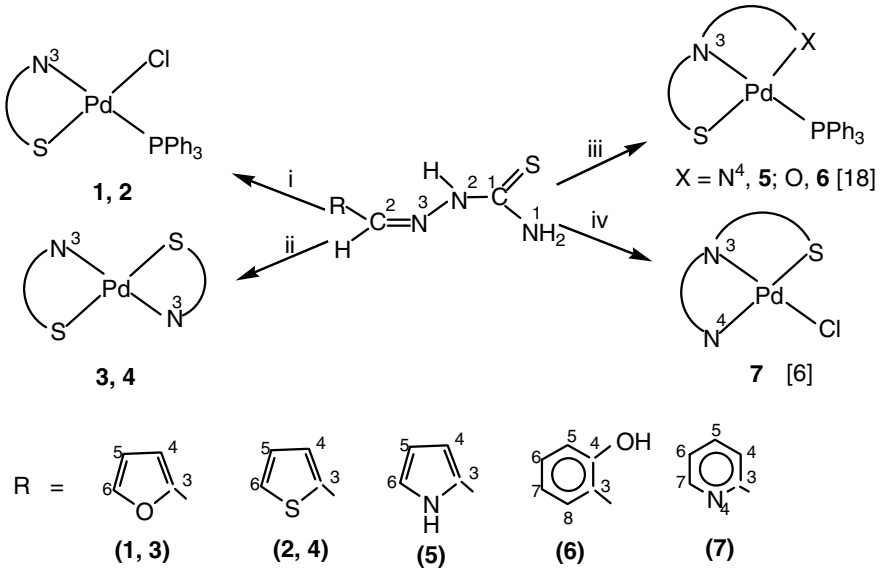
2.6. X-ray crystallography

The data for compounds **1** and **2** were collected at 293 and 295 K, respectively, on a Siemens P4 diffractometer. The θ–2θ technique was used to measure the intensities up to a maximum of $2\theta = 50°$ with graphite monochromatised Mo Kα radiation ($\lambda = 0.71073$ Å). Cell parameters were refined in the θ range 10–12.5° using XSCANS [21]. The data were corrected for Lorentz and polarization factors. An empirical psi absorption correction was applied. The structure was solved by direct methods and refined by full matrix least squares methods based on F^2. All non-hydrogen atoms were refined anisotropically, and hydrogen atoms were assigned calculated positions. Scattering factors from the International Tables for X-ray crystallography were used [22]. Data reduction, structure solution, refinement and molecular graphics were performed using SHELXTL-PC [23] and WINGX [24].

Single crystals of compounds **3** and **4** were mounted on a CCD area detector diffractometer, equipped with a graphite monochromator using Mo Kα radiation ($\lambda = 0.71073$ Å) for **3** and Cu Kα radiation ($\lambda = 1.54178$ Å) for **4**. The unit cell dimensions and intensity data were measured at 273(2) (**3**) and 296(2) K (**4**). The structures were solved by the direct methods and refined by full matrix least square methods based on F^2 with anisotropic thermal parameters for the non-hydrogen atoms, using Bruker SMART (data collection and cell refinement), Bruker SHELXTL (data reduction and computing molecular graphics), SHELXS-97 (structure solution) and SHELXL-97 (structure refinement)] [25]. An empirical psi absorption correction was applied. The calculated positions for the H atoms were used in structure factor (SF) calculations with ω scan to 56° 2θ.

3. Results and discussion

3.1. Synthesis and IR spectroscopy



Scheme 1 depicts the formation of complexes **1**–**6** using a series of thiosemicarbazone ligands, namely Hftsc, Httsc, H_2ptsc, H_2stsc and Hpytsc. The formation of compounds [Pd(η²-N^3,*S*-ftsc)(PPh_3)Cl] (**1**) and [Pd(η²-N^3,*S*-ttsc)-(PPh_3)Cl] (**2**) required the addition of one equivalent of Hftsc or Httsc to the *trans*-$PdCl_2(PPh_3)_2$ precursor, while the addition of two equivalents of thiosemicarbazone to *trans*-$PdCl_2(PPh_3)_2$ yielded compounds [Pd(η²-N^3,*S*-ftsc)$_2$] (**3**) and [Pd(η²-N^3,*S*-ttsc)$_2$] (**4**). In all these complexes, the thiosemicarbazone ligands coordinate via the N^3,*S* donor atoms. Interestingly, the addition of one equivalent of H_2ptsc or H_2stsc to the $PdCl_2(PPh_3)_2$ precursor removed both the Cl anions, forming compounds [Pd(η³-N^4,N^3,*S*-ptsc)(PPh_3)] (**5**) and [Pd(η³-O, N^3,*S*-stsc)(PPh_3)] (**6**) [18]. There was no effect on the stoichiometry when two equivalents of H_2ptsc or H_2stsc were used. It may be noted that in compounds **1**–**4**, only the hydrazinic hydrogen (–N^2H) is removed, whereas in complexes **5** and **6**, both –N^2H as well as –N^4H (pyrrole, **5**) or –OH (**6**) groups were deprotonated [18]. Thus, the presence of acidic hydrogens in the rings at the C^2 carbon (pyrrole, 2-hydroxyphenyl) modulated the dentacy of the H_2ptsc or H_2stsc ligands from the usual bidentate mode to a tridentate mode. Pyridine-2-carbaldehyde thiosemicarbazone (Hpytsc) with $PdCl_2(PPh_3)_2$ formed only a square planar complex [Pd(η³-N^4,N^3,*S*-pytsc)Cl] (**7**) [6], and its stoichiometry is unaffected by the addition of two equivalents of Hpytsc [18].

The IR spectra of the complexes reveal the presence of ν(N–H) bands due to the (–NH_2) group in the range 3278–3495 cm^{-1}. The bands in the region 3100–3150 cm^{-1}, expected due to the –N^2H group in the free ligands [19], are found to be absent in the spectra of their complexes **1**–**4**, thus supporting the anionic form of the ligands. The ν(C–H) bands due to the aromatic ring are observed for all the complexes in the region near 3050 cm^{-1}. Further, $\delta(NH_2)$ + ν(C=N) + ν(C–C) vibration modes are unresolved, and are assigned to the range 1635–1515 cm^{-1}. However, the thioamide bands due to the ν(C–S) mode are shifted to lower energy (at ~810 cm^{-1}) as compared with the similar free ligand bands, and this is consistent with its single bond character in the anionic form [19]. The presence of PPh_3 in complexes **1** and **2** is confirmed by the presence of a characteristic ν(C–P) band in the range 1095–1099 cm^{-1} (see Table 1).

3.2. Crystal structures

The atomic numbering schemes for complexes **1**–**4** are given in Figs. 1–4, respectively, and selected bond angles and bond lengths are listed in Table 2. Compounds **1**–**4** crystallized in the monoclinic crystal systems (**1**, **2**), the trigonal system (**3**) or the triclinic system (**4**).

In complex **1**, furan-2-carbaldehyde thiosemicarbazonate ($ftsc^-$) binds via N^3 and *S* donor atoms to the Pd^{II} center, with the furan ring (C_4H_3O) remaining pendant. The other two sites are occupied by the Cl and PPh_3 ligands. The bite angle N^3–Pd–S is 83.09(11)° while the other three angles around the Pd^{II} center, namely, S–Pd–P, P–Pd–Cl and N^3–Pd–Cl, are 91.49(5)°, 90.39(5)° and

Final R indices $[I > 2\sigma(I)]$	$R_1 = 0.0303$, $wR_2 = 0.0741$	$R_1 = 0.0293$, $wR_2 = 0.0764$	$R_1 = 0.0194$, $wR_2 = 0.0575$	$R_1 = 0.0528$, $wR_2 = 0.1250$

95.02(11)°, respectively. Compound **2**, with the thiophene ring (C_4H_3S) in lieu of furan (C_4H_3O), has similar corresponding bond angles, namely 83.00(7)° (N^3–Pd–S), 91.73(3)° (S–Pd–P), 92.08(3)° (P–Pd–Cl) and 94.14(7)° (N^3–Pd–Cl). Among the trans bond angles, the N^3–Pd–P angles are similar, {174.58(11)°, **1**; 171.63(8)°, **2**}, while the S–Pd–Cl angles are different {177.98(16)°, **1**; 169.86 (4)°, **2**}. The bite angles of **1** and **2** (Table 3) are similar to that of complex **8** (Chart 2) {N^3–Pd–S, 83.19(11)°} [16a], but the N^3–Pd–P and S–Pd–X (X = Cl, **1**, **2**; C, **8**) trans angles of **1** and **2** are different from that of **8** {N^3–Pd–P, 178.75(11)°; S–Pd–C 164.5(2)°} [16a]. Further, the Pd–P bond distances of **1**, **2** and **8** are comparable (Table 3), but the Pd–N^3 and Pd–S distances are different due to the difference in the chemical environments in the three cases (Table 3). It is concluded from the above that there is no metallation involving the furan or thiophene rings in compounds **1** and **2**, a behaviour unlike that observed

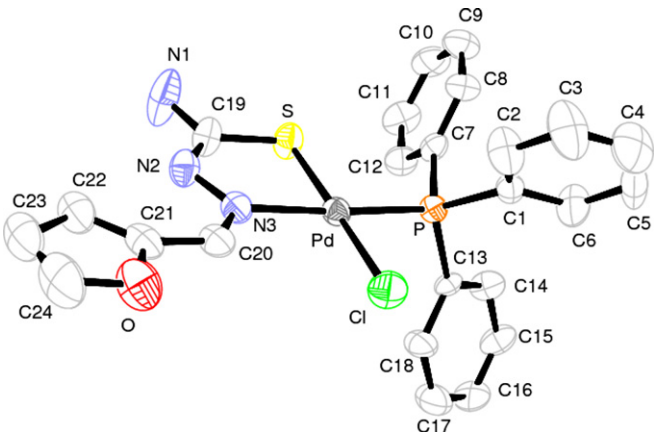

Fig. 1. Structure of the complex [Pd(η^2-N^3,*S*-ftsc)(PPh_3)Cl] (**1**) with the atomic numbering scheme.

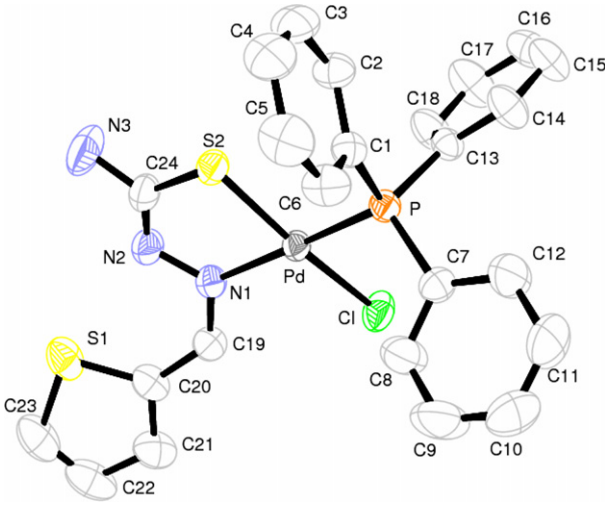

Fig. 2. Structure of the complex [Pd(η^2-N^3,*S*-ttsc)(PPh_3)Cl] (**2**) with the atomic numbering scheme.

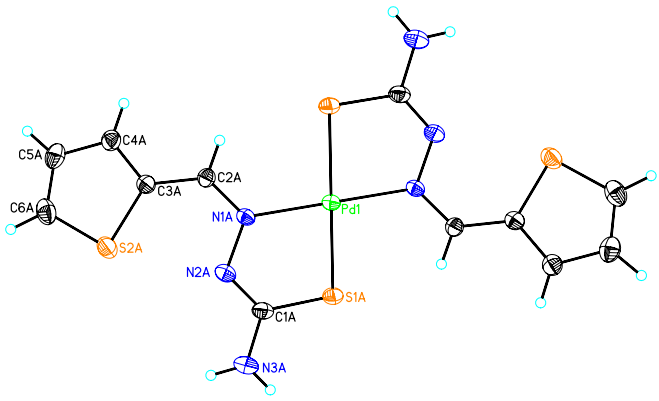

Fig. 4a. Structure of the complex [Pd(η^2-N^3,*S*-ttsc)] (**4**) with the atomic numbering scheme.

for compound **8** and its other analogues as listed in Chart 2.

A second mole of the Hftsc or Httsc ligand was added to the reaction systems of complexes **1** and **2**, with the objective that the coordination might proceed in one of three ways: (i) it may coordinate via the S-donor atom of the anionic thiosemicarbazone by replacing a chloride ion, (ii) it may chelate via N^3, S donor atoms and replace the chloride as well as PPh_3, and (iii) the pendant ring might metallate during the attempt to remove chloride by the presence of a second mole of ligand. The formation of compounds *trans*-[Pd(η^2-N^3,*S*-ftsc)$_2$] (**3**), and *trans*-[Pd(η^2-N^3,*S*-ttsc)$_2$] (**4**), has demonstrated that it is the second path which has been adopted by the reaction systems. It may be attributed to the chelate effect of the anionic thiosemicarbazones (ftsc$^-$ and ttsc$^-$), which have removed both Cl^- as well as PPh_3, and yielded the most symmetric products **3** and **4**. No metallation occurred, however, under these conditions.

In complexes **3** and **4**, the Pd^{II} ion is coordinated by two thiosemicarbazonate moieties (ftsc$^-$ and ttsc$^-$, respectively) via N^3 and S donor atoms in a *trans*-N_2S_2 manner with pendant heterocyclic rings. The bite angles {N^3–Pd–S, 83.67°, **3**; 82.89°, **4**} are similar to those in complexes **1** and **2**. The trans angles N^3–Pd–N^3 and S–Pd–S for both the complexes are linear (180.0° each). Interestingly, crystals of complex **4** reveal that there are three independent

Table 3
Comparison of bond lengths (Å) and bond angles (°) of complexes **1**–**6** with some literature values

	Pd–P	Pd–S	Pd–N^3	Pd–Cl	N–Pd–S	*trans* angles
1	2.2580	2.2430	2.103	2.3459	83.09	177.98, 174.58
2	2.2609	2.2395	2.085	2.3450	82.95	171.63, 169.86
3		2.2710	2.0305		83.67	180, 180
4		2.2869	2.031		82.89	179.99, 179.99
5 [18]	2.275	2.2453	2.0190		84.16	176.53, 164.22

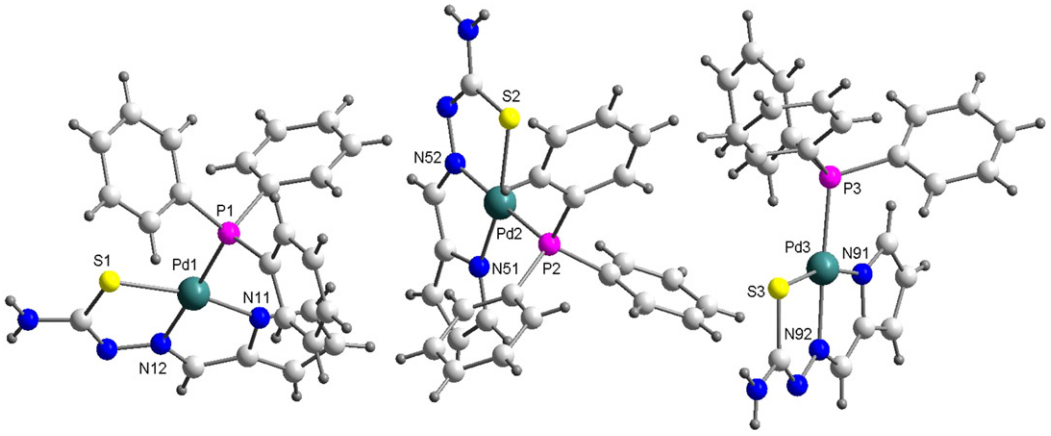

Fig. 5. Three molecules in the unit cell of complex **5**.

molecules with different orientations in the same unit cell (Fig. 4b), and with minor differences in bond parameters (Table 2). The existence of the three different types of molecules appears to be due to the presence of different intermolecular hydrogen bonds between the amino hydrogens ($-NH_2$) and the coordinated sulfur atom, as is shown in its packing diagram. The Pd–S and Pd–N bond lengths of complexes **3**, {2.2710(5) and 2.0305(13) Å}, and **4** {2.2869(15) and 2.031(5) Å}, are also similar. On comparing the bond lengths of **1** and **3**, it is found that the Pd–S distance of **1** is shorter than that of complex **3**, whereas the Pd–N distance is longer (Table 3). Similar differences in bond lengths are observed for complexes **2** and **4**. It may be added here that the N^3–Pd–S bite angles shown by complexes **1**–**4** are similar to those of complexes **5** and **6**. Further, compound **5** also showed three types of independent molecule with different bond parameters (Fig. 5) [18], similar to those shown by compound **4**.

3.3. NMR spectroscopy

The signals due to $-N^2H$ protons in the free ligands [19] were absent in complexes **1**–**4**, thus supporting deprotonation during complexation in all the complexes. The $-NH_2$ protons appear as single peaks in all the complexes due to the free rotation of the N^1H_2 group along the C^1-N^1 bond axis, instead of two broad peaks as observed in the free ligands due to the restricted rotation of the $-N^1H_2$ group along the C^1-N^1 bond axis at room temperature [19]. The peaks due to C^2H and ring protons are given in the experimental section. The ^{31}P NMR spectra of complexes **1** and **2** show a coordination shift of 32.6 ppm each, which is close to the shift observed for complexes **5** and **6** [18].

4. Conclusion

It may be concluded that for R = furan or thiophene at the C^2 carbon, the thiosemicarbazone ligands (Hftsc and Httsc) act as uninegative bidentate coordinating ligands to the metal center via N^3,*S*-donor atoms, forming five membered chelate rings, and the resulting products (**1**–**4**) are dependent on the metal to ligand molar ratio. For R = pyrrole or 2-hydroxyphenyl, the ligands act as dinegative tridentate coordinating ligands via N^4,N^3,*S*- or *O*,N^3,*S*-donor atoms (**5**, **6**), and for R = pyridyl, the ligand is uninegative tridentate (N^4,N^3,*S*) (**7**). There was no effect on stoichiometry when two equivalents of H_2ptsc, H_2stsc or Hpytsc were used.

5. Supplementary material

CCDC 650112, 650113, 650114 and 650115 contain the supplementary crystallographic data for **1**, **2**, **3** and **4**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the

Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

$C_6H_{14}N_4O_2$) and several counter ions. In the solid state, these compounds show interesting supramolecular structures, self-assembly and self-organization, with infinite single-, double- or triple-stranded helicates. As a consequence of the versatility of the positively charged guanidinium group, a binding site for H-bonds, arginine forms many complexes on reaction with organic and inorganic acids, and also incorporating metal ions [13,14]. The self-assembly is governed by hydrogen bonding, by the coordination of the metal ions, as well as by the nature of the counter ions. The metal compounds studied by Yamauchi and collaborators are essentially three dimensional and we are not aware of any dinuclear or polynuclear metal complex formation either with arginine or with other amino acid. As pointed out by Dey et al. [15] the ligands obtained by forming dinuclear metal complexes are effective devices for the recognition and assembly of external species, and also to mimic sites in which two metal ions cooperate to form a biologically relevant active centre. Thus, as part of our working lines on metal derivatives of amino acids, we found interesting to obtain and characterize dinuclear or polynuclear copper–arginine compounds using appropriate counter ions.

In recent years, Youngme and collaborators [16–18] prepared and characterized structurally and magnetically double and triply bridged dinuclear Cu(II) complexes containing the aromatic ligands 1,10-phenanthroline, 2,2′-bipyridine and di-2-pyridylamine and the $H_xPO_4^{(3-x)-}$ ($x = 1, 2$) oxoanions. In these compounds, the phosphate groups form bridges of different coordination types supporting weak antiferromagnetic interactions between neighbour copper ions. Here we exploited the bridging capabilities of phosphate groups as counter ions and report the synthesis, X-ray crystal structure and magnetic measurements of $[Cu_2(\text{L-arg})_2(\mu\text{-}HPO_4\text{-}O)(\mu\text{-}HPO_4\text{-}O,O')(\mu\text{-}OH)]^- \cdot (H_3O)^+ \cdot (H_2O)_6$ (**1**), a new dinuclear copper complex of L-arginine bridged by hydrogenphosphate and hydroxyl groups exhibiting unusual dinuclear interactions with a Cu(II) coordination and bridging mode which has not been observed previously for copper–amino acid complexes.

2. Material and methods

The growth solutions were prepared in a two-step process. In the first step, L-arginine phosphate ($C_6H_{14}N_4O_2 \cdot H_3PO_4 \cdot H_2O$) was synthesized by dissolving equimolar quantities of L-arginine (Ajinomoto Co.) and orthophosphoric acid (Merck) in a saturated water solution. The pH value of this solution was adjusted to 4.25. In the second step, Cu(II) ions as copper acetate with mole fractions 0.275 and 0.50, were added to the solution. All reagents were of analytical grade. Slow solvent evaporation at constant temperature was employed in the crystal growth and plate like crystals of **1** with intense blue colour and elongated along one direction, were obtained after few weeks. Atomic Absorption Spectroscopy (Perkin–Elmer Analyst 200) and a CHN analyser (Perkin–Elmer Series II 2400) were used for elemental analyses of C, H, N and Cu contents in **1**. *Anal.* Calc. for $C_{12}H_{46}Cu_2N_8O_{20}P_2$: C, 17.76; H, 5.71; Cu, 15.66; N, 13.81; O, 39.43; P, 7.63. Found: C, 17.98; H, 5.59; Cu, 15.8; N, 13.76%. Oxygen and phosphorus were not measured. The crystal density obtained by the Arquimedes' method is (1.682 ± 0.004) Mg/m^3. The experimentally measured composition and density are in good agreement with the values obtained from the X-ray diffraction structural determination.

Diffraction data were collected at 153 K with an Enraf-Nonius Kappa-CCD diffractometer with sealed tube source and graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). The unit cell parameters were derived from least squares refinement of 10451 reflections from $\theta = 0.998°$ to $\theta = 27.485°$. The data collection was within $\theta = 27.485°$; however, the final refinement improved when the weakest reflections beyond the usual $\theta = 25.000°$ were removed, and this condition was maintained. Data collection was made using the COLLECT program [19] and the integration and scaling of the reflections were performed with the HKL Denzo-Scalepack system of programs [20]. Absorption correction was carried out using the multi-scan method [21]. The structure of the complex was solved by the Patterson method using SHELXS-97 [22] and refined by full-matrix least-squares method on $(F_{obs})^2$ using SHELXL-97 [23]. The crystal data and details of the refinement are given in Table 1. Only one H atom of the phosphate groups was found in the difference Fourier maps, and had their coordinates refined. The hydrogen atoms of the water molecules could not be unequivocally assigned from the difference Fourier maps and those of the N atoms were found on Fourier maps, although the free refinement resulted in an unacceptable geometry. Thus, the H-atoms were refined with restraints N–H = 0.96 Å for N1A and N1B, H···H distances of 1.60 Å compatible with tetrahedral geometry, and N–H = 0.86 Å for other N atoms, with H···H distances of 1.80 Å, compatible with amino group geometry. The remaining H atoms were placed at calculated positions, assigned a fixed displacement and restrained to ideal geometry with C–H = 0.99 Å. The thermal parameters of all hydrogen atoms were related to those of their parent atoms by $U(\text{H}) = 1.2U_{eq}(\text{C,N})$. The absolute configuration of the arginine molecule was determined by the anomalous dispersion method from 3582 Friedel pairs with a Flack parameter of −0.01(1) [24]. The final value of R was 0.0433 for 4995 observed reflections ($F_0 > 4\sigma(F_0)$) and the final value of R_w was 0.1309 for 5174 unique reflections which were not merged before the last refinement cycle. The weighting scheme was $w^{-1} = [\sigma^2(F_o^2) + (0.0894P)^2 + 0.09P]$ where $P = [\max(F_o^2, 0) + 2F_c^2]/3$. The final difference map showed a peak of 1.36 e Å^{-3}, without exhibiting significant features.

The magnetic susceptibility of a powdered sample of 140 mg of **1** placed in a gelatine capsule sample holder was measured between 2 and 300 K with applied magnetic fields $B_0 = \mu_0 H = 0.2$ and 0.5 T (μ_0 being the vacuum per-

3. Results and analysis

3.1. Crystal structure of *1*

An ORTEP [25] view of the basic structural unit with the corresponding numbering system is depicted in Fig. 1. Selected bond lengths and bond angles are given in Table 2. The crystal structure contains two $[Cu(L\text{-arg})]^{2+}$ cations, two $(HPO_4)^{2-}$ anions, one OH^- anion, one H_3O^+ hydronium and six water molecules in the unit cell. These two Cu(L-arg) units are connected by three bridges: a didentate hydrogenphosphate anion, a monodentate hydrogenphosphate anion and a hydroxyl anion. FT-IR spectrum showed a band at 969 cm^{-1} and a shoulder around 3452 cm^{-1} that are assigned to the vibration modes of the OH [26]. In comparison with the other six water molecules, the geometrical analysis of the structure around the isolated oxygen atom O7W shows a tetrahedral environment with the shortest distances with respect to neighbouring oxygen atoms, which leads us to attribute this oxygen to the location of a hydronium ion. This hypothesis is corroborated by thermogravimetric measurements that show two stages. The first is associated to the loss of the six water

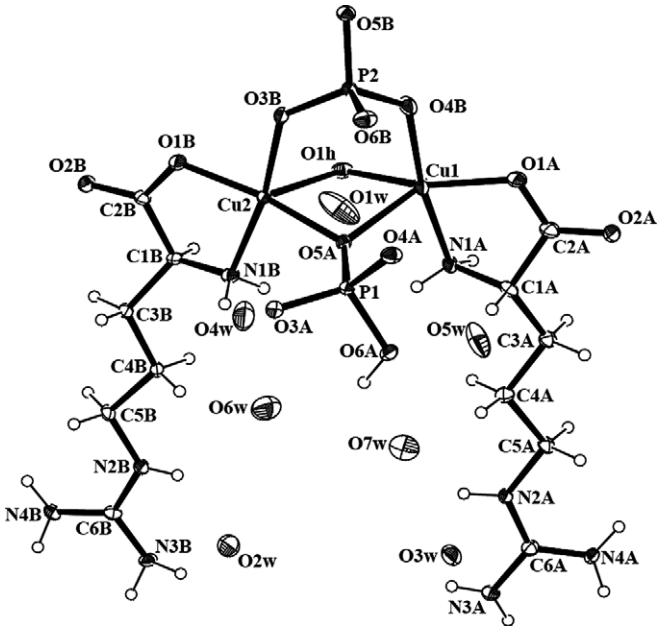

Fig. 1. ORTEP drawing at 30% probability level of **1**. Hydrogen atoms are represented as spheres of arbitrary size, except those of the water molecules which were not found, as explained in the text.

molecules and the second is consistent with the loss of the H_3O^+ and OH^- groups. The six free water molecules and the hydronium ion which lead to solvent channels parallel to the crystallographic *a*-axis are involved in a complicated hydrogen bonding network and contribute to stabilize the structure of the complex and the crystal packing. Since the H atoms of the water molecules and the hydronium ion were not located on difference maps, detailed description of the H-bonding network is difficult.

The two phosphate groups show two longer lengths consistent with P–OH bonds. The O6B atom at 2.705(5) Å from the O4A atom, is a good candidate for an H donor because it has the longest distance P2–O6B = 1.609(6) Å.

Both chemically different Cu atoms in the dinuclear unit are in distorted square-pyramidal coordination with different basal planes (see Fig. 1). The Cu1 ion coordinates one carboxylate oxygen (O1A) and one amino nitrogen (N1A) of the associated L-arginine molecule. In its basal plane it also coordinates two oxygen atoms, one from the didentate hydrogenphosphate group (O4B) and the other from the hydroxyl anion (O1h). The apical position of the Cu1 centre is occupied by one oxygen atom from the monodentate hydrogenphosphate group [Cu1–O5A = 2.243(3) Å]. The Cu1 atom is 0.249(2) Å above the basal plane, towards the O5A oxygen atom. The Cu2 ion coordinates one carboxylate oxygen (O1B) atom and one amino nitrogen atom (N1B) of the second L-arginine molecule in a square planar geometry together with two oxygen atoms from both di- (O3B) and monodentate (O5A) hydrogenphosphate groups. In this case, the apical position is occupied by the OH^- anion [Cu2–O1h = 2.396(4) Å]. The Cu2 atom is 0.118(2) Å above the basal plane, towards the OH^- anion. The two pyramids share the edge made by O1h–O5A = 2.803(5) Å, resulting in two strained angles O1h–Cu1–O5A = 81.1(1)° and O1h–Cu2–O5A = 79.6(1)°. The dihedral angle between the least squares planes defined by the basal atoms O1h–N1A–O1A–O4B and O1B–N1B–O3B–O5A is 13.8(2)°. Both basal planes are close to the planes of the corresponding L-arginine molecule. The quasi-planar conformation of the L-arginine molecules in **1** is markedly different from that observed in L-arginine phosphate monohydrate [27].

Each $[Cu(L\text{-arg})]^{2+}$ is connected to adjacent ones through two hydrogen bonds with similar lengths. One of these bonds is between one of the guanidinium NH_2 moieties and the oxygen atom of the coordinated carboxylate group. The other is between the second guanidinium NH_2 moiety and the oxygen atom of the uncoordinated carbonyl group. The result is a layered structure (see Fig. 2) with layers nearly parallel to the plane defined by four atoms of four neighbouring molecules of the dinuclear complex: N3B, $N3B^{i}$, $N4A^{ii}$ and $N4A^{iii}$, with translational symmetry operations (i) = $-1+x$, $-1+y$, $-2+z$; (ii) = $2+x$, $1+y$, $1+z$; (iii) = $1+x$, y, $-1+z$, having Miller indices (1 −3 1), and interplanar distance 3.552 Å.

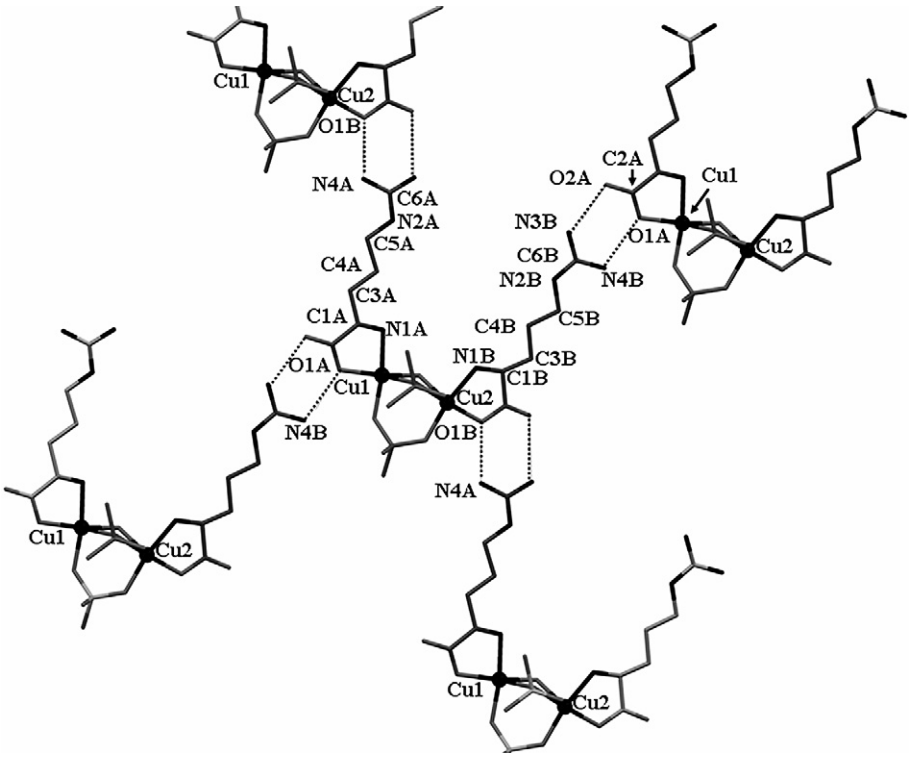

Fig. 2. Crystallographic packing of structure **1.** Cu1 and Cu2 ions of neighbour dinuclear units in a layer are bridged through a pair of H-bonds connecting the tale of the guanidinium group associated to one Cu, to the oxygens of the L-arginine carboxylate group coordinated to the other neighbour copper in the layer. Dashed lines indicate H-bonds. The bridge includes nine diamagnetic atoms plus the proton in the H-bond. The distance between coppers is 13.339 Å and that measured along the bond is 17.006 Å.

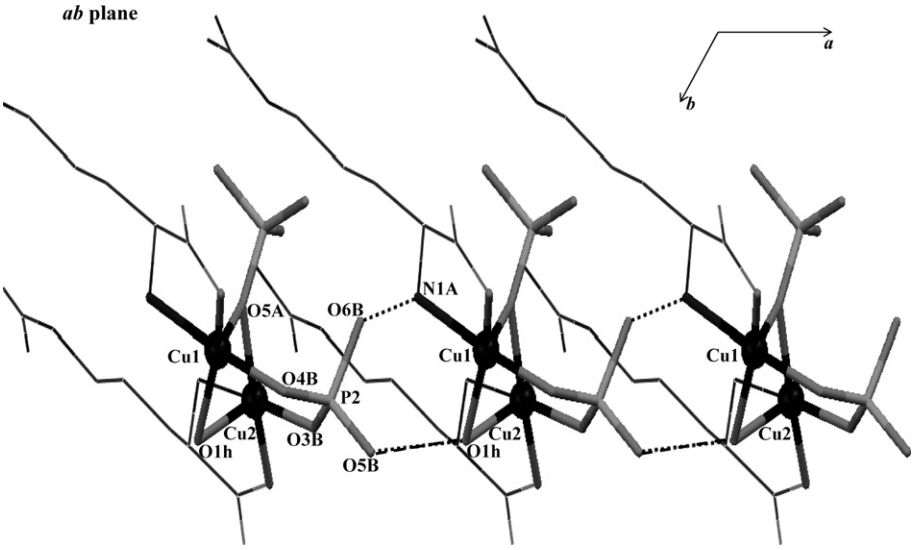

Fig. 3. Chemical bridges connecting dinuclear units in neighbour layers. Oxygens O5B and O6B belonging to the phosphate group providing the O–P–O bridge in dinuclear units are H-bonded to the N1A and O1h ligands to the Cu1 of the neighbour dinuclear unit. This bridge contains 4 diamagnetic atoms plus the H-bond. The distance between Cu1 atoms is 7.234 Å and that measured along the bond is 11.201 Å.

The copper ions are 3.1948(8) Å apart and the chemical paths connecting them are the two equatorial–apical bridges with bond lengths d[Cu1–O1h–Cu2] = 4.417 Å and d[Cu1–O5A–Cu2] = 4.194 Å, and one O–P–O bridge with bond length d[Cu1–O4B–P2–O3B–Cu2] = 6.863 Å, that support the intradinuclear exchange interaction. The bridging angles Cu1–O5A–Cu2 and Cu1–O1h–Cu2 are 98.97° and 91.25°, respectively.

The connections between rotated copper ions in neighbouring dinuclear units in the same layer are described in Fig. 2. One of them has 10 diamagnetic atoms including one moderate H-bond (Cu1–N1A–C1A–C3A–C4A–C5A–N2A–C6A–N4A–H42A···O1B–Cu2) with total bond length of 17.006 Å, and Cu1–Cu2 distance of 13.339 Å. The other similar connection, Cu1–O1A···H42B–N4B–C6B–N2B–C5B–C4B–C3B–C1B–N1B–Cu2 has a total bond length of 15.633 Å and the distance between copper atoms is 13.263 Å. The chemical bridges connecting Cu dinuclear units in adjacent layers of **1** are shown in Fig. 3; all of them being through the phosphate groups. The distance between two Cu1 atoms or two Cu2 atoms is the same, d = 7.234 Å, and the total bond lengths are 11.201 Å and 9.958 Å, respectively. The first path (Cu1–O4B–P2–O6B···H11A–N1A–Cu1) contains four diamagnetic atoms and a weak H-bond defined according to Steiner's criteria [28] (dotted line in the figure) with d[O6B–N1A] = 3.039 Å, while the second path (Cu2–O3B–P2–O5B–O1h–Cu2) is similar to the first one but includes one short contact d[O5B–O1h] = 2.068 Å. The third chemical path connect Cu1 to Cu2 (Cu1–O4B–P2–O5B–O1h–Cu2) separated by a distance of 7.943 Å, with total bond length of 9.949 Å containing four diamagnetic atoms and one short contact O5B–O1h. Finally, the fourth chemical path connect Cu2 to Cu1 (Cu2–O3B–P2–O6B···H11A–N1A–Cu1) separated by a distance of 7.872 Å, with total bond length of 11.210 Å containing four diamagnetic atoms and one H-bond. Considering the different number of diamagnetic atoms and the lengths of the chemical paths connecting dinuclear units described in Figs. 2 and 3, we conclude that the most relevant paths in supporting exchange interactions are those coupling each dinuclear unit with two dinuclear units in neighbour layers (Fig. 3).

3.2. Magnetic results

The dc magnetic susceptibility data corresponding to one mol of Cu_2 dinuclear units in **1** measured with B_0 = 0.5 T at temperatures T between 2 and 300 K are displayed in Fig. 4 as $T\chi(T)$. The values measured with

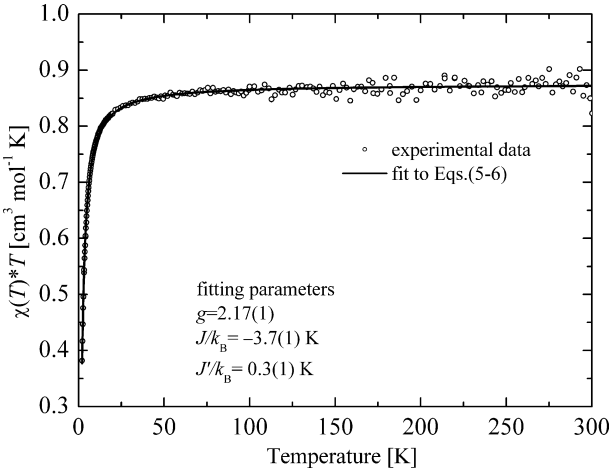

Fig. 4. Values of $T\chi(T)$ obtained with an applied field B_0 = 0.5 T at temperatures T between 2 and 300 K in a powder sample of **1** (circles). The solid line displays the best global fit of Eqs. (5) and (6) to the susceptibility, obtained for a dinuclear unit within a molecular field approximation. The values of the parameters obtained in the fit are shown.

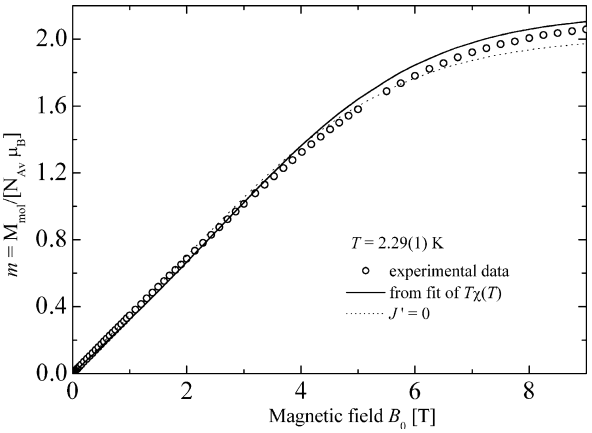

Fig. 5. Values of the molecular magnetization $m(B_0)$ observed with applied fields $0 < B_0 < 9$ T at $T = 2.29(1)$ K in a powder sample of **1** (symbols). The solid line displays the magnetization calculated with a molecular field approximation using Eqs. (2) and (3), considering the intradinuclear and interdinuclear interactions evaluated from the susceptibility data. The dashed line is obtained as the best fitting with a model ignoring the interactions between dinuclear units.

$B_0 = 0.2$ T (not shown) agree within the experimental uncertainty with those in Fig. 4. The molecular magnetization measured at 2.29(1) K as a function of B_0 is shown in Fig. 5. The contributions of the sample holder, the diamagnetism and temperature independent paramagnetism of the sample have been already subtracted from the data displayed in Figs. 4 and 5. At room temperature $T\chi(T) = 0.871$ cm^3 K/mol. This value is reduced to $T\chi(T) = 0.38$ cm^3 K/mol at 2 K, indicating a predominant antiferromagnetic coupling between copper ions (Fig. 4). The magnetic moment per dinuclear unit at 2.29 K and at the highest field (9 T), where still is not fully saturated, amounts 2.06 μ_B (Fig. 5).

The susceptibility data were fitted assuming a Hamiltonian involving equal values for the angular average of the g-factor of the two copper ions, and isotropic intra- and interdinuclear exchange interactions J and J', respectively. The interdinuclear interactions J' with the relevant $z = 2$ neighbouring dinuclear units are identical (see the structural description and Fig. 3), so in the molecular field approximation the Hamiltonian of a dinuclear unit can be written as:

$$\mathscr{H} = \mu_B g(S_{1z} + S_{2z})B_0 - J\mathbf{S}_1 \cdot \mathbf{S}_2 - zJ'(S_{1z} + S_{2z})\langle S_z\rangle \qquad (1)$$

In the last term, $\langle S_z\rangle$ is the thermal average of the component along B_0 of the spin of a neighbour dinuclear unit. Thus, in units of μ_B, the molecular magnetization m of a dinuclear unit under an effective field B acting on each copper ion pair at temperature T is:

$$m = (M_m/N_{Av}) = 2g\exp(J/k_BT)\sinh(g\mu_B B/k_BT)/Z \qquad (2)$$

where Z is the partition function:

$$Z = 1 + \exp(J/k_BT)[1 + 2\cos h(g\mu_B B/k_BT)] \qquad (3)$$

In the molecular field model used in Eq. (1), the effective field B is the sum of the applied field B_0 plus a contribution due to the interaction with the neighbour dinuclear units:

$$B = B_0 - \frac{zJ'}{g\mu_B}\langle S_z\rangle = B_0 - \frac{zJ'}{g^2\mu_B^2}m \qquad (4)$$

As shown by O'Connor [29] and Kahn [30] the Bleaney–Bowers equation [31] for the magnetic susceptibility of this dinuclear unit is:[1]

$$T\chi(T) = \frac{2N_{Av}g^2\mu_B^2}{3k_B}\frac{T}{(T-\theta)[1+\frac{1}{3}\exp(-J/k_BT)]} \qquad (5)$$

with:

$$\theta = \frac{-2zJ'/k_B}{3 + \exp(-J/k_BT)} \qquad (6)$$

A least squares fit of Eqs. (5) and (6) to the susceptibility data in Fig. 4 gives $g = 2.17(1)$, $J/k_B = -3.7(1)$ K and $zJ'/k_B = 0.6(1)$ K, indicating antiferromagnetic intradinuclear exchange interaction, as indicated by the low temperature behaviour of $T\chi(T)$ in Fig. 4, and an effective ferromagnetic coupling $J'/k_B = 0.3$ K (considering $z = 2$) between neighbour dinuclear units. The solid line in Fig. 4 is calculated with these parameters. They were also used to evaluate the molecular magnetization m considering Eqs. (2) and (4) and the results are shown as a solid line in Fig. 5. The prediction for the molecular magnetization m is not as good as that for $T\chi(T)$. The two types of data correspond to well separate regions in the phase diagram of the generalized susceptibility through the quantity $T\frac{1}{N_{Av}}\left(\frac{\partial M_m}{\partial B_0}\right)$ versus T and B_0. Consequently, it is not surprising to find small discrepancies between the predictions in the values of M_m versus B_0 using the parameters obtained from the $T\chi(T)$ data. To emphasize the role of the interdinuclear interactions, we also display in Fig. 5 results obtained by fitting these data with a model that neglects the interdinuclear coupling J'.

The antiferromagnetic intra-dinuclear interaction $J/k_B = -3.7$ K is associated with the Cu–O–Cu and Cu–O–P–O–Cu bridges shown in Fig. 1. We propose that the smaller ferromagnetic coupling $J'/k_B = 0.3$ K between dinuclear units in neighbour layers is supported by the paths described in Fig. 3.

4. Discussion and conclusions

Our single crystal X-ray diffraction measurements indicate that the synthesized ternary copper compound **1** is triclinic with two chemically different copper ions in dinuclear units. Each copper ion is in a square pyramidal geometry coordinated to a nitrogen from the α-amino group and to an oxygen from the carboxylate group of the L-arginine molecules. They are bridged by two HPO_4^{2-} and one OH^- anions, showing a dinuclear copper structure that is not common in metal derivatives of amino acids. This structure appears as a consequence of the bonding possibilities offered by the phosphate groups bridging these units,

[1] See Eq. (6.5.12) in Ref. [30].

combined with the ample possibilities of bonding of the guanidinium group of arginine. The magnetic measurements indicate a weak antiferromagnetic intradinuclear coupling ($J/k_B = -3.7$ K) between copper ions supported by Cu–O–Cu and phosphate bridges, and a smaller ferromagnetic coupling ($J'/k_B = 0.3$ K) between dinuclear units in neighbour layers, supported by bridges containing four diamagnetic atoms plus the H-bond (Fig. 3). As discussed earlier, the distance between the connected Cu1 atoms in neighbour dinuclear units 7.234 Å and that measured along the path is 11.201 Å.

Our structural results for the dinuclear units in **1** show two equatorial–apical paths, one involving a phosphate oxygen (O5A) and the other through an O1h. Because of the distortion of the pyramidal units one may guess that the ground orbital states of the individual Cu ions in dimeric units are not a pure $d_{x^2-y^2}$ orbital (supported by a $g = 2.17$). Thus, one expects some small contributions to the antiferromagnetic coupling caused by this distortion. The basal planes around each Cu are not parallel producing a lack of orthogonality between apical and equatorial electronic densities. A third connection between the Cu ions is produced by an equatorial–equatorial path –O4B–P2–O3B– that will also contribute to the coupling, in spite that this occurs through three diamagnetic atoms.

A search in the Cambridge Crystallographic Database [32–34] was performed without much success to locate other compounds with similar intradinuclear chemical bridges. Dinuclear copper compounds with hydrogenphosphate bridges were reported recently by Youngme and collaborators [16–18] for dinuclear compounds with the aromatic ligands di-2-pyridylamine, 1,10-phenanthroline and 2,2′-bipyridine bipyridine ($[Cu(dpyam)(\mu\text{-}H_2PO_4)(H_2PO_4)]_2$, $[Cu_2(phen)_2(\mu\text{-}H_2PO_4\text{-}O,O')_2(H_2PO_4)]$, $[Cu_2(phen)_2(\mu\text{-}H_2PO_4\text{-}O,O')(\mu\text{-}H_2PO_4\text{-}O)(\mu\text{-}HPO_4\text{-}O)]_2(H_2O)_9$, and $[Cu_2(bpy)_2(\mu,\eta^2\text{-}HPO_4)\text{-}(\mu,\eta^1\text{-}H_2PO_4)(\mu,\eta^2\text{-}H_2PO_4)]_n$). In order to make comparisons or find similarities, it is worth to remark that in the compound studied here the Cu1–Cu2 coupling in the dinuclear unit is supported by three bonds (see Fig. 3).

In Ref. [16], two compounds with di-2-pyridylamine are reported. In the first one, there are two equatorial–equatorial didentate dihydrogenphosphate bridging ligands connecting copper ions at 5.14 Å. The reported exchange interaction $J/k_B \sim -4$ K is similar to that observed for **1**, but the two equatorial–equatorial bridges supporting the interaction and the distance between coppers are too different to allow comparisons. The second compound is polymeric, and the magnitude J of the interaction, supported by an equatorial–equatorial tridentate hydrogenphosphate bridge is much larger than that in compound **1**. Reference [17] reports a compound containing phenanthroline having two chemically different dinuclear units in the unit cell. One of them (unit B) is similar to compound **1**, with a distance $d = 3.074(3)$ Å between coppers and similar bridges and they attribute to this unit a *ferromagnetic* coupling $J/k_B \sim 1.4$ K. However, the experimental uncertainty of this value introduced by the coexistence of two different dinuclear units may be large, and a comparison with our result for **1** is hard to make. Our situation seems to be closer to that reported by Phuengphai et al. [18] for their compound named 1, except for the non-existence of the equatorial–apical bond formed through O1h. They estimate $J/k_B = -7.4$ K for that compound. Even if, the structure of the phosphate bridge is different from ours as to establish a clear cut comparison of the magnetic interaction observed in **1**, one is tempted to speculate that the lack of the equatorial–apical bond formed through O1h, tend to enhance the antiferromagnetic behaviour, as observed in Ref. [18].

Regarding the observed interactions between dinuclear units, Chattopadhyay et al. [35] claimed that bridges containing H-bonds propagate antiferromagnetic interactions between metal centres. However, for the title compound and for the compounds reported in Refs. [16,17], the coupling J' is ferromagnetic. Clarifying this point would require more experimental information in other similar situations and detailed calculations.

5. Supplementary material

CCDC 292513 contains the supplementary crystallographic data for **1**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Scheme 1.

anion, which is formed upon deprotonation of bis(2-pyridylcarbonyl)amine Hbpca (see Scheme 1). Mononuclear, dinuclear (homonuclear and heteronuclear), and trinuclear complexes have been identified for various divalent and trivalent metal ions [M(II) = Cu(II), Fe(II), Mn(II), Co(II), Ni(II), and Zn(II); M(III) = Fe(III), Rh(III)] [8–14]. Among these compounds, a ternary complex of copper(II) with one $bpca^-$ and another derivative formed during the hydrolysis process, namely 2-picolinamide, has been described [9]. The ptO_2^- is obtained by means of a Cannizzaro-type reaction of pyridine-2-carboxaldehyde and NaNCO in the presence of a copper metal ion [15]. Recently, we have determined the crystal structures of different copper carboxylates and fluoride complexes with ptO_2^- [16].

In this paper, we describe for the first time the crystal structures of copper(II)–chlorobenzoate complexes with ptO_2^-. The influence of the chlorine atom in positions 2, 3, and 4 of the chlorobenzoate anions on the crystal structures and the spectroscopic properties of the copper complexes with ptO_2^- has also been studied.

2. Experimental

2.1. Materials and physical measurements

Reagents and solvents were commercially available and used without further purification.

Elemental analyses (C, N, H) were performed on a Carlo Erba AAS instrument. IR spectra (KBr disks) were taken on a Mattson satellite FT-IR in the range 4000–400 cm^{-1}. Diffuse reflectance spectra (nujol mulls) of the complexes were carried out on a Shimadzu UV-2101 PC spectrophotometer. UV–Vis spectra of the complex solutions were carried out on an HP 8453 spectrophotometer. Electronic paramagnetic resonance (EPR) spectra were taken at the Q-band frequency at room temperature with a Bruker ELEXSYS spectrometer. Electrochemical measurements were made with the aid of a Princeton Applied Research Model 273A potentiostat/galvanostat. Cyclic voltammograms were obtained for acetonitrile and DMF solutions of the complexes with [TBA][ClO_4] as the supporting electrolyte under argon atmosphere. The electrochemical cell employed had a standard three-electrode configuration: a platinum working electrode, a platinum wire counter electrode, and an Ag–AgCl reference electrode.

2.2. Synthesis of the complexes [Cu(ptO_2)(2-Clbenz)(H_2O)] (1), [Cu(ptO_2)(3-Clbenz)] (2), and [Cu(ptO_2)(4-Clbenz)(DMF)] (3)

Ten millilitres of an aqueous solution of $Cu(ClO_4)_2 \cdot 6H_2O$ (370 mg, 1 mmol) were added to 40 mL of a yellow DMF solution containing 137 mg (1 mmol) of chlorobenzoic acid (2-chloro, 3-chloro, or 4-chloro), 312 mg (1 mmol) of ptz and 2 ml of a methanolic solution of KOH 2 N. A dark green solution was formed immediately; after 30 min it turned blue-green in color and overnight it became blue. Slow evaporation of the solution yielded blue, needle-like crystals. Yield: 57, 72, and 68% respectively. Analytical data for **1**: *Anal.* Calc. for $C_{19}H_{14}ClCuN_3O_5$: C, 49.25; H, 3.04; N, 9.07. Found: C, 49.01; H, 3.12; N, 8.98%. Analytical data for **2**: *Anal.* Calc. for $C_{19}H_{12}ClCuN_3O_4$: C, 51.24; H, 2.71; N, 9.43. Found: C 50.98; H 2.69; N 9.28%. absorption using SADABS [18]. The data for **2** and **3** were processed with collect and HKL DENZO and SCALEPACK programs [19,20]. The structures were solved by direct methods [21,22], which revealed the position of all non-hydrogen atoms. These atoms were refined on F^2 by a full-matrix least-squares procedure using anisotropic displacement parameters [23]. The hydrogen atoms were located from difference syntheses or in their calculated positions (C–H, 0.93–0.97 Å), and were refined using a riding model [24,25]. Atom scattering factors were taken from the International Tables for Crystallography [26]. Crystal and refinement data are listed in Table 1.

3. Results and discussion

3.1. Crystal structures

[Cu(ptO$_2$)(2-Clbenz)(H$_2$O)] (**1**): Fig. 1 shows an ORTEP view of the molecule with the atomic numbering scheme. Selected bond distances and angles are listed in Table 2. The coordination sphere of copper(II) is best described as a distorted square based pyramid, as can be deduced from the τ value of 0.16 [27]. The basal positions are occupied by the three nitrogen atoms from the ptO$_2^-$ ligand and one oxygen atom from the monodentate 2-chlorobenzoate anion. The apical site is occupied by the oxygen atom from the coordinated water molecule. The Cu–N bond distances, ranging from 1.9470(13) to 2.0140(13) Å, are very similar to those found in other previously reported

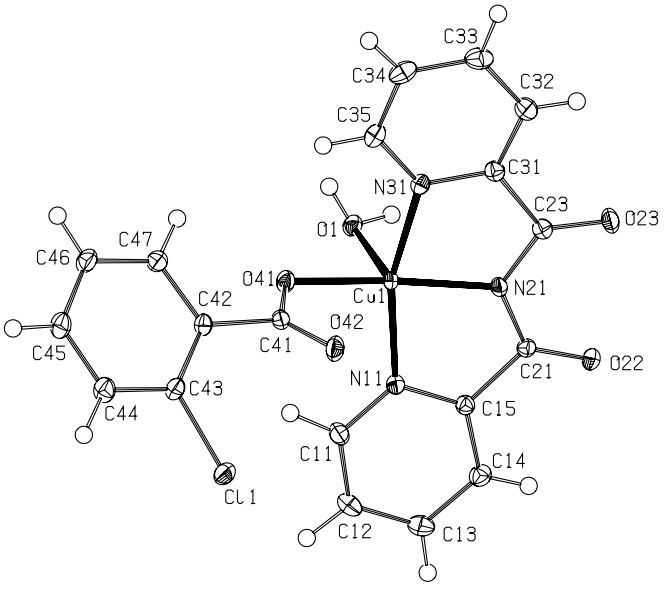

Fig. 1. ORTEP drawing of [Cu(ptO$_2$)(2-Clbenz)(H$_2$O)] (**1**).

copper(II) complexes with ptO$_2^-$ [8,16]. The Cu–O(2–chlorobenzoate) and the Cu–O water bond distances are 1.9465(11) and 2.3180(11) Å, respectively. The four basal atoms are quasi coplanar, and the copper ion is displaced 0.143 Å below the plane. A distorted octahedron could be considered due to fact that the Cu–O(42) distance is 2.6890(12) Å. In this case, the carboxylate acts as a

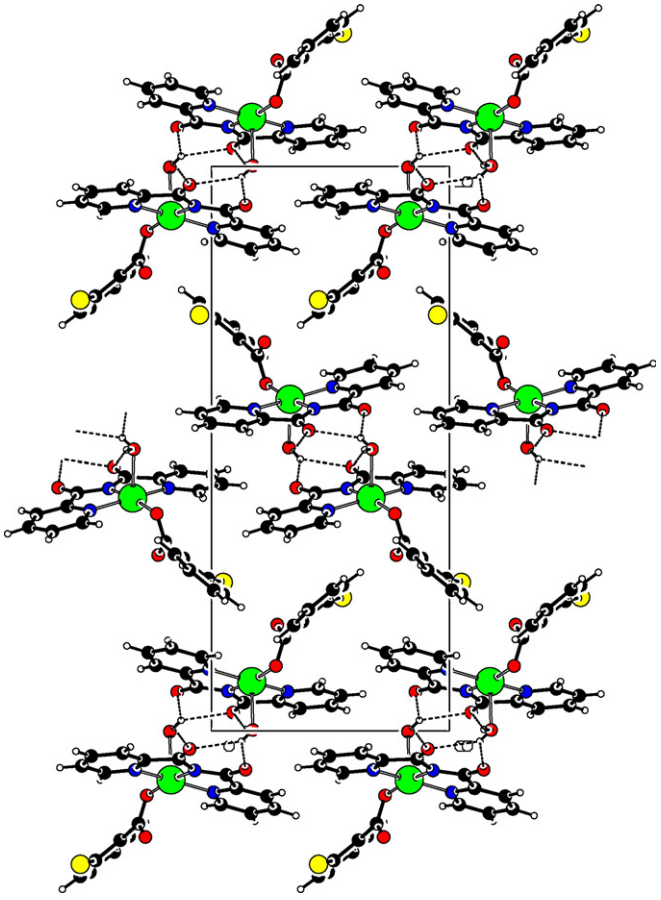

Fig. 2. Crystal packing of [Cu(ptO$_2$)(2-Clbenz)(H$_2$O)] (**1**) showing the hydrogen bonds.

bidentate ligand as is also the case in the [Cu(ptO$_2$)(benz)]·(H$_2$O) complex [16].

The crystal packing is achieved by intermolecular hydrogen bonds (see Fig. 2). A moderate hydrogen bond is formed between the O1W and the carbonyl O23 [O1W ··· O23 = 2.9127(15) Å, O1W–H1A–O23 = 137.3°].

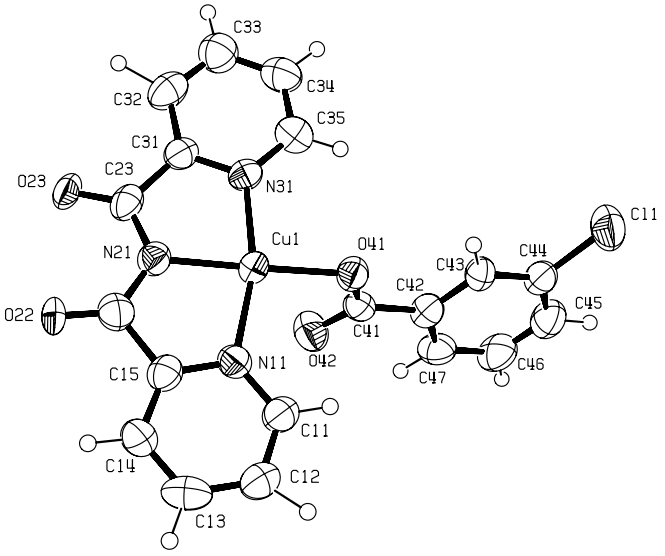

Fig. 3. ORTEP drawing of [Cu(ptO$_2$)(3-Clbenz)] (**2**).

In addition, the O1W forms two moderate hydrogen bonds with the other carbonyl O22 [O1W ··· O22, 2.8838(14) and 3.0218(16) Å, O1W–H1A–O22 = 160.3° and O1W–H1B–O22 = 142.3°] [28].

*[Cu(ptO$_2$)(3-Clbenz)] (**2**):* Fig. 3 displays the structure of the complex with the labeling scheme. Selected interatomic distances and angles are listed in Table 2. The geometry of the copper(II) ion can best be described as very slightly distorted square planar. The distortion of the square planar geometry is determined by the dihedral angle between the CuN$_2$ and CuNO planes. Thus, when the dihedral angle is 0°, the geometry is planar while when the angle is 90°, the stereochemistry is tetrahedral. In this complex, the dihedral angle value is 1.91(0.23)°, which indicates a very slightly distorted square planar configuration [29]. The coordination polyhedron is formed by a ptO$_2^-$, which functions as a tridentate ligand through the nitrogen atoms, and one carboxylate O atom from the 3-chloro-

benzoate ligand. The three Cu–N bond distances, which are all within the 1.928(7)–2.002(7) Å range, are comparable not only to those of the complex described above, but also to those found for other copper(II)–ptO_2 complexes [8]. The distance between the other $O_{carboxylate}$ and the copper(II) is 2.6120(64) Å, which is too large to be considered coordinated, but a semicoordination might be possible. Moreover, the bond distance between one of the $O_{carbonyl}$ atoms of the ptO_2^- and the copper(II) of the contiguous molecule is 2.7189(65) Å, thus the crystal structure is a linear chain in which the ptO_2^- acts as bridging ligand (Fig. 4). The influence of this semicoordination of one of the $O_{carbonyl}$ atoms is confirmed by the differences found in the two carbonyl bond distances [C(21)–O(22) 1.207(11) and C(23)–O(23) 1.235(10) Å, respectively]. In contrast, the C=O bond lengths are similar in the two other chlorobenzoate copper complexes, [(1.2299(18) and 1.2202(19) Å for **1** and 1.214(5) and 1.219(5) Å for **3**]. This Cu–$O_{carbonyl}$ semicoordinated bond probably helps stabilize the structure.

*[Cu(ptO₂)(4-Clbenz)DMF] (**3**):* An ORTEP view of the complex with the atom numbering scheme is shown in Fig. 5. Selected bond distances and angles are presented in Table 2. The coordination sphere of copper(II) in this complex can best be described as a very slightly distorted square based pyramid, as can be deduced from the τ value of 0.016 [27]. The basal positions are occupied by the three nitrogen atoms from the ptO_2^- ligand and one oxygen atom from the monodentate 4-chlorobenzoate anion. The apical site is occupied by the oxygen atom from the coordinated DMF molecule. The Cu–N bond distances, ranging from 1.950(3) to 2.018(3) Å, are very similar to those found in other previously reported copper(II) complexes with ptO_2^- [8,16]. The Cu–O(4–chlorobenzoate) and the Cu–O(DMF) bond distances are 1.951(3) and 2.284(3) Å, respectively. The four basal atoms are quasi coplanar, with the copper ion displaced 0.1836 Å above the plane. The second oxygen of the 4-chlorobenzoate anion is located at the long distance of 2.7410(38) Å from copper(II). As in the compound described above, if we consider this distance to be a semicoordination, the geometry of the copper(II) can be defined as a distorted octahedron.

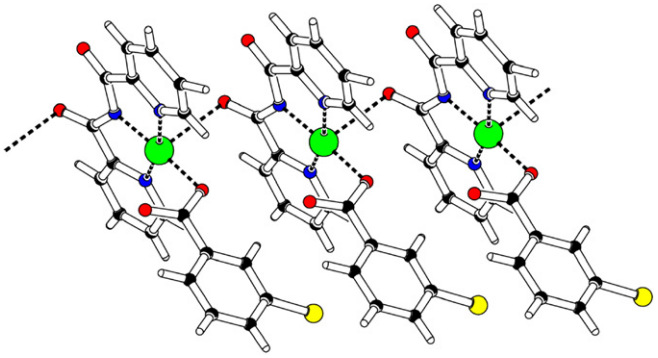

Fig. 4. Crystal packing of [Cu(ptO_2)(3-Clbenz)] (**2**).

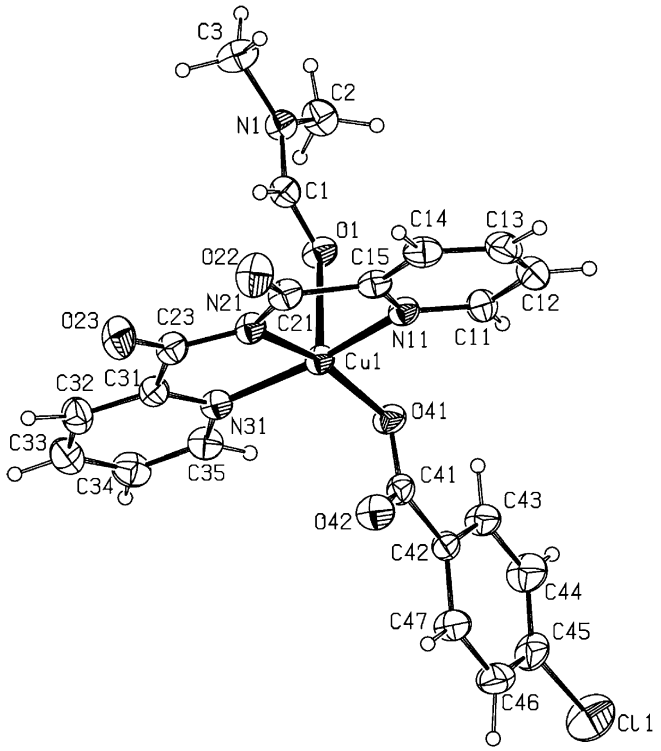

Fig. 5. ORTEP drawing of [Cu(ptO_2)(4-Clbenz)(DMF)] (**3**).

The individual pyrimidyl rings of the ptO_2^- ligand in the three complexes are planar; indeed, the largest deviation from planarity is less than 0.0073 Å.

The crystal packing, displayed in Fig. 6, shows π–π stacking interactions between the ptO_2^- rings. No hydrogen bonds were observed.

3.2. Spectroscopic properties

The most important feature in the IR spectra of the three complexes is the presence of a high-intensity band centered at 1712 cm^{-1} [ν(C=O) vibration], which indicates that the hydrolysis of ptz has occurred [8]. Another remarkable aspect of the ν(C=O) vibration of the ptO_2^- in complex **2** is the presence of a strong, sharp band at 1650 cm^{-1} that can be attributed to a second ν(C=O) vibration. This is probably due to the semicoordination of one of the oxygen atoms of the carbonyl group to the copper(II) ion of a contiguous molecule, a hypothesis that is corroborated by the differences observed in the C=O bond distances (C(21)–O(22) and C(23)–O(23) 1.207(11) and 1.235(10), respectively). All the spectra exhibit bands at about 1600 and 1350 cm^{-1} which correspond to the ν_{as} (COO^-) and ν_s(COO^-) vibrations from the chlorobenzoate group. The $\Delta\nu = \nu_{as}(COO)-\nu_s(COO) = 250\ cm^{-1}$ indicates that the carboxylate acts as a monodentate ligand [30], in agreement with the crystal structures. The band that appears at 1621 cm^{-1} in the IR spectrum of **3** can be assigned to the ν(C=O) of the DMF. The high region of the IR spectrum of **1** shows a strong, sharp band at 3523 cm^{-1} due to the presence of coordinated water [31].

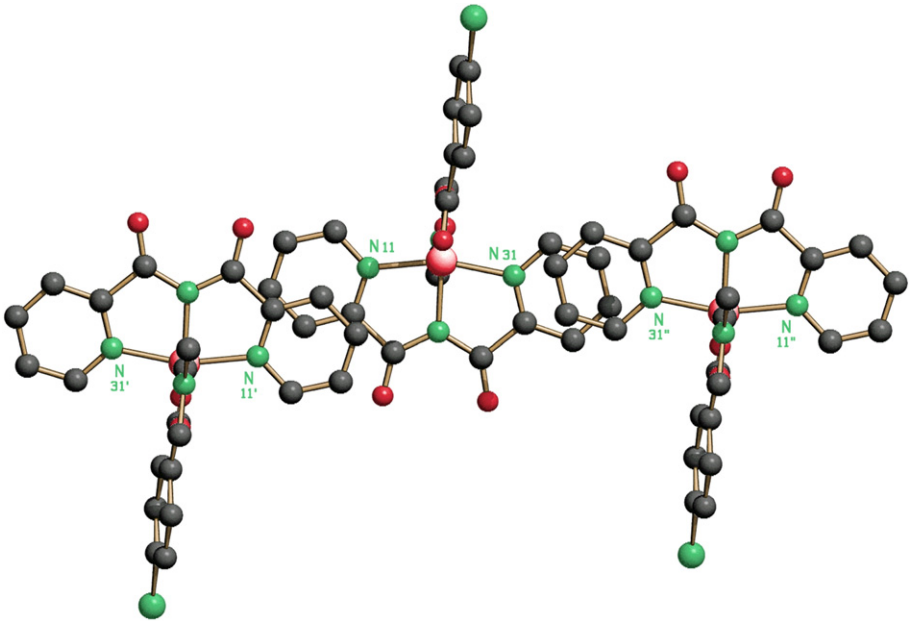

Fig. 6. Crystal packing of [Cu(ptO$_2$)(4-Clbenz)(DMF)] (**3**).

The reflectance spectra of the three complexes show an unresolved d–d band at 633, 643, and 598 nm, respectively, and a shoulder at about 432 nm. The latter can be attributed to a MLCT band.

The UV–Vis spectra of saturated aqueous solutions of the three complexes show the same maxima at 634 nm, indicating that in solution the three compounds have the same chromophore as a result of the coordination of water molecules and the dissociation of the carboxylate anions. Moreover, a weak LMCT band at about 400 nm, similar to that observed in the solid state spectra, is observed. The spectrum of 5.3 mM acetonitrile solutions of **1** exhibits a band at 609 nm ($\varepsilon = 115\ M^{-1}\ cm^{-1}$) and a shoulder at ≈406 nm. The spectrum of **1** in DMF solution at 1.4 mM shows a band at 631 nm ($\varepsilon = 150\ M^{-1}\ cm^{-1}$). The differences in the position of the d–d maximum among the spectra in solution may be due to the different donor properties of the solvents themselves. The spectrum of **3** in DMSO solution at 3.8 mM shows a band at 635 nm ($\varepsilon = 105\ M^{-1}\ cm^{-1}$). In any case, the spectra of the three complexes are similar to those reported in a previous study, in which acetate, formate and benzoate were used. These findings all confirm that the main species in solution is the CuptO$_2^+$ cation [16].

3.3. EPR spectroscopy

The Q-band spectra of polycrystalline samples of the complexes were recorded at room temperature. Powder samples of **1**–**3** were prepared from single crystals. The EPR parameters were obtained from simulations made with WINEPRSimphonia [32]. The Q-band EPR spectra of the three compounds are axial, with $g_\parallel = 2.244$; 2.215; 2.24 and $g_\perp = 2.061$; 2.045; 2.049 for **1**, **2** and **3**, respectively. These results point to a mainly copper(II) d_{x2-y2} orbital ground state ($g_\parallel > g_\perp$). The pattern of the EPR spectra is in good agreement with the crystal structures.

3.4. Electrochemical behavior

The cyclic voltammogram of **1** in the electroactive domain of acetonitrile/Bu$_4$NClO$_4$ is shown in Fig. 7. First, a reduction peak around −1.0 mV (versus SCE) was observed towards cathodic potentials; this can be attributed to the reduction of Cu(II) to Cu(I). On the reverse scan, an anodic peak at about −0.034 mV was found. The voltammogram is clearly irreversible, probably

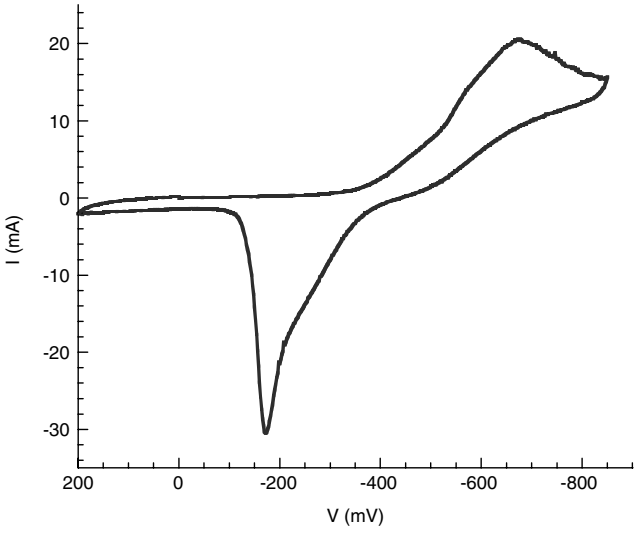

Fig. 7. Cyclic voltammogram of [Cu(ptO$_2$)(2-Clbenz)(H$_2$O)] (**1**) in acetonitrile.

because after the reduction of Cu(II), the Cu(I) species thus formed is unstable. The reduction peak at −1.0 mV relative to SCE corresponds to −0.78 mV relative to NHE. Irreversible cyclic voltammograms are also obtained from the complex in DMF solution, which shows a reduction peak at −0.654 mV relative to SCE. The negative values indicate a strong stabilization of the copper(II) state through the formation of the complex.

4. Conclusions

In this paper, we present the crystal structures of three copper(II) chlorobenzoate complexes with the hydrolysis derivative of 2,4,6-tris(2-pyridyl)-1,3,5-triazine (ptz), the ptO_2^- ligand. An in-depth study of these crystal structures has revealed several interesting differences. In the [Cu(ptO_2)(3-Clbenz)] (**2**) complex, the copper(II) ion is semicoordinated to a carbonyl oxygen atom of the ptO_2^- of another contiguous molecule with a Cu–O distance of 2.719 Å. In the other two complexes, the corresponding distances are 3.929 Å and 4.707 Å for [Cu(ptO_2)(2-Clbenz)(H_2O)] (**1**) and [Cu(ptO_2)(4-Clbenz)(DMF)] (**3**), respectively. These differences are influenced by the position of the chlorine atom in the benzoate. When the chlorine atom is in position 2 or 4, the donor effect of the carboxylate oxygen atoms involved in the metal complexation is reinforced whereas a chlorine in position 3 reduces this effect. In this last case, the electronic density on the copper(II) is lower, which leads the metal ion in the [Cu(ptO_2)(3-Clbenz)] (**2**) complex to form a semicoordinative bond with a contiguous ptO_2^-, which, in turn, gives rise to a chain structure.

reduction reactions of vanadium is of great importance. Bis(2,4-pentanedionato-O,O′) oxovanadium(IV) [VO-(acac)$_2$], was found to have insulin-mimetic properties superior to those of $VOSO_4$ in cell culture studies [9].

4-Acyl-5-pyrazolones are an interesting class of β-diketones, containing a pyrazole ring fused to a chelating arm [10]. The interest in the coordination chemistry of pyrazolones has increased greatly in the last decade [11]. Due to the presence of two oxygen donor atoms and facile keto–enol tautomerism, they easily coordinate with metal ions after deprotonation of the enolic hydrogen and provide stable metal complexes with six-membered chelate rings. Pyrazolones are used in analytical chemistry for the determination and isolation of almost all metal ions due to their high extracting ability, intense colour of the complex extracts and low solubility of the complex in some solvents [12,13]. Square pyramidal oxovanadium(IV) compounds with 4-acyl-5-pyrazolones have been reported [10]. However, to the best of our knowledge nobody has reported the reduction of oxovanadium(V) salts with 4-acyl-5-pyrazolones.

Herein, we report the reduction of oxovanadium(V) by 1-phenyl-3-methyl-4-toluoyl-5-pyrazolone at neutral and acidic pH conditions. The resulting vanadium complex was characterized by electron paramagnetic resonance spectroscopy, magnetic susceptibility, FT-IR, UV–Vis and mass spectroscopy. Finally, the probable structure of the oxovanadium(IV) complex was deduced from the spectral data and further confirmed by molecular modelling investigations.

2. Experimental

2.1. Materials

Vanadyl sulfate, ammonium monovanadate and the starting materials for the synthesis of the ligand was obtained from Sigma–Aldrich. All the other chemicals used were of analytical reagent grade and were used without further purification.

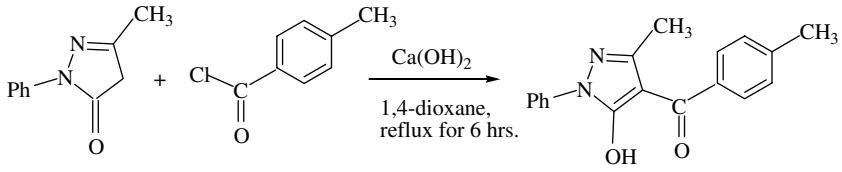
2.2. Physical measurements

Absorbance was measured using a Shimadzu UV-2450 spectrophotometer. Deconvolution of UV spectra was done using Peak Fit 4.12 software. Elemental analyses were performed with a Perkin–Elmer Series 2 Elemental Analyser 2400. The mass of the complexes were determined by fast atom bombardment high-resolution mass spectrometry (FAB-HRMS; JEOL JSM600). A Nicolet FT-IR 560 Magna spectrometer using KBr (neat) was used to obtain IR spectral data and a Bruker 300 MHz NMR spectrometer was used to obtain ^{1}H NMR and ^{13}C NMR spectra of the compounds in $CDCl_3$. The EPR spectra were recorded on a Varion E-112 spectrometer at liquid nitrogen as well as room temperature. The magnetic moments were measured using a model 155 vibrating sample magnetometer system.

Cyclic voltammetric experiments were conducted using a Cypress Systems Model CS-1090 computer-controlled voltammetric analyzer (BAS 100 electrochemical analyzer Graphtec WX 1200 recorder). All the experiments were done under a nitrogen atmosphere at ambient temperature in solutions with 0.1 M tetrabutylammonium hexafluorophosphate as the supporting electrolyte. Cyclic voltammograms (CVs) were obtained using a three-electrode system consisting of glassy-carbon working, Pt wire auxiliary and SCE reference electrodes. The ferrocenium/ferrocene couple was used to monitor the reference electrode and was observed at 0.450 V with $\Delta E_p = 0.120$ V and $i_{pc}/i_{pa} \approx 1.0$ in acetonitrile under these conditions.

2.3. Synthesis

1-Phenyl-3-methyl-4-toluoyl-5-pyrazolone, Hpmtp, was synthesized from 1-phenyl-3-methyl-5-pyrazolone and para-toluoyl chloride and is summarised in Scheme 1 [12].



2.3.1. Preparation of vanadium complexes

The complex of oxovanadium(V) with Hpmtp was prepared at both acidic and neutral pH conditions. The exact preparation steps adopted are described below.

To a well-stirred ethanol solution of 2.0 mM Hpmtp, an aqueous solution of NaOH (2.0 mM) was added. The pH was adjusted to 7 ($VO(pmtp)_2$ (**1**)) and 1 ($VO(pmtp)_2$ (**2**)) after the complete dissolution of Hpmtp and 1.0 mM ammonium monovanadate was then added, and the reaction mixture was stirred for 8 h. The precipitate formed was filtered, washed with ethanol, then with distilled water, and dried in a desiccator over fused calcium chloride. M.p.: 259.1 °C. IR (KBr) data ν (cm^{-1}): 1566, 1519, 962, 752. Mass spectrum: (M+1) peak 650.53 (Figs. 1 and S1).

2.3.2. Polymerization

In order to identify the formation of a free radical in the reduction process, the polymerization reaction of 5% (v/v) acrylonitrile has been carried out at room temperature in an inert atmosphere in the presence of oxovanadium(V) (0.001 mol dm^{-3}) and Hpmtp (0.01 mol dm^{-3}). A cloudy suspension was observed within a few minutes after the addition of the metal solution. The reaction was then kept, under stirring, for 2 h. A large amount of polymer was then precipitated by adding methanol to the reaction mixture. On the other hand, in the absence of either Hpmtp or oxovanadium(V) no detectable polymerization was noticed. Although these experiments are not helpful in finding out the free-radical species formed during the reduction of oxovanadium(V) by Hpmtp, they definitely indicate the formation of a free radical in the process, which is ultimately responsible for the acrylonitrile polymerization.

Scheme 1.

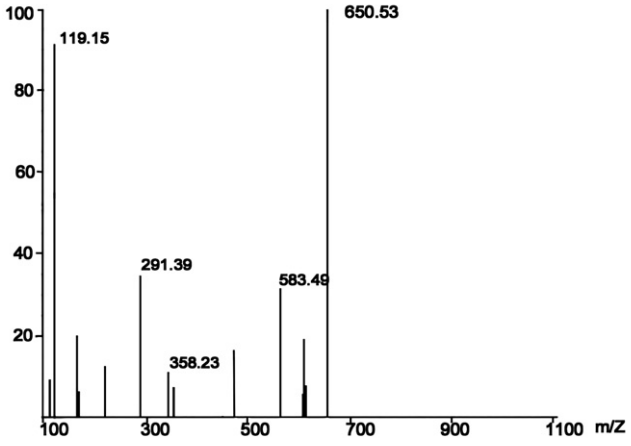


Fig. 1. Mass spectrum of $VO(pmtp)_2$ (**1**).

2.3.3. DFT calculations

The electronic structure of the complex $VO(pmtp)_2$ was calculated with the unrestricted density functional theory (DFT) using the B3LYP functional [14–16] as implemented in the GAUSSIAN-03 suite of programs [17]. For the V atom, the LANL2DZ basis set was selected together with the effective core potential of Hay and Wadt [18–20]. For the other elements, the 6-31G* basis sets were selected [21]. The geometry of the ligand system pmtp was also optimized at the B3LYP/6-31G* level of theory.

2.3.4. X-ray crystallography data collection and processing

X-ray single crystal data were recorded at room-temperature on a Bruker Smart 6000 diffractometer equipped with a CCD detector and a copper tube source. Data were processed using SAINTPLUS (SAINTPLUS, program suite for data processing, Bruker AXS, Inc., Madison, Wisconsin, USA). Structures were solved and refined using SHELXL-97 [22]. Non-hydrogen atoms were refined anisotropically and a riding model was used for C–H hydrogen atoms. The hydroxyl protons were placed in positions calculated for optimum hydrogen bonding.

3. Results and discussion

3.1. Characterization of Hpmtp

The synthesized Hpmtp was characterized by IR and ^1H NMR spectral data and elemental analysis. ^1H NMR ($CDCl_3$) data δ (ppm): 7.2–7.98 (m, 9H, phenyl), 2.14 (s, 3H, methyl of pyrazole ring), 2.45 (s, 3H, methyl of aromatic ring). IR (KBr) data ν (cm^{-1}): 1598, 1537, 753. Elemental Anal. Calc. for $C_{18}H_{16}N_2O_2$: C, 73.97; H, 5.48; N, 9.59. Found: C, 74.64; H, 5.66; N, 9.57%. In the ^1H NMR spectrum of Hpmtp, no peak corresponding to the enolic OH was observed. However, the absence of a peak at δ 3.4 ppm, corresponding to the methyne proton at the fourth position of the pyrazolone ring, confirms the existence of Hpmtp in the enolic form. The structure of Hpmtp was finally confirmed by the single crystal X-ray analysis (Fig. 2).

The single crystal X-ray diffraction study on this compound clearly indicates that the compound exists in the enol form. The structural data shows that the C(9)–O(1) distance in this compound is 1.327 Å, comparable with the distance found for C–OH in some pyrazolone derivatives [23] and the C(11)–O(2) distance is 1.258 Å, which is in the range of C=O distances in similar compounds [24].

3.2. Electron transfer from Hpmtp to oxovanadium(V)

In order to understand the redox chemistry of Hpmtp in the presence and absence of oxovanadium(V), cyclicvoltametric studies have been conducted in the range from 2.0 to −2.0 V and the corresponding voltammograms are depicted in Fig. 3. The voltammogram of Hpmtp (Fig. 3a) in acetonitrile solution (Hpmtp = 25 mM) has an irreversible oxidation peak around 1.37 V, which indicates the formation of a stable oxidised species of Hpmtp. Existence of a similar stable oxidised species of 1-phenyl-3-methyl-4-benzoyl-5-pyrazolone has been well documented elsewhere [25]. As can be seen from the voltammogram (Fig. 3b) of Hpmtp (5.0 cm^3 of 25 mM) in acetonitrile solution in the presence of 25 mM (2.0 cm^3) of oxovanadium(V), the peak current corresponding to the oxidation of the ligand at 1.37 V gradually decreases with the increase of concentration of oxovanadium(V), and a new peak

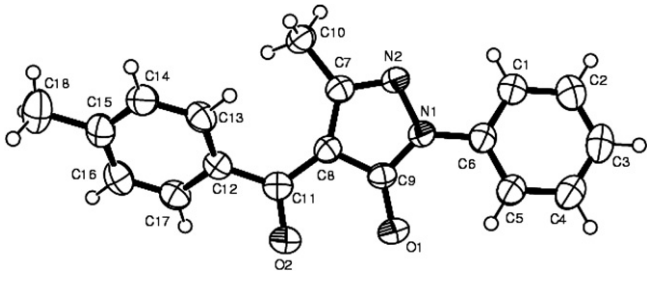

Fig. 2. Single crystal X-ray structure of Hpmtp.

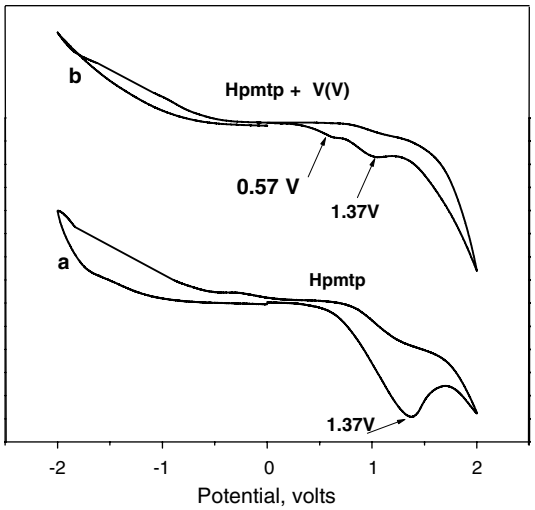

Fig. 3. Cyclicvoltammograms recorded in acetonitrile: (a) Hpmtp; (b) Hpmtp (5 ml of 25 mM) in presence of oxovanadium(V) (2 ml of 25 mM). Solute concentration 25 mM. Scan rate 50 mV s^{-1}. SCE was used as the reference electrode.

corresponding to the oxidation of oxovanadium(IV) to oxovanadium(V) appears at ~0.57 V. Since the reduction of oxovanadium(V) to oxovanadium(IV) occurs at a potential [26] lower than the oxidation potential of the ligand, the transfer of one electron is possible from the ligand to oxovanadium(V). An electron transfer process has also been reported for 1-phenyl-3-methyl-4-benzoyl-5-pyrazolone by Toropchina et al. [25].

3.3. Formation of a free-radical intermediate of Hpmtp

It is clear from the cyclic voltammetric studies that the ligand, Hpmtp transfers one electron to oxovanadium(V) and forms a free-radical intermediate, as indicated in Scheme 2. An indirect evidence for the formation of a free-radical intermediate has been ascertained by investigating the polymerization of acrylonitrile in the presence of oxovanadium(V) and Hpmtp. In the absence of either Hpmtp or oxovanadium(V), no detectable polymerization was noticed. This is an indirect evidence for the formation of a free-radical intermediate during the complexation process. Thus in the present study, it has been presumed that the reaction proceeds *via* a free-radical mechanism wherein oxovanadium(V) undergoes a one-electron reduction, as is evident from the cyclic voltammetric studies. The free radical thus generated finally couples with another free radical and forms a stable dimer. The dimeric species of the ligand has been isolated from the filtrate of the complexing medium and characterized by IR, ^{1}H NMR and ^{13}C NMR spectra (Figs. S2 and S3). In the ^{1}H NMR spectrum of the dimer, the δ values show a considerable shift from that of Hpmtp which indicates the formation of a new species. The IR spectrum of the dimer shows two strong absorptions in the region 1668–1610 cm^{-1}, indicating the presence of two C=O groups. Upon dimerisation, the sp^2 hybridised (δ 110–140 ppm) carbon in the pyrazole ring (C_4) of Hpmtp becomes an sp^3 hybridised one (δ 0–80 ppm), which can be clearly seen from the ^{13}C NMR spectrum of the dimer and Hpmtp (Fig. S4).

3.4. Stoichiometry

Hpmtp reduces aqueous oxovanadium(V) in both acidic and neutral media according to the following equation:

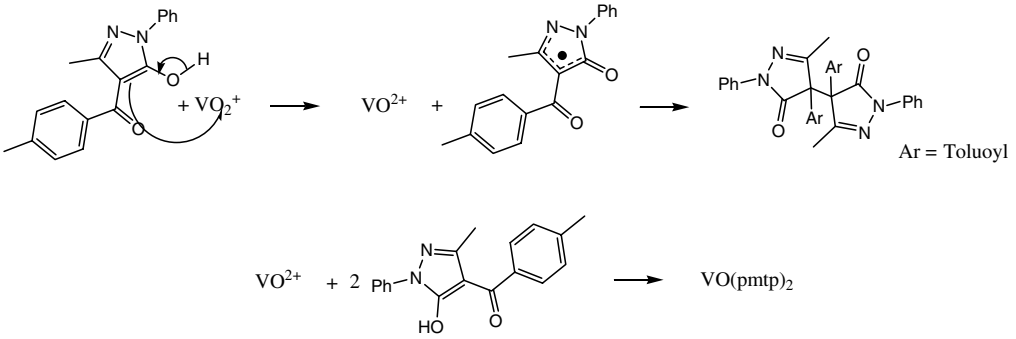
$$2VO_2^+ + 6HL \rightarrow 2VOL_2 + \text{Dimer} + 2H_2O + 2H^+$$

The 1:3 stoichiometry of the metal to ligand was confirmed at pH 1 and 7 by analysing both the filtrate of the complexing media and the resultant complex formed.

3.5. Mechanism of reduction of oxovanadium(V) to oxovanadium(IV) and subsequent complexation by Hpmtp

Based on the above studies the detailed scheme for the reduction of vanadium(V) to vanadium(IV) and subsequent complexation can be expressed in Scheme 2.

3.6. Spectroscopic characterization of $VO(pmtp)_2$



The elemental analyses and HRMS studies of the complexes prepared at both acidic and neutral pH conditions show a metal-to-ligand ratio of 1:2. Further, these values correspond to a oxovanadium(IV) species rather than a oxovanadium(V) species.

3.6.1. Infrared spectroscopy

The vanadium complex exhibits strong absorption bands at 1600–1515 cm^{-1} assigned to the stretching ν(C=O), ν(C=C) and ν(C=N) modes of the arylpyrazolone ring coordinated to the metal ion. Further, a signal at about 960 cm^{-1} in the region for a ν(V=O) stretch of the complex is observed. On the other hand, Uzouwku [27] has reported the V=O asymmetric stretching frequency at 895 cm^{-1} in a series of oxovanadium(IV) complexes of 4-acyl-5-pyrazolones. Usually, ν(V=O) stretches in most oxovanadium(IV) complexes are observed in the region 930–1010 cm^{-1} [28]. The low ν(V=O) value may arise from the presence of a bridging vanadyl group [29,30]. The absence of a broad absorption in the region 3000–3500 cm^{-1}, due to the –OH group of H_2O in the complex, indicates the absence of coordinated water. This is consistent with the thermogravimetric analysis of the complex in that there is no weight loss with an increase in temperature from 50 to 400 °C.

3.6.2. Magnetic and EPR measurements

The room-temperature magnetic susceptibility data for $VO(pmtp)_2$, prepared under acidic and neutral pH conditions, show essentially paramagnetic behaviour attributed to the d^1 system. The effective magnetic moments obtained for the oxovanadium(IV) complexes (1.79–1.83 BM) were within the normal range (1.57–2.1 BM) [31,32]. These

Scheme 2. Reduction and complexation of oxovanadium(V) with 1-phenyl-3-methyl-4-benzoyl pyrazolone.

values are as expected for the spin only μ_s of a d^1-system when the orbital contribution is completely quenched [33].

The X-band EPR spectra (Figs. 4 and S5) of the vanadium complexes exhibit a set of eight hyperfine lines arising from the interaction of the unpaired electron with the $^{51}V(IV)$ ($I = 7/2$) nucleus. The eight lines in the spectra of the complexes are an indication of their monomeric structure [32]. Symmetry reduction due to geometry distortion produces significant changes in EPR spectra. For square pyramidal complexes with C_{4v} symmetry, where the V=O bond is along the z-axis and the four donor atoms are along the x and y axes, an anisotropic EPR spectrum is expected, exhibiting two g ($g_z = g_\| < g_| = g_x = g_y$) and two A ($A_z = A_\| > A_| = A_x = A_y$) values. A distortion from the square pyramidal geometry can give three g and three A values. It is clear from the EPR parameters of the complexes **1** and **2** listed in Table S2 that both the complexes have a slightly distorted square pyramidal geometry. The

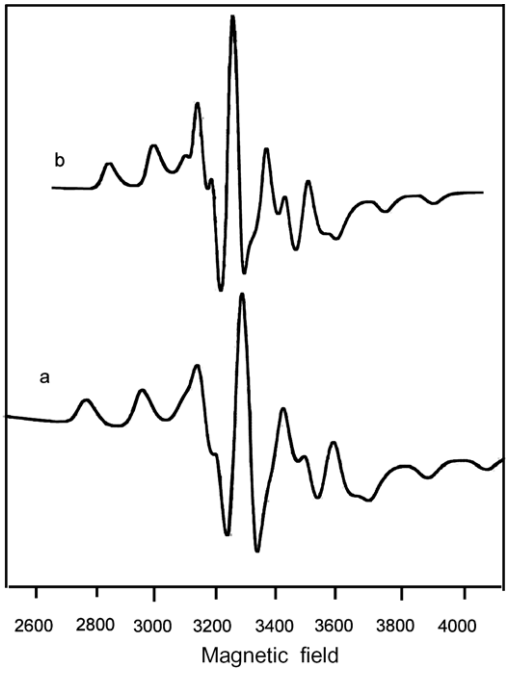


Fig. 4. ESR spectra of $VO(pmtp)_2$ (**1**). (a) Solid at 77 K; (b) dissolved in acetonitrile at 77 K.

g-values lie in the 1.9–1.99 range and agree with the fact that when the d-shell is less than half filled the spin–orbit effect reduces the g value from that of a free electron (2.0023) [3]. The order and magnitude of the resonance parameters are typical of the spectra displayed by a slightly distorted square pyramidal oxovanadium(IV) complexes with the unpaired electron in an orbital of mostly d_{xy} character.

3.6.3. Electronic absorption spectra

In the electronic spectra of Hpmtp in acetonitrile solution, the n–π^* transition of the carbonyl group was observed at around 285 nm, and the π–π^* transition of the phenyl group was observed at 245 nm and both transitions had an ε value of the order of 10^5 mol^{-1} cm^{-1}. In the complex, these absorption bands are red shifted to 305 and 250 nm, respectively, indicating the involvement of the carbonyl group in the complex formation with the metal ion. A similar behaviour has been reported elsewhere for the electronic spectral analysis of a series of oxovanadium(IV) 4-acyl-5-pyrazolone complexes [27]. The UV–Vis spectrum of the complex has overlapping peaks in the 400–800 cm^{-1} region. Hence, curve fitting of the spectrum was carried out using Peak Fit 4.12 software. In the curve fitting procedure, the peaks were assumed to be a number of Gaussian peaks, but no physical significance was attached to these peaks apart from the fact that their presence results in satisfactory curve fitting. The deconvoluted spectra of $VO(pmtp)_2$ prepared at acidic (Fig. 5) and neutral (Fig. S6) pH conditions have four transitions in the visible region. The observed absorption peaks correspond to transitions from the d_{xy} orbital to the d_{xz} (794 nm), d_{yz} (643 nm), $d_{x^2-y^2}$ (501 nm) and d_{z^2} (424 nm) orbitals in accordance with reports on the transitions of oxovanadium(IV) complexes having distorted square pyramidal geometries. The d–d absorption spectra of square pyramidal oxovanadium(IV) complexes are generally interpreted by the scheme proposed by Ballhausen and Gray [34]. The V=O bond defines the z-axis, and the x and y axes are in the equatorial plane. The energy levels predicted for the 3d orbitals in this scheme follow the order: $d_{xy}(b_2) < d_{xz}, d_{yz}(e) < d_{x^2-y^2}(b_1) < d_{z^2}(a_1)$. The three transitions, $b_2 \rightarrow e$, $b_2 \rightarrow b_1$ and $b_2 \rightarrow a_1$, are typical of a square pyramidal complex.

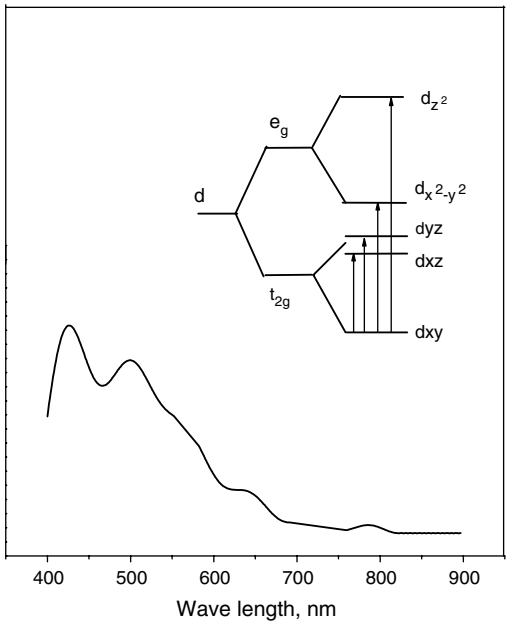

Fig. 5. Deconvoluted UV spectrum of $VO(pmtp)_2$ (**1**).

A distortion from the square pyramidal geometry removes the degeneracy between the d_{xz} and d_{yz} orbitals. The *e* level will then split into two, $b_1(d_{xz})$ and $b_2(d_{yz})$, and accordingly four transitions will be observed in the case of a complex with a distorted square pyramidal geometry [31,32]. This type of d–d transitions is also observed by Fukuda et al. [35] and Klich et al. [36]. It can be concluded from the above spectral data that the oxovanadium(IV) ion with two coordinating ligands will be present in a slightly distorted square pyramidal geometry.

3.6.4. Optimized geometry of a distorted square pyramidal oxovanadium(IV) complex

A square pyramidal geometry containing two $pmpt^-$ moieties is considered as the most probable oxovanadium(IV) complex. The optimized geometry of this system at the B3LYP/6-31G* level of DFT is depicted in Fig. 6. In this structure, the four oxygen atoms from the two $pmpt^-$ ligands are at the base and a VO double bond of length 1.584 Å is pointing towards the apex of the pyramid. Two different V–O single bonds can be seen, a short one of length 1.963 Å with the pyrazolone oxygen and a long one of 1.994 Å with the toluoyl oxygen. The high coordination power of the pyrazolone oxygen is reflected in its short V–O bond, in accordance with the highest negative MESP of −157.6 kcal/mol observed for this oxygen in the $pmpt^-$ system (Fig. S7). The molecular orbital and the spin density analysis of the complex showed that the unpaired electron of the vanadium atom is mainly localized on the d_{xy} orbital, further supporting the earlier mentioned electronic transitions originating from this orbital. The V–O bond distances to $pmtp^-$ are significantly longer than the VO double bond, as observed in the X-ray crystal structure of $VO(acac)_2$ (acac = acetylacetone) [35] and $VO(acac\text{-}NMe_2)_2$ (acac-NMe_2 = *N*,*N*-dimethoxyacetylacetamido) [37]. Further, the VO double bond of length in $VO(pmtp)_2$ (1.584 Å), deduced by DFT, is in the same range as observed in $VO(acac)_2$ (1.592 Å) [32]. The electronic transitions of $VO(pmtp)_2$ predicted using GAUSSIAN-03 [782 nm (d_{xy} orbital to d_{xz}), 654 nm (to d_{yz}), 520 nm (to $d_{x^2-y^2}$) and 420 nm (to d_{z^2})] were in good agreement with the experimental data [794 nm (d_{xy} orbital to d_{xz}), 643 nm (to d_{yz}), 501 nm (to $d_{x^2-y^2}$) and 424 nm (to d_{z^2})].

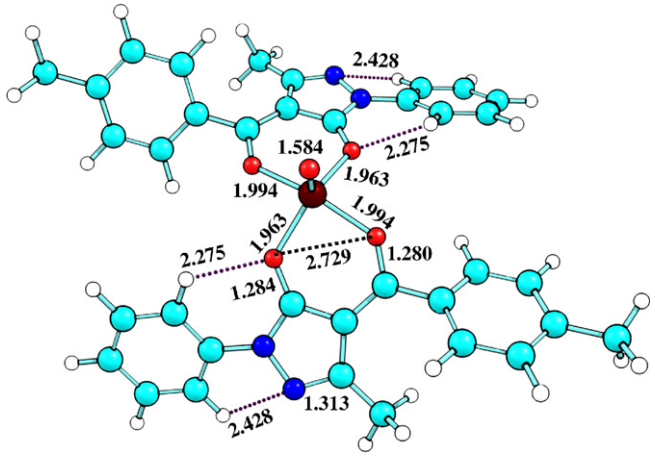

Fig. 6. The optimized geometry of this system at the B3LYP/6-31G* level of DFT.

The distortion of a square pyramidal structure to a trigonal bipyramid is measured in terms of the τ parameter [34]. This parameter is $(\alpha - \beta)/60$ where α is the angle formed by the two pseudo-axial atoms at the vanadium atom and β is the angle formed by the two pseudo-equatorial atoms. For purely square pyramidal complexes τ is zero. Complexes with $0 < \tau < 0.5$ will be distorted square pyramid and those with $0.5 < \tau < 1$ will be distorted trigonal bipyramid. For $VO(pmtp)_2$ the τ value obtained is 0.1, indicating a slight distortion from the square pyramidal geometry. It can be concluded from the DFT calculations that the vanadium ion exhibits a distorted square pyramidal coordination environment in $VO(pmtp)_2$. A similar geometry has been observed earlier in the oxovanadium(IV) complexes of β-diketonates as evidenced by X-ray single crystal studies [38].

4. Conclusions

Hpmtp instantaneously reduces vanadium(V) over the pH range 1–7 and forms $VO(pmtp)_2$ by the transfer of one electron to VO_2^+, via the formation of a free-radical intermediate. The voltammogram of Hpmtp has an irreversible oxidation peak around 1.37 V indicating the formation of a stable oxidised species. Further, the oxidation potential of Hpmtp is higher than the redox potential of vanadium(V), which clearly highlights that the ligand can reduce vanadium(V) to vanadium(IV) by transferring one electron. The existence of vanadium(IV) in the complex has been ascertained by electron paramagnetic

resonance spectroscopy, magnetic susceptibility and electronic spectroscopy. These reduction reactions occur under physiological conditions and thus could be important for the reduction of vanadium(V)-containing coordination compounds used as insulin-enhancing agents for treatment of diabetics.

Scheme 1.

and luminescence behaviour of a dinuclear compound of the type $[Cd_2(pbap)(OH_2)_2(N_3)_4]$ (**1**) [pbap = *N*-(1-pyridin-2-ylbenzylidene)-*N*-[2-(4-{2-[(1-pyridin-2-ylbenzylidene)amino]ethyl}piperazin-1-yl)ethyl]amine (Scheme 1)] and a polymeric compound of the type $[Cd_2(pfap)(\mu_{1,3}\text{-NCS})(\mu_{1,3}\text{-SCN})(NCS)_2]_n$ (**2**) [pfap = *N*-(1-pyridin-2-ylformy-lidene)-*N*-[2-(4-{2-[(1-pyridin-2ylformy-lidene)amino]ethyl}piperazin-1-yl)ethyl]amine (Scheme 1)] in combination with tailored hexadentate N-donor Schiff bases (pbap/pfap) and azide/thiocyanate.

2. Experimental

2.1. Materials

High purity 2-benzoylpyridine (Fluka, Germany), pyridine-2-carboxaldyde (Fluka, Germany), 2-[4-(2-aminoethyl)piperazin-1-yl]ethylamine (Aldrich, USA), sodium azide (Aldrich, USA), ammonium thiocyanate (E. Merck, India) and cadmium(II) nitrate tetrahydrate (E. Merck, India) were purchased from the respective concerns and were used as received. Cadmium(II) perchlorate hexahydrate was prepared by treatment of cadmium(II) carbonate (E. Merck, India) with perchloric acid (E. Merck, India) followed by slow evaporation on steam-bath, filtration through a fine glass-frit and preservation in a desiccator containing concentrated sulfuric acid (E. Merck, India) for subsequent use. All other chemicals and solvents were AR grade and were used as received.

2.2. Physical measurements

Elemental analyses (carbon, hydrogen and nitrogen) were measured using a Perkin–Elmer 2400 CHNS/O elemental analyser. IR spectra (KBr discs, 4000–300 cm^{-1}) were recorded using a Perkin–Elmer FTIR model RX1 spectrometer. Molar conductances were measured using a Systronics conductivity meter where the cell constant was calibrated with 0.01 (M) KCl solution and DMF was used as the solvent. Thermal analysis was recorded using a Perkin–Elmer Diamond TG/DTA system under a flow of nitrogen (30 ml min^{-1}). The sample was heated at a rate of 10 °C min^{-1} with inert alumina as a reference. Ground state absorption and steady-state fluorescence measurements were made with a Jasco model V-530 UV–Vis spectrophotometer and Hitachi model F-4010 spectrofluorimeter, respectively. Time-resolved fluorescence measurements were carried out using a time-correlated single photon counting (TCSPC) spectrometer Edinburgh Instruments, model 199; a hydrogen filled coaxial flash lamp with a pulse width of 1.2 ns at FWHM and a Philips XP-2020Q photomultiplier tube were used as the excitation source and the fluorescence detector.

2.3. Preparation of the Schiff bases

2.3.1. N-(1-Pyridin-2-ylbenzylidene)-N-[2-(4-{2-[(1-pyridin-2-ylbenzylidene)amino]ethyl}piperazin-1-yl)ethyl]amine (pbap)

2-[4-(2-Aminoethyl)piperazin-1-yl]ethylamine (0.172 g, 1 mmol) with 2-benzoylpyridine (0.366 g, 2 mmol) was refluxed in dehydrated alcohol in a 1:2 molar ratio. After 10 h reflux the reaction solution was evaporated under reduced pressure to a gummy mass, which was dried and stored *in vacuo* over $CaCl_2$ for subsequent use; yield, 1.928 g (70%). IR (KBr disc, cm^{-1}): ν(C=N) 1594. UV–Vis (λ_{max}, nm): 245, 293.

2.3.2. N-(1-Pyridin-2-ylformylidene)-N-[2-(4-{2-[(1-pyridin-2ylformylidene)amino]ethyl}pipera-zin-1-yl)ethyl]amine (pfap)

2-[4-(2-Aminoethyl)piperazin-1-yl]ethylamine (0.172 g, 1 mmol) and pyridine-2-carboxaldyde (0.214 g, 2 mmol) were mixed together and refluxed in anhydrous ethanol (25 cm^3) for 10 h. The yellowish brown solution that resulted was concentrated on a steam bath and dried *in vacuo* over $CaCl_2$ to a yellowish brown semi-solid for subsequent use. Yield: 1.525 g (75%). IR (KBr disc, cm^{-1}): ν(C=N) 1592. UV–Vis (λ_{max}, nm): 242, 290.

2.4. Preparation of the complexes

2.4.1. $[Cd_2(pbap)(OH_2)_2(N_3)_4]$ (1)

Pbap (0.476 g, 1 mmol) dissolved in methanol (20 cm^3) was added to an acetonitrile solution (20 cm^3) of cadmium perchlorate hexahydrate (0.622 g, 2 mmol) with continuous stirring. To this, a methanolic solution (20 cm^3) of sodium azide (0.260 g, 4 mmol) was added. The resulting light yellow solution was filtered and kept for slow evaporation. After 7 days colourless crystals were separated, washed with toluene and dried *in vacuo* over silica gel indicator. Yield: 0.823 g (50%). *Anal.* Calc. for $C_{32}H_{38}N_{18}O_2Cd_2$ (**1**): C, 41.3; H, 4.0; N, 27.0. Found: C, 41.2; H, 4.1; N, 27.1%. IR (KBr, cm^{-1}): $\nu(N_3)$ 2070; ν(OH) 3300–3500 (broad). UV–Vis (λ, nm) 340. Λ_M (MeOH, Ω^{-1} cm^2 mol^{-1}): 5.

2.4.2. $[Cd_2(pfap)(\mu_{1,3}\text{-NCS})(\mu_{1,3}\text{-SCN})(NCS)_2]_n$ (2)

An acetonitrile solution (5 cm^3) of pfap (0.175 g, 1 mmol) was added dropwise to a solution of $Cd(NO_3)_2 \cdot 4H_2O$ (0.308 g, 2 mmol) in methanol (5 cm^3). NH_4NCS (0.152 g, 4 mmol) in methanol (5 cm^3) was added slowly to this solution. The resultant solution was filtered and kept for slow evaporation. After 5 days **2** was separated, washed with methanol and dried *in vacuo* over $CaCl_2$. Yield: 1.570 g (60%). *Anal.* Calc. for $C_{24}H_{26}N_{10}S_4Cd_2$ (**2**): C, 35.7; H, 3.2;

2.5. Crystallographic data collection and refinement

Single-crystals suitable for X-ray work were grown by slow evaporation of a methanol–acetonitrile solution of **1** and **2** at 298 K [crystal size: **1**, $0.10 \times 0.10 \times 0.07$ mm^3; **2**, $0.12 \times 0.05 \times 0.05$ mm^3]. Data were collected on a Siemens SMART CCD area diffractometer equipped with a graphite-monochromator Mo Kα radiation ($\lambda = 0.71073$ Å). The intensity data were corrected for Lorentz and polarization effects and an empirical absorption correction was employed using the SAINT [16] and SADABS [17] programs for the crystals. Diffraction data for the crystals were measured using the φ- and ω-scan techniques. Systematic absence led to the identification of space groups $P2(1)/c$ for **1** and $C2/c$ for **2**. A summary of the crystallographic data and structure refinement parameters are given in Table 1.

Table 1
Crystallographic data and structure refinement for $[Cd_2(pbap)(OH_2)_2(N_3)_4]$ (**1**) and $[Cd_2(pfap)(\mu_{1,3}\text{-NCS})(\mu_{1,3}\text{-SCN})(NCS)_2]_n$ (**2**)

Completeness to theta (%)	92.6 (28.27°)	91.5 (28.27°)
Data/restraints/ parameters	4325/0/252	2381/0/181
T_{max} and T_{min}	1.000 and 0.794	1.000 and 0.805
Goodness-of-fit on F^2	1.011	0.996
Final R indices [$I > 2\sigma(I)$]	$R_1 = 0.0379$, $wR_2 = 0.0794$	$R = 0.0476$, $wR_2 = 0.1003$
R indices (all data)	$R_1 = 0.0510$, $wR_2 = 0.0843$	$R = 0.0767$, $wR_2 = 0.1107$
Largest peak and hole (e Å^{-3})	0.934 and −0.355	1.04 and −0.42

Weighting Scheme: $R_1 = \sum|F_o| - |F_c||/\sum|F_o|$, $wR_2 = [\sum w(F_o^2 - F_c^2)_2/\sum w(F_o^2)^2]^{1/2}$, Calc. $w = 1/[\sigma^2(F_o^2) + (0.0495P)^2 + 0.0000P]$ for **1** and $w = 1/[\sigma^2(F_o^2) + (0.0341P)^2 + 0.0000P]$ for **2** where $P = (F_o^2 + 2F_c^2)/3$.

The structures were solved by direct methods and the structure solution and refinement were based on $|F|^2$. Of the 11344 (**1**) and 3523 (**2**) reflections, 4325 and 2381 with $I > 2\sigma(I)$ were used for the structure solution. All non-hydrogen atoms were refined with anisotropic displacement parameters whereas hydrogen atoms were placed in calculated positions when possible and given isotropic U values 1.2 times that of the atom to which they are bonded. At convergence, the final residual were $R_1 = 0.0379$ (**1**) and 0.0476 (**2**); $wR_2 = 0.0794$ (**1**) and 0.1003 (**2**) with $I > 2\sigma(I)$, goodness-of-fit = 1.011 (**1**) and 0.996 (**2**). The final differences Fourier map showed the maximum and minimum peak heights of 0.934 and −0.355 e Å^{-3} for **1**, and 1.04 and −0.42 e Å^{-3} for **2**. All crystallographic calculations were conducted with SHELXL-97 [18], ORTEP-32 [19] and PLATON [20] programs.

3. Results and discussion

3.1. Synthesis and formulation

The Schiff bases, *N*-(1-pyridin-2-ylbenzylidene)-*N*-[2-(4-{2-[(1-pyridin-2-ylbenzylidene)amino]ethyl}piperazin-1-yl)ethyl]amine (pbap) or *N*-(1-pyridin-2-ylformylidene)-*N*-[2-(4-{2-[(1-pyridin-2-ylformylidene)amino]ethyl}piperazin-1-yl)ethyl]amine (pfap) were synthesized by refluxing 2-[4-(2-aminoethyl)piperazin-1-yl]ethylamine (1 mol) with 2-benzoylpyridine or pyridine-2-carboxaldehyde (2 mol) in dehydrated alcohol. The reaction of cadmium(II) chlorate hexahydrate/cadmium(II) nitrate tetrahydrate, pbap/pfba and sodium azide/ammonium thiocyanate in a 2:1:4 molar ratio in MeOH–MeCN solvent mixture at room temperature results in a dimeric and a polymeric compound, as shown in Eqs. (1) and (2):

$$2\,Cd(ClO_4)_2.6H_2O + pbap + 4\,NaN_3 \xrightarrow[298\ K]{\text{MeOH-MeCN}} [Cd_2(pbap)(OH_2)_2(N_3)_4] + 4\,NaClO_4 + 10\,H_2O \quad (\mathbf{1}) \tag{1}$$

$$2n\,Cd(NO_3)_2.4H_2O + n\,pfap + 4n\,NH_4SCN \xrightarrow[298\ K]{\text{MeOH-MeCN}} [Cd_2(pfap)(\mu_{1,3}\text{-NCS})(\mu_{1,3}\text{-SCN})(NCS)_2]_n + 4n\,NH_4NO_3 + 8n\,H_2O \quad (\mathbf{2}) \tag{2}$$

The air-stable, moisture-insensitive compounds are powders, soluble in a range of common organic solvents such as methanol, ethanol, acetonitrile, dimethylformamide and dimethylsulfoxide, but insoluble in water. Microanalytical (C, H and N) results and spectroscopic data are useful to formulate the product. In methanolic solution they behave as non-electrolytes, as reflected from their low conductivity values (~5 ohm^{-1} cm^2 mol^{-1}). In the IR spectra, **1** shows a strong absorption band at 2070 cm^{-1}, which is assignable to the stretching vibration of the terminal azide $\nu(N_3)$, and also shows a broad band in the region 3300–3500 cm^{-1} due to ν(O–H), indicating the presence of

the coordinated water molecules [21]. Two strong peaks at 2125 and 2105 cm^{-1}, assignable to ν_{as}(SCN) stretching vibrations of the thiocyanate [21], are observed for **2**. The position (>2100 cm^{-1}) and number of signals strongly suggest a mutual *cis* alignment as well as N- and S-coordination of the bound thiocyanates. The solutions are colourless and exhibit absorptions at 340 nm for **1** and 312 nm for **2**. Reflectance (in Nujol) and electronic (in MeOH solution) spectra are akin in each complex, reflecting a similar gross structure and electronic structure in the solid state and in solution. The transition may correspond to an intramolecular n–π^*/π–π^* charge transfer [22]. According to the thermal study (TG-DTA), compound **1** upon heating loses two molecule of water at ~140 °C, suggesting that the water molecules are involved in coordination and in strong hydrogen bonding interactions.

3.2. X-ray crystal structures

3.2.1. Crystal structure of $[Cd_2(pbap)(OH_2)_2(N_3)_4]$ (1)

The dinucleating hexadentate character or alternatively bis(tridentate) view of the ligand and two pairs of donor set arrangements through the incorporation of the ring within the bridge, is clearly evident and is shown in Fig. 1. Relevant bond distances and bond angles in **1** are listed in Table 2. C–H···π and O–H···N hydrogen bondings leading to the superstructure formation are shown in Figs. 2–5. The structure of **1** is a centrosymmetric dimer linked by the bis(tridentate) congregator. Cd(1) is surrounded by two terminal azide nitrogen atoms [N(4), N(7)], one coordinated water molecule [O(1)] and three N atoms [N(1), N(2), N(3)] of the new Schiff base ligand (pbap), whereas the neighboring Cd(1A) is ligated to the other three N donor set atoms [N(1A), N(2A), N(3A)] of the same pbap ligand, completing its bis(tridentate) mode, two terminal azides [N(4A), N(7A)] and one water [O(1A)] molecule. The basal dimeric plane consists of a six N-donor set of the congregator and two terminal azide nitrogen atoms, while the axial coordination sites of each cadmium center are occupied by an azide nitrogen [N(4)/N(4A)] and the coordinated water [O(1)/O(1A)]. The cadmium(II) centers are six-coordinate (CdN_5O) with a substantial departure from an ideal octahedral geometry [*cisoid* angles: 68.88(9)–122.47(10)°; *transoid* angles: 141.95(9)–175.42(10)°]. Cd–N(pbap) distances are in the range 2.335(3)–2.459(2) Å, and Cd–N(azido) distances are within the range 2.243(3)–2.335(3) Å. It is worth mentioning that none of the azido anions behave as a bridging ligand; this is an unusual azido coordination mode [15,16]. The intramolecular Cd···Cd distance in **1** is quite large [6.473(2) Å]. The azido ligands are quasi-linear with N(4)–N(5)–N(6) and N(7)–N(8)–N(9) angles of 178.0(5)° and 177.7(4)°; The N4–N5 and N(7)–N(8) bond lengths [1.181(4) Å] are larger than N(5)–N(6) [1.149(5) Å] and N(8)–N(9) [1.148(4) Å], indicating coordination of N(4) and N(7) to the cadmium center.

Table 2

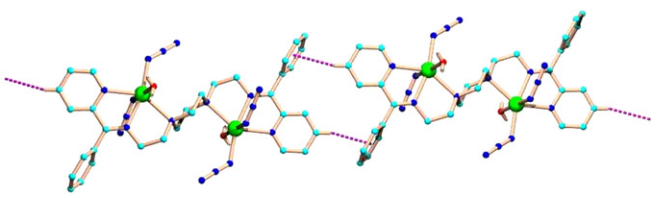

Fig. 2. C–H···π interactions in 1 forming a 1D chain in the 110 direction.

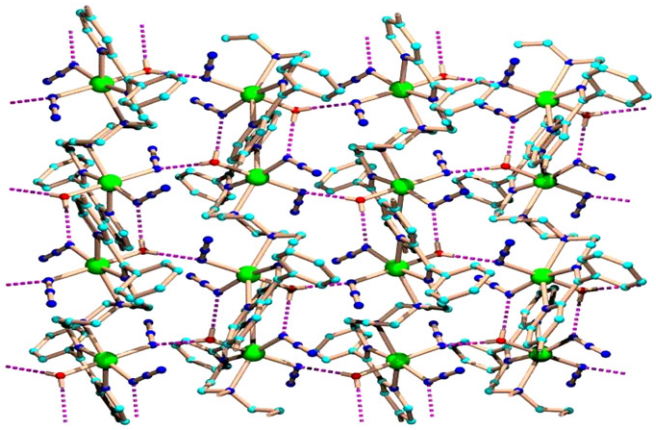

Fig. 3. O–H···N hydrogen bonding in **1** forming a sheet in the *bc* plane.

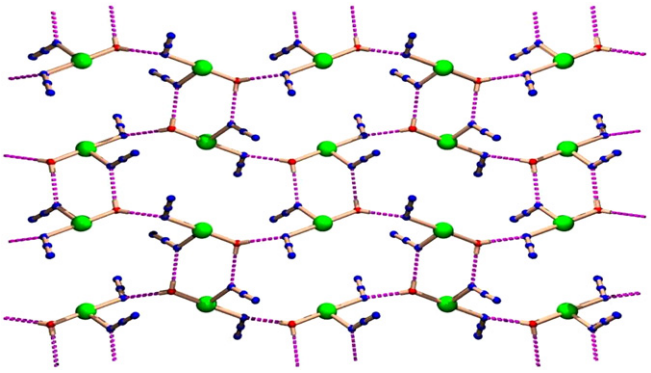

Fig. 4. Sheet formation in **1** in the *bc* plane through hydrogen bonding (omitting the ligand frame for clarity).

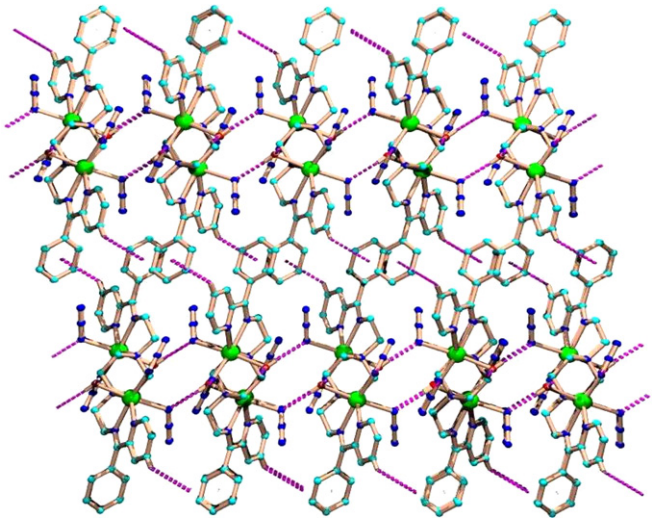

Fig. 5. O–H···N hydrogen-bonded sheet interwoven by C–H···π interactions in **1** forming a 3D network.

H···Cg: 147°, symmetry code: $1-x$, y, $2-z$). Two types of O–H···N hydrogen bonds (O(1)–H(1)···N(4): H···A:2.02(4) Å, D···A: 2.767(4) Å, angle D–H···A: 177(3)°, symmetry code x, $1/2-y$, $-1/2+z$ and O(1)–H(2)···N(7): H···A: 0.72(4) Å, D···A: 2.840(4) Å, angle D–H···A: 177(4)°, symmetry code $2-x$, y, $2-z$) form a 2D sheet in the *bc* plane (Figs. 3 and 4). These hydrogen bonds and C–H···π interactions are interwoven to form a 3D network (Fig. 5).

3.2.2. Crystal structure of $[Cd_2(pfap)(\mu_{1,3}\text{-NCS})(\mu_{1,3}\text{-SCN})(NCS)_2]_n$ (2)

A single crystal X-ray diffraction study of **2** shows that the crystal lattice consists of a $[Cd_2(pfap)(\mu_{1,3}\text{-NCS})(\mu_{1,3}\text{-SCN})(NCS)_2]_n$ unit (Fig. 6). The layer structure for **2**, through π···π interactions, is displayed in Fig. 7. Selected bond distances and bond angles relevant to the metal ion coordination sphere are given in Table 2. The polynuclear unit of **2** contains two symmetry related cadmium(II) centers [Cd(1), Cd(1*)] connected by a Schiff base acting as a bis(tridentate) ligand, and two end-to-end ($\mu_{1,3-}$) bi-bridged thiocyanate/isothiocyanate intermediaries and one N-coordinated isothiocyanate are attached to each of the two cadmium(II) centers completing the hexacoordination of the metal ions with a distorted octahedral CdN_5S coordination environment, which propagates forming the 1D polymeric chain. The N-coordination of the terminal NCS^- ligands indicates that the three N-atoms of the Schiff base (pfba) and the N-donation of the $\mu_{1,3-}$ bridged NCS^- ligand create a hardness in cadmium(II) center that enforces the ambidentate ligand to be bound in such a fashion. Cd(1) is attached by three nitrogen atoms, viz. the piperazine nitrogen [N(3)], the imine nitrogen [N(4)] and the pyridine nitrogen [N(5)], of the Schiff base and two end-to-end ($\mu_{1,3-}$) bi-bridged nitrogen [N(1)] and sulfur [S(1)] atoms and one terminal nitrogen [N(2)] atom of the thiocyanate ligands, whereas the neighbouring symmetry related Cd(1*) is ligated to the other three N donor set of the same Schiff base, completing its bis(tridentate)mode, and the counter ends [S(1*) and N(1*)] of two end-to-end ($\mu_{1,3-}$) bi-bridged thiocyanate ligands and the one terminal nitrogen [N(2*)] of the pseudohalide. Each metal center contains one eight-membered bridging loop and two five-membered chelate loops. The eight-membered Cd–$(SCN)_2$–Cd bridging loops adopt a chair confirmation. The equatorial plane of Cd(1) consists of three nitrogen atoms [N(3), N(4), N(5)] of the bis(tridentate) Schiff base and one sulfur atom [S(1)] of a bridging thiocyanate, whereas the axial positions are occupied by a bridging nitrogen atom [N(1)] and a terminal nitrogen atom [N(2)] of the thiocyanate ligands. The maximum deviation of the Cd(1) center from the mean plane is 0.1713 Å. The degrees of distortion from an ideal octahedral geometry are reflected in the *cisoid* [70.45(15)–113.82(10)°] and *transoid* [143.66(14)–177.80(18)°] angles. The Cd–N [2.250(5)–2.524(4) Å] bond lengths are shorter than the bridging Cd–S [2.6161(14) Å] distance, as expected, and are consistent [15] with the corresponding values of the cadmium(II) thiocyanato bridging system. The Cd(1)–N(3) [piperazine] distance [2.524(4) Å] is longer than the Cd(1)–N(5) [pyridine] distance [2.395(4) Å] and Cd(1)–N(4) (imine) bond length [2.295(4) Å]. The intradimer Cd···Cd separation

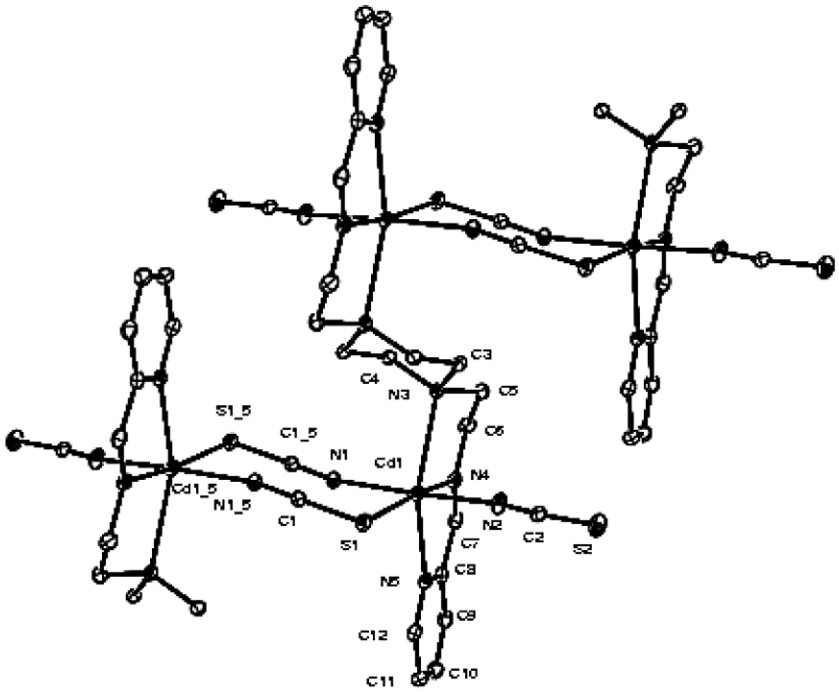

Fig. 6. Thermal ellipsoid plot of the polynuclear $[Cd_2(pfap)(\mu_{1,3}\text{-NCS})(\mu_{1,3}\text{-SCN})(NCS)_2]_n$ (**2**) with the atom labelling scheme and 30% probability ellipsoids for all non-hydrogen atoms.

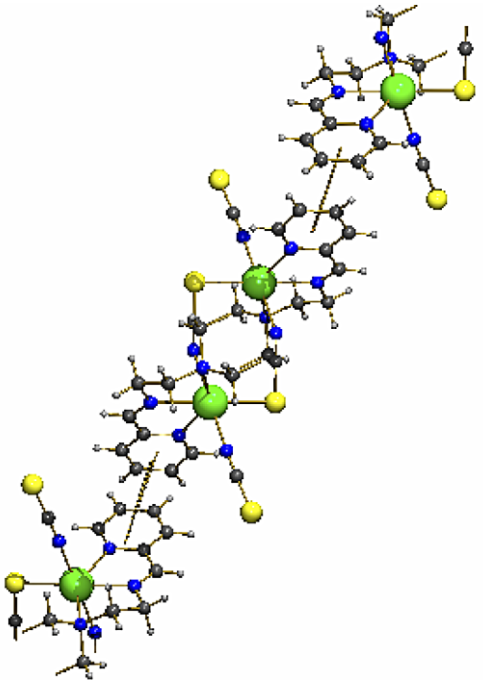

Fig. 7. Layer structure in **2** through π···π interactions.

[6.640(5) Å], through the bis(tridentate) bridge of the Schiff base is larger than the Cd···Cd separation [5.849(5) Å] through the bi-bridged thiocyanates. The angle between the terminal and bridging thiocyanates [S(1)–Cd(1)–N(2)] is 86.78(12)°, reflecting the *cis* alignment of the N- and S-coordination of the bound thiocyanates. N(1) and S(1) from two bridging isothiocyanate and thiocyanate ligands, and N(2) from the terminal isothiocyanate are in the meridional position of the distorted octahedron. The thiocyanates are coordinated in a linear fashion as seen from the N(1*)–C(1)–S(1) and N(2)–C(2)–S(2) angles [178.5(5) and 176.4(5)°]. The N(2)–C(2) length [1.121(7) Å] is shorter than C(2)–S(2) [1.624(5) Å], reflecting N-coordination of the terminal thiocyanate.

In crystal lattice the 1D covalent chain of **2** forms a layer structure with a face-to-face π···π interaction from two terminal pyridine rings [Ring(4)-ring(4)]: Cg(4)–Cg(4) [(a)] separation: 5.1732(3) Å, vertical displacement of Cg: 4.873 Å; [(a)] $1/2 - x,\ -1/2 + y,\ 3/2 - z$; Cg(4) = N(5)–C(8)–C(9)–C(10)–C(11)–C(12)] (Fig. 7).

3.3. Luminescence spectra

The fluorescence behaviour of **1** and **2** has been examined. The fluorescent emission was measured in MeOH solution at 298 K. Upon photoexcitation at 340 and 312 nm an intense fluorescent band was observed with a maximum at 465 and 410 nm and a lifetime of 2.63 and 2.58 ns for **1** and **2**, respectively. The higher lifetime may be due to the presence of stronger weak interactions, which are mainly responsible [23,24] for fluorescence. In glassy solutions (77 K) a red shift is observable at 535 and 510 nm for **1** and **2**, which is presumably due to $^3(\pi\text{–}\pi^*)$ phosphorescence.

4. Conclusion

In conclusion, X-ray crystallographic characterization of new dimeric cadmium(II) azido and polymeric cad-

mium(II) thiocyanato compounds is reported herein. To the best of our knowledge, this the first report of a Schiff base containing polymeric cadmium(II) pseudohalide compound, where the versatility of the tailored hexadentate blocker is realized through its bis(tridentate) congregation behaviour encapsulating two metal ions instead of the classical hexacoordination binding a single metal ion. Again, intermolecular cooperative [25] forces are harnessed to engineer novel crystalline architectures. Both the compounds are examples of good luminous materials.

Acknowledgements

We are thankful to the Department of Science and Technology (DST) and the Council of Scientific and Industrial Research (CSIR), New Delhi, India for financial support. The authors thank Prof. M. J. Zaworotko, The University of South Florida, USA for the X-ray study.

5. Supplementary material

CCDC 205911 and 205912 contain the supplementary crystallographic data for **1** and **2**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

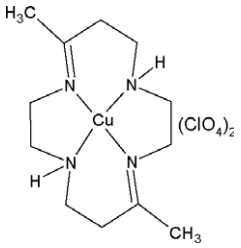
and M(II) 3d metal ions (M = Ni, Mn) bridged by thiocyanate groups. Due to its ambident character, the thiocyanate group, like cyanide, may serve as a bridging ligand. It is interesting to learn how the arrangement of molecules in the crystal lattice, configuration of the nitrogen atom ligands and the type of paramagnetic centers in the heterometallic systems influence the magnetic properties of the compounds studied (Scheme 1).

2. Experimental

2.1. Materials



All materials used in this work were of the reagent grade purity. They were used as commercially obtained. $[CuL_\alpha](ClO_4)_2$ was prepared as previously reported [5].

2.2. Synthesis of the complex $\{CuL_\alpha[Ni(NCS)_4(H_2O)_2]\}$ (1)

A solution of $[CuL_\alpha](ClO_4)_2$ (73.02 mg, 0.15 mmol) in CH_3CN (10 mL) was added dropwise to an aqueous solution (10 mL) containing KSCN (58.31 mg, 0.6 mmol) and $NiCl_2 \cdot 4H_2O$ (35.64 mg, 0.15 mmol). The mixture was subsequently stirred. After a few days, a dark-pink crystalline solid was formed from the violet solution by slow evaporation. It was filtered and washed using diethyl ether (2×10 mL). Yield: 86.15 mg (93%). Violet crystals suitable for X-ray diffraction studies were obtained by slow evaporation of a solution of all the reagents in CH_3CN–H_2O (1:1) at room temperature. IR/cm^{-1}: bands associated with the thiocyanate ligand appear at 2121 (vs), 2088 (vs), 815 (vw), 480 (w), 474 (w), 460 (w). *Anal.* Calc. for $C_{16}H_{28}N_8O_2S_4NiCu$ (614.95): C, 31.25; H, 4.59; N, 18.22; S, 20.86. Found: C, 31.16; H, 4.38; N, 18.21; S, 19.56%. The copper and manganese content was determined by the ICP method: Calc. Ni 9.54, Cu 10.33. Found: Ni 9.22, Cu 10.02.

2.3. Synthesis of complex $\{CuL_\alpha[Mn(NCS)_4(H_2O)_2]\}$ (2)

A solution of $[CuL_\alpha](ClO_4)_2$ (73.02 mg, 0.15 mmol) in CH_3CN (10 mL) was added dropwise to an aqueous solution (10 mL) containing KSCN (58.31 mg, 0.6 mmol) and $MnCl_2 \cdot 4H_2O$ (29.68 mg, 0.15 mmol). The mixture was subsequently stirred. The resulting orange precipitate was filtered off, washed with diethyl ether (2×10 ml) and dried at room temperature. Yield: 80.35 mg (88%). Violet crystals of **2** suitable for X-ray diffraction studies were obtained by slow evaporation of a CH_3CN–H_2O (1:1) solution of the previously prepared precipitate. IR/cm^{-1}: bands associated with the thiocyanate ligand appear at 2103 (vs), 2071 (vs), 814 (vw), 470 (w). *Anal.* Calc. for $C_{16}H_{28}N_8O_2S_4MnCu$ (611.18): C, 31.44; H, 4.62; N, 18.33; S, 20.99. Found: C, 31.02; H, 4.58; N, 18.12; S, 19.88. The nickel and manganese content was determined by the ICP method: Calc. Mn 8.99, Cu 10.40. Found: Mn 8.44, Cu 9.96.

Scheme 1. Schematic view of the macrocyclic copper(II) complex.

2.4. Magnetic measurement

Magnetic measurements in the temperature range 1.8–300 K were performed using a Quantum Design SQUID-based MPMSXL-5-type magnetometer. The SQUID magnetometer was calibrated with a palladium rod sample (Materials Research Corporation, measured purity 99.9985%). The superconducting magnet was generally operated at a field strength ranging from 0 to 5 T. Measurements were undertaken at a magnetic field of 0.5 T. Corrections are based on subtracting the sample holder signal and the contribution χ_D estimated from Pascal constants [6].

2.5. EPR spectra

EPR spectra were recorded at room temperature and 77 K on a Bruker ESP 300 spectrometer operating at X-band equipped with an ER 035M Bruker NMR gaussmeter and HP 5350B Hewlett-Packard microwave frequency counter. The spectra at a temperature of 4.2 K were measured with an X-band Radiopan SE/X 2543 spectrometer.

2.6. X-ray crystallographic analysis

Single-crystal X-ray measurements of complexes **1** and **2** were accomplished on a Kuma KM4CCD κ-axis diffractometer with graphite–monochromated MoKα radiation at 100 K. The crystals were positioned 65 mm from the KM4CCD camera. 1204 frames were measured at 1.0° intervals with a counting time of 20 s for complex **1** and 17 s for complex **2**. The data were corrected for Lorentz and polarization effects. A numerical absorption correction was applied. Data collection, cell refinement and data reduction were carried out with the Kuma Diffraction programs: CrysAlisCCD and CrysAlisRED [7]. The structures were solved by direct methods [8] and refined using SHELX [9]. The refinement was based on F^2 for all reflections except those with very negative F^2. Weighted R factors wR and all goodness-of-fit S values are based on F^2. Conventional R factors are based on F with F set to zero for negative F^2. The $F_0^2 > 2s(F_0^2)$ criterion was used only for calculating R factors and is not relevant to the choice of reflections for the refinement. The R factors based on F^2 are about twice as large as those based on F. Most of

the hydrogen atoms were located from a difference map and refined isotropically. All remaining hydrogen atoms were located at the idealized averaged geometrical positions and allowed to ride on the heavy atoms. Scattering factors were taken from Tables 6.1.1.4 and 4.2.4.2 in Ref. [10]. Details concerning crystal data and refinement are given in Table 1.

3. Results and discussion

3.1. Structural description

The molecular structure of the complex $\{CuL_\alpha[Ni(NCS)_4(H_2O)_2]\}$ (**1**) is isostructural with the complex $\{CuL_\alpha[Mn(NCS)_4(H_2O)_2]\}$ (**2**). They both crystallize in the triclinic $P\bar{1}$ space group with only half of the molecule in the independent part of the unit cell {1/2 CuL_α^{2+} and 1/2 $[Ni(NCS)_4(H_2O)_2]^{2-}$ for complex **1** and 1/2 $[Mn(NCS)_4(H_2O)_2]^{2-}$ anion for complex **2**}. The anions and the CuL_α^{2+} cations are located at the inversion centers, therefore only halves of the moieties are independent (Fig. 1).

The Mn(II) and Ni(II) ions are connected with the Cu(II) ions via thiocyanate bridges, thus complexes **1** and **2** create infinite polymeric zig-zag chains in the crystal lattice (Fig. 2). These chains are assembled from the repeating units of the CuL cations and $[Ni(NCS)_4(H_2O)_2]$ (**1**) or $[Mn(NCS)_4(H_2O)_2]$ (**2**) complex anions. The molecular packing of the polymeric chains is shown in Fig. 3. The 3D structure consists of regular columns of stacked molecules.

Each Cu(II) cation is octahedrally coordinated by four nitrogen atoms of the macrocyclic ring and two sulfur atoms from the bridging ligand. The Cu–S distances are equal, 2.922 and 2.949 Å in complexes **1** and **2**, respectively. The Cu–N distances are similar for both complexes and vary from 1.982 to 2.001 Å. The coordination geometry of the Ni(II) and Mn(II) ions is close to a slightly distorted octahedron. The nickel and manganese ions are bound to two bridging and two non-bridging thiocyanate ions through four nitrogen atoms. The last two coordination sites are occupied by water molecules. In **1**, the Ni–N distances are equal to 2.070 and 2.064 Å, whereas the Ni–O distances are 2.116 Å. In the case of complex **2**, the corresponding distances are longer and are equal to 2.204 and 2.215 Å, and 2.240 Å for Mn–N and Mn–O, respectively. The thiocyanate groups are almost linear. All remaining distances and angles are provided in Table 2. Two non-bridging thiocyanate ligands create hydrogen bonds with the oxygen atoms from water molecules belonging to neighboring polymeric chains. Hydrogen bonds are

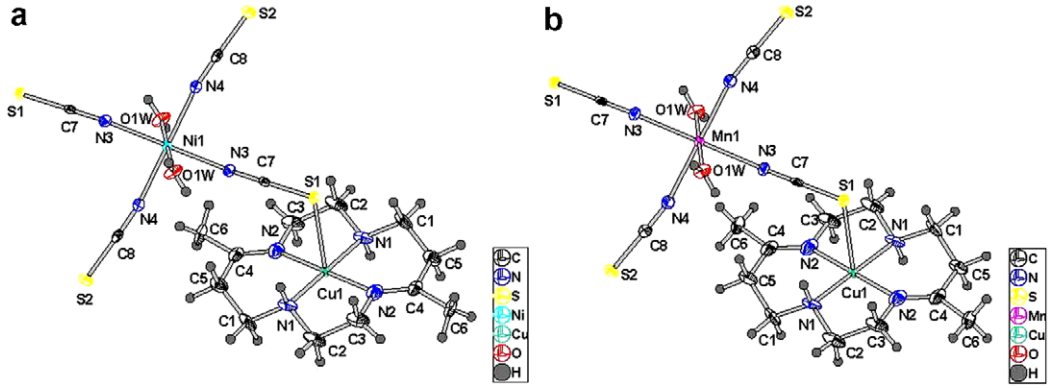

Fig. 1. Thermal ellipsoid representation of (a) complex **1** and (b) complex **2** with atom labels. Both macrocyclic ligand and anion are located at the inversion centers.

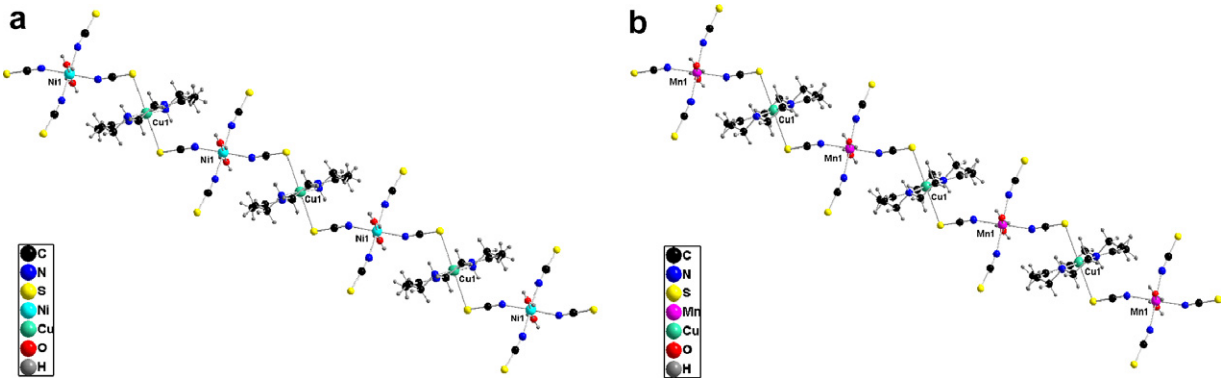

Fig. 2. Polymeric chains created by moieties of (a) complex **1** and (b) complex **2**.

also formed between the nitrogen atoms of the macrocyclic ring and the sulfur atoms (Table 3). The shortest intramolecular distances between the metallic centres in the same chain are *ca.* 6.342 Å (Cu1···Ni1) and 6.421 Å (Cu1···Mn1). The distances between the metallic ions in neighboring chains are equal to 7.283 Å (X, $1+Y$, Z) (Cu1···Ni1) and 7.473 Å ($1+X$, Y, Z) (Cu1···Cu1). The corresponding values in complex **2** are: 7.316 Å (X, $1+Y$, Z) (Cu1···Mn1) and 7.476 Å ($1+X$, Y, Z) (Cu1···Cu1). In the crystal lattice both complexes creates 1D polymeric chains.

3.2. Magnetic properties

The magnetic behavior of **1** is shown in Fig. 4 in the form of a $\chi_M T$ versus T plot, where χ_M stands for the magnetic susceptibility per Cu(II)Ni(II) unit. The value of $\chi_M T$ at room temperature is 1.53 $cm^3\ mol^{-1}$ K for compound **1**, which is as expected for a magnetically non-interacting Cu(II)Ni(II) entity with the local spins $S_{Cu} = 1/2$ and $S_{Ni} = 1$.

$\chi_M T$ smoothly decreases over a wide range of decreasing temperatures, and rapidly decreases at the lowest temperatures. The slight decrease of $\chi_M T$ can either be due to the zero-field splitting effect of the Ni^{II} ions and/or to intra- or intermolecular exchange interactions characterised by J_{Ni-Ni} and J_{Cu-Ni}. As mentioned in the structural discussion, this complex can be viewed as a heterobimetallic pseudo one-dimensional chain. It is interesting why in the present case a minimum for $\chi_M T$ is not observed. Since the J_{Cu-Ni} interaction is relatively large, the ratio $|D|/|J|$, where D is due to both local anisotropy and anisotropic exchange, is likely to be much too small to account for the absence of the minimum. On the other hand, no other relatively efficient interchain exchange pathways seem to be possible. The distances between the metallic ions in the neighboring chains are equal to 7.283 Å (Cu(II)–Ni(II)) and 7.473 Å (Cu(II)–Cu(II)), a little longer than the intermolecular distances between the metallic centers in the same chain 6.342 Å (Cu(II)–Ni(II)). This might provide an interchain exchange pathway. The same kind of magnetic interaction was observed in other Cu(II)–Ni(II) complexes, $CuNi(C_2O_4)_2 \cdot 4H_2O$ [11] and $CuZn(C_2O_4)_2 \cdot 4H_2O$ [12]. In such cases, the magnetic exchange parameter may be expressed as a sum of contributions, including pairs of magnetic orbitals, according to the formulae:

$$J_{CuCu} = J_{b_1b_1}$$
$$J_{NiNi} = 1/4(J_{b_1b_1} + J_{a_1a_1} + 2J_{a_1b_1})$$
$$J_{CuNi} = 1/2(J_{b_1b_1} + J_{a_1b_1})$$

where a_1 and b_1 are magnetic orbitals.

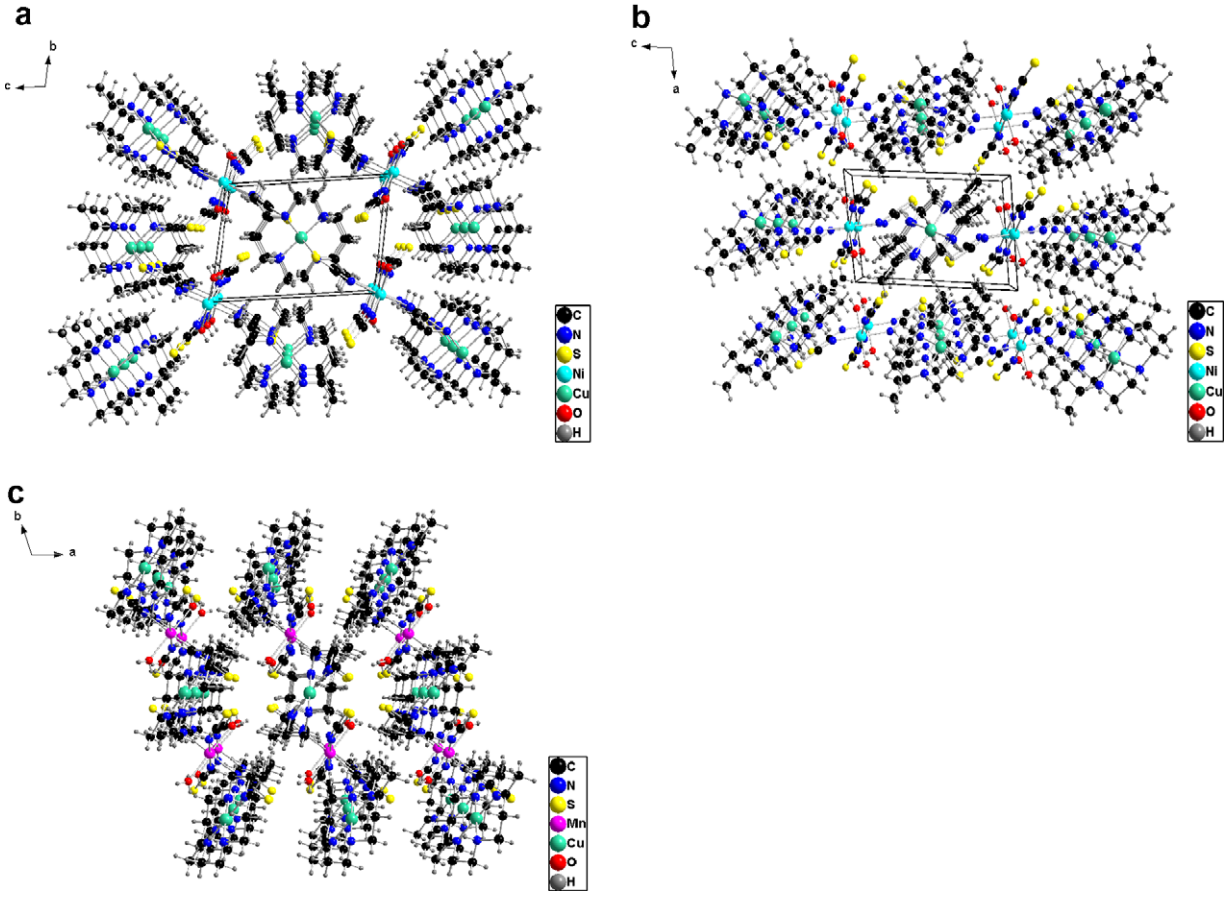

Fig. 3. Perspective views along: (a) *x*-axis (complex **1**), (b) *y*-axis (complex 1) and (c) *z*-axis (complex **2**). Because of the isostructural nature of the crystals, the other crystal views for complex **2** look exactly the same as for complex **1**.

Symmetry transformations used to generate equivalent atoms: #1 = X, $1+Y$, Z; #2 = $1+X$, Y, Z; #3 = X, $1+Y$, $1+Z$.

On the other hand, the chains are linked together through hydrogen bonding formed between the nitrogen atoms of the macrocyclic ring and the sulfur atoms or between the non-bridging thiocyanate ligands and the oxygen atoms of water molecules. These facts create further possibilities of a magnetic exchange pathway.

On the basis of the above hypothesis, the magnetic susceptibility of the chain χ_{chain} was calculated by Eq. (1), where the first term describes an infinite Ni(II) chain (Eq. (1)), according to the polynomial expression of Hiller [13], and the second term is a temperature independent contribution from Cu(II).

$$\chi_{chain} = \frac{Ng_{Mn}^2\beta^2}{kT}[A + Bx^2][1 + Cx + Dx^3]^{-1} + \frac{Ng_{Cu}^2\beta^2}{3kT}S_{Cu}(S_{Cu}+1) + TIP \quad (1)$$

where $x = |J|/kT$, $A = 0.6667$, $B = 2.5823$, $C = 3.6035$ and $D = 39.558$. J is the exchange coupling constant and TIP is the temperature-independent paramagnetism (60×10^{-6} $cm^3\,mol^{-1}$). Taking into account the 2D interactions, we modified the molar magnetic susceptibility χ_m employing Eq. (2) [14], where J' is the interchain coupling constant and $z = 2$, the number of nearest Ni(II) neighbours. Other symbols have their usual meaning.

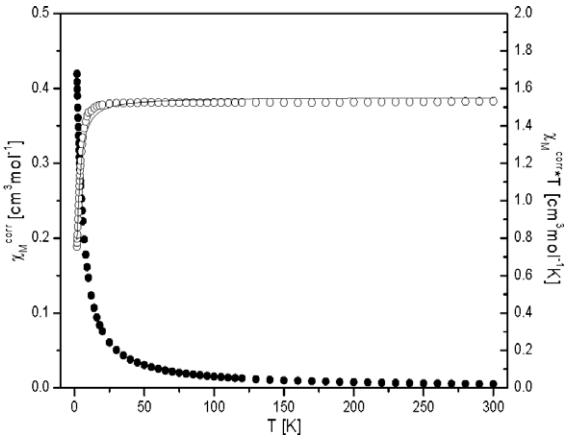

Fig. 4. Thermal dependence of χ_M (●) and $\chi_M T$ (○) for {CuL$_\alpha$[Ni(NCS)$_4$(H$_2$O)$_2$]} (**1**). The solid line is the calculated curve.

$$\chi_M^{corr} = \chi_{chain}/[1 - \chi_{chain}(2zJ'/Ng^2\beta^2)] \quad (2)$$

The least-squares fit of Eq. (2) to the data gives $J = -1.35 \times 10^{-5}$ cm^{-1}, zJ′ = −1.0 cm^{-1}, $g_{Cu} = g_{Ni} = 2.33$, and the agreement factor, defined as $R = [(\chi_M)^{obsd} - (\chi_M)^{cald}]^2/[(\chi_M)^{obsd}]^2$, equals 5.06×10^{-4}. This result suggests that there is no interaction (J) between the nearest Ni(II) ions in the chain and the antiferromagnetic interchain interaction (*J*′) possibility cannot be ruled out.

Since the decrease of $\chi_M T$ at low temperature can be attributed to the zero-field splitting (ZFS) of the Ni(II) ions, we used the following Eqs. (3)–(5) [15] for isolated Ni(II) and Cu(II) ions with ZFS:

$$\chi_M = \frac{\chi_\parallel + 2\chi_\perp}{3} + \frac{Ng^2\beta^2}{4kT} \quad (3)$$

$$\chi_\parallel = \frac{2Ng_\parallel^2\beta^2}{kT}\frac{\exp(-D/kT)}{1 + 2\exp(-D/kT)} \quad (4)$$

and

$$\chi_\perp = \frac{2Ng_\perp^2\beta^2}{D}\frac{1 - \exp(-D/kT)}{1 + 2\exp(-D/kT)} \quad (5)$$

where *D* (axial zero-field splitting parameter) is the energy difference between $M_s = \pm 1$ and $M_s = 0$ levels. The best fit leads to the values $|D| = 5.51$ cm^{-1} (the sign of *D* cannot be determined from powder magnetic susceptibility data) and $g_{avNi} = 2.19$, $g_{Cu} = 2.00$ ($R = 9.59 \times 10^{-5}$). The calculated value of the *D* parameter suggests that the zero-field splitting effect of the Ni(II) ions is dominant in the examined compound.

One can conclude that according to the above results the magnetic susceptibility of compound **1** can be calculated by Eq. (6), as a sum of independent contributions from the Ni(II) and Cu(II) paramagnetic ions with a molecular field correction (Eq. (2)).

$$\chi = \frac{Ng_{Ni}^2\beta^2}{3kT}S_{Ni}(S_{Ni} + 1) + \frac{Ng_{Cu}^2\beta^2}{3kT}S_{Cu}(S_{Cu} + 1) \quad (6)$$

The least-squares fitting allows exactly the same values of g_{Cu}, g_{Ni} and zJ' parameters to be obtained and confirms our conclusions.

The molar magnetization as a function of magnetic field up to 50 KOe at 2 K is shown in Fig. 5. It (M) is expressed in B.M. units and M_s is the expected saturation value. The magnetization increases gradually to a saturation value of $M_S = 2.23$ B.M., as expected for the zero-field splitting effect for the Ni(II) ions, and antiferromagnetic coupling of the pair of metal ions (Cu, Ni) cannot be ruled out.

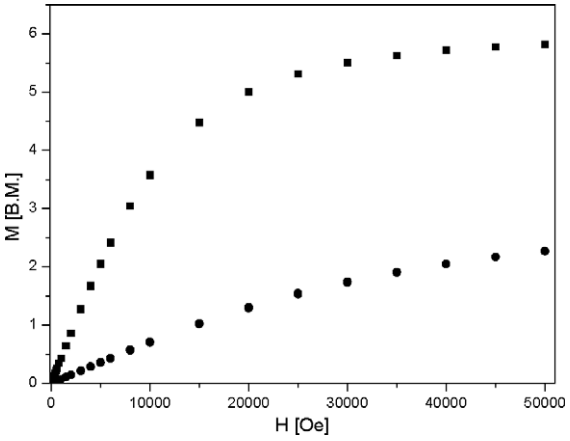

Fig. 5. Field dependence of the magnetization for complexes (●){CuL$_\alpha$[Ni(NCS)$_4$(H$_2$O)$_2$]} (**1**) and (■) {CuL$_\alpha$[Mn(NCS)$_4$(H$_2$O)$_2$]} (**2**).

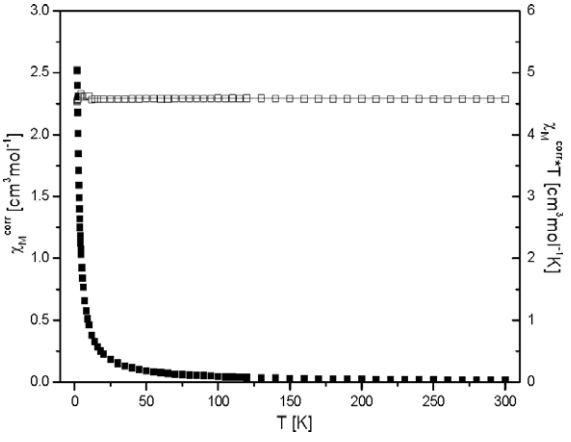
Complex **2** exhibits similar magnetic properties (Fig. 6). At room temperature, the $\chi_M T$ value is 4.57 cm^3Kmol^{-1}, close to that (4.57 cm^3Kmol^{-1}) expected for the $S = {}^5/_2$ and $S = ½$ spins. This value remains nearly constant over a wide range of temperature, and smoothly decreases below 3 K.

According to Kahn's theory, in an antiferromagnetic exchange ($J < 0$) within an alternating Mn(II)–Cu(II) chain, the net spins ($S = S_{Mn}–S_{Cu} = 2$) are parallel to each other in the ground state, and $\chi_M T$ should diverge below the critical temperature. In the examined compound there is no minimum on the $\chi_M T$ versus T curve, which is typical for ferrimagnetic behaviour.

In the absence of the minimum, the decrease of $\chi_M T$ observed at the lowest temperature for this compound is attributed to either very weak Mn(II)···Mn(II) antiferromagnetic interactions within the chain or, alternatively, cooperative interchain Mn(II)···Cu(II) interactions, which gives rise to the ferrimagnetic behaviour (or may lead to a cancellation of the spins (Scheme 2)).

As already mentioned, the $Mn(NCS)_4(H_2O)_2$ fragment approaches a distorted octahedral symmetry. The copper ions are located in an almost octahedral environment with the bridging SCN groups occupying the axial positions. For this kind of symmetry the unpaired electron on the copper ion is described by the xy-like orbital transformed as dz^2 and localized on the nitrogen ligand only.

Under these circumstances, the Mn···Mn superexchange within the chain propagated by the filled dz^2-like orbital of the NCS–Cu–SCN pathway may prevail over the Mn···Cu and Cu···Cu interactions. A similar situation is observed in the $[Cu(en)_2[Mn(NCS)_4(H_2O)_2]_n$ [16] and $Cu(en)_2MnCl_4$ [17] complexes. For the purpose of magnetic analysis, the magnetic susceptibility equation for χ_{chain} (Eq. (7)) was used with a correction for the molecular field (Eq. (2)). The first term describes an infinite Mn(II) chain [13] and the second term is a temperature independent contribution from Cu(II).



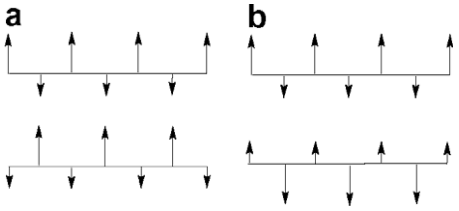


Fig. 6. Thermal dependence of χ_M (■) and $\chi_M T$ (□) for $\{CuL_\alpha[Mn(NCS)_4(H_2O)_2]\}$ (**2**). The solid line is the calculated curve.

Scheme 2. Schematic representation of two modes of interchain metal–metal magnetic interactions: (a) antiferromagnetic interchain interaction between the nearest manganese and copper ions, giving rise to a ferrimagnetic behaviour; (b) on the contrary, a cancellation of the spins.

$$\chi_{chain} = \frac{Ng_{Mn}^2\beta^2}{kT}[A + Bx^2][1 + Cx + Dx^3] + \frac{Ng_{Cu}^2\beta^2}{3kT}S_{Cu}(S_{Cu} + 1) + TIP \quad (7)$$

where $x = |J|/kT$, $A = 2.9167$, $B = 208.04$, $C = 15.543$ and $D = 2707.2$, J is the exchange coupling constant and TIP is the temperature-independent paramagnetism (60×10^{-6} cm^3mol^{-1}). The least-squares fit of the formula from Eq. (7) to the experimental data gives $J = -0.002$ cm^{-1}, $zJ' = -0.01$ cm^{-1}, $g_{Cu} = g_{Mn} = 1.98$, and the agreement factor, defined as $R = [(\chi_M T)^{obsd} - (\chi_M T)^{cald}]^2/[(\chi_M T)^{obsd}]^2$ equals 2.21×10^{-5}. These results suggest that inside the chain non-interacting magnetic centers exist, so this system may be treated as isolated.

As a second step, we tried to analyse the magnetic behavior, including the zero-field splitting effect, within the $S = 5/2$ local ground states of the Mn(II) ions. For this purpose we used the modified Eqs. (8) and (9) presented in the literature [18]:

$$\chi_{ZFS} = \frac{Ng_{Mn}^2\beta^2}{4kT}\left[\frac{1 + 9\exp(2D/kT) + 25\exp(6D/kT)}{1 + \exp(2D/kT) + \exp(6D/kT))}\right] \quad (8)$$

$$\chi_m = \chi_{ZFS} + \frac{Ng_{Cu}^2\beta^2}{3kT}S_{Cu}(S_{Cu} + 1) + TIP \quad (9)$$

where D is the axial zero-field splitting parameter for Mn(II). Least-squares fitting gives $D = 6 \times 10^{-4}$ cm^{-1}, $g_{Cu} = 2.25$, $g_{Mn} = 1.94$, and the agreement factor R is equal to 4.96×10^{-5}. In this case, the magnetic susceptibility may by expressed as a combination of the Mn···Mn interaction and the zero-field splitting. The expression of Hiller [13] then was modified by replacing the $NS(S + 1)g_{Mn}{}^2\beta^2/3kT$ term with χ_{ZFS}, which is shown by Eq. (9) [19]. The final expression is then as follows:

$$\chi_{chain} = \frac{12}{35}\chi_{ZFS}[A + Bx^2][1 + Cx + Dx^3] + \frac{Ng_{Cu}^2\beta^2}{3kT}S_{Cu}(S_{Cu} + 1) + TIP$$
$$\chi_M^{corrr} = \chi_{chain}/[1 - \chi_{chain}(2zJ'/Ng^2\beta^2)] \quad (10)$$

This leads to the parameters $J = -0.002$ cm^{-1}, $zJ' = -0.01$ cm^{-1}, $D = 2 \times 10^{-4}$ cm^{-1}, $g_{Cu} = g_{Mn} = 1.98$. The agreement factor R is equal to 6.72×10^{-5}. As a con-

sequence, one obtains a near zero value of the D parameter which allows us to conclude that in the examined compound a very weak antiferromagnetic interaction between the Mn(II) ions in the neighboring chain is dominant. Finally, the magnetic susceptibility data of compound **2** can be calculated by Eq. (11), as a sum of independent contributions from Mn(II) and Cu(II) paramagnetic ions with molecular field correction.

$$\chi = \frac{Ng_{\mathrm{Mn}}^2\beta^2}{3kT} S_{\mathrm{Mn}}(S_{\mathrm{Mn}}+1) + \frac{Ng_{\mathrm{Cu}}^2\beta^2}{3kT} S_{\mathrm{Cu}}(S_{\mathrm{Cu}}+1) \qquad (11)$$

Least-squares fitting gives exact values of the g_{Cu}, g_{Mn} and zJ' parameters and confirms our expectations. This fully confirms the magnetization versus field dependence at 2 K illustrated in Fig. 5. In such a case, the ground state is $S_{\max} = 1/2 + {}^5/_2 = {}^6/_2$ and the magnetization (per Cu–Mn unit) should saturate to the value of $M = 6\mu_{\mathrm{B}}$. Experimental data show that at a magnetic field $B = 5$ T and temperature as low as $T = 2.0$ K, the magnetization M is equal 5.82 μ_{B}, very close to the theoretical value. This fact evidences a very small role of the zero-field splitting effect.

It is interesting to compare the magnetic behavior of complex **2** with the results obtained for the $[CuL]_2[Mn(NCS)_4](ClO_4)_2$ trimer (L = *N*-dl-5,5,7,1212,14-hexamethyl-1,4,8,11-tetraazacyclotetradeca-4,11-diene) [20]. The differences in the crystalline structures of the two complexes have a significant influence on the values of the magnetic properties. A partial conversion of the macrocyclic ring conformation in the trimer is caused by increasing the number of methyl groups in the macrocyclic rings. As a consequence of the methyl group in a Cu–Mn–Cu trimer block, one of the axial sites at the CuL^{2+} ion is occupied and only one vacant site at the central cooper(II) ion is available. The macrocyclic ion, with a Cu^{II} magnetic center, is only linked by a thiocyanate bridge to one Mn unit to form a ferromagnetically interacting trimer structure, very much different from the chain structure in compound **2**. Also the change of bond lengths and valence angles, (e.g., the Cu–S distances in **1** are 2.9486(8) and 2.841(1) Å in the trimer, and the Mn–N lengths are 2.204(3) and 2.075(2) Å in the trimer) seem to play a role. These results suggest that when the Cu–S distances increase, the magnitude of the exchange coupling constant decreases, as expected for a weak overlap of the magnetic orbitals.

It is also worthwhile to compare the magnitude of the intrachain exchange parameter in the reported binuclear Cu(II)–M(II) species, containing the same bridging and terminal ligands but different M(II) ions. The literature data for similar $Cu^{II}Ni^{II}$[11] and $Cu^{II}Mn^{II}$ [16,17] complexes suggest that, according to Kahn's theory [2], the J_{CuM} parameter can be related to the contributions from pairs of magnetic orbitals by $J_{\mathrm{CuM}} = \left(\sum_{\mu} J_{\mu b_1}\right) n_{\mathrm{M}}$, where n_{M} is the number of magnetic orbitals around M, b_1 stands for the symmetry of the unique magnetic orbitals ($d_{x^2-y^2}$) around Cu, and μ for the symmetry of the magnetic orbital around M. The magnetic orbital for the bimetallic systems will be as follows:

$$J_{\mathrm{CuNi}} = \frac{1}{2}(J_{b_1b_1} + J_{a_1b_1})$$

$$J_{\mathrm{CuMn}} = \frac{1}{5}(J_{b_1b_1} + J_{a_1b_1} + J'_{a_1b_1} + J_{a_2b_1} + J_{b_2b_1})$$

where $J_{b_1b_1}$ are the magnetic orbitals located in the plane of the bridging network with the predominant antiferromagnetic contribution, dependent on M. Mn(II) and Ni (II) ions are 3d transition metals. The 3d orbital energy for Mn is higher than for Ni. This is because of the increase of the nuclear charge. A lower 3d energy means a smaller energy gap between the singly occupied 3d orbital of M and the symmetry adapted orbital of the bridging ligand. On the other hand, the M–N distance also decreases. Both effects result in an increasing overlap between the b_1 – type magnetic orbitals of Cu and M because of an increase of delocalization of the magnetic orbital from M towards the bridge. As a consequence, the antiferromagnetic contribution $J_{b_1b_1}$ also increases. In complexes **1** and **2**, a stronger antiferromagnetic exchange reaction is observed for the $Cu^{II}Ni^{II}$ compound than for that of $Cu^{II}Mn^{II}$.

3.3. EPR spectra

The EPR spectrum of a polycrystalline sample of complex **1** at 293 shows an isotropic signal at $g = 2.041$ with a peak-to-peak linewidth of 75 G (Fig. 7). Only one other signal at $g = 2.042$ ($\delta_{\mathrm{Hpp}} = 80$ G) is observed at 77 K. The EPR spectrum at 4.2 K is composed of two lines at $g = 2.091$ and 2.218. The structure is associated only with the electronic configuration ($S = 1/2$) of the cooper centers in an octahedral ligand field.

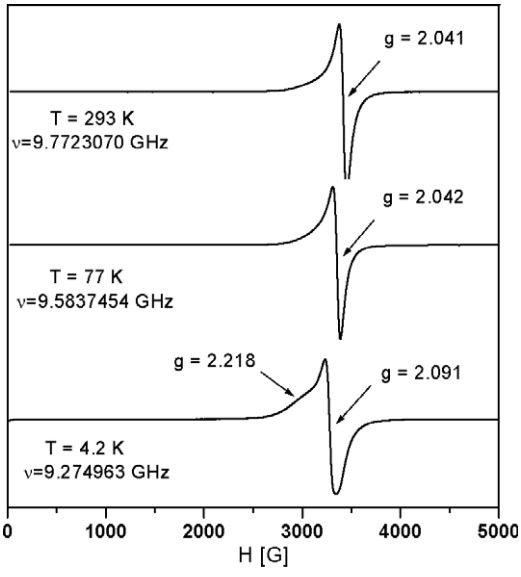

Fig. 7. EPR spectra for $\{CuL_\alpha[Ni(NCS)_4(H_2O)_2]\}$ at room temperature, 77 K and 4.2 K.

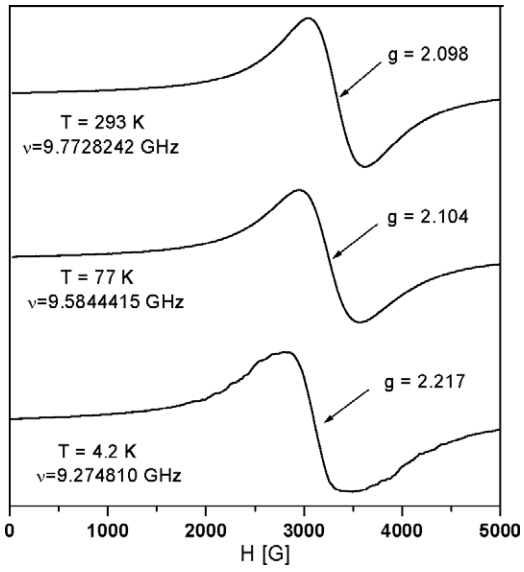

Fig. 8. EPR spectra for $\{CuL_\alpha[Mn(NCS)_4(H_2O)_2]\}$ at room temperature, 77 K and 4.2 K.

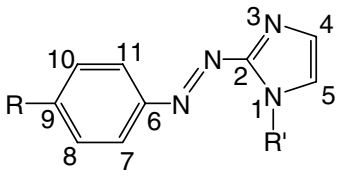
The EPR spectrum of a polycrystalline powdered sample of **2** at 293 K shows an isotropic line at $g = 2.098$ with a peak-to-peak linewidth of 575 G (Fig. 8). At 77 K the spectrum displays the same isotropic line at $g = 2.104$, but with a larger peak-to-peak linewidth amounting to 610 G. These results suggest that in the temperature range from 77 to 293 K only one signal is observed as a result of superposition of copper(II) and manganese(II) signals. At 4.2 K the fine structure consists of the stronger asymmetric line at $g = 2.217$ ($\delta_{Hpp} = 730$ G).

4. Conclusion

We would like to finish the present work with a brief comment on its chemical relevance. Up until now only a few $Mn^{II}Cu^{II}$ [21,22] and $Ni^{II}Cu^{II}$ [11] ordered bimetallic chains have been described. In these complexes, the metals ions were connected by dithiooxalato or oxalate bridges. The magnetic behaviour of these compounds is different from that of **1** and **2** (for example, the presence of a minimum and maximum in the $\chi_M T$ versus T plot). The differences result from the fact that the dithiooxalato or oxalate ligands are more efficient than the thiocyanide bridge in transmitting the antiferromagnetic interactions between the two metal ions. Complexes **1** and **2** are apparently very poor one-dimensional systems and the minimum of the $\chi_M T$ versus T plot is quenched by the interchain interactions. The dominant interchain interactions in **1** and **2** correspond to the shortest metal···metal interchain distances, i.e., $Cu^{II}Cu^{II}$, $Mn^{II}Mn^{II}$ and $Ni^{II}Ni^{II}$. Although being further apart from each other, the chains can interact through a hydrogen bond network. Additionally, in complex **2** a larger D value than J indicates a dominant zero-field splitting with the $S = 1$ local ground states of the Ni(II) ions.

Supplementary material



CCDC 288834 and 288835 contain the supplementary crystallographic data for **1** and **2**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223 336 033; or e-mail: deposit@ccdc.cam. ac.uk.

synthesis of cyclopentadienyl ruthenium [11], indenyl-ruthenium [12] and arene-ruthenium [13] complexes with a variety of nitrogen-based ligands. However, the analogous pentamethylcyclopentadienyl rhodium(III) and iridium(III) azo complexes have not been explored as much as the corresponding isoelectronic cyclopentadienyl and arene-ruthenium(II) complexes. As a part of our continuing study, we would like to report herein the syntheses and characterization of new cationic pentamethylcyclopentadienyl rhodium(III) and iridium(III) complexes with N,N-donor arylazoimidazole ligands.

2. Results and discussion

1-Methyl-2-(arylazo)imidazole (aai-Me), 1-ethyl-2-(arylazo)imidazole (aai-Et) and 2-(arylazo)imidazole (aai-H) were synthesized by coupling the aryldiazonium ions with imidazole in aqueous sodium carbonate solution (pH 7) and purified by the reported method [26]. The alkylation was carried out by adding alkyl halide in dry THF solution to the corresponding 2-(arylazo)imidazole in the presence of sodium hydride [14].

Six arylazoimidazole (RaaiR′) (see Scheme 1) ligands have been used in this work. Ligands are unsymmetrical N,N′-bidentate chelates, where N and N′ abbreviated to N (imidazole) and N′ (azo) donor centers, respectively. The pentamethylcyclopentadienyl rhodium and iridium dimers $[\{(\eta^5\text{-}C_5Me_5)M(\mu\text{-}Cl)Cl\}_2]$ where M = Rh and Ir reacted with arylazoimidazoles (RaaiR′) in the presence of ammonium salts in methanol to form mononuclear cationic complexes having the general formula $[(\eta^5\text{-}C_5Me_5)MCl(RaaiR')]^+$ (C_5Me_5 = pentamethylcyclopentadienyl; M = Rh or Ir) (Scheme 2). The cationic complexes **1**–**6** are orange, while the complexes **7**–**12** are brown in colour. These complexes are non-hygroscopic, air-stable, shiny crystalline solids. They are sparingly soluble in methanol and benzene, soluble in dichloromethane, chloroform, acetone, acetonitrile, and insoluble in hexane, petroleum ether and diethyl ether.

The analytical data of these complexes are consistent with the formulations (Table 1). The formation of cationic complexes **1**–**6** and **7**–**12** are confirmed by the appearance of the strong band at around 840 cm^{-1} due to the $\nu_{(P-F)}$ of the PF_6^- anion. The bands appearing at around 1600 and 1400 cm^{-1} are assigned for $\nu_{(C=N)}$ and $\nu_{(N=N)}$, respectively, of the ligand [15].

The ^1H NMR spectrum of complexes shows a singlet for the pentamethylcyclopentadienyl protons in the range 1.38–1.71 ppm, indicating downfield shift from the starting dimeric complexes. A downfield shift in the position of the pentamethylcyclopentadienyl protons might result from a change in electron density on the metal center due to chelation of the arylazoimidazole ligand through its nitrogen atoms. The N–H proton of complexes **1**, **4**, **7** and **10** is exhibited a singlet in the range 8.2–9.2 ppm. The N-methyl protons (N-Me) of complexes **2**, **5**, **8** and **11** appear as a singlet at 3.82–4.19 ppm. The N-methylene proton (N-CH_2) of complexes **3**, **6**, **9** and **12** appears as a quartet in the range 4.14–4.55 ppm. All these complexes show doublet and multiplet in the range of 5.75–7.96 ppm due to the phenyl protons of the azoimine ligand.

The ^{31}C $\{^1H\}$ NMR spectrum of complexes **1**–**6** and **7**–**12** contain resonances for the pentamethylcyclopentadienyl ring carbons at around 90 ppm. The resonance observed at 155 ppm may be due to the azoimine (C=N) carbon of the ligand. The spectra also show resonances in the range of 122.1–162.2 ppm for the aromatic carbons and carbons of imidazole C–H group.

2.1. Electronic spectra

The low spin d^6 configuration of the mononuclear complexes provides filled orbitals of proper symmetry, which can interact with low lying π^* orbitals of the arylazoimidazole ligands (RaaiR′). A band attributable to the MLCT ($t_{2g} \rightarrow \pi^*$) transition is therefore expected in the electronic spectra [16], where the transition energy of these bands varies with the nature of the ligands acting as π-acceptors. The presence of electron donating groups (H, CH_3, C_2H_5) on the imidazole nitrogen of the azoimine ligand should decrease the energy of transition, causing a red shift in

11	$[(\eta^5\text{-}C_5Me_5)IrCl(Tai\text{-}Me)]PF_6$	407	333	311	
12	$[(\eta^5\text{-}C_5Me_5)IrCl(Tai\text{-}Et)]PF_6$	407	333	311	

MLCT maxima [17], while an electron withdrawing group should increase the transition energy. The electronic spectra of pentamethylcyclopentadienyl rhodium azoimine complexes (**1**–**6**) with the formulations $[\eta^5\text{-}C_5Me_5RhCl(RaaiR')]^+$ displayed very weak bands at 408–423 nm, a medium absorption band at ~390 nm and a very strong absorption band at ~330 nm (Table 2). The band at 390 nm has been assigned to a MLCT transitions [t_{2g} {Rh(III) → π*(azoimine)}]. The λ_{max} value of this band is consistent with those of the azoimine ligand bound to the complexes of rhodium [18].

The free ligand itself shows intraligand charge-transfer transitions (n–π*, π–π*) of high intensity ($\varepsilon \sim 10^4$–$10^5\ M^{-1}\ cm^{-1}$) at <400 nm. The transitions at ~350 nm and below are thus not considered further. Other two transitions at longer wavelength region (410–460 nm and 370–390 nm) differ in their intensities. The first transition (410–460 nm) is of moderate intensity and has been assigned to the MLCT band dπ(Rh) → π*(azoimine) in the complexes [19] or else from the hybrid orbitals composed of dπ(Rh) and π(Cp*) to the π*(azoimine) orbitals of the ligand. The weak transition at ~650 nm may originate from a singlet–triplet transition, particularly that allowed by the strong spin–orbit coupling in rhodium [20].

Electronic spectra of iridium complexes (**7**–**12**) display bands in the region ~450 nm, ~380 nm and ~320 nm. The broad medium intensity bands centering around 450 nm are assigned to MLCT bands arising from drift of electron density from the filled Ir(III) → dπ(t_{2g}) orbitals to the low lying π* orbitals of the RaaiR′ ligand. The position of this band is consistent with those in other metal-azo complexes [21]. The band around 320 nm is assigned to an MLCT transition [Ir(III) → dπ* on the Cp* ring].

2.2. Molecular structure of complex $[(\eta^5\text{-}C_5Me_5)RhCl(Me\text{–}C_6H_4\text{–}N{=}N\text{–}C_3H_3N_2)]^+$ (**4**)

The complex **4**[PF_6] crystallizes in the monoclinic $P2_1/n$ space group. The ORTEP drawing of the molecule along with the atom-numbering scheme is shown in Fig. 1. The asymmetric unit consists of a rhodium atom displaying

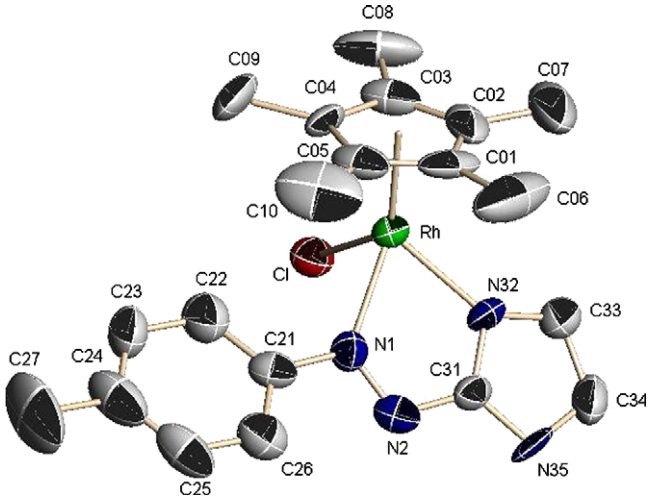

Fig. 1. ORTEP diagram of complex **4** at 50% probability level with hydrogen atoms and hexafluorophosphate anion omitted for clarity. Selected bond lengths (Å) and bond angles (°): Rh–N(1) 2.132(7), Rh–N(32) 2.105(8), Rh–Cl 2.423(3), N(1)–N(2) 1.275(10), Rh–C* 1.795 (* centroid is at $x = 0.7413$, $y = 0.1825$, $z = 0.9899$ at 1.795 Å to Rh); N(1)–Rh–N(32) 74.9(3), N(1)–Rh–Cl 92.5(2), N(32)–Rh–Cl 86.9(2).

the three-legged 'piano-stool' geometry. The metal is coordinated to one $\eta^5\text{-}C_5Me_5$ group, one chloride and two nitrogen atoms of Tai-H which binds to the metal in a bidentate chelating mode, as postulated from experimental data.

The pentamethylcyclopentadienyl ligand is symmetrically bound to the metal ion. All the Cp* atoms lie in a plane, and indicated by the similar bond distances between carbons. The Rh–Cl bond length is 2.432(3) Å which is slightly longer than the other two-coordinated chelating Schiff base rhodium complex $[(\eta^5\text{-}C_5Me_5)RhCl(C_5H_4N\text{-}2\text{-}CH{=}N\text{–}C_6H_4\text{-}p\text{-}Cl)]^+$ [2.3756(7) Å] [22].

The Rh–N distances are unequal with Rh–N(1), 2.132(7) Å and Rh–N(32), 2.105(8) Å. This has been observed in other complexes involving bidentate rhodium terpyridine $[(\eta^5\text{-}C_5Me_5)RhCl(Ph\text{-}terpy)]BF_4$ [23]. Rhodium to pentamethylcyclopentadienyl ring centroid distance is 1.759 Å and is consistent with those reported for the other rhodium(III) Cp* complexes [22]. The bond angles N(1)–Rh–Cl and N(32)–Rh–Cl are 92.5(2) and 86.9(2), respectively, indicating a piano stool type of structure at rhodium center. The N=N bond distance, N(1)–N(2) is 1.275(10) Å which is longer than free ligand value [1.250(1) Å] [24]. This refers to significant charge delocalization from metal d-orbital, dπ(Rh) → π*(azo) in the coordinated Tai-H.

3. Experimental

3.1. General remarks

$[\{(\eta^5\text{-}C_5Me_5)M(\mu\text{-}Cl)Cl\}_2]$ (M = Rh, Ir) [25] and arylazoimidazole (RaaiR′) ligands [26] were prepared according to published methods. All other reagents were

commercially available and were used as received. UV/visible absorption spectra were recorded on a Hitachi – 300 spectrophotometer using precision cells made of quartz (1 cm). The ^{1}H and ^{13}C $\{^{1}H\}$NMR spectra were recorded in $CDCl_3$ solvent with TMS as internal standard and recorded on JEOL 500 (500 MHz) or Bruker ACF-300 (300 MHz) spectrometers, the coupling constants J are given in Hz. Infrared spectra were recorded as KBr pellets on a Perkin–Elmer-model-983 spectrophotometer. Microanalyses were performed on a Perkin–Elmer-2400 CHN/O analyzer, SAIF-NEHU, Shillong, India.

3.2. Synthesis of $[(\eta^5\text{-}C_5Me_5)RhCl(L)]PF_6$ {L = Phai-H (1), Phai-Me (2), Phai-Et (3), Tai-H (4), Tai-Me (5), Tai-Et (6)}

A mixture of $[(\eta^5\text{-}C_5Me_5)RhCl_2]_2$ (100 mg, 0.16 mmol), arylazoimidazole (RaaiR′) (0.36 mmol) and potassium hexafluorophosphate (0.41 mmol) was stirred in dry methanol (20 mL) at 0 °C for 3 h. The solution becomes clear before the product precipitates. After 3 h the orange solid precipitated and the product was filtered, washed with diethylether (3 × 10 ml) and then dried *in vacuo* to afford 70–80% yield of the complexes.

3.3. Synthesis of $[(\eta^5\text{-}C_5Me_5)IrCl(L)]PF_6$ {L = Phai-H (7), Phai-Me (8), Phai-Et (9), Tai-H (10), Tai-Me (11), Tai-Et (12)}

These compounds was prepared by the same procedure as described above for [**1**–**6**][PF_6] using $[(\eta^5\text{-}C_5Me_5)Ir(\mu\text{-}Cl)(Cl)]_2$ (100 mg, 0.125 mmol), arylazoimidazole (RaaiR′) (0.26 mmol) and potassium hexafluorophosphate (0.41 mmol). Brown solid, Yield 65–75%.

4. Structure analysis and refinement

X-ray quality crystals of the complex **4**[PF_6] were grown by slow diffusion of hexane into dichloromethane solution. An orange crystal of complex **4**[PF_6] was mounted on a Bruker Apex CCD diffractometer in a full reciprocal sphere equipped with CCD detector and used for data collection. X-ray intensity data were collected with graphite monochromated Mo Kα radiation (0.71073 Å) at 293(2) K, with 0.3° scans in ω scan in mode and 10 s per frame. The intensity data were corrected for Lorentz and polarization effects. An empirical absorption correction was made by modeling a transmission surface by spherical harmonics employing equivalent reflections with $I > 2\sigma(I)$ (program SADABS) [27]. The structure was solved by direct methods [28]. All the non-hydrogen atoms were refined anisotropically using the full-matrix, least-squares technique on F^2 using the SHELXL-97 software [29]. All the hydrogen atoms were found from difference Fourier synthesis after four cycles of anisotropic refinement using a ''riding'' model. A summary of crystal data, data collection parameters and convergence results is compiled in Table 3.

Table 3
Crystal data and structure refinement for complex **4**[PF_6]

Empirical formula	$C_{20}H_{25}ClF_6N_4PRh$
Formula weight	604.77
Temperature (K)	293(2)
Wavelength (Å)	0.71073
Crystal system	Monoclinic
Space group	$P21/n$
Unit cell dimensions	
a (Å)	8.386(9)
b (Å)	27.72(3)
c (Å)	10.717(12)
β (°)	91.11(2)
Volume (Å^3)	2491(5)
Z	4
D_{calc} (Mg/m^3)	1.613
Absorption coefficient (mm^{-1})	0.917
$F(000)$	1216
Crystal size (mm)	0.15 × 0.10 × 0.07
θ Range for data collection (°)	1.47–28.26
Index ranges	$-9 \leqslant h \leqslant 9$, $-35 \leqslant k \leqslant 17$ $-13 \leqslant l \leqslant 4$
Reflections collected	7814
Independent reflections [R_{int}]	4514 [0.0796]
Completeness to theta (°, %)	28.26, 73.2
Absorption correction	Empirical
Refinement method	Full-matrix least-squares on F^2
Data/restraints/parameters	4514/0/284
Goodness-of-fit on F^2	0.999
Final R indices [$I > 2\sigma(I)$]	$R_1 = 0.0791$, $wR_2 = 0.1360$
R indices (all data)	$R_1 = 0.1839$, $wR_2 = 0.1696$
Largest difference peak and hole (e Å^{-3})	0.657 and −0.513

Appendix A. Supplementary material

CCDC 272064 contains the supplementary crystallographic data for **4**[PF_6]. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK, fax: (+44) 1223-336-033, or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2007.07.007.

observed only in films consisting of a mixture of monoclinic grains and the amorphous phase, but not in films having a triclinic phase structure. In this connection, there have been some works that were devoted to structural studies of evaporated PbPc films [21,22].

Substituted lead phthalocyanines are not so thoroughly investigated as compared to the unsubstituted Pb(II)Pc. Non-peripheral 1,4,8,11,15,18,22,25-octakis(hexylsulfanyl)phthalocyanine has been synthesized and characterized by X-ray crystallography in the work of Cook and co-workers [10]. Furthermore, non-peripheral tetraalkoxy [16], tetra- and octa-diethoxymalonyle substituted [17], (cumylphenoxy) [12] tetranitro- and tetraamino substituted [18] lead phthalocyanines were synthesized and characterized. The first mesomorphic lead phthalocyanines were reported in 1987 [11,19]. Simon and co-workers [11] have shown that alkoxymethyl substituted phthalocyaninato lead(II) complexes [$PbPcR_8$, with $R = -CH_2OC_nH_{2n+1}$ ($n = 8$, 12, 18)] form a hexagonal columnar mesophase, which is stable at room temperature when $n = 8$ and 12; since then Ford et al. indicated that octa-(2-ethylhexyloxy) lead phthalocyanines exist in mesophases from −100 to +200 °C [13–15]. These derivatives have been alkoxy [13–15] and alkoxy methyl [11] octasubstituted mesogens with side chains substituted at the 2,3-positions on the benzene ring, but mesomorphic alkylthio-substituted lead pc compounds have not been synthesized yet.

In this work, the synthesis of new octakis (alkylthio)-substituted lead phthalocyanines (**1a** and **2a**) is described. The mesogenic properties of these new materials are studied by differential scanning calorimetry and optical microscopy. The preparation of thin films of these phthalocyanines and their investigation by the method of UV–Vis absorption spectroscopy are also reported. The current–voltage characteristics and electrical switching behaviour in the sandwich structures of Au/$PbPcR_8$ (**1a**)/Au are also discussed.

2. Experimental

2.1. Materials

1,2-Di(13,17-dioxanonacosane-15-sulfanylmethyl) phthalonitrile (**1**) [23] and 1,2-di(13,17-dioxanonacosane-15-sulfanyl) phthalonitrile (**2**) [24] were synthesized according to the reported procedures. All other reagents and solvents were reagent-grade quality, obtained from commercial suppliers and were dried as described by Perrin and Armarego [25] before use.

2.2. Measurements

Elemental analyses were obtained from a Thermo Finnigan Flash 1112. Infrared spectra in KBr pellets were recorded on a Bio-Rad FTS 175C FT-IR spectrophotometer. Optical spectra in the UV–Vis region were recorded with a UV–Vis-3101PC Shimadzu using 1 cm pathlength cuvettes at room temperature. Mass spectra were obtained from an Esquire 6000 Ion Trap LC/MS(n)-System (Bruker Daltonik GmbH). ^1H and ^{13}C NMR spectra were recorded in $CDCl_3$ solutions on a Varian 500 MHz spectrometer. A domestic microwave oven ARÇELİK, model MD 272 (max. 850 W, min. 60 W) with five select power levels was used to carry out the synthesis with the microwave. The phase transition behaviour of these compounds was observed by means of a polarizing microscope (Leitz Wetzler Orthoplan-pol.) equipped with a hot stage (Linkam TMS 93) and temperature-controller (Linkam LNP). Transition temperatures were determined with a scan rate of 5 °C min^{-1} using a Mettler Toledo Star^e Thermal Analysis System/DSC 822^e. A differential scanning calorimeter system was calibrated with indium from 3 to 4 mg samples under a nitrogen atmosphere.

2.3. Synthesis

2.3.1. 2,3;9,10;16,17;23,24-Octakis(13,17-dioxanonacosane-15-sulfanylmethyl) phthalocyaninato lead (II) (*1a*)

2.3.1.1. Method A. A round-bottomed flask fitted with a condenser was degassed and flame-dried under dry argon. The flask was charged under argon with 1,2-di(13,17-dioxanonacosane-15-sulfanylmethyl) phthalonitrile (**1**) (0.600 g, 0.576 mmol) and anhydrous Pb(II)O (0.064 g, 0.288 mmol). The mixture was heated at 210 °C with stirring under an argon atmosphere for 5 h without solvent. The reaction mixture was dissolved in chloroform then centrifuged and the precipitate, including inorganic impurities, was removed. Thus the inorganic impurities were eliminated. The solvent was evaporated and the crude product was passed through a Bio Beads column (Bio-Rad Laboratories) using CH_2Cl_2 as the eluent to eliminate organic impurities. This purification step was repeated two times. Purification was further achieved by preparative thin layer chromatography [silica gel; eluent CH_2Cl_2/*n*-hexane, 1:1 (v/v)]. Yield: 55 mg (9%).

*2.3.1.2. Method B (Microwave-assisted synthesis method for compound **1a**).* A mixture of dinitrile **1**, (0.300 g, 0.288 mmol), anhydrous Pb(II)O (0.032 g, 0.144 mmol), 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU, 0.2 ml) and 2 ml *n*-pentanol was irradiated in a microwave (350 W) for 8 min. Compound **1a** was purified by the same procedure as described for method A. Yield: 60 mg (19%). *Anal.* Calc. for $C_{256}H_{464}N_8PbO_{16}S_8$ requires: C, 70.29; H, 10.69; N, 2.56. Found: C, 70.50; H, 10.43; N, 2.25%. IR (KBr) [υ, cm^{-1}] 3040, 2926, 2855, 1621, 1464, 1421, 1373, 1340, 1329, 1261, 1105. MS (APPI-MS), *m*/*z* (%): 4371 $[M + H]^+$ (100). ^1H NMR (500 MHz, $CDCl_3$): δ 0.87 (t, 48H, CH_3), 1.02–1.45 (m, 288H, CH_2), 1.60 (m, 32H, CH_2), 3.22–3.67 (m, 64H, OCH_2), 3.78 (t, 8H, CH), 4.70 (s, 16H, CH_2S), 9.53 (s, 8H, CH_{ar}). ^{13}C NMR (500 MHz, $CDCl_3$): δ 14.35 (CH_3), 22.94 (CH_2), 26.46 (CH_2), 29.51–32.18 (CH_2), 33.39–33.69 (CH_2), 38.72 (CH_2S), 46.18 (CH), 71.58

(OCH_2), 71.80 (CH_2O), 125.41 ($C_{ar}H$), 137.18 (C_{ar}), 139.75 (C_{ar}), 154.20 (C_{ar} C=N).

*2.3.2. 2,3;9,10;16,17;23,24-Octakis (13,17-dioxanonacosane-15-sulfanyl) phthalocyaninato lead (II) (**2a**)*

2.3.2.1. Method A. Compound **2a** was prepared by the same procedure as described for **1a** by starting with 1,2-di(13,17-dioxanonacosane-15-sulfanyl) phthalonitrile (**2**) (0.400 g, 0.394 mmol), and anhydrous Pb(II)O (0.043 g, 0.197 mmol). The reaction mixture was dissolved in chloroform then centrifuged, and the precipitate including inorganic impurities was removed. The solvent was evaporated and the crude product was passed through a Bio Beads column using CH_2Cl_2 as the eluent to eliminate organic impurities. Furthermore, this product was purified with preparative thin layer chromatography [silica gel, eluent CH_2Cl_2/*n*-hexane, 2:3 (v/v)]. Yield: 40 mg (10%).

*2.3.2.2. Method B (Microwave-assisted synthesis method for compound **2a**).* A mixture of dinitrile **2**, (400 mg, 0.394 mmol), anhydrous Pb(II)O (0.043 g, 0.197 mmol), 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU, 0.3 ml) and 2.5 ml *n*-pentanol was irradiated in a microwave (350 W) for 8 min. Compound **2a** was purified by the same procedure as described for method A. Yield: 85 mg (20%). *Anal.* Calc. for $C_{248}H_{448}N_8PbO_{16}S_8$ requires: C, 69.89; H, 10.60; N, 2.63. MS (APPI-MS), *m*/*z* (%): 4259 $[M + H]^+$ (100). ^1H NMR (500 MHz, $CDCl_3$): δ 0.77 (t, 48H, CH_3), 1.05–1.34 (m, 288H, CH_2), 1.61 (m, 32H, OC–CH_2), 3.52 (t, 32H, OCH_2), 3.93 (d, 32H, CH_2O), 4.05 (m, 8H, CH), 9.42 (s, 8H, CH_{ar}). ^{13}C NMR (500 MHz, $CDCl_3$): δ 14.36 (CH_3), 22.91 (CH_2), 26.50 (CH_2), 29.58–30.05 (CH_2), 32.16 (CH_2), 48.12 (CH), 70.55 (OCH_2), 71.90 (O CH_2-CHS), 126.05 ($C_{ar}H$), 138.12 (C_{ar}), 140.60 (C_{ar}–S), 154.10 (C_{ar} C=N).

2.4. Film preparation and characterization

Small volumes of solutions of the derivatives **1a** and **2a** in chloroform (10 mg/ml) were dispensed via a glass pipette onto an ultrasonically cleaned substrate held onto a photoresist spinner (Microsystem model 4000). The speed of substrate rotation was 2000 rpm, and spinning was continued for 30 s during which time the solvent had evaporated to generate a film of the phthalocyanine derivative. Some films were annealed at 50 °C for 1 h in a nitrogen atmosphere for comparison with the as-deposited layers. The substrates used were varied according to the experimental requirements for different characterization.

Absorption spectra of the films on quartz substrates were recorded with a UV–Vis scanning spectrophotometer (UV–Vis-3101PC "Shimadzu") in the range 350–800 nm. Spectroscopic ellipsometric measurements on spun films on silicon substrates were performed by using a Woolam *TM V M* 2000 – rotating analyzer spectroscopic ellipsometer in the spectral range 370–1000 nm. The angle of incidence was fixed at 60°. Dedicated software was used for data acquisition and analysis of the measured ellipsometric parameters $\Psi(\lambda)$ and $\Delta(\lambda)$.

A silicon slide covered by an Au layer was used as a substrate for the measurements of conductivity. For electrical measurements on samples in the form of a sandwich structure, top electrodes of Au 100 nm in thickness were deposited by thermal evaporation in a vacuum of about 10^{-6} torr.

Current–voltage measurements were performed using a Keithley 236 electrometer in a microprocessor controlled measuring system. The bias voltage was taken to be positive when the bottom contact was at a higher voltage than the top electrode. All electrical measurements were performed in air at room temperature and at −10 °C. The *I*–*V* characteristics were recorded for two sweep directions (+V to −V and −V to +V) and also in voltage loops (0 to +V to −V to +V).

3. Results and discussion

3.1. Synthesis and general properties

Generally, substituted phthalocyanines are prepared by cyclotetramerization of substituted 1,2-dicyanobenzenes or 1,3-diimino-1H-isoindolines [26]. Fig. 1 shows the synthesis of the lead phthalocyanines (**1a** and **2a**). PbPc can be prepared by heating PbO or $Pb(OAc)_2$ with the respective phthalonitrile derivative without solvent [12–17] or in *n*-pentanol [16]. Addition of anhydrous lead(II) acetate to a solution of Li_2Pc or H_2Pc in anhydrous alcohol gives PbPc [16,27]. PbPc can also be obtained by a microwave method [18]. In this work, we performed melting and microwave methods to prepare the target PbPcs. Firstly cyclotetramerization of the dinitrile compounds was carried out in the presence of dried PbO without any solvent. In this method, we obtained the PbPcs in a low yield. Therefore, the synthesis of the desired PbPcs was carried out in *n*-pentanol and DBU by a microwave method. The yields using microwave irradiation were in all cases higher than that obtained with the classical method. Although the microwave technique has been used to synthesize other Pcs, this technique is fairly new for PbPcs. To the best of the authors' knowledge there has been only one publication about this so far [18]. To increase the yield of the pcs (**1a**, **2a**) we tried two experiments with different molar ratios, 4:1 and 2:1, and the 2:1 ratio of the dinitrile derivatives and PbO was found to be the most appropriate. Also, in the literature an excess of the lead salts was used for the synthesis of the lead pcs [11,13].

The crude product was firstly passed through a Bio Beads column for eliminating organic impurities and then the lead phthalocyanines (**1a** and **2a**) were purified by using preparative thin layer chromatography as quickly as

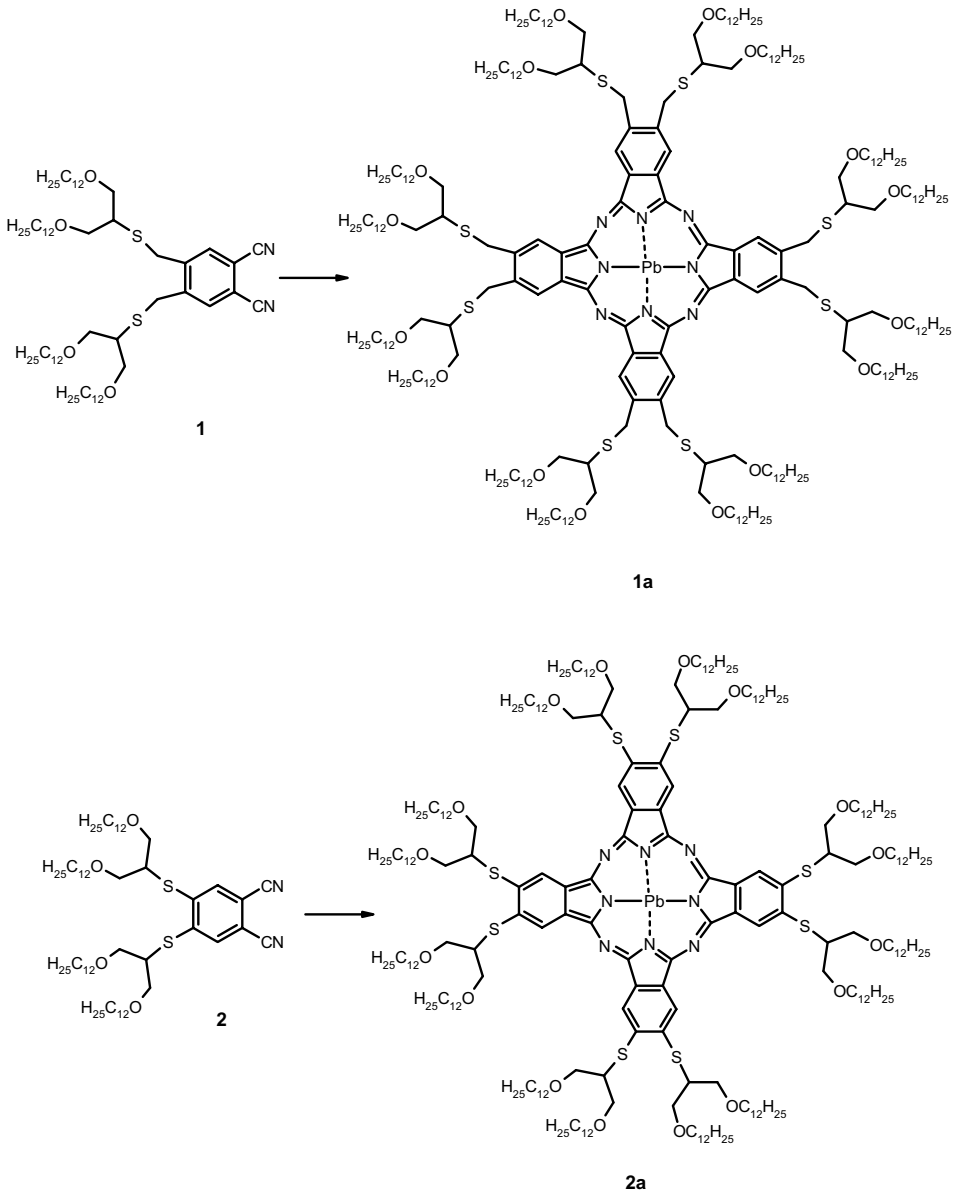

Fig. 1. Synthetic route of the compounds **1a** and **2a**.

possible because the PbPcs turned into the metal-free analogues on the preparative card. The intense brownish-green waxy products are very soluble in polar and non-polar solvents, such as chloroform, benzene, carbontetrachloride and tetrahydrofuran.

3.2. Spectroscopic characterization

The new (phthalocyaninato)lead complexes **1a** and **2a** were characterized by elemental analysis and various spectroscopic methods. The mass spectra of the phthalocyanines were obtained by the atmospheric pressure photoionization (APPI) technique and the full scan mass spectra of these compounds clearly showed intense signals for the protonated molecular ion $[M + H]^+$. The diamagnetic lead(II) compounds **1a** and **2a** gave well-resolved ^1H NMR spectra in $CDCl_3$. Fig. 2 shows the spectrum of **2a** in which there is one singlet at δ 9.42 for one set of the phthalocyanine ring protons. The aliphatic protons' signals can also be assigned unambiguously due to well-resolved multiplicity and integration of all the signals. The triplet at δ 4.05, the multiplet at δ 3.93 and the triplet at δ 3.52 are due to the CH, OCH_2 and CH_2O protons, respectively. Methyl group peaks belonging to the alkyl chain appeared as multiplets in the range δ 1.59–1.08. The ^1H NMR spectrum of compound **1a** shows similar spectral features except for a singlet peak at δ 4.70 ppm corresponding to Ar–CH_2.

In the ^{13}C NMR spectra of compounds **1a** and **2a**, the carbon atom of the N=C–N group in the phthalocyanine core could be assigned by comparison of the chemical shift measured with data reported in the literature [23,24].

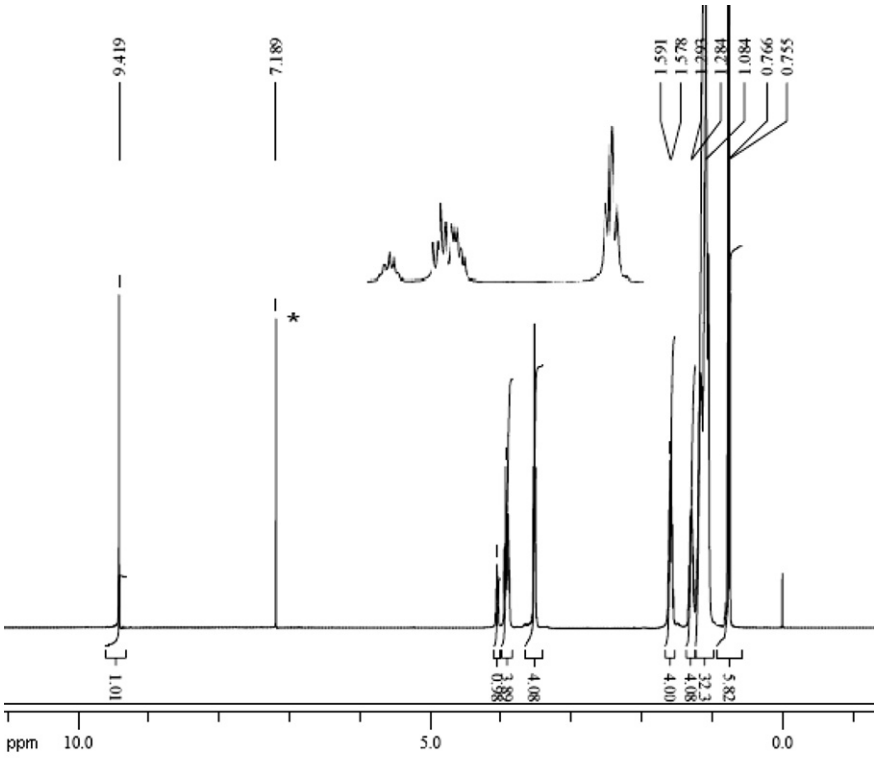

Fig. 2. ^{1}H NMR spectrum of **2a** in $CDCl_3$. The signal due to residue $CHCl_3$ is denoted as ∗.

^{13}C NMR spectra of the phthalocyanines show signals for four aromatic carbon atoms between ca. 125 and 154 ppm.

The IR spectral results of the phthalocyanine derivatives (**1a**, **2a**) are different from the phthalocyanine precursors **1** and **2**, so the sharp peak for the C≡N vibrations around 2220–2235 cm^{-1} associated with nitrile groups disappeared after phthalocyanine formation. In addition, a group of absorption bands were also seen in the range 2850–2955 cm^{-1} in the IR spectra of **1a** and **2a**. These can be attributed to the C–H stretching vibrations of the substituted alkyl chains.

In the electronic spectra of the Pcs, the phthalocyanine derivatives (**1a** and **2a**) show intense Q absorption bands above 700 nm (Figs. 4 and 5). The presence of methylene bridges in compound **1a**, distinct from **2a**, shifts the Q-band to a shorter wavelength by about 27 nm. The reason for the shifting to shorter wavelengths is that the methylene bridges reduce the electron releasing ability of the sulfur atoms to the pc core [23,24,28]. Furthermore, the effect of the central metal ion shows a shift of these intense Q-bands to higher wavelengths in comparison with their nickel and metal free derivatives [24].

3.3. The mesogenic properties of the PbPc complexes (*1a* and *2a*)

The phase transition temperatures were determined by differential scanning calorimetry (DSC). The DSC measurements were performed on the virgin materials with a scanning rate of 5 °C/min. Phase transition temperatures and the corresponding enthalpy changes of the PbPc complexes (**1a** and **2a**) are summarized in Table 1. The DSC measurements of **1a** and **2a** show a significant sharp peak in the vicinity of −10 °C which relates to an isotropic phase transition. The sharpness of the isotropic point gives an indication of the purity of the compound. No additional peaks are observed for compounds **1a** and **2a**, which excludes further phase transitions (see Table 1).

Also, the phase transition temperatures of the complexes (**1a** and **2a**) have been surveyed by polarization microscopy. The birefringence textures observed by polarizing optical microscopy were best observed by slowly cooling from the isotropic phase to the mesophase. The textures observed by microscopy for these studied complexes (**1a** and **2a**) are very similar to those described in the literature [23,24,29]. Fig. 3 shows the photomicrograph of the

Table 1
Phase transition temperatures and enthalpies for the compounds **1a** and **2a** as determined by DSC[a]

Compound	$T_{Col\ h \rightarrow I}$/°C [ΔH/kJ mol^{-1}]	
	Heating	Cooling
1a	−1.91 [115.25]	−9.26 [119.17]
2a	−9.62 [189.29]	−13.16 [177.99]

Heating and cooling rates: 5 °C, heating range: −50 to 100 °C.
[a] Phase nomenclature: Col_h = discotic hexagonal columnar mesophase, I = isotropic phase.

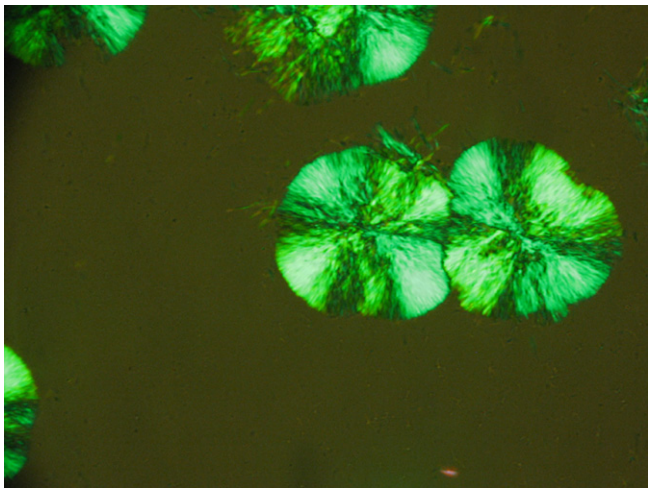

Fig. 3. Optical texture of **2a** at −20°C.

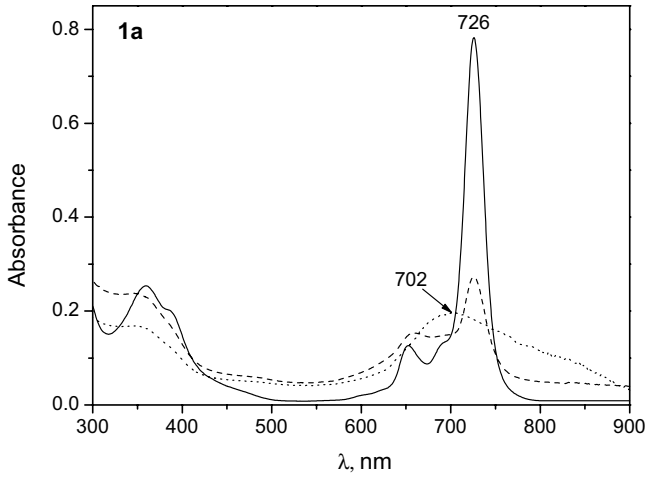

Fig. 4. Absorption spectra of **1a**: solutions in chloroform (——); films on quartz at room temperature (– – – – –) and slowly cooled down to −10 °C (· · · · · · · · ·).

mesophase of **2a** at −20 °C. This typical fan-shaped texture is often observed for Col_h, hence these mesophases could thus be confirmed as the Col_h phases [30–37].

In mesogen metalleted Pcs, Pb(II) sterically destabilizes the cofacial columnar structure and dramatically reduces both crystal-to-mesophase and mesophase-to-isotropic transition temperatures [1a]. A decrease in the clearing point temperatures was observed for the coordination of Pb^{2+} for **1a** and **2a** in comparasion with their Ni(II) and free derivatives [23,24]. Also, when compared to the influence of substition with alkylthiamethyl and alkylthia upon the mesomorphic properties of the Pc derivatives (**1a** and **2a**), the clearing point of **1a** subtituted with alkylthiamethyl was lower than that of **2a** subtituted with alkylthia. It could be seen that the addition of methylene bridges to the phthalocyanine core decreases the clearing point temperature as given in the literature [23,24]. According to the literature, the same behaviour was observed for the alkoxy and alkoxymethyl derivatives [14,15].

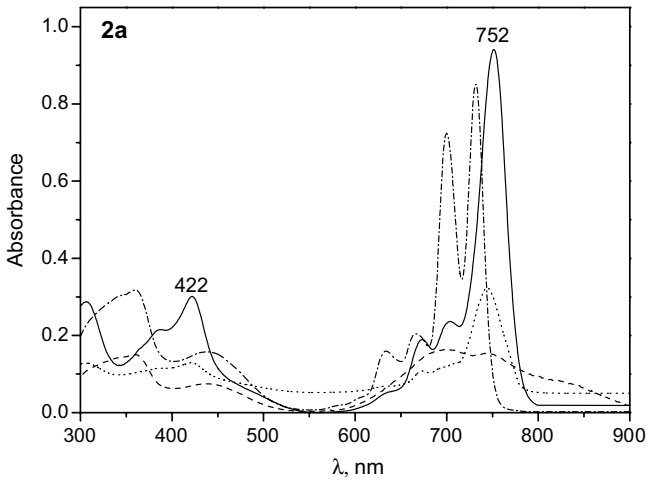

Fig. 5. Absorption spectra of **2a**: solutions in chloroform (——); films on quartz immediately after deposition (· · · · · · · · ·) and 3 h (– – – –) after deposition, and solution in chloroform obtained by washing away the films 3 h after deposition (–·–·–·).

3.4. Film investigation

The absorption spectra of **1a** and **2a** solutions in chloroform are presented in Figs. 4 and 5, respectively. The spectra of solutions are characterized by an intense electronic absorption in the visible region, with the Q-band at 726 and 752 nm for **1a** and **2a**, respectively. Compound **2a** is characterized by low chemical stability and loses the Pb^{2+} central ion during storage in chloroform in the room atmosphere after some hours to form the metal-free phthalocyanine (H_2Pc). It decomposes both in solution and in the form of a thin film. Fig. 5 shows the absorption spectra of the film of **2a** immediately after deposition and 3 h later. The loss of the Pb^{2+} central ion is clearly observed. This is further confirmed when the film was washed away by chloroform and the spectrum of the resulting solution was recorded. The splitting of the Q-band indicates the formation of H_2Pc [24,26]. Therefore, transformation of this derivative to the metal free phthalocyanine makes further investigation of **2a** films difficult.

Compound **1a** is characterized by a higher stability and does not lose the central metal at least for some weeks. Therefore the data of the electrical properties investigation are presented for thin films of compound **1a** only.

It has already been shown in a previous publication [37,38] that the slow cooling of phthalocyanines exhibiting mesogenic properties from the isotropic liquid leads to the formation of films with an ordered structure. These compounds are liquid at room temperature (Table 1). To obtain a film with an ordered structure, thin films of compound **1a** were slowly cooled from room temperature down to −10 °C. The absorption spectrum of **1a** film at room temperature, as well as at −10 °C, is given in Fig. 4. The spectrum for a solution of **1a** in chloroform is also included

for comparison. The absorption spectrum of the film at room temperature (Fig. 4, dashed line) is similar to that of the chloroform solution. The spectrum of **1a** film at −10 °C is completely different (Fig. 4, dotted line). Indeed, the position of the Q-band absorption provides good evidence for a change of the molecular ordering [39]. The broadened and blue-shifted Q-bands in the visible absorption spectra of the film provide good evidence for molecular ordering and indicate a stacking arrangement of the molecules in the film [40].

Unsubstituted lead phthalocyanine is known to have unique electronic properties which originate from its one dimensional structure. Earlier publications [20,41] reported an electrical switching effect in the film of unsubstituted PbPc of the monoclinic structure and suggested an electric field-induced order–disorder transition mechanism in the stacking direction.

It is therefore interesting to examine the electrical switching in thin films of substituted phthalocyanines. Sandwich structures of the type Au/PbPc (**1a**)/Au were prepared for the investigation of the electrical properties. *I–V* characteristics of Au/PbPc (**1a**)/Au have been recorded for two sweep directions; in the first case, the film was at room temperature and in the second case, the film was slowly cooled down to −10 °C. The Au/$PbPcR_8$ (**1a**)/Au structure, in which the film of PbPc (**1a**) is disordered at room temperature, shows *I–V* dependence close to symmetric with no switching effect being observed. A typical *I–V* curve for the structure cooled down slowly to −10 °C is shown in Fig. 6. The figure shows that when the dc bias was swept from a positive voltage ($V_{max} = 1$ V), the device current was very small for both polarities until about −0.9 V. The state of phthalocyanine can be termed as the OFF state, which then switches to the ON state at −1 V. During the sweep from negative voltage, PbPc retained the high-conducting ON state. When the device is in its OFF state, the shape of the *I–V* dependence is almost symmetric. In contrast to the OFF state, the ON state displays an asymmetrical *I–V* characteristic, thus suggesting that the charge injection is modified. The switching behaviour is asymmetric with a larger ON/OFF ratio (∼50) for negative voltage. The device could be cycled between the two states many times without degradation. This characteristic was stable for an applied bias between −1 V and +1 V. Exceeding those limits resulted in an irreversible transition to a lower resistance switching state. These molecular devices show repeatable switching and may be applicable to memory cells and other logic devices in the future. However, in order to get reproducible and reliable device characteristics it is very important to understand the basic transport mechanisms in these diodes and measure quantitative switching characteristics of the devices.

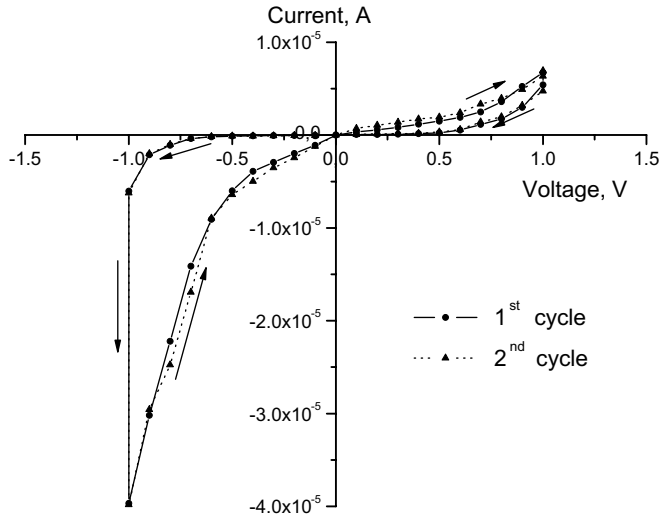

Fig. 6. *I–V* characteristics of the Au/$PbPcR_8$ (**1a**)/Au sandwich cell slowly cooled to −10 °C for two voltage sweeping directions (shown by arrows).

4. Conclusions

In this work, the synthesis of new mesomorphic octakis (alkylthio)-substituted phthalocyanines of Pb(II) were described, using microwave irradiation with higher yield and heating without solvent methods. The Pb(II) pcs were characterized using different spectroscopic techniques (NMR, UV–Vis, FT-IR and MS). The microwave technique is a fairly novel approach for the synthesis of lead phthalocyanines. These complexes are viscous waxy liquids at room temperature and form liquid crystalline phases in the vicinity of −10 °C. Compound **2a** loses Pb^{2+} during storage in atmosphere after some hours to form the metal-free phthalocyanine (H_2Pc). Compound **1a** is characterized by higher stability and loses the central metal ion after some weeks at least. The Au/PbPc (**1a**)/Au structure, in which the film of PbPc (**1a)** is disordered at room temperature, shows *I–V* dependence close to symmetric and does not display any switching effect. To obtain films with an ordered structure the film of **1a** was slowly cooled from room temperature down to −10 °C. It was shown that the slowly cooled Au/PbPc(**1a**)/Au structure shows repeatable and stable switching for applied bias voltages between −1 V and +1 V.

When Pc is substituted with alkylthiamethyl chains, the Q-band shifts to shorter wavelength and the clearing point temperatures decrease compared with alkylthia chains. Furthermore, the coordination of Pb^{2+} with the Pc core was responsible for lower the clearing temperature and Q band absorption occurring at longer wavelenghts for compounds **1a** and **2a**, compared with other derivatives.

2. Experimental

2.1. General procedures

All air-sensitive manipulations, unless stated otherwise, were performed using standard Schlenk techniques under an atmosphere of high-purity argon or glovebox techniques. Toluene and *n*-hexane were dried by refluxing over sodium and benzophenone and distilled under argon prior to use. C_6D_6 was dried over activated 4 Å molecular sieves and vacuum-transferred to a sodium-mirrored air-free flask. $CDCl_3$ was dried over CaH_2 for 48 h and vacuum-transferred to an air-free flask. $ZnEt_2$ was purchased from Aldrich and used as received. The 7-amino-2,4-dimethylquinoline [10], 3,5-di-*tert*-butyl-2-hydroxyl-benzaldehyde [11a], 5-bromo-2-hydroxyl-benzaldehyde [11b] and 3,5-dibromo-2-hydroxyl-benzaldehyde [11c] were synthesized according to the literature methods. NMR spectra were measured using a Varian Mercury-300 or Bruker AVANCE-500 NMR spectrometer. IR spectra were recorded on a Nicolet Impact 410 FTIR spectrometer using KBr pellets. The elemental analyses were performed on a Perkin–Elmer 2400 analyzer. UV–Vis absorption spectra were recorded on a UV-3100 spectrophotometer. Fluorescent measurements were carried out on a RF-5301PC spectrophotometer. Mass spectra were recorded on an 1100 LC/MS system (Agilent Technology Corporation). All melting points were determined by an X-5 micro-melting point apparatus and are uncorrected.

2.2. General procedure for the salicylaldimine ligands

The condensation of salicylaldehydes with 1 equiv. of 7-amino-2,4-dimethylquinoline was carried out by refluxing the two reactants in ethanol for 8 h. Upon cooling the resulting reaction solution to room temperature, a yellow or orange-red solid precipitated from the solution. The solid product was filtered and washed with cold ethanol and then dried in vacuo to give the desired salicylaldimine ligand in excellent yields.

2.3. Synthesis of $C_{18}H_{16}N_2O$ (**1a**)

2-Hydroxyl-benzaldehyde (2.10 mL, 18.6 mmol) and 7-amino-2,4-dimethylquinoline (3.21 g, 18.6 mmol) in 35 ml of refluxing ethanol afforded 4.16 g of compound **1a** as a yellowish solid. Yield: 81%. m.p.: 137–138.6 °C. ES–MS (MeOH) *m/z*: 277.0 [$(M+1)^+$]. *Anal.* Calc. for $C_{18}H_{16}N_2O$ (276.33): C, 78.24; H, 5.84; N, 10.14. Found: C, 78.36; H, 5.77; N, 10.10%. ^{1}H NMR (300 MHz, $CDCl_3$, 298.3 K): δ (ppm) 2.70 (s, 3H, quinolyl-CH_3), 2.75 (s, 3H, quinolyl-CH_3), 6.97 (t, $J = 7.5$ Hz, 1H, aryl), 7.05 (d, $J = 7.5$ Hz, 1H, Ph-H), 7.15 (s, 1H, quinolyl-H), 7.39–7.44 (m, 2H, Ph-H), 7.51 (d, $J = 8.7$ Hz, 1H, quinolyl-H), 7.94 (s, 1H, quinolyl-H), 8.01 (d, $J = 8.7$ Hz, 1H, quinolyl-H), 8.77 (s, 1H, CH=N), 13.11 (s, 1H, OH).^{13}C NMR (75.4 MHz, $CDCl_3$, 298.3 K): δ (ppm) 18.6 (quinolyl-CH_3), 25.0 (quinolyl-CH_3), 117.2, 118.3, 119.2, 121.3, 122.6, 124.8, 125.4, 132.5, 133.5, 144.5, 148.1, 149.3 (quinolyl-7-C), 159.5 (Ph-2-C), 161.2 (quinolyl-2-C), 163.7 (CH=N). IR (KBr, cm^{-1}): υ 3377 (br) 3046 (w), 2984 (m), 2951 (m), 2921 (m), 1972 (w), 1926 (w), 1622 (s), 1605 (vs), 1574 (vs), 1514 (s), 1497 (vs), 1460 (s), 1372 (s), 1336 (m), 1284 (vs), 1259 (s), 1191 (vs), 1161 (vs), 1136 (s), 1030 (m), 1001 (w), 972 (m), 959 (w), 943 (m), 901 (m), 874 (vs), 826 (vs), 666 (m), 630 (m), 595 (w), 570 (w), 541 (w), 470 (m), 450 (w), 428 (w).

2.4. Synthesis of $C_{26}H_{32}N_2O$ (**1b**)

Similarly, 3,5-di-*tert*-butyl-2-hydroxybenzaldehyde (1.72 g, 7.36 mmol) and 7-amino-2,4-dimethylquinoline (1.27 g, 7.36 mmol) in 25 ml of refluxing ethanol afforded 2.36 g of complex **1b** as an orange solid. Yield: 85%. m.p.: 185.5–186.5 °C. ES–MS (DMSO) *m/z*: 389.2 [$(M+1)^+$]. *Anal.* Calc. for $C_{26}H_{32}N_2O$ (388.55): C, 80.37; H, 8.30; N, 7.21. Found: C, 80.29; H, 8.25; N, 7.23%. ^{1}H NMR (300 MHz, $CDCl_3$, 298.3 K): δ (ppm) 1.34 (s, 9H, $C(CH_3)_3$), 1.50 (s, 9H, $C(CH_3)_3$), 2.70 (s, 3H, quinolyl-CH_3), 2.75 (s, 3H, quinolyl-CH_3), 7.15 (s, 1H, Ph-H), 7.25 (s, 1H, Ph-H), 7.49–7.54 (m, 2H, quinolyl-H), 7.94 (s, 1H, quinolyl-H), 7.99 (d, $J = 8.7$ Hz, 1H, quinolyl-H), 8.80 (s, 1H, CH=N), 13.56 (s, 1H, OH). ^{13}C NMR (75.4 MHz, $CDCl_3$, 298.3 K): δ (ppm) 18.6 (quinolyl-CH_3), 24.9 (quinolyl-CH_3), 29.4 ($C(CH_3)_3$), 31.4 ($C(CH_3)_3$), 34.1 ($C(CH_3)_3$), 35.1 ($C(CH_3)_3$), 117.7, 118.3, 121.9, 122.4, 124.7, 125.2, 127.1, 128.5, 137.0, 140.8, 144.4, 148.4, 149.9 (quinolyl-7-C), 158.4 (Ph-2-C), 159.3 (quinolyl-2-C), 165.0 (CH=N). IR (KBr, cm^{-1}): υ 3493 (br), 2960 (m), 2912 (w), 2868 (w), 1603 (m), 1580 (s), 1509 (w), 1472 (w), 1438 (m), 1392 (w), 1369 (w), 1361 (w), 1378 (w), 1273 (w), 1251 (w), 1193 (w), 1168 (m), 1139 (w), 1029 (w), 1004 (w), 962 (w), 933 (w), 888 (m), 862 (w), 838 (w), 809 (w), 764 (w), 726 (w), 662 (w), 641 (w), 601 (w), 572 (w), 524 (w), 497 (w).

2.5. Synthesis of $C_{18}H_{15}BrN_2O$ (**1c**)

Similarly, 5-bromo-2-hydroxybenzaldehyde (0.92 g, 4.6 mmol) and 7-amino-2,4-dimethylquinoline (0.79 g, 4.6 mmol) in 35 ml of refluxing ethanol afforded 1.42 g of compound **1c** as an orange solid. Yield: 87%. m.p.: 177.7–178.7 °C. ES–MS (MeOH) *m/z*: 357.0 [$(M+1)^+$]. *Anal.* Calc. for $C_{18}H_{15}BrN_2O$ (355.23): C, 60.86; H, 4.26; N, 7.89. Found: C, 60.92; H, 4.16; N, 7.78%. ^{1}H NMR (300 MHz, $CDCl_3$, 298.3 K): δ (ppm) 2.72 (s, 3H, quinolyl-CH_3), 2.79 (s, 3H, quinolyl-CH_3), 6.95 (d, $J = 8.7$ Hz, 1H, Ph-H), 7.14 (s, 1H, Ph-H), 7.47–7.54 (m, 3H, quinolyl-H and Ph-H), 8.01–8.04 (m, 2H, quinolyl-H), 8.70 (s, 1H, CH=N), 13.10 (s, 1H, OH). ^{13}C NMR (75.4 MHz, $CDCl_3$, 298.3 K): δ (ppm) 18.9 (quinolyl-CH_3), 24.2 (quinolyl-CH_3), 110.7, 117.2, 119.3, 120.5, 122.0, 122.8, 123.1, 125.2, 125.4, 125.6, 134.6, 136.3, 159.0 (Ph-2-C), 160.3 (quinolyl-2-C), 162.8 (CH=N). IR

(KBr, cm^{-1}): υ 3444 (br), 3038 (w), 2967 (w), 2917 (m), 1896 (w), 1717 (w), 1601 (vs), 1555 (vs), 1511 (m), 1476 (s), 1449 (m), 1412 (m), 1370 (s), 1340 (s), 1281 (s), 1212 (m), 1195 (s), 1167 (vs), 1130 (m), 1092 (w), 1072 (w), 1028 (w), 993 (w), 955 (w), 935 (w), 897 (s), 859 (s), 824 (vs), 770 (m), 743 (w), 691 (w), 674 (m), 656 (s), 623 (m), 595 (w), 540 (m), 465 (w), 441 (w).

2.6. Synthesis of $C_{18}H_{14}Br_2N_2O$ (**1d**)

Similarly, 3,5-di-bromo-2-hydroxybenzaldehyde (2.37 g, 8.46 mmol) and 7-amino-2,4-dimethylquinoline (1.46 g, 8.46 mmol) in 35 ml of refluxing ethanol afforded 3.01 g of compound **1d** as an orange-red solid. Yield: 82%. m.p.: 174.7–175.7 °C. ES–MS (DMSO) *m/z*: 434.9 [$(M+1)^+$]. *Anal.* Calc. for $C_{18}H_{14}Br_2N_2O$ (434.12): C, 49.80; H, 3.25; N, 6.45. Found: C, 49.73; H, 3.20; N, 6.54%. ^{1}H NMR (300 MHz, $CDCl_3$, 298.3 K): δ (ppm) 2.72 (s, 3H, quinolyl-CH_3), 2.78 (s, 3H, quinolyl-CH_3), 7.47–7.54 (m, 3H, quinolyl-H and Ph-H), 8.01–8.04 (m, 2H, quinolyl-H), 7.10 (s, 1H, Ph-H), 7.13 (s, 1H, Ph-H), 7.36 (s, 1H, quinolyl-H), 7.78–7.89 (m, 2H, quinolyl-H), 8.05 (s, 1H, quinolyl-H), 8.70 (s, 1H, CH=N), 14.21 (s, 1H, OH). ^{13}C NMR (75.4 MHz, d_6-DMSO, 298.3 K): δ (ppm) 18.5 (quinolyl-CH_3), 24.7 (quinolyl-CH_3), 109.4, 111.6, 117.8, 118.6, 118.9, 119.4, 119.9, 120.9, 122.7, 125.6, 126.4, 134.4, 137.6, 157.3 (Ph-2-C), 159.4 (quinolyl-2-C), 163.0 (CH=N). IR (KBr, cm^{-1}): υ 3492 (br), 3069 (w), 2982 (w), 2956 (w), 2918 (w), 1917 (w), 1898 (w), 1753 (w), 1733 (w), 1720 (w), 1594 (vs), 1554 (s), 1513 (m), 1435 (s), 1370 (s), 1349 (m), 1339 (m), 1294 (m), 1272 (m), 1211 (m), 1197 (m), 1161 (vs), 1138 (s), 1029 (m), 1000 (m), 961 (m), 933 (m), 878 (s), 861 (s), 816 (s), 769 (w), 741 (m), 690 (m), 678 (w), 661 (w), 651 (m), 597 (w), 556 (w), 540 (w), 496 (w), 441 (w).

2.7. Synthesis of $C_{36}H_{30}N_4O_2Zn$ (**2a**)

To a solution of ligand **1a** (0.30 g, 1.07 mmol) dissolved in 30 ml of dry toluene was added a solution of $ZnEt_2$ (0.51 mmol) in toluene (5 ml) at −78 °C with stirring. The reaction mixture was allowed to warm to room temperature for 2 h, and heated at 80 °C for an additional 8 h. The solvent was removed under vacuum and the residue was washed with dry ^{n}hexane (3×20 ml). Then the crude product was further purified by recrystallization from toluene/^{n}hexane (1:6 in v/v) to give yellowish-green plate crystals (0.27 g, 86%) m.p.: 263.3–264.2 °C. *Anal.* Calc. for $C_{36}H_{30}N_4O_2Zn$ (616.04): C, 70.19; H, 4.91; N, 9.09. Found: C, 70.13; H, 4.85; N, 9.14%. ^{1}H NMR (300 MHz, $CDCl_3$, 298.3 K): δ (ppm) 2.57 (s, 3H, quinolyl-CH_3), 2.59 (s, 3H, quinolyl-CH_3), 6.78 (t, $J = 6.9$ Hz, 1H, Ph-H), 6.98 (d, $J = 8.4$ Hz, 1H, Ph-H), 7.05 (s, 1H, quinolyl-H), 7.22 (dd, $J = 6$ Hz, 1.8 Hz, 1H, quinolyl-H), 7.36–7.46 (m, 2H, Ph-H), 7.54 (s, 1H, quinolyl-H), 7.78 (d, $J = 9$ Hz, 1H, quinolyl-H), 8.57 (s, 1H, CH=N). ^{13}C NMR (75.4 MHz, $CDCl_3$, 298.3 K): δ (ppm) 18.5 (quinolyl-CH_3), 25.1 (quinolyl-CH_3), 115.4, 118.4, 118.8, 121.3, 122.7, 123.8, 125.3, 125.4, 136.6, 136.9, 144.2, 148.3, 149.5, 159.7 (quinolyl-2-C), 170.1 (Ph-2-C), 171.7 (CH=N). IR (KBr, cm^{-1}): υ 3039 (w), 3020 (w), 2953 (w), 2911 (w), 1604 (m), 1582 (m), 1531 (m), 1510 (w), 1462 (w), 1435 (w), 1392 (w), 1343 (w), 1315 (w), 1248 (w), 1187 (w), 1170 (w), 1170 (w), 1151 (w), 1125 (w), 1030 (w), 991 (w), 949 (w), 915 (w), 887 (w), 858 (w), 839 (w), 817 (w), 775 (w), 758 (w), 677 (w), 629 (w), 599 (w), 568 (w), 541 (w), 525 (w), 505 (w), 472 (w), 452 (w).

2.8. Synthesis of $C_{52}H_{62}N_4O_2Zn$ (**2b**)

Complex **2b** was synthesized by the same procedures as those used for **2a** with **1b** (0.45 g, 1.17 mmol) as a starting material. Pure **2b** (0.45 g, 91%) was obtained as a yellow powder by recrystallization from toluene/^{n}hexane (1:6 in v/v). m.p.: 246.1–248 °C. *Anal.* Calc. for $C_{52}H_{62}N_4O_2Zn$ (840.46): C, 74.31; H, 7.44; N, 6.67. 2.11. X-ray structure determination of 2b

Single crystals of **2b** suitable for X-ray structural analysis were obtained from a saturated solution of **2b** in toluene/^{n}hexane (1:6, v/v) at room temperature. Diffraction data were collected at 293 K on a Bruker Smart diffractometer equipped with graphite-monochromated Mo Kα radiation (λ = 0.71073 Å) for **2b**. The structure was solved by direct methods [12] and refined by full-matrix least-squares on F^2. Most non-hydrogen atoms, except those in the disordering groups, were refined anisotropically. All hydrogen atoms, except those on disordered carbon atoms, were calculated and their contributions in structural factor calculations were included. All calculations were performed using the SHELXTL crystallographic software packages [13]. Details of the crystal data, data collection and structure refinements are summarized in Table 1.

3. Results and discussion

3.1. Synthesis of the ligands

Ligands **1a**–**1d** were readily prepared by simple condensation of salicyaldehydes with 7-amino-2,4-dimethylquinoline in EtOH in high yields (Scheme 1). Compounds **1a**–**1d** were characterized via ^{1}H, ^{13}C NMR and IR spectroscopies, as well as elemental analysis. The ^{1}H NMR spectra of **1a**–**1d** exhibit resonances at δ = 8.77, 8.80, 8.70 and 8.70 ppm, respectively, for the CH imino protons, with

Scheme 1. Synthetic route for ligands **1a**–**1d** and complexes **2a**–**2d**.

the corresponding ^{13}C resonance at $\delta = 163.7$, 165.0, 162.8, 163.0 ppm, respectively. The OH resonances appear at characteristically low field shifts ($\delta = 13.11$ ppm for **1a**, 13.56 ppm for **1b**, 13.10 ppm for **1c** and 14.21 ppm for **1d**). The infrared absorption band of the imine C=N stretching vibration occurs in the region 1594–1605 cm^{-1}.

3.2. Synthesis of the zinc complexes

The bis-salicylaldiminato zinc complexes **2a**–**2d** were conveniently synthesized in higher yields (83–91%) by the reaction of $ZnEt_2$ with two equivalents of the corresponding ligand by alkane elimination (Scheme 1). Complexes **2a**–**2d** were always obtained when the molar ratio of ligand/$ZnEt_2$ was 1:1 or 2:1 in toluene, which is due to the fact that the salicylaldiminato ligands are not sterically bulky enough to inhibit the formation of bis-ligand species [14]. Complexes **2a**–**2d** have different solubilities in common solvents. Complexes **2a** and **2c** are well soluble in methylene chloride, diethyl ether and THF, moderately soluble in toluene, and sparingly soluble in saturated hydrocarbon solvents. Complex **2b** is well soluble in common solvents. Complex **2d** is soluble in DMSO (dimethyl sulfone), moderately soluble in methylene chloride and sparingly soluble in other common solvents. Complexes **2a**–**2d** were all characterized by elemental analyses, ^1H, ^{13}C NMR and IR spectroscopies, and satisfactory analytical results were obtained. In the ^1H NMR spectra of these complexes, the resonance for the CH imino protons in **2a** (8.57 ppm), **2b** (8.16 ppm), **2c** (8.40 ppm) and **2d** (8.65 ppm) shifts by about 0.2 ppm, 0.64 ppm, 0.30 ppm and 0.05 ppm, respectively, towards high field compared to the corresponding signals of the free ligands. However the resonances (171.7 ppm for **2a**, 170.8 ppm for **2b,** 170.4 ppm for **2c** and 168.4 ppm for **2d**) for the CH imino carbons in the ^{13}C NMR spectra shift by about 8 ppm, 5.8 ppm, 7.6 ppm and 5.4 ppm, respectively, to low field in comparison with the corresponding ones of the free ligands. The O–H proton signals of the free ligands disappear in the ^1H NMR and IR spectra of the complexes **2a**–**2d**, which indicates the formation of a Zn–O bond in these complexes. All the complexes are stable to air and moisture in the solid state and can be left in the air for several days without obvious decomposition.

3.3. The crystal structure of complex *2b*

Crystals of complex **2b** suitable for X-ray crystal structure determination were grown from toluene/^{n}hexane at room temperature. The ORTEP drawing of the molecular structure of **2b** is shown in Fig. 1, top. Selected bond lengths and angles for complex **2b** are given in Table 2.

There are two ^{n}hexane solvent molecules in the unit cell of complex **2b**, and the ^{n}hexane solvate exhibits molecular disorder. The high residual peaks in a difference fourier map with suitable geometry were refined isotropically with occupancies factors (0.25:0.25) for each ^{n}hexane moiety.

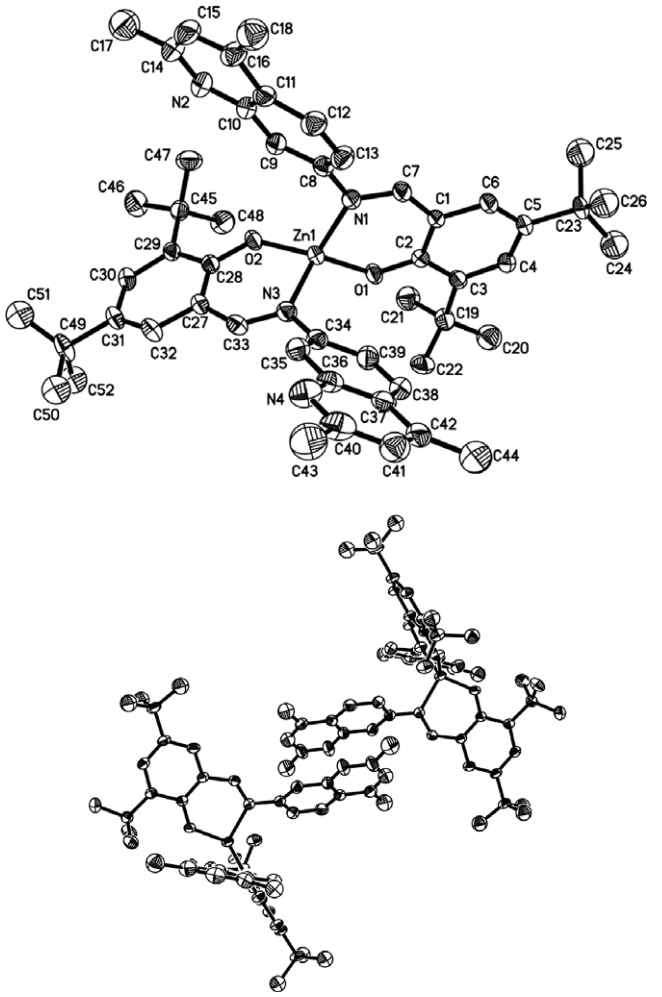

Fig. 1. Top: Molecular structure of complex **2b**; bottom: Crystal packing diagram between two adjacent molecules of complex **2b** showing the existence of the π–π stacking interaction in the solid state. (Thermal ellipsoids are drawn at 30% probability. All H atoms and the disordered ^{n}hexane solvate are omitted for clarity.)

Table 2
Selected bond lengths (Å) and angles (°) for complex **2b**

Complex **2b**			
Zn(1)–N(1)	1.994(3)	N(1)–Zn(1)–N(3)	110.98(13)
Zn(1)–N(3)	2.016(3)	N(3)–Zn(1)–O(1)	115.21(13)
Zn(1)–O(1)	1.903(3)	N(3)–Zn(1)–O(2)	95.65(12)
Zn(1)–O(2)	1.901(3)	O(1)–Zn(1)–O(2)	121.66(12)
N(1)–C(7)	1.305(5)	C(7)–N(1)–Zn(1)	120.9(3)
N(3)–C(33)	1.298(5)	C(8)–N(1)–Zn(1)	121.5(2)
N(1)–Zn(1)–O(1)	121.66(12)	C(33)–N(3)–Zn(1)	119.9(3)
N(1)–Zn (1)–O(2)	118.79(13)	C(34)–N(3)–Zn(1)	123.1(3)

The X-ray analysis reveals that complex **2b** adopts a distorted tetrahedral geometry with the metal center chelated by two bidentate ligands via the phenolate oxygen atom and imine nitrogen atom. The O–Zn–O angle in **2b** (121.66(12)°) is larger than those values (105–112.5°) in the similar bis-salicylaldiminato zinc complexes $(NR^2C_7H_{5-x}(R^1)_xO)_2Zn$ [$x = 1$ or 2; R^1 = Me, ^{t}Bu, Cl, OMe;

$R^2 = 2,6\text{-}^iPr_2C_6H_3$] [14], while the N–Zn–N angle in **2b** (110.98(13)°) is smaller than those in the latter complexes (122.9–128.9°). The two dihedral angles between the quinolyl ring and the six-membered chelating ring are 46.5 and 48.9°, respectively. The two six-membered chelating rings are nearly planar with the zinc atoms lying 0.0454 and 0.0328 Å out of the plane, and they are closely perpendicular to each other with the dihedral angle being 88.7°. The imino C=N bonds in complex **2b** retain their double bond character, being 1.305(5) and 1.298(5) Å. In addition, the X-ray diffraction analysis reveals that an intermolecular π–π interaction appears in the solid state of complex **2b**, forming an antiparallel dimeric structure (Fig. 1, bottom). One quinolyl ring in complex **2b** stacks together with the corresponding one in an adjacent molecule by the π–π interaction with a distance of 3.64 Å [15]. Moreover, one thing that should be mentioned is that all the methyl groups of the ^{t}Bu group at the 5-position of the salicylene ring in **2b** display rotational disordering over two sites, with 50% occupancy factors for each site. The H-atoms are placed in calculated positions on the disordered atoms.

3.4. Luminescent property

Table 3 summarizes the absorption and emission data for compounds **1a**–**1d** and **2a**–**2d** in solution and the solid state. As shown in Table 3, it can be seen that the four complexes **2a**–**2d** show three main absorption bands similar to those in the ligands **1a**–**1d** in the UV region. The electronic absorption spectra of those complexes in the maximum absorption wavelength are red-shifted relative to the ligands due to the perturbation of the intraligand π–π* transition of the salicylaldiminato unit by the metal atom.

Fig. 2 shows the emission spectra of **1a**–**1d** and **2a**–**2d** in solution. And Fig. 3 shows the emission spectra of **1a**–**1d** and **2a**–**2d** in the solid state. In comparison with the corresponding free ligands ($\lambda_{max} = 476$, 524, 478 and 486 nm, respectively, for **1a**–**1d**), complexes **2a**–**2d** in solution exhibit red-shifts with $\lambda_{max} = 503$, 532, 514 and 515 nm, respectively. The coordinated zinc atom plays a dual role in the luminescence of **2a**–**2d** as pointed out in the literature for coordination complexes [16]. First, the formation of covalent bonds between the Zn and O atoms *via* π-donation of

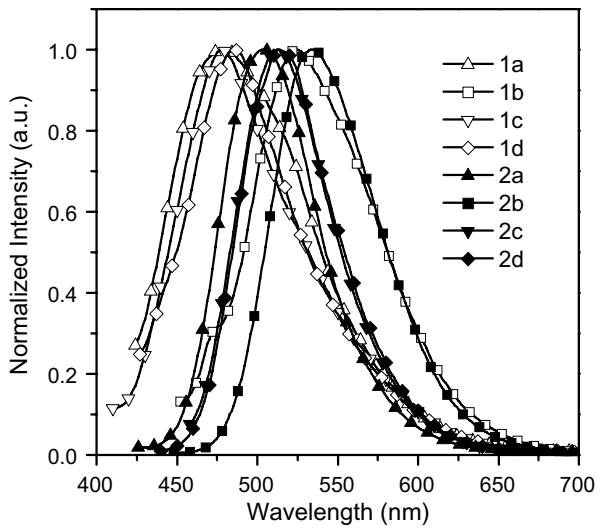

Fig. 2. Emission spectra of ligands **1a**–**1d** and complexes **2a**–**2d** in CH_2Cl_2.

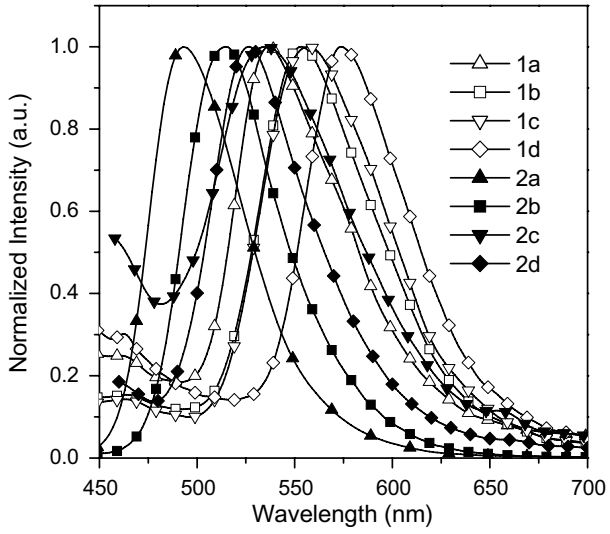

Fig. 3. Emission spectra of ligands **1a**–**1d** and complexes **2a**–**2d** in the solid state.

a lone-pair electrons of the O atom to the Zn atom changes the emission energy, due to the lowering of the energy gap between π* and π. Second, the coordination of the ligands with the Zn atom increases the rigidity of the ligands, which can diminish the loss of energy *via* vibrational motions and increase the emission efficiency. The emission maximum of complexes **2b**–**2d** in solution is red-shifted by about 29, 11 and 12 nm, respectively, compared to that of the complex **2a**, which is possibly due to the fact that the electron-donating nature of the *tert*-butyl group and bromo group on the phenyl ring lowers the energy gap between π* and π. The quantum yields of all the compounds have been determined in solution. It was found that the quantum yields of the complexes are higher than those of the corresponding ligands, considering that the coordination of the ligands to the zinc atom increases the rigidity of the molecule. The quantum yields of complexes **2c** and **2d** are lower than those of **2a** and **2b** due to the fact that the bromo atom can quench the fluorescence and results in luminescence decay. All compounds **1a**–**1d** and **2a**–**2d** emit bright fluorescence in the solid state at room temperature. Complexes **2a**–**2d** exhibit a bright emission with $\lambda_{max} = 493$, 519, 535 and 526 nm, respectively ($\lambda_{max} = 536$, 553, 558 and 578 nm for ligands **1a**–**1d**). The emission maxima of these complexes are blue-shifted compared to those of the corresponding free ligand in the solid state, which is probably due to the disappearance of the intramolecular hydrogen bonding in compounds **1a**–**1d** after coordination with the zinc atom [17]. The emission maxima of complexes **2a** and **2b** in the solid state are blue-shifted compared to their corresponding emission maxima in solution, while the emission maxima of complexes **2c** and **2d** in the solid state are red-shifted compared to their corresponding emission maxima in solution. Blue shifting probably results from the diminished conjugated extent of the two complexes **2a** and **2b** since the free rotation of the quinolyl ring in these complexes is blocked in the solid state. Red shifting of emission maximum can be normally observed for most fluorescent compounds in the solid state, probably due to π–π stacking of the aromatic rings in the molecules.

4. Conclusions

A series of bis-salicylaldiminato zinc complexes have been synthesized and characterized. Our research results indicate that the chelating bidentate salicylaldiminato conjugated ligands are well suitable for synthesizing four-coordinate zinc complexes by the reaction of $ZnEt_2$ with the corresponding ligands. These complexes produce bright fluorescence in both solution and the solid state, and the emission color in solution can be tuned by the 3- and 5-position substituents on the salicylene rings of the ligands. The four-coordinate zinc complexes are a new class of luminescent material with potential applications in opto-electronic devices.

5. Supplementary material

CCDC 634611 contains the supplementary crystallographic data for **2b**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Recently, the importance of metallo-organic complexes has been associated with supramolecular chemistry. In addition, there has been considerable interest for inorganic metal clusters, coordination complexes and organic molecules into extended motifs held together either by strong metal-ligand bonding or by weaker bonding forces such as hydrogen-bonding, π–π interactions (face-to-face) and C–H–π interactions (T-shaped geometry, edge-face or herringbone interactions) [23–25]. These weak non-covalent bonds can sustain supramolecular synthons which are structure determining.

We report here the template synthesis of phenylmercury(II) and cadmium(II) complexes of a tridentate N_2S donor ligand, diacetylmonoximemorpholine *N*-thiohydrazone (Hdammth) (H_2dammthiol, the thiol form of this hydrazone is actually involved in the complex formation) and their characterization by elemental analyses, spectral data (electronic, infrared and ^{1}H NMR), and by X-ray crystal structure analysis. The supramolecular structure of these complexes is also reported.

2. Experimental

2.1. Physical measurements

The elemental analyses were carried out at the Sophisticated Analytical Instrument Facility, Central Drug Research Institute, Lucknow, India. The electronic spectra were recorded on a Shimadzu UV-1601 spectrophotometer, infrared spectral data were collected (KBr pellets) on a Perkin-Elmer L120-000A spectrophotometer, and NMR spectra were recorded at the Indian Institute of Chemical Biology, Kolkata, India.

2.2. Materials

The solvents and chemicals were purified and dried prior to use by standard procedures. Diacetylmonoxime was purchased from Aldrich and morpholine *N*-thiohydrazide was prepared by published methods [26,27]. [PhHg(OAc)] and $[Cd(OAc)_2]\cdot 2H_2O$ were purchased from SRL Mumbai, India. The molar conductance was measured using an Elico CM-180 conductivity bridge in chloroform (10^{-3} M solution).

2.3. Synthesis of [PhHg(Hdammthiol)] (1)

A mixture of diacetylmonoxime (0.2 g, 0.002 mol) and morpholine *N*-thiohydrazide (0.32 g, 0.002 mol) was heated under gentle reflux in the presence of [PhHg(OAc)] (0.67 g, 0.002 mol). The concentrated yellow solution produced yellow colored crystals upon cooling. This compound was recrystallized from chloroform, which gave suitable single crystals for X-ray study. Yield: ~0.68 g, (65%).

2.4. Synthesis of [Cd(Hdammthiol)$_2$] (2)

This compound was prepared by the same method described above. To the refluxing solution of a mixture of diacetylmonoxime (0.5 g, 0.005 mol) and morpholine *N*-thiohydrazide (0.8 g, 0.005 mol), $[Cd(OAc)_2]\cdot 2H_2O$ (0.67 g, 0.0025 mol) was added and further refluxed for another 30 min. The resulting yellow solution was filtered and concentrated to yield a yellow compound. This compound was recrystallized from chloroform, which gave suitable single crystals for X-ray study. Yield: ~1.12 g, (75%).

Anal. Calc. for $C_{18}H_{30}O_4N_8S_2Cd$: C, 36.09; H, 5.05; N, 18.71; Cd, 18.77. Found: C, 35.93; H, 5.14; N, 18.86; Zn, 18.91%. $\Lambda_M = 13.54\ \Omega^{-1}\ cm^2\ mol^{-1}$. λ (max) (in chloroform) 247 nm, 323 nm, 382 nm and 487 nm (shoulder).

2.5. X-ray crystallography

Crystallographic data and refinement details are given in Table 1. Intensity data were measured on a Bruker APEX CCD based diffractometer employing Mo Kα radiation. Data processing and absorption correction were accomplished with SAINT [28]. The structures were solved by direct methods [28] and refinement (anisotropic displacement

parameters, hydrogen atoms in the riding model approximation and weighting scheme of the form $w = 1/[\sigma^2(F_o^2) + (0.0434P)^2]$, where $P = (F)_o^2 + 2F_c^2)/3$ was on F^2). Graphics were obtained with ORTEP 3 for Windows at the 50% probability level [29,30]. Additional figures were drawn with PLATON for Windows [31,32].

3. Results and discussion

Metal template reactions of diacetylemonoxime with morpholine *N*-thiohydrazide in the presence of [PhHg(OAc)] and $[Cd(OAc)_2] \cdot 2H_2O$ produced [PhHg(Hdammthiol)] (**1**) and $[Cd(Hdammthiol)_2]$ (**2**), respectively, with good yields. Elemental analyses confirm these formulations. The molar conductance values suggest their non-electrolytic nature in chloroform. Taking these results and considering the X-ray crystal structures of these complexes (see later discussion), we conclude that the hydrazone ligand transformed to its thiol form (H_2dammthiol) and functions as a monobasic bidentate (NS) donor in the phenylmercury(II) complex and as a monobasic tridentate (NNS) donor ligand in the cadmium(II) complex.

3.1. Crystal structure of [PhHg(Hdammthiol)] (1)

The phenylmercury(II) compound **1** crystallizes in the space group $P\bar{1}$ (2) and the molecule adopts a tricoordinated T-shaped geometry within the crystal (Fig. 1). The mercury(II) atom (Hg1) is coordinated by the phenyl carbon and by S1 and N3 of the hydrazone ligand. The Hg(II) atom is 0.027(1) Å above the plane. Selected bond lengths and angles are given in Table 2.

The Hg1–C1 bond distance of 2.035(4) Å is in the accepted range for unperturbed mercury–carbon bonds (2.05–2.09 Å) [33]. This Hg–C bond distance is shorter than that in the analogous methylmercury(II) compound where Hg–C = 2.09 Å [34]. This may be due to a contribution of electron flow from mercury to the π^* orbitals of the phenyl group in the phenylmercury(II) compound. The Hg–S bond distance of 2.3351(14) Å is similar to that of methylmercury(II) compounds [2.380(3) Å] with a sulfur containing ligand [34]. The Hg–N bond distance 2.543(4) is comparable to the Hg–N distance of an earlier reported organomercury(II) compound [34]. The coordination of nitrogen and sulfur of the thiohydrazone ligand to mercury leads to the formation of a five-membered chelate ring, necessitating deviation of the C_{ph}–Hg–S bond angles from linearity (166.92(10)°), as also shown by the methylmercury(II) compound [34].

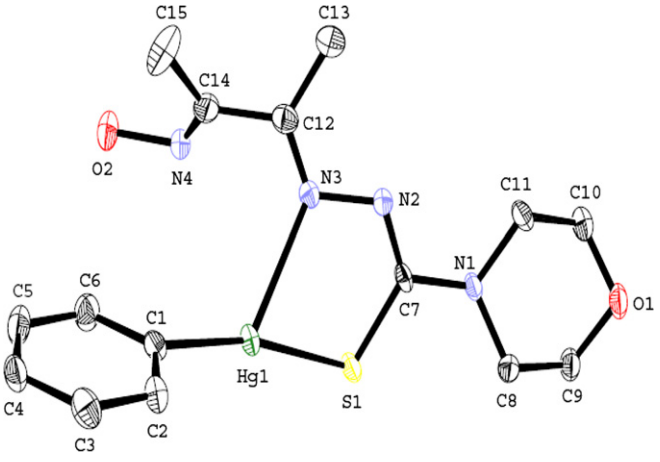

Fig. 1. ORTEP diagram of [PhHg(Hdammthiol)] (**1**) with 50% probability ellipsoids.

The C–S bond distance 1.744(4) Å is shorter than a C–S single bond (1.81 Å) but longer than a C–S double bond (1.62 Å) [35,36] suggesting partial double bond character in the complex, similar to related thiosemicarbazonates of methylmercury(II) and dimethylthallium(III) [34,37,38].

The C–N bond distance of N(3)–C(12) [d(C=N) = 1.270(6) Å] and N(4)–C(14) [d(C=N) = 1.262(6) Å] conform to the double-bond distances and deprotonation of hydrazinic NH proton also induces double bond character to the N(2)–C(7) [d(C=N) = 1.287(5) Å] bond [34,35,37,38].

It is interesting to note that there is no intermolecular π–π interaction between the phenyl rings. But a weak interaction between C(8)–H(8A) and a π group (phenyl ring) links the two phenylmercury molecules into a supramolecular dimer having a C–H···π synthon (Fig. 2). The C–H···π interaction is characterized by the H···Cg distance of 2.84 Å (Cg being the mid point of the phenyl ring) with a C(8)–H(8A)···Cg angle of 136°.

Besides this C–H···π interaction, intermolecular hydrogen bonds (C(2)–H(2)···O(1)[a]; a = $-x$, $1-y$, $1-z$ and C(4)–H(4)···O(2)[b] b = $1-x$, $-y$, $-z$) form a two-dimensional sheet in the *ac* plane (Fig. 3). The D···A separations are 3.228(6) and 3.327(6) Å and the D–H···A angles are 148° and 147°, respectively. The intermolecular hydrogen bonding between O(2)–H(2A) and N(4)[c] (c = $1-x$, $1-y$, $-z$) form a $R_2^2(6)$ synthon. The D···A bond separation is 2.763(5) Å with a D–H···A angle of 147° (Fig. 3).

3.2. Crystal structure of [Cd(Hdammthiol)$_2$] (2)

The cadmium compound crystallizes in the triclinic space group $P\bar{1}$ (2). The cadmium(II) atom is coordinated by two thiohydrazone ligands. The coordination sphere of the Cd(II) centre is best described as a trapezoidal bipyramid (Fig. 4). The S1, N3, N4, N7 atoms define the equatorial plane. The axial positions are occupied by N8 and S2 atoms with a N8–Cd–S2 angle of 142.08(5)°.

The Cd(1)–S(1) and Cd(1)–S(2) bond distances are 2.5684(14) and 2.5646(14) Å, respectively. The Cd(1)–N(3) (2.342(2) Å) and Cd(1)–N(7) (2.331(2) Å) distances are longer than Cd(1)–N(4) (2.495(2) Å) and Cd(1)–N(8) (2.427(2) Å), which are consistent with the Cd–N bond distance of a cadmium hexamine complex [33].

The C–S bond distances of the cadmium complex are 1.735(2) and 1.738(3) Å, and these are shorter than those

Table 2
Selected bond lengths (Å) and bond angles (°) for [PhHg(Hdammthiol)] (**1**) and [Cd(Hdammthiol)$_2$] (**2**)

Complex **1**		Complex **2**

		S(1)–Cd(1)–N(3)	74.26(5)		

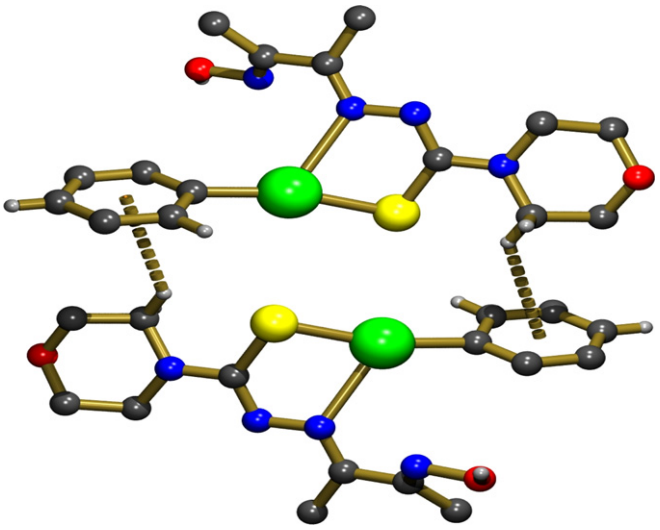

Fig. 2. Two-dimensional supramolecular dimer having a C–H···π synthon of [PhHg(Hdammthiol)] (**1**).

of the mercury complex (d(C–S) = 1.744(4) Å). These bond distances are also shorter than a C–S single bond (1.81 Å) but longer than a C–S double bond (1.62 Å), suggesting partial double bond character in the complex as found in related thiosemicarbazonates [39].

The C–N average bond distance of N(3)–C(12) [d(C=N) = 1.270(6) Å] and N(4)–C(14) [d(C=N) = 1.262(6) Å] conforms to double-bond distances and deprotonation of the hydrazinic NH proton induces double bond character with the result that N(2)–C(7) [d(C=N) = 1.287(5) Å] is close to that of a double bond [34,35,37,38].

Complex **2** forms a 2D supramolecular sheet in the *bc* plane through hydrogen bonding interactions (O–H···O and C–H···O) (Fig. 5). The average D···A separations of O–H···O (O(2)–H(2)···O (3)[d]; d = 1 − x, −y, 1−z and O(4)–H(4)···O(1)[e] d = 2 − x, 2 − y, 2 − z) hydrogen bonds are 2.69 (3) Å and the average D–H···A angle is 144°. The D···A separation of the C–H···O (C(14)–H(14A)···O(4)[f]; f = 1 − x, 1 − y, 1 − z) hydrogen bond is 3.394(3) Å and the D–H···A angle is 145°. These supramolecular sheets stack along [1 0 0] (Fig. 6). No directional weak interactions (π–π, C–H···π, hydrogen bonding) are operative between the two sheets. Thus, an intermolecular Van der Waals interaction is responsible for this stacking. The methyl terminals of the ligand from adjacent sheets face each other in this arrangement.

The crystal structure possesses an impressively short intermolecular C(sp3)···O(sp3) contact [C9···O4* 2.958(3) Å; * = 1 − x, 1 − y, 2 − z]. A CSD search was carried out to query for the intermolecular distance from a

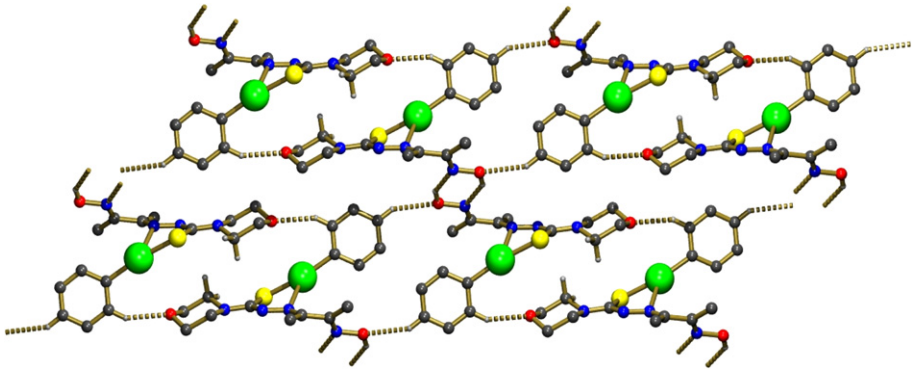

Fig. 3. Two-dimensional O–H···O and C–H···O hydrogen bonded sheet and O–H···N synthons of [PhHg(Hdammthiol)] (**1**).

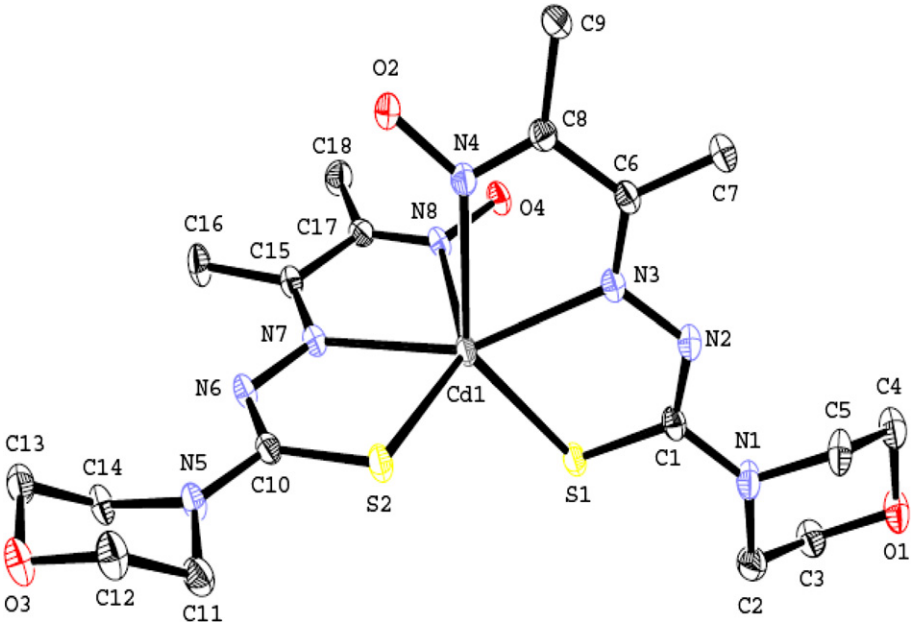

Fig. 4. ORTEP diagram of [Cd(Hdammthiol)$_2$] (**2**) with 50% probability ellipsoids.

N=C(CH3)–C(CH3) = N moiety to an oxime NOH moiety. When the non-bonding interaction between the two fragments was constrained with the O···C distance being less than 3.22 Å, the search resulted in 27 hits with a range 3.033–3.218 Å, and the three shortest distances were 3.033, 3.073 and 3.078 Å [40–42]. A closer look at the geometry of the O(sp3)···C (sp3) contact reported here reveals an interesting packing force using an uncommon interaction (Fig. 7). The O4 atom of the oxime is directed towards the centre of the plane formed by three H atoms (H9A, H9B, H9C) of the methyl group of the propylidene moiety, and is evidenced by the angle ∠C8–C9···O4* of 172.0°. The C9–H9A···O4*, C9–H9B···O4* and C9–H9C···O4* angles are 89.0°, 83.8° and 97.6°, respectively. It is interesting to note that if the strength of the C···O attraction is greater, the ∠C–H···O angle will be less in contrast to the normal C–H···O interaction. So, the angles rendered by the interaction are less than the generally accepted ∠C–H···O angles (~110°). The cooperative effect of the three individual interactions acts on the face of the plane of the three methyl hydrogens of the C9 atom due to their high acidic character. This non-conventional interaction could prove to be a good supramolecular synthon. We may term it as a CH_3···O interaction.

3.3. Comparison between the supramolecular structures

In summary, the hydrogen-bonding motifs of complexes **1** and **2** exhibit unique synergy through linear and cyclic supramolecular assemblies. In complex **1**, the primary structure directing agent is the oxime–oxime interaction which leads to a complimentary hydrogen-bonding $R_2^2(6)$ synthon. Linear C–H···O bonds to both oxime and morpholinic oxygen acceptors guide the assembly into a 2D sheet in the *ac* plane. Further, despite the presence of an aromatic ring no π···π interaction appears, but C–H···π interactions between the 2D sheets lead to the crystal synthesis. In complex **2**, a complimentary hydrogen bond (O–H···O) between the morpholine–oxime moieties prevails along with a C–H···O hydrogen bond. Bertolasi et al., have shown that oximes are able to form three types of hydrogen bonds where the oxygen atom of the oxime can act as a donor as well as an acceptor [43]. Our investigation supports this. The linear O–H···O and C–H···O supramolecular glue generate an infinite sheet architecture in the *bc* plane involving C(3) synthons.

In the literature, molecules (organic or metal complex) bearing non-deprotonated oximes showed the capability of generating aesthetic extended networks with the potential to be a crystal engineering tool [44–46]. The most common hydrogen bonding network arrangement reigning in these systems is the oxime–oxime $R_2^2(6)$ ring, and less often the C(3) chain and $R_2^4(6)(12)$ rings [47,48]. The first two synthons exist in our case also. Aakeröy et al., investigated silver complexes of pyridine–oxime ligands. They showed that the oxime–oxime interaction [$R_2^2(6)$] is not disrupted and is able to withstand the potentially disruptive influences of anions and pyridine–oxime interactions. In complex **2**, we have the opportunity to notice that the morpholine substituted moiety disrupts the $R_2^2(6)$ synthons to C(3) [morpholine···oxime O–H···O] synthons. This shows that morpholine···oxime C(3) synthon is even stronger for this complex.

3.4. ^{1}H NMR and infrared spectra

The ^{1}H NMR spectrum of the mercury complex [PhHg(Hdammthiol)] (**1**) in $CDCl_3$ at room temperature exhibits sharp singlets at δ 3.17 ppm and δ 3.6 ppm due to N–CH_2 (4 H) and O–CH_2 (4H), respectively, of the mor-

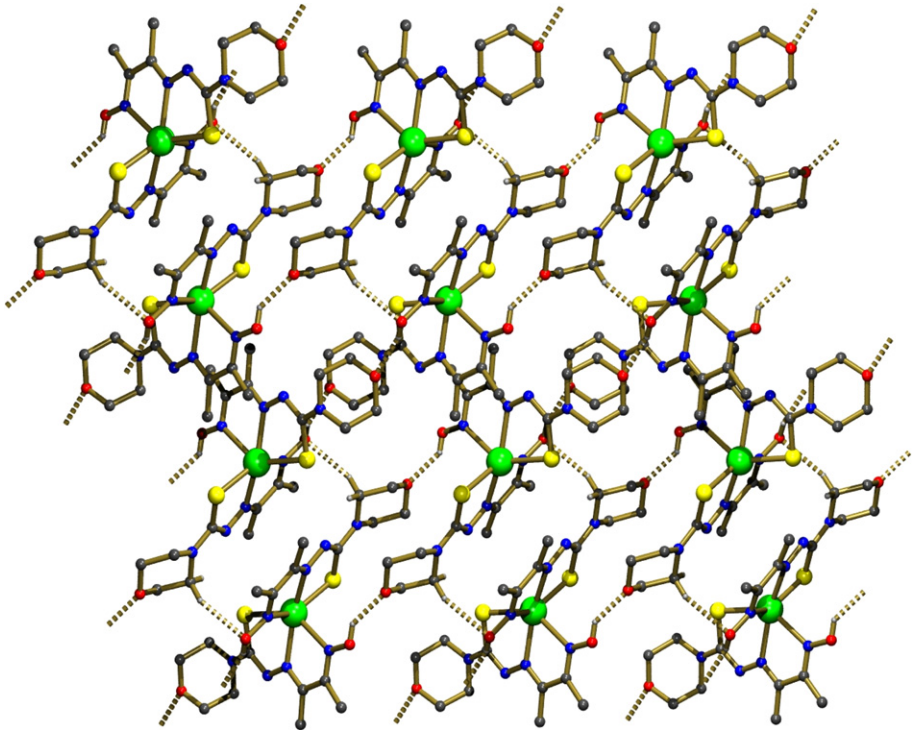

Fig. 5. Two-dimensional hydrogen bonding sheet of [Cd(Hdammthiol)$_2$] (**2**) along the *bc* plane.

pholine ring. Whereas in the cadmium(II) complex [Cd(Hdammthiol)$_2$] (**2**), these resonances are observed at δ 3.27 ppm and δ 3.69 ppm, respectively. These values are consistent with earlier reported values [49]. Two singlets, one at δ 2.50 ppm and another at δ 1.92 ppm, are tentatively assigned to the methyl protons of the mercury com-

pound [50], while the methyl resonances of the cadmium complex are observed at δ 2.32 ppm and δ 2.04 ppm [50]. The aromatic proton resonances of phenylmercury(II) are observed as multiplets in the range δ 7.23–7.44 ppm.

The ν(C=S) of the thioketo form of the ligand generally absorbs at around 800 cm^{-1} in the infrared spectrum [51]. In the phenylmercury(II) and cadmium(II) complexes no such bands were observed in this region; instead bands at 730 cm^{-1} for the phenylmercury(II) complex and 745 cm^{-1} for the cadmium(II) complex were observed and assigned to ν(C–S). This suggests coordination of the phenylmercury(II) and cadmium(II) ions through the thiol sulfur via deprotonation [52]. The broad infrared spectral bands around 3350 cm^{-1} may be assignable to ν_{oxime}(OH), suggesting non-involvement of this group in bond formation in both complexes [53]. The observed bands, one at 1605 cm^{-1} and another at 1580 cm^{-1}, are tentatively assigned to ν_{oxime}(C=N) and $\nu_{hydrazone}$(C=N) groups, respectively [53,54].

4. Conclusion

We have synthesized two new complexes, one with the phenylmercury(II) ion and another with the cadmium(II) ion, involving the thiol form of the ligand diacetylmonoximemorpholine *N*-thiohydrazone. X-ray structure crystallography shows that the phenylmercury(II) complex has an tricoordinated distorted T-shaped topology, while a trapezoidal bipyramidal geometry is present in the cadmium(II) complex. Very few such tricoordinated distorted T-shaped structures for a phenylmercury(II) complex have been reported. Two-dimensional supramolecular assemblies of both the complexes and a new non-conventional $CH_3\cdots O$ interaction in cadmium complex are postulated.

Acknowledgements

One of us (K.D.) is thankful to the University Grants Commission, New Delhi for Emeritus Fellowship and Financial grants to conduct this work. We are also thankful to the Sophisticated Instrumentation Facility, Central Drug Research Institute, Lucknow, India for elemental analysis and spectroscopic data. Facilities provided by the DST, Govt. of India, New Delhi under FIST are also gratefully acknowledged. We are also grateful to the referees for their valuable comments.

Appendix A. Supplementary material

CCDC 653350 and 653351 contain the supplementary crystallographic data for complexes **1** and **2**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2007.07.027.

point apparatus. The IR spectra were obtained by using IR grade KBr disks on a Perkin–Elmer 1600 Series FTIR spectrophotometer in the range of 4000–250 cm^{-1}. The electronic spectra were obtained using a Cary 1E UV–Visible spectrophotometer (Varian). The thermogravimetry/differential thermal analysis (TG/DTA) measurements were run on a Shimadzu DTG-60H. In this study, thermogravimetric curves were obtained with a flow rate of the carrier gas of 100 mL/min and a heating rate of 10 °C/min in nitrogen (3 bar) with an alumina pan. The experiments were carried out in the range 35–750 °C and with a cleaned up range of 750–800 °C under oxygen atmosphere. The recorded data were analyzed with the help of the TA-60 WS Version 2.01 software.

2.2. Synthesis

2.2.1. Ligand (bdmpp)

The ligand bdmpp was prepared from 2,6-dichloropyridine and the potassium salt of 3,5-dimethyl-*N*-pyrazol by refluxing in diglime as described previously in the literature (Scheme 1) [10]. 3,5-Dimethylpyrazol was synthesized by the reaction of hydrazine hydrate and 2,4-pentandione [11].

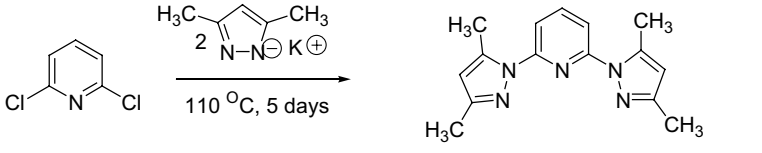
2.2.2. [Hg(bdmpp)(SCN)$_2$] (1)

A 20 ml solution of 2,6-bis(3,5-dimethyl-*N*-pyrazolyl)pyridine (bdmpp) (0.266 g, 1 mmol) in hot acetonitrile was added to a 20 ml hot methanolic solution of $Hg(SCN)_2$ (0.316 g, 1 mmol). The mixture was filtered off while the solution was hot. The resulting mixture was set aside for two days and colourless fine crystals formed. The crystals were filtered off and dried in the open air. Yield: 80%, mp: 201–203 °C, ^{1}H NMR (400 MHz, 25 °C, $CDCl_3$,) 2.44 (s, 6H), 2.60 (s, 6H), 6.20 (s, 2H), 7.42 (d, 2H, $J = 8.12$ Hz), 8.06 (t, 1H, $J = 8.08$ Hz). *Anal.* Calc. for $C_{17}H_{17}HgN_7S_2$: C, 34.96; H, 2.93; N, 16.79. Found: C, 34.62; H, 2.78; N, 16.07. Suitable crystals were selected for the XRD study.

2.3. Computational details

GAUSSIAN03 program package [12] was used in the calculations. The geometry of the title complex was optimized by semi-empirical molecular orbital treatment at both the PM3 level and density functional theory (DFT) using Becke's three-parameter hybrid method (B3) [13] and the exchange functional of Lee, Yang and Parr (LYP) [14] in conjuction with the LANL2DZ basis set, which includes the effective core potential (ECP) proposed by Hay and Wadt, plus double basis-ξ for Cl- and I-atoms [15]. Whether the stationary points were minima or first-order saddle points was determined by analytical computation of vibrational frequencies at the level of geometry optimization.

2.4. X-ray structure determination



Diffraction measurements were made on a three-circle CCD diffractometer using graphite monochromated Mo-K(α) radiation ($\lambda = 0.71073$ Å) at −100 °C for compound **1**. The intensity data were integrated using the SAINT [16] program. Absorption, Lorentz and polarisation corrections were applied. The structure was solved by direct methods and refined by full-matrix least-squares against F^2 using SHELXTL [17]. All non-hydrogen atoms were assigned anisotropic displacement parameters and were refined without positional constraints. Hydrogen atoms were included in idealised positions with isotropic displacement parameters constrained to 1.5 times the U_{eq} of their attached carbon atoms for methyl hydrogens, and 1.2 times the U_{eq} of their attached carbon atoms for all others.

3. Results and discussion

3.1. Description of the crystal structure

Crystal data collection and refinement of the title compound [Hg(bdmpp)(SCN)$_2$] (L = 2,6-bis(3,5-dimethyl-*N*-pyrazolyl)pyridine) is summarized in Table 1. The ORTEP and molecular packing diagrams are displayed in Figs. 2 and 3. Selected bond lengths and angles in the complex are listed in Table 2.

The Hg(II) atom is pentacoordinated, with three nitrogen atoms (N1, N3 and N5) from the 2,6-bis(3,5-dimethyl-*N*-pyrazolyl ligand and two sulfur atoms from the thiocyanate ligand. Both mercury and sulfur atoms

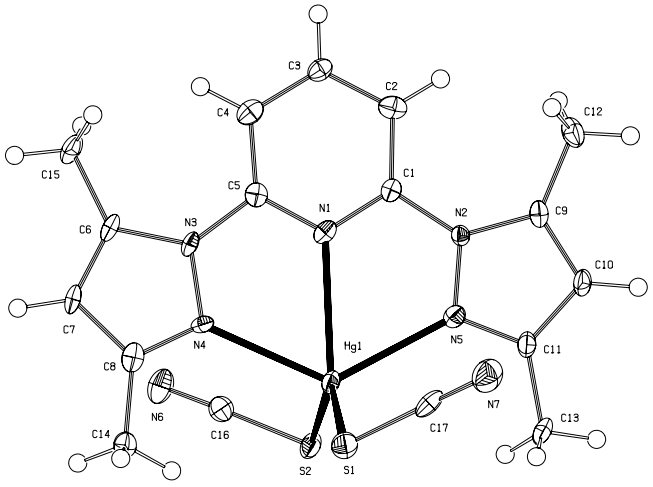

Fig. 2. The molecular structure of the title compound. Displacement ellipsoids are plotted at the 50% probability level.

are soft according to Pearson theory [18], so the thiocyanate ions that are bonded to metal terminally are the S atoms. In five coordinate compounds, the coordination sphere could be described either as square-pyramidal or trigonal bipyramidal, depending on the parameter, $\tau = (\beta - \alpha)/60$ (α and β are the two largest bond angles around the metal ion). When τ is 0, the coordination is assumed to be an ideal square pyramid; for an ideal trigonal bipyramid τ is 1 [19]. The largest bond angles in the coordination sphere are 127.89° [N5–Hg–N4] and 116.36° [S2–Hg–N3], which give a τ value of 0.1921. This value is closer to that of a distorted square-pyramid around the mercury atom.

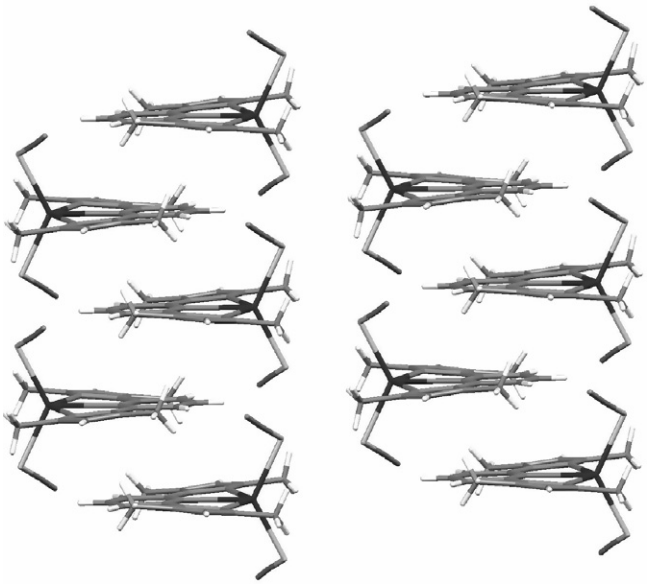

Fig. 3. Packing diagram of the title complex.

The Hg–N bond distances are in the range 2.385(6)–2.557(4) Å, and the Hg–S1 and Hg–S2 bond distances are 2.462(2) and 2.472(2) Å, respectively (Table 2). All the bond lengths and angles are comparable with similar structures [20–22].

3.2. Geometry

PM3 calculations are generally satisfactory for the prediction of structure of organic and organotin compounds [23]. On the other hand, DFT methods are very successful in modelling organic systems [24]. To compare their results for the organomercury compound, the geometry of $[Hg(bdmpp)(SCN)_2]$ was optimized in a singlet state using PM3 and B3LYP/LanL2DZ methods. Selected calculated bond lengths, bond angles and dihedral angles of **1** are gathered in Table 1. The differences among the calculated values of geometrical parameters are insignificant for the PM3 and B3LYP/LanL2DZ methods used. For both calculations, bond angles and dihedral angles remain in sufficient agreement, except for the Hg(1)–S(1)–C(17) bond angle. In particular, the B3LYP/LanL2DZ results are better than those obtained by using PM3. On the contrary, the theoretical bond lengths at the B3LYP/LanL2DZ level are overestimated by 1.5, 5.3, 9.4 and 3.9% for the Hg(1)–N(1), Hg(1)–N(4), Hg(1)–S(1) and S(1)–C(17) bonds, respectively. The bond lengths calculated at the PM3 level are more overestimated for the first two bonds by 15.1% and 5.6%, respectively, but less overestimated for the last two bonds by 0.3% and 2.1%, respectively. Our calculations

Table 2
Selected observed and calculated bond lengths (Å) and angles (°) for the [Hg(bdmpp)(SCN)$_2$] complex

prove that the quality of the data obtained with the DFT method (B3LYP/LanL2DZ) is not much better than that of the semi-empirical data (PM3). The discrepancy between the experimental (X-ray) and calculated values for the atomic coordinates might result from the different environments of a molecule in the experimental crystalline state and in the theoretical gas phase. However, it may be stated that the modelling techniques applied in the present work properly reflect the main properties of the actual structure and can be successfully applied for predicting the features of the [Hg(bdmpp)(SCN)$_2$] complex.

3.3. Spectroscopic properties

3.3.1. FTIR spectra

The IR spectrum of [Hg(bdmpp)(SCN)$_2$] in KBr pellets exhibits two strong bands corresponding to ν(C=N) at 2340 and 2360 cm^{-1}. The band corresponding to the ν(C=S) stretching vibration appears at 785 cm^{-1}. The FTIR spectrum of the free ligand shows weak peaks at 2977, 2921 cm^{-1} and 3134, 3106 cm^{-1}, assignable to CH_3 and aromatic hydrogen bonds, respectively.

For the [Hg(bdmpp)(SCN)$_2$] complex, the experimental IR spectral frequencies were 3054, 2118 and 1599 cm^{-1}, those in the DFT computation were 3051, 2139 and 1631 cm^{-1} and those in the PM3 computations were 3040, 2290 and 1689 cm^{-1}. As can be seen from Table 3, the PM3 results are always higher than the experimental ones. On the contrary, there is no such apparent tendency for the DFT results.

Table 3
The observed and calculated vibrational frequencies of B3LYP/LanL2DZ and PM3 for [Hg(bdmpp)(SCN)$_2$]

Observed frequency	Calculated frequency	
	B3LYP/LanL2DZ	PM3
518	514	616
735	742	677
786	759	726
833	832	857
985	865	994
1039	1011	1074
1138	1130	1093
1303	1324	1292
1347	1351	1339
1383	1385	1389
1447	1410	1460
1560	1604	1578
1599	1631	1689
2118	2139	2290
3054	3051	3040

To make a comparison with the experimental observation, we present correlation graphics in Fig. 4 based on the calculations. It can be seen that both graphs match each other well, but the experimental vibrational frequencies are especially in better agreement with the DFT results at the B3LYP/LanL2DZ level than the semi-empirical results at the PM3 level.

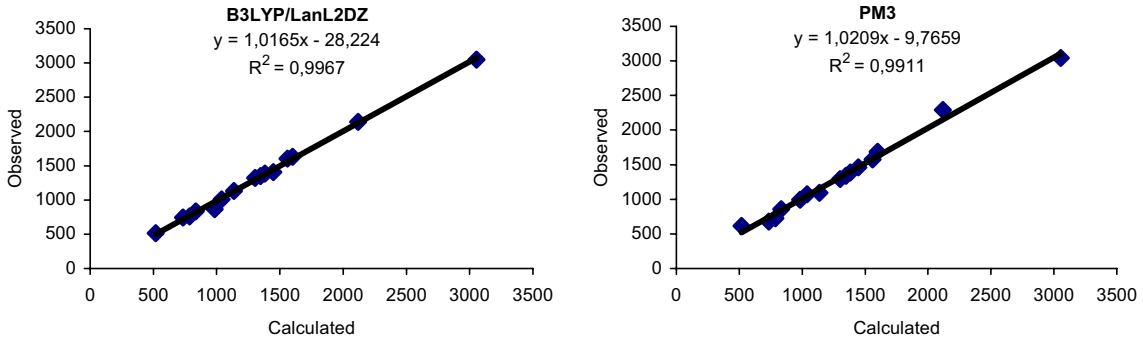

Fig. 4. Correlation graphics of observed and calculated (B3LYP/LanL2DZ and PM3 level) frequencies (cm^{-1}) of $[Hg(bdmpp)(SCN)_2]$.

3.3.2. Absorption spectra

The absorption spectra of the ligand (bdmpp) and complex $[Hg(bdmpp)(SCN)_2]$ were recorded in dimethylformamide. The UV spectra for the ligand and complex show two absorptions bands between 250 and 310 nm. For the bdmpp complex, a band occurs near 267 nm ($\varepsilon_1 = 16{,}000$ M^{-1} cm^{-1}) and 298 nm ($\varepsilon_2 = 17{,}340$ M^{-1} cm^{-1}). The spectrum of the free ligand exhibits intense peaks at 258 (12,800 M^{-1} cm^{-1}) and 300 nm. This indicates ligand-centered bands occur in this region, though other charge-transfer transitions also may contribute significant intensity. A similar observation was mentioned by Willison et al. [25].

3.4. Thermal analysis

The TGA and DTA analysis of $[Hg(bdmpp)(SCN)_2]$ was investigated both under inert and open-air atmosphere. Thermal analysis shows the weight lost under a nitrogen atmosphere between 188 and 227 °C is about 44–45%, which is nearly the same with the mass of the bdmpp ligand in the complex and, at 201 °C the melting peak point can be observed easily. Between 277 and 440 °C there is a new decomposition observed and approximately at 700 °C the mass nearly vanishes. This situation shows that $Hg(SCN)_2$ in the medium turns to gas by decomposing first fast and then slowly.

3.5. Orbitals

In the conjugated molecules, the frontier molecular orbital energies play an important role in the electric and optical properties, as well as in UV–Vis spectra and chemical reactions [26]. (Fig. 5) shows the distributions and energy levels of the HOMO − 1, HOMO, LUMO and LUMO + 1 orbitals computed at the B3LYP/LanL2DZ level for the HgSCN complex. The HOMO–LUMO gap is 0.141 eV, so electron movement between these orbitals could easily occur so that we observe a peak around 310 nm in the UV–Vis spectrum. Moreover, one can see that the HOMO − 1 and HOMO are substantially localized on the SCN parts of the complex. On the contrary, LUMO and LUMO + 1 are mainly confined in the aromatic part of the complex.

4. Conclusion

Pseudohalide ions are attractive as co-ligands due to their bridging of metal ions to each other and neutralizing the charges of the complexes. In addition, the aim of this study was to form mononuclear complex structures coordinated by bdmpp with the help of cyanate. The structure of the title complex has been characterized by X-ray diffraction and by means of elemental analyses, IR and electronic spectra. Studies along these lines are currently in progress in our laboratory.

employed as either homogeneous [2] or heterogeneous [3] catalysts in a variety of chemical reactions. Rhodium-based homogeneous catalysts in particular may be used *inter alia* in carbon–carbon bond formation [4], cyclopropanation [5], decarbonylation of aldehydes [6], hydroboration of olefins [7], hydroformylation of olefins [8], hydrogenation [9], hydrosilation [10] and carbon monoxide insertion reactions [11–13]. Oxidative addition of iodomethane to square planer rhodium(I) or iridium(I) complexes and subsequent CO insertion reactions is important in the Monsanto and Cativa industrial processes [12,14] for the production of acetic acid from methanol. The rate-determining step in the rhodium-based Monsanto process is the oxidative addition of methyl iodide to $[Rh(CO)_2I_2]^-$. In contrast, during *cis*-$[Ir(CO)_2I_2]^-$-catalyzed methyl carbonylation in the Cativa process, CO insertion in $[CH_3Ir(CO)_2I_3]^-$ to give $[(CH_3CO)Ir(CO)_2I_3]^-$ is rate-determining. It is known [15–17] that rhodium(I) complexes of the type $[Rh(L,L')(CO)(PPh_3)]$, L,L′ = mono charged bidentate ligands, can also facilitate the formation of an acetyl species following oxidative addition of methyl iodide. Depending on what L,L′ is, a variety of reaction mechanisms for this reaction has been reported. These mechanisms are summarized in Eq. (1) (L,L′) = methyl(2-methyl-amino-1-cyclopentene-1-dithiocarboxylato, [17]), (2) (L,L′ ¯thioacetylacetonato [15d]), (3) (L,L′ = *inter alia* 1,1,1-trifluoro-2,4-pentanedionato [15a]) and (4) (L,L′ = *inter alia* 2,4-pentanedionato [15b]) below. The notation Rh^{III}-alkyl1 and Rh^{III}-acyl1 in the four equations below indicates the first formed alkylated, $[Rh^{III}(R)]$, or acylated rhodium(III) species, $[Rh^{III}(COR)]$. When the last number in the notation changes to "2", such as in Rh^{III}-alkyl2 in Eqs. (3) and (4), it shows that after the first alkylated or acylated species has formed, it converted to a second, different but more stable, alkylated or acylated geometrical isomer.

$$Rh^{I} + CH_3I \underset{k_{-1}}{\overset{k_1,K}{\rightleftharpoons}} Rh^{III}\text{-alkyl1} \xrightarrow{k_2} Rh^{III}\text{-acyl1} \quad (1)$$

$$Rh^{I} + CH_3I \xrightarrow{k_1} Rh^{III}\text{-alkyl1} \xrightarrow{k_2} Rh^{III}\text{-acyl1} \quad (2)$$

$$Rh^{I} + CH_3I \underset{k_{-1}}{\overset{k_1,K}{\rightleftharpoons}} Rh^{III}\text{-alkyl1} \overset{k_2}{\mapsto} Rh^{III}\text{-acyl1} \xrightarrow{k_3} Rh^{III}\text{-alkyl2} \quad (3)$$

$$Rh^{I} + CH_3I \underset{k_{-1}}{\overset{k_1,K}{\rightleftharpoons}} Rh^{III}\text{-alkyl1} \underset{k_{-2}}{\overset{k_2}{\rightleftharpoons}} Rh^{III}\text{-acyl1} \underset{k_{-3}}{\overset{k_3}{\rightleftharpoons}} Rh^{III}\text{-alkyl2} \quad (4)$$

In, for example, Eq. (4), $[Rh(H_3CCOCHCOCH_3)(CO)(PPh_3)(CH_3)(I)]$ would be a typical formula describing the two different Rh^{III}-alkyl1 or Rh^{III}-alkyl2 geometrical isomers. The first example of a single crystal structure determination of a Rh^{III}-alkyl species of this type is described later in this publication and Fig. 8 shows clearly the coordination modes. For the Rh^{III}-acyl1 isomer of Eq. (4), the formula $[Rh(H_3CCOCHCOCH_3)(COCH_3)(PPh_3)(I)]$ is representative. Structurally it differs from the alkyl species in that the CO ligand inserted between the Rh center and the alkyl, here a methyl ligand, to generate an acyl ligand.

We were interested to establish whether a ferrocenyl (Fc) fragment as part of the β-diketonato ligand in complexes of the type [Rh(β-diketonato)(CO)(PPh$_3$)] may enhance acyl formation during oxidative addition. Utilizing L,L′ = $(FcCOCHCOCF_3)^-$ = fctfa, we show with this communication that incorporation of the ferrocenyl group in the β-diketonato ligand significantly enhances the rate of acyl formation as well as the ensuing carbonyl insertion and deinsertion to form new Rh^{III}-alkyl and Rh^{III}-acyl species during the oxidative addition of CH_3I to [Rh(fctfa)-(CO)(PPh$_3$)]. We especially demonstrate how a variety of different spectroscopic techniques (UV/Vis, IR, ^{1}H and ^{31}P NMR) may be used to obtain different information packages and a better insight into the overall process that takes place during this general type of reaction. Especially satisfying was the realization that each of the previous proposed mechanisms (Eqs. (1)–(4)) are only special cases of the more general mechanism given in the abstract for the reaction between [Rh(fctfa)(CO)(PPh$_3$)] and CH_3I.

2. Experimental

2.1. Materials and apparatus

NMR measurements, at 298 K unless otherwise stated, were recorded on a Bruker Advance DPX 300 NMR spectrometer [^{1}H (300.130 MHz), and ^{31}P (121.495 MHz)]. Chemical shifts are reported as δ values relative to $SiMe_4$ at 0 ppm for the ^{1}H spectra or relative to 85% H_3PO_4 at 0 ppm for the ^{31}P spectra. Infrared spectra were recorded on a Hitachi 270-50 infrared spectrometer either in a KBr matrix or in chloroform or acetone solutions. UV measurements were recorded on a GBC-916 UV/Vis spectrometer. Liquid reactants and solvents were distilled prior to use, water was double distilled. DMF was dried according to published methods [18]. Solutions of [Rh(fctfa)(CO)(PPh$_3$)] in acetone, methanol, ethyl acetate, benzene and chloroform [19] were tested for stability by means of ^{1}H NMR and overlay IR and UV spectra for at least 24 h.

Synthesis of [Rh(fctfa)(CO)(PPh$_3$)(CH$_3$(I)]: Methyl iodide (1.9 g, 13.4 mmol) was added to [Rh(fctfa)-(CO)(PPh$_3$)] [20] (75 mg, 0.1 mmol) dissolved in hexane (70 ml) at 30 °C. N_2 was purged through the reaction vessel before it was sealed and left at room temperature in the dark. After 5 days crystals suitable for X-ray structure determination were obtained from the reaction mixture, 90% yield, m.p.: 235 °C; C, 47.5; H 3.2, $C_{34}H_{28}F_3FeO_3$-RhPI requires C, 47.6; H, 3.3%). IR (KBr), ν_{max}/cm^{-1}: 2056 (C=O); ^{1}H NMR($CDCl_3$): isomer A: 1.78 (3H, d d, CH_3), 4.30 (5H, s, C_5H_5 and 1H, m, C_5H_4), 4.40 (1H, m, C_5H_4), 4.48 (1H, m, C_5H_4), 4.77 (1H, m, C_5H_4), 5.31 (1H, s, CH) and 7.25–7.50 (15H, m, aromatic); isomer B: 1.78 (3H, d d, CH_3), 4.24 (5H, s, C_5H_5 and 1H, m, C_5H_4), 4.38 (1H, m, C_5H_4), 4.60 (1H, m, C_5H_4), 4.80

(1H, m, C_5H_4), 5.45 (1H, s, CH) and 7.25 – 7.50 (15H, m, aromatic).

2.2. Crystallography

Crystal density of [Rh(fctfa)(CO)(PPh_3)CH_3(I)] was determined by flotation in sodium iodide solution. A crystal of dimensions $0.075 \times 0.150 \times 0.650$ mm was used for data collection on a Syntex P-1 diffractometer with Nb filtered utilizing Mo Kα radiation. The $\omega/2\theta$-scan technique was used with variable scan width $\Delta\omega = (0.43 + 0.34 \tan\theta)°$, scan speed 5.49° min^{-1} in ω and a maximum scan time of 60 s per reflection. Unit cell parameters were determined from least-squares refinement of 25 reflections with $15 < \theta < 20°$ (total measuring range $3 < \theta < 25°$). Empirical absorption corrections [21] were applied with minimum and maximum correction factors of 0.4529 and 0.7413, respectively. The mean intensity of three standard reflections, measured over 7200 s of X-ray exposure time, varied from the initial value by less than −1%. All possible reflections with $(\sin\theta)/\lambda < 0.59$ Å^{-1} in the range $-12 < h < 12.0 < k < 18.0 < l < 24$ were measured, giving 4420 unique reflections of which 4414 were considered observed [$I > 2.0\sigma(I)$]. The structure was solved by the heavy-atom method using SHELXS86 [22] and was subjected to anisotropic full-matrix least-squares refinement on F (a total of 380 parameters refined) using SHELXS93 [23]. The H-atom positions were calculated riding on the adjacent C atoms assuming C–H = 0.930 Å, and were refined with an overall temperature factor. Neutral-atom scattering factors were taken from Cromer and Mann [24] and anomalous-dispersion corrections for rhodium from *International Tables for X-ray Crystallography* [25]. Final $R = 0.0588$ and $wR = 0.1692$ (unit weights), $(\Delta\rho)_{max} = 1.841$, $(\Delta\rho)_{min} = -1.087$ e Å^{-3} and $(\Delta/\sigma)_{max} = -0.745$. The high value of the maximum residual electron density $(\Delta\rho)_{max}$ of 1.841 is due to irrelevant peaks near the heavy Rh-atom.

2.3. Kinetic measurements

The kinetic rate constants were determined utilizing UV/Vis (by monitoring the change in absorbance at 375, 400, 530 and 580 nm), IR (by monitoring formation and disappearance of the carbonyl peaks at 2082, 2064, 1990, 1729 and 1714 cm^{-1}), ^1H and ^{31}P NMR spectroscopy (by monitoring the change in integration units of the various signals with time as specified in Table 2 and Fig. 6). A linear relationship between UV absorbance, A, and concentration, C, confirmed the validity of the Beer Lambert law ($A = \varepsilon Cl$ with l = path length = 1 cm) for the [Rh(fctfa)(CO)(PPh_3)] complex. All kinetic measurements were monitored under pseudo first-order conditions with CH_3I concentrations 7–10 000 times the concentration of the [Rh(fctfa)(CO)(PPh_3)] complex. At least five different concentrations within this range were utilized. The concentration of [Rh(fctfa)(CO)(PPh_3)] was $\leqslant 0.0004$ mol dm^{-3} for UV/Vis measurements and $\leqslant 0.01$ mol dm^{-3} for IR and NMR measurements. The activation parameters $\Delta H^{\#}$, $\Delta S^{\#}$ and $\Delta G^{\#}$ for the reaction in chloroform and acetone were obtained from kinetic runs between 15.0 and 35.0 °C. At least three temperatures, held constant within 0.1 °C, were employed to establish the temperature dependence for each substitution reaction.

2.4. Calculations

Pseudo first-order rate constants, k_{1obs}, for reaction set 1 were calculated by fitting kinetic data to the first-order equation [26]

$$[A]_t = [A]_0 \exp(-k_{1obs} t) \tag{5}$$

with $[A]_t$ and $[A]_0$ the absorbance of the indicated species at time t and 0 (UV/Vis or IR experiments), or integral values for the specified peaks on NMR spectra, and were converted to second order rate constants, k_1, by determining the slope of the linear plots of k_{1obs} against the concentration of the incoming CH_3I ligand with

$$k_{obs} = k_{-1} + k_1[CH_3I] \tag{6}$$

Here k_{-1} is the first-order rate constant for the reverse step [26] in the general mechanism

$$A + CH_3I \underset{k_{-1}}{\overset{k_1}{\rightleftharpoons}} B$$

with A = [Rh(fctfa)(CO)(PPh_3)] and B = {[Rh(fctfa)(CH_3)(CO)(PPh_3)(I)] ⇌ [Rh(fctfa)($COCH_3$)(PPh_3)(I)]}, or more conveniently expressed as [Rh^{III}-alkyl1 ⇌ Rh^{III}-acyl1]. First-order rate constants for reaction set 2, k_3, and reaction set 3, k_4, were also determined from Eq. (5) by replacing k_{1obs} with k_3 or k_4. Kinetic data for the consecutive reaction treatment [26] of IR data obtained in acetone and applicable to the general reaction $A \xrightarrow{k_1} B \xrightarrow{k_3} C$ were fitted to Eq. (5) when monitoring the disappearance of A, Eq. (7) for monitoring the appearance and disappearance of B and Eq. (8) for monitoring the appearance of C, here Rh^{III}-alkyl2. A and B were defined above.

$$[B]_t = \frac{k_{1obs}[A]_0}{k_3 - k_{1obs}} [\exp(-k_{1obs} t) - \exp(-k_3 t)] \tag{7}$$

$$[C]_t = [A]_0 \left\{ 1 - \frac{1}{k_3 - k_{1obs}} [k_3 \exp(-k_{1obs} t) - k_{1obs} \exp(-k_3 t)] \right\} \tag{8}$$

Activation parameters [26] were obtained from a fit on Eq. (9) with k_i ($i = 1, 3$) the kinetic rate constants for reaction steps 1 and 3.

$$\ln \frac{k_i}{T} = -\frac{\Delta H^{\#}}{RT} + \frac{\Delta S^{\#}}{R} + \ln \frac{k_B}{h} \tag{9}$$

All kinetic mathematical fits were done utilizing the fitting program MINSQ [27]. The error of all the data is presented according to crystallographic conventions. For example $k_{1obs} = 0.0446(1)$ s^{-1} implies $k_{1obs} = 0.0446 \pm 0.0001$ s^{-1}.

3. Results and discussion

3.1. The UV/Vis study, solvent and temperature dependence

As illustrated in Fig. 1, three general reaction steps for the oxidative addition reaction between CH_3I and [Rh(fctfa)(CO)(PPh_3)] could be identified by UV/Vis spectrophotometry. Due to the larger change in absorbance for the second and third reaction step at 375 nm, more accurate k_3 and k_4 rate constants were obtainable at this wavelength. For reaction step 1, data obtained at 530 nm gave more accurate k_1 and k_{-1} rate constants.

The first reaction showed a first-order dependence on CH_3I, while the second and third (not illustrated) reactions are independent (i.e. zero order) of CH_3I concentration, Fig. 2. It is clear that the relationship between k_{1obs} and [CH_3I] in chloroform does not pass through the origin. This implies [26] that reaction step one is an equilibrium process of the form

$$A + B \underset{k_{-1}}{\overset{k_1}{\rightleftharpoons}} C$$

However, when the reaction was studied in methanol, acetone, ethyl acetate and benzene, k_{-1} was found to be so small as to be undetected. The temperature dependence in chloroform for the first and second stages of the oxidative addition reaction is also demonstrated in Fig. 2.

The increase in the rate of the first step of oxidative addition depends linearly on the dielectric constant, DE [28], of each solvent, Fig. 3. Chloroform does not fit the trend suggested by the other solvents because it follows a different mechanism (k_{-1} is measurable).

Rate constants, results of the solvent dependence study and activation parameters which were obtained from the temperature dependence study utilizing Eq. (9) are summarized in Table 1.

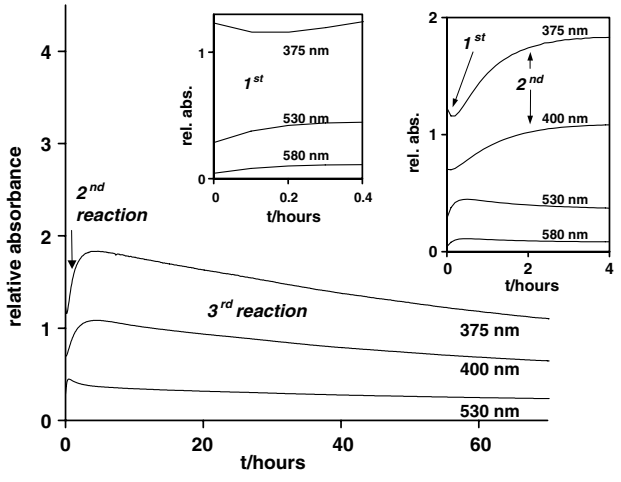

Fig. 1. Relative absorbance *vs.* time data at 25 °C for the UV/Vis monitored oxidative addition of CH_3I to [Rh(fctfa)(CO)(PPh_3)] in chloroform at the indicated wavelengths for the first reaction step (insert top left), the second reaction step (insert top right) and the third reaction step (main graph, starting at approximately 5 h), [Rh(fctfa)(CO)(PPh_3)] = 0.00015 mol dm^{-3}, [CH_3I] = 0.1416 mol dm^{-3}.

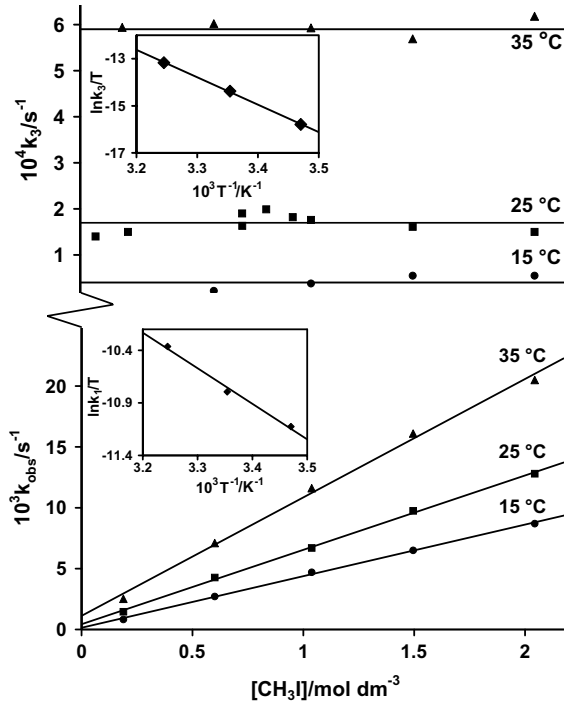

Fig. 2. CH_3I concentration dependence for the UV/Vis monitored oxidative addition of CH_3I to [Rh(fctfa)(CO)(PPh_3)] in chloroform at 530 nm for the first reaction step, bottom, and for the second reaction step, top. Insets: The linear dependence between $\ln(k/T)$ and $1/T$ allowed the determination of activation parameters.

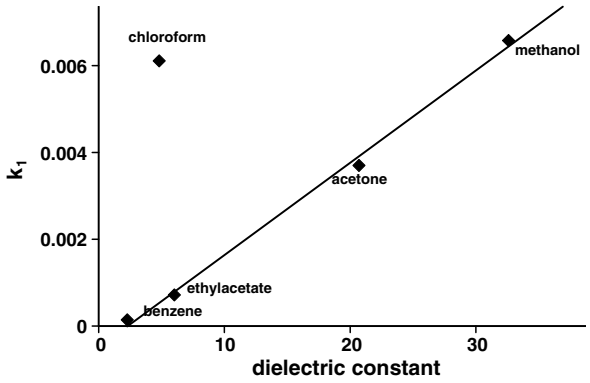

Fig. 3. Relationship between the second-order rate constant, k_1, in units of $dm^3\ mol^{-1}\ s^{-1}$, and the dielectric constant of the solvent during the UV monitoring of the first reaction set of the oxidative addition of CH_3I to [Rh(fctfa)(CO)(PPh_3)] at 25 °C.

Of special interest is the observation that $\Delta S^{\#}$ values for all the reaction steps that are independent of [CH_3I] (the k_{-1} and k_3 steps), approaches zero within experimental error, whereas $\Delta S^{\#}$ for the second order reaction step related to k_1 are large negative. This is consistent with an interpretation that the transition state for the forward step 1 reaction occurs via an associative mechanism where the coordination number changes from 4 to 6. For the other reaction steps, the coordination number changes from 6 to 5 implying the transition state undergoes much less dramatic coordination changes. This results in $\Delta S^{\#}$ approaching zero.

Table 1
Kinetic rate constants for the oxidative addition reaction of CH_3I to [Rh(fctfa)(CO)(PPh_3)] as obtained by various spectroscopic methods at 25 °C by considering each reaction step in isolation during data work-up with Eq. (5), as well as by a consecutive reaction treatment of data with Eqs. (7) and (8)

Activation parameters in $CHCl_3$ are summarized in the table heading. RS is the reaction sequence and Et is the ethyl.

[a] DE is the dielectric constant at 25 °C, except for $CHCl_3$ where DE is at 20 °C. The sited wave lengths were used to monitor the reaction by UV/Vis in $CHCl_3$.

[b] Units of $\Delta H^{\#}$ is kJ mol^{-1}, that of $\Delta S^{\#}$ is J mol^{-1} K^{-1}. For the extremely slow reaction sequence 3 ($t_{1/2} < 35$ h), no activation parameters were determined. Also, k_{-3} and $k_{-4} \neq 0$ but *very* small.

[c] Cited rate constants are the average from several reactions with different CH_3I concentrations.

[d] In acetone, $\Delta H^{\#} = 50(4)$ kJ mol^{-1}, $\Delta S^{\#} = -124(4)$ J mol^{-1} K^{-1}.

[e] IR data for each reaction set fitted to the indicated kinetic model Eqs. (5), (7) or (8), conditions for the consecutive reaction treatment of IR data were $[CH_3I] = 0.2604$ mol dm^{-3}, [Rh(fctfa)(CO)(PPh_3)] = 0.002 mol dm^{-3}, $T = 25$ °C.

Results of the UV/Vis section only of this study are interpreted to imply that the first reaction step represents an oxidative addition process whereby the Rh^{I} nucleus converts to a Rh^{III} nucleus. The product of this oxidative addition step may be either an alkyl or acyl species, [Rh(fctfa)(CH_3)(CO)(PPh_3)(I)] or [Rh(fctfa)($COCH_3$)(PPh_3)(I)] (or both), but the UV/Vis technique cannot distinguish between these possibilities. Since the second and third reaction steps are independent of [CH_3I], one may deduce that these two reactions either involve slow solvent exchange with any of the ligands of the newly formed Rh^{III} complex or it may be isomerization from an alkyl to an acyl product (or *vice versa*). To obtain more insight on the nature of the Rh^{III}-products, an infrared study of the reaction was conducted as this technique is ideal to distinguish between metal–CO bonds that vibrates at ~1900–2100 cm^{-1}, and metal–$COCH_3$ bonds that vibrates at ~1600–1800 cm^{-1}.

3.2. Infrared study

3.2.1. Chloroform as solvent

Three reaction steps could also be identified by IR spectroscopy, Fig. 4. In the first reaction step, the rate of disappearance of the Rh^{I} species [Rh^{I}(fctfa)(CO)(PPh_3)] in chloroform at 25 °C, as monitored by the disappearance of the CO peak at 1990 cm^{-1} corresponds exactly with the rate of formation of *both* a Rh^{III}-alkyl1 species, [Rh^{III}-(fctfa)(CH_3)(CO)(PPh_3)(I)], monitored by the appearance of the CO-peak at 2082 cm^{-1}, and a Rh^{III}-acyl1 species, [Rh^{III}(fctfa)($COCH_3$)(PPh_3)(I)], monitored at 1729 cm^{-1}. The half-life of the first reaction step under pseudo first-order conditions with [CH_3I] = 1.673 mol dm^{-3} and at 25 °C, Fig. 4, is 63 s. Since it is highly unlikely that the Rh^{III}-acyl1 species can be formed by fast isomerization of an *undetected* Rh^{III}-alkyl species with total different ligand coordination pattern than the *detected* Rh^{III}-alkyl1 species at *exactly* the same rate as the detected Rh^{III}-alkyl1 species, this result is considered to imply that an equilibrium exist between the Rh^{III}-alkyl1 and Rh^{III}-acyl1 species that is fast enough to be maintained on the time scale of [Rh(fctfa)-(CO)(PPh_3)] disappearance. The same conclusion could be drawn using ^1H NMR data and will be discussed under the NMR heading. This first set of reactions may, therefore, be presented by reaction sequence (10) where k_i represents forward rate constants and k_{-i} reverse rate constants, $i = 1$ or 2.

$$[Rh^{I}(fctfa)(CO)(PPh_3)] + CH_3I \underset{k_{-1}}{\overset{k_1}{\rightleftharpoons}} \left[Rh^{III}\text{-alkyl1} \underset{k_{-2}}{\overset{k_2}{\rightleftharpoons}} Rh^{III}\text{-acyl1}\right] \quad (10)$$

The k_{-1} step in Eq. (10) was only detected in $CHCl_3$ solutions. The equilibrium constant between the Rh^{III}-alkyl1 and Rh^{III}-acyl1 species is defined as $K_2 = k_2/k_{-2}$. Pseudo first-order rate constants k_{1obs} for reaction 10 utilizing nine different CH_3I concentrations between 0.12 and 1.70 mol dm^{-3} were determined. A graph (not shown) of k_{1obs} *versus* [CH_3I] in chloroform solution, was linear with *y*-intercept 0.0006(2) s^{-1}. This satisfies Eq. (6) with

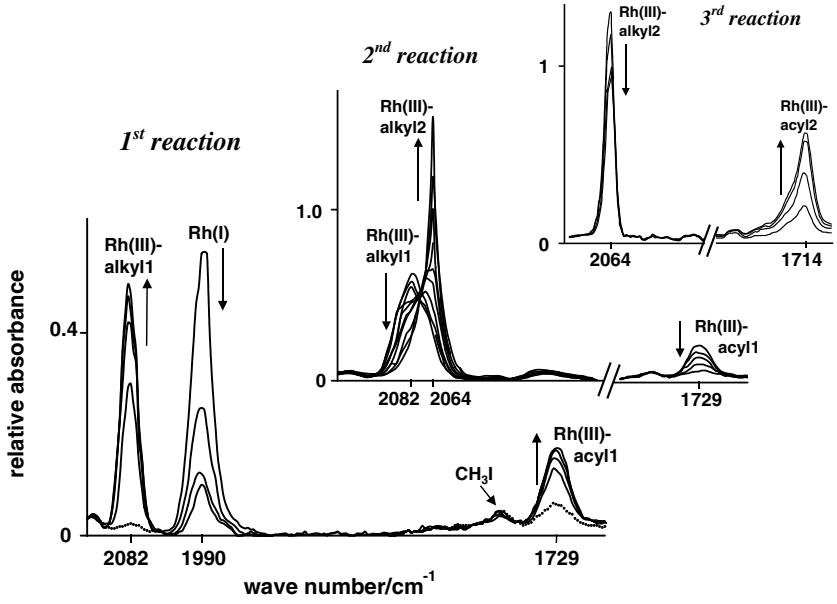

Fig. 4. The reaction between CH_3I (1.673 mol dm^{-3}) and [Rh(fctfa)(CO)(PPh_3)] (0.0100 mol dm^{-3}) in chloroform at 25 °C as monitored by IR spectroscopy. The first set of reactions (bottom spectrum, spectrum times are $t = 0$ (.....), not shown for Rh^{I} due to high amplitude), 74, 149, 224 and 299 s) shows the disappearance of Rh(I) at 1990 cm^{-1} ($k_{1obs} = 0.011\ s^{-1}$) and the simultaneous appearance at the same rate of a Rh^{III}-alkyl1, at 2082 cm^{-1}, and a Rh^{III}-acyl1 species at 1729 cm^{-1}. The middle insert illustrates the simultaneous disappearance of Rh^{III}-alkyl1 ($t = 554$, 734, 1094, 1919, 2819, 3719, 4905, 7605, 10305 and 20205 s) and Rh^{III}-acyl1 ($t = 554$, 1919, 3719, 7605 and 20205 s) and the formation of a Rh^{III}-alkyl2 species at 2064 cm^{-1} ($k_3 = 0.00017(3)\ s^{-1}$ for all three cases) during the second set of reactions. The third set of reactions (top right inset) is illustrated by the disappearance of the Rh^{III}-alkyl2 species (spectra were recorded at $t = 40408$, 121558, 248726 and 335308 s) and the simultaneous formation of a new Rh^{III}-acyl2 species at 1714 cm^{-1} ($k_4 = 4.3(2) \times 10^{-6}\ s^{-1}$).

k_1 the second order forward rate constant and k_{-1} the first-order reverse rate constant for reaction (10). Individual values for k_1 and k_{-1} are tabulated in Table 1. The mutual consistency of k_1 and k_{-1} values as determined by the UV/Vis and IR methods are obvious.

A second, much slower ($t_{1/2} \approx 1.1$ h ≈ 4000 s) set of reactions that are CH_3I independent is illustrated in the middle insert in Fig. 4, where the Rh^{III}-acyl1 species at 1729 cm^{-1} and the Rh^{III}-alkyl1 species at 2082 cm^{-1} both disappear at the same rate ($k_2 = 0.00017(1)$ s^{-1}) as the formation of a new Rh^{III}-alkyl2 geometrical isomer ($k_3 = 0.00017(3)$ s^{-1}) at 2064 cm^{-1}. Again, this is regarded as additional proof that the equilibrium between the Rh^{III}-acyl1 species and the Rh^{III}-alkyl1 species is fast. The $[CH_3I]$-independent second reaction step is $0.011/0.00017 \approx 65$ times slower (from rate constants from Fig. 4) than the $[CH_3I]$-dependent first reaction at $[CH_3I] = 1.673$ mol dm^{-3}. Kinetic data of the second reaction is consistent with the equilibrium

$$A \underset{k_{-3}}{\overset{k_3}{\rightleftharpoons}} B \tag{11}$$

where $A = [Rh^{III}\text{-alkyl1} \rightleftharpoons Rh^{III}\text{-acyl1}]$ and $B = Rh^{III}$-alkyl2. As discussed later, $k_{-3} \lll k_3$. The structure of the Rh^{III}-alkyl2 geometrical isomer having the molecular formula $[Rh^{III}(fctfa)(CH_3)(CO)(PPh_3)(I)]$ has also been solved and is reported later in this publication.

The second set of reactions was followed by a very slow ($t_{1/2} \approx 40$ h) $[CH_3I]$-independent third reaction and corresponds to the slow first-order disappearance of the Rh^{III}-alkyl2 species ($k_4 = 4.9(5) \times 10^{-6}$ s^{-1}) at 2064 cm^{-1} and the appearance, at the same rate, of a new Rh^{III}-acyl2 geometrical isomer at 1714 cm^{-1} ($k_4 = 4.4(2) \times 10^{-6}$ s^{-1}, Fig. 4, top right inset). The long half-life of the third reaction implied that it could not be followed with great accuracy, as solvent evaporation became difficult to control. The kinetic data of the third reaction is consistent with the general reaction sequence

$$Rh^{III}\text{-acyl2} \xrightarrow{k_4} Rh^{III}\text{-alkyl2} \tag{12}$$

Utilizing the combined information obtained by the UV/Vis and IR study only, the overall reaction sequence for this oxidative addition reaction may therefore be represented as

$$\begin{array}{c} [Rh^{I}(fctfa)(CO)(PPh_3)] + CH_3I \\ k_{-1} \uparrow\downarrow k_1 \\ \left[\begin{array}{c} [Rh^{III}(fctfa)(CH_3)(CO)(PPh_3)(I)]^1 \\ k_{-2} \uparrow\downarrow k_2 \\ [Rh^{III}(fctfa)(COCH_3)(PPh_3)(I)]^1 \end{array}\right] \\ \downarrow k_3 \\ [Rh^{III}(fctfa)(CH_3)(CO)(PPh_3)(I)]^2 \\ \downarrow k_4 \\ [Rh^{III}(fctfa)(COCH_3)(PPh_3)(I)]^2 \end{array} \tag{13}$$

where the superscripts "1" and "2" refer to Rh^{III}-alkyl1, Rh^{III}-acyl1, and Rh^{III}-alkyl2 or Rh^{III}-acyl2, respectively. As was the case with the first set of reactions, k_3 and k_4 obtained by the IR method are consistent with the results from the UV/Vis method.

3.2.2. Consecutive reaction treatment in acetone as solvent

In chloroform, the k_{obs} *versus* $[CH_3I]$ graph for the first step did not pass through the origin for both the UV/Vis and IR detection methods, and this is indicative of a noticeable equilibrium in the first reaction step of the total reaction. However, IR results in acetone indicate, in agreement with the UV/Vis results in acetone (Table 1), that this equilibrium was shifted so far to the right that the k_{-1} step is not observable. The apparent absence of a k_{-1} step in acetone allowed us to treat results from an IR study in acetone utilizing consecutive reaction kinetic models.

The IR observed reaction sequence of this reaction in acetone in the range 1960–2100 cm^{-1} was basically the same as observed in chloroform. However, the formation of the Rh^{III}-acyl complexes could not be measured due to the strong IR absorbance of the solvent, acetone, in the 1650–1800 cm^{-1} region. The Rh^{I} peak was monitored at 1987 cm^{-1} and the Rh^{III}-alkyl1 and Rh^{III}-alkyl2 species at 2082 and 2059 cm^{-1}, respectively. By treating data for every reaction sequence in isolation utilizing Eq. (5), as was done in chloroform, rate constants was determined for all the reaction steps and corresponded to those of the UV/Vis study. Rate constants are listed in Table 1.

Because the equilibrium K_2 was found to be fast enough to be maintained during Rh(I) depletion, and since CH_3I was in large excess over Rh(I), it was possible to determine the rate constants k_1, k_3 and k_4 for the studied reaction in acetone by using the consecutive reaction treatment on the general reaction sequence, $A \xrightarrow{k_1} B \xrightarrow{k_3} C \xrightarrow{k_4} D$ (A, B and C was defined in Sections 3.1 and 3.2.1, $D = Rh^{III}$-acyl2). By ignoring the very slow k_4 step (i.e. D) in the reaction sequence and upon performing a least-squares fit of the available IR absorbance *vs.* time data of the Rh^{III}-alkyl1 peak for the reaction in acetone to Eq. (7), see graph shown in Fig. 5, top, the rate constants were determined as $k_{1obs} = 0.0012(1)$ s^{-1} ($k_1 = 0.0046$ dm^3 mol^{-1} s^{-1}), and $k_3 = 0.00010(1)$ s^{-1}. The value of k_{1obs} corresponds very close with those obtained from data treatment utilizing Eq. (5) (values summarized in Table 1). The value of k_3 was slightly (37%) smaller than the value of 0.00016(2) s^{-1} which was determined by treating reaction 2 in isolation.

In addition, fitting of the available absorbance/time data of the Rh^{III}-alkyl2 peak to Eq. (8), see Fig. 5, bottom, resulted in $k_{1obs} = 0.0022(6)$ s^{-1} ($k_1 \approx 0.0084$ dm^3 mol^{-1} s^{-1}), while $k_3 = 0.00018(1)$ s^{-1}. This value of k_3 corresponds well to the value obtained by treating data sets as separate, isolated quantities for each reaction according to Eq. (5). Utilizing Eq. (8), k_1 was 83% (1.83 times) larger than the value obtained from Eq. (5) but it is still kinetically equivalent. This drift in k_1 and k_3 was accentuated because of the difficulty of obtaining large

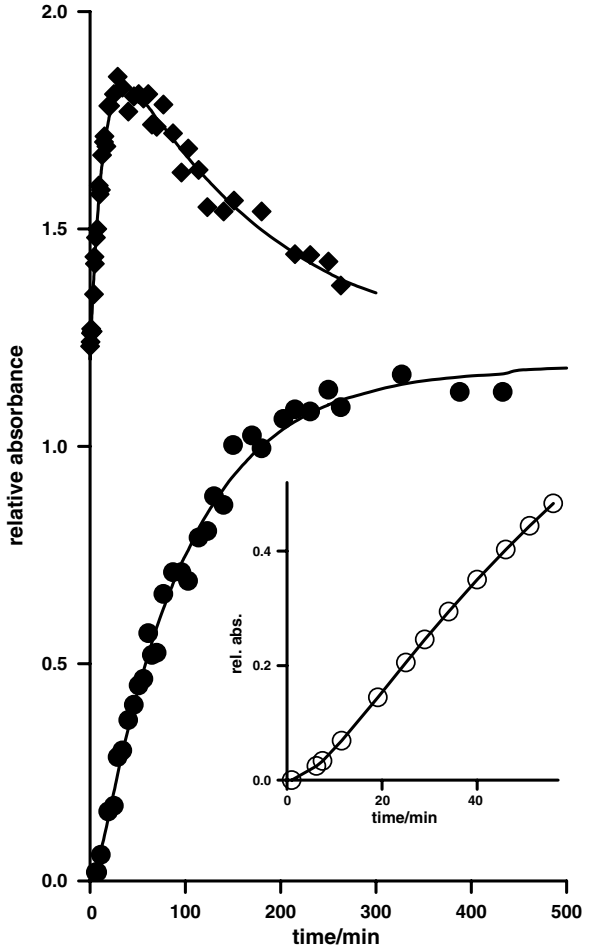

Fig. 5. Relative IR absorbance *vs.* time data of the reaction between CH_3I (0.2604 mol dm^{-3}) and [Rh(fctfa)(CO)(PPh_3)] (0.002 mol dm^{-3}) in acetone at 25 °C. Top: Kinetic data were fitted to the consecutive reaction model Eq. (7), relative absorbancies of the Rh^{III}-alkyl1 species are illustrated. Bottom: A data fit of Rh^{III}-alkyl2 IR absorbances to Eq. (8) is shown. Inset: An enlargement of the initial stages of Rh^{III}-alkyl2 formation. The slow initial formation of the Rh^{III}-alkyl2 species in the region $t < 10$ min is apparent.

amounts of data points for relatively fast reactions quickly enough with overlay spectra utilizing an infrared spectrophotometer. It led to too little available data to fit complicated equations.

By ignoring the fast k_1 step (i.e. A) in $A \xrightarrow{k_1} B \xrightarrow{k_3} C \xrightarrow{k_4} D$ and by applying the consecutive reaction kinetic model, Eq. (7), to intermediate C for the compound series B, C and D, values of k_3 and k_4 were found to $1.6(1) \times 10^{-4}$ and $5.5(3) \times 10^{-6}$ s^{-1}. The value for k_3 corresponded well to the previously determined values. The value for k_4 is larger by a factor 2 than the value obtained from the treatment of data in isolation, which gave $k_4 = 2.6(5) \times 10^{-6}$ s^{-1}. This twofold difference between the k_4 values are again not regarded as significant. Eq. (8) could not be fitted to formation data of D, from the reaction in acetone as solvent, due to interference of the acetone carbonyl peak in the region of Rh^{III}-acyl2 detection.

All things considered, the calculated rate constants obtained by the consecutive reaction treatment (Eqs. (7) and (8)) and as individual data sets utilizing Eq. (5) are regarded as mutually consistent and confirm the proposed mechanism. It is, however, important to note that consistency between the consecutive reaction treatment of data and treatment of kinetic data of each reaction step in isolation would not have been observed if reaction step 1 was not much faster than reaction step 2 and if reaction step 3 was not much slower than reaction step 2. If the rates did not differ as much as demonstrated by the half lives cited in Section 3.2.1, reaction steps 1, 2 and 3 would be overlapping so much that accurate rate constants would not be obtainable by regarding each reaction step in isolation.

When the consecutive reaction treatment of data was applied to reactions performed in *chloroform* (data for Section 3.2.1), the mathematical models (Eqs. (7) and (8)) were not found to be appropriate as data could not be satisfactorily fitted to it. The breakdown of the model is attributed to the detected k_{-1} step in the mechanism

$$A \underset{k_{-1}}{\overset{k_1}{\rightleftharpoons}} B \xrightarrow{k_3} C$$

The mathematical treatment of such monophasic reversible reactions is quite complex [29].

3.3. ^1H and ^{31}P NMR study

The reaction between CH_3I and [Rh(fctfa)(CO)(PPh_3)] was also monitored by ^1H and ^{31}P NMR in order to obtain additional insight into this reaction. By carefully comparing the positions and integrals of the different signals, the spectral parameters of different isomers could be identified, Table 2, see also Ref. [19]. The same reaction sequence as observed by IR and UV/Vis, was observed utilizing ^1H NMR, Fig. 6 and ^{31}P NMR, Fig. 7. The new feature introduced by the NMR study is the existence of more than one geometrical isomer for each intermediate. The two main isomers of each intermediate will be referred to as A and B, *e.g.* Rh^{III}-alkyl1A and Rh^{III}-alkyl1B, the choice of the labels are arbitrary and have no significance. The A and B isomers of each species exist in a fast equilibrium with each other, because the observed rate constant for the disappearance or formation of an A and a B isomer of the same species was found to be within experimental error the same and also because the ratio Rh(I)A/Rh(I)B = 1.5 (obtained by integral evaluation) is not the same as the ratio Rh^{III}-alkyl1A/Rh^{III}-alkyl1B = 0.39 or the ratio Rh^{III}-acyl1A/Rh^{III}-acyl1B = 1.0 (Table 2). If the reaction was ($Rh^{I}A + CH_3I \rightleftharpoons$ {Rh^{III}-alkyl1A $\rightleftharpoons$ Rh^{III}-acyl1A}) for the A isomers and separately ($Rh^{I}B + CH_3I \rightleftharpoons$ {Rh^{III}-alkyl1B $\rightleftharpoons$ Rh^{III}-acyl1B}) for the B isomers, and if no equilibrium between isomers A and B existed, the ratio A:B of these isomers would have been the same throughout the entire reaction sequence involving steps 1, 2 and 3.

Rate constants obtained from ^1H NMR are summarized in Table 1. It can be seen good agreement exist between the

Table 2
The equilibrium constant K_c and ^{1}H and ^{31}P NMR spectral parameters of the different isomeric forms of [Rh(fctfa)(CO)(PPh$_3$)] and the Rh^{III} complexes formed during the oxidative addition reaction of CH_3I to [Rh(fctfa)(CO)(PPh$_3$)]

[e] Peaks could not uniquely be identified due to excessive overlapping.

kinetic rate constants obtained by utilizing UV/Vis, IR, ^{1}H NMR and ^{31}P NMR spectroscopic methods.

The structure of one of the isomers of the [Rh^I(fctfa)-(CO)(PPh$_3$)] is reported elsewhere [20], while the structure of the [Rh^{III}(fctfa)(CH$_3$)(CO)(PPh$_3$)(I)]^{2B} species is reported in this communication. The structure of the other Rh^{III} acyl compounds is as yet unknown and the indicated formulas relate to molecular stoichiometry only and not to a specific geometry. The ^{1}H and ^{31}P NMR spectrum of the crystalline isolated Rh^{III}-alkyl2B isomer were identical to the spectrum of isomer Rh^{III}-alkyl2B as observed during the monitoring of the second set of reactions during the oxidative addition reaction of [Rh(fctfa)(CO)(PPh$_3$)] with CH_3I in $CDCl_3$ solutions. An important observation was that upon dissolving the solid crystalline Rh^{III}-alkyl2B isomer in $CDCl_3$, isomerization to the Rh^{III}-alkyl2A isomer sets in. After 4 days, traces of Rh(I), Rh^{III}-alkyl1 and Rh^{III}-acyl1 were also observed on ^{1}H and ^{31}P NMR. This means that Eq. (13) also has a k_{-3} and k_{-4} step, but these rate constants are so small that the k_{-3} and k_{-4} steps are simply not kinetically determinable. Taking into account there exist two main isomers of each reactant and reaction product, the complete reaction sequence for the oxidative addition of CH_3I to [Rh(fctfa)(CO)(PPh$_3$)] is therefore

$$\begin{bmatrix} [Rh^I(fctfa)(CO)(PPh3)]_A \\ \Updownarrow K_{c1} \\ [Rh^I(fctfa)(CO)(PPh3)]_B \end{bmatrix} + CH_3I$$

$$k_{-1} \Updownarrow k_1 \quad \textit{First set of reactions}$$

$$\begin{bmatrix} [Rh^{III}\text{-alkyl1A}] & & [Rh^{III}\text{-acyl1A}] \\ \Updownarrow K_{c2} & K_2=k_2/k_{-2} & \Updownarrow K_{c3} \\ [Rh^{III}\text{-alkyl1B}] & & [Rh^{III}\text{-acyl1B}] \end{bmatrix} \quad (14)$$

$$k_{-3} \Updownarrow k_3 \quad \textit{Second set of reactions}$$

$$\begin{bmatrix} [Rh^{III}\text{-alkyl2A}] \\ \Updownarrow K_{c4} \\ [Rh^{III}\text{-alkyl2B}] \end{bmatrix} \underset{k_{-4}}{\overset{k_4}{\rightleftharpoons}} \begin{bmatrix} [Rh^{III}\text{-acyl2A}] \\ \Updownarrow K_{c5} \\ [Rh^{III}\text{-acyl2B}] \end{bmatrix}$$

Third set of reactions

The above mechanism is a completely general mechanism. As such it caters for all previously encountered special cases sighted in Eqs. (1)–(4). Each one of these four equations can be generated by careful manipulation of the size of the individual rate constants. For example, Eq. (14) will simplify to Eq. (3) provided $k_{-2} = k_{-3} = k_4 = k_{-4} = 0\ s^{-1}$. The equilibrium constants for the equilibrium between the isomers, defined as K_{ci} = [RhB-species]/[RhA-species], $i = 1, 2, \ldots 5$, were determined from the ^{1}H NMR integration data of suitable identifiable and well resolved peaks at 25 °C in $CDCl_3$ and are documented in Table 2.

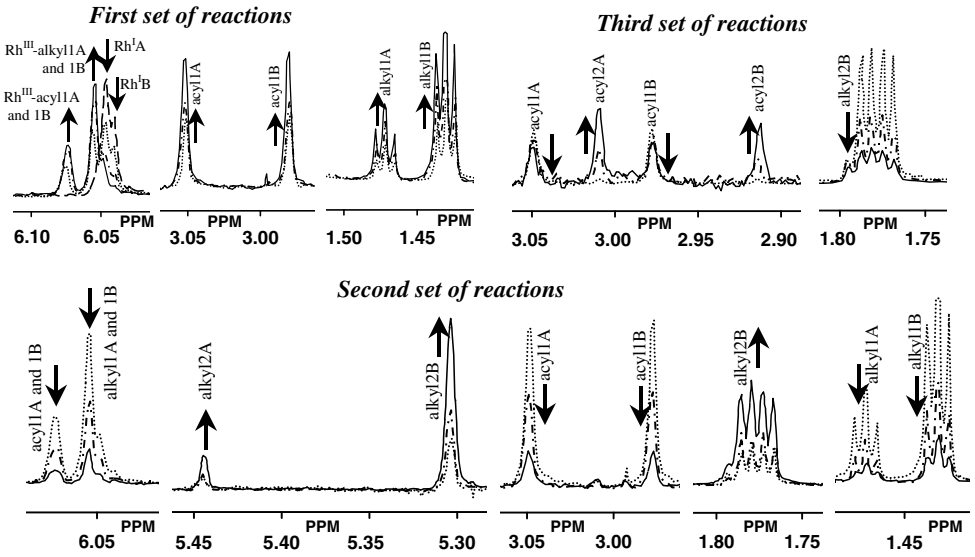

Fig. 6. Fragments of the ^{1}H NMR spectra in $CDCl_3$ illustrating reaction sequences during the oxidative addition and the ensuing carbonyl insertion and deinsertion reactions of 0.3674 mol dm^{-3} CH_3I to 0.0183 mol dm^{-3} [Rh(fctfa)(CO)(PPh_3)] in $CDCl_3$ at $T = 25$ °C. *Top left*: Selected spectra for the first set of reactions illustrating changes in the signal of the methine proton of the β-diketonato ligand of the indicated isomers in the region 6.04–6.08 ppm, the growing signals of the CH_3-group of indicated Rh^{III}-acyl isomers at 3.05 and 2.98 ppm and of Rh^{III}-alkyl isomers at 1.47 and 1.42 ppm. *Bottom*: Signal intensity changes of the second reaction sequence showing the methine proton of the β-diketonato ligand of the indicated isomers at 5.30–6.08 ppm, the CH_3 signal disappearance for the Rh^{III}-acyl isomers at 3.05 and 2.98 ppm and Rh^{III}-alkyl isomers at 1.47 and 1.42 ppm, and the increase in signal intensity of the CH_3-group of the overlapping alkyl 2 isomers at 1.78 ppm. *Top right*: The third set of reactions is illustrated by changes in signal intensity of the CH_3-group of the Rh^{III}-alkyl2 isomers at 1.78 ppm, and of the Rh^{III}-acyl2A and 2B species at 3.01 and 2.92 ppm. The multiplicity of the signal of the CH_3 group of the Rh^{III}-alkyl1 and 2 isomers is due to coupling with Rh (spin 1/2) and P (spin 1/2). Supplementary data shows further spectra highlighting NMR changes.

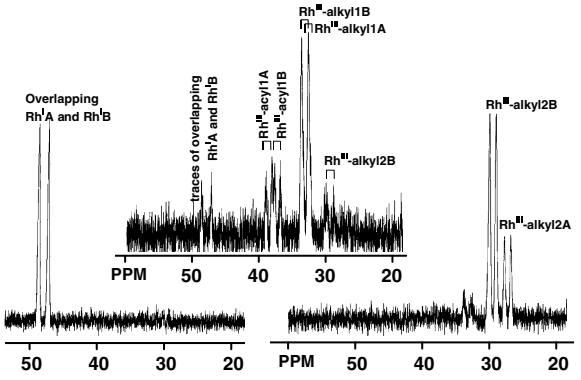

Fig. 7. Selected ^{31}P NMR spectra illustrating doublet ^{31}P peaks of the indicated reactants and products during the three sets of reactions for the oxidative addition of 0.500 mol dm^{-3} CH_3I to 0.021 mol dm^{-3} [Rh(fctfa)(PPh_3)(CO)] in $CDCl_3$ at 25 °C. Bottom left: at time $t = 0$ (reagent). Middle top: $t = 1070$ s (towards the end of the first set of reactions). Bottom right: $t = 69520$ s (near the end of the second set of reactions).

3.4. The crystal structure data of [Rh(fctfa)(CO)(PPh_3)(CH_3)(I)]

The numbering system of the atoms in [Rh(fctfa)-(CO)(PPh_3)(CH_3)(I)] is shown in Fig. 8 while the crystal data are summarized in Table 3. Selected bond lengths and bond angles are given in Table 4. An obvious feature of [Rh(fctfa)(CO)(PPh_3)(CH_3)(I)] and similar known Rh^{III}-alkyl complexes in which the fctfa ligand is replaced with other bidentate ligands [15,30] is that the iodo ligand, I, is bonded in the axial position of the octahedron, above or below the equatorial plane of the octahedron formed by O(1), O(2), C(5)O and C(6)H_3. The Rh–I bond axis deviated 3.6(1)° towards O(2) from the expected 90° and the Rh–P bond deviates by more than 2° away from O(1) and O(2).

This resulted in a 2.26(5)° deviation from linearity for the I–Rh–P bond axis. A similar deviation from linearity (3.4°) for the I–Rh–P bond axis was found for [Rh(cupf)-(CO)(PPh_3)(CH_3)(I)] [15]. The Rh^{III}–I bond length of the present study, 2.716(1) Å, is shorter (~0.1 Å) than Rh–I bonds in complexes having the CH_3 group *trans* to the iodine atom [30] and this is the result of the smaller *trans* influence of PPh_3 compared to that of an alkyl group. The various ligand–rhodium–ligand bond angles in the equatorial plane formed by O(1), O(2), C(6) and C(5), *viz.* C(5)–Rh–C(6) = 88.4(4)°, C(5)–Rh–O(2) = 97.3(3)°, O(2)–Rh–O(1) = 88.0(2)° and O(1)–Rh–C(6) = 86.1(3)°, deviate 2–7° from 90°. The Rh–C(5)–O(3) bond angle, 175.7(8)°, is not completely linear, with the C(5)–O(3) bond length 1.12(1) Å, significantly shorter than the C(5)–O(3) bond distance of 1.147(5) Å in [Rh^{I}(fctfa)(CO)(PPh_3)] [20].

In accordance with the π bonding concept [31] the Rh–C(5) bond length of 1.830(8) Å is larger than the corresponding bond length, 1.801(5) Å, in [Rh^{I}(fctfa)-(CO)(PPh_3)] because decreasing electron density on the rhodium center in changing the oxidation state from I to III, imply less electron donating capability from the metal

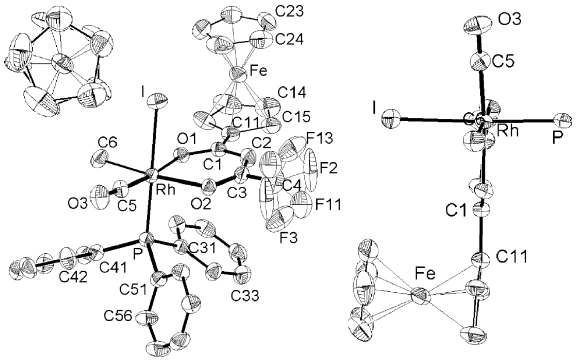

Fig. 8. A perspective view of [Rh(fctfa)(CO)(PPh_3)(CH_3)(I)] showing atom labelling. Thermal ellipsoids were drawn at a 30% probability level. The view from above down the ferrocenyl axis (top left) shows the cyclopentadienyl ring deviates 12.7° from a fully eclipsed conformation. Right: The cyclopentadienyl rings are planar and almost parallel, they deviate 3.1(5)° from co-planarity with the plane through the Rh chelate.

d-orbital into the π^* orbital of the carbonyl ligand. This leads to a longer (weaker) Rh–C bond length and a stronger C–O bond. The Rh–O(1) bond is 0.085 Å shorter than the Rh–O(2) bond which indicates the structure is not symmetric around the β-diketonato ligand. However, both Rh–O(1) and Rh–O(2) bonds in [Rh^{III}(fctfa)(CO)(PPh_3)(CH_3)(I)] are longer than the corresponding bonds in [Rh^{I}(fctfa)(CO)(PPh_3)] [20], 2.048(3) Å and 2.070(3) Å. The Rh–O(1) bond in both the Rh(I) and Rh(III) complexes is *trans* to the CO group, but Rh–O(2) is *trans* to the PPh_3 group in [Rh^{I}(fctfa)(CO)(PPh_3)] and *trans* to the CH_3 group in [Rh^{III}(fctfa)(CO)(PPh_3)(CH_3)(I)]. The C(3)–O(2) and C(1)–O(1) bonds in the β-diketonato skeleton of the [Rh(β-diketonato)(CO)(PPh_3)(CH_3)(I)] complex are similar, 1.271(9) Å and 1.265(8) Å, respectively, and both bonds are smaller than the corresponding bonds in free Hfctfa [32]. The change in oxidation state from Rh(I) to Rh(III) did not influence the C(3)–O(2) and C(1)–O(1) bond lengths. The C(1)–C(2) and C(2)–C(3) bonds of the present Rh(III) complex are similar, contrary to what was found for both [Rh^{I}(fctfa)(CO)(PPh_3)] (corresponding bonds were 1.413(5) and 1.368(6) Å), or the free Hfctfa ligand where asymmetric enolization was observed (C(1)–C(2) = 1.432(6) Å, C(2)–C(3) = 1.345(6) Å). As was the case for [Rh(fctfa)(CO)(PPh_3)], deviations up to 10° from the expected 120° for sp^2 hybridization for the C atoms of the β-diketonato skeleton were found, Table 4. The largest deviations were at the C atoms bound to O(1) and O(2). In the case of the free Hfctfa [32] the corresponding bond angles were all within experimental error 120°.

Table 4
Selected bond lengths (Å) and angles (°) for [Rh(fctfa)(CO)(PPh_3)(CH_3)(I)]

Atoms	Bond	Atoms	Bond
Rh–C(5)	1.830(8)	F(1)–C(4)	1.39(3)
Rh–O(1)	2.075(5)	C(1)–C(2)	1.40(1)
Rh–C(6)	2.076(8)	C(2)–C(3)	1.38(1)
Rh–O(2)	2.160(5)	C(3)–C(4)	1.51(1)
Rh–P	2.320(2)	C(1)–C(11)	1.47(1)
Rh–I	2.716(1)	C(11)–C(12)	1.41(1)
P–C(51)	1.822(7)	C(11)–C(15)	1.45(1)
O(3)–C(5)	1.12(1)	C(12)–C(13)	1.40(1)
O(2)–C(3)	1.271(9)	C(21)–C(22)	1.39(2)
F(2)–C(4)	1.40(3)	C(41)–C(42)	1.40(1)
	Angles	Atoms	Angles
C(5)–Rh–O(1)	173.8(3)	O(1)–C(1)–C(2)	126.5(6)
O(1)–Rh–O(2)	88.0(2)	O(2)–C(3)–C(2)	129.3(7)
O(2)–Rh–P	92.9(2)	C(2)–C(3)–C(4)	118.9(7)
O(1)–Rh–I	89.7(1)	C(3)–C(2)–C(1)	125.3(7)
O(1)–C(1)–C(11)	114.2(7)	Rh–C(5)–O(3)	175.7(8)
O(2)–C(3)–C(4)	111.9(7)	P–Rh–I	177.74(5)
C(34)–C(33)–C(32)	119.6(9)		

The standard deviation of the last decimal is given in brackets.

The cyclopentadienyl rings are within experimental error, planar and almost parallel [dihedral angle 1.4(6)°] while the average angle of deviation from a fully eclipsed configuration is 12.7°, Fig. 8. The cyclopentadienyl ring which is bonded to the β-diketonato chelate ring at C(1) deviates 3.1(5)° from co-planarity with the plane defined by atoms O(1), O(2), C(1), C(2), C(3) and Rh, i.e. the plane through the chelate ring.

The average C–C bond distance, 1.38(1) Å, in the phenyl rings is within experimental error near the normal value (1.394 Å) for the aromatic C–C bond [33]. The bond angles around P differ no more than 7° from 109°28′, the angle for a regular tetrahedron. The mean P–C distance is 1.82(1) Å, and almost the same [20] as in the parent rhodium(I) complex [Rh^{I}(fctfa)(CO)(PPh_3)], where it was 1.824 Å. The Rh^{III}–P bond distance for the present complex of

Table 3
Crystal data and structure refinement for [Rh(fctfa)(CO)(PPh_3)(CH_3)(I)]

Empirical formula	$C_{34}H_{28}F_3FeO_3RhPI$	*Z*, density (calculated) (g/cm^3)	4, 1.716
Formula weight	858.2219	Temperature (K)	293(2)
Crystal system	Monoclinic	Wavelength (Å)	0.71073
Space group	$P2_1/c$	Absorption coefficient (mm^{-1})	1.961
Unit cell dimensions			
a (Å)	10.769(2)	Reflections collected	4717
b (Å)	15.153(3)	Unique reflections	4420 [$R_{int} = 0.0588$]
c (Å)	20.413(5)	Refinement method	Full-matrix least-squares on F^2
β (°)	94.31(2)	Data [$I > 2\sigma(I)$]; parameters	4414; 429
Volume (Å^3)	3221(1)	Final *R* indices [$I > 2\sigma(I)$]	$R = 0.0588$, $R_w = 0.1692$

2.320(2) Å is, however, much longer than the Rh–P bond distance for [Rh^{I}(fctfa)(CO)(PPh_3)], 2.232(1) Å, indicating a change in oxidation state from Rh(I) to Rh(III) results in a weaker Rh–P bond. The Rh^{III}–P bond length for the [Rh(fctfa)(CO)(PPh_3)(CH_3)(I)] complex is, however, in the same order as was found for a variety of other Rh^{III}-alkyl complexes including [Rh(cupf)(CO)(PPh_3)(CH_3)(I)] [15c], 2.327(4) Å, and [Rh(ox)(CO)(PPh_3)(CH_3)I] [30b], 2.321(2) Å, (average of two molecules found in one unit cell, Hcupf = *N*-hydroxy-*N*-nitroso-benzeneamine).

The trifluoromethyl group in [Rh(fctfa)(CO)(PPh_3)-(CH_3)(I)] is disordered, similar to what was found for the free β-diketone Hfctfa [32]. An intermolecular interaction was observed between F and either a hydrogen on a ferrocenyl group, or a hydrogen on a phenyl ring from *another* molecule (indicated by H′): F(3)–H′(53) = 2.661 Å, F(3)–H′(12) = 2.669 Å, F(12)–H′(53) = 2.652 Å, F(12)–H′(13) = 2.667 Å, F(13)–H′(36) = 2.606 Å. These intermolecular interactions link one molecule to another in the unit cell and it is partially the cause of the CF_3 disorder. However, the CF_3 disorder is also the result of intramolecular interaction that prevents rotation of the CF_3 group. Two preferred CF_3 orientations are observed. The first involves a strong intramolecular interaction between F(2) and H(2) (the hydrogen bonded to C(2)) and a weak interaction between both F(1) and F(3) with O(2). The contact distances are F(2)–H(2) = 2.362 Å, F(1)–O(2) = 2.702 Å and F(3)–O(2) = 2.718 Å, respectively. The other CF_3 orientation, involving F(12), F(11) and F(13), is the result of a strong interaction between F(12) and O(2) and a weak interaction of both F(11) and F(13) with H(2). The intramolecular contact distances are F(12)–O(2) = 2.485 Å, F(11)–H(2) = 2.727 Å and F(13)–H(2) = 2.624 Å, respectively.

4. Conclusion

A three-step reaction sequence was found for the oxidative addition of iodomethane to [Rh(fctfa)(CO)(PPh_3)], the final product of the reaction was found to be a Rh^{III}-acyl species. UV/Vis studies alone could only provide reaction rates and the amount of reaction steps. Utilizing IR spectroscopic techniques, alkyl and acyl Rh^{III} species could be identified, but only NMR spectroscopy revealed that each reaction product exists in solution as two main isomers in a fast equilibrium with each other. This study is the first to observe a fast equilibrium between Rh^{III}-alkyl and Rh^{III}-acyl intermediates (equilibrium K_2) and it was the first to determine the actual rate of conversion from a Rh^{III}-alkyl2 species to a Rh^{III}-acyl2 species. The incorporation of a ferrocenyl group in the β-diketonato ligand slightly accelerated the rate of CH_3I oxidative addition when compared with the rate of oxidative addition to either the corresponding $CH_3COCHCOCF_3^-$ [15a] or PhCOCH-$COCF_3^-$ complex [34]. A completely general mechanism for the oxidative addition of CH_3I to [Rh(β-diketonato)(CO)(PPh_3)] could be derived and all previously proposed mechanisms for a variety of such reactions are special cases of the general mechanism that emanated from this study. The structure of the intermediate Rh^{III}-alkyl2B geometric isomer, [Rh(fctfa)(CO)(PPh_3)(CH_3)(I)], was solved. It was asymmetric in nature and the phosphine and iodo ligands were found to be the axial ligands.

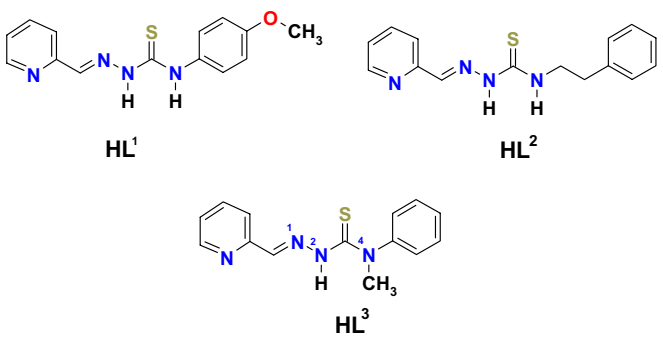
and potassium thiocyanate (Merck) were used as supplied and solvents were purified by standard procedures before use. *Caution:* Perchlorate complexes of metals with organic ligands are potentially explosive and should be handled with care.

2.2. Syntheses of ligands

The thiosemicarbazone ligands (Scheme 1) were synthesized by adopting and modifying a reported procedure of Scovill et al. [9]. The syntheses of HL^1 [7], HL^2 [10] and HL^3 [7] have been published earlier.

2.3. Syntheses of complexes

2.3.1. Syntheses of $[MnL^1_2] \cdot H_2O \cdot EtOH$ (*1*) and $[MnL^1_2] \cdot 3H_2O$ (*3*)



To a solution of the respective ligand (2 mmol) in hot ethanol (25 ml) was added $MnCl_2 \cdot 4H_2O$ (1 mmol), and the resulting solution was heated at reflux for 2 h and then kept at room temperature (overnight). The complexes formed were filtered, washed thoroughly with water, ethanol and then ether and dried *in vacuo* over P_4O_{10}. However compound **1** crystallized as $[MnL^1_2] \cdot H_2O$ (**1a**) on slow evaporation of its solution in ethanol in air.

2.3.2. Synthesis of $[Mn(L^1)(HL^1)]OAc$ (*2*)

To a solution of HL^2 (2 mmol) in hot ethanol (25 ml) was added $Mn(OAc)_2 \cdot 4H_2O$ (1 mmol), and the resulting solution was heated at reflux for 2 h and then kept at room temperature (overnight). The complex formed was filtered, washed thoroughly with water, ethanol and then ether and dried *in vacuo* over P_4O_{10}.

2.3.3. Synthesis of $[MnL^3_2] \cdot 3H_2O$ (*4*)

To a solution of HL^3 (2 mmol) in hot ethanol (25 ml) was added $Mn(ClO_4)_2 \cdot 6H_2O$ (1 mmol), and the resulting solution was heated at reflux for 2 hours and then kept at room temperature (overnight). The complex formed was filtered, washed thoroughly with water, ethanol and then ether and dried *in vacuo* over P_4O_{10}.

Scheme 1. The thiosemicarbazones HL^1, HL^2 and HL^3. The numbering scheme used is shown for HL^3.

2.3.4. Synthesis of $[Mn(HL^3)_2](SCN)_2 \cdot MeOH$ (*5*)

To a solution of HL^3 (2 mmol) in hot ethanol (25 ml) was added $MnCl_2 \cdot 4H_2O$ (1 mmol), and the resulting solution was heated at reflux for 2 h. The mixture was then cooled and stirred with KCNS for 30 min and kept at room temperature (overnight). The complex formed was filtered, washed thoroughly with water, ethanol and then ether and dried *in vacuo* over P_4O_{10}.

2.4. Physical measurements

Elemental analyses of the ligands and the complexes were done on a Heracus elemental analyzer at the CDRI, Lucknow, India and on a Vario EL III CHNS analyzer at SAIF, Kochi, India. The IR spectra were recorded on a Thermo Nicolet AVATAR 370 DTGS model FT-IR spectrophotometer with KBr pellets at the SAIF, Kochi. Electronic spectra of the complexes were recorded on a Cary 5000, version 1.09 UV–Vis–NIR spectrophotometer from solutions in $CHCl_3$. The EPR spectra of the complexes in the solid state at 298 K and in DMF solution at 77 K were recorded on a Varian E-112 spectrometer using TCNE as the standard, with 100 kHz modulation frequencies and 0.2 mT modulation amplitude at the SAIF, IIT, Bombay, India. The magnetic susceptibility measurements were carried out at the Indian Institute of Technology, Roorkee, India, at room temperature in the polycrystalline state on a PAR model 155 Vibrating Sample Magnetometer at 5 kOe field strength. The molar conductivities of the complexes in dimethylformamide solutions (10^{-3} M) at room temperature were measured using a direct reading conductivity meter.

2.5. X-ray crystallography

Single crystals of compound $[MnL^1_2] \cdot H_2O$ (**1a**) of X-ray diffraction quality were grown from a solution of **1** in ethanol by slow evaporation at room temperature in air. The crystallographic data and structure refinement parameters are given in Table 1. Intensity data and cell parameters were recorded at room temperature (293 K) on a Nonius, MACH3 diffractometer equipped with graphite monochromated Mo Kα ($\lambda = 0.71073$ Å) radiation. A single crystal of dimensions $0.35 \times 0.30 \times 0.30$ mm^3 was used for data collection. The Maxus (Nonius software) was used for data reduction [11]. The trial structure was solved using SHELXS-97 [12] and refinement was carried out by full-matrix least squares on F^2 (SHELXL) [12]. The non-hydrogen atoms were refined with anisotropic thermal parameters. All hydrogen atoms, with the exception of those on N4, were geometrically fixed and refined using a riding model. The hydrogen atoms of the N4 atoms were located from difference Fourier maps. However, the hydrogen atoms of the water molecule could not be located and were ignored. The molecular graphics employed were ORTEP-III [13] and PLATON [14].

Table 1
Crystal refinement parameters of compound $[MnL^1_2]\cdot H_2O$ (**1a**)

Parameters	$[MnL^1_2]\cdot H_2O$
Empirical formula	$C_{28}H_{28}Mn_1N_8O_3S_2$
Formula weight (M)	643.63

3. Results and discussion

All the five compounds are bis(thiosemicarbazone) complexes. In the compounds **1**, **3** and **4**, the thiosemicarbazones deprotonate and chelate in the thiolate form, as proven by the IR spectral data. In **5**, the ligand moieties are in the thione form, whereas in **2**, one of them is in the thione form and the other in the thiolate form. Elemental analyses and conductivity data are in agreement with the general empirical formula $[MnL_2]$ for the complex part of compounds **1**, **3** and **4**. Compound **2** is found to be [Mn(L)(HL)]OAc and **5** turned out to be $[Mn(HL)_2](SCN)_2$. The colors, partial elemental analyses, molar conductivities and magnetic susceptibilities of the metal complexes are shown in Table 2. The room temperature magnetic moments of powdered samples of all the complexes are consistent with manganese in the +2 oxidation state, with no significant exchange interactions between adjacent metal centers [15]. The molar conductivity values for 10^{-3} M DMF solutions of complexes **1**, **3** and **4** suggest that these complexes are non-electrolytes and the values for **2** and **5** show that they are probably 1:1 and 1:2 electrolytes respectively [16].

3.1. Crystal structure of $[MnL^1_2]\cdot H_2O$ (*1a*)

The molecular structure of $[MnL^1_2]\cdot H_2O$, obtained from single crystal X-ray diffraction studies, showed a six coordinate Mn(II) center in a distorted octahedral geometry. The molecular structure of the compound along with the atom numbering scheme is given in Fig. 1. The asymmetric unit contains one half of the molecule and the other half is generated by a twofold axis passing through the metal center. The Mn(II) center is coordinated in an N_4S_2 *meridional* manner by two anionic ligand moieties using pairs of *cis* pyridyl-*N*, *trans* azomethine-*N* and *cis* thiolate-*S* atoms. The coordination of sulfur occurs through deprotonation after enolization, and was confirmed by the partial single and double bond nature of the C7–S1 [1.735(4) Å] and N3–C7 [1.316(5) Å] bonds [17].

The bond parameters (Table 3) show that the geometry around Mn(II) is distorted significantly from a perfect octahedron. The metal center is shared by four fused five membered chelate rings. The planes comprising Mn1, S1, C7, N2, N3 and Mn1, N1, C5, C6, N2, with a maximum deviation from the mean plane of 0.013(4) Å for N3 and −0.020(4) Å for C5 respectively, make an angle of 1.79(12)°. The mean plane of the bicyclic chelate rings Mn1, N1, C5, C6, N2, N3, C7, S1, having a maximum deviation of −0.059(4) Å for the C5 atom, makes a dihedral angle of 87.84(7)° with its counterpart. The Mn–$N_{azomethine}$, Mn–N_{py} and Mn–S bond lengths are comparable with the previously reported manganese complexes [5,6,17].

The molecules are connected in the crystal lattice through an intermolecular hydrogen bond N4–H4···S1 [symmetry code: $-x$, $-y$, $-z$; with a H···S distance of 2.62(6) Å and angle 148(5)°] interactions and make six

membered rings leading to a three dimensional network (Figs. 2 and 3).

A weak intramolecular hydrogen bond C13–H13···N3 [with an H···N distance of 2.33 Å and an angle of 121°] stabilizes each molecule, while π···π interactions between rings comprised of the N1, C1, C2, C3, C4 and C5 atoms [Cg(5)–Cg(5), symmetry code: $1/2 - x$, $1/2 - y$, $-z$; with a distance of 3.738(3) Å between the ring centroids] reinforces the crystal structure cohesion in the packing (Fig. 3).

3.2. Infrared and electronic spectra

The shifts in IR spectral bands assigned in the spectra of the ligands because of coordination are given in Tables 4 and 5. A medium band in the range 3129–3158 cm^{-1} in the free ligands HL^1, HL^2 and HL^3, due to a $\nu(^2N–H)$

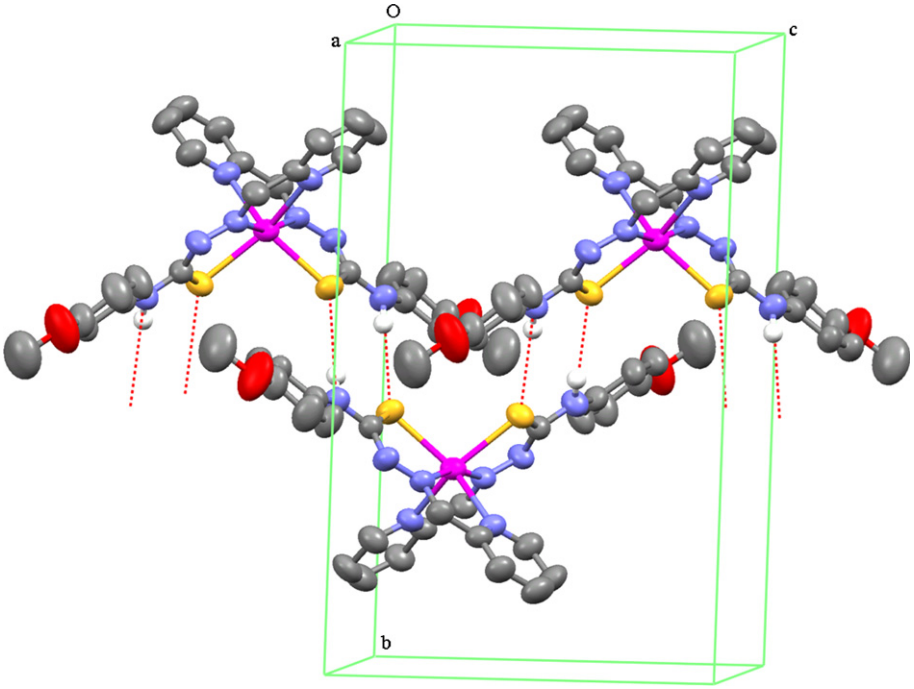

Fig. 2. The intermolecular hydrogen bonds in $[MnL^1_2] \cdot H_2O$ with 25% probability ellipsoids. Hydrogen atoms engaged in hydrogen bonds are shown with an arbitrary radius while others are omitted for clarity.

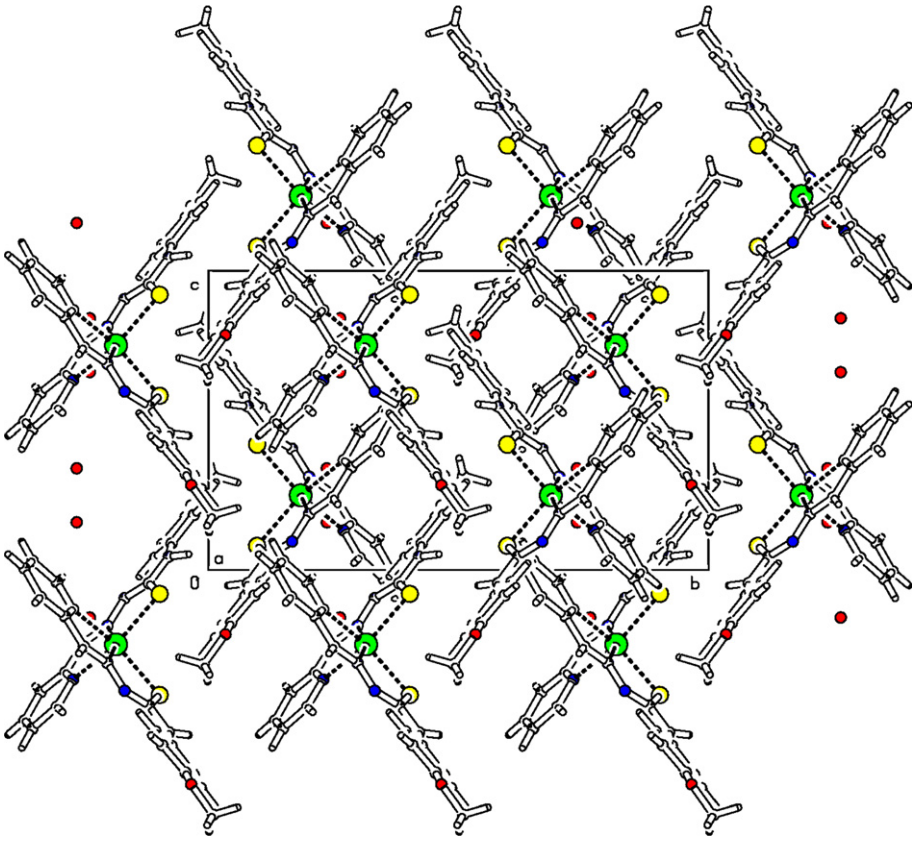

Fig. 3. A view of the unit cell packing of $[MnL^1_2] \cdot H_2O$ along the *a* axis.

vibration, disappears in the spectra of complexes **1**, **3** and **4**, providing strong evidence for ligand coordination to the manganese(II) ion in the deprotonated thiolate form [6]. In complexes **2** and **5**, the $\nu(^2N–H)$ bands are present since these complexes have the ligands in the thione form. The strong bands at 3310 and 3374 cm^{-1} in the spectra of HL^1 and HL^2, assigned to $\nu(^4N–H)$, shift to higher energies. The ν(C=N) bands of thiosemicarbazones are found to be shifted to lower frequencies in all the complexes indicating coordination *via* the azomethine nitrogen. The coordination of this nitrogen is also supported by a shift in ν(N–N) to higher frequencies [5]. In the spectra of all the complexes the bands corresponding to the newly formed N=C bond $[\nu(^2N=^3C)]$ due to the enolization of the ligands are present at *ca.*1600 cm^{-1}. Coordination *via* the thiolate sulfur is indicated by the negative shift of the two bands assigned to ν(C–S + C–N) and δ(C–S + C–N) vibrations. The out-of-plane and in-plane bending vibrations of the pyridine ring in the uncomplexed ligands shift to higher frequencies on complexation, confirming the coordination of the ligands to the metal *via* the pyridine nitrogen [18]. The manganese-donor atom stretching frequencies in the ranges 402–420 $cm^{-1}[\nu(Mn–N_{imine})]$, 352–381 cm^{-1} $[\nu(Mn–S)]$ and 248–289 $cm^{-1}[\nu(Mn–N_{py})]$. provide further evidence for the coordination of the azomethine nitrogen, thione/thiolate sulfur and pyridyl nitrogen.

The strong band at 2054 cm^{-1} $[\nu(CN)]$ and a medium band at 481 cm^{-1} $[\delta(SCN)]$ indicates the presence of ionic thiocyanate in **5** [19]. The spectrum of the acetate-containing complex **3** displays relatively strong bands at 1628 $[\nu_a(COO)]$ and 1397 cm^{-1}, $[\nu_s(COO)]$ indicating the ionic nature of the acetate in this compound [20].

Electronic transition intensities of octahedral manganese(II) complexes are very low since the transitions from the ground state $^6A_{1g}$ are doubly forbidden. The absorptions of the organic ligands tailing into the visible region obscure the very weak d–d absorption bands of the manganese(II) complexes. The broad band at *ca.* 23000 cm^{-1}, typical of octahedral manganese(II) complexes due to the $^4T_{2g} \leftarrow {}^6A_{1g}$ transitions, is observed for all the complexes. The very weak bands at *ca.* 18000 cm^{-1} are assigned to $^4T_{1g} \leftarrow {}^6A_{1g}$ transitions. The electronic spectral assignments are summarized in Table 6.

3.3. EPR spectra

The spin Hamiltonian used to represent the EPR spectra of Mn(II) is given by

$$\widehat{H} = g\beta HS + D[S_z^2 - S(S+1)/3] + E(S_x^2 - S_y^2)$$

where H is the magnetic field vector, g is the spectroscopic splitting factor, β is the Bohr magneton, D is the

axial zero field splitting term, E is rhombic zero field splitting parameter and S is the electron spin vector [21]. If D and E are very small compared to $g\beta HS$, five EPR transitions are expected. The solid state EPR spectra of complexes **1**, **3** and **5**, at 298 K are characterized by broad signals with g values of 1.99, 2.03 and 2.02, respectively. The signals of **2** and **4** were very broad due to dipolar interactions and a random orientation of the Mn^{2+} ions [18]. In the spectra from DMF solutions at 77 K, a hyperfine sextet is observed with g values 1.98, 1.99, 1.99 and 1.98, and A values 98, 98, 100 and 100 G, respectively, for **1**, **3**, **4** and **5** (Fig. 4). The six hyperfine lines are due to the interaction of the electron spin with the nuclear spin (^{55}Mn, $I = 5/2$). However, hyperfine splitting is not observed for **2**.

The observed g values are very close to the free electron spin value, suggestive of the absence of spin orbit coupling in the ground state. The A_{iso} values are consistent with an octahedral coordination, since A_{iso} in tetrahedral sites is 20–25% lower than in octahedral sites. The A_{iso} values are somewhat lower than pure ionic compounds, which reflects the covalent nature of the metal–ligand bond in the complexes. The mixing of the nuclear hyperfine levels with the zero field splitting factor produces low intensity forbidden lines with an average spacing of 38 G, lying between each of the two main hyperfine lines in the frozen solution spectra of the complexes [5].

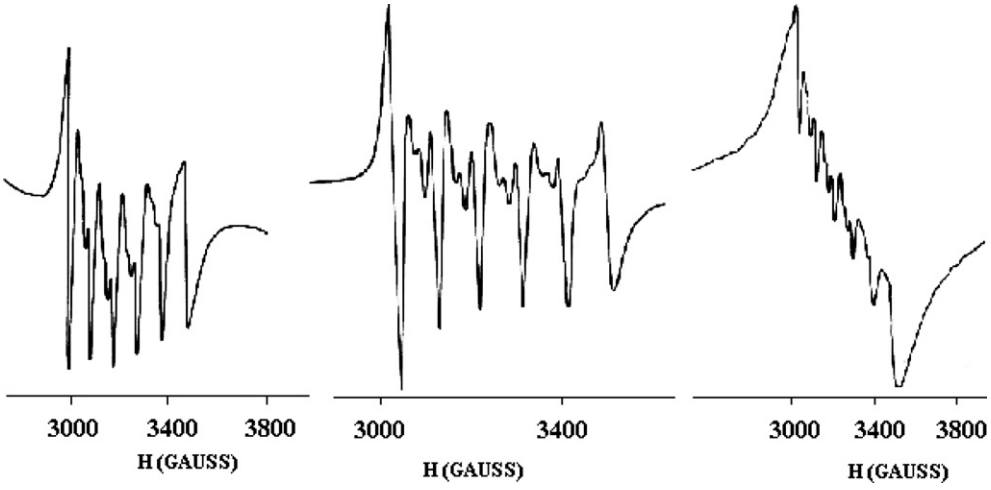

Fig. 4. EPR spectrum of **3** (left), **4** (middle) and **5** (right) in DMF at 77 K.

(H-TFA), which circumvent the solubility, volatility, and carbonate problems [1,2].

Since the TFA ligand has the potential to adopt numerous binding modes such as terminal (TFA), chelating (TFA_c), bridging (μ-TFA), and bridging chelating (μ_c-TFA) it is difficult to predict the final A^E-TFA structure; however, in order to fully optimize the final materials' properties, it is critical to know the precursors' structural properties. While several alkaline earth TFA derivatives are now crystallographically available [23–36], half were solved in the presence of a transition metal [24–28,31,34], which is not of use for production of complex ceramic materials. Of the remaining A^E homocationic species [29,30,32,33,35,36], most were solved in the presence of crown ether modifiers [29,30,35] or had water present [33,35,36]. Both of these conditions are unattractive for materials processing due to the potential for increased carbon contamination or uncontrolled reactivity.

Therefore, we undertook the synthesis of the simple A^E-TFA congeners, to investigate the structural properties of simple A^E homocationic species, following Eq. (1). The synthesis, and subsequent crystallization from a Lewis basic solvent [tetrahydrofuran (THF) or pyridine (py)] yielded: $Mg(TFA)_2(py)_4$ (**1**), $\{[Ca_2(\mu\text{-}TFA)_3(THF)_4](\mu\text{-}TFA)\}_n$ (**2**), $\{[(\mu\text{-}TFA)_2Sr(\mu_c\text{-}TFA)][H\text{-}py]py\}_n$ (**3**), and $\{[Ba(\mu_c\text{-}TFA)_2(\mu_c\text{-}TFA)(py)][H\text{-}py]\}_n$ (**4**). The synthesis and characterization of **1**–**4** are presented in this report.

$$M^0 + (xs)H\text{-}TFA \xrightarrow{solv} \text{“}M(TFA)_2(solv)\text{”}$$

2. Experimental

All compounds described below were handled with rigorous exclusion of air and water using standard Schlenk line and glove box techniques. All reactions were run under an argon atmosphere in a glovebox. All solvents were stored under argon and used as received (Aldrich) in SureSeal™ bottles, including tetrahydrofuran (THF) and pyridine (py). The following chemicals were used as received (Aldrich and Alfa Aesar): Mg^0, Ca^0, Ba^0, Sr^0, and H-TFA.

FT-IR data were obtained on a Bruker Vector 22 Instrument using KBr pellets under an atmosphere of flowing nitrogen. Elemental analysis was performed on a Perkin-Elmer 2400 CHN-S/O Elemental Analyzer. All NMR samples were prepared from dried crystalline materials that were handled and stored under an argon atmosphere. Solution NMR data were obtained on a 400 MHz Bruker NMR spectrometer with the materials dissolved in the parent solvent. The solution ^{19}F NMR data were obtained at 376.23 MHz with the chemical shifts referenced to an external standard of $CFCl_3$ ($\delta = 0.00$ ppm), while the solution ^{13}C NMR data were obtained at 100.1 MHz, and referenced to residual protonated solvent signal. The solid-state MAS NMR spectra were obtained on a Bruker Avance 400 using either a 4 or 2.5 mm MAS probe using a 15 kHz spinning speed. Both direct polarization (DP) decays (^{19}F and ^{13}C) and cross-polarization (CP) experiments ($^{13}C\{^1H\}$) were obtained. The ^{13}C MAS NMR spectra being obtained using either ^{19}F or ^1H TPPM decoupling, but because of instrumental limitations we were not able to obtain both ^1H and ^{19}F decoupling simultaneously. The solid-state ^{19}F MAS NMR chemical shifts were referenced to a secondary standard Teflon™, ($\delta = -122$ ppm) with respect to $CFCl_3$ $\delta = 0.0$ ppm. The solid-state ^{13}C MAS NMR spectra were referenced to the secondary standard adamantane $\delta = 28.5$ ppm with respect to TMS, $\delta = 0.0$ ppm.

2.1. General synthesis of "A^E-TFA_2 (solv)"

The appropriate metal was added to a stirring solution of H-TFA in a flat bottom flask. The reaction immediately began to bubble and was allowed to stir for 12 h. After this time, the bubbling was complete and if the metal was not dissolved, the reaction mixture was heated at reflux temperatures on a Schlenk line until all of the metal was consumed. The solution was dried *in vacuo* to yield off-white powders. This material was assumed to be '$A^E(TFA)_2$' was redissolved in a minimum of the appropriate Lewis basic solvent and X-ray quality crystals were allowed to form by slow evaporation of the volatile component of the reaction.

2.2. $Mg(TFA)_2(py)_4$ (**1**)

Used Mg^0 (5.00 g, 206 mmol), H-TFA (93.8 g, 823 mmol). "$Mg(TFA)_2$" Yield: 99.8% (51.5 g). Used "$Mg(TFA)_2$" (1.00 g, 3.99 mmol), py (~10 mL). Yield: 79.5% (1.80 g). FT-IR (KBr, cm^{-1}) 3152(w), 3112(m), 3084(m), 2967(w), 2918(w), 2862(w), 1740(w,sh), 1700(s), 1604(m,sh), 1538(w), 1490(w,sh), 1469(m), 1447(m,sh), 1210(s), 1150(s,sh), 1069(m), 1041(m), 1006(w,sh), 845(m), 802(m), 759(m), 721(w,sh), 705(m), 629(w,sh), 608(m), 522(m), 474(m), 427(w,sh). ^{13}C NMR (100.5 MHz, py-d_5) δ 162.6 (q, O_2CCF_3, $J_{C-F} = 293$ Hz), 117.9 (q, O_2CCF_3, $J_{C-F} = 29$ Hz). Elemental analysis for $C_{24}H_{20}F_6MgN_4O_4$ for **1** (%): C, 50.86; H, 3.55; N, 9.88; O 11.292. $C_{12.75}H_{8.75}MgF_6N_{1.75}O_4$ (**1** − 2.25 py) Calc. C, 39.39; H, 2.27; N, 6.30. Found: C, 39.90; H, 2.55; N, 6.30%.

2.3. $\{[Ca_2(\mu\text{-}TFA)_3(THF)_4](\mu\text{-}TFA)\}_n$ (**2**)

Used Ca^0 (5.00 g, 125 mmol), H-TFA (56.8 g, 499 mmol). "$Ca(TFA)_2$" Yield: 99.8% (33.2 g). Used "$Ca(TFA)_2$" (1.00 g, 3.76 mmol), THF (~10 mL). Yield: 65.4% (1.01 g). 2.6. General X-ray crystal structure information [37]

Each crystal was mounted onto a thin glass fiber from a pool of Fluorolube™ and immediately placed under a liquid N_2 stream, on a Bruker AXS diffractometer. The radiation used was graphite monochromatized Mo Kα radiation ($\lambda = 0.7107$ Å). The lattice parameters were optimized from a least-squares calculation on centered reflections. Lattice determination and data collection were carried out using SMART Version 5.054 software. Data reduction was performed using SAINT Version 6.01 software. The structure refinement was performed using XSHELL 3.0 software. The data were corrected for absorption using the SADABS program within the SAINT software package.

Each structure was solved using direct methods. This procedure yielded the heavy atoms, along with a number of the C, F, and O atoms. Subsequent Fourier synthesis yielded the remaining atom positions. The final refinement of each compound included anisotropic thermal parameters on all atoms. For the non-centrosymmetric structure **3**, the coordination of the TFA ligands about the Sr atoms is dictated by a 2_1-screw axis along the polymer propagation direction (*c*-axis). The polymer chain occupies both the edge of the cell along the c-axis as well as propagating through the center of the cell (through the center of the *a*–*b*-plane), which disallows the screw axis a center of inversion, resulting in the non-centrosymmetric symmetry. Additional information concerning the data collection and final structural solutions (Table 1) of these compounds can be found in the supplemental information or by accessing CIF files through the Cambridge Crystallographic Data Base.

3. Results and discussion

As mentioned previously, there are only a hand-full of A^E-TFA derivatives that have been crystallographically characterized [23–36], wherein most homocationic A^E species utilized crown ether modifications to increase their volatility for metal organic chemical vapor deposition (MOCVD) applications [29,30,35]. However, the characteristics that make these excellent MOCVD precursors, also make them ineffective for sol–gel processes. The other derivatives without a crown ether possess water, such as $\{[Sr(TFA)(\mu\text{-}TFA)(H_2O)_2]_n[N_2H_5C_3][TFA]\}$ [33] and $[Ca(TFA)_2(H_2O)_2]_n$ [36], which will introduce uncontrolled reactivity to precursor solution. Due to the void of simple TFA derivatives of A^E precursors, we proceeded to characterize this set of precursors.

3.1. Synthesis

The A^E-TFA adducts were synthesized simply by dissolving the bulk A^E metal in TFA(neat) (Eq. (1)). After the extensive effervescence was complete, if any metal remained, the mixture was heated until the metal was completely consumed. Attempts to isolate crystals of these compounds directly from the reaction mixtures were not successful which is most likely due to the formation of extended polymeric networks based on the large cation size to ligand charge ratio the A^E-TFA system will posses. Therefore, the reaction mixture was dried to a powder that displayed only limited solubility in standard non-polar solvents. However, using Lewis basic solvents (i.e., py or THF) – chosen due to their compatibility with the materials processing parameters employed and their known ability to act as a Lewis bases for A^E cations [3] – the powders were easily solubilized. Crystals were isolated for each congener as **1**–**4**, shown in Figs. 1–4, respectively. Data collection parameters are available in Table 1 and select metrical data are tabulated in Table 2.

The structure of **1**, the smallest cation of the A^E congener set, was found to be monomeric. Each Mg cation was found to adopt a 6-coordinated octahedral (Oh) geometry by binding four equatorial py solvent molecules and two axial, terminal TFA ligands (Fig. 1). It is of note that there are two unique monomeric molecules in this structure, which are chemically identical and differ only in their packing

behavior. For this reason, we present only one of the observed molecules in Fig. 1 to represent this structure which is the first report of a Mg-TFA derivative[23] and only the second structurally characterized A^E-TFA that employs a py solvent molecule, the other of which is [(py)(TFA)-(TFA$_c$)Ba(18-Crown-6)$_2$]$_2$ [30]. Of the alkaline earth TFA derivatives, only seven possess a terminal TFA molecule [23–25,30,31] and only two of those possess *only* A^E cations. For the later molecules, the TFA is forced to be terminal due to the steric crowding of crown ether ligands [30]; whereas for **2**, the multiple bound py solvent molecules and small Mg cation limit the chelating behavior of the TFA ligands.

Compound **2** was solved as a polymeric species (see Fig. 2). The molecule is constructed from two Ca metal centers bridged by three μ-TFA ligands to form the initial moiety. Two of these dinuclear moieties are linked together using a fourth μ-TFA ligand yielding the general constructs of **2**. The slightly distorted Oh geometry of each Ca was completed through the binding of two THF molecules in a *cis* equatorial arrangement. This is the first A^E-TFA system noted with bound THF [23–32,36]. The Ca–O distances were found to range from 2.27 to 2.38 Å with similar distances noted for THF ligands. The bite angle of the TFA ligands are all nearly identical at ~130°. It is of note that a water solvated Ca-TFA identified as {[(H$_2$O)$_2$Ca-(μ-TFA)(μ-TFA)$_2$]$_2$Ca}$_n$ has been reported, however, a μ-TFA ligand cross-links the chains in this molecule [36]. This is not present in **2** where the chains were not found to interact. The structure displays disorder on some of the CF_3 and THF ligands; however, this disorder was not modeled due to the inability to obtain a stable refinement while modeling potential disordered C sites (THF) or F sites (CF_3).

Compound **3** was also found to be an asymmetric polymeric chain as noted Fig. 3a and b. Each Sr atom possesses two μ-TFA and one μ_c-TFA ligand and completes its irregular 7-coordination by binding to each of the TFA ligands from the next Sr metal center (Fig. 3a). The μ- and μ_c-TFA ligands are arranged in a *trans* arrangement down the polymer chain (Fig. 3b). The μ_c-TFA binding mode has only been previously observed for Ba-TFA derivatives [23,29,31]. The Sr–O distance range from 2.49 to 2.70 Å with the longer distances associated with the μ_c-TFA ligands. The Sr—Sr distance was found to be 4.32 Å. The bite angle of the

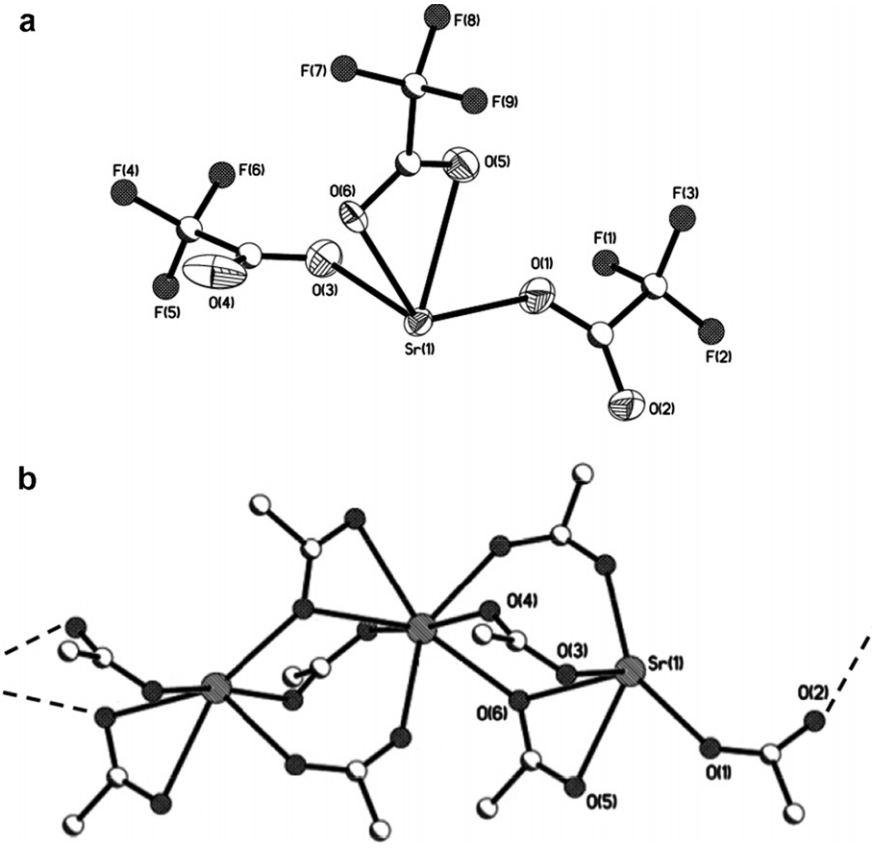

Fig. 3. Structure plot of **3**: (a) Unit cell – heavy atoms thermal ellipsoids drawn at 30% level and carbon and fluorine atoms drawn as ball and stick for simplicity. (b) Diagram of core to show extended network. H- and F- and some C-removed for clarity.

μ_c-TFA (128.6°) and the two μ-TFA (129.2° and 130.0°) are nearly identical. For **3**, a proton is needed to have a charge neutral molecule. In the lattice two pyridine solvent molecules are readily identified and a search of the electron density map indicates a proton was located *between* these two pyridine rings. The bond distances suggest that one of these is a pyrdinium molecule that solves the charge balance issue; however, the 'free' pyridine appears to have a substantial interaction with the pyridinium atom as well. For orientation, the Sr polymer chain is meshed in between this py–H—py complex along the edge of the cell and down the middle. This arrangement is relatively unusual with only four examples of the structural characterization of the py–H—py interaction noted for a variety of derivatized pyridines [38–41]. The bond lengths of the N(1)-C(7) in **3** are 1.33 Å, which is consistent with literature values, however, the N(1)–C(11) distance is slightly shorter at 1.30 Å. Structure **3** also displays disorder on some of the CF_3 ligands but again as noted for **2**, the disorder was not modeled due to the inability to obtain a stable refinement while modeling potential disordered of the F sites (CF_3).

Again, an asymmetric polymeric structure was observed for **4**, with one molecule of co-crystallized py (Fig. 4a). Each Ba adopts an irregular 10-coordinated geometry using the six O atoms of three μ_c-TFA ligands and three O atoms from the neighboring μ_c-TFA (Fig. 4b). The coordination was completed through the binding of a py solvent molecule. The Ba metal centers are separated by nearly 4.40 Å with Ba–O distances ranging from 2.74 to 2.99 Å, wherein the μ-TFA distances being the longest. The bite angles of the three μ_c-TFA (128.5°, 128.2°, and 127.5°) are similar to each other but significantly smaller than those noted for the other congeners. Again, a proton must be included for formal charge balance and was located between one of the oxygens of the TFA ligand and the lattice py (Fig. 4c). The N(2)–H(1)–O(3A) angle is ~169.7°

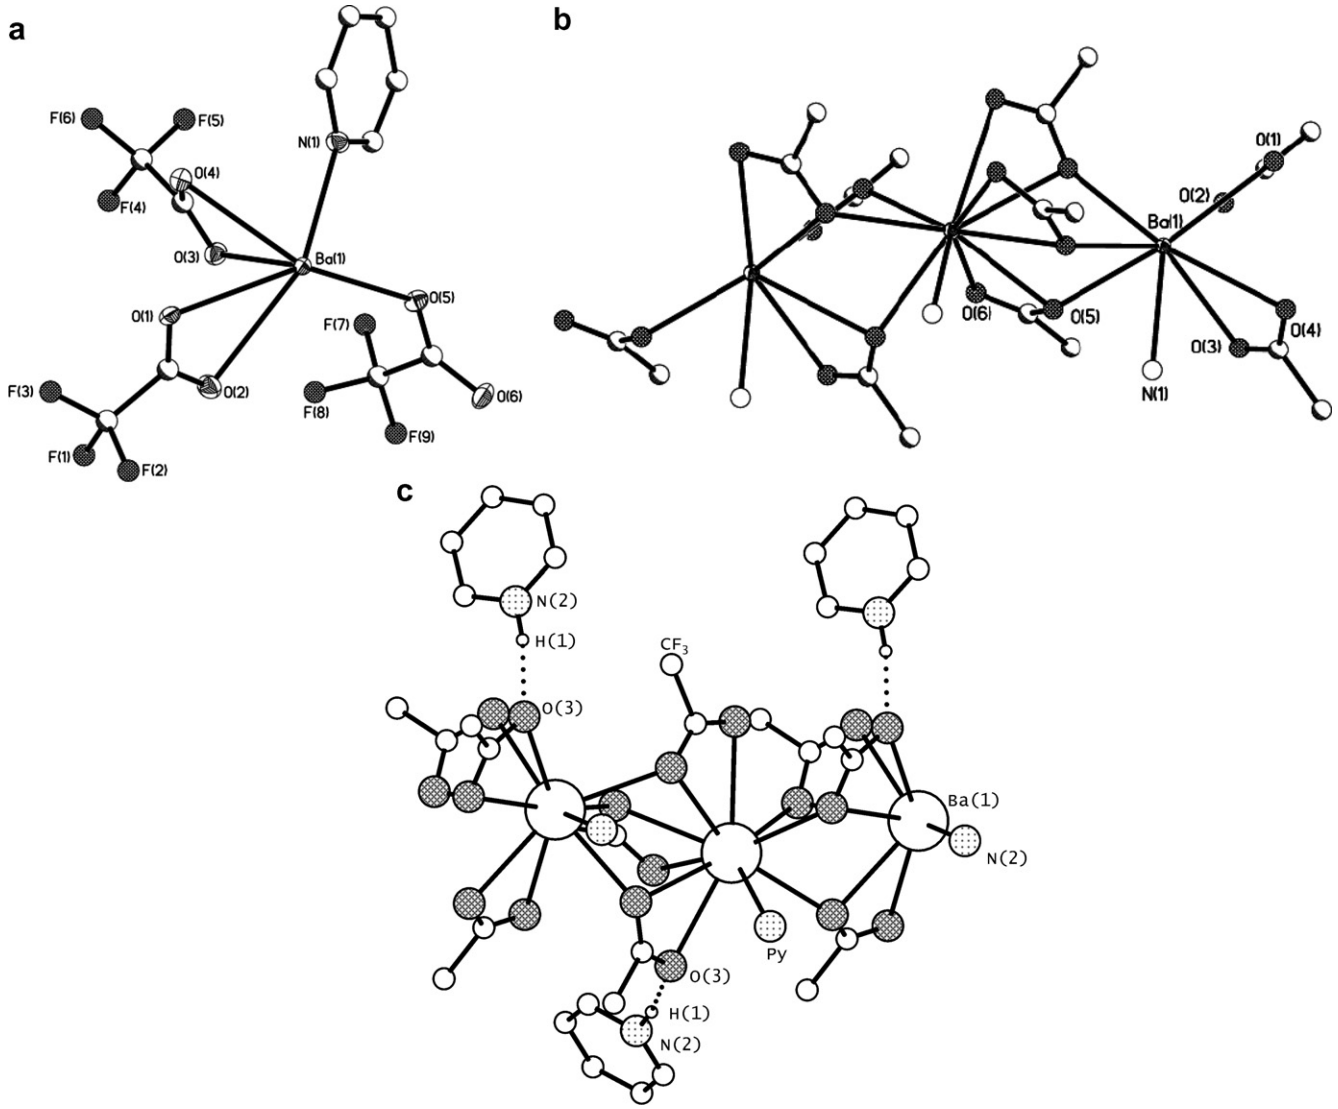

Fig. 4. Structure plot of **4**: (a) Unit cell – heavy atoms thermal ellipsoids drawn at 30% level and carbon and fluorine atoms drawn as ball and stick for simplicity. 			O(4)–Ba(1)–N(1)	65.15(10)
			O–C–O	128.2

with a N–H distance of 0.92 Å versus a 1.77 Å for the H-TFA distance. Based on these distances and comparison to the literature bond distances, this molecule is also a pyrdinium salt as noted in **3** [38–41]. As mentioned previously, the μ-TFA ligand has been observed in Ba-TFA derivatives [23,29,31], however, this molecule is unique in both arrangement, py coordination, and salt formation.

The transition from the smallest to the largest congener of this series reveals the different bonding modes available to the TFA ligand dependant upon the size of the cation. For instance, the smallest cation Mg only has terminal monodentate TFA ligands noted in **1**; whereas, Ba the largest, **4**, has only μ_c-TFA. For **3**, Ca is of such a size as to only form both μ- and μ_c-TFA ligand arrangements. This occurs even while there is room to solvate the cation, as noted for **2** and **4**. There was no sign of simple chelation by the TFA ligand in these systems that must be due to a combination of the electron donation by the Lewis basic solvents, their occupation of open coordination sites, and the size of the various A^E cations explored. Interestingly, the use of py has serendipitously yielded pyridinium ions for **3** and **4**, which appears to facilitate crystallization.

Analyses of the bulk powders were undertaken to verify they were consistent with the solid-state X-ray structures isolated. Not surprisingly, the elemental analyses of **1**–**4** were not consistent with the simple structures reported. The variations between the bulk powder and single crystal structure were associated with the bound solvents noted for **1**,**2**, and **4** as well as the free solvents or pyridinium salts found in **3** and **4**, that notoriously cause discrepancies in the elemental analyses [3,12–19]. Removal of fractional solvent molecules show an agreement can be rendered for these compounds; however, this is less than desirable in identifying these compounds.

Therefore, solid-state NMR data were collected to further characterize the bulk powders (listed in Table 3). For the majority of samples, a single ^{19}F MAS NMR resonance was observed resulting from the TFA fluoro-methyls. However, compound **2** revealed an overlap of multiple ^{19}F resonances with very similar chemical environments. These most likely represent crystal packing inequivalencies. The inability to distinguish the different TFA bonding motifs led to the analysis of both the $^{13}C\{^{19}F\}$ and $^{13}C\{^{1}H\}$ MAS NMR spectra. For the TFA moiety, a carboxyl (HOC(O)R) ^{13}C resonance around 165 ppm and a trifluoro-(CF_3) group around 114 ppm should be observed. The spectra of **1**–**4** (Fig. 5) all possess the expected TFA resonances but in general these peaks are either very broad or composed of a cluster of closely overlapping resonances. It was not possible to distinguish between the different μ_c-TFA, μ-TFA, and TFA carbon environments in the solid-state ^{13}C MAS experiments. Compounds **1** and **4** also display broad pyridine resonances whereas **2** displays a set of broad THF resonances all associated with the coordinated solvents within their respective crystal structures. Interestingly, **3** also display an additional set of py resonances that may reflect the py–H—py salt observed in the solid-state structure. These

Table 3

4	162.0 (O_2C–CF_3)	−75.6 (815)	165.6(O_2C–CF_3)	−75.2
	116.9 (CF_3)		119.7 (CF_3)	
	149.8–126.4 (py)		(py-d_5)	

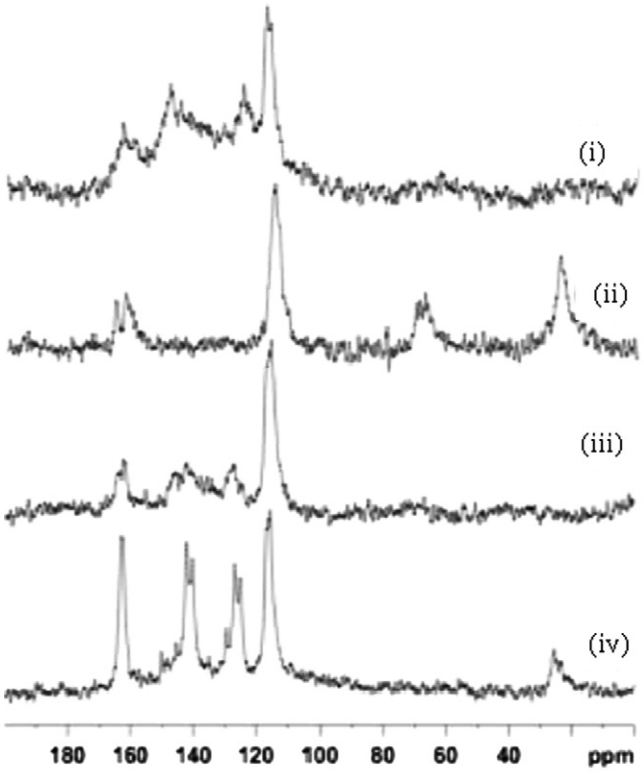

Fig. 5. The $^{13}C\{^{19}F$ decoupled} MAS NMR spectra (i) **1**, (ii) **2**, (iii) **3**, and (iv) **4**.

py and THF solvent resonances reveal very poor CP efficiencies (thus the ^{13}C NMR were obtained using DP) suggesting a high degree of mobility of these pyridine and THF environments at room temperature.

Solution $^{13}C\{^{1}H\}$ and ^{19}F NMR spectra of the materials dissolved in THF were also obtained (Table 3). The standard resonances associated with the bound solvent and a multiplet for the carboxylate ligand due to J_{C-F} splitting was observed. The ^{19}F NMR spectrum of **1** revealed two resonances in a 60:40 ratio, which is in contrast to the single resonance observed in the solid-state ^{19}F MAS NMR. The two ^{19}F NMR resonances at δ −74.8 and −76 ppm may represent a nuclearity change associated with a monomer-dimer equilibrium. Low temperature studies could not be undertaken due to the low solubility of these compounds. For **2**–**4** only a single ^{19}F resonance δ −75 ppm was observed in solution. As noted above in the solid-state, compound **2** has four overlapping resonances but in solution these packing variations averaged out yielding the single resonance noted in Table 3.

Since the carboxylate ligand is indicative of binding modes, the FT-IR spectra of these compounds were collected to further assist in identifying the bulk powder. The spectra indicated that the TFA ligand had fully reacted based on the lack of OH stretches coupled with significant changes in the C=O stretch of the TFA. For **1** two stretches (1778 and 1690 cm^{-1}) were present which would correspond to the terminally bound TFA ligands present in the observed structure. In contrast, for **2**, only one stretch was noted at 1668 cm^{-1} that would be consistent with μ-TFA ligands; for **4**, two peaks at 1773 and 1672 cm^{-1} were observed and associated with μ_c-TFA ligands; however, for **3**, three peaks at 1753, 1678, and 1665 cm^{-1} were observed. By combining the stretches noted for **2** and **4**, it is apparent that **3** have both μ- and μ_c-TFA ligands present. These FTIR spectra, along with the above data, indicate that the bulk powders of **1**–**4** were consistent with the single crystal structures noted.

4. Summary and conclusion

The structural aspects of solvated TFA alkaline earth derivatives have been solved with several novel aspects present, such as the first: Mg-TFA species, THF solvated species, pyridinium salts derivatives. The TFA ligand coordination were found to bind in several arrangements including terminal, μ-TFA, and μ_c-TFA, the nature of which is determined by the size of the cation and bound solvent molecules. Interestingly, the above conditions were not conducive to the formation of TFA_c in any instance but the use of py as a Lewis basic solvent for the system led to the formation of pyridinium salts for two of the congeners. While each of these types of binding modes have been observed in the literature [23–32,36], this family of compounds is unusual for alkaline earth carboxylates due to their lack of crown ethers and the inclusion of Lewis bases which may lend some insight into the processing of superconductor or other alkaline earth based materials.

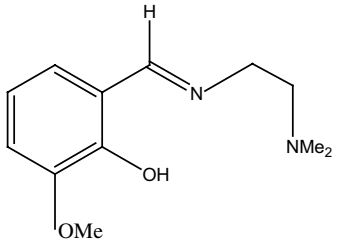
Lewis acid activation of the substrate, generation of a reactive nucleophile (Zn-OH) and stabilization of the leaving group [19]. Schiff bases can act as useful blockers due to their preparational accessibility, structural varieties and varied denticities. Pseudohalides are efficient intermediates; of them the flexidentate homoatomic azide and ambidentate heteroatomic cyanate and thiocyanate ions form various networks with several transition and non-transition metal ions together with organic spacers of varied denticities [15]. In an effort to isolate and study new forms of such aggregates, we have been exploring the coordination behaviour of a potentially tetradentate Schiff base ligand (**LH**, Scheme 1), the condensation product of *o*-vanillin and 2-dimethylaminoethylamine, towards zinc(II) centers in combination with pseudohalides (azide, cyanate and thiocyanate ions).

Moreover, luminescent compounds are attracting much current research interest because of their many applications including emitting materials for organic light emitting diodes, light harvesting materials for photocatalysis and fluorescent sensors for organic or inorganic analytes [20]. Introduction of electron-donating groups into the salicylidene moiety of Zn(II) complexes enhances the quantum yield of photoluminescence [21]. Hence it is important to understand the coordination chemistry and luminescence between Group 12 metal ions for developing new materials which can function as fluorescent sensors [20].



Our research group has already reported some mono- and dinuclear transition metal complexes using the ligand **LH** [3,7,22]. In continuation, using zinc trichloroacetate hydrate as the metal salt, three new dinuclear zinc(II) complexes, $[Zn(L)(\mu_{1,1}\text{-}N_3)Zn(L)(N_3)]\cdot 1.5H_2O$ (**1**), $[Zn(L)(\mu_{1,1}\text{-}NCO)Zn(L)(NCO)]\cdot 1.5H_2O$ (**2**) and $[Zn(L)(\mu_{1,1}\text{-}NCS)Zn(L)(NCS)(OH_2)]$ (**3**), have been synthesized with **LH**. In this paper, we have reported the synthetic details, spectral characterizations, thermal investigations, along with X-ray crystal structures and fluorescence studies of **1**, **2** and **3**, where pseudohalides act as terminal ligands as well as adopting an *end-on* bridging mode in the presence of a potentially tetradentate Schiff base (**LH**).

2. Experimental

2.1. Materials

2-Dimethylaminoethylamine (Fluka, Germany), *o*-vanillin (Lancaster, UK), sodium azide, sodium cyanate and sodium thiocyanate (Aldrich, USA) were used as received. Zinc(II) trichloroacetate hydrate was prepared by treatment of zinc carbonate (E. Merck, India) with trichloroacetic acid (E. Merck, India) followed by slow evaporation on a steam-bath, then filtration through a fine glass-frit, and it was preserved in a desiccator containing $CaCl_2$ for subsequent use. All the solvents were of AR grade and were used as received.

Caution! Azido compounds of metal ions are potentially explosive, especially in the presence of organic ligands. Only a small amount of material should be prepared and it must be handled with care.

Scheme 1. **LH**.

2.2. Physical measurements

The infrared spectra of the complexes were recorded on a Perkin-Elmer RX I FT-IR spectrophotometer with KBr discs (4000–300 cm^{-1}). Elemental analyses (C, H, N) were carried out using a Perkin-Elmer 2400 II elemental analyzer. ^1H NMR spectra were recorded on a Bruker 300 MHz FT-NMR spectrometer using trimethylsilane as an internal standard in $CDCl_3$ for complexes **1** and **2**, and in d^6-DMSO for complex **3**. The thermal analyses of **2** and **3** were done on a Mettler Toledo TGA/SDTA-851e thermal analyzer system in a dynamic atmosphere of dinitrogen (flow rate: 30 cm^3 min^{-1}) in an alumina crucible at a heating rate of 10 °C min^{-1}. Ground state absorptions for the ligand and the complexes were made with a Perkin-Elmer Lambda 40 (UV–Vis) spectrophotometer in methanol. A "JOBIN YVON Fluoro Max 3. A" spectrofluorimeter model was used for the steady state fluorescence measurements for all the three complexes and the Schiff base ligand at room temperature (298 K). The solutions of the ligand and complexes **1**, **2** and **3** were prepared in a 2:1 water–methanol mixed solvent ratio and the OD for each of the solutions at the wavelength for fluorescence excitation was recorded. The fluorescence quantum yields of the Schiff base (**LH**) and its zinc-pseudohalides complexes were determined using quinine sulfate as the reference with a known φ_R of 0.70 in methanol. The complexes, along with ligand and the reference compound, were excited at 370 nm and the emission spectra were recorded from 385 to 700 nm. The area of the emission spectrum was integrated using the software available in the instrument and the quantum yield was calculated according to the following equation:

$$\varphi_S/\varphi_R = [A_S/A_R] \times [(OD)_R/(OD)_S] \times [\eta_S^2/\eta_R^2]$$

Here φ_S and φ_R are the fluorescence quantum yields of the sample and reference, respectively, A_S and A_R are the areas under the fluorescence spectra of the sample and the reference, respectively. $(OD)_S$ and $(OD)_R$ are the respective optical densities of the sample and the reference solution at the wavelength of excitation, and η_S and η_R are the values of refractive index for the respective solvents used for the sample and reference [23].

2.3. Synthesis of the Schiff base ligand and metal complexes

2.3.1. Schiff base $[(CH_3)_2NCH_2CH_2N{=}CHC_6H_3(OH)(OMe)]$ (**LH**)

The Schiff base was obtained by refluxing a methanolic solution (50 ml) of *o*-vanillin (10 mmol) and 2-dimethylaminoethylamine (10 mmol) for 30 min. The resulting orange yellow solution containing the required product was used without further purification.

2.3.2. $[Zn(L)(\mu_{1,1}\text{-}N_3)Zn(L)(N_3)]\cdot 1.5H_2O$ (**1**)

To an aqueous methanolic solution (30 ml) of zinc trichloroacetate hydrate (0.390 g, 1 mmol), a solution of the Schiff base **LH** (1 mmol) was added, followed by a solution of sodium azide (0.065 g, 1 mmol) in a minimum volume of methanol with constant stirring for 10 min. This mixture was kept at room temperature, yielding light yellow hexagonal crystals suitable for X-ray diffraction after 10 days. The crystals were isolated by filtration and air-dried. Yield: 61%. *Anal.* Calc. for $C_{24}H_{37}N_{10}O_{5\cdot5}Zn_2$: C, 42.08; H, 5.40; N, 20.45. Found: C, 42.02; H, 5.38; N, 20.41%.

2.3.3. $[Zn(L)(\mu_{1,1}\text{-}NCO)Zn(L)(NCO)]\cdot 1.5H_2O$ (**2**)

Complex **2** was synthesized in a similar manner as described above, but adding sodium cyanate (0.065 g, 1 mmol) instead of sodium azide. Light yellow, hexagonal crystals suitable for X-ray diffraction were obtained after 2 weeks. The crystals were collected by filtration and air-dried. Yield: 53%. *Anal.* Calc. for $C_{26}H_{37}N_6O_{7\cdot5}Zn_2$: C, 45.59; H, 5.40; N, 12.27. Found: C, 45.52; H, 5.37; N, 12.22 %.

2.3.4. $[Zn(L)(\mu_{1,1}\text{-}NCS)Zn(L)(NCS)(OH_2)]$ (**3**)

Complex **3** was prepared following the same procedure as for **1** and **2**, except by adding sodium thiocyanate (0.0808 g, 1 mmol) as the bridging ligand instead of NaN_3 or NaOCN. Light yellow block shaped crystals suitable for X-ray diffraction were obtained after 7 days. The crystals were collected by filtration and air-dried. Yield: 68%. *Anal.* Calc. for $C_{26}H_{36}N_6O_5Zn_2S_2$: C, 44.14; H, 5.13; N, 11.88. Found: C, 44.08; H, 5.09; N, 11.81%.

2.4. Crystallographic data collection and structure refinements

Intensity data for the light yellow coloured crystals of **1** and **2** were collected on a Bruker X8 Apex 2 diffractometer whilst data for **3** were collected on a Rigaku AFC7 four circle serial diffractometer. Data were corrected for absorption empirically by means of multi-scans (SADABS) (**1**, **2**) and psi scans (**3**). The structures were solved by direct and difference Fourier methods and refined by full-matrix least-squares on F^2. All non-hydrogen atoms were refined with anisotropic displacement parameters. The crystallographic computing was performed using SHELXTL [24] programs. Further details have been given in Table 1.

3. Results and discussion

3.1. Description of crystal structures of 1, 2 and 3

Complex **1** is isostructural with complex **2**, but it contains N_3^- instead of NCO^-. However **3**, which differs only in the pseudohalide (SCN^-) has some significant structural differences when compared to **1** and **2**.

The ORTEP diagrams of **1**, **2** and **3** are shown in Figs. 1–3, respectively with selected bond dimensions given in Tables 2–5. Complex **1** and **2** contain two geometrically distinct zinc(II) centers. Zn1 has a predominantly square pyramidal geometry (N_4O donor set) with $\tau = 0.02$ and 0.017 for **1** and **2**, respectively ($\tau = 0$ and 1 for the perfect square pyramidal and trigonal bipyramidal geometries, respectively) [25] whilst Zn2 has a distorted octahedral geometry (N_3O_3 donor set). The two Zn(II) centers in all the three complexes are doubly bound together by a μ_2-phenolato oxygen atom O1 of the deprotonated Schiff base $\mathbf{L}^-$ and a $\mu_{1,1}$-pseudohalide nitrogen atom N1 (of azide for **1**, cyanate for **2** and thiocyanate for **3**). The distance between the two non-bonded Zn(II) centers are 3.2130(2) Å (**1**), 3.1745(2) Å (**2**) and 3.1918(5) Å (**3**), which is comparable to similar systems [22]. In **1** and **2**, the N6 atom of the terminal pseudohalide ligand binds to the apical site on Zn1 whilst the N_2O donors (N2, N3 and O1 atoms) of the deprotonated Schiff base $\mathbf{L}^-$ together with the bridging N_3^-/NCO^- nitrogen atom N1 form the square base. Conversely the Zn2 center has a distorted octahedral coordination geometry composed of a N_3O_3 donor set (N1, N4, N5, O1, O2 and O3 atoms) from both Schiff base ligands and the bridging pseusohalide ligand. However in **3**, the geometry around both zinc(II) centers is distorted octahedral with a N_3O_3 donor set for Zn1 and a N_4O_2 donor set for Zn2. The water to Zn distance is much shorter [Zn2–O4, 2.369(2) Å] than that found in **1** and **2**, where there is a water molecule near the vacant sixth site of the square pyramidal Zn centers [O5–Zn1, 2.774(1) Å (**1**) and 2.873(1) Å (**2**)]. The square base around Zn1 is formed by phenolato and methoxy oxygen atoms (O1 and O2, respectively) from the bridging $\mathbf{L}^-$, imino nitrogen N3 from chelating $\mathbf{L}^-$ and bridging thiocyanato nitrogen N1, whereas the axial sites are occupied by the phenolato oxygen O3 and amino nitrogen N2 atom of the chelating $\mathbf{L}^-$. On the other side the N_2O donor set (N4, N5 and

The two Schiff base ligands also display flexible coordination modes in all the three structures such that one is tetradenate (N_2O_2 donor set) whilst the other is tridentate (N_2O donor set) with a non-bonded methoxy (–OMe) group. Further variation is found in the pseudohalide coordination as one binds two metal centers in an *end-on* bridging mode and the other as a terminal ligand.

In **1**, the unbound (O1W) water participates in the shortest hydrogen bond with the azido nitrogen, whilst the weakly bound water molecule O5 interacts with the phenolato and methoxy oxygen atoms of the Schiff base (Table 3, Supplementary material 1). The zinc complexes interact directly with each other with $\pi-\pi$ stacking between the rings (C4 to C9), where the C4...C6i distance (where i is the symmetry code $2-x, -y, 1-z$) is 3.317 Å. The hydrogen bonding patterns are similar in **2**, the shortest hydrogen bond involves the pseudohalide and solvent water (although the H atoms were not located for O2s, the O...O distance is 2.686 Å). There is also π–π stacking between adjacent aromatic rings where the C4...C6i distance (where i is the symmetry code $-x, 1-y, 1-z$) is 3.348 Å. (Supplementary material 2, Table 4). In **3**, unlike **1** and **2**, the zinc complexes are directly connected as a centrosymmetric dimer *via* two intermolecular hydrogen bonds involving the weakly coordinated water molecule with S1 of the bridging thiocyanate. This may be because the SCN^- ligand is significantly larger than N_3^- or NCO^- and **3** has to take on a slightly different packing motif to incorporate this difference. However, the intramolecular hydrogen bonds involving the methoxy and phenoxo O atoms are very similar to those found for **1** and **2** (Table 5, Supplementary material 3).

3.2. Infrared spectra

The infrared spectra of the complexes are consistent with the structural data given in this paper. The bifurcated bands at 2082, 2051 cm^{-1} for **1**, 2208, 2187 cm^{-1} for **2** and 2067, 2028 cm^{-1} for **3** are attributed to the bridging azido (N_3^-), cyanato (NCO^-) and thiocyanato (SCN^-) groups in **1**, **2** and **3**, respectively [26]. The strong $\nu_{C=N}$ bands occurring at 1630, 1632 and 1629 cm^{-1} for **1**, **2** and **3** respectively are shifted considerably towards lower frequencies compared to that of the free Schiff base ligand (1635 cm^{-1}),

Table 6

1	2.14 (12H, s, H9); 2.65 (4H, t, $J=3.4$ Hz, H8); 3.46 (4H, t, $J=4.2$ Hz, H7); 4.01 (6H, s, H6); 3.88 (3H, s, H6′); 6.50 (2H, d, $J=7.2$ Hz, H2); 6.83 (2H, d, $J=7.4$ Hz, H4); 8.13 (2H, t, $J=7.6$ Hz, H3); 8.33 (2H, s, H5)
2	2.14 (12H, s, H9); 2.65 (4H, t, $J=3.2$ Hz, H8); 3.46 (4H, t, $J=3.9$ Hz, H7); 4.03 (6H, s, H6); 3.86 (3H, s, H6′); 6.51 (2H, d, $J=6.8$ Hz, H2); 6.83 (2H, d, $J=7.4$ Hz, H4); 8.13 (2H, t, $J=7.8$ Hz, H3); 8.35 (2H, s, H5)
3	2.14 (12H, s, H9); 2.59 (2H, s, H10); 2.65 (4H, t, $J=3.2$ Hz, H8); 3.46 (4H, t, $J=3.9$ Hz, H7); 4.02 (6H, s, H6); 3.87 (3H, s, H6′); 6.50 (2H, d, $J=6.8$ Hz, H2); 6.82 (2H, d, $J=7.4$ Hz, H4); 8.12 (2H, t, $J=7.8$ Hz, H3); 8.34 (2H, s, H5)

indicating coordination of the imino nitrogen atom [27]. Ligand coordination to the metal centers is substantiated by two bands appearing for ν_{M-N} at 459, 448, 448 cm^{-1} and for ν_{M-O} at 372, 368, 370 cm^{-1} for **1**, **2** and **3**, respectively.

3.3. ^1H NMR spectra

^1H NMR spectroscopy has been used to extract information regarding the coordination mode of the ligand with the metal ions for the complexes **1**, **2** and **3**; the NMR data are summarized in Table 6. The ^1H NMR spectra (Fig. 5) of **1** and **2** are almost indistinguishable and are slightly different from that of **3**, which contains only one additional singlet peak for the coordinated water molecule. In all the complexes **1**, **2** and **3**, the signal due to the phenolic hydrogen (H1) of the free molecule (5.2623 ppm) is absent, indicating the coordination of a deprotonated ligand in these complexes. The signals for the amino methyl group (H9) show downfield shifts (0.08 ppm) from its position of the free molecule due to the coordination of the amino nitrogen atom with the metal centers. The singlet due to the proton (H5) attached to the imino (–C=N) group shows a downfield shift (0.03–0.05 ppm) compared to its position in the free molecule, reflecting the coordination of the deprotonated Schiff base ligand ($\mathbf{L}^-$) to the metal centers through the imine nitrogen atom. In the spectra of all the complexes, the signals for the methoxy hydrogens (H6 and H6′) give two bands with close δ values, one with significant downfield shifts (0.15–0.17 ppm, H6), and another with minor shifts (0.02 ppm, H6′) suggesting the presence of two types of methoxy group in the complexes, one coordinating and the other non-coordinating. The phenyl hydrogens show significant shifts [0.15–0.16 ppm (H2), 0.22 ppm (H4), 0.12 ppm (H3)] indicating the involvement of the phenolato oxygen in coordination with the metal centers. For the complexes, the protons (H7) of the CH_2 group attached to the imine nitrogen and the protons (H8) of the CH_2 group associated with the amine nitrogen show downfield shifts of 0.04 ppm and 0.01 ppm, respectively from the free ligand values. The spectrum of complex **3** contains one extra singlet signal at 2.59 ppm due to the hydrogen atoms (H10) of the water molecule attached to the Zn2 center. The results obtained from the NMR spectra support the structures obtained by the X-ray analysis and suggest that the structures of complexes **1** and **2** are retained in $CDCl_3$ solution and **3** in d^6-DMSO. The NMR spectrum of **3** is recorded in the solution phase and it is different from those of **1** and **2**, which indicates that the different structure of **3** shown in the solid state is also maintained in solution.

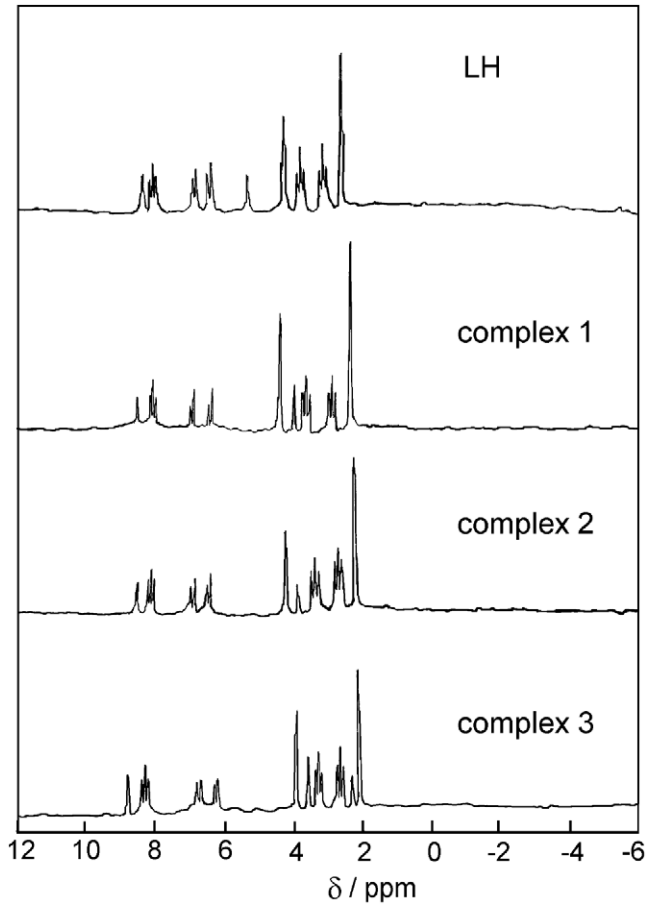

Fig. 5. NMR spectra of LH and complexes **1**, **2** and **3**.

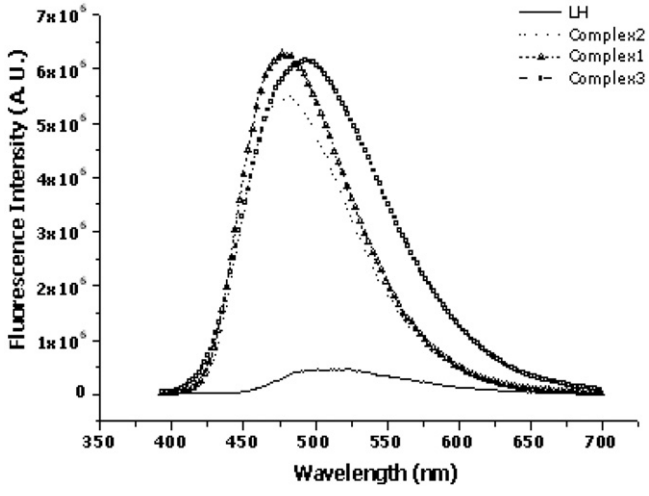

Fig. 4. Fluorescence spectra of LH and complexes **1**, **2** and **3** in methanol-water (λ_{exc} = 370 nm).

3.4. Thermogravimetric analyses

The thermal study of complex **1** was not carried out in order to avoid an explosion of the azide compound. The TGA experiments for **2** and **3** indicated that the crystals of **2** and **3** are stable up to ~100 °C and ~168 °C, respectively. At temperatures above ~100 °C and ~168 °C, the crystals of the respective complexes started to lose weight. For complex **2**, the first stage of weight loss (~3.92%) occurs between 100 °C and 110 °C, which corresponds to

Table 7
Photophysical parameters of **LH** and complexes **1**, **2** and **3** in methanol–water at 298 K; excitation at 370 nm; reference compound is quinine sulfate ($\varphi_R = 0.07$ in methanol)

Compound	Abs (λ_{max}), nm	Emission (λ_{max}), nm	Quantum yield (φ)
LH	417	524	0.0021
1	375	475	0.1385
2	375	475	0.0077
3	370	495	0.0162

the loss of the intramolecular hydrogen bonded water molecule present in the crystal lattice. For complex **3**, the first stage of weight loss (~2.61%) takes place between 168 °C and 178 °C, corresponding to the loss of one coordinated water molecule.

3.5. Fluorescence spectral studies

The fluorescence properties of the Schiff base ligand (**LH**) and its Zn(II) complexes (**1**, **2** and **3**) were studied at room temperature (298 K) in methanol–water solutions (Fig. 4). All the three complexes exhibit strong fluorescence in comparison to **LH**. For Zn(II) complexes, no emission originating from metal-centered MLCT/LMCT excited states are expected, since the Zn(II) ion is difficult to oxidize or reduce due to its stable d^{10} configuration. Thus, the emission observed in the complexes is tentatively assigned to the $^1(\pi–\pi^*)$ intraligand fluorescence [23]. It is interesting that the Zn(II) complexes show a higher intensity than that of the free ligand. This is supported from their calculated quantum yield values (Table 7) with reference to quinine sulfate. Metal ions can enhance or quench the fluorescence emission of some Schiff base ligands containing an aromatic ring. Quenching of fluorescence of a ligand by transition metal ions during complexation is a rather common phenomenon which is explained by processes such as magnetic perturbation, redox activity, electronic energy transfer, etc. Enhancement of fluorescence through complexation is, however, of much interest as it opens up the opportunity for photochemical applications of these complexes [28]. In the absence of metal ions the fluorescence of the ligand is probably quenched by the occurrence of a photoinduced electron transfer (PET) process due to the presence of a lone pairs of electrons of the donor atoms in the ligand. Such a PET process is prevented by the complexation of **LH** with metal ions; thus the fluorescence intensity may be greatly enhanced by the coordination of Zn(II). The chelation of the ligand to Zn(II) increases the rigidity of the ligand and thus reduces the loss of energy by thermal vibrational decay [23].

4. Conclusion

The Schiff base **LH** forms three dinuclear Zn(II) complexes with the $Zn(TCA)_2 \cdot \times H_2O$ metal salt, where the two Zn(II) centers are bridged by a μ_2-phenolato O atom of $\mathbf{L}^-$ and a $\mu_{1,1}$- pseudohalide nitrogen atom. The deprotonated Schiff base $\mathbf{L}^-$ shows flexible coordination (both tridentate and tetradentate coordination modes) in all the complexes. The azido and cyanato complexes are isostructural but the thiocyanato species has two, rather than one, six coordinated Zn centers owing to the coordination of solvent water. This may be because the SCN^- ligand is significantly larger than N_3^- and NCO^- and so chooses a slightly different packing motif. Although the zinc TCA salt has been used to prepare the complexes, the TCA anion is totally absent from the crystal lattice in all the complexes. This is in contrast to the previously reported zinc complex of zinc acetate dihydrate [22]. This may be explained by the fact that the −I effect of the three chlorine atoms in the TCA anion decreases the coordination ability and thus it is a weaker nucleophile compared to the pseudohalide ligands forming the bridge between the two metal centers. Furthermore, the three dinuclear Zn(II) complexes each displays intense fluorescence at room temperature. It is suggested that these compounds exhibit the potential for use in applications as photoactive materials.

Acknowledgements

We gratefully acknowledge Jadavpur University, Kolkata, India for providing Laboratory facilities. We are thankful to Dr. Andrés Ibañez M. for the structural data analysis of complex **3**. Our thanks are also extended to Dr. S. Das, Department of Chemistry, Jadavpur University, Kolkata, India and Mr. P.S. Guin, Saha Institute of Nuclear Physics, Kolkata, India for recording the fluorescence spectra. We are grateful to Mr. J. Chakraborty, Jadavpur University, Kolkata for modification of Fig. 4.

Appendix A. Supplementary material

CCDC 628347, 628348 and 637863 contain the supplementary crystallographic data for **1**, **2** and **3**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2007.07.025.

Presently we report on the syntheses, crystal structures, thermal- and magnetic properties of two novel 3D carboxylato-bridged coordination polymers of Mn(II) with two different dicarboxylate ligands, $\{[Mn(aip)(DMF)]\}_n$, CPO-9, and $\{[Mn_3(Hatp)_2(atp)_2](H_2O)_2(DEF)_4\}_n$, CPO-10 [aip = 5-aminoisophthalate, atp = 2-aminoterephthalate, DMF = dimethylformamide, DEF = diethylformamide].

2. Experimental

2.1. Synthesis

$\{[Mn(aip)(DMF)]\}_n$, CPO-9. Dark brown single crystals were prepared from a starting mixture of $MnCl_2 \cdot 4H_2O$ (148 mg, 0.75 mmol), 5-aminoisophthalic acid (aip, 272 mg, 1.5 mmol), tetrahydrofuran (THF, 4.0 mL) and dimethylformamide (DMF, 8.0 mL). The crystallization took place in a teflon lined steel autoclave at 110 °C for 24 h. The product was filtered and washed with DMF, and dried at ambient overnight. The yield was 75% based on Mn. *Anal.* Calc. for $C_{11}H_{12}MnN_2O_5$: C, 43.01; H, 3.94; N, 9.12. Found: C, 42.80; H, 4.02; N, 8.56%.

$\{[Mn_3(Hatp)_2(atp)_2]\ (H_2O)_2(DEF)_4\}_n$, CPO-10. Light brown single crystals were obtained from a reaction conducted at 110 °C for 24 h. The starting mixture was composed of $MnCl_2 \cdot 4H_2O$ (148 mg, 0.75 mmol), 2-aminoterephthalic acid (atp, 272 mg, 1.5 mmol), tetrahydrofuran (THF, 4.0 mL) and diethylformamide (DEF, 8.0 mL). The reaction took place in a teflon lined steel autoclave. The product was filtered and washed with DMF, and dried at ambient overnight. The yield was 70% based on Mn. *Anal.* Calc. for $C_{52}H_{70}Mn_3N_8O_{22}$: C, 47.17; H, 5.33; N, 8.47. Found: C, 46.53; H, 5.04; N, 8.21%.

2.2. Single-crystal X-ray diffraction

Single-crystal X-ray diffraction data were collected using a Bruker ApexII diffractomer with a graphite monochromator and Mo Kα radiation ($\lambda = 0.71073$ Å). The crystals were glued to glass fibres, and data were collected at room temperature. Data reduction and empirical absorption correction were carried out using the programs SAINT [17] and SADABS [18], respectively. The crystal structures were solved by direct methods and refined using the WINGX program package [19]. For CPO-9 the refinement of the structure was straightforward with all non-hydrogen atoms being refined anisotropically, and the organic hydrogen atoms being generated geometrically and refined in the riding mode. In case of CPO-10, the aminogroups of the 2-aminoterephthalate anions are disordered over two positions. The solvent molecules inside the pores of CPO-10 were severely disordered, and no satisfactory model for the disorder could be found. The electron density was taken into account with the SQUEEZE procedure in PLATON [20]. In the same way as for CPO-9, the non-hydrogen atoms were refined anisotropically, and the organic hydrogen atoms were generated geometrically and refined in the riding mode. The crystallographic data and details on the refinements for both compounds are listed in Table 1, and selected bond distances and angles are given in Table 2.

2.3. Thermogravimetric analysis (TGA)

TGA was performed on a Perkin–Elmer TGA. The samples of CPO-9 and CPO-10 (about 20 mg) were heated to 700 °C in flowing nitrogen gas at a heating rate of 5 °C/min.

2.4. High-temperature powder X-ray diffraction (HT-PXRD)

HT-PXRD data for CPO-9 and -10 were collected in transmission mode with a Siemens D5000 diffractometer using Cu $K\alpha_1$ radiation selected with an incident beam Ge monochromator. The detector was a Braun PSD. The sample was kept in a rotating 0.5 mm quartz capillary

which was heated from 30 to 270 °C with a gas blower. Diffraction patterns were collected continuously while heating the samples. The measurement time for each powder pattern was 2 h, meaning that each pattern represents an average for a temperature interval of about 24 °C.

2.5. Magnetic measurements

The magnetization measurements were performed using a Quantum Design MPMS SQUID system. Data for zero field cooled samples were collected in the range 2–300 K in an applied field of 1000 G. Gelatin sample holders were used. A Pd standard was used for calibration.

3. Result and discussion

3.1. Crystal structures

CPO-9 crystallizes in the orthorhombic space group $Pna2_1$ (no. 33). The asymmetric unit of CPO-9 contains one aip^{2-}, one Mn(II) and one DMF molecule. The Mn(II) ion exhibits five-coordination with a distorted trigonal bipyramidal geometry (Fig. 1). Four of the oxygen atoms (O1, O2, O3 and O4) originate from four distinct aip

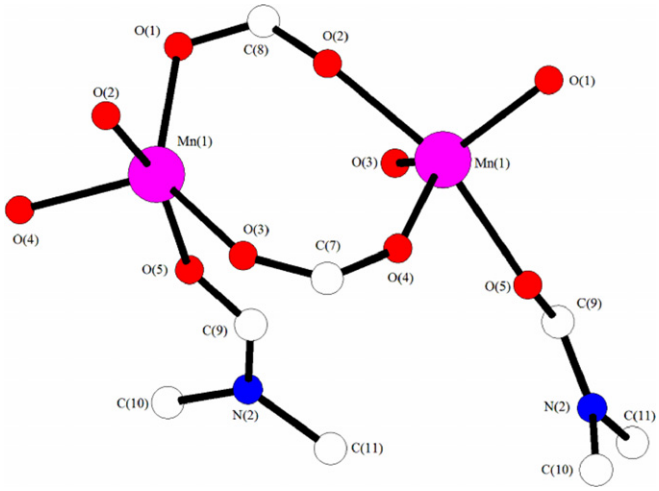

Fig. 1. Coordination environment for Mn in CPO-9.

ligands, while the last oxygen atom, O5, comes from a DMF molecule. Mn–O bonding distances in the range 2.073(2)–2.177(2) Å are fully consistent with previously reported results [21–23]. The adjacent Mn(II) centres are doubly bridged by the carboxylate groups of the aip ligands to form infinite chains of Mn–O polyhedra running along [1 0 0]. The two carboxylate groups bridging subsequent Mn atoms adopt a syn–syn and a syn–anti conformation, respectively. The Mn–Mn distance within the chains is 4.1177(4) Å.

Each of the infinite chains is connected to four adjacent chains by the ring system of the aip ligands to form a 3D coordination polymer. The structure contains 1D channels running along [1 0 0] (Fig. 2). The dimensions of these channels are 8.3×8.3 Å (measured between atom centres). The DMF molecules and the amino groups of the aip ligands protrude into the channels. Crystal structures containing similar infinite chains of five-coordinated Mn being doubly bridged by carboxylate groups as in CPO-9 are known in literature. One 1D and two 3D coordination polymers show the same structural motif [24–26]. However, the

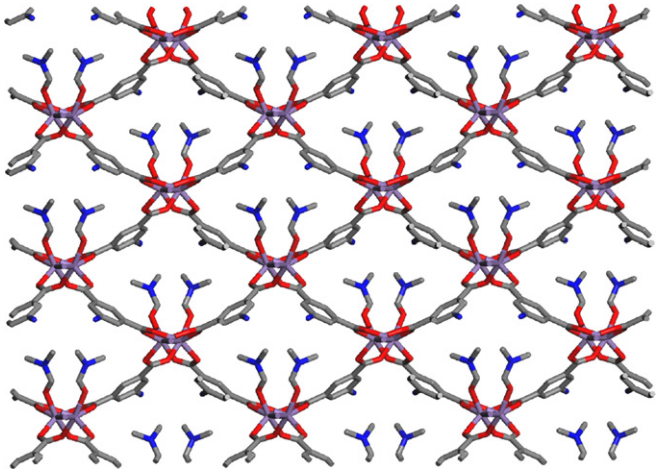

Fig. 2. The crystal structure of CPO-9 seen along [1 0 0].

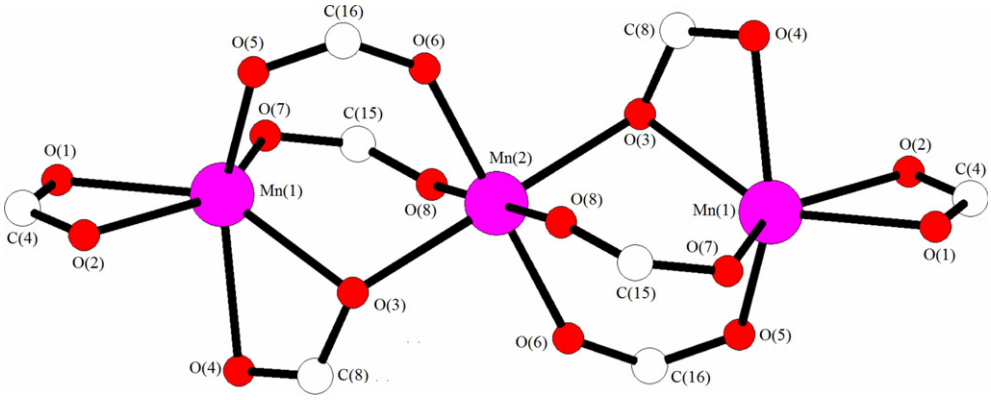

Fig. 3. The trinuclear Mn_3 building units observed in CPO-10.

connectivity within the chains differs between these structures. In addition to CPO-9, one more Mn(II) compound based on aip have been identified in the literature [27,28].

CPO-10 crystallizes in the monoclinic space group $C2/c$ (no. 15). A linear trinuclear Mn_3 unit forms the fundamental building unit of CPO-10 (Fig. 3). Such trinuclear units exist in a number of molecular complexes containing Mn(II) [29–35], and also in three dimensional coordination polymers based on Ni [36], Zn [37] and Mg [38]. The central Mn(2) atom in the Mn_3 units shows a rather regular octahedral coordination geometry involving six carboxylate oxygen atoms, while the terminal Mn(1) atoms in the Mn_3 units show a far more irregular six-coordination involving carboxylate oxygen atoms, Table 2. The bonding distances of 2.076(3)–2.343(3) Å for Mn(1) and 2.085(2)–2.250(2) Å for Mn(2) are within the expected range for divalent Mn(II). The divalent nature of the Mn atoms is further confirmed by bond valence calculations [39]. The Mn–Mn distance of 3.5232(6) Å within the Mn_3 units is consistent with findings for similar trinuclear compounds [29,34]. The Mn atoms in the Mn_3 units are connected by two syn-syn bridging bidentate carboxylate groups and one bridging/chelating carboxylate group. The trinuclear units are terminated by bidentate chelating carboxylate groups.

The linear Mn_3 units are linked via the atp ligands to form a 3D coordination polymer containing channels of dimension 10.1×10.4 Å (measured between atom centers) running along [0 0 1] (Fig. 4). These channels are occupied by two water molecules and four DEF molecules per formula unit. Because of disorder, the channel contents could not be established on the basis of the single crystal X-ray diffraction data, and is therefore determined on the basis of TGA and elemental analysis. The solvent accessible void volume of the crystal structure was calculated by PLATON [20] as 51.9% of the unit cell volume, i.e. a rather high value compared with other materials so far described.

In order to achieve charge neutrality of the CPO-10 material, either some atp ligands have extra protons attached or the channel content must be protonated. Since all the oxygen atoms of carboxylate groups are involved in bonding to Mn, it is most likely that hydrogen atoms are attached to the nitrogen atoms of the amino groups. These amino groups are, however, disordered over two positions, and thus the hydrogen atoms cannot be located by difference Fourier analysis of the X-ray diffraction data. The disorder of the channel content also makes it impossible to locate any protons. Formally we suggest that two atp ligands per formula units are protonated in order to obtain charge neutralization of CPO-10.

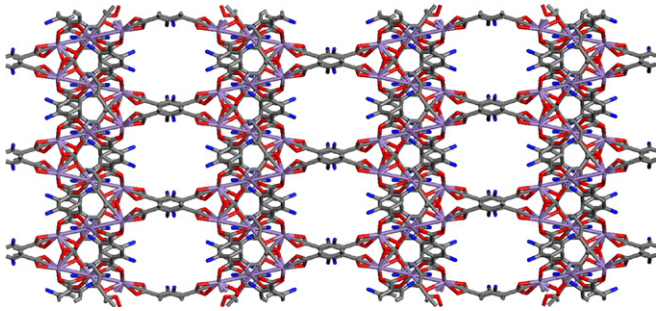

Fig. 4. The crystal structure of CPO-10 seen along [0 0 1].

3.2. Thermal properties

A three dimensional representation of the progressive change in the high temperature powder X-ray diffraction patterns for CPO-9 over the temperature range 30–270 °C is shown in Fig. 5. The patterns reveal that CPO-9 transforms into an amorphous phase at 250 °C. The TGA curve (Fig. 6) shows that this transformation correlates with a partial loss of DMF molecules at 180–250 °C. From 250 to 400 °C, there is a gradual weight loss involving the rest of the DMF molecules, presumably also an OH group being bonded to Mn (observed 23.16 wt%, calculated 23.80 wt%). The final weight loss starting at 400 °C reflects the decomposition of the aip ligands.

The thermal behaviour of CPO-10 is analogous to CPO-9, and exhibits low thermal stability by being transformed into an amorphous phase at 250 °C. The TGA curve shows two weight losses up to 250 °C involving the loss of two

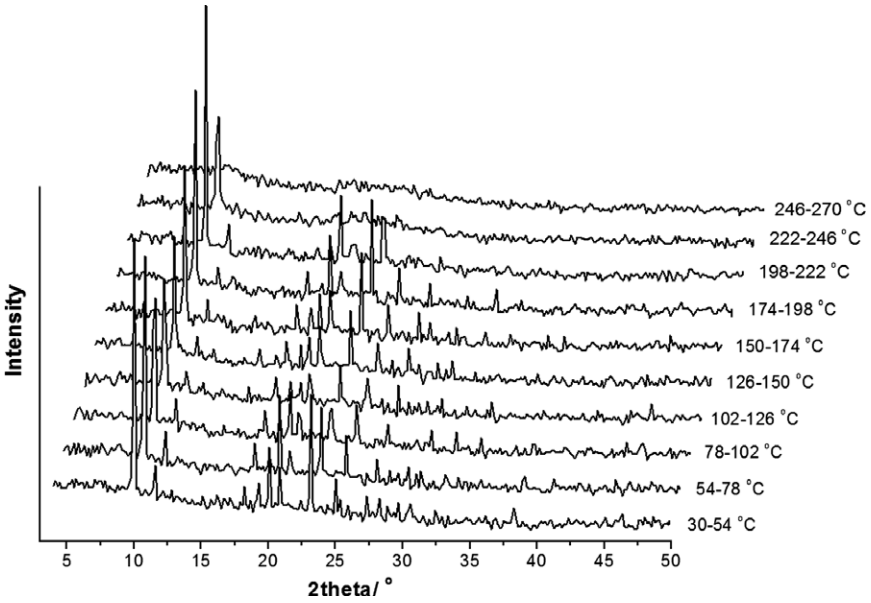

Fig. 5. Three-dimensional representation of high-temperature powder X-ray data for CPO-9 between 30 and 270 °C.

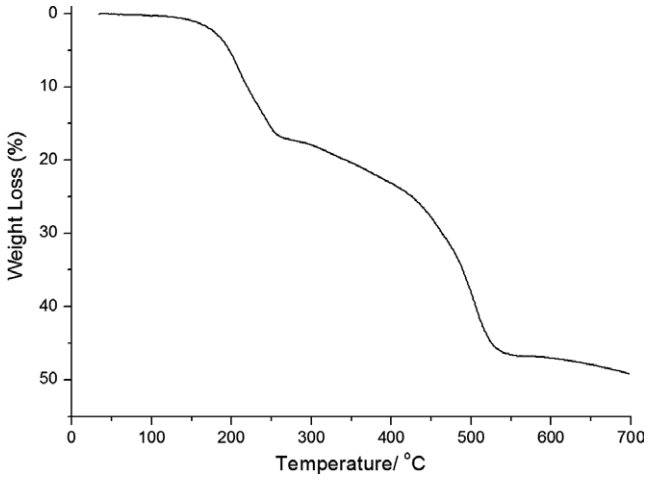

Fig. 6. TGA curve for CPO-9 heated in N_2 at a rate of 5 K/min.

water molecules (observed 2.77 wt%, calculated 2.73 wt%) and four DEF molecules (observed 30.12 wt%, calculated 30.61 wt%). These weight losses are followed by the decomposition of the atp ligands starting gradually already at 250 °C.

3.3. Magnetic properties

Variable-temperature magnetic susceptibility data for CPO-9 is presented in Fig. 7. At room-temperature, $\chi_m T$ is 4.32 cm^3 K mol^{-1}, which is slightly lower than the value of 4.38 cm^3 K mol^{-1} expected for uncoupled Mn(II) atoms ($S = 5/2$ and $g = 2$). As the temperature is lowered, $\chi_m T$ decreases gradually down to around 50 K and thereafter sharply to reach 0.43 cm^3 K mol^{-1} at 2 K. This behaviour indicates that weak antiferromagnetic interactions between the Mn(II) ions dominate the magnetic properties of

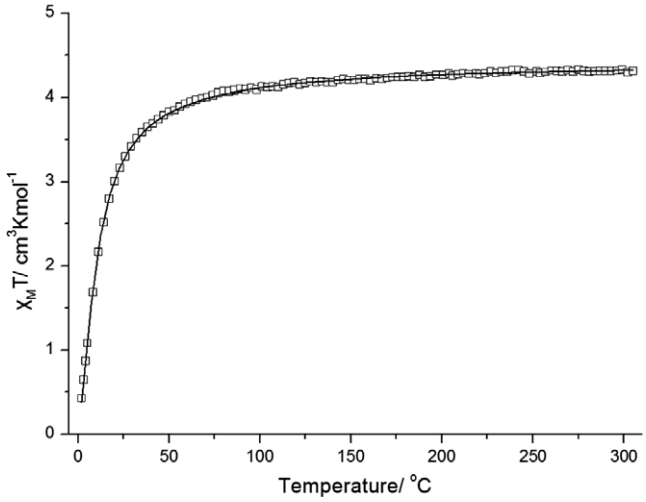

Fig. 7. $\chi_m T$ versus T for CPO-9; the solid line represents the best theoretical fit, see text.

CPO-9. On basis of the crystal structure of CPO-9, there are two possible exchange pathways; an intrachain interaction through the carboxylate bridges and an interchain interaction via the extended aip ligand. Thus the magnetic behaviour can be interpreted by means of the analytical expression derived by Fisher [40] for an infinite chain of classical spins based on the Hamiltonian $H = -J\Sigma S_i S_{i+1}$. The interchain interaction is taken into account by combining this expression with interchain interactions (J') under the molecular field approximation [41]. The analytical expression will then be: $\chi_m = [Ng^2\beta^2F(S,T)]/[1 - 2zJ'F(S,T)]$ where $F(S,T) = [S(S+1)(1+u)]/[3kT(1-u)]$ and $u = \coth(JS(S+1)/kT) + (JS(S+1)/kT)^{-1}$. With allowance for all parameters to vary, the best least squares fit shown in Fig. 7 gives $g = 2.010 \pm 0.001$, $J/k = -1.55 \pm 0.02$ K and $zJ'/k = 0.35 \pm 0.03$ K. The J/k value, which is comparable to previously reported results for doubly bridged carboxylate Mn(II) compounds [42], indicate weak antiferromagnetic interactions through the carboxylate bridges. The positive zJ'/k value indicate a weak interchain ferromagnetic interaction through the 5-aminoisophthalo ligand. Such an interaction has also been earlier reported for an Mn(II) terephthalte compound [43].

The variable-temperature magnetic susceptibility data for CPO-10 (Fig. 8) also reveal an overall antiferromagnetic behaviour. The value of $\chi_m T$ decreases gradually from 13.07 at room temperature to 4.58 cm^3 K mol^{-1} at 2 K. The room temperature value is slightly lower than the expected value of 13.125 cm^3 K mol^{-1} for three uncoupled Mn(II) ions, each with $S_i = 5/2$ and $g_i = 2$. Considering the crystal structure of CPO-10 with linear trinuclear units of Mn(II), the spin Hamilitonian would be $H_s = J(S_1S_2 + S_2S_1) + J'(S_1S_1)$, where S_i is the spin of the Mn(II) atom with number i (Fig. 3). However, the magnetic interactions between the Mn(1) terminal manganese ions is assumed to be negligible in this linear complex ($J' = 0$), and hence only the Mn(1)···Mn(2) interaction (J) is considered. The energies of the states are then given by $E(S_{11},S) = -J[S(S+1) - S_{11}(S_{11}+1)]$ where S is the total spin of the Mn_3 unit and $S_{11} = S_1 + S_1$ is the spin quantum number associated with the spin of the terminal Mn ions. We have the conditions $0 \leqslant S_{11} \leqslant 5$ and $|S_{11} - 5/2| \leqslant S \leqslant S_{11} + 5/2$. The Van Vleck expression for the susceptibility is then $\chi_m = [Ng^2\beta^2\Sigma S(S+1)(2S+1)\exp(-E(S_{11},S)/kT)]/[3kT\Sigma(2S+1)\exp(-E(S_{11},S)/kT)]$. In addition the magnetic interactions between trinuclear units through the atp ligands are taken into account by the molecular field approximation [41]. The expression for the susceptibility is then $\chi_{MFC} = \chi_m/[1 - (2zJ'\chi_m)/(Ng^2\beta^2)]$. The best least squares fit shown in Fig. 8 gives $g = 2.072 \pm 0.001$, $J/k = -4.72 \pm 0.04$ K, $zJ'/k = 0.0006 \pm 0.005$ K. The J/k value of CPO-10 are well within the range reported for other Mn(II) compounds containing the same trinuclear units [29–33,35], and indicates weak antiferromagnetic coupling mediated by the carboxylate bridges. The zJ'/k value is close to zero indicating no magnetic couplings between the trinuclear units.

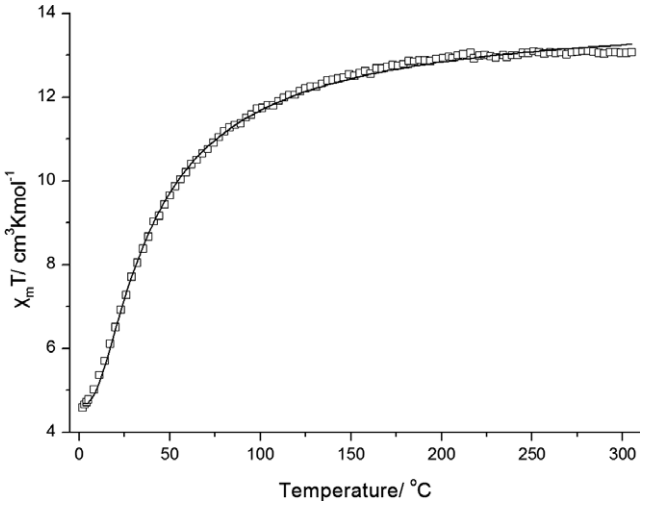

Fig. 8. $\chi_m T$ versus T for CPO-10; the solid line represents the best theoretical fit, see text.

4. Conclusions

In conclusion, two novel 3D coordination based on Mn(II) have been obtained by solvothermal methods. Both structures contain void volumes filled with solvent molecules. However, these molecules cannot be removed without the structures collapsing into amorphous phases at 250 °C. There are antiferromagnetic couplings between the Mn(II)ions in both compounds.

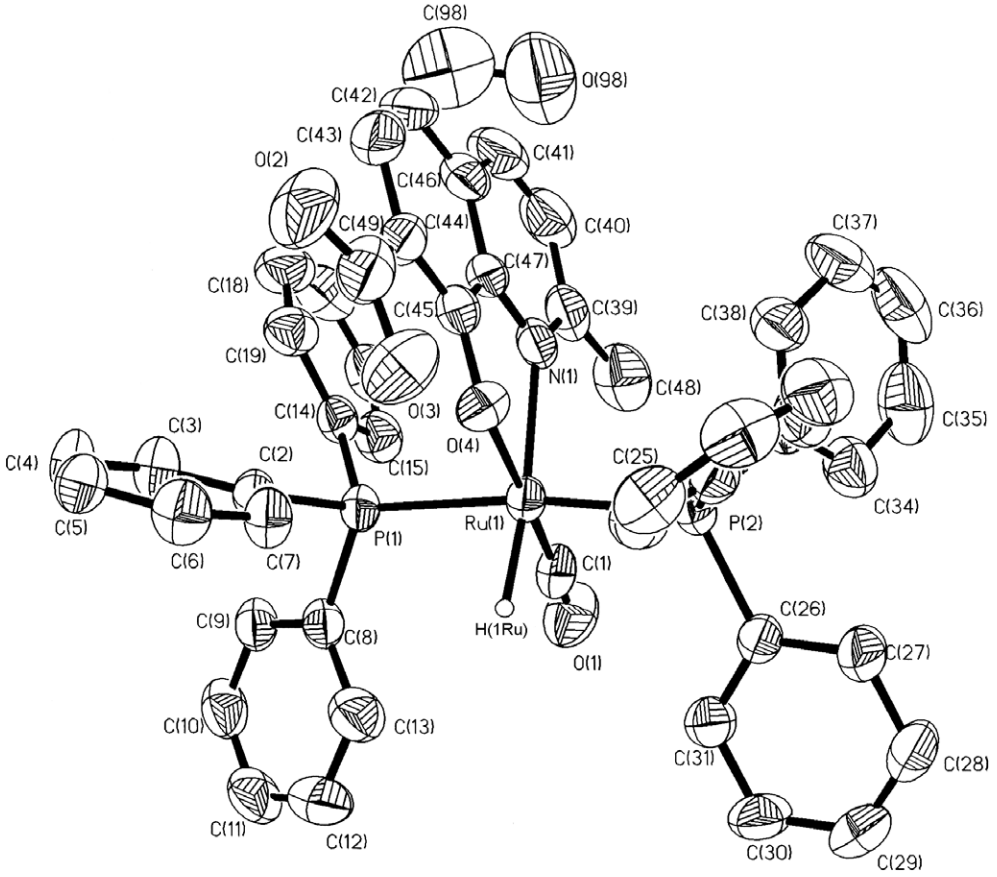

Fig. 1. Drawing of $[(PPh_3)_2RuH(CO)(C_{10}H_8NO_3)]\cdot 0.5CH_3OH$ with 50% probability displacement ellipsoids. The hydrogen atoms except H(1Ru) are omitted.

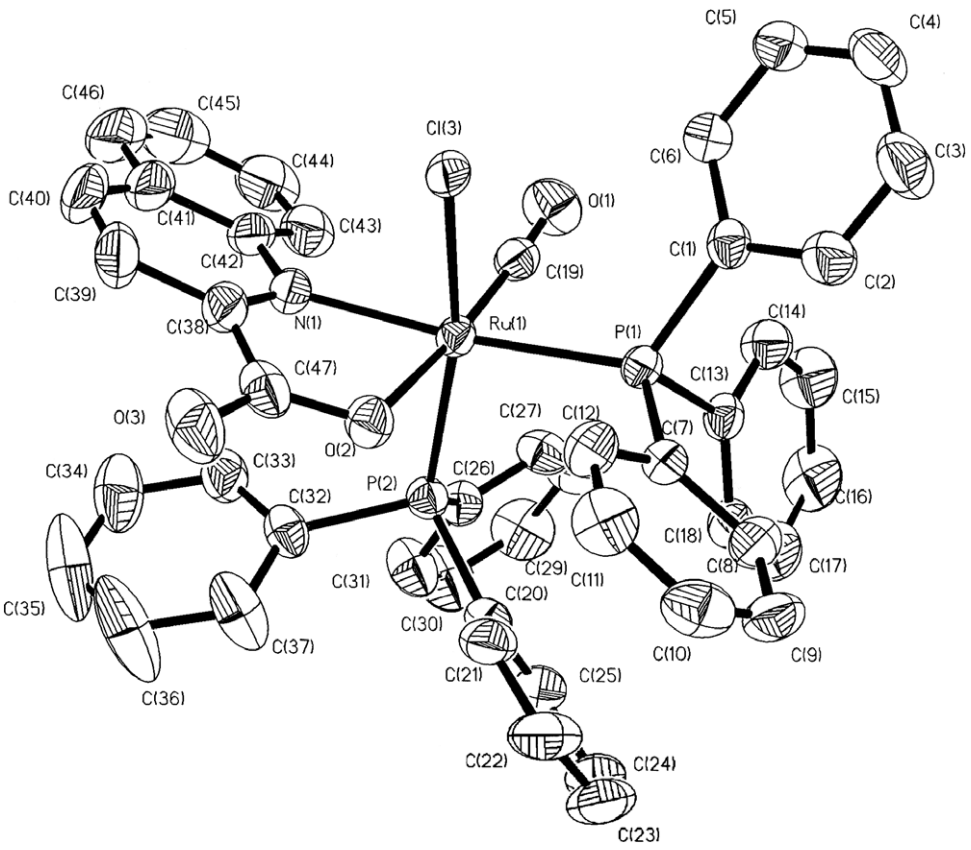

Fig. 2. Drawing of $[(PPh_3)_2RuCl(CO)(C_9H_6O_2)]$ with 50% probability displacement ellipsoids. The hydrogen atoms are omitted for clarity.

with the samples in the form of KBr pellets. Electronic spectra were measured on a Lab Alliance UV–Vis 8500 spectrophotometer in the range 800–200 nm in dichloromethane solution. Elemental analyses (C, H, N) were performed on a Perkin–Elmer CHN–2400 analyzer.

All reagents, except the 8-hydroxy-2-methylquinoline-7-carboxylic acid, used for the synthesis of the complexes are commercially available and were used without further purification. The $[RuHCl(CO)(PPh_3)_3]$ complex was synthesised using a literature method [22]. The 8-hydroxy-2-methylquinoline-7-carboxylic acid was synthesised as described in the literature [13].

2.2. Synthesis of $[(PPh_3)_2RuH(CO)(C_{10}H_8NO_3)]$ (1) and $[(PPh_3)_2RuCl(CO)(C_9H_6O_2)]$ (2)

A suspension of $[RuHCl(CO)(PPh_3)_3]$ (0.95 g, 1×10^{-3} mol) and 8-hydroxy-2-methyl-quinoline-7-carboxylic acid (0.21 g) or quinoline-2-carboxylic acid (0.18 g) in methanol (100 cm^{-3}) was refluxed until the solid dissolved, then the solution was cooled and filtered. Crystals suitable for X-ray crystal analysis were obtained by slow evaporation of the reaction mixture. Yield 78% (**1**) and 82% (**2**).

Anal. Calc. for **1**: $C_{47}H_{36}ClNO_3P_2Ru$: C, 63.94; H, 4.58; N, 3.64. Found: C, 64.01; H, 4.53; N, 3.66%.

2: $C_{50}H_{42}ClNO_3P_2Ru$: C, 66.48; H, 4.69; N, 1.55. Found: C, 66.28; H, 4.59; N, 1.51%.

2.3. DFT calculations

The GAUSSIAN-03 program [23] was used for the calculations. The geometry optimisation was carried out using the DFT method with the B3LYP functional [24,25]. The electronic transitions were calculated with the PCM model [26] with dichloromethane as the solvent. The calculation was performed using the DZVP basis set [27] with f functions and with exponents 1.94722036 and 0.748930908 on the ruthenium atom and polarisation functions for all other atoms: 6–31g(2d,p) – chlorine, 6–31g** – carbon, nitrogen, oxygen, and 6–31g(d,p) – hydrogen. Natural bond orbital (NBO) calculations were performed using the NBO code [28] included in GAUSSIAN-03.

2.4. Crystal structure determination and refinement

A green prism of complex **1** and a white prism of **2** were mounted in turn on a KM-4-CCD automatic diffractometer equipped with a CCD detector, and were used for data

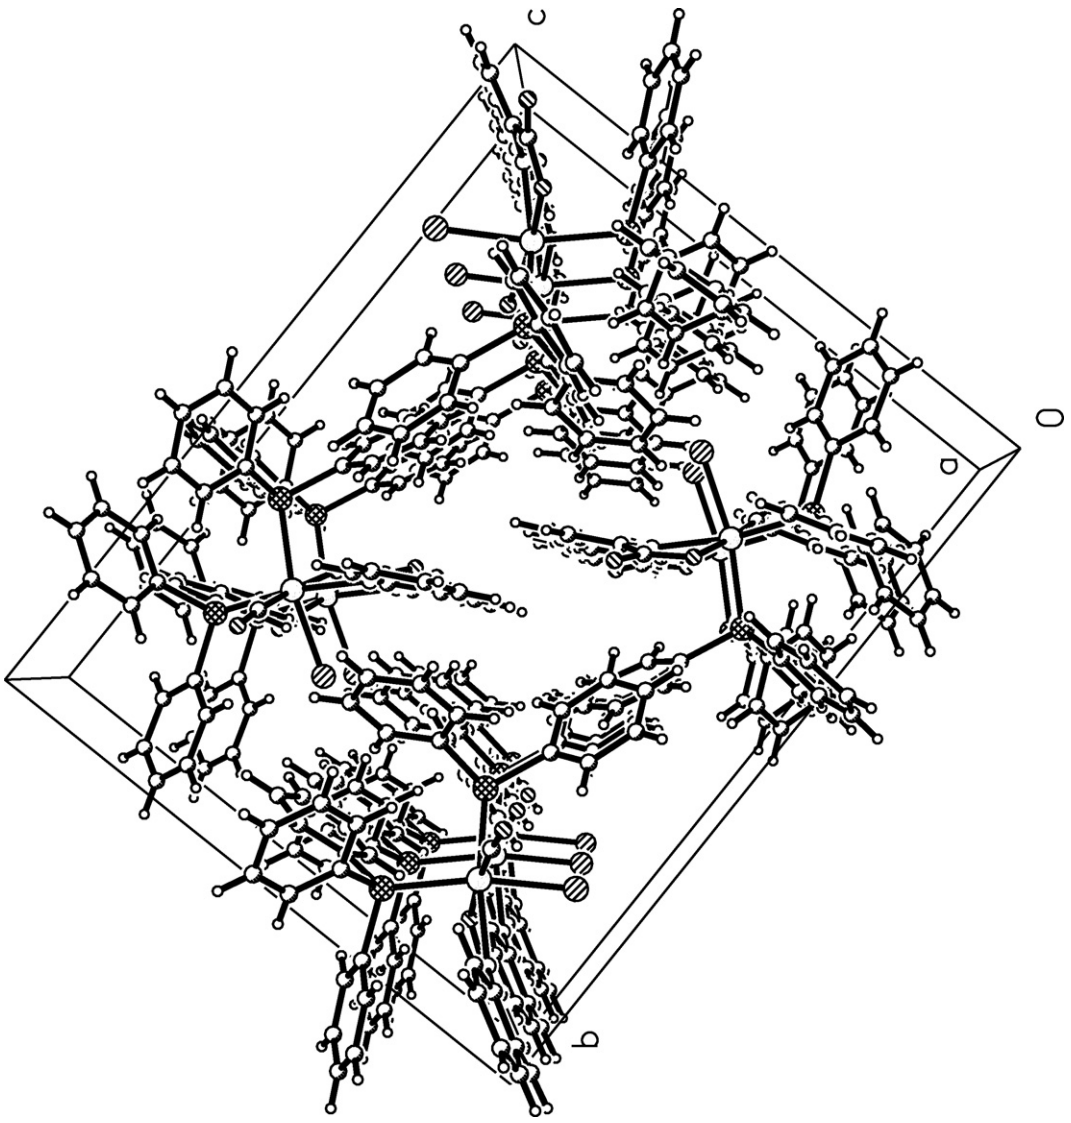

Fig. 6. Part of the molecular packing $[(PPh_3)_2RuCl(CO)(C_9H_6O_2)]$.

collection. X-ray intensity data were collected with graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at the temperature 295.0(3) K, with the ω scan mode. The Ewald sphere reflections were collected up to $2\theta = 50.0°$ for both complexes. The unit cell parameters were determined from least-squares refinement of the setting angles of 7333 and 6860 strongest reflections for complexes **1** and **2**, respectively. Details concerning the crystal data and refinement are gathered in Table 1. The reference frames, monitored every 40 measurement frames, show 1.01% decay for the crystal of compound **1** and no decay for the crystal of compound **2**. During the data reduction of compound **1** a decay correction was taken into account. Lorentz, polarisation and numerical absorption [29] corrections were applied. The structures were solved using the Patterson method combined with a partial structure expansion procedure. All the non-hydrogen atoms were refined anisotropically using the full-matrix, least-squares technique on F^2. The hydrogen atoms were found from difference Fourier synthesis after four cycles of anisotropic refinement, and refined as ''riding'' on the adjacent atom with an individual isotropic temperature factor equal to 1.2 times the value of the equivalent temperature factor of the parent atom. The H(1Ru) atom in complex **1** was placed in a calculated position (Ru–H distance 1.6 Å) according to similar compounds [30–36]. SHELXS97 [37], SHELXL97 [38] and SHELXTL [39] programs were used for all calculations. Atomic scattering factors had values incorporated in the computer programs.

3. Results and discussion

The reaction between the $[RuHCl(CO)(PPh_3)_3]$ complex and 8-hydroxy-2-methyl-quinoline-7-carboxylic acid or quinoline-2-carboxylic acid in methanolic solution gives the mononuclear ruthenium(II) compounds $[(PPh_3)_2RuH-$

$(CO)(C_{10}H_8NO_3)]$ (green, air-stable, crystalline solid) and $[(PPh_3)_2RuCl(CO)(C_9H_6O_2)]$ (white solid). Infrared spectra of the complexes exhibit characteristic bands of coordinated ligands – quinoline carboxylic acid, CO, PPh_3 and the hydride group.

The strong bands at 1938 and 1918 cm^{-1} for complex **1** and **2**, respectively, are assigned to the ν_{CO} stretching vibrations of the ruthenium bonded carbonyl group, and the band at 1945 cm^{-1} corresponds to ν_{Ru-H} of the hydride ligand (complex **1**). The ν_{CO} and ν_{Ru-H} stretching vibrations in the $[RuHCl(CO)(PPh_3)_3]$ complex are at 2020 and 1903 cm^{-1}, respectively. The bands at 1610 and 1650 cm^{-1} are attributed to the CN stretching vibration of the quinoline ligand. The asymmetric and symmetric ν_{COO} stretching bands are at 1590, 1596 cm^{-1} and 1378, 1348 cm^{-1} for compounds **1** and **2**, respectively.

The positions of the ν_{CO} and ν_{Ru-H} bands in the IR spectrum of complex **1** indicate a decrease of the metal–carbonyl carbon interaction and an increase of the Ru–H bond order. Taking into account the IR spectra of both complexes, the quinoline type ligand is a σ-donor that induces a large Ru–CO back-bonding.

3.1. Crystal structure

Both obtained complexes crystallise in the monoclinic space group $P2_1/n$. The crystal data of complexes **1** and **2** are given in Table 1. The molecular structures of **1** and **2** are presented in Figs. 1 and 2 (see Figs. 3, 4), respectively, and molecular packing is depicted, receptively, in Figs. 5 and 6. The ruthenium atom in the complex $[(PPh_3)_2RuH(CO)(C_{10}H_8NO_3)]$ is in a distorted octahedral environment with *trans*-triphenylphosphine ligands (angle P(1)–Ru(1)–P(2) 172.19(3)°). The carbonyl ligand is in a *trans*-position to the O donor atom (C(1)–Ru(1)–O(4) 178.12(11)°) and the hydrido ion lies *trans* to the coordinated nitrogen from the quinoline ligand – with an angle of 170.0°. The Ru–N bond distance is longer in complex **1** than in complex **2** due to the *trans* effect of the hydride ligand. The interatomic distances in the carbonyl and triphenylphosphine ligands are normal.

In the structure of compound **1** one very weak intramolecular O(4)–HO(3) hydrogen bond (D···A distance 2.554(3) Å and D–H···A angle 151.7°) and one very weak intermolecular C(40)–H(40)O(98) hydrogen bond (D···A distance 3.290(10) Å and D–H···A angle 139.5°) can be found.

The ruthenium atom of complex **2**, $[(PPh_3)_2RuCl(CO)(C_9H_6O_2)]$, is also in a distorted octahedral environment with *cis*-triphenylphosphine ligands (angle P–Ru–P 99.28(2)°). The carbonyl ligand is in a *trans* position to the carboxylic O donor atom (O(2)–Ru–C(19) 174.95(9)°) and the chloride ion is *trans* to the P(2) atom −166.11(2)°. All Ru–ligand distances, namely Ru–Cl 2.4250(6), Ru–P 2.3763(7), 2.3861(7), Ru–N 2.169(2), Ru–C 1.826(3) and Ru–O 2.1035(16) Å, are normal and comparable with distances in other ruthenium complexes containing heterocyclic ligands.

The molecules in the crystal are connected by four very weak C–H···O intramolecular hydrogen bonds: C(12)–H(12)···O(2) (D···A distance 3.059(3) Å, D–H···A angle 120.0°), C(21)–H(21)···O(2) (D···A distance 3.074(3) Å, D–H···A 145.6°), C(6)–H(6)···Cl(3) (D···A distance 3.208(3) Å, D–H···A angle 108.90°) and C(43)–H(43)···O(1) (D···A distance 3.267(4) Å, D–H···A angle 132.6°).

3.2. Geometry optimisation

The geometries of the studied complexes were optimised by the DFT method with the B3LYP functional. The geometry parameters for the optimised complexes are gathered in Table 2. In general, the predicted bond lengths and angles are in agreement with the X-ray structural data. The largest difference is found for the C(1)–O(1) bond (~0.072 Å) (compound **1**). The maximum differences between the optimised and experimental geometry of compound **2** are exhibited in the Ru(1)–N(1) distance (0.074 Å) and N(1)–Ru(1)–P(1) angle (5.9°).

3.3. Charge distribution and NBO analysis

The calculated charges on the ruthenium atom in the studied complexes are considerable lower than the formal charge of +2 and are close to −0.01 and 0.26 for **1** and **2**, respectively. The charges on the P atoms are positive and close to 1.15 (1.20); the charge on the chloride ligand in $[(PPh_3)_2RuCl(CO)(C_9H_6O_2)]$ is larger than −1 (−0.55), the charge on the quinoline carboxylic acid ligands is close to −0.64 for **1** and −0.52 for **2**. The occupancies of the ruthenium d orbitals, obtained from the NBO analysis, are as follow: $d_{xy} - 1.73$; $d_{xz} - 1.84$; $d_{yz} - 1.21$; $d_{x^2-y^2} - 1.23$; $d_{z^2} - 1.61$ for $[(PPh_3)_2RuH(CO)(C_{10}H_8NO_3)]$ and $d_{xy} - 1.80$; $d_{xz} - 1.74$; $d_{yz} - 1.75$; $d_{x^2-y^2} - 1.13$; $d_{z^2} - 0.96$ for $[(PPh_3)_2RuCl(CO)(C_9H_6O_2)]$.

The Ru–C bond orbitals in the two studied complexes are polarised towards the carbon atom, and the C≡O bond orbitals are polarised towards the oxygen end. The oxygen atoms of the carbonyl ligands have one lone pair (LP) orbital. The occupancies of the Ru–C bonds are (*anti*-bonding NBOs are given in round brackets)

for complex **1**: 1.976 (0.398) and for complex **2**: 1.938 (0.272).

3.4. Electronic structure

The energies and characters of several highest occupied and lowest unoccupied molecular orbitals of the studied complexes are presented in Table 3. The HOMO–LUMO gaps of complexes **1** and **2** are 3.69 and 4.09 eV, respectively. In both cases, the ruthenium atom possesses a d^6 configuration. The highest MO is d_{xz} with a contribution of the p_π antibonding orbitals from the quinoline ligand in the case of complex **1** and from the chlorine ligands of compound **2**. The π_{Ru-CO} bonding interaction contribute in the H-2 and H-3 orbitals of compounds **1** and **2**. The π^*_{Ru-CO} orbitals are also distributed among several unoccupied molecular orbitals. They contribute in L + 12, L + 13 (complex **1**) and L + 9, L + 11 for **2**. The LUMO orbitals are localised on the quinoline ring. The d_{z^2} orbital of the Ru atom

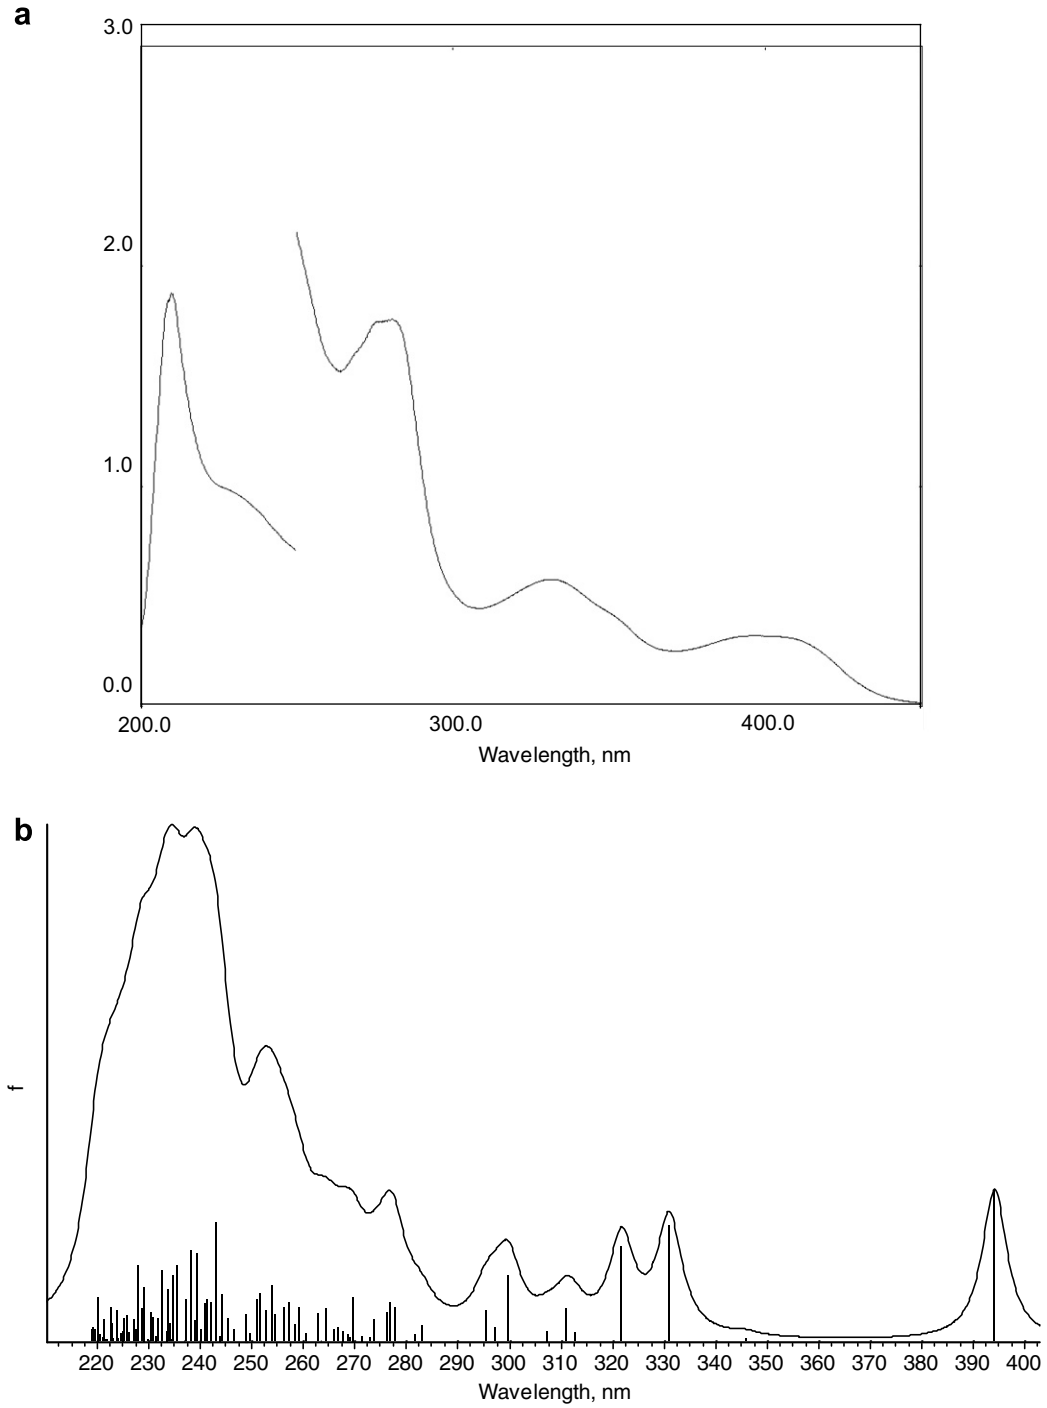

Fig. 7. The UV–Vis spectra of $[(PPh_3)_2RuH(CO)(C_{10}H_8NO_3)]$: (a) experimental; (b) calculated.

makes the largest contribution into L + 3, whereas the L + 4 molecular orbital has $d_{x^2-y^2}$ character in the studied complexes.

3.5. Electronic spectrum

The experimental and calculated electronic spectra of allowed singlet transitions, calculated with the TDDFT method, are presented in Figs. 7 and 8, respectively, for complexes **1** and **2**. The contour of the calculated spectrum was broadening by the Lorentzian function, calculated by the equation:

$$I = \frac{I_0}{1 + \left(\frac{\nu - \nu_0}{\gamma}\right)^2}; \quad \text{where}$$

$\gamma = 1/2$ the spectral width at $1/2$ height.

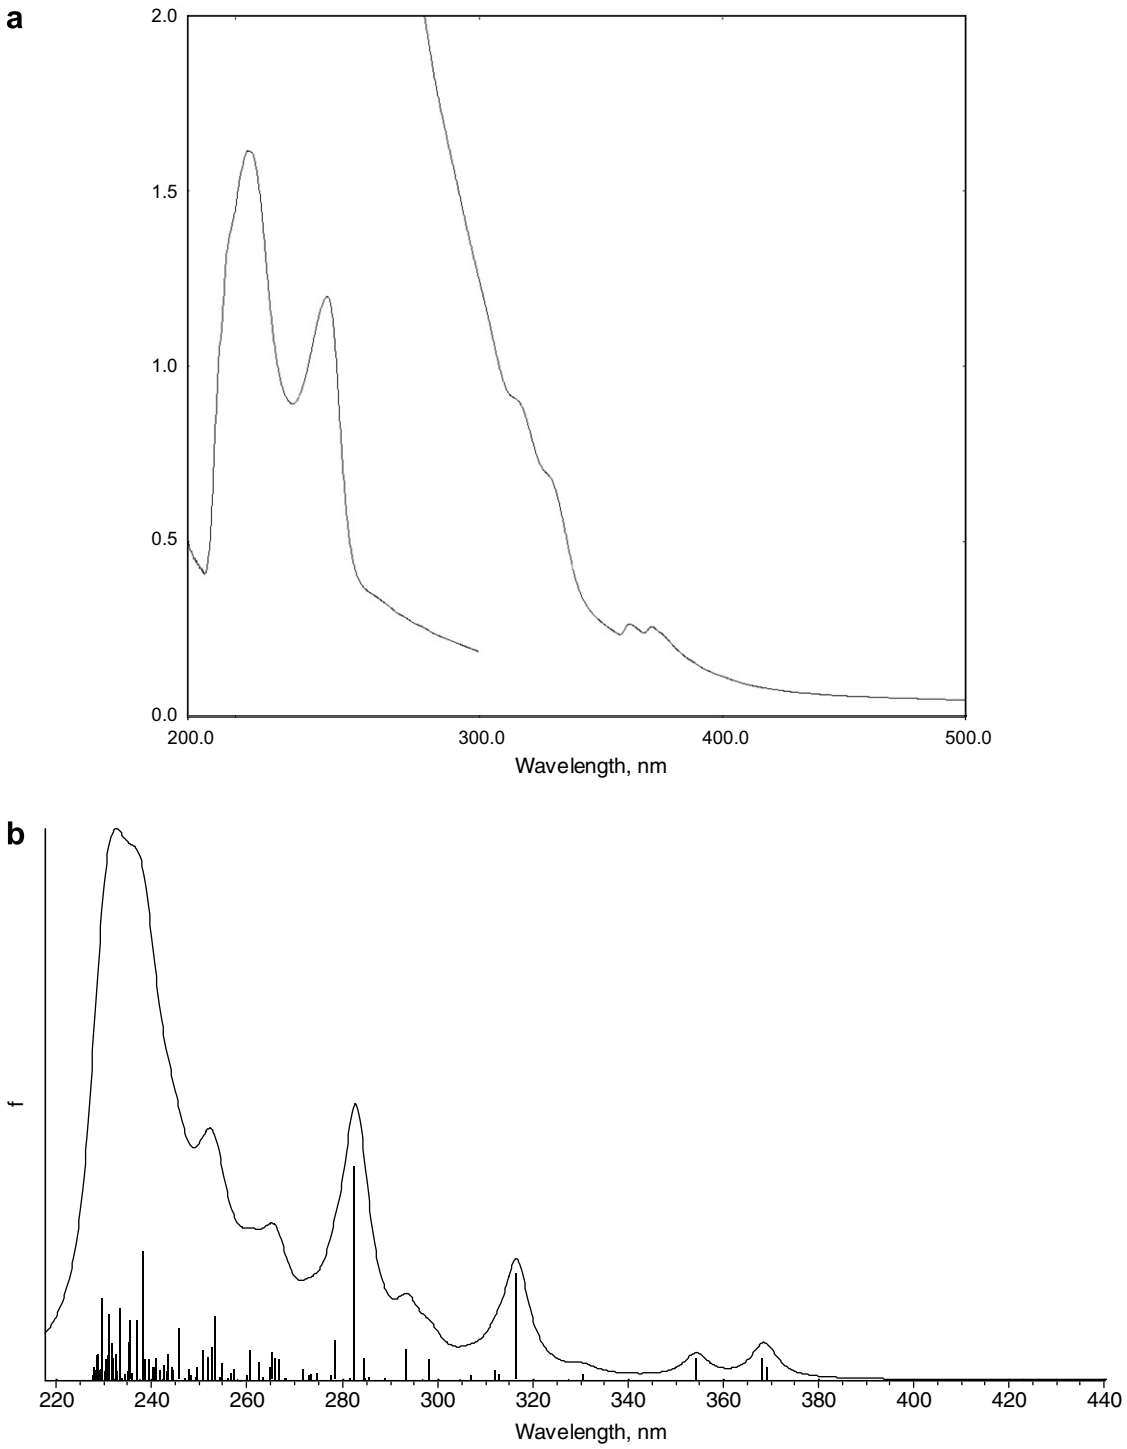

Fig. 8. The UV–Vis spectra of $[(PPh_3)_2RuCl(CO)(C_9H_6O_2)]$: (a) experimental; (b) calculated.

Hundred electronic transitions were calculated for the studied complexes using the DZVP with the f functions basis set on the ruthenium atom, and they do not comprise all the experimental absorption bands. The UV–Vis spectra were calculated up to ~225 nm, so the shortest wavelength experimental bands cannot be assigned to calculated transitions. However, considering that the solution spectra of PPh_3 and quinoline type ligands exhibit intense absorption bands in the 260–200 nm region, some additional intraligand and interligand transitions are expected to be found at higher energies in the calculations.

The assignments of the calculated transitions to the experimental bands are based on the criterion of the energy and oscillator strength of the calculated transitions. In the description of the electronic transitions only the main components of the molecular orbitals are taken into consideration.

The first experimental bands at 400 and 357 nm in $[(PPh_3)_2RuH(CO)(C_{10}H_8NO_3)]$ (**1**) and at 350.0 nm in $[(PPh_3)_2RuCl(CO)(C_9H_6O_2)]$ (**2**) consist of $d \rightarrow \pi^*_{qu}$ MLCT (Metal–Ligand Charge Transfer) transitions (HOMO/H-1 → LUMO). The next bands with maxima at 332 and 280 nm for complex **1** and 283 nm for **2** were calculated as the d → d LF (Ligand Field) transitions with contributions of MLCT excitation between *d* ruthenium and $\pi^*_{phosphine/qu}$ orbitals. For the higher energy band (maximum at 238 nm) of complex **2**, mainly intra- and interligand transitions are observed ($\pi_{qu} \rightarrow \pi^*_{Ph}$; $\pi_{qu} \rightarrow \pi^*_{qu}$; $\pi_{Cl} \rightarrow \pi^*_{Ph}$; $\pi_{CO} \rightarrow \pi^*_{Ph}$; $\pi_{CO} \rightarrow \pi^*_{qu}$). The bands at 210 and 206 nm for complexes **1** and **2**, respectively, were not calculated but in the energy region some additional intraligand and interligand transitions are expected.

Scheme 1.

tetrahedral geometry, whereas the cationic units contain two slightly distorted square planar mononuclear fragments with different types of interactions:

(i) square planar entities interacting through the S atoms yielding a dinuclear complex with a $[Cu_2(\mu\text{-}S)_2]$ core;
(ii) square planar moieties joined through the Cl ligands forming a dinuclear complex containing a $[Cu_2(\mu\text{-}Cl)_2]$ core.

It appeared that the mode of bridging was being governed by the choice of solvent. Magnetic susceptibility studies showed that both compounds showed an overall antiferromagnetic behaviour. For a better understanding of superexchange mechanisms in binuclear Cu(II) complexes [2,3] and in order to investigate the influence of increased steric bulk brought about by the replacement of ethyl groups by *i*-Pr and *i*-Bu at the terminal positions of the carboxamide side arms [Scheme 1], we have studied the structure, and magnetic behaviour of two new tetranuclear Cu(II) compounds containing *N*,*N*,*N*′,*N*′-tetraalkylpyridine-2,6-dithiocarboxamide (R = *iso*-butyl and *iso*-propyl) chelating ligands. The X-ray structures and magnetic data are discussed.

2. Experimental

2.1. Materials

All reactions were carried out in anhydrous solvents under dry N_2 atmosphere. Solvents and other reagents were dried using standard techniques as described previously [1]. The ligands *N*,*N*,*N*′,*N*′-tetraisopropylpyridine-2,6-dithiocarboxamide (S-dppt) and *N*,*N*,*N*′,*N*′-tetraisobutylpyridine-2,6-dithiocarboxamide (S-dbpt) were prepared as per the method given for S-dept [1] except that *N*,*N*,*N*′,*N*′-tetraisopropylpyridine-2,6-dicarboxamide(DPAP) [4] and *N*,*N*,*N*′,*N*′-tetraisobutylpyridine-2,6-dicarboxamide(DBAP) were respectively used as the starting materials. The latter compound was obtained as a white crystalline solid by using a similar method as reported for the preparation of DPAP. M.p., 61 °C. *Anal.* Calc. for $C_{23}H_{39}N_3O_2$: C, 70.95; H, 10.02; N, 10.79. Found: C, 70.68; H, 9.92; N, 10.60%. $\nu_{C=O}$: 1640 cm^{-1}. ^1H NMR ($CDCl_3$, TMS): $\delta = 0.82$ (d, 12H, CH_3), 0.94 (d, 12H, CH_3), 1.67 (hept, 2H, CH), 2.04 (d, 2H, CH), 3.20 (d, 4H, CH_2), 3.26 (d, 4H, CH_2), 7.49 (d, 2H, py), 7.77 (t, 1H, py). S-dppt is a yellow crystalline solid. M.p., 141 °C. *Anal.* Calc. for $C_{19}H_{31}N_3S_2$: C, 62.46; H, 8.49; N, 11.50. Found: C, 63.12; H, 7.84; N, 11.23%. S-dbpt is also a yellow crystalline solid. M.p. 87 °C. *Anal.* Calc. for $C_{23}H_{39}N_3S_2$: C, 65.55; H, 9.26; N, 9.97. Found: C, 66.13; H, 9.80; N, 9.47%.

2.2. $[\{Cu(S\text{-}dbpt)\}_2(\mu\text{-}Cl)_2][\{CuCl_2\}_2(\mu\text{-}Cl)_2]$ (**1**) and $[CuCl(S\text{-}dppt)]_2[\{CuCl_2\}_2(\mu\text{-}Cl)_2]$ (**2**)

Both compounds were prepared following exactly the same experimental procedure as that used for $[Cu_2Cl_2(\mu\text{-}S\text{-}dept)_2][Cu_2Cl_4(\mu\text{-}Cl)_2]$ [1] but by using S-dbpt and S-dppt as ligands and isobutanol/acetonitrile (1:1) and isopropanol/acetonitrile (1:1) as the reaction solvents for the preparation of **1** and **2**, respectively. **1**: M.p., 232 °C. *Anal.* Calc. for $C_{23}H_{39}N_3S_2Cl_4Cu_2$: C, 40.00; H, 5.65; N, 6.08; Cl, 20.6. Molar conductance (Ω^{-1} cm^2 mol^{-1}): 194 (CH_3CN). UV–Vis [λ_{max}, nm ($\in$, M^{-1} cm^{-1})] in MeOH: 767 (198). **2**: M.p., 220 °C. *Anal.* Calc. for $C_{19}H_{31}N_3S_2Cl_4Cu_2$: C, 35.96; H, 4.88; N, 6.62; Cl, 22.4 Found: C, 35.14; H, 5.02; N, 6.41; Cl, 22.0%. IR (KBr pellet, cm^{-1}): 1597s, 1582m, 1518m, 1460s, 1375m, 1355m, 1294m, 1264m, 1138m, 1099m, 1026m, 1017w, 959w, 814w, 760w, 722w, 634m, 438w. Molar conductance (Ω^{-1} cm^2 mol^{-1}): 186 (CH_3CN). UV–Vis [λ_{max}, nm ($\in$, M^{-1} cm^{-1})] in MeOH: 762 (283).

2.3. Physical methods

Elemental analyses (C, H, N) were performed on a Perkin–Elmer model 2400 CHN elemental analyzer. Chlorine was estimated as chloride by Volhard's method. IR spectra were recorded as KBr pellets on a Perkin–Elmer RX-1 FTIR spectrophotometer. Molar conductances were measured using a digital conductivity bridge model CC601. The UV–Vis spectra were recorded on a JASCO V-530 UV–Vis spectrophotometer. Magnetic susceptibility measurements for powdered samples of **1** and **2** were carried out at the "Unitat de Mesures Magnètiques" of the Universitat de Barcelona with a Quantum design SQUID MPMS-XL susceptometer. The magnetic susceptibility data were recorded in the 2–300 K temperature range under magnetic fields of 500 G (2–30 K) and 10 000 G (2–300 K).

2.4. X-ray crystallography

Crystallization of $[\{Cu(S\text{-}dbpt)\}_2(\mu\text{-}Cl)_2][\{CuCl_2\}_2(\mu\text{-}Cl)_2]$ **1** and $[CuCl(S\text{-}dppt)]_2[\{CuCl_2\}_2(\mu\text{-}Cl)_2]$ **2** by slow evaporation of their saturated solutions in acetonitrile and isopropanol, respectively, at room temperature yielded good single crystals. The data were collected on a Siemens P4 single crystal diffractometer using graphite

monochromatized Mo Kα radiation ($\lambda = 0.71073$ Å). Table 1 shows the unit cell parameters and other crystallographic details. The quality of the crystals for compound **2** was not good as is apparent from high value for R_{int} for the measured data. Data collection and cell refinement were done with XSCANS [5]. The data were corrected for Lorentz and polarization effects. Emperical absorption corrections were performed for both the compounds using psi scans. The structures were solved by direct methods and refined anisotropically by the full matrix least squares method. All the hydrogen atoms were fixed geometrically as riding atoms with a displacement parameter equal to 1.2 (CH, CH_2) or 1.5 (CH_3) times that of the parent atoms. Data reduction, structure solutions, refinement and molecular graphics were performed using SHELXLTL-PC [6]. Torsion angles and least square planes were calculated by using PARST [7].

3. Results and discussion

3.1. Synthesis and structure

Compounds **1** and **2** were obtained in about 80% yield by refluxing anhydrous $CuCl_2$ with S-dbpt and S-dppt, respectively in anhydrous CH_3CN mixed with the corresponding alcohol (isobutanol or isopropanol) in a 1:1 ratio (on a volume basis). The same product was obtained in each case irrespective of whether the metal–ligand ratio was 1:1 or 2:1. Both compounds are air and moisture stable and were characterized through elemental analyses, IR data, conductivity measurements, X-ray crystallography and low temperature magnetic measurements. The compounds readily dissolve in many polar organic solvents. Millimolar solutions of complexes **1** and **2** in CH_3CN show significant dissociation but due to the large sizes of the cation and anion, the conductivities are less than the expected values for bi-bivalent and uni-bivalent electrolytes [8].

Crystallization of **1** and **2** by slow evaporation of their saturated solutions in acetonitrile and isopropanol, respectively, at room temperature yields good single crystals. The relevant crystallographic data and selected bond lengths and bond angles are summarized in Tables 1 and 2, respectively. The crystal structure for **1** is depicted in Fig. 1. The compound contains a cationic binuclear unit, $[\{Cu(S\text{-}dbpt)\}_2(\mu\text{-}Cl)_2]^{2+}$ and an anionic binuclear unit $[\{CuCl_2\}_2(\mu\text{-}Cl)_2]^{2-}$. In the cationic fragment, each copper atom is pentacoordinated by the pyridine N atom, two S atoms of the S-dbpt ligand and by two chloro ligands acting in the bridging mode. The bridging through chloro groups is unsymmetrical with one distance being 2.233(2) Å and the other being 2.723(2) Å. Each metal atom has a slightly distorted square pyramidal geometry [Reedijk's factor is 0.05, denoting an almost regular square

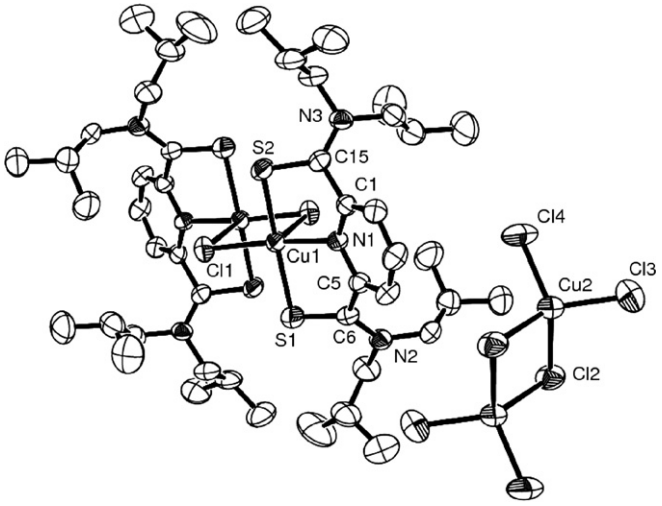

Fig. 1. ORTEP drawing of compound **1** and the numbering scheme used in the structure analysis.

pyramidal geometry] [9], where the basal plane is defined by N1, S1, S2 and Cl1. The apical position of the square pyramid is occupied by one of the chlorine atoms coordinated to the second Cu metal center, acting as a bridging ligand. The structure may be imagined as two square pyramids sharing a basal to apical edge. The Cu1 atom is 0.223(1) Å above the mean plane defined by the four basal atoms. The Cu1···Cu1* distance is 3.355 Å and the Cu–Cl–Cu angle is 84.6°. Complexes containing a $Cu_2(\mu\text{-}Cl)_2$ core, containing five coordinated metal ions in a square pyramid geometry, generally have a base sharing arrangement in which the apical groups point in opposite directions. The other two possible arrangements of the polyhedra are parallel (parallel disposition of the basal planes) and perpendicular (perpendicular disposition of the basal planes) [2b]. The present dinuclear unit is in the parallel mode, which makes the basal atoms of the two sharing polyhedra parallel to each other (Fig. 2). A mean plane passing through the two thioamide groups indicates that the C1, C15, S2, N3 and C5, C6, S1, N2 planes are twisted with respect to the pyridine ring by 47.7(1)° and 46.1(1)°, respectively.

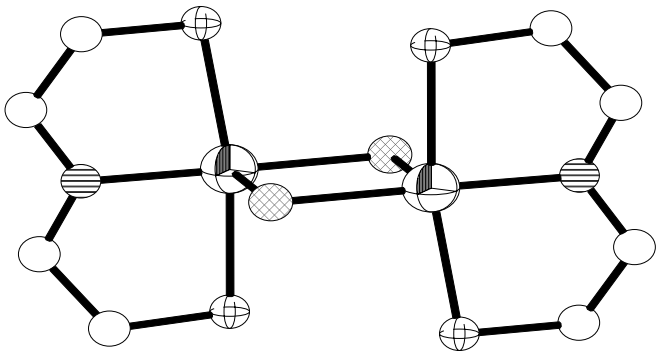

Fig. 2. Core plot of the cationic complex present in compound **1**, showing the parallel disposition of the basal planes of the square pyramids around each Cu(II) ion.

The anionic moiety in complex **1**, $[\{CuCl_2\}_2(\mu\text{-}Cl)_2]^{2-}$, consists of two tetracoordinated Cu metal centers bridged by two chloro anions and each Cu atom is also bonded to two terminal Cl ligands. The $[Cu_2(\mu\text{-}Cl)_2]$ core is planar and the Cu···Cu^{i} distance is 3.354(1) Å (where i = $-x$, $-y$, $2-z$) and the Cu–(μ-Cl)–Cu^{i} angle is 92.8°. Torsion angles of 40° and 44° are observed for Cu(2)–Cl(2)–Cu(2)^{i}–Cl(4) and Cu(2)–Cl(2)–Cu(2)^{i}–Cl(3), respectively. All the chlorine atoms in the anion $[Cu_2Cl_4(\mu\text{-}Cl)_2]^{2-}$ interact with hydrogen atoms of neighboring symmetry related cations (Fig. 3). The non-bridging chloro ligand Cl(3)^{ii} (where ii = $-x+1$, $-y+1$, $-z+2$) is an acceptor to two interactions, i.e., with the pyridine H(4) and Bu H(13B) hydrogen atoms of a cationic complex [2.885(2) and 2.883(3) Å, respectively]. The other non-bridging chloro group Cl(4)^{iii} (where iii = $-x+1$, $-y+1$, $-z+2$) is involved in one H-bonding interaction with the butyl H16B hydrogen atom of another cationic complex [2.837(2) Å]. The bridging chloro groups Cl(2)^{iv} (where iv = $-x+1$, $-y+1$, $-z+2$) are each involved in interactions with H(8) to form a C(8)–H(8)···Cl(2)^{iv} hydrogen bond, each one with a different cationic complex [2.839(1) Å]. In all cases, the C–H···Cl distances are shorter than 2.95 Å (the sum of van der Waals radii of H and Cl) [10]. The anion is thus involved in a total of eight weak H-bonding interactions of the type C–H···Cl (six between non-bridging and two between bridging chloro groups), with six dinuclear cationic complexes.

The structure of compound **2** consists of two cationic units, $[CuCl(S\text{-}dppt)]^{+}$, and the anionic dinuclear $[Cu_2Cl_4(\mu\text{-}Cl)_2]^{2-}$ (Fig. 4). The cationic fragment is monomeric with a distorted square planar geometry around the Cu(1) atom. Mean plane calculations indicated that N1, S1, S2 and Cl1 do not lie in one plane. The ligand coordinates through the two thioamide S atoms and pyridine N atom. The fourth coordination site is occupied by the chlorine atom Cl(1).

The anionic fragment in complex **2** shows identical structural features as those observed for **1**. The Cu2···Cu2^{i} distance is 3.330 Å and the twist angle phi, Cu2^{i}–Cl2–Cu2–Cl4 (where i = $-x$, $-y$, $-z$), is 42.3°. Comparison of bond distances of compounds **1** and **2** (Table 2) reveals that all the metal ligand bond distances are shorter in **2**. This may suggest that the metal ion is more tightly held by the S-dppt ligand. This is further borne by the fact that in compound **2**, Cu(1) lies 0.0343(4) Å above the mean plane, whereas the metal ion is 0.223(1) Å above the mean plane in the case of the S-dbpt compound. This probably decreases the area available around the Cu^{2+} ion in the case of compound **2** for coordination by another ligand, and so only a monomer having a square planar geometry is formed. It appears that the mode of bridging is governed by the nature of the solvent and the steric factors due to the increased size of the groups attached to the carboxamide N atoms of the side arms [1].

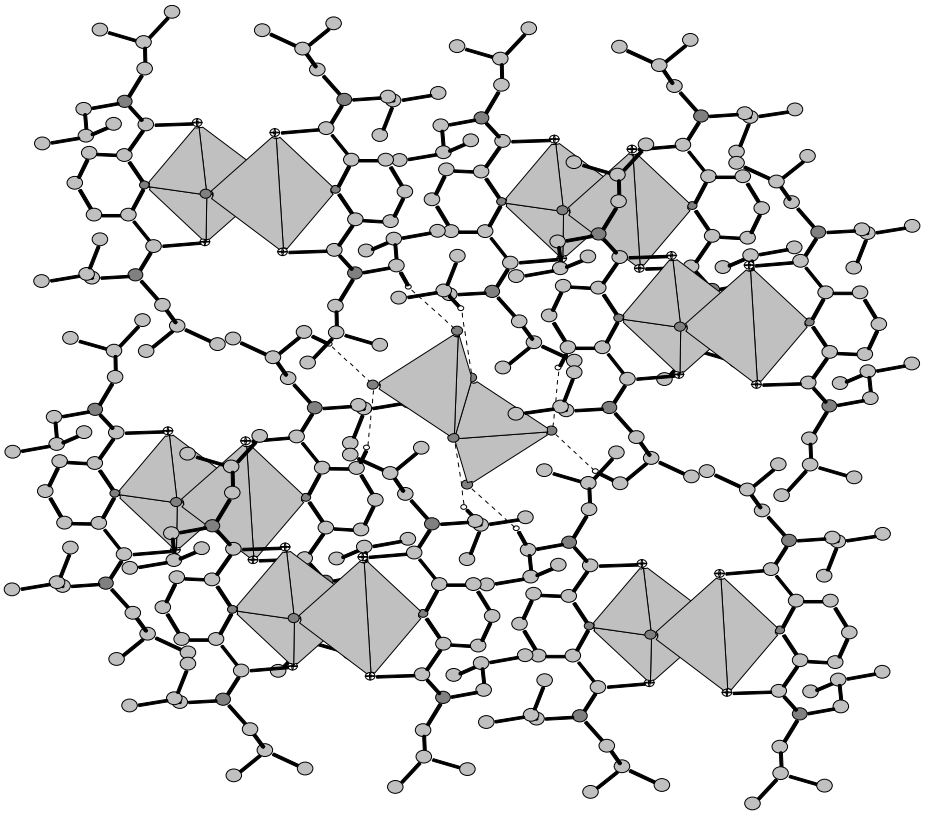

Fig. 3. Plot showing the weak C–H···Cl interaction between the anionic dinuclear complex $[Cu_2Cl_4(\mu\text{-}Cl)_2]^{2-}$ and the cationic dinuclear complex in compound **1**.

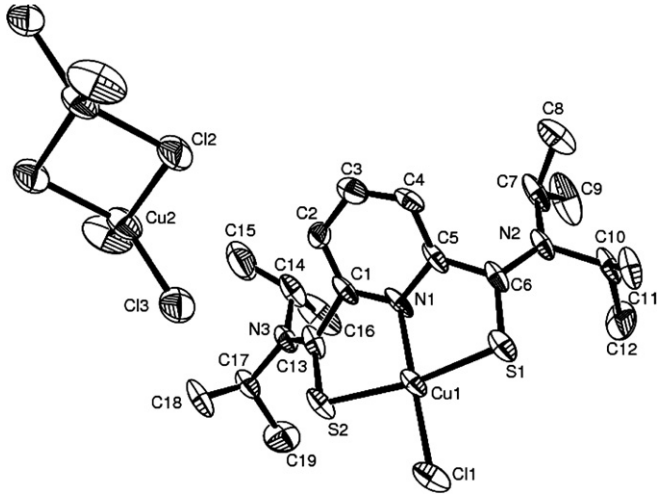

Fig. 4. The coordination modes of compound **2**.

3.2. Magnetic properties

The magnetic behaviour of compounds **1** and **2** has been investigated in the 2–300 K temperature range. Fig. 5 shows a plot of $\chi_M T$ *versus* T for compound **1**. The $\chi_M T$ product at room temperature is 1.68 $cm^3\ mol^{-1}$ K and this value increases upon cooling, reaching a maximum value at 2 K (1.82 $cm^3\ mol^{-1}$ K). This behaviour is indicative of a ferromagnetic interaction. Consequently, bearing in mind that this compound is constituted of two dinuclear species, at least one of them must show a ferromagnetic interaction between the Cu(II) ions.

The experimental data corresponding to the two dinuclear species in compound **1**, $\chi_M T = (\chi_M T)_1 + (\chi_M T)_2$, were fitted in Eq. (1), which was obtained using the Bleaney–Bowers equation [11] based on the spin Hamiltonian $H = -JS_1 \cdot S_2$ for each dinuclear species.

$$\chi_M T = (2Ng_1^2\beta^2/[k(3+\exp(-J_1/kT))]) + (2Ng_2^2\beta^2/[k(3+\exp(-J_2/kT))]) \quad (1)$$

The best fit was obtained with $J_1 = -0.77\ cm^{-1}$, $g_1 = 2.0$, $J_2 = 3.19\ cm^{-1}$, $g_2 = 2.21$ and $R = 1.6 \times 10^{-5}$.

For compound **2**, the $\chi_M T$ *versus* T plot is shown in Fig. 6. This compound is constituted of two mononuclear cationic species and one dinuclear anionic species, thus the $\chi_M T$ values correspond to four Cu(II) ions. The $\chi_M T$ values are around 1.5 $cm^3\ mol^{-1}$ K, from room temperature to 13 K. On cooling below this temperature, $\chi_M T$ decreases reaching a value of 1.38 $cm^3\ mol^{-1}$ K at 2 K. For this compound, the $\chi_M T$ values are the sum of two contributions, from the dinuclear complex and from the two mononuclear complexes, $\chi_M T = (\chi_M T)_{dinuclear} + 2(\chi_M T)_{mononuclear}$, therefore the experimental data were fitted by

$$\chi_M T = (2Ng_d^2\beta^2/[k(3+\exp(-J/kT))]) + 2(Ng_m^2\beta^2/4k) \quad (2)$$

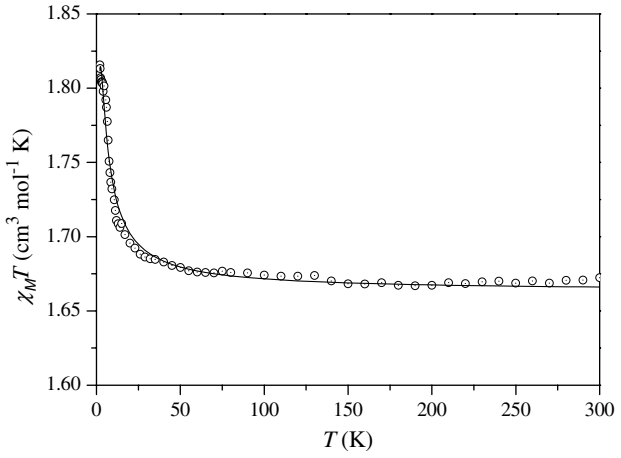

Fig. 5. $\chi_M T$ *vs.* T plot for **1**. Solid line corresponds to the best fit obtained.

The best fit was obtained with $J = -0.83\ \text{cm}^{-1}$, $g_d = g_m = 2.0$ and $R = 9.9 \times 10^{-6}$.

Compound **1**, with anionic and cationic dinuclear complexes, shows two kinds of magnetic interactions, ferromagnetic and antiferromagnetic, and for assignment of these to each appropriate dinuclear entity it is necessary to compare the magneto-structural values with analogous compounds. A number of compounds containing the $[\{CuCl_2\}_2(\mu\text{-}Cl)_2]^{2-}$ anion are reported in the literature. The magnetic interaction in this species is very sensitive to the structural parameters, and the magnetic coupling constant is generally found between +53 and $-93\ \text{cm}^{-1}$. In most compounds, this species is planar [12–16], in some cases, the counter cation could be coordinated in an axial position [14,16,17,20]. In several compounds, an interaction between the dinuclear anions is observed and the compound is described as a one-dimensional system [14–16,20]. In other cases, the compound is formulated as $MCuCl_3$ and shows an alternating chain structure [18–20]. Very few systems show isolated dinuclear anions, and in these cases, the geometry around the Cu(II) ions is very sensitive to the volume of the counter cation. Complexes with EPh_4^+ (E = P, As, Sb) as a cation show a pseudo-tetrahedral distortion

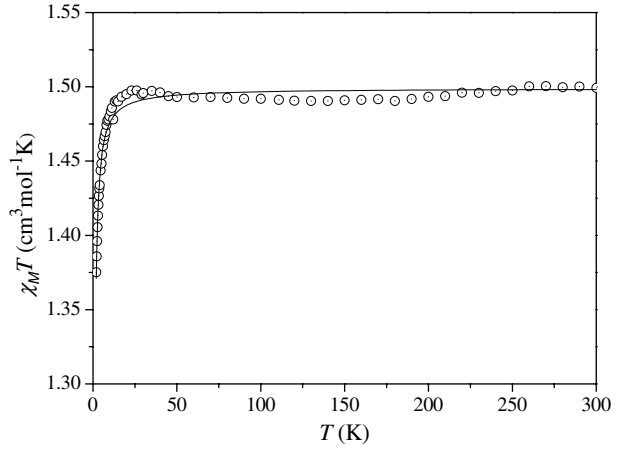

Fig. 6. $\chi_M T$ *vs.* T plot for **2**. Solid line corresponds to the best fit.

and the magnetic interaction is ferromagnetic [21,22]. For these compounds the ferromagnetic interaction decreases from $+80\ \text{cm}^{-1}$ for the PPh_4^+ $+40\ \text{cm}^{-1}$ for the $AsPh_4^+$ complex, due to the diminution of the Cu–Cl_b–Cu angle from 93.7° to 93.3°.

It is well known that for complexes with a planar Cu_2X_2 core, the magnetic interaction is very sensitive to the CuXCu angle, being ferromagnetic when this angle is close to 90° [12]. Some studies are reported in the literature about the effect of the distortions around the Cu(II) ions on the magnetic properties [1,23–25]. Deviation from planarity between the Cl_tCuCl_t and Cl_bCuCl_b planes affects the energy of the ϕ_a and ϕ_s orbitals. The minimum energy gap is expected for angles around 35–45°, for larger angles, this gap increases again. For the PPh_4^+ compound, the dihedral angle between the Cl_tCuCl_t and Cl_bCuCl_b planes (τ) is 50° [21,22].

Structural parameters for the $[\{CuCl_2\}_2(\mu\text{-}Cl)_2]^{2-}$ anion in **1** and **2** are very close, consequently the magnetic coupling constant J must be similar. As it was indicated, compound **2** contains only this dinuclear species with a very weak antiferromagnetic coupling ($J = -0.83\ \text{cm}^{-1}$), therefore the magnetic coupling constant for this anionic species in compound **1** could be assigned to J_1 ($-0.77\ \text{cm}^{-1}$). However, for the analogous compound reported in the literature with the ethyl derivative ligand, $[\{Cu(S\text{-}dept)\}_2(\mu\text{-}Cl)_2][\{CuCl_2\}_2(\mu\text{-}Cl)_2]$ [1], the magnetic interaction due to the anionic species was antiferromagnetic, with a J value of $-19\ \text{cm}^{-1}$. As it was indicated, a ferromagnetic interaction could be found for $\alpha \sim 90°$ and $\tau \sim 40°$. The three complexes show Cu–Cl_b–Cu angles (α) close to 90°, and quite different dihedral angles between the Cl_tCuCl_t and Cl_bCuCl_b planes (τ): for the species present in **1** and **2** this angle is 56°, while for the ethyl compound it was 63° [1]. Therefore the τ angle for the species in compounds **1** and **2** are closest to the ferromagnetic situation.

So, if the magnetic properties of the anionic species of **1** are described by J_1, the cationic species $[\{Cu(S\text{-}dbpt)\}_2(\mu\text{-}Cl)_2]^{2+}$ must show ferromagnetic behaviour with a magnetic coupling constant $J_2 = 3.19\ \text{cm}^{-1}$. The kind and magnitude of the magnetic interaction is similar to the reported value for the analogous cationic complex $[\{Cu(S\text{-}dept)\}_2(\mu\text{-}Cl)_2]^{2+}$ [1], in agreement with the resemblance of the structural parameters in the two complexes.

For dinuclear dichlorobridged pentacoordinated copper complexes, the local geometry around the Cu(II) ions is generally square pyramid, and three relative arrangements of the square pyramids have been found: (a) the square pyramids sharing basal edge (coplanar bases); (b) the square pyramids sharing a base-to-apex edge so that the Cl atom situated at the vertex of one base becomes the apical vertex of the other square pyramid, and just the opposite happens for the other Cl bridging ligand (parallel bases); and (c) the two square pyramids sharing a base-to-apex edge, but in this case, the apical chloro ligand of one pyramid is also the apical atom of the other square pyramid (perpendicular bases) [2].

Table 3
Structural and magnetic data of some di-μ-chloro-bridged Cu(II) complexes with parallel basal planes ($H = -JS_1 \cdot S_2$)

Complex	α (°)	α/R[a]	J (cm^{-1})	d(Cu–Cl$_b$)[b] (Å)	R (Å)

Ligand abbreviation: TMSO: tetramethylene sulfoxide; baamo; 8-amino-5-aza-4-methyl-3-octene-2-onate; 2-pic: 2-methylpyridine; dmgH: dimethylglyoxime; terpy: 2,2′:6′,2″-terpyridine; dien: diethylenetriamine; apyhist: (4-imidazolyl)ethylene-2-amino-1-ethylpyridine; L^1: 1,5-bis(pyridin-4-ylmethyl)-1,5-diazacyclooctane; L^2: 1-(pyridin-2-ylmethyl)-1,4-diazacycloheptane; Mebta: methylbenzotriazole; S-dept: *N*,*N*,*N*′,*N*′-tetraethylpyridine-2,6-dithiocarboxamide.

[a] $R = d(\text{Cu–Cl}_{\text{apical}})$.

[b] $\text{Cl}_b = \text{Cl}_{\text{basal}}$.

Extensive magneto-structural correlations for these kinds of complexes have been reported. These studies show that the Cu–Cl–Cu (α) angle and the longer Cu–Cl distance (*R*) have a strong influence on the magnetic interaction. A correlation between the singlet–triplet gap (ΔE_{S-T}) and α/*R* [26] was found, with a ferromagnetic behaviour observed for α/*R* values between 32.6 and 34.8. However, this rule is only valid for complexes with similar arrangement of the square pyramids [2b].

Table 3 summarizes the most relevant structural parameters and magnetic coupling constants for complexes with parallel basal planes. These compounds show a weak ferro or antiferromagnetic interaction, with coupling constant values between −16 and +11 cm^{-1}. For Cu(II) ions in a square pyramidal geometry, the d orbital of each copper involved in the magnetic interaction is the x^2–y^2 orbital, and these orbitals are parallel. So, in an ideal case, the overlap through the chloride bridges must be negligible, and a ferromagnetic behaviour must be attended. However, a small distortion of the coordination polyhedron and Cu–Cl–Cu angles different from 90° create an overlap route through the bridge, and an antiferromagnetic coupling could be observed.

In agreement with the Hatfield's rule [26], the majority of ferromagnetic compounds reported in Table 3 show a quotient α/*R* between 32.6 and 34.8. However, the cationic complexes [{Cu(S-dept)}$_2$(μ-Cl)$_2$]$^{2+1}$ and [{Cu(S-dbpt)}$_2$(μ-Cl)$_2$]$^{2+}$ (**1**) show minor values of α/*R*. These complexes have two sulfur atoms coordinated to the Cu(II) ions in the basal plane of the square pyramid, while the other compounds have N or O donor ligands.

3.3. Molecular orbitals

Extended Hückel calculations based on the crystallographic coordinates of compounds **1** and **2** have been carried out with the CACAO program [35], with the aim to compare the present results with the analogous complex formed with the S-dept ligand [1]. For the cationic species a major overlap of population between the Cu-donor atom (N, S or Cl) was observed for the complex in **2**, more than in complex **1**, in agreement with the shorter distances found in **2**. Moreover, the singly occupied molecular orbital (SOMO), with an important contribution of the x^2–y^2 orbital of the Cu(II) ion, shows a small contribution of the pyridine ring in complex **2**, and it is not present in **1** or in the analogous dinuclear cationic species obtained with the S-dept ligand [1].

A comparison of the energy gap between the two SOMO's for the dinuclear species with S-dbpt (in **1**) (0.042 eV) and S-dept (0.011 eV) [1] agrees with the magnetic properties. Both compounds show a very small energy gap and a ferromagnetic interaction is observed. Moreover, the smaller gap corresponds to the compound with a major ferromagnetic coupling constant (4.5 cm^{-1} as compared to 3.2 cm^{-1} for **1**).

For the anionic species [{CuCl$_2$}$_2$(μ-Cl)$_2$]$^{2-}$ the energy gap is greater than for the cationic species, and is similar for both compounds (0.367 eV for complex **1** and 0.354 eV for complex **2**). A major value was reported for [{CuCl}$_2$(μ-S-dept)$_2$] [{CuCl$_2$}$_2$(μ-Cl)$_2$]^1 (0.435 eV), which showed greater antiferromagnetic coupling ($J = -19$ cm^{-1}).

to multinuclear systems [5–7]. Tridentate and tetradentate ligands such as salen-type Schiff bases are quite capable of forming complexes with certain metal ions which can exhibit unusual coordination, high thermodynamic stability and kinetic inertness. The coordination geometry of these complexes depends upon the electronic configuration and size of the metal ions, repulsions between non-bonded atoms in different ligand arms, and the inherent rigidity due to the presence of aromatic rings, etc. [8]. Such topologies are also based on strong metal–ligand covalent bonds [9] and multiple weak non-covalent forces like hydrogen bonding [10] and π–π interactions [11]. The role of different transition and non-transition metal ions as templates, Schiff bases as blocking units and pseudohalides or carboxylates as bridges are very much noteworthy in this regard [12–15]. Pseudohalides, especially azide, thiocyanate or dicyanamide, have long been known for their versatile coordination modes to exploit the desired architectures. Cadmium(II), well suited with its d^{10} configuration, permits a wide range of symmetries and coordination numbers and hence reports on hexacoordinated cadmium(II) complexes are well documented [14,15]. However, heptacoordinated cadmium(II) complexes are not very common [12,16]. All these features have prompted us to develop new coordination complexes with increased dimensionality using the variation of donor sites. Both the Schiff bases used to prepare the reported complexes are symmetric in nature. The most interesting fact is that although the ligands are quite symmetric in nature, their coordination behaviour to the metal atoms is not at all similar. The geometry of the coordination around the metal centers is mostly distorted octahedral, but one of the complexes shows a unique presence of both hexa- and heptacoordinated metal centers. From the report, it is very much clear that the coordination environment around the metal centre is largely influenced by the steric demand of the long chain multidentate ligand.

We have successfully prepared three trinuclear Cd(II) complexes and characterised them on the basis of microanalytical, spectroscopic and other physicochemical properties. X-ray crystallographic studies have been made to establish their structures. The present paper reports a systematic study of three new trimeric Cd(II) complexes with two multidentate Schiff bases. In addition, the investigation of the coordination properties of cadmium is of interest because of the environmental aspects and biological activity of Cd(II). The details of syntheses, structures and other spectroscopic behaviours are described below.

2. Experimental

2.1. Materials

All the chemicals and solvents used for the syntheses were of analytical grade. Cadmium nitrate, tetrahydrate; salicylaldehyde; 3-methoxysalicylaldehyde; sodium thiocyanate; sodium dicyanamide and diethylenetriamine were purchased from Aldrich Chemical Co. Inc. and were used without any further purification. Methanol and *N*,*N*-dimethylformamide ($HCONMe_2$) were used as solvents. Both the solvents were super dried before use. AR grade methanol was distilled with a good fractionating column for the exclusion of moisture. In this method, the water content was reduced to *ca*. 100 ppm. The solvent dimethyl formamide (AR) was distilled over di-phosphorus pentoxide before use in order to minimise the moisture content in the solvents. Hydrated cadmium (II) trifluoroacetate $[Cd(CF_3COO)_2 \cdot xH_2O]$ was prepared by the treatment of cadmium(II) carbonate, $CdCO_3$, (AR grade, E. Merck, India) with 60% trifluoroacetic acid (AR grade, E. Merck, India) followed by slow evaporation on a steam bath. It was then filtered through a fine glass-frit and preserved in a $CaCl_2$ desiccator.

2.2. Syntheses

Caution! Although no problems were encountered in this work, trifluoroacetic acid and its vapour are potentially corrosive to human skin. It should be handled with every care.

2.2.1. Synthesis of the Schiff base ligands

2.2.1.1. Synthesis of $(OH)C_6H_4CH{=}N(CH_2)_2NH(CH_2)_2N{=}CHC_6H_4(OH)$ ($\boldsymbol{H_2L^1}$). The Schiff base chelator H_2L^1 was prepared following a reported [17] procedure with a slight modification. Salicylaldehyde (0.244 g, 2 mmol) was refluxed with diethylenetriamine (0.103 g, 1 mmol) in dehydrated methanol. After 1 h, a deep orange yellow solution was obtained. It was subjected to TLC which revealed the presence of some unreacted starting materials along with the Schiff base product. The Schiff base product was isolated by column chromatography in order to get it in the purified form. The purified ligand was then evaporated under reduced pressure to yield a gummy mass, which was dried and stored *in vacuo* over $CaCl_2$ for subsequent use. Yield: 0.264 g (85%). *Anal*. Calc. for $C_{18}H_{21}N_3O_2$: C, 69.43; H, 6.80; N, 13.49. Found: C, 69.40; H, 6.82; N, 13.50%. Mass spectrum (EI): *m*/*z* 311($M^+ = L^+$). FT-IR (KBr, cm^{-1}): *ν*(C=N) 1640. UV–Vis (*λ*, nm): 242, 369.

2.2.1.2. Synthesis of $(OH)(OCH_3)C_6H_3CH{=}N(CH_2)_2NH(CH_2)_2N{=}CHC_6H_3(OH)(OCH_3)$ ($\boldsymbol{H_2L^2}$). The Schiff base chelator H_2L^2 was prepared following the same procedure as adopted for H_2L^1 except 3-methoxysalicylaldehyde (0.305 g, 2 mmol) was refluxed with diethylenetriamine (0.103 g, 1 mmol) in dehydrated methanol. Yield: 0.304 g (82%). *Anal.* Calc. for $C_{20}H_{25}N_3O_4$: C, 64.67; H, 6.78; N, 11.31. Found: C, 64.65; H, 6.80; N, 11.30%. Mass spectrum (EI): *m*/*z* 371 ($M^+ = L^+$). FT-IR (KBr, cm^{-1}): *ν*(C=N) 1641. UV–Vis (*λ*, nm): 240, 372.

2.2.2. Syntheses of the Schiff base complexes

2.2.2.1. Synthesis of $[Cd_3(L^1)_2(SCN)_2(CF_3COO)_2]$ (**1**). The appropriate quantity of solid Schiff base ligand H_2L^1

(0.622 g, 2 mmol) was dissolved in dry methanol (20 ml). A solution of $Cd(CF_3COO)_2 \cdot 2H_2O$ (1.123 g, 3 mmol) in dry methanol (10 ml) was added to this solution (3:2 molar ratio, M:L) followed by the addition of a 5 ml methanolic solution of 0.162 g (2 mmol) NaSCN. The mixture was refluxed for 2 h at 80 °C. The resulting yellow coloured solution was then filtered off and the filtrate was left undisturbed. After 5 days fine colourless needle shaped X-ray diffraction quality single crystals separated out. They were filtered, washed with methanol and dried *in vacuo* over $CaCl_2$. Yield: 85%. *Anal.* Calc. for $C_{42}H_{40}Cd_3F_6N_8O_8S_2$: C, 38.80; H, 3.10; N, 8.62. Found: C, 38.82; H, 3.07; N, 8.65%.

*2.2.2.2. Synthesis of $[Cd_3(L^1)_2(SCN)_2(HCONMe_2)]$ (**2**).* 0.622 g (2 mmol) of the solid Schiff base ligand H_2L^1 was dissolved in dry methanol (20 ml). A gently warm solution of $Cd(NO_3)_2 \cdot 4H_2O$ (0.930 g, 3 mmol) in dry methanol (10 ml) was added to this solution (3:2 molar ratio, M:L) followed by the addition of 5 ml NaSCN solution (0.162 g, 2 mmol). The solution turned turbid. *N*,*N*-Dimethylformamide was added dropwise till the turbidity just disappeared. The mixture was refluxed for 3 h at 80 °C. The resulting yellow coloured solution was then filtered off and the filtrate was left undisturbed. After 2 h colourless plate shaped X-ray diffraction quality single crystals separated out. They were filtered, washed with methanol and dried *in vacuo* over $CaCl_2$. Yield: 65%. *Anal.* Calc. for $C_{41}H_{43}Cd_3N_9O_5S_2$: C, 43.08; H, 3.79; N, 11.03. Found: C, 43.05; H, 3.80; N, 11.00%.

*2.2.2.3. Synthesis of $[Cd_3(L^2)_2\{N(CN)_2\}_2]$ (**3**).* 0.742 g (2 mmol) of the solid Schiff base ligand H_2L^2 was dissolved in 10 ml methanol. The solution was then added to a 10 ml gently warm solution of $Cd(NO_3)_2 \cdot 4H_2O$ (0.930 g, 3 mmol) followed by the slow dropwise addition of 5 ml sodium dicyanamide solution (0.178 g, 2 mmol). The mixture was then refluxed for 45 min at 85 °C. The resulting yellow coloured solution was filtered off and the filtrate was left undisturbed. After 5 days, yellow block shaped X-ray diffraction quality single crystals separated out from the medium. They were filtered, washed with methanol and dried *in vacuo* over $CaCl_2$. Yield: 87%. *Anal.* Calc. for $C_{44}H_{46}Cd_3N_{12}O_8$: C, 43.74; H, 3.84; N, 13.91. Found: C, 43.76; H, 3.80; N, 13.94%.

2.3. Physical measurements

The Fourier Transform infrared spectra of the ligands and the complexes were recorded on a Perkin–Elmer RX-I FT-IR spectrophotometer with a KBr disc in the range 4000–200 cm^{-1}. Elemental analyses (C, H, N) were carried out using a Perkin–Elmer 2400 II elemental analyser. The electronic spectra of the ligands were recorded on a Perkin–Elmer Lambda 40 (UV/Vis) spectrometer in methanol. Steady state fluorescence measurements were performed using a Spex Fluorolog-II spectrofluorimeter. For spectroscopic measurements, the concentration of the solutions were *ca.* 2×10^{-5} M. Mass spectra were obtained with a MAT 8200 (electron ionization, EIMS) instrument.

2.4. Single crystal X-ray structure determination

A good diffraction quality air stable single crystal of **1** (dim $0.01 \times 0.01 \times 0.01$ mm) was mounted in a Nonius KappaCCD diffractometer while that of **2** (dim $0.12 \times 0.12 \times 0.03$ mm) and **3** (dim $0.40 \times 0.50 \times 0.50$ mm) in Bruker X8 APEXII CCD and Bruker AXS P4 diffractometers, respectively. All the diffractometers were equipped with graphite monochromated Mo Kα radiation ($\lambda = 0.71069$ Å for **1** and 0.71073 Å for **2** and **3**). Crystal data were collected using the software COLLECT [18a] at a temperature of 293 K for **1** and using Bruker SMART [18b] and Bruker XCANS [18c] softwares at a temperature 123 K for **2** and **3**, respectively. Cell refinements were carried out using DENZO-SCALEPACK [18a], Bruker SAINT and Bruker XCANS for **1**, **2** and **3**, respectively. No significant intensity variation was observed for each of them. A total of 8876 reflections (6368 unique reflections, $R_{int} = 0.021$), 16 582 reflections (8470 unique reflections, $R_{int} = 0.087$) and 27 073 reflections (6801 unique reflections, $R_{int} = 0.049$) for **1**, **2** and **3** were collected applying the boundary condition $I > 3\sigma(I)$ for **1** and $I \geqslant 2\sigma(I)$ for **2** and **3**. No absorption correction was applied to the data sets for **1** and **3**. Multiscan absorption correction was applied to the intensity values ($T_{max} = 0.9533$, $T_{min} = 0.8302$) empirically using SADABS for **2** [18d]. Data reduction was performed using DENZO-SCALEPACK for **1** [18a], while Bruker SAINT [18e] and Bruker SHELXTL [18f] softwares were used for **2** and **3**, respectively. According to the observed systematic extinctions, the structure of **1** was solved by direct methods using the SIR97 [18g] program combined with Fourier difference syntheses and refined against F using reflections maintaining the boundary condition $I/\sigma(I) > 3$ (CRYSTALS program [18(h)]). For **2** and **3**, the final structures were solved by direct methods using the program SHELXS-97 and refined with full-matrix least-squares based on F^2 using SHELXL-97 [18i]. The molecular graphics and crystallographic illustrations were prepared using the CAMERON [18j], ORTEP-III [18k] and CRYSTALMAKER [18l], Bruker SHELXTL [18f] programs for **1**, **2** and **3**, respectively. For all non-hydrogen atoms, the anisotropic displacement parameters have been refined successfully. Hydrogen atoms of the aromatic rings and the imino groups were placed geometrically and refined as a riding model taken from a difference Fourier map and refined with isotropic thermal parameters. Maximum and minimum peaks (e $Å^{-3}$) in the final difference Fourier synthesis were found as 1.96 and −1.99, 1.363 and −1.273, 1.12 and −0.84 for **1**, **2** and **3**, respectively. Relevant crystallographic data and structure refinement parameters for all the three complexes are summarised in Table 1.

Table 1
Crystallographic parameters for complexes **1**, **2** and **3**

Complex	**1**	**2**	**3**

[b] $R_w = \{\sum[w(|F_o - F_c|)^2]/\sum[w|F_o|^2]\}^{1/2}$.

3. Results and discussion

3.1. Fourier Transform infrared spectra

The solid state Fourier Transform infrared spectra of all the complexes, recorded on a FT-IR spectrophotometer in the range 4000–200 cm^{-1} are fully consistent with their single crystal structures. The samples were studied as powders dispersed in KBr pellets. The spectral region for all the complexes is more or less similar due to the similarity in coordination modes of the ligands with the metal centres. Sharp peaks were found at 1640 cm^{-1} and 1641 cm^{-1} for H_2L^1 and H_2L^2, respectively, which can be correlated to the stretching frequency of the azomethine (CH=N) group in the Schiff base ligands. This stretching frequency of the azomethine (CH=N) group observed near about 1640 cm^{-1}, is shifted to lower frequency values upon complexation with the metal by 20–40 cm^{-1} [19,20], suggesting coordination via the azomethine nitrogen in all the complexes. ν(N–H) at 3435 cm^{-1} in the IR spectrum of complex **1**, suggests the presence of a protonated nitrogen atom in the ligand [21]. Several sharp weak peaks observed for the complexes in the range 3180–2855 cm^{-1} are likely to be due to the aromatic stretches [22]. Sharp bands appearing at 455 and 375 cm^{-1} correspond to ν(Cd–N), and ν(Cd–O), respectively in all the complexes. The ν(C–O) mode is present as a very strong band at about 1240 cm^{-1}. Complex **1** also shows asymmetric and symmetric stretching vibrations of the trifluoroacetate groups at 1600 and 1450 cm^{-1}, respectively. The difference between ν_{asym}(COO) and ν_{sym}(COO) ($\Delta\nu = 150$ cm^{-1}), which is smaller than 164 cm^{-1} observed in ionic trifluoroacetate, reflects the bidentate bridging coordination mode [21]. In the mid energy range, characteristic absorption peaks for terminal SCN^- groups were found at 2105 cm^{-1}and 2109 cm^{-1}, respectively for **1** and **2**, along with the distinctive peaks in the low energy region near 1215 cm^{-1} attributable to δ_{CN} vibrations [22]. In the case of complex **3**, sharp characteristic peaks are found at 2300, 2245 and 2185 cm^{-1}, which may be assigned to $\nu_{\text{sym}} + \nu_{\text{asym}}$(CN), ν_{asym}(CN) and ν_{sym}(CN) stretching frequencies, respectively. The characteristic peaks invariably prove the presence of a terminal dicyanamide group in complex **3** [12a].

3.2. UV/Vis spectra

Electronic spectra of all the complexes have been measured in HPLC grade methanol. In a like manner, the bands in the 465–335 nm range can be assigned to the n–π^* transition from the azomethine (CH=N) group [4]. In the spectra of the complexes, these n–π^* transitions, are shifted to lower frequencies indicating that the imine nitrogen atom is involved in coordination to the Cd(II) metal ion. The bands at higher energies (300–210 nm range) are associated with benzene π–π^* transitions. The spectra of the complexes show intense bands in the high-energy region at 305–375 nm which can be attributed to L → M charge transfer bands [23]. Although the precise nature of this transition involving the phenoxide group is not fully

clear (it has been considered to be an O(phenoxide) → Cd(II) LMCT [24] or a Cd(II) → π* (phenoxide) MLCT [25] transition), it is agreed that a higher energy component should exist near 330 nm [26].

3.3. X-ray crystal structures of the complexes

3.3.1. $[Cd_3(L^1)_2(SCN)_2(CF_3COO)_2]$ (1)

The crystal structure of **1** consists of only one crystallographically independent molecule. Fig. 1 gives a labelled ORTEP diagram of **1**. Selected bond lengths and angles are presented in Table 2a. The complex crystallises in the $P\bar{1}$ space group. The structure found for complex **1** is a linear trinuclear array of three Cd(II) atoms coupled by both doubly μ-phenolato oxygens of the Schiff base ligand and simultaneously two trifluoroacetate anions in the *syn–syn* bridging mode. The crystal structure is also well supported and documented by different characterisation data found for the complex through elemental analysis and detailed spectral investigation. The coordination geometry around the terminal Cd(II) centers may be regarded as distorted octahedral. The equatorial plane of each of the two equivalent terminal Cd atoms are formed by the two imine nitrogen atoms [N(9), N(15)] and two phenolic oxygen atoms [O(1), O(23)] coming from the same ligand [N(9)–Cd(2)–O(23) = 138.99(18)° and N(15)–Cd(2)–O(1) = 142.36(17)°]. The apical positions are occupied by one sulfur atom (S37) from the terminal SCN^- ligand and another oxygen atom (O25) from the bridging trifluoroacetate group [S(37)–Cd(2)–O(25) = 161.55(18)°]. The Cd(2)–imine nitrogen [2.318(5) and 2.399(5) Å], Cd(2)–phenolic oxygen [2.284(4) and 2.342(3) Å] bond distances are in the range observed for similar systems [12,27]. The average bite angle of the extremely puckered eight membered chelate ring N(9)–C(10)–C(11)–N(12)–C(13)–C(14)–N(15)–Cd(2) is ~139.46°, thus introducing considerable steric strain in the fragment, enhancing a considerable distortion to the octahedral Cd(2) centre (Fig. 2). In the Schiff base ligand, the N(12) atom is protonated (Fig. 2), which is supported by the comparatively larger distance [Cd(2)–N(12): 2.446 Å] than for the other nitrogen atoms of the ligand [Cd(2)–N(9): 2.318(5) and Cd(2)–N(15): 2.399(5) Å]. However, the coordination geometry of the central Cd(1) atom deviates very slightly from an ideal octahedron

Table 2a
Selected bond distances (Å) and angles (°) for **1**

	Bond lengths	(Å)	Bond angles	(°)
1	Cd(1)–O(1)	2.287(3)	Cd(1)–O(1)–Cd(2)	98.35(13)
	Cd(1)–O(23)	2.266(3)	Cd(1)–O(23)–Cd(2)	100.72(17)
	Cd(1)–O(24)	2.363(4)	O(1)–Cd(1)–O(1*)	180.00
	Cd(2)–O(1)	2.342(3)	O(23)–Cd(1)–O(23*)	180.00
	Cd(2)–O(23)	2.284(4)	O(24)–Cd(1)–O(24*)	180.00
	Cd(2)–O(25)	2.356(4)	O(1)–Cd(2)–O(23)	74.25(15)
	Cd(2)–N(9)	2.318(5)	O(1)–Cd(2)–S(37)	112.82(19)
	Cd(2)–N(15)	2.399(5)	N(9)–Cd(2)–N(15)	139.5(2)
	Cd(2)–S(37)	2.546(6)	N(9)–Cd(2)–O(23)	138.99(18)
	C(8)–N(9)	1.287(9)	N(15)–Cd(2)–O(1)	142.36(17)
	C(16)–N(15)	1.261(9)	C(38)–S(37)–Cd(2)	149.5(6)
	C(26)–O(25)	1.224(7)	S(37)–Cd(2)–O(25)	161.55(18)

*: $-x, -y, -z$.

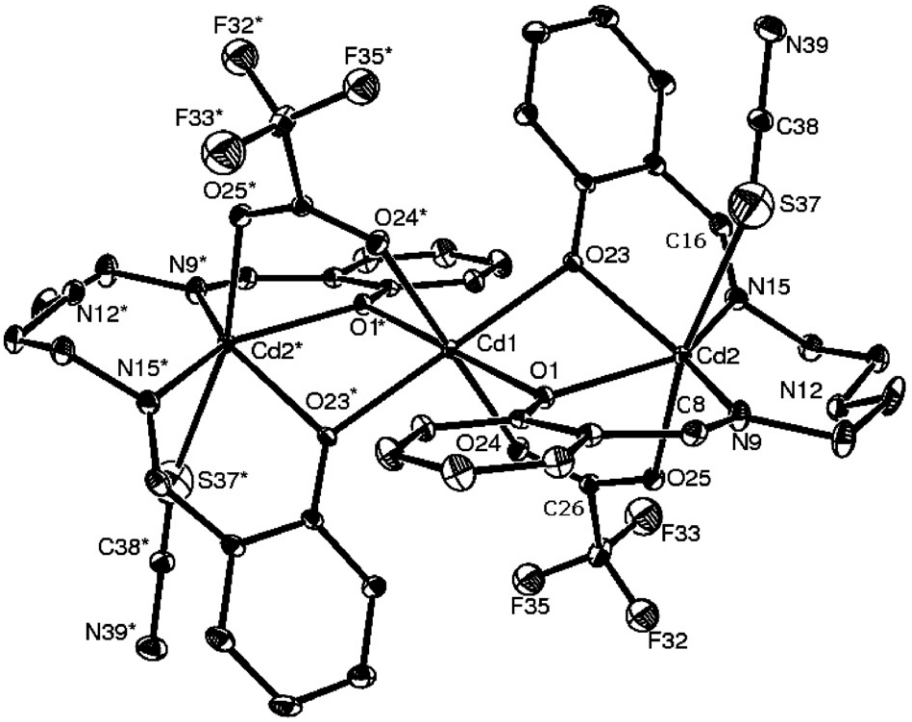

Fig. 1. ORTEP diagram of **1** with the atom numbering scheme (non-hydrogen atoms have been shown at 40% ellipsoid probability). Symmetry operation *: $-x, -y, -z$.

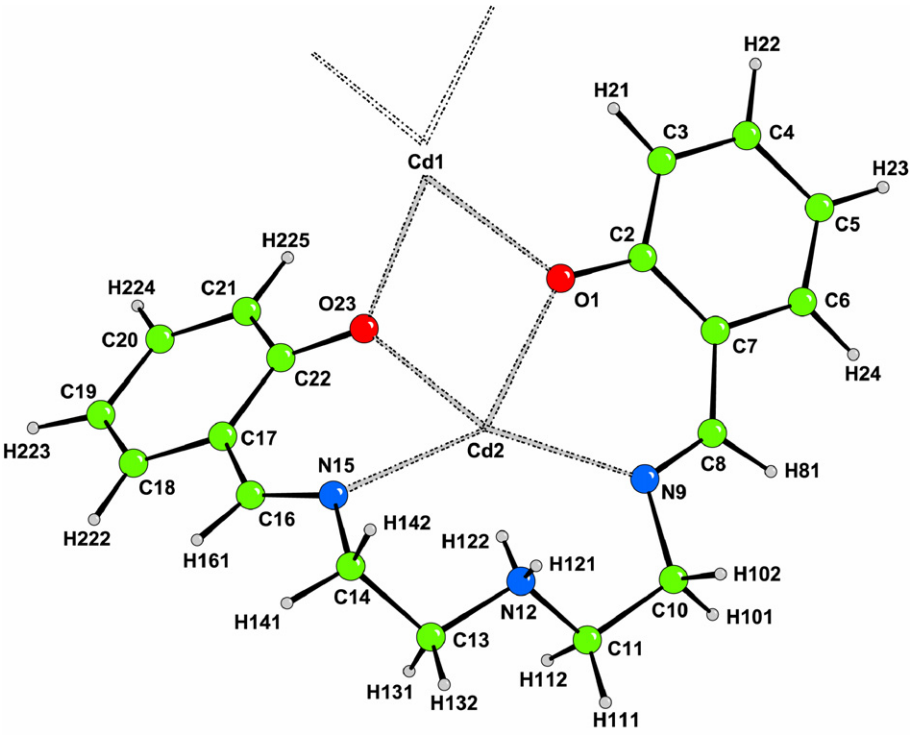

Fig. 2. Isolated view of the Cd(2) centre of **1** showing the imposed strain by the ligand (trifluoroacetate ligands have not been shown for picture clarity).

[O(1)–Cd(1)–O(1*), O(23)–Cd(1)–O(23*), O(24)–Cd(1)–O(24*) are each 180°]. The central Cd(1) atom has an O_2O_2 donor set from the two ligands. Again each of the two trifluoroacetate anions bridges the terminal Cd(2) and central Cd(1) atoms in a *syn–syn* fashion, but remaining to each other coordinated in a *trans*-fashion. Hence the central Cd(1) atom finally has an $O_2O_2O_2$ donor set (four equatorial oxygens coming from four deprotonated phenolic oxygens of the two ligands and two axial oxygens from the bridging trifluroacetates). The complex appears to be the most symmetric in nature with an inversion centre lying on the central Cd(1) atom, which is reflected by exactly the same *trans*-Cd–O(phenolate)–Cd bond angles [Cd(1)–O(1)–Cd(2): 98.35(13)°, Cd(1)–O(1*)–Cd(2*): 98.35(13)°, Cd(1)–O(23)–Cd(2): 100.72(17)°, Cd(1)–O(23*)–Cd(2*): 100.72(17)°]. The closest distance between two neighbouring cadmium atoms in the molecule is 3.503(3) Å and it is just half of the distance between the terminal cadmium centres (7.006 Å). In the crystal packing, each of the neutral metal–ligand clusters is isolated from another one. No interaction is found between the isolated clusters because the shortest distance between clusters is equal to ~8.204 Å (Fig. 3).

3.3.2. $[Cd_3(L^1)_2(SCN)_2(HCONMe_2)]$ (**2**)

Unlike the previous complex, complex **2** is a novel example of a doubly μ_3-phenoxo bridged cyclic Cd(II) trimer (Fig. 4). According to the best of our knowledge, it is the first of its kind reported in the literature where both six and seven coordinated Cd(II) centres are coexisting in the same μ_3-phenoxo bridged cyclic Cd(II) trimeric system. In the complex all the three metal centers bear dissimilar coordination patterns. Among them, the Cd(1) and Cd(3) centres are six coordinated whilst the remaining Cd(2) metal centre is seven coordinated. Both the Cd(1) and Cd(3) centres display a highly distorted octahedral environment. The Cd(1) centre is enjoying a N_3O_3 donor set. The severely strained equatorial plane is constructed by a N_2O_2 donor set [among them N(1) and N(3) are imine nitrogens; O(1) and O(3) are phenolate oxygen atoms] while the apical sites are occupied by O(2) coming from the phenolate oxygen atom of the Schiff base ligand and N(2), the free secondary nitrogen donor site present within the ligand backbone [O(2)–Cd(1)–N(2): 135.5(3)°, the highest among all the Cd(1) centred bond angles]. The average bite angles of the five membered chelate rings range from ~70° to 77°. It is also clearly reflected by the reduction in the bond angles around the Cd(1) centre (Table 2b). The Cd(3) centre also shows a distorted octahedral geometry with the equatorial plane constructed by an O_3N donor set [all the oxygen atoms are phenolate oxygens and the nitrogen atom N(8) is from the terminal thiocyanate]. The axial sites are occupied by one nitrogen atom N(7) from another terminal thiocyanate and O(2), a phenolate oxygen atom coming from the Schiff base ligand [N(7)–Cd(3)–O(2): 172.3(3)°]. The Cd(3) atom is shifted from the mean basal plane O(1)O(3)O(4)N(8) by 0.425(3) Å towards the apically coordinated N(7) atom. The most interesting coordination environment in this complex is manifested by the Cd(2) centre which is heptacoordinated, in contrast to its hexaco-

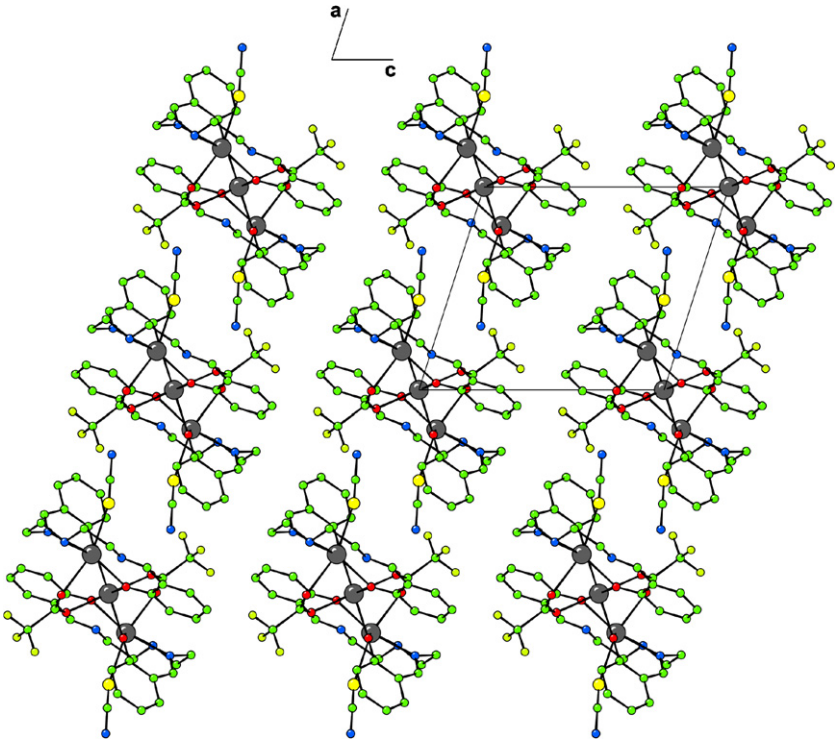

Fig. 3. Packing diagram of **1** along the *ac* plane.

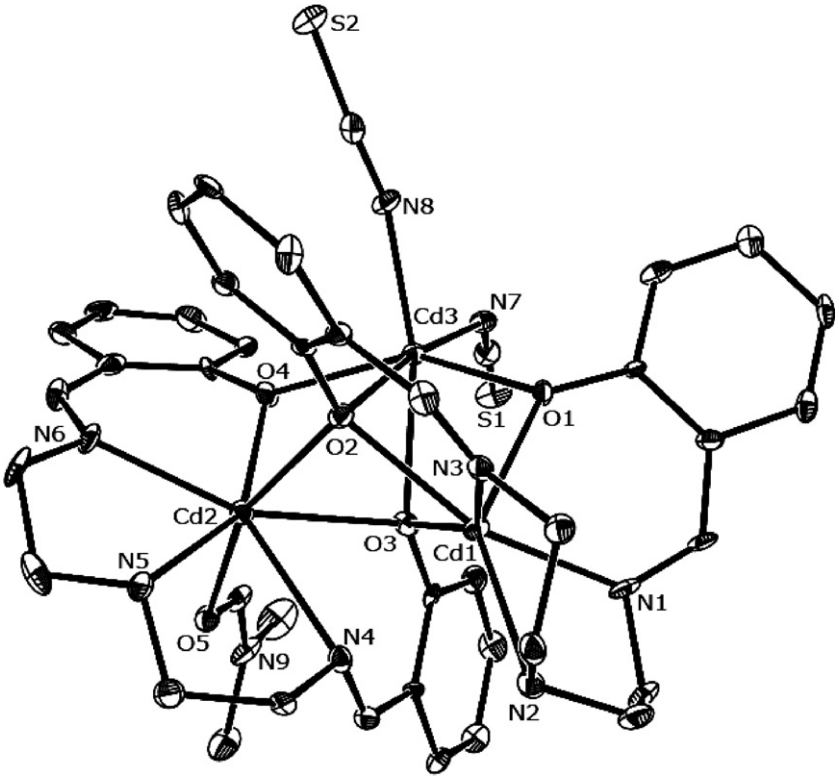

Fig. 4. ORTEP diagram of **2** with the atom numbering scheme (non-hydrogen atoms have been shown at 40% ellipsoid probability).

ordinated neighbours Cd(1) and Cd(3). The geometry around the metal centre can be best described as a severely distorted monocapped octahedron. The equatorial plane is constructed by a O_3N donor set [among them N(4) is an imine nitrogen; O(4) is a μ-phenolato oxygen bridging the Cd(2) and Cd(3) centres; O(2) is a μ_3-phenolato oxygen

Table 2b
Selected bond distances (Å) and angles (°) for **2**

Bond lengths		(Å)	Bond angles	(°)

	Cd(3)–O(3)	2.393(8)	Cd(1)–O(3)–Cd(2)	93.3(2)
	Cd(3)–O(4)	2.266(8)	Cd(2)–O(3)–Cd(3)	89.4(2)
	Cd(3)–N(7)	2.285(10)	Cd(1)–O(3)–Cd(3)	92.4(2)
	Cd(3)–N(8)	2.211(10)	Cd(2)–O(4)–Cd(3)	94.3(3)

which simultaneously bridges all the three Cd centres and O(5) comes from the coordinated $HCONMe_2$ molecule]. The *trans*-axial sites are occupied by one nitrogen atom N(5) from the secondary nitrogen donor site of the diamine fragment and O(3), a μ_3-phenolato oxygen. Another bond, Cd(2)–N(6), is directed through the centre of the trigonal face furnished by N(5), O(4) and O(5). It fulfils the seven coordinated geometry around the metal centre [the Cd(2)–N(4), Cd(2)–O(2), Cd(2)–O(4) and Cd(2)–O(5) bond lengths are 2.594(10), 2.277(6), 2.331(9) and 2.316(3) Å, respectively in the equatorial plane; Cd(2)–N(5) and Cd(2)–O(3) are 2.380(11) and 2.398(7) Å, respectively in the apical zone and Cd(2)–N(6) is 2.343(9) Å]. The apparent anomaly in the corresponding bond lengths around the Cd(2) centre is probably due to the severe strain imposed by the ligand system to the metal atom [the Cd(2) centre is deviated from the mean plane constructed by N(4), O(2), O(4) and O(5) by 0.6561(2) Å towards the apical N(5) atom]. The most noteworthy structural novelty of complex **2** lies in the interesting variation of the coordination behaviour of the "salen" moieties present in the two fag ends of the completely symmetric ligand H_2L^1. In the doubly deprotonated ligand (L^{2-}), one phenoxo oxygen [O(1) or O(4)] is μ-bridged between two adjacent metal centres [Cd(1)–Cd(3) or Cd(2)–Cd(3)] while its immediate neighbour on the other end [O(2) or O(3)] bridges three Cd(II) centers simultaneously, which is a very rare phenomenon observed in the chemical literature in the case of such salen-type Schiff base complexes. Thus there are actually two different kinds of phenolato oxygen atoms present in the ligand: one of them doubly coordinated to the adjacent metal centres and the other kind shows a μ_3 bridging mode which helps to afford a cyclic trimer of Cd(II). The average M–O(phenolate)–M bond angles are around 93°. All other relevant bond lengths and bond angles are given in Table 2b. The nearest Cd–Cd distances are: Cd(1)–Cd(2), 3.477(3); Cd(2)–Cd(3), 3.370(5); Cd(1)–Cd(3), 3.445(2) Å, thereby showing the least chance of interactions among the adjacent metal centres. Again from the view of crystal packing, any sort of non-covalent or weak interaction is absent amongst the neutral metal-Schiff base clusters, with them being isolated at large distances.

3.3.3. $[Cd_3(L^2)_2\{N(CN)_2\}_2]$ (**3**)

A perspective view of the trimeric asymmetric unit of complex **3** has been represented in Fig. 5 as an ORTEP plot and a packing diagram is shown in Fig. 6. Coordi-

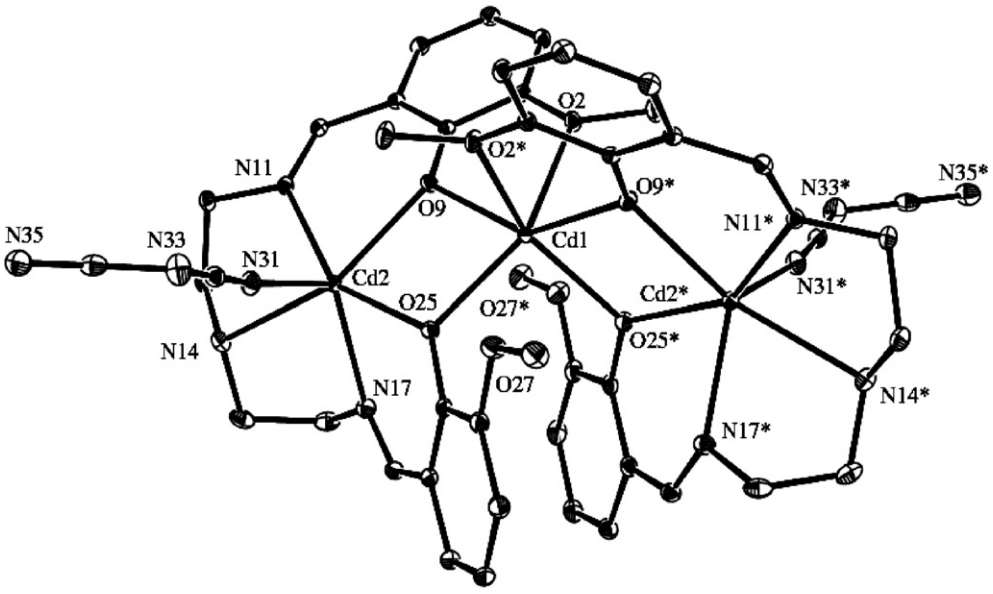

Fig. 5. ORTEP diagram of **3** with the atom numbering scheme (non-hydrogen atoms have been shown at 40% ellipsoid probability). Symmetry operation *: $1 - x$, y, $1/2 - z$.

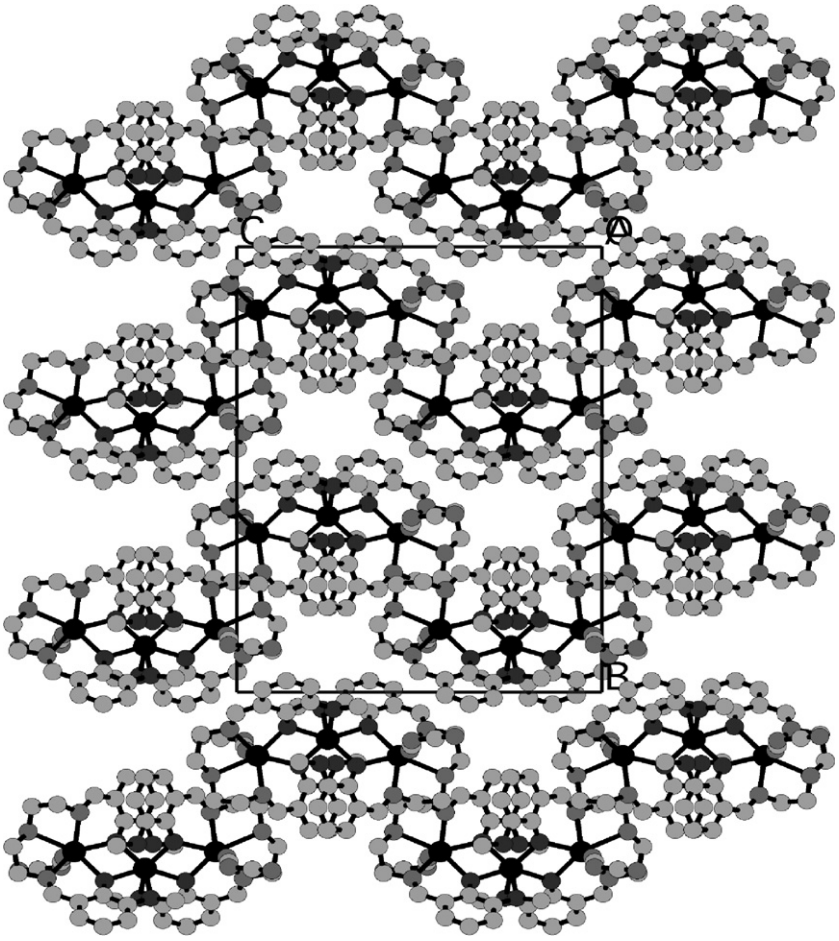

Fig. 6. Packing diagram of **3**.

nates of the non-hydrogen atoms, and selected bond distances and bond angles are given in Table 2c. The structure is a linear trimeric one, bearing two equivalent terminal Cd(II) centres. Complex **3** crystallises in the *C*2/*c* (monoclinic) space group. Adjacent Cd(II) atoms in the linear trinuclear array are coupled to each other doubly with μ-phenoxo bridges. The crystal structure is also well supported and documented by different characterisation data found for the complex through elemental analysis and detailed spectroscopic investigation. The coordination geometry around the central Cd(1) can be best described as a distorted octahedron. The central Cd(1) has an $O_2O_2O_2$ donor set from the two ligands, among the four equatorial oxygens, two are from two deprotonated phenolic oxygens [O(25) and O(25*)] while the other two are from two methoxy oxygens [O(2) and O(2*)] from the two different ligands. The two axial sites are occupied by two phenolic oxygens [O(9) and O(9*)]. The O(9)–Cd(1)–O(9*) angle of 145.12(5)° is the highest among all the *trans*-bond angles. The other *trans*-equatorial bond angles, O(2)–Cd(1)–O(25) and O(2*)–Cd(1)–O(25*), are same [142.84(5)°]. The coordination geometry around each symmetrically equivalent terminal Cd(II) centre may be regarded as a distorted octahedron. The terminal Cd(2) centre enjoys a N_4O_2 donor set. The severely strained equatorial plane is constructed by a N_3O donor set [among them N(17) is a imine nitrogen, N(14) is the free secondary nitrogen donor site and O(9) is a phenolate oxygen atom of the same Schiff base ligand, while N(31) comes from the terminal dicyanamide ligand]. The apical sites are occupied by O(25) coming from the phenolate oxygen atom and N(11), the imine nitrogen donor site

Table 2c
Selected bond distances (Å) and angles (°) for **3**

Bond lengths		(Å)	Bond angles	(°)
3	Cd(1)–O(2)	2.3702(17)	O(9)–Cd(1)–O(9*)	145.12(5)
	Cd(1)–O(2*)	2.3702(17)	O(2)–Cd(1)–O(25)	142.84(5)
	Cd(1)–O(9)	2.2601(15)	O(2*)–Cd(1)–O(25*)	142.84(5)
	Cd(1)–O(9*)	2.2601(15)	O(25)–Cd(1)–O(25*)	95.97(6)
	Cd(1)–O(25)	2.2134(15)	N(11)–Cd(2)–O(25)	149.63(6)
	Cd(1)–O(25*)	2.2134(15)	N(14)–Cd(2)–O(9)	147.90(6)
	Cd(2)–O(9)	2.3256(15)	N(17)–Cd(2)–N(31)	115.55(8)
	Cd(2)–O(25)	2.3077(15)	O(9)–Cd(2)–O(25)	71.99(5)
	Cd(2)–N(11)	2.2932(18)	N(11)–Cd(2)–N(14)	71.96(6)
	Cd(2)–N(14)	2.560(2)	O(9)–Cd(2)–N(11)	77.80(6)
	Cd(2)–N(17)	2.290(2)	Cd(1)–O(9)–Cd(2)	105.36(6)
	Cd(2)–N(31)	2.246(2)	Cd(1)–O(25)–Cd(2)	107.52(6)

*: $1 - x, y, 1/2 - z$.

present in the same Schiff base ligand. The *trans*-axial bond angle N(11)–Cd(2)–O(25) is 149.63(6)°. The average bite angles of the two puckered five and six membered chelate rings are ~71.31° and 77.25°, respectively, which initiate a considerable distortion to the octahedral Cd(2) centre (Fig. 5). The comparatively larger distance [Cd(2)–N(14): 2.560(2) Å] than for the other nitrogen atoms of the Schiff base ligand [Cd(2)–N(11): 2.2932(18) and Cd(2)–N(17): 2.290(2) Å] may be attributed to the considerable steric strain present in the fragment. The most interesting feature lies in the variation of the coordination pattern of the *o*-vanilin moieties at the two ends of the Schiff base ligand (H_2L^2). In the doubly deprotonated ligand L^{2-}, one –OMe group is coordinated to the central Cd(1) centre while its counterpart in the other end of the same ligand remains free. The same behaviour is also observed for the other ligand. The closest distance between two terminal Cd atoms in the molecule is 7.050 Å and it is approximately double that between the neighbouring Cd centres (3.647 Å). In the packing diagram we did not find any trace of non-covalent or weak interactions among the neutral metal-Schiff base clusters (Fig. 6).

3.4. Luminescence properties

Steady-state fluorescence studies have been performed to establish the metal Schiff base coordination for all the three complexes. Fluorescence spectra for both the Schiff base ligands and their respective Cd(II) complexes have been measured in methanol (Fig. 7). All of them show characteristic broad fluorescence emissions indicating a ligand-to-metal charge transfer (LMCT) nature of the bands. Significant differences in the positions of the emission maximum of the complexes from that of the ligands may be considered as an evidence of metal–ligand complexation. All the complexes show intense bands at *ca.* 360 nm, which may be assigned to intraligand $^1(\pi-\pi^*)$ transitions. The emission energy of all the complexes in methanol solutions at 298 K is almost same and is assignable to intraligand fluorescence [12,28–30]. The lifetimes of the complexes are in range 2.50–2.60 ns. In glassy solutions (methanol at 77 K) both fluorescence and $^3(\pi-\pi^*)$ phosphorescence are observed at 525 nm.

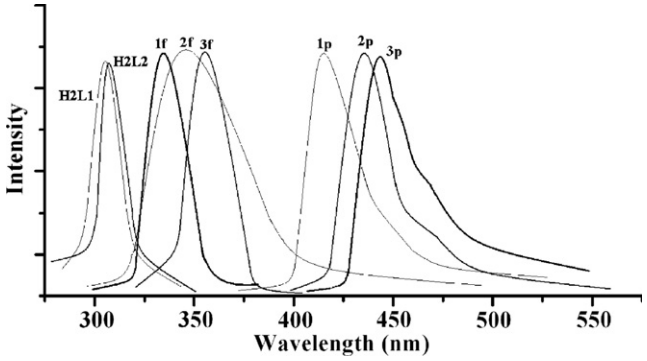

Fig. 7. Luminescence spectra for the ligands and the complexes H2L1: fluorescence spectra for the ligand H_2L^1, H2L2: fluorescence spectra for the ligand H_2L^2, **1f**, **2f**, **3f**: fluorescence spectra of **1**, **2**, **3** in MeOH solution at 298 K, respectively. 1p, 2p, 3p: Phosphorescence spectra of **1**, **2**, **3** in MeOH glassy solution at 77 K, respectively.

4. Conclusion

The present study shows that the reaction of long chain multidentate salen-type Schiff base ligands with various metal salts can afford a variety of fascinating metal-cluster frameworks. Both the ligands are flexible enough due to their long chain lengths and hence they are able to adjust their conformations in order to fit with the geometries of the metal ion thereby reducing the steric strain within the ligand backbone. We have been able to synthesise three novel trinuclear coordination complexes with two analogous multidentate Schiff base ligands. The novelty of the work lies in the interesting variation of the coordination pattern of the different donor sites due to the flexibility of the long chain ligand backbone.

Acknowledgements

Joy Chakraborty is especially grateful to the University Grants Commission, New Delhi, Government of India for the award of a Senior Research Fellowship to him. J.C. is also thankful to Dr. Arnab Mukherjee, Department of Chemical Engineering, University Institute of Chemical Technology, Mumbai for the technical support to the luminescence studies of the complexes. Santarupa Thakurta is grateful to the CSIR, Govt. of India for a Junior Research Fellowship.

properties. Several recently synthesized nickel complexes have been tested for inhibition of cancer cell proliferation [20–22].

Among the compounds tested a bis(citronellal thiosemicarbazonato)nickel(II), [Ni(tcitr)2], and the corresponding free ligand Htcitr showed a remarkable activity in apoptosis induction [23]. In accordance, we have decided to extend our research to other nickel complexes of aliphatic long-chain thiosemicarbazones that differ from those previously studied in the apoptosis assay for the chain length and for the substituents on the thiosemicarbazone terminal nitrogen atom. In this frame we have synthesized, modifying a procedure described in the literature [24], and characterized nine ligands and prepared the corresponding nickel derivatives starting from nickel acetate. Five of these complexes and namely bis(heptanal thiosemicarbazonato)nickel(II) (**10**), bis(decanal thiosemicarbazonato) nickel(II) (**13**), bis(N^1-methyldecanal thiosemicarbazonato) nickel(II) (**14**), bis(N^1-allyldecanal thiosemicarbazonato) nickel(II) (**15**) and bis(N^1-allylundecanal thiosemicarbazonato)nickel(II) (**18**), were characterized by X-ray diffractometry. Among the synthesized compounds the two that overcame an initial screening on solubility and stability in the culture broth of leukemia cells (human lymphoma) were chosen: the heptanal thiosemicarbazone and its nickel complex. These two compounds were then used to test the biological activity on leukemia line U937 in order to compare the effect of the simple ligand versus the action of the complex.

2. Experimental

2.1. Materials and methods

Undecanal 97% (Lancaster), decanal 97% (Alfa Aesar), heptanal 97% (Alfa Aesar), 4-methylthiosemicarbazide 97% (Aldrich), 4-allylthiosemicarbazide 97% (Aldrich), $Ni(CH_3COO)_2 \cdot 4H_2O$ (Carlo Erba) were commercially available and used without further purification. Elemental analyses (C, H, N, S) were performed with a Carlo Erba model EA 1108 automatic analyzer. IR spectra (4000–400 cm^{-1}) for KBr discs were recorded on a Nicolet 5PC FT. Chemical ionization-mass (*m*/*z*, 70 eV) fragmentation patterns were obtained, using samples dissolved in methanol, with a Finnegan 1020 6c mass spectrometer equipped with a quadrupole mass selector MATSSQ 710. The ^1H NMR spectra were recorded on a Bruker 300 spectrometer. Chemical shifts are reported in parts per million referenced to that of residual solvent protons. Melting points were determined with a Gallenkamp instrument. UV–Vis measurements were performed on a Perkin–Elmer UV/Vis Lambda 25 spectrometer with quartz cuvettes.

2.2. Preparation of the ligands

In a typical procedure to a methanol solution (45 mL) of appropriate thiosemicarbazide (0.90 mmol) obtained by magnetic stirring and slight heating, an equimolar amount of aliphatic aldehyde was added dropwise (Scheme 1). For the synthesis of the compounds **1**–**5**, **7** and **8** was necessary boiling the respective reaction mixtures under reflux condition, while for **6** and **9** stirring at room temperature was sufficient. By following this general procedure after 8 h a transparent and colorless solution was obtained for all the ligands except for **6** and **9** which it appear pale yellow. From standing solution separates a white microcrystalline product (yellow for **6** and **9**) that was then isolated by filtration and analyzed.

2.2.1. Heptanal thiosemicarbazone (*1*)

2.3. Preparation of the complexes

All nickel complexes were prepared by reacting $Ni(CH_3COO)_2$ (1 mmol dissolved in methanol, 20 mL) and the corresponding ligand (2 mmol, dissolved in methanol, 30 mL) in a 1:2 ratio. After stirring for 2 h at room temperature the resulting brown solution is placed standing to allow the solvent to evaporate and the product is formed as microcrystals or a microcrystalline powder. UV spectra of complexes (CH_3OH) show absorption bands in the region 650–400 nm (*ε*, 50–500 $L \times cm^{-1} \times mol^{-1}$) due to d–d transitions together to very strong absorptions below 300 nm due to ligand $n \rightarrow \sigma^*$ and $n \rightarrow \pi^*$ transitions.

*2.3.1. Bis(heptanal thiosemicarbazonato)nickel(II) (**10**)*

Yield: 0.324 g, 75%. M.p.: 156 °C. 2.3.9. Bis(N^1-allyl undecanal thiosemicarbazonato)nickel(II) (**18**)

Yield: 0.436 g, 70%. M.p.: 62 °C. IR(KBr, cm^{-1}): 3404(s) ν(NH); 2921(s) ν(CH$_{al}$); 1536(vs) ν(C=N); 1497(s) and 1271(m) ν(C–N); 723(w) ν(C=S). *Anal.* Calc. for $C_{30}H_{56}N_6NiS_2$: C, 57.8; H, 9.0; N, 13.5; S, 10.3. Found: C, 58.1; H, 9.2; N, 13.8; S, 10.5%. ^{1}H NMR (300 MHz, DMSO-d_6): δ_H (ppm) 7.68 (t, 1H, C*H*=N), 6.45 (q, 1H, N*H*CH$_2$), 5.93 (m, 1H, CH$_2$=C*H*–CH$_2$), 5.20 (dd, 1H, CH_2=CH, Hβ), 5.15 (dd, 1H, CH_2=CH, Hα), 4.24 (dd, 2H, CH–CH_2–NH), 2.46 (m, 2H, CH_2 in C2), 1.78–1.56 (m, 4H, CH_2 in C3 + C4), 1.46–1.12 (m, 12H, CH_2 in C5 + C6 + C7 + C8 + C9 + C10), 0.95 (t, 3H, CH_3).

2.4. X-ray crystallography

Single crystals of complexes **10**, **13**, **14**, **15** and **18** were mounted on glass fibers and used for X-ray diffraction experiments. Data were collected at room temperature for compounds **15** and **18** on a Bruker-Siemens SMART AXS 1000 equipped with CCD detector, while those of **10**, **13**, **14** on a Philips PW1100 diffractometer; in both cases graphite monochromated Mo Kα radiation ($\lambda = 0.71069$ Å) was used. Data collection details for the Bruker-Siemens SMART AXS 1000 are: crystal to detector distance = 5.0 cm, 2424 frames collected (complete sphere mode), time per frame = 20 s, oscillation $\Delta\sigma = 0.300°$. No crystal decay was observed in all cases. Data reduction was performed up to a 0.90 Å resolution by the SAINT pack-

age [25] and data were corrected for absorption effects by the SADABS [26] procedure; in the data collection carried out on the Philips PW1100 diffractometer the intensities were measured using a modified version [27] of the profile analysis method of Lehman and Larsen [28] and were corrected for Lorentz and polarization effects. The phase problem was solved by direct methods [29] and the structures were refined by full-matrix least-squares on all F^2 performed using SHELXL97 [30], as implemented in the WINGX [31]. Anisotropic displacement parameters were refined for non-hydrogen atoms in all complexes except in complex **15** for the carbon atoms of the allyl substituent which is disordered on two positions with occupancy factor of 0.5. All hydrogen atoms were located from Fourier maps and refined isotropically except those of the disordered allyl group in **15**. Only five hydrogen atoms were introduced in calculated positions, and more exactly those on the last two carbons of compound **18**.

Analytical expressions of neutral atom scattering factors were employed according to the International Tables [32]. Molecular geometry calculations were performed using the PARST [33] computer program and the structure drawings obtained with the ORTEPIII [34] and PLATON [35] programs. Further details for structural analysis are summarized in Tables 2a and 2b.

2.5. Biological activity testing

The compounds were tested for their solubility in the culture medium and in DMSO. At the same time the biological action of the solvent has been evaluated at the different concentration used. Compound **1** and its nickel derivative **10** were chosen as suitable for biological testing for their solubility and their purity. Cells were also treated with the inorganic nickel salt at the same concentrations used for 11 and no effect was observed on cell proliferation. Compounds were evaluated *in vitro* for their cytotoxicities, using peripheral blood mononuclear cells (PBMC) as a control, on human leukemic cell line U937 from a patient with histiocytic lymphoma. This line was grown in RPMI-1640 medium added of antibiotics (penicillin 100 U/ml, streptomycin 100 μg/ml), L-glutamine 2 mM and fetal bovine serum (FBS) 10% and kept at 37 °C in humid atmosphere at 5% CO_2.

2.5.1. Cell growth

The cells were seeded in a 96-well tray at a concentration of 1×10^5/ml in culture medium and kept in culture for 24 h until they reach a concentration of about 2×10^5/ml in exponential phase. The cells were then treated with the compounds in different concentrations in order to evaluate the IC50 through the ProCheckTM cell viability assay (Intergen). In each well were placed 100 μl of cell culture with 20 μl of ProCheckTM reagent to a final volume of 120 μl. After 1–4 h of incubation at 37 °C and under a 5% CO_2 humidified atmosphere the measurement was carried out through an ELX800 Packard spectrophotometer at 475 nm wavelength. Cell mortality was evaluated after 24 h by the trypan blue exclusion method and determined by using a hemocytometer.

2.5.2. Apoptosis assay

To evaluate apoptosis the cytofluorimetric method was followed, through the Mebcyto Apoptosis Kit, where Annexin-V and Propidium Iodide are used to discriminate early and late apoptosis. Early during the process of apoptosis, cells lose their phospholipid membrane asymmetry and expose phosphatidylserine (PS) at the cell surface. This

process can be monitored by using Annexin-V which is a Ca^{2+}-dependent, phospholipid-binding protein with high affinity for PS, and is useful for identifying apoptotic cells with exposed PS. Translocation of PS to the external cell surface is not unique to apoptosis, but occurs also during cell necrosis. The difference between these two forms of cell death is that during the initial stages of apoptosis the cell membrane remains intact, while at the very moment that necrosis occurs the cell membrane looses its integrity and becomes leaky. Therefore, necrotic cells easily stained with Propidium Iodide as well as Annexin-V, whereas apoptotic cells are stained only with Annexin-V.

3. Results and discussion

The ligands synthesized are characterized by a long hydrophobic tail and by a polar thiosemicarbazone head. By varying the length of the tail and the substitution on the polar head with a methyl or an allyl fragment their physicochemical properties have been modified. The presence of substituents on the terminal nitrogen of the thiosemicarbazide group influences the hydrogen bond pattern of the molecules and this is particularly apparent in the crystal packing. These compounds were synthesized as part of a wider screening project in order to gain an insight into the causes that render many thiosemicarbazone metal complexes so active on cell proliferation inhibition and apoptosis induction.

3.1. Crystal and molecular structure

The crystals of compounds **10** and **13** are made up of complex molecules of formula $[Ni(C_8H_{17}N_3S)_2]$ and $[Ni(C_{11}H_{23}N_3S)_2]$, respectively. The structure of the complex units, as can be seen in the Ortep plot reported in Figs. 1 and 2, is formed by a nickel(II) ion, lying on a center of symmetry that coordinates two molecules of the ligand in its monodeprotonated form. In the asymmetric unit the coordinated thiosemicarbazonate unit chelates through the sulfur and the iminic nitrogen forming a 5-member chelation rings. The metal to donor distances are only slightly different: the Ni1–N3 bonds are 1.909(2) Å and 1.918(2) Å and the Ni1–S1 bonds of 2.174(1) Å and 2.168(1) Å for **10** and **13**, respectively. Also the corresponding N–Ni–S angles are quite similar: 85.49(5)° in the first and in the second 85.37(6)°. Another feature that these two compounds have in common is the

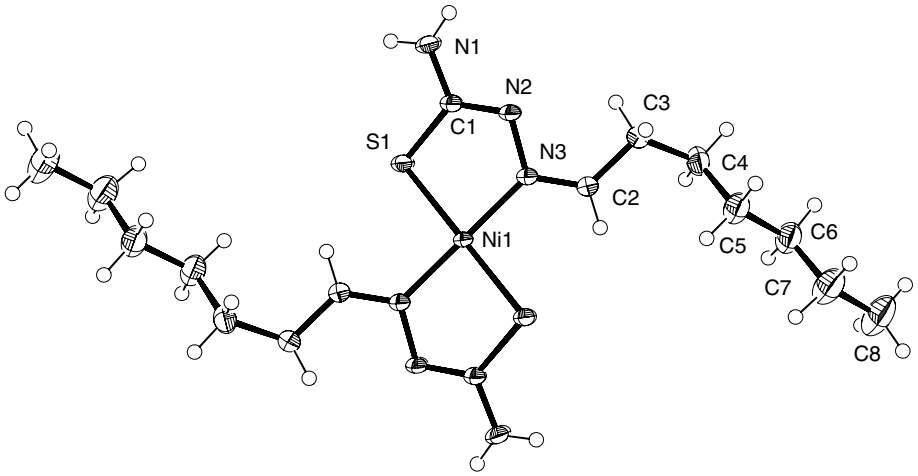

Fig. 1. ORTEP drawing of complex **10** with thermal ellipsoids at the 50% probability level.

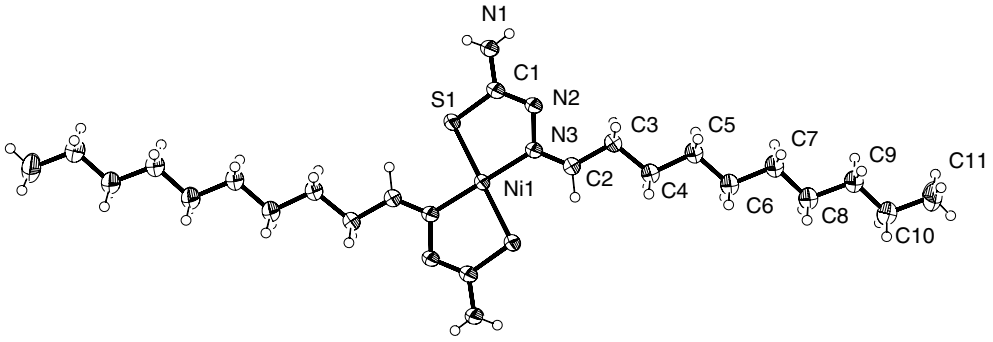

Fig. 2. ORTEP drawing of complex **13** with thermal ellipsoids at the 50% probability level.

terminal amine nitrogen that is involved in two hydrogen bonds. One of the hydrogens is used for a hydrogen bond with the deprotonated hydrazinic nitrogen of an adjacent molecule and the second hydrogen binds the sulfur of another adjacent molecule. In **10** the hydrogens bonds are N1–H2···N2 $(-x+1, -y+2, -z+2)$ 3.036(3) Å 168(4)° and N1—H1···S1 $(-x+1, -y+2, -z+1)$ 3.638(3) Å 162(4)° while in **13** N1–H2···N2 $(-x-1, -y, -z+1)$ 3.132(4) Å 171.4(2)° and N1–H1···S1 $(-x-1, -y+1, -z+1)$ 3.618(3) Å 138.7(2)°. These two hydrogen bonds generate bidimensional sheets that are distorted by the presence of the hydrophobic tails. The strain can be perceived by the more significant differences that can be found in the puckering amplitude [36] of the coordination ring that in **10** is larger than in **13** [**10** $q2 = 0.268(2)$ Å $\varphi 2$ di $-1.9(5)°$; **13** $q2 = 0.175(1)$ Å $\varphi 2 = -3.8(6)°$]. The sheets are then packed through hydrophobic interaction between the lipophilic chains protruding from the hydrogen bonds planes. Noteworthy in compound **13** is the lengthening of the chain that causes a change in the angle between the average line defined by the hydrophobic chain and the normal to the coordination plane defined by the nickel and the four donor atoms. In compound **10** the angle is 71.03(5)° while in compound **13** it increases up to 79.26(5)°.

The structure of compound **14**, **15** and **18** $[Ni(C_{12}H_{24}N_3S)_2]$, $[Ni(C_{15}H_{26}N_3S)_2]$ and $[Ni(C_{15}H_{28}N_3S)_2]$ are reported as ORTEP plots in Figs. 3–5. In these molecules one hydrogen of the terminal nitrogen is substituted with a methyl or an allyl group and the formation of the NH···N hydrogen bond is thus prevented. In these crystals the complexes are arranged as ribbons flanked by alternating protruding hydrophobic chains. The lack of a second hydrogen bond allow the aliphatic chains to lie in the coordination planes and this change influences the strain on the coordination moiety as can be seen from the puckering amplitude that drops to an average value of 0.081(2) Å.

The hydrogen bonds observed in the three packings are N1–H21···S1 $(-x, -y, -z+1)$ 3.607(3) Å 151(3)° in **14**, N1–H21···S1 $(-x, -y+1, -z+1)$ 3.550(4) Å 154(4)° in **15** and N1–H20···S1 $(-x, -y+1, -z+1)$ 3.572(3) Å 151.4(2)° in **18** and these bonds are slightly tighter than the ones found in the first two compounds in agreement with a lesser strain.

To sum up, the five complexes can be classified into two groups: those with two possible hydrogen bonds and those with one (Fig. 6). In the former the packing is based on planes generated by hydrogen bonds that developed in two different directions and these planes are subsequently stacked one upon the other to form the crystal through

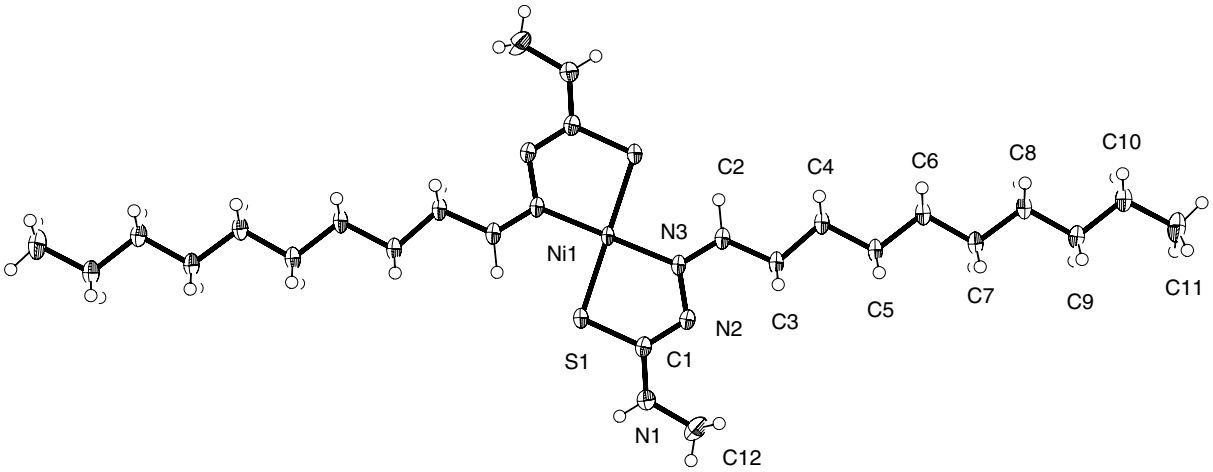

Fig. 3. ORTEP drawing of complex **14** with thermal ellipsoids at the 50% probability level.

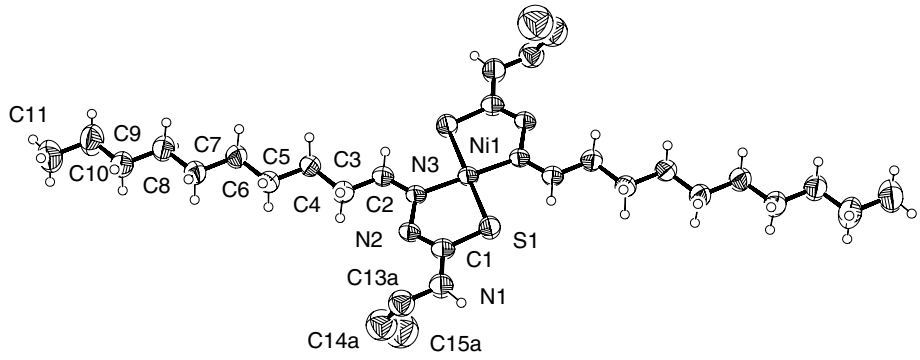

Fig. 4. ORTEP drawing of complex **15** with thermal ellipsoids at the 50% probability level. Atoms labelled with "a" correspond to one of the two possible positions occupied by the disordered allyl group.

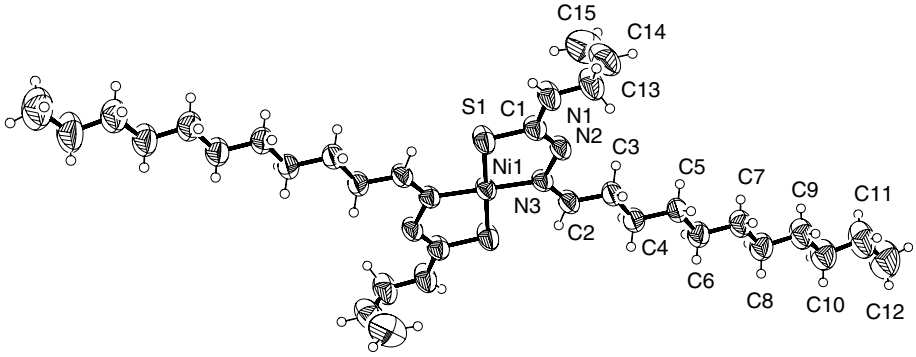

Fig. 5. ORTEP drawing of complex **18** with thermal ellipsoids at the 50% probability level.

van der Waals interactions. In the second group ribbons of molecules are formed by the only possible hydrogen bond interaction and the second dimension is obtained by the intercalation of the hydrophobic tails and all this approximately in a plane. These planes are then piled up through hydrophobic interactions to form the third dimension. In this second group the packing is looser and the lack of one of the hydrogen bond can be identified as the main cause of their lower melting points (**14**, **15** and **18** m.p. 77°, 55° and 62°) with respect to those of the complexes obtained from unsubstituted thiosemicarbazones (**10** and **13** m.p. 156° and 124°). Selected bond distances and angles are reported in Table 1.

3.2. Effects on cell proliferation and apoptosis

Before carrying out biological tests to compare the *in vitro* apoptotic activity of the thiosemicarbazones and

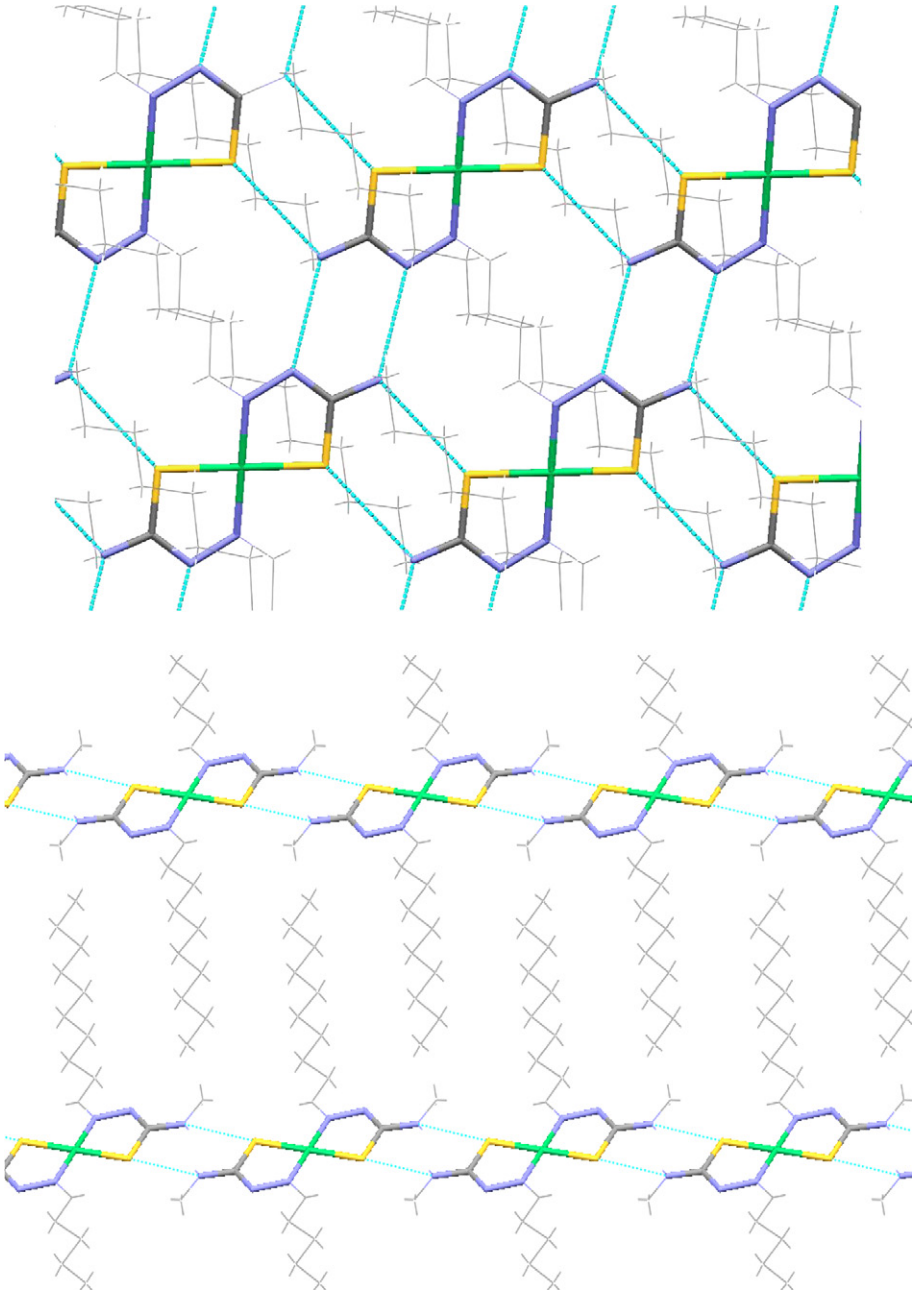

Fig. 6. Hydrogen bond patterns found in the structures: group 1 (above) and group 2 (below).

their corresponding nickel complexes, the compounds were dissolved in DMSO and the solution was tested in the culture medium to check that the compounds remain in solution. The biological action of DMSO could above certain concentrations be responsible for inhibition, and was therefore evaluated in blank experiments. Based on the solubility of the 18 compounds our biological investigations were carried out with ligand **1** and its nickel complex **10**, considered the most suitable for the biological tests.

To evaluate the IC50 for cell line U937 using a modified MTT test, ligand **1** was used in a range between 1 and 54 μM and the corresponding complex between 0.5 and 4.61 μM. From these tests resulted that, after 24 h, the ligand did not show any significant effect on proliferation even at high concentrations (54 μM) while complex **10** was able to inhibit cell proliferation at 50% with a concentration of 3.46 μM with DMSO lower than 0.02%. The data were obtained using the MTT test and were confirmed by controlling the cell vitality with Trypan blue after 24 h.

The complex has been therefore tested to verify if it acts by inducing apoptosis. What has been found is that in short times (2 and 6 h) there are no signs of apoptosis in the cells while after 12 h of incubation in the presence of an IC_{50} concentration of the complex a 8.6% of cells in early apoptosis with respect to the untreated control and after 24 h this percentage increased to 16% (Fig. 7).

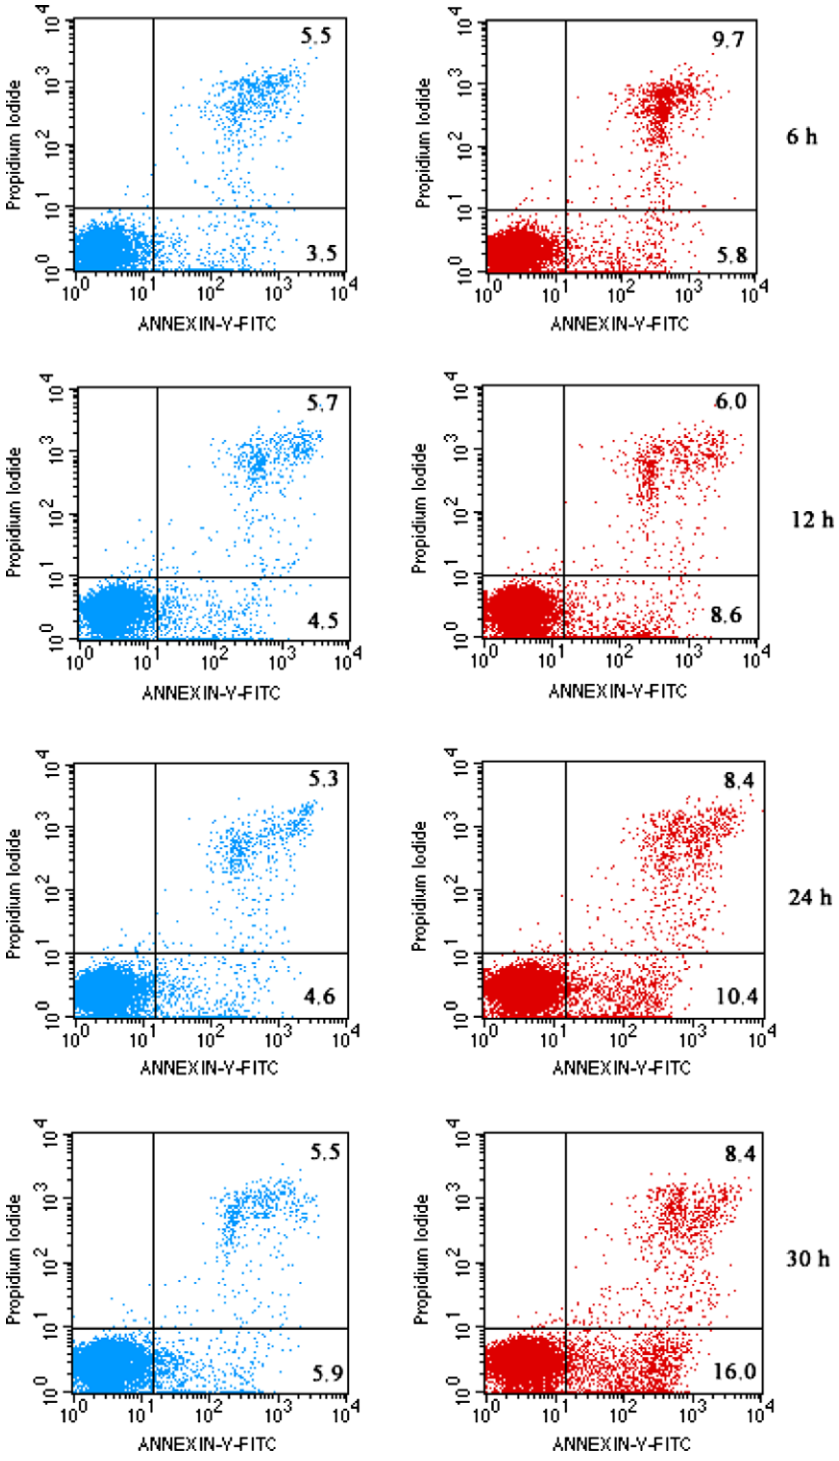

Fig. 7. Apoptosis assays: the dot plots represent the % of cells in early apoptosis, Annexin-V positive (lower right quadrant), and cells in late apoptosis, Annexin-V and Propidium Iodide positive (upper left quadrant), the dot plots on the left refer to the untreated cells.

4. Conclusions

At present an accepted theory concerning the action of this class of compounds centers on the ability of thiosemicarbazones to sequester iron and to inhibit the iron-dependent enzyme ribonucleotide reductase [37,38]. This inhibition would prevent cells to accomplish their DNA synthesis step in their duplication cycle. The properties of thiosemicarbazones through which ribonucleotide reductase is deactivated are two and namely their ability to sequester iron, the metal center in ribonucleotide reductase, and their capacity to react with a radical species present in the vicinity of the active site involved in the attack on ribose to transform it in deoxyribose. An hindrance in

the synthesis phase of the cell cycle is one of those events that ultimately lead the cell to the apoptotic process. This theory has its drawbacks and in particular it does not explain the systematic higher activity of complexes with respect to the ligands for instance, and also the fact that we observed in a previous work where the cell cycle stopped after the DNA duplication had been completed (G2/M phase) [39].

Besides these interactions with ribonucleotide reductase concomitant processes such as the generation of reactive oxygen species (ROS) that can cause damages within the cell or interactions with external cell receptors that stimulate programmed cell death are equally conceivable.

From our experiments with compounds **1** and **10** three facts are relevant and more precisely that the ligand by itself, even at higher concentrations, gives no interference in the cell cycle, secondly also a nickel acetate solution with the same concentration shows no effect on cell proliferation and thirdly that the nickel complex has no effect on a normal cell line taken as a reference. An hypothesis that can be proposed is that since the molecules presented in this work are characterized by hydrophobic tails, they can easily cross the cell membrane and could also get inserted into the mitochondrial lipidic bilayer. A redox center anchored to a mitochondrion is particularly subject to generate ROS being exposed to oxygen and to the electrons of the respiratory chain and can become a real Troy horse for the cell. Damages on the lipidic bilayer of mitochondria caused by ROS could eventually lead to a leak of cytochrome c that is one of the key events that leads to apoptosis: the assembly of the so called ''apoptosome'' and the consequent triggering of the caspase cascade. A further point that could support our hypothesis is that mitochondria of tumoral and in particular leukemic cells are characterized by a decreased activity of radical scavenging enzyme Mn SOD [40] and this could explain the selectivity of compound **10** towards leukemia cell line U937 with respect to healthy peripheral blood mononuclear cells.

A further hypothesis of action, given the planarity of the nickel complexes and the consequent unsaturated coordination sphere of the metal, is the intercalation of these molecules between the nucleic bases and subsequent reactions that could include hydrolysis of the DNA backbone, formation of nickel adducts and even oxidative damage to the nucleobases.

which are used as fluorescent brighteners as well. The first optical brightener, 2-styryl-1,3-benzothiazole (styryl = phenylethenyl) was prepared for the first time in the XIXth century. Apart from the above-mentioned properties of benzothiazole and its derivatives, they are of chemical interest from a coordination point of view since these molecules contain both S and N heteroatoms besides the π-aromatic system and show a wide variety of metal complexes.

As a part of our comprehensive investigation of the coordination chemistry of the 12th group of metals with various ligands, we recently started to explore the complexes of Zn and Hg with benzothiazole derivatives acting as dominantly monodentate neutral ligands through the N donor atom [8–10]. To our best knowledge there is only one article published so far on 2-styryl-1,3-benzothiazole complexes with mercury(II) halides [11] in which Battaglia and co-workers reported the existence of a few other mercury(II) complexes of the formula Hg_2Cl_4(sb), $HgBr_2$(sb), HgI_2(sb) and HgI_2(sb)$_2$. Complex **5**, $HgBr_2$(sb)$_2$, isolated and characterized by us, is isostructural with the later one.

In this paper, we report the synthesis and structural characterization of 2-styryl-1,3-benzothiazole and our results of a study on its coordinating ability with mercury(II) chloride and bromide. We also report, for the first time, the crystal and molecular structures of the cycloaddition reaction products of 2-styryl-1,3-benzothiazole as well as of 2-(4-chlorostyryl)-1,3-benzothiazole.

2. Experimental

2.1. Materials and physical measurements

Mercury(II) chloride and mercury(II) bromide were used as received from Aldrich without further purification. CHNS analyses were performed in the Analytical Services Laboratories of the Institute Ruđer Bošković. The mercury content was determined by complexometric titration with sodium diethyldithiocarbamate of the solution obtained after decomposition of the specimen in *aqua regia* [12].

The IR spectra were obtained from KBr pellets in the range 4000–450 cm^{-1} with a Perkin–Elmer Spectrum RX I FT-spectrometer. The Raman spectra in the range 600–100 cm^{-1} were obtained with a Bruker Equinox 55 spectrometer. The thermal measurements were performed using a simultaneous TGA–DTA analyser (Mettler-Toledo TGA/SDTA 851^e). The TGA and DTA curves were obtained by placing the samples (approximately 10 mg in mass) in small alumina pans, with heating rate of 10 °C/min and nitrogen (purity above 99.996%) flowing at a rate of 20 mL/min.

2.2. Preparations

2.2.1. 2-Styryl-1,3-benzothiazole (sb) (*1*)

2-Styryl-1,3-benzothiazole was previously prepared in our laboratory by the condensation of benzaldehyde with 2-methylbenzothiazole, using the described procedures [13,14]. The single crystals of sb were obtained by the liquid diffusion crystallization method of an ethanol/*n*-pentane solution.

M.p. = 111 °C. IR ν_{max} (cm^{-1}): 3058w, 3028w, 2992w, 1628m, 1616w, 1572w, 1554w, 1497s, 1475m, 1453m, 1445vs, 1434s, 1315s, 1281w, 1261w, 1242m, 1233m, 1219w, 1190s, 1173w, 1155w, 1123w, 1073w, 1012m, 961vs, 942m, 880w, 760vs, 727vs, 691vs, 670m, 511w, 485w.

2.2.2. (2-Styrylbenzothiazole-N)mercury(II) chloride-μ-chlorobis(2-styrylbenzothiazole-N)mercury(II), $[Hg_2Cl_4(sb)_3]$ (*2*)

A solution of 2-styryl-1,3-benzothiazole (0.15 g, 0.632 mmol) in 15 mL of ethanol was added slowly to a solution of mercury(II) chloride (0.085 g, 0.313 mmol) in 7 mL of ethanol. The reaction mixture was refluxed for 5 h and then left to evaporate at room temperature. After 10 days yellow-green crystals were filtered off, washed several times with ethanol and dried. Yield: 0.16 g (81.6%). *Anal.* Calc. for $C_{45}H_{33}Hg_2Cl_4N_3S_3$ (1254.96): C, 43.07; H, 2.65; Hg, 31.98; N, 3.35; S, 7.66. Found: C, 42.95; H, 2.71; Hg, 32.05; N, 3.60; S, 7.79%. M.p. = 216 °C (dec.). IR ν_{max} (cm^{-1}): 3057w, 3024w, 1624m, 1576w, 1560w, 1497m, 1469m, 1455m, 1447m, 1432s, 1318m, 1274w, 1244w, 1224w, 1199w, 1183w, 1153w, 1106w, 1068w, 1017w, 951m, 888w, 854w, 759s, 750vs, 725m, 720s, 698m, 680s, 614w, 512w, 477w.

2.2.3. 1,3-Bis(1,3-benzothiazol-2-yl)-2,4-diphenylcyclobutane (*3*)

Two weeks after the isolation of compound **2**, a small amount of yellow crystals was obtained from filtrate. Yield: few crystals. IR ν_{max} (cm^{-1}): 3055m, 3023m, 2996w, 2371w, 2344w, 1931w, 1895w, 1800w, 1734w, 1653w, 1629m, 1575w, 1554w, 1500m, 1478m, 1455m, 1446s, 1434s, 1340w, 1332w, 1316m, 1282w, 1191m, 1183m, 1164w, 1155w, 1123w, 1109w, 1072w, 106w, 1011m, 999w, 964m, 956vs, 935m, 913w, 964m, 867w, 849w, 756vs, 750vs, 724vs, 710m, 670m, 686vs, 664s, 612w, 584w, 547w, 522w, 511m, 503w, 480m, 453w.

2.2.4. 1,3-Bis(1,3-benzothiazol-2-yl)-2,4-bis(4-chlorophenyl)cyclobutane (*4*)

Compound **4** was previously prepared in our laboratory by condensation of *p*-chlorobenzaldehyde with 2-methylbenzothiazole, using the described procedures [14,15]. Yield: 8.2%. Compound **4** is soluble in CH_2Cl_2, $CHCl_3$, less soluble in EtOH and acetone.

Single crystals of **4** were obtained by the liquid diffusion crystallization method of an ethanol/*n*-pentane solution i.e. in contrast to compound **1**, cycloaddition occurred during crystallization.

2.2.5. Dibromobis(trans-2-styrylbenzothiazole-N)mercury(II), $[HgBr_2(sb)_2]$ (*5*)

A solution of 2-styryl-1,3-benzothiazole (0.14 g, 0.590 mmol) in 15 mL of ethanol was added slowly to a solution of mercury(II) bromide (0.10 g, 0.277 mmol) in

5 mL of ethanol. The reaction mixture was refluxed for 3 h and then left to evaporate at room temperature. After two weeks yellow crystals were filtered off, washed several times with ethanol and dried. Yield: 0.15 g (75.0%). *Anal*. Calc. for $C_{30}H_{22}HgBr_2N_2S_2$ (835.24): C, 43.14; H, 2.66; Hg, 24.02; N, 3.35; S, 7.68. Found: C, 43.62; H, 2.91; Hg, 24.11; N, 3.80; S, 7.94%. M.p. = 196 °C. IR ν_{max} (cm^{-1}): 3052w, 3024w, 1624m, 1576w, 1560w, 1497m, 1469m, 1455m, 1447m, 1432s, 1318m, 1274w, 1244w, 1224w, 1199m, 1183, 1153w, 1106w, 1068w, 1017w, 951s, 887w, 854w, 759s, 750vs, 725m, 720m, 699m, 680m, 614w, 512w, 477w.

2.3. X-ray diffraction experiment

The general and crystal data and summary of intensity data collection and structure refinement for compounds **1**–**5** are given in Table 1.

The data collection for all the structures were carried out on an Xcalibur four-circle kappa geometry single-crystal diffractometer with an Xcalibur Sapphire 3 CCD detector by applying the CrysAlis Software system, Versions 171.23 and 171.26 at ambient temperature [16]. The Lorentz-polarization effect was corrected and intensity data reduced by the CrysAlis RED application of the CrysAlis Software system, Version 171.23 [16]. The diffraction data for **2** and **5** were corrected for absorption by the multi-scan procedure.

The structure solution procedure for all five structures were performed by direct methods with the SHELXS program [17]. The coordinates and anisotropic thermal displacement parameters for all non-hydrogen atoms were refined by the least-squares methods based on F^2 using the SHELXL-97 program [18]. The all hydrogen atoms, which belong to phenyl and ethenyl carbon atoms were generated at ideal geometrical positions [Csp^2–H 0.93 Å, Csp^3–H 0.98 Å; U_{iso}(-H) = 1.2U_{eq}(C)] and refined applying the riding model. The molecular graphics were done using the PLATON-98 program [19].

3. Results and discussion

3.1. Preparation

We have examined reactions of sb with mercury(II) chloride and bromide in ethanol solution. The molar ratio of sb to mercury halide was 2:1. The halide complexes described herein have different formulae from those reported by Battaglia and co-workers [11]. The complexes were only sparingly soluble in common organic solvents (ethanol, methanol, DMSO, DMF).

3.2. IR and Raman spectra

The IR spectra of styrylbenzothiazoles and their metal complexes in the range 1650–1380 cm^{-1} can be associated with overall ring-skeletal (benzene and thiazole ring) stretching modes [20,21]. Ring-breathing and CH in-plane deformations fall into range 1320–935 cm^{-1}. Vibration modes in the 880–720 cm^{-1} range can be attribute to the CH out-of-plane deformations. 2-Styryl-1,3-benzothiazole exhibits an absorption band assigned to ν(CN) at 1475 cm^{-1}, which is shifted upon coordination to the mercury atom to 1469 cm^{-1} in both complexes and is in accordance with the literature data regarding other metal complexes containing the bta moiety [22,23]. A small shift towards lower energy indicates decreased C=N double bond character due to coordination of the ligand through the ring nitrogen atom.

Complementary information is obtained from low frequency Raman spectra. The spectra of the halide complexes in the range 300–150 cm^{-1} show bands which are not seen in the spectrum of the free ligand. These bands are assigned to terminal and bridging ν(Hg–halide) modes [11,24–26]. The strong bands in the spectrum of the chloride complex at 289 and 181 cm^{-1} are attributed to the Hg–Cl terminal and Hg–Cl bridging stretching modes, respectively. The mononuclear bromide complex shows only a Hg–Br terminal stretching vibration at 178 cm^{-1}.

The IR and Raman spectra of the mercury(II) complexes are in agreement with their crystal structures.

3.3. Crystal structure description

ORTEP plots of the molecular structures for compounds **1**–**5** are depicted in Fig. 1. The selected molecular geometries are listed in Table 2 for organic molecules **1**, **3** and **4** and Table 3 for complexes **2** and **5**.

3.3.1. Compounds *1*, *3* and *4*

On surveying of the CSD (Version 5.28, November 2006, update January 2007) [27], only one organic derivative of 2-styryl-1,3-benzothiazole was found, 2-[2-(3,4-dichlorophenyl)vinyl]benzo[*d*]thiazole [28].

The 2-styryl-1,3-benzothiazole molecule, sb, **1** is essentially planar (Fig. 1a) with a dihedral angle of only 2.9(1)° between the benzothiazole and phenyl rings. The benzothiazole and phenyl rings are essentially planar, with a maximum deviation from the least-squares plane of only 0.017(2) and −0.007(2) Å for atoms C7 and C15, respectively. The S1–C2 bond distance of 1.731(2) Å is slightly shorter than the S1–C1 bond distance of 1.766(3) Å (1.739(4) Å and 1.760(4) Å in the structure of 2-[2-(3,4-dichlorophenyl)vinyl]benzo[*d*]thiazole [28]) due to the pronounced delocalization in the –S–C=N– fragment of the thiazole ring of the ligands, but both of them are between a pure σ S–C bond (1.82 Å) and a double S=C bond (1.56 Å) [29]. A similar trend is observed for the N1–C1 and N1–C7 bond distances (1.278(3) and 1.379(3) Å, respectively). The bond angle around the S1 atom (C2–S1–C1 89.07(11)°) is in agreement with that found in the structure of 2-[2-(3,4-dichlorophenyl)vinyl]benzo[*d*]thiazole (89.1(2)°) [28]. The configuration around C8=C9 is *E*. The molecules are arranged with antiparallel stacking, attracted

[a] $w = 1/[\sigma^2(F_o^2)] + [g_1P + g_2P]$ where $P = (F_o^2 + 2F_c^2)/3$.
[b] $R = \sum\|F_o| - |F_c\|/\sum|F_o|$.
[c] $wR = [\sum(F_o^2 - F_c^2)^2/\sum w(F_o^2)^2]^{1/2}$.
[d] $S = \sum[w(F_o^2 - F_c^2)^2/(N_{obs} - N_{param})]^{1/2}$.

by π–π interactions (Fig. 2a). The intramolecular distance H9···S1 of 2.837(1) Å cannot be regarded as a C–H···S hydrogen bond, rather it is a consequence of molecular stereochemistry. Otherwise, only van der Waals interactions are present.

The molecular structures of compounds **3** and **4** are characterized by three moieties defined by the atoms of the benzothiazole, phenyl and cyclobutane rings (Figs. 1 b and c). Since the ring centroids lie at a crystallographic centre of symmetry, the cyclobutane rings in **3**

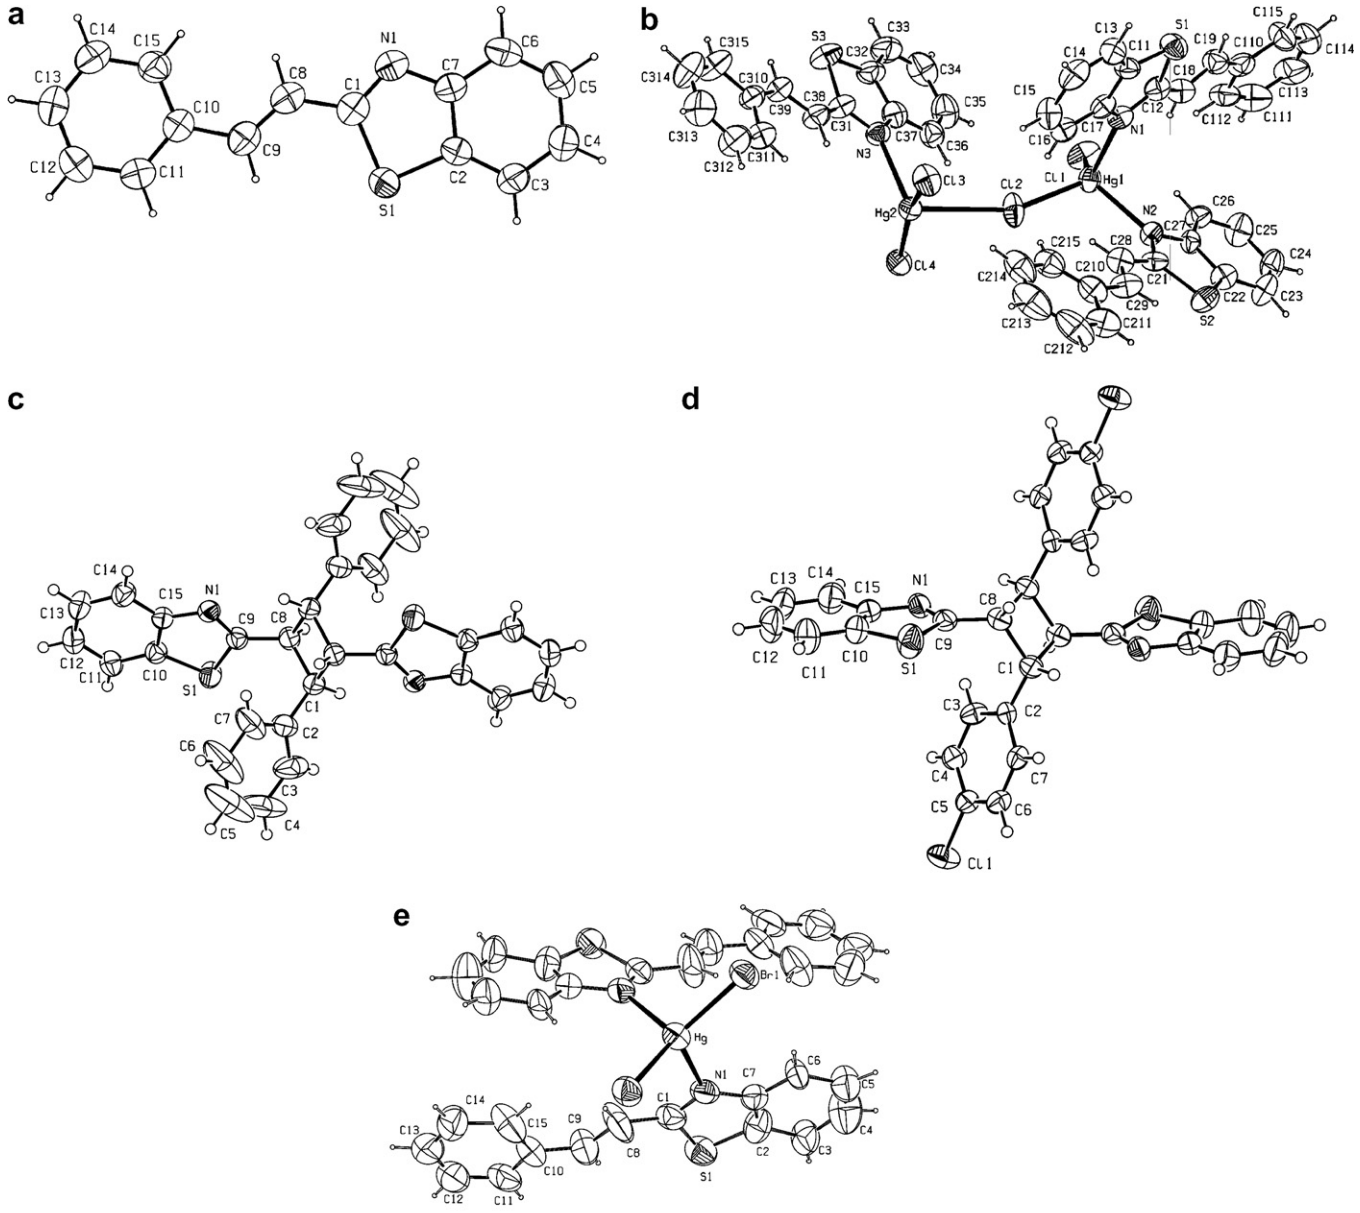

Fig. 1. ORTEP drawing of 2-styryl-1,3-benzothiazole (sb) (**1**) (a), $[Hg_2Cl_4(sb)_3]$ (**2**) (b), 1,3-bis(1,3-benzothiazol-2-yl)-2,4-diphenylcyclobutane (**3**) (c), 1,3-bis(1,3-benzothiazol-2-yl)-2,4-bis(4-chlorophenyl)cyclobutane (**4**) (d), and $[HgBr_2(sb)_2]$ (**5**) (e) with the atomic numbering scheme of asymmetric unit. The thermal ellipsoids are drawn at the 50% probability level at 293 K, except in the case of compound **5** (e) (30% probability at 293 K).

and **4** are strictly planar. The cyclobutane ring bond distances are in agreement with those found for planar cyclobutane rings according to Allen [30] (Table 2). The mean C–C value for planar cyclobutane rings according to Ref. [30] is 1.558(3) Å and it is marginally longer in relation to the value for puckered rings. The cyclobutane ring geometry reflects the balance between ring strain forces (which are minimized in the planar form) and repulsive interactions between substituents, and it is not influenced by possible conjugative interactions with π-substituents.

The shortness of the exocyclic C8–C9 bond, the distance being 1.494(3) and 1.484(6) Å in **3** and **4**, respectively, is related to higher s character in the orbitals involved in the exocyclic C–C bonds.

The dihedral angles between the benzothiazole and cyclobutane rings are 61.4(3)° and 52.9(2)° for **3** and **4**, respectively. The dihedral angles between the benzothiazole and phenyl rings are 70.2(2)° and 51.3(2)° for **3** and **4**, respectively.

The S1–C9 and S1–C10 bonds are 1.750(2) and 1.729(2) Å in **3** and 1.743(5) and 1.732(6) Å in **4**. The molecules are arranged into antiparallel pairs of benzothiazole rings attracted by π–π interactions in both structures **3** and **4** (Fig. 2b and c). Except these and van der Waals interactions, there are no other contacts in these structures.

3.3.2. Compound *2*

In **2**, the sb ligand is coordinated to the mercury atom as a neutral monodentate ligand through the thiazolyl nitrogen atom (Fig. 1b). The crystal and molecular structure of $Hg_2Cl_4(sb)_3$ reveals a dinuclear complex with two differently coordinated mercury(II) ions, with the Cl^- ion participating in a very non-symmetrical linear bridge. One Hg(II) ion is tetrahedrally coordinated with two Cl^- ions (Hg1–Cl1(terminal) 2.396(2) Å, Hg1–Cl2 (bridging) 2.452(2) Å), and two thiazole N nitrogen atoms from two ligand molecules (Hg1–N1 2.368(6) Å and Hg1–N2 2.316(6) Å). The bond angles values are in the range 93.6(2)° (for the N2–Hg1–N1 angle) to 116.5(2)° (for the N2–Hg1–Cl1 angle) revealing, along with the Hg1–Cl1 bond value of 2.396(2) Å, that the terminal Cl1 atom is more strongly bound to the Hg(II) ion than the N atom from the ligand. The sum of the covalent radii of Hg and Cl amounts to 2.48 Å (tetrahedral mercury covalent radius of 1.48 Å + covalent radius of Cl 0.99 Å) [31–34]. According to that value, Hg1–Cl1(terminal) and Hg1–Cl2 (bridging) bond values of 2.396(2) and 2.452(2) Å, respectively, are shorter than the calculated sum. On the other hand, the sum of the covalent radii of Hg and N amounts to 2.18 Å. Therefore, the Hg1–N1 and Hg1–N2 bond values of 2.368(6) and 2.316(6) Å, respectively, are longer than 2.18 Å, and thus belong to contacts slightly longer than the sum of the covalent radii, but shorter than the sum of the van der Waals radii for Hg (1.55–1.65 Å) [34] and N (1.5–1.55 Å) [30]. Such bond distance values are followed up by bond angle values.

The other Hg(II) ion is coordinated by three Cl^- ions (two terminal Hg2–Cl3 and Hg2–Cl4 of 2.326(2) and 2.359(2) Å, respectively, and one bridging Hg2–Cl2 of 2.939(2) Å) and one N atom from the ligand (Hg2–N3 of 2.468(6) Å) in a 2+2 fashion, rather than in a deformed tetrahedral form. The Hg2–Cl(terminal) bond distance values are inbetween the calculated sum for diagonal and tetrahedral mercury coordination (1.30 + 0.99 = 2.29 Å for a diagonal Hg–Cl environment) [31–34]. On the other hand, the Hg2–Cl2 bond value is close to the van der Waals sum for Hg and Cl (3.05 Å). Similar rather long Hg–Cl bond values are found in the structure of $[Hg\{(CH_3)_2(C_2H_5)P\}_2Cl]^+[Hg\{(CH_3)_2(C_2H_5)P\}Cl_3]^-$ [36] where complex cations and anions are linked by Cl bridges with Hg–Cl(bridging) distances of 3.07(1) and 3.25(1) Å. Some authors consider that a cut-off is at 3.35 Å, and all Hg–Cl distances up to this value are considered to be a part of the mercury coordination sphere [37].

The largest angle around mercury is for Cl3–Hg2–Cl4, 160.7(1)°, correspondingly followed by the shortest bond value. This value is in the range 158–170° established for diagonal mercury coordination with additional contacts, as is given by Holloway and Melnik in their classification and analysis of crystallographic and structural data for mercury coordination compounds [35]. The smallest angle around mercury is for Cl4–Hg2–Cl2, 84.7(1)°.

The coordinated ligand molecules in compound **2** are essentially planar with dihedral angles of only 1.03(1)° and 2.00(1)° between the benzothiazole and phenyl rings (C21–C215) and (C31–C315), respectively, except for the

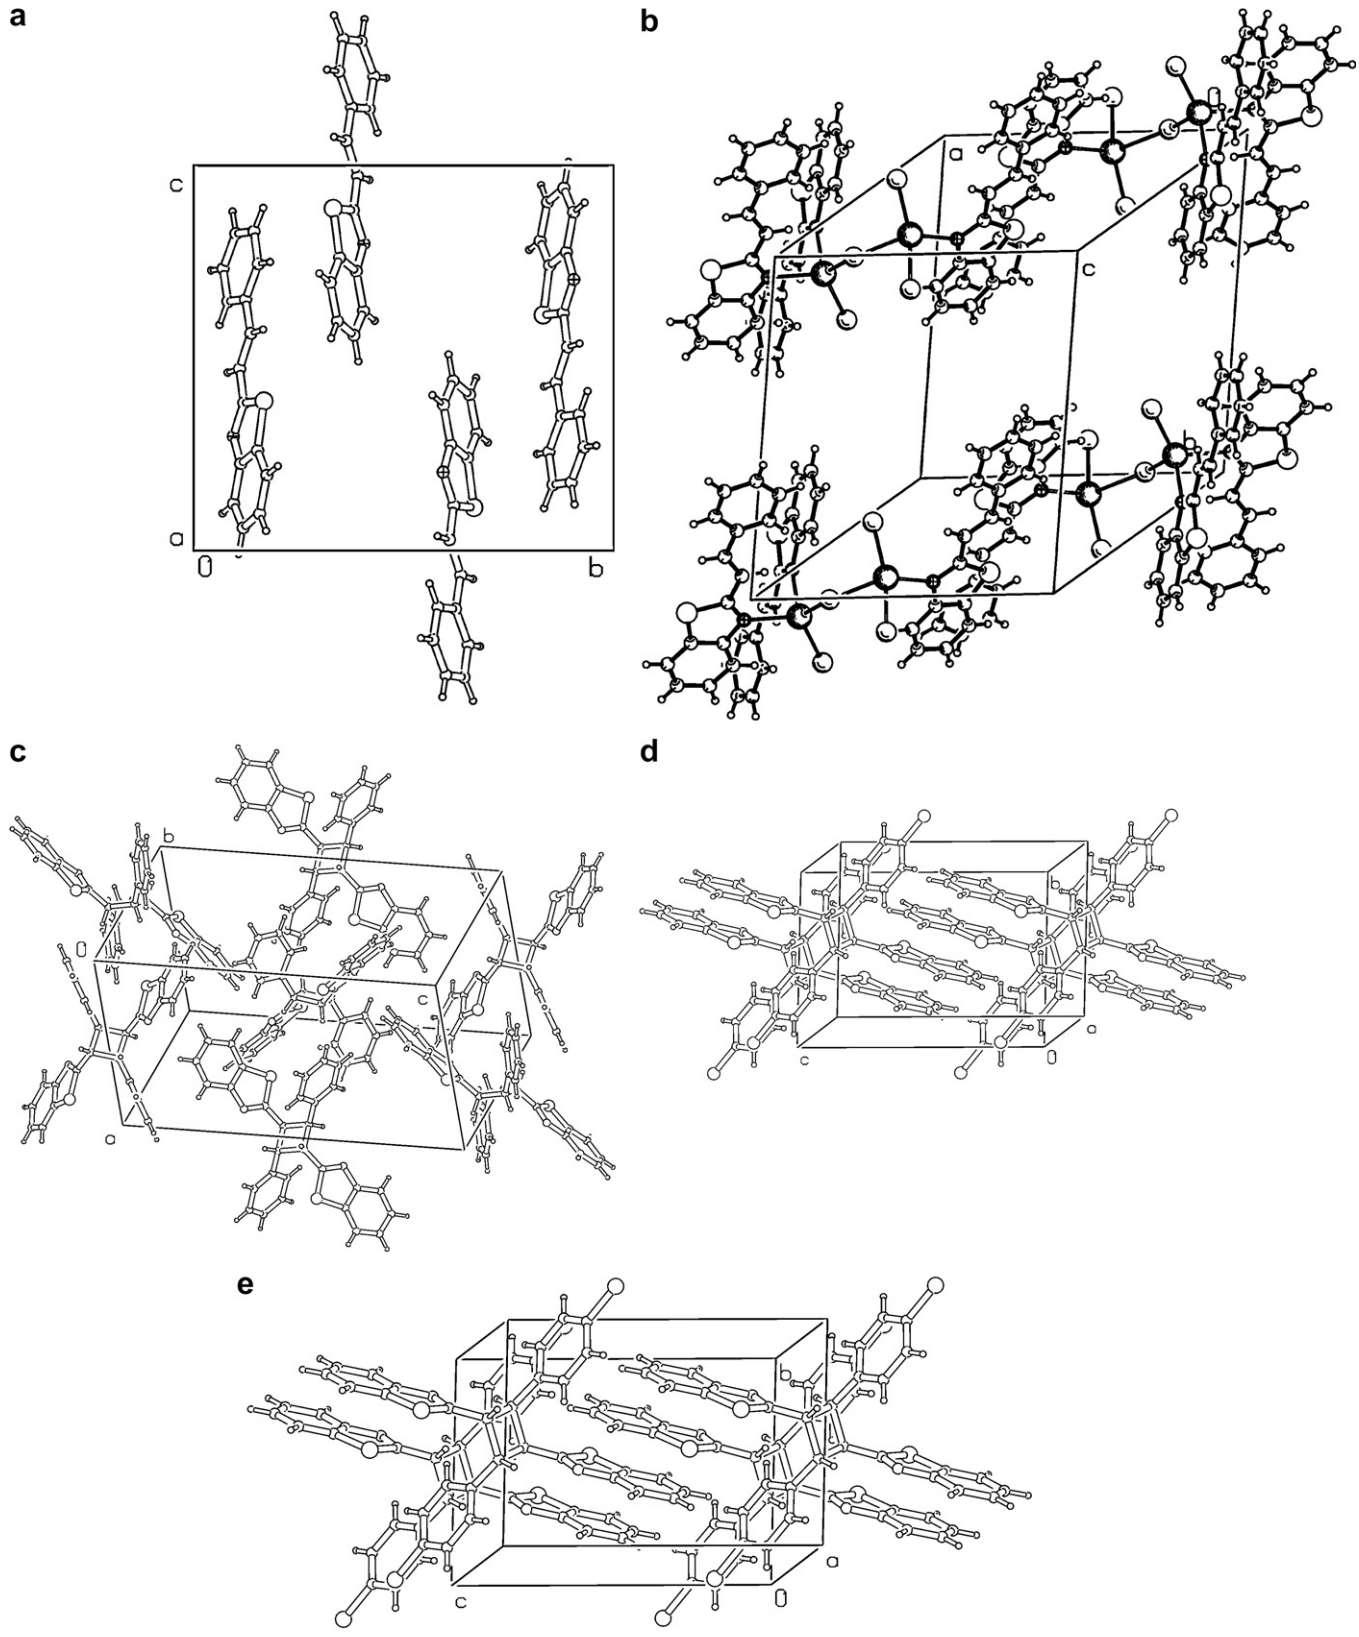

Fig. 2. PLATON view of crystal structures of (**1**) (a), (**2**) (b), (**3**) (c), (**4**) (d) and (**5**) (e).

first molecule (C11–C115), which is almost planar with a corresponding angle of 6.41(1)°. The dihedral angles between the planes defined by the atoms of the ligands as a whole amount 89.00(1)° (molecules C11–C115 and C21–C215), 76.83(1)° (molecules C11–C115 and C31–C315) and 12.28(1)° (molecules C21–C215 and C31–C315).

All approaches of the type C–H···Cl and C–H···S (3.10(1)–3.64(1) Å) are intramolecular in character and could not be recognized as hydrogen bonds (Fig. 2d).

3.3.3. Compound 5

Compound **5** has a deformed tetrahedral geometry around the mercury(II) ion with the neutral monodentate ligand 2-styryl-1,3-benzothiazole **1** coordinated through the thiazolyl nitrogen atom (Fig. 1e). The mercury(II) ion is situated at the crystallographic twofold axis with the distances Hg–Br1 2.515(2) Å and Hg–N1 2.387(12) Å. An indication of the tetrahedral deformation from ideal bond angles values is represented by the angle Br1–Hg–$Br1^{i}$ ($i = -x, y, 1/2 - z$), 124.82(9)°. The Hg–Br1 bond distance value is shorter than the sum of the covalent radii of Hg and Br ($1.48 + 1.14 = 2.62$ Å) [31–34], while the Hg–N1 bond distance value is the only contact shorter than the van der Waals radii sum of Hg and N. That is accompanied by a decrease in the N1–Hg–$N1^{i}$ ($i = -x, y, 1/2 - z$) bond angle of 93.2(7)°.

The ligand is almost planar with a dihedral angle of 6.7(1)° between the planes calculated through the atoms of the benzothiazole and phenyl rings.

The molecules are mutually joined only by van der Waals interactions with two contacts C6–H6···Br1 and C9–H9···S1 of 3.780(17) and 3.16(2) Å (H6···Br1 and H9···S1 are 2.919 and 2.731 Å with the angles of 155° and 109°, respectively) (Fig. 2e).

3.4. Thermal analysis (TGA–DTA)

Samples of the mercury(II) complexes **2** and **5** were heated from room temperature up to 600 °C. The TGA curves of **2** and **5** show a continuous thermal decomposition which starts at around 210 °C for **2** and at around 190 °C for **5**. The decomposition of the halide complexes is represented by exothermic peaks at 235.2 °C for **2** and at 202.2 °C for **5**. Exothermic peaks in the DTA curves can be connected with sublimation of the corresponding mercury(II) halides.

4. Conclusions

Two novel mercury(II) halide complexes with 2-styryl-1,3-benzothiazole (sb) have been prepared. $Hg_2Cl_4(sb)_3$ and $HgBr_2(sb)_2$ were characterized by elemental analysis, IR, Raman spectroscopy and thermal methods. Their crystal and molecular structures were determined by X-ray crystal structure analysis as well as the structure of the uncoordinated sb. 2-Styryl-1,3-benzothiazole and 2-(4-chlorostyryl)-1,3-benzothiazole undergo intermolecular cycloaddition and the corresponding dimeric cyclobutane derivatives have been obtained and structurally characterized. IR and Raman data of the mercury(II) complexes are in good agreement with the data obtained by structural analysis.

$\{[Cu_3(CN)_3(4\text{-PyHBIm})_4]\cdot 2H_2O\}_n$ (**3**) and $[Cu_5(CN)_3(4\text{-PyBIm})_2]_n$ (**4**) have been prepared and structurally characterized. Their structures vary from one- to two-dimensions along with the change of the position of pyridyl N atom. Herein, we report their syntheses, crystal structures, thermal stabilities and luminescent properties.

2. Experimental

2.1. Materials and methods

The ligands 2-(*n*-pyridyl)benzimidazole ($n = 2,3,4$) were prepared according to the literature method [12]. Other chemicals were of reagent grade and used as received without further purification. Elemental analyses were performed on a Vario EL III elemental analyzer. Infrared spectra were recorded with a Nicolet A370 FT-IR spectrometer by KBr pellets in the range 400–4000 cm^{-1}. Thermogravimetric analyses were completed on a Netzsch STA 449C thermal analyzer at a heating rate of 10 °C min^{-1} in air. Fluorescent spectra were recorded on a Shimadzu RF-5301 spectrophotometer.

2.2. Synthesis

$[Cu_2(CN)(2\text{-PyBIm})]_n$ (**1**). A mixture of CuCN (0.50 mmol), $K_3[Fe(CN)_6]$ (0.25 mmol), 2-PyHBIm (0.25 mmol) in 7 mL water was added 3 drops of aqueous NH_3 and then sealed in a 15-mL Teflon-lined reactor. The mixture was heated in an oven at 180 °C for 72 h and slowly cooled to room temperature at a rate of 10 °C h^{-1}. Yellow block crystals of **1** were obtained with 50% yield based on 2-PyHBIm. *Anal*. Calc. for $C_{13}H_8Cu_2N_4$: C, 44.95; H, 2.32; N, 16.13. Found: C, 44.71; H, 2.29; N, 16.20%. IR (KBr pellet, cm^{-1}): 2136s, 1599s, 1453m, 1422s, 1403s, 790w, 733s.

$[Cu_2(CN)_2(3\text{-PyHBIm})]_n$ (**2**). The reaction was carried out in a method similar to that for **1**, used 3-PyHBIm instead of 2-PyHBIm and sealed at 170 °C for 12 h. Yellow block crystals were obtained with 42% yield based on 3-PyHBIm. *Anal*. Calc. for $C_{14}H_9Cu_2N_5$: C, 44.92; H, 2.42; N, 18.71. Found: C, 45.03; H, 2.39; N, 18.50%. IR (KBr pellet, cm^{-1}): 3361s, 2127s, 1597m, 1447s, 1393m, 811m, 750s, 697s, 568s.

$\{[Cu_3(CN)_3(4\text{-PyHBIm})_4]\cdot 2H_2O\}_n$ (**3**) and $[Cu_5(CN)_3(4\text{-PyBIm})_2]_n$ (**4**). The reaction was carried out in a method similar to that for **1**, used 4-PyHBIm instead of 2-PyHBIm and sealed at 170 °C for 12 h. Two kinds of crystals, yellow block crystals of **3** and red stick crystals of **4**, were obtained with 35% yield of **3** and 24% yield of **4** based on 4-PyHBIm. Complex **3**: *Anal*. Calc. for $C_{51}H_{40}Cu_3N_{15}O_2$: C, 56.43; H, 3.714; N, 19.35. Found: C, 56.43; H, 3.61; N, 19.40%. IR (KBr pellet, cm^{-1}): 3534m, 3387m, 3053m, 2119s, 1612s, 1435s, 1317m, 835m, 745s. Complex **4**: *Anal*. Calc. for $C_{27}H_{16}Cu_5N_9$: C, 41.35; H, 2.06; N, 16.07. Found: C, 41.89; H, 2.05; N, 16.29%. IR (KBr pellet, cm^{-1}): 2137s, 1606s, 1426s, 1389m, 828m, 750s.

2.3. X-ray crystallography

The well-shaped single crystals of **1**–**4** were selected for X-ray diffraction study. The diffraction data were collected on a Bruker Smart Apex-II CCD diffractometer with graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at 293(2) K. Determinations of the crystal system, orientation matrix and cell dimensions were performed according to the established procedures. Empirical absorption corrections were applied using the SADABS program. The structures

were solved by direct method with SHELXS-97 program and refined by full-matrix least squares on F^2 with SHELXL-97 program [13]. All non-hydrogen atoms were refined anisotropically, and hydrogen atoms were located and included at their calculated positions. The crystal data and structure refinement results are summarized in Table 1. Selected bond lengths and angles are listed in Table 2.

3. Results and discussion

3.1. General characterization

The hydrothermal reactions of CuCN, $K_3Fe(CN)_6$ with 2-PyHBIm or 3-PyHBIm in a 2:1:1 molar ratio afforded complex $[Cu_2(CN)(2\text{-PyBIm})]_n$ (**1**) or $[Cu_2(CN)_2(3\text{-PyHBIm})]_n$ (**2**). Similar reaction using 4-PyHBIm instead of 2/3-PyHBIm afforded a mixture of $\{[Cu_3(CN)_3(4\text{-PyHBIm})_4]\cdot 2H_2O\}_n$ (**3**) and $[Cu_5(CN)_3(4\text{-PyBIm})_2]_n$ (**4**). Herein, $K_3[Fe(CN)_6]$ acts as cyanide source [14]. Try to prepare complexes **1**–**4** without $K_3[Fe(CN)_6]$ failed. Three drops of aqueous NH_3 was used as base in each reaction. Complexes **1** and **4** possess deprotonated 2/4-PyBIm ligands, while complexes **2** and **3** contain neutral 3/4-PyHBIm ligands. Their formulas have been confirmed by elemental analysis data.

Corresponding to transition metal cyanides, IR absorption bands in the region of 2000–2200 cm^{-1} are due to the presence of CN^- stretching vibrations [15]. The characteristic strong absorption of cyanide for **1**–**4** appears at 2136, 2127, 2119, 2137 cm^{-1}, respectively. Single peak of CN^- indicates that the cyanide groups coordinate to Cu(I) in sole mode. The characteristic absorption bands of *n*-PyBIm exist in the spectra of **1**–**4**. However, complexes **2** and **3** show N–H stretching vibration near 3361, 3387 cm^{-1}, respectively, while complexes **1** and **4** have not N–H absorption bands. This phenomenon also indicates that the 2/4-PyHBIm ligands are deprotonated in complexes **1** and **4**.

3.2. Description of crystal structures

X-ray structural analysis reveals that the complex **1** is a one-dimensional coordination polymer in which 2-(2-pyridyl)benzimidazole is deprotonated and adopts a tridentate coordination mode. As shown in Fig. 1a, there are two unique metal sites in complex **1**. Cu1 is two-coordinated by a cyanide group and a 2-PyBIm ligand via N_{BIm}-donor atom (Cu1–N1 = 1.823(4), Cu1–N2 = 1.857(4) Å, N1–Cu1–N2 = 173.6(2)°). Cu2 is in a planar trigonal coordination environment and coordinates to a 2-PyBIm via N_{Py}, N_{BIm} and a cyanide group (Cu2–N3 = 1.969(5), Cu2–N4 = 2.130(5), Cu2–C1 = 1.830(5) Å). In 2-PyBIm ligand, the pyridyl ring is almost coplanar with benzimidazole aromatic plane. However, the adjacent 2-PyBIm ligands have a dihedral angle of 33.4°. 2-PyBIm acting as a tridentate ligand links $Cu_2(CN)$ units to form a one-dimensional infinite chain (Fig. 1b). As packing diagram showing (Fig. 1c), the linear chains stack face to face with the 2-PyBIm ligands in a distance of 3.422 Å, falling in a separation of π–π interaction.

Complex **2** consists of infinite Cu(I)-cyanide zigzag chains and bidentate 3-PyHBIm bridging ligands. As shown in Fig. 2a, the structure possesses two unique metal sites. Both Cu1 and Cu2 are in trigonal geometries. However, the detail coordination environment of these two sites is some different. Cu1 is coordinated by a N_{Py}-donor atom and two cyanide groups, while Cu2 is coordinated by a N_{Bim}-donor atom and two cyanide groups. Different from the deprotonated 2-PyBIm ligand in **1**, the 2-(3-pyridyl)benzimidazole ligand of **2** does not deprotonate and acts as a neutral bidentate ligand. The bridging cyanide ligands connect the Cu(I) atoms to form one-dimensional chain and each bidentate 3-PyHBIm bridging ligand links

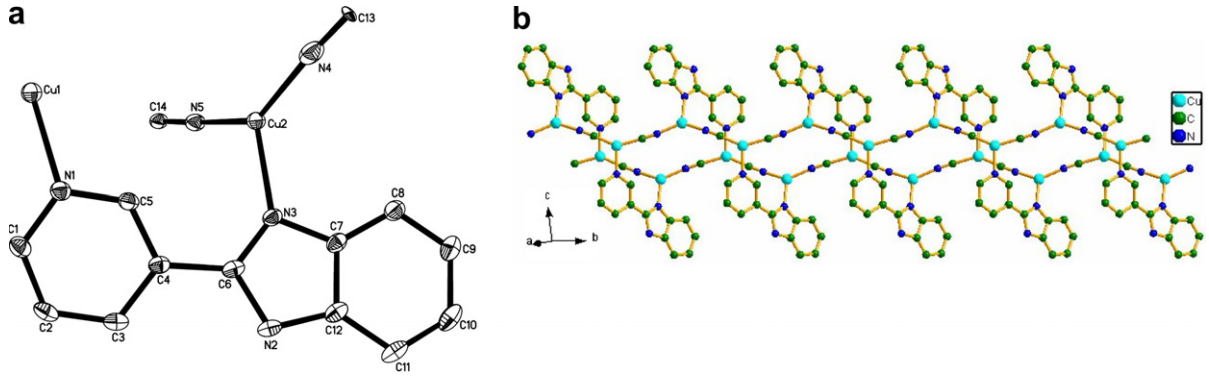

Fig. 2. Views of asymmetric structural unit (a) and ladder-like double chain (b) of **2**.

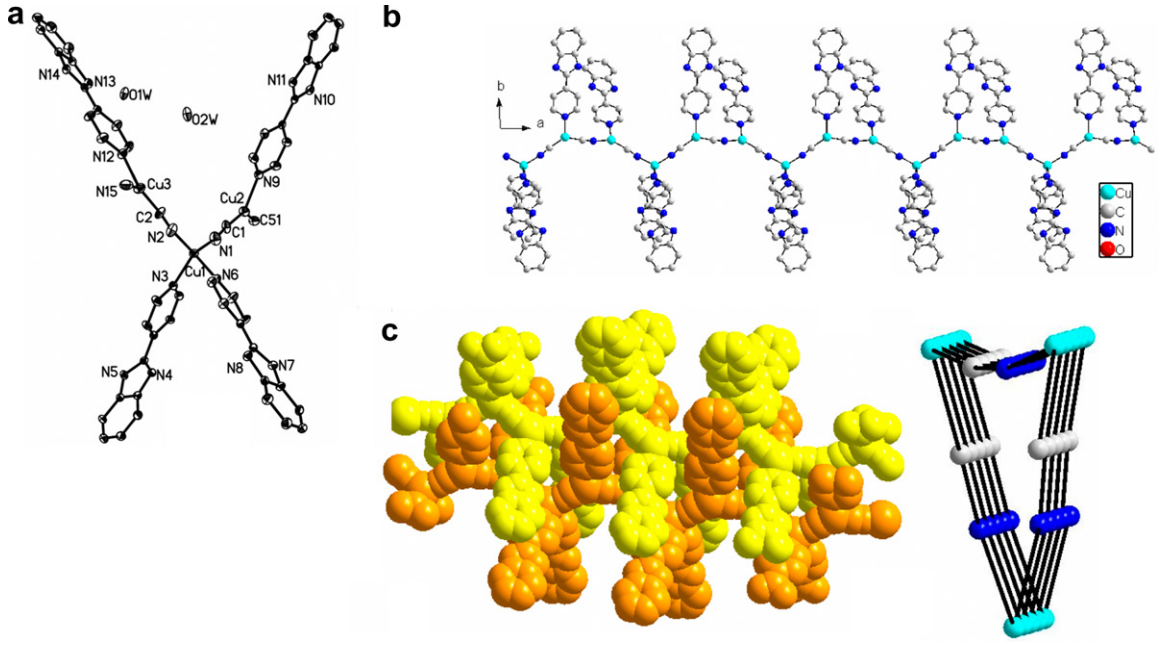

Fig. 3. Views of asymmetric structural unit (a), one-dimensional chain (b), and interpenetrating structure (c) of **3**.

two Cu(I) atoms of adjacent $[Cu–CN]_n$ chains to form ladder structure (Fig. 2b). The distance between the aromatic rings of adjacent 3-PyBIm is *ca.* 3.682 Å, indicating the presence of some π–π stacking interaction.

Complexes **3** and **4** were separated in same preparation reaction. X-ray analysis reveals that the complex **3** is constructed as one-dimensional helical chain architecture. As shown in Fig. 3a, there are three distinct copper atoms in the asymmetric structural unit. All the cyanide groups playing μ_2-bridge link Cu(I) atoms to form a one-dimensional helical chain (Fig. 3b). 4-PyHBIm does not deprotonate and adopts monodentate coordination mode through pyridyl nitrogen atom. Cu1 atom is in a distorted tetrahedral geometry. In addition to two N_{Py}-donor atoms from two 4-PyHBIm ligands, Cu1 is yet bonded to two cyanide groups. Two 4-PyHBIm ligands coordinated to Cu1 have a dihedral angle of 63.6°. Both Cu2 and Cu3 are in trigonal geometry and coordinate to two cyanide groups and a N_{Py}-donor atom. 4-PyHBIm ligands coordinated to Cu(I) atoms outstretching to four directions display a saddle-shaped structure. The one-dimensional helical chains containing saddle-shaped structural units pack in an interpenetrating mode (Fig. 3c), through weak π–π interaction of the lateral 4-PyBIm ligands with a separation of 3.702 Å, into a two-dimensional network.

Complex **4** is attributed to a two-dimensional network, wherein 2-(4-pyridyl)benzimidazole is deprotonated and acts as a tridentate bridging ligand. There are five crystallographically independent Cu(I) atoms which adopt two kinds of coordination geometries, namely two- and three-coordination (Fig. 4a). Cu3 and Cu4 atoms are trigonally three-coordinated by two μ_2-cyanide groups and a 4-PyBIm ligand via N_{Py}-donor atom, while Cu1, Cu2 and Cu5 atoms are all in two coordinating environment. Cu1 is coordinated by two N_{BIm}-donor atoms belong to different 4-PyBIm ligands. Cu2 and Cu5 both coordinate to a μ_2-cyanide group and a N_{BIm}-donor atom. All these kinds of Cu(I) atoms are connected by μ_2-cyanide groups and N_{BIm}-donor atoms into infinite zigzag chains, which are further connected through N_{Py}-donor atoms of 4-PyBIm into a two-dimensional layer polymeric structure (Fig. 4b). The pyridyl ring deviates from the aromatic plane of benzimidazole with a dihedral angle of 20.8° and 32.5°, respectively, for both independent 4-PyBIm ligands.

3.3. Thermal stabilities and luminescent properties

Thermal analyses for complexes **1**–**4** were performed in the temperature range of 20–900 °C. These coordination polymers were stable up to 200 °C, and then took place two steps of weight-loss. Complex **1** decomposed in the temperature range 440–500 °C and 540–740 °C, which corresponds to the releases of a cyanide group (found: 11.36%, calc. 7.49%) and a 2-PyBIm ligand (found: 42.20%, calc. 46.70%) [16,17]. The final, thermal stable residue is CuO (found: 46.44%, calc. 45.81%). Complex **2** lost two cyanide groups in the range 220–340 °C (found: 15.36%, calc. 13.90%) and a 3-PyHBIm ligand in 440–880 °C (found: 44.08%, calc. 43.60%) with CuO residue left (found: 40.56%, calc. 42.50%). Complex **3** released lattice water in 160–210 °C (found: 3.72%, calc. 3.32%). The decomposition occurred in the range of 230–290 °C may be assigned to a mixed process of three cyanide groups released and two benzimidazole groups decomposed (found: 26.92%, calc. 28.59%). The pyridyl residues and other two 4-PyHBIm ligands were released in 410–570 °C (found: 45.82%, calc. 43.32%) with thermal stable CuO residue left (found: 23.54%, calc. 21.98%). Complex **4** lost three cyanide groups and a benzimidazole group in 220–310 °C (found: 22.15%, calc. 24.63%). The pyridyl residue and another 4-PyBIm ligand decomposed in 400–690 °C with CuO residue left (found: 38.29%, calc. 50.72%). The reason leading to less CuO residue left is unclear. It is also possible to produce metal Cu residue (calc. 40.51%) [18,19]. Usually, the detailed decomposition mechanisms of metal cyanide and 2-(*n*-pyridyl)benzimidazole are too complicated to explain [20,21]. Comparing the complex structures and their thermal stabilities, 2-PyBIm adopts chelating and bridging coordination mode, which leads to the higher thermal stability of polymer **1**.

In the solid states, complexes **1**–**4** exhibit photoluminescence under 365 nm light excitation (Fig. 5). Amongst

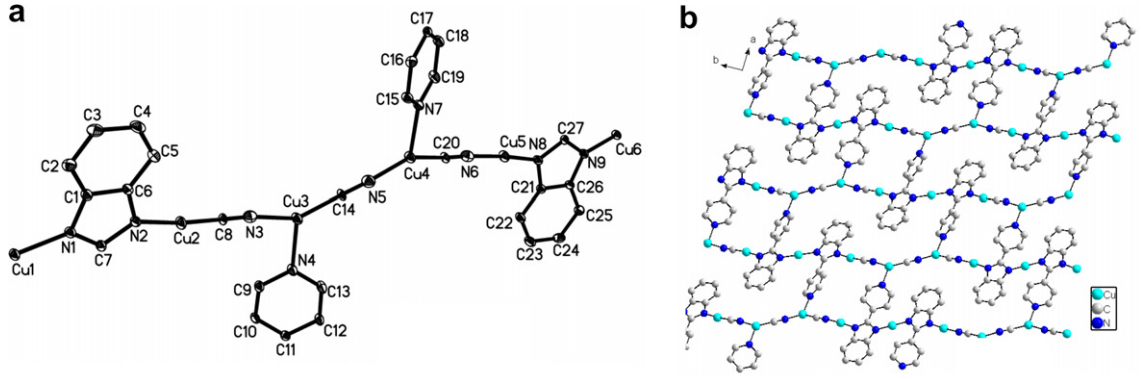

Fig. 4. Views of asymmetric structural unit (a) and two-dimensional polymeric network (b) of **4**.

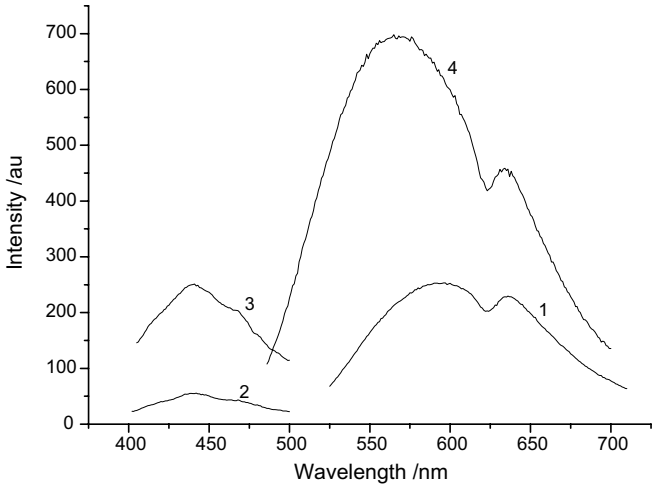

Fig. 5. Emission spectra of **1**–**4**.

them, complexes **1** and **4** constructed through deprotonated 2/4-PyBIm gave strong emission peak maximum at 595, 575 nm with shoulder peak at 640, 635 nm, respectively. While complexes **2** and **3** containing neutral 3/4-PyHBIm gave weak emission peak maximum at 440, 435 nm. It has been reported that organic compound 4-PyHBIm has weak emission band centered at 492 nm, while 4-PyHBIm-Ag(I) complexes exhibit intense luminescence near 540 nm [23]. Generally, metal-to-ligand charge transfer (MLCT) is the most common assignment for the luminescence of d^{10} transition metal complexes [22]. Most of copper(I)-cyanide complexes exhibit luminescence in the range 400–500 nm [5]. So the luminescence of title complexes may be assigned to MLCT where the electron is transferred from Cu(I) to 2/4-PyBIm ligand for **1**, **4**, and transferred from Cu(I) to cyanide group for **2**, **3**.

4. Conclusions

Four copper(I) cyanide coordination polymers containing 2-(*n*-pyridyl)benzimidazole ligands have been prepared by hydrothermal reactions. These complexes possess one-dimensional linear chain, ladder-like double chain, saddle-shaped helical chain, and two-dimensional layer polymeric structures. The cyanide groups in four complexes all act as bidentate bridging ligands. The ratio of Cu/CN, the position of pyridine N atom in three 2-(*n*-pyridyl)benzimidazole ($n = 2, 3, 4$) ligands, and the deprotonated or neutral ligands influence the coordination structures, thermal stabilities and luminescent properties.

emitting units with suitable metal ions and weak interactions could fabricate a variety of luminescent materials. H_2atpt is a more suitable candidate for assembling such compounds due to its interesting structural features. Compared with tpt ligand (H_2tpt = terephthalic acid), the introduction of an amino group in H_2atpt results in the following two effects at least: (i) a supramolecular effect, namely providing more hydrogen-bonding donor or acceptor sites in the construction of the supramolecular packing; (ii) a coordination effect, namely, adding a new coordination site to coordinate with more metal centers. To the best of our knowledge, there are no Cd(II) compounds and rare Zn(II) compounds which have been structurally characterized by X-ray analysis among all the reported compounds with the atpt ligand [35–46]. So, we have started a systematic study on M(II) coordination to the atpt ligand (M = Cd and Zn). One of the aims of this project is to analyze the influence that factors, such as hydrogen bonding, rigidity and the possibility of specific attractive interactions between aromatic rings, can exert on the structure and photoluminescent properties of atpt–containing M(II) compounds. Furthermore, the introduction of N-containing aromatic ligands (bipy and phen, *etc.*) may induce a new structural evolution. A N-containing aromatic ligand is important in maintaining the desired low dimensional coordination polymer and may provide potential recognition sites for π–π aromatic stacking interactions. So, we assumed that the atpt ligand could be useful in the formation of supramolecular networks with some important features in the presence of N-containing aromatic ligands. Here we report the syntheses, structures, properties and weak interactions of two novel coordination compounds [Cd(atpt)phen-$(H_2O)]\cdot H_2O$ (**1**) and $[Zn_2(atpt)_2(bipy)_2(H_2O)_2]$ (**2**) with the atpt ligand. X-ray analysis reveals that compound **2** exhibits an unusual coordination mode of the atpt ligand, which has been observed for the first time (Scheme 1b). There are altogether nine crystallographically established coordination modes of the atpt ligand among the reported compounds, which have been summarized by Cheng et al., besides the one reported by Jin et al. [40,41]. To the best of our knowledge, compound **1** is the first structurally characterized Cd(II) complex with the atpt ligand, although Decker and Frye had reported the synthesis but no crystal structure of one Cd(II) compound with this ligand [46]. So far, there is only one structural report that the amino group of the atpt ligand coordinates to trivalent lanthanide ions [41]. Compound **2** is the first structurally characterized case where the amino group of the atpt ligand coordinates to divalent metal ions. Compounds **1** and **2** exhibit green photoluminescence in the solid state at room temperature.

Scheme 1. Coordination modes of the atpt ligand in the title compounds: (a) (**1**); (b) (**2**).

2. Experimental

2.1. Materials and instruments

All reagents were purchased commercially. Elemental analyses (C, H and N) were carried out on a 240 C Elemental analyzer. FT-IR spectra (400–4000 cm^{-1}) were recorded from KBr pellets in a Magna 750 FT-IR spectrophotometer. Solid state emission spectra were recorded using a 48000DSCF fluorescence spectrometer. Thermogravimetric analyses (TG) were taken on a NETZSCH STA 409 PG/PC instrument.

2.2. Synthesis

2.2.1. $[Cd(atpt)phen(H_2O)]\cdot H_2O$ (**1**)

Phen (0.0131 g, 0.066 mmol) was dissolved in methanol (3 ml) and then a solution of $Cd(NO_3)_2\cdot 4H_2O$ (0.0204 g, 0.066 mmol) in water (3 ml) was added. To this solution a mixture of H_2atpt (0.0120 g, 0.066 mmol) and NaOH (0.0053 g, 0.132 mmol) in water (10 ml) was added and then the resulting solution was filtered. The filtrate was kept at ambient temperature for several days and yellow crystals formed. They were filtered and washed with methanol and dried in vacuum (yield: 30% based on H_2atpt). *Anal.* Calc. for $C_{20}H_{15}CdN_3O_{5.5}$: C, 48.61; H, 3.23; N, 8.43. Found: C, 48.75; H, 3.26; N, 8.31%.

2.2.2. $[Zn_2(atpt)_2(bipy)_2(H_2O)_2]$ (**2**)

Bipy (0.0156 g, 0.100 mmol) was dissolved in methanol (4 ml) and then a solution of $Zn(NO_3)_2\cdot 4H_2O$ (0.0297 g, 0.100 mmol) in water (5 ml) was added while stirring. To this solution a mixture of H_2atpt (0.0181 g, 0.100 mmol) and NaOH (0.0088 g, 0.200 mmol) in water (10 ml) was added and then the resulting solution was filtered. The filtrate was kept at ambient temperature for several days and yellow crystals formed. They were filtered and washed with methanol and dried in vacuum (yield: 60% based on H_2atpt). *Anal.* Calc. for $C_{18}H_{17}N_3O_6Zn$: C, 49.50; H, 3.92; N, 9.62. Found: C, 49.60; H, 3.74; N, 9.61%.

2.3. X-ray single-crystal structure determination

Crystallographic data for all the compounds were collected at 293(2) K with a Siemens SMART CCD diffractometer using graphite-monochromated (Mo Kα) radiation ($\lambda = 0.71073$ Å), ψ and ω scans modes. The structures were solved by direct methods and refined by the full-matrix least-squares on F^2 method using the SHELXL-97 program [47]. Intensity data were corrected for Lorenz and polarization effects and an empirical absorption correction was performed. All non-hydrogen atoms were refined anisotropically. The carbon-bound hydrogen atoms were added geometrically and allowed to ride on their respective parent atoms. The oxygen-bound hydrogen atoms were located in the difference Fourier map and kept fixed in those positions. The contribution of these hydrogen atoms was included in the structure factor calculations. Details of crystal data, collection and refinement are listed in Table 1.

3. Results and discussion

3.1. Preparation

The ligand atpt was chosen as a bridging ligand and the N-containing ligands as chelating ligands and π-stacking moieties. Synthesis conditions, such as starting materials, solvents, reaction temperature, pH, molar ratio and the method to grow single crystals, usually have a great effect on the structure of the compound. Compounds **1** and **2** were obtained by a solution-mixed method under the addition of NaOH (H_2atpt:NaOH = 1:2). These compounds are insoluble in water and common organic solvents, such as methanol, acetone and DMF, *etc*. Therefore, single-crystals used for X-ray analysis were directly grown from the reaction medium.

3.2. Structural analysis of [Cd(atpt)phen(H_2O)] · H_2O (1)

Compound **1** is a 1D zigzag chain (Fig. 1). It is interesting that the center of the benzene ring of the atpt ligand in **1** lies on the crystallographic inversion center, so its amino group is disordered over two sites. In the asymmetric unit of **1** there is one Cd atom, one atpt ligand, one phen ligand, one coordinated water and one lattice water molecule. The Cd atom is seven-coordinated by two nitrogen atoms from the phen ligand and five oxygen atoms from the atpt ligand and H_2O molecule. The coordination geometry of the Cd(II) center can be described as a distorted monocapped octahedral geometry (Table 2).

The atpt ligand in **1** shows the usual bis-chelating coordination mode reported in the literature (Scheme 1a) [41]. The Cd atoms are linked into a 1D zigzag chain with a nearest Cd···Cd distance of 11.417 Å. The dihedral angles between the carboxylate group O1C17O2 and C18C19C20C18bC19bC20b is 7.45°, which is smaller than that between the carboxylate group O3C13O4 and C14C15C16C14aC15aC16a (17.01°). The phen ligands are arranged on two sides of the 1D chain, alternatively. The benzene ring C18C19C20C18bC19bC20b of the atpt ligand is almost in the same plane as the phen ligand (dihedral angle: 2.22°), while the adjacent benzene ring C14C15C16C14aC15aC16a of the atpt ligand is almost perpendicular to the phen ligand (dihedral angle: 83.29°). 1D zigzag chains are further linked by interchain C–H···π and π–π stacking interactions and hydrogen bonds (Fig. 2). The centeroid···centeroid distance between the nearest benzene ring of the atpt ligand and the aromatic ring C2C3C4C5N2 of phen in the nearest adjacent chain is 3.905 Å. The distance, 2.697 Å, between the H10 atom attached to the C10 atom of the phen ligand in one chain and the centeroid of the nearest benzene ring of the atpt ligand in the nearest chain shows that there are interchain C10–H10···π interactions in the compound

Symmetry codes for **1**: #1 $x+1/2$, $-y+3/2$, $z+1/2$ #2 $-x+1/2$, $-y+3/2$, $-z$; **3**: #1 $-x$, $-y+1$, $-z$; **4**: #1 $-x$, $y+1/2$, $-z+3/2$; #2 $-x+1$, $y-1/2$, $-z+3/2$.

(C–H···Cg = 3.583 Å; ∠ C–H···Cg = 159.65°). This kind of contact further stabilizes the 3D supramolecular framework.

Hydrogen bonds exist extensively in **1** (Table 3). There are two strong intramolecular hydrogen bonds: one exists between the coordinated carboxylate oxygen atom O2 and the nitrogen atom N4 [N4–H5A···O2 2.555(5) Å], while the other exists between the nitrogen atom N(3) of the amino group and the coordinated carboxylate oxygen atom O4 [N3–H3B···O4 2.6653 Å]. The 1D chains are further assembled by strong intermolecular hydrogen bonds [N3–H3A···O2 $(1-x, -y, 1-z)$ 2.9956 Å; N4–H4A···O5 $(1-x, -y, 2-z)$ 3.0285 Å; O5–H5A···O6 $(-1+x, y, 1+z)$ 2.7039 Å; O5–H5B···O3 $(-x, -y, 2-z)$ 2.7263 Å]. Thus a 3D supramolecular framework featuring a 1D channel with the dimensions 11.477×11.579 Å^2 occupied by the phen ligand is formed (Fig. 3).

3.3. Structural analysis of $[Zn_2(atpt)_2(bipy)_2(H_2O)_2]$ (2)

Compound **2** exhibits a center-symmetrical binuclear structure (Fig. 4). The zinc atom exhibits a distorted octahedral geometry (Table 2). The atpt ligand employs its one carboxylate groups and an amino group in turn to coordinate to the two zinc centers (Scheme 1b). Quite different from the coordination modes in all the other compounds with the atpt ligand, the coordination mode of the atpt ligand in **2** is new. One of its two carboxylate groups acts as a monodentate ligand, whereas the other carboxylate group does not participate in coordination to Zn(II). To the best of our knowledge, this is the first case where only one carboxylate group of atpt coordinates with metal ions, from the reported compounds with the atpt ligand [35–46]. The amino group of atpt coordinates to the other zinc(II) center. Thus, a dinuclear compound is formed as a result of atpt ligand bridging, with an intramolecular Zn···Zn distance of 7.638 Å.

The other interesting characteristic in this structure is that the benzene ring of the atpt ligand C11C12C13C14C15C16 is approximately parallel to the bipy ring. The bipy ligand is almost planar, the dihedral angle between the two pyridyl planes is 6.90° and its bond lengths and angles are almost the same as those for free bipy [48]. The dihedral angle between the benzene ring and the pyridyl plane C1C2C3C4C5N1 is 11.28°. The centeroid–centeroid distance between them is 3.484 Å. Thus an unusual intramolecular strong π–π stacking interaction between the benzene ring of the atpt ligand and the Zn(II)-coordinated bipy ring takes place.

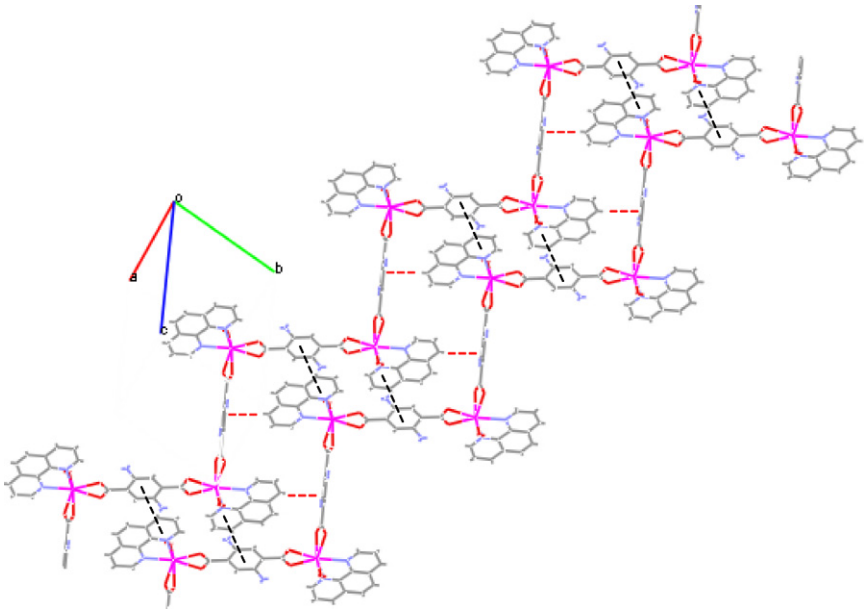

Fig. 2. View of the C–H···π (the red dashed line) and the π–π (the black dashed line) stacking interactions between the nearest chains in **1**.

Table 3
The details of the hydrogen bonds for the title compounds

D–H···A	*d*(D–H)	*d*(H···A)	*d*(D···A)	∠DHA	Symmetry of A
Compound **1**					
N3–H3A···O2	0.8600	2.2400	2.9956	146.00	$1-x, -y, 1-z$
N3–H3B···O4	0.8600	2.0400	2.6653	129.00	
N4–H4A···O5	0.8600	2.5100	3.0285	119.00	$1-x, -y, 2-z$
N4–H4B···O2	0.8600	1.8900	2.5555	133.00	
O5–H5A···O6	0.8500	1.9300	2.7039	151.00	$-1+x, y, 1+z$
O5–H5B···O3	0.8500	1.9600	2.7263	149.00	$-x, -y, 2-z$
Compound **2**					
N3–H3A···O3	0.9000	2.4000	3.0623	131.00	$x, 1/2-y, 1/2+z$
N3–H3B···O4	0.9000	1.9900	2.7337	139.00	
O5–H5A···O2	0.8500	1.9400	2.6910	146.00	
O5–H5B···O3	0.8500	1.8500	2.6959	174.00	$1+x, 1/2-y, 1/2+z$
O6–H6A···O2	0.8500	2.1800	2.9494	151.00	$x, 1/2-y, 1/2+z$
O6–H6B···O4	0.8500	1.7900	2.6291	171.00	$1+x, 1/2-y, 1/2+z$

Hydrogen bonds exist extensively in **2** (Table 3). There are two kinds of intramolecular hydrogen bonds: one exists between the uncoordinated carboxylate oxygen atom O2 and oxygen atom O5 from the coordinated water molecule [O5–H5A···O2 $(1+x, -1+y, z)$ 2.691(8) Å], while the other exists between the nitrogen atom N3 of the amino group and the uncoordinated carboxylate oxygen atom O4 [N3–H3B···O4 2.7337 Å]. The binuclear zinc(II) units are further linked by strong intermolecular hydrogen bonds [N3–H3A···O3 $(x, 1/2-y, 1/2+z)$ 3.0623 Å; O5–H5B···O3 $(1+x, 1/2-y, 1/2+z)$ 2.6959 Å; O6–H6A···O2 $(x, 1/2-y, 1/2+z)$ 2.9494 Å; O6–H6B···O4 $(1+x, 1/2-y, 1/2+z)$ 2.6291 Å]. Thus a 3 D supramolecular network is formed (Fig. 5). The distance, 2.697 Å, between the H4 atom attached to the C4 atom of the bipy ring and the centeroid of the benzene ring of the atpt ligand, shows there are intermolecular C4–H4···π interactions (C–H···Cg = 3.488 Å; ∠C–H···Cg = 143.40°). This kind of contact further stabilizes the 3D network.

3.4. FT-IR spectra

The FT-IR spectra of compounds **1** and **2** show broad peaks in the range of 3600–3200 cm^{-1} due to the existence of water molecules and the amino group of the atpt ligand. The IR results are commonly employed to distinguish the coordination modes of the carboxylate groups. A correlation of the carboxylate coordination mode to metal ions is usually made by examining the difference $\Delta\nu(COO) = \nu_{as}(COO) - \nu_{s}(COO)$ of the compound [49]. The vibrations of $\nu_{as}(COO)$ and $\nu_{s}(COO)$ are at 1619, 1549 cm^{-1} and 1427, 1375 cm^{-1} for **1** and at 1580, 1563 cm^{-1} and 1440, 1372 cm^{-1} for **2**, respectively. These facts indicate that the carboxylate groups

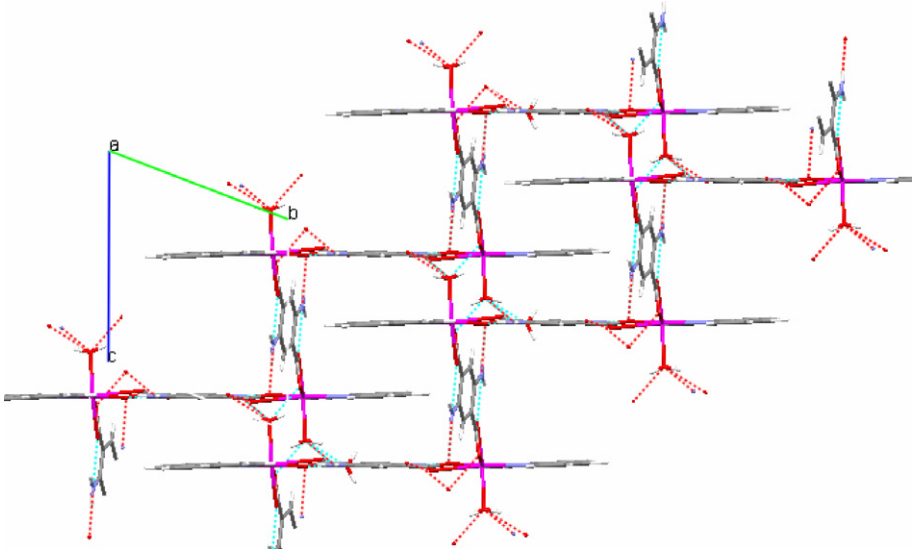

Fig. 3. View of the 3D supramolecular network formed by hydrogen bonding, π–π and C–H···π interactions (down the *a* axis) in **1**.

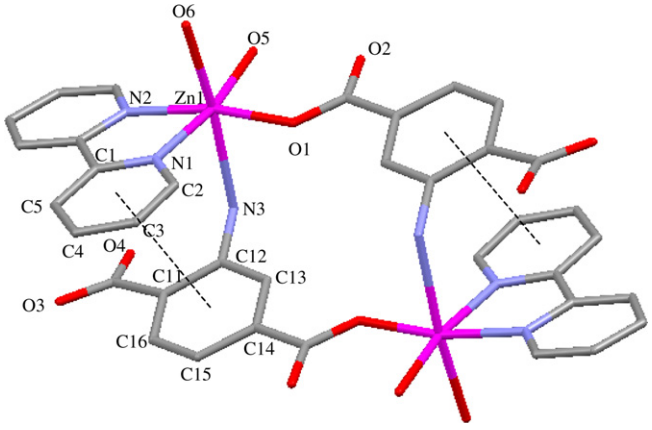

Fig. 4. Molecular structure of **2**, the black dashed line indicates the intramolecular π–π stacking interactions.

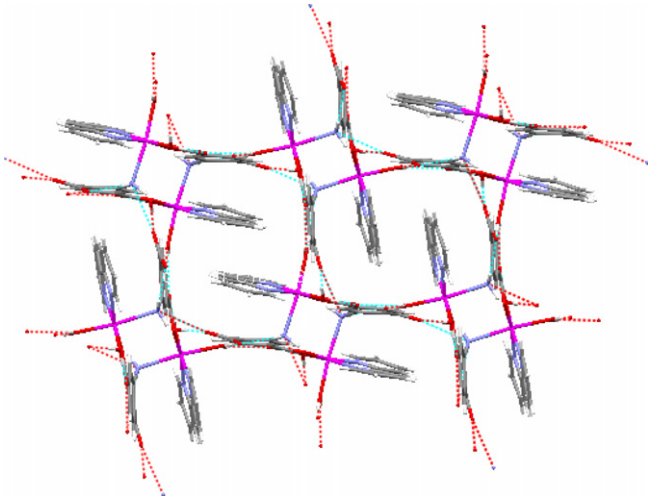

Fig. 5. View of the 3D supramolecular network formed by hydrogen bonding and C4–H4···π interactions between the C4 atom of the bipy ring and the centroid of the benzene ring of the atpt ligand in **2** (down the *a* axis).

of the atpt ligand exhibit the bis-chelating coordination mode in **1**. One of the two carboxylate groups of the atpt ligand in **2** displays a monodentate motif. In all these cases, the results of the X-ray analysis allowed the unambiguously assignment of the binding modes of the carboxylate groups.

3.5. Thermogravimetric analysis

To study the thermal stability of the compounds, thermogravimetric analysis (TG) was performed on polycrystalline samples under a nitrogen atmosphere in flowing N_2 with a heating rate of 10 °C min^{-1} (Fig. 6). Compound **1** releases the coordinated H_2O and lattice H_2O molecules from 46 to 148 °C with a weight loss of 5.3% (calcd. 5.4%). Compound **1** decomposes at 279 °C. TGA for **2**shows that two H_2O molecules are lost in the temperature range 51–160 °C (calc. 8.3%; obsd. 8.1%) and this compound decomposes at 241 °C.

3.6. Photoluminescence properties

The solid-state photoluminescence spectra of H_2atpt and the title complexes at room temperature are depicted in Fig. 7. H_2atpt exhibits a broad strong fluorescent emission centered on 588 nm with an excitation maximum at 358 nm. Green fluorescence for both **1** and **2** can be observed, where the maximum emission wavelengths, λ_{em}, are at 538 nm and 553 nm, respectively, by exciting the solid sample under UV at $\lambda_{ex} = 385$ nm and 335 nm, respectively. The excited-state origins for **1** and **2** seem to be due to a metal-to-ligand charge-transfer transition (MLCT). The fluorescent intensity of **1** is stronger than that of **2**, which may be attributed to the fact that the conjugation degree of the phen ligand is larger than that of the bipy ligand.

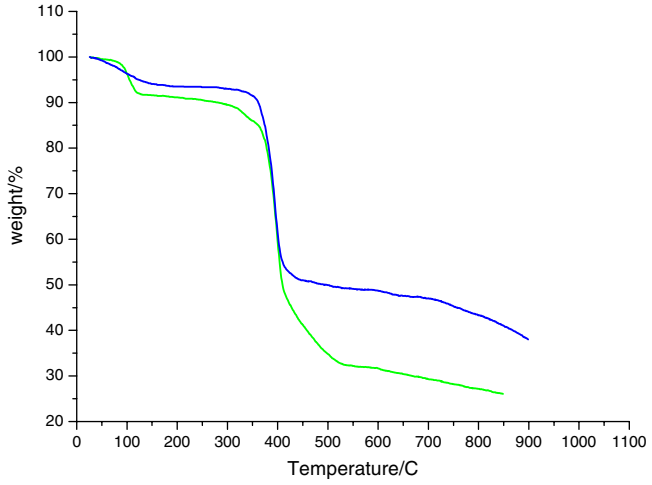

Fig. 6. TG curves of **1** (blue) and **2** (green). (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

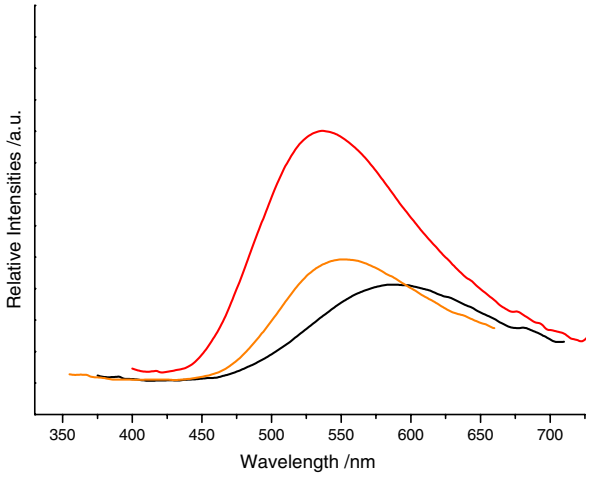

Fig. 7. The emission spectra of H_2atpt (black), **1** (red) and **2** (orange) in the solid state at 298 K. The corresponding excitation wavelengths, λ_{ex}, are 358, 385 and 335 nm, respectively. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

4. Conclusions

In conclusion, two new coordination compounds based on the H_2atpt ligand have been obtained. Compound **1** is the first structurally characterized Cd complex with the atpt ligand. The amino group of the atpt ligand in **2** coordinates to the divalent metal ions for the first time. The atpt ligand exhibits different coordination modes in these two compounds. Furthermore, the atpt ligand in **2** exhibits a newly observed coordination mode compared with all the reported compounds with the atpt ligand. Compound **1** is a 1D zigzag chain, which further assembles into a 3D supramolecular framework. Compound **2** exhibits a binuclear structure with intramolecular π–π stacking interactions. The strong intermolecular hydrogen bonding and C4–H4···π interactions in **2** lead to the formation of a 3D supramolecular network. Green fluorescence can be observed for both **1** and **2**.

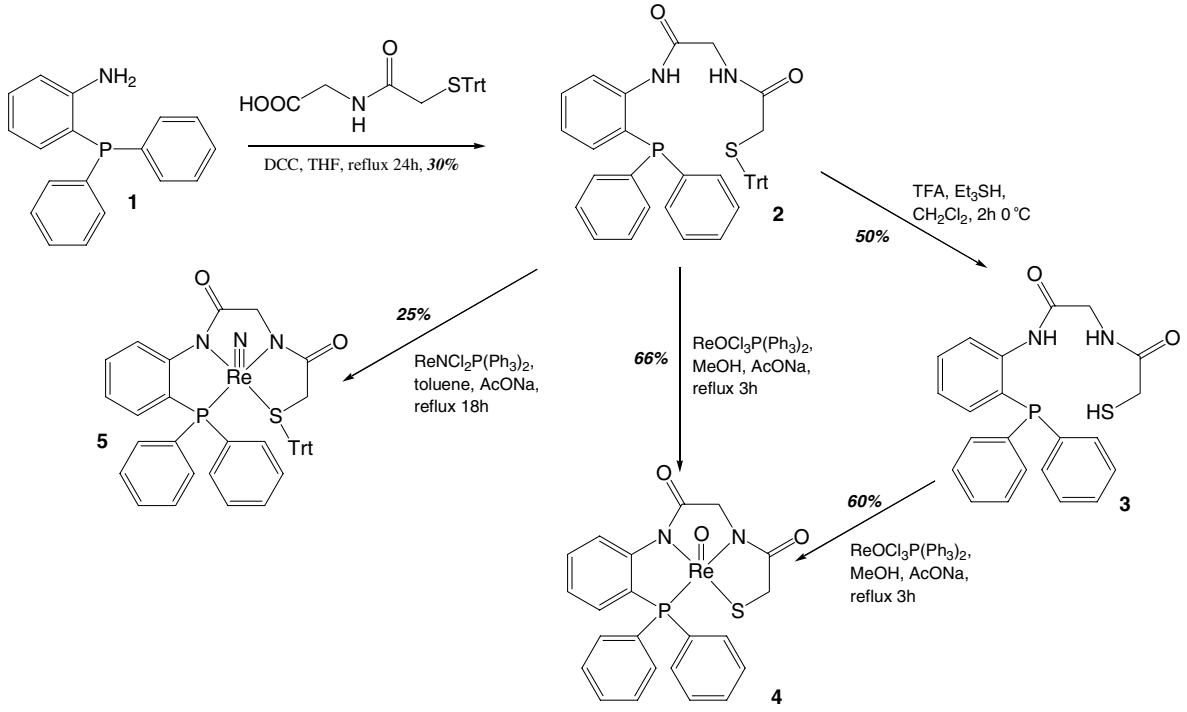
the stable analogous neutral ReO complexes starting with Ph–XN_2S-type ligands acting as a trianionic ligand $XN^-N^-S^-$ (X = OMe, SMe, NMe_2).



Due to their tendency to delocalize the electron density on the metal – a result of their σ-donor and π-acceptor character – phosphines often lead to the stabilization of the complexes in which they are contained [5]. This led us to anticipate that the incorporation of one phosphine group in the chelate ring should enhance the reactivity of the ligand towards the MO^{3+} core (M = Tc or Re) and consequently increase the stability of the resulting neutral metallic complexes. This expectation has been realized in the isolation of two neutral semi-rigid PN_2S rhenium(V) complexes and the structural characterization of one of them, [ReO{Ph-P(Ph_2)N_2S}] (**4**). To our knowledge, these compounds are the first Re^VN and Re^VO species including a semi-rigid PN_2S framework, the only previous examples in ReO chemistry being the PN_2S-tetradentate monooxorhenium complexes obtained with the non-semi-rigid ligands 3-diphenylphosphinoglycyl-L-(S-protected)cysteine and its methyl ester [6]. It is noteworthy that a Re^VO species including a semi-rigid Ph-P_2N_2 framework has been reported by Tisato et al. [7].

2. Results and discussion

The ligands of this study have been prepared under a strictly inert atmosphere according to the method outlined in Scheme 1. Thus, reaction of 2-iodoaniline with diphenylphosphine in the presence of NEt_3 and $Pd(PPh_3)_4$ as a catalyst in warm acetonitrile afforded the 2-diphenylphosphinoaniline (**1**), in quite good yield [8]. A conventional carbodiimide amide coupling of *N*-[(S-trityl)acetyl]glycine [3b] with **1** in THF, followed by the cleavage of the trityl group under acidic conditions (TFA, Et_3SiH) [9] gave the ligands [Ph-P(Ph_2)N_2S(Trt)] (**2**) and [Ph-P(Ph_2)N_2SH] (**3**), respectively. The ligands showed good solubility in methanol, ethanol, dichloromethane, chloroform and acetonitrile. They were characterized by elemental analysis, ^1H and ^{31}P NMR spectroscopy, all consistent with the formula shown in Scheme 1. In particular, the ^{31}P spectra of **2** and **3** revealed only one peak at ≈−21.5 ppm corresponding to P^{III} species. The IR spectrum of **3** exhibited an absorption band at 2482 cm^{-1}, which corresponds to the S–H stretching vibration.

Ligand-exchange reactions in warm methanol of labile $ReOCl_3(PPh_3)_2$ with a slight excess of the relevant tritylated or detritylated ligand (1:1.2 metal:ligand ratio) in the presence of a methanolic sodium acetate solution as a deprotonating agent led to the same neutral complex **4** in satisfactory yield (Scheme 1). The cleavage of the trityl group of **2**, accomplished during the coordination of the ligand to the ReO^{3+} core, is explained by the acidic contribution of the metal (Lewis acid) in the mechanism of sulfur detritylation. Complex **4** crystallised from CH_2Cl_2/hexane solution by slow evaporation and afforded purple crystals suitable for X-ray analysis.

The spectroscopic characteristics of the oxo-rhenium complex **4** of the general formula [ReO{Ph-P(Ph_2)N_2S}], as evident from the elemental analysis, were similar to the analogous anionic complexes described previously [3b,10], i.e. (i) the characteristic rhenium(V) oxo isotopic pattern

Scheme 1. Synthesis of compounds **4** and **5**.

consistent with the presence of a neutral mononuclear complex ([M+H$^+$] = 607/609), (ii) an intense band in the IR spectrum attributable to the Re=O stretching vibration at 966 cm^{-1}, (iii) a non-equivalence of the two hydrogens of each methylene group (AX pattern) of the tetradentate ligand framework in the proton NMR spectrum, the downfield signal of both AX patterns being assigned to the *endo* protons (*syn* to the Re=O group) and the upfield signals to the *exo* ones (*anti* to the Re=O group) [6b,11]. The ^{31}P NMR spectrum showed a singlet peak in agreement with phosphine coordination,[12] the pertinent peak moving downfield to the +38.7 ppm positive region from the −21.6 and −21.2 ppm values exhibited by the uncoordinated detritylated and tritylated ligands, respectively. Thus only one single isomer was produced. The formation of a single isomer is important as isomerism can markedly influence the pharmacokinetics of a radiopharmaceutical [13].

As shown in Fig. 1, the crystal structure of **4** consists of a discrete monomeric and neutral monooxo complex packed with no intermolecular contacts shorter than the van der Waals radii sum. Selected interatomic distances and bond angles are listed in Table 2. The coordination geometry about the metal is distorted square pyramidal with the phosphorous of the linked phosphine, the two amide nitrogen and the sulfur atom occupying the equatorial plane and the oxo group directed in the apical position. The description in terms of a square pyramid is supported by the nearly equal N(2)–Re(1)–S(1) and N(1)–Re(1)–P(1) angles, leading to a very low trigonality index τ of 0.05 (N(2)–Re(1)–S(1) = 135.91(15)° and N(1)–Re(1)–P(1) = 138.88(14)°) [14]. This value is similar to those found for our analogous anionic complexes ($0.00 < \tau < 0.07$) [4,10] and the semi-rigid neutral complex [ReO{Ph-N$_3$O}] recently developed by Papachristou et al. [15] ($\tau = 0.01$). The Re atom lies 0.78 Å above the basal plane, which is reflected by the O=Re–N and O=Re–S/P angles ranging from 106.73(15)° to 114.1(2)°. This value is in agreement with the displacement normally observed for square-pyramidal rhenium complexes [4,16]. The tetradentate coordination mode of the triply deprotonated ligand leads to a three (5,5,5)-membered chelate ring system around the rhenium atom. The two phenyl rings of the phosphine are roughly perpendicular to the Ph–PN$_2$S plane; the mean planes passing through them make angles of 87.9° and 125.0° with the pyramidal basal plane. The same planes define an angle to each other of 64.2°.

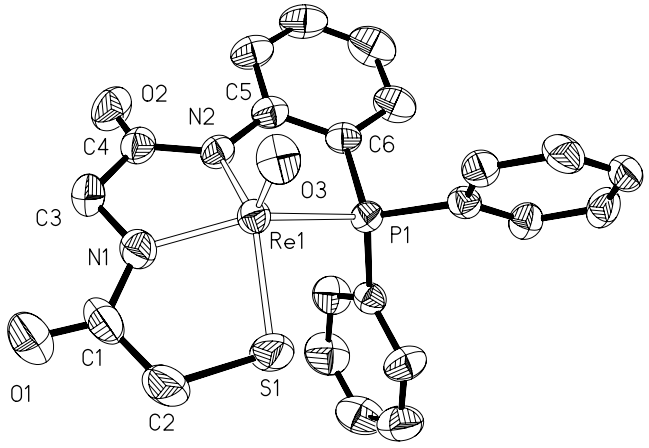


Fig. 1. ORTEP diagram of **4** with 50% probability thermal ellipsoids showing the atomic labelling scheme.

The valence bond distances are unexceptional and are within the range observed for Re-oxo (1.675(4) Å), Re–N$_{amide}$ (ca. 1.99 Å) and Re–S$_{thiolate}$ (2.2614(17) Å) bonds in ReO five-coordinate square-pyramidal complexes. The dominating feature of this structure is the Re–P distance. The latter is 2.4052(14) Å, and it is far shorter than that reported for the non-semi-rigid [ReO{P(Ph$_2$)N$_2$S}] compound developed by Mazzi et al. [6b] 2.4446(2) Å. The rigidity imposed by the aromatic ring conjugated with the strained five-membered chelate ring Re(1)–P(1)–C(6)–C(5)–N(2) instead of a six-membered chelate ring for the Mazzi complex explains this difference. Consequently, the P(1)–Re(1)–N(2) angle is shorter in our complex than in Mazzi's one (78.84(14)° versus 90.5(2)°). It is noteworthy that the length of the X–Re bond in our [ReO(Ph–XN$_2$S)] complexes (X = O, S, NH, PPh$_2$) is greatly influenced by the nature of the X atom. As expected, the bulkier is the X atom, the longer is the X–Re bond, with the following order: d_{N-Re} 1.968(2)Å $< d_{O-Re}$ 2.000(4) Å $\ll d_{S-Re}$ 2.2969(18) Å $< d_{P-Re}$ 2.4052(14) Å. In return, there are no significative differences for the other Re–N or Re–S bonds.

By using the above coordination conditions, treatment of **2** with the ReNCl$_2$(PPh$_3$)$_2$ precursor afforded an intractable mixture, from which the isolation of pure and defined species was not possible. Surprisingly, use of solid sodium acetate as a deprotonating agent and toluene instead of methanol as the solvent allowed us to isolate an unprecedented non-detritylated neutral nitridorhenium(V) complex in 25% yield, as sketched in Scheme 1. [ReN{Ph-P(Ph$_2$)N$_2$S(Trt)}] (**5**) was characterized by spectroscopical methods, even though crystals suitable for X-ray work could not be obtained. In particular, both ^{31}P and ^{1}H NMR spectra demonstrated that **5** is diamagnetic, suggesting a low-spin d^2 configuration, typical of distorted octahedral or distorted square-pyramidal species bearing a multiple oxo- or nitrido-core [17]. The presence of the trityl group is revealed by the integration ratio of total aromatic/aliphatic protons (29/4), consistent with three more phenyl rings in the complex. As expected, the methylene protons of the tetradentate ligand framework were found to be diastereotopic (AX pattern) with coupling constants in the range 17.5–19.5 Hz (Fig. 2). The DCI-MS spectrum of complex **5** showed the production of molecular cations at *m/z* 848/850 ([M+H$^+$]) and *m/z* 865/867 ([M+NH$_4^+$]), with a detectable fragment ion at *m/z* 243 ([Trt$^+$]), revealing the loss of the trityl group. The IR spectrum of **5** exhibited an absorption band at 1098 cm^{-1} assigned to the characteristic ReN stretching vibration. No multiple strong bands were detected in the ranges 1500–1560 and 3200–3400 cm^{-1} of complex **5**, confirming the deprotonation of the amide functions. The complex is

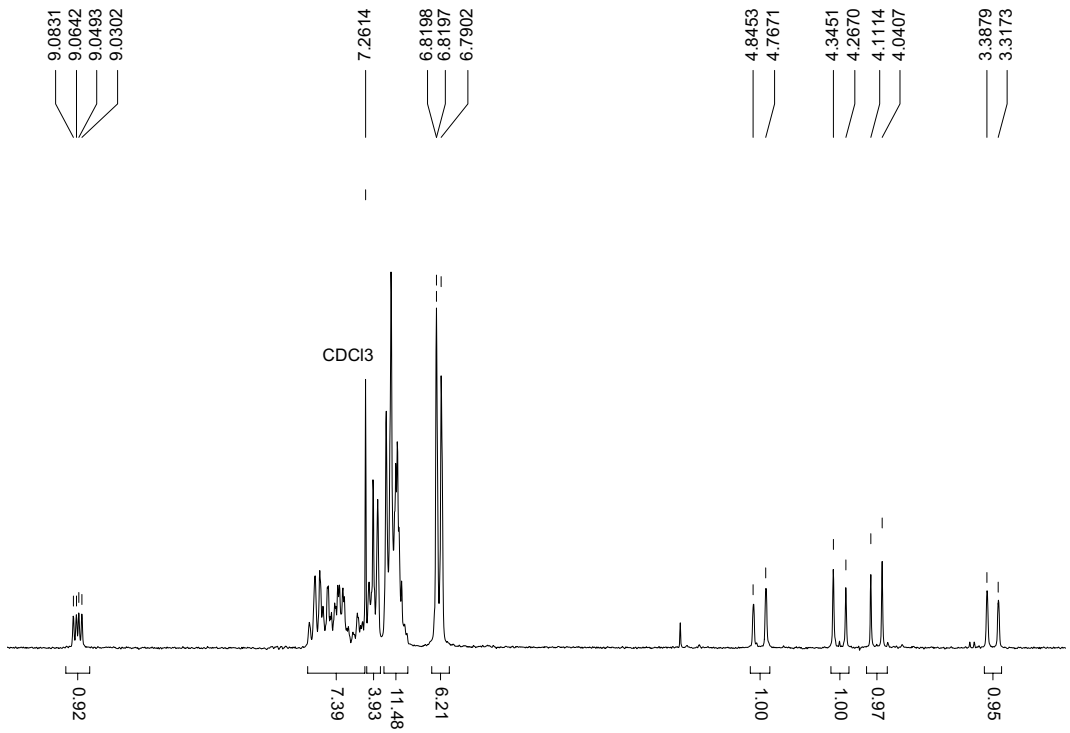

Fig. 2. ^{1}H NMR spectrum of [ReN{Ph-P(Ph$_2$)N$_2$S(Trt)}] (**5**) ($CDCl_3$; 250 MHz; 25 °C).

non-conducting in acetonitrile solutions, as expected [18]. So, chelation of the ReN core proceeds by coordination with the PN_2S^{2-} donor atom set formed from one neutral phosphine, two deprotonated amide groups and one neutral thioether. This is the first example where metal catalysed removal of the trityl group does not occur during a Re^{V} complexation.

The isolation of these two complexes conjugated with the fact that we never succeeded in isolating a neutral Re^{V} complex with [Ph–X(Me)N$_2$S(Trt)] ligands (X = O or S) suggested that the phosphorus atom of the chelate (i) enhances the reactivity of the ligand towards the ReO^{3+} core, (ii) binds first to the metal and this bond acts as the driving force for coordination. The latter hypothesis is consistent with the mechanism proposed by Visentin et al. for their similar ReO complexes with a P,N,N,S donor atom set [6b]. Our complexes are extremely stable in the solid state as well as in organic solvents for long periods of time, as shown by NMR spectroscopy. Their stability is not affected by the presence of air. The mixing of a π-donor S atom with a π-acceptor P atom ensures an appropriate electronic balance around the ReO or ReN core and this event contributes to the overall robustness of the system.

3. Conclusion

In conclusion, the new semi-rigid PN_2S ligand studied here exhibits high chelating affinity for the rhenium(V) core. A neutral stable monooxorhenium(V) complex was produced as a single isomer by reacting the tritylated or detritylated ligand with a ReO precursor, in good yield. The high affinity of the PN_2S set toward $Re^{V}O$ can be expected also for ^{99m}TcO, making this ligand potentially useful as a ^{99m}TcO-based brain perfusion or brain receptor imaging agent. A radio-labelling study with ^{99m}Tc will start soon. Investigations on the unexpected neutral complex [ReN{Ph-P(Ph$_2$)N$_2$S(Trt)}], isolated during the complexation of the tritylated ligand with $ReNCl_2(PPh_3)_2$, are still going on to better understand the formation of this complex.

4. Experimental

4.1. General methods

All preparations and manipulations were carried out under a nitrogen atmosphere using standard Schlenk techniques. All chemicals were of the highest purity commercially available. Rhenium(VII) oxide was purchased from Aldrich Chem. Co. It was converted to $ReOCl_3(PPh_3)_2$ and $ReNCl_2(PPh_3)_2$ according to published protocols [19]. Solvents were dried and distilled by standard methods before use and stored over 0.3 nm molecular sieves. 2-(diphenylphosphino)aniline (**1**) [8] and *N*-[(S-trityl)acetyl]glycine [3b] were prepared as described previously. Silica gel (0.060–0.200 nm) was purchased from Acros. TLC was performed using precoated Kieselgel 60 plates F_{254} (TLC plates, Merck) and was visualised by UV or iodine. Column chromatography was carried out using "gravity" silica (Merck). Infrared spectra (4000–400 cm^{-1}) were recorded as KBr pellets on a Vector 22 Bruker spectrophotometer. NMR spectra were recorded on a Bruker AC 200 (81.015 MHz for ^{31}P) and AC 250

apparatus (250.133 MHz for ^1H). Chemical shifts are indicated in δ values (ppm) downfield from internal TMS. For the $^{31}P\{^1H\}$ spectra the external standard was H_3PO_4 (82% D_2O, $\delta = 0.0$ ppm). DCI-Mass spectra were obtained on a NERMAG R10-10 mass spectrometer. Microanalysis was performed by the Microanalytical Department of the Ecole Nationale Supérieure de Chimie de Toulouse.

4.2. Synthetic work

4.2.1. N-[2-(diphenylphosphino)phenyl]-2-[(triphenylmethylmercapto)methylcarbonylamino] ethanamide (2)

N-[(S-trityl)acetyl]glycine (1.957 g, 5 mmol) and **1** (1.385 g, 5 mmol) were dissolved in anhydrous degassed THF (25 mL). Dicyclohexylcarbodiimide (1.135 g, 5.5 mmol) was added and the mixture was heated at reflux for 24 h. After cooling to room temperature, the insoluble dicyclohexylurea was removed by filtration and the filtrate evaporated under reduced pressure. The obtained brown oil was dissolved in AcOEt (20 mL) and cooled at 0 °C. A white solid was collected by filtration and washed with cold AcOEt. The solid was purified by column chromatography on silica gel (eluent: CH_2Cl_2/AcOEt, 96/4) to give **2** as a white powder (1.002 g, 30%).

Anal. Calc. for $C_{41}H_{35}N_2O_2PS$: C, 75.67; H, 5.42; N, 4.30; S, 4.93. 4.2.2. N-[2-(diphenylphosphino)phenyl]-2-[mercaptomethylcarbonylamino]ethanamide (3)

To a chilled solution of **2** (0.250 g, 0.38 mmol) in degassed CH_2Cl_2 (30 mL) were added TFA (13 mL) and triethylsilane (121 μL, 0.76 mmol). The solution became colourless and it was stirred for 2 h. After removal of the solvents under vacuum, the resulting residue was crystallised as a white powder upon addition of hexane (77 mg, 50%).

Anal. Calc. for $C_{22}H_{21}N_2O_2PS$: C, 64.69; H, 5.18; N, 6.86; S, 7.85. Found: C, 64.80; H, 5.01; N, 6.50; S, 7.64%; IR (KBr) ν (cm^{-1}) 3338, 3241 (NH); 2482 (SH); 1696, 1640 (CO); MS (DCI/NH_3): *m/z* 409 [$M+H^+$]; $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ (ppm): −21.6 (s) ; ^1H NMR ($CDCl_3$) δ (ppm): 1.33 (t, 1H, $J = 8.8$ Hz, SH); 3.22 (d, 2H, $J = 8.8$ Hz, SCH_2); 3.93 (d, 2H, $J = 5.5$ Hz, CH_2N); 6.90 (m, 1H, NH); 6.92 (m, 1H, CH_{Ar}); 7.06-7.41 (m, 11H, CH_{Ar}); 7.55 (m, 1H, CH_{Ar}); 8.10 (broad s, 1H, NH); 8.35 (m, 1H, CH_{Ar}).

4.2.3. [N-(2-diphenylphosphinophenyl)-2-(mercaptomethylcarbonylamino)ethanamido(4-)-κ^4P,N,N′,S]oxorhenate(V) or [ReO{Ph-P(Ph$_2$)N$_2$S}] (4)

Method 1: To a suspension of **2** (200 mg, 0.308 mmol) and $ReOCl_3(PPh_3)_2$ (307 mg, 0.370 mmol) in degassed MeOH (30 mL) was added a 1 M solution of sodium acetate in degassed MeOH (3 mL, 3 mmol). After refluxing for 3 h, the solution turned violet and clear. After cooling, the solution was filtered off and evaporated to dryness. The obtained brown violet solid was recrystallised from CH_2Cl_2/hexane (2/1) to afford **4** as a violet powder (123 mg, 66%).

Method 2: The same procedure as method 1 starting with **3** (50 mg, 0.122 mmol), $ReOCl_3(PPh_3)_2$ (122 mg, 0.147 mmol) and sodium acetate in MeOH (1 mL, 1 mmol). After recrystallisation, **4** was obtained as a violet powder (44 mg, 60%).

Anal. Calc. for $C_{22}H_{18}N_2O_3PReS$: C, 43.49; H, 2.99; N, 4.61; S, 5.28. Found: C, 43.60; H, 3.12; N, 4.58; S, 5.12%; IR (KBr): ν(cm^{-1}) 1665, 1647 (CO); 966 (ReO); MS (DCI/NH_3): *m/z* (%) 607 (11), 609 (20) [$M+H^+$], 623 (1), 625 (2) [$M+NH_4^+$]; $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ (ppm): 38.7 (s); ^1H NMR ($CDCl_3$) δ (ppm): 3.88 (d, 1H, $J = 17.4$ Hz, SCH_2); 4.04 (d, 1H, $J = 17.4$ Hz, SCH_2); 4.78 (d, 1H, $J = 19.0$ Hz, CH_2N); 5.22 (d, 1H, $J = 19.0$ Hz, CH_2N); 7.20 (t, 1H, $J = 7.3$ Hz, CH_{Ar}); 7.28–7.91 (m, 12H, CH_{Ar}); 9.10 (dd, 1H, $J_{HH} = 8.5$ Hz, $J_{HP} = 4.6$ Hz, CH_{Ar}).

4.2.4. [N-(2-diphenylphosphinophenyl)-2-{(triphenylmethylmercapto) methylcarbonylamino}ethanamido(4-)-κ^4P,N,N′,S]nitridorhenate(V) or [ReN{Ph-P(Ph$_2$)N$_2$S(Trt)}] (5)

To a suspension of **2** (200 mg, 0.308 mmol) and $ReNCl_2(PPh_3)_2$ (294 mg, 0.370 mmol) in degassed toluene (30 mL) was added sodium acetate (304 mg, 3.7 mmol). After refluxing for 18 h the solution turned brown and clear. After cooling, the solution was filtered off and evaporated to dryness. Addition of ether (10 mL) gave a precipitate which was filtered off. The precipitate was dissolved in CH_2Cl_2. Addition of hexane gave a precipitate which was filtered off. The filtrate was concentrated to give **5** as a reddish-brown powder (65 mg, 25%).

Anal. Calc. for $C_{41}H_{33}N_3O_2PReS$: C, 58.00; H, 3.92; N, 4.95; S, 3.78. Found: C, 58.08; H, 4.20; N, 4.60; S, 3.56%; IR (KBr): ν(cm^{-1}) 3050 (CH_{Ar}); 1661, 1637 (CO); 1098 (ReN); MS (DCI/NH_3): *m/z* (%) 243 (14) [Trt^+], 848 (60), 850 (100) [$M+H^+$], 865 (3), 867 (6) [$M+NH_4^+$]; $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ (ppm): 39.0 (s); ^1H NMR ($CDCl_3$) δ (ppm): 3.31 (d, 1H, $J = 17.6$ Hz, SCH_2); 4.04 (d, 1H, $J = 17.6$ Hz, SCH_2); 4.26 (d, 1H, $J = 19.5$ Hz, CH_2N); 4.76 (d, 1H, $J = 19.5$ Hz, CH_2N); 6.70–6.82 (m, 6H, CH_{Ar}); 7.05–7.60 (m, 22H, CH_{Ar}); 9.05 (dd, 1H, $J_{HH} = 8.5$ Hz, $J_{HP} = 4.7$ Hz, CH_{Ar}). Λ_M (CH_3CN): 21.10 Ω^{-1} cm^2 mol^{-1} (neutral).

4.3. X-ray crystal structure determination of complex 4

[ReO{Ph-P(Ph_2)N_2S}] (**4**) was crystallised by slow evaporation of a CH_2Cl_2/hexane solution. A purple crystal of **4** thus produced was mounted on a Nonius Kappa CCD diffractometer equipped with a CDD detector, and was used for data collection. X-ray intensity data were collected with

Table 1
Summary of the crystal data for complex **4**

graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at a temperature of 298 K. The most significant details of the crystallographic study are reported in Table 1. A collection of selected bond distances and angles are shown in Table 2. The structure was solved by direct methods. All the non-hydrogen atoms were refined anisotropically using the full-matrix, least-squares procedure based on F^2. Structure determination and refinement were performed using the maXus [20] and shelx-97 [21] programs. 3621 independent reflections with $I \geqslant 2\sigma(I)$ were used for refinement of the unit cell ($\theta \leqslant 25°$). Hydrogens for the mater molecule were not located.

Appendix A. Supplementary material

CCDC 651266 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2007.07.032.

On the other hand, an interest in the chemistry of Nb(V) and Ta(V) fluorides is essentially connected with the development of suitable methods for concentration (separation) of these elements, the processes being based on the recrystallization or extraction of the proper complexes from acidic aqueous solutions [3]. Recently, we revealed some interesting features of the "host–guest" complexes formed as a result of the interaction of Nb and Ta pentafluorides with crown ethers. Two synthetic routes were applied: the interaction of the corresponding M_2O_5 oxides with hydrofluoric acid in the presence of the CE, and the direct interaction of MF_5, also in the presence of HF, with the same crown ethers. These two pathways resulted in crystalline complexes of the composition $[CE \cdot H_3O][MF_6]$ for the hexadentate benzo-18-crown-6 [4], *cis-syn-cis*-dicyclohexyl-18-crown-6 [5] and diphenyl-20-crown-6 [6], $[(1.5DB18C6)_2 \cdot H_7O_3][MF_6]$ complexes for 1.5-dibenzo-18C6 [6] and $[TB30C10 \cdot H_5O_2][MF_6]$ for tetrabenzo-30-crown-10 (M = Nb, Ta) [7]. Complexes with B18C6 and *cis-syn-cis*-DCH18C6 provided examples of supramolecular isomers: monoclinic ($P2_1/n$) and orthorhombic (*Pbca*) polymorphs for $[B18C6 \cdot H_3O][TaF_6]$ that are distinct by the subtle packing changes [4], and monoclinic again ($P2_1/n$) and triclinic ($P\bar{1}$) polymorphs for [*cis-syn-cis*-$DCH18C6 \cdot H_3O][TaF_6]$, differing by the pronounced conformational changes in the macrocyclic molecule and in the crystal packing [5]. The occurrence of supramolecular isomerism (SI) [8] implies a superstructural diversity for a given building block. Complexes with conformationally flexible CEs and aza-macrocycles give some examples of supramolecular isomers [9].

The next intriguing feature of the studied complexes is a diversity of the encapsulated oxonium ions [10]. The use of hexadentate B18C6, *cis-syn-cis*-DCH18C6 and DP20C6 resulted in crystalline complexes of the general formula $[CE \cdot H_3O][MF_6]$, where the macrocyclic cavity includes the simplest oxonium cation H_3O^+ (also called an Eigen core [10]), while the use of TB30C10 afforded the opportunity for the extraction of the $[H_5O_2]^+$ Zundel cation, $[H_2O\cdots H\cdots OH_2]^+$ [10] within the complex of the same stoichiometry. The decrease in number of oxygen atoms accessible for interaction with the tripodal oxonium cation in the case of [1.5] DB18C6 resulted in the storage of the three-membered oxonium cluster $[H_7O_3]^+$ within the cage formed by two [1.5] DB18C6 molecules in the complex of composition $[(1.5DB18C6)_2 \cdot H_7O_3][MF_6]$ (M = Nb, Ta) [6].

In this paper, we selected gradually diminishing in size classic 18-crown-6 (18C6), 15-crown-5 (15C5), benzo-15-crown-5 (B15C5) and benzo-12-crown-4 (B12C4) as macrocyclic ligands to react with Nb and Ta pentafluorides. Five new complexes, $[18C6 \cdot H_3O][NbF_6]$ (**1**), $[18C6 \cdot H_3O][TaF_6]$ (**2**), $[15C5 \cdot H_5O_2][TaF_6]$ (**3**), $[(B15C5)_2 \cdot H_5O_2][(B15C5)_2 \cdot H_3O)\ ][TaF_6]_2$ (**4**) and $[(B12C4)_2 \cdot H_3O][TaF_6]$ (**5**), were obtained. The crystals were obtained by the two above described synthetic routes, resulting in both cases (four crown ethers used) in crystallographically identical complexes. The details of their synthesis and structure are reported.

2. Experimental

2.1. Materials and apparatus

Caution! Hydrofluoric acid should be treated as an extremely aggressive liquid. All crown ethers were purchased from ACROS, Ta_2O_5/Nb_2O_5 and TaF_5/NbF_5 were purchased from Aldrich and were used without further purification. Complexes $[18C6 \cdot H_3O][NbF_6]$ (**1**), $[18C6 \cdot H_3O][TaF_6]$ (**2**), $[15C5 \cdot H_5O_2][TaF_6]$ (**3**), $[(B15C5)_2 \cdot H_5O_2][TaF_6]$ $[(B15C5)_2 \cdot H_3O][TaF_6]$ (**4**) and $[(B12C4)_2 \cdot H_3O][TaF_6]$ (**5**) were obtained by two synthetic pathways: by an interaction of the corresponding oxides with 40% aqueous HF followed by treatment of the resulting solution with the corresponding crown ether, and by the interaction of the initial corresponding metal pentafluoride, NbF_5/TaF_5, with the CE in a medium of 40% HF. All the complexes were analyzed for C, H and F in a Perkin–Elmer 240 °C instrument. The X-ray structural analysis revealed the identity of the complexes obtained under the different synthetic conditions, the best crystallographic results are discussed in this paper.

2.2. Synthesis

I route: To Nb_2O_5/Ta_2O_5 (0.5 mmol) dissolved in 45% HF (6–7 ml), the corresponding CE (1 mmol) dissolved in 8–10 ml methanol was added. The resulting solution was stored at 20–25 °C in a Teflon exsiccator for a low evaporation of solvent to a volume of 5–6 ml over several days.

II route: To solution of CE (1 mmol) was added a solution of NbF_5/TaF_5 (1 mmol) in 10–12 ml of 45% hydrofluoric acid. The resulting solution was stored at 20–25 °C in a Teflon exsiccator for a low evaporation of solvent to a volume of 5–6 ml over several days.

2.2.1. $[18C6 \cdot H_3O][NbF_6]$ (1)

Crystals of complex **I** separated in a yield of 72% (0.350 g), and are colorless transparent prisms, soluble in methanol, ethanol; m.p.: >220 °C (decomp). *Anal.* Calc. for $C_{12}H_{27}F_6NbO_7$: C, 29.40; H, 5.55; F, 23.25. Found: C, 29.33; H, 5.58; F, 23.45%.

2.2.2. $[18C6 \cdot H_3O][TaF_6]$ (2)

Crystals of **2** separated in a yield of 75% (0.430 g), and are colorless transparent prisms, soluble in methanol, ethanol; m.p.: >195 °C (decomp). *Anal.* Calc. for $C_{12}H_{27}F_6TaO_7$: C, 29.42; H, 4.71; F, 19.71. Found: C, 24.87; H, 4.68; F, 19.70%.

2.2.3. $[15C5 \cdot H_5O_2][TaF_6]$ (3)

Crystals of **3** separated in a yield of 74% (0.280 g), and are colorless transparent prisms, soluble in methanol, ethanol; m.p.: 124–125 °C (decomp). *Anal.* Calc. for

$C_{10}H_{25}F_6O_7Ta$: C, 31.10; H, 5.87; F, 14.76. Found: C, 31.13; H, 5.92; F, 14.82%.

2.2.4. $[(B15C5)_2 \cdot H_5O_2][TaF_6][(B15C5)_2 \cdot H_3O][TaF_6]$ (4)

Crystals of **4** were separated in a yield of 82% (0.350 g), and are colorless transparent crystals, soluble in methanol, ethanol; m.p.: 126–127 °C (decomp). *Anal.* Calc. for $C_{56}H_{88}F_{12}O_{23}Ta_2$: C, 39.12; H, 5.16; F, 13.26. Found: C, 39.59; H, 5.17; F, 13.34%.

2.2.5. $[(B12C4)_2 \cdot H_3O][TaF_6]$ (5)

Crystals of **5** were separated in a yield of 95% (0.360 g), and are colorless transparent crystals, soluble in methanol, ethanol; m.p.: >180 °C (decomp). *Anal.* Calc. for $C_{24}H_{35}F_6O_9Ta$: C, 37.81; H, 4.63; F, 14.95. Found: C, 37.78; H, 4.67; F, 14.91%.

2.3. X-ray diffraction determination

The X-ray intensity data for complexes **1**, **2**, **4** and **5** were recorded at 123 K on a Bruker SMART 1000 CCD area detector diffractometer employing graphite monochromatized Mo Kα radiation ($\lambda = 0.71073$ Å) in the ϕ and ω scan mode. Final unit cell dimensions and positional data were obtained and refined on the entire data set. Integration and scaling resulted in a data set corrected for Lorentz and polarization effects using DENZO [11]. The scaling as well as the global refinement of the crystal parameters were performed by SCALEPACK [11]. The experimental data for complex **3** were recorded at ambient temperature (295 K) on an Xcalibur S with a CCD detector (Mo-Kα radiation, graphite monochromator, ω scan mode). The absorption correction for **2**–**5** was applied using SADABS [12]. The structure solution and refinement proceeded similarly using the SHELX-97 program package [13] for all the structures. Direct methods yielded all non-hydrogen atoms of the asymmetric unit. These atoms were treated anisotropically (full-matrix least squares method on F^2). In complexes **1** and **2** the macrocycle and oxonium cation occupy the special position 2/*m*, that makes it impossible to localize the oxonium hydrogen atoms, and in the next section only O···O distances will be discussed. In complex **3** the mirror plane *m* bisects the macrocycle through the O(1) atom and the C(5)–C(5′) valent bond, both oxygen atoms and one hydrogen atom of the $(H_5O_2)^+$ oxonium cation. The crown oxygen atom O(3) is disordered over two positions with equal occupancies. In complexes **4** and **5** the oxonium ion occupies a position on a two-fold axis, being equally disordered. C-bound H atoms were placed in calculated positions, with C–H distances of 0.93 or 0.97 Å, and were treated using a riding-model approximation with $U_{iso}(H) = 1.2\,U_{eq}(C)$. H atoms of water molecules and oxonium ions were determined from difference Fourier maps and were then allowed to refine isotropically with $U_{iso}(H) = 1.5U_{eq}(O)$ and O–H distances subjected to DFIX restraints.

The X-ray data and details of the refinement for **1**–**5** are summarized in Table 1, selected geometric parameters are given in Table 2 and the hydrogen bonding geometries for **3**–**5** are given in Table 3.

3. Results and discussion

3.1. Description of the structures

Complexes **1** and **2** are isostructural (Table 1), so only complex **2** is further discussed. Both complexes crystallize in the orthorhombic space group *Pbam*. The NbF_6^- anion in complex **1** resides on an inversion centre and is characterized by an octahedral core with Nb–F distances ranging from 1.844(2) up to 1.876(2) Å and F–Nb–F valent angles between *cis*-fluorine atoms practically being equal to 90°. The geometry of the NbF_6^- anion is close to that found in 3-chloro-1,3,4,2,5-thiadiselenadiazolium hexafluoroniobium [14] and in bis(pyrazine)dicopper bis(hexafluoroniobium) piperazine solvate [15]. The TaF_6^- anions in complexes **2**–**5** also adopt the usual octahedral geometry with Ta–F distances ranging from 1.854(5) to 1.877(7) Å in **2**, from 1.868(8) to 1.887(7) Å in **3**, from 1.845(4) to 1.874(4) Å in **4**, and from 1.881(3) to 1.888(2) Å in **5**, the maximal deviation for the F–Ta–F valent angle between *cis*-fluorine atoms from a right angle being 1.5°. This geometry is close to that found in catena-[(μ-chloro)-bis(μ-fluoro)tetrafluoro-hexamethyltantalum)] ditin [16] and in methyltriphenylphosphonium hexafluorotantalate [17].

3.1.1. $[18C6 \cdot H_3O][TaF_6]$ (2)

The ORTEP view for complex **2** is shown in Fig. 1. The 18C6 molecule and oxonium cation $(H_3O)^+$ are situated in the 2/*m* position: the *m* plane passes through the O(1) and O(1′) atoms, and the twofold axis bisects the C(3)–C(3′) bond. The arrangement of both macrocycle and oxonium ion on a special position explains the availability of only two different O(oxonium)···O(crown) distances, being equal to 2.777(6) Å [to O(1) and its symmetry-related counterpart], and 2.708(5) Å [to O(2) and its three symmetry-related counterparts]. The 18C6 molecule is characterized by the idealized D_{3d} symmetry with the *trans-gauche-trans*-sequence of torsion angles and ±0.171(5) Å deviation of oxygen atoms from the mean plane.

3.1.2. $[15C5 \cdot H_5O_2][TaF_6]$ (3)

Complex **3**, of the composition $[15C5 \cdot H_5O_2][TaF_6]$, crystallises in the orthorhombic crystal system, space group *Pnma*. The ORTEP view for complex **3** is shown in Fig. 2. The asymmetric unit of **3** comprises of one half of the TaF_6^- anion, one half of the 15C5 molecule and one half of the $(H_5O_2)^+$ Zundel cation, all these species residing on a mirror plane. Within the Zundel cation, the water molecule and oxonium ion are held together *via* a strong OH···O hydrogen bond, the O···O separation being 2.462(12) Å. Its interaction with two neighboring crown molecules related by the glide plane occurs in such a way

that the $(H_3O)^+$ oxonium part is involved in two equal OH···O bifurcated hydrogen bonds to the O(2) and O(3A) atoms, the O···O separations being 2.646 and 2.945 Å, while the 'water part' *via* O(4) is involved in the O(4)···O(3) interaction, the O···O separation being 2.995(15) Å (Table 3). The crown molecules and $(H_5O_2)^+$ cations alternate in the infinite chain. The atom O(4) deviates by 1.692(4) Å from the mean plane of crown oxygen atoms that are coplanar to within ±0.28 Å, while atom O(5) deviates by 1.692(4) Å from the same atoms of the next crown molecule. In the macrocyclic framework all the C–O–C–C torsion angles are *anti*-, four O–C(sp^3)–C(sp^3)–O angles are *gauche*-and the O(3)–C(5)–C5′–O3′ angle is 0.0° due to the mirror symmetry (Table 2).

3.1.3. *[(B15C5)$_2$ · H$_5$O$_2$] [(B15C5)$_2$ · H$_3$O][TaF$_6$]$_2$ (**4**)*

Complex **4**, of the composition [(B15C5)$_2$ · H$_5$O$_2$][(B15C5)$_2$ · H$_3$O][TaF$_6$]$_2$, crystallises in the monoclinic crystal system, space group *C*2/*c*. It is built of two different in composition sandwich cations (associated with A and B macrocycles) and two TaF_6^- anions. The ORTEP view for complex **4** is shown in Fig. 3. The asymmetric unit of **4** comprises two halves of the TaF_6^- anions, (one is situated on an inversion center and the other is situated on a twofold axis), two B15C5 molecules (designated A and B) in general positions, and two oxonium oxygen atoms O(6A) and O(6B) (associated with the similarly labelled macrocycles), the former being located on a twofold axis, the latter being located in a general position in the vicinity of an inversion center and forming a $(H_5O_2)^+$ Zundel cation. In sandwich **A** the oxonium ion is equally disordered over the inversion center, forming correspondingly two and one hydrogen bonds to two crown molecules in the sandwich, the O(oxonium)···O(crown) separations falling in the range 2.742(3)–3.031(3) Å. The O(6A) oxygen atom deviates by 1.811(2) Å from the mean plane of the crown oxygen atoms that are coplanar to within ±0.28 Å. In molecule **A** the dihedral angle between the plane through the phenyl ring and 5 oxygens is equal to 26.2(1)°. Along the 15-membered heterocyclic framework all O–C(sp^3)–C(sp^3)–O torsion angles are *gauche*-, while O–C(sp^2)–C(sp^2)–O that belongs to the phenyl ring is *cis*, of 10 C–C–O–C torsions 8 are *anti*- and two adopt the *gauche*-conformation, giving rise to the sequence of two *gauche*-torsion angles meeting at C(3A) and C(6A) atoms (Table 2). In sandwich **B**, having the composition [(B15C5)$_2$ · H$_5$O$_2$], the O···O separation of 2.409 Å within the Zundel cation is the shortest among the corresponding O···O distances that are of concern in the cited data [9]. The other O···O distances to crown oxygens range from 2.651 to 3.012 Å (Table 3). The atom O(6B) deviates by 1.692(4) Å from the mean plane of crown oxygen atoms that are coplanar to within ±0.28 Å. In molecule **B** the dihedral angle between the planes through the phenyl ring and 5 oxygens is equal to 17.5(1)°, all C–O–C–C torsion angles are *anti*-, all O–C(sp^3)–C(sp^3)–O angles are *gauche*-, and the O–C(sp^2)–C(sp^2)–O angle is *cis* (Table 2). The dependence of the hydrogen bonding on the system is evident on changing the crown ether conformation.

3.1.4. *[(B12C4)$_2$ · H$_3$O][TaF$_6$] (**5**)*

Complex **5**, of the composition [(B12C4)$_2$ · H$_3$O][TaF$_6$], crystallises in the triclinic space group $P\bar{1}$. The ORTEP view for this complex is shown in Fig. 4. The TaF_6^- anion occupies a position on an inversion center. The macrocyclic cation has a typical B12C4 sandwich-like structure with the oxonium ion enclosed between two inversion-related macrocycles with three main O···O separations to crown oxygens equal to 2.652(3), 2.819(3) and 2.881(3) Å. The oxonium cation O(5) deviates by 1.953(2) Å from the mean

three adopt a *gauche*-conformation and give rise to two corner fragments with a sequence of two *gauche*-torsion angles at the C(3) and C(5) atoms and meets with a *cis*-torsion angle at the C(7) atom (Table 2).

Analysis of CSD [18] data for oxonium-containing crown complexes of the composition $[CE \cdot H(H_2O)_n^+ \cdot An]$ (where CE – crown ether, An – halogen-containing anion) reveals that 18C6 and its benzo-, dicyclohexano- and tetracarboxylic derivatives are highly selective for H_3O^+ because of the size and symmetry fit between them, allowing the inclusion of the oxonium ion within the 18-membered crown ether cavity with the formation of three strong OH···O hydrogen bonds [19]. However, both larger and smaller in size macrocycles are capable of accommodating the Eigen core as well. As examples, dibenzo-30C10 simultaneously contains two H_3O^+ cations within the cavity [20], two B15C5 molecules enclose the oxonium cation in a sandwich structure [21] similar to complex **4**, two dibromo-15C5 molecules incapsulate two H_3O^+ cations within sandwich structure [22]. Smaller in size, benzo-15C5 and 12C4 are also capable of fixing the oxonium ion either in a sandwich mode [23] or through an additional contact with the anion [24]. The next in size $[H_2O\cdots H\cdots OH_2]^+$Zundel cation is perfectly displayed on one side of the DB18C6 macrocycle in the DB18C6 oxonium perchlorate trihydrate [25], within 24- and 30-

membered macrocycles [19u] or between two molecules of B15C5, as in bis(B15C5) tetrachloro-aurate(III) oxonium monohydrate [2] and in our complex **3**, while tetrabenzo30C10 excellently stores the Zundel cation within one cavity [7]. On the contrary, the fixation of the $[H_7O_3]^+$ cation by crown ethers is relatively uncommon and only few examples are known so far where $[H_7O_3]^+$ oxonium cations alternate with crown ether in hydrogen-bonded chains with long-range interactions to the anions [2,26] or are encapsulated within the cage formed by two crown molecules [6]. A comparison of novel compounds with the known literary examples shows the reproducibility of the crown ether–oxonium ion supramolecular architecture for 18C6, 15C5 and B15C5. A reliable comparison of subtle effects (hydrogen bond lengths and angles) for these units cannot be made due to the location of the oxonium species on the crystallographic symmetry elements.

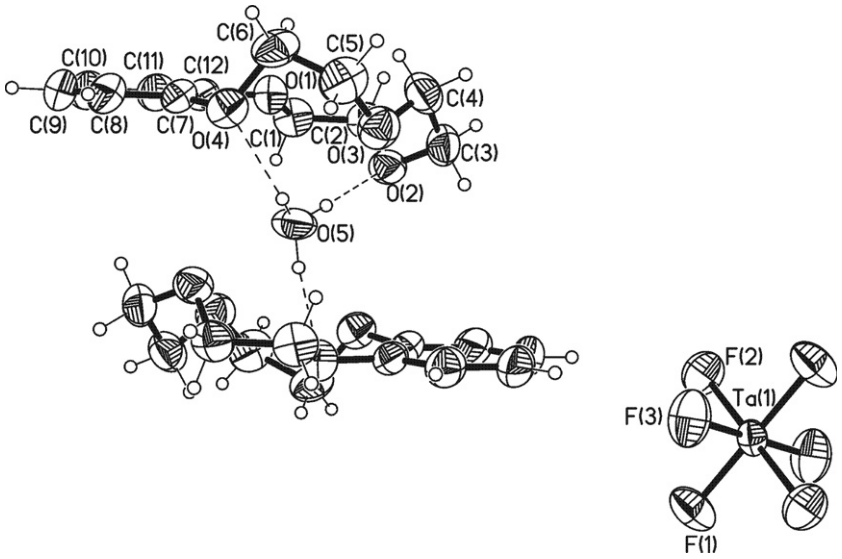

Fig. 4. ORTEP drawing of **5** with the numbering scheme and hydrogen bonding shown by dashed lines. Thermal ellipsoids are shown at the 50% probability level.

The crystal packing in **1**–**5** exhibits common structural features. The all H-bonding coordination abilities of the $[H_3O]^+$ or $[H_5O_2]^+$ cations are used to interact with the crown ether oxygen atoms since both NbF_6^- and TaF_6^- behave as very non-coordinating anions, being much poorer hydrogen bond acceptors than for example $AuCl_4^-$ which contributes to the interactions with oxonium species [2]. The decisive factor in the supramolecular organization are weak CH(crown)···F interactions. Similar to all previously reported complexes of this family [4–7], the crystal packing in **1**–**5** represents an alternation of rows of organic (macrocyclic cations in **1**–**2**, or macrocyclic sandwiches in **3**–**5**) and inorganic (Nb_6^-/TaF_6^- anions) components (Fig. 5), being held together by CH···F interactions. The simplest case of crystal packing is evident for **1**–**2**. For the perfectly regular structure **2**, shown in Fig. 4a, the C(3)H···F(2) contact (H···F 2.61, C···F 3.394(15) Å, CHF angle 138° slightly exceeds the accepted limit (H···Acceptor = 2.6 Å). In **5**, due to the shortest C(1)H···F(1) contact (H···F 2.52, C···F 3.211(5) Å, CHF angle 128°, charged components alternate in the chain. In the layer structure **4** two independent TaF_6^- anions fulfill different structural functions: the $Ta(1)F_6$ anion is located on an inversion center and acts as a bridge between two different macrocyclic sandwiches (**A** and **B**) *via* the F(1) atom, [C(7A)–H(7A1)···F(1)(x, $1-y$, $0.5+z$) 2.55, C···F 3.250(6) Å, CHF angle 129° and C(5B)–H(5B2)···F(1) 2.55, C···F 3.343(6) Å, CHF angle 140°], while the second anion, $Ta(2)F_6$, located on a two-fold axis, bridges only **B** sandwiches *via* C(14B)···F(5) interactions [C(14B)–H(14B)···F(5)(3/2−x, $-0.5+y$, 3/2 − z) 2.54, C···F 3.312(6) Å, CHF angle 141°].

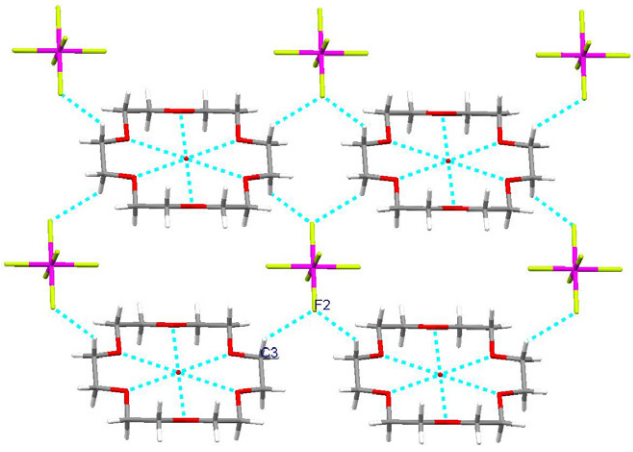

Fig. 5. Fragment of the crystal packing for **2**. Only atoms responsible for short CH···F contacts are labelled.

4. Conclusion

The interaction of Nb_2O_5/Ta_2O_5 or NbF_5/TaF_5 with 18-,15- and 12-membered CEs in the presence of hydrofluoric acid results in complexes of the compositions $[18C6 \cdot H_3O][NbF_6]$ (**1**), $[18C6 \cdot H_3O][TaF_6]$ (**2**), $[15C5 \cdot H_5O_2][TaF_6]$ (**3**) $[(B15C5)_2 \cdot H_5O_2]$ $[(B15C5)_2 \cdot H_3O][TaF_6]_2$ (**4**) and $[(B12C4)_2 \cdot H_3O][TaF_6]$ (**5**). All compounds represent ionic species with direct interactions between the oxonium ion and oxygen atoms of the macrocyclic molecule and a lack of any interactions between the oxonium ion and the anion. According to the X-ray data, the $[H_3O]^+$ oxonium cation centers the 18-membered crown cavity in isostructural complexes **1**–**2**, and bridges two smaller 12-membered macrocycles in **5**. Compound **5** is the first example of an oxonium ion direct interaction with the small B12C4 macrocycle. The crystal **3** contains the $[H_5O_2]^+$ dioxonium cation and alternates with 15C5 molecules in the infinite chains, whereas complex **4** represents a unique example

of the co-existence of both the $[H_3O]^+$ Eigen core and $[H_2O\cdots H\cdots OH_2]^+$ Zundel cations within one structure, both being incorporated in two sandwich-type organized macrocyclic cations. The B15C5 molecules that form these sandwiches differ by their conformations.

Facility, Kochi using a VarioEL III CHNS. The room temperature magnetic susceptibility measurements were carried out in the polycrystalline state on a Vibrating Sample Magnetometer (VSM) at 5.0 kOe field strength at the Indian Institute of Technology, Roorkee, India. Infrared spectral measurements were done on an ABB Bomem FTIR instrument using KBr pellets for spectra in the region 4000–500 cm^{-1}. An Ocean Optics SD 2000 Fiber Optic spectrometer was used to measure solid-state reflectance spectra in the range 200–900 nm. NMR measurements were carried out on a Varian Mercury Plus300 NMR spectrometer using DMSO as the solvent and EPR spectral measurements were carried out on a Varian E-112 X-band spectrometer using TCNE as a standard, at the Sophisticated Analytical Instruments Facility, Indian Institute of Technology, Mumbai, India.

2.3. X-ray crystallography

Single crystal X-ray diffraction measurements were carried out on a Bruker Smart Apex CCD diffractometer equipped with a fine-focused sealed tube. The unit cell parameters were determined and the data collections were performed using a graphite-monochromated Mo Kα ($\lambda = 0.71073$ Å) radiation. The data collected were reduced using the SAINT program [29] and the empirical absorption corrections were carried out using the SADABS program [30]. The trial structure was obtained by direct methods [31] using SHELXS-97, which revealed the position of all non-hydrogen atoms, and was refined by full-matrix least squares on F^2 (SHELXL-97) [32] and the graphics tool used was DIAMOND version 3.0 [33]. All non-hydrogen atoms were refined anisotropically, while the hydrogen atoms were placed in calculated positions and refined as riding atoms.

2.4. Synthesis of ligands

The ligand HL^1 (Fig. 1) was synthesized as follows: ethanolic solutions of cyclohexyl isothiocyanate (0.706 g, 5 mmol) and hydrazine hydrate (0.250 g, 5 mmol) were mixed with constant stirring. The stirring was continued for one more hour and the white product, *N*(4)-cyclohexyl thiosemicarbazide formed was filtered, washed, dried and recrystallized from ethanol. A methanolic solution of *N*(4)-cyclohexyl thiosemicarbazide (0.519 g, 3 mmol) was then refluxed with di-2-pyridyl ketone (0.553 g, 3 mmol) in 5 ml methanol continuously for 4 h after adding a few drops of acetic acid. There was no immediate formation of the product. After refluxing for 6 h continuously, the reaction mixture was kept aside for slow evaporation at room temperature. After one week, needle shaped crystals suitable for single crystal analyses were formed, which were carefully separated. Colour: light yellow, m.p. 104 °C, yield 0.95 g (47%). ^{1}H NMR: δ (ppm) 8.78 (d, C11H), 8.57 (d, C4H), 8.11 (d, C8H and C1H), 7.91 (dt, N4H and N5H), 7.67 (m, C10H and C3H), 7.53 (m, C2H and C9H), 4.14 (m, C13H), 2.07 (m, cyH), 1.29 (m, cyH).

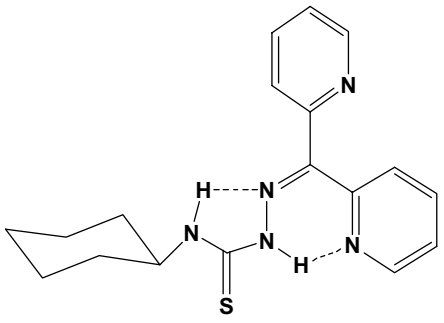

Fig. 1. Structure of the compound HL^1.

Preparation of the ligand HL^2 was done as described previously [34].

2.5. Preparation of the complexes

2.5.1. $CoL^1NCS \cdot 2H_2O$ (**1**)

$Co(OAc)_2 \cdot 4H_2O$ (0.249 g, 1 mmol) dissolved in 10 ml methanol was added to a refluxing methanolic solution of di-2-pyridyl ketone (0.184 g, 1 mmol) and 4-cyclohexyl-3-thiosemicarbazide (0.173 g, 1 mmol). Fifteen minutes later, KSCN (0.097 g, 1 mmol) dissolved in 10 ml of water was added to the reaction mixture and further refluxed for three hours. The product that separated out was collected, washed with ether and dried *in vacuo*. Colour: Brown. Yield: 0.40 g (58%), $\mu_{eff} = 3.23$ BM. Elemental *Anal.* Calc. for **1**: C, 46.43; H, 4.92; N, 17.10. Found: C, 46.31; H, 5.03; N, 17.04%.

2.5.2. $[Co(L^1)_2]ClO_4$ (**2**)

An ethanolic solution of $Co(ClO_4)_2 \cdot 6H_2O$ (0.365 g, 1 mmol) was added to a refluxing methanolic solution of di-2-pyridyl ketone (0.184 g, 1 mmol) and 4-cyclohexyl-3-thiosemicarbazide (0.173 g, 1 mmol) and further refluxed for 3 h. The resulting precipitate was washed with ether and dried over P_4O_{10} *in vacuo*. Colour: Brown. Yield: 0.35 g (49%). Elemental *Anal.* Calc. for **2**: C, 49.62; H, 5.09; N, 16.08. Found: C, 49.83; H, 4.95; N, 16.24%. ^{1}H NMR: δ (ppm) 8.76 (d, C11H), 8.54 (d, C4H), 7.88 (t, N5H), 7.81 (d, C8H and C1H), 7.72 (m, C2H, C3H, C9H and C10H), 4.23 (m, C13H), 2.01 (m, cyH), 1.25 (m, cyH).

2.5.3. $CoL^2Cl \cdot 2H_2O$ (**3**)

$CoCl_2 \cdot 6H_2O$ (0.237 g, 1 mmol) in 15 ml of ethanol was added to an ethanolic solution of HL^2 (0.317 g, 1 mmol) and refluxed for 4 h. The crystalline product that separated out was filtered and washed with ether and dried over P_4O_{10} *in vacuo*. Colour: Brown. Yield: 0.36 g (65%), $\mu_{eff} = 3.23$ BM. Elemental *Anal.* Calc. for **3**: C, 46.71; H, 3.92; N, 15.13. Found: C, 46.83; H, 4.11; N, 15.40%.

2.5.4. $[Co(L^2)_2]NO_3 \cdot 3H_2O$ (4)

A solution of $Co(NO_3)_2 \cdot 6H_2O$ (0.291 g, 1 mmol) in 10 ml of ethanol was added to HL^2 (0.317 g, 1 mmol) and refluxed for 6 h. The resulting precipitate was washed with ether and dried over P_4O_{10} *in vacuo*. Colour: Light brown. Yield: 0.32 g (52%). Elemental *Anal.* Calc. for **4**: C, 51.49; H, 4.08; N, 18.35. Found: C, 51.61; H, 3.98; N, 18.53%. ^{1}H NMR: δ (ppm) 10.65 (s, N5H), 8.72 (d, C11H), 8.50 (d, C4H), 8.29 (d, C8H and C1H), 7.80 (m, C14H and C18H), 7.68 (m, C2H, C3H, C9H and C10H), 7.46 (m, C15H and C17H), 7.26 (m, C16 H).

2.5.5. $CoL^2(NCS)_2 \cdot 3H_2O$ (5)

For the preparation of compound **5**, 1 mmol of $Co(OAc)_2 \cdot 4H_2O$ (0.249 g) dissolved in ethanol (15 ml) was added to an ethanolic solution of HL^2 (0.317 g, 1 mmol) and refluxed. An aqueous solution of KSCN (0.097 g, 1 mmol) was then added to the solution which was further refluxed for 3 h. The product that separated out was collected, washed with ether and dried *in vacuo*. Colour: Dark brown. Yield: 0.38 g (55%), Elemental *Anal.* Calc. for **5**: C, 42.78; H, 3.59; N, 17.46. Found: C, 42.89; H, 3.62; N, 16.98%. ^{1}H NMR: δ (ppm) 8.82 (d, C11H), 8.58 (d, C4H), 7.82 (m, PyH), 7.75 (t, N5H), 7.56 (m, Phenyl H).

2.5.6. $CoL^2Br_2 \cdot 4.5H_2O$ (6)

HL^2 (0.317 g, 1 mmol) was dissolved in ethanol (15 ml) and refluxed with $CoBr_2$ (0.218 g, 1 mmol) dissolved in 10 ml of hot water. The product that separated out was collected, washed with ether and dried *in vacuo*. Colour: Light brown. Yield: 0.31 g (55%). Elemental *Anal.* Calc. for **6**: C, 34.20; H, 3.67; N, 11.08. Found: C, 34.53; H, 3.51; N, 10.71%. ^{1}H NMR: δ (ppm) 10.50 (s, N5H), 8.68 (d, C11H), 8.49 (d, C4H), 7.84 (m, PyH), 7.64 (d, C14H and C18H), 7.45 (m, C15H, C16H and C17H).

3. Results and discussion

3.1. Synthesis of compounds

X-ray quality single crystals of HL^1 were isolated from a methanolic solution of the compound. In the complexes **1** and **3**, the cobalt revealed the +2 oxidation state, while in compounds **2**, **4**, **5** and **6**, it showed the +3 oxidation state. In compound **2**, the Co^{3+} nucleus appeared to be six-coordinated with two anionic ligand moieties, whereas a perchlorate ion remained outside the coordination sphere. This stoichiometry was in accordance with the elemental analyses results. The molar conductivity value was measured to be 60.23 $ohm^{-1}\,cm^2\,mol^{-1}$ in DMF, which was in the expected range for 1:1 electrolytes [35]. For compound **4**, a possible stoichiometry with two anionic ligand units coordinated to the metal centre along with a nitrate group in the outer sphere was suggested by the elemental analyses, and the molar conductivity value was measured to be 50.08 $ohm^{-1}\,cm^2\,mol^{-1}$ in DMF. Co(II) complexes **1** and **3** were observed to show a 1:1:1 ratio of metal:thiosemicarbazone:gegenion, with the general formula $Co(L)X \cdot 2H_2O$ [X = NCS when HL = HL^1 and X = Cl when HL = HL^2]. Co(III) complexes **2** and **4** possess the metal:thiosemicarbazone:gegenion ratio of 1:2:1, with the general formula $Co(L)_2X \cdot yH_2O$ [X = ClO_4, $y = 0$ when HL = HL^1 and X = NO_3 $y = 3$ when HL = HL^2], while compounds **5** and **6** revealed the metal:thiosemicarbazone:gegenion ratio as 1:1:2, with the general formula $CoL(X)_2 \cdot yH_2O$ [X = NCS, $y = 3$ when HL = HL^1 and X = Br, $y = 4.5$ when HL = HL^2].

3.2. Crystal structure of HL^1

The molecular structure of HL^1, along with the atom numbering scheme is given in Fig. 2. The crystal data and structural refinement parameters are given in Table 1 and selected bond lengths and angles are given in Table 2. The compound crystallized into a monoclinic lattice with the space group $P2_1$. The molecule exists in the *Z* conformation with respect to the C6–N3 bond. However, the S1 and N3 atoms are in the *E* conformation with respect to the N4–C12 bond, and hence the thiosemicarbazone moiety as a whole exists in the *ZE* conformation. This is contrary to the observations in 3-piperidyl and 3-hexamethyliminyl-di-2-pyridyl ketone thiosemicarbazones [27], which revealed a *ZZ* conformation for the thiosemicarbazone moiety. However, *N*4-methyl-di-2-pyridyl ketone thiosemicarbazone was observed to be in the *ZE* conformation [28]. In HL^1, the thiosemicarbazone moiety comprising of atoms N3, N4, C12, S1 and N5 is almost planar, with a maximum mean plane deviation of 0.0375(1) Å. A torsion angle of 175.21(16)° corresponding to the S1–C12–N4–N3 moiety implies a trans alignment of the thiocarbonyl S1 atom in HL^1. The azomethine bond, C6–N3 (1.297(3) Å) is in conformity with a formal C=N double bond (1.28 Å) and the C12–S1 bond distance of

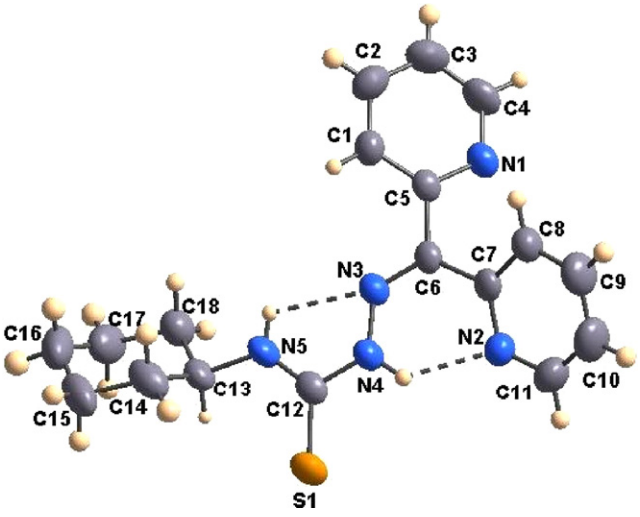

Fig. 2. Molecular structure of HL^1. Ellipsoids are drawn at 50% probability and intramolecular hydrogen bonding interactions are shown as dashed lines.

1.672(2) Å, is very close to a formal C=S bond length (1.60 Å) [36]. It confirms the existence of the thiosemicarbazone in the thione form in the solid state. The N3–N4 (1.359(3)) and N4–C12 (1.372(3)) bond distances in HL^1 are intermediate between formal single or double N–N and C–N bonds, giving evidence for an extended π delocalization along the thiosemicarbazone chain. Interestingly, the hydrogen bonding interactions by N2 and the resultant increased electron density on the ring imparts slight deviations in the C–C bond distances of the corresponding atoms in the two pyridyl rings. Mean plane deviation calculations showed that the lowest deviation exists between the pyridyl ring Cg(1) comprising of atoms N1, C1, C2, C3, C4 and C5, and the thiosemicarbazone moiety (atoms N3, N4, C12, S1 and N5) with a dihedral angle of 38.34° between the planes. The intramolecular hydrogen bonding interaction, N5–H5A–N3, lead to the formation of one five-membered ring comprising of atoms N3, N4, C12, N5 and H5A. Ring puckering analyses and least square planes calculations show that the cyclohexyl ring, Cg(3), adopts a chair conformation ($Q_T = 0.5422$ Å). The molecular packing of HL^1 is shown in Fig. 3. The unit cell is viewed down the '*a*' axis. Each molecule gets repeated in a one-dimensional manner in the crystal lattice, and these one-dimensional arrays are aligned in an offset manner, which effects a two-dimensional zig-zag packing in the unit cell. The π–π, C–H–π and hydrogen bonding interactions were observed to be rather weak in the crystal lattice.

Table 2
Selected bond lengths (Å) and bond angles (°) of HL^1

Bond distance	HL^1	Bond angle	HL^1
C6–N3	1.297(3)	C7–C6–C5	119.22(18)
N3–N4	1.359(3)	C5–C6–N3	113.83(18)

C6–C7	1.478(3)	C12–N5–C13	126.9(2)
C5–C6	1.489(3)		

3.3. IR and electronic spectra

The infrared spectral data of the ligand HL^1 was observed to be in conformity with the structural results. The compound exhibits a few weak discrete bands at 3749, 3646 and 3326 cm^{-1} possibly due to the association of the thioamide groups in different molecules. The –NH stretching vibrations at $N(4)$ can also give rise to bands around 3300 cm^{-1}. The –CH stretching vibrations of the cyclohexyl moiety are observed as two sharp bands at 2929 and 2850 cm^{-1}. The absence of any bands in the 2800–2550 cm^{-1} region reveals the presence of only the thione tautomer in the solid state, due to the lack of –SH stretching absorptions in that region. The ν(C=N) vibrations are observed at 1585 cm^{-1}. The N–H bending and C–N stretching vibrations of the thioamide function give rise to weak bands at 1563 and 1547 cm^{-1} and the ν(CS) and δ(CS) vibrations are observed at 1323 and 801 cm^{-1}. In the complexes, a medium band centred around 3200 cm^{-1} is consistent with the lattice water content in the samples, while a weak band around 3050 cm^{-1} can be assigned to the ν(NH) vibration at the N(4)–H position. The cyclohexyl stretching vibrations appear as two sharp bands at 2929 and 2852 cm^{-1}. In compound **1**, a sharp band at 2067 cm^{-1} is characteristic of the N-coordinated thiocyanate group in the compound, and the unsplit attribute of the band is in accordance with the presence of a single thiocyanate species. Support for the non-coordinated nature of the perchlorate ion in compound **2** is provided by an unsplit band at 1082 cm^{-1} and a sharp band at 622 cm^{-1}, which are assigned to the $\nu_3(ClO_4)$ and $\nu_4(ClO_4)$ vibrations of the free perchlorate anion [37,38]. The IR spectrum of compound **4** reveals an unsplit sharp band at 745 cm^{-1}, a characteristic in-plane bending vibration band (ν_4) of the free nitrate ion [37]. Upon coordination, the ν_4 band is expected to split into two bands, the lack of which supports the non-coordinated nature of the nitrato ion in the compound. For compound **5**, the elemental analyses data suggest a Co^{3+} metal centre with two thiocyanate groups in the molecule. Interestingly, the IR spectrum supports this stoichiometry with a characteristic strong band split into two at 2048 and 2089 cm^{-1}, corre-

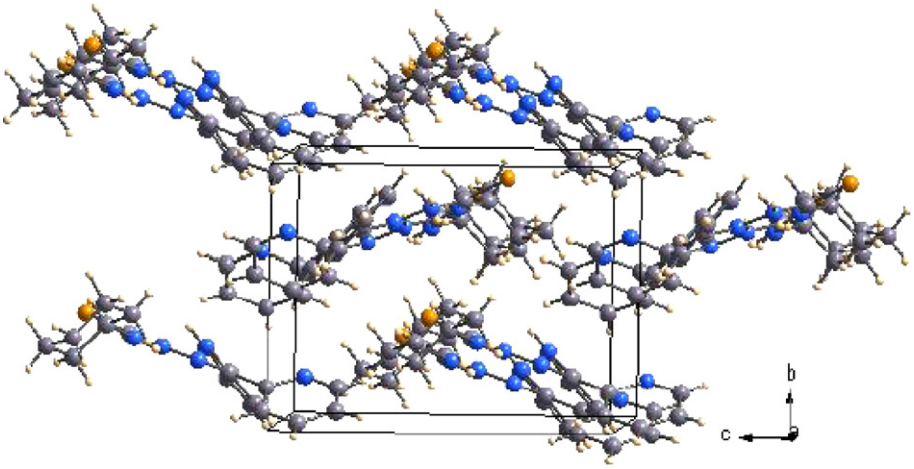

Fig. 3. Molecular packing diagram of HL^1, the unit cell is viewed down the '*a*' axis.

sponding to the possible presence of more than one thiocyanate group. Another weak split is also observed in the band at 2156 cm^{-1}. These support the proposed stoichiometry of the compound and also suggest that the thiocyanate groups are N-bonded to the metal centre, since the characteristic bands are observed near or below 2150 cm^{-1} [37]. The ν(CoBr) vibrations of the terminal bromine groups appear at 274 cm^{-1} in compound **6**. In all the complexes, the azomethine vibration bands are shifted in the range 8–40 cm^{-1} as a result of coordination. The newly formed N=C bond due to enolization of the ligands resonates near 1590 cm^{-1} in the complexes. The thiolate bending bands in the complexes are observed near 750 cm^{-1}, which are also shifted from the corresponding value in the ligand, due to coordination. The solid-state reflectance spectrum of HL^1 reveals the $\pi \rightarrow \pi^*$ transitions of the pyridyl ring and the thiosemicarbazone imine function at 263 and 291 nm. The $\pi \rightarrow \pi^*$ transitions of the thiocarbamide group and the $n \rightarrow \pi^*$ transition of the pyridine ring are observed at 364 and 384 nm respectively. In the electronic spectra of the complexes, the intraligand transitions are slightly shifted as a result of coordination. The d−d transitions are rather weak, appearing as shoulders near 500 nm. The electronic spectral details of the complexes are given in Table 3.

3.4. Nuclear magnetic resonance studies

The ^1H NMR studies of HL^1 and the diamagnetic complexes were carried out and interpreted based on the atom labelling in Figs. 2 and 4. The spectrum of HL^1 reveals two doublets at δ 8.78 and 8.57 ppm corresponding to protons at C11 and C4, respectively. The electronic effect of the adjacent pyridyl nitrogens shifts the signals to lower field and the more downfield shift of C11 H can be attributed to the increased charge density on the hydrogen bonded N2 [39]. A doublet at δ 8.11 ppm corresponds to the protons on C1 and C8, while two multiplets at δ 7.67 and 7.53 ppm belong to the other pyridyl protons. The proton resonances on the electronegative N4 and N5 atoms appear as a doublet of triplets at 7.91 ppm due to quadrupole splitting. The cyclohexyl proton C13 H is deshielded by the adjacent electronegative nitrogen, resulting in a multiplet at δ 4.14 ppm. The cyclohexyl moiety exists in the chair conformation, and the equatorial protons are observed at more downfield values ($\delta = 2.07$ ppm) compared to their axial counterparts ($\delta = 1.29$ ppm). The ^1H NMR spectra of the complexes reveal that the resonance peaks are shifted from their corresponding values in the ligand, as a result of coordination. However, the protons on the phenyl and cyclohexyl rings, which do not take part in coordination, remain more or less unchanged in the complexes, even if there are slight variations in their resonances due to the delocalisation of electron density in the system. The NMR spectra of the complexes are less resolved than that of the ligands, perhaps due to the low solubility of the complexes. For instance, the alpha proton in the pyridyl rings is clearly resolved in the spectra of the complexes, whereas some aromatic proton resonances appear as

Table 3

multiplets, making it difficult to distinguish the individual proton resonances. The NMR assignments are given in Section 2.5.

3.5. Magnetic and EPR studies

Room temperature magnetic susceptibility studies reveal complexes **1** and **3** to be paramagnetic, with μ_{eff} values of 3.23 and 3.52 BM, respectively. The observed magnetic moments are much lower than that expected of four coordinate Co(II) tetrahedral complexes (4.4–4.8 BM) [40,41]. This suggests a possible tendency towards a square planar geometry in the complexes, which is further supported by the EPR studies. The X-band EPR spectrum of $CoL^1NCS \cdot 2H_2O$ (**1**) in DMSO at 77 K is given in Fig. 5. The spectrum reveals axial features with the g values, $g_{\parallel} = 2.299$ and $g_{\perp} = 1.996$. The Co(II) nucleus has a nuclear spin of 7/2 and hence eight hyperfine lines are expected in the EPR spectrum in the frozen state. The hyperfine splittings are more clearly resolved in the perpendicular region. It should be noted that the EPR spectrum at 77 K reveals that $g_{\parallel} > g_{\perp}$, which is characteristic of four coordinate square planar complexes. The magnetically dilute disposition observed in EPR spectrum denotes that the bridging interactions are weakened in the frozen state at 77 K. The EPR spectrum of the compound $CoL^2Cl \cdot 2H_2O$ (**3**) in DMSO at 77 K is given in Fig. 6, which reveals features similar to that of the compound $CoL^1NCS \cdot 2H_2O$. The spectrum appears to be axial with two g values, $g_{\parallel} = 2.282$ and $g_{\perp} = 1.994$, and it should be noted that in compound **3** also, the hyperfine splittings are more clearly resolved in the perpendicular region.

thiazoline (TnInA). The characterization of these complexes has been carried out by means of elemental analysis, IR and X-ray diffraction. The cobalt complexes have also been characterized through UV–VIS-NIR diffuse reflectance and magnetic susceptibility measurements and the zinc complexes through ^{1}H NMR and ^{13}C NMR spectroscopy.

2. Experimental

2.1. Synthesis of 2-(indazol-1-yl)-2-thiazoline (TnInA)

This ligand was synthesized according to the method described previously [9]. ^{1}H NMR (DMSO): δ 8.41 (s, 1H), 8.36 (d, $J = 8.4$ Hz, 1H), 7.88 (d, $J = 8.4$ Hz, 1H), 7.59 (t, $J = 7.7$ Hz, 1H), 7.36 (t, $J = 7.8$ Hz, 1H), 4.39 (t, $J = 8.0$ Hz, 2H), 3.48 (t, $J = 8.2$ Hz, 2H); ^{13}C NMR (DMSO): δ 158.0, 138.8, 138.4, 129.1, 125.9, 124.0, 121.8, 114.0, 62.0, 32.9. *Anal.* Calc. for $C_{10}H_9N_3S$: C, 59.09; H, 4.46; N, 20.67; S, 15.77. Found: C, 59.45; H, 4.83; N, 20.22; S, 15.43%. UV–Vis (EtOH): λ_{max}, nm; (ε, L mol^{-1} cm^{-1}) 232 (26000), 295 (9248), 306 (9585).

2.2. Synthesis of the complexes

Metal complexes were prepared by reacting an ethanol solution (1 mL) of the metal(II) salt (chloride or nitrate) (0.5 mmol) with an ethanol solution (15 mL) of the ligand (100 mg, 0.5 mmol). Upon evaporation solid precipitates were obtained. The solids were filtrated and washed with cold ether and finally air-dried.

2.2.1. $[CoCl_2(TnInA)_2]\cdot C_2H_6O$ (1)

Yield: 51.8 mg, 36.2%. X-ray quality red crystals were grown by slow evaporation from an EtOH solution. *Anal.* Calc. for $C_{20}H_{18}Cl_2CoN_6S_2\cdot C_2H_6O$: C, 45.36; H, 4.15; N, 14.43; S, 11.01. Found: C, 45.06; H, 4.22; N, 14.35; S, 10.94%.

2.2.2. $[ZnCl_2(TnInA)]$ (2)

Yield: 68.7 mg, 38.9%. ^{1}H NMR (DMSO): δ 8.40 (s, 1H), 8.34 (d, $J = 8.0$ Hz, 1H), 7.87 (d, $J = 8.0$ Hz, 1H), 7.58 (t, $J = 7.6$ Hz, 1H), 7.36 (t, $J = 7.4$ Hz, 1H), 4.38 (t, $J = 8.2$ Hz, 2H), 3.47 (t, $J = 8.4$ Hz, 2H); ^{13}C NMR (DMSO): δ 158.1, 138.9, 138.5, 129.3, 126.0, 124.1, 121.9, 114.1, 62.1, 33.0. *Anal.* Calc. for $C_{10}H_9Cl_2ZnN_3S\cdot 0.75H_2O$: C, 34.11; H, 3.01; N, 11.93; S, 9.11. Found: C, 34.14; H, 2.90; N, 11.54; S, 9.17%. UV–Vis (EtOH): λ_{max}, nm; (ε, L mol^{-1} cm^{-1}) 232 (28756), 294 (13093), 306 (10861).

2.2.3. $[Co(TnInA)_2(H_2O)_2](NO_3)_2$ (3)

Yield: 77.3 mg, 50.3%. By means of slow evaporation of the ethanol solution at room temperature, red crystals were isolated. *Anal.* Calc. for $C_{20}H_{22}CoN_8O_8S_2$: C, 38.40; H, 3.54; N, 17.92; S, 10.25. Found: C, 38.18; H, 3.37; N, 17.56; S, 9.92%.

2.2.4. $[Zn(TnInA)_2(H_2O)_2](NO_3)_2$ (4)

Yield: 53.8 mg, 34.6%. By means of slow evaporation of the ethanol solution at room temperature, colourless crystals were isolated. ^{1}H NMR (DMSO): δ 8.41 (s, 1H), 8.34 (d, $J = 8.2$ Hz, 1H), 7.88 (d, $J = 8.2$ Hz, 1H), 7.58 (t, $J = 7.7$ Hz, 1H), 7.36 (t, $J = 7.6$ Hz, 1H), 4.37 (t, $J = 7.8$ Hz, 2H), 3.47 (t, $J = 6.8$ Hz, 2H); ^{13}C NMR (DMSO): δ 158.2, 139.0, 138.6, 129.4, 126.1, 124.2, 122.0, 114.2, 62.1, 33.1. *Anal.* Calc. for $C_{20}H_{22}ZnN_8O_8S_2$: C, 38.02; H, 3.51; N, 17.73; S, 10.13. Found: C, 37.76; H, 3.62; N, 17.52; S, 10.39%. UV–Vis (EtOH): λ_{max}, nm; (ε, L mol^{-1} cm^{-1}) 232 (17276), 295 (6924), 306 (6282).

2.3. Instrumental procedures

The carbon, hydrogen, nitrogen and sulfur contents of the compounds were determined on a Leco CHNS-932 microanalyser. IR spectra were recorded on a Perkin–Elmer FT-IR 1720 spectrophotometer, from KBr pellets in the 4000–370 cm^{-1} range and on a Perkin–Elmer FT-IR 1700X spectrophotometer, from polyethylene pellets in the 500–150 cm^{-1} range. Electronic spectra in solution of the ligand and the zinc complexes were measured on a Shimadzu UV-3101 PC using a 10 mm quartz cell. Solid state electronic spectra for the cobalt complexes in the 200–1500 nm range were obtained from pellets of the samples, using a Shimadzu UV-3101 PC spectrophotometer and $BaSO_4$ as a reference. Magnetic susceptibility measurements were performed on polycrystalline samples using a magnetometer with a pendulum MANICS DSM8, equipped with a helium continuous-flow cryostat and an electromagnetometer DRUSCH EAF 16 UE. Data were corrected for temperature independent paramagnetism and diamagnetic contributions, which were estimated from the Pascal constants. ^{1}H (400 MHz) and ^{13}C NMR (100 MHz) spectra were recorded in DMSO on a Bruker AM 400 instrument.

2.4. Crystal structure determinations

Experimental details of crystal structure determinations including crystal data, data collection, structure determinations and refinement parameters for **1**, **3** and **4** are listed in Table 1. X-ray diffraction measurements were performed using a Bruker SMART CCD diffractometer equipped with graphite-monochromated Mo-Kα radiation ($\lambda = 0.71073$ Å) for **1** and **3** and an Enraf Nonius CAD4 diffractometer equipped with graphite-monochromated Cu-Kα radiation ($\lambda = 1.5418$ Å) for **4**. The intensity data were collected using the ϕ-ω scan technique (**1**, **3**) and ω-2θ scan technique (**4**). Empirical absorption corrections were applied using the SADABS [10] program for the cobalt complexes whereas semi-empirical absorption corrections were made based on the psi-scan application using the WINGX [11] package for **4**. The structures were solved by direct methods and subsequent Fourier differences using the programs SHELXS-86 [12] and SHELXS-97 [13] and refined

by full-matrix least-squares on F^2 with SHELXL-97 [14], included in the WINGX package [11]. All non-hydrogen atoms were refined with anisotropic displacement parameters. Hydrogen atoms attached to carbon and nitrogen atoms were positioned geometrically, with U_{iso} values derived from U_{eq} values of the corresponding carbon and nitrogen atoms. However, hydrogen atoms of the water molecules were detected by Fourier differences and were refined with fixed O–H and H–H distances (0.957(3) and 1.513(3) Å, respectively). The final electron density map for compound **1** contained various electron density peaks clustered in one region of the unit cell. These could not sensibly be resolved into a molecule and presumably represent a severely disordered solvent molecule. Despite exhaustive attempts at modelling this severely disordered solvent molecule, satisfactory solutions were not obtained and a diffuse solvent correction was applied using the SQUEEZE routine in PLATON [15]. The unit cell contains four cavities centered at (1/2, 1/7, 3/4), (0, 5/14, 1/4), (0, 9/13, 3/4) and (1/2, 6/7, 1/4), filled with disordered solvent, probably ethanol. The volume of each cavity is 82.7 Å^3, with a total of 25 electrons, corresponding to approximately one ethanol molecule per cavity.

3. Results and discussion

3.1. Crystal structure of the complex $[CoCl_2(TnInA)_2] \cdot C_2H_6O$ (1)

The X-ray study of **1** reveals that the crystals are made up of monoclinic cells, each one containing four complex molecules and four solvent ethanol molecules. Solvent molecules were disordered and included in the model using the SQUEEZE procedure [15]. A molecular view of the complex together with the atom numbering scheme is shown in Fig. 1, and selected bond lengths and angles are given in Table 2.

The complex molecule possesses a non-crystallographic C_2 symmetry, with the twofold axis being coincident with the bisector of the Cl–Co–Cl(a) angle. This arrangement results in the cis geometry.

The environment around the cobalt(II) atom may be described as a distorted octahedral geometry with the metal coordinated to two chlorine atoms [Co–Cl = 2.396(1) Å], two thiazoline nitrogen atoms [Co–N(1) = 2.184(1) Å] and two indazole nitrogen atoms [Co–N(3) = 2.119(1) Å]. The ligand–metal–ligand bite angles differ from the ideal value of 90°, varying between 74.6(1)° and 102.6(1)°.

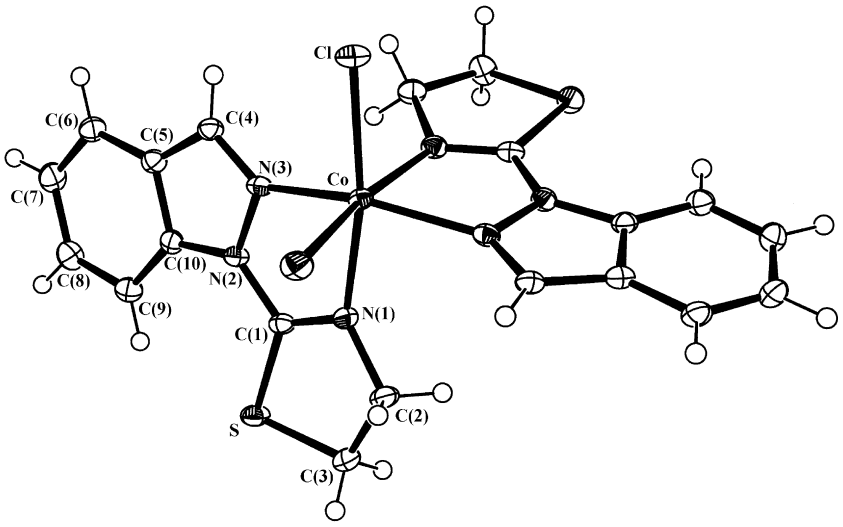

Fig. 1. Molecular structure of **1**, showing the atom-numbering scheme. The thermal ellipsoids are plotted at the 50% probability level.

The Co–Cl bond distance is comparable with the calculated average value [2.446(80) Å] for 51 six-coordinate cobalt(II) chloro-complexes with a chromophore group CoN_4Cl_2, obtained using the CONQUEST software [16] from the Cambridge Structural Database (CSD, Version v5.28, May 2007) [8]. Likewise, the Co–$N_{indazole}$ bond length is similar to those found in bis(hydrotris(indazol-1-yl)borato)-cobalt(II) chloroform solvate (1/3.5) (2.116 Å) [17], but somewhat shorter than those observed in hydrogen-tris(7-methylindazol-2-yl)borate–hydrogen-tris(3-neopentylpyrazol-1-yl) borate–cobalt (2.236 Å) [18]. The Co–$N_{thiazoline}$ bond distance is longer than that found in catena-(hexakis (μ_2-azido-*N*,*N*)-tris-2,2′-bithiazolinyl-*N*,*N*′)-tri-cobalt(II) (2.151 Å) [19], $[Co(NO_3)(PyTT)_2(H_2O)]NO_3$ (2.059 Å; 2.074 Å) [20] and $[CoCl_2(PyTn)_2]\cdot 2H_2O$ (2.097 Å) [21].

The chelate ring Co–N(1)–C(1)–N(2)–N(3) shows a conformation near to half-chair, as indicated by the parameters calculated according to Cremer and Pople [$q = 0.107$ Å; $\phi = 15.4°$] [22], with the atoms Co and N(1) deviating by −0.114 and 0.089 Å, respectively, above the plane formed by C(1), N(2) and N(3).

The thiazoline ring shows an intermediate form between envelope and half-chair with the C(2) and C(3) atoms deviating by −0.100 Å and 0.131 Å, respectively, above the plane formed by S, C(1) and N(1). This geometry is proved by the puckering parameters $q = 0.142$ Å and $\phi = 312.2°$ [22].

*3.2. Crystal structures of the complexes [(Co or Zn)(TnInA)$_2$(H$_2$O)$_2$](NO$_3$)$_2$ (**3**, **4**)*

Complex **3** crystallizes into monoclinic unit cells, each one containing two $[Co(TnInA)_2(H_2O)_2]^{2+}$ cations and four nitrate anions held by a two-dimensional hydrogen bonding network. The overall view and labelling of the atoms of the complex cation are displayed in Fig. 2. Table 2 lists the selected bond lengths, angles and hydrogen-bond parameters.

As can be observed in Fig. 2, the complex cation possesses a C_i symmetry, with an inversion centre at the cobalt atom. This arrangement results in the N(1) and N(3) atoms being cis to each other whereas the O(1W) atoms are trans. The environment around the cobalt(II) atom may be described as a distorted octahedral geometry with the ligand–metal–ligand bite angles varying between 76.9(1)° [N(1)–Co–N(3)] and 103.1(1)° [N(1a)-Co–N(3)]. The metallic atom is coordinated by two thiazoline nitrogen atoms [Co–N(1) = 2.101(1) Å], two indazole nitrogen atoms [Co–N(3) = 2.134(1) Å] and two oxygen atoms from two water molecules [Co–O(1W) = 2.056(1) Å].

The $Co–O_{water}$ bond distance is shorter than the mean value [2.099(49) Å] calculated using the data of 84 six-coordinate cobalt(II) aqua-complexes with an N_4O_2 environment in the CSD [8]. The $Co–N_{thiazoline}$ and $Co–N_{indazole}$ bond lengths are similar to those observed in complex **1**.

The chelate ring Co–N(1)–C(1)–N(2)–N(3) is essentially planar with a maximum mean plane deviation for N(1) (0.038 Å). However, the thiazoline ring shows an intermediate conformation between envelope and half-chair with the apex at C(3), deviating 0.441 Å from the mean plane formed by Co, N(1), C(1) and N(2). This geometry is proved by the puckering parameters $q = 0.278$ Å and $\phi = 321.9°$ [22].

The crystal structure presents a two-dimensional hydrogen-bonding network perpendicular to the a axis, in which oxygen atoms O(1) and O(2) from nitrate groups act as acceptors of hydrogen, whereas water molecules act as donors. A diagram showing this network is given in Fig. 3.

Complexes **3** and **4** are isostructural, crystallizing in the monoclinic system with the same space group, comparable cell dimensions and similar internal atomic coordinates. This fact is common enough among Co(II) and Zn(II) coordination compounds, as indicated in a Ref. [23]. Thus the complex cation of **4** shows a six-coordinated environment around zinc(II) with two oxygen atoms from two water molecules [Zn–O(1W) = 2.099(2) Å], two thiazoline nitrogen atoms [Zn–N(1) = 2.085(2) Å] and two indazole nitrogen atoms [Zn–N(3) = 2.185(2) Å]. The overall view and labelling of the atoms of the complex are displayed in Fig. 4. Table 2 lists the selected bond lengths, angles and hydrogen-bond parameters. The disposition of the six donor atoms is described as a distorted octahedron with a C_2 symmetry, with the twofold axis going through the zinc atom and being coincident with the Zn–O(1W) bond. The ligand–metal–ligand bite angles vary between 76.9(1)° [N(1)–Zn–N(3)] and 103.1(1)° [N(1a)–Zn–N(3)].

The $Zn–O_{water}$ bond distance is shorter than the average value [2.16(10) Å] obtained using the data of 58 six-coordinate zinc(II) complexes with an N_4O_2 environment in the CSD [8]. The $Zn–N_{indazole}$ bond length is similar to those found in bis(hydrotris(indazol-1-yl)borato)-zinc(II) dioxane solvate (1/3.5) (2.154 Å) [17]. The $Zn–N_{thiazoline}$ bond distance is similar to that found in Micacocidin A [2.050 Å] [24], [$ZnCl_2$(TdTn)] (TdTn = 2-(3,4-dichlorophenyl)imino-*N*-(2-thiazolin-2-yl)thiazolidine) [2.022 Å] [25], [$ZnCl_2$(PyTT)] (PyTT = 2-(2-pyridyl)imino-*N*-(2-thiazolin-2-yl)thiazolidine) [2.021 Å] [26] and [$ZnCl_2$(TzHy)] (TzHy = (4,5-dihydro-1,3-thiazol-2-yl)hydrazine) [2.029 Å] [27].

The chelate ring Zn–N(1)–C(1)–N(2)–N(3) is essentially planar with a maximum mean plane deviation for N(3) (0.032 Å). However, the thiazoline ring shows an intermediate conformation between envelope and half-chair with the apex at C(3), deviating 0.380 Å from the mean plane formed by Zn, N(1), C(1) and N(2). This geometry is proved by the puckering parameters $q = 0.240$ Å and $\phi = 322.7°$ [22].

The crystal structure presents a two-dimensional hydrogen-bond network perpendicular to the a axis, in which oxygen atoms O(1) and O(3) from nitrate groups act as acceptors of hydrogen, whereas water molecules act as donors. A diagram showing this network is given in Fig. 5.

Finally, it should be pointed out that the main difference in all the complexes with respect to the structure of free TnInA is due to the different degree of rotation of the thiazoline ring around the C(1)–N(2) bond, which permits coordination through N(1) [torsion angle N(1)–C(1)–N(2)–N(3) = −4.5° in **1**; −4.5° in **3**; 2.4° in **4**; −176.9° in TnInA].

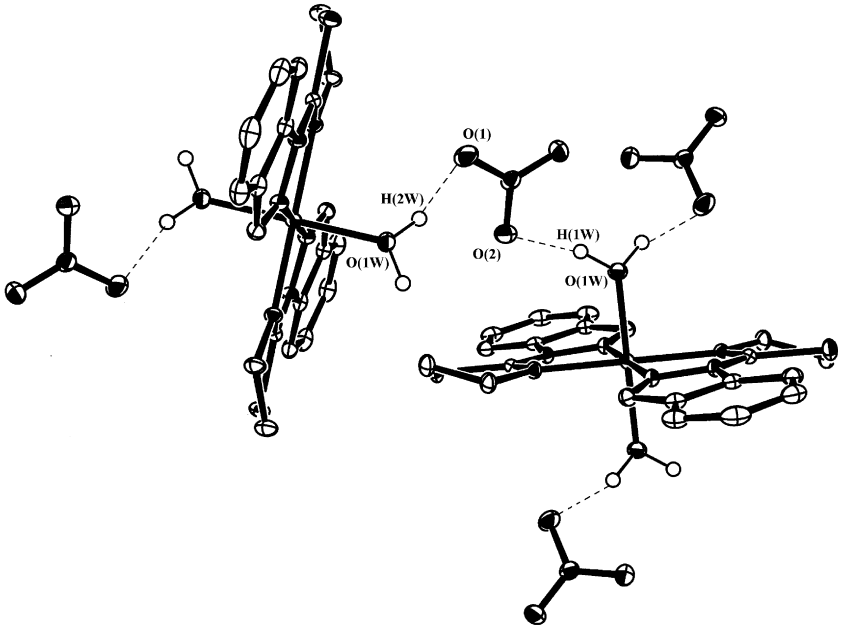

Fig. 3. View of the hydrogen bonds network of **3**.

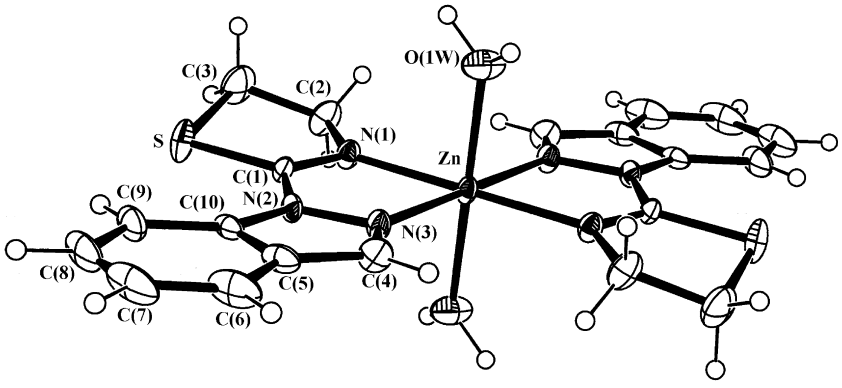

Fig. 4. Molecular structure of the cationic complex $[Zn(TnInA)_2(H_2O)_2]^{2+}$ of **4**, showing the atom-numbering scheme. The thermal ellipsoids are plotted at the 40% probability level.

3.3. Spectroscopic properties

A comparative study of the IR spectral data of the complexes with the uncomplexed ligand [9] provide meaningful information regarding the bonding sites of the primary ligand molecule. Thus, it can be observed in all the complexes that the bands assigned to the ν(C=N) vibration of the indazole ring and the in-plane stretching vibrations corresponding to ν(C=N) skeletal vibrations of the heterocyclic rings (W_1) suffer a negative shift when compared with that for the uncoordinated ligand (Table 3). This feature is indicative of coordination through the indazole and thiazoline nitrogen atoms [9,28–30].

In addition, the peaks centered at 3197 cm^{-1} in the IR spectra of complex **3**, and at 3256 cm^{-1} in the IR spectra of complex **4** are attributed to the ν(O–H) vibration of coordinated water molecules [31].

Moreover, according to the method of Lever and coll. [32], the bands registered at 1750 cm^{-1} (for **3**) and 1749 cm^{-1} (for **4**) are assigned to ($\nu_1 + \nu_4$) combination bands of the ionic nitrate group. Other bands due to the nitrate ion group are registered at 1386 cm^{-1} (ν_3), 1040 cm^{-1} (ν_1) and 829 cm^{-1} (ν_2) for **3** and at 1392 cm^{-1} (ν_3), 1041 cm^{-1} (ν_1) and 829 cm^{-1} (ν_2) for **4** [31–33].

The appearance of the new bands at low frequencies can be assigned to ν(M-ligand) modes. Tentative assignments are listed in Table 4. Thus, in the Co(II) spectra the $\nu(Co–N_{indazole})$ vibrations [34] are registered between 247 and 265 cm^{-1}, the bands in the region 212–231 cm^{-1} can be tentatively attributed to the $\nu(Co–N_{thiazoline})$ vibrations [20,21,26,35], the bands at 376 and 385 cm^{-1} in the spectrum of complex **3** are assigned to the $\nu(Co–O_{water})$ vibration [20,36–38] whereas one band due to the ν(Co–Cl) vibration [21,26,39] is found at 309 cm^{-1} for **1**. Likewise,

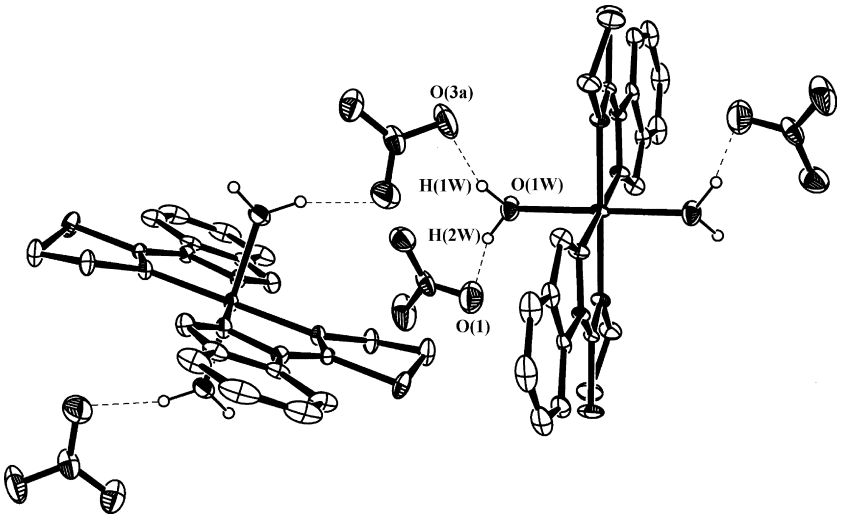

Fig. 5. View of the hydrogen bonds network of **4**.

Table 3
IR bands (cm^{-1}) with assignments for the ligand and the complexes

Compound	W_1	ν(C=N)
TnInA	1632 vs	1614 s
1	1612 vs	1612 vs
2	1608 vs	1608 vs
3	1604 vs	1604 vs
4	1608 vs	1608 vs

in the Zn(II) spectra the bands at 227–237 cm^{-1} could assigned to the $\nu(Zn–N_{indazole})$ vibrations and the band at 227 cm^{-1} to the $\nu(Zn–N_{thiazoline})$ vibrations, according to the Refs. [26,35,39–43]. Finally the band at 311 cm^{-1} in the spectrum of complex **4** is attributed to the $\nu(Zn–O_{water})$ vibration [33] and the bands at 300 and 316 cm^{-1} in the spectrum of complex **2** are assigned to the ν(Zn–Cl) vibration in accord to the literature data for this type of bond [26,35,44].

The values obtained for molar magnetic susceptibility for the cobalt(II) complexes are consistent with an octahedral environment around the metal [45]. These values were corrected for diamagnetism and temperature-independent paramagnetism to provide the fully corrected magnetic moment at room temperature ($\mu = 4.94$ BM for **1**; $\mu = 4.97$ BM for **3**).

Table 4
Far IR bands (cm^{-1}) with tentative assignments

Compound	$\nu(M–N_{thiazoline})$	$\nu(M–N_{indazole})$	ν(M–Cl)	$\nu(M–O_{water})$
1	231 s	255 s	309 m	
2	227 m	237 w	316 s 300 s	
3	225 m 212 s	265 m 247 s		385 m 376 m
4	227 s	227 s		311 s

The diffuse reflectance spectrum of **1** shows a very strong band at 32260 cm^{-1} which is assigned to the $\pi \rightarrow \pi^*$ transition of the organic ligand. Moreover, this spectrum exhibits two bands at 8870 cm^{-1} and 8050 cm^{-1} corresponding to splitting of the lowest energy transition ν_1 [$^4T_{2g}(F) \leftarrow {}^4T_{1g}(F)$] for an octahedral Co(II) complex. Therefore, the value for ν_1 has been made by calculating the baricenter of these two bands. The highest energy transition ν_3 [$^4T_{1g}(P) \leftarrow {}^4T_{1g}(F)$] is displayed at 18800 cm^{-1} in an admixture with a shoulder at 14750 cm^{-1}, which is most probably caused by a spin forbidden transition to a doublet state (^2G) [46].

The electronic spectrum of **3** gives three bands at 9190 cm^{-1}, 20240 cm^{-1} and 32680 cm^{-1}. The third of them refers to a transition of the organic ligand in a similar form to **1** whereas the first two bands are assigned to the transitions [$^4T_{2g}(F) \leftarrow {}^4T_{1g}(F)$] and [$^4T_{1g}(P) \leftarrow {}^4T_{1g}(F)$], respectively.

These results for both complexes suggest that there is an octahedral geometry around the Co(II) ion. The ligand field parameters, 10 Dq and B, were calculated using the following known relationships [47] for octahedral d^7 complexes:

$$\nu_1[{}^4T_{1g}(F) \rightarrow {}^4T_{2g}(F)] = 1/2(10Dq - 15B) + 1/2[(10Dq + 15B)^2 - 12B \cdot 10Dq]^{1/2}$$

$$\nu_3[{}^4T_{1g}(F) \rightarrow {}^4T_{1g}(P)] = [(10Dq + 15B)^2 - 12B \cdot 10Dq]^{1/2}$$

The calculated values of the ligand field parameters (10 Dq = 9547 cm^{-1} and B = 763 cm^{-1} for **1**, 10 Dq = 10376 cm^{-1} and B = 816 cm^{-1} for **3**), are in fair agreement with the predicted values for octahedral complexes of Co(II). It is also possible to notice that the position of the d–d transitions of **3** are shifted to higher energies compared to spectrum for **1** and the value obtained for 10 Dq in complex **3** is greater than that calculated for **1**. These two facts are in agreement with the chromophore groups

presents in these complexes, $[CoN_4O_2]$ for **3** and $[CoCl_2N_4]$ for **1** [20,21,37,46]. Likewise, the splitting of v_1 in **1** and the lack of splitting in **3** are in agreement with the cis and trans geometries, respectively, for these complexes [46].

4. Conclusion

In summary we have synthesized and structurally characterized Co(II) and Zn(II) complexes with 2-(indazol-1-yl)-2-thiazoline (TnInA), which acts as a bidentate ligand coordinating to the metal ion through the indazole and thiazoline nitrogen atoms. Crystallographic studies of **1**, **3** and **4** show a distorted octahedral geometry around the metal center. Elemental analysis and spectroscopic studies of **2** indicate a coordination number equal to four for a zinc(II) ion. Given that the zinc ion does not have a preferable geometry by crystal field stabilization, it can be expected that the coordination polyhedron is a tetrahedron, conditioned by steric requirements.

Finally, the results of diffuse reflectance spectroscopy for **1** and **3** are consistent with the positions in the spectrochemical series of the non-organic ligands present in both complexes (H_2O for **3** and Cl for **1**).

2. Experimental

2.1. General procedures

The flexible ligand 1,2-bis(1,2,4-triazol-1-yl)ethane was synthesized according to the literature method [27]. All other reagents and solvents employed were commercially available and were used as received without further purification. The C, H, N microanalyses were carried out with a Perkin–Elmer 240C analyser. IR spectra were obtained for KBr pellets on a Nicolet 170SX FT-IR spectrophotometer in the 4000–400 cm^{-1} region. Thermogravimetric data were collected on a Thermal Analyst 2100 TA Instrument and SDT 2960 Simutaneous TGA-DTA Instrument in flowing dinitrogen at a heating rate 10 °C/min. Variable-temperature magnetic susceptibility measurement and field dependence of magnetization were performed with a quantum Design MPMS XL-5 SQUID system. The experimental susceptibilities were corrected for the diamagnetism of the constituent atoms (Pascal's tables).

2.2. Syntheses of $[Co(bte)_2(dca)_2]_n$ (1) and $\{[Co(bte)(dca)_2]\cdot H_2O\}_n$ (2)

A methanolic solution (15 ml) of bte (0.164 g, 1.0 mmol)was added to an aqueous solution (15 ml) of $Co(NO_3)_2\cdot 6H_2O$ (0.291 g, 1.0 mmol) and $NaN(CN)_2$ (0.178 g, 2.0 mmol) with stirring. The mixture was stirred at room temperature and the resultant solution was filtered. After the filtrate was allowed to stand in air for 3 days, light red single crystals of **1** were obtained. Standing was continued in air for the mother solution for several more days, and deep red single crystals of **2** were obtained. *Anal.* Calc. for **1** $C_{16}H_{16}CoN_{18}$: C, 37.00; H, 3.11; N, 48.55. Found: C, 36.88; H, 3.07; N, 48.52%. *Anal.* Calc. for **2** $C_{10}H_{10}CoN_{12}O$: C, 32.18; H, 2.70; N, 45.04. Found: C, 32.06; H, 2.59; N, 44.93%. IR data (cm^{-1}) for **1**: 3445w, 3125w, 2272m, 2218m, 2160s, 1532m, 1435w, 1385m, 1339m, 1285m, 1215w, 1130m, 1015w, 884w, 664 m and 529 w. IR data (cm^{-1}) for **2**: 3472w, 3113w, 2307m, 2238m, 2195s, 2164s, 1609w, 1528w, 1443w, 1385m, 1354m, 1285m, 1134m, 992w, 671w and 525w.

2.3. Crystal structure determination

All data collections were performed at a temperature of 193(2) K on a Rigaku Mercury CCD diffractometer with the ω-scan technique. The structures were solved by direct methods and refined with the full-matrix least-squares technique using the SHELXS-97 and SHELXL-97 programs [28]. Anisotropic thermal parameters were assigned to all non-hydrogen atoms. The hydrogen atoms of the bte ligands were generated geometrically (C–H 0.93 Å for triazole and 0.97 Å for ethane) and those of the water molecules were located from difference maps. Crystallographic data are listed in Table 1. Selected bond lengths and angles are listed in Table 2.

3. Results and discussion

3.1. Syntheses and characterization

The C≡N stretching vibrations of $[N(CN)_2]^-$ are 2272, 2218 and 2160 cm^{-1} in **1**, and are assigned to $\nu_{sym}+\nu_{asym}$ (C≡N), ν_{asym} (C≡N) and ν_{sym} (C≡N), respectively. The C≡N stretching vibrations of $[N(CN)_2]^-$ are 2307, 2238, 2195 and 2164 cm^{-1} in **2**, suggesting $[N(CN)_2]^-$ acts as a μ-$_{1,5}$ bridge [29].

Thermal analysis shows that polymer **1** is stable up to 211 °C, and begins to decompose above this temperature.

Polymer **2** displays that the solvent water molecule is lost in a continuous fashion (Obsd., 4.5; Calc., 4.8%) in the temperature range 84–170 °C. Then complex begins to decompose.

3.2. Crystal structure

The crystal structure of **1** is isostructural to $[Mn(bte)_2(dca)_2]_n$ [23] and $[Zn(bte)_2(dca)_2]_n$ [24], and is similar to that of the polymers $\{[Co(bte)_2(NCO)_2](H_2O)\}_n$, $[Co(bte)_2(NCS)_2]_n$ [21] and $\{[Cd(bte)_2(H_2O)_2](H_2O)_2(ClO_4)_2\}_n$ [22]. The complex molecule displays center symmetry and the cobalt(II) atom lies on an inversion center (Fig. 1). The coordination geometry of the cobalt(II) atom is a distorted compressed octahedron, and coordinates with four nitrogen atoms from the triazole rings of four symmetry-related bte ligands and two *trans*-nitrogen atoms from two symmetry-related monodentate dca ligands. The ligand bte exhibits the *gauche* conformation in **1**. The dihedral angle between the planes of the two triazole rings of one bte ligand is 57.9(1)°. The cobalt atoms are linked by bte ligands *via* the nitrogen atoms in the 4-positions of the two triazole rings. The ligand bte is twisted during coordination, and the N(1)–C(5)–C(6)–N(4) torsion angle is 58.2(3)°. Two strands of bte ligands are wrapped around one another and are held together by cobalt(II) atoms, forming an infinite double-chain structure. Each chain consists of 18-membered spiro-fused rings, in which two cobalt(II) atoms are joined *via* two bte molecules. The chains extend along the *b* axis, and all of the Co(II) atoms in one chain are on the axial line (Fig. 2). The Co···Co separation across the bridging bte ligand is equal to the *b*-axis translation, 8.345 Å.

Compound **2** crystallizes in the chiral space group $P2_12_12_1$, formed by the coordination polymer with the absolute structure parameter 0.018(14). The structure of **2** is depicted in Fig. 3. Each cobalt(II) atom has a distorted octahedral coordination geometry, and coordinates with two exodentate nitrogen atoms at the 4-position of the triazole rings of two symmetry-related bte ligands [Co(1)–N(3), 2.139(2) Å; Co(1)–N(6)^{ii}, 2.125(2) Å] and four nitrogen atoms from four symmetry-related dca ligands [Co(1)–N(7), 2.142(2) Å; Co(1)–N(9)^{iii}, 2.145(2) Å; Co(1)–N(10), 2.128(2) Å; Co(1)–N(12)^{i}, 2.090(2) Å]. The bte ligand exhibits the *gauche* conformation. The dihedral angle between the planes of the two triazole rings of one bte ligand is 121.4(1)°. The bte ligand is twisted during coordination, and the N(1)–C(5)–C(6)–N(4) torsion angle is 53.5(3)°. Each bte ligand bridges two cobalt(II) atoms *via* two 4-position nitrogen atoms of the triazole rings and each dca ligand bridges two cobalt(II) atoms in the μ-$_{1,5}$dca mode. Each cobalt atom links six adjacent cobalt(II) atoms through four μ-$_{1,5}$-dca ligands and two bridging bte ligands and a three-dimensional network is formed (Fig. 4). The adjacent Co···Co distances are 7.759 Å, 7.858 Å and 6.809 Å for Co(dca)Co of the N(7) dca ligand, Co(dca)Co of the N(10) dca ligand and Co(bte)Co, respectively. The Co···Co separation (6.809 Å) *via* the bte bridges in **2** is shorter than the corresponding value (8.345 Å) in **1**. There is a hydrogen bonding interaction between the solvent water molecule and the uncoordinated N(2) atom at the 2-position of the triazole ring of bte (O(1)···N(2) 2.922(5) Å, O(1)–HWA···N(2) 147(7)°.

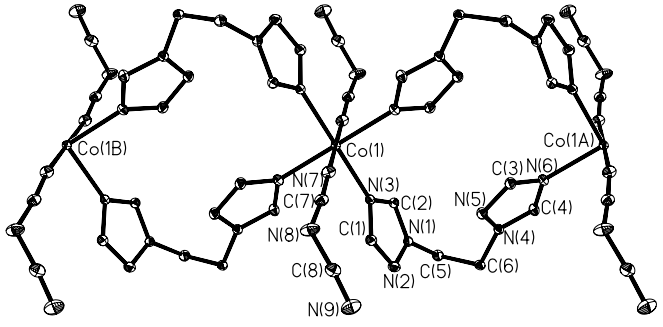

Fig. 1. The coordination environment around the cobalt(II) center in **1** with 30% thermal ellipsoids.

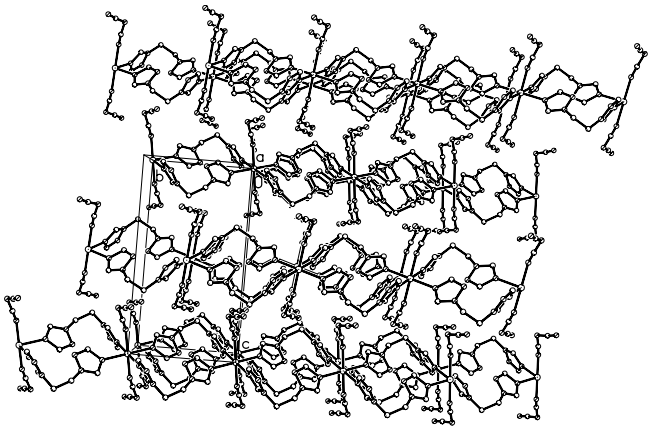

Fig. 2. The cell packing of **1** viewing along the *a* direction.

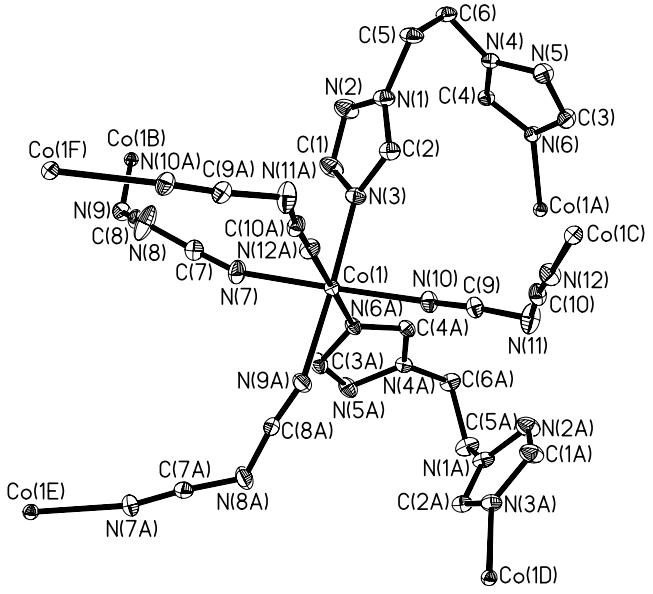

Fig. 3. The coordination environment around the cobalt(II) center in **2** with 30% thermal ellipsoids.

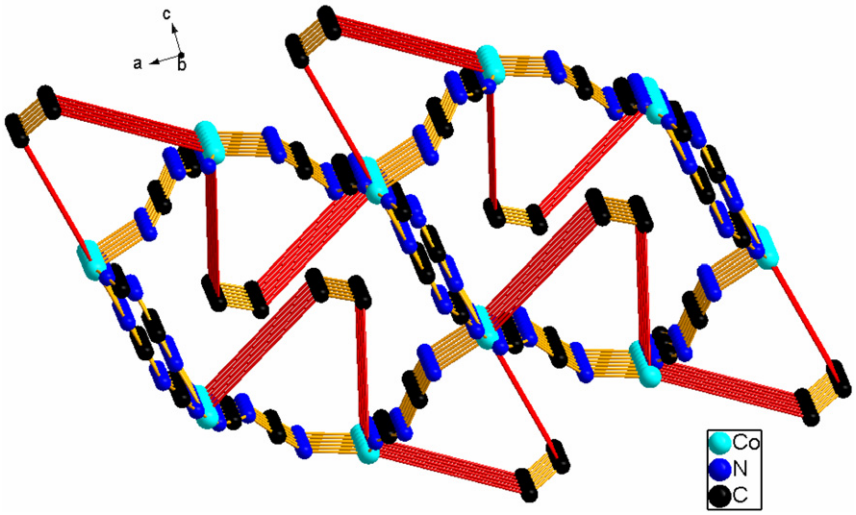

Fig. 4. Schematic view of the three-dimensional network of **1**. The representation of the bte ligands is simplified by showing the ethylene atoms.

The three-dimensional network structure of **2** is completely different from that of the similar complexes $[M(dca)_2(bpp)]_n$ (M=Co, Mn, Zn and Cd, bpp = 1,3-bis(4-pyridyl)propane) [30], in which adjacent metal ions are triply linked by two μ-1,5-dca and one bpp bridge, and a sinusoidal chain is formed. Previously we synthesized six Co-bte coordination polymers $\{[Co(bte)_2(H_2O)_2](NO_3)_2\}_n$, $\{[Co(bte)(H_2O)_2(NCO)_2](H_2O)_2\}_n$, $\{[Co(bte)_2(NCO)_2](H_2O)\}_n$, $[Co(bte)_2(NCS)_2]_n$, $\{[Co(bte)(H_2O)_2(NCS)_2][Co(bte)_2(NCS)_2]\}_n$ [21] and $[Co(bte)(NCS)_2]_n$ [20], which consist of a two-dimensional (4,4) network, single chain, double chain, double chain, a combination of single chain and double chain, and two-dimensional (4,4) network, respectively.

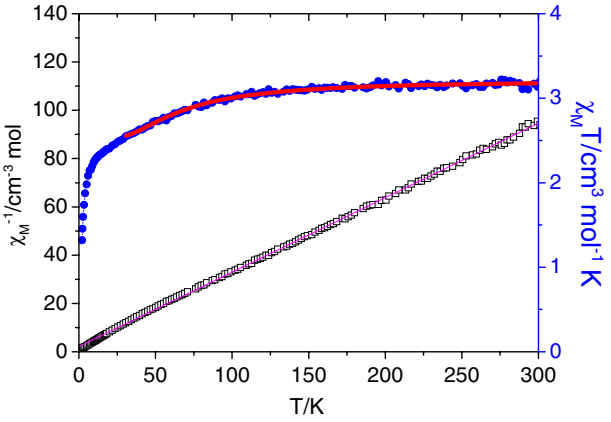

Fig. 5. Temperature dependence of $\chi_M T$ and $1/\chi_M$ for **1**.

3.3. Magnetic properties

The molar magnetic susceptibility χ_M of **1** is measured in the temperature range 2–300 K in a field of 20 KOe. The $\chi_M T$ value is 3.2 $cm^3\ mol^{-1}$ K at 300 K, which is significantly larger than the spin-only value of high-spin cobalt(II), 1.875 $cm^3\ mol^{-1}$ K, indicating a contribution of the orbital momentum typical for the $^4T_{1g}$ ground state. Upon cooling, $\chi_M T$ decreases slowly to 2.73 $cm^3\ mol^{-1}$ K at 18 K, and then decreases rapidly and reaches 1.32 $cm^3\ mol^{-1}$ K at 2 K (Fig. 5). The magnetic susceptibility obeys the Curie–Weiss law with the Weiss constant, $\theta = -0.57$ K, and the Curie constant, $C = 2.80\ cm^3\ mol^{-1}$ K. From the fitted Curie constant, C, one can deduce the g value to be about 2.45.

From the structural information, we know that the Co(II) ions are well separated, so we can treat the magnetic data by considering a mononuclear Co^{2+} with a spin–orbit coupling parameter λ ($H = -\lambda LS$) in a molecular-field approximation. The χ_{mono} for mononuclear Co^{2+} in an octahedral environment can be calculated from Eq. (1), with $x = \lambda/k_B T$ [31,32]. The parameter A gives a measure of the crystal field strength relative to the inter-electronic repulsions and it is equal to 1.5 for a weak crystal field and 1.0 for a strong field. Considering the molecular-field approach with zJ as the total exchange coupling between Co^{2+} ions, we can fit our experimental data with Eq. (2) [33].

$$\chi_{mono} = \frac{1}{T} \times \frac{\frac{7(3-A)^2x}{5} + \frac{12(2+A)^2}{25A} + \left\{\frac{2(11-2A)^2x}{45} + \frac{176(2+A)^2}{675A}\right\} \times \exp\left(\frac{-5Ax}{2}\right) + \left\{\frac{(5+A)^2x}{9} - \frac{20(2+A)^2}{27A}\right\} \exp(-4Ax)}{\frac{8x}{3}\left\{3 + 2\exp\left(\frac{-15Ax}{2}\right) + \exp(-14Ax)\right\}} \quad (1)$$

$$\chi = \frac{\chi_{mono}}{1 - (2zJ/Ng^2\beta^2)\chi_{mono}} \quad (2)$$

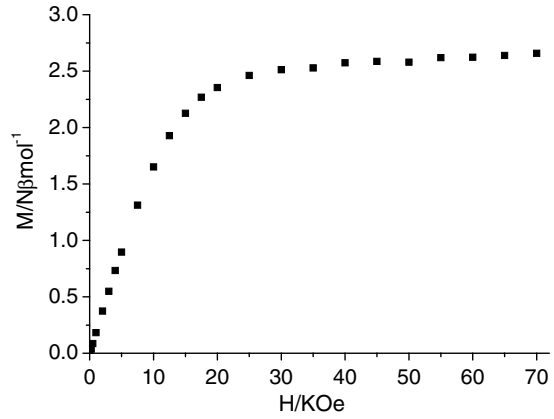

Fig. 6. Field dependence of magnetization curve from 0 to 70 k for **1** at 1.8 K.

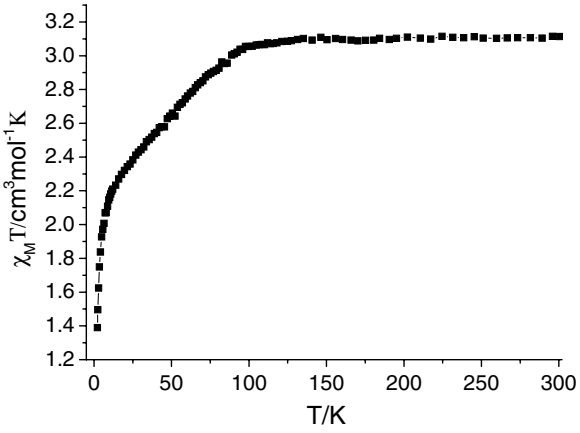

Fig. 7. Temperature dependence of $\chi_M T$ for **2**.

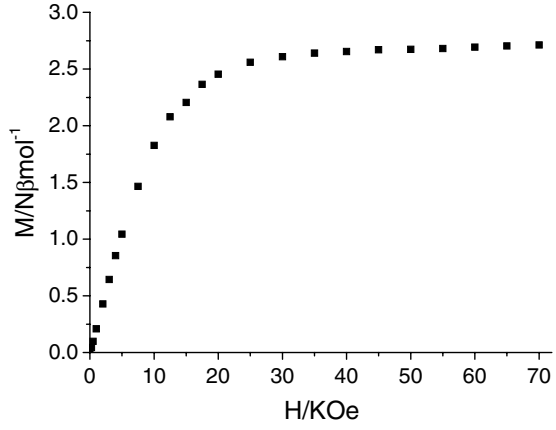

Fig. 8. Field dependence of magnetization curve from 0 to 70 k for **2** at 1.7 K.

In Eqs. (1) and (2), N, g, β, k_B and T have their usual meanings. The best fitting of the susceptibility data in the temperature range 30–300 K gives $\lambda = -104(2)\ cm^{-1}$, $A = 1.24(1)$ and $zJ = 1.33(7)\ cm^{-1}$ with $R = 4.9 \times 10^{-5}$ [$R = [\sum(\chi_{obs} - \chi_{calcd})^2 / \sum(\chi_{obs})^2]$. The field dependence of the magnetization of **1** measured at 1.8 K shows a nearly linear increase below 20 KOe and reaches a value of 2.66 $N\beta$ at 70 KOe (Fig. 6).

The molar magnetic susceptibility χ_M of **2** is measured in the temperature range 2–300 K in a field of 20 KOe. The $\chi_M T$ value remains almost constant (3.05–3.11 $cm^3\ mol^{-1}\ K$) in the temperature range 100–300 K, which is significantly larger than the spin-only value of high-spin cobalt(II), 1.875 $cm^3\ mol^{-1}\ K$, indicating a contribution of the orbital momentum typical for the $^4T_{1g}$ ground state, and decreases gradually upon cooling to 2.21 $cm^3\ mol^{-1}\ K$ at 12 K, and then decreases rapidly and reaches 1.39 $cm^3\ mol^{-1}\ K$ at 2 K (Fig. 7). The $\chi_M T$ value shows no obvious magnetic coupling between the Co(II) ions. Typically very weak antiferromagnetic coupling between the metal ions is observed for $\mu_{1,5}$-dca bridging systems [1–9,31]. The field dependence of the magnetization of **2** measured at 1.7 K shows a nearly linear increase below 20 KOe and reaches a value of 2.71 $N\beta$ at 70 KOe (Fig. 8), showing a typical paramagnetic behavior without any sign of long range ordering of **2**.

4. Conclusion

Using the anionic co-ligand dca and the flexible bis(triazole) ligand bte and Co^{2+}, we synthesized two novel cobalt(II) coordination polymers, $[Co(bte)_2(dca)_2]_n$ (**1**) and $\{[Co(bte)(dca)_2]\cdot H_2O\}_n$ (**2**). **1** is a double-chain containing metallocycles of $[Co_2(bte)_2]$. In **2**, each Co(II) center is bonded by two bridging bte ligands and four dca ligands as μ-1,5-dca in different orientations in the 3D network. The magnetic properties of these polymers were studied.

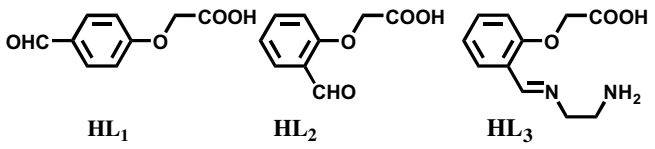
above studies in which the phenoxy acetic acid derivatives (**HL_1**, **HL_2** and **HL_3**) with carboxylate groups to form extended solid state structures has been explored. We reported herein the six mixed-ligand mononuclear complexes of Cu(II), Co(II), Co(III) and Mn(II).

2. Experimental

2.1. Materials and methods



The aldehydes and the liquid olefins were distilled prior to use. Metal salts and solid olefins are used as supplied from commercial sources. All the solvents were purified prior to use by standard procedure. The IR spectra were recorded on a *Perkin–Elmer-Spectrum One* FT-IR Spectrometer with KBr disks in the range 4000–400 cm^{-1}. The thermo gravimetric analyses (TGA) of the compounds were performed by using an *SDTA 851e TGA* thermal analyzer (Mettler Toledo) with a heating rate of 2 °C per min in a N_2 atmosphere. Optical spectra were recorded in CH_3CN on a *Perkin–Elmer-Lambda 25-UV–Visible Spectrometer* at 298 K. Solid-state magnetic susceptibility of the complexes at room temperature was recorded using *Sherwood Scientific balance MSB-1*. Solution electrical conductivity measurements measured with a *Systronics Conductivity meter 306*. Elemental analyses were done using *Carlo Erba 1108* and *Perkin–Elmer series II 2400* instrument. GCMS analyses were performed using a *Perkin–Elmer Clarus* 500 gas chromatograph coupled with the *Perkin–Elmer Clarus 500* mass spectrometer.

2.2. Synthesis of ligands HL_{1-3}

Both the ligands (Scheme 1) (4-formyl-phenoxy)-acetic acid (**HL_1**) [24] and (2-formyl-phenoxy)-acetic acid (**HL_2**) [25] were synthesized following the reported procedure.

2.2.1. Synthesis of ligands HL_3

To a stirred solution of **HL_2** (111 mg, 0.5 mmol) in MeOH (10 ml) was added ethylene diamine (30 mg, 0.5 mmol) in MeOH (2 ml) at ice-cold condition. Mixture was then refluxed for 15 min and then allowed to cool to RT. Slow evaporation results the formation of yellow crystals, which was washed several times with cold MeOH. Yield 65%, m.p.: 186 °C; ESI–MS, *m/z* (%): 222 (86) $[HL_3]^+$; *Anal.* Calc. for $C_{11}H_{14}N_2O_3$: C, 59.45; H, 6.35; N, 12.60. Found: C, 59.63; H, 6.31; N 12.55%. ^1H NMR (400 MHz, $CDCl_3$, 25 °C, TMS) δ (ppm): 3.2 (*t*, 2H), 3.8 (*t*, 2H), 4.7 (*s*, 2H), 6.8–7.6 (*m*, 4H), 8.2 (*s*, 1H), ^{13}C NMR (100 MHz, $CDCl_3$, 25 °C, TMS) δ (ppm): 42.8, 58.3, 79.8, 116.8, 121.5, 123.7, 131.2, 132.6, 161.4, 165.2, 174.1. FT-IR (KBr): 3442 ν(OH); 3351 $\nu(NH_2)$; 1765 ν(C=O); 1602 ν(C=N); 1490 ν(C=C); 1164 ν(COC) cm^{-1}.

Scheme 1. The phenoxy acetic acid derivatives **HL_1**, **HL_2** and **HL_3**.

2.3. Synthesis of complexes

2.3.1. Synthesis of $[Co(L_1)_2(H_2O)_4]$ (1a)

To a stirred solution of **HL_1** (18 mg, 0.1 mmol) in MeOH (5 ml) was added $CoCl_2 \cdot 6H_2O$ (23.8 mg, 0.1 mmol) in water (5 ml) at RT. The resulting solution was continued to stir for another 30 min. Slow evaporation of the reaction mixture afforded the complex **1a** as red crystals. These were employed directly for the X-ray crystallographic study. Yield: 85%, *Anal.* Calc. for $CoC_{18}H_{22}O_{12}$: C, 44.18; H, 4.53; Co, 12.04. Found: C, 44.24; H, 4.51; Co, 12.11%. Molar conductance (in CH_3CN): 4.1 S cm^2 mol^{-1}; solid-state RT $\mu_{eff} = 5.22$ BM; UV–Vis: 456 nm (sh) $[^4A_{1g} \rightarrow {}^4A_{2g}(F)]$, 511 nm $[^4T_{1g}(F) \rightarrow {}^4T_{1g}(P)]$.

2.3.2. Synthesis of $[Mn(L_1)_2(H_2O)_4]$ (1b)

Complex **1b** was synthesized following the same procedure as **1a**, only $MnCl_2 \cdot 4H_2O$ (20 mg, 0.1 mmol) was used instead of Co-salt. A light pink colored crystal of **1b** was studied by X-ray crystallography. Yield: 78%. *Anal.* Calc. for $MnC_{18}H_{22}O_{12}$: C, 44.54; H, 4.56; Mn, 11.32. Found: C, 44.51; H, 4.52; Mn, 11.39%. Solid-state RT $\mu_{eff} = 5.91$.

2.3.3. Synthesis of $[Cu(L_1)_2(H_2O)_2]$ (1c)

Complex **1c** was synthesized following the same procedure as **1a**, only $CuCl_2 \cdot 2H_2O$ (27 mg, 0.2 mmol) was used instead of Co-salt. A blue colored crystal of **1c** was studied by X-ray crystallography. Yield: 55%. *Anal.* Calc. for $CuC_{18}H_{18}O_{10}$: C, 47.21; H, 3.96; Cu, 13.87. Found: C, 47.17; H, 3.99; Cu, 13.92%; UV–Vis: 720 nm $[^2E \rightarrow {}^2T_2]$, 900 nm (sh).

2.3.4. Synthesis of $[Cu(L_1)_2(H_2O)(Py)_2]$ (1d)

Complex **1d** was synthesized following the same procedure as **1c**, only pyridine (24 mg, 0.3 mmol) was added after addition of metal salt solution and stirring was continued for additional 45 min in a closed container at RT. Dark blue crystal of **1d** was studied by X-ray crystallography. Yield: 42%. *Anal.* Calc. for $CuC_{30}H_{26}N_2O_9$: C, 57.92; H, 4.21; N, 4.50; Cu, 10.21. Found: C, 57.96; H, 4.25; N 4.46; Cu, 10.27%.

2.3.5. Synthesis of $[Cu(L_3)(H_2O)Cl] \cdot H_2O$ (3a)

To a stirred solution of **HL_3** (11 mg, 0.05 mmol) in MeOH (3 ml) was added $CuCl_2 \cdot 2H_2O$ (7 mg, 0.05 mmol) in water (5 ml) at RT. The resulting solution was refluxed with continues stirring for another 15 min. The mixture was cooled to RT and slow evaporation of the reaction mixture afforded the complex **3a** as blue crystals. These crystals were used directly for the X-ray crystallographic study. Yield: 52%. *Anal.* Calc. for $CuC_{11}H_{18}N_2O_5Cl$: C,

36.97; H, 5.07; N, 7.84; Cu, 17.78. Found: C, 36.91; H, 5.02; N, 7.91; Cu, 17.72%.

2.3.6. Synthesis of $[Co(Sal)(H_2O)(Py)_3]\cdot 2ClO_4\cdot H_2O$ (**3b**)

To a stirred solution of **HL_3** (11 mg, 0.05 mmol) in MeOH (3 ml) was added $Co(ClO_4)_2\cdot 6H_2O$ (18.3 mg, 0.05 mmol) in water (5 ml) at RT. After 45 min of stirring at RT, excesses pyridine was added to this mixture. The resulting mixture was continued to stir for additional 45 min in a closed container at ~60 °C. Green crystal of **3b** was studied by X-ray crystallography. The perchlorate salts must be handled with care as this form potentially explosive mixtures with organic compounds. Yield: 48%. *Anal.* Calc. for $CoC_{25}H_{24}N_3O_{12}Cl_2$: C, 43.62; H, 3.51; N, 6.10; Co, 8.56. Found: C, 43.66; H, 3.54; N 6.17; Co, 8.51%; UV–Vis: 648 nm (ε 101 M^{-1} cm^{-1}) and 364 nm (ε 1420 M^{-1} cm^{-1}).

2.4. X-ray crystallography

The intensity data were collected using a Bruker SMART APEX-II CCD diffractometer, equipped with a fine focus 1.75 kW sealed tube Mo Kα radiation (λ = 0.71073 Å) at 273(3) K, with increasing ω (width of 0.3° per frame) at a scan speed of 3 s/frame. The SMART software was used for data acquisition. Data integration and reduction were undertaken with SAINT and XPREP [26] software. Multi-scan empirical absorption corrections were applied to the data using the program SADABS [27]. Structures were solved by direct methods using SHELXS-97 [28] and refined with full-matrix least squares on F^2 using SHELXL-97 [28]. All non-hydrogen atoms were refined anisotropically. Most of the hydrogen atoms were located from the difference Fourier maps and refined isotropically. While other hydrogen atoms are added in a fixed geometry. Selected crystallographic data summarized in Table 1.

3. Results and discussion

3.1. Crystal structure of $[Co(L_1)_2(H_2O)_4]$ (**1a**) and $[Mn(L_1)_2(H_2O)_4]$ (**1b**)

The complexes **1a** and **1b** were crystallized from methanol/water (1:1) mixture as red and pink colored crystals respectively. The molecular structures with atom numbering scheme of the Co(II) complex (**1a**) and Mn(II) complex

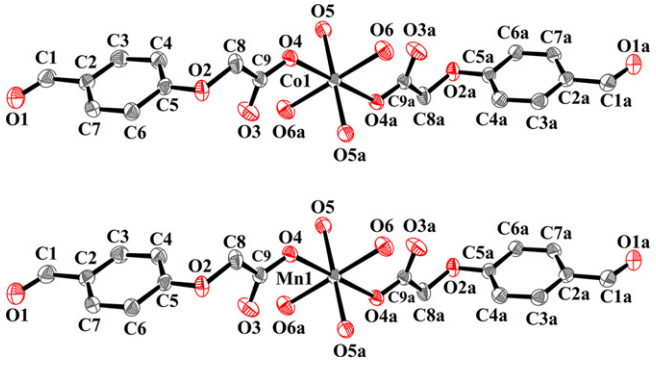


Fig. 1. ORTEP plot of complexes **1a** and **1b** with atom numbering scheme. Selected bond lengths for **1a**: Co(1)–O(4) = 2.1424(10), Co(1)–O(5) = 2.1029(14), Co(1)–O(6) = 2.0841(13); **1b**: Mn(1)–O(4) = 2.2301(9), Mn(1)–O(5) = 2.2018(12), Mn(1)–O(6) = 2.1596(12).

(**1b**) are shown in Fig. 1. Single-crystal X-ray analyses revealed both **1a** and **1b** are neutral and mononuclear in nature. In both the complex, metal ion is in similar coordination environment and each of them exhibits an octahedral geometry with MO_6 coordination. Bond angles and distances of mononuclear complex indicate a slightly distorted octahedral coordination with *trans*-geometry. Among the six O atoms around the metal ion, two carboxylato oxygen atoms are of ligand $\mathbf{L}_1$ and four oxygen atoms are from water molecules. Metal bound four water molecules form the equatorial planes and $\mathbf{L}_1$ is bonded in the axial positions. The little elongation of the M–O4 bond lengths agree with the bulkier nature of the ligand compared to the water molecules. The Co(II)/Mn(II) atom lies on a centre-of-inversion in the crystal structure. All the O atoms of the water and the Co or Mn atom lie exactly on the O_4 plane.

As shown in Fig. 1, carboxylate act as a uni-dentate ligand. In the crystal lattice, the coordinated water molecules are in two different environments within the 3D network. One set of water molecules has chelate type intramolecular hydrogen bonding with carbonyl group of carboxylate. The other set is hydrogen bonded to aldehyde group in the *para* position. This results in the formation of hydrogen bonded 2D tape type network along crystallographic *a* axis (see Supporting information). In the 2D tape network, the two neighboring M(II) ions show a distance of 13.113 Å (in **1a**) and 13.256 Å (in **1b**). However, the distance between benzene ring is 5.908 Å (in **1a**) and 5.945 Å (in **1b**) and they form an oval-shaped metallocycle unit. Uncoordinated O3 atom of carboxylic acid is intramolecularly hydrogen bonded to the nearest coordinated water molecule. Due to this each axial M–O4 bond is slightly tilted towards the M–O6 bond ($\angle$O(6a)–Co(1)–O(4) = 88.26 and $\angle$O(6a)–Mn(1)–O(4) = 87.92). In addition to this, both the carboxylate oxygen atoms are intermolecularly hydrogen bonded to the neighboring coordinated water molecules. Overall hydrogen bonding results the formation of staircase network viewed along crystallographic *a* axis (Fig. 2), Individual molecule is arranged in zig-zag fashion and helps to make the alternate steps of the staircase network.

The IR spectrum of complex **1a** shows typical antisymmetric and symmetric stretching bands of carboxylate groups at 1710 and 1280 cm^{-1}, respectively. The separation (Δ) between $\nu_{asym}(CO_2)$ and $\nu_{sym}(CO_2)$ is 430 cm^{-1}, indicating the presence of uni-dentate coordination modes in **1a** [29]. This result is in good agreement with the crystal structure analysis. The OH stretching for water appearing at 3571 cm^{-1} and 3483 cm^{-1} shows that there are two different types of environment for water molecules.

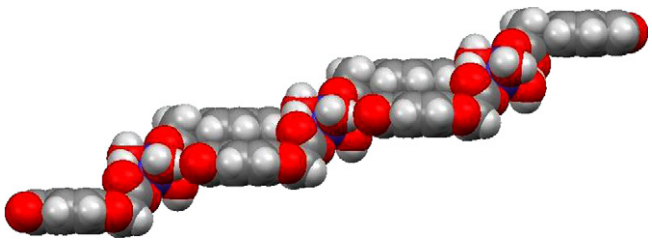

Fig. 2. Stair case network of **1a** along *a* axis.

Solid-state arrangement of complex **1b** is similar to that of **1a**, they are isostructural. The Mn–O bond distances for equatorially coordinated hetero atoms are typical for Mn(II) octahedral complexes [30,31]. It also shows the formation of similar 2D hydrogen bonded tape as well as the 3D stair case network viewed along *a* axis. The separation (Δ) between $\nu_{asym}(CO_2)$ and $\nu_{sym}(CO_2)$ is 405 cm^{-1} in the IR spectrum of **1b**, which also confirms the uni-dentate binding nature of the carboxylic acid group. In both the complex, the overall structure is stabilized by several weaker C–H···O and C–H···π interactions in addition to the stronger O–H···O hydrogen bonding (see Supporting information). Complex **1b** is very faint pink in color and have no absorption bands in the visible region, in accordance with the high-spin d^5 electronic configuration of the Mn(II) ion. This complex is very stable in spite of being based on Mn(II). They may be stored in normal laboratory atmosphere without taking any precautions for more than two months.

3.2. Crystal structure of $[Cu(L_1)_2(H_2O)_2]$ (**1c**) and $[Cu(L_1)_2(H_2O)(Py)_2]$ (**1d**)

The molecular structures with atom numbering scheme of both the Cu(II) complexes **1c** and **1d** are shown in Fig. 3.

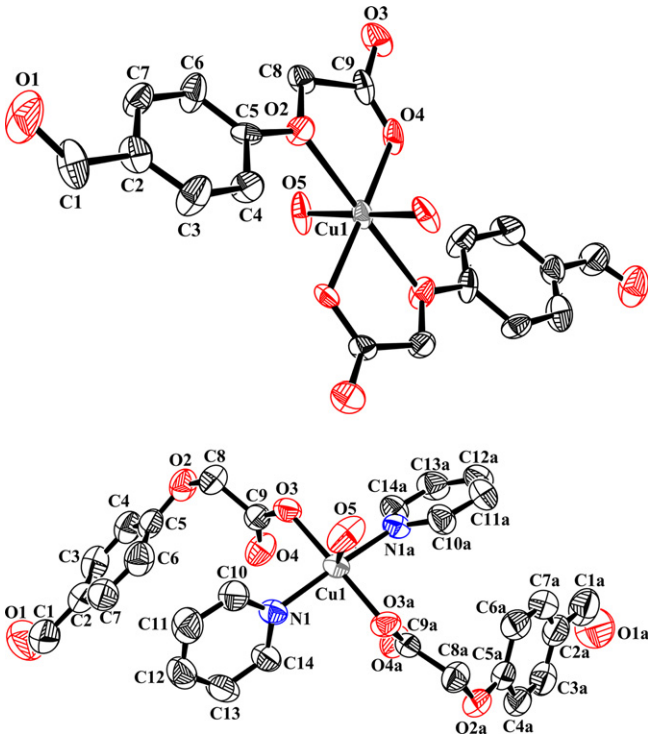

Fig. 3. ORTEP plot of complexes **1c** and **1d**. Selected bond lengths for **1c**: Cu(1)–O(2) = 2.4141(14), Cu(1)–O(4) = 1.9487(15), Cu(1)–O(5) = 1.9457(15); **1d**: Cu(1)–N(1) = 2.015(3), Cu(1)–O(3) = 1.962(2), Cu(1)–O(5) = 2.184(3).

In complex **1c** the Cu(II) atom is in the MO_6 coordination environment. It is ligated by six oxygen atoms: two carboxylato oxygen and two ether oxygen from ligand $\mathbf{L}_1$ and two oxygen from water molecules. The carboxylato oxygen atoms bonds more strongly with the Cu(II) than ether oxygen atoms. Complex **1c** has two five-membered O,O-chelate rings. Bond angles and distances of neutral, mononuclear complex indicate a slightly distorted octahedral coordination with *trans*-geometry. The bond distances and bond angles involving the metal ions are similar with the similar type of coordination environment [32,33]. The shortening of the Cu–O4 bond lengths agree with the stronger chelating ability of the carboxylate oxygen compared to ether oxygen atoms. Due to the formation of five-membered chelate rings both the axial bonds are inclined towards the carboxylate donor in the equatorial plane ($\angle$O(3)–Cu(1)–O(10) = 88.6 and $\angle$O(7)–Cu(1)–O(6) = 74.70). Carboxylate oxygen atoms and water molecules form the equatorial plane while weakly bonded ether oxygen atoms occupy the axial positions. Cu(II) atom exactly lie within the equatorial plane without any deviation from the plane. The strong O–H···O and weaker C–H···O and C–H···π type intermolecular hydrogen bonding play a major role in stabilizing the solid-state structure. Each carboxylate oxygen atom form hydrogen bond with coordinated water molecules, which result in the formation of 2D sheet of metallacycle along *b* axis (see supporting information). All the Cu atoms form linear arrays in all three directions. Shortest Cu–Cu distance in each layer of 2D sheet is 7.088 Å, while shortest Cu–Cu distance between layers is 13.050 Å. Adjacent layers run in the same direction along the *b* axis. Each aldehyde oxygen forms two C–H···O type bond which leads to the formation of 3D double-staircase network in solid-state (Fig. 4). The ν(COC) band near 1105 cm^{-1} is shifted by 35 cm^{-1} in the FT-IR spectrum of complex **1c** to a lower frequency than the free ligand, which is also confirmed form X-ray structure analysis. Carboxylic acid is uni-dentate ligand here also, which shows the separation (Δ) between $\nu_{asym}(CO_2)$ and $\nu_{sym}(CO_2)$ stretching frequency of 395 cm^{-1}. Solid-state magnetic moment of **1c** is 1.85 BM. This value is consistent with a Cu(II) complex having an octahedral coordination geometry [34,35].

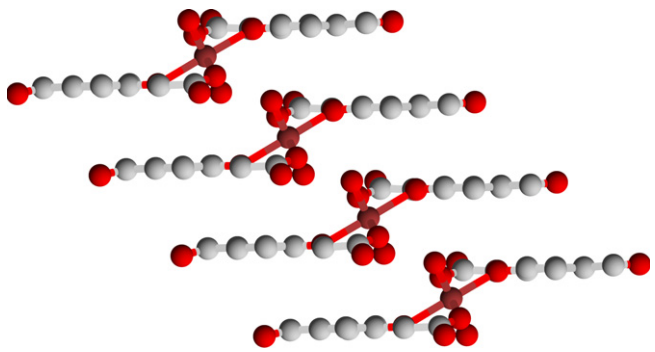

Fig. 4. Double-staircase network along *b* axis in **1c**.

Weaker coordination of the ether oxygen to the Cu(II) centre is lost, when stronger coordinating ligand pyridine is added during complex preparation. Complex **1d** crystallizes as a neutral monomer. The overall coordination environment changes from distorted octahedral to square pyramidal with *trans* geometry (Fig. 3), where the O atom of the water occupies the axial position. Square plane is formed by N_2O_2 coordination from $\mathbf{L}_1$ and pyridine molecules. In this complex also, $\mathbf{L}_1$ ligand coordinates to the copper in a uni-dentate fashion. Selected bond length and bond angels confirm the slightly distorted square pyramidal mononuclear Cu(II) complex. The equatorial Cu–O and Cu–N bond lengths are comparable with square-pyramidal CuN_2O_3 coordination spheres [36,37]. The axial Cu–O(5) bond length (2.184(3) Å) is consistent with the trend observed in other square-pyramidal Cu(II) complexes [38]. Cu(II) lies in the N_2O_2 mean plane with out any deviation. Both the ligands are bent in the opposite direction with respect to the coordinated water molecule that results in the formation of V-shape architecture. Fig. 5 shows the formation of 2D tape structure along *b* axis via formation of strong O–H···O hydrogen bond between carboxylate oxygen and water molecule. Shortest Cu–Cu distance in the same plane is 8.106 Å whereas shortest Cu–Cu distance between adjacent planes is 15.412 Å. It is also interesting to note that the pyridine molecules in the basal plane are twisted such that they are inclined at an angle of 38.93° from a common plane. This puckering brings the carbonyl group of the carboxylic acid group to the proximity of a hydrogen atom present at the 3-position of a coordinated pyridine molecule, resulting in a weak C–H···O interaction in the lattice. Due to steric crowding, two basal pyridines do not remain in the same plane. Water molecules are arranged in opposite direction on adjacent layer *i.e.* adjacent layer propagate along *b* axis in the opposite direction. Adjacent 2D tape is connected through C–H···O type

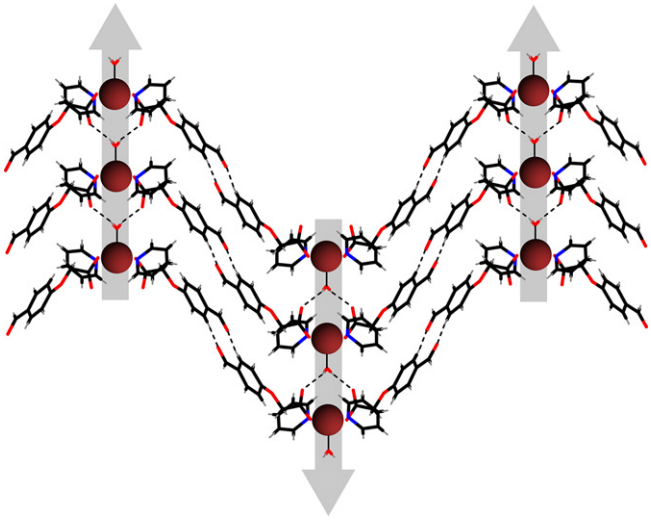

Fig. 5. Packing of **1d** along *b* axis showing O–H···O and C–H···O interactions.

hydrogen bond involving the aldehyde groups (Fig. 5), In contrast to the complex **1c**, benzene ring of the ligand in **1d** form π–π stacking interactions with another benzene ring in the adjacent layer. Upon complex formation in-pane ring deformation frequency of pyridine at 604 cm^{-1} is shifted to 643 cm^{-1} [39]. Although the electronic spectra of the copper complexes with multidentate Schiff base ligands are not in general good indicators of geometry [40], but act as supporter of it. The solid-state Nujol mull absorption spectrum for **1d** appeared at 650, 340 and 244 nm. The broad absorption band at 650 nm is attributable to a copper ion in square pyramidal chromophore CuN_2O_3 [41]. This broad visible absorption band at 650 nm is shifted slightly to a lower energy (678 nm) in acetonitrile solution, consistent with square pyramidal geometry in solution phase. The complex displays two strong absorption bands at 340 and 244 nm in solid which are clearly $\sigma(N) \rightarrow Cu(II)$ LMCT in origin and these two bands are shifted to 348 and 248 nm, respectively, in solution. The solid-state magnetic moment number for **1d** is 1.91, which is typical [42] of a discrete mononuclear Cu(II) complex.

3.3. Crystal structure of $[Cu(L_3)(H_2O)Cl] \cdot H_2O$ (**3a**)

Complex **3a** crystallizes as a neutral monomer. The molecular structures with atom numbering scheme of the Cu(II) complex is shown in Fig. 6. In the complex Cu(II) atom is in the N_2O_3Cl coordination environment. Here all six coordination site is occupied by six different coordination group. Three oxygen atoms ligate it: one carboxylato oxygen, one ether oxygen from ligand L_3 and one from water molecule. Two nitrogen atoms are from imine and primary amine groups. The carboxylato oxygen atoms bonds more strongly with the Cu(II) than ether and water oxygen atoms. The geometry of the ligand forced the ether oxygen to form a bond with the Cu(II) in more strongly nature than water molecule, which is not common to our knowledge. Complex **3a** has two five-member O,O and N,N-chelate rings along with one six-member N,O-chelate ring. Bond angles and distances of this mixed-ligand mononuclear complex indicate a slightly distorted octahedral coordination [18]. Water oxygen atom and chloride ion occupy the axial positions. Cu(II) atom exactly lie within the N_2O_2 equatorial plane without any deviation from the plane. Due to the formation two five-member and one six-member chelate rings in the same side of the complex, both the axial bonds are inclined towards the benzene ring of the donor in the equatorial plane. Uncoordinated carboxylate oxygen form hydrogen bond with neighboring coordinated water molecule. Hydrogen of NH_2 group simultaneously forms hydrogen bond with coordinated carboxylate oxygen atom and crystal water molecule.

Chloride ion form relative weaker hydrogen bond with both coordinated and uncoordinated water molecules (see Supporting information). The conventional strong O–H···O, N–H···O hydrogen bonding along with unconventional weaker C–H···O, C–H···Cl type intermolecular hydrogen bonding and π···π interactions form 3D zig-zag network (Fig. 7). All the benzene rings of the ligand form continuous π-stacking along *a* axis. Overall network is formed by 2D sheet arrangement of metallacycle along *a* axis. All the Cu atoms form rectangular boxes when viewed along *b* axis with a Cu–Cu distance of 9.347 Å and 7.848 Å, respectively. Each of the crystal water is acting as single acceptor and double donor, which stabilize the overall network.

In aqueous solution, complex has a λ_{max} value of 619 nm ($\varepsilon = 46\ M^{-1}\ cm^{-1}$) in the visible region due to a d–d transition and a λ_{max} value of 244 nm ($\varepsilon = 5055\ M^{-1}\ cm^{-1}$) in the UV region due to a LMCT transition. As these values are far from that of aqueous $CuCl_2$ at 819 nm, it is reasonable to assume that at least most of complex species of **3a** are not dissociated in solution.

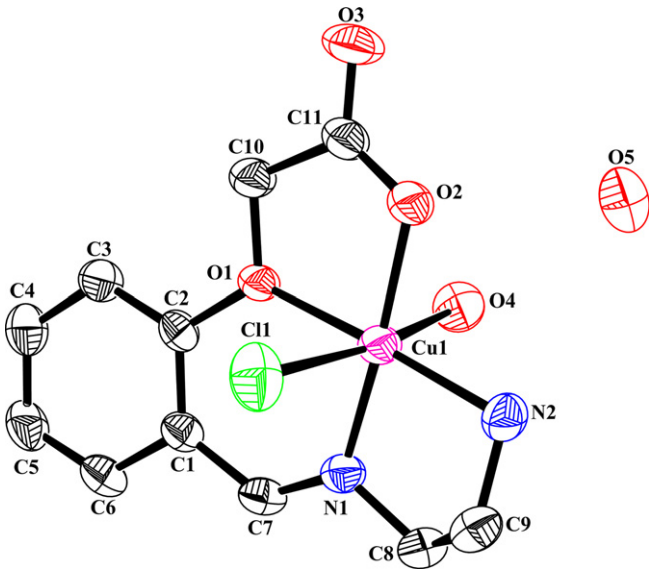

Fig. 6. ORTEP plot of Complex **3a**. Selected bond lengths are Cu(1)–O(1) = 2.051(2), Cu(1)–O(2) = 1.933(3), Cu(1)–O(4) = 2.529(3), Cu(1)–Cl(1) = 2.7102(12), Cu(1)–N(1) = 1.940(3) and Cu(1)–N(2) = 2.004(3).

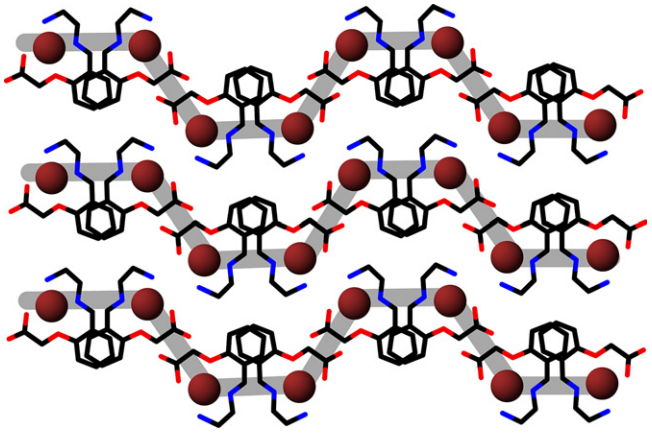

Fig. 7. Packing of **3a** along *a* axis.

3.4. Crystal structure
$[Co(Sal)(H_2O)(Py)_3]\cdot 2ClO_4\cdot H_2O$ (**3b**)

When $\mathbf{L_3}$ was treated with $Co(ClO_4)_2$ salt in open atmosphere with subsequent treatment of excesses pyridine, we got salicylaldehyde Co(III) complex **3b**. Both the Schiff base and ether linkage has been cleaved and Co(II) is oxidized to Co(III) species during complex formation in open atmospheric condition. Unit cell contains one mononuclear Co(III) complex, one water and two perchlorate ions. Fig. 8 shows the ORTEP plot of complex **3b** without the counter anions. The geometry of the complex is distorted octahedral. Three pyridine nitrogen atoms and phenolate oxygen form the equatorial plane while axial positions are occupied by aldehyde and water oxygen. Pyridine molecules in the *trans* position are almost orthogonal to each other with an torsion angle ∠C23–N4–N2–C10 = 86.10°. There is no deviation of Co(III) from N_3O basal plane. π-stacking interaction between pyridine rings forms the dimmer.

Crystal water forms hydrogen bonds with two perchlorate anions and coordinated water molecule in single acceptor–double donor way. Overall metallacycle formed 2D MOF along *ab* plane by water and perchlorate anion (Fig. 9). Overall, 3D mosaic structure is obtained via formation of different types of hydrogen bonds (see Supporting information). All the Co(III) atoms form rectangular boxes along *b* axis with a Co–Co distance of 11.642 Å and 6.819 Å, respectively.

A strong peak in FT-IR spectrum of **3b** in 1625 cm^{-1} is attributable to the η^1-bonded aldehyde (C=O) stretching vibrations. Another strong peak at 1118 cm^{-1} is attributed to the ClO_4^- ion.

3.5. Thermal and powder XRD analysis

Both **1a** and **1b** decomposed thermally in a number of steps. These complexes show successive thermal release of coordinated water molecules and the CO_2 followed by complete decomposition of the complex. The robustness of the framework is reflected in the thermo gravimetric analysis (TGA). TG analysis of complex **1a** in N_2 atmosphere shows the release of four coordinated water molecules (50–150 °C; Δm = 14.66% Calc.; 15.68% found) and two CO_2 molecules from the two coordinated carboxylate groups (230–420 °C; Δm = 21.00% Calc.; 20.93% found) (Fig. 10), which is in good agreement with the X-ray crystal structure. Complete decomposition is achieved at ~600 °C. The DSC-plot shows two endothermic peaks at 60 °C and 100 °C due to the loss of water molecules. It also shows two exothermic peaks at 260 °C and 330 °C due to the decomposition of the carboxylic acid groups. For complex **1b**, dehydration occurs at same temperature range that of **1a**, but decarboxylation occurs at 230–420 °C.

Thermal analysis of complex **1c** shows 8.69% (calculated 7.82%) weight loss in the 120–180 °C due to the removal of two coordinated water molecules. It also shows the releases of two CO_2 molecules in the temperature range of 260–320 °C associated with 21.42% weight loss (calculated 20.75%). Complete decomposition takes place at 580 °C. DSC profile shows two endothermic and one exothermic

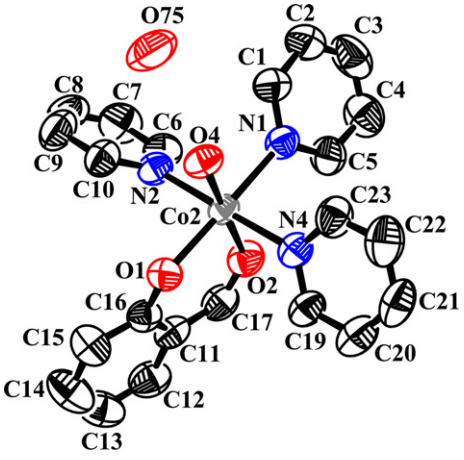

Fig. 8. ORTEP plot of complex **3b**, perchlorate anions are omitted for clarity. Selected bond lengths are Co(2)–O(1) = 2.036(2), Co(2)–O(2) = 2.055(2), Co(2)–O(4) = 2.067(3), Co(2)–N(1) = 2.124(3), Co(2)–N(2) = 2.104(3), Co(2)–N(4) = 2.105(3).

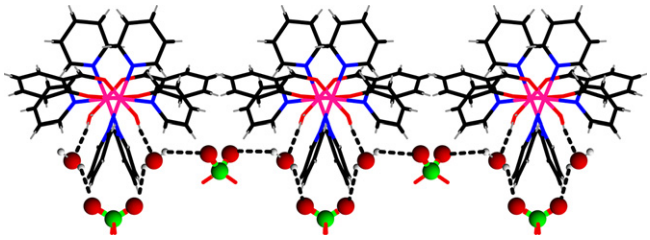

Fig. 9. Water and perchlorate assisted MOF along *ab* plane of **3b**.

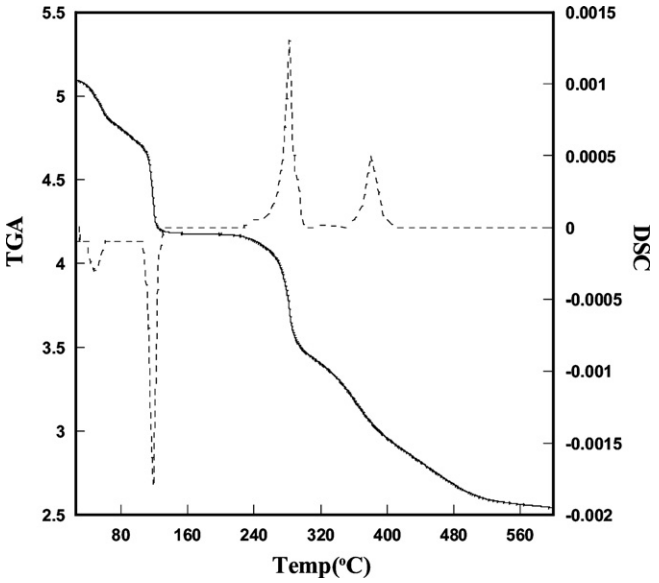

Fig. 10. TG–DSC curve of complex **1a**.

peak at 140 °C, 480 °C and 280 °C, respectively. TG analysis of **1d** exhibits a curve that corresponds to a weight loss of 28.88% (Calculated 21.17%) in the 110–190 °C range corresponds to the removal of one water, two pyridine and a further 21.42% (Calculated 20.75%) loss in the 300–490 °C temperature range, which corresponds to the release of two CO_2 molecules. DSC analysis shows one endothermic peak at 180 °C and one exothermic peak at 400 °C. Generally, a lattice water molecule is expected to be lost at a lower temperature. Thus, one would anticipate a loss of two water molecules of crystallization at a lower temperature than the coordinated water molecules in complex **3a**. TG analysis of complex **3a** in N_2 atmosphere shows the sequential release of crystal water (90–180 °C; $\Delta m = 5.05\%$ Calc.; 6.37% found) and coordinated water molecule (180–230 °C; $\Delta m = 5.32\%$ Calc.; 6.72% found). In the temperature range 300–410 °C it shows the release of chloride and one CO_2 ($\Delta m = 24.82\%$ Calc.; 36.47% found). The DSC-plot shows two endothermic peaks at 125 °C and 205 °C due to the loss of water molecules. It also shows two exothermic peaks at 470 °C and 500 °C. Thermal analysis was not performed with **3b** due to the presence of perchlorate salt.

PXRD patterns also confirm the crystalline nature of the complexes. PXRD patterns of **1a** show significant changes in the peak positions as well as intensities before and after water removal (Fig. 11). After heating the crystal of **1a** at 200 °C for 5 h in a muffle furnace, powder XRD was recorded. Loss of overall crystallinity after water removal confirms that the stability of MOF in the solid state is a result of the strong hydrogen bonding interactions involving coordinated water molecules. Similar observation was made with **1b** also. Complex **1b** was heated at 180 °C for 5 h in a muffle furnace to get rid of the coordinated water molecules. All the other complexes shows the similar type of changes in the PXRD pattern before and after the removal of water molecules (see Supporting information).

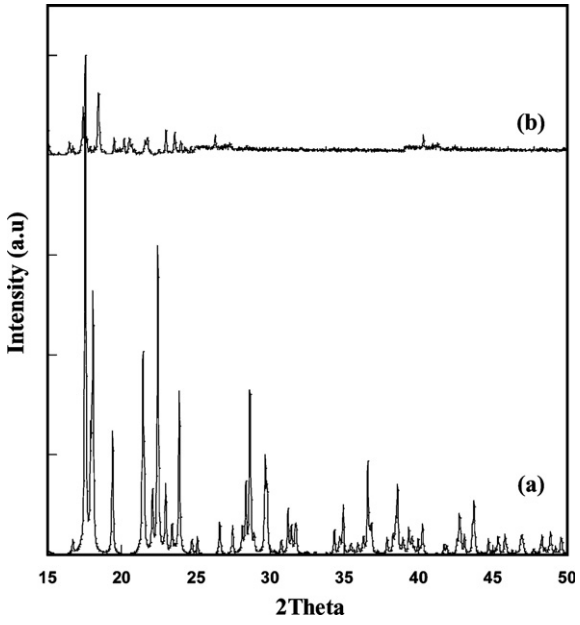

Fig. 11. Powder XRD pattern of complex **1a**. (a) Before water removal and (b) after water removal.

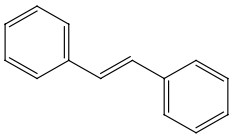

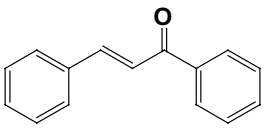

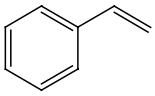

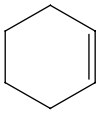

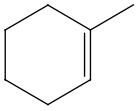

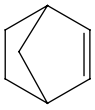

3.6. Catalytic activities of the complexes

All six water soluble complexes are tested as a catalyst in the epoxidation of linear and cyclic olefins under Mukaiyama's conditions [43]. It is found that only Co(II) complex **1a**, Cu(II) complexes **1c** and **3a** are found to be able to act as a catalyst in the epoxidation of alkenes by molecular oxygen in the presence of a sacrificial aldehyde, *i*-butyraldehyde [43–47] (Table 2). In all cases, blank tests performed in identical conditions but without metal catalyst gave negligible conversions of the substrates. It is interesting to note that the pyridine complexes (**1d**, **3b**) show very poor catalytic activity in the same reaction condition. Compared to the complexes **1a**, **1c** and **3a**, pyridine complexes required more reaction time and yielded less amount of product. In a typical experiment, a substrate (10 mmol) and *i*-butyraldehyde (20 mmol) were added to acetonitrile (15 ml) containing 5 mol% catalyst under an atmosphere of molecular oxygen at ambient pressure and temperature. TLC followed progress of the reaction. After completion or interruption of the reaction, the solid catalyst was filtered through a short plug of silica gel. The *i*-butyric acid formed is removed by washing with an aqueous $NaHCO_3$ solution. The excess of unreacted *i*-butyraldehyde is evaporated under vacuum together with the solvent. Aqueous workup followed by column chromatography afforded the corresponding epoxides. The epoxides were identified by comparison of their MS spectra and retention times in GC analysis with those of authentic samples. In absence of *i*-butyraldehyde, none of the complexes was able to cause epoxidation even if used stoichiometrically. This simple, environment friendly methodology has some drawbacks. It is not applicable to unreactive olefins. Yields are not quantitative. One has to invest stoichiometric amounts of *i*-butyraldehyde as a sacrificial reducer, whose role is that of an oxygen transfer agent. The likely mechanism is co-oxidation of the sacrificial aldehyde and the olefin. The mechanism can be compared with that of the reported in literature [47]. Detailed mechanisms of the catalytic processes are currently being investigated in our laboratory with some other acid–metal complexes, which are already published from our laboratory. A direct oxidation without using these catalysts *i.e.* the control reaction did not lead to any substantial oxidation product.

4. Conclusion

In conclusion, we reports the synthesis and crystal structure of six mononuclear mixed-ligand complexes of phenoxyacetic acid derivatives and Schiff base of Cu(II), Co(II)/(III), Mn(II). The carbonyl groups in the acetic acid

moiety provide the anchor to form two distinguishable sets of hydrogen-bonded motifs in all the complexes. It is interesting to note that carboxylic acid acts as a uni-dentate ligand in all the complexes. The Schiff base ligand has unique structure, which contains four different ligating atoms in one molecule. We have shown in the manuscript that ether oxygen can also bind to the metal center, which has very poor ligating capability. We demonstrated in the manuscript that the precise control of the coordination environment of the metal center has an effect on the formation of 3D metallo-organic framework (MOF) in the solid state. 3D MOF structure has been critically analyzed and explained based on the monomer structure. We have tested the catalytic properties of all the metal complexes. We observed that subtle change in the coordination environment changes the catalytic properties drastically. Out of six complexes, **1c** and **3a** complexes shows marginal catalytic activities in the epoxidation of olefins by molecular

oxygen in the presence of *i*-butyraldehyde under Mukaiyama's conditions. We have not been able to observe addition or insertion of oxygen into the aromatic ring with any of these complexes.

and electrochemical responses to specific analytes, and they are capable of binding multiple metal ions for the development of new molecules/macrocycles [17–21].

To date, a great variety of symmetrical or pseudo-symmetrical mononuclear phthalocyanines have been comprehensively studied. Nevertheless, there have been a limited number of reports on functional phthalocyanines, mainly because of the difficulties for their preparation and purification [19–22]. In the present article, the synthesis of tetrasubstituted-phthalocyanine {M[Pc(S-$C_6H_{13}OCOC_4H_3S)_4$]} (M = 2H (**1**), Cu (**2**)) substituted with four thiophene terminated hexylsulfanyl moieties is described. Electrochemical and specific cation binding properties are also investigated.

2. Experimental

Chloroform ($CHCl_3$), tetrahydrofuran (THF), tetrabutylammonium tetrafluoroborate ($TBATBF_4$), $CuCl_2$, tetrabutylammonium perchlorate (TBAP) and dimethylsulfoxide (DMSO) were purchased from Sigma Aldrich and were used without purification. 4-Nitrophthalonitrile, 4-(6-hydroxyhexylthio)-1,2-dicyanobenzene and 6-(3,4-dicyanophenylthio)-hexylthiophene-2-carboxylate were prepared according to the literature procedure [23,24]. The purity of the products was tested in each step by TLC (SiO_2, $CHCl_3$, hexane and MeOH).

FTIR (thin solution film) were recorded on an ATI UNICOM-Mattson 1000 spectrophotometer. Chromatography was performed with silica gel (Merck grade 60 and sephadex) from Aldrich. Elemental analysis (C, H and N) was performed at the instrumental Analysis Laboratory of Marmara University. UV–Vis spectra were obtained in a quartz cuvette on a Unicom UV-2 spectrometer. ^1H NMR and ^{13}C NMR spectra were recorded on a Bruker 300 spectrometer instrument.

The cyclic voltammetry (CV), differential pulse voltammetry (DPV) and controlled potential coulometry (CPC) measurements were carried out with a Gamry Reference 600 potentiostat/galvanostat controlled by an external PC and utilizing a three-electrode configuration at 25 °C. The working electrode was a Pt plate with a surface area of 0.071 cm^2. The surface of the working electrode was polished with a diamond suspension before each run. A Pt wire served as the counter electrode. A saturated calomel electrode (SCE) was employed as the reference electrode and separated from the bulk of the solution by a double bridge. Ferrocene was used as an internal reference. Electrochemical grade tetrabutylammonium perchlorate (TBAP) in extra pure dimethylsulfoxide (DMSO) was employed as the supporting electrolyte at a concentration of 0.10 mol dm^{-3}. High purity N_2 was used for deoxygenating the solution for at least 15 min prior to each run and for maintaining a nitrogen blanket during the measurements.

During the voltammetric measurements, the reference electrode tip was moved as close as possible to the working electrode so that uncompensated resistance of the solution was a smaller fraction of the total resistance, and therefore the potential control error was low. Moreover, IR compensation was applied to the CV scans to further minimizing the potential control error.

For CPC studies, a Pt gauze working electrode (10.5 cm^2 surface area), a Pt wire counter electrode separated by a glass bridge, and a SCE as a reference electrode were used.

2.1. Maldi sample preparation

A 2,5-dihydroxybenzoic acid (DHB) (20 mg/mL in an acetonitrile–water mixture in a 1:1 ratio) matrix for compounds **1** and **2** was prepared. MALDI samples were prepared by mixing the complex (2 mg/mL in tetrahydrofuran (THF)) with the matrix solution (1:10 v/v) in a 0.5 mL Eppendorf® micro tube. Finally, 1 μL of this mixture was deposited on the sample plate, dried at room temperature and then analyzed.

2.2. Maldi mass spectrometry

Mass spectra were acquired on a Voyager-DETM PRO MALDI-TOF mass spectrometer (Applied Biosystems, USA) equipped with a nitrogen UV-Laser operating at 337 nm. Spectra were recorded in the reflectron mode with an average of 50 shots.

2.3. Synthesis

2.3.1. 2,9,16,23-Tetrakis-{6-(-thiophene-2-carboxylate)-hexylthio} metal-free pthalocyanine (*1*)

6-(3,4-Dicyanophenylthio)-hexylthiophene-2-carboxylate (0.150 g, 0.405 mmol) was heated in dry *N*,*N*′-(dimethylamino)ethanol (0.5 cm^3) in the presence of DBU (mmol) under stirring and refluxing for 48 h. After the mixture was cooled, it was treated several times with MeOH, and then with CH_3CN. Finally dark green-blue compound **1** was filtered until the filtrates were clear. The residue was then further purified by column chromatography with silica gel (eluent: $CHCl_3$/MeOH; (100:1 v/v)).

Yield: 0.025 g (16.66%). *Anal*. Calc. for $C_{76}H_{74}N_8O_8S_8$ (1482 g/mol): C, 61.53; H, 4.85; N, 7.56; S, 17.27. Found: C, 61.07; H, 4.84; N, 7.12; S, 16.59%. FTIR (KBr thin film) ν/cm^{-1}: 3284 (w, NH), 3084 (w, broad, Ar-H), 2933, 2855, 2850 (Aliph-CH_2), 1707 (–COOR thiophene, strong), 1581 (st), 1535, 1441, 1357, 1315, 1258, 1156, 1085, 1056, 970, 854, 822, 739, 721. ^1H NMR ([d_6]-DMSO) *J*/Hz δ/ppm: 7.84 (dd, 1H, *ortho* to COOR, thiophene H2), 7.82 (s, isomer, 1H, *meta* to CN and CS, Phenyl H5), 7.65 (dd, 1H, *ortho* to SR and CN, Phenyl H2), 7.70 (dd, 1H, *ortho* to CN, and Ar-H, thiophene H6), 7.58 (dd, 1H, *meta* to Ar-S, and Ar-H, thiophene H5), 7.21 (dd, 1H, *meta* to thiophene-S, and thiophene-H, thiophene H4) 4.21 (t, br, –CH_2COO Aliph. (thiophene)), 3.03 (CH_2CH_2–S–Ar), 1.65–1.78 (m, 4H, –O–CH_2CH_2–CH_2–), 1.26–1.35 (m, 4H, –$OCH_2CH_2CH_2$–CH_2–), −1.45–(−1.48) (2H, NH *inner*). 2.3.2. 2,9,16,23-Tetrakis-{6-(thiophene-2-carboxylate)-hexylthio}phthalocyaninato copper(II) (2)

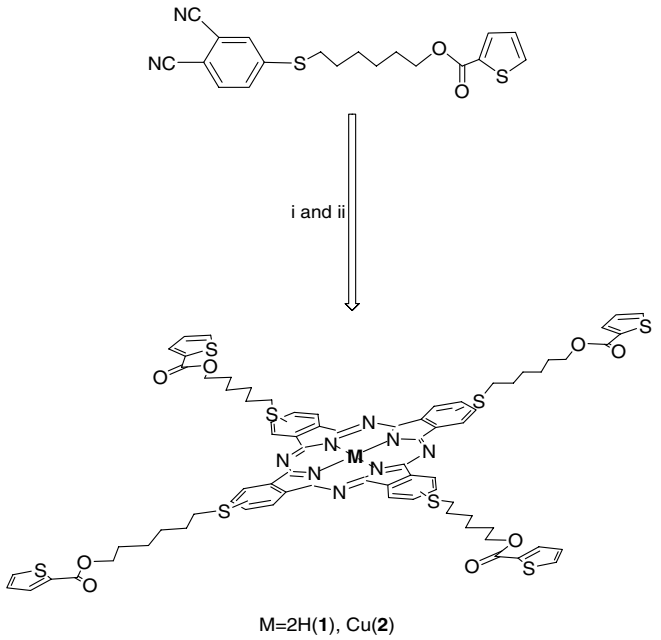
Compound **1** (0.150 g, 0.405 mmol), 6-(3,4-dicyanophenylthio)-hexylthiophene-2-carboxylate and anhydrous $CuCl_2$ (0.015 g, 0.107 mmol) in *n*-hexanol (~1 cm^3) were refluxed in a sealed tube under N_2 atmosphere for 6 h. The colour of the mixture turned into green-blue during the course of the reaction. After the mixture was heated for an additional 4 h, the green-blue product was cooled to room temperature. Then the mixture was diluted with petroleum ether. The crude product formed was washed several times successively, with first *i*-PrOH, and then with cold CH_3CN to remove any organic and inorganic impurities. Finally, the product was further purified by silica gel chromatography {$CHCl_3$ and then with $CHCl_3$/MeOH (20:1 v/v) and sephadex with THF/$CHCl_3$}. After the resulting oily product was washed with copious amounts of hexane, diethylether and finally with *i*-PrOH, it was dried in vacuo. The final product is soluble in THF, DMF, DMSO, pyridine and insoluble in EtOH.



Yield: 0.029 g (18.56%). *Anal*. Calc. for $C_{76}H_{72}N_8O_8S_8Cu$ (1543.5 g/mol): C, 59.08; H, 4.66; N, 7.26; S, 16.57. Found: C, 58.77; H, 4.74; N, 7.02; S, 16.12%. FTIR (KBr, thin film) ν/cm^{-1}: 3091 (Ar-H), 2927, 2854 (Aliph-H), 1700 (COOR), 1600, 1522, 1448, 1417, 1356, 1310, 1256, 1224, 1142, 1087, 1070, 931, 897, 857, 816, 745, 718; UV–Vis (THF), λ_{max}/nm: 688 (Q), 416 (CT), 342 (B); MS (Maldi-TOF, dihydroxybenzoic acid (DHBA as matrix)): *m*/*z* (%): 1543 $[M+H]^+$, 1545 $[M+3H]^+$, 1547 $[M+4H]^+$ (Fig. 1).

3. Results and discussion

In the present work, metal ion sensor metal-free and copper phthalocyanines (**1** and **2**) bearing thiophene were prepared by heating a pulverized mixture of 6-(3,4-dicyanophenylthio)-hexylthiophene-2-carboxylate without a metal salt or with the anhydrous $CuCl_2$ salt at ca. 170–180 °C under a N_2 atmosphere in the presence of 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU) (Scheme 1). The presence of isomers could be verified by a slight broadening encountered in the UV–Vis absorption bands and broadening in the ^1H NMR spectra when compared with those of octa-substituted phthalocyanines composed of a single isomer [16]. The yields of the reactions were rather low (16.65% for **1**, 18.56% for **2**). The structures of phthalocyanines **1** and **2** were verified by FTIR, ^1H NMR, UV–Vis and MALDI-TOF MS spectroscopic methods, as well as by elemental analysis. All the analytical and spectral data are consistent with the predicted structures.

Cyclotetramerization of the dinitrile derivative, 6-(3,4-dicyanophenylthio)-hexylthiophene-2-carboxylate to the phthalocyanines was confirmed by the disappearance of the sharp –C≡N vibration at 2233 cm^{-1} and the strong COOR (R = thiophene) band in compound **1** at around 1700–1710 cm^{-1} came out with a small shift. The IR spectra of the phthalocyanines are very similar with the exception of the NH stretching band at 3284 cm^{-1} due to the inner core imino group in the metal-free phthalocyanine (**1**). In the FTIR spectrum of **2**, the absence of the characteristic bands of the N–H groups also confirms the formation of compound **2**.

The ^1H NMR spectra of **1** is somewhat broader than the corresponding signals in the starting dinitrile derivative. This broadening is likely due to chemical exchange caused by an aggregation–disaggregation equilibria and the fact that the product obtained in these reactions is a mixture

Scheme 1. Synthetic route of 2,9,16,23-tetrakis-{6-(-thiophene–2-carboxylate)-hexylthio}-metallophthalocyanine {$M[Pc(S-_6H_{13}OH)_4]_2$} (M = 2H, Cu(II)); (i) *N*,*N*-dimethylaminoethanol, dbu and (ii) anhydrous $CuCl_2$, dbu.

of positional isomers which are expected to show chemical shifts that differ slightly from each other. The inner NH proton of the metal-free phthalocyanine was also identified in the ^{1}H NMR spectrum with a broad chemical shift between δ −1.45 and −1.48 ppm as a consequence of the 18 π-electron system of the planar molecule, and this signal disappears on deuterium oxide (D_2O) exchange [12]. The other resonances related to $OOCCH_2$, CH_2, SCH_2 and Ar-H protons in the ^{1}H NMR spectrum are very similar to that of the precursor compound and show the typical chemical shifts for protons of –thiophene: $–CH_2COO$ (4.21 ppm), $–CH_2$ (1.65–1.26 ppm, all CH_2) S–CH_2 (3.03 ppm) and Ar-H (7.84–7.20).

The UV–Vis spectra of the phthalocyanine complexes exhibit characteristic Q- and B-bands, one in the visible region at ca. 600–750 nm (Q-band) attributed to the π–π* transition from the HOMO to the LUMO of the Pc^{2-} ring, and the other in the UV region at ca. 300–400 nm (B-band) arising from the deeper π–π* transitions [16].

While the divalent copper phthalocyanine (**2**) gave a single Q-band of high intensity due to a single π–π* transition, as expected as a result of its D_{4h} symmetry, the metal-free phthalocyanine (**1**) gave a split Q-band as a result of D_{2h} symmetry, with shoulders at the slightly higher energy side of the Q-band in addition to B-bands in the UV region [12,16,18,21]. The Q-band absorptions in THF of the free and copper phthalocyanines (**1**–**2**) were observed at 714, 682 (Qx and Qy), and 688 nm, respectively, with shoulders at the slightly higher energy side of the Q-band for each phthalocyanine. The band between 400 and 450 nm in **2** may be due to charge transfer from the electron-rich ring to the electron-poor acceptor metal. The B-bands are broad due to the superimposition of the B1- and B2-bands in the 330–350 nm region in the case of complex **2** [25].

The aggregation behavior of compound **1** was investigated in different solvents ($CHCl_3$, DCM, DCE, chlorobenzene, benzene, CCl_4, CH_3CN and ethylacetate) at different concentrations. Compound **1** is soluble in a wide range of solvents from THF to non-polar solvents because of the amphiphilic property of the compound. Some examples of absorption spectra of compound **1** in various solvents are depicted in Fig. 4. The solvent effect on polymerization has been studied at 25.0 °C through absorption spectroscopy. The absorption bands at 682 and 714 nm (Q-band) for **1** are strongly affected by the two solvent parameters, donor number (DN) and Dimroth ET value [16,28]. Compound **1** is predominantly present as a polymer in polar solvents, such as CH_3CN and ethylacetate. As can be seen from the DN, which is an index of the donating property of the solvent, compound **1** is soluble in both less polar and non-polar solvents; that is, these peaks are very small in high DN solvents and disappear in CH_3CN and ethylacetate [16,20]. The change of the molar extinction coefficient is not quantitatively analyzed because the degree of aggregation is not unambiguous. The decrease in the peak height at 682 and 714 nm is attributed to the formation of a polymer of compound **1**. The molar extinction coefficients of compound **1** in chloroform and ethylacetate hardly change with a concentration change of the compound.

3.1. Spectroscopic metal ion binding titrations

It is known that the effect of S-substitution on the periphery for all phthalocyanines was a shift in these intense Q-bands to longer wavelengths because of the electron-donating thioether substituents when compared with those of unsubstituted, alkyl or O-substituted derivatives [17–20,26–28]. Sulfur donor atoms on the periphery of the tetra or octa substituted phthalocyanines act as a low-valent transition metals ionophore (IB and IIB) and impart a preference for coordination, especially with Ag^I and Pd^{II}, when the peripheral heteroatoms are able to interact with the metals [17–20,29], resulting in the formation of aggregates. These interactions are readily monitored by UV–Vis spectroscopy. In the aggregated state, the electronic structure of the phthalocyanine rings is perturbed, resulting in an alternation of the ground and excited state electronic structures [30,31].

In this study, titrations were carried out using a THF/MeOH solution of the Pc's (5:1, v/v) to ensure complete dissolution of the analyte salts, $AgNO_3$, Na_2PdCl_4, $CdCl_2$, $HgCl_2$ and $Pb(O_2CCH_3)_2$ dissolved in MeOH. Here the concentration of each Pc and the metal salt was ca. 10^{-5} and 10^{-3} mol dm^{-3}, respectively. The reason for the higher concentration of the metal salt was to produce negligible changes by dilution after its addition to the phthalocyanine solution.

Both **1** (H_2Pc) and **2** (CuPc) exhibit optical changes that are indicative of metal-ion binding, when they were titrated with Ag^I and Pd^{II} ions. Before the titration of the **1** with soft-metal ions, the spectrum of the compound gives a shoulder (652 nm) at the slightly higher energy side of the split Q-band. This shoulder shows aggregation of the compound in THF. Complex **2** shows similar aggregation behavior to **1**. The room temperature gradual addition (μL) of Ag^I and Pd^{II} to the THF/MeOH solution of **1** and **2** caused a decrease of these shoulders and the formation of new shoulders at the slightly higher energy side of these shoulders due to oligomeric metal-Pc complexation. A gradual color change from blue-green to dark green also supports metal-Pc complexation. Fig. 2(a–c) shows that while Ag^I, and Pd^{II} binding to the donor atoms of **1** result in pronounced effects in the spectrum of **1**, Hg^{II} has no effect. This observation is in harmony with previously reported studies [17–19,27,28]. As shown in Figs. 2 and 3, the addition of small increments of Ag^I to **1** and **2** leads to the gradual disappearance of the absorptions of monomeric species at 714, 682, 652, 425 and 345 nm, simultaneously enhancing the intensity of the oligomeric aggregated species at around 642, 298 and 241 nm for **1**, and the gradual disappearance of monomeric species absorptions for **2** at 688, 655, 414 and 346 nm, enhancing the intensity of the oligomeric aggregated species at around 629 nm. The B-bands of the complexes shift to higher

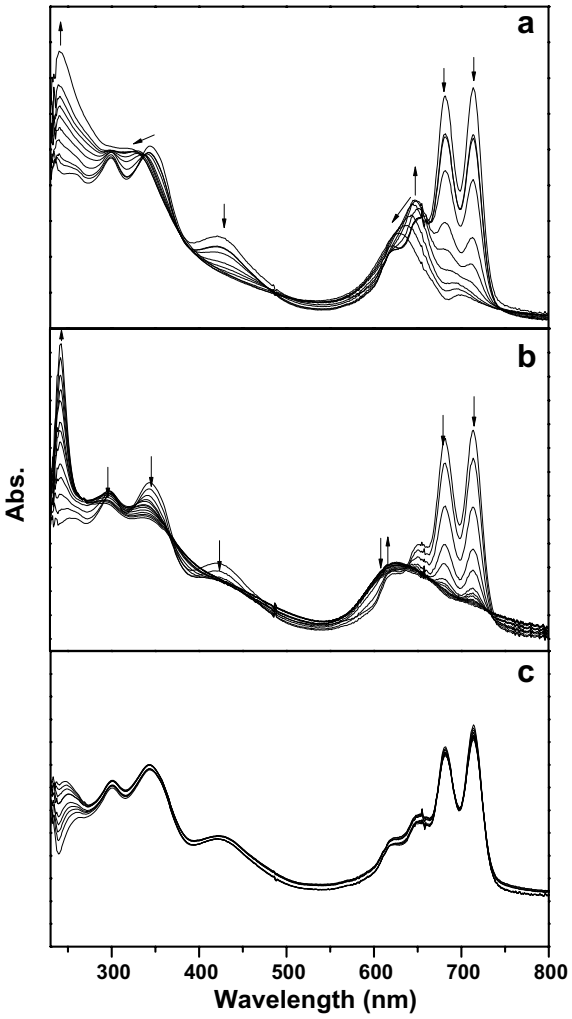


Fig. 2. UV–visible spectra of **1** in THF/MeOH during titration by Pd^{2+} (a), Ag^{+} (b) and Hg^{2+} (c) (in MeOH).

energy sides by about 5–15 nm, with a change in intensity. These spectroscopic changes indicate the coordination of Ag^{I} by the donor atoms of the phthalocyanines to form less soluble oligomeric aggregated species. At higher Ag^{I} concentration, the intensity of the absorption band of the oligomeric species decreases because of the precipitation of the aggregated species. As appeared in Fig. 2b and 3, the titrations show clear isobestic points at 734, 639, 474, 390, 365, 325 and 268 nm for **1**, and 725, 648, 614, 543, 463, 381 and 326 nm for **2**.

The titration of **1** (Fig. 2a) and **2** with Pd^{II} gives similar spectra. Addition of Pd^{II} in MeOH to the solutions of **1** and **2** in THF–MeOH (5:1, v/v) causes a decrease of the absorption of the Q-bands and increase of the absorption intensity of the aggregation shoulders with a blue shift. An immediate color change also supports the complexation of the compounds with the Pd^{II} ion. At higher Pd^{II} concentrations, the aggregation shoulders starts to decrease in intensity with a blue shift due to the precipitation of polymeric species [17–19].

Borderline-metals, such as Hg^{II}, Cd^{II} and Pb^{II} did not significantly changed the visible spectra of the Pc's upon addition of $HgCl_2$ (Fig. 2c), $CdCl_2$ and $Pb(O_2CCH_3)_2$, except for a dilution in the spectra. This lack of change in the visible spectra would be consistent with very weak or no coordination of the donor atoms on the periphery to the Hg^{II}, Cd^{II} and Pb^{II} ions [17–19,27].

3.2. Electrochemical measurements

The electrochemical behavior of the phthalocyanines was investigated by cyclic voltammetry (CV) and differential pulse voltammetry (DPV) on a platinum working electrode. The half-wave redox potential values ($E_{1/2}$) vs SCE, anodic to cathodic peak separation (ΔE_p) and peak current ratios (I_{pa}/I_{pc}) are summarized in Table 1.

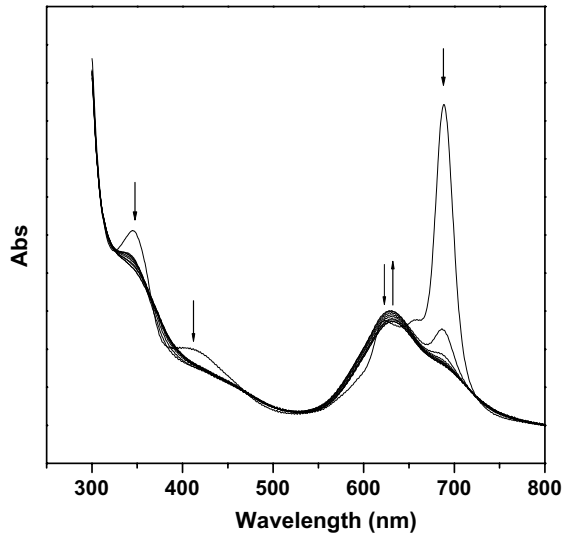

Fig. 3. UV–visible spectra of **2** in THF/MeOH during titration by Ag^{+} (in MeOH).

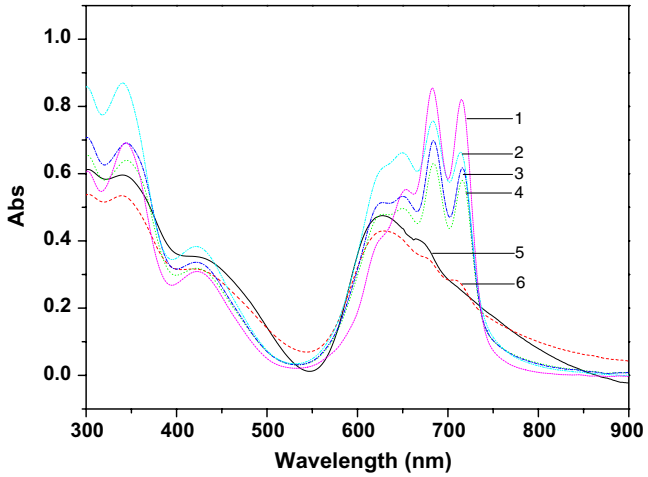

Fig. 4. Absorption spectra of **1** in various solvents. Concentration of **1** is 1.0×10^{-5} M. (1) Chloroform, (2) dichloromethane, (3) benzene, (4) carbon tetrachloride, (5) acetonitrile, (6) ethylacetate.

Table 1
Voltammetric data for the complexes (**1** and **2**)

Complexes	O_1			R_1			R_2			R_3		
	$E^a_{1/2}$ (V)	ΔE^b_p (mV)	I_{pc}/I^c_{pa}	$E^a_{1/2}$ (V)	ΔE^b_p (mV)	I_{pc}/I^c_{pa}	$E^a_{1/2}$ (V)	ΔE^b_p (mV)	I_{pc}/I^c_{pa}	$E^a_{1/2}$ (V)	ΔE^b_p (mV)	I_{pc}/I^c_{pa}
1 (H_2Pc)	0.64 (0.44[d])			−0.62	110	0.98	−0.93	100	0.90	−1.76		
2 (CuPc)	0.33	232	0.89	−0.78	73	0.95	−1.04	78	0.87			

[a] $E_{1/2} = (E_{pa} + E_{pc})/2$ at 100 mV s^{-1} scan rate vs. SCE.
[b] $\Delta E_p = E_{pa} + E_{pc}$ at 100 mV s^{-1} scan rate.
[c] I_{pa}/I_{pc} values are given for reduction and $I_{pc}/I_{pa}I_{pc}$ values are given for oxidation processes at 100 mV s^{-1} scan rate.
[d] O'_1 wave of the complex resulting from the aggregated species.

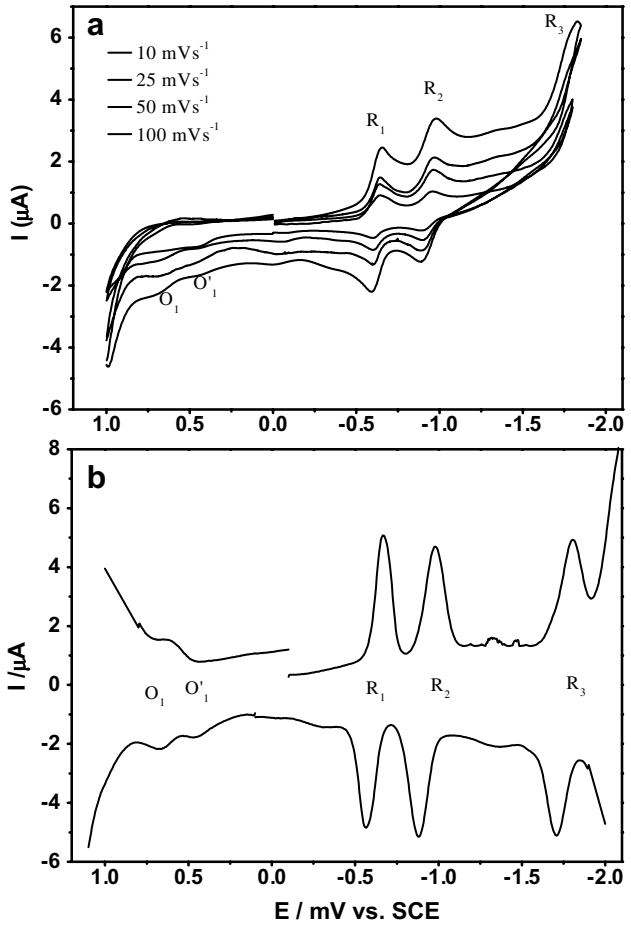

Fig. 5. Cyclic (a) and differential pulse (b) voltammograms of **1** at various scan rates on Pt in DMSO/TBAP.

Fig. 5 shows the CV and DPV of compound **1** in DMSO containing TBAP. Compound **1** gives three one-electron reduction processes labelled as R_1 at −0.62 V, R_2 at −0.93 V and R_3 at −1.76 and two one-electron irreversible oxidation processes labelled as O'_1 at 0.44 V and O_1 at 0.64 V vs. SCE at 0.100 V s^{-1} scan rate. Based on the well-known electrochemical behavior of phthalocyanine complexes, all couples in Fig. 5 are assigned to the phthalocyanine ring. The values of I_{pa}/I_{pc} for the R_1 and R_2 couples of **1** are close to unity, and the anodic to cathodic peak separation (ΔE_p) is changed from 65 to 140 mV with scan rates from 0.010 to 0.500 V s^{-1} (ΔE_p was changed from 60 to 110 mV for ferrocene), suggesting reversible electron transfer. Reversibility is illustrated by the similarity in the forward and reverse DPV scans (Fig. 5b) [32,33]. The peak currents increase linearly with the square root of the scan rates for scan rates ranging from 0.010 to 0.500 V s^{-1}, indicating the purely diffusion-controlled behaviors of the couples R_1 and R_2 [32,33]. Splitting of the oxidation processes (O_1 and O'_1) shows the aggregation of the compound during the positive potential scan, while it is present as monomeric species under negative potentials. Disappearance of O'_1 with dilution supports the aggregation processes of the compound. Peak currents of the oxidation processes are much smaller than the reduction processes for compound **1**, because during the positive potential scans the compound is aggregated. The aggregation of the complex decrease the concentration of the monomers and give a split into small peaks corresponding to the aggregated (O'_1) and monomeric species (O_1).

As is shown in Fig. 6, within the electrochemical window of TBAP/DMSO, **2** undergoes a one-electron oxidation at 0.33 V, labelled as O_1, and two one-electron reductions at −0.78 and −1.10 V at 0.100 V s^{-1} scan rate, labelled as R_1 and R_2, having reversible diffusion-controlled electron transfer characters. Because of the electro-inactive metal center of the complex, all of these processes are attributed to successive removal of electrons from, or addition of electrons to, the macrocycle orbitals. Differential pulse voltammetry of the complex confirms the recorded redox processes clearly. Reversibility is illustrated by the similarity in the forward and reverse DPV scans (inset in Figs. 6A and B). When compared with the common metallophthalocyanines, the oxidation process of **2** is recorded at a less positive potential, resulting in a significantly decreased potential difference between the first reduction and first oxidation redox processes, i.e., a decreased HOMO–LUMO gap (1.11 V) of the complex. However, the position of the reduction couples and the peak separation of the first and second reduction couples (0.38 V) are in harmony with common metallophthalocyanines [16,17,19,34–39].

CPC is used to determine the overall number of electrons in a faradic reaction. Unlike voltammetric techniques where the electrode area and diffusion coefficient of the redox species must be known, CPC can determine the overall number of electrons in the redox process without prior knowledge of the electrode area or diffusion coefficient.

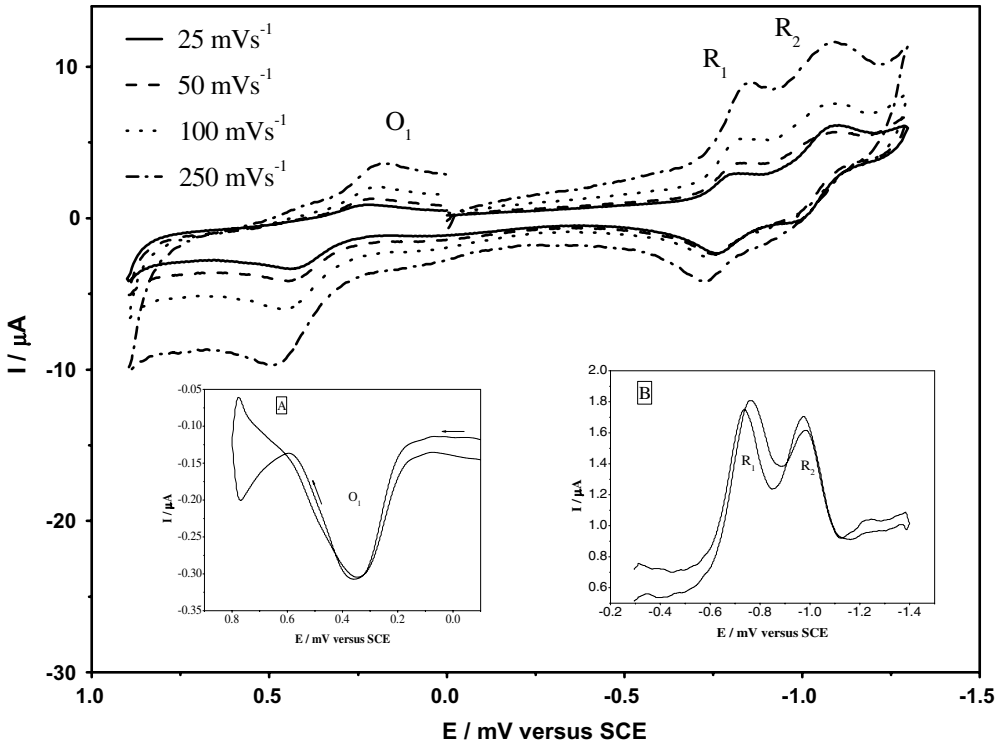

Fig. 6. Cyclic and differential pulse voltammograms of **2** (A = Oxidation) (B = Reduction) at various scan rates on Pt in DMSO/TBAP.

Applied potentials were selected approximately 50 mV higher than the reduction/oxidation peak to compensate the possible change of the peak potential due to the different cell and electrode configuration of the CPC measurement. The CPC studies indicated that the number of electrons transferred for the first reduction processes of the complexes **1** and **2** was approximately one. Since both reduction processes have very similar peak currents (except the oxidation processes of **1**), the number of electrons transferred for the remaining processes should also be one. To obtain a more accurate measurement of the redox equivalency, reduction processes were studied by DPSC. Plots of Q (charge) versus $t^{1/2}$ (time) shows a linear behavior for both first two reduction processes. Slopes with a 1:1 ratio were consistent with the involvement of one electron for R_1 and R_2 and O_1 processes of the complexes. DPSC experiments also showed the reversibility of the R_1 and R_2 processes with approximately the same slopes of the Cottrell lines representing the two potential steps of the processes.

denoting the axial and rhombic parts, respectively. In powder EPR spectra, the hyperfine interaction is not visible in most cases, presumably due to intermolecular dipole–dipole interactions which broaden the EPR transitions. When the manganese ion is magnetically diluted, the hyperfine interaction can be detected. In these dilute conditions, a unique feature centred around $g = 2$ is present in the EPR spectrum, corresponding to the central transition $|5/2, -1/2\rangle \rightarrow |5/2, +1/2\rangle$. This feature is split into several lines (six in the high field limit) because each electronic spin state is composed of six nuclear spin sublevels ($I = 5/2$). The transitions expected between the other Zeeman levels are not detected because they are very broad due to their dependence on the orientation of the zfs interaction. Since g-values are always close to 2.0023 because of the quasi-spherical symmetry of the fundamental spectroscopic term of the Mn(II) ion [18], the shape of the multiplet depends mainly on the magnitude of the A, D and E parameters and the microwave frequency used for the EPR experiment.

Mononuclear Mn(II) complexes display a large range of D values up to 1.21 cm^{-1} [1–13], depending on the nature and geometry of the coordination sphere of the metal ion. For mononuclear four-, five- and *trans* six-coordinate dihalide Mn(II) complexes the D values are in the range 0.9–1.2 cm^{-1} for iodo complexes, 0.5–0.7 cm^{-1} for bromo, and 0.16–0.30 cm^{-1} for chloro, whereas for *cis*-six-coordinate systems the D values are significantly lower: $|D_I| \sim 0.60\ cm^{-1}$, $|D_{Br}| \sim 0.36\ cm^{-1}$, $|D_{Cl}| \sim 0.12\ cm^{-1}$ [1–9]. Recently, we reported a HF-EPR investigation performed on the series *cis*-[Mn(tpa)X_2] (tpa = tris(2-pyridylmethyl)amine; X = I, Br, Cl) which was complemented by DFT calculations [8]. The general trend observed for Mn(II) halide complexes ($D_I > D_{Br} > D_{Cl}$) can be explained by the fact that the halide spin orbit coupling (SOC) dominates the D-value in these systems with a major contribution arising from interference terms between metal- and halide-SOC contributions which are proportional to the product of the SOC constants of Mn and X [8].

In studies of manganese sites present in metalloproteins or metalloenzymes, the samples obviously correspond to diluted conditions in which only the $|5/2, -1/2\rangle \rightarrow |5/2, +1/2\rangle$ transition can be observed. In this paper, our aim was to check the efficacy of HF-EPR for the precise determination of the electronic parameters of Mn(II) in diluted conditions over a large range of D-values. We used the corresponding Zn(II) complexes as diamagnetic hosts for the [Mn(tpa)X_2] complexes, as we have already used this strategy for the study of the [Zn(Mn)tButerpy$(N_3)_2$] (tButerpy = 4,4′,4″-tri-*tert*-butyl-2,2′:6′,2″-terpyridine) complex [9]. Only the X-ray structures of [Zn(tpa)I]·(ClO_4) [19], and [Zn(tpa)Cl]·Y (Y = BPh_4 [20]; ClO_4 [19]) have been reported in the literature. Since counter anions cannot be added during the synthesis of the Zn complexes doped with Mn, the molecular structure determined by X-ray diffraction of the neat Zn complexes [Zn(tpa)I]I (**1a**), [Zn(tpa)Br]$(ZnBr_4)_{0.5}$ (**2a**), [Zn(tpa)Cl]$(ZnCl_4)_{0.5}$ (**3a**) and [Zn(tpa)$(NCS)_2$] (**4a**) obtained under these conditions have been resolved and are presented here. The electronic properties of the [Mn(tpa)X_2] complexes doped into the corresponding Zn complexes (X = I (**1b**), Br (**2b**) and Cl (**3b**)) have been determined by HF-EPR. We use our experimental results to discuss the utility of multifrequency EPR in the interpretation of the spectra of these complexes recorded under diluted conditions with diverse D-values.

2. Results and discussion

2.1. Synthesis

The $[Zn(tpa)X]^+$ (X = I (**1a**), Br(**2a**), Cl (**3a**)) complexes were isolated from a mixture of equimolar amounts of ZnX_2 and tpa in MeOH, whereas [Zn(tpa)$(NCS)_2$] (**4a**) was isolated from the reaction of equimolar amounts of $Zn(NO_3)_2 \cdot 6H_2O$ and tpa in the presence of two equivalents of KSCN in MeOH.

The $[Zn(tpa)X]^+$ complexes doped with [Mn(tpa)X_2] (X = I (**1b**), Br (**2b**), Cl (**3b**)) were prepared in MeOH solution using a ZnX_2/MnX_2 ratio of 95/5 together with one equivalent of tpa ligand. After reflux for 30 min, the complexes were isolated by addition of diethyl ether. The Zn thiocyanate complex cannot be doped with the corresponding Mn compound since the solubility discrepancy between the Zn and the Mn complexes precludes the co-crystallization of both species.

2.2. X-ray structures

Suitable crystals for X-ray diffraction were obtained by slow diffusion of ethyl acetate into methanolic solutions of complexes **1a** and **4a**. Single crystals of complexes **2a** and **3a** were obtained similarly, but using diethyl ether. Tables 1 and 2 provide the principal crystallographic data together with selected bond distances and angles, and Fig. 1 displays the ORTEP diagrams of complexes **1a**–**4a**.

The halide complexes **1a**–**3a** are five-coordinate, whereas the thiocyanate complex **4a** is six-coordinate. There is a noticeable difference in the arrangement of the tpa ligand around the Zn cation in the latter. For compounds **1a**–**3a** the tpa ligand displays a pseudo-C_3 symmetry with N_{pyr}–Zn–N_{pyr} angles between 120° and 110°. Deviation from the theoretical 120° is due to the fact that the Zn atom is not in the N(2)–N(3)–N(4) plane. As the thiocyanate complex is six-coordinate, the pseudo-C_3 symmetry is lost and the corresponding angles approach a 90° value.

Complexes **1a**–**3a** adopt almost perfect trigonal bipyramid geometries, with τ values ranging from 0.94 to 1.04, similar to those observed in other monomeric structurally characterized transition metal complexes containing the tpa ligand [19,20]. The halide ligand is coordinated *trans* to the tertiary aliphatic nitrogen atom N(1) in all cases. Bond lengths within the chloride and iodide complexes are consistent with previously reported $[Zn(tpa)X]^+$ com-

pounds [21,22], with distances between the Zn ion and the pyridine nitrogen atoms ranging between 2.062 and 2.096 Å, and significantly higher values for the Zn–N(1) bond (2.237–2.264 Å). As expected, the previously unreported $[Zn(tpa)Br]^+$ compound displays a Zn–Br bond length (2.4078 Å) ranging between the Zn–Cl (2.2744 Å) and the Zn–I (2.6397 Å) bond lengths in the analogous chloride and iodide complexes.

On the other hand, compound **4a** shows a pseudo-octahedral geometry where the two NCS anions are coordinated in a *cis* fashion. This complex is isostructural with its manganese parent compound [23]. As found for the Mn complex, the Zn–N bonds *trans* to the anionic ligands are significantly longer (2.204 and 2.269 Å) than the other Zn–N_{tpa} distances (2.126 and 2.124 Å). This *trans* effect has also been observed in other similar complexes [23,24].

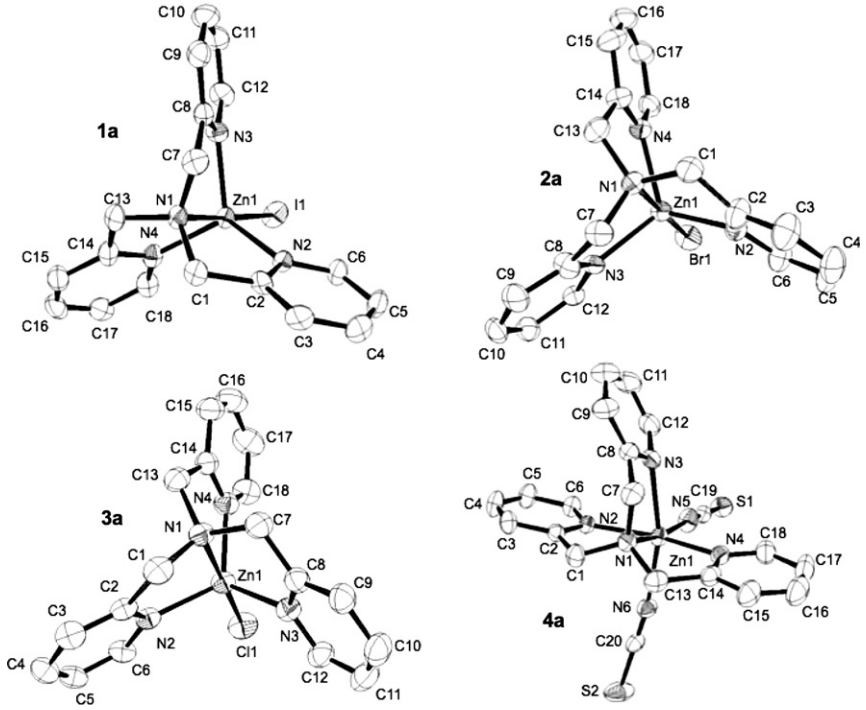

Fig. 1. ORTEP diagrams showing the molecular structures of complexes **1a**–**4a**.

2.3. Multifrequency EPR experiments

HF-EPR spectra were recorded on the magnetically diluted complexes **1b**–**3b**, at different frequencies (95–285 GHz) over the temperature range 10–50 K. The maximum intensity is found at 30 K. 285 GHz spectra recorded at 30 K are shown in Fig. 2. Features are only observed in a small field range (about 300 mT) around $g = 2.0$ due to the central $|5/2,-1/2\rangle \rightarrow |5/2,+1/2\rangle$ transition. The complexity of the spectra originates not only from the hyperfine interaction but also from the second order contribution of the zfs. Normally, six transitions are expected between the six nuclear sublevels of the two Zeeman levels ($m_s = \pm 1/2$) following the rule $\Delta m_i = 0$. However, when the second order contribution of the zfs is larger than the hyperfine interaction, other transitions are detected involving the simultaneous change in the nuclear and electronic spin state. The intensity of the latter transitions depends on the ratio between the zero field and the Zeeman interactions.

We obtained good quality spectra for the bromide and chloride complexes, but MnI_2 impurities were apparently present in the iodide complex. This causes the presence of intense lines centred at $g = 2$, which mask features belonging to compound **1b**. Fortunately, because of the large zfs parameters, the visible outer lines allow us to extract the spin Hamiltonian parameters of the system.

As can be seen in Fig. 2, the EPR spectra at the same frequency (285 GHz) become dramatically more complex as the magnitude of D increases, in accord with theoretical predictions. Whereas the EPR spectrum of the chloride compound characterized by the smallest D value is almost a sextuplet, the EPR signature of the bromide and iodide complexes is a very large multiplet. The total width of the spectra increases from complex **3b** to **1b**, being 80, 140 and 400 mT for **3b**, **2b** and **1b**, respectively. Fig. 3 shows the magnetic field effect on the complexity of the spectra. Spectra of **2b** recorded at frequencies of 95, 190 and 285 GHz reveal that the increasing magnetic field simplifies the spectra which tend toward a sextuplet at the highest field. Generally, the multifrequency character of the EPR study is of interest since at high field when a sextuplet is reached, the hyperfine coupling constant A (but not the zfs parameters) can be accurately determined. Conversely, at low field the complexity of the spectra allows a precise determination of the zfs parameters while the hyperfine coupling constant is not determined.

To determine the spin Hamiltonian parameters, the EPR spectra of **1b**–**3b** were simulated by using a full-matrix diagonalization procedure of Eq. (1). The best simulated spectra are shown in Figs. 2 and 3 and the corresponding zfs parameters are reported in Table 3 together with those obtained for the $[Mn(tpa)X_2]$ complexes.

The spin Hamiltonian parameters obtained from simulation of the HF-EPR spectra recorded on the $[Mn(tpa)X_2]$ and doped Zn complexes are essentially the same, indicating a similar environment around the Mn(II) ion in both pure and diluted lattices. The minor differences can be related to structural changes between the doped system versus the pure lattice since these two systems are not completely isostructural [8]. The A value is extracted from the magnetically diluted complexes, whereas the sign of D is obtained from the $[Mn(tpa)X_2]$ compounds.

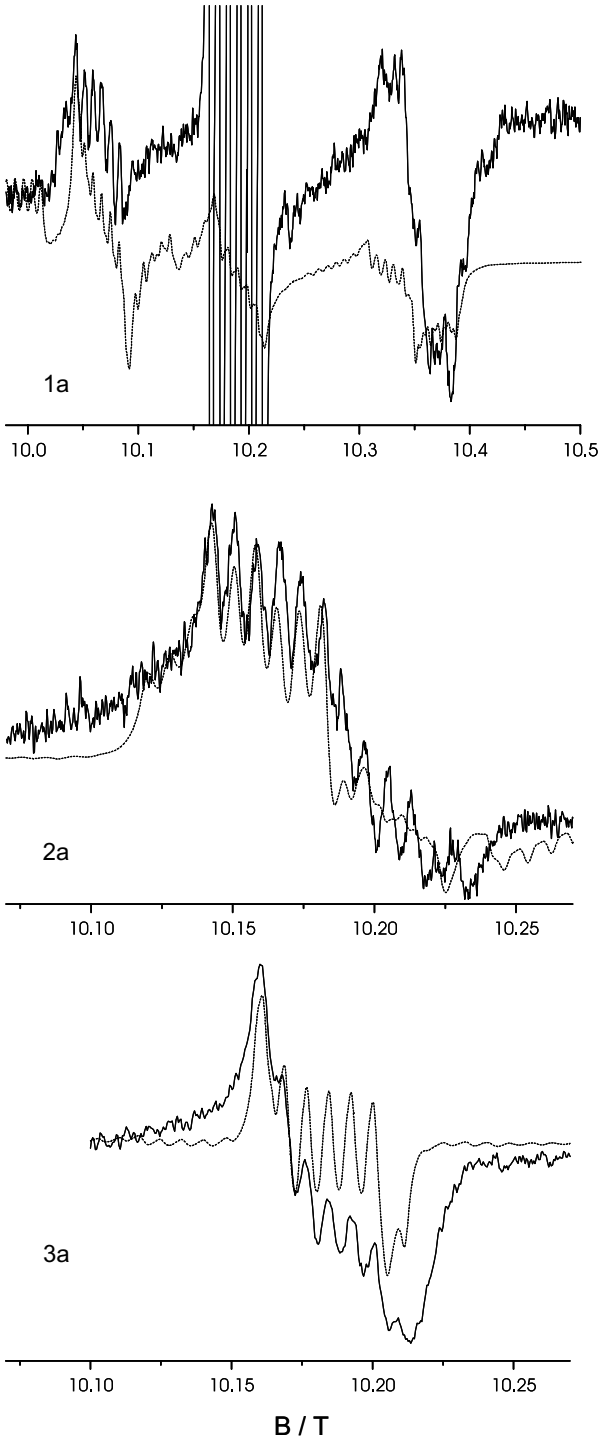

Fig. 2. Experimental (solid line) and simulated (dotted line) powder HF-EPR spectra of complexes **1b**, **2b** and **3b** at 285 GHz recorded at 30 K.

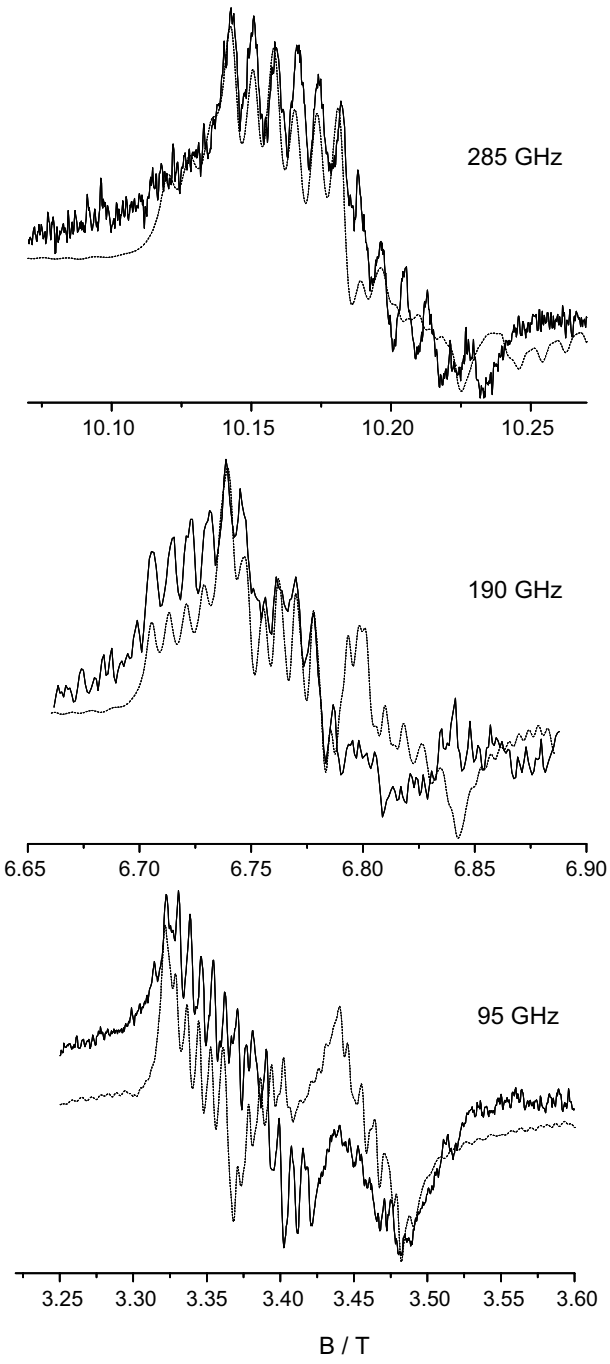

Fig. 3. Experimental (solid line) and simulated (dotted line) powder HF-EPR spectra of complex **2b** at 95, 190 and 185 GHz recorded at 30 K.

Because of the different D values of the halide complexes, this study provides a good illustration of the effect of the D parameter and the magnetic field on the shape of the multiplet observed in diluted conditions. Thus, depending on the D value of the complex and the parameters to be determined, the choice of EPR frequency becomes crucial. The accuracy of the determination of A is improved when high field conditions are reached (sextuplet) while, for the zfs parameters, a gain in precision is afforded when more complicated multiplets are obtained.

HF-EPR experiments on metalloenzymes containing a mononuclear Mn(II) site are obviously performed under diluted conditions. This study is a new example of how multifrequency HF-EPR spectroscopy can be used to explore minor changes in the environment of biological Mn(II) sites for mechanistic investigations. Furthermore,

Table 3
Electronic parameters determined by multifrequency HF-EPR on the doped **1b**–**3b** complexes and the [Mn(tpa)X_2] complexes

Complex	D (cm^{-1})	E (cm^{-1})	$\lvert E/D\rvert$	g_x, g_y, g_z	$A \times 10^{-4}$ (cm^{-1})
1b	0.635(2)	0.120(1)	0.189	2.00, 2.00, 2.00	68
2b	0.360(1)	0.069(1)	0.192	2.00, 2.00, 2.00	68
3b	0.115(2)	0.023(1)	0.200	2.00, 2.00, 2.00	68
[Mn(tpa)I_2] [8]	−0.600	0.095	0.158	1.99, 1.98, 2.00	n.d.[a]
[Mn(tpa)Br_2] [8]	−0.360	0.073	0.203	2.00, 1.98, 2.005	n.d.
[Mn(tpa)Cl_2] [8]	+0.115	0.020	0.174	1.97, 2.00, 2.00	n.d.

The sign of D is given when it can be determined.
[a] n.d. = not determined.

since the zfs parameters of the Mn(II) ion are very sensitive toward its environment (ligand exchange with halide or a change in coordination number), this ion is a good structural fingerprint and can potentially be used to substitute for other difficult to study metals in metalloenzymes.

3. Experimental

3.1. General

Reagents and solvents (analytical grade) were purchased from Aldrich and Fluka and used as received. Tris(2-pyridylmethyl)amine (tpa) was prepared according to the literature method [25]. Infrared spectra were recorded on a Perkin–Elmer Spectrum GX FTIR spectrometer.

3.2. Synthesis of the complexes

3.2.1. Synthesis of [Zn(tpa)I]I (**1a**)

To a stirred solution of tpa (50.6 mg, 0.174 mmol) in 5 mL of methanol was added a methanolic solution (2 mL) of ZnI_2 (55.6 mg, 0.174 mmol). The resulting colourless solution was stirred for 1 h and filtered. Colourless single crystals were obtained by slow diffusion of ethyl acetate into the filtrate.

Compound **1a**: Yield: 0.058 g (55%).

IR in cm^{-1} (KBr) v = 3430 (vs), 1609 (s), 1572 (m), 1482 (m), 1437 (s), 1367 (w), 1314 (m), 1270 (m), 1157 (w), 1126 (w), 1103 (m), 1053 (m), 1023 (s), 979 (w), 964 (w), 906 (w), 836 (w), 781 (s), 770 (m), 729 (w), 651 (w), 502 (w), 471 (w), 414 (w), 328 (w).

3.3. Synthesis of [Zn(tpa)Br]($ZnBr_4$)$_{0.5}$ (**2a**)

To a stirred solution of tpa (32.3 mg, 0.111 mmol) in 3 mL of methanol was added $ZnBr_2$ (25 mg, 0.111 mmol). The resulting colourless solution was stirred for half an hour. Colourless single crystals were obtained by slow diffusion of diethyl ether.

Compound **2a**: Yield: 0.016 g (34%).

IR in cm^{-1} (KBr) v = 3418 (vs), 1609 (s), 1573 (m), 1483 (m), 1439 (s), 1368 (w), 1315 (m), 1295 (w), 1270 (m), 1157 (w), 1126 (w), 1103 (m), 1053 (m), 1024 (s), 984 (w), 965 (w), 911 (w), 836 (w), 775 (s), 732 (w), 650 (m), 504 (m), 474 (w), 416 (m), 332 (w).

3.4. Synthesis of [Zn(tpa)Cl]($ZnCl_4$)$_{0.5}$ (**3a**)

To a stirred solution of tpa (54.6 mg, 0.188 mmol) in 3 mL of methanol was added a methanolic solution (3 mL) of $ZnCl_2 \cdot 6H_2O$ (25 mg, 0.188 mmol). The resulting colourless solution was stirred for half an hour. Colourless single crystals were obtained by slow diffusion of diethyl ether.

Compound **3a**: Yield: 0.028 g (44%).

IR in cm^{-1} (KBr) v = 3450 (vs), 1609 (s), 1573 (m), 1483 (m), 1438 (s), 1369 (w), 1315 (m), 1295 (w), 1269 (m), 1158 (w), 1126 (w), 1102 (m), 1054 (m), 1024 (s), 984 (w), 963 (w), 910 (w), 837 (w), 773 (s), 732 (w), 651 (m), 504 (m), 474 (w), 415 (m), 330 (w).

3.4.1. Synthesis of [Zn(tpa)($NCS)_2$] (**4a**)

To a stirred solution of tpa (62.7 mg, 0.216 mmol) and $Zn(NO_3)_2 \cdot 6H_2O$ (64.6 mg, 0.217 mmol) in 3 mL of methanol was added a methanolic solution (6 mL) of KSCN (42 mg, 0.433 mmol). The resulting colourless solution was stirred for half an hour. Colourless single crystals were obtained by slow diffusion of ethyl acetate.

Compound **4a**: Yield: 0.055 g (54%).

IR in cm^{-1} (KBr) v = 3462 (m), 3451 (w), 2918 (w), 2057 (vs), 1602 (s), 1573 (m), 1484 (m), 1435 (s), 1389 (w), 1370 (w), 1350 (w), 1351 (w), 1312 (m), 1287 (m), 1268 (m), 1220 (w), 1154 (m), 1121 (w), 1098 (m), 1052 (m), 1020 (m), 991 (w), 976 (w), 955 (w), 908 (w), 834 (w), 767 (s), 733 (w), 640 (w), 514 (w), 502 (w), 475 (w), 419 (m).

3.4.2. Synthesis of [Zn(tpa)I]I doped with [Mn(tpa)I_2] (**1b**)

To a stirred solution of tpa (120 mg, 0.413 mmol) in 2 mL of methanol was added a methanolic solution (1 mL) of MnI_2 (6.38 mg (5%), 0.021 mmol) and a methanolic solution (2 mL) of ZnI_2 (125.13 mg (95%), 0.392 mmol). The resulting colourless solution was heated to reflux for half an hour and then cooled to room temperature. Addition of diethyl ether to this solution yielded a white precipitate corresponding to **1b**. Yield: 0.176 g (70%).

IR similar as **1a**.

3.4.3. Synthesis of [Zn(tpa)Br]($ZnBr_4$)$_{0.5}$ doped with [Mn(tpa)Br_2] (**2b**)

To a stirred solution of tpa (80.9 mg, 0.279 mmol) in 2 mL of methanol was added a methanolic solution

(1 mL) of $MnBr_2$ (3.1 mg (5%), 0.014 mmol) and a methanolic solution (2 mL) of $ZnBr_2$ (60.0 mg (95%), 0.266 mmol). The resulting colourless solution was heated to reflux for half an hour and then cooled to room temperature. Addition of diethyl ether to this solution yielded a white precipitate corresponding to **2b**. Yield: 0.061 g (52%).

IR similar as **2a**.

3.4.4. Synthesis of $[Zn(tpa)Cl](ZnCl_4)_{0.5}$ doped with $[Mn(tpa)Cl_2]$ (**3b**)

To a stirred solution of tpa (81.0 mg, 0.279 mmol) in 2 mL of methanol was added a methanolic solution (1 mL) of $MnCl_2$ (0.7 mg (2%), 0.006 mmol) and a methanolic solution (2 mL) of $ZnCl_2$ (37.5 mg (98%), 0.270 mmol). The resulting colourless solution was heated to reflux for half an hour and then cooled to room temperature. Addition of diethyl ether to this solution yielded a white precipitate corresponding to **3b**. Yield: 0.044 g (46%).

IR similar as **3a**.

3.5. Physical measurements

High-frequency and high-field EPR spectra were recorded on a laboratory made spectrometer [26] using powder samples pressed in pellets to avoid preferential orientation of the crystallites in the strong magnetic field. Gunn diodes operating at 95 GHz and 115 GHz and equipped with a second- and third-harmonic generator have been used as the radiation source. The magnetic field was produced by a superconducting magnet (0–12 T). The simulation of the HF-EPR spectra was performed using the SIM program written by Weihe [2]. SIM performs a full-matrix diagonalization of the spin Hamiltonian. It is therefore adequate for spin systems with any value of the zfs parameter relative to the operating frequency. The program also takes into account the Boltzmann population factor in calculating transition intensities. Its detailed description is available on the Web site http://sophus.kiku.dk/software/epr/epr.html.

3.6. Crystal structure determination

Diffraction data were collected on a Bruker SMART diffractometer with Mo Kα radiation. Crystal of complexes of dimensions $0.50 \times 0.30 \times 0.20$ mm for **1a**, $0.40 \times 0.20 \times 0.06$ mm for **2a**, $0.50 \times 0.40 \times 0.40$ mm for **3a**, and $0.40 \times 0.20 \times 0.10$ mm for **4a** were selected. The crystallographic data are summarized in Tables 1 and 2. All calculations were effected using the SHELXTL computer program [27].

for 6 h, the mixture was filtered and the filtrate was allowed to stand at room temperature. Colorless crystals appeared in about eight weeks. Colorless crystals suitable for X-ray diffraction analysis were obtained after the filtrate was carefully dealt with at low temperature and slowly evaporated. The filtrate of the lanthanide–amino acid complexes was reported to easily precipitate under near physiological pH conditions [7], however, no precipitate was observed in the process of crystal growth under our conditions.

Element analysis of the complexes was carried out on Elementar Aanlysensysteme GmbH Vario EL (HAMAU, Germany). 2.2. X-ray diffraction determination

Single crystal X-ray data were collected on a Siemens SMART CCD diffractometer with graphite-monochromatic Mo Kα ($\lambda = 0.71073$ Å) radiation at a temperature of 298 ± 2K. The structures were solved by direct methods using the SHELXTL-97 crystallographic software package and refined by full matrix least-squares on F^2 [11]. The details of crystal data, refinement and final statistics are summarized in Table 1.

2.3. Bioassay

The various DNA oligonucleotides were synthesized by Sangon (Shanghai, China) and were used without further purification. The DNA extinction coefficient was calculated through the nearest neighbor method [12,13]. Experiments were carried out in aqueous Tris buffer (10 mM Tris, 100 mM NaCl, pH 7.1) unless stated otherwise.

Absorbance measurements were made on a JASCO V-550 UV–Vis spectrophotometer, equipped with a Peltier temperature control accessory. Fluorescence measurements and circular dichroism (CD) spectra were measured on a JASCO FP-6500 spectrofluorometer and a JASCO J-810 spectropolarimeter equipped with a temperature-controlled water-bath. The job plot was constructed from emission data [12,13]. The total concentration of the complex and DNA (in units of base) was held constant at 60 μM over the course of the titration. DNA binding constants were determined by fluorescence titration as described previously [14–17]. Titration data were fit directly by non-linear least-squares methods to get binding constants.

3. Results and discussion

X-ray structure analysis reveals a structural diversity of the complexes (Figs. 1–4), demonstrating that the cubane-like structure is one of the structures obtained under higher pH. Table 2 summarizes the bond distances for these complexes. For complex **1** (Fig. 1), a very interesting structure of the sulfur bridge is found. Complex **1** is prepared in cysteine acid, however, no separated cysteine acid can be

type 1 (as shown Fig. 1b), the carboxyl group from a cysteine acid connects two terbium ions forming an oxygen bridge, and the S atom connects with another S atom from the neighboring cysteine acid, which connects to an additional two terbium ions through its carboxyl group. This form constructs an infinite chain structure and 70% of complex **1** is in this form (Fig. 1). In type 2, two cysteine acids are connected to the same two terbium ions by their carboxyl groups, and a S′–S′ bond is formed. Type 2 is regarded as an independent dimer and is only 30% of the whole structure of complex **1** (Fig. 1c). The energy minimization performed under an MM+ force field using the program HyperChem 7.0 shows that type 1 is more energy favorable (106.537 kcal/mol) than type 2 (114.895 kcal/mol), which is in consistent with type 1 being predominant in the complex. The structure of lanthanide–cysteine acid has never been reported, even under extensively

investigated acid conditions, because the final product forms colloids easily. Only a Nd–Cystine complex, $(Nd_2(Cystine)_2(H_2O)_8)(ClO_4)_6 \cdot 3H_2O$, at pH 4 was reported as an infinite layer structure [18], which is different from the structure reported here.

Complex **2** forms a cubane-like structure (Fig. 2), similar to the previously reported structures of $[Dy_4(\mu_3\text{-}OH)_4(Asp)_3(H_2O)_8](ClO_4)_2 \cdot 10H_2O$ and $[Er_4(\mu_3\text{-}OH)_4(HGlu)_3(H_2O)_8](ClO_4)_5 \cdot 6H_2O$ [6,7], and is capable of forming a three-dimensional network based on the Eu_4O_4 cubane core with bridging Asp ligands. However, significant differences exist in this structure: two kinds of ligand valence (three ligands for −1 and two ligands for −2) and two europium coordination numbers (8 and 9) were observed, which was not reported in the previous cubane-like structures [6,7]. The differences can result from solution conditions and the 1:1 ratio of Ln/amino acid we used as the initial molar ratio instead of a 2:1 ratio [6,7].

For complex **3**, an unusual structure of four non-equivalent isolated dimers is found (Fig. 3). In each dimer, two europium atoms are connected by the quadruple bridge from four carboxyl groups of valine molecules. The isolated dimer structure is common, however, a structure with four non-equivalent isolated dimers has rarely been reported, and this presents another type of their structures.

For complex **4**, a simple dimeric form is obtained (Fig. 4). This structure is similar to those reported at low pH, and is consistent with the structure of a gadolinium–alanine complex obtained under near physiological pH conditions [19].

Therefore, only complex **2** is a cubane-like structure under near physiological pH conditions at a 1:1 ratio and the other three complexes show different structural characters, demonstrating the structural diversity of lanthanide–amino acid complexes. It was reported that a high reaction temperature was necessary to facilitate the hydrolytic pro-

cess [7]. Lanthanide ions prefer to form oxo-hydroxo lanthanide clusters at neutral pH under high temperature [20]. The reported structures all obtained under a high reaction temperature (80 °C) and can be regarded as amino acid oxo-hydroxo lanthanide clusters. In our experiments, at room temperature, we found that the hydrolysis of lanthanide ions can be inhibited by increasing the proportion of amino acid, and the lanthanide–amino acid complexes show structural diversity.

It should be pointed out that a Tb–cys or Tb–Val complex was formed by terbium with a 50:50 mixture of racemic amino acids, the same case in form 1 or form 2 (see Supplementary material). Lanthanide–amino acid complexes were obtained under near physiological pH conditions and have potential application in DNA detection since their fluorescence is greatly enhanced upon their binding to single-stranded DNA [1]. UV–Vis, fluorescence and circular dichroism (CD) spectroscopy were employed [14–17] to study the interactions between these complexes and five single-stranded DNA. The DNA sequences are listed in Table 3. Similar changes were observed for the terbium or europium series. Tb complex **1** and Eu complex **3** are reported in Figs. 5 and 6. Upon being complex bound, the DNA absorbance decreased and even shifted and the complex fluorescence was greatly enhanced when excited at 270 nm, showing that single-stranded DNA (ssDNA), except polydA (ssDNA 5), can transfer their excited-stated energy to the complex efficiently [1]. Typical fluorescence spectra are shown in Fig. 5a. DNA binding constants were determined by fluorescence titration as described previously [14–17]. The binding constants and F_b/F_0 (fluorescence emission intensity, $F_0 = F_{TbCys}$, $F_b = F_{TbCys\text{-}DNA}$) are summarized in Table 3 and show that the binding affinity and the fluorescence enhancement are sequence dependent, the stronger the binding affinity, the more the fluorescence enhancement. The continuous variation method was used to get the binding stoichiometry (n) of complex **1** with DNA. Typical data of complex **1** with ssDNA 5 are shown in Fig. 6. Table 3 summarizes the binding stoichiometries. The different binding stoichiometries further indicates that the complex is bound to the single-stranded DNA differently, which is also a demonstration that the difference is not from terbium ion itself but related to the property of amino acids and the structure of the complex (see Table 3), in accordance with UV–Vis and fluorescence results.

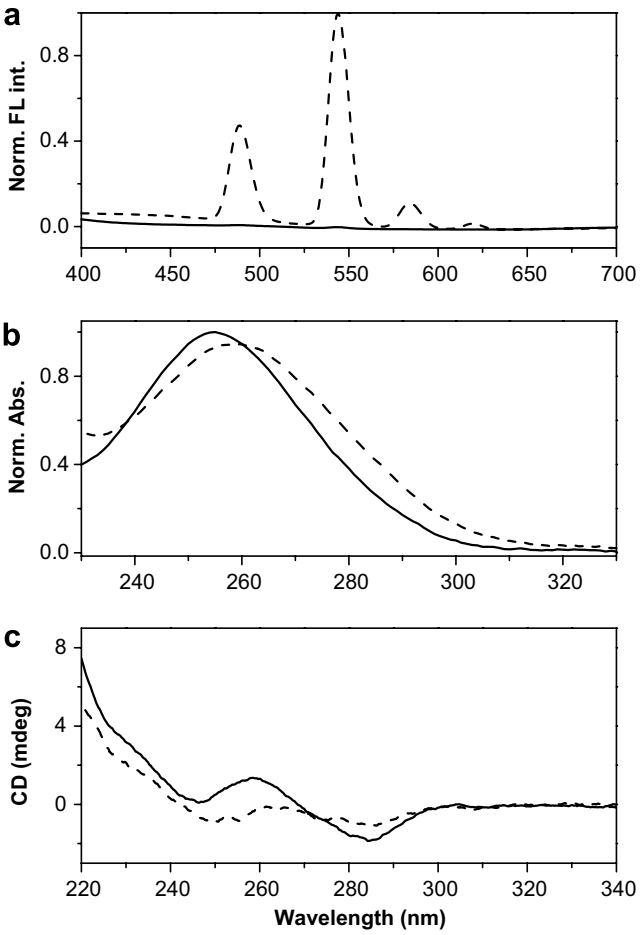

Fig. 5. (a) Fluorescence emission spectra of complex **1** in the absence (solid line) and presence (dash line) of ssDNA 4 ($\lambda_{ex} = 270$ nm). The concentration of complex **1** is 20 μM and the concentration of DNA is 40 μM. (b) UV–Vis absorbance spectra of ssDNA 4 in the absence (solid line) and presence (dash line) of complex **1**. The concentration of DNA is 20 μM and the concentration of complex **1** is 40 μM. (c) CD spectra of ssDNA 4 in the absence (solid line) and presence of complex **1** (dash line). The concentration of complex **1** is 30 μM and the DNA concentration is 60 μM. The DNA concentration is used in the base unit.

Although the UV–Vis absorption and circular dichroism spectral changes are similar, the fluorescence enhancement is different between the terbium and europium series when bound to DNA. Fig. 7 clearly shows the fluorescence enhancement for the europium complex following the order: ssDNA 1 > ssDNA 2 > ssDNA 3. SsDNA 4 and

Table 3
Summary of spectral changes and the binding parameters of complex **1** with five single-stranded DNA (ssDNA)

DNA	DNA sequence (22 mers)	K^a ($\times 10^4$)	F_b/F_0	n^b	UV maximum absorbance	CD ellipticity (mdeg)
ssDNA 1	$T_3(CCT)_4CT_6$	7.0	31	1.5	decrease	decrease (at 250 nm and 280 nm)
ssDNA 2	$T_6(CTT)_5T$	6.7	27	3.0	decrease	decrease (at 250 nm and 280 nm)
ssDNA 3	T_{22}	1.8	20	2.3	decrease	decrease (at 250 nm and 280 nm)
ssDNA 4	$A_3(GGA)_4GA_6$	8.2	38	1.0	shift 4 nm	decrease (at 260 nm and 285 nm) and shift (at 260 nm)
ssDNA 5	A_{22}				shift 3 nm	decrease (at 250 nm and 280 nm) and shift (at 280 nm)

[a] DNA binding constant. Titration data were fit directly by non-linear least-squares methods to get binding constants. The errors were within 10–15%.
[b] The binding stoichiometry ([base]/[TbCys]) which was obtained with a continuous variation method.

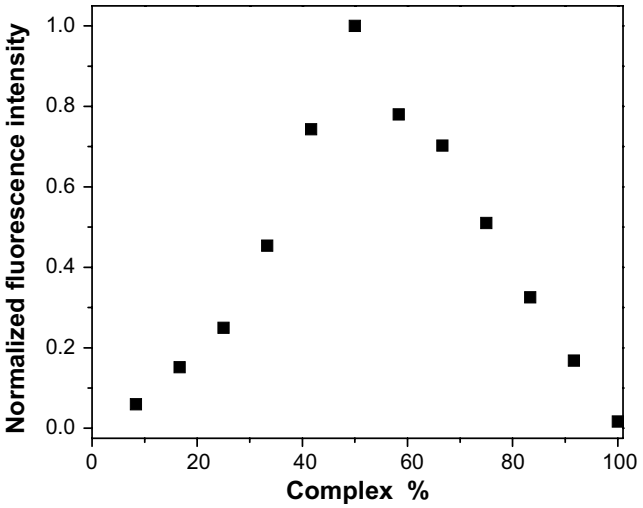

Fig. 6. Job plot of complex **1** with ssDNA 4. Total concentration of the complex and DNA (in units of base) was held constant at 60 μM over the course of the titration.

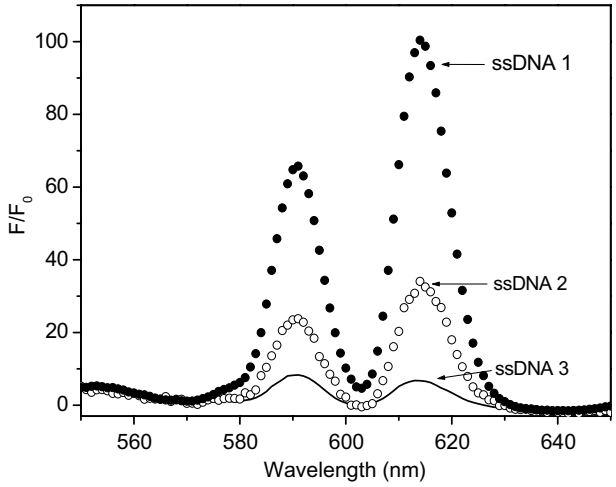

Fig. 7. Fluorescence emission spectra of complex **3** in the presence of ssDNA 1 (solid circles), ssDNA 2 (open circles) and ssDNA 3 (line). The excitation wavelength $\lambda_{ex} = 270$ nm. The emission spectra were recorded from 550 nm to 650 nm. The concentration of complex **3** is 20 μM and the concentration of DNA is 40 μM.

ssDNA 5 did not enhance the complex fluorescence but ssDNA 4 greatly increased terbium fluorescence.

Different DNA structure selectivity was found for europium amino acid complexes, such as the europium-L-aspartic acid complex [12,13]. Europium-L-aspartic acid complex is a cubane-like complex which can selectively stabilize non-B form DNA polydApolydT but destabilize polydGdCpolydGdC and polydAdTpolydAdT [12], and convert the B-form polydGdCpolydGdC to the Z-form under low salt conditions; the europium-L-valine complex can cause single-stranded polydA and polyrA to self-structure. The sigmoidal melting curve profiles indicate the transition is cooperative, similar to the cooperative melting of a duplex DNA [13]. Detailed structural studies are clearly needed to clarify their DNA selectivity.

Furthermore, the observed hypochromicity for ssDNA 1-3 and red shift for ssDNA 4-5 in the UV–Vis measurements, the different binding affinity and fluorescence enhancement, and DNA CD spectral changes indicate that the interactions between the complex and DNA are sequence dependent and are related to the structure of the complex, except for the electrostatic attraction [12,13] between the phosphate backbone and the free amino groups ($-NH_3^+$) of the amino acids and terbium ions, consistent with the DNA structural changes upon being complex bound, which was observed in circular dichroism measurements.

4. Conclusion

In summary, we have synthesized four different lanthanide–amino acid complexes under near physiological pH conditions. From the crystal structure analysis, we find they have diverse structures, and the general cubane-like structure is just one of them. The interactions of the synthesized complexes with five single-stranded DNA were studied with absorption, fluorescence and circular dichroism spectroscopy and their binding affinity was detected. We find that the recognition of DNA is sequence dependent and has some relationship with the structure of the lanthanide–amino acid complexes.

Acknowledgments

We are grateful for the referees' helpful comments on the manuscript. This project was supported by NSFC (20331020, 20325101, 20473084, 20637010), funds from the Chinese Academy of Sciences and Jilin Province.

Scheme 1. (−)-4,5 Pinene bipyridine (L_{RR}) (left) and (+)-4,5 pinene bipyridine (L_{SS}) (right).

representative examples are lanthanide tris-(β-diketonates) with N-containing ligands such as 2,2′-bipyridine [21,22], 1,10-phenanthroline [17,23] and their derivatives [24].

In addition, chiral ligands play an important role in the design of functional complexes showing specific physical properties, for example, second harmonic generation (SHG), ferroelectricity, etc. [25,26]. Many metal complexes with chiral ligands have had successful applications in asymmetric catalysis, enantiomerselective synthesis, chirality sensing, etc. [27–29]. However, to the best of our knowledge, there are no examples of triboluminescent lanthanide chiral complexes simultaneously showing polarizing optical activity. In this paper, using β-diketones as an efficient light-harvesting 'antennae' and introducing other chiral 2,2′-bipyridine derivative ligands, L_{SS} (+)-4,5-pinene bipyridine and L_{RR} (−)-4,5-pinene bipyridine (Scheme 1), we have successfully prepared two triboluminescent Eu(III)-based chiral complexes **1** and **2** with the formula $[Eu(DBM)_3L]$ (L_{SS} in**1**, L_{RR} in **2**, DBM = dibenzoylmethanate). Herein, we report the synthesis, crystal structures, triboluminescence and photoluminescence properties of **1** and **2**.

2. Experimental

2.1. Materials

All chemicals were purchased from commercial suppliers and were used as received. The L_{SS} and L_{RR} ligands were synthesized according to previously reported procedures [30,31] and $Eu(DBM)_3 \cdot 2H_2O$ was synthesized by a literature method [32].

2.2. Physical measurements

Elemental analyses for C, H and N were performed on a Perkin–Elmer 240C analyzer. Triboluminescence spectra, by grinding the crystals of **1** and **2** with a glass rod in a small beaker, and photoluminescence measurements were performed on an AMINCO-BOWMAN series 2 Luminescence spectrometer. The circular dichroism spectra were recorded on a JASCO J-810 Spectropolarimeter in THF (THF = tetrahydrofuran). Infrared spectra were acquired on a Vector22 Bruker spectrophotometer using the KBr pellet technique in the 400–4000 cm^{-1} region.

2.3. X-ray data collection and structure determination

The crystal structures of complexes **1** and **2** were determined on a Bruker SMART CCD diffractometer with graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at room temperature using both Φ- and ω-scan modes. Intensity data were collected in the θ range of 0.996–26 for complex **1** and 0.999–26 for complex **2**; data reduction was made with the Bruker SAINT package. Absorption correction was performed using the SADABS program. The structures were solved by direct methods and refined on F^2 by full matrix least-squares using SHELXL-97 with anisotropic displacement parameters for all non-hydrogen atoms. H atoms were introduced in the calculations using the riding model. All computations were carried out using the SHELXTL-2000 program package. Crystallographic data for complexes **1** and **2** are summarized in Table 1.

2.4. Synthesis of $Eu(DBM)_3L_{SS}$ (1)

A solution of $Eu(DBM)_3 \cdot 2H_2O$ (85.1 mg, 0.1 mmol) in ethanol (10 ml) was added to a solution of the chiral 2,2′-bipyridine derivative, (+)-4,5-pinene bipyridine (25 mg, 0.1 mmol), in acetone (10 ml) with gentle stirring for 10 min. The mixture was placed undisturbed for three weeks. Yellow block crystals of **1** were obtained in 67% yield. *Anal.* Calc. for **1** ($C_{62}H_{51}N_2O_6Eu$): C, 69.41; H, 4.76; N, 2.61. Found: C, 69.67; H, 4.71; N, 2.69%. IR (KBr, cm^{-1}): ν 1601 s (C=O stretching), 1552 s (C=N stretching).

2.5. Synthesis of $Eu(DBM)_3L_{RR}$ (2)

Complex **2** was prepared as yellow block crystals by a method similar to that of **1** using (−)-4,5-pinene bipyridine instead of (+)-4,5-pinene bipyridine. Yield: 71%. *Anal.* Calc. for **2** ($C_{62}H_{51}N_2O_6Eu$): C, 69.41; H, 4.76; N, 2.61.

D_{calc} (g/cm^{-3})	1.424	1.419
μ (Mo Kα) (mm^{-1})	1.311	1.306
Data/restraints/parameters	9376/1/642	8215/1/642
θ Range (°)	0.996–26.00	0.999–26.00
R_{int} (on F^2)	0.0610	0.0396
Goodness of fit on F^2	1.143	1.013
R_1 [$I > 2\,\delta\,(I)$][a]	0.0610	0.0488
wR_2 (all data)[b]	0.1328	0.1199

[a] $R_1 = \sum ||F_o| - |F_c|| / \sum |F_o|$.
[b] $wR_2 = [\sum w(|F_o^2| - |F_c^2|)^2 / \sum w(|F_o^2|)^2]^{1/2}$.
